COROLLARY 4.2. *Let $\bar{x}$ be a minimizer of (*). Then there exist $\beta \geq 0$, $\lambda_i \geq 0$, and α_j, not all zero, such that $\lambda_i g_i(\bar{x}) = 0$ for all i and*

$$0 \in \beta \partial_M f(\bar{x}) + \sum_{i=1}^{m} \lambda_i \partial_M g_i(\bar{x}) + \sum_{j=1}^{k} \partial_M(\alpha_j h_j)(\bar{x}) + N_M U\bar{x}.$$

If one uses the pseudo-Lipschitz behavior of the multifunction Φ, defined in section 3, one can remove MGG from the result. Professor A. Ioffe has stated that, if one does not use a convex or usc generalized gradient, a constraint qualification is necessary for a Lagrange multiplier result. We use the pseudo-Lipschitz behavior of Φ. This result is tighter than the above result since the pseudo-Lipschitz behavior of Φ is equivalent to $0 \notin \sum_{j=1}^{k} [N_M C_j \bar{x} \backslash \{0\}] + [N_M U\bar{x} \backslash \{0\}]$. The proof is almost identical to that for Theorem 4.1.

THEOREM 4.3. *Let $\bar{x}$ be a minimizer of (*) and assume that $\Phi(v)$ is pseudo-Lipschitz at $(0, \bar{x})$. Then there exist $\beta \geq 0$, $\lambda_i \geq 0$, and α_j, not all zero, such that $\lambda_i g_i(\bar{x}) = 0$ for all i and*

$$0 \in \beta \partial_\ell f(\bar{x}) + \sum_{i=1}^{m} \lambda_i \partial_\ell g_i(\bar{x}) + \sum_{j=1}^{k} \partial_\ell(\alpha_j h_j)(\bar{x}) + N_\ell U\bar{x}.$$

Now we turn our attention to examples showing that these results actually differ from previous results. We first give an example where a nonconvex set constraint excludes using Ioffe's result.

Example 4.1. Consider the problem

$$\min_{x,y \in \mathbb{R}} 2\,|y| - x \qquad \text{subject to} \qquad (x, y) \in U,$$

where $U = \{(x, y) : x \geq y \text{ or } x \leq -y\}$. Ioffe's result doesn't apply since U is not convex. If one uses MGG, CGG, or LGG, the only critical point is $\bar{x} = (0, 0)$, where MGG, CGG, and LGG coincide:

$$\partial f(\bar{x}) = \partial_M f(\bar{x}) = \partial_\ell f(\bar{x}) = \{-1\} \times [-2, 2].$$

Also

$$N_M U\bar{x} = N_\ell U\bar{x} = [0, \infty) \times \{(1, -1), (1, 1)\}.$$

Remark 4.1. It is important to note that multiplier existence results may depend on how the constraint region is represented. That is, the same constraint region can satisfy a constraint qualification using one representation while it does not with another. Unfortunately, it is sometimes difficult, if not impossible, for the modeler to determine whether or not a given representation has the right properties. An example of this phenomenon occurs in Example 4.1. In this example, if the set U is written as a functional constraint, $y - |x| \leq 0$, then Ioffe's result applies.

The next example shows that, even without a set constraint, the results in this paper are sharper than those using convex generalized gradients. Here ∂_P denotes the MPGG and ∂ denotes the CGG.

Example 4.2. Let f be an arbitrary differentiable function from $\mathbb{R}^2 \to \mathbb{R}$ and define g by

$$g(x,y) = \begin{cases} -x + y, & x, y > 0, \\ x + y, & x < 0, y > 0, \\ -x - y, & x > 0, y < 0, \\ x - y, & x, y < 0. \end{cases}$$

The point we consider is $(0,0)$. For this function we have

$$\partial_\ell g(0,0) = \partial_M g(0,0) = \{-1, 1\} \times [-1, 1]$$

and

$$\partial g(0,0) = \partial_P g(0,0) = [-1,1] \times [-1,1].$$

For the problem

$$\min f(x,y) \quad s.t. \quad g(x,y) \leq 0,$$

the feasible set is $\{(x,y) : |x| \geq |y|\}$. For any Lipschitz f the point $(0,0)$ is a critical point for CGG and MPGG. On the other hand, the multiplier conditions for MGG and LGG in this paper are met only if there is a (v,w) in $\partial_M f(0,0)$ or $\partial_\ell f(0,0)$ with $|v| = |w|$.

The fact that the multifunction $\Phi(v)$ is always pseudo-Lipschitz if there is a single equality constraint allows simple examples to demonstrate that Theorem 4.3 is sharper than Theorem 4.1. The basis of the following example is that the constraint function is Fréchet differentiable at the point of interest but it is not strictly differentiable there.

Example 4.3. Let $f(x,y) = (y-1)^2$ and let

$$h(x,y) = \begin{cases} \frac{1}{n} + \frac{1}{(100n)^2} - 10|x - \frac{1}{n}| & \text{if } x \in \left(\frac{1}{n} - \frac{1}{90000n^2}\,,\ \frac{1}{n} + \frac{1}{110000n^2}\right) \\ & \quad \text{for } n \in \mathbb{N}, \\ x & \text{otherwise.} \end{cases}$$

Consider the problem

$$\min f(x,y) \quad s.t. \quad h(x,y) = 0.$$

The feasible set $C = \{(x,y) : h(x,y) = 0\}$ is the y-axis. This means that the optimal point is $(0,1)$. Since h is Fréchet differentiable along the y-axis, $\partial_\ell f(0,y) = (1,0)$ and the only critical point is $(0,1)$ when one applies Theorem 4.3. On the other hand one can calculate that $\partial_M h(0,y) = [-10,10] \times \{0\}$ for any $y \in \mathbb{R}$. This means that all feasible points are critical points for Theorem 4.1. Here the MGG result is not as tight as the result using only LGG.

