LEMMA 4.1. *The adjoint S^* from $(H^{2,m})^* = H^{2,-m}$ to $(\ell^2((1+2^j)^{2m}))^* = \ell^2((1+2^j)^{-2m})$ is given by the formula*

$$S^* : G \mapsto \{\langle G, \Psi_{j,k}\rangle\}, \quad G \in H^{2,-m}.$$

Proof. Suppose that $G \in H^{2,-m}$ and let ϕ_G be the functional corresponding to G. Then, for any sequence $\boldsymbol{\lambda} = (\lambda_{j,k})$ belonging to $\ell^2((1+2^j)^{2m})$, it follows from the definition of S^* that

$$\begin{aligned}(S^*\phi_G)(\boldsymbol{\lambda}) &= \langle G, S\boldsymbol{\lambda}\rangle \\ &= \sum_{j,k} \lambda_{j,k} \langle G, \Psi_{j,k}\rangle .\end{aligned}$$

Thus S^* maps $G \mapsto \langle G, \Psi_{j,k}\rangle$. □

LEMMA 4.2. *S^* has zero kernel.*

Proof. By definition, if $G \in H^{2,-m}$,

$$\begin{aligned}\|S^*G\|_{2,-m}^2 &= \sup_{\boldsymbol{\lambda}\in\ell^2((1+2^j)^{2m})} \frac{|(S^*G)(\boldsymbol{\lambda})|^2}{\|\boldsymbol{\lambda}\|_{2,m}^2} \\ &= \sup_{\boldsymbol{\lambda}\in\ell^2((1+2^j)^{2m})} \frac{\left|\sum_{j,k} \lambda_{j,k} \langle G, \Psi_{j,k}\rangle\right|^2}{\|\boldsymbol{\lambda}\|_{2,m}^2}. \qquad (4.1)\end{aligned}$$

We now define the sequence $(\lambda_{j,k})$ by

$$\lambda_{j,k} = \overline{\langle G, \Psi_{j,k}\rangle}(1+2^j)^{-2m}.$$

Then

$$\begin{aligned}\|(\lambda_{j,k})\|_{2,m}^2 &= \sum_{j,k} |\langle G, \Psi_{j,k}\rangle|^2 (1+2^j)^{-4m}(1+2^j)^{2m} \\ &= \sum |\langle G, \Psi_{j,k}\rangle|^2 (1+2^j)^{-2m} \\ &\le B_{-m}\|G\|_{2,-m}^2\end{aligned}$$

by Theorem 1.1, and so is a candidate for the supremum in equation (4.1). Therefore

$$\begin{aligned}\|S^*G\|_{2,-m}^2 &\geq \frac{\left(\sum_{j,k} |\langle G, \Psi_{j,k}\rangle|^2 (1+2^j)^{-2m}\right)^2}{\sum_{j,k} |\langle G, \Psi_{j,k}\rangle|^2 (1+2^j)^{-2m}} \\ &= \sum_{j,k} |\langle G, \Psi_{j,k}\rangle|^2 (1+2^j)^{-2m} \\ &\geq A_{-m}\|G\|_{2,-m}^2, \end{aligned} \tag{4.2}$$

by Theorem 1.1. This completes the proof. □

LEMMA 4.3. *S^* has closed range.*

Proof. Let $((\lambda_{j,k}^n))_n$ be a Cauchy sequence in $\ell^2(1+2^j)^{-2m}$ in the range of S^*, so that $((\lambda_{j,k}^n))_n \to (\lambda_{j,k})$. Then each sequence $(\lambda_{j,k}^n) = S^*G_n$, where G_n belongs to $H^{2,m}$. By the inequality derived in (4.2) it follows that (G_n) is a Cauchy sequence in $H^{2,-m}$ so that $G_n \to G$. Therefore, it follows from the continuity of S^* that $(\lambda_{j,k}) = S^*(G)$ and we have the desired result. □

The first part of Theorem 1.2 follows immediately from Lemmas 4.1, 4.2, 4.3, and Banach's closed range theorem.

The lower bound in (1.3) follows immediately from an elementary duality argument. To obtain the upper bound let $N = \ker S$ and $X = \ell^2((1+2^j)^{2m})/N$ and define $U : X \to H^{2,m}$ by $U[\boldsymbol{\lambda}] = S\boldsymbol{\mu}$, $(\boldsymbol{\mu} \in [\boldsymbol{\lambda}] \in X)$. Plainly, U is a bounded linear bijection of X onto $H^{2,m}$ and so, by Banach's isomorphism theorem, has a bounded inverse. Therefore U^* is a bounded linear bijection from $H^{2,-m}$ onto X^*. From the proof of Lemma 4.2 we know that

$$\begin{aligned} A_{-m}\|G\|_{2,-m}^2 &\leq \sup\{\|(S^*G)(\boldsymbol{\lambda})\|_{2,-m}^2 : \boldsymbol{\lambda} \in \ell^2((1+2^j)^{2m})\} \\ &= \sup\{\|\langle F, U[\boldsymbol{\lambda}]\rangle : [\boldsymbol{\lambda}] \in X, \|[\boldsymbol{\lambda}]\| \leq 1\} \\ &= \|U^*G\|. \end{aligned}$$

Hence $\|U^{-1}\| = \|(U^*)^{-1}\| \leq A_{-m}^{-1}$. This completes the proof of Theorem 1.2.

Remark. The usefulness of Banach's closed range theorem in establishing atomic decompositions is clear from papers of D. H. Luecking (see, for example, [29] and [30]), who used it to prove decompositions of Bergman and Hardy spaces. In particular, a duality proof of the Coifman–Rochberg decomposition of L_a^p, $p > 1$, was given [9]. In [6] Bonsall gave an abstract formulation of this method giving various applications, and in [7] he gave an elementary proof of a general atomic decomposition theorem.

5. Proof of Theorem 1.3. We consider the operator

$$TF = \sum \langle F, \Psi_{j,k}\rangle \Psi_{j,k}, \quad F \in H^{2,m}, \tag{5.1}$$

where $\langle \cdot, \cdot \rangle$ is the L^2-inner product. We proceed to show that T is bounded on both $H^{2,1}$ and $H^{2,-1}$ and in fact is a bijection. Note that T is symmetric with respect to $\langle \cdot, \cdot \rangle$ and bounded on H^2.

LEMMA 5.1. *T is a bounded operator $H^{2,m} \to H^{2,m}$ for both $m = 1$ and $m = -1$.*

Proof. Let T_N be the partial sum operator

$$T_N = \sum_{|j|,|k| \leq N} \langle \cdot, \Psi_{j,k}\rangle \Psi_{j,k}.$$

Let $F \in H^{2,m}$ and $G \in H^{2,-m}$. Then, by the Cauchy–Schwarz inequality,

$$\begin{aligned}
|\langle T_N F, G\rangle|^2 &= \left|\left\langle \sum \langle F, \Psi_{j,k}\rangle \Psi_{j,k}, G\right\rangle\right|^2 \\
&= \left|\sum \langle F, \Psi_{j,k}\rangle \overline{\langle G, \Psi_{j,k}\rangle}\right|^2 \\
&\le \sum |\langle F, \Psi_{j,k}\rangle|^2 (1+2^j)^{2m} \sum |\langle G, \Psi_{j,k}\rangle|^2 (1+2^j)^{-2m} \\
&\le B_m \|F\|_{2,m}^2 \times B_{-m}\|G\|_{2,-m}^2,
\end{aligned}$$

by Theorem 1.1. Now, by duality,

$$\|T_N F\|_{2,m}^2 = \sup_{G\in H^{2,-m}} \frac{|\langle T_N F, G\rangle|^2}{\|G\|_{2,-m}^2} \le B_m B_{-m} \|F\|_{2,m}^2,$$

so that T_N is bounded (independently of N) on $H^{2,m}$ and so must T be. By the symmetry of T (with respect to the duality pairing given by $\langle\cdot,\cdot\rangle$) we conclude also that T is bounded on $H^{2,-m}$. □

Next we wish to establish that T is a bijection $H^{2,m} \to H^{2,m}$, for $m = 1$ and $m = -1$. To do this we estimate $\|TF\|_{2,m}^2$ from below. It follows from duality that

$$\begin{aligned}
\|TF\|_{2,m} &= \sup_{G\in H^{2,-m}} \frac{|\langle TF, G\rangle|}{\|G\|_{2,-m}} \\
&= \sup_{G\in H^{2,-m}} \frac{|\sum_{j,k} \langle F, \Psi_{j,k}\rangle \overline{\langle G, \Psi_{j,k}\rangle}|}{\|G\|_{2,-m}}.
\end{aligned}$$

We need to find a suitable candidate for G so that we may show that $\|TF\|_{2,m}^2 \ge K_m \|F\|_{2,m}^2$. We proceed to analyze $\sum_{j,k} \langle F, \Psi_{j,k}\rangle \overline{\langle G, \Psi_{j,k}\rangle} = \sum_{j,k} \langle f, \psi_{j,k}\rangle \overline{\langle g, \psi_{j,k}\rangle}$ using the same technique as in the proof of Theorem 3.1. We obtain

(5.2)
$$\begin{aligned}
\sum_{j,k} \langle F, \Psi_{j,k}\rangle \overline{\langle G, \Psi_{j,k}\rangle} &= \frac{2\pi}{b_0} \sum_j \int_0^\infty f(t)\overline{g}(t)|\psi(2^{-j}t)|^2 dt \\
&\quad + \frac{2\pi}{b_0} \sum_j \sum_{k\ne 0} \int_0^\infty f(t)\overline{g}(t - 2\pi k 2^j b_0^{-1}) \overline{\psi}(2^{-j}t)\psi(2^{-j}t - 2\pi k b_0^{-1}) dt.
\end{aligned}$$

It is clear in view of (5.2) that an appropriate candidate for G is given by $g(t) = f(t)(1+t)^{2m}$ (so that $\|g\|_{2,-m}^2 = \|f\|_{2,m}^2$). Next we analyze the second sum on the right of (5.2) with this choice of g, which we denote by $\mathrm{rest}(f)$. We deduce

$$|\,\mathrm{rest}(f)| \le \frac{2\pi}{b_0} \sum_j \sum_{k\ne 0} I_1 \times I_2,$$

where

$$I_1 = \left\{ \int_0^\infty |f(t)|^2 (1+t)^{2m} (1+t-2\pi k 2^j b_0^{-1})^{2m} |\psi(2^{-j}t)||\psi(2^{-j}t - 2\pi k b_0^{-1})| dt \right\}^{1/2}$$

and

$$\begin{aligned}
I_2 = \Bigg\{ \int_0^\infty |f(t - 2\pi k 2^j b_0^{-1})|^2 (1+t-2\pi k 2^j b_0^{-1})^{2m} (1+t)^{-2m} |\psi(2^{-j}t)| \\
\times |\psi(2^{-j}t - 2\pi k b_0^{-1})| dt \Bigg\}^{1/2}.
\end{aligned}$$

TABLE 5.1
Estimates of the lower bound for $\|TF\|_{2,1}$.

b_0	0.1	0.2	0.25	0.3	0.5
K	33.947	16.974	13.578	11.297	−4.222

We define

$$\mu = \inf_{0<t<\infty} \sum_j |\psi(2^{-j}t)|^2,$$
$$\delta_1^m(s) = \sup_{0<t<\infty} \sum_j (1+t+2^j s)^{2m} |\psi(2^{-j}t)||\psi(2^{-j}t+s)|,$$
$$\delta_2^m(s) = \sup_{0<t<\infty} \sum_j (1+t+2^j s)^{-2m} |\psi(2^{-j}t)||\psi(2^{-j}t+s)|.$$

If $\sum_{k\neq 0}\{\delta_1^m(\frac{2\pi k}{b_0})\delta_2^m(\frac{2\pi k}{b_0})\}^{1/2} = \sum_{k\neq 0}\{\delta_1^{-m}(\frac{2\pi k}{b_0})\delta_2^{-m}(\frac{2\pi k}{b_0})\}^{1/2}$ converges and diminishes to 0 with b_0, there exists $\tilde{b_0}$ such that for $b < \tilde{b_0}$, the quantity $K = \frac{2\pi}{b_0}(\mu - \sum_{k\neq 0}\{\delta_1^m(\frac{2\pi k}{b_0})\delta_2^m(\frac{2\pi k}{b_0})\}^{1/2}) > 0$, and we obtain $\|TF\|_{2,m} \geq K\|F\|_{2,m}$. Plainly, we can apply this argument to the mother wavelet $\Psi(y) = (1+iy)^{-3}$. We refer to Table 5.1 for estimates of the constant K for $\Psi(y)$ and for different b_0. Note that for $b_0 = 0.5$ the value of K is negative, and so we cannot deduce that T is bounded below.

As in section 4 it is now plain that $T : H^{2,m} \to H^{2,m}$ has closed range. Next we observe that $\{TF : F \in H^{2,m}\}$ is dense in $H^{2,m}$. Suppose that $G \in H^{2,-m}$ and that

$$\langle TF, G\rangle = \langle F, TG\rangle = 0, \quad F \in H^{2,m}.$$

If we take $F = \mathcal{L}f$ defined by $f(t) = g(t)(1+t)^{-2m}$, we deduce that

$$0 = \frac{\sup |\langle TF, G\rangle|}{\|G\|_{2,-m}} \geq K\|G\|_{2,-m},$$

and so $G = 0$. It follows from the Hahn–Banach theorem that the set $\{TF : F \in H^{2,m}\}$ is dense in $H^{2,m}$. Hence, since T has closed range in $H^{2,m}$, we deduce that range$(T) = H^{2,m}$. This completes the proof of Theorem 1.3.

Remark. The proof given here should be compared with the proof of Proposition 2.12 in [12], which unfortunately contains an error. However, we achieve similarly symmetric lower and upper bounds for $\|TF\|_{2,m}$, and as Daubechies points out in Remark 2, it follows by interpolation that T is bounded above and below on $H^{2,m'}$ for $-1 \leq m' \leq 1$. (See section IX.4, particularly Example 3 (rigged Hilbert spaces), in [41].)

5.1. Proof of Theorem 1.1: General case. To obtain Theorem 1.1 for $-1 \leq m \leq 1$ it is simplest to proceed (as a referee has observed) by interpolation. The upper bound

$$\sum_{j,k} |\langle F, \Psi_{j,k}\rangle|^2 (1+2^j)^{2m} \leq B_m \|F\|_{2,1}^2 \tag{5.3}$$

is obtained by applying a theorem of Stein (Theorem 3.6 in Chapter 4 of [4]) to the operator R defined by

$$RF = (\langle F, \Psi_{j,k}\rangle),$$

which, as we have seen, can be regarded as a bounded operator between weighted Hilbert spaces as follows:

$$R : L^2(0,\infty;\,(1+t)^{(1-2\theta)}dt) \to \ell^2((1+2^j)^{(1-2\theta)})$$

for $\theta = 0$ and 1. Hence, by Stein's theorem, it is bounded for all intermediate values of θ, and we can take $B_{(1-2\theta)} \le B_1^{1-\theta} B_{-1}^{\theta}$.

The lower bound is now most simply obtained by duality between $H^{2,m}$ and $H^{2,-m}$. Namely, by Theorem 1.3 we can find a constant $C_m > 0$ such that $\|TF\| \ge C_m\|F\|$ for each $F \in H^{2,m}$. Then there exists a normalized vector $G \in H^{2,-m}$ such that

$$|\,\langle TF, G\rangle\,| \ge C_m \|F\|_{2,m}.$$

Hence, by the Cauchy–Schwarz inequality,

$$\sum |\,\langle F, \Psi_{j,k}\rangle\,|^2 (1+2^j)^{2m} \sum |\,\langle G, \Psi_{j,k}\rangle\,|^2 (1+2^j)^{-2m} \ge C_m^2 \|F\|_{2,m}^2$$

and so

$$\sum |\,\langle F, \Psi_{j,k}\rangle\,|^2 (1+2^j)^{2m} \ge C_m^2 B_{-m}^{-2} \|F\|_{2,m}^2,$$

as required.

6. Wavelets for the half-plane algebra. An interesting class of wavelets is obtained when $p = 1$ in section 1.3. That is, $\Psi(y) = (1+iy)^{-1}$ is the Cauchy kernel. This wavelet does not fall under the Daubechies theory since is does not have vanishing mean value, but the system $\Psi_{j,k}$ does constitute a fundamental set for the half-plane algebra $A(\mathbb{C}_+)$, and so one can use the Cauchy kernel to obtain approximations in the uniform norm. In [16] it was shown using the Hayman–Lyons theory that certain sets of Cauchy kernels formed complete model sets in the disc algebra. By using inequalities due to Borwein and Erdélyi [8] it was shown how these model sets could be used for worst-case identification.

In this section we consider the half-plane analogue of the main results in [16]. Since they are deduced from [16] by conformal mapping the proofs will be abbreviated.

Let $\mathbb{D}$ be the unit disc and $A(\mathbb{D}) = \{f(z) : f(z)$ is analytic in $\mathbb{D}$ and continuous in $\overline{\mathbb{D}}\}$ be the disc algebra. Next let $Q_{j,k}$ be the Whitney cube partition of $\mathbb{D}$ defined for $j = 1, 2, \ldots$ and $k = 1, 2, \ldots, 2^j$ by

$$Q_{j,k} = \left\{ z : 1 - \frac{1}{2^j} \le |z| \le 1 - \frac{1}{2^{j+1}}, \frac{2k\pi}{2^j} \le \arg z \le \frac{2(k+1)\pi}{2^j} \right\}.$$

If $A \subset D$ we set $A_{j,k} = A \cap Q_{j,k}$ and $z_{j,k} = \left(1 - \frac{1}{2^j}\right) \exp \frac{2\pi i k}{2^j}$. Finally, we define $s(\theta)$ by

$$s(\theta) = s(\theta, A) = \sum_{A_{j,k} \ne \emptyset} \left(\frac{1 - |z_{j,k}|}{|z_{j,k} - e^{i\theta}|} \right)^2. \tag{6.1}$$

We say that A satisfies the *Hayman–Lyons condition* if, and only if, $s(\theta) = +\infty$ for all $\theta \in [0, 2\pi]$. In [16] the following result was established.

THEOREM D. *Suppose that $A \subset \mathbb{D}$ and that A satisfies the Hayman–Lyons condition. Then if $f \in A(\mathbb{D})$ and $\epsilon > 0$, there exists $\lambda_1, \dots, \lambda_n \in \mathbb{C}$ and $a_1, \dots, a_N \in A$ such that*

$$\left\| f(z) - \sum_{k=1}^{N} \lambda_k \frac{1}{1 - \overline{a}_k z} \right\|_\infty < \epsilon.$$

That is, the set $\mathcal{W} = \{C_w(z) : w \in A\}$, where $C_w(z) = (1 - \overline{w}z)^{-1}$ is a fundamental set for $A(\mathbb{D})$.

Our next result is a half-plane version of Theorem D. Let $A(\mathbb{C}_+)$ be the half-plane algebra for $\mathbb{C}_+$, that is, the set of $F(s)$ analytic in $\mathbb{C}_+$, continuous up to the imaginary axis and such that $\lim_{y \to \pm\infty} F(iy)$ exists. Plainly, the map $M_z = (1 - z)(1 + z)^{-1}$ gives an isometric isomorphism between $A(\mathbb{C}_+)$ and $A(\mathbb{D})$.

THEOREM 6.1. *Let $C'_w(s) = (\overline{w} + s)^{-1}$ be the Cauchy kernel for $\mathbb{C}_+$ and $\mathcal{L} \subset \mathbb{C}_+$ be the lattice*

$$\mathcal{L} = \{Z_{j,k} : \Re(Z_{j,k}) = 2^{-j}, \Im(Z_{j,k}) = k2^{-j}, j, k \in \mathbb{Z}\}.$$

Then the set $\mathcal{W} = \{1\} \cup \{C'_w(iy) : w \in \mathcal{L}\}$ is a fundamental set for $A(\mathbb{C})$. That is, given $F(s) \in A(\mathbb{C}_+)$ and $\epsilon > 0$ there exists $\lambda_1, \dots, \lambda_N, K \in \mathbb{C}$ and $w_1, \dots, w_N \in \mathcal{L}$ such that

$$\left\| F(s) - \sum_{k=1}^{N} \lambda_k \frac{1}{\overline{w}_k + s} - K \right\|_\infty < \epsilon.$$

We sketch the proof. We need to reformulate the Hayman–Lyons condition. Let $\tilde{Q}_{j,k}$ be the Whitney cube division of $\mathbb{C}_+$ defined by

$$\tilde{Q}_{j,k} = \left\{ s = x + iy : \frac{1}{2^j} \le x \le \frac{1}{2^{j-1}}, \frac{k}{2^j} \le y \le \frac{(k+1)}{2^j} \right\}.$$

For a set A in $\mathbb{C}_+$ let $A_{j,k} = A \cap Q_{j,k}$ and $Z_{j,k} = X_{j,k} + iY_{j,k} = 2^{-j} + ik2^{-j}$. It is easy to see by conformal transformation that the series in the Hayman–Lyons condition (6.1) takes the form

$$S(iy) = S(iy, A) = \sum_{A_{j,k} \neq \emptyset} \left(\frac{X_{j,k}}{|Z_{j,k} - iy|} \right)^2.$$

If iy is infinite $S(\infty)$ is defined by

$$S(\infty) = S(\infty, A) = \sum_{A_{j,k} \neq \emptyset} \left(\frac{X_{j,k}}{|Z_{j,k}|} \right)^2.$$

It is then straightforward to show that if $S(iy) = \infty$ for all y in $\overline{\mathbb{R}}$ where for each y we sum over all those cubes $Q_{j,k}$ which meet a disc with center iy, that $\{C'_w(iy) : w \in A\} \cup \{1\}$ is a fundamental set for $A(\mathbb{C}_+)$. Suppose that $G(s) \in A(\mathbb{C}_+)$. Then $G((1-z)(1+z)^{-1}) \in A(\mathbb{D})$. Let $\mathcal{A}$ be the inverse image of A by $(1-s)(1+s)^{-1}$. Then, since the hyperbolic metric is conformally invariant it follows that $s(e^{i\theta}, \mathcal{A}) = +\infty$

for $\theta \in [0, 2\pi]$, so that given $\epsilon > 0$, there exists $\lambda_1, \ldots, \lambda_N \in \mathbb{C}$ and $a_1, \ldots, a_N \in \mathcal{A}$ such that

$$\left\| G\left(\frac{1-z}{1+z}\right) - \sum_{k=1}^{N} \lambda_k \frac{1}{1-\overline{a}_k z} \right\|_\infty < \epsilon. \tag{6.2}$$

Suppose that $\overline{a}_k = (1-\overline{w}_k)(1+\overline{w}_k)^{-1}$ and $z = (1-s)(1+s)^{-1}$. Then

$$\begin{aligned} \frac{1}{1-\overline{a}_k z} &= \frac{1+s}{(1-\overline{a}_k) + s(1+\overline{a}_k)} \\ &= \frac{1+\overline{w}_k}{2}\left(1 + (1-\overline{w}_k) C'_{w_k}(s)\right). \end{aligned}$$

Hence (6.2) takes the form

$$\left\| G(s) - \sum_{k=1}^{N} \lambda'_k C'_{w_k}(s) - K \right\|_\infty < \epsilon.$$

Plainly, the lattice $\mathcal{L}$ satisfies the Hayman–Lyons condition for the right half-plane, and so for A in the above argument we may take the lattice $\mathcal{L}$ and deduce that the corresponding set of wavelets $\mathcal{W}$ is a fundamental set for $A(\mathbb{C}_+)$

Remark. The Hayman–Lyons condition can be formulated in a potential theoretic way: let $A \subset \mathbb{C}_+$ and define the sequence $A'_{j,k}$ to be $A_{j,k}$ if $A_{j,k} \neq \emptyset$ and $\emptyset$ otherwise. Let $Z_{j,k}$ be a point in $A'_{j,k}$ and $K(Z_{j,k}, \delta)$ be a hyperbolic ball with center $Z_{j,k}$. Then $S(iy_0, A) = \infty$ if the union of hyperbolic balls $K(Z_{j,k}, \delta)$ is not minimally thin at iy_0 (see [18] for more on this topic).

An interesting application of Theorem 6.1 is given to a problem in robust identification. Here one is given corrupted frequency response measurements $a_k = F(iy_k) + \eta_k$, $k = 1, \ldots, n$, on the imaginary axis of an unknown function $F(s)$ in the half-plane algebra $A(\mathbb{C}_+)$, where η_k is the measurement error (sometimes called *noise*, although it could for example be due to deterministic effects such as nonlinearities), which is assumed to be small (say, $|\eta_k| \leq \epsilon$) for each k. Then the intention is to produce an approximate model $\tilde{F} \in A(\mathbb{C}_+)$ for F in such a way that the following *robust convergence* condition is satisfied:

$$\lim_{\substack{n\to\infty \\ \epsilon\to 0}} \sup_{\|\eta\| \leq \epsilon} \|\tilde{F} - F\|_\infty = 0 \quad \text{for all } F \in A(\mathbb{C}_+). \tag{6.3}$$

An algorithm for reconstructing $F(s)$ is given by applying the following result [38].

THEOREM E. *Let X be a separable infinite-dimensional normed space over a field $\mathbb{F}$, and let $\{\phi_k\}_{k=1}^{\infty}$ be a uniformly bounded sequence of elements in the dual space X^*. Then there exist maps $T_n : \mathbb{F} \to X$ such that*

$$\lim_{\substack{n\to\infty \\ \epsilon\to 0}} \sup_{\|\eta\| \leq \epsilon} \|x_n - x\| = 0 \quad \textit{for all } x \in X,$$

with $x_n = T_n((\phi_k(x) + \eta_k)_{k=1}^n)$, if and only if there exists $\delta > 0$ with

$$\sup |\phi_k(x)| \geq \delta \|x\| \quad \textit{for all } x \in X.$$

In order to implement Theorem E we first note that for ϕ_k we can take evaluation functionals $\phi_k(F) = F(iy_k)$ and then we choose a complete model set $\{X_p\}_{p\geq 1}$ for $A(\mathbb{C}_+)$; that is, a sequence of finite-dimensional subspaces $\{X_p\}_{p\geq 1}$ of $A(\mathbb{C}_+)$ which satisfies the following two conditions:

(i) $X_1 \subset X_2 \subset X_3 \subset \cdots$,
(ii) $\cup_{p=1}^{\infty} X_p$ is dense in $A(\mathbb{C}_+)$.

The vectors $T_n(a_1, \ldots, a_n)$ are then constructed to be solutions $G_p \in X_p$ of the minimax problem:

$$s = \min_{G \in X_p} \max_{1 \le k \le n} |\phi_k(G) - a_k|,$$

where $a_k = F_k(x) + \eta_k$. Here p is chosen, depending on n, to be as large as possible such that

$$\max_{1 \le k \le n} |\phi_k(G)| \ge (\delta/2)\|G\|_\infty \quad \text{for all } G \in X_p.$$

Since this optimization problem can be solved by linear programming, the computational burden is not excessive.

We have just shown in Theorem 6.1 that $\{C_w(iy) : w \in \mathcal{L}\} \cup \{1\}$ is a complete model set for $A(\mathbb{C}_+)$, and we may for instance take X_p to be the finite-dimensional space spanned by the set

$$\{1\} \cup \{C'_w(iy) : s = 2^{-j} + ik2^{-j}, -p \le k \le p, 0 \le j \le p\}.$$

On transforming to the disc, this subspace corresponds to a subspace $\tilde{X}_p$ of the disc algebra spanned by Cauchy kernels $C_a(z) = 1/(1 - \bar{a}z)$, where the points a lie on a finite lattice $\mathcal{L}_p$, say. Now if $w = u + iv$ and $a = (1 - w)/(1 + w)$, then the following identity holds:

$$1 - \left|\frac{1-w}{1+w}\right|^2 = \frac{4|u|}{|1+w|^2},$$

and this implies that the points of $\mathcal{L}_p$ are not too close to the unit circle. Specifically, we easily obtain the uniform bound $1 - |a|^2 \ge (2/3)2^{-p}$, which implies that the poles of the functions in $\tilde{X}_p$ lie in the region $\{|z| \ge R\}$, where $(R+1)/(R-1) \le 6.2^p$.

We may now use the Borwein–Erdélyi extension of Bernstein's inequality which applies to rational functions with poles in a region $\{|z| \ge R\}$, namely,

$$\|g'\|_\infty \le N \frac{R+1}{R-1} \|g\|_\infty$$

where $\dim \tilde{X}_p = N$ [8], and perform a calculation similar to that of [16] to show that, provided that the interpolation points (iy_k), $k = 1, \ldots, n(p)$, on the imaginary axis are chosen so that the maximum gap Δ_n between their images $(1 - iy_k)/(1 + iy_k)$ on the unit circle is sufficiently small, one does indeed have

$$\max |G(iy_k)| \ge (1/2)\|G\|_\infty \quad \text{for all } G \in X_p.$$

In the example we are considering this condition is satisfied if $\Delta_n \le 1/(6N2^p)$ and $N = 2p^2 + 3p + 3$.

This means that the Cauchy kernels can be used as a complete model set for identification purposes along the lines of [38, 16].

7. Error estimates. There is extensive literature on the model reduction of infinite-dimensional linear systems, both in the H^∞ norm [22, 23, 24, 26] and the H^2 norm [25, 1]. Recent research has focused on two approaches which can be applied

to a wide class of systems. First, there is the use of orthogonal basis functions such as Laguerre and Kautz models [26, 31, 37, 27, 43] where the poles normally lie in a fixed finite set. Second, there is the approach based on rational wavelets [39, 40, 15] where the poles lie on some appropriate infinite lattice, and this is the approach we have adopted in this paper.

In order to illustrate the techniques involved, we shall consider the class of retarded delay systems in the sense of Bellman and Cooke [3]. These have perhaps the simplest irrational transfer functions that occur frequently and, unlike the transfer functions obtained from partial differential equations, tend to be difficult to approximate efficiently. Other examples, the discrete-time fractional filters, were considered by analogous methods in [15], and delay systems were considered by transforming them to the disc.

In this section we shall specialize to delay systems of the form $R(s)e^{-sT}$, $R(s)$ rational, because the results on approximation of such systems have a particularly simple form. However, general retarded delay systems (of the form $N(s)/D(s)$ where N and D are sums of terms of the form $p(s)e^{-Ts}$ with p a polynomial and $T > 0$) can be analyzed by similar means (the techniques for decomposing such systems can be found in [23, 25, 37]).

For a delay system of the form $G(s) = R(s)e^{-sT}$, where $R(s)$ is asymptotic to Cs^{-k} at infinity, the following approximation results are known [22, 23, 24, 25].

There exist constants A, $B > 0$ such that the minimal achievable error in H^∞ and H^2 rational approximation by degree-n systems satisfies

$$An^{-k} \le E_n^\infty(G) \le Bn^{-k}$$

and

$$An^{-k+1/2} \le E_n^2(G) \le Bn^{-k+1/2}.$$

This implies immediately that the $H^{2,1}$ error must satisfy

$$E_n^{2,1}(G) \ge An^{-k+1/2},$$

but it seems that a tight upper estimate is not known.

Now if we consider the integral operator Ω on $L^2(0,\infty)$ defined by

$$(\Omega u)(t) = \int_0^\infty w(t)h(t+\tau)w(\tau)u(\tau)\,d\tau, \tag{7.1}$$

where w is a suitable weight function, then its rank is the same as the rank of the usual Hankel operator and its Hilbert–Schmidt norm squared is

$$\int_{t=0}^\infty \int_{\tau=0}^\infty |w(t)|^2|h(t+\tau)|^2|w(\tau)|^2\,dt\,d\tau,$$

which equals

$$\int_{r=0}^\infty \int_{t=0}^r |w(t)|^2|h(r)|^2|w(r-t)|^2\,dt\,dr.$$

Choosing $w(t) = \sqrt{(2\sqrt{t} + b/\sqrt{t})}$ gives a Hilbert–Schmidt norm squared of

$$\int_0^\infty (r^2 + 4br + 2b^2)|h(r)|^2\pi/2\,dr,$$

since one has

$$\int_0^r (2\sqrt{t} + b/\sqrt{t})(2\sqrt{r-t} + b/\sqrt{r-t})\,dt = (r^2 + 4br + 2b^2)\pi/2.$$

We do not know a weight w such that

$$\int_0^r |w(t)|^2\,|w(r-t)|^2\,dt = (r+1)^2,$$

or even r^2+1, but by choosing $b = 1/\sqrt{2}$ we have the bounds

$$(r+1)^2 \le r^2 + 4br + 2b^2 \le (1/2 + 1/\sqrt{2})(r+1)^2$$

for $r \ge 0$, and so we have the fairly tight inequality

$$(\pi/2)\|h\|_{2,1}^2 \le \|\Omega\|_{HS}^2 \le ((\sqrt{2}+1)\pi/4)\|h\|_{2,1}^2,$$

with corresponding bounds for rational approximation errors in the $H^{2,1}$ norm. Namely, if the singular values of Ω are $(\omega_r)_{r\ge1}$, then we have the following error bound for $\|h - h_n\|_{2,1}$ when h_n is the impulse response of any degree-n system and corresponds to an operator Ω_n of rank n:

$$\begin{aligned}\|h - h_n\|_{2,1}^2 &\ge C\|\Omega - \Omega_n\|_{HS}^2 \\ &\ge C\sum_{r=n+1}^{\infty} \omega_r^2,\end{aligned}$$

where $C = 4(\sqrt{2}-1)/\pi$. Similar weighted Hankel integral operators were considered in [25] for the purposes of estimating error bounds in L^2 approximation, and in [11] for the purposes of estimating the singular values of Hankel operators on Bergman spaces. Here we have the additional complication that it does not seem possible to choose w in closed form so that the Hilbert–Schmidt norm of Ω and the $H^{2,1}$ norm of h are equal, although we can obtain equivalence of norms.

The following result generalizes both Theorem 3.2 of [25] and Lemma 14 of [11]. It applies directly to transfer functions of the form $(e^{-sT}-1)/s$ with $T > 0$, and, by standard decomposition techniques [37], to many other delay systems.

THEOREM 7.1. *Let $w(t)$ be a smooth positive function in $L^2(0,T)$ and let $h(t) = \chi_{[0,T]}(t)$. Then the singular values of the scaled Hankel operator Ω defined by* (7.1) *satisfy $r\omega_r \to J(w)$, where*

$$J(w) = \frac{1}{\pi}\int_0^T w(t)w(T-t)\,dt.$$

Proof. The proof here is a simple modification of the proof given in [25], so we shall omit many of the details. The operator Ω is self-adjoint and solving for its eigenvalues leads directly to the Sturm–Liouville differential equation

$$\frac{d}{dt}\left(\frac{v'(t)}{w(T-t)^2}\right) + \frac{v(t)w(t)^2}{\lambda^2} = 0,$$

with boundary conditions $v(T) = 0 = v'(0)$. Analysis of this equation by the Liouville–Green method [33, 35] shows that its eigenvalues are asymptotic to those

of the equation $z'' + z/\lambda^2$ over the interval $[0, X]$ with boundary conditions $z(0) = z(X) = 0$, where

$$X = \int_0^T w(t)w(T-t)\,dt,$$

and this gives the result. ∎

Unfortunately, for the weights w considered above, the integral $J(w)$ cannot be obtained in closed form, although it can be estimated numerically.

We conclude this section with a further result which applies particularly to delay systems, and can be regarded as an appendix to Theorem 1.1 above. There we considered the wavelet coefficients $\langle F, \Psi_{j,k}\rangle$ for $F \in H^{2,1}$ regarded as functions of j. It would clearly be useful to be able to estimate them as functions of k as well (so that an infinite series could be truncated to a finite sum by discarding the less significant terms) and this is what we now do.

LEMMA 7.2. *Suppose that $f(y)$, $g(y) \in L^2(\mathbb{R})$ satisfy $|f(y)| \le A|y|^{-m}$ and $|g(y)| \le B|y-C|^{-n}$, where m, $n > 1/2$ and $C > 0$. Then the following inequality holds:*

$$\langle f, g\rangle \le \frac{B\|f\|_2}{\sqrt{2n-1}(C/2)^{n-1/2}} + \frac{A\|g\|_2}{\sqrt{2m-1}(C/2)^{m-1/2}}.$$

Proof. Using the Cauchy–Schwarz inequality we have, for any r with $0 < r < C$,

$$\langle f, g\rangle \le \|f\|_2 \left(\int_{-\infty}^{r} |g(y)|^2\,dy\right)^{1/2} + \|g\|_2 \left(\int_{r}^{\infty} |f(y)|^2\,dy\right)^{1/2},$$

and this easily gives the result when we take $r = C/2$. ∎

The conditions of the following theorem will apply to any strictly proper delay system, and one can always take $m \ge 1$. Clearly, the result is of greatest use when $j < 0$, because then we obtain a good approximation with fewer translates $\Psi_{j,k}$.

THEOREM 7.3. *Let $\Psi(y) = (1+iy)^{-3}$ and let $\Psi_{j,k}(y) = 2^{j/2}\Psi(2^j y - kb_0)$ where $j, k \in \mathbb{Z}$, and let $\langle\cdot,\cdot\rangle$ be the usual L^2-inner product.*

Suppose that $|F(iy)| \le A|y|^{-m}$, where $m > 1/2$. Then for $k \ne 0$ the wavelet coefficients $\langle F, \Psi_{j,k}\rangle$ satisfy

$$\langle F, \Psi_{j,k}\rangle \le \frac{2^{5/2}\|f\|_2}{\sqrt{5}|kb_0|^{5/2}} + \frac{A\|\Psi\|_2}{\sqrt{2m-1}(|kb_0|2^{-j-1})^{m-1/2}}.$$

Proof. Clearly, we may assume without loss of generality that $k > 0$. We now apply Lemma 7.2, with $g = \Psi_{j,k}$, noting that $\|\Psi_{j,k}\|_2 = \|\Psi\|_2$ and that

$$|\Psi_{j,k}(y)| \le 2^{-5j/2}|y - kb_0 2^{-j}|^{-3}. \qquad ∎$$

8. Applications to system modeling. It is desired to approximate an infinite-dimensional model by a finite-dimensional model in the Hardy–Sobolev norm. That is, given a transfer function in $H^{2,1}$, we desire to approximate $F(s)$ by a degree n rational function. The framework developed in this paper gives a method by which we can approximate $F(s)$ by a sum of degree 3 rational functions.

In order to implement the techniques of Theorems 1.2 or 1.3 in the model reduction of a transfer function in the Hardy–Sobolev space $H^{2,1}$, we present three algorithms.

ALGORITHM 1. This is based on Theorem 1.2 and a matching pursuit (MP) algorithm of Mallat and Zhang [32]. With $\Psi(y)$ as in Theorem 1.2, it follows that the linear span of the collection $\mathcal{D} = \{\Psi_{j,k}(y) : j,k \in \mathbb{Z}\}$ is dense in $H^{2,1}$. Let $\langle \cdot, \cdot \rangle_{2,1}$ be the $H^{2,1}$-inner product. Take $0 < \alpha \leq 1$ and $F_1 \in H^{2,1}$. Choose $\Psi_{j_1,k_1}(y)$ such that

$$|\langle F_1, \Psi_{j_1,k_1} \rangle_{2,1}| \geq \alpha \sup_{\Psi_{j,k} \in \mathcal{D}} |\langle F_1, \Psi_{j,k} \rangle_{2,1}|.$$

There exists F_2 in the orthogonal complement of the subspace spanned by Ψ_{j_1,k_1} with $F_1 = \langle F_1, \Psi_{j_1,k_1} \rangle_{2,1} \Psi_{j_1,k_1} + F_2$. Next we choose $\Psi_{j_2,k_2} \in \mathcal{D}$ such that

$$|\langle F_2, \Psi_{j_2,k_2} \rangle_{2,1}| \geq \alpha \sup_{\Psi_{j,k} \in \mathcal{D}} |\langle F_2, \Psi_{j,k} \rangle_{2,1}|.$$

There exists F_3 in the orthogonal complement of the subspace spanned by Ψ_{j_2,k_2} with $F_2 = \langle F_2, \Psi_{j_2,k_2} \rangle_{2,1} \Psi_{j_2,k_2} + F_3$. Proceeding in this manner we obtain a sequence $\{\Psi_{j_n,k_n}\}_{n=1}^{\infty}$ and a sequence of *residual vectors* $\{F_n\}_{n=1}^{\infty}$ such that

$$F_n = \langle F_n, \Psi_{j_n,k_n} \rangle_{2,1} \Psi_{j_n,k_n} + F_{n+1}$$

and

$$\|F_n\|_{2,1}^2 = |\langle F_n, \Psi_{j_n,k_n} \rangle_{2,1}|^2 + \|F_{n+1}\|_{2,1}^2.$$

Therefore,

$$\begin{aligned} F_1 &= \sum_{n=1}^{m-1} (F_n - F_{n+1}) + F_m \\ &= \sum_{n=1}^{m-1} \langle F_n, \Psi_{j_n,k_n} \rangle_{2,1} \Psi_{j_n,k_n} + F_m, \end{aligned}$$

and

$$\begin{aligned} \|F_1\|_{2,1}^2 &= \sum_{n=1}^{m-1} (\|F_n\|_{2,1}^2 - \|F_{n+1}\|_{2,1}^2) + \|F_m\|_{2,1}^2 \\ &= \sum_{n=1}^{m-1} |\langle F_n, \Psi_{j_n,k_n} \rangle_{2,1}|^2 + \|F_m\|_{2,1}^2. \end{aligned}$$

Mallat and Zhang (Theorem 1, [32]) prove that $\|F_m\|_{2,1} \to 0$, and so

$$F_1 = \sum_{n=1}^{\infty} \langle F_m, \Psi_{j_n,k_n} \rangle_{2,1} \Psi_{j_n,k_n}$$

and $\|F_1\|_{2,1}^2 = \sum_{n=1}^{\infty} |\langle F_n, \Psi_{j_n,k_n} \rangle_{2,1}|^2$.

ALGORITHM 2. This is an adaptation of Algorithm 1. MP may converge somewhat slowly (see [15, section 4.2]), but it is possible to adapt it so that we obtain geometric convergence in the $H^{2,1}$ norm by projecting onto larger subspaces. For example, let $V_n = \text{span}\{\Psi_{j,k} : -n \leq j \leq n, -2^n \leq k \leq 2^n\}$ and let P_{V_n} be the projection onto V_n in the L^2 norm. Let $\langle \cdot, \cdot \rangle$ denote the L^2-inner product.

To proceed with the algorithm fix a positive ϵ and $F_1 \in H^{2,1}$. By Theorem 1.1 we may choose n_1 so large that

$$(A_1 - \epsilon)\|F_1\|_{2,1}^2 \leq \sum_{|k|,|j|\leq n_1} |\langle F_1, \Psi_{j,k}\rangle|^2(1+2^j)^2. \tag{8.1}$$

The vector $F_2 = F_1 - P_{V_{n_1}}F_1$ is orthogonal to V_{n_1} in L^2 and so $\langle F_2, \Psi_{j,k}\rangle = 0$. Therefore $\langle F_1, \Psi_{j,k}\rangle = \langle P_{V_{n_1}}F_1, \Psi_{j,k}\rangle$, $|j|, |k| \leq n_1$. Therefore, by (8.1) and Theorem 1.1, we have

$$(A_1 - \epsilon)\|F_1\|_{2,1}^2 \leq \sum_{|k|,|j|\leq n_1} |\langle P_{V_{n_1}}F_1, \Psi_{j,k}\rangle|^2(1+2^j)^2 \leq B_1\|P_{V_{n_1}}F_1\|_{2,1}^2.$$

Thus $B_1\|P_{V_{n_1}}F_1\|_{2,1}^2 \geq (A_1-\epsilon)\|F_1\|_{2,1}^2$. Increasing n_1 if necessary, we obtain similarly that $B_1\|P_{V_{n_1}}F_1\|_{2,1}^2 \geq (A_1 - \epsilon)\|P_{V_{n_1}}F_1 - F_2\|_{2,1}^2$. By the parallelogram law we have

$$\|F_2\|_{2,1}^2 + \|P_{V_{n_1}}F_1\|_{2,1}^2 = \frac{1}{2}(\|F_1\|_{2,1}^2 + \|P_{V_{n_1}}F_1 - F_2\|_{2,1}^2).$$

Therefore

$$\begin{aligned}\|F_2\|_{2,1}^2 &\leq \left(\frac{1}{2} - \left(1 - \frac{B_1}{2(A_1-\epsilon)}\right)\frac{(A_1-\epsilon)}{B_1}\right)\|F_1\|_{2,1}^2 \\ &= \left(1 - \frac{(A_1-\epsilon)}{B_1}\right)\|F_1\|_{2,1}^2. \end{aligned} \tag{8.2}$$

With the same ϵ and F_1 replaced by F_2 we repeat the procedure. Continuing in this manner we obtain a sequence $\{F_k\}_{k\geq 1}$ such that $F_k = P_{V_{n_k}}F_k + F_{k+1}$, where the $P_{V_{n_k}}F_k$ and F_{k+1} are orthogonal in the L^2 norm and such that

$$\|F_{k+1}\|_{2,1}^2 \leq \left(1 - \frac{A_1-\epsilon}{B_1}\right)^k \|F_1\|_{2,1}^2.$$

In (8.2) we have assumed b_0 is chosen so that $B_1 < 2A_1$. We may take, for example, $b_0 = 0.5$ and estimate by computer $A_1 = 4.503$ and $B_1 = 6.789$.

Remark. It is perhaps surprising that the algorithm given is based on taking projections in the L^2 norm and obtaining an expansion which converges in the Hardy–Sobolev norm.

ALGORITHM 3. This is based on ideas in Theorem 1.3. Since the operator TF is not a positive operator on $H^{2,1}$ it does not follow immediately that we can choose some constant K such that $\|I - KT\|_{2,1} < 1$. However, using a simple manipulation of Daubechies' techniques one may establish the following elementary result.

PROPOSITION 8.1. *Let $\Psi_{j,k}$ be as in Theorem* 1.3*, and*

$$RF = F - K\sum_{j,k}\langle F, \Psi_{j,k}\rangle\,\Psi_{j,k}, \qquad F \in H^{2,1}.$$

Define

$$\begin{aligned} m &= \inf_{0<t<\infty}\sum_j |\psi(2^{-j}t)|^2, \quad M = \sup_{0<t<\infty}\sum_j |\psi(2^{-j}t)|^2, \\ \beta_1(s) &= \sup_{0<t<\infty}(1+t)^{-2}\sum_j |\psi(2^{-j}t)||\psi(2^{-j}t - s)|, \\ \beta_2(s) &= \sup_{0<t<\infty}(1+t)^{2}\sum_j |\psi(2^{-j}t)||\psi(2^{-j}t + s)|. \end{aligned}$$

If $K = b_0/\pi(m+M)$, *then*

$$\|RF\|_{2,1} \le \frac{M - m + 2\sum_{k\neq 0}\left\{\beta_1\left(\frac{2\pi}{b_0}k\right)\beta_2\left(\frac{2\pi}{b_0}k\right)\right\}^{1/2}}{m+M}\|F\|_{2,1}.$$

Proof. The proof follows the lines of the proof of Theorem 1.3, and so the details are only sketched. We let G belong to $H^{2,-1}$ and estimate the modulus of

$$\begin{aligned}\langle RF, G\rangle &= \langle Rf, g\rangle \\ &= \langle f, g\rangle - K\sum_{j,k}\langle f, \psi_{j,k}\rangle\,\overline{\langle g, \psi_{j,k}\rangle} \\ &= \int_0^\infty f(t)\overline{g}(t)dt - \frac{2\pi K}{b_0}\left\{\sum_j\int_0^\infty f(t)\overline{g}(t)|\psi(2^{-j}t)|^2dt + \operatorname{rest}(f,g)\right\} \\ &= \int_0^\infty f(t)\overline{g}(t)\left\{1 - \frac{2\pi K}{b_0}\sum_j|\psi(2^{-j}t)|^2\right\}dt + \operatorname{rest}(f,g). \qquad (8.3)\end{aligned}$$

Analyzing the rest term we obtain with $\beta_1(s)$ and $\beta_2(s)$ defined above that

$$|\operatorname{rest}(f,g)| \le \frac{2\pi}{b_0}\sum_{k\neq 0}\left\{\beta_1\left(\frac{2\pi}{b_0}k\right)\beta_2\left(\frac{2\pi}{b_0}k\right)\right\}^{1/2}\|f\|_{2,1}\|g\|_{2,-1}. \qquad (8.4)$$

Therefore, substituting (8.4) into (8.3), we deduce

$$\|RF\|_{2,1} \le \left\{1 - \frac{2\pi K}{b_0}\left(m - \sum_{k\neq 0}\left\{\beta_1\left(\frac{2\pi}{b_0}k\right)\beta_2\left(\frac{2\pi}{b_0}k\right)\right\}^{1/2}\right)\right\}\|F\|_{2,1}.$$

With $K = b_0/2\pi(m+M)$ we obtain the conclusion of the proposition.

In a forthcoming paper it is intended to present some numerical results on the model reduction of several systems using the methods which appear in this study.

Acknowledgments. In conclusion, we would like to express our gratitude to the following friends and colleagues who have helped us in conversations and correspondence to understand frames and wavelets: Professors Ingrid Daubechies, Maurice Dodson, Walter Hayman F.R.S., and E. Christopher Lance. It will be plain to the informed reader the debt we owe to the work of Daubechies. We are also very grateful to one of the referees for reading a manuscript very carefully and making some pertinent comments. Finally, we would like to acknowledge a special debt to Ingrid Dudley Ward for writing some programs in C to estimate the frame constants given in this paper.

SLIDING MODES IN SOLVING CONVEX PROGRAMMING PROBLEMS*

MICHAEL P. GLAZOS†, STEFEN HUI‡, AND STANISLAW H. ŻAK§

Abstract. Sliding modes are used to analyze a class of dynamical systems that solve convex programming problems. The analysis is carried out using concepts from the theory of differential equations with discontinuous right-hand sides and Lyapunov stability theory. It is shown that the equilibrium points of the system coincide with the minimizers of the convex programming problem, and that irrespective of the initial state of the system the state trajectory converges to the solution set of the problem. The dynamic behavior of the systems is illustrated by two numerical examples.

Key words. sliding modes, differential inclusions, convex programming, stability, continuous algorithms, gradient system

1. Introduction.

Most of the traditional methods for solving constrained optimization problems are iterative algorithms [17]. However, over the past two decades considerable effort has been given to developing continuous-time methods for solving constrained optimization problems. The impetus for much of the early development in this area was a desire to solve constrained optimization problems using an electronic analog computer. Perhaps the first to develop a continuous-time algorithm was Pyne [18], who in 1956 proposed a method for solving linear programming problems using an electronic analog computer. Soon after, other methods [12, 21, 22] were proposed for solving various mathematical programming problems on an electronic analog computer. More recently, a class of analog systems known as artificial neural networks have been used to solve certain constrained optimization problems; see, for example, [3, 4, 13, 15, 16, 19, 23]. Many of these networks are suitable for monolithic implementation and are thus well suited for applications that require on-line optimization.

An approach commonly used in developing analog optimizers is to first convert the constrained optimization problem into an associated unconstrained optimization problem, and then design an analog network that solves the unconstrained problem. Such a network is typically an implementation of the dynamic gradient system for minimizing the objective function of the unconstrained problem. (See [6, 9, 8, 11, 14, 5] and references therein for other continuous-time methods for solving constrained optimization problems.)

One method for converting a constrained optimization problem into an unconstrained optimization problem is the penalty function method [17]. The idea behind the penalty function method is to replace the constrained optimization problem

$$\begin{array}{ll} \text{minimize} & f(\boldsymbol{x}) \\ \text{subject to} & \boldsymbol{x} \in \Omega \end{array}$$

with an unconstrained problem of the form

$$\text{minimize} \quad f(\boldsymbol{x}) + \zeta p(\boldsymbol{x}),$$

where $f : \mathbb{R}^n \to \mathbb{R}$ is continuous on $\mathbb{R}^n$, $\Omega \subset \mathbb{R}^n$, ζ is a positive constant, and $p : \mathbb{R}^n \to \mathbb{R}$ is continuous on $\mathbb{R}^n$ and satisfies

$$\text{(i)} \quad p(\boldsymbol{x}) \geq 0 \quad \text{for all} \quad \boldsymbol{x} \in \mathbb{R}^n$$

and

$$\text{(ii)} \quad p(\boldsymbol{x}) = 0 \quad \text{if and only if} \quad \boldsymbol{x} \in \Omega.$$

If for a finite value of the penalty parameter ζ the solution of the unconstrained problem coincides with the solution of the constrained problem, then the penalty function p is said to be exact. Bertsekas [2] has shown that except for trivial cases an exact penalty function must not be everywhere differentiable. Quite often we can find an exact penalty function that results in the function $f(\boldsymbol{x}) + \zeta p(\boldsymbol{x})$ being piecewise smooth. However, the dynamic gradient system for such a function will have a discontinuous right-hand side. As such, an analysis of its behavior cannot be carried out using only methods derived from the classical theory of differential equations. Rather, the analysis of the system must be carried out using other methods, for example, those reported in [7, 1]. Such an approach was taken by Karpinskaya [12], and more recently by Utkin [25] and Żak et al. [27], among others.

Rodríguez-Vázquez et al. [19] proposed a class of neural networks for optimization problems whose design is based on concepts from the penalty function method. This class of optimizers is particularly attractive for two reasons. First, their design does not require the calculation of a penalty parameter. Second, these networks can be realized using switched-capacitor technology, and thus are suitable for monolithic implementation. In light of these properties we feel that a rigorous analysis of the dynamics of these systems is in order. Since such an analysis is not provided in [19], we do so here.

In this paper we perform an analysis of the dynamics of the analog networks proposed in [19] when applied to a broad class of convex programming problems. The paper is organized as follows. The statement of the problem is given in section 2. The main results of the paper are presented in section 3. In section 4 we illustrate the dynamic behavior of the analyzed networks by presenting the results of two computer simulations. Concluding remarks are offered in section 5.

2. Problem statement. We consider the constrained optimization problem

$$\begin{array}{ll} \text{minimize} & f(\boldsymbol{x}) \\ \text{subject to} & g_i(\boldsymbol{x}) \leq 0, \quad i = 1, 2, \ldots, m, \end{array} \tag{1}$$

where $\boldsymbol{x} \in \mathbb{R}^n$, $f : \mathbb{R}^n \to \mathbb{R}$, and $g_i : \mathbb{R}^n \to \mathbb{R}$, $i = 1, 2, \ldots, m$. Before proceeding further we first introduce some notation. We let Ω denote the feasible region for problem (1); that is,

$$\Omega = \bigcap_{i=1}^{m} \{\boldsymbol{x} : g_i(\boldsymbol{x}) \leq 0\}.$$

The collection of all interior points of Ω is denoted by Ω^o, and the boundary points of Ω are denoted by $\partial\Omega$. Also, we define

$$\Delta_i = \{\boldsymbol{x} : g_i(\boldsymbol{x}) = 0\}, \quad i = 1, 2, \ldots, m,$$

and

$$\Delta = \bigcup_{i=1}^{m} \Delta_i.$$

We let Γ denote the collection of all relative minimizers of problem (1). Lastly, we introduce the index sets

$$I(\boldsymbol{x}) = \{i : g_i(\boldsymbol{x}) = 0\}$$

and

$$J(\boldsymbol{x}) = \{i : g_i(\boldsymbol{x}) > 0\}.$$

We assume the following.

A1. The sets $\{\boldsymbol{x} : g_i(\boldsymbol{x}) > 0\}$, $i = 1, 2, \ldots, m$, are all nonempty.

A2. The functions f and g_i, $i = 1, 2, \ldots, m$, are convex over $\mathbb{R}^n$ and have continuous first partial derivatives on $\mathbb{R}^n$; that is, $f \in \mathrm{C}^1$ and $g_i \in \mathrm{C}^1$, $i = 1, 2, \ldots, m$.

A3. The set Ω is nonempty and bounded.

A4. The constraints are everywhere regular; that is, the vectors $\nabla g_i(\boldsymbol{x})$, $i \in I(\boldsymbol{x})$, are linearly independent for any $\boldsymbol{x} \in \mathbb{R}^n$.

Remark 1. Note that there is no loss of generality by assuming A1. Indeed, when treating a constrained optimization problem we can simply ignore any constraints that are satisfied everywhere.

Remark 2. It follows from A2 that problem (1) is a convex programming problem. Specifically, by A3, we are asked to minimize a convex function f over a compact convex set Ω.

Remark 3. It follows from A1–A4 that

1. the sets $\{\boldsymbol{x} : g_i(\boldsymbol{x}) < 0\}$, $i = 1, 2, \ldots, m$, are all nonempty;
2. the points in Δ_i define a smooth $(n-1)$-dimensional surface in $\mathbb{R}^n$ that separates the regions $\{\boldsymbol{x} : g_i(\boldsymbol{x}) > 0\}$ and $\{\boldsymbol{x} : g_i(\boldsymbol{x}) < 0\}$, $i = 1, 2, \ldots, m$;
3. $\Omega^o = \bigcap_{i=1}^{m} \{\boldsymbol{x} : g_i(\boldsymbol{x}) < 0\}$, $\partial\Omega = \Omega \cap \Delta$, and both Ω^o and $\partial\Omega$ are nonempty.

The class of analog networks proposed by Rodríguez-Vázquez et al. [19] for solving problem (1) is modeled by

$$\begin{aligned} \tau\dot{\boldsymbol{x}}(t) &= \boldsymbol{h}(\boldsymbol{x}(t)) \\ &= \begin{cases} -\mu \sum_{i \in J(\boldsymbol{x}(t))} \nabla g_i(\boldsymbol{x}(t)) & \text{if} \quad \boldsymbol{x}(t) \notin \Omega, \\ -\nabla f(\boldsymbol{x}(t)) & \text{if} \quad \boldsymbol{x}(t) \in \Omega, \end{cases} \\ \boldsymbol{x}(t_0) &= \boldsymbol{x}_0, \end{aligned} \tag{2}$$

where τ and μ are positive design constants. Observe that the function $\boldsymbol{h}$ is piecewise continuous over $\mathbb{R}^n$ and, in general, discontinuous on the surfaces $\Delta_1, \Delta_2, \ldots, \Delta_m$. As such, our analysis must use methods from the theory of differential equations with discontinuous right-hand sides. Here, as in [7], we take a solution of (2) to be a solution of the differential inclusion

$$\tau\dot{\boldsymbol{x}}(t) \in H(\boldsymbol{x}(t)), \tag{3}$$

where for each $\boldsymbol{x}$, $H(\boldsymbol{x})$ is the smallest closed convex set containing the cluster values of the function $\boldsymbol{h}(\boldsymbol{y})$ as $\boldsymbol{y} \to \boldsymbol{x}$, $\boldsymbol{y} \notin \Delta$. That is, a solution of (2) is an absolutely continuous function $\boldsymbol{x}(t)$ defined on an interval or segment L for which $\tau\dot{\boldsymbol{x}}(t) \in H(\boldsymbol{x}(t))$

almost everywhere on L [7]. Observe that if the function $\boldsymbol{h}$ is continuous at a point $\boldsymbol{x}$, that is, $\boldsymbol{x} \notin \Delta$, then $H(\boldsymbol{x})$ consists of a single point, namely $\boldsymbol{h}(\boldsymbol{x})$, and the solution satisfies (2) in the usual sense. However, if $\boldsymbol{x} \in \Delta$, then $\boldsymbol{x}$ lies on one or more of the surfaces $\Delta_1, \Delta_2, \ldots, \Delta_m$. Denoting the elements of $I(\boldsymbol{x})$ by $i_1, i_2, \ldots, i_k$ it follows from A4 that for sufficiently small $\delta > 0$ the surfaces $\Delta_{i_1}, \Delta_{i_2}, \ldots, \Delta_{i_k}$ partition the δ-neighborhood of $\boldsymbol{x}$ into 2^k regions, $\mathcal{R}_1, \mathcal{R}_2, \ldots, \mathcal{R}_{2^k}$, in each of which the function $\boldsymbol{h}$ is continuous. Let $\boldsymbol{h}_j$ denote the function $\boldsymbol{h}$ restricted to the region $\mathcal{R}_j$. Then, $H(\boldsymbol{x})$ is the smallest closed convex set containing the set

$$\bigcup_{j=1}^{2^k} \bigcap_{n=1}^{\infty} \boldsymbol{h}_j \left(\left\{ \boldsymbol{y} \in \mathcal{R}_j : \|\boldsymbol{y} - \boldsymbol{x}\| \leq \frac{1}{n} \right\} \right).$$

We note that a rigorous justification for using (3) to analyze the behavior of system (2), as well as theorems guaranteeing the existence of solutions of system (2), is provided in [7, Chapter 2]. We also point out that differential inclusions are also used in continuous-time algorithms for solving nonsmooth convex programming problems; see, for example, [9, 8].

Our goal is to show that the solution set, Γ, of the optimization problem (1) is precisely the set of equilibrium points of system (2), and that all trajectories of system (2) converge to Γ, where convergence is understood in the sense of the following definition.

DEFINITION 1. *A trajectory $\boldsymbol{x} : [t_0, \infty) \to \mathbb{R}^n$ is said to converge to the solution set, Γ, if*

$$\lim_{t \to \infty} d(\boldsymbol{x}(t), \Gamma) = 0,$$

where

$$d(\boldsymbol{x}, \Gamma) = \inf_{\boldsymbol{y} \in \Gamma} \|\boldsymbol{x} - \boldsymbol{y}\|_2.$$

Recalling the well-known result that any relative minimizer of a convex programming problem is a global minimizer, it then follows from A2 and A3 that Γ is both closed and bounded. Therefore, the infimum in Definition 1 is achieved; that is,

$$d(\boldsymbol{x}, \Gamma) = \min_{\boldsymbol{y} \in \Gamma} \|\boldsymbol{x} - \boldsymbol{y}\|_2.$$

3. Main results. In this section we show that the equilibrium points of system (2) coincide with the minimizers of problem (1), and that all trajectories of system (2) converge to the solution set, Γ, of problem (1). Before proceeding further, we make a remark concerning the analysis of system (2). A phenomenon commonly occurring in systems such as (2) is the so-called sliding mode, where the motion of the system is confined to one or more of the discontinuity surfaces—see [14, 24, 25] for accounts of sliding modes and their applications in control and optimization. Consequently, we must consider two cases when analyzing the dynamic behavior of system (2). The first case is when the motion of the system is not confined to any of the surfaces $\Delta_1, \Delta_2, \ldots, \Delta_m$. The second case is when the system is in a sliding mode on one or more of the surfaces $\Delta_1, \Delta_2, \ldots, \Delta_m$. We only need to consider these two cases, for every trajectory of system (2) is composed of these two types of motion. Namely, every trajectory $\boldsymbol{x}(t)$ of system (2) can be broken up over a countable number of intervals, $(t_0, t_1), (t_1, t_2), (t_2, t_3), \ldots$, on each of which both index sets $I(\boldsymbol{x}(t))$ and

$J(\boldsymbol{x}(t))$ are constant. If $I(\boldsymbol{x}(t))$ is not empty, then the system is in a sliding mode on that interval, and if $I(\boldsymbol{x}(t))$ is empty, then the system is not in a sliding mode.

We begin our analysis by introducing the function $V : \mathbb{R}^n \to \mathbb{R}$ as

$$V(\boldsymbol{x}) = \sum_{i=1}^{m} \max\{g_i(\boldsymbol{x}), 0\},$$

or equivalently,

$$V(\boldsymbol{x}) = \begin{cases} \sum_{i \in J(\boldsymbol{x})} g_i(\boldsymbol{x}) & \text{if} \quad \boldsymbol{x} \notin \Omega, \\ 0 & \text{if} \quad \boldsymbol{x} \in \Omega. \end{cases} \tag{4}$$

Remark 4. It follows from A2 that the function V is continuous and convex on $\mathbb{R}^n$. Also, by definition, $V(\boldsymbol{x}) > 0$ for all $\boldsymbol{x} \notin \Omega$, and $V(\boldsymbol{x}) = 0$ for all $\boldsymbol{x} \in \Omega$.

We first show that every trajectory of system (2) reaches the feasible region Ω in finite time, and is thereafter confined to Ω. To prove the claim we need the following technical result.

LEMMA 1. *V is a decreasing function of time when evaluated on any trajectory of system* (2).

Proof. Let $\boldsymbol{x} : [t_0, \infty) \to \mathbb{R}^n$ be any particular trajectory of system (2). It follows directly from Remark 4 and the fact that $\boldsymbol{x}(t)$ is absolutely continuous that to prove the lemma it is enough to show that $\frac{d}{dt}V(\boldsymbol{x}(t)) \leq 0$ almost everywhere on $\{t : \boldsymbol{x}(t) \notin \Omega\}$. As noted earlier, we must consider two cases when analyzing the dynamic behavior of system (2).

Case 1. Suppose that on the interval (t_{l-1}, t_l) the trajectory $\boldsymbol{x}(t)$ does not intersect Ω or any of the surfaces $\Delta_1, \Delta_2, \ldots, \Delta_m$; that is,

$$\boldsymbol{x}(t) \notin \Omega \cup \Delta \quad \text{for all} \quad t \in (t_{l-1}, t_l). \tag{5}$$

Given $t' \in (t_{l-1}, t_l)$, let $\tilde{V} : \mathbb{R}^n \to \mathbb{R}$ be the function defined as

$$\tilde{V}(\boldsymbol{x}) = \sum_{i \in J(\boldsymbol{x}(t'))} g_i(\boldsymbol{x}).$$

It follows from (5) and the fact that $\boldsymbol{x}(t)$ is absolutely continuous that $I(\boldsymbol{x}(t)) = \emptyset$ and $J(\boldsymbol{x}(t)) = J(\boldsymbol{x}(t')) \neq \emptyset$ for all $t \in (t_{l-1}, t_l)$. Thus, on the interval (t_{l-1}, t_l), the trajectory $\boldsymbol{x}(t)$ must satisfy (2) in the usual sense; that is,

$$\tau \dot{\boldsymbol{x}}(t) = -\mu \nabla \tilde{V}(\boldsymbol{x}(t))$$

almost everywhere on the interval (t_{l-1}, t_l). Also, it follows from (4) that $V(\boldsymbol{x}(t)) = \tilde{V}(\boldsymbol{x}(t))$ for all $t \in (t_{l-1}, t_l)$. Applying the chain rule yields

$$\frac{d}{dt}V(\boldsymbol{x}(t)) = -\frac{\mu}{\tau} \left\| \nabla \tilde{V}(\boldsymbol{x}(t)) \right\|_2^2 \tag{6}$$

almost everywhere on the interval (t_{l-1}, t_l). This concludes the analysis for the first case.

Case 2. Suppose that on the interval (t_{l-1}, t_l) the trajectory $\boldsymbol{x}(t)$ is confined to one or more of the surfaces $\Delta_1, \Delta_2, \ldots, \Delta_m$ and does not intersect Ω. Specifically, suppose there exist nonempty index sets $\tilde{I}$ and $\tilde{J}$ such that

(i) $I(\boldsymbol{x}(t)) = \tilde{I}$ for all $t \in (t_{l-1}, t_l)$, and
(ii) $J(\boldsymbol{x}(t)) = \tilde{J}$ for all $t \in (t_{l-1}, t_l)$.

Let $i_1, i_2, \ldots, i_k$ denote the elements of $\tilde{I}$, and let S denote the surface to which the trajectory $\boldsymbol{x}(t)$ is confined on the interval (t_{l-1}, t_l); that is,

$$S = \bigcap_{i \in \tilde{I}} \Delta_i.$$

As in Case 1, let

$$\tilde{V}(\boldsymbol{x}) = \sum_{i \in \tilde{J}} g_i(\boldsymbol{x}).$$

We next define the function $\tilde{\boldsymbol{G}} : \mathbb{R}^n \to \mathbb{R}^{n \times k}$ as

$$\tilde{\boldsymbol{G}}(\boldsymbol{x}) = \left[\begin{array}{cccc} \nabla g_{i_1}(\boldsymbol{x}) & \nabla g_{i_2}(\boldsymbol{x}) & \cdots & \nabla g_{i_k}(\boldsymbol{x}) \end{array} \right].$$

We note that it follows from A4 that $\tilde{\boldsymbol{G}}(\boldsymbol{x})$ is of full rank for any $\boldsymbol{x} \in S$. Given $t' \in (t_{l-1}, t_l)$, it follows from A4 and (i) above that for sufficiently small $\delta > 0$ the surfaces $\Delta_{i_1}, \Delta_{i_2}, \ldots, \Delta_{i_k}$ partition the δ-neighborhood of $\boldsymbol{x}(t')$ into 2^k regions, in each of which the function $\boldsymbol{h}$ is continuous. One can show that $H(\boldsymbol{x}(t'))$ is the set of all vectors $\boldsymbol{w}$ having the form

$$\boldsymbol{w} = -\mu \nabla \tilde{V}(\boldsymbol{x}(t')) - \mu \sum_{j=0}^{2^k - 1} \alpha_j \tilde{\boldsymbol{G}}(\boldsymbol{x}(t')) \boldsymbol{u}_j, \tag{7}$$

where $\alpha_j \geq 0$, $j = 0, 1, \ldots, 2^k - 1$,

$$\sum_{j=0}^{2^k - 1} \alpha_j = 1,$$

and $\boldsymbol{u}_j \in \mathbb{R}^k$, $j = 0, 1, \ldots, 2^k - 1$, are defined as

$$\begin{aligned}
\boldsymbol{u}_0 &= \left[\begin{array}{ccccccc} 0 & 0 & 0 & \cdots & 0 & 0 & 0 \end{array} \right]^T, \\
\boldsymbol{u}_1 &= \left[\begin{array}{ccccccc} 0 & 0 & 0 & \cdots & 0 & 0 & 1 \end{array} \right]^T, \\
\boldsymbol{u}_2 &= \left[\begin{array}{ccccccc} 0 & 0 & 0 & \cdots & 0 & 1 & 0 \end{array} \right]^T, \\
\boldsymbol{u}_3 &= \left[\begin{array}{ccccccc} 0 & 0 & 0 & \cdots & 0 & 1 & 1 \end{array} \right]^T, \\
&\vdots \\
\boldsymbol{u}_{2^k-3} &= \left[\begin{array}{ccccccc} 1 & 1 & 1 & \cdots & 1 & 0 & 1 \end{array} \right]^T, \\
\boldsymbol{u}_{2^k-2} &= \left[\begin{array}{ccccccc} 1 & 1 & 1 & \cdots & 1 & 1 & 0 \end{array} \right]^T, \\
\boldsymbol{u}_{2^k-1} &= \left[\begin{array}{ccccccc} 1 & 1 & 1 & \cdots & 1 & 1 & 1 \end{array} \right]^T.
\end{aligned}$$

Let $T(\boldsymbol{x})$ denote the tangent plane to the surface S at the point $\boldsymbol{x}$. Observe that $\dot{\boldsymbol{x}}(t) \in T(\boldsymbol{x}(t))$ almost everywhere on the interval (t_{l-1}, t_l) because the trajectory $\boldsymbol{x}(t)$ is confined to the surface S on the interval (t_{l-1}, t_l). Thus, $\boldsymbol{x}(t)$ is an absolutely continuous function that satisfies

$$\tau \dot{\boldsymbol{x}}(t) \in H(\boldsymbol{x}(t)) \cap T(\boldsymbol{x}(t))$$

almost everywhere on the interval (t_{l-1}, t_l). We note that since the trajectory $\boldsymbol{x}(t)$ is confined to the surface S on the interval (t_{l-1}, t_l), the set $H(\boldsymbol{x}(t)) \cap T(\boldsymbol{x}(t))$ is

by assumption nonempty for all $t \in (t_{l-1}, t_l)$. In particular, we see that $H(\boldsymbol{x}(t')) \cap T(\boldsymbol{x}(t'))$ is the set of all vectors $\boldsymbol{w}$ that have the form (7) and also lie on the tangent plane $T(\boldsymbol{x}(t'))$. Observe, however, that

$$\sum_{j=0}^{2^k-1} \alpha_j \tilde{\boldsymbol{G}}(\boldsymbol{x}(t'))\boldsymbol{u}_j \in \operatorname{span}\left\{\nabla g_i(\boldsymbol{x}(t')) : i \in \tilde{I}\right\}$$

and thus is orthogonal to $T(\boldsymbol{x}(t'))$. Therefore, the set $H(\boldsymbol{x}(t')) \cap T(\boldsymbol{x}(t'))$ contains exactly one element, namely, the orthogonal projection of the vector $-\mu\nabla\tilde{V}(\boldsymbol{x}(t'))$ on the tangent plane $T(\boldsymbol{x}(t'))$. Hence, for each $t \in (t_{l-1}, t_l)$ the set $H(\boldsymbol{x}(t)) \cap T(\boldsymbol{x}(t))$ contains exactly one element, and thus $\dot{\boldsymbol{x}}(t)$ is uniquely determined almost everywhere on the interval (t_{l-1}, t_l). Specifically,

$$\tau\dot{\boldsymbol{x}}(t) = -\mu \boldsymbol{P}_{\boldsymbol{x}(t)} \nabla\tilde{V}(\boldsymbol{x}(t))$$

almost everywhere on the interval (t_{l-1}, t_l), where $\boldsymbol{P}_{\boldsymbol{x}}$ is the orthogonal projector onto the tangent plane $T(\boldsymbol{x})$; that is,

$$\boldsymbol{P}_{\boldsymbol{x}} = \boldsymbol{I}_n - \tilde{\boldsymbol{G}}(\boldsymbol{x})\left(\tilde{\boldsymbol{G}}^T(\boldsymbol{x})\tilde{\boldsymbol{G}}(\boldsymbol{x})\right)^{-1}\tilde{\boldsymbol{G}}^T(\boldsymbol{x}),$$

where $\boldsymbol{I}_n$ denotes the $n \times n$ identity matrix. Note that from (4) and (ii) above, $V(\boldsymbol{x}(t)) = \tilde{V}(\boldsymbol{x}(t))$ for all $t \in (t_{l-1}, t_l)$. Applying the chain rule yields

$$\frac{d}{dt}V(\boldsymbol{x}(t)) = -\frac{\mu}{\tau}\nabla^T\tilde{V}(\boldsymbol{x}(t))\boldsymbol{P}_{\boldsymbol{x}(t)}\nabla\tilde{V}(\boldsymbol{x}(t))$$

almost everywhere on the interval (t_{l-1}, t_l). Observing that

$$\boldsymbol{P}_{\boldsymbol{x}} = \boldsymbol{P}_{\boldsymbol{x}}^T = \boldsymbol{P}_{\boldsymbol{x}}^2,$$

we conclude that

$$\frac{d}{dt}V(\boldsymbol{x}(t)) = -\frac{\mu}{\tau}\left\|\boldsymbol{P}_{\boldsymbol{x}(t)}\nabla\tilde{V}(\boldsymbol{x}(t))\right\|_2^2 \tag{8}$$

almost everywhere on the interval (t_{l-1}, t_l). This completes the analysis for the second case.

It follows directly from (6) and (8) that $\frac{d}{dt}V(\boldsymbol{x}(t)) \leq 0$ almost everywhere on $\{t : \boldsymbol{x}(t) \notin \Omega\}$. This completes the proof of the lemma. □

Before stating the next result we introduce the following notation. For $\boldsymbol{y} \in \mathbb{R}^n$ and $r > 0$, we let $\mathcal{B}(\boldsymbol{y}, r)$ denote the open ball with center $\boldsymbol{y}$ and radius r; that is,

$$\mathcal{B}(\boldsymbol{y}, r) = \{\boldsymbol{x} : \|\boldsymbol{x} - \boldsymbol{y}\|_2 < r\}.$$

THEOREM 1. *Every trajectory of system* (2) *reaches the feasible set,* Ω*, in finite time and is thereafter confined to* Ω*.*

Proof. Let $\boldsymbol{x} : [t_0, \infty) \to \mathbb{R}^n$ be any particular trajectory of system (2). To prove the theorem, we must show that there exists a number $T_\Omega(\boldsymbol{x}_0) \geq t_0$ such that $\boldsymbol{x}(t) \in \Omega$ for all $t \geq T_\Omega(\boldsymbol{x}_0)$. It follows from Remark 4 and Lemma 1 that $T_\Omega(\boldsymbol{x}_0) = t_0$ if $\boldsymbol{x}_0 \in \Omega$. We now consider the case when $\boldsymbol{x}_0 \notin \Omega$. Once again, we need to consider two cases when analyzing the dynamic behavior of system (2). In the proof, we use the fact that the sublevel set

$$\{\boldsymbol{x} : V(\boldsymbol{x}) \leq a\}$$

is bounded for any $a \in \mathbb{R}$ (see, for example, [25, p. 229]).

Case 1. Consider again the analysis presented in Case 1 of the proof of Lemma 1. By the boundedness of the sublevel sets of V, there exist $\boldsymbol{y} \in \Omega^o$ and $r(\boldsymbol{x}_0) > 0$ such that

$$\mathcal{B}(\boldsymbol{y}, r(\boldsymbol{x}_0)) \supset \{\boldsymbol{x} : V(\boldsymbol{x}) \leq V(\boldsymbol{x}_0)\}.$$

Observe that by A2, the function $\tilde{V}$ is convex over $\mathbb{R}^n$ and has continuous first partial derivatives on $\mathbb{R}^n$. Consequently, the inequality

$$\nabla^T \tilde{V}(\boldsymbol{x}(t))\,(\boldsymbol{x}(t) - \boldsymbol{y}) \geq \tilde{V}(\boldsymbol{x}(t)) - \tilde{V}(\boldsymbol{y}) \tag{9}$$

is satisfied for all $t \in (t_{l-1}, t_l)$. Applying the Cauchy–Schwarz inequality to (9) yields

$$\left\| \nabla \tilde{V}(\boldsymbol{x}(t)) \right\|_2 \|\boldsymbol{x}(t) - \boldsymbol{y}\|_2 \geq \tilde{V}(\boldsymbol{x}(t)) - \tilde{V}(\boldsymbol{y}) \tag{10}$$

for all $t \in (t_{l-1}, t_l)$. We see from Remark 3 that $\tilde{V}(\boldsymbol{y}) < 0$. Also, by definition, $\tilde{V}(\boldsymbol{x}(t)) > 0$ for all $t \in (t_{l-1}, t_l)$. Combining these two facts together with (10), we conclude that

$$\left\| \nabla \tilde{V}(\boldsymbol{x}(t)) \right\|_2 \geq -\frac{\tilde{V}(\boldsymbol{y})}{\|\boldsymbol{x}(t) - \boldsymbol{y}\|_2} \tag{11}$$

for all $t \in (t_{l-1}, t_l)$. It follows from the fact that $\mathcal{B}(\boldsymbol{y}, r(\boldsymbol{x}_0)) \supset \{\boldsymbol{x} : V(\boldsymbol{x}) \leq V(\boldsymbol{x}_0)\}$ and from Lemma 1 that $\boldsymbol{x}(t) \in \mathcal{B}(\boldsymbol{y}, r(\boldsymbol{x}_0))$ for all $t \in (t_{l-1}, t_l)$. Hence, $\|\boldsymbol{x}(t) - \boldsymbol{y}\|_2 \leq r(\boldsymbol{x}_0)$ for all $t \in (t_{l-1}, t_l)$. This fact, together with (11), implies that

$$\left\| \nabla \tilde{V}(\boldsymbol{x}(t)) \right\|_2 \geq -\frac{\tilde{V}(\boldsymbol{y})}{r(\boldsymbol{x}_0)} \tag{12}$$

for all $t \in (t_{l-1}, t_l)$. Now let $\tilde{\eta}(\boldsymbol{x}_0)$ be the positive constant defined as

$$\tilde{\eta}(\boldsymbol{x}_0) = \frac{\mu}{\tau} \left(\frac{\tilde{V}(\boldsymbol{y})}{r(\boldsymbol{x}_0)} \right)^2. \tag{13}$$

Then, it follows from (6), (12), and (13) that

$$\frac{d}{dt} V(\boldsymbol{x}(t)) \leq -\tilde{\eta}(\boldsymbol{x}_0) \tag{14}$$

almost everywhere on the interval (t_{l-1}, t_l). However, (14) combined with the fact that there is a finite number of constraints, that is, m is finite, implies the existence of a number $\eta_1(\boldsymbol{x}_0) > 0$ such that

$$\frac{d}{dt} V(\boldsymbol{x}(t)) \leq -\eta_1(\boldsymbol{x}_0) \tag{15}$$

almost everywhere on $\{t : \boldsymbol{x}(t) \notin \Omega \cup \Delta\}$. This concludes the analysis for the first case.

Case 2. Consider again the analysis presented in Case 2 of the proof of Lemma 1. By the boundedness of the sublevel sets of V, there exist $\boldsymbol{y} \in \Omega^o$ and $r(\boldsymbol{x}_0) > 0$ such that

$$\mathcal{B}(\boldsymbol{y}, r(\boldsymbol{x}_0)) \supset \{\boldsymbol{x} : V(\boldsymbol{x}) \leq V(\boldsymbol{x}_0)\}.$$

Following the argument of our analysis for Case 2 of the proof of Lemma 1, we conclude that there exist nonnegative constants $\beta_{i_1}, \beta_{i_2}, \ldots, \beta_{i_k}$, such that

$$\boldsymbol{P}_{\boldsymbol{x}(t')} \nabla \tilde{V}(\boldsymbol{x}(t')) = \nabla \tilde{V}(\boldsymbol{x}(t')) + \sum_{j \in \tilde{I}} \beta_j \nabla g_j(\boldsymbol{x}(t')). \tag{16}$$

Let $\hat{V} : \mathbb{R}^n \to \mathbb{R}$ be the function defined as

$$\hat{V}(\boldsymbol{x}) = \tilde{V}(\boldsymbol{x}) + \sum_{j \in \tilde{I}} \beta_j g_j(\boldsymbol{x}).$$

By virtue of A2, the function $\hat{V}$ is convex over $\mathbb{R}^n$ and has continuous first partial derivatives on $\mathbb{R}^n$. Using arguments similar to those used in Case 1, we have

$$\left\| \nabla \hat{V}(\boldsymbol{x}(t')) \right\|_2 \geq -\frac{\tilde{V}(\boldsymbol{y})}{r(\boldsymbol{x}_0)}.$$

It then follows from (16) and the definition of $\hat{V}$ that

$$\left\| \boldsymbol{P}_{\boldsymbol{x}(t)} \nabla \tilde{V}(\boldsymbol{x}(t)) \right\|_2 = \left\| \nabla \hat{V}(\boldsymbol{x}(t)) \right\|_2 \geq -\frac{\tilde{V}(\boldsymbol{y})}{r(\boldsymbol{x}_0)}$$

for all $t \in (t_{l-1}, t_l)$. As in Case 1, we conclude that there exists a number $\eta_2(\boldsymbol{x}_0) > 0$, such that

$$\frac{d}{dt} V(\boldsymbol{x}(t)) \leq -\eta_2(\boldsymbol{x}_0) \tag{17}$$

almost everywhere on $\{t : \boldsymbol{x}(t) \in \Delta \setminus \Omega\}$. This concludes the analysis for the second case.

Let $\eta(\boldsymbol{x}_0) = \min\{\eta_1(\boldsymbol{x}_0), \eta_2(\boldsymbol{x}_0)\}$. Then, combining (15) and (17) we obtain

$$\frac{d}{dt} V(\boldsymbol{x}(t)) \leq -\eta(\boldsymbol{x}_0) \tag{18}$$

almost everywhere on $\{t : \boldsymbol{x}(t) \notin \Omega\}$. Let

$$T_\Omega(\boldsymbol{x}_0) = t_0 + \frac{V(\boldsymbol{x}_0)}{\eta(\boldsymbol{x}_0)}. \tag{19}$$

By Lemma 1, Remark 4, (18), and (19), the trajectory $\boldsymbol{x}(t) \in \Omega$ for all $t \geq T_\Omega(\boldsymbol{x}_0)$. This completes the proof. □

Having established this last result, we now turn our attention to analyzing the dynamic behavior of system (2) when its motion is confined to the feasible set Ω. We begin by introducing the function $F : \mathbb{R}^n \to \mathbb{R}$ as

$$F(\boldsymbol{x}) = f(\boldsymbol{x}) - f^*,$$

where f^* is the optimal value of f for problem (1).

Remark 5. It follows from A2 that the function F is convex over $\mathbb{R}^n$ and has continuous first partial derivatives on $\mathbb{R}^n$. Also, by definition, $F(\boldsymbol{x}) = 0$ for all $\boldsymbol{x} \in \Gamma$, and $F(\boldsymbol{x}) > 0$ for all $\boldsymbol{x} \in \Omega \setminus \Gamma$.

We will show that F tends to zero with time when evaluated on any trajectory of system (2). We need the following technical result.

LEMMA 2. *F is a decreasing function of time when evaluated on any trajectory of system* (2) *while it is confined to the feasible set* Ω.

Proof. Let $\boldsymbol{x} : [t_0, \infty) \to \mathbb{R}^n$ be any particular trajectory of system (2). It follows from Remark 5 and the fact that $\boldsymbol{x}(t)$ is absolutely continuous that to prove the lemma it is enough to show that $\frac{d}{dt}F(\boldsymbol{x}(t)) \leq 0$ almost everywhere on $\{t : \boldsymbol{x}(t) \in \Omega\}$. As before, we consider two cases when analyzing the dynamic behavior of system (2).

Case 1. Suppose that $\boldsymbol{x}(t) \in \Omega^o$ for all $t \in (t_{l-1}, t_l)$. Using arguments similar to those used in Case 1 of the proof of Lemma 1, we conclude that

$$\tau \dot{\boldsymbol{x}}(t) = -\nabla f(\boldsymbol{x}(t)) \tag{20}$$

almost everywhere on the interval (t_{l-1}, t_l). Applying the chain rule, we obtain

$$\frac{d}{dt}F(\boldsymbol{x}(t)) = -\frac{1}{\tau}\left\|\nabla f(\boldsymbol{x}(t))\right\|_2^2 \tag{21}$$

almost everywhere on the interval (t_{l-1}, t_l). This concludes the analysis for the first case.

Case 2. Suppose that $\boldsymbol{x}(t) \in \partial\Omega$ and $I(\boldsymbol{x}(t))$ is constant for all $t \in (t_{l-1}, t_l)$. We use the same notation as in Case 2 of the proof of Lemma 1. The first part of the proof is almost identical to that of Case 2 of the proof of Lemma 1, and we omit the details. We only observe that now we have the following.

(i) $H(\boldsymbol{x}(t'))$ is the set of all vectors $\boldsymbol{w}$ having the form

$$\boldsymbol{w} = -\alpha_0 \nabla f(\boldsymbol{x}(t')) - \mu \sum_{j=1}^{2^k-1} \alpha_j \tilde{\boldsymbol{G}}(\boldsymbol{x}(t'))\boldsymbol{u}_j,$$

where $\alpha_j \geq 0$, $j = 0, 1, \ldots, 2^k - 1$, $\sum_{j=0}^{2^k-1} \alpha_j = 1$, and $\boldsymbol{u}_j \in \mathbb{R}^k$, $j = 1, 2, \ldots, 2^k - 1$, are as defined in the proof of Lemma 1.

(ii) Suppose $\hat{\boldsymbol{w}} \in H(\boldsymbol{x}(t')) \cap T(\boldsymbol{x}(t'))$, with

$$\hat{\boldsymbol{w}} = -\hat{\alpha}_0 \nabla f(\boldsymbol{x}(t')) - \mu \sum_{j=1}^{2^k-1} \hat{\alpha}_j \tilde{\boldsymbol{G}}(\boldsymbol{x}(t'))\boldsymbol{u}_j, \tag{22}$$

where $\hat{\alpha}_j \geq 0$, $j = 0, 1, \ldots, 2^k - 1$, and $\sum_{j=0}^{2^k-1} \hat{\alpha}_j = 1$. Then, the vector $\hat{\boldsymbol{w}}$ must satisfy the equation

$$\hat{\boldsymbol{w}} = -\hat{\alpha}_0 \boldsymbol{P}_{\boldsymbol{x}(t')} \nabla f(\boldsymbol{x}(t')). \tag{23}$$

It follows from (22) and (23) that

$$-\hat{\alpha}_0 \left(\boldsymbol{I}_n - \boldsymbol{P}_{\boldsymbol{x}(t')}\right) \nabla f(\boldsymbol{x}(t')) = \mu \sum_{j=1}^{2^k-1} \hat{\alpha}_j \tilde{\boldsymbol{G}}(\boldsymbol{x}(t'))\boldsymbol{u}_j. \tag{24}$$

Now, let $\boldsymbol{U} \in \mathbb{R}^{k \times (2^k-1)}$ be the matrix with columns $\boldsymbol{u}_1, \boldsymbol{u}_2, \ldots, \boldsymbol{u}_{2^k-1}$, and let $\hat{\boldsymbol{\alpha}} \in \mathbb{R}^{2^k-1}$ be the column vector with components $\hat{\alpha}_1, \hat{\alpha}_2, \ldots, \hat{\alpha}_{2^k-1}$; that is,

$$\boldsymbol{U} = \begin{bmatrix} \boldsymbol{u}_1 & \boldsymbol{u}_2 & \cdots & \boldsymbol{u}_{2^k-1} \end{bmatrix}$$

and

$$\hat{\boldsymbol{\alpha}} = \begin{bmatrix} \hat{\alpha}_1 & \hat{\alpha}_2 & \cdots & \hat{\alpha}_{2^k-1} \end{bmatrix}^T.$$

Using the above notation, we can rewrite (24) as

$$-\frac{\hat{\alpha}_0}{\mu}\left(\boldsymbol{I}_n - \boldsymbol{P}_{\boldsymbol{x}(t')}\right)\nabla f(\boldsymbol{x}(t')) = \tilde{\boldsymbol{G}}(\boldsymbol{x}(t'))\boldsymbol{U}\hat{\boldsymbol{\alpha}}. \tag{25}$$

Premultiplying both sides of (25) by $\left(\tilde{\boldsymbol{G}}^T(\boldsymbol{x}(t'))\tilde{\boldsymbol{G}}(\boldsymbol{x}(t'))\right)^{-1}\tilde{\boldsymbol{G}}^T(\boldsymbol{x}(t'))$, we obtain

$$-\frac{\hat{\alpha}_0}{\mu}\left(\tilde{\boldsymbol{G}}^T(\boldsymbol{x}(t'))\tilde{\boldsymbol{G}}(\boldsymbol{x}(t'))\right)^{-1}\tilde{\boldsymbol{G}}^T(\boldsymbol{x}(t'))\nabla f(\boldsymbol{x}(t')) = \boldsymbol{U}\hat{\boldsymbol{\alpha}}.$$

Taking the 1-norm yields

$$\frac{\hat{\alpha}_0}{\mu}\left\|\left(\tilde{\boldsymbol{G}}^T(\boldsymbol{x}(t'))\tilde{\boldsymbol{G}}(\boldsymbol{x}(t'))\right)^{-1}\tilde{\boldsymbol{G}}^T(\boldsymbol{x}(t'))\nabla f(\boldsymbol{x}(t'))\right\|_1 = \left\|\boldsymbol{U}\hat{\boldsymbol{\alpha}}\right\|_1.$$

Hence,

$$\frac{\hat{\alpha}_0}{\mu}\left\|\left(\tilde{\boldsymbol{G}}^T(\boldsymbol{x}(t'))\tilde{\boldsymbol{G}}(\boldsymbol{x}(t'))\right)^{-1}\tilde{\boldsymbol{G}}^T(\boldsymbol{x}(t'))\right\|_1 \left\|\nabla f(\boldsymbol{x}(t'))\right\|_1 \geq \left\|\boldsymbol{U}\hat{\boldsymbol{\alpha}}\right\|_1. \tag{26}$$

However,

$$\left\|\boldsymbol{U}\hat{\boldsymbol{\alpha}}\right\|_1 \geq \sum_{j=1}^{2^k-1}\hat{\alpha}_j = 1 - \hat{\alpha}_0. \tag{27}$$

Moreover, by A2 and the fact that $\Omega \cap S$ is by definition compact, there exist nonnegative constants M_1 and M_2 such that

$$M_1 \geq \left\|\left(\tilde{\boldsymbol{G}}^T(\boldsymbol{x})\tilde{\boldsymbol{G}}(\boldsymbol{x})\right)^{-1}\tilde{\boldsymbol{G}}^T(\boldsymbol{x})\right\|_1 \quad \text{for all} \quad \boldsymbol{x} \in \Omega \cap S, \tag{28}$$

and

$$M_2 \geq \left\|\nabla f(\boldsymbol{x})\right\|_1 \quad \text{for all} \quad \boldsymbol{x} \in \Omega \cap S. \tag{29}$$

Using (26)–(29) we obtain

$$\frac{\hat{\alpha}_0 M_1 M_2}{\mu} \geq 1 - \hat{\alpha}_0,$$

which implies that $\hat{\alpha}_0 > 0$. Therefore

$$\frac{M_1 M_2}{\mu} \geq \frac{1-\hat{\alpha}_0}{\hat{\alpha}_0} = \frac{1}{\hat{\alpha}_0} - 1,$$

and hence

$$\hat{\alpha}_0 \geq \frac{\mu}{\mu + M_1 M_2}. \tag{30}$$

Let $\sigma = \frac{\mu}{\mu + M_1 M_2}$; then (23) and (30) imply that

$$H(\boldsymbol{x}(t)) \cap T(\boldsymbol{x}(t)) \subset \left\{-\alpha \boldsymbol{P}_{\boldsymbol{x}(t)} \nabla f(\boldsymbol{x}(t)) : \sigma \leq \alpha \leq 1\right\} \tag{31}$$

for all $t \in (t_{l-1}, t_l)$, and therefore

$$\tau \dot{\boldsymbol{x}}(t) \in \left\{-\alpha \boldsymbol{P}_{\boldsymbol{x}(t)} \nabla f(\boldsymbol{x}(t)) : \sigma \leq \alpha \leq 1\right\} \tag{32}$$

almost everywhere on the interval (t_{l-1}, t_l). Applying the chain rule and observing that $\boldsymbol{P}_{\boldsymbol{x}} = \boldsymbol{P}_{\boldsymbol{x}}^T = \boldsymbol{P}_{\boldsymbol{x}}^2$, we obtain

$$\frac{d}{dt} F(\boldsymbol{x}(t)) \in \left\{-\frac{\alpha}{\tau} \left\| \boldsymbol{P}_{\boldsymbol{x}(t)} \nabla f(\boldsymbol{x}(t)) \right\|_2^2 : \sigma \leq \alpha \leq 1\right\}$$

almost everywhere on the interval (t_{l-1}, t_l). Hence,

$$\frac{d}{dt} F(\boldsymbol{x}(t)) \leq -\frac{\sigma}{\tau} \left\| \boldsymbol{P}_{\boldsymbol{x}(t)} \nabla f(\boldsymbol{x}(t)) \right\|_2^2 \tag{33}$$

almost everywhere on the interval (t_{l-1}, t_l). This concludes the analysis for the second case.

It now follows from (21) and (33) that $\frac{d}{dt} F(\boldsymbol{x}(t)) \leq 0$ almost everywhere on $\{t : \boldsymbol{x}(t) \in \Omega\}$. The proof is complete. □

Before presenting the next lemma we introduce the following notation. For each $\varepsilon > 0$, let

$$\Phi_\varepsilon = \Omega \cap \{\boldsymbol{x} : F(\boldsymbol{x}) < \varepsilon\}.$$

LEMMA 3. *F tends to zero with time when evaluated on any trajectory of system (2).*

Proof. Let $\boldsymbol{x} : [t_0, \infty) \to \mathbb{R}^n$ be any particular trajectory of system (2). To prove the lemma, it is enough to show that given any $\varepsilon > 0$, there exists a number $T(\boldsymbol{x}_0, \varepsilon) \geq t_0$ such that $\boldsymbol{x}(t) \in \Phi_\varepsilon$ for all $t \geq T(\boldsymbol{x}_0, \varepsilon)$. By Theorem 1, there is a number $T_\Omega(\boldsymbol{x}_0) \geq t_0$ such that $\boldsymbol{x}(t) \in \Omega$ for all $t \geq T_\Omega(\boldsymbol{x}_0)$. It follows from Theorem 1 and Lemma 2 that

$$T(\boldsymbol{x}_0, \varepsilon) = T_\Omega(\boldsymbol{x}_0) \quad \text{if} \quad \boldsymbol{x}\left(T_\Omega(\boldsymbol{x}_0)\right) \in \Phi_\varepsilon.$$

We now consider the case when $\boldsymbol{x}\left(T_\Omega(\boldsymbol{x}_0)\right) \notin \Phi_\varepsilon$. Once again, we must consider two cases when analyzing the dynamic behavior of system (2).

Case 1. Consider again the analysis presented in Case 1 of the proof of Lemma 2, and suppose that $\boldsymbol{x}(t) \in \Omega \setminus \Phi_{\varepsilon/2}$ for all $t \in (t_{l-1}, t_l)$. Let $\boldsymbol{y} \in \Gamma$ and $r > 0$ such that $\mathcal{B}(\boldsymbol{y}, r) \supset \Omega$. The existence of an open ball with this property is a consequence of A3. By Remark 5

$$\nabla^T F(\boldsymbol{x}(t))(\boldsymbol{x}(t) - \boldsymbol{y}) \geq F(\boldsymbol{x}(t)) - F(\boldsymbol{y}) \tag{34}$$

for all $t \in (t_{l-1}, t_l)$. Applying the Cauchy–Schwarz inequality to (34) yields

$$\|\nabla F(\boldsymbol{x}(t))\|_2 \, \|\boldsymbol{x}(t) - \boldsymbol{y}\|_2 \geq F(\boldsymbol{x}(t)) - F(\boldsymbol{y}) \tag{35}$$

for all $t \in (t_{l-1}, t_l)$. Observe from Remark 5 that $F(\boldsymbol{y}) = 0$. Also, by definition, $F(\boldsymbol{x}(t)) \geq \varepsilon/2$ for all $t \in (t_{l-1}, t_l)$. Combining these two facts together with (35), we obtain

$$\|\nabla F(\boldsymbol{x}(t))\|_2 \geq \frac{\varepsilon}{2\|\boldsymbol{x}(t) - \boldsymbol{y}\|_2}$$

for all $t \in (t_{l-1}, t_l)$. However, $\|\boldsymbol{x}(t) - \boldsymbol{y}\|_2 \leq r$ for all $t \in (t_{l-1}, t_l)$ since $\mathcal{B}(\boldsymbol{y}, r) \supset \Omega$ and $\boldsymbol{x}(t) \in \Omega$ for all $t \in (t_{l-1}, t_l)$. Hence,

$$\|\nabla F(\boldsymbol{x}(t))\|_2 \geq \frac{\varepsilon}{2r}$$

for all $t \in (t_{l-1}, t_l)$. Let $\eta_1(\varepsilon)$ be the positive constant defined as

$$\eta_1(\varepsilon) = \frac{\varepsilon^2}{4\tau r^2}.$$

It now follows from (21) and the definition of F that

$$\frac{d}{dt} F(\boldsymbol{x}(t)) \leq -\eta_1(\varepsilon) \tag{36}$$

almost everywhere on $\{t : \boldsymbol{x}(t) \in \Omega^o \setminus \Phi_{\varepsilon/2}\}$. This concludes the analysis for the first case.

Case 2. Consider again the analysis presented in Case 2 of the proof of Lemma 2, and suppose that $\boldsymbol{x}(t) \in \Omega \setminus \Phi_{\varepsilon/2}$ for all $t \in (t_{l-1}, t_l)$. Let $\boldsymbol{y} \in \Gamma$ and $r > 0$ such that $\mathcal{B}(\boldsymbol{y}, r) \supset \Omega$. It follows from (22), (23), and (30) that there exist nonnegative constants $\beta_{i_1}, \beta_{i_2}, \ldots, \beta_{i_k}$ such that

$$\boldsymbol{P}_{\boldsymbol{x}(t')} \nabla f(\boldsymbol{x}(t')) = \nabla f(\boldsymbol{x}(t')) + \sum_{j \in \tilde{I}} \beta_j \nabla g_j(\boldsymbol{x}(t')). \tag{37}$$

Let $\tilde{F} : \mathbb{R}^n \to \mathbb{R}$ be the function defined as

$$\tilde{F}(\boldsymbol{x}) = F(\boldsymbol{x}) + \sum_{j \in \tilde{I}} \beta_j g_j(\boldsymbol{x}).$$

Observe that by virtue of A2 and Remark 5, the function $\tilde{F}$ is convex over $\mathbb{R}^n$ and has continuous first partial derivatives on $\mathbb{R}^n$. Therefore, the inequality

$$\nabla^T \tilde{F}(\boldsymbol{x}(t'))(\boldsymbol{x}(t') - \boldsymbol{y}) \geq \tilde{F}(\boldsymbol{x}(t')) - \tilde{F}(\boldsymbol{y})$$

holds. Applying the Cauchy–Schwarz inequality and observing that $\tilde{F}(\boldsymbol{y}) \leq 0$ and $\tilde{F}(\boldsymbol{x}(t')) \geq \varepsilon/2$, we obtain

$$\left\| \nabla \tilde{F}(\boldsymbol{x}(t')) \right\|_2 \geq \frac{\varepsilon}{2\|\boldsymbol{x}(t') - \boldsymbol{y}\|_2}.$$

However, $\|\boldsymbol{x}(t') - \boldsymbol{y}\|_2 \leq r$ since $\boldsymbol{x}(t') \in \Omega$ and $\mathcal{B}(\boldsymbol{y}, r) \supset \Omega$. Therefore,

$$\left\| \nabla \tilde{F}(\boldsymbol{x}(t')) \right\|_2 \geq \frac{\varepsilon}{2r}.$$

Taking into account (37) and the definition of $\tilde{F}$ it follows that

$$\left\| \boldsymbol{P}_{\boldsymbol{x}(t)} \nabla f(\boldsymbol{x}(t)) \right\|_2 \geq \frac{\varepsilon}{2r} \tag{38}$$

for all $t \in (t_{l-1}, t_l)$. Now let $\tilde{\eta}(\varepsilon)$ be the positive constant defined as

$$\tilde{\eta}(\varepsilon) = \frac{\sigma \varepsilon^2}{4\tau r^2}.$$

It then follows from (33) that

$$\frac{d}{dt}F(\boldsymbol{x}(t)) \leq -\tilde{\eta}(\varepsilon) \tag{39}$$

almost everywhere on the interval (t_{l-1}, t_l). However, (39) combined with the fact that there is a finite number of constraints, that is, m is finite, implies the existence of a constant $\eta_2(\varepsilon) > 0$ such that

$$\frac{d}{dt}F(\boldsymbol{x}(t)) \leq -\eta_2(\varepsilon) \tag{40}$$

almost everywhere on $\left\{t : \boldsymbol{x}(t) \in \partial\Omega \setminus \Phi_{\varepsilon/2}\right\}$. This concludes the analysis for the second case.

Let $\eta(\varepsilon) = \min\{\eta_1(\varepsilon), \eta_2(\varepsilon)\}$. It follows directly from (36) and (40) that

$$\frac{d}{dt}F(\boldsymbol{x}(t)) \leq -\eta(\varepsilon) \tag{41}$$

almost everywhere on $\left\{t : \boldsymbol{x}(t) \in \Omega \setminus \Phi_{\varepsilon/2}\right\}$. Now let

$$T(\boldsymbol{x}_0, \varepsilon) = T_\Omega(\boldsymbol{x}_0) + \frac{F\left(\boldsymbol{x}(T_\Omega(\boldsymbol{x}_0))\right) - \frac{\varepsilon}{2}}{\eta(\varepsilon)}. \tag{42}$$

Then, by Theorem 1, Lemma 2, (41), and (42), we have $\boldsymbol{x}(t) \in \Phi_\varepsilon$ for all $t \geq T(\boldsymbol{x}_0, \varepsilon)$, which completes the proof of the lemma. □

We are now ready to present the main results of this paper. Before doing so we introduce the following notation. For each $\delta > 0$, let

$$\Gamma_\delta = \Omega \cap \{\boldsymbol{x} : d(\boldsymbol{x}, \Gamma) < \delta\}.$$

THEOREM 2. *Every trajectory of system* (2) *converges to the solution set,* Γ*, of problem* (1)*.*

Proof. Let $\boldsymbol{x} : [t_0, \infty) \to \mathbb{R}^n$ be any particular trajectory of system (2). To prove the theorem, it is enough to show that given any $\delta > 0$, there exists a number $T_\delta(\boldsymbol{x}_0) \geq t_0$ such that $\boldsymbol{x}(t) \in \Gamma_\delta$ for all $t \geq T_\delta(\boldsymbol{x}_0)$. Let

$$\begin{aligned}\varepsilon &= \varepsilon(\delta)\\ &= \min\{F(\boldsymbol{x}) : \boldsymbol{x} \in \Omega \cap \{\boldsymbol{x} : d(\boldsymbol{x}, \Gamma) = \delta\}\}.\end{aligned}$$

Note that ε is well defined since, by definition, the function F is continuous and the set $\Omega \cap \{\boldsymbol{x} : d(\boldsymbol{x}, \Gamma) = \delta\}$ is compact. Also, observe that, by definition, $\varepsilon > 0$. Now it is a direct consequence of the fact that F is a convex function and Ω is a convex set that $\Phi_{\varepsilon/2} \subset \Gamma_\delta$. By Lemma 3, there exists a number $T(\boldsymbol{x}_0, \varepsilon/2) \geq t_0$ such that $\boldsymbol{x}(t) \in \Phi_{\varepsilon/2}$ for all $t \geq T(\boldsymbol{x}_0, \varepsilon/2)$. Let $T_\delta(\boldsymbol{x}_0) = T(\boldsymbol{x}_0, \varepsilon/2)$. Then, we have $\boldsymbol{x}(t) \in \Gamma_\delta$ for all $t \geq T_\delta(\boldsymbol{x}_0)$. This completes the proof. □

We now show that the equilibrium points of system (2) coincide with the minimizers of the optimization problem (1).

THEOREM 3. *A point* $\boldsymbol{x}^* \in \mathbb{R}^n$ *is an equilibrium point of system* (2) *if and only if it is a minimizer of problem* (1)*.*

Proof. It follows from Theorem 2 that any equilibrium point of system (2) must be contained in Γ. Thus, it remains to show that every point in Γ is an equilibrium point of system (2). To this end, let $\boldsymbol{x} : [t_0, \infty) \to \mathbb{R}^n$ be any particular trajectory

of system (2) with $\boldsymbol{x}_0 \in \Gamma$. Note that by Remarks 4 and 5, and Lemmas 1 and 2, $\boldsymbol{x}(t) \in \Gamma$ for all $t \geq t_0$. When analyzing the behavior of the trajectory $\boldsymbol{x}(t)$ we need only consider the two cases considered in the proof of Lemma 2.

Case 1. Consider again the analysis presented in Case 1 of the proof of Lemma 2. It follows from the first-order necessary conditions for problem (1), and the fact that $\boldsymbol{x}(t) \in \Gamma$ for all $t \geq t_0$, that $\nabla f(\boldsymbol{x}(t)) = \boldsymbol{0}$ for all $t \in (t_{l-1}, t_l)$. It then follows from (20) that $\dot{\boldsymbol{x}}(t) = \boldsymbol{0}$ almost everywhere on the interval (t_{l-1}, t_l). This concludes the analysis for the first case.

Case 2. Consider again the analysis presented in Case 2 of the proof of Lemma 2. It follows from the first-order necessary conditions for problem (1), and the fact that $\boldsymbol{x}(t) \in \Gamma$ for all $t \geq t_0$, that there exist nonnegative constants, $\lambda_{i_1}, \lambda_{i_2}, \ldots, \lambda_{i_k}$, such that

$$\nabla f(\boldsymbol{x}(t')) + \sum_{j \in \tilde{I}} \lambda_j \nabla g_j(\boldsymbol{x}(t')) = \boldsymbol{0}. \tag{43}$$

It now follows from (43) and (22) that $\boldsymbol{0} \in H(\boldsymbol{x}(t')) \cap T(\boldsymbol{x}(t'))$. However, we see from (31) that all of the elements of $H(\boldsymbol{x}(t')) \cap T(\boldsymbol{x}(t'))$ differ by a positive multiplicative constant. Therefore, $H(\boldsymbol{x}(t')) \cap T(\boldsymbol{x}(t')) = \{\boldsymbol{0}\}$, and hence, $H(\boldsymbol{x}(t)) \cap T(\boldsymbol{x}(t)) = \{\boldsymbol{0}\}$ for all $t \in (t_{l-1}, t_l)$. Using (32), we conclude that $\dot{\boldsymbol{x}}(t) = \boldsymbol{0}$ almost everywhere on the interval (t_{l-1}, t_l). This concludes the analysis for the second case.

It now follows from the above arguments that $\dot{\boldsymbol{x}}(t) = \boldsymbol{0}$ almost everywhere on the interval $[t_0, \infty)$, and hence, $\boldsymbol{x}(t) = \boldsymbol{x}_0$ for all $t \geq t_0$. This completes the proof. ∎

We see from (20) and (32) that while confined to Ω, (2) can be viewed as a continuous-time gradient projection method. We note that a discrete-time gradient projection method for nonlinear programming was first proposed by Rosen [20] and that other continuous-time methods using gradient projections are reported in [5] and references therein.

Similarities between the dynamic system approach to solving optimization problems and the so-called interior point methods are discussed in [26]. For a review of interior point methods, as well as path-following methods, we refer the reader to Gonzaga [10].

4. Examples. In this section, we illustrate the dynamic behavior of system (2) by presenting the results of two computer simulations.

Example 1. In this example, we consider the quadratic programming problem

$$\begin{array}{ll} \text{minimize} & \frac{1}{2}\boldsymbol{x}^T\boldsymbol{Q}\boldsymbol{x} + \boldsymbol{c}^T\boldsymbol{x}, \quad \boldsymbol{x} \in \mathbb{R}^2, \\ \text{subject to} & \boldsymbol{A}\boldsymbol{x} \leq \boldsymbol{b}, \end{array}$$

where

$$\boldsymbol{Q} = \begin{bmatrix} 4 & 1 \\ 1 & 2 \end{bmatrix}, \quad \boldsymbol{c} = \begin{bmatrix} -12 \\ -10 \end{bmatrix}, \quad \boldsymbol{A} = \begin{bmatrix} 5 & 1 \\ -5 & 1 \\ -1 & -2 \end{bmatrix}, \quad \text{and} \quad \boldsymbol{b} = \begin{bmatrix} 0 \\ 10 \\ 10 \end{bmatrix}.$$

The above optimization problem clearly satisfies A1–A4, and one can verify that the point $\boldsymbol{x}^* = \begin{bmatrix} -19/22 & 95/22 \end{bmatrix}^T$ is a unique minimizer for the problem; that is, $\Gamma = \{\boldsymbol{x}^*\}$. Note that $\boldsymbol{x}^* \in \Delta_1$. A phase-plane portrait for system (2) that solves the above optimization problem is shown in Figure 1. Observe that each of the trajectories in the phase-plane portrait converges to the point $\boldsymbol{x}^*$ while sliding along the surface Δ_1.

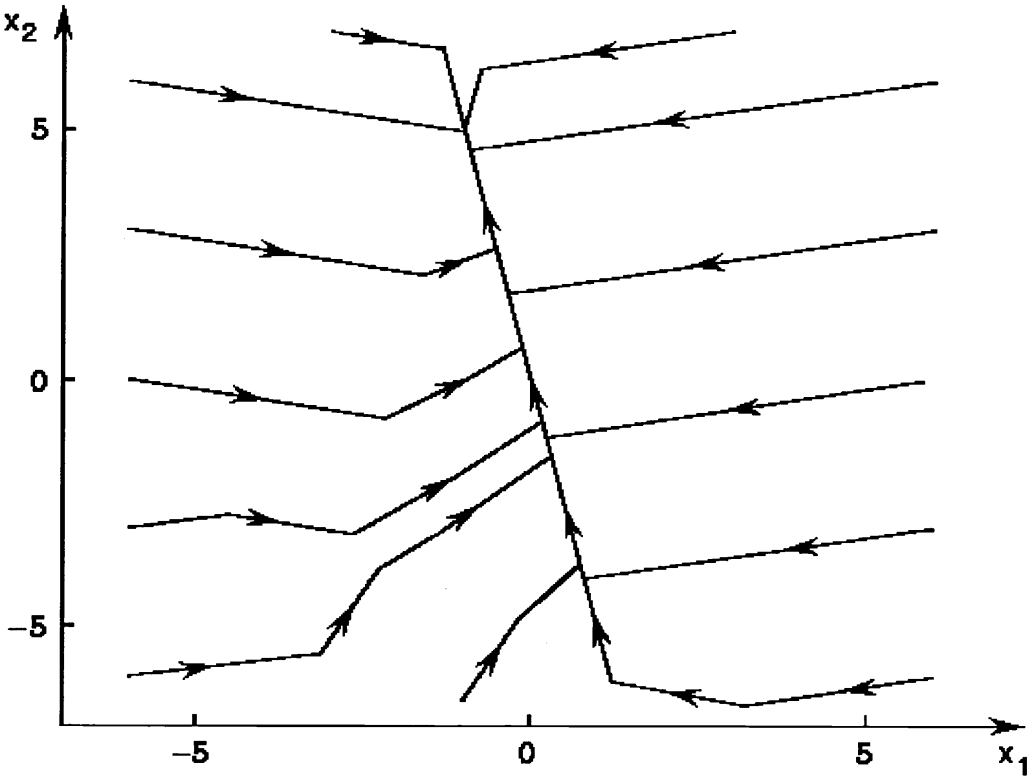

FIG. 1. *Phase-plane portrait for the system in Example* 1.

Example 2. In this example, we consider the convex programming problem

$$\begin{array}{ll} \text{minimize} & \frac{1}{2}\boldsymbol{x}^T\boldsymbol{Q}\boldsymbol{x} + \boldsymbol{c}^T\boldsymbol{x}, \quad \boldsymbol{x} \in \mathbb{R}^2, \\ \text{subject to} & g_i(\boldsymbol{x}) \leq 0, \quad i = 1, 2, 3, \end{array}$$

where

$$\begin{aligned} g_1(\boldsymbol{x}) &= x_1^2 + (x_2 - 4)^2 - 64, \\ g_2(\boldsymbol{x}) &= (x_1 + 3)^2 + x_2^2 - 36, \\ g_3(\boldsymbol{x}) &= (x_1 - 3)^2 + x_2^2 - 36, \end{aligned}$$

and $\boldsymbol{Q}$ and $\boldsymbol{c}$ are as defined in Example 1. One can easily verify that the above optimization problem satisfies A1–A4 and that the point $\boldsymbol{x}^* = \begin{bmatrix} 1.776 & 3.629 \end{bmatrix}^T$ is a unique minimizer for the problem; that is, $\Gamma = \{\boldsymbol{x}^*\}$. Note that $\boldsymbol{x}^* \in \Delta_2$. A phase-plane portrait for system (2) solving the above optimization problem is shown in Figure 2. Note that each of the trajectories in the phase-plane portrait converges to the point $\boldsymbol{x}^*$ while sliding along the surface Δ_2.

We close this section by noting that both of the simulations were performed on a Northgate 486 personal computer using the SIMNON software package.

5. Conclusions. We analyzed a class of dynamic systems proposed by Rodríguez-Vázquez et al. [19] for solving convex programming problems. We showed that the equilibrium points of the system coincide with the minimizers of the convex programming problem, and that all trajectories of the system converge to the solution set of

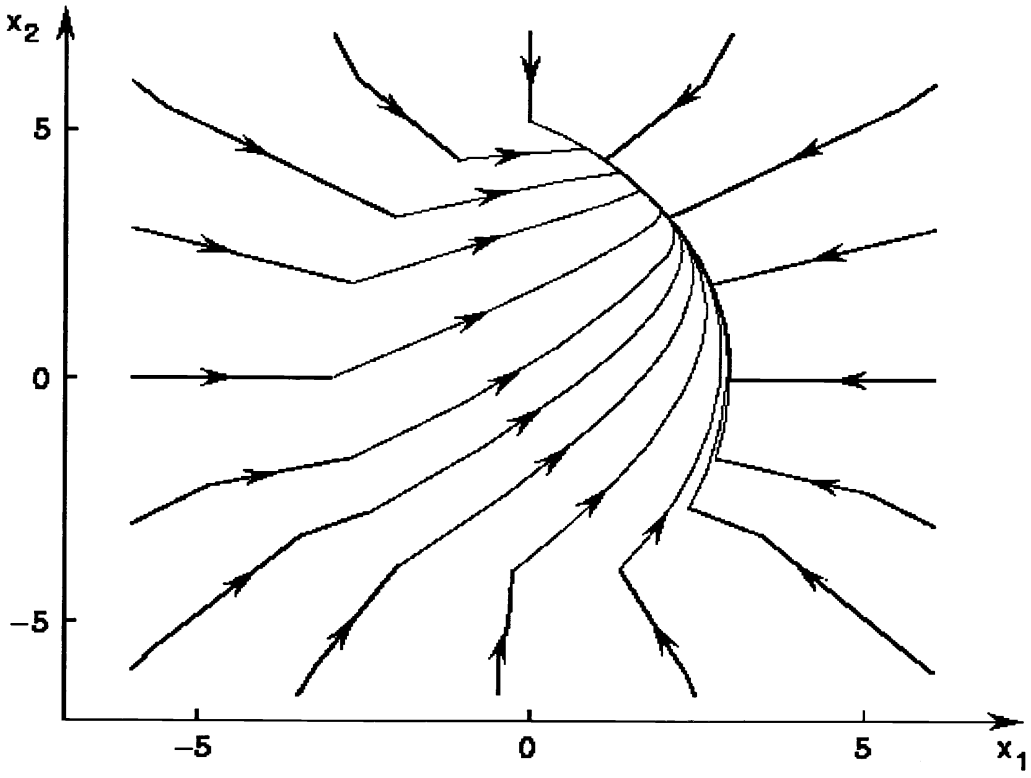

FIG. 2. *Phase-plane portrait for the system in Example* 2.

the problem. In carrying out the analysis we used concepts from the theory of differential equations with discontinuous right-hand sides and Lyapunov stability theory. Our analysis method can also be applied to other classes of analog dynamic optimizers whose designs are based on exact penalty functions. An open problem is to extend the results obtained herein to a more general class of mathematical programming problems.

LIPSCHITZIAN STABILITY FOR STATE CONSTRAINED NONLINEAR OPTIMAL CONTROL*

A. L. DONTCHEV† AND W. W. HAGER‡

Abstract. For a nonlinear optimal control problem with state constraints, we give conditions under which the optimal control depends Lipschitz continuously in the L^2 norm on a parameter. These conditions involve smoothness of the problem data, uniform independence of active constraint gradients, and a coercivity condition for the integral functional. Under these same conditions, we obtain a new nonoptimal stability result for the optimal control in the L^∞ norm. And under an additional assumption concerning the regularity of the state constraints, a new tight L^∞ estimate is obtained. Our approach is based on an abstract implicit function theorem in nonlinear spaces.

Key words. optimal control, state constraints, Lipschitzian stability, implicit function theorem

1. Introduction.

We consider the following optimal control problem involving a parameter:

$$\text{minimize} \int_0^1 h_p(x(t), u(t))dt \tag{1}$$

subject to

$$\dot{x}(t) = f_p(x(t), u(t)) \text{ a.e. } t \in [0,1], \quad x(0) = x^0,$$
$$g_p(x(t)) \le 0 \text{ for all } t \in [0,1], \ \ u \in L^\infty, \ \ x \in W^{1,\infty},$$

where the state $x(t) \in \mathbf{R}^n$, $\dot{x} \equiv \frac{d}{dt}x$, the control $u(t) \in \mathbf{R}^m$, the parameter p lies in a metric space, the functions $h_p : \mathbf{R}^n \times \mathbf{R}^m \to \mathbf{R}$, $f_p : \mathbf{R}^n \times \mathbf{R}^m \to \mathbf{R}^n$, and $g_p : \mathbf{R}^n \to \mathbf{R}^k$. Throughout the paper, $L^\alpha(J; \mathbf{R}^m)$ denotes the usual Lebesgue space of functions $u : J \to \mathbf{R}^m$ with $|u(\cdot)|^\alpha$ integrable, equipped with its standard norm

$$\| u \|_{L^\alpha} = \left(\int_J |u(t)|^\alpha dt \right)^{1/\alpha},$$

where $|\cdot|$ is the Euclidean norm. Of course, $\alpha = \infty$ corresponds to the space of essentially bounded functions. Let $W^{m,\alpha}(J; \mathbf{R}^n)$ be the usual Sobolev space consisting of vector-valued functions whose jth derivative lies in L^α for all $0 \le j \le m$; its norm is

$$\| u \|_{W^{m,\alpha}} = \sum_{j=0}^{m} \| u^{(j)} \|_{L^\alpha} .$$

When either the domain J or the range $\mathbf{R}^n$ is clear from context, it is omitted. We let H^m denote the space $W^{m,2}$, and Lip denote $W^{1,\infty}$, the space of Lipschitz continuous

functions. Subscripts on spaces are used to indicate bounds on norms; in particular, $W^{m,\alpha}_{\kappa}$ denotes the set of functions in $W^{m,\alpha}$ with the property that the L^α norm of the mth derivative is bounded by κ, and Lip_κ denotes the space of Lipschitz continuous functions with Lipschitz constant κ. Throughout, c is a generic constant, independent of the parameter p and time t, and $B_a(x)$ is the closed ball centered at x with radius a. The L^2 inner product is denoted $\langle\cdot,\cdot\rangle$, the complement of a set $\mathcal{A}$ is $\mathcal{A}^c$, and the transpose of a matrix B is B^T. Given a vector $y \in \mathbf{R}^m$ and a set $\mathcal{A} \subset \{1, 2, \ldots, m\}$, $y_\mathcal{A}$ denotes the subvector consisting of components associated with indices in $\mathcal{A}$. And if $Y \in \mathbf{R}^{m\times n}$, then $Y_\mathcal{A}$ is the submatrix consisting of rows associated with indices in $\mathcal{A}$.

We wish to study how a solution to either (1) or the associated variational system representing the first-order necessary condition depends on the parameter p. We assume that the problem (1) has a local minimizer $(x, u) = (x_*, u_*)$ corresponding to a reference value $p = p_*$ of the parameter, and the following smoothness condition holds.

Smoothness. The local minimizer (x_*, u_*) of (1) lies in $W^{2,\infty}\times$ Lip. There exists a closed set $\Delta \subset \mathbf{R}^n \times \mathbf{R}^m$ and a $\delta > 0$ such that $B_\delta(x_*(t), u_*(t)) \subset \Delta$ for every $t \in [0, 1]$. The function values and first two derivatives of $f_p(x, u)$, $g_p(x, u)$, and $h_p(x, u)$, and the third derivatives of $g_p(x)$, with respect to x and u, are uniformly continuous relative to p near p_* and $(x, u) \in \Delta$. And when either the first two derivatives of $f_p(x, u)$ and $h_p(x, u)$ or the first three derivatives of $g_p(x)$, with respect to x and u, are evaluated at (x_*, u_*), the resulting expression is differentiable in t, and the L^∞ norm of the time derivative is uniformly bounded relative to p near p_*.

Let A, B, and K be the matrices defined by

$$A = \nabla_x f_*(x_*, u_*), \quad B = \nabla_u f_*(x_*, u_*), \quad \text{and } K = \nabla_x g_*(x_*).$$

Here and elsewhere the * subscript is always associated with p_*. Let $\mathcal{A}(t)$ be the set of indices of the active constraints at $(x_*(t), p_*)$; that is,

$$\mathcal{A}(t) = \{i \in \{1, 2, \cdots, k\} : g_*(x_*(t))_i = 0\}.$$

We introduce the following assumption.

Uniform independence at $\mathcal{A}$. The set $\mathcal{A}(0)$ is empty and there exists a scalar $\alpha > 0$ such that

$$\left| \sum_{i\in\mathcal{A}(t)} v_i K_i(t) B(t) \right| \geq \alpha |v_{\mathcal{A}(t)}|$$

for each $t \in [0, 1]$ where $\mathcal{A}(t) \neq \emptyset$ and for each choice of v.

Uniform independence implies that the state constraints are first-order (see [12] for the definition of the order of a state constraint). This condition can be generalized to higher order state constraints (see Maurer [17]), however, the generalization of the stability results in this paper to higher order state constraints is not immediate.

It is known (see, for instance, Theorem 7.1 of the recent survey [12] and the regularity analysis in [8]) that under appropriate assumptions, the first-order necessary conditions (Pontryagin's minimum principle) associated with a solution (x_*, u_*) of (1) can be written in the following way. There exist $\psi_* \in W^{2,\infty}$ and $\nu_* \in$ Lip such that $x = x_*$, $\psi = \psi_*$, $u = u_*$, and $\nu = \nu_*$ are a solution at $p = p_*$ of the variational system:

$$\dot{x} = f_p(x, u), \; x(0) = x^0, \tag{2}$$

$$\dot{\psi} = -\nabla_x H_p(x, \psi, u, \nu), \ \psi(1) = 0, \tag{3}$$

$$0 = \nabla_u H_p(x, \psi, u, \nu), \tag{4}$$

$$g_p(x) \in N(\nu), \ \nu(1) \le 0, \ \dot{\nu} \ge 0 \ \text{ a.e.} \tag{5}$$

Here H_p is the Hamiltonian defined by

$$H_p(x, \psi, u, \nu) = h_p(x, u) + \psi^{\mathsf{T}} f_p(x, u) - \nu^{\mathsf{T}} \nabla g_p(x) f_p(x, u),$$

and the set-valued map N is defined in the following way: given a nondecreasing Lipschitz continuous function ν, a continuous function y lies in $N(\nu)$ if and only if

$$y(t) \le 0, \ \dot{\nu}(t)^{\mathsf{T}} y(t) = 0 \text{ for a.e. } t \in [0, 1], \ \text{ and } \ \nu(1)^{\mathsf{T}} y(1) = 0.$$

Defining

$$Q = \nabla_{xx} H_*(w_*), \ \ M = \nabla_{xu} H_*(w_*), \text{ and } R = \nabla_{uu} H_*(w_*),$$

where $w_* = (x_*, \psi_*, u_*, \nu_*)$, let $\mathcal{B}$ be the quadratic form

$$\mathcal{B}(x, u) = \frac{1}{2} \int_0^1 x(t)^{\mathsf{T}} Q(t) x(t) + u(t)^{\mathsf{T}} R(t) u(t) + 2x(t)^{\mathsf{T}} M(t) u(t) dt,$$

and let L be the linear and continuous operator from $H^1 \times L^2$ to L^2 defined by $L(x, u) = \dot{x} - Ax - Bu$. We introduce the following growth assumption for the quadratic form.

Coercivity. There exists a constant $\alpha > 0$ such that

$$\mathcal{B}(x, u) \ \ge \ \alpha \langle u, u \rangle \quad \text{for all } \ (x, u) \in \mathcal{M},$$

where

$$\mathcal{M} = \{(x, u) : x \in H^1, \ u \in L^2, L(x, u) = 0, \ x(0) = 0\}. \tag{6}$$

In the terminology of [12], the form of the minimum principle we employ is the "indirect adjoining approach with continuous adjoint function." A different approach, found in [13], for example, involves a different choice for the multipliers and for the Hamiltonian. The multipliers in these two approaches are related in a linear fashion as shown in [11]. Normally, the multiplier ν, associated with the state constraint, and the derivative of ψ have bounded variation. In our statement of the minimum principle above, we are implicitly assuming some additional regularity so that ν and $\dot{\psi}$ are not only of bounded variation, but Lipschitz continuous. This regularity can be proved under the uniform independence and coercivity conditions (see [8]).

In section 3 we establish the following result.

THEOREM 1.1. *Suppose that the problem* (1) *with* $p = p_*$ *has a local minimizer* (x_*, u_*) *and that the smoothness and the uniform independence conditions hold. Let* ψ_* *and* ν_* *be the associated multipliers satisfying the variational system* (2)–(5) *with* $\psi_* \in W^{2,\infty}$ *and* $\nu_* \in$ *Lip. If the coercivity condition holds, then there exist a constant* μ *and neighborhoods* V *of* p_* *and* U *of* $w_* = (x_*, \psi_*, u_*, \nu_*)$ *in* $W^{1,\infty} \times W^{1,\infty} \times L^\infty \times L^\infty$, *such that for every* $p \in V$, *there is a unique solution* $w = (x, \psi, u, \nu) \in U$ *to the first-order necessary conditions* (2)–(5) *with the property that* $(\dot{x}, \dot{\psi}, u, \nu) \in \mathrm{Lip}_\mu$ *and* (x, u) *is a local minimizer of the problem* (1) *associated with* p. *Moreover, for every* $p_i \in V, i = 1, 2$, *if* $w_i = (x_i, \psi_i, u_i, \nu_i)$ *is the corresponding solution of* (2)–(5), *the following estimate holds:*

$$\|x_1 - x_2\|_{H^1} + \|\psi_1 - \psi_2\|_{H^1} + \|u_1 - u_2\|_{L^2} + \|\nu_1 - \nu_2\|_{L^2} \le c E_2, \tag{7}$$

where

$$E_\alpha = \|f_{p_1}(x_1,u_1) - f_{p_2}(x_1,u_1)\|_{L^\alpha} + \|\nabla_x H_{p_1}(w_1) - \nabla_x H_{p_2}(w_1)\|_{L^\alpha} + \|\nabla_u H_{p_1}(w_1) - \nabla_u H_{p_2}(w_1)\|_{L^\alpha} + \|g_{p_1}(x_1) - g_{p_2}(x_1)\|_{W^{1,\alpha}}.$$

In addition, we have

$$\|x_1 - x_2\|_{W^{1,\infty}} + \|\psi_1 - \psi_2\|_{W^{1,\infty}} + \|u_1 - u_2\|_{L^\infty} + \|\nu_1 - \nu_2\|_{L^\infty} \le cE_2^{2/3}.$$

The proof of Theorem 1.1 is based on an abstract implicit function theorem appearing in section 2. In section 4 we show that the L^∞ estimate of Theorem 1.1 can be sharpened if the points where the state constraints change between active and inactive are separated. In section 5 we comment briefly on related work.

2. An implicit function theorem in nonlinear spaces. The following lemma provides a generalization of the implicit function theorem that can be applied to nonlinear spaces. To simplify the notation, we let $\|x - y\|_X$ denote the distance between the elements x and y of the metric space X.

LEMMA 2.1. *Let X and Π be metric spaces with X complete, let Y be a subset of Π, and let P be a set. Given $w_* \in X$ and $r > 0$, let W denote the ball $B_r(w_*)$ in X and suppose that $T : W \times P \to Y$ and $F : X \to 2^\Pi$ (the subsets of Π) have the following properties.*

(P1) *$T(w_*, p_*) \in F(w_*)$ for some $p_* \in P$.*

(P2) *For some $\beta > 0$, $\|T(w_*, p_*) - T(w_*, p)\|_\Pi \le \beta$ for all $p \in P$.*

(P3) *For some $\epsilon > 0$, $\|T(w_1, p) - T(w_2, p)\|_\Pi \le \epsilon \|w_1 - w_2\|_X$ for all $w_1, w_2 \in W$ and $p \in P$.*

(P4) *F^{-1} restricted to Y is single-valued and Lipschitz continuous, with Lipschitz constant λ.*

If $\epsilon\lambda < 1$ and $r \ge \lambda\beta/(1 - \epsilon\lambda)$, then for each $p \in P$, there exists a unique $w \in W$ such that $T(w, p) \in F(w)$. Moreover, for every $p_i \in P, i = 1, 2$, if w_i denotes the w associated with p_i, then we have

$$\|w_1 - w_2\|_X \le \frac{\lambda}{1 - \lambda\epsilon} \|T(w_1, p_1) - T(w_1, p_2)\|_\Pi. \tag{8}$$

Proof. Fix $p \in P$ and define $\Phi(w) = F^{-1}(T(w, p))$ for $w \in W$. Observe that

$$\begin{aligned}\|\Phi(w_1) - \Phi(w_2)\|_X &= \|F^{-1}(T(w_1, p)) - F^{-1}(T(w_2, p))\|_X \\ &\le \lambda \|T(w_1, p) - T(w_2, p)\|_\Pi \le \lambda\epsilon \|w_1 - w_2\|_X\end{aligned}$$

for each $w_1, w_2 \in W$. Since $\lambda\epsilon < 1$, Φ is a contraction on W with contraction constant $\lambda\epsilon$. Let $w \in W$. Since $w_* = F^{-1}(T(w_*, p_*))$ and $r \ge \lambda\beta/(1 - \epsilon\lambda)$, we have

$$\begin{aligned}\|w_* - \Phi(w)\|_X &= \|F^{-1}(T(w_*, p_*)) - F^{-1}(T(w, p))\|_X \\ &\le \lambda(\|T(w, p) - T(w_*, p)\|_\Pi + \|T(w_*, p) - T(w_*, p_*)\|_\Pi) \\ &\le \lambda(\epsilon r + \beta) \le r.\end{aligned}$$

Thus Φ maps W into itself. By the Banach contraction mapping principle, there exists a unique $w \in W$ such that $w = \Phi(w)$. Since $w = \Phi(w)$ is equivalent to $T(w, p) \in F(w)$ for $w \in W$, we conclude that for each $p \in P$, there is a unique $w(p) \in W$ such that

$T(w(p),p) \in F(w(p))$. Defining $w_1 = w(p_1)$ and $w_2 = w(p_2)$, we have

$$\begin{aligned}\|w_1 - w_2\|_X &= \|F^{-1}(T(w_1,p_1)) - F^{-1}(T(w_2,p_2))\|_X \\ &\le \lambda\|T(w_1,p_1) - T(w_2,p_2)\|_\Pi \\ &\le \lambda\|T(w_1,p_1) - T(w_1,p_2)\|_\Pi + \lambda\|T(w_1,p_2) - T(w_2,p_2)\|_\Pi \\ &\le \lambda\|T(w_1,p_1) - T(w_1,p_2)\|_\Pi + \lambda\epsilon\|w_1 - w_2\|_X.\end{aligned}$$

Rearranging this inequality, the proof is complete. ∎

Let X, Y, and $\mathcal{P}$ be metric spaces and let $w_* \in X$. Using the terminology of [3], $f : X \times \mathcal{P} \to Y$ is strictly stationary at $w = w_*$, uniformly in p near p_*, if for each $\epsilon > 0$, there exists $\delta > 0$ with the property that

$$\|f(w_1,p) - f(w_2,p)\|_Y \le \epsilon\|w_1 - w_2\|_X$$

for all $w_1, w_2 \in B_\delta(w_*)$ and $p \in B_\delta(p_*)$.

THEOREM 2.2. *Let X be a complete metric space, let Π be a linear metric space, let Y be a subset of Π, and let $\mathcal{P}$ be a metric space. Suppose that $\mathcal{F} : X \to 2^\Pi$, that $\mathcal{T} : X \times \mathcal{P} \to \Pi$, that $\mathcal{L} : X \to \Pi$ is continuous, and that for some $w_* \in X$ and $p_* \in \mathcal{P}$ we have:*

(Q1) *$\mathcal{T}(w_*, p_*) \in \mathcal{F}(w_*)$;*
(Q2) *$\mathcal{T}(w_*, \cdot\,)$ is continuous at p_*;*
(Q3) *$\mathcal{T}(w,p) - \mathcal{L}(w)$ is strictly stationary at $w = w_*$, uniformly in p near p_*;*
(Q4) *$(\mathcal{F} - \mathcal{L})^{-1}$ restricted to Y is single-valued and Lipschitz continuous, with Lipschitz constant λ;*
(Q5) *$\mathcal{T} - \mathcal{L}$ maps a neighborhood of (w_*, p_*) into Y.*

Then for each $\lambda_+ > \lambda$, there exist neighborhoods W of w_* and P of p_* such that for each $p \in P$, a unique $w \in W$ exists satisfying $\mathcal{T}(w,p) \in \mathcal{F}(w)$; moreover, for every $p_i \in P, i = 1,2$, if w_i denotes the $w \in W$ associated with p_i, then we have

$$\|w_1 - w_2\|_X \le \lambda_+\|\mathcal{T}(w_1,p_1) - \mathcal{T}(w_1,p_2)\|_\Pi.$$

Proof. By (Q5) there exist neighborhoods U' of w_* and P' of p_* such that $\mathcal{T}(w,p) - \mathcal{L}(w) \in Y$ for each $w \in U'$ and $p \in P'$. We apply Lemma 2.1 with the following identifications: X, Y, and Π are as defined in the statement of the theorem, $F(w) = \mathcal{F}(w) - \mathcal{L}(w)$, and $T(w,p) = \mathcal{T}(w,p) - \mathcal{L}(w)$. (P1) and (P4) follow immediately from (Q1) and (Q4), respectively. Choose $\epsilon > 0$ such that $\epsilon < (\lambda_+ - \lambda)/(\lambda_+\lambda)$. Since $\lambda_+ > \lambda$, it follows that for this choice of ϵ, we have $\epsilon\lambda < 1$ and $\lambda/(1-\lambda\epsilon) < \lambda_+$. By (Q3) and the identity $T(w_1,p_1) - T(w_1,p_2) = \mathcal{T}(w_1,p_1) - \mathcal{T}(w_1,p_2)$, there exist neighborhoods $P = B_r(p_*) \subset P'$ of p_* and $W = B_r(w_*) \subset U'$ of w_* such that (P3) of Lemma 2.1 holds. Let β satisfy $\lambda\beta/(1-\epsilon\lambda) \le r$, and by (Q2), choose P smaller if necessary so that (P2) holds. By Lemma 2.1, for each $p \in P$, there exists a unique $w \in W$ such that $T(w,p) \in F(w)$, and the estimate (8) holds. Since $T(w,p) \in F(w)$ if and only if $\mathcal{T}(w,p) \in \mathcal{F}(w)$, the proof is complete. ∎

A particular case of Theorem 2.2 corresponds to the well-known Robinson implicit function theorem [20] in which X is a Banach space, Π is its dual X^*, $\mathcal{F}(w) = N_\Omega(w)$, Ω is a closed, convex set in X, $N_\Omega(w)$ is the normal cone to the set Ω at the point w, $\mathcal{T}$ is differentiable with respect to w, both $\mathcal{T}$ and its derivative $\nabla_w\mathcal{T}$ are continuous in a neighborhood of (w_*, p_*), and $\mathcal{L}(w) = \mathcal{T}(w_*,p_*) + \nabla_w\mathcal{T}(w_*,p_*)(w - w_*)$ is the linearization of $\mathcal{T}$. The Robinson framework is applicable to control problems with control constraints after the range space X^* is replaced by a general Banach

space Y (see the discussion in section 5). However, for problems with state constraints, there are difficulties in applying Robinson's theory since stability results for state constrained quadratic problems, analogous to the results for control constrained problems, have not been established. In our previous paper [3], we extend Robinson's work in several different directions. For the solution map of a generalized equation in a linear metric space, we showed that Aubin's pseudo-Lipschitz property, that the existence of a Lipschitzian selection, and that local Lipschitzian invertibility are "robust" under nonlinear perturbations that are strictly stationary at the reference point. In Theorem 2.2, we focus on the latter property, giving an extension of our earlier result to nonlinear spaces. In this nonlinear setting, we are able to analyze the state constrained problem, obtaining a Lipschitzian stability result for the solution.

3. Lipschitzian stability in L^2. To prove Theorem 1.1, we apply Theorem 2.2 using the following identifications. First, we define

$$w = (x, \psi, u, \nu), \tag{9}$$

where

$$x,\ \psi \in W^{2,\infty}_{\mu} \text{ (with the } H^1 \text{ norm)},\ x(0) = x^0,\ \psi(1) = 0, \tag{10}$$

$$u,\ \nu \in \mathrm{Lip}_{\mu} \text{ (with the } L^2 \text{ norm)},\ \nu(1) \le 0 \text{ and } \dot{\nu} \ge 0 \text{ a.e.} \tag{11}$$

An appropriate value for μ is chosen later in the analysis. The space X consists of the collection of functions x, ψ, u, and ν satisfying (10) and (11) with the norm defined in (10) and (11). Observe that the norms we use are not the natural norms. For example, the u and ν components of elements in X lie in $W^{1,\infty}$, but we use the L^2 norm to measure distance. Despite the apparent mismatch of space and norm, X is complete by Lemma 3.2 below.

The functions $\mathcal{T}$ and $\mathcal{F}$ of Theorem 2.2 are selected in the following way:

$$\mathcal{T}(w,p) = \begin{pmatrix} \dot{x} - f_p(x,u) \\ \dot{\psi} + \nabla_x H_p(x,u,\psi,\nu) \\ \nabla_u H_p(x,u,\psi,\nu) \\ g_p(x) \end{pmatrix} \text{ and } \mathcal{F}(w) = \begin{pmatrix} 0 \\ 0 \\ 0 \\ N(\nu) \end{pmatrix}. \tag{12}$$

The continuous operator $\mathcal{L}$ is obtained by linearizing the map $\mathcal{T}(\cdot, p_*)$ in L^∞ at the reference point $w_* = (x_*, \psi_*, u_*, \nu_*)$. In particular,

$$\mathcal{L}(w) = \begin{pmatrix} \dot{x} - Ax - Bu \\ \dot{\psi} + A^{\mathsf{T}}\psi + Qx + Mu - (\dot{K}^{\mathsf{T}} + A^{\mathsf{T}}K^{\mathsf{T}})\nu \\ Ru + M^{\mathsf{T}}x + B^{\mathsf{T}}\psi - B^{\mathsf{T}}K^{\mathsf{T}}\nu \\ Kx \end{pmatrix}. \tag{13}$$

Defining $\pi_* = \mathcal{T}(w_*, p_*) - \mathcal{L}(w_*)$, let a_*, s_*, r_*, and b_* denote the components of π_*:

$$\begin{aligned} a_* &= -f_*(x_*, u_*) + Ax_* + Bu_*, \\ s_* &= \nabla_x H_*(w_*) - A^{\mathsf{T}}\psi_* - Qx_* - Mu_* + (\dot{K}^{\mathsf{T}} + A^{\mathsf{T}}K^{\mathsf{T}})\nu_*, \\ r_* &= \nabla_u H_*(w_*) - Ru_* - M^{\mathsf{T}}x_* - B^{\mathsf{T}}\psi_* + B^{\mathsf{T}}K^{\mathsf{T}}\nu_*, \\ b_* &= g_*(x_*) - Kx_*. \end{aligned}$$

The space Π is the product $L^2 \times L^2 \times L^2 \times H^1$, while the elements π in Y have the form $\pi = (a, s, r, b)$, where

$$\begin{aligned} &a,\ s,\ r\ \in \mathrm{Lip} \text{ (with the } L^2 \text{ norm)},\ b \in W^{2,\infty} \text{ (with the } H^1 \text{ norm)}, \\ &\|a - a_*\|_{W^{1,\infty}} + \|r - r_*\|_{W^{1,\infty}} + \|s - s_*\|_{W^{1,\infty}} + \|b - b_*\|_{W^{2,\infty}} \le \kappa, \end{aligned} \tag{14}$$

where κ is a small positive constant chosen so that two related quadratic programs, (37) and (41), introduced later have the same solution. As we will see, the constant μ associated with the space X must be chosen sufficiently large relative to κ. Note that the inverse $(\mathcal{F}-\mathcal{L})^{-1}\pi$ is the solution (x,ψ,u,ν) of the linear variational system:

$$\dot{x} = Ax + Bu - a,\ x(0) = x^0, \tag{15}$$

$$\dot{\psi} = -A^{\mathsf{T}}\psi - Qx - Mu + (\dot{K} + A^{\mathsf{T}}K^{\mathsf{T}})\nu - s,\ \psi(1) = 0, \tag{16}$$

$$0 = Ru + M^{\mathsf{T}}x + B^{\mathsf{T}}\psi - B^{\mathsf{T}}K^{\mathsf{T}}\nu + r, \tag{17}$$

$$Kx + b \in N(\nu),\ \nu(1) \le 0,\ \dot{\nu} \ge 0 \ \text{ a.e.} \tag{18}$$

Referring to the assumptions of Theorem 2.2, (Q1) holds by the definition of X, and by the minimum principle, (Q2) follows immediately from the smoothness condition. In Lemma 3.3, we deduce (Q3) from the smoothness condition and a Taylor expansion. In Lemma 3.6, (Q5) is obtained by showing that for w near w_* and p near p_*, $\mathcal{T}(w,p) - \mathcal{L}(w)$ and its associated derivatives are near those of $\pi_* = \mathcal{T}(w_*,p_*) - \mathcal{L}(w_*)$. Finally, in a series of lemmas, (Q4) is established through manipulations of quadratic programs associated with (15)–(18).

To start the analysis, we show that X is complete using the following lemma.

LEMMA 3.1. *If $u \in \mathrm{Lip}_\mu([0,1];\mathbf{R}^1)$, then we have*

$$\|u\|_{L^\infty} \le \ \max\{\ \sqrt{3}\|u\|_{L^2},\ \sqrt[3]{3\mu}\|u\|_{L^2}^{2/3}\ \}\ .$$

Proof. Since u is continuous, its maximum absolute value is achieved at some time t_m on the interval $[0,1]$. Let $u_m = u(t_m)$ denote the associated value of u. We consider two cases.

Case 1. $u_m > \mu$. Let us examine the maximum ratio between the ∞-norm and the 2-norm:

$$\text{maximize } \{\|u\|_{L^\infty}/\|u\|_{L^2} : \|u\|_{L^\infty} = u_m, u \in \ \mathrm{Lip}_\mu\}.$$

Since $u_m > \mu$, the maximum is attained by the linear function v satisfying $v(0) = u_m$ and $\dot{v} = -\mu$. The 2-norm of this function is readily evaluated:

$$\|v\|_{L^2}^2 = u_m^2(3 - 3\alpha + \alpha^2)/3, \text{ where } \alpha = \mu/u_m.$$

Since $\alpha \in [0,1]$ and since $3 - 3\alpha + \alpha^2 \ge 1$ on this interval, we have $\|v\|_{L^2}^2 \ge u_m^2/3$. Taking square roots gives

$$\|v\|_{L^\infty}/\|v\|_{L^2} \le \sqrt{3},$$

which establishes the lemma in Case 1.

Case 2. $u_m \le \mu$. In this case, let us examine the maximum ratio between the ∞-norm and the 2-norm to the 2/3-power:

$$\text{maximize } \{\|u\|_{L^\infty}/\|u\|_{L^2}^{2/3} : \|u\|_{L^\infty} = u_m, u \in \ \mathrm{Lip}_\mu\}.$$

The maximum is attained by the piecewise linear function v satisfying $v(0) = u_m$, $\dot{v} = -\mu$ on $[0, u_m/\mu]$, and $v = 0$ elsewhere. Since

$$\|v\|_{L^2}^2 = \frac{u_m^3}{3\mu},$$

it follows that

$$\|v\|_{L^\infty}/\|v\|_{L^2}^{2/3} \le \sqrt[3]{3\mu},$$

which completes the proof of Case 2. ∎

LEMMA 3.2. *The space X of functions w satisfying* (9), (10), *and* (11) *is complete.*

Proof. Suppose that $w_k = (x_k, u_k, \psi_k, \nu_k)$ is a Cauchy sequence in X. We analyze the ν-component of w_k. The sequence ν_k is a Cauchy sequence in L^∞ by Lemma 3.1. Since L^∞ is complete, there exists a limit point $\bar\nu \in L^\infty$. Since the ν_k converge pointwise to $\bar\nu$ and since each of the ν_k is Lipschitz continuous with Lipschitz constant μ, $\bar\nu$ is Lipschitz continuous with Lipschitz constant μ. Since each of the ν_k is nondecreasing, it follows from the pointwise convergence that $\bar\nu$ is nondecreasing; hence, $\dot{\bar\nu} \ge 0$. Since $\nu_k(1) \le 0$ for each k, the pointwise convergence implies that $\bar\nu(1) \le 0$. This shows that the ν-component of X is complete. The other components can be analyzed in a similar fashion. ∎

LEMMA 3.3. *If the smoothness condition holds, then for $\mathcal{T}$ and $\mathcal{L}$ defined in* (12) *and* (13), *respectively, $\mathcal{T} - \mathcal{L}$ is strictly stationary at w_*, uniformly in p near p_*.*

Proof. Only the first component of $\mathcal{T}(w,p) - \mathcal{L}(w)$ is analyzed, since the other components are treated in a similar manner. To establish strict stationarity for the first component, we need to show that for any given $\epsilon > 0$,

$$\|(f_p(x,u) - f_p(y,v)) - A(x-y) - B(u-v)\|_{L^2} \le \epsilon\|x-y\|_{H^1} + \epsilon\|u-v\|_{L^2}, \tag{19}$$

for p near p_* and for (x,u) and $(y,v) \in W^{2,\infty}_\mu \times \mathrm{Lip}_\mu$ near (x_*,u_*) in the norm of $H^1 \times L^2$, where $A = \nabla_x f_*(x_*,u_*)$ and $B = \nabla_u f_*(x_*,u_*)$. By Lemma 3.1, (x,u) and (y,v) are also near (x_*,u_*) in L^∞. After writing the difference $f_p(x,u) - f_p(y,v)$ as an integral over the line segment connecting (x,u) and (y,v), we have

$$(f_p(x,u) - f_p(y,v)) - A(x-y) - B(u-v) = (A_p - A)(x-y) + (B_p - B)(u-v),$$

where (A_p, B_p) is the average of the gradient of f_p along the line segment connecting (x,u) and (y,v). By the smoothness condition, $\|A_p - A\|_{L^\infty} \to 0$ and $\|B_p - B\|_{L^\infty} \to 0$ as p approaches p_* and as both (x,u) and (y,v) approach (x_*,u_*) in L^∞. This completes the proof. ∎

LEMMA 3.4. *If the smoothness condition holds, then for $\mathcal{T}$ and $\mathcal{L}$ defined in* (12) *and* (13), *respectively, and for any choice of the parameter $\kappa > 0$ in* (14), *there exists $\delta > 0$ such that $\mathcal{T}(w,p) - \mathcal{L}(w) \in Y$ for all $p \in B_\delta(p_*)$ and $w \in B_\delta(w_*) \cap X$.*

Proof. Again, we focus on the first component of $\mathcal{T} - \mathcal{L}$, since the other components are treated in a similar manner. Referring to the definition of Y, we should show that

$$\|(f_p(x,u) - f_*(x_*,u_*)) - A(x-x_*) - B(u-u_*)\|_{W^{1,\infty}} \le \kappa/4 \tag{20}$$

for p near p_* and for $(x,u) \in W^{2,\infty}_\mu \times \mathrm{Lip}_\mu$ near (x_*,u_*) in the norm of $H^1 \times L^2$. The $W^{1,\infty}$ norm in (20) is composed of two norms, the L^∞ norm of the function values, and the L^∞ norm of the time derivative. By the same expansion used in Lemma 3.3, we obtain the bound

$$\|(f_p(x,u) - f_*(x_*,u_*)) - A(x-x_*) - B(u-u_*)\|_{L^\infty} \le \kappa/8$$

for p near p_* and for (x,u) near (x_*,u_*). Differentiating the expression within the norm of (20) gives

$$\begin{aligned}&\tfrac{d}{dt}\big(f_p(x,u) - f_*(x_*,u_*) - A(x-x_*) - B(u-u_*)\big)\\ &= \big(\nabla_x f_p(x,u) - A\big)\dot x + \big(\nabla_u f_p(x,u) - B\big)\dot u - \dot A(x-x_*) - \dot B(u-u_*).\end{aligned}$$

By the smoothness condition, $\dot{A}$ and $\dot{B}$ lie in L^∞, and by the definition of X, we have $\|\dot{u}\|_{L^\infty} \le \mu$. By the triangle inequality and by Lemma 3.1,

$$\|\dot{x}\|_{L^\infty} \le \|\dot{x}_*\|_{L^\infty} + \|\dot{x} - \dot{x}_*\|_{L^\infty} \le \|\dot{x}_*\|_{L^\infty} + \sqrt[3]{3\mu}\|x - x_*\|_{H^1}^{2/3}$$

for x near x_*. Moreover, by Lemma 3.1 and by the smoothness condition, $\nabla_x f_p(x,u)$ approaches A and $\nabla_u f_p(x,u)$ approaches B in L^∞ as p approaches p_* and (x,u) approaches (x_*,u_*). Hence, for p near p_* and (x,u) near (x_*,u_*), we have

$$\left\| \frac{d}{dt}\big(f_p(x,u) - f_*(x_*,u_*) - A(x-x_*) - B(u-u_*)\big)\right\|_{L^\infty} \le \kappa/8.$$

Analyzing each of the components of $\mathcal{T} - \mathcal{L}$ in this same way, the proof is complete. ∎

We now begin a series of lemmas aimed at verifying (Q4). After a technical result (Lemma 3.5) related to the constraints, a surjectivity property (Lemma 3.6) is established for the linearized constraint mapping. Then we study a quadratic program corresponding to the linear variational system (15)–(18). We show that the solution (Lemma 3.9) and the multipliers (Lemma 3.10) depend Lipschitz continuously on the parameters. And utilizing the solution regularity derived in [8], the solution and the multipliers lie in X for μ sufficiently large.

To begin, let I be any map from $[0,1]$ to the subsets of $\{1,2,\dots,k\}$ with the property that the following sets I_i are closed for every i:

$$I_i = I^{-1}(i) = \{t \in [0,1] : i \in I(t)\}\ .$$

We establish the following decomposition property for the interval $[0,1]$.

LEMMA 3.5. *If uniform independence at I holds, then for every $\alpha', 0 < \alpha' < \alpha$, there exist sets $J_1, J_2, \dots, J_l$, corresponding points $0 = \tau_1 < \tau_2 < \cdots < \tau_{l+1} = 1$, and a positive constant $\rho < \min_i(\tau_{i+1} - \tau_i)$ such that for each $t \in [\tau_i - \rho, \tau_{i+1} + \rho] \cap [0,1]$, we have $I(t) \subset J_i$, and if J_i is nonempty, then*

$$\left| \sum_{j \in J_i} v_j K_j(t) B(t) \right| \ge \alpha' |v_{J_i}| \tag{21}$$

for every choice of v. The set J_1 can always be chosen empty.

Proof. For each $t \in (0,1)$ with $I(t)^c \ne \emptyset$, there exists an open interval O centered at t with $O \subset \cap_{i \in I(t)^c} I_i^c$. If $t = 0$ or 1, then we can choose a half-open interval O, with t the closed end of the interval, such that $O \subset \cap_{i \in I(t)^c} I_i^c$. If $I(t)^c$ is empty, take $O = [0,1]$. For any fixed $t \in [0,1]$ with $I(t) \ne \emptyset$, choose O smaller if necessary so that

$$\left| \sum_{i \in I(t)} v_i K_i(s) B(s) \right| \ge \alpha' |v_{I(t)}| \tag{22}$$

for each $s \in O$ and for each choice of v. Since B and K are continuous, it is possible to choose O in this way. Observe that by the construction of O, we have $I(s) \subset I(t)$ for each $s \in O$ and (22) holds if $I(t)$ is nonempty. Given any interval O on $(0,1)$, let $O_{1/2}$ denote the open interval with the same center but with half the length; for the open intervals associated with $t = 0$ or 1, let $O_{1/2}$ denote the half-open interval with the same endpoint, 0 or 1, but with half the length. The sets $O_{1/2}$ form an open cover

of $[0,1]$. Let $O_1, O_2, \ldots, O_l$ be a finite subcover of $[0,1]$ and let $t_1, t_2, \ldots, t_l$ denote the associated centers of interior intervals, and the closed endpoint of the intervals associated with $t = 0$ or 1. It can be arranged so that no O_i is contained in the union of other elements of the subcover (by discarding these extra sets if necessary). Arrange the indices of the O_i so that the left side of O_i is to the left of the left side of O_{i+1} for each i. Let $\tau_1, \tau_2, \ldots, \tau_{l-1}$ denote the successive left sides of the O_i, and let ρ be 1/4 of the length of the smallest O_i. Defining $J_i = I(t_i)$ for $i \geq 1$, it follows from the construction of the O_i that $I(t) \subset J_i$ and (22) holds for each t in an interval associated with t_i and with length twice that of O_i. Since $(\tau_i, \tau_{i+1}) \subset O_i$, we have (21). By taking ρ smaller if necessary, we can enforce the condition $\rho < \min_i(\tau_{i+1} - \tau_i)$. □

LEMMA 3.6. *If uniform independence at I holds, then for each $a \in L^\infty$ and $b \in W^{1,\infty}$, there exist $x \in W^{1,\infty}$ and $u \in L^\infty$ such that $L(x,u) + a = 0$, $x(0) = x^0$, and*

$$K_j(t)x(t) + b_j(t) = 0 \ \text{ for each } \ j \in I(t), \ \ t \in [0,1]. \tag{23}$$

This (x,u) pair is an affine function of (a,b), and for each $\alpha \geq 1$, there exists a constant $c > 0$ such that

$$\|x_1 - x_2\|_{W^{1,\alpha}} + \|u_1 - u_2\|_{L^\alpha} \leq c(\|a_1 - a_2\|_{L^\alpha} + \|b_1 - b_2\|_{W^{1,\alpha}}) \tag{24}$$

for every $(a_i, b_i) \in L^\infty \times W^{1,\infty}$, $i = 1,2$, where (x_i, u_i) is the pair associated with (a_i, b_i).

Proof. We use the decomposition provided by Lemma 3.5 to enforce the equations

$$\dot{x}(t) - A(t)x(t) - B(t)u(t) + a(t) = 0, \ \ x(0) = x^0, \tag{25}$$

$$K_j(t)x(t) + b_j(t) = 0 \ \text{ for each } \ j \in J_i \setminus J_{i-1}, \ \ t \in [\tau_i + \rho, \tau_{i+1}], \tag{26}$$

$$K_j(t)x(t) + b_j(t) = 0 \ \text{ for each } \ j \in J_i \cap J_{i-1}, \ \ t \in [\tau_i, \tau_{i+1}], \tag{27}$$

$i = 2, 3, \ldots, l$. Since J_1 is empty, (23) holds trivially on $[\tau_1, \tau_2] = [0, \tau_2]$. Suppose that $i > 1$, and let us consider (23) on the interval $[\tau_i, \tau_{i+1}]$. Since $I(t) \subset J_i$ for $t \in [\tau_i, \tau_{i+1}]$, we conclude that any $j \in I(t)$ is contained in either $J_i \cap J_{i-1}$ or $J_i \setminus J_{i-1}$. If $j \in J_i \cap J_{i-1}$, then by (27), (23) holds. If $j \in J_i \setminus J_{i-1}$, then by the construction of the J_i, $j \notin I(t)$ for $t \in [\tau_i, \tau_i + \rho]$. Hence, (26) implies that (23) holds.

Suppose that $j \in J_i$ and let σ_j be any given Lipschitz continuous function. Observe that if

$$K_j(\tau_i)x(\tau_i) + \sigma_j(\tau_i) = 0 \ \text{ and } \ \frac{d}{dt}\big(K_j(t)x(t) + \sigma_j(t)\big) = 0 \ \text{ a.e. } \ t \in [\tau_i, \tau_{i+1}], \tag{28}$$

then $K_j(t)x(t) + \sigma_j(t) = 0$ for all $t \in [\tau_i, \tau_{i+1}]$. Carrying out the differentiation in the second relation of (28) and substituting for $\dot{x}$ using the state equation (25), we obtain a linear equation for u. By Lemma 3.5, this equation has a solution, and for fixed t and x, the minimum norm solution can be written:

$$u(t,x) = M_i(t)[-\dot{\sigma}_{J_i}(t) + K_{J_i}(t)a(t) - \dot{K}_{J_i}(t)x - K_{J_i}(t)A(t)x], \tag{29}$$

where

$$M_i(t) = (K_{J_i}(t)B(t))^{\mathsf{T}}[K_{J_i}(t)B(t)(K_{J_i}(t)B(t))^{\mathsf{T}}]^{-1}. \tag{30}$$

In the special case where J_i is empty, we simply set $u(t,x) = 0$.

These observations show how to construct x and u in order to satisfy (26) and (27). On the initial interval $[0, \tau_2]$, u is simply 0 and x is obtained from (25). Assuming x and u have been determined on the interval $[0, \tau_i]$, their values on $[\tau_i, \tau_{i+1}]$ are obtained in the following way: the control is given in feedback form by (29), where for $j \in J_i \cap J_{i-1}$,

$$\sigma_j(t) = b_j(t) \quad \text{for} \quad t \in [\tau_i, \tau_{i+1}]. \tag{31}$$

For $j \in J_i \setminus J_{i-1}$, $\sigma_j(t) = b_j(t)$ for $t \in [\tau_i + \rho, \tau_{i+1}]$, while σ_j is linear on $[\tau_i, \tau_i + \rho]$ with

$$\sigma_j(\tau_i) = -K_j(\tau_i)x(\tau_i) \quad \text{and} \quad \sigma_j(\tau_i + \rho) = b_j(\tau_i + \rho). \tag{32}$$

With this choice for σ, the first equation in (28) is satisfied, and with x and u given by (25) and (29), respectively, the second equation in (28) is satisfied. Also, by the choice of σ,

$$K_j(t)x(t) + \sigma_j(t) = K_j(t)x(t) + b_j(t) = 0$$

for each $j \in J_i \cap J_{i-1}$ and $t \in [\tau_i, \tau_{i+1}]$, and for each $j \in J_i \setminus J_{i-1}$ and $t \in [\tau_i + \rho, \tau_{i+1}]$. Hence, (26) and (27) hold, which yields (23).

For $j \in J_i$, it follows from the definition of σ that

$$|\dot\sigma_j(t)| \le c\big(|x(\tau_i)| + \|b\|_{W^{1,\infty}}\big) \quad \text{a.e.} \quad t \in [\tau_i, \tau_{i+1}].$$

When u in (29) is inserted in (25) and this bound on $|\dot\sigma_j(t)|$ is taken into account, we obtain by induction that $x \in W^{1,\infty}$ and $u \in L^\infty$. By the equations (25) for the state, (29) for the control, and (31)–(32) for σ, (x, u) is an affine function of (a, b). Moreover, the change $(\delta x, \delta u)$ in the state and control associated with the change $(\delta a, \delta b)$ in the parameters satisfies

$$\|\delta x\|_{W^{1,\alpha}([0,\tau_i])} + \|\delta u\|_{L^\alpha([0,\tau_i])} \le c\big(\|\delta a\|_{L^\alpha([0,\tau_i])} + \|\delta\dot\sigma\|_{L^\alpha([0,\tau_i])}\big), \tag{33}$$

for each i where σ is specified in (31)–(32).

To complete the proof, we need to relate the σ term of (33) to the b term of (24). For $j \in J_i$, $\delta\sigma_j(t) = \delta b_j(t)$ if $t \in [\tau_i + \rho, \tau_{i+1}]$ or if $j \in J_{i-1}$ and $t \in [\tau_i, \tau_i + \rho]$. For $j \in J_i \setminus J_{i-1}$ and $t \in [\tau_i, \tau_i + \rho]$, we have

$$\begin{aligned} |\delta\dot\sigma_j(t)| &\le \big(|\delta b_j(\tau_i + \rho)| + |K_j(\tau_i)\delta x(\tau_i)|\big)/\rho \le c\big(\|\delta b\|_{L^\infty} + |\delta x(\tau_i)|\big) \\ &\le c\big(\|\delta b\|_{W^{1,\alpha}} + |\delta x(\tau_i)|\big). \end{aligned}$$

Consequently, for almost every $t \in [\tau_i, \tau_{i+1}]$,

$$|\delta\dot\sigma(t)| \le c\big(\|\delta b\|_{W^{1,\alpha}} + |\delta\dot b(t)| + |\delta x(\tau_i)|\big). \tag{34}$$

Since $\delta x(0) = 0$, let us proceed by induction and assume that

$$|\delta x(\tau_i)| \le c(\|\delta a\|_{L^\alpha} + \|\delta b\|_{W^{1,\alpha}}) \quad \text{for} \quad i = 1,\ 2, \ldots, j.$$

Combining this with (34) and (33) for $i = j + 1$ gives

$$\|\delta x\|_{W^{1,\alpha}([0,\tau_{j+1}])} + \|\delta u\|_{L^\alpha([0,\tau_{j+1}])} \le c\ \big(\ \|\delta a\|_{L^\alpha} + \|\delta b\|_{W^{1,\alpha}}\ \big)\ .$$

Since $|\delta x(\tau_{j+1})| \le \|\delta x\|_{W^{1,\alpha}([0,\tau_{j+1}])}$, the induction step is complete. ∎

In the following lemma, we prove a pointwise coercivity result for the quadratic form $\mathcal{B}$. See [4] and [7] for more general results of this nature.

LEMMA 3.7. *If coercivity holds, then there exists a scalar $\alpha > 0$ such that*

$$\mathcal{B}(x,u) \geq \alpha[\langle x,x\rangle + \langle u,u\rangle + \langle \dot{x},\dot{x}\rangle] \quad \text{for all} \quad (x,u) \in \mathcal{M} \tag{35}$$

and

$$v^{\mathsf{T}} R(t) v \geq \alpha v^{\mathsf{T}} v \text{ for every } t \in [0,1] \text{ and } v \in \mathbf{R}^m. \tag{36}$$

Proof. If $(x,u) \in \mathcal{M}$, then $L(x,u) = 0$ and $x(0) = 0$. Hence, the L^2 norm of x and $\dot{x}$ are bounded in terms of the L^2 norm of u, and (35) follows directly from the coercivity condition. To establish (36), we consider the control u_ϵ defined by

$$u_\epsilon(s) = \begin{cases} v \text{ for } t - \epsilon/2 \leq s \leq t + \epsilon/2, \\ 0 \text{ otherwise.} \end{cases}$$

Let the state x_ϵ be the solution to $L(x_\epsilon, u_\epsilon) = 0$, $x_\epsilon(0) = 0$. For any $t \in (0,1)$, we have

$$\lim_{\epsilon \to 0} \frac{\mathcal{B}(x_\epsilon, u_\epsilon)}{\epsilon} = v^{\mathsf{T}} R(t) v \text{ and } \lim_{\epsilon \to 0} \frac{\langle u_\epsilon, u_\epsilon\rangle}{\epsilon} = v^{\mathsf{T}} v.$$

Combining this with the coercivity condition gives (36). ∎

Consider the following linear-quadratic problem involving the parameters a, s, $r \in L^\infty$ and $b \in W^{1,\infty}$:

$$\begin{aligned} &\text{minimize } \mathcal{B}(x,u) + \langle s,x\rangle + \langle r,u\rangle \\ &\text{subject to} \\ &\qquad L(x,u) + a = 0, \quad x(0) = x^0, \\ &\qquad K_{I(t)}(t)x(t) + b_{I(t)}(t) \leq 0 \text{ for all } t \in [0,1], \\ &\qquad x \in W^{1,\infty}([0,1];\mathbf{R}^n), \quad u \in L^\infty([0,1];\mathbf{R}^m). \end{aligned} \tag{37}$$

If the feasible set for (37) is nonempty, then coercivity implies the existence of a unique minimizer over $H^1 \times L^2$. Using the following lemma, we show that this minimizer lies in $W^{1,\infty} \times L^\infty$, and that it exhibits stability relative to the L^2 norm.

LEMMA 3.8. *If coercivity and uniform independence at I hold, then* (37) *has a unique solution for every $a, r, s \in L^\infty$ and $b \in W^{1,\infty}$. Moreover, the change $(\delta x, \delta u)$ in the solution to* (37) *corresponding to a change $(\delta a, \delta b, \delta s, \delta r)$ in the parameters satisfies the estimate*

$$\|\delta x\|_{H^1} + \|\delta u\|_{L^2} \leq c(\|\delta a\|_{L^2} + \|\delta b\|_{H^1} + \|\delta s\|_{L^2} + \|\delta r\|_{L^2}). \tag{38}$$

Proof. By Lemma 3.6, uniform independence at I implies that the feasible set for (37) is nonempty, while the coercivity condition implies the existence of a unique solution (x_*, u_*) in $H^1 \times L^2$. From duality theory (for example, see [10]), there exists $\lambda \in L^\infty$ with the property that $u = u_*$ is the minimum with respect to u of the expression

$$\mathcal{B}(x,u) + \langle s,x\rangle + \langle r,u\rangle + \langle \lambda, \dot{x} - Ax - Bu + a\rangle$$

over all $u \in L^\infty$. It follows that

$$R(t)u_*(t) + M(t)^{\mathsf{T}} x_*(t) + r(t) - B(t)^{\mathsf{T}} \lambda(t) = 0, \tag{39}$$

and by (36), $u_*(t)$ is uniformly bounded in t. From the equations $L(x_*, u_*) = 0$ and $x_*(0) = x^0$, $x_* \in W^{1,\infty}$.

The estimate (38) can be obtained, as in Lemma 5 in [2], by eliminating the perturbation in the constraints. Let Λ be the affine map in Lemma 3.6 relating the feasible pair (x, u) to the parameters (a, b). By making the substitution $(x, u) = (y, v) + \Lambda(a, b)$, we transform (37) to an equivalent problem of the form

$$\begin{aligned} &\text{minimize } \mathcal{B}(y, v) + \langle \sigma, y\rangle + \langle \rho, v\rangle \\ &\text{subject to} \\ &\qquad L(y, v) = 0, \quad y(0) = 0, \\ &\qquad K_{I(t)}(t)y(t) \le 0 \text{ for all } t \in [0, 1], \\ &\qquad y \in W^{1,\infty}([0, 1]; \mathbf{R}^n), \quad v \in L^\infty([0, 1]; \mathbf{R}^m). \end{aligned} \tag{40}$$

Here σ and ρ are affine functions of a, b, s, and r. Utilizing the coercivity condition and the analysis of [9, section 2], we obtain the following estimate for the change $(\delta y, \delta v)$ corresponding to the change $(\delta\sigma, \delta\rho)$:

$$\begin{aligned} \alpha(\|\delta y\|_{H^1}^2 + \|\delta v\|_{L^2}^2) &\le \|\delta\sigma\|_{L^1}\|\delta y\|_{L^\infty} + \|\delta\rho\|_{L^2}\|\delta v\|_{L^2} \\ &\le \|\delta\sigma\|_{L^1}\|\delta y\|_{H^1} + \|\delta\rho\|_{L^2}\|\delta v\|_{L^2}. \end{aligned}$$

Hence,

$$\|\delta y\|_{H^1} + \|\delta v\|_{L^2} \le c(\|\delta\sigma\|_{L^1} + \|\delta\rho\|_{L^2}).$$

Taking into account the relations between (x, u), (y, v), (σ, ρ), and (a, b, s, r), the proof is complete. □

Now let us consider the full linear-quadratic problem where the subscript I on the state constraint has been removed:

$$\begin{aligned} &\text{minimize } \mathcal{B}(x, u) + \langle s, x\rangle + \langle r, u\rangle \\ &\text{subject to} \\ &\qquad L(x, u) + a = 0, \quad x(0) = x^0, \\ &\qquad K(t)x(t) + b(t) \le 0 \text{ for all } t \in [0, 1], \\ &\qquad x \in W^{1,\infty}([0, 1]; \mathbf{R}^n), \quad u \in L^\infty([0, 1]; \mathbf{R}^m). \end{aligned} \tag{41}$$

The first-order necessary conditions for this problem are precisely (15)–(18). Observe that x_*, u_*, ψ_*, and ν_* satisfy (15)–(18) when $\pi = \pi_*$. Since the first-order necessary conditions are sufficient for optimality when coercivity holds, (x_*, u_*) is the unique solution to (41) at $\pi = \pi_*$. In addition, if uniform independence holds, we now show that the multipliers ψ and ν satisfying (16)–(18) are unique; hence, x_*, u_*, ψ_*, and ν_* are the unique solution to (15)–(18) for $\pi = \pi_*$.

To establish this uniqueness property for the multipliers, we apply Lemma 3.5 to the active constraint map $\mathcal{A}$ of section 1. Let J_i be the index sets associated with $I = \mathcal{A}$ in Lemma 3.5. Since $\mathcal{A}(t) \subset J_i$ for each $t \in [\tau_i, \tau_{i+1}]$, the complementary slackness condition $\nu_*(1)^{\mathsf{T}} g_*(1) = 0$, associated with the condition (5) of the minimum principle, implies that $(\nu_*)_{J_l^c} = 0$ on $[\tau_l, 1]$, while (21) along with (16) and (17) imply that $(\nu_*)_{J_l}$ and ψ_* are uniquely determined on $[\tau_l, 1]$. Proceeding by induction, suppose that ψ_* and ν_* are uniquely determined on the interval $[\tau_{i+1}, 1]$. Since $(\nu_*)_{J_i^c}$ is constant on $[\tau_i, \tau_{i+1}]$, it is uniquely determined by the continuity of ν_*, while $(\nu_*)_{J_i}$

and ψ_* on $[\tau_i, \tau_{i+1}]$ are uniquely determined by (21), (16), and (17). This completes the induction step.

We now use Lemma 3.8 to show that the solution to (41) depends Lipschitz continuously on the parameters when coercivity and uniform independence at $\mathcal{A}$ hold. We do this by making a special choice for the map I. Again, let J_i be the index sets associated with $I = \mathcal{A}$ by Lemma 3.5. Since $\mathcal{A}(t) \subset J_i$ for each $t \in [\tau_i, \tau_{i+1}]$, the parameter

$$\epsilon_i = -\sup\{(g_*)_j(t) : t \in [\tau_i, \tau_{i+1}], j \in J_i^c\} \tag{42}$$

is strictly positive for each i. Setting $\epsilon = .5 \min \epsilon_i$, we consider (37) in the case $I = \mathcal{A}_\epsilon$ where $\mathcal{A}_\epsilon(t)$ is the index set associated with the ϵ-active constraints for the linearized problem:

$$\mathcal{A}_\epsilon(t) = \{i : K_i(t)x_*(t) + (b_*)_i(t) \geq -\epsilon\} = \{i : (g_*)_i(t) \geq -\epsilon\}. \tag{43}$$

Since $\mathcal{A}_\epsilon(t) \subset J_i$ for each $t \in [\tau_i, \tau_{i+1}]$, Lemma 3.5 implies that uniform independence at $\mathcal{A}_\epsilon$ holds.

We now observe that the solution (x_*, u_*) of (41) at $\pi = \pi_*$ is the solution of (37) for $I = \mathcal{A}_\epsilon$ and $\pi = \pi_*$. First, (x_*, u_*) is feasible in (37) since there are fewer constraints than in (41). By the choice $I = \mathcal{A}_\epsilon$, all feasible pairs for (37) near (x_*, u_*) are also feasible in (41). Since (x_*, u_*) is optimal in (41), it is locally optimal in (37) as well, and by the coercivity condition and Lemma 3.7, (x_*, u_*) is the unique minimizer of (37) for $\pi = \pi_*$. By Lemma 3.8, we have an estimate for the change in the solution to (37) corresponding to a change in the parameters. Since $\|\delta x\|_{L^\infty} \leq \|\delta x\|_{H^1}$, it follows that for small perturbations in the data, the solution to (37) is feasible, and hence optimal, for (41). Hence, our previous stability analysis for (37) provides us with a local stability analysis for (41). We summarize this result in the following way.

LEMMA 3.9. *If coercivity and uniform independence at $\mathcal{A}$ hold, then for s, r, and a in an L^∞ neighborhood of s_*, r_*, and a_*, respectively, and for b in a $W^{1,\infty}$ neighborhood of b_*, there exists a unique minimizer of* (41)*, and the estimate* (38) *holds. Moreover, taking $I = \mathcal{A}_\epsilon$ with $\epsilon = .5 \min \epsilon_i$, where ϵ_i is defined in* (42)*, the solutions to* (37) *and* (41) *are identical in these neighborhoods.*

Now let us consider the multipliers associated with (41).

LEMMA 3.10. *If coercivity and uniform independence at $\mathcal{A}$ hold, then for s, r, and a in an L^∞ neighborhood of s_*, r_*, and a_*, respectively, and for b in a $W^{1,\infty}$ neighborhood of b_*, there exists a unique minimizer of* (41) *and associated unique multipliers satisfying the estimate:*

$$\|\delta\psi\|_{H^1} + \|\delta\nu\|_{L^2} \leq c(\|\delta a\|_{L^2} + \|\delta b\|_{H^1} + \|\delta s\|_{L^2} + \|\delta r\|_{L^2}). \tag{44}$$

Proof. Let $\mathcal{A}_\epsilon$ be the ϵ-active constraints defined by (43), where $\epsilon = .5 \min \epsilon_i$. Let J_i be the index sets and let ρ be the positive number associated with $I = \mathcal{A}$ by Lemma 3.5. Consider $\pi = \pi_* + \delta\pi$ where $\delta\pi$ is small enough that the active constraint set for (41) is a subset of $\mathcal{A}_\epsilon(t)$ for each t. By the same analysis used to establish uniqueness of (ψ_*, ν_*), there exist unique Lagrange multipliers $(\psi, \nu) = (\psi_*, \nu_*) + (\delta\psi, \delta\nu)$ corresponding to $\pi = \pi_* + \delta\pi$. We will show that

$$\|\delta\psi\|_{H^1} + \|\delta\nu\|_{L^2} \leq c(\|\delta x\|_{L^2} + \|\delta u\|_{L^2} + \|\delta s\|_{L^2} + \|\delta r\|_{L^2}). \tag{45}$$

Combining this with Lemma 3.9 yields Lemma 3.10.

We prove (45) by induction. Let us start with the interval $[\tau_l - \rho, 1]$. If $i \in J_l^c$, then $\nu_i(t) = 0$ for each $t \in [\tau_l - \rho, 1]$. Hence, $\delta\nu_{J_l^c} = 0$ on $[\tau_l - \rho, 1]$. Multiplying (17) by KB, we can solve for $\delta\nu_{J_l}$ and substitute in (16) to eliminate ν. Since $\psi(1) = 0$, it follows that

$$\|\delta\psi\|_{H^1([\sigma-\rho,1])} + \|\delta\nu\|_{L^2([\sigma-\rho,1])} \le c(\|\delta x\|_{L^2} + \|\delta u\|_{L^2} + \|\delta s\|_{L^2} + \|\delta r\|_{L^2}) \tag{46}$$

for $\sigma = \tau_l$.

Proceeding by induction, suppose that (46) holds for $\sigma = \tau_{j+1}$; we wish to show that it holds for $\sigma = \tau_j$. If $i \in J_j^c$, then $\nu_i(t)$ is constant on $[\tau_j - \rho, \tau_{j+1}]$, and we have

$$\int_{\tau_j-\rho}^{\tau_{j+1}} \delta\nu_i(t)^2 dt = \frac{\tau_{j+1} - \tau_j + \rho}{\rho} \int_{\tau_{j+1}-\rho}^{\tau_{j+1}} \delta\nu_i(t)^2 dt.$$

Combining this with (46) for $\sigma = \tau_{j+1}$, it follows that

$$\|\delta\nu_i\|_{L^2([\sigma-\rho,1])} \le c(\|\delta x\|_{L^2} + \|\delta u\|_{L^2} + \|\delta s\|_{L^2} + \|\delta r\|_{L^2})$$

for $\sigma = \tau_j$. Again, multiplying (17) by KB, we solve for $\delta\nu_{J_j}$ and substitute in (16). Since $|\delta\psi(\tau_j)| \le \|\delta\psi\|_{H^1([\tau_j,1])}$, the induction bound (46) for $\sigma = \tau_{j+1}$ coupled with the bound already established for $\delta\nu_i$, $i \in J_j^c$, gives (46) for $\sigma = \tau_j$. This completes the induction. ∎

LEMMA 3.11. *Suppose that smoothness, coercivity, and uniform independence at $\mathcal{A}$ hold and let κ be small enough that Y is contained in the neighborhoods defined in Lemmas* 3.9 *and* 3.10. *Then for some $\mu > 0$ and for each $\pi \in Y$, there exists a unique solution (x, u) to* (41) *and associated multipliers (ψ, ν) satisfying the estimates* (38) *and* (44), *$(x, \psi, u, \nu) = (\mathcal{F} - \mathcal{L})^{-1}\pi$, and we have $\dot{x}$, $\dot{\psi}$, u, $\nu \in \mathrm{Lip}_\mu$.*

Proof. If $w = (x, \psi, u, \nu)$ denotes $(\mathcal{F} - \mathcal{L})^{-1}\pi$, then w satisfies the first-order necessary conditions (15)–(18) associated with (41). Lemmas 3.9 and 3.10 tell us that the unique solution and multipliers for (41) satisfy the estimates (38) and (44) for π near π_*. Since the first-order necessary conditions are sufficient for optimality when coercivity holds, the variational system (15)–(18) has a unique solution, for π near π_*, that is identical to the solution and multipliers for (41), and the estimates (38) and (44) are satisfied.

To complete the proof, we need to show that $\dot{x}$, $\dot{\psi}$, u, $\nu \in \mathrm{Lip}_\mu$ for some constant $\mu > 0$. This follows from the regularity results of [8], where it is shown that the solution to a constant coefficient, linear-quadratic problem satisfying the uniform independence condition and with R positive definite, Q positive semidefinite, and $M = 0$ has the property that the optimal u and associated ν are Lipschitz continuous in time, while the derivatives of x and ψ are Lipschitz continuous in time. Moreover, the Lipschitz constant in time is bounded in terms of the constant α in the uniform independence condition and the smallest eigenvalue of R. Exactly the same analysis applies to a linear-quadratic problem with time-varying coefficients; however, the bound for the Lipschitz constant of the solution depends on the Lipschitz constants of the matrices of the problem and of the parameters a, r, s, and b, as well as on a uniform bound for the smallest eigenvalue of $R(t)$ on $[0, 1]$ and for the parameter α in the uniform independence condition. By Lemma 3.9 and with the choice for I given in the statement of the lemma, the quadratic programs (37) and (41) have the same solution for s, r, and a in an L^∞ neighborhood of s_*, r_*, and a_* and for b in a $W^{1,\infty}$ neighborhood of b_*. Hence, for parameters in this neighborhood of π_*, the indices of the active constraints are contained in $I(t)$ for each t, and the independence condition (21) holds. Lemma 3.7 provides a lower bound for the eigenvalues of

$R(t)$. If $(a, s, r, b) \in Y$, then the Lipschitz constants for a, s, r, and $\dot{b}$ are bounded by those for a_*, s_*, r_*, and $\dot{b}_*$ plus κ. Hence, taking μ sufficiently large, the proof is complete. □

Proof of Theorem 1.1. We apply Theorem 2.2 with the identifications given at the beginning of this section and with μ chosen sufficiently large in accordance with Lemma 3.11. The completeness of X is established in Lemma 3.2, (Q1) is immediate, (Q2) follows from smoothness, (Q3) is proved in Lemma 3.3, (Q4) follows from Lemma 3.11, and (Q5) is established in Lemma 3.4. Applying Theorem 2.2, the estimate (7) is established. Under the uniform independence condition, coercivity is a second-order sufficient condition for local optimality (see [4, Theorem 1]) which is stable under small changes in either the parameters or the solution of the first-order optimality conditions. Finally, we apply Lemma 3.1 to obtain the L^∞ estimate of Theorem 1.1. □

We note that the coercivity condition we use here is a strong form of a second-order sufficient optimality condition; it not only provides optimality, but also guarantees Lipschitz continuity of the optimal solution and multipliers when uniform independence holds. As recently proved in [6] for finite-dimensional optimization problems, Lipschitzian stability of the solution and multipliers necessarily requires a coercivity condition stronger than the usual second-order condition. For the treatment of second-order sufficient optimality under conditions equivalent to coercivity, see [18] and [21]. These sufficient conditions can be applied to state constraints of arbitrary order. For recent work concerning the treatment of second-order sufficient optimality in state constrained optimal control, see [16], [19], and [22].

4. Lipschitzian stability in L^∞. One way to sharpen the L^∞ estimate of Theorem 1.1 involves an assumption concerning the regularity of the solution to the linear-quadratic problem (41). The time t is a contact point for the ith constraint of $Kx + b \leq 0$ if $(K(t)x(t) + b(t))_i = 0$ and there exists a sequence $\{t_k\}$ converging to t with $(K(t_k)x(t_k) + b(t_k))_i < 0$ for each k.

Contact separation. There exists a finite set $I_1, I_2, \ldots, I_N$ of disjoint, closed intervals contained in $(0, 1)$ and neighborhoods of (a_*, r_*, s_*) in $W^{1,\infty}$ and of b_* in $W^{2,\infty}$ with the property that for each a, r, s, and b in these neighborhoods, and for each solution to (41), all contact points are contained in the union of the intervals I_i with exactly one contact point in each interval and with exactly one constraint changing between active and inactive at this point.

Observe that if for (1) with $p = p_*$, there are a finite number of contact points, at each contact point exactly one constraint changes between active and inactive, and each contact point in the linear-quadratic problem (41) depends continuously on the parameters, then contact separation holds. The finiteness of the contact set is a natural condition in optimal control; for example, in [5] it is proved that for a linear-quadratic problem with time invariant matrices and one state constraint, the contact set is finite when uniform independence and coercivity hold.

THEOREM 4.1. *Suppose that the problem* (1) *with $p = p_*$ has a local minimizer (x_*, u_*) and that smoothness, contact separation, and uniform independence at $\mathcal{A}$ hold. Let ψ_* and ν_* be the associated multipliers satisfying the first-order necessary conditions* (2)–(5). *If the coercivity condition holds, then there exist neighborhoods V of p_* and U of $w_* = (x_*, \psi_*, u_*, \nu_*)$ in $W^{1,\infty} \times W^{1,\infty} \times L^\infty \times L^\infty$, such that for every $p \in V$, there exists a unique solution $w = (x, \psi, u, \nu) \in U$ to the first-order necessary conditions* (2)–(5) *and (x, u) is a local minimizer of the problem* (1) *associated with p. Moreover, for every $p_i \in V, i = 1, 2$, if $w_i = (x_i, \psi_i, u_i, \nu_i)$ is the corresponding*

solution of (2)–(5)*, the following estimate holds:*

$$\|x_1 - x_2\|_{W^{1,\infty}} + \|\psi_1 - \psi_2\|_{W^{1,\infty}} + \|u_1 - u_2\|_{L^\infty} + \|\nu_1 - \nu_2\|_{L^\infty} \le cE_\infty.$$

To prove this result, we need to supplement the 2-norm perturbation estimates provided by Lemmas 3.9 and 3.10 with analogous ∞-norm estimates.

LEMMA 4.2. *If coercivity, uniform independence at $\mathcal{A}$, and contact separation hold, then there exist neighborhoods of (a_*, r_*, s_*) in $W^{1,\infty}$ and of b_* in $W^{2,\infty}$ such that for each a_i, r_i, s_i, and b_i, $i = 1, 2$, in these neighborhoods, the associated solutions (x_i, u_i) of* (41) *satisfy*

$$\begin{aligned} &\|\delta x\|_{W^{1,\infty}} + \|\delta\psi\|_{W^{1,\infty}} + \|\delta u\|_{L^\infty} + \|\delta\nu\|_{L^\infty} \\ &\le c(\|\delta a\|_{L^\infty} + \|\delta b\|_{W^{1,\infty}} + \|\delta r\|_{L^\infty} + \|\delta s\|_{L^\infty}). \end{aligned} \tag{47}$$

Proof. Letting $\mathcal{A}_\epsilon$ denote the ϵ-active set defined in (43), we again choose $\epsilon = .5 \min \epsilon_i$, where ϵ_i is defined in (42). We consider parameters a, r, s, and b chosen within the neighborhoods of the contact separation condition, and sufficiently close to a_*, r_*, s_*, and b_* that the active constraint set for the solution of the perturbed linear-quadratic problem (41) is contained in $\mathcal{A}_\epsilon(t)$ for each t. By eliminating the perturbations in the constraints, as we did in the proof of Lemma 3.8, there is no loss of generality in assuming that $a = b = 0$. We refer to the quadratic programs corresponding to the parameters (r_1, s_1) and (r_2, s_2) as Problems 1 and 2.

Let (x, u) be either (x_1, u_1) or (x_2, u_2). If $t \in (0, 1)$ is a time for which $K_i(t)x(t) = 0$ for some i, then $\frac{d}{dt}(K_i x) = \dot{K}_i x + K_i \dot{x} = 0$. Substituting for $\dot{x}$ using the state equation $\dot{x} = Ax + Bu$ and for u using the necessary condition (17) yields

$$K_i B R^{-1} (KB)^{\mathsf{T}} \nu = -\dot{K}_i x - K_i A x + K_i B R^{-1}(B^{\mathsf{T}}\psi + M^{\mathsf{T}} x + r).$$

This equation has the form

$$N_i \nu = S_i x + T_i \psi + U_i r \tag{48}$$

for suitable choices of the row vectors N_i, S_i, T_i, and U_i. Hence, at any time t where $K_i(t)x_1(t) = K_i(t)x_2(t) = 0$, the change in solution and multipliers corresponding to a change in parameters satisfies the equation

$$N_i(t)\delta\nu(t) = S_i(t)\delta x(t) + T_i(t)\delta\psi(t) + U_i(t)\delta r(t). \tag{49}$$

By the contact separation condition, Problems 1 and 2 have the same active set near $t = 1$. Since the components of ν corresponding to inactive constraints are constant and since $\nu_i(1) = 0$ if $K_i(1)x(1) < 0$, it follows that $\delta\nu_i(t) = 0$ for t near 1 when $K_i x_1(1) < 0 > K_i x_2(1)$. The relation (49) combined with uniform independence, with the L^2 estimates provided in Lemmas 3.9 and 3.10, and with a bound for the L^∞ norm in terms of the H^1 norm, gives

$$\|\delta\nu\|_{L^\infty[t,1]} \le c(\|\delta r\|_{L^\infty} + \|\delta s\|_{L^\infty}). \tag{50}$$

Using the bound (36) of Lemma 3.7 in (17) and applying Gronwall's lemma to (16), we have

$$\begin{aligned} &\|\delta x\|_{W^{1,\infty}[t,1]} + \|\delta\psi\|_{W^{1,\infty}[t,1]} + \|\delta u\|_{L^\infty[t,1]} + \|\delta\nu\|_{L^\infty[t,1]} \\ &\le c(\|\delta r\|_{L^\infty} + \|\delta s\|_{L^\infty}) \end{aligned} \tag{51}$$

for all $t < 1$ in some neighborhood of $t = 1$. As t decreases, this estimate is valid until the first contact point is reached for either Problem 1 or Problem 2. Proceeding by induction, suppose that we have established (51) up to some contact point; we now wish to show that (51) holds up to the next contact point.

Again, by the contact separation condition, there is precisely one constraint, say constraint j, that makes a transition between active and inactive at the current contact point. Suppose that on the interval (α, β), the active sets for Problems 1 and 2 differ by the element j, and let τ be the first contact point to the left of α for either Problem 1 or Problem 2. If there is no such point, we take $\tau = 0$. By the contact separation condition, the difference $\alpha - \tau$ is uniformly bounded away from zero for all choices of the parameters s and r near s_* and r_*. There are essentially two cases to consider.

Case 1. Constraint j is active in Problem 2 to the left of $t = \beta$, and constraint j is active in Problem 1 to the left of $t = \alpha$.

Case 2. Constraint j is active in Problem 2 to the right of $t = \alpha$, and constraint j is active in Problem 1 to the right of $t = \beta$.

Case 1. Since constraint j is active in both Problems 1 and 2 at $t = \alpha$, it follows from (49) and from the uniform independence condition that

$$|\delta\nu_\Gamma(\alpha)| \le c(\|\delta r\|_{L^\infty} + \|\delta s\|_{L^\infty}) + c|\delta\nu_{\Gamma^c}(\alpha)|,$$

where Γ is the set of indices of active constraints at $t = \alpha$. Since $\delta\nu_i$ is constant for $i \in \Gamma^c$ on (α, β), the induction hypothesis yields

$$|\delta\nu_{\Gamma^c}(\alpha)| = |\delta\nu_{\Gamma^c}(\beta)|_{L^\infty} \le c(\|\delta r\|_{L^\infty} + \|\delta s\|_{L^\infty}). \tag{52}$$

Hence, we have

$$|\delta\nu(\alpha)| \le c(\|\delta r\|_{L^\infty} + \|\delta s\|_{L^\infty}). \tag{53}$$

Since ν_j is constant in Problem 1 on (α, β), and since it is monotone in Problem 2, the bound (53) coupled with the bound (51) at $t = \beta$ implies that

$$\|\delta\nu_j\|_{L^\infty([\alpha,\beta])} \le c(\|\delta r\|_{L^\infty} + \|\delta s\|_{L^\infty}). \tag{54}$$

Since $\delta\nu_i$ is constant on (α, β) for $i \in \Gamma^c$, it follows from (51) that

$$\|\delta\nu_{\Gamma^c}\|_{L^\infty([\alpha,\beta])} \le c(\|\delta r\|_{L^\infty} + \|\delta s\|_{L^\infty}). \tag{55}$$

Relation (49), for $i \in \Gamma^- = \Gamma \setminus \{j\}$, along with (54) and (55) yield

$$\|\delta\nu_{\Gamma^-}\|_{L^\infty([\alpha,\beta])} \le c(\|\delta r\|_{L^\infty} + \|\delta s\|_{L^\infty}). \tag{56}$$

Combining (54)–(56) gives

$$\|\delta\nu\|_{L^\infty([\alpha,\beta])} \le c(\|\delta r\|_{L^\infty} + \|\delta s\|_{L^\infty}). \tag{57}$$

On the interval from $t = \alpha$ down to the next contact point τ, precisely the same constraints are active in both Problems 1 and 2. Again, the relation (49) combined with uniform independence, with the L^2 estimates provided in Lemmas 3.9 and 3.10, and with a bound for the L^∞ norm in terms of the H^1 norm gives

$$\|\delta\nu\|_{L^\infty([\tau,\alpha])} \le c(\|\delta r\|_{L^\infty} + \|\delta s\|_{L^\infty}). \tag{58}$$

Relation (50) for $t = \beta$, along with (57) and (58), gives

$$\|\delta\nu\|_{L^\infty([\tau,1])} \le c(\|\delta r\|_{L^\infty} + \|\delta s\|_{L^\infty}).$$

And combining this with (15)–(17) gives (51) for $t = \tau$. This completes the induction step in Case 1.

Case 2. The mean value theorem implies that for some $\gamma \in (\tau, \alpha)$, we have

$$\begin{aligned}(\alpha - \tau)\frac{d}{dt}K_j(t)\delta x(t)\big|_{t=\gamma} &= K_j(\alpha)\delta x(\alpha) - K_j(\tau)\delta x(\tau)\\ &\le 2\|K_j\|_{L^\infty}\|\delta x\|_{L^\infty} \le c(\|\delta r\|_{L^\infty} + \|\delta s\|_{L^\infty}).\end{aligned}$$

Hence, even though the derivative of $K_j x_i$ may not vanish on (τ, α), the derivative of the change $K_j\delta x$ is still bounded by the perturbation in the parameters at some $\gamma \in (\tau, \alpha)$:

$$\left|\frac{d}{dt}(K_i(t)\delta x(t))\right|_{t=\gamma} \le c(\|\delta r\|_{L^\infty} + \|\delta s\|_{L^\infty})/(\alpha - \tau). \tag{59}$$

Since α and τ lie in disjoint closed sets I_k associated with the contact separation condition, $\alpha - \tau$ is bounded away from zero by the distance between the closest pair of sets. Focusing on the left side of (59), we substitute $\delta\dot{x} = A\delta x + B\delta u$, and we substitute for δu using (17) to obtain the relation

$$N_j(\gamma)\delta\nu(\gamma) = S_j(\gamma)\delta x(\gamma) + T_j(\gamma)\delta\psi(\gamma) + U_j(\gamma)\delta r(\gamma) + \Delta_j, \tag{60}$$

where $|\Delta_j| \le c(\|\delta r\|_{L^\infty} + \|\delta s\|_{L^\infty})/(\alpha - \tau)$. Let Γ denote the set of indices of the active constraints at $t = \beta$. Combining (60) with (49) for $i \in \Gamma^- = \Gamma \setminus \{j\}$ gives

$$|\delta\nu_\Gamma(\gamma)| \le c(\|\delta r\|_{L^\infty} + \|\delta s\|_{L^\infty}) + c|\delta\nu_{\Gamma^c}(\gamma)|.$$

The analysis for Case 1 can now be applied, starting with (52) but with α replaced by γ. □

Remark 4.3. In the proof of Lemma 4.2, we needed to ensure that the difference $\alpha - \tau$, appearing in Case 2, was bounded away from zero. The contact separation condition ensures that this difference is bounded away from zero, since α and τ lie in disjoint closed intervals I_k. On the other hand, any condition that ensures a positive separation for the contact points α and τ in Case 2 can be used in place of the contact separation assumption of Theorem 4.1 and Lemma 4.2.

Proof of Theorem 4.1. The functions $\mathcal{T}$, $\mathcal{F}$, and $\mathcal{L}$ and the sets X, Π, and Y are the same as in the proof of Theorem 1.1 except that L^2 is replaced by L^∞ and H^1 is replaced by $W^{1,\infty}$ everywhere. Except for this change in norms, and the replacement of the L^2 estimates (38) and (44) referred to in Lemma 3.11 by the corresponding L^∞ estimate (47) of Lemma 4.2, the same proof used for Theorem 1.1 can be used to establish Theorem 4.1. □

5. Remarks. As mentioned in section 2, Theorem 2.2 is a generalization of Robinson's implicit function theorem [20] to nonlinear spaces. His theorem assumes that the nonlinear term is strictly differentiable and that the inverse of the linearized map is Lipschitz continuous. In optimal control, the latter condition amounts to Lipschitz continuity in L^∞ of the solution-multiplier vector associated with the linear-quadratic approximation. For problems with control constraints, this property for the solution is obtained, for example, in [1] or [4].

In this paper, we obtain Lipschitzian stability results for state constrained problems utilizing a new form of the implicit function theorem applicable to nonlinear spaces. We obtain optimal Lipschitzian stability results in L^2 and nonoptimal stability results in L^∞ under the uniform independence and the coercivity conditions. And with an additional contact separation condition, we obtain a tight L^∞ stability result. These are the first L^∞ stability results that have been established for state constrained control problems.

The uniform independence condition was introduced in [8], where it was shown that this condition together with the coercivity condition yield Lipschitz continuity in time of the solution and the Lagrange multipliers of a convex state and control constrained optimal control problem. Using Hager's regularity result, Dontchev [1] proved that the solution of this problem has a Lipschitz-type property with respect to perturbations. Various extensions of these results have been proposed by several authors. A survey of earlier results is given in [2].

In a series of papers (see [14], [15], and the references therein), Malanowski studied the stability of optimal control problems with constraints. In [15] he considers an optimal control problem with state and control constraints. His approach differs from ours in the following ways: he uses an implicit function theorem in linear spaces and a compactness argument, and the second-order sufficient condition he uses is different from our coercivity condition. Although there are some similar steps in the analysis of L^2 stability, the two approaches mainly differ in their abstract framework.

A prototype of Lemma 3.5 is given in [1, Lemma 2.5]. Lemma 3.6 is related to Lemma 3 in [2], although the analysis in Lemma 3.6 is much simpler since we ignore indices outside of $\mathcal{A}(t)$. In the analysis of the linear-quadratic problem (37), we follow the approach in [4].

Acknowledgment. The authors wish to thank both Kazimierz Malanowski for his comments on an earlier version of this paper and the reviewers for their constructive suggestions.

RATES OF CONVERGENCE FOR APPROXIMATION SCHEMES IN OPTIMAL CONTROL*

PAUL DUPUIS† AND MATTHEW R. JAMES‡

Abstract. We present a simple method for obtaining rate of convergence estimates for approximations in optimal control problems. Although the method is applicable to a wide range of approximation problems, it requires in all cases some type of smoothness of the quantity being approximated. We illustrate the method by presenting a number of examples, including finite difference schemes for stochastic and deterministic optimal control problems. A general principle can be abstracted, and indeed the method may be applied to a variety of approximation problems, such as the numerical approximation of nonlinear PDEs not a priori related to control theory.

Key words. optimal control, numerical approximation, rate of convergence, finite differences, ergodic control, reflected diffusions, nonlinear PDE

1. Introduction.

A fundamental problem in numerical analysis is the determination of the rate of convergence of approximation schemes. In general, the rate of convergence depends on the nature of the approximation and on the smoothness of the quantity being approximated. For example, the standard finite difference scheme for Laplace's equation in a smooth domain converges with a rate proportional to the discretization step size.

In optimal control theory, one is often faced with the problem of computing the minimal cost function, also referred to as the value function. In many cases, the value function can be characterized as an appropriate solution to a Hamilton–Jacobi–Bellman (HJB) equation that takes the form of a nonlinear PDE. In general, one cannot compute the value function explicitly, and instead must resort to a numerical approximation. Various approximation schemes are available (e.g., finite difference or finite element), and convergence results are either analytic (e.g., Crandall and Lions [5], Barles and Souganidis [1]) or probabilistic (e.g., Kushner [18], Kushner and Dupuis [19]). There are two types of results available on the rate of convergence. One is a global rate of convergence for deterministic problems which makes few assumptions regarding the regularity of the minimal cost function. The first paper to obtain results of this type was [5]. The rate is in the form of an upper bound on the error and is proportional to the square root of the discretization step size. Later papers considered a number of extensions, such as deterministic control problems (e.g., Capuzzo Dolcetta and Falcone [3], Capuzzo Dolcetta and Ishii [4], Gonzalez and Rofman [17]) and differential games (Souganidis [26]). In all these papers the same type of global but locally suboptimal rate estimate as in [5] is obtained. A second type of rate was obtained by Menaldi [23] in the context of control of a nondegenerate diffusion process

with discounted cost. Here the regularity of the minimal cost function was exploited to obtain sharp rates of convergence.

In this paper we present a simple method for obtaining rate of convergence estimates that is applicable to a range of approximation problems, including the important case of numerical approximation. The approach is closer in spirit to that of Menaldi rather than Crandall and Lions in that we exploit, wherever possible, smoothness of the minimal cost to obtain sharp rates and in some cases an expansion of the error in terms of the discretization parameter. A minimal requirement for the applicability of our method is local smoothness of the quantity that is being approximated. For example, in the setting of deterministic optimal control problems we obtain a rate of convergence that is proportional to the discretization step size in these regions. The practice of considering separately those regions where greater regularity applies is standard in numerical analysis, and the information so obtained is often more useful than a global but locally suboptimal rate of convergence.

The basic idea is as follows. In the problems we consider, the quantity V to be approximated is represented as a functional of some process x, and the approximating quantity V^h is analogously represented as a functional of an approximating process x^h. For a very simple (uncontrolled) example, suppose that V has a representation of the form

$$V(x) = \mathbf{E}_x \left[\int_0^\infty e^{-\lambda t} k(x_t) dt \right],$$

where x is, say, a diffusion process. Suppose also that V^h has the representation

$$V^h(x) = \mathbf{E}_x \left[\int_0^\infty e^{-\lambda t} k(x_t^h) dt \right]$$

in terms of an approximating process x^h, which for simplicity we will assume to be Markov. As we illustrate via several examples below, the assumed regularity properties of V allow one to derive a second representation for V, this time in terms of the process x^h:

$$V(x) = \mathbf{E}_x \left[\int_0^\infty e^{-\lambda t} \left(k(x_t^h) + e^h(x_t^h) \right) dt \right].$$

The function $e^h = V - V^h$ is given explicitly in terms of the function V and the generators of the processes x and x^h. Since V^h is supposed to be close to V, one would expect x^h to be close in some sense to x. In fact, one typically has the weak convergence of x^h to x. When this convergence is coupled with the explicit form for the error e^h, a comparison of the two representations of V gives a rate of convergence, and also formulas for rate coefficients when enough regularity is available.

The rate of convergence has a number of uses, the most obvious being as a guide in the selection of step sizes and the comparison of algorithms in numerical approximations. A second use in this setting is in comparing the contributions to the overall error made by various "parts" of an approximation; e.g., one can consider a problem that is posed on a bounded domain and compare the contributions made by approximations on the interior and approximations to the boundary condition. This is done for a reflecting diffusion problem with ergodic cost in section 4.

To show that the basic idea can be used in a variety of situations, we give the details for a number of problems that are quite different. In section 2, we consider

the stochastic control problem analyzed by Menaldi [23], where the value function is known to be smooth: $V \in C^{2,\alpha}$ and the (global) rate of convergence for a finite difference scheme is $O(h^\alpha)$. Our approach appears to be simpler than Menaldi's. The focus shifts in section 3 to a general class of approximations to a finite time deterministic optimal control problem, including finite difference schemes. In section 4 we treat an ergodic control problem for a reflecting diffusion process.

Other types of approximations arise in control theory. For example, a diffusion model is often a surrogate for a more realistic and more complicated controlled process. Underlying this replacement is (implicitly or explicitly) an approximation argument, in which it is supposed that the realistic process is embedded in a sequence of processes whose weak limit is the controlled diffusion process. Rate of convergence estimates are also useful in this context, and the method we discuss can in some cases be used here as well. We conclude with remarks on such possibilities and other extensions in section 5.

2. A stochastic optimal control example. In this section we introduce the basic method for calculating rates of convergence. In order to place it in perspective, it is appropriate that we begin by considering one of the few stochastic control problems for which a rate of convergence is known, namely, the stochastic control problem studied by Menaldi [23].

The dynamics are given by the controlled stochastic differential equation (SDE)

$$dx_t = b(x_t, u_t)\,dt + dw_t, \tag{2.1}$$

and the value function is defined by

$$V(x) \doteq \inf_{u\in\mathcal{U}} \mathbf{E}_x \left[\int_0^\tau e^{-\lambda t} k(x_t, u_t)\,dt\right] \tag{2.2}$$

for $x \in D$. Here, $D \subset \mathbf{R}^n$ is a smooth bounded domain, $\tau = \tau(x) = \inf\{t > 0 : x_t \notin D\}$ is the exit time from D, $\lambda > 0$, $\mathcal{U}$ is a set of admissible U-valued control processes, $U \subset \mathbf{R}^m$ is compact, $b \in C^\infty(\mathbf{R}^n \times \mathbf{R}^m, \mathbf{R}^n)$ and $k \in C^\infty(\mathbf{R}^n \times \mathbf{R}^m)$ are bounded and uniformly Lipschitz continuous, and $\mathbf{E}_x$ denotes expectation conditioned on $x_0 = x$. For the definition of admissible controls, see [23].

Although in certain cases (e.g., uncontrolled systems or one-dimensional problems) V may be more regular, it is known [16], [23, pp. 601–602] that in general $V \in C^{2,\alpha}(\bar{D})$ for some $0 < \alpha < 1$, and also that V is a classical solution of the dynamic programming or HJB equation

$$\begin{cases} \lambda V(x) = \min_{u\in U} [L_u V(x) + k(x,u)] & \text{in } D, \\ V(x) = 0 & \text{on } \partial D. \end{cases} \tag{2.3}$$

In the last display L_u is the controlled diffusion generator defined for $f \in C^2(\mathbf{R}^n)$ by

$$L_u f(x) \doteq \langle b(x,u), f_x(x)\rangle + \frac{1}{2}\mathrm{tr}[f_{xx}(x)],$$

where $\mathrm{tr}A$ denotes the trace of a square matrix A, and where $f_x(x)$ and $f_{xx}(x)$ denote the gradient and Hessian of f at x, respectively.

For a real-valued function $g(y)$ we define $g^+(y) = g(y) \vee 0$ and $g^-(y) = -(g(y) \wedge 0)$. For $h > 0$ let $h\mathbf{Z}^n = \{hz : z_i \in \mathbf{Z}, i = 1, 2, \ldots, n\}$. There are a number of ways to construct an approximation to V that has domain $h\mathbf{Z}^n$. We focus for now on the

method that is probably most familiar. Thus we replace the differential operator L_u by the finite difference operator L_u^h defined by

$$L_u^h f(x) \doteq \frac{1}{2}\sum_{i=1}^{n}\left[f(x+he_i)+f(x-he_i)-2f(x)\right]/h^2 + \sum_{i=1}^{n} b_i^{\pm}(x,u)\left[f(x\pm he_i)-f(x)\right]/h,$$

where $x \in h\mathbf{Z}^n$ and e_i, $i=1,\dots,n$, are the standard unit vectors in $\mathbf{R}^n$. Let us fix $h_0 > 0$, and suppose that D' is an open set containing the closed h_0-neighborhood of D. Given a function $f \in C^{2,\alpha}(\bar{D})$, there exists a function $f' \in C_0^{2,\alpha}(D')$ such that $f = f'$ in $\bar{D}$ (see [16, Lemma 6.37]). Henceforth, we assume $h \le h_0$ and simply write f for the extension f'. By Taylor's theorem, we see that the operator L_u^h approximates L_u in the sense that if we define the "error"

$$e_f^h(x,u) \doteq L_u f(x) - L_u^h f(x), \tag{2.4}$$

then

$$|e_f^h(x,u)| \;=\; O(h^\alpha) \text{ uniformly in } \bar{D}\times U \tag{2.5}$$

for all $f \in C^{2,\alpha}(\bar{D})$. Note that this estimate is well defined, in view of our convention of extension. The finite difference replacement of (2.3) that we consider is

$$\begin{cases} \lambda V^h(x) \;=\; \min_{u\in U}\left[L_u^h V^h(x) + k(x,u)\right] & \text{in } D^h, \\ V^h(x) \;=\; 0 & \text{on } \partial D^h, \end{cases} \tag{2.6}$$

where $D^h = D \cap h\mathbf{Z}^n$ and $\partial D^h = (\mathbf{R}^n \backslash D) \cap h\mathbf{Z}^n$.

For $v \in \mathbf{R}^n$ and $p \in [1,\infty)$ define $\|v\|_p \doteq (|v_1|^p + \cdots + |v_n|^p)^{1/p}$. The equation (2.6) can be interpreted as the HJB equation for a controlled Markov chain problem. To see this, multiply both sides of the first equation in (2.6) by $\Delta t^h(x)$, add $V^h(x)$, and then divide by $(1+\lambda\Delta t^h(x))$. We thereby obtain the equation

$$V^h(x) \;= \min_{u\in U}\left[\sum_{z\in N^h(x)} \frac{1}{1+\lambda\Delta t^h(x)}\left(p^h(x,z|u)V^h(z) + \Delta t^h(x)k(x,u)\right)\right], \tag{2.7}$$

where

$$\Delta t^h(x) \;\doteq\; \frac{h^2}{n + h\max_{u\in U}\|b(x,u)\|_1} \tag{2.8}$$

is a time interpolation scale, and the functions $p^h(x,z|u)$ are transition probabilities defined by

$$p^h(x,z|u) \;\doteq\; \begin{cases} \dfrac{h(\max_{u\in U}\|b(x,u)\|_1 - \|b(x,u)\|_1)}{n + h\max_{u\in U}\|b(x,u)\|_1} & \text{if } z = x, \\ \dfrac{1/2 + hb_i^{\pm}(x,u)}{n + h\max_{u\in U}\|b(x,u)\|_1} & \text{if } z = x \pm he_i, \text{ some } i = 1,\dots,n, \\ 0 & \text{otherwise.} \end{cases} \tag{2.9}$$

The functions p^h and $\Delta t^h(x)$ are defined as they are so that equation (2.7) can be interpreted as an HJB equation for a problem involving a controlled Markov chain. If $\{\xi_k^h, k = 0, 1, \ldots\}$ is a controlled Markov chain satisfying

$$\mathbf{P}_x^h \left(\xi_{k+1}^h = z \,|\, \xi_l^h, u_l,\, l = 0, \ldots, k\right) \;=\; p^h(\xi_k^h, z|u_k^h),$$

then V^h has the representation

$$V^h(x) \;=\; \inf_{u \in \mathcal{U}^h} \mathbf{E}_x^h \left[\sum_{k=0}^{N^h-1} \left(\prod_{l=0}^{k-1} \frac{1}{1 + \lambda \Delta t^h(\xi_l^h)} \right) k(\xi_k^h, u_k^h) \Delta t^h(\xi_k^h) \right]. \tag{2.10}$$

Here, N^h is the exit time from D^h and $\mathcal{U}^h$ is an appropriate set of control policies [19]. The minimal cost $V^h(x)$ for this problem is well defined and also the unique solution to (2.6) [18, 19]. It is easy to formally check that (2.6) is the HJB equation for (2.10). For a rigorous proof, we refer the reader to [25].

The original motivation for (2.6) is as a finite difference replacement for (2.3). The replacement of the problem (2.3) by the problem (2.6) could be viewed as an approximation at the level of the PDE. An alternative point of view is to approximate at the level of the *process*, and this is the perspective naturally associated with (2.7) and the representation (2.10). More precisely, for the transition probabilities and interpolation interval defined by (2.8) and (2.9), we have

$$\mathbf{E}_x^h \left[\xi_{k+1}^h - \xi_k^h | \, \xi_l^h, u_l,\, l = 0, \ldots, k\right] = b(\xi_k^h, u_k^h) \Delta t^h(\xi_k^h) \tag{2.11}$$

and

(2.12)

$$\mathbf{cov}_x^h \left[\xi_{k+1}^h - \xi_k^h | \, \xi_l^h, u_l,\, l = 0, \ldots, k\right] = I \Delta t^h(\xi_k^h) + O(h) \Delta t^h(\xi_k^h) + [O(\Delta t^h(\xi_k^h))]^2,$$

where **cov** stands for conditional covariance. These equations imply that an interpolated version of the chain $\{(\xi_k^h, u_k^h)\}$ that uses the interpolation intervals $\Delta t^h(\xi_k^h)$ is a good approximation to the original controlled process (2.1) in the sense of weak convergence (see [19] and section 3). Although in this section we have motivated the forms of the transition probabilities and interpolation interval by starting with finite difference approximations, in later sections we will find it more convenient to construct them directly. We refer the reader to [19, Chapter 5] for an in-depth discussion on methods for constructing these interpolation times and transition functions and for a precise statement of the conditions they should satisfy.

Using either weak convergence methods [18, 19] or viscosity solution methods [1, 14], one can show that the approximation V^h converges to V:

$$\lim_{h \to 0} \sup_{x \in D^h} |V^h(x) - V(x)| \;=\; 0.$$

A rate of convergence result was obtained by Menaldi [23], in a more general setting. Here we show that the same rate estimate can be obtained easily by employing a probabilistic representation for V in terms of the controlled Markov chain. Indeed, using (2.3) and (2.4), we see that V satisfies

$$\lambda V(x) \;=\; \min_{u \in U} \left[L_u^h V(x) + k(x, u) + e^h(x, u)\right] \quad \text{in } D^h. \tag{2.13}$$

A comparison of (2.13) with (2.6) indicates that V has a representation of exactly the same form as (2.10), save that the perturbed running cost $k + e^h$ is used; viz.,

(2.14)
$$V(x) = \inf_{u\in\mathcal{U}^h} \mathbf{E}_x^h \left[\sum_{k=0}^{N^h-1} \left(\prod_{l=0}^{k-1} \frac{1}{1+\lambda\Delta t^h(\xi_l^h)} \right) \left(k(\xi_k^h, u_k^h) + e^h(\xi_k^h, u_k^h) \right) \Delta t^h(\xi_k^h) \right].$$

Note in particular that the two representations are in terms of the same controlled Markov chain. This easily leads to the following rate of convergence result.

THEOREM 2.1. *Given that $V \in C^{2,\alpha}(\bar{D})$, we have*

$$\sup_{x\in D^h} |V^h(x) - V(x)| \;=\; O(h^\alpha) \tag{2.15}$$

as $h \downarrow 0$.

Proof. For $\varepsilon > 0$ consider an ε-optimal control policy for the right-hand side of (2.10), and let $\{(\xi_k^h, u_k^h)\}$ denote the associated controlled chain. Thus

$$V^h(x) \;\geq\; \mathbf{E}_x^h \left[\sum_{k=0}^{N^h-1} \left(\prod_{l=0}^{k-1} \frac{1}{1+\lambda\Delta t^h(\xi_l^h)} \right) k(\xi_k^h, u_k^h)\Delta t^h(\xi_k^h) \right] - \varepsilon.$$

From the representation (2.14) we obtain the estimate

$$V(x) - V^h(x) \leq \mathbf{E}_x^h \left[\sum_{k=0}^{N^h-1} \left(\prod_{l=0}^{k-1} \frac{1}{1+\lambda\Delta t^h(\xi_l^h)} \right) e^h(\xi_k^h, u_k^h)\Delta t^h(\xi_k^h) \right] + \varepsilon.$$

The definition of $\Delta t^h(x)$ implies the existence of $0 < \gamma_1 \leq \gamma_2 < \infty$ such that $\gamma_1 h^2 \leq \Delta t^h(x) \leq \gamma_2 h^2$ for all $x \in h\mathbf{Z}^h$. Using the bound (2.5), the last equation implies

$$V(x) - V^h(x) \leq \left[\sum_{k=0}^{\infty} \left(\frac{1}{1+\lambda\gamma_1 h^2} \right)^k \gamma_2 h^2 \right] O(h^\alpha) + \varepsilon = O(h^\alpha) + \varepsilon,$$

where $O(h^\alpha)$ is uniform in all admissible controls and $x \in D^h$. Since $\varepsilon > 0$ is arbitrary we have $V(x) - V^h(x) \leq O(h^\alpha)$ uniformly in $x \in D^h$. The reverse inequality $V^h(x) - V(x) \leq O(h^\alpha)$ is proved in the same way, save that we consider policies that are ε-optimal for the right-hand side of (2.14). □

Remark 2.2. The results of this section continue to hold if the SDE (2.1) has a uniformly elliptic diffusion coefficient $\sigma(x, u)$.

A formula for the rate. If V enjoys greater regularity than was used above, and if there exist a unique (in law) optimal policy u^* and process x^* for each initial condition $x \in D$, then one can derive an explicit formula for the rate of convergence. For example, if $V \in C^{3,\alpha}(\bar{D})$, then

$$\frac{e^h(x,u)}{h} \;=\; -\frac{1}{2}\sum_{i=1}^{n} |b_i(x,u)| V_{x_i x_i}(x) + O(h^\alpha).$$

To simplify, we assume that all points where the controlled chain might be stopped lie in ∂G. It turns out that the assumed uniqueness allows one to show that interpolated

versions of the optimal discrete time process and control converge weakly to the optimal control and process for the continuous time problem. This can in turn be used to show that

$$\lim_{h\to 0}\frac{V^h(x)-V(x)}{h} \;=\; \mathbf{E}_x\left[\int_0^\tau e^{-\lambda t}\frac{1}{2}\sum_{i=1}^n |b_i(x_t^*,u_t^*)|V_{x_ix_i}(x_t^*)\,dt\right]. \tag{2.16}$$

The analogous argument for a different control problem will be given in detail in section 3.

As an example of how such information might be useful, suppose that instead of the one-sided approximations to $\langle b(x,u), f_x(x)\rangle$ used above, we consider instead a central difference approximation:

$$\langle b(x,u), f_x(x)\rangle \to \sum_{i=1}^n b_i(x,u)\left(f(x+he_i)-f(x-he_i)\right)/2h.$$

In this case $V^h(x)$ has an interpretation as a functional of a controlled Markov chain if and only if $h|b_i(x,u)| \le 1$ for all i, x, and u of interest. Let us assume that this condition holds. Then, under the assumption that $V \in C^{3,\alpha}(\bar{D})$, we obtain $V^h(x)-V(x)=O(h^{1+\alpha})$. Under additional regularity one can obtain an even more refined expression in the spirit of (2.16).

Remark 2.3. Although we have used in a crucial way the fact that V solves the HJB equation (2.3), it is not actually necessary to make an analogous assumption with respect to the value functions for the approximations. This can be useful in cases where the HJB equations for the prelimit problems are not sufficiently well understood. In such cases an additional argument is needed to show that the minimal costs for the prelimit problems can be arbitrarily well approximated by problems for which the associated HJB equations are known to hold rigorously, e.g., approximation in terms of a countable state space controlled Markov chain. This can be established in wide generality by means of weak convergence techniques [19]. However, even if they hold only in a formal sense the relations between the HJB equations for the limiting and prelimit control problems are very useful in motivating the general line of reasoning that we use.

3. A deterministic optimal control example. Consider the following deterministic control system:

$$\begin{cases} \dot{x}_s \;=\; b(x_s,u_s), \quad t<s<T, \\ x_t \;=\; x, \end{cases} \tag{3.1}$$

and finite-horizon value function

$$V(x,t) \;=\; \inf_{u\in\mathcal{U}_t}\left[\int_t^T k(x_s,u_s)\,ds + g(x_T)\right], \tag{3.2}$$

where b, k, etc., are as in section 2, $\mathcal{U}_t$ consists of all measurable functions $u : [t,T]\to U$, and $g\in C^\infty(\mathbf{R}^n)$ is bounded and uniformly Lipschitz continuous. Define $L_uf(x,t)=\langle b(x,u), f_x(x,t)\rangle$. Then $V\in C(\mathbf{R}^n\times[0,T])$ is Lipschitz continuous and is the unique (viscosity) solution of the HJB equation [14]

$$\begin{cases} V_t+\min\limits_{u\in U}\left[L_uV(x,t)+k(x,u)\right] \;=\; 0 \;\text{ in } \mathbf{R}^n\times(0,T), \\ V(x,T) \;=\; g(x) \;\text{ for } x\in\mathbf{R}^n. \end{cases} \tag{3.3}$$

In this section we will consider a general class of approximations to V. In the previous section we assumed that the solution to the appropriate HJB equation was regular on the entire domain of interest. In contrast, in these deterministic examples we can consider the case where the solution may be regular only on a subset of the domain. In the first subsection we introduce a class of approximations to (3.2). In the second and third subsections we consider the cases where the value function is globally regular and regular only on a subset, respectively. Besides proving a rate result, we also show how under certain conditions the coefficients can be identified. Finally, in section 3.4 we give examples from finite difference numerical approximation.

3.1. A general approximation. The class of approximations to (3.1) and (3.3) we consider can be thought of as discrete time "small noise" approximations. Included are small noise optimal control problems associated with the large deviation theory for small noise discrete time stochastic systems, as well as explicit finite difference schemes for the numerical approximation of V. Let $\delta > 0$ denote the approximation parameter. We will restrict δ to values such that T/δ is an integer. While this is done in part just for convenience, it also turns out that this assumption plays a role in determining the specific form for the rate of convergence. See the remark after Theorem 3.3.

For each such $\delta > 0, x \in \mathbf{R}^n$, and $u \in U$, let $\mu^\delta_{x,u}$ denote a probability measure on $\mathbf{R}^n$. In order to have the processes we work with well defined, we assume that the mapping $(x,u) \to \mu^\delta_{x,u}(A)$ is Borel measurable for each Borel set $A \subset \mathbf{R}^n$. Define $t^\delta_k = k\delta$ and $N^\delta = T/\delta$. We consider controlled discrete time processes $\{\xi^\delta_i\}$ that evolve according to

$$\mathbf{P}^\delta_{x,t^\delta_k}\left(\frac{\xi^\delta_{i+1}-\xi^\delta_i}{\delta} \in A \middle| (\xi^\delta_j, u^\delta_j), j \in \{k,\dots,i\}\right) = \mu^\delta_{\xi^\delta_i,u^\delta_i}(A).$$

Here $\mathbf{P}^\delta_{x,t^\delta_k}$ denotes probability conditioned on $\xi^\delta_k = x$.

We consider the family of value functions

$$V^\delta(x,t^\delta_k) \doteq \inf_{u^\delta \in \mathcal{U}^\delta} \mathbf{E}^h_{x,t^\delta_k}\left[\sum_{i=k}^{N^\delta-1} k(\xi^\delta_i, u^\delta_i)\delta + g(\xi^\delta_{N^\delta})\right].$$

The admissible controls in this case can be taken to be the feedback control laws (i.e., each u^δ_k is simply a measurable function from $\mathbf{R}^n$ to U), which implies that the controlled process is a nonstationary Markov chain. In order for V^δ to be close to V we must impose some conditions on $\mu^\delta_{x,u}$. Define $b^\delta(x,u)$ to be the mean of $\mu^\delta_{x,u}(dy)$:

$$b^\delta(x,u) \doteq \int_{\mathbf{R}^n} y\mu^\delta_{x,u}(dy).$$

We require that

$$b^\delta(x,u) = b(x,u) + O(\delta) \quad \text{and} \quad \int_{\mathbf{R}^n} \|y\|^2 \mu^\delta_{x,u}(dy) = O(1), \tag{3.4}$$

where the $O(\delta)$ and $O(1)$ are uniform on compact subsets of $\mathbf{R}^n \times U$. For convenience we will also assume that the supports of the measures $\mu^\delta_{x,u}(dy)$ are bounded uniformly for all $\delta > 0$, $x \in \mathbf{R}^n$, and $u \in U$, which automatically implies the second part of

(3.4). A less restrictive assumption that could be used instead is a uniform bound on the moment generating functions: for each $\alpha \in \mathbf{R}^n$

$$\sup_{\delta>0, u\in U, x\in\mathbf{R}^n} \int_{\mathbf{R}^n} \exp\langle \alpha, y\rangle \mu^\delta_{x,u}(dy) < \infty. \tag{3.5}$$

Of course, this condition is implied by the assumption of a uniform bound on the supports. These conditions are usually easy to check.

The minimal costs V^δ satisfy the following HJB equation [2]:

$$\begin{aligned} \partial^\delta_t V^\delta(x, t^\delta_k) + \min_{u\in U} \left[L^\delta_u V^\delta(x, t^\delta_{k+1}) + k(x,u)\right] &= 0 \ \text{ in } \mathbf{R}^n \times \{0, \dots, N^\delta - 1\}, \\ V^\delta(x, T) &= g(x) \ \text{ for } x \in \mathbf{R}^n, \end{aligned} \tag{3.6}$$

where

$$\partial^\delta_t f(x, t^\delta_k) \doteq \left(f(x, t^\delta_{k+1}) - f(x, t^\delta_k)\right)/\delta$$

and

$$L^\delta_u f(x,t) \doteq \int_{\mathbf{R}^n} (f(x+\delta y, t) - f(x,t))\, \mu^\delta_{x,u}(dy)/\delta.$$

By weak convergence methods [18, 19] (or, alternatively, by viscosity solution methods [1, 14]), one can prove convergence for this scheme:

$$\lim_{\delta\to 0} \sup_{x\in\mathbf{R}^n,\, |x|\le C} \sup_{k=0,1,\dots,N^\delta} |V^\delta(x, t^\delta_k) - V(x, t^\delta_k)| = 0$$

for each $C < \infty$. The rate of convergence depends on the smoothness of the value function V. In general, V is merely Lipschitz continuous and may fail to be differentiable everywhere. However, when V is smooth a rate estimate can easily be established.

3.2. The globally smooth case. Assume now that $V \in C^2(\mathbf{R}^n \times [0,T])$. To obtain a rate of convergence we follow the same procedure as in section 2. Thus the first step is to obtain a representation for V in terms of the controlled chain. By Taylor's theorem, V satisfies the discrete equation

$$\partial^\delta_t V(x, t^\delta_k) + \min_{u\in U} \left[L^\delta_u V(x, t^\delta_{k+1}) + k(x,u) + e^\delta(x, u, t^\delta_k)\right] = 0 \tag{3.7}$$

in $\mathbf{R}^n \times \{0, \dots, N^\delta - 1\}$, where

$$e^\delta(x,u,t) \doteq \left(L_u V(x,t) - L^\delta_u V(x,t)\right) + \left(V_t(x,t) - \partial^\delta_t V(x,t)\right).$$

We therefore have the representation

$$V(x, t^\delta_k) = \inf_{u^\delta \in \mathcal{U}^\delta} \mathbf{E}^\delta_{x, t^\delta_k} \left[\sum_{i=k}^{N^\delta - 1} \left(k(\xi^\delta_i, u^\delta_i) + e^\delta(\xi^\delta_i, u^\delta_i, t^\delta_i)\right)\delta + g(\xi^\delta_{N^\delta}) \right]. \tag{3.8}$$

Equation (3.4) implies $e^\delta(x,u,t) = O(\delta)$ uniformly on compact subsets.

This representation leads to the following result, whose proof is exactly analogous to the proof of Theorem 2.1.

THEOREM 3.1. *Assume that* $V \in C^2(\mathbf{R}^n \times [0,T])$ *and that* (3.4) *holds. Then for each* $C < \infty$ *we have*

$$\sup_{x \in \mathbf{R}^n,\, |x| \le C} \sup_{k=0,1\ldots,N^\delta} |V^\delta(x, t_k^\delta) - V(x, t_k^\delta)| \;=\; O(\delta) \tag{3.9}$$

as $\delta \downarrow 0$.

Remark 3.2. Similar results can be obtained for differential game problems, and also for implicit schemes [19].

If V enjoys a greater degree of regularity and (3.4) is replaced by a stronger assumption, we can refine this result and obtain an explicit expression for the coefficient in the rate of convergence. Let B be any $n \times n$ symmetric matrix. In place of (3.4) we assume

$$\begin{aligned} b^\delta(x,u) &= b(x,u) + \delta s(x,u) + o(\delta), \\ \int_{\mathbf{R}^n} \langle By, y\rangle \mu^\delta_{x,u}(dy) &= q(x,u,B) + o(1), \end{aligned} \tag{3.10}$$

where $s(x,u)$ and $q(x,u,B)$ are continuous in (x,u,B), and where the $o(\delta)$ and $o(1)$ terms are uniform in compact subsets of $\mathbf{R}^n \times U$. We will also need to make the following assumption:

$$\begin{aligned} &\min_{u \in U} [b(x,u) \cdot p + k(x,u)] \quad \text{attains a unique minimum} \\ &\text{at } U^*(x,p), \text{ where } U^* \text{ is of class } C^1. \end{aligned} \tag{3.11}$$

Define

$$r(x,u,t) \;\doteq\; \langle V_x(x,t), s(x,u)\rangle + q(x,u,V_{xx}(x,t)) + \frac{1}{2} V_{tt}(x,t).$$

Note that $-e^\delta(x,u,t)/\delta \to r(x,u,t)$ uniformly on compact sets.

THEOREM 3.3. *Assume that* $V \in C^3(\mathbf{R}^n \times [0,T])$ *and* (3.10), (3.11) *hold. Then we have the explicit rate of convergence*

$$\lim_{\delta \to 0,\, x^\delta \to x,\, t_k^\delta \to t} \frac{V^\delta(x^\delta, t_k^\delta) - V(x^\delta, t_k^\delta)}{\delta} \;=\; \int_t^T r(x_s^*, u_s^*, s)\, ds, \tag{3.12}$$

uniformly on compact subsets, where x_s^* *is the optimal trajectory corresponding to the unique optimal feedback control* $u_s^* = u^*(x_s^*, s) = U^*(x_s^*, V_x(x_s^*, s))$, $t \le s \le T$, *with initial condition* $x_t^* = x$.

Proof. We first prove that u^* is the unique optimal control. Let $\tilde{u}_s$ be any control and let $\tilde{x}_s$ be the associated controlled trajectory that starts at x at time t [24]. We follow the convention of saying that $\tilde{u} = u^*$ if and only if $\tilde{u}_s = u_s^*$ for almost every (a.e.) $s \in [t,T]$. From equation (3.3) we obtain

$$V_s(x,s) + L_{\tilde{u}_s} V(x,s) + k(x, \tilde{u}_s) \ge 0,$$

with equality if and only if $\tilde{u}_s = u^*(x,s)$. Integrating along the trajectory yields

$$\int_t^T k(\tilde{x}_s, \tilde{u}_s)\, ds + g(\tilde{x}_T) \ge V(x,t), \tag{3.13}$$

with equality if and only if $\tilde{u}_s = u^*(\tilde{x}_s, s)$ for a.e. $s \in [t,T]$. Since the solution to $\dot{\phi}_s = b(\phi_s, u^*(\phi_s, s))$ is unique for any initial condition (i.e., $\tilde{x} = x^*$), we obtain equality if and only if $\tilde{u} = u^*$.

We now prove the rate result. Following the argument of Theorem 2.1, we let $\{(\xi_i^\delta, u_i^\delta)\}$ be a δ^2-optimal chain and control for the representation of $V(x^\delta, t_k^\delta)$ given in (3.8). Define interpolated state and control processes x^δ, u^δ by $x_s^\delta = \xi_i^\delta$, $u_s^\delta = u_i^\delta$ on $[t_i^\delta, t_{i+1}^\delta)$ [18, 19]. It follows from the boundedness of the supports of the measures $\mu_{x,u}^\delta$ that the random processes $\{(x^\delta, u^\delta), \delta > 0\}$ are tight (for the precise topology used on the control process, see [19]). It follows from (3.4) and an elementary martingale argument that any limit satisfies (3.1) with probability 1 (w.p.1). Since we have equality in (3.13) if and only if $\tilde{u} = u^*$, the fact that $V^\delta(x^\delta, t_k^\delta) \to V(x,t)$ (Theorem 3.1) and an argument by contradiction imply the weak convergence

$$x^\delta, u^\delta \Longrightarrow x^*, u^*$$

as $\delta \to 0$, $x^\delta \to x$, $t_k^\delta \to t$. Now since $\{(\xi_i^\delta, u_i^\delta)\}$ is δ^2-optimal in the representation (3.8),

$$\frac{V^\delta(x^\delta, t_k^\delta) - V(x^\delta, t_k^\delta)}{\delta} \le \mathbf{E}^\delta_{x^\delta, t_k^\delta}\left[\sum_{i=k}^{N^\delta - 1} \left(r(\xi_i^\delta, u_i^\delta, t_i^\delta) + o(1)\right)\delta\right] + \delta,$$

where the $o(1)$ term is uniform on compact sets. Thus, by the dominated convergence theorem,

$$\limsup_{\delta \to 0, x^\delta \to x,\, t_k^\delta \to t} \frac{V^\delta(x^\delta, t_k^\delta) - V(x^\delta, t_k^\delta)}{\delta} \le \int_t^T r(x_s^*, u_s^*, s)\, ds.$$

The opposite inequality is proven similarly, completing the proof. □

Remark 3.4. Although the assumption that T/δ is an integer is not needed for convergence or even Theorem 3.1, it is needed if we wish to identify the rate coefficient as in the last theorem.

3.3. The general case. In general, V is not smooth everywhere, and consequently one obtains a slower global rate of convergence (see the discussion in the following subsection on rates for numerical schemes). However, because V is smooth in certain regions $\mathcal{N} \subset \mathbf{R}^n \times [0,T]$ [11, 12], one might expect the rate to be faster in these regions of smoothness. We now show that the rate is $O(\delta)$ in such regions.

Let $\mathcal{N}$ be an open, bounded subset of $\mathbf{R}^n \times [0,T]$. Following [12, 13], the set $\mathcal{N}$ is called a *region of strong regularity* (RSR) provided

1. $V \in C^3(\bar{\mathcal{N}})$.
2. Assumption (3.11) holds.
3. Given $(x,t) \in \mathcal{N}$, denote by x_s^* and $u_s^* = u^*(x_s^*, s) = U^*(x_s^*, V_x(x_s^*, s))$, $t \le s \le T$, the unique optimal state trajectory and control with initial condition $x_t^* = x$. Define

$$\sigma = \sigma_{x,t} = \inf\{s > t : (x_s^*, s) \notin \mathcal{N}\},$$

$$y = y_{x,t} = x^*(\sigma), \qquad z = z_{x,t} = (y, \sigma).$$

Then $(x,t) \in \mathcal{N}$ implies $(x_s^*, s) \in \mathcal{N}$, $t \le s < \sigma$, and $\sigma_{x,t} = T$.

4. $\partial\mathcal{N} = \Gamma_1 \cup \Gamma_2$, where $\Gamma_1 = \{z_{x,t} : (x,t) \in \mathcal{N}\}$ is an open subset of $\mathbf{R}^n \times \{T\}$. For information regarding the existence of RSRs, we refer the reader to [11, 12].

THEOREM 3.5. *Assume* (3.10) *and let* $\mathcal{N}$ *be an RSR. Then*

$$\lim_{\delta \to 0,\, x^\delta \to x,\, t_k^\delta \to t} \frac{V^\delta(x^\delta, t_k^\delta) - V(x^\delta, t_k^\delta)}{\delta} \;=\; \int_t^T r(x_s^*, u_s^*, s)\, ds \tag{3.14}$$

uniformly on compact subsets of $\mathcal{N}$. *Consequently,*

$$|V^\delta - V| \;=\; O(\delta) \quad \text{in } \mathcal{N}$$

as $\delta \to 0$.

Proof (sketch). This result is proven by modifying the proof of Theorem 3.3 along the lines of [12, 13]. However, in this proof we use a slightly modified representation for $V(x,t)$. In place of (3.8) we exploit the strong Markov property to write

$$V(x, t_k^\delta) = \inf_{u^\delta \in \mathcal{U}^\delta} \mathbf{E}^\delta_{x, t_k^\delta} \left[\sum_{i=k}^{M^\delta - 1} \left(k(\xi_i^\delta, u_i^\delta) + e^\delta(\xi_i^\delta, u_i^\delta, t_i^\delta) \right) \delta + V(z^\delta) \right],$$

where $M^\delta = \inf\{i > k : (x_i^\delta, t_i^\delta) \notin \mathcal{N}\}$ is the discrete time of first exit from $\mathcal{N}$, $\sigma^\delta = t^\delta_{M^\delta}$, and $z^\delta = (\xi^\delta_{M^\delta}, \sigma^\delta)$. We can also write an analogous representation for $V^\delta(x, t_k^\delta)$ in terms of this stopping time and location. If we let $\{(\xi_i^\delta, u_i^\delta)\}$ be δ^2-optimal for V as in the proof of Theorem 3.3, then we obtain

$$\frac{V^\delta(x^\delta, t_k^\delta) - V(x^\delta, t_k^\delta)}{\delta} \le \mathbf{E}^\delta_{x^\delta, t_k^\delta} \left[\sum_{i=k}^{M^\delta - 1} \left(r(\xi_i^\delta, u_i^\delta, t_i^\delta) + o(1) \right) \delta + \frac{V^\delta(z^\delta) - V(z^\delta)}{\delta} \right] + \delta.$$

Recall that the bound (3.5) holds for the moment generating functions of the distributions $\mu^\delta_{x,u}$. Because of this bound an upper large deviation principle holds for the interpolated processes x_s^δ [7, 8]. The large deviation upper bound implies that if $x^\delta \to x$ and $t_k^\delta \to t$ as $\delta \to 0$, then given $\eta > 0$, there exists $c > 0$ such that for all sufficiently small $\delta > 0$,

$$\mathbf{P}^\delta_{x^\delta, t_k^\delta} \left(\sup_{t_k^\delta \le s \le T} |x_s^\delta - x_s^*| > \eta \right) \;\le\; e^{-c/\delta},$$

and thus by parts (iii) and (iv) of the definition of a RSR, for all sufficiently small $\eta > 0$,

$$\mathbf{P}^\delta_{x^\delta, t_k^\delta} \left(|z^\delta - z| > \eta \right) \;\le\; e^{-c/\delta}.$$

Since $V(x,t)$ and $V^\delta(x,t)$ are uniformly bounded in $(x,t) \in \mathbf{R}^n \times [0,T]$ and $\delta \in (0,1)$, $(V^\delta(z^\delta) - V(z^\delta))/\delta$ is uniformly bounded above by some constant times $1/\delta$. Therefore

$$\begin{aligned} \frac{V^\delta(x^\delta, t_k^\delta) - V(x^\delta, t_k^\delta)}{\delta} \;\le\; & \mathbf{E}^\delta_{x^\delta, t_k^\delta} \left[\left(\int_{t_k^\delta}^{T \wedge \sigma^\delta} r(x_s^\delta, u_s^\delta, s)\, ds + o(1) \right) 1_{\{|z^\delta - z| < \eta\}} \right] \\ & + O(e^{-c/\delta}) \left(1 + O(1/\delta)\right), \end{aligned}$$

and we can conclude as in the proof of Theorem 3.3. ∎

3.4. Numerical approximations. In this subsection we specialize from the previous two subsections to the case of an explicit finite difference approximation V^h to V. As in section 2, let $h > 0$ denote the space discretization step size, Δt^h denote the time discretization, etc. Select $v > 0$ such that

$$v \geq \max_{x \in \mathbf{R}^n,\, u \in U} \|b(x,u)\|_1,$$

and define the time step size

$$\Delta t^h \doteq h/v.$$

We restrict attention to values of $h > 0$ such that $N^h = T/\Delta t^h$ is an integer. We define the discrete times $t_k^h \doteq k\Delta t^h$ and consider the transition probabilities

$$p^h(x,z|u) \doteq \begin{cases} 1 - \|b(x,u)\|_1/v & \text{if } z = x, \\ b_i^{\pm}(x,u)/v & \text{if } z = x \pm he_i \text{ for some } i = 1,\dots,n, \\ 0 & \text{otherwise.} \end{cases}$$

We fit this example into the general framework by setting $\delta \doteq h/v$ and defining $\mu_{x,u}^{\delta}$ by

$$\mu_{x,u}^{\delta}(A) \doteq \sum_{w \in \mathbf{Z}^n : vw \in A} p^h(x, x + hw|u)$$

for all Borel sets $A \subset \mathbf{R}^n$. These definitions imply

$$\int_{\mathbf{R}^n} y\mu_{x,u}^{\delta}(dy) = b(x,u),$$

$$\int_{\mathbf{R}^n} \langle By, y\rangle \mu_{x,u}^{\delta}(dy) = \sum_{i=1}^{n} vB_{ii}|b_i(x,u)|,$$

where $B = (B_{ij})$. Hence equation (3.4) holds and we may apply Theorem 3.1. The function $r(x,u,t)$ in this example takes the form

$$v\sum_{i=1}^{n} V_{x_i x_i}(x,t)|b_i(x,u)| + \frac{1}{2}V_{tt}(x,t),$$

and under the appropriate conditions Theorems 3.3 and 3.5 hold as well.

As an application of the rate of convergence results, consider the following modification of the numerical approximation. It is well known that it is at least theoretically advantageous to allow the interpolation times Δt^h to depend on the state and control: $\Delta t^h = \Delta t^h(x,u)$. While it is obvious that such added flexibility in the selection of a numerical scheme can only help, it may not be the case that the additional effort required to program such schemes is worth the improvement in accuracy. The rate result allows one to estimate the improvement before implementing a more complicated scheme. Note also that the total time taken to complete the numerical computations may be reduced if the interpolation times are allowed to depend on the state and control.

We consider such a modification for the example that was just considered. The underlying reason why one expects state- and control-dependent interpolation times

to improve numerical performance is because they allow one to reduce the probability that the controlled chain remains at any given state; i.e., they allow one to design chains for which $p^h(x,x|u) = 0$ [19, Chapter 5]. With only a little effort, one can modify the proofs of the theorems stated above to allow such state and control dependency of the interpolation times. (Note that if $\Delta t^h(x)$ is state- or control-dependent then for any given x one does not know a priori which continuous times correspond to the interpolation times chosen by the discrete algorithm. Because of this, one must keep track of the interpolation times used as one iterates backward when solving the discrete HJB equation and define $V^h(x,0)$ via an interpolation.) The state-dependent interpolation times and transition probabilities that are appropriate are $\Delta t^h(x,u) = h/|b(x,u)\|_1$ and

$$p^h(x,z|u) = \begin{cases} 0 & \text{if } z = x, \\ b_i^{\pm}(x,u)/\|b(x,u)\|_1 & \text{if } z = x \pm he_i \text{ for some } i = 1,\dots,n, \\ 0 & \text{otherwise.} \end{cases}$$

The measures $\mu^{\delta}_{x,u}$ are defined as before. With these definitions, we again have $\int_{\mathbf{R}^n} y\mu^{\delta}_{x,u}(dy) = b(x,u)$, but now

$$r(x,u,t) = \|b(x,u)\|_1 \sum_{i=1}^{n} V_{x_i x_i}(x,t)|b_i(x,u)| + \frac{1}{2}V_{tt}(x,t).$$

Since $v \geq \|b(x,u)\|_1$ for all x and u, one expects the rate with the new transition probabilities and interpolation times to often be better than that of the previous setup. If v is much larger than "typical values" of $\|b(x,u)\|_1$, then the extra programming effort may indeed be worthwhile. However, if one has a bound such as $a \leq \inf_{x,u} \|b(x,u)\|_1 \leq \sup_{x,u} \|b(x,u)\|_1 \leq Ca$, where C is not very large, then it is probably not worthwhile.

4. An example with ergodic cost and a reflecting diffusion. In order to demonstrate the versatility of the approach, in this section we will consider a variation on the numerical approximation problem considered in section 2. More precisely, we treat the analogous problem where the cost to be minimized is an ergodic cost, and where a reflecting diffusion replaces the model (2.1). In order to define the reflecting diffusion model we must specify a reflection direction for each point of ∂D. Let $n(x)$ denote the inward unit normal to ∂D at $x \in \partial D$. The reflection direction will be denoted by a unit vector $r(x)$. We will assume that $\langle r(x), n(x)\rangle > 0$ for all $x \in \partial D$, and that $r \in C^{\infty}(\mathbf{R}^m)$. Since ∂D is smooth, we can assume that the function n is defined and smooth in an open neighborhood O of ∂D, and that $\langle r(x), n(x)\rangle$ is uniformly bounded below away from zero on O.

We next describe the reflected diffusion model. Since the theory of such equations is not our focus here, the description will only be heuristic. A precise definition can be found in [21] or [6]. The replacement for (2.1) takes the form

$$dx_t = b(x_t, u_t)\,dt + dw_t + dz_t, \tag{4.1}$$

where b satisfies all the assumptions used in section 2. The process z_t is a w.p.1 bounded variation function of t that constrains x_t to remain in $\bar{D}$. It acts in the following way. As long as $x_t \in D$ (recall that D is open), z_t does not affect the process x_t at all, which means that $dz_t = 0$ for all such t. If $x_t \in \partial D$, then z_t can "push" the process so as to maintain $x_t \in \bar{D}$. The requirements on the "push" are:

- that it be in the direction $r(x_t)$,
- that $x_t \in \bar{D}$ for all t w.p.1.

These requirements are formalized by the equations

$$|z|_t = \int_0^t I_{\{x_s \in \partial D\}} d|z|_s \quad \text{and} \quad z_t = \int_0^t r(x_s) d|z|_s,$$

where $|z|_t$ denotes the total variation of z on the interval $(0, t]$. Under the assumptions made above on b, r, and D, a solution to (4.1) exists and is unique. For precise statements and more discussion, we refer the reader to [21, 6, 19].

The reflecting diffusion model described above is especially useful when the controlled process is considered on an infinite time horizon, since it allows the domain on which the process is defined to be bounded without actually stopping the process when it hits ∂D. In some problems, there is a cost proportional to the constraining action of the process z_t. Because of this, we consider the minimal cost defined by

$$\gamma \doteq \inf_{u \in \mathcal{U}} \limsup_{T \to \infty} \frac{1}{T} \mathbf{E}_x \left[\int_0^T k(x_t, u_t)\, dt + \int_0^T l(x_t)\, d|z|_t \right], \tag{4.2}$$

where $l \in C^\infty(\mathbf{R}^n)$ is bounded and uniformly Lipschitz continuous. Although a priori the minimal cost might depend on the initial condition x, it turns out under our assumptions that the cost is independent of x.

The appropriate HJB equation for this problem is

$$\begin{cases} \gamma = \min_{u \in U} [L_u V(x) + k(x, u)] & \text{in } D, \\ 0 = l(x) + \langle V_x(x), r(x) \rangle & \text{on } \partial D, \end{cases} \tag{4.3}$$

where L_u is again defined by

$$L_u f(x) \doteq \langle b(x, u), f_x(x) \rangle + \frac{1}{2} \mathrm{tr}[f_{xx}(x)].$$

The solution to this equation is the pair $(\gamma, V(\cdot))$. Note that if $(\gamma, V(\cdot))$ solves (4.3), then so does $(\gamma, V(\cdot) + c)$ for any $c \in \mathbf{R}$. It turns out that this is exactly the form of nonuniqueness associated with the solutions to (4.3); i.e., if $(\gamma_1, V_1(\cdot))$ and $(\gamma_2, V_2(\cdot))$ both solve (4.3), then $\gamma_1 = \gamma_2$ and $V_1(\cdot) - V_2(\cdot)$ is a constant. We will assume, as in section 2, that $V \in C^{2,\alpha}(\bar{D})$ (see [22]).

A general reference for the Markov chain optimal control problems discussed in this section is section 5 of Chapter 7 in [19]. Recall the definition $D^h \doteq D \cap h\mathbf{Z}^n$. While the process x_t is in D it is the same as the process of section 2. This suggests that we can continue to use the transition probabilities and interpolation intervals defined by (2.9) and (2.8), respectively. However, we must still define the approximations for the boundary condition. Define the operator A by

$$Af(x) = \langle f_x(x), r(x) \rangle$$

for $f \in C^1(\mathbf{R}^n)$. Then the boundary condition can be written $0 = l(x) + AV(x)$ for $x \in \partial D$. Let ∂D^h_+ be a set that contains all points in $(\mathbf{R}^n \backslash D) \cap h\mathbf{Z}^n$ that can be reached from some point in D^h in one step for some choice of the control, i.e., all y such that

$$p^h(x, y|u) > 0 \text{ for some } x \in D^h \text{ and } u \in U.$$

We interpret ∂D_+^h as the "discrete reflecting boundary." Although one can often take ∂D_+^h to be exactly those points that can be reached in one step from D^h, the formulation as given above, which allows a bigger set, is sometimes needed. We will assume that for all h sufficiently small, $\partial D_+^h \subset O$, and remind the reader that O is an open set on which both $n(\cdot)$ and $r(\cdot)$ are defined.

We next consider the transition probabilities for $x \in \partial D_+^h$. The role of these transitions will be to "mimic" the behavior of the reflecting term z_t. The construction of the transition functions obviously depends on the shape of ∂D, $D^h \cup \partial D_+^h$, and the function $r(\cdot)$. For most problems the construction is straightforward and intuitive, since we are dealing here with only first-order boundary operators. Since it is not our goal to discuss methods for constructing these functions, we will simply assume the existence of transition probabilities that satisfy the local consistency equations (4.4) and (4.5) below, and refer the reader to Chapters 5 and 8 of [19] for further information.

Let $p^h(x,y)$ be the transition function for points $x \in \partial D_+^h$. (Note that we do not include a control for such states. This is because in our setup the reflection direction is not controlled. An interesting example where the reflection direction is controlled appears in [20].) Let $\alpha^h(x)r(x)+s^h(x)$ denote the decomposition of the mean discrete reflection $m^h(x) \doteq \sum_{y \in D^h \cup \partial D_+^h} [y-x]\, p^h(x,y)$ into the orthogonal projection onto the subspace spanned by $r(x)$ and its complement. Then the minimal type of "local consistency" we require of the functions $p^h(x,y)$ is

$$\inf_{h>0, x \in \partial D_+^h} \alpha^h(x)/h > 0,$$

$$s^h(x)/h \to 0 \text{ uniformly in } x \in \partial D_+^h, \tag{4.4}$$

and

$$c^h(x)/h \doteq \sum_{y \in D^h \cup \partial D_+^h} \left[y-x-m^h(x)\right] \left[y-x-m^h(x)\right]' p^h(x,y)/h \to 0 \tag{4.5}$$

uniformly in $x \in \partial D_+^h$. This last equation is automatic if p^h is only supported on neighboring points. The essential consequence of these conditions is that $s^h(x)/\alpha^h(x) \to 0$ and $c^h(x)/\alpha^h(x) \to 0$ uniformly in ∂D_+^h, the first of which shows that the component orthogonal to $r(x)$ vanishes faster than the component in the direction $r(x)$, and the second of which shows that the quadratic variation around the mean vanishes faster than $\alpha^h(x)$. It is often the case that one can choose the probabilities so that $s^h(x) \equiv 0$. We must also assume that the "radius" of ∂D_+^h tends to zero:

$$\sup_{x \in \partial D_+^h} \inf_{y \in D^h} \|x-y\| \to 0 \tag{4.6}$$

as $h \to 0$.

Define the operator A^h by

$$A^h f(x) = \sum_{y \in D^h \cup \partial D_+^h} [f(y)-f(x)] \frac{p^h(x,y)}{\alpha^h(x)}$$

for points $x \in \partial D_+^h$. Then the conditions given above imply for all $f \in C^1(\mathbf{R}^n)$ that

$$\left|Af(x) - A^h f(x)\right| = o(1)$$

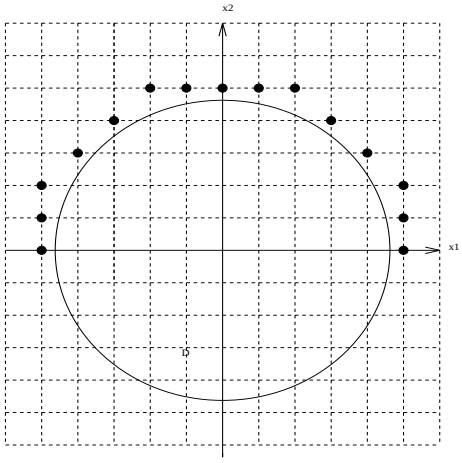

FIG. 4.1. *Boundary portion* ∂D_+^h.

uniformly in $x \in \partial D_+^h$, which is sufficient for convergence. However, in order to specify a rate of convergence, we need to be more precise in describing how fast $s^h(x)$ and $c^h(x)$ tend to zero. We will assume that

$$s^h(x) = O(h^2), \quad c^h(x) = O(h^2) \tag{4.7}$$

uniformly in $x \in \partial D_+^h$. (Note that if we want to identify coefficients, then more is needed; i.e., we need expansions of the form

$$s^h(x) = h^2 \tilde{s}(x) + o(h^2), \quad c^h(x) = h^2 \tilde{c}(x) + o(h^2)$$

for some continuous functions $\tilde{s}(x)$ and $\tilde{c}(x)$.)

Example 4.1. We consider the case $n = 2$, $D = \{x : \|x\| \le 1\}$, and $r(x) = n(x)$. Suppose $h = 1/k$, where k is an integer. In this case we can take the set ∂D_+^h to be as in Figure 4.1. The definition is

$$p^h(x,y) = \begin{cases} \dfrac{x_1^{\mp}}{|x_1| + |x_2|} & \text{if } y = x \pm h(1,0), \\ \dfrac{x_2^{\mp}}{|x_1| + |x_2|} & \text{if } y = x \pm h(0,1), \\ 0 & \text{otherwise.} \end{cases}$$

For this example, we have

$$m^h(x) = hr(x)\|x\|_2/\|x\|_1, \quad \alpha^h(x) = h\|x\|_2/\|x\|_1, \quad s^h(x) = 0,$$

and

$$c^h(x) = h^2 \frac{x_2^2|x_1| + x_1^2|x_2|}{\|x\|_1^3} \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}.$$

The transition probabilities at the points of ∂D_+^h will play the role of the constraining process z in (4.1); i.e., if the process attempts to leave D^h then it is returned

instantly by a "push" in the appropriate direction [19]. Because of the instantaneous nature of the push, the interpolation interval that is correct for the points in ∂D_+^h is $\Delta t^h(x) = 0$.

The discrete replacement for (4.3) is

$$\begin{cases} \gamma^h &= \min_{u\in U}\left[L_u^h V^h(x) + k(x,u)\right] \quad \text{in } D^h, \\ 0 &= l(x) + A^h V^h(x) \quad \text{on } \partial D_+^h, \end{cases} \tag{4.8}$$

where L_u^h is as in section 2.

For an admissible control $\{u_k^h, k = 0, 1, \ldots\}$, let $\{\xi_k^h, k = 0, 1, \ldots\}$ be the corresponding controlled Markov chain; i.e.,

$$\mathbf{P}_x^h\left(\xi_{k+1}^h = z \,|\, \xi_l^h, u_l,\, l = 0, \ldots, k\right) \;=\; p^h(\xi_k^h, z|u_k^h) \quad \text{if } x \in D^h,$$

and

$$\mathbf{P}_x^h\left(\xi_{k+1}^h = z \,|\, \xi_l^h, u_l,\, l = 0, \ldots, k\right) \;=\; p^h(\xi_k^h, z) \quad \text{when } x \in \partial D_+^h.$$

Define $T_N^h = \sum_{i=0}^{N-1} \Delta t^h(\xi_i^h)$. Note that when $\xi_i^h \in \partial D_+^h$ the corresponding summand in T_N^h is zero. Equation (4.8) is the HJB equation for the Markov chain stochastic optimal control problem whose transition probabilities are those given above and for which the cost to be minimized is

$$\gamma^h = \limsup_{N\to\infty} \mathbf{E}_x^h\left[\left(\sum_{i=0}^{N-1} k(\xi_i^h, u_i^h)\Delta t^h(\xi_i^h) + \sum_{i=0}^{N-1} I_{\{\xi_i^h \in \partial D_+^h\}} l(\xi_i^h)\alpha^h(\xi_i^h)\right)/T_N^h\right]$$

(cf. [19, Chapter 7]). One can easily check that the chain is ergodic for any time independent feedback control. Because of this, the limit superior is actually a limit, and the limiting value is independent of x. The equation (4.8) exhibits the same type of nonuniqueness as the original HJB equation (4.2), namely, if $(\gamma_1^h, V_1^h(\cdot))$ and $(\gamma_2^h, V_2^h(\cdot))$ both solve (4.8), then $\gamma_1^h = \gamma_2^h$ and $V_1^h(\cdot) - V_2^h(\cdot)$ is a constant.

Define the boundary error

$$g^h(x) \doteq AV(x) - A^h V(x).$$

Thanks to our assumptions on V and (4.7), we have

$$|g^h(x)| = O(h).$$

We can then rewrite (4.3) in a form analogous to that of (4.8):

$$\begin{cases} \gamma &= \min_{u\in U}\left[L_u^h V(x) + k(x,u) + e^h(x,u)\right] \quad \text{in } D^h, \\ 0 &= l(x) + A^h V(x) + g^h(x) \quad \text{on } \partial D_+^h, \end{cases} \tag{4.9}$$

where e^h is defined as in section 2 by

$$e^h(x,u) \doteq L_u V(x) - L_u^h V(x).$$

(Recall that $|e^h(x,u)| = O(h^\alpha)$.) Thus γ has a representation as the minimal cost for the Markov chain optimal control problem whose transition probabilities are the same

as those for γ^h and for which the cost to be minimized is

$$\gamma = \limsup_{N\to\infty} \mathbf{E}_x^h \left[\left(\sum_{i=0}^{N-1} \left[k(\xi_i^h, u_i^h) + e^h(\xi_i^h, u_i^h) \right] \Delta t^h(\xi_i^h) \right.\right.$$
$$\left.\left. + \sum_{i=0}^{N-1} I_{\{\xi_i^h \in \partial D_+^h\}} \left[l(\xi_i^h) + g^h(\xi_i^h) \right] \alpha^h(\xi_i^h) \right) / T_N^h \right].$$

A comparison of these two representations allows us to prove the following rate of convergence.

THEOREM 4.2. *Assume* (4.7) *and all the smoothness conditions assumed of* b, k, ∂D, *etc., in this section and section* 2. *Given that* $V \in C^{2,\alpha}(\bar{D})$, *we have*

$$\sup_{x\in D^h} |V^h(x) - V(x)| \;=\; O(h^\alpha) \tag{4.10}$$

as $h \downarrow 0$.

Proof. We can use the same proof as that of Theorem 2.1 as soon as we show that

$$\limsup_{N\to\infty} \mathbf{E}_x^h \left[\left(\sum_{i=0}^{N-1} e^h(\xi_i^h, u_i^h) \Delta t^h(\xi_i^h) + \sum_{i=0}^{N-1} I_{\{\xi_i^h \in \partial D_+^h\}} g^h(\xi_i^h) \alpha^h(\xi_i^h) \right) / T_N^h \right] \tag{4.11}$$
$$= O(h^\alpha)$$

uniformly in all admissible controls and $x \in D^h$.

The main difficulty in proving such a bound is in dealing with the second term in the sum. Let $\theta(x)$ (a C^2 function from $\mathbf{R}^n \to \mathbf{R}$) and $\eta > 0$ be such that for all sufficiently small $h > 0$

$$\inf_{x\in\partial D_+^h} \left\langle \frac{\alpha^h(x) r(x) + s^h(x)}{\alpha^h(x)}, \theta_x(x) \right\rangle \geq \eta. \tag{4.12}$$

Then for any $k = 0, 1, 2, \ldots$,

$$\theta(\xi_k^h) - \theta(\xi_0^h) \;= \sum_{i=0}^{k-1} \left[\theta(\xi_{i+1}^h) - \theta(\xi_i^h) \right]$$
$$= \sum_{i=0}^{k-1} \langle \xi_{i+1}^h - \xi_i^h, \theta_x(\xi_i^h) \rangle + \frac{1}{2} \sum_{i=0}^{k-1} \left(\xi_{i+1}^h - \xi_i^h \right)' \theta_{xx}(\tilde{\xi}_i^h) \left(\xi_{i+1}^h - \xi_i^h \right),$$

where $\tilde{\xi}_i^h$ is an appropriately selected point between ξ_i^h and ξ_{i+1}^h. We rewrite this last equation as

$$\sum_{i=0}^{k-1} I_{\{\xi_i^h \in \partial D_+^h\}} \langle \xi_{i+1}^h - \xi_i^h, \theta_x(\xi_i^h) \rangle + \frac{1}{2} \sum_{i=0}^{k-1} I_{\{\xi_i^h \in \partial D_+^h\}} \left(\xi_{i+1}^h - \xi_i^h \right)' \theta_{xx}(\tilde{\xi}_i^h) \left(\xi_{i+1}^h - \xi_i^h \right)$$
$$= \; \theta(\xi_k^h) - \theta(\xi_0^h)$$
$$- \sum_{i=0}^{k-1} I_{\{\xi_i^h \in D^h\}} \langle \xi_{i+1}^h - \xi_i^h, \theta_x(\xi_i^h) \rangle - \frac{1}{2} \sum_{i=0}^{k-1} I_{\{\xi_i^h \in D^h\}} \left(\xi_{i+1}^h - \xi_i^h \right)' \theta_{xx}(\tilde{\xi}_i^h) \left(\xi_{i+1}^h - \xi_i^h \right).$$

By using (4.12), the fact that $c^h(x) = o(\alpha^h(x))$ uniformly in x, and equations (2.11) and (2.12), we obtain

$$\frac{\eta}{2}\mathbf{E}_x^h \sum_{i=0}^{k-1} I_{\{\xi_i^h \in \partial D_+^h\}} \alpha^h(\xi_i^h) \le 2\|\theta\|_\infty + K\mathbf{E}_x^h T_k^h,$$

for all sufficiently small $h > 0$, where $K < \infty$ is independent of both h and k.

For $T \in [0, \infty)$, define the stopping time $M_T = \min\{k : T_k^h \ge T\}$. Note that $T_{M_T}^h / T \to 1$ uniformly. It follows from the last display and the fact that M_T is a stopping time that

$$\frac{\eta}{2}\mathbf{E}_x^h \sum_{i=0}^{M_T-1} I_{\{\xi_i^h \in \partial D_+^h\}} \alpha^h(\xi_i^h) \le 2\|\theta\|_\infty + K\mathbf{E}_x^h T_{M_T}^h. \tag{4.13}$$

We can now bound (4.11). According to equation (2.5) in section 2 $|e^h(\xi_i^h, u_i^h)| = O(h^\alpha)$. Thus

$$\limsup_{N\to\infty} \mathbf{E}_x^h \left[\left(\sum_{i=0}^{N-1} e^h(\xi_i^h, u_i^h) \Delta t^h(\xi_i^h) \right) / T_N^h \right] = O(h^\alpha).$$

On the other hand, we recall that $\left|g^h(x)\right| = \left|AV(x) - A^h V(x)\right| = O(h)$. By combining this with (4.13), we obtain

$$\limsup_{N\to\infty} \mathbf{E}_x^h \left[\left(\sum_{i=0}^{N-1} I_{\{\xi_i^h \in \partial D_+^h\}} g^h(\xi_i^h) \alpha^h(\xi_i^h) \right) / T_N^h \right]$$

$$= \limsup_{T\to\infty} \mathbf{E}_x^h \left[\left(\sum_{i=0}^{M_T-1} I_{\{\xi_i^h \in \partial D_+^h\}} g^h(\xi_i^h) \alpha^h(\xi_i^h) \right) / T_{M_T}^h \right] = O(h),$$

which proves (4.11). □

An examination of the proof just given shows that the errors in the approximations to the boundary condition are of smaller order than the approximations on the interior.

As in other sections, with added regularity one can identify the coefficient of the rate of convergence. In this problem one finds two terms in the rate. One term is a functional of the x_s process and represents errors due to approximation on D, while the other is a functional of the boundary local time process z_s and represents errors due to the approximation of the boundary condition.

5. Comments and extensions. In this final section we make some general comments and discuss some extensions of our methodology.

5.1. General method. The general method we have employed can be summarized with the following heuristics.

Consider the problem of approximating the solution V to the equation

$$A(V) + k = 0 \tag{5.1}$$

by an approximation V^h given by

$$A^h(V^h) + k = 0. \tag{5.2}$$

The key to our method lies in the use of appropriate representations to solutions of equations of the type (5.2). Let us suppose that

$$V^h = \mathcal{R}^h(k), \tag{5.3}$$

for some representation operator $\mathcal{R}^h$. The operators A, A^h, and $\mathcal{R}^h$ are in general nonlinear. We have assumed that they are obtainable from linear operators via min, max, min-max, or max-min operations. Let us write

$$e^h = A(V) - A^h(V).$$

Then equation (5.1) can be rewritten as

$$A^h(V) + [e^h + k] = 0,$$

and consequently V has a representation determined by the method of approximation:

$$V = \mathcal{R}^h(e^h + k). \tag{5.4}$$

To compare V with V^h, we formally use the fact that $\mathcal{R}^h$ is obtained from a linear operator by one or more minimization or maximization operations. This allows us to write

$$V = \mathcal{R}^h(e^h + k) = \mathcal{R}^h(k) + O(|e^h|). \tag{5.5}$$

Thus if $|e^h| = O(h^\alpha)$, depending on the smoothness of V, this yields the rate of convergence estimate

$$V^h - V = O(h^\alpha). \tag{5.6}$$

More detailed information is available with stronger assumptions. Suppose that $e^h = h^\alpha \phi + O(h^{\alpha+\delta})$, for some $\delta > 0$, and (5.5) is improved:

$$V = \mathcal{R}^h(e^h + k) = \mathcal{R}^h(k) + \mathcal{R}_1^h(e^h). \tag{5.7}$$

Then we have the explicit limit

$$\lim_{h \to 0} \frac{V^h - V}{h^\alpha} = \mathcal{R}_1(\phi). \tag{5.8}$$

5.2. Partial differential equations. Our approach is applicable to PDEs which need not have any a priori connection to control theory. The simplest instance is that of linear equations. For example, consider a linear uniformly elliptic PDE with smooth coefficients, boundary, and boundary data. Such a boundary value problem has a smooth solution, of sufficient regularity to apply our theory and obtain rate of convergence estimates for a variety of approximation methods. The representation for linear equations and their approximations is quite simple, in that no minimizations or maximizations are required (cf. Feynman–Kac formulas).

A second instance of interest is the case of quasi-linear or even fully nonlinear uniformly elliptic/parabolic PDE. Smooth classical solutions are often available; see [16]. To apply our approach, a representation is needed, and indeed this can be obtained in a great many cases using control or game theory.

To illustrate, let us consider an example similar to the problem of section 2. We wish only to communicate the general idea, and omit technical details. Suppose that the fully nonlinear equation

$$\begin{cases} \lambda V(x) \;=\; F(V_{xx}(x)) + k(x) \;\text{ in } D, \\ \;\; V(x) \;=\; 0 \;\text{ on } \partial D, \end{cases} \tag{5.9}$$

has a unique classical solution $V \in C^{2,\alpha}(\bar{D})$, where F is a smooth nonlinear function with bounded gradient satisfying

(i) $\xi' F_{XX}(X)\xi \geq c|\xi|^2$, $c > 0$, and

(ii) $\lim_{|X|\to\infty} |F(X)|/|X| = 0$.

We have not assumed that F is convex, nor any other specific form. Following [9] (see also [10]), F admits a max-min representation:

$$F(X) = \max_{v\in\mathbf{R}^{n^2}} \min_{u\in\mathbf{R}^{n^2}} \left[\sum_{i,j=1}^{n} \left(\int_0^1 \frac{\partial F}{\partial X_{ij}}((1-r)v + ru)\, dr \right) (X_{ij} - v_{ij}) + F(v) \right]. \tag{5.10}$$

In view of this, let us write

$$F(X) + k = \max_{v\in\mathbf{R}^{n^2}} \min_{u\in\mathbf{R}^{n^2}} \left[\sum_{i,j=1}^{n} a_{ij}(u,v) X_{ij} + \hat{k}(x,u,v) \right],$$

where the matrix $a_{ij}(u,v)$ is defined from (5.10) and $\hat{k}(x,u,v) = k(x) - \sum_{i,j=1}^{n} a_{ij}(u,v)v_{ij} + F(v)$. Suppose that we can write $a(u,v) = \frac{1}{2}\sigma(u,v)\sigma(u,v)'$ for some Lipschitz matrix function σ.

The desired game theoretic representation for V is

$$V(x) \;=\; \inf_{u_\cdot} \sup_{v_\cdot} \mathbf{E}_x \left[\int_0^\tau e^{-\lambda t} \hat{k}(x_t, u_t, v_t)\, dt \right], \tag{5.11}$$

where

$$dx_t = \; \sigma(u_t, v_t)\, dw_t.$$

For precise information concerning games and their strategies, see [15].

A finite difference approximation V^h can be constructed, along the same lines as in section 2, which will have a game representation. Note that the various quantities will depend on the additional control variable v. Then a straightforward modification of the proof of Theorem 2.1 yields the rate of convergence estimate

$$\sup_{x\in D^h} |V^h(x) - V(x)| \;=\; O(h^\alpha)$$

as $h \downarrow 0$.

A NEW VALUE ITERATION METHOD FOR THE AVERAGE COST DYNAMIC PROGRAMMING PROBLEM*

DIMITRI P. BERTSEKAS†

Abstract. We propose a new value iteration method for the classical average cost Markovian decision problem, under the assumption that all stationary policies are unichain and that, furthermore, there exists a state that is recurrent under all stationary policies. This method is motivated by a relation between the average cost problem and an associated stochastic shortest path problem. Contrary to the standard relative value iteration, our method involves a weighted sup-norm contraction, and for this reason it admits a Gauss–Seidel implementation. Computational tests indicate that the Gauss–Seidel version of the new method substantially outperforms the standard method for difficult problems.

Key words. dynamic programming, average cost, value iteration

1. Introduction.

We consider a controlled discrete-time dynamic system with n states, denoted $1,\dots,n$. At each time, if the state is i, a control u is chosen from a given finite constraint set $U(i)$, and the next state is j with given probability $p_{ij}(u)$. An admissible policy is a sequence of functions from states to controls, $\pi = \{\mu_0, \mu_1, \dots\}$, where $\mu_k(i) \in U(i)$ for all i and k. The average cost corresponding to π and initial state i is

$$J_\pi(i) = \limsup_{N\to\infty} \frac{1}{N} E\left\{ \sum_{k=0}^{N-1} g\big(x_k, \mu_k(x_k)\big) \,\middle|\, x_0 = i \right\},$$

where x_k is the state at time k and g is a given cost function. A *stationary policy* is an admissible policy of the form $\pi = \{\mu, \mu, \dots\}$, and its corresponding cost function is denoted by $J_\mu(i)$. For brevity, we refer to $\{\mu, \mu, \dots\}$ as the stationary policy μ. We want to solve the classical problem of finding an optimal policy, that is, an admissible policy π such that $J_{\pi^*}(i) = \min_\pi J_\pi(i)$ for all i.

A stationary policy is called *unichain* if it gives rise to a Markov chain with a single recurrent class. Throughout the paper, we assume the following.

Assumption 1: All stationary policies are unichain. Furthermore, state n is recurrent in the Markov chain corresponding to each stationary policy.

It is well known that under Assumption 1, the optimal cost $J^*(i)$ has a common value for all initial states, which is denoted by λ^*,

$$J^*(i) = \lambda^*, \qquad i = 1, \dots, n.$$

Furthermore, λ^* together with a differential cost vector $h = \big(h(1), \dots, h(n)\big)$ satisfies Bellman's equation

$$\lambda^* + h(i) = \min_{u\in U(i)} \left[g(i,u) + \sum_{j=1}^{n} p_{ij}(u) h(j) \right], \qquad i = 1, \dots, n. \tag{1}$$

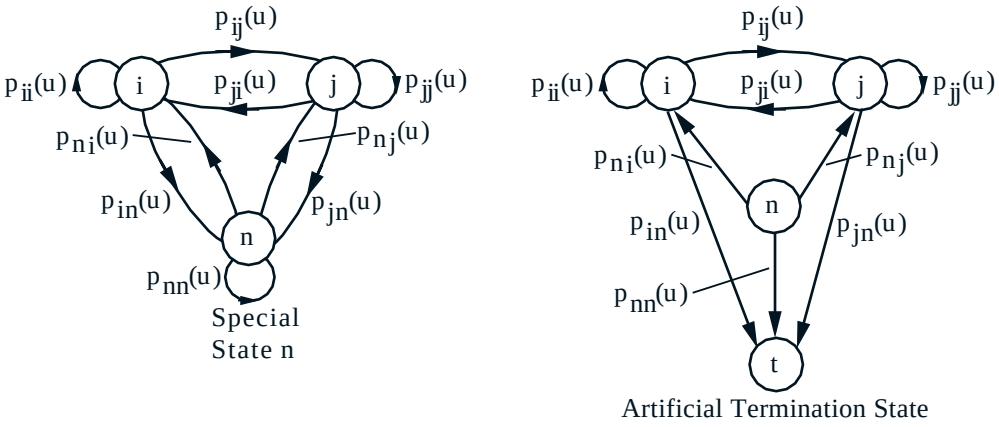

FIG. 1. *Transition probabilities for an average cost problem and its associated stochastic shortest path problem. The latter problem is obtained by introducing, in addition to* $1, \ldots, n$, *an artificial termination state* t *to which we move from each state* i *with probability* $p_{in}(u)$, *by setting all transition probabilities* $p_{in}(u)$ *to* 0, *and by leaving unchanged all other transition probabilities.*

In addition, a stationary policy μ is optimal if and only if $\mu(i)$ attains the minimum in the above equation for all i. These results can be shown under the assumption that all stationary policies are unichain, without requiring the additional condition that there is a common recurrent state to all stationary policies. However, for the methods of this paper, the existence of a common recurrent state is essential, at least for the purposes of analysis. From the computational point of view, the existence of a common recurrent state is less significant, as long as all stationary policies are unichain. One may modify the problem so that Assumption 1 holds by adding a very small positive ϵ to all transition probabilities of the form $p_{in}(u)$. The effect on the average cost per stage of each stationary policy will be $O(\epsilon)$.

Under Assumption 1 we can make an important connection of the average cost problem with an associated stochastic shortest path problem, which has been the basis for a recent textbook treatment of the average cost problem [Ber95, Vol. I, section 7.4]. This problem is obtained by leaving unchanged all transition probabilities $p_{ij}(u)$ for $j \neq n$, by setting all transition probabilities $p_{in}(u)$ to 0, and by introducing an artificial cost-free and absorbing termination state t to which we move from each state i with probability $p_{in}(u)$; see Fig. 1. The expected stage cost at state i of the stochastic shortest path problem is $g(i,u) - \lambda$, where λ is a scalar parameter. Let $h_{\mu,\lambda}(i)$ be the cost of stationary policy μ for this stochastic shortest path problem, starting from state i; that is, $h_{\mu,\lambda}(i)$ is the total expected cost incurred starting from state i up to reaching the termination state t. We refer to this problem as λ-SSP. Let $h_\lambda(i) = \min_\mu h_{\mu,\lambda}(i)$ be the corresponding optimal cost of the λ-SSP. Then the following can be shown (see Fig. 2).

(a) For all μ and λ, we have

$$h_{\mu,\lambda}(i) = h_{\mu,\lambda_\mu}(i) + (\lambda_\mu - \lambda)N_\mu(i), \qquad i = 1, \ldots, n, \tag{2}$$

where $N_\mu(i)$ is the average number of steps required to reach n under μ starting from state i, and λ_μ is the average cost corresponding to μ.

(b) The functions

$$h_\lambda(i) = \min_\mu h_{\mu,\lambda}(i), \qquad i = 1, \ldots, n, \tag{3}$$

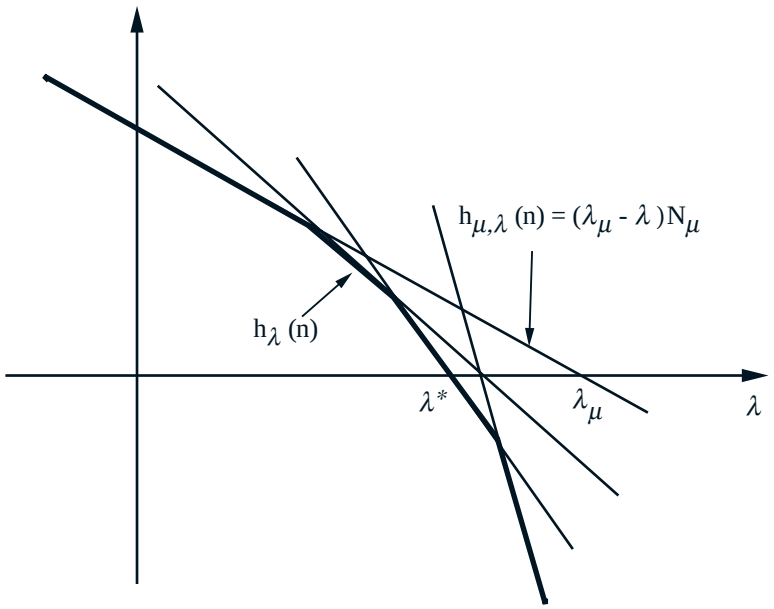

FIG. 2. *Relation of the costs of stationary policies in the average cost problem and the associated stochastic shortest path problem.*

are concave, monotonically decreasing, and piecewise linear as functions of λ, and

$$h_\lambda(n) = 0 \qquad \text{if and only if} \qquad \lambda = \lambda^*. \tag{4}$$

Furthermore, the vector h_{λ^*} satisfies Bellman's equation (1) together with λ^*.

From Fig. 2, it can be seen that λ^* can be obtained by a one-dimensional search procedure that brackets λ^* within a sequence of nested and diminishing intervals; see [Ber95, Vol. II, Fig. 4.5.2]. This method is probably inefficient because it requires the (exact) solution of several λ-SSPs, corresponding to several different values of λ. An alternative method, which is also inefficient because it requires the exact solution of several λ-SSPs, is to update λ by an iteration of the form

$$\lambda^{k+1} = \lambda^k + \gamma^k h_{\lambda^k}(n), \tag{5}$$

where γ^k is a positive stepsize parameter. This iteration is motivated by Fig. 2, where it is seen that $\lambda < \lambda^*$ (or $\lambda > \lambda^*$) if and only if $h_\lambda(n) > 0$ (or $h_\lambda(n) < 0$, respectively). Indeed, it can be seen from Fig. 2 that the sequence $\{\lambda^k\}$ generated by (5) converges to λ^* provided the stepsize γ^k is the same for all iterations and does not exceed the threshold value $1/\max_\mu N_\mu(n)$. Such a stepsize is sufficiently small to guarantee that the difference $\lambda - \lambda^*$ does not change sign during the algorithm (5). Note that each λ-SSP can be solved by value iteration, which has the form

$$h^{k+1}(i) = \min_{u \in U(i)} \left[g(i,u) + \sum_{j=1}^{n-1} p_{ij}(u) h^k(j) \right] - \lambda, \qquad i = 1, \ldots, n, \tag{6}$$

with λ kept fixed throughout the value iteration method.

In this paper we propose algorithms based on the λ-SSP, which are more efficient than the algorithms mentioned above. In particular, we change λ during the value iteration process (6) by using an iteration of the form (5), but with $h_{\lambda^k}(n)$ replaced by an approximation, the current value iterate $h^{k+1}(n)$. Such an algorithm may be viewed as a *value iteration algorithm for a slowly varying stochastic shortest path problem*. It has the form

$$h^{k+1}(i) = \min_{u \in U(i)} \left[g(i,u) + \sum_{j=1}^{n-1} p_{ij}(u) h^k(j) \right] - \lambda^k, \qquad i = 1, \ldots, n, \tag{7}$$

$$\lambda^{k+1} = \lambda^k + \gamma^k h^{k+1}(n), \tag{8}$$

where γ^k is a positive stepsize. We prove convergence of this method for the case where γ^k is a sufficiently small constant. Convergence can also be similarly proved for a variety of other stepsize rules.

Our method should be contrasted with the standard relative value iteration method for average cost problems due to [Whi63], which takes the form (see, e.g., [Ber95], [Put94])

$$\lambda^{k+1} = \min_{u \in U(n)} \left[g(n,u) + \sum_{j=1}^{n} p_{nj}(u) h^k(j) \right], \tag{9}$$

$$h^{k+1}(i) = \min_{u \in U(i)} \left[g(i,u) + \sum_{j=1}^{n} p_{ij}(u) h^k(j) \right] - \lambda^{k+1}, \qquad i = 1, \ldots, n. \tag{10}$$

If we use (7) to write iteration (8) in the equivalent form

$$\lambda^{k+1} = (1 - \gamma^k)\lambda^k + \gamma^k \min_{u \in U(n)} \left[g(n,u) + \sum_{j=1}^{n-1} p_{nj}(u) h^k(j) \right],$$

we see that if $\gamma^k = 1$ for all k, the new value iteration (7)–(8) becomes similar to the standard value iteration (9)–(10): the updating formulas are the same in both methods (because we have $h^k(n) = 0$ for all $k \geq 1$ in the iteration (9)–(10)), but the order of updating λ is just reversed relative to the order of updating h. Despite the similarity of the two methods, the proof of convergence of the standard method (9)–(10) (as given, for example, in [Ber95, Vol. II] or [Put94]) does not seem to be applicable to the new method. The line of proof given in the next section is substantially different, and makes essential use of Assumption 1 and the connection with the stochastic shortest path problem. Furthermore, one can construct examples where Assumption 1 is violated because state n is transient under some stationary policy, and where the new method (7)–(8) does not converge while the known method (9)–(10) converges. Conversely, it can be seen that the standard aperiodicity assumption required for convergence of the standard method (9)–(10) (see, e.g., [Ber95], [Put94]) is not needed for the new method. We note also that there is a variant of the standard method (9)–(10) that does not require an aperiodicity assumption and involves interpolations

between h^k and h^{k+1} according to a stepsize parameter (see [Sch71, [Pla77], [Var78], [PBW79], [Put94], [Ber95]). However, the new method does not seem as closely related to this variant.

A significant improvement in the algorithm, which guarantees that bounded iterates will be generated for any choice of stepsize, is to calculate upper and lower bounds on λ^* from iteration (7) and then modify iteration (8) to project the iterate $\lambda^k + \gamma^k h^k(n)$ on the interval of the bounds. In particular, based on the Odoni bounds [Odo69] for the relative value iteration method (see, e.g., [Ber95, Vol. II, p. 209], it can be seen that

$$\underline{\beta}^k \leq \lambda^* \leq \overline{\beta}^k,$$

where

$$\underline{\beta}^k = \lambda^k + \min\left[\min_{i \neq n}\big[h^{k+1}(i) - h^k(i)\big],\, h^{k+1}(n)\right], \tag{11}$$

$$\overline{\beta}^k = \lambda^k + \max\left[\max_{i \neq n}\big[h^{k+1}(i) - h^k(i)\big],\, h^{k+1}(n)\right]. \tag{12}$$

Thus we may replace the iteration $\lambda^{k+1} = \lambda^k + \gamma^k h^{k+1}(n)$ (cf. (8)) by

$$\lambda^{k+1} = \Pi_k\big[\lambda^k + \gamma^k h^{k+1}(n)\big], \tag{13}$$

where $\Pi_k[c]$ denotes the projection of a scalar c on the interval

$$\left[\max_{m=0,\ldots,k} \underline{\beta}^m,\ \min_{m=0,\ldots,k} \overline{\beta}^m\right]. \tag{14}$$

We note that the issue of stepsize selection is crucial for the success of our algorithm. In particular, if γ^k is a chosen constant but very small, or diminishing at the rate of $1/k$ (as is common in stochastic approximation algorithms), then λ changes slowly relative to h, and the iteration (8) essentially becomes identical to iteration (5) but with a very small stepsize, which leads to slow convergence. On the other hand, if γ^k is too large, λ^k will oscillate and diverge. One may keep the stepsize γ^k constant at a value found by trial and error, but there are some better alternatives. One possibility that has worked quite reliably and efficiently in our tests is to start with a fairly large γ^k and gradually diminish it if $h^k(n)$ changes sign frequently; for example, we may use

$$\gamma^k = m(\hat{k})\gamma, \tag{15}$$

where

(a) γ is the initial stepsize (a positive constant),

(b) $m(\hat{k})$ is a decreasing function of $\hat{k}$, which is defined as the number of indexes $t \leq k$ such that $h^{t-1}(n)h^t(n) < 0$ and $|h^t(n)|$ is greater than some fixed threshold θ.

Examples of functions $m(\cdot)$ that we tried are

$$m(\hat{k}) = \frac{1}{\hat{k}+1} \tag{16a}$$

and

$$m(\hat{k}) = \xi^{\hat{k}}, \tag{16b}$$

where ξ is a fixed scalar from the range $(0,1)$, so that γ^k is decreased by a factor ξ each time $\hat{k}$ is incremented. Our experience indicates that it is best to choose the initial stepsize γ in the range $[1,5]$. Typically, the stepsize is reduced quickly according to (15) to an appropriate level (which depends on the problem) and then stays constant for the remaining iterations. In our experiments, we have used the preceding choices of γ^k with $\gamma = 1$, $\xi = 0.95$, and $\theta = 1$.

The motivation for our method is that value iteration for stochastic shortest path problems involves a contraction. In particular, consider the mapping $F : \Re^n \to \Re^n$ with components given by

$$F_i(h) = \min_{u \in U(i)} \left[g(i,u) + \sum_{j=1}^{n-1} p_{ij}(u) h(j) \right], \qquad i = 1, \ldots, n.$$

It is known (see, e.g., [BeT89, p. 325] or [Tse90]) that, under Assumption 1, F is a contraction mapping with respect to some weighted sup-norm; that is, for some positive scalars $v_1, \ldots, v_n$, and some scalar $\alpha \in (0,1)$, we have

$$\max_{i=1,\ldots,n} \frac{|F_i(h) - F_i(\overline{h})|}{v_i} \leq \alpha \max_{i=1,\ldots,n} \frac{|h(i) - \overline{h}(i)|}{v_i} \qquad \forall\ h,\ \overline{h} \in \Re^n. \tag{17}$$

Note here that while there is coupling between the iteration of h as per (7) and the iteration for λ as per (8), the latter iteration can be made much slower than the former through the use of the stepsize γ, so that the weighted sup-norm contraction character of the iteration (7) is preserved. Furthermore, even when the stepsize γ is not small, the contraction property of F is analytically convenient, as will be seen, for example, in the analysis of section 3. By contrast, the standard relative value iteration method (9)–(10) does not involve a weighted sup-norm contraction, and in fact it may not involve a contraction of any kind, unless an additional aperiodicity assumption on the Markov chains corresponding to the stationary policies is imposed. We speculate that the sup-norm contraction structure may be helpful in other contexts, beyond those discussed in this paper; for example, in Q-learning (stochastic approximation) variants of the method and when parallel asynchronous variations are considered. In fact, an analysis of Q-learning variants of our method that admit a parallel asynchronous implementation is the subject of a forthcoming report [ABB97].

The new method (7)–(8) can be viewed as a Jacobi type of method, since all the components of h are simultaneously updated. A particularly interesting fact is that the weighted sup-norm contraction property of the mapping F can also be exploited to construct valid Gauss–Seidel variants, where the components of h are updated sequentially in some order. In particular, the method of proof of the next section can be used to show convergence for the Gauss–Seidel version of the method, given by

$$h^{k+1}(i) = G_i(h^k, \lambda^k), \qquad i = 1, \ldots, n,$$

$$\lambda^{k+1} = \lambda^k + \gamma^k h^{k+1}(n),$$

where $G : \Re^{n+1} \to \Re^n$ is the Gauss–Seidel mapping based on F, having components given by

$$G_1(h, \lambda) = \min_{u \in U(1)} \left[g(1,u) + \sum_{j=1}^{n-1} p_{1j}(u) h(j) \right] - \lambda,$$

$$G_i(h,\lambda) = \min_{u\in U(i)} \left[g(i,u) + \sum_{j=1}^{i-1} p_{ij}(u) G_j(h,\lambda) + \sum_{j=i}^{n-1} p_{ij}(u) h(j) \right] - \lambda, \qquad i = 2,\ldots,n.$$

By contrast, we do not know of any convergent Gauss–Seidel version of the standard value iteration (9)–(10). In fact, simple counterexamples show that the straightforward Gauss–Seidel variant of the standard method may diverge.

Note that the Odoni bounds (11)–(12) are not available when the Gauss–Seidel variant is used. However, it is still possible to use the projection (13)–(14) by performing once in a while (say, every 10 iterations) the regular (Jacobi) version (7)–(8) of the method, and obtain corresponding Odoni bounds that can be used for projection at all subsequent iterations. This device proved to be very effective in our experiments.

Regarding a theoretical comparison of the performance of the new methods and the standard method, it can be seen with simple examples that neither type of method dominates the other. Suppose, for instance, that there is only one policy and that the corresponding transition probability matrix is

$$\begin{pmatrix} \epsilon & 1-\epsilon \\ 1-\epsilon & \epsilon \end{pmatrix},$$

where ϵ is a scalar from $[0,1]$. Then both methods (7)–(8) and (9)–(10) become linear iterations, and their rate of convergence is governed by the eigenvalues of the corresponding iteration matrix. The eigenvalues corresponding to the standard relative value iteration (9)–(10) can be shown to be 0 and $1-2\epsilon$, so that the method converges very fast for $\epsilon \sim 1/2$ and slowly for $\epsilon \sim 0$ or $\epsilon \sim 1$. It can also be verified that, for a constant but well-chosen value of γ, the eigenvalue structure of the new value iteration method (7)–(8) is worse than the one for the standard method for $\epsilon \sim 1/2$, more favorable for $\epsilon \sim 0$, and comparably unfavorable for $\epsilon \sim 1$.

Our limited computational experiments also indicate that the Jacobi version (7)–(8) of the new method, when properly implemented with the adaptive stepsize rule (15) and the projection scheme of (11)–(14), is competitive with the relative value iteration method of (9)–(10). There are problems where one method outperforms the other and vice versa. When the initial stepsize γ in (15) is equal to 1, the performance of the two methods appears to be quite similar for many problems (see, e.g., Tables 2 and 3 in section 4). On the other hand, our computational results indicate that the Gauss–Seidel variant of the new method substantially outperforms the standard method for relatively difficult problems. This is not surprising, since Gauss–Seidel methods are known to have better performance than their Jacobi counterparts when a weighted sup-norm contraction is involved. Both the standard method and the new methods can be very slow on unfavorably structured problems. This is to be expected, since these methods exhibit convergence rate behavior similar to linear iterations and are subject to ill-conditioning.

The paper is organized as follows. In the next section we prove a convergence result for the Jacobi version of the new method. In section 3 we extend this result to apply to the Gauss–Seidel variant. The method of proof can also be used to prove convergence of a variety of other variants involving different orders of updating the components of the vector h, as well as asynchronous versions. All this flexibility is possible thanks to the weighted sup-norm contraction property of the mapping F. Finally, in section 4 we describe some of our computational experience. In particular, we compare the standard method (9)–(10) with implementations of the Jacobi and Gauss–Seidel versions of our method, which involve an adaptive stepsize rule like the

one of (15) and the projection scheme of (11)–(14). We find that the Gauss–Seidel method outperforms the other methods on the more difficult problems.

2. Convergence analysis. We now investigate the convergence of the new value iteration algorithm. For convenience, let us denote by $\|\cdot\|$ the weighted sup-norm with respect to which the contraction property of (17) holds; that is,

$$\|h\| = \max_{i=1,\ldots,n} \frac{|h(i)|}{v_i} \qquad \forall\ h \in \Re^n.$$

Let us also normalize the vector v so that its last coordinate is equal to 1; that is,

$$v_n = 1.$$

Note that since h_λ is the optimal cost vector of the λ-SSP, we have that h_λ is the unique fixed point of the contraction mapping $F(h) - \lambda e$; that is,

$$h_\lambda = F(h_\lambda) - \lambda e \qquad \forall\ \lambda \in \Re. \tag{18}$$

By writing for all stationary policies μ, states i, and scalars λ and λ',

$$h_{\mu,\,\lambda}(i) = h_{\mu,\,\lambda'}(i) + N_\mu(i)(\lambda' - \lambda),$$

and by using the definition $h_\lambda(i) = \min_\mu h_{\mu,\lambda}(i)$, we obtain the following relation:

$$h_{\lambda'}(i)+\underline{N}(\lambda'-\lambda) \le h_\lambda(i) \le h_{\lambda'}(i)+\overline{N}(\lambda'-\lambda) \qquad \forall\, i = 1,\ldots,n, \text{ and } \lambda,\, \lambda' \in \Re, \tag{19}$$

where $\underline{N}$ and $\overline{N}$ are the positive scalars

$$\underline{N} = \min_\mu \min_{i=1,\ldots,n} N_\mu(i), \qquad \overline{N} = \max_\mu \max_{i=1,\ldots,n} N_\mu(i).$$

We can write (19) in the equivalent form

$$N|\lambda' - \lambda| \le |h_\lambda(i) - h_{\lambda'}(i)| \le \overline{N}|\lambda' - \lambda|, \qquad \forall\ i \text{ and } \lambda, \lambda' \in \mathcal{R}. \tag{20}$$

We can interpret $\underline{N}$ and $\overline{N}$ as uniform lower and upper bounds on the slope of the piecewise linear function $h_\lambda(i)$, viewed as a function of λ (see Fig. 2).

The following is our main result.

PROPOSITION 1. *There exists a positive scalar $\overline{\gamma}$ such that if*

$$\underline{\gamma} \le \gamma^k \le \overline{\gamma} \tag{21}$$

for some positive scalar $\underline{\gamma}$ and all k, the sequence (h^k, λ^k) generated by iteration (7), (8) converges to $(h_{\lambda^*}, \lambda^*)$ at the rate of a geometric progression.

Proof. We will show that there exists a threshold value $\overline{\gamma} > 0$ and a continuous function $c(\gamma)$ with $0 \le c(\gamma) < 1$ for all $\gamma \in (0, \overline{\gamma}]$ such that for any $B > 0$, the relations

$$\|h^k - h_{\lambda^k}\| \le B \quad \text{and} \quad |\lambda^k - \lambda^*| \le \frac{B}{\underline{N}} \tag{22}$$

imply that

$$\|h^{k+1} - h_{\lambda^{k+1}}\| \le c(\gamma^k)B \quad \text{and} \quad |\lambda^{k+1} - \lambda^*| \le \frac{c(\gamma^k)B}{\underline{N}}. \tag{23}$$

This implies that for a stepsize sequence satisfying the assumptions of the proposition, the sequence $|\lambda^k - \lambda^*|$ converges to zero at the rate of a geometric progression, and the same is true of the sequence $\|h^k - h_{\lambda^k}\|$. Since, using (20), we have

$$\|h^k - h_{\lambda^*}\| \le \|h^k - h_{\lambda^k}\| + \|h_{\lambda^k} - h_{\lambda^*}\| \le \|h^k - h_{\lambda^k}\| + O\big(|\lambda^k - \lambda^*|\big),$$

we see that $\|h^k - h_{\lambda^*}\|$ also converges to zero at the rate of a geometric progression.

We first show two preliminary relations. We have, using (18),

$$\begin{aligned}\|h_{\lambda^{k+1}} - h_{\lambda^k}\| &= \|F\big(h_{\lambda^{k+1}}\big) - \lambda^{k+1}e - F\big(h_{\lambda^k}\big) + \lambda^k e\| \\ &\le \|F\big(h_{\lambda^{k+1}}\big) - F\big(h_{\lambda^k}\big)\| + \|(\lambda^{k+1} - \lambda^k)e\| \\ &\le \alpha\|h_{\lambda^{k+1}} - h_{\lambda^k}\| + |\lambda^{k+1} - \lambda^k|\|e\|.\end{aligned}$$

Thus

$$\|h_{\lambda^{k+1}} - h_{\lambda^k}\| \le \frac{\|e\|}{1-\alpha}|\lambda^{k+1} - \lambda^k|. \tag{24}$$

Also, by subtracting the relations

$$h^{k+1}(n) = F_n(h^k) - \lambda^k,$$

$$h_{\lambda^k}(n) = F_n(h_{\lambda^k}) - \lambda^k,$$

we have

$$|h^{k+1}(n) - h_{\lambda^k}(n)| = |F_n(h^k) - F_n(h_{\lambda^k})| \le \alpha\|h^k - h_{\lambda^k}\|. \tag{25}$$

Using this relation and (19), we obtain

$$|h^{k+1}(n)| \le |h^{k+1}(n) - h_{\lambda^k}(n)| + |h_{\lambda^k}(n)| \le \alpha\|h^k - h_{\lambda^k}\| + \overline{N}|\lambda^k - \lambda^*|. \tag{26}$$

We will now derive functions $c_1(\cdot)$ and $c_2(\cdot)$ for which the first and the second relations in (22), respectively, hold. We will then use $c(\gamma) = \max\big[c_1(\gamma), c_2(\gamma)\big]$ in (22). Regarding the first relation in (23), we note that

$$\begin{aligned}\|h^{k+1} - h_{\lambda^{k+1}}\| &= \|F(h^k) - \lambda^k e - F\big(h_{\lambda^{k+1}}\big) + \lambda^{k+1}e\| \\ &\le \|F(h^k) - F\big(h_{\lambda^{k+1}}\big)\| + |\lambda^{k+1} - \lambda^k|\,\|e\| \\ &\le \alpha\|h^k - h_{\lambda^{k+1}}\| + |\lambda^{k+1} - \lambda^k|\,\|e\| \\ &\le \alpha\|h^k - h_{\lambda^k}\| + \alpha\|h_{\lambda^k} - h_{\lambda^{k+1}}\| + |\lambda^{k+1} - \lambda^k|\,\|e\|.\end{aligned} \tag{27}$$

Using the above inequality and (22), (24), and (26), we obtain

$$\begin{aligned}\|h^{k+1} - h_{\lambda^{k+1}}\| &\le \alpha B + \left(\frac{\alpha}{1-\alpha} + 1\right)|\lambda^{k+1} - \lambda^k|\,\|e\| \\ &= \alpha B + \frac{\|e\|\gamma^k}{1-\alpha}|h^{k+1}(n)| \\ &\le \alpha B + \frac{\|e\|\gamma^k}{1-\alpha}\big(\alpha\|h^k - h_{\lambda^k}\| + \overline{N}|\lambda^k - \lambda^*|\big) \\ &\le \alpha B + \frac{\|e\|\gamma^k}{1-\alpha}\left(\alpha B + \frac{\overline{N}B}{\underline{N}}\right) \\ &= c_1(\gamma^k)B,\end{aligned} \tag{28}$$

where $c_1(\cdot)$ is the function

$$c_1(\gamma) = \alpha + \frac{\gamma\|e\|(\alpha + \overline{N}/\underline{N})}{1-\alpha}. \tag{29}$$

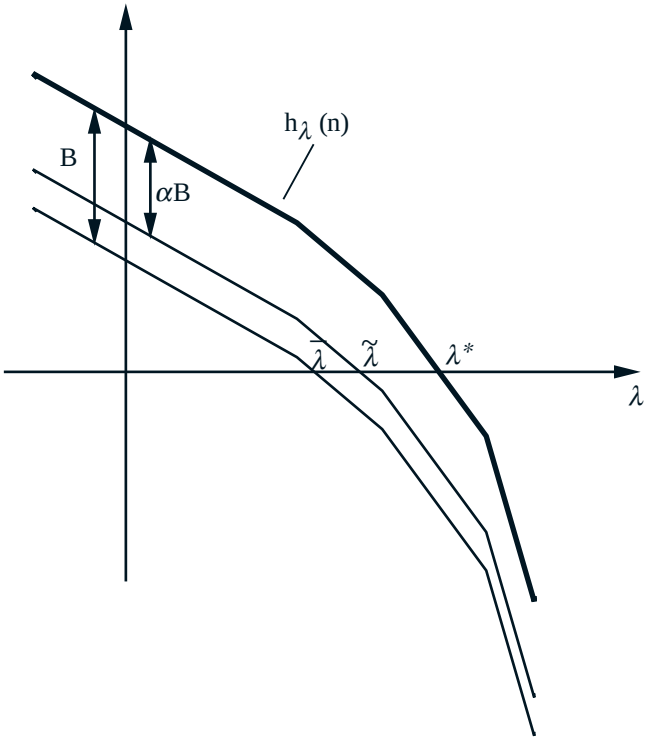

FIG. 3. *Definition of* $\overline{\lambda}$ *and* $\tilde{\lambda}$ *in the proof of Proposition* 1.

Note that if

$$\gamma < \frac{(1-\alpha)^2}{\|e\|(\alpha + \overline{N}/\underline{N})},$$

we have $c_1(\gamma) < 1$.

We now turn to the second relation in (23); that is, we show that

$$|\lambda^{k+1} - \lambda^*| \leq \frac{c_2(\gamma^k)B}{\underline{N}}$$

for an appropriate continuous function $c_2(\gamma)$. Let $\overline{\lambda}$ and $\tilde{\lambda}$ be the unique scalars such that

$$h_{\overline{\lambda}}(n) = B, \qquad h_{\tilde{\lambda}}(n) = \alpha B \tag{30}$$

(see Fig. 3). Also let $\hat{\lambda}$ be the midpoint between $\overline{\lambda}$ and $\tilde{\lambda}$:

$$\hat{\lambda} = \frac{\overline{\lambda} + \tilde{\lambda}}{2}. \tag{31}$$

Note that from (19), we have

$$\frac{(1-\alpha)B}{\overline{N}} \leq \tilde{\lambda} - \overline{\lambda} \leq \frac{(1-\alpha)B}{\underline{N}} \tag{32}$$

and that

$$\frac{\alpha B}{\overline{N}} \leq \lambda^* - \tilde{\lambda} \leq \frac{\alpha B}{\underline{N}},$$

$$\frac{B}{\overline{N}} \leq \lambda^* - \overline{\lambda} \leq \frac{B}{\underline{N}}.$$

From the last three relations, we also obtain

$$\frac{(1+\alpha)B}{2\overline{N}} \leq \lambda^* - \hat{\lambda} \leq \frac{(1+\alpha)B}{2\underline{N}}, \tag{33}$$

$$\frac{(1-\alpha)B}{2\overline{N}} \leq \tilde{\lambda} - \hat{\lambda} \leq \frac{(1-\alpha)B}{2\underline{N}}. \tag{34}$$

We assume that $\lambda^k \leq \lambda^*$; the complementary case where $\lambda^k \geq \lambda^*$ is handled similarly. We distinguish between two cases:

(a) $\lambda^k \leq \hat{\lambda}$,

(b) $\hat{\lambda} < \lambda^k \leq \lambda^*$.

In the case where $\lambda^k \leq \hat{\lambda}$, we have, using (19) and (30)–(32),

$$h_{\lambda^k}(n) \geq h_{\hat{\lambda}}(n) \geq h_{\tilde{\lambda}}(n) + \underline{N}(\tilde{\lambda} - \hat{\lambda}) = \alpha B + \underline{N}(\tilde{\lambda} - \hat{\lambda}) \geq \alpha B + \frac{(1-\alpha)B\underline{N}}{2\overline{N}}. \tag{35}$$

On the other hand, from (22) and (25), we have $|h^{k+1}(n) - h_{\lambda^k}(n)| \leq \alpha B$ so that

$$h^{k+1}(n) \geq h_{\lambda^k}(n) - \alpha B. \tag{36}$$

By combining (35) and (36), we obtain

$$h^{k+1}(n) \geq \frac{(1-\alpha)B}{2\overline{N}^2}.$$

We now have, using the above equation,

$$\lambda^* - \lambda^{k+1} = \lambda^* - \lambda^k - \gamma^k h^{k+1}(n) \leq \frac{B}{\underline{N}} - \frac{\gamma^k(1-\alpha)B\underline{N}}{2\overline{N}} = \frac{B}{\underline{N}^2}\left(1 - \frac{\gamma^k(1-\alpha)\underline{N}}{2\overline{N}}\right), \tag{37}$$

and we also have, using (25), (22), and (19)

$$\lambda^* - \lambda^{k+1} = \lambda^* - \lambda^k - \gamma^k h^{k+1}(n) \geq \lambda^* - \lambda^k - \gamma^k\big(h_{\lambda_k}(n) + \alpha B\big) \geq (1 - \gamma^k\overline{N})(\lambda^* - \lambda^k) - \gamma^k\alpha B. \tag{38}$$

It can be seen now from (38) that for $\gamma^k \in (0, 1/\overline{N}]$, we have $\lambda^* - \lambda^{k+1} \geq -\gamma^k\alpha B$, and it follows using also (37) that

$$|\lambda^* - \lambda^{k+1}| \leq \frac{c_2(\gamma^k)B}{\underline{N}},$$

where $c_2(\cdot)$ is the continuous function

$$c_2(\gamma) = \max\left[1 - \frac{\gamma(1-\alpha)\underline{N}^2}{2\overline{N}},\ \gamma\alpha\underline{N}\right].$$

Since there exists a threshold value $\overline{\gamma} > 0$ such that the continuous function $c_2(\gamma)$ satisfies $0 < c(\gamma) < 1$ for all $\gamma \in (0, \overline{\gamma}]$, the desired relation (23) is proved in the case $\lambda^k \leq \hat{\lambda}$.

In the case where $\hat{\lambda} < \lambda^k \leq \lambda^*$, there are two possibilities.

(1) $h^{k+1}(n) \geq 0$. Then $\lambda^k \leq \lambda^{k+1}$, and by also using (33), we have

$$\lambda^* \leq \hat{\lambda} + \frac{(1+\alpha)B}{2\underline{N}} \leq \lambda^k + \frac{(1+\alpha)B}{2\underline{N}} \leq \lambda^{k+1} + \frac{(1+\alpha)B}{2\underline{N}}. \tag{39}$$

Furthermore, from (22) and (26), we have

$$\lambda^{k+1} = \lambda^k + \gamma^k h^{k+1}(n) \leq \lambda^* + \gamma^k \left(\alpha B + \frac{\overline{N}B}{\underline{N}} \right).$$

Thus, by choosing γ^k sufficiently small, we can guarantee that

$$\lambda^{k+1} \leq \lambda^* + \frac{(1+\alpha)B}{2\underline{N}}. \tag{40}$$

From (39) and (40), it follows that for γ^k less than some positive constant, we have

$$|\lambda^{k+1} - \lambda^*| \leq \frac{(1+\alpha)B}{2\underline{N}},$$

proving the second relation in (23), with $c_2(\gamma) = (1+\alpha)/2$.

(2) $h^{k+1}(n) < 0$. In this case, since from (22) and (25) we have

$$h_{\lambda^k}(n) \leq h^{k+1}(n) + \alpha B \leq \alpha B, \tag{41}$$

and since $h_{\tilde{\lambda}}(n) = \alpha B$ and $h_\lambda(n)$ is monotonically decreasing in λ, it follows that $\tilde{\lambda} \leq \lambda^k$. Since $\lambda^k \leq \lambda^*$, we also have $0 \leq h_{\lambda^k}(n) \leq \alpha B$, so that by using (41) and the fact $h_{\lambda^k}(n) \geq 0$, we obtain $|h^{k+1}(n)| \leq \alpha B$ and

$$|\gamma^k h^{k+1}(n)| \leq \gamma^k \alpha B.$$

By choosing

$$\gamma^k \in \left(0, \frac{1-\alpha}{2\alpha\overline{N}} \right], \tag{42}$$

the above inequality, together with (34), yields

$$|\gamma^k h^{k+1}(n)| \leq \frac{(1-\alpha)B}{2\overline{N}} \leq \tilde{\lambda} - \hat{\lambda} \leq \lambda^k - \hat{\lambda}.$$

Thus, we have

$$\lambda^{k+1} = \lambda^k + \gamma^k h^{k+1}(n) \geq \hat{\lambda},$$

and from (33), using also the fact $\lambda^{k+1} \leq \lambda^k \leq \lambda^*$, we obtain for γ^k satisfying (42),

$$|\lambda^{k+1} - \lambda^*| \leq \frac{(1+\alpha)B}{2\underline{N}},$$

proving the second relation in (23) for the case $h^{k+1}(n) < 0$ as well.

Thus, (23) holds with $c(\cdot)$ given by

$$c(\gamma) = \max \left[\alpha + \frac{\gamma \|e\| (\alpha + \overline{N}/\underline{N})}{1-\alpha},\ 1 - \frac{\gamma(1-\alpha)\underline{N}^2}{2\overline{N}},\ \gamma\alpha\underline{N},\ \frac{1+\alpha}{2} \right]. \qquad \square$$

3. Convergence analysis of the Gauss–Seidel version. In this section, we prove the result of Proposition 1 for the Gauss–Seidel version of the method, given by

$$h^{k+1}(i) = G_i(h^k, \lambda^k), \qquad i = 1, \ldots, n, \tag{43}$$

$$\lambda^{k+1} = \lambda^k + \gamma^k h^{k+1}(n), \tag{44}$$

where the components of the mapping $G = (G_1, \ldots, G_n)$ are given by

$$G_1(h, \lambda) = \min_{u \in U(1)} \left[g(1, u) + \sum_{j=1}^{n-1} p_{1j}(u) h(j) \right] - \lambda, \tag{45}$$

(46)

$$G_i(h, \lambda) = \min_{u \in U(i)} \left[g(i, u) + \sum_{j=1}^{i-1} p_{ij}(u) G_j(h, \lambda) + \sum_{j=i}^{n-1} p_{ij}(u) h(j) \right] - \lambda, \qquad i = 2, \ldots, n.$$

The proof of Proposition 1 essentially carries through with the aid of the following result.

PROPOSITION 2. *The mapping G of* (45) *and* (46) *satisfies for all $h \in \Re^n$, $\overline{h} \in \Re^n$, $\lambda \in \Re$, and $\overline{\lambda} \in \Re$:*

$$\frac{|G_i(h, \lambda) - G_i(\overline{h}, \overline{\lambda})|}{v_i} \leq \alpha \|h - \overline{h}\| + \delta_i |\lambda - \overline{\lambda}| \qquad \forall\ i = 1, \ldots, n, \tag{47}$$

where α is the contraction modulus of F, $v_1, \ldots, v_n$ are the weights of the sup-norm $\|\cdot\|$ with respect to which F is a contraction (cf. (17)*), and $\delta_1, \ldots, \delta_n$ are defined recursively by*

$$\delta_1 = \frac{1}{v_1}, \qquad \delta_i = \frac{1 + \max_{j=1,\ldots,i-1} \delta_j}{v_i}, \quad i = 2, \ldots, n. \tag{48}$$

In particular, by taking the maximum over i in (47)*, we obtain*

$$\|G(h, \lambda) - G(\overline{h}, \overline{\lambda})\| \leq \alpha \|h - \overline{h}\| + \delta |\lambda - \overline{\lambda}| \qquad \forall\ h \in \Re^n,\ \overline{h} \in \Re^n,\ \lambda \in \Re,\ \overline{\lambda} \in \Re, \tag{49}$$

where

$$\delta = \max_{i=1,\ldots,n} \delta_i.$$

Proof. We prove (47) by induction. For the case where $i = 1$, we have from the contraction property of the mapping F (cf. (17)):

$$\frac{|G_1(h, \lambda) - G_1(\overline{h}, \lambda)|}{v_1} \leq \alpha \max_{i=1,\ldots,n} \frac{|h(i) - \overline{h}(i)|}{v_i} = \alpha \|h - \overline{h}\|.$$

Therefore,

$$\begin{aligned} \frac{G_1(h, \lambda)}{v_1} &\leq \frac{G_1(\overline{h}, \lambda)}{v_1} + \alpha \|h - \overline{h}\| \\ &\leq \frac{G_1(\overline{h}, \overline{\lambda})}{v_1} + \alpha \|h - \overline{h}\| + \frac{|\lambda - \overline{\lambda}|}{v_1}. \end{aligned}$$

Similarly, we obtain

$$\frac{G_1(\overline{h},\overline{\lambda})}{v_1} \le \frac{G_1(h,\lambda)}{v_1} + \alpha\|h-\overline{h}\| + \frac{|\lambda-\overline{\lambda}|}{v_1}.$$

By combining the last two relations, we see that

$$\frac{|G_1(h,\lambda)-G_1(\overline{h},\overline{\lambda})|}{v_1} \le \alpha\|h-\overline{h}\| + \delta_1|\lambda-\overline{\lambda}|,$$

so that (47) is proved for $i=1$.

Assume that (47) holds for $i=1,\dots,m-1$. We will show that it holds for $i=m$. We have from the contraction property of the mapping F and the induction hypothesis

$$\begin{aligned}
&\frac{|G_m(h,\lambda)-G_m(\overline{h},\lambda)|}{v_m} \\
&\quad\le \alpha\max\left\{\max_{i=1,\dots,m-1}\frac{|G_i(h,\lambda)-G_i(\overline{h},\lambda)|}{v_i}, \max_{i=m,\dots,n}\frac{|h(i)-\overline{h}(i)|}{v_i}\right\} \\
&\quad\le \alpha\|h-\overline{h}\|.
\end{aligned}$$

Using this relation and the induction hypothesis, we obtain

$$\begin{aligned}
\frac{G_m(h,\lambda)}{v_m} &\le \frac{G_m(\overline{h},\lambda)}{v_m} + \alpha\|h-\overline{h}\| \\
&= \frac{1}{v_m}\min_{u\in U(m)}\left[g(m,u)+\sum_{j=1}^{m-1}p_{mj}(u)G_j(\overline{h},\lambda)+\sum_{j=m}^{n-1}p_{mj}(u)\overline{h}(j)\right] \\
&\quad -\frac{\lambda}{v_m}+\alpha\|h-\overline{h}\| \\
&\le \frac{1}{v_m}\min_{u\in U(m)}\left[g(m,u)+\sum_{j=1}^{m-1}p_{mj}(u)G_j(\overline{h},\overline{\lambda})+\sum_{j=m}^{n-1}p_{mj}(u)\overline{h}(j)\right]-\frac{\overline{\lambda}}{v_m} \\
&\quad +\frac{|\lambda-\overline{\lambda}|}{v_m}+\max_{j=1,\dots,m-1}\delta_j\frac{|\lambda-\overline{\lambda}|}{v_m}+\alpha\|h-\overline{h}\| \\
&= \frac{G_m(\overline{h},\overline{\lambda})}{v_m}+\delta_m|\lambda-\overline{\lambda}|+\alpha\|h-\overline{h}\|.
\end{aligned}$$

Similarly, we obtain

$$\frac{G_m(\overline{h},\overline{\lambda})}{v_m} \le \frac{G_m(h,\lambda)}{v_m} + \delta_m|\lambda-\overline{\lambda}| + \alpha\|h-\overline{h}\|,$$

thus proving (47) for $i=m$. This completes the induction. □

Note that Proposition 1 implies that for any λ, $G(\cdot,\lambda)$ is a weighted sup-norm contraction when viewed as a function of h. It can be easily verified that

$$h_\lambda = G(h_\lambda,\lambda) \qquad \forall\ \lambda\in\Re,$$

so it follows that for all λ, the mapping $G(\cdot,\lambda)$ has h_λ as its unique fixed point. The following result proves convergence of the Gauss–Seidel method and parallels Proposition 1.

PROPOSITION 3. *There exists a positive scalar $\overline{\gamma}$ such that if*

$$\underline{\gamma} \leq \gamma^k \leq \overline{\gamma}$$

for some positive scalar $\underline{\gamma}$ and all k, the sequence (h^k, λ^k) generated by the Gauss–Seidel iteration (43), (44) converges to $(h_{\lambda^*}, \lambda^*)$ at the rate of a geometric progression.

Proof. The proof is essentially identical to the one of Proposition 1. The only difference is that the three relations (27), (28), and (29) must be modified to involve the mapping G and to make use of Proposition 2. In particular, (27) becomes

$$\|h^{k+1} - h_{\lambda^{k+1}}\| \leq \alpha\|h^k - h_{\lambda^k}\| + \alpha\|h_{\lambda^k} - h_{\lambda^{k+1}}\| + \delta|\lambda^{k+1} - \lambda^k|,$$

and (28) becomes

$$\|h^{k+1} - h_{\lambda^{k+1}}\| \leq c_1(\gamma^k)B,$$

where the function $c_1(\cdot)$ of (29) is now given by

$$c_1(\gamma) = \alpha + \gamma\left(\frac{\alpha\|e\|}{1-\alpha} + \delta\right)\left(\alpha + \frac{\overline{N}}{\underline{N}}\right).$$

The remainder of the proof goes through with no modification. □

4. Implementation and experimentation. In this section we describe some of our computational experience with the standard method (9)–(10) and with the new Jacobi and Gauss–Seidel methods. The latter methods were implemented with an adaptive stepsize rule of the form $\gamma^k = m(\hat{k})\gamma$ (cf. (15)), using an initial stepsize γ equal to 1. We used the function $m(\hat{k})$ of (16a) for the test results of Tables 1–3 and the function $m(\hat{k})$ of (16b) for the test results of Table 4. The projection

scheme of (11)–(14) was also used. To obtain error bounds on which to project in the Gauss–Seidel method, we performed one Jacobi iteration following nine consecutive Gauss–Seidel iterations. Each Jacobi iteration yielded an upper and a lower bound for λ^*, and the λ-iterate obtained by each iteration was projected on the interval of the best upper and lower bounds obtained so far. For each problem, the three methods were initialized with $h = 0$ and (for the case of the new methods) $\lambda = n/2$. Note that because of the device of projection on the error bound range, the initial choice of λ is not critical.

Our computational results with randomly generated problems are summarized in Tables 1–4 for the three methods labeled STANDARD (which is the known iteration (9)–(10)), SSP-JACOBI (which is the Jacobi version of the new method (7)–(8)), and SSP-Gauss–Seidel (which is the Gauss–Seidel version of the new method (43)–(44)). Let us describe how the test problems were generated. Regarding cost structure, in all problems and for each pair (i, u), the one-stage cost at state i was randomly selected from the range $(0, n)$ according to a uniform distribution. Regarding the transition probabilities, in all the problems, we specified the structure of the transition probability graph by specifying for each state-control pair (i, u), according to some (possibly random) rule, the states j for which the transition probability $p_{ij}(u)$ is nonzero. We then generated each of the nonzero transition probabilities by randomly selecting a corresponding number from the interval $(0, 1)$ according to uniform probability distribution, and by normalizing so that $\sum_{j=1}^{n} p_{ij}(u) = 1$ for all pairs (i, u). The test problems were generated as follows.

(1) Problems of Table 1. Here there is only one control available at each state. The sparsity of the transition probability graph is controlled by a parameter $q \in (0, 1)$. In particular, each possible transition probability is selected to be nonzero with a given probability q. We used sparsity parameters $q = 0.5$, $q = 0.1$, and $q = 0.05$ in our tests.

(2) Problems of Table 2. Here also there is only one control available at each state. At states i with $1 < i < n$, the nonzero transition probabilities are the ones to

the states $i-1$, i, and $i+1$. At state 1 the nonzero transition probabilities are to states 1 and 2, and at state n the nonzero transition probabilities are to states $n-1$ and n. This type of transition probability graph arises in queueing systems.

(3) Problems of Table 3. Here there are two controls available at each state, call them u_1 and u_2. Under u_1, the transition probabilities are specified in the same way as for the problems of Table 2. Under u_2, at each state i with $1 < i < n$, the nonzero transition probabilities are the ones to the states $i-1$ and $i+1$. At state 1 the only nonzero transition probabilities are the ones to the states 1 and 2, and at state n the only nonzero transition probabilities are the ones to the states $n-1$ and n.

(4) Problems of Table 4. Here there are three controls available at each state, call them u_1, u_2, and u_3. Under u_1, the transition probabilities are specified in the same way as for the problems of Table 2. Under u_2, at each state i with $1 < i < n-10$, the nonzero transition probabilities are the ones to the states $i-1$ and $i+10$. At state 1 the only nonzero transition probabilities are the ones to the states 1 and 11, and at states $i = n-10, n-9, \ldots, n$ the only nonzero transition probabilities are the ones to the states $i-1$ and n. Under u_3, at each state i with $10 < i < n$, the nonzero transition probabilities are the ones to the states $i-10$ and $i+1$. At states $i = 1, \ldots, 10$, the only nonzero transition probabilities are the ones to the states 1 and $i+1$, and at state n the only nonzero transition probabilities are the ones to the states $n-10$ and n.

Tables 1–4 give the number of iterations required by each method for the difference between the upper and lower bounds to become smaller than 10^{-3}. Each entry of the tables represents the average of two problems. We should note here that the number of iterations varies a great deal from one problem to another, so the variance of the number of iterations for a given type of problem is very large. For example, one of the two problems in the fourth entry of Table 2 is extremely difficult and requires a much larger number of iterations than the other. However, it is generally true that if a problem is difficult for one method (requires a lot of iterations), it is also difficult for all the other methods.

It can be seen that the problems of Table 1 are generally much easier than the problems of Tables 2–4. Generally, it appears that these problems become more difficult as the sparsity of the transition probability graph increases. On some of these problems (generally the easier ones), the standard method performs extremely well and much better than the new methods. This is probably due to the need for stepsize selection in the new methods. The adaptive stepsize rule that we used generally works well, but on occasion may end up with a stepsize that is either too large or too small for optimal performance. We believe that the subject of appropriate stepsize selection method is a potential topic for theoretical or empirical research.

On the more difficult problems of Tables 2 and 3, the Gauss–Seidel version of the new method is uniformly faster than the other methods. In fact, the Gauss–Seidel method has substantially outperformed the other methods on every single problem with the queueing structure that we tried. The Jacobi version of the new method performs comparably to the standard method on the problems of Tables 2 and 3. What happens here is that for the problems of Tables 2 and 3, the difference between the iterations (7)–(8) and (9)–(10) are minor, particularly when the number of states is large (see the discussion following (9)–(10)).

For the larger problems of Table 4, again the Jacobi version of the new method performs comparably to the standard method. The Gauss–Seidel version of the new method is generally faster than the other methods, but the factor of superiority is problem dependent and its variance is substantial.

5. Conclusions. The methods of this paper were derived by exploiting the connection between average cost and stochastic shortest path problems. We developed a new value iteration method that involves the same type of weighted sup-norm contraction that arises in stochastic shortest path problems. This method is the first, to our knowledge, that admits a convergent Gauss–Seidel implementation. We also believe that the weighted sup-norm contraction property inherent in our method is likely to prove useful in other related contexts.

MULTIDIMENSIONAL SYSTEMS WITH FINITE SUPPORT BEHAVIORS: SIGNAL STRUCTURE, GENERATION, AND DETECTION*

ETTORE FORNASINI† AND MARIA ELENA VALCHER†

Abstract. The main features of finite multidimensional behaviors are introduced as properties of the trajectories supports and connected with the polynomial matrices adopted for their description.

Observability and local detectability are shown to be equivalent to the kernel representation of a behavior via some parity check matrix H^T. The main properties of locally undetectable behaviors as well as their connections with the notion of constrained variables are investigated, and a general representation result for finite support behaviors is derived.

The input-output representation via generator matrices is finally discussed, and some connections between matrix primeness and the constraints every trajectory imposes on the support of the corresponding input are analyzed.

Key words. multidimensional systems, behavior theory, polynomial matrices, parity checks, observability, local detectability/undetectability

1. Introduction.

Behavior theory is the study of the trajectories a dynamical system produces according to its evolution laws. It originated in the analysis of one-dimensional (1D) systems and was developed in a complete and useful form by J. C. Willems in the past two decades. In a series of papers [18, 19, 20], Willems provided a thorough description of the ways a system interacts with its environment, as well as a clear conceptual apparatus for analyzing and identifying the attributes a family of trajectories possibly exhibits. Perhaps the most important of the notions he introduced is external controllability, which displays the way memory function operates and hence constitutes a powerful tool for obtaining state space models of infinite behaviors.

Recently, purely ring-theoretic extensions of Willems theory have been obtained by F. Fagnani, S. K. Mitter, and S. Zampieri in [3, 22]. The new field of research is relevant for the investigation of many classes of systems and makes it quite clear how several concepts of behavior theory depend on the nature of the underlying algebraic structures. Nevertheless, a certain continuity with Willems's former results is apparent, if for no other reason than that the analysis is normally developed and thought of in a standard 1D time domain.

A second stage in the development of behavior theory, initiated by P. Rocha and J. C Willems at the end of the 1980s [13, 14], resulted in the absorption of two-dimensional (2D) signals into the theory. The analysis of 2D behaviors has led to new insights into the classical theory of 2D systems and to new investigations of Laurent polynomial operators, centering around the algebra of matrix pairs and various primeness conditions for polynomial matrices.

Another development in behavior theory is the work of G. D. Forney and M. D. Trott on the behavioral approach to group systems [8]. Like the original work on minimal bases of rational spaces [7], Forney's papers find several applications in the theory of convolutional codes. At the same time, however, they draw on duality theory and suggest new problems on observability and memory span. Also, they emphasize the importance of topological groups in behavior and coding theory.

During the last few years, there has been an increasing interest in convolutional coding of multidimensional (nD) data [4, 16], motivated to a large extent by the possibility of investigating code performances and properties in a behavior context. Also, multidimensional convolutional codes have been a fruitful source of problems and conjectures, both in polynomial modules algebra and in signal processing of discrete data arrays [15].

The aim of this paper is to present, in as self-contained a manner as possible, the behavior theory of finite support multidimensional signals. The finite support assumption is motivated by the fact that in several applications the independent variables represent spatial coordinates, and the phenomenon one aims to model regards only a finite region of the space. So, infinite behaviors, which constitute the core of Willems's theory, are only marginally touched on here. A detailed analysis of the main connections between finite and infinite nD signals falls within the scope of duality theory, and as far as the 2D case is concerned, has been carried on in [16].

Not intending to be inclusive of all aspects of the subject, we have concentrated on what seem to be the most interesting topics to be investigated and have included some preliminary material, as necessary for the discussion. Particular attention has been devoted to the supports of the signals and to certain elementary operations (restriction, extension, and concatenation) which have a concrete meaning from the signal processing standpoint. Actually, several "internal" properties of a behavior have been introduced in terms of these operations and expressed as possibilities of "cutting and pasting together" pieces of different trajectories into a new one.

As each of these features mirrors a particular polynomial matrix representation, an explicit link between the parity checks description of an nD behavior and the concept of observability is derived; indeed, the support of the parity check matrix measures the range of action of the system laws and provides useful bounds on the region where parity checks apply when detecting if some signal is a legal sequence.

The trajectories of an observable behavior can be expressed as the solutions of a system of multidimensional difference equations, and hence can be recognized by means of local testing procedures. Locally undetectable behaviors, instead, exhibit opposite properties, because every finite signal can be completed into a legal trajectory and no local recognition procedure can be successfully implemented. Interestingly enough, these two classes of behaviors allow every finite behavior to be described via intersection operations.

A point of view somewhat complementary to detection calls for an input-output analysis of the way behavior trajectories are generated, and the supports of the trajectories are related to the corresponding inputs. This problem appears particularly relevant when the behavior sequences are injectively generated, and hence a given trajectory is produced by a unique input. Although no general statement can be made about the way these supports are related, specific assumptions on the structure of the generating matrices allow us to uniformly confine the support of each input signal into a suitable extension of the support of the associated output trajectory.

The use of nD Laurent polynomial (L-polynomial) matrices is pervasive throughout the paper; no attempt has been made, however, to give a complete account of

their algebraic properties. For these we may refer the reader to recent books [2] and articles [5, 17, 21] dealing with that part of abstract algebra. A certain attention, however, has been paid to the analysis of the supports of nD L-polynomial vectors, and some results obtained in this context seem to be original.

The paper is organized as follows. The first part introduces the basic definitions and properties of nD finite behaviors; in particular, operations which involve only the supports are sufficient to define the notions of (external) controllability and observability. While controllability is well established [8, 14], and in the context of finite support signals, it follows from linearity and shift invariance, the observability definition we will adopt comes from duality issues and is fully justified when a parity-checks description of the behavior trajectories is adopted. Actually, as shown in section 3, an observable behavior is characterized by a finite set of parity checks one has to apply in order to recognize its trajectories. This result allows observable behaviors to be identified with kernels of polynomial matrix operators or, in more abstract terms, as maximal submodules of given rank in the module of all finite support signals.

In section 4 the notions of unconstrained variables and locally undetectable behaviors are introduced. A general representation result is then provided, showing that every finite behavior can be expressed as the intersection of an observable and a (generally not unique) locally undetectable behavior.

In the last part of the paper we develop the theory of input-output generation of nD behaviors and present some relevant connections between support conditions on the input-output pairs and primeness requirements on the generator matrices.

2. Finite support behaviors: Preliminary definitions and basic properties. Let $\mathbb{F}$ be an arbitrary field and denote by $\mathbf{z}$ the n-tuple $(z_1, z_2, \ldots, z_n)$, so that $\mathbb{F}[\mathbf{z}]$ and $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]$ are shorthand notations [1] for the polynomial and the Laurent polynomial (L-polynomial) rings in the indeterminates $z_1, \ldots, z_n$, respectively.

For any sequence $\mathbf{w} = \{\mathbf{w}(\mathbf{h})\}_{\mathbf{h}\in\mathbb{Z}^n}$, taking values in $\mathbb{F}^p$, the *support* of $\mathbf{w}$ is the set of points where $\mathbf{w}$ is nonzero, i.e., $\mathrm{supp}(\mathbf{w}) := \{\mathbf{h} = (h_1, h_2, \ldots, h_n) \in \mathbb{Z}^n : \mathbf{w}(\mathbf{h}) \neq 0\}$. Also, $\mathbf{w}$ can be represented via a formal power series

$$\sum_{h_i\in\mathbb{Z}} \mathbf{w}(h_1, h_2, \ldots, h_n)\; z_1^{h_1} z_2^{h_2} \cdots z_n^{h_n} = \sum_{\mathbf{h}\in\mathbb{Z}^n} \mathbf{w}(\mathbf{h})\; \mathbf{z}^{\mathbf{h}},$$

where $\mathbf{h}$ stands for the n-tuple $(h_1, h_2, \ldots, h_n)$ and $\mathbf{z}^{\mathbf{h}}$ for the term $z_1^{h_1} z_2^{h_2} \ldots z_n^{h_n}$. On the other hand, power series can be viewed as representing vectors with entries in $\mathcal{F}_\infty := \mathbb{F}^{\mathbb{Z}^n}$, thus setting a bijective map between nD sequences taking values in $\mathbb{F}^p$ and formal power series with coefficients in $\mathbb{F}^p$. This allows us to identify nD sequences with the associated power series, in particular, finite support nD signals with L-polynomial vectors, and to denote both of them with the same symbol $\mathbf{w}$. Sometimes, mostly when a power series $\mathbf{w}$ is obtained as a Cauchy product, it will be useful to denote the coefficient of $\mathbf{z}^{\mathbf{h}}$ in $\mathbf{w}$ as $(\mathbf{w}, \mathbf{z}^{\mathbf{h}})$.

Linear operators on the sequence space are represented by appropriate matrices with elements in $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]$, whose primeness features find a counterpart in terms of properties of the associated operators. The main primeness notions which arise in the nD context are the following.

DEFINITION 2.1. *An L-polynomial matrix $G \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{p\times m}$, $p \geq m$, is*

- unimodular *if $p = m$ and $\det G$ is a unit in $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]$, i.e., $\det G = c\mathbf{z}^{\mathbf{h}}$ for some nonzero $c \in \mathbb{F}$ and some $\mathbf{h} \in \mathbb{Z}^n$;*
- right factor prime *(rFP) if in every factorization $G = \bar{G}T$, with $\bar{G} \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{p\times m}$ and $T \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{m\times m}$, T is a unimodular matrix;*

- right minor prime *(rMP) if its maximal order minors have no common factors;*
- right variety prime *(rVP) if the ideal $\mathcal{I}_G$, generated by its maximal order minors, includes (nonzero) L-polynomials in $\mathbb{F}[z_i, z_i^{-1}]$ for every $i = 1, 2, \ldots, n$;*
- right zero prime *(rZP) if the ideal $\mathcal{I}_G$ is the ring $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]$ itself.*

The support of a matrix $G \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{p\times m}$ is the union of the supports of its elements.

An nD (finite) *behavior $\mathfrak{B}$ with p components* is a set of finite support signals (trajectories) taking values in $\mathbb{F}^p$ and endowed with the following properties.

(L) [Linearity]. *If $\mathbf{w}_1$ and $\mathbf{w}_2$ belong to $\mathfrak{B}$, then $\alpha\mathbf{w}_1 + \beta\mathbf{w}_2 \in \mathfrak{B}$ for all α, β in $\mathbb{F}$.*

(SI) [Shift-invariance]. *$\mathbf{w} \in \mathfrak{B}$ implies $\mathbf{v} = \mathbf{z}^{\mathbf{h}}\mathbf{w} \in \mathfrak{B}$ for every $\mathbf{h} \in \mathbb{Z}^n$; i.e., $\mathfrak{B}$ is invariant with respect to the shifts along the coordinate axes in $\mathbb{Z}^n$.*

As every nD behavior $\mathfrak{B}$ can be viewed as an $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]$-submodule of $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$, which is a Noetherian module [11], $\mathfrak{B}$ is finitely generated; i.e., there exists a finite set of column vectors $\mathbf{g}_1, \mathbf{g}_2, \ldots, \mathbf{g}_m$ in $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$ such that

$$\mathfrak{B} \equiv \left\{ \sum_{i=1}^{m} \mathbf{g}_i u_i : u_i \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}] \right\} = \{\mathbf{w} = G\mathbf{u} : \mathbf{u} \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^m\} =: \mathrm{Im}G. \tag{2.1}$$

The L-polynomial matrix $G := \mathrm{row}\{\mathbf{g}_1, \mathbf{g}_2, \ldots, \mathbf{g}_m\}$ is called the *generator matrix* of $\mathfrak{B}$.

$G_1 \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{p\times m_1}$ and $G_2 \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{p\times m_2}$ are generator matrices of the same behavior if and only if there exist $P_1 \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{m_1\times m_2}$ and $P_2 \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{m_2\times m_1}$ such that $G_1P_1 = G_2$ and $G_2P_2 = G_1$. Consequently, G_1 and G_2 have the same rank r over the field of rational functions $\mathbb{F}(\mathbf{z})$. Being an invariant with respect to all generator matrices of $\mathfrak{B}$, r is called the *rank of* $\mathfrak{B}$. It somehow represents a complexity index of the behavior, as r independent trajectories can be found in $\mathfrak{B}$, while $r + 1$ trajectories $(\mathbf{w}_1, \mathbf{w}_2, \ldots, \mathbf{w}_{r+1})$ always satisfy an autoregressive equation $\mathbf{w}_1p_1 + \mathbf{w}_2p_2 + \cdots + \mathbf{w}_{r+1}p_{r+1} = \mathbf{0}$, with at least one nonzero $p_i \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]$.

A behavior $\mathfrak{B}$ of rank r is *free* if it admits a full column rank generator matrix, that is, a generator matrix G with r columns. This amounts to saying that each trajectory $\mathbf{w}$ in $\mathfrak{B}$ is uniquely expressed as a linear combination $\mathbf{w} = \mathbf{g}_1u_1 + \mathbf{g}_2u_2 + \cdots + \mathbf{g}_ru_r$, $u_i \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]$, of the columns of G.

The main properties of a finite behavior $\mathfrak{B}$ are connected with certain elementary operations we can perform on the system trajectories. These operations essentially reduce to "pasting" pieces of different trajectories into legal elements of $\mathfrak{B}$ or to "cutting" a set of samples out of a given trajectory, so as to obtain a new behavior sequence.

One of the pillars of Willems's behavior theory is the notion of (external) controllability. For 1D controllable behaviors the past has no lasting implications about the future [19], which means that the restriction of a 1D trajectory to $(-\infty, t]$ does not provide any information about the values the trajectory takes on $[t + \delta, +\infty)$, when $\delta > 0$ is properly chosen. In a multidimensional context the notions of "past" and "future" are quite elusive and, in many cases, unsuitable for classifying and processing the available data. What seems more reasonable, instead, is to investigate to what extent the values a trajectory $\mathbf{w}$ assumes on a subset $\mathcal{S}_1 \subset \mathbb{Z}^n$ influence the values on a subset $\mathcal{S}_2$, disjoint from $\mathcal{S}_1$, and to check if there exists a lower bound on the distance

$$d(\mathcal{S}_1, \mathcal{S}_2) := \min \left\{ \sum_{i=1}^{n} |h_i - k_i| : (h_1, h_2, \ldots, h_n) \in \mathcal{S}_1, (k_1, k_2, \ldots, k_n) \in \mathcal{S}_2 \right\}, \tag{2.2}$$

which guarantees that $\mathbf{w}|\mathcal{S}_2$, the *restriction to* $\mathcal{S}_2$ *of the sequence* $\mathbf{w}$, is independent of $\mathbf{w}|\mathcal{S}_1$. This point of view led to the following definition [13].

(C_1) [Controllability]. *A finite behavior* $\mathfrak{B}$ *is* controllable *if there exists an integer* $\delta > 0$ *such that, for any pair of nonempty subsets* $\mathcal{S}_1, \mathcal{S}_2$ *of* $\mathbb{Z}^n$*, with* $d(\mathcal{S}_1, \mathcal{S}_2) \geq \delta$*, and any pair of trajectories* $\mathbf{w}_1$ *and* $\mathbf{w}_2 \in \mathfrak{B}$ *, there exists* $\mathbf{v} \in \mathfrak{B}$ *such that*

$$\mathbf{v}|\mathcal{S}_1 = \mathbf{w}_1|\mathcal{S}_1 \qquad \textit{and} \qquad \mathbf{v}|\mathcal{S}_2 = \mathbf{w}_2|\mathcal{S}_2. \tag{2.3}$$

While definition (C_1) requires pasting together different signals into a new one, the following statement refers to the possibility of finding a legal extension for every portion $\mathbf{w}|\mathcal{S}$ of a behavior trajectory $\mathbf{w}$ by adjusting the sample values in a small area surrounding $\mathcal{S}$. More precisely, by introducing for $\varepsilon \geq 0$ the ε-*extension* of the set $\mathcal{S}$

$$\mathcal{S}^{\varepsilon} := \{\mathbf{h} \in \mathbb{Z}^n : d(\mathbf{h}, \mathcal{S}) \leq \varepsilon\},$$

one can give the following definition.

(C_2) [Zero-controllability]. *A finite behavior* $\mathfrak{B}$ *is* zero-controllable *if there exists an integer* $\varepsilon > 0$ *such that, for any nonempty set* $\mathcal{S}$ *of* $\mathbb{Z}^n$ *and any* $\mathbf{w} \in \mathfrak{B}$*, there exists* $\mathbf{v} \in \mathfrak{B}$ *satisfying*

$$\mathbf{v}|\mathcal{S} = \mathbf{w}|\mathcal{S} \qquad \textit{and} \qquad \mathrm{supp}(\mathbf{v}) \subseteq \mathcal{S}^{\varepsilon}. \tag{2.4}$$

Properties (C_1) and (C_2) make sense for both finite and infinite support behaviors, and the proof of (C_1) $\Leftrightarrow$ (C_2) given below holds for both of them. However, while conditions (C_1) and (C_2) are always met by a finite behavior $\mathfrak{B}$, and essentially follow from the module structure of $\mathfrak{B}$, for an infinite behavior, controllability constitutes an additional constraint with respect to linearity and shift-invariance [13, 14].

PROPOSITION 2.2. *Controllability and zero-controllability are equivalent.*

Proof. (C_1) $\Rightarrow$ (C_2) Assume that $\mathfrak{B}$ meets condition (C_1). Given $\mathbf{w} \in \mathfrak{B}$ and $\mathcal{S} \subset \mathbb{Z}^n$, take in ($C_1$) $\mathbf{w}_1 = \mathbf{w}$, $\mathbf{w}_2 = \mathbf{0}$, $\mathcal{S}_1 = \mathcal{S}$, and $\mathcal{S}_2 = \mathcal{C}\mathcal{S}^{\delta}$, where $\mathcal{C}\mathcal{S}$ denotes the complementary set of $\mathcal{S}$. Then the trajectory $\mathbf{v}$ which fulfills (2.3) satisfies (2.4) with $\varepsilon = \delta$.

(C_2) $\Rightarrow$ (C_1) Assume that $\mathfrak{B}$ satisfies condition (C_2). Given $\mathbf{w}_1$ and $\mathbf{w}_2 \in \mathfrak{B}$ and $\mathcal{S}_1, \mathcal{S}_2 \subset \mathbb{Z}^n$, with $d(\mathcal{S}_1, \mathcal{S}_2) > \varepsilon$, by ($C_2$) there exist $\mathbf{v}_1$ and $\mathbf{v}_2 \in \mathfrak{B}$ such that

$$\mathbf{v}_i|\mathcal{S}_i = \mathbf{w}_i|\mathcal{S}_i, \quad \mathrm{supp}(\mathbf{v}_i) \subset \mathcal{S}_i^{\varepsilon}, \qquad i = 1, 2.$$

Thus $\mathbf{v} := \mathbf{v}_1 + \mathbf{v}_2 \in \mathfrak{B}$ satisfies $\mathbf{v}|\mathcal{S}_i = \mathbf{w}_i|\mathcal{S}_i$, $i = 1, 2$, and (C_1) holds for $\delta = \varepsilon + 1$. □

PROPOSITION 2.3. *A finite behavior* $\mathfrak{B}$ *is controllable.*

Proof. Suppose that $G \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{p \times m}$ is a generator matrix of $\mathfrak{B}$, and let η be a positive integer such that $B(\mathbf{0}, \eta)$, the ball of radius η and center in the origin, includes $\mathrm{supp}(G)$. Consider any set $\mathcal{S} \subset \mathbb{Z}^n$ and $\mathbf{w} = G\mathbf{u} \in \mathfrak{B}$. If $\bar{\mathbf{u}}$ is the sequence which coincides with $\mathbf{u}$ on $\mathcal{S}^{\eta}$ and is zero elsewhere, the trajectory $\mathbf{v} := G\bar{\mathbf{u}}$ satisfies $\mathbf{v}|\mathcal{S} = \mathbf{w}|\mathcal{S}$ and has support which does not exceed $\mathcal{S}^{2\eta}$. So (C_2) is met with $\varepsilon = 2\eta$. □

Given two disjoint sets $\mathcal{S}_1$ and $\mathcal{S}_2$ which are far enough apart, controllability expresses the possibility of steering any behavior sequence known in $\mathcal{S}_1$ into another element of $\mathfrak{B}$ assigned on $\mathcal{S}_2$, meanwhile producing a legal trajectory. Like controllability, observability will also be introduced without reference to the concept of state, according to some recent works of Forney et al. [8, 12]. Observability formalizes the

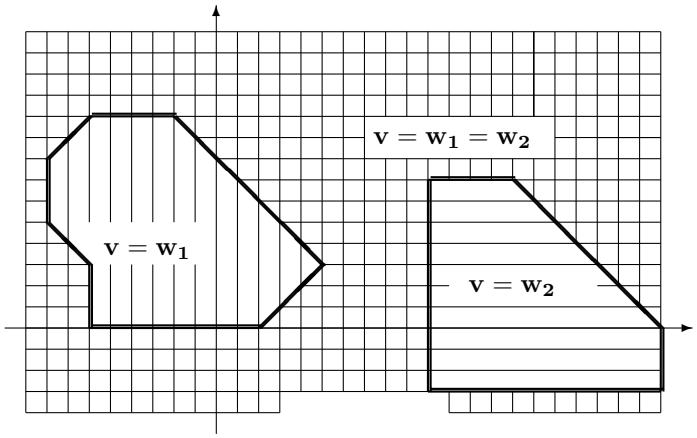

FIG. 2.1.

possibility of pasting into a legal sequence any pair of trajectories that take the same values on a sufficiently large subset of $\mathbb{Z}^n$. This is equivalent to saying that, however a sequence $\mathbf{w} \in \mathfrak{B}$ and a subset $\mathcal{S} \subset \mathbb{Z}^n$ are chosen, the possible extensions of $\mathbf{w}|\mathcal{S}$ only depend on the values of $\mathbf{w}$ on a boundary region of $\mathcal{S}$.

Under this viewpoint, observability endows a behavior with a "separation property" that allows us to take into account only a small amount of data in order to extend a portion of the behavior sequence. Furthermore, once we think of the samples in $\mathcal{S}$ as the information about the past dynamics of the system, observability enables us to design the "future" evolution by considering only the most "recent" data (those on the boundary), thus reminding us of the notion of state.

(O_1) [Observability]. *A finite behavior* $\mathfrak{B}$ *is* observable *if there exists an integer* $\delta > 0$ *such that, for any pair of nonempty subsets* $\mathcal{S}_1, \mathcal{S}_2$ *of* $\mathbb{Z}^n$*, with* $d(\mathcal{S}_1, \mathcal{S}_2) \geq \delta$*, and any pair of trajectories* $\mathbf{w}_1$*,* $\mathbf{w}_2 \in \mathfrak{B}$*, satisfying* $\mathbf{w}_1|\mathcal{C}(\mathcal{S}_1 \cup \mathcal{S}_2) = \mathbf{w}_2|\mathcal{C}(\mathcal{S}_1 \cup \mathcal{S}_2)$*, the trajectory*

$$\mathbf{v}(\mathbf{h}) = \begin{cases} \mathbf{w}_1(\mathbf{h}), & \mathbf{h} \in \mathcal{S}_1, \\ \mathbf{w}_1(\mathbf{h}) = \mathbf{w}_2(\mathbf{h}), & \mathbf{h} \in \mathcal{C}(\mathcal{S}_1 \cup \mathcal{S}_2), \\ \mathbf{w}_2(\mathbf{h}), & \mathbf{h} \in \mathcal{S}_2, \end{cases} \tag{2.5}$$

is an element of $\mathfrak{B}$ (*see Fig.* 2.1).

Observability can be equivalently restated as follows: if the support of a behavior sequence $\mathbf{w}$ can be partitioned into a pair of disjoint subsets, which are far enough apart, the restrictions of $\mathbf{w}$ to each subset represent legal trajectories.

(O_2) [Zero-observability]. *A finite behavior* $\mathfrak{B}$ *is* zero-observable *if there exists an integer* $\varepsilon > 0$ *such that for any* $\mathbf{w} \in \mathfrak{B}$ *satisfying* $\mathbf{w}|(\mathcal{S}^\varepsilon \setminus \mathcal{S}) = \mathbf{0}$*,* $\mathcal{S}$ *a nonempty set in* $\mathbb{Z}^n$*, the sequence*

$$\mathbf{v}(\mathbf{h}) = \begin{cases} \mathbf{w}(\mathbf{h}), & \mathbf{h} \in \mathcal{S}, \\ 0 & \textit{elsewhere} \end{cases} \tag{2.6}$$

belongs to $\mathfrak{B}$ (*see Fig.* 2.2).

PROPOSITION 2.4. *Observability and zero-observability are equivalent.*

Proof. (O_1) $\Rightarrow$ (O_2) Assume that $\mathfrak{B}$ fulfills condition (O_1). Given $\mathcal{S} \subset \mathbb{Z}^n$ and $\mathbf{w} \in \mathfrak{B}$ such that $\mathbf{w}|(\mathcal{S}^\delta \setminus \mathcal{S}) = \mathbf{0}$, take in ($O_1$) $\mathbf{w}_1 = \mathbf{w}$, $\mathbf{w}_2 = \mathbf{0}$, $\mathcal{S}_1 = \mathcal{S}$, and $\mathcal{S}_2 = \mathcal{C}\mathcal{S}^\delta$. The trajectory $\mathbf{v} \in \mathfrak{B}$ satisfying (2.5), also satisfies (2.6), with $\varepsilon = \delta$.

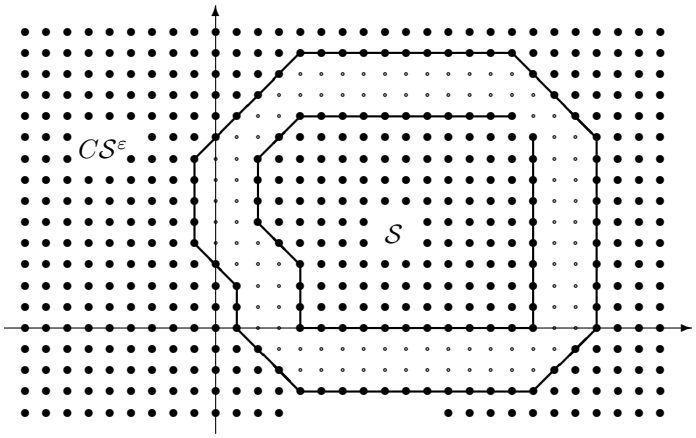

FIG. 2.2.

$(O_2) \Rightarrow (O_1)$ Assume that $\mathfrak{B}$ fulfills condition (O_2). Given $\mathcal{S}_1, \mathcal{S}_2 \subset \mathbb{Z}^n$, with $d(\mathcal{S}_1, \mathcal{S}_2) > \varepsilon$, and $\mathbf{w}_1, \mathbf{w}_2 \in \mathfrak{B}$ satisfying $\mathbf{w}_1|\mathcal{C}(\mathcal{S}_1 \cup \mathcal{S}_2) = \mathbf{w}_2|\mathcal{C}(\mathcal{S}_1 \cup \mathcal{S}_2)$, the sequence $\mathbf{w}_1 - \mathbf{w}_2 \in \mathfrak{B}$ satisfies $(\mathbf{w}_1 - \mathbf{w}_2)|\mathcal{C}(\mathcal{S}_1 \cup \mathcal{S}_2) = \mathbf{0}$. As a consequence, the sequence $\mathbf{w}$ given by

$$\mathbf{w}(\mathbf{h}) = \begin{cases} \mathbf{w}_1(\mathbf{h}) - \mathbf{w}_2(\mathbf{h}), & \mathbf{h} \in \mathcal{S}_1, \\ 0 & \text{elsewhere}, \end{cases}$$

is in $\mathfrak{B}$, and $\mathbf{v} := \mathbf{w} + \mathbf{w}_2 \in \mathfrak{B}$ fulfills (2.5). So, (O_1) holds for $\delta = \varepsilon + 1$. □

3. Parity checks and trajectory recognition. Underlying the definition of controllability is the idea of driving a portion of a trajectory into another one, provided that there is room enough for adjustments. In rough terms, one's objective is to manipulate the control variables to cause the system to behave in $\mathcal{S}_2$ in a more desirable manner than is expected by watching the system trajectory on $\mathcal{S}_1$. So, controllability is naturally connected with the generation of $\mathfrak{B}$ as the image of some matrix G, acting on the input space.

Observability is somehow related to the "dual" issue of recognizing whether a given sequence $\mathbf{v} \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$ is an element of $\mathfrak{B}$. This problem, which typically arises in fault detection and convolutional encoding contexts, can be managed by resorting to a linear filter (residual generator or syndrome former) that produces an identically zero output signal when the input is an admissible trajectory of $\mathfrak{B}$. From a mathematical point of view, this requires us to find a set of sequences (parity checks) endowed with the property that their convolution with every element of $\mathfrak{B}$ is zero.

So, for a given behavior $\mathfrak{B} \subseteq \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$, a (finite) *parity check* is a column vector $\mathbf{s} \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$ that satisfies $\mathbf{s}^T\mathbf{w} = \mathbf{0}$ for all $\mathbf{w} \in \mathfrak{B}$. The set $\mathfrak{B}^\perp$ of all finite parity checks of $\mathfrak{B}$ is the *orthogonal behavior*, and as a submodule of $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$, it is generated by the columns of some matrix $H \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{p \times q}$, that is,

$$\mathfrak{B}^\perp = \{\mathbf{s} \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p : \mathbf{s} = H\mathbf{x}, \mathbf{x} \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^q\} = \mathrm{Im}H. \tag{3.1}$$

Condition $\mathbf{s}^T\mathbf{w} = \mathbf{0}$, $\forall\ \mathbf{s} \in \mathfrak{B}^\perp$, however, need not imply $\mathbf{w} \in \mathfrak{B}$. In general,

$$\mathfrak{B}^{\perp\perp} := \{\mathbf{w} \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p : \mathbf{s}^T\mathbf{w} = \mathbf{0} \forall\ \mathbf{s} \in \mathfrak{B}^\perp\} \tag{3.2}$$

properly includes $\mathfrak{B}$ and is the set of all L-polynomial vectors obtained by combining the columns of G over the field of rational functions $\mathbb{F}(\mathbf{z})$. It is clear that $\mathfrak{B}$ can be identified via a finite set of parity checks if and only if $\mathfrak{B} = \mathfrak{B}^{\perp\perp}$ or, equivalently,

$$\mathfrak{B} = \ker H^T := \{\mathbf{w} \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p : H^T\mathbf{w} = \mathbf{0}\}. \tag{3.3}$$

In this setting, observability finds a somewhat more substantial interpretation. Actually, if $\mathfrak{B} = \ker H^T$, the restriction of a trajectory to a set $\mathcal{S}$ still provides a legal signal every time the distance between $\mathcal{S}$ and the remaining support of the trajectory exceeds the range of action of the parity check matrix H.

Proposition 3.1 below shows that kernel representations are possible, as can be expected, only for observable behaviors, and makes it clear that observability induces further constraints on the structure of $\mathfrak{B}$, in addition to linearity and shift-invariance.

PROPOSITION 3.1. *A behavior $\mathfrak{B} \subseteq \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$ is observable if and only if there exist an integer $h > 0$ and an L-polynomial matrix $H^T \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{h\times p}$ such that $\mathfrak{B} = \ker H^T$.*

The proof of the proposition depends on a couple of technical lemmas.

LEMMA 3.2. *Let R be an integral domain, and consider the polynomial in $R[z]$,*

$$m(z) = \alpha_0\ z^r - \alpha_1\ z^{r-1} + \alpha_2\ z^{r-2} + \cdots + (-1)^r\alpha_r.$$

For any $\rho \geq 0$ there is a $p(z) \in R[z]$ such that $p(z)m(z) \in R[z^{\rho+1}]$.

Proof. Let Q be the field of fractions of R, and L the algebraic closure of Q. Then $m(z)$ can be written as $m(z) = \alpha_0 \prod_{i=1}^r (z - \xi_i)$, where $\xi_i \in L,\ i = 1, 2, \ldots, n$, and

$$\sum_i \xi_i = \alpha_1/\alpha_0, \qquad \sum_{i<j} \xi_i\xi_j = \alpha_2/\alpha_0, \quad \ldots \quad \xi_1\xi_2\cdots\xi_r = \alpha_r/\alpha_0. \tag{3.4}$$

Consider the following polynomial in $L[z]$:

$$\begin{aligned}\tilde{p}(z) &= \prod_{i=1}^r (z^\rho + \xi_i z^{\rho-1} + \xi_i^2 z^{\rho-2} + \cdots + \xi_i^{\rho-1} z + \xi_i^\rho) \\ &= \sum_{0\leq i_1,i_2,\ldots,i_r\leq\rho} z^{r\rho - i_1 - i_2 - \cdots - i_r} \xi_1^{i_1}\xi_2^{i_2}\cdots\xi_r^{i_r} = \sum_{t=0}^{r\rho} z^{r\rho-t} \sum_{\substack{i_1+i_2+\cdots+i_r=t \\ 0\leq i_1,i_2,\ldots,i_r\leq\rho}} \xi_1^{i_1}\xi_2^{i_2}\cdots\xi_r^{i_r}.\end{aligned}$$

Each coefficient of $\tilde{p}(z)$ is a symmetric polynomial in the indeterminates $\xi_1, \xi_2, \ldots, \xi_r$, with integer coefficients, and hence it is expressible [11] as a polynomial in the elementary symmetric polynomials defined in (3.4), again with integer coefficients. Thus $\tilde{p}(z)$ is in $Q[z]$, the denominators of its coefficients are powers of α_0, and there exists a positive integer ν such that $p(z) := \alpha_o^\nu\, \tilde{p}(z)$ belongs to $R[z]$. To conclude the proof, we note that $p(z)m(z)$ is an element of $R[z^{\rho+1}]$ since

$$\begin{aligned}p(z)m(z) &= \alpha_o^\nu \prod_{i=1}^r [(z^\rho + \xi_i z^{\rho-1} + \xi_i^2 z^{\rho-2} + \cdots + \xi_i^\rho)(z - \xi_i)] \\ &= \alpha_o^\nu \prod_{i=1}^r (z^{\rho+1} - \xi_i^{\rho+1}). \qquad \square\end{aligned}$$

LEMMA 3.3. *Let $m(\mathbf{z})$ be in $\mathbb{F}[\mathbf{z}]$. For any integer $\rho > 0$ there is $p(\mathbf{z}) \in \mathbb{F}[\mathbf{z}]$ s.t.*

$$m(\mathbf{z})p(\mathbf{z}) \ \in\ \mathbb{F}[\mathbf{z}^\rho] := \mathbb{F}[z_1^\rho, \ldots, z_n^\rho]. \tag{3.5}$$

Proof. As $m(\mathbf{z}) = m(z_1, \ldots, z_n)$ can be viewed as an element of $\mathbb{F}[z_1, \ldots, z_{n-1}][z_n]$, by Lemma 3.2 there exists $p_1(z_1, \ldots, z_n) \in \mathbb{F}[z_1, \ldots, z_{n-1}][z_n]$ such that

$$m_1(z_1, \ldots, z_n^\rho) := m(z_1, \ldots, z_n) p_1(z_1, \ldots, z_n) \in \mathbb{F}[z_1, \ldots, z_{n-1}][z_n^\rho].$$

Looking at $m_1(z_1, \ldots, z_n^\rho)$ as a polynomial in $\mathbb{F}[z_1, \ldots, z_{n-2}, z_n^\rho][z_{n-1}]$, we know that there exists $p_2(z_1, \ldots, z_{n-1}, z_n^\rho)$ such that

$$m_2(z_1, \ldots, z_{n-1}^\rho, z_n^\rho) := m_1(z_1, \ldots, z_{n-1}, z_n^\rho) p_2(z_1, \ldots, z_{n-1}, z_n^\rho) \in \mathbb{F}[z_1, \ldots, z_{n-2}, z_n^\rho][z_{n-1}^\rho].$$

In n steps we end up with a polynomial

$$\begin{aligned} m_n(z_1^\rho, z_2^\rho, \ldots, z_n^\rho) : = & \, m(z_1, \ldots, z_n) p_1(z_1, \ldots, z_n) \\ & \cdot \; p_2(z_1, z_2, \ldots, z_{n-1}, z_n^\rho) \ldots p_n(z_1^\rho, z_2^\rho, \ldots, z_n^\rho) \in \mathbb{F}[z_1^\rho, z_2^\rho, \ldots, z_n^\rho], \end{aligned}$$

and (3.5) holds with $p = p_1 \; p_2 \; \ldots \; p_n$. ∎

Proof of Proposition 3.1. Assume that $\mathfrak{B} = \mathrm{Im}G$, $G \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{p \times m}$, is an observable behavior, and let $\mathfrak{B}^\perp = \mathrm{Im}\; H$, $H \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{p \times q}$, denote the orthogonal behavior introduced in (3.1). We will show that $\mathfrak{B} \equiv \ker H^T$. Since $H^T G = \mathbf{0}$, it is clear that $\ker H^T \supseteq \mathfrak{B}$. To prove the converse, express $\mathbf{w} \in \ker H^T$ as $\mathbf{w} = G\mathbf{n}/d(\mathbf{z})$, $d \in \mathbb{F}[\mathbf{z}], \mathbf{n} \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{m \times 1}$. By Lemma 3.3, for every integer $\rho > 0$, there is a suitable polynomial $p(\mathbf{z})$ such that $p(\mathbf{z})d(\mathbf{z}) \in \mathbb{F}[z_1^\rho, \ldots, z_n^\rho]$. If property (O_2) holds for $\varepsilon > 0$, and $r > 0$ is an integer such that $\mathrm{supp}(\mathbf{w}) \subseteq B(\mathbf{0}, r)$, we choose $\rho > 2r + \varepsilon$. So, the behavior sequence $p(\mathbf{z})d(\mathbf{z})\mathbf{w} = G\mathbf{n}p(\mathbf{z})$ can be written as

$$\sum_{i_1, i_2, \ldots, i_n} c_{i_1, i_2, \ldots, i_n} z_1^{\rho i_1} z_2^{\rho i_2} \cdots z_n^{\rho i_n} \; \mathbf{w}$$

and thus is the sum of disjoint shifted copies of $\mathbf{w}$, and the distance between two arbitrary copies exceeds ε. So, by (O_2), each copy of $\mathbf{w}$, and hence $\mathbf{w}$ itself, is in $\mathfrak{B}$.

Conversely, let $\mathfrak{B} = \ker H^T$ and set $\varepsilon = 2s$, with $s > 0$ an integer s.t. $B(\mathbf{0}, s) \supseteq \mathrm{supp}(H^T)$. If $\mathcal{S}$ is a subset of $\mathbb{Z}^n$ and $\mathbf{w} \in \mathfrak{B}$ satisfies $\mathbf{w}|(\mathcal{S}^\varepsilon \setminus \mathcal{S}) = \mathbf{0}$, the sequence

$$\mathbf{v}(\mathbf{h}) = \begin{cases} \mathbf{w}(\mathbf{h}), & \mathbf{h} \in \mathcal{S}, \\ 0 & \text{elsewhere} \end{cases}$$

is in $\ker H^T$ and hence in $\mathfrak{B}$. Consequently, $\mathfrak{B}$ is zero-observable. ∎

The kernel description given in Proposition 3.1 leads to new insights into the internal structure of an observable behavior. Observability, indeed, expresses a sort of "localization" of the system laws or, equivalently, the existence of a bound on the size of all windows (in $\mathbb{Z}^n$) we have to look at when deciding whether a signal belongs to $\mathfrak{B}$. Denoting by $\mathfrak{B}|\mathcal{S} := \{\mathbf{w}|\mathcal{S} : \mathbf{w} \in \mathfrak{B}\}$ the set of all restrictions to $\mathcal{S}$ of behavior trajectories, the above localization property finds a formal statement as follows.

(O_3) [Local detectability]. *A finite behavior* $\mathfrak{B}$ *is* locally detectable *if there is an integer* $\nu > 0$ *such that every signal* $\mathbf{w}$ *satisfying* $\mathbf{w}|\mathcal{S} \in \mathfrak{B}|\mathcal{S}$ *for every* $\mathcal{S} \subset \mathbb{Z}^n$ *with* $\mathrm{diam}(\mathcal{S}) \leq \nu$ *is in* $\mathfrak{B}$.

PROPOSITION 3.4. *Local detectability and observability are equivalent.*

Proof. Assume that $\mathfrak{B}$ satisfies (O_3) for a certain $\nu > 0$. Given $\mathcal{S} \subset \mathbb{Z}^n$ and $\mathbf{w} \in \mathfrak{B}$ such that $\mathbf{w}|(\mathcal{S}^\nu \setminus \mathcal{S}) = \mathbf{0}$, define $\mathbf{v}$ as follows:

$$\mathbf{v}(\mathbf{h}) = \begin{cases} \mathbf{w}(\mathbf{h}), & \mathbf{h} \in \mathcal{S}^\nu, \\ 0 & \text{elsewhere.} \end{cases} \tag{3.6}$$

Consider any window $\mathcal{W}$, with $\operatorname{diam}(\mathcal{W}) \leq \nu$. If $\mathcal{W}$ is included in $\mathcal{S}^\nu$, then $\mathbf{v}|\mathcal{W} = \mathbf{w}|\mathcal{W} \in \mathfrak{B}|\mathcal{W}$; otherwise we have $\mathcal{W} \cap \mathcal{S} = \emptyset$, and therefore

$$\mathbf{v}|\mathcal{W} = \mathbf{0}|\mathcal{W} \in \mathfrak{B}|\mathcal{W}. \tag{3.7}$$

So, by (O_3), $\mathbf{v}$ is a legal trajectory, and (O_2) holds for $\varepsilon = \nu$.

Conversely, assume that $\mathfrak{B}$ is observable. By Proposition 3.1, there exists an L-polynomial matrix $H \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{p\times q}$ such that $\mathfrak{B} = \ker H^T$. Let $\nu > 0$ be an integer such that $\operatorname{supp}(H^T) \subseteq B(\mathbf{0}, \nu)$, and suppose that $\mathbf{v}$ is any signal satisfying $\mathbf{v}|\mathcal{S} \in \mathfrak{B}|\mathcal{S}$ for every $\mathcal{S} \subset \mathbb{Z}^n$ with $\operatorname{diam}(\mathcal{S}) \leq 2\nu$. If $\bar{\mathcal{S}} := -\operatorname{supp}(H^T)$, the computation of the coefficient of $\mathbf{z}^{\mathbf{k}}$ in $H^T\mathbf{v}$ involves only samples of $\mathbf{v}$ indexed in

$$\mathbf{k} + \bar{\mathcal{S}} := \{\mathbf{h} \in \mathbb{Z}^n : \mathbf{h} - \mathbf{k} \in \bar{\mathcal{S}}\} = -\operatorname{supp}(\mathbf{z}^{\mathbf{k}} H^T). \tag{3.8}$$

On the other hand, since $\operatorname{diam}(\mathbf{k} + \bar{\mathcal{S}}) \leq 2\nu$, there exists $\mathbf{w}_{\mathbf{k}} \in \mathfrak{B}$ which satisfies $\mathbf{v}|(\mathbf{k} + \bar{\mathcal{S}}) = \mathbf{w}_{\mathbf{k}}|(\mathbf{k} + \bar{\mathcal{S}})$, and this result holds for every $\mathbf{k} \in \mathbb{Z}^n$. So, the coefficient of $\mathbf{z}^{\mathbf{k}}$ in $H^T\mathbf{v}$ is the same as in $H^T\mathbf{w}_{\mathbf{k}} \equiv \mathbf{0}$, and hence $\mathbf{v} \in \ker H^T = \mathfrak{B}$. □

The equivalent descriptions of observability given in $(\mathrm{O}_1) \div (\mathrm{O}_3)$ rely on the trajectories' supports, whereas Proposition 3.1 involves parity checks and kernel representations. A different approach to this notion consists of regarding behaviors with p components as elements in the lattice of submodules of $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$, and investigating whether observable elements enjoy some special ordering properties.

In keeping with the same spirit, we may investigate how an observable behavior is affected by certain "extension operations" that merge lattice elements into larger ones. There are essentially two natural ways to perform these extensions: one consists of embedding $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$, and therefore each of its submodules, in the rational vector space $\mathbb{F}(\mathbf{z})^p$, the other of considering $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$ as a submodule of $\mathcal{F}_\infty^p$, the set of nD trajectories with p components, whose supports possibly extend to the whole space $\mathbb{Z}^n$.

Once a behavior $\mathfrak{B}$ with p components is given, in the first case we have to consider the smallest vector subspace of $\mathbb{F}(\mathbf{z})^p$ including $\mathfrak{B}$,

$$\mathfrak{B}_{\mathrm{rat}} := \left\{ \sum_{i=1}^{r} \mathbf{w}_i a_i : \mathbf{w}_i \in \mathfrak{B},\ a_i \in \mathbb{F}(\mathbf{z}),\ r \in \mathbb{N} \right\}, \tag{3.9}$$

and restrict our attention to the submodule $\mathfrak{B}_{\mathrm{rat}} \cap \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$ of finite support sequences. In general, this properly includes $\mathfrak{B}$, and hence is a larger element of the lattice. In the other case, we merge $\mathfrak{B}$ in

$$\mathfrak{B}_\infty := \left\{ \sum_{i=1}^{r} \mathbf{w}_i a_i : \mathbf{w}_i \in \mathfrak{B},\ a_i \in \mathcal{F}_\infty,\ r \in \mathbb{N} \right\}, \tag{3.10}$$

the smallest $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]$-submodule of $\mathcal{F}_\infty^p$ which includes $\mathfrak{B}$. Again, we have to confine ourselves to the set of its finite elements $\mathfrak{B}_\infty \cap \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$, which clearly includes all trajectories of $\mathfrak{B}$.

PROPOSITION 3.5. *Let $\mathfrak{B} \subseteq \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$ be a behavior of rank r. The following statements are equivalent:*

i) $\mathfrak{B}$ *is observable;*
ii) $\mathfrak{B} \equiv \mathfrak{B}_\infty \cap \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$*;*
iii) $\mathfrak{B} \equiv \mathfrak{B}_{\mathrm{rat}} \cap \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$*;*
iv) $\mathfrak{B}$ *is maximal in the set of all submodules of $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$ of rank r;*
v) $s\mathbf{w} \in \mathfrak{B} \Rightarrow \mathbf{w} \in \mathfrak{B}$ *for every $\mathbf{w} \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$ and every nonzero $s \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]$;*
vi) $\mathfrak{B} = \mathfrak{B}^{\perp\perp}$.

Proof. i) ⇒ ii) As $\mathfrak{B}$ is observable, there exists $H \in \mathbb{F}[\mathbf{z},\mathbf{z}^{-1}]^{p\times q}$ such that $\mathfrak{B} = \ker H^T = \{\mathbf{w} \in \mathbb{F}[\mathbf{z},\mathbf{z}^{-1}]^p : H^T\mathbf{w} = \mathbf{0}\}$. If $\mathbf{w} \in \mathfrak{B}_\infty \cap \mathbb{F}[\mathbf{z},\mathbf{z}^{-1}]^p$, then $\mathbf{w} = \sum_i \mathbf{w}_i a_i$, $a_i \in \mathcal{F}_\infty, \mathbf{w}_i \in \mathcal{B}$, and therefore $H^T\mathbf{w} = H^T(\sum_i \mathbf{w}_i a_i) = \sum_i (H^T\mathbf{w}_i)a_i = \mathbf{0}$. Thus $\mathbf{w} \in \ker H^T = \mathfrak{B}$, which implies $\mathfrak{B} \supseteq \mathfrak{B}_\infty \cap \mathbb{F}[\mathbf{z},\mathbf{z}^{-1}]^p$. The reverse inclusion is obvious.

ii) ⇒ iii) This follows immediately from $\mathfrak{B} \subseteq \mathfrak{B}_{\rm rat} \cap \mathbb{F}[\mathbf{z},\mathbf{z}^{-1}]^p \subseteq \mathfrak{B}_\infty \cap \mathbb{F}[\mathbf{z},\mathbf{z}^{-1}]^p$.

iii) ⇒ iv) If $\mathfrak{B}' \supseteq \mathfrak{B}$ and $\text{rank}\mathcal{B}' = \text{rank}\mathfrak{B}$, it is clear that $\mathfrak{B}$ and $\mathfrak{B}'$ generate the same $\mathbb{F}(\mathbf{z})$-subspace of $\mathbb{F}(\mathbf{z})^p$ and, consequently, $\mathfrak{B}_{\rm rat} \cap \mathbb{F}[\mathbf{z},\mathbf{z}^{-1}]^p = \mathfrak{B}'_{\rm rat} \cap \mathbb{F}[\mathbf{z},\mathbf{z}^{-1}]^p$. So, the inclusions chain $\mathfrak{B}_{\rm rat} \cap \mathbb{F}[\mathbf{z},\mathbf{z}^{-1}]^p \supseteq \mathfrak{B}' \supseteq \mathfrak{B}$ and assumption iii) together imply $\mathfrak{B}' = \mathfrak{B}$, which means that $\mathfrak{B}$ is maximal.

iv) ⇒ v) Suppose $s\mathbf{w} \in \mathfrak{B}$, $s \in \mathbb{F}[\mathbf{z},\mathbf{z}^{-1}]$. The behavior $\mathfrak{B}'$ generated by $\mathfrak{B}$ and $\mathbf{w}$ has the same rank of $\mathfrak{B}$, and hence, by the maximality assumption, coincides with $\mathfrak{B}$.

v) ⇒ vi) As $\mathfrak{B}$ and $\mathfrak{B}^{\perp\perp}$ have the same rank r and $\mathfrak{B}^{\perp\perp} \supseteq \mathfrak{B}$, both behaviors generate the same $\mathbb{F}(\mathbf{z})$-subspace of $\mathbb{F}(\mathbf{z})^p$. In particular, $\mathbf{w} \in \mathfrak{B}^{\perp\perp}$ implies $\mathbf{w} \in (\mathfrak{B}^{\perp\perp})_{\rm rat} = \mathfrak{B}_{\rm rat}$. So, there exist $p_i, s_i \in \mathbb{F}[\mathbf{z},\mathbf{z}^{-1}]$ and $\mathbf{w}_i \in \mathfrak{B}$, such that $\mathbf{w} = \sum_{i=1}^r \mathbf{w}_i\, p_i/s_i$, which implies $s\mathbf{w} \in \mathfrak{B}$, where s is the least common multiple (ℓ.c.m.) of the s_i's. By assumption v), also, $\mathbf{w}$ is in $\mathfrak{B}$.

vi) ⇒ i) Since $\mathfrak{B}^\perp$ is a submodule of $\mathbb{F}[\mathbf{z},\mathbf{z}^{-1}]^p$, there exists a suitable L-polynomial matrix H such that $\mathfrak{B}^\perp = \text{Im}H$. So

$$\mathfrak{B}^{\perp\perp} = (\mathfrak{B}^\perp)^\perp = \{\mathbf{w} \in \mathbb{F}[\mathbf{z},\mathbf{z}^{-1}]^p : \mathbf{v}^T\mathbf{w} = \mathbf{0} \forall \mathbf{v} \in \text{Im}H\} = \ker H^T.$$

By assumption vi), $\mathfrak{B}$ coincides with $\ker H^T$ and hence is observable. □

4. Behavior decomposition. In this section we take a first step toward a structural analysis of finite support behaviors. The scope of structure theory is to describe general behaviors in terms of some simpler ones—simpler in some perceptible way, perhaps concreteness, or tractability. Of essential importance, after one has decided upon these simpler objects, is to find a method of passing down to them and to discover how they weave together to yield the general behavior with which we began.

Observable behaviors constitute good candidates for these simpler objects, as each behavior can be embedded into an observable one. In order to represent a general behavior $\mathfrak{B}$, then, we have to slice out of its enveloping observable behavior $\mathcal{B}^{\perp\perp}$ a certain part. This can be done by intersecting $\mathcal{B}^{\perp\perp}$ with a suitable, not necessarily unique, element of a behavior class that exhibits properties which are as far as possible from observability and hence from local detectability. The definition of this class depends on the notion of constrained variables which we now introduce.

DEFINITION 4.1. *Let $\mathfrak{B} \subseteq \mathbb{F}[\mathbf{z},\mathbf{z}^{-1}]^p$ be a finite support behavior and $\{i_1, i_2, \ldots, i_r\}$, $r < p$, a subset of $\{1, 2, \ldots, p\}$. We call $w_{i_1}, w_{i_2}, \ldots, w_{i_r}$* constrained variables *of $\mathfrak{B}$ if for every pair of trajectories $\mathbf{v}, \mathbf{v}' \in \mathfrak{B}$, $v_j = v'_j$ for every $j \notin \{i_1, i_2, \ldots, i_r\}$ implies $\mathbf{v} = \mathbf{v}'$.*

As shown in the following lemma, the maximum number of constrained variables of a behavior $\mathfrak{B}$ in $\mathbb{F}[\mathbf{z},\mathbf{z}^{-1}]^p$ can be expressed in terms of the rank and the number of components of $\mathfrak{B}$.

LEMMA 4.2. *Let $\mathfrak{B} \subseteq \mathbb{F}[\mathbf{z},\mathbf{z}^{-1}]^p$ be a behavior of rank r. The maximum number of constrained variables of $\mathfrak{B}$ is $p - r$.*

Proof. Let $G \in \mathbb{F}[\mathbf{z},\mathbf{z}^{-1}]^{p\times m}$ be a generator matrix of $\mathfrak{B}$ and suppose, for sake of simplicity, that the first r rows of G are linearly independent, so that in

$$G = \begin{bmatrix} G_1 \\ G_2 \end{bmatrix} \begin{matrix} \}r \\ \}p-r \end{matrix},$$

G_1 has full row rank. The components w_i, $i = r+1, r+2, \ldots, n$, are constrained variables. If not, there would be a trajectory $\mathbf{w} = \left[\begin{smallmatrix} \mathbf{0} \\ \mathbf{w}_2 \end{smallmatrix}\right]$ in $\mathfrak{B}$, with $\mathbf{w}_2 \neq 0$, and hence an L-polynomial vector $\mathbf{u} \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^m$ s.t. $\left[\begin{smallmatrix} G_1 \\ G_2 \end{smallmatrix}\right]\mathbf{u} = \left[\begin{smallmatrix} \mathbf{0} \\ \mathbf{w}_2 \end{smallmatrix}\right]$. This is a contradiction, however, because

$$\text{rank } G_1 = \text{rank} \begin{bmatrix} G_1 \\ G_2 \end{bmatrix} \qquad \Rightarrow \qquad \ker G_1 = \ker \begin{bmatrix} G_1 \\ G_2 \end{bmatrix}.$$

It remains to prove that the number of constrained variables cannot exceed $p - r$. Suppose, instead, that $k > p - r$ variables of $\mathfrak{B}$, say the last k, are constrained, and partition the generator matrix G into

$$G = \begin{bmatrix} \hat{G}_1 \\ \hat{G}_2 \end{bmatrix} \begin{matrix} \}p-k \\ \}k \end{matrix}.$$

As $r = \text{rank } G > \text{rank}\hat{G}_1$, $\ker\hat{G}_1$ properly includes $\ker G$. Consequently, there exists $\mathbf{u}$ s.t. $\hat{G}_2\mathbf{u} \neq \mathbf{0}$ and both $\left[\begin{smallmatrix} \mathbf{0} \\ \mathbf{0} \end{smallmatrix}\right]$ and $\left[\begin{smallmatrix} \mathbf{0} \\ \hat{G}_2\mathbf{u} \end{smallmatrix}\right], \hat{G}_2\mathbf{u} \neq \mathbf{0}$, are in $\mathfrak{B}$, which contradicts the assumption that the last k components are constrained. □

A behavior $\mathfrak{B}$ devoid of constrained variables exhibits the very peculiar feature that for every finite set $\mathcal{S} \subset \mathbb{Z}^n$, $\mathfrak{B}|\mathcal{S}$ coincides with $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p \mid \mathcal{S}$. This property, which appears somehow opposite to local detectability, makes it impossible to recognize the trajectories of $\mathfrak{B}$ by resorting to a local checking procedure.

(LU) [Local undetectability]. *A behavior* $\mathfrak{B} \subseteq \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$ *is* locally undetectable *if there exists* $\delta > 0$ *s.t. for every sequence* $\mathbf{v} \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$ *and every set* $\mathcal{S} \subset \mathbb{Z}^n$, *a trajectory* $\mathbf{w} \in \mathfrak{B}$ *can be found satisfying*

$$\mathbf{w}|\mathcal{S} = \mathbf{v}|\mathcal{S} \qquad \textit{and} \qquad \text{supp}(\mathbf{w}) \subseteq \mathcal{S}^\delta. \tag{4.1}$$

PROPOSITION 4.3. *Let* $\mathfrak{B} \subseteq \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$ *be a finite support behavior. The following facts are equivalent:*

i) $\mathfrak{B}$ *is devoid of constrained variables;*

ii) $\mathfrak{B}$ *is the image of some L-polynomial matrix* $G \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{p\times m}$ *with rank* p*;*

iii) $\mathfrak{B}$ *is locally undetectable.*

Proof. i) $\Leftrightarrow$ ii) The proof is immediate from Lemma 4.1.

ii) $\Rightarrow$ iii) Let $\mathbf{v}$ be an arbitrary sequence in $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$ and $\mathcal{S}$ a finite set. If $\mathfrak{B} = \text{Im}G$, for some $G \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{p\times m}$ of rank p, $\mathbf{v}$ can be obtained as the image of some rational vector $\mathbf{u} \in \mathbb{F}(\mathbf{z})^p$, i.e., $\mathbf{v} = G\mathbf{u}$. Consider a power series expansion of $\mathbf{u}$ with support in a suitable cone of $\mathbb{Z}^n$, and introduce the finite sequence

$$\bar{\mathbf{u}}(\mathbf{h}) := \begin{cases} \mathbf{u}(\mathbf{h}), & \mathbf{h} \in \mathcal{S}^\varepsilon, \\ \mathbf{0} & \text{elsewhere,} \end{cases}$$

where ε is the radius of a ball centered in the origin and including the support of G. The behavior sequence $\bar{\mathbf{v}} := G\bar{\mathbf{u}}$ coincides with $\mathbf{v}$ on $\mathcal{S}$ and has support included in $\mathcal{S}^{2\varepsilon}$. So, (4.1) holds with $\delta = 2\varepsilon$.

iii) $\Rightarrow$ ii) Suppose that $\mathfrak{B}$ is locally undetectable and assume, by contradiction, that $\mathfrak{B} = \text{Im}G$, for some $G \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{p\times m}$ with rank less than p. Then there exists a nonzero L-polynomial vector $\mathbf{h} \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$ satisfying $\mathbf{h}^T G = 0$. Consider a sequence $\mathbf{v} \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$ s.t. $\mathbf{h}^T\mathbf{v} \neq 0$ and a set $\mathcal{T} \subset \mathbb{Z}^n$ which includes both $\text{supp}(\mathbf{v})$ and $\text{supp}(\mathbf{h}^T\mathbf{v})$, and define $\mathcal{S} := \mathcal{T}^\rho$, where ρ is the radius of a ball, centered in the origin, which includes $\text{supp}(\mathbf{h})$. If property (LU) holds for some $\delta > 0$, there is a trajectory $\mathbf{w} \in \mathfrak{B}$ that can be expressed as $\mathbf{w} = \mathbf{v} + \mathbf{r}$ for some $\mathbf{r}$ with support in $\mathcal{S}^\delta \setminus \mathcal{S}$ (see Fig. 4.1). As $\mathbf{w} = G\mathbf{a}$, for some $\mathbf{a} \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^m$, it follows that

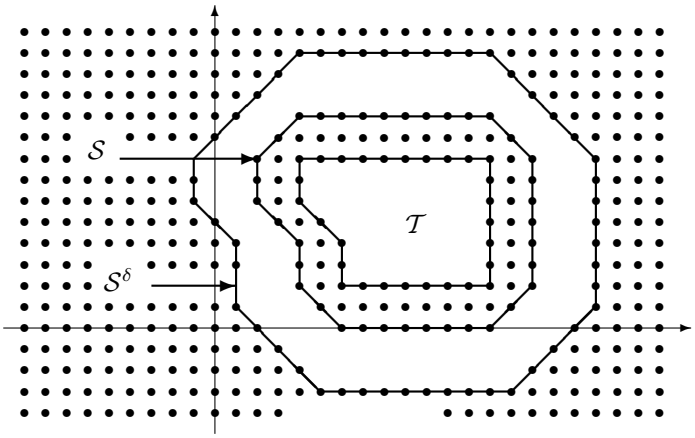

FIG. 4.1.

$$0 = \mathbf{h}^T G\mathbf{a} = \mathbf{h}^T\mathbf{w} = \mathbf{h}^T\mathbf{v} + \mathbf{h}^T\mathbf{r}.$$

This is not possible, however, since $\mathcal{T}$ includes the support of $\mathbf{h}^T\mathbf{v}$ without intersecting $\text{supp}(\mathbf{h}^T\mathbf{r})$. □

PROPOSITION 4.4. *For every behavior $\mathfrak{B} \subseteq \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$ there exist an observable behavior $\mathfrak{B}_0$ and a locally undetectable behavior $\mathfrak{B}_{\text{lu}}$ in $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$ s.t.*

$$\mathfrak{B} = \mathfrak{B}_0 \cap \mathfrak{B}_{\text{lu}}. \tag{4.2}$$

Moreover, $\mathfrak{B}_0$ is uniquely determined as $\mathfrak{B}^{\perp\perp}$, the smallest observable behavior including $\mathfrak{B}$.

Proof. Let $\mathfrak{B} = \text{Im}G$ and $\mathfrak{B}_0 := \mathcal{B}^{\perp\perp} = \ker H^T$. Clearly, $\mathfrak{B}_0$ is an observable behavior including $\mathfrak{B}$. If G has rank r, we can assume, for the sake of simplicity, that its first r rows are linearly independent. So, G can be partitioned as

$$G = \begin{bmatrix} G_1 \\ G_2 \end{bmatrix} \begin{matrix} \}r \\ \}p-r \end{matrix},$$

where G_1 is a full rank matrix. Let

$$G_{\text{lu}} := \begin{bmatrix} G_1 & 0 \\ 0 & I_{p-r} \end{bmatrix}$$

and $\mathfrak{B}_{\text{lu}} := \text{Im}G_{\text{lu}}$. Clearly, $\mathfrak{B}_{\text{lu}}$ is a locally undetectable behavior, and it includes $\mathfrak{B}$ as

$$G = \begin{bmatrix} G_1 \\ G_2 \end{bmatrix} = \begin{bmatrix} G_1 & 0 \\ 0 & I_{p-r} \end{bmatrix} \begin{bmatrix} I \\ G_2 \end{bmatrix}.$$

So, one obviously gets $\mathfrak{B} \subset \mathfrak{B}_0 \cap \mathfrak{B}_{\text{lu}}$.

To prove the reverse inclusion, consider $\mathbf{w} \in \mathfrak{B}_0 \cap \mathcal{B}_{\text{lu}}$. Clearly, $\mathbf{w}$ satisfies $H^T\mathbf{w} = 0$ and can be expressed as

$$\mathbf{w} = \begin{bmatrix} G_1\mathbf{u}_1 \\ \mathbf{u}_2 \end{bmatrix}.$$

Factoring G into the product of a (full column rank) right factor prime matrix $\bar{G}$ and a full row rank rational matrix Q [17], one gets

$$\begin{bmatrix} G_1 \\ G_2 \end{bmatrix} = G = \bar{G}Q = \begin{bmatrix} \bar{G}_1 \\ \bar{G}_2 \end{bmatrix} Q.$$

As the columns of $\bar{G}$ generate the $\mathbb{F}(\mathbf{z})$-vector space orthogonal to the rows of H^T, there exists $\mathbf{v} \in \mathbb{F}(\mathbf{z})^r$ s.t. $\mathbf{w} = \bar{G}\mathbf{v}$. But then $\bar{G}_1\mathbf{v} = G_1\mathbf{u}_1 = \bar{G}_1 Q\mathbf{u}_1$ implies $\mathbf{v} = Q\mathbf{u}_1$, and thus $\mathbf{u}_2 = \bar{G}_2\mathbf{v} = \bar{G}_2 Q\mathbf{u}_1$ and

$$\mathbf{w} = \begin{bmatrix} G_1\mathbf{u}_1 \\ \mathbf{u}_2 \end{bmatrix} = \begin{bmatrix} \bar{G}_1 \\ \bar{G}_2 \end{bmatrix} Q\mathbf{u}_1 = G\mathbf{u}_1.$$

This implies that $\mathbf{w}$ is in $\mathfrak{B}$.

It remains to prove the uniqueness of $\mathfrak{B}_0$ in the above representation. To this end we need the following technical lemma.

LEMMA 4.5. *Let $\mathfrak{B}_i \subset \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$, $i = 1, 2$, be finite support behaviors with p components. If $\mathfrak{B} = \mathfrak{B}_1 \cap \mathfrak{B}_2$, then*

$$\mathfrak{B}_{\text{rat}} = (\mathfrak{B}_1)_{\text{rat}} \cap (\mathfrak{B}_2)_{\text{rat}}. \tag{4.3}$$

Proof. Let G, G_1, and G_2 be generator matrices of $\mathfrak{B}$, $\mathcal{B}_1$ and $\mathfrak{B}_2$, respectively. Clearly, $\mathfrak{B}_{\text{rat}} = \text{Im}_{\mathbb{F}(\mathbf{z})} G := \{\mathbf{v} \in \mathbb{F}(\mathbf{z})^p : \mathbf{v} = G\mathbf{u}, \mathbf{u} \text{ rational}\}$, and similarly, $(\mathfrak{B}_i)_{\text{rat}} = \text{Im}_{\mathbb{F}(\mathbf{z})} G_i$, $i = 1, 2$. Therefore, $\mathbf{v} \in \mathfrak{B}_{\text{rat}}$ implies $\mathbf{v} = G\mathbf{n}/d$, for some L-polynomial vector $\mathbf{n}$ and some L-polynomial d, and hence $d\mathbf{v} \in \mathfrak{B} = \mathfrak{B}_1 \cap \mathfrak{B}_2$. But then $d\mathbf{v} = G_1\mathbf{u}_1 = G_2\mathbf{u}_2$ for suitable L-polynomial vectors $\mathbf{u}_1$ and $\mathbf{u}_2$, which implies $\mathbf{v} \in (\mathfrak{B}_1)_{\text{rat}} \cap (\mathfrak{B}_2)_{\text{rat}}$.

Conversely, if $\mathbf{v} \in (\mathfrak{B}_1)_{\text{rat}} \cap (\mathfrak{B}_2)_{\text{rat}}$, it can be expressed as $\mathbf{v} = G_1\mathbf{n_1}/d_1 = G_2\mathbf{n_2}/d_2$, for suitable L-polynomial vectors $\mathbf{n}_i$ and L-polynomials d_i, $i = 1, 2$. If $d := \ell\text{.c.m.}\ (d_1, d_2)$, it is clear that $d\mathbf{v}$ is an element of $\mathfrak{B}_1 \cap \mathfrak{B}_2$, and hence of $\mathfrak{B}$. Consequently, $\mathbf{v}$ is in $\mathfrak{B}_{\text{rat}}$. ∎

We now return to the proof of the uniqueness of $\mathfrak{B}_0$. Suppose, by contradiction, that $\mathfrak{B} = \hat{\mathfrak{B}}_0 \cap \hat{\mathfrak{B}_{\text{lu}}}$ for some observable behavior $\hat{\mathfrak{B}}_0 \neq \mathfrak{B}^{\perp\perp}$ and some locally undetectable behavior $\hat{\mathfrak{B}_{\text{lu}}}$. As $\mathfrak{B}^{\perp\perp}$ is the smallest observable behavior including $\mathfrak{B}$ and is maximal in the class of modules of rank r, $\hat{\mathfrak{B}}_0$ must have rank greater than r. Consequently, $(\hat{\mathfrak{B}}_0)_{\text{rat}} \supsetneq (\mathfrak{B}^{\perp\perp})_{\text{rat}}$. On the other hand

$$(\mathfrak{B}_{\text{lu}})_{\text{rat}} = (\hat{\mathfrak{B}_{\text{lu}}})_{\text{rat}} = \mathbb{F}(\mathbf{z})^p,$$

and therefore $(\mathfrak{B}^{\perp\perp})_{\text{rat}} \cap (\mathfrak{B}_{\text{lu}})_{\text{rat}} = (\mathfrak{B}^{\perp\perp})_{\text{rat}} \subsetneq (\hat{\mathfrak{B}}_0)_{\text{rat}} = (\hat{\mathfrak{B}}_0)_{\text{rat}} \cap (\hat{\mathfrak{B}_{\text{lu}}})_{\text{rat}}$. But this is not possible, as $\mathfrak{B}^{\perp\perp} \cap \mathfrak{B}_{\text{lu}} = \mathfrak{B} = \hat{\mathfrak{B}}_0 \cap \hat{\mathfrak{B}_{\text{lu}}}$ should imply, by the above lemma, $(\mathfrak{B}^{\perp\perp})_{\text{rat}} \cap (\mathfrak{B}_{\text{lu}})_{\text{rat}} = (\hat{\mathfrak{B}}_0)_{\text{rat}} \cap (\hat{\mathfrak{B}_{\text{lu}}})_{\text{rat}}$. ∎

5. Input-output description and trajectory generation. The analysis we carried out in the previous sections focused on the properties of behavior trajectories without concern for the way they are generated. Once a behavior $\mathfrak{B}$ is represented via a finite set of generators $\mathbf{g}_1, \mathbf{g}_2, \ldots, \mathbf{g}_m$, however, it is natural to look at $G := [\mathbf{g}_1\ \mathbf{g}_2\ \cdots\ \mathbf{g}_m]$ as a transfer matrix, and hence to consider $\mathfrak{B}$ as the image of an input-output map acting on $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^m$. This point of view seems particularly appropriate when $\mathfrak{B}$ is a convolutional code [4, 16], as it is customary to regard it as the result of an encoding process, and, consequently, its trajectories (codewords)

as the outputs of a dynamical encoder. In a wider context, the trajectories of $\mathfrak{B}$ are obtained from certain processing operations applied to multidimensional data, or from different transformations (desired or not) performed on the original signal. In both cases the analysis of the algebraic properties of the generator matrices makes possible a detailed knowledge of the behavior structure.

When an input-output description is adopted, it is often imperative to associate trajectories of $\mathfrak{B}$ and input sequences bijectively. In data transmission the meaning of this requirement is clear, as input signals represent information messages to be retrieved from the received codewords, and an unambiguous decision at the decoding stage is possible when each codeword encodes a unique information sequence. This amounts to saying that the *encoder* G induces a 1-1 map.

Throughout this section we steadily assume that $\mathfrak{B}$ has a full column rank generator matrix G, and hence is free. Under this assumption, G admits (possibly infinitely many) rational left inverses G^{-1}. Each of them, when applied to a behavior trajectory $\mathbf{w} = G\mathbf{u}$, uniquely retrieves the (finite) input sequence $\mathbf{u}$. When $\mathfrak{B}$ represents a finite convolutional code, this implies that every estimate $\hat{\mathbf{w}} \in \mathfrak{B}$ of the codeword $\mathbf{w}$ produces a finite error $\mathbf{e_u} := \mathbf{u} - G^{-1}\hat{\mathbf{w}} = G^{-1}(\mathbf{w} - \hat{\mathbf{w}})$ in reconstructing the information sequence $\mathbf{u}$. Consequently, when a codeword estimator is available, no catastrophic error can arise [4, 6]. However, if we apply the "decoder" G^{-1} directly to the noisy sequence $\mathbf{v} = \mathbf{w} + \mathbf{r}$, as $\mathbf{r}$ generally is not an element of $\mathfrak{B}$, the decoding algorithm possibly gives an infinite support sequence, which differs from the correct input in infinitely many points and clearly is not even an admissible information sequence. This drawback can be avoided if and only if G^{-1} is an L-polynomial matrix.

Proposition 5.1 below provides equivalent conditions for the existence of an L-polynomial inverse, and in particular shows that such an inverse exists if and only if G is left zero prime.

DEFINITION 5.1. *Let G be in $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{p\times m}$ and $\hat{G} = \mathbf{z^h}G = z_1^{h_1}\cdots z_n^{h_n}G$ in $\mathbb{F}[\mathbf{z}]^{p\times m}$ for some $\mathbf{h} \in \mathbb{N}^n$. If $\mathbb{K}$ denotes the algebraic closure of $\mathbb{F}$, the* L-variety $\mathcal{V}^L(G)$ of the maximal order minors of G *is the algebraic set*

$$\mathcal{V}^L(G) := \mathcal{V}(\hat{G}) \setminus \left\{(k_1, k_2, \ldots, k_n) : k_i \in \mathbb{K},\ \prod_i k_i = 0\right\}, \tag{5.1}$$

where $\mathcal{V}(\hat{G})$ denotes the variety (in $\mathbb{K}$) of the maximal order minors of $\hat{G}$.

The above definition is well posed, as (5.1) does not depend on the choice of $\hat{G}$.

PROPOSITION 5.2. *Let G be a $p \times m$ L-polynomial matrix. The following statements are equivalent:*

i) *G is rzp;*

ii) *there exists an L-polynomial matrix $P \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{m\times p}$ such that $PG = I_m$;*

iii) *$\mathcal{V}^L(G)$ is empty;*

iv) *Im $G^T = \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^m$.*

Proof. i) $\Rightarrow$ ii) Let $m_i(G)$ denote the ith maximal order minor of G, $i = 1, 2, \ldots, \binom{p}{m}$. By the zero primeness assumption, there exist L-polynomials $h_i \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]$ such that $\sum_i h_i m_i(G) = 1$. If S_i is the $m \times p$ matrix which selects in G the m rows corresponding to $m_i(G)$, from $I_m = \sum_i h_i m_i(G) I_m = \sum_i h_i\big(\mathrm{adj}(S_iG)\big)(S_iG)$, we find that $P := \sum_i h_i\big(\mathrm{adj}(S_iG)\big)S_i$ is a left inverse of G with elements in $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]$.

ii) $\Rightarrow$ iii) Let $\mathbf{z^r} = z_1^{r_1}\cdots z_n^{r_n}$ be a suitable term such that $\hat{P} = \mathbf{z^r}P$ is in $\mathbb{F}[\mathbf{z}]^{m\times p}$. By applying the Binet–Cauchy formula [9] to equation $\hat{P}\hat{G} = z_1^{h_1+r_1}\cdots z_n^{h_n+r_n} I_m$, we

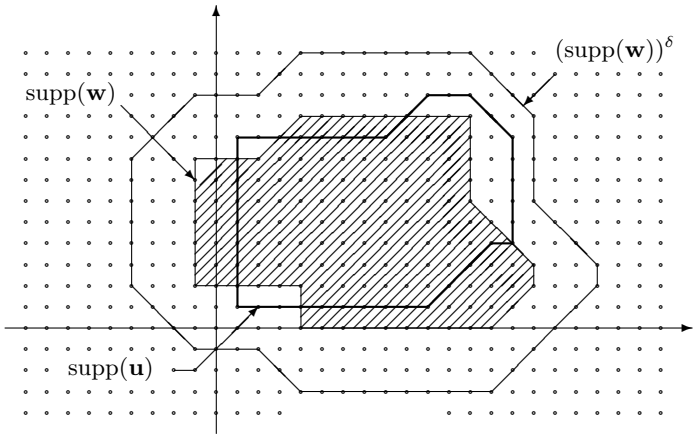

FIG. 5.1.

get

$$\sum_i m_i(\hat{P}) m_i(\hat{G}) = z_1^{m(h_1+r_1)} z_2^{m(h_2+r_2)} \cdots z_n^{m(h_n+r_n)}, \tag{5.2}$$

where $m_i(\hat{P})$ and $m_i(\hat{G})$ are corresponding maximal order minors of $\hat{P}$ and $\hat{G}$, respectively. Then $\mathcal{V}(\hat{G})$ is included in the variety of $z_1^{m(h_1+r_1)} z_2^{m(h_2+r_2)} \cdots z_n^{m(h_n+r_n)}$, which is a subset of $\mathcal{K} := \{(k_1, k_2, \ldots, k_n) : k_i \in \mathbb{K},\ \prod_i k_i = 0\}$.

iii) $\Rightarrow$ i) As $\mathcal{K}$ is the variety of $\mathbf{z} = z_1 \cdots z_n$, by assumption iii), $\mathcal{V}(\hat{G})$ is included in the variety of $\mathbf{z}$. So, by Hilbert's Nullstellensatz [11], an integer $r > 0$ exists such that $z_1^r \cdots z_n^r$ belongs to the ideal generated in $\mathbb{F}[\mathbf{z}]$ by the maximal order minors of $\hat{G}$:

$$z_1^r \cdots z_n^r = \sum_i \bar{h}_i\ m_i(\hat{G}), \qquad \bar{h}_i \in \mathbb{F}[\mathbf{z}]. \tag{5.3}$$

As each maximal order minor $m_i(\hat{G})$ differs from $m_i(G)$ in a unit of $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]$, the zero primeness of G easily follows after dividing both members of (5.3) by $z_1^r \cdots z_n^r$.

ii) $\Leftrightarrow$ iv) This is obvious. □

When the generator matrix G has an L-polynomial inverse, a uniform bound can be found on the support of the input sequences which correspond to the behavior trajectories. Actually, if P is such an inverse, $\mathbf{w} \in \mathfrak{B}$ is generated by the input signal $\mathbf{u} = P\mathbf{w}$ whose support cannot exceed "too much" that of $\mathbf{w}$ (see Fig. 5.1). This feature, which we will refer to as the *wrapping input property*, is quite appealing, as the mere recognition of the support of a trajectory allows the derivation of a uniformly tight bound on the support of the corresponding input sequence. In particular, in the context of finite convolutional codes, the above property guarantees that small errors in the codeword estimate reflect into small errors in the information sequence reconstruction.

(WI) [Wrapping input property]. *A finite behavior* $\mathfrak{B}$ *has the* wrapping input property *if there exist a full column rank generator matrix* G *and a positive integer* δ *such that* $\mathbf{w} = G\mathbf{u}$ *implies*

$$\operatorname{supp}(\mathbf{u}) \subseteq \big(\operatorname{supp}(\mathbf{w})\big)^{\delta}. \tag{5.4}$$

It is worthwhile to notice that property (WI) does not depend on the particular full column rank generator matrix of $\mathfrak{B}$ we are considering. In fact, it is easily seen that if (5.4) holds for any one of these generator matrices, then it holds for all of them (in general, for a different δ). On the other hand, when noninjective generator matrices of $\mathfrak{B}$ are considered and the uniqueness of the input sequence producing a given trajectory is lost, a particular input can be found whose support satisfies (5.4), as shown by the following proposition.

PROPOSITION 5.3. *Assume that $\mathfrak{B}$ has the (WI) property for some full column rank matrix G and some integer $\delta > 0$. Then, for every generator matrix $\bar{G} \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{p\times q}$, an integer $\bar{\delta} > 0$ can be found s.t. each trajectory $\mathbf{w} \in \mathfrak{B}$ can be expressed as $\mathbf{w} = \bar{G}\bar{\mathbf{u}}$ for some input $\bar{\mathbf{u}}$ with* $\operatorname{supp}(\bar{\mathbf{u}}) \subseteq \big(\operatorname{supp}(\mathbf{w})\big)^{\bar{\delta}}$.

Proof. Since G and $\bar{G}$ are generator matrices of the same behavior, there exists a full column rank L-polynomial matrix Q such that $G = \bar{G}Q$. Let τ be the radius of a ball, with center in the origin, including $\operatorname{supp}(Q)$, and consider $\mathbf{w} \in \mathfrak{B}$. By property (WI), there is $\mathbf{u}$ such that $\mathbf{w} = G\mathbf{u}$ and $\operatorname{supp}(\mathbf{u}) \subseteq \big(\operatorname{supp}(\mathbf{w})\big)^{\delta}$. So, $\bar{\mathbf{u}} := Q\mathbf{u}$ satisfies $\mathbf{w} = G\mathbf{u} = \bar{G}Q\mathbf{u} = G\bar{\mathbf{u}}$, and $\operatorname{supp}(\bar{\mathbf{u}}) = \operatorname{supp}(Q\mathbf{u}) \subseteq \big(\operatorname{supp}(\mathbf{u})\big)^{\tau} \subseteq \big(\operatorname{supp}(\mathbf{w})\big)^{\tau+\delta}$. Consequently, the proposition holds for $\bar{\delta} = \tau + \delta$. □

Interestingly enough, the zero primeness of G is not only sufficient but also necessary for property (WI). So, free behaviors satisfying property (WI) can be identified with behaviors that are generated by ℓ zero prime matrices.

PROPOSITION 5.4. *A finite behavior $\mathfrak{B}$ has the (WI) property if and only if it admits an rzp generator matrix.*

Proof. The "if" part has already been proved. To show the converse, we need the following characterization of rZP matrices.

LEMMA 5.5. *Let $G \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{p\times q}$ be a Laurent polynomial matrix and denote by $\mathbb{F}[[\mathbf{z}, \mathbf{z}^{-1}]]$ the space of bilateral scalar formal power series in the indeterminates $z_1, \ldots, z_n$. Then G is rzp if and only if*

$$G\mathbf{s} = \mathbf{0} \tag{5.5}$$

for some sequence $\mathbf{s} \in \mathbb{F}[[\mathbf{z}, \mathbf{z}^{-1}]]^q$ implies $\mathbf{s} = \mathbf{0}$.

Proof. Introduce in $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^q \times \mathbb{F}[[\mathbf{z}, \mathbf{z}^{-1}]]^q$ the following nondegenerate bilinear form

$$\langle \cdot, \cdot \rangle_q : \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^q \times \mathbb{F}[[\mathbf{z}, \mathbf{z}^{-1}]]^q \to \mathbb{F}$$

defined by : $\langle \mathbf{u}, \mathbf{v} \rangle_q = (\mathbf{u}\mathbf{v}^T, 1) = \sum_{\mathbf{h}\in\mathbb{Z}^n} u(\mathbf{h})v^T(-\mathbf{h})$.

With this position, the space $\mathbb{F}[[\mathbf{z}, \mathbf{z}^{-1}]]^q$ is naturally viewed as $L(\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^q)$, the algebraic dual of $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^q$ [10, 16]. In fact, we can associate with every $\mathbf{v} \in \mathbb{F}[[\mathbf{z}, \mathbf{z}^{-1}]]^q$ the linear functional on $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^q$ defined by

$$f_{\mathbf{v}}(\cdot) = \langle \cdot, \mathbf{v} \rangle_q, \tag{5.6}$$

and, conversely, every linear functional on $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^q$ can be represented as in (5.6) for an appropriate choice of $\mathbf{v} \in \mathbb{F}[[\mathbf{z}, \mathbf{z}^{-1}]]^m$. Upon identifying $\mathbb{F}[[\mathbf{z}, \mathbf{z}^{-1}]]^q$ with $L(\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^q)$, we can resort to the well-known relation

$$\begin{aligned} \ker_\infty G &:= \{\mathbf{s} \in \mathbb{F}[[\mathbf{z}, \mathbf{z}^{-1}]]^q : G\mathbf{s} = \mathbf{0}\} \\ &\equiv \{\mathbf{s} \in \mathbb{F}[[\mathbf{z}, \mathbf{z}^{-1}]]^q : \mathbf{s}^T\mathbf{v} = \mathbf{0}\ \forall \mathbf{v} \in \operatorname{Im}G^T\} =: (\operatorname{Im}G^T)^{\perp\!\!\!\perp}. \end{aligned}$$

If $\operatorname{Im}G^T = \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^q$, all canonical vectors $\mathbf{e}_i$ and all monomial vectors $z_1^h z_2^k \mathbf{e}_i$ belong to $\operatorname{Im}G^T$, and therefore $\mathbf{s} \in (\operatorname{Im}G^T)^{\perp\!\!\!\perp}$ implies $\langle z_1^h z_2^k \mathbf{e}_i, \mathbf{s} \rangle_q = 0$, $h, k \in \mathbb{Z}$, and $i =$

$1, 2, \ldots, q$, and hence $\mathbf{s} = 0$. So, it is clear that $\ker_\infty G = \{\mathbf{0}\}$ if and only if $\mathrm{Im}G^T = \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^q$, and this happens if and only if G is rZP. □

Suppose, now, that $\mathfrak{B}$ has the (WI) property with respect to some positive integer δ and some full column rank generator matrix G. We aim to prove that G is rZP. If not, there would be a sequence $\mathbf{s} \in \mathbb{F}[[\mathbf{z}, \mathbf{z}^{-1}]]^q$ satisfying (5.5). Let η be the radius of a ball, $B(\mathbf{0}, \eta)$, centered in the origin and including $\mathrm{supp}(G)$. If $\mathbf{k}$ is an element of $\mathrm{supp}(\mathbf{s})$, the finite support sequence

$$\mathbf{u}(\mathbf{h}) := \begin{cases} \mathbf{s}(\mathbf{h}), & \mathbf{h} \in B(\mathbf{k}, 2\delta + \eta), \\ \mathbf{0} & \text{elsewhere} \end{cases}$$

generates a behavior sequence $\mathbf{w} := G\mathbf{u}$ that does not fulfill (5.4). □

The (WI) property introduces very severe constraints on the supports of the input sequences which produce the behavior trajectories. So, it is not unexpected that it reflects into the strongest primeness property a generator matrix can be endowed with, i.e., zero primeness. Obviously, weaker requirements on the supports of the generating sequences correspond to weaker primeness properties of G. In particular, minor primeness guarantees that the signal producing a behavior sequence $\mathbf{w}$ exhibits a support which slightly exceeds a parallelepipedal box including $\mathrm{supp}(\mathbf{w})$, whereas variety primeness ensures that each projection of $\mathbf{u}$ and $\mathbf{w}$ onto a coordinate hyperplane gives a pair of signals with the (WI) property.

A standpoint which proves to be quite fruitful in analyzing the above-mentioned connections is to regard an arbitrary finite support sequence $\mathbf{w} \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^p$ as a vector with entries in certain L-polynomial rings that properly include $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]$. Actually, $\mathbf{w}$ can be thought of as an element of $\mathbb{F}(z_i^c)[z_i, z_i^{-1}] := \mathbb{F}(z_1, \ldots, z_{i-1}, z_{i+1}, \ldots, z_n)[z_i, z_i^{-1}]$,

$$\mathbf{w} = \sum_{h_i \in \mathbb{Z}} \mathbf{w}_{h_i}(z_i^c) z_i^{h_i},$$

or as an element of $\mathbb{F}(z_i)[z_i^c, (z_i^c)^{-1}] := \mathbb{F}(z_i)[z_1, \ldots, z_{i-1}, z_{i+1}, \ldots, z_n, z_1^{-1}, \ldots, z_{i-1}^{-1}, z_{i+1}^{-1}, \ldots, z_n^{-1}]$

$$\mathbf{w} = \sum_{h_1, \ldots, h_{i-1}, h_{i+1}, \ldots, h_n \in \mathbb{Z}} \mathbf{w}_{h_1, \ldots, h_{i-1}, h_{i+1}, \ldots, h_n}(z_i) z_1^{h_1} \cdots z_{i-1}^{h_{i-1}} z_{i+1}^{h_{i+1}} \cdots z_n^{h_n}.$$

Correspondingly, we are led to introduce the following support sets:

$$\mathrm{supp}_i(\mathbf{w}) := \{(h_1, \ldots, h_n) \in \mathbb{Z}^n : \mathbf{w}_{h_i}(z_i^c) \neq 0\},$$
$$\mathrm{supp}_{i^c}(\mathbf{w}) := \{(h_1, \ldots, h_n) \in \mathbb{Z}^n : \mathbf{w}_{h_1, \ldots, h_{i-1}, h_{i+1}, \ldots, h_n}(z_i) \neq 0\}.$$

LEMMA 5.6 (see [17]). *Let $G \in \mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]^{p \times m}$ be a full column rank matrix. Then*

i) *G is rMP if and only if G is right (zero) prime in $\mathbb{F}(z_i^c)[z_i, z_i^{-1}]$ for every $i = 1, 2, \ldots, n$;*

ii) *G is rVP if and only if G is rZP in $\mathbb{F}(z_i)[z_i^c, (z_i^c)^{-1}]$ for every $i = 1, 2, \ldots, n$.*

PROPOSITION 5.7. *Let $\mathfrak{B}$ be a finite behavior. Then*

i) *$\mathfrak{B}$ has a rMP generator matrix if and only if there exist an integer $\delta > 0$ and a full column rank generator matrix G, such that $\mathbf{w} \in \mathfrak{B}$ implies $\mathbf{w} = G\mathbf{u}$ with*

$$\mathrm{supp}(\mathbf{u}) \subseteq \bigcap_{i=1}^{n} \Big(\mathrm{supp}_i(\mathbf{w})\Big)^{\delta}; \tag{5.7}$$

ii) $\mathfrak{B}$ *has a rVP generator matrix if and only if there exist an integer* $\delta > 0$ *and a full column rank generator matrix* G*, such that* $\mathbf{w} \in \mathfrak{B}$ *implies* $\mathbf{w} = G\mathbf{u}$ *with*

$$\operatorname{supp}(\mathbf{u}) \subseteq \bigcap_{i=1}^{n} \Big(\operatorname{supp}_{i^c}(\mathbf{w})\Big)^{\delta}. \tag{5.8}$$

Proof. i) It is easy to realize that condition (5.7) is equivalent to the set of conditions $\operatorname{supp}_i(\mathbf{u}) \subseteq (\operatorname{supp}_i(\mathbf{w}))^{\delta}$, $i = 1, 2, \ldots, n$. These hold true if and only if G is an rZP matrix in $\mathbb{F}(z_i^c)[z_i, z_i^{-1}]$ for every $i = 1, 2, \ldots, n$; namely, G is rMP in $\mathbb{F}[\mathbf{z}, \mathbf{z}^{-1}]$.

ii) The result is shown along the same lines as i), after replacing $\mathbb{F}(z_i^c)[z_i, z_i^{-1}]$ with $\mathbb{F}(z_i)[z_i^c, (z_i^c)^{-1}]$. □

6. Conclusions. In this paper we have focused on some features of finite support nD behaviors which are relevant for multidimensional signal generation and recognition. Two opposite situations have been considered, namely the case when a local testing procedure suffices to decide whether a given signal belongs to the behavior, and the case when every finite signal can be completed into a legal trajectory, and hence behavior sequences cannot be recognized by means of local checks.

Observable and locally undetectable behaviors, which correspond to these two situations, have been characterized in terms of both their internal properties and their polynomial matrix descriptions. Any finite support behavior, being the intersection of an observable and an unconstrained behavior, exhibits intermediate properties.

Finally, adopting an input-output point of view, the connections between the support of a behavior trajectory and that of its generating input have been enlightened.

Acknowledgments. The authors are indebted to S. Zampieri for shortening the proof of Proposition 5.3.

STABILITY AND EULER APPROXIMATION OF ONE-SIDED LIPSCHITZ DIFFERENTIAL INCLUSIONS*

TZANKO DONCHEV† AND ELZA FARKHI‡

Abstract. Ordinary differential and functional-differential inclusions with compact right-hand sides are considered. Stability theorems of Filippov's type in the convex and nonconvex case are proved under a one-sided Lipschitz condition, which extends the notions of Lipschitz continuity, dissipativity, and the uniform one-sided Lipschitz condition for set-valued mappings. The accuracy of approximation of the solution sets by means of the Euler discretization scheme for both types of inclusions is estimated.

Key words. one-sided Lipschitz continuity, differential inclusions, Filippov theorem, Euler method

1. Introduction.

Let I be the interval [0,1], $X = \mathbf{R}^n$, and K_0 be a compact subset of X. We consider a multifunction F from $I \times X$ to the set of all convex compact subsets of X. We study the following initial value problem:

$$\dot{x}(t) \in F(t, x(t)) \quad \text{for a.e. } t \in I, \quad x(0) \in K_0 \ , \tag{1.1}$$

where $x(\cdot)$ is an absolutely continuous (AC) vector function from I to X.

Stability properties of the solutions of differential equations and inclusions with respect to various perturbations are of great importance for their qualitative and quantitative analysis. They are closely related to existence and relaxations theory, on the one hand, and to sensitivity and approximations analysis, on the other.

In this sense the stability theorem, published by Filippov [11], and sometimes referred to as the Gronwall–Filippov–Ważewski theorem (see [3] for a more general setting), takes a central place in the theory of differential inclusions. It gives an estimate of sensitivity of the reachable set of (1.1) with respect to perturbations in the initial condition and the right-hand side. The assumptions, for which the theorem was originally proven in [11], are

1°. $F(\cdot, \cdot)$ is Hausdorff continuous with nonempty closed values.

2°. $F(t, \cdot)$ is Lipschitz continuous; i.e., there is a nonnegative integrable function $L : I \to \mathbf{R}$ such that

$$haus(F(t, x'), F(t, x'')) \le L(t)|x' - x''| \quad \text{for any} \quad x', x'' \quad \text{and a.e.} \quad t \in I.$$

FILLIPPOV'S THEOREM [11]. *Let $y : I \to X$ be absolutely continuous and $dist(\dot{y}(t),\ F(t, y(t))) \le g(t)$ for a.e. $t \in I$, where $g(\cdot)$ is summable. Let $1°, 2°$ be satisfied in the region $\{(t, x) : t \in I, |x - y(t)| \le b\}$, $K_0 = \{x_0\}$ be such that $|x_0 - y(0)| < b$,*

and

$$m(t) = \int_0^t L(r)dr, \quad v(t) = e^{m(t)} \left(|x_0 - y(0)| + \int_0^t e^{-m(s)} g(s)ds \right).$$

Then there is a solution $x(\cdot)$ *of* (1.1) *on the interval* $\Delta = [t : t \in I, v(t) \leq b]$ *that satisfies*

$$|x(t) - y(t)| \leq v(t), \quad \textit{for all } t \in \Delta, \quad x(0) = x_0,$$

$$|\dot{x}(t) - \dot{y}(t)| \leq L(t)v(t) + g(t) \quad \textit{for a.e. } t \in \Delta.$$

It is worth stressing the wide range of applications of this theorem. It is a basic tool in studying the relations between the original and the convexified problem (or so-called "relaxed problem") (cf. [2], [5]), implying density of the solution set of (1.1) in the solution set of the relaxed problem. Naturally, it is very helpful in perturbations analysis and studying various discrete approximations (see, e.g., [7], [22]).

We should mention that this work was inspired by Veliov's paper [22], where a refinement of the above theorem had been proved and applied to singularly perturbed differential inclusions.

The aim of this paper is to weaken the continuity assumptions of the theorem in a manner that admits inference of the same estimate for the trajectories. The Lipschitz continuity (LC) of $F(t, \cdot)$ is replaced by a one-sided Lipschitz (OSL) condition and upper semicontinuity. Convexity of the right-hand side compensates for the lack of continuity of $F(t, \cdot)$ and ensures existence of a solution to (1.1). A growth condition appears to bound the derivatives, which are not necessarily bounded anymore. One should note that for the OSL right-hand side the estimate holds true for the state variables, but not for the velocities.

The OSL condition we use is introduced in [8], [10] and naturally generalizes the existing notions of LC, of dissipativity (or monotonicity; cf., e.g., [2], [5]), and the (uniform) OSL condition [15], [7] of set-valued maps. It does not, however, imply continuity of $F(t, \cdot)$, as the Lipschitz condition, nor uniqueness of the trajectory starting from a given point, as the latter (uniform) OSL condition.

Nevertheless, it assures stability of the attainable set, which is important for the sensitivity and approximations analysis of (1.1). This gives a positive answer to Artstein's question [1] of whether there is some general condition other than the Lipschitz one leading to stability of the attainable set.

We give an implementation of the above-mentioned theorem to obtain error estimates for Euler discrete approximation of differential inclusions.

Let us now formulate the Euler approximation for (1.1).

For any natural N divide I into N equal subintervals by $t_i = ih$, $i = 0, 1, \ldots, N$, where $h = \frac{1}{N}$. Approximate the solutions of (1.1) by piecewise linear functions $x : I \to X$ satisfying

$$\text{(1.2)} \qquad \begin{cases} x(t) = x(t_i) + (t - t_i)f_i \quad \text{for all} \quad t \in [t_i, t_{i+1}], \quad x(0) \in K_0, \\ \quad \text{where} \quad f_i \in F(t_i, x(t_i)), \quad i = 0, 1, \ldots, N-1. \end{cases}$$

This discretization has been studied by different authors (see, e.g., the survey [7]). We note here papers [6], [19], where an error of order $\mathcal{O}(h)$ is obtained for Lipschitz continuous $F(t, \cdot)$; Artstein's paper [1], containing error estimates in terms of the modulus of continuity of $F(\cdot, \cdot)$ provided it is uniformly continuous and the

attainable set satisfies a stability condition; and the result of Lempio [18], achieving rate of convergence $\mathcal{O}(h)$ for a "strengthened one-sided Lipschitz continuous" $F(t,\cdot)$, which may be discontinuous with respect to the state variable.

Our estimate involves moduli of continuity of the right-hand side that are uniform with respect to the state variable and averaged with respect to the time. It implies an error of order $\mathcal{O}(h^\alpha)$ for $F(t,\cdot)$ Hölder continuous of degree α and with uniformly bounded $1/\alpha$-variation with respect to the time variable.

A notion of OSL continuity for the following system with time lag is defined:

$$\dot{x}(t) \in F(t, x_t), \quad x_0 = \varphi, \tag{1.3}$$

where x_t, φ belong to the space $E = C([-\theta, 0], X)$ of the continuous functions from the interval $[-\theta, 0]$ to X, $x_t : [-\theta, 0] \to X$ is defined by $x_t(s) = x(t+s)$, and F is a set-valued function defined for every $t \in I$ and $x_t \in E$. Assuming that $F(t,x)$ is nonconvex-valued, Hausdorff continuous in x, and OSL, an "asymptotic"-type stability theorem is proved for (1.3): for every $\varepsilon > 0$ there exists a solution of (1.3), which satisfies Filippov's inequality for the trajectories with a defect ε. This result holds true for nonconvex-valued ordinary differential inclusion (1.1) as a special case of (1.3). Error estimates for the Euler approximation of the system (1.3) are also obtained.

The paper is organized as follows: section 2 is devoted to the OSL condition. Comparisons with the existing notions and some examples are given there. The main theorem for OSL inclusion (1.1) is proven in section 3. The Euler discrete approximations of (1.1) are studied in section 4. All the respective results for the functional-differential inclusion (1.3) are grouped in section 5. Section 6 contains some additional examples with applications of the OSL constants.

2. OSL continuous multifunctions. Let $X = \mathbf{R}^n$ and denote by $\langle \cdot, \cdot \rangle$ the inner product, and by $|\cdot|$ the norm in X, and let U be the unit ball and S the unit sphere in X.

Let $\mathcal{K}$ be the set of all nonempty compacts and $\mathcal{KK}$ the family of all convex compacts in X. Let $A, B \in \mathcal{K}$ and $x \in X$. The distance from x to A is given by $dist(x, A) = \inf\{|x - a| : a \in A\}$, the one-sided excess of A from B is

$$ex(A, B) = \inf\{\alpha > 0 : A \subset B + \alpha U\},$$

and Hausdorff metrics in $\mathcal{K}$ are defined as

$$haus(A, B) = \max\{ex(A, B), ex(B, A)\}.$$

Endowed with the Hausdorff distance, $\mathcal{K}$ becomes a complete separable metric space. We denote $|A| = \sup\{|a| : a \in A\}$. Denote the support function of the set $A \in \mathcal{K}$ by

$$\sigma(x, A) = \max\{\langle x, a\rangle : a \in A\}.$$

Note that σ can be defined for nonconvex sets. For convex A, $\sigma(\cdot, A)$ uniquely determines A. Remember that for $A, B \in \mathcal{KK}$

$$haus(A, B) = \max\{|\sigma(e, A) - \sigma(e, B)| : e \in S\}.$$

Let Y be a normed space. A multifunction $F : Y \to \mathcal{K}$ is called upper-semicontinuous (USC) [resp., lower-semicontinuous (LSC)] in a point $x_o \in Y$, if for every $\varepsilon > 0$

there exists $\delta > 0$ such that $F(x) \subset F(x_0) + \varepsilon U$ (resp., $F(x_0) \subset F(x) + \varepsilon U$) $\forall x \in x_0 + \delta U$. It is called continuous in x_o if it is USC and LSC in x_o, i.e., continuous with respect to the Hausdorff distance. $F : I \times Y \to \mathcal{K}$ is called almost USC (resp., almost LSC, or almost continuous) if for every $\varepsilon > 0$ there is a compact $I_\varepsilon \subset I$ with $\mathrm{meas}(I \backslash I_\varepsilon) < \varepsilon$ such that F is USC (LSC, continuous) on $I_\varepsilon \times Y$.

DEFINITION 2.1. *The set-valued mapping $F : I \times X \to \mathcal{K}$ is called one-sided Lipschitz* (OSL) *continuous (with respect to x) if there is an integrable function $L : I \to \mathbf{R}$ such that for every $x, y \in X$, $t \in I$, and $v \in F(t, x)$, there exists $w \in F(t, y)$ such that*

$$\langle x - y, v - w \rangle \le L(t)|x - y|^2.$$

Let us give an equivalent definition in terms of the support function: there exists integrable $L(\cdot)$ such that for any $x, y \in X$ and $t \in I$

$$\sigma(x - y, F(t, x)) - \sigma(x - y, F(t, y)) \le L(t)|x - y|^2.$$

In other words, there is an integrable function $L(\cdot)$ such that for each direction $e \in S$ and every $x \in X$, the scalar function $\phi : I \times \mathbf{R} \to \mathbf{R}$, defined by $\phi(t, s) = \sigma(e, F(t, x + se))$, is OSL continuous, i.e., satisfies the inequality

$$(\phi(t, s) - \phi(t, r))(s - r) \le L(t)(s - r)^2$$

for every $s, r \in \mathbf{R}$ and $t \in I$.

Note that an OSL mapping is characterized by its support function in each direction, i.e., only by the behavior of its support faces. Besides, for Lipschitz convex-valued maps the absolute value of the support functions difference is bounded, while for OSL mappings the bound is one-sided and the support function may decrease in an arbitrary way in some directions.

Remark 2.1. It is easy to prove that F is OSL iff $\overline{co}F$ is OSL.

Remark 2.2. As follows from Definition 2.1, the OSL condition extends the notion of OSL continuity for vector-valued functions (cf. [4]) and also the notions of Lipschitz continuity, dissipativity (monotonicity; cf. [2], [5]), and (uniform) OSL continuity for set-valued mappings [15], [7]. Remember that $G : X \to \mathcal{K}$ is dissipative if $\langle x - y, v - w \rangle \le 0$ for all $x, y \in X$ and $v \in F(x)$, $w \in F(y)$. Then the map $-G$ is called monotone. The dissipativity notion was weakened by Kastner-Maresch [15], replacing the zero in the definition by $L|x - y|^2$. Such mappings were called (uniformly) one-sided Lipschitz (UOSL) continuous in [15], [7]. By simple use of Gronwall's inequality one can see that UOSL inclusions have at most one trajectory starting from a given point [15]. The uniqueness of the trajectory is the main difference between UOSL and OSL inclusions. An OSL system may have many solutions. Error estimates for implicit Runge–Kutta approximations of UOSL inclusions are presented in [15], provided the unique trajectory possesses suitable smoothness properties. Lempio [18] introduced a strengthened UOSL condition that ensures an $O(h)$ rate of convergence for Euler's method, even for right-hand side, discontinuous in the state variable.

The following simple examples show that the OSL continuity is an essential extension of LC, the uniform OSL continuity, and the dissipativity.

Example 2.1 (discontinuous OSL interval function which is neither LC nor UOSL).

$$F(x) = \begin{cases} [0, 1] & \text{for } x < 0, \\ [-1, 1] & \text{for } x \ge 0. \end{cases}$$

Example 2.2. Consider the following control system:

$$\dot{x}(t) = f(t, x, u),\ x(0) = x_0;\ u \in U,$$

where $f : \mathbf{R}^{1+n+m} \to \mathbf{R}^n$ is continuous in u, U is compact in $\mathbf{R}^m$, and $f(t, \cdot, u)$ is an OSL continuous vector function, uniformly in $u \in U$. Then $F(t, \cdot) = f(t, \cdot, U)$ is an OSL continuous mapping in the sense of Definition 2.1 but may not be UOSL in the sense of [15], [7], as the next example shows.

Example 2.3 (continuous OSL interval function, neither Lipschitz nor UOSL). Let $m = n = 1$, $U = [-1, 1]$, and $f(x, u) = -x^{\frac{1}{3}} + u$. Then the map

$$F(x) = f(x, U) = -x^{\frac{1}{3}} + [-1, 1]$$

is a continuous OSL mapping that does not satisfy the UOSL condition of [15], [7].

3. Filippov Theorem for convex one-sided Lipschitz differential inclusions. The following basic assumptions are made.

A1. F is defined on $I \times X$, with nonempty compact and convex values, $F(\cdot, x)$ measurable for each x, and $F(t, \cdot)$ USC for all t.

A2. (integrably linear growth of F). There is an integrable function $\lambda : I \to \mathbf{R}_+$ such that $|F(t, x)| \le \lambda(t)(1 + |x|)$ for all $x \in X$ and almost all $t \in I$.

A3. F is OSL continuous with an integrable function $L(\cdot)$.

We first prove boundedness of the approximate trajectories set. Naturally, if the growth condition A2 is satisfied, an easy application of the Gronwall inequality will give the needed boundedness. We show here that the OSL condition implies boundedness of the state variable, provided the set $F(\cdot, K_0) = \bigcup_{x \in K_0} F(\cdot, x)$ is integrably bounded.

LEMMA 3.1. *Let F satisfy* A1, A3 *and the function $|F(\cdot, K_0)|$ be bounded by an integrable function $\mu(\cdot) : I \to \mathbf{R}_+$, and let $g : I \to \mathbf{R}_+$ be summable. Then all the solutions of the inclusion*

$$\dot{x}(t) \in F(t, x(t)) + g(t)U, \quad x(0) \in K_0 + d_o U,$$

are contained in a ball of radius $M = |K_0| + \max_{t \in I} |v(t)|$, centered in the origin.

Here $v(t) = \{d_o e^{m(t)} + \int_0^t e^{m(t)-m(s)}(\mu(s) + g(s))ds\}$ and $m(t) = \int_0^t L(r)dr$.

Proof. Given a solution $x(\cdot)$ of the given inclusion and $t \in I$, choose $x_0 \in K_0$ such that $|x(0) - x_0| \le d_o$ and $z \in g(t)U$ for which $\dot{x}(t) + z \in F(t, x(t))$.

By A3 there is a $w \in F(t, x_0)$ satisfying

$$\langle x(t) - x_0, \dot{x}(t) + z - w \rangle \le L(t)|x(t) - x_0|^2.$$

Therefore

$$\begin{aligned}\langle x(t) - x_0, \dot{x}(t) \rangle &\le \langle x(t) - x_0, w - z \rangle + L(t)|x(t) - x_0|^2 \\ &\le (|F(t, x_0)| + g(t))|x(t) - x_0| + L(t)|x(t) - x_0|^2.\end{aligned}$$

Denoting $s(t) = |x(t) - x_0|$, it is easy to verify that $s(\cdot)$ is an absolutely continuous function. At every $t \in I$, for which $s(\cdot)$ is differentiable, we have the inequality

$$s(t) \cdot \dot{s}(t) = \frac{1}{2}\frac{d}{dt}s^2(t) = \langle x(t) - x_0, \dot{x}(t) \rangle \le L(t)s^2(t) + (\mu(t) + g(t))s(t).$$

Define the set $T = \{t \in I : s(t) = 0\}$ and let T' be the set of all density points of T. It is well known that $meas(T') = meas(T)$. If $t \notin T$, then $\dot{s}(t) \le L(t)s(t) + \mu(t) + g(t)$, since $s(t) > 0$. If $t \in T'$ and if $\dot{s}(t)$ exists, then $\dot{s}(t) = 0$. Hence $\dot{s}(t) \le L(t)s(t) + \mu(t) + g(t)$ for a.e. $t \in I$. We calculate $\frac{d}{dt}[e^{-m(t)}(s(t) - v(t))] \le 0$. Therefore $e^{-m(t)}(s(t) - v(t)) \le s(0) - v(0) \le 0$; i.e., $s(t) \le v(t)$ for all $t \in I$. Hence $|x(t)| \le |x_0| + s(t) \le M$. □

Remark 3.1. Note that by the OSL condition we estimate only the norm of the solutions and not the norm of the derivatives. Generally, the velocities may be unbounded, and we need some growth condition so as to ensure existence of a trajectory. Clearly, if in addition A2 holds, then for every solution $x(\cdot)$ of (1.1), $|\dot{x}(t)| \le \lambda(t)(1 + M)$. These bounds provide extendability of the solutions on the whole interval I (the proof of this fact is standard and reiterated in Proposition 5.3).

The main result of this section follows.

THEOREM 3.2. *Suppose* A1, A2, A3 *hold and* $y : I \to X$ *is an AC function satisfying* $dist(\dot{y}(t), F(t, y(t))) \le g(t)$ *for a.e.* $t \in I$, *where* g *is integrable. Then for every* $K_0 \in \mathcal{K}$ *there exists a solution* $x(\cdot)$ *of* (1.1) *on the interval* I, *such that*

$$|x(t) - y(t)| \le de^{m(t)} + \int_0^t e^{m(t)-m(s)} g(s)ds, \tag{3.1}$$

where $d = dist(y(0), K_0)$, $m(t) = \int_0^t L(s)ds$.

Proof. Consider the ordinary differential inclusion

$$\dot{x}(t) \in G(t, x(t)), \quad x(0) = x_0, \tag{3.2}$$

where $x_0 \in K_0$ satisfies $|y(0) - x_0| = dist(y(0), K_0)$, $G(t, x) = F(t, x) \cap H(t, x)$, and $H(t, x)$ is determined by

$$H(t, x) = \{v \in X | \langle y(t) - x, \dot{y}(t) - v\rangle \le L(t)|y(t) - x|^2 + g(t)|y(t) - x|\}.$$

We will prove that (3.2) has a solution on I that satisfies the desired inequality by use of a known existence theorem for USC differential inclusions (cf. [5, Theorem 5.2]). It suffices to verify that

(i) $G(t, x)$ is nonempty, convex, and closed-valued, measurable in t;
(ii) for each t, $G(t, \cdot)$ has a closed graph, which implies that $G(t, \cdot)$ is USC;
(iii) $G(\cdot, \cdot)$ satisfies the growth condition A2.

We first prove that $G(t, x) \ne \emptyset$ for each t, x. Given t, x, let $w \in F(t, y(t))$ be such that $|\dot{y}(t) - w| = dist(y(t), F(t, y(t)))$. By the OSL condition we can choose $v \in F(t, x)$ so as to satisfy $\langle y(t) - x, w - v\rangle \le L(t)|y(t) - x|^2$. Hence

$$\begin{aligned}\langle y(t) - x, \dot{y}(t) - v\rangle &= \langle y(t) - x, \dot{y}(t) - w\rangle + \langle y(t) - x, w - v\rangle \\ &\le |y(t) - x|g(t) + L(t)|y(t) - x|^2, \quad \text{i.e., } v \in G(t, x)\ .\end{aligned}$$

Obviously $G(t, x)$ is convex, closed-valued, measurable in t, and satisfies A2 since F does. Moreover,

$$Graph\ G(t, \cdot) = Graph\ F(t, \cdot) \bigcap Graph\ H(t, \cdot),$$

and it is closed because the graphs of $F(t, \cdot)$ and $H(t, \cdot)$ are closed. From Theorem 5.2 of [5] we conclude that there exists a solution $x(\cdot)$ of (3.2) on I. Denoting $s(t) =$

$|x(t)-y(t)|$, one gets that $s(\cdot)$ is an AC function. Furthermore, if $\dot{s}(t)$ exists, then

$$s(t)\cdot\dot{s}(t)=\frac{1}{2}\frac{d}{dt}s^2(t)=\langle x(t)-y(t),\dot{x}(t)-\dot{y}(t)\rangle\le L(t)s^2(t)+g(t)s(t).$$

As in the previous lemma, we infer that $\dot{s}(t)\le L(t)s(t)+g(t)$ for a.e. $t\in I$, and the proof is completed by a simple comparison argument that repeats the one of Lemma 3.1. □

Let $0\le t_0\le t\le 1$. Denote by $A(t,t_0,K)$ the attainable set of (1.1) with initial condition $x(t_0)\in K$.

A direct consequence of Theorem 3.2 is the following stability condition, used by Artstein [1] to get a global error estimate for the attainable set in the Euler method.

COROLLARY 3.3. *Under the conditions of Theorem* 3.2, *if F is OSL with a constant L, then for given $a\le t_0\le t\le b$ and $K_1,K_2\in\mathcal{K}$*

$$haus(A(t,t_0,K_1),A(t,t_0,K_2))\le(1+Le^{L(b-a)}(t-t_0))haus(K_1,K_2).$$

Proof. The proof comes directly from Theorem 3.2 and the inequality $e^{L(t-t_0)}\le 1+Le^{L(b-a)}(t-t_0)$ for $a\le t_0\le t\le b$. □

Remark 3.2. The function L in OSL and (3.1) can take negative values. This advantage is used in some examples in section 6 for getting better estimates via the OSL constant.

Remark 3.3. Let us note that this theorem does not generalize Filippov's Theorem. As was mentioned in the Introduction, Filippov proved it without convexity of the right-hand side, assuming LC of $F(t,\cdot)$ and getting convergence of the successive approximations method for the velocities and trajectories and thus the existence of a solution. We replace here the continuity of $F(t,\cdot)$ by convexity and upper-semicontinuity, to ensure existence of a solution of (3.2). Note that for an OSL system a solution may exist without convergence of the successive approximations method (see the example in [16, p. 37]).

As is well known (cf. [5]), there are differential inclusions, discontinuous with respect to the state variable, that have no solution. The case when $F(t,\cdot)$ is continuous and nonconvex-valued is considered in section 5 (Theorem 5.4). The result proved there holds for ordinary differential inclusions as well.

Remark 3.4. Note that measurability of the function $dist(\dot{y}(t),F(t,y(t)))$ (cf. [3]) is not necessary, if we need only an estimate from above. Its integrable boundedness is sufficient.

Remark 3.5. A general form of Filippov's theorem, that is less known, was proven by Pliś [20] for measurable $F(\cdot,x)$, that satisfies a Kamke-type continuity condition with respect to x, instead of the Lipschitz one. A one-sided extension of Pliś' theorem can be obtained for $F(\cdot,\cdot)$ satisfying a general one-sided Kamke-type condition [10] by obvious modifications in the proof.

4. Euler method. Suppose that $A\subset X$ is compact and $F: I\times A\to\mathcal{KK}$ is uniformly bounded, measurable in the first argument, and continuous in the second one, i.e., almost continuous (cf. [5]). For given $t\in I$, $x\in A$ we define two local moduli of continuity of $F(\cdot,\cdot)$ with respect to each argument:

$$\chi(F,A,t,h)=\sup\{haus(F(t,x),F(t,y)):\ |y-x|\le h,x,y\in A\},$$

$$\tau(F,A,t,h)=\sup\{\sup(haus(F(s,x),F(r,x)):s,r\in[t-h/2,t+h/2]\cap I):x\in A\}.$$

These two moduli are measurable functions of t since for a.e. $t \in I$ they can be represented as supremum of countably many measurable functions of t, obtained for values of x in a countable dense subset of X.

Note that these moduli are local only in t and global in $x \in A$. The corresponding averaged L_p-moduli are

$$\chi(F,A,h)_p = \left(\int_0^1 \chi(F,A,t,h)^p dt\right)^{\frac{1}{p}}, \quad \tau(F,A,h)_p = \left(\int_0^1 (\tau(F,A,t,h))^p dt\right)^{\frac{1}{p}},$$

where $1 \le p < \infty$. For $p = 1$ we denote $\tau(F,A,h) = \tau(F,A,h)_1$, $\chi(F,A,h) = \chi(F,A,h)_1$. For additional information about averaged moduli of continuity we refer the reader to [21], [6], and [9].

Let us note that if F is integrably Hölder continuous in x of degree α (i.e., there exists an integrable function $L : I \to X$ such that for any $x, y \in A$, $haus(F(t,x), F(t,y)) \le L(t)|x-y|^\alpha$), then $\chi(F,A,h)_p = O(h^\alpha)$. If F has bounded p-variation in t, uniformly in $x \in A$, i.e.,

$$W_p(F) = \sup_k \left\{ \sum_{i=1}^{k-1} \sup_{x\in A} (haus(F(x,t_{i+1}), F(x,t_i)))^p, 0 \le t_1 \le \cdots \le t_k \le 1 \right\} < \infty,$$

then $\tau(F,A,h)_p = O(h^{\frac{1}{p}})$ [14], [9].

Consider the discrete approximation (1.2) of the initial problem (1.1). Obviously, if F has compact convex images, then for all $t \in I$ the attainable set of (1.2) coincides with the attainable set of the differential inclusion

$$\begin{cases} \dot{x}(t) \in F(t_i, x(t_i)) \quad \text{for a.e. } t \in (t_i, t_{i+1}),\ i = 0,1,\ldots,N-1\ , \\ x(0) \in K_0. \end{cases} \tag{4.1}$$

This technical note means that one can work with trajectories of (4.1) instead of (1.2) and vice versa. It is used in some further proofs.

Denote by R_1, R_2 the solution sets of (1.1) and (1.2), respectively, metrized by the C-norm of the solutions and the Hausdorff metrics for the solution sets.

We prove first boundedness of the discrete trajectories.

LEMMA 4.1. *Let* A2 *hold with a Riemann integrable* $\lambda(\cdot)$. *Then every trajectory* $x(\cdot)$ *of* (1.2) *is bounded by*

$$\max_{t\in I} |x(t)| \le e^{\Lambda}(|K_0| + \Lambda), \quad \textit{where} \quad \Lambda = \sup_{N\in\mathbf{N}} \frac{1}{N} \sum_{i=0}^{N} \lambda(t_i)\ .$$

Proof. Note that Λ is finite because of the Riemann integrability of $\lambda(\cdot)$. Let $x(\cdot)$ be a solution of (1.2). Denote for $i = 0,1,\ldots,N$, $x_i = x(t_i)$, $\lambda_i = \lambda(t_i)$. Clearly, it is sufficient to estimate x_i, $i = 1,\ldots,N$. From the equality $x_{i+1} = x_i + hf_i$, where $|f_i| \le \lambda_i(1 + |x_i|)$, and A2 we obtain

$$\begin{aligned} |x_{i+1}| &\le (1 + h\lambda_i)|x_i| + h\lambda_i \le \cdots \\ &\le \prod_{k=0}^{i} (1 + h\lambda_k)|x_0| + h \sum_{k=0}^{i-1} \lambda_k \prod_{j=k+1}^{i} (1 + h\lambda_j)\ . \end{aligned}$$

The simple observation that $1+h\lambda_j \le e^{h\lambda_j}$ implies $\prod_{j=1}^{N}(1+h\lambda_j) \le \exp(h\sum_{j=1}^{N}\lambda_j) \le e^{\Lambda}$. Then

$$\max\{|x_i| \mid 0 \le i \le N\} \le e^{\Lambda}\left(|K_0| + h\sum_{k=1}^{N-1}\lambda_k\right) \le e^{\Lambda}(|K_0|+\Lambda). \qquad \square$$

Remark 4.1. Lemmas 3.1 and 4.1 give boundedness of all "almost" trajectories, being continuous or discrete, i.e., satisfying the inclusions (1.1) or (1.2) with some integrably bounded defect $g(\cdot)$ (see Lemma 3.1). In the discrete case we require Riemann integrability of $g(\cdot)$. If $\lambda(\cdot)$ is integrable (or Riemann integrable in the discrete case), then the velocities are integrably bounded. If λ is a constant, then all the trajectories of (1.1), (1.2), and (4.1) are contained in a bounded set A, and all the velocities, in a bounded set B.

LEMMA 4.2. *Suppose* A1, A2, A3 *are satisfied with a constant* λ, *and* $F(t,\cdot)$ *is continuous. Then, for every solution* $x(\cdot)$ *of* (1.1), *there exists a trajectory* y *of* (4.1) *such that*

$$\max_{t\in[0,1]}|x(t)-y(t)| \le c(\tau(F,A,h)+\chi(F,A,h)),$$

where $c = e^{m(1)}\max(2,|B|)$, $m(t)$ *is defined in Lemma* 3.1, *and* A, B *are defined in the previous remark.*

Proof. Let $y(0)=x(0)$ and suppose $y(\cdot)$ exists on $[0,t_i]$. We prove inductively that it exists on $I_i=[t_i,t_{i+1}]$ $(i=0,1,\dots,N-1)$.

For given $t\in I_i$ and $u\in X$ consider the map $G(t,u)=F(t_i,y(t_i))\cap H(t,u)$, where

$$H(t,u)=\{v\in X|\langle v-\dot{x}(t),u-x(t)\rangle \le |x(t)-u|[L(t)|x(t)-u| + ex(F(t,u),F(t_i,y(t_i))]\},$$

where $ex(A,B)$ is the one-sided excess of A from B. As in Theorem 3.2 we get existence of a solution of the initial problem

$$\dot{y}(t)\in G(t,y), \quad y(t_i) \text{ known.}$$

In order to apply the existence theorem ([5, Theorem 5.2]), we verify that $G(\cdot,\cdot)$ satisfies (i), (ii), (iii).

(i) G is nonempty for every t,u. Indeed, there is a $z\in F(t,u)$ such that $\langle x(t)-u,\dot{x}(t)-z\rangle \le L(t)|x(t)-u|^2$. Further, for z we find $v\in F(t_i,y(t_i))$ satisfying

$$|z-v| = dist(z,F(t_i,y(t_i))) \le ex(F(t,u),F(t_i,y(t_i))).$$

Then $\langle x(t)-u,\dot{x}(t)-v\rangle \le L(t)|x(t)-u|^2+|x(t)-u|ex(F(t,u),F(t_i,y(t_i)))$; i.e., $v\in G(t,u)$. Obviously $G(\cdot,\cdot)$ is convex and closed-valued, measurable in t on I_i.

(ii) For fixed t, $G(t,\cdot)$ has a closed graph, as $H(t,\cdot)$ has. This fact follows from the upper-semicontinuity of the function $ex(F(t,\cdot),A)$ when $F(t,\cdot)$ is USC.

(iii) $G(\cdot,\cdot)$ trivially satisfies a growth condition being a subset of $F(t_i,x(t_i))$.

This way we infer existence of $y(\cdot)$ on I_i, $i=0,1,\dots,N-1$. Denote $\Delta(t)=x(t)-y(t)$. Then for $t\in I_i$

$$\frac{1}{2}\frac{d}{dt}\Delta^2(t)=\langle\Delta(t),\dot{\Delta}(t)\rangle \le |\Delta(t)|\,[L(t)|\Delta(t)| + haus(F(t,y(t)),F(t,y(t_i))) + haus(F(t,y(t_i)),F(t_i,y(t_i)))].$$

We repeat the arguments from Theorem 3.2 to obtain that for a.e. $t \in I$

$$\frac{d}{dt}|\Delta(t)| \le L(t)|\Delta(t)| + \chi(F, A, t, |B|h) + \tau(F, A, t, 2h),\ \Delta(0) = 0\ .$$

The proof is completed by a comparison argument and the observation that $\chi(F, A, |B|h) \le |B|\chi(F, A, h)$ and $\tau(F, A, 2h) \le 2\tau(F, A, h)$ (cf. [21]). ∎

THEOREM 4.3. *Under the conditions of the previous lemma*

$$haus(R_1, R_2) \le c_o(\tau(F, A, h) + \chi(F, A, h) + h),$$

where $c_o = \max\{e^{m_+(1)} \max(2, |B|), |B|\}$ *and* $m_+(t) = \int_0^t \max\{L(s), 0\}\, ds$.

Proof. Let $x(\cdot)$ be a solution of the discrete system (1.2). Then

$$\begin{aligned} &dist(\dot{x}(t), F(t, x(t))) \le ex(F(t_i, x(t_i)), F(t, x(t))) \\ &\le haus(F(t_i, x(t_i)), F(t, x(t_i))) + haus(F(t, x(t_i)), F(t, x(t))) \\ &\le \tau(F, A, t, 2h) + \chi(F, A, t, |B|h)\ . \end{aligned}$$

Applying Theorem 3.2, we obtain

$$\begin{aligned} &dist(x(\cdot), R_1) \\ &\le \int_0^1 e^{m(1)-m(t)}(\tau(F, A, t, 2h) + \chi(F, A, t, |B|h))dt \\ &\le e^{m_+(1)}(2\tau(F, A, h) + |B|\chi(F, A, h))\ . \end{aligned}$$

Let $y(\cdot)$ be a solution of (1.1). The previous lemma gives the existence of a solution $z(\cdot)$ of (4.1) with the desired property.

Now, take the piecewise-linear approximation of $z(\cdot)$,

$$x(t) = z(t_i) + (t - t_i)\frac{(z(t_{i+1}) - z(t_i))}{h} \quad \text{for} \quad t \in [t_i, t_{i+1}], \quad i = 0, 1, \ldots, N-1.$$

Obviously, $\max_{t\in I} |x(t) - z(t)| \le |B|h$, and by the triangle inequality we complete the proof. ∎

COROLLARY 4.4. *If additionally* $F(t, x)$ *is integrably Hölder continuous in* x *of degree* $\frac{1}{p}$, $1 \le p < \infty$, *and has uniformly bounded* p*-variation in* t, *then* $haus(R_1, R_2) = \mathcal{O}(h^{\frac{1}{p}})$.

Remark 4.2. If $L < 0$ and $\tau(F, A, t, h) \le Ph^\alpha$, $\chi(F, A, t, h) \le Qh^\beta$ $(0 < \alpha, \beta \le 1)$, the following inequality holds:

$$haus(R_1, R_2) \le \frac{1}{|L|}(1 - e^L)[P(2h)^\alpha + Q(|B|h)^\beta] + |B|h.$$

If, additionally, F does not depend on t, then

$$haus(R_1, R_2) \le \frac{1}{|L|}(1 - e^L)Q(|B|h)^\beta + |B|h.$$

5. The functional-differential case. In this section we will extend our results to the case of functional-differential inclusion (1.3). We will follow the style of [13].

The extension of OSL condition in this case possesses some specific problems. The state variable x_t and the velocities are not elements of the same space. These problems are overcome in the case of functional-differential equations in [17], where a Razumikhin-type Lipschitz condition is exploited.

Denote $E_0 = \{\alpha \in E : |\alpha(0)| = \max\{|\alpha(s)| : s \in [-\theta, 0]\}\}$. The mapping $F : E \to K$ is Lipschitz continuous (in Razumikhin sense) iff $haus(F(\alpha), F(\beta)) \le L|\alpha - \beta|_E$ for all $\alpha, \beta \in E$ such that $\alpha - \beta \in E_0$. We introduce a Razumikhin-type OSL condition, which will be called OSL here for the reader's convenience.

DEFINITION 5.1. *The multifunction $F : I \times E \to K$ is said to be OSL when there exists an integrable function $L(\cdot)$ such that*

$$\sigma(\alpha(0) - \beta(0), F(t, \alpha)) - \sigma(\alpha(0) - \beta(0), F(t, \beta)) \le L(t)|\alpha(0) - \beta(0)|^2$$

for every $\alpha, \beta \in E$ such that $\alpha - \beta \in E_0$.

Remark 5.1. Note that the conditions hold true not for all α, β, but only when $\alpha - \beta \in E_0$. In the proof of the stability theorem we cannot use the same approach to obtain existence as in the previous sections, since the mapping $G(\cdot, \cdot)$, defined in Theorem 3.2 would not be USC anymore. In order to apply the existence theory for LSC mappings, we suppose that $F(t, .)$ is continuous. In this case we cannot use negative OSL constants.

The main assumptions in this section follow.

H1. F is nonempty, compact-valued, and integrably bounded on bounded sets.

H2. F is OSL with integrable function $L(t)$, and $F(\cdot, \alpha)$ is measurable, while $F(t, \cdot)$ is continuous.

As was noted, in this case we suppose that $L(t) \ge 0$ or replace it by $L_+(t) = \max\{0, L(t)\}$.

Denote for $A \in \mathcal{K}$ the set $F(I, A) = \bigcup_{t \in I, x \in A} F(t, x)$.

PROPOSITION 5.2. *Let F be bounded on the bounded sets and OSL with a constant L. Then the multifunction $\alpha \to F(I, \alpha + U)$ is also OSL with constant L.*

Proof. Let $\alpha - \beta \in E_0$. Fix $\varepsilon > 0$. Therefore there exist $\tilde{t} \in I$ and $\tilde{l} \in U$ such that $\sigma(\alpha(0) - \beta(0), F(I, \alpha + U)) \le \sigma(\alpha(0) - \beta(0), F(\tilde{t}, \alpha + \tilde{l})) + \varepsilon$. The following inequalities complete the proof, since $\varepsilon > 0$ is arbitrary:

$$\begin{aligned} &\sigma(\alpha(0) - \beta(0), F(I, \alpha + U)) - \sigma(\alpha(0) - \beta(0), F(I, \beta + U)) \\ &\le \sigma(\alpha(0) - \beta(0), F(\tilde{t}, \alpha + \tilde{l})) - \sigma(\alpha(0) - \beta(0), F(\tilde{t}, \beta + \tilde{l})) + \varepsilon \\ &\le L|\alpha(0) - \beta(0)|^2 + \varepsilon. \qquad \square \end{aligned}$$

We approximate the solutions of (1.3) by polygonal functions

$$\begin{cases} x(t) = x(t_i) + (t - t_i) f_i \quad \text{for } t \in [t_i, t_{i=1}], \\ \text{where } f_i \in F(t_i, x_{t_i}), \quad i = 0, 1, \ldots, N-1, \quad x(0) \in K_0. \end{cases} \tag{5.1}$$

As in section 4, if F has compact convex images, the attainable set of (5.1) coincides with the attainable set of the inclusion

$$\begin{cases} \dot{x}(t) \in F(t_i, x_{t_i}) \quad \text{for } t \in (t_i, t_{i+1}),\ i = 0, 1, \ldots, N-1, \\ x(0) \in K_0. \end{cases} \tag{5.2}$$

Denote by R_3, R_4 the solution sets of (1.3) and (5.1), respectively, metrized by the C-norm of the solutions and the Hausdorff metrics for the solution sets.

If $L(.)$ is not a constant, the conclusion of Proposition 5.2 need not be valid. Next we prove the following proposition.

PROPOSITION 5.3. *Under* H1, H2 *the solutions' set of* (1.3) *is bounded and every solution is extendable on the whole* I.

Proof. Let $x(\cdot)$ be a solution of (1.3). Denote $s(t) = |x_t|_E$. Let $x_t \notin E_0$. Then there exists $h > 0$ such that $|x_{t+h}(0)| < |x_{t+h}|_E$, since $x(.)$ is continuous. So in this case $\dot{s}(t) \le 0$. If $x_t \in E_0$, then $\langle x(t), \dot{x}(t)\rangle \le \sigma(x(t), F(t, x_t)) \le L(t)|x(t)|^2 + |F(t,0)||x(t)|$. Therefore $\dot{s}(t) \le L_+(t)s(t) + |F(t,0)|$, $s(0) = |\phi|_E$. Hence $s(t) \le e^{m(t)}(|\phi| + \int_0^1 e^{-m(\tau)}|F(\tau,0)|\,d\tau)$. Thus $x(\cdot)$ is bounded. Let $x(\cdot)$ be defined on $[0,T)$ with $T < 1$. Then $x(\cdot)$ is AC, since F is integrably bounded on the bounded sets. Therefore $x(T) = \lim_{t\to T^-} x(t)$ exists and hence $x(\cdot)$ may be extended on some larger interval. Applying the Zorn lemma, one proves that $x(.)$ exists on the whole I. □

Remark 5.2. Let $\dot{x}(t) \in F(I, x_t + U)$. If the conditions of Proposition 5.2 hold, then it is easy to show as above that

$$\frac{d}{dt}|x(t)| \le L_+|x(t)| + |F(I,U)|, \text{ therefore } |x(t)| \le e^{L_+ t}\{|\phi| + |F(I,U)|\} = M.$$

Denote $V = MU, W = |F(I, MU)|$. Then $x(.)$ is Lipschitz with a constant W. If $Wh < 1$, then every solution of (5.2) is also a solution of

$$\dot{x}(t) \in F(I, x_t + U), \quad x_0 \in K_0.$$

Hence, if the requirements of Proposition 5.2 hold, then for every solution of (1.3) or of (5.2), $x(t) \in V$, $|F(t, x_t)| \le W$. Therefore, without loss of generality, we can suppose that the right-hand side F is bounded by the constant W.

Now we will prove a Filippov-type theorem for the nonconvex case.

THEOREM 5.4. *Suppose* H1 *and* H2 *hold and that* $y(\cdot)$ *is an AC function with* $dist(\dot{y}(t), F(t, y_t)) \le f(t)$ *for some integrable* $f(\cdot)$. *Then for every* $\varepsilon > 0$ *and every* $x_0 \in X$ *there exists a solution* $x(\cdot)$ *of* (1.3) *such that*

$$|x(t) - y(t)| \le de^{m(t)} + \int_0^t e^{m(t)-m(s)} f(s)\,ds + \varepsilon, \quad x(0) = x_0, \tag{5.3}$$

where $d = |x_0 - y(0)|$, $m(t) = \int_0^t L_+(s)\,ds$, $L_+(t) = \max\{L(t), 0\}$.

Proof. For $\delta > 0$ define the multifunction

$$G_\delta(t,u) = \begin{cases} F(t,u), & u - y_t \notin E_o, \\ \{v \in F(t,y_t) : |v - \dot{y}(t)| = dist(\dot{y}(t), F(t,y_t))\}, & u = y_t, \\ \mathrm{cl}\{v \in F(t,u) : \langle y(t) - u(0), \dot{y}(t) - v\rangle \\ < L(t)|y(t) - u(0)|^2 + |y(t) - u(0)|(f(t) + \delta)\} & \text{elsewhere.} \end{cases}$$

We are going to prove that the differential inclusion

$$\dot{x}(t) \in G_\delta(t, x_t)$$

has a solution. In order to use the existence theorem of [12], we prove that $G_\delta(\cdot,\cdot)$ has closed values and is almost LSC. Observe that, as in the proof of Theorem 3.2, $G_\delta(\cdot,\cdot)$ is nonempty, compact-valued.

Further, we prove that $G_\delta(\cdot,\cdot)$ is almost LSC. Since E is separable, one can apply the Scorza–Dragoni theorem. Fix $\nu > 0$. From the Scorza–Dragoni theorem and

Lusin's theorem there exists $I_\nu \subset I$ with $meas(I \setminus I_\nu) < \nu$ such that $\dot{y}(\cdot), f(\cdot), L(\cdot)$ are continuous on I_ν and $F(\cdot,\cdot)$ is continuous on $I_\nu \times E$. Let $t \in I_\nu, u - y_t \in E_o, u \neq y_t, v \in G_\delta(t,u)$. Suppose $t = \lim_{i\to\infty} t_i, u = \lim_{i\to\infty} u_i$. Hence $f(t) = \lim_{i\to\infty} f(t_i)$, $F(t,u) = \lim_{i\to\infty} F(t_i,u_i)$, $\dot{y}(t) = \lim_{i\to\infty} \dot{y}(t_i)$. Let

$$\langle y(t) - u(0), \dot{y}(t) - v\rangle = L(t)|y(t) - u(0)|^2 + |y(t) - u(0)|(f(t) + \delta - \mu)$$

where $\mu > 0$. Since $y_t - u \in E_o$ and $y_t \neq u$, it follows that $|y(t) - u(0)| > 0$. Therefore

$$\langle y(t) - u(0), \dot{y}(t) - v\rangle = L(t)|y(t) - u(0)|^2 + |y(t) - u(0)|(f(t) + \delta) - c,$$

where $c > 0$. Define $v_i \in F(t_i,u_i)$ such that $|v - v_i| = dist(v, F(t_i,u_i))$. The continuity of $F(\cdot,\cdot)$ implies $\lim_{i\to\infty} v_i = v$. Moreover, $v_i \in G_\delta(t_i,u_i)$ for sufficiently large i. If $u_i - y_t \notin E_o$, then obviously $\lim_{i\to\infty} G_\delta(t_i,u_i) = \lim_{i\to\infty} F(t_i,u_i) \supset G_\delta(t,u)$. If $u = y_t$, let $v_i \in F(t_i,u_i)$ be such that $|v - v_i| = dist(v, F(t_i,u_i))$. Because of the continuity of $F(\cdot,\cdot), \dot{y}(\cdot), f(\cdot), L(\cdot)$, we get $\lim_{i\to\infty} v_i = v$. Thus $G_\delta(.,.)$ is almost LSC. From Theorem 1 of [12] we infer that the upper inclusion admits a solution $x(\cdot)$. As in the previous proof, by use of Lemma 2.1 of [17], one can show that

$$|x(t) - y(t)| \leq de^{m(t)} + \int_o^t e^{m(t)-m(s)}(\delta + f(s))ds.$$

Evidently choosing appropriate small δ, one completes the proof. □

COROLLARY 5.5. *Under the conditions of Theorem* 5.4, *if F is also convex-valued, one can replace ε by zero.*

Proof. The solution set of (1.3) is compact, since F is convex compact-valued. Let $x_n(\cdot)$ be a sequence of solutions of (1.3), satisfying the conditions of Theorem 5.4 with $\varepsilon = \frac{1}{n}$. Passing to subsequences, if necessary, one concludes that $\lim_{n\to\infty} x_n(t) = x(t)$, where $x(.)$ obviously satisfies the conclusion. □

Remark 5.3. Obviously, the proof of Theorem 5.4 is valid for ordinary differential inclusions. Generally, without the convexity assumption, the defect ε cannot be removed. Nevertheless, this result is sufficient for many applications.

In the rest of this section we will suppose as follows.

H3. $L(\cdot)$ is constant and F is convex-valued and bounded on bounded sets.

The following lemma corresponds to Lemma 4.2 for the functional-differential case.

LEMMA 5.6. *Suppose $F : I \times E \to \mathcal{KK}$ satisfy* H1, H2, H3. *If $x(\cdot)$ is a solution of* (1.3), *then there exists an AC solution $y(\cdot)$ of* (5.2), *such that $|x(t) - y(t)| \leq r(t)$, where $r(\cdot)$ is a nonnegative function satisfying*

$$\dot{r}(t) = L_+ r(t) + 2\chi(F,V,t,h) + W\tau(F,V,t,h),$$

and V, W are as defined in Remark 5.2.

Proof. Let $0 = t_0 < t_1 < \cdots < t_N = 1$ be a uniform grid of I with $h = \frac{1}{N}$. Suppose $y(\cdot)$ is constructed on $[0,t_i]$ and $t \in [t_i, t_{i+1}]$. Fix $\varepsilon > 0$ and for given y_i, t, u define the map

$$G_\varepsilon(t,u) = \begin{cases} F(t_i,y_i), & u - x_t \notin E_o, \\ \{v \in F(t_i,y_i) : |v - \dot{x}(t)| = dist(\dot{x}(t), F(t_i,y_i))\}, & u = x_t, \\ \mathrm{cl}\{v \in F(t_i,y_i) : \langle x(t) - u(0), \dot{x}(t) - v\rangle < \psi(t,u,y_i)\} & \text{elsewhere,} \end{cases}$$

where $y_i = y_{t_i}, \psi(t,u,y_i) = L_+|x(t)-u(0)|^2+|x(t)-u(0)|[\varepsilon+haus(F(t,u),F(t,y_i))+haus(F(t_i,y_i),F(t,y_i))]$. As above, one can show that $G_\varepsilon(\cdot,\cdot)$ is compact-valued and almost LSC. Since $F(t_i,y_i)$ is bounded, it follows that the differential inclusion

$$\dot{y}(t) \in G_\varepsilon(t,y_t), \quad y(t_i) \text{ fixed}, \quad t \in [t_i, t_{i+1}]$$

has a solution $y^\varepsilon(\cdot)$ in $[t_i,t_{i+1}]$. If we denote $r^\varepsilon(t) = \max_{-\theta\le s\le\theta}|x(t+s)-y^\varepsilon(t+s)|$ and suppose $y_o^\varepsilon = \phi$, then

$$\dot{r}^\varepsilon(t) \le Lr^\varepsilon(t) + \varepsilon + haus(F(t_i,y_i^\varepsilon),F(t,y_t^\varepsilon)), \quad r^\varepsilon(0) = 0 \text{ or } \dot{r}^\varepsilon(0) = 0.$$

Or $\dot{r}^\varepsilon(t) \le 0$. Now it is easy to show by induction that

$$r^\varepsilon(t) \le e^{L_+t}\left\{\varepsilon t + \sum_{k=0}^{i-1}\int_{t_k}^{t_{k+1}} haus(F(t_k,y_k^\varepsilon),F(s,y_s^\varepsilon))ds + \int_{t_i}^{t} haus(F(t_i,y_i^\varepsilon),F(s,y_s^\varepsilon))ds\right\}.$$

Since the solution set of the upper inclusions is compact and decreasing for $\varepsilon > 0$ decreasing, one gets existence of a trajectory $y(\cdot)$ such that $|x(t)-y(t)| \le r(t)$, where

$$r(t) \le e^{L_+t}\left\{\sum_{k=0}^{i-1}\int_{t_k}^{t_{k+1}} haus(F(t_k,y_k),F(s,y_s))\,ds + \int_{t_i}^{t} haus(F(t_i,y_i),F(s,y_s))\,ds\right\}.$$

By induction one can extend this $y(.)$ on the whole I. Furthermore, $haus(F(t_k,y_k),F(s,y_s)) \le haus(F(t_k,y_k),F(s,y_k)) + haus(F(s,y_k),F(s,y_s)) \le \tau(F,V,t,2h)+\chi(F,V,t,Wh)$. Hence

$$\dot{r}(t) = L_+r(t) + \chi(F,V,t,Wh) + \tau(F,V,t,2h). \qquad \square$$

Now it is easy to prove the main result of this section.

THEOREM 5.7. *Under the conditions of the previous lemma*

$$haus(R_3,R_4) \le c_1(2\tau(F,V,h) + W\chi(F,V,h) + h),$$

where $c_1 = \max\{e^{L_+}\max(2,W), W\}$.

The proof is similar to the proof of Theorem 4.3 and is omitted.

Remark 5.4. As the reader has noted, the exposition of this section is similar to the previous one. Some specific technical difficulties have been overcome by modifying the definitions and proofs. Moreover, Theorem 5.4 also holds for infinite-dimensional spaces, assuming some compactness conditions to get the existence of solutions. In this case the OSL condition should be defined as in [8], where it is called "a dissipative type condition." Besides, Lemma 5.6 and Theorem 5.7 are valid in Hilbert spaces (under some additional compactness assumptions again). We will not go into details of the infinite-dimensional case, since it is more complicated and goes beyond the scope of this paper. Finally, we present two examples.

Example 5.1. Consider the following system with maximum:

$$\dot{x}(t) \in -x + -x^{3/5} + \max_{t\in[-\theta,0]}|x^{3/5}(t+s)| + y + [-1,1], \quad x(s) = 0, s \in [-\theta,0],$$

$$\dot{y}(t) \in -y + [0,1], \quad y(0) = 0.$$

Since the OSL condition holds for $x_t \in E_0$, this system is OSL with constant $L = -\sqrt{2}$. So we have to replace L by 0. Moreover, this system is Hölder continuous of degree $\alpha = 3/5$. Therefore there exists a constant C such that $haus(R_3,R_4) \le Ch^{3/5}$.

Example 5.2. This example presents an integrodifferential inclusion

$$\dot{x}(t) \in -x^{5/7} + \int_{-\tau}^{0} x(t+s)\,ds + [-1,1], \quad x(s) = 0, s \in [-\tau, 0].$$

Obviously, the right-hand side is OSL with constant less than 1 and Hölderian of degree 5/7. Hence $haus(R_3, R_4) \le Ch^{5/7}$, where C can be estimated by Theorem 5.7.

6. Examples. Let $l, m \in \mathbf{N}$, $\alpha = \frac{2l+1}{2m+1}$. First, we prove the useful fact that if $|x-y| = h$, then $|x^\alpha - y^\alpha| \le 2^{1-\alpha}h^\alpha$. Let $f(x) = (x+h)^\alpha - x^\alpha$. Then $f'(x)$ exists for every $x \ne 0$. Calculating $f(0) = f(-h) = h^\alpha$, we see that $f(.)$ has a maximal value when $f'(x) = 0$, i.e., for $x = -\frac{h}{2}$.

Let us give some examples.

Example 6.1 (continuous OSL system that is not Lipschitz).

$$\dot{x}(t) \in -x - x^{3/5} + y + [-1,1], \quad x(0) = 0,$$
$$\dot{y}(t) \in -y + [0,1], \quad y(0) = 0.$$

It is easy to calculate $0 \le y(t) \le 1 - \exp(-t)$. Besides, for $|x| \le 1$, one has $|x| \le |x|^{3/5}$. Thus $\dot{x}(t) \le -2x + y + 1$. Hence $x(t) \le 1 - \exp(-t)$. Thus $0 \le y(t) \le 1 - \exp(-t)$ and $-1 + \exp(-t) \le x(t) \le 1 - \exp(-t)$. Obviously, every discrete trajectory also approximately satisfies the same inequalities. Hence, without loss of generality, one can suppose

$$|F(x,y)| \le \sqrt{[(1-e^{-1})^{3/5} + (3-2e^{-1})]^2 + (2-e^{-1})^2}$$
$$< \sqrt{(1-e^{-1})^{6/5} + 2(1-e^{-1}) + (3-2e^{-1})^2 + (2-e^{-1})^2}$$
$$\le \sqrt{20 - 25e^{-1} + 9e^{-2}} < 3.7.$$

Denote $z = (x, y)$. Then

$$haus(F(z_1), F(z_2)) \le \sqrt{3(x_1-x_2)^2 + 3(x_1^{3/5} - x_2^{2/5})^2 + 4(y_1-y_2)^2}$$
$$\le 2|z_1 - z_2| + \sqrt{3} \cdot 2^{3/5}|z_1 - z_2|^{3/5}.$$

Indeed, we showed in the beginning of this section that $|a^{3/5} - b^{3/5}| \le 2|\frac{a-b}{2}|^{3/5}$. Clearly, also,

$$\sigma(z_1 - z_2, F(z_1)) - \sigma(z_1 - z_2, F(z_2))$$
$$= -(x_1-x_2)^2 - (x_1-x_2)(x_1^{3/5} - x_2^{3/5}) + (x_1-x_2)(y_1-y_2) - (y_1-y_2)^2$$
$$\le -\frac{1}{2}[|x_1-x_2|^2 + |y_1-y_2|^2] = -\frac{1}{2}|z_1 - z_2|^2.$$

By these facts and Theorem 4.3 we obtain

$$haus(R_1, R_2) \le 3.7(3h + \sqrt{3} \cdot 2^{2/5}h^{3/5}).$$

Example 6.2 (OSL system that is not Lipschitz on a dense set). Let $\{x_k\}_{k=1}^{\infty}$ be the set of all rational numbers in $[0,1]$ ordered in sequence. Consider the following

system:

$$\dot{x}(t) \in -2x + \sum_{k=1}^{\infty} \frac{1}{2^k}(x_k - x)^{5/7} + [0,1], \quad x(0) = 0.$$

Then

$$\sigma(x-y, F(x)) - \sigma(x-y, F(y)) \le -2|x-y|^2.$$

Moreover, for every measurable $g(t) \in [0,1]$,

$$2 - 2x \ge -2x + \sum_{k=1}^{\infty} \frac{1}{2^k}(x_k - x)^{5/7} + g(t) > -3x,$$

i.e., for every solution $0 \le x(t) \le 1 - e^{-2t}$. The last inequality is also valid for every discrete trajectory. Thus $|F(x)| \le 2$. As in the beginning of this section one can prove that $|x^{5/7} - y^{5/7}| \le 2|\frac{x-y}{2}|^{5/7}$. Therefore $haus(F(x), F(y)) < 2|x-y| + 2^{2/7}|x-y|^{5/7}$. Thus, by Remark 4.2,

$$haus(R_1, R_2) \le \frac{1}{2}(1 - e^{-2})(4h + 2h^{5/7}) + 2h \le 4h + h^{5/7}.$$

Even when the right-hand side F is Lipschitz, sometimes the OSL constant gives a better estimate.

Example 6.3 (Lipschitz continuous multifunction with better OSL constant).

$$\dot{x}(t) \in -6x + y + G(t), \quad x(0) = 0,$$
$$\dot{y}(t) \in x - 6y + H(t), \quad y(0) = 0.$$

Denote again $z = (x, y)$. Therefore

$$haus(F(z_1), F(z_2)) = \sqrt{37(x_1 - x_2)^2 + 37(y_1 - y_2)^2 - 24(x_1 - x_2)(y_1 - y_2)}.$$

Hence the Lipschitz constant is $L = 7$. Furthermore

$$\sigma(z_1 - z_2, F(z_1)) - \sigma(z_1 - z_2, F(z_2))$$
$$-6(x_1 - x_2)^2 + 2(x_1 - x_2)(y_1 - y_2) - 6(y_1 - y_2)^2 \le -5|z_1 - z_2|^2.$$

Let $G(t) \subset [0,1]$ and let $H(t) \subset [0,1]$. It is easy to calculate $0 \le \dot{x}(t) \le 1 - 6x + y$ and $0 \le \dot{y}(t) \le 1 + x - 6y$. Now one can conclude that $0 \le x(t) \le 1/5$, $0 \le y(t) \le 1/5$. Hence $|F(x,y)| \le \sqrt{(1 + 1/5)^2 + (1 + 1/5)^2} = \frac{6\sqrt{2}}{5} \le 2$. If, moreover, $H(t) \equiv G(t) \equiv [0,1]$, then by Remark 4.2, $haus(R_1, R_2) \le \frac{14}{5}(1 - e^{-5})h + 2h \le 5h$. This estimate is much better than the one obtained with the ordinary Lipschitz constant $L = 7$: $haus(R_1, R_2) \le (e^7 - 1)h$.

Acknowledgments. We wish to thank the anonymous referees of the first version of this paper for their valuable comments and suggestions, which contributed much to improve the presentation. We are also grateful to Mrs. Diana Yellin of the School of Mathematical Sciences at Tel-Aviv University for her help in preparing the LaTeX version of this manuscript.

EQUILIBRIUM CONDITIONS FOR YOUNG MEASURES*

PABLO PEDREGAL†

Abstract. We explore variations of Young measures in order to establish equilibrium conditions for minimizers of generalized variational principles where Young measures enter the minimization problem. The slicing measure decomposition is extremely useful in rendering equilibrium conditions tractable; they usually yield information on the support of generalized minimizers. It also enables us to describe new, equivalent variational principles where these equilibrium constraints are taken into account. The only case where computations can be made explicit is the scalar, one-dimensional case.

Key words. generalized variational principles, necessary conditions for equilibrium, slicing measures

AMS subject classifications. 40K27, 35D05

1. Introduction.

Nonconvex variational problems are important from the point of view of applications. For emerging, interesting problems in optimization and the calculus of variations, lack of convexity leads to the analysis of generalized or relaxed principles that provide information on the behavior of minimizing sequences for the original problem. Young measures are fundamental to this approach since they furnish the competing objects for these new variational problems. Some basic references for nonconvexity, Young measures, and applications to several situations in continuum mechanics and in the theory of optimal control (where Young measures were originally introduced) are [2], [5], [6], [7], [8], [9], [14], [15], [16], [17], [18], [19], [27], [28], [29].

Let us consider the problem of finding a minimizer for

$$J(u) = \int_\Omega W(x, u(x), \nabla u(x))\, dx, \quad u \in W^{1,p}(\Omega), u - U \in W_0^{1,p}(\Omega),$$

where $\Omega \subset \mathbf{R}^N$ is a regular domain and U is a given function in $W^{1,p}(\Omega)$. The integrand

$$W : \Omega \times \mathbf{R}^m \times \mathbf{M}^{m\times N} \to \mathbf{R}$$

is assumed to be as smooth as we may need to avoid technicalities in the derivation of equilibrium conditions, and verifies the bounds

$$\begin{aligned} c\left(|A|^p + |\lambda|^p - 1\right) \le W(x,\lambda,A) &\le C\left(|A|^p + |\lambda|^p + 1\right), \\ \left|\frac{\partial W}{\partial A}(x,\lambda,A)\right| &\le C(|A|^{p-1} + |\lambda|^{p-1} + 1), \\ \left|\frac{\partial^2 W}{\partial A^2}(x,\lambda,A)\right| &\le C(|A|^{p-2} + |\lambda|^{p-2} + 1) \end{aligned} \tag{1.1}$$

for $p > 1$ for the bounds on the first derivative, $p > 2$ for the bounds on the second derivative, and $0 < c < C$. The condition that guarantees existence of minimizers for

*Received by the editors March 20, 1996; accepted for publication (in revised form) February 8, 1997. This work was supported by DGICYT (Spain) grant PB93-0070.

J is the property of quasiconvexity (for the vector case $m > 1$) or convexity (for the scalar case $m = 1$) [1], [3], [4], [10], [12], [13], [24]. W is said to be quasiconvex if

$$W(x, \lambda, F) \leq \frac{1}{|\Omega|} \int_\Omega W(x, \lambda, F + \nabla w(y))\, dy \tag{1.2}$$

for every pair $(x, \lambda) \in \Omega \times \mathbf{R}^m$, every matrix $F \in \mathbf{M}^{m\times N}$, and every test function w. When the integrand W enjoys this property, the direct method of the calculus of variations provides minimizers for our problem. The quasiconvexity condition (1.2) together with the bounds (1.1) ensures the weak lower semicontinuity property of the functional J in $W^{1,p}(\Omega)$ [1]. For the scalar case ($m = 1$) (1.2) reduces to plain convexity.

If the quasiconvexity condition (1.2) fails, the problem might not have minimizers; minimizing sequences converge weakly, but weak limits may not be minimizers. In fact, in many situations of interest minimizers do not exist. In some others, existence of minimizers may be established with different techniques (there is a rather large amount of papers on this issue, but we do not include any specific reference because it is not relevant to our discussion here). We would like to place ourselves in the situation where we do not have minimizers so that the quasiconvexity condition (1.2) fails to hold. At this stage, the analysis may proceed in two ways. We may consider the so-called relaxed problem, defined by

$$QJ(u) = \int_\Omega QW(x, u(x), \nabla u(x))\, dx, \quad u \in W^{1,p}(\Omega), u - U \in W_0^{1,p}(\Omega),$$

where QW is the quasiconvexification of W with respect to the gradient variable

$$QW(x, \lambda, F) = \inf_w \frac{1}{|\Omega|} \int_\Omega W(x, \lambda, F + \nabla w(y))\, dy.$$

The infimum is taken over the set of test functions w [11], [12], [13], [22], [23]. Alternately, we may retain the functional J and allow Young measures to enter the minimization problem; this viewpoint is extensively studied in [26]. The crucial point here is to make sure that the admissible Young measures for our problem are generated by sequences of gradients. Under the bounds (1.1), we call those $W^{1,p}$-Young measures: they are generated as the parametrized measure corresponding to the gradients of a bounded sequence in $W^{1,p}(\Omega)$ [5]. We define J on families of probability measures $\nu = \{\nu_x\}_{x\in\Omega}$ by putting

$$J(\nu) = \int_\Omega \int_{\mathbf{M}^{m\times N}} W(x, u(x), A)\, d\nu_x(A)\, dx,$$

where ν is a $W^{1,p}$-Young measure such that

$$\nabla u(x) = \int_{\mathbf{M}^{m\times N}} A\, d\nu_x(A), \quad \text{a.e. } x \in \Omega, \tag{1.3}$$

$u \in W^{1,p}(\Omega)$, and $u - U \in W_0^{1,p}(\Omega)$. Equation (1.3) gives the link between ν and u.

$W^{1,p}$-Young measures are intimately connected to the quasiconvexity condition. Indeed, this class of Young measures are characterized by Jensen's inequality for quasiconvex functions [20], [21]. Precisely, we have the following theorem. For notational convenience, set

$$\mathcal{A} = \left\{ \nabla u : u \in W^{1,p}(\Omega), u - U \in W_0^{1,p}(\Omega) \right\},$$
$$\overline{\mathcal{A}} = \left\{ \nu = \{\nu_x\}_{x\in\Omega} : \nu \text{ is associated with a sequence in } \mathcal{A} \right\}.$$

THEOREM 1.1. *$\nu = \{\nu_x\}_{x\in\Omega}$ belongs to $\overline{\mathcal{A}}$ if and only if*
1. *$\nabla u(x) = \int_{\mathbf{M}^{m\times N}} A\, d\nu_x(A)$ for some $u \in \mathcal{A}$;*
2.

$$\varphi(\nabla u(x)) \le \int_{\mathbf{M}^{m\times N}} \varphi(A)\, d\nu_x(A)$$

for a.e. $x \in \Omega$ and every quasiconvex function φ with growth of order less than p at infinity;

3.

$$\int_\Omega \int_{\mathbf{M}^{m\times N}} |A|^p \; d\nu_x(A)\, dx < \infty.$$

The significance of the different variational principles discussed above and the relationship between them is established in the following important relaxation theorem [10], [12], [13], [21], [26].

THEOREM 1.2.

1.

$$\inf_{\mathcal{A}} J = \inf_{\mathcal{A}} QJ = \inf_{\overline{\mathcal{A}}} J;$$

2. *the last two infima are attained;*
3. *if $\nu = \{\nu_x\}_{x\in\Omega}$ is a minimizer for J in $\overline{\mathcal{A}}$, $u \in \mathcal{A}$ determined by*

$$\nabla u(x) = \int_{\mathbf{M}^{m\times N}} A\, d\nu_x(A), \quad \text{a.e. } x \in \Omega, \tag{1.4}$$

is a minimizer for QJ and

$$QW(x, u(x), \nabla u(x)) = \int_{\mathbf{M}^{m\times N}} W(x, u(x), A)\, d\nu_x(A), \quad \text{a.e. } x \in \Omega; \tag{1.5}$$

conversely, if $u \in \mathcal{A}$ is a minimizer for QJ and $\nu = \{\nu_x\}_{x\in\Omega}$ is such that (1.4) *and* (1.5) *hold, ν is a minimizer for J in $\overline{\mathcal{A}}$;*

4. *if ν is a minimizer for J in $\overline{\mathcal{A}}$,*

$$\operatorname{supp}(\nu_x) \subset \{W(x, u(x), \cdot) = QW(x, u(x), \cdot)\}, \quad \text{a.e. } x \in \Omega.$$

This result is the main motivation for our present analysis. It says that under the bounds (1.1), the functional J always admits minimizers in $\overline{\mathcal{A}}$ regardless of the convexity properties of the integrand W. We would like to derive necessary (equilibrium) conditions that these minimizers should verify, and that may help in understanding their properties. In particular, new, equivalent variational principles may be considered incorporating, as part of admissibility, these equilibrium conditions. Notice that by (1.4) and (1.5), those equilibrium conditions should essentially yield information on the quasiconvexification (or convexification) of functions. Our point of view, however, does not preclude any a priori information on the convex hulls of the integrands involved. We believe that our main contribution here is the way to understand and manipulate "variations" of Young measures (section 2) so that analytical equilibrium conditions can be derived more or less explicitly. On the other hand we provide a clear variational interpretation of some well-known facts about convex hulls of scalar functions.

We concentrate in this paper especially on the scalar ($m = 1$), one-dimensional ($N = 1$) case where the equilibrium conditions lead to specific and concrete conclusions. Notice that in this case quasiconvexity reduces to convexity in the usual sense.

The vector case or even the scalar higher-dimensional case are much more delicate. It is not clear whether equilibrium conditions may provide explicit, nontrivial, helpful information in either of these two situations.

Our analysis is close to that considered in [9]. In this work, the authors talk about Young measures minimizers and Young measures equilibria. The restrictions under which they pursue their analysis (nonlinear elasticity, vector case $m > 1$, rotation, and symmetry invariance) make hard to describe equilibrium as we intend to do here. They pay attention to variations of the domain, and get some helpful equilibrium criteria.

We proceed in several steps of increasing complexity. In section 3, we restrict attention to the scalar, one-dimensional case, where W depends only upon the derivative variable. Spatial dependence does not play a role in this case, and the analysis of the first and second variations lead to restrictions on the support of the minimizer ν. The next step (section 4) allows for the full generality for W depending on x and u as well, but still in the scalar, one-dimensional case. The final section consists of a description of the difficulties with the scalar, higher-dimensional case and the vector case. Some examples to illustrate our results are considered.

2. Variations of Young measures. The basic issue in deriving necessary conditions for equilibrium is to understand "variations" of Young measures: a continuous family of admissible Young measures depending on one parameter. Assume that

$$\nu^{(0)} = \left\{\nu_x^{(0)}\right\}_{x\in\Omega} \in \overline{\mathcal{A}}$$

is a minimizer for J in $\overline{\mathcal{A}}$

$$J(\nu^{(0)}) = \inf_{\overline{\mathcal{A}}} J.$$

Let $\{\nabla u_j\}$ be a generating sequence for $\nu^{(0)}$ so that $\{u_j\} \subset \mathcal{A}$ is minimizing for J in $\mathcal{A}$. For any sequence $\{w_j\}$ such that $w_j \in W_0^{1,p}(\Omega)$ and any t we may consider $\{u_j + tw_j\} \subset \mathcal{A}$. Therefore, the Young measure associated with $\{\nabla(u_j + tw_j)\}$, $\nu^{(t)} = \{\nu_x^{(t)}\}_{x\in\Omega}$, is admissible, and hence

$$J(\nu^{(t)}) \geq J(\nu^{(0)}) \quad \text{for all } t.$$

The function $g(t) = J(\nu^{(t)})$ has a minimum for $t = 0$. This is the classical idea of equilibrium. The issue here is how to manipulate this function g.

Let $\mu = \{\mu_x\}_{x\in\Omega}$ be the Young measure corresponding to the sequence of pairs $\{(\nabla u_j, \nabla w_j)\}$. Clearly, $\nu_x^{(t)}$ is defined via the formula

$$\langle \nu_x^{(t)}, \varphi\rangle = \int_{\mathbf{M}^{m\times N}\times\mathbf{M}^{m\times N}} \varphi(A_0 + tA_1)\, d\mu_x(A_0, A_1).$$

The clue to finding interesting equilibrium conditions is to consider the slicing measure decomposition for μ_x. In general terms, this is a way of decomposing any measure (not just product measures) supported on a product space. In this regard it may be considered as a generalization of Fubini's theorem. The following theorem can be found in [15].

THEOREM 2.1. *Let μ be a nonnegative, finite, Radon measure on $\mathbf{R}^{n+m}$, and let σ be its canonical projection onto $\mathbf{R}^n$ ($\sigma(E) = \mu(E \times \mathbf{R}^m)$). For σ-a.e $x \in \mathbf{R}^n$ there exists a probability measure ν_x on $\mathbf{R}^m$ such that*

i) *the map*

$$x \mapsto \int_{\mathbf{R}^m} f(x,y)\, d\nu_x(y)$$

is σ-measurable;

ii) *for every bounded, continuous function f,*

$$\int_{\mathbf{R}^{n+m}} f(x,y)\, d\mu(x,y) = \int_{\mathbf{R}^n} \left(\int_{\mathbf{R}^m} f(x,y)\, d\nu_x(y) \right) d\sigma(x).$$

A useful way to shorten the statement in ii) is to write

$$\mu(x,y) = \nu_x(y) \otimes \sigma(x).$$

An interesting remark is that this theorem can be the starting point of a treatment of Young measures based on slicing measure decompositions, as was the motivation in [15].

If we apply Theorem 2.1 to each μ_x, we can write

$$\mu_x(A_0, A_1) = \mu_x^{(A_0)}(A_1) \otimes \nu_x^{(0)}(A_0),$$

so that if $\Psi : \mathbf{M}^{m\times N} \times \mathbf{M}^{m\times N} \to \mathbf{R}$ is bounded and continuous, then

$$\int_{\mathbf{M}^{m\times N}\times\mathbf{M}^{m\times N}} \Psi(A_0,A_1)\, d\mu_x(A_0,A_1) = \int_{\mathbf{M}^{m\times N}} \left(\int_{\mathbf{M}^{m\times N}} \Psi(A_0,A_1)\, d\mu_x^{(A_0)}(A_1) \right) d\nu_x^{(0)}(A_0).$$

This same identity holds if Ψ is integrable with respect to μ_x; it is enough to consider bounded truncations of Ψ and conclude by monotone convergence.

Going back to our derivation of equilibrium conditions, we have that $g(t) = J(\nu^{(t)})$ becomes

$$\int_\Omega \int_{\mathbf{M}^{m\times N}} \left(\int_{\mathbf{M}^{m\times N}} W(x, u_0(x) + tw(x), A_0 + tA_1)\, d\mu_x^{(A_0)}(A_1) \right) d\nu_x^{(0)}(A_0)\, dx, \tag{2.1}$$

where, again,

$$\nabla u_0(x) = \int_{\mathbf{M}^{m\times N}} A\, d\nu_x^{(0)}(A) = \int_{\mathbf{M}^{m\times N}\times\mathbf{M}^{m\times N}} A_0\, d\mu_x(A_0,A_1)$$

and

$$\nabla w(x) = \int_{\mathbf{M}^{m\times N}\times\mathbf{M}^{m\times N}} A_1\, d\mu_x(A_0,A_1), \quad w \in W_0^{1,p}(\Omega). \tag{2.2}$$

Notice that the first projection of μ_x is precisely $\nu_x^{(0)}$ and the second one is the parametrized measure generated by $\{\nabla w_j\}$ so that ∇w in (2.2) is its weak limit.

Under suitable smoothness assumptions on W the function g is smooth and the equilibrium conditions (first and second variations) become $g'(0) = 0$ and $g''(0) \geq 0$. The condition on the first derivative (first variation) is written explicitly in the form (the hypotheses assumed on W allow derivation under the integral sign)

$$\int_\Omega \int_{\mathbf{M}^{m\times N}} \left[\frac{\partial W}{\partial \lambda}(x, u_0(x), A_0)\, w(x) + \frac{\partial W}{\partial A}(x, u_0(x), A_0) \int_{\mathbf{M}^{m\times N}} A_1\, d\mu_x^{(A_0)}(A_1) \right] d\nu_x^{(0)}(A_0)\, dx = 0$$

for any such measure μ. If we let

$$\Upsilon_1(x,A_0)=\int_{\mathbf{M}^{m\times N}} A_1\,d\mu_x^{(A_0)}(A_1) \tag{2.3}$$

so that

$$\nabla w(x)=\int_{\mathbf{M}^{m\times N}\times\mathbf{M}^{m\times N}} A_1\,d\mu_x(A_0,A_1)=\int_{\mathbf{M}^{m\times N}}\Upsilon_1(x,A_0)\,d\nu_x^{(0)}(A_0) \tag{2.4}$$

and $w\in W_0^{1,p}(\Omega)$, the first necessary condition may be put in the following way:

$$\begin{aligned}\int_\Omega\int_{\mathbf{M}^{m\times N}}\Big[&\frac{\partial W}{\partial\lambda}\,(x,u_0(x),A_0)\,w(x)\\ &+\frac{\partial W}{\partial A}\,(x,u_0(x),A_0)\,\Upsilon_1(x,A_0)\Big]\,d\nu_x^{(0)}(A_0)\,dx=0.\end{aligned} \tag{2.5}$$

The connection between w and Υ_1 is given in (2.4). Equation (2.5) should be valid for all possible Υ_1 coming from all admissible μ corresponding to all pairs $\{(\nabla u_j,\nabla w_j)\}$ as indicated. The analysis and characterization of the possible test fields Υ_1 are vital.

All this formalism based on the slicing measure decomposition is nothing more than a convenient way of manipulating the function

$$g(t)=\lim_{j\to\infty}\int_\Omega W(x,u_j(x)+tw_j(x),\nabla u_j(x)+t\nabla w_j(x))\,dx.$$

As we have seen, the derivative of g at the origin can be computed by differentiating formally the above limit, interchanging the limit and the derivative

$$\begin{aligned}g'(0)&=\int_\Omega\int_{\mathbf{M}^{m\times N}\times\mathbf{M}^{m\times N}}\Big[\frac{\partial W}{\partial\lambda}\,(x,u_0(x),A_0)\,w(x)\\ &\qquad+\frac{\partial W}{\partial A}\,(x,u_0(x),A_0)\,A_1\Big]\,d\mu_x(A_0,A_1)\,dx\\ &=\lim_{j\to\infty}\int_\Omega\Big[\frac{\partial W}{\partial\lambda}\,(x,u_j(x),\nabla u_j(x))\,w_j(x)\\ &\qquad+\frac{\partial W}{\partial A}\,(x,u_j(x),\nabla u_j(x))\,\nabla w_j(x)\Big]\,dx.\end{aligned}$$

For the second variation we get something similar but more complicated to write. The condition is

$$\begin{aligned}\int_\Omega\int_{\mathbf{M}^{m\times N}}\Big[&\frac{\partial^2 W}{\partial\lambda^2}\,(x,u_0(x),A_0)\,w(x)w(x)\\ &+2\frac{\partial^2 W}{\partial\lambda\partial A}\,(x,u_0(x),A_0)\,w(x)\Upsilon_1(x,A_0)\\ &+\frac{\partial^2 W}{\partial A^2}\,(x,u_0(x),A_0)\,\Upsilon_2(x,A_0)\Big]\,d\nu_x^{(0)}(A_0)\,dx\ge 0,\end{aligned} \tag{2.6}$$

where Υ_1 and w are as in (2.3) and (2.4) and $\Upsilon_2(x,A_0)$ is the tensor of second moments of $\mu_x^{(A_0)}$, in short form,

$$\Upsilon_2(x,A_0)=\int_{\mathbf{M}^{m\times N}} A_1A_1\,d\mu_x^{(A_0)}(A_1). \tag{2.7}$$

Understanding (2.6) would require comprehending the conditions on the tensor of second moments Υ_2 for all admissible μ as before, and its relationship to Υ_1 and w.

We pursue in subsequent sections the analysis of (2.5) and (2.6) in cases of increasing complexity. This amounts to characterizing the test fields Υ_1 and Υ_2 in each case. Remember that these are associated with the slicing decomposition of μ and this in turn is the Young measure associated to pairs of sequences $\{(\nabla u_j, \nabla w_j)\}$ where $u_j \in \mathcal{A}$ and $w_j \in W_0^{1,p}(\Omega)$. Our main task consists of understanding restrictions on Young measures associated with pairs of gradients.

3. The simplest problem. We start by looking at the equilibrium necessary conditions for the simplest case: the scalar, one-dimensional problem when the integrand W depends only on the derivative. Our functional is

$$J(\nu) = \int_\Omega \int_{\mathbf{R}} W(A)\, d\nu_x(A)\, dx,$$

where $\Omega = (0,1)$, W is assumed to be sufficiently smooth and verifying

$$\begin{aligned} c\left(|A|^p - 1\right) \leq W(A) &\leq C\left(|A|^p + 1\right), \\ |W'(A)| &\leq C\left(|A|^{p-1} + 1\right), \\ |W''(A)| &\leq C\left(|A|^{p-2} + 1\right) \end{aligned} \tag{3.1}$$

for $p > 1$ or $p > 2$, $0 < c < C$. The admissibility conditions on ν reduce in this case to requiring

$$\int_\Omega \int_{\mathbf{R}} A\, d\nu_x(A)\, dx = \lambda, \quad \int_\Omega \int_{\mathbf{R}} |A|^p\, d\nu_x(A)\, dx < \infty.$$

The number λ is given and determined by the boundary conditions. Notice that quasiconvexity reduces to convexity and therefore Jensen's inequality does not place any restriction on ν. Let $\overline{\mathcal{A}}$ denote again the class of admissible measures ν.

By Theorem 1.2, J admits minimizers in $\overline{\mathcal{A}}$. An elementary observation is that, since there is no dependence on x, there always exist minimizers $\nu^{(0)}$ not depending on x. Said differently, if $\nu^{(0)} = \{\nu_x^{(0)}\}_{x\in\Omega}$ is a minimizer, the probability measure obtained by "averaging" (see [21]) will also be a minimizer. The converse is also true: if $\nu^{(0)}$ is a minimizer with no spatial dependence, any admissible Young measure whose "average" is $\nu^{(0)}$ will also be a minimizer. The real issue is to find the homogeneous minimizers. We simplify accordingly the setup of the problem:

$$\begin{aligned} J(\nu) &= \int_{\mathbf{R}} W(A)\, d\nu(A), \quad \nu \in \overline{\mathcal{A}}, \\ \overline{\mathcal{A}} &= \left\{ \nu : \lambda = \int_{\mathbf{R}} A\, d\nu(A), \int_{\mathbf{R}} |A|^p\, d\nu(A) < \infty \right\}. \end{aligned}$$

Clearly, we are looking for $CW(\lambda)$, where CW is the convexification of W and $\nu^{(0)}$ is such that

$$CW(\lambda) = J(\nu^{(0)}).$$

In this case the restriction on the pth powers in $\overline{\mathcal{A}}$ does not play a real role. Indeed, by Carathéodory's theorem (see, for instance, [13]), we know that

$$CW(\lambda) = \inf\left\{ tW(\alpha) + (1-t)W(\beta) : t\alpha + (1-t)\beta = \lambda, t \in [0,1] \right\}.$$

Under the coerciveness assumption (3.1) there always exists a minimizer of the form

$$\nu^{(0)} = t\delta_\alpha + (1-t)\delta_\beta.$$

We would like, however, to find necessary equilibrium conditions that must verify all minimizers, not only those supported on two points, and possibly some other elements in $\overline{\mathcal{A}}$.

In this case the first necessary condition (2.5) becomes (recall that we do not have dependence on x)

$$\int_{\mathbf{R}} W'(A_0)\Upsilon_1(A_0)\, d\nu^{(0)}(A_0) = 0 \tag{3.2}$$

for all first moments

$$\Upsilon_1(A_0) = \int_{\mathbf{R}} A_1\, d\mu^{(A_0)}(A_1),$$

where

$$\mu(A_0, A_1) = \mu^{(A_0)}(A_1) \otimes \nu^{(0)}(A_0)$$

is the slicing decomposition of μ generated by a sequence $\left\{(u_j', w_j')\right\}$, $u_j, w_j \in W^{1,p}(\Omega)$, $u_j(1) - u_j(0) = \lambda$, $w_j(1) = w_j(0)$. Let z_j denote the pairs $\left\{(u_j', w_j')\right\}$ so that $z_j : \Omega \subset \mathbf{R} \to \mathbf{R}^2$. $\{z_j\}$ is not a sequence of scalar-valued functions. Yet, since the dimension of Ω is one ($N = 1$), Jensen's inequality does not place any restriction on Young measures generated by derivatives because quasiconvexity collapses to convexity in this case as well (for a full discussion see [13] and [26]). Accordingly, the only constraints on μ to be generated by such sequence of pairs are

$$\begin{aligned} &\int_{\mathbf{R}\times\mathbf{R}} A_0\, d\mu(A_0, A_1) = \lambda, \\ &\int_{\mathbf{R}\times\mathbf{R}} A_1\, d\mu(A_0, A_1) = 0, \\ &\int_{\mathbf{R}\times\mathbf{R}} |A_i|^p\, d\mu(A_0, A_1) < \infty, \quad i = 0, 1. \end{aligned} \tag{3.3}$$

The restrictions that we obtain on the test fields $\Upsilon_1(A_0)$ are

$$\begin{aligned} &\int_{\mathbf{R}} \Upsilon_1(A_0)\, d\nu^{(0)}(A_0) = 0, \\ &\int_{\mathbf{R}} |\Upsilon_1(A_0)|^p\, d\nu^{(0)}(A_0) < \infty. \end{aligned} \tag{3.4}$$

If (3.4) holds, the measure

$$\mu(A_0, A_1) = \delta_{\Upsilon_1(A_0)}(A_1) \otimes \nu^{(0)}(A_0)$$

verifies (3.3).

PROPOSITION 3.1 (first necessary condition). *Equation* (3.2) *is equivalent to the existence of a constant* $k \in \mathbf{R}$ *such that*

$$\operatorname{supp}(\nu^{(0)}) \subset \{W' = k\}.$$

Proof. The proof reduces to examining (3.2) under the constraints (3.4). Let $\Upsilon(A_0)$ be any function such that

$$\int_{\mathbf{R}} |\Upsilon(A_0)|^p\, d\nu^{(0)}(A_0) < \infty.$$

In this case, $\Upsilon_1(A_0) = \Upsilon(A_0) - \overline{\Upsilon}$ satisfies (3.4), where

$$\overline{\Upsilon} = \int_{\mathbf{R}} \Upsilon(A)\, d\nu^{(0)}(A).$$

Put

$$k = \int_{\mathbf{R}} W'(A)\, d\nu^{(0)}(A) \in \mathbf{R}.$$

After some manipulation (3.2) becomes, for this choice of Υ_1,

$$\int_{\mathbf{R}} (W'(A_0) - k)\, \Upsilon(A_0)\, d\nu^{(0)}(A_0) = 0$$

for all such Υ. To conclude, take any Υ such that

$$\Upsilon(A) = \frac{W'(A) - k}{|W'(A) - k|^{(p-2)/(p-1)}}$$

if $W'(A) - k \neq 0$, which is admissible.

The converse is immediate. □

The treatment of the second variation follows along the same lines. Equation (2.6) is simplified to

$$\int_{\mathbf{R}} W''(A_0)\Upsilon_2(A_0)\, d\nu^{(0)}(A_0) \geq 0 \tag{3.5}$$

for all second moments

$$\Upsilon_2(A_0) = \int_{\mathbf{R}} (A_1)^2\ d\mu^{(A_0)}(A_1),$$

where, again,

$$\mu(A_0, A_1) = \mu^{(A_0)}(A_1) \otimes \nu^{(0)}(A_0).$$

The constraints on $\Upsilon_2(A_0)$ simply are

$$\Upsilon_2 \geq 0, \quad \int_{\mathbf{R}} |\Upsilon_2(A_0)|^{p/2}\ d\nu^{(0)}(A_0) < \infty. \tag{3.6}$$

This is elementary to derive. Notice that in order to consider the second variation we take $p \geq 2$ so that the power function with exponent $p/2$ is convex. If (3.6) holds for Υ_2, the measure

$$\mu(A_0, A_1) = \frac{1}{2}\left(\delta_{\sqrt{\Upsilon_2(A_0)}}(A_1) + \delta_{-\sqrt{\Upsilon_2(A_0)}}(A_1)\right) \otimes \nu^{(0)}(A_0)$$

satisfies (3.3).

PROPOSITION 3.2 (second necessary condition). *Equation* (3.5) *is equivalent to*

$$\operatorname{supp}(\nu^{(0)}) \subset \{W'' \geq 0\}.$$

Proof. It is enough to take

$$\Upsilon_2(A_0) = \chi_{\{W''<0\}}(A_0)$$

(χ stands for the characteristic function of the corresponding set) in (3.5). This choice is permitted according to (3.6). □

We gathered the two preceding propositions in the following statement.

THEOREM 3.3. *Let $\nu^{(0)}$ be a minimizer for J in $\overline{\mathcal{A}}$. There exists a constant k such that*

$$\operatorname{supp}(\nu^{(0)}) \subset \{W' = k\} \cap \{W'' \geq 0\}\,. \tag{3.7}$$

It is interesting to notice that these conditions on the support of minimizers do not determine the minimizers themselves so that there might be many equilibrium Young measures. Consider the typical example

$$W(A) = \left(A^2 - 1\right)^2, \quad p = 4,$$

and take $\lambda = 0$. A few easy computations show that (3.7) is verified by a one-parameter family of probability measures

$$\nu_\alpha = t(\alpha)\delta_\alpha + (1 - t(\alpha))\,\delta_{\beta(\alpha)}, \tag{3.8}$$

where $\alpha \in [1/\sqrt{3}, t_0]$, $t_0^3 - t_0 = 2/(3\sqrt{3})$, $\beta^3 - \beta = \alpha^3 - \alpha$, $\beta \in [-t_0, -1/\sqrt{3}]$, and t is determined by $0 = t\alpha + (1-t)\beta$. Of all those, the unique minimizer corresponds to $\alpha = 1$

$$\nu_1 = \frac{1}{2}\delta_1 + \frac{1}{2}\delta_{-1}.$$

We also notice, in view of this example, that there are variations not captured by our scheme in section 2. The family given in (3.8) cannot be reproduced by a variation of the form discussed in section 2. The reason is that the one-parameter family of probability measures obtained as variations of $\nu^{(0)}$, $\nu^{(t)}$, comes from a measure on the product $\mathbf{R} \times \mathbf{R}$, μ, and is such that the two projections are $\nu^{(0)}$ and any other admissible Young measure $\nu \in \overline{\mathcal{A}}$. In this simplified situation, unless $\nu = \nu^{(0)}$, μ has to be a product measure and therefore $\nu^{(t)}$ is supported in four different points. It can never be supported in two points, as is the case with the probabilities in (3.8).

Our conclusions for the case we are analyzing in this section are elementary and well known. They can be easily derived by basic geometric and/or analytical arguments. Indeed, under our coerciveness assumptions on W,

$$CW(\lambda) = \min\left\{tW(\alpha) + (1-t)W(\beta) : \lambda = t\alpha + (1-t)\beta\right\}. \tag{3.9}$$

By Theorem 3.3,

$$\begin{aligned} CW(\lambda) = \min\{&tW(\alpha) + (1-t)W(\beta) : \lambda = t\alpha + (1-t)\beta,\\ &W'(\alpha) = W'(\beta), W''(\alpha) \geq 0, W''(\beta) \geq 0\}\,. \end{aligned}$$

The equilibrium condition $W'(\alpha) = W'(\beta)$ is actually recovered by solving the constrained problem (3.9). This is a good calculus exercise. After some algebra we find

$$CW(\lambda) = tW(\alpha) + (1-t)W(\beta),$$

where

$$\begin{gathered} \frac{W(\alpha) - W(\beta)}{\alpha - \beta} = W'(\alpha) = W'(\beta),\\ W''(\alpha) \geq 0, \quad W''(\beta) \geq 0,\\ \lambda = t\alpha + (1-t)\beta. \end{gathered}$$

It is remarkable that these facts can be interpreted as some sort of equilibrium criterion of a clear variational nature.

4. The scalar, one-dimensional case. We consider in this section the general scalar, one-dimensional case. The functional J is

$$J(\nu) = \int_\Omega \int_{\mathbf{R}} W(x, u(x), A)\, d\nu_x(A)\, dx,$$

where $\Omega = (0,1)$ and the set of admissible measures, ν, is

$$\overline{\mathcal{A}} = \left\{ \nu = \{\nu_x\}_{x\in\Omega} : u'(x) = \int_{\mathbf{R}} A\, d\nu_x(A), u \in W^{1,p}(\Omega), u(0) = 0, \right.$$
$$\left. u(1) = \lambda, \int_\Omega \int_{\mathbf{R}} |A|^p\, d\nu_x(A)\, dx < \infty \right\}.$$

W is assumed to satisfy the coerciveness hypothesis (1.1), and λ is given a priori. The first necessary condition (2.5) becomes in this situation

$$\int_\Omega \int_{\mathbf{R}} \left[\frac{\partial W}{\partial \lambda}(x, u_0(x), A_0)\, w(x) + \frac{\partial W}{\partial A}(x, u_0(x), A_0)\, \Upsilon_1(x, A_0) \right] d\nu_x^{(0)}(A_0)\, dx = 0. \tag{4.1}$$

Remember that

$$u_0'(x) = \int_{\mathbf{R}} A_0\, d\nu_x^{(0)}(A_0).$$

Υ_1 and w are given by

$$\Upsilon_1(x, A_0) = \int_{\mathbf{R}} A_1\, d\mu_x^{(A_0)}(A_1),$$
$$w'(x) = \int_{\mathbf{R}\times\mathbf{R}} A_1\, d\mu_x(A_0, A_1) = \int_{\mathbf{R}} \Upsilon_1(x, A_0)\, d\nu_x^{(0)}(A_0),$$

where $\mu = \{\mu_x\}_{x\in\Omega}$ can be any measure supported on $\mathbf{R}\times\mathbf{R}$ with first projection $\nu^{(0)} = \{\nu_x^{(0)}\}_{x\in\Omega}$ and verifying

$$\int_\Omega \int_{\mathbf{R}\times\mathbf{R}} A_0\, d\mu_x(A_0, A_1)\, dx = \lambda,$$
$$\int_\Omega \int_{\mathbf{R}\times\mathbf{R}} A_1\, d\mu_x(A_0, A_1)\, dx = 0, \tag{4.2}$$
$$\int_\Omega \int_{\mathbf{R}\times\mathbf{R}} |A_i|^p\, d\mu_x(A_0, A_1)\, dx < \infty, \quad i = 0, 1.$$

The restrictions that we obtain on the test fields $\Upsilon_1(x, A_0)$ are

$$\int_\Omega \int_{\mathbf{R}} \Upsilon_1(x, A_0)\, d\nu_x^{(0)}(A_0)\, dx = 0,$$
$$\int_\Omega \int_{\mathbf{R}} |\Upsilon_1(x, A_0)|^p\, d\nu_x^{(0)}(A_0)\, dx < \infty. \tag{4.3}$$

If (4.3) holds, the family of measures

$$\mu_x(A_0, A_1) = \delta_{\Upsilon_1(x,A_0)}(A_1) \otimes \nu_x^{(0)}(A_0)$$

verifies (4.2) trivially.

Relying on this description of the test fields Υ_1 we can identify the first necessary condition.

PROPOSITION 4.1. *Let*

$$F(x) = \int_{\mathbf{R}} \frac{\partial W}{\partial A}\,(x, u_0(x), A_0)\; d\nu_x^{(0)}(A_0),$$
$$G(x) = \int_{\mathbf{R}} \frac{\partial W}{\partial \lambda}\,(x, u_0(x), A_0)\; d\nu_x^{(0)}(A_0)$$

for $x \in \Omega$. Equation (4.1) *is equivalent to*

1. $G - F' = 0$ *(in a weak sense);*
2. $$\operatorname{supp}(\nu_x^{(0)}) \subset \left\{ \frac{\partial W}{\partial A}(x, u_0(x), \cdot) = F(x) \right\}, \quad \text{a.e. } x \in \Omega.$$

Proof. Let $\Upsilon(x, A_0)$ be any function such that

$$\int_\Omega \int_{\mathbf{R}} |\Upsilon(x, A_0)|^p \; d\nu_x^{(0)}(A_0)\, dx < \infty.$$

Consider

$$\Upsilon_1(x, A_0) = \eta(x)\left[\Upsilon(x, A_0) - \overline{\Upsilon}(x)\right] + \xi'(x),$$

which is admissible in (4.1) for any arbitrary smooth function η and any test function ξ, where

$$\overline{\Upsilon}(x) = \int_{\mathbf{R}} \Upsilon(x, A_0)\, d\nu_x^{(0)}(A_0).$$

Equation (4.1) reduces in this case to

$$\int_\Omega \eta(x) \int_{\mathbf{R}} \frac{\partial W}{\partial A}(x, u_0(x), A_0)\left[\Upsilon(x, A_0) - \overline{\Upsilon}(x)\right]\; d\nu_x^{(0)}(A_0)\; dx$$
$$+ \int_\Omega \xi(x)\,(G(x) - F'(x))\; dx = 0.$$

Taking $\eta \equiv 0$, the arbitrariness of ξ leads to 1 in the statement of the proposition, and taking $\xi \equiv 0$, the arbitrariness of η implies

$$\int_{\mathbf{R}} \frac{\partial W}{\partial A}(x, u_0(x), A_0)\left[\Upsilon(x, A_0) - \overline{\Upsilon}(x)\right]\; d\nu_x^{(0)}(A_0) = 0, \quad \text{a.e. } x \in \Omega.$$

This identity can be rewritten as

$$\int_{\mathbf{R}} \left[\frac{\partial W}{\partial A}(x, u_0(x), A_0) - \int_{\mathbf{R}} \frac{\partial W}{\partial A}(x, u_0(x), A)\, d\nu_x^{(0)}(A)\right] \Upsilon(x, A_0)\, d\nu_x^{(0)}(A_0) = 0.$$

If we choose $\Upsilon(x, A_0)$ such that

$$\Upsilon(x, A_0) = \frac{\dfrac{\partial W}{\partial A}(x, u_0(x), A_0) - \displaystyle\int_{\mathbf{R}} \frac{\partial W}{\partial A}(x, u_0(x), A)\, d\nu_x^{(0)}(A)}{\left|\dfrac{\partial W}{\partial A}(x, u_0(x), A_0) - \displaystyle\int_{\mathbf{R}} \frac{\partial W}{\partial A}(x, u_0(x), A)\, d\nu_x^{(0)}(A)\right|^{(p-1)/(p-2)}}$$

whenever the denominator does not vanish, we are led to 2.

The converse is immediate. ∎

For the second variation, when $p \geq 2$ we get

$$\begin{aligned}\int_\Omega \int_{\mathbf{R}} \Big[& \frac{\partial^2 W}{\partial \lambda^2}(x, u_0(x), A_0)\, w(x) w(x) \\ & + 2 \frac{\partial^2 W}{\partial \lambda \partial A}(x, u_0(x), A_0)\, w(x) \Upsilon_1(x, A_0) \\ & + \frac{\partial^2 W}{\partial A^2}(x, u_0(x), A_0)\, \Upsilon_2(x, A_0) \Big]\, d\nu_x^{(0)}(A_0)\, dx \geq 0,\end{aligned} \tag{4.4}$$

where Υ_1 and w are as before, and $\Upsilon_2(x, A_0)$ is the second moment of $\mu_x^{(A_0)}$

$$\Upsilon_2(x, A_0) = \int_{\mathbf{R}} A_1 A_1\, d\mu_x^{(A_0)}(A_1).$$

The relationship between Υ_1 and Υ_2 is clear. Indeed, the constraints on the pair (Υ_1, Υ_2) to be admissible are

$$\begin{gathered}\int_\Omega \int_{\mathbf{R}} \Upsilon_1(x, A)\, d\nu_x^{(0)}(A)\, dx = 0, \\ \int_\Omega \int_{\mathbf{R}} |\Upsilon_2(x, A)|^{p/2}\, d\nu_x^{(0)}(A)\, dx < \infty, \\ \Upsilon_2 \geq \Upsilon_1^2 \geq 0.\end{gathered}$$

To show this, it is enough to consider the family of probability measures

$$\mu_x(A_0, A_1) = \left[\delta_{\Upsilon_1(x, A_0)}(A_1) + \frac{1}{2} \left(\delta_{\Upsilon(x, A_0)}(A_1) + \delta_{-\Upsilon(x, A_0)}(A_1) \right) \right] \otimes \nu_x^{(0)}(A_0),$$

where $\Upsilon(x, A_0) = \sqrt{\Upsilon_2(x, A_0) - \Upsilon_1(x, A_0)^2}$, which is clearly admissible.

PROPOSITION 4.2. *Equation* (4.4) *is equivalent to*

1.

$$\operatorname{supp}(\nu_x^{(0)}) \subset \left\{ \frac{\partial^2 W}{\partial A^2}(x, u_0(x), \cdot) \geq 0 \right\}, \quad \textit{a.e. } x \in \Omega;$$

2. *for all admissible* Υ_1

$$\begin{aligned}\int_\Omega \int_{\mathbf{R}} \Big[& \frac{\partial^2 W}{\partial \lambda^2}(x, u_0(x), A_0)\, w(x) w(x) \\ & + 2 \frac{\partial^2 W}{\partial \lambda \partial A}(x, u_0(x), A_0)\, w(x) \Upsilon_1(x, A_0) \\ & + \frac{\partial^2 W}{\partial A^2}(x, u_0(x), A_0)\, \Upsilon_1^2(x, A_0) \Big]\, d\nu_x^{(0)}(A_0)\, dx \geq 0,\end{aligned}$$

where, again,

$$w'(x) = \int_{\mathbf{R}} \Upsilon_1(x, A_0)\, d\nu_x^{(0)}(A_0)$$

is a test function.

The proof consists in examining (4.4), keeping in mind the restrictions on the pairs (Υ_1, Υ_2). Notice that part 1 is the usual condition yielding further information on the support of $\nu^{(0)}$. Condition 2 expresses the interplay of the different partial derivatives of W. It cannot be easily simplified.

THEOREM 4.3. *Let $\nu^{(0)}$ be a minimizer for J in $\overline{\mathcal{A}}$ and put*

$$F(x) = \int_{\mathbf{R}} \frac{\partial W}{\partial A}\,(x, u_0(x), A_0)\; d\nu_x^{(0)}(A_0),$$
$$G(x) = \int_{\mathbf{R}} \frac{\partial W}{\partial \lambda}\,(x, u_0(x), A_0)\; d\nu_x^{(0)}(A_0)$$

for $x \in \Omega$, where

$$u_0'(x) = \int_{\mathbf{R}} A_0\, d\nu_x^{(0)}(A_0).$$

Then $G - F' = 0$ in a weak sense and

$$\operatorname{supp}(\nu_x^{(0)}) \subset \left\{ \frac{\partial W}{\partial A}(x, u_0(x), \cdot) = F(x) \right\} \cap \left\{ \frac{\partial^2 W}{\partial A^2}(x, u_0(x), \cdot) \geq 0 \right\}, \quad \text{a.e. } x \in \Omega.$$

Let us examine several examples. Take first

$$W(x, A) = \left(A^2 + 2x - 1\right)^2, \quad x \in \Omega = (0, 1),$$

independent of u. In this case $G \equiv 0$ and F is constant. The Young measures equilibria, $\nu = \{\nu_x\}_{x \in \Omega}$, satisfy

$$\operatorname{supp}(\nu_x) \subset \left\{ \frac{\partial W}{\partial A}(x, \cdot) = k \right\} \cap \left\{ \frac{\partial^2 W}{\partial A^2}(x, \cdot) \geq 0 \right\}$$

for some constant k that varies with ν. For this example

$$\operatorname{supp}(\nu_x) \subset \left\{ A \in \mathbf{R} : 4\left(A^2 + 2x - 1\right) A = k \right\} \cap \left\{ A \in \mathbf{R} : 3A^2 + 2x - 1 \geq 0 \right\}.$$

Since W is a polynomial of degree four, the conditions on the support of ν imply that all Young measures equilibria are a convex combination of two deltas

$$\nu_x = t(x)\delta_{\alpha_1(x)} + (1 - t(x))\delta_{\alpha_2(x)},$$

where for some k

$$\begin{aligned} 4\left(\alpha_i(x)^2 + 2x - 1\right)\alpha_i(x) = k, \quad i = 1, 2, \\ 3\alpha_i(x)^2 + 2x - 1 \geq 0, \quad i = 1, 2, \end{aligned} \tag{4.5}$$

and we take $\alpha_1 \leq \alpha_2$. Finally, $t(x) \in [0, 1]$ is determined by the condition

$$\int_\Omega \left[t(x)\alpha_1(x) + (1 - t(x))\alpha_2(x)\right] dx = \lambda. \tag{4.6}$$

The Young measure minimizer would correspond to particular values of k and $t(x)$ in such a way that we can set up a new, equivalent (in the sense that it shares the same minimizers) variational principle where pairs $(k, t(x))$ are the competing objects. In fact set

$$I(k, t) = \int_\Omega \left[t(x)\left(\alpha_1(x)^2 + 2x - 1\right)^2 + (1 - t(x))\left(\alpha_2(x)^2 + 2x - 1\right)^2 \right] dx,$$

where α_i are determined uniquely by (4.5) and the function t verifies the constraint (4.6).

We claim that if

$$|\lambda| \leq \int_0^{1/2} \sqrt{1 - 2x}\, dx, \tag{4.7}$$

the minimizers are of the form

$$\nu_x = \delta_0, \quad x \geq \frac{1}{2},$$
$$\nu_x = t(x)\delta_{\sqrt{1-2x}} + (1-t(x))\delta_{-\sqrt{1-2x}}, \quad x \leq \frac{1}{2},$$

where $t(x)$ is such that

$$\int_0^{1/2} t(x)\sqrt{1-2x}\,dx = \frac{1}{2}\left(\lambda + \int_0^{1/2}\sqrt{1-2x}\,dx\right).$$

Observe that (4.7) permits us to have $t(x) \in [0,1]$. The value of the minimum, m, is

$$m = \int_{1/2}^1 (2x-1)^2\,dx.$$

These facts are easy to derive because α_i have been chosen to be pointwise a minimum of W.

Another example is

$$W(x,u,A) = \left(A^2-1\right)^2 + (u-f(x))^2,$$

where f is a given, smooth function. All of our conditions hold for $p=4$. In this case the conditions for equilibrium are

$$F(x) = \int_{\mathbf{R}} 4A\left(A^2-1\right)\,d\nu_x(A),$$
$$G(x) = 2\left(u(x)-f(x)\right),$$
$$u'(x) = \int_{\mathbf{R}} A\,d\nu_x(A),$$
$$\operatorname{supp}(\nu_x) \subset \left\{4A(A^2-1) = F(x)\right\} \cap \left\{\left(-\infty, -\frac{1}{\sqrt{3}}\right] \cup \left[\frac{1}{\sqrt{3}}, \infty\right)\right\}.$$

The equation $G - F' = 0$ is

$$2\left(u(x)-f(x)\right) - F' = 0,$$

so that

$$u(x) = f(x) + \frac{1}{2}F'(x)$$

and

$$u'(x) = f'(x) - \frac{1}{2}F''(x)$$

must be the first moment of ν_x. Let I_k stand for the convex hull of the set of roots of the equation

$$4A\left(A^2-1\right) = k.$$

For the field F we get the restrictions

$$\begin{aligned} &f'(x) + \frac{1}{2}F''(x) \in I_{F(x)}, \\ &F'(0) = -2f(0), \\ &F'(1) = 2\left(\lambda - f(1)\right). \end{aligned} \tag{4.8}$$

For any such F there exists a unique $\nu = \{\nu_x\}_{x\in\Omega}$, equilibrium measure, which is of the form

$$\nu_x = t(x)\delta_{\alpha_1(x)} + (1-t(x))\delta_{\alpha_2(x)},$$

where α_i are uniquely determined by the conditions

$$\begin{gathered} 4\alpha_i\left(\alpha_i^2-1\right) = F, \quad i=1,2, \\ \alpha_1 \in \left(-\infty, -\frac{1}{\sqrt{3}}\right], \ \alpha_2 \in \left[\frac{1}{\sqrt{3}}, \infty\right), \end{gathered} \tag{4.9}$$

and t is chosen so that

$$t(x)\alpha_1(x) + (1-t(x))\alpha_2(x) = f'(x) + \frac{1}{2}F''(x). \tag{4.10}$$

Consider the functional

$$I(F) = \int_\Omega \left[t(x)\left(\alpha_1(x)^2-1\right)^2 + (1-t(x))\left(\alpha_2(x)^2-1\right)^2 + \frac{1}{4}\left(F'(x)\right)^2\right] dx,$$

under the admissibility conditions (4.8). This problem has a minimizer, F_0, that corresponds exactly to the minimizer $\nu^{(0)} = \{\nu_x^{(0)}\}_{x\in\Omega}$ of J. Notice that by the basic properties of $I_{F(x)}$ we should have

$$4\left(f'(x) - \frac{1}{2}F''(x)\right)\left(\left(f'(x) - \frac{1}{2}F''(x)\right)^2 - 1\right) = F(x)$$

whenever $|F(x)| > 8/(3\sqrt{3})$. In a subsequent work, [25], we will pursue the analysis of this type of variational principle and how it can help in finding $\nu^{(0)}$.

5. Final remarks. We would like to point out the main difficulties with the scalar, higher-dimensional and the vector cases. Concerning the latter, the difficulties are clear. Jensen's inequality with respect to quasiconvex functions places a real and fundamental restriction on Young measures generated by gradients that we do not really understand. What is quite surprising is that almost the same troubles arise in the scalar, higher-dimensional case even though quasiconvexity reduces to convexity in this case.

The whole point is that the class of variations we are considering are associated to Young measures, μ, generated by "pairs" of sequences of gradients $\{(\nabla u_j, \nabla w_j)\}$. Even though each u_j and w_j are scalar-valued, the pair is vector-valued, so that there are restrictions on μ in the form of Jensen's inequality for quasiconvex functions unless the domain Ω is one dimensional. The description of the test fields Υ_1 is the same:

$$\begin{aligned} \Upsilon_1(x, A_0) &= \int_{\mathbf{R}^2} A_1 \, d\mu_x^{(A_0)}(A_1), \\ \mu_x(A_0, A_1) &= \mu_x^{(A_0)}(A_1) \otimes \nu_x^{(0)}(A_0). \end{aligned}$$

But now the constraints we have on Υ_1 are not simply

$$\begin{gathered} \int_{\mathbf{R}^2} \Upsilon_1(x, A_0)\, d\nu_x^{(0)}(A_0) = \nabla w(x), \quad w \in W_0^{1,p}(\Omega), \\ \int_\Omega \int_{\mathbf{R}^2} |\Upsilon_1(x, A_0)|^p \, d\nu_x^{(0)}(A_0)\, dx < \infty, \end{gathered}$$

but also the fact that μ has to be generated by gradients. As we know, this is a profound restriction on μ and the analysis should go deeper than the one carried out in this work.

DIFFERENTIAL GAMES WITH UNBOUNDED VERSUS BOUNDED CONTROLS*

FRANCO RAMPAZZO†

Abstract. A zero-sum differential game with an unbounded control and no coercivity assumptions is investigated. By means of suitable reparameterization techniques one is able to avoid the serious drawbacks which derive from the lack of a sufficiently fast growth hypothesis. In particular, one achieves a remarkable regularization of the two related Hamilton–Jacobi boundary value problems. One also proves that the latter admit unique continuous solutions, which coincide necessarily with the upper and lower values of the game.

Key words. slow growth, differential games, upper and lower values

1. Introduction.

In this paper dynamic programming is investigated for a zero-sum, finite horizon, differential game defined as follows: the dynamics is given by the differential equation

$$\begin{cases} \dot{x} = f(t, x, a, c), \\ x(\bar{t}) = \bar{x}, \end{cases}$$

while the payoff has the form

$$P[\bar{t}, \bar{x}; a, c] \doteq \int_{\bar{t}}^{T} l(t, x, a, c)\ dt + g(x(T)),$$

where the antagonist controls a and c take values in a compact subset $A \subset \mathbb{R}^q$ and a cone $C \subset \mathbb{R}^m$, respectively. Though no bounds are imposed on the values of the control c, the latter is subject to an integral bound of the form

$$\int_{\bar{t}}^{T} |c(t)|\ dt \leq K - \bar{k},$$

where, just like $\bar{t}$ and $\bar{x}$, $\bar{k}$ ($\in [0, K]$) has to be considered as an initial data of the problem. Besides some mild regularity conditions, we assume that the dynamics f and the Lagrangian l are *sublinear* in the unbounded control c, in a sense made precise in section 2. The player maneuvering the *conventional* control a, say, the a-Player, wishes to minimize the functional P, while the c-Player pursues the goal of maximizing P. Of course, the policies of the two players are described as *strategies* (see section 2).

Let us remark that in most cases involving unbounded controls (but an exception is represented by [5]), a superlinear growth assumption involving f and h allows one to exclude the occurrence of controls c which take values larger than a fixed constant which depends on the sole initial data $(\bar{t}, \bar{x})$ (see, e.g., [27]). This makes the problem locally equivalent to the one where only bounded controls are allowed.

*Received by the editors December 6, 1995; accepted for publication (in revised form) February 11, 1997.

On the contrary, the crucial slow growth assumption on f and l can make the exploitation of larger and larger values of c necessary. This is clearly a phenomenon of the same kind as those occurring in connection with problems of calculus of variations with slow growth.

A motivation for studying slow growth differential games (with integral constraints) is trivially represented by the fact that in some practical situations it happens that (the dynamics and the Lagrangian are sublinear and) one of the two controls coincides with the (unbounded) derivative (i.e., the *rate of expenditure*) of some stocked quantity (see, e.g., [10], [12], [15], [17], [23], [26]). A further motivation comes from $\mathcal{H}_\infty$ control problems, with a sublinear performance index replacing the usual quadratic one (see, e.g., [28], [6] for a general account on $\mathcal{H}_\infty$ control problems).

The first question to be answered concerns the regularity of the upper value $\mathcal{U}$ and the lower value $\mathcal{V}$, here defined according to Roxin, Varaya, Elliott, and Kalton (see, e.g., [13]). This question has been treated in a preliminary paper [24], where some continuity properties of both $\mathcal{V}$ and $\mathcal{U}$ have been proved.

In the present paper we complete the program started in [24] by establishing upper value boundary value problems UVBVP and lower value boundary value problems LVBVP (see section 6), whose unique continuous solutions turn out to coincide with $\mathcal{U}$ and $\mathcal{V}$, respectively. It is already known from analogous questions arising in control theory (see [21], [22]) that in the general case a formal extension of the dynamic programming approach finds serious drawbacks. For instance, because of the lack of sufficient growth assumptions, the formal Hamiltonians turn out to be highly discontinuous. Moreover, unless strong commutativity hypotheses are assumed on f and l, no measure-theoretical interpretation of the dynamics accounts for the limits of trajectories corresponding to controls c which take larger and larger values (see, e.g., [8]).

Let us mention incidentally that differential games with measures, appearing linearly with constant coefficients, has been investigated by Yong [29] within the framework of impulse control problems introduced by Bensoussans and Lions [7]. It is easy to see that the involved trajectories are limits of trajectories with unbounded ordinary controls. However, though the dynamics considered in Yong's work represents the simplest case in the class of dynamics we study here, the associated payoff is not a Boltz functional. In particular, Yong's problem cannot be regarded as a *representation* of a standard problem with unbounded controls and slow growth.

The present paper is organized as follows. In section 2 the game is described and the upper and lower value maps are introduced. These maps depend on the initial data $(\bar{t}, \bar{x})$ and on the constant $\bar{k} \in [0, K]$ appearing in the integral constraint on c. Hence they turn out to be defined on the domain $[0, T[\times\mathbb{R}^n \times [0, K]$. Moreover, in [24] it has been proved that these maps are continuous and can be continuously extended to $\bar{t} = T$. In section 3, by suitably developing arguments already exploited in the study of slow growth control problems (see [18], [8], [19], [20]), we define the *reparameterized space-time game*. This game turns out to be equivalent to the original one; i.e., it has the same values. However, it enjoys the advantage of involving controls with *bounded values*. Afterwards, we prove a dynamic programming principle (DPP; see section 4) which differs from the usual one in that it involves intervals of integration varying with the controls c. Moreover, this principle takes a special form at the points where $\mathcal{V} > g$ or $\mathcal{U} > g$. This turns out to be essential when one derives the boundary conditions at $\bar{t} = T$. Successively, this DPP is converted into a *reparameterized dynamic programming principle* (RDPP). The latter allows one to establish Isaacs equations with *continuous* Hamiltonians (see section 5). In section

6 we study the boundary conditions of the problem. They are relatively simple, in that they just involve a subsolution relation and a Dirichlet inequality. Unlike the equations, the boundary conditions for the lower value coincide with the ones for the upper value. Though this is true in the conventional case as well, it is not so obvious in the present case. In fact, in a recent paper [5] boundary conditions for the lower value are established which differ from the ones of the upper value.

In section 6 it is also shown that the lower and upper values are the unique solutions of the corresponding boundary value problems. From the uniqueness result one infers an Isaacs condition that has a standard form (i.e., it consists of the identity of two Hamiltonians).

In section 7 we specialize our results to a particular problem, which has already been investigated by Barron, Jensen, and Menaldi [5], with a different approach. In fact, they consider the case where (the state x and) the control c is scalar and belongs to $C \doteq \{c \in \mathbb{R} : c \geq 0\}$. Moreover, they assume that the dynamics and the Lagrangian reduce to

$$(*) \qquad \begin{aligned} f(t,x,a,c) &= f_0(t,x,a) + f_1(t,a)c, \\ h(t,x,a,c) &= h_0(t,x,a) + h_1(t,a)c, \end{aligned}$$

respectively. (Actually, the results in [5] can be easily extended to the case when h_1—but *not* f_1—depends on x; in particular, this allows the authors to show that the classical minimax control problem is a particular case of the game they are investigating.) On the one hand, the fact that f_1 is independent of x is crucial and allows the authors of [5] to adopt a measure-theoretical definition of trajectory. On the other hand, this approach cannot be extended to the larger class of problems investigated here. Moreover, the Hamiltonians utilized in [5] are discontinuous, and their values are calculated by means of minimizations over sets which depend on the gradient of the value functions themselves. On the contrary, the Isaacs equation we derive in section 5 involves continuous Hamiltonians whose values are the results of min-max operations over a *compact, constant* set. Finally, the boundary conditions established here are quite standard, whereas the ones in [5] need the resolution of an auxiliary boundary value problem.

2. The game. We consider the following zero-sum differential game of fixed duration: a dynamics is given of the form

$$(2.1) \qquad \dot{x} = f(t,x,a,c), \qquad x(\bar{t}) = \bar{x}, \qquad t \in [\bar{t}, T],$$

where $0 \leq \bar{t} < T$, $a(\cdot)$ ranges on a compact subset $A \subset \mathbb{R}^q$, and the control $c(\cdot)$ takes values in a closed cone $C \subset \mathbb{R}^m$ (by *cone* we mean a subset of a real vector space closed under multiplication by nonnegative scalars). The admissible controls $a(\cdot)$ are Borel measurable maps from $[\bar{t}, T]$ into A, and we denote this set by $\mathcal{A}(\bar{t})$. These controls may be thought as implemented by a *player*, say, the a-Player. The opponent will be called the c-Player. Let $K > 0$ be an upper bound for the L^1 norm of the control $c(\cdot)$ maneuvered by the c-Player. For every nonnegative $\bar{k} \leq K$ let us define the family $\mathcal{C}(\bar{t}, \bar{k})$ of admissible controls for the c-Player as the set of integrable maps $c(\cdot)$ from $[\bar{t}, T]$ into C satisfying the inequality

$$\int_{\bar{t}}^{T} |c(t)| dt \leq K - \bar{k}.$$

Throughout the paper we shall assume hypotheses (i) and (ii) below, which, for every control pair $(a, c) \in \mathcal{A}(\bar{t}) \times \mathcal{C}(\bar{t}, \bar{k})$, guarantees global existence, uniqueness,

and exponential growth of each solution to (2.1). Let us denote such a solution by $x[\bar{t},\bar{x};a,c]$ or, whenever the initial data are meant from the context, by $x[a,c]$. Let $g:\mathbb{R}^n\to\mathbb{R}$ be a continuous bounded function and let $l=l(t,x,a,c)$ be a scalar function defined on the domain of f. Let us consider the payoff:

$$P[\bar{t},\bar{x};a,c]\doteq g(x[a,c](T))+\int_{\bar{t}}^{T} l(t,x[a,c](t),a(t),c(t))\,dt.$$

Whenever the initial condition is meant by the context we shall write $P[a,c]$ instead of $P[\bar{t},\bar{x};a,c]$.

We shall assume the following hypotheses on the maps l and f.

Hypotheses.

(i) (*Regularity*) The functions f and l are continuous on $[0,T]\times\mathbb{R}^n\times A\times C$. Moreover, for every compact subset $Q\subset\mathbb{R}^n$, there exists a constant $L>0$ such that

$$\begin{aligned}|(f,l)(t',x',a,c)-(f,l)(t,x,a,c)|\le L(1+|c|)|(t',x')-(t,x)|\\ \forall(t',x',a,c),(t,x,a,c)\in[0,T]\times Q\times A\times C.\end{aligned}\tag{2.2}$$

(ii) (*Sublinear growth in c*) There exist continuous maps l^∞ and f^∞, called the *recession function of l and f*, respectively, such that

$$\lim_{r\to+\infty} r^{-1}l(t,x,a,rc)=l^\infty(t,x,a,c),$$
$$\lim_{r\to+\infty} r^{-1}f(t,x,a,rc)=f^\infty(t,x,a,c),$$

uniformly on compact sets of $[0,T]\times\mathbb{R}^n\times A\times C$, with Q compact. Moreover, for suitable constants $M,N\ge 0$, the map l verifies

$$|l(t,x,a,c)|\le M+N|c|$$

for all $(t,x,a,c)\in[0,T]\times\mathbb{R}^n\times A\times C$.

Under hypothesis (i), for every admissible pair $(a,c)\in\mathcal{A}(\bar{t})\times\mathcal{C}(\bar{t},\bar{k})$, the trajectory $x[a,c]$ and the payoff $P[a,c]$ are well defined. Moreover, it is straightforward to check (see [20, Thm. 2.1]) that if $\bar{x}\in Q$, with Q a compact subset, then there exists a compact set $Q'\supset Q$ such that all trajectories starting at $\bar{t}$ from $\bar{x}$ remain inside Q' during the time-interval $[\bar{t},T]$. Obviously, hypothesis (i) can be replaced by any else condition guaranteeing existence, uniqueness, and a priori boundedness of the trajectories.

On the contrary, hypothesis (ii) is not conventional and makes the problem hardly confrontable by means of standard arguments. In fact, on one hand the formal Hamiltonians are highly discontinuous. On the other hand, no a priori bounds can be assumed on the values of the control c.

As in the case with bounded controls, the game consists of the following: at almost each instant $\tilde{t}\in[\bar{t},T]$ the a-Player, with knowledge of the control implemented by the c-Player in the past interval $[\bar{t},\tilde{t}]$, chooses the control a in order to minimize the payoff, while the c-Player chooses c (with knowledge of a on $[\bar{t},\tilde{t}]$) at almost each instant with the goal of maximizing the payoff. To make the notion of game precise we need a notion of *strategy*. This goal will be achieved by formally adapting Roxin, Varaya, Elliot, and Kalton's definition of strategy (see, e.g., [13]).

DEFINITION 2.1. *A strategy for the a-Player relative to the initial data $(\bar{t},\bar{k})$ is a map $\alpha:\mathcal{C}(\bar{t},\bar{k})\to\mathcal{A}(\bar{t})$ which satisfies the following condition: $\forall\tilde{t}\in[\bar{t},T]$ and for any*

pair of controls $c_1, c_2 \in \mathcal{C}(\bar t, \bar k)$,

$$\begin{aligned} &\textit{if} \quad c_1(t) = c_2(t) \quad \textit{for almost every } t \in [\bar t, \tilde t] \\ &\textit{then} \quad \alpha(c_1)(t) = \alpha(c_2)(t) \quad \textit{for almost every} \quad t \in [\bar t, \tilde t]. \end{aligned}$$

The set of strategies for the a-Player relative to the initial data $(\bar t, \bar k)$ *will be denoted by* $\Delta(\bar t, \bar k)$.

A strategy for the c-Player relative to the initial data $(\bar t, \bar k)$ *is a map* $\gamma : \mathcal{A}(\bar t) \to \mathcal{C}(\bar t, \bar k)$ *which satisfies the following condition:* $\forall \tilde t \in [\bar t, T]$ *and for any pair of controls* $a_1, a_2 \in \mathcal{A}(\bar t)$,

$$\begin{aligned} &\textit{if} \quad a_1(t) = a_2(t) \quad \textit{for almost every} \quad t \in [\bar t, \tilde t] \\ &\textit{then} \quad \gamma(v_1)(t) = \gamma(v_2)(t) \quad \textit{for almost every} \quad t \in [\bar t, \tilde t]. \end{aligned}$$

The set of strategies for the c-Player relative to the pair $(\bar t, \bar k)$ *will be denoted by* $\Gamma(\bar t, \bar k)$.

We recall that maps like α and γ are called *nonanticipating.*

DEFINITION 2.2. *For every* $(\bar t, \bar x, \bar k) \in [0, T[\times \mathbb{R}^n \times [0, K]$ *let us set*

$$\mathcal{V}(\bar t, \bar x, \bar k) \doteq \inf_{\alpha \in \Delta(\bar t, \bar k)} \sup_{c \in \mathcal{C}(\bar t, \bar k)} P[\bar t, \bar x, \alpha(c), c]$$

and

$$\mathcal{U}(\bar t, \bar x, \bar k) \doteq \sup_{\gamma \in \Gamma(\bar t, \bar k)} \inf_{a \in \mathcal{A}(\bar t)} P[\bar t, \bar x, a, \gamma(a)].$$

The maps $\mathcal{V}$ *and* $\mathcal{U}$ *are called the lower value and the upper value of the game, respectively.*

Theorem 2.1 below has been proved in [24].

THEOREM 2.1. *The functions* $\mathcal{U}$ *and* $\mathcal{V}$ *are bounded and continuous. Moreover, they can be continuously extended to the closed domain* $[0, T] \times \mathbb{R}^n \times [0, K]$.

3. Reparameterization of the game. A reparameterization technique (extending one already exploited in optimal control problems (see, e.g., [8], [19], [20], [18])) is now introduced in order to obtain an equivalent (space-time) game where only *bounded controls* and *bounded strategies* are implemented. In turn, this will allow us to establish dynamic programming equations for $\mathcal{V}$ and $\mathcal{U}$ which involve *continuous* Hamiltonians. Let us begin by introducing the notions of space-time control and space-time strategy.

DEFINITION 3.1. *The set* $\widetilde{\mathcal{C}}(\bar t, \bar k)$ *of space-time controls for the c-Player consists of all (bounded) measurable maps* (w_0, w) *from an interval* $[0, L]$, $T - \bar t \le L \le T + K - \bar t - \bar k$, *into* $\mathbb{R}^{m+1}$, *enjoying the following properties:* (1) *for almost every* $s \in [0, L]$, $|(w_0, w)(s)| = 1$ *and* $w(s) \in C$; (2) $w_0(s) > 0$ *for almost every* $s \in [0, L]$, *and* $\int_0^L w_0(s)\, ds = T - \bar t$; (3) *the map* w *satisfies the integral bound* $\int_0^L |w(s)|\, ds \le K - \bar k$.

DEFINITION 3.2. *Let* $c \in \mathcal{C}(\bar t, \bar k)$ *and let* $s(t) \doteq \int_{\bar t}^t |(1, c(\tau))|\, d\tau$, $L_c = s(T)$. *Let us define the map* $c^* = (w_0, w) : [0, L_c] \to [0, \infty) \times \mathbb{R}^m$ *by setting, for every* $s \in [0, L_c]$, $c^*(s) = (w_0, w)(s) = \left(\frac{dt}{ds}(s), \frac{dt}{ds}(s) \cdot c \circ t(s)\right)$ *for every* $s \in [0, L_c]$, *where* $t(s)$ *is the inverse of* $s(t)$.

Conversely, for any $(w_0, w) \in \widetilde{\mathcal{C}}(\bar t, \bar k)$, *let* $s(t)$ *be the inverse map of* $t(s) \doteq \bar t + \int_0^s w_0(\sigma)\, d\sigma$ *and let us define the map* $(w_0, w)_* = c : [\bar t, T] \to \mathbb{R}^m$ *by setting* $c(t) \doteq \frac{w}{w_0} \circ s(t)$ *for every* $t \in [\bar t, T]$.

With standard arguments one can check that for every $c \in \mathcal{C}(\bar{t}, \bar{k})$ one has $c^* \in \widetilde{\mathcal{C}}(\bar{t}, \bar{k})$. Conversely, for every $(w_0, w) \in \widetilde{\mathcal{C}}(\bar{t}, \bar{k})$ one has $(w_0, w)_* \in \mathcal{C}(\bar{t}, \bar{k})$. Moreover, it is easy to prove the following.

PROPOSITION 3.1. *For all $c \in \mathcal{C}(\bar{t}, \bar{k})$ and $(w_0, w) \in \widetilde{\mathcal{C}}(\bar{t}, \bar{k})$ one has*

$$(c^*)_* = c, \qquad ((w_0, w)_*)^* = (w_0, w).$$

In other words, the map $c \mapsto c^*$ establishes a one-to-one correspondence between the sets $\mathcal{C}(\bar{t}, \bar{k})$ and $\widetilde{\mathcal{C}}(\bar{t}, \bar{k})$, and the map $(w_0, w) \mapsto (w_0, w)_*$ is its inverse.

We denote the set of Borel measurable maps from $[0, 1]$ into A by $\widetilde{\mathcal{A}}$. It will be called the set of *space-time controls for the a-Player.*

Let $\rho_{\bar{t}}$ denote the unique increasing linear transformation from $[\bar{t}, T]$ onto $[0, 1]$, and let $\tau_{\bar{t}}$ be the inverse of $\rho_{\bar{t}}$. For any $a \in \mathcal{A}(\bar{t})$ and $v \in \tilde{\mathcal{A}}$ let us set

$$a^* \doteq a \circ \tau_{\bar{t}}, \qquad v_* \doteq v \circ \rho_{\bar{t}}.$$

It is trivial to verify that $a \to a^*$ is a bijection and $v \to v_*$ is its inverse.

For every mapping $\nu : \widetilde{\mathcal{C}}(\bar{t}, \bar{k}) \to \widetilde{\mathcal{A}}$ let us define the map $\nu_* : \mathcal{C}(\bar{t}, \bar{k}) \to \mathcal{A}(\bar{t})$ by setting, for every $c \in \mathcal{C}(\bar{t}, \bar{k})$,

$$\nu_*(c) \doteq \big(\nu(c^*)\big)_*.$$

Conversely, if α maps $\mathcal{C}(\bar{t}, \bar{k})$ into $\mathcal{A}(\bar{t})$, let $\alpha^* : \widetilde{\mathcal{C}}(\bar{t}, \bar{k}) \to \widetilde{\mathcal{A}}$ be the function defined by

$$\alpha^*(w_0, w) \doteq \big(\alpha((w_0, w)_*)\big)^*$$

for every $(w_0, w) \in \widetilde{\mathcal{C}}(\bar{t}, \bar{k})$.

DEFINITION 3.3. *A map $\nu : \widetilde{\mathcal{C}}(\bar{t}, \bar{k}) \to \widetilde{\mathcal{A}}$ is called a space-time strategy for the a-Player provided ν_* is a strategy (i.e., ν_* is nonanticipating). We shall denote the set of space-time strategies for the a-Player by $\widetilde{\Delta}(\bar{t}, \bar{k})$.*

PROPOSITION 3.2. *For all strategies $\alpha \in \Delta(\bar{t}, \bar{k})$ and for all space-time strategies $\nu \in \widetilde{\Delta}(\bar{t}, \bar{k})$ one has*

$$(\alpha^*)_* = \alpha, \qquad (\nu_*)^* = \nu.$$

In particular, α^* is a space-time strategy if and only if α is a strategy.

By Proposition 3.2 the map $\alpha \mapsto \alpha^*$ establishes a one-to-one correspondence between the set of strategies $\Delta(\bar{t}, \bar{k})$ and the set of space-time stategies $\widetilde{\Delta}(\bar{t}, \bar{k})$. Moreover, the map $\nu \mapsto \nu_*$ is the inverse of $\alpha \mapsto \alpha^*$.

We now recall from [20] the notion of space-time extension of the pair (l, f).

DEFINITION 3.4 (see [21]). *Let (l, f) be a pair satisfying hypotheses* (i) *and* (ii). *For every $(t, x, a, w_0, w) \in [0, T] \times \mathbb{R}^n \times A \times [0, +\infty) \times C$ we set*

$$(\bar{l}, \overline{f})(t, x, a, w_0, w) \doteq \begin{cases} w_0 \cdot (l, f)(t, x, a, w/w_0) & \text{if } w_0 \neq 0, \\ (l^\infty, f^\infty)(t, x, a, w) & \text{if } w_0 = 0, \end{cases}$$

where l^∞ and f^∞ are the recession functions introduced with hypothesis (i). *The vector field $\overline{f}$ (resp., the map $\bar{l}$) will be called the space-time extension of f (resp., of l).*

Let us introduce the *space-time version of the differential game*. Given a control $(v, w_0, w) \in \widetilde{\mathcal{A}} \times \widetilde{\mathcal{C}}(\bar{t}, \bar{k})$, let us consider the solution (t, z), defined on the domain $[0, L]$ of (w_0, w), of

$$\begin{cases} t'(s) = w_0(s), \\ z'(s) = \overline{f}\big(t(s), z(s), v_* \circ t(s), w_0(s), w(s)\big), \\ (t, z)(0) = (\bar{t}, \bar{x}) \end{cases} \tag{3.1}$$

and the corresponding payoff

$$\overline{P}[\bar{t}, \bar{x}; v, w_0, w] \doteq g(z(L)) + \int_0^L \bar{l}\big(t(s), z(s), v_* \circ t(s), w_0(s), w(s)\big)\, ds.$$

We shall denote the solution of (3.1) by $(t, z)[\bar{t}, \bar{x}; v, w_0, w]$. Whenever the initial condition is known by the context we shall write $(t, z)[v, w_0, w]$ and $\overline{P}[v, w_0, w]$ instead of $(t, z)[\bar{t}, \bar{x}; v, w_0, w]$ and $\overline{P}[\bar{t}, \bar{x}; v, w_0, w]$, respectively.

The relationship occurring between the original game and its space-time version is illustrated by Propositions 3.3 and 3.4 below.

PROPOSITION 3.3. *Let us consider a control $c \in \mathcal{C}(\bar{t}, \bar{k})$ and a strategy $\alpha \in \Delta(\bar{t}, \bar{x})$. Let us set $L_c \doteq \int_{\bar{t}}^T |1, c(t)|\, dt$, $(w_0, w) \doteq c^*$, and $t(s) \doteq \bar{t} + \int_0^s w_0(\sigma)\, d\sigma$. Then, for every $s \in [0, L_c]$, one has*

$$x[\alpha(c), c] \circ t(s) = z[\alpha^*(c^*), c^*](s)$$

and

$$P[\alpha(c), c] = \overline{P}[\alpha^*(c^*), c^*].$$

As a corollary, in view of Propositions 3.1 and 3.2, one also has the converse passage from space-time trajectories to ordinary ones.

PROPOSITION 3.4. *Let us consider a space-time control $(w_0, w) \in \widetilde{\mathcal{C}}(\bar{t}, \bar{x})$ and a space-time strategy $\nu \in \widetilde{\Delta}(\bar{t}, \bar{x})$. Then, for every $t \in [\bar{t}, T]$, one has*

$$z[\nu(w_0, w), (w_0, w)] \circ s(t) = x[\nu_*((w_0, w)_*), (w_0, w)_*](t)$$

and

$$\overline{P}[\nu(w_0, w), (w_0, w)] = P[\nu_*((w_0, w)_*), (w_0, w)_*],$$

where $s(\cdot)$ denotes the inverse of $t(s) \doteq \bar{t} + \int_0^s w_0(\sigma)\, d\sigma$.

Proof of Proposition 3.3. Let us set $x(t) \doteq x[\alpha(c), c](t)$, $z(s) = z[\alpha^*(c^*), c^*](s)$, $(w_0, w) \doteq c^*$. Then, if $s(\cdot)$ denotes the inverse of $t(\cdot)$ one has

$$\begin{aligned} (x \circ t)'(s) &= t'(s) \cdot f\big(t, x(t), \alpha(c)(t), c(t)\big)_{|_{t=t(s)}} \\ &= w_0(s) \cdot f\left(t, x(t), \alpha(c)(t), \frac{w}{w_0} \circ s(t)\right)_{|_{t=t(s)}} \\ &= \overline{f}\left(t(s), x \circ t(s), \big(\alpha^*(c^*)\big)_* \circ t(s), w_0(s), w(s)\right) \\ &= \overline{f}\left(t(s), x \circ t(s), \big(\alpha^*(c^*)\big)_* \circ t(s), c^*(s)\right). \end{aligned}$$

By the uniqueness of the solution to (3.1) we conclude that the former equality of the thesis is verified. The latter equality is a straightforward consequence of the former. □

As a consequence of the previous results we obtain that the value of the original game and of its space-time version do coincide. Indeed, let us set

$$j(\bar t,\bar x,\bar k,\alpha)\doteq\sup_{c\in\mathcal{C}(\bar t,\bar k)}P[\bar t,\bar x,\bar k,\alpha(c),c],$$
$$\tilde j(\bar t,\bar x,\bar k,\nu)\doteq\sup_{(w_0,w)\in\widetilde{\mathcal{C}}(\bar t,\bar k)}\overline{P}[\bar t,\bar x,\bar k,\nu(w_0,w),(w_0,w)],$$
$$\widetilde{\mathcal{V}}(\bar t,\bar x,\bar k)\doteq\inf_{\nu\in\widetilde{\Delta}(\bar t,\bar k)}\tilde j(\bar t,\bar x,\bar k,\nu).$$

The map $\widetilde{\mathcal{V}}$ will be called the *lower value of the space-time version of the game*. Observe that, by definition, $\mathcal{V}(\bar t,\bar x,\bar k)=\inf_{\alpha\in\Delta(\bar t,\bar k)}j(\bar t,\bar x,\bar k,\alpha)$. By Propositions 3.3 and 3.4 it follows that, $\forall\alpha\in\Delta(\bar t,\bar k)$ and $\forall\nu\in\widetilde{\Delta}(\bar t,\bar k)$,

$$\tilde j(\alpha^*)\le j(\alpha),\qquad j(\nu_*)\le\tilde j(\nu).$$

Hence, by $j(\alpha)=j\big((\alpha^*)_*\big)\le\tilde j(\alpha^*)$, one obtains

$$\tilde j(\alpha^*)=j(\alpha),$$

which, by $\nu=(\nu_*)^*$, implies

$$j(\nu_*)=\tilde j(\nu)$$

as well.

From the previous identities and Proposition 3.2 one infers that the lower value of the original game and of the reparameterized one do coincide.

PROPOSITION 3.5. *For every* $(\bar t,\bar x,\bar k)\in[0,T[\times\mathbb{R}^n\times[0,K]$ *one has*

$$\mathcal{V}(\bar t,\bar x,\bar k)=\widetilde{\mathcal{V}}(\bar t,\bar x,\bar k).$$

Similarly, a space-time extension of the notion of strategy for the c-Player can be introduced. We just write down the definitions and the related results, the proofs being quite similar to the ones concerning the lower value case.

Let (ξ_0,ξ) be a mapping from $\widetilde{\mathcal{A}}$ into $\widetilde{\mathcal{C}}(\bar t,\bar k)$ and let us define the function $(\xi_0,\xi)_*:\mathcal{A}(\bar t)\to\mathcal{C}(\bar t,\bar k)$ by setting, for every $a\in\mathcal{A}(\bar t)$,

$$(\xi_0,\xi)_*(a)\doteq[(\xi_0,\xi)(a^*)]_*.$$

DEFINITION 3.5. *The map* (ξ_0,ξ) *is called a space-time strategy for the c-Player provided* $(\xi_0,\xi)_*$ *is a strategy (i.e., it is nonanticipating). The set of space-time strategies for the c-Player will be denoted by* $\tilde\Gamma(\bar t,\bar k)$.

On the other hand, for every map $\gamma:\mathcal{A}(\bar t)\to\mathcal{C}(\bar t,\bar k)$ let us define the function $\gamma^*:\widetilde{\mathcal{A}}\to\widetilde{\mathcal{C}}(\bar t,\bar k)$ by setting, for every $v\in\widetilde{\mathcal{A}}$,

$$\gamma^*(v)\doteq[\gamma(v_*)]^*.$$

PROPOSITION 3.6. *For every strategy* $\gamma\in\Gamma(\bar t,\bar k)$ *and every space-time control* $(\xi_0,\xi)\in\widetilde{\Gamma}(\bar t,\bar x)$, *one has*

$$(\gamma^*)_*=\gamma,\qquad[(\xi_0,\xi)_*]^*=(\xi_0,\xi).$$

In particular γ^* *is a space-time strategy if and only if* γ *is a strategy.*

By Proposition 3.6 we obtain that the map $\gamma \mapsto \gamma^*$ establishes a one-to-one correspondence between the set of strategies $\Gamma(\bar t, \bar k)$ and the set of space-time stategies $\widetilde\Gamma(\bar t, \bar k)$. Moreover, the map $(\xi_0, \xi) \mapsto (\xi_0, \xi)_*$ is the inverse of $\gamma \mapsto \gamma^*$. Propositions 3.7 and 3.8 below are the anologues of Propositions 3.3 and 3.4 for the upper value.

PROPOSITION 3.7. *Let us consider a control $a \in \mathcal{A}(\bar t)$ for the a-Player and a strategy $\gamma \in \Gamma(\bar t, \bar x)$ for the c-Player. Then, for every $s \in [0, L_{\gamma(a)}]$, $L_{\gamma(a)} \doteq \int_{\bar t}^T |1, \gamma(a)(t)|\, dt$, one has*

$$x[a, \gamma(a)] \circ t(s) = z[a^*, \gamma^*(a^*)](s)$$

and

$$P[a, \gamma(a)] = \overline{P}[a^*, \gamma^*(a^*)],$$

where $t(s) \doteq \bar t + \int_0^s w_0(\sigma)\, d\sigma$.

PROPOSITION 3.8. *Let us consider a space-time control $v \in \widetilde{\mathcal{A}}$ and a strategy $(\xi_0, \xi) \in \widetilde\Gamma(\bar t, \bar x)$, and let us set $(w_0, w) \doteq (\xi_0, \xi)(v)$. Then, for every $t \in [\bar t, T]$, one has*

$$z[v, (\xi_0, \xi)(v)] \circ s(t) = x[v_*, (\xi_0, \xi)_*(v_*)](t)$$

and

$$\overline{P}[v, (\xi_0, \xi)(v)] = P[v_*, (\xi_0, \xi)_*(v_*)],$$

where $s(t)$ denotes the inverse of $t(s) \doteq \bar t + \int_0^s w_0(\sigma)\, d\sigma$.

Let us set

$$\begin{aligned} i[\bar t, \bar x, \bar k, \gamma] &\doteq \inf_{a \in \mathcal{A}(\bar t)} P[\bar t, \bar x, \bar k, a, \gamma(a)], \\ \tilde i[\bar t, \bar x, \bar k, (\xi_0, \xi)] &\doteq \inf_{v \in \widetilde{\mathcal{A}}} \overline{P}[\bar t, \bar x, \bar k, v, (\xi_0, \xi)(v)], \\ \widetilde{\mathcal{U}}(\bar t, \bar x, \bar k) &\doteq \sup_{(\xi_0, \xi) \in \widetilde\Gamma(\bar t, \bar k)} \tilde i[\bar t, \bar x, \bar k, (\xi_0, \xi)]. \end{aligned}$$

The map $\widetilde{\mathcal{U}}$ will be called the *upper value of the space-time version of the game.* Just as in the case of the lower value, we have

$$\tilde i[\gamma^*] = i[\gamma], \qquad i[(\xi_0, \xi)_*] = \tilde i[(\xi_0, \xi)],$$

from which the following proposition follows.

PROPOSITION 3.9. *For every $(\bar t, \bar x, \bar k) \in [0, T[\times \mathbb{R}^n \times [0, K]$ one has*

$$\mathcal{U}(\bar t, \bar x, \bar k) = \widetilde{\mathcal{U}}(\bar t, \bar x, \bar k).$$

4. Dynamic programming. Let us set, for every $c \in \mathcal{C}(\bar t, \bar k)$ and $t \in [\bar t, T]$,

$$s_c(t) \doteq \int_{\bar t}^t |1, c(\tau)|\, d\tau,$$

and let $t_c : [0, s_c(T)] \to [\bar t, T]$ be the inverse of s_c. Notice that, for every $c \in \mathcal{C}(\bar t, \bar k)$, one has $[0, T - \bar t] \subseteq [0, s_c(T)]$.

In Theorem 4.1 below and throughout the paper we shall adopt the following convention: whenever an initial condition $(\bar t,\bar x,\bar k)$, a control (a,c), and a pair $(x,k)(\cdot)$ appear in the same formula, it is meant that

$$(x,k)(t) \doteq \left(x[\bar t,\bar x;a,c](t), \bar k + \int_{\bar t}^{t} |c(\tau)|\, d\tau\right).$$

For every $\sigma>0$ let us define the subset $\mathcal{C}_\sigma(\bar t,\bar k)\subset\mathcal{C}(\bar t,\bar k)$ as the set of those controls c such that the domain $[0,L_c]$ of the corresponding c^* and of t_c contains the interval $[0,\sigma]$, i.e.,

$$\mathcal{C}_\sigma(\bar t,\bar k) \doteq \left\{ c\in\mathcal{C}(\bar t,\bar k) \quad : \quad \int_{\bar t}^{T} |(1,c)| > \sigma \right\}.$$

Observe that $\mathcal{C}_\sigma(\bar t,\bar k)\neq\emptyset$ for every $\sigma\in]0,\max\{T-\bar t,K-\bar k\}[$, in that the constant control $c\doteq(K-\bar k)/(T-\bar t)$ belongs to $\mathcal{C}_\sigma(\bar t,\bar k)$. Let us also define the subset of strategies $\Gamma_\sigma(\bar t,\bar k)\subset\Gamma(\bar t,\bar k)$ by setting

$$\Gamma_\sigma(\bar t,\bar k) \doteq \big\{\gamma\in\Gamma(\bar t,\bar k) \quad | \quad \gamma(a)\in\mathcal{C}_\sigma(\bar t,\bar k) \quad \forall a\in\mathcal{A}(\bar t)\big\}.$$

Since the constant mappings from $\mathcal{A}(\bar t)$ into $\mathcal{C}(\bar T,\bar k)$ are strategies, for every $\sigma\in]0,\max\{T-\bar t,K-\bar k\}[$ we have that $\Gamma_\sigma(\bar t,\bar k)\neq\emptyset$ as well. It is also straightforward to check that for every $\sigma<T-\bar t$ one has $\mathcal{C}_\sigma(\bar t,\bar k)=\mathcal{C}(\bar t,\bar k),\Gamma_\sigma(\bar t,\bar k)=\Gamma(\bar t,\bar k)$. Before stating a Dynamic Programming Principle for our problem let us show that as soon as $\mathcal{U}>g$ (resp., $\mathcal{V}>g$) one can replace the set Γ (resp., $\mathcal{C}$) in the definition of $\mathcal{U}$ (resp., $\mathcal{V}$) with a subset Γ_σ (resp., $\mathcal{C}_\sigma$), for a suitable choice of σ.

PROPOSITION 4.1. *Let $Q\subset\mathbb{R}^n$ be a compact subset and let $\eta>0$. Then there exists a constant $\hat\sigma$ such that for every $(\bar t,\bar x,\bar k)\in[0,T[\times Q\times[0,K]$ verifying $\mathcal{U}(\bar t,\bar x,\bar k)-g(\bar x)\geq\eta$ (resp., $\mathcal{V}(\bar t,\bar x,\bar k)-g(\bar x)\geq\eta$) one has*

$$\mathcal{U}(\bar t,\bar x,\bar k) = \sup_{\gamma\in\Gamma_\sigma(\bar t,\bar k)} \inf_{a\in\mathcal{A}(\bar t)} P[\bar t,\bar x;a,\gamma(a)]$$

(resp.,

$$\mathcal{V}(\bar t,\bar x,\bar k) = \inf_{\alpha\in\Delta(\bar t)} \sup_{c\in\mathcal{C}_\sigma(\bar t,\bar k)} P[\bar t,\bar x;\alpha(c),c])$$

for all $\sigma\leq\hat\sigma$.

Proof. The fact that the right-hand sides are less than or equal to the corresponding left-hand sides is trivial. Let us prove that the converse inequalities hold true. We claim that for every $\epsilon>0$ there exists a σ such that the set reachable from $(\bar t,\bar x,\bar k)$ with controls $(a,c)\in\mathcal{A}(\bar t)\times(\mathcal{C}(\bar t,\bar k)\backslash\mathcal{C}_\sigma(\bar t,\bar k))$ is contained in the ball $B[(\bar t,\bar x,\bar k);\epsilon]$ of center $(\bar t,\bar x,\bar k)$ and radius ϵ. Indeed, if $c\in\mathcal{C}(\bar t,\bar k)\backslash\mathcal{C}_\sigma(\bar t,\bar k)$, one has

$$T-\bar t\leq\sigma, \qquad k(T)-\bar k\doteq\int_{\bar t}^{T}|c(t)|dt\leq\sigma.$$

Moreover, for every $(a,c)\in\mathcal{A}(\bar t)\times\mathcal{C}(\bar t,\bar k)$, one has

$$x[\bar t,\bar x;a,c](T)-\bar x = z[\bar t,\bar x;a^*,c^*](s_c(T))-\bar x.$$

Hence the claim follows from a trivial application of Gronwall's lemma to the space-time system (3.1), in that the controls (a^*, c^*) take values in the compact set $A \times \{(w_0, w) \in \mathbb{R}^{m+1} : |(w_0, w)| = 1\}$.

Therefore, in view of the assumptions on l and of the uniform continuity of g on Q, we can infer the existence of a $\hat\sigma$ such that for every $\sigma \le \hat\sigma$ one has

$$|P[\bar t, \bar x; a, c] - g(\bar x)| = |\overline{P}[\bar t, \bar x; a^*, c^*] - g(\bar x)| \le \frac{\eta}{2}$$

for all $(a, c) \in \mathcal{A}(\bar t) \times (\mathcal{C}(\bar t, \bar k) \backslash \mathcal{C}_\sigma(\bar t, \bar k))$. Since the values $\mathcal{U}(\bar t, \bar x, \bar k)$ and $\mathcal{V}(\bar t, \bar x, \bar k)$ belong to the closure of the set $\big\{P[\bar t, \bar x; a, c] \ : \ (a, c) \in \mathcal{A}(\bar t) \times \mathcal{C}(\bar t, \bar k)\big\}$, it follows that

$$\mathcal{U}(\bar t, \bar x, \bar k) > \sup_{\gamma \in (\Gamma(\bar t, \bar k) \backslash \Gamma_\sigma(\bar t, \bar k))} \inf_{a \in \mathcal{A}(\bar t)} P[\bar t, \bar x; a, \gamma(a)]$$

and

$$\mathcal{V}(\bar t, \bar x, \bar k) > \inf_{\alpha \in \Delta(\bar t)} \sup_{c \in (\mathcal{C}(\bar t, \bar k) \backslash \mathcal{C}_\sigma(\bar t, \bar k)} P[\bar t, \bar x; \alpha(c), c],$$

which implies the thesis. □

THEOREM 4.1 (Dynamic Programming Principle (DPP)). *For every* $(\bar t, \bar x, \bar k) \in [0, T[\times \mathbb{R}^n \times [0, K]$ *and* $0 < \sigma < T - \bar t$ *one has*

$$\mathcal{V}(\bar t, \bar x, \bar k) = \inf_{\alpha \in \Delta(\bar t, \bar k)} \sup_{c \in \mathcal{C}(\bar t, \bar x)} \left\{ \int_{\bar t}^{t_c(\sigma)} l\big(t, x(t), \alpha(c)(t), c(t)\big)\, dt + \mathcal{V}\big(t_c(\sigma), x \circ t_c(\sigma), k_c \circ t_c(\sigma)\big) \right\} \tag{4.1}$$

and

$$\mathcal{U}(\bar t, \bar x, \bar k) = \sup_{\gamma \in \Gamma(\bar t, \bar k)} \inf_{a \in \mathcal{A}(\bar t)} \left\{ \int_{\bar t}^{t_{\gamma(a)}(\sigma)} l\big(t, x(t), a(t), \gamma(a)(t)\big)\, dt + \mathcal{U}\big(t_{\gamma(a)}(\sigma), x \circ t_{\gamma(a)}(\sigma), k \circ t_{\gamma(a)}(\sigma)\big) \right\}, \tag{4.2}$$

where, for every $c \in \mathcal{C}(\bar t, \bar k)$, t_c *is defined as in the beginning of this section.*

Moreover, if $Q \subset \mathbb{R}^n$ *is a compact subset and* $(\bar t, \bar x, \bar k) \in [0, T[\times Q \times [0, K[$ *satisfies* $\mathcal{U}(\bar t, \bar x, \bar k) - g(x) \ge \eta > 0$ *(resp.,* $\mathcal{V}(\bar t, \bar x, \bar k) - g(x) \ge \eta > 0$*), there exists a* $\hat\sigma > 0$ *such that*

$$\mathcal{V}(\bar t, \bar x, \bar k) = \inf_{\alpha \in \Delta(\bar t, \bar k)} \sup_{c \in \mathcal{C}_\sigma(\bar t, \bar x)} \left\{ \int_{\bar t}^{t_c(\sigma)} l\big(t, x(t), \alpha(c)(t), c(t)\big)\, dt + \mathcal{V}\big(t_c(\sigma), x \circ t_c(\sigma), k_c \circ t_c(\sigma)\big) \right\} \tag{4.3}$$

(resp.,

$$\mathcal{U}(\bar t, \bar x, \bar k) = \sup_{\gamma \in \Gamma_\sigma(\bar t, \bar k)} \inf_{a \in \mathcal{A}(\bar t)} \left\{ \int_{\bar t}^{t_{\gamma(a)}(\sigma)} l\big(t, x(t), a(t), \gamma(a)(t)\big)\, dt + \mathcal{U}\big(t_{\gamma(a)}(\sigma), x \circ t_{\gamma(a)}(\sigma), k \circ t_{\gamma(a)}(\sigma)\big) \right\} \tag{4.4}$$

for all $\sigma \le \hat\sigma$.

Remark 4.1. The idea of the proof of this theorem is not far from the one exploited in the conventional case (see, e.g., [13]), where only bounded controls are involved. However, unlike the conventional case, the intervals of integration involved in (4.1)–(4.4) are not constant for a fixed σ, and the variable k is constrained to be less than or equal to K. Let us also remark that the validity of (4.3) and (4.4) does not find a counterpart in the conventional case. These equalities mean that as soon as $\mathcal{V}$ or $\mathcal{U}$ is greater than the cost function, one can take a smaller set of controls c in the corresponding DPP. This fact will be *essential* when we establish the boundary conditions for $\mathcal{U}$ and $\mathcal{V}$ on $t = T$ (see Theorem 6.1).

Proof of Theorem 4.1. Denoting the right-hand side of (4.1) and (4.2) by $W(\bar{t}, \bar{x}, \bar{k})$ and $Y(\bar{t}, \bar{x}, \bar{k})$, respectively, we shall limit ourselves to demonstrate that

$$W(\bar{t}, \bar{x}, \bar{k}) \geq \mathcal{V}(\bar{t}, \bar{x}, \bar{k}) \tag{4.5}$$

and

$$Y(\bar{t}, \bar{x}, \bar{k}) \geq \mathcal{U}(\bar{t}, \bar{x}, \bar{k}), \tag{4.6}$$

the proof of the converse inequality of (4.5) (resp., (4.6)) being quite similar to the proof of (4.6) (resp., (4.5)). Moreover, in view of Proposition 4.1, the proofs of (4.3) and (4.4) can be straightforwardly obtained by the ones of (4.1) and (4.2), respectively, by formally replacing $\mathcal{C}(\bar{t}, \bar{k})$ with $\mathcal{C}_\sigma(\bar{t}, \bar{k})$ and $\Gamma(\bar{t}, \bar{k})$ with $\Gamma_\sigma(\bar{t}, \bar{k})$.

Let us fix a $\sigma \in]0, T - \bar{t}[$. For a given $\epsilon > 0$ there exists a strategy $\alpha_1 \in \Delta(\bar{t}, \bar{k})$ such that

$$\begin{aligned} W(\bar{t}, \bar{x}, \bar{k}) \geq \sup_{c \in \mathcal{C}(\bar{t}, \bar{k})} \Bigg\{ & \int_{\bar{t}}^{t_c(\sigma)} l\big(t, x(t), \alpha_1(c)(t), c\big)\, dt \\ & + \mathcal{V}\big(t_c(\sigma), x \circ t_c(\sigma), k \circ t_c(\sigma)\big) \Bigg\} - \epsilon. \end{aligned} \tag{4.7}$$

For every $c \in \mathcal{C}(\bar{t}, \bar{k})$ there is a strategy $\alpha_c \in \Delta\big(t_c(\sigma), k(t_c(\sigma))\big)$ such that

$$\begin{aligned} & \mathcal{V}\big(t_c(\sigma), x \circ t_c(\sigma), k \circ t_c(\sigma)\big) \\ & \quad \geq \sup_{\tilde{c} \in \mathcal{C}\left(t_c(\sigma), k \circ t_c(\sigma)\right)} P[t_c(\sigma), x \circ t_c(\sigma); \alpha_c(\tilde{c}), \tilde{c}] - \epsilon. \end{aligned} \tag{4.8}$$

Let us define a strategy $\alpha_2 \in \mathcal{A}(\bar{t})$ by setting

$$\alpha_2(c)(t) \doteq \begin{cases} \alpha_1(c)(t) & \forall t \in [\bar{t}, t_c(\sigma)[, \\ \alpha_c\left(c_{|_{[t_c(\sigma), T]}}\right)(t), & t \in [t_c(\sigma), T], \end{cases}$$

where, for every $c \in \mathcal{C}(\bar{t}, \bar{k})$, $c_{|_{[t_c(\sigma), T]}}$ denotes the restriction of c to the interval $[t_c(\sigma), T]$. It is not difficult to verify that α_2 is in fact nonanticipating. By (4.7), (4.8), we obtain, for every $c \in \mathcal{C}(\bar{t}, \bar{k})$,

$$W(\bar{t}, \bar{x}, \bar{k}) \geq P[\alpha_2(c), c] - 2\epsilon,$$

which, by the arbitrariness of ϵ, yields (4.5).

In order to prove (4.6), let us select a strategy $\gamma_1 \in \Gamma_\sigma(\bar{t}, \bar{k})$ satisfying

$$\mathcal{U}(\bar{t}, \bar{x}, \bar{k}) \leq \inf_{a \in \mathcal{A}(\bar{t})} P[\bar{t}, \bar{x}; a, \gamma_1(a)] + \epsilon.$$

By the definition of Y one obtains

$$Y(\bar t,\bar x,\bar k)\geq \inf_{a\in\mathcal{A}(\bar t)}\left\{\int_{\bar t}^{t_{\gamma_1(a)}(\sigma)} l\big(t,x(t),a(t),\gamma_1(a)(t)\big)\ dt \right.$$
$$\left. +\,\mathcal{U}\left(t_{\gamma_1(a)}(\sigma),x\circ t_{\gamma_1(a)}(\sigma),k\circ t_{\gamma_1(a)}(\sigma)\right)\right\},$$

thence there exists an $a_1\in\mathcal{A}(\bar t)$ so that

$$Y(\bar t,\bar x,\bar k)+\epsilon\geq \int_{\bar t}^{t_{\gamma_1(a_1)}(\sigma)} l\big(t,x(t),a_1(t),\gamma_1(a_1)(t)\big)\ dt$$
$$+\,\mathcal{U}\left(t_{\gamma_1(a_1)}(\sigma),x\circ t_{\gamma_1(a_1)}(\sigma),k\circ t_{\gamma_1(a_1)}(\sigma)\right).$$

For every $a\in\mathcal{A}(t_{\gamma_1(a_1)}(\sigma))$ let us define a control $\hat a\in\mathcal{A}(\bar t)$ by setting

$$\hat a(t)\doteq\begin{cases} a_1 & \forall t\in[\bar t,t_{\gamma_1(a_1)}(\sigma)],\\ a & \forall t\in]t_{\gamma_1(a_1)}(\sigma),T].\end{cases}$$

The function $\gamma_2:\mathcal{A}(t_{\gamma_1(a_1)}(\sigma))\to\mathcal{C}\big(t_{\gamma_1(a_1)}(\sigma),k\circ t_{\gamma_1(a_1)}(\sigma)\big)$, which maps a control $a\in\mathcal{A}(t_{\gamma_1(a_1)}(\sigma))$ into the control

$$\gamma_2(a)(t)\doteq(\gamma_1(\hat a))(t),\qquad t\in[t_{\gamma_1(a_1)}(\sigma),T],$$

turns out to belong to $\Gamma\big(t_{\gamma_1(a_1)}(\sigma),k\circ t_{\gamma_1(a_1)}(\sigma)\big)$. Indeed, it is nonanticipating, and for every $a\in\mathcal{A}(t_{\gamma_1(a_1)}(\sigma))$, one has

$$\int_{t_{\gamma_1(a_1)}(\sigma)}^{T}|\gamma_2(a)(t)|dt\leq K-\bar k-\left(k\circ t_{\gamma_1(a_1)}(\sigma)-\bar k\right).$$

In particular, it follows that

$$\mathcal{U}\left(t_{\gamma_1(a_1)}(\sigma),x\circ t_{\gamma_1(a_1)}(\sigma),k\circ t_{\gamma_1(a_1)}(\sigma)\right)$$
$$\geq\inf_{a\in\mathcal{A}(t_{\gamma_1(a_1)}(\sigma))}P[a,\gamma_2(a)].$$

Hence, there exists a control $a_2\in\mathcal{A}(t_{\gamma_1(a_1)}(\sigma))$ so that

$$\mathcal{U}\left(t_{\gamma_1(a_1)}(\sigma),x\circ t_{\gamma_1(a_1)}(\sigma),k\circ t_{\gamma_1(a_1)}(\sigma)\right)$$
$$\geq P[a_2,\gamma_2(a_2)]-\epsilon.$$

Finally, the previous inequalities imply that

$$Y(\bar t,\bar x,\bar k)\geq\int_{\bar t}^{t_{\gamma_1(a_1)}(\sigma)} l\left(t,x(t),a_1(t),\gamma_1(a_1)(t)\right)\ dt$$
$$+\int_{t_{\gamma_1(a_1)}(\sigma)}^{T} l\left(t,x(t),a_2(t),\gamma_2(a_2)(t)\right)\ dt+g(x(T))-2\epsilon$$
$$\geq P[\hat a_2,\gamma_1(\hat a_2)]-2\epsilon\geq\inf_{a\in\mathcal{A}(\bar t)}P[a,\gamma_1(a)]-2\epsilon\geq\mathcal{U}(\bar t,\bar x,\bar k)-3\epsilon,$$

from which (4.6) follows, in view of the the arbitrariness of ϵ. □

As a consequence of Theorem 4.1 and of Propositions 3.3–3.5 and 3.7–3.9, we obtain the reparameterized dynamic programming principle (RDPP) below. In turn, the latter allows us to establish boundary value problems for $\mathcal{U}$ and $\mathcal{V}$ involving continuous Hamiltonians and rather simple boundary conditions (see sections 5 and 6). In the statetement of Theorem 4.2 below and in the rest of the paper we adopt the following convention: whenever an initial condition $(\bar t, \bar x, \bar k)$, a control (v, w_0, w), and a triple $(t, z, k)(\cdot)$ appear in the same formula, it is meant that

$$(t,z,k)(s) \doteq \left(\bar t + \int_0^s w_0(\eta)\, d\eta, z[\bar t, \bar x; v, w_0, w](s), \bar k + \int_0^s |w(\eta)|\, d\eta\right)$$

for every $s \in [0,1]$.

Let us define the subsets $\tilde{\mathcal{C}}_\sigma(\bar t, \bar k)$ and $\tilde\Gamma_\sigma(\bar t, \bar k)$ by setting

$$\begin{aligned}\tilde{\mathcal{C}}_\sigma(\bar t, \bar k) &\doteq \big\{(w_0, w) \in \tilde{\mathcal{C}}(\bar t, \bar k) \quad | \quad (w_0, w)_* \in \mathcal{C}_\sigma(\bar t, \bar k)\big\},\\ \tilde\Gamma_\sigma(\bar t, \bar k) &\doteq \big\{(\xi_0, \xi) \in \tilde\Gamma(\bar t, \bar k) \quad | \quad (\xi_0, \xi)_* \in \Gamma_\sigma(\bar t, \bar k)\big\}.\end{aligned}$$

Clearly, for every $\sigma \in]0, \max\{T - \bar t, K - \bar k\}[$ one has $\tilde{\mathcal{C}}_\sigma(\bar t, \bar k) \neq \emptyset$ and $\tilde\Gamma_\sigma(\bar t, \bar k) \neq \emptyset$.

THEOREM 4.2 (reparameterized dynamic programming principle (RDPP)). *For every $(\bar t, \bar x, \bar k) \in [0, T[\times\mathbb{R}^n \times [0, K]$ and $0 < \sigma < T - \bar t$ one has*

$$\mathcal{V}(\bar t, \bar x, \bar k) = \inf_{\nu \in \tilde\Delta(\bar t, \bar k)} \sup_{(w_0, w) \in \tilde{\mathcal{C}}(\bar t, \bar k)} \left\{ \int_0^\sigma \bar l\big(t(s), z(s), (\nu(w_0, w))_* \circ t(s), w_0(s), w(s)\big)\, ds + \mathcal{V}(t(\sigma), z(\sigma), k(\sigma)) \right\}$$

and

$$\mathcal{U}(\bar t, \bar x, \bar k) = \sup_{(\xi_0, \xi) \in \tilde\Gamma(\bar t, \bar k)} \inf_{v \in \tilde{\mathcal{A}}} \left\{ \int_0^\sigma \bar l\big(t(s), z(s), v_* \circ t(s), \xi_0(v)(s), \xi(v)(s)\big)\, ds + \mathcal{U}(t(\sigma), z(\sigma), k(\sigma)) \right\}.$$

Moreover, if $Q \subset \mathbb{R}^n$ is a compact subset and $(\bar t, \bar x, \bar k) \in [0, T[\times Q \times [0, K[$ verifies $\mathcal{U}(\bar t, \bar x, \bar k) - g(x) \geq \eta > 0$ (resp., $\mathcal{V}(\bar t, \bar x, \bar k) - g(x) \geq \eta > 0$), there exists a $\hat\sigma > 0$ such that

$$\mathcal{V}(\bar t, \bar x, \bar k) = \inf_{\nu \in \tilde\Delta(\bar t, \bar k)} \sup_{(w_0, w) \in \tilde{\mathcal{C}}_\sigma(\bar t, \bar k)} \left\{ \int_0^\sigma \bar l\big(t(s), z(s), (\nu(w_0, w))_* \circ t(s), w_0(s), w(s)\big)\, ds + \mathcal{V}(t(\sigma), z(\sigma), k(\sigma)) \right\}$$

(resp.,

$$\mathcal{U}(\bar t, \bar x, \bar k) = \sup_{(\xi_0, \xi) \in \tilde\Gamma_\sigma(\bar t, \bar k)} \inf_{v \in \tilde{\mathcal{A}}} \left\{ \int_0^\sigma \bar l\big(t(s), z(s), v_* \circ t(s), \xi_0(v)(s), \xi(v)(s)\big)\, ds + \mathcal{U}(t(\sigma), z(\sigma), k(\sigma)) \right\}.\Big)$$

5. Hamilton–Jacobi equations for $\mathcal{U}$ and $\mathcal{V}$. In this section we establish Hamilton–Jacobi differential equations for $\mathcal{U}$ and $\mathcal{V}$. These equations are not formal extensions of the ones concerning games with bounded controls. Indeed, this would imply the use of *discontinuous* Hamiltonians. On the contrary, the space-time version of the game presented in section 3 and the consequent RDPP (Theorem 4.2) allow one to obtain equations involving continuous Hamiltonians.

For the reader's convenience let us recall the definition of viscosity solution (see, e.g., [11], [16]).

DEFINITION 5.1. *Let E be any subset of $\mathbb{R}^N$ and let $F : E\times\mathbb{R}\times\mathbb{R}^N \to \mathbb{R}$ be a continuous function. A map $u \in C^0(E)$ is a viscosity subsolution (resp., supersolution) at $y \in E$ of the first-order partial differential equation*

$$F(y, u, \nabla u) = 0 \tag{PDE}$$

if for any $\varphi \in C^\infty(\mathbb{R}^N)$ such that $u - \varphi$ has a local maximum (resp., minimum) at y on E, one has

$$F(y, u, \nabla\varphi) \le 0 \qquad (\textit{resp.,}\ F(y, u, \nabla\varphi) \ge 0),$$

where $\nabla\varphi$ denotes the gradient of φ. A map $u \in C^0(E)$ is called a viscosity solution of (PDE) *at y if it is both a viscosity subsolution and a viscosity supersolution.*

Let us set $\Omega \doteq [0, T[\times\mathbb{R}^n \times [0, K[$. Moreover, let us define the *upper Hamiltonian* H^+ and the *lower Hamiltonian* H^- by setting, for every $(t, x, p_t, p_x, p_k) \in (\mathbb{R}\times\mathbb{R}^n)\times(\mathbb{R}\times\mathbb{R}^n\times\mathbb{R})$,

$$H^+(t, x, p_t, p_x, p_k) \doteq \min_{a\in A} \max_{(w_0,w)\in S^m_+} \big\{p_t w_0 + p_x \cdot \bar f(t, x, a, w_0, w) + \bar l(t, x, a, w_0, w) + p_k|w|\ \big\}$$

and

$$H^-(t, x, p_t, p_x, p_k) \doteq \max_{(w_0,w)\in S^m_+} \min_{a\in A} \big\{p_t w_0 + p_x \cdot \bar f(t, x, a, w_0, w) + \bar l(t, x, a, w_0, w) + p_k|w|\ \big\},$$

respectively, where $S^m_+ \doteq \{(w_0, w) : |(w_0, w)| = 1, w_0 \ge 0\}$.

If Φ is a map defined on Ω, let us denote the gradients of Φ with respect to t, x, and k by $\nabla_t\Phi$, $\nabla_x\Phi$, and $\nabla_k\Phi$, respectively.

THEOREM 5.1. *The maps $\mathcal{V}$ and $\mathcal{U}$ are viscosity solutions on Ω of the lower value equation*

$$-H^-(t, x, \nabla_t\Phi, \nabla_x\Phi, \nabla_k\Phi) = 0 \tag{LVE}$$

and of the upper value equation

$$-H^+(t, x, \nabla_t\Phi, \nabla_x\Phi, \nabla_k\Phi) = 0, \tag{UVE}$$

respectively.

We will just outline the proof of this theorem. Actually, in view of the RDPP, the proof is partially based on some arguments already exploited in the conventional case [13]. However, some changes are needed, due to the fact that within our setting

the integral constraint on c becomes a state constraint, while the finite horizon $t = T$ has to be regarded as a target.

Proof. Let us prove that $\mathcal{V}$ is a subsolution of (LVE). Let $(\bar{t}, \bar{x}, \bar{k}) \in \Omega$ and let φ be a smooth function such that $\mathcal{V} - \varphi$ has a local maximum at $(\bar{t}, \bar{x}, \bar{k})$. Hence, in a neighborhood of $(\bar{t}, \bar{x}, \bar{k})$ one has

$$\mathcal{V}(t, x, k) - \mathcal{V}(\bar{t}, \bar{x}, \bar{k}) \le \varphi(t, x, k) - \varphi(\bar{t}, \bar{x}, \bar{k}). \tag{5.1}$$

If we define

$$\begin{aligned} &Q(t, x, k, a, w_0, w) \\ &\doteq \nabla_t \varphi(t, x, k) \cdot w_0 + \nabla_x \varphi(t, x, k) \cdot \bar{f}(t, x, a, w_0, w) + \bar{l}(t, x, a, w_0, w) + \nabla_k \varphi(t, x, k) \cdot |w|, \end{aligned}$$

the thesis is expressed by the inequality

$$- \max_{(w_0, w) \in S^m_+} \min_{a \in A} Q(\bar{t}, \bar{x}, \bar{k}, a, w_0, w) \le 0.$$

Assume by contradiction that

$$\max_{(w_0, w) \in S^m_+} \min_{a \in A} Q(\bar{t}, \bar{x}, \bar{k}, a, w_0, w) \le -\theta,$$

with $\theta > 0$. By Lemma 5.1 below there exists a strategy $\nu \in \widetilde{\Delta}(\bar{t}, \bar{k})$ and a $\bar{\sigma} \in]0, T - \bar{t}[$ such that, for every $(w_0, w) \in \widetilde{\mathcal{C}}_\sigma(\bar{t}, \bar{k})$ and every $\sigma \le \bar{\sigma}$, one has

$$\int_0^\sigma Q(t(s), z(s), (\nu(w_0, w))_* \circ t(s), w_0(s), w(s)) \le -\frac{\theta \sigma}{2}.$$

By applying the RDPP we obtain a contradiction. Indeed, for every $\sigma \le \min\{\bar{\sigma}, T - \bar{t}\}$ one has

$$\begin{aligned} 0 &= \inf_{\nu \in \widetilde{\Delta}(\bar{t}, \bar{k})} \sup_{(w_0, w) \in \widetilde{\mathcal{C}}(\bar{t}, \bar{k})} \left\{ \int_0^\sigma \bar{l}\big(t(s), z(s), (\nu(w_0, w))_* \circ t(s), w_0(s), w(s)\big)\, ds \right. \\ &\qquad \left. + \mathcal{V}(t(\sigma), z(\sigma), k(\sigma)) - \mathcal{V}(\bar{t}, \bar{x}, \bar{k}) \right\} \\ &\le \inf_{\nu \in \widetilde{\Delta}(\bar{t}, \bar{k})} \sup_{(w_0, w) \in \widetilde{\mathcal{C}}(\bar{t}, \bar{k})} \left\{ \int_0^\sigma \bar{l}\big(t(s), z(s), (\nu(w_0, w))_* \circ t(s), w_0(s), w(s)\big)\, ds \right. \\ &\qquad \left. + \varphi(t(\sigma)), z(\sigma), k(\sigma)) - \varphi(\bar{t}, \bar{x}, \bar{k}) \right\} \\ &= \inf_{\nu \in \widetilde{\Delta}(\bar{t}, \bar{k})} \sup_{(w_0, w) \in \widetilde{\mathcal{C}}(\bar{t}, \bar{k})} \left\{ \int_0^\sigma Q\big(t(s), z(s), (\nu(w_0, w))_* \circ t(s), w_0(s), w(s)\big)\, ds \right\} \\ &\le -\frac{\theta \sigma}{2}. \end{aligned}$$

In view of Lemma 5.1 below, the proofs that $\mathcal{V}$ and $\mathcal{U}$ are a supersolution of (LVE) and a solution of (UVE) on Ω, respectively, proceed similarly. Hence we omit them. □

LEMMA 5.1. *Let Q be defined as in the proof of the previous theorem. Then the following hold.*

(i) *If*

$$\max_{(w_0,w)\in S^m_+}\min_{a\in A} Q(\bar t,\bar x,\bar k,a,w_0,w)\le -\theta \qquad (\textit{resp.},\ \ge\theta),$$

there exist a $\bar\sigma\in]0,T-\bar t[$ *and a strategy* $\nu\in\widetilde\Delta(\bar t,\bar k)$ *(resp., an* $\epsilon>0$ *and a control* $(w_0,w)\in\widetilde{\mathcal C}(\bar t,\bar k)$ $(=\widetilde{\mathcal C}_{\bar\sigma}(\bar t,\bar k))$*, with* $w_0\ge\epsilon$*) such that, for every* $(w_0,w)\in\widetilde{\mathcal C}(\bar t,\bar k)$ $(=\widetilde{\mathcal C}_{\bar\sigma}(\bar t,\bar k))$ *(resp., every strategy* $\nu\in\widetilde\Delta(\bar t,\bar k)$*) and every* $\sigma\le\bar\sigma$*, one has*

$$\int_0^\sigma Q(t(s),z(s),k(s),(\nu(w_0,w))_*\circ t(s),w_0(s),w(s))\le -\frac{\theta\sigma}{2}\qquad\left(\textit{resp.},\ \ge\frac{\theta\sigma}{2}\right).$$

(ii) *If*

$$\min_{a\in A}\max_{(w_0,w)\in S^m_+} Q(\bar t,\bar x,\bar k,a,w_0,w)\ge\theta\qquad(\text{resp.},\ \le-\theta),$$

there exist a $\bar\sigma\in]0,T-\bar t[$*, an* $\epsilon>0$*, and a strategy* $(\xi_0,\xi)\in\widetilde\Gamma(\bar t,\bar k)$ $(=\widetilde\Gamma_{\bar\sigma}(\bar t,\bar k))$ *verifying* $\xi_0(v)\ge\epsilon\ \forall v\in\widetilde{\mathcal A}$ *(resp., a control* $v\in\widetilde{\mathcal A}$*) such that, for every* $v\in\widetilde{\mathcal A}$ *(resp., every strategy* $(\xi_0,\xi)\in\widetilde\Gamma(\bar t,\bar k)$ $(=\widetilde\Gamma_{\bar\sigma}(\bar t,\bar k)))$ *and every* $\sigma\le\bar\sigma$*, one has*

$$\int_0^\sigma Q(t(s),z(s),k(s),v_*\circ t(s),\xi_0(v)(s),\xi(v)(s))\ge\frac{\theta\sigma}{2}\qquad\left(\textit{resp.},\le-\frac{\theta\sigma}{2}\right).$$

Proof. We shall limit ourselves to prove only the second of the statements in (i) and the first of the statements in (ii), the proofs of the remaining two statements being similar.