5. Bilevel optimization. An application of the main results of paper is given in this section. It is a simple bilevel problem that demonstrates how one might use the linear and Mordukhovich generalized gradients in tandem. The problem is

$$\text{(UL)} \qquad \min f(x,y) \quad \text{subject to}$$
$$\text{(LL}_1\text{)} \qquad y \in \operatorname{argmin}\{\min_y g(x,y)\}.$$

Here we assume that $f : \mathbb{R}^n \to \mathbb{R}$ and $g : \mathbb{R}^m \to \mathbb{R}$ are Lipschitz functions. There has been a large amount of recent research on bilevel problems, see for example [1, 6, 23, 24]. If one tries to derive necessary conditions for this problem one encounters several problems almost immediately. The first is that the lower level constraint on the upper level problem is not "nice." Another is that a second order derivative is required to directly include a necessary condition for LL_1 as a constraint on the upper level problem. If one uses a good generalized gradient $\partial_\#$, the necessary condition for the lower level problem LL_1 is

$$0 \in \partial_{\#,y} g(x,y).$$

Let $S_1(x) = \{y : 0 \in \partial_{\#,y} g(x,y)\}$. Since one must make strong assumptions to make

$$S_1(x) = \operatorname{argmin}\{\min_y g(x,y)\},$$

we first replace the original problem with

$$\text{(UL)} \qquad \min f(x,y) \quad \text{subject to}$$
$$\text{(LL)} \qquad y \in S_1(x).$$

When considering which generalized gradients to use for a second order object, most people require that the graph of $z \to \partial_\# g(z)$ is a multifunction with closed graph. (A requirement that sets be closed is used in the definitions of almost all normal cones and generalized gradients.) In our situation this means that the object one should use for the first order condition on the lower level problem is either MGG or CGG. Since, as was mentioned earlier, CGG is not appropriate, we use MGG. An additional problem is that using MGG in the lower level necessary condition will only make $S_1(x)$ closed for each x. What is actually desired is that $S_1(x)$ have closed graph. In order to do this, one must expand $S_1(x)$ again. The easiest way is to replace S_1 with

$$S(x) = \{y : (x^*, 0) \in \partial_M g(x,y)\}.$$

Under our assumption that g is Lipschitz, we have $S_1(x) \subset S(x)$. Replacing $S_1(x)$ with $S(x)$, we express the graph of S as the first two components of the intersection of the two sets; $C_1 = \operatorname{gph}\partial_M g(x,y)$ and $C_2 = \{(x,y,x^*,0) : x, x^* \in \mathbb{R}^n,\ y \in \mathbb{R}^m \text{ and } 0 \in \mathbb{R}^m\}$. The second set can be written as an equality constraint $h(x,y,z,w) = w = 0$. The problem now becomes

$$\text{(5.1)} \qquad \min_{x,y,z,w} f(x,y) \quad \text{subject to } (x,y,z,w) \in \operatorname{gph}\partial_M g(x,y)$$
$$\text{and} \quad h(x,y,z,w) = 0.$$

Applying Theorem 4.1 to problem (5.1) gives the following condition. There exist z^* and $\lambda \geq 0$, not both zero, and x^* such that

$$(x^*, 0) \in \partial_M g(x,y)$$

and

$$(0,0,0,0) \in \lambda\partial_\ell f(x,y) \times \{0\} \times \{0\} + N_M \text{gph}\partial_M g(x,y)(x,y,x^*,0) + (0,0,0,z^*).$$

The second condition can be rewritten as there exists $(x_1^*, y_1^*) \in D^*\partial_M g(x,y)(s^*, w^*)$ such that

$$(0,0) \in \partial_\ell f(x,y) + (x_1^*, y_1^*)$$

and

$$(0,0) \in (s^*, w^*) + (0, z^*).$$

Here D^* is the co-derivative of Mordukhovich. This says there exist w^* and $\lambda \geq 0$, not both zero, and

$$(x_1^*, y_1^*) \in D^*\partial_M \big(g(x,y)(x,y,x^*,0)\big)(0,w^*)$$

such that

$$(0,0) \in \lambda\partial_\ell f(x,y) + (x_1^*, y_1^*).$$

The above gives the following result. This result does not make any assumptions about the properties of $\partial_M g(x,y)$ except for the closed graph property. This is different from most results since there are no qualifications on the argmin set of LL.

THEOREM 5.1. *Let $(\bar{x}, \bar{y})$ be a solution to* (5.1). *Then there exist $\lambda \geq 0$ and $w^* \in \mathbb{R}^m$, not both zero, such that*

$$-\lambda\partial_\ell f(\bar{x},\bar{y}) \cap D^*\partial_M \big(g(x,y)(\bar{x},\bar{y},x^*,0)\big)(0,w^*) \neq \emptyset.$$

Many of the qualifications used in necessary conditions for bilevel programming guarantee that the multifunction $S(x)$ is well behaved. Convexity of $g(x,y)$ in y implies that $S(x)$ is a closed convex set for each x and strict convexity reduces S to a function. Both of these give that $S(x)$ is closed valued. Other conditions are used to guarantee that, in addition, $S(x)$ has closed graph. In some sense, these usually come down to giving $S(x)$ some Lipschitz property. The type of condition used in Zhang [24] involves the inverse of the multifunction $(x,y) \to \partial_M g(x,y)$. The condition we use is that this inverse is pseudo-Lipschitz. The similarity with Zhang's condition is discussed in his paper. Since C_2 is a subspace that contains the range space of the inverse, this implies that $\Psi(v)$, the intersection of our two sets under perturbations, is pseudo-Lipschitz. Applying Theorem 4.1. gives the following result.