Let us assume

$$\max_{(w_0,w)\in S^m_+}\min_{a\in A} Q(\bar t,\bar x,\bar k,a,w_0,w)\ge\theta.$$

Hence there exists an $\epsilon>0$ and a $(\bar w_0,\bar w)\in S^m_+$, with $\bar w_0>\epsilon$, such that

$$Q(\bar t,\bar x,\bar k,a,\bar w_0,\bar w)\ge\frac34\theta$$

for every $a\in A$. Since A is a compact subset, by the hypotheses on f and l, there exists a σ such that for every $s\le\sigma$ and $v\in\widetilde{\mathcal A}(\bar t)$ one has

$$|(t(s),z(s),k(s))-(\bar t,\bar x,\bar k)|\le Ms,$$

where we have set $\big(t(s),z(s),k(s)\big)\doteq((t,z)[v,\bar w_0,\bar w](s),\bar k+\int_0^s|\bar w|(\eta)d\eta\big)$. Hence, since Q is uniformly continuous, by choosing a suitable $\bar\sigma>0$ one has

$$Q(t(s),z(s),k(s),(\nu(\bar w_0,\bar w))_*\circ t(s),\bar w_0,\bar w)\ge\frac12\theta$$

for every $s\in[0,\bar\sigma]$ and every $\nu\in\widetilde\Delta(\bar t,\bar x)$, from which the thesis follows, with $(w_0,w)(s)\doteq(\bar w_0,\bar w)$.

Now let us assume that

$$\min_{a\in A}\max_{(w_0,w)\in S^m_+} Q(\bar t,\bar x,\bar k,a,w_0,w)\ge\theta.$$

By the continuity of Q and the compactness of A this implies that there exists an $\epsilon > 0$ such that

$$\max_{(w_0,w)\in S^m_+, w_0\geq\epsilon} Q(\bar t,\bar x,\bar k,a,w_0,w)\geq \frac{5}{6}\theta$$

for every $a\in A$. Since the multivalued map

$$W(a)\doteq \operatorname{argmax}\big\{Q(\bar t,\bar x,\bar k,a,w_0,w),\ (w_0,w)\in S^m_+, w_0\geq\epsilon\big\}$$

is upper semicontinuous, it admits a Borel measurable selection, say, $(w_0^a,w^a)\in W(a)$ (see, e.g., [1]). The map $\tilde c: A\to C$ defined by $\tilde c(a)\doteq \frac{w^a}{w_0^a}$ turns out to be Borel measurable. Then it is easy to check that the functional γ which maps a control $a\in\mathcal{A}(\bar t)$ into the control

$$\gamma(a)(t)\doteq\begin{cases}\tilde c\big(a(t)\big) & \forall t\in[\bar t,t_a],\\ 0 & \forall t\in]t_a,T],\end{cases}$$

with

$$t_a\doteq\sup\left\{t\in[\bar t,T]:\int_{\bar t}^t|\tilde c\circ a(\tau)|\,d\tau\leq K-\bar k\right\},$$

is a nonanticipating map from $\mathcal{A}(\bar t)$ into $\mathcal{C}(\bar t,\bar k)$; i.e., $\gamma\in\Gamma(\bar t,\bar k)$. Let us consider the strategy $(\xi_0,\xi)\doteq\gamma^*\in\widetilde\Gamma(\bar t,\bar k)$. As in the first part of the proof, we can find a $\bar\sigma\in]0,T-\bar t[$ such that, for every $v\in\widetilde{\mathcal{A}}(\bar t)$ and $s\in[0,\bar\sigma]$, one has

$$|Q\big(t(s),z(s),k(s),v_*\circ t(s),(\xi_0,\xi)(v)(s)\big)-Q\big(\bar t,\bar x,\bar k,v_*\circ t(s),(\xi_0,\xi)(v)(s)\big)\leq\frac{2}{6}\theta,$$

where

$$(t,z,k)(s)\doteq\left((t,z)[\bar t,\bar x;v,(\xi_0,\xi)(v)](s),\bar k+\int_0^s|\xi(v)(\eta)|d\eta\right).$$

Since $(\xi_0,\xi)(v)(s)=\big(w_0^{v_*(t(s))},w^{v_*(t(s))}\big)$ we obtain that, for every $s\in[0,\bar\sigma]$,

$$Q\big(t(s),z(s),k(s),v_*\circ t(s),(\xi_0,\xi)(v)(s)\big)\geq\frac{5}{6}\theta-\frac{2}{6}\theta=\frac{1}{2}\theta,$$

which yields the thesis. □

6. Boundary value problems for $\mathcal{U}$ and $\mathcal{V}$. In this section we establish the LVBVP and the UVBVP below, whose unique bounded continuous solutions coincide with $\mathcal{V}$ and $\mathcal{U}$, respectively.

On the basis of Theorem 2.1 the maps $\mathcal{U}$ $(=\widetilde{\mathcal{U}})$ and $\mathcal{V}$ $(=\widetilde{\mathcal{V}})$ can be continuously extended on the closure of $[0,T[\times\mathbb{R}^n\times[0,K]$.

Let $\partial\Omega$ denote the boundary of Ω and let us set

$$\partial_T\Omega\doteq\{T\}\times\mathbb{R}^n\times[0,K],\qquad \partial'\Omega\doteq\partial\Omega\backslash\partial_T\Omega.$$

DEFINITION 6.1. *We say that a continuous map Φ is a solution of the LVBVP (resp., UVBVP) if the following hold:* (1) Φ *is a viscosity solution of* (LVE) (*resp.,* (UVE)) *in* Ω; (2) $\Phi(T,x,k)\geq g(x)$ *for every* $(T,x,k)\in\partial_T\Omega$; (3) Φ *is a viscosity*

subsolution of (LVE) (*resp., of* (UVE)) *on* $\partial'\Omega$ *and at any point* $(T,\bar x,\bar k)\in\partial_T\Omega$ *such that* $\Phi(T,\bar x,\bar k)>g(\bar x)$.

THEOREM 6.1. *The maps* $\mathcal{V}$ *and* $\mathcal{U}$ *are the unique bounded solutions of the LVBVP and the UVBVP, respectively.*

Proof. The fact that $\mathcal{V}$ and $\mathcal{U}$ satisfy (1) in Definition 6.1 coincides with the statement of Theorem 5.1.

In order to prove that $\mathcal{V}$ and $\mathcal{U}$ verify (2) in Definition 6.1, let us consider the constant space-time control $(\hat w_0,\hat w)(s)=(1,0)$, $s\in[0,\frac1n]$, which belongs to $\widetilde{\mathcal{C}}(T-\frac1n,k)$.

For each control $v:[0,1]\to A$ the trajectory

$$(t(s),z(s))\doteq(t,z)[T-\frac1n,\bar x,k;v,\hat w_0,\hat w](s)$$

verifies

$$\left|z\left(\frac1n\right)-\bar x\right|\le M\frac1n, \tag{6.1}$$

$$\left|\int_0^{\frac1n}\bar l(t(s),z(s),v_*\circ t(s),\hat w_0(s),\hat w(s))\,ds\right|\le M\frac1n$$

for a suitable $M>0$. For every strategy ν one has

$$\int_0^{\frac1n}\bar l(t(s),z(s),(\nu(\hat w_0,\hat w)_*)\circ t(s),\hat w_0(s),\hat w(s))\,ds+g\left(z\left(\frac1n\right)\right)$$

$$\le\sup_{(w_0,w)\in\widetilde{\mathcal{C}}(T-\frac1n,k)}\left\{\int_0^L\bar l(t(s),z(s),(\nu(w_0,w)_*)\circ t(s),w_0(s),w(s))\,ds+g(z(L))\right\},$$

where the L in the expression in brackets denotes the right endpoint of the domain of (w_0,w). As a consequence, one has

$$\mathcal{V}\left(T-\frac1n,\bar x,k\right)$$

$$\ge\inf_{\nu\in\widetilde\Delta(T-\frac1n,k)}\left\{\int_0^{\frac1n}\bar l(t(s),z(s),(\nu(\hat w_0,\hat w))_*\circ t(s),\hat w_0(s),\hat w(s))\,ds+g\left(z\left(\frac1n\right)\right)\right\}$$

for every natural number n. Together with 6.1, this implies

$$\mathcal{V}(T,\bar x,k)\ge g(\bar x).$$

On the other hand, for every $n\in\mathbb{N}$, there exists a control $\hat v\in\widetilde{\mathcal{A}}$ such that

$$\int_0^{\frac1n}\bar l(t(s),z(s),\hat v_*\circ t(s),\hat w_0(s),\hat w(s))\,ds+g\left(z\left(\frac1n\right)\right)$$

$$\le\inf_{v\in\widetilde{\mathcal{A}}}\left\{\int_0^{\frac1n}\bar l(t(s),z(s),v_*\circ t(s),\hat w_0(s),\hat w(s))\,ds+g\left(z\left(\frac1n\right)\right)\right\}+\epsilon$$

$$\le\mathcal{U}\left(T-\frac1n,\bar x,k\right)+\epsilon,$$

which, in view of (6.1), implies

$$g(\bar x)\le\mathcal{U}(T,\bar x,k).$$

Let us prove that $\mathcal{V}$ and $\mathcal{U}$ verify condition (3) of Definition 6.1. The part of the proof of Theorem 5.1 which concerns the subsolution properties of $\mathcal{V}$ and $\mathcal{U}$ can be easily extended in order to include the points of $[0,T[\times\mathbb{R}^n\times\{K\}$. Hence, in order to verify (3) in Definition 6.1, it remains to prove that $\mathcal{V}$ (resp., $\mathcal{U}$) is a viscosity subsolution of (LVE) (resp., of (UVE)) at any point of $\partial_T\Omega$ where $\mathcal{V} > g$ (resp., $\mathcal{U} > g$).

Let $(T,\bar{x},\bar{k})$ verify $\bar{k} < K$ and $\mathcal{V}(T,\bar{x},\bar{k}) > g(\bar{x})$, and let φ be a smooth function such that $\mathcal{V}-\varphi$ has a maximum at $(T,\bar{x},\bar{k}) \in \{T\}\times\mathbb{R}^n\times[0,K[$. Hence, in a neighborhood of $(T,\bar{x},\bar{k})$, one has

$$\mathcal{V}(t,x,k) - \mathcal{V}(T,\bar{x},\bar{k}) \le \varphi(t,x,k) - \varphi(T,\bar{x},\bar{k}).$$

Setting, as in the proof of Theorem 5.1,

$$\begin{aligned} Q(t,x,k,a,w_0,w) \doteq \nabla_t\varphi(t,x,k)w_0 + &\nabla_x\varphi(t,x,k)\cdot\bar{f}(t,x,a,w_0,w) \\ &+ \bar{l}(t,x,a,w_0,w) + \nabla_k\varphi(t,x,k)|w|, \end{aligned}$$

we have to prove that

$$\max_{(w_0,w)\in S^m_+}\min_{a\in A} Q(T,\bar{x},\bar{k},a,w_0,w) \ge 0.$$

Assume, by contradiction, that there exists a positive θ such that

$$\min_{a\in A} Q(T,\bar{x},\bar{k},a,w_0,w) \le -\theta$$

for all $(w_0,w)\in S^m_+$. Rephrasing the second part of the proof of Lemma 5.1 one can find a Borel measurable map $v(w_0,w)$ such that

$$Q(T,\bar{x},\bar{k},v(w_0,w),w_0,w) \le -\theta$$

for every $(w_0,w)\in S^m_+$. Let $\{\bar{t}_n\}$ be a sequence converging to T from the left, and let us define the strategies $\nu_n \in \widetilde{\Gamma}(\bar{t}_n,\bar{k})$ as follows. If $(w_0,w)\in\widetilde{\mathcal{C}}(\bar{t}_n,\bar{k})$, set $t_n(s) \doteq \bar{t}_n + \int_0^s w_0(\eta)\,d\eta$ and let $s_n(\cdot)$ denote the inverse of $t_n(\cdot)$. Then it is not difficult to check that the maps $\nu_n : \widetilde{\mathcal{C}}(\bar{t}_n,\bar{k}) \to \widetilde{\mathcal{A}}$ defined by

$$\nu_n(w_0,w) \doteq (v\circ(w_0,w)\circ s_n)^*$$

are strategies (see Definition 3.1). From the inequality

$$Q(T,\bar{x},\bar{k},(\nu_n(w_0,w))_*\circ t_n(s),w_0(s),w(s)) \le -\theta,$$

valid for every control $(w_0,w)\in\widetilde{\mathcal{C}}(\bar{t}_n,\bar{k})$ and every $s\in[0,s_n(T)]$, it follows that there exist $\epsilon,\bar{\sigma}>0$ such that, if $\bar{t}_n\in[T-\epsilon,T]$ and $0\le s\le\bar{\sigma}$, one has

$$Q\big(t_n(s),z(s),k(s),(\nu_n(w_0,w))_*\circ t_n(s),w_0(s),w(s)\big) \le -\frac{\theta}{2},$$

where $(t_n,z)(s) \doteq (t,z)[\bar{t}_n,\bar{x},\nu_n(w_0,w),w_0,w](s)$, $k(s)\doteq\bar{k}+\int_0^s|w(\xi)|d\xi$. Integrating the terms in the last inequality, for every $\sigma\le\bar{\sigma}$ and every $(w_0,w)\in\widetilde{\mathcal{C}}_\sigma(\bar{t}_n,\bar{k})$, one has

$$\begin{aligned} \int_0^\sigma \bar{l}\big(t_n(s),z(s),(\nu_n(w_0,w))_*\circ t_n(s),w_0(s),w(s)\big)\,ds \\ + \varphi(t_n(\sigma),z(\sigma),k(\sigma)) - \varphi(\bar{t}_n,\bar{x},\bar{k}) \le \frac{-\theta\sigma}{2}. \end{aligned} \tag{6.2}$$

On the other hand, in a neighborhood of $(T,\bar x,\bar k)$ one has $\mathcal{V}-g>\eta>0$. Hence, on the basis of the RDPP (Theorem 4.2), there exists a $\hat\sigma>0$ such that for every $\sigma<\hat\sigma$

$$0\le \sup_{(w_0,w)\in\widetilde{\mathcal{C}}_\sigma(\bar t_n,\bar k)}\Big\{\int_0^\sigma \bar l\big(t_n(s),z(s),(\nu_n(w_0,w))_*\circ t_n(s),w_0(s),w(s)\big)\,ds \\ +\mathcal{V}\big(t_n(\sigma),z(\sigma),k(\sigma)\big)-\mathcal{V}(\bar t_n,\bar x,\bar k)\Big\}.$$

In particular, for every $\sigma<\hat\sigma$ and every n, there exists a control $(w_{0\,n}^\sigma,{w^\sigma}_n)\in\widetilde{\mathcal{C}}_\sigma(\bar t_n,\bar k)$ such that

$$\int_0^\sigma \bar l(t_n^\sigma(s),z_n^\sigma(s),(\nu_n(w_{0\,n}^\sigma,{w^\sigma}_n))_*\circ t_n^\sigma(s),w_{0\,n}^\sigma(s),{w^\sigma}_n(s))\,ds \\ +\mathcal{V}\big(t_n^\sigma(\sigma),z_n^\sigma(\sigma),k_n^\sigma(\sigma)\big)-\mathcal{V}(\bar t_n,\bar x,\bar k)>-\frac{\theta\sigma}{4}, \tag{6.3}$$

where we have set

$$z_n^\sigma(s)\doteq z[\bar t_n,\bar x;\nu_n(w_{0\,n}^\sigma,{w^\sigma}_n),w_{0\,n}^\sigma,{w^\sigma}_n](s),$$
$$k_n^\sigma(s)\doteq\bar k+\int_0^s|{w^\sigma}_n(\mu)|\,d\mu.$$

Setting

$$p_n^\sigma\doteq\int_0^\sigma \bar l\,(t_n^\sigma(s),z_n^\sigma(s),(\nu_n(w_{0\,n}^\sigma,{w^\sigma}_n))_*\circ t_n^\sigma(s),w_{0\,n}^\sigma(s),{w^\sigma}_n(s))\;ds,$$

by Ascoli–Arzelà's theorem we obtain the existence of a subsequence $\{z_{n'}^\sigma,k_{n'}^\sigma,p_{n'}^\sigma\}$ such that $\{z_{n'}^\sigma\}$ and $\{k_{n'}^\sigma\}$ converge to continuous maps z_∞^σ and k_∞^σ, respectively, uniformly on $[0,\sigma]$, and $\{p_{n'}^\sigma\}$ converge to a constant p_∞^σ.

For any $\sigma\in]0,\min\{\bar\sigma,\hat\sigma\}[$, letting n tend to infinity in (6.2)–(6.3), one obtains

$$-\frac{\theta\sigma}{4}\le p_\infty^\sigma+\mathcal{V}(T,z_\infty^\sigma(\sigma),k_\infty^\sigma(\sigma))-\mathcal{V}(T,\bar x,\bar k)$$
$$\le p_\infty^\sigma+\varphi(T,z_\infty^\sigma(\sigma),k_\infty^\sigma(\sigma))-\varphi(T,\bar x,\bar k)\le-\frac{\theta\sigma}{2},$$

a contradiction for every $\sigma>0$. Let us prove now that $\mathcal{U}$ is a subsolution of (UVE) at a point $(T,\bar x,\bar k)$ such that $\bar k<K$ and $\mathcal{U}(T,\bar x,\bar k)>g(\bar x)$. Let φ be a smooth map such that

$$\mathcal{U}(t,x,k)-\mathcal{U}(T,\bar x,\bar k)\le\varphi(t,x,k)-\varphi(T,\bar x,\bar k)$$

for every (t,x,k) in a neighborhood of $(T,\bar x,\bar k)$. Let Q be defined as above. The thesis amounts to proving that

$$\min_{a\in A}\max_{(w_0,w)\in S_+^m}Q(T,\bar x,\bar t,a,w_0,w)\ge0.$$

Assume, by contradiction, that there is a $\theta>0$ such that

$$\min_{a\in A}\max_{(w_0,w)\in S_+^m}Q(T,\bar x,\bar t,a,w_0,w)\le-\theta.$$

Then there exists an $\bar{a} \in A$ such that

$$\max_{(w_0,w)\in S^m_+} Q(T, \bar{x}, \bar{t}, \bar{a}, w_0, w) \leq -\theta.$$

It follows that, setting $v(s) = \bar{a}\ \forall s \in [0,1]$, for a $\bar{\sigma}$ sufficiently small and $\bar{t}$ sufficiently close to T one has

$$Q(t(s), z(s), k(s), v_* \circ t(s), \xi_0(a)(s), \xi(a)(s)) \leq -\frac{\theta}{2}$$

for every $s \in [0, \bar{\sigma}]$ and every strategy $(\xi_0, \xi) \in \widetilde{\Gamma}(\bar{t}, \bar{k})$. Integrating both terms, one obtains

$$\int_0^\sigma \bar{l}(t(s), z(s), v_* \circ t(s), \xi_0(v)(s), \xi(v)(s))\, ds + \varphi\big(t(\sigma), z(\sigma), k(\sigma)\big) - \varphi(\bar{t}, \bar{x}, \bar{k}) \leq -\frac{\theta\sigma}{2}$$

for every $\sigma \leq \bar{\sigma}$ and every $(\xi_0, \xi) \in \widetilde{\Gamma}_\sigma(\bar{t}, \bar{k})$. An argument analogous to the one exploited for $\mathcal{V}$ now leads to a contradiction with the RDPP, according to which there exists a $\hat{\sigma}$ such that for every sequence $\{\bar{t}_n\}$ converging to T and every $\sigma < \hat{\sigma}$ one can find strategies $({\xi_0}^\sigma{}_n, {\xi}^\sigma{}_n) \in \widetilde{\Gamma}(\bar{t}_n, \bar{k})$ verifying

$$\int_0^\sigma \bar{l}\big(t_n^\sigma(s), z_n^\sigma(s), v_* \circ t_n^\sigma(s), {\xi_0}^\sigma{}_n(v)(s), {\xi}^\sigma{}_n(v)(s)\big) + \mathcal{U}\big(t_n^\sigma(\sigma), z_n^\sigma(\sigma) k_n^\sigma(\sigma)\big) - \mathcal{U}\big(\bar{t}_n, \bar{x}, \bar{k}\big) > -\frac{\theta\sigma}{4},$$

with obvious meanings of t_n^σ, z_n^σ, and k_n^σ. This concludes the proof of condition (3) of Definition 6.1.

The uniqueness property stated in the thesis is a straighforward consequence of the comparison criterion below, which, in turn, is deduced—via suitable changes of variable—from Theorem 1.1 of [3]. □

Remark 6.1. In the proof of the boundary conditions at $\bar{t} = T$, an essential role is played by the fact that at the points of $\{T\} \times Q \times [0, K]$, where $\mathcal{V} - g \geq \eta$ (resp., $\mathcal{U} - g \geq \eta$), the DPP for $\mathcal{V}$ (resp., $\mathcal{U}$) (and its reparameterized version) holds for every $\sigma \in]0, \hat{\sigma}[$, with $\hat{\sigma}$ depending just on η (and Q). This fact reflects the essentially *impulsive* nature of the problem.

PROPOSITION 6.1 (comparison). *Let $\mathcal{G}_i : \overline{\Omega} \to \mathbb{R}, i = 1, 2$, be continuous and bounded and assume that $\mathcal{G}_1$ is a viscosity subsolution of* (LVE) *and $\mathcal{G}_2$ is a viscosity supersolution of* (LVE) *in Ω. Moreover, let us assume that in $\partial\Omega$ either $\mathcal{G}_1 \leq \mathcal{G}_2$ or $\mathcal{G}_1$ is a subsolution of* (LVE). *Then $\mathcal{G}_1 \leq \mathcal{G}_2$ in $\overline{\Omega}$. The same statement holds true if we replace equation* (LVE) *with* (UVE).

Proof. Let G be a lower bound for both $\mathcal{G}_1$ and $\mathcal{G}_2$ and, for some $q > 0$ to be fixed later, consider the maps $\mathcal{F}_i$ defined by

$$\mathcal{F}_i(t, x, k) \doteq \frac{1}{q(1 + t + k)} \log[\mathcal{G}_i(T - t, x, K - k) + G + 1], \qquad i = 1, 2.$$

Then, setting

$$\tilde{H}^-(t,x,k,r,p_t,p_x,p_k)$$
$$\doteq \min_{(w_0,w)\in S^m_+}\max_{a\in A}\frac{1+t+k}{w_0+|w|}\left\{qp_tw_0 - qp_x\cdot\bar{f}(T-t,x,a,w_0,w) + qp_k|w| \right.$$
$$\left. -\frac{\bar{l}(T-t,x,a,w_0,w)}{(1+t+k)\exp(qr)} + (q-1)r(w_0+|w|)\right\},$$

one can easily check that the maps $\mathcal{F}_1$ and $\mathcal{F}_2$ are a viscosity subsolution and supersolution of

$$\mathcal{F} + \tilde{H}^-(t,x,k,\mathcal{F},\nabla\mathcal{F}) = 0 \tag{LVE$'$}$$

in $]0,T]\times\mathbb{R}^n\times]0,K]$, respectively. Moreover, on $\partial\Omega$, either $\mathcal{F}_1\le\mathcal{F}_2$ or $\mathcal{F}_1$ is a subsolution of (LVE$'$).

Let us observe that, in view of the hypotheses assumed on l, the map $\bar{l}$ is bounded. This implies that for a q sufficiently large the function

$$r\mapsto\tilde{H}^-(t,x,k,r,p_t,p_x,p_k)$$

is nondecreasing for every $(t,x,k,p_t,p_x,p_k)\in[0,T]\times\overline{\Theta}\times[0,K]\times\mathbb{R}^{1+n+1}$.

Hence it is straightforward to check that the Hamiltonian $\tilde{H}^-$ and the domain $\overline{\Theta}$ verify the hypotheses of Theorem 1.1 in [3], from which it follows that $\mathcal{F}_1\le\mathcal{F}_2$ on $\overline{\Theta}$.

By inverting the considered change of (dependent and independent) coordinates, one obtains the assertion concerning (LVE).

The results concerning (UVE) can be straightforwardly proved by just replacing $\tilde{H}^-$ with the Hamiltonian

$$\tilde{H}^+(t,x,k,r,p_t,p_x,p_k)$$
$$\doteq \max_{a\in A}\min_{(w_0,w)\in S^m_+}\frac{1+t+k}{w_0+|w|}\left\{qp_tw_0 - qp_x\cdot\bar{f}(T-t,x,a,w_0,w) + qp_k|w| \right.$$
$$\left. -\frac{\bar{l}(T-t,x,a,w_0,w)}{(1+t+k)\exp(qr)} + (q-1)r(w_0+|w|)\right\}. \qquad \square$$

As a corollary of Theorem 6.1 we obtain an *Isaacs condition*, i.e., a sufficient condition for the game to have a value.

COROLLARY 6.1 (Isaacs condition). *If*

$$H^+ = H^-, \tag{IC}$$

then the game has a value; i.e., $\mathcal{V}=\mathcal{U}$.

Remark 6.2. The case where both the dynamics f and the Lagrangian l are affine in the unbounded control, which includes the problem investigated in [5] (see section 7), i.e.

$$f = f_0(t,x,v) + \sum_{i=1}^m f_i(t,x,v)c_i,$$
$$l = l_0(t,x,v) + \sum_{i=1}^m l_i(t,x,v)c_i,$$

is particularly interesting: indeed, as soon as $f_0,\dots,f_m,l_0,\dots,l_m$ are convex in v the min-max theorem (see e.g., [2]) implies that (IC) is satisfied, so the game has a value.

7. On a former result concerning a particular case. Barron, Jensen, and Menaldi [5] have studied the particular case where c is scalar-valued and positive, i.e. $c \in C \doteq \mathbb{R}^+$, and

$$f(t,x,v,c) = f_0(t,x,v) + f_1(t,v)c, \qquad l(t,x,v,c) = l_0(t,x,v) + l_1(t,v)c. \tag{7.1}$$

The fact that f_1 is independent of the state x is crucial. Indeed, this allows the authors to give a notion of (possibly discontinuous) trajectory even when c is a measure.

Remark 7.1. Incidentally, let us remark that such a trajectory depends strongly on the values of v at the atoms of the measure c. However, this does not trouble the dynamic programming approach pursued in [5], for each of these trajectories can be interpreted as a *space-time solution*, according to [20]. And this allows one to interpret these trajectories as elements of the closure—in a suitable topology—of the set of trajectories corresponding to ordinary controls.

Let us begin by observing that the approach presented in [5] cannot be extended to some cases of interest, which, instead, are included in our investigation. Indeed, the arguments of [5] do not apply as soon as f_1 depends on x. The main reason for that relies on the fact that, unless very restrictive commutative conditions are in force [9], no robust notion of t-parameterized solution can be given (see, e.g., [8], [14], [18], [19], [25]).

Second, the approach proposed in the present paper, once specialized to the case under consideration, yields a boundary value problem much more regular than the one established in [5].

In order to be more precise, let us record the main result in [5] and afterwards let us specialize Theorem 6.1 to the present case.

THEOREM 7.1 (see [5]). *Let us assume that f and l are as in* (7.1)*, and let $K = 1$, $x \in \mathbb{R}$.*

Define the upper Hamiltonian $\hat{H}^+$ as

$$\hat{H}^+(t,x,p_x,p_k) \doteq \min_{a \in A(t,p_x,p_k)} \{p_x \cdot f_0(t,x,a) + l_0(t,x,a)\},$$

where

$$A(t,p_k,p_x) \doteq \{a \in A : \quad p_x \cdot f_1(t,a) + l_1(t,a) + p_k \le 0\}.$$

If $A(t,p_x,p_k) = \emptyset$ then one sets $\hat{H}^+ = +\infty$.

Moreover, define the lower Hamiltonian $\hat{H}^-$ as

$$\hat{H}^-(t,x,p_x,p_k) \doteq \min\{p_x \cdot \beta_0 + \delta_0 : (\beta_0,\delta_0,\beta_1,\delta_1) \in \mathcal{R}(t,x,p_x,p_k)\},$$

where

$$\mathcal{F}(t,x) \doteq \overline{co}\left\{\left(f_0(t,x,a), l_0(t,x,a), f_1(t,a), l_1(t,a)\right) : a \in A\right\},$$
$$\mathcal{R}(t,x,p_x,p_k) \doteq \{(\beta_0,\delta_0,\beta_1,\delta_1) \in \mathcal{F}(t,x) : p_x\beta_1 + \delta_1 + p_k \le 0\}.$$

The upper value $\mathcal{U}$ (resp., the lower value $\mathcal{V}$) is the unique continuous (viscosity) solution in $]0,T[\times\mathbb{R}\times]0,1[$ of

$$-\nabla_t u - \hat{H}^+(t,x,\nabla_x u, \nabla_k u) = 0 \tag{ÛV̂Ê}$$

(resp.,

$$(\hat{\mathrm{L}}\hat{\mathrm{V}}\hat{\mathrm{E}}) \qquad -\nabla_t u - \hat{H}^-(t,x,\nabla_x u,\nabla_k u) = 0)$$

in $]0,T[\times\mathbb{R}\times]0,1[$ *that satisfies the boundary conditions*

$$\text{(TC)} \quad \begin{gathered} u(T,x,k) = \min_{a\in A}\max_{k\le\chi\le 1}\big\{g\big(x+f_1(T,a)(\chi-k)\big)+l_1(T,a)(\chi-k)\big\} \\ \Big(\textit{resp.},\quad u(T,x,k) = \max_{k\le\chi\le 1}\min_{a\in A}\big\{g\big(x+f_1(T,a)(\chi-k)\big)+l_1(T,a)(\chi-k)\big\}\Big) \end{gathered}$$

and

$$\text{(BC)} \qquad u(t,x,1) = r(t,x),$$

where $r(t,x)$ *is the value function of the minimum problem*

$$\underset{a(\cdot)\in\mathcal{A}(t)}{\textit{minimize}} \int_t^T l_0(\tau,x(\tau),a(\tau))\,d\tau, \qquad \frac{dx}{d\tau} = f_0(\tau,x(\tau),a(\tau)), \quad x(t)=x.$$

Remark 7.2. In the previous theorem an extension (due to Ishii [30]) of the original notion of viscosity solution is adopted, in that the Hamiltonians $\hat{H}^+$ and $\hat{H}^-$ are discontinuous.

On the other hand, by specializing Theorem 6.1 to the problem considered in [5] we obtain the following theorem.

THEOREM 7.2. *The upper value* $\mathcal{U}$ *(resp., the lower value* $\mathcal{V}$*) is the unique viscosity solution in* $\Omega \doteq [0,T[\times\mathbb{R}\times[0,1[$ *of the equation*

$$\text{(UVE)} \qquad -H^+(t,x,\nabla_t,\nabla_x u,\nabla_k u) = 0$$

(resp.,

$$\text{(LVE)} \qquad -H^-(t,x,\nabla_t,\nabla_x u,\nabla_k u) = 0),$$

which satisfies the following boundary conditions: (1) *for every* $(x,k)\in\mathbb{R}\times[0,K]$, *one has*

$$\mathcal{U}(T,x,k) \ge g(x) \quad (\textit{resp.},\ \mathcal{V}(T,x,k)\ge g(x)].$$

(2) $\mathcal{U}$ *(resp.,* $\mathcal{V}$*) is a viscosity subsolution of* (UVE) (*resp., of* (LVE)) *on* $\partial'\Omega$ *and at the points of* $\partial_T\Omega$ *where* $\mathcal{U}-g>0$ (*resp.,* $\mathcal{V}-g>0$).

Four main facts can be pointed out from comparing the two results.

1. Unlike the Hamiltonians $\hat{H}^+$ and $\hat{H}^-$ exploited in [5], the Hamiltonians H^+ and H^- here considered are continuous.
2. The domains of minimization involved in the definitions of $\hat{H}^+$ and $\hat{H}^-$ *depend on the gradient of the solution* (this happens also in the minimax control problem [4], which in fact can be considered (see [5]) as a particular case of this problem); on the contrary, the domain involved in the definitions of H^+ and H^- is a *constant, compact* set.
3. The boundary conditions of (BC) need the resolution of an auxiliary boundary value problem and, moreover, condition (TC) for the lower value does not coincide with condition (TC) for the upper value; on the contrary, the boundary conditions (1) and (2) established here, besides being common to $\mathcal{V}$ and $\mathcal{U}$, involve just a subsolution relation and a Dirichlet inequality.
4. The Isaacs condition established in [5] involves the final cost function g, whereas the Isaacs condition found here (Corollary 6.1) has a standard form; i.e., it reduces to the equality of the lower Hamiltonian and the upper one.

ASYNCHRONOUS STOCHASTIC APPROXIMATIONS*

VIVEK S. BORKAR†

Abstract. The asymptotic behavior of a distributed, asynchronous stochastic approximation scheme is analyzed in terms of a limiting nonautonomous differential equation. The relation between the latter and the relative values of suitably rescaled relative frequencies of updates of different components is underscored.

Key words. distributed algorithms, asynchronous algorithms, communication delays, stochastic approximation, ODE limit

AMS subject classifications. 62L20, 93E25

1. Introduction.

There has been a resurgence of interest in stochastic approximation algorithms, particularly as mechanisms for learning systems. They can, for example, be a learning algorithm for neural networks [13] or a model of learning by boundedly rational agents in a macroeconomic system [20], in addition to their traditional applications in adaptive engineering systems [2]. These applications call for a distributed, asynchronous implementation of stochastic approximation schemes. In engineering applications, this is a natural consequence of dealing with large interconnected systems. In macroeconomics, it is simply the reality of life. It is not, however, apparent that the traditional analysis of these schemes, extensively dealt with in [2], automatically holds ground in the new scenario. Prompted by these and similar concerns, there have been studies of distributed implementations of these algorithms [17, 18, 21, 22]. (See [3] for an extensive account of parallel distributed algorithms in general). The present work is in the same spirit, but with some crucial differences.

1. Our model of asynchronism postulates a set-valued random process that marks the indices to be updated at each iteration. This clumping of indices into sets can be an artifice as long as causal relationships are not violated; thus the set-up is very general indeed. We impose on this process a natural condition that requires all indices to be updated comparably often in a precise sense.

2. In addition, we allow random, possibly nonstationary and unbounded delays that are required to satisfy a mild conditional moment condition.

3. The analysis depends on proving that the algorithm asymptotically tracks a nonautonomous ODE, in contrast to the traditional autonomous "ODE limit." In particular, it gives a handle on situations when the latter may not be feasible.

4. The ODE in question differs from the traditional one in that each component of the driving vector field is now weighted by a time-varying nonnegative scalar. These scalars add to 1 and may be interpreted as relative frequencies of updates of different components after suitable time-scaling. This clearly brings out the desired relationships between update schemes for different components and paves the way for analyzing situations where they are not desirable (see remark 4 of the conclusion).

The paper is organized as follows. The remainder of this section describes the problem framework. The next section states the key assumptions and their immediate consequences. The third section provides the convergence analysis. The final section highlights some further possibilities.

Let TS (for tapering stepsize) denote the set of sequences $\{a(n)\}$ in (0,1) satisfying

$$\sum_n a(n) = \infty, \qquad \sum_n a(n)^2 < \infty. \tag{1.1}$$

The standard stochastic approximation algorithm is the recursive scheme in R^d, $d \geq 1$, described by

$$X(n+1) = X(n) + a(n)F(X(n), \xi(n)), \tag{1.2}$$

where $\{a(n)\} \in \text{TS}$, $X(n) = [X_1(n), \ldots, X_d(n)]^T \in R^d$ with a prescribed $X(0)$, $F(\cdot,\cdot) : R^d \times R^k \to R^d$, and $\{\xi(n)\}$ is a stationary random process in R^k. For simplicity, we take $\{\xi(n)\}$ to be independently and identically distributed (i.i.d.) with a common law ψ (say). The ith row of this vector iteration reads

$$X_i(n+1) = X_i(n) + a(n)F_i(X_1(n), \ldots, X_d(n), \xi(n)). \tag{1.3}$$

A distributed but synchronous version of (1.2) could be as follows. Let $I = \{1, 2, \ldots, d\}$ and S be a collection of nonempty subsets of I that cover I. Let $\{Y_n\}$ be an S-valued random process that selects the coordinates to be updated at time n, and for each n, let $\tau_{ij}(n)$, $i \neq j \in I$, be random variables taking values in $\{0, 1, \ldots, n\}$ that represent communication delays. We set $\tau_{ii}(n) = 0\ \forall i, n$. The synchronous distributed version of (1.3) is then

$$X_i(n+1) = X_i(n) + a(n)F_i(X_1(n - \tau_{i1}(n)), \ldots, X_d(n - \tau_{id}(n)), \xi(n))I\{i \in Y_n\} \tag{1.4}$$

for $i \in I$, $n \geq 0$. Special instances of (1.4) were studied in [5, 6]. The reason this is a synchronous version is that the decision to use stepsize $a(n)$ at time n by the processor updating the ith component (say) presupposes the availability of a global clock to all processors. This is not reasonable in an asynchronous environment. The asynchronous version we propose is as follows. Let $\{a(n,i)\} \in \text{TS}$, $i \in I$, and define

$$\nu(n,i) = \sum_{m=0}^{n} I\{i \in Y_m\}, \quad i \in I, \quad n \geq 0,$$
$$\overline{a}(n,i) = a(\nu(n,i), i), \quad i \in I, \quad n \geq 0.$$

The first of these is the total number of times the ith component was updated up until time n. Assuming that each component of the iteration is assigned to one and only one processor once and for all, $\overline{a}(n,i)$ is a random variable known to the ith processor at time n. The proposed algorithm is

$$X_i(n+1) = X_i(n) + \overline{a}(n,i)F_i(X_1(n - \tau_{i1}(n)), \ldots, X_d(n - \tau_{id}(n)), \xi(n))I\{i \in Y_n\} \tag{1.5}$$

for $i \in I$, $n \geq 0$. This is the algorithm analyzed in this paper, under the assumptions stipulated in the next section. We conclude this section with the remark that even the implicit presence of an unobserved global clock in the background in (1.5) is not really needed. The clumping of updated coordinates into Y_m's could be a complete artifice as long as causal relationships are not violated and the additional assumptions of the next section (notably (A3)) remain valid.

2. Preliminaries. The additional assumptions and their consequences that we present in this section concern, respectively, the stepsize routines $\{a(n,i)\}$, the sampling process $\{Y_n\}$, the communication delays $\{\tau_{ij}(n)\}$, and the function F. We proceed in that order. These assumptions, (A1)–(A5), are enforced throughout the paper without further mention.

Let ITS (for "ideal tapering stepsize") denote the subset of TS consisting of $\{a(n)\}$ satisfying:

(i) $a(n+1) \leq a(n)$ from some n onwards;

(ii) there exists $r \in (0,1)$ such that

$$\sum_n a(n)^{1+q} < \infty, \qquad q \geq r; \tag{2.1}$$

(iii) for $x \in (0,1)$,

$$\sup_n a([xn])/a(n) < \infty, \tag{2.2}$$

where $[\cdots]$ stands for the integer part of "$\cdots$";

(iv) for $x \in (0,1)$ and $A(n) \triangleq \sum_{i=0}^{n} a(i)$,

$$A([yn])/A(n) \to 1 \tag{2.3}$$

uniformly in $y \in [x,1]$.

By (i), (2.2) may be strengthened to

$$\sup_n \sup_{y \in [x,1]} a([yn])/a(n) < \infty. \tag{2.4}$$

It is easy to construct examples of $\{a(n)\}$ in TS which violate (2.2). Condition (iv) can be given an alternative formulation. Let $h : R^+ \to R^+$ be an eventually nonincreasing function satisfying $h(n) = a(n)$, $n \geq 0$. Then (2.3) is equivalent to

$$\lim_{t \to \infty} \frac{\int_0^{yt} h(s)ds}{\int_0^t h(s)ds} = 1, \tag{2.5}$$

which, by l'Hôpital's rule, reduces to

$$\lim_{t \to \infty} yh(yt)/h(t) = 1.$$

One needs this to hold uniformly in $y \in [x,1]$. One sufficient condition for this would be that the derivative of the left-hand side of (2.5) in y, which is $th(yt)/\int_0^t h(s)ds$, be bounded uniformly in y, t, ensuring the equicontinuity in y for the ratio in (2.5). It is not clear whether (iv) is implied by (i)–(iii). Examples of $\{a(n)\}$ satisfying (i)–(iv) are $\{1/n\}$, $\{1/n\log n\}$, and $\{\log n/n\}$, with suitable modification for $n = 0, 1$ where needed.

One property of $\{a(n)\} \in$ TS that we shall need later is the following.

LEMMA 2.1. *For $s \in (0,1)$, $a(n)^{-s}/n \to 0$.*

Proof. It suffices to prove that $(a(n)n^x)^{-1} \to 0$ for $x = 1/s > 1$, or equivalently, that $(a(n) + n^{-x})/a(n) \to 1$. Let $h_1, h_2 : R^+ \to R^+$ be continuous functions linearly interpolated from $h_1(n) = a(n) + n^{-x}$, $h_2(n) = a(n)$, $n \geq 0$. Since $\int_0^t h_1(y)dy \to \infty$ as $t \to \infty$ and $\int_1^\infty t^{-x}dt < \infty$, we have

$$\lim_{t \to \infty} \frac{\int_0^t h_2(y)dy}{\int_0^t h_1(y)dy} = 1.$$

The claim now follows from l'Hôpital's rule. ∎

Our first assumption then is:

(A1) $\{a(n,i)\} \in$ ITS for $i \in I$.

Next, introduce for $n \geq 0$ the σ-fields $\mathcal{F}_n = \sigma(X(m), Y(m), m \leq n, \tau_{ij}(m), \xi(m), m < n, i, j \in I)$ and $\mathcal{G}_n = \sigma(X(m), Y(m), \tau_{ij}(m), \xi(m), m \leq n, i, j \in I)$. Our assumption concerning $\{Y_n\}$ is as follows.

(A2) There exists a $\delta > 0$ such that for any A, $B \in S$, the quantity

$$P(Y_{n+1} = B / Y_n = A, \mathcal{G}_n) \tag{2.6}$$

is either always zero almost surely (a.s.) or always exceeds δ a.s. That is, having picked A at time n, picking B at time $n+1$ is either improbable or probable with a conditional probability of at least δ, regardless of n and the "history" $\mathcal{G}_n$. Furthermore, if we draw a directed graph with node set S and an edge from A to B whenever (2.6) exceeds δ a.s., the graph is irreducible; i.e., there is a directed path from any $A \in S$ to any $B \in S$. (As will become apparent later, this may be replaced by the weaker requirement that every communicating class of the directed graph comprises sets that together cover I.)

This has the following important consequence. Let $\mathcal{P}(\cdots)$ denote the space of probability vectors on "$\cdots$."

LEMMA 2.2. *There exists a deterministic constant $\Delta > 0$ such that for any $A \in S$,*

$$\liminf_{n\to\infty} \frac{1}{n} \sum_{m=0}^{n-1} I\{Y_m = A\} \geq \Delta \quad a.s. \tag{2.7}$$

Proof. For $A \in S$, let $D_A = \{B \in S |$ (2.6) exceeds δ a.s.$\}$ and $V_A = \{u \in \mathcal{P}(D_A) | u(B) \geq \delta \ \forall B \in D_A\}$, $V = \prod_A V_A$. Define $p : S \times S \times V \to [0,1]$ by $p(A,B,u) = u_A(B)$, where u_A is the Ath component of u. Define V-valued random variables $\{Z^n\}$ by

$$Z_A^n(B) = P(Y_{n+1} = B / \mathcal{G}_n) I\{Y_n = A\} + \psi_A I\{Y_n \neq A\},$$

where ψ_A is a fixed element of V_A for $A \in S$. Then (2.6) equals $p(A, B, Z^n)$ and $\{Y_n\}$ may be viewed as an S-valued controlled Markov chain with action space V and transition probability function p. (This is a pure artifice for the sake of the proof. It is in no way implied that $\{Z^n\}$ is an actual control process.) In particular, this allows us to conceive of a stationary policy π associated with a map π: $S \to V$. (A1) implies, in particular, that $\{Y_n\}$ will be an ergodic Markov chain under a stationary policy π with a corresponding stationary distribution $\nu_\pi \in \mathcal{P}(S)$. Then the left-hand side of (2.7) a.s. exceeds $\min_\pi \nu_\pi(A) > 0$ by Lemmas 1.2 and 2.1 of [4, pp. 56, 60]. □

For the communication delays, we assume the following. (Recall the r in (2.1).)

(A3) $\tau_{ij}(n) \in \{0, 1, \ldots, n\}, \tau_{ii}(n) = 0 \ \forall i, a$. There exist $b > r/(1-r), C > 0$ such that

$$E[(\tau_{ij}(n))^b / \mathcal{F}_n] \leq C \quad \text{a.s.} \quad \forall i, j, n. \tag{2.8}$$

(In particular, we do not require the delays to be either bounded or stationary.) Also, $\{\xi(n)\}$ is i.i.d. and independent of $\{X_0, \xi(m), \tau_{ij}(m), m < n\}$ for all n.

Next come the conditions on F.

(A4) F is assumed to be measurable and uniformly Lipschitz in the first argument; i.e., for some $K > 0$,

$$\|F(x,z) - F(y,z)\| \leq K\|x - y\| \quad \forall\ x, y, z.$$

Other conditions on F will be given in terms of the function $f : R^d \to R^d$ defined by

$$f(x) = \int F(x,y)\psi(dy). \tag{2.9}$$

Under our conditions on F, f is Lipschitz with Lipschitz constant K. The traditional analysis of (1.2) [2] proceeds by showing that it asymptotically tracks the ODE

$$\dot{x}(t) = f(x(t)), \tag{2.10}$$

which in turn has trajectories converging to $J = \{x | f(x) = 0\}$.

(A5) J is assumed to be compact and nonempty.

We shall also have reason to consider a related nonautonomous ODE. Let $\mathcal{D}$ denote the set of diagonal $d \times d$ matrices with nonnegative diagonal entries that add to 1. For $a > 0$, say that $M = \text{diag}(m_1, \ldots, m_d)$ is a-thick if $m_i \geq a \ \forall i$. The ODE in question is

$$\dot{x}(t) = M(t)f(x(t)), \tag{2.11}$$

where $t \to M(t)$ is a $\mathcal{D}$-valued measurable process.

We consider two scenarios.

Case 1: *Strict Liapunov systems.* A continuously differentiable function $V : R^d \to R^+$ is said to be a strict Liapunov function for (2.10) if $\nabla V.\, f < 0$ outside J. Call (2.10) a strict Liapunov system if it has bounded trajectories and a strict Liapunov function V exists. The latter implies the former if $V(x) \to \infty$ as $\|x\| \to \infty$, which we assume to hold. (Call this assumption (A6).) Examples of such systems can be found among gradient systems and their variants, certain systems arising in neural networks [14], and analog fixed point algorithms wherein $f(x) = g(x) - x$ and g is either a contraction under a $\|.\|_p$-norm for $p \in [1, \infty]$ or nonexpansive under a $\|.\|_p$- norm for $p \in (1, \infty)$. (Here $V(.) = \|. - x^*\|_p$, where $x^* \in J$, will do. For $p = \infty$, this is not continuously differentiable, but this does not pose any problems for contractions [7].)

Finally, a strict Liapunov system as above will be said to be a-robust for some $a > 0$ if $\nabla V.\, Mf < 0$ outside J for any a-thick $M \in \mathcal{D}$.

Given $T, \delta > 0$, a (T, δ)-perturbation of (2.10) (resp., (2.11)) is a function $y : R^+ \to R^d$ such that there exist $0 = T_0 < T_1 < \cdots < T_n \uparrow \infty$ and solutions $x^j(t)$, $t \in [T_j, T_{j+1}]$, $j \geq 0$, of (2.10) (resp., (2.11)) such that $T_{j+1} - T_j \geq T$ for $j \geq 0$ and

$$\|y(t) - x^j(t)\| < \delta, \quad T_j \leq t \leq T_{j+1}, j \geq 0.$$

For $\epsilon > 0$, let $J^\epsilon = \{x \in R^d | \, \|x - y\| < \epsilon \text{ for some } y \in J\}$.

LEMMA 2.3. *Under* (A6), *we have:* (a) *For any* $T, \epsilon > 0$, *there exists a* $\delta_0 = \delta_0(T, \epsilon) > 0$ *such that for* $\delta \in (0, \delta_0)$, *any* (T, δ)*-perturbation of* (2.10) *converges to* J^ϵ. *(In particular, solutions of* (2.10) *converge to* J.*)*

(b) *Suppose that* (2.10) *is a-robust for some* $a > 0$ *and* $M(t)$ *in* (2.11) *is a-thick for almost every* t. *Then, for any* $T, \epsilon > 0$, *there exists a* $\delta_0 = \delta_0(T, \epsilon, a) > 0$ *such that for* $\delta \in (0, \delta_0)$, *any* (T, δ)*-perturbation of* (2.11) *converges to* J^ϵ. *(In particular, the solutions of* (2.11) *converge to* J.*)*

These are straightforward adaptations of Theorem 1 of [14, p. 339].

Case 2: ∞*-nonexpansive maps.* In this case $f(x) = g(x) - x$, where g is ∞-nonexpansive, i.e., $\|g(x) - g(y)\|_\infty \leq \|x - y\|_\infty, x, y \in R^d$. Thus J is the set of fixed points of g. This case is important in dynamic programming applications [3, 7].

For this case, we have the following analog of Lemma 2.3.

LEMMA 2.4. *The conclusions of Lemma* 2.3(a) *continue to hold. Those of Lemma* 2.3(b) *hold if* $M(t)$ *is* a*-thick for almost every* t*, for some* $a > 0$.

This is proved in Theorem 2.1 and Corollary 2.2 of [5].

3. Convergence. We start by establishing a link between (1.4) and (2.11). Our first observation is that we may equivalently consider the recursion

$$X_i(n+1) = X_i(n)+\overline{a}(n,i)F_i(X_i(n-\tau_{ij}(n)),\dots,X_d(n-\tau_{id}(n)),\tilde{\xi}(n))I\{\varphi_n = i\}, \tag{3.1}$$

where $\{\varphi_n\}$ is an I-valued random process satisfying the following statement. There exists a deterministic constant $\eta > 0$ such that

$$\liminf_{n\to\infty} \frac{1}{n}\sum_{m=0}^{n-1} I\{\varphi_n = i\} \geq \eta \quad \text{a.s.} \quad \forall i \in I \tag{3.2}$$

and $\tilde{\xi}(n) = \xi(k(n))$ for a nondecreasing map $n \to k(n)$, satisfying $k(n+1) - k(n) \in \{0,1\}$.

This is achieved simply by unfolding each iteration as follows.

Let $Y_n = \{i_1,\dots,i_{c(n)}\}$ (say) with the elements arranged in ascending order. Replace the iteration (1.4) by $c(n)$ distinct iterations such that the jth iteration among them updates only the i_jth component in accordance with (1.4). Next, relabel the iteration index and the delays to obtain a correspondence with (3.1). Then (3.2) is an immediate consequence of Lemma 2.2. Note that this blows up the delays at most d fold, thus still retaining (A3). Note also that for $m > n$, $\varphi_m = \varphi_n$ implies $k(m) > k(n)$. With these considerations, we proceed to analyze (3.1). We start with some preliminaries.

Let U be the space of $\mathcal{P}(I)$-valued trajectories $\overline{\mu} = \{\mu_t, t \geq 0\}$ with the coarsest topology that renders continuous the maps $\overline{\mu} \to \int_0^T h(t)\mu_t(i)dt$ for $T \geq 0$, $i \in I$, $h \in L_2[0,T]$. U is compact metrizable. Say that $\mu \in \mathcal{P}(I)$ is α-thick for some $\alpha > 0$ if $\mu(i) \geq \alpha\ \forall i$. Say that $\overline{\mu} \in U$ is α-thick, $\alpha > 0$, if μ_t is so for almost every t. Say that μ (resp., $\overline{\mu}$) is thick if it is α-thick for some $\alpha > 0$.

LEMMA 3.1. (a) *For* $\alpha > 0$, $\{\overline{\mu}|\overline{\mu}$ *is* α*-thick*$\}$ *is compact in* U. (b) *The map* $(\overline{\mu}, x) \to x(\,.\,) : U \times R^d \to C([0,\infty); R^d)$ *defined via*

$$\dot{x}(t) = M^{\overline{\mu}}(t)f(x(t)), \qquad x(0) = x, \tag{3.3}$$

with $M^{\overline{\mu}}(t) = \mathrm{diag}(\mu_t(1),\dots,\mu_t(d))$, *is continuous.*

Proof. (i) For $i \in I, t > s, n \geq 1$, and any α-thick $\overline{\mu}$, $\alpha > 0$,

$$\int_s^t \mu_y(i)dy \geq \alpha(t-s).$$

The relation is preserved under limits in U, implying the claim.

(ii) Let $(\overline{\mu}^n, x_n) \to (\overline{\mu}^\infty, x_\infty)$. For $n \geq 1$, let $x^n(\,.\,)$ satisfy

$$\dot{x}^n(t) = M^{\overline{\mu}^n}(t)f(x^n(t)), \qquad x^n(0) = x_n. \tag{3.4}$$

Using the Gronwall lemma and the Arzela–Ascoli theorem, one verifies that $\{x^n(\,.\,)\}$ is relatively compact in $C([0,\infty); R^d)$, and a straightforward limiting argument (keeping in mind our topology on U) shows that any limit $x^\infty(\,.\,)$ thereof must satisfy (3.4) with $n = \infty$. The claim follows. □

Let $\tilde{a}(n) = \overline{a}(n, \varphi_n)$ and rewrite (3.1) as

$$X(n+1) = X(n) + \tilde{a}(n)W(n)$$

for appropriately defined $W(n) = [W_1(n), \ldots, W_d(n)]^T$. Redefine $\mathcal{F}_n$ by $\mathcal{F}_n = \sigma(X(m), m \leq k^{-1}(n), \xi(m), m < k^{-1}(n), \tau_{ij}(m), m < n, \varphi_m, m \leq n)$, where $k^{-1}(n) = \min\{j | k(j) = n\}$. Set $\hat{W}(n) = E[W(n)/\mathcal{F}_n], n \geq 0$, the conditioning bring componentwise. Write $\hat{W}(n) = [\hat{W}_1(n), \ldots, \hat{W}_d(n)]^T$. Define $f^i : R^d \to R^d$ by $f^i_j(x) = f_i(x)\delta_{ij}$, $i, j \in I$, δ_{ij} being the Kronecker delta. Let $b(n) = \max_i \overline{a}(n, i), n \geq 0$. Let Q denote the set of sample points for which $\hat{X} \triangleq \sup_n \|X(n)\| < \infty$.

LEMMA 3.2. *$\{b(n)\}$ satisfies $\sum_n b(n)^{1+r} < \infty$ a.s., and for $a \in (0, 1]$,*

$$\sup_n \sup_{\alpha \in [a,1]} b([\alpha n])/b(n) < \infty \quad a.s.$$

Proof. By (2.4) and (3.2), $\sup_n \overline{a}(n, i)/a(n, i) < \infty$ a.s., $i \in I$. Combining this with property (2.1) for $\{a(n, i)\}$, we have $\sum \overline{a}(n, i)^{1+r} < \infty$ a.s. The first claim follows. The second follows easily from (2.4) applied to $\{a(n, i)\}$. □

LEMMA 3.3. *Almost surely on Q, there exist $K_1 > 0$, $N \geq 1$ (random) such that for $n \geq N$,*

$$\|f^{\varphi_n}(X(n)) - \hat{W}(n)\| < K_1 b(n)^r.$$

Proof. Consider $\omega \in Q$. Let K_2 be an upper bound on $\{\|f(x)\|_\infty \mid \|x\| \leq \hat{X}\}$. Let $\tilde{W}_i(n) = f_i^{\varphi_n}(X_1(n - \tau_{i1}(n)), \ldots, X_d(n - \tau_{id}(n)))$. Let $c = 1 - r$. For $i \in I$, we have

(3.5)

$$|f_i^{\varphi_n}(X(n)) - \hat{W}_i(n)| \leq E[|f_i^{\varphi_n}(X(n)) - \tilde{W}_i(n)| I\{\tau_{ij}(n) \leq b(n)^{-c} \ \forall i, j\}/\mathcal{F}_n]$$
$$+ E[|f_i^{\varphi_n}(X(n)) - \tilde{W}_i(n)| I\{\tau_{ij}(n) > b(n)^{-c} \text{ for some } i, j\}/\mathcal{F}_n] \quad \text{a.s.}$$

By (A3) and the conditional Chebyshev inequality, the second term is a.s. bounded by $2K_2 C d^2 b(n)^{bc}$. Let $\overline{n} = [b(n)^{-c}]$. By Lemma 2.1, $\overline{n}$ is $o(1)$ a.s. as $n \to \infty$, and outside a zero probability set, we may pick n large enough so that $n > \overline{n}$. Then for $m \leq \overline{n}$,

$$\|X(n) - X(n-m)\| \leq 2K_2 d \sum_{j=n-\overline{n}}^{n} b(j) \leq K_3 b(n)^{1-c}$$

for a suitable (random) $K_3 > 0$, by the above lemma. Thus the first term in (3.5) is bounded by $K_4 b(n)^r$ for a suitable (random) $K_4 > 0$. Since $b > r/(1-r)$, the claim follows. □

Let $T > 0$. Define $t_0 = T_0 = 0, t_n = \sum_{m=0}^{n-1} \tilde{a}(m)$, $n \geq 1$, and $T_n = \min\{t_m | t_m \geq T_{n-1} + T\}$, $n \geq 1$. Then $T_n = t_{m(n)}$ for a strictly increasing sequence $\{m(n)\}$. Let $I_n = [T_n, T_{n+1}]$, $n \geq 0$. Define $\overline{x}^n(t)$, $t \in I_n$, by $\overline{x}^n(T_n) = X(m(n))$ and

$$\overline{x}^n(t_{m(n)+k+1}) = \overline{x}^n(t_{m(n)+k}) + \tilde{a}(m(n)+k) f^{\varphi_{m(n)+k}}(\overline{x}^n(t_{m(n)+k})),$$

with linear interpolation on each interval $[t_{m(n)+k}, t_{m(n)+k+1}]$. Define $x(t)$, $t \geq 0$, by $x(t_n) = X(n)$ with linear interpolation on each interval $[t_n, t_{n+1}]$.

LEMMA 3.4. $\lim_{n\to\infty} \sup_{t\in I_n} \|x(t) - \overline{x}^n(t)\| = 0$ *a.s. on* Q.

Proof. Let $n \geq 1$. For $i \geq m(n)$, we have

$$x(t_{i+1}) = x(t_i) + \tilde{a}(i)f^{\varphi_i}(x(t_i)) + \tilde{a}(i)(\hat{W}(i) - f^{\varphi_i}(x(t_i))) + \tilde{a}(i)(W(i) - \hat{W}(i)).$$

Let $\overline{M}_i = \sum_{j=0}^{i} \tilde{a}(j)(W(j) - \hat{W}(j))$ and $\lambda_i = \overline{M}_i - \overline{M}_{m(n)}, i \geq m(n)$. Also, let $M_i^k = \sum_{j=0}^{k} \tilde{a}(j)(W(j) - \hat{W}(j))I\{\varphi_j = k\}, 1 \leq k \leq d$. Recall that $m > n$ and $\varphi_m = \varphi_n$ implies $k(m) > k(n)$. Then, for each k, $\{M_i^k, \mathcal{F}_i\}$ is a zero mean–bounded increment vector martingale, and the quadratic variation process of each of its component martingales is a.s. convergent on Q. By Proposition VII-3-(c) of [19, pp. 149–150], each $\{M_i^k\}$ and hence $\{\overline{M}_i\}$ converges a.s. on Q. Fix a sample point for which this convergence holds and let $\epsilon > 0$. Then $\sup_{i\geq m(n)} \|\lambda_i\| < \epsilon/2$ for sufficiently large n. Let $\hat{x}_{i+1} = x(t_{i+1}) - \lambda_i, i \geq m(n)$, with $\hat{x}_{m(n)} = X(m(n))$. Then, for $i \geq m(n)$, we have

$$\hat{x}_{i+1} = \hat{x}_i + \tilde{a}(i)f^{\varphi_i}(\hat{x}_i) + \tilde{a}(i)(f^{\varphi_i}(\hat{x}_i + \lambda_{i-1}) - f^{\varphi_i}(\hat{x}_i)) + \tilde{a}(i)(\hat{W}(i) - f^{\varphi_i}(x(t_i))).$$

Also,

$$\overline{x}^n(t_{i+1}) = \overline{x}^n(t_i) + \tilde{a}(i)f^{\varphi_i}(\overline{x}^n(t_i)).$$

Fix $\omega \in Q$, where the foregoing and Lemma 3.3 hold. Subtracting and using Lemma 3.3, we have, for n sufficiently large,

$$\|\hat{x}_{i+1} - \overline{x}^n(t_{i+1})\| \leq (1 + K\tilde{a}(i))\|\hat{x}_i - \overline{x}^n(t_i)\| + \tilde{a}(i)\|\lambda_{i-1}\|K + K_1\tilde{a}(i)b(i)^{1+r}.$$

By increasing n if necessary, we may suppose that

$$\sum_{i\geq n} b(i)^{1+r} < \epsilon/2.$$

Then using the inequality $1 + x \leq \exp(x)$ and iterating, we have

$$\sup_{m(n)\leq i\leq m(n+1)} \|\hat{x}_i - \overline{x}^n(t_i)\| \leq e^{K(T+1)}(K_1 + K(T+1))\epsilon$$

for sufficiently large n. Since $\|\hat{x}_i - x(t_i)\| < \epsilon/2$, $i \geq m(n)$ for sufficiently large n, $\sup_{m(n)\leq i\leq m(n+1)} \|x(t_i) - \overline{x}^n(t_i)\| \leq \tilde{K}\epsilon$ for a suitable $\tilde{K} > 0$. Since $\epsilon > 0$ was arbitrary, the claim follows on noting that both $x(\,.\,)$ and $\overline{x}^n(\,.\,)$ are linearly interpolated from their values at $\{t_i\}$. □

Next, define $\overline{\mu} \in U$ by $\mu_t =$ the Dirac measure at φ_n for $t \in [t_n, t_{n+1}), n \geq 0$. Define $\tilde{x}^n(t)$, $t \in I_n$, by $\tilde{x}^n(t_{m(n)}) = x(t_{m(n)})$ and

$$\dot{\tilde{x}}^n(t) = M^{\overline{\mu}}(t)f(\tilde{x}^n(t)), \qquad t \in I_n. \tag{3.6}$$

LEMMA 3.5. $\lim_{n\to\infty} \sup_{t\in I_n} \|\tilde{x}^n(t) - \overline{x}^n(t)\| = 0$ *a.s.*

Proof. This follows easily from the Gronwall inequality. □

For $\overline{\mu}$ as above, define $\overline{\mu}^t = \{\mu_{t+s}, i \geq 0\} \in U$ for $t \geq 0$. Combining the foregoing with Lemmas 2.3 and 2.4, we have the following theorem.

THEOREM 3.1. (a) *Suppose there exists an* $a > 0$ *such that* (2.10) *is an* a*-robust strict Liapunov system,* (A6) *applies, and all limit points of* $\overline{\mu}^t$ *in* U *as* $t \to \infty$ *are* a*-thick a.s. Then the algorithm converges to* J *a.s. on* Q.

(b) *For the ∞-nonexpansive case (Case 2), suppose all limit points of $\overline{\mu}^t$ in U as $t \to \infty$ are a-thick for some $a > 0$, a.s. Then the algorithm converges to J a.s. on Q.*

Remark. For Case 1 without the a-robustness hypothesis, the above analysis still gives some clue about the convergence of the algorithm: if all limit points of $\overline{\mu}^t$ are a-thick a.s., the algorithm will converge to the smallest closed set outside which $\nabla V.\, Mf < 0$ for a-thick M.

Clearly, one would like $P(Q) = 1 = P\ (\hat{X} < \infty)$. One observes that the boundedness of $\hat{X}$ is used twice: in Lemma 3.3 and to prove almost sure convergence on Q of $\{\overline{M}_n\}$. In either case, it is unnecessary if f (or, in Case 2, g) is bounded. If not, the problem of establishing $P(Q) = 1$ remains. This is so even for the traditional "centralized" algorithm, and it is not unusual to find results that state convergence if the iterates remain bounded or visit a neighborhood of the desired attractor infinitely often, a.s. There is no general scheme for showing $P(Q) = 1$. There are, however, problem-specific techniques for special problem classes. We list a few recent ones below without details, referring the reader to the original works for those.

(i) *Martingale methods.* These usually take the form of establishing the "almost supermartingale" property [19, p. 33] for $\{V(X(n))\}$, where $V : R^d \to R^+$ is a continuously differentiable "stochastic Liapunov function" satisfying $V(x) \to \infty$ as $\|x\| \to \infty$. This leads to the almost sure boundedness of $\{V(X(n))\}$, hence of $\{X(n)\}$. For strict Liapunov systems, the Liapunov function therein will itself suffice in most cases. The adaptation of this approach to the asynchronous case, however, is rendered difficult by the presence of delays. Specific instances of it have been worked out, a good example being the stochastic gradient schemes discussed in [3, section 7.8]. For the "centralized" case without delays, see [2, p. 239].

(ii) *Projection and related schemes.* One way to escape the boundedness issue is to alter the algorithm by projecting the iterates back onto a prescribed, large bounded set whenever they exit from the same. The trade-off is that the limiting ODE becomes more complicated. It is now confined to the said set and thus involves a "reflection at the boundary" of the same in an appropriate sense. The analysis of such schemes for the centralized case is by now standard, and an excellent exposition appears in [16, pp. 191–194]. It seems possible to extend it to the present case. (See [1] for a specific instance.)

In an ingenious boundedness proof for the case when $F(x, y)$ is homogeneous of degree 1 in its first argument (important in certain "learning" algorithms), Jaakola, Jordan, and Singh [15] use the almost sure convergence of the algorithm with rescaling to deduce the almost sure boundedness of the one without. See [1] for some extensions of this idea and application to a specific asynchronous situation.

In a somewhat similar spirit, but using different techniques, Chen [8] discusses stabilization of the (centralized) algorithm by truncating the iterates while slowly increasing the truncation bounds.

(iii) *Tsitsiklis conditions.* For Case 2 (nonexpansive maps) studied above, Tsitsiklis [21] gives a remarkable set of conditions for almost sure boundedness when additional structure is available, such as an appropriate monotonicity property of the map or contraction property under a suitable norm. These are very useful for applications arising from dynamic programming.

In some special cases (e.g., when $F(\cdot\,, y)$ has a common fixed point), one may adapt the conditions of [3, p. 433], for deterministic algorithms to prove almost sure boundedness. See [5] for an instance of this.

In [5], almost sure a-thickness of the limit points of $\{\overline{\mu}^t\}$ for a suitable $a > 0$ is established for the synchronous case. That argument does not follow for the asynchronous case. In fact, it will soon become clear that such a result need not hold in general, and whether it does depends crucially on the relationships between the sequences $\{a(n,i)\} \in \text{ITS}$, $i \in I$. We now consider an important special case where things work out.

Say that the family $\{a(n,i)\}, i \in I$, is balanced if there exist $a_{ij} > 0, i, j \in I$, such that

$$\lim_{n\to\infty} \frac{\sum_{m=0}^{n} a(m,j)}{\sum_{m=0}^{n} a(m,i)} = a_{ij}.$$

Equivalently, if h_i, h_j are continuous, eventually nonincreasing functions $R^+ \to R^d$ that restrict to $\{a(n,i)\}$, $\{a(n,j)\}$, respectively, at integer values of their arguments, then

$$\lim_{t\to\infty} \frac{\int_0^t h_j(s)ds}{\int_0^t h_i(s)ds} = a_{ij}. \tag{3.7}$$

Certain relations between a_{ij}'s are obvious: $a_{ii} = 1$, $a_{ik} = a_{ij}a_{jk}$, $a_{ji} = 1/a_{ij}$. An important special case is $a_{ij} = 1\ \forall i, j$, which would be true, e.g., when all $\{a(n,i)\}, i \in I$, are identical. Let $\beta(i) = a_{1i}/a_{11}$ and $\overline{\beta}(i) = \beta(i)/\sum_j \beta(j)$. Then $\overline{\beta}(i) \in (0,1)\ \forall i$ and $\sum_i \overline{\beta}(i) = 1$. Also $a_{ij} = \overline{\beta}(j)/\overline{\beta}(i)\ \forall i, j$. Set $\overline{a} = \min \overline{\beta}(i)$.

THEOREM 3.2. *If $\{a(n,i)\}, i \in I$, are balanced, the conclusions of Theorem* 3.1(b) *hold. Those of Theorem* 3.1(a) *hold if, in addition, $a \le \overline{a}$.*

Proof. For $i \in I$, let $q(i,n) = \sum_{m=0}^{n} I\{\varphi_m = i\}$. By (3.2),

$$\liminf_{n\to\infty} q(i,n)/n \ge \eta \quad \text{a.s.}, \quad i \in I. \tag{3.8}$$

Fix $i, j \in I$. Then, for $z > 0$,

$$\begin{aligned}
\lim_{t\to\infty} \frac{\int_z^t \mu_s(j)ds}{\int_z^t \mu_s(i)ds} &= \lim_{n\to\infty} \frac{\sum_{m=0}^{q(j,n)} a(m,j)}{\sum_{m=0}^{q(i,n)} a(m,i)} \\
&= \lim_{n\to\infty} \frac{\int_0^{q(j,n)} h_j(s)ds}{\int_0^{q(i,n)} h_i(s)ds} \\
&= \lim_{n\to\infty} \frac{\int_0^{q(j,n)} h_j(s)ds}{\int_0^n h_j(s)ds} \cdot \frac{\int_0^n h_j(s)ds}{\int_0^n h_i(s)ds} \cdot \frac{\int_0^n h_i(s)ds}{\int_0^{q(i,n)} h_i(s)ds} \\
&= a_{ij} \quad \text{a.s.}
\end{aligned}$$

uniformly in z in a compact interval, by (2.5) and (3.8).

Thus, for $x > 0$,

$$\lim_{t\to\infty} \frac{\int_0^x \int_0^t \mu_{s+y}(j)dsdy}{\int_0^x \int_0^t \mu_{s+y}(i)dsdy} = \lim_{t\to\infty} \frac{\int_0^t \int_0^x \mu_{s+y}(j)dsdy}{\int_0^t \int_0^x \mu_{s+y}(i)dsdy} = a_{ij} \quad \text{a.s.}$$

By l'Hôpital's rule,

$$\lim_{t\to\infty} \frac{\int_0^x \mu_{t+y}(j)dy}{\int_0^x \mu_{t+y}(i)dy} = a_{ij} \quad \text{a.s.}$$

It follows that, a.s., any limit point $\overline{\mu}^*$ of $\{\overline{\mu}^t\}$ in U as $t \to \infty$ must satisfy $\int_0^x \mu_t^*(j)dt / \int_0^x \mu_t^*(i)dt = a_{ij}$. Then so will $\overline{\mu}^{*t}$, $t \geq 0$. Since $x > 0$ was arbitrary, we have $\mu_t^*(j)/\mu_t^*(i) = a_{ij}$ for almost every t, where we may drop the "almost every t" by taking a suitable modification. Then we must have $\mu_t^*(i) = \overline{\beta}(i)\ \forall i,\ t$, and the matrix $M^{\overline{\mu}^*}(t)$ is the constant diagonal matrix $M^* = \text{diag}(\overline{\beta}(1), \ldots, \overline{\beta}(d))$. The rest is easy. □

Remark. In the latter case, one may in fact replace the a-robustness condition and the condition $a \leq \overline{a}$ by the simpler condition $\nabla V.\, M^* f < 0$ outside J.

In particular, if $\{a(n,i)\}$ are identical, $M^{\overline{\mu}^*}$ is $1/d$ times the identity matrix, implying that the rescaled time axis is apportioned equally to all components. One may dub this the "asymptotic equipartition of time."

4. Conclusions. The foregoing analysis raises several interesting issues, which are listed below.

1. We have not presented any results on the convergence rate. For the ODE, the rate of convergence to J^ϵ for $\epsilon > 0$ could be gleaned from the Liapunov function and would be eventually mimicked by the interpolated algorithm $x(\cdot)$. There are two catches here. One is that "eventually" could be a long way into the future. Second, the passage from $\{X(n)\}$ to $x(\cdot)$ involves a time-scaling $n \to t(n)$, which has to be inverted to obtain the actual convergence rate of $\{X(n)\}$. These aspects need further study.

2. It seems plausible that one could retain the above results if (3.7) were replaced by the weaker requirement that the corresponding liminf be bounded away from zero. One cannot then expect $\{\overline{\mu}^t\}$ to a.s. converge to a fixed element, but it is conjectured that one will still retain the property that all limit points of $\{\overline{\mu}^t\}$ in U are a-thick for some $a > 0$.

3. In engineering applications, $\{a(n,i)\}$ are design parameters and can be chosen to be balanced. This may not, however, be so in "emergent" computations or when (1.4) is merely a computational paradigm for a natural process such as a macroeconomic learning system. An interesting problem, then, is to let each agent (processor) "learn" its stepsize scheme in real time based on observations of stepsizes used by, say, "neighboring" agents. One may then try to show that under reasonable conditions, this leads to balanced schemes.

4. If we had allowed some of the a_{ij}'s to be zero, it is clear that the corresponding diagonal elements of M^* will be zero and M^* is no longer thick. This reflects different time scales in the speed of adjustment of different learners. It would be interesting to analyze this situation using the theory of singularly perturbed differential equations.

5. If (1.2) had no extraneous randomness, i.e., $F(X(n), \xi(n)) = H(X(n))\ \forall n$ for a suitable H, the foregoing shows that a stepsize scheme from ITS suppresses the effects of communication delays in deterministic recursions under a mild conditional moment condition (A3). This is in contrast to the usual role of ITS as a pure noise-suppressing mechanism. Compare this with the fact that even linear recursions with constant stepsize show very complex behavior in the presence of communication delays [12].

6. Yet another possibility to explore is the use of the Wentzell–Freidlin theory of small noise asymptotics [10] to get a dynamic picture of the behavior of the algorithm in the vicinity of J, in particular, to see if it favors certain points in J. This is in the spirit of some recent work on annealing algorithms [11] and equilibrium selection in evolutionary games [9].

Acknowledgments. This work has benefited significantly from discussions with Profs. Vinod Sharma and Daniel Ocone, and by the comments of the referees and the associate editor.

BOUNDARY VALUE PROBLEMS AND OPTIMAL BOUNDARY CONTROL FOR THE NAVIER–STOKES SYSTEM: THE TWO-DIMENSIONAL CASE*

A. V. FURSIKOV†, M. D. GUNZBURGER‡, AND L. S. HOU§

Abstract. We study optimal boundary control problems for the two-dimensional Navier–Stokes equations in an unbounded domain. Control is effected through the Dirichlet boundary condition and is sought in a subset of the trace space of velocity fields with minimal regularity satisfying the energy estimates. An objective of interest is the drag functional. We first establish three important results for inhomogeneous boundary value problems for the Navier–Stokes equations; namely, we identify the trace space for the velocity fields possessing finite energy, we prove the existence of a solution for the Navier–Stokes equations with boundary data belonging to the trace space, and we identify the space in which the stress vector (along the boundary) of admissible solutions is well defined. Then, we prove the existence of an optimal solution over the control set. Finally, we justify the use of Lagrange multiplier principles, derive an optimality system of equations in the weak sense from which optimal states and controls may be determined, and prove that the optimality system of equations satisfies in appropriate senses a system of partial differential equations with boundary values.

Key words. optimal control, Navier–Stokes equations, boundary value problem, drag minimization

1. Introduction.

Optimal control problems for fluid flows have been a subject of interest to experimenters and designers since at least the time of Prandtl. In more recent times, they have also become of substantial interest to mathematicians and computational scientists. For the steady state Navier–Stokes system, complete and systematic mathematical and numerical analyses of optimal control problems of different types (e.g., having Dirichlet, Neumann, and distributed controls and also finite-dimensional controls) were given in [15, 16, 17, 18]. Mathematical treatments of optimal control problems for the time-dependent Navier–Stokes system were given in [2], [6, 7, 8, 9, 10, 11, 12, 13], [20], and [24, 25, 26, 27]. In [6], free convection problems with boundary heat flux controls were considered; the existence of optimal solutions was proved and necessary conditions that characterize optimal controls and states were derived. In [11, 12, 13], the existence of optimal distributed controls was shown, an optimality system of equations was derived, and the question of the uniqueness

of optimal solutions was resolved. Distributed controls were also considered in [20]. Various optimal control problems involving both distributed and boundary controls were considered in [2], although detailed proofs were provided only for the case of distributed controls. In [7, 8, 9, 10] and [24, 25, 26, 27] extensive studies of optimal control problems were given for Dirichlet controls in a special case, namely, when the control is of the separation-of-variable type.

In this paper we consider general Dirichlet controls for the time-dependent, two-dimensional Navier–Stokes system in the exterior of a bounded domain. Our eventual goal is to derive an optimality system from which optimal controls and states may be determined. A feature of the Dirichlet boundary control problem is as follows: one can derive an optimality system only in spaces of sufficiently smooth functions for which the nonlinear terms of the Navier–Stokes system are subordinate to the linear terms. (In the case of distributed control the situation is different; see [13].) In the two-dimensional case, the space of minimal smoothness possessing this property is the space of functions with "finite energy." Therefore, we first identify the space of boundary values which allows us to obtain finite energy solutions for the Navier–Stokes equations. Then, we prove the existence of an optimal solution in the finite energy space. Note that it would be easier to prove the solvability of an optimal control problem in a certain space of nonsmooth functions, but such a result is useless for the derivation of an optimality system. Finally, we use Lagrange multiplier techniques to derive a boundary value problem that the optimal states and control must satisfy. This boundary value problem is called the optimality system. We rigorously justify the boundary conditions for this system by means of techniques for elliptic boundary value problems in spaces of distributions and a theory, given below, about stress regularity for solutions of the Navier–Stokes equations with nonhomogeneous Dirichlet boundary conditions. In contrast to parabolic boundary value problems, it is here necessary to fulfill the compatibility conditions for boundary and initial values even in the case of nonsmooth solutions.

2. Formulation of the problem.

2.1. Derivation of the cost functional. We will formally derive the drag functional for flows surrounding a finite body. We consider the motion of an incompressible fluid in an unbounded domain that is described by the system

$$\rho\partial_t \mathbf{v} - \mu\Delta\mathbf{v} + \rho\mathbf{v}\cdot\nabla\mathbf{v} + \nabla p = \mathbf{0} \qquad \text{and} \qquad \nabla\cdot\mathbf{v} = 0 \qquad \text{in } (0,T)\times\Omega\,, \tag{2.1}$$

$$\mathbf{v}|_{t=0} = \mathbf{v}_0 \quad \text{for } \mathbf{x}\in\Omega\,, \qquad \mathbf{v}|_{\partial\Omega} = \mathbf{g} \quad \text{for } t\in(0,T)\,, \tag{2.2}$$

and

$$\mathbf{v} \to \mathbf{v}_\infty \quad \text{as } |\mathbf{x}|\to\infty\,. \tag{2.3}$$

Here, $\partial_t = \partial/\partial t$, Ω is the region exterior to a bounded body $B \subset \mathbb{R}^2$, and $\partial\Omega$ is its boundary. For simplicity we assume $\partial\Omega$ is of class C^∞ and is a connected closed curve without self-intersections. Also, the density ρ is a constant and $\mathbf{v}_\infty$ is a constant vector; the exact nature of the behavior at infinity will be discussed later. Later on we will add a condition on p so that, for given $\mathbf{v}_0$, $\mathbf{g}$, and $\mathbf{v}_\infty$, the problem (2.1)–(2.3) has a unique solution. When $\mathbf{g} = \mathbf{0}$, (2.1)–(2.3) is the problem of a fluid moving around the body B with uniform velocity $\mathbf{v}_\infty$ at infinity.

Denote by $\partial\Omega_\epsilon$ a smooth closed curve in a neighborhood of $\partial\Omega$, surrounding $\partial\Omega$ and lying inside Ω; Ω_ϵ is the part of Ω bounded by $\partial\Omega_\epsilon$ and containing the point at

infinity. Let $\mathcal{T} = -p\mathcal{I} + 2\mu\mathcal{D}$ be the stress tensor; here, $\mathcal{D} = \mathcal{D}(\mathbf{v}) = \frac{1}{2}(\nabla\mathbf{v} + \nabla\mathbf{v}^T)$ is the rate of deformation tensor for the flow. Then, for $\mathbf{x} \in \partial\Omega_\epsilon$, $(\mathcal{T}\mathbf{n})(t, \mathbf{x})$ is the force at a point $\mathbf{x}$ on $\partial\Omega_\epsilon$ which acts on the fluid in Ω_ϵ at the time t; here, $\mathbf{n}$ denotes the unit normal to the curve $\partial\Omega_\epsilon$ which is outer with respect to Ω_ϵ. Thus,

$$\int_0^T dt \int_{\partial\Omega_\epsilon} (\mathbf{v} - \mathbf{v}_\infty) \cdot (\mathcal{T}\mathbf{n})\, ds$$

is the work needed to overcome the drag exerted on the "body" $B_\epsilon = \mathbb{R}^2 \backslash \Omega_\epsilon$ over the time interval $(0, T)$. After passing to the limit as $\epsilon \to 0$, we obtain the work needed to overcome the drag exerted on the given body $B = \mathbb{R}^2 \backslash \Omega$:

$$\mathcal{W} = \int_0^T dt \int_{\partial\Omega} (\mathbf{v} - \mathbf{v}_\infty) \cdot (\mathcal{T}\mathbf{n})\, ds\,.$$

Using the definitions of $\mathcal{T}$ and D, and taking into account that $\mathbf{v}_\infty$ is a constant vector, we have that

$$\begin{aligned}\mathcal{W} &= \int_0^T dt \int_{\partial\Omega} (\mathbf{v} - \mathbf{v}_\infty) \cdot \{-p\mathbf{n} + \mu(\nabla\mathbf{v} + \nabla\mathbf{v}^T)\mathbf{n}\}\, ds \\ &= \int_0^T dt \int_{\partial\Omega} (\mathbf{v} - \mathbf{v}_\infty) \cdot \big\{-p\mathbf{n} + \mu\big(\nabla(\mathbf{v} - \mathbf{v}_\infty) + \nabla(\mathbf{v} - \mathbf{v}_\infty)^T\big)\mathbf{n}\big\}\, ds\,.\end{aligned}$$

Upon setting $\mathbf{w} = \mathbf{v} - \mathbf{v}_\infty$,

$$\mathcal{W} = \int_0^T \int_{\partial\Omega} \mathbf{w} \cdot \{-p\mathbf{n} + 2\mu\mathcal{D}(\mathbf{w})\mathbf{n}\}\, ds\, dt\,. \tag{2.4}$$

Let $\Omega_R = \Omega \cap \{\mathbf{x} \in \mathbb{R}^2 : |\mathbf{x}| < R\}$ and $\Gamma_R = \partial\Omega_R \setminus \partial\Omega$ for sufficiently large R such that the circle of radius R centered at the origin contains Ω. Using Green's formula we obtain

$$\begin{aligned}&\int_{\Omega_R} \mathbf{w} \cdot \big(\nabla \cdot \mathcal{D}(\mathbf{w})\big)\, d\mathbf{x} \\ &\qquad = \int_{\partial\Omega} \mathbf{w} \cdot \mathcal{D}(\mathbf{w})\mathbf{n}\, ds + \int_{\Gamma_R} \mathbf{w} \cdot \mathcal{D}(\mathbf{w})\mathbf{n}\, ds - \int_{\Omega_R} \mathcal{D}(\mathbf{w}) : \nabla\mathbf{w}\, d\mathbf{x}\,,\end{aligned} \tag{2.5}$$

where $\partial_j = \partial/\partial x_j$; i.e., ∂_j denotes the partial derivative with respect to the jth coordinate, $\nabla \cdot \mathcal{S}$ for a two-tensor $\mathcal{S} = \{S_{ij}\}$ is defined as the vector $(\partial_j S_{1j}, \partial_j S_{2j})^T$, and the colon notation denotes the scalar product operation on two two-tensors; i.e., for two-tensors $\mathcal{T} = \{T_{ij}\}$ and $\mathcal{S} = \{S_{ij}\}$, $\mathcal{T} : \mathcal{S} = T_{ij}S_{ij}$. Also, we have employed the convention that repeated indices imply summation. From (2.1) we have that $\mathbf{w} = \mathbf{v} - \mathbf{v}_\infty$ satisfies $\nabla \cdot \mathbf{w} = 0$ so that (2.5) and the identity

$$2\nabla \cdot \mathcal{D}(\mathbf{w}) = \Delta\mathbf{w} + \nabla(\nabla \cdot \mathbf{w})$$

yield

$$\int_{\partial\Omega} \mathbf{w} \cdot \mathcal{D}(\mathbf{w})\mathbf{n}\, ds = \frac{1}{2}\int_{\Omega_R} \mathbf{w} \cdot \Delta\mathbf{w}\, d\mathbf{x} + \int_{\Omega_R} \mathcal{D}(\mathbf{w}) : \nabla\mathbf{w}\, d\mathbf{x} - \int_{\Gamma_R} \mathbf{w} \cdot \mathcal{D}(\mathbf{w})\mathbf{n}\, ds\,.$$

The symmetry of the tensor $\mathcal{D}(\mathbf{w})$ yields

$$\int_{\Omega_R} \mathcal{D}(\mathbf{w}) : \nabla\mathbf{w}\, d\mathbf{x} = \int_{\Omega_R} \mathcal{D}(\mathbf{w}) : \mathcal{D}(\mathbf{w})\, d\mathbf{x}$$

so that

$$\int_{\partial\Omega} \mathbf{w}\cdot\mathcal{D}(\mathbf{w})\mathbf{n}\,ds = \frac{1}{2}\int_{\Omega_R} \mathbf{w}\cdot\Delta\mathbf{w}\,d\mathbf{x} + \int_{\Omega_R} \mathcal{D}(\mathbf{w}):\mathcal{D}(\mathbf{w})\,d\mathbf{x} - \int_{\Gamma_R} \mathbf{w}\cdot\mathcal{D}(\mathbf{w})\mathbf{n}\,ds\,.$$

Since $\mathcal{D}(\mathbf{w}) = \mathcal{D}(\mathbf{v})$, the substitution of the last equation into (2.4) yields

$$\begin{aligned}\mathcal{W} = \int_0^T\int_{\Omega_R} \mathbf{w}\cdot(\mu\Delta\mathbf{w} - \nabla p)\,d\mathbf{x}\,dt + 2\mu\int_0^T\int_{\Omega_R} \mathcal{D}(\mathbf{v}):\mathcal{D}(\mathbf{v})\,d\mathbf{x}\,dt\\ - 2\mu\int_0^T\int_{\Gamma_R} \mathbf{w}\cdot\mathcal{D}(\mathbf{w})\mathbf{n}\,ds\,dt + \int_0^T\int_{\Gamma_R} p\mathbf{w}\cdot\mathbf{n}\,ds\,dt\end{aligned}$$

so that by taking the limit $R\to\infty$ we obtain

$$\mathcal{W} = \int_0^T\int_{\Omega} \mathbf{w}\cdot(\mu\Delta\mathbf{w} - \nabla p)\,d\mathbf{x}\,dt + 2\mu\int_0^T\int_{\Omega} \mathcal{D}(\mathbf{v}):\mathcal{D}(\mathbf{v})\,d\mathbf{x}\,dt\,. \tag{2.6}$$

From (2.1) we have that $\mathbf{w} = \mathbf{v} - \mathbf{v}_\infty$ satisfies

$$\rho\partial_t\mathbf{w} - \mu\Delta\mathbf{w} + \rho\mathbf{v}\cdot\nabla\mathbf{w} + \nabla p = \mathbf{0}\,.$$

Combining (2.6) and the last equation yields

$$\begin{aligned}\mathcal{W} &= 2\mu\int_0^T dt\int_\Omega \mathcal{D}(\mathbf{v}):\mathcal{D}(\mathbf{v})\,d\mathbf{x} + \frac{\rho}{2}\int_0^T dt\int_\Omega \partial_t|\mathbf{w}|^2\,d\mathbf{x}\\ &\qquad + \rho\int_0^T dt\int_\Omega (\mathbf{v}\cdot\nabla\mathbf{w})\cdot\mathbf{w}\,d\mathbf{x}\\ &= 2\mu\int_0^T dt\int_\Omega \mathcal{D}(\mathbf{v}):\mathcal{D}(\mathbf{v})\,d\mathbf{x} + \frac{\rho}{2}\int_0^T dt\int_{\partial\Omega} |\mathbf{w}|^2\mathbf{v}\cdot\mathbf{n}\,ds\\ &\qquad + \frac{\rho}{2}\int_\Omega |\mathbf{w}(T,\mathbf{x})|^2\,d\mathbf{x} - \frac{\rho}{2}\int_\Omega |\mathbf{w}(0,\mathbf{x})|^2\,d\mathbf{x}\,.\end{aligned} \tag{2.7}$$

The integral $\frac{\rho}{2}\int_\Omega |\mathbf{w}(t,\mathbf{x})|^2\,d\mathbf{x}$ is the (finite) kinetic energy of the difference flow $\mathbf{w} = \mathbf{v} - \mathbf{v}_\infty$. (Note that the kinetic energy of the flow $\frac{\rho}{2}\int_\Omega |\mathbf{v}(t,\mathbf{x})|^2\,d\mathbf{x} = \infty$.) We can rewrite (2.7) as the energy equality

$$\begin{aligned}&\frac{\rho}{2}\int_\Omega |\mathbf{w}(0,\mathbf{x})|^2\,d\mathbf{x} + \int_0^T dt\int_{\partial\Omega} \mathbf{w}\cdot\mathcal{T}\mathbf{n}\,ds\\ &\qquad = \frac{\rho}{2}\int_\Omega |\mathbf{w}(T,\mathbf{x})|^2\,d\mathbf{x} + 2\mu\int_0^T dt\int_\Omega \mathcal{D}(\mathbf{v}):\mathcal{D}(\mathbf{v})\,d\mathbf{x} + \frac{\rho}{2}\int_0^T dt\int_{\partial\Omega} |\mathbf{w}|^2\mathbf{v}\cdot\mathbf{n}\,ds\,.\end{aligned}$$

This relation may be interpreted as follows: the initial kinetic energy of the difference flow plus the work due to drag is equal to the final, i.e., at $t = T$, value of the kinetic energy of the difference flow plus the energy dissipated due to friction plus the work done by the boundary control. Whenever the control is absent, i.e., whenever $\mathbf{v}|_{\partial\Omega} = \mathbf{g} = \mathbf{0}$, the third integral on the right-hand side of the last equation vanishes. Since the initial kinetic energy of the difference flow is given, it is quite natural to take the right-hand side of the last equation as the cost functional (for convenience, we introduce a factor of one-half):

$$\begin{aligned}\mathcal{J}(\mathbf{w}) = \frac{\rho}{4}\int_\Omega |\mathbf{w}(T,\mathbf{x})|^2\,d\mathbf{x} + \mu\int_0^T dt\int_\Omega \mathcal{D}(\mathbf{v}):\mathcal{D}(\mathbf{v})\,d\mathbf{x}\\ + \frac{\rho}{4}\int_0^T dt\int_{\partial\Omega} |\mathbf{w}|^2\mathbf{v}\cdot\mathbf{n}\,ds\,.\end{aligned} \tag{2.8}$$

2.2. Constraints on the control. For both physical and mathematical reasons, the size of the control should be constrained. Physically, one cannot realize controls of arbitrary size. Moreover, the cost of effecting control should be accounted for in the optimization process; e.g., one would not usually want to reduce the drag by a small amount if the cost of doing so is prohibitive. Limits on the size of the control are also needed in order to obtain a mathematically meaningful problem, e.g., to guarantee the existence of an optimal solution in a certain function class. Of course, the physical and mathematical needs for limiting the size of the control are not unrelated.

It is simpler to explain the ideas concerning constraining the size of the control in the steady state context in which we have the governing system

$$-\mu\Delta\mathbf{v} + \rho\mathbf{v}\cdot\nabla\mathbf{v} + \nabla p = \mathbf{0} \qquad \text{and} \qquad \nabla\cdot\mathbf{v} = 0 \qquad \text{in } \Omega\,, \tag{2.9}$$

$$\mathbf{v}|_{\partial\Omega} = \mathbf{g}\,, \qquad \text{and} \qquad \mathbf{v} \to \mathbf{v}_\infty \quad \text{as } |\mathbf{x}| \to \infty \tag{2.10}$$

and the cost functional

$$\mathcal{J}_s(\mathbf{v}) = \int_{\partial\Omega} \mathbf{w}\cdot\mathcal{T}\,\mathbf{n}\,ds = \mu\int_\Omega \mathcal{D}(\mathbf{v}) : \mathcal{D}(\mathbf{v})\,d\mathbf{x} + \frac{\rho}{4}\int_{\partial\Omega} |\mathbf{w}|^2\mathbf{v}\cdot\mathbf{n}\,ds\,, \tag{2.11}$$

where $\mathbf{w} = \mathbf{v} - \mathbf{v}_\infty$, as noted previously. In all physically interesting situations one would want to minimize the drag functional (2.11). If there are no constraints on the control, i.e., on $\mathbf{v}$ along the boundary $\partial\Omega$, then it is easy to find a trivial control such that $\mathcal{J}_s(\mathbf{v}) = 0$. Indeed, if we take $\mathbf{v}|_{\partial\Omega} = \mathbf{v}_\infty$, then the solution of (2.9)–(2.10) is given by $\mathbf{v}(\mathbf{x}) = \mathbf{v}_\infty$ and $\nabla p = \mathbf{0}$, and then, clearly, $\mathcal{J}_s(\mathbf{v}) = \mathcal{J}_s(\mathbf{v}_\infty) = 0$. This implies that $\mathcal{J}_s(\mathbf{v})$ can possibly be negative, thereby the object occupying the region B is being propelled rather than being dragged, exactly the opposite of what we want to study. Thus, constraining the control is not only natural from the physical point of view of conserving resources, but is necessary for the minimization problem to model properly the desired physical objectives. (Note that in the time-dependent case, we cannot choose $\mathbf{v} = \mathbf{v}_\infty$ due to the initial condition of (2.2); however, we still want to limit the size of the control for the same reasons as in the steady state case.)

There are two common ways of constraining the control. The first one is to impose an explicit bound on the control. In the steady state case, we can impose

$$\int_{\partial\Omega} |\mathbf{v}|^k\,ds \le M \text{ for some } k \ge 3 \tag{2.12}$$

or

$$|\mathbf{v}(\mathbf{x})| \le M \quad \forall\,\mathbf{x} \in \partial\Omega\,, \tag{2.13}$$

where M is a prescribed positive constant. The constraint (2.12) allows the control to concentrate on small portions of the boundary and is therefore more useful in providing information about the locations where the control is most effective. Such information will be helpful in the study of "local controls," i.e., the application of control at a number of chosen locations on the boundary. (We will study local control problems elsewhere.) For this reason we will not pursue constraints of the type (2.13) any further in this paper. The second way of constraining the control is to add some norm of the control to the cost functional; e.g., instead of (2.11), we consider the functional

$$\mu\int_\Omega \mathcal{D}(\mathbf{v}) : \mathcal{D}(\mathbf{v})\,d\mathbf{x} + \frac{\rho}{4}\int_{\partial\Omega} |\mathbf{w}|^2\mathbf{v}\cdot\mathbf{n}\,ds + \rho N\int_{\partial\Omega} |\mathbf{v}|^k\,ds \tag{2.14}$$

for some $k \geq 3$ and $N > 0$. If $k = 3$, we will need $N > \frac{1}{4}$. In both ways of constraining the control, one can use different norms to measure the control. The physical problem does not tell us which norm to use, although desirable physical properties, e.g., having no sharp peaks in the control along the boundary, should influence the choice. The choice of norm is also influenced by the need to establish the well-posedness of the problem, e.g., the existence of an optimal solution in some function class, the regularity of the optimal solution, etc. For example, the constraints on the value of k are motivated by the need to have the cost of control, i.e., the last term in (2.14), dominate (in an appropriate sense that will be made clear later in this paper) the second term.

Our interest in this paper is in the time-dependent problem, and we now discuss how we can choose a convenient norm for measuring the control. Our starting point is the requirement that solutions of the Navier–Stokes system have energy estimates that will be needed later in this paper in studying the optimal control problems, and particularly in the derivation of the optimality system of equations. The minimum level of smoothness for the velocity field $\mathbf{v}$ at which the energy estimates are valid is $\mathbf{v} - \mathbf{v}_\infty \in L^2\big(0,T;\mathbf{H}^1(\Omega)\big)$ and $\partial_t \mathbf{v} \in L^2\big(0,T;\mathbf{H}^{-1}(\Omega)\big)$. Note that these inclusions imply a certain behavior at infinity. (The Sobolev space notation used here is established in section 3.1.) The boundary control should belong to a subset of the trace space on $\partial\Omega$ of the space for the vector field $\mathbf{v}$. The norm on the trace space will be shown to be

$$\begin{aligned}&\|\mathbf{v}\cdot\mathbf{n}\|_{L^2(0,T;H^{1/2}(\partial\Omega))} + \|\mathbf{v}\cdot\mathbf{n}\|_{H^{3/4}(0,T;H^{-1}(\partial\Omega))}\\ &+ \|\mathbf{v}\cdot\boldsymbol{\tau}\|_{L^2(0,T;H^{1/2}(\partial\Omega))} + \|\mathbf{v}\cdot\boldsymbol{\tau}\|_{H^{1/4}(0,T;L^2(\partial\Omega))}\,,\end{aligned}$$

where $\boldsymbol{\tau}$ denotes the counterclockwise unit tangent vector to $\partial\Omega$. Naturally, the control should be measured in a norm that is not weaker than the norm for the desired trace space. For computational convenience, we will strengthen the fractional time derivative to the first derivative ∂_t in the functional. Also, the particular form of the functional (2.8), i.e., the term $\int_0^T\!\int_\Omega \mathcal{D}(\mathbf{v}) : \mathcal{D}(\mathbf{v})\, d\mathbf{x}dt$, implies that in order for $\mathbf{v}$ to belong to the desired trace space, it is sufficient to use the norm

$$\int_0^T \int_{\partial\Omega} |\partial_t \mathbf{v}|^2 \, ds\, dt$$

for the controls. Also, as in (2.12), we have to include the constraints connected with the term $\int_0^T\!\int_{\partial\Omega} |\mathbf{v}|^k \, ds\, dt$ for some $k \geq 3$.

Hence, the two approaches of constraining the control in the time-dependent case can now be described as follows. The first approach, i.e., imposing an explicit bound on the control, requires that, for some constant $M > 0$,

$$\int_0^T \int_{\partial\Omega} |\mathbf{v}|^k \, ds\, dt + \int_0^T \int_{\partial\Omega} |\partial_t \mathbf{v}|^2 \, ds\, dt \leq M\,, \tag{2.15}$$

where $k \geq 3$. The second approach, i.e., adding a norm of the control to the functional, uses the functional

(2.16)

$$\begin{aligned}\mathcal{J}_N(\mathbf{v}) = \mu \int_0^T \int_\Omega \mathcal{D}(\mathbf{v}) : \mathcal{D}(\mathbf{v})\, d\mathbf{x}dt + \frac{\rho}{4}\int_0^T \int_{\partial\Omega} |\mathbf{w}|^2 \mathbf{v}\cdot\mathbf{n}\, ds\, dt\\ + \frac{\rho}{4}\int_\Omega |\mathbf{w}(T,\mathbf{x})|^2\, d\mathbf{x} + \rho N \left(\int_0^T \int_{\partial\Omega} |\mathbf{v}|^k \, ds\, dt + \int_0^T \int_{\partial\Omega} |\partial_t \mathbf{v}|^2 \, ds\, dt \right),\end{aligned}$$

where $\mathbf{w} = \mathbf{v} - \mathbf{v}_\infty$, $k \geq 3$, and $N > 0$ ($N > \frac{1}{4}$ if $k = 3$).

3. Precise statement of extremal problems. We will use the standard notations for the Lebesgue function space $L^r(\Omega)$ and the Sobolev spaces $W^{m,r}(\Omega)$, $H^m(\Omega)$, $W^{l,s}(\partial\Omega)$, and $H^l(\partial\Omega)$ for real numbers r, m, l, s, where m, l are the smoothness indices and r, s are the integrability indices. Also, $H^m(\Omega) = W^{m,2}(\Omega)$ and $H^l(\partial\Omega) = W^{l,2}(\partial\Omega)$. For $m \geq 0$, we introduce the subspaces of the Sobolev spaces $W^{m,r}(\Omega)$:

$$W_0^{m,r}(\Omega) = \text{the closure of } C_0^\infty(\Omega) \text{ in } W^{m,r}(\Omega)$$

and the dual spaces

$$W^{-m,r}(\Omega) = \big(W_0^{m,r'}(\Omega)\big)^*, \quad \text{where } \frac{1}{r} + \frac{1}{r'} = 1,\ 1 < r, r' < \infty\,.$$

Also, $H_0^m(\Omega) = W_0^{m,2}(\Omega)$ and $H^{-m}(\Omega) = W^{-m,2}(\Omega)$. The vector counterparts of these spaces are denoted by $\mathbf{L}^r(\Omega)$, $\mathbf{W}^{m,r}(\Omega)$, $\mathbf{H}^m(\Omega)$, $\mathbf{W}^{l,s}(\partial\Omega)$, $\mathbf{H}^l(\partial\Omega)$, $\mathbf{W}_0^{m,r}(\Omega)$, and $\mathbf{H}_0^m(\Omega)$. For details, see [1] and [14]. We will also use the solenoidal spaces

$$\mathbf{V}^m(\Omega) = \left\{\mathbf{u} \in \mathbf{H}^m(\Omega)\ :\ \nabla\cdot\mathbf{u} = 0,\ \int_{\partial\Omega} \mathbf{u}\cdot\mathbf{n}\, ds = 0\right\} \qquad \text{for } m \geq 0$$

and

$$\mathbf{V}_0^m(\Omega) = \text{the closure of } \mathbf{C}_0^\infty(\Omega) \cap \mathbf{V}^0(\Omega) \text{ in the } \mathbf{H}^m(\Omega)\text{-norm} \qquad \text{for } m \geq 0\,,$$

where when $m = 0$, $\int_{\partial\Omega} \mathbf{u}\cdot\mathbf{n}\, ds$ is understood as the $H^{-1/2}(\partial\Omega)$–$H^{1/2}(\partial\Omega)$ duality pairing between the function $(\mathbf{u}\cdot\mathbf{n}) \in H^{-1/2}(\partial\Omega)$ and the constant scalar function $1 \in H^{1/2}(\partial\Omega)$. Note that in the definition of $\mathbf{V}^m(\Omega)$ (Ω being unbounded), the condition $\int_{\partial\Omega} \mathbf{u}\cdot\mathbf{n}\, ds = 0$ does not follow from $\operatorname{div}\mathbf{u} = 0$ unless some additional assumptions are made on $\mathbf{u}$ at ∞. Note also that for simplicity, we have assumed $\partial\Omega$ is a connected curve; otherwise, we need to require $\int_{\Gamma_i} \mathbf{u}\cdot\mathbf{n}\, ds = 0$ on each connected component Γ_i of $\partial\Omega$. Identifying $\big(\mathbf{V}^0(\Omega)\big)^*$ with $\mathbf{V}^0(\Omega)$ we introduce the dual spaces

$$\mathbf{V}^{-m}(\Omega) = [\mathbf{V}_0^m(\Omega)]^* \qquad \text{for } m \geq 1\,.$$

The norms on $\mathbf{V}^m(\Omega)$ and $\mathbf{V}_0^m(\Omega)$ are chosen to be that of $\mathbf{H}^m(\Omega)$. We also introduce the temporal-spatial function space, defined on $Q = \mathbb{R}\times\Omega$,

$$\mathcal{H}^{(s)}(Q) = \{f \in L^2\big(\mathbb{R}; H^s(\Omega)\big)\ :\ \partial_t f \in L^2\big(\mathbb{R}; H^{s-2}(\Omega)\big)\}$$

with norm

$$\|f\|^2_{\mathcal{H}^{(s)}(Q)} = \|f\|^2_{L^2(\mathbb{R};H^s(\Omega))} + \|\partial_t f\|^2_{L^2(\mathbb{R};H^{s-2}(\Omega))}\,,$$

and the corresponding solenoidal function space

$$\mathcal{V}^{(s)}(Q) = \{\mathbf{v} \in L^2\big(\mathbb{R}; \mathbf{V}^s(\Omega)\big) : \partial_t\mathbf{v} \in L^2\big(\mathbb{R}; \mathbf{V}^{s-2}(\Omega)\big)\}$$

with norm

$$\|\mathbf{v}\|^2_{\mathcal{V}^{(s)}(Q)} = \|\mathbf{v}\|^2_{L^2(\mathbb{R};\mathbf{V}^s(\Omega))} + \|\partial_t\mathbf{v}\|^2_{L^2(\mathbb{R};\mathbf{V}^{s-2}(\Omega))}\,.$$

Analogously, we may define the function spaces $\mathcal{H}^{(s)}(Q_T)$ and $\mathcal{V}^{(s)}(Q_T)$ defined on $Q_T = (0,T)\times\Omega$.

With the help of the spaces defined above, we may define the solution for the Navier–Stokes equations (2.1)–(2.3). We first quote a useful lemma.

LEMMA 3.1. *The space* $\mathcal{V}^{(1)}(Q_T)$ *is continuously imbedded into* $C\big([0,T];\mathbf{V}^0(\Omega)\big)$.

Proof. Solving in Q_T the equations $\partial F(t,x)/\partial x_2 = u_1$, $\partial F(t,x)/\partial x_1 = -u_2$, and $\int_\Omega F(t,x)dx = 0$ almost everywhere (a.e.) $t \in (0,T)$ for an arbitrary $u = (u_1,u_2) \in \mathcal{V}^{(1)}(Q_T)$, we reduce the proof of the lemma to a proof of the continuity of the embedding $\mathcal{H}^{(2)}(Q_T) \subset C([0,T];H^1(\Omega))$. The last assertion is proved in [4] or [21]. (For an alternate proof, see [5] or [28].) ∎

Below, for the sake of simplicity, we set the constant density $\rho = 1$ or, more precisely, we introduce nondimensionalized variables so that now μ is the inverse of the Reynolds number.

DEFINITION 3.2. $\mathbf{v}$ *is said to be a solution of* (2.1)–(2.3) *if* $\mathbf{v} = \mathbf{w} + \mathbf{v}_\infty$, *where* $\mathbf{w} \in \mathcal{V}^{(1)}(Q_T)$ *satisfies*

$$\begin{aligned}\langle \partial_t \mathbf{w}(t), \mathbf{z}\rangle + 2\mu\int_\Omega \mathcal{D}(\mathbf{w}(t)) : \mathcal{D}(\mathbf{z})\,d\mathbf{x} + \int_\Omega \big(\mathbf{w}(t)\cdot\nabla\big)\mathbf{w}(t)\cdot\mathbf{z}\,d\mathbf{x} \\ + \int_\Omega \big(\mathbf{v}_\infty\cdot\nabla\big)\mathbf{w}(t)\cdot\mathbf{z}\,d\mathbf{x} = 0 \qquad \forall\,\mathbf{z}\in\mathbf{V}_0^1(\Omega),\quad \textit{a.e. } t\in(0,T)\,,\end{aligned} \tag{3.1}$$

$$\mathbf{w} = \mathbf{b} \equiv \mathbf{g} - \mathbf{v}_\infty \qquad \textit{in } L^2\big(0,T;\mathbf{H}^{1/2}(\partial\Omega)\big)\,, \tag{3.2}$$

and

$$\mathbf{w}|_{t=0} = \mathbf{w}_0 \equiv \mathbf{v}_0 - \mathbf{v}_\infty \qquad \textit{in } \mathbf{V}^0(\Omega)\,. \qquad ∎$$

Note that the initial condition in Definition 3.2 makes sense because of Lemma 3.1. Here and elsewhere in this paper, $\langle\cdot,\cdot\rangle$ denotes the duality pairing between a Banach space and its dual space; the underlying Banach space may vary depending on the context. In particular, $\langle\cdot,\cdot\rangle$ in (3.1) denotes the duality pairing between $\mathbf{V}^{-1}(\Omega)$ and $\mathbf{V}_0^1(\Omega)$. Also, note that we have used the identity

$$2\int_\Omega \mathcal{D}(\mathbf{w}) : \mathcal{D}(\mathbf{z})\,d\mathbf{x} = \int_\Omega \nabla\mathbf{w} : \nabla\mathbf{z}\,d\mathbf{x} \qquad \forall\,\mathbf{w}\in\mathbf{V}^1(\Omega),\,\mathbf{z}\in\mathbf{H}_0^1(\Omega)\,.$$

The extremal problems we study involve the objective of drag minimization. Based on the two ways of constraining the control, we have the two functionals (2.8) or (2.16) so that we state two extremal problems. It is more convenient to use the variable $\mathbf{w} = \mathbf{v} - \mathbf{v}_\infty$. Also, we will simply use $\mathbf{w}|_{\partial\Omega}$ to denote the Dirichlet control and, thus, we will not introduce a separate notation to denote the control variable and the boundary condition (3.2) will not be explicitly imposed as a constraint. Extremal solutions are sought in the space

$$\begin{aligned}Y = \Bigg\{ \mathbf{w}\in\mathcal{V}^{(1)}(Q_T)\ :\ (\partial_t\mathbf{w})|_{\partial\Omega}\in L^2\big(0,T;\mathbf{L}^2(\partial\Omega)\big), \\ \int_{\partial\Omega}\partial_t\mathbf{w}\cdot\mathbf{n}\,ds = 0\,,\quad \mathbf{w}|_{\partial\Omega}\in\mathbf{L}^k\big((0,T)\times\partial\Omega\big)\Bigg\}\end{aligned}$$

equipped with the norm

$$\|\mathbf{w}\|_Y = \|\mathbf{w}\|_{\mathcal{V}^{(1)}(Q_T)} + \|\partial_t\mathbf{w}\|_{L^2(0,T;\mathbf{L}^2(\partial\Omega))} + \|\mathbf{w}\|_{\mathbf{L}^k((0,T)\times\partial\Omega)}\,,$$

where $k \geq 3$ and $\mathbf{n}$ is the outward normal on $\partial\Omega$.

We also introduce the space

$$\mathbf{W} = \{\mathbf{w} \in \mathbf{V}^0(\Omega) : (\mathbf{w}\cdot\mathbf{n})|_{\partial\Omega} \in H^{1/4}(\partial\Omega) \cap L^{1+k/2}(\partial\Omega)\}\,.$$

Since the trace $\gamma_{n,\partial\Omega}(\mathbf{w}) \equiv (\mathbf{w}\cdot\mathbf{n})|_{\partial\Omega}$ is well defined and belongs to $H^{-1/2}(\partial\Omega)$ (see [28]), the definition of $\mathbf{W}$ makes sense. Note that the restriction operator

$$\gamma_0 : Y \to \mathbf{W}$$

defined by $\gamma_0\mathbf{w} = \mathbf{w}|_{t=0}$ is continuous. Indeed, we denote

$$Y_\delta = \left\{ \mathbf{w} \in L^2\big(0,T;\mathbf{H}^{1/2}(\partial\Omega)\big) \cap \mathbf{L}^k\big((0,T)\times\partial\Omega\big) : \right.$$
$$\left. \partial_t\mathbf{w} \in \mathbf{L}^2\big((0,T)\times\partial\Omega\big), \int_{\partial\Omega} \partial_t\mathbf{w}\, ds\, ds = 0 \right\}.$$

Then, since the trace operators $\gamma_{n,\partial\Omega} : Y \to Y_\delta$ and $\gamma_0 : Y_\delta \to H^{1/4}(\partial\Omega)\cap L^{1+k/2}(\partial\Omega)$ are continuous, the restriction $\gamma_0\mathbf{w}$ for an arbitrary $\mathbf{w} \in Y$ possesses the property

$$\gamma_{n,\partial\Omega}(\gamma_0\mathbf{w}) = \gamma_0(\gamma_{n,\partial\Omega}\mathbf{w}) \in H^{1/4}(\partial\Omega) \cap L^{1+k/2}(\partial\Omega)\,.$$

This proves that the imbedding $\gamma_0 Y \subset \mathbf{W}$ is continuous. We intend to look for an extremal solution in the space Y. Thus, we are compelled to replace the initial condition in Definition 3.2 by

$$\mathbf{w}|_{t=0} = \mathbf{w}_0 \equiv \mathbf{v}_0 - \mathbf{v}_\infty \in \mathbf{W}. \tag{3.3}$$

Problem I. Suppose that $\mathbf{w}_0 \equiv \mathbf{v}_0 - \mathbf{v}_\infty \in \mathbf{W}$. Seek a $\mathbf{w} \in Y$ such that the functional

$$\begin{aligned}\mathcal{J}_N(\mathbf{w}) &= \mu\int_0^T\int_\Omega \mathcal{D}(\mathbf{w}) : \mathcal{D}(\mathbf{w})\, d\mathbf{x}dt \\ &\quad + \frac{1}{4}\int_0^T\int_{\partial\Omega} |\mathbf{w}|^2(\mathbf{w}+\mathbf{v}_\infty)\cdot\mathbf{n}\, ds\, dt + \frac{1}{4}\int_\Omega |\mathbf{w}(T,\mathbf{x})|^2\, d\mathbf{x} \\ &\quad + N\int_0^T\int_{\partial\Omega}\big(|\mathbf{w}+\mathbf{v}_\infty|^k + |\partial_t\mathbf{w}|^2\big)\, ds\, dt\end{aligned} \tag{3.4}$$

is minimized subject to the constraints (3.1) and (3.3), where $k \geq 3$ and $N > 0$ with $N > \frac{1}{4}$ if $k = 3$.

Problem II. Suppose that $\mathbf{w}_0 \equiv \mathbf{v}_0 - \mathbf{v}_\infty \in \mathbf{W}$. Seek a $\mathbf{w} \in Y$ such that the functional

$$\begin{aligned}\mathcal{J}(\mathbf{w}) = \mu\int_0^T\int_\Omega \mathcal{D}(\mathbf{w}) : \mathcal{D}(\mathbf{w})\, d\mathbf{x}dt + \frac{1}{4}\int_0^T\int_{\partial\Omega} |\mathbf{w}|^2(\mathbf{w}+\mathbf{v}_\infty)\cdot\mathbf{n}\, ds\, dt \\ + \frac{1}{4}\int_\Omega |\mathbf{w}(T,\mathbf{x})|^2\, d\mathbf{x}\end{aligned} \tag{3.5}$$

is minimized subject to the constraints (3.1), (3.3), and

$$\int_0^T\int_{\partial\Omega}\big(|\mathbf{w}+\mathbf{v}_\infty|^k + |\partial_t\mathbf{w}|^2\big)\, ds\, dt \leq M\,, \tag{3.6}$$

where $k \geq 3$ and $M > 0$.

Note that Lemma 3.1 ensures that the functionals (3.4) and (3.5) are well defined on Y. We now give definitions for an admissible element and for a solution of Problem I or II.

DEFINITION 3.3. *An element* $\mathbf{w} \in Y$ *is called admissible if it satisfies* (3.1) *and* (3.3) *in the case of Problem* I *and satisfies* (3.1), (3.3), *and* (3.6) *in the case of Problem* II. *The set of admissible elements is denoted by* $\mathcal{V}_{ad}$. □

DEFINITION 3.4. *An element* $\widehat{\mathbf{w}} \in \mathcal{V}_{ad}$ *is called a solution of Problem* I *if*

$$\mathcal{J}_N(\widehat{\mathbf{w}}) = \inf_{\mathbf{w}\in\mathcal{V}_{ad}} \mathcal{J}_N(\mathbf{w})\,,$$

where $\mathcal{J}_N$ *is defined by* (3.4). *An element* $\widehat{\mathbf{w}} \in \mathcal{V}_{ad}$ *is called a solution of Problem* II *if*

$$\mathcal{J}(\widehat{\mathbf{w}}) = \inf_{\mathbf{w}\in\mathcal{V}_{ad}} \mathcal{J}(\mathbf{w})\,,$$

where $\mathcal{J}$ *is defined by* (3.5). □

4. An extension theorem, solutions of the Navier–Stokes equations, and the stress vector on the boundary. Our aim is to prove the existence of optimal solutions for Problems I and II and to obtain optimality systems of partial differential equations that optimal solutions must satisfy. To this end, we first prove three results that are of considerable interest in their own right in the study of Dirichlet boundary value problems for the Navier–Stokes equations.

The first result (section 4.1) is the identification of the trace space of $\mathcal{V}^{(1)}(Q_T) = L^2\big(0,T;\mathbf{V}^1(\Omega)\big)\cap H^1\big(0,T;\mathbf{V}^{-1}(\Omega)\big)$, i.e., the collection of velocity boundary data that can be extended into functions belonging to $\mathcal{V}^{(1)}(Q_T)$. The second result (section 4.2) is the existence of a solution of the Navier–Stokes equations with boundary values in these trace spaces along with a priori estimates for the solution. The third result (section 4.3) is the identification of the space in which the trace of the stress vector (on the boundary) of admissible solutions is well defined.

4.1. An extension theorem for boundary data. We prove some results concerning the extension of functions from the lateral surface of the time-space cylinder to the entire cylinder, i.e., from $(0,T)\times\partial\Omega$ to $(0,T)\times\Omega$.

We set $Q = \mathbb{R}\times\Omega$ (the infinite time-space cylinder) and $S = \mathbb{R}\times\partial\Omega$ (the lateral surface of the infinite time-space cylinder). The problem we want to consider is to describe the space of vector fields defined on S which can be extended to solenoidal vector fields defined on Q which belong to the space $\mathcal{V}^{(1)}(Q)$, where we recall, from section 3, the definition

$$\mathcal{V}^{(s)}(Q) = \{\mathbf{v}\in L^2\big(\mathbb{R};\mathbf{V}^{(s)}(\Omega)\big)\ :\ \partial_t\mathbf{v}\in L^2\big(\mathbb{R};\mathbf{V}^{(s-2)}(\Omega)\big)\}\,. \tag{4.1}$$

Alternatively, the task here is to characterize the trace space of $\mathcal{V}^{(1)}(Q)$. We will see that it is necessary to examine the normal trace and tangential trace separately, as they belong to different function spaces.

We denote by $\boldsymbol{\tau} = (\tau_1,\tau_2)^T$ and $\mathbf{n} = (n_1,n_2)^T$ the unit counterclockwise tangent and outward normal vectors, respectively, along $\partial\Omega$. We have the following relations:

$$\tau_1 = n_2 \quad\text{and}\quad \tau_2 = -n_1\,.$$

Given a boundary vector field

$$\mathbf{b}(t,\mathbf{x}) = b_n(t,\mathbf{x})\mathbf{n}(\mathbf{x}) + b_\tau(t,\mathbf{x})\boldsymbol{\tau}(\mathbf{x}) \qquad \text{a.e. } (t,\mathbf{x})\in S \tag{4.2}$$

satisfying

$$\int_{\partial\Omega} \mathbf{b}\cdot\mathbf{n}\, ds = 0 \qquad \text{a.e. } t \in \mathbb{R}\,, \tag{4.3}$$

where $b_n = \mathbf{b}\cdot\mathbf{n}$ and $b_\tau = \mathbf{b}\cdot\boldsymbol{\tau}$, we seek a solenoidal extension $\mathbf{u} = (u_1, u_2)^T \in \mathcal{V}^{(1)}(Q)$ of the form (see [19])

$$u_1 = \partial_2 F \qquad \text{and} \qquad u_2 = -\partial_1 F\,, \tag{4.4}$$

where F is the streamfunction for $\mathbf{u}$ and $\partial_i F = \partial F/\partial x_i$. In other words, given a boundary vector field $\mathbf{b}$ satisfying (4.3), we seek an F such that

$$b_n = -(\nabla F\cdot\boldsymbol{\tau})|_S \equiv -\partial_\tau F|_S \tag{4.5}$$

and

$$b_\tau = (\nabla F\cdot\mathbf{n})|_S \equiv \partial_n F|_S\,. \tag{4.6}$$

Note that the assumption (4.3) is necessary since we are seeking a solenoidal extension of the boundary data $\mathbf{b}$.

With the assumption (4.3), the relation (4.5) is equivalent to

$$F|_S = h \equiv -\int_{\mathbf{x}_0}^{\mathbf{x}} b_n(t, \mathbf{x}(s))\, ds\,, \tag{4.7}$$

where the line integral is taken along $\partial\Omega$ in the counterclockwise direction starting from a fixed point $\mathbf{x}_0 \in \partial\Omega$. Thus, for each given pair (b_τ, h) defined on S, we want to construct an $F \in \mathcal{H}^{(2)}(Q)$ satisfying (4.6) and (4.7), where

$$\mathcal{H}^{(s)}(\mathbb{R}\times\Theta) = \{u \in L^2\big(\mathbb{R}; H^s(\Theta)\big) \;:\; \partial_t u \in L^2\big(\mathbb{R}; H^{s-2}(\Theta)\big)\}\,.$$

Here $s \in \mathbb{R}$, Θ is any spatial domain, and the norm on $\mathcal{H}^{(s)}(\mathbb{R}\times\Theta)$ is defined by

$$\|F\|^2_{\mathcal{H}^{(s)}(\mathbb{R}\times\Theta)} = \|F\|^2_{L^2(\mathbb{R};H^s(\Theta))} + \|\partial_t F\|^2_{L^2(\mathbb{R};H^{s-2}(\Theta))} \quad \forall\, F \in \mathcal{H}^{(s)}(\mathbb{R}\times\Theta)\,.$$

We now prove that such an extension F exists provided that the boundary data (b_τ, h) belongs to an appropriate function space.

PROPOSITION 4.1. *A pair of functions (b_τ, h) defined on S possess an extension $F \in \mathcal{H}^{(2)}(Q)$ satisfying* (4.6), (4.7),

$$\begin{aligned}\|F\|^2_{\mathcal{H}^{(2)}(Q)} \le C\Big\{ &\|b_\tau\|^2_{L^2(\mathbb{R};H^{1/2}(\partial\Omega))} + \|b_\tau\|^2_{H^{1/4}(\mathbb{R};L^2(\partial\Omega))} \\ &+ \|h\|^2_{L^2(\mathbb{R};H^{3/2}(\partial\Omega))} + \|h\|^2_{H^{3/4}(\mathbb{R};L^2(\partial\Omega))}\Big\}\,,\end{aligned} \tag{4.8}$$

and

$$F \text{ vanishes outside a neighborhood of } S = \mathbb{R}\times\partial\Omega\,, \tag{4.9}$$

where C is a constant independent of b_τ, h, and F, if and only if

$$b_\tau \in L^2\big(\mathbb{R}; H^{1/2}(\partial\Omega)\big) \cap H^{1/4}\big(\mathbb{R}; L^2(\partial\Omega)\big) \tag{4.10}$$

and

$$h \in L^2\big(\mathbb{R}; H^{3/2}(\partial\Omega)\big) \cap H^{3/4}\big(\mathbb{R}; L^2(\partial\Omega)\big)\,. \tag{4.11}$$

Proof. Given b_τ and h satisfying (4.10)–(4.11), we construct an extension F satisfying (4.6)–(4.9); the converse result is easily proved as well. $\partial\Omega$ being of class C^∞, we may choose a neighborhood U of $\partial\Omega$ and a coordinate system $(x_1', x_2')^T$ such that $U = \big\{\mathbf{x} = (x_1', x_2')^T : (x_1', 0)^T \in \partial\Omega, x_2' \in [0, \epsilon]\big\}$ for some $\epsilon > 0$. The space $\mathcal{H}^{(2)}(\mathbb{R} \times U)$ can be rewritten in the form

$$\begin{aligned}
&\mathcal{H}^{(2)}(\mathbb{R} \times U)\\
&\quad = \big\{F(x_2', t, x_1') \in L^2\big(0, \epsilon; L^2(\mathbb{R}; H^2(\partial\Omega))\big) \cap L^2\big(0, \epsilon; H^1(\mathbb{R}; L^2(\partial\Omega))\big) :\\
&\qquad\qquad \partial_{x_2'x_2'} F \in L^2\big(0, \epsilon; L^2(\mathbb{R}; L^2(\partial\Omega))\big)\big\}\,.
\end{aligned}$$

By virtue of a trace theorem of [21], we have that the mappings $\gamma_0 : F \mapsto F|_{x_2'=0}$ and $\gamma_1 : F \mapsto \partial_{x_2'} F|_{x_2'=0}$ are well defined on $\mathcal{H}^{(2)}(\mathbb{R} \times U)$; furthermore, the mapping

$$\begin{aligned}
&F \mapsto (\gamma_0 F, \gamma_1 F) :\\
&\quad \mathcal{H}^{(2)}(\mathbb{R} \times U) \to \big[L^2\big(\mathbb{R}; H^2(\partial\Omega)\big) \cap H^1\big(\mathbb{R}; L^2(\partial\Omega)\big), L^2\big(\mathbb{R}; L^2(\partial\Omega)\big)\big]_{3/4}\\
&\qquad\qquad \times \big[L^2\big(\mathbb{R}; H^2(\partial\Omega)\big) \cap H^1\big(\mathbb{R}; L^2(\partial\Omega)\big), L^2\big(\mathbb{R}; L^2(\partial\Omega)\big)\big]_{1/4}
\end{aligned}$$

is continuous and surjective. Here we have used the intermediate spaces $[\mathcal{X}, \mathcal{Y}]_\alpha$, $\alpha \in [0, 1]$, of the Hilbert spaces $\mathcal{X}$ and $\mathcal{Y}$ as defined in [21]. Using the definition of these intermediate spaces (see [21]), we obtain

$$\begin{aligned}
&\big[L^2\big(\mathbb{R}; H^2(\partial\Omega)\big) \cap H^1\big(\mathbb{R}; L^2(\partial\Omega)\big), L^2\big(\mathbb{R}; L^2(\partial\Omega)\big)\big]_{3/4}\\
&\qquad = L^2\big(\mathbb{R}; H^{3/2}(\partial\Omega)\big) \cap H^{3/4}\big(\mathbb{R}; L^2(\partial\Omega)\big)
\end{aligned}$$

and

$$\begin{aligned}
&\big[L^2\big(\mathbb{R}; H^2(\partial\Omega)\big) \cap H^1\big(\mathbb{R}; L^2(\partial\Omega)\big), L^2\big(\mathbb{R}; L^2(\partial\Omega)\big)\big]_{1/4}\\
&\qquad = L^2\big(\mathbb{R}; H^{1/2}(\partial\Omega)\big) \cap H^{1/4}\big(\mathbb{R}; L^2(\partial\Omega)\big)\,.
\end{aligned}$$

Hence the mapping $F \mapsto (\gamma_0 F, \gamma_1 F)$ is continuous and surjective from $\mathcal{H}^{(2)}(\mathbb{R} \times U)$ to $\big[L^2\big(\mathbb{R}; H^{3/2}(\partial\Omega)\big) \cap H^{3/4}\big(\mathbb{R}; L^2(\partial\Omega)\big)\big] \times \big[L^2\big(\mathbb{R}; \mathbf{H}^{1/2}(\partial\Omega)\big) \cap H^{1/4}\big(\mathbb{R}; \mathbf{L}^2(\partial\Omega)\big)\big]$. Finally, we may choose another neighborhood $\widetilde{U}$ of $(0, \varepsilon) \times \partial\Omega$ such that the closure of U is contained in $\widetilde{U}$. Well-known extension results allow us to extend continuously the space $\mathcal{H}^{(2)}(\mathbb{R} \times U)$ into the space $\big\{F \in \mathcal{H}^{(2)}(\mathbb{R} \times \Omega) : F \text{ vanishes outside } \widetilde{U}\big\}$. ∎

We are now in a position to prove the main extension result. We denote the finite time-space cylinder by $Q_T = (0, T) \times \Omega$ and its lateral surface by $S_T = (0, T) \times \partial\Omega$.

THEOREM 4.2. *Assume that b_n and b_τ satisfy*

$$\int_{\partial\Omega} b_n \, ds = 0 \quad \text{a.e. } t \in [0, T]\,, \tag{4.12}$$

$$b_n \in L^2\big(0, T; H^{1/2}(\partial\Omega)\big) \cap H^{3/4}\big(0, T; H^{-1}(\partial\Omega)\big)\,, \tag{4.13}$$

and

$$b_\tau \in L^2\big(0,T;H^{1/2}(\partial\Omega)\big) \cap H^{1/4}\big(0,T;L^2(\partial\Omega)\big)\,. \tag{4.14}$$

Then, there exists a $\mathbf{u} \in \mathcal{V}^{(1)}(Q_T)$ *satisfying*

$$\mathbf{u}|_{S_T} = \mathbf{b} \equiv b_n\mathbf{n} + b_\tau\boldsymbol{\tau} \tag{4.15}$$

and the estimate

$$\begin{aligned}\|\mathbf{u}\|^2_{\mathcal{V}^{(1)}(Q_T)} \le C\Big\{ &\|b_n\|^2_{L^2(0,T;H^{1/2}(\partial\Omega))} + \|b_n\|^2_{H^{3/4}(0,T;H^{-1}(\partial\Omega))} \\ &+ \|b_\tau\|^2_{L^2(0,T;H^{1/2}(\partial\Omega))} + \|b_\tau\|^2_{H^{1/4}(0,T;L^2(\partial\Omega))}\Big\}\,,\end{aligned} \tag{4.16}$$

where C *is a constant independent of* b_n *and* b_τ*, and such that* $\mathbf{u}$ *vanishes outside a neighborhood of* $(0,T)\times\partial\Omega$*.*

Proof. By definition, the space $H^r\big(0,T;H^s(\partial\Omega)\big)$ with fractional indices r and s is the restriction to $(0,T)\times\partial\Omega$ of $H^r\big(\mathbb{R};H^s(\partial\Omega)\big)$. Thus, we may extend the data in time; i.e., there exists a $\widetilde{b}_n \in L^2\big(\mathbb{R};H^{1/2}(\partial\Omega)\big)\cap H^{3/4}\big(\mathbb{R};H^{-1}(\partial\Omega)\big)$ and $\widetilde{b}_\tau \in L^2\big(\mathbb{R};H^{1/2}(\partial\Omega)\big)\cap H^{1/4}\big(\mathbb{R};L^2(\partial\Omega)\big)$ such that

$$\widetilde{b}_n = b_n \quad\text{and}\quad \widetilde{b}_\tau = b_\tau \quad \text{on } (0,T)\times\partial\Omega\,,$$

$$\begin{aligned}&\|\widetilde{b}_n\|^2_{L^2(\mathbb{R};H^{1/2}(\partial\Omega))} + \|\widetilde{b}_n\|^2_{H^{3/4}(\mathbb{R};H^{-1}(\partial\Omega))} \\ &\qquad\le C\big\{\|b_n\|^2_{L^2(0,T;H^{1/2}(\partial\Omega))} + \|b_n\|^2_{H^{3/4}(0,T;H^{-1}(\partial\Omega))}\big\}\end{aligned}$$

and

$$\begin{aligned}&\|\widetilde{b}_\tau\|^2_{L^2(\mathbb{R};H^{1/2}(\partial\Omega))} + \|\widetilde{b}_\tau\|^2_{H^{1/4}(\mathbb{R};L^2(\partial\Omega))} \\ &\qquad\le C\big\{\|b_\tau\|^2_{L^2(0,T;H^{1/2}(\partial\Omega))} + \|b_\tau\|^2_{H^{1/4}(0,T;L^2(\partial\Omega))}\big\}\,.\end{aligned}$$

Furthermore, we may assume, without loss of generality, that

$$\int_{\partial\Omega} \widetilde{b}_n\, ds = 0 \qquad \text{a.e. } t \in \mathbb{R}\,.$$

Indeed, we can reset $\widetilde{\widetilde{b}}_n = \widetilde{b}_n - \big(\int_{\partial\Omega}\widetilde{b}_n\, ds \Big/ \int_{\partial\Omega} ds\big)$, if necessary. We define

$$\widetilde{h}(t,\mathbf{x}) = -\int_{\mathbf{x}_0}^{\mathbf{x}} \widetilde{b}_n(t,\mathbf{x}(s))\, ds \qquad \forall\,\mathbf{x}\in\partial\Omega\,,$$

where the line integral on the right-hand side is taken counterclockwise along $\partial\Omega$, starting from a given point $\mathbf{x}_0 \in \partial\Omega$. Evidently, $\widetilde{h} \in L^2\big(\mathbb{R};H^{3/2}(\partial\Omega)\big)\cap H^{3/4}\big(\mathbb{R};L^2(\partial\Omega)\big)$. Then, Proposition 4.1 implies that there exists an $F \in \mathcal{H}^{(2)}(Q)$ which vanishes outside a neighborhood of $\mathbb{R}\times\partial\Omega$ such that

$$F|_S = \widetilde{h} \qquad\text{and}\qquad \partial_n F|_S = \widetilde{b}_\tau\,.$$

By setting

$$\mathbf{u} = \mathbf{curl}\, F = \begin{pmatrix} \partial_2 F \\ -\partial_1 F \end{pmatrix}$$

we see that

$$\mathbf{u} \in \mathcal{V}^{(1)}(Q)\,,$$

$$(\mathbf{u}\cdot\mathbf{n})|_S = \mathbf{curl}\, F\cdot\mathbf{n}|_S = -\nabla F\cdot\boldsymbol{\tau} = -\partial_\tau F = -\partial_\tau \widetilde{h} = \widetilde{b}_n\,,$$

and

$$(\mathbf{u}\cdot\boldsymbol{\tau})|_S = \mathbf{curl}\, F\cdot\boldsymbol{\tau}|_S = \nabla F\cdot\mathbf{n} = \partial_n F = \widetilde{b}_\tau\,.$$

Hence, $\mathbf{u}|_{S_T} = \widetilde{\mathbf{b}} \equiv \widetilde{b}_n\mathbf{n} + \widetilde{b}_\tau\boldsymbol{\tau}$; i.e., $\mathbf{u}$ satisfies (4.15). The estimate (4.16) follows from Proposition 4.1. □

REMARK. We see from the proofs of Proposition 4.1 and Theorem 4.2 that the restriction operator $\mathbf{u}\mapsto(\mathbf{u}\cdot\mathbf{n})|_{\partial\Omega}$ is continuous from $\mathcal{V}^{(1)}(Q_T)$ to $H^{3/4}\big(0,T;H^{-1}(\partial\Omega)\big)\cap L^2\big(0,T;H^{1/2}(\partial\Omega)\big)$. Also, the trace operator $b_n\mapsto b_n|_{t=0}$ is continuous from the space $H^{3/4}\big(0,T;H^{-1}(\partial\Omega)\big)\cap L^2\big(0,T;H^{1/2}(\partial\Omega)\big)$ to $H^{-1/2}(\partial\Omega)$ (see [21]). Hence, the composition of these two operators, i.e., the operator $\mathbf{u}\mapsto[(\mathbf{u}\cdot\mathbf{n})|_{\partial\Omega}]|_{t=0}$, is continuous from $\mathcal{V}^{(1)}(Q_T)$ to $H^{-1/2}(\partial\Omega)$. On the other hand, the composition of the operators $\mathbf{u}\mapsto\mathbf{u}|_{t=0}$ and $\mathbf{u}|_{t=0}\mapsto(\mathbf{u}|_{t=0}\cdot\mathbf{n})|_{\partial\Omega}$ is continuous from $\mathcal{V}^{(1)}(Q_T)$ to $H^{-1/2}(\partial\Omega)$ (see Lemma 3.1 and [28]). Hence, using the denseness of $\mathbf{C}^\infty(Q_T)\cap\mathcal{V}^{(1)}(Q_T)$ in $\mathcal{V}^{(1)}(Q_T)$ we obtain the following compatibility condition for the extension $\mathbf{u}$ of Theorem 4.2:

$$(\mathbf{u}|_{t=0}\cdot\mathbf{n})\big|_{\partial\Omega} = \big((\mathbf{u}\cdot\mathbf{n})|_{\partial\Omega}\big)\big|_{t=0} \qquad \forall\,\mathbf{u}\in\mathcal{V}^{(1)}(Q_T)\,. \qquad \square$$

4.2. Estimates for the solutions of the Navier–Stokes equations with nonhomogeneous Dirichlet boundary data. We now consider the boundary value problem for the Navier–Stokes equation in the form introduced in Definition 3.2. The boundary data $\mathbf{b}$ is assumed to satisfy the compatibility condition (4.12). Our goal here is, with the help of the extension theorem of section 4.1, to establish the existence of a solution for (3.1)–(3.3) and derive estimates for the solutions in the space of *critical smoothness* in terms of the data $\mathbf{w}_0$ and $\mathbf{b}$.

Let b_n and b_τ be the normal and tangential components of the boundary value $\mathbf{b}$. We assume that b_n and b_τ satisfy (4.12)–(4.14) and that

$$\mathbf{w}_0 \in \mathbf{V}^0(\Omega)\,. \tag{4.17}$$

We also assume the compatibility condition

$$(\mathbf{w}_0\cdot\mathbf{n})\big|_{\partial\Omega} = b_n\big|_{t=0} \tag{4.18}$$

(see the remark at the end of section 4.1). We express the solution $\mathbf{w}$ of (3.1)–(3.3) in the form

$$\mathbf{w} = \mathbf{u} + \boldsymbol{\eta}\,,$$

where $\mathbf{u}\in\mathcal{V}^{(1)}(Q_T)$ is the vector field constructed in Theorem 4.2 satisfying (4.15) and (4.16). Note that the fact that $\mathbf{u}\in\mathcal{V}^{(1)}(Q)$ implies that $\mathbf{u}|_{t=0}\in\mathbf{L}^2(\Omega)$; see Lemma 3.1. Substituting $\mathbf{w}=\mathbf{u}+\boldsymbol{\eta}$ into (3.1)–(3.3), we obtain for $\boldsymbol{\eta}$

$$\begin{aligned}\langle\partial_t\boldsymbol{\eta}(t),\mathbf{z}\rangle + \mu\int_\Omega \nabla\boldsymbol{\eta}(t):\nabla\mathbf{z}\,d\mathbf{x} + \int_\Omega\big((\boldsymbol{\eta}(t)+\mathbf{u}(t)+\mathbf{v}_\infty)\cdot\nabla\big)\boldsymbol{\eta}(t)\cdot\mathbf{z}\,d\mathbf{x}\\ + \int_\Omega\big(\boldsymbol{\eta}(t)\cdot\nabla\big)\mathbf{u}(t)\cdot\mathbf{z}\,d\mathbf{x} = \langle\mathbf{f}(t),\mathbf{z}\rangle \qquad \forall\,\mathbf{z}\in\mathbf{V}^1_0(\Omega),\ \text{ a.e. } t\in(0,T)\,,\end{aligned} \tag{4.19}$$

$$\boldsymbol{\eta}|_{S_T} = \mathbf{0} \qquad \text{in } L^2\big(0,T;\mathbf{H}^{1/2}(\partial\Omega)\big)\,, \tag{4.20}$$

and

$$\boldsymbol{\eta}|_{t=0} = \boldsymbol{\eta}_0 \equiv \mathbf{w}_0 - \mathbf{u}|_{t=0} \qquad \text{in } \mathbf{V}_0^0(\Omega)\,, \tag{4.21}$$

where

$$\langle \mathbf{f}(t), \mathbf{z}\rangle = -\mu\int_\Omega \nabla\mathbf{u}(t) : \nabla\mathbf{z}\,d\mathbf{x} - \langle \partial_t\mathbf{u}(t), \mathbf{z}\rangle - \int_\Omega [(\mathbf{u}(t)+\mathbf{v}_\infty)\cdot\nabla]\mathbf{u}(t)\cdot\mathbf{z}\,d\mathbf{x}\,. \tag{4.22}$$

LEMMA 4.3. *Assume that the hypotheses of Theorem* 4.2 *hold. Let* $\mathbf{u}$ *be the vector field constructed in Theorem* 4.2. *Assume also that the compatibility condition* (4.18) *holds. Then, there exists a unique solution* $\boldsymbol{\eta} \in \mathcal{V}^{(1)}(Q_T)$ *of system* (4.19)–(4.21). *Moreover,* $\boldsymbol{\eta}$ *satisfies the estimate*

$$\begin{aligned}&\|\partial_t\boldsymbol{\eta}\|^2_{L^2(0,T;\mathbf{V}^{-1}(\Omega))} + \|\boldsymbol{\eta}\|^2_{L^\infty(0,T;\mathbf{V}^0(\Omega))} + \|\boldsymbol{\eta}\|^2_{L^2(0,T;\mathbf{V}^1(\Omega))}\\ &\quad\le A\left(\|\mathbf{f}\|_{L^2(0,T;\mathbf{V}^{-1}(\Omega))}\,,\ \|\mathbf{u}\|_{\mathcal{V}^{(1)}(Q_T)}\,,\ \|\boldsymbol{\eta}_0\|_{\mathbf{V}^0(\Omega)}\,,\ |\mathbf{v}_\infty|\right)\,,\end{aligned}$$

where $A(\cdot,\cdot,\cdot,\cdot)$ *is a continuous positive function defined on* $\mathbb{R}\times\mathbb{R}\times\mathbb{R}\times\mathbb{R}$ *and* $A(\lambda_1,\lambda_2,\lambda_3,|\mathbf{v}_\infty|)\to 0$ *as* $\boldsymbol{\lambda} = (\lambda_1,\lambda_2,\lambda_3)\to(0,0,0)$.

Proof. The existence and uniqueness of the solution $\boldsymbol{\eta}\in\mathcal{V}^{(1)}(Q_T)$ for (4.19)–(4.21) can be proved in exactly the same way as that for the two-dimensional Navier–Stokes equations with homogeneous boundary conditions in exterior domains; see, e.g., [19] or [28]. We only need to prove the estimate. (Note that $\boldsymbol{\eta}_0\in\mathbf{V}_0^0(\Omega)$.)

Letting $\mathbf{z} = \boldsymbol{\eta}(t,\cdot)$ in (4.19) yields

$$\begin{aligned}\frac{1}{2}\partial_t\|\boldsymbol{\eta}(t,\cdot)\|^2_{\mathbf{L}^2(\Omega)} + \mu\|\nabla\boldsymbol{\eta}(t,\cdot)\|^2_{\mathbf{L}^2(\Omega)} &= \langle\mathbf{f}(t,\cdot),\boldsymbol{\eta}(t,\cdot)\rangle - \int_\Omega(\boldsymbol{\eta}\cdot\nabla)\mathbf{u}\cdot\boldsymbol{\eta}\,d\mathbf{x}\\ &\le \frac{1}{\mu}\|\mathbf{f}(t,\cdot)\|^2_{\mathbf{V}^{-1}(\Omega)} + \frac{\mu}{4}\left(\|\nabla\boldsymbol{\eta}(t,\cdot)\|^2_{\mathbf{L}^2(\Omega)} + \|\boldsymbol{\eta}(t,\cdot)\|^2_{\mathbf{L}^2(\Omega)}\right)\\ &\qquad + \|\nabla\mathbf{u}(t,\cdot)\|_{\mathbf{L}^2(\Omega)}\,\|\boldsymbol{\eta}(t,\cdot)\|^2_{\mathbf{L}^4(\Omega)}\,.\end{aligned}$$

Applying to the last term the Ladyzhenskaya inequality (see [19, Lemma 1])

$$\|\eta\|^2_{L^4(\Omega)} \le \sqrt{2}\,\|\eta\|_{L^2(\Omega)}\,\|\nabla\eta\|_{L^2(\Omega)} \quad \forall\,\eta\in H^1(\Omega)$$

and then integrating with respect to t, we obtain

$$\begin{aligned}&\|\boldsymbol{\eta}(t,\cdot)\|^2_{\mathbf{L}^2(\Omega)} + \mu\int_0^t\|\nabla\boldsymbol{\eta}(t,\cdot)\|^2_{\mathbf{L}^2(\Omega)}\,dt \le \|\boldsymbol{\eta}_0\|^2_{\mathbf{L}^2(\Omega)}\\ &\quad + \frac{2}{\mu}\int_0^t\|\mathbf{f}(\tau,\cdot)\|^2_{\mathbf{V}^{-1}(\Omega)}\,d\tau + \int_0^t\left(\frac{\mu}{2} + \frac{4}{\mu}\|\nabla\mathbf{u}(\tau,\cdot)\|^2_{\mathbf{L}^2(\Omega)}\right)\|\boldsymbol{\eta}(\tau,\cdot)\|^2_{\mathbf{L}^2(\Omega)}\,d\tau\,.\end{aligned}$$

Then, the Gronwall inequality yields the estimate

$$\begin{aligned}&\|\boldsymbol{\eta}\|^2_{L^\infty(0,T;\mathbf{L}^2(\Omega))} + \|\boldsymbol{\eta}\|^2_{L^2(0,T;\mathbf{H}^1(\Omega))}\\ &\quad\le A_1\left(\|\mathbf{f}\|_{L^2(0,T;\mathbf{V}^{-1}(\Omega))}\,,\ \|\mathbf{u}\|_{\mathbf{L}^2(0,T;\mathbf{H}^1(\Omega))}\,,\ \|\boldsymbol{\eta}_0\|_{\mathbf{L}^2(\Omega)}\right)\,,\end{aligned}$$

where $A_1(\cdot,\cdot,\cdot)$ is a continuous positive function defined on $\mathbb{R}\times\mathbb{R}\times\mathbb{R}$. Evidently, this last estimate implies

$$\begin{aligned}&\|\boldsymbol{\eta}\|^2_{L^\infty(0,T;\mathbf{V}^0(\Omega))} + \|\boldsymbol{\eta}\|^2_{L^2(0,T;\mathbf{V}^1(\Omega))}\\ &\quad\le A_1\left(\|\mathbf{f}\|_{L^2(0,T;\mathbf{V}^{-1}(\Omega))}\,,\ \|\mathbf{u}\|_{\mathcal{V}^{(1)}(Q_T)}\,,\ \|\boldsymbol{\eta}_0\|_{\mathbf{V}^0(\Omega)}\right)\,.\end{aligned} \tag{4.23}$$

Now, taking the supremum of (4.19) with respect to $\mathbf{z} \in \mathbf{V}_0^1(\Omega)$ with $\|\mathbf{z}\|_{\mathbf{V}_0^1(\Omega)} = 1$ and again applying the Ladyzhenskaya inequality we obtain

$$\begin{aligned}\|\partial_t \boldsymbol{\eta}(t,\cdot)\|_{\mathbf{V}^{-1}(\Omega)} \le{}& \mu\|\boldsymbol{\eta}(t,\cdot)\|_{\mathbf{H}^1(\Omega)} + C\|\boldsymbol{\eta}(t,\cdot)\|_{\mathbf{H}^1(\Omega)}\,\|\boldsymbol{\eta}(t,\cdot)\|_{\mathbf{L}^2(\Omega)}\\ &+ C\|\mathbf{u}(t,\cdot)\|_{\mathbf{H}^1(\Omega)}^{1/2}\,\|\mathbf{u}(t,\cdot)\|_{\mathbf{L}^2(\Omega)}^{1/2}\,\|\boldsymbol{\eta}(t,\cdot)\|_{\mathbf{H}^1(\Omega)}^{1/2}\,\|\boldsymbol{\eta}(t,\cdot)\|_{\mathbf{L}^2(\Omega)}^{1/2}\\ &+ C|\mathbf{v}_\infty|\|\boldsymbol{\eta}(t,\cdot)\|_{\mathbf{L}^2(\Omega)} + \|\mathbf{f}(t,\cdot)\|_{\mathbf{V}^{-1}(\Omega)}\end{aligned}$$

so that

$$\begin{aligned}&\|\partial_t \boldsymbol{\eta}(t,\cdot)\|^2_{L^2(0,T;\mathbf{V}^{-1}(\Omega))}\\ &\le C\|\boldsymbol{\eta}(t,\cdot)\|^2_{L^2(0,T;\mathbf{H}^1(\Omega))} + C\|\boldsymbol{\eta}(t,\cdot)\|^2_{L^\infty(0,T;\mathbf{L}^2(\Omega))}\,\|\boldsymbol{\eta}(t,\cdot)\|^2_{L^2(0,T;\mathbf{H}^1(\Omega))}\\ &\quad + C\,\|\mathbf{u}(t,\cdot)\|_{L^\infty(0,T;\mathbf{L}^2(\Omega))}\,\|\boldsymbol{\eta}(t,\cdot)\|_{L^\infty(0,T;\mathbf{L}^2(\Omega))}\\ &\qquad\quad \cdot \|\mathbf{u}(t,\cdot)\|_{L^2(0,T;\mathbf{H}^1(\Omega))}\,\|\boldsymbol{\eta}(t,\cdot)\|_{L^2(0,T;\mathbf{H}^1(\Omega))}\\ &\quad + C|\mathbf{v}_\infty|^2\,\|\boldsymbol{\eta}(t,\cdot)\|^2_{L^2(0,T;\mathbf{L}^2(\Omega))} + C\|\mathbf{f}(t,\cdot)\|^2_{L^2(0,T;\mathbf{V}^{-1}(\Omega))}\,.\end{aligned}$$

Hence, using (4.23) and Lemma 3.1, we obtain the desired estimate. ∎

Lemma 4.3 and Theorem 4.2 lead to the following result.

THEOREM 4.4. *Let* $\mathbf{b}$ *and* $\mathbf{w}_0$ *satisfy* (4.12)–(4.14) *and* (4.17)–(4.18). *Then, there exists a unique solution* $\mathbf{w} \in \mathcal{V}^{(1)}(Q_T)$ *for the problem* (3.1)–(3.3). *Moreover, the solution satisfies the estimate*

$$\begin{aligned}&\|\mathbf{w}\|^2_{\mathcal{V}^{(1)}(Q_T)}\\ &\qquad \le B\Big(\|\mathbf{w}_0\|_{\mathbf{L}^2(\Omega)}\,,\ \|b_n\|_{L^2(0,T;H^{1/2}(\partial\Omega))} + \|b_n\|_{H^{3/4}(0,T;H^{-1}(\partial\Omega))}\,,\\ &\qquad\qquad \|b_\tau\|_{L^2(0,T;H^{1/2}(\partial\Omega))} + \|b_\tau\|_{H^{1/4}(0,T;L^2(\partial\Omega))}\,,\ |\mathbf{v}_\infty|\Big)\,,\end{aligned} \tag{4.24}$$

where $B(\cdot,\cdot,\cdot,\cdot)$ *is a continuous positive function defined on* $\mathbb{R}\times\mathbb{R}\times\mathbb{R}\times\mathbb{R}$.

Proof. Let $\mathbf{u} \in \mathcal{V}^{(1)}(Q_T)$ be the extension of the data $\mathbf{b}$ into Q_T constructed in Theorem 4.2 and let $\boldsymbol{\eta}$ be the solution of (4.19)–(4.21) with $\mathbf{f}$ defined by (4.22). The existence and uniqueness of such an $\boldsymbol{\eta}$ is guaranteed by Lemma 4.3. Set $\mathbf{w} = \mathbf{u} + \boldsymbol{\eta}$; then $\mathbf{w}$ is clearly the unique solution of (3.1)–(3.3). Thus, it only remains to prove the estimate (4.24).

From (4.22) and the fact (see Theorem 4.2) that $\mathbf{u}$ has bounded support, we have that

$$\begin{aligned}\|\mathbf{f}(t,\cdot)\|_{\mathbf{V}^{-1}(\Omega)} \le{}& \mu\|\mathbf{u}(t,\cdot)\|_{\mathbf{H}^1(\Omega)} + \|\partial_t\mathbf{u}(t,\cdot)\|_{\mathbf{V}^{-1}(\Omega)}\\ &+ \|\mathbf{u}(t,\cdot)\|_{\mathbf{L}^2(\Omega)}\|\mathbf{u}(t,\cdot)\|_{\mathbf{H}^1(\Omega)} + |\mathbf{v}_\infty|\,\|\mathbf{u}(t,\cdot)\|_{\mathbf{H}^1(\Omega)}\,.\end{aligned} \tag{4.25}$$

Also, from (4.21), we have that

$$\|\boldsymbol{\eta}_0\|_{\mathbf{L}^2(\Omega)} \le \|\mathbf{w}_0\|_{\mathbf{L}^2(\Omega)} + \|\mathbf{u}(0,\cdot)\|_{\mathbf{L}^2(\Omega)}\,. \tag{4.26}$$

Hence, (4.24) follows from Theorem 4.2, Lemmas 3.1 and 4.3, (4.25), and (4.26). ∎

REMARK. We stress that the normal and tangential components of the boundary condition for the Navier–Stokes equations have different smoothness. This is a feature that is not exhibited in boundary value problems for general second-order parabolic systems. ∎

4.3. The stress vector (on the boundary) of admissible solutions. We now show that the stress vector on the boundary $\big(-pI+\mu(\nabla\mathbf{w}+(\nabla\mathbf{w})^T)\big)\cdot\mathbf{n}|_{(0,T)\times\partial\Omega}$, where $\mathbf{w}\in Y$ is an admissible solution in the sense of Definition 3.3 and p is an associated pressure field, is well defined in a certain function space. This result will be needed in section 6.4 in order to derive the optimality system in the form of a boundary value problem for a system of partial differential equations. Note that the requirement $\mathbf{w}\in\mathcal{V}_{ad}$ is stronger than $\mathbf{w}\in\mathcal{V}^{(1)}(Q_T)$ merely being a solution of (3.1) and (3.3). (We will actually show that each of $(p\mathbf{n})|_{(0,T)\times\partial\Omega}$, $(\nabla\mathbf{w}\cdot\mathbf{n})|_{(0,T)\times\partial\Omega}$, and $((\nabla\mathbf{w})^T\cdot\mathbf{n})|_{(0,T)\times\partial\Omega}$ is well defined.)

Let $\mathbf{w}\in Y$ be an admissible element; then $\mathbf{w}$ satisfies (3.1) and (3.3). From the definition of Y we see that $\mathbf{w}|_{(0,T)\times\partial\Omega}$ is well defined and

$$\mathbf{w}|_{(0,T)\times\partial\Omega}\in H^1\big(0,T;\mathbf{L}^2(\partial\Omega)\big)\cap L^2\big(0,T;\mathbf{H}^{1/2}(\partial\Omega)\big)\cap\mathbf{L}^k\big((0,T)\times\partial\Omega\big)\,.$$

By de Rham's lemma (see [14] and [28]), there exists a $p\in L^2\big(0,T;L^2_{\rm loc}(\Omega)\big)$ such that $\nabla p\in L^2\big(0,T;\mathbf{H}^{-1}(\Omega)\big)$ and

$$\partial_t\mathbf{w}-\mu\Delta\mathbf{w}+[(\mathbf{w}+\mathbf{v}_\infty)\cdot\nabla]\mathbf{w}+\nabla p=\mathbf{0} \tag{4.27}$$

in the sense of distributions on Q_T. To study the normal stress on $\partial\Omega$, the behavior of $\mathbf{w}$ and p at infinity is irrelevant and we can restrict our attention to a bounded domain whose boundary contains $\partial\Omega$. To this end, we let $\Theta\subset\Omega$ be a bounded domain with C^∞ boundary $\partial\Theta$ such that $\partial\Theta\cap\partial\Omega=\partial\Omega$. We denote by γ the restriction operator on $\partial\Theta$. Let F be a streamfunction of $\mathbf{w}$ which can constructed as in section 4.1, satisfying on Θ

$$w_1=\partial_2 F\qquad\text{and}\qquad w_2=-\partial_1 F\,. \tag{4.28}$$

Since $\mathbf{w}\in Y(Q_\Theta)\subset\mathcal{V}^{(1)}(Q_\Theta)$, where $Q_\Theta=(0,T)\times\Theta$, we have $F\in\mathcal{H}^{(2)}(Q_\Theta)$. The restriction of (4.27) and the divergence-free condition for $\mathbf{w}$ on Q_Θ yields

$$\partial_t\mathbf{w}-\mu\Delta\mathbf{w}+[(\mathbf{w}+\mathbf{v}_\infty)\cdot\nabla]\mathbf{w}+\nabla p=\mathbf{0} \tag{4.29}$$

and

$$\operatorname{div}\mathbf{w}=0\,, \tag{4.30}$$

where the derivatives are understood in the sense of distributions in Q_Θ. Applying the curl operator to (4.29) and taking into account (4.28) we obtain

$$\partial_t\Delta F-\mu\Delta^2F=G\,, \tag{4.31}$$

where

$$G=-\operatorname{curl}\{[(\mathbf{w}+\mathbf{v}_\infty)\cdot\nabla]\mathbf{w}\}=-(w_1+v_{\infty,1})\Delta w_2+(w_2+v_{\infty,2})\Delta w_1\,. \tag{4.32}$$

LEMMA 4.5. *Assume $\mathbf{w}\in Y$ is a solution of (3.1) and G is defined by (4.32). Then, $G\in L^1\big(0,T;W^{-1,\alpha}(\Theta)\big)$ for every $\alpha\in(1,2)$.*

Proof. Let α' and β be defined by

$$\frac{1}{\alpha'}+\frac{1}{\alpha}=1\qquad\text{and}\qquad\frac{1}{\beta}+\frac{1}{\alpha'}=\frac{1}{2}\,.$$

Let $\phi \in W_0^{1,\alpha'}(\Theta)$ be given. By integration by parts and Hölder's inequality, we have that a.e. $t \in (0,T)$,

$$\begin{aligned}
&\Big| \int_\Theta (w_1 + v_{\infty,1}) \Delta w_2 \phi \, d\mathbf{x} \Big| \\
&\qquad = \Big| \int_\Theta \Big(\phi \nabla w_1 \cdot \nabla w_2 + (w_1 + v_{\infty,1}) \nabla w_2 \cdot \nabla \phi \Big) \, d\mathbf{x} \Big| \\
&\qquad\qquad \le \|\nabla w_1\|_{\mathbf{L}^2(\Theta)} \, \|\nabla w_2\|_{\mathbf{L}^2(\Theta)} \, \|\phi\|_{L^\infty(\Theta)} \\
&\qquad\qquad\quad + \|w_1 + v_{\infty,1}\|_{L^\beta(\Theta)} \, \|\nabla w_2\|_{\mathbf{L}^2(\Theta)} \, \|\nabla \phi\|_{\mathbf{L}^{\alpha'}(\Theta)} \, .
\end{aligned} \tag{4.33}$$

Since $\alpha' \in (2,\infty)$ and $\beta \in (2,\infty)$, Sobolev imbedding theorems imply

$$\|\phi\|_{L^\infty(\Theta)} \le C \, \|\phi\|_{W^{1,\alpha'}(\Theta)} \qquad \text{and} \qquad \|w_1 + v_{\infty,1}\|_{L^\beta(\Theta)} \le C \, \|w_1 + v_{\infty,1}\|_{H^1(\Theta)}$$

so that, from (4.33),

$$\|(w_1 + v_{\infty,1}) \Delta w_2\|_{L^1(0,T;W^{-1,\alpha}(\Theta))} \le C\big(\|\mathbf{w}\|^2_{\mathcal{V}^{(1)}(Q_\Theta)} + |\mathbf{v}_\infty|^2 \big) \, .$$

Similarly, we can show

$$\|(w_2 + v_{\infty,2}) \Delta w_1\|_{L^1(0,T;W^{-1,\alpha}(\Theta))} \le C\big(\|\mathbf{w}\|^2_{\mathcal{V}^{(1)}(Q_\Theta)} + |\mathbf{v}_\infty|^2 \big) \, .$$

It follows from the last two inequalities and (4.32) that $G \in L^1\big(0,T;W^{-1,\alpha}(\Theta)\big)$. □

Since $F \in \mathcal{H}^{(2)}(Q_\Theta)$, we have $\Delta F \in L^2\big(0,T;L^2(\Theta)\big)$. From (4.31), (4.32), and Lemma 4.5, we see that

$$\Delta(\partial_t F - \mu \, \Delta F) \in L^1\big(0,T;W^{-1,\alpha}(\Theta)\big) \, .$$

We now introduce the space

$$X_\alpha = \big\{ f \in L^2(\Theta) : \Delta f \in W^{-1,\alpha}(\Theta) \big\}$$

equipped with the norm

$$\|f\|_{X_\alpha} = \|f\|_{L^2(\Theta)} + \|\Delta f\|_{W^{-1,\alpha}(\Theta)} \quad \forall \, f \in X_\alpha \, .$$

It is easy to verify that X_α is a Banach space. We will establish a trace theorem for X_α. To this end, we first prove two lemmas.

LEMMA 4.6. *Every bounded linear functional L on X_α has the representation*

$$Lf = (f,\phi) + \langle \Delta f, \psi \rangle \quad \forall \, f \in X_\alpha \, , \tag{4.34}$$

where $\phi \in L^2(\Theta)$, $\psi \in W_0^{1,\alpha'}(\Theta)$, $(\cdot,\cdot)$ denotes the $L^2(\Theta)$-inner product, and $\langle \cdot,\cdot \rangle$ denotes the duality pairing between $W^{-1,\alpha}(\Theta)$ and $W_0^{1,\alpha'}(\Theta)$.

Proof. In $L^2(\Theta) \times W^{-1,\alpha}(\Theta)$, we consider the subspace $\Pi = \big\{ (f, \Delta f) : f \in X_\alpha \big\}$. Clearly, Π is closed under the Cartesian norm for $L^2(\Theta) \times W^{-1,\alpha}(\Theta)$ and the mapping $\pi : f \mapsto (f, \Delta f)$ establishes an isomorphism between X_α and Π. Let an arbitrary bounded linear functional L on X_α be given. Then, there exists a unique functional K on Π such that $Lf = K(f, \Delta f)$. Using the Hahn–Banach theorem we can extend the functional K defined on Π into a functional $\widetilde{K}$ defined on the entire space $L^2(\Theta) \times W^{-1,\alpha}(\Theta)$ with the functional norm preserved, i.e., with $\|\widetilde{K}\| = \|K\|$.

Since $L^2(\Theta) \times W^{-1,\alpha}(\Theta)$ is reflexive, there exist $\phi \in L^2(\Theta)$ and $\psi \in W_0^{1,\alpha'}(\Theta)$ such that

$$\widetilde{K}(f,g) = (f,\phi) + \langle g,\psi\rangle \quad \forall\, (f,g) \in L^2(\Theta) \times W^{-1,\alpha}(\Theta)\,,$$

so that on the subspace Π,

$$K(f,\Delta f) = (f,\phi) + \langle \Delta f,\psi\rangle \quad \forall\, (f,\Delta f) \in \Pi\,.$$

The last relation is equivalent to (4.34). ∎

LEMMA 4.7. *$C^\infty(\overline{\Theta})$ is dense in X_α.*

Proof. We need only show that if a bounded linear functional L on X_α satisfies $Lf = 0$ for all $f \in C^\infty(\overline{\Theta})$, then $L = 0$. We assume that L is a bounded linear functional on X_α satisfying $Lf = 0$ for all $f \in C^\infty(\overline{\Theta})$. By Lemma 4.6, there exist $\phi \in L^2(\Theta)$ and $\psi \in W_0^{1,\alpha'}(\Theta)$ such that

$$Lf = (f,\phi) + \langle \Delta f,\psi\rangle = 0 \quad \forall\, f \in C^\infty(\overline{\Theta})\,.$$

This implies that, in the sense of distributions,

$$\Delta\psi = -\phi\,.$$

As $\psi \in W_0^{1,\alpha'}(\Theta)$ and $\phi \in L^2(\Theta)$, we deduce from elliptic regularity that $\psi \in W_0^{1,\alpha'}(\Theta) \cap H^2(\Theta)$ and $\Delta\psi = -\phi$ in $L^2(\Theta)$, which in turn implies $\partial_n\psi \in H^{1/2}(\partial\Omega)$. For each $f \in C^\infty(\overline{\Theta})$, we are justified in using integration by parts to obtain

$$\begin{aligned} 0 = (f,\phi) + \langle \Delta f,\psi\rangle &= (f,\phi) + (\Delta f,\psi) \\ &= (f,\phi) + (f,\Delta\psi) - \langle \partial_n\psi, f\rangle \\ &= (f,\phi) + (f,-\phi) - \langle \partial_n\psi, f\rangle = -\langle \partial_n\psi, f\rangle \end{aligned}$$

so that $\partial_n\psi\big|_{\partial\Omega} = 0$ and $\psi \in H_0^2(\Theta)$. Using the denseness of $C_0^\infty(\Theta)$ in $H_0^2(\Theta)$ we may choose a sequence $\{\psi_n\} \subset C_0^\infty(\Theta)$ such that $\psi_n \to \psi$ in $H^2(\overline{\Theta})$. Then, for each $f \in X_\alpha$ we have

$$\begin{aligned} (f,\phi) + \langle \Delta f,\psi\rangle &= (f,\phi) + \lim_{n\to\infty} \langle \Delta f,\psi_n\rangle \\ &= (f,\phi) + \lim_{n\to\infty} (f,\Delta\psi_n) = (f,\phi) + (f,\Delta\psi) = (f,\phi) + (f,-\phi) = 0; \end{aligned}$$

i.e., we have shown that

$$Lf = 0 \quad \forall\, f \in X_\alpha\,.$$

Hence, $L = 0$. ∎

In the sequel, we will make use of Besov spaces $B^{s,q}(\partial\Theta)$, where s is the smoothness index and q is the integrability index. For the definition of Besov spaces, see [4] and [29], where the Besov spaces $B^{s,q}(\partial\Theta)$ are denoted by $B^s_{q,q}(\partial\Theta)$. One can also consult [1] for the definition of Besov spaces and the relations between Besov spaces and Sobolev spaces. One important feature of Besov spaces is that they coincide with the traces of Sobolev spaces. In particular, we have the following precise result: if we denote by γ the mapping $\gamma f = f|_{\partial\Theta}$ for functions defined in Θ, then the mapping

$$(\gamma, \gamma\partial_n) : W^{2,\alpha'}(\Theta) \to B^{2-1/\alpha',\alpha'}(\partial\Theta) \times B^{1-1/\alpha',\alpha'}(\partial\Theta) \tag{4.35}$$

is continuous and establishes an epimorphism; see [4] and [29].

PROPOSITION 4.8. *Assume that* $1 < \alpha < 2$. *Then, the operator* γ, *defined on* $C^\infty(\overline{\Theta})$ *by* $\gamma f = f|_{\partial\Theta}$, *can be extended continuously into the trace operator*

$$\gamma \in \mathcal{L}\big(X_\alpha; B^{-1/\alpha,\alpha}(\partial\Theta)\big)\,. \tag{4.36}$$

Proof. By (4.35), we can choose a continuous linear operator

$$K : B^{1-1/\alpha',\alpha'}(\partial\Theta) \to W^{2,\alpha'}(\Theta) \tag{4.37}$$

such that

$$\gamma K\phi = 0 \qquad \text{and} \qquad \gamma\partial_n K\phi = \phi \qquad \forall\,\phi \in B^{1-1/\alpha',\alpha'}(\partial\Theta)\,. \tag{4.38}$$

Let $f \in X_\alpha$. We define a linear functional Z on $B^{1-1/\alpha',\alpha'}(\partial\Theta)$ by

$$Z\phi = Z_K(\phi) = (f, \Delta K\phi) - \langle \Delta f, K\phi\rangle \qquad \forall\,\phi \in B^{1-1/\alpha',\alpha'}(\partial\Theta)\,.$$

We claim that Z does not depend on the choice of K. Indeed, let K_1 and K_2 be two continuous linear operators satisfying (4.37)–(4.38). Then, by (4.38),

$$\gamma(K_1 - K_2)\phi = 0 \qquad \text{and} \qquad \gamma\partial_n(K_1 - K_2)\phi = 0 \qquad \forall\,\phi \in B^{1-1/\alpha',\alpha'}(\partial\Theta)$$

so that if $f \in C^\infty(\overline{\Theta})$, then integration by parts yields

$$Z_{K_1}(\phi) - Z_{K_2}(\phi) = (f, \Delta(K_1 - K_2)\phi) - \langle \Delta f, (K_1 - K_2)\phi\rangle = 0\,.$$

By virtue of Lemma 4.7, this equality is true for an arbitrary $f \in X_\alpha$. Hence, we have shown that $Z_{K_1} = Z_{K_2}$, i.e., that the operator Z is well defined. Evidently, Z_K is bounded on $B^{1-1/\alpha',\alpha'}(\partial\Theta)$. Hence, by the Riesz theorem, there exists an element $Rf \in B^{-1/\alpha,\alpha}(\partial\Theta)$ such that

$$(Rf, \phi) = Z(\phi) = (f, \Delta K\phi) - \langle \Delta f, K\phi\rangle \quad \forall\,\phi \in B^{1-1/\alpha',\alpha'}(\partial\Theta)\,,$$

where R is the Riesz map. If $f \in C^\infty(\overline{\Theta})$, then using Green's formula in the last equation we obtain $Rf = \gamma f$. By virtue of Lemma 4.7 and the boundedness of the operator in (4.37), we can extend the operator γ continuously into the mapping of (4.36). □

We introduce the set

$$\Upsilon = \{\mathbf{w} \in Y : \mathbf{w} \text{ satisfies (3.1)}\}$$

equipped with the topology generated by the norm of Y.

THEOREM 4.9. *Let* $\mathbf{w} \in Y$ *be a solution of* (3.1) *and* $F \in \mathcal{H}^{(2)}(Q_\Theta)$ *be defined by* (4.28). *Let* $G \in L^1\big(0,T; W^{-1,\alpha}(\Theta)\big)$, $\alpha \in (1,2)$, *be defined by* (4.32). *Then,* $\gamma\big(\nabla\mathbf{w}\cdot\mathbf{n}\big) \in L^1\big(0,T;\mathbf{B}^{-1/\alpha,\alpha}(\partial\Theta)\big)$ *and* $\gamma\big((\nabla\mathbf{w})^T\cdot\mathbf{n}\big) \in L^1\big(0,T;\mathbf{B}^{-1/\alpha,\alpha}(\partial\Theta)\big)$. *Moreover, the mappings* $\mathbf{w} \mapsto \gamma(\nabla\mathbf{w}\cdot\mathbf{n})$ *and* $\mathbf{w} \mapsto \gamma\big((\nabla\mathbf{w})^T\cdot\mathbf{n}\big)$ *are continuous from the topological space* Υ *to* $L^1\big(0,T;\mathbf{B}^{-1/\alpha,\alpha}(\partial\Theta)\big)$.

Proof. From the assumptions on F and G, we easily deduce that $\partial_t F - \mu\,\Delta F \in L^2\big(0,T;L^2(\Theta)\big)$ and $\Delta(\partial_t F - \mu\,\Delta F) \in L^1\big(0,T;W^{-1,\alpha}(\Theta)\big)$. Hence, Proposition 4.8 implies that for almost every $t \in (0,T)$, the restriction $\gamma\big(\partial_t F(t,\cdot) - \mu\,\Delta F(t,\cdot)\big)$ is well defined and

$$\gamma(\partial_t F - \mu\,\Delta F) \in L^1\big(0,T; B^{-1/\alpha,\alpha}(\partial\Theta)\big)\,, \tag{4.39}$$

where $1 < \alpha < 2$. Since $F \in \mathcal{H}^{(2)}(Q_\Theta)$, we have that $\nabla\partial_t F \in H^1\big(\Theta; H^{-1}(0,T)\big)$. Therefore, the restriction $F \mapsto \gamma(\partial_t \nabla F)$ on $(0,T)\times\partial\Theta$ is well defined on the space $H^{1/2}\big(\partial\Theta; H^{-1}(0,T)\big)$. Moreover, the fact that $\mathbf{w} = (\partial_2 F, -\partial_1 F) \in Y$ implies $\gamma\partial_t\nabla F \in \mathbf{L}^2\big((0,T)\times\partial\Theta\big)$. Hence

$$\gamma\partial_t\partial_n F \in L^2\big((0,T)\times\partial\Theta\big) \quad \text{and} \quad \gamma\partial_t\partial_\tau F \in L^2\big((0,T)\times\partial\Theta\big)\,. \tag{4.40}$$

Relation (4.40) implies that

$$\gamma\partial_t F \in L^2\big(0,T; H^1(\partial\Theta)\big)\,. \tag{4.41}$$

By (4.39) and (4.41), we have that

$$\gamma\Delta F \in L^1\big(0,T; B^{-1/\alpha,\alpha}(\partial\Theta)\big) \tag{4.42}$$

for $1 < \alpha < 2$. Since

$$F \in \mathcal{H}^{(2)}(Q_\Theta) \subset L^2\big(0,T; H^2(\Theta)\big)\,, \tag{4.43}$$

we see that

$$\gamma F \in L^2\big(0,T; H^{3/2}(\partial\Theta)\big)\,, \quad \gamma\partial_\tau F \in L^2\big(0,T; H^{1/2}(\partial\Theta)\big) \tag{4.44}$$

and

$$\gamma\partial_n F \in L^2\big(0,T; H^{1/2}(\partial\Theta)\big)\,. \tag{4.45}$$

We claim that

$$\gamma\partial_{n\tau} F \in L^2\big(0,T; H^{-1/2}(\partial\Theta)\big) \quad \text{and} \quad \gamma\partial_{\tau\tau} F \in L^2\big(0,T; H^{-1/2}(\partial\Theta)\big)\,. \tag{4.46}$$

To prove this claim, we proceed as follows. We multiply F by a cut-off function with support in a neighborhood of $\partial\Theta$. We assume without loss of generality that Θ coincides with the half-plane $\mathbb{R}^2_+ = \{(x_1,x_2) : x_2 \ge 0\}$ and $\partial\Theta$ coincides with $\{(x_1,x_2) : x_2 = 0\}$. We set $F_1 = \partial_\tau F$ and $F_2 = \partial_{\tau\tau} F$. From (4.43), we easily deduce that

$$F_2 \in L^2\big((0,T)\times\mathbb{R}^2_+\big)\,, \quad \partial_{\tau\tau}F_2 \in L^2\big((0,T)\times\mathbb{R}_+; H^{-2}(\mathbb{R})\big) \tag{4.47}$$

and

$$\Delta F_2 = \partial_{\tau\tau}(\partial_{nn} + \partial_{\tau\tau})F \in L^2\big((0,T)\times\mathbb{R}_+; H^{-2}(\mathbb{R})\big)\,. \tag{4.48}$$

These in turn imply

$$\partial_{nn}F_2 = \Delta F_2 - \partial_{\tau\tau}F_2 \in L^2\big((0,T)\times\mathbb{R}_+; H^{-2}(\mathbb{R})\big)\,. \tag{4.49}$$

Relations (4.47)–(4.49) and the trace theorem [21, Chapter 5, section 3] yield the second relation in our claim (4.46). We can similarly prove the first relation in (4.46).

By denoting the unit normal vector by $\mathbf{n} = (n_1, n_2)$ and the unit tangential vector by $\boldsymbol{\tau} = (n_2, -n_1)$, we obtain that

$$\partial_1 F = n_1\partial_n F + n_2\partial_\tau F, \qquad \partial_2 F = n_2\partial_n F - n_1\partial_\tau F, \tag{4.50}$$

and

$$\Delta F = \partial_{nn}F + \partial_{\tau\tau}F + \rho_1\partial_n F + \rho_2\partial_\tau F\,, \tag{4.51}$$

where ρ_1 and ρ_2 are smooth functions. Expressing $\partial_{nn}F$ by ΔF, $\partial_{\tau\tau}F$, $\partial_n F$, and $\partial_\tau F$ in (4.51) and taking into account (4.42), (4.44)–(4.46), and the imbedding

$$L^2\big(0,T;H^{-1/2}(\partial\Theta)\big) \subset L^1\big(0,T;B^{-1/\alpha,\alpha}(\partial\Theta)\big)\,, \qquad 1<\alpha<2\,,$$

we deduce that $\partial_{nn}F$ possesses a trace on $\partial\Theta$ and that the trace satisfies

$$\gamma\partial_{nn}F \in L^1\big(0,T;B^{-1/\alpha,\alpha}(\partial\Theta)\big)\,. \tag{4.52}$$

Equations (4.28) and (4.50) yield

$$\nabla w_1\cdot\mathbf{n} = n_2\partial_{nn}F - n_1\partial_{n\tau}F + \beta_1\partial_n F + \beta_2\partial_\tau F$$

and

$$\nabla w_2\cdot\mathbf{n} = -n_1\partial_{nn}F - n_2\partial_{n\tau}F + \delta_1\partial_n F + \delta_2\partial_\tau F\,,$$

where β_1, β_2, δ_1, and δ_2 are smooth functions. These two relations give us the expression for $\nabla\mathbf{w}\cdot\mathbf{n}$ in terms of $\partial_{nn}F$, $\partial_{n\tau}F$, $\partial_n F$, and $\partial_\tau F$. Similarly, we obtain the expression for $(\nabla\mathbf{w})^T\cdot\mathbf{n}$ in terms of $\partial_{nn}F$, $\partial_{n\tau}F$, $\partial_n F$, and $\partial_\tau F$:

$$(\partial_1\mathbf{w})\cdot\mathbf{n} = -n_2\partial_{\tau\tau}F - n_1\partial_{n\tau}F + b_1\partial_n F + b_2\partial_\tau F$$

and

$$(\partial_2\mathbf{w})\cdot\mathbf{n} = n_1\partial_{\tau\tau}F - n_2\partial_{n\tau}F + d_1\partial_n F + d_2\partial_\tau F\,,$$

where b_1, b_2, d_1, and d_2 are smooth functions. These relations together with (4.44)–(4.46) and (4.52) imply the assertions of the theorem. □

Now we prove a trace result for the pressure field p that satisfies (4.27).

THEOREM 4.10. *Assume* $\mathbf{w}$ *satisfies the hypotheses of* Theorem 4.9 *and let* p *be a scalar field such that* $p\in L^2\big(0,T;L^2_{\rm loc}(\Omega)\big)$, $\nabla p\in L^2\big(0,T;\mathbf{H}^{-1}(\Omega)\big)$, *and* (4.27) *holds. Then* $p\in L^1\big(0,T;X_\alpha(\Theta)\big)$ *and the restriction mapping* $\gamma: p\mapsto (p\mathbf{n})\big|_{\partial\Omega}$ *belongs to* $\mathcal{L}\Big(L^1\big(0,T;X_\alpha(\Theta)\big), L^1\big(0,T;\mathbf{B}^{-1/\alpha,\alpha}(\partial\Omega)\big)\Big)$, *where* $1<\alpha<2$.

Proof. Taking the divergence of (4.27) and using the divergence-free condition (4.30) for $\mathbf{w}$, we obtain

$$\Delta p = E, \tag{4.53}$$

where $E=-2[(\partial_1 w_1)^2+(\partial_1 w_2)(\partial_2 w_1)]$. Let α' be the reciprocal conjugate of α, i.e., $(1/\alpha)+(1/\alpha')=1$. Since $\alpha'>2$, the imbedding $W^{1,\alpha'}(\Theta)\hookrightarrow C(\overline{\Theta})$ is continuous so that

$$\begin{aligned}\int_0^T\int_\Theta E(t,\mathbf{x})\phi(\mathbf{x})\,d\mathbf{x}\,dt &\le 2\int_0^T \|\mathbf{w}\|^2_{\mathbf{V}^1(\Theta)}\,dt\,\|\phi\|_{C(\overline{\Theta})}\\ &\le C\,\|\mathbf{w}\|^2_{L^2(0,T;\mathbf{V}^1(\Theta))}\,\|\phi\|_{W^{1,\alpha'}(\Theta)} \qquad \forall\,\phi\in W^{1,\alpha'}(\Theta)\,.\end{aligned}$$

Hence $\Delta p\in L^1\big(0,T;W^{-1,\alpha}(\Theta)\big)$. Also, $p\in L^2\big(0,T;L^2(\Theta)\big)$. Hence we conclude that $p\in L^1\big(0,T;X_\alpha\big)$ so that the desired result about the trace of p follows from Proposition 4.8 and the fact that $\partial\Omega$ is of class C^∞. □

Combining Theorems 4.9 and 4.10, we obtain the following result for the stress vector on the boundary corresponding to admissible solutions.

COROLLARY 4.11. *Assume that* $\mathbf{w}$ *and* p *satisfy the hypotheses of Theorems* 4.9 *and* 4.10. *Then, the stress vector* $\big(-p\mathbf{n}+\mu(\nabla\mathbf{w}+(\nabla\mathbf{w})^T\big)\cdot\mathbf{n})|_{(0,T)\times\partial\Omega}$ *on the boundary belongs to* $L^1\big(0,T;\mathbf{B}^{-1/\alpha,\alpha}(\partial\Omega)\big)$.

5. The existence of an optimal solution. In this section we prove the existence of an optimal solution for both Problem I and Problem II. We first establish a useful lemma.

LEMMA 5.1. *Let* $R>0$ *be a constant such that* $\partial\Omega\subset\big\{\mathbf{x}:|\mathbf{x}|<R\big\}$ *and define* $\Omega_R=\Omega\cap\big\{\mathbf{x}:|\mathbf{x}|<R\big\}$. *Then there exists a positive constant* C *depending only on* R *such that*

$$\|\mathbf{u}\|_{\mathbf{H}^1(\Omega_R)}\le C\Big(\int_{\Omega_R}|D(\mathbf{u})|^2\,d\mathbf{x}+\int_{\partial\Omega}|\mathbf{u}|^2\,ds\Big)\qquad\forall\,\mathbf{u}\in\mathbf{H}^1(\Omega_R).$$

Proof. Assume the lemma is false; then we may choose a sequence $\{\mathbf{u}_n\}\subset\mathbf{H}^1(\Omega_R)$ such that $\|\mathbf{u}_n\|_{\mathbf{H}^1(\Omega_R)}=1$ and

$$1>n\Big(\int_{\Omega_R}|D(\mathbf{u}_n)|^2\,d\mathbf{x}+\int_{\partial\Omega}|\mathbf{u}_n|^2\,ds\Big)$$

so that

$$\int_{\Omega_R}|D(\mathbf{u}_n)|^2\,d\mathbf{x}\to0\qquad\text{and}\qquad\int_{\partial\Omega}|\mathbf{u}_n|^2\,ds\to0\qquad\text{as } n\to\infty;\tag{5.1}$$

i.e., $D(\mathbf{u}_n)\to\mathbf{O}$ in $\mathbf{L}^2(\Omega_R)$ (where $\mathbf{O}$ is the zero tensor) and $\mathbf{u}_n\to\mathbf{u}$ in $\mathbf{L}^2(\partial\Omega)$. The fact that $\|\mathbf{u}_n\|_{\mathbf{H}^1(\Omega_R)}=1$ implies that there exists a subsequence (still denoted by $\{\mathbf{u}_n\}$) such that as $n\to\infty$,

$$\mathbf{u}_n\rightharpoonup\mathbf{u}\text{ in }\mathbf{H}^1(\Omega_R),\qquad\mathbf{u}_n\to\mathbf{u}\text{ in }\mathbf{L}^2(\Omega_R),\qquad\text{and}\qquad\mathbf{u}_n\to\mathbf{u}\text{ in }\mathbf{L}^2(\partial\Omega)\tag{5.2}$$

for some $\mathbf{u}\in\mathbf{H}^1(\Omega_R)$, which in turn implies $D(\mathbf{u}_n)\rightharpoonup D(\mathbf{u})$ in $\mathbf{L}^2(\Omega_R)$. Hence we have $D(\mathbf{u})=\mathbf{O}$ in $\mathbf{L}^2(\Omega_R)$ and $\mathbf{u}=\mathbf{0}$ in $\mathbf{L}^2(\partial\Omega)$, i.e., $D(\mathbf{u})\equiv\mathbf{O}$ in Ω_R and $\mathbf{u}\equiv\mathbf{0}$ on $\partial\Omega$. Hence $\mathbf{u}$ is a rigid-body motion which can be expressed in the form $\mathbf{u}=\mathbf{a}+\mathbf{b}\times\mathbf{x}$ for all $\mathbf{x}\in\Omega_R$, where $\mathbf{a}$ and $\mathbf{b}$ are constant vectors (see [22] or [23]). $\mathbf{u}$ being a linear function and $\mathbf{u}\equiv\mathbf{0}$ on $\partial\Omega$ easily leads us to $\mathbf{a}=\mathbf{0}$ and $\mathbf{b}=\mathbf{0}$, i.e., $\mathbf{u}\equiv\mathbf{0}$ in Ω_R. On the other hand, we deduce from (5.1) and (5.2) that $D(\mathbf{u}_n)\to D(\mathbf{u})$ in $\mathbf{L}^2(\Omega_R)$ and $\mathbf{u}_n\to\mathbf{u}$ in $\mathbf{L}^2(\Omega_R)$. Then, using Korn's second inequality (see, e.g., [22, p. 31]),

$$\int_{\Omega_R}\Big(|D(\mathbf{z})|^2+|\mathbf{z}|^2\Big)\,d\mathbf{x}\ge C\|\mathbf{z}\|^2_{\mathbf{H}^1(\Omega_R)}\qquad\forall\,\mathbf{z}\in\mathbf{H}^1(\Omega_R),$$

we conclude $\mathbf{u}_n\to\mathbf{u}$ in $\mathbf{H}^1(\Omega_R)$ so that $\|\mathbf{u}\|_{\mathbf{H}^1(\Omega_R)}=\lim_{n\to\infty}\|\mathbf{u}_n\|_{\mathbf{H}^1(\Omega_R)}=1$, i.e., $\mathbf{u}\ne\mathbf{0}$. This gives a contradiction. Hence the lemma is proved. ∎

As a consequence of Lemma 5.1, we obtain the following.

COROLLARY 5.2. *There exists a constant* $C>0$ *depending only on* Ω *such that*

$$\|\mathbf{u}\|_{\mathbf{H}^{1/2}(\partial\Omega)}\le C\Big(\int_{\Omega}|D(\mathbf{u})|^2\,d\mathbf{x}+\int_{\partial\Omega}|\mathbf{u}|^2\,ds\Big)\qquad\forall\,\mathbf{u}\in\mathbf{H}^1(\Omega).$$

Proof. We fix an $R>0$ such that $\partial\Omega\subset\{\mathbf{x}:|\mathbf{x}|<R\}$ (R is determined, albeit not uniquely, by Ω). Then by Lemma 5.1 and the trace theorem for $\mathbf{H}^1(\Omega_R)$, there

exists a constant $C > 0$ (depending only on R and Ω) such that

$$\|\mathbf{u}\|_{\mathbf{H}^{1/2}(\partial\Omega)} \le C\Big(\int_{\Omega_R} |D(\mathbf{u})|^2 \, d\mathbf{x} + \int_{\partial\Omega} |\mathbf{u}|^2 \, ds \Big) \qquad \forall\, \mathbf{u} \in \mathbf{H}^1(\Omega_R).$$

Thus the desired estimate follows from the last inequality and the fact that $\Omega_R \subset \Omega$. □

THEOREM 5.3. *There exists a solution* $\mathbf{w} \in Y$ *for Problem* I*; there exists a solution* $\mathbf{w} \in Y$ *for Problem* II.

Proof. The proofs for Problem I and Problem II are essentially the same, and we will only consider Problem I. Theorem 4.4 guarantees that the admissible set $\mathcal{V}_{ad}$ is nonempty; indeed, we choose a boundary data in $\mathbf{C}^\infty\big([0,T] \times \partial\Omega\big)$, and then by Theorem 4.4, there exists a solution in $\mathcal{V}^{(1)}(Q_T)$ for the Navier–Stokes equations satisfying this chosen smooth boundary data. This solution clearly belongs to $\mathcal{V}_{ad}$; i.e., $\mathcal{V}_{ad}$; is nonempty. It is easy to verify that $\mathcal{J}_N(\cdot)$ is bounded from below in Y. Thus, we may choose a sequence $\{\mathbf{w}_n\} \subset \mathcal{V}_{ad}$ such that

$$\lim_{n\to\infty} \mathcal{J}_N(\mathbf{w}_n) = \inf_{\mathbf{w}\in\mathcal{V}_{ad}} \mathcal{J}_N(\mathbf{w}) \,,$$

$$\begin{aligned} \langle \partial_t \mathbf{w}_n, \mathbf{z} \rangle + \mu \int_\Omega \nabla \mathbf{w}_n : \nabla \mathbf{z} \, d\mathbf{x} + \int_\Omega \big([\mathbf{w}_n + \mathbf{v}_\infty] \cdot \nabla \big) \mathbf{w}_n \cdot \mathbf{z} \, d\mathbf{x} \\ = 0 \qquad \forall\, \mathbf{z} \in \mathbf{V}_0^1(\Omega), \quad \text{a.e. } t \in (0,T) \,, \end{aligned} \tag{5.3}$$

and

$$\mathbf{w}_n|_{t=0} = \mathbf{w}_0 \qquad \text{in } \mathbf{V}^0(\Omega) \,.$$

Using (3.4) and the conditions on k and N given in the definition of Problem I, we obtain that

$$\mu \int_0^T \int_\Omega \mathcal{D}(\mathbf{w}_n) : \mathcal{D}(\mathbf{w}_n) \, d\mathbf{x}dt + \int_0^T \int_{\partial\Omega} \big(|\partial_t \mathbf{w}_n|^2 + |\mathbf{w}_n|^k \big) \, ds \, dt \le C \,. \tag{5.4}$$

The last inequality and Corollary 5.2 imply that

$$\|\mathbf{w}_n\|_{L^k((0,T)\times\partial\Omega)} + \|\mathbf{w}_n\|_{H^1(0,T;\mathbf{L}^2(\partial\Omega))} + \|\mathbf{w}_n\|_{L^2(0,T;\mathbf{H}^{1/2}(\partial\Omega))} \le C \,. \tag{5.5}$$

Thus, the estimate of Theorem 4.4 with (5.5) gives us the bound

$$\|\partial_t \mathbf{w}_n\|_{L^2(0,T;\mathbf{V}^{-1}(\Omega))} + \|\mathbf{w}_n\|_{L^2(0,T;\mathbf{V}^1(\Omega))} \le C,$$

which allows us to choose a weakly convergent subsequence

$$\mathbf{w}_n \rightharpoonup \widehat{\mathbf{w}} \quad \text{in } L^2\big(0,T;\mathbf{V}^1(\Omega)\big) \tag{5.6}$$

and

$$\partial_t \mathbf{w}_n \rightharpoonup \partial_t \widehat{\mathbf{w}} \quad \text{in } L^2\big(0,T;\mathbf{V}^{-1}(\Omega)\big) \tag{5.7}$$

for some $\widehat{\mathbf{w}} \in \mathcal{V}^{(1)}(Q_T)$. For each $R > 0$ we let $B_R = \{\mathbf{x} \in \mathbb{R}^2 : |\mathbf{x}| < R\}$. Since the space

$$\mathcal{V}_R^{(1)}(\Omega \cap B_R) \equiv \big\{ \mathbf{u} \in L^2\big(0,T;\mathbf{V}^1(\Omega \cap B_R)\big) : \partial_t \mathbf{u} \in L^2\big(0,T;\mathbf{V}^{-1}(\Omega \cap B_R)\big) \big\}$$

equipped with the norm $\|\mathbf{u}\|^2_{\mathcal{V}^{(1)}_R(\Omega\cap B_R)} = \|\mathbf{u}\|^2_{L^2(0,T;\mathbf{V}^1(\Omega\cap B_R))}+\|\partial_t\mathbf{u}\|^2_{L^2(0,T;\mathbf{V}^{-1}(\Omega\cap B_R))}$ is compactly imbedded into $\mathbf{L}^2\big((0,T)\times(\Omega\cap B_R)\big)$, we may use (5.6) and (5.7) to conclude that

$$\mathbf{w}_n \to \widehat{\mathbf{w}} \quad \text{in } \mathbf{L}^2\big((0,T)\times(\Omega\cap B_R)\big)\,. \tag{5.8}$$

For each arbitrarily given $\mathbf{z}\in\mathbf{C}^\infty_0(\Omega)\cap\mathbf{V}^1_0(\Omega)$, relations (5.6)–(5.8) allow us to pass to the limit in (5.3) to deduce that

$$\langle\partial_t\widehat{\mathbf{w}}(t),\mathbf{z}\rangle + \mu\int_\Omega \nabla\widehat{\mathbf{w}}(t):\nabla\mathbf{z}\,d\mathbf{x} + \int_\Omega \big([\widehat{\mathbf{w}}(t)+\mathbf{v}_\infty]\cdot\nabla\big)\widehat{\mathbf{w}}(t)\cdot\mathbf{z}\,d\mathbf{x} = 0 \qquad \text{a.e. } t\in(0,T)\,.$$

Then, using the denseness of $\mathbf{C}^\infty_0(\Omega)\cap\mathbf{V}^1_0(\Omega)$ in $\mathbf{V}^1_0(\Omega)$, we obtain

$$\langle\partial_t\widehat{\mathbf{w}}(t),\mathbf{z}\rangle + \mu\int_\Omega \nabla\widehat{\mathbf{w}}(t):\nabla\mathbf{z}\,d\mathbf{x} + \int_\Omega \big([\widehat{\mathbf{w}}(t)+\mathbf{v}_\infty]\cdot\nabla\big)\widehat{\mathbf{w}}(t)\cdot\mathbf{z}\,d\mathbf{x} = 0 \qquad \forall\,\mathbf{z}\in\mathbf{V}^1_0(\Omega),\ \text{ a.e. } t\in(0,T); \tag{5.9}$$

i.e., $\widehat{\mathbf{w}}$ satisfies the weak form of the Navier–Stokes equations.

Relations (5.6) and trace theorems imply

$$\mathbf{w}_n \rightharpoonup \widehat{\mathbf{w}} \quad \text{in } L^2\big(0,T;\mathbf{H}^{1/2}(\partial\Omega)\big)$$

so that

$$\mathbf{w}_n \rightharpoonup \widehat{\mathbf{w}} \quad \text{in } \mathbf{L}^2\big((0,T)\times\partial\Omega\big)\,.$$

The estimate (5.5) implies

$$\mathbf{w}_n \rightharpoonup \mathbf{h} \quad \text{in } \mathbf{L}^k\big((0,T)\times\partial\Omega\big)\cap H^1\big(0,T;\mathbf{L}^2(\partial\Omega)\big)\cap L^2\big(0,T;\mathbf{H}^{1/2}(\partial\Omega)\big)$$

for some $\mathbf{h}\in\mathbf{L}^k\big((0,T)\times\partial\Omega\big)\cap H^1\big(0,T;\mathbf{L}^2(\partial\Omega)\big)\cap L^2\big(0,T;\mathbf{H}^{1/2}(\partial\Omega)\big)$. Hence we deduce that $\mathbf{h}=\widehat{\mathbf{w}}$ on $(0,T)\times\partial\Omega$ so that

$$\mathbf{w}_n \rightharpoonup \widehat{\mathbf{w}} \quad \text{in } \mathbf{L}^k\big((0,T)\times\partial\Omega\big)\cap H^1\big(0,T;\mathbf{L}^2(\partial\Omega)\big)\cap L^2\big(0,T;\mathbf{H}^{1/2}(\partial\Omega)\big)\,. \tag{5.10}$$

Thus, we have shown that $\widehat{\mathbf{w}}\in Y$. The continuous imbedding of $\mathcal{V}^{(1)}(Q_T)$ into $\mathbf{C}\big([0,T];\mathbf{V^0}\big)$ (see Lemma 3.1) yields that for each $\tau\in[0,T]$, the trace operator $\mathbf{w}\mapsto\mathbf{w}|_{t=\tau}$ is bounded from $\mathcal{V}^{(1)}(Q_T)$ into $\mathbf{V}^0(\Omega)$. Hence, using the weak convergence $\mathbf{w}_n\rightharpoonup\widehat{\mathbf{w}}$ in $\mathcal{V}^{(1)}(Q_T)$ and the fact that bounded linear operators preserve weak convergence we obtain

$$\mathbf{w}_0=\mathbf{w}_n|_{t=0}\rightharpoonup\widehat{\mathbf{w}}|_{t=0} \quad \text{in } \mathbf{V}^0(\Omega)$$

and

$$\mathbf{w}_n|_{t=T}\rightharpoonup\widehat{\mathbf{w}}|_{t=T} \quad \text{in } \mathbf{V}^0(\Omega)\,.$$

Now, we pass to the limit in the functional $\mathcal{J}_N$. We first examine the term $\int_0^T\int_{\partial\Omega}|\mathbf{w}|^2\mathbf{w}\cdot\mathbf{n}\,ds\,dt$ in the functional. By the compact imbedding result (see [1])

$$\begin{aligned}&\mathbf{L}^k\big((0,T)\times\partial\Omega\big)\cap H^1\big(0,T;\mathbf{L}^2(\partial\Omega)\big)\cap L^2\big(0,T;\mathbf{H}^{1/2}(\partial\Omega)\big)\\ &\hookrightarrow \mathbf{H}^{1/2}\big((0,T)\times\partial\Omega\big)\hookrightarrow\hookrightarrow\mathbf{L}^3\big((0,T)\times\partial\Omega\big)\,,\end{aligned}$$

we obtain from (5.10) that

$$\mathbf{w}_n|_{\partial\Omega} \to \widehat{\mathbf{w}}|_{\partial\Omega} \quad \text{in } \mathbf{L}^3\big((0,T)\times\partial\Omega\big)$$

so that

$$\lim_{n\to\infty}\int_0^T\int_{\partial\Omega}|\mathbf{w}_n|^2\mathbf{w}_n\cdot\mathbf{n}\,ds\,dt=\int_0^T\int_{\partial\Omega}|\widehat{\mathbf{w}}|^2\hat{\mathbf{w}}\cdot\mathbf{n}\,ds\,dt\,.$$

All the remaining terms in the functional $\mathcal{J}_N$ are sequentially weakly lower semicontinuous; thus, using the weak convergence results obtained earlier, we have that

$$\mathcal{J}_N(\widehat{\mathbf{w}})\le\liminf_{n\to\infty}\mathcal{J}_N(\mathbf{w}_n)\,.$$

Hence, we have shown that $\widehat{\mathbf{w}}\in Y$ is indeed a solution to Problem I. □

REMARK. The proof of Theorem 5.2 for Problem II can proceed first by substituting $w=w_n$ into (3.5) and (3.6) to obtain the estimate (5.4) and then passing to the limit as $n\to\infty$. □

REMARK. Since the optimal solution is sought in the space Y whose boundary values are more regular than the trace of $\mathcal{V}^{(1)}(Q_T)$, we expect the optimal solution to be more regular than merely in $\mathcal{V}^{(1)}(Q_T)$. □

REMARK. The result also holds for many other cost functionals such as the L^2-norm of the vorticity functional used in [2] or the velocity matching functional

$$\mathcal{K}(\mathbf{w})=\frac{1}{2}\int_0^T\int_\Omega|\mathbf{w}-\mathbf{w}_0|^2\,d\mathbf{x}dt+\frac{1}{2}\int_0^T\int_{\partial\Omega}\big(|\partial_t\mathbf{w}|^2+|\mathbf{w}|^2+|\nabla_s\mathbf{w}|^2\big)\,ds\,dt\,,$$

where ∇_s denotes the surface gradient on $\partial\Omega$. Using similar arguments we may, for example, conclude that there exists a $\widehat{\mathbf{w}}\in\mathcal{V}_{ad}$ such that $\mathcal{K}(\widehat{\mathbf{w}})=\inf_{\mathbf{w}\in\mathcal{V}_{ad}}\mathcal{K}(\mathbf{w})$. □

6. The optimality system. Having proved that an optimal solution $\mathbf{w}$ exists, we now use Lagrange multiplier principles to characterize the optimal solution; i.e., we obtain an optimality system of partial differential equations that the optimal solution $\mathbf{w}$ and Lagrange multipliers must satisfy. This optimality system can serve as the basis for computing approximations to optimal solutions numerically.

6.1. Abstract Lagrange multiplier principles. We consider an abstract minimization problem. Let X_1 and X_2 be two Banach spaces. Let $f:X_1\to\mathbb{R}$ and $g_j:X_1\to\mathbb{R}$ be functionals and $F:X_1\to X_2$ be a mapping. We seek a $w\in X_1$ such that

$$f(w)=\inf_{u\in\mathcal{W}_{ad}}f(u)\,, \tag{6.1}$$

where

$$\mathcal{W}_{ad}=\big\{u\in X_1:F(u)=0,\ \text{and}\ \ g_j(u)\le 0\ \text{for}\ j=1,\dots,m\big\}\,.$$

The Lagrange functional for the minimization problem (6.1) is defined by

$$\mathcal{L}(w,\boldsymbol{\lambda},q)=\lambda_0 f(w)+\langle F(w),q\rangle+\sum_{i=1}^m\lambda_j g_j(w)$$

for all $w \in X_1$, $\boldsymbol{\lambda} = (\lambda_0, \lambda_1, \ldots, \lambda_m)^T \in \mathbb{R}^{m+1}$, and $q \in X_2^*$. We quote a standard abstract Lagrange principle in the following particular form (see [3]).

THEOREM 6.1. *Let w be a solution of (6.1). Assume that the mappings f, g_j, and F are continuously differentiable and that the image of the operator $F'(w) : X_1 \to X_2$ is closed. Then there exists a $q \in X_2^*$ and a $\boldsymbol{\lambda} = (\lambda_0, \lambda_1, \ldots, \lambda_m)^T \in \mathbb{R}^{m+1}$ such that the pair $(q, \boldsymbol{\lambda}) \neq (0, \mathbf{0})$,*

$$\langle \mathcal{L}_w(w, \boldsymbol{\lambda}, q), h \rangle = 0 \qquad \forall\, h \in X_1\,, \tag{6.2}$$

$$\lambda_j \geq 0, \quad j = 0, 1, \ldots, m\,, \qquad \text{and} \qquad \lambda_j g_j(w) = 0, \quad j = 1, \ldots, m\,, \tag{6.3}$$

where $\mathcal{L}_w(\cdot, \cdot, \cdot)$ denotes the Fréchet derivative of $\mathcal{L}$ with respect to the first argument. Furthermore, if $F'(w) : X_1 \to X_2$ is an epimorphism and the constraints $g_i(w) \leq 0$ are absent in problem (6.1), then $\lambda_0 \neq 0$ and λ_0 can be taken as 1. ∎

6.2. The weak form of an optimality system. Now we apply the abstract Lagrange principle to Problem I and Problem II to obtain an optimality system of equations for each case. We first examine Problem I. We first derive the adjoint equation, in the weak form, for the optimal control problem.

THEOREM 6.2. *Assume $\mathbf{w} \in \mathcal{V}^{(1)}(Q_T)$ is a solution for Problem* I. *Then there exists a $\mathbf{q} \in \mathcal{V}^{(1)}(Q_T) \cap L^2\big(0, T; \mathbf{V}_0^1(\Omega)\big)$ such that*

$$\begin{aligned}
&2\mu \int_0^T \int_\Omega \mathcal{D}(\mathbf{w}) : \mathcal{D}(\mathbf{h})\, d\mathbf{x}dt + 2\mu \int_0^T \int_\Omega \mathcal{D}(\mathbf{h}) : \mathcal{D}(\mathbf{q})\, d\mathbf{x}dt \\
&\quad + \int_0^T \int_\Omega \big\{(\mathbf{h} \cdot \nabla)\mathbf{w} + (\mathbf{w} \cdot \nabla)\mathbf{h} + (\mathbf{v}_\infty \cdot \nabla)\mathbf{h}\big\} \cdot \mathbf{q}\, d\mathbf{x}dt \\
&\quad + \int_0^T \langle \partial_t \mathbf{h}(t, \cdot)\,,\, \mathbf{q}(t, \cdot) \rangle\, dt \\
&\quad + N\Big(\int_0^T \int_{\partial\Omega} 2\partial_t \mathbf{w} \cdot \partial_t \mathbf{h}\, ds\, dt + k \int_0^T \int_{\partial\Omega} |\mathbf{w} + \mathbf{v}_\infty|^{k-2} (\mathbf{w} + \mathbf{v}_\infty) \cdot \mathbf{h}\, ds\, dt \Big) \\
&\quad + \frac{1}{2} \int_0^T \int_{\partial\Omega} \left\{ (\mathbf{w} + \mathbf{v}_\infty) \cdot \mathbf{n} (\mathbf{w} \cdot \mathbf{h}) + \frac{1}{2} (\mathbf{h} \cdot \mathbf{n}) |\mathbf{w}|^2 \right\} ds\, dt \\
&\quad + \frac{1}{2} \int_\Omega \mathbf{w}(T, \mathbf{x}) \cdot \mathbf{h}(T, \mathbf{x})\, d\mathbf{x} = 0 \qquad \forall\, \mathbf{h} \in Y_0,
\end{aligned} \tag{6.4}$$

where $Y_0 \equiv \{\mathbf{y} \in Y : \mathbf{y}|_{t=0} = \mathbf{0}\}$.

Proof. We use the Lagrange multiplier principle (Theorem 6.1) to prove the desired result. We set $X_1 = Y_0$ and $X_2 = L^2\big(0, T; \mathbf{V}^{-1}(\Omega)\big)$. We define the mappings $f : X_1 \to \mathbb{R}$ and $F : X_1 \to X_2$ as follows:

$$f(\mathbf{y}) = \mathcal{J}_N(\mathbf{w} + \mathbf{y})$$

and

$$F(\mathbf{y}) = \partial_t(\mathbf{w} + \mathbf{y}) - \mu P \Delta(\mathbf{w} + \mathbf{y}) + P\big[\big((\mathbf{w} + \mathbf{y} + \mathbf{v}_\infty) \cdot \nabla\big)(\mathbf{w} + \mathbf{y})\big],$$

where $P : \mathbf{H}^{-1}(\Omega) \to \mathbf{V}^{-1}(\Omega)$ is the projection operator. Constraints $g_i \leq 0$ are absent in Problem I. Then $\mathbf{y} = \mathbf{0}$ is the solution of the corresponding extremal problem and $F'(\mathbf{0}) : X_1 \to X_2$ is defined by

$$\langle F'(\mathbf{0}), \mathbf{y} \rangle = \partial_t \mathbf{y} - \mu P \Delta \mathbf{y} + P\big[(\mathbf{y} \cdot \nabla)\mathbf{w} + \big((\mathbf{w} + \mathbf{v}_\infty) \cdot \nabla\big)\mathbf{y}\big].$$

To show that $F'(\mathbf{0})$ is an epimorphism, we first observe that this operator is continuous. Next we need to show that for each $\mathbf{f} \in L^2\big(0,T;\mathbf{V}^{-1}(\Omega)\big)$ the system

(6.5)
$$\begin{aligned}&\langle \partial_t \mathbf{y}(t), \mathbf{z}\rangle + \mu\int_\Omega \nabla\mathbf{y}(t) : \nabla\mathbf{z}\,d\mathbf{x} + \int_\Omega \big((\mathbf{w}(t)+\mathbf{v}_\infty)\cdot\nabla\big)\mathbf{y}(t)\cdot\mathbf{z}\,d\mathbf{x}\\ &\quad + \int_\Omega \big(\mathbf{y}(t)\cdot\nabla\big)\mathbf{w}(t)\cdot\mathbf{z}\,d\mathbf{x} = \int_\Omega \mathbf{f}(t)\cdot\mathbf{z}\,d\mathbf{x} \qquad \forall\,\mathbf{z}\in\mathbf{V}_0^1(\Omega),\ \text{ a.e. } t\in(0,T)\,,\end{aligned}$$

and

$$\mathbf{y}|_{t=0} = \mathbf{0} \qquad \text{in } \mathbf{V}^0(\Omega) \tag{6.6}$$

has a solution $\mathbf{y}\in Y_0$. We supplement this system with the boundary condition

$$\mathbf{y}|_{(0,T)\times\partial\Omega} = \mathbf{0}\,. \tag{6.7}$$

Using the techniques in the proof of Theorem 4.4 we see that (6.5)–(6.7) indeed has a (unique) solution $\mathbf{y}\in\mathcal{V}^{(1)}(Q_T)$. (The situation now is even simpler, as the system (6.5)–(6.7) is linear.) Clearly, $\mathbf{y}\in Y_0$. Hence, we have verified all the assumptions in Theorem 6.1 and we conclude that there exists a $\mathbf{q}\in X_2^* = L^2\big(0,T;\mathbf{V}_0^1(\Omega)\big)$ such that

$$\big\langle \mathcal{L}_{\mathbf{y}}\big(\mathbf{y},\mathbf{q}\big),\mathbf{h}\big\rangle|_{y=0} = 0 \qquad \forall\,\mathbf{h}\in Y_0\,, \tag{6.8}$$

where the Lagrange functional for Problem I is defined by

$$\begin{aligned}\mathcal{L}\big(\mathbf{y},\mathbf{q}\big) &= \mu\int_0^T\!\!\int_\Omega |\mathcal{D}(\mathbf{w}+\mathbf{y})|^2\,d\mathbf{x}dt + \frac14\int_\Omega |\mathbf{w}(T,\mathbf{x})+\mathbf{y}(T,\mathbf{x})|^2\,d\mathbf{x}\\ &\quad + \frac14\int_0^T\!\!\int_{\partial\Omega} (\mathbf{w}+\mathbf{y}+\mathbf{v}_\infty)\cdot\mathbf{n}|\mathbf{w}+\mathbf{y}|^2\,ds\,dt\\ &\quad + \int_0^T\!\!\int_\Omega \partial_t(\mathbf{w}+\mathbf{y})\cdot\mathbf{q}\,d\mathbf{x}dt + 2\mu\int_0^T\!\!\int_\Omega \mathcal{D}(\mathbf{w}+\mathbf{y}) : \mathcal{D}(\mathbf{q})\,d\mathbf{x}dt\\ &\quad + \int_0^T\!\!\int_\Omega \big\{[(\mathbf{w}+\mathbf{y})\cdot\nabla](\mathbf{w}+\mathbf{y}) + (\mathbf{v}_\infty\cdot\nabla)(\mathbf{w}+\mathbf{y})\big\}\cdot\mathbf{q}\,d\mathbf{x}dt\\ &\quad + N\Big(\int_0^T\!\!\int_{\partial\Omega} |\partial_t\mathbf{w}+\partial_t\mathbf{y}|^2\,ds\,dt + \int_0^T\!\!\int_{\partial\Omega} |\mathbf{w}+\mathbf{y}+\mathbf{v}_\infty|^k\,ds\,dt\Big)\end{aligned} \tag{6.9}$$

for all $\mathbf{y}\in X_1$ and $\mathbf{q}\in X_2^* = L^2\big(0,T;\mathbf{V}_0^1(\Omega)\big)$. (Note that we have chosen $\lambda_0 = 1$ in the definition (6.9); this is justified by Theorem 6.1 and the fact that $F'(\mathbf{0})$ is an epimorphism.) Substituting (6.9) into (6.8) we obtain (6.4). By varying $\mathbf{h}$ in $\mathcal{E} = \big\{\mathbf{v}\in\mathbf{C}_0^\infty\big((0,T)\times\Omega\big) : \operatorname{div}\mathbf{v} = 0\big\}\subset Y_0$, we obtain in the sense of distributions defined on solenoidal vector fields:

$$-\partial_t\mathbf{q} - \mu\Delta\mathbf{q} + \mathbf{q}\cdot(\nabla\mathbf{w})^T - (\mathbf{w}\cdot\nabla)\mathbf{q} - (\mathbf{v}_\infty\cdot\nabla)\mathbf{q} = \mu\Delta\mathbf{w} \qquad \text{in } \mathcal{E}'\,, \tag{6.10}$$

or equivalently,

$$-\partial_t\mathbf{q} = \mu\Delta\mathbf{q} - \mathbf{q}\cdot(\nabla\mathbf{w})^T + (\mathbf{w}\cdot\nabla)\mathbf{q} + (\mathbf{v}_\infty\cdot\nabla)\mathbf{q} + \mu\Delta\mathbf{w} \qquad \text{in } \mathcal{E}'\,.$$

From the fact that $\mathbf{w}\in\mathcal{V}^{(1)}(Q_T)$ and $\mathbf{q}\in L^2\big(0,T;\mathbf{V}_0^1(\Omega)\big)$, we easily deduce $\partial_t\mathbf{q}\in L^2\big(0,T;\mathbf{V}^{-1}(\Omega)\big)$. Hence, we have proved $\mathbf{q}\in\mathcal{V}^{(1)}(Q_T)$. □

6.3. Green's formulae. To interpret the weak optimality system (6.4) as a system of partial differential equations with boundary conditions, we will need some Green's formulae for the optimal solution $\mathbf{w}$, the Lagrange multiplier $\mathbf{q}$, and their associated pressure fields p and r, respectively.

We note that if $\mathbf{q}$ is a solution of (6.4) or (6.10), then by De Rham's lemma (see [14] and [28]), there exists an $\widetilde{r} \in L^2\big(0,T;L^2_{\rm loc}(\Omega)\big)$ such that $\nabla\widetilde{r} \in L^2\big(0,T;\mathbf{H}^{-1}(\Omega)\big)$ and

$$-\partial_t\mathbf{q} - \mu\Delta\mathbf{q} + \mathbf{q}\cdot(\nabla\mathbf{w})^T - (\mathbf{w}\cdot\nabla)\mathbf{q} - (\mathbf{v}_\infty\cdot\nabla)\mathbf{q} + \nabla\widetilde{r} = \mu\Delta\mathbf{w} \tag{6.11}$$

in the sense of distributions. Through the change of variable $r = \widetilde{r} + p$, where p satisfies (4.27), we see that $r \in L^2\big(0,T;L^2_{\rm loc}(\Omega)\big)$, $\nabla r \in L^2\big(0,T;\mathbf{H}^{-1}(\Omega)\big)$, and

$$-\partial_t\mathbf{q} - \mu\Delta\mathbf{q} + \mathbf{q}\cdot(\nabla\mathbf{w})^T - (\mathbf{w}\cdot\nabla)\mathbf{q} - (\mathbf{v}_\infty\cdot\nabla)\mathbf{q} + \nabla r = \mu\Delta\mathbf{w} - \nabla p \tag{6.12}$$

in the sense of distributions. We now prove the trace theorems for $\big((\nabla\mathbf{q}) + (\nabla\mathbf{q})^T\big)\cdot\mathbf{n}$ and r as was done for $\big((\nabla\mathbf{w}) + (\nabla\mathbf{w})^T\big)\cdot\mathbf{n}$ and p in section 4.3; we will also derive some Green's formulae that are useful in interpreting the weak optimality system as a boundary value problem for a system of partial differential equations.

LEMMA 6.3. *Assume* $\mathbf{w}$ *is a solution for Problem* I *and let* $\mathbf{q} \in \mathcal{V}^{(1)}(Q_T) \cap L^2\big(0,T;\mathbf{V}^1_0(\Omega)\big)$ *be a solution of* (6.4). *Let* $r \in L^2\big(0,T;L^2_{\rm loc}(\Omega)\big)$ *satisfy* (6.12) *and* $\nabla r \in L^2\big(0,T;\mathbf{H}^{-1}(\Omega)\big)$. *Then*

$$\gamma\big[(\nabla\mathbf{q})\cdot\mathbf{n}\big] \in L^1\big(0,T;\mathbf{B}^{-1/\alpha,\alpha}(\partial\Omega)\big)\,,\ \gamma\big[(\nabla\mathbf{q})^T\cdot\mathbf{n}\big] \in L^1\big(0,T;\mathbf{B}^{-1/\alpha,\alpha}(\partial\Omega)\big)\,, \tag{6.13}$$

$$\gamma(r\mathbf{n}) \in L^1\big(0,T;\mathbf{B}^{-1/\alpha,\alpha}(\partial\Omega)\big)\,, \tag{6.14}$$

and therefore

$$\gamma\big[\big(-rI + (\nabla\mathbf{q}) + (\nabla\mathbf{q})^T\big)\cdot\mathbf{n} \in L^1\big(0,T;\mathbf{B}^{-1/\alpha,\alpha}(\partial\Omega)\big)\big]\,, \tag{6.15}$$

where $1 < \alpha < 2$.

Proof. As in section 4.3, we introduce the bounded subdomain $\Theta \subset \Omega$ such that $\partial\Omega \subset \partial\Theta$. We introduce on Θ the streamfunction E for $\mathbf{q} = (q_1, q_2)$ such that

$$q_1 = \partial_2 E \qquad \text{and} \qquad q_2 = -\partial_1 E\,.$$

Then, by applying the curl operator to (6.11), we obtain that

$$\Delta(\partial_t E + \mu E + \mu\Delta F) = G_1, \tag{6.16}$$

where F is the streamfunction for $\mathbf{w}$ introduced in (4.28) and

$$G_1 = 2(\partial_1 w_1)(\partial_2 q_1 + \partial_1 q_2) + 2(\partial_2 q_2)(\partial_1 w_2 + \partial_2 w_1) + (w_1 + v_{\infty,1})\Delta q_2 - (w_2 + v_{\infty,2})\Delta q_1\,.$$

Also, the fact that $\mathbf{q}|_{S_T} = \mathbf{0}$ allows us to choose E to satisfy $E|_{S_T} = 0$. Analogous to the proof of Lemma 4.5, we obtain

$$G_1 \in L^1\big(0,T;W^{-1,\alpha}(\Theta)\big), \qquad 1 < \alpha < 2\,. \tag{6.17}$$

Since $\mathbf{q} \in \mathcal{V}^{(1)}(Q_T)$ we have $E \in \mathcal{H}^{(2)}(Q_T)$. Thus, (6.16) and (6.17) yield

$$\partial_t E + \mu\Delta E + \mu\Delta F \in L^1(0,T;X_\alpha), \qquad 1 < \alpha < 2\,.$$

By virtue of Proposition 4.8 we obtain

$$\gamma(\partial_t E + \mu\Delta E + \mu\Delta F) \in L^1\big(0,T;B^{-1/\alpha,\alpha}(\partial\Omega)\big)\,. \tag{6.18}$$

The fact that $E|_{S_T} = 0$ implies $\gamma\partial_t E|_{S_T} = 0$. Recall from (4.42) that $\gamma\Delta F \in L^1\big(0,T;B^{-1/\alpha,\alpha}(\partial\Omega)\big)$ so that from (6.18),

$$\gamma\Delta E \in L^1\big(0,T;B^{-1/\alpha,\alpha}(\partial\Omega)\big), \qquad 1<\alpha<2\,.$$

Repeating the arguments in the proof of Theorem 4.9 we obtain (6.13). To prove the trace result for r, we proceed in the same way as in the proof of Theorem 4.10 for p. Taking the divergence of (6.12) we obtain

$$-\Delta r = G_2 + \Delta p,$$

where

$$G_2 = \partial_1 q_2(\partial_1 w_2 - \partial_2 w_1) + \partial_2 q_1(\partial_2 w_1 - \partial_1 w_2) + q_1\Delta w_1 + q_2\Delta w_2\,.$$

Analogous to the proof of Lemma 4.5 we have

$$G_2 \in L^1\big(0,T;W^{-1,\alpha}(\Theta)\big), \qquad 1<\alpha<2\,.$$

Hence, the last three relations and the fact that $r \in L^2\big(0,T;L^2(\Theta)\big)$ and $\Delta p \in L^1\big(0,T;W^{-1,\alpha}(\Theta)\big)$ yield

$$r \in L^1\big(0,T;X_\alpha\big),$$

so that from Proposition 4.8, $\gamma r \in L^1\big(0,T;B^{-1/\alpha,\alpha}(\partial\Omega)\big)$ for $1<\alpha<2$; i.e., (6.14) holds. Finally, (6.15) follows trivially from (6.13)–(6.14). □

We now establish some Green's formulae.

LEMMA 6.4. *Let $r \in X_\alpha(\Theta)$, $1<\alpha<2$. Then the distribution ∇r can be extended continuously into the functional defined by*

$$\langle \nabla r, \mathbf{h}\rangle = \langle r\mathbf{n}, \mathbf{h}\rangle_{\partial\Omega} - \int_\Theta r \operatorname{div}\mathbf{h}\, d\mathbf{x} \tag{6.19}$$

for every $\mathbf{h} \in \mathbf{C}^\infty(\overline{\Theta})$ which vanishes near $(0,T)\times(\partial\Theta\setminus\partial\Omega)$. Here $\langle\nabla r,\cdot\rangle$ denotes the defined functional and $\langle\cdot,\cdot\rangle_{\partial\Omega}$ denotes the duality pairing between $\mathbf{B}^{1/\alpha,\alpha'}(\partial\Theta)$ and $\mathbf{B}^{-1/\alpha,\alpha}(\partial\Theta)$.

Proof. By Lemma 4.7 we may choose a sequence $\{r_n\} \subset C^\infty(\overline{\Theta})$ such that $r_n \to r$ in X_α. Formula (6.19) holds for $r = r_n$ by the classical Stokes theorem. Since the right side of (6.19) with $r = r_n$ converges as $n\to\infty$ to the same expression with r, formula (6.19) defines the desired functional for $r \in X_\alpha(\Theta)$. □

REMARK. On $C^\infty(\overline{\Theta})$, the definition of the operator ∇ found in Lemma 6.4 coincides with the classical definition. □

LEMMA 6.5. *Let $\mathbf{w} \in Y$ be a solution of* (3.1)–(3.3). *Then there exists a sequence of solutions of* (3.1), *$\{\mathbf{w}^{(k)}\} \subset Y \cap L^\infty\big(0,T;\mathbf{V}^2(\Theta)\big)$, such that $\mathbf{w}^{(k)} \to \mathbf{w}$ in Y.*

Proof. Let $U \subset \Theta$ be a (bounded) neighborhood of $\partial\Omega$ such that the extension $\mathbf{u}$ of the boundary data $\mathbf{b}$ constructed in Theorem 4.2 has support in U and we can choose a coordinate system $(x_1,x_2)^T$ such that $U = \{(x_1,x_2)^T \in \mathbb{R}^2 : 0<x_2<d\}$ and $\partial\Omega = \{(x_1,x_2)^T \in \mathbb{R}^2 : x_2 = 0\}$. We consider the sequence $\{\mathbf{u}^{(k)}\}$ defined by

$$\mathbf{u}^{(k)}(t,\mathbf{x}) \equiv \int_0^T\int_U k^3\phi\big(k(t-s),k(x_1-y_1),k(x_2-y_2)\big)\mathbf{u}(s,y_1,y_2)\,dy_1\,dy_2\,ds\,, \tag{6.20}$$

where $\phi \in C_0^\infty(\mathbb{R}^3)$, $\int_{\mathbb{R}^3} \phi \, dt \, d\mathbf{x} = 1$, and $\operatorname{supp} \phi \in \{(t, x_1, x_2)^T \in \mathbb{R}^3 : -1 < t < 1, -1 < x_1 < 1, -1 < x_2 < 0\}$. Evidently, each $\mathbf{u}^{(k)} \in \mathbf{C}^\infty\big((0,T) \times \Theta\big)$ and

$$\|\mathbf{u} - \mathbf{u}^{(k)}\|_{\mathcal{V}^{(1)}(Q_T)} \to 0 \quad \text{as } k \to \infty \,. \tag{6.21}$$

We set

$$\mathbf{b}^{(k)} = \mathbf{u}^{(k)}|_{(0,T)\times\partial\Omega} \,.$$

We choose a sequence $\{\mathbf{w}_0^{(k)}\} \subset \mathbf{V}^2(\Omega)$ such that

$$\mathbf{w}_0^{(k)} \to \mathbf{w}_0 \quad \text{in } \mathbf{V}^0(\Omega) \tag{6.22}$$

and each $\mathbf{w}_0^{(k)}$ satisfies the compatibility condition

$$(\mathbf{w}_0^{(k)} \cdot \mathbf{n})|_{\partial\Omega} = (\mathbf{b}_0^{(k)} \cdot \mathbf{n})|_{t=0} \,.$$

Moreover, we choose $\mathbf{w}_0^{(k)}$ such that $\mathbf{w}_0^{(k)} - \mathbf{u}^{(k)}|_{t=0} \in \mathbf{V}_0^1(\Omega)$. We then consider (3.1) with the boundary and initial conditions

$$\mathbf{w}|_{(0,T)\times\partial\Omega} = \mathbf{b}^{(k)} \qquad \text{and} \qquad \mathbf{w}|_{t=0} = \mathbf{w}_0^{(k)} \,. \tag{6.23}$$

Let $b_n^{(k)}$ and $b_\tau^{(k)}$ be the normal and tangential components of $\mathbf{b}^{(k)}$, respectively:

$$\mathbf{b}^{(k)} = b_n^{(k)} \mathbf{n} + b_\tau^{(k)} \boldsymbol{\tau} \,.$$

Clearly, $b_n^{(k)}$, $b_\tau^{(k)}$, and $\mathbf{w}_0^{(k)}$ satisfy conditions (4.12)–(4.14) and (4.18) of Theorem 4.4. Hence, by Theorem 4.4, there exists a solution $\mathbf{w}^{(k)} \in Y$ for (3.1) and (6.23). We now show that $\mathbf{w}^{(k)} \to \mathbf{w}$ in Y. We obviously have

$$(\mathbf{w}^{(k)} - \mathbf{w})|_{(0,T)\times\partial\Omega} = \mathbf{b}^{(k)} - \mathbf{b} \to \mathbf{0}$$

in $H^1\big(0,T;\mathbf{L}^2(\partial\Omega)\big) \cap L^2\big(0,T;\mathbf{H}^{1/2}(\partial\Omega)\big) \cap \mathbf{L}^k\big((0,T)\times\partial\Omega\big)$. Thus we only need to show $\mathbf{w}^{(k)} \to \mathbf{w}$ in $\mathcal{V}^{(1)}(Q_T)$. We rewrite $\mathbf{w} - \mathbf{w}^{(k)}$ in the form

$$\mathbf{w} - \mathbf{w}^{(k)} = (\mathbf{u} - \mathbf{u}^{(k)}) + \boldsymbol{\eta}^{(k)}, \tag{6.24}$$

where $\boldsymbol{\eta}^{(k)}$ satisfies (4.20), (4.21) with $\boldsymbol{\eta}_0^{(k)} = (\mathbf{w}_0 - \mathbf{w}_0^{(k)}) - (\mathbf{u} - \mathbf{u}^{(k)})|_{t=0}$, and the following analog of (4.19):

$$\begin{aligned}
&\langle \partial_t \boldsymbol{\eta}^{(k)}(t), \mathbf{z}\rangle + \mu \int_\Omega \nabla \boldsymbol{\eta}^{(k)}(t) : \nabla \mathbf{z} \, d\mathbf{x} + \int_\Omega (\boldsymbol{\eta}^{(k)}(t) \cdot \nabla)\mathbf{w}(t) \cdot \mathbf{z} \, d\mathbf{x} \\
&+ \int_\Omega \big((\mathbf{w}^{(k)}(t) + \mathbf{v}_\infty) \cdot \nabla\big)\boldsymbol{\eta}^{(k)}(t) \cdot \mathbf{z} \, d\mathbf{x} = \langle \mathbf{f}^{(k)}(t), \mathbf{z}\rangle \qquad \forall\, \mathbf{z} \in \mathbf{V}^1(\Omega), \text{ a.e. } t \in (0,T),
\end{aligned}$$

where $\mathbf{f}^{(k)}$ is defined by the following analog of (4.22):

$$\begin{aligned}
\langle \mathbf{f}^{(k)}(t), \mathbf{z}\rangle = &-\mu \int_\Omega \nabla(\mathbf{u}(t) - \mathbf{u}^{(k)}(t)) : \nabla \mathbf{z} \, d\mathbf{x} - \langle \partial_t(\mathbf{u}(t) - \mathbf{u}^{(k)}(t)), \mathbf{z}\rangle \\
&- \int_\Omega \big((\mathbf{u}(t) - \mathbf{u}^{(k)}(t)) \cdot \nabla\big)\mathbf{w}(t) \cdot \mathbf{z} \, d\mathbf{x} \\
&- \int_\Omega \big((\mathbf{w}^{(k)}(t) + \mathbf{v}_\infty) \cdot \nabla\big)(\mathbf{u}(t) - \mathbf{u}^{(k)}(t)) \cdot \mathbf{z} \, d\mathbf{x}.
\end{aligned}$$

We can estimate $\boldsymbol{\eta}^{(k)}$ and $\mathbf{f}^{(k)}$ as in the proof of Lemma 4.3 and (4.25) to obtain

$$\begin{aligned}&\|\boldsymbol{\eta}^{(k)}\|_{\mathcal{V}^{(1)}(Q_T)}\\&\le A\big(\|\mathbf{f}^{(k)}\|_{L^2(0,T;\mathbf{V}^{-1}(\Omega))}, \|\mathbf{u}-\mathbf{u}^{(k)}\|_{\mathcal{V}^{(1)}(Q_T)}, \|\boldsymbol{\eta}_0^{(k)}\|_{\mathbf{V}^0(\Omega)}, \|\mathbf{w}\|_{\mathcal{V}^{(1)}(Q_T)}, |\mathbf{v}_\infty|\big)\end{aligned}$$

and

$$\begin{aligned}\|\mathbf{f}^{(k)}\|_{L^2(0,T;\mathbf{V}^{-1}(\Omega))} \le C\Big(&\|\mathbf{u}-\mathbf{u}^{(k)}\|_{\mathcal{V}^{(1)}(Q_T)} + \|\mathbf{u}-\mathbf{u}^{(k)}\|_{\mathcal{V}^{(1)}(Q_T)}\,\|\mathbf{w}\|_{\mathcal{V}^{(1)}(Q_T)}\\&+ \|\mathbf{u}-\mathbf{u}^{(k)}\|_{\mathcal{V}^{(1)}(Q_T)}\left(\|\mathbf{w}^{(k)}\|_{\mathcal{V}^{(1)}(Q_T)} + |\mathbf{v}_\infty|\right)\Big),\end{aligned}$$

where $A(\cdot)$ is a continuous positive function on $\mathbb{R}^5$ and $A(\lambda_1,\lambda_2,\lambda_3,\lambda_4,\lambda_5)\to 0$ as $(\lambda_1,\lambda_2,\lambda_3)\to(0,0,0)$ for fixed λ_4,λ_5. Taking into account (6.21)–(6.22) and the boundedness of $\|\mathbf{w}^{(k)}\|_{\mathcal{V}^{(1)}(Q_T)}$ (which follows from Theorem 4.4), we obtain

$$\|\boldsymbol{\eta}^{(k)}\|_{\mathcal{V}^{(1)}(Q_T)} \to 0 \quad \text{as } k\to\infty\,. \tag{6.25}$$

Relations (6.21) and (6.25) imply the convergence $\mathbf{w}^{(k)}\to\mathbf{w}$ in $\mathcal{V}^{(1)}(Q_T)$. Finally, we prove that $\mathbf{w}^{(k)}\in L^\infty\big(0,T;\mathbf{V}^2(\Theta)\big)$. To this end, we write $\mathbf{w}^{(k)}$ in the form

$$\mathbf{w}^{(k)} = \mathbf{u}^{(k)} + \boldsymbol{\xi}^{(k)}\,. \tag{6.26}$$

Then $\boldsymbol{\xi}^{(k)}$ is the solution of problem (4.19)–(4.21) with $\mathbf{u}$ replaced by $\mathbf{u}^{(k)}$ and $\mathbf{f}$ defined by (4.22), wherein $\mathbf{f}$ is replaced by $\mathbf{f}^{(k)}$ and $\mathbf{u}$ is replaced by $\mathbf{u}^{(k)}$. Note that by (6.20) the inclusion $\mathbf{u}^{(k)}\in\mathbf{C}^\infty(\overline{\Theta})$ holds. By (4.22) we have

$$\mathbf{f}^{(k)} = P\Big(\mu\Delta\mathbf{u}^{(k)} - \partial_t\mathbf{u}^{(k)} + [(\mathbf{u}^{(k)}+\mathbf{v}_\infty)\cdot\nabla]\mathbf{u}^{(k)}\Big), \tag{6.27}$$

where P is the orthogonal projection from $\mathbf{L}^2(\Theta)$ onto $\mathbf{V}_0^0(\Theta)$. Since $\mathbf{u}^{(k)}\in\mathbf{C}^\infty(\overline{\Theta})$, we have $\mathbf{f}^{(k)}\in L^\infty\big(0,T;\mathbf{V}_0^0(\Theta)\big)$, $\partial_t\mathbf{f}^{(k)}\in L^2\big(0,T;\widehat{\mathbf{V}}^{-1}(\Theta)\big)$, and $\mathbf{f}^{(k)}|_{t=0}\in\mathbf{V}_0^0(\Theta)$, where $\widehat{\mathbf{V}}^{-1}$ is the completion of $\mathbf{V}_0^0$ under the norm $\sup_{\|\phi\|_{\mathbf{V}_0^1=1}}\int_\Theta f\cdot\phi\,d\mathbf{x}$. By (6.26) and by properties of $(\mathbf{w}^{(k)}-\mathbf{u}^{(k)})|_{t=0}$ we have that $\boldsymbol{\xi}^{(k)}|_{t=0}\in\mathbf{V}^2(\Omega)\cap\mathbf{V}_0^1(\Omega)$. Hence, by a result in [28, pp. 299–302], we have $\boldsymbol{\xi}^{(k)}\in L^\infty\big(0,T;\mathbf{V}^2(\Theta)\big)$ so that $\mathbf{w}^{(k)}\in L^\infty\big(0,T;\mathbf{V}^2(\Theta)\big)$. □

We may prove a similar result for the solution $\mathbf{q}$ for the adjoint equation (6.12). We consider the boundary value problem

$$-\partial_t\mathbf{q}^{(k)} - \mu\Delta\mathbf{q}^{(k)} + \mathbf{q}^{(k)}\cdot(\nabla\mathbf{w}^{(k)})^T - [(\mathbf{w}^{(k)}+\mathbf{v}_\infty)\cdot\nabla]\mathbf{q}^{(k)} + \nabla\widetilde{r}^{(k)} = \mu\Delta\mathbf{w}^{(k)}, \tag{6.28}$$

$$\operatorname{div}\mathbf{q}^{(k)} = 0, \tag{6.29}$$

and

$$\mathbf{q}^{(k)}|_{t=T} = \mathbf{q}_0^{(k)}\in\mathbf{V}_0^0(\Theta), \qquad \mathbf{q}^{(k)}|_{(0,T)\times\partial\Omega} = \mathbf{0}\,. \tag{6.30}$$

The existence and uniqueness of the solution $\mathbf{q}^{(k)}\in\mathcal{V}^{(1)}(Q_T)$ for (6.28)–(6.30) can be shown by the standard techniques (see [19], [28]).

LEMMA 6.6. *Let* $\mathbf{q}\in\mathcal{V}^{(1)}(Q_T)\cap L^2\big(0,T;\mathbf{V}_0^1(\Omega)\big)$ *and* $\widetilde{r}\in L^2\big(0,T;L^2_{\mathrm{loc}}(\Omega)\big)$ *be the solution of* (6.11), $\mathbf{w}^{(k)}$ *be the solution of* (3.1) *and* (6.22), *and* $\mathbf{q}^{(k)}$ *be the solution*

of (6.28)–(6.30)*, where* $\mathbf{q}_0^{(k)} \in \mathbf{V}_0^1(\Omega)$ *and* $\|\mathbf{q}_0^{(k)} - \mathbf{q}(T,\cdot)\|_{\mathbf{V}_0^0(\Omega)} \to 0$ *as* $k \to \infty$*. Then for every* k*,* $\mathbf{q}^{(k)} \in L^2\big(0,T;\mathbf{V}^2(\Theta)\big)$ *and* $\|\mathbf{q}^{(k)} - \mathbf{q}\|_{\mathcal{V}^{(1)}(Q_T)} \to 0$ *as* $k \to \infty$*.*

Proof. By Lemma 6.5, $\|\mathbf{w}^{(k)} - \mathbf{w}\|_{\mathcal{V}^{(1)}(Q_T)} \to 0$ as $k \to \infty$. Subtracting (6.11) from (6.28) and doing estimation as in Lemma 4.3 we obtain

$$\|\mathbf{q}^{(k)} - \mathbf{q}\|_{\mathcal{V}^{(1)}(Q_T)} \to 0 \quad \text{as } k \to \infty\,.$$

By Lemma 6.5, $\mathbf{w}^{(k)} \in \mathcal{V}^{(1)}(Q_T) \cap L^\infty\big(0,T;\mathbf{V}^2(\Theta)\big)$. Also, $\mathbf{q}^{(k)} \in \mathcal{V}^{(1)}(Q_T)$. Thus we have that

$$\mathbf{g} \equiv \mu\Delta\mathbf{w}^{(k)} - \mathbf{q}^{(k)} \cdot (\nabla\mathbf{w}^{(k)})^T - [(\mathbf{w}^{(k)} + \mathbf{v}_\infty)\cdot\nabla]\mathbf{q}^{(k)} \in \mathbf{L}^2\big((0,T)\times\Theta\big)\,.$$

We rewrite (6.28) in the form

$$-\partial_t\mathbf{q}^{(k)} - \mu\Delta\mathbf{q}^{(k)} + \nabla\widetilde{r}^{(k)} = \mathbf{g}\,.$$

Applying to this last equation the regularity result for the Stokes equations (see [19]) we obtain $\mathbf{q}^{(k)} \in L^2\big(0,T;\mathbf{V}^2(\Theta)\big)$. ∎

LEMMA 6.7. *Let* $\mathbf{w} \in Y$ *be a solution of problem* (3.1)–(3.3) *and* $\mathbf{q} \in \mathcal{V}^{(1)}(Q_T) \cap L^2\big(0,T;\mathbf{V}_0^1(\Omega)\big)$ *be a solution of the adjoint equation* (6.11)*. Then the distribution* $\Delta\mathbf{w}$ *defined on* $\mathbf{C}_0^\infty(\Omega)\cap\mathbf{V}^0(\Omega)$ *can be extended continuously into a functional defined by*

$$\int_\Theta \Delta\mathbf{w}\cdot\mathbf{h}\,d\mathbf{x} = \int_{\partial\Omega}\big((\nabla\mathbf{w}) + (\nabla\mathbf{w})^T\big)\mathbf{n}\cdot\mathbf{h}\,ds - 2\int_\Theta \mathcal{D}(\mathbf{w}) : \mathcal{D}(\mathbf{h})\,d\mathbf{x} \tag{6.31}$$

for every $\mathbf{h} \in \mathbf{C}^\infty(\overline{\Theta})$ *which vanishes near* $(0,T)\times(\partial\Theta\setminus\partial\Omega)$*. Furthermore, the time-dependent version of* (6.31) *also holds; i.e.,*

$$\begin{aligned}&\int_0^T\int_\Theta \Delta\mathbf{w}\cdot\mathbf{h}\,d\mathbf{x}\,dt\\ &\quad= \int_0^T\int_{\partial\Omega}\big((\nabla\mathbf{w}) + (\nabla\mathbf{w})^T\big)\mathbf{n}\cdot\mathbf{h}\,ds\,dt - 2\int_0^T\int_\Theta \mathcal{D}(\mathbf{w}) : \mathcal{D}(\mathbf{h})\,d\mathbf{x}\,dt\end{aligned} \tag{6.32}$$

for every $\mathbf{h} \in \mathbf{C}^\infty((0,T)\times\overline{\Theta})$ *which vanishes near* $(0,T)\times(\partial\Theta\setminus\partial\Omega)$*. Formulae* (6.31) *and* (6.32) *also hold if* $\mathbf{w}$ *is replaced by* $\mathbf{q}$*.*

Proof. If $\mathbf{w} = \mathbf{w}^{(k)} \in L^\infty\big(0,T;\mathbf{V}^2(\Theta)\big)$, (6.32) is the well-known Green's formula (see (2.5) and the ensuing formulae). We substitute into (6.32) the solution $\mathbf{w}^{(k)}$ for the problem (3.1) and (6.23) as constructed in Lemma 6.5. By this lemma we have $\mathbf{w}^{(k)} \to \mathbf{w}$ in $\mathcal{V}^{(1)}(Q_T)$, and therefore,

$$\int_0^T\int_\Theta \mathcal{D}(\mathbf{w}^{(k)}) : \mathcal{D}(\mathbf{h})\,d\mathbf{x}\,dt \to \int_0^T\int_\Theta \mathcal{D}(\mathbf{w}) : \mathcal{D}(\mathbf{h})\,d\mathbf{x}\,dt$$

as $k \to \infty$. Theorem 4.9 yields that the operator $\mathbf{w} \mapsto \gamma\big((\nabla\mathbf{w}) + (\nabla\mathbf{w})^T\big)\mathbf{n}$ is continuous from the set $\{\mathbf{w} \in Y : \mathbf{w} \text{ satisfies (3.1)}\}$ to the space $L^1\big(0,T;\mathbf{B}^{-1/\alpha,\alpha}(\partial\Omega)\big)$, $1 < \alpha < 2$. Hence,

$$\int_0^T\int_{\partial\Omega}\big((\nabla\mathbf{w}^{(k)}) + (\nabla\mathbf{w}^{(k)})^T\big)\mathbf{n}\cdot\mathbf{h}\,ds\,dt \to \int_0^T\int_{\partial\Omega}\big((\nabla\mathbf{w}) + (\nabla\mathbf{w})^T\big)\mathbf{n}\cdot\mathbf{h}\,ds\,dt$$

as $k \to \infty$. Substituting $\mathbf{w} = \mathbf{w}^{(k)}$ into (6.32) and passing to the limit as $k \to \infty$ in the right-hand side of this formula we obtain the desired extension of the distribution $\Delta\mathbf{w}$ which is defined by (6.32). The steady state formula (6.31) can be similarly proved. The case of the distribution $\Delta\mathbf{q}$ can be proved analogously. ∎

6.4. The optimality system in the form of a boundary value problem for a system of partial differential equations. We now interpret the optimality system (3.1), (3.3), and (6.4) as a system of partial differential equations with boundary conditions on the entire boundary of the cylinder $Q_T = (0,T)\times\Omega$.

We first recall from section 3 that

$$\mathbf{V}^0(\Omega) = \{\mathbf{v}\in\mathbf{L}^2(\Omega) : \operatorname{div}\mathbf{v} = 0\}$$

and

$$\mathbf{V}_0^0(\Omega) = \text{the closure of } \mathbf{C}_0^\infty(\Omega)\cap\mathbf{V}^0(\Omega) \text{ in the } \mathbf{L}^2(\Omega)\text{-norm}\,.$$

We have the well-known Weyl decomposition (see [14] and [19])

$$\mathbf{L}^2(\Omega) = \mathbf{V}_0^0(\Omega)\oplus\big(\nabla H^1(\Omega)\big),$$

where $\nabla H^1(\Omega) = \{\nabla g : g\in H^1(\Omega)\}$. We claim that

$$\mathbf{V}^0(\Omega) = \mathbf{V}_0^0(\Omega)\oplus\big(\nabla H_\pi\big),$$

where $\nabla H_\pi = \{\nabla g : g\in H^1(\Omega),\ \Delta g = 0\}$. Indeed, since for each $\mathbf{w}\in\mathbf{V}^0(\Omega)$ we have $\mathbf{w} = \mathbf{w}_\sigma + \nabla w_\pi$ from the Weyl decomposition with $\mathbf{w}_\sigma\in\mathbf{V}_0^0(\Omega)$ and $w_\pi\in H^1(\Omega)$, we obtain by taking the divergence of $\mathbf{w}$ that $\Delta w_\pi = \operatorname{div}\mathbf{w} - \operatorname{div}\mathbf{w}_\sigma = 0$.

We are now prepared to interpret the optimality system in the weak form as a system of partial differential equations with boundary conditions on the entire boundary of the cylinder $Q_T = (0,T)\times\Omega$.

THEOREM 6.8. *Assume* $\mathbf{w}\in Y$ *is a solution for Problem* I *and* $\mathbf{q}\in\mathcal{V}^{(1)}(Q_T)$ *is as defined in Theorem* 6.2. *Then there exist a* $p\in L^2\big(0,T;L^2_{\mathrm{loc}}(\Omega)\big)$ *and an* $r\in L^2\big(0,T;L^2_{\mathrm{loc}}(\Omega)\big)$ *such that the quadruplet* $(\mathbf{w},p,\mathbf{q},r)$ *satisfies the partial differential equations (in the sense of distributions)*

$$\partial_t\mathbf{w} - \mu\Delta\mathbf{w} + ((\mathbf{w}+\mathbf{v}_\infty)\cdot\nabla)\mathbf{w} + \nabla p = \mathbf{0} \qquad \text{in } (0,T)\times\Omega\,, \tag{6.33}$$

$$\nabla\cdot\mathbf{w} = 0 \qquad \text{in } (0,T)\times\Omega\,, \tag{6.34}$$

$$-\partial_t\mathbf{q} - \mu\Delta\mathbf{q} + \mathbf{q}\cdot(\nabla\mathbf{w})^T - (\mathbf{w}\cdot\nabla)\mathbf{q} - (\mathbf{v}_\infty\cdot\nabla)\mathbf{q} + \nabla r = \mu\Delta\mathbf{w} - \nabla p\,, \tag{6.35}$$

and

$$\nabla\cdot\mathbf{q} = 0 \qquad \text{in } (0,T)\times\Omega\,, \tag{6.36}$$

the initial and terminal conditions

$$\mathbf{w}(0,\cdot) = \mathbf{w}_0(\cdot) \quad \text{in } \mathbf{V}^0(\Omega)\,, \tag{6.37}$$

and

$$\mathbf{q}(T,\cdot) + \frac{1}{2}\mathbf{w}_\sigma(T,\cdot) = 0 \quad \text{in } \mathbf{V}_0^0(\Omega), \tag{6.38}$$

and the (lateral) boundary condition

$$\mathbf{q}|_{S_T} = \mathbf{0}\,, \tag{6.39}$$

where $\mathbf{w}_\sigma(T,\cdot)$ *is the projection of* $\mathbf{w}(T,\cdot)$ *onto* $\mathbf{V}_0^0(\Omega)$. *Moreover,*

$$\partial_{tt}(\gamma\mathbf{w}) \in L^1\big(0,T;\mathbf{B}^{-1/\alpha,\alpha}(\partial\Omega)\big)\,, \tag{6.40}$$

$$\gamma\big[\big((\nabla\mathbf{w})+(\nabla\mathbf{w})^T\big)\cdot\mathbf{n}\big] \in L^1\big(0,T;\mathbf{B}^{-1/\alpha,\alpha}(\partial\Omega)\big)\,, \tag{6.41}$$

$$\gamma p \in L^1\big(0,T;B^{-1/\alpha,\alpha}(\partial\Omega)\big)\,, \quad \int_{\partial\Omega} p\,ds = 0, \tag{6.42}$$

$$\gamma\big[\big((\nabla\mathbf{q})+(\nabla\mathbf{q})^T\big)\cdot\mathbf{n}\big] \in L^1\big(0,T;\mathbf{B}^{-1/\alpha,\alpha}(\partial\Omega)\big)\,, \tag{6.43}$$

and

$$\gamma r \in L^1\big(0,T;B^{-1/\alpha,\alpha}(\partial\Omega)\big)\,, \quad \int_{\partial\Omega} r\,ds = 0, \tag{6.44}$$

where $1<\alpha<2$ *and the following boundary conditions hold:*

$$2N\partial_{tt}^2(\gamma\mathbf{w}) - \mathcal{A}(\mathbf{w}) - \mathcal{T}(\mathbf{w},p)\mathbf{n} - \mathcal{T}(\mathbf{q},r)\mathbf{n} = \eta(t)\mathbf{n}, \tag{6.45}$$

where

$$\mathcal{T}(\mathbf{w},p) = -pI + 2\mu\mathcal{D}(\mathbf{w}) \quad \textit{and} \quad \mathcal{T}(\mathbf{q},r) = -rI + 2\mu\mathcal{D}(\mathbf{q})\,, \tag{6.46}$$

$$\mathcal{A}(\mathbf{w}) = \gamma\Big(kN|\mathbf{w}+\mathbf{v}_\infty|^{k-2}(\mathbf{w}+\mathbf{v}_\infty) + \frac{1}{2}\big((\mathbf{w}+\mathbf{v}_\infty)\cdot\mathbf{n}\big)\mathbf{w} + \frac{|\mathbf{w}|^2}{4}\mathbf{n}\Big) \tag{6.47}$$

and

$$\eta(t) = -\int_{\partial\Omega}\mathcal{A}(\mathbf{w})\cdot\mathbf{n}\,ds \Big/ \int_{\partial\Omega} ds\,. \tag{6.48}$$

Furthermore, the following compatibility conditions hold:

$$\big[(\gamma\mathbf{w})\cdot\mathbf{n}\big]\big|_{t=0} = (\gamma\mathbf{w}_0)\cdot\mathbf{n}\,, \tag{6.49}$$

$$(\partial_t\gamma\mathbf{w})\cdot\boldsymbol{\tau}|_{t=T} = 0 \qquad \textit{and} \qquad \left(\frac{1}{2}\gamma w_\pi + 2N\partial_t\gamma\mathbf{w}\cdot\mathbf{n}\right)|_{t=T} = 0\,, \tag{6.50}$$

where $\boldsymbol{\tau}$ *is the unit tangential along* $\partial\Omega$ *and* $w_\pi(t,\cdot)$ *is the primitive function of the projection of* $\mathbf{w}(t,\cdot)$ *onto* ∇H_π *determined by the condition*

$$\int_{\partial\Omega} w_\pi(t,\cdot)\,ds = 0\,. \tag{6.51}$$

Proof. $\mathbf{w}\in\mathcal{V}^{(1)}(Q_T)$ as a solution of Problem I satisfies (3.1) and (6.37). By the De Rham lemma, or recall from (4.27), there exists a $p\in L^2\big(0,T;L^2_{\rm loc}(\Omega)\big)$ such that (6.33) holds. Relation (6.49) follows from the inclusion $\mathbf{w}\in Y$ and the remark at the end of section 4.1. For the Lagrange multiplier $\mathbf{q}\in\mathcal{V}^{(1)}(Q_T)\cap L^2\big(0,T;\mathbf{V}_0^1\big)$ we recall from (6.12) that there exists an $r\in L^2\big(0,T;L^2_{\rm loc}(\Omega)\big)$ such that (6.35) holds. (6.34) and (6.36) simply follow from the fact that $\mathbf{w}\in\mathcal{V}^{(1)}(Q_T)$ and $\mathbf{q}\in\mathcal{V}^{(1)}(Q_T)$; (6.39)

follows from the fact that $\mathbf{q} \in L^2\big(0,T;\mathbf{V}_0^1(\Omega)\big)$. From Theorem 4.10 and Lemma 6.3 we see that the traces of p and r live in the space $L^1\big(0,T;B^{-1/\alpha,\alpha}(\partial\Omega)\big)$ for $1<\alpha<2$. Also, note that in (6.33) and (6.35), we can add an arbitrary constant to p and r so that, in particular, we can choose p and r satisfying $\int_{\partial\Omega} p\,ds = 0$ and $\int_{\partial\Omega} r\,ds = 0$, respectively, where the integrals are understood as the duality pairings $\langle p, 1\rangle$ and $\langle r, 1\rangle$, respectively. This eliminates the arbitrary constant from p and r and also will facilitate some later discussion. Hence (6.42) and (6.44) are verified. Relations (6.41)–(6.44) follow from Theorems 4.9 and 4.10 and Lemma 6.3.

We now examine (6.45). By taking $\mathbf{h} \in \mathbf{C}^\infty$ in (6.4) with $\operatorname{div}\mathbf{h} = 0$, $\mathbf{h}|_{t=0} = \mathbf{0}$, $\mathbf{h}|_{t=T} = \mathbf{0}$ and integrating by parts (which is justified by Lemma 6.7), we obtain

$$\begin{aligned}(6.52)\qquad &\int_0^T\!\!\int_\Omega \Big(-\partial_t\mathbf{q} - \mu\Delta\mathbf{q} + \mathbf{q}\cdot(\nabla\mathbf{w})^T - [(\mathbf{w}+\mathbf{v}_\infty)\cdot\nabla]\mathbf{q} - \mu\Delta\mathbf{w}\Big)\cdot\mathbf{h}\,d\mathbf{x}dt\\ &\quad + \int_0^T\!\!\int_{\partial\Omega}\Big(2N\partial_t\mathbf{w}\cdot\partial_t\mathbf{h} + \big(\mathcal{A}(\mathbf{w}) + 2\mu\mathcal{D}(\mathbf{w})\mathbf{n} + 2\mu\mathcal{D}(\mathbf{q})\mathbf{n}\big)\cdot\mathbf{h}\Big)\,ds\,dt = 0\,,\end{aligned}$$

where $\mathcal{A}(\mathbf{w})$ is defined by (6.47). Also, the integrals are understood as duality pairings if necessary. Equations (6.35) and (6.52) yield

$$\begin{aligned}(6.53)\qquad &-\int_0^T\!\!\int_\Omega (\nabla r + \nabla p)\cdot\mathbf{h}\,d\mathbf{x}dt\\ &\quad + \int_0^T\!\!\int_{\partial\Omega}\Big(2N\partial_t\mathbf{w}\cdot\partial_t\mathbf{h} + \big(\mathcal{A}(\mathbf{w}) + 2\mu\mathcal{D}(\mathbf{w})\mathbf{n} + 2\mu\mathcal{D}(\mathbf{q})\mathbf{n}\big)\cdot\mathbf{h}\Big)\,ds\,dt = 0\,.\end{aligned}$$

Using Lemma 6.4 and the last equation, we obtain

$$(6.54)\qquad \int_0^T\!\!\int_{\partial\Omega}\Big(2N\partial_t\mathbf{w}\cdot\partial_t\mathbf{h} + \big(\mathcal{A}(\mathbf{w}) + \mathcal{T}(p,\mathbf{w})\mathbf{n} + \mathcal{T}(r,\mathbf{q})\mathbf{n}\big)\cdot\mathbf{h}\Big)\,ds\,dt = 0\,,$$

where $\mathcal{T}$ is the stress tensor defined by (6.46). Since $1<\alpha<2$, we have the continuous imbeddings $B^{1/\alpha,\alpha'}(\partial\Omega) \hookrightarrow L^\infty(\partial\Omega)$, where $\alpha' = \alpha/(\alpha-1)$ so that $L^1(\partial\Omega) \hookrightarrow B^{-1/\alpha,\alpha}(\partial\Omega)$. Hence,

$$\gamma\Big(2kN|\mathbf{w}+\mathbf{v}_\infty|^{k-2}(\mathbf{w}+\mathbf{v}_\infty) + \frac{1}{2}\big((\mathbf{w}+\mathbf{v}_\infty)\cdot\mathbf{n}\big)\mathbf{w} + \frac{|\mathbf{w}|^2}{4}\mathbf{n}\Big) \in \mathbf{L}^1(\partial\Omega) \hookrightarrow \mathbf{B}^{-1/\alpha,\alpha}(\partial\Omega)\,.$$

Using Theorems 4.9 and 4.10, Lemma 6.3, and the last relation, we see that

$$(6.55)\qquad \mathcal{A}(\mathbf{w}) + \mathcal{T}(p,\mathbf{w})\mathbf{n} + \mathcal{T}(r,\mathbf{q})\mathbf{n} \in L^1\big(0,T;\mathbf{B}^{-1/\alpha,\alpha}(\partial\Omega)\big).$$

Since $\mathbf{h}$ and $\partial_t\mathbf{w}$ are solenoidal (from the definition of the spaces $\mathcal{V}^{(1)}(Q_T)$ and Y), we have

$$\int_{\partial\Omega}\mathbf{h}\cdot\mathbf{n}\,ds = 0 \qquad \text{and} \qquad \int_{\partial\Omega}\partial_t\mathbf{w}\cdot\mathbf{n}\,ds = 0\,.$$

Thus, from (6.54)–(6.55), we deduce (6.40) and

$$(6.56)\qquad \int_0^T\!\!\int_{\partial\Omega}\Big(2N\partial_{tt}\mathbf{w} - \mathcal{A}(\mathbf{w}) - \mathcal{T}(p,\mathbf{w})\mathbf{n} - \mathcal{T}(r,\mathbf{q})\mathbf{n}\Big)\cdot\mathbf{h}\,ds\,dt = 0\,.$$

Hence, (6.45) follows from (6.55) and (6.56) with $\eta(t)$ defined by

$$(6.57)\qquad \eta(t) = \int_{\partial\Omega}\mathbf{n}\cdot\Big(2N\partial_{tt}\mathbf{w} - \mathcal{A}(\mathbf{w}) - \mathcal{T}(p,\mathbf{w})\mathbf{n} - \mathcal{T}(r,\mathbf{q})\mathbf{n}\Big)\,ds \Big/ \int_{\partial\Omega} ds\,.$$

Note that for every $\phi(t) \in C_0^\infty(0,T)$,

$$\int_0^T \int_{\partial\Omega} \partial_{tt}\mathbf{w}\cdot\mathbf{n}\,ds\,\phi(t)\,dt = \int_0^T \int_{\partial\Omega} \mathbf{w}\cdot\mathbf{n}\,ds\,\partial_{tt}\phi(t)\,dt = 0$$

as $\int_{\partial\Omega} \mathbf{w}\cdot\mathbf{n}\,ds = 0$ for every divergence-free function $\mathbf{w}$. Thus, for almost all $t \in (0,T)$,

$$\int_{\partial\Omega} \partial_{tt}\mathbf{w}\cdot\mathbf{n}\,ds = 0\,. \tag{6.58}$$

Taking into account (6.42) we obtain for each $\phi(t) \in C_0^\infty(0,T)$,

$$\begin{aligned} &\int_0^T \int_{\partial\Omega} \mathbf{n}\cdot\mathcal{T}(p,\mathbf{w})\mathbf{n}\,ds\,\phi(t)\,dt \\ &= \int_0^T \int_{\partial\Omega} \Big(\mathbf{n}\cdot\mu\big((\nabla\mathbf{w}) + (\nabla\mathbf{w})^T\big)\mathbf{n} - p\Big)\,ds\,\phi(t)\,dt \\ &= \int_0^T \int_{\partial\Omega} \Big(\mathbf{n}\cdot\mu\big((\nabla\mathbf{w}) + (\nabla\mathbf{w})^T\big)\mathbf{n}\Big)\,ds\,\phi(t)\,dt\,. \end{aligned} \tag{6.59}$$

Let $\epsilon > 0$ be given. For each $s \in \partial\Omega$, we consider the normal $\widetilde{\mathbf{n}}(s)$ to $\partial\Omega$ which is directed into Ω. We choose the point $K(\epsilon, s)$ along $\widetilde{\mathbf{n}}(s)$ such that the distance between $K(\epsilon, s)$ and $\partial\Omega$ equals ϵ. If ϵ is sufficiently small, then the set $\{K(\epsilon, s) : s \in \partial\Omega\}$ is a C^∞-manifold which we denote by $\partial\Omega_\epsilon$. Since $\mathbf{w} \in \mathbf{V}^0(\Omega)$,

$$\int_{\partial\Omega} \mathbf{w}\cdot\widetilde{\mathbf{n}}\,ds = 0 \quad \text{and} \quad \int_{\partial\Omega_\epsilon} \mathbf{w}\cdot\widetilde{\mathbf{n}}_\epsilon\,ds = 0,$$

where $\widetilde{\mathbf{n}}_\epsilon$ is the outward normal to $\partial\Omega_\epsilon$. Hence,

$$\begin{aligned} &\int_0^T \int_{\partial\Omega} \Big(\mathbf{n}\cdot\big((\nabla\mathbf{w}) + (\nabla\mathbf{w})^T\big)\mathbf{n}\Big)\,ds\,\phi(t)\,dt \\ &= 2\int_0^T \int_{\partial\Omega} \partial_n\mathbf{w}\cdot\mathbf{n}\,ds\,\phi(t)\,dt \\ &= \lim_{\epsilon\to 0} \frac{1}{\epsilon} \int_0^T \Big(\int_{\partial\Omega} \mathbf{w}\cdot\mathbf{n}\,ds - \int_{\partial\Omega_\epsilon} \mathbf{w}\cdot\widetilde{\mathbf{n}}_\epsilon\,ds\Big)\,\phi(t)\,dt = 0\,. \end{aligned} \tag{6.60}$$

Thus, (6.59) and (6.60) yield

$$\int_{\partial\Omega} \mathbf{n}\cdot\mathcal{T}(p,\mathbf{w})\mathbf{n}\,ds = 0 \quad \text{for almost every } t \in (0,T)\,. \tag{6.61}$$

Similarly, we have

$$\int_{\partial\Omega} \mathbf{n}\cdot\mathcal{T}(r,\mathbf{q})\mathbf{n}\,ds = 0 \quad \text{for almost every } t \in (0,T)\,. \tag{6.62}$$

From relations (6.58) and (6.61)–(6.62) we conclude that the function $\eta(t)$ defined in (6.57) equals the function defined in (6.48).

Now we choose $\mathbf{h} \in \mathbf{C}^\infty(Q_T)$ in (6.4) with $\operatorname{div} \mathbf{h} = 0$ and $\mathbf{h}|_{t=0} = \mathbf{0}$. Integration by parts (which again is justified by Lemmas 6.4 and 6.7) yields

$$\begin{aligned}
&\int_0^T \int_\Omega \Big(- \partial_t \mathbf{q} - \mu \Delta \mathbf{q} + \mathbf{q} \cdot (\nabla \mathbf{w})^T - [(\mathbf{w} + \mathbf{v}_\infty) \cdot] \mathbf{q} - \mu \Delta \mathbf{w} \Big) \cdot \mathbf{h} \, d\mathbf{x} dt \\
&+ \int_0^T \int_{\partial\Omega} \Big(- 2N \partial_{tt} \mathbf{w} \cdot \mathbf{h} + \big(\mathcal{A}(\mathbf{w}) + 2\mu \mathcal{D}(\mathbf{w}) \mathbf{n} + 2\mu \mathcal{D}(\mathbf{q}) \mathbf{n} \big) \cdot \mathbf{h} \Big) \, ds \, dt \\
&+ \int_\Omega \left[\mathbf{q}(T, \mathbf{x}) + \frac{1}{2} \mathbf{w}(T, \mathbf{x}) \right] \cdot \mathbf{h}(T, \mathbf{x}) \, d\mathbf{x} + \int_{\partial\Omega} 2N \partial_t \mathbf{w}(T, \mathbf{x}) \cdot \mathbf{h}(T, \mathbf{x}) \, ds = 0 \,.
\end{aligned} \tag{6.63}$$

Note that (6.53) and (6.56) hold for the present $\mathbf{h}$ so that using (6.35), (6.53), (6.56), and (6.63), we are led to

$$\int_\Omega \left[\mathbf{q}(T, \mathbf{x}) + \frac{1}{2} \mathbf{w}(T, \mathbf{x}) \right] \cdot \mathbf{h}(T, \mathbf{x}) \, d\mathbf{x} + \int_{\partial\Omega} 2N \partial_t \mathbf{w}(T, \mathbf{x}) \cdot \mathbf{h}(T, \mathbf{x}) \, ds = 0 \,. \tag{6.64}$$

Using the fact that $\mathbf{q}(T, \cdot) \in \mathbf{V}_0^0(\Omega)$ and $\mathbf{w}(T, \cdot) \in \mathbf{V}^0(\Omega)$ we obtain (6.38). Substituting (6.38) into (6.64) we obtain by integration by parts that

$$\int_{\partial\Omega} \Big(\frac{1}{2} w_\pi(T, \mathbf{x}) \mathbf{n}(\mathbf{x}) \cdot \mathbf{h}(T, \mathbf{x}) + 2N \partial_t \mathbf{w}(T, \mathbf{x}) \cdot \mathbf{h}(T, \mathbf{x}) \Big) \, ds = 0,$$

which implies (6.50) with (6.51). □

6.5. The case of Problem II. We derive now the optimality system for Problem II.

THEOREM 6.9. *Assume that* $\mathbf{v}_0 \equiv \mathbf{w}_0 + \mathbf{v}_\infty \in \mathbf{V}_0^1(\Omega)$ *and* $\mathbf{w} \in Y$ *is a solution of Problem* II. *Then there exists a triplet* $(\mathbf{q}, r, \lambda) \in \mathcal{V}^{(1)}(Q_T) \times L^2_{\mathrm{loc}}(Q_T) \times \mathbb{R}_+$ *and* $p \in L^2_{\mathrm{loc}}(Q_T)$ *such that* $(\mathbf{q}, r, \lambda) \neq (\mathbf{0}, 0, 0)$ *and the collection* $(\mathbf{w}, \mathbf{q}, p, r, \lambda)$ *satisfies* (6.33)–(6.44) *and the boundary conditions*

$$2\lambda \partial_{tt}^2 \gamma \mathbf{w} - \widetilde{\mathcal{A}}(\mathbf{w}) - \mathcal{T}(\mathbf{w}, p)\mathbf{n} - \mathcal{T}(\mathbf{q}, r)\mathbf{n} = \widetilde{\eta}(t)\mathbf{n}, \tag{6.65}$$

where $\mathcal{T}(\mathbf{w}, p)$ *and* $\mathcal{T}(\mathbf{q}, r)$ *are defined by* (6.46),

$$\widetilde{\mathcal{A}}(\mathbf{w}) = \gamma \Big(k\lambda |\mathbf{w} + \mathbf{v}_\infty|^{k-2} (\mathbf{w} + \mathbf{v}_\infty) + \frac{1}{2} \big((\mathbf{w} + \mathbf{v}_\infty) \cdot \mathbf{n} \big) \mathbf{w} + \frac{|\mathbf{w}|^2}{4} \mathbf{n} \Big), \tag{6.66}$$

and

$$\widetilde{\eta}(t) = - \int_{\partial\Omega} \widetilde{\mathcal{A}}(\mathbf{w}) \cdot \mathbf{n} \, ds \Big/ \int_{\partial\Omega} ds \,. \tag{6.67}$$

Moreover, the following compatibility conditions hold:

$$(\gamma \mathbf{w}) \cdot \mathbf{n}|_{t=0} = (\gamma \mathbf{w}_0) \cdot \mathbf{n} \,, \tag{6.68}$$

$$\lambda \big[(\partial_t \gamma \mathbf{w}) \cdot \boldsymbol{\tau} \big] \big|_{t=T} = 0 \,, \qquad \textit{and} \qquad \Big(\frac{1}{2} \gamma w_\pi + 2\lambda \partial_t \gamma \mathbf{w} \cdot \mathbf{n} \Big) \Big|_{t=T} = 0 \,, \tag{6.69}$$

where $\boldsymbol{\tau}$ *is the unit tangential along* $\partial\Omega$ *and* $w_\pi(t, \cdot)$ *is the primitive function of the projection of* $\mathbf{w}(t, \cdot)$ *onto* ∇H_π *determined by the condition* (6.51). *Furthermore, the conditions of nonnegativeness and complementary slackness are valid; i.e.,*

$$\lambda \geq 0 \tag{6.70}$$

and

$$\lambda\Big(\int_0^T\int_{\partial\Omega}\big(|\mathbf{w}+\mathbf{v}_\infty|^k+|\partial_t\mathbf{w}|^2\big)\,ds\,dt-M\Big)=0\,. \tag{6.71}$$

Proof. Let $\mathbf{w}\in Y$ be a solution of Problem II. We fit Problem II into the framework of Theorem 6.1. We set $X_1=Y_0$ and $X_2=L^2\big(0,T;\mathbf{V}^{-1}(\Omega)\big)$. The Lagrange functional for Problem II is defined by

$$\begin{aligned}\mathcal{L}(\mathbf{y},\mathbf{q})=\lambda_0\Big(&\mu\int_0^T\int_\Omega|\mathcal{D}(\mathbf{w}+\mathbf{y})|^2\,d\mathbf{x}dt+\frac14\int_\Omega|\mathbf{w}(T,\mathbf{x})+\mathbf{y}(T,\mathbf{x})|^2\,d\mathbf{x}\\&+\frac14\int_0^T\int_{\partial\Omega}|\mathbf{w}+\mathbf{y}|^2(\mathbf{w}+\mathbf{y}+\mathbf{v}_\infty)\cdot\mathbf{n}\,ds\,dt\Big)\\&+\lambda\int_0^T\int_{\partial\Omega}\Big(|\mathbf{w}+\mathbf{y}+\mathbf{v}_\infty|^k+|\partial_t\mathbf{w}+\partial_t\mathbf{y}|^2-M\Big)\,ds\,dt\\&+\int_0^T\int_\Omega(\partial_t\mathbf{w}+\partial_t\mathbf{y})\cdot\mathbf{q}\,d\mathbf{x}dt+2\mu\int_0^T\int_\Omega\mathcal{D}(\mathbf{w}+\mathbf{y}):\mathcal{D}(\mathbf{q})\,d\mathbf{x}dt\\&+\int_0^T\int_\Omega\big\{[(\mathbf{w}+\mathbf{y})\cdot\nabla](\mathbf{w}+\mathbf{y})+(\mathbf{v}_\infty\cdot\nabla)(\mathbf{w}+\mathbf{y})\big\}\cdot\mathbf{q}\,d\mathbf{x}dt\end{aligned} \tag{6.72}$$

for all $\mathbf{y}\in X_1$ and $\mathbf{q}\in X_2^*=L^2\big(0,T;\mathbf{V}_0^1(\Omega)\big)$. Note that (6.72) differs from (6.9) in that λ_0 has to be included in the Lagrangian functional and λ_0 can be zero. We define the functionals

$$f(\mathbf{y})=\mathcal{J}(\mathbf{w}+\mathbf{y})$$

and

$$g_1(\mathbf{y})=\int_0^T\int_{\partial\Omega}\big(|\mathbf{w}+\mathbf{y}+\mathbf{v}_\infty|^k+|\partial_t\mathbf{w}+\partial_t\mathbf{y}|^2\big)\,ds\,dt-M\,;$$

see (3.5)–(3.6). We define the mapping $F:X_1\to X_2$ as in the proof of Theorem 6.2. Analogous to the proof of Theorem 6.2, we can verify that $F'(\mathbf{0})$ is an epimorphism, and therefore the image of $F'(\mathbf{0})$ is closed. Hence, we have verified all the assumptions in Theorem 6.1 and we conclude that there exist a $\mathbf{q}\in X_2^*=L^2\big(0,T;\mathbf{V}_0^1(\Omega)\big)$ and a $(\lambda_0,\lambda)\in\mathbb{R}^2$ such that $(\mathbf{q},\lambda_0,\lambda)\neq(\mathbf{0},0,0)$,

$$\big\langle\mathcal{L}_{\mathbf{y}}(\mathbf{y},\mathbf{q}),\mathbf{h}\big\rangle\Big|_{\mathbf{y}=0}=0\qquad\forall\,\mathbf{h}\in Y\,, \tag{6.73}$$

$$\lambda_0\geq0\,,\qquad\lambda\geq0\,, \tag{6.74}$$

and

$$\lambda\Big(\int_0^T\int_{\partial\Omega}\big(|\partial_t\mathbf{w}|^2+|\mathbf{w}+\mathbf{v}_\infty|^k\big)\,ds\,dt-M\Big)=0\,. \tag{6.75}$$

As in Theorems 6.2 and 6.8, we derive from (6.73) relations (6.33)–(6.34), (6.36)–(6.37), (6.39)–(6.44),

$$-\partial_t\mathbf{q}-\mu\Delta\mathbf{q}+\mathbf{q}\cdot(\nabla\mathbf{w})^T-(\mathbf{w}\cdot\nabla)\mathbf{q}-(\mathbf{v}_\infty\cdot\nabla)\mathbf{q}+\nabla r=\lambda_0(\mu\Delta\mathbf{w}-\nabla p) \tag{6.76}$$

and

$$\mathbf{q}(T,\cdot)+\frac{\lambda_0}{2}\mathbf{w}_\sigma(T,\cdot)=0 \quad \text{in } \mathbf{V}_0^0(\Omega)\,, \tag{6.77}$$

where $\mathbf{w}_\sigma(T,\cdot)$ is the projection of $\mathbf{w}(T,\cdot)$ onto $\mathbf{V}_0^0(\Omega)$. Moreover, we derive the following boundary condition:

$$2\lambda\partial_{tt}^2\gamma\mathbf{w}-\widetilde{\mathcal{A}}(\mathbf{w})-\mathcal{T}(\mathbf{w},p)\mathbf{n}-\mathcal{T}(\mathbf{q},r)\mathbf{n}=\widetilde{\eta}(t)\mathbf{n}\,, \tag{6.78}$$

where

$$\widetilde{\mathcal{A}}(\mathbf{w})=\gamma\Big\{k\lambda|\mathbf{w}+\mathbf{v}_\infty|^{k-2}(\mathbf{w}+\mathbf{v}_\infty)+\lambda_0\Big(\frac{1}{2}\big((\mathbf{w}+\mathbf{v}_\infty)\cdot\mathbf{n}\big)\mathbf{w}+\frac{|\mathbf{w}|^2}{4}\mathbf{n}\Big)\Big\}$$

and

$$\widetilde{\eta}(t)=-\int_{\partial\Omega}\widetilde{\mathcal{A}}(\mathbf{w})\cdot\mathbf{n}\,ds\Big/\int_{\partial\Omega}ds\,.$$

Furthermore, the following compatibility conditions hold:

$$\big[(\gamma\mathbf{w})\cdot\mathbf{n}\big]\big|_{t=0}=(\gamma\mathbf{w}_0)\cdot\mathbf{n}\,,$$

$$\Big(\frac{1}{2}\lambda_0\gamma w_\pi+2\lambda\partial_t\gamma\mathbf{w}\cdot\mathbf{n}\Big)|_{t=T}=0\,,\quad (\lambda\partial_t\gamma\mathbf{w})\cdot\boldsymbol{\tau}|_{t=T}=0\,, \tag{6.79}$$

where w_π is the primitive for the projection ∇w_σ of $\mathbf{w}$ onto ∇H_π determined by (6.51).

To complete the proof, it remains to show that $\lambda_0\neq 0$ so that we can choose $\lambda_0=1$. Assume $\lambda_0=0$. Then (6.76), (6.77), (6.36), and (6.39) yield $\mathbf{q}\equiv\mathbf{0}$ by standard techniques of energy estimates and the Gronwall inequality. Also, equation (6.76) and the condition $\int_{\partial\Omega}r\,ds=0$ imply $r=0$. We note that $\lambda\neq 0$ because $(\mathbf{q},\lambda_0,\lambda,r)=(\mathbf{0},0,\lambda,0)\neq(\mathbf{0},0,0,0)$. By (6.70), $\lambda>0$. Then, by virtue of (6.71), $\mathbf{w}$ is also a solution of the following modified minimization problem: seek a $\mathbf{w}\in Y$ such that the functional (3.5) is minimized subject to the *equality* constraints (3.1), (3.3), and

$$\int_0^T\int_{\partial\Omega}(|\mathbf{w}+\mathbf{v}_\infty|^k+|\partial_t\mathbf{w}|^2)\,ds\,dt=M\,. \tag{6.80}$$

We now show that this minimization problem satisfies the conditions of Theorem 6.1. Indeed, we set $X_1=Y_0$ and $X_2=L^2\big(0,T;\mathbf{V}^{-1}(\Omega)\big)\times\mathbb{R}$. We define the mapping f by $f(\mathbf{y})=\mathcal{J}(\mathbf{w}+\mathbf{y})$, where $\mathcal{J}$ is the functional (3.5) and define

$$\widetilde{F}(\mathbf{y})=\begin{pmatrix}\partial_t(\mathbf{w}+\mathbf{y})-\mu P\Delta(\mathbf{w}+\mathbf{y})+P\big[\big((\mathbf{w}+\mathbf{y}+\mathbf{v}_\infty)\cdot\nabla\big)(\mathbf{w}+\mathbf{y})\big]\\ \int_0^T\int_{\partial\Omega}(|\mathbf{w}+\mathbf{y}+\mathbf{v}_\infty|^k+|\partial_t\mathbf{w}+\partial_t\mathbf{y}|^2)\,ds\,dt-M\end{pmatrix},$$

where $P:\mathbf{H}^{-1}(\Omega)\to\mathbf{V}^{-1}(\Omega)$ is the orthogonal projection. Then $\widetilde{F}'(\mathbf{0}):X_1\to X_2$ is defined by

$$\langle\widetilde{F}'(\mathbf{0}),\mathbf{y}\rangle=\begin{pmatrix}\partial_t\mathbf{y}-\mu P\Delta\mathbf{y}+P(\mathbf{y}\cdot\nabla)\mathbf{w}+P\big((\mathbf{w}+\mathbf{v}_\infty)\cdot\nabla\big)\mathbf{y}\\ \int_0^T\int_{\partial\Omega}(k|\mathbf{w}+\mathbf{v}_\infty|^{k-2}(\mathbf{w}+\mathbf{v}_\infty)\cdot\mathbf{y}+2\partial_t\mathbf{w}\cdot\partial_t\mathbf{y})\,ds\,dt\end{pmatrix}.$$

To show that $\widetilde{F}'(\mathbf{0})$ is an epimorphism, we first observe that this operator is continuous. Next we need to show that for each $\mathbf{f} \in L^2\big(0,T;\mathbf{V}^{-1}(\Omega)\big)$ and $\zeta \in \mathbb{R}$, the system

$$\begin{aligned}&\langle \partial_t \mathbf{y}(t), \mathbf{z}\rangle + \mu \int_\Omega \nabla \mathbf{y}(t) : \nabla \mathbf{z}\, d\mathbf{x} + \int_\Omega \big((\mathbf{w}(t)+\mathbf{v}_\infty)\cdot\nabla\big)\mathbf{y}(t)\cdot\mathbf{z}\, d\mathbf{x} \\ &+ \int_\Omega \big(\mathbf{y}(t)\cdot\nabla\big)\mathbf{w}(t)\cdot\mathbf{z}\, d\mathbf{x} = \int_\Omega \mathbf{f}(t)\cdot\mathbf{z}\, d\mathbf{x} \qquad \forall\, \mathbf{z}\in \mathbf{V}_0^1(\Omega),\ \text{a.e. } t\in(0,T)\,,\end{aligned} \tag{6.81}$$

$$\mathbf{y}|_{t=0} = \mathbf{0} \qquad \text{in } \mathbf{V}^0(\Omega), \tag{6.82}$$

and

$$\int_0^T \int_{\partial\Omega} \Big(k|\mathbf{w}+\mathbf{v}_\infty|^{k-2}(\mathbf{w}+\mathbf{v}_\infty)\cdot\mathbf{y} + 2\partial_t\mathbf{w}\cdot\partial_t\mathbf{y}\Big)\, ds\, dt = \zeta \tag{6.83}$$

has a solution $\mathbf{y} \in Y_0$.

To this end we first look for a $\mathbf{y} \in \gamma_{S_T} Y_0$ satisfying (6.83). ($\gamma_{S_T} Y_0$ is the space of functions belonging to Y_0 restricted to S_T.) It suffices to show that there exists a $\mathbf{y} \in \gamma_{S_T} Y_0$ for which the left side of (6.83) is not zero, for then we can obtain (6.83) by multiplying $\mathbf{y}$ by a suitable constant. Suppose that for every $\mathbf{y} \in \gamma_{S_T} Y_0$ the equality

$$\int_0^T \int_{\partial\Omega} \Big(k|\mathbf{w}+\mathbf{v}_\infty|^{k-2}(\mathbf{w}+\mathbf{v}_\infty)\cdot\mathbf{y} + 2\partial_t(\mathbf{w}+\mathbf{v}_\infty)\cdot\partial_t\mathbf{y}\Big)\, ds\, dt = 0$$

holds. This equality and (6.79) with $\lambda_0 = 0$ imply that $\mathbf{w}+\mathbf{v}_\infty$ satisfies the relations

$$-2\partial_{tt}(\mathbf{w}+\mathbf{v}_\infty) + k|\mathbf{w}+\mathbf{v}_\infty|^{k-2}(\mathbf{w}+\mathbf{v}_\infty) = \mathbf{0} \qquad \text{on } (0,T)\times\partial\Omega \tag{6.84}$$

and

$$\partial_t(\mathbf{w}+\mathbf{v}_\infty)\big|_{t=T} = \mathbf{0} \qquad \text{on } \partial\Omega\,. \tag{6.85}$$

Note also that

$$(\mathbf{w}+\mathbf{v}_\infty)\big|_{t=0,\mathbf{x}\in\partial\Omega} = \mathbf{v}_0\big|_{\partial\Omega} \equiv \mathbf{0}\,. \tag{6.86}$$

We multiply (6.84) by $\partial_t\big(\mathbf{w}+\mathbf{v}_\infty\big)$ and obtain

$$-\partial_t|\partial_t(\mathbf{w}+\mathbf{v}_\infty)|^2 + \partial_t|\mathbf{w}+\mathbf{v}_\infty|^k = 0 \qquad \text{on } (0,T)\times\partial\Omega\,,$$

which together with (6.85) implies

$$-|\partial_t(\mathbf{w}+\mathbf{v}_\infty)|^2 + |\mathbf{w}+\mathbf{v}_\infty|^k = |\mathbf{w}(T,\cdot)+\mathbf{v}_\infty|^k \qquad \text{on } (0,T)\times\partial\Omega\,.$$

This equality taken at $t=0$ yields

$$-\big|\partial_t\big(\mathbf{w}(0,\mathbf{x})+\mathbf{v}_\infty\big)\big|^2 = |\mathbf{w}(T,\mathbf{x})+\mathbf{v}_\infty|^k \qquad \text{on } \partial\Omega\,,$$

which implies

$$\big|\partial_t\big(\mathbf{w}(0,\mathbf{x})+\mathbf{v}_\infty\big)\big|^2 = 0 \qquad \text{and} \qquad |\mathbf{w}(T,\mathbf{x})+\mathbf{v}_\infty|^k = 0 \qquad \text{on } \partial\Omega\,,$$

or we rewrite the last relation as

$$\mathbf{w}(T,\mathbf{x}) + \mathbf{v}_\infty = \mathbf{0} \qquad \text{on } (0,T)\times\partial\Omega\,. \tag{6.87}$$

We deduce from the differential equation (6.84) and boundary conditions (6.85) and (6.87) that $(\mathbf{w}+\mathbf{v}_\infty)=\mathbf{0}$ on $(0,T)\times\partial\Omega$. This contradicts (6.80). Therefore, there exists a $\mathbf{z}\in\gamma_{S_T}Y_0$ satisfying (6.83), where $\mathbf{y}$ is replaced by $\mathbf{z}$.

We supplement the system (6.81)–(6.82) with the boundary condition

$$\mathbf{y}|_{(0,T)\times\partial\Omega} = \mathbf{z}\,. \tag{6.88}$$

Using the techniques in the proof of Theorem 4.4 we see that (6.81)–(6.82) and (6.88) indeed has a (unique) solution $\mathbf{y}\in\mathcal{V}^{(1)}(Q_T)$ (the situation now is even simpler, as the system (6.81)–(6.82) is linear). Note that substituting $\mathbf{z}$ from (6.88) into (6.83) in place of $\mathbf{y}$ makes (6.83) valid. Clearly, $\mathbf{y}\in Y_0$. Hence we have proved that $\widetilde{F}'(0)$ is an epimorphism, so that we have verified all the assumptions in Theorem 6.1. By virtue of Theorem 6.1, every Lagrange multiplier triplet $(\widetilde{\mathbf{q}},\widetilde{\lambda}_0,\widetilde{\lambda})$ such that (6.73) holds where $\mathcal{L}$ is defined by (6.72) satisfies $\widetilde{\lambda}_0\neq 0$; in particular, $(\mathbf{q},\lambda_0,\lambda)$ is such a triplet, and therefore $\lambda_0\neq 0$. This contradicts the assumption $\lambda_0=0$. Hence $\lambda_0\neq 0$. □

REMARK. Note that, since we have not employed a separate variable for the control, the boundary condition (3.2) does not appear in the optimality systems of sections 6.3–6.5. In fact, in order to satisfy (3.2) one merely has to choose, once $\mathbf{w}$ is determined from the above optimality system, a control $\mathbf{g}$ such that $\mathbf{g}=\mathbf{w}|_{\partial\Omega}+\mathbf{v}_\infty$ for $t\in(0,T)$. □

REMARK. The complexity of the optimality systems makes it nontrivial to study the regularity of solutions for these systems. The regularity of solutions will be studied elsewhere. □

EXISTENCE OF AN OPTIMAL SOLUTION OF A SHAPE CONTROL PROBLEM FOR THE STATIONARY NAVIER–STOKES EQUATIONS*

MAX D. GUNZBURGER† AND HONGCHUL KIM‡

Abstract. This paper is concerned with an optimal shape control problem for the stationary Navier–Stokes system. A two-dimensional channel flow of an incompressible, viscous fluid is examined to determine the shape of a bump on a part of the boundary that minimizes the viscous drag. After giving a precise formulation of the extremal problem in a function analytic setting, it is shown that optimal solutions exist.

Key words. shape control, optimal design, Navier–Stokes equations, drag minimization

1. Introduction.

The control of fluid flow has long been a subject of interest to engineers and scientists and, recently, due to interest in more complex technological applications, it has also become a subject of intense study in the mathematical community. Broadly speaking, optimal control problems can be characterized by some specified physical objective, e.g., drag reduction, and by a means of achieving that objective, i.e., by specifying the control mechanisms. The latter can be divided into two classes, namely, value controls and shape controls. Value controls include data adjustments such as external body forces, boundary stresses, boundary velocities, heat sources, and heat fluxes and temperatures on the boundary. Meeting the objective through the use of shape controls requires the identification of a shape of the domain, i.e., of the boundary, among a specified class of domains. In this sense, a shape control problem can be viewed as a "free boundary problem."

It is believed that the Navier–Stokes equations describe general flows of fluids ranging from certain gas motions to the lubrication of ball bearings. Thus, optimal shape control problems associated with the Navier–Stokes equations, if settled successfully, have wide and valuable application to aerodynamic and hydrodynamic problems such as the design of car hoods, airplane wings, inlet shapes for jet engines, etc. In this paper, we are concerned with some mathematical issues in a shape control problem associated with flows governed by the stationary, two-dimensional, incompressible Navier–Stokes equations. Such studies are in their infancy and at present, only a scant mathematical literature is available. One of the first studies devoted to an optimal shape design problem for the Navier–Stokes equations is found in [16]; there, attempts were made at determining a minimum drag profile submerged in a homogeneous, steady, viscous fluid by utilizing optimal control theories for distributed parameter systems. In [9], a finite difference method is used in some computational

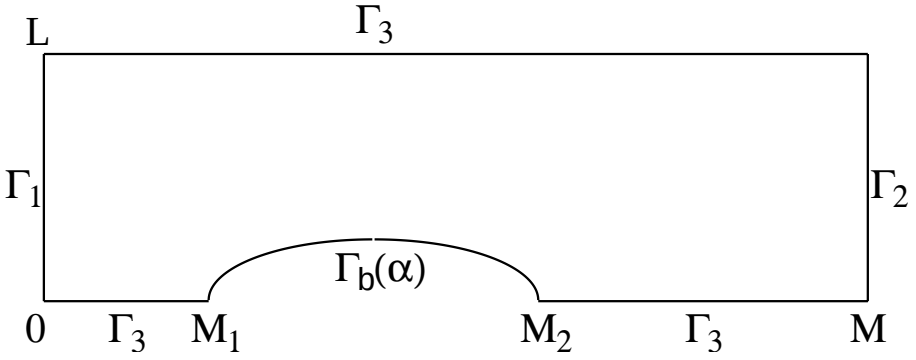

FIG. 1. *The domain* $\Omega(\alpha)$ *for flow through a channel with a bump.*

experiments for determining minimal drag profiles. A successful application of optimal shape theory in fluid mechanics can be found in the design of riblets as a drag reduction device by considering a simplified boundary layer approximation of the Navier–Stokes equations; see [1]. For drag reduction in linear Stokes flow, some rigorous mathematical results for the sensitivity analysis are given in [19]. While the general objective in these studies was drag reduction, one may also consider optimal shapes for other purposes, e.g., lift enhancement, the location of transitional points from laminar to turbulent flow, etc.

In this paper, we deal with a specific drag minimization problem in two dimensions. However, the approach used is discussed in general terms and is applicable to many other optimal control problems involving different objectives and classes of shape controls. Our aim here is to provide a systematic formulation of a problem in which the viscous drag is minimized through the use of shape modifications and to show the existence of optimal solutions. In subsequent papers we will discuss sensitivity and numerical analyses for the shape control problem; these analyses will include the derivation of a formula for the shape gradient that may be used within an optimization algorithm to determine optimal shapes.

2. The model problem. We consider the two-dimensional incompressible flow of a viscous fluid passing through a channel having a finite depth; see Figure 1. Let $\mathbf{g}_1$ and $\mathbf{g}_2$ be the preset velocities at the inflow Γ_1 and outflow Γ_2 of the channel, respectively. Along the bottom and top sides of the channel the velocity vanishes. (If some other type of boundary conditions, e.g., specifying some components of the stress vector, is specified along the left or right or top boundary, the results given below are still valid, although the analyses may be more complicated.) The arc $\Gamma_b(\alpha)$, which is part of the bottom boundary, represents the bump, which is to be determined.

Let the boundary shape corresponding to the bump be represented by the graph of the curve $\alpha : [M_1, M_2] \to [0, L)$. (We thus avoid the separation of the in- and out-flows.) The domain $\Omega(\alpha)$ is composed of two fixed rectangles and a domain with an unknown boundary. Thus, the domain $\Omega(\alpha)$ is determined by the shape of the unknown boundary $\Gamma_b(\alpha)$, which we assume is given by

$$\Gamma_b(\alpha) = \{(x_1, x_2) \in [M_1, M_2] \times [0, L) \mid x_2 = \alpha(x_1)\},$$

where $\alpha(x_1)$ is a function to be determined by the optimization process. Let $\Gamma(\alpha) = \partial\Omega(\alpha) = \cup_{i=1}^{3}\Gamma_i \cup \Gamma_b(\alpha)$, where $\Gamma_3 = \Gamma \backslash (\Gamma_1 \cup \Gamma_2 \cup \Gamma_b(\alpha))$. Assume that both end points

of $\Gamma_b(\alpha)$ are fixed (at $x_1 = M_1, x_2 = 0$ and at $x_1 = M_2, x_2 = 0$) for all admissible domains. Since the domain $\Omega(\alpha)$ is determined by the shape of $\Gamma_b(\alpha)$, one may define the admissible family of curves defining $\Gamma_b(\alpha)$ as follows:

$$\mathcal{U}_{ad} = \{\, \alpha \in C^{0,1}([M_1, M_2]) \mid 0 \le \alpha(x_1) \le L_0 < L,\ |\alpha(x_1) - \alpha(\overline{x}_1)| \le \beta |x_1 - \overline{x}_1|, \\ \forall x_1,\ \overline{x}_1 \in [M_1, M_2],\ \text{and}\ \alpha(M_1) = \alpha(M_2) = 0 \,\},$$

where β is a given *fixed* positive constant. We have denoted the set of Lipschitz continuous functions in $[M_1, M_2]$ by the symbol $C^{0,1}([M_1, M_2])$.

The condition $|\alpha(x_1) - \alpha(\overline{x}_1)| \le \beta |x_1 - \overline{x}_1|$ is invoked to prevent the "blow-up" of the boundary, i.e., to suppress *excessive* oscillations of $\Gamma_b(\alpha)$ and to support the uniform Lipschitz continuity of the moving boundary $\Gamma(\alpha)$. In [17], an example is provided illustrating the observation that when the boundary is allowed to oscillate, the limit of a sequence that minimizes the objective functional may have nothing to do with the given optimization problem. Furthermore, equipped with this condition, it is possible to show that all allowable domains $\Omega(\alpha)$ have the uniform extension property (see [5] and section 4).

We consider, for each $\alpha \in \mathcal{U}_{ad}$, the viscous, incompressible, stationary Navier–Stokes equations in nondimensional form in $\Omega(\alpha)$. Let $\mathbf{u} = (u_1, u_2)^T$ denote the velocity and p the pressure. Then, we have

$$-\nu \Delta \mathbf{u} + (\mathbf{u} \cdot \nabla)\mathbf{u} + \nabla p = \mathbf{f} \qquad \text{in } \Omega(\alpha) \tag{2.1}$$

and

$$\nabla \cdot \mathbf{u} = 0 \qquad \text{in } \Omega(\alpha) \tag{2.2}$$

along with the Dirichlet boundary conditions

$$\mathbf{u} = \mathbf{g} = \begin{cases} \mathbf{g}_1 \text{ on } \Gamma_1, \\ \mathbf{g}_2 \text{ on } \Gamma_2, \\ \mathbf{0} \text{ on } \Gamma_3 \cup \Gamma_b(\alpha), \end{cases} \tag{2.3}$$

where $\mathbf{f}$ and $\mathbf{g}_i$, $i = 1, 2$, are given, fixed functions. Here, Δ and ∇ denote the Laplacian and gradient operators in $\mathbb{R}$, respectively, $\mathbf{f}$ denotes the given external force, and, in the nondimensional form of the Navier–Stokes equations, ν denotes the reciprocal of the Reynolds number *Re*. Note that the constant density has been absorbed into the pressure and the body force. For the compatibility and regularity of solutions, we assume

$$\text{support of } \mathbf{g}_i \subset \Gamma_i \quad \text{and} \quad \int_{\Gamma_1} \mathbf{g}_1 \cdot \mathbf{n}\, d\Gamma + \int_{\Gamma_2} \mathbf{g}_2 \cdot \mathbf{n}\, d\Gamma = 0\,. \tag{2.4}$$

One can examine several objectives for determining the shape of the bump, e.g., the reduction of the drag due to viscosity or the identification of the velocity at a fixed vertical slit downstream of the bump. To fix ideas, we focus on the minimization of the cost functional (or, in the terminology of shape optimization, the design performance functional)

$$\begin{aligned} \mathcal{J}(\alpha) = \mathcal{J}\Big(\Omega(\alpha), \mathbf{u}(\alpha)\Big) &= 2\nu \int_{\Omega(\alpha)} D(\mathbf{u}) : D(\mathbf{u})\, d\Omega \\ &= \frac{\nu}{2} \sum_{i,j=1}^{2} \int_{\Omega(\alpha)} \left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \right)^2 d\Omega\,, \end{aligned} \tag{2.5}$$

where $\mathbf{u}(\alpha)$ is a solution of (2.1)–(2.3) in $\Omega(\alpha)$ and $D(\mathbf{u}) = \frac{1}{2}(\nabla\mathbf{u} + (\nabla\mathbf{u})^T)$ is the deformation tensor for the flow $\mathbf{u}$. This functional represents the rate of energy dissipation due to deformation. Physically, except for an unimportant additive constant whose value depends on the boundary data $\mathbf{g}_1$ and $\mathbf{g}_2$, this functional represents the viscous drag of the flow. In (2.5), the colon denotes the scalar product operator between two tensors. (Again, our results remain valid if we consider other functionals such as the identification of the velocity at a location downstream of the bump.)

The extremal problem we consider is then given as follows:

$$\begin{aligned} &\min_{\alpha\in\mathcal{U}_{ad}} \mathcal{J}(\Omega(\alpha), \mathbf{u}(\alpha)) \quad \text{such that, for some } p(\alpha), \\ &(\mathbf{u}(\alpha), p(\alpha)) \text{ is a solution of (2.1)–(2.3) in } \Omega(\alpha)\,. \end{aligned} \tag{2.6}$$

In preparation for showing the existence of optimal solutions satisfying (2.6), we recast, in the next section, this problem into a precise function space setting.

3. Function space setting of extremal problem.

3.1. Notation. Throughout, depending on the context, $\mathcal{I}$ will denote the identity mapping or the identity matrix; C denotes a generic constant whose value also depends on context. We denote by $H^s(\mathcal{D})$, $s \in \mathbb{R}$, the standard Sobolev space of order s with respect to the set $\mathcal{D}$, which is either the flow domain Ω, or its boundary Γ, or part of its boundary. Whenever m is a nonnegative integer, the inner product over $H^m(\mathcal{D})$ is given by

$$(f,g)_{m,\mathcal{D}} = (f,g)_{0,\mathcal{D}} + \sum_{0<|\sigma|\le m} (D^\sigma f, D^\sigma g)_{0,\mathcal{D}}\,,$$

where $(f,g)_0 = \int_{\mathcal{D}} fg\,d\mathcal{D}$ denotes the inner product over $H^0(\mathcal{D}) = L^2(\mathcal{D})$ and σ denotes a multi-index. Hence, we naturally associate the norm on $H^m(\mathcal{D})$ with $\|f\|_{m,\mathcal{D}} = \sqrt{(f,f)_{m,\mathcal{D}}}$. Whenever there is no chance for confusion, we will, for the flow domain $\Omega(\alpha)$, let $(\cdot,\cdot)_{m,\Omega(\alpha)} = (\cdot,\cdot)_m$ and $\|\cdot\|_{m,\Omega(\alpha)} = \|\cdot\|_m$.