THEOREM 5.2. *Let $(\bar{x}, \bar{y})$ be a solution to* (5.1). *If the inverse of $(x,y) \to \partial_M g(x,y)$ is pseudo-Lipschitz at $(x^*, 0, \bar{x}, \bar{y})$ for all $(x^*, 0) \in \partial_M g(\bar{x}, \bar{y})$, then there exist $\lambda \geq 0$ and w^*, not both zero, and a z^* such that*

$$(z^*, 0) \in \partial_M g(x,y),$$

and there is $(x_1^*, y_1^*, 0, w^*) \in N_\ell \text{gph}\partial_M g(x,y)(\bar{x},\bar{y},z^*,0)$ with

$$-(x_1^*, y_1^*) \in \lambda\partial_\ell f(\bar{x},\bar{y}).$$

These two results show how the two generalized gradients, in combination, give nice results for a complicated situation. It is very difficult to give examples when the functions under consideration are not smooth. If the functions are all assumed to be C^2, one can rewrite Theorem 5.1.

COROLLARY 5.3. *Let $(\bar{x}, \bar{y})$ be a minimizer of problem (5.1) where f and g are C^2 functions. Then there are $\lambda \geq 0$ and w^*, not both zero, such that*

$$0 = \partial_y g(\bar{x}, \bar{y})$$

and

$$\lambda \nabla f(\bar{x}, \bar{y}) = Jg(\bar{x}, \bar{y})(0, w^*).$$

This is the desired necessary condition for a smooth unconstrained bilevel problem. The following is a simple example to show how this can be used.

Example 5.1. Let $f(x, y) = 4x^2 + y^2$ and

$$g(x, y) = \begin{cases} \cos(\sqrt{x^2 + y^2}) & \text{if } (x, y) \neq (0, 0), \\ 1 & \text{if } (x, y) = (0, 0). \end{cases}$$

The first condition in Corollary 5.3 yields that $\sqrt{x^2 + y^2} = k\pi/2$ for any k or $y = 0$. This includes both local minima and local maxima. Adding on the second condition gives the points $(k\pi/2, 0)$ and $(0, k\pi/2)$ for $k = 0, 1, 2, \ldots$. This is the best that one can do with first order necessary conditions. It is interesting to note that the number of possible minima is extremely large. This is an unfortunate, but very common, situation.

Acknowledgments. I wish to thank A. D. Ioffe, Philip Loewen, and Boris Mordukhovich for conversations concerning the LGG. I would also like to thank a referee whose general comments about revisions of papers were well taken.

A SPECTRAL TEST FOR OBSERVABILITY AND REACHABILITY OF TIME-VARYING SYSTEMS*

M. A. PETERS[†] AND P. A. IGLESIAS[†]

Abstract. A spectral test for the observability and reachability of linear time-invariant systems—the Popov–Belevitch–Hautus test—is well known and serves as a powerful characterization of these properties. In this paper it is shown that similar tests exist for linear time-varying systems. The test presented here involves a check over a subset of the spectrum of the weighted block shift known as the set of *almost eigenvalues*.

Key words. observability, operator-theoretic methods, controllability, exponential stability, time-varying systems, discrete-time systems

1. Introduction.

For linear time-invariant (LTI) systems described by a state-space realization, spectral tests exist to determine fundamental properties of the realization such as stability, reachability, and observability.

It has long been known that, for linear time-varying (LTV) systems, the location of eigenvalues of the "A" matrix in the realization does not furnish meaningful information regarding the system's stability. However, it was shown in [5, 8] that for discrete-time systems, stability could be characterized by the spectral radius of an operator arising from the state-space realization. In this paper we show how only part of the spectrum, the set of *almost eigenvalues*, is required to characterize stability.

For reachability and observability regarding LTI systems, the PBH (for Popov–Belevitch–Hautus; see [9]) test allows one to determine these properties based on the eigenvalues/eigenvectors of the A matrix. For LTV systems, however, no corresponding test in known. In this paper we show that a test analogous to the PBH test for discrete-time LTV systems can be formulated. Moreover, it will be reminiscent of the spectral test for stability developed in [5, 8].

The rest of the paper is organized as follows. In section 2 we describe the operator-theoretic setting that will be used throughout the paper. This setting is used in section 3 to review the characterization of stability developed in [5, 8]. Spectral tests for observability and detectability are considered in sections 4 and 5, respectively, whereas the dual results for reachability and stabilizability are found in section 6. Finally, concluding remarks are presented in section 7.

2. Preliminaries.

In this section we introduce the class of systems that will be considered, as well as the notation and some basic concepts used throughout the paper.

The notation is standard. All matrices and vectors are assumed real. For a matrix $M \in \mathbb{R}^{m\times n}$, M^T denotes its transpose. We consider the set of sequences from $\mathbb{Z} \to \mathbb{R}^n$. The subset of square summable sequences is denoted ℓ_2^n. This is a Hilbert

space with inner product

$$\langle \boldsymbol{x}, \boldsymbol{y} \rangle_{\ell_2^n} := \sum_{k=-\infty}^{\infty} x_k^T y_k$$

and norm

$$\|\boldsymbol{x}\|_2 = \sqrt{\sum_{k=-\infty}^{\infty} |x_k|^2} < \infty\,.$$

Where the dimension of the underlying space is immaterial this will be omitted.

In the space of linear operators we will consider only the subset of bounded operators mapping ℓ_2^m to ℓ_2^p. A linear operator $\boldsymbol{G}$, mapping ℓ_2^m to ℓ_2^p, has an infinite-dimensional matrix representation $(\boldsymbol{G})_{k,j} = G_{k,j}$, where $G_{k,j} \in \mathbb{R}^{p\times m}$ for every $k, j \in \mathbb{Z}$. The subspace of operators which are memoryless is denoted by $\mathcal{M}$. These are the operators with block-diagonal matrix representations, and in general we will use the shorter notation $\boldsymbol{G} = \mathrm{diag}\{G_k\}$.

By the adjoint of an operator $\boldsymbol{G} : \ell_2^m \to \ell_2^p$ we denote the unique operator $\boldsymbol{G}^* : \ell_2^p \to \ell_2^m$ satisfying

$$\langle \boldsymbol{x}, \boldsymbol{G}\boldsymbol{y} \rangle_{\ell_2^p} = \langle \boldsymbol{G}^*\boldsymbol{x}, \boldsymbol{y} \rangle_{\ell_2^m}$$

$\forall\ \boldsymbol{x} \in \ell_2^m$ and $\boldsymbol{y} \in \ell_2^p$. Note that, for the operators that we consider, the adjoint is just the transpose of the infinite-dimensional matrix $\boldsymbol{G}$.

By the norm of an operator we mean the ℓ_2-induced operator norm

$$\|\boldsymbol{G}\| = \sup_{\boldsymbol{0}\neq \boldsymbol{w}\in\ell_2^m} \frac{\|\boldsymbol{G}\boldsymbol{w}\|_2}{\|\boldsymbol{w}\|_2}.$$

An operator $\boldsymbol{T} : \ell_2^n \to \ell_2^n$ is called invertible if there exists $\boldsymbol{S} : \ell_2^n \to \ell_2^n$ such that $\boldsymbol{TS} = \boldsymbol{ST} = \boldsymbol{I}$. The operator $\boldsymbol{S}$ is the inverse of $\boldsymbol{T}$, denoted $\boldsymbol{S} = \boldsymbol{T}^{-1}$.

We say that an operator $\boldsymbol{W} : \ell_2^n \to \ell_2^n$ is positive definite ($\boldsymbol{W} > \boldsymbol{0}$) if $\boldsymbol{W} = \boldsymbol{W}^*$ and if there exists an $\epsilon > 0$ such that $\langle \boldsymbol{x}, \boldsymbol{W}\boldsymbol{x} \rangle \geq \epsilon \langle \boldsymbol{x}, \boldsymbol{x} \rangle$ for all $\boldsymbol{x} \in \ell_2^n$. It can be checked that if $\boldsymbol{W} > \boldsymbol{0}$, then $\boldsymbol{W}$ is invertible and $\boldsymbol{W}^{-1} > \boldsymbol{0}$.

In the following discussion we will consider systems of the form

$$\begin{aligned} x_{k+1} &= A_k x_k + B_k u_k, \\ y_k &= C_k x_k. \end{aligned} \tag{2.1}$$

To simplify the notation in the sequel, we form block-diagonal operators using the state-space matrix sequences $\{A_k\}$, $\{B_k\}$, and $\{C_k\}$,

$$\boldsymbol{A} := \mathrm{diag}\{A_k\}, \qquad \boldsymbol{B} := \mathrm{diag}\{B_k\}, \qquad \boldsymbol{C} := \mathrm{diag}\{C_k\},$$

which are all memoryless operators. We will always assume that these sequences are uniformly bounded. One further operator is needed. Let $\boldsymbol{Z}$ be the usual unit advance operator, satisfying $(\boldsymbol{Z}\boldsymbol{x})_k = x_{k+1}$. Note that $\boldsymbol{Z}^*\boldsymbol{Z} = \boldsymbol{Z}\boldsymbol{Z}^* = \boldsymbol{I}$. Using these operators we can describe the system (2.1) as

$$\begin{aligned} \boldsymbol{Z}\boldsymbol{x} &= \boldsymbol{A}\boldsymbol{x} + \boldsymbol{B}\boldsymbol{u}, \\ \boldsymbol{y} &= \boldsymbol{C}\boldsymbol{x}. \end{aligned} \tag{2.2}$$

The operator $\boldsymbol{G}$, mapping $\boldsymbol{u} \in \ell_2^m$ to $\boldsymbol{y} \in \ell_2^p$, will often be called the system $\boldsymbol{G}$.

Finally, to abbreviate notation we will use the weighted shifts $\mathcal{A} := \boldsymbol{Z}^*\boldsymbol{A}$ and $\mathcal{B} := \boldsymbol{Z}^*\boldsymbol{B}$, and we introduce the spectral radius of an operator $\boldsymbol{T} : \ell_2^n \to \ell_2^n$, which is defined as

$$\rho(\boldsymbol{T}) := \lim_{n\to\infty} \|\boldsymbol{T}^n\|^{1/n}. \tag{2.3}$$

In the next section we will relate stability properties of the system (2.2) to conditions on the spectrum of the shifted operator $\mathcal{A}$.

3. Uniform exponential stability. We say that the operator $\boldsymbol{A}$ is uniformly exponentially stable (UES) if there exist constants $c > 0$ and $\beta \in [0, 1)$ such that $\forall\ k \in \mathbb{Z}$ and $l \in \mathbb{N}$

$$\|A_{k+l-1}A_{k+l-2}\cdots A_k\| \leq c\beta^l.$$

An equivalent expression is that $\forall\ k_0$ and x_{k_0}, the inequality

$$|x_k| \leq c\beta^{k-k_0}|x_{k_0}|$$

is satisfied $\forall\ k > k_0$.