For vector-valued functions and spaces, we use boldface notation. For example, $\mathbf{H}^s(\Omega) = [H^s(\Omega)]^n$ denotes the space of $\mathbb{R}$-valued functions such that each component belongs to $H^s(\Omega)$. Of special interest to us is the space

$$\mathbf{H}^1(\Omega) = \left\{ v_j \in L^2(\Omega) \;\middle|\; \frac{\partial v_j}{\partial x_k} \in L^2(\Omega) \quad \text{for } j,k = 1,2 \right\}$$

equipped with the norm $\|\mathbf{v}\|_1 = (\sum_{i=1}^2 \|v_i\|_1^2)^{1/2}$. For $\Gamma_s \subset \Gamma = \partial\Omega$ with nonzero measure, we also consider the subspace

$$\mathbf{H}^1_{\Gamma_s}(\Omega) = \{\, \mathbf{v} \in \mathbf{H}^1(\Omega) \,|\, \mathbf{v} = \mathbf{0} \text{ on } \Gamma_s \,\};$$

we let $\mathbf{H}^1_0(\Omega) = \mathbf{H}^1_\Gamma(\Omega)$. For any $\mathbf{v} \in \mathbf{H}^1(\Omega)$, we let

$$|\!|\!|\mathbf{v}|\!|\!| = 2\left(\int_\Omega D(\mathbf{v}) : D(\mathbf{v})\,d\Omega\right)^{1/2} = \frac{1}{2}\Big(\sum_{i,j=1}^2 \|\frac{\partial v_i}{\partial x_j} + \frac{\partial v_j}{\partial x_i}\|_0^2\Big)^{1/2}.$$

By applying Korn's inequality and a compactness argument, we obtain the following result.

LEMMA 3.1. *Let Ω be a Lipschitz continuous bounded domain and let Γ_s be a subset of Γ, the boundary of Ω, with a positive measure. Then, there exists a positive constant C such that*

$$|||\mathbf{v}||| \geq C\|\mathbf{v}\|_1 \quad \textit{for all } \mathbf{v} \in \mathbf{H}^1_{\Gamma_s}(\Omega)\,. \qquad \square \tag{3.1}$$

Note that the constant C in (3.1) is independent of the choice of $\mathbf{v}$. Thus, we have that $|||\cdot|||$ is a norm which is equivalent to the norm $\|\cdot\|_{1,\Omega}$ on $\mathbf{H}^1_{\Gamma_s}(\Omega)$. Hence, if we take the inner product on $\mathbf{H}^1_{\Gamma_s}(\Omega)$ as $((\mathbf{u},\mathbf{v}))_1 = 2(D(\mathbf{u}), D(\mathbf{v}))_0$, then $|||\mathbf{u}||| = ((\mathbf{u},\mathbf{u}))_1^{1/2}$.

For each $\alpha \in \mathcal{C}^{0,1}([M_1, M_2])$, let $\Gamma_0(\alpha) = \Gamma_3 \cup \Gamma_b(\alpha)$ and $\Gamma_g = \Gamma_1 \cup \Gamma_2$ so that $\overline{\Gamma} = \overline{\Gamma_0(\alpha)} \cup \overline{\Gamma_g}$. Since $\mathbf{u} = \mathbf{0}$ on $\Gamma_0(\alpha)$, we may take a generalized velocity space to be

$$\mathbf{V}_\alpha = \mathbf{H}^1_{\Gamma_0(\alpha)}(\Omega(\alpha)) = \{\, \mathbf{u} \in \mathbf{H}^1(\Omega(\alpha)) \;\mid\; \mathbf{u} = \mathbf{0} \text{ on } \Gamma_0(\alpha) \,\};$$

$\mathbf{V}_\alpha$ is the space of $\mathbf{H}^1(\Omega(\alpha))$-functions that vanish on $\Gamma_0(\alpha)$; i.e., $\mathbf{V}_\alpha$ is the space on which the *homogeneous* essential boundary conditions are imposed. Let $\mathbf{V}^*_\alpha$ be the dual space of $\mathbf{V}_\alpha$. Note that $\mathbf{V}^*_\alpha$ is a subspace of $\mathbf{H}^{-1}(\Omega(\alpha))$, where the latter is the dual space of $\mathbf{H}^1_0(\Omega(\alpha))$. The duality between $\mathbf{V}^*_\alpha$ and $\mathbf{V}_\alpha$ is denoted by $\langle\cdot,\cdot\rangle_{-1}$.

Let

$$\mathbf{L}^2_g(\Gamma) = \{\, \mathbf{s} \in \mathbf{L}^2(\Gamma) \mid \mathbf{s} = \mathbf{0} \text{ on } \Gamma_0(\alpha) \,\}$$

and let $\gamma_g : \mathbf{V}_\alpha \to \mathbf{L}^2_g(\Gamma)$ be the trace mapping. Let us define

$$\mathbf{W}_\alpha = \gamma_g(\mathbf{V}_\alpha)\,.$$

Let $\mathbf{W}^*_\alpha$ denote its dual space and let $\langle\cdot,\cdot\rangle_{-1/2,\Gamma_g}$ denote the duality pairing between $\mathbf{W}^*_\alpha$ and $\mathbf{W}_\alpha$. For each $l \geq 0$, we denote by $\mathbf{H}^l(\Gamma_g)$ the space of the restrictions to Γ_g of the functions of $\mathbf{H}^l(\Gamma)$, and by $\mathbf{H}^{-l}(\Gamma_g)$, its dual space. It is clear that the restrictions to Γ_g of the functions belonging to $\mathbf{W}_\alpha$ form a closed subspace of $\mathbf{H}^{1/2}(\Gamma_g)$.

Now, let $\mathbf{s}$ be an element of $\mathbf{W}_\alpha$. It is well known that $\mathbf{W}_\alpha$ is a Hilbert space with the norm

$$\|\mathbf{s}\|_{1/2,\Gamma_g} = \inf_{\mathbf{v}\in\mathbf{V}_\alpha,\, \gamma_g\mathbf{v}=\mathbf{s}} \|\mathbf{v}\|_{1,\Omega(\alpha)} \qquad \forall\, \mathbf{s} \in \mathbf{W}_\alpha\,.$$

Let $\mathbf{s}^*$ belong to $\mathbf{W}^*_\alpha$. By the definition of the dual norm, we note that

$$\|\mathbf{s}^*\|_{-1/2,\Gamma_g} = \sup_{\mathbf{s}\in\mathbf{W}_\alpha,\, \mathbf{s}\neq\mathbf{0}} \frac{\langle \mathbf{s}^*, \mathbf{s}\rangle_{-1/2,\Gamma_g}}{\|\mathbf{s}\|_{1/2,\Gamma_g}} \qquad \forall\, \mathbf{s}^* \in \mathbf{W}^*_\alpha\,.$$

For later use, we can derive an alternate definition for the norm $\|\cdot\|_{-1/2,\Gamma_g}$.

LEMMA 3.2. *It holds that*

$$\|\mathbf{s}^*\|_{-1/2,\Gamma_g} = \sup_{\mathbf{v}\in\mathbf{V}_\alpha,\, \mathbf{v}\neq\mathbf{0}} \frac{\langle \mathbf{s}^*, \gamma_g\mathbf{v}\rangle_{-1/2,\Gamma_g}}{\|\mathbf{v}\|_{1,\Omega(\alpha)}} \qquad \forall\, \mathbf{s}^* \in \mathbf{W}^*_\alpha\,. \tag{3.2}$$

Proof. Using the continuity of the trace mapping, it follows that for any $\mathbf{s}^* \in \mathbf{W}^*_\alpha$,

$$\begin{aligned}\langle \mathbf{s}^*, \gamma_g\mathbf{v}\rangle_{-1/2,\Gamma_g} &\leq \|\mathbf{s}^*\|_{-1/2,\Gamma_g}\|\gamma_g\mathbf{v}\|_{1/2,\Gamma_g} \\ &\leq \|\mathbf{s}^*\|_{-1/2,\Gamma_g}\|\mathbf{v}\|_{1,\Omega(\alpha)} \quad \forall\, \mathbf{v} \in \mathbf{V}_\alpha\,.\end{aligned}$$

Hence, we obtain

$$\sup_{\mathbf{v}\in\mathbf{V}_\alpha,\,\mathbf{v}\neq\mathbf{0}} \frac{\langle \mathbf{s}^*, \gamma_g\mathbf{v}\rangle_{-1/2,\Gamma_g}}{\|\mathbf{v}\|_{1,\Omega(\alpha)}} \le \|\mathbf{s}^*\|_{-1/2,\Gamma_g} \qquad \forall\, \mathbf{s}^* \in \mathbf{W}_\alpha^*\,. \tag{3.3}$$

Now, given $\mathbf{s}\in\mathbf{W}_\alpha$, let $\boldsymbol{\xi}$ be an element in $\mathbf{V}_\alpha$ such that $\gamma_g\boldsymbol{\xi}=\mathbf{s}$ and

$$\int_{\Omega(\alpha)}\Big(\nabla\boldsymbol{\xi} : \nabla\boldsymbol{\eta} + \boldsymbol{\xi}\cdot\boldsymbol{\eta}\Big)\,d\Omega = 0 \qquad \forall\,\boldsymbol{\eta}\in\mathbf{H}_0^1(\Omega(\alpha))\,.$$

Clearly, such a $\boldsymbol{\xi}$ is uniquely determined and $\|\boldsymbol{\xi}\|_{1,\Omega(\alpha)} \le \|\boldsymbol{\psi}\|_{1,\Omega(\alpha)}$ for all $\boldsymbol{\psi}\in\mathbf{V}_\alpha$ such that $\gamma_g\boldsymbol{\psi}=\mathbf{s}=\gamma_g\boldsymbol{\xi}$; then, by the definition of $\|\cdot\|_{1/2,\Gamma_g}$, it follows that $\|\mathbf{s}\|_{1/2,\Gamma_g} = \|\boldsymbol{\xi}\|_{1,\Omega(\alpha)}$. As a result, we have that for all $\mathbf{s}\in\mathbf{W}_\alpha$ and $\mathbf{s}^*\in\mathbf{W}_\alpha^*$,

$$\frac{\langle \mathbf{s}^*, \mathbf{s}\rangle_{-1/2,\Gamma_g}}{\|\mathbf{s}\|_{1/2,\Gamma_g}} = \frac{\langle \mathbf{s}^*, \gamma_g\boldsymbol{\xi}\rangle_{-1/2,\Gamma_g}}{\|\boldsymbol{\xi}\|_{1,\Omega(\alpha)}} \le \sup_{\mathbf{v}\in\mathbf{V}_\alpha,\,\mathbf{v}\neq\mathbf{0}} \frac{\langle \mathbf{s}^*, \gamma_g\mathbf{v}\rangle_{-1/2,\Gamma_g}}{\|\mathbf{v}\|_{1,\Omega(\alpha)}}\,.$$

Then, from the definition of $\|\cdot\|_{-1/2,\Gamma_g}$, we have that

$$\|\mathbf{s}^*\|_{-1/2,\Gamma_g} \le \sup_{\mathbf{v}\in\mathbf{V}_\alpha,\,\mathbf{v}\neq\mathbf{0}} \frac{\langle \mathbf{s}^*, \gamma_g\mathbf{v}\rangle_{-1/2,\Gamma_g}}{\|\mathbf{v}\|_{1,\Omega(\alpha)}} \qquad \forall\,\mathbf{s}^*\in\mathbf{W}_\alpha^*\,. \tag{3.4}$$

The combination of (3.3) and (3.4) yields the desired result. ∎

Since the pressure is determined only up to a constant in the mathematical formulation of the Navier–Stokes equations with velocity boundary conditions, we define the space of generalized pressures to be

$$S = \Big\{\, p\in L^2(\Omega(\alpha)) \;\Big|\; \int_{\Omega(\alpha)} p\,d\Omega = 0 \,\Big\}\,.$$

Thus, S consists of square integrable functions having zero mean over $\Omega(\alpha)$.

3.2. Weak variational formulation of the state equations. For the weak variational formulation, we will use the forms

$$\begin{aligned} a(\mathbf{u},\mathbf{v}) &= ((\mathbf{u},\mathbf{v}))_1 = 2\int_{\Omega(\alpha)} D(\mathbf{u}) : D(\mathbf{v})\,d\Omega \\ &= \frac{1}{2}\sum_{i,j=1}^{2}\int_{\Omega(\alpha)}\left(\frac{\partial u_i}{\partial x_j}+\frac{\partial u_j}{\partial x_i}\right)\left(\frac{\partial v_i}{\partial x_j}+\frac{\partial v_j}{\partial x_i}\right)d\Omega \quad \forall\,\mathbf{u},\,\mathbf{v}\in\mathbf{H}^1(\Omega(\alpha)), \end{aligned}$$

$$b(\mathbf{v},q) = -\int_{\Omega(\alpha)} q\,\nabla\cdot\mathbf{v}\,d\Omega = -\sum_{i=1}^{2}\int_{\Omega(\alpha)} q\,\frac{\partial v_i}{\partial x_i}\,d\Omega \quad \forall\,\mathbf{u}\in\mathbf{H}^1(\Omega(\alpha))\,, q\in L^2(\Omega(\alpha))\,,$$

and

$$c(\mathbf{w},\mathbf{u},\mathbf{v}) = \int_{\Omega(\alpha)} (\mathbf{w}\cdot\nabla)\mathbf{u}\cdot\mathbf{v}\,d\Omega = \sum_{i,j=1}^{2}\int_{\Omega(\alpha)} w_j\frac{\partial u_i}{\partial x_j}v_i\,d\Omega \quad \forall\,\mathbf{u},\,\mathbf{v},\,\mathbf{w}\in\mathbf{H}^1(\Omega(\alpha))\,.$$

Obviously, $a(\cdot,\cdot)$ is a continuous bilinear form on $\mathbf{H}^1(\Omega(\alpha))\times\mathbf{H}^1(\Omega(\alpha))$ and $b(\cdot,\cdot)$ is a continuous bilinear form on $\mathbf{H}^1(\Omega(\alpha))\times L^2(\Omega(\alpha))$; also, $c(\cdot,\cdot,\cdot)$ is a continuous trilinear form on $\mathbf{H}^1(\Omega(\alpha))\times\mathbf{H}^1(\Omega(\alpha))\times\mathbf{H}^1(\Omega(\alpha))$ which can be verified by the

Sobolev embedding of $\mathbf{H}^1(\Omega(\alpha)) \subset \mathbf{L}^4(\Omega(\alpha))$ and Hölder's inequality. Moreover, as a consequence of (3.1), we have the coercivity property

$$a(\mathbf{v},\mathbf{v}) \geq C\|\mathbf{v}\|_1^2 \quad \forall\, \mathbf{v} \in \mathbf{V}_\alpha$$

and the inf-sup condition (or LBB condition)

$$\inf_{q\in S} \sup_{\mathbf{v}\in \mathbf{H}_0^1(\Omega)} \frac{b(\mathbf{v},q)}{\|\mathbf{v}\|_1 \|q\|_0} \geq C\,. \tag{3.5}$$

For details concerning these forms and their properties, one may consult [7], [8], [10], [13], [21], or [22].

One can show that (2.1)–(2.3) have the following weak formulation: for each $\alpha \in \mathcal{U}_{ad}$, find $\mathbf{u} \in \mathbf{V}_\alpha$, $p \in S$, and $\mathbf{t} \in \mathbf{W}_\alpha^*$ satisfying

$$\nu a(\mathbf{u},\mathbf{v}) + c(\mathbf{u},\mathbf{u},\mathbf{v}) + b(\mathbf{v},p) - \langle \mathbf{t}, \gamma_g \mathbf{v}\rangle_{-1/2,\Gamma_g} = \langle \mathbf{f},\mathbf{v}\rangle_{-1} \quad \forall \mathbf{v} \in \mathbf{V}_\alpha\,, \tag{3.6}$$

$$b(\mathbf{u},q) = 0 \quad \forall q \in S\,, \tag{3.7}$$

and

$$\langle \mathbf{s},\mathbf{u}\rangle_{-1/2,\Gamma_g} = \langle \mathbf{s},\mathbf{g}\rangle_{-1/2,\Gamma_g} \quad \forall \mathbf{s} \in \mathbf{W}_\alpha^*\,. \tag{3.8}$$

In showing that (3.6) is a weak formulation of (2.1), it is convenient to replace the viscous term in the latter with $2\nu\nabla\cdot(D(\mathbf{u}))$; the equivalence of the two forms of the viscous terms follows from the incompressibility constraint (2.2). Note that the boundary condition on the velocity is enforced weakly through the use of Lagrange multipliers; see [2], [11], and [12].

It can be shown that, in the sense of distributions, $\mathbf{t}$ is the stress vector on Γ_g; i.e.,

$$\mathbf{t} = -p\mathbf{n} + 2\nu D(\mathbf{u})\cdot\mathbf{n} = -p\mathbf{n} + \nu(\nabla\mathbf{u} + (\nabla\mathbf{u})^T)\cdot\mathbf{n} \quad \text{on } \Gamma_g\,.$$

Existence and uniqueness results for solutions of the system (3.6)–(3.8) are contained in the following theorem; for a proof, one may consult [8], [11], [13], [18], [21], or [22].

THEOREM 3.3. *Let $\alpha \in \mathcal{U}_{ad}$ be fixed and let the data satisfy $\mathbf{f} \in \mathbf{V}_\alpha^*$, $\mathbf{g} \in \mathbf{W}_\alpha$, and the compatibility condition* (2.4). *Then,*

I. *there exists at least one solution $(\mathbf{u},p,\mathbf{t}) \in \mathbf{V}_\alpha \times S \times \mathbf{W}_\alpha^*$ of* (3.6)–(3.8)*;*

II. *if $\mathcal{S}$ denotes a set of velocity fields that are solutions of* (3.6)–(3.8)*, then $\mathcal{S}$ is closed in $\mathbf{H}^1(\Omega(\alpha))$ and is compact in $\mathbf{L}^2(\Omega(\alpha))$; and*

III. *if $\nu > \nu_0(\Omega(\alpha);\mathbf{f},\mathbf{g})$ for some positive constant ν_0 whose value is determined by the given data, then $\mathcal{S}$ is composed of a single element.* □

Note that the solutions of (3.6)–(3.8) exist for any Reynolds number; however, III implies that uniqueness can be guaranteed only for "large enough" values of ν or for "small enough" values of the data $(\mathbf{f},\mathbf{g}) \in \mathbf{V}_\alpha^* \times \mathbf{W}_\alpha$.

3.3. The extremal problem. In the notation introduced in section 3.2, the cost functional $\mathcal{J}$ defined in (2.5) can be expressed in the form

$$\mathcal{J}(\alpha) = \mathcal{J}\Big(\Omega(\alpha),\mathbf{u}(\alpha)\Big) = 2\nu \int_{\Omega(\alpha)} D(\mathbf{u}) : D(\mathbf{u})\, d\Omega = \nu((\mathbf{u},\mathbf{u}))_1 = \nu|\!|\!|\mathbf{u}|\!|\!|^2\,. \tag{3.9}$$

We introduce the admissibility set of controls and velocities

$$\mathcal{V}_{ad} = \Big\{ (\alpha, \mathbf{u}(\alpha)) \in \mathcal{U}_{ad} \times \mathbf{V}_\alpha \;\Big|\; \mathcal{J}(\alpha, \mathbf{u}(\alpha)) < \infty, \text{ and there exist } p(\alpha) \in S \text{ and } \mathbf{t}(\alpha) \in \mathbf{W}_\alpha^* \text{ such that } (\mathbf{u}(\alpha), p(\alpha), \mathbf{t}(\alpha)) \text{ is a solution of (3.6)–(3.8)} \Big\}.$$

Then, the extremal problem (2.6) can be restated in the following precise form:

$$\min_{(\alpha, \mathbf{u}(\alpha)) \in \mathcal{V}_{ad}} \mathcal{J}(\alpha, \mathbf{u}(\alpha)) \,. \tag{3.10}$$

4. Convergence notions in sequences of domains. We introduce some concepts dealing with convergence in function spaces and domains.

Let X be a normed vector space, X^* its dual space, and let $\langle \cdot, \cdot \rangle_{X^*}$ denote the duality pairing between functions belonging to X^* and X. We use the notation "$x_n \rightharpoonup x$" to denote the *weak convergence* of a sequence $\{x_n\}$ in X to x, i.e.,

$$x_n \rightharpoonup x \iff \langle f, x_n \rangle_{X^*} \xrightarrow{n \to \infty} \langle f, x \rangle_{X^*} \quad \forall\, f \in X^* \,.$$

Let Y be a subspace of X. Y is called a *weakly closed subspace* of X if, for every sequence $\{x_n\}$ in Y, whenever $x_n \rightharpoonup x^*$ in X, we have $x^* \in Y$. In connection with optimal controls, the following result (see [20]) is very useful for verifying the weak convergence of sequences.

LEMMA 4.1. *Let X be a normed vector space. A sequence $\{x_n\}$ in X converges weakly to $x \in X$ if and only if $\sup_n \|x_n\|_X < \infty$ and $\langle f, x_n \rangle \to \langle f, x \rangle$ for each $f \in F$, where F is a linear span of a set which is dense in X^*. Moreover, if X is a reflexive Banach space, each bounded sequence in X contains a weakly convergent subsequence.* □

In general, the most crucial concept in optimization is semicontinuity, especially when the cost functional contains the gradient of the function. Let S be a subset of X and $\mathcal{K}$ be a real functional on S. We say that $\mathcal{K}$ is (*weakly*) *lower semicontinuous* if, for every sequence $\{x_n\}$ in S, whenever

$$x_n \longrightarrow x \;\; (x_n \rightharpoonup x) \quad \text{in } X \,,$$

we have

$$\liminf_{n \to \infty} \mathcal{K}(x_n) \;\geq\; \mathcal{K}(x) \,.$$

Note that the notion of (weak) lower semicontinuity is a local property.

To deal with domain optimization, we need to define an appropriate convergence criterion with respect to domains. Since domains and corresponding function spaces are changing, we need a fixed domain $\widehat{\Omega}$ such that $\cup_{\alpha \in \mathcal{U}_{ad}} \Omega(\alpha) \subset \widehat{\Omega}$ in order to discuss the convergence of domains and corresponding functions. Thus, in the current setting, we let $\widehat{\Omega}$ and Ω_0 denote the interiors of the rectangular shaded regions depicted in the top and bottom pictures in Figure 2, respectively, so that

$$\bigcup_{\alpha \in \mathcal{U}_{ad}} \Omega(\alpha) \subset \overline{\widehat{\Omega}} \qquad \text{and} \qquad \bigcup_{\alpha \in \mathcal{U}_{ad}} \Gamma_b(\alpha) \subset \overline{\Omega}_0 \,.$$

Note that the definition of $\mathcal{U}_{ad}$ implies that the graph of α for each $\alpha \in \mathcal{U}_{ad}$ lies in the rectangular region Ω_0.

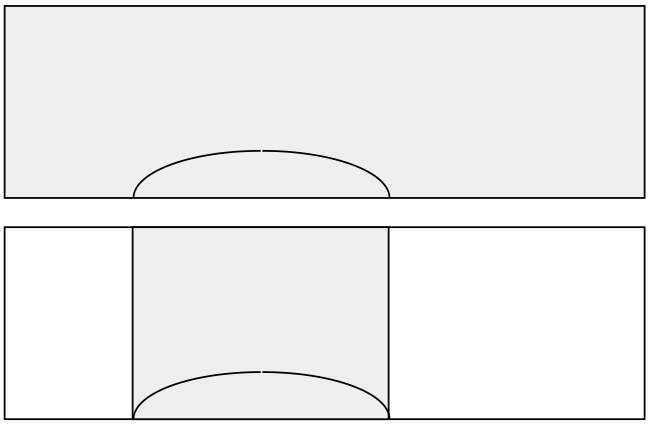

FIG. 2. *The domains* $\widehat{\Omega}$ (*top*) *and* Ω_0 (*bottom*).

A domain class for which optimal shape problems usually have an optimal solution has been studied in [5] and [6]. It was shown in [5] that the set of domains with the cone property is compact for the strong $L^2(\widehat{\Omega})$-topology of the characteristic functions of its elements. Let χ_Ω denote the characteristic function of the domain Ω which is included in $\widehat{\Omega}$. The convergence of the sequence $\{\Omega_m\}$ of domains having the cone property may be defined by

$$\Omega_m \to \Omega \iff \int_{\widehat{\Omega}} |\chi_{\Omega_m} - \chi_\Omega|^2 \, d\Omega \to 0 \quad \text{as } m \to \infty \,.$$

This method of convergence using characteristic functions is often used to solve some specific shape optimization problems such as the transmission problem governed by a pair of different elliptic equations over adjacent regions; see, e.g., [4] and [16]. However, since the convergence of characteristic functions does not preserve the regularity of domains, it is not appropriate for dealing with general shape optimization problems in which the regularity of domains is a concern.

In our case, the domains $\{\Omega(\alpha)\}_{\alpha \in \mathcal{U}_{ad}}$ are determined by the variable part $\Gamma_b(\alpha)$ of the boundary $\Gamma(\alpha)$. Thus, it is more natural to define the convergence of domains in terms of functions α belonging to $\mathcal{U}_{ad}$. Let $\{\alpha_n\}$ be a sequence in $\mathcal{U}_{ad}$. For each $\alpha_n \in \mathcal{U}_{ad}$, let $\Omega_n = \Omega(\alpha_n)$. We define the convergence of Ω_n to $\Omega(\alpha)$ by

$$\Omega_n \to \Omega(\alpha) \iff \|\alpha_n - \alpha\|_\infty = \max_{M_1 \le x_1 \le M_2} |\alpha_n(x_1) - \alpha(x_1)| \to 0 \,.$$

Remark. In general shape optimization problems, more stringent topologies are often introduced to enforce the convergence of geometrical elements; see, e.g., [14] and [16]. When the inclusive relation between subdomains of $\mathbb{R}$ is the main issue, as in problems of domain identification, the topology induced by the following *Hausdorff metric* is widely used: let A and B be two closed subsets of $\mathbb{R}$ and define the Hausdorff metric δ by

$$\delta(A,B) = \max\{\rho(A,B), \rho(B,A)\} \,, \qquad \text{where} \qquad \rho(A,B) = \sup_{x \in A} \inf_{y \in B} |x-y|_{\mathbb{R}} \,.$$

Then, the topology on the closed subsets of $\mathbb{R}$ is defined by

$$A_m \longrightarrow A \iff \delta(A_m, A) \to 0 \,.$$

The most important property of this topology is that it preserves the relation of domain inclusions.

Remark. Another important topology can be used in conjunction with mapping techniques. Let A be a fixed domain in $\mathbb{R}$. Suppose domain perturbations are described by a family of bijective mappings having some regularities, for example, $\mathcal{F}_k = \{T(A) \mid T \in C^k \text{ and } T \text{ is bijective}\}$. Then, the convergence of domains can be defined using the minimal norm $\|T - \mathcal{I}\| + \|T^{-1} - \mathcal{I}\|$ among the mappings T such that $T(A) \in \mathcal{F}_k$.

Recall that $\alpha \in \mathcal{C}^{0,1}([M_1, M_2])$ so that $\Omega(\alpha)$ is Lipschitz continuous. In fact, $\Omega(\alpha)$ is a uniformly Lipschitz continuous domain for each $\alpha \in \mathcal{U}_{ad}$ so that the possibility of domains $\{\Omega(\alpha)\}_{\alpha \in \mathcal{U}_{ad}}$ having a *cusp* is excluded. Hence, for each $\alpha \in \mathcal{U}_{ad}$, the domain $\Omega(\alpha)$ has the uniform extension property which we now discuss.

Let Γ denote the boundary of the domain Ω. Ω is said to have a *cusp* at $x \in \Gamma$ if no affine image in $\overline{\Omega}$ of a finite cone has a vertex at x. We observe that if a certain domain has the *cone property*, then using the homogeneity along a line segment emanating from the vertex of the cone, a function with small support in a neighborhood of the vertex may be perturbed into the whole cone. Based on this fact, the following result is given in [5].

LEMMA 4.2. *The open sets satisfying the cone property are the uniform Lipschitz sets.* □

For domain perturbations, the following extension property given in, e.g., [15], plays a central role.

PROPOSITION 4.3 (Calderón's extension theorem). *For every uniform Lipschitz domain Ω in $\mathbb{R}$ and every positive integer m there exists a linear continuous extension operator*

$$P : H^m(\Omega) \longrightarrow H^m(\mathbb{R}) \tag{4.1}$$

such that for each $f \in H^m(\Omega)$

$$\|Pf\|_{m,\mathbb{R}} \leq C \|f\|_{m,\Omega}\,, \tag{4.2}$$

where the positive constant C depends only on the cone embedded in Ω. □

Let γ_Ω denote the restriction operator from $\mathbb{R}$ to Ω. Then, note that for each m, $\gamma_\Omega \circ P = \mathcal{I}_{H^m(\Omega)}$, the identity map over $H^m(\Omega)$. For this reason, P is often called a *lifting*. For a domain $\Omega \subset \mathbb{R}$, if there exists an extension operator P satisfying (4.1) and (4.2) for m, then the domain Ω is said to have an *m-extension property*. Proposition 4.3 states that Lipschitz continuous domains have the m-extension property for each m. Hence, we have the following compact embedding property for bounded Lipschitz continuous domains which can be proved using Rellich's theorem for the compact embedding of $H_0^{m+1}(\Omega)$ into $H_0^m(\Omega)$ and an approriately defined extension operator P.

LEMMA 4.4. *For a bounded Lipschitz continuous domain Ω, the natural injection of $H^{m+1}(\Omega)$ into $H^m(\Omega)$ is compact.* □

Now, let us return to the setting of the extremal problem (3.10). For any $\mathbf{v} \in \mathbf{V}_\alpha$, let $\widehat{\mathbf{v}}$ be its Calderón extension to $\mathbf{H}^1(\widehat{\Omega})$, i.e.,

$$\widehat{\mathbf{v}} = P_{\widehat{\Omega}} \mathbf{v}\,,$$

where $P_{\widehat{\Omega}}$ is the Calderón extension operator (defined on $\Omega(\alpha)$) to $\widehat{\Omega}$. Then, by Proposition 4.3, there exists a positive constant C such that $\|\widehat{\mathbf{v}}\|_{1,\widehat{\Omega}} \leq C \|\mathbf{v}\|_{1,\Omega(\alpha)}$.

Let $\{\alpha_n\}$ be a sequence in $\mathcal{U}_{ad}$ and let

$$\mathbf{V}_{\alpha_n} = \mathbf{H}^1_{\Gamma_0(\alpha_n)}(\Omega(\alpha_n)) = \{\, \mathbf{u} \in \mathbf{H}^1(\Omega(\alpha_n)) \;\mid\; \mathbf{u} = \mathbf{0} \text{ on } \Gamma_0(\alpha_n) \,\}\,.$$

If $\mathbf{v}_n \in \mathbf{V}_{\alpha_n}$ and $\mathbf{v} \in \mathbf{V}_{\alpha}$, the convergence "$\mathbf{v}_n \to \mathbf{v}$" is defined by

$$\mathbf{v}_n \longrightarrow \mathbf{v} \iff \widehat{\mathbf{v}}_n = P_{\widehat{\Omega}}\mathbf{v}_n \rightharpoonup P_{\widehat{\Omega}}\mathbf{v} \equiv \widehat{\mathbf{v}} \quad \text{in } \mathbf{H}^1(\widehat{\Omega})\,.$$

A certain class of functionals with the lower semicontinuity property in domain optimization problems was studied in [6]. We state one useful result.

LEMMA 4.5. *Let Ω and $\{\Omega_m\}$ be bounded domains having the cone property. Let u and u_m be elements in $H^1(\Omega)$ and $H^1(\Omega_m)$ such that $u_m \to u$. Assume that $f(s)$ is continuous, nonnegative, and convex for $s \in \mathbb{R}$. Then, the inequality*

$$\int_{\Omega} f(\nabla u(x))\, d\Omega \le \liminf_{m\to\infty} \int_{\Omega_m} f(\nabla u_m(x))\, d\Omega$$

holds. ∎

5. Existence of optimal solutions. We now turn to the question of existence of optimal solutions for the problem (3.10). We will use what is called *a direct method* in the calculus of variations; i.e., we will try to minimize the cost functional directly rather than to solve the Euler–Lagrange equations.

THEOREM 5.1. *There exists at least one optimal solution $(\alpha^*, \mathbf{u}(\alpha^*)) \in \mathcal{V}_{ad}$ for the problem* (3.10).

Proof. The nonemptiness of $\mathcal{V}_{ad}$ follows from Theorem 3.3 for the existence of solutions of the weak variational formulation (3.6)–(3.8) of the Navier–Stokes system.

We define $\mathbf{u}_n = \mathbf{u}(\alpha_n)$, where $\{\alpha_n, \mathbf{u}(\alpha_n)\}$ is a sequence in $\mathcal{V}_{ad}$. Let $\Omega_n = \Omega(\alpha_n)$ and let $p_n = p(\alpha_n)$ and $\mathbf{t}_n = \mathbf{t}(\alpha_n)$, where $(\mathbf{u}(\alpha_n), p(\alpha_n), \mathbf{t}(\alpha_n))$ is a solution of (3.6)–(3.7) for $\Omega(\alpha_n)$. Since $\mathcal{J}(\alpha, \mathbf{u}(\alpha))$ is obviously bounded from below for every $\alpha \in \mathcal{U}_{ad}$, there exists a minimizing subsequence, which is denoted by the same notation $\{(\alpha_n, \mathbf{u}_n)\}$; i.e, there exists a sequence $\{(\alpha_n, \mathbf{u}_n)\} \in \mathcal{V}_{ad}$ such that

$$\lim_{n\to\infty} \mathcal{J}(\alpha_n, \mathbf{u}_n) = \inf_{(\alpha, \mathbf{u}(\alpha)) \in \mathcal{V}_{ad}} \mathcal{J}(\alpha, \mathbf{u}(\alpha))\,.$$

Since $\Omega_0(\alpha_n)$ is contained in $\overline{\widehat{\Omega}}$ for $\{\alpha_n\} \subset \mathcal{U}_{ad}$, the latter is a family of uniformly bounded equicontinuous functions. Hence, by the definition of $\mathcal{U}_{ad}$ and the Ascoli–Arzelà theorem, there exists a subsequence of $\{\alpha_n\}$, which we again denote by the same notation $\{\alpha_n\}$, and an $\alpha^* \in \mathcal{U}_{ad}$ such that $\alpha_n \to \alpha^*$ uniformly in $[M_1, M_2]$.

Note that for any $(\alpha, \mathbf{u}(\alpha)) \in \mathcal{V}_{ad}$, we have that

$$\nu C_1 \|\mathbf{u}(\alpha)\|^2_{1,\Omega(\alpha)} \le \mathcal{J}(\alpha, \mathbf{u}(\alpha)) = \nu \,|\!|\!|\mathbf{u}(\alpha)|\!|\!|^2 \le \nu C_2 \|\mathbf{u}(\alpha)\|^2_{1,\Omega(\alpha)}\,, \tag{5.1}$$

where C_1 and C_2 are positive constants. The first inequality follows from (3.1), and the last, from the Cauchy–Schwarz inequality. Note that the constant C_2 is independent of $\mathbf{u}(\alpha)$ and $\Omega(\alpha)$; i.e., its value is independent of α. According to (5.1) and the definition of $\mathcal{V}_{ad}$, there exists a positive constant K such that $\|\mathbf{u}_n\|_{1,\Omega_n} < K < \infty$ for all n. Furthermore, due to the uniform extension property we can choose an extension $\widehat{\mathbf{u}}_n$ of $\mathbf{u}_n$ to $\widehat{\Omega}$ and a positive constant C that is independent of n such that

$$\|\widehat{\mathbf{u}}_n\|_{1,\widehat{\Omega}} \le C \|\mathbf{u}_n\|_{1,\Omega_n}\,.$$

Thus, $\|\widehat{\mathbf{u}}_n\|_{1,\widehat{\Omega}}$ is uniformly bounded in $\mathbf{H}^1(\widehat{\Omega})$. From (3.5), (3.6), and the fact that $\|\mathbf{u}_n\|_{1,\Omega_n}$ is uniformly bounded, we have that $\|p_n\|_{0,\Omega_n}$ is uniformly bounded. Let $\widehat{p}_n$ be an extension by zero of p_n to $\widehat{\Omega}$, i.e., $\widehat{p}_n|_{\Omega_n} = p_n$ and $\widehat{p}_n|_{\widehat{\Omega}/\Omega_n} = 0$; clearly, $\|\widehat{p}_n\|_{0,\widehat{\Omega}} = \|p_n\|_{0,\Omega_n}$ so that $\|\widehat{p}_n\|_{0,\widehat{\Omega}}$ is uniformly bounded. From (3.6), Lemma 3.2, and the facts that $\|\mathbf{u}_n\|_{1,\Omega_n}$ and $\|p_n\|_{0,\Omega_n}$ are uniformly bounded, we have that $\|\mathbf{t}_n\|_{-1/2,\Gamma_g}$ is uniformly bounded. Consequently, using the compactness of the continuous embeddings $\mathbf{H}^1(\widehat{\Omega}) \subset \mathbf{L}^2(\widehat{\Omega})$ and $\mathbf{H}^{1/2}(\Gamma_g) \subset \mathbf{L}^2(\Gamma_g)$, one may extract from the sequence $\{\widehat{\mathbf{u}}_n, \widehat{p}_n, \mathbf{t}_n\}$ a subsequence (denoted again by $\{\widehat{\mathbf{u}}_n, \widehat{p}_n, \mathbf{t}_n\}$) in $\mathbf{H}^1(\widehat{\Omega}) \times L^2(\widehat{\Omega}) \times \mathbf{H}^{-1/2}(\Gamma_g)$ such that

$$
\begin{aligned}
\widehat{\mathbf{u}}_n &\rightharpoonup \widehat{\mathbf{u}} && \text{in } \mathbf{H}^1(\widehat{\Omega}),\\
\widehat{\mathbf{u}}_n &\to \widehat{\mathbf{u}} && \text{in } \mathbf{L}^2(\widehat{\Omega}),\\
\widehat{p}_n &\rightharpoonup \widehat{p} && \text{in } L^2(\widehat{\Omega}),\\
\mathbf{t}_n &\rightharpoonup \mathbf{t} && \text{in } \mathbf{H}^{-1/2}(\Gamma_g),\\
\gamma_g\widehat{\mathbf{u}}_n &\rightharpoonup \gamma_g(\widehat{\mathbf{u}}) && \text{in } \mathbf{H}^{1/2}(\Gamma_g),\\
\gamma_g\widehat{\mathbf{u}}_n &\to \gamma_g(\widehat{\mathbf{u}}) && \text{in } \mathbf{L}^2(\Gamma_g)
\end{aligned}
\tag{5.2}
$$

for some $(\widehat{\mathbf{u}}, \widehat{p}, \mathbf{t}) \in \mathbf{H}^1(\widehat{\Omega}) \times \mathbf{L}^2(\widehat{\Omega}) \times \mathbf{H}^{-1/2}(\Gamma_g)$.

Now, define $\mathbf{u}(\alpha^*) = \widehat{\mathbf{u}}\Big|_{\Omega(\alpha^*)}$, $p(\alpha^*) = \widehat{p}\Big|_{\Omega(\alpha^*)}$, and $\mathbf{t}(\alpha^*) = \mathbf{t}$. We wish to show that $(\mathbf{u}(\alpha^*), p(\alpha^*), \mathbf{t}(\alpha^*))$ is a solution of (3.6)–(3.8) over $\Omega(\alpha^*)$. To this end, let us define the function spaces

$$\mathcal{W}_n = \{\, \boldsymbol{\phi} \in [C^\infty(\overline{\Omega}_n)]^2 \;\mid\; \boldsymbol{\phi} = \mathbf{0} \text{ in a neighborhood of } \Gamma_0(\alpha_n) = \Gamma_3 \cup \Gamma(\alpha_n) \,\}$$

and

$$\mathcal{W} = \{\, \boldsymbol{\phi} \in [C^\infty(\overline{\Omega}(\alpha^*))]^2 \;\mid\; \boldsymbol{\phi} = \mathbf{0} \text{ in a neighborhood of } \Gamma_0(\alpha^*) = \Gamma_3 \cup \Gamma(\alpha^*) \,\}\,.$$

Then, it is clear that

$$
\begin{aligned}
\mathbf{V}_{\alpha_n} &= \mathbf{H}^1_{\Gamma_0(\alpha_n)}(\Omega_n) = \text{the closure of } \mathcal{W}_n \text{ in } \mathbf{H}^1(\Omega_n) \quad \text{and}\\
\mathbf{V}^*_{\alpha_n} &= \mathbf{H}^1_{\Gamma_0(\alpha^*)}(\Omega(\alpha^*)) = \text{the closure of } \mathcal{W} \text{ in } \mathbf{H}^1(\Omega(\alpha^*))\,.
\end{aligned}
$$

We may consider $\mathbf{H}^1_{\Gamma_0(\alpha^*)}(\Omega(\alpha^*))$ as a closed subspace of

$$\mathbf{H}^1_L(\widehat{\Omega}) = \{\, \mathbf{u} \in \mathbf{H}^1(\widehat{\Omega}) \;\mid\; \mathbf{u}(x_1, 0) = \mathbf{u}(x_1, L) = \mathbf{0} \,\}$$

by extending all the elements of $\mathbf{H}^1_{\Gamma_0(\alpha^*)}(\Omega(\alpha^*))$ by $\mathbf{0}$ in $\overline{\widehat{\Omega}} - \Omega(\alpha^*)$. Let us take $\boldsymbol{\phi} = (\phi_1, \phi_2)^T \in \mathcal{W}$. Since $\alpha_n \to \alpha^*$ uniformly, $\boldsymbol{\phi} \in \mathcal{W}_m$ for sufficiently large m, say, for $m \geq m_0$. We first consider the equation (3.6) over Ω_m for $m \geq m_0$. If we substitute $\boldsymbol{\phi}$ for $\mathbf{v}$, we obtain that

$$
\begin{aligned}
2\nu \int_{\Omega_m} D(\mathbf{u}_m) : D(\boldsymbol{\phi})\, d\Omega + \int_{\Omega_m} ((\mathbf{u}_m \cdot \nabla)\, \mathbf{u}_m) \cdot \boldsymbol{\phi}\, d\Omega\\
- \int_{\Omega_m} p_m\, \nabla \cdot \boldsymbol{\phi}\, d\Omega - \langle \mathbf{t}_m, \boldsymbol{\phi} \rangle_{-1/2,\Gamma_g} = \langle \mathbf{f}, \boldsymbol{\phi} \rangle_{-1,\Omega_m}\,.
\end{aligned}
\tag{5.3}
$$

We examine each term separately. We first note that

$$\begin{aligned}\int_{\Omega_m} D(\mathbf{u}_m) : D(\boldsymbol{\phi})\, d\Omega &= \int_{\widehat{\Omega}} D(\widehat{\mathbf{u}}_m) : D(\boldsymbol{\phi})\, d\Omega \qquad \text{(by the extension of } \mathbf{u}_m \text{ to } \widehat{\Omega}) \\ &\xrightarrow{m\to\infty} \int_{\widehat{\Omega}} D(\widehat{\mathbf{u}}) : D(\boldsymbol{\phi})\, d\Omega \qquad \text{(by the first equation of (5.2))} \\ &= \int_{\Omega(\alpha^*)} D(\mathbf{u}(\alpha^*)) : D(\boldsymbol{\phi})\, d\Omega \qquad \text{(since we chose } \boldsymbol{\phi} \in \mathcal{W}) .\end{aligned}$$

In a similar fashion, using the third equation of (5.2),

$$\int_{\Omega_m} p_m \nabla\cdot\boldsymbol{\phi}\, d\Omega \xrightarrow{m\to\infty} \int_{\Omega(\alpha^*)} p(\alpha^*) \nabla\cdot\boldsymbol{\phi}\, d\Omega$$

and, using the fourth equation of (5.2),

$$\langle \mathbf{t}_m, \boldsymbol{\phi}\rangle_{-1/2,\Gamma_g} \xrightarrow{m\to\infty} \langle \mathbf{t}(\alpha^*), \boldsymbol{\phi}\rangle_{-1/2,\Gamma_g} .$$

Next, we estimate the nonlinear convective term. Since $\mathbf{u}_m = \mathbf{0}$ on $\Gamma_0(\alpha_m)$ for every m, using integration by parts, we have that

$$\begin{aligned}\int_{\Omega_m} ((\mathbf{u}_m\cdot\nabla)\,\mathbf{u}_m)\cdot\boldsymbol{\phi}\, d\Omega &= \int_{\Gamma_g} (\mathbf{u}_m\cdot\mathbf{n})\,(\mathbf{u}_m\cdot\boldsymbol{\phi})\, d\Gamma \\ &\quad - \int_{\Omega_m} (\nabla\cdot\mathbf{u}_m)\,(\mathbf{u}_m\cdot\boldsymbol{\phi})\, d\Omega - \int_{\Omega_m} ((\mathbf{u}_m\cdot\nabla)\,\boldsymbol{\phi})\cdot\mathbf{u}_m\, d\Omega .\end{aligned} \tag{5.4}$$

Note that the outward unit normal vector $\mathbf{n}$ along Γ_g is fixed throughout the domain perturbations. It follows from the last two equations of (5.2) that

$$\begin{aligned}\int_{\Gamma_g} (\mathbf{u}_m\cdot\mathbf{n})\,(\mathbf{u}_m\cdot\boldsymbol{\phi})\, d\Gamma &= \int_{\Gamma_g} (\mathbf{g}\cdot\mathbf{n})\,(\mathbf{g}\cdot\boldsymbol{\phi})\, d\Gamma \\ &= \int_{\Gamma_g} (\widehat{\mathbf{u}}_m\cdot\mathbf{n})\,(\widehat{\mathbf{u}}_m\cdot\boldsymbol{\phi})\, d\Gamma \\ &\xrightarrow{m\to\infty} \int_{\Gamma_g} (\mathbf{u}(\alpha^*)\cdot\mathbf{n})\,(\mathbf{u}(\alpha^*)\cdot\boldsymbol{\phi})\, d\Gamma .\end{aligned}$$

For the second and third terms of (5.4), we use the fact that every one of the components ϕ_i and $(\nabla\boldsymbol{\phi})_{ij}$ belongs to $L^\infty(\Omega(\alpha^*))$. Since $\|\nabla\cdot\widehat{\mathbf{u}}_m\|_{L^2(\widehat{\Omega})} \le \|\widehat{\mathbf{u}}_m\|_{1,\widehat{\Omega}} < \infty$ for all m, we may extract a subsequence, which is again denoted by $\nabla\cdot\widehat{\mathbf{u}}_m$, such that

$$\nabla\cdot\widehat{\mathbf{u}}_m \rightharpoonup \nabla\cdot\widehat{\mathbf{u}} \qquad \text{in } L^2(\widehat{\Omega}) . \tag{5.5}$$

We note that

$$\begin{aligned}&\int_{\widehat{\Omega}} (\nabla\cdot\widehat{\mathbf{u}}_m)\,(\widehat{\mathbf{u}}_m\cdot\boldsymbol{\phi})\, d\Omega - \int_{\widehat{\Omega}} (\nabla\cdot\widehat{\mathbf{u}})\,(\widehat{\mathbf{u}}\cdot\boldsymbol{\phi})\, d\Omega \\ &= \int_{\widehat{\Omega}} (\nabla\cdot\widehat{\mathbf{u}}_m)(\widehat{\mathbf{u}}_m - \widehat{\mathbf{u}})\cdot\boldsymbol{\phi}\, d\Omega + \int_{\widehat{\Omega}} (\nabla\cdot\widehat{\mathbf{u}}_m - \nabla\cdot\widehat{\mathbf{u}})(\widehat{\mathbf{u}}\cdot\boldsymbol{\phi})\, d\Omega \xrightarrow{m\to\infty} 0 ,\end{aligned}$$

using that $\nabla \cdot \widehat{\mathbf{u}}_m$ is uniformly bounded in $L^2(\widehat{\Omega})$. Consequently, using (5.5) and the uniform extension property, it holds that

$$\begin{aligned}\int_{\Omega_m} (\nabla \cdot \mathbf{u}_m)\,(\mathbf{u}_m \cdot \boldsymbol{\phi})\,d\Omega &= \int_{\widehat{\Omega}} (\nabla \cdot \widehat{\mathbf{u}}_m)\,(\widehat{\mathbf{u}}_m \cdot \boldsymbol{\phi})\,d\Omega \\ &\xrightarrow{m\to\infty} \int_{\widehat{\Omega}} (\nabla \cdot \widehat{\mathbf{u}})\,(\widehat{\mathbf{u}} \cdot \boldsymbol{\phi})\,d\Omega \\ &= \int_{\Omega(\alpha^*)} (\nabla \cdot \mathbf{u}(\alpha^*))\,(\mathbf{u}(\alpha^*) \cdot \boldsymbol{\phi})\,d\Omega\,.\end{aligned}$$

In a similar fashion, we have that

$$\int_{\Omega_m} ((\mathbf{u}_m \cdot \nabla)\,\boldsymbol{\phi}) \cdot \mathbf{u}_m\,d\Omega \xrightarrow{m\to\infty} \int_{\Omega(\alpha^*)} ((\mathbf{u}(\alpha^*) \cdot \nabla)\,\boldsymbol{\phi}) \cdot \mathbf{u}(\alpha^*)\,d\Omega\,.$$

Therefore, combining all the results for the three terms in (5.4), we have that

$$\begin{aligned}&\int_{\Omega_m} ((\mathbf{u}_m \cdot \nabla)\,\mathbf{u}_m) \cdot \boldsymbol{\phi}\,d\Omega \\ &\quad= \int_{\Gamma_g} (\mathbf{u}_m \cdot \mathbf{n})\,(\mathbf{u}_m \cdot \boldsymbol{\phi})\,d\Gamma - \int_{\Omega_m} (\nabla \cdot \mathbf{u}_m)\,(\mathbf{u}_m \cdot \boldsymbol{\phi})\,d\Omega - \int_{\Omega_m} ((\mathbf{u}_m \cdot \nabla)\,\boldsymbol{\phi}) \cdot \mathbf{u}_m\,d\Omega \\ &\quad\xrightarrow{m\to\infty} \int_{\Gamma_g} (\mathbf{u}(\alpha^*) \cdot \mathbf{n})\,(\mathbf{u}(\alpha^*) \cdot \boldsymbol{\phi})\,d\Gamma - \int_{\Omega(\alpha^*)} (\nabla \cdot \mathbf{u}(\alpha^*))\,(\mathbf{u}(\alpha^*) \cdot \boldsymbol{\phi})\,d\Omega \\ &\qquad - \int_{\Omega(\alpha^*)} ((\mathbf{u}(\alpha^*) \cdot \nabla)\,\boldsymbol{\phi}) \cdot \mathbf{u}(\alpha^*)\,d\Omega = \int_{\Omega(\alpha^*)} ((\mathbf{u}(\alpha^*) \cdot \nabla)\,\mathbf{u}(\alpha^*)) \cdot \boldsymbol{\phi}\,d\Omega\,.\end{aligned}$$

Collecting various results, we have, up to the present, shown that

$$\begin{aligned}\nu \int_{\Omega(\alpha^*)} D(\mathbf{u}(\alpha^*)) : D(\boldsymbol{\phi})\,d\Omega + \int_{\Omega(\alpha^*)} ((\mathbf{u}(\alpha^*) \cdot \nabla)\,\mathbf{u}(\alpha^*)) \cdot \boldsymbol{\phi}\,d\Omega \\ + \int_{\Omega(\alpha^*)} p(\alpha^*)\,\nabla \cdot \boldsymbol{\phi}\,d\Omega - \langle \mathbf{t}, \boldsymbol{\phi} \rangle_{-1/2,\Gamma_g} = \langle \mathbf{f}, \boldsymbol{\phi} \rangle_{-1,\Omega(\alpha^*)}\end{aligned}$$

for any $\boldsymbol{\phi} \in \mathcal{W}$. Since $\mathcal{W}$ is dense in $\mathbf{H}^1_{\Gamma_0(\alpha^*)}(\Omega(\alpha^*))$, we can then conclude that $(\mathbf{u}(\alpha^*), p(\alpha^*), \mathbf{t}(\alpha^*))$ satisfies (3.6) over $\Omega(\alpha^*)$.

In a similar manner it can be shown that $(\mathbf{u}(\alpha^*), p(\alpha^*), \mathbf{t}(\alpha^*))$ also satisfies (3.7) and (3.8) over $\Omega(\alpha^*)$. Therefore, $(\alpha^*, \mathbf{u}(\alpha^*)) \in \mathcal{V}_{ad}$ and this implies that $\mathcal{V}_{ad}$ is weakly closed. Also, $\mathcal{J}(\alpha, \mathbf{u}(\alpha))$ is coercive and strongly continuous over $\mathbf{V}_\alpha$ for each $\alpha \in \mathcal{U}_{ad}$. Moreover, it readily follows that $\mathcal{J}(\alpha, \mathbf{u}(\alpha))$ is convex with respect to $\mathbf{u}$. Hence $\mathcal{J}(\alpha, \mathbf{u}(\alpha))$ is weakly lower semicontinuous by Lemma 4.5. Since $(\alpha_n, \mathbf{u}_n)$ is a minimizing sequence such that $(\alpha_n, \mathbf{u}_n) \to (\alpha^*, \mathbf{u}(\alpha^*))$ in $\mathcal{V}_{ad}$,

$$\begin{aligned}\inf_{(\alpha,\mathbf{u}(\alpha))\in\mathcal{V}_{ad}} \mathcal{J}(\alpha, \mathbf{u}(\alpha)) &= \liminf_{n\to\infty} \mathcal{J}(\alpha_n, \mathbf{u}_n) \\ &\geq \mathcal{J}(\alpha^*, \mathbf{u}(\alpha^*)) \geq \inf_{(\alpha,\mathbf{u}(\alpha))\in\mathcal{V}_{ad}} \mathcal{J}(\alpha, \mathbf{u}(\alpha))\,.\end{aligned}$$

Consequently we have $\mathcal{J}(\alpha^*, \mathbf{u}(\alpha^*)) = \inf_{(\alpha,\mathbf{u}(\alpha))\in\mathcal{V}_{ad}} \mathcal{J}(\alpha, \mathbf{u}(\alpha))$ and $(\alpha^*, \mathbf{u}(\alpha^*))$ is an optimal solution for the problem (3.10). ∎

Remark. Since the steady-state Navier–Stokes equations have multiple solutions for large Reynolds numbers, we cannot expect a unique optimal solution. Even when the state equation has a unique solution, the optimal shape need not be unique. This was indicated in [3] for optimal shape control problems for elliptic state equations. The same argument can also be applied to our case.

Acknowledgements. The authors wish to acknowledge the many helpful comments and suggestions of one of the referees that resulted in an improved paper.

CENTRAL LIMIT THEOREM AND LAW OF ITERATED LOGARITHM FOR LEAST SQUARES ALGORITHMS IN ADAPTIVE TRACKING*

BERNARD BERCU†

Abstract. In autoregressive adaptive tracking, we prove that the least squares and the weighted least squares algorithms possess the same asymptotic properties, sharing the same central limit theorem and the same law of iterated logarithm. We also obtain the same asymptotic behavior and show the limitations of these results in the autoregressive with moving average framework.

Key words. linear regression, least squares, central limit theorem, law of iterated logarithm

Notations. For any square matrix A, $\mathrm{tr}(A)$ is the trace of A and $\det(A)$ denotes the determinant of A. In addition, $\lambda_{min}A$ and $\lambda_{max}A$ are the minimum and the maximum eigenvalues of A, respectively. Finally, for any vectorial sequence $X=(X_n)$ and any integer $p\geq 1$, $X_n^p=(X_n^t,\ldots,X_{n-p+1}^t)$.

1. Introduction. Let $(\Omega,\mathcal{A},P)$ be a probability space endowed with a filtration $\mathbf{F}=(\mathcal{F}_n)_{n\geq 0}$, where $\mathcal{F}_n$ is the σ-algebra of the events occurring up to time n. Consider the controlled autoregressive with moving average (ARMA) model of order (p,r) given, for all $n\geq 0$, by

$$X_{n+1}=\theta^t\Psi_n+U_n+\varepsilon_{n+1}, \tag{1}$$

where X_n, U_n, and ε_n are, respectively, the d-dimensional system output, input, and driven noise and $\Psi_n=(X_n^p,\varepsilon_n^r)^t$. In order to estimate the unknown $\delta\times d$ matrix θ with $\delta=d\,(p+r)$, we use the weighted least squares (WLS) algorithm that satisfies, for all $n\geq 0$,

$$\hat{\theta}_{n+1}=\hat{\theta}_n+a_nS_n^{-1}(a)\Phi_n\left(X_{n+1}-U_n-\hat{\theta}_n^t\Phi_n\right)^t, \tag{2}$$

$$S_n(a)=\sum_{k=0}^{n}a_k\Phi_k\Phi_k^t+S, \tag{3}$$

$$\hat{\varepsilon}_{n+1}=X_{n+1}-U_n-\hat{\theta}_{n+1}^t\Phi_n,\qquad \Phi_n=(X_n^p,\hat{\varepsilon}_n^r)^t, \tag{4}$$

where the initial value $\hat{\theta}_0$ is arbitrarily chosen and S is a deterministic, symmetric, and positive definite matrix. We set

$$S_n=\sum_{k=0}^{n}\Phi_k\Phi_k^t+S,\qquad s_n=\mathrm{tr}(S_n). \tag{5}$$

The choice of the weighted sequence $a=(a_n)$ is crucial. If

$$a_n=1 \tag{6}$$

we find again the extended least squares (ELS) algorithm. Otherwise, if

$$a_n = \left(\frac{1}{\log s_n}\right)^{1+\gamma} \tag{7}$$

with $\gamma > 0$, we obtain the WLS algorithm proposed by Duflo and Bercu [4], [5]. For these two algorithms, a wide literature concerning the strong consistency and the optimality in adaptive tracking is available (see, e.g., [4], [5], [6], [8], [9], [10], [11], [13], [15], [20], [26]). In these papers, it is always necessary to establish an excitation property for the regressive sequence $\Phi = (\Phi_n)$. To be more precise, for the strong consistency, one has to prove that

$$\lambda_{min} S_n \longrightarrow +\infty, \qquad \log \lambda_{max} S_n = o(\lambda_{min} S_n) \qquad \text{almost surely (a.s.)} \tag{8}$$

and, for the optimality, that $s_n = O(n)$ a.s. In fact, one always has to show that $n = O(\lambda_{min} S_n)$ and $\lambda_{max} S_n = O(n)$ a.s. In autoregressive (AR) adaptive tracking with $r = 0$, we improve the previous results showing the almost sure convergence

$$\frac{S_n}{n} \longrightarrow L_p, \tag{9}$$

$L_p = \text{diag}\,(\Gamma, \ldots, \Gamma)$, where Γ is the conditional covariance matrix of the driven noise. This convergence allows us to obtain a central limit theorem (CLT) and a law of iterated logarithm (LIL) for both LS and WLS algorithms. Since the WLS introduces less weight to the more recent information than the LS, one may expect that WLS may be inferior to LS in asymptotic properties. However, we prove that in the AR framework, the LS and WLS algorithms possess the same asymptotic properties, sharing the same CLT,

$$\sqrt{n}(\hat{\theta}_n - \theta) \xrightarrow{\mathcal{L}} \mathcal{N}(0, L_p^{-1} \otimes \Gamma), \tag{10}$$

and the same LIL. In addition, we also obtain that the ELS and WLS algorithms have the same asymptotic behavior in the ARMA framework. Finally, there is no loss in asymptotic efficiency by using WLS, which has many other advantages [4], [5], [17], [22] over LS or ELS in adaptive control theory.

The paper is organized as follows. In section 2, we establish in the AR framework the same CLT and LIL for LS and WLS algorithms. In AR adaptive tracking, the limit matrix given in (9) is positive definite, while this is no longer true in ARMA adaptive tracking. In the ARMA framework, in order to obtain strong consistency results, it is necessary to introduce an excitation on the adaptive tracking control. In section 3, we prove that the effect of this excitation is to make the limit matrix in (9) positive definite. Therefore, for the ARMA models of orders one, we establish the same CLT and LIL for ELS and WLS algorithms. In section 4, we show by simulations the limitation of these last results if the ARMA orders are greater than one. A short conclusion is given in section 5. All technical proofs are collected in the Appendices.

2. AR adaptive tracking. We first consider the AR framework with $r = 0$. Let $x = (x_n)$ be a predictable reference trajectory, to track, step by step, by the observation $X = (X_n)$. To this end, we use the adaptive tracking control proposed by Aström and Wittenmark [1] given, for all $n \geq 0$, by

$$U_n = x_{n+1} - \hat{\theta}_n^t \Phi_n. \tag{11}$$

Relation (1) can then be rewritten as

$$X_{n+1} - x_{n+1} = \pi_n + \varepsilon_{n+1}, \tag{12}$$

where $\pi_n = (\theta - \hat{\theta}_n)^t \Phi_n$. Throughout the following, we assume that the reference trajectory x satisfies

$$\sum_{k=1}^{n} \| x_k \|^2 = o(n) \qquad \text{a.s.} \tag{13}$$

We also assume that the driven noise $\varepsilon = (\varepsilon_n)$ is a martingale difference sequence with

$$E\left[\varepsilon_{n+1} \varepsilon_{n+1}^t \mid \mathcal{F}_n \right] = \Gamma, \tag{14}$$

where Γ is a positive definite deterministic covariance matrix. Finally, we assume that ε satisfies the strong law of large numbers; i.e., if

$$\Gamma_n = \frac{1}{n} \sum_{k=1}^{n} \varepsilon_k \varepsilon_k^t, \tag{15}$$

Γ_n converges a.s. to Γ. This is the case if, for example, ε has finite conditional moment of order > 2 or ε is a white noise, i.e., if ε is independant and identically distributed with mean 0 and covariance matrix Γ. Let (C_n) be the average cost matrix sequence defined by

$$C_n = \frac{1}{n} \sum_{k=1}^{n} (X_k - x_k)(X_k - x_k)^t. \tag{16}$$

The adaptive tracking is said to be optimal if C_n converges a.s. to Γ. Let L_p be the block diagonal square matrix of order $\delta_p = dp$,

$$L_p = \operatorname{diag}(\Gamma, \ldots, \Gamma). \tag{17}$$

THEOREM 2.1. *Consider the AR framework with $r = 0$. Assume that ε has finite conditional moment of order > 2. Then, for the LS algorithm, we have*

$$\frac{S_n}{n} \longrightarrow L_p \qquad \textit{a.s.} \tag{18}$$

In addition, the tracking is optimal:

$$\| C_n - \Gamma_n \| = O\left(\frac{\log n}{n} \right) \qquad \textit{a.s.} \tag{19}$$

We can be more precise in (19) *as follows*

$$\frac{1}{\log n} \sum_{k=1}^{n} (X_k - x_k - \varepsilon_k)(X_k - x_k - \varepsilon_k)^t \longrightarrow \delta_p \Gamma \qquad \textit{a.s.} \tag{20}$$

Finally, $\hat{\theta}_n$ is a strongly consistent estimator of θ:

$$\| \hat{\theta}_n - \theta \|^2 = O\left(\frac{\log n}{n} \right) \qquad \textit{a.s.} \tag{21}$$

Proof. The proof is given in Appendix A. □

THEOREM 2.2. *Consider the AR framework with $r=0$. Assume that either ε is a white noise or ε has finite conditional moment of order >2. Then, for the WLS algorithm with $a_n^{-1}=(\log s_n)^{1+\gamma}$, where $\gamma>0$, we have*

$$(\log n)^{1+\gamma}\frac{S_n(a)}{n} \longrightarrow L_p \qquad a.s. \tag{22}$$

In addition, the tracking is optimal:

$$\| C_n - \Gamma_n \| = o\left(\frac{(\log n)^{1+\gamma}}{n}\right) \qquad a.s. \tag{23}$$

Finally, $\hat{\theta}_n$ is a strongly consistent estimator of θ:

$$\| \hat{\theta}_n - \theta \|^2 = O\left(\frac{(\log n)^{1+\gamma}}{n}\right) \qquad a.s. \tag{24}$$

Proof. The proof is given in Appendix B. □

Remark. Theorem 2.2 is similar to Theorem 2.1. On the one hand, it is not necessary to require a conditional moment of order >2 for the noise ε. On the other hand, we note a loss in $(\log n)^{\gamma}$ in the rates of convergence.

THEOREM 2.3. *Consider the AR framework with $r=0$. Assume that ε has finite conditional moment of order $\alpha>2$ and that x has the same regularity in norm as ε; i.e., for all $2<\beta<\alpha$,*

$$\sum_{k=1}^{n} \| x_k \|^{\beta} = O(n) \qquad a.s. \tag{25}$$

Then, the LS and the WLS algorithms share the same CLT,

$$\sqrt{n}(\hat{\theta}_n - \theta) \xrightarrow{\mathcal{L}} \mathcal{N}(0, L_p^{-1} \otimes \Gamma), \tag{26}$$

with $L_p^{-1} \otimes \Gamma = \mathrm{diag}(\Gamma^{-1} \otimes \Gamma, \ldots, \Gamma^{-1} \otimes \Gamma)$. In addition, for any vectors $u \in \mathbb{R}^d$ and $v \in \mathbb{R}^{dp}$, they also share the same LIL,

$$\begin{aligned} \limsup_{n\to\infty} \left(\frac{n}{2\log\log n}\right)^{1/2} v^t(\hat{\theta}_n - \theta)u &= -\liminf_{n\to\infty} \left(\frac{n}{2\log\log n}\right)^{1/2} v^t(\hat{\theta}_n - \theta)u \\ &= (v^t L_p^{-1} v)^{1/2}(u^t \Gamma u)^{1/2} \qquad a.s. \end{aligned} \tag{27}$$

In particular,

$$\left(\frac{\lambda_{min}\Gamma}{\lambda_{max}\Gamma}\right) \le \limsup_{n\to\infty} \left(\frac{n}{2\log\log n}\right) \| \hat{\theta}_n - \theta \|^2 \le \left(\frac{\lambda_{max}\Gamma}{\lambda_{min}\Gamma}\right) \qquad a.s. \tag{28}$$

Proof. The proof is given in Appendix C. □

Remark. First, one can realize that (28) improves Theorem 3.1 of Guo [16] for the LS algorithm. Next, we can also prove that Theorem 2.3 holds for the cost matrix sequence (C_n). To be more precise, assume that ε satisfies the following CLT:

$$\sqrt{n}(\Gamma_n - \Gamma) \xrightarrow{\mathcal{L}} \mathcal{N}(0, \Lambda), \tag{29}$$

where Λ is an appropriate deterministic covariance matrix. Then, by (19) or (23), it immediately follows that

$$\sqrt{n}(C_n - \Gamma) \xrightarrow{\mathcal{L}} \mathcal{N}(0, \Lambda) \tag{30}$$

for both LS and WLS algorithms. Moreover, via (19) or (23), we can also obtain an LIL for the sequence (C_n). Finally, in AR adaptive tracking, we can avoid the restrictive assumption (13) on the reference trajectory x. Using the same approach developed in Appendix A, we only need to assume that x satisfies the strong law of large numbers

$$\frac{1}{n}\sum_{k=1}^{n} x_k x_k^t \longrightarrow \Delta \qquad \text{a.s.}, \tag{31}$$

where Δ is a deterministic covariance matrix. Then, we just have to replace Γ by $\Gamma+\Delta$ in relation (17).

3. ARMA adaptive tracking. We now consider the ARMA framework. We always use the adaptive tracking control given, for all $n \geq 0$, by

$$U_n = x_{n+1} - \hat{\theta}_n^t \Phi_n, \tag{32}$$

where the reference trajectory x satisfies (13). Relation (1) can be rewritten as

$$X_{n+1} - x_{n+1} = \pi_n + \varepsilon_{n+1}, \tag{33}$$

where $\pi_n = \theta^t \Psi_n - \hat{\theta}_n^t \Phi_n$. Let L_r be the block diagonal square matrix of order $\delta_r = dr$,

$$L_r = \mathrm{diag}(\Gamma, \ldots, \Gamma). \tag{34}$$

For $s = \inf\{p, r\}$, let K be the rectangular matrix of dimension $\delta_p \times \delta_r$ with all coefficients equal to 0 except its left superior block, which is the block diagonal square matrix of order ds, L_s. Finally, let L be the square matrix of order $\delta = \delta_p + \delta_r$:

$$L = \begin{pmatrix} L_p & K \\ K^t & L_r \end{pmatrix}. \tag{35}$$

Throughout the following, we make use of the traditional assumption of passivity: if C is the matrix polynomial associated with the moving average (MA) part of (1) and I_d is the identity matrix of order d,

$$C^{-1} - \frac{1}{2} I_d \tag{P}$$

is strictly positive real. In the ARMA framework, many results concerning the tracking optimality are available (see, e.g., [2], [5], [11], [15], [16]). It is also well known that we can't directly obtain strong consistency for both ELS or WLS algorithms (see, e.g., [5], [7], [11], [13], [17]). Nevertheless, we prove in the following lemma that convergences (18) and (22) still hold here, replacing L_p by L. This can lead to interesting asymptotic properties.

LEMMA 3.1. *For the ARMA model, assume that* (P) *is satisfied. Then, for the ELS algorithm, if ε has finite conditional moment of order > 2, we have*

$$\frac{S_n}{n} \longrightarrow L \quad \text{a.s.} \tag{36}$$

In addition, for the WLS algorithm with $a_n^{-1} = (\log s_n)^{1+\gamma}$, *where* $\gamma > 0$, *if* ε *is a white noise or if* ε *has finite conditional moment of order* > 2, *we have*

$$(\log n)^{1+\gamma} \frac{S_n(a)}{n} \longrightarrow L \quad a.s. \tag{37}$$

Proof. The proof is given in Appendix D. □

THEOREM 3.2. *For the ARMA model, assume that* (P) *is satisfied and consider the regulation problem with* $x = 0$. *Assume that* ε *has finite conditional moment of order* > 2. *For a positive, nonincreasing, and deterministic sequence* (α_n) *such that* $\alpha_n = O(n)$, *assume that* $\| \varepsilon_n \|^2 = O(\alpha_n)$. *Let* (λ_n) *be a positive, nonincreasing, and deterministic sequence such that* $n^c \alpha_n = O(\lambda_n)$, $n^{1+c}\alpha_n = O(\lambda_n^2)$ *with* $0 < c < 1$ *for the ELS algorithm, and* $c = 0$ *for the WLS algorithm. Finally, assume that*

$$\| \Gamma_n - \Gamma \| = o\left(\frac{\lambda_n}{n}\right) \quad a.s. \tag{38}$$

Then, for both ELS and WLS algorithms, the tracking is optimal:

$$\| C_n - \Gamma \| = o\left(\frac{\lambda_n}{n}\right) \quad a.s. \tag{39}$$

Moreover, we also have

$$\left\| \frac{S_n}{n} - L \right\| = o\left(\frac{\lambda_n}{n}\right) \quad a.s. \tag{40}$$

Finally, on the one hand, it results for the ELS estimator that

$$\| L^{1/2}(\hat{\theta}_n - \theta) \|^2 = o\left(\lambda_n \frac{\log n}{n}\right) \quad a.s. \tag{41}$$

On the other hand, we have for the WLS estimator that

$$\| L^{1/2}(\hat{\theta}_n - \theta) \|^2 = o\left(\frac{\lambda_n}{n}\right) \quad a.s. \tag{42}$$

Remark. If ε has finite conditional moment of order $\alpha > 2$, we can take by Chow's lemma (see, e.g., Corollary 2.8.5 of Stout [23] or [12]) the sequence (λ_n) such that

$$\sum_{k=1}^{\infty} \left(\frac{1}{\lambda_n}\right)^{\alpha/2} < +\infty. \tag{43}$$

We can choose, for example, $\lambda_n = n^\beta$ with $2\alpha^{-1} < \beta < 1$. One can realize that (41) improves Theorem 3.2 (i) of Guo [16].

Proof. By Theorem 1 of Guo and Chen [15] and Theorem 5 of Bercu [5] on the prediction errors sequence (π_n), respectively, we have

$$\sum_{k=0}^{n} \| \pi_k \|^2 = o(n^c \alpha_n) \quad \text{a.s.} \tag{44}$$

with $c > 0$ for the ELS algorithm and

$$\sum_{k=0}^{n} \| \pi_k \|^2 = o(a_n^{-1} + \alpha_n) \quad \text{a.s.} \tag{45}$$

for the WLS algorithm. Then, for these two algorithms, we find that

$$\sum_{k=0}^{n} \| \pi_k \|^2 = o(\lambda_n) \qquad \text{a.s.} \tag{46}$$

By (33), we also have

$$\| C_n - \Gamma_n \| = O\left(\frac{1}{n}\sum_{k=1}^{n} \| \pi_{k-1} \|^2\right) \qquad \text{a.s.,} \tag{47}$$

and we immediately obtain relation (39). Therefore (33), (44), and (45), together with the second assumption on the sequence $\lambda = (\lambda_n)$, imply (40). Finally, for the ELS estimator, by Theorem 1 of Lai and Wei [19], we have $\| \hat{\theta}_{n+1} - \theta \|^2 = O(\log n)$ a.s. Moreover, by Theorem 1 of Bercu [5], the WLS estimator is always a.s. bounded, $\| \hat{\theta}_{n+1} - \theta \|^2 = O(1)$. Therefore, (40) clearly implies (41) and (42), completing the proof of Theorem 3.2. □

In order to obtain strong consistency for ELS and WLS algorithms, we are brought to introduce an excitation on the adaptive tracking control. As one can see below, the effect of this excitation is to make the limit matrix in Lemma 3.1 positive definite. First, we use the continually disturbed control given, for all $n \geq 0$, by

$$U_n = x_{n+1} - \hat{\theta}_n^t \Phi_n + \xi_{n+1}, \tag{48}$$

where the reference trajectory x satisfies (13) and ξ is an exogenous noise of dimension d, adapted to $\mathbf{F}$, with mean 0 and positive definite covariance matrix Λ. In addition, we assume that ξ is independent of ε, of x, and of the initial state of the system. Let

$$\Delta_n = \frac{1}{n}\sum_{k=1}^{n} (\varepsilon_k + \xi_k)(\varepsilon_k + \xi_k)^t. \tag{49}$$

Assume that ξ satisfies the strong law of large numbers, so Δ_n converges a.s. to $\Gamma + \Lambda$. Relation (1) can be rewritten as

$$X_{n+1} - x_{n+1} = \pi_n + \varepsilon_{n+1} + \xi_{n+1}. \tag{50}$$

The adaptive tracking is said to be residually optimal if C_n converges a.s. to $\Gamma + \Lambda$. Let H be the square matrix of order $\delta = \delta_p + \delta_r$,

$$H = \begin{pmatrix} H_p & K \\ K^t & L_r \end{pmatrix}, \tag{51}$$

where H_p is the block diagonal square matrix of order $\delta_p = dp$:

$$H_p = \operatorname{diag}(\Gamma + \Lambda, \ldots, \Gamma + \Lambda). \tag{52}$$

THEOREM 3.3. *For the ARMA model, assume that* (P) *is satisfied. Assume that* ε *has finite conditional moment of order* > 2. *Then, for the ELS algorithm, we have*

$$\frac{S_n}{n} \longrightarrow H \qquad \textit{a.s.} \tag{53}$$

In addition, the tracking is residually optimal:

$$\| C_n - \Delta_n \| = O\left(\frac{\log n}{n}\right) \qquad \textit{a.s.} \tag{54}$$

Finally, $\hat{\theta}_n$ is a strongly consistent estimator of θ:

$$\| \hat{\theta}_n - \theta \|^2 = O\left(\frac{\log n}{n}\right) \qquad a.s. \tag{55}$$

Proof. The proof is given in Appendix D. □

THEOREM 3.4. *For the ARMA model, assume that* (P) *is satisfied. Assume that either ε is a white noise or ε has finite conditional moment of order > 2. Then, for the WLS algorithm with $a_n^{-1} = (\log s_n)^{1+\gamma}$, where $\gamma > 0$, we have*

$$(\log n)^{1+\gamma} \frac{S_n(a)}{n} \longrightarrow H \qquad a.s. \tag{56}$$

In addition, the tracking is residually optimal:

$$\| C_n - \Delta_n \| = o\left(\frac{(\log n)^{1+\gamma}}{n}\right) \qquad a.s. \tag{57}$$

Finally, $\hat{\theta}_n$ is a strongly consistent estimator of θ:

$$\| \hat{\theta}_n - \theta \|^2 = O\left(\frac{(\log n)^{1+\gamma}}{n}\right) \qquad a.s. \tag{58}$$

Proof. The proof is given in Appendix D. □

Remark. We note that Theorems 3.3 and 3.4 are similar to Theorems 2.1 and 2.2. In addition, it is easy to see that the matrix H is positive definite. In fact, if $p \leq r$, then $\det H = (\det \Gamma)^r (\det \Lambda)^p$, and if $p > r$, then $\det H = (\det \Gamma)^r (\det \Lambda)^r (\det(\Gamma + \Lambda))^{p-r}$.

THEOREM 3.5. *For the ARMA model, assume that* (P) *is satisfied, with p and r equal to* 1. *Assume that ε and ξ have finite conditional moments of order $\alpha > 2$. On the one hand, assume that x satisfies* (25) *and*

$$\sum_{k=1}^{n} \| x_k \|^2 = o\left(\frac{n}{\log n}\right) \qquad a.s. \tag{59}$$

for the ELS algorithm. On the other hand, assume that x satisfies (25) *and*

$$\sum_{k=1}^{n} \| x_k \|^2 = o\left(\frac{n}{(\log n)^{2+2\gamma}}\right) \qquad a.s. \tag{60}$$

for the WLS algorithm with $a_n^{-1} = (\log s_n)^{1+\gamma}$, where $\gamma > 0$. Then, the ELS and the WLS algorithms share the same CLT,

$$\sqrt{n}(\hat{\theta}_n - \theta) \xrightarrow{\mathcal{L}} \mathcal{N}(0, H^{-1} \otimes \Gamma). \tag{61}$$

For any vectors $u \in \mathbb{R}^d$ and $v \in \mathbb{R}^\delta$, they also share the same LIL,

$$\begin{aligned} \limsup_{n\to\infty} \left(\frac{n}{2\log\log n}\right)^{1/2} v^t(\hat{\theta}_n - \theta)u &= -\liminf_{n\to\infty} \left(\frac{n}{2\log\log n}\right)^{1/2} v^t(\hat{\theta}_n - \theta)u \\ &= (v^t H^{-1} v)^{1/2} (u^t \Gamma u)^{1/2} \qquad a.s. \end{aligned} \tag{62}$$

In particular,

$$\left(\frac{\lambda_{min}\Gamma}{\lambda_{max}H}\right) \leq \limsup_{n\to\infty} \left(\frac{n}{2\log\log n}\right) \| \hat{\theta}_n - \theta \|^2 \leq \left(\frac{\lambda_{max}\Gamma}{\lambda_{min}H}\right) \quad a.s. \tag{63}$$

Proof. The proof is given in Appendix E. □

4. Simulations. The goal of this section is to show that Theorem 3.5 is no longer true if the orders p or r are greater than 1. From relations (1) and (2), we have

$$S_{n-1}(a)(\hat{\theta}_n - \theta) = M_n(a) - R_{n-1}(a)\theta, \tag{64}$$

$$M_n(a) = M_0 + \sum_{k=1}^{n} a_{k-1}\Phi_{k-1}\varepsilon_k^t, \qquad R_n(a) = \sum_{k=0}^{n} a_k\Phi_k(\Phi_k - \Psi_k)^t \tag{65}$$

with $M_0 = S(\hat{\theta}_0 - \theta)$. By Lemmas C.1 or C.2 in Appendix C, we know how to deal with $M_n(a)$. The remainder $R_n(a)$ is much more complicated to study. This remainder vanishes in the AR framework. Consequently, we can easily establish CLT and LIL as in Theorem 2.3. In order to obtain similar results in the ARMA framework, we have to prove that the remainder $R_n(a)$ can be neglected. This was done with p and r equal to 1 in Theorem 3.5. Unfortunately, if p or r is greater than 1, $R_n(a)$ plays a prominent part and is really very complicated to study. We shall now show it by simulations for the ELS algorithm. Consider the following two models:

$$X_{n+1} = \frac{5}{4}X_n + \frac{1}{2}X_{n-1} + U_n + \frac{3}{4}\varepsilon_n + \varepsilon_{n+1}, \tag{I}$$

$$X_{n+1} = \frac{5}{4}X_n + U_n + \frac{3}{4}\varepsilon_n + \frac{1}{4}\varepsilon_{n-1} + \varepsilon_{n+1}, \tag{II}$$

where ε is a Gaussian white noise $N(0,1)$. For simplicity, we study the regulation problem taking the reference trajectory $x = 0$. Therefore, we use the continually disturbed control

$$U_n = -\hat{\theta}_n^t\Phi_n + \xi_{n+1}, \tag{66}$$

where ξ is an exogenous Gaussian white noise $N(0,1)$. We base our simulations on $M = 500$ realizations of sample size $N = 10000$. In order to keep this section brief, we focus our attention on the behavior of the statistic

$$Z_N = \sqrt{N}H^{1/2}(\hat{\theta}_N - \theta), \tag{67}$$

where the matrix H is for models (I) and (II), respectively:

$$\begin{pmatrix} 2 & 0 & 1 \\ 0 & 2 & 0 \\ 1 & 0 & 1 \end{pmatrix}, \qquad \begin{pmatrix} 2 & 1 & 0 \\ 1 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}. \tag{68}$$

We expect at least that each component of Z_N has $N(0,1)$ distribution. Figure 1 represents the three coordinates of Z_N in model (I). One can realize that the second coordinate is not $N(0,1)$. Figure 2 represents the three coordinates of Z_N in model (II). One can realize that the third coordinate is not $N(0,1)$. Next, if we consider an ARMA model of orders $p = 2$ and $r = 2$, we can also see that the second and the fourth coordinates of Z_N are not $N(0,1)$. We can conclude that if p or r is greater than 1, $R_n(a)$ plays a prominent part which can't be neglected. It would be very nice to clarify the behavior of $R_n(a)$ in ARMA adaptive tracking.

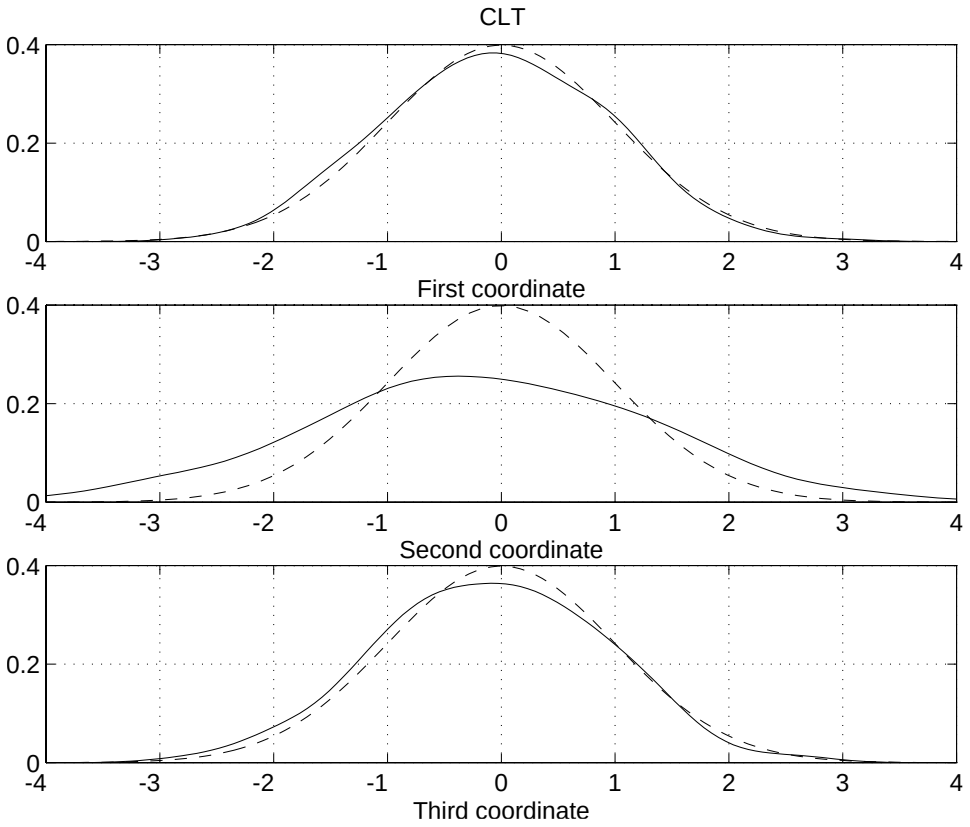

FIG. 1.

5. Conclusion. In AR adaptive tracking, we have proved that the LS and the WLS algorithms share the same CLT and LIL. We have also extended and shown the limitations of these results in the ARMA framework. One can ask the natural question: Why make use of the WLS algorithm?

• First, we have seen in this paper that WLS performs as well as ELS for parameter estimation when the system is persistently excited. There is no loss in asymptotic efficiency by using the WLS algorithm.

• Next, as it was shown in [5], the WLS algorithm is more convenient than the ELS in the analysis of autoregressive with moving average and exogenous control (ARMAX) adaptive tracking thanks to the behavior of the prediction errors sequence. The convergence rates proved for the tracking optimality are in general better for the WLS [5] than for the ELS [15].

• In the ARMAX framework, the leading matrix associated with the control is usually called the high frequency gain. For ARX models with known or unknown high frequency gain, strong consistency and tracking optimality results have been established in [16]. It is reasonable to conjecture that CLT and LIL could also be proved for ARX models with known high frequency gain. However, it would be extremely difficult in the general case.

• Finally, Guo [17] has recently proved the almost sure self-convergence of the WLS algorithm. This property can lead to various applications in adaptive control theory such as adaptive pole-placement and LQG problems [17], [22] for ARMAX models.

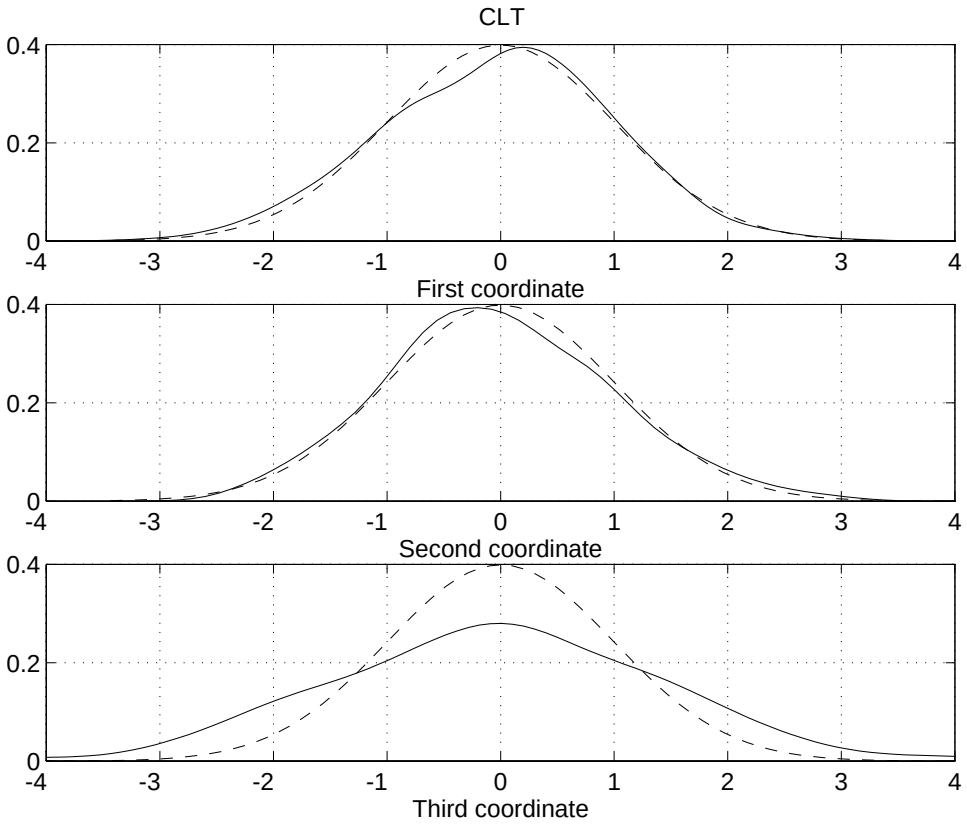

FIG. 2.

Appendix A.

Proof of Theorem 2.1. By the strong law of large numbers and relation (12), we easily prove that $n = O(s_n)$. By Lemma 1 of Guo and Chen [15] or Theorem 1 of Bercu [3] on the prediction errors sequence (π_n), we have

$$\sum_{k=1}^{n}(1 - f_k) \parallel \pi_k \parallel^2 = O(\log s_n) \qquad \text{a.s.}, \tag{A.1}$$

where $f_n = \Phi_n^t S_n^{-1} \Phi_n$. If ε has finite conditional moment of order $\alpha > 2$, using the same approach as Chen and Guo [11], [15], we can show by (A.1) that $\parallel \Phi_n \parallel^2 = O(s_n^\beta)$ with $2\alpha^{-1} < \beta < 1$. We also find by (A.1) and (12) that

$$\sum_{k=1}^{n} \parallel \pi_k \parallel^2 = o(s_n^\beta \log s_n) \qquad \text{a.s.}, \tag{A.2}$$

$$\sum_{k=1}^{n} \parallel X_{k+1} \parallel^2 = o(s_n^\beta \log s_n) + O(n) \qquad \text{a.s.} \tag{A.3}$$

Finally, we obtain that $s_n = o(s_n) + O(n)$, so $s_n = O(n)$. Consequently, we prove the

tracking optimality, as by (12) and (A.2),

$$\| C_n - \Gamma_n \| = O(\frac{1}{n} \sum_{k=1}^{n} \| \pi_{k-1} \|^2) \qquad \text{a.s.}, \tag{A.4}$$

$$\sum_{k=1}^{n} \| \pi_k \|^2 = o(n) \qquad \text{a.s.} \tag{A.5}$$

We still have to establish the convergence rate given in (19). As the reference trajectory x satisfies (13), we have already proven the almost sure convergence

$$\frac{1}{n} \sum_{k=0}^{n} X_k X_k^t \longrightarrow \Gamma. \tag{A.6}$$

Recalling (12), we have for $1 \leq i \leq p-1$ that

$$\sum_{k=1}^{n} X_k X_{k-i}^t = \sum_{k=1}^{n} (\pi_{k-1} + x_k) X_{k-i}^t + \sum_{k=1}^{n} \varepsilon_k X_{k-i}^t. \tag{A.7}$$

The right-hand side of (A.7) is a regressive sequence. Therefore, we have a.s.

$$\left\| \sum_{k=1}^{n} X_k X_{k-i}^t \right\| \leq \sum_{k=1}^{n} \| \pi_{k-1} + x_k \| \| X_{k-i} \| + o\left(\sum_{k=1}^{n} \| X_{k-i} \|^2 \right). \tag{A.8}$$

We prove, by (13) and (A.5), together with the Cauchy–Schwarz inequality, that

$$\sum_{k=1}^{n} X_k X_{k-i}^t = o(n) \qquad \text{a.s.}, \tag{A.9}$$

which implies the convergence (18). As the matrix L_p is positive definite, it clearly follows that $n = O(\lambda_{min} S_n)$, $\| \Phi_n \|^2 = o(n)$, and f_n tends a.s. towards 0. Then, by (A.1), we find that

$$\sum_{k=1}^{n} \| \pi_k \|^2 = O(\log n) \qquad \text{a.s.}, \tag{A.10}$$

and consequently, we obtain the relation (19). By a well-known result established in Theorem 1 of Lai and Wei [19], [20] for the LS estimator, we also have

$$\| \hat{\theta}_{n+1} - \theta \|^2 = O\left(\frac{\log s_n}{\lambda_{min} S_n} \right) \qquad \text{a.s.}, \tag{A.11}$$

which implies (21). Moreover, if $\check{\theta}_n = \hat{\theta}_n - \theta$, we immediately deduce from (28) that

$$\| S_{n-1}^{1/2} \check{\theta}_n \|^2 = o(\log n) \qquad \text{a.s.} \tag{A.12}$$

By Duflo, Senoussi, and Touati [14, p. 560], we also have the almost sure convergence

$$\frac{1}{\log n} \left(\check{\theta}_n^t S_{n-1} \check{\theta}_n + \sum_{k=0}^{n-1} (1 - f_k) \pi_k \pi_k^t \right) \longrightarrow \delta_p \Gamma. \tag{A.13}$$

Finally, (A.12) and (A.13) imply (20), completing the proof of Theorem 2.1. □

Appendix B.

Proof of Theorem 2.2. By Theorem 1 of Bercu and Duflo [4], [5] on the prediction errors sequence (π_n), we have

$$\sum_{n=1}^{\infty} a_n(1-f_n(a)) \parallel \pi_n \parallel^2 < +\infty \qquad \text{a.s.}, \tag{B.1}$$

where $f_n(a) = a_n \Phi_n^t S_n^{-1}(a) \Phi_n$. Then, as $a_n^{-1} = O(s_n)$, we find by (B.1) together with Kronecker's lemma that

$$\sum_{k=1}^{n} \parallel \pi_k \parallel^2 = o(s_n) \qquad \text{a.s.} \tag{B.2}$$

Contrary to the LS algorithm, we can easily prove that $s_n = O(n)$. In fact, (B.2) and (12) immediately imply

$$\sum_{k=1}^{n} \parallel X_{k+1} \parallel^2 = o(s_n) + O(n) \qquad \text{a.s.} \tag{B.3}$$

Therefore, $s_n = o(s_n) + O(n)$, so $s_n = O(n)$. Finally, we have established the tracking optimality. In Appendix A, we have also shown that $n^{-1}S_n$ converges a.s. to L_p. Consequently, as the weighting sequence $a = (a_n)$ is nonincreasing, it results that $a_n S_n \leq S_n(a)$ so $na_n = O(\lambda_{min} S_n(a))$ and $f_n(a)$ tends a.s. towards 0. We can conclude by (B.1) that

$$\sum_{k=1}^{n} \parallel \pi_k \parallel^2 = o(a_n^{-1}) \qquad \text{a.s.}, \tag{B.4}$$

which implies relation (23) as s_n has the same order as n, so a_n^{-1} is a.s. equivalent to $(\log n)^{1+\gamma}$. We can also deduce (24), as by Theorem 1 of Bercu and Duflo [4], [5],

$$\parallel \hat{\theta}_{n+1} - \theta \parallel^2 = O\left(\frac{1}{\lambda_{min} S_n(a)}\right) \qquad \text{a.s.} \tag{B.5}$$

Now, we have

$$S_n(a) = a_{n+1} S_n + \sum_{k=1}^{n} b_k \frac{S_k}{k} + R \tag{B.6}$$

with $b_n = n(a_n - a_{n+1})$ and $R = S_0(a) - a_1 S_0$. In addition,

$$\sum_{k=1}^{n} b_k = \sum_{k=1}^{n} a_k - n a_{n+1}. \tag{B.7}$$

Next, as a_n^{-1} is a.s. equivalent to $(\log n)^{1+\gamma}$,

$$\sum_{k=1}^{n} b_k \sim (1+\gamma) \frac{n a_n}{\log n}, \qquad \sum_{k=1}^{n} b_k = o(n a_n) \qquad \text{a.s.} \tag{B.8}$$

Finally, (B.6), together with Toeplitz's lemma, imply the convergence (22), completing the proof of Theorem 2.2. □

Appendix C.

Proof of Theorem 2.3. In order to prove Theorem 2.3, we need the two following lemmas on regressive sequences. They result from the CLT on triangular arrays [18], [21], [25] and from the LIL on martingales [14], [23], [24]. Let $\varepsilon = (\varepsilon_n)$ be a d-dimensional noise, adapted to $\mathbf{F}$, which satisfies (14) where Γ is a deterministic covariance matrix. Let $\varphi = (\varphi_n)$ be a δ-dimensional sequence of random vectors, adapted to $\mathbf{F}$. Set, for $n \geq 0$,

$$M_n = M_0 + \sum_{k=1}^{n} \varphi_{k-1}\varepsilon_k^t, \qquad S_n = \sum_{k=0}^{n} \varphi_k \varphi_k^t + S.$$

LEMMA C.1. *Let (c_n) be a deterministic real sequence increasing to infinity. Assume that, for all $\epsilon > 0$,*

$$(H_1) \qquad c_n^{-1} S_{n-1} \xrightarrow{\mathcal{P}} L,$$

$$(H_2) \qquad c_n^{-1} \sum_{k=1}^{n} E\left[\| \Delta M_k \|^2 \mathbf{1}_{\left\{\|\Delta M_k\| \geq \epsilon\sqrt{c_n}\right\}} \mid \mathcal{F}_{k-1} \right] \xrightarrow{\mathcal{P}} 0,$$

where $\Delta M_n = M_n - M_{n-1}$. Then, $c_n^{-1} M_n$ tends a.s. towards 0 and

$$\frac{1}{\sqrt{c_n}} M_n \xrightarrow{\mathcal{L}} \mathcal{N}(0, L \otimes \Gamma).$$

In addition, if L is positive definite, we have the CLT

$$\sqrt{c_n} S_{n-1}^{-1} M_n \xrightarrow{\mathcal{L}} \mathcal{N}(0, L^{-1} \otimes \Gamma).$$

Remark. Assume that ε has finite conditional moment of order > 2. Then, Lindeberg's condition (H_2) is satisfied if $\| \varphi_n \|^2 = o(c_n)$ a.s.

LEMMA C.2. *Let (c_n) be a deterministic real sequence increasing to infinity. Assume that the noise ε has finite conditional moment of order $\alpha > 2$. Also assume that*

$$(H_3) \qquad c_n^{-1} S_{n-1} \longrightarrow L \quad \text{a.s.},$$

$$(H_4) \qquad \sum_{n=1}^{\infty} \left(\frac{\| \varphi_n \|}{\sqrt{c_n}} \right)^{\beta} < +\infty \quad \text{a.s.},$$

with $2 < \beta \leq \alpha$. Then, for any vector $u \in \mathbb{R}^d$ and $v \in \mathbb{R}^\delta$ such that $v^t L v > 0$, we have

$$\limsup_{n\to\infty} \left(\frac{1}{2c_n \log\log c_n} \right)^{1/2} v^t M_n u = -\liminf_{n\to\infty} \left(\frac{1}{2c_n \log\log c_n} \right)^{1/2} v^t M_n u$$
$$= (v^t L v)^{1/2} (u^t \Gamma u)^{1/2} \quad \text{a.s.}$$

In addition, if L is positive definite, we have the LIL

$$\limsup_{n\to\infty} \left(\frac{c_n}{2\log\log c_n} \right)^{1/2} v^t S_{n-1}^{-1} M_n u = -\liminf_{n\to\infty} \left(\frac{c_n}{2\log\log c_n} \right)^{1/2} v^t S_{n-1}^{-1} M_n u$$
$$= (v^t L^{-1} v)^{1/2} (u^t \Gamma u)^{1/2} \quad \text{a.s.}$$

Theorem 2.3 is a direct application of Lemmas C.1 and C.2. By the relations (1) and (2), we have

$$\hat{\theta}_n - \theta = S_{n-1}^{-1}(a) M_n(a), \tag{C.1}$$

$$M_n(a) = M_0 + \sum_{k=1}^{n} a_{k-1} \Phi_{k-1} \varepsilon_k^t \tag{C.2}$$

with $M_0 = S(\hat{\theta}_0 - \theta)$. On the one hand, for the LS algorithm, we choose $\varphi_n = \Phi_n$ and $c_n = n$. On the other hand, for the WLS algorithm, we take $\varphi_n = a_n \Phi_n$ and $c_n = n/(\log n)^{2+2\gamma}$. First, for the LS algorithm, (26) can be clearly deduced via Lemma C.1 together with (18) and equation (C.1). In addition, if ε has finite conditional moment of order $\alpha > 2$, for all $2 < \beta < \alpha$, we have by Chow's lemma (see, e.g., Corollary 2.8.5 of Stout [23]) that

$$\sum_{k=1}^{n} \| \varepsilon_k \|^\beta = O(n) \qquad \text{a.s.} \tag{C.3}$$

Since the reference trajectory x satisfies (25), we show by (A.10) that

$$\sum_{k=1}^{n} \| X_k \|^\beta = O(n), \qquad \sum_{k=1}^{n} \| \Phi_k \|^\beta = O(n) \quad \text{a.s.} \tag{C.4}$$

Therefore, as $\beta > 2$, (C.4) implies

$$\sum_{n=1}^{\infty} \left(\frac{\| \Phi_n \|}{\sqrt{n}} \right)^\beta < +\infty \qquad \text{a.s.} \tag{C.5}$$

Finally, we find (27) via Lemma C.2 together with (18) and equation (C.1). Next, for the WLS algorithm, set

$$Q_n(a) = \sum_{k=0}^{n} a_k^2 \Phi_k \Phi_k^t + S. \tag{C.6}$$

As in (22), we prove that $c_n^{-1} Q_n(a)$ converges a.s. to L_p. Hence, (22) and equation (C.1) clearly imply (26). In addition, if ε has finite conditional moment of order $\alpha > 2$, for all $2 < \beta < \alpha$, we have by Chow's lemma [23], together with (B.4),

$$\sum_{k=1}^{n} (a_k \| \Phi_k \|)^\beta = O(n) \qquad \text{a.s.} \tag{C.7}$$

Then, it follows from (C.7) that

$$\sum_{n=1}^{\infty} \left(\frac{a_n \| \Phi_n \|}{\sqrt{c_n}} \right)^\beta < +\infty \qquad \text{a.s.} \tag{C.8}$$

Finally, we prove (27) via Lemma C.2 together with (22) and equation (C.1), completing the proof of Theorem 2.3. □

Appendix D.

Proof of Theorems 3.3 and 3.4. First, we prove Lemma 3.1 for both ELS and WLS algorithms. On the one hand, relation (A.1) holds for the ELS algorithm in the ARMAX framework [3], [11], [15]. In addition, by Theorem 1 of Lai and Wei [19], [20], we also have

$$\sum_{k=1}^{n} \| \Phi_k - \Psi_k \|^2 = O(\log s_n) \qquad \text{a.s.} \tag{D.1}$$

If ε has finite conditional moment of order $\alpha > 2$, we can show as in Appendix A that $\| \Phi_n \|^2 = O(s_n^\beta)$ with $2\alpha^{-1} < \beta < 1$. Hence, we find by (A.1) and (33) that

$$\sum_{k=1}^{n} \| \pi_k \|^2 = o(s_n^\beta \log s_n) \qquad \text{a.s.,} \tag{D.2}$$

$$\sum_{k=1}^{n} \| X_{k+1} \|^2 = o(s_n^\beta \log s_n) + O(n) \qquad \text{a.s.} \tag{D.3}$$

Finally, (D.1) together with (D.3) imply that $s_n = o(s_n) + O(n)$, so $s_n = O(n)$. Consequently, we find by (D.2) that

$$\sum_{k=1}^{n} \| \pi_k \|^2 = o(n) \qquad \text{a.s.} \tag{D.4}$$

We now recall that the reference trajectory x satisfies (13). Therefore, exactly as in Appendix A, (33), (D.1), and (D.4) imply the convergence (36) for the ELS algorithm. On the other hand, concerning the WLS algorithm, relation (B.1) holds in the ARMAX framework [4], [5]. In addition, we also have, by Theorem 1 of Bercu [5],

$$\sum_{n=1}^{\infty} a_n \| \Phi_n - \Psi_n \|^2 < +\infty \qquad \text{a.s.} \tag{D.5}$$

As $a_n^{-1} = (\log s_n)^{1+\gamma}$ with $\gamma > 0$, we find by (33), (B.2), and (D.5) together with Kronecker's lemma that $s_n = o(s_n) + O(n)$, so $s_n = O(n)$. Consequently, we immediately obtain by (B.2) that

$$\sum_{k=1}^{n} \| \pi_k \|^2 = o(n) \qquad \text{a.s.} \tag{D.6}$$

Therefore, (33), (D.5), and (D.6) imply the convergence (36) for the WLS algorithm. Finally, via (B.6)–(B.8), we also find the convergence (37) for the WLS algorithm, completing the proof of Lemma 3.1. We now prove Theorems 3.3 and 3.4. We can easily switch to the continually disturbed tracking situation. Indeed, as ξ is an exogenous noise that satisfies the strong law of large numbers, we prove by (50) the convergences (53) and (56) exactly as in Lemma 3.1. Furthermore, since the matrix H is positive definite, we find for the ELS algorithm that $n = O(\lambda_{min} S_n)$, and for the WLS algorithm, that $n a_n = O(\lambda_{min} S_n(a))$. Finally, as the relations (A.1), (A.11) and (B.1), (B.5) hold in the ARMAX framework, Theorems 3.3 and 3.4 are established. □

Appendix E.

Proof of Theorem 3.5. We finally prove Theorem 3.5 for both ELS and WLS algorithms. On the one hand, for the ELS algorithm, by (1) and (2), we have

$$S_{n-1}(\hat{\theta}_n - \theta) = M_n - R_{n-1}\theta, \tag{E.1}$$

$$M_n = M_0 + \sum_{k=1}^{n} \Phi_{k-1}\varepsilon_k^t, \qquad R_n = \sum_{k=0}^{n} \Phi_k(\Phi_k - \Psi_k)^t \tag{E.2}$$

with $M_0 = S(\hat{\theta}_0 - \theta)$. In order to study the remainder R_n, it is enough by (D.1) to work on

$$P_n = \sum_{k=0}^{n} X_k\check{\varepsilon}_k^t, \qquad Q_n = \sum_{k=0}^{n} \varepsilon_k\check{\varepsilon}_k^t, \tag{E.3}$$

where $\check{\varepsilon}_n = \hat{\varepsilon}_n - \varepsilon_n$. The first equality of (4) can be rewritten as

$$\check{\varepsilon}_{n+1} = (1 - f_n)\pi_n - f_n\varepsilon_{n+1} \tag{E.4}$$

with $f_n = \Phi_n^t S_n^{-1}\Phi_n$. By (A.1) and (E.4) together with Chow's lemma [23], we have the almost sure convergence

$$\frac{1}{\log n}\sum_{k=0}^{n} \varepsilon_k\check{\varepsilon}_k^t \longrightarrow -\delta\Gamma. \tag{E.5}$$

Therefore, we immediately obtain $Q_n = o(\sqrt{n})$ a.s. In addition, by (A.1), we also have

$$\left\|\sum_{k=1}^{n} \pi_{k-1}\check{\varepsilon}_k^t\right\| = O(\log n) \qquad \text{a.s.} \tag{E.6}$$

Finally, as the trajectory x satisfies relation (59), we can conclude by (50), (A.1), and the Cauchy–Schwarz inequality that $P_n = o(\sqrt{n})$, so $R_n = o(\sqrt{n})$ a.s. Lemmas C.1 and C.2 together with (53) lead to (61) and (62) for the ELS algorithm. On the other hand, for the WLS algorithm, by (1) and (2), we have

$$S_{n-1}(a)(\hat{\theta}_n - \theta) = M_n(a) - R_{n-1}(a)\theta, \tag{E.7}$$

$$M_n(a) = M_0 + \sum_{k=1}^{n} a_{k-1}\Phi_{k-1}\varepsilon_k^t, \qquad R_n(a) = \sum_{k=0}^{n} a_k\Phi_k(\Phi_k - \Psi_k)^t \tag{E.8}$$

with $M_0 = S(\hat{\theta}_0 - \theta)$. Set

$$P_n(a) = \sum_{k=0}^{n} a_k X_k\check{\varepsilon}_k^t, \qquad Q_n(a) = \sum_{k=0}^{n} a_k\varepsilon_k\check{\varepsilon}_k^t. \tag{E.9}$$

The first equality of (4) can be rewritten as

$$\check{\varepsilon}_{n+1} = (1 - f_n(a))\pi_n - f_n(a)\varepsilon_{n+1} \tag{E.10}$$

with $f_n(a) = a_n\Phi_n^t S_n^{-1}(a)\Phi_n$. The main property of the weighted sequence $a = (a_n)$ is that

$$\sum_{n=1}^{\infty} a_n f_n(a) < +\infty \qquad \text{a.s.} \tag{E.11}$$

Therefore, as $a=(a_n)$ is nonincreasing, we find by (B.1), (E.10), and (E.11) that

$$\left\|\sum_{k=0}^{n} a_k \varepsilon_k \check{\varepsilon}_k^t\right\| = o((\log n)^{1+\gamma}) \qquad \text{a.s.}, \tag{E.12}$$

so $Q_n(a)=o(\sqrt{c_n})$ a.s. with $c_n=n/(\log n)^{2+2\gamma}$. In addition, by (B.1) and (D.5), as $f_n(a)$ tends a.s. towards 0,

$$\left\|\sum_{k=1}^{n} \pi_{k-1} \check{\varepsilon}_k^t\right\| = O(1) \qquad \text{a.s.} \tag{E.13}$$

Finally, as the trajectory x satisfies relation (60), we can conclude by (50), (B.1), and the Cauchy–Schwarz inequality that $P_n(a)=o(\sqrt{c_n})$, so $R_n(a)=o(\sqrt{c_n})$ a.s. Lemmas C.1 and C.2, together with (56), lead to (61) and (62) for the WLS algorithm, completing the proof of Theorem 3.5. □

STOCHASTIC NEAR-OPTIMAL CONTROLS: NECESSARY AND SUFFICIENT CONDITIONS FOR NEAR-OPTIMALITY*

XUN YU ZHOU†

Abstract. Near-optimization is as sensible and important as optimization for both theory and applications. This paper concerns dynamic near-optimization, or near-optimal controls, for systems governed by the Ito stochastic differential equations (SDEs), where both the drift and diffusion terms are allowed to depend on controls and the systems are allowed to be degenerate. Necessary and sufficient conditions for a control to be near-optimal are studied. It is shown that any near-optimal control nearly maximizes the "$\mathcal{H}$-function" (which is a generalization of the usual Hamiltonian and is quadratic with respect to the diffusion coefficients) in some integral sense, and vice versa if certain additional concavity conditions are imposed. Error estimates for both the near-optimality of the controls and the near-maximum of the $\mathcal{H}$-function are obtained, based on some delicate estimates of the adjoint processes. Examples are presented to demonstrate the results.

Key words. stochastic near-optimal control, necessary and sufficient condition, adjoint equation, $\mathcal{H}$-function, Hamiltonian, Ekeland's principle

1. Introduction.

This paper is one in a series of papers studying near-optimal controls. In view of both theory and applications, near-optimality makes as good sense as the (exact) optimality. First, many more near-optimal controls are available than optimal ones. Indeed, optimal controls may not even exist in many situations, while near-optimal controls *always* exist. Second, it is usually much easier to obtain near-optimal controls than optimal ones, both analytically and numerically. For example, optimal production controls for a stochastic two-machine flowshop may involve very complicated switching curves. However, Sethi and Zhou [11] showed that a near-optimal control can be found in the class of the so-called threshold-type policies which involve only two real parameters. Therefore, the original problem can be greatly simplified in analysis, computation, and implementation by considering near-optimal controls. Third, since there are many more candidates for near-optimal controls, it is possible to select among them appropriate ones that are easier for analysis and implementation. For example, optimal feedback controls for linear systems are usually of "bang-bang" type, as is well known. These controls are not continuous in state, making it very difficult to handle analytically. Indeed, even the existence of system states under such controls are not clear in general. However, one can always modify the bang-bang controls into Lipschitz continuous controls with only a small loss in the objective value. Fourth, an optimal control is usually very sensitive for the external perturbation because it is too "greedy" (by the nature of "optimality"!) and does not usually leave allowance to accommodate changing situations. This pitfall becomes significant for stochastic systems, where uncertainties and perturbations are inherent. A good example is optimal production planning for manufacturing systems. The so-called zero-inventory policy is in general optimal in deterministic cases [6], but is no

*Received by the editors April 29, 1996; accepted for publication (in revised form) March 5, 1997. This work was supported by the RGC Earmarked Grant CUHK 249/94E.

†Department of Systems Engineering and Engineering Management, The Chinese University of Hong Kong, Shatin, Hong Kong (xyzhou@se.cuhk.edu.hk).

longer optimal in stochastic cases, even for the simplest one-machine, one-product systems [1]. The reason is that the zero-inventory policy, while resulting in zero surplus cost, is prone to cause shortage (due to various uncertainties involved) which is usually even more costly. Last but not least, for many real systems, insisting on optimal solutions is not only unrealistic but also *unnecessary*, because a near-optimal solution can satisfactorily serve the ultimate purpose of the decision makers in most practical situations.

In the first two papers [13, 14] in this series, near-optimal controls for deterministic dynamic systems (governed by ordinary differential equations) are investigated. Necessary and sufficient conditions of near-optimality are derived and dynamic programming approach is employed to study the behavior of those "good-enough" controls. Starting from this paper, we proceed to treat the stochastic cases. As mentioned earlier, near-optimization makes even better sense in stochastic systems than in deterministic ones due to the presence of uncertainties.

The stochastic systems under consideration in this paper are of the diffusion type, namely, they are governed by the Ito SDEs. As is well known, this kind of models occur in many real-world systems, including those of finance, economy, and manufacturing. The specific purpose of this paper is to derive necessary and sufficient conditions of near-optimality for the controlled diffusion processes. Elliott and Kohlmann [4] studied the necessity part, but as in almost all the previous papers studying the similar problem for deterministic cases based on the Ekeland variational principle, their necessary conditions were derived only for *some* near-optimal controls (see [4, Theorem 4.4]). In this paper, we shall derive necessary conditions for *all* near-optimal controls. More specifically, we will show that *any* ε-optimal control nearly maximizes the so-called $\mathcal{H}$-function in an integral form with an error order of "almost" $\varepsilon^{\frac{1}{3}}$ (see Theorem 4.1 for the precise meaning). Moreover, we prove that under certain concavity conditions, an ε-maximum condition in terms of the $\mathcal{H}$-function in the integral form is sufficient for the near-optimality of order $\varepsilon^{\frac{1}{2}}$. Our results are based on some delicate estimates for the solutions of adjoint equations, which are linear backward SDEs, along with the Ekeland principle.

The plan of the rest of the paper is as follows. In section 2, we formulate the problem and define near-optimality. In section 3, we study some continuity of the adjoint processes with respect to a prescribed metric in the set of admissible controls. Sections 4 and 5 are devoted to the necessary and sufficient conditions for near-optimal controls, respectively. Section 6 discusses the results obtained and presents an example to demonstrate them. Finally, section 7 concludes the paper.

2. Problem formulation and preliminaries. We consider in this paper stochastic optimal control problems of the following kind. For a given $s \in [0, T]$, by the set of admissible controls $U_{ad}[s, T]$ we mean the collection of (i) standard probability spaces $(\Omega, \mathcal{F}, P)$ along with l-dimensional Brownian motions $B = \{B(t) : s \leq t \leq T\}$ with $B(s) = 0$, and (ii) Γ-valued $\mathcal{F}_t^s$-adapted measurable processes $u(\cdot) = \{u(t) : s \leq t \leq T\}$, where $\mathcal{F}_t^s$ is the natural filtration generated by $B(t)$ augmented by all the P-null sets in $\mathcal{F}$, and Γ is a given closed set in some Euclidean space R^m. We denote $(\Omega, \mathcal{F}, P, B; u(\cdot)) \in U_{ad}[s, T]$, but occasionally we will write only $u(\cdot) \in U_{ad}[s, T]$ if no ambiguity arises.

Let $(s, y) \in [0, T) \times R^n$ be given, representing the initial time and initial state, respectively, of the system. For each $(\Omega, \mathcal{F}, P, B; u(\cdot)) \in U_{ad}[s, T]$, the corresponding cost is

$$J(s,y;u(\cdot)) = E\left\{\int_s^T L(t,x(t),u(t))dt + h(x(T))\right\}, \tag{2.1}$$

where $x(\cdot) = \{x(t) : s \le t \le T\}$ is the solution of the following Ito SDE on the filtered space $(\Omega, \mathcal{F}, P; \mathcal{F}_t^s)$:

$$\begin{cases} dx(t) = f(t,x(t),u(t))dt + \sigma(t,x(t),u(t))dB(t), \\ x(s) = y. \end{cases} \tag{2.2}$$

The solution $x(\cdot)$ of the above SDE is called the response of the control $u(\cdot) \in U_{ad}[s,T]$, and $(x(\cdot),u(\cdot))$ is called an *admissible* pair. The objective of the optimal control problem is to minimize the cost function $J(s,y;u(\cdot))$, for a given $(s,y) \in [0,T) \times R^n$, over all $u(\cdot) \in U_{ad}[s,T]$. We denote the above problem by $C_{s,y}$ to recall the dependence on the initial time s and the initial state y. The value function is defined as

$$V(s,y) = \inf_{u(\cdot)\in U_{ad}[s,T]} J(s,y;u(\cdot)). \tag{2.3}$$

An admissible pair $(x^*(\cdot),u^*(\cdot))$ is called *optimal* for $C_{s,y}$ if $u^*(\cdot)$ achieves the infimum of $J(s,y;u(\cdot))$ over $U_{ad}[s,T]$.

Since the objective of this paper is to study near-optimal rather than optimal controls of the system, we give here the precise definition of the near-optimality, following [13].

DEFINITION 2.1. *For a given $\varepsilon > 0$, an admissible pair $(x^\varepsilon(\cdot),u^\varepsilon(\cdot))$, or simply $u^\varepsilon(\cdot)$, is called* ε-optimal *with respect to (s,y) if*

$$|J(s,y;u^\varepsilon(\cdot)) - V(s,y)| \le \varepsilon.$$

DEFINITION 2.2. *Both a family of admissible pairs $\{(x^\varepsilon(\cdot),u^\varepsilon(\cdot))\}$ parameterized by $\varepsilon > 0$ and any element $(x^\varepsilon(\cdot),u^\varepsilon(\cdot))$, or simply $u^\varepsilon(\cdot)$, in the family are called* near-optimal *with respect to (s,y) if*

$$|J(s,y;u^\varepsilon(\cdot)) - V(s,y)| \le r(\varepsilon)$$

holds for sufficiently small ε, where r is a function of ε satisfying $r(\varepsilon) \to 0$ as $\varepsilon \to 0$. The estimate $r(\varepsilon)$ is called an error bound. *If $r(\varepsilon) = c\varepsilon^\delta$ for some $\delta > 0$ independent of the constant c, then $u^\varepsilon(\cdot)$ is called near-optimal with order ε^δ.*

In the above definitions, the terms "admissible," "optimal," "ε-optimal," and "near-optimal" are dependent on the initial time s and initial state y. In the following discussion, however, the phrase "with respect to (s,y)" may be omitted if no confusion would occur.

Notation. We make use of the following notation in this paper:

$a \cdot b$	:	the inner product of any two vectors a and b;
$\lvert a\rvert$	:	$= \lvert a^1\rvert + \cdots + \lvert a^n\rvert$ for any vector $a = (a^1, \ldots, a^n)$;
M^*	:	the transpose of any vector or matrix M;
ρ_x	:	the gradient or Jacobian of a function ρ with respect to the variable x;

ρ_{xx}	:	the Hessian of a scalar function ρ with respect to the variable x;
χ_A	:	the indicator function of a set A;
$X+Y$	:	$=\{x+y : x\in X, y\in Y\}$ for any set X and Y;
$C, C_i, i=1,2,\dots$	:	multiplicative constants required in the analysis.

Given a probability space $(\Omega,\mathcal{F},P)$ with a filtration $\{\mathcal{F}_t : a\le t\le b\}$ $(-\infty\le a<b\le+\infty)$, a Hilbert space X with the norm $\|\cdot\|_X$, and p $(1\le p\le+\infty)$, define the Banach space $L^p_{\mathcal{F}}(a,b;X)=\{\phi(\cdot)=\{\phi(t,\omega) : a\le t\le b\}|\ \phi(\cdot)$ is an $\mathcal{F}_t$ - adapted, X-valued measurable process on $[a,b]$, and $E\int_a^b \|\phi(t,\omega)\|_X^p\ dt<+\infty\}$, with the norm

$$\|\phi(\cdot)\|_{\mathcal{F},p}=\left(E\int_a^b \|\phi(t,\omega)\|_X^p\ dt\right)^{\frac{1}{p}}.$$

In the rest of this paper, we shall employ the usual convention of suppressing the ω-dependence of all random functions whenever no confusion arises.

Assumptions. The following basic assumptions will be in force throughout this paper:

(A1) $f:[0,T]\times R^n\times\Gamma\to R^n$, $\sigma:[0,T]\times R^n\times\Gamma\to R^{n\times l}$, and $L:[0,T]\times R^n\times\Gamma\to R^1$ are measurable in (t,x,u), twice continuously differentiable in x for each (t,u), and there exists a constant $C>0$ such that for $\rho=f,\sigma,L$,

$$|\rho(t,x,u)|\le C(1+|x|), \tag{2.4}$$

$$|\rho(t,x,u)-\rho(t,x',u)|+|\rho_x(t,x,u)-\rho_x(t,x',u)|\le C|x-x'|. \tag{2.5}$$

(A2) $h:R^n\to R^1$ is twice continuously differentiable, and

$$|h(x)|\le C(1+|x|), \tag{2.6}$$

$$|h(x)-h(x')|+|h_x(x)-h_x(x')|\le C|x-x'|. \tag{2.7}$$

Remark 2.1. Under (A1) and (A2), the existence and uniqueness of (strong) solutions of (2.2) hold for any given $(\Omega,\mathcal{F},P,B;u(\cdot))\in U_{ad}[s,T]$. Moreover, it is well known that for every solution $x(\cdot)$ of (2.2) and any $p\ge 0$, it holds that

$$E\sup_{s\le t\le T}|x(t)|^p\le C(p), \tag{2.8}$$

where $C(p)$ is a constant depending only on p.

Before concluding this section, let us recall the definition of the Clarke generalized gradient as well as the Ekeland variational principle.

DEFINITION 2.3 (Clarke [2]). *Let X be a convex set in R^d and let $\eta(\cdot):X\to R^1$ be a locally Lipschitz function. The* generalized gradient *of v at $\hat{x}\in X$, denoted by $\partial_x\eta(\hat{x})$, is a set defined by*

$$\partial_x\eta(\hat{x})=\{p\in R^d | p\cdot\xi\le\eta^0(\hat{x};\xi),\ \textit{for any } \xi\in R^d\},$$

where $\eta^0(\hat{x};\xi) = \limsup_{x\in X, x+h\xi\in X, x\to\hat{x}, h\to 0+} \frac{\eta(x+h\xi)-\eta(x)}{h}$.

LEMMA 2.4 (Ekeland's principle [3]). *Let* (S,d) *be a complete metric space and* $\rho(\cdot): S\to R^1$ *be lower-semicontinuous and bounded from below. For* $\varepsilon\geq 0$, *suppose* $u^\varepsilon\in S$ *satisfies*

$$\rho(u^\varepsilon)\leq \inf_{u\in S}\rho(u)+\varepsilon.$$

Then for any $\lambda>0$, *there exists* $u^\lambda\in S$ *such that*

$$\begin{aligned}&\rho(u^\lambda)\leq\rho(u^\varepsilon),\\ &d(u^\lambda,u^\varepsilon)\leq\lambda,\ \textit{and}\\ &\rho(u^\lambda)\leq\rho(u)+\tfrac{\varepsilon}{\lambda}d(u,u^\lambda)\ \textit{for all}\ u\in S.\end{aligned}$$

3. Adjoint equations: Backward SDEs. From now on, let us assume that the initial time s and initial state y of the system are fixed, and the Brownian motion B is one dimensional for notational simplicity. We also set $\mathcal{F}_t=\mathcal{F}_t^s$. Define a metric on $U_{ad}[s,T]$:

$$d(u(\cdot),u'(\cdot))=\tilde{P}\{(t,\omega)\in[s,T]\times\Omega: u(t,\omega)\neq u'(t,\omega)\},\tag{3.1}$$

where $\tilde{P}$ is the product measure of the Lebesgue measure and P. Since Γ is closed, it can be shown similarly to [4, Lemma 3.2] that $U_{ad}[s,T]$ is a complete metric space under d.

As is well known, the study of adjoint equations plays a key role in deriving the necessary and sufficient conditions of optimality. In the stochastic (diffusion) case, there are first-order and second-order adjoint processes corresponding to each given admissible control. The equations which they satisfy are (linear) backward SDEs with the terminal conditions given. This section is mainly devoted to investigating certain continuity of the adjoint processes with respect to the metric d.

Our first lemma below, however, is concerned with the continuity of the state processes under d.

LEMMA 3.1. *For any* $0<\alpha<1$ *and* $p\geq 0$ *satisfying* $\alpha p<1$, *there is a constant* $C_1=C_1(\alpha,p)>0$ *such that for any* $u(\cdot),u'(\cdot)\in U_{ad}[s,T]$ *along with the corresponding trajectories* $x(\cdot),x'(\cdot)$, *it holds that*

$$E\sup_{s\leq t\leq T}|x(t)-x'(t)|^{2p}\leq C_1 d(u(\cdot),u'(\cdot))^{\alpha p}.\tag{3.2}$$

Proof. In the proof below, all the constants C_i are understood to be dependent only on α and p. First we assume $p\geq 1$. We can compute, for any $r\geq s$,

$$\begin{aligned}&E\sup_{s\leq t\leq r}|x(t)-x'(t)|^{2p}\\ \leq\ & C_2E\textstyle\int_s^r\{|f(t,x(t),u(t))-f(t,x'(t),u'(t))|^{2p}\\ &+|\sigma(t,x(t),u(t))-\sigma(t,x'(t),u'(t))|^{2p}\}dt\\ \leq\ & C_3E\textstyle\int_s^r\{|f(t,x(t),u(t))-f(t,x(t),u'(t))|^{2p}\\ &+|\sigma(t,x(t),u(t))-\sigma(t,x(t),u'(t))|^{2p}\}\chi_{u(t)\neq u'(t)}(t)dt\\ &+C_3E\textstyle\int_s^r\{|f(t,x(t),u'(t))-f(t,x'(t),u'(t))|^{2p}\\ &+|\sigma(t,x(t),u'(t))-\sigma(t,x'(t),u'(t))|^{2p}\}dt.\end{aligned}\tag{3.3}$$

Taking $q' = \frac{1}{\alpha p} > 1$ and $p' > 1$ such that $\frac{1}{p'} + \frac{1}{q'} = 1$, and applying the Cauchy–Schwarz inequality, we obtain

$$
\begin{aligned}
&E\textstyle\int_s^r \{|f(t,x(t),u(t)) - f(t,x(t),u'(t))|^{2p}\}\chi_{u(t)\neq u'(t)}(t)dt \\
&\le \big\{E\textstyle\int_s^r |f(t,x(t),u(t)) - f(t,x(t),u'(t))|^{2pp'}\big\}^{\frac{1}{p'}} \big\{E\textstyle\int_s^r \chi_{u(t)\neq u'(t)}(t)dt\big\}^{\frac{1}{q'}} \\
&\le C_4\big\{E\textstyle\int_s^r (1+|x(t)|^{2pp'})dt\big\}^{\frac{1}{p'}} d(u(\cdot),u'(\cdot))^{\alpha p} \\
&\le C_5 d(u(\cdot),u'(\cdot))^{\alpha p}.
\end{aligned} \tag{3.4}
$$

The same inequality holds if f above is replaced by σ. Therefore, by noting (A1), we conclude from (3.3) that

$$
E\sup_{s\le t\le r}|x(t)-x'(t)|^{2p} \le C_6\left\{\int_s^r E\sup_{s\le t\le\theta}|x(t)-x'(t)|^{2p}d\theta + d(u(\cdot),u'(\cdot))^{\alpha p}\right\}.
$$

Hence (3.2) follows from the Gronwall inequality.

Now assume $0 \le p < 1$. Then the Cauchy–Schwarz inequality yields

$$
\begin{aligned}
E\sup_{s\le t\le T}|x(t)-x'(t)|^{2p} &\le \{E\sup_{s\le t\le T}|x(t)-x'(t)|^2\}^p \\
&\le \{C_1 d(u(\cdot),u'(\cdot))^{\alpha}\}^p \\
&= C_1^p d(u(\cdot),u'(\cdot))^{\alpha p}.
\end{aligned}
$$

This completes the proof. □

For any $u(\cdot) \in U_{ad}[s,T]$ and the corresponding state trajectory $x(\cdot)$, we define the first-order adjoint process $\psi(\cdot)$ and the second-order adjoint process $Q(\cdot)$ as the ones satisfying the following two backward SDEs, respectively:

$$
\begin{cases}
d\psi(t) = & -\{f_x(t,x(t),u(t))^*\psi(t) + \sigma_x(t,x(t),u(t))^*K(t) \\
& \quad + L_x(t,x(t),u(t))\}dt + K(t)dB(t), \\
\psi(T) = & h_x(x(T)),
\end{cases} \tag{3.5}
$$

(3.6)

$$
\begin{cases}
dQ(t) = & -\{f_x(t,x(t),u(t))^*Q(t) + Q(t)f_x(t,x(t),u(t)) \\
& \quad + \sigma_x(t,x(t),u(t))^*Q(t)\sigma_x(t,x(t),u(t)) + \sigma_x(t,x(t),u(t))^*R(t) \\
& \quad + R(t)\sigma_x(t,x(t),u(t)) + \Lambda(t)\}dt + R(t)dB(t), \\
Q(T) = & h_{xx}(x(T)),
\end{cases}
$$

where $\Lambda(t) = L_{xx}(t,x(t),u(t)) + \sum_{i=1}^n \{\psi^i(t)f^i_{xx}(t,x(t),u(t)) + K^i(t)\sigma^i_{xx}(t,x(t),u(t))\}$.

Note that under assumptions (A1) and (A2), the first-order adjoint equation (3.5) admits one and only one $\mathcal{F}_t$-*adapted* solution *pair* $(\psi,K) \in L^2_{\mathcal{F}}(0,1;R^n)\times L^2_{\mathcal{F}}(0,1;R^n)$, and the second-order adjoint equation (3.6) admits one and only one $\mathcal{F}_t$-*adapted* solution *pair* $(Q,R) \in L^2_{\mathcal{F}}(0,1;R^{n\times n}) \times L^2_{\mathcal{F}}(0,1;R^{n\times n})$. Moreover, since f_x, σ_x, L_x, and h_x are bounded by C by assumptions (A1) and (A2), there exists a constant $C_1 > 0$, independent of $(x(\cdot),u(\cdot))$, such that the solutions of (3.5) and (3.6) have the following estimates:

$$
E\left\{\sup_{s\le t\le T}|\psi(t)|^2 + \int_s^T |K(t)|^2dt\right\} \le C_1, \tag{3.7}
$$

$$E\left\{\sup_{s\le t\le T}|Q(t)|^2+\int_s^T|R(t)|^2dt\right\}\le C_1; \tag{3.8}$$

(see [12, Corollaries 2.2, 2.4]). It should also be noted that *no* supremum estimates for $K(t)$ and $R(t)$ are available.

The following lemma gives the pth moment continuity of the solutions to the adjoint equations with respect to the metric d. It plays a key role in proving the necessary condition in the next section.

LEMMA 3.2. *For any $0<\alpha<1$ and $1<p<2$ satisfying $(1+\alpha)p<2$, there is a constant $C_1=C_1(\alpha,p)>0$ such that for any $u(\cdot),u'(\cdot)\in U_{ad}[s,T]$ along with the corresponding trajectories $x(\cdot),x'(\cdot)$ and the solutions $(\psi(\cdot),K(\cdot),Q(\cdot),R(\cdot)),(\psi'(\cdot),K'(\cdot),Q'(\cdot),R'(\cdot))$ of the corresponding adjoint equations, it holds that*

$$E\int_s^T\{|\psi(t)-\psi'(t)|^p+|K(t)-K'(t)|^p\}dt\le C_1d(u(\cdot),u'(\cdot))^{\frac{\alpha p}{2}} \tag{3.9}$$

and

$$E\int_s^T\{|Q(t)-Q'(t)|^p+|R(t)-R'(t)|^p\}dt\le C_1d(u(\cdot),u'(\cdot))^{\frac{\alpha p}{2}}. \tag{3.10}$$

Proof. Once again, all the constants C_i below depend only on α and p. Note that $(\bar\psi(t),\bar K(t))\equiv(\psi(t)-\psi'(t),K(t)-K'(t))$ satisfies the following backward SDE:

$$\begin{cases} d\bar\psi(t)= & -\{f_x(t,x(t),u(t))^*\bar\psi(t)+\sigma_x(t,x(t),u(t))^*\bar K(t)\\ & \quad+\bar f(t)\}dt+\bar K(t)dB(t),\\ \bar\psi(T)= & h_x(x(T))-h_x(x'(T)),\end{cases} \tag{3.11}$$

where

$$\begin{aligned}\bar f(t)= & \{f_x(t,x(t),u(t))^*-f_x(t,x'(t),u'(t))^*\}\psi'(t)\\ & +\{\sigma_x(t,x(t),u(t))^*-\sigma_x(t,x'(t),u'(t))^*\}K'(t)\\ & +\{L_x(t,x(t),u(t))-L_x(t,x'(t),u'(t))\}.\end{aligned} \tag{3.12}$$

Now let ρ be the solution of the following linear (forward) SDE:

$$\begin{cases} d\rho(t)= & \{f_x(t,x(t),u(t))\rho(t)+|\bar\psi(t)|^{p-1}\mathrm{sgn}(\bar\psi(t))\}dt\\ & +\{\sigma_x(t,x(t),u(t))\rho(t)+|\bar K(t)|^{p-1}\mathrm{sgn}(\bar K(t))\}dB(t),\\ \rho(s)=0,\end{cases}$$

where $\mathrm{sgn}(a)\equiv(\mathrm{sgn}(a^1),\dots,\mathrm{sgn}(a^n))^*$ for a vector $a=(a^1,\dots,a^n)^*$. Note that the existence and uniqueness of solutions to the above equation are verified by (A1) and the fact that

$$E\int_s^T\left\{\left||\bar\psi(t)|^{p-1}\mathrm{sgn}(\bar\psi(t))\right|^2+\left||\bar K(t)|^{p-1}\mathrm{sgn}(\bar K(t))\right|^2\right\}dt<+\infty.$$

Since $1<p<2$, there is $q>2$ such that $\frac1p+\frac1q=1$. So

$$\begin{aligned}E\sup_{s\le t\le T}|\rho(t)|^q\le & \ C_2E\textstyle\int_s^T\{|\bar\psi(t)|^{pq-q}+|\bar K(t)|^{pq-q}\}dt\\ = & \ C_2E\textstyle\int_s^T\{|\bar\psi(t)|^p+|\bar K(t)|^p\}dt.\end{aligned} \tag{3.13}$$

Note that the right side of (3.13) is bounded due to (3.7). On the other hand, by applying the Ito formula to $\bar{\psi}(t)\cdot\rho(t)$ and taking expectations, we obtain

$$\begin{aligned}
& E\int_s^T\Big\{\bar{\psi}(t)\cdot[|\bar{\psi}(t)|^{p-1}\mathrm{sgn}(\bar{\psi}(t))]+\bar{K}(t)\cdot[|\bar{K}(t)|^{p-1}\mathrm{sgn}(\bar{K}(t))]\Big\}dt\\
= \;& E\Big\{\int_s^T\bar{f}(t)\cdot\rho(t)dt+[h_x(x(T))-h_x(x'(T))]\cdot\rho(T)\Big\}\\
\le \;& \{E\int_s^T|\bar{f}(t)|^pdt\}^{\frac{1}{p}}\{E\int_s^T|\rho(t)|^qdt\}^{\frac{1}{q}}+\{E|h_x(x(T))-h_x(x'(T))|^p\}^{\frac{1}{p}}\{E|\rho(T)|^q\}^{\frac{1}{q}}\\
\le \;& C_3\Big\{E\int_s^T[|\bar{\psi}(t)|^p+|\bar{K}(t)|^p]dt\Big\}^{\frac{1}{q}}\Big\{[E\int_s^T|\bar{f}(t)|^pdt]^{\frac{1}{p}}+[E|h_x(x(T))-h_x(x'(T))|^p]^{\frac{1}{p}}\Big\}.
\end{aligned}$$

Noting that the left side of the above inequality is equal to $E\int_s^T[|\bar{\psi}(t)|^p+|\bar{K}(t)|^p]dt$, we deduce

$$E\int_s^T\{|\bar{\psi}(t)|^p+|\bar{K}(t)|^p\}dt\le C_4E\left\{\int_s^T|\bar{f}(t)|^pdt+|h_x(x(T))-h_x(x'(T))|^p\right\}. \tag{3.14}$$

We proceed to estimate the right side of (3.14). First, noting that $\frac{\alpha p}{2}<1-\frac{p}{2}<1$, we can apply Lemma 3.1 to get

$$E|h_x(x(T))-h_x(x'(T))|^p\le C^pE|x(T)-x'(T)|^p\le C_5d(u(\cdot),u'(\cdot))^{\frac{\alpha p}{2}}. \tag{3.15}$$

Next, by repeatedly applying the Cauchy–Schwarz inequality, we can estimate

$$\begin{aligned}
& E\int_s^T|f_x(t,x(t),u(t))^*-f_x(t,x'(t),u'(t))^*|^p|\psi'(t)|^pdt\\
\le \;& C_6E\int_s^T\{|f_x(t,x(t),u(t))^*-f_x(t,x(t),u'(t))^*|^p|\psi'(t)|^p\\
& \qquad +|f_x(t,x(t),u'(t))^*-f_x(t,x'(t),u'(t))^*|^p|\psi'(t)|^p\}dt\\
\le \;& C_7E\int_s^T\{\chi_{u(t)\neq u'(t)}(t)|\psi'(t)|^p+|x(t)-x'(t)|^p|\psi'(t)|^p\}dt\\
\le \;& C_7\Big\{E\int_s^T|\psi'(t)|^2dt\Big\}^{\frac{p}{2}}d(u(\cdot),u'(\cdot))^{1-\frac{p}{2}}\\
& +C_7\Big\{E\int_s^T|\psi'(t)|^2dt\Big\}^{\frac{p}{2}}\Big\{E\int_s^T|x(t)-x'(t)|^{\frac{2p}{2-p}}dt\Big\}^{1-\frac{p}{2}}.
\end{aligned} \tag{3.16}$$

Noting that $1-\frac{p}{2}>\frac{\alpha p}{2}$ and $d(u(\cdot),u'(\cdot))\le1$, we know that the first term of the right side of (3.16) is bounded by $C_8d(u(\cdot),u'(\cdot))^{\frac{\alpha p}{2}}$. Further, since $\frac{\alpha p}{2-p}<1$, we conclude from Lemma 3.1 that

$$E\int_s^T|x(t)-x'(t)|^{\frac{2p}{2-p}}dt\le C_9d(u(\cdot),u'(\cdot))^{\frac{\alpha p}{2-p}}.$$

Hence the second term in the right side of (3.16) is also dominated by $C_{10}d(u(\cdot),u'(\cdot))^{\frac{\alpha p}{2}}$. So, (3.16) yields

$$E\int_s^T|f_x(t,x(t),u(t))^*-f_x(t,x'(t),u'(t))^*|^p|\psi'(t)|^pdt\le C_{11}d(u(\cdot),u'(\cdot))^{\frac{\alpha p}{2}}. \tag{3.17}$$

Notice that the estimate in (3.16) involved only $E\int_s^T|\psi'(t)|^2dt$ and therefore is adaptable to terms involving $K'(t)$. Hence we can similarly prove that

$$E\int_s^T|\sigma_x(t,x(t),u(t))^*-\sigma_x(t,x'(t),u'(t))^*|^p|K'(t)|^pdt\le C_{12}d(u(\cdot),u'(\cdot))^{\frac{\alpha p}{2}}. \tag{3.18}$$

Similarly (in fact, more easily) one can prove that

$$E\int_s^T |L_x(t,x(t),u(t)) - L_x(t,x'(t),u'(t))|^p dt \le C_{13} d(u(\cdot),u'(\cdot))^{\frac{\alpha p}{2}}. \tag{3.19}$$

It follows from (3.12), (3.17), (3.18), and (3.19) that

$$E\int_s^T |\bar f(t)|^p dt \le C_{14} d(u(\cdot),u'(\cdot))^{\frac{\alpha p}{2}}.$$

The desired result (3.9) then follows immediately from (3.14) and (3.15). Similarly one can prove (3.10). □

4. Necessary conditions of near-optimality. Define the (usual) Hamiltonian

$$H(t,x,u,p,q) = -L(t,x,u) - p\cdot f(t,x,u) - q\cdot\sigma(t,x,u) \tag{4.1}$$

for $(t,x,u,p,q)\in[s,T]\times R^n\times\Gamma\times R^n\times R^n$. Furthermore, we define the $\mathcal{H}$-function *corresponding to* a given admissible pair $(x(\cdot),u(\cdot))$ as follows:

$$\begin{aligned}\mathcal{H}^{(x(\cdot),u(\cdot))}(t,x,u) &= H(t,x,u,\psi(t),K(t)-Q(t)\sigma(t,x(t),u(t)))\\ &\quad -\frac{1}{2}\sigma(t,x,u)^*Q(t)\sigma(t,x,u)\end{aligned} \tag{4.2}$$

for $(t,x,u)\in[s,T]\times R^n\times\Gamma$, where $\psi(t)$, $K(t)$, and $Q(t)$ are determined by adjoint equations (3.5) and (3.6) corresponding to $(x(\cdot),u(\cdot))$.

THEOREM 4.1. *For any $\gamma\in[0,\frac{1}{3})$, there exists a constant $C_1=C_1(\gamma)>0$ such that for any $\varepsilon>0$ and any ε-optimal pair $(x^\varepsilon(\cdot),u^\varepsilon(\cdot))$ of the problem $C_{s,y}$, it holds that*

$$\begin{aligned}E\int_s^T \Big\{&\tfrac{1}{2}[\sigma(t,x^\varepsilon(t),u)-\sigma(t,x^\varepsilon(t),u^\varepsilon(t))]^*Q^\varepsilon(t)[\sigma(t,x^\varepsilon(t),u)-\sigma(t,x^\varepsilon(t),u^\varepsilon(t))]\\ &+\psi^\varepsilon(t)\cdot[f(t,x^\varepsilon(t),u)-f(t,x^\varepsilon(t),u^\varepsilon(t))]\\ &+K^\varepsilon(t)\cdot[\sigma(t,x^\varepsilon(t),u)-\sigma(t,x^\varepsilon(t),u^\varepsilon(t))]\\ &+L(t,x^\varepsilon(t),u)-L(t,x^\varepsilon(t),u^\varepsilon(t))\Big\}dt \ge -C_1\varepsilon^\gamma,\end{aligned} \tag{4.3}$$

where $(\psi^\varepsilon(\cdot),K^\varepsilon(\cdot))$ and $(Q^\varepsilon(\cdot),R^\varepsilon(\cdot))$ are the solutions to (3.5) *and* (3.6)*, respectively, corresponding to $(x^\varepsilon(\cdot),u^\varepsilon(\cdot))$.*

Proof. First note that the multiplicative constants C_i required in the analysis below do not depend on ε. By assumptions (A1) and (A2), it is easy to see that $J(s,y;u(\cdot))$ is continuous on $U_{ad}[s,T]$ endowed with the metric d defined by (3.1). By the Ekeland principle (Lemma 2.1) with $\lambda=\varepsilon^{\frac{2}{3}}$, there is an admissible pair $(\tilde x^\varepsilon(\cdot),\tilde u^\varepsilon(\cdot))$ such that

$$d(u^\varepsilon(\cdot),\tilde u^\varepsilon(\cdot)) \le \varepsilon^{\frac{2}{3}} \tag{4.4}$$

and

$$\tilde J(s,y;\tilde u^\varepsilon(\cdot)) \le \tilde J(s,y;u(\cdot)) \text{ for any } u(\cdot)\in U_{ad}[s,T], \tag{4.5}$$

where

$$\tilde J(s,y;u(\cdot)) = J(s,y;u(\cdot)) + \varepsilon^{\frac{1}{3}} d(u(\cdot),\tilde u^\varepsilon(\cdot)). \tag{4.6}$$

This means that $(\tilde{x}^\varepsilon(\cdot), \tilde{u}^\varepsilon(\cdot))$ is an optimal pair for the system (2.2) with a new cost function $\tilde{J}$. Next we use the spike variation technique to derive a "maximum principle" for $(\tilde{x}^\varepsilon(\cdot), \tilde{u}^\varepsilon(\cdot))$. To this end, let $\bar{t} \in [s, T)$ and $u \in \Gamma$ be fixed. For any $\delta > 0$, define $u_\delta \in U_{ad}[s, T]$ by

$$u_\delta(t) = \begin{cases} u, & t \in [\bar{t}, \bar{t} + \delta], \\ \tilde{u}^\varepsilon(t), & t \in [s, T] \setminus [\bar{t}, \bar{t} + \delta]. \end{cases} \tag{4.7}$$

The fact that

$$\tilde{J}(s, y; \tilde{u}^\varepsilon(\cdot)) \le \tilde{J}(s, y; u_\delta(\cdot))$$

and

$$d(u_\delta(\cdot), \tilde{u}^\varepsilon(\cdot)) \le \delta$$

imply that

$$-\varepsilon^{\frac{1}{3}}\delta \le J(s, y; u_\delta(\cdot)) - J(s, y; \tilde{u}^\varepsilon(\cdot)). \tag{4.8}$$

However, by (5.14) in [12] (with ε there replaced by δ), the right-hand side of the above inequality is equal to

$$\begin{aligned} E\int_{\bar{t}}^{\bar{t}+\delta} \Big\{ & \tfrac{1}{2}[\sigma(t, \tilde{x}^\varepsilon(t), u) - \sigma(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t))]^* \tilde{Q}^\varepsilon(t)[\sigma(t, \tilde{x}^\varepsilon(t), u) - \sigma(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t))] \\ & + \tilde{\psi}^\varepsilon(t) \cdot [f(t, \tilde{x}^\varepsilon(t), u) - f(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t))] \\ & + \tilde{K}^\varepsilon(t) \cdot [\sigma(t, \tilde{x}^\varepsilon(t), u) - \sigma(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t))] \\ & + [L(t, \tilde{x}^\varepsilon(t), u) - L(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t))] \Big\} dt + o(\delta). \end{aligned}$$

Dividing (4.8) by δ and sending δ to 0, we conclude that

$$\begin{aligned} E\Big\{ & \tfrac{1}{2}[\sigma(t, \tilde{x}^\varepsilon(t), u) - \sigma(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t))]^* \tilde{Q}^\varepsilon(t)[\sigma(t, \tilde{x}^\varepsilon(t), u) - \sigma(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t))] \\ & + \tilde{\psi}^\varepsilon(t) \cdot [f(t, \tilde{x}^\varepsilon(t), u) - f(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t))] \\ & + \tilde{K}^\varepsilon(t) \cdot [\sigma(t, \tilde{x}^\varepsilon(t), u) - \sigma(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t))] \\ & + [L(t, \tilde{x}^\varepsilon(t), u) - L(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t))] \Big\} \ge -\varepsilon^{\frac{1}{3}}. \end{aligned} \tag{4.9}$$

Now we are to derive an estimate for the term similar to the left side of (4.9) with all the $\tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t)$, etc. replaced by $x^\varepsilon(t), u^\varepsilon(t)$, etc. To this end, we first estimate the following difference:

$$\begin{aligned} & E\int_s^T \Big\{ \tilde{K}^\varepsilon(t) \cdot [\sigma(t, \tilde{x}^\varepsilon(t), u) - \sigma(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t))] \\ & \qquad - K^\varepsilon(t) \cdot [\sigma(t, x^\varepsilon(t), u) - \sigma(t, x^\varepsilon(t), u^\varepsilon(t))] \Big\} dt \\ & = E\int_s^T \{\tilde{K}^\varepsilon(t) - K^\varepsilon(t)\} \cdot \{\sigma(t, \tilde{x}^\varepsilon(t), u) - \sigma(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t))\} dt \\ & \quad + E\int_s^T K^\varepsilon(t) \cdot \{\sigma(t, \tilde{x}^\varepsilon(t), u) - \sigma(t, x^\varepsilon(t), u)\} dt \\ & \quad - E\int_s^T K^\varepsilon(t) \cdot \{\sigma(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t)) - \sigma(t, x^\varepsilon(t), u^\varepsilon(t))\} dt \\ & = I_1 + I_2 + I_3, \text{ say.} \end{aligned}$$

For any $\gamma \in [0, \frac{1}{3})$, let $\alpha = 3\gamma \in [0, 1)$. Fix a $p \in (1, 2)$ so that $(1 + \alpha)p < 2$. Take $q \in (2, +\infty)$ with $\frac{1}{p} + \frac{1}{q} = 1$. Then, appealing to Lemma 3.2,

$$\begin{aligned} I_1 \leq\ & \big\{E\textstyle\int_s^T |\tilde{K}^\varepsilon(t) - K^\varepsilon(t)|^p dt\big\}^{\frac{1}{p}} \big\{E\textstyle\int_s^T |\sigma(t, \tilde{x}^\varepsilon(t), u) - \sigma(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t))|^q dt\big\}^{\frac{1}{q}} \\ & \leq \{C_2 d(u^\varepsilon(\cdot), \tilde{u}^\varepsilon(\cdot))^{\frac{\alpha p}{2}}\}^{\frac{1}{p}} \big\{C_2 E\textstyle\int_s^T (1 + |\tilde{x}^\varepsilon(t)|^q) dt\big\}^{\frac{1}{q}} \\ & \leq C_3 \varepsilon^{\frac{\alpha}{3}} \text{ (note (4.4))} \\ & = C_3 \varepsilon^\gamma. \end{aligned}$$

Next,

$$\begin{aligned} I_2 \leq\ & \big\{E\textstyle\int_s^T |K^\varepsilon(t)|^2 dt\big\}^{\frac{1}{2}} \big\{E\textstyle\int_s^T |\sigma(t, \tilde{x}^\varepsilon(t), u) - \sigma(t, x^\varepsilon(t), u))|^2 dt\big\}^{\frac{1}{2}} \\ & \leq C_4 \big\{E\textstyle\int_s^T |\tilde{x}^\varepsilon(t) - x^\varepsilon(t)|^2 dt\big\}^{\frac{1}{2}} \\ & \leq C_5 \{d(u^\varepsilon(\cdot), \tilde{u}^\varepsilon(\cdot))^\alpha\}^{\frac{1}{2}} \\ & \leq C_5 \{\varepsilon^{\frac{2\alpha}{3}}\}^{\frac{1}{2}} \\ & = C_5 \varepsilon^\gamma. \end{aligned}$$

Further,

$$\begin{aligned} I_3 =\ & - E\textstyle\int_s^T K^\varepsilon(t) \cdot \{\sigma(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t)) - \sigma(t, \tilde{x}^\varepsilon(t), u^\varepsilon(t))\} dt \\ & - E\textstyle\int_s^T K^\varepsilon(t) \cdot \{\sigma(t, \tilde{x}^\varepsilon(t), u^\varepsilon(t)) - \sigma(t, x^\varepsilon(t), u^\varepsilon(t))\} dt \\ \leq\ & \big\{E\textstyle\int_s^T |K^\varepsilon(t)|^2 dt\big\}^{\frac{1}{2}} \big\{E\textstyle\int_s^T |\sigma(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t)) \\ & \qquad - \sigma(t, \tilde{x}^\varepsilon(t), u^\varepsilon(t))|^2 \chi_{\tilde{u}^\varepsilon(t) \neq u^\varepsilon(t)}(t) dt\big\}^{\frac{1}{2}} + C_5 \varepsilon^\gamma. \end{aligned}$$

By the Cauchy–Schwarz inequality, one has

$$\begin{aligned} & E\textstyle\int_s^T |\sigma(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t)) - \sigma(t, \tilde{x}^\varepsilon(t), u^\varepsilon(t))|^2 \chi_{\tilde{u}^\varepsilon(t) \neq u^\varepsilon(t)}(t) dt \\ \leq\ & \big\{E\textstyle\int_s^T |\sigma(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t)) - \sigma(t, \tilde{x}^\varepsilon(t), u^\varepsilon(t))|^4 dt\big\}^{\frac{1}{2}} \big\{E\textstyle\int_s^T \chi_{\tilde{u}^\varepsilon(t) \neq u^\varepsilon(t)}(t) dt\big\}^{\frac{1}{2}} \\ \leq\ & C_6 d(\tilde{u}^\varepsilon(\cdot), u^\varepsilon(\cdot))^{\frac{1}{2}} \\ \leq\ & C_6 \varepsilon^{\frac{1}{3}} \\ \leq\ & C_6 \varepsilon^\gamma. \end{aligned}$$

Thus, we have proved that

$$\begin{aligned} & E\textstyle\int_s^T \Big\{\tilde{K}^\varepsilon(t) \cdot [\sigma(t, \tilde{x}^\varepsilon(t), u) - \sigma(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t))] \\ & \qquad - K^\varepsilon(t) \cdot [\sigma(t, x^\varepsilon(t), u) - \sigma(t, x^\varepsilon(t), u^\varepsilon(t))]\Big\} dt \\ \leq\ & C_7 \varepsilon^\gamma. \end{aligned} \tag{4.10}$$

Similarly,

$$\begin{aligned} & E\textstyle\int_s^T \Big\{\big\{\frac{1}{2}[\sigma(t, \tilde{x}^\varepsilon(t), u) - \sigma(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t))]^* \tilde{Q}^\varepsilon(t) [\sigma(t, \tilde{x}^\varepsilon(t), u) - \sigma(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t))] \\ & - \frac{1}{2}[\sigma(t, x^\varepsilon(t), u) - \sigma(t, x^\varepsilon(t), u^\varepsilon(t))]^* Q^\varepsilon(t) [\sigma(t, x^\varepsilon(t), u) - \sigma(t, x^\varepsilon(t), u^\varepsilon(t))]\big\} \\ & + \big\{\tilde{\psi}^\varepsilon(t) \cdot [f(t, \tilde{x}^\varepsilon(t), u) - f(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t))] \\ & \quad - \psi^\varepsilon(t) \cdot [f(t, x^\varepsilon(t), u) - f(t, x^\varepsilon(t), u^\varepsilon(t))]\big\} \\ & + \big\{[L(t, \tilde{x}^\varepsilon(t), u) - L(t, \tilde{x}^\varepsilon(t), \tilde{u}^\varepsilon(t))] \\ & \quad - [L(t, x^\varepsilon(t), u) - L(t, x^\varepsilon(t), u^\varepsilon(t))]\big\}\Big\} dt \\ \leq\ & C_8 \varepsilon^\gamma. \end{aligned} \tag{4.11}$$

The inequality (4.3) therefore follows from combining (4.9), (4.10) and (4.11). □

COROLLARY 4.2. *Under the conditions of Theorem* 4.1, *it holds that*

$$E\int_s^T \mathcal{H}^{(x^\varepsilon(\cdot),u^\varepsilon(\cdot))}(t,x^\varepsilon(t),u^\varepsilon(t))dt \geq \sup_{u(\cdot)\in U_{ad}[s,T]} E\int_s^T \mathcal{H}^{(x^\varepsilon(\cdot),u^\varepsilon(\cdot))}(t,x^\varepsilon(t),u(t))dt - C_1\varepsilon^\gamma. \tag{4.12}$$

Proof. In the definition of the perturbed control $u_\delta(\cdot)$ in (4.7), the point $u \in \Gamma$ can be replaced by any admissible control $u(\cdot) \in U_{ad}[s,T]$, and the subsequent argument still goes through. So (4.3) holds with u replaced by $u(t)$ for any $u(\cdot) \in U_{ad}[s,T]$, which is an easy variant of (4.12). □

Let us now look at an example.

Example 4.1. Let $n = l = 1, s = y = 0, T = 1, f = 0, \sigma = u, L = -u, h = \frac{1}{2}x^2, \Gamma = [0,1]$. For a given admissible pair $(x^\varepsilon(\cdot), u^\varepsilon(\cdot))$, the corresponding second-order adjoint equation is

$$\begin{cases} dQ^\varepsilon(t) = R^\varepsilon(t)dB(t), \\ Q^\varepsilon(1) = 1. \end{cases}$$

By the uniqueness of its solutions, $(Q^\varepsilon(t), R^\varepsilon(t)) = (1,0)$. Then for any admissible control $u(\cdot)$ we have

$$\begin{aligned} \mathcal{H}^{(x^\varepsilon(\cdot),u^\varepsilon(\cdot))}(t,x^\varepsilon(t),u(t)) &= u(t) - (K^\varepsilon(t) - Q^\varepsilon(t)u^\varepsilon(t))u(t) - \tfrac{1}{2}Q^\varepsilon(t)u^2(t) \\ &= -\tfrac{1}{2}(u(t) - u^\varepsilon(t) + K^\varepsilon(t) - 1)^2 + \tfrac{1}{2}(u^\varepsilon(t) - K^\varepsilon(t) + 1)^2 \end{aligned}$$

and

$$\mathcal{H}^{(x^\varepsilon(\cdot),u^\varepsilon(\cdot))}(t,x^\varepsilon(t),u^\varepsilon(t)) = \frac{1}{2}[u^\varepsilon(t)]^2 - (K^\varepsilon(t) - 1)u^\varepsilon(t).$$

Hence a simple calculation shows that if

$$u^\varepsilon(t) - K^\varepsilon(t) + 1 \in \Gamma, \tag{4.13}$$

then (4.12) gives

$$E\int_0^1 (K^\varepsilon(t) - 1)^2 dt \leq C_1\varepsilon^\gamma. \tag{4.14}$$

The above condition reveals the "minimum" qualification for the pair $(x^\varepsilon(\cdot), u^\varepsilon(\cdot))$ to be ε-optimal. For example, the controls $u^\varepsilon(t) \equiv 1 - \varepsilon^{\frac{1}{2}}$ are candidates for ε-optimality. To see this, note that the first-order adjoint equation is

$$\begin{cases} d\psi^\varepsilon(t) = K^\varepsilon(t)dB(t), \\ \psi^\varepsilon(1) = x^\varepsilon(1). \end{cases}$$

It is clear that if we choose $u^\varepsilon(t) \equiv 1 - \varepsilon^{\frac{1}{2}}$ with the corresponding $x^\varepsilon(t) = (1 - \varepsilon^{\frac{1}{2}})B(t)$, then the unique solution pair of the first-order adjoint equation will be $(\psi^\varepsilon(t), K^\varepsilon(t)) = ((1 - \varepsilon^{\frac{1}{2}})B(t), 1 - \varepsilon^{\frac{1}{2}})$. Hence (4.13) and (4.14) will be satisfied.

Remark 4.1. Corollary 4.1 says that *any* ε-optimal control nearly maximizes the $\mathcal{H}$-function (in the integral sense) with an error bound of order of "almost" $\varepsilon^{\frac{1}{3}}$. We believe, although we are not able to prove at this moment, that the error bound can be improved.

Remark 4.2. The necessary conditions of near-optimal controls are derived in terms of the near-maximum condition of the $\mathcal{H}$-function in an integral form. It is well known that, for exact optimality, the integral form and the pointwise form of the maximum condition are equivalent (cf. [7]), but it is certainly not the case for near-optimality. On the other hand, when $\varepsilon = 0$, Theorem 4.1 reduces to the stochastic maximum principle [9, 12].

5. Sufficient conditions of near-optimality. In this section, we will show that, under certain concavity conditions, the near-maximum condition of the $\mathcal{H}$-function in the integral form is sufficient for near-optimality, with the following additional assumption:

(A3) ρ is differentiable in u for $\rho = f, \sigma, L$, and there is a constant $C > 0$ such that

$$|\rho(t,x,u) - \rho(t,x,u')| + |\rho_u(t,x,u) - \rho_u(t,x,u')| \le C|u - u'|. \tag{5.1}$$

THEOREM 5.1. *Let $(x^\varepsilon(\cdot), u^\varepsilon(\cdot))$ be an admissible pair, and $(\psi^\varepsilon(\cdot), K^\varepsilon(\cdot))$ be the solution to* (3.5) *corresponding to $(x^\varepsilon(\cdot), u^\varepsilon(\cdot))$. Assume that $H(t,\cdot,\cdot,\psi^\varepsilon(t), K^\varepsilon(t))$ is concave for a.e. $t \in [s,T]$, $P-a.s.$, and $h(\cdot)$ is convex. If, for some $\varepsilon > 0$,*

$$E\int_s^T \mathcal{H}^{(x^\varepsilon(\cdot),u^\varepsilon(\cdot))}(t, x^\varepsilon(t), u^\varepsilon(t))dt \ge \sup_{u(\cdot)\in U_{ad}[s,T]} E\int_s^T \mathcal{H}^{(x^\varepsilon(\cdot),u^\varepsilon(\cdot))}(t, x^\varepsilon(t), u(t)) - \varepsilon, \tag{5.2}$$

then

$$J(s,y;u^\varepsilon(\cdot)) \le \inf_{u(\cdot)\in U_{ad}[s,T]} J(s,y;u(\cdot)) + C_1\varepsilon^{\frac{1}{2}}, \tag{5.3}$$

where $C_1 > 0$ is a constant independent of ε.

Proof. All the constants C_i appearing in this proof are independent of ε. The key step in the proof is to show that $H_u(t, x^\varepsilon(t), u^\varepsilon(t), \psi^\varepsilon(t), K^\varepsilon(t))$ is very small and to estimate it in terms of ε. To this end, let us fix an $\varepsilon > 0$. Define a new metric $\tilde{d}$ on $U_{ad}[s,T]$ as follows:

$$\tilde{d}(u(\cdot), u'(\cdot)) = E\int_s^T \nu^\varepsilon(t)|u(t) - u'(t)|dt, \tag{5.4}$$

where

$$\nu^\varepsilon(t) = 1 + |\psi^\varepsilon(t)| + |K^\varepsilon(t)| + |Q^\varepsilon(t)| + |Q^\varepsilon(t)||x^\varepsilon(t)| \ge 1. \tag{5.5}$$

Obviously $\tilde{d}$ is a metric, and it is a complete metric as a weighted L^1 norm.

Define a functional W on $U_{ad}[s,T]$ as follows:

$$W(u(\cdot)) = E\int_s^T \mathcal{H}^{(x^\varepsilon(\cdot),u^\varepsilon(\cdot))}(t, x^\varepsilon(t), u(t))dt.$$

A simple calculation shows that

$$|W(u(\cdot)) - W(u'(\cdot))| \le C_2 E\int_s^T \nu^\varepsilon(t)|u(t) - u'(t)|dt.$$

Therefore, W is continuous on $U_{ad}[s,T]$ with respect to $\tilde{d}$. By (5.2) and the Ekeland principle, there exists a $\tilde{u}^\varepsilon(\cdot)\in U_{ad}[s,T]$ such that

$$\tilde{d}(u^\varepsilon(\cdot),\tilde{u}^\varepsilon(\cdot))\le \varepsilon^{\frac{1}{2}} \tag{5.6}$$

and

$$E\int_s^T \tilde{\mathcal{H}}(t,x^\varepsilon(t),\tilde{u}^\varepsilon(t))dt=\max_{u(\cdot)\in U_{ad}[s,T]} E\int_s^T \tilde{\mathcal{H}}(t,x^\varepsilon(t),u(t))dt, \tag{5.7}$$

where

$$\tilde{\mathcal{H}}(t,x,u)=\mathcal{H}^{(x^\varepsilon(\cdot),u^\varepsilon(\cdot))}(t,x,u)-\varepsilon^{\frac{1}{2}}\nu^\varepsilon(t)|u-\tilde{u}^\varepsilon(t)|. \tag{5.8}$$

The integral-form maximum condition (5.7) implies a pointwise maximum condition, namely, for a.e. $t\in[s,T]$ and $P-$ a.s.,

$$\tilde{\mathcal{H}}(t,x^\varepsilon(t),\tilde{u}^\varepsilon(t))=\max_{u\in\Gamma}\tilde{\mathcal{H}}(t,x^\varepsilon(t),u). \tag{5.9}$$

This, in turn, yields [2, Proposition 2.3.2]

$$0\in\partial_u\tilde{\mathcal{H}}(t,x^\varepsilon(t),\tilde{u}^\varepsilon(t)). \tag{5.10}$$

By (5.8) and the fact that the generalized gradient of the sum of two functions is contained in the sum of the generalized gradients of the two functions [2, Proposition 2.3.3], we deduce

$$\begin{aligned}
&\partial_u\tilde{\mathcal{H}}(t,x^\varepsilon(t),\tilde{u}^\varepsilon(t))\\
\subset\ &\partial_u\tilde{\mathcal{H}}^{(x^\varepsilon(\cdot),u^\varepsilon(\cdot))}(t,x^\varepsilon(t),\tilde{u}^\varepsilon(t))+[-\varepsilon^{\frac{1}{2}}\nu^\varepsilon(t),\varepsilon^{\frac{1}{2}}\nu^\varepsilon(t)]\\
=\ &\partial_u H(t,x^\varepsilon(t),\tilde{u}^\varepsilon(t),\psi^\varepsilon(t),K^\varepsilon(t))+[-\varepsilon^{\frac{1}{2}}\nu^\varepsilon(t),\varepsilon^{\frac{1}{2}}\nu^\varepsilon(t)]\\
&+\{\sigma_u(t,x^\varepsilon(t),\tilde{u}^\varepsilon(t))^*Q^\varepsilon(t)(\sigma(t,x^\varepsilon(t),u^\varepsilon(t))-\sigma(t,x^\varepsilon(t),\tilde{u}^\varepsilon(t)))\}.
\end{aligned}$$

Since H is differentiable in u by assumption (A3), the inclusion (5.10) implies that there is $\beta^\varepsilon(t)\in[-\varepsilon^{\frac{1}{2}}\nu^\varepsilon(t),\varepsilon^{\frac{1}{2}}\nu^\varepsilon(t)]$ such that

$$\begin{aligned}
&H_u(t,x^\varepsilon(t),\tilde{u}^\varepsilon(t),\psi^\varepsilon(t),K^\varepsilon(t))\\
=\ &-\beta^\varepsilon(t)-\sigma_u(t,x^\varepsilon(t),\tilde{u}^\varepsilon(t))^*Q^\varepsilon(t)(\sigma(t,x^\varepsilon(t),u^\varepsilon(t))-\sigma(t,x^\varepsilon(t),\tilde{u}^\varepsilon(t))).
\end{aligned} \tag{5.11}$$

Consequently, by noting (A3),

$$\begin{aligned}
&|H_u(t,x^\varepsilon(t),u^\varepsilon(t),\psi^\varepsilon(t),K^\varepsilon(t)|\\
\le\ &|H_u(t,x^\varepsilon(t),u^\varepsilon(t),\psi^\varepsilon(t),K^\varepsilon(t))-H_u(t,x^\varepsilon(t),\tilde{u}^\varepsilon(t),\psi^\varepsilon(t),K^\varepsilon(t))|\\
&+|H_u(t,x^\varepsilon(t),\tilde{u}^\varepsilon(t),\psi^\varepsilon(t),K^\varepsilon(t))|\\
\le\ &C_3\nu^\varepsilon(t)|u^\varepsilon(t)-\tilde{u}^\varepsilon(t)|+|\beta^\varepsilon(t)|\\
&+|\sigma_u(t,x^\varepsilon(t),\tilde{u}^\varepsilon(t))^*Q^\varepsilon(t)(\sigma(t,x^\varepsilon(t),u^\varepsilon(t))-\sigma(t,x^\varepsilon(t),\tilde{u}^\varepsilon(t)))|\\
\le\ &C_4\nu^\varepsilon(t)|u^\varepsilon(t)-\tilde{u}^\varepsilon(t)|+\varepsilon^{\frac{1}{2}}\nu^\varepsilon(t).
\end{aligned} \tag{5.12}$$

By the concavity of $H(t,\cdot,\cdot,\psi^\varepsilon(t),K^\varepsilon(t))$, we have

$$\begin{aligned}
&H(t,x(t),u(t),\psi^\varepsilon(t),K^\varepsilon(t))-H(t,x^\varepsilon(t),u^\varepsilon(t),\psi^\varepsilon(t),K^\varepsilon(t))\\
\le\ &H_x(t,x^\varepsilon(t),u^\varepsilon(t),\psi^\varepsilon(t),K^\varepsilon(t))(x(t)-x^\varepsilon(t))\\
&+H_u(t,x^\varepsilon(t),u^\varepsilon(t),\psi^\varepsilon(t),K^\varepsilon(t))(u(t)-u^\varepsilon(t))
\end{aligned} \tag{5.13}$$

for any admissible pair $(x(\cdot), u(\cdot))$. Upon taking integrations on both sides and noting (5.1) and (5.12), we obtain

(5.14)
$$\begin{aligned} & E\int_s^T \{H(t,x(t),u(t),\psi^\varepsilon(t),K^\varepsilon(t)) - H(t,x^\varepsilon(t),u^\varepsilon(t),\psi^\varepsilon(t),K^\varepsilon(t))\}dt \\ \leq\ & E\int_s^T H_x(t,x^\varepsilon(t),u^\varepsilon(t),\psi^\varepsilon(t),K^\varepsilon(t))(x(t)-x^\varepsilon(t))dt + C_5\{\varepsilon^{\frac{1}{2}} + \tilde{d}(u^\varepsilon(\cdot),\tilde{u}^\varepsilon(\cdot))\} \\ \leq\ & E\int_s^T H_x(t,x^\varepsilon(t),u^\varepsilon(t),\psi^\varepsilon(t),K^\varepsilon(t))(x(t)-x^\varepsilon(t))dt + C_6\varepsilon^{\frac{1}{2}}. \end{aligned}$$

On the other hand, the state equation (2.2) can be rewritten as

$$\begin{aligned} & d(x(t)-x^\varepsilon(t)) \\ =\ & f_x^\varepsilon(t)(x(t)-x^\varepsilon(t))dt + \sigma_x^\varepsilon(t)(x(t)-x^\varepsilon(t))dB(t) \\ & + [-f_x^\varepsilon(t)(x(t)-x^\varepsilon(t)) + f(t,x(t),u(t)) - f(t,x^\varepsilon(t),u^\varepsilon(t))]dt \\ & + [-\sigma_x^\varepsilon(t)(x(t)-x^\varepsilon(t)) + \sigma(t,x(t),u(t)) - \sigma(t,x^\varepsilon(t),u^\varepsilon(t))]dB(t), \end{aligned}$$

where $f_x^\varepsilon(t) = f_x(t,x^\varepsilon(t),u^\varepsilon(t))$, etc. By applying the Ito formula to $\psi^\varepsilon(t)\cdot(x(t)-x^\varepsilon(t))$ we have

$$\begin{aligned} & E\{\int_s^T L_x^\varepsilon(t)\cdot(x(t)-x^\varepsilon(t))dt + h_x(x^\varepsilon(T))\cdot(x(1)-x^\varepsilon(1))\} \\ =\ & E\int_s^T \Big\{\psi^\varepsilon(t)\cdot[-f_x^\varepsilon(t)(x(t)-x^\varepsilon(t)) + f(t,x(t),u(t)) - f(t,x^\varepsilon(t),u^\varepsilon(t))] \\ & \quad + K^\varepsilon(t)\cdot[-\sigma_x^\varepsilon(t)(x(t)-x^\varepsilon(t)) + \sigma(t,x(t),u(t)) - \sigma(t,x^\varepsilon(t),u^\varepsilon(t))]\Big\}dt. \end{aligned}$$

Hence,

$$\begin{aligned} & E\int_s^T \{H_x(t,x^\varepsilon(t),u^\varepsilon(t),\psi^\varepsilon(t),K^\varepsilon(t))(x(t)-x^\varepsilon(t)) \\ & \qquad + \psi^\varepsilon(t)\cdot[f(t,x(t),u(t)) - f(t,x^\varepsilon(t),u^\varepsilon(t))] \\ & \qquad + K^\varepsilon(t)\cdot[\sigma(t,x(t),u(t)) - \sigma(t,x^\varepsilon(t),u^\varepsilon(t))]\}dt \\ =\ & E\{h_x(x^\varepsilon(T))(x(T)-x^\varepsilon(T))\} \\ \leq\ & E\{h(x(T)) - h(x^\varepsilon(T))\}. \end{aligned} \tag{5.15}$$

Combining (5.14) and (5.15), we arrive at

$$J(u^\varepsilon(\cdot)) \leq J(u(\cdot)) + C_1\varepsilon^{\frac{1}{2}}.$$

Since $u(\cdot)$ is arbitrary, the desired result follows. □

COROLLARY 5.2. *Under the assumptions of Theorem* 5.1, *a sufficient condition for an admissible pair* $(x^\varepsilon(\cdot), u^\varepsilon(\cdot))$ *to be* ε*-optimal is*

$$\begin{aligned} & E\int_s^T \mathcal{H}^{(x^\varepsilon(\cdot),u^\varepsilon(\cdot))}(t,x^\varepsilon(t),u^\varepsilon(t))dt \\ & \geq \sup_{u(\cdot)\in U_{ad}[s,T]} E\int_s^T \mathcal{H}^{(x^\varepsilon(\cdot),u^\varepsilon(\cdot))}(t,x^\varepsilon(t),u(t)) - \left(\frac{\varepsilon}{C_1}\right)^2. \end{aligned} \tag{5.16}$$

Example 5.1. Consider the problem presented in Example 4.1. Since the Hamiltonian

$$H(t,x,u,p,q) = u - qu$$

is concave in (x, u), we can apply Corollary 5.1 to conclude that $u^\varepsilon(t) \equiv 1 - (\frac{\varepsilon}{C_1})^2$ (which in view of Theorem 4.1 is a candidate for ε-optimality for sufficiently small ε) is indeed an ε-optimal control.

Remark 5.1. Theorem 5.1 asserts that the ε-maximum condition of the $\mathcal{H}$-function implies near-optimality with order $\varepsilon^{\frac{1}{2}}$. In Example 4.1, the control $u^\varepsilon(t) = 1 - \varepsilon^{\frac{1}{2}}$ (with the corresponding $K^\varepsilon(t) = 1 - \varepsilon^{\frac{1}{2}}$) satisfies the ε-maximum condition of the $\mathcal{H}$-function; see the left-hand side of (4.14). However, the underlying cost function

$$J = -E\int_0^1 u(t)dt + \frac{1}{2}E\int_0^1 u(t)^2 dt = \frac{1}{2}E\int_0^1 [u(t)-1]^2 dt - \frac{1}{2}.$$

Therefore, the minimum value of the cost function is $-\frac{1}{2}$. Moreover, we see that $u^\varepsilon(t) = 1 - \varepsilon^{\frac{1}{2}}$ is actually a near-optimal control with order ε. This suggests that we may lose some sharpness in estimating the error bound when applying Theorem 5.1. just as with Theorem 4.1. The setback basically comes from the Ekeland principle (Lemma 2.1), where a smaller value of λ results in a better knowledge about the position of u^λ at the cost of a less sharp estimate on the value of $\rho(u^\lambda)$.

Remark 5.2. If (5.2) holds with $\varepsilon = 0$, then Theorem 5.1 becomes a sufficiency theorem for (exact) optimality. In this case, the sufficient condition (5.2) is equivalent to Zhou's sufficient condition [15]:

$$\mathcal{H}^{(x^\varepsilon(\cdot),u^\varepsilon(\cdot))}(t, x^\varepsilon(t), u^\varepsilon(t)) = \max_{u\in\Gamma} \mathcal{H}^{(x^\varepsilon(\cdot),u^\varepsilon(\cdot))}(t, x^\varepsilon(t), u),\ P-\text{ a.s., a.e. } t \in [s, T].$$

6. Some discussions. In sections 4 and 5, we established necessary and sufficient conditions, respectively, for stochastic near-optimal controls in terms of a small parameter ε. Here ε may appear in two different situations. First, it may reflect the loss in the objective value allowed by the decision maker, who may have set this "tolerance level" before he started to seek a near-optimal policy. Second, ε may be a parameter representing the complexity of the original decision problem that can be approximated by simpler models as ε is sufficiently small. For the second situation, two good examples are hierarchical production models (see, e.g., [10, 11, 16]) and discrete approximation (see, e.g., [5, 8]).

Many practical systems are so complicated that it is simply impossible to obtain their optimal controls. A commonly used approach is to approximate the original optimal control problems by simpler ones and then construct controls based on the optimal controls of the approximating problems. Theorems 4.1 and 5.1 provide a possible way to show analytically that the constructed controls are near-optimal for the original complicated stochastic control problems. The idea behind it, in some abstract form, is as follows. Suppose we have a family of stochastic control problems $\mathcal{P}^\varepsilon$ parameterized by $\varepsilon > 0$ and a stochastic control problem $\mathcal{P}$ which is much easier to solve than each $\mathcal{P}^\varepsilon$. Let $U_{ad,\varepsilon}[s, T]$ and $U_{ad}[s, T]$ be the sets of admissible controls for $\mathcal{P}^\varepsilon$ and $\mathcal{P}$, respectively. Now we solve $\mathcal{P}$ and obtain an optimal or near-optimal (in terms of ε) control $u^*(\cdot)$. Then the stochastic maximum principle [9, 12] or Corollary 4.1 of this paper yields

$$\mathcal{H}^{(x^*(\cdot),u^*(\cdot))}(t, x^*(t), u^*(t)) = \max_{u\in\Gamma} \mathcal{H}^{(x^*(\cdot),u^*(\cdot))}(t, x^*(t), u),\quad P-\text{ a.s., a.e. } t. \tag{6.1}$$

or

$$
\begin{aligned}
&E\int_s^T \mathcal{H}^{(x^*(\cdot),u^*(\cdot))}(t,x^*(t),u^*(t))dt \\
&\qquad \geq \sup_{u(\cdot)\in U_{ad}[s,T]} E\int_s^T \mathcal{H}^{(x^*(\cdot),u^*(\cdot))}(t,x^*(t),u(t))dt - C_1\varepsilon^{\gamma},
\end{aligned} \tag{6.2}
$$

depending on whether $u^*(\cdot)$ is optimal or near-optimal. Here $\mathcal{H}^{(x^*(\cdot),u^*(\cdot))}$ is the $\mathcal{H}$-function associated with problem $\mathcal{P}$ and $(x^*(\cdot),u^*(\cdot))$. We then construct $u^\varepsilon(\cdot)$ for $\mathcal{P}^\varepsilon$ from $u^*(\cdot)$ (the way of constructions depends on each particular situation). Let $\mathcal{H}_\varepsilon^{(x^\varepsilon(\cdot),u^\varepsilon(\cdot))}$ be the $\mathcal{H}$-function associated with problem $\mathcal{P}^\varepsilon$ and $(x^\varepsilon(\cdot),u^\varepsilon(\cdot))$. If we can prove that

$$
\begin{aligned}
& E\textstyle\int_s^T \mathcal{H}_\varepsilon^{(x^\varepsilon(\cdot),u^\varepsilon(\cdot))}(t,x^\varepsilon(t),u^\varepsilon(t))dt \\
\geq\ & E\textstyle\int_s^T \mathcal{H}^{(x^*(\cdot),u^*(\cdot))}(t,x^*(t),u^*(t))dt - C'\varepsilon^{\alpha} \\
\geq\ & \sup_{u(\cdot)\in U_{ad}[s,T]} E\textstyle\int_s^T \mathcal{H}^{(x^*(\cdot),u^*(\cdot))}(t,x^*(t),u(t))dt - C'\varepsilon^{\beta} \\
\geq\ & \sup_{u(\cdot)\in U_{ad,\varepsilon}[s,T]} E\textstyle\int_s^T \mathcal{H}_\varepsilon^{(x^\varepsilon(\cdot),u^\varepsilon(\cdot))}(t,x^\varepsilon(t),u(t))dt - C''\varepsilon^{\delta},
\end{aligned} \tag{6.3}
$$

where the second inequality above is due to (6.1) or (6.2) and the first and third inequalities may be obtained by some estimates on the difference between the trajectories $x^\varepsilon(\cdot)$ and $x^*(\cdot)$, then $u^\varepsilon(\cdot)$ is near-optimal for $\mathcal{P}^\varepsilon$ with an error bound of order $\varepsilon^{\delta/2}$ if all the other assumptions of Theorem 5.1 are satisfied.

The above general idea has been applied to the hierarchical controls of stochastic manufacturing systems [16] (although the controlled process there is piecewise deterministic rather than of diffusion type). To be more specific, in [16], $\mathcal{P}^\varepsilon$ is an optimal production planning problem with stochastic machine capacity and ε representing the reciprocal of the fluctuation rate of the machine capacity process, and $\mathcal{P}$ is a deterministic problem where the random machine capacity has been averaged out. Certainly, $\mathcal{P}$ is much easier to solve analytically than $\mathcal{P}^\varepsilon$. A near-optimal control for $\mathcal{P}^\varepsilon$ is constructed based on an optimal control for $\mathcal{P}$ and its near-optimality is proved via a sequence of inequalities similar to (6.3) (see [16, section 5]).

Here we present another example which realizes the above idea.

Example 6.1. Consider the following problem:

$$
\begin{aligned}
&\text{minimize} \quad J^\varepsilon(u(\cdot)) = E\{\textstyle\int_0^1 \varepsilon g(u(t))dt + \frac{1}{2}x(1)^2\} \\
&\text{subject to} \quad \begin{cases} dx(t) = u(t)dt + u(t)dB(t), \\ x(0) = x_0, \end{cases}
\end{aligned} \tag{6.4}
$$

where $\varepsilon > 0$ is a small parameter and g (independent of ε) is a nonlinear, convex function satisfying assumption (A3) (see (5.1)). Let the control region $\Gamma = R^1$ and denote the problem by $\mathcal{P}^\varepsilon$. The running cost is nonlinear, which becomes small if ε becomes small. If one insists on solving the problem optimally, then he has to take the nonlinearity into full account, and it may turn out to be very hard to obtain an analytical solution. Let us do it differently. What we are going to show is that we can easily get a near-optimal (feedback) control analytically based on the optimal control of a simpler problem, called $\mathcal{P}$, which is obtained by setting $\varepsilon = 0$ in (6.4), namely,

by neglecting the nonlinearity. Indeed, $\mathcal{P}$ can be solved directly. To see this, applying Ito's formula yields

$$d(e^{t-1}x(t)^2) = e^{t-1}(u(t)+x(t))^2dt + e^{t-1}u(t)dB(t).$$

Hence

$$Ex(1)^2 = Ee^{-1}x_0^2 + E\int_0^1 e^{t-1}(u(t)+x(t))^2dt.$$

It follows that the optimal control for problem $\mathcal{P}$ is a feedback $u(t) = -x(t)$. Now we are to prove that the *same* feedback control is near-optimal for the original problem $\mathcal{P}^\varepsilon$ when ε becomes sufficiently small. First, notice that the system dynamics are the same with $\mathcal{P}^\varepsilon$ and $\mathcal{P}$ (the only difference lies in the cost functions), thus the state trajectories and all adjoint processes coincide for both problems under the same controls. Denote optimal state and control under the feedback $u(t) = -x(t)$ with initial x_0 by $(x^*(\cdot), u^*(\cdot))$ and the corresponding solutions to the first- and second-adjoint equations by $(\psi(\cdot), K(\cdot))$ and $(Q(\cdot), R(\cdot))$, respectively. It is easy to show that $Q(t) \equiv 1$. Then the $\mathcal{H}$-function for $\mathcal{P}$ is

$$\mathcal{H}^{(x^*(\cdot),u^*(\cdot))}(t,x,u) = -\frac{1}{2}u^2 - (\psi(t)+K(t)-u^*(t))u.$$

Since $u^*(\cdot)$ is optimal, by stochastic maximum principle, it is necessary that $u^*(t)$ maximizes the $\mathcal{H}$-function a.s., namely,

$$-u^*(t) - (\psi(t)+K(t)-u^*(t)) = 0, \quad P- \text{ a.s., a.e. } t.$$

So

$$\psi(t)+K(t) = 0, \quad P- \text{ a.s., a.e. } t.$$

However, the $\mathcal{H}$-function for $\mathcal{P}^\varepsilon$ is

$$\begin{aligned}\mathcal{H}_\varepsilon^{(x^*(\cdot),u^*(\cdot))}(t,x,u) &= -\tfrac{1}{2}u^2 - (\psi(t)+K(t)-u^*(t))u - \varepsilon g(u)\\ &= -\tfrac{1}{2}u^2 + u^*(t)u - \varepsilon g(u).\end{aligned}$$

The above function is maximized at u^ε, which satisfies

$$u^\varepsilon = u^*(t) - \varepsilon\dot{g}(u^\varepsilon). \tag{6.5}$$

Hence

$$\begin{aligned}&\mathcal{H}_\varepsilon^{(x^*(\cdot),u^*(\cdot))}(t,x,u^*(t)) - \max_{u\in\Gamma}\mathcal{H}_\varepsilon^{(x^*(\cdot),u^*(\cdot))}(t,x,u)\\ =\ &\mathcal{H}_\varepsilon^{(x^*(\cdot),u^*(\cdot))}(t,x,u^*(t)) - \mathcal{H}_\varepsilon^{(x^*(\cdot),u^*(\cdot))}(t,x,u^\varepsilon)\\ =\ &\tfrac{1}{2}(u^\varepsilon - u^*(t))^2 + \varepsilon[g(u^\varepsilon) - g(u^*(t))]\\ \le\ &\tfrac{1}{2}\varepsilon^2|\dot{g}(u^\varepsilon)|^2 + C\varepsilon^2|\dot{g}(u^\varepsilon)|\\ \le\ &C'\varepsilon^2.\end{aligned}$$

Moreover, the Hamiltonian for problem $\mathcal{P}^\varepsilon$ is

$$H(t,x,u,\psi(t),K(t)) = -\varepsilon g(u) - \psi(t)u - K(t)u = -\varepsilon g(u),$$

which is concave. It follows then by Theorem 5.1 that $u^*(\cdot)$ is near-optimal for $\mathcal{P}^\varepsilon$ with an error order of ε when ε is sufficiently small.

It is worth mentioning that the idea in the above example may also apply to some cases where there are nonlinearities in system dynamics. If those nonlinearities are "small", then one considers a (usually) simpler linear system (by ignoring the nonlinearities) and solves the original nonlinear problem near-optimally based on the solutions to the linear system. In a more general setting, many optimal control problems are difficult because some small components of the systems are difficult to handle. The whole problems might be insurmountable if we insist on taking those components into consideration. However, the problems may become easily solvable if we ignore those small but difficult parts and consider near-optimality instead. It also should be noted that by saying some components are "small" we meant that they are small compared with other components of the systems; so it is in a relative sense. In hierarchical production planning, for instance, ε being small means that the machine capacity process changes much faster than other processes involved, such as discounting process. See [10, 11, 16] for details.

7. Concluding remarks. In this paper, we established necessary and sufficient conditions for near-optimal stochastic controls in terms of a small parameter ε. The theory developed in this paper is parallel to the classical Pontryagin maximum principle in exact optimization. It would be interesting to investigate the dynamic programming approach applied to near-optimality. Another challenging problem is to improve the error bounds obtained in this paper. We hope to study these problems in forthcoming papers.

THE SYMMETRIC RENDEZVOUS-EVASION GAME*

STEVE ALPERN† AND WEI SHI LIM‡

Abstract. E. J. Anderson and R. R. Weber, *J. Appl. Probab.*, 28 (1990), pp. 839–851, considered the problem of two rendezvousers, R_1, R_2, randomly placed among n indistinguishable locations, who seek to meet in least expected time, using the same mixed strategy. We retain their dynamics but modify the rendezvousers' aim to meeting each other before either encounters an enemy searcher S. We solve this zero-sum game in minimal space (3 locations) and time (2 steps after placement), and find that optimal play requires that the rendezvous team use a mixture over behavioral strategies. While such complicated strategies are known to be necessary in principal for team games (the theory of Isbell and Alpern), we believe this is the first naturally occuring game where such a solution is derived. (An earlier paper by Lim solved a similar game in which R_1 and R_2 were allowed to use different strategies and joint randomization.)

Key words. rendezvous search, zero-sum game

1. Introduction.

The problem dealt with in this paper can best be introduced in terms of the "telephone problem" posed by the first author about 20 years ago: In two similar rooms in New York and San Francisco, there are n telephones strewn about, which are randomly connected in pairs. The original problem asked how two friends, placed in rooms in New York and San Francisco, should choose which phones to pick up at a sequence of discrete time points. Their aim is to minimize the expected time when they first pick up paired phones, subject to the restriction that they must use the same mixed strategy (otherwise one would stay at a fixed phone, the other would pick a permutation of the phones). This problem was reformulated by Anderson and Weber [3] in terms of two players moving among n distinct locations, who meet when they first occupy the same location. They found a family of strategies that give an expected meeting time of $0.8288n$ for large n. This is markedly better than the random strategy, which has expected meeting time n.

The rendezvous-evasion game, posed a few years ago by the first author, can be put into the "telephone" setting by adding an enemy "phone-tapper" S (for Searcher) who is placed in a Chicago room through which all n cables pass. At the times when the rendezvousers R_1, R_2 pick up phones and say something, S picks a cable to "tap." The rendezvous team wins the game if they pick corresponding phones before either talks on a line overheard by S. In terms of the distinct location version of Anderson and Weber, the rendezvous team wins if they meet before either meets S (and before the time runs out, if it is limited to m steps). Thus this game is something of a hybrid between a search game in the sense of Gal [4] and a rendezvous problem in the sense of Alpern [1]. (It may be viewed more generally as a geometric game, in the sense of Ruckle [10].) The *asymmetric* version of the rendezvous-evasion game, in which R_1 and R_2 are allowed to use *different* strategies, has been studied and solved

for some cases by Lim [6]. (Unlike the pure rendezvous problem, where asymmetric players could simply stay put and search exhaustively, respectively, Lim found that complex joint randomization was required for optimal play by the rendezvous team.) This problem has some similarities to that studied by Nakai [8], where two searchers compete to find a stationary target first. In that problem, the target has a given distribution and there is the added complexity of an overlook probability. Another rendezvous problem involving more than two agents is studied in [7], but in that version all agents have the common objective of minimizing the time required for a group meeting.

The present paper deals with the *symmetric* version of the rendezvous-evasion game on discrete locations. We consider the minimal problem in terms of space and time, by assuming three locations, and a time limit of two steps after placement of the players at distinct locations. (If no meeting has occured after two steps, we say that S has won.) We consider that the three locations are placed in the plane, so that all three agents have a common (clockwise) ordering of them. This common ordering allows each individual strategy to simply be expressed as a sequence of positions relative to the initial position.

The symmetry requirement for the rendezvous team can be viewed in terms of a "team coordinator," who broadcasts a strategy which is received by R_1, R_2 (but not S) in each play of the game. The broadcast strategy must be behavioral, i.e., require R_1, R_2 to (independently) randomize before each move; if they followed the same *pure* strategy they would always stay in the same relative position and hence never meet. Since the rendezvous team coordinator can also randomize before deciding which behavioral strategy to broadcast, the rendezvous team's most general strategy is a mixture over behavioral strategies. In fact we shall see that such a complex strategy is indeed required for optimal play.

Since the time-limited rendezvous-evasion game is apparently a finite, two-person, zero-sum game, the necessity of mixtures over behavioral strategies requires some explanation. Actually there are two explanations, depending on whether it is viewed as an infinite game or a finite team game (game with repeated decisions, as in [2]). If one takes the infinite game viewpoint, one says that the rendezvous coordinator's pure strategies (those to be actually used in an individual play of the game) are in fact the behavioral strategies that he broadcasts. So the general theory of infinite (compact) games says that some mixture over these strategies is optimal. The more sophisticated viewpoint is to say that the game is finite, but it is a team game which is equivalent to one with "repeated decisions." This means that it is equivalent to one with an extensive form where some paths pass through an information set more than once (in fact, once for R_1 and once for R_2). The theory of such games [5], [2] says that finite mixtures over behavioral strategies may be required, and [2] gives a bound on the maximum number of behavioral strategies that must be used. In the game considered here we find that the rendezvous team must mix over three behavioral strategies. While the possible necessity of such mixed-behavioral strategies has been noted in the theory of team games (and illustrated by examples), we believe this is their first occurrence in a naturally arising game. We should observe that, for games of the type considered here, no general solution algorithms have been developed. So a pair of proposed solutions must be individually shown to ensure the same value. In this sense the game studied here is like an infinite, compact game.

The paper is organized as follows. In section 2 we formally define and solve the two-step, symmetric rendezvous-evasion game on three locations. In section 3 we consider certain qualitative aspects of the solution obtained in section 2. We explain

the need for the rendezvous team to use a mixture over behavioral strategies in terms of the information structure of the game, and we show that no single behavioral strategy is adequate. We also show that the optimal rendezvous strategy given in section 2 is stable with respect to unilateral deviations by an individual rendezvous agent, and thus not subject to the Piccione–Rubinstein's "absent-minded driver paradox." Finally, we show that, for asymmetric or symmetric rendezvous-evasion games on n locations with $m \leq \infty$ steps, the optimal solution is the same as for a pure rendezvous game (i.e., with no enemy searcher) where the agents receive a fixed prize when they meet, which they time discount with a common factor. This formulation shows that the rendezvous team does better against the searcher when they are allowed to jointly randomize over pure strategy pairs, winning with probability 36/81 instead of 24/81 for the symmetric problem. In section 4 we discuss what happens in the rendezvous-evasion game if we drop the assumption of a common knowledge ordering of the three locations. We show that the resulting game is better for the searcher in that the value (optimal probability that the searcher wins) increases.

We conclude this introduction with a small technical note for those readers familiar with the Anderson–Weber formulation [3]. They begin their problem with a random initial placement of the two agents, including the possibility that they are placed on the same location. We consider a different but equivalent start in which the three agents are placed according to a random permutation. This is what the Anderson–Weber start gives in the nontrivial case that no two are at the same location. Thus step k in our model corresponds to step $k+1$ in theirs.

2. The rendezvous-evasion game. In this section we define and solve a rendezvous-evasion game Γ played between a searcher S and a rendezvous team R consisting of two agents called R_1 and R_2. The three are initially placed randomly at three distinct locations, which we view as the vertices of a triangle. We assume they all have a common notion of a clockwise direction around these vertices but otherwise have no common labeling. (In the formal notation of rendezvous search described in [1], this corresponds to the case where the given group G of symmetries is the group of the three rotations of the triangle, the group generated by any cycle of the three locations.) At each of two time steps, they may each move to any vertex (including the one they currently occupy). This is a zero-sum game which is won by the rendezvous team R (with payoff $\pi = 0$) if R_1 and R_2 meet each other before either meets the enemy searcher S and before the game ends at the end of step two; otherwise the searcher S wins (with $\pi = 1$). Thus the value of the game, if it exists, is the probability that S wins, given optimal play on both sides. We assume that the agents R_1 and R_2 have not met prior to play to agree which role each should play (e.g., one stationary and one searching), and so must play the same mixed strategy.

To formally describe strategies, we assume that each agent labels his initial position as 0 and labels the remaining two in a clockwise direction as 1 and 2. The possibility of such a labeling is justified by the symmetry assumptions described above, formalized in the definition of G. Thus there are nine pure strategies,

$$\{(0,0),(1,2),(2,1),(0,1),(1,0),(2,2),(0,2),(1,1),(2,0)\},$$

which we number in this order as $w_i, i = 1, \ldots, 9$. Note that in this numbering,

$$\text{if } w_i = (x_1, x_2), i = 1, \ldots, 3, \quad \text{then } w_{i+3j} = (x_1, x_2 + j \bmod 3). \tag{2.1}$$

A probability distribution b over these nine strategies, with b_i interpreted as the probability of playing the pair w_i, will be called a behavioral strategy. (The way

we have described it would usually be called a mixed strategy, but it is certainly equivalent to a behavioral strategy giving a distribution for x_1 and a conditional distribution for x_2; we have reasons for preferring our chosen terminology.)

The times of meeting between pairs of agents depend on the random initial placement and the strategies used. Specifically, suppose that the initial location of $R_1$and R_2 in S-labels is denoted by (r_1, r_2), which is either $(1, 2)$ or $(2, 1)$. If the pure strategies played by R_1, R_2, and S are denoted x, y, z, then the rendezvous meeting time and the searcher meeting time are given, respectively, by

$$T_R = \min\{t : x_t - y_t = r_2 - r_1\}, \tag{2.2}$$
$$T_S = \min\{t : z_t = r_1 + x_t \text{ or } r_2 + y_t\}.$$

The payoff π to the maximizing searcher S is given by

$$\pi = \begin{cases} 0 & \text{if} \quad T_R \le \min(T_S - 1, 2), \\ 1 & \text{otherwise.} \end{cases}$$

We will be concerned with the four following behavioral strategies, the first three for R and the fourth random strategy for S.

$$\begin{aligned} \hat{b}^1 &= \tfrac{1}{3}(1,1,1,0,0,0,0,0,0), \\ \hat{b}^2 &= \tfrac{1}{3}(0,0,0,1,1,1,0,0,0), \\ \hat{b}^3 &= \tfrac{1}{3}(0,0,0,0,0,0,1,1,1), \\ \hat{s} &= \tfrac{1}{9}(1,1,1,1,1,1,1,1,1). \end{aligned}$$

We will show that $\hat{s}$ is optimal for the searcher S and that the mixture $\beta = \frac{1}{3}\hat{b}^1 + \frac{1}{3}\hat{b}^2 + \frac{1}{3}\hat{b}^3$ of three behavioral strategies is optimal for the rendezvous team R. (An optimal strategy for the controller of the rendezvous agents is to choose equiprobably among the $\hat{b}^k$ and to broadcast the chosen one for the two rendezvousers to use, with each of them randomizing independently.)

We begin our analysis of the strategy β by showing that it has two important properties; it has early rendezvous (T_R small), and unpredictable paths for its agents. These properties are established in the following two lemmas.

LEMMA 2.1. *If the two rendezvous agents both use the same behavioral strategy $\hat{b}^k$ for some $k = 1, 2, 3$, then*

$$\Pr(T_R = 1) = \Pr(T_R = 2) = \frac{1}{3}.$$

Proof. The simplest proof is a straightforward checking of the nine equiprobable cases that arise from the common use of $\hat{b}^k$. We consider $\hat{b}^1$ in detail and then show how the remaining two behavioral strategies give the same result. For $\hat{b}^1$ the nine equiprobable cases are listed below, and for each pair the probability of rendezvous in one or two steps is given.

	$(0,0)$	$(1,2)$	$(2,1)$
$(0,0)$	$0, 0$	$1/2, 1/2$	$1/2, 1/2$
$(1,2)$	$1/2, 1/2$	$0, 0$	$1/2, 1/2$
$(2,1)$	$1/2, 1/2$	$1/2, 1/2$	$0, 0$

To see how the entries were calculated, consider for example the situation of R_1 follows the path $(0, 0)$ and stays still, while R_2 follows path $(1, 2)$, a clockwise circuit.

If R_2 was initially placed one unit clockwise of R_2, then $T_R = 2$; otherwise $T_R = 1$. Since six of the nine pairs have entry $1/2, 1/2$, we have that

$$\Pr(T_R = 1) = \Pr(T_R = 2) = \frac{6}{9} * \frac{1}{2} = \frac{1}{3}.$$

The corresponding result for the behavioral strategies $\hat{b}^i, i = 2, 3$ follows from that of $\hat{b}^1$ and the equation noted above, $w_{i+3j} = (x_1, x_2 + j \bmod 3)$. The behavior on step 1 is identical, while the behavior on step 2 is rotated by the same amount for both players. (An equal rotation of two paths preserves their distance and hence their rendezvous time.) □

LEMMA 2.2. *If an agent is following the mixed behavioral strategy* $\beta = \frac{1}{3}\hat{b}^1 + \frac{1}{3}\hat{b}^2 + \frac{1}{3}\hat{b}^3$, *then*

1. *his position at step* 1 *is random, and*
2. *his position at step* 2 *is random and independent of his position at step* 1.

Proof. Property 1 is obviously true of each constituent behavioral strategy $\hat{b}^i$ and hence also true for any mixture. Property 2 is not true of the constituent strategies but is true of the mixture. Both properties can also be seen to hold from observing that β choose each of the nine pure strategy pairs equiprobably. □

THEOREM 2.3. *If the rendezvous team R follows the mixed behavioral strategy* $\beta = \frac{1}{3}\hat{b}^1 + \frac{1}{3}\hat{b}^2 + \frac{1}{3}\hat{b}^3$, *then it wins against any pure strategy x of the searcher with probability* $\frac{24}{81}$. *That is,*

$$\pi(\beta, x) = \frac{57}{81}.$$

Proof. The searcher S can win the game in three mutually exclusive ways: by meeting a rendezvouser on step 1, by meeting a rendezvouser on step 2, or if no meetings at all have occurred by the end of step 2. Hence we have

$$\Pr(S \text{ wins}) = \Pr(T_S = 1) + \Pr(T_S = 2 \wedge T_R > 1) + \Pr(T_S > 2 \wedge T_R > 2).$$

If we condition the above equation according to the three events $T_R = 1, 2, > 2$, which all have probability $1/3$ by Lemma 2.1, we obtain

$$\begin{aligned} \Pr(S \text{ wins}) &= \tfrac{1}{3}\left(\tfrac{1}{3} + 0 + 0\right) + \tfrac{1}{3}\left(\tfrac{2}{3} + \tfrac{1}{9} + 0\right) + \tfrac{1}{3}(1) \\ &= \tfrac{57}{81}. \end{aligned}$$

The above equation is explained easily as follows. If $T_R = 1$, then by Lemma 2.2, part 1, the search will be at their common meeting location on step 1 with probability $1/3$, regardless of the search strategy. If $T_R = 2$, then similarly at step 1 the searcher will be at one of the two locations occupied by the rendezvousers with probability $2/3$. Furthermore, if the searcher is not at either of these locations (which occurs with probability $1/3$), then at step 2 he will be at their common meeting place with probability $1/3$, by the second part of Lemma 2.2. (The independence asserted in that part of the lemma is needed to show that the searcher cannot use any knowledge gained in step 1 to improve his chances at step 2.) Finally, the third term is simply the statement that S is defined to be the winner if no meeting has occurred in the first two steps. □

We now turn to a consideration of the searcher's optimal strategy, which is simply the random strategy denoted by $\hat{s}$, which picks the location on each step randomly and independently of previous choices. According to the theory of games of this type, we

must evaluate $\hat{s}$ against any behavioral strategy of the opponent, since pure strategies in general will do worse.

LEMMA 2.4. *Suppose the searcher is employing the random strategy $\hat{s}$. Then the rendezvous team R will not do worse by replacing any behavioral strategy b by the strategy b', which is the average of b on each of the three groups $\{w_{3k+1}, w_{3k+2}, w_{3k+3}\}, k = 0, 1, 2$. That is, for any behavioral strategy b, we have*

$$\pi(b', \hat{s}) \leq \pi(b, \hat{s}), \text{ where } b'_{3k+m} = \sum_{j=1}^{3} b_{3k+j}/3,\ k = 0, 1, 2,\ m = 1, 2, 3.$$

Furthermore, equality holds only for the three strategies $\hat{b}^i, i = 1, 2, 3$.

Proof. For $i, j = 1, \ldots, 9$, let a_{ij} denote the probability that the random searcher strategy $\hat{s}$ wins when R_1 and R_2 follow the paths w_i and w_j, respectively. If R_1 and R_2 follow a pair of paths for which the probability that $T_R = t$ is denoted $p_t, t = 1, 2$, then they win on step 1 if S misses their meeting place (probability $2/3$) and they win on step 2 if S missed both their positions at step 1 (probability $1/3$) and also missed their common position on step 2 (probability $2/3$). Hence the team R wins with probability $1 - \pi = p_1(2/3) + p_2(2/9)$. It turns out that there are only four possible values for the pair (p_1, p_2), and the following table gives the value of π for these pairs.

p_1	p_2	π
0	0	9/9
0	1/2	8/9
1/2	0	6/9
1/2	1/2	5/9

These pairs occur in the following situations. When both agents of R use the same path, they cannot meet, and this gives the 9s on the diagonal in the matrix $9A$ below. If they do the same thing on step 1 and different things on step 2, then we are in the second row of the table and $\pi = 8/9$. Pairs that differ in step 1 then meet with probability $1/2$ and either never or always meet on step 2, giving the respective values of $6/9$ and $5/9$ for π (rows three and four of the table). The complete matrix $A = \{a_{ij}\}$ is given below, with the fractions cleared.

$$9A = \begin{array}{c} \\ (0,0) \\ (1,2) \\ (2,1) \\ (0,1) \\ (1,0) \\ (2,2) \\ (0,2) \\ (1,1) \\ (2,0) \end{array} \begin{array}{c} \begin{array}{ccccccccc} (0,0) & (1,2) & (2,1) & (0,1) & (1,0) & (2,2) & (0,2) & (1,1) & (2,0) \end{array} \\ \begin{pmatrix} 9 & 5 & 5 & 8 & 6 & 6 & 8 & 6 & 6 \\ 5 & 9 & 5 & 6 & 8 & 6 & 6 & 8 & 6 \\ 5 & 5 & 9 & 6 & 6 & 8 & 6 & 6 & 8 \\ 8 & 6 & 6 & 9 & 5 & 5 & 8 & 6 & 6 \\ 6 & 8 & 6 & 5 & 9 & 5 & 6 & 8 & 6 \\ 6 & 6 & 8 & 5 & 5 & 9 & 6 & 6 & 8 \\ 8 & 6 & 6 & 8 & 6 & 6 & 9 & 5 & 5 \\ 6 & 8 & 6 & 6 & 8 & 6 & 5 & 9 & 5 \\ 6 & 6 & 8 & 6 & 6 & 8 & 5 & 5 & 9 \end{pmatrix} \end{array}$$

Thus for any behavioral strategy (probability 9-vector) b, we have

$$\pi(b, \hat{s}) = \sum_{i,j} b_i b_j a_{ij} = b^\top A b.$$

Observe that we may write the averaged strategy b' in terms of b according to the equation

$$b' = Cb, \text{where } C = \begin{pmatrix} M & 0 & 0 \\ 0 & M & 0 \\ 0 & 0 & M \end{pmatrix}, \text{with } M = (1/3)\begin{pmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{pmatrix},$$

and the 0s in the matrix C denote the 3×3 matrix of zeros. Thus we have that

$$\pi(b, \hat{s}) - \pi(b', \hat{s}) = b^\top Ab - (Cb)^\top A(Cb) = b^\top (A - C^\top AC)b.$$

The matrix $A - C^\top AC$ has 9 real eigenvalues 2,2,2,2,0,0,0,8,8. Since all are nonnegative, it is positive semi-definite. It follows that the right-hand side of the above equation is nonnegative for any behavioral strategy b. Since there are only three zero eigenvalues, there can be at most three linearly independent solutions to the equation $\pi(b, \hat{s}) - \pi(b', \hat{s})$, and these must be the strategies $\hat{b}^i, i = 1, 2, 3$. □

THEOREM 2.5. *For any behavioral strategy b employed by the rendezvous team R, the random searcher strategy wins with probability at least 57/81. Specifically, $\pi(b, \hat{s}) \geq 57/81$, with equality only for the three behavioral strategies $\hat{b}^k, k = 1, 2, 3$.*

Proof. By the previous lemma, we may assume that the strategy b is already averaged over each of the three groups, that is, $b = (x, x, x, y, y, y, z, z, z)$. It is easily calculated that

$$\begin{aligned} \pi(b, \hat{s}) &= [x(19x + 20y + 20z) + y(20x + 19y + 20z) + z(20x + 20y + 19z)]/3 \\ &= (1/3)(x, y, z)\begin{pmatrix} 19 & 20 & 20 \\ 20 & 19 & 20 \\ 20 & 20 & 19 \end{pmatrix}\begin{pmatrix} x \\ y \\ z \end{pmatrix}, \end{aligned}$$

which has a minimum, over the set $0 \leq x, y, z \leq 1/3$, $x+y+z = 1/3$, of $19/27 = 57/81$. This minimum is obtained exactly when one of the three variables is equal to $1/3$, which corresponds to one of the three strategies $\hat{b}^i, i = 1, 2, 3$. □

Combining the last two theorems, we obtain the following corollary.

COROLLARY 2.6. *The value of the game Γ is 57/81. An optimal strategy for the rendezvous team is the equiprobable mixture of the three behavioral strategies $\hat{b}^k, k = 1, 2, 3$, which optimize against the random strategy for the searcher. An optimal strategy for the searcher is the random strategy.*

3. Properties of the solution. In this section we consider some qualitative and interpretative questions related to our proposed solution $(\beta, \hat{s})$ to the rendezvous-evasion game Γ on three locations with two time steps. We consider whether and why the rendezvous strategy β needs to be so complicated (mixed behavioral), and whether one of the rendezvous agents would wish to deviate from it if allowed to do so. We also show that the game Γ is in some sense equivalent to a pure rendezvous problem, with no enemy searcher, in which the agents get a fixed prize when they meet, which is discounted with respect to the meeting time. Thus this paper has something new to say about the pure rendezvous problem, as well as extending it to a game theoretic setting.

When the rendezvous players are viewed as agents of a team, this team player has imperfect recall because neither agent is aware of the other's previous choices. Actually, the situation is even worse, as an agent who is asked by a referee to make a choice does not know if he is the first or second agent to be asked such a question. That is, the paths of the extensive form game will enter an information set more than once.

Games of this type have been studied by Isbell [5] and Alpern [2], who have shown that mixtures over behavioral strategies may be required. The latter paper also gives a bound on the number of behavioral strategies needed, which for the three-location, two-step game Γ solved in section 2 turns out to be 27. (We found that in fact only three behavioral strategies were needed.) Recent interest in this problem has been generated by the provocative paper of Piccione and Rubinstein [9], who consider models of single-person decision making with this type of forgetting. Later in this section we will consider whether our problem is subject to an intertemporal paradox they find for certain games of this type. The first qualitative question we consider in this section is whether a single behavioral strategy will suffice for the rendezvous team in the sense of ensuring the value of the game. The following result answers this question in the negative.

THEOREM 3.1. *No behavioral strategy b for the rendezvous team ensures that the searcher cannot win with probability greater than the value, i.e., that $\pi(b,s) \leq 57/81$, for all s.*

Proof. Suppose that b is a behavioral strategy with $\pi(b,s) \leq 57/81$ for every behavioral strategy s of the searcher. Taking s equal to the random strategy $\hat{s}$, we see that the only possibilities for b are the three strategies $\hat{b}^k, k = 1,2,3$, by the last part of Theorem 2.5. However, the searcher has an effective answer to each of these strategies. Against $\hat{b}^1$, the pure strategy $w_2 = (1,2)$ is quite effective. The following matrix gives the probability that w_2 wins against each of the nine cases arising from the use of $\hat{b}^1$ by the rendezvousers.

	$(0,0)$	$(1,2)$	$(2,1)$
$(0,0)$	1	3/4	3/4
$(1,2)$	3/4	1	1/2
$(2,1)$	3/4	1/2	1

It follows that

$$\pi\left(\hat{b}^1, w_2\right) = \left(3 * 1 + 4 * \frac{3}{4} + 2 * \frac{1}{2}\right)/9 = 7/9 = 63/81 > 57/81.$$

A similar argument works for $\hat{b}^2$ and $\hat{b}^3$. □

We now consider whether our proposed solution $(\beta, \hat{s})$ is subject to a variation of the absent-minded driver paradox of [9]. More precisely, we consider whether a rendezvous agent who has heard the announcement of one of the component behavioral strategies $\hat{b}^i, 1,2,3$, and believes that his partner is following this behavioral strategy, can improve the team's payoff by deviating from the announced $\hat{b}^i$. A solution subject to this problem would still be considered a valid solution to the symmetric form of the rendezvous-evasion game as defined in section 2 but would restrict the interpretations of this game to scenarios in which the agents were constrained to follow orders. However, we find that our solution is in fact immune to this problem, as stated below.

THEOREM 3.2. *The solution $(\beta, \hat{s})$ is stable for the rendezvous agents in the following sense. Once a particular behavioral strategy $\hat{b}^i, i = 1,2,3$, is randomly selected for common use, neither of the rendezvous agents can benefit from a unilateral deviation.*

Proof. It can be seen from the matrix $9A$ given in the proof of Lemma 2.4 that if the searcher plays the random strategy $\hat{s}$ and the row rendezvous agent chooses the first three rows with probability 1/3 each ($\hat{b}^1$), then the values of $9 \cdot 3 \cdot \pi$ corresponding

to the nine columns are given by

$$(19, 19, 19, 20, 20, 20, 20, 20, 20)\,.$$

Consequently the column rendezvous agent minimizes π by choosing any behavioral strategy concentrated on the first three columns; in particular, by choosing $\hat{b}^1$. A similar argument applies to $\hat{b}^i, i = 2, 3$. □

In the rendezvous-evasion game Γ of section 2, the enemy searcher S is introduced to give an incentive to the rendezvous team to meet quickly. However, it may be thought by some that the searcher unnecessarily complicates the basic rendezvous problem. We now show that the game Γ is in fact strategically equivalent to a pure rendezvous problem (with no enemy searcher). This result can be stated in somewhat greater generality than our main result; we need no restriction on the number of locations or time steps, except that the former still needs to be finite.

THEOREM 3.3. *The symmetric rendezvous-evasion game $\Gamma(n, m)$ on n locations with rendezvous required by step $m \leq \infty$ is equivalent to the following pure rendezvous problem $R(n, m)$, in the sense that an optimal rendezvous strategy for one determines an optimal rendezvous strategy for the other.*

> *$R(n, m)$: Two indistinguishable agents rendezvous on n locations, for m steps. They each get a fixed prize when they meet, which they discount in time by the same factor.*

Proof. Suppose the rendezvous team R in the game $\Gamma(n, m)$ follows a strategy b (either behavioral or mixed behavioral) where the probability that they meet for the first time at time $i = 1, 2, \ldots$ is denoted by p_i,

$$\Pr(T_R = i) = p_i.$$

Suppose that the rendezvous team modifies this strategy by rotating each agent's position on each step i by a common amount e_i, where the vector e is chosen (by the controller) randomly according to the product measure on $\prod_{i=1,m} \{0, 1, 2\}$. It can be seen that the modified strategy b' has the same probabilities p_i, by referring to the formula (2.2) for the meeting time T_R, and observing that $x_t - y_t = (x_t + e_t) - (y_t + e_t)$. The modified strategy satisfies the same properties given in Lemma 2.2 for the mixed behavioral strategy β (which in this language is the modification of $\hat{b}^1$). That is, the position of each agent at each time is random (equiprobable) and independent of previous positions. Consequently it follows exactly as in the proof of Theorem 2.3 that every pure searcher strategy does equally well against this modified rendezvous strategy. Hence each pure searcher strategy is an optimal response, and therefore so is the random searcher strategy (an average of optimal strategies is optimal).

In fact there is a more intuitive way of seeing that the random searcher strategy is optimal. Note that if a random sequence of rotations e_t is applied to any pure searcher strategy z_t, the resulting strategy $z_t + e_t$ is what we have called the random searcher strategy. It follows that if the rendezvous team applies a common random sequence of rotations $-e_t$ to their strategies, it is strategically equivalent to the situation where they use their original strategies and the searcher is using his original strategy modified by $+e_t$, i.e., a random strategy. Hence it is as if the rendezvous team can force the searcher to use a random strategy, without any restrictions on their own strategy. Hence if the searcher had a better strategy than the random strategy, the rendezvous team could change that to a random strategy, so no other strategy is better.

Let q_i denote the probability that team R wins at the i'th step,

$$q_i = \Pr(T_R = i \wedge T_S > i)\,.$$

Then the probability that R wins, using b when S plays randomly, is

$$V = 1 - \pi(b, \hat{s}) = \sum_{i=1,m} q_i,$$

$$\begin{aligned}\Pr(T_R = i \wedge T_S > i-1) &= \Pr(T_R = i) \Pr(T_S > i-1 \backslash T_R = i) \\ &= p_i \left(\frac{n-2}{n}\right)^{i-1},\end{aligned}$$

$$\begin{aligned}q_i &= \Pr(T_R = i \wedge T_S > i-1) * \Pr(T_S > i \backslash T_R = i \wedge T_S > i-1) \\ &= p_i \left(\frac{n-2}{n}\right)^{i-1} * \left(\frac{n-1}{n}\right) = \left(\frac{n-1}{n}\right) p_i \left(\frac{n-2}{n}\right)^{i-1}.\end{aligned}$$

Therefore the payoff function $V(b)$ is the same as if the team R is given $(n-1)/n$ dollars when they meet, assuming their discount factor is $(n-2)/n$, and step 1 takes place at time zero and so is not discounted.

$$V(b) = \frac{n-1}{n} \sum_{i=1,m} p_i \left(\frac{n-2}{n}\right)^{i-1}. \tag{3.1}$$

This is exactly the payoff function for the pure rendezvous problem $R(n, m)$, where the agents get a fixed prize when they meet which is discounted by both at $\left(\frac{n-2}{n}\right)$ per step, and so the rendezvousers' aim for the problem or the game is to attain the $p_i's$ which maximize (3.1). □

The above reasoning applies equally well for an asymmetric rendezvous, in which case the unmodified strategy b can be a pair of pure strategies (w_k, w_j). Consider the same setting as that of section 2, namely $n = 3$ locations and $m = 2$ time steps. In this case it is clear that the maximum values of p_1 and p_2 are $1/2$ each, obtained by the strategy pair $((0,0),(1,2))$, where one rendezvous agent waits and the other searches. (An optimal strategy is then obtained by applying a common random rotation e_1, e_2, giving the strategy pair $(e_1, e_2), (1+e_1, 2+e_2)$, which is an average over 9 pairs.) Substituting into (3.1) gives the value $V = \frac{2}{3}(\frac{1}{2} * 1 + \frac{1}{2}\frac{1}{3}) = \frac{4}{9}$, which corresponds to an optimal payoff (probability of S winning) $\pi = 1 - V = 5/9 = 45/81$, which is much less than the $57/81$ obtainable optimally when the rendezvous team acts symmetrically. By the way, one optimal strategy for this game is an equiprobable joint randomization over the pairs giving a 5 in the matrix $9A$.

4. Rendezvous with full isometry group. In formalizing the rendezvous-evasion game Γ discussed in section 2, we took the assumption that the players had a common notion of a clockwise direction around the three locations. This would be reasonable if the three locations were on a surface where the players had a common notion of up. The associated group of isometries for the game Γ was the rotation group generated by the unit's clockwise rotation (with the identity and the anticlockwise rotation as the other two elements). We now consider how the problem may change if the full isometry group (six permutations of the three locations) is given. This would be the relevant group to describe the problem if the three locations were three arbitrary general position points in space. We denote the rendezvous-evasion game on three locations, with two time steps and the full permutation group as Γ', and its value by V'. We show that the searcher benefits from enlarging the set of symmetries, in that V' is greater than V. (In both cases the value is the optimal probability that the searcher wins.)

When the rendezvous evasion game on three locations is played with the full isometry group of the 3!=6 permutations of the three locations, the pure strategies of the players can be condensed into the following form. For each player (actually agent, in the case of the rendezvous team) let the initial position be labeled a, and the subsequent positions b and c, if reached. (This is the labeling procedure used by Anderson and Weber [3].) There are five possible strategies, $\{aa, bc, ab, bb, ba\}$, which we label as $z_i, i = 1, \ldots, 5$. For example, the strategy $z_3 = ab$ says to stay still on step 1 and then go equiprobably to one of the two remaining locations at step 2. Strategy $z_2 = bc$ says to move equiprobably to one of the other two locations at step 1 and then to the remaining location at step 2. Since each of the z_i involves at most one binary choice, there are at most eight equiprobable scenarios associated with any triple of strategies. Thus the probabilities $A_k(i, j)$ that the searcher S wins when R_1 follows z_i, R_2 follows z_j, and S follows z_k are integers divided by eight. The rationalized matrices $8A_k$ are given below.

$$8A_1 = \begin{pmatrix} 8 & 4 & 4 & 4 & 4 \\ 4 & 8 & 4 & 8 & 8 \\ 4 & 4 & 8 & 4 & 4 \\ 4 & 8 & 4 & 8 & 6 \\ 4 & 8 & 4 & 6 & 8 \end{pmatrix}, 8A_2 = \begin{pmatrix} 8 & 4 & 6 & 4 & 4 \\ 4 & 6 & 4 & 8 & 8 \\ 6 & 4 & 6 & 4 & 4 \\ 4 & 8 & 4 & 8 & 7 \\ 4 & 8 & 4 & 7 & 8 \end{pmatrix}, 8A_3 = \begin{pmatrix} 8 & 4 & 8 & 6 & 6 \\ 4 & 6 & 4 & 8 & 8 \\ 6 & 4 & 6 & 4 & 4 \\ 4 & 8 & 4 & 8 & 7 \\ 4 & 8 & 4 & 7 & 8 \end{pmatrix},$$

$$8A_4 = \begin{pmatrix} 8 & 4 & 8 & 6 & 6 \\ 4 & 6 & 6 & 5 & 6 \\ 8 & 6 & 8 & 5 & 6 \\ 6 & 5 & 5 & 6 & 5 \\ 6 & 6 & 6 & 5 & 6 \end{pmatrix}, 8A_5 = \begin{pmatrix} 8 & 4 & 8 & 6 & 6 \\ 4 & 6 & 6 & 6 & 5 \\ 8 & 6 & 8 & 6 & 5 \\ 6 & 6 & 6 & 6 & 5 \\ 6 & 5 & 5 & 5 & 6 \end{pmatrix}.$$

For any behavioral strategies u (for the rendezvous team) and v (for the searcher), i.e., distributions over the z_i, the payoff (probability that S wins) is given by

$$\pi(u, v) = uA_v u^\top, \text{ where } A_v = \sum_i v_i A_i.$$

The theory of "games with forgetting" [5], [2] says that since no path passes through an information set of S more than once, some single behavioral strategy is optimal for S. This means that

$$V' = \max_v \min_u \pi(u, v) \leq \min_u \max_v \pi(u, v),$$

where V' is the value of the game Γ' with the full isometry group. (In order to ensure equality, we must minimize over mixed behavioral strategies in the rightmost expression.)

THEOREM 4.1. *With optimal play, the searcher S does better in Γ' (with the full permutation group of isometries) than in the game Γ (with the rotation subgroup). In particular, we have*

$$\frac{57}{81} = V < \frac{58}{81} < V' \leq \frac{59}{81},$$

where the values are the optimal probabilities of S winning.

Proof. To obtain the upper bound for V', assume that the rendezvous team plays randomly. In this case (as in section 2) the best that S can do is also play randomly.

Thus the rendezvous team wins at step 1 if they meet (1/3) and they don't meet S (2/3, conditionally). The rendezvous team wins at step 2 if the game proceeds to step 2 ($\frac{2}{3} * \frac{1}{3}$) and they meet each other (1/3) but not S (2/3, conditionally). Thus the rendezvous team wins with probability

$$\frac{1}{3}\frac{2}{3} + \left(\frac{2}{3}\ \frac{1}{3}\right)\left(\frac{1}{3}\frac{2}{3}\right) = \frac{22}{81}$$

under random play, or S wins with probability $\frac{59}{81}$, as claimed.

Observe that in the current notation, random play by the searcher S is denoted by the probability distribution $(1/9, 2/9, 2/9, 2/9, 2/9)$. If we perturb this a bit in the z_2 direction, say (-e,4e,-e,-e,-e) with e=1/18, the resulting distribution is $\bar{v} = (1, 8, 3, 3, 3)/18$. The minimum over u of the payoff function $uA_{\bar{v}}u^{\top}$ is easily calculated to be at $u = (73, 184, 0, 4, 4)/265$, with a minimum of 191/265, which is more than 58/81. A good approximation to the value V' and an optimal strategy for the searcher could be obtained by analyzing the quadratic program $V' = \max_v \min_u \pi(u, v)$, but we know of no algorithm for finding the optimal mixed behavioral strategy for the rendezvous team. □

AN INTEGRAL INVARIANCE PRINCIPLE FOR DIFFERENTIAL INCLUSIONS WITH APPLICATIONS IN ADAPTIVE CONTROL*

E. P. RYAN†

Abstract. The Byrnes–Martin integral invariance principle for ordinary differential equations is extended to differential inclusions on $\mathbb{R}^N$. The extended result is applied in demonstrating the existence of adaptive stabilizers and servomechanisms for a variety of nonlinear system classes.

Key words. adaptive control, differential inclusions, invariance principles, nonlinear systems, universal servomechanisms

1. Introduction.

Suppose that $\dot{x} = f(x)$ generates a semidynamical system on $\mathbb{R}^N$ with semiflow φ, and so, for each $x^0 \in \mathbb{R}^N$, $x(\cdot) = \varphi(\cdot, x^0)$ is the unique maximal forward-time solution of the initial-value problem $\dot{x} = f(x)$, $x(0) = x^0$. In [2], Byrnes and Martin prove the following integral invariance principle: if $\varphi(\cdot, x^0)$ is bounded and $\int_0^\infty l(\varphi(t, x^0))dt < \infty$ for some continuous function $l : \mathbb{R}^N \to \mathbb{R}_+ := [0, \infty)$, then $\varphi(t, x^0)$ tends, as $t \to \infty$, to the largest invariant (with respect to the differential equation) set in $l^{-1}(0)$, the zero level set of l. This result has ramifications in adaptive control, some of which are highlighted in the present paper. However, we wish to consider the (adaptive) control problem in a fairly general setting that allows time variation in the underlying differential equations, possible nonuniqueness of solutions, and discontinuous feedback strategies; each of these features places the problem outside the scope of [2]. For this reason we develop, in Theorem 2.10, an integral invariance principle for initial-value problems of the form $\dot{x} \in X(x)$, $x(0) = x^0$, where the set-valued map X is defined on some open domain $G \subset \mathbb{R}^N$ and is assumed to be upper semicontinuous with nonempty, convex, and compact values. In the case $G = \mathbb{R}^N$, Theorem 2.10 contains the following generalization of the Byrnes–Martin result: if $x(\cdot) : \mathbb{R}_+ \to \mathbb{R}^N$ is a bounded solution and $\int_0^\infty l(x(s))ds < \infty$ for some lower semicontinuous $l : \mathbb{R}^N \to \mathbb{R}_+$, then $x(t)$ tends, as $t \to \infty$, to the largest weakly invariant (with respect to the differential inclusion) set in $l^{-1}(0)$. One particular consequence of Theorem 2.10 is to facilitate the derivation of a nonsmooth extension, to differential inclusions, of LaSalle's invariance principle for differential equations; this extension may be of independent interest and is presented in Theorem 2.11. The remainder of the paper is devoted to the application (in a collection of five lemmas) of the generalized integral invariance principle to demonstrate, by construction and for a variety of nonlinear system classes, the existence of a single adaptive controller that achieves (without system identification, parameter estimation, or injection of probing signals) some prescribed objective for every system in the underlying class.

2. Differential inclusions. Some known facts (tailored[1] to our immediate purpose) pertaining to differential inclusions are first assembled.

2.1. Maximal solutions. Consider the nonautonomous initial-value problem

$$\dot{x}(t) \in X(t, x(t)), \quad x(t) \in G, \quad x(t_0) = x^0, \tag{2.1}$$

where $G \neq \emptyset$ is an open subset of $\mathbb{R}^N$. The set-valued map $(t, x) \mapsto X(t, x) \subset \mathbb{R}^N$ in (2.1) is assumed to be upper semicontinuous[2] on $\mathbb{R} \times G$, with nonempty, convex, and compact values. This is sufficient (see, for example, [1, Chapter 2, Theorem 3]) to ensure that, for each $(t_0, x^0) \in \mathbb{R} \times G$, (2.1) admits a solution: an X-arc[3] $x \in AC([t_0, \omega); G)$, with $x(t_0) = x^0$.

DEFINITION 2.1. *A solution x of* (2.1) *is said to be* maximal *if it does not have a proper right extension which is also a solution of* (2.1).

PROPOSITION 2.2. *Every solution of* (2.1) *can be extended to a maximal solution.*

DEFINITION 2.3. *A solution $x \in AC([t_0, \omega); G)$ of* (2.1) *is* precompact *if it is maximal and the closure* $\mathrm{cl}(x([t_0, \omega)))$ *of its trajectory is a compact subset of G.*

PROPOSITION 2.4. *If $x \in AC([t_0, \omega); G)$ is a precompact solution of* (2.1)*, then $\omega = \infty$.*

2.2. Limit sets. Here, we specialize to the autonomous case of (2.1), rewritten as

$$\dot{x}(t) \in X(x(t)), \quad x(t) \in G, \quad x(0) = x^0, \tag{2.2}$$

where, without loss of generality, $t_0 = 0$ is assumed. The map $x \mapsto X(x) \subset \mathbb{R}^N$ (with domain G) is upper semicontinuous with nonempty, convex, and compact values.

DEFINITION 2.5. *Let $x \in AC([0, \omega); G)$ be a maximal solution of* (2.2)*. A point $\bar{x} \in \mathbb{R}^N$ is an* ω-limit point of x *if there exists an increasing sequence $(t_n) \subset [0, \omega)$ such that $t_n \to \omega$ and $x(t_n) \to \bar{x}$ as $n \to \infty$. The set $\Omega(x)$ of all ω-limit points of x is the* ω-limit set of x.

DEFINITION 2.6. *Let $C \subset \mathbb{R}^N$ be nonempty. A function $x \in AC([0, \omega); G)$ is said to* approach *C if $d_C(x(t)) \to 0$ as $t \to \omega$, where d_C is the (Euclidean) distance function for C defined (on $\mathbb{R}^N$) by $d_C(v) := \inf\{\|v - c\| \mid c \in C\}$.*

DEFINITION 2.7. *Relative to* (2.2)*, $S \subset \mathbb{R}^N$ is said to be a* weakly invariant set *if, for each $x^0 \in S \cap G$, there exists at least one maximal solution $x \in AC([0, \omega); G)$ of* (2.2) *with $\omega = \infty$ and with trajectory $x([0, \omega))$ in S.*

PROPOSITION 2.8. *If x is a precompact solution of* (2.2)*, then $\Omega(x)$ is a nonempty, compact, connected subset of G. Moreover, $\Omega(x)$ is the smallest closed set approached by x and is weakly invariant.*

2.3. Invariance principles. For later use, the following fact (a specialization of a more general result [4, Theorem 3.1.7]) is first recorded.

---

[1] Variants of Propositions 2.2, 2.4, and 2.8 can be found in, for example, [8], [19]; for general treatments of differential inclusions and related topics in set-valued analysis, nonsmooth control, and optimization, see [1], [4], [6], [7], [8], and [12].

[2] The set-valued map X is upper semicontinuous if it is upper semicontinuous at every point $\bar{\xi}$ of its domain in the sense that, for each $\varepsilon > 0$ there exists $\delta > 0$ such that $X(\xi) \subset X(\bar{\xi}) + \varepsilon\mathbb{B}$ for all ξ with $\|\xi - \bar{\xi}\| < \delta$, where $\mathbb{B}$ (with closure $\bar{\mathbb{B}}$) denotes the open unit ball centred at 0 in $\mathbb{R}^N$.

[3] For an interval $I \subset \mathbb{R}$ and $S \subset \mathbb{R}^N$, $AC(I; S)$ denotes the space of functions $I \to S$ that are absolutely continuous on compact subintervals of I. For simplicity, we write $AC(I)$ in place of $AC(I; I)$; the same notational convention applies to other function spaces. A function $x \in AC(I; G)$ is said to be an X-arc if it satisfies the differential inclusion in (2.1) almost everywhere.

PROPOSITION 2.9. *Let $I = [a, b]$, let nonempty $K \subset G$ be compact. If $(x_n) \subset AC(I; K)$ is a sequence of X-arcs and there exists a scalar Φ such that, for all n, $\|\dot{x}_n(t)\| \leq \Phi$ for almost all $t \in I$, then (x_n) has a subsequence converging uniformly to an X-arc $x \in AC(I; K)$.*

We now arrive at the main result, which generalizes [2, Theorem 1.2].

THEOREM 2.10. *Let $l : G \to \mathbb{R}$ be lower semicontinuous. Suppose that $U \subset G$ is nonempty and that $l(z) \geq 0$ for all $z \in U$. If x is a precompact solution of (2.2) with trajectory in U and $l \circ x \in L^1(\mathbb{R}_+)$, then x approaches the largest weakly-invariant set in $\Sigma := \{z \in \mathrm{cl}(U) \cap G |\ l(z) \leq 0\}$.*

Proof. By Proposition 2.4, x has maximal interval of existence $\mathbb{R}_+ = [0, \infty)$ and, by Proposition 2.8, has nonempty ω-limit set $\Omega(x)$. Clearly $\Omega(x) \subset \mathrm{cl}(U) \cap G$. Let $\bar{x} \in \Omega(x)$, and so there exists $(t_n) \subset \mathbb{R}_+$ with $t_n \to \infty$ and $x(t_n) \to \bar{x}$ as $n \to \infty$. Define $K := \mathrm{cl}(x(\mathbb{R}_+))$. By upper semicontinuity of X together with compactness of its values, $X(K)$ is compact, and so $\dot{x} \in L^\infty(\mathbb{R}_+; \mathbb{R}^N)$, with norm $\|\dot{x}\|_\infty$. Write $I = [0, 1]$ and define a sequence (x_n) of X-arcs $x_n \in AC(I; K)$ by $x_n(s) := x(s + t_n)$. Evidently, $x_n(0) \to \bar{x}$ as $n \to \infty$. By Proposition 2.9 (with $\Phi = \|\dot{x}\|_\infty$), (x_n) has a subsequence, which we do not relabel, converging uniformly to an X-arc $x^* \in AC(I; K)$, with $x^*(0) = \bar{x}$.

Define $\lambda^* \in L^1(I; \mathbb{R})$ by $\lambda^*(s) := l(x^*(s))$ and the sequence $(\lambda_n) \subset L^1(I; \mathbb{R})$ by $\lambda_n(s) := l(x_n(s))$. By lower semicontinuity of l, together with continuity of x, x^* and (uniform) convergence of (x_n) to x^*, it follows that λ^* and λ_n, $n \in \mathbb{N}$, are lower semicontinuous with $\liminf_{n\to\infty} \lambda_n(s) \geq \lambda^*(s)$ for all $s \in I$. By Fatou's lemma,

$$\int_0^t \lambda^*(s)ds \leq \int_0^t \liminf_{n\to\infty} \lambda_n(s)\, ds \leq \liminf_{n\to\infty} \int_0^t \lambda_n(s)\, ds \quad \forall\ t \in I.$$

By the hypotheses, $l(x(t)) \geq 0$ for all t and $\int_0^\infty l(x(t))dt < \infty$. Therefore,

$$W(t) := \int_t^\infty l(x(s))ds \quad \forall\ t \geq 0$$

defines a monotone function $W \in AC(\mathbb{R}_+)$ with $W(t) \downarrow 0$ as $t \to \infty$. Hence,

$$\begin{aligned} 0 = \lim_{n\to\infty} W(t_n) - \lim_{n\to\infty} W(t + t_n) &= \lim_{n\to\infty} \int_{t_n}^{t+t_n} l(x(s))ds \\ &= \lim_{n\to\infty} \int_0^t l(x(s + t_n))ds = \lim_{n\to\infty} \int_0^t \lambda_n(s)ds \geq \int_0^t \lambda^*(s)ds \quad \forall\ t \in I. \end{aligned}$$

Seeking a contradiction, suppose $\epsilon := \lambda^*(0) > 0$. Then, by lower semicontinuity of λ^*, there exists $t \in (0, 1]$ such that $\lambda^*(s) > \lambda^*(0) - \frac{1}{2}\epsilon = \frac{1}{2}\epsilon$ for all $s \in (0, t)$, whence the contradiction

$$0 \geq \int_0^t \lambda^*(s)ds > \frac{1}{2}\epsilon t > 0.$$

Therefore, $0 \geq \lambda^*(0) = l(x^*(0)) = l(\bar{x})$, and so $\bar{x} \in \Sigma$. Since $\bar{x} \in \Omega(x)$ is arbitrary, we have $\Omega(x) \subset \Sigma$. By Proposition 2.8, x approaches $\Omega(x)$ and the latter is a weakly invariant set. Therefore, x approaches the largest weakly invariant set in Σ. ∎

The next result is a nonsmooth extension, to differential inclusions, of LaSalle's theorem [11, Chapter 2, Theorem 6.4]; a smooth version (that is, restricted to smooth functions V) is given in [19, Theorem 1] and a nonsmooth version is proved in [23,

Theorem 3]; the alternative proof given below is considerably simpler, by virtue of its use of the integral invariance principle. First, we give Clarke's [4] definition of a generalized directional derivative $V^o(z;\phi)$ of a locally Lipschitz function $V : G \to \mathbb{R}$ at z in direction ϕ:

$$V^o(z;\phi) := \limsup_{\substack{y \to z \\ h \downarrow 0}} \frac{V(y+h\phi) - V(y)}{h} .$$

The map $(z,\phi) \mapsto V^o(z;\phi)$ is upper semicontinuous (in the sense of real-valued functions) and, for each z, the map $\phi \mapsto V^o(z;\phi)$ is Lipschitz continuous.

THEOREM 2.11. *Let $V : G \to \mathbb{R}$ be locally Lipschitz. Define*

$$u : G \to \mathbb{R}, \quad z \mapsto u(z) := \max\{V^o(z;\phi) |\ \phi \in X(z)\}.$$

Suppose that $U \subset G$ is non-empty and that $u(z) \le 0$ for all $z \in U$. If x is a precompact solution of (2.2) with trajectory in U, then, for some constant $c \in V(\mathrm{cl}(U) \cap G)$, x approaches the largest weakly invariant set in $\Sigma \cap V^{-1}(c)$, where

$$\Sigma = \{z \in \mathrm{cl}(U) \cap G |\ u(z) \ge 0\}.$$

Proof. This result is essentially a corollary to Theorem 2.10 insofar as the essence of the proof is to show that the hypotheses of Theorem 2.10 hold with $l := -u$.

We first show that u is upper semicontinuous (and so, $l \equiv -u$ is lower semicontinuous). Let $z \in G$ be arbitrary and let $(z_n) \subset G$ be such that $z_n \to z$ as $n \to \infty$. From $(u(z_n))$ we extract a subsequence $(u(z_{n_k}))$ with $u(z_{n_k}) \to \limsup_{n\to\infty} u(z_n)$ as $k \to \infty$. For each k, let ϕ_k be a maximizer of continuous $V^o(z_{n_k};\cdot)$ over compact $X(z_{n_k})$, and so $u(z_{n_k}) = V^o(z_{n_k};\phi_k)$. Let $\varepsilon > 0$. By upper semicontinuity of X, we have $X(z_{n_k}) \subset X(z) + \varepsilon\mathbb{B}$ for all k sufficiently large. Since $\phi_k \in X(z_{n_k})$ and $X(z)$ is compact, (ϕ_k) contains a subsequence converging to $\phi^* \in \mathrm{cl}(X(z) + \varepsilon\mathbb{B})$. Since $\varepsilon > 0$ is arbitrary and $X(z)$ is compact, $\phi^* \in X(z)$. Thus, invoking upper semicontinuity of $V^o(\cdot;\cdot)$, we may conclude that $\limsup_{n\to\infty} u(z_n) \le V^o(z;\phi^*) \le u(z)$, whence upper semicontinuity of u.

Observe that, for all $z \in U$,

$$V_+(z;\phi) := \liminf_{h\downarrow 0} \frac{V(z+h\phi) - V(z)}{h} \le V^o(z;\phi) \le u(z) \le 0 \quad \forall\ \phi \in X(z). \tag{2.3}$$

By Proposition 2.4, x has interval of existence $\mathbb{R}_+$. Let $\mathcal{O} \subset \mathbb{R}_+$ denote the set of measure zero on which the derivative $\dot{x}(t)$ fails to exist. Since V is locally Lipschitz, for each $t \in \mathbb{R}_+\backslash\mathcal{O}$ there exists a constant L_t such that, for all $h > 0$ sufficiently small,

$$\begin{aligned} V(x(t+h)) - V(x(t)) &\le V(x(t) + h\dot{x}(t)) - V(x(t)) + L_t|x(t+h) - x(t) - h\dot{x}(t)| \\ &\le V(x(t+h)) - V(x(t)) + 2L_t|x(t+h) - x(t) - h\dot{x}(t)|. \end{aligned}$$

Therefore,

$$\liminf_{h\downarrow 0} \frac{V(x(t+h)) - V(x(t))}{h} = V_+(x(t);\dot{x}(t)) \quad \forall\ t \in \mathbb{R}_+\backslash\mathcal{O}. \tag{2.4}$$

Next, we prove that $V \circ x :\ t \mapsto V(x(t))$ is nonincreasing on $\mathbb{R}_+$. This we do by showing that $V \circ x$ is nonincreasing on every compact subinterval. Let $[\alpha,\beta] \subset \mathbb{R}_+$,

and let $K \subset G$ be compact and such that $x([\alpha,\beta]) \subset K$. Since V is locally Lipschitz on G, it is Lipschitz on K. Thus, the restriction of $V \circ x$ to $[\alpha,\beta]$ is a composition of a Lipschitz function and an absolutely continuous function and so is itself absolutely continuous. It now follows from (2.3) and (2.4) that

$$V(x(t)) - V(x(\tau)) \;=\; \int_\tau^t (V \circ x)' \;\leq\; \int_\tau^t u(x(s))ds \leq 0 \quad \forall\, t,\tau \in [\alpha,\beta],\ t \geq \tau.$$

Therefore, $t \mapsto V(x(t))$ is nonincreasing on $[\alpha,\beta]$. Since $[\alpha,\beta] \subset \mathbb{R}_+$ is arbitrary, we conclude that $V \circ x$ is nonincreasing on $\mathbb{R}_+$ with

$$V(x(t)) - V(x(\tau)) \leq \int_\tau^t u(x(s))ds \leq 0 \quad \forall\, t,\tau \in \mathbb{R}_+,\ t \geq \tau. \tag{2.5}$$

By continuity of V and precompactness of x, we conclude that $V(x(\cdot))$ is bounded. Therefore, $V(x(t)) \downarrow c := \inf_{t\in\mathbb{R}_+} V(x(t)) \in \mathbb{R}$ as $t \to \infty$. It follows that (i) $\Omega(x) \subset V^{-1}(c)$ and (ii) for all $t \geq 0$,

$$\int_0^t l(x(s))ds \equiv -\int_0^t u(x(s))ds \leq V(x(0)) - V(x(t)) \leq V(x(0)) - c < \infty.$$

An application of Theorem 2.10 completes the proof. □

3. Adaptive control. Approaches to adaptive control may be classified into methods that—either implicitly or explicitly—exhibit some aspect of identification of the process to be controlled and methods that seek only to control. The latter approach, to be adopted here and sometimes referred to as universal control, has its origins in the work of Byrnes and Willems [3], [27], Mårtensson [13], [14], [15], Morse [16], Nussbaum [17] and others (see [9] for a survey and comprehensive bibliography). In common with its above-cited precursors, this section of the present paper is concerned with demonstrating the existence—under relatively weak assumptions—of a single controller that achieves some prescribed objective for every system in the underlying class. In contrast with its above-cited precursors (which deal mainly with classes of linear systems, possibly subject to "mild" nonlinear perturbations, in a context of adaptive linear feedback), the present paper considers strongly nonlinear systems and nonsmooth feedback (for an overview of adaptive control of nonlinear systems in the context of *smooth* feedback, see [18]). In essence, the ensuing two subsections provide a unified analysis—unified through its use of the integral invariance principle—of various problems in nonlinear adaptive control (some closely related problems have been individually investigated, via alternative analyses, in [5], [10], [20], and [21]).

3.1. Scalar systems. First, consider scalar systems of the form

$$\dot{y}(t) = f(p(t),y(t)) + bu(t), \quad y(t),u(t) \in \mathbb{R},\ p(t) \in \mathbb{R}^P, \quad y(t_0) = y^0, \tag{3.1}$$

where parameters $b \in \mathbb{R}$, $P \in \mathbb{N}$, and functions f, p are unknown. The state $y(t)$ is available for feedback. We will identify (3.1) with the quadruple (b,f,p,P).

For any function $\phi : \mathbb{R}_+ \to \mathbb{R}_+$ that is both continuous and positive definite ($\phi(s) > 0$ for all $s \neq 0$), we denote, by $\mathcal{N}_\phi$, the set of system quadruples (b,f,p,P) satisfying the following three assumptions.

Assumption A. $b \neq 0$.

Assumption B. $(p,y) \mapsto f(p,y)$, $\mathbb{R}^P \times \mathbb{R} \to \mathbb{R}$ is a continuous function and is ϕ-bounded uniformly with respect to p in compact sets; precisely, for every compact $K \subset \mathbb{R}^P$, there exists scalar μ_K such that $|f(p,y)| \leq \mu_K \phi(|y|)$ for all $(p,y) \in K \times \mathbb{R}$.

Assumption C. $p(\cdot) \in L^\infty(\mathbb{R}; \mathbb{R}^P)$.

By virtue of Assumption C, without loss of generality, $t_0 = 0$ may be assumed in (3.1); this we will do, without further comment, throughout this subsection.

Examples. (a) Let $\phi : |y| \mapsto \exp(|y|)$. Then all polynomial systems, of arbitrary degree, of the form $\dot{y}(t) = p_1(t) + p_2(t)y(t) + \cdots + p_P(t)y^{P-1}(t) + bu(t)$, with $b \neq 0$ and coefficient functions $p_i(\cdot) \in L^\infty(\mathbb{R})$, are of class $\mathcal{N}_\phi$.

(b) Suppose that Assumptions A and C hold and that the only a priori information on continuous f is its behavior "at infinity," captured in the following manner: for some known continuous $\hat{\phi} : \mathbb{R}_+ \to \mathbb{R}_+$, $(p, y) \mapsto f(p, y)$ is $O(\hat{\phi}(|y|))$ as $|y| \to \infty$, uniformly with respect to p in compact sets in the sense that, for every compact $K \subset \mathbb{R}^P$, there exist scalars c_K and C_K such that, for all $p \in K$, $|f(p, y)| \leq c_K \hat{\phi}(|y|)$ for all $|y| > C_K$. Then Assumption B holds with $\phi := 1 + \hat{\phi}$, and so $(b, f, p, P) \in \mathcal{N}_\phi$.

3.1.1. Adaptive stabilizer. Let $\phi : \mathbb{R}_+ \to \mathbb{R}_+$ be a continuous, positive-definite function. Assuming only that the function ϕ and the instantaneous state $y(t)$ are available for control purposes, we will show that the following adaptive feedback strategy (appropriately interpreted) is a $\mathcal{N}_\phi$-universal stabilizer in the sense that it assures that the state of (3.1) approaches $\{0\}$ for all quadruples $(b, f, p, P) \in \mathcal{N}_\phi$ while maintaining boundedness of the controller function $\lambda(\cdot)$:

$$u(t) = \nu(\lambda(t))\phi(|y(t)|)\mathrm{sgn}(y(t)), \quad \dot{\lambda}(t) = \phi(|y(t)|)|y(t)|, \quad \lambda(0) = \lambda^0, \tag{3.2}$$

where ν is any continuous function $\mathbb{R} \to \mathbb{R}$ with the properties

$$\text{(a)} \quad \limsup_{\eta \to \infty} \frac{1}{\eta} \int_0^\eta \nu = +\infty, \qquad \text{(b)} \quad \liminf_{\eta \to \infty} \frac{1}{\eta} \int_0^\eta \nu = -\infty. \tag{3.3}$$

For example, $\nu : \theta \mapsto \theta^2 \cos\theta$ suffices.

In view of the discontinuous nature of the feedback (however, note that, if $\phi(0) = 0$, then the feedback is continuous), we interpret the strategy (3.2) in the set-valued sense

$$u(t) \in \nu(\lambda(t))\phi(|y(t)|)\sigma(y(t)), \quad \dot{\lambda}(t) = \phi(|y(t)|)|y(t)|, \ \lambda(0) = \lambda^0 \tag{3.4}$$

with $y \mapsto \sigma(y) \subset \mathbb{R}$ given by

$$\sigma(y) := \begin{cases} \{\mathrm{sgn}(y)\}, & y \neq 0, \\ [-1, +1], & y = 0\ . \end{cases} \tag{3.5}$$

Let $(b, f, p, P) \in \mathcal{N}_\phi$. By properties of $f(\cdot, \cdot)$ and boundedness of $p(\cdot)$, there exists a scalar μ such that $|f(p(t), y)| \leq \mu\phi(|y|)$ for all (t, y).

We embed the feedback-controlled system in a differential inclusion on $\mathbb{R}^2$:

$$\dot{x}(t) \in X(x(t)), \quad x(t) = (y(t), \lambda(t)) \in G := \mathbb{R}^2, \quad x(0) = x^0 = (y^0, \lambda^0), \tag{3.6}$$

where $x \mapsto X(x) \subset \mathbb{R}^2$ is given by

$$X(x) \equiv X(y, \lambda) := \{v + bu| \ |v| \leq \mu\phi(|y|), \ u \in \nu(\lambda)\phi(|y|)\sigma(y)\} \times \{\phi(|y|)|y|\}.$$

X is upper semicontinuous on $\mathbb{R}^2$ with nonempty, convex, and compact values. Therefore for each $x^0 \in \mathbb{R}^2$, the initial-value problem (3.6) has a solution and, by Proposition 2.2, every solution can be extended to a maximal solution.

LEMMA 3.1. *Let $x^0 \in \mathbb{R}^2$ be arbitrary and let $x(\cdot) = (y(\cdot), \lambda(\cdot))$ be a maximal solution of* (3.6)*, defined on its maximal interval of existence $[0, \omega)$. Then* (i) *$\omega = \infty$;* (ii) *$\lim_{t\to\infty} \lambda(t)$ exists and is finite;* (iii) *$y(t) \to 0$ as $t \to \infty$.*

Proof. The essence of the proof is to establish boundedness of $x(\cdot)$, whence, by Proposition 2.4, assertion (i) and, by monotonicity, assertion (ii): state convergence to zero (assertion (iii)) is then an immediate consequence of Theorem 2.10.

For almost all $t \in [0, \omega)$, we have

$$y(t)\dot{y}(t) \leq [\mu + b\nu(\lambda(t))]\,\phi(|y(t)|)|y(t)| = [\mu + b\nu(\lambda(t))]\dot{\lambda}(t), \tag{3.7}$$

which, on integration, yields

$$0 \leq y^2(t) \leq y^2(\tau) + 2\mu[\lambda(t) - \lambda(\tau)] + 2b\int_{\lambda(\tau)}^{\lambda(t)} \nu \quad \forall\ t, \tau \in [0, \omega),\ t \geq \tau. \tag{3.8}$$

Seeking a contradiction, suppose that solution component $\lambda(\cdot)$ (monotone increasing) is unbounded. Fix τ such that $\lambda(\tau) \geq 1$. Dividing by $\lambda(t) \geq \lambda(\tau) \geq 1$ in (3.8) gives

$$0 \leq \text{constant} + \frac{b}{\lambda(t)}\int_{\lambda(\tau)}^{\lambda(t)} \nu \quad \forall\ t \in [\tau, \omega).$$

Recalling that $b \neq 0$ and taking limit inferior as $t \uparrow \omega$ ($\lambda(t) \uparrow \infty$) lead to a contradiction of one or the other of properties (3.3). Hence, $\lambda(\cdot)$ is bounded, and so, by (3.8), $y(\cdot)$ is also bounded. Therefore, $x(\cdot) = (y(\cdot), \lambda(\cdot)) \in AC([0, \omega); \mathbb{R}^2)$ is a precompact solution of (3.6), and so, by Proposition 2.4, $\omega = \infty$. Defining $l : \mathbb{R}^2 \to \mathbb{R}_+$, $x \equiv (y, \lambda) \mapsto \phi(|y|)|y|$, for which $l^{-1}(0) = \{0\} \times \mathbb{R}$ and $\dot{\lambda} = l \circ x$, we may conclude, by boundedness of $\lambda(\cdot)$, that $l \circ x \in L^1(\mathbb{R}_+)$, and so, by Theorem 2.10 (with $U = \mathbb{R}^2$), $x(\cdot) = (y(\cdot), \lambda(\cdot))$ approaches the set $\{0\} \times \mathbb{R}$. In particular, $y(t) \to 0$ as $t \to \infty$ and, by boundedness and monotonicity of $\lambda(\cdot)$, $\lim_{t\to\infty} \lambda(t)$ exists and is finite. ∎

3.1.2. Adaptive servomechanism. We now turn attention to the servomechanism problem for scalar systems (3.1), that is, the construction of controls that cause the state to track, asymptotically, reference signals $r(\cdot)$ of some given class in the sense that $|y(t) - r(t)| \to 0$ as $t \to \infty$. For the class of reference signals (previously adopted in [20], [10], [21]) we take the (Sobolev) space $\mathcal{R} = W^{1,\infty}(\mathbb{R})$ of functions $r \in (AC \cap L^\infty)(\mathbb{R})$ with essentially bounded derivative $\dot{r} \in L^\infty(\mathbb{R})$, equipped with the norm $\|r\|_{1,\infty} = \|r\|_\infty + \|\dot{r}\|_\infty$, where $\|\ \|_\infty$ denotes the norm on $L^\infty(\mathbb{R})$.

We impose a stronger assumption on the function f by requiring that Assumption B should hold for some known, continuous, positive-definite, nondecreasing function ϕ with the additional property that, for each $R \geq 0$, there exists a scalar ρ_R such that

$$\phi(|e + r|) \leq \rho_R \phi(|e|) \quad \forall\ (e, r) \in \mathbb{R} \times [-R, R]. \tag{3.9}$$

Note that, by positive definiteness of ϕ together with property (3.9), $\phi(0) > 0$.

Example. Let $\phi : |y| \mapsto \exp(|y|)$, which has the property (3.9), and so all polynomial systems (of arbitrary degree and with coefficients in $L^\infty(\mathbb{R})$), as cited in a previous Example, remain admissible.

Let ϕ be a continuous, positive-definite, nondecreasing function with property (3.9). We claim that, in order to assure that the tracking error $e(\cdot) = y(\cdot) - r(\cdot)$ approaches $\{0\}$ for all reference signals $r \in \mathcal{R}$ and all quadruples $(b, f, p, P) \in \mathcal{N}_\phi$, it suffices to replace every occurrence of $y(t)$ in (3.4) by $e(t)$. Proof of this claim follows.

Let $(b, f, p, P) \in \mathcal{N}_\phi$. Write $\tilde{P} = P + 2$ and define the continuous function

$$\tilde{f} : \mathbb{R}^{\tilde{P}} \times \mathbb{R} \to \mathbb{R}, \quad (\tilde{p}, e) \equiv (p, r, s, e) \mapsto f(p, e + r) - s.$$

Let $\tilde{K} \subset \mathbb{R}^{\tilde{P}}$ be compact, and so there exist compact $K \subset \mathbb{R}^P$ and $R > 0$ such that $\tilde{K} \subset K \times [-R, R]^2$. By properties of f and ϕ, there exist constants μ_K and ρ_R such that, for all $(p, r, s) \equiv \tilde{p} \in \tilde{K} \subset K \times [-R, R]^2$,

$$|\tilde{f}(\tilde{p}, e)| \leq |f(p, e + r)| + |s| \leq \mu_K \phi(|e + r|) + R \leq \mu_K \rho_R \phi(|e|) + R \leq \tilde{\mu}_{\tilde{K}} \phi(|e|),$$

with $\tilde{\mu}_{\tilde{K}} := \mu_K \rho_R + R/\phi(0)$. Thus, $\tilde{f}$ is ϕ-bounded uniformly with respect to $\tilde{p}$ in compact sets.

Let $r \in \mathcal{R}$ be arbitrary. Then $\tilde{p}(\cdot) := (p(\cdot), r(\cdot), \dot{r}(\cdot)) \in L^\infty(\mathbb{R}; \mathbb{R}^{\tilde{P}})$, and so $(b, \tilde{f}, \tilde{p}, \tilde{P}) \in \mathcal{N}_\phi$. Expressed in terms of the tracking error $e(t) = y(t) - r(t)$, the system dynamics have the form

$$\dot{e}(t) = \tilde{f}(\tilde{p}(t), e(t)) + bu(t), \quad \tilde{p}(t) = (p(t), r(t), \dot{r}(t)) \in \mathbb{R}^{\tilde{P}}, \quad e(0) = e^0.$$

We are now in precisely the same context, modulo notation, as in the case of an adaptive stabilizer, and so, replacing all occurrences of $y(t)$ in (3.4) with $e(t)$ to yield

$$u(t) \in \nu(\lambda(t))\phi(|e(t)|)\sigma(e(t)), \quad \dot{\lambda}(t) = \phi(|e(t)|)|e(t)|, \ \lambda(0) = \lambda^0, \tag{3.10}$$

then the same argument (as used to establish Lemma 3.1) applies *mutatis mutandis* to conclude that (3.10) is an $(\mathcal{R}, \mathcal{N}_\phi)$-universal servomechanism: for each $r(\cdot) \in \mathcal{R}$ and $(b, f, p, P) \in \mathcal{N}_\phi$, every solution $(e(\cdot), \lambda(\cdot))$ of the controlled system has maximal interval of existence $\mathbb{R}_+$ with $e(t) \to 0$ as $t \to \infty$, and $\lim_{t\to\infty} \lambda(t)$ exists and is finite.

3.1.3. Practical stabilization and tracking by continuous feedback. The adaptive strategies outlined above are (generically) of a discontinuous feedback nature. From a viewpoint of practical utility, this feature might be regarded as unpleasant. Here, we investigate the possibility of adopting smooth approximations to the discontinuous feedbacks. Of course, in so doing, one would expect to pay a price. It will be shown that, if the objective of attractivity of the zero state (in the stabilization case) or asymptotic tracking (in the case of a servomechanism) is weakened to requiring global attractivity of any (arbitrarily small) prescribed neighborhood of zero or, for the servomechanism problem, tracking to within any prescribed (arbitrarily small but nonzero) error margin, then such approximations are feasible. We will present this result only in the context of the stabilization problem (imposing the additional property (3.9), the corresponding result for the servomechanism problem is readily inferred by analogy with section 3.1.2). The naïve idea, as developed in [10] and [21], is to inhibit the adaption whenever the state lies within the prescribed neighborhood of zero.

Let $\epsilon > 0$ be arbitrary and let d_ϵ denote the distance function for the set $[-\epsilon, \epsilon]$; thus, $d_\epsilon(x) := |x| - \epsilon$ if $|x| \geq \epsilon$; $d_\epsilon(x) = 0$ if $|x| < \epsilon$.

Let $\phi : \mathbb{R}_+ \to \mathbb{R}_+$ be continuous and positive-definite. Let $\mathrm{sat}_\epsilon : \mathbb{R} \to \mathbb{R}$ be any continuous function (arbitrarily smooth) such that (i) $|\mathrm{sat}_\epsilon(x)| \leq 1$ for all x and (ii) $\mathrm{sat}_\epsilon(x) = \mathrm{sgn}(x)$ whenever $|x| \geq \epsilon$. We will show that the following strategy assures that the state of (3.1) approaches the interval $[-\epsilon, \epsilon]$ for all quadruples $(b, f, p, P) \in \mathcal{N}_\phi$:

$$u(t) = \nu(\lambda(t))\phi(|y(t)|)\mathrm{sat}_\epsilon(y(t)), \quad \dot{\lambda}(t) = \phi(|y(t)|)d_\epsilon(y(t)), \quad \lambda(0) = \lambda^0,$$

where, as before, ν is any continuous function with properties (3.3).

Let $(b, f, p, P) \in \mathcal{N}_\phi$, and so there exists constant μ such that $|f(p(t), y)| \le \mu\phi(|y|)$ for all (t, y). Define the set-valued map $y \mapsto \sigma_\epsilon(y)$ by

$$\sigma_\epsilon(y) := \begin{cases} \{\mathrm{sgn}(y)\}, & |y| \ge \epsilon, \\ [-1, +1], & |y| < \epsilon. \end{cases}$$

Evidently, sat_ϵ is a continuous selection from σ_ϵ. We now embed the smooth-feedback–controlled system in the following differential inclusion on $\mathbb{R}^2$:

$$\dot{x}(t) \in X_\epsilon(x(t)), \quad x(t) = (y(t), \lambda(t)) \in \mathbb{R}^2, \quad x(0) = x^0 = (y^0, \lambda^0), \tag{3.11}$$

where $x \mapsto X_\epsilon(x) \subset \mathbb{R}^2$ is given by

$$X_\epsilon(x) \equiv X_\epsilon(y, \lambda) := \{v + bu|\ |v| \le \mu\phi(|y|),\ u \in \nu(\lambda)\phi(|y|)\sigma_\epsilon(y)\} \times \{\phi(|y|)d_\epsilon(y)\}.$$

X_ϵ is upper semicontinuous on $\mathbb{R}^2$ with nonempty, convex, and compact values. Therefore for each $x^0 \in \mathbb{R}^2$, the initial-value problem (3.11) has a solution and every solution has a maximal extension.

LEMMA 3.2. *Let $x^0 \in \mathbb{R}^2$ be arbitrary and let $x(\cdot) = (y(\cdot), \lambda(\cdot))$ be a maximal solution of* (3.11), *defined on its maximal interval of existence* $[0, \omega)$. *Then* (i) $\omega = \infty$; (ii) $\lim_{t\to\infty} \lambda(t)$ *exists and is finite;* (iii) $d_\epsilon(y(t)) \to 0$ *as* $t \to \infty$.

Proof. For almost all $t \in [0, \omega)$,

$$\begin{aligned}(d/dt)(\frac{1}{2}d_\epsilon^2(y(t))) &= d_\epsilon(y(t))\mathrm{sat}_\epsilon(y(t))\dot{y}(t) \\ &\le [\mu + b\nu(\lambda(t))]\,\phi(|y(t)|)d_\epsilon(y(t)) = [\mu + b\nu(\lambda(t))]\dot{\lambda}(t),\end{aligned}$$

which, on integration, yields

$$0 \le d_\epsilon^2(y(t)) \le d_\epsilon^2(y(\tau)) + 2\mu[\lambda(t) - \lambda(\tau)] + 2b\int_{\lambda(\tau)}^{\lambda(t)} \nu \tag{3.12}$$

valid for all $t, \tau \in [0, \omega)$, with $t \ge \tau$. By precisely the same contradiction argument as employed previously in the case of the discontinuous stabilizer, we may deduce that $x(\cdot) = (y(\cdot), \lambda(\cdot)) \in AC([0, \omega); \mathbb{R}^2)$ is a precompact solution of (3.11), and so, $\omega = \infty$. Defining $l : \mathbb{R}^2 \to \mathbb{R}$, $x \equiv (y, \lambda) \mapsto \phi(|y|)d_\epsilon(y)$ (and so, $\dot{\lambda} = l \circ x$), we conclude, by boundedness of $\lambda(\cdot)$, that $l \circ x \in L^1(\mathbb{R}_+)$). Therefore, by Theorem 2.10 (with $U = \mathbb{R}^2$), $x(\cdot) = (y(\cdot), \lambda(\cdot))$ approaches the set $l^{-1}(0) \equiv \{(y, \lambda)|\ d_\epsilon(y) = 0\}$. In particular, $d_\epsilon(y(t)) \to 0$ as $t \to \infty$ and, by monotonicity of bounded $\lambda(\cdot)$, $\lim_{t\to\infty} \lambda(t)$ exists and is finite. ∎

3.1.4. Dynamically perturbed scalar systems. Let $\phi : \mathbb{R}_+ \to \mathbb{R}_+$ be continuous and positive definite. Let $\Sigma_1 = (b, f, p, P) \in \mathcal{N}_\phi$. We wish to consider the situation wherein Σ_1 is subject to perturbations generated through its interconnection with a dynamical system Σ_2 (Fig. 3.1).

System Σ_2 is assumed to correspond to a differential equation (driven by the state of the scalar system Σ_1) on $\mathbb{R}^N$ of the form

$$\Sigma_2 : \qquad \dot{\zeta}(t) = g(y(t), \zeta(t)), \quad w(t) = h(\zeta(t)), \quad \zeta(0) = \zeta^0 \in \mathbb{R}^N, \tag{3.13}$$

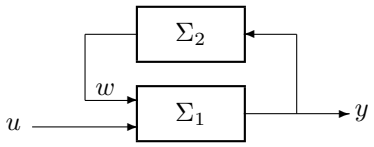

FIG. 3.1.

with input $y(t)$, and scalar output $w(t)$ perturbing Σ_1. Notationally, we identify the system Σ_2 with the triple (g, h, N). The overall system has representation (on $\mathbb{R}\times\mathbb{R}^N$)

$$\begin{cases} \dot{y}(t) = f(p(t), y(t)) + h(\zeta(t)) + bu(t), \\ \dot{\zeta}(t) = g(y(t), \zeta(t)), \quad (y(0), \zeta(0)) = (y^0, \zeta^0). \end{cases} \tag{3.14}$$

We will define, via Assumption D below, a class $\mathcal{P}_\psi$ of admissible systems $\Sigma_2 = (g, h, N)$, such that the $\mathcal{N}_\phi$-universal stabilizer of section 3.1.1 is readily modified to yield a $(\mathcal{N}_\phi, \mathcal{P}_\psi)$-universal stabilizer. Before stating Assumption D, we cite Sontag's concept of input-to-state stability [24], [25] (see also [26]) in the context of (3.13), with g assumed to be locally Lipschitz and with $y(\cdot)$ regarded as an independent input of class $L^\infty_{\rm loc}(\mathbb{R}_+;\mathbb{R})$. System (3.13) is *input-to-state stable* (ISS) if there exist a continuous, strictly increasing function $\gamma : \mathbb{R}_+ \to \mathbb{R}_+$, with $\gamma(0) = 0$, and a continuous function $\beta : \mathbb{R}_+ \times \mathbb{R}_+ \to \mathbb{R}_+$, with $\beta(0, t) = 0$ for all t and having the properties that, for each $t \geq 0$, $\beta(\cdot, t)$ is strictly increasing and, for each $s \geq 0$, $\beta(s, t) \downarrow 0$ as $t \to \infty$, such that, for every $\zeta^0 \in \mathbb{R}^N$ and every $y(\cdot) \in L^\infty_{\rm loc}(\mathbb{R}_+;\mathbb{R})$, the (unique) maximal solution $\zeta(\cdot)$ of the initial-value problem (3.13) satisfies $\|\zeta(t)\| \leq \beta(\|\zeta^0\|, t)+\gamma(\|y_t\|_\infty)$ for all $t \geq 0$, where y_t denotes the truncation of y at t, that is, $y_t(s) = y(s)$ if $s \leq t$ and $y_t(s) = 0$ if $s > t$. If (3.13) is ISS, then it is forward complete and has the convergent-input, convergent-state property: for each $\zeta^0 \in \mathbb{R}^N$ and $y \in L^\infty_{\rm loc}(\mathbb{R}_+;\mathbb{R})$, the unique solution $\zeta(\cdot)$ of the initial-value problem has maximal interval of existence $\mathbb{R}_+$ and, if $y(t) \to 0$ as $t \to \infty$, then $\zeta(t) \to 0$ as $t \to \infty$.

For continuous $\psi : \mathbb{R}_+ \to \mathbb{R}_+$, we denote by $\mathcal{P}_\psi$ the set of system triples $\Sigma_2 = (g, h, N)$ satisfying the following assumption.

Assumption D. (i) $g : \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}^N$ is locally Lipschitz; (ii) system (3.13) is ISS; (iii) $h : \mathbb{R}^N \to \mathbb{R}$ is continuous; (iv) there exist a function $\alpha_0 : \mathbb{R}_+ \to \mathbb{R}_+$ and scalar $\alpha_1 > 0$, such that, for each $(\zeta^0, y(\cdot)) \in \mathbb{R}^N \times L^\infty_{\rm loc}(\mathbb{R}_+;\mathbb{R})$, the (unique) solution $\zeta(\cdot)$ of (3.13) satisfies

$$\int_0^t h(\zeta(s))y(s)ds \leq \alpha_0(\|\zeta^0\|) + \alpha_1 \int_0^t \psi(|y(s)|)|y(s)|ds \quad \forall\ t \geq 0.$$

While Assumption D is rather restrictive, it is not difficult to identify nontrivial classes of systems for which the assumption holds. Three such examples follow, the first of which is easily seen; the second and third can be verified by arguments invoking [22, Theorem 2].

Examples. (a) Let $\psi : |y| \mapsto |y|$ and suppose (g, h, N) defines a linear system with $g : (y, \zeta) \mapsto A\zeta + By$, $h : \zeta \mapsto C\zeta$. If A has spectrum, spec(A), in the open left half complex plane $\mathbb{C}_-$, then $(g, h, N) \in \mathcal{P}_\psi$.

(b) More generally, let $\psi : |y| \mapsto |y|^k$, $k \geq 1$. Assume $g : \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}^N$ is locally Lipschitz and $h : \mathbb{R}^N \to \mathbb{R}$ is continuous. In addition, assume g and h are positively homogeneous of degree k. If $\{0\}$ is an asymptotically stable equilibrium of

the unforced system $\dot{\zeta}(t) = g(0, \zeta(t))$, then $(g, h, N) \in \mathcal{P}_\psi$. For example, with $k = 3$ and $\psi : |y| \mapsto |y|^3$, systems (with $N = 1$ and with unknown real parameters a_i) of the form $\dot{\zeta} = a_1\zeta^3 + a_2\zeta^2 y + a_3\zeta y^2 + a_4 y^3$, with output $w = a_5\zeta^3$, are of class $\mathcal{P}_\psi$, provided that $a_1 < 0$.

(c) Let $k > 0$, $k_h \geq 1$ and $\psi : |y| \mapsto \frac{1}{2}\left(|y|^{(k+1)k_h - 1} + |y|^{1/k}\right)$. Assume $g : \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}^N$ is locally Lipschitz and that $h : \mathbb{R}^N \to \mathbb{R}$ is continuous and positively homogeneous of degree k_h. If, in addition, g is positively homogeneous of degree k_g, with $1 \leq k_g \leq (k+1)k_h$, and $\{0\}$ is an asymptotically stable equilibrium of the unforced system $\dot{\zeta}(t) = g(0, \zeta(t))$, then $(g, h, N) \in \mathcal{P}_\psi$. For example, systems (with $N = 1$ and unknown parameters ρ, $a_i \in \mathbb{R}$) of the form $\dot{\zeta} = |\zeta|^\rho[a_1\zeta + a_2 y]$, with linear output $y = a_3\zeta$ (in which case $k_h = 1$), are of class $\mathcal{P}_\psi$, provided that $a_1 < 0$ and $0 \leq \rho \leq k$.

Let $\phi : \mathbb{R}_+ \to \mathbb{R}_+$ be continuous and positive definite. Let $\psi : \mathbb{R}_+ \to \mathbb{R}_+$ be continuous. We will show that, for $(\mathcal{N}_\phi, \mathcal{P}_\psi)$-universal stabilization, it suffices to replace both occurrences of ϕ in (3.4) with $\phi + \psi$ to yield

$$u(t) \in \nu(\lambda(t))(\phi + \psi)(|y(t)|)\sigma(y(t)),\ \dot{\lambda}(t) = (\phi + \psi)(|y(t)|)|y(t)|,\ \lambda(0) = \lambda^0. \tag{3.15}$$

Let $(b, f, p, P) \in \mathcal{N}_\phi$ and $(g, h, N) \in \mathcal{P}_\psi$. Then there exists constant μ such that $|f(p(t), y)| \leq \mu\phi(|y|)$ for all (t, y). The feedback-controlled system (3.14)–(3.15) can be embedded in a differential inclusion on $\mathbb{R}^{N+2}$:

$$\begin{cases} \dot{x}(t) \in X(x(t)), \quad x(t) = (y(t), \zeta(t), \lambda(t)) \in G := \mathbb{R}^{N+2}, \\ x(0) = x^0 = (y^0, \zeta^0, \lambda^0), \end{cases} \tag{3.16}$$

where $x = (y, \zeta, \lambda) \mapsto X(x) \subset \mathbb{R}^{N+2}$ is given by

$$\begin{aligned} X(x) \equiv X(y, \zeta, \lambda) := \{h(\zeta) + v + bu|\ |v| \leq \mu\phi(|y|),\ u \in \nu(\lambda)(\phi + \psi)(|y|)\sigma(y)\} \\ \times \{g(y, \zeta)\} \times \{(\phi + \psi)(|y|)|y|\}. \end{aligned}$$

X is upper semicontinuous on $\mathbb{R}^{N+2}$ with nonempty, convex, and compact values. Therefore, for each $x^0 \in \mathbb{R}^{N+2}$, the initial-value problem (3.16) has a solution and every solution can be maximally extended.

LEMMA 3.3. *Let $x^0 \in \mathbb{R}^{N+2}$ be arbitrary and let $x(\cdot) = (y(\cdot), \zeta(\cdot), \lambda(\cdot))$ be a maximal solution of* (3.16)*, defined on its maximal interval of existence $[0, \omega)$. Then* (i) *$\omega = \infty$;* (ii) *$\lim_{t\to\infty} \lambda(t)$ exists and is finite;* (iii) *$(y(t), \zeta(t)) \to (0, 0)$ as $t \to \infty$.*

Proof. For almost all $t \in [0, \omega)$, we have

$$\begin{aligned} y(t)\dot{y}(t) &\leq h(\zeta(t))y(t) + \mu\phi(|y(t)|)|y(t)| + b\nu(\lambda(t))(\phi + \psi)(|y(t)|)|y(t)| \\ &\leq h(\zeta(t))y(t) + [\mu + b\nu(\lambda(t))]\dot{\lambda}(t) \end{aligned}$$

which, on integration, yields

$$0 \leq y^2(t) \leq y^2(\tau) + 2\int_\tau^t h(\zeta(s))y(s)ds + 2\mu[\lambda(t) - \lambda(\tau)] + 2b\int_{\lambda(\tau)}^{\lambda(t)} \nu$$

valid for all $t, \tau \in [0, \omega)$, with $t \geq \tau$. Invoking Assumption D, we have

$$0 \leq y^2(t) \leq y^2(\tau) + 2\alpha_0(\|\zeta(\tau)\|) + 2[\alpha_1 + \mu][\lambda(t) - \lambda(\tau)] + 2b\int_{\lambda(\tau)}^{\lambda(t)} \nu. \tag{3.17}$$

By the same contradiction argument as that employed in the proof of Lemma 3.1, we may deduce that $\lambda(\cdot)$ is bounded. Boundedness of $y(\cdot)$ then follows from (3.17). That $\zeta(\cdot)$ is bounded is a consequence of the ISS property of $\Sigma_2 = (g, h, N)$. Therefore, $x(\cdot) = (y(\cdot), \zeta(\cdot), \lambda(\cdot)) \in AC([0, \omega); \mathbb{R}^{N+2})$ is a precompact solution of (3.16), and so, $\omega = \infty$. Defining $l : \mathbb{R}^{N+2} \to \mathbb{R}, \quad x \equiv (y, \zeta, \lambda) \mapsto (\phi + \psi)(|y|)|y|$ (and so $\dot{\lambda} = l \circ x$), we may conclude, by boundedness of $\lambda(\cdot)$, that $l \circ x \in L^1(\mathbb{R}_+)$. Therefore by Theorem 2.10 (with $U = \mathbb{R}^{N+2}$), $x(\cdot)$ approaches the set $\{(y, \zeta, \lambda) |\ y = 0\}$. In particular, $y(t) \to 0$ as $t \to \infty$, and so, by the convergent-input, convergent-state property of the ISS system $\Sigma_2 = (g, h, N)$, we may also conclude that $\zeta(t) \to 0$ as $t \to \infty$. Finally, by boundedness and monotonicity of $\lambda(\cdot)$, $\lim_{t\to\infty} \lambda(t)$ exists and is finite. □

Example. Linear, minimum-phase systems of relative degree one. This class has played a central role in the development of universal adaptive control. In appropriate coordinates, such systems have state space representations of the form

$$\dot{y} = A_1 y + A_2 \zeta + CBu, \quad \dot{\zeta} = A_3 y + A_4 \zeta. \tag{3.18}$$

In the single-input, single-output case, we identify (3.18) and (3.14) with

$$f : (p, y) \mapsto A_1 y, \quad h : \zeta \mapsto A_2 \zeta, \quad b = CB, \quad g : (y, \zeta) \mapsto A_3 y + A_4 \zeta.$$

By the relative-degree-one assumption, $b = CB \neq 0$ and, by the minimum-phase assumption, $\mathrm{spec}(A_4) \subset \mathbb{C}_-$. Defining $\phi \equiv \psi : |y| \mapsto \frac{1}{2}|y|$, we see that every single-input, single-output, linear, minimum-phase system of relative degree one is of class $(\mathcal{N}_\phi, \mathcal{P}_\psi)$ and the control (3.15) reduces to the ubiquitous Byrnes–Willems strategy: $u(t) = \nu(\lambda(t))y(t)$, $\dot{\lambda}(t) = y^2(t)$, $\lambda(0) = \lambda^0$.

Remarks. In considering the case of dynamically perturbed scalar systems, we treated only the problem of adaptive stabilization. The adaptive servomechanism of section 3.1.2 can also be modified to incorporate dynamically perturbed systems when the dynamic perturbations are generated by linear systems $\dot{\zeta} = A\zeta + By$, $w = C\zeta$, $\mathrm{spec}(A) \subset \mathbb{C}_-$, as described in the previous Example. For such perturbations, the (modified) servomechanism ensures convergence to zero of the tracking error, convergence to a finite limit of the adapting parameter, and boundedness of the evolution $t \mapsto \zeta(t)$ of the perturbing system. We omit full details here.

3.2. Planar systems. In all applications of the integral invariance principle in section 3.1 above, the conclusion that $x(t)$ tends, as $t \to \infty$, to the zero level set $l^{-1}(0)$ proved sufficient for our purposes; the additional property that $x(\cdot)$ approaches the largest weakly invariant subset of $l^{-1}(0)$ was redundant. Here, we treat a class of systems for which the latter property can be fruitfully exploited. We consider planar systems (with scalar control u) described by a second-order differential equation:

$$\begin{cases} \ddot{y}(t) = d(t)\dot{y}(t) + f(p(t), y(t)) + bu(t), \quad y(t), u(t), d(t) \in \mathbb{R}, \quad p(t) \in \mathbb{R}^P, \\ (y(t_0), \dot{y}(t_0)) = (y^0, v^0), \end{cases} \tag{3.19}$$

where the parameters $b \in \mathbb{R}$, $P \in \mathbb{N}$, and functions d, f, p are unknown. The variable $y(t)$, but not its derivative $\dot{y}(t)$, is available for feedback. We identify (3.19) with the quintuple (b, d, f, p, P). For $\delta > 0$ and continuous, positive-definite, nondecreasing function $\phi : \mathbb{R}_+ \to \mathbb{R}_+$, we denote, by $\mathcal{N}_{\delta,\phi}$, the set of system quintuples (b, d, f, p, P) for which Assumption A (that is, $b \neq 0$) holds, together with the following three assumptions.

Assumption E. $d \in (C \cap L^\infty)(\mathbb{R})$ and, for some $\epsilon > 0$, $d(t) \leq -\delta - 2\epsilon$ for all t.

Assumption F. $(p, y) \mapsto f(p, y)$, $\mathbb{R}^P \times \mathbb{R} \to \mathbb{R}$ is continuous and is continuously differentiable in its first argument. Both f and $D_1 f$ ($\equiv \partial f/\partial p$) are ϕ-bounded uniformly with respect to p in compact sets; precisely, for every compact $K \subset \mathbb{R}^P$, there exists scalar μ_K such that $|f(p, y)| + \|D_1 f(p, y)\| \leq \mu_K \phi(|y|)$ for all $(p, y) \in K \times \mathbb{R}$.

Assumption G. $p(\cdot) \in W^{1,\infty}(\mathbb{R}; \mathbb{R}^P)$.

By virtue of Assumptions E and G, without loss of generality, $t_0 = 0$ may be assumed in (3.19); this we will do, without further comment, throughout.

In section 3.2.1 below, we will show that $(b, d, f, p, P) \in \mathcal{N}_{\delta,\phi}$, for some known $\delta > 0$ and known continuous positive-definite nondecreasing function ϕ, is sufficient *a priori* information for adaptive stabilizability of (3.19) by feedback of the variable $y(t)$ alone; in essence, Assumption E compensates for the inaccessibility of the velocity variable $\dot{y}(t)$ by requiring that the system should exhibit dissipitive dependence (loosely quantifiable by the known constant δ) on that variable.

Example. As motivation for (3.19), consider a single-degree-of-freedom mechanical system with position, but not velocity, available for feedback and with some constant (but unknown) natural damping d quantified by a known parameter δ in the sense that $d < -\delta < 0$. If we suppose that Assumption F holds with $\phi : |y| \mapsto 1 + |y|^3$, then, for example, the following particular realizations are admissible.

Nonlinear pendulum with disturbed support (disturbance $p(\cdot) \in W^{1,\infty}(\mathbb{R})$):

$$\ddot{y}(t) = d\dot{y}(t) + (a + p(t)) \sin(y(t)) + bu(t), \quad a, b \in \mathbb{R},\ b \neq 0.$$

Duffing equation with extraneous disturbance ($p(\cdot) \in W^{1,\infty}(\mathbb{R})$):

$$\ddot{y}(t) = d\dot{y}(t) + a_1 y(t) + a_2 y^3(t) + p(t) + bu(t), \quad a_1, a_2, b \in \mathbb{R},\ b \neq 0.$$

In the absence of control, such systems are potentially "chaotic."

3.2.1. Adaptive stabilizer. Let $\delta > 0$ and let $\phi : \mathbb{R}_+ \to \mathbb{R}_+$ be a continuous, positive-definite, nondecreasing function. Assuming only that δ, ϕ and the instantaneous state $y(t)$ are available for control purposes, our goal is to demonstrate the existence of an adaptive feedback strategy that provides $\mathcal{N}_{\delta,\phi}$-universal stabilization in the sense that it assures that the state of (3.19) approaches $\{0\}$ for all quintuples $(b, d, f, p, P) \in \mathcal{N}_{\delta,\phi}$ while maintaining boundedness of the controller function $\lambda(\cdot)$.

Define the continuous function $\gamma : \mathbb{R}_+ \to \mathbb{R}_+$ by $\gamma(\xi) := \xi + \phi(\xi)$ and let Γ denote its indefinite integral: $\Gamma : \mathbb{R}_+ \to \mathbb{R}_+$, $\xi \mapsto \int_0^\xi \gamma$. We claim that the following (formal) strategy is a $\mathcal{N}_{\delta,\phi}$-universal stabilizer:

$$\begin{cases} u(t) = \nu(\eta(t))\gamma(|y(t)|)\mathrm{sgn}(y(t)), \quad \eta(t) := \delta\lambda(t) + \Gamma(|y(t)|), \\ \dot{\lambda}(t) = \gamma(|y(t)|)|y(t)|, \quad \lambda(0) = \lambda^0 \in \mathbb{R}, \end{cases} \tag{3.20}$$

where ν is any continuous function with properties (3.3).

Let $(b, d, f, p, P) \in \mathcal{N}_{\delta,\phi}$. Introducing the coordinate transformation $z(t) = \dot{y}(t) + \delta y(t)$, we may express (3.19) in the form

$$\begin{cases} \dot{y}(t) = -\delta y(t) + z(t), \\ \dot{z}(t) = (\delta + d(t))(z(t) - \delta y(t)) + f(p(t), y(t)) + bu(t), \\ (y(0), z(0)) = (y^0, z^0). \end{cases} \tag{3.21}$$

The feedback (3.20) is interpreted in the set-valued sense:

$$\begin{cases} u(t) \in \nu(\eta(t))\gamma(|y(t)|)\sigma(y(t)), \quad \eta(t) = \delta\lambda(t) + \Gamma(|y(t)|), \\ \dot{\lambda}(t) = \gamma(|y(t)|)|y(t)|, \quad \lambda(0) = \lambda^0, \end{cases} \tag{3.22}$$

with the map $y \mapsto \sigma(y)$ defined as before in (3.5).

Writing $x(t) = (y(t), z(t), \lambda(t))$, the overall adaptive feedback controlled system may be embedded in the following differential inclusion on $\mathbb{R}^3$:

$$\dot{x}(t) \in X(t, x(t)), \quad x(0) = x^0 = (y^0, z^0, \lambda^0), \tag{3.23}$$

where $X : (t, x) \equiv (t, y, z, \lambda) \mapsto \{-\delta y + z\} \times X_2(t, x) \times \{\gamma(|y|)|y|\} \subset \mathbb{R}^3$, with

$$X_2(t, x) := \{(\delta + d(t))(z - \delta y) + f(p(t), y) + bu |\ u \in \nu(\delta\lambda + \Gamma(|y|))\gamma(|y|)\sigma(y)\}.$$

X is upper semicontinuous on $\mathbb{R}\times\mathbb{R}^3$ and takes nonempty, convex, and compact values in $\mathbb{R}^3$. Therefore, for each $x^0 \in \mathbb{R}^3$, the initial-value problem (3.23) has a solution and every solution can be extended into a maximal solution.

LEMMA 3.4. *Let $x^0 \in \mathbb{R}^3$ be arbitrary and let $x(\cdot) = (y(\cdot), z(\cdot), \lambda(\cdot))$ be a maximal solution of* (3.23) *defined on its maximal interval of existence $[0, \omega)$. Then* (i) *$\omega = \infty$;* (ii) *$\lim_{t\to\infty} \lambda(t)$ exists and is finite;* (iii) *$(y(t), z(t)) \to (0, 0)$ as $t \to \infty$.*

Proof. On $\mathbb{R}$, define the locally Lipschitz function $\Phi : r \mapsto \Gamma(|r|)$, with directional derivative at r in direction s given by

$$\Phi^\dagger(r; s) = \lim_{h\downarrow 0} \frac{\Phi(r + hs) - \Phi(r)}{h} = \begin{cases} \gamma(|r|)\mathrm{sgn}(r)s, & r \neq 0, \\ \gamma(0)|s|, & r = 0. \end{cases} \tag{3.24}$$

Let $F_1 \in AC([0, \omega); \mathbb{R})$ denote the composition $\Phi \circ y$ and let $\mathcal{O}_1 \subset [0, \omega)$ be the set (of measure zero) of points t at which the derivative $\dot{F}_1(t)$ fails to exist. A straightforward argument (analogous to that yielding (2.4)) gives

$$\dot{F}_1(t) = \Phi^\dagger(y(t); \dot{y}(t)) \quad \forall\ t \in [0, \omega)\backslash\mathcal{O}_1. \tag{3.25}$$

By properties of f and p (Assumptions F and G), the function

$$F_2 : t \mapsto \int_0^{y(t)} f(p(t), \xi)\, d\xi$$

is of class $AC([0, \omega); \mathbb{R})$. Let $\mathcal{O}_2$ denote the set (of measure zero) of points t at which $\dot{p}(t)$ fails to exist. Again by properties of f and p, there exists $\mu > 0$ such that

$$\begin{aligned} \dot{F}_2(t) = \int_0^{y(t)} \langle D_1 f(p(t), \xi), \dot{p}(t)\rangle\, d\xi + f(p(t), y(t))\dot{y}(t) \\ \geq -\mu\phi(|y(t)|)|y(t)| + f(p(t), y(t))z(t) \quad \forall\ t \in [0, \omega)\backslash\mathcal{O}_2. \end{aligned} \tag{3.26}$$

Define $F_c \in AC([0, \omega); \mathbb{R})$, parameterized by $c > 0$, as $F_c : t \mapsto cF_1(t) - F_2(t)$. By Assumptions F and G and the definition of Γ, F_c is such that, for all c sufficiently large,

$$F_c(t) \geq \frac{1}{2} c y^2(t) \quad \forall\ t. \tag{3.27}$$

Moreover, by (3.25) and (3.26),

$$\begin{aligned}(3.28)\quad \dot{F}_c(t) &= c\dot{F}_1(t) - \dot{F}_2(t) = c[\dot{\eta}(t) - \delta\gamma(|y(t)|)|y(t)|] - \dot{F}_2(t)\\ &\le c\dot{\eta}(t) + (\mu - c\delta)\gamma(|y(t)|)|y(t)| - z(t)f(p(t), y(t)) \quad \forall\ t \in [0,\omega)\backslash(\mathcal{O}_1 \cup \mathcal{O}_2).\end{aligned}$$

Let $Y := \{t \in [0,\omega) |\ (y(t), \dot{y}(t)) \neq (0,0)\}$ be the set of points t at which $y(t)$ and $\dot{y}(t)$ are not both zero. Observe that (i) every point t of the subset $\mathcal{O}_0 := \{t \in Y |\ y(t) = 0\}$ is an isolated point implying that $\mathcal{O}_0$ is countable and so has measure zero, and (ii) $y(t) = \dot{y}(t) = z(t) = 0$ for all $t \in [0,\omega)\backslash Y$. From these observations, together with (3.24), (3.25), and writing $\mathcal{O} := \mathcal{O}_0 \cup \mathcal{O}_1 \cup \mathcal{O}_2$ (of measure zero), we deduce that

$$\begin{aligned}(3.29)\qquad \forall\ t \in [0,\omega)\backslash\mathcal{O}, \quad uz(t) &= \nu(\eta(t))[\delta\gamma(|y(t)|)|y(t)| + \Phi^{\dagger}(y(t); \dot{y}(t))]\\ &= \nu(\eta(t))\dot{\eta}(t) \quad \forall\ u \in \nu(\eta(t))\gamma(|y(t)|)\sigma(y(t)).\end{aligned}$$

Define $V_c \in AC([0,\omega);\mathbb{R})$ by $V_c(t) := F_c(t) + \frac{1}{2}z^2(t)$. Invoking (3.28), (3.29), and Assumption E,

$$\begin{aligned}(3.30)\qquad \dot{V}_c(t) &\le \dot{F}_c(t) - 2\epsilon z^2(t) - (d(t)+\delta)\delta y(t)z(t)\\ &\qquad + z(t)f(p(t), y(t)) + b\nu(\eta(t))\dot{\eta}(t)\\ &\le [\Delta^2/(4\epsilon) + \mu - c\delta]\gamma(|y(t)|)|y(t)| - \epsilon z^2(t) + [c + b\nu(\eta(t))]\dot{\eta}(t)\end{aligned}$$

for almost all $t \in [0,\omega)$, wherein we have used the fact that

$$-(d(t)+\delta)\delta y(t)z(t) \le \Delta|y(t)z(t)| \le \epsilon z^2(t) + \frac{\Delta^2}{4\epsilon}y^2(t) \le \epsilon z^2(t) + \frac{\Delta^2}{4\epsilon}\gamma(|y(t)|)|y(t)|,$$

with $\Delta := (\|d(\cdot)\|_\infty + \delta)\delta$. Now fix c sufficiently large so that $\Delta^2(4\epsilon)^{-1} + \mu - c\delta \le 0$ and (3.27) holds, in which case, $V_c(t) \ge \frac{1}{2}\left[cy^2(t) + z^2\big(t\big)\right]$ for all t and

$$(3.31)\qquad \dot{V}_c(t) \le [c + b\nu(\eta(t))]\dot{\eta}(t) \quad \text{for a.a. } t \in [0,\omega),$$

which, on integration, yields

$$(3.32)\qquad 0 \le \frac{1}{2}\left[cy^2(t) + z^2(t)\right] \le V_c(t) \le V_c(\tau) + c[\eta(t) - \eta(\tau)] + b\int_{\eta(\tau)}^{\eta(t)} \nu$$

for all $t, \tau \in [0,\omega)$, with $t \ge \tau$.

We first show that the function $\eta(\cdot)$ (and hence $\lambda(\cdot)$) is bounded. By properties (3.3) of ν, there exist increasing sequences $(\hat{\eta}_n)_{n\in\mathbb{N}}$ and $(\tilde{\eta}_n)_{n\in\mathbb{N}}$, with $\hat{\eta}_n \to \infty$ and $\tilde{\eta}_n \to \infty$ as $n \to \infty$, such that

$$(3.33)\qquad \text{(a)}\quad \frac{1}{\hat{\eta}_n}\int_{\hat{\eta}_1}^{\hat{\eta}_n} \nu(\theta)d\theta\ \to +\infty, \qquad \text{(b)}\quad \frac{1}{\tilde{\eta}_n}\int_{\tilde{\eta}_1}^{\tilde{\eta}_n} \nu(\theta)d\theta\ \to -\infty$$

as $n \to \infty$. Without loss of generality, we may assume $\hat{\eta}_1, \tilde{\eta}_1 \ge 1$. Seeking a contradiction, suppose that $\eta(\cdot)$ is unbounded. Now, $\eta(\cdot)$ is bounded from below (in particular, $\eta(t) \ge \delta\lambda^0$ for all $t \ge 0$), and so, by the supposition, $\eta(\cdot)$ is unbounded from above. Therefore, there exist increasing sequences $(\hat{t}_n), (\tilde{t}_n) \subset [0,\omega)$ such that, for all n,

$$\eta(\hat{t}_n) = \hat{\eta}_n \quad \text{and} \quad \eta(\tilde{t}_n) = \tilde{\eta}_n.$$

Now, either $b > 0$ or $b < 0$. If $b > 0$, then (3.32) and (3.33b) combine to yield the contradiction

$$0 \leq \text{constant} + \frac{b}{\tilde{\eta}_n} \int_{\tilde{\eta}_1}^{\tilde{\eta}_n} \nu \;\rightarrow\; -\infty \quad \text{as } n \rightarrow \infty.$$

If $b < 0$, then (3.32) and (3.33a) combine to yield the contradiction

$$0 \leq \text{constant} - \frac{|b|}{\hat{\eta}_n} \int_{\hat{\eta}_1}^{\hat{\eta}_n} \nu \;\rightarrow\; -\infty \quad \text{as } n \rightarrow \infty.$$

Therefore $\eta(\cdot)$ (and hence, $\lambda(\cdot)$) is bounded. Boundedness of $\eta(\cdot)$ and $\lambda(\cdot)$, together with (3.32), imply boundedness of $y(\cdot)$ and $z(\cdot)$. This establishes assertion (i) and assertion (ii) follows by monotonicity of $\lambda(\cdot)$. It remains to prove assertion (iii).

By boundedness of $d(\cdot)$, $p(\cdot)$, and $x(\cdot)$, there exists $\rho > 0$ such that $X_2(t, x(t)) \subset \rho\bar{\mathbb{B}}$ for all $t \in [0, \infty)$, and so, $x(\cdot) = (y(\cdot), z(\cdot), \lambda(\cdot))$ is a precompact solution of the autonomous initial-value problem

$$\dot{x}(t) \in \{-\delta y(t) + z(t)\} \times \rho\bar{\mathbb{B}} \times \{\gamma(|y(t)|)|y(t)|\}, \quad x(0) = x^0. \tag{3.34}$$

Moreover, by boundedness of $\lambda(\cdot)$,

$$\int_0^\infty y^2(s)ds \leq \int_0^\infty \dot{\lambda}(s)ds < \infty.$$

Therefore, by Theorem 2.10, $x(\cdot)$ approaches the largest weakly-invariant (relative to the autonomous differential inclusion (3.34)) set W in $\{(y, z, \lambda)|\ y = 0\}$. Let $\bar{w} = (0, \bar{z}, \bar{\lambda}) \in W$. By definition of weak invariance, the initial-value problem

$$\dot{w}(t) = (\dot{w}_1(t), \dot{w}_2(t), \dot{w}_3(t)) \in \{-\delta w_1(t) + w_2(t)\} \times \rho\bar{\mathbb{B}} \times \{\gamma(|w_1(t)|)|w_1(t)|\}, \quad w(0) = \bar{w}$$

has at least one solution $w(\cdot) = (w_1(\cdot), w_2(\cdot), w_3(\cdot))$ with maximal interval of existence $\mathbb{R}_+$ and with trajectory in $W \subset \{(y, z, \lambda)|\ y = 0\}$. Since $\dot{w}_1(t) = -\delta w_1(t) + w_2(t)$ and $w_1(\cdot) \equiv 0$ in W, it follows that $w_2(\cdot) \equiv 0$, and so, $\bar{z} = w_2(0) = 0$. Therefore, we conclude that the largest weakly-invariant set in W is contained in the set $\{(y, z, \lambda)|\ y = 0 = z\}$, and so the solution $x(\cdot)$ approaches the set $\{(0, 0)\} \times \mathbb{R}$. In particular, $(y(t), z(t)) \rightarrow (0, 0)$ as $t \rightarrow \infty$. □

3.2.2. Adaptive servomechanism. We now turn attention to the servomechanism problem for planar systems (3.21), that is, the construction of controls that cause the system to track, asymptotically, any reference signal $r(\cdot)$ of some given class, in the sense that both the tracking error $e(t) = y(t) - r(t)$ and its derivative $\dot{e}(t) = \dot{y}(t) - \dot{r}(t)$ tend to zero as $t \rightarrow \infty$. For the class of reference signals we take the (Sobolev) space $\mathcal{R} = W^{3,\infty}(\mathbb{R})$ of functions $r \in \left(C^2 \cap L^\infty\right)(\mathbb{R})$ with $\dot{r} \in \left(C^1 \cap L^\infty\right)(\mathbb{R})$ and $\ddot{r} \in W^{1,\infty}(\mathbb{R})$, equipped with the norm

$$\|r\|_{3,\infty} = \|r\|_\infty + \|\dot{r}\|_\infty + \|\ddot{r}\|_\infty + \|\dddot{r}\|_\infty.$$

For the servomechanism problem, we restrict the underlying class of systems by imposing a stronger assumption on the function f. Assumption F* below should hold for some known, continuous, positive-definite, nondecreasing function ϕ having the additional property (3.9). Specifically, for real $\delta > 0$ and continuous, positive-definite, nondecreasing function $\phi : \mathbb{R}_+ \rightarrow \mathbb{R}_+$ with property (3.9), we denote, by $\mathcal{N}^*_{\delta,\phi}$, the set of quintuples (b, d, f, p, P) satisfying Assumptions A, E, and F*.