If $\boldsymbol{A}$ is UES, we say that the corresponding system (2.2) is stable. The notion of uniform exponential stability can be characterized in terms of the spectral radius of the block-weighted shift $\mathcal{A}$, in a way which is reminiscent of the well-known result for LTI systems.

Lemma 3.1 (see [5, 8]). *Suppose that the operator $\boldsymbol{A} \in \mathcal{M}$. Then $\boldsymbol{A}$ is UES if and only if $\rho(\mathcal{A}) < 1$.*

For an LTI system (i.e., $A_k = A\ \forall\ k$) it can easily be shown that $\rho(\mathcal{A}) = \rho(A)$. Hence, an LTI system is stable if and only if all the eigenvalues of A have magnitude less than 1.

For time-varying systems, however, we will be checking for points λ in the spectrum of the block-weighted shift $\mathcal{A}$. Because this is an infinite-dimensional operator, which may not have eigenvalues, we will work with the slightly more general sets of *almost eigenvalues* and *almost eigenvectors* [2]. A number $\lambda \in \mathbb{C}$ is an almost eigenvalue of an operator $\boldsymbol{T}$ if there exists a sequence $\{\boldsymbol{x}_n\}_{n\geq 0}$, where each of the $\boldsymbol{x}_n$ is an element of ℓ_2 with $\|\boldsymbol{x}_n\|_2 = 1$, such that

$$\lim_{n\to\infty} \|\boldsymbol{T}\boldsymbol{x}_n - \lambda\boldsymbol{x}_n\|_2 = 0.$$

The sequence $\{\boldsymbol{x}_n\}$ is called an almost eigenvector corresponding to λ. We find the following.

Lemma 3.2. *If $\boldsymbol{A} \in \mathcal{M}$ is UES, then all almost eigenvalues of $\mathcal{A}$ have magnitude less than* 1.

Proof. The spectral radius of an operator is the maximum modulus of all elements of the spectrum of the operator. The set of almost eigenvalues of an operator is a subset of the spectrum [2]. Hence, if $\boldsymbol{A}$ is UES, from Lemma 3.1 all elements of the spectrum have magnitude less than 1, and hence so do all almost eigenvalues of $\mathcal{A}$. □

The result of this lemma follows directly from those of [5, 8]. The converse, however, is new. We now show that instead of checking for the maximum magnitude over all elements of the spectrum, we need only check the subset of the spectrum consisting of the almost eigenvalues.

LEMMA 3.3. *For $\boldsymbol{A} \in \mathcal{M}$, if all almost eigenvalues of $\mathcal{A}$ have magnitude less than* 1, *then $\boldsymbol{A}$ is UES.*

Proof. Suppose that $\boldsymbol{A}$ is not UES. Then

$$(\forall c > 0)(\forall \beta \in [0,1))(\exists k_0 \in \mathbb{Z})(\exists l \in \mathbb{N}) \qquad \|A_{k_0+l-1}A_{k_0+l-2}\cdots A_{k_0}\| > c\beta^l.$$

Now, for $n \in \mathbb{N}$ take $c = n$ and $\beta = 1 - 1/n$. Then there exists $k_0 \in \mathbb{Z}$, $l \in \mathbb{N}$, and $|x_{k_0}| = 1$ such that

$$|A_{k_0+l-1}\cdots A_{k_0}x_{k_0}| > n(1-1/n)^l. \tag{3.1}$$

The reason for taking $c = n$ is that it forces l to go to infinity in case n goes to infinity, which we will use later on. Define the number

$$r_n := |A_{k_0+l-1}\cdots A_{k_0}x_{k_0}|^{-1/l},$$

which is well defined, with $1/r_n > (1-1/n)n^{1/l} \geq 1 - 1/n$. With this notation we define the sequence

$$(\boldsymbol{x}_n)_k := \begin{cases} x_{k_0} & \text{for } k = k_0, \\ r_n^{k-k_0}A_{k-1}\cdots A_{k_0}x_{k_0} & \text{for } k = k_0+1,\ldots,k_0+l-1, \\ 0 & \text{elsewhere} \end{cases}$$

and $\bar{\boldsymbol{x}}_n := \boldsymbol{x}_n/\|\boldsymbol{x}_n\|_2$. Obviously $\|\bar{\boldsymbol{x}}_n\|_2 = 1$. For the sequence $\bar{\boldsymbol{x}}_n$ we can compute

$$\begin{aligned} \left\|\mathcal{A}\bar{\boldsymbol{x}}_n - \frac{1}{r_n}\bar{\boldsymbol{x}}_n\right\|_2^2 &= \frac{1}{r_n^2}\frac{|x_{k_0}|^2}{\|\boldsymbol{x}_n\|_2^2} + \frac{r_n^{2(l-1)}}{\|\boldsymbol{x}_n\|_2^2}|A_{k_0+l-1}\cdots A_{k_0}x_{k_0}|^2 \\ &= \frac{1}{r_n^2\|\boldsymbol{x}_n\|_2^2}\left(1 + r_n^{2l}|A_{k_0+l-1}\cdots A_{k_0}x_{k_0}|^2\right) \\ &= \frac{2}{r_n^2\|\boldsymbol{x}_n\|_2^2}, \end{aligned}$$

where we used the definition of r_n.