Assumption F*. $(p,y) \mapsto f(p,y)$, $\mathbb{R}^P \times \mathbb{R} \to \mathbb{R}$ is continuously differentiable. Both f and its gradient function $Df = (D_1 f, D_2 f)$ $(\equiv (\partial f/\partial p, \partial f/\partial y))$ are ϕ-bounded uniformly with respect to p in compact sets; precisely, for every compact $K \subset \mathbb{R}^P$, there exists scalar μ_K such that $|f(p,y)| + \|Df(p,y)\| \leq \mu_K \phi(|y|)$ for all $(p,y) \in K \times \mathbb{R}$.

Example. The function $\phi : |y| \mapsto 1 + |y|^3$ has property (3.9) and the mechanical systems described in the previous Example are admissible.

Let $\delta > 0$ and let ϕ be a continuous, positive-definite, nondecreasing function with property (3.9). We claim that, in order to assure convergence to zero of both the tracking error $e(t) = y(t) - r(t)$ and its derivative $\dot{e}(t)$ for all reference signals $r \in \mathcal{R}$ and all quintuples $(b,d,f,p,P) \in \mathcal{N}^*_{\delta,\phi}$, it suffices to replace every occurrence of $y(t)$ in (3.20) by $e(t)$. Proof of this claim follows.

Let $(b,d,f,p,P) \in \mathcal{N}^*_{\delta,\phi}$. Write $\tilde{P} = P + 3$ and define the continuous function

$$\tilde{f} : \mathbb{R}^{\tilde{P}} \times \mathbb{R} \to \mathbb{R}, \quad (\tilde{p}, e) \equiv (p, r, v, w, e) \mapsto f(p, e + r) - \delta v - w.$$

By properties of f, $\tilde{f}$ is continuously differentiable with respect to its first argument $(\tilde{p})$, with $D_1 \tilde{f}$ given by

$$D_1 \tilde{f}(\tilde{p}, e) \equiv (\partial \tilde{f}/\partial \tilde{p})(\tilde{p}, e) = (D_1 f(p, e + r), D_2 f(p, e + r), -\delta, -1).$$

Let $\tilde{K} \subset \mathbb{R}^{\tilde{P}}$ be compact, and so there exist compact $K \subset \mathbb{R}^P$ and $R > 0$ such that $\tilde{K} \subset K \times [-R, R]^3$. By properties of f and ϕ, there exist constants μ_K and ρ_R such that, for all $(p, r, v, w) \equiv \tilde{p} \in \tilde{K} \subset K \times [-R, R]^3$,

$$\begin{aligned} |\tilde{f}(\tilde{p}, e)| + \|D_1 \tilde{f}(\tilde{p}, e)\| &\leq |f(p, e + r)| + \delta|v| + |w| + \|Df(p, e + r)\| + \delta + 1 \\ &\leq \mu_K \phi(|e + r|) + (1 + \delta)(1 + R) \\ &\leq \mu_K \rho_R \phi(|e|) + (1 + \delta)(1 + R) \leq \tilde{\mu}_{\tilde{K}} \phi(|e|), \end{aligned}$$

with $\tilde{\mu}_{\tilde{K}} := \mu_K \rho_R + ((1 + \delta)(1 + R))/\phi(0)$. Therefore, $\tilde{f}$ satisfies Assumption F.

Let $r \in \mathcal{R} \equiv W^{3,\infty}(\mathbb{R})$. Then $t \mapsto \tilde{p}(t) := (p(t), r(t), \dot{r}(t), \ddot{r}(t)) \in \mathbb{R}^{\tilde{P}}$ is of class $W^{1,\infty}(\mathbb{R}; \mathbb{R}^{\tilde{P}})$, and so $(b, d, \tilde{f}, \tilde{p}, \tilde{P}) \in \mathcal{N}_{\delta,\phi}$. Expressed in terms of the tracking error $e(t) = y(t) - r(t)$ and adopting the coordinate transformation $z(t) = \dot{e}(t) + \delta e(t)$, the underlying dynamics have the form

$$\text{(3.35)} \qquad \begin{cases} \dot{e}(t) = -\delta e(t) + z(t), \\ \dot{z}(t) = (\delta + d(t))(z(t) - \delta e(t)) + \tilde{f}(\tilde{p}(t), e(t)) + bu(t), \\ (e(0), z(0)) = (e^0, z^0). \end{cases}$$

We are now in precisely the same context, modulo notation, as in the case of an adaptive stabilizer, and so, replacing all occurrences of $y(t)$ in (3.20) by $e(t)$, viz.

$$\text{(3.36)} \qquad \begin{cases} u(t) \in \nu(\eta(t))\gamma(|e(t)|)\sigma(e(t)), \quad \eta(t) = \delta\lambda(t) + \Gamma(|e(t)|), \\ \dot{\lambda}(t) = \gamma(|e(t)|)|e(t)|, \ \lambda(0) = \lambda^0, \end{cases}$$

then the same argument, as used to establish Lemma 3.4, applies *mutatis mutandis* to conclude that (3.36) is an $(\mathcal{R}, \mathcal{N}^*_{\delta,\phi})$-universal servomechanism; for each $r(\cdot) \in \mathcal{R}$ and $(b,d,f,p,P) \in \mathcal{N}^*_{\delta,\phi}$, every solution $(e(\cdot), z(\cdot), \lambda(\cdot))$ of the feedback controlled system has maximal interval of existence $\mathbb{R}_+$ with $(e(t), z(t)) \to (0,0)$ as $t \to \infty$ and, moreover, $\lim_{t\to\infty} \lambda(t)$ exists and is finite.

3.2.3. Dynamically perturbed planar systems. Let $\delta > 0$ and let the function $\phi : \mathbb{R}_+ \to \mathbb{R}_+$ be continuous, positive definite, and nondecreasing. Let $\Sigma_1 = (b, d, f, p, P) \in \mathcal{N}_{\delta,\phi}$. Here we consider the case where Σ_1 is subject to perturbations generated through its interconnection with a dynamical system Σ_2 (as depicted in Figure 3.1).

The system Σ_2 is assumed to correspond to a differential equation (driven by the variable $y(t)$ of system Σ_1) on $\mathbb{R}^N$ of the form (3.13) with input $y(t)$, and scalar output $w(t)$ perturbing Σ_1. As before, we identify the system Σ_2 with the triple (g, h, N). Writing $z(t) = \dot{y}(t) + \delta y(t)$, the overall system has representation (on $\mathbb{R} \times \mathbb{R} \times \mathbb{R}^N$)

$$\text{(3.37)} \quad \begin{cases} \dot{y}(t) = -\delta y(t) + z(t), \\ \dot{z}(t) = (\delta + d(t))z(t) - (\delta + d(t))\delta y(t) + f(p(t), y(t)) + h(\zeta(t)) + bu(t), \\ \dot{\zeta}(t) = g(y(t), \zeta(t)), \quad (y(0), z(0), \zeta(0)) = (y^0, z^0, \zeta^0). \end{cases}$$

We will define, via Assumption H below, a class $\mathcal{P}_\psi$ of admissible systems $\Sigma_2 = (g, h, N)$, such that the $\mathcal{N}_{\delta,\phi}$-universal stabilizer of section 3.2.1 is readily modified to yield a $(\mathcal{N}_{\delta,\phi}, \mathcal{P}_\psi)$-universal stabilizer.

For continuous $\psi : \mathbb{R}_+ \to \mathbb{R}_+$, we denote, by $\mathcal{P}_\psi$ the set of system triples $\Sigma_2 = (g, h, N)$ satisfying the following.

Assumption H. (i) $g : \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}^N$ is locally Lipschitz; (ii) system (3.13) is ISS; (iii) $h : \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}$ is continuous; (iv) there exist a function $\alpha_0 : \mathbb{R}_+ \to \mathbb{R}_+$ and a scalar $\alpha_1 > 0$, such that, for each $(\zeta^0, y(\cdot)) \in \mathbb{R}^N \times L^\infty_{\text{loc}}(\mathbb{R}_+)$, the (unique) solution $\zeta(\cdot)$ of (3.13) satisfies

$$\int_0^t h^2(\zeta(s))ds \le \alpha_0(\|\zeta^0\|) + \alpha_1 \int_0^t \psi(|y(s)|)|y(s)|ds.$$

Examples. (a) Assumption H holds for the class of linear systems considered in the first Example of section 3.1.4.

(b) More generally, assume $g : \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}^N$ is locally Lipschitz and $h : \mathbb{R}^N \to \mathbb{R}$ is continuous. Assume further that h is positively homogeneous of degree $k \ge 1$ and that g is positively homogeneous of degree k_g, $1 \le k_g \le 2k$. Let $\psi : |y| \mapsto |y|^{2k-1}$. If $\{0\}$ is an asymptotically stable equilibrium of the unforced system $\dot{\zeta}(t) = g(0, \zeta(t))$, then it can be shown (by an argument invoking [22, Theorem 2]) that $(g, h, N) \in \mathcal{P}_\psi$. For example, if $\psi : |y| \mapsto |y|$, then systems (with $N = 1$ and with unknown real parameters a_i) of the form $\dot{\zeta} = a_1\zeta|\zeta| + a_2y^2$, $w = a_3\zeta$, are of class $\mathcal{P}_\psi$, provided that $a_1 < 0$.

Let $\delta > 0$ and let $\phi : \mathbb{R}_+ \to \mathbb{R}_+$ be continuous, positive definite, and nondecreasing. As before, let $\gamma : \xi \mapsto \xi + \phi(\xi)$ and $\Gamma : \xi \mapsto \int_0^\xi \gamma$. Let $\psi : \mathbb{R}_+ \to \mathbb{R}_+$ be continuous with indefinite integral $\Psi : \mathbb{R}_+ \to \mathbb{R}_+$, $\xi \mapsto \int_0^\xi \psi$.

We will show that, for $(\mathcal{N}_{\delta,\phi}, \mathcal{P}_\psi)$-universal stabilization, it suffices to replace both occurrences of γ in (3.20) by $\gamma + \psi$ and to replace the single occurrence of Γ with $\Gamma + \Psi$ to yield

$$\text{(3.38)} \quad \begin{cases} u(t) \in \nu(\eta(t))(\gamma + \psi)(|y(t)|)\sigma(y(t)), \quad \eta(t) = \delta\lambda(t) + (\Gamma + \Psi)(|y(t)|), \\ \dot{\lambda}(t) = (\gamma + \psi)(|y(t)|)|y(t)|, \ \lambda(0) = \lambda^0. \end{cases}$$

Let $(b, d, f, p, P) \in \mathcal{N}_{\delta,\phi}$ and $(g, h, N) \in \mathcal{P}_\psi$. The feedback-controlled system (3.37)–

(3.38) can be embedded in a differential inclusion on $\mathbb{R}^{N+3}$:

$$\text{(3.39)}\quad \begin{cases} \dot{x}(t) \in X(t, x(t)), \\ x(t) = (y(t), z(t), \zeta(t), \lambda(t)) \in G := \mathbb{R}^{N+3}, \quad x(0) = x^0 = (y^0, z^0, \zeta^0, \lambda^0), \end{cases}$$

where the set-valued map $(t, x) \equiv (t, y, z, \zeta, \lambda) \mapsto X(t, x) \subset \mathbb{R}^{N+3}$ is given by

$$X(t, x) = \{-\delta y + z\} \times X_2(t, x) \times \{g(y, \zeta)\} \times \{(\gamma + \psi)(|y|)|y|\},$$

$$X_2(t, x) := \{(\delta + d(t))z - (\delta + d(t))\delta y + f(p(t), y) + h(\zeta) + bu| \\ u \in \nu(\delta\lambda + (\Gamma + \Psi)(|y|)\sigma(y)\}.$$

X is upper semicontinuous on $\mathbb{R} \times \mathbb{R}^{N+3}$ and takes nonempty, convex, and compact values in $\mathbb{R}^{N+3}$. Therefore, for each $x^0 \in \mathbb{R}^{N+3}$, the initial-value problem (3.39) has a solution, and every solution can be maximally extended.

LEMMA 3.5. *Let $x^0 \in \mathbb{R}^{N+3}$ be arbitrary and let $x(\cdot) = (y(\cdot), z(\cdot), \zeta(\cdot), \lambda(\cdot))$ be a maximal solution of* (3.39) *defined on its maximal interval of existence $[0, \omega)$. Then* (i) *$\omega = \infty$;* (ii) *$\lim_{t\to\infty} \lambda(t)$ exists and is finite;* (iii) *$(y(t), z(t), \zeta(t)) \to (0, 0, 0)$ as $t \to \infty$.*

Proof. Let F_c and V_c, parameterized by $c > 0$, be defined as in the proof of Lemma 3.4. By an argument essentially the same as that adopted in the proof of Lemma 3.4 and choosing c sufficiently large, we arrive at a counterpart to (3.30):

$$\text{(3.40)}\qquad \dot{V}_c(t, y(t), z(t)) \le -\epsilon z^2(t) + |h(\zeta(t))||z(t)| + [c + b\nu(\eta(t))]\dot{\eta}(t)$$

for almost all $t \in [0, \omega)$. Invoking the inequality $|h(\zeta)||z| \le \frac{1}{2}\epsilon z^2 + \frac{1}{2}\epsilon^{-1}h^2(\zeta)$, then integrating and invoking Assumption H, we have (for c sufficiently large)

$$\text{(3.41)}\quad \frac{1}{2}[cy^2(t) + z^2(t)] \le V_c(t, y(t), z(t)) \le V_c(\tau, y(\tau), z(\tau)) \\ + \frac{1}{2}\epsilon^{-1}\alpha_0(\|\zeta(\tau)\|) + \frac{1}{2}\epsilon^{-1}\alpha_1[\lambda(t) - \lambda(\tau)] \\ + c[\eta(t) - \eta(\tau)] + b\int_{\eta(\tau)}^{\eta(t)} \nu$$

for all $t, \tau \in [0, \omega)$, with $t \ge \tau$. A straightforward modification of the contradiction argument used previously in the proof of Lemma 3.4 establishes boundedness of $\eta(\cdot)$ (and hence, of $\lambda(\cdot)$). Boundedness of $\eta(\cdot)$ and $\lambda(\cdot)$, together with (3.41), imply boundedness of $y(\cdot)$ and $z(\cdot)$. That $\zeta(\cdot)$ is bounded is a consequence of the ISS property of $\Sigma_2 = (g, h, N)$. This establishes assertion (i) and assertion (ii) follows by monotonicity of $\lambda(\cdot)$. It remains to prove assertion (iii). With minor modification, the argument used in the proof of Lemma 3.4 applies to conclude that $x(\cdot)$ approaches the set $\{(y, z, \zeta, \lambda)|\ y = 0 = z\}$. In particular, $(y(t), z(t)) \to (0, 0)$ as $t \to \infty$, and so, by the convergent-input, convergent-state property of the ISS system $\Sigma_2 = (g, h, N)$, we may also conclude that $\zeta(t) \to 0$ as $t \to \infty$. □

Example. Linear minimum-phase systems of relative degree two. Let (A, B, C) define a linear, single-input u, single-output y minimum-phase system on $\mathbb{R}^{N+2}$ of relative degree two. Denoting its Markov parameters by $m_k := CA^{k-1}B$, then $m_1 = 0$, $m_2 \ne 0$, and the system has a representation (on $\mathbb{R}^2 \times \mathbb{R}^N$) of the form

$$\text{(3.42)}\qquad \ddot{y} = A_1 y + (m_3/m_2)\dot{y} + A_2\zeta + m_2 u, \quad \dot{\zeta} = A_3 y + A_4\zeta.$$

If we assume that $-m_3/m_2 > \delta > 0$ (that is, the system exhibits natural damping quantified by known δ), then we may identify (3.42) and (3.37) by setting

$$f : (p, y) \mapsto A_1 y,\ g : (y, \zeta) \mapsto A_3 y + A_4 \zeta,\ h : \zeta \mapsto A_2 \zeta, \quad b = m_2,\ d(\cdot) \equiv m_3/m_2.$$

By the relative-degree-two assumption, $b = m_2 \neq 0$ and, by the minimum-phase assumption, $\mathrm{spec}(A_4) \subset \mathbb{C}_-$. Defining $\phi \equiv \psi : |y| \mapsto \frac{1}{2}|y|$, we see that every relative-degree-two, minimum-phase system with $m_3/m_2 < -\delta$ is of class $(\mathcal{N}_{\delta,\phi}, \mathcal{P}_\psi)$ and we recover (modulo notation) the adaptive stabilizer proposed previously in [5]:

$$u(t) = \nu(\eta(t))y(t), \quad \eta(t) = \delta\lambda(t) + y^2(t), \quad \dot{\lambda}(t) = 2y^2(t),\ \lambda(0) = \lambda^0.$$

Remarks. We conclude with some observations on the servomechanism problem for dynamically perturbed planar systems. Akin to the Remarks in section 3.1.4, the adaptive servomechanism of section 3.2.2 can also be modified to incorporate dynamically perturbed systems, when the dynamic perturbations are generated by linear systems $\dot{\zeta} = A\zeta + By$, $w = C\zeta$, $\mathrm{spec}(A) \subset \mathbb{C}_-$. For such perturbations, the (modified) servomechanism assures convergence to zero of the tracking error and its derivative, convergence to a finite limit of the adapting parameter, and boundedness of the evolution $t \mapsto \zeta(t)$ of the perturbing system. For brevity, we omit full details here.

OPTIMAL BOUNDARY CONTROL OF THE STOKES FLUIDS WITH POINT VELOCITY OBSERVATIONS*

PUHONG YOU†, ZHONGHAI DING‡, AND JIANXIN ZHOU†

Abstract. This paper studies constrained linear-quadratic regulator (LQR) problems in distributed boundary control systems governed by the Stokes equation with point velocity observations. Although the objective function is not well defined, we are able to use hydrostatic potential theory and a variational inequality in a Banach space setting to derive a first-order optimality condition and then a characterization formula of the optimal control. Since matrix-valued singularities appear in the optimal control, a singularity decomposition formula is also established, with which the nature of the singularities is clearly exhibited. It is found that in general, the optimal control is not defined at observation points. A necessary and sufficient condition that the optimal control is defined at observation points is then proved.

Key words. LQR, Stokes fluid, distributed boundary control, point observation, hydrostatic potential, boundary integral equation, singularity decomposition

1. Introduction.

In this paper, we are concerned with the problems in boundary control of fluid flows. We consider the following constrained optimal boundary control problems in the systems governed by the Stokes equation with point velocity observations.

Let $\Omega \subset \mathbb{R}^3$ be a bounded domain with smooth boundary Γ, Γ_1 an open subset of Γ and $\Gamma_0 = \Gamma \setminus \Gamma_1$.

$$\text{(LQR)} \qquad \begin{cases} \min\limits_{\vec{u}\in\mathcal{U}} J(\vec{u}) = \sum\limits_{k=1}^{m} \mu_k |\vec{w}(P_k) - \vec{Z}_k|^2 + \gamma \int_{\Gamma_1} |\vec{u}(x)|^2 d\sigma_x, \\ \text{subject to (1.1)} \begin{cases} \nu\Delta\vec{w}(x) - \nabla p(x) = 0 & \text{in } \Omega, \\ \text{div } \vec{w}(x) = 0 & \text{in } \Omega, \\ \vec{\tau}(\vec{w})(x) = \vec{g}(x) & \text{on } \Gamma_0, \\ \vec{\tau}(\vec{w})(x) = \vec{u}(x) & \text{on } \Gamma_1, \end{cases} \end{cases}$$

where

$\vec{w}(x)$ is the velocity vector of the fluid at $x \in \Omega$;

$p(x)$ is the pressure of the fluid at $x \in \Omega$;

$\vec{\tau}(\vec{w})(x)$ is the surface stress of the fluid along Γ defined by

$$\vec{\tau}(\vec{w})(x) = (\tau_1(\vec{w})(x), \tau_2(\vec{w})(x), \tau_3(\vec{w})(x))^T,$$

$$\tau_i(\vec{w})(x) = \sum_{k=1}^{3} \left[\frac{\partial w_i(x)}{\partial x_k} + \frac{\partial w_k(x)}{\partial x_i} \right] n_k(x) - p(x) n_i(x);$$

$\vec{n}(x) = (n_1(x), n_2(x), n_3(x))$ is the unit outnormal vector of Γ at x;
$\vec{g}$ is a given (surface stress) Neumann boundary data (B.D.) on Γ_0;
$\vec{u}(x) \in \mathcal{U}$ is the (surface stress) Neumann boundary control on the surface Γ_1;
$\mathcal{U}$ is the admissible control set to be defined later for well-posedness of the problem and for applications;
$\gamma, \mu_k > 0, 1 \le k \le m$, are given weighting factors;
$P_k \in \Gamma, 1 \le k \le m$, are prescribed "observation points";
$Z_k \in \mathbb{R}^3, 1 \le k \le m$, are prescribed "target values" at P_k;
ν, a positive quantity, is the kinematic viscosity of the fluid. For simplicity, throughout this paper we assume that $\nu = 1$ and the density of the fluid is the constant one.

Let

$$M_0 = \{\vec{a} + \vec{b} \times \vec{x} \mid \vec{a}, \vec{b} \in \mathbb{R}^3\}, \tag{1.2}$$

which is the subspace of the rigid body motions in $\mathbb{R}^3$. Multiplying the Stokes equation by $\vec{a} + \vec{b} \times \vec{x} \in M_0$ and integration by parts yield the compatibility condition of the Stokes system, i.e.,

$$\int_\Gamma \vec{\tau}(\vec{w})(x) \cdot (\vec{a} + \vec{b} \times \vec{x}) d\sigma_x = 0$$

or

$$\vec{\tau}(\vec{w}) \perp M_0.$$

For $q \ge 1$, let A be a subspace of $(L^q(\Gamma))^3$ and denote

$$(L^q(\Gamma))^3_{\perp A} = \{\vec{f} \in (L^q(\Gamma))^3 | \vec{f} \perp A\}.$$

The Stokes equation (1.1) describes the steady state of an incompressible viscous fluid with low velocity in $\mathbb{R}^3$. It is a frequently used model in fluid mechanics and an interesting model in linear elastostatics due to its similarities. During the past years, considerable attention has been given to the problem of active control of fluid flows (see [1], [2], [7], [18], [19], and references therein). This interest is motivated by a number of potential applications, such as control of separation, combustion, fluid-structure interaction, and super maneuverable aircraft. In the study of those control problems and Navier–Stokes equations, the Stokes equations, which describe the slow steady flow of a viscous fluid, play an important role because of the needs in stability analysis, iterative computation of numerical solutions, boundary control, etc. The theoretical and numerical discussion of the Stokes equations on smooth or Lipschitz domains can be found from [14], [16], [17], [22], [25], [26], [27].

Our objective in this paper is to find the optimal surface stress $\vec{u}(x)$ on Γ_1, which yields a desired velocity distribution $\vec{w}(x)$, such that (s.t.) at observation points $P_k, 1 \le k \le m$, the observation values $\vec{w}(P_k)$ are as close as possible to the

target values Z_k with a least possible control cost $\int_{\Gamma_1} |\vec{u}(x)|^2 d\sigma_x$, which arise from the contemporary fluid control problems in the fluid mechanics.

Notice that point observations are assumed in the problem setting, because they are much easier to be realized in applications than distributed observations. They can be used in modeling contemporary "smart sensors."

Sensors can be used in boundary control systems (BCS) governed by partial differential equations (PDE) to provide information on the state as a feedback to the systems. According to the space-measure of the data that sensors can detect, sensors can be divided into two types, point sensors and distributed sensors. Point sensors are much more realistic and easier to design than distributed sensors. In contemporary "smart materials," piezoelectric or fiber-optic sensors (called *smart sensors*) can be embedded to measure deformation, temperature, strain, pressure, etc. Each smart sensor detects only the *average* of the data in between the sensor, and its size can be less than 10^{-6}m [29], [30], [24]. So in any sense, they should be treated as point sensors. As a matter of fact, so far *distributed sensors* have not been used in any real applications, to the best of our knowledge. However, once point observations on the boundary are used in a BCS, singularities will appear, and very often the system becomes ill-posed. Mathematically and numerically, it becomes very tough to handle. On the other hand, when point observations are used in the problem setting, the state variable has to be continuous, so the regularity of the state variable stronger than the one in the case of distributed observations is required. The fact is that in the literature of related optimal control theory, starting from the classic book [23] by J. L. Lions until recent papers [3], [4] by E. Casas and others, distributed observations are always assumed and the optimal controls are characterized by an adjoint system. The system is then solved numerically, typically by a finite-element method, which cannot efficiently tackle the singularity in the optimal control along the boundary.

On the other hand, since it is important in the optimal control theory to obtain a state-feedback characterization of the optimal control, with the bound constraints in the system, the Lagrange–Kuhn–Tucker approach is not desirable because theoretically it cannot provide us with a state-feedback characterization of the optimal control, which is important in our regularity/singularity analysis of the optimal control, and numerically it leads to a numerical algorithm to solve an optimization problem with a huge number of inequality constraints. A refinement of the boundary will double the number of the inequality constraints, so the numerical algorithm will be sensitive to the partition number of the boundary. Since the BCS is governed by a PDE system in $\mathbb{R}^3$, the partition number of the boundary can be very large and any numerical algorithm sensitive to the partition number of the boundary may fail to carry out numerical computation or provide reliable numerical solutions.

Recently in the study of a linear quadratic BCS governed by the Laplace equation with point observations, the potential theory and boundary integral equations (BIE) have been applied in [20], [10], [11], [12] to derive a characterization of the optimal control in terms of the optimal state directly and therefore bypass the adjoint system. This approach shows certain important advantages over others. It provides rather explicit information on the control and the state, and it is amenable to direct numerical computation through a boundary element method (BEM), which can efficiently tackle the singularities in the optimal control along the boundary.

In [10], [11], [9] several regularity results are obtained. The optimal control is characterized directly in terms of the optimal state. The exact nature of the singularities in the optimal control is exhibited through a decomposition formula. Based on

the characterization formula, numerical algorithms are also developed to approximate the optimal control. Their insensitivity to the discretization of the boundary and fast uniform convergences are mathematically verified in [12], [31].

The case with the Stokes system is much more complicated than the one with the Laplace equation due to the fact that the fundamental solution of the Stokes system is matrix-valued and has rougher singular behaviors. In this paper, we assume that the control is active on a part of the surface and the control variable is bounded by two vector-valued functions. A Banach space setting has been used in our approach. We first prove a necessary and sufficient condition for a variational inequality problem (VIP) which leads to a first-order optimality condition of our original optimization problem. A characterization of the optimal control and its singularity decomposition formula are then established. Our approach can be easily adopted to handle other cases, and it shows the essence of the characterization of the optimal control, through which gradient-related numerical algorithms can be designed to approximate the optimal control.

The organization of this paper is as follows. In the rest of section 1, we introduce some basic definitions and known regularity results that are required in the later development. In section 2, we first prove an existence theorem for an orthogonal projection. Next we derive a characterization result for a variational inequality which serves as a first-order optimality condition to our LQR problem. Then a state-feedback characterization of the optimal control is established. Section 3 will be devoted to study regularity/singularity of the optimal control. Since the optimal control contains a singular term, we first derive a singularity decomposition formula for the optimal control, with which we find that in general the optimal control is not defined at observation points. A necessary and sufficient condition that the optimal control is defined at observation points is then established. Some other regularities of the optimal control will also be studied in this section. Based on our characterization formulas, in a subsequent paper, we design a conditioned gradient projection method (CGPM) to approximate the optimal control. Numerical analysis for its (uniform) convergence and (uniform) convergence rate are presented there. We show that CGPM converges uniformly subexponentially, i.e., faster than any integer power of $\frac{1}{n}$. Therefore CGPM is insensitive to discretization of the boundary. The insensitivity of our numerical algorithm to discretization of boundary is a significant advantage over other numerical algorithms. Since the fundamental solution of the Stokes system is matrix valued with a very rough singular behavior, numerical analysis is also much more complicated than the case with scalar-valued fundamental solution, e.g., the Laplacian equation.

Let us now briefly recall some hydrostatic potential theory, BEM, and some known regularity results. Throughout this paper, for a sequence of elements in $\mathbb{R}^n$, we use a superscript to denote sequential index and a subscript to denote components, e.g., $\{x^k\} \subset \mathbb{R}^n$ and $x^k = (x_1^k, \ldots, x_n^k)$. We may also use $\vec{x}^k$ to emphasize that x^k is a vector. We may write $\vec{w}(x, \vec{u})$ to indicate that the velocity $\vec{w}$ depends also on $\vec{u}$. Unless stated otherwise, we assume $p > 2, q > 1$ with $\frac{1}{p} + \frac{1}{q} = 1$, $|\cdot|$ is the Euclidean norm in $\mathbb{R}^n$, and $\|\cdot\|$ is the norm in $(L^h(\Gamma))^n (h \geq 1)$.

Let $\{E(x,\xi), \vec{e}(x,\xi)\} = \{[E_{ij}(x,\xi)]_{3\times 3}, [e_i(x,\xi)]_{3\times 1}\}$ be the fundamental solution of the Stokes systems, i.e.,

$$\begin{cases} \Delta_x E(x,\xi) - \nabla_x \vec{e}(x,\xi) = -\delta(x-\xi) I_3, \\ \qquad\qquad \operatorname{div}_x E(x,\xi) = 0, \end{cases} \tag{1.3}$$

where $\delta(x-\xi)$ is the unit Dirac delta function at $x=\xi$ and I_3 is the 3×3 identity matrix. It is known [22] that

$$E_{ij}(x,\xi)=\frac{1}{8\pi}\left(\frac{\delta_{ij}}{|x-\xi|}+\frac{(x_i-\xi_i)(x_j-\xi_j)}{|x-\xi|^3}\right),\quad 1\le i,j\le 3,$$
$$e_i(x,\xi)=\frac{1}{4\pi}\frac{x_i-\xi_i}{|x-\xi|^3},$$

where $\delta_{i,j}$ is the Kronecker symbol.

Remark 1.1. The significant difference between the case with point observations and the case with distributed observations is as follows. For a given vector $\vec{V}\in\mathbb{R}^3$ the function

$$x\mapsto\sum_{k=1}^{m}\mu_k E(P_k,x)\vec{V} \tag{1.4}$$

has a singularity of order $O(\frac{1}{|x-P_k|})$ at $x=P_k$; however, it may oscillate between $-\infty$ and $+\infty$ as $x\to P_k$, so it is very tough to deal with, whereas the function

$$x\mapsto\int_{\Gamma_0}E(\xi,x)\vec{V}d\sigma_\xi \tag{1.5}$$

is well defined and continuous.

On the other hand, if $E(P_k,x)$ in (1.4) and (1.5) is replaced by the fundamental solution of the Laplace equation, in this case, $E(P_k,x)$ becomes scalar-valued, then (1.4) has the same order $O(\frac{1}{|x-P_k|})$ of singularity at $x=P_k$, but the limit as $x\to P_k$ exists (including $-\infty$ or $+\infty$). So the singularity can be easily handled. □

It is then known that the solution $(\vec{w},p)$ of the Stokes equation (1.1) has a simple-layer representation

$$\vec{w}(x)=\int_\Gamma E(x,\xi)\vec{\eta}(\xi)d\sigma_\xi+\vec{a}+\vec{b}\times\vec{x}\quad\forall\, x\in\overline{\Omega}, \tag{1.6}$$

$$p(x)=\int_\Gamma\vec{e}(x,\xi)\cdot\vec{\eta}(\xi)d\sigma_\xi+a\quad\forall\, x\in\Omega \tag{1.7}$$

for some constants $\vec{a},\vec{b}\in\mathbb{R}^3$ and $a\in\mathbb{R}$. $\vec{\eta}$ is called the layer density and $\vec{a}+\vec{b}\times\vec{x}$ represents a rigid body motion. By the jump property of the layer potentials, we obtain the BIE

$$\vec{\tau}(\vec{w})(x)=\frac{1}{2}\vec{\eta}(x)+\text{p.v.}\int_\Gamma T(x,\xi)\vec{\eta}(\xi)d\sigma_\xi\quad\forall\, x\in\Gamma, \tag{1.8}$$

where p.v. stands for principle value and

$$T(x,\xi)=[\vec{\tau}_x(E_1)(x,\xi),\vec{\tau}_x(E_2)(x,\xi),\vec{\tau}_x(E_3)(x,\xi)]=[T_{ij}(x,\xi)]_{3\times 3},$$
$$T_{ij}(x,\xi)=-\frac{3}{4\pi}\frac{(x_i-\xi_i)(x_j-\xi_j)}{|x-\xi|^5}(x-\xi)\cdot\vec{n}_x.$$

With a given Neumann B.D., the layer density $\vec{\eta}$ can be solved from the above BIE (1.8). Once the layer density is known, the solution $(\vec{w}(x),p(x))$ can be computed from (1.6) and (1.7). The velocity solution $\vec{w}(x)$ is unique only up to a rigid body motion, and the pressure solution $p(x)$ is unique up to a constant.

In BEM, the boundary $\Gamma = \Gamma_1 \bigcup \Gamma_0$ is divided into N elements with nodal points x_i. Assume that the layer density $\vec{\eta}(x)$ is piecewise smooth, e.g., piecewise constant, piecewise linear, etc. Then the BIE (1.8) becomes a linear algebraic system. This system can be solved for $\vec{\eta}(x_i)$ and then $(\vec{w}(x), p(x))$ can be computed from a discretized version of (1.6) and (1.7) for any $x \in \overline{\Omega}$.

For each $\vec{f} \in (L^2(\Gamma))^3$ and $x \in \mathbb{R}^3$, we define the simple layer potential of velocity $\mathcal{S}_v(\vec{f})$ by

$$\mathcal{S}_v(\vec{f})(x) = \int_\Gamma E(x,\xi)\vec{f}(\xi)d\sigma_\xi.$$

For each $\vec{f} \in (L^2(\Gamma))^3$ and $x \in \Gamma$, we define the boundary operators $\mathcal{K}$ and $\mathcal{K}^*$ by

$$\mathcal{K}(\vec{f})(x) = \text{p.v.} \int_\Gamma Q(x,\xi)\vec{f}(\xi)d\sigma_\xi,$$
$$\mathcal{K}^*(\vec{f})(x) = \text{p.v.} \int_\Gamma T(x,\xi)\vec{f}(\xi)d\sigma_\xi,$$

where

$$Q(x,\xi) = [\vec{\tau}_\xi(E_1)(x,\xi), \vec{\tau}_\xi(E_2)(x,\xi), \vec{\tau}_\xi(E_3)(x,\xi)] = [Q_{ij}(x,\xi)]_{3\times 3},$$
$$Q_{ij}(x,\xi) = \frac{3}{4\pi}\frac{(x_i-\xi_i)(x_j-\xi_j)}{|x-\xi|^5}(x-\xi)\cdot\vec{n}_\xi.$$

Next we collect some regularity results on $\mathcal{S}_v, \mathcal{K}$, and $\mathcal{K}^*$ into a lemma. Let

$$N = \ker\left(\frac{1}{2}I + \mathcal{K}^*\right),$$

which represents the set of all layer densities corresponding to the zero Neumann B.D., with which the Stokes system has only a rigid body motion. Hence we have

$$M_0 = \mathcal{S}_v(N) = \ker\left(\frac{1}{2}I + \mathcal{K}\right). \tag{1.9}$$

LEMMA 1.1. *Let $\Omega \subset \mathbb{R}^3$ be a bounded, simply connected domain with smooth boundary Γ.*

(a) $\mathcal{S}_v : (L^p(\Gamma))^3 \mapsto (C^{0,\alpha}(\mathbb{R}^3))^3$ *is a bounded linear operator for $p > 2$ and $0 < \alpha < \frac{p-2}{p}$.*

(b) *For any $1 \le p < +\infty$, $\mathcal{K}$ ($\mathcal{K}^*$) : $(L^p(\Gamma))^3 \mapsto (L^p(\Gamma))^3$ is a bounded linear operator and $\mathcal{K}$ ($\mathcal{K}^*$) is the adjoint of $\mathcal{K}^*$ ($\mathcal{K}$).*

(c) *For $p > 2$ and $0 < \alpha < \frac{p-2}{p}$, $\mathcal{K} : (L^p(\Gamma))^3 \mapsto (C^{0,\alpha}(\Gamma))^3$ is a bounded linear operator.*

(d) *For $1 < p < \infty$*

(1) $(\frac{1}{2}I + \mathcal{K}^*) : (L^p(\Gamma))^3_{\perp M_0} \mapsto (L^p(\Gamma))^3_{\perp M_0}$ *is invertible,*

(2) $(\frac{1}{2}I + \mathcal{K}) : (L^p(\Gamma))^3_{\perp M_0} \mapsto (L^p(\Gamma))^3_{\perp N}$ *is invertible.*

(e) *For $1 < q < 2$ and $s < \frac{2q}{2-q}$, $\mathcal{K} : (L^q(\Gamma))^3 \mapsto (L^s(\Gamma))^3$ is a bounded linear operator. Therefore $\mathcal{K}\circ\mathcal{K} : (L^q(\Gamma))^3 \mapsto (C^{0,\alpha}(\Gamma))^3$ for every $q > 1$ and $0 < \alpha < \frac{q-1}{q}$;*

(f) $(\frac{1}{2}I + \mathcal{K}) : (C(\Gamma))^3_{\perp M_0} \mapsto (C(\Gamma))^3_{\perp N}$ *is invertible.*

Proof. (a)–(d) can be found from [5], [6], [8], [13], [14], [22], [28].

To prove (e), since $\Gamma \subset \mathbb{R}^3$ is a compact set, it suffices to prove (e) for $q < s < \frac{2q}{2-q}$. Then we have $\frac{1}{q} > \frac{1}{s} > \frac{1}{q} - \frac{1}{2} = \frac{1}{2} + \frac{1}{q} - 1$. There exists an $\varepsilon \in (0,1)$, s.t. $\frac{1}{s} = \frac{1}{2-\varepsilon} + \frac{1}{q} - 1$. Let $r = 2-\varepsilon,\ \alpha = \frac{r'}{s'},\ \beta = \frac{q'}{s'}$, where r', q', s' are the conjugates of r, q, s, respectively. It can be verified that $1 < r < 2$ and

$$\frac{1}{\alpha} + \frac{1}{\beta} = 1, \quad \left(1 - \frac{q}{s}\right) s' = \frac{q}{\alpha}, \quad \left(1 - \frac{r}{s}\right) s' = \frac{r}{\beta}, \quad \frac{1}{\alpha} \cdot \frac{s}{s'} = \frac{s-q}{q}, \quad \frac{1}{\beta} \cdot \frac{s}{s'} = \frac{s-r}{r}.$$

Note

$$|Q_{ij}(x,\xi)| \le \frac{C}{|x-\xi|}, \quad 1 \le i, j \le 3, \tag{1.10}$$

and

$$\left(\int_\Gamma \frac{1}{|x-\xi|^r} \, d\sigma_\xi \right) < M < \infty \quad \forall x \in \Gamma,$$

where M is a constant independent of $x \in \Gamma$. Let $h(x) = \mathcal{K}(\vec{f})(x)$. Applying Hölder's inequality twice, we get

$$\begin{aligned}
|h(x)|^s &\le C^s \left(\int_\Gamma \frac{1}{|x-\xi|} |\vec{f}(\xi)| \, d\sigma_\xi \right)^s \\
&\le C^s \left(\int_\Gamma \left(\frac{1}{|x-\xi|} \right)^{\frac{r}{s}} |\vec{f}(\xi)|^{\frac{q}{s}} \left(\frac{1}{|x-\xi|} \right)^{1-\frac{r}{s}} |\vec{f}(\xi)|^{1-\frac{q}{s}} \, d\sigma_\xi \right)^s \\
&\le C^s \left(\int_\Gamma \frac{1}{|x-\xi|^r} |\vec{f}(\xi)|^q \, d\sigma_\xi \right) \left(\int_\Gamma \left(\frac{1}{|x-\xi|} \right)^{\frac{r}{\beta}} |\vec{f}(\xi)|^{\frac{q}{\alpha}} \, d\sigma_\xi \right)^{\frac{s}{s'}} \\
&\le C^s \left(\int_\Gamma \frac{1}{|x-\xi|^r} |\vec{f}(\xi)|^q \, d\sigma_\xi \right) \left(\int_\Gamma \frac{1}{|x-\xi|^r} \, d\sigma_\xi \right)^{\frac{s-r}{r}} \left(\int_\Gamma |\vec{f}(\xi)|^q \, d\sigma_\xi \right)^{\frac{s-q}{q}} \\
&\le C^s M^{s-r} \left(\int_\Gamma \frac{1}{|x-\xi|^r} |\vec{f}(\xi)|^q \, d\sigma_\xi \right) \cdot \|\vec{f}\|_q^{s-q}.
\end{aligned}$$

Thus

$$\begin{aligned}
\|h\|_{L^s(\Gamma)} &= \left(\int_\Gamma |h(x)|^s \, d\sigma_x \right)^{\frac{1}{s}} \\
&\le C M^{\frac{s-r}{s}} \left(\int_\Gamma \int_\Gamma \frac{1}{|x-\xi|^r} |\vec{f}(\xi)|^q \, d\sigma_\xi d\sigma_x \right)^{\frac{1}{s}} \cdot \|\vec{f}\|_q^{\frac{s-q}{s}} \\
&\le C M \|\vec{f}\|_q.
\end{aligned}$$

This proves the first part of (e). The second part follows from (c).

To prove (f), by (1.10), $Q_{ij}(x,\xi)$ is weakly singular for $1 \le i, j \le 3$. Thus $\mathcal{K}$ is an integral operator with a weakly singular kernel. By Theorem 2.22 in [21], $\mathcal{K}$ is a compact operator from $(C(\Gamma))^3$ to $(C(\Gamma))^3$. The rest follows from the Fredholm alternative (see [21, p. 44]. □

For a given Neumann B.D. $\vec{g} \in (L^p(\Gamma_0))^3$, we extend our control bound constraints $Bl, Bu \in (L^p(\Gamma_1))^3$ to the entire boundary Γ by

$$Bl(x) = \begin{cases} Bl(x), & x \in \Gamma_1, \\ \vec{g}(x), & x \in \Gamma_0, \end{cases} \quad \text{and} \quad Bu(x) = \begin{cases} Bu(x), & x \in \Gamma_1, \\ \vec{g}(x), & x \in \Gamma_0, \end{cases}$$

with

$$Bl(x) \le -\vec{B} < \vec{B} \le Bu(x) \quad \forall\, x \in \Gamma_1,$$

where $\vec{B} > 0$ is a constant vector depending on $\vec{g}$ and will be specified later. Define the feasible control set

$$\mathcal{U} = \left\{ \vec{u} \in (L^p(\Gamma))^3 \mid Bl(x) \le \vec{u}(x) \le Bu(x)\ \forall\, x \in \Gamma \text{ and } \vec{u} \perp M_0 \right\}, \tag{1.11}$$

where $\vec{u} \perp M_0$ stands for the compatibility condition of the Neumann B.D. in the Stokes system (1.1). It is clear that $\mathcal{U}$ is a closed bounded convex set in $(L^p(\Gamma))^3$.

According to Lemma 1.1 (a), for each given Neumann B.D. $\vec{u} \in \mathcal{U}$, the Stokes system (1.1) has a solution $\vec{w}$ in $(C(\overline{\Omega}))^3$ unique up to a vector $\vec{a} + \vec{b} \times \vec{x} \in M_0$, i.e.,

$$\vec{w}(x, \vec{u}) = \mathcal{S}_v \circ \left(\frac{1}{2} I + \mathcal{K}^* \right)^{-1} (\vec{u})(x) + \vec{a} + \vec{b} \times \vec{x}, \quad x \in \Omega, \tag{1.12}$$

$$= \vec{w}_0(x, \vec{u}) + \vec{a} + \vec{b} \times \vec{x}, \quad x \in \Omega, \tag{1.13}$$

where

$$\vec{w}_0(x, \vec{u}) = \mathcal{S}_v \circ \left(\frac{1}{2} I + \mathcal{K}^* \right)^{-1} (\vec{u})(x). \tag{1.14}$$

That is, for each given $\vec{u}$, the velocity state variable $\vec{w}$ is multiple valued, so the objective function $J(\vec{u})$ is not well defined. However, among all these velocity solutions, there is a unique solution $\vec{w}$ s.t.

$$\sum_{k=1}^{m} \mu_k |\vec{w}(P_k) - \vec{Z}_k|^2 = \min_{\vec{h} \in M_0} \sum_{k=1}^{m} \mu_k |\vec{w}_0(P_k) + \vec{h}(P_k) - \vec{Z}_k|^2. \tag{1.15}$$

A direct calculation yields that $\vec{w}(x) = \vec{w}_0(x) + \vec{a} + \vec{b} \times \vec{x}$ must satisfy

$$\begin{cases} \displaystyle\sum_{k=1}^{m} \mu_k (\vec{w}_0(P_k) + \vec{a} + \vec{b} \times \vec{P}_k - \vec{Z}_k) = 0, \\ \displaystyle\sum_{k=1}^{m} \mu_k (\vec{w}_0(P_k) + \vec{a} + \vec{b} \times \vec{P}_k - \vec{Z}_k) \times \vec{P}_k = 0. \end{cases} \tag{1.16}$$

Since such a $\vec{w}$ is unique and continuous, the point observations $\vec{w}(P_k)$ in our LQR problem setting make sense and the LQR problem is well posed.

From (1.14) and Lemma 1.1, we know

$$|\vec{w}(x, \vec{u}) - \vec{a}_u - \vec{b}_u \times \vec{x}| = |\vec{w}_0(x, \vec{u})| \le C \|\vec{u}\|_{L^p(\Gamma))^3}, \tag{1.17}$$

where C is a constant depending only on Γ. Let us observe (1.16). If we notice that $\vec{w}_0(x, \vec{u})$ is linear in $\vec{u}$, then we have the following lemma.

LEMMA 1.2. *Let $\vec{a}_0, \vec{b}_0 \in \mathbb{R}^3$ be the unique solution to*

$$\begin{cases} \vec{a}_0 \left(\displaystyle\sum_{k=1}^{m} \mu_k \right) + \vec{b}_0 \times \left(\displaystyle\sum_{k=1}^{n} \mu_k \vec{P}_k \right) = \displaystyle\sum_{k=1}^{m} \mu_k \vec{Z}_k \\ \vec{a}_0 \times \left(\displaystyle\sum_{k=1}^{m} \mu_k \vec{P}_k \right) + \displaystyle\sum_{k=1}^{m} \mu_k (\vec{b}_0 \times \vec{P}_k) \times \vec{P}_k = \displaystyle\sum_{k=1}^{m} \mu_k \vec{Z}_k \times \vec{P}_k. \end{cases}$$

Then for $\vec{u}_1, \vec{u}_2 \in \mathcal{U}$ *and* $t_1, t_2 \in \mathbb{R}$,

$$\vec{w}(x, t_1\vec{u}_1 + t_2\vec{u}_2) = t_1\vec{w}(x, \vec{u}_1) + t_2\vec{w}(x, \vec{u}_2) + (1 - t_1 - t_2)(\vec{a}_0 + \vec{b}_0 \times \vec{x}) \tag{1.18}$$

and

$$|\vec{w}(x, \vec{u}_1) - \vec{w}(x, \vec{u}_2)| \le C\|\vec{u}_1 - \vec{u}_2\|_{(L^p(\Gamma))^3}, \tag{1.19}$$

where C *is a constant depending only on* Γ.

2. Characterization of the optimal control. We establish an optimality condition of the LQR problem through a VIP. The characterization of the optimal control is then derived from the optimality condition.

In optimal control theory it is important to obtain a state-feedback characterization of the optimal control; i.e., the optimal control is stated as an explicit function of the optimal state. So the optimal control can be determined by a physical measurement of the optimal state. Our efforts are devoted to deriving such a result.

For each $\vec{f} \in (L^1(\Gamma))^3$, we define the vector-valued truncation function

$$\left[\vec{f}\right]_{Bl}^{Bu} = \left\{ [f_i(x)]_{Bl_i(x)}^{Bu_i(x)} = \left\{ \begin{array}{lll} Bu_i(x) & \text{if} & f_i(x) \ge Bu_i(x) \\ f_i(x) & \text{if} & Bl_i(x) < f_i(x) < Bu_i(x) \\ Bl_i(x) & \text{if} & f_i(x) \le Bl_i(x) \end{array} \right\} \right.$$

Let $\langle \cdot, \cdot \rangle$ be the pairing on $((L^q(\Gamma))^3, (L^p(\Gamma))^3)$. Since our feasible control set $\mathcal{U}$ defined in (1.11) is a convex closed bounded set in $(L^p(\Gamma))^3$, it is known that $\vec{u}^*$ is an optimal control of the LQR problem if

$$\langle \nabla J(\vec{u}^*), \vec{u} - \vec{u}^* \rangle \ge 0 \quad \forall\, \vec{u} \in \mathcal{U}. \tag{2.1}$$

For any $\alpha > 0$, (2.1) is equivalent to

$$\langle \vec{u}^* - (\vec{u}^* - \alpha \nabla J(\vec{u}^*)), \vec{u} - \vec{u}^* \rangle \ge 0 \quad \forall\, \vec{u} \in \mathcal{U}. \tag{2.2}$$

To derive an optimality condition, we need to find a characterization of a solution to the above variational inequality.

THEOREM 2.1. *For each* $f \in (L^q(\Gamma))^3$, u^f *is a solution to the variational inequality*

$$\langle u^f - f, u - u^f \rangle \ge 0 \quad \forall\, u \in \mathcal{U} \tag{VIP}$$

if and only if

$$u^f = [f + z^f]_{Bl}^{Bu}, \tag{2.3}$$

where $z^f \in M_0$ *such that* $[f + z^f]_{Bl}^{Bu} \perp M_0$ *(refer to Theorem* 2.2 *for the existence of such a* z^f*).*

Moreover, (2.3) *is well defined in the sense that if* z^1 *and* z^2 *are two vectors in* M_0 *s.t.*

$$[f + z^1]_{Bl}^{Bu} \perp M_0 \quad \textit{and} \quad [f + z^2]_{Bl}^{Bu} \perp M_0;$$

then

$$[f(x) + z^1(x)]_{Bl}^{Bu} = [f(x) + z^2(x)]_{Bl}^{Bu} \quad \textit{almost everywhere (a.e.)}\ x \in \Gamma. \tag{2.4}$$

Proof. By Theorem 2.2, there exists $z^f \in M_0$ s.t. $[f+z^f]_{Bl}^{Bu} \perp M_0$. Let $u^f = [f+z^f]_{Bl}^{Bu}$. We have for each $u \in \mathcal{U}$,

$$\begin{aligned}
&\langle u^f - f, u - u^f\rangle \\
&= \langle u^f - (f+z^f), u - u^f\rangle \\
&= \sum_{i=1}^{3} \int_\Gamma \left\{[f_i(x) + z_i^f(x)]_{Bl_i}^{Bu_i} - (f_i(x) + z_i^f(x))\right\} \left\{u_i(x) - [f_i(x) + z_i^f(x)]_{Bl_i}^{Bu_i}\right\} d\sigma_x \\
&\geq 0,
\end{aligned}$$

where the last inequality holds since each integrand, the product of two terms, is nonnegative.

Next we assume that u^f is a solution to the VIP; i.e.,

$$\langle u^f - f, u - u^f\rangle \geq 0 \quad \forall\, u \in \mathcal{U}.$$

Taking $u = [f+z^f]_{Bl}^{Bu}$, which is in $\mathcal{U}$, we obtain

$$\langle u^f - f, [f+z^f]_{Bl}^{Bu} - u^f\rangle \geq 0. \tag{2.5}$$

By the first part, we have

$$\langle [f+z^f]_{Bl}^{Bu} - f, u - [f+z^f]_{Bl}^{Bu}\rangle \geq 0 \quad \forall\, u \in \mathcal{U}. \tag{2.6}$$

Taking $u = u^f$ in (2.6) yields

$$\langle [f+z^f]_{Bl}^{Bu} - f, u^f - [f+z^f]_{Bl}^{Bu}\rangle \geq 0. \tag{2.7}$$

Combining (2.5) with (2.7) gives us

$$\langle u^f - [f+z^f]_{Bl}^{Bu}, u^f - [f+z^f]_{Bl}^{Bu}\rangle \leq 0. \tag{2.8}$$

Thus

$$u^f = [f+z^f]_{Bl}^{Bu}.$$

The proof of the second part of the theorem follows directly from taking $z^f = z^1$ and $u^f = [f+z^2]_{Bl}^{Bu}$ in (2.8). ∎

In a Hilbert space setting, the above theorem is called a characterization of projection. When $\mathcal{U}$ is a convex closed subset of a Hilbert space H, for each $f \in H$, u_f is a solution to the VIP if and only if

$$u_f = P_{\mathcal{U}}(f);$$

i.e., u_f is the projection of f on $\mathcal{U}$. This characterization is used to derive a first-order optimality condition for convex inequality constrained optimal control problems. However, this result is not valid in general Banach spaces. Instead we prove a characterization of truncation, which is a special case of a projection. Note that in a Hilbert space setting, a projection maps a point in the space into a subset of the same space. However, our truncation is a projection that maps a point in $(L^q(\Gamma))^3$ into a subset of $(L^p(\Gamma))^3 (p > 2, \frac{1}{p} + \frac{1}{q} = 1)$. It crosses spaces. This characterization gives a connection between the truncation and the solution to VIP, in our case, an optimality condition

in terms of the gradient. That is, by our characterization of truncation, $\vec{u}^* \in \mathcal{U}$ is a solution to the VIP (2.2) if and only if

$$\vec{u}^* = [\vec{u}^* - \alpha \nabla J(\vec{u}^*) + \vec{z}^*]_{Bl}^{Bu}, \tag{2.9}$$

where $\vec{z}^* \in M_0$ is defined in Theorem 2.2 s.t.

$$[\vec{u}^* - \alpha \nabla J(\vec{u}^*) + \vec{z}^*]_{Bl}^{Bu} \perp M_0.$$

To prove the existence of a rigid body motion z^f in (2.3), we establish the following existence theorem for an orthogonal projection, which is given in a very general case and plays a key role in establishing the optimality condition. It can be used to solve LQR problems governed by PDEs, e.g., the Laplacian, the Stokes, the linear elastostatics, etc., where the PDE has multiple solutions for given Neumann-type boundary data satisfying a certain orthogonality condition.

THEOREM 2.2. *Let Γ be a bounded closed set in $\mathbb{R}^n$ and $\Gamma_0 \subset \Gamma$ be a subset s.t. meas $(\Gamma_1) > 0$, where $\Gamma_1 = \Gamma \setminus \Gamma_0$. Let $\vec{g} \in (L^p(\Gamma_0))^n$ and $\vec{B}l, \vec{B}u \in (L^p(\Gamma))^n$ $(p \geq 2)$ be given s.t.*

$$\vec{B}l(x) < -\vec{B} < \vec{B} < \vec{B}u(x) \quad (a.e.) \quad \forall\, x \in \Gamma_1,$$

where $\vec{B} = (B, \ldots, B)$ is given by (2.17) and

$$\vec{B}l(x) = \vec{g}(x) = \vec{B}u(x) \quad \forall\, x \in \Gamma_0.$$

Assume that M_0 is an m-dimensional subspace in $(L^q(\Gamma))^n$ $(q \leq 2, \frac{1}{p} + \frac{1}{q} = 1)$ and $M_1 = \{\vec{z}|_{\Gamma_1} \mid \vec{z} \in M_0\}$. Then a necessary and sufficient condition that for each $\vec{f} \in (L^1(\Gamma))^n$ there exists $\vec{z}_f \in M_0$ s.t.

$$\left[\vec{f}(x) + \vec{z}_f(x)\right]_{Bl}^{Bu} \perp M_0 \tag{2.10}$$

is that

$$\vec{g} \perp M_1^c = \{\vec{z}|_{\Gamma_0} \mid \vec{z} \in M_0, \vec{z}|_{\Gamma_1} = 0\}. \tag{2.11}$$

Moreover the set of all solutions $\vec{z}_f$ in (2.10) is locally uniformly bounded in the sense that for each given $\vec{f} \in (L^1(\Gamma))^n$ there exist $r_0 > 0$ and $b > 0$ s.t. for any $\vec{h} \in (L^1(\Gamma))^n$ with $\|\vec{f} - \vec{h}\| \leq r_0$ and for any $\vec{z}_h \in M_0$ with

$$\left[\vec{h}(x) + \vec{z}_h(x)\right]_{Bl}^{Bu} \perp M_0$$

we have

$$\|\vec{z}_h\| \leq b. \tag{2.12}$$

Proof. Case 1. $\dim(M_1) = \dim(M_0)$, i.e., $M_1^c = \{0\}$. Let $y = (\vec{y}^1, \ldots, \vec{y}^m)$ be an orthonormal basis in M_1 and M_0. To prove the first part of the theorem, we have to show that for each $\vec{f} \in (L^1(\Gamma))^n$, there exists $C^f = (c_1^f, \ldots, c_m^f) \in \mathbb{R}^m$ s.t.

$$\left\langle \left[\vec{f}(x) + \sum_{i=1}^{m} c_i^f \vec{y}^i(x)\right]_{Bl}^{Bu}, \vec{y}^j \right\rangle_{\Gamma} = 0 \quad \forall\, j = 1, \ldots, m.$$

For each $\vec{f} \in (L^1(\Gamma))^n$, we define a map $T_f : \mathbb{R}^m \mapsto \mathbb{R}^m$, for $C = (c_1, \ldots, c_m) \in \mathbb{R}^m$, by

$$T_f(C) = \left\{ \left\langle \left[\vec{f}(x) + \sum_{i=1}^{m} c_i \vec{y}^i(x) \right]_{Bl}^{Bu}, \vec{y}^j \right\rangle_{\Gamma} \right\}_{j=1,\cdots,m}. \tag{2.13}$$

Then to prove the first part, it suffices to show that for each $\vec{f} \in (L^1(\Gamma))^n$, there exists $C_f \in \mathbb{R}^m$ s.t.

$$T_f(C_f) = 0.$$

It is easy to check that for any $\vec{f}, \vec{h} \in (L^1(\Gamma))^n$ and $C_1, C_2 \in \mathbb{R}^m$, there exist two constants γ_1, γ_2 depending only on Γ and the basis y s.t.

$$|T_f(C_1) - T_h(C_2)| \le \gamma_1 |\vec{f} - \vec{h}|_{L^1} + \gamma_2 |C_1 - C_2|. \tag{2.14}$$

So $C \mapsto T_f(C)$ is a bounded (depends on Bl and Bu) Lipschitz continuous map. To show that T_f has a zero, we prove that there exists a constant $R > 0$ s.t. when $C \in \mathbb{R}^m$ and $|C| > R$, we have

$$T_f(C) \cdot C > 0. \tag{2.15}$$

Once (2.15) is verified, we have

$$\begin{aligned} |C - T_f(C)|^2 &= |C|^2 - 2T_f(C) \cdot C + |T_f(C)|^2 \\ &< |C|^2 + |T_f(C)|^2 \qquad\qquad \forall\, C \in \mathbb{R}^m,\ |C| > R. \end{aligned}$$

By Altman's fixed-point theorem [15], the map $C \mapsto C - T_f(C)$ has a fixed point $C^f \in B_R$ (B_R is the ball of radius R at the origin), i.e.,

$$T_f(C^f) = 0.$$

So it remains to verify (2.15). Define

$$D = \left\{ C = (c_1, \ldots, c_m) \in \mathbb{R}^m \mid \sum_{i=1}^{m} c_i^2 = 1 \right\}.$$

It suffices to show that there exists $R > 0$ s.t. for $t > R$,

$$T_f(tC) \cdot C > 0 \quad \forall\, C \in D.$$

In the following, we prove that for each given $\vec{f} \in (L^1(\Gamma))^n$ and $C \in D$, there exist $r_0 > 0$ and $R > 0$ s.t. when $t > R$, for any $\vec{h} \in (L^1(\Gamma))^n$ with $\|\vec{f} - \vec{h}\|_{L^1} \le r_0$, we have

$$T_h(tC) \cdot C > 0 \quad \forall\, C \in D.$$

So the second part of the theorem also follows. For each $C \in D$, we denote

$$\vec{y}^C(x) = \sum_{i=1}^{m} c_i \vec{y}^i(x).$$

It is obvious that

$$\int_{\Gamma_1} |\vec{y}^C(x)| d\sigma_x$$

is continuous in C and positive on the compact set D. Hence

$$m_y = \min_{C\in D} \left\{ \int_{\Gamma_1} | \vec{y}^C(x)| d\sigma_x \right\} > 0 \tag{2.16}$$

and we set

$$B = \frac{\max_{C\in D} \int_{\Gamma_0} |\vec{g}(x)\cdot \vec{y}^C(x)| d\sigma_x}{m_y}. \tag{2.17}$$

For any given $\varepsilon > 0$, we assume

$$Bl_i(x) \le -B-\varepsilon, \quad Bu_i(x) \ge B+\varepsilon \quad \forall\, x\in\Gamma_1, \ \ i=1,\dots,n.$$

For each $C\in D, t>0$,

$$\begin{aligned} T_f(tC)\cdot C &= \sum_{j=1}^m \left(\int_\Gamma \left[\vec{f}(x) + \sum_{i=1}^m tc_i \vec{y}^i(x) \right]_{Bl}^{Bu} \cdot \vec{y}^j(x) d\sigma_x \right) c_j \\ &= \int_\Gamma [\vec{f}(x) + t\vec{y}^C(x)]_{Bl}^{Bu} \cdot \vec{y}^C(x) d\sigma_x \\ &= \int_{\Gamma_1} \left[\vec{f}(x) + t\vec{y}^C(x) \right]_{Bl}^{Bu} \cdot (\vec{y}^C(x)) d\sigma_x + \int_{\Gamma_0} \vec{g}(x)\cdot \vec{y}^C(x) d\sigma_x \\ &= \sum_{i=1}^n I_i^C(t) + \int_{\Gamma_0} \vec{g}(x)\cdot \vec{y}^C(x) d\sigma_x, \end{aligned}$$

where for $i=1,\dots,n$,

$$I_i^C(t) = \int_\Gamma [f_i(x) + t y_i^C(x)]_{Bl_i(x)}^{Bu_i(x)} y_i^C(x) d\sigma_x.$$

Let

$$\Gamma_i^{C+} = \{x\in\Gamma_1 \mid y_i^C(x) > 0\} \quad \text{and} \quad \Gamma_i^{C-} = \{x\in\Gamma_1 \mid y_i^C(x) < 0\}.$$

We have

$$\begin{aligned} \lim_{t\to+\infty} I_i^C &= \int_{\Gamma_i^{C+}} Bu_i(x)\cdot y_i^C(x) d\sigma_x + \int_{\Gamma_i^{C-}} Bl_i(x)\cdot y_i^C(x) d\sigma_x \\ &\ge (B+\varepsilon) \int_{\Gamma_1} |y_i^C(x)| d\sigma_x. \end{aligned}$$

Thus

$$\begin{aligned} \lim_{t\to+\infty} T_f(tC)\cdot C &\ge (B+\varepsilon) \sum_{i=1}^n \int_{\Gamma_1} |y_i^C(x)| d\sigma_x + \int_{\Gamma_0} \vec{g}(x)\cdot \vec{y}^C(x) d\sigma_x \\ &\ge (B+\varepsilon) \int_{\Gamma_1} |y^C(x)| d\sigma_x + \int_{\Gamma_0} \vec{g}(x)\cdot \vec{y}^C(x) d\sigma_x \\ &\ge \varepsilon m_y, \end{aligned}$$

where m_y given by (2.16) is independent of C. From (2.14), we see that $T_f(C)\cdot C$ is continuous in both $\vec{f}$ and C; therefore, there exist $R^C>0$, r_C and $\delta_C>0$, as $t>R^C$, $\|\vec{h}-\vec{f}\|_{L^1}\le r^C$, and $|C'-C|<\delta_C$. We have

$$T_h(tC')\cdot C'\ge\frac{1}{2}\varepsilon m_y>0.$$

Since D is compact, there exist $C_1,\dots,C_s\in D$ and $\delta_1,\dots,\delta_s$ s.t.

$$D\subset\cup_{k=1}^s B_{\delta_k}(C_k).$$

Let

$$R^0=\max\{R^{C_1},\dots,R^{C_s}\}\quad\text{and}\quad r_0=\min\{r^{C_1},\dots,r^{C_s}\}.$$

When $t>R^0$, for all $\vec{h}\in(L^1(\Gamma))^n$ with $\|\vec{h}-\vec{f}\|_{L^1}\le r_0$, we have

$$T_h(tC)\cdot C\ge\frac{1}{2}\varepsilon m_y>0\quad\forall\, C\in D.$$

So we need only to take

$$\vec{B}=(B,\dots,B)$$

and

$$\vec{B}l<-\vec{B}<\vec{B}<\vec{B}u\quad\text{a.e. on }\Gamma_1.$$

Case 2. $m_1=\dim(M_1)<\dim(M_0)=m$. Let $y=(\vec{y}^1,\dots,\vec{y}^m)$ be an orthonormal basis in M_0, where $(\vec{y}^1,\dots,\vec{y}^{m_1})$ is a basis in M_1 with

$$\vec{y}^i|_{\Gamma_0}=0,\ (i=1,\dots,m_1)\quad\text{and}\quad\vec{y}^j|_{\Gamma_1}=0,\ (j=m_1+1,\dots,m). \tag{2.18}$$

By the proof in Case 1, for each $\vec{f}\in(L^1(\Gamma))^n$, there exists $C^f=(c_1^f,\dots,c_{m_1}^f)\in\mathbb{R}^{m_1}$ s.t.

$$\left\langle\left[\vec{f}(x)+\sum_{i=1}^{m_1}c_i^f\vec{y}^i(x)\right]_{Bl}^{Bu},\vec{y}^j\right\rangle_{\Gamma_1}=0\quad\forall\, j=1,\dots,m_1.$$

Then for any $c_{m_1+1}^f,\dots,c_m^f\in\mathbb{R}$, by (2.18), we have

$$\begin{aligned}\left\langle\left[\vec{f}(x)+\sum_{i=1}^{m}c_i^f\vec{y}^i(x)\right]_{Bl}^{Bu},\vec{y}^j\right\rangle_{\Gamma}&=\langle\vec{g}(x),\vec{y}^j\rangle_{\Gamma_0}+\left\langle\left[\vec{f}(x)+\sum_{i=1}^{m_1}c_i^f\vec{y}^i(x)\right]_{Bl}^{Bu},\vec{y}^j\right\rangle_{\Gamma_1}\\&=0\quad\forall j=1,\dots,m_1.\end{aligned}$$

On the other hand, when $j>m_1$, for any $c_1,\dots,c_m\in\mathbb{R}$, by (2.18), we have

$$\left\langle\left[\vec{f}(x)+\sum_{i=1}^{m}c_i\vec{y}^i(x)\right]_{Bl}^{Bu},\vec{y}^j\right\rangle_{\Gamma}=\langle\vec{g}(x),\vec{y}^j\rangle_{\Gamma_0}.$$

Therefore

$$\left\langle\left[\vec{f}(x)+\sum_{i=1}^{m}c_i\vec{y}^i(x)\right]_{Bl}^{Bu},\vec{y}^j\right\rangle_{\Gamma}=0,\quad j>m_1,$$

if and only if

$$\langle \vec{g}(x), \vec{y}^j \rangle_{\Gamma_0} = 0, \quad j > m_1;$$

i.e., (2.11) is satisfied. The proof is complete. □

Remark 2.1. In the above theorem,

(1) when rigid body motion is considered,

$$M_0 = \{\vec{a} + \vec{b} \times \vec{x} \mid \vec{a}, \vec{b} \in \mathbb{R}^3\},$$

we have $\dim(M_0) = \dim(M_1) = 6$, so all the conditions in the theorem are satisfied. So for each $\vec{f} \in (L^1(\Gamma))^3$ there is $\vec{a}_f + \vec{b}_f \times \vec{x} \in M_0$ s.t.

$$\left[\vec{f} + \vec{a}_f + \vec{b}_f \times \vec{x}\right]_{Bl}^{Bu} \perp M_0;$$

(2) if

$$Bl(x) \equiv -\infty \quad \text{or} \quad Bu(x) \equiv +\infty \quad \text{on } \Gamma_1$$

the conclusion still holds for each $\vec{f} \in (L^l(\Gamma))^n$ $(l \geq 1)$ and M_0 an m-dimensional subspace of $(L^q(\Gamma))^n$, where $q \geq 1$, $\frac{1}{h} + \frac{1}{q} = 1$, and $h = \min\{l, p\}$. When $h = 1$, $q = +\infty$;

(3) the vector C in (2.13) represents the rigid body motion in our case. From the above theorem, we can see that the solution C_f such that $T_f(C_f) = 0$ is not unique.

The following error estimate contains a uniqueness result, which will also be used in proving the uniform convergence rate of an algorithm in a subsequent paper.

THEOREM 2.3. *Let us maintain all the assumptions in Theorem* 2.2. *Let* $\vec{f}, \vec{h}$ *be given in* $(L^1(\Gamma))^n$, C_f, C_h *be, respectively, two zeros of* T_f *and* T_h *defined by* (2.13). *If*

$$meas\,(\Gamma_{C_f}) + meas\,(\Gamma_{C_h}) > 0,$$

where

$$meas\,(\Gamma_{C_f}) = \sum_{i=1}^{n} meas\,\{x \in \Gamma \mid Bl_i(x) < f_i(x) + y_i^{C_f}(x) < Bu_i(x)\},$$

$$meas\,(\Gamma_{C_h}) = \sum_{i=1}^{n} meas\,\{x \in \Gamma \mid Bl_i(x) < h_i(x) + y_i^{C_h}(x) < Bu_i(x)\},$$

$$y^{C_f}(x) = \sum_{i=1}^{m} c_i^f y^i(x) \quad \textit{and} \quad y^{C_h} = \sum_{i=1}^{m} c_i^h y^i(x),$$

then

$$|C_f - C_h| \leq \gamma \|\vec{f} - \vec{h}\|_{(L^1(\Gamma))^n}, \tag{2.19}$$

where the constant γ *is independent of* C_f *and* C_h.

Proof. We may assume that

$$\text{meas}\,(\Gamma_{C_f}) > 0.$$

For $T_f(C)$, we denote

$$\Gamma_C^k = \{x \in \Gamma \mid Bl_k(x) < f_k(x) + y_k^C(x) < Bu_k(x)\},$$

where

$$y_k^C(x) = \sum_{i=1}^{m} c_i y_k^i(x).$$

Write

$$\text{meas}\,(\Gamma_C) = \sum_{k=1}^{n} \text{meas}\,(\Gamma_C^k).$$

Since $T_f(C)$ is Lipschitz continuous in C, a direct calculation leads to the Fréchet derivative

$$T_f'(C) = \left[\sum_{k=1}^{n} \langle y_i^k, y_j^k \rangle_{\Gamma_C^k}\right]_{m\times m} \quad \text{a.e. } C \in \mathbb{R}^m,$$

a Gram-matrix, which is symmetric positive semidefinite; i.e., for any nonzero vector $b = (b_1, \ldots, b_m) \in \mathbb{R}^m$,

$$(b_1, \ldots, b_m) T_f'(C)(b_1, \ldots, b_m)^T = \sum_{k=1}^{n} \left\langle \sum_{i=1}^{m} b_i y_i^k, \sum_{i=1}^{m} b_i y_i^k \right\rangle_{\Gamma_C^k} \geq 0,$$

where "$>$" holds strictly if

$$\text{meas}\,(\Gamma_C) > 0,$$

because $\{\vec{y}_1, \ldots, \vec{y}_m\}$ is linearly independent.

On the other hand, we have

$$\left[\sum_{k=1}^{n} \langle y_i^k, y_j^k \rangle_{\Gamma_C^k}\right]_{m\times m} + \left[\sum_{k=1}^{n} \langle y_i^k, y_j^k \rangle_{\Gamma\setminus\Gamma_C^k}\right]_{m\times m} = \left[\sum_{k=1}^{n} \langle y_i^k, y_j^k \rangle_{\Gamma}\right]_{m\times m} = I_{m\times m},$$

where the Gram-matrix

$$\left[\sum_{k=1}^{n} \langle y_i^k, y_j^k \rangle_{\Gamma\setminus\Gamma_C^k}\right]_{m\times m}$$

is also symmetric positive semidefinite. Therefore

$$0 \leq |T_f'(C)| \leq 1 \quad \text{a.e. } C \in \mathbb{R}^m,$$

where "$<$" holds strictly in the first inequality if meas $(\Gamma_C) > 0$ and "$<$" holds strictly in the second inequality if meas $(\Gamma \setminus \Gamma_C) > 0$. Next, for given f, h in $(L^1(\Gamma))^n$ and two zeros C_f, C_h of T_f and T_h, respectively, we let

$$C_t = tC_h + (1-t)C_f, \quad t \in (0,1).$$

Since $T_f(C)$ is Lipschitz continuous in C, once meas $(\Gamma_{C_f}) > 0$, there exists $\varepsilon > 0$ s.t.

$$\text{meas}\,(\Gamma_{C_t}) > 0 \quad \forall\, 0 < t < \varepsilon.$$

It follows that $T_f'(C_t)$ is a symmetric positive definite matrix with

$$0 < |T_f'(C_t)| \le 1 \quad \text{a.e. } 0 < t < \varepsilon.$$

Therefore $\int_0^1 T_f'(C_t)dt$ defines a symmetric positive definite matrix with

$$0 < \left| \int_0^1 T_f'(C_t)dt \right| \le 1.$$

For any $0 < \mu < 1$, we have

$$0 < \left| I - \mu \int_0^1 T_f'(C_t)dt \right| = (1 - \lambda_f) < 1$$

for some $0 < \lambda_f < 1$. Taking

$$C_f - \mu T_f(C_f) = C_f \quad \text{and} \quad C_h - \mu T_h(C_h) = C_h$$

into account, we arrive at

$$\begin{aligned} |C_f - C_h| &= |C_f - C_h - \mu(T_f(C_f) - T_h(C_h))| \\ &= |C_f - C_h - \mu(T_f(C_f) - T_f(C_h) + T_f(C_h) - T_h(C_h))| \quad \text{(use (2.14))} \\ &\le \left| I - \mu \int_0^1 T_f'(C_t)dt \right| |C_f - C_h| + \mu\gamma_1 \|f - h\|_1 \\ &= (1 - \lambda_f)|C_f - C_h| + \mu\gamma_1 \|f - h\|_1. \end{aligned}$$

Consequently we have

$$|C_f - C_h| \le \frac{\gamma_1 \mu}{\lambda_f} \|f - h\|_{(L^1(\Gamma))^n},$$

and the proof is complete. □

As a direct consequence of Theorem 2.3, we obtain the following uniqueness result.

COROLLARY 2.4. *Let us maintain all the assumptions in Theorem* 2.2. *For given* $\vec{f} \in (L^1(\Gamma))^n$, *if* C_f *is a zero of* T_f *with*

$$\textit{meas}\,(\Gamma_{C_f}) > 0,$$

then C_f *is the unique zero of* T_f. □

Now we present a state-feedback characterization of the optimal control.

THEOREM 2.5. *Let* $\Omega \subset \mathbb{R}^3$ *be a bounded domain with smooth boundary* Γ. *The LQR problem has a unique optimal control* $\vec{u}^* \in \mathcal{U}$ *and a unique optimal velocity state* $\vec{w}^* \in (C(\Gamma))^3$ *s.t.*

$$\text{(2.20)} \qquad \begin{cases} \displaystyle\sum_{k=1}^{M} \mu_k(\vec{w}^*(P_k) - \vec{Z}_k) = 0, \\ \displaystyle\sum_{k=1}^{M} \mu_k(\vec{w}^*(P_k) - \vec{Z}_k) \times \vec{P}_k = 0. \end{cases}$$

and

$$\vec{u}^*(x) = \left[-\frac{1}{\gamma} \left(\frac{1}{2} I + \mathcal{K} \right)^{-1} \left(\sum_{k=1}^{m} \mu_k E(P_k, \cdot)(\vec{w}^*(P_k) - \vec{Z}_k) \right)(x) + \vec{a} + \vec{b} \times \vec{x} \right]_{Bl}^{Bu}, \quad \forall\, x \in \Gamma, \tag{2.21}$$

where $\vec{a} + \vec{b} \times \vec{x}$ *is defined in Theorem* 2.2 *s.t.* $\vec{u}^* \perp M_0$ *and* M_0 *is given in* (1.2).

Proof. Let $X = (L^p(\Gamma))^3_{\perp M_0}$. Since our objective function $J(\vec{u})$ is strictly convex and differentiable, and the feasible control set $\mathcal{U}$ is a closed bounded convex subset in the reflexive Banach space X, the existence and uniqueness of the optimal control are well established. Equation (2.20) is just a copy of (1.16). By our characterization of truncation, Theorem 2.1 with $\alpha = \frac{1}{2\gamma}$,

$$\vec{u}^*(x) = \left[\vec{u}^*(x) - \frac{1}{2\gamma} \nabla J(\vec{u})(x) + \vec{a} + \vec{b} \times \vec{x} \right]_{Bl}^{Bu} \quad \forall\, x \in \Gamma,$$

where $\vec{a} + \vec{b} \times \vec{x} \in M_0$ is defined in Theorem 2.2 s.t.

$$\left[\vec{u}^* - \frac{1}{2\gamma} \nabla J(\vec{u}) + \vec{a} + \vec{b} \times \vec{x} \right]_{Bl}^{Bu} \perp M_0.$$

To prove (2.21), we need only to show

$$\nabla J(\vec{u}) = 2 \left\{ \left(\frac{1}{2} I + \mathcal{K} \right)^{-1} \sum_{k=1}^{m} \mu_k E(P_k, \cdot)(\vec{w}(P_k, \vec{u}) - \vec{Z}_k) + \gamma \vec{u} \right\}. \tag{2.22}$$

Applying (1.9), i.e., $M_0 = \mathcal{S}_v(N)$ and (2.20), we get

$$\sum_{k=1}^{m} \mu_k E(P_k, \cdot)(\vec{w}(P_k, \vec{u}) - \vec{Z}_k) \in (L^q(\Gamma))^3_{\perp N}, \tag{2.23}$$

and then

$$\left(\frac{1}{2} I + \mathcal{K} \right)^{-1} \left\{ \sum_{k=1}^{m} \mu_k E(P_k, \cdot)(\vec{w}(P_k, \vec{u}) - \vec{Z}_k) \right\} \in (L^q(\Gamma))^3_{\perp M_0}. \tag{2.24}$$

Since $\nabla J(\vec{u})$ defines a bounded linear functional on X, for any $\vec{h} \in X$, taking (1.12) into account, we have

$$\begin{aligned}
&\langle \nabla J(\vec{u}), \vec{h} \rangle \\
&= 2 \sum_{k=1}^{m} \mu_k (\vec{w}(P_k, \vec{u}) - \vec{Z}_k) \mathcal{S}_v \left(\left(\frac{1}{2} I + \mathcal{K}^* \right)^{-1} \vec{h} \right)(P_k) + 2\gamma \langle \vec{u}, \vec{h} \rangle \\
&= 2 \sum_{k=1}^{m} \mu_k (\vec{w}(P_k, \vec{u}) - \vec{Z}_k) \int_\Gamma E(P_k, \xi) \left[\left(\frac{1}{2} I + \mathcal{K}^* \right)^{-1} \vec{h} \right](\xi) d\sigma_\xi + 2\gamma \langle \vec{u}, \vec{h} \rangle \\
&= 2 \int_\Gamma \left(\frac{1}{2} I + \mathcal{K} \right)^{-1} \left[\sum_{k=1}^{m} \mu_k E(P_k, \cdot)(\vec{w}(P_k, \vec{u}) - \vec{Z}_k) \right](\xi) \cdot \vec{h}(\xi) d\sigma_\xi + 2\gamma \langle \vec{u}, \vec{h} \rangle \\
&= 2 \left\langle \left[\left(\frac{1}{2} I + \mathcal{K} \right)^{-1} \sum_{k=1}^{m} \mu_k E(P_k, \cdot)(\vec{w}(P_k, \vec{u}) - \vec{Z}_k) \right] + \gamma \vec{u}(\cdot), \vec{h}(\cdot) \right\rangle.
\end{aligned}$$

So (2.22) is verified and the proof is complete. ∎

3. Regularities of the optimal control. It is clear that (2.21) is a feedback characterization of the optimal control. To obtain such a characterization, $\alpha = \frac{1}{2\gamma}$ in (2.9) is crucial. Later on we will see that $\alpha = \frac{1}{2\gamma}$ is also crucial in proving the uniform convergence of our numerical algorithms in a subsequent paper. Observe that when $Bl = -\infty$ and $Bu = +\infty$, it corresponds to the LQR problem without constraints on the control variable. The optimal solution, if it exists, becomes

$$\vec{u}^*(x) = -\frac{1}{\gamma}\left(\frac{1}{2}I + \mathcal{K}\right)^{-1}\left(\sum_{k=1}^{m}\mu_k E(P_k,\cdot)(\vec{w}^*(P_k) - \vec{Z}_k)\right)(x) + \vec{a} + \vec{b}\times\vec{x} \quad \forall\, x \in \Gamma,$$

where $\vec{a}+\vec{b}\times\vec{x}$ is defined in Theorem 2.2 s.t. $\vec{u}^* \perp M_0$ (see Remark 2.1). But according to Lemma 1.1 (d), such a solution $\vec{u}^*$ is only in $(L^q(\Gamma))^3$ $(q < 2)$, since $E(P_k,\cdot)$ is only in $(L^q(\Gamma))^3$. So it is reasonable to apply bound constraints Bl and Bu on the control variable $\vec{u}$. However, we notice that the optimal control still contains a singular term

$$\left(\frac{1}{2}I + \mathcal{K}\right)^{-1}\sum_{k=1}^{m}\mu_k E(P_k,\cdot)(\vec{w}(P_k,\vec{u}) - \vec{Z}_k)(x),$$

which is not computable at $x = P_k$. In order to carry out the truncation by Bl and Bu, we have to know the sign of this singular term. Hence we derive a singularity decomposition formula of (2.21), in which the singular term is expressed as continuous bounded terms plus a simple dominant singular term and a lower-order singular term. With the simple dominant singular term, the nature of the singularity is clearly exposed.

THEOREM 3.1. *For the optimal control $\vec{u}^*$ given in* (2.21), *let*

$$\vec{f}^*(x) = \sum_{k=1}^{m}\mu_k E(P_k,x)(\vec{w}^*(P_k) - \vec{Z}_k).$$

Then

$$\left(\frac{1}{2}I + \mathcal{K}\right)^{-1}\vec{f}^*(x) = 2\vec{f}^*(x) - 4\mathcal{K}\vec{f}^*(x) + 4\left(\frac{1}{2}I + \mathcal{K}\right)^{-1}\circ\mathcal{K}\circ\mathcal{K}\vec{f}^*(x) + \vec{a}_* + \vec{b}_*\times\vec{x}, \tag{3.1}$$

where in the singular part, the second term $4\mathcal{K}\vec{f}^*(x)$ is dominated by the first term $2\vec{f}^*(x)$, whose nature of singularity can be determined at each P_k and the regular term $4(\frac{1}{2}I + \mathcal{K})^{-1}\circ\mathcal{K}\circ\mathcal{K}\vec{f}^*(x)$ is continuous on Γ.

Proof. For given $\vec{g} \in (L^q(\Gamma))^3_{\perp N}$ with $q > 2 - \varepsilon(\Gamma)$, we have

$$\left(\frac{1}{2}I + \mathcal{K}\right)^{-1}\vec{g} = 2\vec{g} - 4\mathcal{K}\vec{g} + 4\left(\frac{1}{2}I + \mathcal{K}\right)^{-1}\circ\mathcal{K}\circ\mathcal{K}\vec{g} + \vec{a}_g + \vec{b}_g\times\vec{x}. \tag{3.2}$$

Let

$$\vec{f}^*(x) = \sum_{k=1}^{m}\mu_k E(P_k,x)(\vec{w}^*(P_k) - \vec{Z}_k).$$

By (2.23), $\vec{f}^* \in (L^q(\Gamma))^3_{\perp N}$ for every $q < 2$; thus (3.1) follows. The first part of Lemma 1.1 (e) states that the singularity in $2\vec{f}^*$ dominates the one in $4\mathcal{K}\vec{f}^*$, whereas the second part of Lemma 1.1 (e) and (f) imply that $(\frac{1}{2}I + \mathcal{K})^{-1}\circ\mathcal{K}\circ\mathcal{K}\vec{f}^*$ is continuous. ∎

The above singularity decomposition formula plays an important role in our singularity analysis and also in our numerical computation. It is used to prove the uniform convergence and to estimate the uniform convergence rate of our numerical algorithms in a subsequent paper.

Note that the fundamental velocity solution

$$E(\xi,x)=\left\{\frac{1}{8\pi}\left(\frac{\delta_{ij}}{|x-\xi|}+\frac{(x_i-\xi_i)(x_j-\xi_j)}{|x-\xi|^3}\right)\right\},\quad 1\le i,j\le 3,$$

is not defined when $\xi=P_k$ and $x\to P_k$, in the sense that when $x\to P_k$, some of the entries may oscillate between $-\infty$ and $+\infty$. So if we look at the simple dominant singular term in the singularity decomposition formula of the optimal control, we can see that in general, the optimal control $\vec{u}^*(x)$ is not defined at P_k, even with the truncation by Bl and Bu. This is a significant difference between systems with scalar-valued fundamental solution and with matrix-valued fundamental solution. For the formal case, e.g., the Laplacian, the optimal control is continuous at every point where Bl and Bu are continuous. Of course, if $Bl(P_k)=Bu(P_k)=\vec{g}(P_k)$, i.e., $P_k\in\Gamma_0$, which means the control is not active at P_k, then trivially $\vec{u}^*(P_k)=\vec{g}(P_k)$, a prescribed value. This is the case when a sensor is placed at P_k, then a control device cannot be put at the same point P_k. However, in general point observation case, the control may still be active at P_k. The above analysis then states that the optimal control is not defined at P_k unless some other conditions are posed. This is the nature of point observations. Notice that a distributed parameter control is assumed in our problem setting. Theoretically the values of the control variable at finite points will not affect the system. However, in numerical computation we can only evaluate the optimal control $\vec{u}^*$ at a finite number of points. The observation points P_k's usually are of the most interest. On the other hand, the optimal velocity state $\vec{w}^*$ is well defined and continuous at P_k whether $\vec{u}^*(P_k)$ is defined or not. So if one does want the optimal control $\vec{u}^*$ to be defined at P_k, when $Bl(P_k)=Bu(P_k)$, $k=1,\dots,m$, it is clear that $\vec{u}^*(P_k)$ is defined at each P_k. When $Bl(P_k)<Bu(P_k)$ for some $k=1,\dots,m$, then we have the following necessary and sufficient condition.

THEOREM 3.2. *Let $Bl(P_k)<Bu(P_k)$ for some $k=1,\dots,m$, then the optimal control $\vec{u}^*$ is well defined at the observation points P_k if and only if*

$$|(\vec{w}(P_k,\vec{u}^*)-\vec{Z}_k)_i|\le 2|(\vec{w}(P_k,\vec{u}^*)-\vec{Z}_k)_j|,\quad 1\le i\ne j\le 3, \tag{3.3}$$

where for each fixed k and i, the equality holds for at most one $j\ne i$ unless

$$\vec{w}(P_k,\vec{u}^*)=\vec{Z}_k.$$

When $\vec{u}^*$ is well defined at P_k, we have

$$(\vec{u}^*(P_k))_i=\begin{cases} Bl_i(P_k) & \text{if}\quad (\vec{w}(P_k,\vec{u}^*)-\vec{Z}_k)_i<0,\\ Bu_i(P_k) & \text{if}\quad (\vec{w}(P_k,\vec{u}^*)-\vec{Z}_k)_i>0.\end{cases} \tag{3.4}$$

Proof. If we observe the fundamental velocity solution, we can see that the proof follows from the following argument. For $x=(x_1,x_2,x_3)$ and $1\le i,j,k\le 3$,

$$\begin{aligned}\lim_{x\to 0}\bar{e}_i(x)&=\lim_{x\to 0}\left(c_i\left(\frac{1}{|x|}+\frac{x_i^2}{|x|^3}\right)+c_j\frac{x_ix_j}{|x|^3}+c_k\frac{x_ix_k}{|x|^3}\right)\\&=\lim_{x\to 0}\frac{1}{|x|^3}\left((c_ix_i^2+c_jx_ix_j+c_ix_j^2)+(c_ix_i^2+c_kx_ix_k+c_ix_k^2)\right)\end{aligned}$$

exists (including $\pm\infty$) if and only if

$$c_j^2 - 4c_i^2 \le 0 \quad \text{and} \quad c_k^2 - 4c_i^2 \le 0, \tag{3.5}$$

where at most one equality can hold unless $c_i = c_j = c_k = 0$. Notice that when (3.5) holds, $c_i = 0$ leads to $c_j = c_k = 0$. So if $c_i \neq 0$ and two equalities hold in (3.5), then

$$\bar{e}_i(x) = \frac{c_i}{|x|^3}\left((x_i \pm x_j)^2 + (x_i \pm x_k)^2\right).$$

We can make the limit either equal to zero by taking $x_i = \mp x_j = \mp x_k \to 0$ or equal to sign $(c_i)\infty$ by taking $x_i \neq \mp x_j$ or $x_i \neq \mp x_k$ and $x \to 0$. So the limit will not exist. When $\lim_{x\to 0} \bar{e}_i(x)$ exists and $c = (c_1, c_2, c_3) \neq 0$, we have

$$\lim_{x\to 0} \bar{e}_i(x) = \text{sign } (c_i)\infty. \qquad \square$$

With the above result and the singularity decomposition formula for the optimal control, the following continuous result can be easily verified.

THEOREM 3.3. *Let Bu and Bl be continuous on Γ_1. If for each $k = 1, \ldots, m$ either $Bl(P_k) = Bu(P_k)$ or the condition* (3.3) *holds strictly with $(\vec{w}(P_k, \vec{u}_p^0) - \vec{Z}_k)_i \neq 0$, then the optimal control $\vec{u}^*$ is continuous on Γ_1. So the equality in* (2.4) *holds for every point on Γ.*

From the state-feedback characterization (2.20), the control can be determined by a physical measurement of the state at a finite number of observation points $P_k, k = 1, \ldots, m$. The question is then asked, "will a small error in the measurement of the state cause a large deviation in the control?" Due to the appearance of the singular term in (2.20), in general the answer is yes; i.e., the state-feedback system is not stable. However, under certain conditions, we can prove that the state-feedback system is uniformly stable.

THEOREM 3.4. *Let $\vec{w}(P_k)$ be the exact velocity state at observation points and $\vec{u}_p$ be the control determined from* (2.20) *in terms of $\vec{w}(P_k)$. If for each $k = 1, \ldots, m$ either Bl and Bu are continuous and equal at P_k or Bu and Bl are locally bounded at P_k, the condition* (3.3) *holds strictly with $(\vec{w}(P_k, \vec{u}_p^0) - \vec{Z}_k)_i \neq 0$. Then the state-feedback system* (2.20) *is uniformly stable in the sense that for any $\varepsilon > 0$, there is $\delta > 0$ such that for any measurement $\vec{w}'(P_k)$ of $\vec{w}(P_k)$,*

$$|\vec{u}'(x) - \vec{u}(x)| < \varepsilon \quad \forall x \in \Gamma \qquad \textit{whenever } |\vec{w}'(P_k) - \vec{w}(P_k)| < \delta,$$

where $\vec{u}'$ is the control determined from (2.20) *in terms of $\vec{w}'(P_k)$.*

Proof. For each $\varepsilon > 0$. For each fixed $k = 1, \ldots, m$, if Bl and Bu are continuous and equal at P_k, there is $d_k' > 0$ s.t.

$$Bu(x) - Bl(x) < \varepsilon \quad \forall x \in \Gamma_1,\ |x - P_k| \le d_k'.$$

Since the control variable is bounded by Bl and Bu,

$$|\vec{u}'(x) - \vec{u}(x)| < \varepsilon \quad \forall x \in \Gamma_1,\ |x - P_k| \le d_k'.$$

If instead the condition (3.3) holds strictly with $(\vec{w}(P_k, \vec{u}_p^0) - \vec{Z}_k)_i \neq 0$, let $\delta_1 > 0$ be chosen so that when $|\vec{w}'(P_k) - \vec{w}(P_k)| < \delta_1$, condition (3.3) still holds strictly with $(\vec{w}'(P_k, \vec{u}_p^0) - \vec{Z}_k)_i \neq 0$. Due to the singular term in (2.20) and since Bu and Bl are

locally bounded at P_k, there is $d_k > 0$ such that when $x \in \Gamma$ and $|x - P_k| < d_k$ for some $k = 1, \ldots, m$, we have

$$\left(-\frac{1}{\gamma} \left(\frac{1}{2} I + \mathcal{K} \right)^{-1} \left[\sum_{k=1}^{m} \mu_k E(P_k, \cdot)(\vec{w}'(P_k) - \vec{Z}_k) \right](x) + \vec{a}' + \vec{b}' \times x \right)_i$$

either $> Bu(x)_i$

or $< Bl(x)_i$.

After the truncation by Bu and Bl, it follows that

$$\vec{u}'(x)_i = \vec{u}(x)_i = \text{ either } Bu(x)_i \text{ or } Bl(x)_i \quad \forall x \in \Gamma_1, |x - P_k| < d_k.$$

So if we define

$$\Gamma_+ = \{x \in \Gamma |\ |x - P_k| < \min\{d_k', d_k, k = 1, \ldots, m\} \text{ for some } k = 1, \ldots, m\},$$

then in either case we have

$$|\vec{u}'(x) - \vec{u}(x)| < \varepsilon \quad \forall x \in \Gamma_+.$$

Denote

$$\vec{F}(x) = -\frac{1}{\gamma} \left(\frac{1}{2} I + \mathcal{K} \right)^{-1} \left(\sum_{k=1}^{m} \mu_k E(P_k, \cdot)(\vec{w}(P_k) - \vec{Z}_k) \right)(x),$$

$$\vec{F}'(x) = -\frac{1}{\gamma} \left(\frac{1}{2} I + \mathcal{K} \right)^{-1} \left(\sum_{k=1}^{m} \mu_k E(P_k, \cdot)(\vec{w}'(P_k) - \vec{Z}_k) \right)(x)$$

and

$$\text{meas}\,(\Gamma_{C_F}) = \sum_{i=1}^{3} \text{meas}\,\{x \in \Gamma \mid Bl_i(x) < (\vec{F}(x) + \vec{a} + \vec{b} \times x)_i < Bu_i(x)\},$$

$$\text{meas}\,(\Gamma_{C_{F'}}) = \sum_{i=1}^{3} \text{meas}\,\{x \in \Gamma \mid Bl_i(x) < (\vec{F}'(x) + \vec{a}' + \vec{b}' \times x)_i < Bu_i(x)\}.$$

Since $\text{meas}\,(\Gamma_{C_F}) + \text{meas}\,(\Gamma_{C_{F'}}) = 0$ implies that

$$\vec{u}'(x)_i = \vec{u}(x)_i = \text{ either } Bu(x)_i \text{ or } Bl(x)_i \quad \forall\, x \in \Gamma,$$

there is nothing to prove. So we assume that $\text{meas}\,(\Gamma_{C_F}) + \text{meas}\,(\Gamma_{C_{F'}}) > 0$, and then Theorem 2.3 can be applied. For $x \in \Gamma_- = \Gamma \setminus \Gamma_+$, a compact set, by using (2.20) and triangle inequality, we obtain

$$\begin{aligned} |\vec{u}'(x) - \vec{u}(x)| &= \left| \left[\vec{F}(x) + \vec{a} + \vec{b} \times x \right]_{Bl}^{Bu} - \left[\vec{F}'(x) + \vec{a}' + \vec{b}' \times x \right]_{Bl}^{Bu} \right| \\ &\le \left| -\frac{1}{\gamma} \left(\frac{1}{2} I + \mathcal{K} \right)^{-1} \left[\sum_{k=1}^{m} \mu_k E(P_k, \cdot)(\vec{w}'(P_k) - \vec{w}(P_k)) \right](x) \right| \\ &\qquad + |\vec{a}' + \vec{b}' \times x - (\vec{a} + \vec{b} \times x)| \\ &\equiv |I_1(x)| + |I_2(x)|. \end{aligned}$$

Since the operator $(\frac{1}{2}I + \mathcal{K})^{-1}$ is linear and bounded, and the function $E(P_k, \cdot)$ is continuous and bounded on the compact set Γ_-, there is $\delta_2 > 0$ such that

$$|I_1(x)| < \frac{1}{2}\varepsilon \quad \forall x \in \Gamma_- \quad \text{when } |\vec{w}'(P_k) - \vec{w}(P_k)| < \delta_2.$$

As for $I_2(x)$, Theorem 2.3 yields

$$|(\vec{a}', \vec{b}') - (\vec{a}, \vec{b})| \le \gamma \|\vec{F}' - \vec{F}\|_{(L^1(\Gamma))^3},$$

where the constant γ depends only on Γ. Since there is constant C_0 independent of $\vec{w}'(P_k)$ such that

$$\|\vec{F}' - \vec{F}\|_{(L^1(\Gamma))^3} \le C_0 |\vec{w}'(P_k) - \vec{w}(P_k)|, \quad k = 1, \ldots, m,$$

there is $\delta_3 > 0$ such that

$$|I_2(x)| = |\vec{a}' + \vec{b}' \times x - (\vec{a} + \vec{b} \times x)| < \frac{1}{2}\varepsilon \quad \forall x \in \Gamma_- \quad \text{whenever } |\vec{w}'(P_k) - \vec{w}(P_k)| < \delta_3.$$

Finally, for $\delta = \min\{\delta_1, \delta_2, \delta_3\}$, we have

$$|\vec{u}'(x) - \vec{u}(x)| < \varepsilon \quad \forall x \in \Gamma \quad \text{whenever } |\vec{w}'(P_k) - \vec{w}(P_k)| < \delta \quad \text{for } k = 1, \ldots, m.$$

The proof is complete. □

As a final comment, it is worth indicating that although in the problem setting, the governing differential equation—the Stokes equation—is linear, the bound constraint on the control variable introduces a nontrivial nonlinearity into the system. This can be clearly seen in Theorem 2.2. Also, our approach can be adopted to deal with certain nonlinear boundary control problems.

GLOBALLY AND SUPERLINEARLY CONVERGENT ALGORITHM FOR MINIMIZING A NORMAL MERIT FUNCTION*

ELIJAH POLAK† AND LIQUN QI‡

Abstract. In this paper we present two new concepts related to the solution of systems of nonsmooth equations (NE) and variational inequalities (VI). The first concept is that of a *normal merit function*, which summarizes the simple basic properties shared by various known merit functions. In general, normal merit functions are locally Lipschitz, but not differentiable. The second concept is that of a *Newtonian operator*, whose values generalize the concept of the Hessian for normal merit functions. These two concepts are then used to generalize the nonsmooth Newton method for solving the equation $\nabla f(x) = 0$, where f is a normal merit function with $f \in C^1$, to the case where f is only locally Lipschitz and the set-valued inclusion $0 \in \partial f(x)$ needs to be solved. Combining the resulting generalized Newton method with certain first-order methods, we obtain a globally and superlinearly convergent algorithm for minimizing normal merit functions.

Key words. normal merit function, generalized Newton method, first-order algorithm, global convergence, superlinear convergence

1. Introduction.

Throughout this paper, we let $F : \Re^n \to \Re^n$ be a locally Lipschitz continuous mapping.

The NE problem is to find a vector $x \in \Re^n$ such that

$$F(x) = 0. \tag{1.1}$$

Let S be a nonempty closed convex set in $\Re^n$. The VI problem is to find a vector $x \in S$ such that

$$\langle F(x), y - x\rangle \geq 0 \quad \text{for all } y \in S, \tag{1.2}$$

where $\langle \cdot, \cdot \rangle$ denotes the inner product in $\Re^n$. When $S = \Re^n$, VI reduces to NE. A comprehensive survey of VI is given in [11]. On the other hand, the VI problem (1.2) can be reformulated in the form of the NE problem (1.1) [19]. There are other problems, such as the nonlinear complementarity problem and the maximal monotone operator problem, which can be reformulated as an NE problem. A survey of NEs is given in [19]. In this paper, by "the problem," we mean either the NE problem or the VI problem.

We propose to solve the NE and VI problems by minimizing a *merit function*, $f : \Re^n \to \Re$, using a new extension of Newton's method. A natural merit function f for the NE problem is the norm function

$$f_n(x) := \frac{1}{2}\langle F(x), F(x)\rangle. \tag{1.3}$$

In this case, with $f = f_n : \Re^n \to \Re$, the merit function satisfies the following four properties:

(i) $f(x) \geq 0$ for all $x \in \Re^n$;
(ii) $f(x^*) = 0$ if and only if x^* solves the problem (here, NE);
(iii) f is locally Lipschitz;
(iv) f is strictly differentiable with the derivative equal to zero at a solution x^* of the problem.

In general, by Rademacher's theorem, any locally Lipschitz continuous function $H : \Re^n \to \Re^m$ is differentiable almost everywhere, and the B-differential of H at x is given by

$$\partial_B H(x) := \{V \in \Re^{n\times m} \,|\, V = \lim_{x_k \to x} \nabla H(x_k)^T,\ x_k \in \Omega_H\},$$

where $\Omega_H := \{x \in \Re^n \,|\, H \text{ is differentiable at } x\}$ [24]. For any $x \in \Re^n$, $\partial_B H(x)$ is a nonempty compact set consisting of $n \times n$ matrices. On the other hand, the Clarke Jacobian of H [2] at x is defined by

$$\partial H(x) := \text{conv } \partial_B H(x).$$

We will use g to denote ∇f if it exists, and G to denote ∂f. Using this notation, property (iv) can be expressed as follows:

$$G(x^*) \equiv \partial f(x^*) = \partial_B f(x^*) = \{g(x^*)\} = \{0\}.$$

For the VI problem we can use the recently discovered D-gap function [10, 21, 29]. The D-gap function $f_d : \Re^n \to \Re$ is defined by

$$f_d(x) := h_\alpha(x) - h_\beta(x), \tag{1.4}$$

where α and β are arbitrary positive parameters such that $\alpha < \beta$ and h_α is the regularized gap function

$$h_\alpha(x) := \max_{y\in S} \left\{ \langle F(x), x - y\rangle - \frac{\alpha}{2}\|x - y\|^2 \right\}. \tag{1.5}$$

(The function h_β is defined similarly with α replaced by β.) The D-gap function f_d also satisfies properties (i)–(iv) [10, 21, 29].

We call a merit function for an NE or VI problem a *normal merit function* if it satisfies properties (i)–(iv) above, as well as the following fifth property:

(v) there exists an auxiliary function $p : \Re^n \times \Re^{n\times n} \to \Re^n$ such that for any $x \in \Re^n$ and any $a \in G(x)$ there is $V \in \partial F(x)$ such that

$$a = p(x, V). \tag{1.6}$$

For $f = f_n$, we may let

$$p(x, V) = V^T F(x). \tag{1.7}$$

In particular, when F is smooth, $a = \nabla f_n(x)$, $V = F_x(x)$, and (1.6) holds automatically.

Thus we see that the norm function is a normal merit function for the NE problem. In section 3, we will show that the D-gap function also satisfies property (v). Hence it is a normal merit function for the VI problem.

The results in this paper remain true if we replace the definition $G := \partial f$ by $G := \partial_B f$ and the $V \in \partial F(x)$ by a $V \in \partial_B F(x)$ in (1.6).

Note that most merit functions for the nonlinear complementarity problem can be classified as special cases of the norm function for NE or the D-gap function for VI. Many recently developed algorithms for the nonlinear complementarity problem are based on the norm function of the Fischer NE function or the Pang min NE function of the nonlinear complementarity problem [3, 5, 6, 7, 8, 9, 13, 14, 16, 19, 28], while the implicit Lagrangian of the nonlinear complementarity problem [17] can be regarded as a special case of the D-gap function for VI with $S = \Re^n_+$ [15, 16].

In this paper we will consider the problem of minimizing a normal merit function f for either NE and VI. Thus we need to solve

$$\min_{x \in \Re^n} \quad f(x). \tag{1.8}$$

When f is smooth, the associated stationarity problem for (1.8) is to find an x such that

$$g(x) = 0. \tag{1.9}$$

Note that (1.9) turns out to be a system of NE, since g, in general, is not differentiable. A class of superlinearly convergent generalized Newton methods for solving NE has been developed in [24], [26], and [19]. Suppose that g is locally Lipschitz continuous. The generalized Newton method for solving (1.9) is of the form

$$x_{k+1} = x_k - V_k^{-1} g(x_k), \tag{1.10}$$

where V_k is an $n \times n$ symmetric matrix, which belongs to either $\partial g(x_k)$ or $\partial_B g(x_k)$. Note that all matrices in $\partial g(x)$ are symmetric. If x^* is a solution of (1.9), g is semismooth at x^*, and all the matrices in $\partial g(x^*)$ or $\partial_B g(x^*)$ (dependent upon the choice of V_k in (1.10)) are nonsingular, then the generalized Newton method (1.10) is locally superlinearly convergent at x^*. Furthermore if g is strongly semismooth at x^*, this convergence is quadratic [24, 26, 19].

However, if f is the D-gap function f_d for VI, even when F is smooth, the above generalized Newton method has difficulties:

i) It depends on the Rademacher theorem for the construction of ∂g or $\partial_B g$. Since the Rademacher theorem does not apply in infinite dimensional spaces, the above generalized Newton method cannot be extended to infinite dimensional spaces.

ii) Even if g is locally Lipschitz continuous, as required by the Rademacher theorem, and the problem is finite dimensional, as in this paper, it is difficult to calculate a V in either $\partial g(x)$ or $\partial_B g(x)$ when $g = \nabla f_d$ since there are no exact calculus rules for the Clarke generalized Jacobian and the B-differential.

iii) It follows from the definitions of ∂g and $\partial_B g$ that the computation of a V in either $\partial g(x)$ or $\partial_B g(x)$ when $g = \nabla f_d$ involves the computation of the second derivative of F or the generalized Jacobian of ∇F. This is not practical even if $\nabla^2 F$ exists. When F is only continuously differentiable, the generalized Jacobians of ∇F, $\partial(\nabla F)$, and $\partial_B(\nabla F)$ do not exist at all.

In [27], some approximate substitutes called computable generalized Jacobians are introduced to overcome the above difficulties. Using these computable generalized Jacobians, a globally and superlinearly convergent algorithm for minimizing the D-gap function for the VI problem is presented in [27] when F is smooth and S is defined by some twice-smooth convex functions. In that algorithm, the local method is the generalized Newton method while the global part of that algorithm is a trust region method. Notably, the generalized Newton method for solving (1.9) with $g = \nabla f_d$

in [27] does not require that ∇F or g are locally Lipschitz continuous. The D-gap function is further studied in [15].

When F is only locally Lipschitz, the stationarity problem associated with (1.8) is to find an x such that

$$0 \in G(x). \tag{1.11}$$

So far, there are no generalized Newton methods which solve a system of linear equations as a subproblem, for solving such a set-valued inclusion problem.

In this paper, we will introduce a new operator, called a *Newtonian operator*. For any $x \in \Re^n$, the value of the Newtonian operator, $T(x)$, is a compact set of $n \times n$ symmetric matrices. We will call to the value of the Newtonian operator a *Newtonian*. The calculation of a Newtonian does not involve any second-order properties of F, and Newtonian operators exist even when F is only locally Lipschitz. We will construct a local, superlinearly convergent generalized Newton method, based on our Newtonian operator, for solving both (1.9) and (1.11). Then we will construct a general globally convergent model of some first-order algorithms for solving (1.9) and (1.11). Combining the generalized Newton method and the general model of first-order methods, we will present a general globally and superlinearly convergent algorithm for minimizing a normal merit function in this class.

We use $\|\cdot\|$ for the 2-norms and denote $\mathsf{N} = \{0, 1, 2, \ldots\}$.

2. Newtonian operators and a generalized Newton method. We now formally define the *Newtonian operator*.

DEFINITION 2.1. *Suppose that F is locally Lipschitz and f is a normal merit function. Let $G = \partial f$. Suppose that T is a set-valued operator mapping from $\Re^n$ to $\Re^{n\times n}$. We say that T is a* Newtonian operator *of f if for any x^* solving the problem, there is a neighborhood $U(x^*)$ of x^* such that*

i) *T is upper semicontinuous at x^*;*

ii) *for any $x \in U(x^*)$, $T(x)$ is a nonempty compact set of $n \times n$ symmetric matrices;*

iii) *there is an* auxiliary*, possibly set-valued,* operator *q mapping from $\Re^n \times \Re^{n\times n}$ to $\Re^{n\times n}$ such that for any $x \in U(x^*)$ and $W \in T(x)$ there is a $V \in \partial F(x)$ such that $W \in q(x, V)$;*

iv) *for $d \in \Re^n$ small enough, any $V \in \partial F(x^* + d)$ and any $W \in q(x^* + d, V)$ ($W = q(x^* + d, V)$ if the latter is single-valued),*

$$p(x^* + d, V) - Wd = o(\|d\|), \tag{2.1}$$

where p is the auxiliary function in the definition of the normal merit function. We call T a strong Newtonian operator of f if instead of (2.1) *we have*

$$p(x^* + d, V) - Wd = O(\|d\|^2). \tag{2.2}$$

If F is smooth, we may combine iii) and iv) in the above definition as

iii)$'$ for $d \in \Re^n$ small enough and any $W \in T(x^* + d)$,

$$g(x^* + d) - Wd = o(\|d\|).$$

Recall [26, 25] that a locally Lipschitz continuous function F is said to be *semismooth* at $x \in \Re^n$ if and only if F is directionally differentiable at x and for any $V \in \partial F(x + d)$,

$$F'(x; d) = Vd + o(\|d\|). \tag{2.3}$$

If F is semismooth at x, then for any $V \in \partial F(x+d)$,

$$F(x+d) = F(x) + Vd + o(\|d\|). \tag{2.4}$$

We say that F is *strongly semismooth* at x if F is semismooth at x and for any $V \in \partial F(x+d)$,

$$F'(x;d) = Vd + O(\|d\|^2). \tag{2.5}$$

If F is strongly semismooth at x, then for any $V \in \partial F(x+d)$,

$$F(x+d) = F(x) + Vd + O(\|d\|^2). \tag{2.6}$$

PROPOSITION 2.2. *Consider* (1.1). *Suppose that F is semismooth at all solutions of* (1.1). *Let T be defined by $T(x) = \{V^T V \mid V \in \partial F(x)\}$. Then T is a Newtonian operator of f_n, where f_n is the norm function of NE. If F is strongly semismooth at all solutions of* (1.1), *then T is a strong Newtonian operator of f_n.*

Proof. Clearly, properties i) and ii) of Definition 2.1 hold for T. Let $q(x,V) = V^T V$. Then property iii) holds for T. Let $V \in \partial F(x^*+d)$ and $W = q(x^*+d, V)$. Then by (1.7),

$$\begin{aligned} p(x^*+d,V) - Wd &= V^T F(x^*+d) - V^T V d \\ &= V^T[F(x^*+d) - Vd] \\ &= V^T[F(x^*+d) - F(x^*) - Vd] \quad (\text{since } F(x^*) = 0) \\ &= o(\|d\|) \qquad\qquad\qquad\qquad\qquad\qquad (\text{by (2.4)}). \end{aligned}$$

This shows that property iv) of Definition 2.1 holds for T. Hence T is a Newtonian operator of f_n. Similarly, when F is strongly semismooth, we can show that T is a strong Newtonian operator. This completes the proof. ∎

In the next section, we will show that the D-gap function has a Newtonian operator even when F is only locally Lipschitz. Note that Newtonian operators of a normal merit function are not unique. Suppose that T is a Newtonian operator of a normal merit function f, x_0 is a fixed point in $\Re^n$, and M is a fixed $n \times n$ symmetric matrix. Define $T_0(x) \equiv T(x)$ if $x \neq x_0$ and $T_0(x_0) = T(x_0) \cup \{M\}$. Then T_0 is also a Newtonian operator of f.

We now propose a generalized Newton method for solving (1.11) as follows:

$$x_{k+1} = x_k - W_k^{-1} p(x_k, V_k), \tag{2.7}$$

where $V_k \in \partial F(x_k)$ and $W_k \in q(x_k, V_k)$.

Note that, even when F is smooth, (2.7) is more general than (1.10).

For any $x_0 \in \Re^n$ and $\delta > 0$, let $N(x_0;\delta) = \{x \in \Re^n : \|x - x_0\| \leq \delta\}$. The proof of the following lemma follows directly [26] from the first two properties of a Newtonian operator.

LEMMA 2.3. *Suppose that x^* is a solution of the problem. If all $W \in T(x^*)$ are nonsingular, then there are $c > 0$ and $\delta > 0$ such that for all $x \in N(x^*;\delta)$, all $W \in T(x)$ are nonsingular and*

$$\|W^{-1}\| \leq c. \tag{2.8}$$

We now can state the superlinear convergence theorem for our generalized Newton method (2.7).

THEOREM 2.4. *Suppose that T is a Newtonian operator of a normal merit function f, x^* is a solution of the problem, and all $W \in T(x^*)$ are nonsingular. Then the generalized Newton method* (2.7) *converges to x^* superlinearly in a neighborhood of x^*. Furthermore if T is a strong Newtonian operator of f, then this convergence is quadratic.*

Proof. For x close to x^* enough, we have

$$\begin{aligned}\|x_{k+1} - x^*\| &= \|x_k - x^* - W_k^{-1} p(x_k, V_k)\| && \text{(by (2.7))}\\ &\le \|W_k^{-1}\| \cdot \|p(x_k, V_k) - W_k(x_k - x^*)\| \\ &\le c\|p(x_k, V_k) - W_k(x_k - x^*)\| && \text{(by (2.8))}\\ &= o(\|x_k - x^*\|) && \text{(by (2.1)).}\end{aligned}$$

This shows superlinear convergence. Quadratic convergence can be proved similarly under the condition that T is a strong Newtonian. This completes the proof. ∎

Combining Proposition 2.2 and Theorem 2.4 and noting the equivalence between nonsingularity of all matrices in $\partial F(x^*)$ and nonsingularity of all matrices in $T(x^*)$, we have the following corollary.

COROLLARY 2.5. *Suppose that F is locally Lipschitz on $\Re^n$ and semismooth at a solution x^* of* (1.1). *Suppose that all matrices in $\partial F(x^*)$ are nonsingular. Then in a neighborhood of x^*, the Gauss–Newton method*

$$x_{k+1} = x_k - (V_k^T V_k)^{-1} V_k^T F(x_k),$$

where $V_k \in \partial F(x_k)$, converges to x^* superlinearly. If F is strongly semismooth at x^*, then this convergence is quadratic.

If we use ∂_B instead of ∂ throughout our discussion, then we have the following result.

COROLLARY 2.6. *Suppose that F is locally Lipschitz on $\Re^n$ and semismooth at a solution x^* of* (1.1). *Suppose that all matrices in $\partial_B F(x^*)$ are nonsingular. Then in a neighborhood of x^*, the Gauss–Newton method*

$$x_{k+1} = x_k - (V_k^T V_k)^{-1} V_k^T F(x_k),$$

where $V_k \in \partial_B F(x_k)$, converges to x^* superlinearly. If F is strongly semismooth at x^*, then this convergence is quadratic.

3. The VI problem. We now consider the D-gap function f_d, defined by (1.4) and (1.5). By [29], it satisfies properties (i)–(iv) of a normal merit function.

Assume that F is locally Lipschitz on $\Re^n$. By [27], if F is differentiable at x, then

$$\begin{aligned} g(x) &\equiv \nabla f_d(x) \\ &= \nabla F(x)(y_\beta(x) - y_\alpha(x)) + (\beta - \alpha)x + (\alpha y_\alpha(x) - \beta y_\beta(x)),\end{aligned}$$

where $y_\alpha(x) = \Pi_S(x - \alpha^{-1}F(x))$, $y_\beta(x) = \Pi_S(x - \beta^{-1}F(x))$, and Π_S is the projection operator on the set S. From this, we have

$$G(x) = \partial f_d(x) = \{p(x, V) \mid V \in \partial F(x)\},$$

where

$$p(x, V) = (V^T - \alpha I)(x - y_\alpha(x)) - (V^T - \beta I)(x - y_\beta(x)).$$

Hence property (v) of a normal merit function is also satisfied. This shows that f_d is a normal merit function of the VI problem.

Throughout the rest of this paper, we assume that

$$S = \{y \in \Re^n \mid h_i(y) \leq 0, i = 1, \ldots, m\}, \tag{3.1}$$

where each h_i is twice-continuously differentiable and convex. In [27], a computable generalized Hessian of the D-gap function was constructed for such a set S when F is smooth. By Lemma 4.1 of [27], such a computable generalized Hessian is in fact a Newtonian operator of the D-gap function. We now extend this result to the case when F is only locally Lipschitz on $\Re^n$ and semismooth at solutions.

Let $x \in \Re^n$ and $\bar{y} = \Pi_S(x)$. Then $\bar{y}$ is the unique solution of the following nonlinear programming problem in y :

$$\begin{array}{ll} \min & \dfrac{1}{2}\|y - x\|^2 \\ \text{subject to} & h_i(y) \leq 0, \quad i = 1, \ldots, m. \end{array} \tag{3.2}$$

Let $\mathcal{M}(x)$ denote the set of multipliers $\lambda \in \Re^m$ that satisfy KKT optimality conditions for (3.2) at $\bar{y}$:

$$\begin{gathered} \bar{y} - x + \sum_{i=1}^{m} \lambda_i \nabla h_i(\bar{y}) = 0, \\ \lambda_i \geq 0, \quad h_i(\bar{y}) \leq 0, \quad \lambda_i h_i(\bar{y}) = 0, \quad i = 1, \ldots, m. \end{gathered} \tag{3.3}$$

For any $y \in \Re^n$, we will denote the active set by

$$I(y) = \{i \mid h_i(y) = 0\}.$$

For a nonnegative vector $d \in \Re^m$, we let supp(d), called the support of d, be the subset of $\{1, \ldots, m\}$ consisting of the indices i for which $d_i > 0$. Let $\mathcal{C}(x)$ be a family of subsets of $\{1, \ldots, m\}$ defined as follows: $J \in \mathcal{C}(x)$ if and only if

$$\text{supp}\,(\lambda) \subseteq J \subseteq I(\bar{y}) \tag{3.4}$$

for some $\lambda \in \mathcal{M}(x)$. We say that the linear independence constraint qualification (LICQ) holds at $\bar{y}$ if the family of vectors

$$\{\nabla h_i(\bar{y}) \mid i \in I(\bar{y})\}$$

are linearly independent. We say that the constant rank constraint qualification (CRCQ) holds at $\bar{y}$ if there exists a neighborhood $N(\bar{y})$ of $\bar{y}$ such that for every set $J \subseteq I(\bar{y})$, the family of gradient vectors

$$\{\nabla h_i(y) \mid i \in J\}$$

has the same rank (which depends on J) for all vectors $y \in N(\bar{y})$ [12, 20]. Clearly, CRCQ is weaker than LICQ.

Let $\mathcal{B}(x)$ be the subfamily of $\mathcal{C}(x)$ such that $J \in \mathcal{B}(x)$ if and only if $J \in \mathcal{C}(x)$ and the vectors

$$\{\nabla h_i(\bar{y}) \mid i \in J\} \tag{3.5}$$

are linearly independent. Here, we allow the empty index set to be a member of $\mathcal{B}(x)$ and $\mathcal{C}(x)$.

For any $x \in \Re^n$ where CRCQ holds, we define

$$\Lambda_S(x) := \{P(x;J) \mid J \in \mathcal{B}(x)\}, \tag{3.6}$$

where $P(x;\emptyset) = I$ and if $J \neq \emptyset$,

$$P(x;J) = C^{-1} - C^{-1}D\left(D^TC^{-1}D\right)^{-1}D^TC^{-1}, \tag{3.7}$$

with

$$C \equiv C(x;J) \equiv I + \sum_{i=1}^{m} \lambda_i(x;J)\nabla^2 h_i(\Pi_S(x)), \quad D \equiv D(x;J) \equiv \nabla h_J(\Pi_S(x)), \tag{3.8}$$

and $\lambda = \lambda(x;J)$ is the multiplier used in (3.4) for the definition of J. Notice that the matrix $C = C(x,J)$ does not depend on the multipliers under CRCQ, at least as it operates on critical directions [20]. Since the vectors in (3.5) are linearly independent, by (3.3), $\lambda = \lambda(x;J)$ is uniquely determined by x and J.

Summarizing Lemmas 2.1–2.3 of [27], we have the following lemma.

LEMMA 3.1. *If CRCQ holds at $\bar{y} = \Pi_S(x)$, then there exists a neighborhood $N(x)$ of x, and for each $J \in \mathcal{B}(x)$ there exists a function $y(\cdot;J)$, such that*

(i) *for all $J \in \mathcal{B}(x)$, both $y(\cdot;J)$ and $\lambda(\cdot;J)$ are continuously differentiable in $N(x)$; and for all $z \in N(x)$,*

(ii) *CRCQ holds at $\Pi_S(z)$;*

(iii) *$\mathcal{B}(z) \subseteq \mathcal{B}(x)$;*

(iv) *$\Pi_S(z) = y(z;J)$ for all $J \in \mathcal{B}(z)$;*

(v) *$P(z;J) = \nabla y(z;J)$ is symmetric positive semidefinite and $\|P(z;J)\| \leq 1$, for all $J \in \mathcal{B}(z)$.*

The following theorem follows from the above lemma.

THEOREM 3.2. *If CRCQ holds at $\bar{y} = \Pi_S(x)$, then for any $P \in \Lambda_S(x+d)$,*

$$\Pi_S(x+d) = \Pi_S(x) + Pd + o(\|d\|). \tag{3.9}$$

Furthermore if all $\nabla^2 h_i$ are locally Lipschitz, then

$$\Pi_S(x+d) = \Pi_S(x) + Pd + O(\|d\|^2).$$

Proof. By Lemma 3.1, for $\|d\|$ small enough and $P \in \Lambda_S(x+d)$,

$$\Pi_S(x+d) - \Pi_S(x) - Pd = y(x+d;J) - y(x;J) - \nabla y(x;J)d$$

for some $J \in \mathcal{B}(x)$. Hence, we have our first conclusion.

If all $\nabla^2 h_i$ are locally Lipschitz, then by (3.7) and (3.8), $P(\cdot;J)$ is locally Lipschitz. The second conclusion follows now. □

We now can state the main result in this section.

THEOREM 3.3. *Consider* (1.2). *Suppose that F is semismooth and CRCQ holds at all solutions of* (1.2). *Let T be defined by $T(x) = \{q(x,V) \mid V \in \partial F(x)\}$, where*

$$\begin{aligned} & q(x,V) \\ & = (V^T - \alpha I)(I - \Lambda_S(x - \alpha^{-1}F(x))(I - \alpha^{-1}V)) \\ & -(V^T - \beta I)(I - \Lambda_S(x - \beta^{-1}F(x))(I - \beta^{-1}V)). \end{aligned}$$

Then T is a Newtonian operator of f_d, where f_d is the D-gap function of the VI problem. Furthermore if all $\nabla^2 h_i$ are locally Lipschitz and F is strongly semismooth at all solutions of (1.2)*, then T is a strong Newtonian operator of f_d.*

Proof. Suppose that x^* is a solution of (1.2). Then

$$x^* = \Pi_S(x^* - \alpha^{-1}F(x^*)) = \Pi_S(x^* - \beta^{-1}F(x^*)). \tag{3.10}$$

By Lemma 3.1, Λ_S is upper semicontinuous at x^*. Since ∂F is a closed operator, T is upper semicontinuous at x^*. This proves that property i) of the definition of a Newtonian operator holds for T.

By Lemma 3.1 and (3.10), for x in a neighborhood of x^*, $\Lambda_S(x - \alpha^{-1}F(x))$ and $\Lambda_S(x - \beta^{-1}F(x))$, are nonempty, compact sets of $n \times n$ symmetric matrices. Then, property ii) of the definition of a Newtonian operator follows, for T, from the expression of $q(x, V)$.

By the definition of $q(x, V)$, property iii) of the definition of a Newtonian operator holds.

Let $V \in \partial F(x^* + d)$ and $W \in q(x^* + d, V)$. Then there are $P_\alpha \in \Lambda_S(x^* + d - \alpha^{-1}F(x^* + d))$ and $P_\beta \in \Lambda_S(x^* + d - \beta^{-1}F(x^* + d))$ such that

$$W = (V^T - \alpha I)(I - P_\alpha(I - \alpha^{-1}V)) - (V^T - \beta I)(I - P_\beta(I - \beta^{-1}V)).$$

For $\|d\|$ small enough, we have

$$\begin{aligned}
&p(x^* + d, V) - Wd \\
&= (V^T - \alpha I)[x^* + d - \Pi_S(x^* + d - \alpha^{-1}F(x^* + d)) - (I - P_\alpha(I - \alpha^{-1}V))d] \\
&-(V^T - \beta I)[x^* + d - \Pi_S(x^* + d - \beta^{-1}F(x^* + d)) - (I - P_\beta(I - \beta^{-1}V))d] \\
&= (V^T - \alpha I)[\Pi_S(x^* - \alpha^{-1}F(x^*)) - \Pi_S(x^* + d - \alpha^{-1}F(x^* + d)) + P_\alpha(d - \alpha^{-1}Vd)] \\
&-(V^T - \beta I)[\Pi_S(x^* - \beta^{-1}F(x^*)) - \Pi_S(x^* + d - \beta^{-1}F(x^* + d)) + P_\beta(d - \beta^{-1}Vd)] \\
&\quad \text{(by (3.10))} \\
&= (V^T - \alpha I)[\alpha^{-1}P_\alpha(F(x^* + d) - F(x^*) - Vd) + o(\|\alpha^{-1}(F(x^* + d) - F(x^*)) - d\|)] \\
&-(V^T - \beta I)[\beta^{-1}P_\beta(F(x^* + d) - F(x^*) - Vd) + o(\|\beta^{-1}(F(x^* + d) - F(x^*)) - d\|)] \\
&\quad \text{(by (3.9))} \\
&= (V^T - \alpha I)[P_\alpha \cdot o(\|d\|) + o(\|F(x^* + d) - F(x^*)\|) + o(\|d\|)] \\
&-(V^T - \beta I)[P_\beta \cdot o(\|d\|) + o(\|F(x^* + d) - F(x^*)\|) + o(\|d\|)] \\
&\quad \text{(by (2.4))} \\
&= (V^T - \alpha I) \cdot o(\|d\|) - (V^T - \beta I) \cdot o(\|d\|) \\
&\quad \text{(by Lemma 3.1)} \\
&= o(\|d\|),
\end{aligned}$$

where the last equality is due to local boundedness of ∂F. This shows that property iv) of Definition 2.1 holds for T. Hence T is a Newtonian operator of f_d. Similarly we can prove the strong conclusion from the strong condition. This completes the proof. □

Note that f_d will reduce to $(\alpha^{-1} - \beta^{-1})f_n$ if $S = \Re^n$. Hence we may think the generalized Newton method (2.7) applied to f_d as a generalized version of the Gauss–Newton method for solving the VI problem.

4. First-order methods. Our globalization algorithm for the local Newton methods that we have described depends on the use of first-order, unconstrained optimization methods that are locally uniformly cost decreasing. We define this property as follows.

DEFINITION 4.1. *Consider the unconstrained optimization problem*

$$\min_{x \in \Re^n} f(x), \tag{4.1}$$

where f is at least locally Lipschitz continuous. We will say that an algorithm iteration map $A : \Re^n \to 2^{\Re^n}$ is locally uniformly cost decreasing, with respect to (4.1)*, if*

(i) *for any $x \in \Re^n$ such that $0 \notin \partial f(x)$, there exists a $\rho_x > 0$ and a $\delta_x > 0$ such that*

$$f(x'') - f(x') \leq -\delta_x \tag{4.2}$$

for all $x' \in N(x; \rho_x)$ and all $x'' \in A(x')$; and

(ii) *for all x such that $0 \in \partial f(x)$, $A(x) = \{x\}$.*

The most important property of algorithms that are locally uniformly cost decreasing, with respect to problem (4.1), is given below.

THEOREM 4.2. *Suppose that the algorithm iteration map $A : \Re^n \to 2^{\Re^n}$ is locally uniformly cost decreasing with respect to problem* (4.1) *and that, given an $x_0 \in \Re^n$, the sequence $\{x_i\}_{i=0}^{\infty}$ is constructed according to the rule*

$$x_{i+1} \in A(x_i), \quad i = 0, 1, 2, \ldots. \tag{4.3}$$

Then every accumulation point $\hat{x}$ of $\{x_i\}_{i=0}^{\infty}$ is stationary (i.e., $0 \in \partial f(\hat{x})$).

Proof. Without loss of generality, we can assume that $0 \notin \partial f(x_i)$ for all $i \in \mathsf{N}$. Hence it follows from (4.2) that $f(x_{i+1}) < f(x_i)$ for all $i \in \mathsf{N}$, and hence, if $\{x_i\}_{i=0}^{\infty}$ has an accumulation point $\hat{x}$, we must have that $f(x_i) \to f(\hat{x})$, as $i \to \infty$.

For the sake of contradiction, suppose that $0 \notin \partial f(\hat{x})$. Then, since $\hat{x}$ is an accumulation point of $\{x_i\}_{i=0}^{\infty}$, it follows from (4.2) that there exists a $\hat{\delta} > 0$ and a subsequence $\{x_{i_k}\}_{i=0}^{\infty}$ of $\{x_i\}_{i=0}^{\infty}$, such that $x_{i_k} \to \hat{x}$ as $k \to \infty$, and

$$f(x_{i_{k+1}}) - f(x_{i_k}) \leq -\hat{\delta} \tag{4.4}$$

for all $k \in \mathsf{N}$. Since this implies that $f(x_i) \to -\infty$ as $i \to \infty$, we have a contradiction, which completes our proof. □

When the function f in (4.1) is continuously differentiable, we have at least two choices of an algorithm iteration map $A : \Re^n \to 2^{\Re^n}$, which is locally uniformly cost decreasing, with respect to problem (4.1). The first is the iteration map of Armijo gradient method [1]; the other is a class of trust region methods.

THEOREM 4.3. *Suppose that the function f in* (4.1) *is continuously differentiable. Consider the Armijo gradient method iteration map $A : \Re^n \to 2^{\Re^n}$, for problem* (4.1)*, defined by*

$$A(x) := \{x - \lambda(x)\nabla f(x)\}, \tag{4.5}$$

where, for fixed $\alpha, \beta \in (0,1)$,

$$\lambda(x) := \max_{k \in \mathsf{N}} \{\beta^k | f(x - \beta^k \nabla f(x)) - f(x) + \beta^k \alpha \|\nabla f(x)\|^2 \leq 0\}. \tag{4.6}$$

The map A is locally uniformly cost decreasing, with respect to problem (4.1).

Proof. Suppose that $x^* \in \Re^n$ is such that $\nabla f(x) \neq 0$. Let $\varepsilon > 0$ be such that $\alpha + \varepsilon < 1$. Then there exists a $k^* \in \mathsf{N}$ such that

$$f(x^* - \beta^{k^*} \nabla f(x^*)) - f(x^*) \leq -\beta^{k^*}(\alpha + \varepsilon)\|\nabla f(x^*)\|^2. \tag{4.7}$$

Rearranging the terms in (4.7), we obtain that

$$f(x^* - \beta^{k^*} \nabla f(x^*)) + \beta^{k^*} \alpha \|\nabla f(x^*)\|^2 \leq -\beta^{k^*} \varepsilon \|\nabla f(x^*)\|^2. \tag{4.8}$$

It now follows from the continuity of f and of ∇f that there exists a $\rho^* > 0$ such that for all $x \in N(x^*; \rho^*)$, $\lambda(x) \geq \beta^{k^*}$ and $\|\nabla f(x)\|^2 \geq 1/2 \ \|\nabla f(x^*)\|^2$. Hence for all $x \in N(x^*; \rho^*)$,

$$f(A(x)) - f(x) \leq -1/2 \ \beta^{k^*} \alpha \|\nabla f(x^*)\|^2 := -\delta^*, \tag{4.9}$$

which completes our proof. □

Referring to [23], we find that when the function f in (4.1) is continuously differentiable, the following trust region algorithm iteration map is uniformly cost decreasing, with respect to problem (4.1).

Let H be a symmetric $n \times n$ matrix-valued function defined on $\Re^n$, let $\phi : \Re^n \to \Re$ be defined by

$$\phi(h) := \langle \nabla f(x), h \rangle + 1/2 \ \langle h, H(x)h \rangle, \tag{4.10}$$

let $\alpha, \beta \in (0,1)$, $\sigma_{\max} > 0$ be parameters, let $\Delta : \Re^n \times \mathsf{N} \to \Re^n$ be defined by

$$\Delta(x,k) := \min_{\lambda} \{\phi(-\lambda \nabla f(x)) | \lambda \|\nabla f(x)\| \leq \beta^k \sigma_{\max}\}, \tag{4.11}$$

for any $x \in \Re^n$, $k \in \mathsf{N}$, let $G(x,k) \subset \Re^n$ be defined by

$$G(x,k) := \{h \in \Re^n | \phi(h) \leq \Delta(x,k)\}, \tag{4.12}$$

and let

$$(D(x), K(x)) := \arg\max\{\beta^k | k \in \mathsf{N}, h \in G(x,k), f(x+h) - f(x) \leq \alpha\phi(h)\}. \tag{4.13}$$

Then we define the set-valued trust region algorithm iteration map $A : \Re^n \to 2^{\Re^n}$ as follows:

$$A(x) := \{x + h | h \in D(x)\}. \tag{4.14}$$

We infer from Theorem 1.2.29 in [23] the following result.

THEOREM 4.4. *Suppose that the function f in* (4.1) *is continuously differentiable and that there exists a* $c \in (0, \infty)$ *such that* $||H(x)|| \leq c$ *for all* $x \in \Re^n$. *Then the trust region algorithm iteration map A, defined by* (4.14), *is locally uniformly cost decreasing, with respect to* (4.1).

When the function f in (4.1) is only locally Lipschitz continuous, we can use algorithms based on *augmented convergent direction finding maps* that were introduced in [22]. These were defined as follows.

DEFINITION 4.5. *Let $f : \Re^n \to \Re$ be locally Lipschitz continuous. We shall say that $\bar{G}f : \Re^n \to 2^{\Re^{n+1}}$ is an* augmented convergent direction finding *(a.c.d.f.) map for f if*

(a) *$\bar{G}f$ is continuous (i.e., both upper and lower semicontinuous) and $\bar{G}f(x)$ is convex for all $x \in \Re^n$.*

(b) *for any $x \in \Re^n$, if $\bar{\xi} = (\xi^0, \xi) \in \Re^{n+1}$, where $\xi \in \Re^n$, is an element of $\bar{G}f(x)$, then $\xi^0 \geq 0$.*

(c) *for any $x \in \Re^n$, a point $\bar{\xi} = (0, \xi)$ is an element of $\bar{G}f(x)$ if and only if $\xi \in \partial f(x)$, where $\partial f(x)$ denotes the Clarke generalized gradient.*

In [22], we find the following result.

THEOREM 4.6. *Suppose that $f : \Re^n \to \Re$ is locally Lipschitz continuous and $\bar{G}f$ is an a.c.d.f. map for f. Then for any $x \in \Re^n$,*

(a) *$0 \in \partial f(x)$ if and only if $0 \in \bar{G}f(x)$.*

(b) *The functions $\Theta : \Re^n \to \Re$ and $\bar{h} : \Re^n \to \Re^{n+1}$ defined by*

$$\Theta(x) := \min\{\xi^0 + 1/2 \ \|\xi\|^2 | \bar{\xi} = (\xi^0, \xi) \in \bar{G}f(x)\}, \tag{4.15}$$

where $\xi^0 \in \Re$ and $\xi \in \Re^n$, and

$$\bar{h}(x) := \operatorname{argmin} \{\xi^0 + 1/2 \ ||\xi||^2 | \bar{\xi} \in \bar{G}f(x)\} \tag{4.16}$$

are both continuous. Furthermore $\Theta(x) = 0$ if and only if $0 \in \partial f(x)$.

(c) *Writing $\bar{h}(x) = (h^0(x), h(x))$, with $h(x) \in \Re^n$ we have*

$$d_0 f(x; h(x)) \leq -\Theta(x) \quad \forall x \in \Re^n, \tag{4.17}$$

where $d_0 f(x; h)$ denotes the Clarke generalized directional derivative.

The following algorithm map is a generalization of the Armijo gradient method for differentiable functions. See [22, section 5] for a proof of the following result.

THEOREM 4.7. *Suppose that the function f in* (4.1) *is locally Lipschitz continuous and that $\bar{G}f$ is an a.c.d.f. for f. Consider the generalized Armijo gradient method iteration map $A : \Re^n \to 2^{\Re^n}$, for problem* (4.1)*, defined by*

$$A(x) := \{x + \lambda(x)h(x)\}, \tag{4.18}$$

where $h(x)$ is defined by (4.16) *and, for fixed $\alpha, \beta \in (0, 1)$,*

$$\lambda(x) := \max_{k \in \mathsf{N}} \{\beta^k | f(x + \beta^k h(x)) - f(x) + \beta^k \alpha \Theta(x) \leq 0\}, \tag{4.19}$$

with $\Theta(x)$ defined by (4.15)*. Then the map A is locally uniformly cost decreasing with respect to problem* (4.1)*.*

5. A globally and superlinearly convergent algorithm. We now consider problem (1.8) again, where f is a normal merit function for the NE or VI problem, with F locally Lipschitz on $\Re^n$. Suppose that there is an algorithm iteration map $A : \Re^n \to 2^{\Re^n}$, which is locally uniformly cost decreasing, with respect to problem (1.8). Suppose that T is a Newtonian operator of f, with an auxiliary operator q. Then we have the following algorithm.

ALGORITHM 5.1. Let $x_0 \in \Re^n$ and $\epsilon \in (0, 1)$.

For any $k \in \mathsf{N}$, let

$$\hat{x}_k = x_k - W_k^{-1} p(x_k, V_k), \tag{5.1}$$

where $V_k \in \partial F(x_k)$ and $W_k \in q(x_k, V_k)$. If

$$f(\hat{x}_k) \leq \epsilon f(x_k), \tag{5.2}$$

let $x_{k+1} = \hat{x}_k$. Otherwise let $x_{k+1} \in A(x_k)$.

If $x_{k+1} = \hat{x}_k$, we call this a Newton step. To prove the convergence theorem for this algorithm, we need the following lemma.

LEMMA 5.2. *Suppose that x^* is a solution of the problem. If all $W \in T(x^*)$ are positive definite, then there are $c_1 > c_2 > 0$ and $\delta > 0$ such that for all $x \in N(x^*; \delta)$, all $W \in T(x)$ are positive definite and*

$$c_2\|x - x^*\|^2 \le f(x) \le c_1\|x - x^*\|^2. \tag{5.3}$$

Proof. Since all $W \in T(x^*)$ are positive definite, by the four properties of a Newtonian operator, there are $c_1 > 5c_2 > 0$ and $\delta > 0$ such that for all $x \in N(x^*; \delta)$, all $V \in \partial F(x)$ and all $W \in q(x, V)$,

$$2.5c_2\|x - x^*\|^2 \le (x - x^*)^T W(x - x^*) \le 0.5c_1\|x - x^*\|^2 \tag{5.4}$$

and

$$\|p(x, V) - W(x - x^*)\| \le 0.5c_2\|x - x^*\|. \tag{5.5}$$

Now, by the Lebourg mean-value theorem (MVT) (Theorem 2.3.7 of [2]), for any $x \in N(x^*; \delta)$,

$$\begin{aligned} f(x) &= f(x) - f(x^*) && \text{(since } f(x^*) = 0\text{)} \\ &= p(x^* + t(x - x^*), V)^T(x - x^*) && \text{(by MVT)} \\ &\le t(x - x^*)^T W(x - x^*) + 0.5c_2\|x - x^*\|^2 && \text{(by (5.5))} \\ &\le 0.5tc_1\|x - x^*\|^2 + 0.5c_2\|x - x^*\|^2 && \text{(by (5.4))} \\ &\le c_1\|x - x^*\|^2, \end{aligned}$$

where $0 \le t \le 1, V \in \partial F(x^* + t(x - x^*))$ and $W \in q(x^* + t(x - x^*), V)$. Similarly, for any $x \in N(x^*; \delta)$,

$$\begin{aligned} f(x) &= f(x) - f(x^*) \qquad \text{(since } f(x^*) = 0\text{)} \\ &= \lim_{N\to\infty} \sum_{j=1}^{N} \left[f\left(x^* + \frac{j}{N}(x - x^*)\right) - f\left(x^* + \frac{j-1}{N}(x - x^*)\right)\right] \\ &= \lim_{N\to\infty} \sum_{j=1}^{N} \frac{1}{N} p\left(x^* + \frac{j - 1 + t_j}{N}(x - x^*), V_j\right)^T (x - x^*) \qquad \text{(by MVT)} \\ &\ge \lim_{N\to\infty} \sum_{j=1}^{N} \left[\frac{j - 1 + t_j}{N^2}(x - x^*)^T W_j(x - x^*) - \frac{0.5c_2(j - 1 + t_j)}{N^2}\|x - x^*\|^2 \right] \\ &\quad \text{(by (5.5))} \\ &\ge \lim_{N\to\infty} \sum_{j=1}^{N} \left[\frac{j-1}{N^2}(x - x^*)^T W_j(x - x^*) - \frac{0.5c_2 j}{N^2}\|x - x^*\|^2 \right] \\ &\ge \lim_{N\to\infty} \sum_{j=1}^{N} \left[\frac{2.5c_2(j-1)}{N^2} - \frac{0.5c_2 j}{N^2} \right] \|x - x^*\|^2 \qquad \text{(by (5.4))} \\ &\ge \lim_{N\to\infty} \frac{[1.25N(N-1) - 0.25N(N+1)]c_2}{N^2}\|x - x^*\|^2 \\ &= c_2\|x - x^*\|^2, \end{aligned}$$

where $0 \le t_j \le 1, V_j \in \partial F(x^* + \frac{j-1+t_j}{N}(x - x^*))$, and $W_j \in q(x^* + \frac{j-1+t_j}{N}(x - x^*), V_j)$. This proves the lemma. ∎

For the NE problem with T defined by $T(x) = \{V^T V | V \in \partial F(x)\}$, all $W \in T(x^*)$ are positive definite as long as they are nonsingular. For the VI problem, the positive definiteness of matrices in $T(x^*)$ was established by Theorem 3.1 of [27].

We now can state the convergence theorem for Algorithm 5.1.

THEOREM 5.3. *Every accumulation point $\hat{x}$ of $\{x_k\}_{k=0}^{\infty}$, generated by Algorithm* 5.1*, is a stationary point of* (1.8)*, i.e., $0 \in \partial f(\hat{x})$. Function f has the same value on these accumulation points.*

If the Newton step is used infinitely many times, then every accumulation point of $\{x_k\}_{k=0}^{\infty}$ is a solution of the original problem. If at one of such accumulation point, say x^*, all matrices in $T(x^*)$ are positive definite, then the whole sequence $\{x_k\}_{k=0}^{\infty}$ converges to x^* superlinearly with $x_{k+1} = \hat{x}_k$ for all large k. Furthermore if T is a strong Newtonian operator of f, the convergence is quadratic.

Proof. Notice that

$$f(x_{k+1}) \leq f(x_k) \tag{5.6}$$

for all $k \in \mathsf{N}$.

If the Newton step is not used for all large k, then the conclusions follow from Theorem 4.2 and the nonincreasing property (5.6).

If the Newton step is used infinitely many times, then

$$\lim_{k \to \infty} f(x_k) = 0$$

by (5.2) and (5.6). Then every accumulation point of $\{x_k\}_{k=0}^{\infty}$ is a solution of the original problem. Suppose that x^* is such an accumulation point, hence a solution to the original problem. Suppose that all matrices in $T(x^*)$ are positive definite. Let x_k be close to x^*. Then by the proof of Theorem 2.4, we have

$$\|\hat{x}_k - x^*\| = o(\|x_k - x^*\|).$$

By Lemma 5.2, this implies,

$$f(\hat{x}^k) = o(f(x_k)).$$

This step and the following steps have to be Newton steps and the remaining conclusions follow from Theorem 2.4. □

This algorithm may end with a stationary point of (1.8) which is not a solution of the original problem. See page 152 of [4] for description of this phenomenon. An effort has been made in [18] to overcome this difficulty in the case of smooth nonlinear equations. However, if F is strongly monotone and f is the norm function for the NE problem or the D-gap function for the VI problem, any stationary point of f is the unique solution of the original problem [29, 27]. In this case, our algorithm converges to this unique solution of the original problem globally and superlinearly.

ERGODIC BOUNDARY/POINT CONTROL OF STOCHASTIC SEMILINEAR SYSTEMS*

T. E. DUNCAN†, B. MASLOWSKI‡, AND B. PASIK-DUNCAN†

Abstract. A controlled Markov process in a Hilbert space and an ergodic cost functional are given for a control problem that is solved where the process is a solution of a parameter-dependent semilinear stochastic differential equation and the control can occur only on the boundary or at discrete points in the domain. The linear term of the semilinear differential equation is the infinitesimal generator of an analytic semigroup. The noise for the stochastic differential equation can be distributed, boundary and point. Some ergodic properties of the controlled Markov process are shown to be uniform in the control and the parameter. The existence of an optimal control is verified to solve the ergodic control problem. The optimal cost is shown to depend continuously on the system parameter.

Key words. ergodic control, stochastic semilinear equations, Markov processes in Hilbert spaces, invariant measures, boundary control

1. Introduction.

An ergodic control problem for a stochastic process in a Hilbert space H is formulated and solved where the process is a solution of a parameter-dependent semilinear stochastic differential equation in H. The problem in the general setting is motivated by ergodic control problems for processes governed by stochastic partial differential equations (SPDEs) with control and noise occurring in the boundary conditions or at discrete points in the domain.

For example, consider the stochastic parabolic equation

$$\frac{\partial v}{\partial t}(t,\xi) = Lv(t,\xi) + F(\alpha, v(t,\xi)) + n(t,\xi) \tag{1.1}$$

for $(t,\xi) \in \mathbb{R}_+ \times (0,1)$ with initial and boundary conditions

$$v(0,\xi) = v_0(\xi), \tag{1.2}$$

$$\frac{\partial v}{\partial \xi}(t,0) = h_1(\alpha, v(t,\cdot), u(v(t,\cdot))) + \eta_1(t), \tag{1.3}$$

$$\frac{\partial v}{\partial \xi}(t,1) = h_2(\alpha, v(t,\cdot), u(v(t,\cdot))) + \eta_2(t), \tag{1.4}$$

where n denotes a space-dependent Gaussian noise that is white in time, η_1 and η_2 are one-dimensional standard Wiener processes, and these three processes are mutually independent. Furthermore,

$$Lv = a(\xi)\frac{\partial^2}{\partial \xi^2}v + b(\xi)\frac{\partial}{\partial \xi}v + c(\xi)v$$

is a second-order uniformly elliptic operator, where $a, b, c \in C^\infty([0,1])$, $a > 0$, $c < 0$, $F : \mathcal{A} \times \mathbb{R} \to \mathbb{R}$, $h_i : \mathcal{A} \times H \times \mathcal{K} \to \mathbb{R}$, $i = 1, 2$, where $H = L^2(0,1)$, $\mathcal{A} \subset \mathbb{R}^{d_1}$, and $\mathcal{K} \subset \mathbb{R}^k$ are compact. The control problem is to minimize the ergodic cost functional

$$J(x, u, \alpha) = \limsup_{T \to \infty} \mathbb{E} \frac{1}{T} \int_0^T c(v(t), u(v(t)))dt$$

over the set of Markov controls $\mathcal{U} = \{u : H \to \mathcal{K} \mid u \text{ is Borel measurable}\}$, where $c : H \times \mathcal{K} \to \mathbb{R}$. The $\alpha \in \mathcal{A}$ in (1.1)–(1.4) represents a parameter.

The equations (1.1), (1.3), and (1.4) are only formal because the noise terms n, η_1, and η_2 are not well-defined stochastic processes (random fields). A standard approach for the rigorous treatment of the problem is to rewrite (1.1) as a controlled stochastic differential equation in the Hilbert space H, and to define the noise terms using Wiener processes with infinite-dimensional state spaces and the solution to the equation as a mild solution, using the semigroup theory (cf. [10, 27]).

In the present paper, this general framework is used. The controlled Markov process is defined by a Hilbert space-valued stochastic differential equation ((2.1) below). The linear term of the equation is the infinitesimal generator of an analytic semigroup. The general setting allows us to cover, as special cases, stochastic boundary/point control problems like the above example (see Examples 7.1 and 7.2). The noise for the stochastic differential equation can be distributed, boundary and point. The parameter-dependence occurs in the distributed and the boundary or the point drift terms. The control occurs only in the boundary or point drift term. The fact that the control is not distributed would seem to allow for more physically meaningful models. The noise is allowed to occur in both distributed and discrete forms to ensure more flexibility of the models. Since the H-valued Markov process depends on the control and the parameter, it is shown that some ergodic properties of the process are uniform in these quantities. For the solution of an ergodic control problem the existence of an optimal control is verified. It is shown that the optimal cost depends continuously on the system parameter.

Continuity of the optimal cost on the parameter is an important step in solving the adaptive control problem when the parameter is unknown. This verification is important to show the optimality of an adaptive control defined by means of a family of strongly consistent estimators of the unknown parameter α. In the case when the control and noise are distributed, the existence of an optimal control has been proven in [13], while the continuity of the optimal cost is new for this case.

The continuity of the optimal cost follows readily from the continuous dependence of the invariant measures for the controlled Markov process on the parameter α, uniform in the controls, in the norm of total variation of measures. This result can be of some independent interest and it may be interesting to note that even in some very simple cases the situation for Hilbert space–valued processes is significantly different from the finite-dimensional case. For example, consider the linear stochastic heat equation (without control)

$$\frac{\partial w}{\partial t}(t, \xi) = \alpha \frac{\partial^2 w}{\partial \xi^2}(t, \xi) + n(t, \xi), \quad (t, \xi) \in \mathbb{R}_+ \times (0, 1),$$

with initial and boundary conditions $w(0, \xi) = w_0(\xi)$, $w(t, 0) = w(t, 1) = 0$, where $\alpha \in [1/2, 1]$ and n is a space-time white noise. It is well known (see, e.g., [28]) that for each value of α, the probability laws (in the state space $H = L_2(0,1)$)

of the solutions converge in the norm of total variation to the Gaussian invariant measure $\mu(\alpha) = N(0, Q(\alpha))$, where $Q(\alpha) = \alpha^{-1}Q$, $Q = \int_0^\infty S(2t)dt$, and $S(\cdot)$ is the semigroup generated by the operator of the second derivative on $(0, 1)$, with zero Dirichlet boundary conditions.

However, by the dichotomy result for Gaussian measures it is easy to see that the invariant measures $\mu(\alpha)$ are singular for different values of $\alpha \in [1/2, 1]$, so there is no continuous dependence on α in the norm of total variation (see Remark 4.11 for some comparison between the finite- and infinite-dimensional state spaces).

A brief outline of the paper is given now. In section 2 the control problem is formulated and the basic assumptions are made and explained. The controlled process is the unique, weak, mild solution of the stochastic differential equation and induces a Markov process in H. Some estimates are made of this process, and an approximation of the transition probability function for the Markov process solution of the stochastic differential equation by transition functions of the solutions of the stochastic differential equation with bounded drifts is given, where the approximation is uniform in the control and the parameter. In section 3 the existence and uniqueness of the mild (backward) Kolmogorov equation for the controlled Markov process are verified. An estimate of the derivative of the mild solution of the Kolmogorov equation is given. In section 4 the results of section 3 are used to verify a uniform version of the strong Feller property and the strong (i.e., variation norm) continuity of the transition measures with respect to the parameter that is uniform in the control. The invariant measures of the controlled Markov process are shown to be continuous with respect to the parameter in the variation norm topology that is uniform in the control. In section 5 some tightness properties are verified. Initially it is shown that a "tightness" on balls implies tightness. A Lyapunov-type condition is shown to imply the tightness for the family of invariant measures depending on the parameter and the control. Section 6 contains the main results of the paper: the existence of an optimal control for a fixed parameter and the continuous dependence of the optimal cost on the parameter are verified using the results proven in sections 2, 3, and 4. In section 7 two examples are given that satisfy the assumptions that are made for the control problem: in Example 7.1 the control problem (1.1)–(1.4) is treated, and Example 7.2 contains a similar control problem, where the control and noise occur at given discrete points in the domain rather than on the boundary.

A brief description and a comparison of some previous results on these topics are given now. Similar results for the existence and the uniqueness of the weak, mild solutions to stochastic differential equations with only distributed noise and control are given in [10, 17, 18]. Some results for the existence and the uniqueness of mild solutions for semilinear stochastic equations with boundary or point noise are given in [11, 22, 27]. In [27] an existence result for the invariant measures is given. The methods to obtain the mild solution of the Kolmogorov equation are similar to the methods used in [6, 8, 9] for a fixed stochastic equation without parameter dependency. The approach to verifying the existence of an optimal control uses a standard procedure (see, e.g., [25, 32] for a finite-dimensional process and [13] for an infinite-dimensional process). There seems to be a fairly limited amount of work on infinite-time horizon control problems in infinite-dimensional spaces. Some work is devoted to discounted cost functionals. For this latter problem the existence of an optimal stationary control is shown in [4], and the stationary Hamilton–Jacobi–Bellman equation is investigated in [7, 20]. It seems that the ergodic control problem is only considered in [13], where a distributed control is used.

2. Preliminaries. Consider a controlled, infinite-dimensional process $(X(t),\, t \geq 0)$ that satisfies the stochastic differential equation

$$\begin{aligned} \mathrm{d}X(t) + AX(t)\mathrm{d}t &= (f(\alpha, X(t)) + Bh(\alpha, X(t), u(X(t))))\mathrm{d}t + B\mathrm{d}V(t) + Q^{1/2}\mathrm{d}W(t), \\ X(0) &= x, \end{aligned} \tag{2.1}$$

where $X(0), X(t) \in H$, H is a separable, infinite-dimensional Hilbert space with inner product $\langle \cdot, \cdot \rangle$ and norm $|\cdot|$, $\alpha \in \mathcal{A} \subset \mathbb{R}^d$ is a parameter and $\mathcal{A}$ is compact, U is a separable Hilbert space with inner product $\langle \cdot, \cdot \rangle_U$ and norm $|\cdot|_U$, $\mathcal{K}$ is a compact product of intervals in $\mathbb{R}^k$, $-A : \mathrm{Dom}(-A) \to H$ is the infinitesimal generator of an analytic semigroup $(S(t),\, t \geq 0)$ such that $A^{-1} \in \mathcal{L}(H)$, which is often denoted $A > 0$,

$$\begin{aligned} f &: \mathcal{A} \times H \to H, \\ h &: \mathcal{A} \times H \times \mathcal{K} \to U \end{aligned}$$

are Borel measurable functions, $B \in \mathcal{L}(U, D_A^{\varepsilon - 1})$, the family of bounded linear operators from U to $D_A^{\varepsilon-1}$, where $\varepsilon \in (0, 1]$ is given and D_A^δ for $\delta \geq 0$ is the domain of the fractional power A^δ with the topology induced by the graph norm $|x|_{D_A^\delta} = |A^\delta x|$, while for $\delta < 0$ it is a completion of H in the norm $|\cdot|_{D_A^\delta}$. It is assumed that $Q \in \mathcal{L}(H)$ is positive and self-adjoint and $(V(t),\, t \geq 0)$ and $(W(t),\, t \geq 0)$ are independent, standard cylindrical Wiener processes in the spaces U and H, respectively, that are defined on a filtered, complete probability space $(\Omega, \mathcal{F}, (\mathcal{F}_t), \mathbb{P})$. The family of controls, $\mathcal{U}$, is

$$\mathcal{U} = \{u : H \to \mathcal{K} \mid u \text{ is Borel measurable}\}.$$

The control problem is to minimize, over $u \in \mathcal{U}$, the ergodic cost functional

$$J(x, u, \alpha) = \limsup_{T \to \infty} \mathbb{E} \frac{1}{T} \int_0^T c(X(s), u(X(s)))\mathrm{d}s, \tag{2.2}$$

where $c : H \times \mathcal{K} \to \mathbb{R}_+$ is bounded and Borel measurable.

The following assumptions, (A1)–(A7), are used selectively in this paper.

(A1) There exist a $\gamma \in (0, 1/2]$ and a $\Delta \in (0, 1/2]$ such that $B \in \mathcal{L}_2(U, D_A^{\gamma - 1/2})$ and $Q^{1/2} \in \mathcal{L}_2(H, D_A^{\Delta - 1/2})$, where $\mathcal{L}_2(\cdot, \cdot)$ is the family of Hilbert–Schmidt operators.

(A2) For each $\alpha \in \mathcal{A}$ the function $h(\alpha, \cdot, \cdot) : H \times \mathcal{K} \to U$ is continuous and $f(\alpha, \cdot) : H \to H$ is Lipschitz continuous on the bounded subsets of H, and there are constants k, k_f, k_h, and $\tilde{k}(\alpha)$ such that $|f(\alpha, x)| \leq k + k_f|x|$, $|h(\alpha, x, u)|_U \leq k + k_h|x|$, and $|h(\alpha, x, u)|_U \leq \tilde{k}(\alpha)$ for all $x \in H$, $u \in \mathcal{K}$, and $\alpha \in \mathcal{A}$.

By (A1) and the analyticity of $-A$, the composition $S(r)B$ is well defined for $r > 0$, and furthermore, $S(r)B \in \mathcal{L}_2(U, H)$, $S(r)Q^{1/2} \in \mathcal{L}_2(H)$, and

$$\int_0^t |S(r)B|^2_{\mathcal{L}_2(U,H)} dr + \int_0^t |S(r)Q^{1/2}|^2_{\mathcal{L}_2(H)} dr < \infty$$

for $t > 0$. Therefore, the family of operators $(Q_t, t \geq 0)$

$$Q_t = \int_0^t S(r)BB^*S^*(r)\mathrm{d}r + \int_0^t S(r)QS^*(r)\mathrm{d}r \tag{2.3}$$

is well defined and $Q_t \in \mathcal{L}_2(H)$ for each $t \geq 0$.

(A3) The following are satisfied:

$$\mathcal{R}(\tilde{S}(t)) \subset \mathcal{R}(Q_t^{1/2}), \qquad |Q_t^{-1/2} S(t) A^{1-\varepsilon}|_{\mathcal{L}(H)} \leq \frac{c}{t^\beta}$$

for $t \in (0, T]$ for some $T > 0$, $c > 0$, and $\beta < 1$, where $(\tilde{S}(t),\ t \geq 0)$ is the restriction of $(S(t),\ t \geq 0)$ to the space $D_A^{1-\varepsilon}$ and $\mathcal{R}(\cdot)$ is the range.

(A4) There is a continuous, increasing function $\omega : \mathbb{R}_+ \to \mathbb{R}_+$ with $\omega(0) = 0$ such that

$$|f(\alpha, x) - f(\beta, x)| + |h(\alpha, x, u) - h(\beta, x, u)|_U \leq \omega(|\alpha - \beta|)(1 + |x|)$$

for all $\alpha, \beta \in \mathcal{A}$, $x \in H$, and $u \in \mathcal{K}$.

(A5) For each $u \in \mathcal{U}$ and $\alpha \in \mathcal{A}$ there is an invariant measure $\mu(\alpha, u)$ for the process $(X(t),\ t \geq 0)$ that satisfies (2.1), and the family of measures $(\mu(\alpha, u),\ \alpha \in \mathcal{A},\ u \in \mathcal{U})$ is tight.

(A6) The function $c : H \times \mathcal{K} \to \mathbb{R}_+$ given in (2.2) is bounded and Borel measurable and $c(x, \cdot) : \mathcal{K} \to \mathbb{R}_+$ is continuous for each $x \in H$.

(A7) The set $h(\alpha, x, \mathcal{K}) \times c(x, \mathcal{K}) \subset U \times \mathbb{R}_+$ is convex for each $\alpha \in \mathcal{A}$ and $x \in H$.

Some comments on the above assumptions (A1)–(A7) are given now. Assumption (A1) is a standard condition guaranteeing that the solution of the linear version of the equation (2.1) (i.e., with $f = 0$ and $h = 0$) is an H-valued stochastic process (otherwise it is only a cylindrical process; see, e.g., [12]). Note that (A1) implies that the above-defined operators Q_t are trace class operators on H. They are covariance operators of the (Gaussian) probability distribution of the solution to the linear equation. (Some discussion on the verification of (A1) is contained, for example, in [12, 27]; (A1) is also verified in Examples 7.1, 7.2 of the present paper.)

The assumption (A2) is used to verify that there exists a unique, weak, mild solution to the equation (2.1) (below in this section).

The assumption (A3) is used in section 3 to prove some suitable smoothing properties of the mild backward Kolmogorov equation corresponding to the stochastic equation (2.1), which is needed to show the ergodicity of the solutions to (2.1) and some continuity properties of the transition probability kernels. The assumption is also rather standard in the context of the perturbation methods; for instance, for $\epsilon = 1$ the results of section 3 have been proven in [9, 10]. A class of examples in which (A3) can be easily verified is given also in section 3 (Proposition 3.4).

The assumption (A4) is a continuous dependence of the coefficients of the equation (2.1) on the parameter α. It is used for the verification of the results that are related to the continuous dependence of the optimal cost on the parameter.

The assumption (A5) is a kind of stability assumption that is usually needed in ergodic control problems. In section 5 (A5) is verified in terms of some more explicit conditions on the coefficients of equation (2.1) (Lyapunov-type conditions).

The assumptions (A7) and (A8) are typical conditions that are used in the ergodic control theory ((A7) is sometimes called the Roxin-type condition) and they are used to establish the existence of an optimal control for the given control problem.

Consider the following two stochastic differential equations:

$$\begin{aligned} \mathrm{d}Z(t) + AZ(t)\mathrm{d}t &= B\mathrm{d}V(t) + Q^{1/2}\mathrm{d}W(t), \\ Z(0) &= x, \end{aligned} \tag{2.4}$$

and

$$\begin{aligned} \mathrm{d}X(t) + AX(t)\mathrm{d}t &= f(\alpha, X(t))\mathrm{d}t + B\mathrm{d}V(t) + Q^{1/2}\mathrm{d}W(t), \\ X(0) &= x. \end{aligned} \tag{2.5}$$

Under the assumptions (A1) and (A2) it is easy to verify that each of the equations (2.4) and (2.5) has one and only one mild solution on the probability space $(\Omega, \mathcal{F}, P)$, that is, the solutions to the integral equations

$$Z(t) = S(t)x + \int_0^t S(t-r)B\mathrm{d}V(r) + \int_0^t S(t-r)Q^{1/2}\mathrm{d}W(r), \qquad t \geq 0, \tag{2.6}$$

and

$$\begin{aligned} X(t) = S(t)x &+ \int_0^t S(t-r)f(\alpha, X(t))\mathrm{d}t + \int_0^t S(t-r)B\mathrm{d}V(r) \\ &+ \int_0^t S(t-r)Q^{1/2}\mathrm{d}W(r), \quad t \geq 0. \end{aligned} \tag{2.7}$$

These solutions are D_A^δ-valued processes that belong to $C([0,T], L^p(\Omega, H)) \cap C((0,T], L^p(\Omega, D_A^\delta))$ for any $p \geq 1$, $T > 0$, and $\delta \in [0, \min(\varepsilon, \Delta, \gamma))$ (cf. [27]). Furthermore, the processes $(X(t),\, t \geq 0)$ and $(Z(t),\, t \geq 0)$ have D_A^δ-continuous versions (cf. [11, 30]), and in H they induce two Markov processes in the usual way.

Let $P_\alpha : \mathbb{R}_+ \times H \times \mathcal{B}(H) \to [0,1]$ be the transition probability function for $(X(t),\, t \geq 0)$ in (2.7), that is,

$$P_\alpha(t, x, \Gamma) = \mathbb{P}_x(X(t) \in \Gamma), \tag{2.8}$$

and let $(T(t),\, t \geq 0)$ be the Markov transition semigroup for $(Z(t),\, t \geq 0)$ in (2.6), that is,

$$T_t\varphi(x) = \mathbb{E}_x\varphi(Z(t)), \tag{2.9}$$

where $x \in H$ stands for the initial value of $X(\cdot)$, $t \geq 0$, and $\varphi \in \mathcal{M}(H)$, the bounded, Borel measurable functions on H. It is clear that

$$T_t 1_\Gamma(x) = N(S(t)x, Q_t)(\Gamma),$$

where $t \geq 0$, $\Gamma \in \mathcal{B}(H)$, $x \in H$, and Q_t is given by (2.3) so it is self-adjoint, nonnegative, and nuclear, and $N(S_t x, Q_t)$ is the Gaussian measure on H with mean $S_t x$ and covariance Q_t.

Let $\xi_T^{\alpha,u}$ be the random variable as follows:

$$\xi_T^{\alpha,u} = \int_0^T \langle h(\alpha, X(t), u(X(t))), \mathrm{d}V(t)\rangle_U - \frac{1}{2}\int_0^T |h(\alpha, X(t), u(X(t)))|_U^2 \mathrm{d}t \tag{2.10}$$

for $\alpha \in \mathcal{A}$, $u \in \mathcal{U}$, and $T > 0$, where $(X(t),\, t \in [0,T])$ is the solution of (2.7). A weak solution of (2.1) is constructed following the standard procedure of an absolutely continuous change of probability measure (cf. [10, 15, 17, 23]). For control problems, the method was initiated in [1, 14]. Note that $\mathbb{E}\exp(\xi_T^{\alpha,u}) = 1$ by (A2). There is a probability measure $\mathbb{P}_x^{\alpha,u}$ on $\mathcal{F}$ such that the restriction of $\mathbb{P}_x^{\alpha,u}$ to $\mathcal{F}_T$ is given by

$$\mathbb{P}_x^{\alpha,u}(\mathrm{d}\omega) = \exp(\xi_T^{\alpha,u})\mathbb{P}(d\omega), \tag{2.11}$$

the process $(V^*(t),\, t \geq 0)$ given by

$$V^*(t) = V(t) - \int_0^t h(\alpha, X(s), u(X(s)))\mathrm{d}s$$

is a cylindrical Wiener process on U, and using $\mathbb{P}_x^{\alpha,u}$ and the solution of (2.7), it follows that

(2.12)
$$\begin{aligned} X(t) = \; & S(t)x + \int_0^t S(t-r)f(\alpha, X(r))\mathrm{d}t + \int_0^t S(t-r)Bh(\alpha, X(r), u(X(r)))\mathrm{d}r \\ & + \int_0^t S(t-r)B\mathrm{d}V^*(r) + \int_0^t S(t-r)Q^{1/2}\mathrm{d}W(r). \end{aligned}$$

So there is a weak solution to (2.1) which is weakly unique and induces a Markov process on H whose Markov transition semigroup is denoted as

$$P_t^{\alpha,u}\varphi(x) = \mathbb{E}_x^{\alpha,u}\varphi(X(t)) \tag{2.13}$$

for $t \geq 0$ and $\varphi \in \mathcal{M}(H)$, where $\mathbb{E}_x^{\alpha,u}$ is the expectation using the probability measure $\mathbb{P}_x^{\alpha,u}$ and

$$P^{\alpha,u}(t, x, \Gamma) = P_t^{\alpha,u}1_\Gamma(x) \tag{2.14}$$

for $t \geq 0$, $\Gamma \in \mathcal{B}(H)$, and $x \in H$ is the corresponding transition probability function.

In the remainder of the section, three technical lemmas are given that are useful in what follows. Initially, Proposition 2.2 of [27] is given as the following lemma.

LEMMA 2.1. *If* (A1) *and* (A2) *are satisfied and* $\delta \in [0, \min(\gamma, \Delta, \varepsilon))$, $p > \max((\Delta - \delta)^{-1}, (\gamma - \delta)^{-1}, (\varepsilon - \delta)^{-1})$, *and* $x \in H$, *then for each* $T > 0$ *there is a constant* $C = \hat{C}(T, p, \delta)$ *such that*

$$\mathbb{E}|A^\delta X(T)|^p \leq C(1 + |x|^p), \tag{2.15}$$

where $(X(t),\, t \geq 0)$ *is the solution of* (2.7). *If* $\delta = 0$ *then* C *does not depend on* T *from finite intervals.*

The following two lemmas reduce some of the subsequent proofs to the case where f and h are uniformly bounded.

LEMMA 2.2. *If* (A1) *and* (A2) *are satisfied, then for each* $T > 0$ *and* $R > 0$

$$\lim_{N\to\infty} \inf \mathbb{P}_x^{\alpha,u}\left(\sup_{t\in[0,T]} |X(t)| \leq N \right) = 1, \tag{2.16}$$

where the infimum is taken over $\alpha \in \mathcal{A}$, $u \in \mathcal{U}$, *and* $x \in H$ *with* $|x| \leq R$.

Proof. Recall the equation (2.12) for $(X(t),\, t \geq 0)$. Let $\Omega_{x,N}^{\alpha,u} \subset \Omega$ be given by

$$\Omega_{x,N}^{\alpha,u} = \left\{ \sup_{t\in[0,T]} \left(\left| \int_0^t S(t-r)B\mathrm{d}V^*(r) \right| + \left| \int_0^t S(t-r)Q^{1/2}\mathrm{d}W(r) \right| \right) \leq N \right\}. \tag{2.17}$$

By a maximal inequality (Lemma 2.2 of [30])

$$\begin{aligned} & \mathbb{E}_x^{\alpha,u} \sup_{t\in[0,T]} \left(\left| \int_0^t S(t-r)B\mathrm{d}V^*(r) \right|^2 + \left| \int_0^t S(t-r)Q^{1/2}\mathrm{d}W(r) \right|^2 \right) \\ & \qquad \leq \int_0^T |S(r)B|^2_{\mathcal{L}_2(U,H)}\mathrm{d}r + \int_0^T |S(r)Q^{1/2}|^2_{\mathcal{L}_2(H)}\mathrm{d}r \leq M \end{aligned} \tag{2.18}$$

for some M that does not depend on α, x, and u by (A1) and the analyticity of

$(S(t),\, t \geq 0)$. Thus

(2.19)
$$\mathbb{P}_x^{\alpha,u}\left(\sup_{t\in[0,T]}\left(\left|\int_0^t S(t-r)B\mathrm{d}V^*(r)\right| + \left|\int_0^t S(t-r)Q^{1/2}\mathrm{d}W(r)\right|\right) \geq N\right) \leq \frac{2M}{N^2}.$$

By (A1), (A2), and (2.17) on the set $\Omega_{x,N}^{\alpha,u}$ it follows that

$$|X(t)| \leq c_1|x| + c_2 + c_3\int_0^t \frac{|X(s)|}{(t-s)^{1-\varepsilon}}\mathrm{d}s + N$$

for $t \in [0,T]$, where the constants c_1, c_2, and c_3 depend only on T. The generalized Gronwall lemma (Theorem 7.1 of [21]) implies that

$$|X(t)| \leq c_4|x| + c_5 + N \tag{2.20}$$

for $t \in [0,T]$ on $\Omega_{x,N}^{\alpha,u}$, where c_4 and c_5 only depend on T. Since $\mathbb{P}_x^{\alpha,u}(\Omega_{x,N}^{\alpha,u}) \geq 1 - 2M/N^2$ the equality (2.16) follows. □

By (A2) it follows that there is a sequence $(f_m, h_m,\, m \in \mathbb{N})$ such that for each $m \in \mathbb{N}$

$$(f_m(\alpha,x), h_m(\alpha,x,u)) = (f(\alpha,x), h(\alpha,x,u)) \tag{2.21}$$

for $\alpha \in \mathcal{A}$, $u \in \mathcal{K}$, $x \in H$ with $|x| \leq m$ and

$$|f_m| + |h_m|_U \leq M_m, \tag{2.22}$$

where M_m is a constant depending only on m, $f_m(\alpha,\cdot)$ is Lipschitz continuous, and $h_m(\alpha,\cdot,\cdot)$ is continuous for each $m \in \mathbb{N}$ and

$$|f_m(\alpha,x) - f_m(\beta,x)| + |h_m(\alpha,x,u) - h_m(\beta,x,u)|_U \leq \tilde{\omega}_m(|\alpha-\beta|) \tag{2.23}$$

for $\alpha,\beta \in \mathcal{A}$, $x \in H$, and $u \in \mathcal{K}$, where $\tilde{\omega}_m$ has the same properties as ω in (A4) for each $m \in \mathbb{N}$. It is clear that if f and h are replaced by f_m and h_m, respectively, in (2.1), then the same procedure gives a unique weak solution inducing a Markov process on H.

LEMMA 2.3. *Let $P_m^{\alpha,u} : \mathbb{R}_+ \times H \times \mathcal{B}(H)$ be the transition probability function for the Markov process that is the solution of* (2.1) *with f and h replaced by f_m and h_m, respectively, which are described above. If* (A1) *and* (A2) *are satisfied then*

$$\lim_{m\to\infty} \|P_m^{\alpha,u}(t,x,\cdot) - P^{\alpha,u}(t,x,\cdot)\| = 0 \tag{2.24}$$

uniformly in $\alpha \in \mathcal{A}$, $u \in \mathcal{U}$, and x from bounded sets in H where $\|\cdot\|$ is the variation norm.

The proof of this lemma follows easily from Lemma 2.2 and the local uniqueness theorem for stochastic integrals. Let $(X_m(t),\, t \geq 0)$ be the solution of (2.5) with f replaced by f_m. It easily follows that

$$\Omega_N = \left\{\sup_{\substack{t\in[0,T]\\ \alpha\in\mathcal{A},\ |x|\leq R}} |X_m(t)| \leq N\right\} = \left\{\sup_{\substack{t\in[0,T]\\ \alpha\in\mathcal{A},\ |x|\leq R}} |X(t)| \leq N\right\}$$

for $m \geq N > R > 0$ because the trajectories of $(X_m(t),\, t \geq 0)$ and $(X(t),\, t \geq 0)$ coincide for $t \in [0,T]$ on Ω_N. Lemma 2.2 implies that $\mathbb{P}_x^{\alpha,u}(\Omega_N) \to 1$ as $N \to \infty$ uniformly in $\alpha \in \mathcal{A}$, $u \in \mathcal{U}$, $x \in H$ with $|x| < R$. Defining $\mathbb{P}_{x,m}^{\alpha,u}$ in the same way as $\mathbb{P}_x^{\alpha,u}$ by replacing h by h_m, it follows that the probabilities $\mathbb{P}_{x,m}^{\alpha,u}$ and $\mathbb{P}_x^{\alpha,u}$ restricted to Ω_N coincide for $m \geq N$. Given $\varepsilon > 0$, choose $N \geq 0$ such that $\mathbb{P}_{x,m}^{\alpha,u}(\Omega_N) \geq 1 - \varepsilon$ for $\alpha \in \mathcal{A}$, $u \in \mathcal{U}$, $|x| \leq R$, and $m \geq N$. It follows that

$$|P_m^{\alpha,u}(T,x,\Gamma) - P^{\alpha,u}(T,x,\Gamma)| < \varepsilon$$

for each $\Gamma \in \mathcal{B}(H)$, $|x| \leq R$, $\alpha \in \mathcal{A}$, $u \in \mathcal{U}$, and $m \geq N$.

3. The mild Kolmogorov equation. In this section a version of the mild Kolmogorov equation is considered. The existence and the uniqueness of the solution of this equation is verified, as is an estimate on the derivatives which is important to establish a uniform version of the strong Feller property. Many of the results of this section are verified similarly to the verifications that are used for a single Hilbert space (cf. [6, 8, 9]), so some details are omitted. Recall the definitions of $(T_t,\, t \geq 0)$ in (2.9) and $(P_t^{\alpha,u},\, t \geq 0)$ in (2.13). Let D_x be the Fréchet derivative on H and let $\mathcal{U}_c = \{u \in \mathcal{U} : u \in C(H,\mathcal{K})\}$. Let

$$\mathcal{H} = \left\{ \psi \mid \psi : (0,T] \to C_b^1(H),\ D_x\psi : (0,T] \to C_b(H, D_{A^*}^{1-\varepsilon}),\right.$$
$$\left. |\psi|_{\mathcal{H}} := \sup_{\substack{t\in(0,T)\\ x\in H}} (t^\beta |\psi(t,x)| + t^\beta |D_x\psi(t,x)|_{D_{A^*}^{1-\varepsilon}}) < \infty \right\},$$

where $\beta \in (0,1)$ is given in (A3), which is assumed to be satisfied throughout this section.

PROPOSITION 3.1. *Let $\varphi \in C_b(H)$ and $n(t,x) = T_t\varphi(x)$ for $t \geq 0$ and $x \in H$. Then $n \in \mathcal{H}$ and*

$$|D_x n(t,x)|_{D_{A^*}^{1-\varepsilon}} \leq \frac{c}{t^\beta} \sup|\varphi| \tag{3.1}$$

for $t \in (0,T]$ and $x \in H$, where the constant c does not depend on φ.

Proof. By the absolute continuity of measures it follows that

$$\begin{aligned} n(t,x) &= \int \varphi(y) N(S(t)x, Q_t)(\mathrm{d}y) \\ &= \int \varphi(y) \exp\left[\langle \Gamma_t x, Q_t^{-(1/2)} y\rangle - \frac{1}{2}|\Gamma_t x|^2\right] N(0,Q_t)(\mathrm{d}y), \end{aligned} \tag{3.2}$$

where $\Gamma_t = Q_t^{-(1/2)} S_t \in \mathcal{L}(H)$ by (A3). Applying D_x to (3.2) it follows (cf. [10]) that

$$D_x n(t,x)h = \int \langle \Gamma_t h, Q_t^{-(1/2)} y\rangle \varphi(S(t)x + y) N(0,Q_t)(\mathrm{d}y)$$

for $h \in H$, so that (A3) yields

$$\begin{aligned} \sup_{|h|\leq 1} |D_x n(t,x)(A^{1-\varepsilon}h)| &\leq c_1 \sup_{|h|\leq 1} \int |\langle \Gamma_t A^{1-\varepsilon} h, Q_t^{-(1/2)} y\rangle| N(0,Q_t)(\mathrm{d}y) \sup|\varphi| \\ &\leq c_2 \sup|\varphi|\, |\Gamma_t A^{1-\varepsilon}|_{\mathcal{L}(H)} \leq \frac{c_3}{t^\beta} \sup|\varphi| \end{aligned} \tag{3.3}$$

for $t \in (0,T]$, where $c_i, i = 1,2,3$, are constants independent of φ and t. The inequality (3.1) follows because $(D_A^{\varepsilon-1})' = D_{A^*}^{1-\varepsilon}$. □

Consider the mild Kolmogorov equation of the form

(3.4)
$$v(t,x) = T_t\varphi(x) + \int_0^t T_{t-s}(\langle D_x v(s,\cdot), f(\alpha,\cdot)\rangle + \langle D_x v(s,\cdot), Bh(\alpha,\cdot,u(\cdot)\rangle)(x)\mathrm{d}s$$

for $t \geq 0$, where $\varphi \in C_b(H)$, $\langle\cdot,\cdot\rangle$ is used for the duality between the corresponding domains of the fractional powers of A and A^* as well as the inner product on H, and for notational convenience, the dependence of v on α and u is suppressed. The solution $v(t,x)$ of (3.4) is shown to be $P_t^{\alpha,u}\varphi(x)$.

PROPOSITION 3.2. *If* (A1)–(A3) *are satisfied,* $u \in \mathcal{U}_c$, $\varphi \in C_b(H)$, *and* $|f|$ *and* $|h|_U$ *are bounded independent of* $\alpha \in \mathcal{A}$ *and* $u \in \mathcal{U}_c$, *then the equation* (3.4) *has one and only one solution* $v(t,x) = P_t^{\alpha,u}\varphi(x)$ *in* $\mathcal{H}$ *that satisfies*

$$|D_x v(t,x)|_{D_{A^*}^{1-\varepsilon}} \leq \frac{\tilde{c}}{t^\beta}\sup|\varphi| \tag{3.5}$$

for $t \in (0,T]$, *where the constant* $\tilde{c}$ *does not depend on* $\varphi, u \in \mathcal{U}_c$ *or* $\alpha \in \mathcal{A}$.

Proof. To verify the existence and uniqueness of the solution of (3.4), the Banach fixed point theorem is used for the Banach space $(\mathcal{H}, |\cdot|_{\mathcal{H}})$. Define the mapping $\Phi : \mathcal{H} \to \mathcal{H}$ as follows:

$$\Phi v(t,x) = T_t\varphi(x) + \int_0^t T_{t-s}\psi(D_x v(s,\cdot))(x)\mathrm{d}s \tag{3.6}$$

for $t \in (0,T]$, where

$$\psi(D_x v(s,\cdot)) = \langle f(\alpha,\cdot), D_x v(s,\cdot)\rangle + \langle D_x v(s,\cdot), Bh(\alpha,\cdot,u(\cdot))\rangle \tag{3.7}$$

and the dependence of ψ on $\alpha \in \mathcal{A}$ and $u \in \mathcal{U}_c$ is suppressed. For $v_1, v_2 \in \mathcal{H}$ it follows that

(3.8)
$$\begin{aligned}|\Phi(v_1) - \Phi(v_2)|_{\mathcal{H}} = \sup_{\substack{t\in(0,T)\\ x\in H}} [t^\beta | \int_0^t T_{t-s}(\psi(D_x v_1(s,\cdot)) - \psi(D_x v_2(s,\cdot)))(x)\mathrm{d}s| \\ + t^\beta \int_0^t |(A^*)^{1-\varepsilon} D_x T_{t-s}(\psi(D_x v_1(s,\cdot)) - \psi(D_x v_2(s,\cdot)))(x)|\mathrm{d}s].\end{aligned}$$

Note that

$$\begin{aligned}&|\psi(D_x v_1(s,\cdot)) - \psi(D_x v_2(s,\cdot))| \leq c_1|D_x v_1(s,\cdot) - D_x v_2(s,\cdot)| \\ &\quad + |(A^*)^{1-\varepsilon}(D_x v_1(s,\cdot) - D_x v_2(s,\cdot))| \leq c_2|D_x v_1(s,\cdot) - D_x v_2(s,\cdot)|_{D_{A^*}^{1-\varepsilon}}\end{aligned}$$

for suitable constants c_1 and c_2. Applying this inequality to (3.8) yields

$$\begin{aligned}|\Phi(v_1) - \Phi(v_2)|_{\mathcal{H}} \leq\ & c_2 \int_0^t t^\beta \sup_{s,x} |D_x v_1(s,x) - D_x v_2(s,x)|_{D_{A^*}^{1-\varepsilon}}\mathrm{d}s \\ &+ c_2 c \int_0^t \frac{t^\beta}{(t-s)^\beta} \sup_{s,x} |D_x v_1(s,x) - D_x v_2(s,x)|_{D_{A^*}^{1-\varepsilon}}\mathrm{d}s \\ \leq\ & c_3|v_1 - v_2|_{\mathcal{H}} \left(\int_0^t \frac{t^\beta}{s^\beta}\mathrm{d}s + t^\beta \int_0^t \frac{\mathrm{d}s}{(t-s)^\beta s^\beta}\right).\end{aligned}$$

Thus Φ is a contraction for $t > 0$ sufficiently small. The fact that $\Phi(\mathcal{H}) \subset \mathcal{H}$ is verified similarly. Therefore, for $T > 0$ sufficiently small, there is a unique solution of (3.4). For arbitrary $T > 0$ the interval $[0, T]$ is subdivided into a finite number of small intervals.

To verify (3.5) it follows by (3.1) that

(3.9)

$$\sup_x |D_x v(t,x)|_{D^{1-\varepsilon}_{A^*}} \le \sup_x |D_x T_t \varphi(x)|_{D^{1-\varepsilon}_{A^*}} + \sup_x \int_0^t |D_x T_{t-s} \psi(D_x v(s,\cdot))(x)|_{D^{1-\varepsilon}_{A^*}} \mathrm{d}s$$
$$\le ct^{-\beta} \sup|\varphi| + c_4 \int_0^t \sup_x |D_x v(s,x)|_{D^{1-\varepsilon}_{A^*}} \frac{\mathrm{d}s}{(t-s)^\beta}$$

for $t \in (0, T)$ and c_4 is a constant. Applying the generalized Gronwall lemma (Theorem 7.1 of [21]) to the function $\lambda(t) = \sup_x |D_x v(t,x)|_{D^{1-\varepsilon}_{A^*}}$, it follows that

$$\sup_{x \in H} |D_x v(t,x)|_{D^{1-\varepsilon}_{A^*}} \le \frac{c_5}{t^\beta} \sup|\varphi| \tag{3.10}$$

for $t \in (0, T]$, where the constant c_5 does not depend on $t \in (0, T]$, $\varphi \in C_b(H)$, $\alpha \in \mathcal{A}$, and $u \in \mathcal{U}_c$, though it may depend on the bounds for $|f|$ and $|h|_U$. While it remains to show that $v(t,x)$ is $P^{\alpha,u}_t \varphi(x)$, this verification is identical to the proof of (Theorem 4 of [6]) and is omitted. Only note that (A1) implies that $B \in \mathcal{L}_2(U, D_A^{-1})$ and $Q^{1/2} \in \mathcal{L}_2(H, D_A^{-1})$, which is used here. □

Proposition 3.2 is essential in the following result, which gives a strong Feller property that is uniform for $u \in \mathcal{U}_c$. It is improved in the next section.

LEMMA 3.3. *Let $t > 0$ and $y \in H$ be fixed. If* (A1)–(A2) *are satisfied then there is a function $\tilde{\omega} : \mathbb{R}_+ \to \mathbb{R}_+$ that is increasing and continuous with $\tilde{\omega}(0) = 0$ such that*

$$\|P^{\alpha,u}(t,x,\cdot) - P^{\alpha,u}(t,y,\cdot)\| \le \tilde{\omega}(|x-y|) \tag{3.11}$$

for all $\alpha \in \mathcal{A}$, $u \in \mathcal{U}_c$, and $x \in H$, where $\|\cdot\|$ is the variation norm.

Proof. If $|f|$ and $|h|_U$ are bounded then by (3.5) it follows that

$$\|P^{\alpha,u}(t,x,\cdot) - P^{\alpha,u}(t,y,\cdot)\| = \sup_{\varphi \in C_b,\ |\varphi| \le 1} |P^{\alpha,u}_t \varphi(x) - P^{\alpha,u}_t \varphi(y)| \le \frac{\tilde{c}}{t^\beta} |x-y|_{D_A^{\varepsilon-1}}$$

for $x \in H$, which easily implies (3.11) ($\tilde{c}$ may depend on the bounds for $|f|$ and $|h|_U$). If $|f|$ and $|h|_U$ are not bounded, then use Lemma 2.3 to approximate $P^{\alpha,u}(t,x,\cdot)$ and $P^{\alpha,u}(t,y,\cdot)$ by $P^{\alpha,u}_k(t,x,\cdot)$ and $P^{\alpha,u}_k(t,y,\cdot)$, respectively, uniformly with respect to $\alpha \in \mathcal{A}$, $u \in \mathcal{U}_c$, and x from bounded sets in H. □

This section is concluded with a simple result which can be useful in some cases to verify (A3).

PROPOSITION 3.4. *If $\varepsilon > 1/2$ and $Q^{1/2} = A^{-\eta}\Gamma$, where $\eta \in [0, \varepsilon - 1/2)$ and $\Gamma, \Gamma^{-1} \in \mathcal{L}(H)$, then* (A3) *is satisfied.*

Proof. Let

$${}^1Q_t = \int_0^t S(r) B B^* S^*(r) \mathrm{d}r$$

and

$${}^2Q_t = \int_0^t S(r) Q S^*(r) \mathrm{d}r.$$

It is clear that $Q_t = {}^1Q_t + {}^2Q_t$ and ${}^1Q$ and ${}^2Q$ are nonnegative and self-adjoint. It suffices to verify (A3) with Q_t replaced by ${}^2Q_t$. By the minimum energy principle (cf. Remark B9 of [10]) it follows that

$$|{}^2Q_t^{-(1/2)}S(t)y| \le \left(\int_0^t |u(s)|^2 \mathrm{d}s\right)^{1/2}, \tag{3.12}$$

where $u \in L^2([0,t],H)$ is arbitrary such that the solution $(z(s),\ s\in[0,t])$ of

$$\dot z + Az = Q^{1/2}u, \qquad z(0) = y \tag{3.13}$$

satisfies $z(t) = 0$. The existence of such a function is a necessary condition for ${}^2Q_t^{-(1/2)}S(t) \in \mathcal{L}(H)$. For $x \in D_A^{1-\varepsilon}$ define $\tilde u(r) = -(1/t)Q^{-1/2}S(r)A^{1-\varepsilon}x$. Clearly $\tilde u \in L^2([0,t],H)$ and u gives $z(t) = 0$ if $y = A^{1-\varepsilon}x$. Thus

$$|{}^2Q_t^{-(1/2)}S(t)A^{1-\varepsilon}x| \le \left(\int_0^t |\tilde u(r)|^2 \mathrm{d}r\right)^{1/2} \le |x|\frac{\tilde c}{t^{\eta+(3/2)-\varepsilon}}$$

for a constant $\tilde c$, so (A3) is satisfied with $\beta = \eta + (3/2) - \varepsilon < 1$, □

4. The continuous dependence of some measures on a parameter. In this section, the verifications are made for the continuous dependence of $P^{\alpha,u}(t,x,\cdot)$ on the parameter α and the uniform strong Feller property, which yield (under the tightness condition (A5)) the uniform continuity of the invariant measures with respect to the parameter $\alpha \in \mathcal{A}$. This last result is used in section 6 to prove continuity of the optimal cost for the control problem (2.1), (2.2).

LEMMA 4.1. *If* (A1) *and* (A2) *are satisfied then for each* $t > 0$, $\alpha \in \mathcal{A}$, *and* $x \in H$

$$\lim_{u_n \to u} \|P^{\alpha,u_n}(t,x,\cdot) - P^{\alpha,u}(t,x,\cdot)\| = 0, \tag{4.1}$$

where $u_n \in \mathcal{U}$ *for all* $n \in \mathbb{N}$ *and* $u_n \to u$ *pointwise.*

Proof. By Lemma 2.3 it can be assumed that $|f|$ and $|h|_U$ are bounded uniformly in $\alpha \in \mathcal{A}$ and $u \in \mathcal{U}$. It easily follows that

$$\begin{aligned} \|P^{\alpha,u_n}(t,x,\cdot) - P^{\alpha,u}(t,x,\cdot)\| &= \sup_{\varphi\in C_b,\|\varphi|\le 1} |P_t^{\alpha,u_n}\varphi(x) - P_t^{\alpha,u}\varphi(x)| \\ &\le |\mathbb{E}\varphi(X(t))\exp(\xi_t^{\alpha,u_n}) - \mathbb{E}\varphi(X(t))\exp(\xi_t^{\alpha,u})| \le \mathbb{E}|\exp(\xi_t^{\alpha,u_n}) - \exp(\xi_t^{\alpha,u})|, \end{aligned} \tag{4.2}$$

where $(X(t),\ t \ge 0)$ satisfies (2.5). Since $\mathbb{E}\exp(2\xi_t^{\alpha,u_n}) \le \exp(t\sup|h|)$ the sequence $(\exp(\xi_t^{\alpha,u_n}),\ n\in\mathbb{N})$ is uniformly integrable, so for every $\varepsilon > 0$ there is an $R > 0$ such that

$$\mathbb{E}|\exp(\xi_t^{\alpha,u_n}) - \exp(\xi_t^{\alpha,u})| \le \mathrm{e}^R\mathbb{E}|\xi_t^{\alpha,u_n} - \xi_t^{\alpha,u}| + \varepsilon.$$

From (A2), the boundedness of $|h|_U$, and the dominated convergence theorem, (4.2) is verified. □

The following result is a uniform version of the strong Feller property.

LEMMA 4.2. *If* (A1)–(A3) *are satisfied, then for each* $t > 0$, $y \in H$, *there is a continuous, increasing function* $\tilde\omega : \mathbb{R}_+ \to \mathbb{R}_+$ *with* $\tilde\omega(0) = 0$ *such that*

$$\|P^{\alpha,u}(t,x,\cdot) - P^{\alpha,u}(t,y,\cdot)\| \le \tilde\omega(|x-y|)$$

for all $\alpha \in \mathcal{A}$, $u \in \mathcal{U}$, *and* $x \in H$.

Proof. Take the function $\tilde{\omega}$ from Lemma 3.3 (for the fixed $t > 0$ and $y \in H$) and let $\mathcal{U}' \in \mathcal{U}$ be the set of controls satisfying

$$\sup_{u \in \mathcal{U}'} \|P^{\alpha,u}(t,x,\cdot) - P^{\alpha,u}(t,y,\cdot)\| \leq \tilde{\omega}(|x-y|)$$

for all $x \in H$ and $\alpha \in \mathcal{A}$. By Lemma 3.3, $\mathcal{U}_c \subset \mathcal{U}'$ and by Lemma 4.1, $\mathcal{U}'$ is closed with respect to pointwise convergence. Since the families of Baire and Borel functions $H \to \mathcal{K}$ coincide (cf. [24, Theorem 2.31.IX]) it follows that $\mathcal{U}' = \mathcal{U}$.

PROPOSITION 4.3. *Denote by $\mathcal{P}(H)$ the space of probability measures on the Borel subsets of H endowed with the metric of total variation of measures. If* (A1)–(A4) *are satisfied, then for each $T > 0$ the function*

$$\eta : \mathcal{A} \to \mathcal{P}(H)$$

given by

$$\eta(\alpha) := P^{\alpha,u}(T,x,\cdot) \tag{4.3}$$

is continuous uniformly in $u \in \mathcal{U}$ and $x \in K$ for each compact set $K \subset H$.

Proof. By Lemma 2.3 it can be assumed that $|f|$ and $|h|_U$ are bounded and

$$|f(\alpha,x) - f(\beta,x)| + |h(\alpha,x,u) - h(\beta,x,u)|_U \leq \omega(|\alpha-\beta|) \tag{4.4}$$

for $x \in H$ and $\alpha, \beta \in \mathcal{A}$. Initially, the uniform continuity of (4.3) is verified for $u \in \mathcal{U}_c$. For $v_{\alpha,u}(t,x) = P_t^{\alpha,u}\varphi(x)$ for $x \in H$ and $\varphi \in C_b(H)$ it follows by Proposition 3.2 that

$$v_{\alpha,u}(t,x) = T_t\varphi(x) + \int_0^t T_{t-s}(\psi_{\alpha,u}(D_x v_{\alpha,u}(s,\cdot)))(x)\mathrm{d}s \tag{4.5}$$

for $t \in [0,T]$, where

$$\psi_{\alpha,u}(D_x v_{\alpha,u}(s,\cdot)) = \langle D_x v_{\alpha,u}(s,\cdot), f(\cdot)\rangle + \langle D_x v_{\alpha,u}(s,\cdot), Bh(\alpha,\cdot,u(\cdot))\rangle \tag{4.6}$$

and

$$|D_x v_{\alpha,u}(t,\cdot)|_{D_{A^*}^{1-\varepsilon}} \leq ct^{-\beta}\sup|\varphi| \tag{4.7}$$

for $t \in (0,T]$, where $c > 0$ does not depend on $t \in (0,T]$, $\alpha \in \mathcal{A}$, $u \in \mathcal{U}_c$, and $\varphi \in C_b(H)$. By Proposition 3.1 it follows that

$$\begin{aligned}
&\sup_x |v_{\alpha,u}(t,x) - v_{\alpha_0,u}(t,x)| + \sup_x |D_x v_{\alpha,u}(t,x) - D_x v_{\alpha_0,u}(t,x)|_{D_{A^*}^{1-\varepsilon}} \\
&\quad \leq \sup_x \int_0^t |T_{t-s}(\psi_{\alpha,u}(D_x v_{\alpha,u}(s,\cdot)) - \psi_{\alpha_0,u}(D_x v_{\alpha_0,u}(s,\cdot)))(x)|\mathrm{d}s \\
&\quad + \sup_x \int_0^t |D_x T_{t-s}(\psi_{\alpha,u}(D_x v_{\alpha,u}(s,\cdot)) - \psi_{\alpha_0,u}(D_x v_{\alpha_0,u}(s,\cdot)))(x)|_{D_{A^*}^{1-\varepsilon}}\mathrm{d}s.
\end{aligned} \tag{4.8}$$

By (4.4) and (4.7) it follows that

$$\begin{aligned}
&\sup_x |\psi_{\alpha,u}(D_x v_{\alpha,u}(s,x)) - \psi_{\alpha_0,u}(D_x v_{\alpha_0,u}(s,x))| \\
&\leq c_1 \sup_x |D_x v_{\alpha,u}(s,x) - D_x v_{\alpha_0,u}(s,x)|_{D_{A^*}^{1-\varepsilon}} + c_2 s^{-\beta}\omega(|\alpha-\alpha_0|)
\end{aligned} \tag{4.9}$$

for some constants c_1, c_2 depending only on the bounds for $|f|$, $|h|_U$, and $|B|_{\mathcal{L}(U,D_A^{\varepsilon-1})}$. Let $\lambda_{\alpha,u}(\cdot)$ be the left-hand side of (4.8). By (4.8) and (4.9) it follows that

$$\lambda_{\alpha,u}(t) \le \int_0^t \frac{k_1}{(t-s)^\beta}\lambda_{\alpha,u}(s)\, ds + \omega(|\alpha-\alpha_0|)\int_0^t \frac{k_2}{(t-s)^\beta s^\beta}\mathrm{d}s \tag{4.10}$$

for $t \in (0,T]$ for some constants k_1 and k_2. By the generalized Gronwall lemma (Theorem 7.1 of [21]) it follows that

$$\lambda_{\alpha,u}(t) \le k_3\omega(|\alpha-\alpha_0|)$$

for $t \in (0,T]$, so

$$\|P^{\alpha,u}(T,x,\cdot) - P^{\alpha_0,u}(T,x,\cdot)\| = \sup_{|\varphi|\le 1} |P_T^{\alpha,u}\varphi(x) - P_T^{\alpha_0,u}\varphi(x)| \le k_4\omega(|\alpha-\alpha_0|)$$

for some constants k_3 and k_4 that are independent of $x \in H$ and $u \in \mathcal{U}_c$. The last estimate is extended to $u \in \mathcal{U}$ using Lemma 4.1 by the same argument as in the proof of Lemma 4.2.

The following result is a version of the Itô formula that is applicable to functions of the solution of (2.1).

PROPOSITION 4.4. *If* (A1) *and* (A2) *are satisfied,* $g \in C^2(H)$, $D_x g(x) \in D_{A^*}^{1-\varepsilon}$ *for* $x \in H$, $D_x g : H \to D_{A^*}^{1-\varepsilon}$ *is continuous,* $D_{xx} g : H \to \mathcal{L}(D_A^{-\delta}, D_{A^*}^{\delta}) \cap \mathcal{L}(H, D_{A^*}^{1-\varepsilon})$ *is continuous for* $\delta = \max((1/2)-\Delta, (1/2)-\gamma)$, *where* D_{xx} *is the second Fréchet derivative,* $\langle A\cdot, D_x g(\cdot)\rangle : D_A^1 \to \mathbb{R}$ *can be extended to a continuous function* $\Phi : H \to \mathbb{R}$, *and*

$$|\Phi(x)| + |g(x)| + |D_x g(x)|_{D_{A^*}^{1-\varepsilon}} + |D_{xx} g(x)|_{\mathcal{L}(D_A^{-\delta}, D_{A^*}^{\delta})} \le \hat{k}(1+|x|^p) \tag{4.11}$$

for $x \in H$ *and some* $\hat{k}$ *and* $p > 0$, *then the following equality is satisfied:*

$$\begin{aligned}\mathbb{E}_x^{\alpha,u} g(X(t)) - g(x) = \ & \mathbb{E}_x^{\alpha,u}\int_0^t (-\Phi(X(s)) + \langle f(\alpha, X(s)), D_x g(X(s))\rangle \\ & + \langle h(\alpha, X(s), u(X(s))), B^* D_x g(X(s))\rangle_U \\ & + \frac{1}{2}\mathrm{tr}[(A^*)^{1/2-\gamma} D_{xx} g(X(s)) BB^* (A^*)^{\gamma-1/2}] \\ & + \frac{1}{2}\mathrm{tr}[(A^*)^{1/2-\Delta} D_{xx} g(X(s)) Q (A^*)^{\Delta-1/2}])\mathrm{d}s\end{aligned} \tag{4.12}$$

for $t \ge 0$, $\alpha \in \mathcal{A}$, $u \in \mathcal{U}$, *and* $x \in H$.

Proof. Fix $\alpha \in \mathcal{A}$ and $u \in \mathcal{U}$. Choose a sequence of functions $(h_n, n \in \mathbb{N})$ such that $h_n : H \to U$ is globally Lipschitz continuous and $h_n \to h$ pointwise as $n \to \infty$ and h is bounded by the constant $\tilde{k}(\alpha)$ from (A2). It follows as in Proposition 3.4 of [12] and Proposition 1.5 of [27] that

$$\begin{aligned}\mathbb{E} g(X(t))\exp(\xi_{n,t}) - g(x) = \mathbb{E}\int_0^t & (-\Phi(X(s)) \\ & + \langle f(\alpha, X(s)), D_x g(X(s))\rangle + \langle h_n(X(s)), B^* D_x g(X(s))\rangle_U \\ & + \frac{1}{2}\mathrm{tr}[(A^*)^{1/2-\gamma} D_{xx} g(X(s)) BB^* (A^*)^{\gamma-1/2}] \\ & + \frac{1}{2}\mathrm{tr}[(A^*)^{1/2-\Delta} D_{xx} g(X(s)) Q (A^*)^{\Delta-1/2}])\exp(\xi_{n,s})\mathrm{d}s\end{aligned} \tag{4.13}$$

for $t \geq 0$, where

$$\xi_{n,s} = \int_0^t \langle h_n(\alpha, X(r), u(X(r))), \mathrm{d}V(r)\rangle_U - \frac{1}{2}\int_0^t |h_n(\alpha, X(r), u(X(r)))|_U^2 \mathrm{d}r.$$

The remainder of the proof investigates the particular terms above as $n \to \infty$. As in the proof of Lemma 4.1, it can be shown that

$$\lim_{n\to\infty} \int_0^t \mathbb{E}|\exp(\xi_{n,s}) - \exp(\xi_s^{\alpha,u})|\mathrm{d}s = 0,$$

so there is a subsequence such that $\exp(\xi_{n_k,t}) \to \exp(\xi_t^{\alpha,u})$ on $[0,T]\times\Omega$, $\lambda\times\mathbb{P}$ almost everywhere, where λ is the Lebesgue measure on $\mathbb{R}$. It remains to verify the uniform integrability of the terms on the right-hand side of (4.13). It can be assumed that p in (4.11) is sufficiently large. Thus, for example,

$$\begin{aligned}|\langle f(\alpha, X(s)), D_x g(X(s))\rangle \exp(\xi_{n,s})|^2 &\leq c_1(k + k_f|X(s)|)^2\hat{k}^2(1+|X(s)|^p)^2\exp(2\xi_{n,s})\\ &\leq c_2 + c_3|X(s)|^{2p+2}\exp(2\xi_{n,s}).\end{aligned}$$

By Lemma 2.1 it follows that

$$\sup_{\substack{n\in\mathbb{N}\\ s\in[0,t]}} \mathbb{E}|X(s)|^{2p+2}\exp(2\xi_{n,s}) < \infty.$$

The uniform integrability of the other terms in (4.13) is verified in a similar way. □

REMARK. If the operator A^{-1} is compact and $D_{xx}g(x)BB^*$ can be extended to a nuclear operator on H for all $x \in H$, then

$$\mathrm{tr}[(A^*)^{1/2-\gamma}D_{xx}g(x)BB^*(A^*)^{\gamma-1/2}] = \mathrm{tr}D_{xx}g(x)BB^*$$

(Theorem iii.8.2 of [19]) and the analogous equality is satisfied for the last term on the right-hand side of (4.12). The equality (4.12) then has the usual form, which is called the Itô formula.

Choose and fix $\alpha_1 \in \mathcal{A}$ and let $\eta = P_{\alpha_1}(1,0,\cdot)$ (recall (2.8)). Note that by [27] and (A3) all of the transition functions $P_\alpha(t,x,\cdot)$, $\alpha \in \mathcal{A}$, $t > 0$, and $x \in H$ are equivalent. The following lemma is Lemma 3 of [13].

LEMMA 4.5. *Let $\varphi : H \to U$ and $G : H \to U$ be bounded, Borel measurable functions and let $(G_n, n \in \mathbb{N})$ be a sequence of bounded, Borel measurable functions that converge to G in $\sigma(L^\infty(H,\eta,H), L^1(H,\eta,H))$ (i.e., in the weak* topology of $L^\infty(H,\eta,H)$). If* (A1)–(A3) *are satisfied, then*

$$\lim_{n\to\infty} \mathbb{E}\left(\int_0^t \langle \varphi(X(s)), G_n(X(s)) - G(X(s))\rangle_U \mathrm{d}s\right)^2 = 0, \tag{4.14}$$

where $(X(t), t \geq 0)$ satisfies (2.5) *and $\alpha \in \mathcal{A}$, $x \in H$ are arbitrary.*

The following result is a technical lemma which will play an important role in the proofs of the existence of an optimal control and the uniformly continuous dependence of the invariant measures on the parameter α.

PROPOSITION 4.6. *Let $(\alpha_n, n \in \mathbb{N})$ be a sequence in $\mathcal{A}$ that converges to $\alpha_0 \in \mathcal{A}$ and let $(h(\alpha_0,\cdot,u_n(\cdot)), n \in \mathbb{N})$ be a sequence that converges to $h(\alpha_0,\cdot,u(\cdot))$ in $\sigma(L^\infty(H,\eta,H), L^1(H,\eta,H))$. If* (A1)–(A3) *are satisfied then*

$$\lim_{n\to\infty} P_t^{\alpha_n,u_n}\varphi(x) = P_t^{\alpha_0,u}\varphi(x) \tag{4.15}$$

for each $\varphi \in \mathcal{M}(H)$, $x \in H$, and $t > 0$.

Proof. It easily follows that

(4.16)
$$\begin{aligned}|P_t^{\alpha_n,u_n}\varphi(x) - P_t^{\alpha_0,u}\varphi(x)| &\le |P_t^{\alpha_n,u_n}\varphi(x) - P_t^{\alpha_0,u_n}\varphi(x)| + |P_t^{\alpha_0,u_n}\varphi(x) - P_t^{\alpha_0,u}\varphi(x)| \\ &\le \sup|\varphi|\|P^{\alpha_n,u_n}(t,x,\cdot) - P^{\alpha_o,u_n}(t,x,\cdot)\| \\ &\quad + |P_t^{\alpha_0,u_n}\varphi(x) - P_t^{\alpha_0,u}\varphi(x)|.\end{aligned}$$

By Proposition 4.3 the first term on the right-hand side of (4.16) tends to zero as $n \to \infty$, so it suffices to show that for any subsequence $(u_{n_k},\, k \in \mathbb{N})$

$$\lim_{k\to\infty} \mathbb{E}\varphi(X(t))\exp(\xi_t^{\alpha_0,u_{n_k}}) = \mathbb{E}\varphi(X(t))\exp(\xi_t^{\alpha_0,u}), \tag{4.17}$$

where $(X(t),\, t \ge 0)$ is a solution of (2.1) with $\alpha = \alpha_0$. The sequence $(\exp(\xi_t^{\alpha_0,u_k}),\, k \in \mathbb{N})$ is bounded in $L^1(\Omega,\mathbb{P})$, so there is a subsequence denoted as the full sequence and a $Z \in L^1(\Omega,\mathbb{P})$ such that

$$\lim_{n\to\infty} \exp(\xi_t^{\alpha_0,u_n}) = Z \tag{4.18}$$

in $\sigma(L^1(\Omega,\mathbb{P}), L^\infty(\Omega,\mathbb{P}))$. Since φ is bounded, the equality (4.17) follows if $Z = \exp(\xi_t^{\alpha_0,u})$. Let $g = \bar{g}(\langle x,e_1\rangle,\dots,\langle x,e_n\rangle)$, where $(e_i,\, i \in \mathbb{N})$ is a complete orthonormal basis in H such that $e_i \in D(A^*)$, $\bar{g} \in C_0^\infty(\mathbb{R}^n)$ is arbitrary, and $n \in \mathbb{N}$. By Proposition 4.4 it follows that

$$\begin{aligned}g(X(r)) - \int_0^r &(\langle -A^*D_xg(X(s)), X(s)\rangle + \langle D_xg(X(s)), f(\alpha_0,X(s))\rangle \\ &+ \langle B^*D_xg(X(s)), h(\alpha_0,X(s),u_n(X(s)))\rangle_U \\ &+ \frac{1}{2}\mathrm{tr}[(A^*)^{1/2-\gamma}D_{xx}g(X(s))BB^*(A^*)^{\gamma-1/2}] \\ &+ \frac{1}{2}\mathrm{tr}[(A^*)^{1/2-\Delta}D_{xx}g(X(s))Q(A^*)^{\Delta-1/2}])\mathrm{d}s\end{aligned} \tag{4.19}$$

for $r \in [0,t]$ is a martingale with respect to $\mathbb{P}_x^{\alpha_0,u_n}$. Apply Lemma 4.1 with $\varphi(y) = B^*D_xg(y)$, $G_n(y) = h(\alpha_0,y,u_n(y))$, and $G(y) = h(\alpha_0,y,u(y))$ to obtain

$$\lim_{n\to\infty} \mathbb{E}\left(\int_0^t \langle B^*D_xg(X(s)), h(\alpha_0,X(s),u_n(X(s)) - h(\alpha_0,X(s),u(X(s)))\rangle_U\right)^2 \mathrm{d}s = 0$$

so there is a subsequence such that for each $\Gamma \in \mathcal{F}$

$$\begin{aligned}&\lim_{k\to\infty}\int_\Gamma\int_0^r \langle B^*D_xg(X(s)), h(\alpha_0,X(s),u_{n_k}(X(s)))\rangle_U \exp(\xi_t^{\alpha_0,u_{n_k}})\mathrm{d}\mathbb{P} \\ &\quad = \int_\Gamma\int_0^r \langle B^*D_xg(X(s)), h(\alpha_0,X(s),u(X(s)))\rangle_U Z\mathrm{d}\mathbb{P}\end{aligned} \tag{4.20}$$

for all $r \in [0,t]$ by (4.34) of [2] and (33) of [32]. It follows that (4.19) is a continuous martingale with respect to $Z\mathbb{P}(\mathrm{d}\omega)$, and by the weak uniqueness of the solutions of (2.1) it follows that $Z = \exp(\xi_t^{\alpha_0,u})$ (cf. [18]). □

REMARK 4.7. In the remainder of this section some continuity properties of the invariant measures corresponding to the solution of (2.1) are verified. One of the basic assumptions here is the tightness condition (A5). Using a Lyapunov condition, (A5) is verified in section 5. Furthermore, if (A1)–(A3) are satisfied, then for each $\alpha \in \mathcal{A}$ and $u \in \mathcal{U}$ the transition probabilities $(P^{\alpha,u}(t,x,\cdot),\ t>0,\ x\in H)$ are equivalent, which follows from the equivalence of the transition probabilities $(P_\alpha(t,x,\cdot),\ t>0,\ x\in H)$. This latter fact is an immediate consequence of the strong Feller property (a special case of Lemma 4.2) and irreducibility (Proposition 2.7 of [28]). From the equivalence of $(P^{\alpha,u}(t,x,\cdot),\ t>0,\ x\in H)$, it follows that for each $\alpha\in\mathcal{A}$ and $u\in\mathcal{U}$ the invariant measure $\mu(\alpha,u)$ is ergodic and unique (Proposition 2.5 of [31]).

The following lemma follows basically from Roxin [29] (cf. also the Appendix in [2]).

LEMMA 4.8. *Let $\alpha\in\mathcal{A}$ be fixed. If* (A2), (A6), *and* (A7) *are satisfied then*

$$\{(h(\alpha,\cdot,u(\cdot)),c(\cdot,u(\cdot))) : u\in\mathcal{U}\} \subset L^\infty(H,\eta,U\times\mathbb{R})$$

is compact in the $\sigma(L^\infty(H,\eta,U\times\mathbb{R}),L^1(H,\eta,U\times\mathbb{R}))$ topology.

PROPOSITION 4.9. *If* (A1)–(A7) *are satisfied then*

$$\lim_{\alpha\to\alpha_0}\sup_{u\in\mathcal{U}}\rho_*(\mu(\alpha,u),\mu(\alpha_0,u))=0 \tag{4.21}$$

and

$$\lim_{n\to\infty}\rho_*(\mu(\alpha_0,\hat{u}_n),\mu(\alpha_0,u_0))=0, \tag{4.22}$$

where μ is the invariant measure and ρ_* is a metric for the weak convergence of measures, $\alpha_0\in\mathcal{A}$, $u_0\in\mathcal{U}$ and $(\hat{u}_n,\ n\in\mathbb{N})$ is a sequence in $\mathcal{U}$ such that*

$$\lim_{n\to\infty} h(\alpha_0,\cdot,\hat{u}_n(\cdot)) = h(\alpha_0,\cdot,u_0(\cdot))$$

in the $\sigma(L^\infty(H,\eta,U),L^1(H,\eta,U))$ topology.

Proof. Let $(\alpha_n,\ n\in\mathbb{N})$ be a sequence in $\mathcal{A}$ that converges to α_0 and let $(u_n,\ n\in\mathbb{N})$ be a sequence in $\mathcal{U}$. By Lemma 4.8 there exist subsequences (again denoted $(\alpha_n,\ n\in\mathbb{N})$ and $(u_n,\ n\in\mathbb{N})$) so that $\alpha_n\to\alpha_0$ and $(h(\alpha_0,\cdot,u_n(\cdot)),\ n\in\mathbb{N})$ converges to $h(\alpha_0,\cdot,u(\cdot))$ for some $u\in\mathcal{U}$ in the $\sigma(L^\infty(H,\eta,U),L^1(H,\eta,U))$ topology. To verify (4.21) it is necessary to show that from any such sequences there are subsequences $(\alpha_{n_k},\ k\in\mathbb{N})$ and $(u_{n_k},\ k\in\mathbb{N})$ such that

$$\lim_{k\to\infty}\rho_*(\mu(\alpha_{n_k},u_{n_k}),\mu(\alpha_0,u_{n_k}))=0. \tag{4.23}$$

By the tightness condition (A5) there are measures ν_1 and ν_2 such that $\mu(\alpha_{n_k},u_{n_k})\to\nu_1$ and $\mu(\alpha_0,u_{n_k})\to\nu_2$ as $k\to\infty$ in the weak* topology. It is shown that ν_1 is an invariant measure for $P_t^{\alpha_0,u}$; that is, for each $\varphi\in C_b(H)$,

$$\int\varphi\mathrm{d}\nu_1 = \int P_t^{\alpha_0,u}\varphi\mathrm{d}\nu_1 \tag{4.24}$$

for $t\geq 0$. Again, for notational simplicity, let the subsequences be denoted as $(\alpha_n,\ n\in\mathbb{N})$ and $(u_n,\ n\in\mathbb{N})$. It easily follows that

$$
\begin{aligned}
\left|\int \varphi \mathrm{d}\nu_1 - \int P_t^{\alpha_0,u}\varphi \mathrm{d}\nu_1\right| &\le \left|\int \varphi \mathrm{d}\nu_1 - \int \varphi \mathrm{d}\mu(\alpha_n,u_n)\right| \\
&+ \left|\int \varphi \mathrm{d}\mu(\alpha_n,u_n) - \int P_t^{\alpha_n,u_n}\varphi \mathrm{d}\mu(\alpha_n,u_n)\right| \\
&+ \left|\int P_t^{\alpha_n,u_n}\varphi \mathrm{d}\mu(\alpha_n,u_n) - \int P_t^{\alpha_0,u}\varphi \mathrm{d}\mu(\alpha_n,u_n)\right| \\
&+ \left|\int P_t^{\alpha_0,u}\varphi \mathrm{d}\mu(\alpha_n,u_n) - \int P_t^{\alpha_0,u}\varphi \mathrm{d}\nu_1\right| \\
&:= I_n^1 + I_n^2 + I_n^3 + I_n^4.
\end{aligned} \tag{4.25}
$$

It follows that $I_n^1 + I_n^4 \to 0$ as $n \to \infty$ because $\mu(\alpha_n, u_n) \to \nu_1$ in the weak* topology and $I_n^2 \equiv 0$ because $\mu(\alpha_n, u_n)$ is $P_t^{\alpha_n,u_n}$ invariant. Furthermore,

$$
I_n^3 \le \int_K |P_t^{\alpha_n,u_n}\varphi - P_t^{\alpha_0,u}\varphi| \mathrm{d}\mu(\alpha_n,u_n) + 2\max|\varphi|\mu(\alpha_n,u_n)(H \setminus K) \tag{4.26}
$$

for any compact $K \subset H$. By Proposition 4.6 and Lemma 4.2, $P_t^{\alpha_n,u_n}\varphi \to P_t^{\alpha_0,u}\varphi$ uniformly on compact subsets of H, so this fact and (A5) imply that

$$
\lim_{n\to\infty} I_n^3 = 0.
$$

Therefore, (4.24) is satisfied. Since $\mu(\alpha_0, u)$ is the unique invariant measure for $P_t^{\alpha_0,u}$, $\nu_1 = \mu(\alpha_0, u)$. In the same way it follows that $\nu_2 = \mu(\alpha_0, u)$, which verifies (4.23) and thereby (4.21). To verify (4.22) note that given any sequence $(\mu(\alpha_0, \hat{u}_n),\ n \in \mathbb{N})$ there is a subsequence $(\mu(\alpha_0, \hat{u}_{n_k}),\ k \in \mathbb{N})$ converging to a measure ν_3 in the weak* topology. By analogy to (4.25) it can be shown that ν_3 is $P_t^{\alpha_0,u_0}$ invariant so $\nu_3 = \mu(\alpha_0, u_0)$. □

In Proposition 4.9, (4.21) gives the uniformly continuous dependence of invariant measures on the parameter α. Using Propositions 4.9 and 4.3 a strong version of (4.21) is obtained now.

PROPOSITION 4.10. *If* (A1)–(A7) *are satisfied then*

$$
\lim_{\alpha\to\alpha_0} \sup_{u\in\mathcal{U}} \|\mu(\alpha,u) - \mu(\alpha_0,u)\| = 0, \tag{4.27}
$$

where $\|\cdot\|$ *is the variation norm.*

Proof. It easily follows that

$$
\begin{aligned}
\sup_{u\in\mathcal{U}} \|\mu(\alpha,u) - \mu(\alpha_0,u)\| &= \sup_{u\in\mathcal{U}} \sup_{\substack{|\varphi|\le 1\\ \varphi\in C_b}} \left|\int_H \varphi \mathrm{d}\mu(\alpha,u) - \int_H \varphi \mathrm{d}\mu(\alpha_0,u)\right| \\
&= \sup_{u\in\mathcal{U}} \sup_{|\varphi|\le 1} \left|\int_H P_1^{\alpha,u}\varphi \mathrm{d}\mu(\alpha,u) - \int_H P_1^{\alpha_0,u}\varphi \mathrm{d}\mu(\alpha_0,u)\right| \\
&\le 2\sup_{\alpha,u} \mu(\alpha,u)(H \setminus K) + \int_K \sup_u \|P^{\alpha,u}(1,x,\cdot) - P^{\alpha_0,u}(1,x,\cdot)\| \mu(\alpha,u)(\mathrm{d}x) \\
&+ \sup_{u,\varphi} \left|\int_K P_1^{\alpha,u}\varphi \mathrm{d}\mu(\alpha,u) - \int_K P_1^{\alpha_0,u}\varphi \mathrm{d}\mu(\alpha_0,u)\right|
\end{aligned} \tag{4.28}
$$

for any compact set $K \subset H$. By (A5) the first term on the right-hand side of (4.28) can be made arbitrarily small by choosing a suitable compact set K, and by Proposition 4.3 the second term converges to zero almost surely as $\alpha \to \alpha_0$. Furthermore, by Lemma 4.2 the family of functions $(P_1^{\alpha_0,u}\varphi, |\varphi| \le 1,\ u \in \mathcal{U})$ is uniformly continuous on K, so for sequences $(u_n,\ n \in \mathbb{N})$ and $(\varphi_n,\ n \in \mathbb{N})$, where $u_n \in \mathcal{U}$ and $\varphi_n \in C_b$ for $n \in \mathbb{N}$, there are subsequences $(u_{n_k},\ k \in \mathbb{N})$ and $(\varphi_{n_k},\ k \in \mathbb{N})$ and a $\psi \in C_b(K)$ such that $P_1^{\alpha_0,u_{n_k}}\varphi_{n_k}(x) \to \psi(x)$, as $k \to \infty$, uniformly in $x \in K$. Now the third term on the right-hand side of (4.28) is shown to converge to zero.

$$
\begin{aligned}
&\left|\int_K P_1^{\alpha_0,u_{n_k}}\varphi_{n_k}\mathrm{d}\mu(\alpha,u_{n_k}) - \int_K P_1^{\alpha_0,u_{n_k}}\varphi_{n_k}\mathrm{d}\mu(\alpha_0,u_{n_k})\right| \\
&\qquad \le \int_K |P_1^{\alpha_0,u_{n_k}}\varphi_{n_k} - \psi|\mathrm{d}\mu(\alpha,u_{n_k}) + \left|\int_K \psi\mathrm{d}\mu(\alpha,u_{n_k}) - \int_K \psi\mathrm{d}\mu(\alpha_0,u_{n_k})\right| \\
&\qquad\quad + \int_K |\psi - P_1^{\alpha_0,u_{n_k}}\varphi_{n_k}|\mathrm{d}\mu(\alpha_0,u_{n_k}) \\
&\qquad := I_n^1 + I_n^2 + I_n^3.
\end{aligned} \tag{4.29}
$$

By the uniform convergence $P_1^{\alpha_0,u_{n_k}}\varphi_{n_k} \to \psi$ on K it follows that $I_n^1 + I_n^3 \to 0$ as $n \to \infty$, and by (4.21) it follows that $I_n^2 \to 0$ as $n \to \infty$. This proves that the last term on the right-hand side of (4.28) tends to zero as $\alpha \to \alpha_0$. □

REMARK 4.11. The strong continuous dependence of the invariant measures on a parameter in Proposition 4.10 can be of independent interest even for equations without control. If the parameter occurs linearly in the generator of even a very simple example of an Ornstein–Uhlenbeck process then the invariant measures may not depend continuously on α in the variation norm. For example, consider the stochastic differential equation

$$
\mathrm{d}X(t) + \alpha AX(t)\mathrm{d}t = \mathrm{d}W(t), \qquad X(0) = x, \tag{4.30}
$$

where A and $(W(t),\ t \ge 0)$ are the same as in (2.1) and $\alpha \in [1/2, 2]$. If

$$
\int_0^\infty |S(t)|^2_{\mathcal{L}_2(H)}\mathrm{d}t < \infty \tag{4.31}
$$

then (4.30) has a unique mild solution that is a continuous H-valued process. If (4.31) is satisfied and $\alpha \in [1/2, 2]$, then there is a unique invariant measure $\mu(\alpha)$ for the solution of (4.30), where $\mu(\alpha) = N(0, \alpha^{-1}\tilde{Q})$ and $\tilde{Q} = \int_0^\infty S(t)S^*(t)\mathrm{d}t$. It is easy to verify that the family of measures $(\mu(\alpha),\ \alpha \in [1/2, 2])$ is tight and $\mu(\alpha) \xrightarrow{w^*} \mu(1)$ as $\alpha \to 1$. However, the variation norm convergence $\mu(\alpha) \to \mu(1)$ occurs if and only if $\dim H < \infty$ because the operator $(\alpha^{-1}\tilde{Q})\tilde{Q}^{-1} - I = (\alpha^{-1} - 1)I$ is not Hilbert–Schmidt for $\alpha \ne 1$ and $\dim H = \infty$, and so $\mu(\alpha)$ and $\mu(1)$ are singular by the well-known dichotomy for Gaussian measures. This occurs even in the strong Feller case when the solution of (4.30) converges in law to the invariant measure in the variation norm for each fixed α. For a specific example of this, consider the linear SPDE

$$
\frac{\partial w}{\partial t}(t,\xi) = \alpha\frac{\partial^2 w}{\partial \xi^2}(t,\xi) + n(t,\xi), \tag{4.32}
$$

where $\alpha \in [1/2, 2]$, $(t, \xi) \in \mathbb{R}_+ \times (0, 1)$, $w(0, \xi) = w_0(\xi)$, $w(t, 0) = v(t, 1) = 0$, and $(n(t, \xi),\ t \ge 0,\ \xi \in [0, 1])$ is a space-time white noise which can be expressed as an equation of the form (4.30) for $H = L^2(0, 1)$ (cf. Example 7.1).

5. Existence and tightness of invariant measures. In this section some more explicit sufficient conditions for the validity of (A5) are given by means of some Lyapunov-type inequalities. Throughout this section it is assumed that

(T1) $$A^{-1} \text{ is compact.}$$

Since the semigroup $S(\cdot)$ generated by $-A$ is assumed to be analytic and exponentially stable, there exist some $M > 0$ and $\omega > 0$ such that

(T2) $$|S(t)|_{\mathcal{L}(D_A^{-\delta},H)} \le M\mathrm{e}^{-\omega t}t^{-\delta}$$

for all $t > 0$ and $\delta \le 0$. (The constants M and ω will play some role in the Lyapunov-type conditions given below.)

While in the other sections of this paper the negativity of $-A$ is assumed merely for convenience (because $A + \beta I$ can be used instead of A, and βI can be added to f), in this section it is essential.

Define $\mu_T^{\alpha,u}$ as follows:

$$\mu_T^{\alpha,u}(\cdot) = \frac{1}{T}\int_0^T P^{\alpha,u}(t,0,\cdot)\mathrm{d}t \tag{5.1}$$

for $\alpha \in \mathcal{A}$, $u \in \mathcal{U}$, and $T > 0$. Since the solution of (2.1) is Feller, to verify (A5) it suffices to show that the family of measures $(\mu_T^{\alpha,u},\ \alpha \in \mathcal{A},\ u \in \mathcal{U},\ T \ge 1)$ is tight. In the following proposition it is shown that the tightness of $(\mu_T^{\alpha,u},\ \alpha \in \mathcal{A},\ u \in \mathcal{U},\ T \ge 1)$ follows from a similar property, where compact sets are replaced by balls (5.2). Note that (5.2) does not guarantee the existence of an invariant measure in general (cf. [33]).

PROPOSITION 5.1. *If* (A1), (A2), *and* (T1) *are satisfied and*

$$\lim_{n\to\infty} \mu_T^{\alpha,u}(H \setminus B_n) = 0, \tag{5.2}$$

where the convergence is uniform in $\alpha \in \mathcal{A}$, $u \in \mathcal{U}$, *and* $T \ge 1$, *and* $B_n = \{x \in H : |x| \le n\}$, *then the family of measures* $(\mu_T^{\alpha,u},\ \alpha \in \mathcal{A},\ u \in \mathcal{U},\ T \ge 1)$ *is tight.*

Proof. The weak solution of (2.1) satisfies the equation

$$\begin{aligned} X(t) &= S(t)x + \int_0^t S(t-r)f(\alpha, X(r))\mathrm{d}r \\ &\quad + \int_0^t S(t-r)Bh(\alpha, X(r), u(X(r)))\mathrm{d}r + Z_1(t) + Z_2(t), \end{aligned} \tag{5.3}$$

where

$$Z_1(t) = \int_0^t S(t-r)B\mathrm{d}V^*(r)$$

and

$$Z_2(t) = \int_0^t S(t-r)Q^{1/2}\mathrm{d}W(r)$$

for $t \ge 0$. By (A1) and Lemma 2.2 of [30] it follows that

$$\mathbb{E}_x^{\alpha,u}|Z_1(t)|_\delta^2 + \mathbb{E}_x^{\alpha,u}|Z_2(t)|_\delta^2 \le M_1$$

for $t \in [0,T]$, where $T > 0$ is fixed and the constant M_1 (as well as $M_2, \dots, M_5$ below) does not depend on $\alpha \in \mathcal{A}$, $u \in \mathcal{U}$, and $x \in H$, and $|\cdot|_\delta$ is the D_A^δ norm and

$\delta \in (0, \min(\varepsilon, \gamma, \Delta))$ is fixed. It follows that

$$\mathbb{E}_x^{\alpha,u}|X(t)|_\delta \le M_2|x|t^{-\delta} + \int_0^t \frac{M_3}{(t-s)^{1-\varepsilon+\delta}}\mathbb{E}_x^{\alpha,u}|X(s)|_\delta \mathrm{d}s + M_4 \tag{5.4}$$

for $t \in (0,T]$ and $x \in H$, so the generalized Gronwall lemma (Theorem 7.1 of [21]) implies that

$$\mathbb{E}_x^{\alpha,u}|X(T)|_\delta \le M_5(1+|x|) \tag{5.5}$$

for $\alpha \in \mathcal{A}$, $u \in \mathcal{U}$, and $x \in H$. By the Chebyshev inequality it follows that

$$\sup_{|y|\le R} \mathbb{P}_y^{\alpha,u}(|X(t)|_\delta \ge n) \le \frac{1}{n} M_5(1+R) \tag{5.6}$$

for $n \in \mathbb{N}$, $R > 0$, $\alpha \in \mathcal{A}$, and $u \in \mathcal{U}$.

Let $K_n \subset H$ be given by

$$K_n = \mathrm{Cl}_H A^{-\delta} B_n \tag{5.7}$$

for $n \in \mathbb{N}$, where Cl_H is the closure in H. Since $A^{-\delta}$ is a compact operator, K_n is compact in H. It follows that

(5.8)

$$\begin{aligned}
\frac{1}{T}\int_1^T P^{\alpha,u}(t,0,H\setminus K_n)\mathrm{d}t &= \frac{1}{T}\int_1^T \int_H P^{\alpha,u}(1,y,H\setminus K_n)P^{\alpha,u}(t-1,0,\mathrm{d}y)\mathrm{d}t \\
&= \frac{T-1}{T}\int_H P^{\alpha,u}(1,y,H\setminus K_n)\mu_{T-1}^{\alpha,u}(\mathrm{d}y) \\
&\le \mu_{T-1}^{\alpha,u}(H\setminus B_R) + \mu_{T-1}^{\alpha,u}(B_R)\sup_{|y|\le R} P^{\alpha,u}(1,y,H\setminus K_n) \\
&\le \mu_{T-1}^{\alpha,u}(H\setminus B_R) + \frac{1}{n}M_5(1+R)
\end{aligned}$$

for each $R > 0$. By (5.2) the right-hand side tends to zero as $n \to \infty$ uniformly in $\alpha \in \mathcal{A}$, $u \in \mathcal{U}$, and $T \ge 1$. □

In Theorem 5.3 below, the condition (5.2) is verified by a Lyapunov functional that completes the verification of (A5). Let V be given by

$$V = 2\int_0^\infty S(r)S^*(r)\mathrm{d}r. \tag{5.9}$$

If (T2) is satisfied then $V \in \mathcal{L}(H)$ is well defined, $V = V^*$, and $V \ge 0$.

The following estimates are easily verified.

LEMMA 5.2. *For $\beta, \lambda \in \mathbb{R}_+$ with $\beta + \lambda < 1$, $V \in \mathcal{L}(D_A^{-\beta}, D_A^{\lambda})$ and the following inequality is satisfied:*

$$|V|_{\mathcal{L}(D_A^{-\beta},D_A^{\lambda})} \le 2M^2(2\omega)^{\beta+\lambda-1}\Gamma(1-\beta-\lambda), \tag{5.10}$$

where Γ is the gamma function, M and ω are given in (T2)*, and V is given by* (5.9)*. Furthermore, if A is self-adjoint, then $V = A^{-1}$ and*

$$|V|_{\mathcal{L}(D_A^{-\beta},D_A^{\lambda})} \le \omega^{\beta+\lambda-1} \tag{5.11}$$

and ω is the first eigenvalue of A.

THEOREM 5.3. *If* (A1), (A2), (T1), (T2) *are satisfied and either*

$$M^2\omega^{-1}k_f + 2^{1-\varepsilon}M^2\omega^{-\varepsilon}|B|_{\mathcal{L}(U,D_A^{\varepsilon-1})}\Gamma(\varepsilon)k_h < 1 \tag{5.12}$$

for A not self-adjoint or

$$\omega^{-1}k_f + |B|_{\mathcal{L}(U,D_A^{\varepsilon-1})}\omega^{-\varepsilon}k_h < 1 \tag{5.13}$$

for A self-adjoint, where M and ω are given in (T2) *and Γ is the gamma function, then the condition* (A5) *is satisfied. In particular,* (5.12) *and* (5.13) *are satisfied if* $|f|$ *and* $|h|_U$ *are bounded uniformly with respect to* $\alpha \in \mathcal{A}$ *and* $u \in \mathcal{U}$.

Proof. By Proposition 5.1 it suffices to verify (5.2). Use Proposition 4.4 with $g(x) = \langle Vx, x\rangle$ so that $D_x g(x) = Vx$, $D_{xx}g(x) = V$,

$$|V|_{\mathcal{L}(H,D_{A^*}^{1-\varepsilon})} \le 2M^2(2\omega)^{-\varepsilon}\Gamma(\varepsilon), \tag{5.14}$$

and $\langle Ax, D_x g(x)\rangle = |x|^2$ for $x \in D_A^1$, and by Lemma 5.2 $V \in \mathcal{L}(D_A^{\gamma-1/2}, D_{A^*}^{1/2-\gamma}) \cap \mathcal{L}(D_A^{\Delta-1/2}, D_{A^*}^{1/2-\Delta})$. Thus the assumptions of Proposition 4.4 are satisfied, and by (A2) and (5.14),

$$\begin{aligned}
&\mathbb{E}_x^{\alpha,u}\langle VX(t), X(t)\rangle - \langle Vx, x\rangle \\
&\le \mathbb{E}_x^{\alpha,u}\int_0^t (|X(s)|^2(-1 + M^2\omega^{-1}k_f + 2^{1-\varepsilon}M^2\omega^{-\varepsilon}|B|_{\mathcal{L}(U,D_A^{\varepsilon-1})}\Gamma(\varepsilon)k_h) \\
&\quad + c_1|X(s)| + c_2)\mathrm{d}s
\end{aligned} \tag{5.15}$$

for $t \ge 0$, where the constants c_1 and c_2 (as well as the constants c_3 and c_4 below) do not depend on $\alpha \in \mathcal{A}$ and $u \in \mathcal{U}$. Choosing r such that $M^2\omega^{-1}k_f + 2^{1-\varepsilon}M^2\omega^{-2}|B|_{\mathcal{L}(U,D_A^{\varepsilon-1})}\Gamma(\varepsilon)\cdot k_h < r < 1$, it follows that

$$\mathbb{E}_x^{\alpha,u}\langle VX(t), X(t)\rangle - \langle Vx, x\rangle \le \mathbb{E}_x^{\alpha,u}\int_0^t ((r-1)|X(t)|^2 + c_3)\mathrm{d}s$$

for $t \ge 0$, and since $V \ge 0$ it follows that

$$\sup_{t\ge 1}\frac{1}{t}\int_0^t \mathbb{E}_x^{\alpha,u}|X(s)|^2\mathrm{d}s \le \sup_{t\ge 1}\frac{\langle Vx, x\rangle}{t(1-r)} + \frac{c_3}{1-r} \le c_4. \tag{5.16}$$

By (5.16) and the Chebyshev inequality it follows that (5.2) is satisfied. If A is self-adjoint then (5.11) can be used instead of (5.10). □

6. The existence of an optimal control. Recall that the control problem is described by the system (2.1) and the cost functional

$$J(\alpha, u) = \limsup_{T\to\infty}\mathbb{E}_x^{\alpha,u}\frac{1}{T}\int_0^T c(X(s), u(X(s)))\mathrm{d}s, \tag{6.1}$$

and the optimal cost is $J^*(\alpha) = \inf_{u\in\mathcal{U}} J(\alpha, u)$. If (A1)–(A3), (A5), and (A6) are satisfied then the following equality is satisfied:

$$J(\alpha, u) = \int_H c(y, u(y))\mu(\alpha, u)(\mathrm{d}y) \tag{6.2}$$

(cf. Remark 4.7), so the cost $J(\alpha, u)$ does not depend on the initial condition $X(0) = x \in H$. In this section the existence of an optimal control for the control problem (2.1) and (6.1) with a fixed parameter $\alpha \in \mathcal{A}$ and the continuity of the optimal cost $J^* : \mathcal{A} \to \mathbb{R}$ are verified. In Lemma 6.1 and Theorem 6.2 the parameter is fixed, so it is suppressed for notational convenience.

Recall that $P(t, x, \Gamma)$ is given in (2.8) and $\eta = P(1, 0, \cdot)$.

LEMMA 6.1. *Let $(A_n,\, n \in \mathbb{N})$ be a sequence in $\mathcal{B}(H)$ such that $\eta(A_n) \to 0$ as $n \to \infty$. If* (A1)–(A3) *and* (A5) *are satisfied then*

$$\lim_{n\to\infty} \sup_{u\in\mathcal{U}} \mu(u)(A_n) = 0. \tag{6.3}$$

Proof. Since $P(1, \cdot, \cdot) : H \to \mathcal{P}(H)$ is continuous in the variation norm and $P(1, x, \cdot)$ and η are equivalent for each $x \in K$, where $K \subset H$ is compact, it follows that

$$\lim_{n\to\infty} \sup_{x\in K} P(1, x, A_n) = 0. \tag{6.4}$$

Since, for a fixed $\alpha \in \mathcal{A}$, $|h|_U$ is bounded it follows that

$$\begin{aligned} \sup_{u\in\mathcal{U},\ x\in K} P^u(1, x, A_n) &= \sup_{u\in\mathcal{U}} \sup_{x\in K} \mathbb{E}_x 1_{A_n}(X(1)) \exp(\xi_1^u) \\ &\le \sup_{x\in K} (P(1, x, A_n))^{1/2} \exp(\sup |h|^2). \end{aligned} \tag{6.5}$$

The right-hand side of this inequality tends to zero as $n \to \infty$ by (6.4).

Finally it follows that

$$\begin{aligned} \sup_{u\in\mathcal{U}} \mu(u)(A_n) &= \sup_{u\in\mathcal{U}} \int_H P^u(1, x, A_n)\mu(u)(\mathrm{d}x) \\ &\le \sup_{u\in\mathcal{U}} \mu(u)(H \setminus K) + \int_K \sup_{u\in\mathcal{U}} P^u(1, x, A_n)\mu(u)(\mathrm{d}x). \end{aligned}$$

By (6.5) and the tightness of the family of measures $(\mu(u),\, u \in \mathcal{U})$ the right-hand side of this inequality tends to zero as $n \to \infty$.

THEOREM 6.2. *If* (A1)–(A3) *and* (A5)–(A7) *are satisfied for each $\alpha \in \mathcal{A}$, then there is an optimal control for the control problem given by* (2.1) *and* (6.1).

Proof. Let $(u_n,\, n \in \mathbb{N})$ be a sequence in $\mathcal{U}$ such that there is a subsequence in $(u_n,\, n \in \mathbb{N})$ denoted as $(u_n,\, n \in \mathbb{N})$ for notational convenience, such that

$$\lim_{n\to\infty} (h(\cdot, u_n(\cdot)), c(\cdot, u_n(\cdot))) = (h(\cdot, u(\cdot)), c(\cdot, u(\cdot))) \tag{6.6}$$

in the $\sigma(L^\infty(H, \eta, U \times \mathbb{R}), L^1(H, \eta, U \times \mathbb{R}))$ topology. To verify that u is an optimal control it is necessary to prove that for any subsequence $(u_{n_k},\, k \in \mathbb{N})$,

$$\lim_{k\to\infty} J(u_{n_k}) = J(u). \tag{6.7}$$

As in Lemma 4.5 it follows that

$$\lim_{n\to\infty} \mathbb{E}\left(\int_0^t (c(X(s), u_n(X(s))) - c(X(s), u(X(s))))\mathrm{d}s \right)^2 = 0,$$

where $(X(t),\, t \geq 0)$ satisfies (2.5) with $X(0) = x \in H$ arbitrary (cf. Theorem 2 of [13]). As in the passage to the limit in the proof of Proposition 4.4 it follows that

$$\lim_{n\to\infty} \mathbb{E}_x^{u_n} \int_0^t c(X(s), u_n(X(s)))\mathrm{d}s = \mathbb{E}_x^u \int_0^t c(X(s), u(X(s)))\mathrm{d}s \tag{6.8}$$

for a subsequence again denoted by $(u_n,\, n \in \mathbb{N})$. By Egorov's theorem the convergence in (6.8) is uniform in x except possibly on a set of arbitrarily small η-measure. This fact and Lemma 6.1 imply that

(6.9)

$$\lim_{n\to\infty} \int_H \left| \mathbb{E}_x^{u_n} \int_0^t c(X(s), u_n(X(s)))\mathrm{d}s - \mathbb{E}_x^u \int_0^t c(X(s), u(X(s)))\mathrm{d}s \right| \mu(u_n)(\mathrm{d}x) = 0.$$

For each fixed $t > 0$ it follows that

(6.10)

$$\begin{aligned}
&|J(u_n) - J(u)| \\
&\quad = \left| \int_H c(y, u_n(y))\mu(u_n)(\mathrm{d}y) - \int_H c(y, u(y))\mu(u)(\mathrm{d}y) \right| \\
&\quad \leq \left| \frac{1}{t} \int_0^t \left[\int_H \mathbb{E}_y^{u_n} c(X(s), u_n(X(s)))\mu(u_n)(\mathrm{d}y) \right.\right. \\
&\qquad\qquad \left.\left. - \int_H \mathbb{E}_y^u c(X(s), u(X(s)))\mu(u)(\mathrm{d}y) \right] \mathrm{d}s \right| \\
&\quad \leq \frac{1}{t} \int_H \left| \mathbb{E}_y^{u_n} \int_0^t c(X(s), u_n(X(s)))\mathrm{d}s - \mathbb{E}_y^u \int_0^t c(X(s), u(X(s)))\mathrm{d}s \right| \mu(u_n)(\mathrm{d}y) \\
&\qquad + \frac{1}{t} \int_0^t \left| \int_H \mathbb{E}_y^u c(X(s), u(X(s)))\mu(u_n)(\mathrm{d}y) - \int_H \mathbb{E}_y^u c(X(s), u(X(s)))\mu(u)(\mathrm{d}y) \right| \mathrm{d}s \\
&\quad := I_n^1 + I_n^2.
\end{aligned}$$

By (6.9) it suffices to show that $I_n^2 \to 0$ as $n \to \infty$. Since $c(\cdot, u(\cdot))$ is bounded and Borel measurable, the strong Feller property (Lemma 4.2) implies that

$$\mathbb{E}_\cdot c(X(s), u(X(s))) : H \to \mathbb{R}$$

is continuous for each $s > 0$ where $\mathbb{E}_x c(X(s), u(X(s))) = P_s^u c(\cdot, u(\cdot))(x)$. So by (4.22) and the dominated convergence theorem, $I_n^2 \to 0$ as $n \to \infty$. □

THEOREM 6.3. *If* (A1)–(A7) *are satisfied then the optimal cost* $J^* : \mathcal{A} \to \mathbb{R}$ *is continuous.*

Proof. It follows that

$$\sup_{u\in\mathcal{U}} |J(\alpha, u) - J(\alpha_0, u)| \leq \sup |c| \sup_{u\in\mathcal{U}} \|\mu(u, \alpha) - \mu(u, \alpha_0)\|. \tag{6.11}$$

By Proposition 4.10 it follows that the right-hand side of this inequality tends to zero as $n \to \infty$. Given $\varepsilon > 0$ there is a $\delta > 0$ such that if $|\alpha - \alpha_0| < \delta$ then

$$\sup_{u\in\mathcal{U}} |J(\alpha, u) - J(\alpha_0, u)| < \varepsilon.$$

Let $u_\alpha \in \mathcal{U}$ be an optimal control for the control problem (2.1) and (6.1), that is, $J^*(\alpha) = J(\alpha, u_\alpha)$ for $\alpha \in \mathcal{A}$. Since $J(\alpha, u_{\alpha_0}) \geq J(\alpha, u_\alpha)$ it follows that $J(\alpha_0, u_{\alpha_0}) \geq J(\alpha, u_\alpha) - \varepsilon$. Since $J(\alpha_0, u_{\alpha_0}) \leq J(\alpha_0, u_\alpha)$ it follows that $J(\alpha_0, u_{\alpha_0}) \leq J(\alpha, u_\alpha) + \varepsilon$ for $\alpha \in \mathcal{A}$ and $|\alpha - \alpha_0| < \delta$. □

7. Some Examples.

EXAMPLE 7.1. Consider the scalar stochastic parabolic partial differential equation

$$\frac{\partial v}{\partial t}(t,\xi) = Lv(t,\xi) + F(\alpha, v(t,\xi)) + n(t,\xi) \tag{7.1}$$

for $(t,\xi) \in \mathbb{R}_+ \times (0,1)$ with the initial and boundary conditions

$$v(0,\xi) = v_0(\xi), \tag{7.2}$$

$$\frac{\partial v}{\partial \xi}(t,0) = h_1(\alpha, v(t,\cdot), u(v(t,\cdot))) + \dot{\beta}_1(t), \tag{7.3}$$

$$\frac{\partial v}{\partial \xi}(t,1) = h_2(\alpha, v(t,\cdot), u(v(t,\cdot))) + \dot{\beta}_2(t), \tag{7.4}$$

where n denotes a space-dependent Gaussian noise that is white in time, β_1 and β_2 are one-dimensional standard Wiener processes, and these three processes are mutually independent. Furthermore,

$$Lv = a(\xi)\frac{\partial^2}{\partial \xi^2}v + b(\xi)\frac{\partial}{\partial \xi}v + c(\xi),$$

where $a, b, c \in C^\infty([0,1])$, $a > 0$, $c < 0$, $F : \mathcal{A} \times \mathbb{R} \to \mathbb{R}$, $h_i : \mathcal{A} \times H \times \mathcal{K} \to \mathbb{R}$, $i = 1,2$, where $H = L^2(0,1)$, $\mathcal{A} \subset \mathbb{R}^{d_1}$ is compact, $\mathcal{K} \subset \mathbb{R}^k$ is a compact product of intervals, $F(\alpha,\cdot) : \mathbb{R} \to \mathbb{R}$ is Lipschitz continuous, $h_i(\alpha,\cdot,\cdot) : H \times \mathcal{K} \to \mathbb{R}$, $i = 1,2$, is continuous and bounded for each $\alpha \in \mathcal{A}$ with at most linear growth that is uniform with respect to $\alpha \in \mathcal{A}$, and

$$|F(\alpha,\xi) - F(\beta,\xi)| + \sum_{i=1}^{2} |h_i(\alpha,x,u) - h_i(\beta,x,u)| \ \le \omega(|\alpha-\beta|)(1+\max(|x|,|\xi|)) \tag{7.5}$$

for $\alpha, \beta \in \mathcal{A}$, $\xi \in \mathbb{R}$, $x \in H$, and $u \in \mathcal{K}$, where ω satisfies the properties in (A2). The system of equations (7.1)–(7.4) can be rewritten in the form of (2.1) in a natural way, where $H = L^2(0,1)$, $U = \mathbb{R}^2$, $A = -L$ with

$$\mathrm{Dom}(A) = \left\{ \varphi : \varphi \in H^2(0,1), \frac{\partial}{\partial \xi}\varphi(0) = \frac{\partial}{\partial \xi}\varphi(1) = 0 \right\},$$

$f(\alpha,x)(\xi) = F(\alpha, X(\xi))$, $x \in H$, $\xi \in (0,1)$, and $h = [h_1, h_2]$. The operator B is defined as $B = \hat{A}N$, where $N \in \mathcal{L}(\mathbb{R}^2, D_A^\varepsilon)$, $\varepsilon < 3/4$ is the Neumann map corresponding to the elliptic Neumann problem

$$Lz(\xi) = 0, \qquad \xi \in (0,1), \tag{7.6}$$

$$\frac{\partial z}{\partial \xi}(0) = g_1, \qquad \frac{\partial z}{\partial \xi}(1) = g_2 \tag{7.7}$$

for $g_1, g_2 \in \mathbb{R}$, and $\hat{A} \in \mathcal{L}(D_A^\varepsilon, D_A^{\varepsilon-1})$ is the isomorphic extension of the operator A to D_A^ε. (See [26] for the theory of Dirichlet and Neumann maps, [16] for the identification of D_A^ε with the corresponding Sobolev spaces, and [22] or [27] for the mathematical justification of the form (2.1) for the equations (7.1)–(7.4).) Thus it follows that $B \in \mathcal{L}(U, D_A^{\varepsilon-1})$ for $\varepsilon < 3/4$ in the present case. Now it is verified that (A1) and (A3) are satisfied, where $Q^{1/2} = A^{-\eta}\Gamma$ with $\eta \ge 0$ and $\Gamma, \Gamma^{-1} \in \mathcal{L}(H)$. Since $A^{-\delta}$ is Hilbert–Schmidt for $\delta > 1/4$ (cf. Example 6.1 of [12]) it follows that

$Q^{1/2} \in \mathcal{L}_2(H, D_A^{\Delta-1/2})$ for $\Delta < 1/4 + \eta$. Since the space U is finite-dimensional, $B \in \mathcal{L}_2(U, D_A^{\gamma-1/2})$ for $\gamma < \varepsilon - 1/2$ and γ is positive if $\varepsilon > 1/2$. To verify (A3) use Proposition 3.4, which shows that (A3) is satisfied if $\eta \in [0, \varepsilon - 1/2)$ if $\varepsilon \geq 1/2$. Thus the assumptions (A1) and (A3) are satisfied for $\eta \in [0, 1/4)$ so that ε, γ, and Δ can be chosen to satisfy $\varepsilon \in (\eta + 1/2, 3/4)$, $\gamma < \varepsilon - 1/2$, and $\Delta < 1/4 + \eta$. The assumptions (A2) and (A4) are satisfied by the conditions imposed on F, h_1, and h_2. The tightness condition (A5) can be verified using Theorem 5.3 (note that A^{-1} is compact in the present case). For example, if $|F|$, $|h_1|$, and $|h_2|$ are (uniformly) bounded then (A5) is satisfied. Thus the results of the paper (in particular, Proposition 4.10, Theorems 6.2 and 6.3) can be applied for any cost functional $c : H \times \mathcal{K} \to \mathbb{R}$ that satisfies (A6) and satisfies with h_1 and h_2 the convexity condition (A7). A simple example of a boundary input (7.3), (7.4) that satisfies all the above conditions is

$$\frac{\partial v}{\partial \xi}(t, 0) = u_1(v(t, \cdot)) + \dot{\beta}_1(t), \tag{7.8}$$

$$\frac{\partial v}{\partial \xi}(t, 1) = u_2(v(t, \cdot)) + \dot{\beta}_2(t), \tag{7.9}$$

where $(u_1, u_2) : H \to [-M, M]^2 = \mathcal{K}$.

EXAMPLE 7.2. Consider the stochastic parabolic partial differential equation with pointwise noise and control

$$\frac{\partial v}{\partial t}(t, \xi) = Lv(t, \xi) + F(\alpha, v(t, \xi)) + \sum_{i=1}^{N} [h_i(\alpha, v(t, \cdot), u(v(t, \cdot))) + \dot{\beta}_i(t)]\delta_{\xi_i} + n(t, \xi) \tag{7.10}$$

for $(t, \xi) \in \mathbb{R}_+ \times (0, 1)$ with initial and boundary conditions

$$v(0, \xi) = v_0(\xi), \tag{7.11}$$

$$v(t, 0) = 0, \tag{7.12}$$

$$v(t, 1) = 0 \tag{7.13}$$

for $(t, \xi) \in \mathbb{R}_+ \times (0, 1)$, where L, F, n, β_i, and h_i are the same as in Example 7.1, and δ_{ξ_i}, $i = 1, 2, \ldots, N$, are the Dirac distributions at the points $\xi_i \in (0, 1)$, $i = 1, 2, \ldots, N$. The equation (7.10) is given a precise interpretation by using (2.1) with H and f as in Example 7.1, $V(t) = (\beta_1(t), \ldots, \beta_N(t))$, $U = \mathbb{R}^N$, $h = (h_1, \ldots, h_N)$, and $A = -L$ with $\mathrm{Dom}(A) = H^2(0, 1) \cap H_0^1(0, 1)$. It is possible to use the Neumann boundary conditions in (7.12), (7.13) as well, so that $\mathrm{Dom}(A)$ would be the same as in Example 7.1. Since the domain is one-dimensional it follows by the Sobolev imbedding theorem that $\delta_{\xi_i} \in D_A^{\varepsilon-1}$ for $\varepsilon < 3/4$ (cf. Theorem 1.1 of [5]). It trivially follows that $B \in \mathcal{L}(\mathbb{R}^N, D_A^{\varepsilon-1})$ for $B\lambda = \sum_{i=1}^{N} \lambda_i \delta_{\xi_i}$, $\lambda = (\lambda_1, \ldots, \lambda_N)$. The verification of assumptions (A1)–(A7) in the present example is almost identical to the verifications in Example 7.1 because H and f are the same and U, h, and $V(t)$ are analogous (but the dimension is N instead of 2), $A^{-\delta}$ is Hilbert–Schmidt for $\delta > 1/4$, A^{-1} is compact, and it is again required that $\varepsilon < 3/4$. If the covariance Q of the distributed Wiener process can be expressed as $Q^{1/2} = A^{-\eta}\Gamma$ for $\Gamma, \Gamma^{-1} \in \mathcal{L}(H)$, $\eta \in [0, 1/4)$, then the assumptions (A1) and (A3) are satisfied. Given an $M > 0$ and the set of controls $\mathcal{U} = \{u : H \to [-M, M]^N |\ u \text{ is Borel mesurable}\}$ it is now possible to apply Proposition 4.10 and Theorems 6.2 and 6.3 with any cost functional $c : H \times [-M, M]^N \to \mathbb{R}$ that satisfies (A6) and, together with h, the convexity condition (A7).

PROXIMAL ANALYSIS AND THE MINIMAL TIME FUNCTION*

PETER R. WOLENSKI† AND YU ZHUANG†

Abstract. Under general hypotheses on the target set S and the dynamics of the system, we show that the minimal time function $T_S(\cdot)$ is a proximal solution to the Hamilton–Jacobi equation. Uniqueness results are obtained with two different kinds of boundary conditions. A new propagation result is proven, and as an application, we give necessary and sufficient conditions for $T_S(\cdot)$ to be Lipschitz continuous near S. A Petrov-type modulus condition is also shown to be sufficient for continuity of $T_S(\cdot)$ near S.

Key words. minimal time function, proximal analysis, Hamilton–Jacobi equations, nonsmooth analysis, continuity of value functions

1. Introduction.

The minimal time control problem consists of a given closed set S (the "target set") and a control system in which the goal is to steer an initial point x to the target set along a trajectory of the system in minimal time. The minimal time value is denoted by $T_S(x)$, which could be $+\infty$ if no trajectory from x can reach S. We shall model the control system in this paper as a differential inclusion.

The function $x \mapsto T_S(x)$ is called the minimal time function. The first goal of this paper is to prove that $T_S(\cdot)$ is the unique proximal solution to the Hamilton–Jacobi (HJ) equation. This is Theorem 3.2 below, which holds under very mild hypotheses on F and S.

Solving HJ equations in some nonclassical sense has developed into an active research area with several different schools of thought participating. The viscosity solution method was pioneered by Crandall and Lions [20] and is closely linked with classical PDE theory. See [19] and [22] for historical references. Minimax solutions to HJ in the context of differential games were introduced in the Russian school by Subbotin [33], [34], and one of the important contributions of this approach is its extensive reliance on flow invariance. Clarke and Vinter [17] considered solutions using generalized gradients to construct verification functions, although these are not necessarily unique. More recently, proximal solutions to (HJ) appeared in Clarke and Ledyaev [11], where the various concepts were also unified. See the discussion in [12, Remark 9.4].

Characterizing $T_S(\cdot)$ as a solution to a HJ equation without controllability assumptions requires one to handle discontinuities that may appear, and perhaps infinite values as well. In problems formulated on a fixed time interval, Barron and Jensen [5], [6] initiated the study of lower semicontinuous vicosity solutions and found an appropriate boundary condition to maintain uniqueness results. See also Frankowska

[24] and Clarke et al. [12]. However, the minimal time problem does not fit into the category of problems covered by these results.

HJ theory specifically tailored to handle $T_S(\cdot)$ has also received considerable attention. Viscosity approaches have been undertaken by Bardi [2], Evans and James [21], Staicu [32], and Bardi and Falcone [4]. Local controllability assumptions are made to guarantee that $T_S(\cdot)$ will be continuous in these papers. Bardi and Staicu [3] and Soravia [30] have also used viscosity-type methods without controllability, although the uniqueness result in [3] requires that S be the closure of its interior (and in particular, preclude the target to be a single point). Soravia [30] contains two uniqueness results, one of the type just mentioned and another that is equivalent to our Theorem 3.2 below. Various interesting data perturbations and envelope constructions are made in these papers, but we do not require any of those techniques here. Rather, the approach in this paper is based on flow invariance and mimics the broad outline sketched in [12]. See also Frankowska [24], in which invariance is prominent. Adaptations of the arguments in [24] to minimal time problems are made in Carja, Mignanego, and Pieri [8], where the target set is restricted to be the origin. One common feature in all these papers (except [30]) is that a boundary condition is required at the boundary of the reachable set (this was introduced in [2]), whereas our approach dispenses with any such condition. Although some of the arguments given in section 3 below are routine modifications of those in [12, section 9], we attempt, except in cases where the modifications are obvious, to give detailed proofs for both clarity and completeness.

The basic assumptions on the multifunction F that appears on the right-hand side of the differential inclusion are standard. Namely, F will be locally bounded, have convex values, and exhibit local Lipschitz behavior. We shall not make an a priori growth assumption on F, but an additional hypothesis is required to imply the lower semicontinuity of $T_S(\cdot)$. This additional hypothesis will depend on properties of both S and F, but is always satisfied if F should exhibit linear growth in its state variable.

In Theorem 3.2, the minimal time function is shown to be the unique solution to a proximal form of the HJ equation satisfying an analytic boundary condition in the form of a HJ inequality. This boundary condition is probably the most natural one under the circumstances and allows for the easiest proof of the theorem. In section 4, we give an alternative but equivalent formulation of Theorem 3.2 by introducing a geometric boundary condition. This second boundary condition is closer in spirit to the one introduced by Barron and Jensen [5], [6] (and used in [24], [12]), but is somewhat more difficult to state in the present circumstance. On the other hand, it has a meaningful interpretation directly in terms of the data. The main result in section 5 is Theorem 5.1, which is a characterization of the proximal subgradients of T_S. This result describes the propagation of the level sets of T_S and is a different approach to some work by Soravia [31] on front propagation. In particular, our result does not require assumptions that force the level sets to strictly enlarge at each point. We make one application of Theorem 5.1 in section 6 by giving necessary and sufficient conditions for T_S to be Lipschitz continuous near S, and sufficient conditions are also provided for continuity of an arbitrary modulus. Remarks in that section address the history of such results. Finally, some examples are given in section 7.

2. Preliminaries.

2.1. Background in nonsmooth analysis. We first review some concepts from nonsmooth analysis that are pertinent in this paper. For a complete treatment, see [10], [25], or [13].

For a closed subset of S of $\mathbb{R}^n$, the distance function to S is defined by

$$d_S(x) = \inf\{\|x - s\| : s \in S\}$$

for all $x \in \mathbb{R}^n$.

DEFINITION 2.1. *Suppose $S \subseteq \mathbb{R}^n$ is closed and $s \in S$. A vector $\zeta \in \mathbb{R}^n$ is a* proximal normal *to S at s provided there exists $r > 0$ so that $d_S(s + r\zeta) = r\|\zeta\|$. The set of all proximal normal vectors to S at s is denoted by $N_S^P(s)$.*

DEFINITION 2.2. *Suppose $\theta : \mathbb{R}^n \to (-\infty, \infty]$ is lower semicontinuous and $x \in \operatorname{dom}\theta := \{x' : \theta(x') < \infty\}$. A vector $\xi \in \mathbb{R}^n$ is a* proximal subgradient *of θ at x provided $(\xi, -1) \in N^P_{\operatorname{epi}\theta}(x, \theta(x))$, where $\operatorname{epi}\theta$ denotes the epigraph $\{(x, r) : x \in \operatorname{dom}\theta,\ r \geq \theta(x)\}$ of $\theta(\cdot)$, which is a closed subset of $\mathbb{R}^{n+1}$. The set (which could be empty) of all proximal subgradients of $\theta(\cdot)$ at x is denoted by $\partial_P\theta(x)$. If $x \notin \operatorname{dom}\theta$, then $\partial_P\theta(x) = \phi$ by definition.*

The following analytic descriptions of the proximal objects are often useful. See [25] or [13] for the proofs.

PROPOSITION 2.1.

(a) *Suppose S is closed and $s \in S$. Then $\zeta \in N_S^P(s)$ if and only if there exists $\sigma > 0$ and $\eta > 0$ such that $\langle \zeta, s' - s\rangle \leq \sigma\|s' - s\|^2$ for all $s' \in S \cap \{x + \eta B\}$.*

(b) *Suppose $\theta : \mathbb{R}^n \to (-\infty, \infty]$ is lower semicontinuous and $x \in \operatorname{dom}\theta$. Then $\xi \in \partial_P\theta(x)$ if and only if there exists $\sigma > 0$ and $\eta > 0$ such that*

$$\theta(y) - \langle \xi, y - x\rangle + \sigma\|y - x\|^2 \geq \theta(x)$$

for all $y \in x + \eta B$.

The only nonsmooth constructions in this paper are the proximal objects, but we mention that some of our results have natural formulations in terms of other normal cones and subgradients and can be proven by taking the appropiate limits. We shall not go into those details here, however.

2.2. Background in differential inclusions. Throughout this subsection, $F : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is a given multifunction (i.e., a set-valued map). Associated with F is the differential inclusion

$$\begin{aligned} &\dot{x}(t) \in F\big(x(t)\big) \quad \text{(almost everywhere) } t \in [0, T], \\ &x(0) = x. \end{aligned} \tag{2.1}$$

A solution to (2.1) is an absolutely continuous function $x(\cdot)$ defined on the interval $[0, T]$ with initial value $x(0) = x$, in which case we say that $x(\cdot)$ is a trajectory of F that originates from x. The notation $\dot{x}(t)$ refers to the derivative of $x(\cdot)$ at t and is the right derivative if $t = 0$. The set of endpoints of all such trajectories of F is denoted by $R_F^{(T)}(x)$ and is called the *reachable set* (from x and at time T). That is, $R_F^{(T)}(x) := \{x(T) : x(\cdot)\,\text{satisfies (2.1)}\}$. The notation $R_F^{(\leq T)}(x)$ signifies the set of all points reachable from x at a time less than or equal to T.

Basic hypotheses to be imposed on F in various combinations are the following.

(H1) For each $x \in \mathbb{R}^n$, $F(x) \neq \phi$ with the graph $\operatorname{gr} F := \{(x, v) : v \in F(x)\}$ closed in $\mathbb{R}^{2n}$, and for each compact set $K \subset \mathbb{R}^n$, there exists a constant $M > 0$ such that

$$\sup\big\{\|v\| : x \in K,\ v \in F(x)\big\} \leq M.$$

(H2) For each $x \in \mathbb{R}^n$, $F(x)$ is convex.

(H3) For each compact subset $K \subset \mathbb{R}^n$, there exists a constant $k > 0$ such that

$$F(x) \subseteq F(y) + k\|x - y\|B \quad \text{for all} \quad x, y \in K.$$

In (H3) and below, we use B to designate the *closed* unit ball. The open ball will be written as $\operatorname{int} B$ (the interior of B). The following two propositions contain some elementary properties of differential inclusions.

PROPOSITION 2.2. *Suppose $F : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is a multifunction and satisfies* (H1).

(a) *For each compact set $K \subset \mathbb{R}^n$ and $\varepsilon > 0$, there exists $\tau > 0$ such that*

$$R_F^{(\leq\tau)}(K) := \bigcup_{x \in K} R_F^{(\leq\tau)}(x) \subset K + \varepsilon B.$$

(b) *If $\{x(\cdot)\}$ is a trajectory of F on $[0, T)$ originating from x with $T < \infty$ and satisfies*

$$\liminf_{t \uparrow T} \|x(t)\| < \infty,$$

then the limit of $x(t)$ exists as $t \uparrow T$.

(c) *Suppose in addition that either* (H2) *or* (H3) *holds. Then there exists $T > 0$ such that* (2.1) *admits at least one solution.*

Proof. (a) See [38, Lemma 5.1]. (b) Let $x(\cdot)$ be a trajectory, and suppose K is compact such that $x(t) \in K$ infinitely often as $t \uparrow T$. Let M be as in (H1) associated to the compact set $K + B$, and let τ be chosen as in part (a) (where $\varepsilon = 1$). Now choose $t_0 \in [T - \tau, T)$ so that $x(t_0) \in K$, and by part (a) it follows that $x(t) \in K + B$ for all $t \in [t_0, T)$. By the choice of M, we have for all $t_0 \leq t < t' \leq T$ that

$$\|x(t') - x(t)\| \leq \int_t^{t'} \|\dot{x}(\tau)\|\, d\tau \leq M(t' - t). \tag{2.2}$$

Since T is assumed to be finite, it follows from (2.2) that the limit of $x(t)$ as $t \uparrow T$ exists. (c) This is well known (see [1]). □

The following proposition gives some further information regarding C^1 trajectories of a differential inclusion under (H1)–(H3).

PROPOSITION 2.3. *Suppose F satisfies* (H1)–(H3), *and let $K \subset \mathbb{R}^n$ be compact.*

(a) *There exists $T > 0$ such that associated to every $x \in K$ and $v \in F(x)$ is a C^1 trajectory $x(\cdot)$ defined on $[0, T]$ with $\dot{x}(0) = v$. Moreover, the modulus of continuity of $\dot{x}(\cdot)$ does not depend on the particular initial value $x \in K$.*

(b) *For each solution $x(\cdot)$ of* (2.1) *and $\varepsilon > 0$, there exists a C^1 solution $x_\varepsilon(\cdot)$ of* (2.1) *with $x_\varepsilon(t) \in x(t) + \varepsilon B$ for all $t \in [0, T]$. (In other words, C^1 trajectories are dense with respect to the sup norm in the set of all trajectories.)*

Proof. (a) For the construction of $x(\cdot)$, see [1, pp. 115–117]. See also [38, Lemma 5.3]. (b) See [23, Theorem 6], or [39, Theorem 3.1]. □

The following result is fundamental to differential inclusion theory and is referred to as "the compactness of trajectories" theorem. This nomenclature is slightly misleading because the result says more than just that a bounded set of solutions to (2.1) is relatively compact. Rather, a stronger conclusion holds in that approximate trajectories have subsequences that converge to a trajectory. See [9, Theorem 3.1.7] for the proof.

PROPOSITION 2.4. *Suppose F satisfies* (H1) *and* (H2) *and $\{y_i(\cdot)\}_i$ is a sequence of uniformly bounded absolutely continuous functions with $y_i(0) = x_i$, where $y_i(\cdot)$ is*

defined on an interval $[0,T_i]$ *such that* $T_i \to T > 0$ *and* $x_i \to x$ *as* $i \to \infty$. *Assume further that*

$$\dot{y}_i(t) \in F\big(y_i(t) + r_i(t)\big) + \varepsilon_i B \quad \text{a.e. } t \in I_i,$$

where $\varepsilon_i \downarrow 0$, $\{r_i(\cdot)\}$ *is a sequence of measurable functions converging uniformly to* 0 *as* $i \to \infty$, *and* I_i *is a measurable subset of* $[0,T_i]$ *such that the measure of* I_i *converges to* T. *Then there exists a trajectory* $x(\cdot)$ *of* F *on* $[0,T]$ *with* $x(0) = x$ *and such that a subsequence of* $y_i(\cdot)$ *converges to* $x(\cdot)$ *uniformly and the subsequence of the derivatives* $\dot{y}_i(\cdot)$ *converges to* $\dot{x}(\cdot)$ *weakly in* $L^1[0,T]$.

We shall require no hypothesis that limits the growth of F as $\|x\| \to \infty$, but the lack thereof necessitates the introduction of an "escape time." Even more important to our analysis is that the escape time will record the first instance when a trajectory leaves a given open set. In classical ODE theory (or where trajectories are uniquely defined in passing through any given state), escape times are generally defined depending only on the initial value. However, for differential inclusions in general, the definition we require relies upon the particular trajectory, and subsequently there may be many trajectories originating from a state x with different escape times. Nonetheless, our definition is consistent with the classical one in that the escape time gives a maximal (positive) interval of definition for the trajectory to stay in the open set. We use the notation U^c to denote $\mathbb{R}^n \backslash U$, the complement of a given set U.

DEFINITION 2.3. *Suppose* $U \subseteq \mathbb{R}^n$ *is open,* $x \in U$, *and* $x(\cdot)$ *is a trajectory of* F *with* $x(0) = x$ *and defined on the* half-open *interval* $[0,T)$, *where* $0 < T \leq \infty$. *Then* T *is an* escape time *from* U *(in which case we write* $T =: \mathrm{Esc}(x(\cdot);U)$*), provided at least one of the following conditions hold:*

(a) $T = \infty$ *and* $x(t) \in U$ *for all* $t \geq 0$,

(b) $x(t) \in U$ *for all* $t \in [0,T)$ *and* $\|x(t)\| \to \infty$ *as* $t \uparrow T$, *or*

(c) $T < \infty$, $x(t) \in U$ *for all* $t \in [0,T)$, *and* $d_{U^c}\big(x(t)\big) \to 0$ *as* $t \uparrow T$.

The next proposition says that under standard existence theory assumptions, any trajectory can be extended to a trajectory that has an escape time.

PROPOSITION 2.5. *Suppose* F *satisfies* (H1) *and either* (H2) *or* (H3), *and* $x(\cdot)$ *is a trajectory of* F *on* $[0,T)$ *with* $x(t) \in U$ *for all* $t \in [0,T)$. *If* T *is not an escape time from* U, *then* $x(\cdot)$ *can be extended to a trajectory* $\widetilde{x}(\cdot)$ *defined on a strictly larger interval* $[0,\widetilde{T})$, *and in which* $\widetilde{T} = \mathrm{Esc}(\widetilde{x}(\cdot);U)$.

Proof. Since T is not an escape time, we must have $T < \infty$, for otherwise (a) would hold. We also must have $\sup_{t\in[0,T)} \|x(t)\| < \infty$, for otherwise (b) would hold. Thus, by Proposition 2.2(b), there exists $y \in \mathbb{R}^n$ such that $x(t) \to y$ as $t \uparrow T$. Since (c) does not hold, we must have $y \in U$. Using standard existence theory for differential inclusions (which we quoted in Proposition 2.2(c)), the trajectory $x(\cdot)$ can be extended from y. Such an extension will remain in U on an interval $[0,T+\tau)$ for small $\tau > 0$ by Proposition 2.2(a). Now we take trajectory $\widetilde{x}(\cdot)$ and time $\widetilde{T}$ as a maximal element (in the sense of graph inclusion) over such extensions. It follows that $\widetilde{T} = \mathrm{Esc}(\widetilde{x}(\cdot);U)$, since otherwise the preceding considerations on $x(\cdot)$ and T could be applied to $\widetilde{x}(\cdot)$ and $\widetilde{T}$, which would violate the maximality. ∎

Suppose $U \subseteq \mathbb{R}^n$ is open and $x \in U$. The set of all trajectories of F originating from x that remain in U over a maximal interval is denoted by $\Upsilon_{(F,U)}(x)$. That is, $\Upsilon_{(F,U)}(x)$ consists of those trajectories $x(\cdot)$ of F defined on a half-open interval $[0,T)$ with $x(0) = x$ and for which $\mathrm{Esc}(x(\cdot);U)$ is defined with $T = \mathrm{Esc}(x(\cdot);U)$. By Proposition 2.5, the set $\Upsilon_{(F,U)}(x)$ is nonempty for each $x \in U$.

2.3. The minimal time function. Now suppose $S \subset \mathbb{R}^n$ is closed and $F : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is a multifunction. The minimal time function $T_S : \mathbb{R}^n \to [0, \infty]$ is defined as follows. If $x \notin S$, then

$$T_S(x) := \inf\big\{T : \text{there exists } x(\cdot) \text{ satisfying (2.1)} \\ \text{with } x(0) = x \text{ and } x(T) \in S\big\}. \tag{2.3}$$

If no trajectory of F originating from x can reach S in finite time, then the above infimum is taken over the empty set, and hence $T_S(x) = \infty$ in this case, which is the usual convention. If $x \in S$, then $T_S(x) = 0$ by definition, which is consistent with the above definition if we allow trajectories to be defined on the degenerate interval $[0, 0]$.

It turns out that (H1)–(H3) are not sufficient by themselves to give many of the desired properties of $T_S(\cdot)$. Lower semicontinuity, for example, is not assured (see Example 7.1), nor if the infimum of (2.3) is finite is it necessarily attained (see Example 7.2). There are also several instances below where we shall want to exclude certain kinds of trajectories from entering the discussion, and the following hypothesis serves all of these needs. Note that this assumption is not merely on F, but depends on both F and S.

(H4) For all $x \notin S$ and $x(\cdot) \in \Upsilon_{(F,\mathbb{R}^n)}(x)$, if

$$\mathrm{Esc}(x(\cdot); \mathbb{R}^n) < \infty$$

then

$$\mathrm{Esc}(\bar{x}(\cdot); S^c) < \mathrm{Esc}(x(\cdot); \mathbb{R}^n),$$

where $\bar{x}(\cdot)$ is a restriction of $x(\cdot)$.

Roughly speaking, if (H4) holds, then any trajectory of F escaping to infinity in finite time must pass through S.

Remark 2.1. There are natural hypotheses explicitly given on the data that guarantee that (H4) will hold. For example, if there exist constants c_1, c_2 such that

$$\sup_{v \in F(x)} \|v\| \le c_1 + c_2\|x\| \quad \text{for all} \quad x \in \mathbb{R}^n,$$

then $\mathrm{Esc}(x(\cdot); \mathbb{R}^n) = \infty$ for all trajectories $x(\cdot)$, and so (H4) holds trivially in this case. Other simple conditions pertaining only to the target set could be given; for example, if S^c is bounded or if $\{r_i\}$ is a sequence of numbers converging to $+\infty$ and S is given by

$$S = \bigcup_{i=1}^{\infty} \{x : \|x\| = r_i\},$$

then (H4) is satisfied.

The following two characterizations of $T_S(x)$ are immediate consequences of the definitions.

$$T_S(x) = \inf\big\{T \ge 0 : R^{(T)}(x) \cap S \ne \phi\big\},$$

and if (H4) holds and $x \notin S$,

$$T_S(x) = \inf\big\{\mathrm{Esc}(x(\cdot); S^c) : x(\cdot) \in \Upsilon_{F,S^c}(x)\big\}.$$

PROPOSITION 2.6. *Suppose* $F : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ *satisfies* (H1), (H2), *and* (H4). *If* $x \in S^c \cap \operatorname{dom} T_S$, *then there exists* $x(\cdot) \in \Upsilon_{(F,S^c)}(x)$ *with* $\operatorname{Esc}(x(\cdot), S^c) = T_S(x)$ *and* $x(T_S(x)) \in S$ *(that is, the infimum in* (2.3) *is attained). Furthermore,* $T_S(\cdot)$ *is lower semicontinuous on* $\mathbb{R}^n$.

Proof. Suppose $x \notin S$ and $T_S(x) < \infty$. Let $\{x_i(\cdot)\}$ be a minimizing sequence of (2.3), which means that $x_i(\cdot) \in \Upsilon_{(F,S^c)}(x)$ and $T_i := \operatorname{Esc}(x_i(\cdot); S^c) \to T_S(x)$ as $i \to \infty$ and $x_i(T_i) \in S$ for all i. Let

$$T := \inf\{t \in [0, T_S(x)] : \limsup_{i\to\infty} \|x_i(t)\| = \infty\}.$$

If the limsup is always finite, then we take $T = T_S(x)$ by convention. Note that $0 < T$ by Proposition 2.2(a), and for any $t < T$, the sequence $\{x_i(\cdot)\}$ is uniformly bounded on the interval $[0, t]$. Hence, using a diagonal process and the compactness of trajectories theorem, we may assume that $x_i(\cdot)$ converges uniformly to a trajectory $x(\cdot)$ on each compact interval of $[0, T)$. Since $T \le T_S(x)$, we have

$$\liminf_{t\uparrow T} \|x(t)\| < \infty,$$

since otherwise $\operatorname{Esc}(x(\cdot); \mathbb{R}^n) = T$ and (H4) would be violated. Hence, by Proposition 2.2(b), the limit $\lim_{t\uparrow T} x(t) =: x(T)$ exists. To prove that the infimum in (2.3) is attained, we show that $x(T) \in S$. We first claim that $T = T_S(x)$. Indeed, let $K := \{x(t) : t \in [0, T]\}$ and choose τ as in Proposition 2.2(a) associated to the compact set $K + B$ and $\varepsilon = 1$. If $T < T_S(x)$, then there exists t_0 and $0 < \tau_0 \le \tau$ with

$$0 < t_0 < T < t_0 + \tau_0 \le T_S(x).$$

Since $x_i(t_0) \to x(t_0)$ as $i \to \infty$, we have $x_i(t_0) \in K + B$ for all large i, and by Proposition 2.2(a), it follows that $x_i(t_0 + \tau_0) \in K + 2B$ for all large i. However, the definition of T as an infimum says that $\limsup_{i\to\infty} \|x_i(t_0+\tau_0)\| = \infty$, a contradiction. Hence $T = T_S(x)$ as claimed.

To see that $x(T) \in S$, let M be given as in (H1) associated to the compact set $K + 2B$. Now let $\eta > 0$ be small and choose t_1 such that

$$T - \min\{\tau, \eta/M\} < t_1 < T \quad \text{and} \tag{2.4}$$

$$\|x(T) - x(t_1)\| < \eta. \tag{2.5}$$

We now choose i large enough such that

$$\|x(t_1) - x_i(t_1)\| < \eta \quad \text{and} \tag{2.6}$$

$$(T_i - t_1) < \min\{\tau, \eta/M\}. \tag{2.7}$$

Note that (2.7) is possible in view of (2.4) and since $T_i \to T_S(x) = T$. Observe next that $x_i(t_1) \in K + B$, and thus $x_i(t) \in K + 2B$ for all $t \in [t_1, T_i]$ by Proposition 2.2(a), and consequently

$$\|\dot{x}_i(t)\| \le M \quad \text{a.e. } t \in [t_1, T_i] \tag{2.8}$$

by (H1). Since $x_i(T_i) \in S$, we have

$$\begin{aligned} d_S(x(T)) &\le \|x(T) - x_i(T_i)\| \\ &\le \|x(T) - x(t_1)\| + \|x(t_1) - x_i(t_1)\| + \|x_i(t_1) - x_i(T_i)\| \\ &\le 2\eta + \int_{t_1}^{T_i} \|\dot{x}_i(t)\|\, dt \\ &\le 2\eta + M(T_i - t_1) \\ &\le 3\eta, \end{aligned}$$

where we used (2.5) and (2.6) to deduce the third inequality, (2.8), the fourth, and (2.7), the last. This implies $x(T) \in S$ since η is arbitrary.

To prove lower semicontinuity, suppose $x_i \to x$, and we may assume without loss of generality that

$$0 < \lim_{i\to\infty} T_S(x_i) =: T < \infty.$$

For each $i = 1, 2\ldots$, let $x_i(\cdot) \in \Upsilon_{(F,S^c)}(x_i)$ satisfy $\mathrm{Esc}(x_i(\cdot), S^c) = T_S(x_i)$ and $x_i(T_S(x_i)) \in S$, which exists by part (a). We can proceed at this point in a manner completely analogous to the proof above and produce a trajectory $x(\cdot) \in \Upsilon_{(F,S^c)}(x)$ with $\mathrm{Esc}(x(\cdot); S^c) \le T$ and $x(T) \in S$. (The only difference between here and the above is in the initial values $x_i(0) = x_i$ of the trajectories $x_i(\cdot)$, but the estimates remain valid.) Since $T_S(x)$ is defined as an infimum, we have $T_S(x) \le \mathrm{Esc}(x(\cdot); S^c) \le T$, which proves that $T_S(\cdot)$ is lower semicontinuous. ∎

3. HJ theory.

3.1. Invariance. We shall apply invariance results to objects obtained through modifying the given data, thus these concepts are introduced in terms other than S and F. Moreover, in contrast to [12], we require our notions to be local.

DEFINITION 3.1. *Suppose $E \subseteq \mathbb{R}^n$ is nonempty, $U \subseteq \mathbb{R}^n$ is open, and $\Gamma : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is a multifunction.*

(a) *Then (Γ, E) is* weakly invariant *in U provided that for all $x \in E \cap U$, there exists a trajectory $x(\cdot) \in \Upsilon_{(\Gamma,U)}(x)$ that satisfies $x(t) \in E$ for all $t \in [0, \mathrm{Esc}(x(\cdot); U))$.*

(b) *(Γ, E) is called* strongly invariant *in U provided that for every $x \in E$, every trajectory $x(\cdot) \in \Upsilon_{(\Gamma,U)}(x)$ satisfies $x(t) \in E$ for all $t \in [0, \mathrm{Esc}(x(\cdot); U))$.*

The next proposition relates these concepts to the minimal time problem. Recall that the closed set $S \subset \mathbb{R}^n$ and the multifunction $F : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ are given. We write $-F \times \{1\}$ for the multifunction defined at $(x, r) \in \mathbb{R}^n \times \mathbb{R}$ as

$$\big(-F \times \{1\}\big)(x, r) := \{-v : v \in F(x)\} \times \{1\} \subset \mathbb{R}^{n+1}.$$

A similar notation is in effect for the multifunction $F \times \{-1\}$.

PROPOSITION 3.1. *Suppose F satisfies* (H1) *and* (H2), *and let $E := \mathrm{epi}\, T_S$.*

(a) *If* (H4) *holds, then $(F \times \{-1\}, E)$ is weakly invariant in $U := S^c \times \mathbb{R}$.*

(b) *$(-F \times \{1\}, E)$ is strongly invariant in $\mathbb{R}^{n+1}$.*

Proof. (a) Let $(x, r) \in E \cap U$, and hence $x \notin S$ and $T_S(x) \le r < \infty$. By Proposition 2.6, there exists $x(\cdot) \in \Upsilon_{(F,S^c)}(x)$ satisfying $\mathrm{Esc}(x(\cdot); S^c) = T_S(x)$. By the principle of optimality, we have

$$T_S\big(x(t)\big) = T_S(x) - t \le r - t \tag{3.1}$$

for all $t \in [0, T_S(x)]$. Define $z(t) := \big(x(t), r-t\big)$ for $t \in [0, T_S(x))$. Then $\mathrm{Esc}(z(\cdot); U) = T_S(x)$, and clearly $z(\cdot) \in \Upsilon_{(F\times\{-1\})}(x, r)$. Moreover, it follows immediately from (3.1) that $z(t) \in E$ for all $t \in [0, \mathrm{Esc}(z(\cdot); U))$, which yields (a). (b) Let $(x, r) \in E$ and suppose $z(\cdot) \in \Upsilon_{(-F\times\{1\},\mathbb{R}^{n+1})}(x, r)$. Then $z(\cdot)$ has the representation $z(t) = \big(y(t), r + t\big)$ for $t \in [0, T)$, where $y(\cdot) \in \Upsilon_{(-F,\mathbb{R}^n)}(x)$ and

$$T := \mathrm{Esc}\big(z(\cdot); \mathbb{R}^{n+1}\big) = \mathrm{Esc}\big(y(\cdot); \mathbb{R}^n\big).$$

Fix $t \in [0, T)$. We must show that $z(t) \in E$. For $t' \in [0, t]$, define $x(t') = y(t - t')$. It is clear that $x(\cdot)$ is a trajectory for F since $y(\cdot)$ is a trajectory for $-F$. Hence, by the principle of optimality, we have

$$T_S\big(x(t)\big) + t \geq T_S\big(x(0)\big).$$

Using this and the fact that $(x, r) \in E$, we conclude that

$$r + t \geq T_S(x) + t = T_S(y(0)) + t = T_S(x(t)) + t \geq T_S(x(0)) = T_S(y(t)),$$

which says that $z(t) = \big(y(t), r + t\big) \in E$. Hence (b) holds. □

The notions of invariance lead directly to comparison results between T_S and certain lower semicontinuous functions θ, as the next result shows.

PROPOSITION 3.2. *Suppose F satisfies* (H1) *and* (H2) *and $\theta : \mathbb{R}^n \to (-\infty, \infty]$ is lower semicontinuous and satisfies $\theta(s) = 0$ for all $s \in S$. Let $E := \operatorname{epi}\theta$ and $U := S^c \times \mathbb{R}$.*

(a) *Suppose* (H4) *is also satisfied. If $(F \times \{-1\}, E)$ is weakly invariant in U and $\theta(\cdot)$ is bounded below on $\mathbb{R}^n$, then $\theta(x) \geq T_S(x)$ for all $x \in \mathbb{R}^n$.*

(b) *If $(-F \times \{1\}, E)$ is strongly invariant in $\mathbb{R}^{n+1}$, then $\theta(x) \leq T_S(x)$ for all $x \in \mathbb{R}^n$.*

Proof. (a) Suppose $x \in \mathbb{R}^n$. The conclusion is trivial if $x \in S$ or if $\theta(x) = \infty$, so assume

$$x \in S^c \cap \operatorname{dom}\theta.$$

By weak invariance, there exists a $z(\cdot) \in \Upsilon_{(F\times\{-1\},U)}(x, \theta(x))$ that remains in E. Note that $z(\cdot)$ has the form $z(t) = \big(x(t), \theta(x) - t\big)$, where $x(\cdot) \in \Upsilon_{(F,S^c)}(x)$. By the nature of U, we have

$$T := \mathrm{Esc}(z(\cdot), U) = \mathrm{Esc}(x(\cdot), S^c). \tag{3.2}$$

Observe next that the statement "$z(\cdot)$ remains in E" is equivalent to

$$\theta(x(t)) \leq \theta(x) - t \quad \text{for all} \quad t \in [0, T). \tag{3.3}$$

Since we have assumed that θ is bounded below, it follows from (3.3) that $T < \infty$. Assumption (H4) in conjunction with (3.2) implies that $\inf_{t\in[0,T)} \|x(t)\| < \infty$, and so it follows from Proposition 2.2(b) that $x(t) \to y \in S$ as $t \uparrow T$. We simply set $x(T) := y$. The lower semicontinuity of θ implies that (3.3) holds for $t = T$ as well, and the boundary condition on θ says that $\theta(x(T)) = 0$. Hence we have $\theta(x) \geq T$. Finally, the definition of T_S as an infimum yields that $T \geq T_S(x)$, and we conclude that $\theta(x) \geq T \geq T_S(x)$, which is (a). (b) Suppose $x \in \mathbb{R}^n$. If $T_S(x) = \infty$ or $x \in S$, there is nothing to show, so assume $x \in S^c \cap \operatorname{dom} T_S$. Let $\eta > 0$. There exists $x(\cdot) \in \Upsilon_{(F,S^c)}(x)$ with $\mathrm{Esc}(x(\cdot); S^c) =: T < T_S(x) + \eta$ and $x(T) \in S$. Let

$$z(t) := \big(x(T - t), t\big),$$

which is a trajectory of $-F \times \{1\}$ originating from $\big(x(T), 0\big) \in E$. By the strong invariance assumption, the trajectory $z(\cdot)$ remains in E, and thus

$$t \geq \theta\big(x(T-t)\big) \quad \text{for all} \quad t \in [0,T]. \tag{3.4}$$

Setting $t = T$ in (3.4) says that

$$T_S(x) + \eta > T \geq \theta\big(x(0)\big) = \theta(x),$$

and letting $\eta \downarrow 0$ proves (b). □

3.2. HJ inequalities. Recall that the (minimized) Hamiltonian associated to a multifunction $\Gamma : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is the function $h_\Gamma : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}^1$ given by

$$h_\Gamma(x,\zeta) = \min\big\{\langle v, \zeta\rangle : v \in \Gamma(x)\big\}.$$

It is clear that $\zeta \mapsto h_\Gamma(x,\zeta)$ is positively homogeneous of degree 1.

The following theorem is a local version of results contained in [12], and the proofs given here must differ only to take account of the local nature. We also attempt to fill in a few more details in the strong invariance proof. Note that in part (a), Γ must only be defined (that is, be nonempty) on $E \cap U$, as is pointed out in [12, Remark 2.1(c)]. We also point out that the global version of part (a) was originally proved by Veliov [36], [37], work that was overlooked in the writing of [12].

THEOREM 3.1. *Suppose Γ satisfies* (H1) *and* (H2), *$E \subseteq \mathbb{R}^n$ is closed, and $U \subseteq \mathbb{R}^n$ is open.*

(a) *Then (Γ, E) is weakly invariant in U if and only if $h_\Gamma(x,\zeta) \leq 0$ for all $x \in E \cap U$ and $\zeta \in N_E^P(x)$.*

(b) *In addition, suppose Γ satisfies* (H3). *Then (Γ, E) is strongly invariant in U if and only if $h_\Gamma(x,-\zeta) \geq 0$ for all $x \in E \cap U$ and $\zeta \in N_E^P(x)$.*

Proof. (a)(⇒) The proximal normal cones $N_E^P(x)$ and $N^P_{E\cap\{x+\varepsilon B\}}(x)$ coincide, and thus this direction follows as in [12, Theorem 2.2]. (⇐) Let $x \in E \cap U$. We first choose $\tau > 0$ as in Proposition 2.2(a) with $K = \{x\}$ and $\varepsilon > 0$ chosen so that $x + \varepsilon B \subset U$. Then the construction used in the proof of Theorem 2.1 of [12] is valid here and produces a trajectory $x(\cdot)$ on $[0,\tau]$ that remains in $E \cap U$. We now can choose a trajectory $x(\cdot)$ on a half-open interval $[0,T)$ that has maximal graph and remains in $E \cap U$. For such a maximally defined trajectory, we must have $T = \mathrm{Esc}(x(\cdot); U)$, and thus $x(\cdot)$ is as in Definition 3.1(a). (b)(⇒) Suppose (Γ, E) is strongly invariant in U, $x \in E$, $v \in \Gamma(x)$, and $\zeta \in N_E^P(x)$. By Proposition 2.3(a), there exists a C^1 trajectory $x(\cdot)$ of Γ on $[0,T]$ with $x(0) = x$ and $\dot{x}(0) = v$. For small $t > 0$, $x(t)$ remains in U also. By Proposition 2.1(a), there exists $\sigma > 0$ such that

$$\langle \zeta, x' - x\rangle \leq \sigma \|x' - x\|^2 \quad \text{for all} \quad x \in E. \tag{3.5}$$

The strong invariance assumption implies that $x(t) \in E$ for all t, and thus inserting these values into (3.5) gives

$$\langle \zeta, x(t) - x\rangle \leq \sigma \|x(t) - x\|^2 \quad \text{for all} \quad t \in [0,T]. \tag{3.6}$$

Upon dividing (3.6) by t and letting $t \downarrow 0$ yields

$$\langle \zeta, v\rangle \leq 0. \tag{3.7}$$

Taking the supremum of the left side in (3.7) over $v \in F(x)$ and multiplying through by -1 implies $h_\Gamma(x,-\zeta) \geq 0$. (⇐) Let $x \in E$ and $x(\cdot) \in \Upsilon_{(\Gamma,U)}(x)$. Fix $T < \mathrm{Esc}(x(\cdot); U)$,

and it suffices to show that $x(t) \in E$ for all $t \in [0,T]$. We claim that without loss of generality $x(\cdot)$ is C^1. Indeed, we have $x(t) + \varepsilon B \subset U$ for all $t \in [0,T]$ whenever $\varepsilon > 0$ is small, and there exists a C^1 trajectory $x_\varepsilon(\cdot)$ that is within $x(t) + \varepsilon B$ for all t by Proposition 2.3(b). If it is known that $x_\varepsilon(t) \in E$ for all t and ε, then since E is closed, it follows that $x(t) \in E$ by letting $\varepsilon \downarrow 0$.

Hence we may assume $x(\cdot)$ is C^1. Let $\varepsilon > 0$ such that

$$K := \bigcup_{t\in[0,T]} \{x(t) + \varepsilon B\} \subset U,$$

and let k be the Lipschitz constant for K as in (H3). We now proceed as in the proof of Theorem 3.1 in [12] and define $\widetilde{\Gamma} : [0,T] \times K :\rightrightarrows \mathbb{R}^{n+1}$ by

$$\widetilde{\Gamma}(t,y) := \{1\} \times \big\{v \in F(y) : \|v - \dot{x}(t)\| \le k\|y - x(t)\|\big\}.$$

It is easily seen that Γ satisfies (H1) and (H2) on $[0,T] \times K$. Set

$$\widetilde{E} := \mathbb{R} \times E \quad \text{and} \quad \widetilde{U} := \mathbb{R} \times \operatorname{int} K,$$

where $\operatorname{int} K$ is the interior of K. We claim that $(\widetilde{\Gamma}, \widetilde{E})$ is weak invariant in $\widetilde{U}$. To see this, note that

$$N^P_{\widetilde{E}}(t,y) = \{0\} \times N^P_E(y), \tag{3.8}$$

and observe that for each $\zeta \in N^P_E(y)$, we have by assumption and the definition of $\widetilde{\Gamma}$ that

$$0 \le h_\Gamma(y, -\zeta) \le -h_{\widetilde{\Gamma}}\big((t,y),(0,\zeta)\big). \tag{3.9}$$

Hence, by (3.8) and (3.9), we see that

$$h_{\widetilde{\Gamma}}\big(\tilde{y}, \tilde{\zeta}\big) \le 0$$

for all $\tilde{y} \in \widetilde{E} \cap \widetilde{U}$ and $\tilde{\zeta} \in N^P_{\widetilde{E}}(\tilde{y})$. By part (a), it then follows that $(\widetilde{\Gamma}, \widetilde{E})$ is weakly invariant in $\widetilde{U}$ as claimed. Hence there exists a trajectory $z(\cdot) \in \Upsilon_{(\widetilde{\Gamma},\widetilde{U})}(0,x)$ that remains in $\widetilde{E}$. It is obvious that $z(t)$ has the form $(t, y(t))$ for some trajectory $y(\cdot)$ of Γ, and it follows from Gronwall's inequality that $y(\cdot) = x(\cdot)$ (see [12, Proof of Theorem 2.2]). □

We next interpret these results in terms of state-augmented data and epigraphs of lower semicontinuous functions. The following proposition is the analogue of the monotone results of Theorem 7.4 (a) and (d) in [12], recast into terms relevant to minimal time problems.