Since $\boldsymbol{A}$ is uniformly bounded, there exists an α such that $\|A_k\| < \alpha\ \forall\ k$. (Note that $\alpha \geq 1$; otherwise (3.1) cannot be satisfied for n large enough such that $1 - 1/n > \alpha$.) It is easy to check that $r_n > 1/\alpha$. Hence,

$$\left\|\mathcal{A}\bar{\boldsymbol{x}}_n - \frac{1}{r_n}\bar{\boldsymbol{x}}_n\right\|_2^2 < \frac{2\alpha^2}{\|\boldsymbol{x}_n\|_2^2}. \tag{3.2}$$

Now we see the importance of taking $c = n$. Namely, if n becomes larger, then also l is forced to be large in order to satisfy (3.1) since $\boldsymbol{A}$ is uniformly bounded, and it is easy to show that $l \to \infty$ as $n \to \infty$. Since $|x_{k_0}| = |x_{k_0+l}| = 1$ (by definition of r_n) and $\boldsymbol{A}$ is uniformly bounded, it can be shown that $\|\boldsymbol{x}_n\|_2 \to \infty$ as $n \to \infty$. Hence, the right-hand side of (3.2) goes to zero as n goes to infinity. Since

$$1/\alpha < r_n < 1 - 1/n$$

there exists a subsequence of $n \in \mathbb{N}$ for which r_n converges, say $r_n \to r$ $(n \to \infty)$, and we see that $1/r$ is an almost eigenvalue of $\mathcal{A}$. Since $1/r_n > 1 - 1/n$, we have $1/r \geq 1$. Therefore $\mathcal{A}$ has an almost eigenvalue with magnitude greater than or equal to 1. □

Note that the construction in the proof of Lemma 3.3 leads to an almost eigenvalue of $\mathcal{A}$ which is real and nonnegative (namely $\lambda = 1/r$). In fact, we can show that it is sufficient only to consider real nonnegative almost eigenvalues.

LEMMA 3.4. *If λ is an almost eigenvalue of $\mathcal{A}$, then $|\lambda|$ is also an almost eigenvalue of $\mathcal{A}$, and it has a corresponding real almost eigenvector.*

Proof. Assume $\|\mathcal{A}\boldsymbol{x}_n - \lambda \boldsymbol{x}_n\|_2 \to 0$ as $n \to \infty$ for $\|\boldsymbol{x}_n\|_2 = 1$. Hence, with $\lambda = |\lambda| e^{i\theta}$, we have

$$\sum_{k=-\infty}^{\infty} \left| A_k x_{n_k} - |\lambda| e^{i\theta} x_{n_{k+1}} \right|^2 \to 0 \quad (n \to \infty).$$

This is equivalent to

$$\sum_{k=-\infty}^{\infty} \left| A_k e^{ik\theta} x_{n_k} - |\lambda| e^{i(k+1)\theta} x_{n_{k+1}} \right|^2 \to 0 \quad (n \to \infty), \tag{3.3}$$

which shows that $\tilde{\boldsymbol{x}}_n$, given by $\tilde{x}_{n_k} = e^{ik\theta} x_{n_k}$, is an almost eigenvector for the almost eigenvalue $|\lambda|$. Note that $\|\tilde{\boldsymbol{x}}_n\|_2 = \|\boldsymbol{x}_n\|_2 = 1$. To construct a real almost eigenvector, we can separate the real and the imaginary parts in (3.3), which gives

$$\sum_{k=-\infty}^{\infty} \left| A_k \mathrm{Re}(\tilde{x}_{n_k}) - |\lambda| \mathrm{Re}(\tilde{x}_{n_{k+1}}) \right|^2 + \left| A_k \mathrm{Im}(\tilde{x}_{n_k}) - |\lambda| \mathrm{Im}(\tilde{x}_{n_{k+1}}) \right|^2 \to 0$$

as n goes to infinity. Hence, we can take either

$$\boldsymbol{z}_{1n} := \frac{\mathrm{Re}(\tilde{\boldsymbol{x}}_n)}{\|\mathrm{Re}(\tilde{\boldsymbol{x}}_n)\|_2} \quad \text{or} \quad \boldsymbol{z}_{2n} := \frac{\mathrm{Im}(\tilde{\boldsymbol{x}}_n)}{\|\mathrm{Im}(\tilde{\boldsymbol{x}}_n)\|_2}$$

in order to have a real almost eigenvector. Note that, since $\|\mathrm{Re}(\tilde{\boldsymbol{x}}_n)\|_2^2 + \|\mathrm{Im}(\tilde{\boldsymbol{x}}_n)\|_2^2 = 1$, at least one of them is well defined. □

Remark. In a similar way we can show that $|\lambda| e^{i\psi}$ is an almost eigenvalue for every $\psi \in [0, 2\pi)$. This generalizes the well-known result that for the shift operator $\boldsymbol{Z}^*$ (i.e., $\boldsymbol{A} = \boldsymbol{I}$), the whole unit circle is part of the spectrum.

Example 3.5. We will illustrate the results of Lemma 3.4. In fact, by choosing an LTI system as our example, we show how the result considered is new even for the LTI setting. Consider the LTI system with

$$A_k = A = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}.$$

In this case $\lambda = i$ is an eigenvalue of the matrix A with eigenvector $x = \left[\begin{smallmatrix} 1 \\ i \end{smallmatrix}\right]$, and it is also an almost eigenvalue of $\mathcal{A}$ with almost eigenvector $\boldsymbol{x}_n$ given by

$$x_{n_k} = \begin{cases} \dfrac{1}{\sqrt{2(2n+1)}} \begin{bmatrix} 1 \\ i \end{bmatrix} & \text{for } k = -n, \dots, n-1, n, \\ \begin{bmatrix} 0 \\ 0 \end{bmatrix} & \text{for } k \neq -n, \dots, n-1, n. \end{cases}$$

Following the construction in the lemma we find a real almost eigenvector $\boldsymbol{z}_n$, corresponding to $|\lambda| = 1$, given by

$$z_{n_0} = \frac{1}{\sqrt{(2n+1)}} \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \qquad z_{n_1} = \frac{1}{\sqrt{(2n+1)}} \begin{bmatrix} 0 \\ -1 \end{bmatrix},$$

$$z_{n_2} = \frac{1}{\sqrt{(2n+1)}} \begin{bmatrix} -1 \\ 0 \end{bmatrix}, \qquad z_{n_3} = \frac{1}{\sqrt{(2n+1)}} \begin{bmatrix} 0 \\ 1 \end{bmatrix},$$

$$z_{n_k} = \begin{cases} z_{n_{k \bmod 4}} & \text{for } k = -n, \dots, n-1, n, \\ \begin{bmatrix} 0 \\ 0 \end{bmatrix} & \text{for } k \neq -n, \dots, n-1, n. \end{cases}$$

Remark. The computation of the generalized eigenvalues/eigenvectors will in general not be trivial. Some general comments on the computation of the spectrum of weighted shifts such as those considered here can be found in [10].

Summarizing the results, we have the following theorem.

THEOREM 3.6. *The following statements are equivalent:*

(i) $\boldsymbol{A}$ *is UES.*

(ii) $\rho(\mathcal{A}) < 1$.

(iii) *All almost eigenvalues of* $\mathcal{A}$ *have magnitude less than* 1.

These statements are the time-varying analogues of the well-known LTI results. In the next section we will outline the concept of uniform observability and discuss a PBH-type test which checks whether a system satisfies this property.

4. Uniform observability. Recall that an LTI system is said to be observable if different initial conditions give rise to different outputs. Specifically, for the unforced LTI equation

$$\begin{aligned} x_{k+1} &= Ax_k, \\ y_k &= Cx_k, \end{aligned}$$

the pair (C, A) is observable if $CA^l x_0 = CA^l \bar{x}_0$ for $l = 0, 1, \dots, n-1$ implies that $x_0 = \bar{x}_0$.

As is well known, n is the maximum number of steps needed to recover the initial state from the output, although it might be possible in fewer.

LEMMA 4.1. *An LTI system is observable if and only if*

$$\left.\begin{aligned} Ax &= \lambda x \\ Cx &= 0 \end{aligned}\right\} \Longrightarrow x = 0.$$

That is, A has no unobservable eigenvalues.

Note that it is necessary to perform the PBH test only at eigenvalue/eigenvector pairs of the matrix A.

In the time-varying case, we consider systems of the form

$$\begin{aligned} x_{k+1} &= A_k x_k, \\ y_k &= C_k x_k. \end{aligned}$$

A corresponding notion of observability for time-varying systems can be formulated based on the idea that for an observable system, different initial conditions should lead to different outputs. This leads to the concept of uniform l-step observability [9].

DEFINITION 4.2. *The pair $(\boldsymbol{C}, \boldsymbol{A})$ is called uniformly l-step observable if there exists $\epsilon > 0$ such that $\forall\ k_0$, x_{k_0}, and $\bar{x}_{k_0}$, the inequality*

$$\sum_{k=k_0}^{k_0+l-1} |y_k - \bar{y}_k|^2 \geq \epsilon |x_{k_0} - \bar{x}_{k_0}|^2$$

is satisfied.

The uniform requirement ensures that the same ϵ will be suitable for all starting points k_0.

Example 4.3. Consider a time-varying system with $A_k = 0 \ \forall \ k$ and

$$C_k = \begin{cases} 1 & \text{for } k \leq 0, \\ 1/k & \text{for } k > 0. \end{cases}$$

Based on the observation of the output, at any time k, the initial state, can be recovered in one step, regardless of the particular value of k. Nevertheless, for $k_0 > 0$ we have that

$$y_k = \begin{cases} 1/k_0 x_{k_0} & \text{for } k = k_0, \\ 0 & \text{elsewhere.} \end{cases}$$

It follows that the difference in output $y_k - \bar{y}_k$ can be made arbitrarily small (in an ℓ_2 sense) compared to $x_{k_0} - \bar{x}_{k_0}$ by choosing k_0 large.

For LTI systems, we can always choose $l = n$. For LTV systems, this is not true.

Definition 4.4. *The pair $(\boldsymbol{C}, \boldsymbol{A})$ is called uniformly observable if there exists a positive integer l for which the system is uniformly l-step observable.*

Remark. It is important that l be finite. For example if $A_k = 1 \ \forall \ k$ and

$$C_k = \begin{cases} -1/k & \text{for } k < 0, \\ 1 & \text{for } k \geq 0, \end{cases}$$

it is easy to check that the pair $(\boldsymbol{C}, \boldsymbol{A})$ is not uniformly l-step observable for any finite l, but it is for $l = \infty$.

Since the system is linear, it is easy to check that the definition of uniform l-step observability is dependent only on the difference between the initial states; thus we can assume without loss of generality that $\bar{x}_{k_0} = 0$ and $\bar{y}_k = 0 \ \forall \ k$.

The l-step observability Gramian operator is the block-diagonal operator

$$\boldsymbol{M}_l := \sum_{j=0}^{l-1} (\mathcal{A}^*)^j \boldsymbol{C}^* \boldsymbol{C} \mathcal{A}^j. \tag{4.1}$$

Using this operator we find the following.