PROPOSITION 3.3. *Suppose F satisfies* (H1) *and* (H2), $\theta : \mathbb{R}^n \to (-\infty, \infty]$ *is lower semicontinuous, and $E = \operatorname{epi}\theta$.*

(a) *$(F \times \{-1\}, E)$ is weakly invariant in $S^c \times \mathbb{R}$ if and only if*

$$1 + h_F(x,\xi) \le 0 \quad \textit{for all} \quad x \notin S \textit{ and } \xi \in \partial_P\theta(x).$$

(b) *Suppose F in addition satisfies* (H3). *Then $(-F \times \{1\}, E)$ is strongly invariant if and only if*

$$1 + h_F(x,\xi) \ge 0 \quad \textit{for all} \quad x \in \mathbb{R}^n \textit{ and } \xi \in \partial_P\theta(x).$$

Proof. (a) Let $(x,\xi)\in\mathbb{R}^{2n}$, $r\in\mathbb{R}$, and $\rho<0$ and note that

$$\begin{aligned} h_{(F\times\{-1\})}\big((x,r),(\xi,\rho)\big) &= \inf_{v\in F(x)}\big\{\langle v,\xi\rangle-\rho\big\} \\ &= -\rho\left(1+h_F\left(x,-\frac{\xi}{\rho}\right)\right). \end{aligned} \tag{3.10}$$

($\Rightarrow$) Suppose $x\notin S$ and $\xi\in\partial_P\theta(x)$. By Theorem 3.1(a), we have

$$h_{(F\times\{-1\})}\big((x',r),-\zeta\big)\le 0 \tag{3.11}$$

for all $(x',r)\in E$, $x'\notin S$, and $\zeta\in N_E^P(x,r)$. Using the values $(x',r)=(x,\theta(x))\in \operatorname{epi}\theta=E$ and $\zeta=(\xi,-1)$ (which is a valid choice of ζ by Definition 2.2), we see from (3.10) and (3.11) that

$$1+h_F(x,\xi)\le 0.$$

($\Leftarrow$) Let $(x,r)\in E\cap S^c\times\mathbb{R}$ and $\zeta=(\xi,\rho)\in N_E^P(x,r)$. By the nature of epigraphs, we have $\rho\le 0$. Let us assume first that $\rho<0$, from which it follows that $r=\theta(x)$. Since $N_E^P(x,\theta(x))$ is a cone, we have $(-\xi/\rho,-1)\in N_E^P(x,\theta(x))$, and consequently, $-\xi/\rho\in\partial_P\theta(x)$. By (3.10), we have

$$h_{(F\times\{-1\})}\big((x,\theta(x)),(\xi,\rho)\big)=-\rho\left(1+h_F\big(x,-\xi/\rho\big)\right)\ge 0, \tag{3.12}$$

where we deduced the inequality from $-\rho>0$ and our assumption that $(1+h_F)\ge 0$.

Now suppose $\rho=0$. It is easily checked that $(\xi,0)\in N_E^P(x,\theta(x))$ as well, and so by Rockafellar's horizontality theorem [27], there exist sequences $\{x_i\}$, $\{\xi_i\}$, and $\{\rho_i\}$ such that $x_i\to x$, $\theta(x_i)\to\theta(x)$, $\xi_i\to\xi$, $\rho_i<0$, and $\rho_i\uparrow 0$, and $-\xi_i/\rho_i\in\partial_P\theta(x_i)$. By (3.12) we have

$$-\rho_i\left(1+h_F\big(x_i,-\xi_i/\rho_i\big)\right)\ge 0$$

for all i, and letting $i\to\infty$ yields $h_F(x,\xi)\ge 0$, and hence

$$h_{(F\times\{-1\})}\big((x,r),(\xi,0)\big)=h_f(x,\xi)\ge 0. \tag{3.13}$$

In view of (3.12) and (3.13), it follows from Theorem 3.1(a) that $F\times\{-1\}, E$ is weakly invariant on $S^c\times\mathbb{R}$. (b) The analogue to (3.10) needed here is

$$h_{(-F\times\{1\})}\big((x,r),-(\xi,\rho)\big)=-\rho\big(1+h_F(x,-\xi/\rho)\big), \tag{3.14}$$

which holds for all $(x,\xi)\in\mathbb{R}^{2n}$, $r\in\mathbb{R}$, and $\rho<0$. The proof of the equivalence in (b) is virtually identical to the one of (a), where Theorem 3.1(b) is quoted instead of (a). ∎

3.3. The HJ equation. Again suppose $S\subseteq\mathbb{R}^n$ is closed. We now characterize $T_S(\cdot)$ as the solution to the HJ equation on S^c that satisfies certain boundary conditions.

THEOREM 3.2. *Suppose $F:\mathbb{R}^n\rightrightarrows\mathbb{R}^n$ satisfies* (H1)–(H3), *and $S\subset\mathbb{R}^n$ is closed such that* (H4) *holds. Then there exists a unique lower semicontinuous function $\theta:\mathbb{R}^n\to(-\infty,\infty]$ bounded below on $\mathbb{R}^n$ and satisfying the following.*

(HJ) *For each $x\notin S$ and $\xi\in\partial_P\theta(x)$, we have*

$$1+h_F(x,\xi)=0.$$

(ABC) *Each* $x \in S$ *satisfies* $\theta(x) = 0$ *and*

$$1 + h_F(x, \xi) \geq 0$$

whenever $\xi \in \partial_P \theta(x)$.
The unique such function is $\theta(\cdot) = T_S(\cdot)$.

Remark 3.1. (HJ) is the Hamilton–Jacobi equation as it applies to minimal time problems, but in which proximal subgradients have replaced the usual gradient. (ABC) is an analytic boundary condition. In the next section, we analyze (ABC) in more detail and show that it is equivalent (in the context of the theorem) to a geometric boundary condition (GBC).

Proof. It is obvious that $T_S(\cdot)$ is bounded below by zero and it is lower semicontinuous by Proposition 2.6. It equals zero on S by definition. Propositions 3.1(a) and 3.3(a) combine to imply that

$$1 + h_F(x, \xi) \leq 0 \quad \text{for all} \quad x \notin S \text{ and } \xi \in \partial_P T_S(x). \tag{3.15}$$

Similarly, Propositions 3.1(b) and 3.3(b) combine to imply that

$$1 + h_F(x, \xi) \geq 0 \quad \text{for all} \quad x \in \mathbb{R}^n \text{ and } \xi \in \partial_P T_S(x). \tag{3.16}$$

We conclude from (3.15) and (3.16) that both (HJ) and (ABC) hold for $\theta(\cdot) := T_S(\cdot)$.

To prove uniqueness, suppose $\theta(\cdot)$ is lower semicontinuous, bounded below, and satisfies (HJ) and (ABC). By Propositions 3.3(a) and 3.2(a), we conclude that

$$\theta(x) \geq T_S(x) \tag{3.17}$$

for all $x \in \mathbb{R}^n$. Similarly, by Propositions 3.3(b) and 3.2(b), we conclude that

$$\theta(x) \leq T_S(x) \tag{3.18}$$

for all $x \in \mathbb{R}^n$. Obviously, $\theta(\cdot) = T_S(\cdot)$ follows from (3.17) and (3.18). ∎

4. A geometric boundary condition. In this section we give an alternative to the boundary condition (ABC) of Theorem 3.2 that can be more easily interpreted in terms of the target set and the dynamics of the system. The two conditions are equivalent only in the context of Theorem 3.2. The new boundary condition we consider is the following.

(GBC) For $x \in S$, we have $\theta(x) = 0$, and if $v \in F(x)$ and $\zeta \in N_S^P(x)$ satisfy $\langle v, \zeta \rangle < 0$, then

$$\liminf_{\substack{x' \to x \\ \frac{x'-x}{\|x'-x\|} \to \frac{-v}{\|v\|}}} \theta(x') = 0.$$

Loosely speaking, (GBC) says that if a velocity vector v at a point $x \in S$ makes an obtuse angle with some proximal normal at x, then $\theta(x')$ must go to zero along a sequence approaching x tangentially in the direction $-v$.

THEOREM 4.1. *Suppose the boundary condition* (ABC) *in Theorem* 3.2 *is replaced by* (GBC). *Then the conclusions of Theorem* 3.2 *remain valid.*

Proof. (ABC)⇒(GBC). By the uniqueness assertion in Theorem 3.2, we must show that $T_S(\cdot)$ satisfies (GBC).

Suppose $x \in S$, $v \in F(x)$, and $\zeta \in N_S^P(x)$ satisfy $\langle \zeta, v\rangle < 0$. By Proposition 2.2(b), there exists a C^1 trajectory $y(\cdot)$ on $[0,T]$ of $-F$ originating from x with $\dot y(0) = -v$. Let $x(t) := y(T-t)$, $t \in [0,T]$, and note that $x(\cdot)$ is a trajectory for F with $x(T) = x \in S$. By the principle of optimality, we have

$$T_S(x(t)) \le T - t \quad \text{for all} \quad t \in [0,T],$$

and consequently $T_S(x(t)) \to 0$ as $t \uparrow T$. Moreover,

$$\frac{x(t)-x}{T-t} \to \dot x(T) = \dot y(0) = -v \quad \text{as} \quad t \uparrow T,$$

and thus $x' = x(t)$ as $t \uparrow T$ is an admissible set of values in the liminf in (GBC). It follows that $T_S(\cdot)$ satisfies (GBC).

(GBC)⇒(ABC). Now assume $\theta(\cdot)$ satisfies (GBC) and the conditions in Theorem 3.2, except possibly (ABC). We show, in fact, that (ABC) holds for $\theta(\cdot)$ as well.

Suppose $x \in S$ and $\zeta \in \partial_P \theta(x)$. Hence there exists $\sigma > 0$ and $\eta > 0$ such that

$$\theta(x') - \langle \zeta, x' - x\rangle + \sigma\|x' - x\|^2 \ge \theta(x) = 0 \tag{4.1}$$

for all $x' \in x + \eta B$. We require the following simple lemma.

LEMMA 4.1. *Suppose x, ζ, and $\theta(\cdot)$ are as above. Then $\zeta \in N_S^P(x)$.*

Proof. Since (4.1) holds in particular for all $x' \in S \cap \{x + \eta B\}$, and $\theta(x') = 0$ for such x', we have

$$\langle \zeta, x' - x\rangle \le \sigma\|x' - x\|^2 \tag{4.2}$$

for all $x' \in S \cap \{x + \eta B\}$. Thus by (4.2) and Proposition 2.1(a), we conclude that $\zeta \in N_S^P(x)$. □

Now let $v \in F(x)$ be arbitrary, and it suffices to show that

$$1 + \langle \zeta, v\rangle \ge 0. \tag{4.3}$$

If $\langle \zeta, v\rangle \ge 0$, then (4.3) is trivial, so assume that

$$-\delta := \langle \zeta, v\rangle < 0. \tag{4.4}$$

We have by Lemma 4.1 that $\zeta \in N_S^P(x)$, and by Definition 2.1, there exists $r > 0$ such that

$$U := x + r\|\zeta\| + r\|\zeta\|\operatorname{int} B = \{x' : \|x' - x - r\zeta\| < r\|\zeta\|\}$$

satisfies $\operatorname{cl} U \cap S = \{x\}$, where $\operatorname{cl} U$ signifies the closure of U. Let $K := \operatorname{cl} U + B$, and let M, k be as in (H1), (H3), respectively. We next invoke (GBC) and obtain a sequence $x_i \to x$ such that

$$\theta(x_i) \to 0 \quad \text{and} \quad \frac{x_i - x}{\|x_i - x\|} \to \frac{-v}{\|v\|}. \tag{4.5}$$

Let $v_i = \operatorname{proj}_{F(x_i)}(v)$ be the projection (that is, the closest element) of v in $F(x_i)$. Assumption (H3) says

$$\|v_i - v\| \le k\|x_i - x\| \quad \text{for all} \quad i. \tag{4.6}$$

By Proposition 2.3(a), there exists $T > 0$ such that for each i there is a trajectory $y_i(\cdot)$ of $-F$ with $y_i(0) = x_i$, $\dot{y}(0) = -v_i$, and

$$\|\dot{y}_i(t) + v_i\| \le m(t) \quad \text{for all} \quad i, \tag{4.7}$$

where $m(\cdot)$ is a modulus function ($m(t) \searrow 0$ as $t \downarrow 0$) that is independent of i. We want to show that $y_i(\cdot)$ stays in U if T is small and i is large enough, which is the content of the following lemma.

LEMMA 4.2. *By shrinking T if necessary (but not dependent on i), we have that $y_i(t) \in U$ for all $t \in [0,T]$ and all sufficiently large i.*

Proof. Let τ be as in Proposition 2.2(a) applied to the compact set $\operatorname{cl} U$ and $\varepsilon = 1$, and shrink T if necessary so that $T < \tau$ and satisfies $M^2T + 2r\|\zeta\|m(T) < r\delta$, where δ is as in (4.4). If i is large enough that $2k\|x_i - x\|\|\zeta\| < \delta$, then for all $t \in [0,T]$ we have

$$\begin{aligned}
\|y_i(t) - x - r\zeta\|^2 &= \left\| \int_0^t \dot{y}_i(t')\,dt' \right\|^2 - 2\left\langle r\zeta, \int_0^t \dot{y}_i(t')\,dt' \right\rangle + r^2\|\zeta\|^2 \\
&\le M^2t^2 - 2\left\langle r\zeta, \int_0^t \big(\dot{y}_i(t') + v_i\big)\,dt' \right\rangle \\
&\qquad + 2t\big\langle r\zeta, \big(v_i - v\big)\big\rangle + 2t\langle r\zeta, v\rangle + r^2\|\zeta\|^2 \\
&\le t\big[M^2t + 2r\|\zeta\|m(t) + 2rk\|x_i - x\|\|\zeta\| - 2r\delta\big] \\
&\qquad + r^2\|\zeta\|^2 \\
&< r^2\|\zeta\|^2.
\end{aligned}$$

The second inequality follows from (4.7), (4.6), and (4.4). Hence $y_i(t) \in U$ as claimed. ∎

Recall that $\theta(\cdot)$ satisfies (HJ) and, in particular,

$$1 + h_F(y,\zeta) \ge 0 \quad \text{for all} \quad y \notin S,\ \zeta \in \partial_P\theta(y). \tag{4.8}$$

(The inequality (4.8) is one-half of (HJ), and is actually all that is required in this part of the proof.) By Proposition 3.3(b), it follows that $(-F \times \{1\}, \operatorname{epi}\theta)$ is strongly invariant in U, and thus by Lemma 4.2 we conclude that

$$\theta(y_i(t)) \le \theta(y_i(0)) + t = \theta(x_i) + t \tag{4.9}$$

for all large i and $t \in [0,T]$. By the compactness of trajectories theorem, we may assume without loss of generality that $y_i(\cdot) \to y(\cdot)$ uniformly on $[0,T]$ for some trajectory $y(\cdot)$ of $-F$ originating from x. For fixed $t \in [0,T]$, we let $i \to \infty$ in (4.9) and recall that $\theta(\cdot)$ is lower semicontinuous and $\theta(x_i) \to 0$ (see (4.5)). It follows from (4.9) that

$$\theta(y(t)) \le t \quad \text{for all} \quad t \in [0,T]. \tag{4.10}$$

For t small enough that $y(t) \in x + \eta B$, we can substitute $x' = y(t)$ into (4.1), and using (4.10), conclude that

$$t - \langle \zeta, y(t) - x\rangle + \sigma\|y(t) - x\|^2 \ge 0. \tag{4.11}$$

Observe for $t \in (0, T]$ that

$$\begin{aligned} \left\| \frac{y(t) - x}{t} + v \right\| &= \lim_{i \to \infty} \left\| \frac{y_i(t) - x_i}{t} + v_i \right\| \\ &\leq \frac{1}{t} \int_0^t \|\dot{y}(t') + v_i\| \, dt' \\ &\leq m(t), \end{aligned} \tag{4.12}$$

where in the last inequality we used (4.7). Therefore, dividing (4.11) by t and letting $t \downarrow 0$, we finally see from (4.12) that (4.3) holds, which finishes the proof. □

5. Propagation. In this section we prove an apparently new result that in effect characterizes the proximal subgradients of $T_S(\cdot)$. The result is known in the special case where $F(x) = B$ for all x. In this case, time is parametrized by Euclidean distance, and $T_S = d_S$. Thus Theorem 5.1 generalizes Theorem 3.4 of [16] to allow for much more general F.

For $r \geq 0$, define

$$S(r) := \{x \in \mathbb{R}^n : T_S(x) \leq r\},$$

the r-level set of $T_S(\cdot)$.

THEOREM 5.1. *Suppose $F : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ satisfies* (H1)–(H3), *$S \subseteq \mathbb{R}^n$ is closed, and* (H4) *holds.*

(a) *For all $x \in S$, we have*

$$\partial_P T_S(x) = N_S^P(x) \cap \{\zeta \in \mathbb{R}^n : \min_{v \in F(x)} \langle v, \zeta \rangle \geq -1\}.$$

(b) *Whenever $r > 0$ and $T_S(x) = r$, then we have*

$$\partial_P T_S(x) = N_{S(r)}^P(x) \cap \{\zeta \in \mathbb{R}^n : \min_{v \in F(x)} \langle v, \zeta \rangle = -1\}.$$

Proof. (a) Suppose $x \in S$ and $\zeta \in \partial_P T_S(x)$. Since $T_S(\cdot)$ satisfies the conditions of Theorem 4.1, we have by Lemma 4.1 that $\zeta \in N_S^P(x)$. We also have that

$$\min_{v \in F(x)} \langle v, \zeta \rangle \geq -1 \tag{5.1}$$

holds, since this is precisely the boundary condition (ABC) satisfied by $T_S(\cdot)$, as stated in Theorem 3.2.

For the opposite inclusion, suppose now that ζ satisfies (5.1) and

$$\langle \zeta, x' - x \rangle \leq \sigma \|x' - x\|^2 \quad \text{for all} \quad x' \in S, \tag{5.2}$$

where $\sigma > 0$ and $\eta > 0$. Note that (5.2) is simply the statement that $\zeta \in N_S^P(x)$ (Proposition 2.1(a)). We will show that there exists $\sigma' > 0$ and $\eta' > 0$ so that

$$T_S(x') - \langle \zeta, x' - x \rangle + \sigma' \|x' - x\|^2 \geq 0 \tag{5.3}$$

for all $x' \in x + \eta' B$, which implies $\zeta \in \partial_P T_S(x)$ by Proposition 2.1(b).

For the purpose of obtaining a contradiction, suppose to the contrary, and that (5.3) fails. Then for each $i = 1, 2, \ldots$, there exists x_i such that $x_i \to x$ as $i \to \infty$, and

$$T_S(x_i) - \langle \zeta, x_i - x \rangle < -i \|x_i - x\|^2 \tag{5.4}$$

holds for all i. Observe that since (5.2) holds, we have $x_i \notin S$ for large i. Set $t_i := T_S(x_i)$ and first note that

$$t_i \le \|\zeta\|\|x_i - x\| \tag{5.5}$$

for all i, which is a consequence of the Cauchy–Schwarz inequality and (5.4).

Now let $z_i(\cdot)$ be a time optimal trajectory originating from x_i, which exists by Proposition 2.6. Thus $z_i(\cdot)$ is a trajectory of F defined on $[0, t_i]$ and satisfies $z_i(0) = x_i$ and $z_i(t_i) =: y_i \in S$. Since $x_i \to x$, we deduce from (5.5) that $t_i \to 0$ as $i \to \infty$, and subsequently that for all large i, the entire range of the trajectory $z_i(\cdot)$ remains in $x + \eta B$ by Proposition 2.2(a). We have

$$\begin{aligned} t_i - \langle \zeta, x_i - x\rangle &= t_i + \langle \zeta, y_i - x_i\rangle - \langle \zeta, y_i - x\rangle \\ &\ge t_i + \left\langle \zeta, \int_0^{t_i} \dot z_i(t')\,dt' \right\rangle - \sigma\|y_i - x\|^2, \end{aligned} \tag{5.6}$$

which holds for large i in lieu of (5.2). Next, let $v_i(\cdot)$ be the pointwise projection of $\dot z_i(\cdot)$ onto $F(x)$, which is a measurable function defined on $[0, t_i]$. That is, $v_i(t') := \operatorname{proj}_{F(x)}(\dot z_i(t')) \in F(x)$. Let $K := x + \eta B$ and choose M, k as in (H1), (H3), respectively. We seek appropriate bounds for the last two terms in (5.6).

First we estimate $\|y_i - x\|$. We have

$$\begin{aligned} \|y_i - x\| &\le \|y_i - x_i\| + \|x_i - x\| \\ &\le \int_0^{t_i} \|\dot z_i(t')\|\,dt' + \|x_i - x\| \\ &\le t_i M + \|x_i - x\| \\ &\le \big(1 + M\|\zeta\|\big)\|x_i - x\|, \end{aligned} \tag{5.7}$$

where we used (5.5) to deduce the last inequality.

Next we estimate the integral term in (5.6). Note that any $t' \in [0, t_i]$ satisfies

$$\begin{aligned} \|z_i(t') - x\| &\le \|z_i(t') - x_i\| + \|x_i - x\| \\ &\le \int_0^{t_i} \|\dot z(t')\|\,dt' + \|x_i - x\| \\ &\le M t_i + \|x_i - x\|. \end{aligned} \tag{5.8}$$

We have by (5.1) and the Lipschitz assumption on F that

$$\begin{aligned} \left\langle \zeta, \int_0^{t_i} \dot z_i(t')\,dt' \right\rangle &= \int_0^{t_i} \langle \zeta, v_i(t')\,dt'\rangle + \left\langle \zeta, \int_0^{t_i} \big(\dot z_i(t') - v_i(t')\big)\,dt' \right\rangle \\ &\ge -t_i - k\|\zeta\| \int_0^{t_i} \|z_i(t') - x\|\,dt' \\ &\ge -t_i - t_i k\|\zeta\|\big[M t_i + \|x_i - x\|\big] \\ &\ge -t_i - k\|\zeta\|^2[M\|\zeta\| + 1]\|x_i - x\|^2 \\ &=: -t_i - c\|x_i - x\|^2 \end{aligned} \tag{5.9}$$

for all i, where (5.8) was used to deduce the next to last inequality, and (5.5), the last inequality.

We now insert (5.7) and (5.9) into (5.6) and deduce that

$$t_i - \langle \zeta, x_i - x\rangle \geq -[c + \sigma(1 + M\|\zeta\|)]\|x_i - x\|^2.$$

This contradicts (5.4) whenever i is sufficiently large and finishes the proof. (b) The proof of (b) is very similar to that of (a). The only modifications needed are (1) the substitution of $\theta(x) = r$ rather than 0, and (2) the use of (HJ) rather than (ABC). The details are left to the reader. □

Remark 5.1. It may be noted that $S(r)$ is nothing more than $R_{-F}^{(\leq r)}(S)$, the set of points reachable from S in times less than or equal to r by trajectories of $-F$. Thus Theorem 5.1(b) gives some information regarding the existence of proximal normals to reachable sets. We plan to further exploit this in future work, but in the present paper, we give only one application of this result in the next section.

6. Regularity results. In this section, we give necessary and sufficient conditions for T_S to be Lipschitz continuous near S. A sufficient condition for T_S to be continuous with proscribed modulus of continuity is also derived. Throughout this entire section, we assume that F satisfies (H1) and (H2), $S \subset \mathbb{R}^n$ is compact, and (H4) holds. We often impose (H3) as well, but this will be stated explicitly.

Recall that a modulus function $m(\cdot) : [0, \infty) \to [0, \infty)$ is a nondecreasing continuous function satisfying $m(0) = 0$. For our purposes, the distinguishing property of a modulus function is its behavior near 0. To make this formal, we say that two modulus functions $m_1(\cdot)$ and $m_2(\cdot)$ are equivalent if there exists a constant $c > 0$ such that

$$0 < \liminf_{r\downarrow 0} \frac{m_1(cr)}{m_2(r)} \leq \limsup_{r\downarrow 0} \frac{m_1(cr)}{m_2(r)} < \infty.$$

This defines an equivalence relation among modulus functions, and an equivalence class is called a *modulus class*. Note that if $m_1(\cdot)$ is a modulus function and $m_2(r) := c_1 m(c_2 r)$ for some positive constants c_1, c_2, then m_1 and m_2 belong to the same modulus class.

Let $\mathcal{M}$ be a modulus class. We say that a function f is $\mathcal{M}$-continuous on a set $U \subseteq \mathbb{R}^n$ if there exists $m(\cdot) \in \mathcal{M}$ such that

$$|f(x) - f(y)| \leq m(\|x - y\|) \quad \text{for all} \quad x, y \in U.$$

The first proposition shows that the local $\mathcal{M}$-continuity of $T_S(\cdot)$ near S need only be checked with one of the points belonging to S. This result appears in Soravia [28, Lemma 4.1] for modulus functions of the form $m(r) = c\, r^\alpha$, $0 < \alpha \leq 1$ and $c > 0$.

PROPOSITION 6.1. *Suppose $\mathcal{M}$ is a modulus class and* (H3) *holds. The following are equivalent.*

(a) *There exists $\eta > 0$ such that $T_S(\cdot)$ is $\mathcal{M}$-continuous on $S + \eta B$.*

(b) *There exists $\eta > 0$ and $m(\cdot) \in \mathcal{M}$ such that*

$$T_S(x) \leq m\big(d_S(x)\big)$$

for all $x \in S + \eta B$.

Proof. (a)⇒(b). This is trivial. (b)⇒(a) Let $\eta > 0$ and $m(\cdot)$ be as in (b). By Proposition 2.2(a), there exists $\eta' > 0$ such that

$$R_F^{(\leq m(\eta'))}(S + \eta' B) \subset S + \eta B. \tag{6.1}$$

We show that $T_S(\cdot)$ is continuous on $S+\eta' B$ with modulus of continuity $m_1(\cdot) := m\big(e^{km(\eta')}(\cdot)\big)$, where k is the Lipschitz constant of F on $S+\eta B$. Since $m_1 \in \mathcal{M}$, this is sufficient to prove (a).

Let $x, y \in S+\eta' B$. Since $T_S(x) \le m(\eta') < \infty$, we have by Proposition 2.6 that there exists $x(\cdot) \in \Upsilon_{(F,S^c)}(x)$ with $T := T_S(x)$ and $x(T) \in S$. By a well-known fact regarding the dependence of the reachable set on initial values (cf. [1, p. 120] or [39, Corollary 7.2]), there exists a trajectory $y(\cdot)$ for F originating from y that satisfies

$$\|x(T)-y(T)\| \le e^{kT}\|x-y\|. \tag{6.2}$$

Note that $y(T) \in S+\eta B$ by (6.1). The principle of optimality gives

$$T_S(y) \le T + T_S(y(T)). \tag{6.3}$$

Thus, from (6.3), we have

$$\begin{aligned} T_S(y) - T_S(x) &\le T_S(y(T)) \\ &\le m\big(d_S(y(T))\big) \\ &\le m\big(\|x(T)-y(T)\|\big) \\ &\le m_1\big(\|x-y\|\big). \end{aligned} \tag{6.4}$$

We used (b) in deducing the second inequality, the monotonicity of $m(\cdot)$ and $x(T) \in S$ in the third, and the monotonicity again and (6.2) in the last. Switching the roles of x and y in (6.4) shows that $T_S(\cdot)$ is continuous in $S+\eta' B$ of modulus m_1. □

The following theorem gives necessary and sufficient conditions for Lipschitz continuity of T_S near S.

THEOREM 6.1. *Suppose* (H3) *holds. Then the following are equivalent.*

(a) *There exists $\eta > 0$ such that $T_S(\cdot)$ is Lipschitz continuous on $S+\eta B$.*

(b)
$$\sup\big\{\|\zeta\| :\ \zeta \in \partial_P T_S(s),\ s \in S\big\} < \infty.$$

(c) *There exist $\eta > 0$ and $\delta > 0$ such that $x \in S^c \cap \{S+\eta B\}$ and $\zeta \in x - \mathrm{proj}_S(x)$ imply*
$$h_F(x,\zeta) \le -\delta\|\zeta\|.$$

Proof. (a)⇒(b). Let $s \in S$ and $\zeta \in \partial_P T_S(s)$. From Proposition 2.1(b), there exists $\sigma > 0$ such that for all x near s we have

$$\langle \zeta, x-s\rangle \le T_S(x) + \sigma\|x-s\|^2. \tag{6.5}$$

Since there exists $\lambda > 0$ for which $T_S(x) \le \lambda\|x-s\|$ by (a), (b) follows immediately from (6.5).

(b)⇒(c). If (c) fails, then for each $i = 1, 2\ldots$, there exists $x_i \notin S$ with $d_S(x_i) \to 0$ and $\zeta_i := x_i - s_i \in x_i - \mathrm{proj}_S(x_i)$ such that

$$h_F(x_i,\zeta_i) \ge \frac{-1}{i}\|\zeta_i\| \tag{6.6}$$

for all i. Let k be chosen for the compact set $S+B$ as in (H3). Then $x \mapsto h_F(x,\zeta)$ is Lipschitz of rank $k\|\zeta\|$ on $S+B$. Therefore, by (6.6), we have for large i

$$\begin{aligned} h_F(s_i,\zeta_i) &\ge h_F(x_i,\zeta_i) - k\|x_i-s_i\|\|\zeta_i\| \\ &= -\left[\frac{1}{i} + k d_S(x_i)\right] d_S(x_i), \end{aligned}$$

since $d_S(x_i) = \|x_i - s_i\| = \|\zeta_i\|$. Let $\rho_i := \big[1/i + kd_S(x_i)\big]$. Rewriting the last display and using the positive homogeneity of $h_F(s,\cdot)$ gives

$$h_F\left(s_i, \frac{\zeta_i}{\rho_i d_S(x_i)}\right) \geq -1. \tag{6.7}$$

Since $N_S^P(s_i)$ is a cone, we also have

$$\frac{\zeta_i}{\rho_i d_S(x_i)} \in N_S^P(s_i). \tag{6.8}$$

Thus (6.7), (6.8), and Theorem 5.1(a) imply that

$$\frac{\zeta_i}{\rho_i d_S(x_i)} \in \partial_P T_S(s_i).$$

Let $\lambda > 0$ be the supremum value in (b), and by assumption (b) we have

$$\lambda \geq \frac{\|\zeta_i\|}{\rho_i d_S(x_i)} = \frac{1}{\rho_i}.$$

But $\rho_i \to 0$ as $i \to \infty$, which is a contradiction, and hence we conclude that (c) holds.

(c)⇒(a). Under the hypothesis (c), it is shown in [18, Corollary 3.1] that $T_S(x) \leq c\, d_S(x)$ for some $c > 0$ and for all x sufficiently close to S (this result also appears in Veliov [37]). Hence (a) follows from this and Proposition 6.1. □

Remark 6.1. From the above proof of (b)⇒(c), one can also obtain a relation for the constant δ appearing in (c). Namely, if $0 < \eta \leq 1$ is sufficiently small, then since ρ_i cannot be larger than λ, we can take $\delta = 1/\lambda + k$. Note, however, that the proof does not seem to provide an a priori estimate for η, but it implies that such a value must exist.

Remark 6.2. There is an extensive literature behind the equivalence of (a) and (c) in Theorem 6.1. The implication (c)⇒(a) was first proved by Petrov [26] with $S = \{0\}$ and was extended to arbitrarily closed sets S by Soravia [29]. The converse (a)⇒(c) was shown by Bardi and Falcone [4] in the case when the boundary of S was piecewise C^2. Cannarsa and Sinestrari [7] allowed for "proximally smooth" S (see [16]) in proving this implication, but also required state differentiability in the dynamics. More recently, Yue [40] proved the equivalence in considerable generality, although the dynamics were given an explicit control formulation, as was the dynamics in all of the above-mentioned papers. Veliov [37] goes further yet by allowing the multifunction F to be nonautonomous and to depend measurably on t. The equivalence of condition (b) in our theorem seems to be new, however.

Remark 6.3. The condition that the proximal subgradient of a lower semicontinuous function f is locally bounded on an open set U is equivalent to f locally Lipschitz on U. See [15]. Note that in Theorem 6.1 above, we only used a part of one direction of this equivalence, and only the "easy" direction at that. We emphasize that in Theorem 6.1(b), the boundedness of the proximals is posited only for points in S.

We now give a sufficient condition for $T_S(\cdot)$ to satisfy condition (b) in Proposition 6.1 for some C^2 modulus function $m(\cdot)$, by which we mean that $m(\cdot)$ is a modulus function and is twice continuously differentiable on $(0,\infty)$. The estimate in fact does not require (H3). However, if (H3) holds as well, then it follows (Corollary 6.1) from Proposition 6.1 that $T_S(\cdot)$ is $\mathcal{M}$-continuous near S, where $m(\cdot) \in \mathcal{M}$.

THEOREM 6.2. *Assume that $m(\cdot)$ is a C^2 modulus function with $m'(r) > 0$ for $r > 0$, and that*

$$h_F(x,\zeta) \le \frac{-1}{m'\big(d_S(x)\big)}\|\zeta\| \tag{6.9}$$

for all x near S and $\zeta \in x - \operatorname{proj}_S(x)$. Then $T_S(\cdot)$ satisfies

$$T_S(x) \le m\big(d_S(x)\big)$$

for all x near S.

We require the following technical lemma, which is a version of the chain rule.

LEMMA 6.1. *Suppose $m(\cdot)$ is as in the theorem, and $f : U \to (0,\infty)$ is lower semicontinuous on the open set U. Then $m \circ f$ is lower semicontinuous on U, and $\zeta \in \partial_P f(x)$ if and only if $m'(f(x))\zeta \in \partial_P(m \circ f)(x)$.*

Proof. Let $x \in U$ and $\zeta \in \partial_P f(x)$. There exists $\sigma > 0$ such that

$$f(y) \ge f(x) + \langle \zeta, y - x\rangle - \sigma\|y - x\|^2 \tag{6.10}$$

for all y near x. Since $m(\cdot)$ is strictly increasing, taking m on both sides of (6.10) preserves the inequality (both sides of (6.10) are positive if y is near enough to x), and we have

$$m\big(f(y)\big) \ge m\big(f(x) + \langle \zeta, y - x\rangle - \sigma\|y - x\|^2\big). \tag{6.11}$$

Also, m is C^2, and so there exists a $\sigma' > 0$ such that

$$m(z) \ge m\big(f(x)\big) + m'(f(x))\big(z - f(x)\big) - \sigma'\|z - f(x)\|^2 \tag{6.12}$$

for all z near $f(x)$. Setting $z = f(x) + \langle \zeta, y - x\rangle - \sigma\|y - x\|^2$, we obtain from (6.11) and (6.12) that

$$m\big(f(y)\big) \ge m\big(f(x)\big) + \big\langle m'\big(f(x)\big)\zeta, y - x\big\rangle - \sigma''\|y - x\|^2, \tag{6.13}$$

where $\sigma'' := m'\big(f(x)\big)\sigma + 2\sigma'\|\zeta\|^2$, which holds if y is sufficiently near x. This shows that $m'\big(f(x)\big)\zeta \in \partial_P\big(m \circ f\big)(x)$.

The converse follows since the inverse of $m(\cdot)$ has the same properties as $m(\cdot)$. ∎

We record another fact in the next proposition, which contains results taken from [16] and [14]. This gives the relationship between the vectors $\zeta \in x - \operatorname{proj}_S(x)$ and proximal subgradients of the distance function.

PROPOSITION 6.2. *Suppose $x \notin S$ and $\partial_P d_S(x) \ne \phi$. Then both $\operatorname{proj}_S(x)$ and $\partial_P d_S(x)$ are singletons and equal $\{s_x\}$, $\{(x - s_x)/\|x - s_x\|\}$, respectively. Moreover, the Petrov modulus condition* (6.9) *is equivalent to*

$$h_F(x,\zeta) \le \frac{-1}{m'\big(d_S(x)\big)} \quad \text{for all } \zeta \in \partial_P d_S(x). \tag{6.14}$$

Proof. See [14, Theorem 4.1] for the statements regarding the proximal subgradient and the projection. That (6.9) implies (6.14) is then obvious. The reverse implication follows by taking limits, since if $\zeta = x - s_x \in x - \operatorname{proj}_S(x)$, then $\zeta/\|\zeta\|$ is the single element belonging to $\partial_P d_S(s_x + \varepsilon\zeta)$, $0 < \varepsilon < 1$ (see [16]). ∎

Proof of Theorem 6.2. Let $U := \{S + \eta \operatorname{int} B\} \cap S^c$, where $\eta > 0$ is sufficiently small that (6.9) holds for $x \in S + \eta B$. We shall see that (6.9) and each of the following statements are equivalent:

$$h_F\big(x,\zeta\big) \le \frac{-1}{m'\big(d_S(x)\big)} \quad \text{for all } x \in U, \text{ for all } \zeta \in \partial_P d_S(x), \tag{6.15}$$

$$1 + h_F\big(x, m'\big(d_S(x)\big)\zeta\big) \le 0 \quad \text{for all } x \in U, \text{ for all } \zeta \in \partial_P d_S(x), \tag{6.16}$$

$$1 + h_F\big(x,\zeta\big) \le 0 \quad \text{for all } x \in U, \text{ for all } \zeta \in \partial_P\big(m \circ d_S\big)(x), \tag{6.17}$$

$$\big(F \times \{-1\}, \operatorname{epi}(m \circ d_S)\big) \quad \text{is weakly invariant in } U \times \mathbb{R}. \tag{6.18}$$

The equivalence of (6.9) and (6.15) is contained in Proposition 6.2; that of (6.15) and (6.16) is due only to a rearrangement of terms and the positive homogeneity of $h_F(x,\cdot)$; the equivalence of (6.16) and (6.17) follows from Lemma 6.1, and that of (6.17) and (6.18) is a consequence of Proposition 3.3(a).

By Proposition 2.2(a), there exists $0 < \eta' \le \eta$ such that

$$R_F^{(\le m(\eta'))}(S + \eta' B) \subseteq S + \frac{\eta}{2} B. \tag{6.19}$$

Let $x \in \{S + \eta' B\} \cap S^c$. Our assumption (6.9) has been shown to be equivalent to (6.18), and thus there exists a trajectory $\tilde{x}(\cdot)$ of $F \times \{-1\}$ originating from $\big(x, m\big(d_S(x)\big)\big)$ that remains in epi $\big(m \circ d_S\big)$. We can write $\tilde{x}(t) = \big(x(t), m(d_S(x)) - t\big)$ for $0 \le t < \operatorname{Esc}(\tilde{x}(\cdot); U \times \mathbb{R}) = \operatorname{Esc}(x(\cdot); U) =: T$, where $x(\cdot)$ is a trajectory for F. Since $\tilde{x}(\cdot)$ remains in epi $\big(m \circ d_S\big)$, we have

$$m\big(d_S(x)\big) - t \ge m\big(d_S(x(t))\big) \quad \text{for all } t \in [0, T). \tag{6.20}$$

Since $m \ge 0$, we must have $T \le m\big(d_S(x)\big) \le m(\eta')$, and so it follows from (6.19) that $\lim_{t \uparrow T} x(t) = x(T) \in S$ (that is, $x(\cdot)$ escapes by hitting S first, not by going to the boundary of $S + \eta B$). Letting $t \uparrow T$ in (6.20) yields

$$T_S(x) \le T \le m\big(d_S(x)\big),$$

which finishes the proof. □

The following is an immediate corollary.

COROLLARY 6.1. *Suppose* (H3) *holds in addition to the hypotheses of Theorem* 6.2. *Then* $T_S(\cdot)$ *is* $\mathcal{M}$*-continuous near* S.

Proof. This follows immediately from Theorem 6.2 and Proposition 6.1. □

Remark 6.4. The condition (6.15) reduces to the Petrov–Lipschitz condition in Theorem 6.1(c) if $\mathcal{M}$ contains the modulus function $m(r) = r$, and hence Theorem 6.2 generalizes the implication (c)⇒(a) in Theorem 6.1. The proof also provides an alternative to relying on results from [18], as was done in the proof of Theorem 6.1. We also mention that from (6.20), one can deduce the "rate of weak attainability" estimate derived by other means in [18].

Remark 6.5. If m in the previous theorem is taken as $m(r) = c\, r^\alpha$, where $c > 0$ and $0 < \alpha \le 1$, then Theorem 6.2 is a sufficient condition for α-Hölder continuity of T_S. Soravia [28] gave a sufficient condition for $\alpha = \frac{1}{2}$ under some special hypotheses, and Yue [40] considered any $0 < \alpha \le 1$. Thus Theorem 6.2 extends a result of Yue [40] to arbitrary (albeit C^2) moduli. Although the dynamics in [40] use the control formulation and the hypotheses there are stated using directional derivatives

rather than proximal subgradients, Theorem 6.2 and [40, Theorem 2.1] appear to be equivalent in the case of Hölder moduli.

Remark 6.6. As pointed out in Remark 5.1, the level set $S(r)$, $r > 0$, is the reachable set $R_{-F}^{(\leq r)}(S)$. If it is known that $T_S(\cdot)$ is continuous near S, then it follows immediately that S is contained in the interior of the reachable set associated with $-F$ up to time r. Thus Corollary 6.1 gives a sufficient condition for *small time local controllability*. The converse is also true: that is, small time local controllability of the system $-F$ implies the continuity of $T_S(\cdot)$ near S. There is a considerable literature devoted to local controllability (see Sussmann [35]), and there are systems which are controllable but violate any Petrov modulus condition. Thus a converse to Corollary 6.1 will not hold in general, although it does hold if the continuity is Lipschitz (Theorem 6.1). This can be explained by the fact that Lipschitz continuity is characterized by properties of its proximal subgradient, whereas continuity of a less restrictive modulus is not. We note, however, that a Petrov modulus condition as a sufficient condition for local controllability uses no additional structure of the control system beyond knowledge of certain admissible velocities at points near the target.

7. Examples.

Example 7.1. This is an example where F satisfies (H1)–(H3), but yet $T_S(\cdot)$ fails to be lower semicontinuous. Define $f : \mathbb{R}^2 \to \mathbb{R}^2$ by

$$f(x, y) = \{1\} \times \{1 + y^2\}.$$

Let $F(x, y) := \{f(x, y)\}$ and $S := \left\{\frac{\pi}{2}\right\} \times \mathbb{R}$. One can easily check that $T_S(0, 0) = \infty$, but $T_S(\varepsilon, 0) \to \frac{\pi}{2}$ as $\varepsilon \downarrow 0$.

Example 7.2. Here is an example showing that the existence of optimal trajectories cannot be assured unless additional hypotheses are added to (H1)–(H3). Again, we use state space $\mathbb{R}^2$, and F is obtained by modifying the previous example.

$$F(x, y) = \{1\} \times [0, 1 + y^2] \quad \text{and} \quad S := \left\{(x, y) : x > \frac{\pi}{2},\, y = \frac{1}{x - \frac{\pi}{2}}\right\}.$$

Then

$$R^{(T)}(0, 0) = \begin{cases} \{T\} \times [0, \tan T] & \text{if} \quad 0 \leq T < \frac{\pi}{2}, \\ \{T\} \times [0, \infty) & \text{if} \quad \frac{\pi}{2} \leq T. \end{cases}$$

Then one has $T_S(0, 0) = \frac{\pi}{2}$, but no trajectory reaches S from $(0, 0)$ in this time.

Acknowledgments. The authors wish to express their appreciation for the referees' comments, and their thanks to M. Bardi and P. Soravia for bringing to our attention some of the pertinent literature.

A CLASSICAL APPROACH TO UNIFORM NULL CONTROLLABILITY FOR ELASTIC BEAMS*

MIGUEL ANGEL MORELES†

Abstract. The Rayleigh beam equation is the formal limit of the Timoshenko beam equation as the *shear modulus* $K \to +\infty$. Following a method in W. Littman, *Ann. Scuola Norm. Sup. Pisa Cl. Sci.* (4), 5 (1978), pp. 567–580 and W. Littman, Proc. 24th IEEE CDC, Fort Lauderdale, FL, 1985, controllability is possible. That is, the evolution systems associated with the Rayleigh and Timoshenko equations can be driven to rest by applying appropriate controls at both ends of the beam. In this work we show that the process is uniform; more precisely, controllability of the Rayleigh system can be achieved by letting $K \to +\infty$ in the solution of the Timoshenko controllability problem.

Key words. null controllability, elastic beams, hyperbolic operators

1. Introduction.

Let us recall two problems in boundary controllability.

The null boundary controllability problem (NBCP). Suppose we have a well-posed initial-boundary value problem for an *evolution equation* $Lw = 0$ in a cylindrical domain $Q = \Omega \times [0, +\infty)$, where Ω is a bounded domain in $\mathbb{R}^n$. The NBCP deals with the following question: Given initial data in Ω at $t = 0$, can these data be supplemented with appropriate inhomogeneous time-dependent boundary data (boundary controls), prescribed on the lateral boundary of Q, such that the solution of the initial-boundary value problem will vanish for $t \geq T_0$?

The uniform null boundary controllability problem (UNBCP). Let $L_\varepsilon = L + \varepsilon M$, where L_ε and L are evolution operators with well-posed initial-boundary value problems as before. The UNBCP deals with the following questions: Is it possible to find ε_0 and T_0 with T_0 independent of $\varepsilon \leq \varepsilon_0$ such that one has null controllability for $T > T_0$ for all equations $L_\varepsilon w_\varepsilon = 0$, $\varepsilon \leq \varepsilon_0$, and for $Lw = 0$? And what happens, as $\varepsilon \to 0$ to the boundary controls which drive the system to rest?

We will be concerned with these two problems when L, L_ε are *elastic beam operators.*

In Russell [14] several models for the elastic beam are considered, in particular the model of Timoshenko described by the system

$$I_\rho \psi_{tt} - EI\psi_{xx} + K(\psi - w_x) = 0,$$
$$\rho w_{tt} + K(\psi - w_x)_x = 0$$

plus appropriate initial and boundary conditions.

Here $w(x,t)$ represents the vertical displacement of the *elastic axis* of the beam, and $\psi(x,t)$ is the rotation angle due to bending and shear.

The physical constants in the model are $\rho \equiv$ density, $EI \equiv$ flexural rigidity, $I_\rho \equiv$ rotary inertia, and $K \equiv$ shear modulus.

By formal differentiation the system can be uncoupled to obtain the Timoshenko equation

$$\rho w_{tt} - I_\rho w_{ttxx} + EI w_{xxxx} + \frac{\rho}{K}(I_\rho w_{tttt} - EI w_{ttxx}) = 0. \tag{1.1}$$

*Received by the editors June 7, 1996; accepted for publication (in revised form) April 10, 1997. http://www.siam.org/journals/sicon/36-3/30488.html

†Centro de Investigación en Matemáticas (CIMAT), Apdo. Postal 402, Guanajuato, GTO 36000, Mexico (moreles@fractal.cimat.mx).

In this equation $-I_\rho w_{ttxx}$ is the contribution of rotary inertia and the term due to shear is $\frac{\rho}{K}\left(I_\rho w_{tttt} - EIw_{ttxx}\right)$.

If the shear effect is neglected we are led to the Rayleigh equation

$$\rho w_{tt} - I_\rho w_{ttxx} + EIw_{xxxx} = 0. \tag{1.2}$$

It is observed that (1.1) is a perturbation of (1.2).

In our exposition we deal with the UNBCP for (1.1) and (1.2). Uniformity is studied when $K \to +\infty$. The outline is as follows.

In section 2 we present the main result; roughly speaking it says that the null-controlled problem for the Timoshenko equation converges to that for the Rayleigh equation. The problem is not new, and there are several related results in the literature covering also similar problems for plate systems. The last paragraph of the section, entitled Earlier Results, gives references as well as a brief discussion of these results.

Our proof is carried out in sections 3 and 4. The idea is to follow a well-known result by Littman [9, 10] to solve the NBCP.

Two perturbation problems arise from Littman's method. Section 3 studies convergence of the solution of a homogeneous Cauchy problem for the Timoshenko equation to that of Rayleigh. The Cauchy data, compactly supported, are given in the x-axis. Section 4 deals with the problem in the x-direction, now the Cauchy problems are nonhomogeneous and the Cauchy data, in the t-axis, are zero. It will become apparent that the former is a *singular perturbation* problem, whereas the latter is a *regular perturbation* problem.

A natural continuation to this work is to solve the UNBCP with controls in only one end of the beam. Mention of this, and other problems of related interest is in section 5.

To simplify the statements of results, we shall use the term *smooth* loosely, hoping that the notion of smooth will be clear from the context.

Also, all positive constants independent of the shear modulus K will be denoted by c. When precision is necessary, we distinguish between different constants by using subscripts.

2. Main result. Denote by L_K the Timoshenko operator

$$L_K = \rho\partial_t^2 - I_\rho\partial_t^2\partial_x^2 + EI\partial_x^4 + \frac{\rho}{K}\left(I_\rho\partial_t^4 - EI\partial_t^2\partial_x^2\right)$$

and by L_0 the Rayleigh operator

$$L_0 = \rho\partial_t^2 - I_\rho\partial_t^2\partial_x^2 + EI\partial_x^4.$$

For any $s \in \mathbb{R}$ consider the function (in $\mathbb{R}^n$)

$$\Lambda_s \equiv \Lambda_s(\xi) = \left(1 + |\xi|^2\right)^{\frac{s}{2}} \ . \tag{2.1}$$

Denote as customary by H^s the Sobolev space with norm

$$\|u\|_s^2 = \int \left(\Lambda_s(\xi)\,|\widehat{u}(\xi)|\right)^2 d\xi,$$

where $\widehat{u}(\xi) \equiv (\mathcal{F}u)(\xi)$ is the Fourier transform of u. For bounded domains Ω define $H^s(\Omega)$ as usual.

Let $\Omega = (-a, a)$, $Q = [-a, a] \times [0, +\infty)$, and let L be one of the operators above and let us say its order with respect to t is n, where n is either 2 or 4.

The initial-boundary value problem (IBVP) to consider is the following:

$$\begin{aligned} &Lw = 0, && (x,t) \in Q, \\ &\partial_t^j w(x,0) = w^j(x), && x \in \Omega, \qquad j = 0,1,\dots,n-1 \end{aligned} \tag{2.2}$$

with boundary conditions

$$B_- w(-a,t) = g_-(t), \quad B_+ w(a,t) = g_+(t),$$

where B_-, B_+ are differential boundary operators. We assume that the problem is *well posed.* Later we will see that uniqueness is enough.

For $b \geq 0$ denote by $\sum_b$ the strip $[-a,a] \times [b,+\infty)$. Finally, extend the Cauchy data in (2.2) as smoothly as possible to have compact support, and consider the Cauchy problem in the upper half-plane. Following Littman [9, 10], there exists $T_1 > 0$ and a function w, smooth away from zero, such that w satisfies this new Cauchy problem, and $w(x,t) \equiv 0$ in the strip $\sum_{T_1}$. An important observation is that Littman's proof is constructive and independent of the boundary conditions.

Let w_K be the Littman's solution for the Timoshenko equation and T_{1_K} be the control time. Similarly, w_0 and T_{1_0} for the Rayleigh equation.

The UNBCP is a consequence of the following theorem.

THEOREM 2.1. *Let $m \geq 0$. On the interval $(-a,a)$ let*

$$w^0 \in H^{m+3}, \quad w^1 \in H^{m+2}, \quad w^2, w^3 \in H^m. \tag{2.3}$$

(i) *There exists T_1 independent of K such that $w_K(x,t)$ and $w_0(x,t)$ both vanish in the strip $\sum_{T_1}$ (i.e., $T_1 = T_{1_K} = T_{1_0}$).*

(ii) *For bounded subsets of $\sum_0$ $\partial_x^m \partial_t^l w_K$ converges to $\partial_x^m \partial_t^l w_0$ as $K \to +\infty$ in the L^∞-norm for $l = 0, 1$.*

Several remarks are in order:

1. To solve the NBCP for the Rayleigh and Timoshenko equations we just need to read off appropriate boundary conditions. More precisely, the following must hold:
   Uniqueness assumption. If the IBVP has a solution, it is unique in *sufficiently large* function spaces. This will be made precise in the proof.
   Let c be $-a$ or a. To fulfill this assumption some admissible boundary conditions are
   (i) $w(c,t) = w_x(c,t) = 0$ (clamped end);
   (ii) $w(c,t) = w_{xx}(c,t) = 0$ (simply supported end);
   (iii) $w_{xx}(c,t) = I_\rho w_{ttx}(c,t) - EI w_{xxx}(c,t) = 0$ (free end).
   (see Russell [14].)
2. For clamped and simply supported ends we obtain *strong* convergence as implied by (ii) in the theorem. It will become apparent later that for a free end weaker convergence holds.
3. We shall see that for T_0 as in (3.14) if we restrict to $\sum_{T_0}$ we obtain uniform convergence in compacta.
4. Observe that in (2.3) we require more regularity than necessary to solve the IBVP. This is because of estimates (3.11) and (3.12) in section 3, which we have been unable to improve.
5. Thanks to Littman's method, our result is suitable for numerical implementation. A drawback is the need to impose controls in the whole boundary.

Earlier results. There are several results related to the problem of concern of this paper and with the more complex problem of plate systems. Our problem was

motivated by the works of Lions [7, 8] and Lagnese and Lions [6], where a complete treatment of boundary controllability is given. See also the monograph by Lagnese [3].

Komornik [2] proves that for a Reissner–Mindlin plate, the control time *is independent of* K. For the Timoshenko beam equation a similar result follows. It is not known if the solution to the control problem for the Reissner–Mindlin system (resp., for the Timoshenko system) converges to the solution to the control problem for the Kirchhoff system (resp., the Rayleigh system) as the shear modulus approaches infinity. For the beam problem, our result provides a positive answer.

The perturbation problem, i.e., convergence of solutions of the Timoshenko equation to that of Rayleigh, as well as for plate systems, is dealt in a more complex setting in the works of Lagnese and Leugering [4] and Lagnese, Leugering, and Schmidt [5] . Namely, they describe the dynamics of networks of interconnected Reissner–Mindlin thin plates and establish convergence to the corresponding dynamic model for networks of interconnected Kirchhoff plates.

The proof of Theorem 2.1 is in the next two sections.

3. Singular perturbation. Since we are interested in K large, we assume $K \geq K_0$ for K_0 such that

$$\frac{K_0}{\rho} >> \frac{EI}{I_\rho}. \tag{3.1}$$

In this section the main tool is the Fourier transform; hence it is convenient to introduce the notation

$$D_x \equiv -i\partial_x, \quad D_t \equiv -i\partial_t.$$

The Timoshenko and Rayleigh operators are written, respectively, in the form

$$P_K = D_t^4 - \left[\frac{K}{I_\rho} + \left(\frac{K}{\rho} + \frac{EI}{I_\rho}\right) D_x^2\right] D_t^2 + \frac{KEI}{\rho I_\rho} D_x^4,$$

$$P_0 = \left(1 + \frac{I_\rho}{\rho} D_x^2\right) D_t^2 - \frac{EI}{\rho} D_x^4.$$

The associated Cauchy problems are

$$\begin{gathered} P_K[u_K] = 0, \\ D_t^j u_K(x,0) = w^j(x), \quad j = 0,1,2,3, \end{gathered}$$

and

$$\begin{gathered} P_0[u_0] = 0, \\ u_0(x,0) = w^0(x), \quad D_t u_0(x,0) = w^1(x). \end{gathered}$$

Observe that in the t-direction, the Timoshenko equation is of order 4, whereas the Rayleigh equation is of order 2; there is a *loss* of two initial conditions. Hence, the Timoshenko equation is a singular perturbation of that of Rayleigh.

THEOREM 3.1. *For $m \geq 1$, assume*

$$w^0 \in H^{m+3}, w^1 \in H^{m+2}, w^2 \in H^m, w^3 \in H^{m-1}.$$

Then $D_x^j D_t^l u_K$ converges to $D_x^j D_t^l u_0$ when $K \to \infty$ for $l = 0, 1$; $j \leq m$ in the norm $L^\infty((-\infty,\infty) \times [\tau_0, \tau_1])$ with $0 \leq \tau_0 \leq \tau_1 < \infty$.

The main step of the proof is the theorem below. For the statement we need some notation.

Let U_K be the Fourier transform of u_K and U_0 be that of u_0. Decompose U_K in the form

$$U_K = U_0 + R.$$

Then R satisfies

$$\begin{aligned} &P_K(\xi, D_t)R(\xi,t) = F(\xi,t), \\ &D_t^j R(\xi,0) = R^j(\xi), \quad j = 0,1,2,3, \end{aligned} \tag{3.2}$$

where

$$\begin{aligned} &R^0(\xi) = R^1(\xi) = 0, \\ &R^j(\xi) = W^j(\xi) - D_t^j U_0(\xi,0), \quad j = 2,3, \end{aligned} \tag{3.3}$$

and

$$F(\xi,t) = -\left(D_t^4 U_0 - \frac{EI}{I_\rho}\xi^2 D_t^2 U_0\right).$$

Recall the function Λ_s in (2.1) and observe that $\Lambda_0 = 1$ and $\Lambda_{s+\sigma} = \Lambda_s \Lambda_\sigma$. Moreover $\Lambda_s < \Lambda_\sigma$ if $s < \sigma$.

THEOREM 3.2. *Let $R(\xi,t)$ be the solution of* (3.2). *Then*

$$|R(\xi,t)| \le \frac{c}{K}(1+t)^2\left(\Lambda_2\left|W^0\right| + \Lambda_1\left|W^1\right| + \Lambda_{-2}\left|W^2\right| + \Lambda_{-2}\left|W^3\right|\right) \tag{3.4}$$

and for $l = 1,2,3$

$$\left|D_t^l R(\xi,t)\right| \le \frac{c\,(1+t)}{\left(\sqrt{K}\right)^{2-l}}\left(\Lambda_{l+1}\left|W^0\right| + \Lambda_l\left|W^1\right| + \Lambda_{l-2}\left|W^2\right| + \Lambda_{l-3}\left|W^3\right|\right). \tag{3.5}$$

Proof. It is readily seen that

$$U_0(\xi,t) = W^0(\xi)\cos\lambda t + W^1(\xi)\frac{i}{\lambda}\sin\lambda t$$

with

$$\lambda \equiv \lambda(\xi) = \frac{\sqrt{\frac{EI}{\rho}}\,\xi^2}{\sqrt{1 + \frac{I_\rho}{\rho}\,\xi^2}}.$$

We have the estimates

$$\begin{aligned} |U_0(\xi,t)| &\le \left|W^0(\xi)\right| + t\left|W^1(\xi)\right|, \\ |D_t^n U_0(\xi,t)| &\le c\left(\Lambda_n\left|W^0(\xi)\right| + \Lambda_{n-1}\left|W^1(\xi)\right|\right), \quad n = 1,2,\ldots. \end{aligned} \tag{3.6}$$

Let

$$p_4(\xi,z) = P_K(\xi,z) = \sum_{i=0}^{4} a_i(\xi) z^{4-i};$$

notice that $a_0 = 1$.

Define

$$p_j(\xi,z)=\sum_{i=0}^{j}a_i(\xi)z^{j-i}$$

and

$$G_j(\xi,t)=\frac{1}{2\pi i}\int_C\frac{e^{izt}p_{3-j}(\xi,z)}{p_4(\xi,z)}dz\,,\qquad j=0,1,2,3, \tag{3.7}$$

where C is a simple curve in the z-plane which surrounds the zeros of $p_4(\xi,z)$.

By residues it follows that $G_j(\xi,t)$ satisfies

$$p_4(\xi,D_t)G_j=0$$

and initial data

$$D_t^iG_j(\xi,0)=\begin{cases}1, & i=j,\\ 0, & i\neq j.\end{cases}$$

Hence

$$R(\xi,t)=\sum_{j=0}^{3}R^j(\xi)G_j(\xi,t)+\int_0^tG_3(\xi,t-s)F(\xi,s)ds.$$

Since $R^0(\xi)=R^1(\xi)=0$ we need to bound the t-derivatives of

$$R(\xi,t)=R^2(\xi)G_2(\xi,t)+R^3(\xi)G_3(\xi,t)+\int_0^tG_3(\xi,t-s)F(\xi,s)ds; \tag{3.8}$$

$R_2(\xi)$ and $R_3(\xi)$ as in (3.3). Let us compute the function $G_2(\xi,t)$ explicitly.

The roots of the polynomial

$$P_K(\xi,z)=z^4-\left[\frac{K}{I_\rho}+\left(\frac{K}{\rho}+\frac{EI}{I_\rho}\right)\xi^2\right]z^2+\frac{KEI}{\rho I_\rho}\xi^4$$

are given by

$$z_4=-z_1=\tfrac{1}{\sqrt{2}}\sqrt{a+\sqrt{a^2-4b}}\quad\text{and}\quad z_3=-z_2=\tfrac{1}{\sqrt{2}}\sqrt{a-\sqrt{a^2-4b}},$$

where

$$a=\frac{K}{I_\rho}+\left(\frac{K}{\rho}+\frac{EI}{I_\rho}\right)\xi^2\quad\text{and}\quad b=\frac{KEI}{\rho I_\rho}\xi^4.$$

We obtain by residues in (3.7) that

$$G_2(\xi,t)=\frac{1}{(z_4)^2-(z_3)^2}\left(\cos z_4t-\cos z_3t\right).$$

By the properties of Λ_s we see also that

$$\frac{1}{(z_4)^2-(z_3)^2}\leq\frac{c}{K}\Lambda_{-2},\quad z_3\leq c\Lambda_1,\quad z_4\leq c\sqrt{K}\,\Lambda_1.$$

It follows that

$$|D_t^nG_2(\xi,t)|\leq c\left(\sqrt{K}\right)^{n-2}\Lambda_{n-2}\,,\qquad n=0,1,2,\dots\,. \tag{3.9}$$

Since $D_t G_3(\xi,t) = G_2(\xi,t)$ we have

$$|G_3(\xi,t)| \le c\frac{t}{K}\Lambda_{-2} \quad \text{and} \quad |D_t^n G_3(\xi,t)| \le c\left(\sqrt{K}\right)^{n-3}\Lambda_{n-3}. \tag{3.10}$$

On the other hand, from the estimates in (3.6) for $U_0(\xi,t)$ it follows that

$$|F(\xi,t)| \le c\left(\Lambda_4\left|W^0\right| + \Lambda_3\left|W^3\right|\right).$$

All of these estimates in the expression (3.8) prove the result. □

The estimates (3.4), (3.5), and Parseval's formula imply

$$\begin{aligned} \left|D_x^m\left(u_K(x,t) - u_0(x,t)\right)\right| &\le \frac{c}{K}(1+t)^2\left(\left\|w^0\right\|_{m+3} + \left\|w^1\right\|_{m+2}\right. \\ &\quad \left. + \left\|w^2\right\|_{m-1} + \left\|w^3\right\|_{m-1}\right) \end{aligned} \tag{3.11}$$

and for $l = 1,2,3$

$$\begin{aligned} \left|D_x^m D_t^l\left(u_K(x,t) - u_0(x,t)\right)\right| &\le \frac{c(1+t)}{\left(\sqrt{K}\right)^{2-l}}\left(\left\|w^0\right\|_{m+l+2} + \left\|w^1\right\|_{m+l+1}\right. \\ &\quad \left. + \left\|w^2\right\|_{m+l-1} + \left\|w^3\right\|_{m+l-2}\right). \end{aligned} \tag{3.12}$$

Thus Theorem 3.1 follows as claimed.

For later reference we deduce from (3.6) the estimates

$$\begin{aligned} \left|D_x^m u_0(x,t)\right| &\le c(1+t)\left(\left\|w^0\right\|_{m+1} + \left\|w^1\right\|_{m+1}\right), \\ \left|D_x^m D_t^l u_0(x,t)\right| &\le c\left(\left\|w^0\right\|_{m+l+1} + \left\|w^1\right\|_{m+l}\right), \quad l = 1,2,\dots\ . \end{aligned} \tag{3.13}$$

Remarks.

1. Notice that convergence is valid even at $t = 0$ for $D_x^j u_K$ and $D_x^j D_t u_K$. Also weaker convergence is obtained for second-order derivatives with respect to t as shown by the estimate (3.12).
2. If the Cauchy data are compactly supported, then u_K and u_0 are smooth away from zero. This fact is a consequence of the regularity of the fundamental solutions of the Timoshenko and Rayleigh operators. A brief study follows.

The Timoshenko operator. The *principal part* of the Timoshenko operator is

$$\begin{aligned} P_{K4} &= \frac{\rho I_\rho}{K}\partial_t^4 - \left(I_\rho + \frac{\rho EI}{K}\right)\partial_t^2\partial_x^2 + EI\partial_x^4 \\ &\equiv \frac{\rho I_\rho}{K}\left(\partial_t - \sqrt{\frac{K}{\rho}}\partial_x\right)\left(\partial_t + \sqrt{\frac{K}{\rho}}\partial_x\right)\left(\partial_t - \sqrt{\frac{EI}{I_\rho}}\partial_x\right)\left(\partial_t + \sqrt{\frac{EI}{I_\rho}}\partial_x\right). \end{aligned}$$

Observe that P_K is strictly hyperbolic with respect to both the x- and t-axes. Moreover, there are unique *fundamental solutions* G_+, G_R, G_L of P_K supported, respectively, in the cones

$$\left\{|x| \le \sqrt{\tfrac{K}{\rho}}t, \quad t \ge 0\right\}, \quad \left\{|t| \le \sqrt{\tfrac{EI}{I_\rho}}x, \quad x \ge 0\right\}, \quad \left\{|t| \le \sqrt{\tfrac{EI}{I_\rho}}|x|, \quad x \le 0\right\},$$

denoted, respectively, by Γ_+ , Γ_R , Γ_L . In particular G_+ is smooth in the cone

$$\Gamma = \left\{|x| < \sqrt{\frac{EI}{I_\rho}}t, \quad t > 0\right\}.$$

All these facts follow from the theory of hyperbolic operators extensively covered in the literature. A classical reference is Hörmander [1].

The Rayleigh operator. In the sense of Ortner and Wagner [12, 13] the Rayleigh operator is quasi-hyperbolic with respect to the t-axis. They prove that there is a unique fundamental solution s_0 of P_0 with the properties $s_0 = 0$ for $t < 0$ and $e^{-\sigma t} s_0 \in \mathcal{S}'$. Here $\mathcal{S}'$ is the space of *tempered distributions*. Moreover s_0 is also smooth in the cone Γ. For a constructive proof see Moreles [11].

With respect to the x-axis P_0 is hyperbolic with $\sqrt{\frac{I_\rho}{EI}}$ the maximum speed of propagation. As before, there are unique fundamental solutions G_{0R}, G_{0L} supported, respectively, in the cones Γ_R and Γ_L.

If the Cauchy data are supported in $[-a, a]$ let $t_0 > 3a\sqrt{\frac{I_\rho}{EI}}$. Define

$$T_0 = t_0 - a\sqrt{\frac{I_\rho}{EI}}. \tag{3.14}$$

Then u_K and u_0 are smooth in a neighborhood of $[-a, a] \times [T_0, +\infty)$ because of the smoothness of the fundamental solutions s_0, G_+ of the Rayleigh and Timoshenko operators in the cone Γ.

4. Regular perturbation. Consider the Timoshenko operator in the form

$$\begin{aligned} L_K(\partial_x, \partial_t) &= \partial_x^4 - \left(\frac{I_\rho}{EI} + \frac{\rho}{K}\right)\partial_t^2\partial_x^2 + \frac{\rho I_\rho}{EIK}\partial_t^4 + \frac{\rho}{EI}\partial_t^2 \\ &\equiv \prod_{j=1}^{4}(\partial_x - \mu_j\partial_t) + \frac{\rho}{EI}\partial_t^2, \end{aligned}$$

where

$$\mu_4 = -\mu_1 = \sqrt{\frac{I_\rho}{EI}}, \qquad \mu_3 = -\mu_2 = \sqrt{\frac{\rho}{K}},$$

and the Rayleigh operator

$$L_0(\partial_x, \partial_t) = \partial_x^4 - \frac{I_\rho}{EI}\partial_t^2\partial_x^2 + \frac{\rho}{EI}\partial_t^2.$$

In what follows we only consider $x \geq 0$ since the case $x \leq 0$ is similar. Choose $t_1 > t_0$. Consider a cutoff function of the t variable so that

$$\varphi(t) = \begin{cases} 1, & t \leq t_0, \\ 0, & t \geq t_1. \end{cases}$$

Let

$$T_1 = t_1 + a\sqrt{\frac{I_\rho}{EI}}.$$

Define

$$f_K(x,t) = L_K[\varphi u_K], \qquad f_0(x,t) = L_0[\varphi u_0].$$

Let v_K be the solution of the Cauchy problem

$$\begin{aligned} &L_K[v_K] = f_K, \\ &\partial_x^j v_K(0,t) = 0, \qquad j = 0, 1, 2, 3, \end{aligned}$$

and v_0 the solution of

$$\begin{aligned} &L_0[v_0] = f_0, \\ &\partial_x^j v_0(0,t) = 0, \qquad j = 0,1,2,3. \end{aligned}$$

Observe that f_K and f_0 vanish outside the strip $[t_0, t_1]$. Since L_K and L_0 are hyperbolic, it follows that v_K and v_0 are smooth and for $-a \le x \le a$ vanish in a neighborhood of $t = 0$ and of $t \ge T_1$.

We call the problem of convergence of $v_K \to v_0$ a regular perturbation problem because both the Rayleigh and Timoshenko operators are of order 4 in the x-direction.

Let $v = v_K - v_0$. Then v satisfies

$$\begin{aligned} &L_K[v] = f, \\ &\partial_x^j v(0,t) = 0, \end{aligned} \tag{4.1}$$

where

$$f = f_K - f_0 + \frac{\rho I_\rho}{EIK}\partial_t^4 v_0 + \frac{\rho}{K}\partial_t^2 v_0\,. \tag{4.2}$$

LEMMA 4.1. *The function in* (4.2) *satisfies*

$$\begin{aligned} \left|\partial_x^j f(x,t)\right| \;\le\; & \frac{c}{\sqrt{K}}\,(1+t)^2\left[1 + \left(\max_{1\le i\le 4}\left|\partial_t^i \varphi(t)\right|\right)\right] \\ & \cdot \left(\left\|w^0\right\|_{j+5} + \left\|w^1\right\|_{j+4} + \left\|w^2\right\|_{j+2} + \left\|w^3\right\|_{j+1}\right). \end{aligned}$$

Proof. Here

$$\begin{aligned} f_K \;=\; & -\left(\frac{I_\rho}{EI} - \frac{\rho}{K}\right)\left(\partial_t^2\varphi\partial_x^2 u_K + 2\partial_t\varphi\partial_t\partial_x^2 u_K\right) \\ & + \frac{\rho I_\rho}{EIK}\left[\left(\partial_t^4\varphi\right)u_K + 4\partial_t^3\varphi\partial_t u_K + 6\partial_t^2\varphi\partial_t^2 u_K + 4\partial_t\varphi\partial_t^3 u_K\right] \\ & + \frac{\rho}{EI}\left[\left(\partial_t^2\varphi\right)u_K + 2\partial_t\varphi\partial_t u_K\right] \end{aligned}$$

and

$$f_0 \;=\; -\left(\frac{I_\rho}{EI}\right)\left(\partial_t^2\varphi\partial_x^2 u_0 + 2\partial_t\varphi\partial_t\partial_x^2 u_0\right) + \frac{\rho}{EI}\left[\left(\partial_t^2\varphi\right)u_0 + 2\partial_t\varphi\partial_t u_0\right].$$

Thus

$$\begin{aligned} f_K - f_0 \;=\; & -\left(\frac{I_\rho}{EI}\right)\left[\left(\partial_t^2\varphi\right)\left(\partial_x^2 u_K - \partial_x^2 u_0\right) + \left(2\partial_t\varphi\right)\left(\partial_t\partial_x^2 u_K - \partial_t\partial_x^2 u_0\right)\right] \\ & + \left(\frac{\rho}{EI}\right)\left[\left(\partial_t^2\varphi\right)\left(u_K - u_0\right) + \left(2\partial_t\varphi\right)\left(\partial_t u_K - \partial_t u_0\right)\right] \\ & + \left(\frac{\rho}{K}\right)\left(\partial_t^2\varphi\partial_x^2 u_K + 2\partial_t\varphi\partial_t\partial_x^2 u_K\right) \\ & + \frac{\rho I_\rho}{EIK}\left[\left(\partial_t^4\varphi\right)u_K + 4\partial_t^3\varphi\partial_t u_K + 6\partial_t^2\varphi\partial_t^2 u_K + 4\partial_t\varphi\partial_t^3 u_K\right]. \end{aligned}$$

Hence

$$\begin{aligned} \left|f_K - f_0\right| \;\le\; & c\left(\max_{1\le i\le 4}\left|\partial_t^i\varphi(t)\right|\right)\cdot\left[\left|\partial_x^2 u_K - \partial_x^2 u_0\right| + \tfrac{1}{K}\left|\partial_x^2 u_K\right|\right. \\ & + \left|\partial_t\partial_x^2 u_K - \partial_t\partial_x^2 u_0\right| + \tfrac{1}{K}\left|\partial_t\partial_x^2 u_K\right| + \left|u_K - u_0\right| + \tfrac{1}{K}\left|u_K\right| \\ & \left. + \left|\partial_t u_K - \partial_t u_0\right| + \tfrac{1}{K}\left(\left|\partial_t u_K\right| + \left|\partial_t^2 u_K\right| + \left|\partial_t^3 u_K\right|\right)\right]. \end{aligned}$$

To estimate the right-hand side use (3.11) and (3.12) for the terms of the form $\left|\partial_t^l \partial_x^m u_K - \partial_t^l \partial_x^m u_0\right|$. For the terms with factor $1/K$ add (3.13) and the triangle inequality. To complete the proof notice that v_0 in (4.2) is smooth and independent of K. □

The behavior of v_K as $K \to \infty$ is summarized in the following result.

THEOREM 4.2. *Let l, m be nonnegative integers such that $l = 0, 1$; $m + l \leq 3$. Then $\partial_x^m \partial_t^l v_K$ converges to $\partial_x^m \partial_t^l v_0$ uniformly in compacta.*

Proof. The result is proven by reducing (4.1) to a system. Let us introduce the operators

$$L_i = \prod_{j \neq i} \left(\partial_x - \mu_j \partial_t\right), \qquad i = 1, 2, 3, 4\,.$$

Two observations are in order. First, the operators $\left(\partial_x - \mu_i \partial_t\right) L_i$ and L_K have the same principal part

$$\prod_{j=1}^{4} \left(\partial_x - \mu_j \partial_t\right).$$

Second, the operators L_i constitute a set of 4 linearly independent forms in the third-order derivatives. In particular we obtain by Lagrange's interpolation formula

$$\begin{aligned} \partial_x^m \partial_t^{3-m} &= \sum_{i=1}^{4} (\mu_i)^m \prod_{j \neq i} \frac{\partial_x - \mu_j \partial_t}{\mu_i - \mu_j} \\ &= \frac{1}{\mu} \left((\mu_1)^{m-1} L_1 - (\mu_2)^{m-1} L_2 - (\mu_3)^{m-1} L_3 + (\mu_4)^{m-1} L_4 \right), \end{aligned} \tag{4.3}$$

where

$$\mu = 2 \left(\frac{I_\rho}{EI} - \frac{\rho}{K} \right).$$

By (3.1) $\mu > 0$. Let us make the change of variables

$$\begin{aligned} v_i &= L_i v, \qquad i = 1, 2, 3, 4, \\ v_5 &= v_{tt}\,. \end{aligned}$$

We are led to the following IBVP:

$$\begin{aligned} v_{jx} &= \mu_i v_{jt} - \frac{\rho}{EI} v_5 + f, \qquad j = 1, 2, 3, 4, \\ v_{5x} &= \frac{1}{\mu} \left(v_1 - v_2 - v_3 + v_4 \right), \\ v_j(0, t) &= 0, \qquad j = 1, \ldots, 5, \end{aligned} \tag{4.4}$$

and the boundary conditions

$$v_j(x, t) = 0 \qquad \text{in a neighborhood of} \qquad t = T_0, t = T_1.$$

Let

$$c_l = \begin{cases} c, & l = 0, 1, \\ c\sqrt{K}, & l = 2. \end{cases}$$

We claim that

$$\left|\partial_x^{2-l}\partial_t^l v(x,t)\right| \le c_l \left(\int_0^a \|f(y,\cdot)\|^2\, dy\right)^{\frac{1}{2}}, \tag{4.5}$$

and for third-order derivatives

$$\left|\partial_x^{3-l}\partial_t^l v(x,t)\right| \le c_l \left(\int_0^a \|\partial_y f(y,\cdot)\|^2\, dy\right)^{\frac{1}{2}}. \tag{4.6}$$

Here $\|g\|^2 = \int_{T_0}^{T_1} g(t)^2 dt$.

First we bound the functions in the system (4.4). Multiply the equation corresponding to v_j by v_j to obtain

$$\frac{d}{dx}\sum_{j=1}^{5} \|v_j(x,\cdot)\|^2 \le c_\mu \sum_{j=1}^{5} \|v_j(x,\cdot)\|^2 + 4\|f(y,\cdot)\|^2,$$

where

$$c_\mu = 4\left(1 + \frac{\rho}{EI} + \frac{1}{\mu}\right).$$

Thus by Gronwall's lemma it follows that

$$\|v_j(x,\cdot)\|^2 \le 4\, e^{c_\mu x} \int_0^x \|f(y,\cdot)\|^2\, dy, \qquad (x,t) \in [0,a]\times[T_0,T_1],$$

but $x \le a$ and K is large; hence there is a constant c independent of K such that

$$\|v_j(x,\cdot)\|^2 \le c \int_0^a \|f(y,\cdot)\|^2\, dy, \qquad (x,t) \in [0,a]\times[T_0,T_1]. \tag{4.7}$$

Now consider the second-order derivatives of v, namely $\partial_x^m \partial_t^{2-m} v$ with $m = 0,1,2$. Writing

$$\partial_x^m \partial_t^{2-m} v(x,t) = \int_{T_0}^t \partial_x^m \partial_s^{3-m} v(x,s) ds$$

we have from (4.3)

$$\left|\partial_x^m \partial_t^{2-m} v(x,t)\right| \le \frac{1}{\mu}\sum_{i=1}^{4} |\mu_i|^{m-1} \int_{T_0}^t |v_i|,$$

and by Hölder's inequality and (4.7)

$$\left|\partial_x^m \partial_t^{2-m} v(x,t)\right| \le c\left(\int_0^a \|f(y,\cdot)\|^2\, dy\right)^{\frac{1}{2}}, \quad m = 1,2. \tag{4.8}$$

For $m = 0$ in notice that $\sqrt{\frac{K}{\rho}} = \max\{\frac{1}{|\mu_i|}\}$, thus

$$\left|\partial_t^2 v(x,t)\right| \le c\sqrt{K}\left(\int_0^a \|f(y,\cdot)\|^2\, dy\right)^{\frac{1}{2}}.$$

From the estimate (4.8) and Lemma 4.1 we obtain for $m = 1, 2$ that

$$\begin{aligned}\left|\partial_x^m \partial_t^{2-m} v(x,t)\right| &\leq \frac{c\sqrt{a}}{\sqrt{K}}(1+t)^2\left[1+\left(\max_{1\leq i\leq 4}\left|\partial_t^i\varphi(t)\right|\right)\right] \\ &\quad\cdot\left(\left\|w^0\right\|_5+\left\|w^1\right\|_4+\left\|w^2\right\|_2+\left\|w^3\right\|_1\right)\end{aligned} \tag{4.9}$$

and for $m = 0$

$$\begin{aligned}\left|\partial_t^2 v(x,t)\right| &\leq c\sqrt{a}(1+t)^2\left[1+\left(\max_{1\leq i\leq 4}\left|\partial_t^i\varphi(t)\right|\right)\right] \\ &\quad\cdot\left(\left\|w^0\right\|_5+\left\|w^1\right\|_4+\left\|w^2\right\|_2+\left\|w^3\right\|_1\right)\end{aligned}$$

For third-order derivatives, let $w = v_x$ satisfying $L_K[w] = \partial_x f$ and repeat the foregoing argument to conclude our claim.

From (4.9) we obtain uniform estimates for the second-order derivatives, consequently for $\partial_x v$, $\partial_t v$, v. The theorem then follows. □

Observe that from estimates (4.5) and (4.6), $\partial_x^m \partial_t^2 v$ is bounded in compacta. It follows that $\partial_x^m \partial_t^2 v_K$ converges to $\partial_x^m \partial_t^2 v_0$ in a weaker sense.

To conclude this section let us write for the Timoshenko solution the decomposition

$$w_K = u_K\varphi - v_K,$$

whereas for the Rayleigh solution

$$w_0 = u_0\varphi - v_0.$$

Then w_K (respectively, w_0) coincides with u_K (respectively, u_0) near $t = 0$, satisfies the equation $L_K w_K = 0$ (respectively, $L_0 w_0 = 0$), and is zero for $-a \leq x \leq a$, $t \geq T_1$.

As a corollary of Theorems 3.1 and 4.2 we obtain our main result, Theorem 2.1. Therefore, the null-controlled problem for the Timoshenko equation converges to that for the Rayleigh equation as asserted.

5. Concluding comments. In (1.2) if we assume further that there is no rotary inertia effect, the resulting equation is

$$\rho w_{tt} + EIw_{xxxx} = 0,$$

the so-called Bernoulli–Euler equation.

In essence Theorem 3.1 follows from the estimates (3.9) and (3.10) for the functions $G_2(\xi,t)$ and $G_3(\xi,t)$ in (3.7). Including dependence on the rotary inertia I_ρ we obtain the corresponding estimates

$$|D_t^n G_2(\xi,t)| \leq c\frac{I_\rho}{K}\left(\left(\sqrt{\frac{K}{I_\rho}}\right)^n \Lambda_n + \xi^{2n}\right), \qquad n = 0,1,2,\ldots,$$

and

$$|G_3(\xi,t)| \leq c\frac{I_\rho}{K}t, \quad |D_t^n G_3(\xi,t)| \leq c\frac{I_\rho}{K}\left(\left(\sqrt{\frac{K}{I_\rho}}\right)^{n-1} \Lambda_{n-1} + \xi^{2(n-1)}\right), n = 1,2,\ldots .$$

We may build on this to show that for Cauchy data in suitable Sobolev spaces, the solution of the Cauchy problem for the Timoshenko equation (1.1) converges to that

of the Bernoulli–Euler equation (with like Cauchy data) as $(1/K, I_\rho) \to (0,0)$. This solves a particular case of the singular perturbation problem proposed by Russell [14].

To close our exposition let us mention some problems of related interest, namely, the UNBCP with controls in only one end; a generalization to several space dimensions, e.g., plate equations; the Bernoulli–Euler beam and the corresponding UNBCPs.

These and other considerations are left for future investigations.

Acknowledgment. This work is a summary of the author's doctoral dissertation under the direction of Prof. Walter Littman. It is a pleasure to acknowledge his advice.

EXPONENTIAL DECAY OF ENERGY OF THE EULER–BERNOULLI BEAM WITH LOCALLY DISTRIBUTED KELVIN–VOIGT DAMPING*

KANGSHENG LIU† AND ZHUANGYI LIU ‡

Abstract. In this paper, we consider the longitudinal and transversal vibrations of the Euler–Bernoulli beam with Kelvin–Voigt damping distributed locally on any subinterval of the region occupied by the beam. We prove that the semigroup associated with the equation for the transversal motion of the beam is exponentially stable, although the semigroup associated with the equation for the longitudinal motion of the beam is not exponentially stable. Due to the locally distributed and unbounded nature of the damping, we use a frequency domain method and combine a contradiction argument with the multiplier technique to carry out a special analysis for the resolvent. We also show that the associated semigroups are not analytic.

Key words. exponential stability, semigroup, local Kelvin–Voigt damping

AMS subject classifications. 35B37, 35B40

1. Introduction.

Consider a clamped elastic beam of length L. One segment of the beam is made of a viscoelastic material with Kelvin–Voigt constitutive relation. By the Kirchhoff hypothesis, neglecting the rotatory inertia, the longitudinal and transversal vibration of the beam can be described by the following equations and boundary-initial conditions:

$$\begin{cases} \rho\ddot{u} - (pu' + D_a\dot{u}')' = 0 \quad \text{in } (0,L)\times\mathbf{R}^+, \\ u(0,t) = u(L,t) = 0, \\ u(x,0) = u_0(x),\ \dot{u}(x,0) = u_1(x), \end{cases} \tag{1.1}$$

$$\begin{cases} \rho\ddot{w} + (qw'' + D_b\dot{w}'')'' = 0 \quad \text{in } (0,L)\times\mathbf{R}^+, \\ w(0,t) = w(L,t) = w'(0,t) = w'(L,t) = 0, \\ w(x,0) = w_0(x),\ \ \dot{w}(x,0) = w_1(x), \quad x\in(0,L), \end{cases} \tag{1.2}$$

where u and w represent the longitudinal and transveral displacement of the beam, respectively. The coefficient functions $\rho, p, q, D_a, D_b \in L^\infty(0,L)$, $\rho, p, q \geq c_0 > 0$, $D_a = a(x)\chi_{(\alpha,\beta)}$, $D_b = b(x)\chi_{(\alpha,\beta)}$, with $\chi_{(\alpha,\beta)}$ being the characteristic function of the interval (α,β), $0 < \alpha, \beta < L$, and $a(x), b(x) \geq c_0 > 0$.

Recent advances in material science have provided new means for the suppression of vibrations of elastic structures. One approach is to bond or embed patches made of "smart material" to the underlying structure as passive or active damper. Due to the presence of the patches, the material properties of the structure, such as the density, Young's moduli, and damping coefficients, are changed. In particular, jump discontinuities at the location of the edges of the patch are usually introduced into these properties. Equations (1.1) and (1.2) model these phenomena by taking the

coefficients to have the above special forms. For more information on the modeling aspect, we refer the readers to [BSW].

Our main concern is the following question: Is the locally distributed Kelvin–Voigt damping (on any subinterval of $(0, L)$) strong enough to cause uniform exponential decay of the energy of the beam? That is, do there exist constants $M_\mu, \mu > 0$ such that the energies, $\mathcal{E}(t)$, associated with (1.1) and (1.2) satisfy the inequality

$$\mathcal{E}(t) \le M_\mu e^{-\mu t}\mathcal{E}(0), \quad t > 0? \tag{1.3}$$

The exponential stability of an elastic system with damping distributed either over the entire region or along the boundary of the region has been studied extensively during the past two decades; however, only a relatively small amount of attention was paid to the stability of the system with damping distributed locally inside the domain. Discussions related to this issue were initiated by Lagnese [La] in 1983, where the exact controllability of the wave equation with locally distributed control was considered (see [Li] for the equivalence between the exact controllability and the exponential stabilizability for a conservative system). It is known that, when viscous damping is only distributed on a subinterval of the domain, (1.3) holds for the Euler–Bernoulli beam equation (longitudinal and transveral motion) with both constant coefficients [CFNS] and variable coefficients [K1], [K2]. For a higher dimensional domain (1.3) depends on the geometric properties of the subregion, where viscous damping is applied. We refer to [CFNS] for a two-dimensional Schrödinger equation on a disk and a rectangle, to [Li] for a class of n-dimensional conservative partial differential equations (PDEs), and to [Zu1], [Zu2] for an n-dimensional semilinear wave equation. It should be pointed out that the operator corresponding to the viscous damping is bounded on the underlying space while the one corresponding to the Kelvin–Voigt damping is unbounded, and is not a lower-order perturbation of the elastic operator. The effect of such locally distributed damping on the energy decay is unknown. Recently, we were able to show that locally distributed Kelvin–Voigt damping ensures the asymptotic stability of a general second-order elastic system [CLL]. In this paper, we will show that when Kelvin–Voigt damping is distributed only on a subinterval of the domain, (1.3) holds for the transversal motion but not for the longitudinal motion of the Euler–Bernoulli beam equation.

Our approach is the frequency domain method (FDM). Roughly speaking, the FDM is based on the boundedness on the imaginary axis of the resolvent of a semigroup generator in order to establish the exponential stability of the C_0-semigroup on a Hilbert space (see [Ge], [Hu], [Pr]). This method has been applied successfully to several models with locally distributed viscous damping (see [CFNS], [R]). However, due to the unboundedness of the Kelvin–Voigt damping operator, the arguments used in [CFNS] and [R] are not valid here since their arguments particularly depend on the boundedness of the damping operator. To overcome this difficulty, we combine the FDM with the multiplier technique and carry out a special analysis of the resolvent.

This paper is organized as follows. In section 2, we prove the exponential decay of energy for (1.2). In section 3, we prove the nonexponential decay of energy for (1.1). Finally, in section 4, we show that the C_0-semigroup associated with (1.2) is not analytic.

2. Transversal motion. Let $H = L^2_\rho(0, L)$ with the norm

$$\|v\| = \left(\int_0^L \rho |v(x)|^2 dx \right)^{\frac{1}{2}}$$

and $V = H_0^2(0, L)$ with the norm

$$\|v\|_V = \left(\int_0^L q|v''(x)|dx \right)^{\frac{1}{2}}.$$

Define $\mathcal{H}_1 = V \times H$ with the norm $\|(w, v)\|_{\mathcal{H}_1} = (\|w\|_V^2 + \|v\|^2)^{\frac{1}{2}}$. Then $\mathcal{H}_1$ is a Hilbert space—the finite energy state space. Define in $\mathcal{H}_1$

$$D(\mathcal{A}_1) = \left\{ (w, v) \mid w, v \in V,\ -M \equiv qw'' + D_b v'' \in H^2(0, L) \right\} \tag{2.1}$$

and

$$\mathcal{A}_1(w, v) = \left(v, \frac{1}{\rho} M'' \right). \tag{2.2}$$

Thus, (1.2) can be rewritten as an abstract evolution equation on $\mathcal{H}_1$,

$$(\dot{w}(t), \dot{v}(t)) = \mathcal{A}_1(w(t), v(t)), \quad (w(0), v(0)) = (w_0, w_1). \tag{2.3}$$

It is known that $\mathcal{A}_1$ generates a C_0-semigroup of contractions on $\mathcal{H}_1$. (See [CLL].) Therefore, $(w(t), \dot{w}(t)) = e^{\mathcal{A}_1 t}(w_0, w_1)$ gives the mild solution of (1.2) for every $(w_0, w_1) \in \mathcal{H}_1$. Moreover, $\mathcal{A}_1^{-1}$ is a bounded operator on $\mathcal{H}_1$.

We assume that ρ and q are positive constants on $[0, \alpha)$ and $(\beta, L]$; $b(x), q \in C[\alpha, \beta]$; and $\rho \in C^{1,1}[\alpha, \beta]$.

LEMMA 2.1. *The imaginary axis, $i\mathbf{R}$, $\subset \rho(\mathcal{A}_1)$ the resolvent set of $\mathcal{A}_1$.*

Proof. It is easy to show that there is no point spectrum on the imaginary axis, i.e., $i\mathbf{R} \cap \sigma_p(\mathcal{A}_1) = \emptyset$. By Lemma 4.1 in [CLL], the conclusion of this lemma is true. □

THEOREM 2.2. *Under the above assumptions on the coefficients of* (1.2)*, the semigroup $e^{\mathcal{A}_1 t}$ is exponentially stable; i.e., there exist $\nu > 0, M_\nu \geq 1$ such that*

$$\|e^{\mathcal{A}_1 t}\| \leq M_\nu e^{-\nu t} \quad \forall\, t > 0. \tag{2.4}$$

Proof. We need only to verify the condition for a C_0-semigroup of contractions on a Hilbert space being exponentially stable (see [Hu], [Pr], or [Ge]), i.e.,

$$\sup \left\{ \|(\lambda - \mathcal{A}_1)^{-1}\| \mid \lambda \in i\mathbf{R} \right\} < +\infty. \tag{2.5}$$

Suppose (2.5) is not true. By the continuity of the resolvent and the resonance theorem, there exist $\lambda_n \in i\mathbf{R}, (w_n, v_n) \in D(\mathcal{A}_1)$, $n = 1, 2, \ldots$, such that

$$\|(w_n, v_n)\|_{\mathcal{H}_1} = 1, \quad |\lambda_n| \to \infty, \tag{2.6}$$

and

$$(\lambda_n - \mathcal{A}_1)(w_n, v_n) \equiv (f_n, g_n) \to 0 \ \text{ in } \ \mathcal{H}_1. \tag{2.7}$$

This implies

$$\lambda_n w_n - v_n = f_n \to 0 \ \text{ in } \ V, \tag{2.8}$$

$$\lambda_n v_n \rho - M_n'' = \rho g_n \to 0 \ \text{ in } \ L^2(0, L), \tag{2.9}$$

where $M_n = -(qw_n'' + D_b v_n'')$.

Define

$$J(v) = \int_x^L \int_s^L \rho v(\tau) d\tau ds \tag{2.10}$$

and

$$y_n = \frac{1}{\lambda_n}[M_n + J(g_n)]. \tag{2.11}$$

Comparing (2.9) and (2.11) we have

$$y_n'' = \rho v_n. \tag{2.12}$$

The rest of the proof depends on the following two lemmas. Let $\omega_n = \sqrt{|\lambda_n|}$.

LEMMA 2.3. *The function y_n defined above has the following properties:*

$$y_n \to 0 \quad \textit{in} \ \ H^4(\alpha, \beta), \tag{2.13}$$

$$\lambda_n y_n \to 0 \quad \textit{in} \ \ L^2(\alpha, \beta), \tag{2.14}$$

$$\omega_n y_n \to 0 \quad \textit{in} \ \ H^2(\alpha, \beta). \tag{2.15}$$

Proof. From (2.7),

$$\mathrm{Re}\langle(\lambda_n - \mathcal{A}_1)(w_n, v_n), (w_n, v_n)\rangle_{\mathcal{H}_1} = \int_\alpha^\beta D_b |v_n''|^2 dx \to 0. \tag{2.16}$$

Therefore, from (2.8) we have

$$M_n \ \to \ 0 \quad \text{in} \ \ L^2(\alpha, \beta) \tag{2.17}$$

and

$$\frac{1}{\lambda_n}\|\xi v_n\|_V = \mathcal{O}(1) \tag{2.18}$$

for every $\xi \in C^\infty[0, L]$.

Equations (2.9), (2.17), and (2.18) imply that

$$\int_\alpha^\beta \xi \rho |v_n|^2 dx \to 0 \ \ \forall\, \xi \in C^\infty[0, L], \ \ \text{Supp}\, \xi \subset (\alpha, \beta). \tag{2.19}$$

Applying the interpolation theorem involving compact subdomains [A, Theorem 4.23], we find that (2.16) and (2.19) imply

$$v_n \ \to \ 0 \quad \text{in} \ \ H^2(\alpha, \beta). \tag{2.20}$$

Thus, (2.12) yields

$$\int_\alpha^\beta |y_n''''|^2 dx \ \to \ 0. \tag{2.21}$$

On the other hand, (2.14) follows from

$$\lambda_n y_n = J(g_n) - \frac{q + \lambda_n D_b}{\lambda_n} v_n'' - \frac{q}{\lambda_n} f_n'' \to 0 \quad \text{in} \ \ L^2(\alpha, \beta). \tag{2.22}$$

Since $|\lambda_n| \to \infty$, we obtain that $y_n \to 0$ in $L^2(\alpha, \beta)$. This, combined with (2.21), yields (2.13). From the interpolation inequality [A, Theorem 4.17], we also have (2.15). □

LEMMA 2.4. *The functions $w_n \in H^4(0,\alpha), H^4(\beta, L), n = 1, 2, \ldots$, have the following properties:*

$$\omega_n^4 \left(|w_n(\alpha)|^2 + |w_n'(\alpha)|^2 + |w_n(\beta)|^2 + |w_n'(\beta)|^2\right) \to 0, \tag{2.23}$$

$$\alpha q(0)|w_n''(\alpha^-)|^2 + (L-\beta)q(L)|w_n''(\beta^+)|^2 \to 2, \tag{2.24}$$

$$\omega_n^{-1} w_n'''(\alpha^-), \ \ \omega_n^{-1} w_n'''(\beta^+) \to 0. \tag{2.25}$$

Proof. Since $w_n, v_n \in V \subset H^2(0, L)$, Sobolev's embedding theorem implies that they are also in $C^1[0, L]$. By (2.8) and (2.20),

$$\lambda_n w_n \to 0 \ \ \text{in} \ \ H^2(\alpha, \beta). \tag{2.26}$$

Thus, $\lambda_n w_n$ converges to zero in $C^1[\alpha, \beta]$, which immediately leads to (2.23).

Note that $M_n = -q w_n''$ on $(0, \alpha) \cup (\beta, L)$, $q \equiv q(0)$ on $[0, \alpha)$, and $q \equiv q(L)$ on $(\beta, L]$. From the definition of the domain of $\mathcal{A}_1$, we know $w_n \in H^4(0, \alpha)$, $w_n \in H^4(\beta, L)$. It follows from (2.11) that

$$q(0)w_n''(\alpha^-) = (J(g_n) - \lambda_n y_n)(\alpha), \quad q(L)w_n''(\beta^+) = (J(g_n) - \lambda_n y_n)(\beta), \tag{2.27}$$

$$q(0)w_n'''(\alpha^-) = (J(g_n) - \lambda_n y_n)'(\alpha), \quad q(L)w_n'''(\beta^+) = (J(g_n) - \lambda_n y_n)'(\beta). \tag{2.28}$$

Dividing (2.28) by ω_n we obtain (2.25) by using (2.15) in the previous lemma.

In order to prove (2.24), we substitute (2.8) into (2.9) to get

$$\lambda_n^2 \rho w_n - M_n'' = \rho(g_n + \lambda_n f_n) \quad \text{for} \ \ x \in (0, L). \tag{2.29}$$

We multiply the above equation by $\overline{w}_n$, then integrate by parts on $(0, L)$. This leads to

$$\|\lambda_n w_n\|^2 - \|w_n\|_V^2 \to 0. \tag{2.30}$$

Here, we have used (2.6), (2.8), (2.9), and (2.16). Since $\|w_n\|_V^2 + \|v_n\|^2 = 1$ and $\lambda_n w_n - v_n$ also converges to zero in $L^2(0, L)$, (2.30) implies that both $\|\lambda_n w_n\|^2$ and $\|w_n\|_V^2$ must converge to $\frac{1}{2}$ as $n \to \infty$. This further leads to

$$\lim_{n\to\infty} \left(\int_0^\alpha + \int_\beta^L\right) \rho|\lambda_n w_n|^2 dx = \lim_{n\to\infty} \left(\int_0^\alpha + \int_\beta^L\right) q|w_n''|^2 dx = \frac{1}{2} \tag{2.31}$$

when (2.26) is taken into account.

On the intervals $(0, \alpha)$ and (β, L), (2.29) becomes

$$\lambda_n^2 \rho w_n + q w_n'''' = \rho(g_n + \lambda_n f_n). \tag{2.32}$$

We multiply the above equation by $x\overline{w_n'}$, integrate on $(0, \alpha)$, and then take the real part. Hence,

$$\text{Re} \int_0^\alpha \lambda_n^2 \rho w_n x \overline{w_n'} dx + \text{Re} \int_0^\alpha q w_n'''' x \overline{w_n'} dx = \text{Re} \int_0^\alpha \rho(g_n + \lambda_n f_n) x \overline{w_n'} dx. \tag{2.33}$$

It is easy to see that the term on the right-hand side of (2.33) converges to zero. After a straightforward calculation (integration by parts), the two terms on the left-hand side of (2.33) are

$$\mathrm{Re}\int_0^\alpha \lambda_n^2 \rho w_n x\overline{w_n'}dx = \frac{-\rho}{2}\omega_n^4 \alpha |w_n(\alpha)|^2 + \frac{1}{2}\int_0^\alpha \rho|\lambda_n w_n|^2 dx, \tag{2.34}$$

$$\begin{aligned}\mathrm{Re}\int_0^\alpha q w_n'''' x\overline{w_n'}dx &= q(0)\mathrm{Re}(\alpha w_n'''(\alpha^-) - w_n''(\alpha^-))\overline{w_n'}(\alpha)\\ &\quad + \frac{3}{2}\int_0^\alpha q|w_n''|^2 dx - \frac{\alpha}{2}q(0)|w_n''(\alpha^-)|^2.\end{aligned} \tag{2.35}$$

After substituting these terms into (2.33) and applying (2.23), (2.25), and (2.27), we have

$$\frac{1}{2}\int_0^\alpha \rho|\lambda_n w_n|^2 dx + \frac{3}{2}\int_0^\alpha q|w_n''|^2 dx - \frac{\alpha}{2}q(0)|w_n''(\alpha^-)|^2 \to 0. \tag{2.36}$$

Similarly, we can multiply (2.32) by $(L-x)\overline{w_n'}$ and integrate on (β, L) to get

$$\frac{1}{2}\int_\beta^L \rho|\lambda_n w_n|^2 dx + \frac{3}{2}\int_\beta^L q|w_n''|^2 dx - \frac{1}{2}(L-\beta)q(L)|w_n''(\beta^+)|^2 \to 0. \tag{2.37}$$

Finally, we subtract (2.37) from (2.36) and use (2.31) to obtain (2.24). ∎

In what follows, we will show that

$$|w''(\alpha^-)|^2 + |w''(\beta^+)|^2 \to 0 \tag{2.38}$$

to get a contradiction to (2.24). Denote by

$$\phi_n = \omega_n\left(\frac{\rho}{q}\right)^{\frac{1}{4}}, \quad F_n = \frac{\rho}{q}(g_n + \lambda_n f_n), \quad D = \frac{d}{dx}.$$

Then (2.32) can be rewritten as

$$(D - i\phi_n)(D + i\phi_n)(D^2 - \phi_n^2)w_n = F_n. \tag{2.39}$$

On the interval $(0, \alpha)$, by solving the first-order linear equation, we have

$$(D + i\phi_n)(D^2 - \phi_n^2)w_n = C_1 e^{i\phi_n(x-\alpha)} + \int_\alpha^x e^{i\phi_n(x-s)}F_n(s)ds; \tag{2.40}$$

$$\begin{aligned}(D^2 - \phi_n^2)w_n &= C_2 e^{-i\phi_n(x-\alpha)} + \frac{C_1}{\phi_n}\sin\phi_n(x-\alpha)\\ &\quad + \int_\alpha^x \frac{1}{\phi_n}\sin\phi_n(x-s)F_n(s)ds,\end{aligned} \tag{2.41}$$

where

$$C_1 = w_n'''(\alpha^-) + i\phi_n w_n''(\alpha^-) - \phi_n^2 w_n'(\alpha) - i\phi_n^3 w_n(\alpha), \tag{2.42}$$

$$C_2 = w_n''(\alpha^-) - \phi_n^2 w_n(\alpha); \tag{2.43}$$

and

$$
\begin{aligned}
(D-\phi_n)w_n = &\frac{C_2}{\phi_n(1-i)}\left[e^{-i\phi_n(x-\alpha)}-e^{-\phi_n(x-i\alpha)}\right]\\
&+\frac{C_1}{2\phi_n^2}\left[\sin\phi_n(x-\alpha)-\cos\phi_n(x-\alpha)\right]+\frac{C_1}{2\phi_n^2}e^{-\phi_n x}(\sin\phi_n\alpha+\cos\phi_n\alpha)\\
&+\int_0^x\int_\alpha^\tau e^{-\phi_n(x-\tau)}\frac{1}{\phi_n}\sin\phi_n(\tau-s)F_n(s)dsd\tau. \qquad (2.44)
\end{aligned}
$$

To obtain (2.44), we have used the boundary conditions $w_n(0)=w_n'(0)=0$. Multiplying (2.44) by $2\phi_n$ and taking $x=\alpha$, we have

$$
\begin{aligned}
2\phi_n w_n'(\alpha)-2\phi_n^2 w_n(\alpha) &= (1+i)C_2(1-e^{-\phi_n\alpha}e^{i\phi_n\alpha})-\frac{C_1}{\phi_n}\\
&+\frac{e^{-\phi_n\alpha}}{\phi_n}C_1(\sin\phi_n\alpha+\cos\phi_n\alpha)+2\int_0^\alpha\int_\alpha^\tau e^{-\phi_n(\alpha-\tau)}\sin\phi_n(\tau-s)F_n(s)dsd\tau. \qquad (2.45)
\end{aligned}
$$

We substitute (2.42) and (2.43) into (2.45) and let $n\to\infty$. By the results in Lemma 2.4, (2.45) yields

$$
\lim_{n\to\infty} w_n''(\alpha^-) = -2\lim_{n\to\infty}\int_0^\alpha\int_\alpha^\tau e^{-\phi_n(\alpha-\tau)}\sin\phi_n(\tau-s)F_n(s)dsd\tau. \qquad (2.46)
$$

We argue that the above limit is zero by the following estimates:

$$
\begin{aligned}
\left|\int_0^\alpha\int_\alpha^\tau e^{-\phi_n(\alpha-\tau)}\sin\phi_n(\tau-s)g_n(s)dsd\tau\right| &\le \int_0^\alpha\int_0^\alpha |g_n(s)|dsd\tau\\
&\le \alpha^{\frac{3}{2}}\left(\int_0^\alpha |g_n(s)|^2ds\right)^{\frac{1}{2}}\to 0 \qquad (2.47)
\end{aligned}
$$

and

$$
\begin{aligned}
&\left|\int_0^\alpha\int_\alpha^\tau e^{-\phi_n(\alpha-\tau)}\sin\phi_n(\tau-s)\lambda_n f_n(s)dsd\tau\right|\\
&=\left|\lambda_n\int_0^\alpha\left(\int_0^s e^{-\phi_n(\alpha-\tau)}\sin\phi_n(\tau-s)d\tau\right)f_n(s)ds\right|\\
&=\left|\frac{\lambda_n e^{-\phi_n\alpha}}{2\phi_n}\int_0^\alpha(\cos\phi_n s+\sin\phi_n s-e^{\phi_n s})f_n(s)ds\right|\\
&\le\left(\frac{q}{\rho}\right)^{\frac{1}{2}}\left(\alpha\phi_n e^{-\phi_n\alpha}+\frac{1}{2}-\frac{1}{2}e^{-\phi_n\alpha}\right)\max_{s\in[0,\alpha]}|f_n(s)|\to 0, \qquad (2.48)
\end{aligned}
$$

where we have used the fact that $g_n\to 0$ in $L^2(0,L)$, $f_n\to 0$ in $V\hookrightarrow C^1[0,L]$, and $\phi_n\to+\infty$. Thus we have proved

$$
w_n''(\alpha^-)\to 0 \quad \text{as} \quad n\to\infty. \qquad (2.49)
$$

Let $x'=L-x$, which maps the interval (β,L) onto $(0,L-\beta)$. Repeating the argument after (2.39), we can also prove

$$
w_n''(\beta^+)\to 0 \quad \text{as} \quad n\to\infty. \qquad (2.50)
$$

Equations (2.49) and (2.50) give us the promised contradiction. Thus, the energy of (1.2), $\mathcal{E}_1(t)=\frac{1}{2}\|(w(t),\dot w(t))\|_{\mathcal{H}_1}$, satisfies the inequality (1.3). □

3. Longitudinal motion. In this section, we study the longitudinal motion of the beam described in (1.1). Note that this equation also models the longitudinal vibration of an elastic rod.

Let $H = L^2_\rho(0, L)$ with the norm

$$\|v\| = \left(\int_0^L \rho |v(x)|^2 dx \right)^{\frac{1}{2}}$$

and $V = H^1_0(0, L)$ with the norm

$$\|v\|_V = \left(\int_0^L p |v'(x)| dx \right)^{\frac{1}{2}}.$$

Define $\mathcal{H}_2 = V \times H$ with the norm $\|(u, v)\|_{\mathcal{H}_2} = (\|u\|^2_V + \|v\|^2)^{\frac{1}{2}}$. Then $\mathcal{H}_2$ is a Hilbert space—the finite energy state space. Define in $\mathcal{H}_2$

$$D(\mathcal{A}_2) = \left\{ (u, v) \mid u, v \in V,\ S \equiv pu' + D_a v' \in H^1(0, L) \right\} \tag{3.1}$$

and

$$\mathcal{A}_2(u, v) = \left(v, \frac{1}{\rho} S' \right). \tag{3.2}$$

Thus (1.1) can be rewritten as an abstract evolution equation on $\mathcal{H}_2$:

$$(\dot{u}(t), \dot{v}(t)) = \mathcal{A}_2(u(t), v(t)), \quad (u(0), v(0)) = (u_0, u_1). \tag{3.3}$$

It is known that $\mathcal{A}_2$ generates a C_0-semigroup of contractions on $\mathcal{H}_2$ (see [CLL]). Therefore, $(u(t), \dot{u}(t)) = e^{\mathcal{A}_2 t}(u_0, u_1)$ gives the mild solution of (1.1) for every $(u_0, u_1) \in \mathcal{H}_2$. Moreover, $\mathcal{A}_2^{-1}$ is a bounded operator on $\mathcal{H}_2$.

We assume that the beam is homogeneous on the segments $(0, \alpha), (\alpha, \beta), (\beta, L)$, i.e., the coefficients in (1.1) are

$$\begin{cases} \rho = \rho_1 + (\rho_2 - \rho_1)\chi_{(\alpha,\beta)}, \\ p = p_1 + (p_2 - p_1)\chi_{(\alpha,\beta)}, \\ D_a = a\chi_{(\alpha,\beta)}, \quad \text{damping coefficient}, \end{cases} \tag{3.4}$$

with $\rho_1, \rho_2, p_1, p_2, a$ being positive constants. It is known that $e^{\mathcal{A}_2 t}$ is strongly stable (see [CLL]).

THEOREM 3.1. *The semigroup $e^{\mathcal{A}_2 t}$ for* (1.1) *with coefficients in* (3.4) *is not exponentially stable.*

Proof. We will show that $\|(\lambda - \mathcal{A}_2)^{-1}\|$ is unbounded on the imaginary axis. Let $\gamma_1^2 = \sqrt{\frac{p_1}{\rho_1}}$ and $\lambda = \lambda_n = i\omega_n = i\frac{2n\pi\gamma_1}{L-\beta}$, $n = 1, 2, \ldots$. Define

$$f = f(x, n) = \begin{cases} 0 & \text{in } (0, \beta), \\ \frac{1}{\omega_n} \sin \frac{\omega_n (x-\beta)}{\gamma_1} & \text{in } (\beta, L), \end{cases} \in V,$$

$$g = g(x, n) = \begin{cases} 0 & \text{in } (0, \beta), \\ \cos \frac{\omega_n (x-\beta)}{\gamma_1} & \text{in } (\beta, L), \end{cases} \in H.$$

We solve the resolvent equation $(\lambda-\mathcal{A}_2)(u,v)=(f,g),\ (u,v)\in D(\mathcal{A}_2)$ in the intervals $(0,\alpha),(\alpha,\beta),(\beta,L)$, respectively.

For $x\in(0,\alpha)$, we have

$$\begin{cases} \lambda u - v = 0, \\ \lambda v - \gamma_1^2 u'' = 0, \\ u(0) = 0. \end{cases} \tag{3.5}$$

It is easy to see that

$$u(x) = c_1 \sin \frac{\omega_n}{\gamma_1} x. \tag{3.6}$$

For $x\in(\alpha,\beta)$, we have

$$\begin{cases} \lambda u - v = 0, \\ \lambda v - (\gamma_2^2 + a_2\lambda)u'' = 0, \end{cases} \tag{3.7}$$

where $\gamma_2^2 = \sqrt{\frac{p_2}{\rho_2}}$ and $a_2 = \frac{a}{\rho_2}$. The solution of (3.7) is

$$u(x) = c_2 e^{\mu x} + c_3 e^{-\mu x} \tag{3.8}$$

with

$$\mu = \frac{\omega_n}{(\gamma_2^4 + a_2^2\omega_n^2)^{\frac{1}{4}}} \left(\cos\frac{\theta}{2} + i\sin\frac{\theta}{2}\right), \tag{3.9}$$

$$\cos\theta = \frac{-\gamma_2^2}{(\gamma_2^4 + a_2^2\omega_n^2)^{\frac{1}{2}}} \to 0, \quad \sin\theta = \frac{a_2\omega_n}{(\gamma_2^4 + a_2^2\omega_n^2)^{\frac{1}{2}}} \to 1 \quad \text{as } n\to\infty. \tag{3.10}$$

By the continuity conditions at $x=\alpha$, i.e.,

$$\begin{cases} u(\alpha^-) = u(\alpha^+), \\ \gamma_1^2 u'(\alpha^-) = (\gamma_2^2 + ia_2\omega_n)u'(\alpha^+), \end{cases} \tag{3.11}$$

we solve c_2, c_3 to get

$$u(x) = c_1 \left[\sin\frac{\omega_n\alpha}{\gamma_1}\cosh\mu(x-\alpha) + \frac{\gamma_1\omega_n}{(\gamma_2^2 + ia_2\omega_n)\mu}\cos\frac{\omega_n\alpha}{\gamma_1}\sinh\mu(x-\alpha)\right]. \tag{3.12}$$

Therefore,

$$u(\beta^-) = c_1 \left[\sin\frac{\omega_n\alpha}{\gamma_1}\cosh\mu(\beta-\alpha) + \frac{\gamma_1\omega_n}{(\gamma_2^2 + ia_2\omega_n)\mu}\cos\frac{\omega_n\alpha}{\gamma_1}\sinh\mu(\beta-\alpha)\right], \tag{3.13}$$

$$u'(\beta^-) = c_1 \left[\mu\sin\frac{\omega_n\alpha}{\gamma_1}\sinh\mu(\beta-\alpha) + \frac{\gamma_1\omega_n}{(\gamma_2^2 + ia_2\omega_n)}\cos\frac{\omega_n\alpha}{\gamma_1}\cosh\mu(\beta-\alpha)\right]. \tag{3.14}$$

For $x\in(\beta,L)$, we have

$$\begin{cases} \lambda u - v = f, \\ \lambda v - \gamma_1^2 u'' = g, \\ u(L) = 0. \end{cases} \tag{3.15}$$

Let

$$w_{\pm}(x) = \frac{1}{2}[v(x) \pm \gamma_1 u'(x)].$$

Then (3.15) can be transformed into a first-order, diagonal, nonhomogeneous system:

$$\begin{pmatrix} w_+ \\ w_- \end{pmatrix}' = \begin{pmatrix} \frac{\lambda}{\gamma_1} & 0 \\ 0 & -\frac{\lambda}{\gamma_1} \end{pmatrix} \begin{pmatrix} w_+ \\ w_- \end{pmatrix} + \begin{pmatrix} 0 \\ \frac{1}{\gamma_1} \end{pmatrix} g \equiv A \begin{pmatrix} w_+ \\ w_- \end{pmatrix} + \begin{pmatrix} 0 \\ \frac{1}{\gamma_1} \end{pmatrix} g. \tag{3.16}$$

Using the boundary condition $0 = v(L) = w_+(L) + w_-(L)$, we obtain the solution

$$\begin{pmatrix} w_+(x) \\ w_-(x) \end{pmatrix} = w_+(L) e^{(x-L)A} \begin{pmatrix} -1 \\ 1 \end{pmatrix} + \int_x^L e^{(x-\tau)A} \begin{pmatrix} \frac{1}{\gamma_1} \\ 0 \end{pmatrix} g(\tau) d\tau. \tag{3.17}$$

Since

$$\begin{aligned} v(x) &= w_+(x) + w_-(x) \\ &= w_+(L) \left[-e^{i\frac{2n\pi(x-L)}{L-\beta}} + e^{-i\frac{2n\pi(x-L)}{L-\beta}} \right] - \frac{1}{\gamma_1} \int_x^L e^{i\frac{2n\pi(x-\tau)}{L-\beta}} g(\tau) d\tau \\ &= -2iw_+(L) \sin \frac{2n\pi(x-L)}{L-\beta} - \frac{1}{\gamma_1} \int_x^L e^{i\frac{2n\pi(x-\tau)}{L-\beta}} \cos \frac{2n\pi(x-\beta)}{L-\beta} d\tau, \end{aligned} \tag{3.18}$$

we obtain that

$$v(\beta^+) = -\frac{L-\beta}{2\gamma_1}. \tag{3.19}$$

Furthermore, from $\lambda u(\beta^+) = f(\beta^+) + v(\beta^+) = v(\beta^+)$,

$$u(\beta^+) = i\frac{L-\beta}{2\gamma_1\omega_n}. \tag{3.20}$$

Similarly, from $\gamma_1 u'(x) = w_+(x) - w_-(x)$, we can also get

$$\gamma_1^2 u'(\beta^+) = -2\gamma_1 w_+(L) - \frac{1}{2}(L-\beta). \tag{3.21}$$

Applying the continuity conditions at $x = \beta$, i.e.,

$$\begin{cases} u(\beta^+) = u(\beta^-), \\ \gamma_1^2 u'(\beta^+) = (\gamma_2^2 + ia_2\omega_n) u'(\beta^-), \end{cases} \tag{3.22}$$

from (3.13), (3.14), (3.20), and (3.21), we can solve c_1 and obtain

$$\begin{aligned} &-2\gamma_1 w_+(L) - \frac{1}{2}(L-\beta) \\ &= i(L-\beta)\mu \frac{\gamma_2^2 + ia_2\omega_n}{2\gamma_1\omega_n} \cdot \frac{(\gamma_2^2 + ia_2\omega_n)\mu \sin \frac{\omega_n\alpha}{\gamma_1} + \gamma_1\omega_n \cos \frac{\omega_n\alpha}{\gamma_1} \coth \mu(\beta-\alpha)}{(\gamma_2^2 + ia_2\omega_n)\mu \sin \frac{\omega_n\alpha}{\gamma_1} \coth \mu(\beta-\alpha) + \gamma_1\omega_n \cos \frac{\omega_n\alpha}{\gamma_1}}. \end{aligned} \tag{3.23}$$

It follows from the definition of ω_n and μ that

$$|\coth \mu(\beta-\alpha)| \to 1, \quad |\mu| \to \infty \ \text{ as } \ n \to \infty. \tag{3.24}$$

If $\frac{\omega_n\alpha}{n\pi\gamma_1} = \frac{2\alpha}{L-\beta}$ is a rational number, there exists a subsequence of $\{\omega_n\}$, still denoted by ω_n, such that $\sin\frac{\omega_n\alpha}{\gamma_1} \equiv 0$. If $\frac{2\alpha}{L-\beta}$ is an irrational number, there exists a subsequence of $\{\omega_n\}$, still denoted by ω_n, such that $\sin\frac{\omega_n\alpha}{\gamma_1} \geq \epsilon_0 > 0$. In both cases, (3.23)–(3.24) imply

$$|w_+(L)| \to \infty \text{ as } n \to \infty. \tag{3.25}$$

This further leads to

$$\begin{aligned}\int_\beta^L |v(x)|^2 dx &= \int_\beta^L |w_+(x) + w_-(x)|^2 dx \\ &\geq 4|w_+(L)|^2 \int_\beta^L \sin^2\frac{2n\pi(x-L)}{L-\beta} dx - \frac{(L-\beta)^2}{2\gamma_1} \\ &= 2(L-\beta)|w_+(L)|^2 - \frac{(L-\beta)^2}{2\gamma_1} \to \infty \quad \text{as } n \to \infty. \end{aligned} \tag{3.26}$$

Finally, by $\|(f,g)\|^2_{\mathcal{H}_2} = \rho_1(L-\beta)$ and

$$\begin{aligned}\|(i\omega_n - \mathcal{A}_2)^{-1}(f,g)\|^2_{\mathcal{H}_2} &= \|(u,v)\|^2_{\mathcal{H}_2} \\ &\geq \int_\beta^L |v(x)|^2 dx \to \infty \quad \text{as } n \to \infty \end{aligned} \tag{3.27}$$

we conclude that

$$\sup_{\omega\in\mathbf{R}} \|(i\omega - \mathcal{A}_2)^{-1}\| = \infty. \tag{3.28}$$

Thus, $e^{\mathcal{A}_2 t}$ is not exponentially stable. □

Since the energy of (1.1) is $\mathcal{E}_2(t) = \frac{1}{2}\|(u(t), \dot{u}(t))\|^2_{\mathcal{H}_2} = \frac{1}{2}\|e^{\mathcal{A}_2 t}(u_0, u_1)\|^2_{\mathcal{H}_2}$, inequality (1.3) fails to hold for $\mathcal{E}_2(t)$. We believe that the lack of exponential stability here is due to the discontinuities in the damping coefficient D_a and the high order of damping operator. Some waves outside the interval (α, β) are strongly reflected at α, β. We don't know whether the conclusion in Theorem 3.1 is still true if the D_a is smooth at α and β.

4. Lack of analyticity. It is known that when the Kelvin–Voigt damping is globally distributed over the beam (i.e., $\alpha = 0, \beta = L$ in (1.1) and (1.2)), the corresponding semigroup is analytic (e.g., [CLL]). In this section, we will demonstrate that this is not true when the Kelvin–Voigt damping is only distributed locally. From Theorem 3.1, we already know that $e^{\mathcal{A}_2 t}$ is not analytic.

THEOREM 4.1. *$e^{\mathcal{A}_1 t}$ is not an analytic semigroup.*

Proof. From the analytic semigroup theory [Pa, Theorem 2.5.2], an exponential semigroup $e^{\mathcal{A}_1 t}$ is analytic if and only if

$$\sup\{\|\omega(i\omega - \mathcal{A}_1)^{-1}\| \mid \omega \in \mathbf{R}\} < +\infty. \tag{4.1}$$

We will show that (4.1) is not true. Choose $\gamma > 0$ such that $a = \gamma/\pi < \alpha$. Let

$$x_n = \frac{\pi}{4\gamma n}, \quad \widetilde{x}_n = \frac{\pi}{\gamma} - \frac{\pi}{4\gamma n}, \quad \phi_n(x) = \sin\gamma n x, \tag{4.2}$$

and construct a sequence of functions

$$u_n(x) = \begin{cases} \xi_n(x), & 0 \le x < x_n, \\ \phi_n(x), & x_n \le x < \widetilde{x}_n, \\ \eta_n(x), & \widetilde{x}_n \le x < a, \\ 0, & a \le x \le L, \end{cases} \tag{4.3}$$

where

$$\xi_n(x) = x^4 \sum_{k=0}^{3} b_{n,k} \frac{x^k}{k!}, \quad \eta_n(x) = (x-a)^4 \sum_{k=0}^{3} c_{n,k} \frac{(x-a)^k}{k!}. \tag{4.4}$$

The coefficients $b_{n,k}, c_{n,k}$ are uniquely determined by the smoothly connected conditions

$$\xi_n^{(k)}(x_n) = \phi_n^{(k)}(x_n), \quad \eta_n^{(k)}(\widetilde{x}_n) = \phi_n^{(k)}(\widetilde{x}_n), \quad k = 0, 1, 2, 3. \tag{4.5}$$

Since

$$|\phi_n^{(k)}(x_n)| = |\phi_n^{(k)}(\widetilde{x}_n)| = \frac{\sqrt{2}}{2}(\gamma n)^k, \tag{4.6}$$

we can directly verify that

$$b_{n,k} = \frac{d^k}{dx^k}\left(\frac{\xi_n(x)}{x^4}\right)\Big|_{x=x_n} = \mathcal{O}(n^{4+k}), \qquad (n \to \infty), \tag{4.7}$$

$$c_{n,k} = \frac{d^k}{dx^k}\left(\frac{\eta_n(x)}{(x-a)^4}\right)\Big|_{x=\widetilde{x}_n} = \mathcal{O}(n^{4+k}), \qquad (n \to \infty), \tag{4.8}$$

for $k = 0, 1, 2, 3$. This further leads to

$$\xi_n^{(k)}(x) = \mathcal{O}(n^k) \quad \forall\, x \in [0, x_n] \quad (n \to \infty), \tag{4.9}$$

$$\eta_n^{(k)}(x) = \mathcal{O}(n^k) \quad \forall\, x \in [\widetilde{x}_n, a] \quad (n \to \infty), \tag{4.10}$$

for $k = 0, 1, 2, 3, 4$. It is easy to see that $u_n \in H_0^4(0, L)$ and supp $u_n \subset (0, \alpha)$. Now, let

$$\omega_n = \sqrt{\frac{q(0)}{\rho(0)}}(\gamma n)^2, \quad v_n = i\omega_n u_n. \tag{4.11}$$

Then $(u_n, v_n) \in D(\mathcal{A}_1)$ and

$$(i\omega_n - \mathcal{A}_1)(u_n, v_n) = \left(0, -\omega_n^2 u_n + \frac{q(0)}{\rho(0)} u_n^{(4)}\right). \tag{4.12}$$

Since

$$-\omega_n^2 u_n + \frac{q(0)}{\rho(0)} u_n^{(4)} = \begin{cases} -\omega_n^2 \xi_n + \frac{q(0)}{\rho(0)} \xi_n^{(4)}, & 0 \le x < x_n, \\ 0, & x_n \le x < \widetilde{x}_n, \\ -\omega_n^2 \eta_n + \frac{q(0)}{\rho(0)} \eta_n^{(4)}, & \widetilde{x}_n \le x < a, \\ 0, & a \le x \le L, \end{cases} \tag{4.13}$$

by (4.9) and (4.10) we have

$$\left\| \frac{1}{\omega_n^2}(i\omega_n - \mathcal{A}_1)(u_n, v_n) \right\|_{\mathcal{H}_2} \to 0. \tag{4.14}$$

On the other hand,

$$\begin{aligned} \left\| \frac{1}{\omega_n}(u_n, v_n) \right\|_{\mathcal{H}_2} &\geq \left(\int_0^{\alpha} \rho |u_n|^2 dx \right)^{\frac{1}{2}} \\ &\geq \left(\int_{x_n}^{\widetilde{x}_n} \rho |\phi_n|^2 dx \right)^{\frac{1}{2}} \\ &= \left(\int_{x_n}^{\widetilde{x}_n} \rho \sin^2 \gamma n x dx \right)^{\frac{1}{2}} \to \left(\frac{\rho \pi}{2\gamma} \right)^{\frac{1}{2}}. \end{aligned} \tag{4.15}$$

Equations (4.14) and (4.15) imply that (4.1) is not true. □

Remark. This proof does not depend on the boundary conditions or the type of damping. Thus, we conclude that the semigroups associated with linear beam equations with local damping are never analytic.

OPTIMAL CONTROL OF INFLATION: A CENTRAL BANK PROBLEM*

MARIA B. CHIAROLLA† AND ULRICH G. HAUSSMANN‡

Abstract. This paper models the action of the central bank on the dynamics of the nominal interest rate with the aim of controlling inflation. The problem is set up as a two-dimensional *bounded variation control problem*; it is shown that its variational formulation leads to a stochastic differential game with stopping times between the conservative and the expansionist tendencies of the bank.

Key words. central bank, inflation, bounded variation stochastic control, weak variational inequality, strong variational inequality, stochastic differential game

1. Introduction.

The central bank has many roles to play in an economy. These vary from country to country depending on federal law and government policy. For example, in 1975, the governor of the Bank of Canada announced policies to deal with inflation which can be summarized as follows (cf. Binhammer [4, pp. 586–587]).

- The Bank of Canada has the responsibility and the means to keep the rate of monetary expansion under control.
- The restoration of price stability requires an average rate of growth of the money supply no higher than the long term average rate of growth of production of goods and services.
- The pursuit of a policy of stable monetary expansion requires that nominal interest rates and the foreign exchange rate be allowed to achieve their levels independently.
- Nominal interest rates can be reduced in the long run by reducing inflation. This is to be achieved by a short term rise in interest rates, producing a decline in the growth rate of the money supply. Over the long term interest rates should settle to lower levels.

As noted above, in Canada, the bank controls the demand for money by influencing interest rates through intervention in the weekly auction of 91-day T-bills and by trading in the secondary market for T-bills. The bank rate is then set at 1/4% above the T-bill rate set at the weekly auction. Reserves are provided to the commercial banks to support this action; hence the monetary base is only controlled passively. The bank followed this policy with the exception of the independence of the exchange rate and interest rates. In fact, the short term swings in the bank rate are mostly due to a policy of defending the Canadian dollar against the U.S. dollar. Nevertheless, this situation is somewhat particular to Canada, and so in this work we shall ignore the influence of the exchange rate on interest rates. The general conclusion to be drawn from the above policy statements is that the bank wants to control inflation

by raising nominal interest rates using the bank rate. This policy seems to have been successful during the 1980s and 1990s.

An essential issue at this point is to model the dynamic evolution of the interest and inflation rates over time. Interest rates have received widespread attention over the past decade, usually in the context of the term structure of interest rates; cf. Longstaff and Schwartz [20] and references therein. In general, however, the problem of studying the changes of interest rates due to monetary decisions is quite new in the literature, although several authors have pointed out the relationship between interest rates and inflation. For example, Richard determines the term structure of interest rate in a model whose uncorrelated state variables are the real interest rate and the inflation rate in [24]. The inflation rate appears also in a paper by Cox, Ingersoll, and Ross [8, section 7], but there is a variable without any monetary objective. The effect of monetary policy changes on the relationship between short and long term interest rates is studied by Turnovsky [25], and an equilibrium asset-pricing model in which the real interest rate is negatively correlated with the inflation rate is constructed and estimated by Pennacchi [23]. General observations about correlations among interest rates, inflation, and money supply growth can be found in the work of Mishkin [22].

The recent paper of Fusai [12] analyzes how the term structure of interest rates changes when the central bank tries to stabilize the inflation rate by acting on the money supply. This is an interesting approach, although there may be some mathematical difficulties in the derivation of the model. The problem is set as a stochastic linear regulator, hence a *classical* control problem; the control is given by the money supply and enters the dynamics of the real interest rate and of the inflation rate.

Our model has the following features. The two-dimensional state variable is given by the nominal interest rate $X_{1,s}$ (deduced from the stochastic Fisher law) and the inflation rate $X_{2,s}$; these processes are jointly dependent. This is consistent with some (but not all) models in the literature, e.g., Pennachi [23]. The central bank may modify the dynamics of $X_{1,s}$ by adding a stochastic process $k \in V[0,T]$ of finite variation over the time interval $[0,T]$; the change in k represents the change in the bank rate which is assumed to affect the interest rate directly and additively. Inflation targeting is achieved by minimizing over $V[0,T]$ a certain cost functional. This produces a two-dimensional *singular* stochastic control problem with the control (which, as a function of time, could possibly be singular with respect to the Lebesgue measure) acting only on the x_1-component. We show that the variational formulation of this problem leads to a two-player, zero-sum stochastic differential game with stopping times whose value coincides with the x_1-derivative of the value function of the original problem. The differential game might be interpreted as a game played between the conservative and the expansionist tendencies of the bank. At certain times the conservative tendency asks for low inflation and hence interest rates are increased, whereas at other opportune times the expansionist tendency lowers interest rates in order to stimulate the economy.

Our mathematical model falls in the class of the so-called *bounded variation follower problems with finite horizon*, in the language of the recent singular stochastic control literature. A d-dimensional follower problem for the control of a diffusion process with linear-in-x drift and constant-in-x diffusion coefficient has been sketched by Menaldi and Robin [21]; there compactness methods are used to establish the existence of an optimal control process. More general existence results were established by Haussmann and Suo [15]. On the other hand, the one-dimensional *reflected* follower problem (i.e., a bounded variation follower problem with a reflecting barrier at the origin) for the control of Brownian motion has been extensively studied by El Karoui

and Karatzas [9], Karatzas [16], and Karatzas and Shreve [17], among others. It has been shown that the x-derivative of the value function of the reflected follower problem is the optimal risk of an optimal stopping problem with absorption at the origin. Therefore, our differential game problem seems to be the natural generalization to more than one dimension (but with one-dimensional control) of the stopping problem arising in dimension one. The cost rate of our game depends on the x_2-derivative of the value function of the original problem, i.e., the partial derivative in the direction not controlled, so the game cannot be solved without solving the original problem. It is only in the one-dimensional case where there are no "other" directions, that the derived problem can be stated independently of the original value function.

This paper is organized as follows. In section 2 we formulate the control problem and state the main results. In particular, we find that the value function (derived utility function), $v(x,t)$, satisfies a variational inequality (corresponding to the Bellman equation of dynamic programming), but that an associated problem satisfied by $v_{x_1}(x,t)$ is more relevant than the original variational inequality. Moreover, a stochastic differential game with stopping times is deduced from the associated problem. It is shown that the game has value v_{x_1} and admits a saddle point $(\hat{\theta}_1, \hat{\theta}_2)$, where $\hat{\theta}_1$ is the optimal time to increase interest rates in order to contain the inflation and $\hat{\theta}_2$ is the optimal time to lower interest rates in order to stimulate the economy.

Sections 3, 4, and 5 contain the mathematical analysis of the problem. The nonmathematical reader may skip to section 6. In section 3 we derive some properties of the value function $v(x,t)$. In section 4 we introduce a penalized control problem whose value function $v^\varepsilon(x,t)$ approximates $v(x,t)$ and is regular enough to allow differentiation with respect to x_1 of the corresponding Hamilton–Jacobi–Bellman equation. Then, by taking limits as $\varepsilon \to 0$, in section 5 we obtain a weak variational inequality solved by v_{x_1}. (We point out that the Mignot–Puel method employed in the *monotone* control case to obtain a weak variational inequality (cf. [7, p. 875]) cannot be applied to problems with general bounded variation controls since the penalty term of the differentiated Hamilton–Jacobi–Bellman equation is not nonnegative, and hence it does not correspond to a penalization operator in the sense of Mignot and Puel.) We conclude section 5 by appealing to general existence and uniqueness results established in section 7, to show that v is the unique solution of a pointwise variational inequality. In section 6 we summarize our conclusions regarding the economics problem.

Section 7 stands alone and gives results about variational inequalities. Many of the mathematical techniques used here were inspired by the work of Bensoussan and Lions [2], but in fact our problem falls outside the scope of their work because of an unbounded domain, unbounded coefficients in the state equations, and lack of differentiability of v_{x_2} with respect to time. Using penalization we show that a strong variational inequality has a unique solution, which is related to the unique solution of a weak variational inequality (the one satisfied by $e^{-\lambda(T-t)}v_{x_1}$ in section 5). Finally we show that the solution in fact satisfies a pointwise variational inequality. The appendix contains some technical results used in section 7.

2. Formulation of the problem and results. Pennacchi [23] postulates an economy with a single capital-consumption good and a single technology to transform capital into output. One of the implications of the model is that if $X_{1,s}$, $X_{2,s}$ are the nominal (spot) interest rate and expected rate of inflation, respectively, then they satisfy

$$dX_s = (a + bX_s)ds + \sigma dW_{s-t}, \qquad s \in (t,T]. \tag{2.1}$$

This model does not take into consideration the direct influence of the central bank on the interest rate. It also allows these rates, in particular, the nominal interest rate, to go negative! Nevertheless, as a first step we shall adopt this model except that we add a control term which reflects the actions of the bank. In [14] it is shown that the model, when applied to Canadian data from 1983 through 1988, is not unreasonable; i.e., statistical tests checking for nonnormality of the residuals corresponding to ΔW are not significant. To be fair, we must add that for other time segments of the data this is not the case. If the inflation rate is ignored, i.e., $X_2 = 0$, then the model for the interest rate has been used in derivative pricing; cf. [5].

Let a be a constant vector in $\mathbb{R}^2$ and $e_1 = \binom{1}{0}$, let $b = \binom{b_{11}\, b_{12}}{b_{21}\, b_{22}}$ and σ be constant 2×2 matrices such that $\sigma\sigma^*$ is positive definite. Let $T > 0$ be fixed; then $X_s = \binom{X_{1,s}}{X_{2,s}}$ is the process starting at time $t \in [0, T]$ from $x \in \mathbb{R}^2$ and governed by the stochastic differential equation

$$\begin{cases} dX_s = (a + bX_s)ds + \sigma dW_{s-t} + e_1\, dk_{s-t}, & s \in (t, T], \\ X_t = x + e_1\, k_0 \end{cases} \tag{2.2}$$

on some filtered probability space $(\Omega, \mathcal{F}, \mathcal{F}_s, P)$ with the filtration $\{\mathcal{F}_s, s \in [0, T]\}$ satisfying the usual conditions, where $\{W_s, s \in [0, T]\}$ is a standard two-dimensional Brownian motion and the control $\{k_s, s \in [0, T]\}$ is a real-valued càdlàg (i.e., right-continuous with left limits), $\mathcal{F}_s$-adapted process, almost surely (a.s.) of finite variation. We denote by $V[0, T]$ the set of all such control processes; we refer to (x, t) as "the initial condition" and to T as "the terminal time."

Let $f(x) = \frac{1}{2}[\nu(x_1)^2 + (x_2)^2]$ for $x = (x_1, x_2)$; $\in \mathbb{R}^2$ and $\nu \geq 0$; then the function f is convex. Let $\rho > 0$ be a given discount factor; then the cost corresponding to the control process k is

$$J_{x,t}(k) = E\bigg\{ \int_t^T f(X_s) e^{-\rho(s-t)} ds + \int_t^T e^{-\rho(s-t)} d|k|_{s-t} + |k_0| \bigg\}, \tag{2.3}$$

where $|k|$ is the total variation process of k. The term involving X_1 reflects the desire to keep interest rates low so as to stimulate the economy; the term involving X_2 reflects the desire to keep the inflation rate at zero (we could have chosen any constant), and the terms involving k reflect the bank's reluctance to make large changes in the rate (i.e., it prefers to provide stable interest rates). The coefficient ν is determined by the bank to reflect the weight it wishes to give to fighting inflation compared to stimulating the economy.

The problem is to minimize J and to find the value function

$$v(x, t) = \inf \Big\{ J_{x,t}(k) : k \in V[0, T] \Big\}. \tag{P}$$

In order to state the results we need some notation. Let $p > 1$, $m \in \mathbb{N}$, and let Q denote an open set in $\mathbb{R}^2$; then we set

- $C^{2,1}(Q \times (0, T))$ = the set of all functions u continuous on $Q \times (0, T)$ with continuous partial derivatives $u_{x_i}, u_{x_i x_j}, u_t$, $i, j = 1, 2$;
- $C^{2,1}_{\text{pol}}(Q \times (0, T))$ = the set of all functions $u \in C^{2,1}(Q \times (0, T))$ which satisfy a polynomial growth condition on $Q \times (0, T)$; i.e., for some constants $C > 0$ and $m \in \mathbb{N}$,

$$|u(x, t)| \leq C(1 + |x|^m) \qquad \forall (x, t) \in Q \times (0, T);$$

- $W^{m;p}(Q)$ = the space of all functions g which have weak derivatives $D^\alpha g$ in $L^p(Q)$ for all $|\alpha| \le m$;
- $W^{2,1;p}(Q \times (0,T))$ = the space of all functions u which have weak derivatives $u_t, u_{x_i}, u_{x_i x_j}$, $i,j = 1,2$, in $L^p(Q \times (0,T))$;
- $W^{2,1;p}_{\text{loc}}(\mathbb{R}^2 \times (0,T))$ = the space of all functions u that, for all bounded $Q \subset \mathbb{R}^2$, belong to $W^{2,1;p}(Q \times (0,T))$;
- $\mathcal{L}u(x,t) = \frac{1}{2}\text{trace}[\sigma\sigma^* \mathcal{D}^2 u(x,t)] + (a+bx)\cdot \nabla u(x,t)$, where $\mathcal{D}^2 u(x,t)$ and $\nabla u(x,t)$ are the Hessian matrix and the gradient of $u(x,t)$ with respect to the x-variables, respectively.

The value function can now be characterized by the following theorem.

THEOREM 2.1. *The value function v is the unique solution in $W^{2,1;\infty}_{\text{loc}}(\mathbb{R}^2 \times (0,T))$ of*

$$\begin{cases} v(x,T) = 0 \text{ almost everywhere (a.e.) in } \mathbb{R}^2, \\ \max\Big\{ -v_t + [-\mathcal{L} + \rho]v - f,\ -v_{x_1} - 1,\ v_{x_1} - 1 \Big\} \le 0, \\ (-v_t + [-\mathcal{L} + \rho]v - f)(-v_{x_1} - 1)(v_{x_1} - 1) = 0, \\ \text{a.e. in } \mathbb{R}^2 \times (0,T). \end{cases} \tag{2.4}$$

A proof of this result can be given along the lines of the proof of the next theorem, but as it is similar, we refrain from doing so.

The problem (2.4) is difficult to solve and difficult to interpret in economic terms; an associated problem turns out to have a useful form. Its main actor is the function v_{x_1}.

THEOREM 2.2. *There exists a positive constant C such that*

$$|v_{x_i}(x,t)| \le C(1+|x|), \quad |v_{x_i x_j}(x,t)| \le C, \quad |v_t(x,t)| \le C(1+|x|^2) \tag{2.5}$$

a.s. in $\mathbb{R}^2 \times [0,T]$, $i,j = 1,2$. Assume that $\rho \ge b_{11}$ and set

$$\hat{u} = b_{21} v_{x_2} + \nu x_1.$$

Then the function v_{x_1} is the unique solution in $W^{2,1;6}_{\text{loc}}(\mathbb{R}^2 \times (0,T))$ of the pointwise variational inequality

$$\begin{cases} -1 \le v_{x_1} \le +1 \text{ a.e. in } \mathbb{R}^2 \times (0,T),\ v_{x_1}(x,T) = 0 \text{ a.e. in } \mathbb{R}^2, \\ -v_{x_1 t} + [-\mathcal{L} + (\rho - b_{11})]v_{x_1} = \hat{u} \quad \text{if } -1 < v_{x_1}(x,t) < 1, \\ -v_{x_1 t} + [-\mathcal{L} + (\rho - b_{11})]v_{x_1} \le \hat{u} \quad \text{if } v_{x_1}(x,t) = +1, \\ -v_{x_1 t} + [-\mathcal{L} + (\rho - b_{11})]v_{x_1} \ge \hat{u} \quad \text{if } v_{x_1}(x,t) = -1, \\ \text{a.e. in } \mathbb{R}^2 \times (0,T). \end{cases} \tag{2.6}$$

The proof of this result is technical and is given in the following three sections.

Note that the uniqueness here is for a fixed $\hat{u}$, i.e., for given v_{x_2}. In terms of the unknowns (v_{x_1}, v_{x_2}), this theorem gives existence of solutions, but not uniqueness. The more general uniqueness does not hold without further side conditions; what such conditions are poses an interesting problem. In fact, the above theorem is an intermediate result; what we are after is the interpretation of v_{x_1} as the value of a differential game!

We are now going to show that v_{x_1} is the value of a two-player, zero-sum stochastic differential game. In essence, we have moved from the control problem (P) to the variational inequality satisfied by its value function v, we have differentiated to find a variational inequality for v_{x_1}, and then we have found the corresponding control problem, which happens to be a differential game.

For every $(x,t) \in \mathbb{R}^2 \times [0,T]$ consider the control-free diffusion process starting at time t from x; i.e.,

$$X^0_{s'} = x + \int_t^{s'} (a + bX^0_r)dr + \sigma \int_t^{s'} dW_{r-t} \qquad \forall s' \in [t,T],$$

so if $Y^0_s := X^0_{s+t} = X^0_{s'}$ for $s = s' - t$ then

$$Y^0_s = x + \int_0^s (a + bY^0_r)dr + \sigma \int_0^s dW_r \qquad \forall s \in [0, T-t]. \tag{2.7}$$

For every r, r' with $0 \le r < r' < +\infty$ we set

- $\mathcal{S}_{r,r'}$ = the collection of all stopping times relative to the underlying filtration $\{\mathcal{F}_s\}_{s\in[0,T]}$ and taking values in $[r, r']$.

Let θ_1, θ_2 be stopping times in $\mathcal{S}_{0,T-t}$; if θ_1 and θ_2 play the role of strategies, then we define the *evaluation function* of the game by setting

$$\begin{aligned} G_{x,t}(\theta_1,\theta_2) = E\Big\{ &\int_0^{\theta_1\wedge\theta_2} \hat{u}(Y^0_s, t+s) e^{-(\rho-b_{11})s} ds \\ &- e^{-(\rho-b_{11})\theta_1} \mathbb{I}_{\substack{\theta_1\le\theta_2 \\ \theta_1<T-t}} + e^{-(\rho-b_{11})\theta_2} \mathbb{I}_{\theta_2<\theta_1} \Big\}. \end{aligned} \tag{2.8}$$

Also, we define

- $\hat{\theta}_1 = \inf\{s \in [0,T-t] : v_{x_1}(Y^0_s, t+s) = -1\} \wedge (T-t)$,
- $\hat{\theta}_2 = \inf\{s \in [0,T-t] : v_{x_1}(Y^0_s, t+s) = +1\} \wedge (T-t)$;

then we prove that the differential game has a solution.

THEOREM 2.3. *Assume that $\rho \ge b_{11}$. Then for every initial condition (x,t), the evaluation function $G_{x,t}$ has a saddle point at $(\hat{\theta}_1, \hat{\theta}_2)$ with value $v_{x_1}(x,t)$; i.e.,*

$$\begin{cases} G_{x,t}(\theta_1, \hat{\theta}_2) \le G_{x,t}(\hat{\theta}_1, \hat{\theta}_2) \le G_{x,t}(\hat{\theta}_1, \theta_2) \qquad \forall \theta_1, \theta_2 \in \mathcal{S}_{0,T-t}, \\ v_{x_1}(x,t) = G_{x,t}(\hat{\theta}_1, \hat{\theta}_2), \end{cases} \tag{2.9}$$

and

$$\begin{aligned} v_{x_1}(x,t) &= \inf_{\theta_2\in\mathcal{S}_{0,T-t}} \sup_{\theta_1\in\mathcal{S}_{0,T-t}} G_{x,t}(\theta_1,\theta_2) \\ &= \sup_{\theta_1\in\mathcal{S}_{0,T-t}} \inf_{\theta_2\in\mathcal{S}_{0,T-t}} G_{x,t}(\theta_1,\theta_2). \end{aligned} \tag{2.10}$$

Proof. Clearly (2.10) follows directly from (2.9). Fix (x,t) in $\mathbb{R}^2 \times [0,T]$; for $R > 0$ let τ_R be the first exit time of Y^0 from $B_R = \{x \in \mathbb{R}^2 : |x| < R\}$. Since v_{x_1} is in $W^{2,1;6}_{\mathrm{loc}}(\mathbb{R}^2 \times (0,T))$ (cf. Theorem 2.2), continuous on $\mathbb{R}^2 \times [0,T]$ by Sobolev imbedding, we may apply to $e^{-(\rho-b_{11})s} v_{x_1}(Y^0_s, t+s)$ a generalization of Ito's formula (cf. [2, Chapter 2, Theorem 8.5, p. 185]); hence for any stopping time $\theta \in \mathcal{S}_{0,T-t}$ we obtain

$$\begin{aligned} v_{x_1}(x,t) &= E\Big\{ e^{-(\rho-b_{11})\theta} v_{x_1}(Y^0_\theta, t+\theta) \mathbb{I}_{\theta\le\tau_R} \Big\} \\ &+ E\Big\{ e^{-(\rho-b_{11})\tau_R} v_{x_1}(Y^0_{\tau_R}, t+\tau_R) \mathbb{I}_{\theta>\tau_R} \Big\} \\ &+ E\Big\{ \int_0^{\theta\wedge\tau_R} e^{-(\rho-b_{11})r} \Big(-v_{x_1 t} + [-\mathcal{L} + (\rho - b_{11})] v_{x_1} \Big)(Y^0_r, t+r) dr \Big\}. \end{aligned} \tag{2.11}$$

Since $\tau_R \to +\infty$ a.s. as $R \to +\infty$ and $|v_{x_1}| \le 1$ (cf. (2.6)), we have

$$\begin{cases} \lim\limits_{R\to+\infty} E\Big\{e^{-(\rho-b_{11})\theta} v_{x_1}(Y^0_\theta, t+\theta)\mathbb{I}_{\theta\le\tau_R}\Big\} = E\Big\{e^{-(\rho-b_{11})\theta} v_{x_1}(Y^0_\theta, t+\theta)\Big\}, \\ \lim\limits_{R\to+\infty} E\Big\{e^{-(\rho-b_{11})\tau_R} v_{x_1}(Y^0_{\tau_R}, t+\tau_R)\mathbb{I}_{\theta>\tau_R}\Big\} = 0 \end{cases}$$

by the bounded convergence theorem.

Now, for any stopping time $\theta_2 \in \mathcal{S}_{0,T-t}$, we set

$$\theta = \theta_2 \wedge \hat\theta_1,$$

and we see that (2.6) implies

$$\Big(-v_{x_1 t} + [-\mathcal{L} + (\rho - b_{11})]v_{x_1}\Big)(Y^0_s, t+s) \le \hat u(Y^0_s, t+s) \qquad \forall s \in [0, \hat\theta_1]$$

with equality if $s \le \hat\theta_1 \wedge \hat\theta_2$; therefore, we have

$$\begin{aligned} E\Big\{\int_0^{\theta\wedge\tau_R} e^{-(\rho-b_{11})r}\Big(-v_{x_1 t} + [-\mathcal{L} + (\rho-b_{11})]v_{x_1}\Big)(Y^0_r, t+r)dr\Big\} \\ \le E\Big\{\int_0^{\theta\wedge\tau_R} e^{-(\rho-b_{11})r}\hat u(Y^0_r, t+r)dr\Big\} \end{aligned} \tag{2.12}$$

with equality if $\theta_2 \le \hat\theta_2$. But $|\hat u(Y^0_r, t+r)| \le C(1+|Y^0_r|)$ by $(2.5)_1$, so by applying the dominated convergence theorem we obtain

$$\begin{aligned} \lim_{R\to+\infty} E\Big\{\int_0^{\theta\wedge\tau_R} e^{-(\rho-b_{11})r}\Big(-v_{x_1 t} + [-\mathcal{L} + (\rho-b_{11})]v_{x_1}\Big)(Y^0_r, t+r)dr\Big\} \\ \le E\Big\{\int_0^{\theta} e^{-(\rho-b_{11})r}\hat u(Y^0_r, t+r)dr\Big\} \end{aligned}$$

with equality if $\theta_2 \le \hat\theta_2$. Thus, passing to the limit as $R \to +\infty$ in (2.11) gives

$$\begin{aligned} v_{x_1}(x,t) &\le E\Big\{e^{-(\rho-b_{11})\theta} v_{x_1}(Y^0_\theta, t+\theta)\Big\} \\ &\quad + E\Big\{\int_0^{\theta} e^{-(\rho-b_{11})r}\hat u(Y^0_r, t+r)dr\Big\} \end{aligned} \tag{2.13}$$

with equality if $\theta_2 \le \hat\theta_2$. Finally, $v_{x_1}(Y^0_{T-t}, T) = 0$, $v_{x_1}(Y^0_{\hat\theta_1}, t+\hat\theta_1) = -1$ (this follows from the continuity of v_{x_1} and Y^0), and $v_{x_1} \le 1$ imply

$$\begin{aligned} &E\Big\{e^{-(\rho-b_{11})\theta} v_{x_1}(Y^0_\theta, t+\theta)\Big\} \\ &= E\Big\{-e^{-(\rho-b_{11})\hat\theta_1}\mathbb{I}_{\substack{\theta_2\ge\hat\theta_1 \\ \hat\theta_1<(T-t)}} + e^{-(\rho-b_{11})\theta_2} v_{x_1}(Y^0_{\theta_2}, t+\theta_2)\mathbb{I}_{\theta_2<\hat\theta_1}\Big\} \\ &\le E\Big\{-e^{-(\rho-b_{11})\hat\theta_1}\mathbb{I}_{\substack{\theta_2\ge\hat\theta_1 \\ \hat\theta_1<(T-t)}} + e^{-(\rho-b_{11})\theta_2}\mathbb{I}_{\theta_2<\hat\theta_1}\Big\} \end{aligned} \tag{2.14}$$

with equality if $\theta_2 = \hat\theta_2$. Now from (2.13) and (2.14) it follows that

$$v_{x_1}(x,t) = G_{x,t}(\hat\theta_1, \hat\theta_2) \le G_{x,t}(\hat\theta_1, \theta_2) \qquad \forall \theta_2 \in \mathcal{S}_{0,T-t}.$$

Similarly, by taking $\theta = \theta_1 \wedge \hat{\theta}_2$ for any stopping time $\theta_1 \in \mathcal{S}_{0,T-t}$, we can show that $G_{x,t}(\theta_1, \hat{\theta}_2) \le G_{x,t}(\hat{\theta}_1, \hat{\theta}_2) = v_{x_1}(x,t) \, \forall \theta_1 \in \mathcal{S}_{0,T-t}$. □

The financial interpretation of Theorem 2.3 discloses the complexity of the problem of containing inflation. In fact, (2.10) can be interpreted as a fictitious game between the conservative forces in the central bank, whose goal is to pursue monetary stability, and those forces, either in the bank or outside (e.g., in the government) aiming to stimulate the economy. (The running cost in the game does, however, depend on v_{x_2}, i.e., a derivative of the original value function, so to obtain the control one would not try to solve the game.) The strategies of the conservative forces are given by all stopping times when interest rates are increased in order to reduce the inflation, whereas the strategies of the expansionary forces are all stopping times when interest rates are lowered to favor economic expansion. In this game the role of the "referee" is played by the financial market; according to some economists (cf. Vaciago [26]) the result of the game depends on the efficiency of the financial market. Only if the financial market is "perfect," and hence guarantees long periods of equilibrium, can one assume the complete independence of the central bank from its government, and the stability of prices can then be optimally achieved.

3. Preliminary results. We fix some notation which will be used in the rest of the paper. Let $p > 1$ and let Q denote an open set in $\mathbb{R}^2$ with closure $\bar{Q}$:

- $H^{m+\mu,(m+\mu)/2}(\bar{Q} \times [0,T])$ = the space of all functions u continuous on $\bar{Q} \times [0,T]$ with continuous partial derivatives of the form $D_t^r D_x^j u$ for $2r + j \le m$, whose derivatives of the form $D_t^r D_x^j u$, $2r + j = m$ are Hölder continuous with respect to x (exponent $\mu \in (0,1)$) and whose derivatives of the form $D_t^r D_x^j u$, $0 < m + \mu - 2r - j < 2$, are Hölder continuous with respect to t (exponent $\frac{m+\mu-2r-j}{2} \in (0,1)$) on $\bar{Q} \times [0,T]$ (cf. [19, p. 7], for the norm);
- $H^{m+\mu,(m+\mu)/2}(Q \times (0,T))$ = the set of all functions u such that $u \in H^{m+\mu,(m+\mu)/2}(\bar{\Omega})$ for all Ω such that $\bar{\Omega} \subset Q \times (0,T)$;
- $H^{m+\mu,(m+\mu)/2}_{\text{loc}}(\mathbb{R}^2 \times [0,T])$ is the set of all functions u such that $u \in H^{m+\mu,(m+\mu)/2}(\bar{Q} \times [0,T])$ for all bounded $Q \subset \mathbb{R}^2$;
- $L^p(0,T;Y)$ = the space of all p-integrable functions on $(0,T)$ with values in the Hilbert space Y (notice that

$$W^{2,1;2}(Q \times (0,T)) = \{u \in L^2(0,T; W^{2;2}(Q)), u_t \in L^2(0,T; L^2(Q))\});$$

- $B_N = \{x \in \mathbb{R}^2 : |x| < N\}$;
- $\Omega_N = B_N \times (0,T)$;
- $\pi(x) = (1 + |x|^2)^{-l}$ (any integer $l > 4$);
- $\varphi_i(x) = 2l x_i (1 + |x|^2)^{-1}$ for $x = (x_1, x_2) \in \mathbb{R}^2$, $i = 1, 2$ (notice that $\pi_{x_i}(x) = -\varphi_i(x)\pi(x)$);
- $L^p_\pi(\mathbb{R}^2 \times [0,T]) = \{u : \pi^{1/p} u \in L^p(\mathbb{R}^2 \times [0,T])\}$, i.e., L^p under the measure $\pi(x)dxdt$;
- $L^p_\pi(\mathbb{R}^2) = \{g : \pi^{1/p} g \in L^p(\mathbb{R}^2)\}$;
- $H = L^2_\pi(\mathbb{R}^2)$ with $\|g\|_H^2 = \displaystyle\int_{\mathbb{R}^2} |g(x)|^2 \pi(x) dx$;
- $(g,h) = \int_{\mathbb{R}^2} g(x)h(x)\pi(x)dx$ denotes the inner product in H;
- $V = \{g \in H : g_{x_1}, g_{x_2} \in H\}$ with $\|g\|_V^2 = \|g\|_H^2 + \|g_{x_1}\|_H^2 + \|g_{x_2}\|_H^2$;
- V' = the dual of V (notice that H is identified with its dual and we have $V \subset H \subset V'$);
- $\langle \cdot, \cdot \rangle$ denotes the pairing between V' and V;

- $H_\circ = \{g \in H : |x|g \in H\}$;
- $V_\circ = V \cap H_\circ$;
- $W(0,T) = \{w \in L^2(0,T;V) : w_t \in L^2(0,T;V')\}$ with the Hilbert norm

$$\|w\|_{W(0,T)} = \Big(\int_0^T \|w(t)\|_V^2 \, dt + \int_0^T \|w_t(t)\|_{V'}^2 \, dt \Big)^{\frac{1}{2}}$$

(notice that if $w \in W(0,T)$ then it is continuous in $[0,T] \mapsto H$ and $\frac{d}{dt}\|w(t)\|^2 = 2\langle w(t), w'(t)\rangle$);

- $W_\circ(0,T) = \{w \in W(0,T) : w(t) \in H_\circ \text{ a.e. } t \in [0,T]\}$.

The following simple lemma will often be used.

LEMMA 3.1. *If X_s^0 is the uncontrolled process starting at time t from x, then there exists a positive constant $C > 0$ independent of x and t such that*

$$E\{|X_s^0|^2\} \le C(1 + |x|^2). \tag{3.1}$$

There exists a positive constant C such that for every $k \in V[0,T]$, $x, y \in \mathbb{R}^2$, and $t \in [0,T]$, if X_s^x and X_s^y denote the processes controlled by k and starting at time t from x and y, respectively, then

$$E\{|X_s^y - X_s^x|\} \le C|y - x|, \tag{3.2}$$

$$E\{|X_s^y - X_s^x|^2\} \le C|y - x|^2 \tag{3.3}$$

for every $s \in (t,T]$.

We collect the main properties of $v(x,t)$ in the following theorem. Note that

$$f(x) - f(y) \le C(|x| + |y|)|x - y| \tag{3.4}$$

for all x, y in $\mathbb{R}^2$.

THEOREM 3.2. *There exists a positive constant C such that for every $\lambda \in (0,1)$ and for all x, x' in $\mathbb{R}^2$, $|x'| \le 1$, and t in $[0,T]$, $h > 0$, one has*

$$0 \le v(x,t) \le C(1 + |x|^2); \tag{3.5}$$

$$|v(x,t) - v(x + x', t)| \le C(1 + |x| + |x'|)|x'|; \tag{3.6}$$

$$0 \le v(x + \lambda x', t) + v(x - \lambda x', t) - 2v(x,t) \le C\lambda^2; \tag{3.7}$$

$$v(x, t + h) - v(x,t) \le 0, \qquad h \in (0, T - t]; \tag{3.8}$$

$$v(x, t - h) - v(x,t) \le C(1 + |x|^2)h, \qquad h \in (0,t]. \tag{3.9}$$

Hence $v(x,t)$ is convex in x, nonincreasing in t, and $v \in W^{2,1;p}_{\text{loc}}(\mathbb{R}^2 \times (0,T))$ (any $p \le \infty$) with

$$|v_{x_i}(x,t)| \le C(1 + |x|), \quad |v_{x_i x_j}(x,t)| \le C, \quad |v_t(x,t)| \le C(1 + |x|^2) \tag{3.10}$$

a.s. in $\mathbb{R}^2 \times [0,T]$, $i, j = 1, 2$. In particular, for any $\mu \in (0,1)$, $v \in H^{1+\mu,(1+\mu)/2}_{\text{loc}}$ $(\mathbb{R}^2 \times [0,T])$.

Proof. Our proof borrows from [6] and [7]. Clearly it suffices to consider only those controls which give a cost not greater than $J_{x,t}(0)$, and (3.1) implies

$$J_{x,t}(0) \le C(1+|x|^2) \tag{3.11}$$

and hence also

$$v(x,t) \le C(1+|x|^2) \qquad \forall (x,t) \in \mathbb{R} \times [0,T]. \tag{3.12}$$

Let x, x', t, k be fixed and denote by X_s^x and $X_s^{x+x'}$ the processes controlled by k and starting at time t from x and $x+x'$, respectively. Then (3.4) implies

$$\begin{aligned}
&v(x+x',t) - v(x,t) \\
&\le \sup_{k \in V[0,T]} E\Big\{ \int_t^T \big(f(X_s^{x+x'}) - f(X_s^x)\big) e^{-\rho(s-t)} ds \Big\} \\
&\le C \sup_{k \in V[0,T]} E\Big\{ \int_t^T \big(\big|X_s^{x+x'} - X_s^x\big| + 2\big|X_s^x\big|\big)\big|X_s^{x+x'} - X_s^x\big| e^{-\rho(s-t)} ds \Big\} \\
&\le C \sup_{k \in V[0,T]} \Big(\int_t^T E\big\{\big|X_s^{x+x'} - X_s^x\big|^2\big\} e^{-\rho(s-t)} ds \Big) \\
&\quad + C \sup_{k \in V[0,T]} \Big(\int_t^T E\big\{\big|X_s^{x+x'} - X_s^x\big|^2\big\} e^{-\rho(s-t)} ds \Big)^{\frac{1}{2}} \Big(J_{x,t}(0) \Big)^{\frac{1}{2}}.
\end{aligned}$$

Now we deduce (3.6) and hence $(3.10)_1$ from Lemma 3.1 and (3.11).

We now observe that $J_{x,t}(k)$ is jointly convex in (x,k) since X is affine in k and x, and both the set $V[0,T]$ and the function f are convex; i.e.,

$$J_{\lambda x + (1-\lambda)y, t}(\lambda k + (1-\lambda)k') \le \lambda J_{x,t}(k) + (1-\lambda) J_{y,t}(k')$$

for $\lambda \in [0,1]$. Therefore, the value function $v(x,t)$ is convex in x, and hence the first inequality in (3.7) follows. In order to prove the second one we fix x, x', λ, t, k, and we denote by X_s^x, $X_s^{x+\lambda x'}$, and $X_s^{x-\lambda x'}$ the processes controlled by k and starting at time t from x, $x+\lambda x'$, and $x-\lambda x'$, respectively. Then we have

$$\begin{aligned}
&v(x+\lambda x',t) + v(x-\lambda x',t) - 2v(x,t) \\
&\le \sup_{k \in V[0,T]} E\Big\{ \int_t^T \big(f(X_s^{x+\lambda x'}) + f(X_s^{x-\lambda x'}) - 2f(X_s^x)\big) e^{-\rho(s-t)} ds \Big\}.
\end{aligned}$$

But (2.2) implies

$$X_s^{x+\lambda x'} = X_s^x + \lambda e^{b(s-t)} x',$$

hence from

$$(z_1 + \lambda z_2)^2 + (z_1 - \lambda z_2)^2 - 2{z_1}^2 = 2\lambda^2 {z_2}^2, \qquad z_1, z_2, \lambda \in \mathbb{R},$$

we have

$$\begin{aligned}
&v(x+\lambda x',t) + v(x-\lambda x',t) - 2v(x,t) \\
&\le \lambda^2 (1+\nu) \int_t^T \|e^{b(s-t)}\|^2 e^{-\rho(s-t)} ds
\end{aligned}$$

since $|x'| \le 1$. Now (3.7) and $(3.10)_2$ follow.

Let $t \in (0,T)$ and $h > 0$ such that $t + h \le T$; denote by X_s^t and X_s^{t+h} the processes controlled by k and starting from x at time t and $t+h$, respectively. Then it is easy to check that

$$X_{t+h+s}^{t+h} = X_{t+s}^t \quad \text{a.s.}$$

for all $s \in [0, T-(t+h)]$. Therefore it follows that

$$v(x,t+h) - v(x,t) \le \sup_{k \in V[0,T]} E\Big\{ \int_{T-h}^{T} -\frac{1}{2}[\nu(X_{1,s}^t)^2 + (X_{2,s}^t)^2] e^{-\rho(s-t)} ds \Big\} \le 0;$$

i.e., (3.8) holds.

On the other hand, if $h > 0$ is such that $0 \le t-h$ and if $X_s^{0,t-h}$ is the uncontrolled process (i.e., $k = 0$) starting at time $t-h$ from x, then for every $t-h \le s \le T$ we have

$$v(x,t-h) \le E\Big\{ \int_{t-h}^{s} f(X_r^{0,t-h}) e^{-\rho(r-t+h)} dr + v(X_s^{0,t-h}, s) e^{-\rho(s-t+h)} \Big\},$$

and hence, using (3.1),

$$\begin{aligned} &v(x,t-h) - v(x,t) \\ &\le E\Big\{ \int_{t-h}^{t} f(X_r^{0,t-h}) e^{-\rho(r-t+h)} dr \Big\} + E\Big\{ v(X_t^{0,t-h}, t) e^{-\rho h} - v(x,t) \Big\} \\ &\le \int_{t-h}^{t} C(1+|x|^2) e^{-\rho(r-t+h)} dr + E\Big\{ v(X_t^{0,t-h}, t) e^{-\rho h} - v(x,t) \Big\}. \end{aligned}$$

But for $t \in [0,T]$ fixed we have already shown that $v(\cdot\,,t)$ is a continuous function of polynomial growth whose partial derivatives $v_{x_i}(\cdot\,,t)$ and $v_{x_i x_j}(\cdot\,,t)$ are in $L^p_{\mathrm{loc}}(\mathbb{R}^2)$; that is, $v(\cdot\,,t) \in W^{2;p}_{\mathrm{loc}}(\mathbb{R}^2)$ for any p finite. Hence a generalized Ito's formula holds for $v(\cdot\,,t) e^{-\rho(s-t+h)}$ (cf. [10] or [18]) and we have

$$\begin{aligned} E\Big\{ v(X_t^{0,t-h}, t) e^{-\rho h} - v(x,t) \Big\} &= \int_{t-h}^{t} E\Big\{ \mathcal{L} v(X_r^{0,t-h}, t) \Big\} e^{-\rho(r-t+h)} dr \\ &\le C \int_{t-h}^{t} E\Big\{ 1 + |X_r^{0,t-h}|^2 \Big\} e^{-\rho(r-t+h)} dr \end{aligned}$$

due to the estimates (3.5), $(3.10)_1$, and $(3.10)_2$. Note that in the above, we consider v only as a function of x! Finally, we use (3.1) to obtain

$$E\Big\{ v(X_t^{0,t-h}, t) e^{-\rho h} - v(x,t) \Big\} \le C(1+|x|^2) h,$$

and we conclude that

$$v(x,t-h) - v(x,t) \le C(1+|x|^2) h,$$

and hence $(3.10)_3$ also follows. Finally, the Hölder continuity of v and v_{x_i} follows from an imbedding theorem concerning the space $W^{2,1;p}(\Omega_N)$ with $p > 4$ (cf. [19, Lemma II-3.3, p. 80]). □

4. Penalization. In order to obtain a variational formulation of the problem (P) we introduce a penalized problem as follows. Let β be a $C^\infty(\mathbb{R})$, convex, nondecreasing function such that $\beta(r) = 0$ for $r \le 0$, $\beta(r) > 0$ for $r \in (0,1)$, and $\beta(r) = 2r - 1$ for $r \ge 1$. Then for every $\varepsilon > 0$, the set

$$U^\varepsilon = \Big\{(\eta,\xi) \in \mathbb{R}\times[0,\infty) : |\eta|\theta - \frac{1}{\varepsilon}\beta(\theta(\theta+2)) \le \xi \le \frac{1}{\varepsilon} \text{ for all } \theta \ge 0\Big\} \tag{4.1}$$

is convex and compact. We denote by $V^\varepsilon[0,T]$ the set of all measurable, $\mathcal{F}_s$-adapted processes $(\eta,\xi) : [0,T] \to U^\varepsilon$, and we consider the penalized problem

$$v^\varepsilon(x,t) = \inf\Big\{J^\varepsilon_{x,t}(\eta,\xi) : (\eta,\xi) \in V^\varepsilon[0,T]\Big\}, \tag{P^ε}$$

where

$$J^\varepsilon_{x,t}(\eta,\xi) = E\Big\{\int_t^T \big[f(X_s) + |\eta_{s-t}| + \xi_{s-t}\big]e^{-\rho(s-t)}ds\Big\} \tag{4.2}$$

and X_s is the diffusion determined by the stochastic differential equation

$$\begin{cases} dX_s = (a + bX_s + e_1\,\eta_{s-t})ds + \sigma dW_{s-t}, & s \in (t,T], \\ X_t = x. \end{cases} \tag{4.3}$$

Since X is affine in η and x, the cost $J^\varepsilon_{x,t}(\eta,\xi)$ is simultaneously convex in (η,ξ) and x; i.e.,

$$J^\varepsilon_{\lambda x+(1-\lambda)y,t}(\lambda(\eta,\xi) + (1-\lambda)(\eta',\xi')) = \lambda J^\varepsilon_{x,t}(\eta,\xi) + (1-\lambda)J^\varepsilon_{y,t}(\eta',\xi')$$

for $\lambda \in [0,1]$. Hence the value function $v^\varepsilon(x,t)$ is convex in x.

Estimates analogous to those of Theorem 3.2 hold for v^ε uniformly in ε as stated in the following theorem.

THEOREM 4.1. *There exists a positive constant C such that for every $\varepsilon > 0$, for every $\lambda \in (0,1)$, and for all x, x' in $\mathbb{R}^2$, $|x'| \le 1$, and t in $[0,T]$, $h > 0$, one has*

$$0 \le v^\varepsilon(x,t) \le C(1 + |x|^2); \tag{4.4}$$

$$|v^\varepsilon(x,t) - v^\varepsilon(x+x',t)| \le C(1 + |x| + |x'|)|x'|; \tag{4.5}$$

$$0 \le v^\varepsilon(x+\lambda x',t) + v^\varepsilon(x-\lambda x',t) - 2v^\varepsilon(x,t) \le C\lambda^2; \tag{4.6}$$

$$v^\varepsilon(x,t+h) - v^\varepsilon(x,t) \le 0, \qquad h \in (0, T-t]; \tag{4.7}$$

$$v^\varepsilon(x,t-h) - v^\varepsilon(x,t) \le C(1+|x|^2)h, \qquad h \in (0,t]. \tag{4.8}$$

Hence $v^\varepsilon(x,t)$ is convex in x, nonincreasing in t, and $v^\varepsilon \in W^{2,1;\infty}_{\mathrm{loc}}(\mathbb{R}^2 \times (0,T))$ with

$$|v^\varepsilon_{x_i}(x,t)| \le C(1+|x|), \quad |v^\varepsilon_{x_ix_j}(x,t)| \le C, \quad |v^\varepsilon_t(x,t)| \le C(1+|x|^2) \tag{4.9}$$

a.s. in $\mathbb{R}^2 \times [0,T]$. In particular, $v^\varepsilon, v^\varepsilon_{x_i} \in C(\mathbb{R}^2 \times (0,T))$, $i,j = 1,2$.

Moreover, for each initial condition $(x,t) \in \mathbb{R}^2 \times [0,T]$,

$$\lim_{\varepsilon \to 0+} v^\varepsilon(x,t) = v(x,t). \tag{4.10}$$

Proof. The properties (4.4)–(4.9) can be proved by using arguments similar to those employed in the proof of (3.5)–(3.10).

The pointwise convergence (4.10) is obtained as follows. Since $\xi \geq 0$, then $v^\varepsilon(x,t) \geq v(x,t)$ for every $\varepsilon > 0$ and every $(x,t) \in \mathbb{R}^2 \times [0,T]$. On the other hand, as in [7, Theorem 2.2], one can check that

$$v(x,t) = \inf\Big\{J_{x,t}(k) : k \text{ Lipschitz continuous in } [0,T]\Big\};$$

therefore, for every $\delta > 0$ there exists a Lipschitz continuous control $k_s = \int_0^s \eta_r dr$ in $V[0,T]$ such that

$$J_{x,t}(k) \leq v(x,t) + \frac{\delta}{2}.$$

Then by taking $\xi_s = \frac{\delta}{2}\rho(1 - e^{-\rho(T-t)})^{-1}$ for all $s \in [0,T]$, we can find $\varepsilon_\circ > 0$ such that

$$\begin{cases} (\eta_s, \xi_s) \in U^\varepsilon, \\ J^\varepsilon_{x,t}(\eta,\xi) = J_{x,t}(k) + \dfrac{\delta}{2} \leq v(x,t) + \delta \end{cases}$$

for all $\varepsilon < \varepsilon_\circ$. Thus $v^\varepsilon(x,t) \leq v(x,t) + \delta$ for all $\varepsilon < \varepsilon_\circ$ and (4.10) is proved. □

It can be shown that the Hamilton–Jacobi–Bellman equation for the (P^ε)-problem is

$$-v^\varepsilon_t - \mathcal{L}v^\varepsilon + \rho v^\varepsilon + \frac{1}{\varepsilon}\beta([v^\varepsilon_{x_1}]^2 - 1) = f \tag{4.11}$$

with the boundary condition

$$v^\varepsilon(x,T) = 0 \qquad \forall x \in \mathbb{R}^2. \tag{4.12}$$

PROPOSITION 4.2. *The value function v^ε of the penalized problem (P^ε) is continuous on $\mathbb{R}^2 \times [0,T]$ and is the unique solution in $C^{2,1}_{\text{pol}}(\mathbb{R}^2 \times (0,T))$ of the Hamilton–Jacobi–Bellman equation* (4.11) *with the boundary data* (4.12).

Proof. It suffices to apply Theorem VI-6.2, Theorem VI-6.3, and Corollary VI-4.1 of [10]. □

Remark 4.3. Actually $v^\varepsilon_t, v^\varepsilon_{x_i x_j}$, $i,j = 1,2$, are locally Hölder continuous as shown in the proof of [10, Theorem VI-6.2].

PROPOSITION 4.4. *The value function v^ε is in $H^{4+\mu,(4+\mu)/2}_{\text{loc}}(\mathbb{R}^2 \times [0,T])$ for some $\mu \in (0,1)$.*

Proof. From Proposition 4.2 and Remark 4.3 it follows that

$$v^\varepsilon \in H^{2+\mu,(2+\mu)/2}_{\text{loc}}(\mathbb{R}^2 \times [0,T]);$$

therefore, if we write (4.11) as

$$-v^\varepsilon_t - \mathcal{L}v^\varepsilon + \rho v^\varepsilon = f - \frac{1}{\varepsilon}\beta([v^\varepsilon_{x_1}]^2 - 1),$$

we see that the right-hand side of the equation above is in $H^{1+\mu,(1+\mu)/2}_{\text{loc}}(\mathbb{R}^2 \times [0,T])$. Hence we may apply Theorem III-10 of [11] (with its $p = 1$) to obtain that the derivatives $v^\varepsilon_{x_i}, v^\varepsilon_{x_i x_j}, v^\varepsilon_{x_i x_j x_k}, v^\varepsilon_t, v^\varepsilon_{x_i t}$ are locally Hölder continuous; that is,

$$v^\varepsilon \in H^{3+\mu,(3+\mu)/2}_{\text{loc}}(\mathbb{R}^2 \times [0,T]).$$

So we deduce that the right-hand side above is in $H^{2+\mu,(2+\mu)/2}_{\text{loc}}(\mathbb{R}^2\times[0,T])$, and by an application of Theorem III-11 in [11] (with its $p=2$ and its $q=1$) we conclude that the derivatives $v^\varepsilon_{tt}, v^\varepsilon_{tx_i}, v^\varepsilon_{tx_ix_j}, v^\varepsilon_{x_ix_jx_kx_l}$ are locally Hölder continuous. This completes the proof. ∎

The regularity of v^ε provided by Proposition 4.4 allows us to differentiate (4.11) with respect to x_1; in fact, we have

$$\begin{cases} -u^\varepsilon_t - \mathcal{L}u^\varepsilon + (\rho - b_{11})u^\varepsilon + \dfrac{2}{\varepsilon}\beta'([u^\varepsilon]^2-1)u^\varepsilon u^\varepsilon_{x_1} = b_{21}\tilde{u}^\varepsilon + \nu x_1, \\ u^\varepsilon(x,T) = 0 \qquad \forall x\in\mathbb{R}^2, \end{cases} \tag{4.13}$$

where we have set

$$u^\varepsilon = v^\varepsilon_{x_1} \quad \text{and} \quad \tilde{u}^\varepsilon = v^\varepsilon_{x_2}. \tag{4.14}$$

We will now show that (P^ε) provides an approximation (in some sense) of the original problem (P), and hence we obtain some regularity of the derivatives $v_{x_i}(x,t)$ of the value function.

PROPOSITION 4.5. *There exists a sequence $\{\varepsilon_n\}_{n\in\mathbb{N}}$, $\varepsilon_n\downarrow 0$ as $n\to\infty$, such that if $u^n := u^{\varepsilon_n}$ and $\tilde{u}^n := \tilde{u}^{\varepsilon_n}$, $n\in\mathbb{N}$, then*

$$\begin{cases} \lim\limits_{n\to\infty} u^n = v_{x_1} \text{ weakly in } L^2(0,T;V); \\ \lim\limits_{n\to\infty} \tilde{u}^n = v_{x_2} \text{ weakly in } L^2(0,T;V). \end{cases}$$

Proof. Thanks to the estimates (4.9), there is a constant $C>0$ such that

$$\begin{cases} \|u^\varepsilon(\cdot\,,t)\|_V \le C, \\ \|\tilde{u}^\varepsilon(\cdot\,,t)\|_V \le C \end{cases} \tag{4.15}$$

for $\varepsilon>0, t\in[0,T]$; hence $\{u^\varepsilon\}_{\varepsilon>0}, \{\tilde{u}^\varepsilon\}_{\varepsilon>0}$ lie in a bounded set in $L^\infty(0,T;V)$ which is a subset of $L^2(0,T;V)$. Therefore, there exists a sequence $\{\varepsilon_n\}_{n\in\mathbb{N}}$, $\varepsilon_n\downarrow 0$, as $n\to\infty$, such that $u^n := u^{\varepsilon_n}$ and $\tilde{u}^n := \tilde{u}^{\varepsilon_n}$ converge weakly in $L^2(0,T;V)$. But $v^{\varepsilon_n}\to v$ pointwise by (4.10), and since weak limits are unique, the weak limits of u^n and $\tilde{u}^n$ must be u and $\tilde{u}$, respectively. ∎

LEMMA 4.6. *There exists a positive constant C such that*

$$\|u^\varepsilon_t\|_{L^\infty(0,T;V')} \le C, \tag{4.16}$$

$$\|\tilde{u}^\varepsilon_t\|_{L^\infty(0,T;V')} \le C \tag{4.17}$$

for all $\varepsilon>0$.

Proof. From (4.9) it follows that $|(\mathcal{L}u^\varepsilon(\cdot\,,t),g)| \le C\|g\|_V$ for all $g\in V$, so $\|(\mathcal{L}u^\varepsilon(\cdot\,,t))\|_{V'}\le C$. Moreover, from (4.11) and (4.9), we have

$$\begin{aligned} &\left\| \frac{1}{\varepsilon}\beta([u^\varepsilon(\cdot\,,t)]^2-1)\right\|_H \\ &\qquad = \left\| f + v^\varepsilon_t(\cdot\,,t) + \mathcal{L}v^\varepsilon(\cdot\,,t) - \rho v^\varepsilon(\cdot\,,t)\right\|_H \le C \end{aligned} \tag{4.18}$$

for $t\in[0,T]$ a.e. Also, from (4.15) and $|\beta'(y)|\le 2$, it follows that

$$\|(\beta'([u^\varepsilon]^2-1)u^\varepsilon u^\varepsilon_{x_i})(\cdot\,,t)\|_H \le C,$$

thus $(\beta'([u^\varepsilon]^2-1)u^\varepsilon u^\varepsilon_{x_i})(\cdot\,,t)$ is in H and hence in V' with

$$\begin{aligned}\left\|\frac{2}{\varepsilon}(\beta'([u^\varepsilon]^2-1)u^\varepsilon u^\varepsilon_{x_i})(\cdot\,,t)\right\|_{V'} &= \sup_{\|g\|_V\le 1}\left|\left(\frac{1}{\varepsilon}\frac{\partial}{\partial x_i}\beta([u^\varepsilon(\cdot\,,t)]^2-1),g\right)\right| \\ &= \sup_{\|g\|_V\le 1}\left|-\left(\frac{1}{\varepsilon}\beta([u^\varepsilon(\cdot\,,t)]^2-1),g_{x_i}-\varphi_i g\right)\right| \\ &\le C\left\|\frac{1}{\varepsilon}\beta([u^\varepsilon(\cdot\,,t)]^2-1)\right\|_H;\end{aligned}$$

hence from (4.18)

$$\left\|\frac{2}{\varepsilon}(\beta'([u^\varepsilon]^2-1)u^\varepsilon u^\varepsilon_{x_i})(\cdot\,,t)\right\|_{V'}\le C \qquad \text{a.e. } t\in[0,T]. \tag{4.19}$$

Now (4.16) follows from (4.13).

Similarly, to prove (4.17) we differentiate (4.11) with respect to x_2 and proceed as above. □

PROPOSITION 4.7. *There exists a positive constant $C>0$ such that*

$$\begin{cases}\|v_{x_1t}\|_{L^\infty(0,T;V')}\le C,\\ \|v_{x_2t}\|_{L^\infty(0,T;V')}\le C.\end{cases} \tag{4.20}$$

Proof. Because of (4.16) there exists a sequence u^n_t converging to v_{x_1t} weak-$\star$ in $L^\infty(0,T;V')$ as $n\to\infty$, and this proves $(4.20)_1$. Similarly, from (4.17), $(4.20)_2$ follows. □

Remark 4.8. We point out that from (3.10), (4.9), and $(4.20)_1$, (4.16) follows from $v_{x_1}\in W_\circ(0,T)$ and $u^n\in W_\circ(0,T)$ for all $n\in\mathbb{N}$.

PROPOSITION 4.9. *There exists a sequence $\{\varepsilon_n\}_{n\in\mathbb{N}}$, $\varepsilon_n\downarrow 0$, as $n\to\infty$, such that if $u^n:=u^{\varepsilon_n}$, $n\in\mathbb{N}$, then*

$$\lim_{n\to\infty}u^n=v_{x_1}\quad \textit{pointwise}$$

and

$$\lim_{n\to\infty}u^n=v_{x_1}\ \textit{in}\ L^2_\pi(\mathbb{R}^2\times[0,T]).$$

Proof. For $N<\infty$, (4.9) implies that $u^n(\cdot\,,t)$ lies in a bounded set in $W^{1;\infty}(B_N)$, hence in a compact set in $H^\mu(B_N)$ for any $\mu\in(0,1)$ (by the compact imbedding of Sobolev spaces; cf. [13, Theorem 7.26]). Hence for each t, there exists a subsequence converging uniformly, and by the earlier pointwise convergence of v^n, this limit is v_{x_1}; i.e., for ϕ differentiable with support in B_N,

$$\begin{aligned}\lim_m\int_{B_N}u^{n_m}(x,t)\phi(x)dx &= -\lim_m\int_{B_N}v^{n_m}(x,t)\phi_{x_1}(x)dx\\ &= -\int_{B_N}v(x,t)\phi_{x_1}(x)dx\\ &= \int_{B_N}v_{x_1}(x,t)\phi(x)dx.\end{aligned}$$

Since the limit is unique then the whole sequence must converge to it. As N and t are arbitrary, then $u^n(x,t)\to v_{x_1}(x,t)$ pointwise. The second result now follows from (4.9). □

5. Variational formulations. We would like to obtain a variational inequality for v_{x_1} by taking limits as $\varepsilon \downarrow 0$ in (4.13), but the mixed derivatives $v_{x_i t}$ are not regular enough to allow for a strong variational formulation. We begin by showing that operator $e^{-\lambda(T-t)}v_{x_1}$ solves (uniquely, as will be seen later) a *weak* variational inequality corresponding to the coercive operator $A + \lambda$ (as defined below). General results, developed in section 7, then give a pointwise variational inequality satisfied by v_{x_1}.

We set

- $\hat{u}(x,t) = b_{21}v_{x_2}(x,t) + \nu x_1$;
- $\mathcal{K} = \{g \in V : |g(x)| \le 1 \text{ a.e.}\}$;
- $W^{\mathcal{K}}(0,T) = \{w \in W(0,T) : w(t) \in \mathcal{K} \text{ a.e. } t \in [0,T]\}$;
- $W^{\mathcal{K}}_{\lambda}(0,T) = \left\{\bar{w} \in W(0,T) : \bar{w}(t) = w(t)e^{-\lambda(T-t)} \text{ with } w \in W^{\mathcal{K}}(0,T)\right\}$;
- $\alpha = \frac{1}{2}\sigma\sigma^*$.

Note that $W^{\mathcal{K}}(0,T) \subset W_\circ(0,T)$. There exists $\eta > 0$ such that

$$\sum_{i,j=1}^{2} \alpha_{ij}\xi_i\xi_j \ge 2\eta \sum_{i=1}^{2} \xi_i^2 \qquad \forall \xi_1, \xi_2 \in \mathbb{R}, \tag{5.1}$$

since, by assumption, $\sigma\sigma^*$ is positive definite.

We define the operator $A : V \times V_\circ \to \mathbb{R}$ by setting

$$\begin{aligned} A(g,h) = &\sum_{i,j=1}^{2} \alpha_{ij}(g_{x_i}, h_{x_j} - \varphi_j\, h) \\ &- \sum_{i=1}^{2}([a+bx]_i\, g_{x_i}, h) + (\rho - b_{11})(g,h), \end{aligned} \tag{5.2}$$

where the subscript "i" refers to the ith component (notice that if $g(x)$ is smooth, then $A(g,h) = \langle -\mathcal{L}g + (\rho - b_{11})g, h\rangle$ for every $h \in V_\circ$). Obviously, $h \in V_\circ$ is required to make sense of the second term on the right-hand side above; however, that term can still be defined for $h = g \in V$ by an integration by parts, since

$$\begin{aligned} -([a+bx]_i\, g_{x_i}, g) &= (g, [a+bx]_i\, g_{x_i} + \{b_{ii} - [a+bx]_i\, \varphi_i\}g) \\ &= \frac{1}{2}(\{b_{ii} - [a+bx]_i\, \varphi_i\}g, g) \end{aligned}$$

and $\{b_{ii} - [a+bx]_i\, \varphi_i\}$ is bounded. So $A(g,g)$ is well defined in V and given by

$$\begin{aligned} A(g,g) = &\sum_{i,j=1}^{2} \alpha_{ij}(g_{x_i}, g_{x_j} - \varphi_j\, g) \\ &+ \frac{1}{2}\sum_{i=1}^{2}(\{b_{ii} - [a+bx]_i\, \varphi_i\}g, g) + (\rho - b_{11})(g,g). \end{aligned} \tag{5.3}$$

We begin with the following lemma.

LEMMA 5.1. *The function v_{x_1} is in $W^{\mathcal{K}}(0,T)$.*

Proof. Remark 4.8 provides us with $v_{x_1} \in W_\circ(0,T)$; we need only show that

$$v_{x_1}(\cdot\,, t) \in \mathcal{K} \qquad \text{a.e. } t \in [0,T].$$

In fact, (4.18) implies

$$\|\beta([u^n(\cdot\,,t)]^2-1)\|_H \le C\varepsilon_n \qquad \forall n\in\mathbb{N},\ \text{a.e. } t\in[0,T], \tag{5.4}$$

with u^n as in the previous section; also, β is continuous and $u^n(x,t)\to v_{x_1}(x,t)$ for almost every $t\in[0,T]$, hence

$$\lim_{n\to\infty}\beta([u^n(x,t)]^2-1)=\beta([v_{x_1}(x,t)]^2-1) \qquad \text{a.e. } t\in[0,T].$$

Finally, (4.9) implies

$$0\le\beta([u^n(x,t)]^2-1)\le 2([u^n(x,t)]^2-1)\le C(1+|x|^2);$$

therefore, we can pass to the limit in (5.4) to obtain $\|\beta([v_{x_1}(\cdot\,,t)]^2-1)\|_H^2\le 0$, and hence $v_{x_1}(\cdot\,,t)\in\mathcal{K}$ for $t\in[0,T]$ a.e. □

THEOREM 5.2. *The function $\bar v = v_{x_1}e^{-\lambda(T-t)}$ solves the weak variational inequality*

$$\begin{aligned} -\int_0^T\langle\bar w_t,\bar w-\bar v\rangle dt+\frac{1}{2}\|\bar w(T)\|_H^2+\int_0^T[A+\lambda](\bar v,\bar w-\bar v)dt \\ \ge\int_0^T e^{-\lambda(T-t)}(\hat u,\bar w-\bar v)dt \qquad \forall\bar w\in W_\lambda^{\mathcal{K}}(0,T) \end{aligned} \tag{5.5}$$

with $\bar v\in W_\lambda^{\mathcal{K}}(0,T)$.

Proof. The proof is suggested by one in [27]. Let u^n be as in the previous section, let $\bar u^n = e^{-\lambda(T-t)}u^n$, and let $\hat u^n(x,t)=b_{21}\tilde u^n(x,t)+\nu x_1$. Let $\bar w = e^{-\lambda(T-t)}w\in W_\lambda^{\mathcal{K}}(0,T)$; since integration by parts holds in $W(0,T)$, then we obtain

$$\begin{aligned} \int_0^T(\bar u_t^n,\bar w-\bar u^n)dt=\frac{1}{2}\|\bar w(0)-\bar u^n(0)\|_H^2-\frac{1}{2}\|\bar w(T)\|_H^2 \\ +\int_0^T\langle\bar w_t,\bar w-\bar u^n\rangle dt. \end{aligned} \tag{5.6}$$

Since $\bar u^n\in W_\circ(0,T)$ by Remark 4.8, we may multiply (4.13) by $e^{-\lambda(T-t)}(\bar w-\bar u^n)$ and use (5.6) to obtain

$$\begin{aligned} -\int_0^T\langle\bar w_t,\bar w-\bar u^n\rangle dt-\frac{1}{2}\|\bar w(0)-\bar u^n(0)\|_H^2+\frac{1}{2}\|\bar w(T)\|_H^2 \\ +\int_0^T[A+\lambda](\bar u^n,\bar w-\bar u^n)dt \\ +\frac{2}{\varepsilon_n}\int_0^T e^{\lambda(T-t)}(\beta'([u^n]^2-1)\bar u^n\bar u^n_{x_1},\bar w-\bar u^n)dt \\ =\int_0^T e^{-\lambda(T-t)}(\hat u^n,\bar w-\bar u^n)dt \end{aligned} \tag{5.7}$$

for all $\bar w\in W_\lambda^{\mathcal{K}}(0,T)$. Now we proceed to take limits in (5.7) as $n\to\infty$. Since $u^n\to v_{x_1}$ weakly in $L^2(0,T;V)$ as $n\to\infty$ by Proposition 4.5, then

$$\int_0^T\langle\bar w_t,\bar w-\bar u^n\rangle dt\to\int_0^T\langle\bar w_t,\bar w-\bar v\rangle dt$$

and

$$\int_0^T [A+\lambda](\bar{u}^n,\bar{w})dt \to \int_0^T [A+\lambda](\bar{v},\bar{w})dt$$

as $n\to\infty$. Also, since $\hat{u}^n \to \hat{u}$ weakly in $L^2(0,T;H)$ as $n\to\infty$ (again by Proposition 4.5) and $u^n \to v_{x_1}$ in $L^2_\pi(\mathbb{R}^2\times[0,T])$ as $n\to\infty$ (by Proposition 4.9), then as $n\to\infty$

$$\int_0^T (e^{-\lambda(T-t)}\hat{u}^n, \bar{w}-\bar{u}^n)dt \to \int_0^T (e^{-\lambda(T-t)}\hat{u}, \bar{w}-\bar{v})dt$$

and

$$\int_0^T [A-A_\circ](\bar{u}^n,\bar{u}^n)dt \to \int_0^T [A-A_\circ](\bar{v},\bar{v})dt,$$

where $A_\circ(g,g)=\sum_{i,j}\alpha_{ij}(g_{x_i},g_{x_j})+\lambda\|g\|_H^2$. Finally, since $\Big(A_\circ(g,g)\Big)^{1/2}$ defines a norm on V and $\bar{u}^n\to\bar{v}$ weakly, we have

$$\liminf_{n\to\infty} A_\circ(\bar{u}^n,\bar{u}^n) \ge A_\circ(\bar{v},\bar{v}),$$

hence

$$\liminf_{n\to\infty} A(\bar{u}^n,\bar{u}^n) \ge A(\bar{v},\bar{v}).$$

To prove (5.5) it remains only to show that the penalty term in (5.7) is nonpositive; we examine two cases.

Case 1. On $\{(x,t) : \bar{w}^2(x,t) \ge (\bar{u}^n(x,t))^2\}$ we have $(u^n(x,t))^2 \le 1$ since $w\in W^{\mathcal{K}}(0,T)$, hence

$$\beta'([u^n(x,t)]^2-1)=0.$$

Case 2. On $\{(x,t) : \bar{w}^2(x,t) < (\bar{u}^n(x,t))^2\}$ it follows that

$$\begin{cases} 2\bar{u}^n(x,t)\Big(\bar{w}(x,t)-\bar{u}^n(x,t)\Big) \le (\bar{u}^n(x,t))^2+\bar{w}^2(x,t)-2(\bar{u}^n(x,t))^2<0,\\ \beta'([u^n(x,t)]^2-1)\ge 0,\\ \bar{u}^n_{x_1}=e^{-\lambda(T-t)}v^{\varepsilon_n}_{x_1x_1}\ge 0, \end{cases}$$

since v^{ε_n} is convex by Theorem 4.1. Hence we conclude that

$$\frac{2}{\varepsilon_n}\int_0^T (\beta'([u^n]^2-1)\bar{u}^n\bar{u}^n_{x_1},\bar{w}-\bar{u}^n)dt\le 0,$$

and thus (5.5) is proved. □

The general results in section 7, i.e., Theorems 7.9 and 7.11, now imply that (5.5) has a unique solution which is related to the solution of a pointwise variational inequality; cf. Remark 7.1. In fact, we obtain the following theorem.

THEOREM 5.3. *Assume that $\rho\ge b_{11}$. Then the function v_{x_1} is the unique solution of the pointwise variational inequality*

$$\text{(5.8)}\qquad \begin{cases} v_{x_1}\in W^{2,1;6}_{\mathrm{loc}}(\mathbb{R}^2\times(0,T)),\\ -1\le v_{x_1}\le +1 \text{ a.e. in } \mathbb{R}^2\times(0,T),\ v_{x_1}(x,T)=0 \text{ a.e. in } \mathbb{R}^2,\\ -v_{x_1t}+[-\mathcal{L}+(\rho-b_{11})]v_{x_1}=\hat{u} \quad \text{if } -1<v_{x_1}(x,t)<+1,\\ -v_{x_1t}+[-\mathcal{L}+(\rho-b_{11})]v_{x_1}\le\hat{u} \quad \text{if } v_{x_1}(x,t)=+1,\\ -v_{x_1t}+[-\mathcal{L}+(\rho-b_{11})]v_{x_1}\ge\hat{u} \quad \text{if } v_{x_1}(x,t)=-1,\\ \qquad\qquad \text{a.e. in } \mathbb{R}^2\times(0,T). \end{cases}$$

6. Conclusion. The central bank singular control problem analyzed in this paper gives rise to a free boundary problem; in fact, (5.8) or (2.6) is the variational formulation of a *two-obstacle* problem determining two moving boundaries, ∂_{-1} and ∂_{+1}, which at each time t split the $\mathbb{R}^2$-plane into three regions:

- the *inflation region* $\mathbf{I_t} = \{v_{x_1}(\cdot\,, t) = -1\}$, where interest rates are so low as to produce significant inflation;
- the *inflation-output tradeoff region* $\mathbf{T_t} = \{-1 < v_{x_1}(\cdot\,, t) < +1\}$, where a sort of equilibrium is found between inflation and output growth;
- the *deflation region* $\mathbf{D_t} = \{v_{x_1}(\cdot\,, t) = +1\}$, where interest rates are too high and prevent economic expansion.

In the inflation region $\mathbf{I_t}$ it is optimal for the conservative forces of the Bank to intervene by increasing interest rates; in the inflation-output tradeoff region $\mathbf{T_t}$ the conservative and the expansionist forces of the bank find an equilibrium, and hence it is optimal for both to do nothing; finally, in the deflation region $\mathbf{D_t}$ it is optimal for the expansionist forces to intervene by lowering interest rates.

We point out that Theorem 2.1, which gives a variational problem for the original value function v, might be obtained from (4.11) by taking limits (in some sense) as $\varepsilon \to 0$; that is,

$$\begin{cases} v \in W^{2,1;\infty}_{\mathrm{loc}}(\mathbb{R}^2 \times (0,T)), \quad v(x,T) = 0 \ \text{ a.e. in } \mathbb{R}^2, \\ \max\Big\{ -v_t + [-\mathcal{L} + \rho]v - f,\ -v_{x_1} - 1,\ v_{x_1} - 1 \Big\} \le 0, \\ (-v_t + [-\mathcal{L} + \rho]v - f)(-v_{x_1} - 1)(v_{x_1} - 1) = 0, \\ \qquad\qquad \text{a.e. in } \mathbb{R}^2 \times (0,T). \end{cases} \tag{6.1}$$

Then (6.1) or (2.4) gives us some insight into the optimal control $\hat{k}$ of the original problem (P); $\hat{k}$ must be singular with respect to the Lebesgue measure as a function of time (as in [6]). In fact, by applying the dynamic programming equation we see that $\hat{k}$ should be inactive when the state is in the region $\mathbf{T_t}$, whereas it should make the state jump to a convenient point on the boundary $\partial_{-1} \cup \partial_{+1}$ when the state is in either the inflation or the deflation regions. At the boundary, the optimal control $\hat{k}$ should be active just enough to keep the process inside $\mathbf{T_t}$. Hence the resulting optimal process is a diffusion reflected at the boundary, possibly with an initial jump if the state starts in $\mathbf{I_t}$ or $\mathbf{D_t}$.

Usually the construction of $\hat{k}$ is not an easy task as it requires some regularity of the boundaries ∂_{-1} and ∂_{+1} of the *two-obstacle* problem (5.8); work in this direction is in progress.

Regarding (5.8) or (2.6) from an economics point of view, they correspond to a differential game with stopping times where the players are the conservative and the expansionist forces of the central bank whose primary target is the control of inflation. In order to interpret the evaluation function (2.8) of the game we take $b_{21} = -1$ and $\nu = 0$ for simplicity (notice that it is reasonable to take $b_{21} < 0$ since inflation decreases if interest rates increase). Suppose that the diffusion starts at time t from some point x inside $\mathbf{T_t}$; then the bank will act in such a way as to minimize $J_{x,t}(k)$. However, the conservative forces will not object to any drastic monetary policies aiming to contain inflation, whereas the expansionist forces will be unwilling to accept policies that prevent economic expansion. It is easy to see that, under the present conditions, from (5.8) it follows that

$$\begin{cases} v_{x_2}(\cdot\,, s) \ge 0 \ \text{ in } \mathbf{I_s}, \\ v_{x_2}(\cdot\,, s) \le 0 \ \text{ in } \mathbf{D_s} \end{cases}$$

for $s \in (t,T]$. But $v(\cdot\,,s)$ is convex, hence $v_{x_i}(\cdot\,,s)$ is nondecreasing in the x_i direction; this implies that $\mathbf{I_s}$ must be on the left and above $\mathbf{D_s}$ for all $s \in [0,T]$, and

$$\begin{cases} v_{x_2}(\cdot\,,s) \geq 0, & v_{x_1}(\cdot\,,s) = -1 \quad \text{in } \mathbf{I_s}, \\ v_{x_2}(\cdot\,,s) \leq 0, & v_{x_1}(\cdot\,,s) = +1 \quad \text{in } \mathbf{D_s}. \end{cases}$$

Therefore, the first player (who represents the conservative tendency of the bank) will try to keep the state out of the region $\mathbf{I_s}$, since there the value function v increases with the inflation x_2; on the other hand, the second player will not allow the state to diffuse into the region $\mathbf{D_s}$ where v increases with the interest rate x_1. Thus, knowing that the second player will select the strategic time $\hat{\theta}_2$ in order to avoid high interest rates, the first player will aim to minimize

$$E\Bigg\{ \int_0^{\theta_1 \wedge \hat{\theta}_2} v_{x_2}(Y_s^0, t+s) e^{-(\rho - b_{11})s} ds - e^{-(\rho-b_{11})\theta_1} \mathbb{I}_{\substack{\theta_1 \leq \hat{\theta}_2 \\ \theta_1 < T-t}} + e^{-(\rho-b_{11})\hat{\theta}_2} \mathbb{I}_{\hat{\theta}_2 < \theta_1 \wedge (T-t)} \Bigg\},$$

and this is exactly what Theorem 2.3 states.

There are various directions in which to continue this work. In the first instance, what can we say about the (free) boundary of $\mathbf{T_t}$? What about numerical approximations to $\mathbf{T_t}$? Now we need to estimate the parameters of the model. On a more basic level, we can ask: how realistic is the model (2.2)? Probably, the dynamics we use do not reflect reality very well—certainly other models have been used in the literature. For example, Cox, Ingersoll, and Ross [8] use a diffusion coefficient, volatility, which is not constant but is proportional to the square root of the interest/inflation rate. Also, as mentioned before, for the Canadian economy the exchange rate with the U.S. dollar is certainly important in the decision-making process of the Bank of Canada, and this should be reflected in the cost functional J.

7. Variational inequalities. We begin by establishing existence and uniqueness results for the following weak and strong variational inequalities. The weak inequality is

$$\begin{aligned} -\int_0^T \langle \bar{w}_t, \bar{w} - \bar{v} \rangle dt + \frac{1}{2}\|\bar{w}(T)\|_H^2 + \int_0^T [A + \lambda](\bar{v}, \bar{w} - \bar{v}) dt \\ \geq \int_0^T e^{-\lambda(T-t)} (\hat{u}, \bar{w} - \bar{v}) dt \qquad \forall \bar{w} \in W_\lambda^{\mathcal{K}}(0,T), \end{aligned} \tag{7.1}$$

and the strong one is

$$\begin{cases} -(\hat{v}_t(t), g - \hat{v}(t)) + A(\hat{v}(t), g - \hat{v}(t)) \\ \qquad \geq (\hat{u}(t), g - \hat{v}(t)) \qquad \text{a.e. } t \in [0,T] \quad \forall g \in \mathcal{K}, \\ \hat{v}(T) = 0. \end{cases} \tag{7.2}$$

DEFINITION 7.1. *A solution of the* strong *variational inequality* (7.2) *is a function* $\hat{v} \in L^2(0,T;V)$ *with* $\hat{v}_t \in L^2(0,T;H)$ *and* $\hat{v}(t) \in \mathcal{K}$ *for a.e.* $t \in [0,T]$, *which satisfies* (7.2).

Remark 7.1. The main result is (cf. Theorems 7.9 and 7.11) that both equations have unique solutions; moreover, the solution of (7.2) solves a pointwise variational inequality. The assumptions on $a, b, \sigma, \rho, \nu, \pi, \phi$ are as before, and we assume that

$\hat{u} \in L^2(0,t;V) \cap H^{\mu,\mu/2}_{\text{loc}}(\mathbb{R}^2 \times [0,T])$ for some $\mu \in (0,1)$, $\hat{u}_t \in L^\infty(0,t;V')$, and $|\hat{u}(x,t)| \le K(1+|x|)$ for some constant K. Observe that our previously defined $\hat{u} = b_{21}v_{x_2} + \nu x_1$ satisfies these hypotheses (cf. Theorem 3.2 and Propositions 4.5 and 4.7), hence Theorem 5.2 implies that the unique solution of (7.1) is $e^{-\lambda(T-t)}v_{x_1}$ and the unique solution of (7.2) and (5.8) is v_{x_1}.

DEFINITION 7.2. *The operator A is said to be weakly coercive in V if there exists $\eta > 0$ and $\lambda \ge 0$ such that*

$$A(g,g) \ge \eta \|g\|_V^2 - \lambda \|g\|_H^2 \qquad \forall g \in V. \tag{7.3}$$

It is easy to see that A as defined in (5.2) is weakly coercive in V. This property gives uniqueness.

PROPOSITION 7.2. *The weak variational inequality* (7.1) *has at most one solution* $\bar{v} \in W^{\mathcal{K}}_\lambda(0,T)$.

Proof. We use an idea due to Bensoussan and Lions [2]. Let $\bar{u} = e^{-\lambda(T-t)}u$ and $\bar{z} = e^{-\lambda(T-t)}z$ be two solutions of (7.1), set $\tilde{w} = e^{-\lambda(T-t)}w$ where

$$w = \frac{1}{2}(u+z) \in \mathcal{K},$$

and let w_q be the solution of

$$\begin{cases} -q\dot{w}_q + w_q = w, \\ w_q(T) = 0, \end{cases}$$

where "$\cdot$" denotes the derivative with respect to time. Solving for w_q we notice that $w_q(t) \in \mathcal{K}$ since $\mathcal{K}$ is convex and $0 \in \mathcal{K}$. Hence $w_q \in W^{\mathcal{K}}(0,T)$ and

$$\lim_{q \downarrow 0} w_q(t) = \lim_{q \downarrow 0} \int_0^{(T-t)/q} w(t+qs)e^{-s}ds = w(t)$$

since $W(0,T) \subset C([0,T];H)$. Thus $\bar{w}_q := e^{-\lambda(T-t)}w_q \in W^{\mathcal{K}}_\lambda(0,T)$.

We take $\bar{w} = \bar{w}_q$ in (7.1) for $\bar{u}$ and $\bar{z}$ and add to obtain

$$\begin{aligned} -2\int_0^T \left\langle \frac{\bar{w}_q - \tilde{w}}{q} + \lambda \bar{w}_q, \bar{w}_q - \tilde{w} \right\rangle dt + \int_0^T [A+\lambda](\bar{u}, \bar{w}_q - \bar{u})dt \\ + \int_0^T [A+\lambda](\bar{z}, \bar{w}_q - \bar{z})dt \\ \ge 2\int_0^T e^{-\lambda(T-t)}(\hat{u}, \bar{w}_q - \tilde{w})dt, \end{aligned}$$

hence

$$\begin{aligned} &\int_0^T \Big\{ [A+\lambda](\bar{u}, \bar{w}_q - \bar{u}) + [A+\lambda](\bar{z}, \bar{w}_q - \bar{z}) \Big\} dt \\ &\ge 2\int_0^T e^{-\lambda(T-t)}(\hat{u}, \bar{w}_q - \tilde{w})dt + 2\lambda \int_0^T (\bar{w}_q, \bar{w}_q - \tilde{w})dt. \end{aligned}$$

As $q \downarrow 0$, the right-hand side converges to zero and the left to

$$\int_0^T \Big\{ [A+\lambda](\bar{u}, \tilde{w} - \bar{u}) + [A+\lambda](\bar{z}, \tilde{w} - \bar{z}) \Big\} dt = -\frac{1}{2}\int_0^T [A+\lambda](\bar{u} - \bar{z}, \bar{u} - \bar{z})dt.$$

Therefore, (7.3) implies

$$\frac{1}{2}\int_0^T \eta\|\bar{u}-\bar{z}\|_V^2 dt \le 0,$$

hence $\|\bar{u}-\bar{z}\|_V^2 = 0$ for all $t\in[0,T]$; i.e., $\bar{u}=\bar{z}$ in $W(0,T)$. ∎

LEMMA 7.3. *If $\hat{v}$ solves the strong variational inequality* (7.2) *then $e^{-\lambda(T-t)}\hat{v}$ solves the weak variational inequality* (7.1). *Hence* (7.2) *admits at most one solution.*

Proof. The last result follows by Proposition 7.2. Let $\hat{v}$ be a solution of (7.2) and $\bar{v}=e^{-\lambda(T-t)}\hat{v}$. Then $\bar{v}$ is a solution of

$$\begin{cases} -(\bar{v}_t(t),\bar{g}-\bar{v}(t))+[A+\lambda](\bar{v}(t),\bar{g}-\bar{v}(t)) \\ \qquad \ge (\hat{u}(t)e^{-\lambda(T-t)},\bar{g}-\bar{v}(t)) \qquad \text{a.e. } t\in[0,T] \quad \forall \bar{g}=e^{-\lambda(T-t)}\mathcal{K}, \\ \bar{u}(T)=0. \end{cases}$$

If $\bar{w}\in W_\lambda^{\mathcal{K}}(0,T)$, then $\bar{w}(t)\in\mathcal{K}$ for almost every $t\in[0,T]$ and hence

$$\begin{aligned} -(\bar{v}_t(t),\bar{w}(t)-\bar{v}(t))+[A+\lambda](\bar{v}(t),\bar{w}(t)-\bar{v}(t)) \\ \ge (\hat{u}(t),\bar{w}(t)-\bar{v}(t)) \qquad \text{a.e. } t\in[0,T]. \end{aligned}$$

By integrating over $[0,T]$ and after an integration by parts on the first term, it follows that

$$\begin{aligned} -\int_0^T \langle \bar{w}_t(t),\bar{w}(t)-\bar{v}(t)\rangle dt+\frac{1}{2}\|\bar{w}(T)\|_H^2-\frac{1}{2}\|\bar{w}(0)-\bar{v}(0)\|_H^2 \\ +\int_0^T [A+\lambda](\bar{v}(t),\bar{w}(t)-\bar{v}(t))dt \\ \ge \int_0^T (\hat{u}(t),\bar{w}(t)-\bar{v}(t))dt. \end{aligned}$$

But $\|\bar{w}(0)-\bar{v}(0)\|_H^2\ge 0$ may be dropped to obtain (7.1). ∎

To establish existence of solutions of (7.2) we start by penalizing (7.2). Let $\zeta:\mathbb{R}\to\mathbb{R}$ be defined by $\zeta(r)=(r-1)^+-(r+1)^-$ for $r\in\mathbb{R}$; then ζ is monotone nondecreasing, Lipschitz, and piecewise linear. Also,

$$|r|\ge|\zeta(r)| \qquad \forall r\in\mathbb{R},$$

and hence $r\zeta(r)\ge\zeta^2(r)\ge 0$ for all $r\in\mathbb{R}$, and

$$\zeta'(r)=\mathbb{I}_{\{|r|>1\}} \qquad \forall r\in\mathbb{R}.$$

Then, for every $\varepsilon>0$, we look for a solution $w^\varepsilon\in W_\circ(0,T)$ of the penalized problem

$$\begin{cases} -(w_t^\varepsilon(t),g)+A(w^\varepsilon(t),g)+\dfrac{1}{\varepsilon}(\zeta(w^\varepsilon(t)),g)=(\hat{u}(t),g) \\ \qquad\qquad \text{a.e. } t\in[0,T] \quad \forall g\in V_\circ, \\ w^\varepsilon(T)=0. \end{cases} \tag{7.4}$$

PROPOSITION 7.4. *For every $\varepsilon>0$ there exists at most one solution w^ε in $W_\circ(0,T)$ of the penalized problem* (7.4).

Proof. This follows from the monotonicity of ζ and is similar to the proof in [2, Theorem 2.3, p. 239]. ∎

We now turn to the proof of existence of a solution of (7.4). Due to the lack of a priori bounds of the type (4.9), we take care of the linear-in-x term in A by regularization, and by Galerkin's method we prove (cf. Proposition 8.3) the following proposition.

PROPOSITION 7.5. *There exists a solution $w^\varepsilon \in W(0,T)$ of the penalized variational problem* (7.4). *Moreover, the estimates*

$$\begin{cases} \|w^\varepsilon\|^2_{L^\infty(0,T;H)} + \|w^\varepsilon\|^2_{L^2(0,T;V)} \le C, \\ \|w^\varepsilon_t\|^2_{L^\infty(0,T;H)} + \|w^\varepsilon_t\|^2_{L^2(0,T;V)} \le C, \\ \dfrac{1}{\sqrt{\varepsilon}}\|\zeta(w^\varepsilon)\|_{L^2(0,T;H)} \le C \end{cases} \tag{7.5}$$

hold uniformly in $\varepsilon > 0$.

In order to show that the function w^ε is in $W_\circ(0,T)$ (i.e., $w^\varepsilon(\cdot\,,t) \in V_\circ$ for almost all $t \in [0,T]$), we obtain a bound for w^ε from the pointwise version of (7.4); i.e.,

$$\begin{cases} -\tilde w^\varepsilon_t(x,t) + [-\mathcal{L} + (\rho - b_{11})]\tilde w^\varepsilon(x,t) + \dfrac{1}{\varepsilon}\zeta(\tilde w^\varepsilon(x,t)) = \hat u(x,t) \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \text{a.e. } (x,t) \in \mathbb{R}^2 \times [0,T], \\ \tilde w^\varepsilon(x,T) = 0. \end{cases} \tag{7.6}$$

We will show that (7.6) has a solution $\tilde w^\varepsilon \in H^{2+\mu,(2+\mu)/2}_{\rm loc}$; since any solution of (7.6) is also a solution of (7.4), and this has a unique solution, then $\tilde w^\varepsilon = w^\varepsilon$. However, the pointwise formulation (7.6) will only allow an estimate uniform in ε on the function itself, so we still need the estimates (7.5) and hence the lengthy Galerkin approach for convergence proofs as $\varepsilon \to 0$.

THEOREM 7.6. *For every $\varepsilon > 0$ the function w^ε is a solution of the penalized problem* (7.6) *with $w^\varepsilon \in H^{2+\mu,(2+\mu)/2}_{\rm loc}$ and*

$$|w^\varepsilon(x,t)| \le K(1+|x|) \qquad \text{a.e. in } \mathbb{R}^2 \times [0,T], \tag{7.7}$$

K independent of $\varepsilon > 0$.

Proof. It suffices to show that (7.6) admits a solution $\tilde w^\varepsilon$ enjoying not only the properties above but also $\tilde w^\varepsilon \in W(0,T)$ (see (7.4)); then $\tilde w^\varepsilon = w^\varepsilon$ by uniqueness (cf. Proposition 7.4). Our proof is a modification of one found in [2, Theorem 5.1, p. 464].

We start by taking care of the unbounded coefficients in (7.6), so for every $N \in \mathbb{N}$ and $r \in \mathbb{R}$ we define $\chi^N(r) = N\mathbb{I}_{\{r \ge N\}} - N\mathbb{I}_{\{r \le -N\}}$ and $\chi^N(x) = (\chi^N(x_1), \chi^N(x_2))$ for $x = (x_1, x_2) \in \mathbb{R}^2$, so $|\chi^N(x)|^2 \le 2N^2$. We denote by $\mathcal{L}^N$ the operator $\mathcal{L}$ with $(a + bx)$ replaced by $(a + b\chi^N(x))$. Then, since $\hat u(x,t) \le C(1+|x|)$, we take care of the unbounded right-hand side of (7.6) by the change of variable $\tilde z(x,t) = e^{-\beta t}(1 + |x|^2)^{-1/2} z(x,t)$ with $\beta < 0$ to be chosen later. So we have

$$-\tilde z_t + [-\tilde{\mathcal{L}}^N + (\rho - b_{11})]\tilde z = e^{-\beta t}(1+|x|^2)^{-1/2}\{-z_t + [-\mathcal{L}^N + (\rho - b_{11})]z\}$$

with $\tilde{\mathcal{L}}^N \tilde z := \mathcal{L}^N \tilde z - 2\sum_{i,j}\alpha_{ij}x_i(1+|x|^2)^{-1}\tilde z_{x_j} + E(x)\tilde z$, the bounded function $E(x)$ being given by

$$E(x) := -\mathrm{trace}[\alpha](1+|x|^2)^{-1} + x^*\alpha x(1+|x|^2)^{-2} - (a + b\chi^N(x)) \cdot x(1+|x|^2)^{-1} - \beta.$$

Let $C_b(\Omega)$ denote the space of bounded, continuous functions on Ω with sup norm. So with

$$\begin{cases} \tilde u(x,t) := \hat u(x,t)e^{-\beta t}(1+|x|^2)^{-1/2} \in C_b(\mathbb{R}^2 \times [0,T]), \\ \tilde f^\varepsilon := \tilde u(x,t) + \dfrac{1}{\varepsilon}\dfrac{[2e^{\beta t}(1+|x|^2)^{1/2}\tilde\varphi - \zeta(e^{\beta t}(1+|x|^2)^{1/2}\tilde\varphi)]}{e^{\beta t}(1+|x|^2)^{1/2}} \end{cases}$$

for every $\tilde{\varphi} \in C_b(\mathbb{R}^2 \times [0,T])$, we seek a solution of

$$\begin{cases} -\tilde{z}_t^N(x,t) + [-\tilde{\mathcal{L}}^N + (\rho - b_{11})]\tilde{z}^N(x,t) + \dfrac{2}{\varepsilon}\tilde{z}^N = \tilde{f}^\varepsilon \\ \qquad\qquad\qquad\qquad \text{a.e. } (x,t) \in \mathbb{R}^2 \times [0,T], \\ \tilde{z}(x,T) = 0. \end{cases} \tag{7.8}$$

But $\tilde{f}^\varepsilon$ is in $L^2(0,T;H) \cap L^p(0,T;L^p_\pi(\mathbb{R}^2))$, hence there exists a unique solution $\tilde{z}^N$ of (7.8) in $L^2(0,T;V)$; moreover,

$$\tilde{z}^N \in L^p(0,T;L^p_\pi(\mathbb{R}^2)) \cap L^\infty(0,T;V) \cap W^{2,1;p}_{\text{loc}}(\mathbb{R}^2 \times [0,T]),$$

and for every bounded open set $G \subset \mathbb{R}^2 \times [0,T]$ and every open subset $G' \subset\subset G$:

$$\|\tilde{z}^N\|_{W^{2,1;p}(G')} \le C(\|\tilde{z}^N\|_{L^p(G)} + \|\tilde{f}^\varepsilon\|_{L^p(G)}), \tag{7.9}$$

where the constant C is independent of N and depends only on G, G', and the bounds of the coefficients of $[-\mathcal{L} + (\rho - b_{11})] + \frac{2}{\varepsilon}$ on G (cf. [2, Theorem 6.6, p. 134, Theorem 6.7, p. 139, Remark 6.13, p. 141, and Theorem 6.4, p. 131]). Hence, by Sobolev imbedding, $\tilde{z}^N$ is continuous.

On the other hand, the Feynman–Kac representation (cf. [3, Theorem 8.1, p. 281]) of the solution $\tilde{z}^N$ gives

$$\tilde{z}^N(x,t) = E\left\{ \int_t^T \tilde{f}^\varepsilon(y^N(s),s) e^{-\int_t^s (\rho - b_{11} + E(y^N(r)) + 2/\varepsilon)dr} ds \right\},$$

where $y^N(s)$ is the diffusion starting at time t from x and governed by the stochastic differential equation

$$dy^N = \left[a + b\chi^N(y^N) + 2\frac{\alpha y^N}{1 + |y^N|^2} \right] ds + \sigma dW_{s-t}.$$

But for β sufficiently negative (independent of N and ε) we can find $\delta > 0$ such that

$$\rho - b_{11} + E(x) \ge \delta > 0 \qquad \forall x \in \mathbb{R}^2.$$

Hence

$$\sup_{x,t} |\tilde{z}^N(x,t)| \le \|\tilde{f}^\varepsilon\|_{C_b(\mathbb{R}^2 \times [0,T])} \int_t^T e^{-(\delta + 2/\varepsilon)(s-t)} ds < \infty;$$

i.e., $\tilde{z}^N \in C_b(\mathbb{R}^2 \times [0,T])$.

Now, if $S(\tilde{\varphi}) := \tilde{z}^N$ for $\tilde{\varphi}_1, \tilde{\varphi}_2 \in C_b(\mathbb{R}^2 \times [0,T])$, then we have

$$\begin{aligned} |S(\tilde{\varphi}_1) - S(\tilde{\varphi}_2)| &\le \|\tilde{\varphi}_1 - \tilde{\varphi}_2\|_{C_b(\mathbb{R}^2 \times [0,T])} \left\{ \int_t^T \frac{2}{\varepsilon} e^{-(\delta + 2/\varepsilon)(s-t)} ds \right\} \\ &\le \frac{2}{\varepsilon} \, \frac{1}{\delta + 2/\varepsilon} \, \|\tilde{\varphi}_1 - \tilde{\varphi}_2\|_{C_b(\mathbb{R}^2 \times [0,T])} \\ &= C_{\varepsilon,\delta} \, \|\tilde{\varphi}_1 - \tilde{\varphi}_2\|_{C_b(\mathbb{R}^2 \times [0,T])} \end{aligned}$$

with $C_{\varepsilon,\delta} < 1$ independent of N. Hence $S : C_b(\mathbb{R}^2 \times [0,T]) \to C_b(\mathbb{R}^2 \times [0,T])$ is a contraction, and we denote by $\tilde{w}^{\varepsilon,N}$ its unique fixed point.

Let $\tilde{z}_0 = 0$ and $\tilde{z}_n := S(\tilde{z}_{n-1})$. Then

$$\|\tilde{z}_n\|_{C_b(\mathbb{R}^2\times[0,T])} = \left\| \sum_{i=1}^{n} (\tilde{z}_i - \tilde{z}_{i-1}) \right\|_{C_b(\mathbb{R}^2\times[0,T])} \le \frac{1}{1 - C_{\varepsilon,\delta}} \|\tilde{z}_1\|_{C_b(\mathbb{R}^2\times[0,T])}.$$

But

$$\begin{aligned}\|\tilde{z}_1\|_{C_b(\mathbb{R}^2\times[0,T])} &= \left\| E\left\{ \int_t^T \tilde{u}(y^N(s), s) e^{-\int_t^s (\rho - b_{11} + E(y^N(r)) + 2/\varepsilon) dr} ds \right\} \right\|_{C_b} \\ &\le \|\tilde{u}\|_{C_b(\mathbb{R}^2\times[0,t])} \int_t^T e^{-(\delta + 2/\varepsilon)(s-t)} ds,\end{aligned}$$

which implies

$$\|\tilde{z}_n\|_{C_b(\mathbb{R}^2\times[0,T])} \le \frac{1}{\delta} \|\tilde{u}\|_{C_b(\mathbb{R}^2\times[0,T])} \qquad \forall n \in \mathbb{N},$$

and so also

$$\|\tilde{w}^{\varepsilon,N}\|_{C_b(\mathbb{R}^2\times[0,T])} \le \frac{1}{\delta} \|\tilde{u}\|_{C_b(\mathbb{R}^2\times[0,T])}. \tag{7.10}$$

If $w^{\varepsilon,N}(x,t) := e^{\beta t}(1 + |x|^2)^{1/2}\ \tilde{w}^{\varepsilon,N}(x,t)$, then $w^{\varepsilon,N}$ is a continuous function verifying the polynomial growth condition

$$|w^{\varepsilon,N}(x,t)| \le K(1 + |x|) \qquad \forall (x,t) \in \mathbb{R}^2 \times [0,T]$$

with the constant K independent of ε and N. Moreover, $w^{\varepsilon,N}$ satisfies

$$\begin{cases} -w_t^{\varepsilon,N}(x,t) + [-\mathcal{L}^N + (\rho - b_{11})] w^{\varepsilon,N}(x,t) = \hat{u}(x,t) - \dfrac{1}{\varepsilon} \zeta(w^{\varepsilon,N}(x,t)) \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \text{a.e. } (x,t) \in \mathbb{R}^2 \times [0,T], \\ w^{\varepsilon,N}(x,T) = 0, \end{cases}$$

and

$$\left| \left(\hat{u} - \frac{1}{\varepsilon} \zeta(w^{\varepsilon,N}) \right)(x,t) \right| \le C \left(1 + \frac{1}{\varepsilon} \right) (1 + |x|).$$

Therefore, (7.9) implies (cf. [10, $(E.9)$, p. 207])

$$\begin{aligned}\|w^{\varepsilon,N}\|_{H^{1+\mu,(1+\mu)/2}(G')} &\le C_1 \|w^{\varepsilon,N}\|_{W^{2,1;p}(G')} \\ &\le C \left(\|w^{\varepsilon,N}\|_{L^p(G)} + \left\| \hat{u} - \frac{1}{\varepsilon} \zeta(w^{\varepsilon,N}) \right\|_{L^p(G)} \right) \le K_\varepsilon\end{aligned}$$

for $p > 4, \mu = 1 - \frac{4}{p}, C_1 = C_1(G', p), K_\varepsilon = K_\varepsilon(G, G')$, and G, G' bounded open subsets of $\mathbb{R}^2 \times [0,T]$ with $G' \subset\subset G$. Hence $w^{\varepsilon,N}$ is locally Hölder continuous in $\mathbb{R}^2 \times [0,T]$.

Now let $Q_0 \subset\subset Q$ be bounded open sets in $\mathbb{R}^2$ and let $\psi(x)$ be a smooth function with compact support in Q such that $\psi(x) = 1$ on Q_0. Then the function $w^{\varepsilon,N}(x,t)\psi(x)$ satisfies

$$\begin{cases} -\Big(w^{\varepsilon,N}(x,t)\psi(x) \Big)_t + [-\mathcal{L}^N + (\rho - b_{11})] \Big(w^{\varepsilon,N}(x,t)\psi(x) \Big) \\ \qquad = \hat{u}(x,t)\psi(x) - \dfrac{1}{\varepsilon} \zeta(w^{\varepsilon,N}(x,t))\psi(x) \\ \qquad + g\Big(x, \psi_{x_i}(x) w^{\varepsilon,N}(x,t), \psi_{x_i}(x) w_{x_j}^{\varepsilon,N}(x,t), \psi_{x_i x_j}(x) w^{\varepsilon,N}(x,t) \Big) \\ \qquad\qquad\qquad\qquad \text{a.e. } (x,t) \in Q \times [0,T], \\ w^{\varepsilon,N}(x,T)\psi(x) = 0, \end{cases}$$

with the right-hand side Hölder continuous. Hence (cf. [19, Theorem 5.1, p. 320]) $w^{\varepsilon,N}\psi \in H^{2+\mu,(2+\mu)/2}(\mathbb{R}^2 \times [0,T])$, and so also

$$w^{\varepsilon,N} \in H^{2+\mu,(2+\mu)/2}(\bar{Q_0} \times [0,T]).$$

Then, by [19, Theorem 10.1, p. 351], for all G, G' bounded open subsets of $\mathbb{R}^2 \times [0,T]$ with $G' \subset\subset G$ we also have

$$\|w^{\varepsilon,N}\|_{H^{2+\mu,(2+\mu)/2}(G')} \le K\Big(\Big\|\hat{u} - \frac{1}{\varepsilon}\zeta(w^{\varepsilon,N})\Big\|_{H^{\mu,\mu/2}(G)} + \|w^{\varepsilon,N}\|_{H^{\mu,\mu/2}(G)}\Big) \le K_\varepsilon$$

for all $N \in \mathbb{N}$ (since $\hat{u}$, $w^{\varepsilon,N}$ are locally Hölder continuous, ζ is Lipschitz continuous) and the Hölder norm above is independent of N. Thus, $\{w^{\varepsilon,N}\}_{N\in\mathbb{N}}$ lies in a compact subset of $H^{2+\mu',(2+\mu')/2}(G')$ with $\mu' < \mu$, and hence $w^{\varepsilon,N}$ converges on G' along a subsequence; i.e., there exists $\tilde{w}^\varepsilon$ such that $w^{\varepsilon,N} \to \tilde{w}^\varepsilon$ in $H^{2+\mu',(2+\mu')/2}(G')$ as $N \to \infty$. As $G' \uparrow \mathbb{R}^2 \times [0,T]$ a standard diagonalization argument yields $w^{\varepsilon,N} \to \tilde{w}^\varepsilon$ locally uniformly in $\mathbb{R}^2 \times [0,T]$ with all the x_i-, x_ix_j-, t-derivatives. It follows that $\tilde{w}^\varepsilon$ satisfies (7.6) and the growth condition (7.7).

It remains only to show that $\tilde{w}^\varepsilon \in W(0,T)$. Let $\{\psi_n\}_{n\in\mathbb{N}}$ be a sequence of nonnegative $C^2(\mathbb{R}^2)$-functions such that $\psi_n(x) = 1$ if $|x| < n$ and $\psi_n(x) = 0$ if $|x| > n+2$, with $|(\psi_n)_{x_i}| \le 1$ and $|(\psi_n)_{x_ix_j}| \le 1$. Multiplying (7.6) by $\tilde{w}^\varepsilon(x,t)\psi_n(x)$ and integrating over $\mathbb{R}^2$ yields (after an integration by parts)

$$-\frac{d}{dt}\|\tilde{w}^\varepsilon\|^2_{H_n} + A_n(\tilde{w}^\varepsilon, \tilde{w}^\varepsilon) + \int_{\mathbb{R}^2}\Big(\frac{1}{\varepsilon}\zeta(\tilde{w}^\varepsilon) - \hat{u}\Big)\tilde{w}^\varepsilon\psi_n dx + \int_{\mathbb{R}^2}\sum_{i,j}\alpha_{ij}\tilde{w}^\varepsilon_{x_i}\tilde{w}^\varepsilon\pi\psi_n dx = 0$$

for every $t \in [0,T]$, where H_n and A_n are similar to H and A but with weight $\pi\psi_n$ rather than π. By integrating by parts in the second integral above it is easy to see that it is bounded by a constant independent of n and also of ε (thanks to the uniform growth condition (7.7)); then, by the weak coercivity of A_n, the growth condition (7.7), and the usual energy inequalities, we obtain for some K_ε independent of n

$$\int_0^T \int_{\mathbb{R}^2} (\tilde{w}^\varepsilon_{x_i})^2\pi\psi_n dx \le K_\varepsilon.$$

So, by taking limits as $n \to \infty$, the monotone convergence theorem implies

$$\int_0^T \|\tilde{w}^\varepsilon\|^2_V dt \le K_\varepsilon.$$

Finally we show $\tilde{w}^\varepsilon_t \in L^2(0,T;V')$. In fact, we multiply (7.6) by $u \in L^2(0,T;V_\circ)$ and we integrate over $[0,T]$ (notice that there is no loss of generality since $V_\circ$ is dense in V); then

$$\begin{aligned}\Big\|\int_0^T (\tilde{w}^\varepsilon_t, u)dt\Big\| &\le C\Big(1 + \frac{1}{\varepsilon}\Big)\|\tilde{w}^\varepsilon\|_{L^2(0,T;V)}\|u\|_{L^2(0,T;V)} \\ &\quad + C\|\hat{u}\|_{L^2(0,T;V)}\|u\|_{L^2(0,T;V)} \\ &\le K_1(\varepsilon)\|u\|_{L^2(0,T;V)}.\end{aligned}$$

Therefore, $\tilde{w}^\varepsilon \in W(0,T)$ follows, and so also $\tilde{w}^\varepsilon \in W_\circ(0,T)$ because of the growth condition (7.7). □

Now Propositions 7.4 and 7.5 and Theorem 7.6 imply the following theorem.

THEOREM 7.7. *For every $\varepsilon > 0$ there exists a unique solution w^ε in $W_\circ(0,T)$ of the penalized problem* (7.4).

Finally, we show the existence of a solution to the strong variational problem (7.2) by taking limits as $\varepsilon \downarrow 0$.

LEMMA 7.8. *There exists $\varepsilon_o > 0$ and a positive constant $C = C(\lambda, \hat{u})$ such that for every $\varepsilon < \varepsilon_o$*

$$\frac{1}{\varepsilon}\|\zeta(w^\varepsilon(t))\|_{L^6_\pi(\mathbb{R}^2\times[0,T])} \le C.$$

This is just Lemma 8.4 (in the Appendix) with $p = 6$.

THEOREM 7.9. *The strong variational inequality* (7.2) *has a unique solution $\hat{v}$, and $e^{-\lambda(T-t)}\hat{v}$ is the unique solution of* (7.1). *Moreover, $w^\varepsilon \to \hat{v}$ in $L^2_\pi(\mathbb{R}^2 \times (0,T))$ and weakly in $L^2(0,T;V)$.*

Proof. The bounds (7.5) imply that there exists a function $\hat{v} \in W(0,T)$ with $\hat{v}_t \in L^\infty(0,T;H)$ such that, along a subsequence,

$$\lim_{\varepsilon\downarrow 0} w^\varepsilon = \hat{v} \quad \text{ weakly in } L^2(0,T;V).$$

On the other hand, w^ε solves (7.6), i.e.,

$$-w^\varepsilon_t + [-\mathcal{L} + (\rho - b_{11})]w^\varepsilon = \hat{u}(x,t) - \frac{1}{\varepsilon}\zeta(w^\varepsilon),$$

and (8.7) implies that the right-hand side above is bounded in $L^6_\pi(\mathbb{R}^2 \times [0,T])$, uniformly in $\varepsilon < \varepsilon_0$. Hence if Q is a bounded open set in $\mathbb{R}^2$ we have

$$\left\| \hat{u} - \frac{1}{\varepsilon}\zeta(w^\varepsilon) \right\|_{L^6(Q\times[0,T])} \le C;$$

then, if G, G' are bounded open sets in $\mathbb{R}^2 \times [0,T]$ with $G' \subset\subset G$, it follows from [19, (10.12), p. 355] that

$$\|w^\varepsilon\|_{W^{2,1;6}(G')} \le C\Big(\left\| \hat{u} - \frac{1}{\varepsilon}\zeta(w^\varepsilon) \right\|_{L^6(G)} + \|w^\varepsilon\|_{L^6(G)} \Big) \le C$$

with $C = C(G)$, because of the uniform growth condition (7.7). So also (cf. [10, $(E.9)$, p. 207])

$$\|w^\varepsilon\|_{H^{1+\mu,(1+\mu)/2}(G')} \le C_1 \|w^\varepsilon\|_{W^{2,1;6}(G')} \le C_2$$

for $\mu = \frac{1}{3}, C_1 = C_1(G'), C_2 = C_2(G)$; in particular,

$$\|w^\varepsilon\|_{H^{\mu,\mu/2}(G')} \le C_2,$$

hence w^ε lies in a compact subset of $H^{\mu',\mu'/2}(G')$ with $\mu' < \mu$. This implies that (along a subsequence) w^ε converges to u uniformly in G'; thus, w^ε converges to u locally uniformly in $\mathbb{R}^2 \times [0,T]$ and hence

$$\lim_{\varepsilon\downarrow 0} w^\varepsilon = \hat{v} \quad \text{ in } L^2_\pi(\mathbb{R}^2 \times (0,T)).$$

It remains to show that $\hat{v}$ solves (7.2). Let $w \in W^{\mathcal{K}}(0,T)$; then $w(t) - w^\varepsilon(t) \in V_\circ$ a.e. $t \in [0,T]$ because of Theorem 7.7. Since the simple functions are dense in $L^2(0,T;V)$, then we may set $g = w(t) - w^\varepsilon(t)$ in (7.4) and integrate over $(t,t']$ to obtain

$$\begin{aligned} &-\int_t^{t'} (w_t(s), w(s) - w^\varepsilon(s))ds \\ &\quad + \frac{1}{2}\Big(\|w(t') - w^\varepsilon(t')\|_H^2 - \|w(t) - w^\varepsilon(t)\|_H^2\Big) \\ &\quad + \int_t^{t'} \Big[A(w^\varepsilon(s), w(s)) - A(w^\varepsilon(s), w^\varepsilon(s))\Big]ds \\ &\geq \int_t^{t'} (\hat{u}(s), w(s) - w^\varepsilon(s))ds \end{aligned} \tag{7.11}$$

after taking into account that

$$(\zeta(w^\varepsilon(t)), w(t) - w^\varepsilon(t)) = -(\zeta(w(t)) - \zeta(w^\varepsilon(t)), w(t) - w^\varepsilon(t)) \leq 0$$

because ζ is monotone nondecreasing and $\zeta(w(t)) = 0$ a.e. $t \in [0,T]$. Now, using arguments similar to those employed for the weak variational formulation (cf. Theorem 5.2), we may pass to the limit in (7.11) to obtain

$$\begin{aligned} -\int_t^{t'} (\hat{v}_t(s), w(s) - \hat{v}(s))ds + \int_t^{t'} \Big[A(\hat{v}(s), w(s)) - A(\hat{v}(s), \hat{v}(s))\Big]ds \\ \geq \int_t^{t'} (\hat{u}(s), w(s) - \hat{v}(s))ds. \end{aligned}$$

Since t and t' are arbitrary, we deduce that

$$-(\hat{v}_t(t), g - \hat{v}(t)) + A(\hat{v}(t), g) - A(\hat{v}(t), \hat{v}(t)) \geq (\hat{u}(t), g - \hat{v}(t)) \tag{7.12}$$

for all $g \in \mathcal{K}$ and almost every $t \in [0,T]$.

Also, $(7.5)_3$ implies (again along a subsequence)

$$\lim_{\varepsilon \downarrow 0} \|\zeta(w^\varepsilon)\|_{L^2(0,T;H)} = 0,$$

and, since ζ is Lipschitz, then

$$\lim_{\varepsilon \downarrow 0} \|\zeta(w^\varepsilon) - \zeta(\hat{v})\|_{L^2(0,T;H)} = 0;$$

i.e., $\zeta(\hat{v}(x,t)) = 0$ a.e., so $\hat{v} \in W^{\mathcal{K}}(0,T)$. It follows that $A(\hat{v},\hat{v})$ can be defined by (5.2), hence $A(\hat{v}(t), g) - A(\hat{v}(t), \hat{v}(t)) = A(\hat{v}(t), \hat{v}(t) - g)$ a.e., and hence $\hat{v}$ is a solution of the strong variational inequality (7.2).

Uniqueness and the remainder of the results follow from Lemma 7.3. □

The fact that the function $\hat{v}$ is the unique solution of the strong variational inequality (7.2) says nothing about the derivatives of order two, $(\hat{v})_{x_i x_j}$; however, the approximating functions w^ε and their estimates (7.5) will allow us to obtain more regularity of $\hat{v}$ and hence a variational inequality in the a.e. sense.

LEMMA 7.10. *Assume* $\rho \geq b_{11}$. *Then*

$$\hat{v} \in W^{2,1;6}_{\text{loc}}(\mathbb{R}^2 \times (0,T)). \tag{7.13}$$

Proof. From (8.7) it follows that for some constant C and for all $\varepsilon < \varepsilon_0$

$$\begin{aligned}&\| - w_t^\varepsilon + [-\mathcal{L} + (\rho - b_{11})]w^\varepsilon \|_{L^6_\pi(\mathbb{R}^2\times[0,T])}\\ &= \left\| -\frac{1}{\varepsilon}\zeta(w^\varepsilon) + \hat{u}(t) \right\|_{L^6_\pi(\mathbb{R}^2\times[0,T])} \le C,\end{aligned}$$

and after taking limits as $\varepsilon \downarrow 0$ (because of (7.5))

$$\| - \hat{v}_t + [-\mathcal{L} + (\rho - b_{11})]\hat{v} \|_{L^6_\pi(\mathbb{R}^2\times[0,T])} \le C.$$

Thus $-\hat{v}_t + [-\mathcal{L} + (\rho - b_{11})]\hat{v} := \tilde{u} \in L^6_\pi(\mathbb{R}^2 \times [0,T])$.

Observe that if ψ is a function in $C^\infty(\mathbb{R}^2)$ with compact support in B_N (for some $N \in \mathbb{N}$), then $w^\varepsilon\psi$ also satisfies (cf. (7.4))

$$\begin{cases} -(Z_t(t), g) + A(Z(t), g) \\ \qquad = (\psi[\hat{u}(t) - \frac{1}{\varepsilon}\zeta(w^\varepsilon)], g) - (w^\varepsilon \mathcal{L}\psi + 2(\nabla w^\varepsilon)^* \alpha \nabla\psi, g) \\ \qquad\qquad\qquad\qquad \text{a.e. } t \in [0,T] \quad \forall g \in V_\circ, \\ Z(T) = 0, \end{cases} \tag{7.14}$$

and taking the limit in (7.14) shows that $z := \psi\hat{v}$ satisfies

$$\begin{cases} -(Z_t(t), g) + A(Z(t), g) \\ \qquad = (\psi\tilde{u}(t), g) - (\hat{v}\mathcal{L}\psi + 2(\nabla\hat{v})^* \alpha \nabla\psi, g) \\ \qquad\qquad\qquad\qquad \text{a.e. } t \in [0,T] \quad \forall g \in V_\circ, \\ Z(T) = 0, \end{cases} \tag{7.15}$$

and this equation has a unique solution in $W(0,T)$. Moreover, the unique solution in $W^{2,1;6}(B_N \times (0,T))$ of

$$\begin{cases} -Z_t + [-\mathcal{L} + (\rho - b_{11})]Z = \psi\tilde{u} - \hat{v}\mathcal{L}\psi - 2(\nabla\hat{v})^*\alpha\nabla\psi, \\ Z(T) = 0, \\ Z|_{\partial B_N \times (0,T)} = 0, \end{cases}$$

satisfies (7.15), and hence is z. We conclude that $\hat{v} \in W^{2,1;6}_{\text{loc}}(\mathbb{R}^2 \times (0,T))$. ∎

THEOREM 7.11. *Assume that $\rho \ge b_{11}$. Then the function $\hat{v}$ is the unique solution of the pointwise variational inequality*

$$\begin{cases} \hat{v} \in W^{2,1;6}_{\text{loc}}(\mathbb{R}^2 \times (0,T)), \\ -1 \le \hat{v} \le +1 \ \textit{a.e. in} \ \mathbb{R}^2 \times (0,T), \ \hat{v}(x,T) = 0 \ \textit{a.e. in} \ \mathbb{R}^2, \\ -\hat{v}_t + [-\mathcal{L} + (\rho - b_{11})]\hat{v} = \hat{u} \quad \textit{if} \quad -1 < \hat{v}(x,t) < +1, \\ -\hat{v}_t + [-\mathcal{L} + (\rho - b_{11})]\hat{v} \le \hat{u} \quad \textit{if} \quad \hat{v}(x,t) = +1, \\ -\hat{v}_t + [-\mathcal{L} + (\rho - b_{11})]\hat{v} \ge \hat{u} \quad \textit{if} \quad \hat{v}(x,t) = -1, \\ \qquad\qquad \textit{a.e. in} \ \mathbb{R}^2 \times (0,T). \end{cases} \tag{7.16}$$

Proof. We know that $\hat{v}$ is the unique solution of (7.2) by Theorem 7.9; due to the regularity of $\hat{v}$ we may write (7.2) as

$$\begin{cases} \hat{v}(T) = 0, \\ (-\hat{v}_t(t) + [-\mathcal{L} + (\rho - b_{11})]\hat{v}(t) - \hat{u}(t), g - \hat{v}(t)) \ge 0 \\ \qquad\qquad\qquad\qquad \text{a.e. } t \in [0,T] \quad \forall g \in \mathcal{K}, \end{cases}$$

and by taking $g = \hat{v}(t) + \psi$ with $\psi \in C^\infty(\mathbb{R}^2)$ with compact support, we obtain (7.16). ∎

8. Appendix. The assumptions are as in section 7. We aim first to prove Proposition 7.5. Due to the lack of a priori bounds of the type (4.9), we take care of the linear-in-x term in A by regularization, so we set

- $A_1(g,h) = (x^*b^*\nabla g, x^*b^*\nabla h)$ for $g,h \in V$;
- $\mathcal{V} = \{g \in V : A_1(g,g) < +\infty\}$ with the Hilbert norm

$$\|g\|_{\mathcal{V}}^2 = \|g\|_V^2 + A_1(g,g)$$

(notice that $\mathcal{V} \subset H \subset \mathcal{V}'$ with continuous dense injection);

- $\mathcal{W}(0,T) = \{w \in L^2(0,T;\mathcal{V}) : w_t \in L^2(0,T;\mathcal{V}')\}$.

Clearly, for $\gamma > 0$ the continuous bilinear form $A + \gamma A_1 : \mathcal{V} \times \mathcal{V} \to \mathbb{R}$ verifies

$$A(g,g) + \gamma A_1(g,g) \geq \eta\|g\|_V^2 - \lambda\|g\|_H^2 + \gamma\|x^*b^*\nabla g\|_H^2$$

since A is weakly coercive in V.

Since $\mathcal{V}$ is dense in V, in the limit as $\gamma \downarrow 0$ we will obtain w^ε from the solution of the following γ-approximating problem.

THEOREM 8.1. *For every $\gamma > 0$ there exists a unique solution $w^{\varepsilon,\gamma}$ in $\mathcal{W}(0,T)$ of*

$$\begin{cases} -(w_t(t),g) + A(w(t),g) + \gamma A_1(w(t),g) + \dfrac{1}{\varepsilon}(\zeta(w(t)),g) \\ \qquad\qquad = (\hat{u}(t),g) \qquad \text{a.e. } t \in [0,T] \quad \forall g \in \mathcal{V}, \\ w(T) = 0. \end{cases} \tag{8.1}$$

Proof. We use Galerkin's method. Let $\{\psi_i\}_{i\in\mathbb{N}}$ be a complete orthonormal basis of the separable space H such that $\{\psi_i\}_{i\in\mathbb{N}} \subset \mathcal{V}$ and set

$$w^m(x,t) = \sum_{i=1}^m G_i^m(t)\psi_i(x), \qquad m \in \mathbb{N},$$

where the scalar functions $G_i^m(t)$ are such that

$$\begin{cases} -(w_t^m(t),\psi_j) + A(w^m(t),\psi_j) + \gamma A_1(w^m(t),\psi_j) \\ \qquad + \dfrac{1}{\varepsilon}(\zeta(w^m(t)),\psi_j) = (\hat{u}(t),\psi_j), \qquad j = 1,\dots,m, \\ w^m(T) = 0. \end{cases} \tag{8.2}$$

Now $\zeta^2(r) \leq r\zeta(r)$ and standard energy estimates show that there exists a constant $C > 0$ such that for all $m \in \mathbb{N}$

$$\begin{aligned} \|w^m\|_{L^\infty(0,T;H)}^2 + \|w^m\|_{L^2(0,T;V)}^2 + \frac{1}{\varepsilon}\|\zeta(w^m)\|_{L^2(0,T;H)}^2 \\ + \gamma\int_0^T A_1(w^m(t),w^m(t))dt \leq C; \end{aligned} \tag{8.3}$$

see [2, p. 125] or [1, p. 80] for the idea.

We recall that $\hat{u}_t \in L^\infty(0,T;V')$ and $\psi_j \in \mathcal{V} \subset V$, so $\ddot{G}_i^m$ exists and we have $w_{tt}^m(x,t) = \sum_{i=1}^m \ddot{G}_i^m(t)\psi_i(x)$; thus, from (8.2) it follows that

$$\begin{cases} -(w_{tt}^m(t),\psi_j) + A(w_t^m(t),\psi_j) + \gamma A_1(w_t^m(t),\psi_j) + \dfrac{1}{\varepsilon}(\zeta'(w^m(t))w_t^m(t),\psi_j) \\ \qquad\qquad = \langle \hat{u}_t(t),\psi_j\rangle, \quad j = 1,\dots,m, \\ -(w_t^m(T),\psi_j) = (\hat{u}(T),\psi_j), \qquad\qquad j = 1,\dots,m. \end{cases}$$

Again, standard estimates show that there exists a constant $C > 0$ such that for all $m \in \mathbb{N}$

$$\|w_t^m\|^2_{L^\infty(0,T;H)} + \|w_t^m\|^2_{L^2(0,T;V)} + \frac{1}{\varepsilon}\int_0^T \left\|\frac{d}{dt}\zeta(w^m(t))\right\|^2_H dt + \gamma\int_0^T A_1(w_t^m(t), w_t^m(t))dt \le C. \tag{8.4}$$

It follows from (8.3) and (8.4) that we can extract a subsequence such that

$$\begin{cases} w^m \to w^{\varepsilon,\gamma} \text{ weakly in } L^2(0,T;V) \text{ and weak-}\star \text{ in } L^\infty(0,T;H); \\ w_t^m \to w_t^{\varepsilon,\gamma} \text{ weakly in } L^2(0,T;V) \text{ and weak-}\star \text{ in } L^\infty(0,T;H); \\ \sqrt{\gamma}x^*b^*\nabla w^m \to \sqrt{\gamma}x^*b^*\nabla w^{\varepsilon,\gamma} \text{ weakly in } L^2(0,T;H); \\ \sqrt{\gamma}x^*b^*\nabla w_t^m \to \sqrt{\gamma}x^*b^*\nabla w_t^{\varepsilon,\gamma} \text{ weakly in } L^2(0,T;H); \\ \dfrac{1}{\sqrt{\varepsilon}}\zeta(w^m) \to \dfrac{1}{\sqrt{\varepsilon}}\chi \text{ weakly in } L^2(0,T;H), \end{cases}$$

for some $w^{\varepsilon,\gamma}$ in $\mathcal{W}(0,T)$ and χ in $L^2(0,T;H)$.

To identify the function χ we digress to the following lemma.

LEMMA 8.2. *Let $\{v^m\}$ be a sequence converging weakly in $L^2(0,T;V)$ to v such that*

$$\begin{cases} \|v^m\|^2_{L^2(0,T;V)} \le C, \\ \|v_t^m\|^2_{L^\infty(0,T;H)} \le C. \end{cases} \tag{8.5}$$

Then there exists a subsequence $\{v^{m_k}\}$ converging a.e. to v on $\mathbb{R}^2 \times (0,T)$.

Proof. Fix $N \in \mathbb{N}$ and recall that $\Omega_N = B_N \times (0,T)$ satisfies a uniform interior cone condition. On Ω_N we can drop the weight function π since $\|g\|_{L^2_\pi(B_N)} \le \|g\|_{L^2(B_N)} \le (1+N^2)^l \|g\|_{L^2_\pi(B_N)}$, so from (8.5) it follows that $\|v^m\|_{W^{1,1;2}(\Omega_N)} \le C$; that is, the sequence $\{v^m\}_{m\in\mathbb{N}}$ lies in a bounded set in $W^{1,1;2}(\Omega_N)$ (cf. [13, p. 158 and Problem 7.14]), hence in a compact set in $L^2(\Omega_N)$. Thus a subsequence converges strongly, and the limit must be v, so the whole sequence converges to v in $L^2(\Omega_N)$. Then a subsequence converges to v a.e. on Ω_N, and hence, since N is arbitrary, on $\mathbb{R}^2 \times (0,T)$. ∎

We return now to the proof of the theorem. It follows from the lemma that, at least for a subsequence, again denoted $\{w^m\}$, $w^m \to w^{\varepsilon,\gamma}$ a.e. The bound $|r - \zeta(r)| \le 1$ for all $r \in \mathbb{R}$ allows us to apply the bounded convergence theorem and get

$$\lim_{m\to\infty}(w^m - \zeta(w^m)) = w^{\varepsilon,\gamma} - \zeta(w^{\varepsilon,\gamma}) \quad \text{in } L^2_\pi(\mathbb{R}^2 \times (0,T))$$

since ζ is continuous. But it also converges weakly to $w^{\varepsilon,\gamma} - \chi$; therefore, $\chi = \zeta(w^{\varepsilon,\gamma})$.

Now we go back to (8.2), multiply it by any $\mu(t) \in L^2(0,T)$, and integrate over $[0,T]$ and

$$\int_0^T -(w_t^{\varepsilon,\gamma}(t), \psi_j)\mu(t)dt + \int_0^T [A + \gamma A_1](w^{\varepsilon,\gamma}(t), \psi_j)\mu(t)dt + \int_0^T \frac{1}{\varepsilon}(\zeta(w^{\varepsilon,\gamma}(t)), \psi_j)\mu(t)dt = \int_0^T (\hat{u}(t), \psi_j)\mu(t)dt$$

for every $\mu(t) \in L^2(0,T)$ and $j = 1, 2, \ldots$. It follows that $w^{\varepsilon,\gamma}$ is a solution of (8.1). Moreover, (8.3) and (8.4) imply that for some $C < \infty$ and all $\varepsilon,\ \gamma > 0$,

$$\begin{cases} \|w^{\varepsilon,\gamma}\|^2_{L^\infty(0,T;H)} + \|w^{\varepsilon,\gamma}\|^2_{L^2(0,T;V)} \le C, \\ \|w_t^{\varepsilon,\gamma}\|^2_{L^\infty(0,T;H)} + \|w_t^{\varepsilon,\gamma}\|^2_{L^2(0,T;V)} \le C, \\ \sqrt{\gamma}\|x^* b^* \nabla w^{\varepsilon,\gamma}\|_{L^2(0,T;H)} + \dfrac{1}{\sqrt{\varepsilon}}\|\zeta(w^{\varepsilon,\gamma})\|_{L^2(0,T;H)} \le C. \end{cases} \tag{8.6}$$

Uniqueness follows as in Proposition 7.4. □

We now take limits as $\gamma \downarrow 0$ and we have the following proposition.

PROPOSITION 8.3. *There exists a solution $w^\varepsilon \in W(0,T)$ of the penalized variational problem* (7.4) *and $w^{\varepsilon,\gamma}(x,t) \to w^\varepsilon(x,t)$ a.e. Moreover, w^ε satisfies* (8.6).

Proof. From (8.6) it follows that

$$\int_0^T |A_1(w^{\varepsilon,\gamma}(t), w(t))|dt \le \frac{C}{\sqrt{\gamma}}\|x^* b^* \nabla w\|_{L^2(0,T;H)}$$

for every $w \in \mathcal{V}$; then, after multiplying (8.1) by $\mu(t) \in L^2(0,T)$ and integrating over $[0,T]$, we may take limits as $\gamma \downarrow 0$ (along a subsequence if necessary) to get

$$\begin{aligned} &\int_0^T -(w_t^\varepsilon(t), g)\mu(t)dt + \int_0^T A(w^\varepsilon(t), g)\mu(t)dt \\ &+ \int_0^T \frac{1}{\varepsilon}(\zeta(w^\varepsilon(t)), g)\mu(t)dt = \int_0^T (\hat{u}(t), g)\mu(t)dt \end{aligned}$$

for some $w^\varepsilon \in W(0,T)$ whose existence is guaranteed by the estimates (8.6). In fact, just as above, $\frac{1}{\varepsilon}\zeta(w^{\varepsilon,\gamma})$ converges weakly in $L^2(0,T;H)$ to some function which is then identified as $\frac{1}{\varepsilon}\zeta(w^\varepsilon)$, and $w^{\varepsilon,\gamma}(x,t) \to w^\varepsilon(x,t)$ a.e. thanks to Lemma 8.2. Since $\mu(t)$ is arbitrary in $L^2(0,T)$, we obtain (7.4) for every $g \in \mathcal{V}$, and hence for all $g \in V_\circ$ since $\mathcal{V}$ is dense in $V_\circ$. □

The estimates (7.5) follow from (8.6).

We must also prove Lemma 7.8; it is a special case of the following result.

LEMMA 8.4. *Assume that $2 \le p < 2l - 2$, p even. Then there exists $\varepsilon_o > 0$ and a positive constant $C = C(\lambda, \hat{u})$ such that for every $\varepsilon < \varepsilon_o$*

$$\frac{1}{\varepsilon}\|\zeta(w^\varepsilon(t))\|_{L^p_\pi(\mathbb{R}^2 \times [0,T])} \le C. \tag{8.7}$$

Proof. Recall that $|\zeta(r)| \le |r|$ for all $r \in \mathbb{R}$, hence

$$|\zeta(w^\varepsilon(x,t))| \le |w^\varepsilon(x,t)| \le K(1 + |x|)$$

by (7.7). The relationship between l and p insures that x, hence $\zeta(w^\varepsilon(t))$, is in $L^p_\pi(\mathbb{R}^2)$, and allows us to multiply (7.6) by $(\zeta(w^\varepsilon(t)))^{p-1}\pi$ (recall that $w^\varepsilon_{x_i x_j}$ is well defined because of Theorem 7.6). Also notice that $r\zeta(r) = (\zeta(r))^2 + |\zeta(r)|$. Then, after an integration over $\mathbb{R}^2$ we obtain

$$\begin{aligned} &-\frac{1}{p}\frac{d}{dt}\|\zeta(w^\varepsilon(t))\|^p_{L^p_\pi(\mathbb{R}^2)} \\ &\quad +(p-1)\sum_{i,j=1}^2 \alpha_{ij}([\zeta(w^\varepsilon(t))]^{p/2-1}\zeta(w^\varepsilon(t))_{x_i}, [\zeta(w^\varepsilon(t))]^{p/2-1}\zeta(w^\varepsilon(t))_{x_j}) \end{aligned}$$

$$
\begin{aligned}
&-\sum_{i,j=1}^{2}\alpha_{ij}([\zeta(w^\varepsilon(t))]^{p/2-1}(\zeta(w^\varepsilon(t)))_{x_i},[\zeta(w^\varepsilon(t))]^{p/2}\varphi_j)\\
&-\sum_{i=1}^{2}([a+bx]_i[\zeta(w^\varepsilon(t))]^{p/2-1}(\zeta(w^\varepsilon(t)))_{x_i},[\zeta(w^\varepsilon(t))]^{p/2})\\
&+(\rho-b_{11})([\zeta(w^\varepsilon(t))]^2+|\zeta(w^\varepsilon(t))|,[\zeta(w^\varepsilon(t))]^{p-2})\\
&+\frac{1}{\varepsilon}\|\zeta(w^\varepsilon(t))\|^p_{L^p_\pi(\mathbb{R}^2)}\\
&=(\hat u(t),[\zeta(w^\varepsilon(t))]^{p-1}).
\end{aligned}
$$

Integration by parts can be used to remove all terms involving partial derivatives except the second term in the above equation, but its integrand is nonnegative, so the term is well defined. Hence

$$
\begin{aligned}
&-\frac{1}{p}\frac{d}{dt}\|\zeta(w^\varepsilon(t))\|^p_{L^p_\pi(\mathbb{R}^2)}\\
&\quad+\frac{2}{p}A([\zeta(w^\varepsilon(t))]^{p/2},[\zeta(w^\varepsilon(t))]^{p/2})\\
&\quad+\Big(1-\frac{2}{p}\Big)\frac{2}{p}\int_{\mathbb{R}^2}\nabla\Big([\zeta(w^\varepsilon(t))]^{p/2}\Big)^*\alpha\nabla\Big([\zeta(w^\varepsilon(t))]^{p/2}\Big)\pi dx\\
&\quad+\Big(1-\frac{2}{p}\Big)(\rho-b_{11})\|\zeta(w^\varepsilon(t))\|^p_{L^p_\pi(\mathbb{R}^2)}\\
&\quad+(\rho-b_{11})\|\zeta(w^\varepsilon(t))\|^{p-1}_{L^{p-1}_\pi(\mathbb{R}^2)}+\frac{1}{\varepsilon}\|\zeta(w^\varepsilon(t))\|^p_{L^p_\pi(\mathbb{R}^2)}\\
&=(\hat u(t),[\zeta(w^\varepsilon(t))]^{p-1}).
\end{aligned}
$$

The weak coercivity of A, integration over $(t,T]$, and Young's inequality give

$$
\begin{aligned}
\frac{1}{\varepsilon}\delta\int_t^T\|\zeta(w^\varepsilon(s))\|^p_{L^p_\pi(\mathbb{R}^2)}ds&\le\int_t^T\|\hat u(s)\|_{L^p_\pi(\mathbb{R}^2)}\|\zeta(w^\varepsilon(s))\|^{p-1}_{L^p_\pi(\mathbb{R}^2)}ds\\
&\le\frac{1}{p}\gamma^p\int_t^T\|\hat u(s)\|^p_{L^p_\pi(\mathbb{R}^2)}ds\\
&\quad+\frac{1}{2\varepsilon}\delta\int_t^T\|\zeta(w^\varepsilon(s))\|^p_{L^p_\pi(\mathbb{R}^2)}ds,
\end{aligned}
$$

where $\delta=1-\frac{2}{p}\varepsilon\lambda$ and $\gamma=[\frac{2\varepsilon}{p-2\varepsilon\lambda}(p-1)]^{(p-1)/p}$. ($\lambda$ comes from the weak coercivity of A.) So

$$
\Big(\frac{1}{\varepsilon}\Big)^p\int_t^T\|\zeta(w^\varepsilon(s))\|^p_{L^p_\pi(\mathbb{R}^2)}ds\le\frac{1}{p}\Big(\frac{p-1}{p}\Big)^{p-1}\Big(\frac{2}{\delta}\Big)^p\int_t^T\|\hat u(s)\|^p_{L^p_\pi(\mathbb{R}^2)}ds;
$$

i.e., for some $\varepsilon_0>0$ and all $\varepsilon<\varepsilon_0$ we have

$$
\frac{1}{\varepsilon}\|\zeta(w^\varepsilon(t))\|_{L^p_\pi(\mathbb{R}^2\times[0,T])}\le C(\lambda,p,\hat u),
$$

and hence (8.7) follows. □

CAUSAL INPUT/OUTPUT REPRESENTATION OF 2D SYSTEMS IN THE BEHAVIORAL APPROACH*

SANDRO ZAMPIERI†

Abstract. In this paper the concept of causal input/output representation of two-dimensional (2D) systems in the behavioral approach is introduced. These representations provide an interesting connection between classical 2D systems theory and 2D systems theory in the behavioral approach. Some characterizations of such representations are presented. Finally, a technique that allows us to obtain causal input/output representations is proposed.

Key words. 2D systems, behavioral approach, input/output representation, proper rational matrices, causality

1. Introduction.

The theory of dynamical systems in the behavioral approach has attracted much attention in the last few years. The main characteristic of this approach is that the system variables are not a priori divided into inputs and outputs, and moreover, no causality structure is imposed on the dynamics. This division in inputs and outputs is something that can be obtained a posteriori, analyzing the system equations. This feature is useful above all when there is an unclear distinction between causes and effects, and this happens frequently in the study of multidimensional systems, for instance, systems operating on space-time signals. Moreover, it has been shown recently that in modeling and identification procedures it is in some cases more reasonable to avoid distinctions between inputs and outputs.

On the other hand, if we want to apply the classical control and filtering strategies in this setup, the extraction of the input/output structure becomes an essential step. In the one-dimensional (1D) case this problem has been completely solved by Willems in [10]. In that paper Willems introduces a notion of input/output representation that takes into account a causality relation between inputs and outputs with respect to a time direction. Such representations are obtained exploiting the properties of row proper polynomial matrices. In the two-dimensional (2D) case this has been done only partially in [6, 12, 5, 13], since the input/output representations proposed there do not obey any causality assumption.

In this paper we will propose input/output representations satisfying weakly causal relations between inputs and outputs [1]. In the 1D case [10] these input/output representations are called nonanticipating. In the 2D case we prefer to call them causal input/output representations, which seems to be a more suitable terminology for multidimensional systems. We will analyze the properties of such representations and introduce the concept of impulse response that, as we will show, is strictly connected with the controllable part of the system. Moreover, we will propose a method for verifying if an input/output representation is causal, and finally we will present an algorithm that allows us to obtain causal input/output representations.

During the review process, the possibility of extending the results presented in this paper to the n-dimensional (nD) case has been pointed out by one of the referees.

2. 2D systems theory in the input/output and in the behavioral approach. This section will be devoted to the introduction of some preliminaries on 2D systems theory both in the behavioral approach and in the classical input/output approach. As far as the behavioral approach is concerned, we refer to [6, 8, 12], while for the classical input/output approach, we refer to [2].

In the behavioral approach, a dynamical system is described by a triple

$$\Sigma = (T, W, \mathcal{B}),$$

where T is the time set, W is the signal alphabet and $\mathcal{B}$ is a subset of the set of all signals W^T that is called the *behavior* of the system. In this paper we are interested in the so-called discrete 2D linear shift-invariant complete systems. Discrete 2D systems are dynamical systems whose time set is $\mathbb{Z}^2$ and signal alphabet is $\mathbb{R}^q$ ($\mathbb{R}$ can be replaced by any field). A discrete 2D system is linear shift-invariant and complete if, moreover, the behavior $\mathcal{B}$ is a linear subspace of the vector space $(\mathbb{R}^q)^{\mathbb{Z}^2}$ which is invariant with respect to the backward shifts σ_1, σ_2 in the two directions of $\mathbb{Z}^2$ and satisfies the following requirement:

$$w \in \mathcal{B} \quad \Leftrightarrow \quad w_{|I} \in \mathcal{B}_{|I} \quad \text{for all finite } I \subset \mathbb{Z}^2.$$

Notice that, as shown in [6, 8], the behavior of a linear shift-invariant system is complete if and only if it is a closed set with respect to the pointwise convergence topology in $(\mathbb{R}^q)^{\mathbb{Z}^2}$.

It can be shown that a discrete 2D system is linear shift-invariant complete if and only if its behavior can be specified by a difference equation. More precisely, given any polynomial matrix $R \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{l \times q}$ (the symbol $\mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]$ denotes the ring of Laurent polynomials that are polynomials where the indeterminates may have negative exponent), then R can be written as follows:

$$\sum_{(i,j) \in S} R_{ij} z_1^i z_2^j,$$

where $R_{ij} \in \mathbb{R}^{l \times q}$ and S is a finite subset of $\mathbb{Z}^2$. Then we can associate with R an operator from $(\mathbb{R}^q)^{\mathbb{Z}^2}$ to $(\mathbb{R}^l)^{\mathbb{Z}^2}$, denoted as $R(\sigma_1, \sigma_2)$, operating as follows:

$$(R(\sigma_1, \sigma_2)w)(h, k) := \sum_{(i,j) \in S} R_{ij} w(h + i, k + j), \quad (h, k) \in \mathbb{Z}^2.$$

These operators will be called difference operators. A 2D system $\Sigma = (\mathbb{Z}^2, \mathbb{R}^q, \mathcal{B})$ is a linear shift-invariant and complete system if and only if there exists a positive integer l and a polynomial matrix $R \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{l \times q}$ such that

$$\mathcal{B} = \ker R(\sigma_1, \sigma_2).$$

Since the behaviors of these systems are characterized by a difference equation, they are also called autoregressive (AR) 2D systems.

For our purpose it is important to note that different difference operators may produce the same behavior. More precisely, given two polynomial matrices R_1, R_2, we have $\ker R_1(\sigma_1, \sigma_2) \subseteq \ker R_2(\sigma_1, \sigma_2)$ if and only if there exists a polynomial matrix

X such that $R_2 = XR_1$ and so $\ker R_1(\sigma_1, \sigma_2) = \ker R_2(\sigma_1, \sigma_2)$ if and only if there exist polynomial matrices X_1, X_2 such that $R_2 = X_1 R_1$ and $R_1 = X_2 R_2$.

An important class of 2D AR systems is given by the controllable 2D AR systems. A 2D system $\Sigma = (\mathbb{Z}^2, \mathbb{R}^q, \mathcal{B})$ is said to be controllable if there exists $g \geq 0$ such that, given any pair of trajectories $w_1, w_2 \in \mathcal{B}$ and given any pair of subsets $T_1, T_2 \subseteq \mathbb{Z}^2$ such that the Euclidean distance between T_1 and T_2 is greater than g, there exists $w \in \mathcal{B}$ such that $w_{|T_1} = w_{1|T_1}$ and $w_{|T_2} = w_{2|T_2}$. Controllability has been extensively studied in [6, 9]. If $\Sigma = (\mathbb{Z}^2, \mathbb{R}^q, \mathcal{B})$ is a 2D AR system, then it has been shown in [3] that there exists the greatest controllable AR subsystem of Σ, which is called the controllable subsystem of Σ and is denoted by $\Sigma_c = (\mathbb{Z}^2, \mathbb{R}^q, \mathcal{B}_c)$. Moreover, if $\mathcal{B} = \ker R(\sigma_1, \sigma_2)$, where $R \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{l \times q}$, then there exists a factor left prime matrix $R' \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{l' \times q}$ (that is, a full row rank polynomial matrix whose square left factors must be unimodular) and a full column rank matrix $F \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{l \times l'}$ such that [4]

$$R = FR'. \tag{1}$$

It can be proved that [3]

$$\mathcal{B}_c = \ker R'(\sigma_1, \sigma_2).$$

Notice that when we refer to the rank of a polynomial matrix we mean its rank as a matrix with entries in the field of fractions of the domain $\mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]$.

Let's finally define the concept of free components of a 2D AR system $\Sigma = (\mathbb{Z}^2, \mathbb{R}^q, \mathcal{B})$. We say that components $i_1, \ldots, i_m$ of the system Σ are free if for all $v_1, \ldots, v_m \in \mathbb{R}^{\mathbb{Z}^2}$, there exists $w = (w_1, \ldots, w_q)^T \in \mathcal{B}$ such that $w_{i_1} = v_1, \ldots, w_{i_m} = v_m$.

We pass now to the introduction of 2D systems theory in the classical input/output approach. Consider the spaces

$$\mathcal{U} := \{u \in (\mathbb{R}^m)^{\mathbb{Z}^2} : \text{supp } (\sigma_1^{t_1} \sigma_2^{t_2} u) \subseteq \mathbb{N}^2 \text{ for some } (t_1, t_2) \in \mathbb{Z}^2\},$$
$$\mathcal{Y} := \{y \in (\mathbb{R}^p)^{\mathbb{Z}^2} : \text{supp } (\sigma_1^{t_1} \sigma_2^{t_2} y) \subseteq \mathbb{N}^2 \text{ for some } (t_1, t_2) \in \mathbb{Z}^2\},$$

where $\mathbb{N}$ is the set of nonnegative integers and where supp $(\cdot)$ means the support of 2D sequences. The trajectories in $\mathcal{U}$ are called inputs, while the trajectories in $\mathcal{Y}$ are called outputs. A 2D system in the input/output approach is essentially given by an operator

$$\Psi : \mathcal{U} \longrightarrow \mathcal{Y}.$$

This operator is assumed to satisfy the following properties.

1. Ψ is a linear operator.
2. Ψ is shift-invariant; i.e., for all $u \in \mathcal{U}$ and for all $(t_1, t_2) \in \mathbb{Z}^2$ we have

$$\Psi(\sigma_1^{t_1} \sigma_2^{t_2} u) = \sigma_1^{t_1} \sigma_2^{t_2} \Psi(u).$$

3. Ψ is quarter-plane causal; i.e., if $u_1, u_2 \in \mathcal{U}$ are such that $u_1(h_1, h_2) = u_2(h_1, h_2)$ for all $h_1 \leq t_1, h_2 \leq t_2$ and if $y_1 = \Psi(u_1), y_2 = \Psi(u_2)$, then $y_1(t_1, t_2) = y_2(t_1, t_2)$.

Using the linearity and the shift-invariance it can be shown that the causality property has the following equivalent expression. If $u \in \mathcal{U}$ is such that supp $(u) \subseteq \mathbb{N}^2$, then supp $(\Psi(u)) \subseteq \mathbb{N}^2$.

The causality requirement can be weakened by substituting a general cone $C \subseteq \mathbb{Z}^2$ instead of $\mathbb{N}^2$ in the definitions of $\mathcal{U}$ and $\mathcal{Y}$ and in the causality requirement. 2D systems that are causal with respect to cones are called weakly causal. These systems are extensively treated in [1]. This generalization is essential for our objectives.

Consider the inputs $\delta^{(i)}$ defined for each $i = 1, \dots, m$ as

$$\delta^{(i)}(t) := \begin{cases} e_i & \text{if } t = (0,0), \\ 0 & \text{if } t \neq (0,0), \end{cases} \tag{2}$$

where $e_1, \dots, e_m$ denotes the canonical base in $\mathbb{R}^m$, and let $y^{(i)} := \Psi(\delta^{(i)})$. Then the impulse response associated with the 2D system is the matrix-valued 2D sequence defined as $Y := [y^{(1)}\ y^{(2)} \cdots y^{(m)}] \in (\mathbb{R}^{p\times m})^{\mathbb{Z}^2}$, which is supported in $\mathbb{N}^2$. As shown in [2], the operator Ψ is completely determined by the impulse response. Actually, suppose that u is any input and let $y \in (\mathbb{R}^p)^{\mathbb{Z}^2}$ be defined as follows:

$$y(t_1, t_2) := \sum_{(k_1,k_2)\in\mathbb{Z}^2} Y(t_1 - k_1, t_2 - k_2)u(k_1, k_2); \tag{3}$$

then it can be shown that $y = \Psi(u)$. Note that the sum in the previous formula is finite, and moreover, since Y and u have support in $\mathbb{N}^2$, y also has support in $\mathbb{N}^2$. The operation described in (3) is called convolution.

The theory of 2D systems in the classical input/output approach considers at this point another restriction on the operator Ψ or equivalently on its impulse response Y. Actually, the formal power series

$$\bar{Y} := \sum_{(t_1,t_2)\in\mathbb{Z}^2} Y(t_1, t_2) z_1^{-t_1} z_2^{-t_2} \tag{4}$$

associated with the impulse response Y is assumed to be rational, which means that there exists a nonsingular square polynomial matrix $P \in \mathbb{R}[z_1, z_2]^{p\times p}$ such that $P\bar{Y} = Q$ is a polynomial matrix in $\mathbb{R}[z_1, z_2]^{p\times m}$. The power series $\bar{Y}$ is called a transfer matrix of the 2D system and the representation

$$\bar{Y} = P^{-1}Q$$

is called matrix fraction description (MFD) of the transfer matrix $\bar{Y}$. Notice that the matrices P and Q could be taken left coprime, and in this case the MFD is called left coprime [4]. As shown in [2], rationality ensures that the 2D system is realizable through a state space model.

3. Passing from input/output systems to behavioral systems. Suppose now that we have a 2D input/output system; i.e., we have an input/output operator

$$\Psi : \mathcal{U} \longrightarrow \mathcal{Y}.$$

Then the set of trajectories

$$\left\{ \begin{pmatrix} \Psi(u) \\ u \end{pmatrix} \in (\mathbb{R}^{p+m})^{\mathbb{Z}^2} : u \in \mathcal{U} \right\} \tag{5}$$

is clearly a linear and shift-invariant behavior, but it is not complete or equivalently closed with respect to the pointwise convergence topology. If we denote by $\mathcal{B}(\Psi)$ the

closure of such a set, then $\Sigma(\Psi) = (\mathbb{Z}^2, \mathbb{R}^{p+q}, \mathcal{B}(\Psi))$ is a linear shift-invariant and complete 2D system in the behavioral approach. This is the linear shift-invariant and complete 2D system with the smallest possible behavior containing all the trajectories generated by the input/output map. This is therefore the most natural way to associate with a 2D input/output system a 2D behavioral system. Not every linear shift-invariant and complete 2D system can be obtained in this way. The following proposition shows that the 2D systems that come from 2D input/output systems are always controllable.

PROPOSITION 1. *Let $\Psi : \mathcal{U} \longrightarrow \mathcal{Y}$ be an input/output operator associated with a linear shift-invariant and quarter-plane causal 2D system. Then $\Sigma(\Psi)$ is controllable.*

The proof of this proposition is a direct consequence of the following two lemmas.

LEMMA 1. *Let $P \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{l \times p}$ be a full column rank matrix. Then $y \in \ker\, P(\sigma_1, \sigma_2)$ and $y \in \mathcal{Y}$ if and only if $y = 0$.*

Proof. One direction is trivial. Suppose conversely that $y \in \ker\, P(\sigma_1, \sigma_2) \cap \mathcal{Y}$. Since P is full column rank, there exists a polynomial matrix X such that $XP = fI$, where I is the identity matrix and f is a nonzero polynomial. Then each component of y is in the kernel of $f(\sigma_1, \sigma_2)$. Since the support of such components is in $\mathbb{N}^2$, a simple computation (see also [3]) shows that $y = 0$. □

LEMMA 2. *Let $\Sigma = (\mathbb{Z}^2, \mathbb{R}^q, \mathcal{B})$ be an AR system and $\Sigma_c = (\mathbb{Z}^2, \mathbb{R}^q, \mathcal{B}_c)$ be its controllable subsystem. If $w \in \mathcal{B}$ and if w has support in $\mathbb{N}^2$, then $w \in \mathcal{B}_c$*

Proof. Suppose that $\mathcal{B} = \ker\, R(\sigma_1, \sigma_2)$ and that $R = FR'$, where R' is factor left prime and F is full column rank. Then $\mathcal{B}_c = \ker\, R'(\sigma_1, \sigma_2)$. Suppose that $w \in \mathcal{B}$ and that w has support in $\mathbb{N}^2$. Then $v := R'(\sigma_1, \sigma_2)w \in \ker\, F(\sigma_1, \sigma_2)$. Since F is full column rank and since the support of v is contained in some translation of $\mathbb{N}^2$, then by Lemma 1 $v = 0$ and so $w \in \ker\, R'(\sigma_1, \sigma_2) = \mathcal{B}_c$. □

Remark. Lemma 2 cannot be extended directly to the nD case, since it is based on the factorization (1), which is always possible in the 2D case (see [4]) but is not always possible in the general nD case, when $n > 2$ (see [11]). This is the reason why the extension to the nD case, pointed out by one of the referees, is not straightforward with the techniques used in this paper.

The previous proposition holds also for nonrational 2D input/output systems. If the system is rational we are able to obtain an AR representation of the 2D behavioral system associated with the input/output system directly from a left coprime matrix fraction description of the transfer matrix of the system.

PROPOSITION 2. *Let $\Psi : \mathcal{U} \longrightarrow \mathcal{Y}$ be an input/output operator associated with a linear shift-invariant and quarter-plane causal rational 2D system. Let $\bar{Y} = P^{-1}Q$ be a left coprime MFD of the transfer matrix. Then $\Sigma(\Psi)$ admits the following AR representation:*

$$\mathcal{B}(\Psi) = \ker\, [P(\sigma_1, \sigma_2) \ -Q(\sigma_1, \sigma_2)].$$

Proof. We have to show that

$$\mathcal{B}(\Psi) = \ker\, [P(\sigma_1, \sigma_2) \ -Q(\sigma_1, \sigma_2)].$$

We start showing $\subseteq$. First notice that $P\bar{Y} = Q$ if and only if

$$Q_{k_1,k_2} = \sum_{h_1,h_2} P_{h_1,h_2} Y(-k_1 + h_1, -k_2 + h_2). \tag{6}$$

Suppose that $u \in \mathcal{U}$ and that $y = \Psi(u)$. Then we have

$$\begin{aligned}(P(\sigma_1,\sigma_2)y)(t_1,t_2) &= \sum_{h_1,h_2} P_{h_1,h_2} \sum_{k_1,k_2} Y(t_1+h_1-k_1, t_2+h_2-k_2)u(k_1,k_2)\\ &= \sum_{k_1,k_2} \left(\sum_{h_1,h_2} P_{h_1,h_2} Y(t_1+h_1-k_1, t_2+h_2-k_2) \right) u(k_1,k_2)\\ &= \sum_{k_1,k_2} Q_{k_1-t_1,k_2-t_2} u(k_1,k_2) = (Q(\sigma_1,\sigma_2)u)(t_1,t_2).\end{aligned}$$

We can argue that

$$\left\{ \begin{pmatrix} \Psi(u) \\ u \end{pmatrix} \in (\mathbb{R}^{p+m})^{\mathbb{Z}^2} : u \in \mathcal{U} \right\} \subseteq \ker\, [P(\sigma_1,\sigma_2) \ -Q(\sigma_1,\sigma_2)],$$

and since the behavior $\ker\, [P(\sigma_1,\sigma_2) \ -Q(\sigma_1,\sigma_2)]$ is closed, we are done.

Suppose on the other hand that $\mathcal{B}_f$ is the set of finite supported trajectories in $\ker\, [P(\sigma_1,\sigma_2) \ -Q(\sigma_1,\sigma_2)]$. By controllability [9, Theorem 1], we have that

$$\overline{\mathcal{B}_f} = \ker\, [P(\sigma_1,\sigma_2) \ -Q(\sigma_1,\sigma_2)],$$

where $\overline{\cdot}$ means closure. To prove the assertion we have to show that

$$\mathcal{B}_f \subseteq \left\{ \begin{pmatrix} \Psi(u) \\ u \end{pmatrix} \in (\mathbb{R}^{p+m})^{\mathbb{Z}^2} : u \in \mathcal{U} \right\}.$$

Suppose that u_f, y_f are finite supported trajectories such that

$$P(\sigma_1,\sigma_2)y_f = Q(\sigma_1,\sigma_2)u_f.$$

By the first part of the proof we can argue that

$$P(\sigma_1,\sigma_2)\Psi(u_f) = Q(\sigma_1,\sigma_2)u_f,$$

and so applying Lemma 1 we argue that $y_f = \Psi(u_f)$. □

4. Causal input/output representations. In the last section we have proposed a way to pass from a 2D input/output system to a 2D behavioral system. The following three sections are concerned with the inverse problem of passing from a 2D behavioral system to a 2D input/output system. This problem will be solved by resorting to the concept of causal input/output representation. The concept of input/output representation (without causality) has been introduced and studied in the 2D case in [6, 12, 13]. The construction of this representation is rather simple, since it is connected with the extraction of the free components of a system.

The notion of causal input/output system has been given in [10] only in the 1D case. In the 2D case this notion is a little more involved since it allows much more freedom in the choice of the causality cone. This is specified simply by a pair of elements $d_1, d_2 \in \mathbb{Z}^2$ that generates $\mathbb{Z}^2$ as a group and is defined as

$$C := \{\alpha d_1 + \beta d_2 \in \mathbb{Z}^2 : \alpha, \beta \in \mathbb{N}\}.$$

This definition of cone corresponds to the definition of "causality cone" introduced in [1].

DEFINITION 1. *Let* $P \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{l\times p}$, $Q \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{l\times m}$. *The difference equation*

$$P(\sigma_1, \sigma_2)y = Q(\sigma_1, \sigma_2)u, \tag{7}$$

where $y \in (\mathbb{R}^p)^{\mathbb{Z}^2}$ *and* $u \in (\mathbb{R}^m)^{\mathbb{Z}^2}$, *is an input/output representation of the* 2*D AR system* $\Sigma = (\mathbb{Z}^2, \mathbb{R}^q, \mathcal{B})$ *if*

1. *The difference equation* (7) *determines* $\mathcal{B}$ *up to a permutation of its components: it means that* $p + m = q$ *and that there exists a permutation matrix* $S \in \{0, 1\}^{q\times q}$ *such that*

$$S\begin{bmatrix} y \\ u \end{bmatrix} \in \mathcal{B} \quad \Leftrightarrow \quad P(\sigma_1, \sigma_2)y = Q(\sigma_1, \sigma_2)u.$$

2. u *is free: for all* $u \in (\mathbb{R}^m)^{\mathbb{Z}^2}$ *there exists* $y \in (\mathbb{R}^p)^{\mathbb{Z}^2}$ *such that* $P(\sigma_1, \sigma_2)y = Q(\sigma_1, \sigma_2)u$.

3. *No other components in* y *are free: the* 2*D AR system* $(\mathbb{Z}^2, \mathbb{R}^p, \ker P(\sigma_1, \sigma_2))$ *has no free components.*

The difference equation (7) *is said to be a causal input/output representation with respect to the cone* C *if, moreover,*

4. *the action of* u *on* y *is causal with respect to the cone* C*: if* u *is any signal in* $(\mathbb{R}^m)^{\mathbb{Z}^2}$ *with support in* C, *then there exists a signal* $y \in (\mathbb{R}^p)^{\mathbb{Z}^2}$ *with support in* C *such that*

$$P(\sigma_1, \sigma_2)y = Q(\sigma_1, \sigma_2)u.$$

Notice that it is always possible to perform a change of coordinates and a corresponding change of variables in $\mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]$ in such a way that the cone C coincides with $\mathbb{N}^2$.

Define $(\mathbb{R}^m)^{(C)}$ and $(\mathbb{R}^p)^{(C)}$ to be the set of signals in $(\mathbb{R}^m)^{\mathbb{Z}^2}$ or in $(\mathbb{R}^p)^{\mathbb{Z}^2}$ with support in C. By this notation we can say that an input/output representation

$$P(\sigma_1, \sigma_2)y = Q(\sigma_1, \sigma_2)u \tag{8}$$

is causal if for any $u \in (\mathbb{R}^m)^{(C)}$ there exists $y \in (\mathbb{R}^p)^{(C)}$ such that (8) holds. As a direct consequence of Lemma 1 we have that such a y is also unique. Therefore, it can be defined by an operator

$$\Psi : (\mathbb{R}^m)^{(C)} \to (\mathbb{R}^p)^{(C)}$$

associating with $u \in (\mathbb{R}^m)^{(C)}$ the unique element $y = \Psi(u) \in (\mathbb{R}^m)^{(C)}$ such that (8) holds. This operator is called *input/output operator* associated with the causal input/output representation. It can be extended directly to the set of trajectories whose support is contained in a suitable shift of C, providing in this way a 2D input/output system. Therefore, there exists a direct and natural way to obtain a 2D input/output system from a causal input/output representation.

Notice that the existence of the impulse response is a necessary and sufficient condition for the difference equation (7) to be a causal input/output representation. More precisely the difference equation (7) is a causal input/output representation if and only if for each $i = 1, \ldots, m$ there exists $y^{(i)} \in (\mathbb{R}^p)^{(C)}$ such that $P(\sigma_1, \sigma_2)y^{(i)} = Q(\sigma_1, \sigma_2)\delta^{(i)}$, where $\delta^{(i)}$ are the trajectories defined in (2).

The first useful fact concerning these representations is provided by the following proposition that shows that, in finding causal input/output representations, only the controllable subsystem is really relevant. Moreover, this proposition shows that the 2D input/output system that we obtain from a causal input/output representation is always rational and that a left coprime MFD of its transfer matrix can be obtained directly from the AR representation of the controllable subsystem. This part of the following proposition can be considered the counterpart of Proposition 2.

PROPOSITION 3. *Suppose that* $\Sigma = (\mathbb{Z}^2, \mathbb{R}^q, \mathcal{B})$ *is a 2D AR system and that* $\Sigma_c = (\mathbb{Z}^2, \mathbb{R}^q, \mathcal{B}_c)$ *is its controllable subsystem. Let, moreover,* P, Q, P_c, Q_c *be polynomial matrices of suitable dimensions such that* $[P \ -Q] = F[P_c \ -Q_c]$, *where* F *is full column rank and* $[P_c \ Q_c]$ *is factor left prime. Then the difference equation*

$$P(\sigma_1, \sigma_2)y = Q(\sigma_1, \sigma_2)u$$

is a causal input/output representation of Σ *with respect to the cone* C *if and only if*

$$P_c(\sigma_1, \sigma_2)y = Q_c(\sigma_1, \sigma_2)u$$

is a causal input/output representation of Σ_c *with respect to the cone* C. *Moreover, the input/output operators associated with the previous causal input/output representations coincide, and the associated transfer matrix is*

$$\bar{Y} = P_c^{-1}Q_c.$$

Proof. The fact that if $P_c(\sigma_1, \sigma_2)y = Q_c(\sigma_1, \sigma_2)u$ is a causal input/output representation of Σ_c, then $P(\sigma_1, \sigma_2)y = Q(\sigma_1, \sigma_2)u$ is a causal input/output representation of Σ is trivial. Suppose conversely that $P(\sigma_1, \sigma_2)y = Q(\sigma_1, \sigma_2)u$ is a causal input/output representation of Σ and let u be any signal in $(\mathbb{R}^m)^{(C)}$. Then there exists $y \in (\mathbb{R}^p)^{(C)}$ such that $P(\sigma_1, \sigma_2)y = Q(\sigma_1, \sigma_2)u$. Then

$$S \begin{bmatrix} y \\ u \end{bmatrix} \in \mathcal{B},$$

where S is the permutation matrix introduced in Definition 1 and, moreover, the support of such a trajectory is included in C. Then by Lemma 2 we have that

$$S \begin{bmatrix} y \\ u \end{bmatrix} \in \mathcal{B}_c,$$

and consequently $P_c(\sigma_1, \sigma_2)y = Q_c(\sigma_1, \sigma_2)u$. This also shows that the previous causal input/output representations have the same impulse response and so the same transfer matrix. Finally, by (6), $P_c(\sigma_1, \sigma_2)y^{(i)} = Q_c(\sigma_1, \sigma_2)\delta^{(i)}$, for all $i = 1, \ldots, m$, implies that $P_c\bar{Y} = Q_c$. □

Remark. Since, as shown in the previous proposition, the formal power series associated with the impulse response Y is rational, then it is possible to construct a state space representation of the input/output operator Ψ. Notice that such a state space representation provides a way to obtain an input/state/output representation of the 2D AR system $\Sigma = (\mathbb{Z}^2, \mathbb{R}^q, \mathcal{B})$ associated with the causal input/output representation, similar to what Willems has done in the 1D case. Here the state variable is Markov with respect to a suitable modification of the south-west Markov property introduced in [6, 7].

Two different 2D AR systems may be described by the same input/output operator Ψ and so by the same impulse response. A direct consequence of Propositions 2 and 3 is that the input/output operator Ψ is completely determined by the controllable part of the 2D AR system and vice versa the controllable part uniquely determines Ψ.

5. Characterization of causal input/output representations. In this section we will present a method that allows us to check whether a difference equation like

$$P(\sigma_1, \sigma_2)y = Q(\sigma_1, \sigma_2)u \tag{9}$$

provides a causal input/output representation with respect to a given cone C. First we need to introduce the concept of proper rational matrix with respect to a cone. A rational matrix $H \in \mathbb{R}(z_1, z_2, z_1^{-1}, z_2^{-1})^{p\times m}$ is said to be proper with respect to a cone C if there exists $P = \sum P_{ij} z_1^i z_2^j \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{p\times p}$ and $Q \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{p\times m}$, both supported in $-C$ such that

$$H = P^{-1}Q$$

and such that P_{00} is invertible. In order to prove the next proposition we need the following lemma.

LEMMA 3. *Let $\bar{Y} \in \mathbb{R}[[z_1, z_2]]^{p\times m}$ be a formal power series and let $P = \sum P_{ij} z_1^i z_2^j \in \mathbb{R}[z_1, z_2]^{p\times p}$ and $Q \in \mathbb{R}[z_1, z_2]^{p\times m}$ be factor left coprime polynomial matrices such that P is nonsingular and*

$$P\bar{Y} = Q.$$

Then P_{00} is invertible.

Proof. First consider the scalar case $p = m = 1$. Let $P, Q \in \mathbb{R}[z_1, z_2]$ be coprime polynomials such that $P\bar{Y} = Q$. There exists $M, N \in \mathbb{R}[z_1, z_2]$ such that $F := PM + QN \in \mathbb{R}[z_1]$. Then $P(M + N\bar{Y}) = F$. Let

$$\hat{Y} := M + N\bar{Y} = \sum_{i=l}^{\infty} \hat{Y}_i(z_2) z_1^i, \quad \hat{Y}_l(z_2) \neq 0$$

and

$$P = \sum_{i=h}^{k} P_i(z_2) z_1^i, \quad P_h(z_2) \neq 0.$$

Then $P_h\hat{Y}_l \in \mathbb{R} \setminus \{0\}$ and so P_h has nonzero constant term. With the same reasoning, exchanging z_1 with z_2, we argue that the constant term of P must be nonzero.

Consider now the general case. It is clear that since $\bar{Y}$ is rational, then for each $i = 1, \ldots, p$ and $j = 1, \ldots, m$ there exist coprime $d_{ij}, n_{ij} \in \mathbb{R}[z_1, z_2]$ such that $d_{ij}\bar{Y}_{ij} = n_{ij}$. Therefore we have that $d_{ij}(0, 0) \neq 0$. Let

$$D := \left(\prod_{i=1}^{p} \prod_{j=1}^{m} d_{ij} \right) I,$$

where I is the $p \times p$ identity matrix. Then $N := D\bar{Y} \in \mathbb{R}[z_1, z_2]^{p\times m}$ and the constant term in D is invertible. If $P \in \mathbb{R}[z_1, z_2]^{p\times p}$ and $Q \in \mathbb{R}[z_1, z_2]^{p\times m}$ are factor left

coprime polynomial matrices such that P is nonsingular and $P\bar{Y} = Q$, then we have $P^{-1}Q = D^{-1}N$. Then by Lemma 5.3 in [4] there exists a polynomial matrix $X \in \mathbb{R}[z_1, z_2]^{p\times p}$ such that $D = XP$ and this implies that the constant term of P is also invertible. □

THEOREM 1. *Let $P \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{l\times p}$, $Q \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{l\times m}$. The difference equation*

$$P(\sigma_1, \sigma_2)y = Q(\sigma_1, \sigma_2)u \tag{10}$$

is an input/output representation if and only if $rank P = rank[P\ Q] = p$. The difference equation (10) *is a causal input/output representation with respect to the cone C if and only if, in addition, the rational matrix H such that $Q = PH$ is proper with respect to C.*

Proof. The proof of the first part of the theorem can be found in [12]. Consider the second part. Without loss of generality we can suppose that $C = \mathbb{N}^2$. If the rational matrix H such that $Q = PH$ is proper with respect to C, then there exist polynomial matrices $\bar{P} = \sum \bar{P}_{ij} z_1^{-i} z_2^{-j}, \bar{Q} = \sum \bar{Q}_{ij} z_1^{-i} z_2^{-j}$ with support in $-\mathbb{N}^2$ such that $\bar{P}$, $\bar{Q}$ are factor left coprime, $\bar{P}_{00} = I$, and $\bar{P}^{-1}\bar{Q} = H$. Therefore, $Q = P\bar{P}^{-1}\bar{Q}$, and so by Lemma 5.3 in [4] there exists a polynomial matrix $X \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{l\times p}$ such that $[P\ Q] = X[\bar{P}\ \bar{Q}]$. Suppose now that $u \in (\mathbb{R}^m)^{(C)}$ and let $y \in (\mathbb{R}^p)^{(C)}$ be defined for all $(h, k) \in \mathbb{N}^2$ recursively as follows:

$$y(h,k) := -\sum_{(i,j)\neq(0,0)} \bar{P}_{ij} y(h-i, k-j) + \sum \bar{Q}_{ij} u(h-i, k-j). \tag{11}$$

Since the equation (11) holds for all $(h, k) \in \mathbb{Z}^2$, we have that $\bar{P}(\sigma_1, \sigma_2)y = \bar{Q}(\sigma_1, \sigma_2)u$, and consequently $P(\sigma_1, \sigma_2)y = Q(\sigma_1, \sigma_2)u$.

Suppose conversely that $P(\sigma_1, \sigma_2)y = Q(\sigma_1, \sigma_2)u$ is a causal input/output representation and let $Y \in (\mathbb{R}^{p\times m})^{(C)}$ be its impulse response. Define

$$\bar{Y} := \sum_{i,j\in\mathbb{N}} Y(t_1, t_2) z_1^{-t_1} z_2^{-t_2}$$

as the formal power series in $\mathbb{R}[[z_1^{-1}, z_2^{-1}]]^{p\times m}$ associated with Y. Then we have that

$$P\bar{Y} = Q.$$

Let $\bar{P} \in \mathbb{R}[z_1^{-1}, z_2^{-1}]^{p\times p}$ and $\bar{Q} \in \mathbb{R}[z_1^{-1}, z_2^{-1}]^{p\times m}$ be coprime polynomial matrices such that

$$\bar{P}\bar{Y} = \bar{Q}.$$

By Lemma 3 the constant term of $\bar{P}$ is invertible. Notice now that $P(\sigma_1, \sigma_2)y = Q(\sigma_1, \sigma_2)u$ and $\bar{P}(\sigma_1, \sigma_2)y = \bar{Q}(\sigma_1, \sigma_2)u$ have the same impulse response. If $\mathcal{B}$ is the behavior associated with $P(\sigma_1, \sigma_2)y = Q(\sigma_1, \sigma_2)u$ and $\bar{\mathcal{B}}$ is the behavior associated with $\bar{P}(\sigma_1, \sigma_2)y = \bar{Q}(\sigma_1, \sigma_2)u$, then, since $\bar{\mathcal{B}}$ is controllable, $\bar{\mathcal{B}} = \mathcal{B}_c \subseteq \mathcal{B}$. As mentioned in the preliminaries on the behavioral approach, this implies that there exists a polynomial matrix X such that $P = \bar{P}X$ and $Q = \bar{Q}X$ and so $Q = P\bar{P}^{-1}\bar{Q}$. □

Given a cone C and an input/output representation

$$P(\sigma_1, \sigma_2)y = Q(\sigma_1, \sigma_2)u, \tag{12}$$

the previous theorem suggests an algorithmic method that allows us to verify if (12) is causal with respect to the cone C. It consists of two steps.

1. Perform a change of coordinates in $\mathbb{Z}^2$ and the corresponding change of variables in P, Q in such a way as to transform C in $\mathbb{N}^2$. Let P', Q' be the matrices P, Q after this change of variables.

2. Find $\bar{P} \in \mathbb{R}[z_1^{-1}, z_2^{-1}]^{p\times p}$ and $\bar{Q} \in \mathbb{R}[z_1^{-1}, z_2^{-1}]^{p\times m}$ that are left coprime as matrices with entries in $\in \mathbb{R}[z_1^{-1}, z_2^{-1}]$ and such that

$$P'\bar{P}^{-1}\bar{Q} = Q'.$$

Then (12) is causal with respect to C if and only if the constant term of $\bar{P}$ is invertible.

Notice that the pair of matrices $\bar{P}, \bar{Q}$ through formula (11) provides a computational way to represent the input/output operator associated with the causal input/output representation (12).

6. Existence and construction of causal input/output representations. In the 1D case it can be shown that, given an AR system Σ and a given cone (that in this case can be either $\mathbb{N}$ or $-\mathbb{N}$), it is always possible to find a causal input/output representation of Σ with respect to the cone. In this section we will show that also in the 2D case this is possible with some restrictions. The fact that this representation cannot be found in general for any given cone is shown in the following example.

Example 1. Let $\Sigma = (\mathbb{Z}^2, \mathbb{R}^2, \mathcal{B})$ be a 2D AR system with $\mathcal{B} = \ker R(\sigma_1, \sigma_2)$ and $R = [z_1 - z_2 \mid -1]$. Therefore a trajectory $(w_1, w_2)^T$ is in $\mathcal{B}$ if and only if it satisfies the difference equation

$$w_1(i+1, j) - w_1(i, j+1) - w_2(i, j) = 0. \tag{13}$$

Consider the cone $C = \mathbb{N}^2$. We want to show that there exists no causal input/output representations of Σ with respect to the cone C. This can be verified by applying Theorem 1. Actually, consider the input/output representation

$$P(\sigma_1, \sigma_2)w_1 = Q(\sigma_1, \sigma_2)w_2, \tag{14}$$

where $P = z_1 - z_2$ and $Q = 1$, then $Q = P\bar{P}^{-1}\bar{Q}$, where $\bar{P} = z_1^{-1}z_2^{-1}$ and $\bar{Q} = z_2^{-1} - z_1^{-1}$ are coprime in $\mathbb{R}[z_1^{-1}, z_2^{-1}]$. Observe finally that the constant term of $\bar{P}$ is zero. Similarly, it can be shown that (14) is not causal with respect to $\mathbb{N}^2$ even if we suppose that w_1 is the input and w_2 the output.

The same fact can be shown directly. Suppose we consider the input/output representation (14), where w_1 is considered as the input and w_2 as the output. Suppose that w_1 is 1 in $(0, 0)$ and 0 elsewhere and evaluate the difference equation for $i = -1, j = 0$. Then we obtain that $w_2(-1, 0) = 1$, and so this representation cannot be causal with respect to the cone C.

If conversely we suppose that w_1 is the output and w_2 is the input and if we suppose that w_2 is 1 in $(0, 0)$ and 0 elsewhere, then evaluating the difference equation (13) for $(i, j) = (0, 0)$, we obtain that $w_1(1, 0) - w_1(0, 1) = 1$. Moreover, evaluating the difference equation (13) for $(i, j) = (-1, 1)$ and $(i, j) = (1, -1)$, we see that $w_1(2, -1) = w_1(1, 0)$ and that $w_1(-1, 2) = w_1(0, 1)$ and so $w_1(2, -1) - w_1(-1, 2) = 1$. It follows that $w_1(2, -1), w_1(-1, 2)$ cannot both be equal to zero, and this implies that this input/output representation also cannot be causal with respect to the cone C.

The following theorem shows what can be done.

THEOREM 2. *Let $\Sigma = (\mathbb{Z}^2, \mathbb{R}^q, \mathcal{B})$ be a 2D AR system with $\mathcal{B} = \ker R(\sigma_1, \sigma_2)$. Moreover, let C be any cone in $\mathbb{Z}^2$. Then there exists a cone C' containing C such that there exists a causal input/output representation of Σ with respect to C'.*

In order to prove the previous theorem we need some notations and a technical result. Consider the total ordering $<_T$ in $\mathbb{Z}^2$ defined in the following way:

$$(n_1, n_2) <_T (m_1, m_2) \quad \Leftrightarrow \quad \begin{array}{l} n_1 < m_1 \text{ or} \\ n_1 = m_1 \text{ and } n_2 < m_2. \end{array}$$

Let $f \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]$. Then f can be expressed as follows:

$$f = \sum f_{ij} z_1^i z_2^j, \qquad f_{ij} \in \mathbb{R}.$$

The finite set of $(i, j) \in \mathbb{Z}^2$ such that $f_{ij} \neq 0$ is said to be in the support of f, while the greatest element in the support of f with respect to the total ordering $<_T$ is called the degree of f and is denoted by $\deg f$.

LEMMA 4. *Let $R \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{l \times q}$ be a rank p polynomial matrix. Then there exists a full row rank polynomial matrix $U \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{p \times l}$ and a permutation matrix $S \in \{0,1\}^{q \times q}$ such that*

$$URS = \begin{bmatrix} r_{11} & r_{12} & \cdots & r_{1p} & \cdots & r_{1q} \\ 0 & r_{22} & \cdots & r_{2p} & \cdots & r_{2q} \\ \vdots & \vdots & \ddots & \vdots & \cdots & \vdots \\ 0 & 0 & \cdots & r_{pp} & \cdots & r_{pq} \end{bmatrix} \tag{15}$$

with $r_{ii} \neq 0$ and $\deg r_{ii} \geq \deg r_{ij}$ for all $j \geq i$.

Proof. First we suppose that R is full row rank. We will show the assertion of the lemma by induction on p. If $p = 1$, then the assertion is clearly true. Suppose now that the assertion is true for $p = k-1$ and let $R \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{k \times q}$ be a full row rank polynomial matrix. By the postmultiplication by a suitable permutation matrix $\bar{S} \in \{0,1\}^{q \times q}$ we are able to obtain that the polynomial in position $(1,1)$ in $R\bar{S}$ has the greatest degree among all the polynomials in the first row of $R\bar{S}$. Let $\bar{V} \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{k-1 \times k}$ be a full row rank polynomial matrix such that the first column of $\bar{V}R\bar{S}$ is zero and let

$$\bar{U} := \begin{bmatrix} 1 & 0 & \cdots & 0 \\ & & \bar{V} & \end{bmatrix} \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{k \times k}.$$

Consequently

$$\bar{U}R\bar{S} = \begin{bmatrix} r'_{11} & r'_1 \\ 0 & R' \end{bmatrix},$$

where $r'_1 \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{1 \times q-1}$ and $R' \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{k-1 \times q-1}$. We want to show now that R' is full row rank. Suppose that $v \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{k-1}$ is such that $v^T R' = 0$. Then

$$v^T \bar{V} R\bar{S} = v^T \begin{bmatrix} 0 & R' \end{bmatrix} = 0,$$

and so, since $\bar{S}, R$, and $\bar{V}$ are full row rank, we have $v = 0$. The fact that R' is full row rank implies that $\bar{U}$ is full row rank. By induction, there exists a nonsingular polynomial matrix $U' \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{k-1 \times k-1}$ and a permutation matrix $S' \in \{0,1\}^{q-1 \times q-1}$ such that

$$U'R'S' = \begin{bmatrix} r'_{11} & r'_{12} & \cdots & r'_{1\ k-1} & \cdots & r'_{1\ q-1} \\ 0 & r'_{22} & \cdots & r'_{2\ k-1} & \cdots & r'_{2\ q-1} \\ \vdots & \vdots & \ddots & \vdots & \cdots & \vdots \\ 0 & 0 & \cdots & r'_{k-1\ k-1} & \cdots & r'_{k-1\ q-1} \end{bmatrix}$$

with $r'_{ii} \neq 0$ and $\deg r'_{ii} \geq \deg r'_{ij}$ for all $j \geq i$. Finally, defining

$$U := \begin{bmatrix} 1 & 0 \\ 0 & U' \end{bmatrix} \bar{U}, \quad S := \bar{S} \begin{bmatrix} 1 & 0 \\ 0 & S' \end{bmatrix},$$

a simple computation shows that URS satisfies the thesis.

We now consider the general case. It is not restrictive to assume that the first p rows of R constitute a full row rank polynomial matrix R'. Then there exist a nonsingular polynomial matrix $U' \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{p \times p}$ and a permutation matrix $S \in \{0,1\}^{q \times q}$ such that $U'R'S$ is in the form (15). Put $U := [\, U' \quad 0\,] \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{p \times l}$. Then URS is in the form (15). □

Proof of the theorem. As usual, it is not restrictive to suppose that C coincides with $\mathbb{N}^2$. Suppose that R has rank p. By Lemma 4 there exists a full row rank polynomial matrix $U \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{l \times p}$ and a permutation matrix $S \in \{0,1\}^{q \times q}$ such that (15) holds with $r_{ii} \neq 0$ and $\deg r_{ii} \geq \deg r_{ij}$ for all $j \geq i$. It is not restrictive to assume that $\deg r_{11} = \deg r_{22} = \cdots = \deg r_{pp} = (0,0)$ (this can be obtained by premultiplying URS by a diagonal matrix having suitable monomials on the diagonal). Then there exists a cone C' containing $\mathbb{N}^2$ such that the supports of each polynomial in URS is included in $-C'$. Partition

$$RS = [\, P \quad -Q\,]$$

with $P \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{l \times p}$ and $Q \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{l \times m}$, where $m = q - p$. We want to show that

$$P(\sigma_1, \sigma_1)y = Q(\sigma_1, \sigma_1)u \tag{16}$$

is a causal input/output representation with respect to the cone C'. The difference equation (16) is an input/output representation. Indeed, rank $[P \ -Q] = \text{rank } R = p$, while on one hand rank $P \leq p$, and on the other hand rank $P \geq \text{rank } UP = p$, since UP is a square $p \times p$ upper triangular matrix. Now perform a change of coordinates in $\mathbb{Z}^2$ and the corresponding change of variables in such a way that C' is transformed into $\mathbb{N}^2$. In this way $URS \in \mathbb{R}[z_1^{-1}, z_2^{-1}]^{p \times q}$. Partition

$$URS = [\, P' \quad -Q'\,]$$

with $P' \in \mathbb{R}[z_1^{-1}, z_2^{-1}]^{p \times p}$ and $Q' \in \mathbb{R}[z_1^{-1}, z_2^{-1}]^{p \times m}$. By construction the constant term of P' is an invertible matrix. Let H be the rational matrix such that $Q = PH$. Then $Q' = P'H$ and so $H = P'^{-1}Q'$ is proper with respect to $\mathbb{N}^2$. By Theorem 1 this implies that the input/output representation (16) is causal with respect to C'.

Example 2. Let $\Sigma = (\mathbb{Z}^2, \mathbb{R}^2, \mathcal{B})$ be a 2D AR system with $\mathcal{B} = \ker R(\sigma_1, \sigma_2)$ and

$$R = \begin{bmatrix} z_1 - z_2^2 & 0 & 2z_1z_2 - 1 \\ 1 & z_1 - z_2 & 1 \end{bmatrix}.$$

We want to find a causal input/output representation of Σ with respect to a cone C containing $\mathbb{N}^2$. We apply the algorithm shown in Lemma 4. Since the polynomial with greatest degree in the first row is the third one, postmultiply R by the permutation matrix

$$S = \begin{bmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{bmatrix}$$

which performs the exchange of the first and third columns of R. Notice that if $\bar{V} := [\,-1 \quad 2z_1z_2 - 1\,]$, then

$$\begin{bmatrix} 1 & 0 \\ & \bar{V} \end{bmatrix} RS = \begin{bmatrix} 2z_1z_2 - 1 & 0 & z_1 - z_2^2 \\ 0 & 2z_1^2z_2 - 2z_1z_2^2 - z_1 + z_2 & -z_1^2 + z_2 + 2z_1z_2 - 1 \end{bmatrix}.$$

Therefore, premultiplying by $\operatorname{diag}\{z_1^{-1}z_2^{-1}, z_1^{-2}z_2^{-1}\}$, we obtain a polynomial matrix $U \in \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]^{2\times 2}$ such that

$$URS = \begin{bmatrix} 2 - z_1^{-1}z_2^{-1} & 0 & z_2^{-1} - z_1^{-1}z_2 \\ 0 & 2 - 2z_1^{-1}z_2 - z_1^{-1}z_2^{-1} + z_1^{-2} & -z_2^{-1} + z_1^{-2} + 2z_1^{-1} - z_1^{-2}z_2^{-1} \end{bmatrix}.$$

Let $C := \{\alpha(1,-1) + \beta(0,1) \in \mathbb{Z}^2 : \alpha, \beta \in \mathbb{N}\}$. Then $C \supseteq \mathbb{N}^2$, and moreover, all the entries of URS have support in $-C$. Therefore, if we let

$$P := \begin{bmatrix} 2z_1z_2 - 1 & 0 \\ 1 & z_1 - z_2 \end{bmatrix}, \qquad Q := \begin{bmatrix} z_1 - z_2^2 \\ 1 \end{bmatrix},$$

then $P(\sigma_1, \sigma_1)y = Q(\sigma_1, \sigma_1)u$ is a causal input/output representation of Σ with respect to the cone C.

Remark. The construction of causal input/output representations suggested by Theorem 2 is in some way partial. We would achieve a more satisfactory and complete solution to the problem of constructing causal input/output representations if, given an input/output representation

$$P(\sigma_1, \sigma_1)y = Q(\sigma_1, \sigma_1)u, \tag{17}$$

we were able to parametrize the set of all the cones C such that (17) is causal with respect to C. At the moment, the solution to this problem is unknown to us and its investigation is the object of our future research.

RISK-SENSITIVE PRODUCTION PLANNING OF A STOCHASTIC MANUFACTURING SYSTEM*

W. H. FLEMING† AND Q. ZHANG‡

Abstract. This paper is concerned with long-run average risk-sensitive control of production planning in a manufacturing system with machines that are subject to breakdown and repair. By using a logarithmic transformation, it is shown that the associated Hamilton–Jacobi–Bellman equation has a viscosity solution. The risk-sensitive control problem has a dynamic stochastic game interpretation. Finally, a limiting problem is obtained when the rates of machine breakdown and repair go to infinity.

Key words. risk-sensitive control, production planning, logarithmic transformation, irreducible Markov chain

1. Introduction.

In this paper we consider a manufacturing system which consists of machines that are subject to breakdown and repair. The objective of the problem is to choose a production planning to minimize a risk-sensitive cost criterion over the infinite horizon. In risk-sensitive control theory, typically an exponential-of-integral cost criterion is considered. Such cost functions heavily penalize state trajectories and controls which give large values to the exponent. The risk-sensitive approach has been applied to the so-called disturbance attenuation problem; see, for example, Whittle [17], Fleming and McEneaney [7], Basar and Bernhard [1] and Barron and Jensen [2], Glover and Doyle [12], and references therein. In Fleming and McEneaney [7], risk-sensitive control problems of controlled diffusions are considered. By using the associated dynamic programming equations, they show that as the system noise goes to zero, the value function of the risk-sensitive control problem converges to the value function of a differential game problem.

In this paper, we consider the risk-sensitive control of manufacturing systems with stochastic production capacity. The machine capacity process will be assumed to be an irreducible finite state (jump) Markov chain, with generator Q/ε, where $\varepsilon > 0$ is a parameter related to the frequency of machine breakdown and repair relative to an underlying production time scale. For simplicity, we consider a one-part-type manufacturing system with constant demand. The control is the production rate, which is subject to a random machine capacity constraint, as in Sethi and Zhang [15]. For fixed $\varepsilon > 0$ the goal is to find a control policy which minimizes the long-term growth rate of an expected exponential-of-integral criterion, as in formula (2.2). The minimum growth rate λ^ε and an associated cost potential function w^ε satisfy dynamic programming equations (3.1), which form a system of first-order nonlinear partial differential equations. The function w^ε is a viscosity sense solution.

Theorem 3.3 states that a solution exists. It is proved using the so-called vanishing discount approach often used for analysis of average cost minimization problems. This is done by using a logarithmic transformation introduced by Bensoussan and Nagai [3] to obtain an equivalent problem that is easier to deal with. In section 4, we discuss the asymptotic property of the problem as the rate of fluctuation of the production capacity process goes to infinity ($\varepsilon \to 0$). We show that the risk-sensitive control problem can be approximated by a limiting problem in which the stochastic capacity process can be averaged out and replaced by its average. This procedure is analogous to passing in the disturbance attenuation problem from the risk-sensitive model with small noise intensity to the deterministic robust control limit.

In our model, we assume a positive deterioration rate a for items in storage (formula (2.1)). This corresponds to a stability condition typically imposed for disturbance attenuation problems on an infinite time horizon (see Fleming and McEneaney [7]), and this assumption is essential in the proof of technical estimates in Lemma 3.2. Nevertheless, it would be interesting to weaken the assumption that $a > 0$.

2. Problem formulation. Let us consider a one-part-type and parallel-machine manufacturing system with stochastic production capacity and constant demand for its production over time. For $t \geq 0$, let $x(t)$, $u(t)$, and z denote the surplus level (the state variable), the production rate (the control variable), and the constant demand rate, respectively. We assume $x(t) \in \mathbb{R} = (-\infty, \infty)$, $u(t) \in \mathbb{R}^+ = [0, \infty)$, $t \geq 0$, and z a positive constant. They satisfy the following differential equation:

$$\dot{x}(t) = -ax(t) + u(t) - z, \qquad x(0) = x, \tag{2.1}$$

where $a > 0$ is a constant, representing the deterioration rate (or spoilage rate) of the finished product.

Let $(\Omega, \mathcal{F}, P)$ denote a probability space. Let $\alpha^\varepsilon(t) \in \mathcal{M} = \{0, 1, 2, \ldots, m\}$, $t \geq 0$, denote a Markov process generated by Q/ε, where $\varepsilon > 0$ is a small parameter and $Q = (q_{ij})$, $i, j \in \mathcal{M}$, is an $(m+1) \times (m+1)$ matrix such that $q_{ij} \geq 0$ for $i \neq j$ and $q_{ii} = -\sum_{i \neq j} q_{ij}$. We let $\alpha^\varepsilon(t)$ represent the maximum production capacity of the system at time t. The representation for $\mathcal{M}$ usually stands for the case of m identical machines, each with a unit capacity and having two states: up and down.

The production constraints are given by the inequalities:

$$0 \leq u(t) \leq \alpha^\varepsilon(t), \qquad t \geq 0.$$

Definition 2.1. *A production control process $u(\cdot) = \{u(t),\, t \geq 0\}$ is admissible if* (i) *$u(t)$ is $\sigma\{\alpha^\varepsilon(s), 0 \leq s \leq t)$ progressively measurable and* (ii) *$0 \leq u(t) \leq \alpha^\varepsilon(t)$ for all $t \geq 0$. Let $\mathcal{A}^\varepsilon$ denote the class of admissible controls.*

Let $L(x, u)$ denote a cost function of the surplus and the production. The objective of the problem is to choose $u(\cdot) \in \mathcal{A}^\varepsilon$ to minimize

$$J^\varepsilon(u(\cdot)) = \limsup_{T \to \infty} \frac{\varepsilon}{T} \log E \exp\left(\frac{1}{\varepsilon} \int_0^T L(x(t), u(t))dt\right), \tag{2.2}$$

where $x(\cdot)$ is the surplus process corresponding to the production process $u(\cdot)$. Let $\lambda^\varepsilon = \inf_{u(\cdot) \in \mathcal{A}^\varepsilon} J^\varepsilon(u(\cdot))$.

A motivation for choosing such an exponential cost criterion is that such criteria are sensitive to large values of the exponent which occur with small probability, for example, rare sequences of unusually many machine failures resulting in shortages ($x(t) < 0$).

Remark 2.2. In Zhang [18] a discounted cost criterion

$$J^\varepsilon(u(\cdot)) = \sqrt{\varepsilon}\log E\exp\left(\frac{1}{\sqrt{\varepsilon}}\int_0^\infty e^{-\rho t}L(x(t),u(t))dt\right)$$

is considered. The scale parameter in the cost is $\sqrt{\varepsilon}$ instead of ε as in (2.2). This is because the convergence involving a discounted cost is mainly affected by the convergence rate of $\alpha^\varepsilon(\cdot)$ to its equilibrium distribution, which is of order $\sqrt{\varepsilon}$.

Remark 2.3. The positive spoilage rate a appears in certain crucial estimates (see Lemma 3.2 (ii)). It also implies a uniform bound for $x(t)$. Note that the control $u(\cdot)$ is bounded between 0 and m. This implies that a solution $x(\cdot)$ to (2.1) must satisfy

$$|x(t)| \le |x|e^{-at} + (m+z)\int_0^t e^{-a(t-s)}ds \le |x|e^{-at} + \frac{m+z}{a}. \tag{2.3}$$

For a multidimensional problem, in order to obtain such a bound for $x(t)$, one may replace $a > 0$ by a matrix A with eigenvalues having positive real parts.

We assume that the cost function $L(x,u)$ and the production capacity process $\alpha^\varepsilon(\cdot)$ satisfy the following.

(A1) $L(x,u) \ge 0$ is continuous, bounded, and uniformly Lipschitz in x.

Remark 2.4. In a manufacturing system the running cost function $L(x,u)$ is usually chosen to be of the form $L(x,u) = h(x) + c(u)$ with piecewise linear $h(x)$ and $c(u)$. Note that piecewise linear functions are not bounded as required in (A1). However, this is not important, in view of the uniform bounds on $u(t)$ and on $x(t)$ for initial state $x = x(0)$ in any bounded set.

(A2) Q is *irreducible* in the following sense: the equations

$$\nu Q = 0 \quad \text{and} \quad \sum_{i=0}^m \nu_i = 1$$

have a unique solution $\nu = (\nu_0, \nu_1, \ldots, \nu_m)$ with $\nu_k > 0$, $k = 0, 1, \ldots, m$. The vector ν is called the *equilibrium distribution* of the Markov chain $\alpha^\varepsilon(\cdot)$.

Remark 2.5. One may also consider the model in which the demand rate $z = z(t)$ is a finite state Markov chain. In this case, one needs to consider various rates of fluctuation of $z(t)$ in comparison with that of $\alpha^\varepsilon(t)$. We refer the reader to Sethi and Zhang [15, Chap. 11] for related discussions in connection with production and marketing.

In the next section, we discuss the dynamics of the system and the associated Hamilton–Jacobi–Bellman (HJB) equations.

3. HJB equations. Formally, we can write the associated HJB equation as follows:

$$\frac{\lambda^\varepsilon}{\varepsilon} = \inf_{0\le u\le\alpha}\left\{(-ax+u-z)\frac{w_x^\varepsilon(x,\alpha)}{\varepsilon} + \exp\left(-\frac{w^\varepsilon(x,\alpha)}{\varepsilon}\right)\frac{Q}{\varepsilon}\exp\left(\frac{w^\varepsilon(x,\cdot)}{\varepsilon}\right)(\alpha) + \frac{L(x,u)}{\varepsilon}\right\},$$

where $w^\varepsilon(x,\alpha)$ is the potential function, $w_x^\varepsilon(x,\alpha)$ denotes the partial derivative of $w^\varepsilon(x,\alpha)$ with respect to x, and $Qf(\cdot)(i) := \sum_{j\ne i} q_{ij}(f(j) - f(i))$ for a function f on

$\mathcal{M}$. By multiplying ε on both sides of this equation, we have

$$\lambda^\varepsilon = \inf_{0\le u\le\alpha}\Big\{(-ax+u-z)w_x^\varepsilon(x,\alpha) + \exp\Big(-\frac{w^\varepsilon(x,\alpha)}{\varepsilon}\Big)Q\exp\Big(\frac{w^\varepsilon(x,\cdot)}{\varepsilon}\Big)(\alpha)+L(x,u)\Big\}. \tag{3.1}$$

As in almost all long-run average cost problems, an immediate question is if the equation (3.1) has a solution in some sense. In this paper, we will show that (3.1) indeed has a solution in the viscosity sense. We use a vanishing discount approach. Let $\rho>0$ denote a discount factor and let $w_\rho^\varepsilon(x,\alpha)$ denote the corresponding value function. Then, the associated HJB equation has the form

$$\rho w_\rho^\varepsilon(x,\alpha) = \inf_{0\le u\le\alpha}\Big\{(-ax+u-z)(w_\rho^\varepsilon)_x(x,\alpha) +\exp\Big(-\frac{w_\rho^\varepsilon(x,\alpha)}{\varepsilon}\Big)\frac{Q}{\varepsilon}\exp\Big(\frac{w_\rho^\varepsilon(x,\cdot)}{\varepsilon}\Big)(\alpha)+L(x,u)\Big\}. \tag{3.2}$$

Let

$$\psi_\rho^\varepsilon(x,\alpha)=\exp\Big(\frac{w_\rho^\varepsilon(x,\alpha)}{\varepsilon}\Big).$$

Then, (3.2) becomes

$$\rho\psi_\rho^\varepsilon(x,\alpha)\log\psi_\rho^\varepsilon(x,\alpha) = \inf_{0\le u\le\alpha}\Big\{(-ax+u-z)(\psi_\rho^\varepsilon)_x(x,\alpha) +\frac{L(x,u)\psi_\rho^\varepsilon(x,\alpha)}{\varepsilon}+\frac{Q}{\varepsilon}\psi_\rho^\varepsilon(x,\cdot)(\alpha)\Big\}. \tag{3.3}$$

We would like to get rid of the term $\psi_\rho^\varepsilon(x,\alpha)\log\psi_\rho^\varepsilon(x,\alpha)$. One way of doing so is to use the transform device introduced by Bensoussan and Nagai [3] based on the following expression:

$$-r\log r=\inf_y\{yr+e^{-(y+1)}\}\ \text{ for any } r>0, \tag{3.4}$$

where the minimum is obtained at $y+1=-\log r$. Letting $r=\psi_\rho^\varepsilon(x,\alpha)$, we have

$$\psi_\rho^\varepsilon(x,\alpha)\log\psi_\rho^\varepsilon(x,\alpha)=-\inf_y\{y\psi_\rho^\varepsilon(x,\alpha)+e^{-(y+1)}\}.$$

In view of this and (3.3), the discounted HJB equation (3.2) has the form

$$0=\inf_{0\le u\le\alpha,y}\Big\{(-ax+u-z)(\psi_\rho^\varepsilon)_x(x,\alpha) +\frac{L(x,u)\psi_\rho^\varepsilon(x,\alpha)}{\varepsilon}+\frac{Q}{\varepsilon}\psi_\rho^\varepsilon(x,\cdot)(\alpha)+\rho y\psi_\rho^\varepsilon(x,\alpha)+\rho e^{-(y+1)}\Big\}.$$

By adding $\rho\psi_\rho^\varepsilon(x,\alpha)$ to both sides of this equation and changing $(y+1)$ to y, we obtain

$$\rho\psi_\rho^\varepsilon(x,\alpha) = \inf_{0\le u\le\alpha,y}\Big\{(-ax+u-z)(\psi_\rho^\varepsilon)_x(x,\alpha) +\frac{L(x,u)\psi_\rho^\varepsilon(x,\alpha)}{\varepsilon}+\frac{Q}{\varepsilon}\psi_\rho^\varepsilon(x,\cdot)(\alpha)+\rho y\psi_\rho^\varepsilon(x,\alpha)+\rho e^{-y}\Big\}. \tag{3.5}$$

Remark 3.1. Note that the HJB equation (3.5) consists of a set of equations coupled by a discrete variable α. A viscosity solution of such HJB equations has been considered by Soner [16] and Fleming, Sethi, and Soner [8]; see also Fleming and Soner [10] for a more general setting and Sethi and Zhang [15] for several equivalent definitions.

We consider the following control problem so that the value function is a viscosity solution to this equation:

$$\begin{aligned}
&\text{Minimize}\\
&\quad J_\rho^\varepsilon(x,\alpha,u(\cdot),y(\cdot))\\
&\qquad = E\int_0^\infty e^{-\rho t}\exp\left[\int_0^t\left(\frac{L(x(s),u(s))}{\varepsilon}+\rho y(s)\right)ds\right](\rho e^{-y(t)})dt\\
&\text{subject to}\\
&\quad \dot{x}(t) = -ax(t)+u(t)-z,\ x(0)=x \text{ and}\\
&\quad \text{both } u(\cdot) \text{ and } y(\cdot) \text{ are } \alpha^\varepsilon(\cdot) \text{ adapted such that}\\
&\quad 0\le u(t)\le \alpha^\varepsilon(t) \text{ and } -M_0\le y(t)\le 0,\ t\ge 0\\
&\quad \text{for any constant } M_0 \ge \sup_{x,u}|L(x,u)|/(\rho\varepsilon).
\end{aligned} \tag{3.6}$$

With a little abuse of notation, let $\psi_\rho^\varepsilon(x,\alpha)$ denote the value function of this control problem. We next show that such $\psi_\rho^\varepsilon(x,\alpha)$ is a viscosity solution to (3.5) with some a priori estimates.

LEMMA 3.2. (i) *For all x and α,*

$$1\le \psi_\rho^\varepsilon(x,\alpha)\le \exp\left(\frac{C_1}{\rho\varepsilon}\right),$$

where $C_1 = ||L(x,\alpha)|| := \sup_{x,u}|L(x,u)|$.

(ii) *For all x, $\tilde{x}$, and α,*

$$\exp\left(-\frac{C_2|x-\tilde{x}|}{\varepsilon}\right)\le \frac{\psi_\rho^\varepsilon(x,\alpha)}{\psi_\rho^\varepsilon(\tilde{x},\alpha)}\le \exp\left(\frac{C_2|x-\tilde{x}|}{\varepsilon}\right),$$

where $C_2 = ||L_x(x,u)||/a$.

(iii) *For each $r>0$ there is a constant $C_3>0$ independent of $\rho\le 1$ and ε such that, for all α, $\tilde{\alpha}$, and $|x|\le r$,*

$$e^{-C_3}\le \frac{\psi_\rho^\varepsilon(x,\alpha)}{\psi_\rho^\varepsilon(x,\tilde{\alpha})}\le e^{C_3}.$$

(iv) *$\psi_\rho^\varepsilon(x,\alpha)$ is a viscosity solution to* (3.5).

Proof. We begin with (i). We first show $\psi_\rho^\varepsilon(x,\alpha)\ge 1$. In view of the nonnegativity of $L(x,u)$, it suffices to show for all deterministic Borel measurable $-M_0\le y(t)\le 0$, $t\ge 0$,

$$\int_0^\infty \rho\exp\left(\int_0^t \rho(y(s)-1)ds - y(t)\right)dt \ge 1. \tag{3.7}$$

Let

$$\gamma = \inf_{y(\cdot)}\int_0^\infty \rho\exp\left(\int_0^t \rho(y(s)-1)ds - y(t)\right)dt.$$

First, it is easy to see that $\gamma \geq 0$. By taking $y(t) = 0$, $t \geq 0$, we obtain

$$\int_0^\infty \rho \exp\left(\int_0^t \rho(y(s) - 1)ds - y(t)\right) dt = \int_0^\infty \rho \exp\left(-\rho t\right) dt = 1.$$

Thus, by definition, $\gamma \leq 1$.

In view of the control problem defined in (3.6), we may consider γ as the value function of a problem with no state and control costs, i.e., with $L(x, u)$ replaced by 0. Then, following the standard dynamic programming approach as in Sethi and Zhang [15], we can show that the constant γ is the unique solution to the following HJB equation:

$$\rho\gamma = \inf_{-M_0 \leq y \leq 0} \{\rho y\gamma + \rho e^{-y}\}.$$

The only solution to this equation is $\gamma = 1$. Thus, the inequality (3.7) follows.

Let $y(t) = -M$ for all $t \geq 0$ and let $C_1 = ||L(x, u)||$. Then, for all admissible $u(\cdot)$,

$$\begin{aligned}\psi_\rho^\varepsilon(x, \alpha) &\leq E \int_0^\infty \rho \exp\left[\int_0^t \left(\frac{C_1}{\varepsilon} - \rho(M + 1)\right) ds + M\right] dt \\ &= \frac{\varepsilon\rho e^M}{|C_1 - \rho\varepsilon(M + 1)|}.\end{aligned}$$

Let $M = C_1/(\rho\varepsilon)$. Then, $\varepsilon\rho e^M/|C_1 - \rho\varepsilon(M + 1)| = e^M = e^{C_1/(\rho\varepsilon)}$. This proves (i).

We now prove (ii). Let $(u(\cdot), y(\cdot))$ denote a pair of admissible controls and let $x(t)$ and $\tilde{x}(t)$ denote the corresponding trajectories with initial values x and $\tilde{x}$, respectively. Then,

$$x(t) - \tilde{x}(t) = (x - \tilde{x})e^{-at} \quad \text{for all } t \geq 0.$$

In view of this and the Lipschitz property of $L(x, u)$, we have

$$L(x(t), u(t)) \leq L(\tilde{x}(t), u(t)) + C_0|x - \tilde{x}|e^{-at},$$

where $C_0 = ||L_x(x, u)||$. For notational simplification, let

$$\eta(t, y(\cdot)) = \rho \exp\left(\int_0^t \rho(y(s) - 1)ds - y(t)\right).$$

Then, we have

$$\begin{aligned}&E \int_0^\infty \left[\exp\left(\int_0^t \frac{L(x(s), u(s))}{\varepsilon} ds\right)\right] \eta(t, y(\cdot))dt \\ &\quad \leq E \int_0^\infty \left[\exp\left(\int_0^t \frac{L(\tilde{x}(s), u(s))}{\varepsilon} ds\right) \exp\left(\int_0^t \frac{C_0|x - \tilde{x}|e^{-as}}{\varepsilon} ds\right)\right] \eta(t, y(\cdot))dt \\ &\quad = \exp\left(\int_0^\infty \frac{C_0|x - \tilde{x}|e^{-as}}{\varepsilon} ds\right) E \int_0^\infty \left[\exp\left(\int_0^t \frac{L(\tilde{x}(s), u(s))}{\varepsilon} ds\right)\right] \eta(t, y(\cdot))dt \\ &\quad = \exp\left(\frac{C_0|x - \tilde{x}|}{a\varepsilon}\right) E \int_0^\infty \left[\exp\left(\int_0^t \frac{L(\tilde{x}(s), u(s))}{\varepsilon} ds\right)\right] \eta(t, y(\cdot))dt.\end{aligned}$$

Hence,

$$\psi_\rho^\varepsilon(x, \alpha) \leq \left[\exp\left(\frac{C_0|x - \tilde{x}|}{a\varepsilon} ds\right)\right] \psi_\rho^\varepsilon(\tilde{x}, \alpha).$$

Similarly, we can show the other inequality in (ii).

We now show (iii). Let $\alpha^\varepsilon(0)=\alpha$ and τ denote the first time $\alpha^\varepsilon(\cdot)$ jumps to $\tilde\alpha$. Let

$$G(s)=\frac{L(x(s),u(s))}{\varepsilon}+\rho(y(s)-1)\quad\text{and}\quad h(t)=\rho e^{-y(t)}.$$

Then, the dynamic programming principle with the random stopping time τ (see the Appendix for a sketch of the proof) gives

$$\psi^\varepsilon_\rho(x,\alpha)=\inf_{u(\cdot),y(\cdot)}E\Bigg\{\int_0^\tau\left(\exp\int_0^t G(s)ds\right)h(t)dt + \left(\exp\int_0^\tau G(s)ds\right)\psi^\varepsilon_\rho(x(\tau),\tilde\alpha)\Bigg\}.$$

Using $L\ge 0$ and $h>0$, we have

$$\psi^\varepsilon_\rho(x,\alpha)\ge E\left\{\left(\exp\int_0^\tau\rho(y(s)-1)ds\right)\psi^\varepsilon_\rho(x(\tau),\tilde\alpha)\right\}.$$

For x in any bounded interval, by (ii) and $|x(\tau)-x|\le K\tau(1+|x|)\le K\tau(1+r)$,

$$\frac{\psi^\varepsilon_\rho(x(\tau),\tilde\alpha)}{\psi^\varepsilon_\rho(x,\tilde\alpha)}\ge\exp\left(-\frac{C_2K\tau(1+|x|)}{\varepsilon}\right)\ge\exp\left(-\frac{C_2K\tau(1+r)}{\varepsilon}\right).$$

We can assume $y(t)\ge -||L||/\rho\varepsilon$, which implies

$$\exp\int_0^t\rho(y(s)-1)ds\ge\exp\left(-\left[\frac{||L||}{\varepsilon}+\rho\right]\tau\right).$$

Take $B>||L||+\varepsilon\rho+C_2K(1+r)$. Change of time scale $t=\varepsilon t'$ sends $Q/\varepsilon\to Q$, which implies

$$Ee^{-B\tau/\varepsilon}\ge e^{-C_3}\quad\text{for some } C_3>0.$$

Therefore,

$$\psi^\varepsilon_\rho(x,\alpha)\ge\psi^\varepsilon_\rho(x,\tilde\alpha)e^{-C_3}.$$

Exchange α and $\tilde\alpha$ to get the opposite inequality.

Finally it can be shown as in Sethi and Zhang [15] that $\psi^\varepsilon_\rho(x,\alpha)$ is a viscosity solution to (3.5) under the constraint $-M_0\le y\le 0$; i.e.,

$$\begin{aligned}\rho\psi^\varepsilon_\rho(x,\alpha)=\inf_{0\le u\le\alpha,-M_0\le y\le 0}\Bigg\{&(-ax+u-z)(\psi^\varepsilon_\rho)_x(x,\alpha)\\&+\frac{L(x,u)\psi^\varepsilon_\rho(x,\alpha)}{\varepsilon}+\frac{Q}{\varepsilon}\psi^\varepsilon_\rho(x,\cdot)(\alpha)+\rho y\psi^\varepsilon_\rho(x,\alpha)+\rho e^{-y}\Bigg\}.\end{aligned}\tag{3.8}$$

Since $\psi^\varepsilon_\rho(x,\alpha)\ge 1$ and the minimum in (3.8) is obtained at $y=-\log\psi^\varepsilon_\rho(x,\alpha)\le 0$, $\psi^\varepsilon_\rho(x,\alpha)$ is also a viscosity solution to (3.5). The proof of the lemma is complete. □

THEOREM 3.3. *The HJB equation* (3.1) *has a viscosity solution* $(\lambda^\varepsilon,w^\varepsilon(x,\alpha))$.

Proof. In this proof, ε is fixed. In view of the logarithmic transformation

$$\psi_\rho^\varepsilon(x,\alpha) = \exp\left(\frac{w_\rho^\varepsilon(x,\alpha)}{\varepsilon}\right),$$

we have $w_\rho^\varepsilon(x,\alpha) = \varepsilon \log \psi_\rho^\varepsilon(x,\alpha)$. It follows from Lemma 3.2 that

(i) $0 \le \rho w_\rho^\varepsilon(x,i) \le C_1$, uniformly in ρ;

(ii) $|w_\rho^\varepsilon(x,\alpha) - w_\rho^\varepsilon(\tilde{x},\alpha)| \le C_2|\tilde{x}-x|$, uniformly in ρ;

(iii) for each $r>0$, $|x|\le r$, $\alpha,\tilde{\alpha}\in\mathcal{M}$, $|w_\rho^\varepsilon(x,\alpha) - |w_\rho^\varepsilon(x,\tilde{\alpha})| \le \varepsilon \log C_3$, uniformly in ρ.

Then, in view of these and the Arzela–Ascoli theorem, it is easy to see that, for each (x,α), there exist a sequence $\rho_n \to 0$ such that $\rho_n w_{\rho_n}^\varepsilon(0,0) \to \lambda^\varepsilon$ and

$$\begin{aligned} w_{\rho_n}^\varepsilon(x,\alpha) - w_{\rho_n}^\varepsilon(0,0) &= (w_{\rho_n}^\varepsilon(x,\alpha) - w_{\rho_n}^\varepsilon(0,\alpha)) \\ &\quad +(w_{\rho_n}^\varepsilon(0,\alpha) - w_{\rho_n}^\varepsilon(0,0)) \to w^\varepsilon(x,\alpha) \end{aligned}$$

on any compact subset of $\mathbb{R}\times\mathcal{M}$. Therefore,

$$\begin{aligned} \rho_n w_{\rho_n}^\varepsilon(x,\alpha) &= \rho_n(w_{\rho_n}^\varepsilon(x,\alpha) - w_{\rho_n}^\varepsilon(0,\alpha)) \\ &\quad +\rho_n(w_{\rho_n}^\varepsilon(0,\alpha) - \rho_n w_{\rho_n}^\varepsilon(0,0)) + \rho_n w_{\rho_n}^\varepsilon(0,0) \to \lambda^\varepsilon. \end{aligned}$$

Finally, it can be shown, as in Fleming and Soner [10], that the limit $(\lambda^\varepsilon, w^\varepsilon(x,\alpha))$ is a viscosity solution to the HJB equation (3.1). □

COROLLARY 3.4. *The pair $(\lambda^\varepsilon, w^\varepsilon(x,\alpha))$ obtained in Theorem 3.3 satisfies the following conditions.*

For some constant C independent of $\varepsilon>0$,

(i) $0 \le \lambda^\varepsilon \le C_1$ *and*

(ii) $|w^\varepsilon(x,\alpha) - w^\varepsilon(\tilde{x},\alpha)| \le C_2|x-\tilde{x}|$.

Proof. It is easy to check from the proof of Theorem 3.3 that (i) holds and

$$|w_{\rho_n}^\varepsilon(x,\alpha) - w_{\rho_n}^\varepsilon(\tilde{x},\alpha)| \le C_2|x-\tilde{x}|,$$

$$|w^\varepsilon(x,\alpha) - w^\varepsilon(\tilde{x},\alpha)| = \lim_{\rho_n\to 0} |w_{\rho_n}^\varepsilon(x,\alpha) - w_{\rho_n}^\varepsilon(\tilde{x},\alpha)| \le C_2|x-\tilde{x}|. \qquad \square$$

THEOREM 3.5. *Let $(\lambda^\varepsilon, w^\varepsilon(x,\alpha))$ be a viscosity solution to the HJB equation in (3.1). Assume $w^\varepsilon(x,\alpha)$ to be Lipschitz continuous in x. Then*

$$\lambda^\varepsilon = \inf_{u(\cdot)\in\mathcal{A}^\varepsilon} J^\varepsilon(u(\cdot)),$$

where $J^\varepsilon(u(\cdot))$ is defined in (2.2).

Proof. We divide the proof into two steps.

Step 1. $\lambda^\varepsilon \le \inf_{u(\cdot)\in\mathcal{A}^\varepsilon} J^\varepsilon(u(\cdot))$.

Let $\psi^\varepsilon(x,\alpha) = \exp(w^\varepsilon(x,\alpha)/\varepsilon)$. Then, the HJB equation (3.1) becomes

$$\frac{\lambda^\varepsilon \psi^\varepsilon(x,\alpha)}{\varepsilon} = \inf_{0\le u\le\alpha}\left\{(-ax+u-z)\psi_x^\varepsilon(x,\alpha) + \frac{L(x,u)}{\varepsilon}\psi^\varepsilon(x,\alpha) + \frac{Q}{\varepsilon}\psi^\varepsilon(x,\cdot)(\alpha)\right\}.$$

It is equivalent to

$$0 = \inf_{0\le u\le\alpha}\left\{(-ax+u-z)\psi_x^\varepsilon(x,\alpha) + \frac{L(x,u)-\lambda^\varepsilon}{\varepsilon}\psi^\varepsilon(x,\alpha) + \frac{Q}{\varepsilon}\psi^\varepsilon(x,\cdot)(\alpha)\right\}.$$

It is easy to see that $\psi^\varepsilon(x,\alpha)$ is a viscosity solution to the following time-dependent equation for $\phi(T,x,\alpha)$:

$$\begin{cases} \dfrac{\partial\phi}{\partial T} = \inf\limits_{0\le u\le\alpha}\left\{(-ax+u-z)\phi_x + \dfrac{L-\lambda^\varepsilon}{\varepsilon}\phi + \dfrac{Q}{\varepsilon}\phi\right\}, \\ \phi(0,x,\alpha) = \psi^\varepsilon(x,\alpha). \end{cases} \tag{3.9}$$

As can be shown as in Sethi and Zhang [15, Appendix G], this HJB equation has a unique viscosity solution. Moreover, if we define

$$\phi^\varepsilon(T,x,\alpha) = \inf_{u(\cdot)\in\mathcal{A}^\varepsilon} E\left(\psi^\varepsilon(x(T),\alpha^\varepsilon(T))\exp\int_0^T \frac{L(x(t),u(t))-\lambda^\varepsilon}{\varepsilon}dt\right),$$

then, using the dynamic programming principle (see Appendix), it can be shown that $\phi^\varepsilon(T,x,\alpha)$ is also a viscosity solution to (3.9). Thus, $\phi^\varepsilon(T,x,\alpha) = \psi^\varepsilon(x,\alpha)$ for all $T\ge 0$. Namely,

$$\psi^\varepsilon(x,\alpha) = \inf_{u(\cdot)\in\mathcal{A}^\varepsilon} E\left(\psi^\varepsilon(x(T),\alpha^\varepsilon(T))\exp\int_0^T \frac{L(x(t),u(t))-\lambda^\varepsilon}{\varepsilon}dt\right). \tag{3.10}$$

It follows that for all $u(\cdot)\in\mathcal{A}^\varepsilon$,

$$\begin{aligned} \psi^\varepsilon(x,\alpha) &\le E\left(\psi^\varepsilon(x(T),\alpha^\varepsilon(T))\exp\int_0^T \frac{L(x(t),u(t))-\lambda^\varepsilon}{\varepsilon}dt\right) \\ &= E\left(\psi^\varepsilon(x(T),\alpha^\varepsilon(T))\exp\int_0^T \frac{L(x(t),u(t))}{\varepsilon}dt\right)\exp\left(-\frac{\lambda^\varepsilon T}{\varepsilon}\right). \end{aligned}$$

Taking the logarithm of both sides, we have

$$\log\psi^\varepsilon(x,\alpha) \le \log E\left(\psi^\varepsilon(x(T),\alpha^\varepsilon(T))\exp\int_0^T \frac{L(x(t),u(t))}{\varepsilon}dt\right) - \frac{\lambda^\varepsilon T}{\varepsilon}. \tag{3.11}$$

Recall the Lipschitz property of $w^\varepsilon(x,\alpha)$ in x. It follows for all x and $\tilde{x}$ that

$$\frac{\psi^\varepsilon(\tilde{x},\alpha)}{\psi^\varepsilon(x,\alpha)} = \exp\left(\frac{w^\varepsilon(\tilde{x},\alpha)-w^\varepsilon(x,\alpha)}{\varepsilon}\right) \le \exp\left(\frac{C_2|\tilde{x}-x|}{\varepsilon}\right).$$

Replacing $\tilde{x}$ by $x(T)$ and α by $\alpha^\varepsilon(T)$, respectively, we obtain

$$\psi^\varepsilon(X(T),\alpha^\varepsilon(T)) \le \psi^\varepsilon(x,\alpha^\varepsilon(T))\exp\left(\frac{C_2|x(T)-x|}{\varepsilon}\right).$$

Note also that $|x(T)-x|\le K(1+|x|)$ for some constant K (see (2.3)) and

$$\psi^\varepsilon(x,\alpha^\varepsilon(T)) \le M(x) := \max_{j\in\mathcal{M}}\psi^\varepsilon(x,j).$$

We have

$$\psi^\varepsilon(X(T),\alpha^\varepsilon(T)) \le M(x)\exp\left(\frac{C_2K(1+|x|)}{\varepsilon}\right). \tag{3.12}$$

Combining this inequality with (3.11), we obtain

$$\log \psi^\varepsilon(x,\alpha) \le \log M(x) + \frac{C_2K(1+|x|)}{\varepsilon} + \log E\exp\int_0^T \frac{L(x(t),u(t))}{\varepsilon}dt - \frac{\lambda^\varepsilon T}{\varepsilon}.$$

Dividing both sides by T and letting $T\to\infty$ yields

$$\lambda^\varepsilon \le J^\varepsilon(u(\cdot)) \quad \text{for all } u(\cdot)\in\mathcal{A}^\varepsilon.$$

Thus, $\lambda^\varepsilon \le \inf_{u(\cdot)\in\mathcal{A}^\varepsilon} J^\varepsilon(u(\cdot))$ for all $u(\cdot)\in\mathcal{A}^\varepsilon$.

Step 2. $\lambda^\varepsilon \ge \inf_{u(\cdot)\in\mathcal{A}^\varepsilon} J^\varepsilon(u(\cdot))$.

Let

$$V^\varepsilon(T,x,\alpha) = \inf_{u(\cdot)\in\mathcal{A}^\varepsilon} \log E\exp\left(\int_0^T \frac{L(x(t),u(t))}{\varepsilon}dt\right).$$

We first show that

$$\frac{\lambda^\varepsilon}{\varepsilon} = \lim_{T\to\infty}\frac{1}{T}V^\varepsilon(T,x,\alpha), \tag{3.13}$$

uniformly for x in any compact set.

In fact, as in (3.12), we can show that there exist positive constants K_1 and K_2 such that for all $x=x(0)$ and $T>0$,

$$\exp\left(-\frac{K_1(1+|x|)}{\varepsilon}\right) \le \psi^\varepsilon(x(T),\alpha^\varepsilon(T)) \le \exp\left(\frac{K_2(1+|x|)}{\varepsilon}\right).$$

In view of this and (3.10), we have

$$\begin{aligned}
&\exp\left(-\frac{K_1(1+|x|)}{\varepsilon}\right)\inf_{u(\cdot)\in\mathcal{A}^\varepsilon} E\exp\left(\int_0^T \frac{L(x(t),u(t))}{\varepsilon}dt\right)\\
&\le \psi^\varepsilon(x,\alpha)\exp\left(\frac{\lambda^\varepsilon T}{\varepsilon}\right)\\
&\le \exp\left(\frac{K_2(1+|x|)}{\varepsilon}\right)\inf_{u(\cdot)\in\mathcal{A}^\varepsilon} E\exp\left(\int_0^T \frac{L(x(t),u(t))}{\varepsilon}dt\right).
\end{aligned}$$

Taking the logarithm on both sides and noting that $\inf_{u(\cdot)\in\mathcal{A}^\varepsilon}\log(\cdots) = \log\inf_{u(\cdot)\in\mathcal{A}^\varepsilon}(\cdots)$, we obtain

$$-\frac{K_1(1+|x|)}{\varepsilon} + V^\varepsilon(T,x,\alpha) \le \log\psi^\varepsilon(x,\alpha) + \frac{\lambda^\varepsilon T}{\varepsilon} \le \frac{K_2(1+|x|)}{\varepsilon} + V^\varepsilon(T,x,\alpha).$$

Dividing both sides by T and sending $T\to\infty$, we arrive at (3.13).

In view of (2.3), for any fixed $r>0$, there exists $r_1>0$ such that $|x(t)|\le r_1$ for all $t\ge 0$, $\alpha\in\mathcal{M}$, and $|x|\le r$. Therefore, for each $\delta>0$ there exists T_0 such that

$$\left|\frac{\lambda^\varepsilon}{\varepsilon} - \frac{1}{T_0}V^\varepsilon(T_0,x,\alpha)\right| \le \delta$$

for all $\alpha\in\mathcal{M}$ and $|x|\le r_1$. Hence,

$$V^\varepsilon(T_0,x,\alpha) \le \frac{\lambda^\varepsilon T_0}{\varepsilon} + T_0\delta \tag{3.14}$$

for all $\alpha \in \mathcal{M}$ and $|x| \le r_1$.

On $[0, T_0)$, choose an admissible $u^{(1)}(t)$ such that

$$E \exp\left(\int_0^{T_0} \frac{L(x(t), u^{(1)}(t))}{\varepsilon} dt\right) \le \exp\left(V^\varepsilon(T_0, x, \alpha) + \delta T_0\right) \le \exp\left(\frac{\lambda^\varepsilon T_0}{\varepsilon} + 2\delta T_0\right).$$

Let $\mathcal{G}_{T_0} = \sigma\{(x(t), \alpha^\varepsilon(t)) : \ t \le T_0\}$. On $[T_0, 2T_0)$, if we choose $u^{(2)}(t)$ to be $\sigma\{\alpha^\varepsilon(s) : \ T_0 \le s \le t\}$ measurable, then

$$E\left\{\exp\left(\int_{T_0}^{2T_0} \frac{L(x(t), u^{(2)}(t))}{\varepsilon} dt\right) \Big| \mathcal{G}_{T_0}\right\}$$

is a function of $(T_0, x(T_0), \alpha^\varepsilon(T_0))$. More precisely, if we let

$$\Phi(T_0, x, \alpha, u(\cdot)) = E\left\{\exp\left(\int_{T_0}^{2T_0} \frac{L(x(t), u(t))}{\varepsilon} dt\right) \Big| x(T_0) = x, \alpha^\varepsilon(T_0) = \alpha\right\},$$

then

$$\Phi(T_0, x(T_0), \alpha^\varepsilon(T_0), u^{(2)}(\cdot)) = E\left\{\exp\left(\int_{T_0}^{2T_0} \frac{L(x(t), u^{(2)}(t))}{\varepsilon} dt\right) \Big| \mathcal{G}_{T_0}\right\}.$$

Moreover, by changing the variable $t \to (t - T_0)$, we have

$$V^\varepsilon(T_0, x, \alpha) = \inf_{u(\cdot) \in \mathcal{A}^\varepsilon} \log \Phi(T_0, x, \alpha, u(\cdot)).$$

Similarly, as in the proof of Lemma 3.2 (ii), we can show for some constant C,

$$|V^\varepsilon(T, \tilde{x}, \alpha) - V^\varepsilon(T, x, \alpha)| \le \frac{CT|\tilde{x} - x|}{\varepsilon}$$

for all T, $\tilde{x}$, x, and $\alpha \in \mathcal{M}$.

Let B_1, B_2,..., B_l be a partition of $\{x : \ |x| \le r_1\}$. For any given $\delta > 0$, if the diameter of the B_j's is small enough, then for all $\tilde{x}$ and x in B_j, and $u(\cdot) \in \mathcal{A}^\varepsilon$,

$$|V^\varepsilon(T_0, \tilde{x}, \alpha) - V^\varepsilon(T_0, x, \alpha)| \le \delta T_0 \quad \text{and} \quad \frac{\Phi(T_0, \tilde{x}, \alpha, u(\cdot))}{\Phi(T_0, x, \alpha, u(\cdot))} \le e^{\delta T_0}.$$

For $j = 1, 2, \ldots, l$, pick out $x_j \in B_j$. For each (j, α), choose $u^{(2)}_{j,\alpha}(t)$ on $[T_0, 2T_0)$ such that

$$\Phi(T_0, x_j, \alpha) \le \exp(V^\varepsilon(T_0, x_j, \alpha) + \delta T_0) \le \exp\left(\frac{\lambda^\varepsilon T_0}{\varepsilon} + 2\delta T_0\right).$$

On $[0, 2T_0)$, define

$$u(t) = \begin{cases} u^{(1)}(t) & \text{if } 0 \le t < T_0, \\ \displaystyle\sum_{j,\alpha} I_{\{(x(T_0), \alpha^\varepsilon(T_0)) \in B_j \times \{\alpha\}\}} u^{(2)}_{j,\alpha}(t) & \text{if } T_0 \le t < 2T_0, \end{cases} \tag{3.15}$$

where I_F is the indicator function of a set F. It follows that

$$\begin{aligned} & E\left\{\exp\left(\int_{T_0}^{2T_0}\frac{L(x(t),u(t))}{\varepsilon}dt\right)\Big|\mathcal{G}_{T_0}\right\} \\ &\quad = \sum_{j,\alpha} I_{\{x(T_0)\in B_j\}} I_{\{\alpha^\varepsilon(T_0)=\alpha\}} \Phi(T_0, x(T_0), \alpha, u^{(2)}_{j,\alpha}(t)) \\ &\quad \le \sum_{j,\alpha} I_{\{x(T_0)\in B_j\}} I_{\{\alpha^\varepsilon(T_0)=\alpha\}} \Phi(T_0, x_j, \alpha, u^{(2)}_{j,\alpha}(t)) e^{\delta T_0} \\ &\quad \le \sum_{j,\alpha} I_{\{x(T_0)\in B_j\}} I_{\{\alpha^\varepsilon(T_0)=\alpha\}} \exp\left(\frac{\lambda^\varepsilon T_0}{\varepsilon} + 3\delta T_0\right). \end{aligned}$$

Note that

$$\begin{aligned} & E\exp\left(\int_0^{2T_0}\frac{L(x(t),u(t))}{\varepsilon}dt\right) \\ &\quad = E\left\{\exp\left(\int_0^{T_0}\frac{L(x(t),u(t))}{\varepsilon}dt\right) E\left[\exp\left(\int_{T_0}^{2T_0}\frac{L(x(t),u(t))}{\varepsilon}dt\right)\Big|\mathcal{G}_{T_0}\right]\right\}. \end{aligned}$$

It follows that

$$E\exp\left(\int_0^{2T_0}\frac{L(x(t),u(t))}{\varepsilon}dt\right) \le \exp\left(\frac{\lambda^\varepsilon(2T_0)}{\varepsilon} + 5\delta T_0\right).$$

Continuing this procedure on $[(N-1)T_0, NT_0)$ for $N = 3, \ldots$, we can construct an admissible control $u(t)$ as in (3.15) such that

$$E\exp\left(\int_0^{NT_0}\frac{L(x(t),u(t))}{\varepsilon}dt\right) \le \exp\left(\frac{\lambda^\varepsilon NT_0}{\varepsilon} + \delta(3N-1)T_0\right).$$

Hence,

$$\frac{1}{NT_0}\log E\exp\left(\int_0^{NT_0}\frac{L(x(t),u(t))}{\varepsilon}dt\right) \le \frac{\lambda^\varepsilon}{\varepsilon} + \frac{\delta(3N-1)T_0}{NT_0} \to \frac{\lambda^\varepsilon}{\varepsilon} + 3\delta.$$

Since δ is arbitrary, $\lambda^\varepsilon \ge \inf_{u(\cdot)\in\mathcal{A}^\varepsilon} J^\varepsilon(u(\cdot))$ follows. □

This theorem implies that λ^ε in $(\lambda^\varepsilon, w^\varepsilon(x,\alpha))$ as a viscosity solution is unique.

We next give a verification theorem. In order to incorporate nondifferentiability of the value function, we consider the superdifferential of the function. Let $D^+f(x)$ denote the superdifferential of a function $f(x)$, i.e.,

$$D^+f(x) = \left\{r\in\mathbb{R} : \limsup_{h\to 0}\frac{f(x+h)-f(x)-hr}{|h|} \le 0\right\}.$$

THEOREM 3.6. *Let $(\lambda^\varepsilon, w^\varepsilon(x,\alpha))$ be a viscosity solution to the HJB equation in (3.1). Assume that $w^\varepsilon(x,\alpha)$ is Lipschitz continuous in x. Let $\psi^\varepsilon(x,\alpha) = \exp(w^\varepsilon(x,\alpha)/\varepsilon)$. Suppose that there are $u^*(\cdot)$, $x^*(\cdot)$, and $r^*(t)$ such that*

$$\dot{x}^*(t) = -ax^*(t) + u^*(t) - z, \qquad x^*(0) = x,$$

$r^*(t) \in D^+\psi_x^\varepsilon(x^*(t), \alpha^\varepsilon(t))$ *satisfying*

$$\begin{aligned}\frac{\lambda^\varepsilon}{\varepsilon}\psi^\varepsilon(x^*(t),\alpha^\varepsilon(t)) &= (-ax^*(t)+u^*(t)-z)r^*(t)\\ &\quad+\frac{L(x^*(t),u^*(t))}{\varepsilon}\psi^\varepsilon(x^*(t),\alpha^\varepsilon(t))+\frac{Q}{\varepsilon}\psi^\varepsilon(x^*(t),\cdot)(\alpha^\varepsilon(t))\end{aligned} \tag{3.16}$$

almost everywhere (a.e.) in t *and with probability* 1 *(w.p.*1*). Then,* $\lambda^\varepsilon = J^\varepsilon(u^*(\cdot))$.

Proof. First, note that the HJB equation in (3.1) is equivalent to

$$\begin{aligned}\frac{\lambda^\varepsilon}{\varepsilon}\psi^\varepsilon(x,\alpha) = \inf_{0\le u\le\alpha}\Bigg\{&(-ax+u-z)\psi_x^\varepsilon(x,\alpha)\\ &+\frac{L(x,\alpha)}{\varepsilon}\psi^\varepsilon(x,\alpha)+\frac{Q}{\varepsilon}\psi^\varepsilon(x,\cdot)(\alpha)\Bigg\}.\end{aligned} \tag{3.17}$$

The Lipschitz property of $\psi^\varepsilon(x,\alpha)$ implies that $\psi^\varepsilon(x(t),\alpha)$ is Lipschitz in t. For each $t \ge 0$ such that $(d/dt)\psi^\varepsilon(x(t),\alpha)$ exists and

$$\int_t^{t+h}(-ax(s)+u(s)-z)ds = h(-ax(t)+u(t)-z)+o(h),$$

we have

$$\begin{aligned}\frac{d\psi^\varepsilon(x(t),\alpha)}{dt} &= \lim_{h\to0^+}\frac{1}{h}\left(\psi^\varepsilon(x(t+h),\alpha)-\psi^\varepsilon(x(t),\alpha)\right)\\ &= \lim_{h\to0^+}\frac{1}{h}\left(\psi^\varepsilon\left(x(t)+\int_t^{t+h}(-ax(s)+u(s)-z)ds,\alpha\right)-\psi^\varepsilon(x(t),\alpha)\right)\\ &= \lim_{h\to0^+}\frac{1}{h}\left(\psi^\varepsilon(x(t)+h(-ax(t)+u(t)-z)+o(h),\alpha)-\psi^\varepsilon(x(t),\alpha)\right)\\ &= \lim_{h\to0^+}\frac{1}{h}\left(\psi^\varepsilon(x(t)+h(-ax(t)+u(t)-z),\alpha)-\psi^\varepsilon(x(t),\alpha)\right)\\ &\le (-ax(t)+u(t)-z)r\end{aligned} \tag{3.18}$$

for $r \in D^+\psi^\varepsilon(x(t),\alpha)$; see Zhou [19, Lemma 2.1]. In view of (3.18) and the proof of the Feynman–Kac formula (see Fleming and Soner [10]), we can show, for any $T \ge 0$,

$$\begin{aligned}&E\left[\psi^\varepsilon(x(T),\alpha^\varepsilon(T))\exp\int_0^T\left(\frac{L(x(t),u(t))-\lambda^\varepsilon}{\varepsilon}\right)dt\right]-\psi^\varepsilon(x,\alpha)\\ &\quad= E\int_0^T\frac{d}{dt}\left(\psi^\varepsilon(x(t),\alpha^\varepsilon(t))\exp\int_0^t\left(\frac{L(x(s),u(s))-\lambda^\varepsilon}{\varepsilon}\right)ds\right)dt\\ &\quad\le E\int_0^T\exp\int_0^t\left(\frac{L(x^*(s),u^*(s))-\lambda^\varepsilon}{\varepsilon}\right)ds\\ &\qquad\cdot\Bigg[\left(\frac{L(x^*(t),u^*(t))-\lambda^\varepsilon}{\varepsilon}\right)\psi^\varepsilon(x^*(t),\alpha^\varepsilon(t))\\ &\qquad+(-ax^*(t)+u^*(t)-z)r^*(t)+\frac{Q}{\varepsilon}\psi^\varepsilon(x^*(t),\cdot)(\alpha^\varepsilon(t))\Bigg]dt=0.\end{aligned} \tag{3.19}$$

Note that for any given initial value x, the corresponding trajectory $x(t)$ is bounded. Thus, for each x and $\varepsilon > 0$, there exist positive constants M_1 and M_2 such that

$$0 < M_1 \le \psi^\varepsilon(x(T),\alpha^\varepsilon(T)) \le M_2 \text{ for all } T \ge 0.$$

Hence, it follows from (3.17) and (3.19) that

$$M_1 E\left[\exp\int_0^T\left(\frac{L(x^*(t),u^*(t))}{\varepsilon}\right)dt\right]\exp\left(-\frac{\lambda^\varepsilon}{\varepsilon}\right)\le\psi^\varepsilon(x,\alpha).$$

Taking the logarithm on both sides and dividing by T leads to

$$\frac{\log M_1}{T}+\frac{1}{T}\log E\exp\int_0^T\left(\frac{L(x^*(t),u^*(t))}{\varepsilon}\right)dt-\frac{\lambda^\varepsilon}{\varepsilon}\le\frac{\psi^\varepsilon(x,\alpha)}{T}.$$

Sending $T\to\infty$ yields

$$\lambda^\varepsilon\ge\limsup_{T\to\infty}\frac{\varepsilon}{T}\log E\exp\int_0^T\left(\frac{L(x(t),u(t))}{\varepsilon}\right)dt.$$

Hence, in view of Theorem 3.5, $\lambda^\varepsilon=J^\varepsilon(u^*(\cdot))$. □

4. Limiting problem. In this section, we analyze the asymptotic properties of the HJB equation (3.3.1) as $\varepsilon\to0$. First of all, note that this HJB equation is similar to that for an ordinary long-run average cost problem except for the term involving the exponential functions. In order to get rid of such a term, we make use of the logarithmic transformation in Fleming and Soner [10, p. 275].

Let $\mathcal{V}=\{v=(v(0),\dots,v(m))\in\mathbb{R}^{m+1}:\ v(i)>0,i=0,1,\dots,m\}$. Define

$$Q^v=(q_{ij}^v)\text{ such that }q_{ij}^v=q_{ij}\frac{v(j)}{v(i)}\text{ for }i\ne j\text{ and }q_{ii}^v=-\sum_{j\ne i}q_{ij}^v.$$

Then, in view of the logarithmic transformation, we have, for each $i\in\mathcal{M}$,

$$\begin{aligned}&\exp\left(-\frac{w^\varepsilon(x,\alpha)}{\varepsilon}\right)Q\exp\left(\frac{w^\varepsilon(x,\cdot)}{\varepsilon}\right)(i)\\&\quad=\sup_{v\in\mathcal{V}}\left\{\frac{Q^v}{\varepsilon}w^\varepsilon(x,\cdot)(i)+\frac{Qv(\cdot)(i)}{v(i)}-Q^v(\log v(\cdot))(i)\right\}.\end{aligned}$$

The supermum is obtained at $v(i)=\exp(-w^\varepsilon(x,i)/\varepsilon)$.

The logarithmic transformation suggests that the HJB equation is equivalent to an Isaacs equation of a two-player zero-sum dynamic stochastic game. The Isaacs equation is given as follows:

$$\lambda^\varepsilon=\inf_{0\le u\le\alpha}\sup_{v\in\mathcal{V}}\left\{(-ax+u-z)w_x^\varepsilon(x,\alpha)+\widetilde{L}(x,u,v,\alpha)+\frac{Q^v}{\varepsilon}w^\varepsilon(x,\cdot)(\alpha)\right\},\tag{4.1}$$

where

$$\widetilde{L}(x,u,v,i)=L(x,u)+\frac{Qv(\cdot)(i)}{v(i)}-Q^v(\log v(\cdot))(i)\tag{4.2}$$

for $i\in\mathcal{M}$.

Remark 4.1. Note that if $v=(1,\dots,1)$, then $\widetilde{L}(x,u,v,i)=L(x,u)$ and $Q^v=Q$.

Remark 4.2. In the results to follow, we will not give a precise description of the stochastic dynamic game with Isaacs equation (4.1) since this interpretation will not be used in proving our results about the deterministic limit $\varepsilon\to0$. In the game,

$u(t)$ and $v(t)$ represent minimizing and maximizing controls, based on information available at time t. Note that the maximizing control v produces a change in transition rates, from q_{ij} to q_{ij}^v. This imprecise idea can be made precise using Elliott–Kalton-type strategies (Fleming and Souganidis [11]). Since the order in (4.1) is $\inf(\sup(\cdots))$ rather than $\sup(\inf(\cdots))$, λ^ε turns out to be the upper game value for the game payoff

$$\limsup_{T\to\infty} \frac{1}{T} E \int_0^T \widetilde{L}(x(t), u(t), v(t), \alpha^\varepsilon(t))dt.$$

We consider the limit of the problem as $\varepsilon \to 0$. In order to define a limiting problem, we first define control sets for the limiting problem. Let

$$\Gamma_u = \{U = (u^0, \ldots, u^m);\ 0 \le u^i \le i,\ i = 0, \ldots, m\}$$

and

$$\Gamma_v = \{V = (v^0, \ldots, v^m);\ v^i = (v^i(0), \ldots, v^i(m)) \in \mathcal{V},\ i = 0, \ldots, m\}.$$

For each $V \in \Gamma_v$, let $\overline{Q}^V := (q_{ij}^V)$ such that

$$q_{ij}^{v^i} = q_{ij}^V = \frac{q_{ij} v^i(j)}{v^i(i)} \quad \text{for } i \ne j \quad \text{and} \quad q_{ii}^V = -\sum_{j\ne i} q_{ij}^V,$$

and let $\nu^V = (\nu_0^V, \ldots, \nu_m^V)$ denote the equilibrium distribution of $\overline{Q}^V$. The next lemma says $\overline{Q}^V$ is irreducible. Therefore, there exists a unique positive ν^V for each $V \in \Gamma_v$. Moreover, ν^V depends continuously on V.

LEMMA 4.3. *For each $V \in \Gamma_v$, $\overline{Q}^V$ is irreducible.*

Proof. We divide the proof into three steps.

Step 1. $\operatorname{rank}(\overline{Q}^V) = m$.

First, it is easy to see that the irreducibility of Q implies $q_{kk}^V < 0$ for $k = 0, 1, \ldots, m$. We multiply the first row of $\overline{Q}^V$ by $-q_{k0}^V/q_{00}^V$ and add to the kth row, $k = 1, \ldots, m$, to make the first component of that row 0. Let $Q^{V,1} = (q_{ij}^{V,1})$ denote the resulting matrix. Then, $Q^{V,1}$ must satisfy

$$\begin{aligned}
&q_{0j}^{V,1} = q_{0j}^V, \quad j = 0, 1, \ldots, m,\\
&q_{k0}^{V,1} = 0, \quad k = 1, \ldots, m,\\
&q_{kk}^{V,1} \le 0, \quad k = 1, \ldots, m, \text{ and}\\
&\sum_{j=0}^m q_{kj}^{V,1} = 0 \quad \text{for } k = 0, 1, \ldots, m.
\end{aligned}$$

We now show that $q_{kk}^{V,1} < 0$ for $k = 1, \ldots, m$. For $k = 1$, if $q_{11}^{V,1} \not< 0$, then it must be equal to 0, which implies

$$(q_{12}^V, \ldots, q_{1m}^V) - \left(\frac{q_{10}^V}{q_{00}^V}\right)(q_{02}^V, \ldots, q_{0m}^V) = 0. \tag{4.3}$$

Recall that $q_{11}^V \ne 0$. One must have $q_{10}^V > 0$ since otherwise $q_{10}^V = 0$ implies $q_{11}^V = q_{11}^{V,1} = 0$, which contradicts the fact that $q_{kk}^V < 0$ for $k = 0, 1, \ldots, m$. Thus, $-q_{10}^V/q_{00}^V >$

0. This together with the nonnegativity of q_{ij}^V, $i \neq j$, imply that both of the vectors in (4.3) must be equal to 0, i.e.,

$$(q_{12}^V, \dots, q_{1m}^V) = 0 \quad \text{and} \quad (q_{02}^V, \dots, q_{0m}^V) = 0.$$

These equations contradict the irreducibility of Q since a state in $\{2, 3, \dots, m\}$ is not accessible from a state in $\{0, 1\}$. Therefore, one must have $q_{11}^{V,1} < 0$. Similarly, we can show $q_{kk}^{V,1} < 0$ for $k = 2, \dots, m$.

We repeat this procedure in a similar way by multiplying the second row of $Q^{V,1}$ by $-q_{k1}^{V,1}/q_{11}^{V,1}$, $k = 2, \dots, m$, and add to the kth row. Let $Q^{V,2)} = (q_{ij}^{V,2})$ denote the resulting matrix. Then one has

$$\begin{aligned}
&q_{ij}^{V,2} = q_{ij}^{V,1}, \quad i = 0, 1, \quad j = 0, 1, \dots, m,\\
&q_{ij}^{V,2} = 0, \quad i = 2, \dots, m, \quad j = 0, 1\\
&q_{kk}^{V,2} \leq 0, \quad k = 2, \dots, m, \text{ and}\\
&\sum_{j=0}^{m} q_{kj}^{V,2} = 0 \quad \text{for } k \in \mathcal{M}.
\end{aligned}$$

Similarly, we can show $q_{kk}^{V,2} < 0$ for $k = 2, \dots, m$.

We continue this procedure and transform $Q \to Q^{V,1} \to \cdots \to Q^{V,m-1}$ with $Q^{V,m-1} = (q_{ij}^{V,m-1})$ such that

$$\begin{aligned}
&q_{ij}^{V,m-1} = 0, \quad i > j\\
&q_{kk}^{V,m-1} < 0, \quad k = 0, 1, \dots, m-1,\\
&\sum_{j=0}^{m} q_{kj}^{V,m-1} = 0 \quad \text{for } k \in \mathcal{M} \text{ and}\\
&q_{mm}^{V,m-1} = 0.
\end{aligned}$$

Notice that the prescribed transformations do not change the rank of the original matrix. Thus,

$$\operatorname{rank}(\overline{Q}^V) = \operatorname{rank}(Q^{V,1}) = \cdots = \operatorname{rank}(Q^{V,m-1}) = m.$$

Step 2. $\overline{Q}^V$ is weakly irreducible.

Consider an $(m+1)$ row vector $b = (b_0, \dots, b_m)$ such that

$$b\overline{Q}^V = 0 \quad \text{and} \quad b_0 + \cdots + b_m = 1.$$

It follows as in Sethi and Zhang [15, Lemma C.1] that $(b' \vdots \cdots \vdots b') = \lim_{t\to\infty} \exp(\overline{Q}^V t)$, where A' denotes the transpose of a matrix A. Since $\exp(\overline{Q}^V t)$ represents the transition probabilities, the limit b must be nonnegative. Thus, $b := (\nu_0^V, \dots, \nu_m^V)$ is an equilibrium distribution of $\overline{Q}^V$. Note that $\ker(\overline{Q}^V)' = \operatorname{span}\{(\nu_0^V, \dots, \nu_m^V)\}$ since $\operatorname{rank}(\overline{Q}^V)' = \operatorname{rank}(\overline{Q}^V) = m$. Then, $c = (\nu_0^V, \dots, \nu_m^V)$ is the unique nonnegative solution to $b\overline{Q}^V = 0$ and $b_0 + \cdots + b_m = 1$. Hence $\overline{Q}^V$ is weakly irreducible.

Step 3. $\overline{Q}^V$ is irreducible; i.e., $(\nu_0^V, \dots, \nu_m^V) > 0$.

If not, then, without loss of generality, we may assume $\nu_0^V > 0, \dots, \nu_{k_0}^V > 0$ and $\nu_{k_0+1}^V = 0, \dots, \nu_m^V = 0$ for some $k_0 = 0, 1, \dots, m$. Note that $(\nu_0^V, \dots, \nu_m^V)\overline{Q}^V = 0$ implies that $q_{ij}^V = 0$ and thus $q_{ij} = 0$ for $i = 0, \dots, k_0$ and $j = k_0 + 1, \dots, m$. This in turn implies that Q is not irreducible since the process $\alpha^\varepsilon(\cdot)$ cannot jump from a state in $\{0, 1, \dots, k_0\}$ to a state in $\{k_0 + 1, \dots, m\}$. The contradiction yields the irreducibility of $\overline{Q}^V$. □

THEOREM 4.4. *Let $\varepsilon_n \to 0$ be a sequence such that $\lambda^{\varepsilon_n} \to \lambda^0$ and $w^{\varepsilon_n}(x, \alpha) \to w^0(x, \alpha)$. Then,*

(i) *$w^0(x, \alpha)$ is independent of α, i.e., $w^0(x, \alpha) = w^0(x)$;*

(ii) *$w^0(x)$ is Lipschitz; and*

(iii) *$(\lambda^0, w^0(x))$ is a viscosity solution to the following Isaacs equation:*

$$\lambda^0 = \inf_{U \in \Gamma_u} \sup_{V \in \Gamma_v} \left\{ \left(-ax + \sum_{i=0}^m \nu_i^V u^i - z \right) w_x^0(x) + \sum_{i=0}^m \nu_i^V L(x, u^i) + \left(\sum_{i=0}^m \nu_i^V \frac{Qv^i(\cdot)(i)}{v^i(i)} - \sum_{i=0}^m \nu_i^V \overline{Q}^V (\log v^i(\cdot))(i) \right) \right\}. \tag{4.4}$$

Proof. Note that Lemma 3.2 (iii) implies that

$$|w_\rho^\varepsilon(x, \alpha) - w_\rho^\varepsilon(x, \tilde{\alpha})| \le \varepsilon \log C_3$$

for x in any finite interval. Thus, the limit of $w_\rho^\varepsilon(x, \alpha)$ must be independent of α, i.e.,

$$w^0(x, 0) = \cdots = w^0(x, m) =: w^0(x).$$

The Lipschitz property of $w^0(x)$ follows from the Lipschitz property of $w^\varepsilon(x, \alpha)$.

Finally, note that

$$\nu^V \overline{Q}^V = (\nu_0^V, \dots, \nu_m^V)\overline{Q}^V = 0.$$

It follows that

$$\sum_{i=0}^m \nu_i^V Q^{v^i} w^\varepsilon(x, \cdot)(i) = 0. \tag{4.5}$$

The remaining proof of (iii) is standard and can be carried out as in Fleming, Sethi, and Soner [8]. □

Remark 4.5. We would like to point out that the last term in (4.4) is nonnegative. This can be seen as follows: note that for each $v \in \mathcal{V}$ and $i \in \mathcal{M}$, we have

$$\begin{aligned} &\frac{Qv(\cdot)(i)}{v(i)} - Q^v(\log v(\cdot))(i) \\ &\quad = \sum_{j \ne i} q_{ij} \left(\frac{v(j)}{v(i)} - 1 \right) - \sum_{j \ne i} q_{ij} \frac{v(j)}{v(i)} \log \frac{v(j)}{v(i)} \\ &\quad = \sum_{j \ne i} q_{ij} \left(\frac{v(j)}{v(i)} - 1 - \frac{v(j)}{v(i)} \log \frac{v(j)}{v(i)} \right) \le 0, \end{aligned}$$

because the function $(x - 1 - x \log x)$ is nonnegative on $(0, \infty)$. It follows that

$$\sum_{i=0}^m \nu_i^V \frac{Qv^i(\cdot)(i)}{v^i(i)} - \sum_{i=0}^m \nu_i^V Q^{v^i} (\log v^i(\cdot))(i) \le 0.$$

Let

$$\widehat{L}(x,U,V)=\sum_{i=0}^{m}\nu_i^V L(x,u^i)+\sum_{i=0}^{m}\nu_i^V\frac{Qv^i(\cdot)(i)}{v^i(i)}-\sum_{i=0}^{m}\nu_i^V\overline{Q}^V(\log v^i(\cdot))(i).$$

Note that $\widehat{L}(x,U,V)\le||L||$, where $||\cdot||$ is the sup norm. Moreover, since $L\ge 0$, $\widehat{L}(x,U,1)\ge 0$ where $V=1$ means $v^i(j)=1$ for all i,j. Then, the equation in (4.4) is an Isaacs equation associated with a two-player, zero-sum dynamic game with objective

$$J^0(U(\cdot),V(\cdot))=\limsup_{T\to\infty}\frac{1}{T}\int_0^T\widehat{L}(x(t),U(t),V(t))dt$$

subject to

$$\dot{x}(t)=-ax(t)+\sum_{i=0}^{m}\nu_i^{V(t)}u^i(t)-z,\qquad x(0)=x,$$

where $U(\cdot)$ and $V(\cdot)$ are Borel measurable functions and $U(t)\in\Gamma_u$ and $V(t)\in\Gamma_v$ for $t\ge 0$.

Remark 4.6. Let $I(\mu)$ be the Donsker–Varadhan function, defined for any probability vector $\mu=(\mu_0,\dots,\mu_m)>0$, i.e., $\mu_i>0$ and $\sum_{i=0}^m\mu_i=1$. Then (see the Appendix)

$$-I(\mu)=\sup_{V,\nu^V=\mu}\left\{\sum_{i=0}^{m}\nu_i^V\frac{Qv^i(\cdot)(i)}{v^i(i)}-\sum_{i=0}^{m}\nu_i^V\overline{Q}^V(\log v^i(\cdot))(i)\right\}.\tag{4.6}$$

Thus (4.4) is equivalent to

$$\lambda^0=\inf_{U\in\Gamma_u}\sup_{\mu}\left\{\Big(-ax+\langle\mu,u\rangle-z\Big)w_x^0(x)+\langle\mu,L(x,u)\rangle-I(\mu)\right\}.$$

Similarly, the dynamics of $x(t)$ can be written

$$\dot{x}(t)=-ax(t)+\langle\mu(t),u(t)\rangle-z.$$

Let

$$\begin{aligned}H(x,p)=\inf_{U\in\Gamma_u}\sup_{V\in\Gamma_v}\Bigg\{&\left(-ax+\sum_{i=0}^{m}\nu_i^V u^i-z\right)p+\sum_{i=0}^{m}\nu_i^V L(x,u^i)\\&+\left(\sum_{i=0}^{m}\nu_i^V\frac{Qv^i(\cdot)(i)}{v^i(i)}-\sum_{i=0}^{m}\nu_i^V\overline{Q}^V(\log v^i(\cdot))(i)\right)\Bigg\}.\end{aligned}$$

Then,

$$\begin{aligned}|H(\tilde{x},p)-H(x,p)|&\le(a|p|+||L_x||)|\tilde{x}-x|,\\|H(x,\tilde{p})-H(x,p)|&\le(a|x|+m+z)|\tilde{p}-p|.\end{aligned}$$

These conditions imply the uniqueness of viscosity solution to the following finite time problem:

$$\begin{cases} \dfrac{\partial \Psi}{\partial T} = H(x, \Psi_x) - \lambda^0, \quad T > 0, \\ \Psi(0, x) = w^0(x). \end{cases}$$

Uniqueness is in the class of continuous viscosity solution $\Psi(x, T)$ such that $\Psi(\cdot, T)$ satisfies a uniform Lipschitz condition on every finite time interval $0 \le T \le T_1$; see Crandall and Lions [4] and Ishii [13]. A more general uniqueness theorem in which $\Psi(\cdot, T)$ satisfies a uniform local Lipschitz condition is given in McEneaney [14].

The method of Evans and Souganidis [6] shows that

$$\text{upper value} \left\{ \int_0^T \left(\widehat{L}(x(t), U(t), V(t)) - \lambda^0 \right) dt + w^0(x(T)) \right\}$$

is such a viscosity solution and $w^0(x)$ is also a viscosity solution. So $w^0(x) = \Psi(T, x)$. Namely,

$$w^0(x) = \text{ upper value} \left\{ \int_0^T \left(\widehat{L}(x(t), U(t), V(t)) - \lambda^0 \right) dt + w^0(x(T)) \right\}.$$

In Evans and Souganidis [6] the control spaces for both players are assumed compact, and Γ_v is not compact. This requires minor changes in the arguments in [6] using the special form of the game dynamics and payoff function $\widehat{L} - \lambda_0$; see the Appendix for more details. Using the above equality, one can show as in Fleming and McEneaney [7] that

$$\lambda^0 = \inf_{U(\cdot)} \sup_{V(\cdot)} J^0(U(\cdot), V(\cdot)),$$

which implies the uniqueness of λ^0.

Finally, we would like to comment on how to use the solution to the limiting problem to obtain a control for the original problem. Typically an explicit solution is not available to either of the problems. A numerical scheme has to be used to obtain an approximate solution. The advantage of the limiting problem is its dimensionality, which is much smaller than that of the original problem if the number of states in $\mathcal{M}$ is large.

Let $(U^*(x), V^*(x))$ denote a solution to the upper value problem. Suggested by the ideas of hierarchical control (see Sethi and Zhang [15]), it is expected that the control

$$u(x, \alpha) = \sum_{j=0}^{m} I_{\{\alpha = j\}} u^{i*}(x)$$

is nearly optimal for the original problem.

5. Concluding remarks. This paper deals with the risk-sensitive control with a long-run average cost arising in a failure-prone manufacturing system. Typically the problem with a long-run average cost requires the stability of the system. In this paper, a model with product deterioration is considered. Such a deterioration con-

dition is used to guarantee the desired stability without undue technical difficulties. It would be interesting to study the stability without such a deterioration condition. One possible direction for attacking the problem is to use a "diminishing deterioration" approach by sending the deterioration rate $a \to 0$. In order to obtain the desired convergence of the potential function $w^\varepsilon(x,\alpha)$ as $a \to 0$, it is necessary to have the uniform equicontinuity property that typically is guaranteed by the Lipschitz condition uniform with respect to $a > 0$. A major difficulty, however, is the absence of such a uniform Lipschitz property. This can be seen from (ii) in Lemma 3.2 in which the Lipschitz constant depends on a.

In this paper, a single machine, single product model is considered. It would also be interesting to generalize the results to more general manufacturing systems such as flowshops and jobshops; see Sethi and Zhang [15].

6. Appendix. In section 3 we used the following dynamic programming principle. For brevity, let us write $U(t) = (u(t), y(t))$. Let $G(s)$ and $h(t)$ be as in the proof of Lemma 3.2 (iii). Then for every stopping time τ

$$\text{(DP)} \qquad \psi^\varepsilon_\rho(x,\alpha) = \inf_{U(\cdot)} E\biggl\{\int_0^\tau \biggl(\exp\int_0^t G(s)ds\biggr) h(t)dt + \biggl(\exp\int_0^\tau G(s)ds\biggr)\psi^\varepsilon_\rho(x(\tau),\alpha(\tau))\biggr\}.$$

In the proof of Lemma 3.2 (iii), τ is the first t such that $\alpha^\varepsilon(t) = \tilde\alpha$. To prove that ψ^ε_ρ is a viscosity solution of (3.8), property (DP) is needed for any nonrandom τ. While results of this kind are considered well known, the authors did not find a convenient reference which applies to the class of stochastic control problems considered in this paper. For completeness we sketch a proof of (DP). In the proof of Theorem 3.5, a dynamic programming principle is used, for which an entirely similar proof can be given. Indeed, the argument is slightly simpler since only nonrandom stopping times need to be considered.

Sketch of proof of (DP). It suffices to consider the "canonical" sample space $(\Omega, \{\mathcal{F}_t\}, P)$ with $\Omega = D([0,\infty);\mathcal{M})$ the space of possible $\alpha(\cdot)$ paths, $\mathcal{F}_t = \sigma\{\alpha(s) : 0 \le s \le t\}$ and $P = P^\varepsilon_\alpha$ the probability distribution of a Markov chain $\alpha^\varepsilon(\cdot)$ with generator Q/ε and initial state $\alpha(0) = \alpha$. We wish to establish (DP) for any $\mathcal{F}_t$ -stopping time τ. By using the Lipschitz property in Lemma 3.2 (ii) which does not depend on (DP), it suffices to consider τ with finitely many values $0 < t_1 < t_2 < \cdots < t_n$ because one may approximate τ by a step function $\sum t_k I_{\{t_k \le \tau < t_{k+1}\}}$. Let $\Gamma_k = \{\tau = t_k\}$ and on Γ_k we identify $U(t)$ for $t \ge t_k$ with $U_k(t - t_k, \alpha_{1k}(\cdot), \alpha_{2k}(\cdot))$, where

$$\begin{aligned} \alpha_{1k}(t) &= \alpha(t), \quad 0 \le t \le t_k, \\ \alpha_{2k}(t) &= \alpha(t_k + t), \quad t \ge 0. \end{aligned}$$

If $U(\cdot)$ is admissible (progressively measurable and satisfying the control constraints on $u(t)$ and $y(t)$), then for each fixed $\alpha_{1k}(\cdot)$, $U_k(\cdot)$ is also admissible. Moreover, if $\mathcal{F}_\infty$ is the least σ-algebra containing all $\mathcal{F}_t$, then for any bounded $\mathcal{F}_\infty$- measurable Φ,

$$E(I_{\Gamma_k}\Phi) = \int_{\Gamma_k}\int \Phi(\alpha_{1k},\alpha_{2k}) P^\varepsilon_{\alpha_{1k}(t_k)}(d\alpha_{2k}) P^\varepsilon_\alpha(d\alpha_{1k}).$$

A routine calculation then gives

$$\begin{aligned} E\int_\tau^\infty &\left(\exp\int_0^t G(s)ds\right)h(t)dt \\ &= \sum_{k=1}^n E\left[I_{\Gamma_k}\left(\exp\int_0^{t_k} G(s)ds\right)J_\rho^\varepsilon(x(t_k),\alpha(t_k),U_k(\cdot))\right] \\ &\geq \sum_{k=1}^n E\left[I_{\Gamma_k}\left(\exp\int_0^{t_k} G(s)ds\right)\psi_\rho^\varepsilon(x(t_k),\alpha(t_k))\right] \\ &= E\left(\exp\int_0^{\tau} G(s)ds\right)\psi_\rho^\varepsilon(x(\tau),\alpha(\tau)). \end{aligned}$$

Since $\psi_\rho^\varepsilon(x,\alpha)$ is the inf of $J_\rho^\varepsilon(x,\alpha,U(\cdot))$ taken over all admissible $U(\cdot)$, this implies that

$$\psi_\rho^\varepsilon(x,\alpha) \geq \text{ right side of (DP).}$$

It remains to outline a proof that

$$\psi_\rho^\varepsilon(x,\alpha) \leq \text{ right side of (DP).}$$

Given an initial $x(0)=x$, formula (2.3) implies that $|x(t)|\leq r_1$ for some r_1. As in the proof of Theorem 3.5, given $\delta>0$, partition $\{|x|\leq r_1\}$ into intervals $B_1,B_2,\ldots,B_l$ of length $<\delta$ and choose $x_j\in B_j$ for $j=1,\ldots,l$. Given $\eta>0$, choose admissible $U_{ij}(\cdot)$ such that

$$J_\rho^\varepsilon(x_j,i,U_{ij}(\cdot)) < \psi_\rho^\varepsilon(x_j,i)+\eta.$$

Given admissible $U(\cdot)$, we define $\widetilde{U}(\cdot)$ by

$$\widetilde{U}(t)=U(t) \quad \text{for } 0\leq t<\tau,$$

and for $\tau=t_k$, $\alpha(t_k)=i$, $x(t_k)\in B_j$,

$$\widetilde{U}(t)=U_{ij}(t-t_k), \quad t\geq t_k.$$

Then $\widetilde{U}(\cdot)$ is admissible, and a routine calculation using Lemma 3.2 (ii) gives

$$\psi_\rho^\varepsilon(x,\alpha)\leq J_\rho^\varepsilon(x,\alpha,\widetilde{U}(\cdot)) \leq \text{ right side of (DP) } + F(\delta,\eta),$$

where $F(\delta,\eta)\to 0$ as $\delta,\eta\to 0$.

Remark on upper values and viscosity solutions. In section 4 we used a slight modification of a result of Evans and Souganidis [6]. Let us sketch the changes in [6] needed to account for the fact that the maximizing players' control space Γ_v is not compact. The game dynamics are

$$\dot{x}(t)=\hat{f}(x(t),U(t),V(t)),$$

where

$$\hat{f}(x,U,V)=-ax+\sum_{i=0}^m \nu_i^V u^i - z.$$

Let

$$\widetilde{\Psi}(x,T) = \text{ upper value } \left\{ \int_0^T \widehat{L}(x(t),U(t),V(t))dt + w^0(x(T)) \right\},$$

where the upper value is in the Elliott–Kalton sense. Equivalently,

$$\Psi(x,T) = \widetilde{\Psi}(x,T) - \lambda^0 T$$

is the upper value considered in section 5.

The assertion is that $\widetilde{\Psi}$ is a viscosity solution to

$$\frac{\partial \widetilde{\Psi}}{\partial T} = H(x, \widetilde{\Psi}_x)$$

and that $\widetilde{\Psi}$ is continuous with $\widetilde{\Psi}(\cdot,T)$ satisfying a uniform Lipschitz condition on any finite interval $0 \le T \le T_1$. The first step is to prove the dynamic programming principle (see [6, Theorem 3.1]): for $0 < \tau < T$,

$$\text{(DP)} \qquad \widetilde{\Psi}(x,T) = \text{ upper value } \left\{ \int_0^\tau \widehat{L}(x(t),U(t),V(t))dt + \widetilde{\Psi}(x(\tau),\tau) \right\}.$$

That argument is unchanged. Next, the facts that $\hat{f}_x = -a$ and $\widehat{L}_x = L_x$ is bounded imply a uniform Lipschitz condition for $\widetilde{\Psi}(\cdot,T)$ on any finite time interval. As noted in section 5, $\widehat{L} \le ||L||$ and

$$\sup_V \widehat{L}(x,U,V) \ge \widehat{L}(x,U,1) \ge 0.$$

Moreover, by the form of $\hat{f}$ and compactness of the minimizer's control set Γ_u, for every R, there exists K_R such that $|x| \le R$ implies

$$|x(\tau) - x| \le K_R \tau.$$

By subtracting $\widetilde{\Psi}(x,\tau)$ from both sides of (DP) we then obtain a uniform local Lipschitz condition for $\widetilde{\Psi}(x,\cdot)$.

Finally, to show that $\widetilde{\Psi}$ is a viscosity solution we proceed as in [6, section 4]. Minor changes in the proof of [6, Lemma 4.3] are needed, since Γ_v is not compact. For this we use the inequality for compact maximizer's control space. (The proof of [6, Lemma 4.3(a)] does use compactness of the minimizer's control space, which holds in our case.)

Proof of (4.6). Recall that the Donsker–Varadhan function is defined as $I(\mu) = \sup_{\beta \in \mathcal{V}}[-\langle \mu, \beta^{-1} Q\beta\rangle]$; see Fleming, Sheu, and Soner [9]. For each $V \in \Gamma_v$, let

$$K^V(i) = \overline{Q}^V(\log v^i(\cdot))(i) - \frac{1}{v^i(i)} Q v^i(\cdot)(i).$$

Then (4.6) can be written as $I(\mu) = \inf_{\nu^V = \mu} \langle \mu, K^V \rangle$. We first show that

$$I(\mu) \ge \inf_{\nu^V = \mu} \langle \mu, K^V \rangle. \tag{6.1}$$

It is elementary to show that there exists $\beta^* \in \mathcal{V}$ such that $I(\mu) = \langle \mu, (\beta^*)^{-1} Q \beta^* \rangle$. Then, in view of Lemma 3.2 in [9], we have

$$\mu = \nu^{V^*}, \quad \text{where } v^{i*}(j) = \beta^*(i)/\beta^*(j).$$

It follows that $\langle \mu, K^{V^*} \rangle = -\langle \mu, (\beta^*)^{-1} Q \beta^* \rangle$, because $\langle \mu, \overline{Q}^{V^*}(\phi) \rangle = \langle \nu^{V^*}, \overline{Q}^{V^*} \phi \rangle = 0$. This implies (6.1).

To show the opposite inequality, note that the logarithmic transformation

$$e^{-\phi(i)} Q(e^{\phi(\cdot)})(i) = \sup_{V \in \Gamma_v} [\overline{Q}^V \phi(\cdot)(i) - K^V(i)]$$

for all ϕ. Let $\phi = \beta^*$. Then for each V such that $\nu^V = \mu$, we have

$$\frac{1}{\beta^*} Q \beta^* \geq \overline{Q}^V \phi - K^V.$$

Hence, for $\nu^V = \mu$, we obtain

$$\left\langle \mu, \frac{1}{\beta^*} Q \beta^* \right\rangle \geq \langle \mu, \overline{Q}^V \phi \rangle - \langle \mu, K^V \rangle = -\langle \mu, K^V \rangle.$$

This implies that $I(\mu) \leq \inf_{\nu^V = \mu} \langle \mu, K^V \rangle$. The proof is complete.

Acknowledgments. We would like to thank S.-J. Sheu for pointing out Remark 4.6 and providing its proof. We also thank the referees for comments and suggestions that led to improvement of the paper.

STUDY OF AN OPTIMAL CONTROL PROBLEM FOR DIFFUSIVE NONLINEAR ELLIPTIC EQUATIONS OF LOGISTIC TYPE*

A. CAÑADA†, J. L. GÁMEZ†, AND J. A. MONTERO†

Abstract. An optimal control problem for a nonlinear elliptic equation of logistic type is considered. Under certain assumptions, the existence of at least an optimal control is shown and an optimality system is derived. Then this system is used for proving the uniqueness of and a constructive approximation to the optimal control.

Key words. optimal control, logistic elliptic equations, existence, uniqueness, approximation

1. Introduction. The aim of this paper is to study an optimal control problem for a nonlinear elliptic equation of the Volterra–Lotka type. More precisely, we consider the equation

$$\begin{aligned} -\Delta u(x) &= u(x)[a(x) - f(x) - b(x)u(x)],\ x \in \Omega, \\ u(x) &= 0,\ x \in \partial\Omega, \end{aligned} \tag{1.1}$$

where Ω is a bounded and regular domain in $\mathbb{R}^n$.

The previous equation arises from population dynamics, the study of the evolution of some biological species, and it models the steady-state solutions of the corresponding nonlinear evolution problem (see [12]). Here function u is the species concentration, a represents its intrinsic growth rate, b is the crowding effect, and f plays the role of control. The Laplacian operator Δ shows the diffusive character of the species u in the domain Ω, and the boundary condition in (1.1) may be interpreted as the condition that the species may not stay on $\partial\Omega$.

Under certain assumptions (see Hypothesis H below), equation (1.1) will have, for each given function f, a unique maximal nonnegative solution denoted by u_f, and we will be interested in maximizing the payoff functional

$$J(f) = \int_\Omega (\lambda u_f f - f^2), \tag{1.2}$$

which represents the difference between economic revenue and cost. The real constant λ, which will be taken to be strictly positive, describes the quotient between the price of the species and the cost of the control, whose role is to influence the growth rate of the species just to get better quality with the purpose of obtaining a greater benefit from the harvest. In the second section, some preliminary results are summarized, including the existence of an optimal control, i.e., a function f such that the profitability of the harvest is maximized. In the following, some necessary conditions for a control to be an optimal control are obtained; in particular, the optimality system

is deduced. With the help of some estimations for the solutions of such a system, we prove, in section 4, the uniqueness of the optimal control in two cases: when the parameter λ of the functional (1.2) is small and when the function b in (1.1) is a constant sufficiently large. The same ideas may be useful for studying the case where b is not necessarily constant; in this situation, it is possible to impose a restriction on the quotient between the supremum and the infimum (which, again, must be sufficiently large) of the function b to assure uniqueness (see [5]). In the last section, we give, for λ sufficiently small, a constructive scheme which provides a sequence of functions converging to some special solutions of the optimality system; this will be useful for approximating the optimal control. Of course, similar procedures are valid in other cases such as those considered in the fourth section. Related problems have been considered in [8, 9, 13]. In fact, our work was motivated by [9], where the authors study a problem like (1.1) but with Neumann boundary conditions and the controls are restricted to members of the set

$$C_\delta = \{g \in L^\infty(\Omega) : 0 \le g(x) \le \delta \text{ a.e. in } \Omega\},$$

where $0 < \delta < \inf_{x\in\Omega} a(x)$. The main novelty of our results is that we study the case of Dirichlet boundary conditions, which seems to be different in many aspects from the Neumann case (see [3], [7]). Also, our control space $L^\infty_+(\Omega)$, the set of functions of $L^\infty(\Omega)$ that are nonnegative a.e. in Ω, is different from that of [9] (see the final Remark 1), and we prove not only existence but also uniqueness of the optimal control, which is very important for its possible approximation as is seen in this paper.

2. Preliminary results. In this section we present some previous results and notation which will be useful below. The details may be seen in [1], [3], [6], [7], [10], and [11]. If $e \in L^\infty(\Omega)$, we denote $\underline{e} = \operatorname{ess\,inf}_{x\in\Omega} e(x)$, $\overline{e} = \operatorname{ess\,sup}_{x\in\Omega} e(x)$.

Let us consider equation (1.1). From now on, we assume the following hypothesis.

Hypothesis H. $a, b \in L^\infty(\Omega)$, $\underline{b} > 0$, $f \in L^\infty_+(\Omega) = \{g \in L^\infty(\Omega) : g(x) \ge 0 \text{ a.e. in } \Omega\}$.

For a function $q \in L^\infty(\Omega)$, we define $\sigma_1(q)$ to be the principal eigenvalue of the eigenvalue problem

$$\begin{gathered} -\Delta u(x) + q(x)u(x) = \sigma u(x),\ x \in \Omega, \\ u(x) = 0,\ x \in \partial\Omega. \end{gathered}$$

This principal eigenvalue can be expressed variationally as

$$\sigma_1(q) = \inf_{u\in H^1_0(\Omega)\setminus\{0\}} \frac{\displaystyle\int_\Omega |\nabla u|^2 + \int_\Omega q|u|^2}{\displaystyle\int_\Omega |u|^2}, \tag{2.3}$$

where $H^1_0(\Omega)$ is the usual Sobolev space. It is known that the algebraic multiplicity of $\sigma_1(q)$ is equal to one, and it is possible to choose an associated eigenfunction $\phi_1(q)$ (where the previous infimum is attained, becoming a minimum) such that $\phi_1(q) \in C^{1,\alpha}(\overline{\Omega})$ $\forall \alpha \in (0,1)$, $\phi_1(q) > 0$ in Ω, $\|\phi_1(q)\|_{L^\infty} = 1$.

As a direct consequence of the previous variational characterization, we obtain the following properties:

(i) $\sigma_1(q)$ is strictly increasing with respect to the weight function q; i.e., if $q_1 \le q_2$, we have $\sigma_1(q_1) \le \sigma_1(q_2)$ and this last inequality is strict if, moreover, $q_1(x) < q_2(x)$ on a subset of positive measure.

(ii) $\forall M \in \mathbb{R}$, $\sigma_1(q+M) = \sigma_1(q) + M$.

(iii) $\sigma_1(q)$ is continuous with respect to $q \in L^\infty(\Omega)$.

By using techniques of sub- and supersolutions, one may prove [1] that (1.1) has a (weak) nontrivial and nonnegative solution u_f iff $\sigma_1(-a+f) < 0$. In this case, the solution u_f is the unique nontrivial and nonnegative solution of (1.1), and it verifies the estimates

$$\frac{-\sigma_1(-a+f)}{\overline{b}}\ \phi_1(-a+f)(x) \le u_f(x) \le \frac{\overline{a}-\underline{f}}{\underline{b}}\ \forall x \in \Omega. \tag{2.4}$$

It is known [11] that every solution obtained by this method is a priori stable when considered as an equilibrium solution of an associated time dependent evolution equation. Also, the sub- and supersolutions provide an estimate of the extent of stability. Moreover, any bounded subsolution w of (1.1) must satisfy $w \le u_f$. If $\sigma_1(-a+f) < 0$, then $u_f(x) > 0\ \forall x \in \Omega$, and, therefore, taking into account the previous property (i), we have

$$\sigma_1(-a+f+2bu_f) > \sigma_1(-a+f+bu_f) = 0. \tag{2.5}$$

Note that Lyapunov's indirect argument analyzes stability by considering $u = u_f + \beta v \exp^{\mu t}$ in the time dependent problem, leading to the self-adjoint eigenvalue problem

$$\mu v - \Delta v + [-a+f+2bu_f]v = 0.$$

So, (2.5) provides the condition for linearized stability. Now we may extend the definition of u_f. For this, for each $f \in L^\infty_+(\Omega)$ (and in the same way, for each $f \in L^\infty(\Omega)$), we will denote by u_f the maximal nonnegative solution of equation (1.1). Then $u_f \equiv 0$ iff $\sigma_1(-a+f) \ge 0$ and u_f is strictly positive in Ω iff $\sigma_1(-a+f) < 0$. The following monotonicity property of u_f is easily proved, with respect to f, and is fundamental in many assumptions contained in this paper: if $f, g \in L^\infty(\Omega)$, and $f \le g$, then, $u_f \ge u_g$.

Let λ be a real positive constant and define the functional $J : L^\infty_+(\Omega) \to \mathbb{R}$, given by the expression

$$J(g) = \int_\Omega (\lambda u_g g - g^2).$$

The existence of an optimal control in $L^\infty_+(\Omega)$, i.e., $f \in L^\infty_+(\Omega)$, satisfying

$$J(f) = \sup_{g \in L^\infty_+(\Omega)} J(g)$$

has been done by the authors in [3]. More precisely, we have the following result.

THEOREM 2.1. *Consider problem* (1.1) *under Hypothesis* H. *Then the optimal control problem has a solution in the space* $L^\infty_+(\Omega)$.

The basic idea for the proof of this theorem is that the possible optimal controls must be bounded; in fact, if $f \in L^\infty_+(\Omega)$ and $g = \min\{f, \frac{\overline{a}\lambda}{\underline{b}}\}$, then $J(g) \ge J(f)$. To see this, we consider two cases:

(a) $u_f \equiv 0$. Then $J(f) = -\int_\Omega f^2 \le -\int_\Omega g^2 \le J(g)$.

(b) $u_f > 0$ in Ω. Then by the monotonicity property of u_f, with respect to f, we have $u_g \ge u_f > 0$ in Ω. By careful discussion, one may prove

$$\lambda u_g g - g^2 \ge \lambda u_f f - f^2 \quad \text{a.e. in } \Omega,$$

which implies $J(g) \ge J(f)$.

In particular, if $f \in L^\infty_+(\Omega)$ is an optimal control and $\overline{a} > 0$, then we may assume that

$$f \leq \frac{\overline{a}\lambda}{\underline{b}} \text{ a.e. in } \Omega. \tag{2.6}$$

Now from (2.4) and (2.6) it is easy to prove that if $\{f_n\}$ is any maximizing sequence in $L^\infty_+(\Omega)$ for J, then there exists $f \in L^\infty_+(\Omega)$ such that, for a convenient subsequence,

$$\begin{aligned} f_n &\rightharpoonup f \text{ weakly in } L^2(\Omega), \\ u_{f_n} &\to u_f \text{ strongly in } H^1_0(\Omega). \end{aligned}$$

Consequently, $J(f) = \sup_{g \in L^\infty_+(\Omega)} J(g)$.

Theorem 2.1 assures the existence of optimal control. Moreover, we may give conditions to guarantee the positivity of the benefit, i.e., to conclude that the quantity $\sup_{g \in L^\infty_+(\Omega)} J(g)$ is strictly positive. To do so, note that if this is true, then there exists $g \in L^\infty_+(\Omega)$ such that $J(g) > 0$. So, $u_g > 0$ and $\sigma_1(-a) \leq \sigma_1(-a+g) < 0$. Reciprocally, if $\sigma_1(-a) < 0$ is assumed, then observe that for any $f \in L^\infty_+(\Omega)$ we may write

$$\lambda u_f f - f^2 = \frac{\lambda^2 u_f^2}{4} + \left(f - \frac{\lambda u_f}{2} \right)^2.$$

Also, the condition $\sigma_1(-a) < 0$ implies the existence of a positive f such that $f = \frac{\lambda u_f}{2}$. Consequently, $J(f) > 0$ (see [3] for the details, where some additional estimates for the profit are also given). Therefore,

$$\sup_{g \in L^\infty_+(\Omega)} J(g) > 0 \;\Leftrightarrow\; \sigma_1(-a) < 0,$$

which justifies the hypothesis $\sigma_1(-a) < 0$ that we will assume in many of the next results. Now we present some results about elliptic operators of the Schrödinger type $-\Delta u + q(x)u$, $u \in H^1(\Omega)$.

LEMMA 2.2. *Assume*

$$q \in L^\infty(\Omega),\ \sigma_1(q) > 0.$$

Then the following results hold.

(i) *For each $f \in L^2(\Omega)$ the linear problem*

$$\begin{aligned} -\Delta u + q(x)u &= f \text{ in } \Omega, \\ u &= 0 \text{ on } \partial\Omega, \end{aligned} \tag{2.7}$$

has a unique solution $u \in H^1_0(\Omega)$. Moreover, if $f \in L^\infty(\Omega)$, $u \in C^{1,\alpha}(\overline{\Omega})$ $\forall\, \alpha \in (0,1)$.

(ii) *Let $u_1, u_2 \in H^1(\Omega)$ satisfy $u_2 \leq u_1$ on $\partial\Omega$ and $-\Delta u_2 + q u_2 \leq -\Delta u_1 + q u_1$ in the weak sense; i.e., $\forall\ \phi \in H^1_0(\Omega)$, $\phi \geq 0$,*

$$\int_\Omega \nabla u_2 \nabla \phi + \int_\Omega q u_2 \phi \leq \int_\Omega \nabla u_1 \nabla \phi + \int_\Omega q u_1 \phi.$$

Then $u_2 \leq u_1$ in Ω.

(iii) *Consider* $p \in L^\infty(\Omega)$, $p \geq q$ *in* Ω *and* $f \in L^2(\Omega)$, $f \geq 0$ *in* Ω. *Denote by* $\omega(p), \omega(q)$ *the respective solutions of problems*

$$-\Delta u + p(x)u = f \text{ in } \Omega,$$
$$u = 0 \text{ on } \partial\Omega,$$

and (2.7). *Then*

$$\omega(p) \leq \omega(q) \text{ in } \Omega.$$

Proof. The first part may be proved by applying the Lax–Milgram theorem to the bilinear form $L : H_0^1(\Omega) \times H_0^1(\Omega) \to \mathbb{R}$ defined by

$$L(u, v) = \int_\Omega \nabla u \nabla v + \int_\Omega quv$$

and the functional $\varphi : H_0^1(\Omega) \to \mathbb{R}$ defined by

$$\varphi(v) = \int_\Omega fv.$$

In fact, from the variational characterization of $\sigma_1(q)$ (see (2.3)) it follows that

$$\int_\Omega |\nabla u|^2 + \int_\Omega qu^2 \geq c \int_\Omega |\nabla u|^2 \ \forall\ u \in H_0^1(\Omega),$$

where

$$c = \frac{\sigma_1(q)}{\sigma_1(q) + \|q\|_\infty}. \tag{2.8}$$

Parts (ii) and (iii) are a direct consequence of the maximum principle (see [10] for more details). □

Remark 1. It is important to observe that if the function q in (2.7) belongs to a subset A of $L^\infty(\Omega)$ such that there exist two positive constants M and μ satisfying

$$\|q\|_\infty \leq M,\ \sigma_1(q) \geq \mu \ \forall\ q \in A,$$

then the constant c in (2.8) may be chosen independent of $q \in A$. In fact, we can take

$$c = \frac{\mu}{\mu + M}.$$

To do so, it is sufficient to see that

$$\frac{\mu}{\mu + M} \leq \frac{\sigma_1(q)}{\sigma_1(q) + \|q\|_\infty} \ \forall\ q \in A.$$

3. The optimality system. In this section we obtain some necessary conditions for an element $f \in L_+^\infty(\Omega)$ to be an optimal control. This will be carried out by deducing the optimality system satisfied for some pair (u_f, P_f) associated with f. Among other things, it will allow us to prove, in the next section, the uniqueness of the optimal control when the data of the problem fulfill some restrictions. We begin by proving a property about the directional differentiability of u_f with respect to f.

LEMMA 3.1. *Let $f \in L^\infty(\Omega)$ such that*

$$\sigma_1(-a+f) < 0. \tag{3.9}$$

Then

$$\frac{u_{f+\beta g} - u_f}{\beta} \to \xi$$

in $H_0^1(\Omega)$ as $\beta \to 0$ for any $g \in L^\infty(\Omega)$. Further, ξ is the unique solution of the linear problem

$$\begin{aligned} -\Delta\xi + [-a+f+2bu_f]\xi &= -gu_f \quad \text{in } \Omega, \\ \xi &= 0 \text{ on } \partial\Omega. \end{aligned} \tag{3.10}$$

In particular, this is true for each $f \in L^\infty_+(\Omega)$ such that $J(f) > 0$.

Proof. If $\beta \neq 0$ and

$$\xi_\beta = \frac{u_{f+\beta g} - u_f}{\beta},$$

then it satisfies

$$\begin{aligned} -\Delta\xi_\beta + [-a+f+b(u_{f+\beta g}+u_f)]\xi_\beta &= -gu_{f+\beta g} \quad \text{in } \Omega, \\ \xi_\beta &= 0 \text{ on } \partial\Omega. \end{aligned} \tag{3.11}$$

Since $\sigma_1(q)$ is increasing with respect to $q \in L^\infty(\Omega)$ and u_f is decreasing with respect to f, for each $\epsilon \in \mathbb{R}^+$ we have

$$\sigma_1(-a+f+b(u_{f+\beta g}+u_f)) \geq \sigma_1(-a+f+b(u_{f+\epsilon\|g\|_\infty}+u_f)) \equiv \mu,$$

provided that $|\beta| \leq \epsilon$, where $\|\cdot\|_\infty$ is the usual norm in $L^\infty(\Omega)$. Also, it is possible to take ϵ such that $\mu > 0$. To see this, note that if ϵ is sufficiently small the continuity of $\sigma_1(q)$ with respect to $q \in L^\infty(\Omega)$ and (3.9) imply

$$\sigma_1(-a+f+\epsilon\|g\|_\infty) < 0.$$

Consequently, $bu_{f+\epsilon\|g\|_\infty}$ is strictly positive in Ω and therefore the strict monotonicity of $\sigma_1(q)$ with respect to $q \in L^\infty(\Omega)$ and the monotonicity of $f \to u_f$ imply

$$\sigma_1(-a+f+b(u_{f+\epsilon\|g\|_\infty}+u_f)) > \sigma_1(-a+f+bu_f) = 0.$$

Taking into account the remark after Lemma 2.2 and (3.11), there is a constant c, independent of $\beta \in (-\epsilon,\epsilon)$, such that

$$\begin{aligned} &c\|\xi_\beta\|^2_{H_0^1(\Omega)} \\ &\leq \int_\Omega \{|\nabla\xi_\beta|^2 + [-a+f+b(u_{f+\beta g}+u_f)]\xi_\beta^2\} \\ &= \int_\Omega -gu_{f+\beta g}\xi_\beta \leq K\|\xi_\beta\|_{H_0^1(\Omega)} \end{aligned}$$

for some positive constant K (see (2.4)). Thus there exists some constant d, independent of $\beta \in (-\epsilon,\epsilon)$, such that

$$\|\xi_\beta\|_{H_0^1(\Omega)} \leq d. \tag{3.12}$$

This implies $u_{f+\beta g} \to u_f$ in $H_0^1(\Omega)$ as $\beta \to 0$. Taking into account that $bu_f > 0$ implies $\sigma_1(-a+f+2bu_f) > \sigma_1(-a+f+bu_f) = 0$ we obtain, from the uniqueness of solutions to (3.10), that $\xi_\beta \rightharpoonup \xi$ in $H_0^1(\Omega)$. Now rewriting (3.11) in the form

$$\begin{gathered} -\Delta\xi_\beta + [-a+f+2bu_f]\xi_\beta = -gu_f - \beta[g+b\xi_\beta]\xi_\beta \ \text{ in } \ \Omega, \\ \xi_\beta = 0 \ \text{ on } \ \partial\Omega \end{gathered}$$

one actually has strong convergence $\xi_\beta \to \xi$ in $H_0^1(\Omega)$. □

The previous result allows us to obtain a new step toward the derivation of the optimality system.

LEMMA 3.2. *Assume*

$$\sigma_1(-a) < 0. \tag{3.13}$$

If $f \in L_+^\infty(\Omega)$ is any optimal control, then

$$f = \frac{\lambda}{2}\, u_f(1-P_f)^+ \ \ \textit{a.e. in } \Omega, \tag{3.14}$$

where P_f is the unique solution of the linear problem

$$\begin{gathered} -\Delta P_f + (-a+f+2bu_f)P_f = f \ \ \textit{in } \Omega, \\ P_f = 0 \ \ \textit{on } \partial\Omega. \end{gathered} \tag{3.15}$$

Proof. Let $f \in L_+^\infty(\Omega)$ be an optimal control and $g \in L^\infty(\Omega)$, so that $f + \beta g \in L_+^\infty(\Omega)$ as $\beta \to 0^+$. Then

$$J(f+\beta g) - J(f) \le 0.$$

Dividing by β, we obtain

$$\int_\Omega \left[\lambda\, \frac{u_{f+\beta g} - u_f}{\beta}\, (f+\beta g) + \lambda u_f g - 2gf - \beta g^2\right] \le 0.$$

Letting $\beta \to 0^+$ and using Lemma 3.1, we have

$$\int_\Omega (\lambda\xi f + \lambda u_f g - 2gf) \le 0, \tag{3.16}$$

where ξ is defined by (3.10). Now multiplying equation (3.10) by P_f, multiplying equation (3.15) by ξ, and integrating and subtracting both expressions, we obtain

$$\int_\Omega f\xi + \int_\Omega g u_f P_f = 0. \tag{3.17}$$

Combining (3.16) and (3.17), we deduce in particular

$$\int_\Omega g[\lambda u_f(1-P_f) - 2f] \le 0 \ \forall\ g \in L_+^\infty(\Omega).$$

Therefore,

$$f \ge \frac{\lambda}{2} u_f(1-P_f) \ \text{ a.e. in } \Omega. \tag{3.18}$$

On the other hand, observe that if we take $g = -f$, then $f + \beta g \in L^\infty_+(\Omega)\ \forall\ \beta \in (0,1)$. Consequently, in the same way as before, we obtain

$$\int_{\Omega\cap\{f>0\}} f[\lambda u_f(1-P_f) - 2f] = \int_\Omega f[\lambda u_f(1-P_f) - 2f] \geq 0.$$

So, from (3.18) we must have

$$f = \frac{\lambda}{2} u_f(1-P_f) \ \text{ a.e. in } \ \Omega \cap \{f > 0\}. \tag{3.19}$$

From (3.18) and (3.19) we conclude (3.14). □

Our next purpose would be to prove that if $f \in L^\infty_+(\Omega)$ is an optimal control, then $P_f \leq 1$ a.e. in Ω. To do so, the basic tool may be the assertions (ii) and (iii) of Lemma 2.2; in fact, $P_f \geq 0$ by (ii). Moreover, if one wants to find an upper bound for P_f, the logical way must be to establish an upper bound for f and a lower bound for the function $-a + f + 2bu_f$. The existence of an upper bound for any optimal control is shown in (2.6). The lower bound for the mentioned function is a direct consequence of the continuity of the mapping u_f with respect to f, as we see in the next result.

LEMMA 3.3. *Assume* (3.13) *and choose* $\epsilon \in \mathbb{R}^+$ *such that*

$$\epsilon < \frac{\sigma_1(-a + 2bu_0)}{2\overline{b}}. \tag{3.20}$$

Then there exists a positive constant Λ_0 *depending on* $a, b,$ *and* Ω *such that if*

$$\lambda \leq \Lambda_0, \tag{3.21}$$

the function P_f *defined in* (3.15) *for any optimal control* f *satisfies the inequality*

$$0 \leq P_f \leq \lambda\ Q \text{ a.e. in } \Omega, \tag{3.22}$$

where Q *is the unique solution of the problem*

$$\begin{gathered} -\Delta Q + (-a + 2b(u_0 - \epsilon))Q = \frac{\overline{a}}{\underline{b}} \ \text{ in } \Omega, \\ Q = 0 \ \text{ on } \partial\Omega. \end{gathered} \tag{3.23}$$

Proof. First, note that from (3.13) u_0 is strictly positive in Ω and, therefore, $\sigma_1(-a + bu_0) = 0$. So $\sigma_1(-a + 2bu_0) > 0$. Now take ϵ satisfying (3.20). Then since the mapping $L^\infty_+(\Omega) \to C^1(\overline{\Omega})$, $f \to u_f$, is continuous [2], there is a positive constant Λ_0 such that

$$g \in L^\infty_+(\Omega),\ g \leq \Lambda_0 \frac{\overline{a}}{\underline{b}} \Rightarrow u_g \geq u_0 - \ \epsilon \ \text{ a.e. in } \ \Omega. \tag{3.24}$$

Also, from (3.20) and Lemma 2.2(i), problem (3.23) has a unique solution Q, and the function λQ satisfies the equation

$$-\Delta(\lambda Q) + (-a + 2b(u_0 - \epsilon))\lambda Q = \lambda \frac{\overline{a}}{\underline{b}}. \tag{3.25}$$

Last, if λ satisfies (3.21) and f is an optimal control, from (2.6), (3.24), and statements (ii) and (iii) of Lemma 2.2, we conclude (3.22). □

COROLLARY 3.4. *Let us suppose* (3.13) *and*

$$\lambda \leq \min\left\{\Lambda_0, \frac{1}{\|Q\|_\infty}\right\} \equiv \Lambda_1. \tag{3.26}$$

Then the function P_f *defined in* (3.15) *for any optimal control* f *satisfies the inequality*

$$0 \leq P_f \leq 1 \quad a.e.\ in\ \Omega.$$

Now we can state the main result of this section.

THEOREM 3.5. *Assume* (3.13) *and* (3.26). *Then any optimal control* $f \in L^\infty_+(\Omega)$ *may be expressed in the form*

$$f = \frac{\lambda}{2} u_f (1 - P_f), \tag{3.27}$$

where the pair $(u_f, P_f) \equiv (u, p)$ *satisfies*

$$0 \leq p \leq 1,\ u > 0 \quad a.e.\ in\ \Omega \tag{3.28}$$

and the optimality system

$$\begin{aligned} -\Delta u &= u\left(a - \left[b + \frac{\lambda}{2}(1-p)\right]u\right)\ in\ \Omega, \\ -\Delta p + p(-a + 2bu) &= \frac{\lambda}{2} u (1-p)^2\ in\ \Omega, \\ u = p &= 0\ on\ \partial\Omega. \end{aligned} \tag{3.29}$$

Proof. The proof is trivial using the previous results. □

The expression (3.27) for the optimal controls may be used for deducing some of their qualitative and quantitative properties. For instance, under the hypotheses of Theorem 3.5, all the optimal controls in $L^\infty_+(\Omega)$ have a suitable regularity: they must belong to the space $C^{1,\alpha}(\overline{\Omega})$ for any $\alpha \in (0,1)$. Also, if $\lambda < \Lambda_1$, then any optimal control f is such that $f > 0$ a.e. in Ω. Moreover, the uniqueness and approximation of the optimal control will be a consequence of (3.27); they will be deduced in the next sections.

4. Uniqueness of the optimal control. In this section we prove the uniqueness of the optimal control when the parameter λ of the functional (1.2) is small. To do so, we take into account that in Theorem 3.5 any optimal control is expressed in the form (3.27) with the pair (u, p) satisfying (3.28) and the optimality system (3.29). As a consequence, the uniqueness of the optimal control will be obtained by proving that for λ sufficiently small the optimality system (3.29) has a unique solution (u, p) verifying (3.28). First it is necessary to give some estimations for the solutions of system (3.29).

LEMMA 4.1. *Assume* (3.13) *and* (3.26) (ϵ *is chosen as in* (3.20)). *Let* (v, q) *be any solution of system* (3.29) *satisfying* (3.28). *Then*

$$u_0(x) - \epsilon \leq w(x) \leq v(x) \leq \frac{\overline{a}}{\underline{b}}, \quad 0 \leq q(x) \leq \lambda Q(x) \quad a.e.\ \ in\ \ \Omega, \tag{4.30}$$

where w *is the maximal nonnegative solution of*

$$\begin{aligned} -\Delta w &= w\left[a - \frac{\lambda}{2} w - bw\right]\ \ in\ \Omega, \\ w &= 0\ \ on\ \partial\Omega, \end{aligned} \tag{4.31}$$

and Q *is the unique solution of* (3.23).

Proof. As $\sigma_1(-a) < 0$, the function w is in fact strictly positive a.e. in Ω. So $w = u_{\frac{\lambda}{2}w}$, and since $\frac{\lambda}{2}w \leq \Lambda_0 \frac{\overline{a}}{\underline{b}}$ (see (2.4)), from (3.24) we obtain $w(x) \geq u_0(x) - \epsilon$ a.e. in Ω. On the other hand, it may be directly verified that w is a subsolution of the first equation of the optimality system (3.29); therefore, the maximality property of v (remember that $v = u_{\frac{\lambda}{2}(1-p)v}$) proves $w(x) \leq v(x)$ a.e. in Ω. The last inequality for v, i.e., $v(x) \leq \frac{\overline{a}}{\underline{b}}$, is trivial, taking into account systems (3.29) and (2.4). In relation to the function q, note that it satisfies the problem

$$\begin{aligned} -\Delta q + q(-a + 2bv) &= \frac{\lambda}{2} v(1-q)^2 \quad \text{in } \Omega, \\ q &= 0 \quad \text{on } \partial\Omega. \end{aligned}$$

Moreover, $-a + 2bv \geq -a + 2b(u_0 - \epsilon)$ and $\frac{\lambda}{2}v(1-q)^2 \leq \lambda \frac{\overline{a}}{\underline{b}}$. Consequently, the inequality $q \leq \lambda Q$ is deduced from (3.25) and statements (ii) and (iii) of Lemma 2.2. □

THEOREM 4.2. *Let us suppose* (3.13), *and take* ϵ *as in* (3.20). *Define* $\delta_0 \equiv \sigma_1(-a + 2b(u_0 - \epsilon))$, *which from* (3.20) *is strictly positive. Then if*

$$\lambda \leq \Lambda_2 \equiv \min \left\{ \Lambda_1, \frac{4\delta_0}{4\overline{b}\|Q\|_\infty + 1 + \frac{\overline{a}^2}{\underline{b}^2}} \right\}, \tag{4.32}$$

there can be only one solution (u, p) *of* (3.29) *satisfying* (3.28).

Proof. Let (u, p) and (v, q) be two solutions of (3.29) verifying (3.28). Then

$$\begin{aligned} 0 = &-\Delta(u-v) - a(u-v) + b(u-v)(u+v) \\ &+ \frac{\lambda}{2}(1-p)(u+v)(u-v) - \frac{\lambda}{2}v^2(p-q) \end{aligned} \tag{4.33}$$

and

$$\begin{aligned} 0 = &-\Delta(p-q) - a(p-q) + 2bu(p-q) \\ &+ 2bq(u-v) - \frac{\lambda}{2}(u-v) + \lambda u(p-q) \\ &+ \lambda q(u-v) - \frac{\lambda}{2}u(p-q)(p+q) - \frac{\lambda}{2}q^2(u-v). \end{aligned} \tag{4.34}$$

Multiplying (4.33) by $(u-v)$, multiplying (4.34) by $(p-q)$, integrating on Ω, and adding the two expressions, we obtain

$$\begin{aligned} 0 = &\int_\Omega \left[|\nabla(u-v)|^2 - a(u-v)^2 + b(u+v)(u-v)^2 \right. \\ &\left. + \frac{\lambda}{2}(1-p)(u+v)(u-v)^2 - \frac{\lambda}{2}v^2(u-v)(p-q) \right] \\ &+ \int_\Omega \left[|\nabla(p-q)|^2 - a(p-q)^2 + 2bu(p-q)^2 \right. \\ &+ (u-v)(p-q)\left(2bq - \frac{\lambda}{2} + \lambda q - \frac{\lambda}{2}q^2 \right) \\ &\left. + \frac{1}{2}\lambda u(2 - (p+q))(p-q)^2 \right]. \end{aligned}$$

Now observe that the terms

$$\frac{\lambda}{2}(1-p)(u+v)(u-v)^2$$

and

$$\frac{1}{2}\lambda u(2-(p+q))(p-q)^2$$

in the previous equality are both nonnegative. Also, from Lemma 4.1, functions u and v are greater than or equal to the function $u_0-\epsilon$. Moreover, the variational characterization of δ_0 (see 2.3) implies

$$\int_\Omega |\nabla r|^2 + \int_\Omega (-a+2b(u_0-\epsilon))r^2 \geq \delta_0 \int_\Omega r^2 \quad \forall\, r \in H_0^1(\Omega). \tag{4.35}$$

Therefore,

$$\begin{aligned} 0 \geq \int_\Omega \Bigg[& \delta_0(u-v)^2 + \delta_0(p-q)^2 \\ & + (u-v)(p-q)\left(2bq - \frac{\lambda}{2} + \lambda q - \frac{\lambda}{2}(q^2+v^2)\right)\Bigg] \end{aligned} \tag{4.36}$$

with strict inequality if $p(x) \neq q(x)$ in any subset of Ω with positive measure.

Also, by using the estimations (4.30) and hypothesis (4.32), we have

$$\begin{aligned} & \left|2bq - \frac{\lambda}{2} + \lambda q - \frac{\lambda}{2}(q^2+v^2)\right| \\ & = \left|2bq - \frac{\lambda}{2}(1-q)^2 - \frac{\lambda}{2}v^2\right| \\ & \leq \lambda\left[2\bar{b}\|Q\|_\infty + \frac{1}{2}\left(1+\frac{\overline{a}^2}{\underline{b}^2}\right)\right] \leq 2\delta_0. \end{aligned}$$

So, the integral that appears in (4.36) is also greater than or equal to zero. This implies $p(x)=q(x)$ a.e. in Ω and consequently $u(x)=v(x)$ a.e. in Ω. □

The main consequence of the previous result is the uniqueness of the optimal control for the considered control problem. Before discussing this result, it is convenient to say something more about notation. Our control problem lies in maximizing the functional (1.2) where, for a given function f, u_f means the maximal nonnegative solution to problem (1.1) (this requires Hypothesis H, which was established at the beginning of section 2 and assumed throughout the paper). So, this control problem is completely defined by the domain Ω, the functions a and b, and the parameter λ. Therefore, it is clear to denote it by $P_{\Omega,a,b,\lambda}$. The next corollary shows that when Ω, a, and b are conveniently fixed, the problem $P_{\Omega,a,b,\lambda}$ has a unique solution for λ sufficiently small.

COROLLARY 4.3. *Let us consider the problem $P_{\Omega,a,b,\lambda}$. Assume that the domain Ω and the functions a and b are fixed satisfying Hypothesis H and* (3.13). *Then if*

$$\lambda \leq \Lambda_2,$$

where Λ_2 is defined in (4.32), *the problem $P_{\Omega,a,b,\lambda}$ has a unique optimal control.*

Remark 2. It is important to notice that the positive constant Λ_2 defined in (4.32) depends only on the domain Ω and the functions a and b; so it would be more correct to denote it as $\Lambda_2(\Omega, a, b)$ instead of Λ_2. This observation allows us to prove the uniqueness of the optimal control in situations different from that considered in the previous corollary. For instance, this may be done if we fix Ω, the function a, and the parameter λ and consider b as a constant function to be chosen in a proper manner such as is indicated in the next corollary.

COROLLARY 4.4. *Let us consider the problem $P_{\Omega,a,b,\lambda}$ with b as a positive constant function. Assume that the constant λ, the domain Ω, and the function a are fixed satisfying Hypothesis H and* (3.13). *Choose $\Lambda_2(\Omega, a, 1)$ as in Corollary* 4.3. *Then if*

$$b \geq \frac{\lambda}{\Lambda_2(\Omega, a, 1)},$$

the problem $P_{\Omega,a,b,\lambda}$ has a unique optimal control.

Proof. It is sufficient to observe that

$$b u_{\Omega,a,b,f} = u_{\Omega,a,1,f}, \tag{4.37}$$

where $u_{\Omega,a,b,f}$ means the maximal nonnegative solution of (1.1). As a consequence, we have that for each $f \in L^\infty_+(\Omega)$,

$$J_{\Omega,a,b,\lambda}(f) \equiv \int_\Omega (\lambda u_{\Omega,a,b,f} f - f^2) = J_{\Omega,a,1,\frac{\lambda}{b}}\ (f).$$

Therefore, Corollary 4.3 may be applied to obtain the desired conclusion. □

Remark 3. If b is a positive constant function, the previous identity shows that when the quantity $\frac{\lambda}{b}$ is sufficiently small, the optimal control is unique. This may be carried out if b is fixed and λ is sufficiently small or if λ is fixed and b is sufficiently large. In addition to the treated cases, it is possible to study the other case where Ω, the function a, and the parameter λ are fixed and b is not necessarily a constant function. It does not seem possible to study this last case, proving a relation similar to (4.37). However, an analogous treatment to that considered in the previous results can be done, obtaining a result about the uniqueness of the optimal control, which involves, first, a restriction on the quantity $\frac{\overline{b}}{\underline{b}}$ (basically, this quantity must belong to the interval $[1, 2)$), and, second, $\underline{b}$ must be sufficiently large (see [5]).

Remark 4. We have proved that when λ is small enough or b is a large enough constant, the optimality system (3.29) admits a unique solution satisfying (3.28). We may ask about the essential implication of these two conditions on the functional J. In fact, if the domain Ω and the functions a and b are fixed, satisfying Hypothesis H and (3.13), there exists a different argument to prove that when λ is sufficiently small the optimal control is unique. This argument uses the regularity of the functional J on suitable subsets of $L^\infty(\Omega)$ (which contain the optimal controls), and in addition the monotonicity of its Fréchet derivative (see final Remark 2).

5. Approximation of the optimal control. The main purpose of this section is to give, for λ sufficiently small, a constructive scheme which provides a sequence of functions converging to the unique solution of the optimality system (3.29) satisfying (3.28). Due to the relation (3.27), this may be useful for approximating the optimal control f. For clarity of the exposition, it is convenient to adopt a more general

framework than (3.29). Consider the elliptic system

$$\begin{array}{ll} -\Delta u(x) = B(x,u(x),p(x)), & x \in \Omega, \\ -\Delta p(x) = C(x,u(x),p(x)) + D(x,u(x),p(x)), & x \in \Omega, \\ u(x) = p(x) = 0, & x \in \partial\Omega, \end{array} \tag{5.38}$$

where Ω is a bounded and regular domain in $\mathbb{R}^n$, and the nonlinearities $B, C, D : \overline{\Omega} \times \mathbb{R}^2 \to \mathbb{R}$ satisfy (regularity condition):

Hypothesis H1. B, C and D are continuous with respect to $(u,p) \in \mathbb{R}^2$ for fixed $x \in \overline{\Omega}$. Moreover, $\forall u, p \in L^\infty(\Omega)$, the functions $B(\cdot, u(\cdot), p(\cdot)), C(\cdot, u(\cdot), p(\cdot))$, and $D(\cdot, u(\cdot), p(\cdot))$ belong to $L^\infty(\Omega)$.

DEFINITION 5.1. *Let $\underline{u}, \overline{u}, \underline{p}, \overline{p} \in H^1(\Omega) \cap L^\infty(\Omega)$. Such functions are said to be a* system of upper-lower-solutions *for system* (5.38) *if they verify:* (a)

$$\begin{cases} \underline{u}(x) \le \overline{u}(x), \quad \underline{p}(x) \le \overline{p}(x) & \text{a.e. in } \Omega, \\ \underline{u} \le 0 \le \overline{u}, \qquad \underline{p} \le 0 \le \overline{p} & \text{in } \partial\Omega. \end{cases}$$

(A function $v \in H^1(\Omega)$ is said to be less than or equal to $w \in H^1(\Omega)$ on $\partial\Omega$ when $(v-w)^+ = \max\{0, v-w\} \in H_0^1(\Omega)$.) (b) $\forall \phi \in H_0^1(\Omega)$, $\phi \ge 0$,

$$\int_\Omega \nabla \overline{u} \cdot \nabla \phi \ge \int_\Omega B(x, \overline{u}, \overline{p})\phi,$$

$$\int_\Omega \nabla \underline{u} \cdot \nabla \phi \le \int_\Omega B(x, \underline{u}, \underline{p})\phi,$$

$$\int_\Omega \nabla \overline{p} \cdot \nabla \phi \ge \int_\Omega C(x, \underline{u}, \overline{p})\phi + \int_\Omega D(x, \overline{u}, \overline{p})\phi,$$

$$\int_\Omega \nabla \underline{p} \cdot \nabla \phi \le \int_\Omega C(x, \overline{u}, \underline{p})\phi + \int_\Omega D(x, \underline{u}, \underline{p})\phi.$$

Also, we will assume (monotonicity condition) the following hypothesis.

Hypothesis H2. $\exists\, M > 0$ such that the function $B(x,u,p) + Mu$ is increasing in u and the functions $C(x,u,p) + \frac{M}{2}p$, $D(x,u,p) + \frac{M}{2}p$ are increasing in p for $(x,u,p) \in \overline{\Omega} \times [\text{inf ess } \underline{u}, \text{sup ess } \overline{u}] \times [\text{inf ess } \underline{p}, \text{sup ess } \overline{p}]$. Moreover, functions B, C, and D satisfy the following monotonicity properties with respect to the other variables: $B(x,u,p)$ is increasing in p, the function $C(x,u,p)$ is decreasing in u, and the function $D(x,u,p)$ is increasing in u for $(x,u,p) \in \overline{\Omega} \times [\text{inf ess } \underline{u}, \text{sup ess } \overline{u}] \times [\text{inf ess } \underline{p}, \text{sup ess } \overline{p}]$.

Observe that if $C \equiv 0$, we have a system of cooperative type, whereas if $D \equiv 0$, we have a system of predator–prey type. For our purpose, the most interesting case is when C and D are both nonidentically zero as happens with system (3.29). For this kind of system, we show the next result whose proof may be carried out following the ideas contained in [4] and [7, Chapter V].

THEOREM 5.2. *Consider system* (5.38) *under the Hypotheses* H1 and H2. *Let us suppose that $\exists\, \underline{u}, \overline{u}, \underline{p}, \overline{p} \in H^1(\Omega) \cap L^\infty(\Omega)$, a system of upper–lower solutions for* (5.38).

Define by induction the sequences $\{u_n\},\{u^n\},\{p_n\},\{p^n\}$, *as*

$$u_1=\underline{u},\ u^1=\overline{u},\ p_1=\underline{p},\ p^1=\overline{p},$$

$$\begin{gathered}-\Delta u_n+Mu_n=B(x,u_{n-1},p_{n-1})+Mu_{n-1}\ in\ \Omega,\\ u_n=0\ on\ \partial\Omega,\end{gathered}$$

$$\begin{gathered}-\Delta u^n+Mu^n=B(x,u^{n-1},p^{n-1})+Mu^{n-1}\ in\ \Omega,\\ u^n=0\ on\ \partial\Omega,\end{gathered}$$

$$\begin{gathered}-\Delta p_n+Mp_n=C(x,u^{n-1},p_{n-1})+\frac{M}{2}p_{n-1}+D(x,u_{n-1},p_{n-1})+\frac{M}{2}p_{n-1}\ in\ \Omega,\\ p_n=0\ on\ \partial\Omega,\end{gathered}$$

$$\begin{gathered}-\Delta p^n+Mp^n=C(x,u_{n-1},p^{n-1})+\frac{M}{2}p^{n-1}+D(x,u^{n-1},p^{n-1})+\frac{M}{2}p^{n-1}\ in\ \Omega,\\ p^n=0\ on\ \partial\Omega.\end{gathered}$$

Then the sequence of functions defined above satisfy the order relation

$$\begin{gathered}u_1\le u_2\le\cdots\le u_n\le u^n\le u^{n-1}\le\cdots\le u^1,\\ p_1\le p_2\le\cdots\le p_n\le p^n\le p^{n-1}\le\cdots\le p^1\end{gathered}$$

for all $x\in\Omega$ *and*

$$u_n\nearrow u_*,\ u^n\searrow u^*,\ p_n\nearrow p_*,\ p^n\searrow p^*$$

(pointwise), where u_*,u^*,p_*,p^* *belong to* $C^{1,\alpha}(\Omega)$ *for any* $\alpha\in(0,1)$ *and satisfy the system*

$$\begin{gathered}-\Delta u_*=B(x,u_*,p_*)\ in\ \Omega,\\ -\Delta u^*=B(x,u^*,p^*)\ in\ \Omega,\\ -\Delta p_*=C(x,u^*,p_*)+D(x,u_*,p_*)\ in\ \Omega,\\ -\Delta p^*=C(x,u_*,p^*)+D(x,u^*,p^*)\ in\ \Omega,\\ u_*=u^*=p_*=p^*=0\ on\ \partial\Omega.\end{gathered}\tag{5.39}$$

Moreover, any solution (u,p) *of* (5.38) *with the property*

$$\underline{u}\le u\le\overline{u},\ \underline{p}\le p\le\overline{p},\tag{5.40}$$

must satisfy, for each $n\in\mathbb{N}$,

$$u_n\le u\le u^n,\ p_n\le p\le p^n,$$

and consequently

$$u_*\le u\le u^*,\ p_*\le p\le p^*.$$

Remark 5. Observe that (u^*,u_*,p^*,p_*) is also a solution of (5.39). So, if we are able to prove that there is only one solution (u,v,p,q) of (5.39) satisfying

$$\begin{gathered}\underline{u}\le u\le\overline{u},\ \underline{u}\le v\le\overline{u},\\ \underline{p}\le p\le\overline{p},\ \underline{p}\le q\le\overline{p},\end{gathered}\tag{5.41}$$

then we must have $u_* = u^*$, $p_* = p^*$, and therefore any solution of (5.38) with the property (5.40) must be (u_*, p_*). This is what happens in our optimal control problem as we are going to see next.

First, we assume all the assumptions of Theorem 4.2. Second, with the objective of applying Theorem 5.2 to system (3.29), we choose

$$\begin{aligned} B(x,u,p) &= u\left(a - \left[b + \frac{\lambda}{2}(1-p)\right]u\right), \\ C(x,u,p) &= p(a-2bu), \\ D(x,u,p) &= \frac{\lambda}{2}u(1-p)^2. \end{aligned}$$

Then Hypothesis H clearly implies Hypothesis H1. Also, a valid system of upper–lower solutions as in Definition 5.1 is

$$\underline{u} = w,\ \overline{u} = \frac{\overline{a}}{\underline{b}},\ \underline{p} = 0,\ \overline{p} = \lambda Q,$$

where w and Q are defined in (4.31) and (3.23), respectively.

On the other hand, Hypothesis H2 holds also for a convenient M, because the functions B, C, and D are of class C^1 with respect to (u,p). Consequently, Theorem 5.2 may be applied to system (3.29), obtaining

$$\begin{aligned} -\Delta u_* &= u_*\left(a - \left[b + \frac{\lambda}{2}\right]u_* + \frac{\lambda}{2}p_*u_*\right) \quad \text{in } \Omega, \\ -\Delta u^* &= u^*\left(a - \left[b + \frac{\lambda}{2}\right]u^* + \frac{\lambda}{2}p^*u^*\right) \quad \text{in } \Omega, \\ -\Delta p_* &= (a-2bu^*)p_* + \frac{\lambda}{2}u_*(1-p_*)^2 \quad \text{in } \Omega, \\ -\Delta p^* &= (a-2bu_*)p^* + \frac{\lambda}{2}u^*(1-p^*)^2 \quad \text{in } \Omega, \\ u_* &= u^* = p_* = p^* = 0 \quad \text{on } \partial\Omega. \end{aligned} \tag{5.42}$$

It happens that for λ sufficiently small, the previous system has a unique solution (u,v,p,q) satisfying (5.41), so that the conclusions that were exposed in Remark 5 may be applied. In fact, we have the following theorem.

THEOREM 5.3. *As in Theorem* 4.2, *let us suppose* (3.13) *and take* ϵ *as in* (3.20). *Define* $\delta_0 \equiv \sigma_1(-a + 2b(u_0 - \epsilon))$. *Then if*

$$\lambda \le \Lambda_3 \equiv \min\left\{\Lambda_2, \frac{\delta_0}{2\overline{b}\|Q\|_\infty}, \frac{2\delta_0\underline{b}^2}{\underline{b}^2 + \overline{a}^2}\right\},$$

there can be only one solution (u,v,p,q) *of* (5.42) *satisfying* (5.41).

Proof. We use ideas similar to those of Theorem 4.2. To do so, let (u,v,p,q), (U,V,P,Q) be two solutions of (5.42) verifying (5.41). Then

$$-\Delta(u-U) - a(u-U) + \left(b + \frac{\lambda}{2}\right)(u^2 - U^2) - \frac{\lambda}{2}(pu^2 - PU^2) = 0$$

or, equivalently,

$$\begin{aligned} -\Delta(u-U) - a(u-U) + \left(b + \frac{\lambda}{2}\right)(u+U)(u-U) \\ -\frac{\lambda}{2}u^2(p-P) - \frac{\lambda}{2}P(u^2 - U^2) = 0. \end{aligned}$$

Multiplying the previous expression by $u-U$ and integrating on Ω, we have

$$\begin{aligned}0=\int_\Omega\Big[&|\nabla(u-U)|^2-a(u-U)^2+b(u+U)(u-U)^2\\&+\frac{\lambda}{2}(u+U)(u-U)^2-\frac{\lambda}{2}P(u+U)(u-U)^2\\&-\frac{\lambda}{2}u^2(p-P)(u-U)\Big].\end{aligned}$$

Analogously, we prove

$$\begin{aligned}0=\int_\Omega\Big[&|\nabla(v-V)|^2-a(v-V)^2+b(v+V)(v-V)^2\\&+\frac{\lambda}{2}(v+V)(v-V)^2-\frac{\lambda}{2}Q(v+V)(v-V)^2\\&-\frac{\lambda}{2}v^2(q-Q)(v-V)\Big].\end{aligned}$$

In the same way, we have

$$\begin{aligned}&-\Delta(p-P)-a(p-P)+2b(vp-VP)\\&-\frac{\lambda}{2}(u-U)+\lambda(up-UP)-\frac{\lambda}{2}(up^2-UP^2)=0\end{aligned}\tag{5.43}$$

or, equivalently,

$$\begin{aligned}&-\Delta(p-P)-a(p-P)+2bv(p-P)\\&+2bP(v-V)-\frac{\lambda}{2}(u-U)+\lambda u(p-P)\\&+\lambda P(u-U)-\frac{\lambda}{2}u(p+P)(p-P)-\frac{\lambda}{2}P^2(u-U)=0.\end{aligned}$$

Multiplying by $(p-P)$ and integrating on Ω, we have the result

$$\begin{aligned}0=\int_\Omega\Big[&|\nabla(p-P)|^2-a(p-P)^2+2bv(p-P)^2\\&+2bP(v-V)(p-P)-\frac{\lambda}{2}(u-U)(p-P)\\&+\lambda u(p-P)^2+\lambda P(u-U)(p-P)\\&-\frac{\lambda}{2}u(p+P)(p-P)^2-\frac{\lambda}{2}P^2(u-U)(p-P)\Big].\end{aligned}$$

Analogously,

$$\begin{aligned}0=\int_\Omega\Big[&|\nabla(q-Q)|^2-a(q-Q)^2+2bu(q-Q)^2\\&+2bQ(u-U)(q-Q)-\frac{\lambda}{2}(v-V)(q-Q)\\&+\lambda v(q-Q)^2+\lambda Q(v-V)(q-Q)\\&-\frac{\lambda}{2}v(q+Q)(q-Q)^2-\frac{\lambda}{2}Q^2(v-V)(q-Q)\Big].\end{aligned}$$

Now using relation (4.35) we deduce

$$
\begin{aligned}
0 \geq \int_\Omega \Big\{ & \delta_0[(u-U)^2 + (v-V)^2 + (p-P)^2 + (q-Q)^2] \\
& -\frac{\lambda}{2}[u^2 + (1-P)^2](p-P)(u-U) \\
& -\frac{\lambda}{2}[v^2 + (1-Q)^2](q-Q)(v-V) \\
& + 2bP(v-V)(p-P) + 2bQ(u-U)(q-Q) \Big\}.
\end{aligned} \tag{5.44}
$$

Moreover, from the hypotheses of Theorem 5.2, we obtain

$$
\left|\frac{\lambda}{2}[u^2 + (1-P)^2]\right| \leq \delta_0, \ \left|\frac{\lambda}{2}[v^2 + (1-Q)^2]\right| \leq \delta_0,
$$
$$
|2bP| \leq \delta_0, \ |2bQ| \leq \delta_0,
$$

so that the integral which appears in (5.44) is also nonnegative; it is strictly positive if $p(x) \neq P(x)$ or $q(x) \neq Q(x)$ on any subset of Ω with positive measure. Therefore, $p(x) = P(x)$ and $q(x) = Q(x)$ a.e. in Ω and, consequently, $u = U$ and $v = V$. □

The same ideas may be developed for the case considered in Corollary 4.4.

6. Final remarks. (1) It is possible to use different control spaces from that of $L^\infty_+(\Omega)$. For instance, such as is done in [9] for the case of Neumann boundary conditions, we may consider equation (1.1) and the benefit-cost functional (1.2) defined on the space of admissible controls $C_\rho = \{g \in L^\infty(\Omega) : 0 \leq g \leq \rho \text{ a.e. in } \Omega\}$, $\rho > 0$.

Trivially, Theorem 2.1 remains true, taking C_ρ instead of $L^\infty_+(\Omega)$. Also, it may be proved that

$$
\sup_{g \in C_\rho} J(g) > 0 \ \Leftrightarrow \ \sigma_1(-a) < 0.
$$

To do so, observe that if the profit is positive, as in section 2, $\sigma_1(-a) < 0$. Reciprocally, if $\sigma_1(-a) < 0$, then u_0 is strictly positive in Ω. Using the fact that the mapping $C_\rho \to C^1(\overline{\Omega})$, $f \to u_f$, is continuous [2], there exists some positive number ϵ, $\epsilon < \rho$, such that $u_\epsilon > 0$ in Ω and

$$
J(\epsilon) = \epsilon \int_\Omega (\lambda u_\epsilon - \epsilon|\Omega|) > 0.
$$

Last, from (2.6) we may prove the same results as in Theorems 4.2 and 5.3 concerning the uniqueness and approximation of the optimal control, respectively, if, in addition, we assume $0 < \lambda \frac{\overline{a}}{\underline{b}} < \rho$.

(2) In this remark we sketch some ideas which show the regularity of the functional J and the monotonicity of its Fréchet derivative. This may be a different proof of the fact that when the parameter λ is sufficiently small the optimal control is unique.

Let us begin with the following proposition.

PROPOSITION 6.1. *Let $E \subset L^\infty(\Omega)$ be the open subset defined as*

$$
E = \{f \in L^\infty(\Omega)/\sigma_1(-a+f) < 0\}. \tag{6.45}
$$

Then $J : E \to \mathbb{R}$, $f \to J(f)$, is Fréchet continuously differentiable and

$$J'(f)(g) = \int_\Omega (\lambda \xi_{f,g} f + \lambda u_f g - 2fg) \ \forall\ f \in E \ \forall\ g \in L^\infty(\Omega), \tag{6.46}$$

where $\xi_{f,g}$ is the function given in (3.10).

Proof. If $f \in E$ and $g \in L^\infty(\Omega)$, then, as in Lemma 3.2,

$$\frac{J(f+\beta g) - J(f)}{\beta} \ \to \int_\Omega (\lambda \xi_{f,g} f + \lambda u_f g - 2fg) \quad \text{as} \quad \beta \to 0.$$

If P_f is the function defined in (3.15), then

$$\int_\Omega f \xi_{f,g} + \int_\Omega g u_f P_f = 0,$$

so that

$$\frac{J(f+\beta g) - J(f)}{\beta} \ \to \int_\Omega (-\lambda g u_f P_f + \lambda u_f g - 2fg) \quad \text{as} \quad \beta \to 0.$$

Because of the regularity of the functions u_f and P_f, the mapping $L^\infty(\Omega) \to \mathbb{R}$, $g \to \int_\Omega (-\lambda g u_f P_f + \lambda u_f g - 2fg)$, is linear and continuous. This proves that J is Gateaux differentiable at any $f \in E$ and that

$$J'_G(f)(g) = \int_\Omega (-\lambda u_f P_f g + \lambda u_f g - 2fg) \ \forall\ g \in L^\infty(\Omega). \tag{6.47}$$

Moreover, if $f_n \to f \in E$, then

$$\begin{aligned} &\sup_{g \in B_{L^\infty(\Omega)}(0;1)} |J'_G(f_n)(g) - J'_G(f)(g)| \\ &\leq \sup_{g \in B_{L^\infty(\Omega)}(0;1)} \left| \int_\Omega \left[-\lambda (u_{f_n} P_{f_n} - u_f P_f) + \lambda (u_{f_n} - u_f) - 2(f_n - f) \right] g \right|, \end{aligned}$$

where $B_{L^\infty(\Omega)}(0;1)$ is the closed ball in $L^\infty(\Omega)$ of center 0 and radius 1. Since $f_n \to f$ in $L^\infty(\Omega)$, we have that $u_{f_n} \to u_f$ in $C^1(\overline{\Omega})$ [2] and, therefore, $P_{f_n} \to P_f$, in $C^1(\overline{\Omega})$. Consequently,

$$\sup_{g \in B_{L^\infty(\Omega)}(0;1)} |J'_G(f_n)(g) - J'_G(f)(g)| \to 0,$$

and J is Fréchet continuously differentiable in E. The next step to get the monotonicity of J' requires the parameter λ to be sufficiently small. If this is the case, then, under the hypotheses of the previous proposition,

$$\left[0, \lambda \frac{\overline{a}}{\underline{b}}\right]_{L^\infty(\Omega)} \subset E,$$

and

$$\begin{aligned} &(J'(f) - J'(g))(f-g) \\ &= \int_\Omega [(\lambda u_f (1 - P_f) - 2f)(f-g) - (\lambda u_g (1 - P_g) - 2g)(f-g)] \\ &\forall\ f, g \in \left[0, \lambda \frac{\overline{a}}{\underline{b}}\right]_{L^\infty(\Omega)}. \end{aligned} \tag{6.48}$$

By using similar arguments to those of Lemma 3.1, it is possible to prove that if λ is sufficiently small, the mappings $u, P : \left[0, \lambda\frac{\overline{a}}{\underline{b}}\right] \to L^\infty(\Omega)$ are Lipschitz continuous (to see this, it is sufficient to consider, instead of ξ_β, the function $\xi_h = \frac{u_{f+h}-u_f}{\|h\|_\infty}$, with $f \in \left[0, \lambda\frac{\overline{a}}{\underline{b}}\right]$ and h belonging to a convenient bounded subset of $L^\infty(\Omega)$, and then repeat the reasoning given there). Therefore, the mapping $\left[0, \lambda\frac{\overline{a}}{\underline{b}}\right]_{L^\infty(\Omega)} \to L^\infty(\Omega),\ f \to u_f(1 - P_f)$ is Lipschitz continuous with Lipschitz constant L. Then

$$(J'(f) - J'(g))(f - g) \le \int_\Omega \left[\lambda L(f-g)^2 - 2(f-g)^2\right], \tag{6.49}$$

which proves that if λ is sufficiently small, the optimal control is unique (see (2.6)).

(3) Finally, it is interesting to point out that, a priori, the payoff functional $J(f)$ could seem to be well defined for every $f \in L^2(\Omega)$. As far as we know, it is not possible to define properly the principal eigenvalue $\sigma_1(q)$ for every $q \in L^2(\Omega)$. Accordingly, we cannot define either the solution u_f or the functional $J(f)$ if $f \in L^2(\Omega)$ is not bounded. This is the reason we chose a control space contained in $L^\infty(\Omega)$. □

Acknowledgments. The authors wish to thank the referees for several important remarks and suggestions on the original manuscript.

IDENTIFYING A SPATIAL BODY FORCE IN LINEAR ELASTODYNAMICS VIA TRACTION MEASUREMENTS*

MAURIZIO GRASSELLI† AND MASAHIRO YAMAMOTO‡

Abstract. An elastic and compressible material occupies a bounded domain $\Omega \subset \mathbf{R}^n$, $n \geq 2$, for any time $t \in [0,T]$, $T > 0$ being given. This material is subject to a body force $\mathbf{F} : [0,T] \times \Omega \to \mathbf{R}^n$ of the form $\mathbf{F}(t,x) := \varphi(t)\mathbf{f}(x)$, where $\mathbf{f} : \Omega \to \mathbf{R}^n$ is supposed to be unknown. The evolution of the displacement vector field is described by a Cauchy–Dirichlet problem for the linear elastodynamics system. We study the inverse problem of identifying $\mathbf{f}$ by measuring the traction $\mathbf{g}$ exerted on a portion Γ of the boundary $\partial\Omega$ over the time interval $[0,T]$. Using exact controllability methods, we show uniqueness and continuous dependence results. Also, we prove a representation formula for $\mathbf{f}$ in terms of $\mathbf{g}$.

Key words. inverse problems, exact controllability, linear elastodynamics

1. Introduction.

Consider an elastic and compressible material which occupies, for any time $t \in [0,T]$, $T > 0$, a bounded domain Ω in $\mathbf{R}^3$, for instance. Set $Q_T := (0,T) \times \Omega$ and suppose that the material is subject to a body force field $\mathbf{F} : Q_T \to \mathbf{R}^3$ of the form

$$\mathbf{F}(t,x) := \varphi(t)\mathbf{f}(x), \qquad (t,x) \in Q_T, \tag{1.1}$$

where $\varphi : (0,T) \to \mathbf{R}$ and $\mathbf{f} := (f^1, f^2, f^3) : \Omega \to \mathbf{R}^3$.

Denote by $\mathbf{u} := (u^1, u^2, u^3) : Q_T \to \mathbf{R}^3$ the displacement with respect to the unstressed state. Then, in the linear setting, the evolution of $\mathbf{u}$ is described by the motion equation (see, e.g., [MH, Chap. 6, section 6.2])

$$\varrho \mathbf{u}_{tt} = \nabla \cdot \sigma(\mathbf{u}) + \mathbf{F} \qquad \text{in } Q_T, \tag{1.2}$$

where $\varrho : \overline{\Omega} \to (0, +\infty)$ denotes the medium density, $\nabla\cdot$ stands for the spatial divergence operator, and $\sigma(\mathbf{u}) := [\sigma_{ij}(\mathbf{u})]$, $i,j = 1,2,3$, represents the stress tensor defined by the constitutive law

$$\sigma(\mathbf{u}) = C : \varepsilon(\mathbf{u}). \tag{1.3}$$

Here $C := [C_{ijlk}]$ is the elasticity tensor, $\varepsilon(\mathbf{u}) := [\varepsilon_{lk}(\mathbf{u})]$ is the linear strain, where $\varepsilon_{lk}(\mathbf{u}) = \frac{1}{2}(u^l_{x_k} + u^k_{x_l})$, and the colon indicates the standard product between tensors of order $2m$ and tensors of order m for any $m \in \mathbf{N}$.

Let us associate with (1.2) a set of Cauchy and Dirichlet data, i.e.,

$$\mathbf{u}(0) = \mathbf{u}_0, \qquad \mathbf{u}_t(0) = \mathbf{u}_1 \qquad \text{in } \Omega, \tag{1.4}$$

$$\mathbf{u} = \mathbf{h} \qquad \text{on } (0,T) \times \partial\Omega, \tag{1.5}$$

where $\mathbf{u}_0, \mathbf{u}_1 : \Omega \to \mathbf{R}^3$ and $\mathbf{h} : (0,T) \times \partial\Omega \to \mathbf{R}^3$ are prescribed functions. Consequently, $\mathbf{u}$ is uniquely determined by equation (1.2) and conditions (1.4)–(1.5), provided that the data are smooth enough (see, e.g., [MH, Chap. 6, section 6.2]). Nevertheless, here we assume that the spatial body force $\mathbf{f}$ is a priori unknown. We are thus led to consider the inverse problem of determining $\mathbf{f}$ (see also [BK]). Our main aim consists in showing that $\mathbf{f}$ can be uniquely identified by a boundary traction exerted on a portion Γ of the boundary $\partial\Omega$ over the time interval $[0,T]$, provided that both $T > 0$ and the two-dimensional Lebesgue measure of Γ, say *meas* Γ, are large enough. To be more precise, we suppose

$$\sigma(\mathbf{u}) : \nu = \mathbf{g} \qquad \text{on } (0,T) \times \Gamma, \tag{1.6}$$

where $\nu := (\nu^1, \nu^2, \nu^3) : \partial\Omega \to \mathbf{R}^3$ stands for the outward normal vector field to $\partial\Omega$, $\mathbf{g} := (g^1, g^2, g^3) : (0,T) \times \Gamma \to \mathbf{R}^3$ is the measured traction, and $\Gamma \subset \partial\Omega$ is prescribed. Then, our inverse problem can be formulated thus.

Problem (P_1). Find $\mathbf{f}$ from $\mathbf{g}$, provided that $\mathbf{u}$ fulfills (1.2) and (1.4)–(1.6).

Concerning (P_1), we are able to prove that, for T and *meas* Γ large enough,

(i) the mapping $\mathcal{G} : \mathbf{f} \mapsto \mathbf{g}$ has a Lipschitz continuous inverse;

(ii) $\mathbf{f}$ can be *reconstructed* by means of the eigenfunctions associated with the linear operator $-\varrho^{-1}\nabla \cdot \sigma(\cdot)$ which satisfy homogeneous Dirichlet boundary conditions;

(iii) the range of the adjoint operator $\mathcal{G}^*$ can be partially characterized.

All these results are obtained by extending the technique devised in [Y] to deal with the wave equation. This approach bears upon exact controllability methods presented in [L]. The plan goes as follows. In section 2, some basic preliminary results are introduced. Section 3 is devoted to stating our theorems rigorously. They are then proved in sections 4, 5, and 6. Finally, a proof of a basic technical lemma is given in section 7.

2. Some preliminary results. Here and below, $\Omega \subset \mathbf{R}^n$, $n \geq 2$, is an open, bounded, and connected subset with a boundary $\partial\Omega$ of class $\mathcal{C}^2$ (see Remark 2.1 below, however). Just for the sake of simplicity, we deal with an isotropic material. Therefore, relationship (1.3) becomes

$$\sigma(\mathbf{u}) = \lambda \operatorname{Tr} \varepsilon(\mathbf{u})\delta + 2\mu\varepsilon(\mathbf{u}), \tag{2.1}$$

where $\operatorname{Tr}\varepsilon$ denotes the trace of the linear strain tensor, while δ indicates the Kronecker tensor.

Concerning ϱ, λ, and μ, we assume

$$\varrho,\ \lambda,\ \mu \in C^1(\overline{\Omega}), \tag{2.2}$$

$$\varrho \geq \varrho_0,\ \mu \geq \mu_0,\ \lambda + \mu \geq \alpha_0 \quad \text{in } \overline{\Omega}, \tag{2.3}$$

where ϱ_0, μ_0, and α_0 are positive constants.

Also, we take (cf. (1.5))

$$\mathbf{h} \equiv \mathbf{0} \tag{2.4}$$

and set $H := (L^2(\Omega))^n$, $V := (H_0^1(\Omega))^n$, $V' := (H^{-1}(\Omega))^n$. From now on, $\langle \cdot, \cdot \rangle$ stands for the duality pairing between V' and V, while $(\cdot,\cdot)_X$, X being a real Hilbert space, indicates the *natural* inner product in X. If, in particular, $X = \mathbf{R}^n$, then we set $(\cdot,\cdot) := (\cdot,\cdot)_{\mathbf{R}^n}$. In addition, the symbol $\mathcal{D}(\Theta)$, $\Theta \subseteq \mathbf{R}^n$ being an open set, denotes the space of C^∞ functions having compact support in Θ and taking values in $\mathbf{R}^n$.

We first state a couple of results about the well-posedness of the Cauchy–Dirichlet problem for the elastodynamic system. Their proofs can be derived arguing, e.g., as in [L, Chap. I, sections 3 and 4] (see also [LLT, section 4]).

Let

$$\mathbf{F}\in L^1(0,T;H), \tag{2.5}$$

$$\mathbf{u}_0 \in V, \tag{2.6}$$

$$\mathbf{u}_1 \in H, \tag{2.7}$$

and consider the following problem.

Problem (P_2). Find $\mathbf{u}$ such that

$$\mathbf{u}\in C^1([0,T];H)\cap C^0([0,T];V), \tag{2.8}$$

$$\mathbf{u}_\nu := (\nabla\mathbf{u},\nu) \in L^2(0,T;L^2(\partial\Omega;\mathbf{R}^n)), \tag{2.9}$$

$$\varrho\mathbf{u}_{tt} = \nabla\cdot\sigma(\mathbf{u}) + \mathbf{F} \qquad \text{in } V', \text{ a.e. in } (0,T), \tag{2.10}$$

$$\mathbf{u}(0) = \mathbf{u}_0, \qquad \mathbf{u}_t(0) = \mathbf{u}_1 \qquad \text{a.e. in } \Omega. \tag{2.11}$$

We have the following theorem.

THEOREM 2.1. *Let the assumptions* (2.1)–(2.7) *hold. Then Problem* (P_2) *admits a unique solution. Moreover, there exists a positive constant* Λ_0 *such that*

$$\begin{aligned}&\|\mathbf{u}\|_{C^1([0,T];H)} + \|\mathbf{u}\|_{C^0([0,T];V)} + \|\mathbf{u}_\nu\|_{L^2(0,T;L^2(\partial\Omega;\mathbf{R}^n))}\\ &\le \Lambda_0\left\{\|\mathbf{F}\|_{L^1(0,T;H)} + \|\mathbf{u}_0\|_V + \|\mathbf{u}_1\|_H\right\}.\end{aligned} \tag{2.12}$$

Here Λ_0 *only depends on* Ω, T, ϱ, λ, *and* μ.

Strengthening the assumptions (2.5)–(2.7), i.e., assuming

$$\mathbf{F}\in W^{1,1}(0,T;H), \tag{2.13}$$

$$\mathbf{u}_0 \in V,\ \nabla\cdot\sigma(\mathbf{u}_0)\in H, \tag{2.14}$$

$$\mathbf{u}_1 \in V, \tag{2.15}$$

one gets from Theorem 2.1 the following regularity result (cf. also [Y, Appendix]).

THEOREM 2.2. *Let the assumptions* (2.1)–(2.4) *and* (2.13)–(2.15) *hold. Then the unique solution to Problem* (P_2) *satisfies*

$$\mathbf{u}\in C^2([0,T];H)\cap C^1([0,T];V), \tag{2.16}$$

$$\mathbf{u}_\nu \in H^1(0,T;L^2(\partial\Omega;\mathbf{R}^n)), \tag{2.17}$$

and therefore equation (2.10) *is fulfilled almost everywhere in* Q_T. *Also, one can find a positive constant* Λ_1 *such that*

$$\begin{aligned}&\|\mathbf{u}\|_{C^2([0,T];H)} + \|\mathbf{u}\|_{C^1([0,T];V)} + \|\mathbf{u}_\nu\|_{H^1(0,T;L^2(\partial\Omega;\mathbf{R}^n))}\\ &\le \Lambda_1\left\{\|\mathbf{F}\|_{W^{1,1}(0,T;H)} + \|\mathbf{u}_0\|_V + \|\nabla\cdot\sigma(\mathbf{u}_0)\|_H + \|\mathbf{u}_1\|_V\right\}.\end{aligned} \tag{2.18}$$

Here Λ_1 *only depends on* Ω, T, ϱ, λ, *and* μ.

We now state some results from exact controllability via the Hilbert uniqueness method (HUM) (cf., e.g., [L]). The first one is a technical lemma whose proof can be found in section 7. This lemma generalizes the inverse inequality proved in [L, Chap. IV, section 1].

Let $x^0\in\mathbf{R}^n$ and set (cf. also [L, Chap. I, section 5])

$$\mathbf{m}(x) := x - x^0 \qquad \forall\, x\in\mathbf{R}^n, \tag{2.19}$$

$$\Gamma^{+}(x^0) := \{x \in \partial\Omega \ : \ (\mathbf{m}(x), \nu(x)) > 0\}, \tag{2.20}$$

$$R(x^0) := \|\mathbf{m}\|_{(L^\infty(\Omega))^n}, \tag{2.21}$$

$$\Omega_{\varrho}^{-}(x^0) := \{x \in \Omega \ : \ (\nabla\varrho(x), \mathbf{m}(x)) < 0\}, \tag{2.22}$$

$$\Omega_{\lambda}^{+}(x^0) := \{x \in \Omega \ : \ (\nabla\lambda(x), \mathbf{m}(x)) > 0\}. \tag{2.23}$$

For the sake of simplicity, we assume that μ is constant, i.e.,

$$\mu \equiv \mu_0 \qquad \text{in } \overline{\Omega}. \tag{2.24}$$

However, the result we are going to state can also be proved when μ fulfills (2.2)–(2.3) and is not necessarily constant, provided that condition (2.26) below is suitably modified (cf. [I]; see also [TB]).

Besides, indicate by $d\Sigma$ the $(n-1)$-dimensional Lebesgue measure, while $|\cdot|$ denotes either the euclidean norm in $\mathbf{R}^n$ or the norm defined by

$$|A| := \left(\sum_{i,j=1}^{n} |a_{ij}|^2\right)^{1/2},$$

where $A := [a_{ij}]$ is any $n \times n$ real matrix.

One can prove the following lemma.

LEMMA 2.3. *Let the assumptions* (2.1)–(2.4) *and* (2.6)–(2.7*) hold. Moreover, assume*

$$\mathbf{F} \equiv \mathbf{0}, \tag{2.25}$$

$$R_0 := R(x^0)\left(\left\|\frac{\nabla\lambda}{\lambda}\right\|_{(L^\infty(\Omega_{\lambda}^{+}(x^0)))^n} + \left\|\frac{\nabla\varrho}{\varrho}\right\|_{(L^\infty(\Omega_{\varrho}^{-}(x^0)))^n}\right) < 1, \tag{2.26}$$

$$T > 2\gamma^{-1}(\varrho_0\mu_0)^{-1/2}R(x^0)\|\varrho\|_{L^\infty(\Omega)}, \tag{2.27}$$

where

$$\gamma := 1 - R_0. \tag{2.28}$$

Then

$$\begin{aligned} R\,(x^0)\int_{(0,T)\times\Gamma^{+}(x^0)} &\left[\mu|\nabla\mathbf{u}|^2 + (\lambda+\mu)|\nabla\cdot\mathbf{u}|^2\right] dtd\Sigma \\ &\geq 2\left(\gamma T - 2(\varrho_0\mu_0)^{-1/2}R(x^0)\|\varrho\|_{L^\infty(\Omega)}\right)E_0, \end{aligned} \tag{2.29}$$

where $\mathbf{u}$ *is the unique solution to* (P_2) *and*

$$E_0 := \frac{1}{2}\int_{\Omega}\left[\mu|\nabla\mathbf{u}_0|^2 + (\lambda+\mu)|\nabla\cdot\mathbf{u}_0|^2 + \varrho|\mathbf{u}_1|^2\right] dx. \tag{2.30}$$

Taking advantage of Theorem 2.1, we obtain an adapted version of [L, Chap. I, section 4, Théo. 4.2], as follows.

THEOREM 2.4. *Let the assumptions* (2.1)–(2.3) *hold. Then, for any* $\{\mathbf{z}_0, \mathbf{z}_1, \tilde{\mathbf{v}}\} \in H \times V' \times L^2(0,T;L^2(\partial\Omega;\mathbf{R}^n))$, *there exists a unique* $\mathbf{z}$ *such that*

$$\mathbf{z} \in C^1([0,T];V') \cap C^0([0,T];H), \tag{2.31}$$

$$\begin{aligned} &\int_{Q_T}(\varrho\mathbf{z},\mathbf{r})dtdx = -(\mathbf{z}_0,\mathbf{q}_t(0))_H + \langle\mathbf{z}_1,\mathbf{q}(0)\rangle \\ &-\int_{(0,T)\times\partial\Omega}(\tilde{\mathbf{v}},\sigma(\mathbf{q}):\nu)d\Sigma dt \qquad \forall\,\mathbf{r} \in C^0([0,T];(H^2(\Omega))^n \cap V), \end{aligned} \tag{2.32}$$

where $\mathbf{q} \in C^0([0,T];(H^2(\Omega))^n \cap V)$ *is the unique solution to*

$$\varrho \mathbf{q}_{tt} = \nabla \cdot \sigma(\mathbf{q}) + \mathbf{r} \qquad \text{a.e. in } Q_T \tag{2.33}$$

$$\mathbf{q}(T) = \mathbf{q}_t(T) = \mathbf{0} \qquad \text{a.e. in } \Omega \tag{2.34}$$

$$\mathbf{q} = \mathbf{0} \qquad \text{a.e. on } (0,T) \times \partial\Omega. \tag{2.35}$$

Moreover, there is a positive constant Λ_2 *such that*

$$\begin{aligned} &\| \mathbf{z}\|_{C^0([0,T];H)} + \|\mathbf{z}_t\|_{C^0([0,T];V')} \\ &\le \Lambda_2 \left\{ \|\mathbf{F}\|_{W^{1,1}(0,T;H)} + \|\mathbf{z}_0\|_H + \|\mathbf{z}_1\|_{V'} + \|\mathbf{v}\|_{L^2(0,T;L^2(\partial\Omega;\mathbf{R}^n))} \right\}. \end{aligned} \tag{2.36}$$

Here Λ_2 *only depends on* Ω, T, ϱ, λ, *and* μ.

The proof is as in [L, Chap. I, section 4, pp. 47–50].

Finally, on account of Lemma 2.3 and Theorem 2.4, we can deduce an extension of [L, Chap. IV, section 1, Théo. 1.1] as follows.

THEOREM 2.5. *Let the assumptions* (2.1)–(2.3), (2.24)–(2.27) *hold. Then, there exists a mapping* $\widetilde{\Pi} : H \times V' \to L^2(0,T;L^2(\Gamma^+(x_0);\mathbf{R}^n))$ *such that the unique solution* $\mathbf{z}$ *satisfying* (2.31)–(2.32) *with*

$$\mathbf{v} := \begin{cases} \widetilde{\Pi}(\mathbf{u}_0, \mathbf{u}_1) & \text{on } (0,T) \times \Gamma^+(x_0), \\ 0 & \text{on } (0,T) \times \partial\Omega \backslash \Gamma^+(x_0) \end{cases}$$

fulfills

$$\mathbf{z}(T) \equiv \mathbf{z}_t(T) \equiv \mathbf{0}. \tag{2.37}$$

Moreover, there holds

$$\|\widetilde{\Pi}(\mathbf{z}_0, \mathbf{z}_1)\|_{L^2(0,T;L^2(\Gamma^+(x_0);\mathbf{R}^n))} \le \Lambda_3 \left\{ \|\mathbf{z}_0\|_H + \|\mathbf{z}_1\|_{V'} \right\} \tag{2.38}$$

for some positive constant Λ_3 *which only depends on* Ω, x^0, T, ϱ, λ, *and* μ.

Proof. The existence of a control $\mathbf{v} \in L^2(0,T;L^2(\Gamma^+(x^0);\mathbf{R}^n))$ such that (2.37) holds can be obtained via the HUM method as in [L, Chap. IV, section 1, pp. 227–228], by using our Lemma 2.3, which generalizes the *inverse inequality* proved in [L, Chap. IV, section 1, pp. 225–227]. Estimate (2.38) derives from the construction of $\mathbf{v}$ (see [L, Chap. I, section 2 and Chap. II, section 2]). □

Remark 2.1. All the previous results still hold when Ω is open, bounded, and convex (see [L, section 6, Chap. I]).

Remark 2.2. It is worth observing that, in some cases, condition (2.26) is not so restrictive on λ and ϱ. Consider, for instance, a layered medium with respect to x_3, which occupies a cube in $\mathbf{R}^3$ (cf. Remark 2.1). Then λ and ϱ only depend on the *depth* variable x_3. If, e.g., λ is nondecreasing and ϱ is nonincreasing, then x^0 can be chosen in such a way that $\Omega_\lambda^+(x^0) = \Omega_\varrho^-(x^0) \equiv \emptyset$. Therefore, we have $\gamma = 1$ (cf. (2.26) and (2.28)).

3. Main results. Taking advantage of the linear setting, we make a further harmless simplification letting (cf. (1.4))

$$\mathbf{u}_0 = \mathbf{u}_1 \equiv \mathbf{0}. \tag{3.1}$$

Moreover, we suppose

$$\varphi \in C^1([0,T]). \tag{3.2}$$

Then, from Theorems 2.1 and 2.2, one deduces the following proposition.

PROPOSITION 3.1. *Let the assumptions* (2.1)–(2.4), (3.1)–(3.2) *hold. Then, for any* $\mathbf{f} \in H$ *there exists a unique* $\mathbf{u}$ *which fulfills* (2.16)–(2.17) *and solves*

$$\varrho \mathbf{u}_{tt} = \nabla \cdot \sigma(\mathbf{u}) + \varphi \mathbf{f} \qquad a.e.\ in\ Q_T, \tag{3.3}$$

$$\mathbf{u}(0) = \mathbf{u}_t(0) = \mathbf{0} \qquad a.e.\ in\ \Omega. \tag{3.4}$$

In addition, one has

$$\begin{aligned} &\| \mathbf{u}\|_{C^2([0,T];H)} + \|\mathbf{u}\|_{C^1([0,T];V)} + \|\mathbf{u}_\nu\|_{H^1(0,T;L^2(\partial\Omega;\mathbf{R}^n))} \\ &\le \Lambda_1 \|\varphi\|_{W^{1,1}(0,T)} \|\mathbf{f}\|_H. \end{aligned} \tag{3.5}$$

Consider $\Gamma \subseteq \partial\Omega$ such that $meas\,\Gamma > 0$. Thanks to Proposition 3.1, we can introduce a mapping $\mathcal{G} : H \to H^1(0,T;L^2(\Gamma;\mathbf{R}^n))$ by setting

$$\mathcal{G}(\mathbf{f}) := \sigma(\mathbf{u}(\mathbf{f})) : \nu \qquad \text{on } (0,T) \times \Gamma, \tag{3.6}$$

where $\mathbf{u}(\mathbf{f})$ is the unique solution to (3.3)–(3.4) given by Proposition 3.1. Note that, owing to (2.4),

$$u^i_{x_j} = u^i_\nu \nu_j, \qquad 1 \le i,j \le n. \tag{3.7}$$

Hence $\mathcal{G}$ is Lipschitz continuous because of (3.5).

Our first result concerns the invertibility of $\mathcal{G}$.

THEOREM 3.2. *Let the assumptions* (2.1)–(2.4), (2.24), (2.26)–(2.27), (3.1)–(3.2) *hold. Assume, moreover,*

$$\varphi(0) \neq 0, \tag{3.8}$$

$$\Gamma^+(x^0) \subseteq \Gamma. \tag{3.9}$$

Then, for any $\mathbf{g} \in H^1(0,T;L^2(\Gamma;\mathbf{R}^n))$, *there exists at most a unique* $\mathbf{f} \in H$ *such that* $\mathcal{G}(\mathbf{f}) = \mathbf{g}$. *Also,*

$$\|\mathbf{f}\|_H \le \Lambda_4 \|\mathbf{g}\|_{H^1(0,T;L^2(\Gamma;\mathbf{R}^n))}, \tag{3.10}$$

where Λ_4 *is a positive constant depending only on* $\Omega, x^0, T, \varrho, \lambda, \mu, \varphi$.

In other words, Theorem 2.1 gives some sufficient conditions which ensure the existence of $\mathcal{G}^{-1}$ and its (Lipschitz) continuity. This result extends [Y, Thm. 1].

We are going to state now a generalization of [Y, Thm. 2], i.e., a reconstruction formula for the unknown function $\mathbf{f}$ in terms of $\mathbf{g}$ and the eigenfunctions of the linear operator (cf. (2.1)–(2.3))

$$\mathcal{E}(\mathbf{u}) := -\varrho^{-1} \nabla \cdot \sigma(\mathbf{u}), \qquad \mathbf{u} \in D(\mathcal{E}) := \{\mathbf{w} \in V \ :\ \mathcal{E}(\mathbf{w}) \in H\}. \tag{3.11}$$

Note that, owing to (2.2)–(2.4) and by the regularity of $\partial\Omega$, we have $D(\mathcal{E}) \equiv (H^2(\Omega))^n \cap V$.

To state our second result we need some preliminary considerations. Taking advantage of Theorem 2.4, one can construct a mapping $\Pi : H \to L^2(0,T;L^2(\Gamma;\mathbf{R}^n))$ by setting (see [Y])

$$\mathbf{v} = \Pi(\mathbf{z}_0) := \widetilde{\Pi}(\mathbf{z}_0, \mathbf{0}) \qquad \text{on } (0,T) \times \Gamma \tag{3.12}$$

for any $\mathbf{z}_0 \in H$.

Also, we introduce the linear bounded operator (see [Y]) $\Phi : L^2(0,T;L^2(\Gamma;\mathbf{R}^n)) \to H^1(0,T;L^2(\Gamma;\mathbf{R}^n))$ defined as

$$\xi := \Phi(\eta), \tag{3.13}$$

where ξ is the unique solution in $H^1(0,T;L^2(\Gamma;\mathbf{R}^n))$ to the linear system of Volterra integrodifferential equations

$$\varphi(0)\xi_t(t,\cdot) + \int_t^T [\varphi'(s-t)\xi_t(s,\cdot) + \varphi(s-t)\xi(s,\cdot)]\,ds = \eta(t,\cdot) \quad \text{a.e. in } (0,T)\times\Gamma \tag{3.14}$$

such that $\xi(0,\cdot) = \mathbf{0}$ almost everywhere on Γ.

Before stating the reconstruction formula, it is worth noting that the linear operator $\mathcal{E} : D(\mathcal{E}) \to H$ (see (3.11)) is V-coercive and self-adjoint with respect to the measure $\varrho(x)dx$; then its eigenvalues are all positive with finite multiplicity and they form a nondecreasing sequence $\{\lambda_k\}$, $k \in \mathbf{N}$, where any λ_k appears l times, l being its multiplicity. Besides, we recall that the corresponding eigenfunctions $\{\mathbf{w}_k\}$ can be chosen in order to constitute an orthonormal basis of $H_\varrho := (L^2(\Omega;\varrho(x)dx))^n$, that is,

$$(\mathbf{w}_k,\mathbf{w}_h)_{H_\varrho} := \int_\Omega (\mathbf{w}_k(x),\mathbf{w}_h(x))\varrho(x)dx = \delta_{kh}.$$

We have the following theorem (cf. [Y, Thm. 2]).

THEOREM 3.3. *Let the assumptions* (2.1)–(2.4), (2.24), (2.26)–(2.27), (3.1)–(3.2), *and* (3.8)–(3.9) *hold. Moreover, let*

$$\mathbf{g} \in H^1(0,T;L^2(\Gamma;\mathbf{R}^n)) \tag{3.15}$$

and set

$$\xi_k := -\Phi(\Pi(\mathbf{w}_k)) \qquad \forall\, k \in \mathbf{N}. \tag{3.16}$$

If there exists $\mathbf{f} \in H$ *such that* $\mathcal{G}(\mathbf{f}) = \mathbf{g}$, *then*

$$(\mathbf{f},\mathbf{w}_k)_{H_\varrho} = (\mathbf{g},\xi_k)_{H^1(0,T;L^2(\Gamma;\mathbf{R}^n))} \qquad \forall\, k \in \mathbf{N}. \tag{3.17}$$

Therefore,

$$\mathbf{f} = \sum_{h=1}^{\infty} (\mathbf{g},\xi_k)_{H^1(0,T;L^2(\Gamma;\mathbf{R}^n))}\mathbf{w}_k. \tag{3.18}$$

The final result concerns the characterization of the range $\mathcal{R}(\mathcal{G}^*)$ of the adjoint operator $\mathcal{G}^*$, when $\mathcal{G}$ is regarded as a linear operator from H to $L^2(0,T;L^2(\Gamma;\mathbf{R}^n))$. Indeed, we prove the following theorem (cf. [Y, Thm. 3]).

THEOREM 3.4. *Let the assumptions* (2.1)–(2.4), (2.24), (2.26)–(2.27), (3.1)–(3.2), *and* (3.8)–(3.9) *hold. Then*

$$V \subset \mathcal{R}(\mathcal{G}^*) := \left\{\mathcal{G}^*(\mathbf{g}), \quad \mathbf{g} \in L^2(0,T;L^2(\Gamma;\mathbf{R}^n))\right\} \subset (H^{1/2}(\Omega))^n. \tag{3.19}$$

Remark 3.1. Theorem 3.3 improves [Y, Thm. 3] and it turns out to be useful to construct a Tikhonov regularization procedure for determining *reasonable* approximations of $\mathbf{f}$ which converge to $\mathbf{f}$ in H (see [Y, section 3]).

4. Proof of Theorem 3.2. Suppose there is an $\mathbf{f} \in H$ corresponding to $\mathbf{g} \in H^1(0,T;L^2(\partial\Omega;\mathbf{R}^n))$ (cf. (3.6)).

In Problem (P_2) take

$$\mathbf{F} \equiv \mathbf{0}, \tag{4.1}$$

$$\mathbf{u}_0 \equiv \mathbf{0}, \tag{4.2}$$

$$\mathbf{u}_1 \equiv \mathbf{f}. \tag{4.3}$$

Then, by Theorem 2.1, we infer that (P_2) admits a unique solution $\mathbf{w}$. Moreover, by Lemma 2.3 and (3.7), we have

$$\|\mathbf{f}\|_H \leq \Lambda_5 \|\mathbf{w}_\nu\|_{L^2(0,T;L^2(\Gamma;\mathbf{R}^n))} \tag{4.4}$$

for some positive constant Λ_5 depending on Ω, x^0, T, ϱ, λ, μ.

Now set

$$\tilde{\mathbf{u}} := \varphi * \mathbf{w} \qquad \text{in } Q_T, \tag{4.5}$$

where $*$ stands for the usual time convolution product over the interval $(0,t)$. Thanks to (3.2), one has

$$\tilde{\mathbf{u}} \in C^2([0,T];H) \cap C^1([0,T];V). \tag{4.6}$$

Besides, one can easily check that $\tilde{\mathbf{u}}$ satisfies (2.16)–(2.17) and solves (3.3)–(3.4). Therefore, Proposition 3.1 implies $\tilde{\mathbf{u}} \equiv \mathbf{u}$.

Observe that (cf. (3.2) and (4.5))

$$\mathbf{u}_t = \varphi(0)\mathbf{w} + \varphi' * \mathbf{w} \qquad \text{in } Q_T. \tag{4.7}$$

Then, owing to (3.8), standard arguments (see [Y, section 4]) allow us to deduce from (4.7)

$$\|\mathbf{w}_\nu\|_{L^2(0,T;L^2(\Gamma;\mathbf{R}^n))} \leq \Lambda_6 \|(\mathbf{u}_t)_\nu\|_{L^2(0,T;L^2(\Gamma;\mathbf{R}^n))}, \tag{4.8}$$

where Λ_6 is a positive constant which only depends on $\varphi(0)$ and $\|\varphi'\|_{C^0([0,T])}$.

Combining (4.4) and (4.8), one gets

$$\|\mathbf{f}\|_H \leq \Lambda_7 \|(\mathbf{u}_t)_\nu\|_{L^2(0,T;L^2(\Gamma;\mathbf{R}^n))}, \tag{4.9}$$

where $\Lambda_7 := \Lambda_5\Lambda_6$.

On the other hand, recalling (2.1) and [L, Chap. IV, section 2, eq. (2.2)], from (3.6) and (3.7) we deduce the bound

$$\|\mathbf{u}_\nu\|_{H^1(0,T;L^2(\Gamma;\mathbf{R}^n))} \leq \Lambda_8 \|\mathbf{g}\|_{H^1(0,T;L^2(\Gamma;\mathbf{R}^n))} \tag{4.10}$$

for some positive constant Λ_8 depending only on λ and μ.

Finally, a combination of (4.9) and (4.10) yields estimate (3.10) which, in particular, implies the uniqueness of $\mathbf{f}$ in H.

5. Proof of Theorem 3.3. The argument is based on an identity for the eigenfunctions $\mathbf{w}_k$ of the linear operator $\mathcal{E}$ (cf. (3.11)). To be more precise, we have the following lemma (see [Y, section 5]).

LEMMA 5.1. *Let the assumptions* (2.1)–(2.4), (2.24), (2.26)–(2.27), *and* (3.9) *hold. Then*

$$\left(\lambda_k^{-1/2} \sin(\sqrt{\lambda_k}t)(\sigma(\mathbf{w}_k):\nu), -\Pi(\mathbf{w}_h)\right)_{L^2(0,T;L^2(\Gamma;\mathbf{R}^n))} = \delta_{kh} \tag{5.1}$$

for any k, $h \in \mathbf{N}$.

Let us postpone the proof of Lemma 5.1.

Consider the linear operator $K : L^2(0,T;L^2(\Gamma;\mathbf{R}^n)) \to H^1(0,T;L^2(\Gamma;\mathbf{R}^n))$ defined by (cf. also (3.2) and (4.5))

$$K(\xi) := \varphi * \xi. \tag{5.2}$$

One can easily check that the adjoint operator $K^* : \mathcal{R}(K) \subseteq H^1(0,T;L^2(\Gamma;\mathbf{R}^n)) \to L^2(0,T;L^2(\Gamma;\mathbf{R}^n))$ is given by (cf. (3.14))

$$K^*(\xi)(t,\cdot) = \varphi(0)\xi_t(t,\cdot) + \int_t^T [\varphi'(s-t)\xi_t(s,\cdot) + \varphi(s-t)\xi(s,\cdot)]ds \tag{5.3}$$

almost everywhere in $(0,T)\times\Gamma$.

Hence, recalling the linear operator Φ (see (3.13)–(3.14)), one has

$$K^*(\Phi(\eta)) = \eta \tag{5.4}$$

for any $\eta \in L^2(0,T;L^2(\Gamma;\mathbf{R}^n))$.

On account of (1.6), (3.15)–(3.16), (4.5), and (5.4), we obtain

$$\begin{aligned}(\mathbf{g},\xi_h)_{H^1(0,T;L^2(\Gamma;\mathbf{R}^n))} &= (\sigma(\mathbf{u}):\nu,\xi_h)_{H^1(0,T;L^2(\Gamma;\mathbf{R}^n))}\\ &= (K(\sigma(\mathbf{w}):\nu),\Phi(-\Pi(\mathbf{w}_h)))_{H^1(0,T;L^2(\Gamma;\mathbf{R}^n))}\\ &= (\sigma(\mathbf{w}):\nu,K^*(\Phi(-\Pi(\mathbf{w}_h))))_{L^2(0,T;L^2(\Gamma;\mathbf{R}^n))}\\ &= (\sigma(\mathbf{w}):\nu,-\Pi(\mathbf{w}_h))_{L^2(0,T;L^2(\Gamma;\mathbf{R}^n))}\end{aligned} \tag{5.5}$$

for any $h \in \mathbf{N}$.

Observe that (cf. (4.1)–(4.3))

$$\mathbf{w} = \sum_{k=1}^{\infty} (\mathbf{f},\mathbf{w}_k)_{H_\varrho}\lambda_k^{-1/2}\sin(\sqrt{\lambda_k}t)\mathbf{w}_k. \tag{5.6}$$

Then, recalling (2.1) and taking advantage of (3.7), from (5.6) we get

$$\sigma(\mathbf{w}):\nu = \sum_{k=1}^{\infty} (\mathbf{f},\mathbf{w}_k)_{H_\varrho}\lambda_k^{-1/2}\sin(\sqrt{\lambda_k}t)\,(\sigma(\mathbf{w}_k):\nu)\,, \tag{5.7}$$

where the series converges in $L^2(0,T;L^2(\Gamma;\mathbf{R}^n))$.

Thanks to (5.1) and (5.7), we derive

$$\begin{aligned}&(\ \sigma(\mathbf{w}):\nu,-\Pi(\mathbf{w}_h))_{L^2(0,T;L^2(\Gamma;\mathbf{R}^n))}\\ &= \sum_{k=1}^{\infty} (\mathbf{f},\mathbf{w}_k)_{H_\varrho}(\lambda_k^{-1/2}\sin(\sqrt{\lambda_k}t)(\sigma(\mathbf{w}_k):\nu),-\Pi(\mathbf{w}_h))_{L^2(0,T;L^2(\Gamma;\mathbf{R}^n))}\\ &= (\mathbf{f},\mathbf{w}_h)_{H_\varrho} \qquad\qquad \forall\, h \in \mathbf{N}.\end{aligned} \tag{5.8}$$

Finally, (5.5) and (5.8) yield (3.17) and, consequently, (3.18).

Proof of Lemma 5.1. Let us observe that, thanks to Theorem 2.4, for any given $\tilde{\mathbf{v}} \in L^2(0,T;L^2(\Gamma;\mathbf{R}^n))$, we can find a unique function $\tilde{\mathbf{z}}$ satisfying (2.31), (2.37), and (cf. (2.32)–(2.36))

$$\int_{Q_T} (\varrho\tilde{\mathbf{z}},\mathbf{r})dxdt = -\int_{(0,T)\times\Gamma} (\tilde{\mathbf{v}},\sigma(\tilde{\mathbf{q}}):\nu)d\Sigma dt \qquad \forall\ \mathbf{r} \in C^0([0,T];D(\mathcal{E})), \tag{5.9}$$

where $\tilde{\mathbf{q}} \in C^0([0,T]; D(\mathcal{E}))$ is the unique solution to

$$\varrho \tilde{\mathbf{q}}_{tt} = \nabla \cdot \sigma(\tilde{\mathbf{q}}) + \mathbf{r} \qquad \text{a.e. in } Q_T, \tag{5.10}$$

$$\tilde{\mathbf{q}}(0) = \tilde{\mathbf{q}}_t(0) = \mathbf{0} \qquad \text{a.e. in } \Omega, \tag{5.11}$$

$$\tilde{\mathbf{q}} = \mathbf{0} \qquad \text{a.e. on } (0,T) \times \partial\Omega. \tag{5.12}$$

Note that the roles of 0 and T are exchanged with respect to Theorem 2.4.

Then, provided that $\tilde{\mathbf{z}}$ is smooth enough and recalling that (cf. (3.11)) $\nabla \cdot \sigma(\mathbf{w}_k) = -\lambda_k \varrho \mathbf{w}_k$, we obtain the chain of equalities

$$\begin{aligned}
&\int_0^T \lambda_k^{-1/2} \sin(\sqrt{\lambda_k} t)(\mathbf{w}_k, \nabla \cdot \sigma(\tilde{\mathbf{z}}))_H dt \\
&= \int_0^T \lambda_k^{-1/2} \sin(\sqrt{\lambda_k} t)(\mathbf{w}_k, \tilde{\mathbf{z}}_{tt})_{H_\varrho} dt \\
&= \left(\mathbf{w}_k, \int_0^T \lambda_k^{-1/2} \sin(\sqrt{\lambda_k} t) \tilde{\mathbf{z}}_{tt} dt \right)_{H_\varrho} \\
&= \left(\mathbf{w}_k, -\int_0^T \cos(\sqrt{\lambda_k} t) \tilde{\mathbf{z}}_t dt \right)_{H_\varrho} \\
&= \left(\mathbf{w}_k, \tilde{\mathbf{z}}(0) - \lambda_k \int_0^T \lambda_k^{-1/2} \sin(\sqrt{\lambda_k} t) \tilde{\mathbf{z}} dt \right)_{H_\varrho} \\
&= (\mathbf{w}_k, \tilde{\mathbf{z}}(0))_{H_\varrho} + \int_0^T \lambda_k^{-1/2} \sin(\sqrt{\lambda_k} t)(\nabla \cdot \sigma(\mathbf{w}_k), \tilde{\mathbf{z}})_H dt.
\end{aligned} \tag{5.13}$$

From (5.13), we deduce the identity

$$\int_0^T \lambda_k^{-1/2} \sin(\sqrt{\lambda_k} t) \left[(\mathbf{w}_k, \nabla \cdot \sigma(\tilde{\mathbf{z}}))_H - (\tilde{\mathbf{z}}, \nabla \cdot \sigma(\mathbf{w}_k))_H \right] dt = (\mathbf{w}_k, \tilde{\mathbf{z}}(0))_{H_\varrho}. \tag{5.14}$$

Recalling Theorem 2.5 and (3.12), we can choose $\mathbf{z}_0 = \mathbf{w}_h$, $\mathbf{z}_1 = \mathbf{0}$, $\tilde{\mathbf{v}} = \Pi(\mathbf{w}_h)$. Then, denoting by $\tilde{\mathbf{z}}$ the solution to (2.32) associated with $\{\mathbf{z}_0, \mathbf{z}_1, \tilde{\mathbf{v}}\}$, we infer that $\tilde{\mathbf{z}}$ solves (5.9) as well. Hence identity (5.14) and Green's formula entail (5.1).

The present argument can be made rigorous by means of a standard approximation procedure based on well-known density results (cf. [Y, section 5]). □

6. Proof of Theorem 3.4. Let us consider the linear operator $\mathcal{F} : H \to L^2(0,T; L^2(\Gamma; \mathbf{R}^n))$ defined by

$$\mathcal{F}(\mathbf{f}) := \sigma(\mathbf{w}) : \nu, \tag{6.1}$$

where $\mathbf{w}$ is the unique solution to Problem (P_2) in the assumptions (4.1)–(4.3). Note that $\mathcal{F}$ is bounded owing to Theorem 2.1 and (3.7).

Recalling (3.6), (4.5), and (5.2), one realizes that

$$\mathcal{G}(\mathbf{f}) = K(\mathcal{F}(\mathbf{f})) \tag{6.2}$$

regarding K as a linear operator from $L^2(0,T; L^2(\Gamma; \mathbf{R}^n))$ into itself. Hence, from (6.2) it follows that

$$\mathcal{G}^* = \mathcal{F}^* K^* \tag{6.3}$$

so that

$$\mathcal{R}(\mathcal{G}^*) \equiv \{\mathcal{F}^*(\xi), \quad \xi \in \mathcal{R}(K^*)\}. \tag{6.4}$$

On the other hand, as $K : L^2(0,T;L^2(\Gamma;\mathbf{R}^n)) \to L^2(0,T;L^2(\Gamma;\mathbf{R}^n))$, we have

$$K^*(\eta)(t,\cdot) = \int_t^T \varphi(s-t)\eta(s,\cdot)ds \qquad \text{a.e. on } (0,T)\times\Gamma. \tag{6.5}$$

Therefore (cf. also (3.2)),

$$\mathcal{R}(K^*) \equiv \left\{\xi \in H^1(0,T;L^2(\Gamma;\mathbf{R}^n)) : \ \xi(T,\cdot) = \mathbf{0}\right\}. \tag{6.6}$$

Consequently, combining (6.4) and (6.6), we get

$$\mathcal{R}(\mathcal{G}^*) \equiv \left\{\mathcal{F}^*(\xi), \quad \xi \in H^1(0,T;L^2(\Gamma;\mathbf{R}^n)) : \ \xi(T,\cdot) = \mathbf{0}\right\}. \tag{6.7}$$

Let $\mathbf{v} \in L^2(0,T;L^2(\Gamma;\mathbf{R}^n))$ and consider the function $\tilde{\mathbf{z}} = \tilde{\mathbf{z}}(\mathbf{v})$ solving (5.9). Observe that, by formal computations (cf. (5.10)),

$$\begin{aligned}
\int_0^T (\nabla\cdot\sigma(\tilde{\mathbf{z}}),\mathbf{w})_H dt &= \int_0^T (\tilde{\mathbf{z}}_{tt},\mathbf{w})_{H_\varrho} dt \\
&= -\int_0^T (\tilde{\mathbf{z}}_t,\mathbf{w}_t)_{H_\varrho} dt \\
&= \int_0^T (\tilde{\mathbf{z}},\mathbf{w}_{tt})_{H_\varrho} dt + (\tilde{\mathbf{z}}(0),\mathbf{f})_{H_\varrho} \\
&= \int_0^T (\tilde{\mathbf{z}},\nabla\cdot\sigma(\mathbf{w}))_H dt + (\tilde{\mathbf{z}}(0),\mathbf{f})_{H_\varrho}.
\end{aligned} \tag{6.8}$$

Of course, as in the previous proof of Lemma 5.1, a suitable approximation argument is needed to make the above computations rigorous.

The chain of equalities (6.8) implies

$$\int_0^T \left[(\nabla\cdot\sigma(\tilde{\mathbf{z}}),\mathbf{w})_H - (\tilde{\mathbf{z}},\nabla\cdot\sigma(\mathbf{w}))_H\right] dt = (\tilde{\mathbf{z}}(0),\mathbf{f})_{H_\varrho}, \tag{6.9}$$

and via Green's formula, one derives (cf. also (6.1))

$$-(\mathbf{v},\mathcal{F}(\mathbf{f}))_{L^2(0,T;L^2(\Gamma;\mathbf{R}^n))} = (\tilde{\mathbf{z}}(0),\mathbf{f})_{H_\varrho} \tag{6.10}$$

for any $\mathbf{v} \in L^2(0,T;L^2(\Gamma;\mathbf{R}^n))$.

Identity (6.10) entails

$$\mathcal{F}^*(\mathbf{v}) = -\varrho\tilde{\mathbf{z}}(0). \tag{6.11}$$

Hence, a combination of (6.7) and (6.11) yields

$$\mathcal{R}(\mathcal{G}^*) \equiv \left\{\varrho\tilde{\mathbf{z}}(\mathbf{v})(0), \quad \mathbf{v} \in H^1(0,T;L^2(\Gamma;\mathbf{R}^n)) : \ \mathbf{v}(T,\cdot) = \mathbf{0} \text{ on } \Gamma\right\}. \tag{6.12}$$

The proof is now given by Lemma 6.1.

LEMMA 6.1. *Let the assumptions* (2.1)–(2.4), (2.24), (2.26)–(2.27), *and* (3.9) *hold. Then*

$$V \subset \left\{\varrho\tilde{\mathbf{z}}(\mathbf{v})(0), \quad \mathbf{v} \in H^1(0,T;L^2(\Gamma;\mathbf{R}^n)) : \ \mathbf{v}(T,\cdot) = \mathbf{0} \text{ on } \Gamma\right\} \subset (H^{1/2}(\Omega))^n. \tag{6.13}$$

Proof of Lemma 6.1. Let

$$ {}^0H^1(0,T;L^2(\Gamma;\mathbf{R}^n)) = \left\{ \mathbf{w} \in H^1(0,T;L^2(\Gamma;\mathbf{R}^n)) : \ \mathbf{w}(T,\cdot) = \mathbf{0} \text{ on } \Gamma \ \right\} $$

be a Hilbert space with the norm

$$ \|\mathbf{w}\|_{{}^0H^1} := \left(\int_0^T \int_\Gamma |\mathbf{w}_t|^2 d\Sigma dt \right)^{1/2}. \tag{6.14} $$

It is straightforward to observe that $\|\mathbf{w}\|_{{}^0H^1}$ is equivalent to

$$ \|\mathbf{w}\|_{H^1(0,T;L^2(\Gamma;\mathbf{R}^n))} := \left(\int_0^T \int_\Gamma |\mathbf{w}|^2 + |\mathbf{w}_t|^2 d\Sigma dt \right)^{1/2} $$

for any $\mathbf{w} \in {}^0H^1(0,T;L^2(\Gamma;\mathbf{R}^n))$. Denoting by X_1 the dual of ${}^0H^1(0,T;L^2(\Gamma;\mathbf{R}^n))$, we also have

$$ {}^0H^1(0,T;L^2(\Gamma;\mathbf{R}^n)) \hookrightarrow L^2(\Gamma\times(0,T);\mathbf{R}^n) \hookrightarrow X_1 $$

with dense injections, the dual of $L^2((0,T)\times\Gamma;\mathbf{R}^n)$ being identified with itself.

Indicating now by ${}_{X_1}\langle\cdot,\cdot\rangle_{{}^0H^1}$ the duality pairing between ${}^0H^1(0,T;L^2(\Gamma;\mathbf{R}^n))$ and X_1, we note that

$$ {}_{X_1}\langle \mathbf{v}, \mathbf{w}\rangle_{{}^0H^1} = (\mathbf{v},\mathbf{w})_{L^2((0,T)\times\Gamma;\mathbf{R}^n)} \tag{6.15} $$

for any $\mathbf{v} \in L^2((0,T)\times\Gamma;\mathbf{R}^n)$ and any $\mathbf{w} \in^0 H^1(0,T;L^2(\Gamma;\mathbf{R}^n))$.

On account of Theorem 2.4, take

$$ \mathbf{z}_0 \in H, \quad \mathbf{z}_1 \in V', \quad \tilde{\mathbf{v}} \equiv \mathbf{0}. \tag{6.16} $$

Then, Theorem 2.4 ensures the existence of a unique $\mathbf{z}$ satisfying (2.31)–(2.32).

Assume, for the moment,

$$ \mathbf{z}_0 \in \mathcal{D}(\Omega), \quad \mathbf{z}_1 \in \mathcal{J}(\Omega), \tag{6.17} $$

where

$$ \mathcal{J}(\Omega) := \{ \mathbf{z} = \mathcal{E}(\mathbf{w}) \quad \text{for some } \mathbf{w} \in \mathcal{D}(\Omega) \} \subset C_c^1(\Omega) $$

and $C_c^1(\Omega)$ indicates the space of C^1 functions taking values in $\mathbf{R}^n$ and having compact support in Ω.

Consider Problem (P_2) and take (cf. also (2.2) and (3.11))

$$ \mathbf{F} \equiv \mathbf{0}, \quad \mathbf{u}_0 := -\mathcal{E}^{-1}(\mathbf{z}_1) \in C_c^1(\Omega), \quad \mathbf{u}_1 := \mathbf{z}_0 \in \mathcal{D}(\Omega). \tag{6.18} $$

Consequently, Theorem 2.1 applies and Problem (P_2) admits a unique solution $\mathbf{u}$ fulfilling (2.8)–(2.12). Moreover, taking advantage of (2.12) and Lemma 2.3, one can find a pair of positive constants Λ_9, Λ_{10} such that (cf. also (1.6), (3.7), and (4.10))

$$ \begin{aligned} \Lambda_9 \, \|\sigma(\mathbf{u}) : \nu\|_{L^2((0,T)\times\Gamma;\mathbf{R}^n)} &\le \left(\|\mathbf{u}_0\|_V^2 + \|\mathbf{u}_1\|_H^2 \right)^{1/2} \\ &\le \Lambda_{10} \, \|\sigma(\mathbf{u}) : \nu\|_{L^2((0,T)\times\Gamma;\mathbf{R}^n)}. \end{aligned} \tag{6.19} $$

Here Λ_9 and Λ_{10} depend only on Ω, x^0, T, ϱ, λ, and μ.

A straightforward argument shows that

$$\sigma(\mathbf{z}) : \nu = (\sigma(\mathbf{u}) : \nu)_t \tag{6.20}$$

in the sense of distributions.

Let us prove that $\sigma(\mathbf{z}) : \nu \in X_1$. Indeed, by virtue of (6.18), we have (cf. also (6.15) and (6.20))

$$\begin{aligned} &{}_{X_1}\langle \sigma(\mathbf{z}) : \nu, \mathbf{w} \rangle_{{}_0H_1} \\ &= (\sigma(\mathbf{z}) : \nu, \mathbf{w})_{L^2((0,T)\times\Gamma;\mathbf{R}^n)} = ((\sigma(\mathbf{u}) : \nu)_t, \mathbf{w})_{L^2((0,T)\times\Gamma;\mathbf{R}^n)} \\ &= \left[\int_\Gamma ((\sigma(\mathbf{u}) : \nu)(t), \mathbf{w}(t)) d\Sigma \right]_0^T - (\sigma(\mathbf{u}) : \nu, \mathbf{w}_t)_{L^2((0,T)\times\Gamma;\mathbf{R}^n)} \\ &= - (\sigma(\mathbf{u}) : \nu, \mathbf{w}_t)_{L^2((0,T)\times\Gamma;\mathbf{R}^n)} \end{aligned} \tag{6.21}$$

for any $\mathbf{w} \in {}^0H^1(0,T;L^2(\Gamma;\mathbf{R}^n))$.

Therefore, we deduce

$$\begin{aligned} &\|\sigma(\mathbf{z}) : \nu\|_{X_1} \\ &\quad = \sup \left\{ |{}_{X_1}\langle \sigma(\mathbf{u}) : \nu, \mathbf{w}_t \rangle_{{}_0H^1}| \,;\ \mathbf{w} \in {}^0H^1(0,T;L^2(\Gamma;\mathbf{R}^n)),\ \|\mathbf{w}\|_{{}_0H^1} = 1 \right\}. \end{aligned} \tag{6.22}$$

Observe now that (cf. (6.14))

$$\begin{aligned} &\left\{ \mathbf{w}_t;\ \mathbf{w} \in {}^0H^1(0,T;L^2(\Gamma)),\ \|\mathbf{w}\|_{{}_0H^1} = 1 \right\} \\ &= \left\{ \widetilde{\mathbf{w}} \in L^2((0,T)\times\Gamma;\mathbf{R}^n) \,:\, \|\widetilde{\mathbf{w}}\|_{L^2((0,T)\times\Gamma;\mathbf{R}^n)} = 1 \right\}. \end{aligned}$$

Then, from (6.22) we infer

$$\|\sigma(\mathbf{z}) : \nu\|_{X_1} = \|\sigma(\mathbf{u}) : \nu\|_{L^2((0,T)\times\Gamma;\mathbf{R}^n)}. \tag{6.23}$$

Hence, taking (6.18) and (6.23) into account, from (6.19) we get

$$\Lambda_{11} \|\sigma(\mathbf{z}) : \nu\|_{X_1} \le \left(\|\mathbf{z}_0\|_H^2 + \|\mathbf{z}_1\|_{V'}^2 \right)^{1/2} \le \Lambda_{12} \|\sigma(\mathbf{z}) : \nu\|_{X_1}, \tag{6.24}$$

where Λ_{11} and Λ_{12} are positive constants which depend on Ω, x^0, T, ϱ, λ, and μ. Here we have used the fact that $\varrho\mathcal{E}$ is an isomorphism between V and V' (see (3.11)) along with the inequality

$$\Lambda_{13}\|\phi\|_V \le \|\rho\phi\|_V \le \Lambda_{14}\|\phi\|_V \quad \forall \phi \in V, \tag{6.25}$$

which holds for some positive constants Λ_{13}, Λ_{14} only depending on Ω and ϱ. In fact, the second inequality in (6.25) is straightforward by (2.2). As far as the first inequality is concerned, it suffices to check that

$$\|\phi^j_{x_i}\|_{L^2(\Omega)} \le \Lambda_{15}\|\rho\phi\|_V, \quad 1 \le i,j \le n, \quad \forall\, \phi \in V, \tag{6.26}$$

where Λ_{15} is a positive constant only depending on Ω and ϱ.

By (2.2) and (2.3), we have

$$\begin{aligned} &\| \ (\rho\phi^j)_{x_i}\|^2_{L^2(\Omega)} = \int_\Omega (\rho_{x_i}\phi^j + \rho\phi^j_{x_i})^2 dx \\ &= \int_\Omega \rho^2 (\phi^j_{x_i})^2 + \int_\Omega \rho^2_{x_i} (\phi^j)^2 dx + 2\int_\Omega \rho\rho_{x_i}\phi^j\phi^j_{x_i} dx \\ &\ge \rho_0^2 \|\phi^j_{x_i}\|^2_{L^2(\Omega)} - \Lambda_{16}\|\phi^j\|^2_{L^2(\Omega)} - \Lambda_{16}\int_\Omega 2|\phi^j||\phi^j_{x_i}| dx, \end{aligned}$$

where Λ_{16} is a positive constant depending on ρ. Observe now that

$$\int_\Omega 2|\phi^j||\phi^j_{x_i}|dx \le \frac{\rho_0^2}{2\Lambda_{16}}\int_\Omega |\phi^j_{x_i}|^2dx + \frac{2\Lambda_{16}}{\rho_0^2}\int_\Omega |\phi^j|^2dx.$$

Consequently, we get

$$\|\rho\phi\|_V^2 \ge \|(\rho\phi^j)_{x_i}\|^2_{L^2(\Omega)} \ge \frac{\rho_0^2}{2}\|\phi^j_{x_i}\|^2_{L^2(\Omega)} - \Lambda_{17}\|\phi^j\|^2_{L^2(\Omega)} \tag{6.27}$$

for some positive constant Λ_{17} which only depends on Ω and ϱ.. Then, using the Poincaré inequality and (2.3), from (6.27) we infer (6.26). Hence (6.25) holds.

Consider now $\mathbf{z}_0$, $\mathbf{z}_1$ satisfying (6.16). Recalling (6.17), since $\mathcal{D}(\Omega)$ and $\mathcal{J}(\Omega)$ are dense in H and in V', respectively, one can find two sequences $\{\mathbf{z}_0^m\} \subset \mathcal{D}(\Omega)$ and $\{\mathbf{z}_1^m\} \subset \mathcal{J}(\Omega)$ such that

$$\|\mathbf{z}_0^m - \mathbf{z}_0\|_H \to 0, \quad \|\mathbf{z}_1^m - \mathbf{z}_1\|_{V'} \to 0$$

as $m \nearrow +\infty$. Then, proceeding as in [LLT, Rem. 2.2 and Thm. 2.3], one obtains

$$\|\sigma(\mathbf{z}(\mathbf{z}_0^m, \mathbf{z}_1^m)) : \nu - \sigma(\mathbf{z}(\mathbf{z}_0, \mathbf{z}_1)) : \nu\|_{H^{-1}(0,T;L^2(\Gamma;\mathbf{R}^n))} \to 0$$

as $m \nearrow +\infty$.

Hence, (6.24) holds for any $\mathbf{z}_0 \in H$ and any $\mathbf{z}_1 \in V'$. This shows that the mapping

$$(\mathbf{z}_0, \mathbf{z}_1) \mapsto \sigma(\mathbf{z}) : \nu$$

is an isomorphism between $H \times V'$ and X_1. Then, arguing as in [L, Théo. 6.3, Chap. I, section 6], we deduce

$$V \subset \mathcal{R}(\mathcal{G}^*).$$

It remains to prove that

$$\mathcal{R}(\mathcal{G}^*) \subset (H^{1/2}(\Omega))^n. \tag{6.28}$$

Let $\mathbf{v} \in {}^0H^1(0,T;L^2(\Gamma;\mathbf{R}^n))$ and consider the unique solution $\tilde{\mathbf{w}} \in C^0([0,T];H) \cap C^1([0,T];V')$ to

$$\int_{Q_T} (\varrho\tilde{\mathbf{w}}, \mathbf{r})dtdx = -\int_{(0,T)\times\Gamma} (\mathbf{v}_t, \sigma(\tilde{\mathbf{q}}) : \nu)d\Sigma dt \qquad \forall\ \mathbf{r} \in C^0([0,T];D(\mathcal{E})), \tag{6.29}$$

where $\tilde{\mathbf{q}} \in C^0([0,T];D(\mathcal{E}))$ is the unique solution to (5.10)–(5.12) (see Theorem 2.4).

Then, for any $t \in [0,T]$, set

$$\mathbf{Z}(t) := \int_T^t \tilde{\mathbf{w}}(s)ds \qquad \text{a.e. in } \Omega. \tag{6.30}$$

On account of (6.29), one easily checks that $\mathbf{Z}$ fulfills (5.9). Hence $\mathbf{Z} \equiv \tilde{\mathbf{z}}(\mathbf{v})$. Then (cf. (6.30))

$$\tilde{\mathbf{z}}(\mathbf{v})_{tt} \in C^0([0,T];V')$$

and, consequently,

$$\nabla \cdot \sigma(\tilde{\mathbf{z}}(\mathbf{v})) \in C^0([0,T];V').$$

On the other hand, we have

$$\tilde{\mathbf{z}}(\mathbf{v}) = \begin{cases} \mathbf{v} & \text{on } [0,T]\times\Gamma, \\ 0 & \text{on } [0,T]\times\partial\Omega\setminus\Gamma, \end{cases}$$

and letting $t=0$, one infers

$$\nabla\cdot\sigma(\tilde{\mathbf{z}}(\mathbf{v}))(0)\in V',$$
$$\tilde{\mathbf{z}}(\mathbf{v})(0) = \begin{cases} \mathbf{v}(0) & \text{a.e. on } \Gamma, \\ 0 & \text{a.e. on } \partial\Omega\setminus\Gamma. \end{cases}$$

As $\mathbf{v}(0)\in(L^2(\Gamma))^n$, we conclude (cf., e.g., [KN, Part 1, Chap. 1, section 3.2, Thm. 3.2] and references therein) $\tilde{\mathbf{z}}(\mathbf{v})(0)\in(H^{1/2}(\Omega))^n$, i.e., (6.28). □

7. Proof of Lemma 2.3. Let us recall first the energy identity (cf. (2.29))

$$E(t) := \frac{1}{2}\int_\Omega \left[\mu|\nabla\mathbf{u}(t)|^2 + (\lambda+\mu)|\nabla\cdot\mathbf{u}(t)|^2 + \varrho|\mathbf{u}_t(t)|^2\right]dx = E_0 \tag{7.1}$$

for any $t\in[0,T]$. This identity is obtained by multiplying equation (2.10) by $\mathbf{u}_t$ and then integrating over Q_t, taking (2.4), (2.24)–(2.25) into account and using the divergence theorem. We recall that $|\nabla\mathbf{u}(t)|^2 := \sum_{i,j=1}^n |u^i_{x_j}(t)|^2$, where $\nabla\mathbf{u}(t) := [u^i_{x_j}(t)]$. Following [L, Chap. IV, pp. 225–227], we formally multiply both sides of equation (2.10) by $\nabla\mathbf{u}:\mathbf{m}$ and integrate over Q_T. Recalling (2.11), (2.24), (3.7) and integrating by parts in time, we obtain

$$\begin{aligned} &\left[\int_\Omega(\varrho\mathbf{u}_t(t),\nabla\mathbf{u}(t):\mathbf{m})dx\right]_0^T - \int_{Q_T}(\varrho\mathbf{u}_t,\nabla\mathbf{u}_t:\mathbf{m})dtdx \\ &= \int_{Q_T}(\nabla\cdot\sigma(\mathbf{u}),\nabla\mathbf{u}:\mathbf{m})dtdx. \end{aligned} \tag{7.2}$$

Observe now that

$$(\varrho\mathbf{u}_t,\nabla\mathbf{u}_t:\mathbf{m}) = \frac{1}{2}\nabla\cdot(\varrho\mathbf{m}|\mathbf{u}_t|^2) - \frac{1}{2}[(\nabla\varrho,\mathbf{m}) + n\varrho]|\mathbf{u}_t|^2. \tag{7.3}$$

Also, recalling (2.1) and (2.24), we have

$$\nabla\cdot\sigma(\mathbf{u}) = \mu\Delta\mathbf{u} + \nabla[(\lambda+\mu)\nabla\cdot\mathbf{u}],$$

from which we deduce

$$(\nabla\cdot\sigma(\mathbf{u}),\nabla\mathbf{u}:\mathbf{m}) = \nabla\cdot[A:(\nabla\mathbf{u}:\mathbf{m})] - (B,\nabla(\nabla\mathbf{u}:\mathbf{m})), \tag{7.4}$$

where

$$A := \mu(\nabla\mathbf{u})^{\mathbf{T}} + (\lambda+\mu)(\nabla\cdot\mathbf{u})\delta, \quad B := \mu\nabla\mathbf{u} + (\lambda+\mu)(\nabla\cdot\mathbf{u})\delta, \tag{7.5}$$

the superscript $\mathbf{T}$ denoting the transposition. In addition, note that

$$\begin{aligned} (B,\nabla(\nabla\cdot\mathbf{u}:\mathbf{m})) &= \frac{1}{2}[(\lambda+\mu)|\nabla\cdot\mathbf{u}|^2 + \mu|\nabla\mathbf{u}|^2] \\ &+ \frac{1}{2}\nabla\cdot\{[(\lambda+\mu)|\nabla\cdot\mathbf{u}|^2 + \mu|\nabla\mathbf{u}|^2]\mathbf{m}\} \\ &- \frac{1}{2}(\nabla\lambda,\mathbf{m})|\nabla\cdot\mathbf{u}|^2 + \frac{1-n}{2}[(\lambda+\mu)|\nabla\cdot\mathbf{u}|^2 + \mu|\nabla\mathbf{u}|^2]. \end{aligned} \tag{7.6}$$

Taking (7.1), (7.5)–(7.6) into account and using the divergence theorem, a combination of (7.2) and (7.3)–(7.4) yields

$$\begin{aligned}(7.7)\qquad &\left[\int_\Omega \left(\varrho \mathbf{u}_t(t), \nabla \mathbf{u}(t) : \mathbf{m} + \frac{n-1}{2}\mathbf{u}(t)\right) dx\right]_0^T + TE_0\\ &+\frac{1}{2}\int_{Q_T} (\nabla \varrho, \mathbf{m})|\mathbf{u}_t|^2 dtdx - \frac{1}{2}\int_{Q_T} (\nabla \lambda, \mathbf{m})|\nabla \cdot \mathbf{u}|^2 dtdx\\ &= \frac{1}{2}\int_0^T \int_{\partial\Omega} \left[\mu|\nabla \mathbf{u}|^2 + (\lambda+\mu)|\nabla \cdot \mathbf{u}|^2(\mathbf{m}, \nu)\right] d\Sigma dt.\end{aligned}$$

Here we have also used the formula

$$(A : (\nabla \mathbf{u} : \mathbf{m}), \nu) = [\mu|\nabla \mathbf{u}|^2 + (\lambda+\mu)|\nabla \cdot \mathbf{u}|^2](\mathbf{m}, \nu).$$

Arguing as in [L, Chap. I, section 5, pp. 58–59] and taking advantage of (2.3) and (7.1), we obtain

$$\begin{aligned}(7.8)\qquad &\left|\left[\int_\Omega \left(\varrho \mathbf{u}_t(t), \nabla \mathbf{u}(t) : \mathbf{m} + \frac{n-1}{2}\mathbf{u}(t)\right) dx\right]_0^T\right|\\ &\le 2\|\varrho\|_{L^\infty(\Omega)} \sup_{t\in(0,T)} \left|\left(\mathbf{u}_t(t), \nabla \mathbf{u}(t) : \mathbf{m} + \frac{n-1}{2}\mathbf{u}(t)\right)_H\right|\\ &\le \|\varrho\|_{L^\infty(\Omega)} \|\mathbf{u}_t\|_{L^\infty(0,T;H)} \left\|\nabla \mathbf{u} : \mathbf{m} + \frac{n-1}{2}\mathbf{u}\right\|_{L^\infty(0,T;H)}\\ &\le 2R(x^0)\|\varrho\|_{L^\infty(\Omega)} \|\mathbf{u}_t\|_{L^\infty(0,T;H)} \left(\sup_{t\in(0,T)} \int_\Omega |\nabla \mathbf{u}(t)|^2 dx\right)^{1/2}\\ &\le 2R(x^0)\|\varrho\|_{L^\infty(\Omega)} (\varrho_0\mu_0)^{-1/2} E_0.\end{aligned}$$

Here we have also taken into account that, using the divergence theorem, one has

$$\begin{aligned}&\left\|\nabla \mathbf{u}(t) : \mathbf{m} + \frac{n-1}{2}\mathbf{u}(t)\right\|_H^2 - \|\nabla \mathbf{u}(t) : \mathbf{m}\|_H^2\\ &= (n-1)(\nabla \mathbf{u}(t) : \mathbf{m}, \mathbf{u}(t)) + \frac{(n-1)^2}{4}\|\mathbf{u}(t)\|_H^2\\ &= \frac{(n-1)}{2}\sum_{i,j}\int_\Omega (u^i(t))_{x_j}^2 m^j dx + \frac{(n-1)^2}{4}\|\mathbf{u}(t)\|_H^2 = \frac{n(1-n)}{2}\|\mathbf{u}(t)\|_H^2 \le 0.\end{aligned}$$

Besides, by virtue of (7.1) (cf. also (2.21)–(2.23)), we have

$$(7.9)\qquad \frac{1}{2}\int_{Q_T} (\nabla \varrho, \mathbf{m})|\mathbf{u}_t|^2 dtdx \ge -R(x^0)TE_0 \left\|\frac{\nabla \varrho}{\varrho}\right\|_{(L^\infty(\Omega_\varrho^-(x^0)))^n},$$

$$(7.10)\qquad \frac{1}{2}\int_{Q_T} (\nabla \lambda, \mathbf{m})|\nabla \cdot \mathbf{u}|^2 dtdx \le R(x^0)TE_0 \left\|\frac{\nabla \lambda}{\lambda}\right\|_{(L^\infty(\Omega_\lambda^+(x^0)))^n}.$$

Finally, on account of (2.20), (2.26), and (2.27), the equality (7.7) and the inequalities (7.8)–(7.10) allow us to deduce (2.28).

AN EXAMPLE OF A UNIVERSALLY OBSERVABLE FLOW ON THE TORUS*

ALISA DESTEFANO† AND G. R. HALL‡

Abstract. In this paper we examine the question of existence of a two-dimensional universally observable system, i.e., dynamics which are observable by every continuous nonconstant real-valued function on the state space. We are motivated by the work of D. McMahon, who proved that a class of three-dimensional manifolds with horocycle flow have this property. We examine this example and are able to give sufficient conditions for a flow to be universally observable. We then use these conditions to show the existence of a continuous universally observable flow on the torus. The proofs involve techniques and concepts from topological dynamics and dynamical systems on the torus.

Key words. universal observability, torus, dynamical system

1. Introduction.

Determining the behavior of a dynamical system from some scalar observation of the system has been studied quite extensively in the literature (see [19], [4]). In particular, criteria for observability of nonlinear systems are given, that is, criteria about which systems will be observable by given observation functions and what types of observation functions observe a given system. We will consider the general setting of a Hausdorff space M with a continuous flow ϕ. We ask if a given real-valued function h of the space M distinguishes orbits. If the answer is "yes," then the system is observable under h.

The question arises as to whether there exist systems which are universally observable, i.e., dynamics which are observable by every continuous nonconstant real-valued function on the space. It seems unlikely that one could find such a system, but McMahon [18] proved that a class of three-dimensional manifolds ($SL(2, \mathbf{R})$ modulo a certain type of subgroup) with horocycle flow has this property.

The search for other examples, particularly for low-dimensional universally observable systems, has led to some interesting results but has produced no further examples. Most of the work thus far has focused on smooth dynamical systems, i.e., flows arising from smooth vector fields. Byrnes, Dayawansa, and Martin [3] determined necessary conditions for universally observable systems which lead to the conclusion that if there is a smooth low-dimensional universally observable system then it has to be a minimal flow on the torus.

In [9], it was shown that any universally observable low-dimensional system would be topologically equivalent to constant irrational flow on the torus. Using a property which is equivalent to universal observability developed by Wallace [25], it can be shown that constant irrational flow is not universally observable.

In this paper, we address the general question of existence of a universally observable flow on the torus (not necessarily smooth). We first examine the properties of McMahon's example which were sufficient for universal observability (see [25], [9]).

We give a proof that any flow with these properties, referred to as property V, is universally observable. We then examine these properties, and using results from the field of topological dynamics, we further isolate some sufficient conditions for universal observability. Using these conditions, we are able to construct a continuous flow on the torus which provides the first example of a two-dimensional universally observable system.

2. Universal observability. In this section, we establish notation and give some basic definitions. We then discuss the properties of McMahon's example which are sufficient for universal observability.

Let $\phi(x,t)$ be a continuous flow on a Hausdorff space M. That is,

$$\phi : M \times \mathbf{R} \to M$$

is a continuous function and

$$\phi(x, t_1 + t_2) = \phi(\phi(x, t_1), t_2).$$

DEFINITION 2.1. *Let $h : M \to \mathbf{R}$ be a continuous nonconstant function. We say that h* observes *(M,ϕ) if $h(\phi(x_0,t)) = h(\phi(y_0,t))$ for all $t \geq 0$ implies that $x_0 = y_0$. In this case, we say that (M,ϕ,h) is* observable.

McMahon [18] proved that a class of three-dimensional manifolds ($SL(2,\mathbf{R})$ modulo a discrete, cocompact, nonarithmetic subgroup) with horocycle flow is observable by every nonconstant continuous function from the manifold to the real numbers. We refer to this phenomenon as universal observability. More precisely, we have the following definition.

DEFINITION 2.2. *(M,ϕ) is* universally observable *if (M,ϕ,h) is observable for every continuous nonconstant function $h : M \to \mathbf{R}$.*

McMahon's example had a very stong property which was sufficient for universal observability. Before we discuss this property, we develop some notation and state some definitions.

Given any fixed time t_*, let $f_{t_*}(x) = \phi(x, t_*)$. We consider the discrete flow generated by f_{t_*}, i.e., the iterates $\{f_{t_*}^n : n \in \mathbf{Z}\}$. We use the notation (M, f_{t_*}) to refer to this discrete flow.

DEFINITION 2.3. *The* orbit *of a point $x \in M$ under the flow (M,ϕ) is the set $O(x) = \{\phi(x,t) : t \in \mathbf{R}\}$. The orbit of a point $x \in M$ under the flow (M, f_{t_*}) is the set $O_{f_{t_*}}(x) = \{f_{t_*}^n(x) : n \in \mathbf{Z}\}$.*

DEFINITION 2.4. *The set K is* invariant *under the flow ϕ if $\{\phi(K,t) : t \in R\} \subset K$.*

DEFINITION 2.5. *The flow (M,ϕ) is* minimal *if M has no proper closed invariant sets under ϕ. Equivalently, every point of M has a dense orbit.*

DEFINITION 2.6. *If ϕ is a flow on M, then the* product flow *$\phi \times \phi$ on $M \times M$ is given by $\phi \times \phi((x,y),t) = (\phi(x,t), \phi(y,t))$.*

Now we describe the example of a universally observable system found by McMahon. Let $G = SL(2,\mathbf{R})$ and let Γ be a discrete subgroup of G with compact quotient space $M = \Gamma\backslash G$. Horocycle flow Φ on M is defined by

$$\Phi(\Gamma g, t) = \Gamma g \begin{pmatrix} 1 & 0 \\ t & 1 \end{pmatrix}.$$

In a paper by del Junco and Keane [7], it is remarked that any horocycle flow where Γ is a discrete cocompact maximal nonarithmetic subgroup has the property

that the past and future limit sets of (x, y) are $M \times M$ whenever x and y are on different orbits in (M, Φ). This follows from Theorem 4.5 in [6], which states that this flow has twofold minimal self-joinings, a strong property from ergodic theory; note that this is different from the definition of Markley [21]. Also, this flow has the property that the discrete flow induced by some time t_0 is minimal, so that the positive orbit of each point under the discrete flow is dense. These properties are sufficient for universal observability. Specifically, we now isolate the properties of McMahon's example which imply universal observability. We note that any flow with these properties will be universally observable.

DEFINITION 2.7. *A flow* (M, ϕ) *has* property V *if* (i) *the future limit set of* (x, y) *is* $M \times M$ *whenever* x *and* y *are on different orbits in* (M, ϕ), *and* (ii) *given any fixed time* t_*, *the positive orbit of each point in* (M, f_{t_*}) *is dense in* M.

THEOREM 2.8. *If* (M, ϕ) *has property* V, *then* (M, ϕ) *is universally observable.*

Remark. The following proof is a direct generalization of McMahon's proof (see [18]).

Proof. Consider any nonconstant continuous observation function $h : M \to \mathbf{R}$. First, consider any two points $x, y \in M$ on different orbits. Choose any two open sets $U, V \subset M$ such that the intersection of $h(U)$ and $h(V)$ is empty. Since the future limit set of (x, y) is $M \times M$, there exists some time t_0 such that $\phi(x, t_0) \in U$ and $\phi(y, t_0) \in V$. Therefore, any two points on different orbits can be distinguished by any nonconstant continuous observation function h; specifically, there exists a time t_0 where $h(\phi(x, t_0)) \neq h(\phi(y, t_0))$.

Next consider the case when x and y are on the same orbit, i.e., there is a time t_* such that $y = \phi(x, t_*)$. We assume that these points cannot be distinguished by the flow, i.e., $h(\phi(x, t)) = h(\phi(y, t))$ for all $t \geq 0$. Now consider the discrete flow induced by time t_* above. We denote this discrete flow by (M, f_{t_*}). Now we have $h(x) = h(y)$ and $h(y) = h(\phi(x, t_*))$. So we see that $h(x) = h(f_{t_*}(x))$. Now following the orbit of x under ϕ for time t_* again, we have that $h(f_{t_*}(x)) = h(f_{t_*}^2(x))$, and continuing in this fashion we see that

$$h(x) = h(f_{t_*}(x)) = h(f_{t_*}^2(x)) = h(f_{t_*}^3(x)) = \cdots.$$

So h must be constant since the positive orbit of the discrete flow (M, f_{t_*}) is dense. This contradicts our assumption that h is a nonconstant continuous function. Thus, (M, ϕ) is universally observable. ∎

McMahon's example exhibits very strong ergodic and topological properties. This leads to the question of what ergodic or topological properties are necessary for universal observability. Is there an equivalent notion in topological dynamics? The notion of primeness for flows from topological dynamics is closely related to universal observability. For more on these questions, see [10, 12, 17].

3. A sufficient condition for universal observability. In this section, we will further isolate sufficient conditions for a general system to be universally observable. Here, we consider the more general case of a continuous flow ϕ on a compact Hausdorff space. We first state some relevant definitions from topological dynamics.

DEFINITION 3.1. *The flow* (M, ϕ) *is* topologically ergodic *if every proper closed invariant set (under* ϕ*) is nowhere dense.*

DEFINITION 3.2. *The flow* (M, ϕ) *is* topologically weakly mixing *if the product flow,* $(M \times M, \phi \times \phi)$, *is topologically ergodic.*

Equivalently, the flow (M, ϕ) is topologically weakly mixing if every point of $M \times M$, with the possible exception of a set of first category, has an orbit which is dense (see [23, p. 152]).

Similarly, we can define these notions for the discrete flow as well.

LEMMA 3.3. *Given any topologically weakly mixing flow (M, ϕ) which is minimal, the discrete flow generated by a fixed time t_*, (M, f_{t_*}) is also minimal. That is, the iterates of $f_{t_*}(x)$ for any $x \in M$ form a dense subset of M.*

Remark. This lemma is often used in topological dynamics [5], [20]. For a proof, we refer the reader to the Appendix section 6.

Next we use this lemma to describe sufficient conditions for a flow to be universally observable.

DEFINITION 3.4. *A flow (M, ϕ) has* property W *if it is minimal and satisfies part* (i) *of property* V *(Definition* 2.7*).*

THEOREM 3.5. *If a flow (M, ϕ) has property* W*, then it is universally observable.*

Proof. If a flow satisfies part (i) of property V, then it is obviously topologically weakly mixing. Now by Lemma 3.3, the flow satisfies part (ii) of property V. Therefore, by Theorem 2.8, the flow is universally observable. □

4. Previous results. In this section, we review some results regarding universal observability. These give motivation for our main result, the construction of a universally observable flow on the torus.

First, we recall some results of Byrnes, Dayawansa, and Martin [3]. These give necessary conditions for universal observability.

Suppose X is a locally compact Hausdorff space and

$$\phi : \mathbf{R} \times M \to M$$

is a continuous flow on M.

THEOREM 4.1. *If ϕ is universally observable, then ϕ is minimal; i.e., all positive orbits are dense in M.*

For the next theorem we make the additional assumptions that M is a smooth manifold and f is a smooth vector field on M, so f should be complete.

THEOREM 4.2. *If f is a vector field on M which is universally observable, then M is compact with Euler characteristic zero.*

Now we focus on the question of existence of any low-dimensional systems which are universally observable. It is not hard to see that there cannot be a one-dimensional universally observable system. We consider the two-dimensional case below.

We consider smooth flows on two-dimensional manifolds without boundary. By the results of Byrnes, Dayawansa, and Martin above, we need only consider nonsingular vector fields with all positive orbits dense and manifolds which are compact with Euler characteristic zero. Now the classification of compact surfaces yields only two surfaces with vanishing Euler characteristic, the torus for orientable surfaces and the Klein bottle for nonorientable surfaces.

A result due to Kneser (see [13]) says that every smooth direction field on the Klein bottle has a periodic orbit. Therefore, there is no universally observable system on the Klein bottle. For more details on this, see [9].

Next we consider smooth flows on the torus. We note that any vector field on the torus can be represented by a set of differential equations in the plane which are periodic in the spatial variables. More specifically, let $\mathbf{X}$ be a vector field on the torus, $\mathbf{T}^2 = \mathbf{S}^1 \times \mathbf{S}^1$. Then $\mathbf{X}$ can be represented as a system of differential equations of the following form:

$$\frac{d\eta}{dt} = f(\eta, \theta),$$
$$\frac{d\theta}{dt} = g(\eta, \theta),$$

where $(\eta, \theta) \in \mathbf{T}^2$, and f, g are periodic in η, θ of period one.

A special important case of this type is the linear system

$$(*) \qquad \frac{d\eta}{dt} = \alpha,$$
$$\frac{d\theta}{dt} = 1.$$

This is just the constant vector field with orbits being the lines of slope $\frac{1}{\alpha}$. When α is irrational, we refer to this as constant irrational flow.

We need to discuss equivalence of flows (vector fields).

DEFINITION 4.3. *A C^r vector field $\mathbf{X}$ on M is called* C^k-equivalent *to a C^r vector field $\mathbf{X}'$ on M' if there is a diffeomorphism of class C^k of M onto M' which takes orbits of $\mathbf{X}$ to orbits of $\mathbf{X}'$ preserving orientation but not necessarily parametrization by time.*

The following proposition about vector fields on the torus stems from the work of Denjoy [8] on diffeomorphisms of the circle. This is a sort of classification for certain nonsingular vector fields on the torus.

PROPOSITION 4.4. *Any flow on the torus with no equilibrium points or closed orbits necessarily arises from a vector field C^0 equivalent (topologically equivalent) to the above linear system $(*)$ with α irrational.*

This follows from Denjoy's theorem and relevant facts about nonsingular vector fields on the torus with an irrational rotation number. For a more detailed discussion, see [14] or [2].

Using these facts, we get the following theorem.

THEOREM 4.5. *A universally observable system on the torus is topologically equivalent to system $(*)$ with α irrational.*

For a detailed proof, see [9].

As described by Wallace [25], it is well known that constant irrational flow, i.e., the flow arising from a constant vector field on the torus with orbits being winding lines of irrational slope, is not universally observable. To understand why this is so, we first discuss a topological criterion developed by Wallace [25] and DeStefano [9] which is equivalent to universal observability.

DEFINITION 4.6. *(M, ϕ) has* property U *if there do not exist $x_0, y_0 \in M$ and a one-parameter family of nontrivial open subsets $U_\alpha \subset M$, such that for all $\alpha \in [0,1]$, $cl(U_{\alpha_1}) \subset U_{\alpha_2}$ if and only if $\alpha_1 < \alpha_2$, $cl(U_\alpha) \neq M$, and for all $t \in \mathbf{R}$ and $\alpha \in [0,1]$, $\phi(x_0, t) \in U_\alpha$ if and only if $\phi(y_0, t) \in U_\alpha$.*

Remark. Note that the definition of property U above is slightly more restrictive than that given in [25] (see [9]).

THEOREM 4.7. *(M, ϕ) is universally observable if and only if (M, ϕ) has property* U.

For the proof, the reader is referred to [25] and [9].

Now we can see that this system does not have property U. This is done by constructing the sets U_α as pictured in Figure 4.1 and picking x_0, y_0 on the boundary of U_1.

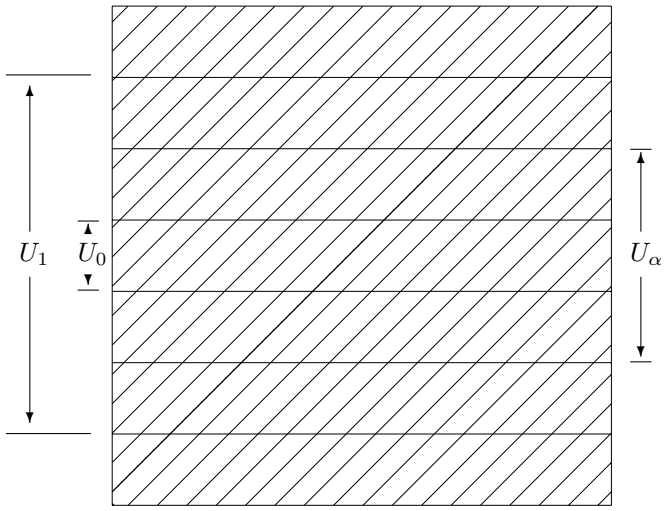

FIG. 4.1. *Construction of the U_α's on the torus.*

These results show that any universally observable flow on the torus is topologically equivalent to constant irrational flow, a flow which itself is not universally observable. So if there is a universally observable flow on the torus, its orbit structure is the same topologically as a flow which is not universally observable.

5. An example of a continuous universally observable flow on the torus. Now we are ready to discuss the existence of a universally observable flow on the torus.

THEOREM 5.1. *There exists a continuous flow on the torus with property* W.

By Theorem 3.5, we immediately obtain the following corollary.

COROLLARY 5.2. *There exists a continuous universally observable flow on the torus.*

The flow we construct is topologically equivalent to the flow on the torus $\mathbf{T}^2$ given by the vector field

$$(*) \qquad \begin{aligned} \frac{d\eta}{dt} &= \alpha, \\ \frac{d\theta}{dt} &= 1, \end{aligned}$$

where α is an irrational number fixed below. Hence the flow is minimal. To obtain a flow $\phi(x,t) : \mathbf{T}^2 \times \mathbf{R} \to \mathbf{T}^2$ with the other part of property W, that certain orbits of the product of the flow with itself, $\phi \times \phi$, are dense in $\mathbf{T}^2 \times \mathbf{T}^2$, we adjust the speed of orbits in the torus.

Interestingly, our example is only a continuous flow and not all irrationals α are admissible for the underlying flow on the torus. These limitations are required by our construction. We do not know if smoother torus flows exist with property W or if smoother universally observable flows on the torus exist. However, it is not unlikely that this is another example of the sort of "small-divisor" problem which commonly appears in the study of torus flows and circle maps (see Hermann [16]).

As noted above, the topology of our flow ϕ is that of a minimal "straight-line" flow. The speeds of the orbits are chosen so that any two points on different ϕ-orbits move with time so that they become arbitrarily far apart in (the lift of) the θ direction. By Lemma 5.4 below, this will suffice to give the density of orbits in $\mathbf{T}^2 \times \mathbf{T}^2$. Finally, we give the definition of the flow ϕ and show that it has the required properties.

We begin with some notation. The dynamics of flows on the torus given by the vector field $(*)$ are intimately connected to the continued fraction expansion of α which determines the slope of the vector field (see Hermann [16]). We use only the following basic facts concerning continued fractions. The reader is referred to Niven [22] or Hardy and Wright [15] for details and proofs.

Recall that each $\alpha \in (0,1)$ can be represented as a continued fraction

$$\alpha = \cfrac{1}{a_1 + \cfrac{1}{a_2 + \cfrac{1}{a_3 + \cdots}}},$$

where each $a_i \in \mathbf{Z}^+ \cup \{0\}$. In the case of an infinite fraction this notation means that

$$\alpha = \lim_{n\to\infty} \frac{p_n}{q_n},$$

where p_n/q_n is the truncation of the continued fraction for α at the nth level, i.e.,

$$\frac{p_n}{q_n} = \cfrac{1}{a_1 + \cfrac{1}{a_2 + \cfrac{1}{a_3 + \cdots + \cfrac{1}{a_n}}}}.$$

This rational p_n/q_n is called the nth convergent of α. The continued fraction expansion is infinite if and only if α is irrational, and the expansion is unique. For rational α, there is a slight ambiguity in the expansion in the last term; see the references cited above.

A general property of the continued fraction expansion of an irrational α with nth-convergent p_n/q_n is

$$\left|\alpha - \frac{p_n}{q_n}\right| < \frac{1}{q_n q_{n+1}},$$

where q_{n+1} is the denominator of the $(n+1)$st convergent. The size of these denominators is controlled by the a_i in the continued fraction. In fact, $q_{n+1} = a_{n+1}q_n + q_{n-1}$ and $p_{n+1} = a_{n+1}p_n + p_{n-1}$ for all n. This property is useful because it picks out the rational numbers with smallest denominator closest to the irrational. For more on this subject, see [15].

5.1. Density of curves in $\mathbf{T}^2$ and $\mathbf{T}^2 \times \mathbf{T}^2$. Since property W relates the topology of orbits in $\mathbf{T}^2$ and $\mathbf{T}^2 \times \mathbf{T}^2$, we need notation for measuring "how dense" a finite length curve is in these spaces. We let the usual metrics on $\mathbf{T}^2$ and $\mathbf{T}^2 \times \mathbf{T}^2$ be denoted by d and d_2, respectively.

DEFINITION 5.3. *A set $A \subset \mathbf{T}^2 \times \mathbf{T}^2$ is* δ-dense *for $\delta > 0$ if, for every $z \in \mathbf{T}^2 \times \mathbf{T}^2$, there exists $w \in A$ such that $d_2(z,w) \le \delta$.*

Finally, we need notation for the universal covers of $\mathbf{T}^2$ and $\mathbf{T}^2 \times \mathbf{T}^2$ and associated lifts. For $a \in \mathbf{R}$, we let $\langle a \rangle$ denote the fractional part of a, i.e., $\langle a \rangle \in [0,1)$ and $a - \langle a \rangle \in \mathbf{Z}$.

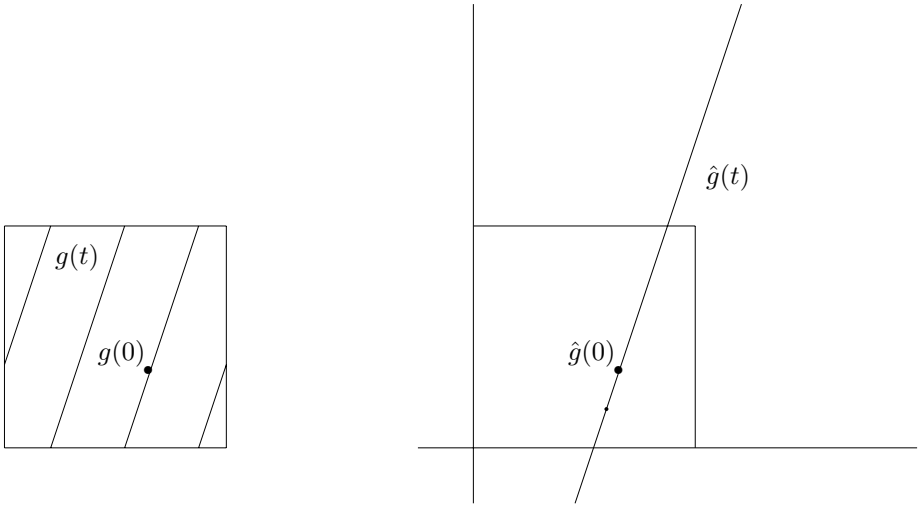

FIG. 5.1. *The lift of a curve on the torus.*

Let $\pi : \mathbf{R}^2 \to \mathbf{T}^2$ denote the projection

$$\pi(x, y) = (\langle x \rangle, \langle y \rangle).$$

This is the usual covering map from $\mathbf{R}^2$ to $\mathbf{T}^2$. Let $\mathbf{X}$ and $\mathbf{Y}$ denote the projections of $\mathbf{R}^2$ onto x and y coordinates, respectively. For $z \in \mathbf{T}^2$, let $\hat{z} \in \mathbf{R}^2$ be the lift of z satisfying $\pi(\hat{z}) = z$, $\mathbf{X}(\hat{z}), \mathbf{Y}(\hat{z}) \in [0, 1)$.

If $g : \mathbf{R} \to \mathbf{T}^2$ is a curve on the torus, then we let $\hat{g} : \mathbf{R} \to \mathbf{R}^2$ denote the continuous lift of g which satisfies $g = \pi \circ \hat{g}$ and $\hat{g}(0) \in [0, 1) \times [0, 1)$ (see Figure 5.1). For a flow ϕ on $\mathbf{T}^2$, we denote a lift by $\hat{\phi}$ where for each $z \in \mathbf{T}^2$, $\hat{\phi}(z, t)$ is the lift specified above of the curve $t \to \phi(z, t)$.

Next we prove a lemma which gives a key step in our construction. We know that a curve in $\mathbf{T}^2$ whose lift is a straight line with irrational slope wraps densely around $\mathbf{T}^2$. We can build a curve in $\mathbf{T}^2 \times \mathbf{T}^2$ by taking the product of two copies of such a line. The resulting curve will not be dense in $\mathbf{T}^2 \times \mathbf{T}^2$ because its image is restricted to the diagonal $\{(z, z) : z \in \mathbf{T}^2\} \subset \mathbf{T}^2 \times \mathbf{T}^2$. However, if we take two lines with slightly different speeds, i.e., slightly out of phase, but with equal irrational slopes, the curve formed in $\mathbf{T}^2 \times \mathbf{T}^2$ visits much more of the space. The following lemma embodies this observation. Its statement is somewhat technical since it is in the form we require below. See the remark below for an explanation of the qualitative meaning and implications of the following technical conditions.

Fix

$$\alpha = \frac{1}{a_1 + \frac{1}{a_2 + \frac{1}{a_3 + \cdots}}},$$

an irrational with $\frac{p_1}{q_1}, \frac{p_2}{q_2}, \ldots$ its convergents. Fix $m < n$ positive integers. Suppose $\sigma_1, \sigma_2 : \mathbf{R} \to \mathbf{T}^2$ are curves with lifts $\hat{\sigma}_1, \hat{\sigma}_2 : \mathbf{R} \to \mathbf{R}^2$ satisfying the following.

(1) Both $\hat{\sigma}_1$ and $\hat{\sigma}_2$ are lines with slope $1/\alpha$.

(2) For t fixed, j a positive integer, let $s_j(t)$ be such that

$$\mathbf{Y}(\hat{\sigma}_1(t + s_j(t))) - \mathbf{Y}(\hat{\sigma}_1(t)) = jq_n.$$

We call $s_j(t)$ the jth q_n return time; in particular, $s_1(t)$ is the q_n return time of $\sigma_1(t)$. Then we assume that there exists $N < \frac{a_{n+1}}{8}$ such that for all $t \leq s_{N+2}(0)$,

$$q_n < \mathbf{Y}(\hat{\sigma_2}(t + s_1(t))) - \mathbf{Y}(\hat{\sigma_2}(t)) < \frac{1}{q_m} + q_n.$$

(3) For N as in (2), we also require that

$$\mathbf{Y}(\hat{\sigma}_2(s_N(0))) - \mathbf{Y}(\hat{\sigma}_2(0)) > Nq_n + 2q_m.$$

Remark. Condition 2 states that the speed along σ_2 is slightly faster than that along σ_1. Condition 3 states that this slight difference eventually adds up to a large difference in positions along the two lines. In particular, it imposes a condition on the irrational α which requires that the a_n's in the continued fraction expansion grow fast enough.

Finally we state the lemma.

LEMMA 5.4. *Suppose σ_1, σ_2 are as above and $2q_m < q_n$. Then the curve given by*

$$(\sigma_1, \sigma_2) : [0, s_N(0)] \to \mathbf{T}^2 \times \mathbf{T}^2 : t \to (\sigma_1(t), \sigma_2(t))$$

is $4/q_m$ dense in $\mathbf{T}^2 \times \mathbf{T}^2$.

Proof. Fix a $t \in [0, s_1(0)]$ and consider the set

$$\{\sigma_1(t + s_j(t)), \sigma_2(t + s_j(t)) : 0 \leq j \leq N\}.$$

By the condition on N, the points $\sigma_1(t + s_j(t))$ are no more than $1/q_n$ from $\sigma_1(t)$. Moreover, $d(\sigma_2(t + s_j(t)), \sigma_2(t + s_{j+1}(t))) < 2/q_m$ for all j. Now for any $z \in \mathbf{T}^2$ there exists j such that $d(z, \sigma_2(t + s_j(t))) < \frac{2}{q_m} + \frac{1}{q_n} < \frac{5}{2q_m}$. Hence, for each point in the set $\{(\sigma_1(t), z) : z \in \mathbf{T}^2\}$ there is a point of the form $(\sigma_1(t + s_j(t)), \sigma_2(t + s_j(t)))$ within $3/q_m$ of it. Since every point of $\mathbf{T}^2$ is within $2/q_n$ of $\sigma_1(t)$ for some $t \in [0, s_1(0)]$, the set $\{(\sigma_1(t), \sigma_2(t)) : t \in [0, s_{N+2}(0)]\}$ is at least $4/q_m$ dense in $\mathbf{T}^2 \times \mathbf{T}^2$. □

5.2. The construction. Next we fix notation and make some choices of the parameters involved in our example. Where it is both possible and convenient, we make explicit choices rather than seeking optimal values.

Fix an irrational

$$\alpha = \frac{1}{a_1 + \frac{1}{a_2 + \frac{1}{a_3 + \dots}}},$$

where $a_i \to \infty$ very quickly as $i \to \infty$ (exactly how quickly will be set below). Let p_n/q_n denote the nth convergent of α.

Let $\rho : [0, 1] \to \mathbf{R}$ be a function given by

$$\rho(\eta) = \sum_{n=1}^{\infty} \beta_{q_n}[\sin(2\pi q_n \eta) + 1] = \sum_{n=1}^{\infty} \beta_{q_n} \left[\frac{e^{2\pi i q_n \eta} - e^{-2\pi i q_n \eta}}{2i} + 1 \right].$$

So $\rho(\eta)$ is given by a Fourier series on $[0,1]$ with nonzero terms having period $1/q_n$ for some n. Let the amplitudes β_{q_n} be given by

$$\beta_{q_n} = \frac{4^n}{2\pi q_n}.$$

Our first assumption on the growth rate of the a_n's (hence the q_n's) is that $q_n >> 4^n$ so that $\rho(\eta)$ converges uniformly to a C^0 function. We note that $\rho(\eta)$ is not C^1 because the q_nth coefficient of the formal Fourier series for $\rho'(\eta)$ grows like 4^n (see Tolstov [24, p. 129]). Since only the tail of $\rho(\eta)$ is important we may assume that $|\rho(\eta)| < 1$ for all η by removing the leading terms if necessary.

We next specify the flow $\phi(x,t) : \mathbf{T}^2 \times \mathbf{R} \to \mathbf{T}^2$. As noted above, we require that ϕ be topologically equivalent to the flow given by

$$(*) \qquad \begin{aligned} \frac{d\eta}{dt} &= \alpha, \\ \frac{d\theta}{dt} &= 1, \end{aligned}$$

where α is the irrational chosen above, so each orbit of ϕ lifts to a straight line with slope $1/\alpha$. Also, we require that for each $\eta \in [0,1)$, if

$$\mathbf{Y}(\hat{\phi}((\eta,0),t)) = 1,$$

then $t = 1 + \rho(\eta)$; that is, the time necessary for the ϕ-orbit of $(\eta,0)$ to loop once in the θ direction is $1 + \rho(\eta)$. With the bound on $|\rho(\eta)|$ above, this implies that we may assume the speed of each point under the flow is less than 4.

Next, we fix some notation concerning how close one point on $\mathbf{T}^2$ is to a segment of a ϕ-orbit of another point. Let

$$\varepsilon_n = \frac{3}{4q_{n+1}}.$$

For $z_1 \in \mathbf{T}^2$ with $\hat{z}_1$ a lift of z_1, let

$$\Sigma_n(z_1) = \pi\left\{\hat{z}_1 + (\alpha t, t) + (\delta, 0) : t \in \left[-\frac{q_n}{2}, \frac{q_n}{2}\right], \delta < \varepsilon_n\right\}.$$

That is, $\Sigma_n(z_1)$ is the set of points on $\mathbf{T}^2$ within ε_n in the η direction of a point in the set $\{\pi(\hat{z}_1 + (\alpha t, t)) : -\frac{q_n}{2} \le t \le \frac{q_n}{2}\}$. This is a narrow strip around the segment of the ϕ-orbit of z_1 which wraps around the torus q_n times in the θ direction.

In order to show that the flow ϕ has property W we proceed as follows.

Step 1. Show that if $z_2 \notin \Sigma_n(z_1)$, i.e., z_2 is not near the initial segment of the ϕ-orbit of z_1, then the average speeds along part of the ϕ-orbits of z_1 and z_2 are slightly different for a long period of time.

Step 2. Show that the difference in speeds of the ϕ-orbits of z_1 and z_2 implies a certain density for the initial segment of the orbit of (z_1, z_2) under $\phi \times \phi$; i.e., apply Lemma 5.4.

Step 3. Verify that if $z_2 \in \bigcap_{n \ge m} \Sigma_n(z_1)$ for some m, then z_2 is on the ϕ-orbit of z_1.

Step 4. Using Steps 1, 2, and 3, verify that if z_2 is not on the ϕ-orbit of z_1, then $\{\phi \times \phi((z_1, z_2), t) : t \ge 0\}$ is dense in $\mathbf{T}^2 \times \mathbf{T}^2$.

In the process of doing Steps 1, 2, and 4, we fix the rate at which the a_n's (hence q_n's) in the definition of α must tend to infinity.

Step 3 is the easiest, so we begin with it.

LEMMA 5.5. *If $z_2 \in \bigcap_{n\geq m} \Sigma_n(z_1)$ for some m, then z_2 is on the ϕ-orbit of z_1.*

Proof. First we note that for each n,

$$\Sigma_n(z_1) \bigcup \Sigma_{n+1}(z_1) = \pi\left\{\hat{z}_1 + (\alpha t, t) + (\delta, 0) : t \in \left[-\frac{q_n}{2}, \frac{q_n}{2}\right], \delta < \varepsilon_{n+1}\right\}.$$

That is, the intersection of the shorter (in the θ direction), wider (in the η direction) strip $\Sigma_n(z_1)$ with the longer, narrower strip $\Sigma_{n+1}(z_1)$ is a short, narrow strip. This follows from the fact that points in the set $\{\pi(\hat{z}_1 + (\alpha t, t)) : t \in [-\frac{q_{n+1}}{2}, \frac{q_{n+1}}{2}]\}$ with the same θ coordinate are approximately $1/q_{n+1}$ apart in the η direction.

By induction we see that

$$\bigcap_{n\geq m_1}^{m_2} \Sigma_n(z_1) = \pi\left\{\hat{z}_1 + (\alpha t, t) + (\delta, 0) : t \in \left[-\frac{q_{m_1}}{2}, \frac{q_{m_1}}{2}\right], \delta < \varepsilon_{m_2}\right\}$$

and hence

$$\bigcap_{n\geq m_1}^{\infty} \Sigma_n(z_1) \subset \pi\left\{\hat{z}_1 + (\alpha t, t) : t \in \mathbf{R}\right\};$$

that is, z_2 is in the ϕ-orbit of z_1. □

To show Step 1, we first fix z_1, z_2, and n so that $z_2 \notin \Sigma_n(z_1)$. Let $\hat{z}_1$ and $\hat{z}_2$ be lifts of z_1, z_2, respectively, and fix times s_j and r_j such that for $j = 1, 2, \ldots,$

$$\mathbf{Y}(\hat{\phi}(\hat{z}_1, s_j)) - \mathbf{Y}(\hat{z}_1) = jq_N,$$

$$\mathbf{Y}(\hat{\phi}(\hat{z}_2, r_j)) - \mathbf{Y}(\hat{z}_2) = jq_N.$$

In order to study the difference in speeds of z_1 and z_2 along their orbits as embodied in the difference in "q_n return times" s_j and r_j, we begin by showing that the effect of terms in $\rho(\eta)$ of period $1/q_m$, where $m \neq n$, $m \neq n+1$, can be safely ignored. We deal first with terms of period q_m for $m < n$.

LEMMA 5.6. *Let $|\cdot|$ denote the modulus of a complex number or absolute value where appropriate. With the notation as above,*

$$\left|\sum_{k=0}^{q_n-1} e^{2\pi i q_m \alpha k}\right| = \left|\frac{1 - e^{2\pi i q_m \alpha q_n}}{1 - e^{2\pi i q_m \alpha}}\right| < \frac{4q_m q_{m+1}}{q_{n+1}}.$$

Proof. From the theory of continued fractions, we know that

$$\left|\alpha - \frac{p_n}{q_n}\right| < \frac{1}{q_n q_{n+1}}$$

and

$$\left|\alpha - \frac{p_m}{q_m}\right| > \frac{1}{2q_m q_{m+1}}$$

provided $a_{m+1} \geq 2$. Hence

$$|q_m q_n \alpha - p_n q_m| < \frac{q_m}{q_{n+1}}$$

and

$$|q_m \alpha - p_m| > \frac{1}{2q_{m+1}}$$

and so

$$|e^{2\pi i q_m \alpha q_n} - 1| < \frac{q_m}{q_{n+1}},$$

$$|e^{2\pi i q_m \alpha} - 1| > \frac{1}{2}\frac{1}{2q_{m+1}}. \qquad \square$$

LEMMA 5.7. *With notation as above and $n \geq 2$,*

$$\left|\frac{d}{d\eta}\left(\sum_{k=0}^{q_n-1}\sum_{m=1}^{n-1}\beta_{q_m}\frac{(e^{2\pi i(\eta+\alpha k)q_m} - e^{-2\pi i(\eta+\alpha k)q_m})}{2i} + 1\right)\right| \leq 4\pi\left(\sum_{m=1}^{n-1} 4^m q_m q_{m+1}\right)/q_{n+1}.$$

Proof. Note that

$$\left|\frac{d}{d\eta}\left(\sum_{k=0}^{q_n-1}\sum_{m=1}^{n-1}\beta_{q_m}\frac{(e^{2\pi i(\eta+\alpha k)q_m} - e^{-2\pi i(\eta+\alpha k)q_m})}{2i} + 1\right)\right|$$

$$\leq \left|\sum_{m=1}^{n-1}\sum_{k=0}^{q_n-1}\pi q_m \beta_{q_m}(e^{2\pi i q_m(\eta+\alpha k)} + e^{-2\pi i q_m(\eta+\alpha k)})\right| \leq 4\pi\left(\sum_{m=1}^{n-1} 4^m q_m q_{m+1}\right)/q_{n+1}$$

by the previous lemma. $\square$

Hence, provided q_{n+1} is sufficiently large, we may assume that the slope of the part of $\rho(\eta)$ coming from period $1/q_m$ terms with $m < n$ is as small as we like, i.e., that we can neglect the differences in q_n return times of z_1 and z_2 caused by these terms.

Similarly, we can bound terms of $\rho(\eta)$ with period $1/q_m$ for $m > n+1$ as follows.

LEMMA 5.8.

$$\left|\sum_{m=n+2}^{\infty}\beta_{q_m}\left(\frac{e^{2\pi i q_m \alpha} - e^{-2\pi i q_m \alpha}}{2i} + 1\right)\right| \leq 2\sum_{m=n+2}^{\infty}\frac{4^m}{2\pi q_m}.$$

Proof. This follows immediately from the definition of $\beta_{q_m} = \frac{4^m}{2\pi q_m}$. Hence all the terms in the tail of the Fourier series of $\rho(\eta)$ tend to zero very quickly (provided the a_n's tend to infinity quickly). $\square$

We can collect these results as follows. Let

$$\rho_n(\eta) = \beta_{q_n}\left(\frac{e^{2\pi i q_n \eta} - e^{-2\pi i q_n \eta}}{2i} + 1\right).$$

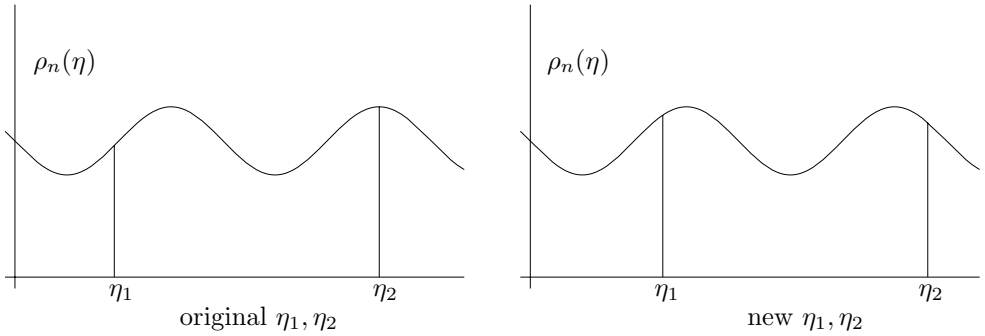

FIG. 5.2. *Evolution of η_1, η_2.*

For z_1, $z_2 \in \mathbf{T}^2$ with $z_2 \notin \Sigma_n(z_1)$, let η_1, η_2 be such that $(\eta_1, 0) + (\alpha\theta, \theta) = \hat{z}_1$ for some $\theta \in [0, 1)$, and similarly for η_2. The q_n return times of z_1 and $(\eta_1, 0)$ are at most order $1/q_{n+1}$ apart because their orbit segments bringing about the return differ only by segments of length order 1 and are at most $1/q_{n+1}$ apart. A similar statement holds for z_2 and $(\eta_2, 0)$. This difference can be ignored because the difference between r_1 and s_1 is at least q_n times as large since this difference is given by q_n times the difference in ρ values. (Similar estimates allow the difference in q_n return times of $\phi(z_1, t)$ and $\phi(z_1, t + k)$ for $k << q_n$ to be neglected.) Then the q_n return times s_1 and r_1 of z_1 and z_2 satisfy

$$s_1 = K + q_n(\rho_n(\eta_1) + \rho_{n+1}(\eta_1) + 1) + \zeta,$$

$$r_1 = K + q_n(\rho_n(\eta_2) + \rho_{n+1}(\eta_2) + 1) + \xi,$$

where K is a constant independent of η, and ζ, ξ tend to zero as the growth rate of the a_n's increases.

Remark. In fact, the same statement holds true for q_n return times if the ρ_{n+1} terms are omitted from the above since $|\rho_{n+1}(\eta)| \leq 2\frac{4^{n+1}}{2\pi q_{n+1}}$ for all η. However, since z_1 and z_2 can be only order $1/q_{n+1}$ apart, the difference in speed resulting from the $\rho_{n+1}(\eta)$ term can be significant; see below.

So we see that z_1 and z_2 have different q_n return times depending on $\rho(\eta_1)$ and $\rho(\eta_2)$. To apply Lemma 5.4 (Step 2 above) we must gain control of these return times. This can be accomplished by replacing z_1 and z_2 by $\phi(z_1, t)$ and $\phi(z_2, t)$, respectively, for a suitably chosen t. The points $\phi(z_1, s_j)$ and $\phi(z_2, r_j)$ are approximately j/q_{n+1} displaced from z_1 and z_2, respectively, in the η direction. Because q_{n+1} may be taken as large as we like, we may choose $t \in [0, q_{n+1}]$, so that if we replace z_1 and z_2 by $\phi(z_1, t)$ and $\phi(z_2, t)$, respectively, for the new η_1 and η_2,

$$0 < \rho_n(\eta_2) - \rho_n(\eta_1) < \frac{1}{q_n q_{n-2}};$$

see Figure 5.2.

First we note that because $z_2 \notin \Sigma_n(z_1)$ we know that the distance in the η direction from z_2 to a point in $\{\pi(\hat{z}_1 + (\alpha t, t)) : t \in [-\frac{q_n}{2}, \frac{q_n}{2}]\}$ is at least $\varepsilon_n = 3/4q_{n+1}$. Also, we know from continued fraction theory that

$$\left|\frac{p_n}{q_n} - \frac{p_{n+1}}{q_{n+1}}\right| = \frac{1}{q_n q_{n+1}}.$$

Hence, for $t \in [-\frac{q_n}{2}, \frac{q_n}{2}]$ the points $\pi(\hat{z}_1 + (\alpha t, t))$ are displaced in the η direction from $\pi(\hat{z}_1 + (\frac{p_n}{q_n}t, t))$ by less than $\frac{1}{2q_{n+1}} \bmod \frac{1}{q_n}$; that is,

$$\min\left\{\frac{|\langle q_n\eta_1 - q_n\eta_2\rangle|}{q_n}, \frac{1 - |\langle q_n\eta_1 - q_n\eta_2\rangle|}{q_n}\right\} \geq \frac{1}{4q_{n+1}}.$$

To apply Lemma 5.4 (Step 2 above) we must use this difference to compute estimates on the difference in q_n return times of z_1 and z_2.

We will deal with two cases depending on the distance between η_1 and η_2 mod $1/q_n$. First suppose η_1 and η_2 are relatively far apart, that is,

$$\min\left\{\frac{|\langle q_n\eta_1 - q_n\eta_2\rangle|}{q_n}, \frac{(1 - |\langle q_n\eta_1 - q_n\eta_2\rangle|)}{q_n}\right\} > \frac{2}{4^n q_n^2}.$$

Then we can choose $t \in [0, q_{n+1}]$ and replace z_1 and z_2 by $\phi(z_1, t)$ and $\phi(z_2, t)$ so that for the new η_1 and η_2,

$$\frac{1}{q_n^2} < \rho_n(\eta_2) - \rho_n(\eta_1) < \frac{1}{q_n q_{n-2}}.$$

Now, taking a_{n+1}, hence q_{n+1}, larger if necessary, we note that z_1 and z_2 are sufficiently close to being q_n periodic that the above inequality holds for $N > 2q_{n-2}q_n^2$ q_n return times of z_1 and z_2. Hence, Lemma 5.4 applies in this case with $m = n - 2$.

Next, suppose

$$\frac{1}{4q_{n+1}} < \min\left\{\frac{|\langle q_n\eta_1 - q_n\eta_2\rangle|}{q_n}, \frac{(1 - |\langle q_n\eta_1 - q_n\eta_2\rangle|)}{q_n}\right\} \leq \frac{2}{4^n q_n^2},$$

that is, η_1 and η_2 are very close mod $1/q_n$. In this case we must deal with the ρ_{n+1} term since the distance between the η's can be as small as $1/4q_{n+1}$.

The first step is to choose $t \in [0, q_{n+2}]$ so that if we replace z_1, z_2 with $\phi(z_1, t)$, $\phi(z_2, t)$, respectively, then for the new η_1, η_2 we have

$$\frac{4^n}{4q_{n+1}} < (\rho_n(\eta_2) + \rho_{n+1}(\eta_2)) - (\rho_n(\eta_1) + \rho_{n+1}(\eta_1)) < \frac{2}{q_n^2}.$$

Hence, the q_n return times are bounded below by $4^n q_n/4q_{n+1}$ and above by $2/q_n$. We must allow t's as large as q_{n+2} to accomplish this so that $\phi(z_1, t)$ and $\phi(z_2, t)$ can be properly placed relative to the period $1/q_{n+1}$ oscillations of $\rho_{n+1}(\eta)$. See Figure 5.3.

Recall that s_j and r_j are the jth q_n return times of z_1 and z_2, respectively. We fix N so that q_n return times of z_1 and z_2 are within 75% of the similar values for $\phi(z_1, s_j)$, $\phi(z_2, r_j)$ for $j \leq N$. How large we can take N depends on the difference between η_1 and η_2 mod $1/q_n$. If we let δ denote this difference, i.e.,

$$\delta = \frac{\min\{|\langle q_n\eta_1 - q_n\eta_2\rangle|, 1 - |\langle q_n\eta_1 - q_n\eta_2\rangle|\}}{q_n},$$

then we may take N to be the greatest integer less than $\frac{a_{n+1}}{8} - 2\delta q_{n+1}$ (recall, a_{n+1} is the number of $1/q_{n+1}$ periods per $1/q_n$ period, i.e., $q_{n+1} = a_{n+1}q_n + q_{n-1}$). Since $\delta < 2/4^n q_n^2$ (by assumption), we have that

$$2\delta q_{n+1} < \frac{4q_{n+1}}{4^n q_n^2} < \frac{8a_{n+1}q_n}{4^n q_n^2} = \frac{8a_{n+1}}{4^n q_n} < \frac{a_{n+1}}{16}.$$

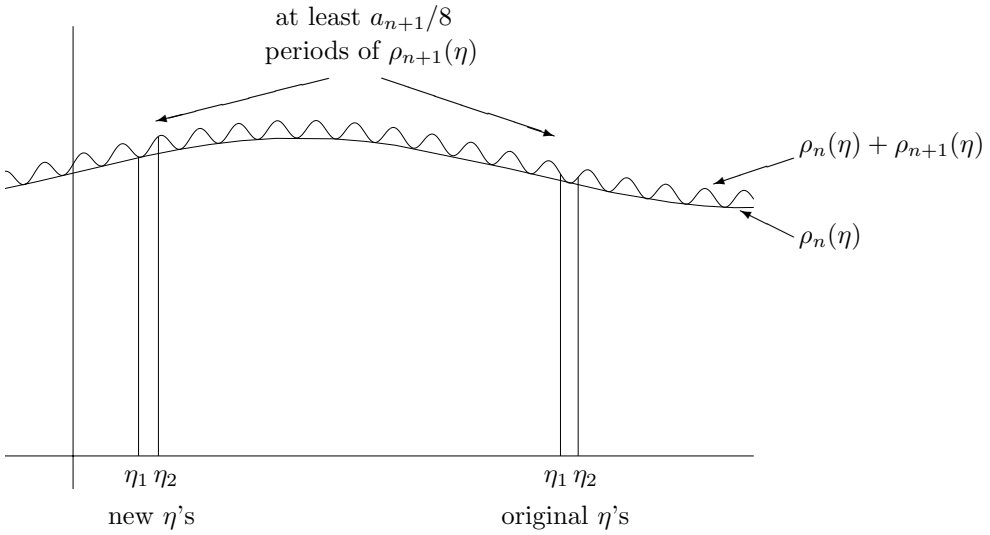

FIG. 5.3. *Proper placement of η_1 and η_2 attained by choosing the appropriate t for $\phi(z_1, t)$ and $\phi(z_2, t)$.*

(We have used $8/4^n q_n < 1/16$; since $q_n \to \infty$ rapidly, this is a very rough estimate.) Hence, in all cases, we may assume $N \geq a_{n+1}/16$. So the difference in q_n return times for $\phi(z_1, s_j)$ and $\phi(z_2, r_j)$ is bounded between $4^{n-1}q_n/4q_{n+1}$ and $2/q_n^2$. Hence,

$$s_N - r_N > N\frac{4^{n-1}q_n}{4q_{n+1}} > 4^{n-3}.$$

So we have (using the bound on $|\rho(\eta)|$) that

$$\mathbf{Y}(\hat{\phi}(\hat{z}_2, s_N)) - \mathbf{Y}(\hat{\phi}(\hat{z}_1, s_N)) > 4^{n-4},$$

and we may apply Lemma 5.4 using any q_m such that $2q_m < 4^{n-4}$.

Collecting this together, we see that if $z_2 \notin \Sigma_n(z_1)$, then for some $t \in [0, q_{n+2}]$ the points $\phi(z_1, t)$, $\phi(z_2, t)$ satisfy the hypotheses of Lemma 5.4 for any $q_m < 4^{n-5}$, and hence

$$\phi((z_1, z_2), [0, 2q_{n+2}]) \subset \mathbf{T}^2 \times \mathbf{T}^2$$

is at least $4/q_m > 4^{-n+6}$ dense in $\mathbf{T}^2 \times \mathbf{T}^2$. Letting $n \to \infty$ we see that if z_2 is not in the ϕ-orbit of z_1, then

$$\phi((z_1, z_2), [0, \infty))$$

is dense in $\mathbf{T}^2 \times \mathbf{T}^2$ and the construction is complete.

Remarks. (1) This construction actually gives a class of continuous flows with property W, since the flow is topologically equivalent to constant irrational flow and is specified by the crossing times and not the particular speed at any given point.

(2) Note that not all irrationals α are admissible. The necessary rate of growth of the a_i's in the continued fraction expansion is specified throughout the proof.

6. Appendix. The proof of Lemma 3.3 which we give below is based on a sketch given to the authors by Markley [20].

Before we give the proof, we will need some definitions, lemmas, and a proposition. For more details, we refer the reader to Auslander [1] or Ellis [11].

DEFINITION 6.1. *Let (M, ϕ) and (N, ψ) be two real continuous flows. A* homomorphism *from M to N is a continuous map $h : M \to N$ such that $h(\phi(x,t)) = \psi(h(x), t)$. If there is a homomorphism h from M onto N, we say that N is a* factor *of M.*

LEMMA 6.2. *A factor of a minimal flow is minimal.*

LEMMA 6.3. *If a minimal flow has a periodic factor, it is not topologically weakly mixing.*

DEFINITION 6.4. *A point $x \in M$ is an* almost periodic point *if for every neighborhood U of x, there is a relatively dense subset $A \subset \mathbf{R}$ such that $\phi(x, A) \subset U$.*

LEMMA 6.5. *Let M be a compact Hausdorff space and ϕ be a flow on M. Then M is a disjoint union of minimal subsets if and only if every point of M is almost periodic. In this case we say that M is pointwise almost periodic.*

Remark. See Corollary 1.10 of [1].

LEMMA 6.6. *Suppose (M, ϕ) is a flow. Consider the discrete flow generated by some time t_*; that is, consider the dynamical system given by iteration of f_{t_*}. Then the original flow is pointwise almost periodic if and only if the discrete flow is pointwise almost periodic.*

Remark. See Corollary 1.13 of [1].

LEMMA 6.7. *Given a flow on a locally compact Hausdorff space M (discrete or continuous), then $x \in M$ is an almost periodic point if and only if the orbit closure of x is a compact minimal set.*

Remark. See Theorem 1.7 of [1].

PROPOSITION 6.8. *The orbit closures for the action of a fixed time from a minimal flow are minimal sets.*

Proof. If the flow $\phi(x,t)$ is minimal, then M is a minimal set. Lemma 6.5 implies that (M, ϕ) is pointwise almost periodic. Now using Lemma 6.6, we have that the discrete flow generated by f_{t_*} is pointwise almost periodic. But by Lemma 6.7, the orbit closure $\overline{O_{f_{t_*}}(x)}$ is a minimal set. □

Proof of Lemma 3.3. Let (M, ϕ) be a minimal flow and consider the discrete flow generated by the fixed time t_*. That is, consider the flow which consists of the iterates of $f_{t_*}(x) = \phi(x, t_*)$. The orbit closure under the discrete flow at each point $x \in M$, $\overline{O_{f_{t_*}}(x)}$, is a minimal set.

Now we define an equivalence relation on M as follows: two points are equivalent if they are in the same orbit closure for the action of a fixed time. More precisely, let

$$R = \{(x, y) \in M \times M : \text{ there exists } \quad z \in M \quad \text{such that } \quad x, y \in \overline{O_{f_{t_*}}(z)}\}.$$

R is an invariant closed equivalence relation. We will denote the equivalence class of a point x by $[x]$. If we mod out by this equivalence relation, we obtain the quotient flow $\hat{\phi}$ on $\tilde{X} = X/R$ given by $\hat{\phi}([x], t) = [\phi(x,t)]$. Now $\hat{\phi}([x], t_*) = [\phi(x, t_*)] = [f_{t_*}(x)] = [x]$, so $\hat{\phi}$ is periodic of period t_*. So by Lemma 6.2, the quotient flow consists of a single periodic orbit. Therefore, Lemma 6.3 implies that the single periodic orbit must be a fixed point. Hence there is only one equivalence class, and the orbit closure for the action of a fixed time is all of M. This shows that the discrete flow generated by the fixed time t_* is minimal.

7. Conclusion. We have shown the existence of a continuous universally observable flow on the torus. Our construction actually gives a class of flows with property W which is sufficient for universal observability. These flows have orbit structure equivalent to constant irrational flow (with an appropriate irrational slope) and are obtained by defining the crossing times in such a way that any pair of points under the product flow get as dense as necessary. The construction sets conditions on how fast the denominators of the convergents in the continued fraction expansion of the irrational determining the slope of the orbits grow in order to achieve the necessary density. The choice of Fourier coefficients in the crossing time function is limited by the dynamics of the flow, and so this construction cannot be made smoother. It is still unknown if there are smoother universally observable flows on the torus.

Because of the connection between universal observability and topological dynamics, the example constructed here exhibits many topological properties of interest. This is explored by DeStefano and Markley in [10].

Acknowledgements. The authors would like to thank Dorothy Wallace and Clyde Martin for introducing them to this interesting and challenging problem.

DIFFERENTIAL FLATNESS AND ABSOLUTE EQUIVALENCE OF NONLINEAR CONTROL SYSTEMS *

M. VAN NIEUWSTADT†, M. RATHINAM†, AND R. M. MURRAY†

Abstract. This paper presents a formulation of differential flatness—a concept originally introduced by Fliess, Levine, Martin, and Rouchon—in terms of absolute equivalence between exterior differential systems. Systems that are differentially flat have several useful properties that can be exploited to generate effective control strategies for nonlinear systems. The original definition of flatness was given in the context of differential algebra and required that all mappings be meromorphic functions. The formulation of flatness presented here does not require any algebraic structure and allows one to use tools from exterior differential systems to help characterize differentially flat systems. In particular, it is shown that, under regularity assumptions and in the case of single input control systems (i.e., codimension 2 Pfaffian systems), a system is differentially flat if and only if it is feedback linearizable via static state feedback. In higher codimensions our approach does not allow one to prove that feedback linearizability about an equilibrium point and flatness are equivalent: one must be careful with the role of time as well as the use of prolongations that may not be realizable as dynamic feedback in a control setting. Applications of differential flatness to nonlinear control systems and open questions are also discussed.

Key words. exterior differential systems, flatness, prolongations, trajectory generation

1. Introduction.

The problem of equivalence of nonlinear systems (in particular to linear systems, that is, feedback linearization) is traditionally approached in the context of differential geometry [16, 17, 22]. A complete characterization of static feedback linearizability in the multi-input case is available, and for single input systems it has been shown that static and dynamic feedback linearizability are equivalent [5]. Some special results have been obtained for dynamic feedback linearizability of multi-input systems, but the general problem remains unsolved. Typically, the conditions for feedback linearizability are expressed in terms of the involutivity of distributions on a manifold.

More recently it has been shown that the conditions on distributions have a natural interpretation in terms of exterior differential systems [14, 26]. In exterior differential systems, a control system is viewed as a Pfaffian module. Some of the advantages of this approach are the wealth of tools available and the fact that implicit equations and nonaffine systems can be treated in a unified framework. For an extensive treatment of exterior differential systems we refer to [1].

Fliess and coworkers [7, 12, 8, 9, 18] studied the feedback linearization problem in the context of differential algebra and introduced the concept of *differential flatness*. In differential algebra, a system is viewed as a differential field generated by a set of variables (states and inputs). The system is said to be differentially flat if one can find a set of variables, called the flat outputs, such that the system is (nondifferential)

algebraic over the differential field generated by the set of flat outputs. Roughly speaking, a system is flat if we can find a set of outputs (equal in number to the number of inputs) such that all states and inputs can be determined from these outputs without integration. More precisely, if the system has states $x \in \mathbb{R}^n$ and inputs $u \in \mathbb{R}^p$, then the system is flat if we can find outputs $y \in \mathbb{R}^p$ of the form

$$y = y(x, u, \dot{u}, \ldots, u^{(l)}) \tag{1.1}$$

such that

$$\begin{aligned} x &= x(y, \dot{y}, \ldots, y^{(q)}), \\ u &= u(y, \dot{y}, \ldots, y^{(q)}). \end{aligned} \tag{1.2}$$

Differentially flat systems are useful in situations where explicit trajectory generation is required. Since the behavior of flat systems is determined by the flat outputs, we can plan trajectories in output space and then map these to appropriate inputs. A common example is the kinematic car with trailers, where the xy position of the last trailer provides flat outputs [20]. This implies that all feasible trajectories of the system can be determined by specifying only the trajectory of the last trailer. Unlike other approaches in the literature (such as converting the kinematics into a normal form), this approach is intrinsic.

A limitation of the differential algebraic setting is that it does not provide tools for regularity analysis. The results are given in terms of meromorphic functions in the variables and their derivatives, without characterizing the solutions. In particular, solutions to the differential polynomials may not exist. For example, the system

$$\begin{aligned} \dot{x}_1 &= u, \\ \dot{x}_2 &= x_1^2, \end{aligned} \tag{1.3}$$

is flat in the differential algebraic sense with flat output $y = x_2$. However, it is clear that the derivative of x_2 always has to be positive, and therefore we cannot follow an arbitrary trajectory in y space.

In the beginning of this century, the French geometer E. Cartan developed a set of powerful tools for the study of equivalence of systems of differential equations [3, 4, 26]. Equivalence need not be restricted to systems of equal dimensions. In particular a system can be *prolonged* to a bigger system on a bigger manifold, and equivalence between these prolongations can be studied. This is the concept of *absolute equivalence* of systems. Prolonging a system corresponds to dynamic feedback, and it is clear that we can benefit from the tools developed by Cartan to study the feedback linearization problem. The connections between Cartan prolongations and feedback linearizability for single input systems were studied in [24].

In this paper we reinterpret flatness in this differential geometric setting. We make extensive use of the tools offered by exterior differential systems and the ideas of Cartan. This approach allows us to study some of the regularity issues and also to give an explicit treatment of time dependence. Moreover, we can easily make connections to the extensive body of theory that exists in differential geometry. We show how to recover the differential algebraic definition and give an exterior differential systems proof for a result proven by Martin [18, 19] in differential algebra: a flat system can be put into Brunovsky normal form by dynamic feedback in an open and dense set (this set need not contain an equilibrium point).

We also give a complete characterization of flatness for systems with a single input. In this case, flatness in the neighborhood of an equilibrium point is equivalent to linearizability by static state feedback around that point. This result is stronger

than linearizability by endogenous feedback as indicated by Martin et al. [9, 18], since the latter only holds in an open and dense set. We also treat the case of time varying versus time invariant flat outputs and show that in the case of a single input time invariant system, the flat output can always be chosen time independent. In exterior differential systems, the special role of the time coordinate is expressed as an independence condition, i.e., a one-form that is not allowed to vanish on any of the solution curves. A fundamental problem with exterior differential systems is that most results only hold on open dense sets [15]. It requires extra effort to obtain results in the neighborhood of a point; see for example [21]. In this paper, too, we can only get local results by introducing regularity assumptions, typically in the form of rank conditions.

Recently, Fliess and coworkers have proposed a geometric framework using Lie–Bäcklund morphisms on infinite-dimensional jet spaces for studying flatness [10, 11]. In the latter paper Fliess and coworkers also introduce a more general notion of flatness called "orbital (or topological) flatness" where the transformations do not necessarily preserve the independent variable. Pomet has also proposed a related approach to differential flatness in [23]. Both approaches closely capture some features of the differential algebra while providing a geometric framework that enables local analysis. These approaches differ from ours in that they do not make extensive use of tools from exterior differential systems.

The organization of the paper is as follows. In section 2 we introduce the definitions pertaining to absolute equivalence and their interpretation in control theory. In section 3 we introduce our definition of differential flatness and show how to recover the differential algebraic results. In section 4 we study the connections between flatness and feedback linearizability. In section 5 we present our main theorems characterizing flatness for single input systems, and in section 6 we summarize our results and point out some open questions.

2. Prolongations and control theory. This section introduces the concept of prolongations and states some basic theorems. It relates these concepts to control theory. Proofs of most of these results can be found in [26]. We assume that all manifolds and mappings are smooth (C^∞) unless explicitly stated otherwise.

DEFINITION 2.1 (Pfaffian system). *A* Pfaffian system I *on a manifold* M *is a submodule of the module of differential one-forms* $\Omega^1(M)$ *over the commutative ring of smooth functions* $C^\infty(M)$. *A set of one-forms* $\omega^1, \dots, \omega^n$ *generates a Pfaffian system* $I = \{\omega^1, \dots, \omega^n\} = \{\Sigma f_k \omega^k | f_k \in C^\infty(M)\}$.

In this paper, we restrict attention to finitely generated Pfaffian systems on finite-dimensional manifolds. It is important to distinguish between a Pfaffian system and its set of generators or the algebraic ideal $\mathcal{I}$ in $\Lambda(M)$ generated by I. Since we are only dealing with Pfaffian systems the term *system* will henceforth mean a Pfaffian system.

For a Pfaffian system I we can define its *derived system* $I^{(1)}$ as $I^{(1)} = \{\omega \in I | d\omega \equiv 0 \bmod \mathcal{I}\}$, where $\mathcal{I}$ is the algebraic ideal generated by I. The derived system is itself a Pfaffian system, so we can define the sequence $I, I^{(1)}, I^{(2)}, \dots$, which is called the *derived flag* of I.

ASSUMPTION 1 (regularity of Pfaffian systems). *Unless stated explicitly otherwise, we will assume throughout this paper that the system is* regular*; i.e.,*

1. *the system and all its derived systems have constant rank;*
2. *for each* k, *the exterior differential system generated by* $I^{(k)}$ *has a degree-*2 *part with constant rank.*

If the system is regular the derived flag is decreasing, so there will be an N such that $I^{(N)} = I^{(N+1)}$. This $I^{(N)}$ is called the *bottom derived system.*

When one studies the system of one-forms corresponding to a system of differential equations, the independent variable time becomes just another coordinate on the manifold along with the dependent variables. Hence the notion of an independent variable is lost. If x denotes the dependent variables, a solution to such a system $c : s \to (t(s), x(s))$ is a curve on the manifold. But we are only interested in solution curves that correspond to graphs of functions $x(t)$. Hence we need to reject solutions for which $\frac{dt}{ds}$ vanishes at some point. This is done by introducing dt as an *independence condition*, i.e., a one-form that is not allowed to vanish on any of the solution curves. An independence condition is well defined only up to a nonvanishing multiple and modulo I. We will write a system with independence condition τ as (I, τ). The form τ is usually exact, but it does not have to be. In this paper we shall always take τ exact, in agreement with its physical interpretation as time.

DEFINITION 2.2 (control system). *A Pfaffian system with independence condition (I, dt) is called a* control system *if $\{I, dt\}$ is integrable.*

In local coordinates, control systems can be written in the form

$$I = \{dx_1 - f_1(x, u, t)dt, \ldots, dx_n - f_n(x, u, t)dt\} \tag{2.1}$$

with states $\{x_1, \ldots, x_n\}$ and inputs $\{u_1, \ldots, u_p\}$. Note that a control system is always assumed to have independence condition dt. If the functions f are independent of time then we speak of a *time invariant* control system.

DEFINITION 2.3 (Cartan prolongation). *Let (I, dt) be a Pfaffian system on a manifold M. Let B be a manifold such that $\pi : B \to M$ is a fiber bundle. A Pfaffian system $(J, \pi^* dt)$ on B is a* Cartan prolongation *of the system (I, dt) if the following conditions hold:*

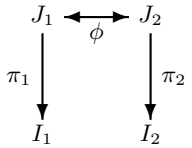
1. *$\pi^*(I) \subset J$;*
2. *for every integral curve of I, $c : (-\epsilon, \epsilon) \to M$, there is a unique lifted integral curve of J, $\tilde{c} : (-\epsilon, \epsilon) \to B$ with $\pi \circ \tilde{c} = c$.*

ASSUMPTION 2 (regularity of Cartan prolongations). *In this paper we only consider Cartan prolongations that preserve codimension.*

Note that all prolongations are required to preserve the independence condition of the original system. The above definition implies that there is a smooth one-to-one correspondence between the integral curves of a system and its Cartan prolongation. Cartan prolongations are useful to study equivalence between systems of differential equations that are defined on manifolds of different dimensions. This occurs in dynamic feedback extensions of control systems. We increase the dimension of the state by adding dynamic feedback, but the extended system is still in some sense equivalent to the original system.

This allows us to define the concept of absolute equivalence introduced by Elie Cartan as follows.

DEFINITION 2.4 (absolute equivalence). *Two systems I_1 and I_2 are* absolutely equivalent *if they have Cartan prolongations J_1 and J_2, respectively, that are equivalent in the usual sense; i.e., there exists a diffeomorphism ϕ such that $\phi^*(J_2) = J_1$. This is illustrated in the following diagram.*



An interesting subclass of Cartan prolongations is formed by *prolongations by differentiation*: if (I, dt) is a system with independence condition on M, if du is an exact one-form on M that is independent of $\{I, dt\}$, and if y is a fiber coordinate of B, then $\{I, du - ydt\}$ is called a *prolongation by differentiation* of I. Note that we have not written $\pi^*(du - ydt)$ where $\pi : B \to M$ is the surjective submersion. We will make this abuse in the rest of the paper for notational convenience. Prolongations by differentiation correspond to adding integrators to a system. In the context of control systems, the coordinate u is the input that is differentiated.

If we add integrators to all controls, we obtain a *total prolongation*: let (I, dt) be a system with independence condition, where $\dim\ I = n$. Let $\dim M = n + p + 1$. Let $u_1, \ldots, u_p$ be coordinates such that $du_1, \ldots, du_p$ are independent of $\{I, dt\}$, and let $y_1, \ldots, y_p$ be fiber coordinates of B; then $\{I, du_1 - y_1 dt, \ldots, du_p - y_p dt\}$ is called a *total prolongation* of I. Total prolongations can be defined independent of coordinates and are therefore intrinsic geometric objects. It can be shown that in codimension 2 (i.e., a system with n generators on an $n + 2$-dimensional manifold), all Cartan prolongations are locally equivalent to total prolongations [26].

We define a *dynamic feedback* to be a feedback of the form

$$\begin{aligned} \dot{z} &= a(x, z, v, t), \\ u &= b(x, z, v, t). \end{aligned}$$

If t does not appear in (a, b) we call (a, b) a *time invariant* dynamic feedback. The dynamic feedback is called *regular* if for each fixed x and t the map $b(x, ., ., t) : (z, v) \mapsto u$ is a submersion. An important question is what type of dynamic feedback corresponds to what type of prolongation. Clearly, prolongations by differentiation correspond to dynamic extension (adding integrators to the inputs).

Cartan prolongations provide an intrinsic, geometric way to study dynamic feedback. We shall show that Cartan prolongations that extend a control system to another control system can be expressed as dynamic feedback in local coordinates. The following example shows that not every dynamic feedback corresponds to a Cartan prolongation.

EXAMPLE 1 (dynamic feedback versus Cartan prolongation). *Consider the control system*

$$\dot{x}_1 = u$$

with feedback

$$\begin{aligned} \dot{z}_1 &= z_2, \\ \dot{z}_2 &= -z_1, \\ u &= g(z)v. \end{aligned}$$

This dynamic feedback introduces harmonic components that can be used to asymptotically stabilize nonholonomic systems (see [6] *for a description of how this might be done). It is not a Cartan prolongation since (z, v) cannot be uniquely determined from (x, u).*

The feedback in Example 1 is somewhat unusual, in that most theorems concerning dynamic feedback are restricted to adding some type of integrator to the inputs of the system. The particular property that this feedback is missing is defined in the following definition.

DEFINITION 2.5 (endogenous feedback). *Let $\dot{x} = f(x, u, t)$ be a control system.*

A dynamic feedback

$$\begin{aligned} \dot{z} &= a(x, z, v, t), \\ u &= b(x, z, v, t), \end{aligned} \tag{2.2}$$

is said to be endogenous *if z and v satisfying* (2.2) *can be expressed as functions of x, u, t, and a finite number of their derivatives*

$$\begin{aligned} z &= \alpha(x, u, \dots, u^{(l)}, t), \\ v &= \beta(x, u, \dots, u^{(l)}, t). \end{aligned} \tag{2.3}$$

An endogenous feedback is called regular *if for each fixed x and t the map $b(x, ., ., t) : (z, v) \mapsto u$ is a submersion.*

Note that this differs slightly from the definition given in [18, 19] due to the explicit time dependence used here. The feedback in Example 1 is not endogenous. The relationship between Cartan prolongations and endogenous dynamic feedback is given by the following two theorems. The first says that a regular endogenous feedback corresponds to a Cartan prolongation.

THEOREM 2.6 (endogenous feedback are Cartan prolongations). *Let I be a control system on an open set $T \times X \times U$ which in coordinates (t, x, u) is given by $\dot{x} = f(x, u, t)$. Let J denote the control system on the open set $T \times X \times Z \times V$ which is obtained from the above system by adding a regular endogenous dynamic feedback. Then J is a Cartan prolongation of I.*

Proof. Define the mapping $F : T \times X \times Z \times V \to T \times X \times U$ by $F(t, x, z, v) = (t, x, b(x, z, v, t))$. Since b is regular, F is a submersion. Furthermore b is surjective since the feedback is endogenous. Therefore F is surjective too. Since F is a surjective submersion, $T \times X \times Z \times V$ is fibered over $T \times X \times U$. Hence we have that solutions $(t, x(t), z(t), v(t))$ of J project down to solutions $(t, x(t), b(x(t), z(t), v(t), t))$ of I. Therefore the first requirement of being a Cartan prolongation is satisfied. The second requirement of unique lifting is trivially satisfied by the fact that z and v are obtained uniquely by equation (2.3). ∎

Conversely, a Cartan prolongation can be realized by endogenous dynamic feedback in an open and dense set if the resulting prolongation is a control system as described in Theorem 2.7.

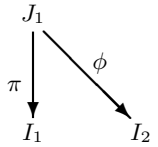
THEOREM 2.7 (Cartan prolongations are locally endogenous feedback). *Let I be a control system on a manifold M with p inputs $\{u_1, \dots, u_p\}$. Every Cartan prolongation $J = \{I, \omega_1, \dots, \omega_r\}$ on B with independence condition dt such that J is again a control system is realizable by endogenous regular feedback on an open and dense set of B.*

Proof. Let r denote the fiber dimension of B over M, and let $\{w_1, \dots, w_r\}$ denote the fiber coordinates. Since I is a control system, $\{I, dt\}$ is integrable, and we can find n first integrals $x_1, \dots, x_n$. Preservation of the codimension and integrability of $\{J, dt\}$ means that we can find r extra functions $a_1, \dots, a_r$ such that $J = \{I, dz_1 - a_1 dt, \dots, dz_r - a_r dt\}$. Here the z_i are first integrals of $\{J, dt\}$ that are not first integrals of $\{I, dt\}$. Pick p coordinates $v(u, w)$ such that $\{t, x, z, v\}$ form a set of coordinates of B. The v coordinates are the new control inputs. Clearly $a_i = a_i(x, z, v, t)$ since we have no other coordinates. Also since $\{t, x, z, v\}$ form coordinates for B, and u is defined on B, there has to be a function b such that $u = b(x, z, v, t)$. Since both (t, x, u, w) and (t, x, z, v) form coordinates on B, there has to be a diffeomorphism ϕ between the two. From the form of the matrix $\frac{\partial \phi}{\partial (t,x,z,v)}$ it can be seen that $\frac{\partial b}{\partial (z,v)}$ is full rank, and hence b is regular. This recovers the form of equation (2.2). Since J

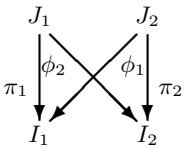
is a Cartan prolongation, every (x, u, t) is lifted to a unique (x, z, v, t). From Lemma 3.5, to be presented in the next section, it then follows that we can express (z, v) as functions of x and u and its derivatives in an open and dense set. We thus obtain the form of equation (2.3). □

3. Differentially flat systems. In this section we present a definition of flatness in terms of prolongations. Our goal is to establish a definition of flatness in terms of differential geometry while capturing the essential features of flatness in differential algebra [8, 9]. We build our definition on the minimal requirements needed to recover these features, namely, the one-to-one correspondence between solution curves of the original system and an unconstrained system, while maintaining regularity of the various mappings. Our definition makes use of the concept of an absolute morphism [26].

DEFINITION 3.1 (absolute morphism). *An* absolute morphism *from a system (I_1, dt) on M_1 to a system (I_2, dt) on M_2 consists of a Cartan prolongation (J_1, dt) on $\pi : B_1 \to M_1$ together with surjective submersion $\phi : B_1 \to M_2$ such that $\phi^*(I_2) \subset J_1$. This is illustrated below.*



DEFINITION 3.2 (invertibly absolutely morphic systems). *Two systems (I_1, dt) and (I_2, dt) are said to be* absolutely morphic *if there exist absolute morphisms from (I_1, dt) to (I_2, dt) and from (I_2, dt) to (I_1, dt). This is illustrated below.*



Two systems (I_1, dt) and (I_2, dt) are said to be invertibly absolutely morphic *if they are absolutely morphic and the following inversion property holds: let $c_1(t)$ be an integral curve of I_1 with $\tilde{c}_1$ the (unique) integral curve of J_1 such that $c_1 = \pi \circ \tilde{c}_1$, and let $\gamma(t) = \phi_2 \circ \tilde{c}_1(t)$ be the projection of $\tilde{c}_1$. Then we require that $c_1(t) = \phi_1 \circ \tilde{\gamma}(t)$, where $\tilde{\gamma}(t)$ is the lift of γ from I_2 to J_2. The same property must hold for solution curves of I_2.*

If two systems are invertibly absolutely morphic, then the integral curves of one system map to the integral curves of the other, and this process is invertible in the sense described above. If two systems are absolutely equivalent then they are also absolutely morphic, since they can both be prolonged to systems of the same dimension which are diffeomorphic to each other. However, for two systems to be absolutely morphic we do not require that any of the systems have the same dimension.

A differentially flat system is one in which the "flat outputs" completely specify the integral curves of the system. More precisely, we have Definition 3.3.

DEFINITION 3.3 (differential flatness). *A system (I, dt) is* differentially flat *if it is invertibly absolutely morphic to the trivial system $I_t = (\{0\}, dt)$.*

Notice that we require that the independence condition be preserved by the absolute morphisms, and hence our notion of time is the same for both systems. Since an independence condition is only well defined up to nonvanishing multiples and modulo

the system, we do allow time scalings between the systems. We also allow time to enter into the absolute morphisms that map one system onto the other.

If the system (I, dt) is defined on a manifold M, then we can restrict the system to a neighborhood around a point in M, which is again itself a manifold. We will call a system flat in that neighborhood if the restricted system is flat.

The following discussion leans heavily on a theorem due to Shadwick and Sluis [25] and Sluis [26], which we recall here for completeness.

THEOREM 3.4. *Let I be a system on a manifold M and let J be a Cartan prolongation of I on $\pi : B \to M$. On an open and dense subset of B, there exists a prolongation by differentiation of J that is also a prolongation by differentiation of I.*

Proof. For the proof see [26, Theorem 24]. ∎

In order to establish the relationship between our definition and the differential algebraic notion of flatness, we need the following straightforward corollary to Theorem 3.4. This lemma expresses the dependence of the fiber coordinates of a Cartan prolongation on the coordinates of the base space.

LEMMA 3.5. *Let (I, dt) be a system on a manifold M with local coordinates $(t, x) \in \mathbb{R}^1 \times \mathbb{R}^n$, and let (J, dt) be a Cartan prolongation on the manifold B with fiber coordinates $y \in \mathbb{R}^r$. Assume the regularity Assumptions 1 and 2 hold. Then on an open dense set, each y_i can be uniquely determined from t, x, and a finite number of derivatives of x.*

Proof. By Theorem 3.4 there is a prolongation by differentiation, on an open and dense set, say, I_2, of J, with fiber coordinates z_i, that is also a prolongation by differentiation of the original system I, say, with fiber coordinates w_i. This means that the (x, y, z, t) are diffeomorphic to (x, w, t): $y = y(x, w, t)$. The w are derivatives of x, and therefore the claim is proven. ∎

This lemma allows us to explicitly characterize differentially flat systems in a local coordinate chart. Let a system in local coordinates (t, x) be differentially flat, and let the corresponding trivial system have local coordinates (t, y). Then on an open and dense set there are surjective submersions h and g with the following property: given any curve $y(t)$, then

$$x(t) = g(t, y(t), \dots, y^{(q)}(t))$$

is a solution of the original system and furthermore the curve $y(t)$ can be obtained from $x(t)$ by

$$y(t) = h(t, x(t), \dots, x^{(l)}(t)).$$

This follows from using definitions of absolute morphisms, the invertibility property, and Lemma 3.5, stating that fiber coordinates are functions of base coordinates and their derivatives and the independent coordinate.

This local characterization of differential flatness corresponds to the differential algebraic definition except that h and g need not be algebraic or meromorphic. Also, we do not require the system equations to be algebraic or meromorphic. The explicit time dependence corresponds to the differential algebraic setting where the differential ground field is a field of functions and is not merely a field of constants. The functions g and h now being surjective submersions enable us to link the concept of flatness to geometric nonlinear control theory where we usually impose regularity. We emphasize that we only required a one-to-one correspondence of solution curves a priori for our definition of flatness, and not that this dependence was in the form of derivatives. The particular form of this dependence followed from our analysis.

Finally, the following theorem allows us to characterize the notion of flatness in terms of absolute equivalence.

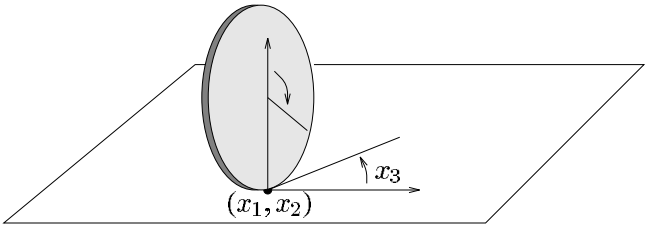


FIG. 3.1. *Rolling penny.*

THEOREM 3.6. *Two systems are invertibly absolutely morphic if and only if they are absolutely equivalent.*

Proof. Sufficiency is trivial. We shall prove necessity. For convenience we shall not mention independence conditions, but they are assumed to be present and do not affect the proof. Let I_1 on M_1 and I_2 on M_2 be invertibly absolutely morphic. Let J_1 on B_1 be the prolongation of I_1 with $\pi_1 : B_1 \to M_1$ and similarly J_2 on B_2 be the prolongation of I_2 with $\pi_2 : B_2 \to M_2$. Let the absolute morphisms be $\phi_1 : B_2 \to M_1$ and $\phi_2 : B_1 \to M_2$.

We now argue that J_2 is a Cartan prolongation of I_1 (and hence I_1 and I_2 are absolutely equivalent). By assumption ϕ_1 is a surjective submersion, and every solution $\tilde{c}_2$ of J_2 projects down to a solution c_1 of I_1 on M_1. The only extra requirement for J_2 on $\phi_1 : B_2 \to M_1$ to be a (Cartan) prolongation is that every solution c_1 of I_1 has a unique lift $\tilde{c}_2$ (on B_2) which is a solution of J_2.

To show existence of a lift, observe that for any given c_1 that is a solution of I_1, we can obtain its unique lift $\tilde{c}_1$ on B_1 (which solves J_1) and get its projection c_2 on M_2 (which solves I_2) and then consider its unique lift $\tilde{c}_2$ on B_2. Now it follows from the invertibility property that $\phi_1 \circ \tilde{c}_2 = c_1$. In other words, $\tilde{c}_2$ projects down to c_1.

To see the uniqueness of this lift, suppose $\tilde{c}_2$ and $\tilde{c}_3$, which are solutions of J_2 on B_2, both project down to c_1 on M_1. Consider their projections c_2 and c_3 (respectively) on M_2. When we lift c_2 or c_3 to B_2 and project down to M_1 we get c_1, which when lifted to B_1 gives, say, $\tilde{c}_1$. By the requirement that the absolute morphisms be invertible, $\tilde{c}_1$ should project down to (via ϕ_2) c_2 as well as c_3. Then uniqueness of projection implies that c_2 and c_3 are the same, which implies $\tilde{c}_2$ and $\tilde{c}_3$ are the same.

Hence J_2 is a Cartan prolongation of I_1 as well. Hence I_1 and I_2 are absolutely equivalent. □

Using this theorem we can completely characterize differential flatness in terms of absolute equivalence as follows.

COROLLARY 3.7. *A system (I, dt) is differentially flat if and only if it is absolutely equivalent to the trivial system $I_t = (\{0\}, dt)$.*

Note that we require the feedback equivalence to preserve time, since both systems have the same independence condition. In the classical feedback equivalence we only consider diffeomorphisms of the form $(t, x, u) \mapsto (t, \phi(x), \psi(x, u))$. For flatness we allow diffeomorphisms of the form $(t, x, u) \mapsto (t, \phi(t, x, u), \psi(t, x, u))$. We could allow time scalings of the form $t \mapsto s(t)$, but this does not change the independence condition and does therefore not gain any generality. In Cartan's notion of equivalence all diffeomorphisms are completely general. This is akin to the notion of *orbital* flatness presented in [10], where one allows time scalings dependent on all states and inputs.

EXAMPLE 2. *Consider the motion of a rolling penny, as shown in Figure* 3.1. *Let (x_1, x_2) represent the xy position of the penny on the plane, let x_3 represent the heading angle of the penny relative to a fixed line on the plane, and let x_4 represent*

the rotational velocity of the angle of Lincoln's head, i.e., the rolling velocity. We restrict $x_3 \in [0, \pi)$ *since we cannot distinguish between a positive rolling velocity* x_4 *at a heading angle* x_3 *and a negative rolling velocity at a heading angle* $x_3 + \pi$.

The dynamics of the penny can be written as a Pfaffian system described by

$$\begin{aligned} \omega^1 &= \sin x_3\, dx_1 - \cos x_3\, dx_2, \\ \omega^2 &= \cos x_3\, dx_1 + \sin x_3\, dx_2 - x_4 dt, \\ \omega^3 &= dx_3 - x_5 dt, \\ \omega^4 &= dx_4 - u_1 dt, \\ \omega^5 &= dx_5 - u_2 dt, \end{aligned} \tag{3.1}$$

where $x_5 = \dot{x}_3$ *is the velocity of the heading angle. The controls* u_1 *and* u_2 *correspond to the torques around the rolling and heading axes. We take* dt *as the independence condition.*

This system is differentially flat away from $x_4 = 0$ *using the outputs* x_1 *and* x_2 *plus knowledge of time. If* dx_1 *and* dx_2 *are not both zero, we can solve for* x_3 *using* ω_1. *Given these three variables plus time, we can solve for all other variables in the system by differentiation with respect to time. This argument also shows that the system is differentially flat, since we only need to know* (x_1, x_2) *and their derivatives up to order three in order to solve for all of the states of the system.*

Often we will be interested in a more restricted form of flatness that eliminates the explicit appearance of time that appears in the general definition.

DEFINITION 3.8. *An absolute morphism from a time invariant control system* (I_1, dt) *to a time invariant control system* (I_2, dt) *is a* time-independent absolute morphism *if locally the maps* $\pi : B_1 \to M_1$ *and* $\phi : B_1 \to M_2$ *in Definition* 3.1 *have the form* $(t, x, u) \mapsto (t, \eta(x, u), \psi(x, u))$*; i.e., the mappings between states and inputs do not depend on time. A system* (I, dt) *is* time-independent differentially flat *if it is differentially flat using time-independent absolute morphisms.*

Note that Example 2 is time-independent differentially flat. We may be tempted to think that if the control system I is time invariant and we know that the trivial system is time invariant, we can assume that the absolute morphism $x = \phi(t, y, y^{(1)}, \ldots, y^{(q)})$ has to be time independent as well. That this is not true is illustrated by the following example.

EXAMPLE 3. *Consider the system* $\dot{y} = ay$ *and the coordinate transformation* $y = x^2 e^{t+x}$. *Then* $\dot{x} = \frac{(a-1)x}{2+x}$. *Both systems are time invariant, but the coordinate transformation depends on time.*

4. Linear systems and linearizability. Conforming to the established literature [2], we define a *linear time-invariant* system as a system of the form

$$\begin{aligned} \dot{x} &= Ax + Bu, \\ y &= Cx + Du. \end{aligned} \tag{4.1}$$

Here (A, B, C, D) are matrices of appropriate dimensions. If the system is controllable, we can put it in *Brunovsky* normal form by a linear coordinate transformation on the states and a static feedback. A system is in Brunovsky normal form if we can write the dynamics as

$$z_i^{(l_i)} = u_i \tag{4.2}$$

for some new outputs z_i.

DEFINITION 4.1 (feedback linearizability). *The time invariant nonlinear system*

$$\dot{x} = f(x, u) \tag{4.3}$$

is feedback linearizable *if there is a* regular endogenous *dynamic feedback*

$$\begin{aligned} \dot{z} &= \alpha(x, z, v), \\ u &= \beta(x, z, v), \end{aligned} \tag{4.4}$$

and new coordinates $\xi = \phi(x, z)$ *and* $\eta = \psi(x, z, v)$ *such that in the new coordinates the system has the form*

$$\dot{\xi} = A\xi + B\eta \tag{4.5}$$

and the mapping ϕ *maps onto a neighborhood of the origin. If* $\dim z = 0$ *then we say the system is* static *feedback linearizable.*

REMARK 1. *It may seem overly restrictive to require the feedback* (4.4) *to be regular endogenous. It is however common practice to impose regularity on the feedback* (*see Definition* 6.1 *in* [22])*, and it avoids anomalies like setting inputs equal to a constant.*

The form in equation (4.5) is the standard form in linear systems theory. It is useful if one wants to design controllers for nonlinear systems around equilibrium points.

It might be that the system can be put in the form (4.5) but that the coordinate transformation is not valid in a neighborhood of the origin of the target system. In that case we can shift the origin of the linear system to put it in the form

$$\dot{\xi} = A\xi + B\eta + E. \tag{4.6}$$

This form is called linear in [20], but most results in linear systems theory cannot be applied since the origin is not an equilibrium point. However, it is still useful in the context of trajectory generation. For example, a nonholonomic system in chained form [21] can be transformed to this state space affine form.

It is clear that systems that are feedback linearizable (by regular endogenous feedback) are flat, since we can put them into Brunovsky normal form. The following theorem shows that the converse is also true in an open and dense subset. An analogous result was proven by Martin in a differential algebraic setting [18, 19] and has also been derived using the formalism of Lie–Bäcklund transformations [10, 11].

THEOREM 4.2. *Every differentially flat system can be put in Brunovsky normal form in an open and dense set through regular endogenous feedback.*

Proof. Let J, J_t be the Cartan prolongations of I, I_t, respectively. Then by Theorem 3.4, on an open and dense set there is a prolongation by differentiation of J_t that is also a prolongation by differentiation of I_t, say, J_{t1}. Let J_1 be the corresponding Cartan prolongation of J. Then J_1 is equivalent to J_{t1}, which is in Brunovsky normal form. In particular, since J_1 is a Cartan prolongation, it can be realized by regular endogenous feedback. □

This proof relies on Theorem 3.4, which restricts its validity to an open and dense set. We conjecture that the result holds everywhere, but the above proof technique does not allow us to conclude that. The obstruction lies in certain prolongations that we cannot prove to be regular.

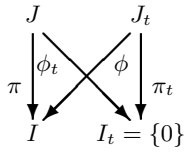
5. Flatness for single input systems. For single input control systems, the corresponding differential system has codimension 2. There are a number of results available in codimension 2 that allow us to give a complete characterization of differentially flat single input control systems. In codimension 2 every Cartan prolongation is a total prolongation around every point of the fibered manifold [26], given our regularity assumptions 1, 2. This allows us to prove the following theorem.

THEOREM 5.1. *Let I be a time invariant control system*

$$I = \{dx_1 - f_1(x,u)dt, \ldots, dx_n - f_n(x,u)dt\},$$

where u is a scalar control; i.e., the system has codimension 2. If I is time-independent differentially flat around an equilibrium point, then I is feedback linearizable by static time invariant feedback at that equilibrium point.

Proof. Let I be defined on M with coordinates (x,u,t), let the trivial system I_t be defined on B_t with coordinates (y_0,t), let the prolongation of I_t be J_t, and let J_t be defined on M_t. This is illustrated below.



First we show that J_t can be taken as a Goursat normal form around the equilibrium point. In codimension 2, every Cartan prolongation is a repeated total prolongation in a neighborhood of every point of the fibered manifold [26, Theorem 5]. Let $I_{t0} = I_t, I_{t1}, I_{t2}, \ldots$ denote the total prolongations starting at I_t, defined on fibered manifolds $B_{t0} = B_t, B_{t1}, \ldots$. If y_1 denotes the fiber coordinate of B_{t1} over B_{t0}, then I_{t1} has the form $\lambda dt + \mu dy_0$, where either λ or μ depends nontrivially on y_1. Since the last derived system of I does not drop rank at the equilibrium, neither does I_{t1} and we have that not both λ and μ vanish at the equilibrium. Now, $\mu \neq 0$ at the equilibrium point. This can be seen as follows: $y_0 \equiv c$ is a solution curve to I_t, and would not have a lift to I_{t1} if $\mu = 0$, since dt is required to remain the independence condition of all Cartan prolongations. From continuity we then have $\mu \neq 0$ around the equilibrium point. So we can define $y_1 := -\lambda/\mu$, and I_{t1} can be written as $dy_0 - y_1 dt$. We can continue this process for every Cartan prolongation, both of I_t and of I. This brings J_t in Goursat normal form in a neighborhood of the equilibrium point.

Now we will argue that we don't need to prolong I to establish equivalence. Since J is a Cartan prolongation, and therefore a total prolongation, its first derived system will be equivalent to the first derived system of J_t. Continuing this we establish equivalence between I and I_{tn}, where $I_{tn} = \{dy_0 - y_1 dt, \ldots, dy_{n-1} - y_n dt\}$. So we have $y = (y_0, \ldots, y_n) = y(x,u,t)$.

Next we will show that $y_0, \ldots, y_n$ are independent of time and that $y_0, \ldots, y_{n-1}$ are independent of u. By assumption y_0 is independent of time. Since the corresponding derived systems on each side are equivalent, $dy_0 - y_1 dt$ is equivalent to the last one-form in the derived flag of I. Since the differential du does not appear in this one-form, y_0 is independent of u. Analogously, $y_i, i = 1, \ldots, n-1$ are all independent of u. Since the $y_i, i = 1, \ldots, n$ are repeated derivatives of y_0, and since I is time invariant, these coordinates are also independent of time.

We still have to show that the mapping $x \mapsto y$ is a valid coordinate transformation. Suppose $dy_0, \ldots, dy_{n-1}$ are linearly dependent at the equilibrium. Then, J_t drops rank at the equilibrium, and since we have equivalence, so would I. But from the form of I we can see this is not the case.

Therefore $y_i = y_i(x), i = 0, \ldots, n-1, y_n = y_n(x,u)$ and the system J_t is just a chain of integrators with input y_n. The original system I is equivalent to this linear system by a coordinate transformation on the states and a state dependent and time invariant feedback. This coordinate transformation is well defined around the equilibrium point. It is therefore feedback linearizable by a static feedback that is

time invariant. Note that $\partial y_n/\partial u \neq 0$ because y_n is the only one of the y variables that depends on u. □

The conclusion that the feedback can be taken static goes back to [5, 23].

EXAMPLE 4. *Notice that in our definition the system*

$$\begin{aligned} \dot{x}_2 &= u, \\ \dot{x}_1 &= x_2^3, \\ y &= x_1, \end{aligned} \tag{5.1}$$

is not flat around the origin, because we get $u = \frac{\ddot{y}}{3\,\dot{y}^{2/3}}$ *so that curves with* $\dot{y} = 0$ *and* $\ddot{y} \neq 0$ *have no lift. It is also not feedback linearizable at the origin.*

We will now show that in the case of a time invariant system we don't need the assumption of time invariant flatness to conclude static feedback linearizability. We will require the following preliminary result, which appeared in a proof in [24].

LEMMA 5.2. *Given a one-form* $\alpha = A_i(x,u)dx_i - A_0(x,u)dt$ *(using implicit summation) on a manifold* M *with coordinates* (x,u,t)*, and suppose we can write* $\alpha = dX(x,u,t) - U(x,u,t)dt$*. Then we can also write* α *as* $\alpha = dY(x) - V(x,u)dt$*; i.e., we can take the function* X *independent of time and the input, and we can take* U *independent of time. If we know in addition that* $\alpha = A_i(x)dx_i - A_0(x)dt$*, then we can scale* α *as* $\alpha = dY(x) - V(x)dt$*; i.e., we can take* V *independent of* u *as well.*

Proof. For the proof see [24]. □

The following theorem seems to be implied in [24], but the proof there refers to a general discussion of Cartan's method of equivalence as applied to control systems in [13]. We work out the proof for this special case.

THEOREM 5.3. *A controllable single input time invariant control system is differentially flat if and only if it is feedback linearizable by static, time invariant feedback.*

Proof. The proof of sufficiency follows trivially from controllability, so we shall only prove necessity. Let the control system be $I = \{dx_1 - f_1(x,u)dt, \ldots, dx_n - f_n(x,u)dt\}$, where u is a scalar control; i.e., the system has codimension 2. Let $\{\alpha^i, i = 1,\ldots,n\}$ and $\{\alpha_t^i, i = 1,\ldots,n\}$ be one-forms adapted to the derived flag of I, I_t, respectively. Thus $I^{(i)} = \{\alpha^1, \ldots, \alpha^{n-i}\}$ and $I_t^{(i)} = \{\alpha_t^1, \ldots, \alpha_t^{n-i}\}$. Since I does not contain the differential du, the forms $\alpha^1, \ldots, \alpha^{n-1}$ can be taken to be independent of u. Since I is time invariant, the forms $\alpha_1, \ldots, \alpha_n$ can be chosen to be independent of time. We can thus invoke the second part of Lemma 5.2 for the forms $\alpha^1, \ldots, \alpha^{n-1}$.

Assume $n \geq 2$. As in Theorem 5.1 we have equivalence between α^1 and $\alpha_t^1 = dy_0(x,t) - y_1(x,t)dt$ (if $n = 1$ we have $y_n = y_n(x,u,t)$, which we will reach eventually). Since I is time invariant we can choose α^1 time independent: $\alpha^1 = A_i(x)dx_i - A_0(x)dt$. From Lemma 5.2 we know that we can write α^1 as $dY_0 - Y_1 dt$ where Y_0, Y_1 are functions of x only.

Again according to Lemma 5.2, we can write $\alpha^2 = dV(x) - W(x)dt$. Now from

$$\begin{aligned} 0 &= d\alpha^1 \wedge \alpha^1 \wedge \alpha^2 \\ &= -dY_1 \wedge dt \wedge dY_0 \wedge dV \end{aligned}$$

we know $V = V(Y_1, Y_0)$. And from

$$\begin{aligned} 0 &\neq d\alpha^2 \wedge \alpha^1 \wedge \alpha^2 \\ &= -dW \wedge dt \wedge dY_0 \wedge dV \end{aligned}$$

we know that $\gamma_1 := \partial V/\partial Y_1 \neq 0$. Then writing $\gamma_0 := \partial V/\partial Y_0$ (and $\simeq$ denotes

equivalence in the sense that both systems generate the same ideal),

$$\begin{aligned}\{\alpha^1, \alpha^2\} &\simeq \{dY_0 - Y_1 dt, \gamma_1 dY_1 + \gamma_0 dY_0 - W dt\} \\ &\simeq \{dY_0 - Y_1 dt, \gamma_1 dY_1 + \gamma_0 Y_1 dt - W dt\} \\ &\simeq \{dY_0 - Y_1 dt, dY_1 - (-\gamma_0 Y_1 + W)/\gamma_1 dt\} \\ &:= \{dY_0 - Y_1 dt, dY_1 - Y_2 dt\}, \end{aligned} \tag{5.2}$$

where Y_2, defined to be $Y_2 = (-\gamma_0 Y_1 + W)/\gamma_1$, is independent of (t, u) since $(\gamma_1, \gamma_0, Y_1, W)$ are. One can continue this procedure, at each step defining a new coordinate Y_i. In the last step the variable $W = W(x, u)$ (this will also be the first step if $n = 1$), and therefore Y_n depends on u nontrivially. Hence we obtain equivalence between I and $\{dY_0 - Y_1 dt, \ldots, dY_{n-1} - Y_n dt\}$ with $Y_i = Y_i(x), i = 0, \ldots, n-1$, and $Y_n = Y_n(x, u)$, i.e., feedback linearizability by static time invariant feedback. □

COROLLARY 5.4. *If a time invariant single input system is differentially flat we can always take the flat output as a function of the states only: $y = y(x)$.*

None of these results extend easily to higher codimensions. The reason for this is that only in codimension 2 can we find regularity assumptions on the original system such that every Cartan prolongation is a total prolongation. This is related to the well-known fact that for SISO systems static linearizability is equivalent to dynamic linearizability. For MIMO systems we cannot express these regularity conditions on the original system: we have to check regularity on the prolonged systems.

6. Concluding remarks. We have presented a definition of flatness in terms of the language of exterior differential systems and prolongations. Our definition remains close to the original definition due to Fliess [8, 9], but it involves the notion of a preferred coordinate corresponding to the independent variable (usually time).

Using this framework we were able to recover all results in the differential algebra formulation. In particular we showed that flat systems can be put in linear form in an open and dense set. This set need not contain an equilibrium point, and this linearizability therefore does not allow one to use most methods from linear systems theory. In other words, although flatness implies a linear *form*, it does not necessarily imply a linear *structure*. For a SISO flat system we resolved the regularity issue and established feedback linearizability around an equilibrium point. We also resolved the time dependence of flat outputs in the SISO case.

The most important open question is a characterization of flatness in codimension higher than 2.

Acknowledgments. The authors would like to thank Willem Sluis for many fruitful and inspiring discussions and for introducing us to Cartan's work and its applications to control theory. We also thank Shankar Sastry for valuable comments on this paper, and Philippe Martin for several useful discussions which led to a more complete understanding of the relationship between endogenous feedback and differential flatness. The reviewers provided many valuable comments which helped improve several specific results and the overall presentation.

GLOBAL ERROR BOUNDS FOR CONVEX INEQUALITY SYSTEMS IN BANACH SPACES*

SIEN DENG†

Abstract. We study conditions under which a global error bound in terms of a natural residual exists for a convex inequality system. Specifically, we obtain an error bound result, which unifies many existing results assuming a Slater condition. We also derive two characterizations for a convex inequality system to possess a global error bound; one is in terms of metric regularity, and the other is in terms of an associated convex inequality system. As a consequence, we show that in $\mathbb{R}^n$ a global error bound holds for such a system under the assumption of the zero vector in the relative interior of the domain of an associated conjugate function along with metric regularity at every point of the feasible set defined by the system. Finally, we discuss some applications of these results to convex programs.

Key words. error bounds, metric regularity, relative interior, Hausdorff distance, weak sharp minima

1. Introduction.

This paper deals with the convex inequality system

$$f(x) \le 0, \quad x \in C \subset X, \tag{1}$$

where X is a Banach space, C is a nonempty closed convex set, and f is a continuous convex function on X. Let S be the set of solutions to (1). We assume throughout that S is nonempty. In this paper, we are interested in knowing conditions under which the following global error bound holds for S: there is a positive constant τ such that

$$d(x, S) \le \tau [f(x)]_+ \quad \text{for all } x \in C, \tag{2}$$

where $d(x, S) = \inf_{y \in S} \|x - y\|$, $[f(x)]_+ = \max\{f(x), 0\}$, and $\|\cdot\|$ denotes the norm on X. When $X = \mathbb{R}^n$, $\|\cdot\|$ denotes the usual Euclidean norm on $\mathbb{R}^n$.

Error bounds in the form of (2), which are expressed in terms of a constant multiple of a natural residual, have found many important applications in sensitivity analysis of convex programs and complementarity problems, and in the convergence analysis of some descent methods. See [21, 24, 25, 26, 28, 5] for more details.

The Slater condition, which postulates the existence of an $x_0 \in C$ such that $f(x_0) < 0$, plays an important role in establishing the global error bound (2). In a normed linear space setting, Robinson [29] proved that (2) holds when S is bounded and (1) satisfies the Slater condition. In a finite-dimensional space setting, Mangasarian [23] established (2) when f is a pointwise maximum of finitely many convex differentiable functions, and (1) satisfies the Slater condition and an asymptotic constraint qualification. Auslender and Crouzeix [1] extended Mangasarian's result by relaxing the differentiability assumptions. Luo and Luo [19] established (2) for convex quadratic systems under the Slater condition. In a Banach space setting, Deng [6]

established (2) under a Slater condition on the associated recession functions. Klatte [13, 14] established (2) under certain Hausdorff continuity assumptions. Li [17] derived an interesting characterization of metric regularity of a convex differentiable inequality system in terms of the Abadie constraint qualification and showed that the Abadie constraint qualification holding at every point of S is a necessary and sufficient condition for (2) to hold when f is a pointwise maximum of finitely many convex quadratic functions. A very recent paper of Lewis and Pang [15] gives an excellent survey on this active research area. By establishing an interesting necessary and sufficient condition involving directional derivatives first, Lewis and Pang [15] derived many interesting results. For other related error bound results, see [3, 8, 9, 12, 16, 20, 22, 27, 32] and references therein.

The purpose of this note is twofold. First, we establish an error bound result involving level set conditions of associated functions. This result unifies and extends many existing results assuming a Slater condition. Second, we derive two characterizations for the existence of the global error bound (2). This part of the research is partly motivated by the recent work of Li [17]. In a Banach space setting, we show that the global error bound (2) holds if and only if (1) is metrically regular at S; see section 2.2 for the definition of metric regularity at a set. When $X = \mathbb{R}^n$ and the affine hull of the domain of the conjugate function f^* is a proper subset of $\mathbb{R}^n$, we obtain another characterization by relating (1) to an associated system. We show that the existence of the global error bound (2) for (1) is equivalent to that for the associated system. As a consequence, we show that (2) holds when the zero vector is in the relative interior of the domain of the conjugate function f^* and (1) is metrically regular at every point of S (see section 2.2 for more details). In section 3, by applying the aforementioned results, we obtain some sufficient conditions for weak sharp minima of convex programs. Our results are complementary to the work done by Lewis and Pang [15] and Li [17].

We now describe the notation and some of the basic concepts used in this paper.

For a nonempty convex set U in $\mathbb{R}^n$, we denote by int (U), ri (U), aff (U), and cl (U), the interior of U, the relative interior of U, the affine hull of U, and the closure of U, respectively. For a nonempty closed convex set U in X, we denote by U^∞ the recession cone of U. For any two nonempty closed sets U_1 and U_2 in X, we define the Hausdorff distance between them as

$$\text{haus}\,(U_1, U_2) = \max\left\{\sup_{x\in U_1} d(x, U_2), \sup_{x\in U_2} d(x, U_1)\right\}.$$

A closed proper convex function g on X is an everywhere defined function with values in $(-\infty, +\infty]$, not identically $+\infty$, such that epi g is a closed convex set in $X \times \mathbb{R}$, where epi g denotes the epigraph of g. Its *effective* domain is the nonempty convex set

$$\text{dom}\, g = \{x \in X \mid g(x) < +\infty\}.$$

For a closed proper convex function g, we denote by $\partial g(x)$, g^*, and g^∞ the subdifferential of g at x $(\in \text{dom}\, g)$, the conjugate function of g, and the recession function of g, respectively.

2. Main results. We study the existence of the global error bound (2). Section 2.1 deals with the case where the Slater condition is satisfied. Section 2.2 deals with the case without such an assumption.

2.1. A level set condition result. We begin with an error bound result assuming certain level set conditions on f for the system (1).

PROPOSITION 1. *Suppose that X is a Banach space, C is a nonempty closed convex set in X, f is continuous and convex on X, and $S = \{x \in C \mid f(x) \le 0\}$. Suppose that there are positive scalars δ and Δ such that*

(a) $\tilde{S} = \{x \in C \mid f(x) \le -\delta\}$ *is nonempty, and*

(b) haus $(\tilde{S}, S) \le \Delta$.

Then

$$d(x, S) \le \delta^{-1}\Delta[f(x)]_+ \qquad \text{for all } x \in C.$$

Before proving Proposition 1, we would like to point out that conditions (a) and (b) hold whenever S is nonempty and bounded, and the system $f(x) \le 0$ satisfies the Slater condition. Moreover, when S is bounded, Δ can be chosen as the diameter of S. Thus Proposition 1 extends Robinson's result [29] in this setting. The proof technique is a refinement of that used in [29].

Proof. We only have to show that (2) holds for any $x \in C$, but $x \notin S$. Given $x \notin S$ and $x \in C$, since the projection of x onto S may not exist, we have to use a limit argument. For any $n > 0$, there is some $y(n) \in \tilde{S}$ such that

$$\|x - y(n)\| \le d(x, \tilde{S}) + 1/n.$$

By a similar argument, the distance between x and $\tilde{S}$ can be bounded by $d(x, S) + \Delta + 1/n$; that is,

$$d(x, \tilde{S}) \le d(x, S) + \Delta + 1/n.$$

Consequently,

$$\|x - y(n)\| \le d(x, S) + \Delta + 2/n. \tag{3}$$

With this given $y(n)$, let

$$x - z(n) = f(x)(f(x) + \delta)^{-1}(x - y(n)). \tag{4}$$

Then $z(n) \in S$ by the convexity of f and C. Since

$$\|x - y(n)\| = \|x - z(n)\| + \|z(n) - y(n)\|, \quad \text{and } d(x, S) \le \|z(n) - x\|, \tag{5}$$

it follows that

$$\begin{aligned} \|z(n) - y(n)\| &= \|x - y(n)\| - \|z(n) - x\| \\ &\le d(x, S) + \Delta + 2/n - d(x, S) \qquad \text{(by (3) and (5))} \\ &\le \Delta + 2/n. \end{aligned} \tag{6}$$

By (4), $\delta(x - z(n)) = f(x)[(x - y(n)) - (x - z(n))]$. Therefore,

$$\begin{aligned} d(x, S) &\le \|x - z(n)\| \\ &\le \delta^{-1} f(x)\|y(n) - z(n)\| \\ &\le \delta^{-1}(\Delta + 2/n)[f(x)]_+ \qquad \text{(by (6))}. \end{aligned}$$

By letting $n \to +\infty$, we obtain the desired inequality. ∎

Remarks. In an early version of this paper, the above result was proved under the assumption that the Banach space X is reflexive. A suggestion of J. Burke led to the present formulation and its proof.

Many known global error bounds assuming the Slater condition can be derived from Proposition 1. By invoking Proposition 1, we can prove the following corollaries. Corollary 1 can be used to show that the global error bound (2) holds for S when $C = X = \mathbb{R}^n$, f is well-posed, and (1) satisfies the Slater condition. Recall [1, 15] that f is well posed if every stationary sequence of f is a minimizing sequence; that is,

$$\left[\lim_{k\to\infty} u^k = 0,\ u^k \in \partial f(x^k), \forall k\right] \Rightarrow \left[\ \lim_{k\to\infty} f(x^k) = \inf_{x\in X} f(x)\right].$$

COROLLARY 1. *For the system* (1)*, suppose that X is a Banach space, C is a nonempty closed convex set in X, S is nonempty, and the global error bound* (2) *holds. Then, for any $\lambda > 0$,*

$$d(x, S_\lambda) \le \tau[f(x) - \lambda]_+ \qquad \text{for all } x \in C,$$

where $S_\lambda = \{x \in C \mid f(x) \le \lambda\}$ and τ is the multiplicative constant in (2).

COROLLARY 2 (see [6]). *Suppose that X is a Banach space, C is a nonempty closed convex set in X, and there is a unit vector $u \in C^\infty$ such that $f^\infty(u) \le -\tau^{-1}$. Then*

$$d\,(x, S) \le \tau[f(x)]_+ \qquad \text{for all } x \in C.$$

Proof. We only need to show that conditions (a) and (b) in Proposition 1 hold with haus $(\tilde{S}, S) \le \tau$, where $\tilde{S} = \{x \in C \mid f(x) \le -1\}$. For any $x \in S$, since

$$f(x + \tau u) \le f(x + \tau u) - f(x) \le \tau f^\infty(u) \le -1,$$

haus $(\tilde{S}, S) \le \tau$ follows from the fact that $x + \tau u \in \tilde{S}$. □

As a referee noted, a direct proof of Corollary 2 can be given by using the inequality $f(x + \lambda u) \le f(x) - \tau^{-1}\lambda$ $(\forall x,\ \lambda \ge 0)$ and putting $\lambda = \tau f(x)$ for $x \in C \backslash S$.

COROLLARY 3. *Suppose that $C = X = \mathbb{R}^n$. Let F be a vector-valued mapping from $\mathbb{R}^n$ to $\mathbb{R}^m$ with each component of F a finite convex function. Let $S = \{x \mid F(x) \le 0\}$. Suppose that there is a vector $b \in -\text{int}\,(\mathbb{R}^m_+)$ and a positive scalar $\tilde{\Delta}$ such that*

(a) $\tilde{S} = \{x \mid F(x) \le b\}$ *is nonempty, and*

(b) haus $(\tilde{S}, S) \le \tilde{\Delta}$.

Then

$$d(z, S) \le \tilde{\delta}^{-1}\tilde{\Delta}\|[F(z)]_+\|_\infty \qquad \text{for all } z \in \mathbb{R}^n,$$

where $\tilde{\delta} = \min_{1\le i\le m}\{-b_i\}$ and b_i is the ith component of b, and $\|\cdot\|_\infty$ denotes the ∞-norm on $\mathbb{R}^m$.

Proof. Let $f(x) = \max_{1\le i\le m}\{f_i(x)\}$, where f_i are components of F for $1 \le i \le m$. Clearly $\{x \mid f(x) \le 0\} = S$. Since $-\tilde{\delta} = -\min_{1\le i\le m}\{-b_i\} = \max_{1\le i\le m}\{b_i\}$, it follows that, for any $x \in X$, $f(x) \le -\tilde{\delta}$ whenever $f_i(x) \le b_i$ for all $1 \le i \le m$. That is, $\bar{S} = \{x \mid f(x) \le -\tilde{\delta}\} \supset \tilde{S}$. Consequently, haus $(\bar{S}, S) \le$ haus $(\tilde{S}, S) \le \tilde{\Delta}$. Thus the system $f(x) \le 0$ satisfies conditions (a) and (b) in Proposition 1. Therefore

$$d(z, S) \le \tilde{\delta}^{-1}\tilde{\Delta}[f(z)]_+ = \tilde{\delta}^{-1}\tilde{\Delta}\|[F(z)]_+\|_\infty \qquad \text{for all } z \in \mathbb{R}^n. \qquad \square$$

The following example illustrates an application of Proposition 1.

Example 1. Let $X = \mathbb{R}^2$, and let $P = \left\{ (x_1, x_2) \in \mathbb{R}^2 \mid x_2 \geq x_1^2 \right\}$. Consider $f(x) = (d(x,P))^2 - 1$, where $d(x,P)$ is the Euclidean distance from a point $x \in \mathbb{R}^2$ to the set P. Let $S = \{x \,|\, f(x) \leq 0\}$. Since $(d(x,P))^2$ is the inf-convolution of $\|\cdot\|^2$ and $\delta_P(\cdot)$, it is easy to see that $f^*(x^*) = 1/4\|x^*\|^2 + \sigma_P(x^*) + 1$ (Theorem 12.3 of [30]), where σ_P is the support function of P. Consequently, dom f^* = dom σ_P. Clearly, S is unbounded, and Robinson's result [29] is not applicable. It is evident that $\{x \,|\, f(x) \leq -1\} = P$. An easy computation shows that

$$\text{haus}(P, S) = 1.$$

By Proposition 1, we have

$$d(z, S) \leq [f(z)]_+ \qquad \text{for all } z \in \mathbb{R}^2.$$

2.2. Metric regularity and global error bounds. For simplicity, throughout the rest of the paper we assume that $C = X$.

The study of error bounds of (1) is closely related to that of metric regularity of (1). By extending the concept of metric regularity at a point to that of metric regularity at a set, we first obtain a useful characterization of the existence of a global error bound, and then study its implications. Note that the Slater condition is not assumed in this section.

DEFINITION 1. *Suppose that the solution set S of* (1) *is nonempty. We say that the system* (1) *is metrically regular at a nonempty set $\hat{S} \subset S$ if there exist positive constants δ and $\tau(\delta)$ such that*

$$d(x, S) \leq \tau(\delta)[f(x)]_+ \qquad \textit{when} \qquad d(x, \hat{S}) \leq \delta.$$

When $\hat{S} = \{z\}$, we say that the system (1) *is metrically regular at z. We say that the system* (1) *is metrically regular at every point of S if the system* (1) *is metrically regular at z for all $z \in S$.*

It is clear that if the system (1) has the global error bound (2), then the system (1) is metrically regular at S. It is the convexity of f that implies the reverse implication. We state this observation as the following theorem.

THEOREM 1. *Suppose that X is a Banach space and f is continuous and convex on X. For the system* (1)*, suppose that S is nonempty. Consider the following statements.*

(a) *The global error bound* (2) *holds.*

(b) *The system* (1) *is metrically regular at any nonempty set $\hat{S} \subset S$.*

(c) *The system* (1) *is metrically regular at S.*

(d) *The system* (1) *is metrically regular at every point of S.*

(e) *The system* (1) *satisfies the Slater condition.*

Then the following implications hold:

$$(a) \Leftrightarrow (b) \Leftrightarrow (c) \Rightarrow (d) \Leftarrow (e).$$

Proof. The implications $(a) \Rightarrow (b) \Rightarrow (c) \Rightarrow (d)$ are trivial.

$[(e) \Rightarrow (d)]$. This is a consequence of the inequality (3) in [29, p. 272].

$[(c) \Rightarrow (a)]$. Since (1) is metrically regular at S, it follows that there are some positive scalars δ and $\tau(\delta)$ such that

$$d(x, S) \leq \tau(\delta)[f(x)]_+ \qquad \text{when } d(x, S) \leq \delta.$$

For any $x \notin S$, let $d(x, S) = r$. Suppose that $r > \delta$; otherwise, the result holds trivially. For any $\epsilon > 0$, let $\bar{x} \in S$ such that $\|\bar{x} - x\| \leq d(x, S) + \epsilon$, and let $y = \lambda x + (1 - \lambda)\bar{x}$ with $\lambda = \delta/(r + \epsilon)$. Then $\|y - \bar{x}\| = \lambda\|x - \bar{x}\| \leq \delta$. Since $d(y, S) + \|y - x\| \geq d(x, S)$,

$$\begin{aligned}\|y - \bar{x}\| &= \|\bar{x} - x\| - \|y - x\| \\ &\leq d(x, S) + \epsilon - (d(x, S) - d(y, S)) \\ &\leq d(y, S) + \epsilon.\end{aligned}$$

Therefore,

$$\begin{aligned}d(x, S) \leq \|x - \bar{x}\| &= (\lambda)^{-1}\|y - \bar{x}\| = (\lambda)^{-1}\,(d(y, S) + \epsilon) \\ &\leq (\lambda)^{-1}\,(\tau(\delta)[f(y)]_+ + \epsilon) \qquad (\text{since } d(y, S) \leq \delta) \\ &\leq (\lambda)^{-1}\,(\tau(\delta)\lambda f(x) + \epsilon) \qquad (\text{by the convexity of } f) \\ &\leq \tau(\delta)[f(x)]_+ + \epsilon(\lambda)^{-1}.\end{aligned}$$

We obtain the desired inequality by letting $\epsilon \downarrow 0$. □

Remarks. A characterization of the existence of the global error bound (2) in terms of directional derivatives can be found in [15]. In [4], directional derivatives are used to characterize weak sharp minima for convex programs. It is not difficult to see that metric regularity at a set can also be characterized in terms of directional derivatives. For $X = \mathbb{R}^n$ and f being a pointwise maximum of finitely many convex differentiable functions, Li [17] is able to characterize metric regularity at a point of S in terms of the Abadie constraint qualification.

In the rest of this paper, we suppose that $X = \mathbb{R}^n$. Since any nonempty bounded closed set in $\mathbb{R}^n$ is compact, an immediate consequence of Theorem 1 is the following corollary.

COROLLARY 4. *Suppose that f is a finite convex function on $\mathbb{R}^n$, S is nonempty, and the system* (1) *is metrically regular at every point of S. If S is bounded, then the global error bound* (2) *holds.*

Proof. By metric regularity at every point of S and the compactness of S, there exist positive scalars τ_i, δ_i, and $\mathbb{B}(x_i, \delta_i)$ for $i = 1, ..., m$ with $x_i \in S$ such that $d(x, S) \leq \tau_i[f(x)]_+$ when $x \in \mathbb{B}(x_i, \delta_i)$ and $S \subset \cup_{i=1}^m \text{int}\,(\mathbb{B}(x_i, \delta_i))$, where $\mathbb{B}(x_i, \delta_i)$ denotes the closed Euclidean ball centered at x_i with radius δ_i. Again, by the compactness of S, there is a $\delta > 0$ such that

$$\{x \mid d(x, S) \leq \delta\} \subset \cup_{i=1}^m \text{int}\,(\mathbb{B}(x_i, \delta_i)).$$

Let $\tau = \max_{1 \leq i \leq m}\{\tau_i\}$. It follows that

$$d(x, S) \leq \tau[f(x)]_+ \qquad \text{when } d(x, S) \leq \delta.$$

The desired result follows by invoking Theorem 1. □

Without the boundedness assumption on S, metrical regularity at every point of S does not guarantee that (2) holds. Examples 1 and 2 in [15] show that the global error bound (2) does not hold even under the Slater condition, which implies metric regularity at every point of S by Theorem 1.

The next issue on our agenda is to obtain conditions along with metric regularity at every point of S under which (2) holds. In [6], we have shown that if $0 \notin \text{cl}\,[\text{dom}\, f^*]$ (which is equivalent to the system $f^\infty(u) < 0$ being solvable since

$f^\infty(u) = \sup_{v\in \mathrm{cl}\,[\mathrm{dom}\, f^*]}\langle v, u\rangle)$ [31], then the system (1) has the global error bound (2). Thus we only need to consider the case when

$$0 \in \mathrm{cl}\,[\mathrm{dom}\,(f^*)].$$

We will show that the existence of the global error bound (2) for S is completely determined by an associated convex inequality system. First, some notation: let $E = \mathrm{aff}(\mathrm{dom}\, f^*)$, which is a subspace since $\mathrm{cl}\,[\mathrm{dom}\,(f^*)] \subset E$ (p. 44 of [30]) and $0 \in \mathrm{cl}\,[\mathrm{dom}\,(f^*)]$. Let $E^\perp$ be the orthogonal complement of E, and $\Pi_E : \mathbb{R}^n \to E$ be the orthogonal projector. Then $\mathbb{R}^n = E \bigoplus E^\perp$. Define

$$f_E^*(x^*) = f^*(\Pi_E(x^*)) \qquad\qquad \forall x^* \in \mathbb{R}^n.$$

Since E is a subspace, by (b) of Lemma 2.1 in [2],

$$f(x) = f_E(\Pi_E(x)) \qquad\qquad \forall x \in \mathbb{R}^n. \tag{7}$$

In view of (7), f_E is convex and continuous on E. Now we consider the following auxiliary inequality system:

$$f_E(x) \le 0, \qquad \text{and } x \in E. \tag{8}$$

Let $S_E \subset E$ be the set of solutions to (8). We list below some basic properties associated with f_E as the following proposition.

PROPOSITION 2. *With the previous notation, we have*

(a) $S = S_E + E^\perp$;

(b) $\mathrm{dom}\ {f_E}^* = \mathrm{dom}\ f^* + E^\perp$ *and* $\mathrm{int}\ [\mathrm{dom}\ {f_E}^*] = \mathrm{ri}\ [\mathrm{dom}\ f^*] + E^\perp$.

Proof. Part (a) follows from the fact that $S_E = \Pi_E(S)$ and the relation (7), and Part (b) is proved in [2, Lemma 2.1]. □

It follows from (a) in Proposition 2 that S_E is nonempty if and only if S is nonempty. By invoking Proposition 2, we have the following lemma.

LEMMA 1. *For the system* (1)*, suppose that S is nonempty, and that E and f_E are defined as above. Then*

$$d(z, S) = d(\Pi_E(z), S_E) \qquad \textit{for all } z \in \mathbb{R}^n.$$

Proof. Since $S = S_E + E^\perp$, for all $x \in S_E$ and $y \in E^\perp$,

$$\begin{aligned}\|z - (x + y)\|^2 &= \|(\Pi_E(z) - x) + [(z - \Pi_E(z)) - y]\|^2 \\ &= \|\Pi_E(z) - x\|^2 + \|(z - \Pi_E(z)) - y\|^2.\end{aligned}$$

It follows that $d(z, S) = d(\Pi_E(z), S_E)$ for all $z \in \mathbb{R}^n$. □

Now we are in a position to state another main result of this paper.

THEOREM 2. *For the system* (1)*, suppose that f is a finite convex function on $\mathbb{R}^n$, S is nonempty, and* $0 \in \mathrm{cl}\ [\mathrm{dom}\ (f^*)]$. *Let* $E = \mathrm{aff}\ [\mathrm{dom}\ (f^*)]$. *Then the following holds:*

$$\Big[\ d(x, S) \le \tau[f(x)]_+\ \forall x \in \mathbb{R}^n\ \Big] \Leftrightarrow \Big[\ d(x, S_E) \le \tau[f_E(x)]_+\ \forall x \in E\ \Big].$$

Proof. ($\Rightarrow$) For any $x \in E$, by Lemma 1 and the relation (7), we have

$$d(x, S_E) = d(x, S) \le \tau[f(x)]_+ = \tau[f_E(x)]_+.$$

($\Leftarrow$) For any $x \in \mathbb{R}^n$, by Lemma 1 and the relation (7), we have

$$d(x, S) = d(\Pi_E(x), S_E) \leq \tau[f_E(\Pi_E(x))]_+ = \tau[f(x)]_+.$$

This completes the proof of Theorem 2. □

As a consequence of Theorem 2, we obtain a useful sufficient condition for (2) to hold.

COROLLARY 5. *For the system* (1)*, suppose that f is a finite convex function on $\mathbb{R}^n$, and S is nonempty. Suppose that the system* (1) *is metrically regular at every point of S, and* $0 \in \text{ri } [\text{dom } f^*]$. *Then the global error bound* (2) *holds.*

Proof. Since the system (1) is metrically regular at every point of S, and $S_E \subset S$, the system (8) is metrically regular at every point of S_E (its proof is similar to that for the necessity part in Theorem 2). By (b) of Proposition 2, $0 \in \text{int } [\text{dom } f_E^*]$. Hence S_E is bounded. The result follows by invoking Corollary 4 and Theorem 2. □

Remarks. The class of functions f with $0 \in \text{ri } [\text{dom } f^*]$ has been extensively studied by Auslender, Cominetti, and Crouzeix in [2].

3. Applications. In this section, we give an application of Corollary 5 in section 2 to convex programs.

Consider

$$(\mathcal{P}) \qquad \begin{aligned} &\text{minimize} \quad h(x) \\ &\text{subject to} \quad g(x) \leq 0, \end{aligned}$$

where h and g are finite convex functions on $\mathbb{R}^n$.

Let $\tilde{S}$ be the set of optimal solutions to $(\mathcal{P})$, and suppose that $\tilde{S}$ is nonempty. Let h_{min} be the optimal value of $(\mathcal{P})$. Following [4], we say that $\tilde{S}$ is a set of weak sharp minima if there exists some positive scalar γ such that

$$h(x) \geq h_{min} + \gamma d(x, \tilde{S}) \qquad \forall x \quad \text{with } g(x) \leq 0.$$

Let $f(x) = \max\{h(x) - h_{min}, g(x)\}$. By invoking Corollary 5, we obtain a sufficient condition for $(\mathcal{P})$ possessing weak sharp minima.

PROPOSITION 3. *Consider $(\mathcal{P})$. With the previous notation, if the system $f(x) \leq 0$ is metrically regular at every point of $\tilde{S}$ and* $0 \in \text{ri } [\text{dom } f^*]$, *then $\tilde{S}$ is a set of weak sharp minima. In particular, the relative interiority condition holds when $\tilde{S}$ is bounded.*

Proof. By Corollary 5, there is a positive scalar τ such that $d(x, \tilde{S}) \leq \tau[f(x)]_+$ for all $x \in \mathbb{R}^n$. In particular, $d(x, \tilde{S}) \leq \tau(h(x) - h_{min})$ for all x with $g(x) \leq 0$. This is what we needed to prove. □

Remarks. According to Theorem 2.4.7 (p. 68) in [10], $\text{dom } f^* = \text{co } [\text{dom } h^* \cup \text{dom } g^*]$. By Theorem 6.9 in [30],

$$\text{ri } [\text{dom } f^*] = \cup\{\lambda \text{ ri } [\text{dom } h^*] + (1 - \lambda) \text{ ri } [\text{dom } g^*] \mid 0 < \lambda < 1\}.$$

In [7], inspired by Corollary 2 in [15], Deng and Hu proved the following error bound result.

PROPOSITION 4. *Consider the system $\tilde{f}(x) \leq 0,\ x \in C$, where C is a nonempty closed convex set in $\mathbb{R}^n$ and $\tilde{f}$ is a finite convex function on $\mathbb{R}^n$. Suppose that $\bar{S}$ is the set of solutions to the system $\tilde{f}(x) \leq 0,\ x \in C$, and $\bar{S}$ is nonempty. Suppose that*

$\tilde{f}$ is Lipschitz continuous on $\mathbb{R}^n$ with a Lipschitz constant l, and there is a positive scalar γ such that

$$d(x, \bar{S}) \leq \gamma[\tilde{f}(x)]_+ \quad \textit{for all } x \in C. \tag{9}$$

Then

$$d(x, \bar{S}) \leq (\gamma l + 1)d(x, C) + \gamma[\tilde{f}(x)]_+ \quad \textit{for all } x \in \mathbb{R}^n. \tag{10}$$

In view of Propositions 3 and 4, we obtain a new characterization of weak sharp minima when g is a finite convex polyhedral function in $(\mathcal{P})$.

COROLLARY 6. *Consider $(\mathcal{P})$. With the same notation as in Proposition 3, suppose that $g(x) = \max_{1\leq i\leq m}\{a_i^T x + b_i\}$, where $a_i \in \mathbb{R}^n$ and $b_i \in \mathbb{R}$, that h is Lipschitz continuous on $\mathbb{R}^n$, and that $0 \in \text{ri}\,[\text{dom}\, f^*]$. Then the following statements are equivalent.*

(a) *$\tilde{S}$ is the set of weak sharp minima for $(\mathcal{P})$;*

(b) *the system $f(x) \leq 0$ is metrically regular at every point of $\tilde{S}$.*

Proof. $[(a) \Rightarrow (b)]$. This is a consequence of Proposition 4 and Hoffman's theorem [11].

$[(b) \Rightarrow (a)]$. This follows from Proposition 3. □

Notes added in revision. The results in section 2.2 were added in a revision of this paper (July 1996). After the paper was resubmitted, the author received a paper of Li and Singer [18], where a result similar to that of the equivalence of (a) and (c) in Theorem 1 was proved for convex multifunctions.

Acknowledgments. The author thanks Professor R. F. Wheeler for some helpful comments on an earlier version of this paper, Professor James Burke and the associate editor for some useful suggestions, and two referees for their insightful comments.

OPTIMAL CONTROL OF A COERCIVE DIRICHLET PROBLEM*

DARIUSZ IDCZAK†

Abstract. In this paper, the maximum principle for some n-dimensional coercive Dirichlet problem of the second order is proved and sufficient conditions for the existence of an optimal solution are given. The results obtained generalize, in the sense of the dimension of the state space, some special case of the maximum principle for the one-dimensional Dirichlet problem, derived in [M. Goebel and V. Raitums, *J. Global Optim.*, 4 (1994), 367–395].

Key words. Dirichlet problem, variational method, maximum principle, existence of an optimal solution

1. Introduction.

In this paper we consider a nonlinear system of ordinary differential equations of the second order with functional parameters (controls) and Dirichlet-type boundary conditions. This system is of the form

$$\frac{d}{dx}(D_{z'}F(x,z(x),z'(x),u(x))) = D_zF(x,z(x),z'(x),u(x)), \quad x \in I=[0,\pi] \text{ a.e.}, \tag{1}$$

$$z(0)=z(\pi)=0, \tag{2}$$

where $z=(z_1,\dots,z_n)$, $u=(u_1,\dots,u_r)$, $F: I\times\mathbb{R}^n\times\mathbb{R}^n\times\mathbb{R}^r\to\mathbb{R}$, $D_zF=(D_{z_1}F,\dots,D_{z_n}F)$, $D_{z'}F=(D_{z'_1}F,\dots,D_{z'_n}F)$, $n\geq 1$, $r\geq 1$.

For more than a hundred years, systems of this type have played an essential role in mathematical models of physical and technical phenomena. This is connected with the principle of minimal action which holds true universally in nature (cf. [10]). So, it seems to be purposeful to investigate optimal processes for system (1)–(2).

The existence of a solution to system (1)–(2) was considered in many papers and monographs (see [2] and [9] and its references).

In our paper we consider system (1)–(2) with a constraint on controls

$$u(x)\in M, \tag{3}$$

and with the performance index

$$\mathcal{F}_0(z,u)=\int_I F_0(x,z(x),z'(x),u(x))\,dx\to\min, \tag{4}$$

where $M\subset\mathbb{R}^r$, $F_0: I\times\mathbb{R}^n\times\mathbb{R}^n\times\mathbb{R}^r\to\mathbb{R}$.

The control problem (1)–(4) is investigated in the spaces

$$H_0^1(I,\mathbb{R}^n)=\{z: I\to\mathbb{R}^n;\ \ z \text{ is absolutely continuous on } I,\ z(0)=z(\pi)=0,\ \ z'\in L^2(I,\mathbb{R}^n)\}$$

of trajectories and

$$\mathcal{U}_M = \{u \in L^2(I, \mathbb{R}^r); \quad u(x) \in M \quad \text{for} \quad x \in I \quad \text{a.e.}\}$$

of controls.

The scalar problem ($n = 1$) of type (1)–(4) was studied by German and Lithuanian mathematicians in many papers (see [4] and its references). In [4] the authors considered this problem with additional inequality and equality constraints, but without u on the left-hand side of (1). They derived the maximum principle by using McShane variations and assuming the existence of a solution to system (1)–(2).

In general, our original control problem cannot be reformulated into a control problem for a normal system of two first-order differential equations. We use the direct method of the calculus of variations to study the original problem.

In this paper we prove the existence of a solution in $H_0^1(I, \mathbb{R}^n)$ to system (1)–(2) for any control $u \in L^2(I, \mathbb{R}^n)$. Next, we derive the maximum principle for problem (1)–(4) in the case of $D_{z'}F$ affine in z' by using the extremum principle for a smooth-convex problem (cf. [6, section 1.1.3], [14, section 1.1.4]). Finally, we obtain a theorem on the existence of an optimal solution for some special form of system (1) by using the results concerning the continuous dependence of solutions to system (1)–(2) on controls, obtained in [15].

2. Existence of a solution to system (1)–(2). To assert the existence of a solution to system (1)–(2) in the space $H_0^1(I, \mathbb{R}^n)$, we shall apply the variational method for solving differential equations (cf. [2], [9]).

We shall say that a function $z \in H_0^1(I, \mathbb{R}^n)$ satisfies system (1) (with a fixed control u) if

$$\int_I D_{z'}F(x, z(x), z'(x), u(x))h'(x)\,dx + \int_I D_z F(x, z(x), z'(x), u(x))h(x)\,dx = 0$$

for any $h \in H_0^1(I, \mathbb{R}^n)$.

From the Du Bois–Reymond lemma (cf. [9]) it follows that if z is a solution of (1) in the above sense, then the function $D_{z'}F(x, z(x), z'(x), u(x))$ is equal almost everywhere (a.e.) on I to an absolutely continuous function

$$\int_0^x D_z F(x, z(x), z'(x), u(x))\,dx + c,$$

where $c \in \mathbb{R}^n$ is some constant.

Consequently, if we identify these functions, we may write

$$\frac{d}{dx}(D_{z'}F(x, z(x), z'(x), u(x))) = D_z F(x, z(x), z'(x), u(x))$$

a.e. on I.

It is easy to see that the space $H_0^1(I, \mathbb{R}^n)$ with the inner product

$$(z, w) = \int_I z'(x)w'(x)\,dx$$

is a Hilbert space; the corresponding norm is given by

$$\|z\| = \Big(\int_I |z'(x)|^2 dx\Big)^{\frac{1}{2}}.$$

Below, we shall use the following estimates:

$$\int_I |z(x)|^2\,dx \le \int_I |z'(x)|^2 dx,$$

$$\max\{|z(x)|;\quad x \in I\} \le \sqrt{\pi}\|z\|$$

for $z \in H_0^1(I,\mathbb{R}^n)$. The first of the above inequalities is called the Poincaré inequality (cf. [9]). The second one is obvious.

Below, we shall use the following lemma.

LEMMA 1 (see [9]). *If*

$$z_n \underset{n\to\infty}{\rightharpoonup} z_0$$

weakly in $H_0^1(I,\mathbb{R}^n)$, *then*

$$z_n \underset{n\to\infty}{\rightrightarrows} z_0$$

uniformly on I.

LEMMA 2. *If*

$$z_n \underset{n\to\infty}{\rightharpoonup} z_0$$

weakly in $H_0^1(I,\mathbb{R}^n)$, *then*

$$z_n' \underset{n\to\infty}{\rightharpoonup} z_0'$$

weakly in $L^2(I,\mathbb{R}^n)$.

Proof. The assertion follows from the fact that the operator

$$H_0^1(I,\mathbb{R}^n) \ni z \mapsto z' \in L^2(I,\mathbb{R}^n)$$

is linear and continuous. So, it preserves weak convergence. □

Below, $\mathbb{R}_0^+$ means $[0,\infty)$ and $\mathbb{R}^+$ means $(0,\infty)$.

In an analogous way to [11] one can prove Theorem 1.

THEOREM 1. *Suppose F satisfies the following conditions.*

(5) *For $x \in I$ a.e., $u \in \mathbb{R}^r$, the function $F(x,\cdot,\cdot,u)$ is continuously differentiable in the Fréchet sense on $\mathbb{R}^n \times \mathbb{R}^n$.*

(6) *For $z, z' \in \mathbb{R}^n$, the function $F(\cdot,z,z',\cdot)$ is of Carathéodory type; i.e. for $x \in I$ a.e., $F(x,z,z',\cdot)$ is continuous on $\mathbb{R}^r$ and, for $u \in \mathbb{R}^r$, $F(\cdot,z,z',u)$ is measurable on I.*

(7) *For $z, z' \in \mathbb{R}^n$, the functions $D_z F(\cdot,z,z',\cdot)$ and $D_{z'}F(\cdot,z,z',\cdot)$ are of Carathéodory type.*

(8) *There exist functions $a(\cdot) \in C(\mathbb{R}_0^+,\mathbb{R}_0^+)$, $b(\cdot) \in L^1(I,\mathbb{R}_0^+)$, $c(\cdot), d(\cdot) \in L^2(I,\mathbb{R}_0^+)$ such that, for $x \in I$ a.e., $z, z' \in \mathbb{R}^n$, $u \in \mathbb{R}^r$, one has*

   (a) $|F(x,z,z',u)| \le a(|z|)(b(x) + |z'|^2 + d(x)|z'| + |u|^2)$,

   (b) $|D_z F(x,z,z',u)| \le a(|z|)(b(x) + |z'|^2 + |z'| + |u|^2)$,

   (c) $|D_{z'}F(x,z,z',u)| \le a(|z|)(c(x) + |z'| + |u|)$.

Then, for any control $u(\cdot) \in L^2(I, \mathbb{R}^n)$*, the functional*

$$f_u : H_0^1(I, \mathbb{R}^n) \ni z \mapsto \int_I F(x, z(x), z'(x), u(x))\, dx \in \mathbb{R}$$

is continuously Fréchet differentiable and

$$f_u'(z) : H_0^1(I, \mathbb{R}^n) \ni h \mapsto \int_I (D_z F(x, z(x), z'(x), u(x))h(x) + D_{z'} F(x, z(x), z'(x), u(x))h'(x))\, dx \in \mathbb{R}$$

for $z \in H_0^1(I, \mathbb{R}^n)$.

We also have Theorem 2.

THEOREM 2. *Let us assume that a function* F *satisfies* (6), (8a), *and*

(9) *for* $x \in I$ *a.e.,* $u \in \mathbb{R}^r$*, the function* $F(x, \cdot, \cdot, u)$ *is continuous on* $\mathbb{R}^n \times \mathbb{R}^n$*,*

(10) *for* $x \in I$ *a.e.,* $z \in \mathbb{R}^n$*,* $u \in \mathbb{R}^r$*, the function* $F(x, z, \cdot, u)$ *is convex on* $\mathbb{R}^n$*,*

(11) *there exists* $\varepsilon > 0$ *such that, for any* $\lambda > 0$*,*

$$|F(x, z_1, z', u) - F(x, z_2, z', u)| \le a_\lambda(x) + \beta_\lambda |z'|^{2-\varepsilon} + \gamma_\lambda |u|^2$$

for $x \in I$ *a.e.,* $|z_1| < \lambda$*,* $|z_2| < \lambda$*,* $z' \in \mathbb{R}^n$*,* $u \in \mathbb{R}^r$*, with some (depending on* λ*) function* $a_\lambda(\cdot) \in L^1(I, \mathbb{R}_0^+)$ *and constants* $\beta_\lambda > 0$*,* $\gamma_\lambda > 0$.

Then, for any control $u(\cdot) \in L^2(I, \mathbb{R}^r)$*, the functional* f_u *is weakly lower semi continuous (l.s.c) on* $H_0^1(I, \mathbb{R}^n)$.

Proof. Let $z_n \rightharpoonup z_0$ weakly in $H_0^1(I, \mathbb{R}^n)$. From Lemmas 1, 2 it follows that $z_n \rightharpoonup z_0$ weakly in $C(I, \mathbb{R}^n)$ and $z_n' \rightharpoonup z_0'$ weakly in $L^2(I, \mathbb{R}^n)$. Applying [13, Thm. 12], we obtain the assertion. □

Remark 1. It is easily seen that the condition

(12) there exists $\varepsilon > 0$, and the functions $a(\cdot) \in C(\mathbb{R}_0^+, \mathbb{R}_0^+)$, $b(\cdot) \in L^1(I, \mathbb{R}_0^+)$, such that for $x \in I$ a.e., $z, z' \in \mathbb{R}^n$, $u \in \mathbb{R}^n$ one has

$$|F(x, z, z', u)| \le a(|z|)(b(x) + \min\{|z'|^2, |z'|^{2-\varepsilon}\} + |u|^2)$$

implies (8a) and (11).

Remark 2. The term $\gamma_\lambda |u|^2$ in condition (11) may be replaced by $\gamma_\lambda(x)|u|$ with $\gamma_\lambda(\cdot) \in L^2(I, \mathbb{R}_0^+)$.

THEOREM 3. *Let us assume that* F *satisfies* (9), (6), (8a) *and suppose that*

(13) *there exist constants* $\alpha_1, \gamma_2, \gamma_3 \in \mathbb{R}^+$ *and functions* $\alpha_2(\cdot)$*,* $\gamma_1(\cdot) \in L^2(I, \mathbb{R}_0^+)$*,* $\beta_1(\cdot)$*,* $\beta_2(\cdot)$*,* $\delta_0(\cdot) \in L^1(I, \mathbb{R}_0^+)$*, such that*

$$\alpha_1 - \pi \int_I \beta_1(x) dx - \sqrt{\pi} \Big(\int_I |\gamma_1(x)|^2 dx \Big)^{\frac{1}{2}} > 0$$

and

$$F(x, z, z', u) \ge \alpha_1 |z'|^2 - \alpha_2(x)|z'| - \beta_1(x)|z|^2 - \beta_2(x)|z| - \gamma_1(x)|z||z'| - \gamma_2 |u|^2 - \gamma_3 |z||u|^2 - \delta_0(x)$$

for $x \in I$ *a.e.,* $z, z' \in \mathbb{R}^n$*,* $u \in \mathbb{R}^r$.

Then, for any control $u \in L^2(I, \mathbb{R}^r)$*, the functional* f_u *is coercive; i.e.,*

$$f_u(z) \to +\infty \quad as \quad \|z\| \to +\infty.$$

Proof. We have

$$\begin{aligned}
f_u(z) = \int_I F(x, z(x), z'(x), u(x))dx &\geq \alpha_1\|z\|^2 - \Big(\int_I |\alpha_2(x)|^2 dx\Big)^{\frac{1}{2}}\|z\| \\
&- \max\{|z(x)|^2; x \in I\}\int_I \beta_1(x)dx - \max\{|z(x)|; x \in I\}\int_I \beta_2(x)dx \\
&- \max\{|z(x)|; x \in I\}\Big(\int_I |\gamma_1(x)|^2 dx\Big)^{\frac{1}{2}}\|z\| - \gamma_2\int_I |u(x)|^2 dx \\
&- \gamma_3 \max\{|z(x)|;\ x \in I\}\int_I |u(x)|^2 dx - \int_I \delta_0(x)dx \\
&\geq \Big(\alpha_1 - \pi\int_I \beta_1(x)dx - \sqrt{\pi}\Big(\int_I |\gamma_1(x)|^2 dx\Big)^{\frac{1}{2}}\Big)\|z\|^2 \\
&- \Big(\Big(\int_I |\alpha_2(x)|^2 dx\Big)^{\frac{1}{2}} + \sqrt{\pi}\int_I \beta_2(x)dx + \gamma_3\int_I |u(x)|^2 dx\Big)\|z\| \\
&- \Big(\int_I \delta_0(x)dx + \gamma_2\int_I |u(x)|^2 dx\Big).
\end{aligned}$$

The proof is completed. □

Now, we can prove Theorem 4.

THEOREM 4. *If F satisfies conditions* (5), (6), (7), (8a), (8b), (8c), (10), (11), *and* (13), *then for any control $u(\cdot) \in L^2(I, \mathbb{R}^r)$, system* (1) *possesses a solution in $H_0^1(I, \mathbb{R}^n)$.*

Proof. The assumptions imply that the conditions of Theorems 2, 3 are satisfied. So, for any control $u(\cdot) \in L^2(I, \mathbb{R}^r)$, there exists a $z_u \in H_0^1(I, \mathbb{R}^n)$ such that

$$f_u(z_u) = \min\{f_u(z) : z \in H_0^1(I, \mathbb{R}^n)\}.$$

Consequently, Theorem 1 yields the equality

$$f_u'(z_u) = 0;$$

i.e.,

$$\int_I D_z F(x, z_u(x), {z_u}'(x), u(x))h(x)dx + \int_I D_2 F(x, z_u(x), {z_u}'(x), u(x))h'(x)dx = 0$$

for any $h \in H_0^1(I, \mathbb{R}^n)$. Thus, as was mentioned,

$$\frac{d}{dx}\Big(D_{z'}F(x, z_u(x), z_u'(x), u(x))\Big) = D_z F(x, z_u(x), z_u'(x), u(x))$$

a.e. on I. Of course, z_u satisfies (2) as a function from $H_0^1(I, \mathbb{R}^n)$ and the proof is completed. □

Remark 3. From Remark 1 it follows that the assumptions of Theorem 4 may be replaced by (5), (6), (7), (8b), (8c), (10), (12), (13).

Remark 4. From convex analysis it follows that z_u will be a unique solution of (1) in $H_0^1(I, \mathbb{R}^n)$ if f_u is strictly convex, i.e., if

$$f_u(\alpha z_1 + \beta z_2) < \alpha f_u(z_1) + \beta f_u(z_2)$$

for $z_1, z_2 \in H_0^1(I, \mathbb{R}^n)$, $z_1 \neq z_2$, $\alpha, \beta > 0$, $\alpha + \beta = 1$.

Remark 5. It is easily seen (cf. also [15]) that the boundary condition (2) in the assertion of Theorem 4 may be replaced by

$$z(0) = a, \quad z(\pi) = b$$

with arbitrary fixed $a, b \in \mathbb{R}^n$. (It suffices to observe that if F satisfies the assumptions of Theorem 4, then $G : I \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^r \to \mathbb{R}$ given by

$$G(x, z, z', u) = F\left(x, z + \frac{1}{\pi}(b-a)x + a, z' + \frac{1}{\pi}(b-a), u\right)$$

also satisfies these assumptions.)

3. Necessary conditions for optimality. In this section we shall assume that F satisfies the assumptions of Theorem 4 and F_0 satisfies the assumptions of Theorem 1 (with F replaced by F_0). Consequently, the functional $\mathcal{F}_0$ is continuously differentiable with respect to $z \in H_0^1(I, \mathbb{R}^n)$ for any fixed control $u(\cdot) \in \mathcal{U}_M$, and

$$(\partial_z \mathcal{F}_0(z,u), h) = \int_I \Big(D_z F_0(x, z(x), z'(x), u(x))h(x) + D_{z'} F_0(x, z(x), z'(x), u(x))h'(x) \Big) dx$$

for $z(\cdot)$, $h(\cdot) \in H_0^1(I, \mathbb{R}^n)$.

Let us define the following operator:

$$\mathcal{F} : H_0^1(I, \mathbb{R}^n) \times \mathcal{U}_M \longrightarrow \Big[H_0^1(I, \mathbb{R}^n)\Big]^*,$$

$$(\mathcal{F}(z,u), h) = \int_I \Big(D_z F(x, z(x), z'(x), u(x))h(x) + D_{z'} F(x, z(x), z'(x), u(x))h'(x) \Big) dx.$$

The optimization problem (1)–(4) may be formulated as

$$(S) \begin{cases} \mathcal{F}_0(z,u) \longrightarrow \min, \\ \mathcal{F}(z,u) = 0, \\ u \in \mathcal{U}_M, \end{cases}$$

where $\mathcal{F}_0 : H_0^1(I, \mathbb{R}^n) \times \mathcal{U}_M \longrightarrow \mathbb{R}$, $\mathcal{F} : H_0^1(I, \mathbb{R}^n) \times \mathcal{U}_M \longrightarrow [H_0^1(I, \mathbb{R}^n)]^*$.

Before we formulate the maximum principle, we shall prove some lemmas.

LEMMA 3. *Let us assume that*

(14) *for $x \in I$ a.e., $u \in \mathbb{R}^r$, the functions $D_z F(x, \cdot, \cdot, u)$, $D_{z'} F(x, \cdot, \cdot, u)$ are continuously differentiable in the Fréchet sense on $\mathbb{R}^n \times \mathbb{R}^n$;*

(15) *for $z, z' \in \mathbb{R}^n$, the functions $D_{zz} F(\cdot, z, z', \cdot)$, $D_{zz'} F(\cdot, z, z', \cdot) = D_{z'z} F(\cdot, z, z', \cdot)$, $D_{z'z'} F(\cdot, z, z', \cdot)$ are of Carathéodory type;*

(16) *there exist functions $\bar{a}(\cdot) \in C(\mathbb{R}_0^+, \mathbb{R}_0^+)$, $\bar{b}(\cdot) \in L^2(I, \mathbb{R}_0^+)$, $\bar{c}(\cdot) \in L^\infty(I, \mathbb{R}_0^+)$ such that, for $x \in I$ a.e., $z, z' \in \mathbb{R}^n$, $u \in \mathbb{R}^r$, one has*

(a) $|D_{zz} F(x, z, z', u)| \le \bar{a}(|z|)(\bar{b}(x) + |z'| + |u|)$,

(b) $|D_{zz'} F(x, z, z', u)| \le \bar{a}(|z|)\bar{c}(x)$,

(c) $|D_{z'z'} F(x, 0, 0, u)| \le \bar{c}(x)$;

(17) *for any* $\mu > 0$, *there exists* $\bar{c}_\mu(\cdot) \in L^\infty(I, \mathbb{R}^+_0)$ *such that, for* $x \in I$ *a.e.,* $z, w \in \mathbb{R}^n$, $|z| < \mu$, $|w| < \mu$, $z', w' \in \mathbb{R}^n$, $u \in \mathbb{R}^r$,

$$|D_{z'z'}F(x, z, z', u) - D_{z'z'}F(x, w, w', u)| \le \bar{c}_\mu(x)|z - w|.$$

Then, the operator $\mathcal{F}$ *is continuously Gâteaux differentiable (thus continuously Fréchet differentiable) with respect to* $z \in H^1_0(I, \mathbb{R}^n)$.

Remark 6. From (16(c)) and (17) it follows that

$$\begin{aligned}|D_{z'z'}F(x, z, z', u)| &\le |D_{z'z'}F(x, z, z', u) - D_{z'z'}F(x, 0, 0, u)| \\ &\quad + |D_{z'z'}F(x, 0, 0, u)| \le \bar{c}_\mu(x)|z| + \bar{c}(x) \le \bar{c}_\mu(x)\mu + \bar{c}(x)\end{aligned}$$

for $x \in I$ a.e., $z \in \mathbb{R}^n$, $|z| < \mu$, $z' \in \mathbb{R}^n$, $u \in \mathbb{R}^r$.

Moreover, from (17) it follows ($z = w$) that the function $D_{z'}F(x, z, \cdot, u)$ is affine.

Proof of Lemma 3. Let us consider the following operator:

$$\partial_z \mathcal{F}(z, u) : H^1_0(I, \mathbb{R}^n) \longrightarrow [H^1_0(I, \mathbb{R}^n)]^*, \tag{18}$$

$$\begin{aligned}\Big((\partial_z \mathcal{F}(z, u), w), h\Big) &= \int_I \Big(D_{zz}F(x, z(x), z'(x), u(x))w(x)\Big)h(x)dx \\ &\quad + \int_I \Big(D_{zz'}F(x, z(x), z'(x), u(x))w'(x)\Big)h(x)dx \\ &\quad + \int_I \Big(D_{z'z}F(x, z(x), z'(x), u(x))w(x)\Big)h'(x)dx \\ &\quad + \int_I \Big(D_{z'z'}F(x, z(x), z'(x), u(x))w'(x)\Big)h'(x)dx,\end{aligned}$$

where $z \in H^1_0(I, \mathbb{R}^n)$, $u \in \mathcal{U}_M$ are fixed and w, $h \in H^1_0(I, \mathbb{R}^n)$.

Its linearity is obvious. Moreover,

$$\begin{aligned}&\|\big((\partial_z \mathcal{F}(z, u), w), \cdot\big)\|_{[H^1_0(I,\mathbb{R}^n)]^*} \\ &\quad \le \sqrt{\pi} \int_I |D_{zz}F(x, z(x), z'(x), u(x))w(x)|dx \\ &\qquad + \sqrt{\pi} \int_I |D_{zz'}F(x, z(x), z'(x), u(x))w'(x)|dx \\ &\qquad + \Big(\int_I |D_{z'z}F(x, z(x), z'(x), u(x))w(x)|^2 dx\Big)^{\frac{1}{2}} \\ &\qquad + \Big(\int_I |D_{z'z'}F(x, z(x), z'(x), u(x))w'(x)|^2 dx\Big)^{\frac{1}{2}} \qquad (19) \\ &\quad \le \pi \cdot \int_I |D_{zz}F(x, z(x), z'(x), u(x))|dx \cdot \|w\| \\ &\qquad + \sqrt{\pi}\Big(\int_I |D_{zz'}F(x, z(x), z'(x), u(x))|^2 dx\Big)^{\frac{1}{2}} \cdot \|w\| \\ &\qquad + \sqrt{\pi}\Big(\int_I |D_{z'z}F(x, z(x), z'(x), u(x))|^2 dx\Big)^{\frac{1}{2}} \|w\| \\ &\qquad + \operatorname{ess}\sup_{x \in I} |D_{z'z'}F(x, z(x), z'(x), u(x))| \cdot \|w\|.\end{aligned}$$

This implies the continuity of (18), i.e., $\partial_z \mathcal{F}(z, u) \in \mathcal{L}(H^1_0(I, \mathbb{R}^n), [H^1_0(I, \mathbb{R}^n)]^*)$.

Now, we shall show that, for any $w \in H_0^1(I,\mathbb{R}^n)$,

$$\lim_{\lambda\to 0}\Big\|\frac{\mathcal{F}(z+\lambda w,u)-\mathcal{F}(z,u)}{\lambda}-(\partial_z\mathcal{F}(z,u),w)\Big\|_{[H_0^1(I,\mathbb{R}^n)]^*}=0, \tag{20}$$

i.e., that $\partial_z\mathcal{F}(z,u)$ is a Gâteaux differential of $\mathcal{F}$ with respect to $z\in H_0^1(I,\mathbb{R}^n)$ at the point (z,u).

Indeed, for any $h\in H_0^1(I,\mathbb{R}^n)$ and $\lambda\in\mathbb{R}\backslash\{0\}$, $|\lambda|\le 1$, we have

$$\begin{aligned}
&\Big|\frac{(\mathcal{F}(z+\lambda w,u),h)-(\mathcal{F}(z,u),h)}{\lambda}-((\partial_z\mathcal{F}(z,u),w),h)\Big|\\
&\le\int_I\Big|\frac{D_zF(x,z(x)+\lambda w(x),z'(x)+\lambda w'(x),u(x))-D_zF(x,z(x),z'(x),u(x))}{\lambda}\\
&\quad-\Big(D_{zz}F(x,z(x),z'(x),u(x))w(x)+D_{zz'}F(x,z(x),z'(x),u(x))w'(x)\Big)\Big|dx\cdot\sqrt{\pi}\|h\|\\
&\quad+\Big(\int_I\Big|\frac{D_{z'}F\big(x,z(x)+\lambda w(x),z'(x)+\lambda w'(x),u(x)\big)-D_{z'}F(x,z(x),z'(x),u(x))}{\lambda}\\
&\quad-\big(D_{z'z}F(x,z(x),z'(x),u(x))w(x)+D_{z'z'}F(x,z(x),z'(x),u(x))w'(x)\big)\Big|^2dx\Big)^{\frac12}\cdot\|h\|.
\end{aligned}$$

So,

$$\begin{aligned}
&\Big|\Big|\frac{\mathcal{F}(z+\lambda w,u)-\mathcal{F}(z,u)}{\lambda}-(\partial_z\mathcal{F}(z,u),w)\Big|\Big|_{[H_0^1(I,\mathbb{R}^n)]^*}\\
&\quad\le\sqrt{\pi}\int_I\Big|\frac{D_zF(x,z(x)+\lambda w(x),z'(x)+\lambda w'(x),u(x))-D_zF(x,z(x),z'(x),u(x))}{\lambda}\\
&\qquad-\Big(D_{zz}F(x,z(x),z'(x),u(x))w(x)+D_{zz'}F(x,z(x),z'(x),u(x))w'(x)\Big)\Big|dx\\
&\qquad+\Big(\int_I\Big|\frac{D_{z'}F(x,z(x)+\lambda w(x),z'(x)+\lambda w'(x),u(x))-D_{z'}F(x,z(x),z'(x),u(x))}{\lambda}\\
&\qquad-\big(D_{z'z}F(x,z(x),z'(x),u(x))w(x)+D_{z'z'}F(x,z(x),z'(x),u(x))w'(x)\big)\Big|^2dx\Big)^{\frac12}.
\end{aligned}$$

From the differentiability of D_zF, $D_{z'}F$ with respect to $(z,z')\in\mathbb{R}^n\times\mathbb{R}^n$ it follows that the above integrands tend (with fixed z, $w\in H_0^1(I,\mathbb{R}^n)$, $u\in\mathcal{U}_M$) pointwise to 0 as $\lambda\to 0$.

Moreover, from the mean value theorem we have

$$\begin{aligned}
&\Big|\frac{D_zF(x,z(x)+\lambda w(x),z'(x)+\lambda w'(x),u(x))-D_zF(x,z(x),z'(x),u(x))}{\lambda}\\
&\qquad-(D_{zz}F(x,z(x),z'(x),u(x))w(x)+D_{zz'}F(x,z(x),z'(x),u(x))w'(x))\Big|\\
&\quad\le\max\{\bar a(|z(x)+t\lambda w(x)|);(x,t,\lambda)\in[0,\pi]\times[0,1]\times[-1,1]\}\\
&\qquad\cdot(\bar b(x)+|z'(x)|+|w'(x)|+|u(x)|)(|w(x)|+|w'(x)|)\\
&\qquad+\ \max\{\bar a(|z(x)+t\lambda w(x)|);(x,t,\lambda)\in[0,\pi]\times[0,1]\times[-1,1]\}\\
&\qquad\cdot\bar c(x)(|w(x)|+|w'(x)|)+\bar a(|z(x)|)(\bar b(x)+|z'(x)|+|u(x)|)(|w(x)|+|w'(x)|)\\
&\qquad+\bar a(|z(x)|)\bar c(x)(|w(x)|+|w'(x)|)
\end{aligned}$$

and, analogously,

$$\begin{aligned}
&\Big|\frac{D_{z'}F(x,z(x)+\lambda w(x),z'(x)+\lambda w'(x),u(x))-D_{z'}F(x,z(x),z'(x),u(x))}{\lambda}\\
&\quad-\big(D_{z'z}F(x,z(x),z'(x),u(x))w(x)+D_{z'z'}F(x,z(x),z'(x),u(x))\big)\Big|^2\\
&\le\Big(\max\{\bar a(|z(x)+t\lambda w(x)|);(x,t,\lambda)\in[0,\pi]\times[0,1]\times[-1,1]\}\bar c(x)(|w(x)|+|w'(x)|)\\
&\quad+(\bar c_{\mu+\nu}(x)(\mu+\nu)+\bar c(x))(|w(x)|+|w'(x)|)+\bar a(|z(x)|)\bar c(x)(|w(x)|+|w'(x)|)\\
&\quad+(\bar c_\mu(x)\mu+\bar c(x))(|w(x)|+|w'(x)|)\Big)^2,
\end{aligned}$$

where $\mu=\max\{|z(x)|:x\in I\}$, $\nu=\max\{|w(x)|:x\in I\}$.

Since the right-hand sides of the above estimates are integrable functions, using the Lebesgue theorem, we therefore obtain (20).

Now, we shall show that (with a fixed $u\in\mathcal{U}_M$) the mapping

$$\partial_z\mathcal{F}(\cdot,u):H_0^1(I,\mathbb{R}^n)\ni z\mapsto\partial_z\mathcal{F}(z,u)\in\mathcal{L}\big(H_0^1(I,\mathbb{R}^n),[H_0^1(I,\mathbb{R}^n)]^*\big)$$

is continuous.

Indeed, in an analogous way as in (19), we assert that

(21)
$$\begin{aligned}
&\big|\big|\partial_z\mathcal{F}(z_n,u)-\partial_z\mathcal{F}(z_0,u)\big|\big|_{\mathcal{L}(H_0^1(I,\mathbb{R}^n),[H_0^1(I,\mathbb{R}^n)]^*)}\\
&\quad\le\pi\cdot\int_I\big|D_{zz}F(x,z_n(x),z_n'(x),u(x))-D_{zz}F(x,z_0(x),z_0'(x),u(x))\big|dx\\
&\qquad+2\sqrt{\pi}\Big(\int_I\big|D_{zz'}F(x,z_n(x),z_n'(x),u(x))-D_{zz'}F(x,z_0(x),z_0'(x),u(x))\big|^2dx\Big)^{\frac12}\\
&\qquad+\operatorname{ess}\sup_{x\in I}\big|D_{z'z'}F(x,z_n(x),z_n'(x),u(x))-D_{z'z'}F(x,z_0(x),z_0'(x),u(x))\big|
\end{aligned}$$

for any z_n, $z_0\in H_0^1(I,\mathbb{R}^n)$.

Now, let us assume that $z_n\xrightarrow[n\to\infty]{}z_0$ in $H_0^1(I,\mathbb{R}^n)$. So,

$$z_n\underset{n\to\infty}{\rightrightarrows}z_0$$

uniformly on I and $z_n'\xrightarrow[n\to\infty]{}z_0'$ in $L^2(I,\mathbb{R}^n)$.

To prove that the first of the above integrals tends to 0, let us observe that its integrand converges in measure to the zero-function. This follows from the fact that the sequence $(z_n(\cdot),z_n'(\cdot))_{n\in\mathbb{N}}$ tends in measure to $(z_0(\cdot),z_0'(\cdot))$ and from the properties of the Nemytskii operator (cf. [8]). Moreover, the sequence of integrands has equi-absolutely continuous integrals (cf. [12]):

(22)
$$\begin{aligned}
&\big|D_{zz}F(x,z_n(x),z_n'(x),u(x))-D_{zz}F(x,z_0(x),z_0'(x),u(x))\big|\\
&\quad\le\bar a(|z_n(x)|)(\bar b(x)+|z_n'(x)|+|u(x)|)\\
&\qquad+\ \bar a(|z_0(x)|)(\bar b(x)+|z_0'(x)|+|u(x)|)\\
&\quad\le\text{const }(2\bar b(x)+2|u(x)|+|z_0'(x)|+|z_n'(x)|).
\end{aligned}$$

Since $z_n'\to z_0'$ in $L^2(I,\mathbb{R}^n)$ and, consequently, in $L^1(I,\mathbb{R}^n)$, the sequence $(|z_n'(x)|)_{n\in\mathbb{N}}$ has equi-absolutely continuous integrals. So, the sequence

$$\Big(\big|D_{zz}F(x,z_n(x),z_n'(x),u(x))-D_{zz}F(x,z_0(x),z_0'(x),u(x))\big|\Big)_{n\in\mathbb{N}}$$

has equi-absolutely continuous integrals. Applying the Vitali theorem on the convergence of an integral [12], we assert that the first term in (21) tends to 0 as $n \to +\infty$.

In an analogous way, replacing (22) by

$$\begin{aligned}&\left|D_{zz'}F(x,z_n(x),z_n'(x),u(x)) - D_{zz'}F(x,z_0(x),z_0'(x),u(x))\right|^2\\ &\quad\le 4\Big(\left|D_{zz'}F(x,z_n(x),z_n'(x),u(x))\right|^2 + \left|D_{zz'}F(x,z_0(x),z_0'(x),u(x))\right|^2\Big)\\ &\quad\le 4\Big((\bar a(|z_n(x)|))^2(\bar c(x))^2 + (\bar a(|z_0(x)|))^2(\bar c(x))^2\Big) \le \text{const},\end{aligned}$$

we assert that the second term in (21) tends to 0 as $n \to +\infty$.

The convergence of the third term follows from the fact that

$$z_n \underset{n\to\infty}{\rightrightarrows} z_0$$

uniformly on I and from (17) because

$$\left|D_{z'z'}F(x,z_n(x),z_n'(x),u(x)) - D_{z'z'}F(x,z_0(x),z_0(x),u(x))\right| \le \bar c_\mu(x)|z_n(x) - z_0(x)|$$

where $|z_n(x)| < \mu$, $n = 1,2,\dots,|z_0(x)| < \mu$ for all $x \in I$.

The proof of the lemma is completed. □

Now, let us denote

$$\begin{aligned}&A(x) = D_{z'z}F(x,z_*(x),z_*'(x),u_*(x)) = D_{zz'}F(x,z_*(x),z_*'(x),u_*(x)),\\ &B(x) = D_{z'z'}F(x,z_*(x),z_*'(x),u_*(x)),\\ &C(x) = D_{zz}F(x,z_*(x),z_*'(x),u_*(x)),\end{aligned} \tag{23}$$

where $z_* \in H_0^1(I,\mathbb{R}^n)$, $u_* \in \mathcal{U}_M$ are fixed.

From (16), (17) it follows that $A(\cdot)$, $B(\cdot) \in L^\infty(I,\mathbb{R}^{n\times n})$, $C(\cdot) \in L^2(I,\mathbb{R}^{n\times n})$.

LEMMA 4. *Let $z_* \in H_0^1(I,\mathbb{R}^n)$, $u_* \in \mathcal{U}_M$ be such that*

(24) *the matrix $B(x)$ is positive for $x \in I$ a.e. (i.e., there exists a set $S \subset I$ of full measure such that, for $x \in S$, $B(x)z'z' > 0$ for $z' \in \mathbb{R}^n - \{0\}$), and*

$$\inf\{B(x)z'z';\ |z'| = 1,\ \ x \in S\} - \pi\int_I |C(x)|dx - 2\pi(\operatorname{ess\ sup}_I |A(\cdot)|) > 0. \tag{25}$$

Then, for any $\Lambda \in [H_0^1(I,\mathbb{R}^n)]^*$, there exists a $w \in H_0^1(I,\mathbb{R}^n)$ such that

$$(\partial_z\mathcal{F}(z_*,u_*),w) = \Lambda;$$

i.e.,

$$\begin{aligned}&\int_I (C(x)w(x) + A(x)w'(x))h(x)dx\\ &\qquad + \int_I (A(x)w(x) + B(x)w'(x))h'(x)dx = (\Lambda,h)\end{aligned}$$

for any $h \in H_0^1(I,\mathbb{R}^n)$.

Proof. Since $H_0^1(I,\mathbb{R}^n)$ is a Hilbert space, there exists an $a \in H_0^1(I,\mathbb{R}^n)$ such that

$$(\Lambda,h) = \int_I a'(x)h'(x)dx$$

for all $h \in H_0^1(I, \mathbb{R}^n)$. So, we have to show the existence of $w \in H_0^1(I, \mathbb{R}^n)$ such that

$$\int_I (A(x)w(x) + B(x)w'(x) - a'(x))h'(x)dx + \int_I (C(x)w(x) + A(x)w'(x))h(x)dx = 0$$

for all $h \in H_0^1(I, \mathbb{R}^n)$; i.e.,

$$\frac{d}{dx}(A(x)w(x) + B(x)w'(x) - a'(x)) = C(x)w(x) + A(x)w'(x)$$

a.e. on I.

Let us denote

$$G(x, w, w') = A(x)ww' - a'(x)w' + \frac{1}{2}B(x)w'w' + \frac{1}{2}C(x)ww$$

for $x \in I$ a.e., w, $w' \in \mathbb{R}^n$.

Of course,

$$D_w G(x, w, w') = A(x)w' + C(x)w,$$
$$D_{w'} G(x, w, w') = A(x)w - a'(x) + B(x)w'$$

for $x \in I$ a.e., w, $w' \in \mathbb{R}^n$.

It is easy to check that G satisfies (5), (6), (7), (10). Now, we show that it satisfies (8a), (8b), (8c), (11), and (13).

Indeed, we have

$$|G(x, w, w')| \le |A(x)\|w\|w'| + |a'(x)||w'| + \frac{1}{2}|B(x)||w'|^2 + \frac{1}{2}|C(x)||w|^2$$
$$\le \max\{1, |w|, |w|^2\}\left((\operatorname{ess\,sup}_I |A(\cdot)|)|w'| + |a'(x)||w'| + \frac{1}{2}(\operatorname{ess\,sup}_I |B(\cdot)|)|w'|^2 + \frac{1}{2}|C(x)|\right)$$
$$= \max\{1, |w|, |w|^2\}\left(\frac{1}{2}|C(x)| + ((\operatorname{ess\,sup}_I |A(\cdot)|) + |a'(x)|)|w'| + \frac{1}{2}(\operatorname{ess\,sup}_I |B(\cdot)|)|w'|^2\right),$$

$$|D_w G(x, w, w')| \le |A(x)||w'| + |C(x)||w| \le (\operatorname{ess\,sup}_I |A(\cdot)|)|w'| + |C(x)||w|$$
$$\le \max\{|w|, 1\}\big(|c(x)| + (\operatorname{ess\,sup}_I |A(\cdot)|)|w'|\big),$$

$$|D_{w'} G(x, w, w')| \le |A(x)||w| + |a'(x)| + |B(x)||w'|$$
$$\le \max\{|w|, 1\}(|A(x)| + |a'(x)| + |B(x)||w'|)$$
$$\le \max\{|w|, 1\}(|A(x)| + |a'(x)| + (\operatorname{ess\,sup}_I |B(\cdot)|)|w'|)$$

for $x \in I$ a.e., w, $w' \in \mathbb{R}^n$. So, (8a), (8b), (8c) are satisfied. Moreover, for any $\lambda > 0$,

$$\Big|G(x, w_1, w') - G(x, w_2, w')\Big|$$
$$= \Big|A(x)w_1w' + \frac{1}{2}C(x)w_1w_1 - A(x)w_2w' - \frac{1}{2}C(x)w_2w_2\Big|$$
$$\le \Big|A(x)(w_1 - w_2)w'\Big| + \frac{1}{2}|C(x)w_1w_1 - C(x)w_2w_2|$$
$$\le (\operatorname{ess\,sup}_I |A(\cdot)|)2\lambda|w'|^{2-1} + |c(x)|\lambda^2$$

for $x \in I$ a.e., $|w_1| < \lambda$, $|w_2| < \lambda$, $w' \in \mathbb{R}^n$. So, (11) is satisfied with $\varepsilon = 1$.

To prove that (13) holds, let us denote $\alpha = \inf\{B(x)z'z', |z'| = 1,\ x \in S\}$ and observe that (24) implies (cf. [5, I.4])

$$B(x)w'w' \geq \alpha|w'|^2$$

for all $x \in S$ and $w' \in \mathbb{R}^n$. Consequently,

$$\begin{aligned} G(x,w,w') &= A(x)ww' - a'(x)w' + \frac{1}{2}B(x)w'w' + \frac{1}{2}C(x)ww \\ &\geq \frac{1}{2}\alpha|w'|^2 - (\operatorname{ess\ sup}_I |A(\cdot)|)|w||w'| - |a'(x)||w'| - \frac{1}{2}|C(x)||w|^2 \end{aligned}$$

and, by (25),

$$\begin{aligned} &\frac{1}{2}\alpha - \pi\int_I \frac{1}{2}|C(x)|dx - \sqrt{\pi}\Big(\int_I (\operatorname{ess\ sup}_I |A(\cdot)|)^2 dx\Big)^{\frac{1}{2}} \\ &\quad = \frac{1}{2}\alpha - \frac{1}{2}\pi\int_I |C(x)|dx - \pi\Big(\operatorname{ess\ sup}_I |A(\cdot)|\Big) > 0. \end{aligned}$$

Hence (13) holds.

Thus, Theorem 4 implies the assertion of the lemma. □

We also have Lemma 5.

LEMMA 5. *If*

(26) *$M \subset \mathbb{R}^r$ is compact and for $x \in I$ a.e., $z, z' \in \mathbb{R}^n$, the set $\{(D_zF(x,z,z',u), D_{z'}F(x,z,z',u), F^0(x,z,z',u)) \in \mathbb{R}^{n+n+1},\ \ u \in M\}$ is convex,*

then, for any $z \in H_0^1(I,\mathbb{R}^n)$, the operator $\mathcal{F}$ and the functional $\mathcal{F}_0$ satisfy the following convexity condition: for any $u_1, u_2 \in \mathcal{U}_M$, $z \in H_0^1(I,\mathbb{R}^n)$, and $\alpha \in [0,1]$ there exists $\bar{u} \in \mathcal{U}_M$ such that

(27) $\mathcal{F}(z,\bar{u}) = \alpha\mathcal{F}(z,u_1) + (1-\alpha)\mathcal{F}(z,u_2)$,

(28) $\mathcal{F}_0(z,\bar{u}) = \alpha\mathcal{F}_0(z,u_1) + (1-\alpha)\mathcal{F}_0(z,u_2)$.

Proof. Let us fix $z \in H_0^1(I,\mathbb{R}^n)$, $u_1, u_2 \in \mathcal{U}_M$, $\alpha \in [0,1]$. For $x \in I$ a.e. there exists a point $u_0(x) \in M$ such that

$$\begin{aligned} &\alpha D_zF(x,z(x),z'(x),u_1(x)) + (1-\alpha)D_zF(x,z(x),z'(x),u_2(x)) \\ &\quad = D_zF(x,z(x),z'(x),u_0(x)), \end{aligned}$$

$$\begin{aligned} &\alpha D_{z'}F(x,z(x),z'(x),u_1(x)) + (1-\alpha)D_{z'}F(x,z(x),z'(x),u_2(x)) \\ &\quad = D_{z'}F(x,z(x),z'(x),u_0(x)), \end{aligned}$$

$$\begin{aligned} &\alpha F^0(x,z(x),z'(x),u_1(x)) + (1-\alpha)F^0(x,z(x),z'(x),u_2(x)) \\ &\quad = F^0(x,z(x),z'(x),u_0(x)). \end{aligned}$$

From the above it follows that the functions $D_zF(x,z(x),z'(x),u_0(x))$, $D_{z'}F(x,z(x),z'(x),u_0(x))$, $F^0(x,z(x),z'(x),u_0(x))$ are measurable. Of course,

$$\begin{aligned} &(D_zF(x,z(x),z'(x),u_0(x)), D_{z'}F(x,z(x),z'(x),u_0(x)), F^0(x,z(x),z'(x),u_0(x))) \\ &\quad \in \{(D_zF(x,z(x),z'(x),u), D_{z'}F(x,z(x),z'(x),u), F^0(x,z(x),z'(x),u));\ u \in M\}. \end{aligned}$$

Applying the implicit function theorem for a set-valued function associated with a Carathéodory function (cf. [7, Chap. II, Thm. 3.12]), we obtain an existence of a measurable function $\bar{u} : I \to M$ such that

$$\begin{aligned} D_z F(x, z(x), z'(x), u_0(x)) &= D_z F(x, z(x), z'(x), \bar{u}(x)), \\ D_{z'} F(x, z(x), z'(x), u_0(x)) &= D_{z'} F(x, z(x), z'(x), \bar{u}(x)), \\ F^0(x, z(x), z'(x), u_0(x)) &= F^0(x, z(x), z'(x), \bar{u}(x)) \end{aligned}$$

for $x \in I$ a.e. The above equalities imply the assertion of the lemma. □

The last lemma is a generalization of [3, ex. 10.5] to the case of a nonlinear functional.

LEMMA 6. *Let $u_* \in \mathcal{U}_M$ and $\varphi : I \times \mathbb{R}^r \to \mathbb{R}$ be of Carathéodory type; i.e., $\varphi(\cdot, u)$ is measurable on I for any $u \in \mathbb{R}^r$ and $\varphi(x, \cdot)$ is continuous on $\mathbb{R}^r$ for any $x \in I$.*

If

$$-\infty < \int_I \varphi(x, u_*(x))dx \leq \int_I \varphi(x, u(x))dx < +\infty$$

for any $u \in \mathcal{U}_M$, then

$$\varphi(x, u_*(x)) \leq \varphi(x, u)$$

for $x \in I$ a.e. and $u \in M$.

Proof. Suppose that the assertion of the lemma is false. Then, the set

$$\begin{aligned} \mathcal{R} &= \{x \in I; \exists_{u \in M} \quad \varphi(x, u) < \varphi(x, u_*(x))\} \\ &= \{x \in I; \exists_{u \in M_0} \quad \varphi(x, u) < \varphi(x, u_*(x))\} \\ &= \bigcup_{u \in M_0} \bigcup_{m \in \mathbb{N}} \Big\{x \in I; \quad \varphi(x, u) - \varphi(x, u_*(x)) < -\frac{1}{m}\Big\}, \end{aligned}$$

where M_0 is a countable, everywhere-dense subset of M, is measurable (in the Lebesgue sense) and $|\mathcal{R}| > 0$. From this we conclude that there exist $\bar{u} \in M_0$, $\bar{m} \in \mathbb{N}$ such that the set

$$\mathcal{R}_{\bar{u}, \bar{m}} = \Big\{x \in I; \quad \varphi(x, \bar{u}) < \varphi(x, u_*(x)) < \frac{-1}{\bar{m}}\Big\}$$

has a positive measure, i.e. $|\mathcal{R}_{\bar{u}, \bar{m}}| > 0$. □

Now, let us define the following element of $\mathcal{U}_M$:

$$\hat{u} : I \ni x \mapsto \begin{cases} \bar{u}, & x \in \mathcal{R}_{\bar{u}, \bar{m}}, \\ u_*(x), & x \notin \mathcal{R}_{\bar{u}, \bar{m}}. \end{cases}$$

We have

$$\begin{aligned} \int_I \varphi(x, \hat{u}(x))dx &= \int_{\mathcal{R}_{\bar{u}, \bar{m}}} \varphi(x, \bar{u})dx + \int_{I \setminus \mathcal{R}_{\bar{u}, \bar{m}}} \varphi(x, u_*(x))dx \\ &\quad + \int_{\mathcal{R}_{\bar{u}, \bar{m}}} \varphi(x, u_*(x))dx - \int_{\mathcal{R}_{\bar{u}, \bar{m}}} \varphi(x, u_*(x))dx \\ &= \int_I \varphi(x, u_*(x))dx + \int_{\mathcal{R}_{\bar{u}, \bar{m}}} (\varphi(x, \bar{u}) - \varphi(x, u_*(x)))dx \\ &\leq \int_I \varphi(x, u_*(x))dx + |\mathcal{R}_{\bar{u}, \bar{m}}| \cdot \left(\frac{-1}{\bar{m}}\right) < \int_I \varphi(x, u_*(x))dx. \end{aligned}$$

This contradicts our assumption. □

We shall say that a pair $(z_*, u_*) \in H_0^1(I, \mathbb{R}^n) \times \mathcal{U}_M$ is a local optimal solution of problem (S) if it satisfies the equality $\mathcal{F}(z_*, u_*) = 0$ and there exists a neighborhood V of z_* in $H_0^1(I, \mathbb{R}^n)$ such that

$$\mathcal{F}_0(z_*, u_*) \leq \mathcal{F}(z, u)$$

for any pair $(z, u) \in V \times \mathcal{U}_M$ satisfying the equality $\mathcal{F}(z, u) = 0$.

In the case when $V = H_0^1(I, \mathbb{R}^n)$, we shall say that (z_*, u_*) is a global optimal solution.

Now, we have Theorem 5.

THEOREM 5 (maximum principle). *Let us assume that the following conditions are satisfied:*

- —(5), (6), (7), (8a), (8b), (8c), (10), (11), *and* (13) *(guaranteeing the existence of a solution in* $H_0^1(I, \mathbb{R}^n)$ *of the equation* $\mathcal{F}(z, u) = 0$ *for any* $u \in \mathcal{U}_M$*);*
- —(14), (15), (16), *and* (17) *(guaranteeing the continuous Fréchet differentiability of* $\mathcal{F}$ *with respect to* $z \in H_0^1(I, \mathbb{R}^n)$*);*
- —*the function* $\mathcal{F}_0$ *satisfies the assumptions of Theorem* 1 *with* $\mathcal{F}$ *replaced by* $\mathcal{F}_0$ *(guaranteeing the continuous Fréchet differentiability of* $\mathcal{F}_0$ *with respect to* $z \in H_0^1(I, \mathbb{R}^n)$ *);*
- —(26) *(guaranteeing the fulfillment of the convexity conditions* (27), (28) *by* $\mathcal{F}$ *and* $\mathcal{F}_0$*).*

If a pair $(z_*, u_*) \in H_0^1(I, \mathbb{R}^n) \times \mathcal{U}_M$ *is such that* (24) *and* (25) *hold with* $A(\cdot)$, $B(\cdot)$, $C(\cdot)$ *given by* (23)*, then the local optimality of the pair* (z_*, u_*) *implies the existence of a function* $\lambda \in H_0^1(I, \mathbb{R}^n)$ *such that*

$$\begin{aligned}\frac{d}{dx}&(D_{z'}F_0(x, z_*(x), z_*'(x), u_*(x)) + A(x)\lambda(x) + B(x)\lambda'(x))\\ &= D_z F_0(x, z_*(x), z_*'(x), u_*(x)) + C(x)\lambda(x) + A(x)\lambda'(x)\end{aligned}$$

for $x \in I$ *a.e. and*

$$\begin{aligned}F_0(x, z^*(x), z_*'(x), u_*(x)) &+ D_z F(x, z_*(x), z_*'(x), u_*(x))\lambda(x)\\ &+ D_{z'}F(x, z_*(x), z_*'(x), u_*(x))\lambda'(x)\\ &= \min_{u \in M}\{F_0(x, z_*(x), z_*'(x), u) + D_z F(x, z_*(x), z_*'(x), u)\lambda(x)\\ &\qquad + D_{z'}F(x, z_*(x), z_*'(x), u)\lambda'(x)\}\end{aligned}$$

for $x \in I$ *a.e.*

Proof. From Lemmas 3, 4, 5 it follows that the assumptions of the extremum principle for a smooth-convex problem are satisfied.

So, there exist a constant $\lambda_0 \geq 0$ and $\Lambda \in [H_0^1(I, \mathbb{R}^n)]^{**}$ (not all zero) such that

$$\lambda_0 \partial_z \mathcal{F}_0(z_*, u_*) + (\partial_z \mathcal{F}(z_*, u_*))^* \Lambda = 0$$

and

$$\lambda_0 \mathcal{F}_0(z_*, u_*) + \Lambda(\mathcal{F}(z_*, u_*)) = \min_{u \in \mathcal{U}_M}\{\lambda_0 \mathcal{F}(z_*, u) + \Lambda(\mathcal{F}(z_*, u))\}.$$

Since the operator

$$\partial_z \mathcal{F}(z^*, u^*) : H_0^1(I, \mathbb{R}^n) \to [H_0^1(I, \mathbb{R}^n)]^*$$

is onto and, consequently, the regularity assumptions of the extremum principle are satisfied, therefore $\lambda_0 > 0$ and it may be assumed without loss of generality that $\lambda_0 = 1$.

The first of the above equalities may be written down as

$$(\partial_z \mathcal{F}_0(z_*, u_*), h) + \Lambda((\partial_z \mathcal{F}(z_*, u_*), h), \cdot) = 0$$

for any $h \in H_0^1(I, \mathbb{R}^n)$. Using the fact that

$$[H_0^1(I, \mathbb{R}^n)]^{**} \cong H_0^1(I, \mathbb{R}^n),$$

we assert that there exists a $\lambda \in H_0^1(I, \mathbb{R}^n)$ such that

$$(\partial_z \mathcal{F}_0(z_*, u_*), h) + ((\partial_z \mathcal{F}(z_*, u_*), h), \lambda) = 0$$

for any $h \in H_0^1(I, \mathbb{R}^n)$; i.e.,

$$\begin{aligned}\int_I &(D_{z'} F_0(x, z_*(x), z_*'(x), u_*(x)) \\ &+ D_{zz'} F(x, z_*(x), z_*'(x), u_*(x))\lambda(x) \\ &+ D_{z'z'} F(x, z_*(x), z_*'(x), u_*(x))\lambda'(x))h'(x)dx \\ &+ \int_I (D_z F_0(x, z_*(x), z_*'(x), u_*(x)) \\ &+ D_{zz} F(x, z_*(x), z_*'(x), u_*(x))\lambda(x) \\ &+ D_{zz'} F(x, z_*(x), z_*'(x), u_*(x))\lambda'(x))h(x)dx = 0\end{aligned}$$

for any $h \in H_0^1(I, \mathbb{R}^n)$; i.e.,

$$\begin{aligned}&\frac{d}{dx}(D_{z'} F_0(x, z^*(x), z_*'(x), u_*(x)) + D_{zz'} F(x, z^*(x), z_*'(x), u_*(x))\lambda(x) \\ &\quad + D_{z'z'} F(x, z^*(x), z_*'(x), u_*(x))\lambda^{'}(x)) = D_z F_0(x, z^*(x), z_*'(x), u_*(x)) \\ &\quad + D_{zz} F(x, z^*(x), z_*'(x), u_*(x))\lambda(x) + D_{zz'} F(x, z^*(x), z_*'(x), u_*(x))\lambda^{'}(x)\end{aligned}$$

for $x \in I$ a.e.

Analogously, we get

$$\begin{aligned}&\int_I (F_0(x, z^*(x), z_*'(x), u_*(x)) + D_z F(x, z^*(x), z_*'(x), u_*(x))\lambda(x) \\ &\quad + D_{z'} F(x, z^*(x), z_*'(x), u_*(x))\lambda^{'}(x))dx = \min_{u \in \mathcal{U}_M} \left\{ \int_I (F_0(x, z^*(x), z_*'(x), u(x)) \right. \\ &\quad \left. + D_z F(x, z^*(x), z_*'(x), u(x))\lambda(x) + D_{z'} F(x, z^*(x), z_*'(x), u(x))\lambda^{'}(x))dx \right\}.\end{aligned}$$

Consequently, from Lemma 6 we obtain

$$\begin{aligned}&F_0(x, z_*(x), z_*'(x), u_*(x)) + D_z F(x, z_*(x), z_*'(x), u_*(x))\lambda(x) \\ &\quad + D_{z'} F(x, z_*(x), z_*'(x), u_*(x))\lambda'(x) = \min_{u \in M} \{F_0(x, z_*(x), z_*'(x), u) \\ &\quad + D_z F(x, z_*(x), z_*'(x), u)\lambda(x) + D_{z'} F(x, z_*(x), z_*'(x), u)\lambda^{'}(x)\}\end{aligned}$$

for $x \in I$ a.e.

The proof is completed. □

4. The existence of an optimal solution. In this section we shall consider control problem (1)–(4) in the case when $M \subset \mathbb{R}^r$ is compact-convex and

$$F(x,z,z',u) = F_1(x,z,z') + F_2(x,z)u \tag{29}$$

for $x \in I$ a.e., z, $z' \in \mathbb{R}^n$, $u \in \mathbb{R}^r$.

We assume that F satisfies the assumptions of Theorem 4 guaranteeing the existence of a solution to system (1)–(2). Additionally, we assume that F_2 is of Carathéodory type and such that, for any $\lambda > 0$, there exists a function $g_\lambda(\cdot) \in L^2(I,\mathbb{R}_0^+)$ such that

$$|F_2(x,z)| \le g_\lambda(x) \tag{30}$$

for $x \in I$ a.e., $|z| < \lambda$.

Moreover, we shall assume that F is convex with respect to $(z,z') \in \mathbb{R}^n \times \mathbb{R}^n$ (cf. (10)), i.e., that

$$F(x,\alpha z + \beta w, \alpha z' + \beta w', u) \le \alpha F(x,z,z',u) + \beta F(x,w,w',u) \tag{31}$$

for $x \in I$ a.e., z, w, z', $w' \in \mathbb{R}^n$, $u \in \mathbb{R}^r$, α, $\beta \ge 0$, $\alpha + \beta = 1$.

The above assumption guarantees that (with a fixed control $u(\cdot)$) the set of all minimizers of f_u and the set of all solutions to (1)–(2) are identical.

Remark 7. One can omit assumption (31) and minimize functional (4) on the set $\{(z,u) \in H_0^1(I,\mathbb{R}^n) \times \mathcal{U}_M;\ \ z \ \text{ is a minimizer of } \ f_u\}$.

Let us denote by V_u the set of all solutions to (1)–(2) corresponding to a control $u(\cdot)$.

In the same way as in [15] one can show that there exists a constant $\rho > 0$ such that

$$\|z\|_{H_0^1(I,\mathbb{R}^n)} \le \rho$$

for all $z \in V_u$ and $u \in \mathcal{U}_M$.

Consequently, as in [15] one can prove the following lemma.

LEMMA 7. *If F, being of form* (29)*, satisfies the assumptions of Theorem* 4*,* (31)*, and F_2 satisfies* (30)*, $u_k \rightharpoonup u_0$ weakly in $L^2(I,\mathbb{R}^r)$, $u_k \in \mathcal{U}_M$, $k = 0,1,\ldots$, z_0 is a weak limit in $H_0^1(I,\mathbb{R}^n)$ of a subsequence of $(z_k)_{k\in\mathbb{N}}$, $z_k \in V_{u_k}$, then $z_0 \in V_{u_0}$.*

On the function $F_0 : I \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^r \to \mathbb{R}$ we assume in this section that

(32) $F_0(\cdot,z,z',u)$ is measurable on I for all z, $z' \in \mathbb{R}^n$, $u \in \mathbb{R}^r$, and $F_0(x,(\cdot,\cdot,\cdot))$ is continuous on $\mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^r$ for $x \in I$ a.e.

(33) $F_0(x,z,(\cdot,\cdot))$ is convex on $\mathbb{R}^n \times M$ for $x \in I$ a.e., $z \in \mathbb{R}^n$,

(34) for any $\lambda > 0$, there exists a function $\Psi_\lambda \in L^1(I,\mathbb{R}_0^+)$ such that

$$F_0(x,z,z',u) \ge -\Psi_\lambda(x)$$

for $x \in I$ a.e., $|z| < \lambda$, $z' \in \mathbb{R}^n$, $u \in M$.

The above assumptions imply that

$$-\infty < \mathcal{F}_0(z,u) \le +\infty \tag{35}$$

for any $z \in H_0^1(I,\mathbb{R}^n)$, $u \in \mathcal{U}_M$.

Moreover, from [1, Thm. 10.8.i] it follows that if $u_k \rightharpoonup u_0$ weakly in $L^2(I,\mathbb{R}^r)$, $u_k \in \mathcal{U}_M$, $k = 0,1,\ldots$, $z_k \rightharpoonup z_0$ weakly in $H_0^1(I,\mathbb{R}^n)$, then

$$\liminf_{k\to\infty} \mathcal{F}_0(z_k,u_k) \ge \mathcal{F}_0(z_0,u_0). \tag{36}$$

Now, we can prove the following theorem.

THEOREM 6. *If the assumptions of Theorem* 4 *and conditions* (29)–(34) *are satisfied and* M *is compact-convex, then there exists a global optimal solution of problem* (1)–(4) *in* $H_0^1(I,\mathbb{R}^n)\times\mathcal{U}_M$.

Proof. Let us denote

$$\mathcal{A}=\bigcup_{u\in\mathcal{U}_M}(V_u\times\{u\})$$

and

$$m=\inf\{\mathcal{F}_0(z,u):(z,u)\in\mathcal{A}\}.$$

If $m=+\infty$, then the existence of an optimal solution is obvious.

So, assume that $-\infty\le m<+\infty$.

Let $(z_k,u_k)_{k\in\mathbb{N}}$ be a minimizing sequence. Of course, without loss of generality we may assume that $u_k\rightharpoonup u_0\in\mathcal{U}_M$ weakly in $L^2(I,\mathbb{R}^r)$ and $z_k\rightharpoonup z_0\in H_0^1(I,\mathbb{R}^n)$ weakly in $H_0^1(I,\mathbb{R}^n)$ (the latter follows from the boundedness of the set $\bigcup_{u\in\mathcal{U}_M}V_u$). From Lemma 7 it follows that $(z_0,u_0)\in\mathcal{A}$. Moreover, by (36),

$$m\le\mathcal{F}_0(z_0,u_0)\le\liminf_{k\to\infty}\mathcal{F}_0(z_k,u_k)=\lim_{k\to\infty}\mathcal{F}_0(z_k,u_k)=m.$$

This means that

$$m=\mathcal{F}_0(z_0,u_0);$$

i.e., in view of (35) $m>-\infty$ and (z_0,u_0) is a global optimal solution of (1)–(4).

The proof is completed. □

COPRIME FACTORIZATIONS AND WELL-POSED LINEAR SYSTEMS*

OLOF J. STAFFANS†

Abstract. We study the basic notions related to the stabilization of an infinite-dimensional well-posed liner system in the sense of Salamon and Weiss. We first introduce an appropriate stabilizability and detectability notion and show that if a system is jointly stabilizable and detectable then its transfer function has a doubly coprime factorization in H^∞. The converse is also true: every function with a doubly coprime factorization in H^∞ is the transfer function of a jointly stabilizable and detectable well-posed linear system. We show further that a stabilizable and detectable system is stable if and only if its input/output map is stable. Finally, we construct a dynamic, possibly non-well-posed, stabilizing compensator. The notion of stability that we use is the natural one for the quadratic cost minimization problem, and it does not imply exponential stability.

Key words. stabilizability, detectability, input/output stability

1. Introduction.

Although the theory of well-posed linear systems in the sense of Salamon and Weiss has been around for some time, applications of this theory to "real" control problems are scarce. This is in sharp contrast to the widespread use of the theory of Pritchard–Salamon systems; see, e.g., [2], [12], [15], [16], and [26] for discussions of different aspects of this theory. A fair number of recent pure frequency domain results for H^∞ transfer functions do exist (some of these are listed in the References), but they have not been connected to the theory of well-posed linear systems. The few connections known to us in the spring of 1995 when the first version of this paper was written were the discussion of the Lyapunov equation in [10], the discussion on feedback and estimation of well-posed systems in [13], the discussion of balanced realizations in [14], the discussion of the connection between internal and external stability in [17], and the discussions of the quadratic cost minimization problem in [19] and [24] (not to mention the basic papers [20], [30], and [31] and the nice review [1]); the list above is certainly not complete. In particular, at that time we were not able to find any reasonably complete results on the stabilizability and detectability of general well-posed linear systems, and the connection of these notions to the notion of a (doubly) coprime factorization of the transfer function of the system.[1] We needed these results in order to solve the quadratic cost minimization problem for unstable systems, and we were forced to develop the needed stabilization theory ourselves.[2]

Subsequently the situation changed significantly with the appearance of the preprints [4], [5], [6], [11], [32], and [33]. Out of these [4], [5], and [6] are fairly closely related to our work. Several of the results that we prove here are also found in [5], in a slightly less general setting. The results given in [4] and [6] overlap those that we

[1] Throughout [13] Morris takes the observation operator to be bounded.

[2] Our solution to the unstable quadratic cost minimization problem is based on the present work, and it is presented in [25].

present in section 5.[3] These preprints have also had a certain influence on a revision carried out in late 1996: we were able to use the ideas presented in [5] to simplify our original proofs of Theorems 4.4 and 5.3, and Remark 5.5 was inspired by [5] and [6]. In addition we added Lemma 3.17 and Corollary 3.18 as an answer to a question asked by George Weiss in the summer of 1996, and we redrew all the diagrams.

The notion of stability that we use was forced upon us by our solution to the quadratic cost minimization problem for stable well posed linear systems. In particular, it does not imply exponential stability. The most important notion is what we call "joint stabilizability and detectability." The word "joint" refers to the fact that in our setting the notions of stabilizability and detectability are not decoupled from each other as they are in the Pritchard–Salamon theory; roughly speaking, the "feedback operator and the output injection operator must be compatible." This is a problem that is not present in a Pritchard–Salamon system, due to the fact that for such systems the admissibility of a particular control operator together with the admissibility of a particular observation operator implies the well posedness of the corresponding input/output map, something that is not true for general well posed linear systems. Maybe the main individual result of this paper is the statement that if a system is jointly stabilizable and detectable, then its transfer function has a doubly coprime factorization in H^∞.[4] The converse is also true: every function that has a doubly coprime factorization in H^∞ is the transfer function of a jointly strongly stabilizable and detectable well-posed linear system.

Having explained the relation between joint stabilizability and detectability on one hand and doubly coprime factorizations on the other hand, we continue with a short discussion of how to use an observer as a stabilizing dynamic compensator. This theory parallels the classical theory, apart from the fact that the well posedness of the observer is not automatically guaranteed.

For the convenience of the reader, we start with a short presentation of well-posed linear systems.

We use the following notation.

$\mathcal{L}(U;Y)$, $\mathcal{L}(U)$: The set of bounded linear operators from U into Y or from U into itself, respectively.

I: The identity operator.

A^*: The (Hilbert space) adjoint of the operator A.

$\mathbf{R}$, $\mathbf{R}^+$, $\mathbf{R}^-$: $\mathbf{R} = (-\infty, \infty)$, $\mathbf{R}^+ = [0, \infty)$, and $\mathbf{R}^- = (-\infty, 0]$.

$L^2(J;U)$: The set of U-valued L^2-functions on the interval J.

$L^2_\omega(J;U)$: $L^2_\omega(J;U) = \left\{ u \in L^2_{\mathrm{loc}}(J;U) \;\middle|\; (t \mapsto \mathrm{e}^{-\omega t}u(t)) \in L^2(J;U) \right\}$.

$H^\infty_\omega(U;Y)$: The set of bounded analytic $\mathcal{L}(U;Y)$-valued functions over the half-plane $\Re z > \omega$, with the sup-norm.

$TI_\omega(U;Y)$, $TI_\omega(U)$: The set of bounded linear time-invariant operators from $L^2_\omega(\mathbf{R};U)$ into $L^2_\omega(\mathbf{R};Y)$ or from $L^2_\omega(\mathbf{R};U)$ into itself.

$TIC_\omega(U;Y)$, $TIC_\omega(U)$: The set of causal operators in $TI_\omega(U;Y)$ or $TI_\omega(U)$.

$\langle \cdot, \cdot \rangle_H$: The inner product in the Hilbert space H.

[3] Curtain, Weiss, and Weiss call the compensator in Theorem 5.3 a "controller with internal loop."

[4] As we mentioned above, the main purpose of this paper is not to prove any particular result but to develop a general theory that can be used in the study of the quadratic cost minimization problem, to which we return in [25].

$\tau(t)$: The time shift group $\tau(t)u(s) = u(t+s)$ (this is a left shift when $t > 0$ and a right shift when $t < 0$).

π_J: $(\pi_J u)(s) = u(s)$ if $s \in J$ and $(\pi_J u)(s) = 0$ if $s \notin J$. Here J is a subset of $\mathbf{R}$.

$\pi_+,\ \pi_-$: $\pi_+ = \pi_{\mathbf{R}^+}$ and $\pi_- = \pi_{\mathbf{R}^-}$.

We extend an L^2_ω-function u defined on a subinterval J of $\mathbf{R}$ to the whole real line by requiring u to be zero outside of J, and we denote the extended function by $\pi_J u$. Thus we use the same symbol π_J both for the embedding operator $L^2_\omega(J) \to L^2_\omega(\mathbf{R})$ and for the corresponding projection operator $L^2_\omega(\mathbf{R}) \to L^2_\omega(J)$. With this interpretation, $\pi_J L^2_\omega(\mathbf{R};U) = L^2_\omega(J;U) \subset L^2_\omega(\mathbf{R};U)$ for each interval $J \subset \mathbf{R}$.

2. A review of well-posed linear systems and time-invariant operators. In order to fix the notation and describe the basic setting we first give a brief presentation of the theory of the Salamon–Weiss class of well-posed linear systems. This theory has been developed in [18], [19], [20], [3], [7], and [27], [28], [30], [31] (and many other papers), and we refer the reader to these sources for additional reading.[5] A recent contribution is found in [24], and the setting that we use here is a slight extension of the one in [24]. The difference is that the discussion in [24] is restricted to the case of (externally) stable systems; here we also need to consider unstable systems. The major parts of this setting are found in [20], too.

In order to formulate the axioms satisfied by a well-posed linear system we introduce exponentially weighted L^2-spaces. For each Hilbert space U and each $\omega \in \mathbf{R}$ we let $L^2_\omega(\mathbf{R};U)$ be the weighted L^2-space

$$L^2_\omega(\mathbf{R};U) = \big\{\, u \in L^2_{\mathrm{loc}}(\mathbf{R};U) \;\big|\; \big(t \mapsto \mathrm{e}^{-\omega t}u(t)\big) \in L^2(\mathbf{R};U) \,\big\}.$$

This is a Hilbert space with the natural norm $\|\mathrm{e}^{-\omega\cdot}u(\cdot)\|_{L^2(\mathbf{R};U)}$. We also need the "past time" projection π_-, the "future time" projection π_+, and the "time shift" group $\tau(t)$ that operate on functions $u \in L^2_\omega(\mathbf{R};U)$ in the following way:

$$(\pi_- u)(s) = \begin{cases} u(s), & s \in \mathbf{R}^-, \\ 0, & s \in \mathbf{R}^+, \end{cases}$$

$$(\pi_+ u)(s) = \begin{cases} u(s), & s \in \mathbf{R}^+, \\ 0, & s \in \mathbf{R}^-, \end{cases}$$

$$(\tau(t)u)(s) = u(t+s), \quad t, s \in \mathbf{R}.$$

DEFINITION 2.1. *Let U, H, and Y be Hilbert spaces, and let $\omega \in \mathbf{R}$. A (causal) ω-stable well-posed linear system on (U,H,Y) is a quadruple $\Psi = \left[\begin{smallmatrix} \mathcal{A} & \mathcal{B} \\ \mathcal{C} & \mathcal{D} \end{smallmatrix}\right]$, where $\mathcal{A}$, $\mathcal{B}$, $\mathcal{C}$, and $\mathcal{D}$ are bounded linear operators of the following type:*

(i) *$\mathcal{A}(t)\colon H \to H$ is a strongly continuous semigroup of bounded linear operators on H satisfying $\sup_{t\in\mathbf{R}^+} \|\mathrm{e}^{-\omega t}\mathcal{A}(t)\| < \infty$;*

(ii) *$\mathcal{B}\colon L^2_\omega(\mathbf{R};U) \to H$ satisfies $\mathcal{A}(t)\mathcal{B}u = \mathcal{B}\tau(t)\pi_- u$ for all $u \in L^2_\omega(\mathbf{R};U)$ and $t \in \mathbf{R}^+$;*

(iii) *$\mathcal{C}\colon H \to L^2_\omega(\mathbf{R};Y)$ satisfies $\mathcal{C}\mathcal{A}(t)x = \pi_+\tau(t)\mathcal{C}x$ for all $x \in H$ and $t \in \mathbf{R}^+$;*

(iv) *$\mathcal{D}\colon L^2_\omega(\mathbf{R};U) \to L^2_\omega(\mathbf{R};Y)$ satisfies $\tau(t)\mathcal{D}u = \mathcal{D}\tau(t)u$, $\pi_-\mathcal{D}\pi_+ u = 0$, and $\pi_+\mathcal{D}\pi_- u = \mathcal{C}\mathcal{B}u$ for all $u \in L^2_\omega(\mathbf{R};U)$ and $t \in \mathbf{R}$.*

[5] In the early literature these systems were called "well-posed semigroup control systems" by Salamon and "abstract linear systems" by Weiss.

If, in addition, $\mathrm{e}^{-\omega t}\mathcal{A}(t)x \to 0$ *as* $t \to \infty$ *for all* $x \in H$*, then* Ψ *is strongly* ω*-stable. The system* Ψ *is [strongly]*[6] *stable iff it is [strongly]* ω*-stable with* $\omega = 0$*, and it is exponentially stable iff it is* ω*-stable for some* $\omega < 0$*.*

The different components of Ψ *are named as follows:* U *is the input space,* H *is the state space,* Y *is the output space,* $\mathcal{A}$ *is the semigroup,* $\mathcal{B}$ *is the controllability map,* $\mathcal{C}$ *is the observability map, and* $\mathcal{D}$ *is the input/output map of* Ψ*.*

This is the same definition as [24, Definition 2.1], except that throughout we took $\omega = 0$ and did not put any restrictions on the growth rate of the semigroup $\mathcal{A}$.

The axioms listed above describe standard properties of the corresponding maps induced by systems with bounded control and observation operators. Whenever when we refer to an ω-stable "classical" system, we mean a system of the following type: we let A be the generator of a semigroup $\mathcal{A}$ on a Hilbert space H satisfying $\sup_{t\in\mathbf{R}^+} \|\mathrm{e}^{\epsilon t}\mathrm{e}^{-\omega t}\mathcal{A}(t)\| < \infty$ for some $\epsilon > 0$, let U and Y be Hilbert spaces, let $B \in \mathcal{L}(U;H)$, $C \in \mathcal{L}(H;Y)$, and $D \in \mathcal{L}(U;Y)$, and consider the system

$$\begin{aligned} x'(t) &= Ax(t) + Bu(t), \\ y(t) &= Cx(t) + Du(t), \qquad t \geq T, \\ x(T) &= x_T, \end{aligned} \tag{2.1}$$

where T is a given initial time and x_T is a given initial value. We call u the control, x the state, y the output (or observation), A the generator, B the control operator, C the observation operator, and D the feed-through operator of this classical system. The state x is required to be a strong solution of (2.1); i.e., the state x and output y are given by

$$x(t) = \mathcal{A}(t)x_T + \int_T^t \mathcal{A}(t-s)Bu(s)\,ds, \quad t \geq T, \tag{2.2}$$

$$y(t) = C\mathcal{A}(t)x_T + \int_T^t C\mathcal{A}(t-s)Bu(s)\,ds + Du(t), \quad t \geq T. \tag{2.3}$$

In this case we define $\mathcal{B}$, $\mathcal{C}$, and $\mathcal{D}$ by

$$\mathcal{B}u = \int_{-\infty}^0 \mathcal{A}(-s)Bu(s)\,ds, \tag{2.4}$$

$$\mathcal{C}x = \left(t \mapsto C\mathcal{A}(t)x,\ t \in \mathbf{R}^+\right), \tag{2.5}$$

$$\mathcal{D}u = \left(t \mapsto \int_{-\infty}^t C\mathcal{A}(t-s)Bu(s)\,ds + Du(t),\ t \in \mathbf{R}\right). \tag{2.6}$$

Thus $\mathcal{B}$ is the mapping from the control $u \in L^2_\omega(\mathbf{R}^-;U)$ to the final state $x(0) \in H$ (take $T = -\infty$, $x_T = 0$, and $t = 0$), $\mathcal{C}$ is the mapping from the initial state $x_0 \in H$ to the output $y \in L^2_\omega(\mathbf{R}^+;Y)$ (take $T = 0$ and $u = 0$), and $\mathcal{D}$ is the mapping from the control $u \in L^2_\omega(\mathbf{R};U)$ to the output $y \in L^2_\omega(\mathbf{R};Y)$ (take $T = -\infty$ and $x_T = 0$). We leave the easy proof of the fact that these operators indeed are bounded linear operators between the given spaces to the reader.

Each well-posed linear system Ψ has a *controlled state* and an *output*. Depending on whether the initial time is finite or infinite these are defined in two slightly different ways as follows.

[6]Square brackets represent optional parts of a sentence. Statements in square brackets are supposed to be true (a) if you omit all square brackets (single or double), (b) if you keep the single brackets, (c) if you keep the double brackets.

DEFINITION 2.2. *Let $\Psi = \left[\begin{smallmatrix} \mathcal{A} & \mathcal{B} \\ \mathcal{C} & \mathcal{D} \end{smallmatrix}\right]$ be an ω-stable well-posed linear system on (U, H, Y), and let $u \in L^2_\omega(\mathbf{R}; U)$. In the time-invariant setting (corresponding to the initial time $-\infty$) the controlled state $x(t)$ at time $t \in \mathbf{R}$ and the output y of Ψ with control u are given by*

$$\begin{bmatrix} x(t) \\ y \end{bmatrix} = \begin{bmatrix} \mathcal{B}\tau(t)u \\ \mathcal{D}u \end{bmatrix},$$

and in the initial value setting with initial time s, initial value $x(s)$, and control u, the controlled state $x(t)$ at time $t \geq s$ and the output y of Ψ are given by

$$\begin{bmatrix} x(t) \\ y \end{bmatrix} = \begin{bmatrix} \mathcal{A}(t-s) & \mathcal{B}\tau(t) \\ \tau(-s)\mathcal{C} & \mathcal{D} \end{bmatrix} \begin{bmatrix} x(s) \\ \pi_{[s,\infty)}u \end{bmatrix} = \begin{bmatrix} \mathcal{A}(t-s)x(s) + \mathcal{B}\tau(t)\pi_{[s,\infty)}u \\ \tau(-s)\mathcal{C}x(s) + \mathcal{D}\pi_{[s,\infty)}u \end{bmatrix},$$

where $\pi_{[s,\infty)} = \tau(-s)\pi_+\tau(s)$ is given by

$$(\pi_{[s,\infty)}u)(t) = \begin{cases} u(t), & t \geq s, \\ 0, & t < s. \end{cases}$$

In particular, in the initial value setting with initial time zero, initial value x_0, and control u, the controlled state $x(t)$ at time $t \in \mathbf{R}^+$ and the output y of Ψ are given by

$$\begin{bmatrix} x(t) \\ y \end{bmatrix} = \begin{bmatrix} \mathcal{A}(t) & \mathcal{B}\tau(t) \\ \mathcal{C} & \mathcal{D} \end{bmatrix} \begin{bmatrix} x_0 \\ \pi_+u \end{bmatrix} = \begin{bmatrix} \mathcal{A}(t)x_0 + \mathcal{B}\tau(t)\pi_+u \\ \mathcal{C}x_0 + \mathcal{D}\pi_+u \end{bmatrix}.$$

Let us remark that the most commonly studied problem is the initial value problem with initial time zero, and in most papers this is the only one that is treated.

REMARK 2.3. *Because of Definition 2.2, we shall frequently use the alternative notation $\left[\begin{smallmatrix} \mathcal{A} & \mathcal{B}\tau \\ \mathcal{C} & \mathcal{D} \end{smallmatrix}\right]$ for the well-posed linear system $\left[\begin{smallmatrix} \mathcal{A} & \mathcal{B} \\ \mathcal{C} & \mathcal{D} \end{smallmatrix}\right]$.*

In the case of the classical ω-stable system (2.1) with bounded control operator B, bounded observation operator C, and control $u \in L^2_\omega(\mathbf{R}; U)$, in the time-invariant setting the state x and output y of Ψ are given by

$$x(t) = \int_{-\infty}^{t} \mathcal{A}(t-s)Bu(s)\,ds, \quad t \in \mathbf{R}, \tag{2.7}$$

$$y(t) = \int_{-\infty}^{t} C\mathcal{A}(t-s)Bu(s)\,ds + Du(t), \quad t \in \mathbf{R}, \tag{2.8}$$

and in the initial value setting with initial time T, initial value x_T, and control u, the state and output are given by (2.2) and (2.3).

An important fact is that the number ω in Definition 2.1 is not uniquely determined as described in Lemma 2.4.

LEMMA 2.4. *Let $\Psi = \left[\begin{smallmatrix} \mathcal{A} & \mathcal{B} \\ \mathcal{C} & \mathcal{D} \end{smallmatrix}\right]$ be an ω-stable well-posed linear system on (U, H, Y). Then Ψ is also an α-stable well-posed linear system on (U, H, Y) for every $\alpha > \omega$. If instead $\alpha < \omega$, then Ψ has a unique extension to an α-stable well-posed linear system on (U, H, Y) iff $\sup_{t \in \mathbf{R}^+} \|\mathrm{e}^{-\alpha t}\mathcal{A}(t)\| < \infty$ and the operators $\mathcal{B}$, $\mathcal{C}$, and $\mathcal{D}$ can be extended to bounded linear operators in $\mathcal{L}(L^2_\alpha(\mathbf{R}; U); H)$, $\mathcal{L}(H; L^2_\alpha(\mathbf{R}; Y))$, and $\mathcal{L}(L^2_\alpha(\mathbf{R}; U); L^2_\alpha(\mathbf{R}; Y))$, respectively.*

Proof. The first claim follows from Lemma 2.9 below and the fact that if $\alpha > \omega$, then $L^2_\alpha(\mathbf{R}^-; U) \subset L^2_\omega(\mathbf{R}^-; U)$ and $L^2_\omega(\mathbf{R}^+; Y) \subset L^2_\alpha(\mathbf{R}^+; Y)$. To prove the second claim it suffices to observe that $L^2_\omega \cap L^2_\alpha$ is dense in L^2_α. ∎

DEFINITION 2.5. *We call Ψ a well-posed linear system on (U, H, Y) iff it is an ω-stable well-posed linear system on (U, H, Y) for some $\omega \in \mathbf{R}$. The infimum of all the numbers ω for which Ψ is ω-stable is the exponential growth rate of Ψ. Thus, Ψ is exponentially stable iff its exponential growth rate is negative.*

As Salamon [20] and Weiss [27], [28], [30] have shown, the growth rate of a system Ψ is equal to the growth rate of its semigroup as explained in Lemma 2.6.

LEMMA 2.6. *The exponential growth rate of a well-posed linear system Ψ is equal to the exponential growth rate $\omega = \lim_{t\to\infty} t^{-1}\log(\|\mathcal{A}(t)\|)$ of its semigroup. In particular, Ψ is exponentially stable iff its semigroup is exponentially stable.*

See [20, Lemma 2.1] or [27, Proposition 2.5], [28, Proposition 2.3], and [30, Proposition 4.1] for proofs.

One of the required properties of the input/output operator $\mathcal{D}$ of Ψ is that it is time invariant.

DEFINITION 2.7. *Let U and Y be two Hilbert spaces. A bounded linear operator $\mathcal{D}\colon L^2_\omega(\mathbf{R};U) \to L^2_\omega(\mathbf{R};Y)$ is time invariant iff it commutes with time shifts; i.e., $\tau(t)\mathcal{D}u = \mathcal{D}\tau(t)u$ for all $u \in L^2_\omega(\mathbf{R};U)$ and all $t \in \mathbf{R}$. We denote this class of operators by $TI_\omega(U;Y)$. The Hankel operator induced by $\mathcal{D}$ is the operator $\pi_+\mathcal{D}\pi_-$, and the anti-Hankel operator induced by $\mathcal{D}$ is the operator $\pi_-\mathcal{D}\pi_+$. The Toeplitz operator induced by $\mathcal{D}$ is the operator $\pi_+\mathcal{D}\pi_+$, and the anti-Toeplitz operator induced by $\mathcal{D}$ is the operator $\pi_-\mathcal{D}\pi_-$.*

The word "causal" that we have included in the definition of a well-posed linear system relates to the fact that all the components of Ψ in Definition 2.1 are causal as follows.

DEFINITION 2.8. *An operator $\mathcal{B}\colon L^2_\omega(\mathbf{R};U) \to H$ is causal [anticausal] if $\mathcal{B}\pi_+ = 0$ [$\mathcal{B}\pi_- = 0$]. An operator $\mathcal{C}\colon H \to L^2_\omega(\mathbf{R};Y)$ is causal [anticausal] if $\pi_-\mathcal{C} = 0$ [$\pi_+\mathcal{C} = 0$]. A time-invariant operator $\mathcal{D}\colon L^2_\omega(\mathbf{R};U) \to L^2_\omega(\mathbf{R};Y)$ is causal [anticausal] if $\pi_-\mathcal{D}\pi_+ = 0$ [$\pi_+\mathcal{D}\pi_- = 0$], and it is static if it is both causal and anticausal. We denote the class of bounded linear time invariant causal operators by $TIC_\omega(U;Y)$.*

Thus, the condition imposed on $\mathcal{D}$ in Definition 2.1 requires that $\mathcal{D} \in TIC_\omega(U;Y)$ (i.e., $\mathcal{D}$ is time invariant and causal) and that the Hankel operator induced by $\mathcal{D}$ is equal to $\mathcal{CB}$. Intuitively, a causal controllability map $\mathcal{B}$ maps past inputs into the present state, a causal observability map $\mathcal{C}$ maps the present state into future outputs, and the past output of a causal input/output map $\mathcal{D}$ does not depend on future inputs.

As is well known, there is a one-to-one correspondence between $TIC_\omega(U;Y)$ and the set of $\mathcal{L}(U;Y)$-valued H^∞-functions over the half-plane $\Re z > \omega$. We denote this set of functions by $H^\infty_\omega(U;Y)$. The norm in this space is the usual H^∞-norm.

LEMMA 2.9. *The two spaces $TIC_\omega(U;Y)$ and $H^\infty_\omega(U;Y)$ are isometrically isomorphic. More precisely, to each operator $\mathcal{D} \in TIC_\omega(U;Y)$ there corresponds a unique function $\widehat{\mathcal{D}} \in H^\infty_\omega(U;Y)$ such that for each $u \in L^2_\omega(\mathbf{R}^+;U)$, the Laplace transform of $\mathcal{D}u$ is given by $\widehat{\mathcal{D}}(z)\widehat{u}(z)$, $\Re z > \omega$, where $\widehat{u}$ is the Laplace transform of u. The function $\widehat{\mathcal{D}}$ is called the transfer function (or symbol) of $\mathcal{D}$.*

Thus, intuitively, $\widehat{\mathcal{D}}$ is the Laplace transform of $\mathcal{D}$. This result is classic; see, for example, [8] or [29].

By a result due to Salamon [20, Section 4], a time-invariant operator $\mathcal{D}$ can be interpreted as the input/output operator of a well-posed linear system Ψ iff it belongs to $TIC_\omega(U;Y)$ for some $\omega \in \mathbf{R}$. Such a system is called a *realization* of $\mathcal{D}$. Two particular realizations are described below.

DEFINITION 2.10. *Let $\omega \in \mathbf{R}$ and $\mathcal{D} \in TIC_\omega(U;Y)$, and let τ be the left-shift group. Then the ω-stable well-posed linear system*

$$\begin{bmatrix} \tau\pi_- & \pi_- \\ \pi_+\mathcal{D}\pi_- & \mathcal{D} \end{bmatrix}$$

on $(U, L^2_\omega(\mathbf{R}^-;U), Y)$ *is called the exactly controllable realization of* $\mathcal{D}$*, and the strongly* ω*-stable well-posed linear system*

$$\begin{bmatrix} \pi_+\tau\pi_+ & \pi_+\mathcal{D}\pi_- \\ I & \mathcal{D} \end{bmatrix}$$

on $(U, L^2_\omega(\mathbf{R}^+;Y), Y)$ *is called the continuously observable realization of* $\mathcal{D}$*.*

Indeed, it is obvious that the two systems defined above satisfy the requirements of Definition 2.1. See [20, section 4] for an explanation of the names of these realizations.

Occasionally we shall need to discuss the stability of the different parts of Ψ separately, and for this purpose we further introduce the following natural terminology.

DEFINITION 2.11. *Let* $\Psi = \left[\begin{smallmatrix} \mathcal{A} & \mathcal{B} \\ \mathcal{C} & \mathcal{D} \end{smallmatrix}\right]$ *be a well-posed linear system on* (U, H, Y)*. Then*

(i) $\mathcal{A}$ *is* ω*-stable iff* $\sup_{t\in\mathbf{R}^+} \|\mathrm{e}^{-\omega t}\mathcal{A}(t)\| < \infty$ *and strongly* ω*-stable iff* $\mathrm{e}^{-\omega t}\mathcal{A}(t)x \to 0$ *as* $t \to \infty$ *for all* $x \in H$*,*

(ii) $\mathcal{B}$ *is* ω*-stable iff* $\mathcal{B} \in \mathcal{L}(L^2_\omega(\mathbf{R};U);H)$*,*

(iii) $\mathcal{C}$ *is* ω*-stable iff* $\mathcal{C} \in \mathcal{L}(H;L^2_\omega(\mathbf{R};Y))$*,*

(iv) $\mathcal{D}$ *is* ω*-stable iff* $\mathcal{D} \in TIC_\omega(U;Y)$*.*

As before, stability of a component of Ψ *means* ω*-stability with* $\omega = 0$*, and exponential stability means* ω*-stability for some* $\omega < 0$*.*

REMARK 2.12. *Almost all results presented below remain valid if we throughout drop the assumption that* $\mathcal{A}$ *is* ω*-stable in condition* (i) *of Definition* 2.1*. Thus for our purposes it suffices if the system is input* ω*-stable* (*condition* (ii))*, output* ω*-stable* (*condition* (iii))*, and input/output* ω*-stable* (*condition* (iv) *of Definition* 2.11)*. In* [24] *this situation was referred to as* external ω*-stability.*

One gets the *adjoint* of a system Ψ by replacing each operator by its adjoint and exchanging the controllability and observability maps with each other. In the computation of the adjoints of $\mathcal{B}$, $\mathcal{C}$, and $\mathcal{D}$ we use the ordinary (unweighted) L^2-inner product. This means that the resulting operators are bounded linear operators on $L^2_{-\omega}$ instead of bounded linear operators on L^2_ω. Moreover, causality is replaced by anticausality. The resulting system is an $(-\omega)$-stable anticausal system of the following type.

DEFINITION 2.13. *Let* Y*,* H*, and* U *be Hilbert spaces. An anticausal* ω*-stable well-posed linear* L^2*-system on* (Y, H, U) *is a quadruple* $\Psi^* = \left[\begin{smallmatrix} \mathcal{A}^* & \mathcal{C}^* \\ \mathcal{B}^* & \mathcal{D}^* \end{smallmatrix}\right]$*, where* $\mathcal{A}^*$*,* $\mathcal{C}^*$*,* $\mathcal{B}^*$*, and* $\mathcal{D}^*$ *are bounded linear operators of the following type:*

(i) $\mathcal{A}^*(t)\colon H \to H$ *is a strongly continuous semigroup of bounded linear operators on* H *satisfying* $\sup_{t\in\mathbf{R}^+} \|\mathrm{e}^{\omega t}\mathcal{A}^*(t)\| < \infty$*;*

(ii) $\mathcal{C}^*\colon L^2_\omega(\mathbf{R};Y) \to H$ *satisfies* $\mathcal{A}^*(-s)\mathcal{C}^*y^* = \mathcal{C}^*\tau(s)\pi_+y^*$ *for all* $y^* \in L^2_\omega(\mathbf{R};Y)$ *and* $s \in \mathbf{R}^-$*;*

(iii) $\mathcal{B}^*\colon H \to L^2_\omega(\mathbf{R};U)$ *satisfies* $\mathcal{B}^*\mathcal{A}^*(-s)x^* = \pi_-\tau(s)\mathcal{B}^*x^*$ *for all* $x^* \in H$ *and* $s \in \mathbf{R}^-$*;*

(iv) $\mathcal{D}^*\colon L^2(\mathbf{R};Y) \to L^2_\omega(\mathbf{R};U)$ *satisfies* $\tau(s)\mathcal{D}^*y^* = \mathcal{D}^*\tau(s)y^*$*,* $\pi_+\mathcal{D}^*\pi_-y^* = 0$*, and* $\pi_-\mathcal{D}^*\pi_+y^* = \mathcal{B}^*\mathcal{C}^*y^*$ *for all* $y^* \in L^2_\omega(\mathbf{R};Y)$ *and* $s \in \mathbf{R}$*.*

If, in addition, $\mathrm{e}^{\omega t}\mathcal{A}^*(t)x^* \to 0$ *as* $t \to \infty$ *for all* $x^* \in H$*, then* Ψ^* *is strongly* ω*-stable. The system* Ψ^* *is [strongly] stable iff it is [strongly]* ω*-stable with* $\omega = 0$*, and it is exponentially stable iff it is* ω*-stable for some* $\omega > 0$*.*

The different components of Ψ^* *are named as follows:* Y *is the input space,* H *is the state space,* U *is the output space,* $\mathcal{A}^*$ *is the semigroup,* $\mathcal{C}^*$ *is the controllability*

map, $\mathcal{B}^*$ is the observability map, and $\mathcal{D}^*$ is the input/output map of Ψ^*.

The controlled *state* and *output* of Ψ^* are defined as follows.

DEFINITION 2.14. *Let $\Psi^* = \left[\begin{smallmatrix} \mathcal{A}^* & \mathcal{C}^* \\ \mathcal{B}^* & \mathcal{D}^* \end{smallmatrix}\right]$ be an ω-stable anticausal well-posed linear system on (Y, H, U) and let $y^* \in L^2_\omega(\mathbf{R}; Y)$. In the time-invariant setting the controlled state $x^*(s)$ at time $s \in \mathbf{R}$ and the output u^* of Ψ^* with control y^* are given by*

$$\begin{bmatrix} x^*(s) \\ u^* \end{bmatrix} = \begin{bmatrix} \mathcal{C}^*\tau(s)y^* \\ \mathcal{D}^*y^* \end{bmatrix},$$

and in the initial value setting with initial time t, initial value $x^*(t)$, and control y^*, the controlled state $x^*(s)$ at time $s \le t$ and the output u^* of Ψ^* are given by

$$\begin{bmatrix} x^*(s) \\ u^* \end{bmatrix} = \begin{bmatrix} \mathcal{A}^*(t-s) & \mathcal{C}^*\tau(s) \\ \tau(-t)\mathcal{B}^* & \mathcal{D}^* \end{bmatrix} \begin{bmatrix} x^*(t) \\ \pi_{(-\infty,t]}y^* \end{bmatrix} = \begin{bmatrix} \mathcal{A}^*(t-s)x^*(t) + \mathcal{C}^*\tau(s)\pi_{(-\infty,t]}y^* \\ \tau(-t)\mathcal{B}^*x^*(t) + \mathcal{D}^*\pi_{(-\infty,t]}y^* \end{bmatrix},$$

where $\pi_{(-\infty,t]} = \tau(-t)\pi_-\tau(t)$ is given by

$$(\pi_{(-\infty,t]}y^*)(s) = \begin{cases} y^*(s), & s \le t, \\ 0, & s > t. \end{cases}$$

In particular, in the initial value setting with initial time zero, initial value x_0^*, and control y^*, the controlled state $x^*(s)$ at time $s \in \mathbf{R}^-$ and the output u^* of Ψ^* are given by

$$\begin{bmatrix} x^*(s) \\ u^* \end{bmatrix} = \begin{bmatrix} \mathcal{A}^*(-s) & \mathcal{C}^*\tau(s) \\ \mathcal{B}^* & \mathcal{D}^* \end{bmatrix} \begin{bmatrix} x_0^* \\ \pi_-y^* \end{bmatrix} = \begin{bmatrix} \mathcal{A}^*(-s)x_0^* + \mathcal{C}^*\tau(s)\pi_-y^* \\ \mathcal{B}^*x_0^* + \mathcal{D}^*\pi_-y^* \end{bmatrix}.$$

The formulas in Definitions 2.2 and 2.14 are chosen in such a way that Ψ and Ψ^* interact in the following way.

LEMMA 2.15. *Let Ψ be a well-posed linear system on (U, H, Y) and Ψ^* its adjoint (with respect to the ordinary unweighted inner product in L^2). Let $-\infty < s < t < \infty$, let x and y be the state and output of Ψ with initial time s and control u, and let x^* and u^* be the state and output of Ψ^* with initial time t and control y^*. Then*

$$\langle x^*(t), x(t)\rangle_H + \int_s^t \langle y^*(v), y(v)\rangle_Y \, dv = \langle x^*(s), x(s)\rangle_H + \int_s^t \langle u^*(v), u(v)\rangle_U \, dv.$$

We leave the easy proof of this lemma to the reader.

We use diagrams of the type drawn in Figure 2.1 to represent the relation between the state x, the output y, the initial value x_0, and the control u of Ψ in the initial value setting with initial time zero. In our diagrams we use the following conventions.

(i) Initial states and controls enter at the top or bottom, and they are acted on by all the operators located in the column to which they are attached. In particular, note that x_0 is attached to the first column and u to the second.

(ii) Final states and outputs leave to the left or right, and they are the sums of all the elements in the row to which they are attached. In particular, note that x is attached to the top row and y to the bottom row.

A similar diagram is used to describe the adjoint system Ψ^*.

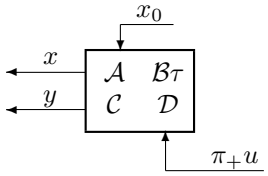

FIG. 2.1. *Input/state/output diagram of* Ψ.

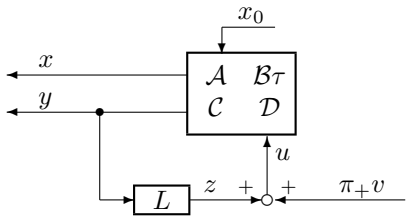

FIG. 3.1. *Static output feedback.*

3. Feedback, stabilizability, and detectability. The notions of stabilizability and detectability deal with the possibility of stabilizing a well-posed linear system by the use of either a state feedback or an output injection. Therefore, before we can study these notions, we must first look at different kinds of feedback connections.

We start with the most basic feedback connection, namely, the notion of a (static) output feedback, drawn in Figure 3.1. Here L is a bounded linear operator from the output space into the input space. Thus if we consider this feedback configuration in the initial value setting with initial time zero, initial value x_0, and control v, we find that the effective input u, the state $x(t)$ at time $t \geq 0$, the output y, and the feedback signal z satisfy the equations

$$\begin{aligned} u &= z + \pi_+ v, \\ x(t) &= \mathcal{A}(t)x_0 + \mathcal{B}\tau(t)u, \\ y &= \mathcal{C}x_0 + \mathcal{D}u, \\ z &= Ly, \end{aligned} \tag{3.1}$$

which formally can be solved as

$$\begin{aligned} u &= (I - L\mathcal{D})^{-1}(L\mathcal{C}x_0 + \pi_+ v), \\ x(t) &= \big(\mathcal{A}(t) + \mathcal{B}\tau(t)L(I - \mathcal{D}L)^{-1}\mathcal{C}\big)x_0 + \mathcal{B}(I - L\mathcal{D})^{-1}\tau(t)\pi_+ v, \\ y &= (I - \mathcal{D}L)^{-1}(\mathcal{C}x_0 + \mathcal{D}\pi_+ v), \\ z &= (I - L\mathcal{D})^{-1}L(\mathcal{C}x_0 + \mathcal{D}\pi_+ v). \end{aligned} \tag{3.2}$$

We say that the feedback operator L is admissible whenever these equations are valid.

DEFINITION 3.1. *Let* $\Psi = \left[\begin{smallmatrix} \mathcal{A} & \mathcal{B} \\ \mathcal{C} & \mathcal{D} \end{smallmatrix}\right]$ *be a well-posed linear system on* (U, H, Y). *Then* $L \in \mathcal{L}(Y;U)$ *is called an admissible output feedback operator for* Ψ *iff the operator* $I - L\mathcal{D}$ *has an inverse in* $TIC_\alpha(U)$ *for some* $\alpha \in \mathbf{R}$ *or, equivalently, iff the operator* $I - \mathcal{D}L$ *has an inverse in* $TIC_\alpha(Y)$ *for some* $\alpha \in \mathbf{R}$.

As Weiss [31, section 6] proved, x and y in (3.2) can be interpreted as the state and output of another well-posed linear system as follows.

PROPOSITION 3.2. *Let $\Psi = \left[\begin{smallmatrix} \mathcal{A} & \mathcal{B} \\ \mathcal{C} & \mathcal{D} \end{smallmatrix}\right]$ be a well-posed linear system on (U, H, Y), and let $L \in \mathcal{L}(Y;U)$ be an admissible output feedback operator for Ψ. Then the system*

$$\begin{aligned}\Psi_L &= \begin{bmatrix} \mathcal{A}_L & \mathcal{B}_L\tau \\ \mathcal{C}_L & \mathcal{D}_L \end{bmatrix} = \begin{bmatrix} \mathcal{A} + \mathcal{B}\tau L\left(I - \mathcal{D}L\right)^{-1}\mathcal{C} & \mathcal{B}\left(I - L\mathcal{D}\right)^{-1}\tau \\ \left(I - \mathcal{D}L\right)^{-1}\mathcal{C} & \mathcal{D}\left(I - L\mathcal{D}\right)^{-1} \end{bmatrix} \\ &= \begin{bmatrix} \mathcal{A} & \mathcal{B}\tau \\ \mathcal{C} & \mathcal{D} \end{bmatrix} + \begin{bmatrix} \mathcal{B}\tau \\ \mathcal{D} \end{bmatrix} L\left(I - \mathcal{D}L\right)^{-1}\begin{bmatrix} \mathcal{C} & \mathcal{D} \end{bmatrix} \\ &= \begin{bmatrix} \mathcal{A} & \mathcal{B}\tau \\ \mathcal{C} & \mathcal{D} \end{bmatrix} + \begin{bmatrix} \mathcal{B}\tau \\ \mathcal{D} \end{bmatrix} L\begin{bmatrix} \mathcal{C}_L & \mathcal{D}_L \end{bmatrix} \\ &= \begin{bmatrix} \mathcal{A} & \mathcal{B}\tau \\ \mathcal{C} & \mathcal{D} \end{bmatrix} + \begin{bmatrix} \mathcal{B}_L\tau \\ \mathcal{D}_L \end{bmatrix} L\begin{bmatrix} \mathcal{C} & \mathcal{D} \end{bmatrix}\end{aligned}$$

is another well-posed linear system on (U, H, Y). We call this system the closed loop system with feedback operator L. In the initial value setting with initial time zero, initial value x_0, and control v, the controlled state $x(t)$ at time t and the output y of Ψ_L are given by (3.2).

See [31, section 6] for a proof. (The major part of this proposition is also contained in [19, Theorem 4.2].)

We remark that if in the classical system (2.1) we replace u by $u = Ly + v$, then we get a new well defined system of the same type iff $I - DL$ is invertible or, equivalently, iff $I - LD$ is invertible. In the new system the operators $\left[\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right]$ have been replaced by

$$\begin{aligned}\begin{bmatrix} A_L & B_L \\ C_L & D_L \end{bmatrix} &= \begin{bmatrix} A + BL\left(I - DL\right)^{-1}C & B\left(I - LD\right)^{-1} \\ \left(I - DL\right)^{-1}C & D\left(I - LD\right)^{-1} \end{bmatrix} \\ &= \begin{bmatrix} A & B \\ C & D \end{bmatrix} + \begin{bmatrix} B \\ D \end{bmatrix} L\left(I - DL\right)^{-1}\begin{bmatrix} C & D \end{bmatrix} \\ &= \begin{bmatrix} A & B \\ C & D \end{bmatrix} + \begin{bmatrix} B \\ D \end{bmatrix} L\begin{bmatrix} C_L & D_L \end{bmatrix} \\ &= \begin{bmatrix} A & B \\ C & D \end{bmatrix} + \begin{bmatrix} B_L \\ D_L \end{bmatrix} L\begin{bmatrix} C & D \end{bmatrix}.\end{aligned} \tag{3.3}$$

Observe the striking similarity between this formula and the one given in Proposition 3.2.[7]

Repeated feedback behaves in the expected way.

PROPOSITION 3.3. *Let $L \in \mathcal{L}(U;Y)$ be an admissible output feedback operator for Ψ. Then $K \in \mathcal{L}(U;Y)$ is an admissible output feedback operator for the closed loop system Ψ_L iff $L + K$ is an admissible output feedback operator for Ψ, and $\Psi_{L+K} = (\Psi_L)_K$. In particular, $-L$ is always an admissible feedback operator for Ψ_L, and $(\Psi_L)_{-L} = \Psi$.*

See [31, Remark 6.4] for the straightforward proof.

DEFINITION 3.4. *The operator $L \in \mathcal{L}(Y;U)$ is a (strongly) ω-stabilizing [stabilizing] [[exponentially stabilizing]] output feedback operator for the well-posed linear system Ψ on (U, H, Y) iff L is an admissible output feedback operator for Ψ and the resulting closed loop system Ψ_L is (strongly) ω-stable [stable] [[exponentially stable]].*

We observe the following basic facts.

LEMMA 3.5. *Let $\Psi = \left[\begin{smallmatrix} \mathcal{A} & \mathcal{B} \\ \mathcal{C} & \mathcal{D} \end{smallmatrix}\right]$ be ω-stable, and let $L \in \mathcal{L}(Y;U)$.*

[7] Usually the feed-through operator D is taken to be zero, in which case this formula simplifies significantly and the invertibility condition on $I - DL$ drops out.

(i) *L is an admissible output feedback operator for Ψ iff there is some $\alpha \geq \omega$ for which the diagram in Figure* 3.1 *(i.e., the set of equations* (3.1)*) with $x_0 = 0$ defines a continuous linear mapping from the external input $v \in L^2_\alpha(\mathbf{R}^+; U)$ to the internal input $u \in L^2_\alpha(\mathbf{R}^+; U)$ or, equivalently, iff the operator $I - L\mathcal{D}$ has an inverse in $TIC_\alpha(U)$ or, equivalently, iff the operator $I - \mathcal{D}L$ has an inverse in $TIC_\alpha(Y)$. The resulting closed loop Ψ_L system is α-stable.*

(ii) *L is ω-stabilizing iff any one of the three equivalent conditions in part* (i) *is true with $\omega = \alpha$ (hence all of them are true with $\omega = \alpha$). In this case the closed loop system Ψ_L is strongly ω-stable iff the open loop system Ψ is strongly ω-stable.*

REMARK 3.6. *Thus if a system is ω-stable but not strongly so, then it is impossible to make it strongly ω-stable by using our notion of admissible output feedback.*

Proof of Lemma 3.5. (i) Most of this follows immediately from Definition 3.1. To see that the resulting system is α-stable we observe that if $I - L\mathcal{D}$ has an inverse in $TIC_\alpha(U)$ (or, equivalently, the operator $I - \mathcal{D}L$ has an inverse in $TIC_\alpha(Y)$), then the formulas for Ψ_L given in Proposition 3.2 imply that Ψ_L is α-stable. (Here we use the fact that ω-stability implies α-stability for every $\alpha \geq \omega$; see Lemma 2.4.)

(ii) Clearly, if the conditions in part (i) are true with $\alpha = \omega$, then L is ω-stabilizing. Conversely, if L is ω-stabilizing, then $\mathcal{D}_L = \mathcal{D}(I - L\mathcal{D})^{-1} \in TIC_\omega(U; Y)$, and this implies that $(I - L\mathcal{D})^{-1} = I + L\mathcal{D}(I - L\mathcal{D})^{-1} = I + L\mathcal{D}_L \in TIC_\omega(U)$.

To prove the second claim in part (ii) it suffices to show that

$$\mathrm{e}^{-\omega t}\mathcal{B}\tau(t)L(I - \mathcal{D}L)^{-1}\mathcal{C}x \to 0 \text{ as } t \to \infty$$

for every $x \in H$, since $\mathcal{A}_L - \mathcal{A} = \mathcal{B}\tau L\,(I - \mathcal{D}L)^{-1}\,\mathcal{C}$. Fix $x \in H$ and split the expression above into

$$\begin{aligned}\mathrm{e}^{-\omega t}\mathcal{B}\tau(t)L(I - \mathcal{D}L)^{-1}\mathcal{C}x &= \mathrm{e}^{-\omega t}\mathcal{B}\tau(t - T)(\pi_+ + \pi_-)\tau(T)L(I - \mathcal{D}L)^{-1}\mathcal{C}x \\ &= \mathcal{B}\mathrm{e}^{-\omega t}\tau(t)\pi_{[T,\infty)}L(I - \mathcal{D}L)^{-1}\mathcal{C}x \\ &\quad + \mathrm{e}^{-\omega t}\mathcal{A}(t - T)\mathcal{B}\tau(T)L(I - \mathcal{D}L)^{-1}\mathcal{C}x.\end{aligned}$$

Here the first term tends to zero as $T \to \infty$, uniformly in $t \geq T$, and the second term tends to zero as $t \to \infty$ and T is fixed. □

REMARK 3.7. *The same proof shows that (with the same terminology as in Remark* 2.12*) if Ψ is input ω-stable and output ω-stable and $L \in \mathcal{L}(Y; U)$ is an admissible output feedback operator, then L is input ω-stabilizing, output ω-stabilizing, and input/output ω-stabilizing iff $\mathcal{D}(I - L\mathcal{D})^{-1} \in TIC_\omega(U)$. Moreover, in this case L is [strongly] ω-stabilizing iff the semigroup of Ψ is [strongly] ω-stable.*

The notion of a *state feedback* can be reduced formally to the notion of an output feedback. Intuitively, a state feedback means that an additional output is created, and this output is then fed back into the input, as shown in Figure 3.2. In this figure the original system is represented by $\left[\begin{smallmatrix}\mathcal{A} & \mathcal{B}\\ \mathcal{C} & \mathcal{D}\end{smallmatrix}\right]$. We find two additional components, namely, a new observability map $\mathcal{K}$ (from the initial state to the new output) and a new input/output map $\mathcal{F}$ (from the original input to the new output). The pair $\begin{bmatrix}\mathcal{K} & \mathcal{F}\end{bmatrix}$ is *admissible* if the resulting system is well posed, i.e., if $\begin{bmatrix}0 & I\end{bmatrix}$ is an admissible output feedback operator for the extended system defined in Definition 3.8.

DEFINITION 3.8. *Let $\Psi = \left[\begin{smallmatrix}\mathcal{A} & \mathcal{B}\\ \mathcal{C} & \mathcal{D}\end{smallmatrix}\right]$ be a well-posed linear system on (U, H, Y). The*

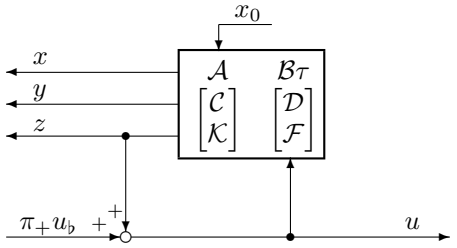

FIG. 3.2. *State feedback connection.*

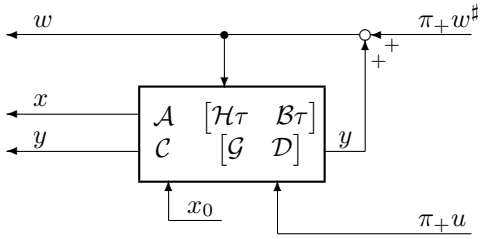

FIG. 3.3. *Output injection connection.*

pair $\begin{bmatrix}\mathcal{K} & \mathcal{F}\end{bmatrix}$ *is an admissible state feedback pair for* Ψ *iff the extended system*

$$\Psi_{\mathrm{SF}} = \begin{bmatrix} \mathcal{A} & \mathcal{B} \\ \begin{bmatrix}\mathcal{C}\\ \mathcal{K}\end{bmatrix} & \begin{bmatrix}\mathcal{D}\\ \mathcal{F}\end{bmatrix} \end{bmatrix}$$

is a well-posed linear system on $(U, H, Y \times U)$ *and* $\begin{bmatrix}0 & I\end{bmatrix}$ *is an admissible output feedback operator for* Ψ_{SF}*; i.e.,* $I - \mathcal{F}$ *has an inverse in* $T\dot{I}C_\omega(U)$ *for some* $\omega \in \mathbf{R}$.[8] *It is (strongly)* ω*-stabilizing [stabilizing] [[exponentially stabilizing]] if the resulting closed loop system is (strongly)* ω*-stable [stable] [[exponentially stable]].*

REMARK 3.9. *We shall frequently regard the signal* u *in Figure* 3.2 *(i.e., the input to the open loop system) as an additional output of the closed loop system (although it is not part of the official definition). This output has the same observability map* $(I - \mathcal{F})^{-1}\mathcal{K}$ *as the output* z.[9] *Its input/output map, given by* $(I - \mathcal{F})^{-1}$*, differs from the input/output map from* $u_\flat$ *to* z *by an identity operator (see Lemma* 3.13*). Similar remarks apply to the signals* w *in Figure* 3.3*,* $u_\flat$ *and* $w^\sharp$ *in Figure* 3.4*,* u *and* $w^\sharp$ *in Figure* 3.5*,* $u_\flat$ *and* w *in Figure* 3.6*, etc.*

The notion of an *output injection* is analogous. In this case a new input is created into which we feed the original output y plus a new perturbation $w^\sharp$, as shown in Figure 3.3. The original system is still represented by $\left[\begin{smallmatrix}\mathcal{A} & \mathcal{B}\\ \mathcal{C} & \mathcal{D}\end{smallmatrix}\right]$. In this figure we find a new controllability map $\mathcal{H}$ (from the new input to the state) and a new input/output map $\mathcal{G}$ (from the new input to the original output). The pair $\left[\begin{smallmatrix}\mathcal{H}\\ \mathcal{G}\end{smallmatrix}\right]$ is *admissible* if the resulting system is well posed.

DEFINITION 3.10. *Let* $\Psi = \left[\begin{smallmatrix}\mathcal{A} & \mathcal{B}\\ \mathcal{C} & \mathcal{D}\end{smallmatrix}\right]$ *be a well-posed linear system on* (U, H, Y).

[8] The input of this system is the signal $u_\flat$ in Figure 3.2, and its outputs are y and z. See also Remark 3.9.

[9] See Lemma 3.13.

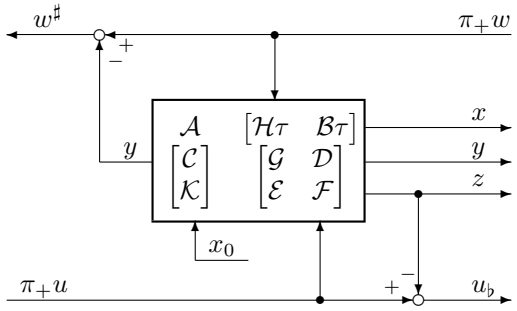

FIG. 3.4. *The extended system.*

The pair $\left[\begin{smallmatrix}\mathcal{H}\\ \mathcal{G}\end{smallmatrix}\right]$ *is an admissible output injection pair for* Ψ *iff the extended system*

$$\Psi_{\mathrm{OI}} = \begin{bmatrix}\mathcal{A} & \begin{bmatrix}\mathcal{H} & \mathcal{B}\end{bmatrix}\\ \begin{bmatrix}\mathcal{C}\\ \mathcal{K}\end{bmatrix} & \begin{bmatrix}\mathcal{G} & \mathcal{D}\\ \mathcal{E} & \mathcal{F}\end{bmatrix}\end{bmatrix}$$

is a well-posed linear system on $(Y\times U, H, Y)$ *and* $\left[\begin{smallmatrix}I\\ 0\end{smallmatrix}\right]$ *is an admissible output feedback operator for* Ψ_{OI}*; i.e.,* $I-\mathcal{G}$ *has an inverse in* $TIC_\omega(Y)$ *for some* $\omega\in\mathbf{R}$.[10] *It is (strongly)* ω*-stabilizing [stabilizing] [[exponentially stabilizing]] if the resulting closed loop system is (strongly)* ω*-stable [stable] [[exponentially stable]].*

In the sequel we shall need to study a case where at the same time we want to add both a state feedback pair $\begin{bmatrix}\mathcal{K} & \mathcal{F}\end{bmatrix}$ and an output injection pair $\left[\begin{smallmatrix}\mathcal{H}\\ \mathcal{G}\end{smallmatrix}\right]$ to a given system $\left[\begin{smallmatrix}\mathcal{A} & \mathcal{B}\\ \mathcal{C} & \mathcal{D}\end{smallmatrix}\right]$. If we try to write a figure similar to Figures 3.2 and 3.3, we immediately observe that we need one more input/output map $\mathcal{E}$ (from the output injection input to the state feedback output); see Figure 3.4. This operator need not always exist,[11] and this forces us to introduce still another definition.

DEFINITION 3.11. *Let* $\Psi = \left[\begin{smallmatrix}\mathcal{A} & \mathcal{B}\\ \mathcal{C} & \mathcal{D}\end{smallmatrix}\right]$ *be a well-posed linear system on* (U, H, Y)*. The pairs* $\begin{bmatrix}\mathcal{K} & \mathcal{F}\end{bmatrix}$ *and* $\left[\begin{smallmatrix}\mathcal{H}\\ \mathcal{G}\end{smallmatrix}\right]$ *are called jointly admissible state feedback and output injection pairs for* Ψ *iff* $\begin{bmatrix}\mathcal{K} & \mathcal{F}\end{bmatrix}$ *is an admissible state feedback pair for* Ψ*,* $\left[\begin{smallmatrix}\mathcal{H}\\ \mathcal{G}\end{smallmatrix}\right]$ *is an admissible output injection pair for* Ψ*, and in addition, there exists a operator* $\mathcal{E}$*, called the interaction operator, such that and the combined extended system*

$$\Psi_{\mathrm{ext}} = \begin{bmatrix}\mathcal{A} & \begin{bmatrix}\mathcal{H} & \mathcal{B}\end{bmatrix}\\ \begin{bmatrix}\mathcal{C}\\ \mathcal{K}\end{bmatrix} & \begin{bmatrix}\mathcal{G} & \mathcal{D}\\ \mathcal{E} & \mathcal{F}\end{bmatrix}\end{bmatrix}$$

is a well-posed linear system on $(Y\times U, H, Y\times U)$*.*

LEMMA 3.12. *Let* $\Psi = \left[\begin{smallmatrix}\mathcal{A} & \mathcal{B}\\ \mathcal{C} & \mathcal{D}\end{smallmatrix}\right]$ *be a well-posed linear system on* (U, H, Y)*. Then the following conditions are equivalent:*

(i) *the pairs* $\begin{bmatrix}\mathcal{K} & \mathcal{F}\end{bmatrix}$ *and* $\left[\begin{smallmatrix}\mathcal{H}\\ \mathcal{G}\end{smallmatrix}\right]$ *are jointly admissible state feedback and output injection pairs with interaction operator* $\mathcal{E}$*;*

(ii) *the system* Ψ_{ext} *in Definition* 3.11 *is a well-posed linear system on* $(Y\times U, H, Y\times U)$*, and both* $\left[\begin{smallmatrix}0 & 0\\ 0 & I\end{smallmatrix}\right]$ *and* $\left[\begin{smallmatrix}I & 0\\ 0 & 0\end{smallmatrix}\right]$ *are admissible output feedback operators for* Ψ_{ext}*.*

[10] The inputs of this system are the signals u and $w^\sharp$ in Figure 3.3, and its output is y. See also Remark 3.9.

[11] More precisely, it need not be a bounded operator. The operator $\mathcal{E}$, if it exists, is determined uniquely modulo a static operator; this follows from [24, Corollary 7].

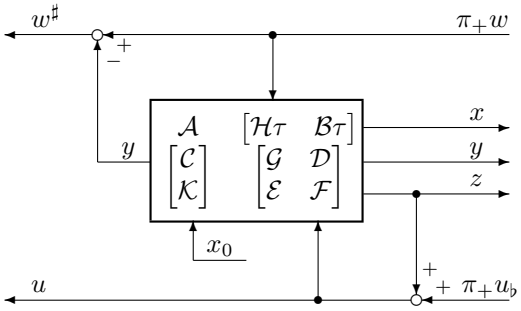

FIG. 3.5. *Right coprime factor.*

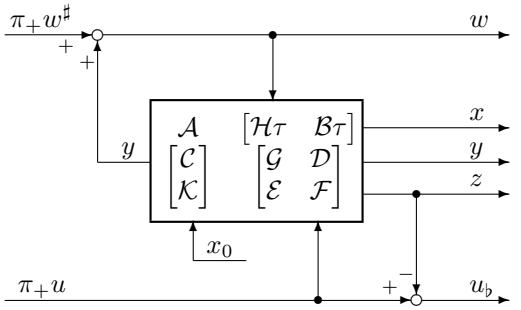

FIG. 3.6. *Left coprime factor.*

(iii) *the system* Ψ_{ext} *in Definition* 3.11 *is a well-posed linear system on* $(Y \times U, H, Y \times U)$, *and* $I - \mathcal{F}$ *and* $I - \mathcal{G}$ *have inverses in* $TIC_\omega(U)$, *respectively,* $TIC_\omega(Y)$ *for some* $\omega \in \mathbf{R}$.

To prove this lemma it suffices to make a straightforward calculation based on Proposition 3.2. As a part of this calculation we get the following expressions for the two closed loop systems in part (ii), drawn in Figures 3.5 and 3.6, respectively.[12]

LEMMA 3.13. *Let* $\Psi = \left[\begin{smallmatrix} \mathcal{A} & \mathcal{B} \\ \mathcal{C} & \mathcal{D} \end{smallmatrix}\right]$ *be a well-posed linear system on* (U, H, Y), *and let* $\begin{bmatrix} \mathcal{K} & \mathcal{F} \end{bmatrix}$ *and* $\left[\begin{smallmatrix} \mathcal{H} \\ \mathcal{G} \end{smallmatrix}\right]$ *be jointly admissible state feedback and output injection pairs for* Ψ *with interaction operator* $\mathcal{E}$. *Then the closed loop system* $\Psi_\flat$ *that we get by using* $\left[\begin{smallmatrix} 0 & 0 \\ 0 & I \end{smallmatrix}\right]$ *as a output feedback operator for* Ψ_{ext} *(see Figure* 3.5*) is given by*[13]

$$
\begin{aligned}
\Psi_\flat &= \begin{bmatrix} \mathcal{A}_\flat & \begin{bmatrix} \mathcal{H}_\flat \tau & \mathcal{B}_\flat \tau \end{bmatrix} \\ \begin{bmatrix} \mathcal{C}_\flat \\ \mathcal{K}_\flat \end{bmatrix} & \begin{bmatrix} \mathcal{G}_\flat & \mathcal{D}_\flat \\ \mathcal{E}_\flat & \mathcal{F}_\flat \end{bmatrix} \end{bmatrix} \\
&= \begin{bmatrix} \mathcal{A} + \mathcal{B}\tau\,(I - \mathcal{F})^{-1}\,\mathcal{K} & \begin{bmatrix} \mathcal{H}\tau + \mathcal{B}\,(I - \mathcal{F})^{-1}\,\mathcal{E}\tau & \mathcal{B}\,(I - \mathcal{F})^{-1}\,\tau \end{bmatrix} \\ \begin{bmatrix} \mathcal{C} + \mathcal{D}\,(I - \mathcal{F})^{-1}\,\mathcal{K} \\ (I - \mathcal{F})^{-1}\,\mathcal{K} \end{bmatrix} & \begin{bmatrix} \mathcal{G} + \mathcal{D}\,(I - \mathcal{F})^{-1}\,\mathcal{E} & \mathcal{D}\,(I - \mathcal{F})^{-1} \\ (I - \mathcal{F})^{-1}\,\mathcal{E} & (I - \mathcal{F})^{-1} - I \end{bmatrix} \end{bmatrix} \\
&= \begin{bmatrix} \mathcal{A} & \begin{bmatrix} \mathcal{H}\tau & \mathcal{B}\tau \end{bmatrix} \\ \begin{bmatrix} \mathcal{C} \\ \mathcal{K} \end{bmatrix} & \begin{bmatrix} \mathcal{G} & \mathcal{D} \\ \mathcal{E} & \mathcal{F} \end{bmatrix} \end{bmatrix} + \begin{bmatrix} \mathcal{B}\tau \\ \mathcal{D} \\ \mathcal{F} \end{bmatrix} (I - \mathcal{F})^{-1} \begin{bmatrix} \mathcal{K} & \mathcal{E} & \mathcal{F} \end{bmatrix},
\end{aligned}
$$

[12] See section 4 for an explanation of the captions of these figures.

[13] The inputs of this system are the signals $u_\flat$ and w in Figure 3.5, and its outputs are y and z. See also Remark 3.9.

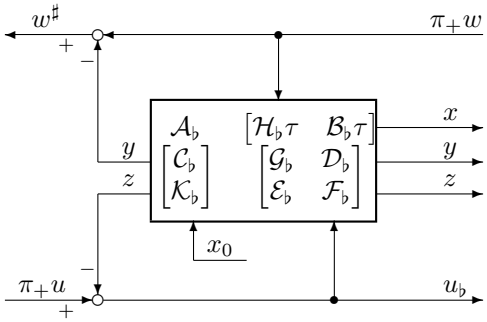

FIG. 3.7. *Cancelation of state feedback.*

and the closed loop system $\Psi^\sharp$ *that we get by using* $\left[\begin{smallmatrix} I & 0\\ 0 & 0\end{smallmatrix}\right]$ *as a output feedback operator for* Ψ_{ext} *(see* Figure 3.6*) is given by*[14]

$$\begin{aligned}\Psi^\sharp &= \begin{bmatrix} \mathcal{A}^\sharp & \begin{bmatrix}\mathcal{H}^\sharp\tau & \mathcal{B}^\sharp\tau\end{bmatrix}\\ \begin{bmatrix}\mathcal{C}^\sharp\\ \mathcal{K}^\sharp\end{bmatrix} & \begin{bmatrix}\mathcal{G}^\sharp & \mathcal{D}^\sharp\\ \mathcal{E}^\sharp & \mathcal{F}^\sharp\end{bmatrix}\end{bmatrix}\\ &= \begin{bmatrix} \mathcal{A}+\mathcal{H}\tau\left(I-\mathcal{G}\right)^{-1}\mathcal{C} & \begin{bmatrix}\mathcal{H}\left(I-\mathcal{G}\right)^{-1}\tau & \mathcal{B}\tau+\mathcal{H}\left(I-\mathcal{G}\right)^{-1}\mathcal{D}\tau\end{bmatrix}\\ \begin{bmatrix}\left(I-\mathcal{G}\right)^{-1}\mathcal{C}\\ \mathcal{K}+\mathcal{E}\left(I-\mathcal{G}\right)^{-1}\mathcal{C}\end{bmatrix} & \begin{bmatrix}\left(I-\mathcal{G}\right)^{-1}-I & \left(I-\mathcal{G}\right)^{-1}\mathcal{D}\\ \mathcal{E}\left(I-\mathcal{G}\right)^{-1} & \mathcal{F}+\mathcal{E}\left(I-\mathcal{G}\right)^{-1}\mathcal{D}\end{bmatrix}\end{bmatrix}\\ &= \begin{bmatrix} \mathcal{A} & \begin{bmatrix}\mathcal{H}\tau & \mathcal{B}\tau\end{bmatrix}\\ \begin{bmatrix}\mathcal{C}\\ \mathcal{K}\end{bmatrix} & \begin{bmatrix}\mathcal{G} & \mathcal{D}\\ \mathcal{E} & \mathcal{F}\end{bmatrix}\end{bmatrix} + \begin{bmatrix}\mathcal{H}\tau\\ \mathcal{G}\\ \mathcal{E}\end{bmatrix}\left(I-\mathcal{G}\right)^{-1}\begin{bmatrix}\mathcal{C} & \mathcal{G} & \mathcal{D}\end{bmatrix}.\end{aligned}$$

REMARK 3.14. *According to Proposition* 3.3*, it is possible to recover the extended system* Ψ_{ext} *from either of the systems* $\Psi_\flat$ *or* $\Psi^\sharp$ *by using negative feedback. For example, the feedback connection drawn in Figure* 3.7 *is equivalent to* Ψ_{ext}*.*

So far we have only looked at the *joint admissibility* of state feedback and output injection pairs. If the resulting closed loop systems drawn in Figures 3.5 and 3.6 are ω-stable, then we call these pairs *jointly* ω*-stabilizing* as follows.

DEFINITION 3.15. *The pairs* $\begin{bmatrix}\mathcal{K} & \mathcal{F}\end{bmatrix}$ *and* $\left[\begin{smallmatrix}\mathcal{H}\\ \mathcal{G}\end{smallmatrix}\right]$ *are called jointly (strongly)* ω*-stabilizing [stabilizing] [[exponentially stabilizing]] state feedback and output injection pairs for* Ψ *if they are jointly admissible state feedback and output injection pairs with some interaction operator* $\mathcal{E}$*, and both the closed loop systems* $\Psi_\flat$ *and* $\Psi^\sharp$ *in Lemma* 3.13 *are (strongly)* ω*-stable [stable] [[exponentially stable]].*

Observe that if the two pairs in Definition 3.15 are ω-stabilizing (but not "jointly" ω-stabilizing), then we know that the operators in the left and right columns of $\Psi_\flat$ and in the top and middle rows of $\Psi^\sharp$ are ω-stable (see the formulas in Lemma 3.13), but we do not know anything about the operators in the middle column of $\Psi_\flat$ and in the bottom row of $\Psi^\sharp$.

DEFINITION 3.16. *Let* Ψ *be a well-posed linear system.*

(i) Ψ *is (strongly)* ω*-stabilizable [stabilizable] [[exponentially stabilizable]] iff there exists a (strongly)* ω*-stabilizing [stabilizing] [[exponentially stabilizing]] state feedback pair for* Ψ*.*

[14]The inputs of this system are the signals u and $w^\sharp$ in Figure 3.6, and its outputs are y and z. See also Remark 3.9.

(ii) Ψ *is (strongly)* ω*-detectable [detectable] [[exponentially detectable]] iff there exists a (strongly)* ω*-stabilizing [stabilizing] [[exponentially stabilizing]] output injection pair for* Ψ*.*

(iii) Ψ *is jointly (strongly)* ω*-stabilizable [stabilizable] [[exponentially stabilizable]] and detectable iff there exist some jointly (strongly)* ω*-stabilizing [stabilizing] [[exponentially stabilizing]] state feedback and output injection pairs for* Ψ*.*

We do not know if it is possible for a system to be both stabilizable and detectable without being jointly stabilizable and detectable.

There is a simple connection between ω-stability, ω-detectability, and input/output ω-stability as shown in Lemma 3.17.

LEMMA 3.17. *Let* $\Psi = \left[\begin{smallmatrix} \mathcal{A} & \mathcal{B} \\ \mathcal{C} & \mathcal{D} \end{smallmatrix}\right]$ *be input/output* ω*-stable [exponentially stable] (i.e., let* $\mathcal{D}$ *be* ω*-stable [exponentially stable]).*

(i) *If* Ψ *is* ω*-stabilizable [exponentially stabilizable], then the observability map* $\mathcal{C}$ *is* ω*-stable [exponentially stable].*

(ii) *If* Ψ *is* ω*-detectable [exponentially detectable], then the controllability map* $\mathcal{B}$ *is* ω*-stable [exponentially stable].*

(iii) *If* Ψ *is both (strongly)* ω*-stabilizable [exponentially stabilizable] and* ω*-detectable [exponentially detectable] (not necessarily jointly), then* Ψ *is (strongly)* ω*-stable [exponentially stable].*

Proof. Introduce the same notation as in Lemma 3.13.

(i) By Lemma 3.13, the observability map $\mathcal{C}$ is given by $\mathcal{C} = \mathcal{C}_\flat - \mathcal{D}\mathcal{K}_\flat$. Thus $\mathcal{C}$ is ω-stable [exponentially stable] whenever $\mathcal{C}_\flat$, $\mathcal{D}$, and $\mathcal{K}_\flat$ are so.

(ii) By the same lemma, the controllability map $\mathcal{B}$ is given by $\mathcal{B} = \mathcal{B}^\sharp - \mathcal{H}^\sharp\mathcal{D}$. Thus $\mathcal{B}$ is ω-stable [exponentially stable] whenever $\mathcal{B}^\sharp$, $\mathcal{H}^\sharp$, and $\mathcal{D}$ are so.

(iii) Again, by Lemma 3.13, $\mathcal{A} = \mathcal{A}_\flat - \mathcal{B}\tau\mathcal{K}_\flat$. Thus $\mathcal{A}$ is (strongly) ω-stable [exponentially stable] whenever $\mathcal{A}_\flat$, $\mathcal{B}$, and $\mathcal{K}_\flat$ are so.[15] □

By adding the trivial converse to part (iii) of Lemma 3.17 we get the following corollary.

COROLLARY 3.18. *A (strongly)* ω*-stabilizable and* ω*-detectable [exponentially stabilizable and detectable] well-posed linear system is (strongly)* ω*-stable [exponentially stable] iff it is input/output* ω*-stable [exponentially stable].*

This result generalizes most other results in this direction such as [17, Corollary 1.8].

Finally, let us present two lemmas concerning exponential stability. Both of these follow directly from Lemma 2.6.

LEMMA 3.19. *Let* Ψ *be a well-posed linear system.*

(i) *The state feedback pair* $\begin{bmatrix} \mathcal{K} & \mathcal{F} \end{bmatrix}$ *is exponentially stabilizing iff it is admissible and the closed loop semigroup* $\mathcal{A}_\flat$ *in Lemma* 3.13 *is exponentially stable.*

(ii) *The output injection pair* $\left[\begin{smallmatrix} \mathcal{H} \\ \mathcal{G} \end{smallmatrix}\right]$ *is exponentially stabilizing iff it is admissible and the closed loop semigroup* $\mathcal{A}^\sharp$ *in Lemma* 3.13 *is exponentially stable.*

(iii) *The state feedback pair* $\begin{bmatrix} \mathcal{K} & \mathcal{F} \end{bmatrix}$ *and the output injection pair* $\left[\begin{smallmatrix} \mathcal{H} \\ \mathcal{G} \end{smallmatrix}\right]$ *are jointly exponentially stabilizing iff they are jointly admissible and both the closed loop semigroups* $\mathcal{A}_\flat$ *and* $\mathcal{A}^\sharp$ *in Lemma* 3.13 *are exponentially stable.*

LEMMA 3.20. *If* $\begin{bmatrix} \mathcal{K} & \mathcal{F} \end{bmatrix}$ *is an exponentially stabilizing state feedback pairs for the system* $\Psi = \left[\begin{smallmatrix} \mathcal{A} & \mathcal{B} \\ \mathcal{C} & \mathcal{D} \end{smallmatrix}\right]$*, then the same feedback pair is exponentially stabilizing for every well-posed extension of* Ψ *of the type*

$$\begin{bmatrix} \mathcal{A} & \mathcal{B} \\ \begin{bmatrix} \mathcal{C} \\ \mathcal{C}_1 \end{bmatrix} & \begin{bmatrix} \mathcal{D} \\ \mathcal{D}_1 \end{bmatrix} \end{bmatrix}.$$

[15] See also Remark 3.6.

4. Coprime factorizations. As is well known, classical (lumped) transfer functions always have doubly coprime factorizations, and these factorizations can be computed by a state space method through the use of a stabilizable and detectable realization. Arbitrary H^∞ transfer functions do not always have coprime factorizations even in the single-input single-output case [12, p. 108], but transfer functions that can be stabilized by a dynamic output feedback do, at least in the case where the input and output spaces are finite dimensional [9, 21]. Below we extend these results and show that the transfer function of every jointly stabilizable and detectable well-posed linear system has a doubly coprime factorization that can be computed by the standard state space method. Conversely, every transfer function with a doubly coprime factorization has a strongly stabilizable and detectable realization.

According to Lemma 2.9, there is a one-to-one correspondence between the set of transfer functions in $H^\infty_\omega(U;Y)$ and the set of causal time-invariant operators in $TIC_\omega(U;Y)$. Rather than switching over to the frequency domain we continue to work in the time domain and leave the transformation of our results to the frequency domain to the reader.

DEFINITION 4.1. *Let U, Y, and Z be Hilbert spaces, and let $\omega \in \mathbf{R}$.*

(i) *The operators $\mathcal{N} \in TIC_\omega(U;Y)$ and $\mathcal{M} \in TIC_\omega(U;Z)$ are right ω-coprime iff there exist operators $\widetilde{\mathcal{Y}} \in TIC_\omega(Y;U)$ and $\widetilde{\mathcal{X}} \in TIC_\omega(Z;U)$ that together with $\mathcal{N}$ and $\mathcal{M}$ satisfy the Bezout identity*

$$\widetilde{\mathcal{Y}}\mathcal{N} + \widetilde{\mathcal{X}}\mathcal{M} = I$$

in $TIC_\omega(U)$. In the case where $\omega = 0$ we call $\mathcal{N}$ and $\mathcal{M}$ right coprime, and in the case where $\omega < 0$ we call $\mathcal{N}$ and $\mathcal{M}$ exponentially right coprime.

(ii) *The operators $\widetilde{\mathcal{N}} \in TIC_\omega(U;Y)$ and $\widetilde{\mathcal{M}} \in TIC_\omega(Z;Y)$ are left ω-coprime iff there exist operators $\mathcal{Y} \in TIC_\omega(Y;U)$ and $\mathcal{X} \in TIC_\omega(Y;Z)$ that together with $\widetilde{\mathcal{N}}$ and $\widetilde{\mathcal{M}}$ satisfy the Bezout identity*

$$\widetilde{\mathcal{N}}\mathcal{Y} + \widetilde{\mathcal{M}}\mathcal{X} = I$$

in $TIC_\omega(Y)$. In the case where $\omega = 0$ we call $\widetilde{\mathcal{N}}$ and $\widetilde{\mathcal{M}}$ left coprime, and in the case where $\omega < 0$ we call $\widetilde{\mathcal{N}}$ and $\widetilde{\mathcal{M}}$ exponentially left coprime.

Thus $\mathcal{N}$ and $\mathcal{M}$ are right ω-coprime iff $\left[\begin{smallmatrix}\mathcal{N}\\ \mathcal{M}\end{smallmatrix}\right]$ has a left inverse in $TIC_\omega(Y \times Z;U)$. $\widetilde{\mathcal{N}}$ and $\widetilde{\mathcal{M}}$ are left ω-coprime iff $\begin{bmatrix}\widetilde{\mathcal{N}} & \widetilde{\mathcal{M}}\end{bmatrix}$ has a right inverse in $TIC_\omega(Y;U \times Z)$.

DEFINITION 4.2. *Let U and Y be Hilbert spaces, let $\omega, \alpha \in \mathbf{R}$ with $\omega \le \alpha$, and let $\mathcal{D} \in TIC_\alpha(U;Y)$.*

(i) *The pair $(\mathcal{N},\mathcal{M})$ is a right ω-coprime factorization of $\mathcal{D}$ if $\mathcal{N} \in TIC_\omega(U;Y)$ and $\mathcal{M} \in TIC_\omega(U)$ are right ω-coprime, $\mathcal{M}$ has an inverse in $TIC_\alpha(U)$, and $\mathcal{D} = \mathcal{N}\mathcal{M}^{-1}$.*

(ii) *The pair $(\widetilde{\mathcal{M}},\widetilde{\mathcal{N}})$ is a left ω-coprime [coprime] [[exponentially coprime]] factorization of $\mathcal{D}$ if $\widetilde{\mathcal{M}} \in TIC_\omega(Y)$ and $\widetilde{\mathcal{N}} \in TIC_\omega(U;Y)$ are left ω-coprime [coprime] [[exponentially coprime]], $\widetilde{\mathcal{M}}$ has an inverse in $TIC_\alpha(Y)$, and $\mathcal{D} = \widetilde{\mathcal{M}}^{-1}\widetilde{\mathcal{N}}$.*

(iii) *A doubly ω-coprime factorization of $\mathcal{D}$ consists of eight operators in TIC_ω (of the appropriate dimensions) satisfying*

$$\begin{bmatrix}\widetilde{\mathcal{M}} & \widetilde{\mathcal{N}}\\ -\widetilde{\mathcal{Y}} & \widetilde{\mathcal{X}}\end{bmatrix}\begin{bmatrix}\mathcal{X} & -\mathcal{N}\\ \mathcal{Y} & \mathcal{M}\end{bmatrix} = \begin{bmatrix}\mathcal{X} & -\mathcal{N}\\ \mathcal{Y} & \mathcal{M}\end{bmatrix}\begin{bmatrix}\widetilde{\mathcal{M}} & \widetilde{\mathcal{N}}\\ -\widetilde{\mathcal{Y}} & \widetilde{\mathcal{X}}\end{bmatrix} = I \tag{4.1}$$

in $TIC_\omega(U \times Y;U \times Y)$, and, in addition, we require that $(\mathcal{N},\mathcal{M})$ is a right ω-coprime and $(\widetilde{\mathcal{M}},\widetilde{\mathcal{N}})$ a left ω-coprime factorization of $\mathcal{D}$. In the case where

$\omega = 0$ we call this a doubly coprime factorization, and in case where $\omega < 0$ we call it a doubly exponentially coprime factorization.

Our definition of coprimeness is slightly nonstandard. It is possible to study coprime factorizations in the quotient field of TIC_ω without our additional assumption that $\mathcal{D}$ belongs to $TIC_\alpha(U;Y)$ and that $\mathcal{M}$ and $\widetilde{\mathcal{M}}$ are invertible in $TIC_\alpha(U)$, respectively, $TIC_\alpha(Y)$ for some $\alpha > \omega$; see, e.g., [9], [12], or [21]. Usually, one only assumes the transfer functions of $\mathcal{M}$ and $\widetilde{\mathcal{M}}$ to be invertible in at least one point in the half-plane $\Re z > \omega$. Observe that if $\mathcal{M}$ is invertible in any reasonable sense, then $\mathcal{D} \in TIC_\alpha(U;Y)$ iff $\mathcal{M}^{-1} \in TIC_\alpha(U)$ because $\mathcal{D} = \mathcal{N}\mathcal{M}^{-1}$ and $\mathcal{M}^{-1} = \widetilde{\mathcal{X}} + \widetilde{\mathcal{Y}}\mathcal{D}$. Likewise, if $\widetilde{\mathcal{M}}$ is invertible in any reasonable sense, then $\mathcal{D} \in TIC_\alpha(U;Y)$ iff $\widetilde{\mathcal{M}}^{-1} \in TIC_\alpha(Y)$ because $\mathcal{D} = \widetilde{\mathcal{M}}^{-1}\mathcal{N}$ and $\widetilde{\mathcal{M}}^{-1} = \mathcal{X} + \mathcal{D}\mathcal{Y}$. According to [20] or [31], if $\mathcal{D}$ does not belong to $TIC_\alpha(U;Y)$ for any $\alpha > \omega$, then $\mathcal{D}$ cannot be realized as the input/output map of a well-posed linear system on a triple of Hilbert spaces.

A coprime factorization is unique, modulo a unit as shown in Lemma 4.3.

LEMMA 4.3. *Let U and Y be Hilbert spaces, let $\omega, \alpha \in \mathbf{R}$ with $\omega \le \alpha$, and let $\mathcal{D} \in TIC_\alpha(U;Y)$.*

(i) *Let $(\mathcal{N},\mathcal{M})$ be a right ω-coprime factorization of $\mathcal{D}$. Then the set of all possible right ω-coprime factorizations of $\mathcal{D}$ can be parameterized in the form $(\mathcal{N}\mathcal{U},\mathcal{M}\mathcal{U})$, where $\mathcal{U}$ is an invertible operator in $TIC_\omega(U)$.*

(ii) *Let $(\widetilde{\mathcal{M}},\widetilde{\mathcal{N}})$ be a left ω-coprime factorization of $\mathcal{D}$. Then the set of all possible left ω-coprime factorizations of $\mathcal{D}$ can be parameterized in the form $(\widetilde{\mathcal{U}}\widetilde{\mathcal{M}},\widetilde{\mathcal{U}}\widetilde{\mathcal{N}})$, where $\widetilde{\mathcal{U}}$ is an invertible operator in $TIC_\omega(Y)$.*

(iii) *If $\mathcal{D}$ has both a right ω-coprime factorization $(\mathcal{N},\mathcal{M})$ and a left ω-coprime factorization $(\widetilde{\mathcal{M}},\widetilde{\mathcal{N}})$, then these two factorizations can be extended to a doubly ω-coprime factorization (i.e., a factorization that contains the given operators $\mathcal{N}$, $\mathcal{M}$, $\widetilde{\mathcal{M}}$, and $\widetilde{\mathcal{N}}$).*

Proof. (i) If $(\mathcal{N},\mathcal{M})$ is a right ω-coprime factorization of $\mathcal{D}$ and $\mathcal{U} \in TIC_\omega(U)$ is invertible in $TIC_\omega(U)$, then it is obvious that $(\mathcal{N}\mathcal{U},\mathcal{M}\mathcal{U})$ is another right ω-coprime factorization. Conversely, suppose that we have two right ω-coprime factorizations $(\mathcal{N},\mathcal{M})$ and $(\mathcal{N}_1,\mathcal{M}_1)$ satisfying the Bezout identities

$$\widetilde{\mathcal{Y}}\mathcal{N} + \widetilde{\mathcal{X}}\mathcal{M} = \widetilde{\mathcal{Y}}_1\mathcal{N}_1 + \widetilde{\mathcal{X}}_1\mathcal{M}_1 = I.$$

Then $\mathcal{M}^{-1} = \widetilde{\mathcal{X}} + \widetilde{\mathcal{Y}}\mathcal{D}$ and $\mathcal{M}_1^{-1} = \widetilde{\mathcal{X}}_1 + \widetilde{\mathcal{Y}}_1\mathcal{D}$ in $TIC_\alpha(U)$, so

$$\mathcal{M}^{-1}\mathcal{M}_1 = \widetilde{\mathcal{X}}\mathcal{M}_1 + \widetilde{\mathcal{Y}}\mathcal{N}_1, \qquad \mathcal{M}_1^{-1}\mathcal{M} = \widetilde{\mathcal{X}}_1\mathcal{M} + \widetilde{\mathcal{Y}}_1\mathcal{N}$$

in $TIC_\alpha(U)$. Define $\mathcal{U} = \mathcal{M}^{-1}\mathcal{M}_1$. We know that $\mathcal{U}$ is invertible in $TIC_\alpha(U)$. However, since $L^2_\omega(\mathbf{R};U) \cap L^2_\alpha(\mathbf{R};U)$ is dense in $L^2_\alpha(\mathbf{R};U)$, the two equations above imply that $\mathcal{U}$ can be extended to an invertible operator in $TIC_\omega(U)$. Moreover, $\mathcal{M}_1 = \mathcal{M}\mathcal{U}$ and $\mathcal{N}_1 = \mathcal{D}\mathcal{M}_1 = \mathcal{D}\mathcal{M}\mathcal{U} = \mathcal{N}\mathcal{U}$. Thus $(\mathcal{N}_1,\mathcal{M}_1) = (\mathcal{N}\mathcal{U},\mathcal{M}\mathcal{U})$, as claimed.

(ii) The proof of (ii) is completely analogous to the proof of (i).

(iii) Choose some operators $\widetilde{\mathcal{Y}}$, $\widetilde{\mathcal{X}}$, $\mathcal{X}$, and $\mathcal{Y}$ in TIC_ω that together with the given operators satisfy the Bezout identities $\widetilde{\mathcal{Y}}\mathcal{N} + \widetilde{\mathcal{X}}\mathcal{M} = I$ and $\widetilde{\mathcal{N}}\mathcal{Y} + \widetilde{\mathcal{M}}\mathcal{X} = I$. Then a direct computation shows that

$$\begin{bmatrix} \widetilde{\mathcal{M}} & \widetilde{\mathcal{N}} \\ -\widetilde{\mathcal{Y}} & \widetilde{\mathcal{X}} \end{bmatrix} \begin{bmatrix} \mathcal{X} - \mathcal{N}(\widetilde{\mathcal{Y}}\mathcal{X} - \widetilde{\mathcal{X}}\mathcal{Y}) & -\mathcal{N} \\ \mathcal{Y} + \mathcal{M}(\widetilde{\mathcal{Y}}\mathcal{X} - \widetilde{\mathcal{X}}\mathcal{Y}) & \mathcal{M} \end{bmatrix} = I.$$

By using the invertibility of $\mathcal{M}$ and $\widetilde{\mathcal{M}}$ in TIC_α, we get

$$\begin{aligned}\mathcal{X}\widetilde{\mathcal{M}}+\mathcal{D}\mathcal{Y}\widetilde{\mathcal{M}}&=I, \qquad \mathcal{X}\widetilde{\mathcal{N}}+\mathcal{D}\mathcal{Y}\widetilde{\mathcal{N}}=\mathcal{D},\\ \mathcal{M}\widetilde{\mathcal{X}}+\mathcal{M}\widetilde{\mathcal{Y}}\mathcal{D}&=I, \qquad \mathcal{N}\widetilde{\mathcal{X}}+\mathcal{N}\widetilde{\mathcal{Y}}\mathcal{D}=\mathcal{D},\end{aligned}$$

and by using these identities we find that

$$\begin{bmatrix}\mathcal{X}-\mathcal{N}(\widetilde{\mathcal{Y}}\mathcal{X}-\widetilde{\mathcal{X}}\mathcal{Y}) & -\mathcal{N}\\ \mathcal{Y}+\mathcal{M}(\widetilde{\mathcal{Y}}\mathcal{X}-\widetilde{\mathcal{X}}\mathcal{Y}) & \mathcal{M}\end{bmatrix}\begin{bmatrix}\widetilde{\mathcal{M}} & \widetilde{\mathcal{N}}\\ -\widetilde{\mathcal{Y}} & \widetilde{\mathcal{X}}\end{bmatrix}=I$$

in TIC_α (as opposed to TIC_ω). However, since all the operators above belong to TIC_ω, and since $L^2_\alpha\cap L^2_\omega$ is dense in L^2_ω, we find that the same identity must be true in TIC_ω, too. Thus, we have a doubly ω-coprime factorization. ∎

As the following theorem shows, if a well-posed linear system is jointly stabilizable and detectable, then its input/output map has a doubly coprime factorization. A converse to this statement is true as well.

THEOREM 4.4.

(i) *Let* $\Psi=\left[\begin{smallmatrix}\mathcal{A} & \mathcal{B}\\ \mathcal{C} & \mathcal{D}\end{smallmatrix}\right]$ *be a jointly* ω*-stabilizable [stabilizable] [[exponentially stabilizable]] and detectable well-posed linear system* (*in the sense of Definition* 3.16). *Then, with the notations of Lemma* 3.13 *and Definition* 4.2,

$$\begin{bmatrix}\widetilde{\mathcal{M}} & \widetilde{\mathcal{N}}\\ -\widetilde{\mathcal{Y}} & \widetilde{\mathcal{X}}\end{bmatrix}\begin{bmatrix}\mathcal{X} & -\mathcal{N}\\ \mathcal{Y} & \mathcal{M}\end{bmatrix}=\begin{bmatrix}I+\mathcal{G}^\sharp & \mathcal{D}^\sharp\\ -\mathcal{E}^\sharp & I-\mathcal{F}^\sharp\end{bmatrix}\begin{bmatrix}I-\mathcal{G}_\flat & -\mathcal{D}_\flat\\ \mathcal{E}_\flat & I+\mathcal{F}_\flat\end{bmatrix}$$

is a doubly ω*-coprime [coprime] [[exponentially coprime]] factorization of* $\mathcal{D}$.

(ii) *Conversely, every* $\mathcal{D}$ *that belongs to* $TIC_\alpha(U;Y)$ *for some* $\alpha\in\mathbf{R}$ *and has a doubly* ω*-coprime [coprime] [[exponentially coprime]] factorization can be realized as the input/output map of a jointly strongly* ω*-stabilizable [stabilizable] [[exponentially stabilizable]] and detectable well-posed linear system* $\Psi=\left[\begin{smallmatrix}\mathcal{A} & \mathcal{B}\\ \mathcal{C} & \mathcal{D}\end{smallmatrix}\right]$.

Proof. $\Psi=\left[\begin{smallmatrix}\mathcal{A} & \mathcal{B}\\ \mathcal{C} & \mathcal{D}\end{smallmatrix}\right]$ be jointly ω-stabilizable and detectable. Then both the systems drawn in Figures 3.5 and 3.6 are ω-stable. In particular, both the input/output map from $\left[\begin{smallmatrix}w\\ u_\flat\end{smallmatrix}\right]$ to $\left[\begin{smallmatrix}w^\sharp\\ u\end{smallmatrix}\right]$ in Figure 3.5, and the input/output map from $\left[\begin{smallmatrix}w^\sharp\\ u\end{smallmatrix}\right]$ to $\left[\begin{smallmatrix}w\\ u_\flat\end{smallmatrix}\right]$ in Figure 3.6 are ω-stable. The former one is given by $\left[\begin{smallmatrix}I-\mathcal{G}_\flat & -\mathcal{D}_\flat\\ \mathcal{E}_\flat & I+\mathcal{F}_\flat\end{smallmatrix}\right]$ (cf. Remark 3.9), and the latter one is given by $\left[\begin{smallmatrix}I+\mathcal{G}^\sharp & \mathcal{D}^\sharp\\ -\mathcal{E}^\sharp & I-\mathcal{F}^\sharp\end{smallmatrix}\right]$. Moreover, by comparing the two figures with each other we immediately realize that they are equivalent in the sense that the relationships between the different signals with the same names are identical in the two diagrams. This means that the input/output map given above are inverses of each other; i.e.,

$$\begin{bmatrix}I-\mathcal{G}_\flat & -\mathcal{D}_\flat\\ \mathcal{E}_\flat & I+\mathcal{F}_\flat\end{bmatrix}=\begin{bmatrix}I+\mathcal{G}^\sharp & \mathcal{D}^\sharp\\ -\mathcal{E}^\sharp & I-\mathcal{F}^\sharp\end{bmatrix}^{-1}.$$

Moreover, as is easily seen, $(\mathcal{D}_\flat,(I+\mathcal{F}_\flat))$ is a right ω-coprime factorization of $\mathcal{D}$, and $((I+\mathcal{G}^\sharp),\mathcal{D}^\sharp)$ is a left ω-coprime factorization of $\mathcal{D}$. This proves part (i) of the theorem.

Conversely, suppose that there exists a doubly coprime factorization of $\mathcal{D}$. Our construction below starts with a realization of the closed loop system $\Psi_\flat$; another equally good choice would be to start with a realization of $\Psi^\sharp$. Motivated by the formula that we found above, we pick the input/output map of $\Psi_\flat$ to be given by

$$\begin{bmatrix}\mathcal{G}_\flat & \mathcal{D}_\flat\\ \mathcal{E}_\flat & \mathcal{F}_\flat\end{bmatrix}=\begin{bmatrix}I-\mathcal{X} & \mathcal{N}\\ \mathcal{Y} & \mathcal{M}-I\end{bmatrix}$$

and choose an arbitrary strongly ω-stable realization of this input/output map, for example, the continuously observable realization presented in Definition 2.10. Since $\mathcal{M}$ is supposed to have an inverse in TIC_α for some $\alpha > \omega$, the operator $\left[\begin{smallmatrix} 0 & 0 \\ 0 & -I \end{smallmatrix}\right]$ is an admissible feedback operator for $\Psi_\flat$. Denote the resulting α-stable closed loop system by Ψ_{ext} and the system that we get by dropping the state feedback row and the output injection column from Ψ_{ext} by Ψ. As a straightforward computation shows, the input/output map of Ψ_{ext} is

$$\begin{aligned} \begin{bmatrix} \mathcal{G} & \mathcal{D} \\ \mathcal{E} & \mathcal{F} \end{bmatrix} &= \begin{bmatrix} I - \mathcal{X} - \mathcal{N}\mathcal{M}^{-1}\mathcal{Y} & \mathcal{N}\mathcal{M}^{-1} \\ \mathcal{M}^{-1}\mathcal{Y} & I - \mathcal{M}^{-1} \end{bmatrix} \\ &= \begin{bmatrix} I - \widetilde{\mathcal{M}}^{-1} & \widetilde{\mathcal{M}}^{-1}\widetilde{\mathcal{N}} \\ \widetilde{\mathcal{Y}}\widetilde{\mathcal{M}}^{-1} & I - \widetilde{\mathcal{X}} - \widetilde{\mathcal{Y}}\widetilde{\mathcal{M}}^{-1}\widetilde{\mathcal{N}} \end{bmatrix}. \end{aligned} \tag{4.2}$$

Observe, in particular, that the input/output map of Ψ is the desired $\mathcal{D} = \mathcal{N}\mathcal{M}^{-1} = \widetilde{\mathcal{M}}^{-1}\widetilde{\mathcal{N}}$. It follows from Proposition 3.3 that the system Ψ that we get in this way is strongly ω-stabilizable (and that the closed loop state feedback system is $\Psi_\flat$). Moreover, by Proposition 3.3 and Lemma 3.5, Ψ is strongly ω-detectable if the operator $\left[\begin{smallmatrix} I & 0 \\ 0 & -I \end{smallmatrix}\right]$ is an ω-stabilizing output feedback operator for $\Psi_\flat$ or, equivalently, if

$$\begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix} - \begin{bmatrix} I & 0 \\ 0 & -I \end{bmatrix} \begin{bmatrix} I - \mathcal{X} & \mathcal{N} \\ \mathcal{Y} & \mathcal{M} - I \end{bmatrix} = \begin{bmatrix} \mathcal{X} & -\mathcal{N} \\ \mathcal{Y} & \mathcal{M} \end{bmatrix}$$

has an inverse in $TIC_\omega(U \times Y, U \times Y)$. But this is true because of the doubly coprimeness assumption. Thus Ψ is jointly strongly ω-stabilizable and detectable. □

The notion of a coprime factorization makes it possible to refine Lemma 3.20 as follows.

LEMMA 4.5. *Assume that both* $\begin{bmatrix} \mathcal{K}^1 & \mathcal{F}^1 \end{bmatrix}$ *and* $\begin{bmatrix} \mathcal{K}^2 & \mathcal{F}^2 \end{bmatrix}$ *are* ω*-stabilizing state feedback pairs for the system* $\Psi = \left[\begin{smallmatrix} \mathcal{A} & \mathcal{B} \\ \mathcal{C} & \mathcal{D} \end{smallmatrix}\right]$. *Then the following conditions are equivalent:*

(i) $\begin{bmatrix} \mathcal{K}^2 & \mathcal{F}^2 \end{bmatrix}$ *is an* ω*-stabilizing state feedback pair for the extended system*

$$\begin{bmatrix} \mathcal{A} & \mathcal{B} \\ \begin{bmatrix} \mathcal{C} \\ \mathcal{K}^1 \end{bmatrix} & \begin{bmatrix} \mathcal{D} \\ \mathcal{F}^1 \end{bmatrix} \end{bmatrix};$$

(ii) *the pair*

$$\begin{bmatrix} (\mathcal{K}^2 - (I - \mathcal{F}^2)(I - \mathcal{F}^1)^{-1}\mathcal{K}^1) & (I - (I - \mathcal{F}^2)(I - \mathcal{F}^1)^{-1}) \end{bmatrix}$$

is an ω*-stabilizing state feedback pair for the closed loop system*

$$\begin{aligned} \Psi_\flat &= \begin{bmatrix} \mathcal{A}_\flat & \mathcal{B}_\flat \\ \begin{bmatrix} \mathcal{C}_\flat \\ \mathcal{K}^1_\flat \end{bmatrix} & \begin{bmatrix} \mathcal{D}_\flat \\ \mathcal{F}^1_\flat \end{bmatrix} \end{bmatrix} \\ &= \begin{bmatrix} \mathcal{A} + \mathcal{B}\tau \left(I - \mathcal{F}^1\right)^{-1} \mathcal{K}^1 & \mathcal{B}\left(I - \mathcal{F}^1\right)^{-1} \\ \begin{bmatrix} \mathcal{C} + \mathcal{D}\left(I - \mathcal{F}^1\right)^{-1} \mathcal{K}^1 \\ \left(I - \mathcal{F}^1\right)^{-1} \mathcal{K}^1 \end{bmatrix} & \begin{bmatrix} \mathcal{D}\left(I - \mathcal{F}^1\right)^{-1} \\ \left(I - \mathcal{F}^1\right)^{-1} - I \end{bmatrix} \end{bmatrix} \end{aligned}$$

that one gets from Ψ *by using the state feedback pair* $\begin{bmatrix} \mathcal{K}^1 & \mathcal{F}^1 \end{bmatrix}$;

(iii) $\mathcal{F}^1(I - \mathcal{F}^2)^{-1}$ *and* $\mathcal{K}^1 + \mathcal{F}^1(I - \mathcal{F}^2)^{-1}\mathcal{K}^2$ *are* ω*-stable.*

A sufficient condition for (i)–(iii) *to hold is that* $\mathcal{D}(I-\mathcal{F}^1)^{-1}$ *and* $(I-\mathcal{F}^1)^{-1}$ *are right* ω*-coprime. This condition is necessary for* (i)–(iii) *to hold whenever* $\mathcal{D}(I-\mathcal{F}^2)^{-1}$ *and* $(I-\mathcal{F}^2)^{-1}$ *are right* ω*-coprime.*

Proof. Let us study the further extended system

$$\begin{bmatrix} \mathcal{A} & \mathcal{B} \\ \begin{bmatrix} \mathcal{C} \\ \mathcal{K}^1 \\ \mathcal{K}^2 \\ \mathcal{K}^2-\mathcal{K}^1 \end{bmatrix} & \begin{bmatrix} \mathcal{D} \\ \mathcal{F}^1 \\ \mathcal{F}^2 \\ \mathcal{F}^2-\mathcal{F}^1 \end{bmatrix} \end{bmatrix},$$

where the last line is the difference between the two previous lines. If we use here the output feedback operator $\begin{bmatrix} 0 & I & 0 & 0 \end{bmatrix}$, then we get an extended version of the closed loop system $\Psi_\flat$ in the statement of the lemma (that we still denote by $\Psi_\flat$), namely,

$$\begin{aligned} \Psi_\flat &= \begin{bmatrix} \mathcal{A}_\flat & \mathcal{B}_\flat \\ \begin{bmatrix} \mathcal{C}_\flat \\ \mathcal{K}^1_\flat \\ \mathcal{K}^2_\flat \\ \mathcal{K}^2_\flat-\mathcal{K}^1_\flat \end{bmatrix} & \begin{bmatrix} \mathcal{D}_\flat \\ \mathcal{F}^1_\flat \\ \mathcal{F}^2_\flat \\ \mathcal{F}^2_\flat-\mathcal{F}^1_\flat \end{bmatrix} \end{bmatrix} \\ &= \begin{bmatrix} \mathcal{A}+\mathcal{B}\tau\left(I-\mathcal{F}^1\right)^{-1}\mathcal{K}^1 & \mathcal{B}\left(I-\mathcal{F}^1\right)^{-1} \\ \begin{bmatrix} \mathcal{C}+\mathcal{D}\left(I-\mathcal{F}^1\right)^{-1}\mathcal{K}^1 \\ \left(I-\mathcal{F}^1\right)^{-1}\mathcal{K}^1 \\ \mathcal{K}^2+\mathcal{F}^2\left(I-\mathcal{F}^1\right)^{-1}\mathcal{K}^1 \\ \mathcal{K}^2-\left(I-\mathcal{F}^2\right)\left(I-\mathcal{F}^1\right)^{-1}\mathcal{K}^1 \end{bmatrix} & \begin{bmatrix} \mathcal{D}\left(I-\mathcal{F}^1\right)^{-1} \\ \left(I-\mathcal{F}^1\right)^{-1}-I \\ \mathcal{F}^2\left(I-\mathcal{F}^1\right)^{-1} \\ \left(I-\mathcal{F}^2\right)\left(I-\mathcal{F}^1\right)^{-1}-I \end{bmatrix} \end{bmatrix}. \end{aligned}$$

If we instead use the output feedback operator $\begin{bmatrix} 0 & 0 & I & 0 \end{bmatrix}$, then we get the system

$$\begin{aligned} \Psi_\natural &= \begin{bmatrix} \mathcal{A}_\natural & \mathcal{B}_\natural \\ \begin{bmatrix} \mathcal{C}_\natural \\ \mathcal{K}^1_\natural \\ \mathcal{K}^2_\natural \\ \mathcal{K}^2_\natural-\mathcal{K}^1_\natural \end{bmatrix} & \begin{bmatrix} \mathcal{D}_\natural \\ \mathcal{F}^1_\natural \\ \mathcal{F}^2_\natural \\ \mathcal{F}^2_\natural-\mathcal{F}^1_\natural \end{bmatrix} \end{bmatrix} \\ &= \begin{bmatrix} \mathcal{A}+\mathcal{B}\tau\left(I-\mathcal{F}^2\right)^{-1}\mathcal{K}^2 & \mathcal{B}\left(I-\mathcal{F}^2\right)^{-1} \\ \begin{bmatrix} \mathcal{C}+\mathcal{D}\left(I-\mathcal{F}^2\right)^{-1}\mathcal{K}^2 \\ \mathcal{K}^1+\mathcal{F}^1\left(I-\mathcal{F}^2\right)^{-1}\mathcal{K}^2 \\ \left(I-\mathcal{F}^2\right)^{-1}\mathcal{K}^2 \\ -\mathcal{K}^1+\left(I-\mathcal{F}^1\right)\left(I-\mathcal{F}^2\right)^{-1}\mathcal{K}^2 \end{bmatrix} & \begin{bmatrix} \mathcal{D}\left(I-\mathcal{F}^2\right)^{-1} \\ \mathcal{F}^1\left(I-\mathcal{F}^2\right)^{-1} \\ \left(I-\mathcal{F}^2\right)^{-1}-I \\ \left(I-\mathcal{F}^1\right)\left(I-\mathcal{F}^2\right)^{-1}-I \end{bmatrix} \end{bmatrix}. \end{aligned}$$

By Proposition 3.3, we get the same system by using $\begin{bmatrix} 0 & -I & I & 0 \end{bmatrix}$ as a feedback operator for $\Psi_\flat$ or, equivalently, by using the feedback operator $\begin{bmatrix} 0 & 0 & 0 & I \end{bmatrix}$. This proves the equivalence of (i) and (ii). We know that the operators on the first, second, and fourth row of $\Psi_\natural$ are stable (since $\begin{bmatrix} \mathcal{K}^2 & \mathcal{F}^2 \end{bmatrix}$ is stabilizing for Ψ), so the full system $\Psi_\natural$ is stable iff the two conditions listed in (iii) hold (recall that the last line is the difference between the two previous lines).

Suppose that $\mathcal{D}(I-\mathcal{F}^1)^{-1}$ and $(I-\mathcal{F}^1)^{-1}$ are right coprime. We claim that (i)–(iii) then hold. To prove this we choose operators $\widetilde{\mathcal{Y}}$ and $\widetilde{\mathcal{X}}$ in TIC that together

with $\mathcal{D}_\flat$ and $I+\mathcal{F}^1_\flat$ satisfy the Bezout identity

$$\widetilde{\mathcal{Y}}\mathcal{D}_\flat + \widetilde{\mathcal{X}}\left(I+\mathcal{F}^1_\flat\right) = \widetilde{\mathcal{Y}}\mathcal{D}\left(I-\mathcal{F}^1\right)^{-1} + \widetilde{\mathcal{X}}\left(I-\mathcal{F}^1\right)^{-1} = I.$$

Then

$$\begin{aligned}\widetilde{\mathcal{Y}}\mathcal{D}_\natural + \widetilde{\mathcal{X}}\left(I+\mathcal{F}^2_\natural\right) &= \widetilde{\mathcal{Y}}\mathcal{D}\left(I-\mathcal{F}^2\right)^{-1} + \widetilde{\mathcal{X}}\left(I-\mathcal{F}^2\right)^{-1}\\ &= \left(\widetilde{\mathcal{Y}}\mathcal{D}+\widetilde{\mathcal{X}}\right)\left(I-\mathcal{F}^2\right)^{-1}\\ &= \left(I-\mathcal{F}^1\right)\left(I-\mathcal{F}^2\right)^{-1},\end{aligned}$$

and this shows that $\left(I-\mathcal{F}^1\right)\left(I-\mathcal{F}^2\right)^{-1}$ is stable; hence, $\mathcal{F}^1\left(I-\mathcal{F}^2\right)^{-1}$ is stable. A similar computation

$$\begin{aligned}\widetilde{\mathcal{Y}}\left(\mathcal{C}_\natural-\mathcal{C}_\flat\right)+\widetilde{\mathcal{X}}\left(\mathcal{K}^2_\natural-\mathcal{K}^2_\flat\right) &= \left(\widetilde{\mathcal{Y}}\mathcal{D}+\widetilde{\mathcal{X}}\right)\left(\left(I-\mathcal{F}^2\right)^{-1}\mathcal{K}^2-\left(I-\mathcal{F}^1\right)^{-1}\mathcal{K}^1\right)\\ &= -\mathcal{K}^1+\left(I-\mathcal{F}^1\right)\left(I-\mathcal{F}^2\right)^{-1}\mathcal{K}^2\end{aligned}$$

shows that $-\mathcal{K}^1+\left(I-\mathcal{F}^1\right)\left(I-\mathcal{F}^2\right)^{-1}\mathcal{K}^2$ is stable; hence, $\mathcal{K}^1+\mathcal{F}^1\left(I-\mathcal{F}^2\right)^{-1}\mathcal{K}^2$ is stable.

Finally, let us assume that (iii) holds, and that $\mathcal{D}(I-\mathcal{F}^2)^{-1}$ and $(I-\mathcal{F}^2)^{-1}$ are right coprime. By interchanging the two feedback pairs with each other and using the statement that we have just proved, we find that $(I-\mathcal{F}^2)(I-\mathcal{F}^1)^{-1}$ is invertible in $TIC(U)$. This, combined with the coprimeness of $\mathcal{D}(I-\mathcal{F}^2)^{-1}$ and $(I-\mathcal{F}^2)^{-1}$ and Lemma 4.3, implies that $\mathcal{D}(I-\mathcal{F}^1)^{-1}$ and $(I-\mathcal{F}^1)^{-1}$ must be right coprime. ∎

5. Dynamic stabilization. As is well known, if the input/output map $\mathcal{D}$ has a right ω-coprime factorization $(\mathcal{N},\mathcal{M})$, and if $\widetilde{\mathcal{Y}}$ and $\widetilde{\mathcal{X}}$ together with $\mathcal{N}$ and $\mathcal{M}$ satisfy the Bezout identity

$$\widetilde{\mathcal{Y}}\mathcal{N}+\widetilde{\mathcal{X}}\mathcal{M}=I,$$

then $\mathcal{Q}=\widetilde{\mathcal{X}}^{-1}\widetilde{\mathcal{Y}}$ is an ω-stabilizing compensator for $\mathcal{D}$, provided it is possible to make sense out of $\widetilde{\mathcal{X}}^{-1}$. A similar statement is true in the case where $\mathcal{D}$ has a left ω-coprime factorization. If $\mathcal{D}$ has a doubly ω-coprime factorization, then, with the notations of Definition 4.2, the stabilizing compensator $\mathcal{Q}$ is given by $\mathcal{Q}=\widetilde{\mathcal{X}}^{-1}\widetilde{\mathcal{Y}}=\mathcal{Y}\mathcal{X}^{-1}$, still provided $\widetilde{\mathcal{X}}^{-1}$ and $\mathcal{X}^{-1}$ make sense. If $\widetilde{\mathcal{X}}$ and $\mathcal{X}$ do not have inverses in TIC_α for any $\alpha>0$, then $\mathcal{Q}$ does not belong to $TIC_\alpha(Y;U)$ for any $\alpha>0$, and $\mathcal{Q}$ cannot be realized as the input/output map of a well-posed linear system (see the discussion following Definition 4.2). Thus it is natural to impose this extra condition on a doubly coprime factorization as follows.

DEFINITION 5.1. *Let $\alpha>\omega$, and let $\mathcal{D}\in TIC_\alpha(U;Y)$ and $\mathcal{Q}\in TIC_\alpha(Y;U)$. A joint doubly ω-coprime factorization of $\mathcal{D}$ and $\mathcal{Q}$ consists of eight operators in TIC_ω (with the appropriate dimensions) satisfying* (4.1)*, and, in addition, we require that $(\mathcal{N},\mathcal{M})$ is a right and $(\widetilde{\mathcal{M}},\widetilde{\mathcal{N}})$ is a left ω-coprime factorization of $\mathcal{D}$, and that $(\mathcal{Y},\mathcal{X})$ is a right and $(\widetilde{\mathcal{X}},\widetilde{\mathcal{Y}})$ is a left ω-coprime factorization of $\mathcal{Q}$. (In particular, all the denominators $\mathcal{M}$, $\widetilde{\mathcal{M}}$, $\mathcal{X}$, and $\widetilde{\mathcal{X}}$ are invertible in TIC_α.)*

LEMMA 5.2. *Let $\Psi=\left[\begin{smallmatrix}\mathcal{A}&\mathcal{B}\\ \mathcal{C}&\mathcal{D}\end{smallmatrix}\right]$ be a jointly ω-stabilizable and detectable well-posed linear system, and let Ψ_{ext}, $\Psi_\flat$, and $\Psi^\sharp$ denote the systems in Definition* 3.11 *and Lemma* 3.13*. Then the following conditions are equivalent:*

(i) *the operator $\left[\begin{smallmatrix}I&0\\0&I\end{smallmatrix}\right]$ is an admissible output feedback operator for Ψ_{ext};*

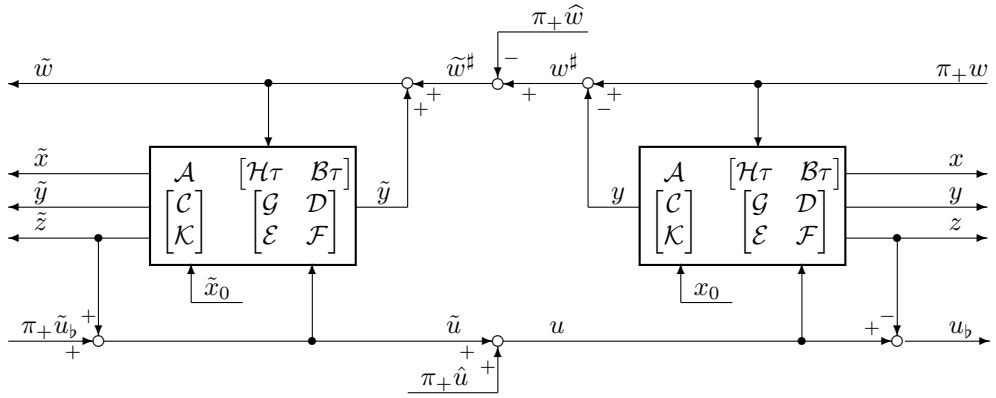

FIG. 5.1. *Dynamic stabilization.*

(ii) $I - \mathcal{G}_\flat$ *has an inverse in* $TIC_\alpha(Y)$ *for some* $\alpha \geq \omega$*;*
(iii) $I - \mathcal{F}^\sharp$ *has an inverse in* $TIC_\alpha(U)$ *for some* $\alpha \geq \omega$.

In these cases the system $\Psi_\flat^\sharp$ *drawn in the left half of Figure* 5.1 *with inputs* $\widetilde{w}^\sharp$ *and* $\tilde{u}_\flat$ *and outputs* $\tilde{y}$, $\tilde{z}$, $\tilde{w}$, *and* $\tilde{u}$ *(i.e., the system that we get by using* $\left[\begin{smallmatrix} I & 0\\ 0 & I\end{smallmatrix}\right]$ *as an output feedback operator for* Ψ_{ext}*) is a well-posed linear system, and the coprime factorization presented in Theorem* 4.4 *is a joint doubly* ω*-coprime factorization of* $\mathcal{D}$ *and* $\mathcal{Q}$*, where* $\mathcal{Q} = \mathcal{E}_\flat(I - \mathcal{G}_\flat)^{-1} = (I - \mathcal{F}^\sharp)^{-1}\mathcal{E}^\sharp$.

This follows from Proposition 3.3.

In the situation described above the input/output map of the closed loop system $\Psi_\flat^\sharp$ is equal to the stabilizing compensator $\mathcal{Q}$, and we can use the observer connection drawn in Figure 5.1 to stabilize the system as shown in Theorem 5.3.

THEOREM 5.3. *Let* $\Psi = \left[\begin{smallmatrix}\mathcal{A} & \mathcal{B}\\ \mathcal{C} & \mathcal{D}\end{smallmatrix}\right]$ *be a jointly* ω*-stabilizable and detectable well-posed linear system, and let* Ψ_{ext} *denote the system in Definition* 3.11. *Then the connection drawn in Figure* 5.1 *defines an* ω*-stable well-posed linear system. Moreover, the input/output maps for the two additional outputs* $\tilde{w}$ *and* $u_\flat$ *are given by*

$$\begin{bmatrix}\tilde{w}\\ u_\flat\end{bmatrix} = \begin{bmatrix}\pi_+ w\\ \pi_+\tilde{u}_\flat\end{bmatrix} + \begin{bmatrix}-I - \mathcal{G}^\sharp & -\mathcal{D}^\sharp\\ -\mathcal{E}^\sharp & I - \mathcal{F}^\sharp\end{bmatrix}\begin{bmatrix}\pi_+\widehat{w}\\ \pi_+\hat{u}\end{bmatrix}.$$

Proof. By Remark 3.14, we can regard Ψ_{ext} as a state feedback perturbed version of the closed loop system $\Psi_\flat$; see Figure 3.7. By substituting this system for Ψ_{ext} in Figure 5.1 we get the equivalent Figure 5.2, which can be interpreted as a feedback connection for an ω-stable system consisting of two copies of $\Psi_\flat$. By part (i) of Lemma 3.5, it suffices to show that the two internal inputs $u_\flat$ and $\tilde{w}$ depend continuously in L^2_ω on the four inputs. By using the equations describing the summation junctions in Figure 5.2 we can eliminate the variables u, $\tilde{u}$, $w^\sharp$, and $\widetilde{w}^\sharp$ to get

$$\begin{bmatrix}I - \mathcal{G}_\flat & -\mathcal{D}_\flat\\ \mathcal{E}_\flat & I + \mathcal{F}_\flat\end{bmatrix}\begin{bmatrix}\pi_+ w - \tilde{w}\\ u_\flat - \pi_+\tilde{u}_\flat\end{bmatrix} = \begin{bmatrix}\pi_+\widehat{w}\\ \pi_+\hat{u}\end{bmatrix}.$$

By Theorem 4.4, the operator on the left-hand side has an inverse in TIC_ω. Inverting this operator we get the formula given in Theorem 5.3. ∎

REMARK 5.4. *Observe that Theorem* 5.3 *is true even if the equivalent conditions listed in Lemma* 5.2 *are false. However, if this is the case, then although the system*

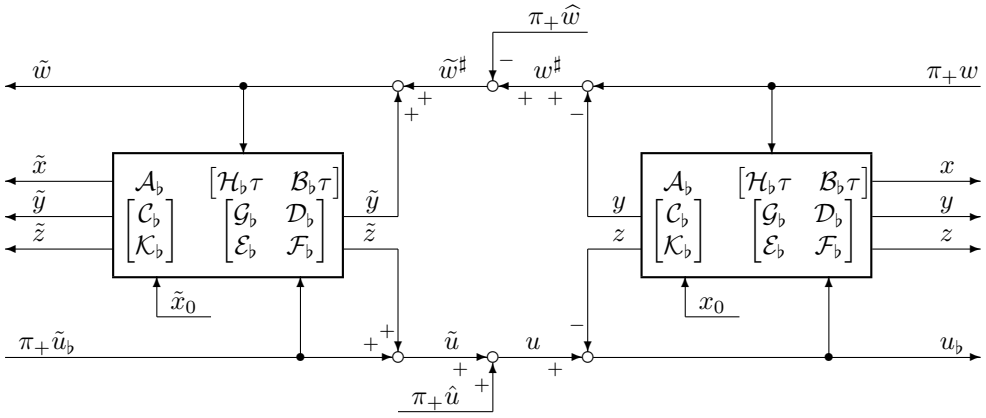

FIG. 5.2. *Alternative version of compensator connection.*

in Figure 5.1 *is an* ω*-stable well-posed linear system, the compensator (the left half of Figures* 5.1 *and* 5.2*) is not well-posed by itself, and the well posedness is lost if the feedback loop from the compensator to the original system is opened.*

REMARK 5.5. *By using Theorem* 5.3 *one can easily develop a Youla parameterization of the set of all stabilizing compensators for* Ψ_{ext}*. The key observation is that the input/output map from* $\left[\begin{smallmatrix}\pi_+ w\\ \pi_+\tilde{u}_\flat\end{smallmatrix}\right]$ *to* $\left[\begin{smallmatrix}\tilde{w}\\ u_\flat\end{smallmatrix}\right]$ *is the identity map. To get the Youla parameterization we simply connect the Youla parameter* Q *from* $\tilde{w}$ *to* $\tilde{u}_\flat$ *in the equivalent Figures* 5.1 *and* 5.2*. This does not affect the stability of the system since* $\tilde{w}$ *does not depend on* $\tilde{u}_\flat$*. The resulting input/output map from* w *to* $u_\flat$ *will be equal to* Q*. The proofs of these claims are essentially the same as the ones given in* [6].

REMARK 5.6. *All the main results of this paper remain valid if throughout we replace the algebra of time-invariant bounded linear operators from* $L^2(\mathbf{R};U)$ *into* $L^2(\mathbf{R};Y)$ *by various subalgebras, for example the algebra of convolution operators induced by measures with finite total variation. This is the algebra around which* [22] *and* [23] *were built.*

SOME PATHOLOGICAL TRAPS FOR STOCHASTIC APPROXIMATION*

ODILE BRANDIÈRE†

Abstract. We consider different kinds of "pathological traps" for stochastic algorithms, thus extending a previous study on regular traps. An illustration is given by the complete proof of the convergence of a principal component analysis (PCA) algorithm when the eigenvalues are multiple.

Key words. stochastic approximation, ordinary differential equations, traps, neural networks

AMS subject classifications. 62L20, 60F99, 58F21, 92B20

PII. S036301299630759X

1. Introduction.

We consider the $\mathbb{R}^d$-valued stochastic algorithm, defined on a probability space $(\Omega, \mathcal{A}, \mathcal{P})$:

$$Z_{n+1} = Z_n + \gamma_n h(Z_n) + \eta_{n+1}, \tag{1}$$

where

- h is a continuous function from an open set $G \subseteq \mathbb{R}^d$ to $\mathbb{R}^d$,
- (γ_n) is a decreasing-to-zero deterministic real sequence satisfying

$$\sum_{n \geq 0} \gamma_n = \infty, \tag{2}$$

- (η_n) is a "small" stochastic disturbance.

The ordinary differential equation (ODE) method (see [3], [8], [14] and others) associates the possible limit sets of (1) with the properties of the associated ODE

$$\frac{dz}{dt} = h(z). \tag{3}$$

When the algorithm is bounded, these sets are compact connected invariant and "chain-recurrent" in the Benaïm sense (see [2]) for the ODE.

It is natural to think that, thanks to the random disturbance, the algorithm (1) avoids some of those limit sets which we shall call "traps."

The most simple limit sets of (1) (and (3)) are the "regular zeros of h": z^* is a "regular trap of h" if z^* is an isolated zero with a neighborhood where h is $\mathcal{C}^1$ with a Lipschitz differential Dh, having at z^* at least one eigenvalue with a positive real part. Such "regular traps" have been studied in [6], [16], and [25].

The aim of this paper is to study some other compact connected chain-recurrent sets L such as

- periodic cycles for the ODE,
- singular equilibria and other "repulsive regions,"
- connected sets of equilibria.

†Université de Marne-la-Vallée, Equipe d'Analyse et de Mathématiques Appliquées, 2, rue de la Butte Verte, 93166 Noisy-le-Grand, France. Current address: Département de Mathématiques, Université Paris Sud, Bâtiment 425, 91405 Orsay, France (brandiere@jm.u-psud.fr).

Our question is: "does $\{\omega\ ;\ d(Z_n(\omega), L) \to 0\}$ have probability zero?"

Throughout this paper, we shall always make the following assumptions.

Assumptions A1. On the "small disturbance"

$$\eta_{n+1} = c_n(\varepsilon_{n+1} + r_{n+1}), \tag{4}$$

where (c_n) is a nonnegative deterministic sequence such that

$$\bullet \gamma_n = O(c_n),\ \Sigma c_n^2 < \infty, \text{ and } c_n \neq 0 \text{ infinitely often}, \tag{5}$$

• (ε_n) and (r_n) are $\mathbb{R}^d$-valued random vector sequences, defined on $(\Omega, \mathcal{A}, \mathcal{P})$ adapted with respect to an increasing sequence of σ-fields $(\mathcal{F}_n)_{n\geq 0}$ and satisfying almost surely (a.s.) on $\{\omega\ ;\ d(Z_n(\omega), L) \to 0\}$

$$E(\varepsilon_{n+1}|\mathcal{F}_n) = 0 \quad \text{and} \quad \Sigma\|r_n\|^2 < \infty. \tag{6}$$

Now we state our main results. The proofs will be given in the following sections. Then we will illustrate some results by the proof of the convergence of a PCA (principal component analysis) algorithm.

Symbols. We denote by

• $\lambda_{min}(A)$, the smallest eigenvalue of the symmetric matrix A,

• $\underline{\lambda}(A)$ (resp., $\overline{\lambda}(A)$), the smallest (resp., largest) real part of eigenvalues of the matrix A,

• $\Gamma(L) = \{\omega\ ;\ d(Z_n(\omega), L) \to 0\}$,

• $L_r = \{x \in \mathbb{R}^d\ ;\ d(x, L) < r\}$,

• $\overline{L_r} = \{x \in \mathbb{R}^d\ ;\ d(x, L) \leq r\}$,

• **C**, a generic positive constant whose value may change,

• i.i.d., independent and identically distributed.

The "ODE" will always be the ODE (3); a "solution" of the ODE, $t \to z(t)$, will be considered for $t \geq 0$, $z(0)$ being the initial condition.

1.1. Cyclic traps. Here we extend the framework of a result of Benaïm [1].

Set $L \subseteq G$, a closed and periodic orbit, solution to the ODE (3). We assume that h is $\mathcal{C}^2$ on a neighborhood of L and that L is a periodic and hyperbolic cycle having at least one characteristic exponent with a positive real part; we shall call such an L a *cyclic trap.*

Then we claim the following theorem.

THEOREM 1.1. *Let L be a cyclic trap of the stochastic algorithm* (1) *under the Assumptions* A1. *Assume that h is $\mathcal{C}^2$ on a neighborhood of L and that for some $a > 2$, a.s. on $\Gamma(L)$,*

$$\limsup_n E(\|\varepsilon_{n+1}\|^a|\mathcal{F}_n) < \infty \quad \textit{and} \quad \liminf_n E(\lambda_{min}(\varepsilon_{n+1}(\varepsilon_{n+1})^T)|\mathcal{F}_n) > 0. \tag{7}$$

Then $P(\Gamma(L)) = 0$; the cyclic trap L is avoided by (1).

The proof of Theorem 1.1 is given in section 2.1.

1.2. Repulsion and singular equilibria. In this section we introduce the notion of repulsive set.

DEFINITION 1. *A compact connected set L which is invariant and chain-recurrent for the ODE will be called* repulsive *if there exists an $r > 0$ such that any solution to the ODE, $(z(t))_{t\geq 0}$, starting from $x \in L_r \setminus L$ leaves L_r within a finite time.*

Some results will be given in section 2.2.3 for such general repulsive sets. The easiest case is the case of singular repulsive equilibria. z^* is a *singular equilibrium* of

h (or of the associated ODE) if it is an isolated zero of h ($L = \{z^*\}$) such that h is $\mathcal{C}^1$ on a neighborhood of z^*, with a Lipschitz differential Dh verifying $Dh(z^*) = 0$.

For those results we consider the algorithm (1) with

$$\gamma_n = c_n = \frac{g}{n}, \qquad g > 0.$$

THEOREM 1.2 (d-dimensional repulsive singular equilibrium). *Set* (1) *under the Assumptions* A1. *We consider an isolated zero z^* of h, repulsive for the ODE, h being $\mathcal{C}^1$ on a neighborhood of z^* with a differential Dh verifying $Dh(z^*) = 0$. Let us assume that a.s. on $\Gamma(z^*)$ and for $a > 4$,*

$$\limsup_n E(\|\varepsilon_{n+1}\|^a | \mathcal{F}_n) < \infty \quad \text{and} \quad \liminf_n E(\|\varepsilon_{n+1}\|^2 | \mathcal{F}_n) > 0. \tag{8}$$

Then $\Gamma(z^*)$ has probability zero.

We prove Theorem 1.2 in section 2.2.1. In one dimension, we obtain the following proposition about singular, but not necessarily repulsive, equilibria.

PROPOSITION 1.3 (one-dimensional general singular equilibrium). *Set* (1) *under the Assumptions* A1 *with $d = 1$. We consider an isolated zero z^* of h such that on a neighborhood of z^*,*

$$h(z) \simeq \alpha(z - z^*)^p \text{ with } \alpha \neq 0, \ p \text{ integer and } p > 1.$$

We assume that a.s. on $\Gamma(z^*)$, (8) is verified with $a > \frac{2p}{p-1}$.

Then, if $\alpha > 0$ and if p is odd, z^* is a.s. avoided by (1).

Otherwise, a.s. on $\Gamma(z^*)$, when $n \to \infty$,

$$|Z_n - z^*| \simeq [|\alpha|(p-1)g \log n]^{-\frac{1}{p-1}},$$

and $(Z_n - z^*)$ has, for n large enough, a constant sign which is necessarily the same as $(-\alpha)$ when p is even.

This proposition is proved in section 2.2.2.

For $p = 2$ and $\alpha > 0$, the almost sure convergence rate,

$$\log n \|Z_n - z^*\| \to \frac{1}{\alpha g},$$

has been obtained by Kersting [13] in a more restrictive framework and later by Wei [27] with a square integrable noise.

1.3. Connected sets of equilibria. Let L be a nonempty, compact, and connected part included in $\{h = 0\}$. It is a possible limit set of (1).

Clearly, when L has a nonempty interior, the algorithm might get "bogged" in L, thus converging to a random point of L. Hence we only consider L with empty interior.

The following framework looks somewhat restrictive but it will be helpful for the proof of Theorem 3.1 on the principal component analysis. We set the following definition.

DEFINITION 2. *A compact connected set of equilibria L is called* homogeneous *if:*

- *on a neighborhood of L, h is $\mathcal{C}^1$ and Dh is Lipschitz;*
- *for all $x \in L$, $\mathbb{R}^d$ is the direct sum of the repulsive subspace K_r, associated to the eigenvalues of $Dh(x)$ with a positive real part, and of the nonrepulsive subspace K_a*

associated to the eigenvalues of $Dh(x)$ with a nonpositive real part. And in a suitable basis $\mathcal{B}$ (the first vectors of $\mathcal{B}$ belong to K_r and the others belong to K_a):

$$\forall x \in L,\ Dh(x) = \begin{pmatrix} J_+ & 0 \\ 0 & J_-(x) \end{pmatrix},$$

where $J_-(x)$ may depend of x but not on J_+; J_+ is repulsive ($\underline{\lambda}(J_+) > 0$) and $\overline{\lambda}(J_-(x)) \leq 0$.

- *K_a contains L.*

Denote by $\varepsilon_{n+1}^{(r)}$ the projection of ε_{n+1} on K_r in the direction of K_a. We claim the following result.

THEOREM 1.4. *Assume that*

- *L is a compact connected set of equilibria, homogeneous and nonattractive ($K_r \neq \{0\}$),*
- *Assumptions* A1 *are satisfied,*
- *a.s. on $\Gamma(L)$,*

$$\limsup_n E(\|\varepsilon_{n+1}\|^2 | \mathcal{F}_n) < \infty \quad \textit{and} \quad \liminf_n E(\|\varepsilon_{n+1}^{(r)}\| | \mathcal{F}_n) > 0; \tag{9}$$

then $P(\Gamma(L)) = 0$.

The proof is given in section 2.3.

2. Proofs of results.

2.1. Proof of Theorem 1.1 about the cyclic traps. A smooth "distance" to the stable manifold of the cycle. Let L be a cyclic trap (see the definition in section 1.1) and denote by $W^s(L)$ the stable manifold of L and by $W^r(L)$ the repulsive (called unstable in [1]) manifold of L.

By an adaptation of the Pemantle method [25] owing to Benaïm [1], under the assumptions of Theorem 1.1, there exist a neighborhood $V(L)$ of L and an $\mathbb{R}_+$-valued function η, defined on $V(L)$, vanishing on $W^s(L) \supset L$ and satisfying the following properties.

- On $V(L) \setminus W^s(L)$, η is $\mathcal{C}^2$ and

$$\forall x \in V(L) \setminus W^s(L)\ \|\nabla \eta(x)\| \geq c_1 > 0, \tag{10}$$

where $\nabla \eta$ is the gradient of η. And for $v \in \mathbb{R}^d$,

$$D\eta(x)v = \langle \nabla \eta(x), v \rangle.$$

- On $V(L) \bigcap W^s(L)$, there exists a "right derivative" that we also denote $D\eta(x)$ and which associates to any vector v of $\mathbb{R}^d$:

$$D\eta(x)v = \lim_{\substack{t \to 0 \\ t>0}} \frac{\eta(x+tv) - \eta(x)}{t}.$$

This "derivative" is continuous, convex, and positively homogeneous.

For all $x \in V(L) \bigcap W^s(L)$ there exist a linear subspace $E_2(x)$ of the repulsive directions and a linear subspace $E_1(x)$ of the stable directions satisfying $\mathbb{R}^d = E_1(x) \bigoplus E_2(x)$ and

$$D\eta(x)v \geq u_x^T v_{E_2(x)}, \tag{11}$$

where $v_{E_2(x)}$ is the component of v on $E_2(x)$ and u_x a vector of $E_2(x)$ such that $\|u_x\| = c_1 > 0$ (c_1 is the same constant as in (10)). Moreover, $x \to u_x$ is continuous and $x \to E_2(x)$ is a $\mathcal{C}^1$ map from $V(L) \bigcap W^s(L)$ into the Grassmann manifold of linear subspaces of the appropriate dimension (see [1]).

• There exist a $k > 0$ and a neighborhood of 0, U_0, satisfying for all v of U_0 and for all x of $V(L)$:

$$\eta(x+v) \geq \eta(x) + D\eta(x)v - k\|v\|^2. \tag{12}$$

• There exists a $\lambda > 0$ such that for all x of $V(L)$ and for all v of $\mathbb{R}^d$,

$$D\eta(x)(h(x)+v) = D\eta(x)h(x) + D\eta(x)v, \tag{13}$$

$$D\eta(x)h(x) \geq \lambda\eta(x). \tag{14}$$

Proof of Theorem 1.1. On $\Gamma(L)$, for n large enough, $Z_n \in V(L)$ and $\gamma_n h(Z_n) + c_n(\varepsilon_{n+1} + r_{n+1}) \in U_0$. Denote

$$\Gamma_N(L) = \Gamma(L) \bigcap \{\forall n \geq N\ ,\ Z_n \in V(L) \text{ and } \gamma_n h(Z_n) + c_n(\varepsilon_{n+1} + r_{n+1}) \in U_0\}.$$

On $\Gamma_N(L)$, for $n \geq N$,

$$Z_{n+1} = Z_n + \gamma_n h(Z_n) + c_n(\varepsilon_{n+1} + r_{n+1}),$$

and by (12)

$$\begin{aligned}\eta(Z_{n+1}) \geq \eta(Z_n) &+ D\eta(Z_n)(\gamma_n h(Z_n) + c_n(\varepsilon_{n+1} + r_{n+1})) \\ &- k\|\gamma_n h(Z_n) + c_n(\varepsilon_{n+1} + r_{n+1})\|^2.\end{aligned}$$

By (13), (14), and (11),

$$\begin{aligned}\eta(Z_{n+1}) \geq \eta(Z_n)(1+\lambda\gamma_n) &+ c_n D\eta(Z_n)\ \mathbb{I}_{\{\eta(Z_n)>0\}}\varepsilon_{n+1} \\ &+ c_n D\eta(Z_n)\ \mathbb{I}_{\{\eta(Z_n)>0\}} r_{n+1} \\ &+ c_n u_{Z_n}^T(\varepsilon_{n+1} + r_{n+1})_{E_2(Z_n)}\ \mathbb{I}_{\{\eta(Z_n)=0\}} \\ &- k\|\gamma_n h(Z_n) + c_n(\varepsilon_{n+1} + r_{n+1})\|^2.\end{aligned}$$

We also obtain

$$\begin{aligned}\eta(Z_{n+1}) \geq \eta(Z_n)(1+\lambda\gamma_n) &+ c_n D\eta(Z_n)\varepsilon_{n+1}\ \mathbb{I}_{\{\eta(Z_n)>0\}} \\ &+ c_n u_{Z_n}^T(\varepsilon_{n+1})_{E_2(Z_n)}\ \mathbb{I}_{\{\eta(Z_n)=0\}} \\ &+ c_n(D\eta(Z_n)\ \mathbb{I}_{\{\eta(Z_n)>0\}} r_{n+1} + u_{Z_n}^T(r_{n+1})_{E_2(Z_n)}\ \mathbb{I}_{\{\eta(Z_n)=0\}}) \\ &- k\|\gamma_n h(Z_n) + c_n(\varepsilon_{n+1} + r_{n+1})\|^2.\end{aligned}$$

Then,

$$\eta(Z_{n+1}) \geq \eta(Z_n)(1+\lambda\gamma_n) + c_n(e_{n+1} + \rho_{n+1}), \tag{15}$$

where

$$e_{n+1} = D\eta(Z_n)\varepsilon_{n+1}\ \mathbb{I}_{\{\eta(Z_n)>0\}} + u_{Z_n}^T(\varepsilon_{n+1})_{E_2(Z_n)}\ \mathbb{I}_{\{\eta(Z_n)=0\}}$$

and

$$\rho_{n+1} = D\eta(Z_n)\ \mathbb{I}_{\{\eta(Z_n)>0\}} r_{n+1} + u_{Z_n}^T (r_{n+1})_{E_2(Z_n)}\ \mathbb{I}_{\{\eta(Z_n)=0\}}$$

$$-c_n k \left\| \frac{\gamma_n}{c_n} h(Z_n) + \varepsilon_{n+1} + r_{n+1} \right\|^2 .$$

On $V(L)$, $h(z)$ and $D\eta(z)$ are bounded. (e_n) and (ρ_n) are two random real sequences that are $(\mathcal{F}_n)$-measurable. By (6) and (7) a.s., on $\Gamma_N(L)$, (e_n) is a noise satisfying

$$E(e_{n+1}|\mathcal{F}_n) = 0 \quad \text{and} \quad \limsup_n E(|e_{n+1}|^a \mid \mathcal{F}_n) < \infty,$$

and

$$\liminf_n E(e_{n+1}^2 \mid \mathcal{F}_n) > 0.$$

By (5), (6), and (7), a.s. on $\Gamma_N(L)$, $\Sigma \rho_n^2 < \infty$.

Theorem 4.1 given in Appendix 1 (section 4.1) applies to $\eta(Z_n) = \zeta_n$ and $P(\Gamma_N(L)) = 0$. Hence $\Gamma(L) = \bigcup \Gamma_N(L)$ and $\Gamma(L)$ has probability zero. □

2.2. Proofs of results about singular traps and repulsive regions. The basic tool in this section is an accompanying result of Benaïm and Hirsch [1], [10] stated in Appendix 2 (section 4.2). Roughly speaking, this result states that under some conditions, (Z_n) and a given solution of the ODE $(z(t))_{t\geq 0}$ have the same asymptotic behavior.

2.2.1. Proof of Theorem 1.2 (*d*-dimensional repulsive singular equilibria). Let V_{z^*} be a neighborhood of z^* where Dh is Lipschitz and such that any solution of the ODE starting from $V_{z^*} \setminus z^*$ leaves V_{z^*} within a finite time. As $Dh(z^*) = 0$, for all $z \in V_{z^*}$, $\|h(z)\| \leq \mathbf{C}\|z - z^*\|^2$.

Under the assumptions of Theorem 1.2, by Appendix 2, there exist on $\Gamma(L)$ a random vector $Y \in V_{z^*}$ and a positive random variable T such that the solution of the ODE $t \to z(t)$ starting from Y satisfies

$$\limsup_n \frac{1}{\log n} \log(\|Z_n - z(s_{n-1} - T)\|) \leq -\left(\frac{1}{2} - \frac{1}{a}\right),$$

where $s_{n-1} = \sum_{j=0}^{n-1} \gamma_j \simeq g \log n$.

Thus we cannot simultaneously have

$$\lim_{n\to\infty} \|Z_n - z^*\| = 0\ ,\ \lim_{n\to\infty} \|Z_n - z(s_{n-1} - T)\| = 0, \text{and } \limsup_{t\to\infty} \|z(t) - z^*\| \neq 0.$$

So if $\lim_{n\to\infty} \|Z_n - z^*\| = 0$, then $Y = z^*$ and $P(\{Y \neq z^*\} \bigcap \Gamma(z^*)) = 0$.

On $\{Y = z^*\} \bigcap \Gamma(z^*)$, $z(0) = z^*$ and since $a > 4$,

$$\limsup \frac{1}{\log n} \log \|Z_n - z^*\| \leq -\left(\frac{1}{2} - \frac{1}{a}\right) < -\frac{1}{4} \tag{16}$$

and

$$0 = Z_n - z^* + \sum_{j=n}^{\infty} c_j \left(\frac{\gamma_j}{c_j} h(Z_j) + \varepsilon_{j+1} + r_{j+1} \right).$$

Set $\Gamma_p = \{Y = z^*\} \bigcap \Gamma(z^*) \bigcap \{\omega\ ;\ Z_n(\omega) \in V_{z^*} \text{ for } n \geq p\}$.
A.s. on Γ_p,

$$\|h(Z_n)\|^2 = O(\|Z_n - z^*\|^4);$$

by (16), $\sum_{j=n}^{\infty} \|h(Z_n)\|^2 < \infty$ and

$$\sum_{j=n}^{\infty} \left\| \frac{\gamma_j}{c_j} h(Z_j) + r_{j+1} \right\|^2 < \infty.$$

By Theorem A of [6] about the distribution of a regressive series, under properties (8) of the noise, $P(\Gamma_p) = 0$, and seeing that $\{Y = z^*\} \bigcap \Gamma(z^*) = \bigcup \Gamma_p$, $P(\{Y = z^*\} \bigcap \Gamma(z^*)) = 0$. So $P(\Gamma(z^*)) = 0$. □

2.2.2. Proof of Proposition 1.3 (one-dimensional general singular equilibria). For any $c \in]0, 1[$, there exists a neighborhood W of z^* such that on W, h is $\mathcal{C}^1$ and

$$(1-c)|\alpha(z-z^*)^p| \leq |h(z)| \leq (1+c)|\alpha(z-z^*)^p|,$$
$$\text{for } z \neq z^* \text{ and } p \text{ even } \alpha h(z) > 0,$$
$$\text{for } z \neq z^* \text{ and } p \text{ odd, } \alpha(z-z^*)h(z) > 0.$$

Set $t \to z(t)$, a solution of the ODE, defined for $t \geq 0$, with an orbit in W and the initial condition $z(0) = y \neq z^*$:

$$\int_y^{z(t)} \frac{dz}{h(z)} = t.$$

Therefore, $z(t) \neq z^*$, $(z(t) - z^*)$ keeps the sign of $(y - z^*)$, and $h(z(t))$ keeps the sign of $\alpha(y - z^*)^p$.

Thus, for $(y - z^*)\alpha > 0$ and p even or for $\alpha > 0$ and p odd, $z(t)$ doesn't converge to z^*.

In the other cases the convergence is slow because

$$(|\alpha|(1-c)(p-1)t + y^{1-p})^{\frac{1}{1-p}} \leq |z(t) - z^*| \leq (|\alpha|(1+c)(p-1)t + y^{1-p})^{\frac{1}{1-p}}.$$

By a similar argument as in section 2.2.1, we obtain on $\Gamma(z^*)$ two random variables $Y \in W$ and $T \geq 0$ such that

$$\limsup_n \frac{1}{\log n} \log(\|Z_n - z(s_{n-1} - T)\|) \leq -\left(\frac{1}{2} - \frac{1}{a}\right) < -\frac{1}{2p},$$

with $z(0) = Y$. On $\Gamma(z^*) \bigcap \{Y = z^*\}$, $\limsup \frac{1}{\log n} \log(\|Z_n - z^*\|) < -\frac{1}{2p}$,

$$0 = Z_n - z^* + \sum_{j=n}^{\infty} c_j \left(\frac{\gamma_j}{c_j} h(Z_j) + \varepsilon_{j+1} + r_{j+1} \right).$$

For $\Gamma_q = \{Y = z^*\} \bigcap \Gamma(z^*) \bigcap \{\omega\ ;\ Z_n(\omega) \in W \text{ for } n \geq q\}$, a.s. on Γ_q,

$$h(Z_n)^2 = O((Z_n - z^*)^{2p}),$$

$\sum_{j=q}^{\infty} h(Z_j)^2 < \infty$, and $P(\{Y = z^*\} \bigcap \Gamma(z^*)) = 0$.

• If p is odd and if $\alpha > 0$, there is no solution of the ODE starting from a state distinct from z^* in W and converging to z^*. So $P(\{Y \neq z^*\} \bigcap \Gamma(z^*)) = 0$. Then z^* is avoided.

• In the other cases the convergence is possible, but for p even and for n large enough, $\alpha(Z_n - z^*) < 0$ on $\Gamma(z^*)$. In addition, a.s. on $\Gamma(z^*)$, for all $\delta < \frac{1}{2p}$,

$$|Z_n - z^*| \geq [(1-c)|\alpha|(p-1)s_{n-1} + |Y - z^*|^{1-p}]^{-\frac{1}{p-1}} + O(n^{-\delta}),$$

$$|Z_n - z^*| \leq [(1+c)|\alpha|(p-1)s_{n-1} + |Y - z^*|^{1-p}]^{-\frac{1}{p-1}} + O(n^{-\delta}).$$

Since c is arbitrary in $]0,1[$ and $s_{n-1} \simeq g \log n$, we have a.s. on $\Gamma(z^*)$,

$$|Z_n - z^*| \simeq [|\alpha|(p-1)g \log n]^{-\frac{1}{p-1}}.$$

This almost sure convergence rate to z^* is very slow. □

2.2.3. Some more general repulsive regions. In this section we give some properties of repulsive regions. First, we obtain a sufficient condition to claim that a region L is repulsive.

PROPOSITION 2.1. *Let L be a compact set connected and invariant for the ODE. If h is $\mathcal{C}^1$ on a neighborhood of L and if for all $z \in L$,*

$$\lambda_{min}(Dh(z) + (Dh(z))^T) > 0, \tag{17}$$

then L is repulsive in the sense of Definition 1.

Proof. Let L_r be a neighborhood of L where h is $\mathcal{C}^1$, and by the continuity of the spectrum of $Dh(z)$, there exists a constant $\lambda > 0$ such that

$$\inf_{z \in L} [\lambda_{min}(Dh(z) + (Dh(z))^T)] > 2\lambda,$$

and for r small enough,

$$\lambda_{min}(Dh(z) + (Dh(z))^T) \geq \lambda \quad \text{on } \overline{L_r}. \tag{18}$$

Set $(\varphi_t(x))_{t \geq 0}$ as the solution to the ODE starting from $x \in L_r \setminus L$ and

$$\tau = \inf\{t \ ; \ \varphi_t(x) \notin L_r\}.$$

Denote by $D\varphi$ the differential of φ with respect to x. For $t < \tau$ and for all $v \in \mathbb{R}^d$,

$$\begin{aligned} \frac{d}{dt}\|D\varphi_t(x)v\|^2 &= 2v^T(D\varphi_t(x))^T Dh(\varphi_t(x))D\varphi_t(x)v \\ &\geq \|D\varphi_t(x)v\|^2 \lambda_{min}(Dh(D\varphi_t(x)) + Dh(D\varphi_t(x))^T). \end{aligned}$$

And by (18),

$$\begin{aligned} \frac{d}{dt}\|D\varphi_t(x)\|^2 &\geq \lambda \|D\varphi_t(x)\|^2, \\ \|D\varphi_t(x)\| &\geq \exp\left(\frac{\lambda t}{2}\right). \end{aligned} \tag{19}$$

Set $z \in L$ such that $d(x, L) = \|z - x\|$. By the smoothness of φ,

$$\varphi_t(x) - \varphi_t(z) = D\varphi_t(x)(x - z) + o(x - z).$$

Then for $0 < t < \tau$ and for $r > 0$ small enough, by (19),

$$\|\varphi_t(x) - \varphi_t(z)\| \geq a\|x - z\|,$$

where $a > 1$. And for all integers $k > 0$,

$$\|\varphi_{kt}(x) - \varphi_{kt}(z)\| \geq a^k d(x, L),$$

as long as $\varphi_t(x) \in L_r$. This implies that $\varphi_t(x)$, $t > 0$, eventually leaves L_r; τ is bounded and L is repulsive. □

Now we still use the accompanying result of Appendix 2, so we assume that $\gamma_n = c_n = \frac{g}{n}$ with $g > 0$, and we denote by L_1 the closure of alpha and omega limit sets of points of L (as L is a compact connected chain recurrent set $L_1 \subseteq L$).

Then we obtain the following proposition.

PROPOSITION 2.2. *Consider the stochastic algorithm* (1) *under Assumptions* A1 *and the following assumptions:*

- *h is $\mathcal{C}^1$ on a neighborhood of L, and for all $z \in L_1$,*

$$\lambda_{min}(Dh(z) + (Dh(z))^T) \geq 0;$$

- *a.s. on $\Gamma(L)$,* (8) *is verified.*

Then, if L is a repulsive region, there exist a random variable T and a solution to the ODE, $t \to z(t)$ $(t \geq 0)$ with values in the invariant set L such that, a.s. on $\Gamma(L)$,

$$\limsup_n \frac{1}{\log n} \log(\|Z_n - z(s_{n-1} - T)\|) \leq -\left(\frac{1}{2} - \frac{1}{a}\right).$$

Proof. By Appendix 2, for $r > 0$ small enough, there exist a random variable $Y \in L_r$ and a positive random variable T such that

$$\limsup_n \frac{1}{\log n} \log(\|Z_n - z(s_{n-1} - T)\|) \leq -\left(\frac{1}{2} - \frac{1}{a}\right)$$

with $z(0) = Y$. But, as in section 2.2.1, L being repulsive, $P(Y \notin L) = 0$. □

So, if all solutions of the ODE included in L have limit sets in $L_1 \subseteq L$, the study of $\Gamma(L)$ reduces to the study of $\Gamma(L_1)$. For example, if L contains a finite number of equilibria, and if the solutions to the ODE included in L converge to one of these equilibria (it is the case of "equilibria cycles"; see [2], [5], and [8]), we reduce the study of $\Gamma(L)$ to the study of $\Gamma(z^*)$ for z^* equilibria of the ODE contained in L. When z^* is regular this case was studied in [6]; the case when we are not in the framework of singular traps is treated in Theorem 1.2.

Example. Let (Z_n) be defined in polar components (ρ_n, θ_n) by

$$\begin{cases} \rho_{n+1} = \rho_n + \frac{1}{n}[(\cos^2\theta_n - \frac{1}{2})g(\rho_n) + \xi_{n+1}], \\ \theta_{n+1} = \theta_n + \frac{1}{n}(\sin^2\theta_n + \xi_{n+1}), \end{cases}$$

and let $L = \{\rho = 1\}$. We assume that g is $\mathcal{C}^1$ on a neighborhood of 1, $g(1) = 0$, $g'(1) > 0$; (ξ_n) is a sequence of i.i.d. random variables with a uniform distribution on $[-\frac{1}{2}, \frac{1}{2}]$. For the ODE, $z_1 = (1, 0)$ and $z_2 = (1, \pi)$ are two equilibria, and the circle L is a repulsive region. The proposition applies and a.s.

$$(d(Z_n, L) \to 0) \Longrightarrow (Z_n \to z_1 \text{ or } Z_n \to z_2).$$

We have reduced the study of $\Gamma(L)$ to the case of repulsive regular traps z_1 and z_2. Thus $\Gamma(L)$ has probability zero.

2.3. Proof of Theorem 1.4.

2.3.1. Linearization of the ODE. Let P be the change of basis matrix from the canonical basis to $\mathcal{B}$. On $\mathcal{B}$, we denote the decomposition of a vector v as

$$v = \begin{pmatrix} v^+ \\ v^- \end{pmatrix} \quad \text{and}$$

$$\begin{pmatrix} g_+(v) \\ g_-(v) \end{pmatrix} = g(v) = Ph(v) = P \begin{pmatrix} h_+(v) \\ h_-(v) \end{pmatrix}.$$

For y in a neighborhood of L, there exists $x \in L$ such that $\|y - x\| = d(y, L)$ and

$$g_+(y^+, y^-) = J_+ y^+ + q_+(y^+, y^-),$$

where the function q_+ vanishes on x and its differential with respect to y^+, D_+q_+ also vanishes on x.

On a suitable neighborhood of x, $\|D_+q_+(y)\| \leq \mathbf{C}\ d(y, L)$. Besides, $g_-(x) = 0$, $D_+g_-(x) = 0$, and $\|D_+g_-(y)\| \leq \mathbf{C}d(y, L)$.

So the solution of the ODE starting from y satisfies

$$\begin{cases} z^+(t) = \exp(tJ_+)y^+ + Q_+(t, y), \\ z^-(t) = \exp(tJ_-(x))(y^- - x) + x + Q_-(t, y), \end{cases}$$

where $Q_\pm(t, x) = 0$, $D_+Q_\pm(t, x) = 0$, and $\|D_+Q_\pm(t, y)\| \leq \mathbf{C}\ d(y, L)$. Set

$$\begin{cases} f_+(y) = \exp J_+ y^+ + Q_+(1, y), \\ f_-(y) = \exp(J_-(x))(y^- - x) + x + Q_-(1, y). \end{cases}$$

Then, $f_-(x) = x$, $D_+f_-(x) = 0$, and $\|D_+f_-(y)\| \leq \mathbf{C}\ d(y, L)$.

Now we describe the linearization method (see Hartman [9, Corollary 5.2, p. 240]). We build recursively a sequence of functions (G_n) from K_a to K_r, by the relations

$$\begin{cases} G_0(x + v^-) = 0, \\ G_n(x + v^-) = G_{n-1}(x + v^-) \\ \qquad\qquad +(\exp J_+)^{-1}[G_{n-1}(x + (f_-(G_{n-1}(x + v^-), x + v^-) - x)) \\ \qquad\qquad\qquad\qquad -f_+(G_{n-1}(x + v^-), x + v^-)]. \end{cases}$$

For all $x \in L$, there exists an $r(x) > 0$ such that for $v^- \in K_s$ and $\|v^-\| \leq r(x)$, $G_n(x + v^-) \to G(x + v^-)$; if $z(0)$ is close enough to x and if $z(0)^+ = G(z(0)^-)$, the relation $z(t)^+ = G(z(t)^-)$ remains true for $t \leq t_0$, t_0 small enough. On a neighborhood of x,

$$[y^+ = G(y^-)] \Longrightarrow [h_+(y) = DG(y^-)h_-(y)].$$

Then, we infer that

• G is $\mathcal{C}^1$ in a ball $\mathbf{B}$ with a center x and a radius $r(x)$, $G(x) = 0$, $DG(x) = 0$, and DG is Lipschitz on $\mathbf{B}$;

• if $\|y - x\| \leq r(x)$, we set $v = y - x$ and

$$\varphi(y) = h_+(y) - DG(y^-)h_-(y).$$

Then $\varphi(G(y^-), y^-) = 0$ and $\varphi(y) = (J^+ + \Delta(y))(y^+ - G(y^-))$, with

$$\begin{aligned} \|\Delta(y)\| &\leq \sup_{0 \leq t \leq 1} \|D_+q_+(ty^+ + (1-t)G(y^-), y^-) \\ &\qquad\qquad -DG(y^-)D_+q_-(ty^+ + (1-t)G(y^-), y^-)\| \\ &\leq \mathbf{C}d(y, L), \end{aligned}$$

because $D_+q_\pm$ is Lipschitz.

We can cover L by a finite number of open balls, centered on $x_1, \ldots, x_q$, belonging to L, and with radius $r(x_1), \ldots, r(x_q)$. Set $r > 0$ such that

$$r < \min\{r(x_1), \ldots, r(x_q)\}.$$

Consider $L_r = \{y \in \mathbb{R}^d \ ; \ d(y^-, L) + \|y^+\| < r\}$. If $y \in L_r$, there exists j, $1 \leq j \leq q$, such that y^- is in the ball with the center x_j and the radius $r(x_j)$.

$$G_n(y^-) = G_n(x_j + (y^- - x_j)) \to G(y^-),$$

and, setting on L_r,

$$\varphi(y) = h_+(y) - DG(y^-)h_-(y), \tag{20}$$

then $\varphi(G(y^-), y^-) = 0$ and

$$\varphi(y) = (J^+ + \Delta(y))(y^+ - G(y^-)), \tag{21}$$

$$\text{where } \Delta(y) = O(d(y, L)). \tag{22}$$

Consequently, if $t \to z(t)$ is a solution of the ODE (3) which converges to L, setting $u(t) = z^+(t) - G(z^-(t))$, we obtain the repulsive ODE

$$\frac{du(t)}{dt} = (J_+ + \delta(t))u(t),$$

where $\|\delta(t)\| = O(d(z(t), L)) \to 0$.

2.3.2. Transformation of the algorithm. Set

$$Y_{n+1} = PZ_{n+1} = Y_n + \gamma_n g(Y_n) + c_n(P(\varepsilon_{n+1} + r_{n+1})).$$

As in [6, p. 401], by using a result of Lai and Wei [15], it is enough to prove Theorem 1.4 with the more restrictive condition that there exist three constants, $K < \infty$, $A > 0$, and $B < \infty$ such that

$$\Sigma\|r_{n+1}\|^2 \leq K, \ E(\|\varepsilon_{n+1}\|^2|\mathcal{F}_n) \leq B, \quad \text{and} \quad E(\|\varepsilon_{n+1}^{(r)}\||\mathcal{F}_n) \geq A > 0.$$

Set

$$\Gamma_p = \{\omega \ ; \ PZ_n(\omega) \in L_r \text{ for } n \geq p\} \bigcap \Gamma(L)$$

and $U_n = Y_n^+ - G(Y_n^-)$. On Γ_p, for $n \geq p$, by (20), (21), and (22), we obtain

$$U_{n+1} = U_n + \gamma_n(J_+ + \Delta_n)U_n + c_n(e_{n+1} + \rho_{n+1}),$$

with $\lim_n \Delta_n = 0$, $e_{n+1} = (P\varepsilon_{n+1})^+ - DG(Y_n^-)(P\varepsilon_{n+1})^-$, and (ρ_n) a sequence adapted with respect to $\mathbb{F}$ and verifying $\Sigma\|\rho_n\|^2 < \infty$ a.s. on $\Gamma(L)$.

$$E(\|DG(Y_n^-)(P\varepsilon_{n+1})^-\|^2|\mathcal{F}_n) \leq \|DG(Y_n^-)\|^2 E(\|(P\varepsilon_{n+1})^-\|^2|\mathcal{F}_n).$$

On $\Gamma(L)$, by the properties of G, $DG(Y_n^-)$ vanishes to 0, and by the assumptions on the noise, a.s. on $\Gamma(L)$,

$$\limsup_n E(\|e_{n+1}\|^2|\mathcal{F}_n) < \infty$$

and

$$\liminf_n E(\|e_{n+1}\| \ |\mathcal{F}_n) = \liminf_n E(\|(P\varepsilon_{n+1})^+\||\mathcal{F}_n) > 0.$$

So Proposition 4 in [6] applies to (U_n) and $P(\Gamma(L)) = 0$. □

3. An application of Theorem 1.4.

3.1. About a principal component analysis algorithm. A scatter plot of N data points of $\mathbb{R}^d$ $(x_1, \dots, x_N)$ with empirical mean zero $(\frac{1}{N}\sum_{k=1}^N x_k = 0)$ and with empirical covariance matrix $C = \frac{1}{N}\sum_{k=1}^N x_k (x_k)^T$ is analyzed.

We search for the j-dimensional principal subspace $(1 \le j \le d)$, where the projection of this scatter plot is the best.

If $\lambda_1 \ge \lambda_2 \ge \cdots \ge \lambda_d > 0$ are the eigenvalues of C, such a subspace has an orthonormal basis $\{V_1, \dots, V_j\}$, where V_i is an eigenvector associated with λ_i $(1 \le i \le j)$.

For j unitary and orthogonal $\mathbb{R}^d$-vectors $a_1, \dots, a_j$, we denote by $[a_1 \dots a_j]$ the $j \times d$ matrix whose column vectors are these vectors; $\mathcal{M}$ is the set of such orthonormalized matrices.

A PCA algorithm is intended for converging to $[V_1 \dots V_j] \in \mathcal{M}$, where V_i is an eigenvector associated with λ_i $(1 \le i \le j)$.

In the framework of the study of linear neural network, Oja [12], [20] naturally built a recursive PCA algorithm by suggesting the following method.

Assume that (X_n) is an i.i.d. sequence of points picked in the scatter plot with a uniform distribution. Then, if $Z_n = [Z_n^1 \dots Z_n^j]$ is the approximation of $[V_1 \dots V_j]$ at the nth step, it is natural, according to the neuronal intuition, to set

$$\tilde{Z}_{n+1} = Z_n + \gamma_n X_{n+1} (X_{n+1})^T Z_n, \tag{23}$$

$$Z_{n+1} = S_{n+1} \tilde{Z}_{n+1}, \tag{24}$$

where S_{n+1} is a matrix which depends on $\tilde{Z}_{n+1}$ and performs the Gram–Schmidt orthonormalization on the columns of $\tilde{Z}_{n+1}$.

(γ_n) is a decreasing nonnegative deterministic sequence such as

$$\sum_{n \ge 0} \gamma_n = \infty \quad \text{and} \quad \sum_{n \ge 0} \gamma_n^2 < \infty.$$

We claim the following result.

THEOREM 3.1. *If C is nonsingular, for any j, $1 \le j \le d$, $[Z_n^1 \dots Z_n^j]$ converges a.s. to a stochastic orthonormalized matrix $[W^1 \dots W^j]$, where $W^k \in \mathcal{S}_k$ for $1 \le k \le j$, $\mathcal{S}_k$ being the unit sphere of the eigensubspace associated to the eigenvalue λ_k.*

3.2. Previous results.

• The same algorithm was proposed by Benzécri [4], and later by Lebart [17]. They use algebraic arguments. The case where $j = 1$ is entirely treated, but the generalization is just given roughly (see [4]). With similar arguments Monnez [19] considers some analogous algorithms. He obtains the almost sure convergence of (Z_n^1) to the subspace associated to λ_1 and, only in the case of the distinct eigenvalues, the almost sure convergence of (Z_n) to $[\pm V^1, \dots, \pm V^d]$.

• Independently, in the framework of the study of the neural behavior, Oja, Karhunen, Sanger, Hornick, Kuan, Becker, Williams, Ogawa, Wangviwattana, and others [11], [12], [20], [21], [22], [23], [24], [26], [28] consider similar algorithms.

For the sequence (Z_n^1), we can find a partial proof in [12] when the eigenvalues have a unit multiplicity, and Delyon [7] treats the case of the multiple eigenvalues but without proving that the traps are avoided.

In the general case, and for the distinct and positive eigenvalues, Oja studies the ODE associated to (23), (24) and determines its asymptotically stable zeros. Then,

thanks to many simulations, he claims that the algorithm (23), (24) converges to these zeros, but without a theoretical proof.

We have chosen the Oja algorithm which better agrees with our framework and seems quite natural. It is a very suitable illustration of our previous study. Our method applies to other similar algorithms aforementioned.

3.3. Proof of Theorem 3.1. By (23) we obtain an algorithm which satisfies

$$\begin{aligned} Z_n &= [Z_n^1 \dots Z_n^j] \in \mathcal{M}, \text{ and for } 1 \le k \le j, \\ Z_{n+1}^k &= Z_n^k + \gamma_n \Bigg[(C_{n+1} - ((Z_n^k)^T C_{n+1} Z_n^k)) Z_n^k \\ &\qquad -2 \sum_{i=1}^{k-1} ((Z_n^k)^T C_{n+1} Z_n^i) Z_n^i \Bigg] + O(\gamma_n^2), \end{aligned} \tag{25}$$

with $C_{n+1} = X_{n+1} X_{n+1}^T$. We denote by $\mathcal{F}_n$ the σ-fields generated by $X_1, \dots, X_n$. Let $\mathcal{B} = \{V^1, \dots, V^d\}$ be an orthonormalized basis of eigenvectors of C, such that V^k is a eigenvector associated to λ_k, and let $\mathcal{S}_k$ be the unit sphere of the eigensubspace F_k associated to λ_k. The algorithm (25) satisfies

$$Z_{n+1} = Z_n + \gamma_n (h(Z_n) + \varepsilon_{n+1} + r_{n+1}), \tag{26}$$

where

$$\begin{aligned} h(Z) &= [h_1(Z) \dots h_j(Z)] \text{ with} \\ h_1(Z) &= CZ^1 - ((Z^1)^T C Z^1) Z^1, \end{aligned} \tag{27}$$

and for $1 \le k \le j$,

$$h_k(Z) = CZ^k - ((Z^k)^T C Z^k) Z^k - 2 \sum_{i=1}^{k-1} ((Z^i)^T C Z^k) Z^i, \tag{28}$$

$$\begin{aligned} \varepsilon_{n+1} &= [\varepsilon_{n+1}^1 \dots \varepsilon_{n+1}^j] \text{ with} \\ \varepsilon_{n+1}^1 &= (C_{n+1} - C) Z_n^1 - ((Z_n^1)^T (C_{n+1} - C) Z_n^1) Z_n^1, \end{aligned} \tag{29}$$

and for $1 \le k \le j$,

$$\begin{aligned} \varepsilon_{n+1}^k &= (C_{n+1} - C) Z_n^k - ((Z_n^k)^T (C_{n+1} - C) Z_n^k) Z_n^k \\ &\qquad -2 \sum_{i=1}^{k-1} ((Z_n^i)^T (C_{n+1} - C) Z_n^k) Z_n^i, \end{aligned} \tag{30}$$

$$\|r_{n+1}\| = O(\gamma_n). \tag{31}$$

(ε_n) and (r_n) are two bounded random sequences that are $(\mathcal{F}_n)$-measurable and satisfy (6).

Step 1. *Possible limit sets.*

LEMMA 3.2. *The possible limit sets L of solutions of the algorithm* (26) *are subsets of $\mathcal{M}$ such that, i being a map from $\{1, \dots, j\}$ to $\{1, \dots, d\}$, $z = [z^1 \dots z^j] \in L$ is characterized by: for $1 \le k \le j$, $z^k \in G_{i(k)}$, where $G_{i(k)}$ is a compact connected set contained in $\mathcal{S}_{i(k)}$, the unit sphere of the eigensubspace $F_{i(k)}$ associated to $\lambda_{i(k)}$.*

Therefore, for $z \in L$, $z^T C z = \operatorname{diag}[\lambda_{i(1)} \dots \lambda_{i(j)}]$.

Proof of Lemma 1. Following [2], we know that L is a compact connected subset of $\mathcal{M}$, invariant and "chain-recurrent" for the ODE.

First, remark that $h_1(x) = 0$(h_1 is given in (27)) if and only if x is a unit eigenvector of C. So the connected components of $\{h_1 = 0\}$ are contained in a unit sphere $\mathcal{S}_i$ $(1 \leq i \leq d)$. If λ_i has unit multiplicity, $\mathcal{S}_i = \{V^i, -V^i\}$ and the corresponding connected components of $\{h_1 = 0\}$ are $\{V^i\}$ or $\{-V^i\}$.

For $x \in \mathbb{R}^d$, set $V(x) = \frac{\exp(\|x\|^2)}{x^T(I+C)x}$ (it is the Lyapounov function used by Delyon in [7]).

$$\nabla V(x) = \frac{\exp(\|x\|^2)}{(x^T(I+C)x)^2}[(x^T(I+C)x)2x - 2(I+C)x],$$
$$\nabla V(x) = -2\frac{V(x)}{x^T(I+C)x}[h_1(x) - (\|x\|^2 - 1)x].$$

(a) For $j = 1$, if $z_0 \in L$, $z(t) \in L$ for all t and

$$\frac{dV(z^1(t))}{dt} = -2\frac{V(z^1(t))}{z^1(t)^T(I+C)z^1(t)}\left\langle h_1(z^1(t)), \frac{dz^1(t)}{dt}\right\rangle$$
$$= -2\frac{V(z^1(t))}{z^1(t)^T(I+C)z^1(t)}\|h_1(z^1(t))\|^2.$$

$V(z^1(t))$ is nonnegative and decreasing. Then, $V(z^1(t))$ converges to V_∞ when $t \to \infty$ and $h_1(z^1(t)) \to 0$. $(z^1(t))$ has a limit set which is a connected component of $\{h_1 = 0\}$ contained in $\mathcal{S}_{i(1)}$, one of the unit spheres described above.

But since L is chain-recurrent, for all t, $z^1(t) \in \mathcal{S}_{i(1)}$ and $L \subseteq \mathcal{S}_{i(1)}$.

(b) For $j > 1$, let $z(t) = [z^1(t), \ldots, z^j(t)]$ be a solution of the ODE with values in L. Assume that there exist $(k-1)$ integers $i(1), \ldots, i(k-1)$ with $z^\ell(t) \in \mathcal{S}_{i(\ell)}$, $1 \leq \ell \leq k-1$. Then, since $z(t) \in \mathcal{M}$, $\|z^k(t)\| = 1$, $z^k(t)$ is orthogonal to $z^i(t)$ if $i \neq k$ and

$$\frac{dz^k(t)}{dt} = h_k(z(t)) = h_1(z^k(t)),$$
$$\frac{dV(z^k(t))}{dt} = -2\frac{V(z^k(t))}{z^k(t)^T(I+C)z^k(t)}\left\langle h_1(z^k(t)), \frac{dz^k(t)}{dt}\right\rangle$$
$$= -2\frac{V(z^k(t))}{z^k(t)^T(I+C)z^k(t)}\|h_1(z^k(t))\|^2.$$

As in (a), we infer that for a given integer $i(k)$, $z^k(t) \in \mathcal{S}_{i(k)}$ for all t.

We have proved by recurrence the characterization of L. □

Remark. By Lemma 3.2, the *traps* of the algorithm (26) correspond to $(i(1), \ldots, i(j)) \neq (1, \ldots, j)$. We shall prove that these traps are regular if any eigenvalue has unit multiplicity while they are homogeneous flat traps in the sense of Theorem 1.4 for multiple eigenvalues.

Step 2. *Proof of* $(i(1) \ldots, i(j)) = (1, \ldots, j)$.

Now we prove the following result.

PROPOSITION 3.3. *For C nonsingular with possibly multiple eigenvalues, the Oja algorithm* (26) *satisfies*

$$Z_n^k \to \mathcal{S}_k \quad for\ 1 \leq k \leq j,$$

where $\mathcal{S}_k$ is the unit sphere of the eigensubspace F_k associated to λ_k.

Proof. Let L be defined as in Lemma 3.2. We proceed by recurrence to prove that $(i(1)\dots,i(j)) = (1,\dots,j)$.

(1) First we consider $j = 1$ and

$$Z^1_{n+1} = Z^1_n + \gamma_n(h_1(Z^1_n) + \varepsilon^1_{n+1} + r^1_{n+1}). \tag{32}$$

Assume that $i(1) = p > 1$ and $\mathcal{S}_p \neq \mathcal{S}_1$.

Let $\mathcal{B}$ be the orthonormalized basis described at the beginning of this section. For $Z^1 \in \mathbb{R}^d$, set $Z^1 = \sum_{i=1}^d z^{1i}V^i$ and $h_1(Z^1) = \sum_{i=1}^d h_1^i(Z^1)V^i$; $h_1^i(Z^1) = \lambda_i z^{1i} - (\sum_{j=1}^d \lambda_j (z^{1j})^2)z^{1i}$.

Determination of Dh_1.

$$\frac{\partial h_1^i}{\partial z^{1i}} = \lambda_i - \sum_{n=i}^d \lambda_n (z^{1n})^2 - 2\lambda_i (z^{1i})^2, \tag{33}$$

$$\frac{\partial h_1^i}{\partial z^{1k}} = -2\lambda_k z^{1k} z^{1i} \quad \text{if } k \neq i. \tag{34}$$

If $\mathcal{S}_p$, with a π-dimension, is generated by $V^{j(1)},\dots,V^{j(\pi)}$, for $p \geq 1$:

$$\text{if } z^1 \in \mathcal{S}_p \ , \ z^1 = \sum_{k=1}^{\pi} \langle z^1, V^{j(k)}\rangle V^{j(k)}.$$

And for $1 \leq k \leq \pi$ and $1 \leq k' \leq \pi$,

$$\begin{cases} \frac{\partial h_1^{j(k)}}{\partial z^{1j(k)}}(z^1) = -2\lambda_p \langle z^1, V^{j(k)}\rangle^2, \\ \frac{\partial h_1^{j(k)}}{\partial z^{1j(k')}}(z^1) = -2\lambda_p \langle z^1, V^{j(k)}\rangle \langle z^1, V^{j(k')}\rangle. \end{cases}$$

By denoting

$$J(z^1) = \begin{bmatrix} \langle z^1, V^{j(1)}\rangle \\ \cdots \\ \cdots \\ \langle z^1, V^{j(\pi)}\rangle \end{bmatrix} [\langle z^1, V^{j(1)}\rangle \dots \langle z^1, V^{j(\pi)}\rangle],$$

$J(z^1)$ is a matrix $\pi \times \pi$ that is symmetric, semidefinite positive, and for $z^1 \in \mathcal{S}_p$,

$$Dh_1(z^1) = \begin{pmatrix} J_+ & 0 & 0 \\ 0 & -2\lambda_p J(z^1) & 0 \\ 0 & 0 & J_- \end{pmatrix},$$

with

$$J_+ = \begin{pmatrix} \lambda_1 - \lambda_p & 0 & . & . \\ 0 & \lambda_2 - \lambda_p & 0 & . \\ \cdots & . & . & . \\ \cdots & . & . & \lambda_{j(1)-1} - \lambda_p \end{pmatrix}$$

and

$$J_- = \begin{pmatrix} \lambda_{j(\pi)+1} - \lambda_p & 0 & . & . \\ 0 & \lambda_{j(\pi)+2} - \lambda_p & 0 & . \\ \cdots & . & . & . \\ \cdots & . & . & \lambda_d - \lambda_p \end{pmatrix}.$$