Lemma 4.5. *The pair $(\boldsymbol{C}, \boldsymbol{A})$ is uniformly l-step observable if and only if $\boldsymbol{M}_l > \boldsymbol{0}$.*

Proof. Since

$$\sum_{k=k_0}^{k_0+l-1} |y_k|^2 = \sum_{k=k_0}^{k_0+l-1} |C_k A_{k-1} \cdots A_{k_0} x_{k_0}|^2 = x_{k_0}^T (\boldsymbol{M}_l)_{k_0} x_{k_0}$$

for arbitrary k_0 and initial condition x_{k_0}, the result is immediate. □

If the system is time-invariant, all the block diagonal elements of $\boldsymbol{M}_l$ are the same. These elements have the form

$$(\boldsymbol{M}_l)_k = \sum_{r=k}^{k+l-1} (A^{r-k})^T C^T C A^{r-k} = \sum_{p=0}^{l-1} (A^p)^T C^T C A^p.$$

For an LTI system it is well known that this matrix is positive definite for a finite l if and only if the system is observable. Hence, we have the following corollary.

COROLLARY 4.6. *For an LTI system, the pair* $(\boldsymbol{C}, \boldsymbol{A})$ *is uniformly observable if and only if the pair* (C, A) *is observable.*

Hence, the LTI results can be recovered directly from results we find for time-varying systems.

Now, we are interested in testing whether a given pair $(\boldsymbol{C}, \boldsymbol{A})$ is uniformly observable, in terms of a PBH test analogous to Lemma 4.1 for LTI systems. This can be done by considering the set of almost eigenvalues corresponding to the weighted shift operator $\mathcal{A}$.

LEMMA 4.7. *If the pair* $(\boldsymbol{C}, \boldsymbol{A})$ *is uniformly observable, then there exists no almost eigenvalue of* $\mathcal{A}$ *for which the corresponding almost eigenvector* $\boldsymbol{x}_n$ *satisfies* $\|\boldsymbol{C}\boldsymbol{x}_n\|_2 \to 0$ *as* $n \to 0$.

Proof. If the pair $(\boldsymbol{C}, \boldsymbol{A})$ is uniformly observable, there exists $l \in \mathbb{N}$ for which $\boldsymbol{M}_l > \boldsymbol{0}$. Now, suppose that λ is an almost eigenvalue of $\mathcal{A}$ with corresponding almost eigenvector $\boldsymbol{x}_n$. Hence, $\|\boldsymbol{x}_n\|_2 = 1$, and we can assume without loss of generality that $\boldsymbol{x}_n$ is such that

$$\mathcal{A}\boldsymbol{x}_n = \lambda \boldsymbol{x}_n + \boldsymbol{q}_n \quad \text{where } \|\boldsymbol{q}_n\|_2 \le 1/n.$$

Also assume that $\|\boldsymbol{C}\boldsymbol{x}_n\|_2 \to 0$ as $n \to 0$, in particular, that $\|\boldsymbol{C}\boldsymbol{x}_n\|_2 \le 1/n$. For $j \ge 1$ we find that

$$\begin{aligned}\|\boldsymbol{C}\mathcal{A}^j\boldsymbol{x}_n\|_2 &= \|\boldsymbol{C}\mathcal{A}^{j-1}(\lambda\boldsymbol{x}_n + \boldsymbol{q}_n)\|_2 \\ &\le |\lambda|\,\|\boldsymbol{C}\mathcal{A}^{j-1}\boldsymbol{x}_n\|_2 + \|\boldsymbol{C}(\boldsymbol{Z}^*\boldsymbol{A})^{j-1}\|\,\|\boldsymbol{q}_n\|_2 \\ &\le |\lambda|\,\|\boldsymbol{C}\mathcal{A}^{j-1}\boldsymbol{x}_n\|_2 + \|\boldsymbol{C}\|\,\|\boldsymbol{Z}^*\boldsymbol{A}\|^{j-1}\,\frac{1}{n}.\end{aligned}$$

By recursion, it follows that $\forall\ j \ge 1$

$$\|\boldsymbol{C}\mathcal{A}^j\boldsymbol{x}_n\|_2 \le \frac{|\lambda|^j}{n} + \frac{\|\boldsymbol{C}\|}{n}\sum_{r=0}^{j-1}\|\mathcal{A}\|^{j-r-1}|\lambda|^r.$$

Now, by defining $\gamma := \max\{1, \|\mathcal{A}\|^{l-1}\}$, we see that for $1 \le j \le l-1$ this is bounded above by

$$\left\|\boldsymbol{C}\mathcal{A}^j\boldsymbol{x}_n\right\|_2 \le \frac{|\lambda|^j}{n} + \frac{\gamma\,\|\boldsymbol{C}\|}{n}\sum_{r=0}^{j-1}|\lambda|^r.$$

This yields

$$\begin{aligned}\langle \boldsymbol{x}_n, \boldsymbol{M}_l\boldsymbol{x}_n\rangle &= \sum_{j=0}^{l-1}\|\boldsymbol{C}\mathcal{A}^j\boldsymbol{x}_n\|_2 \\ &\le \frac{1}{n}\sum_{j=0}^{l-1}|\lambda|^j + \frac{\gamma\,\|\boldsymbol{C}\|}{n}\sum_{j=1}^{l-1}\sum_{r=0}^{j-1}|\lambda|^r \\ &= \frac{1}{n}\frac{1-|\lambda|^l}{1-|\lambda|} + \frac{\gamma\,\|\boldsymbol{C}\|}{n}\frac{1-2|\lambda|+|\lambda|^l}{(1-|\lambda|)^2}\end{aligned}$$

whenever $|\lambda| \ne 1$. For $|\lambda| = 1$ it is easy to compute

$$\langle \boldsymbol{x}_n, \boldsymbol{M}_l\boldsymbol{x}_n\rangle = \sum_{j=0}^{l-1}\|\boldsymbol{C}\mathcal{A}^j\boldsymbol{x}_n\|_2 \le \frac{l}{n} + \frac{\|\boldsymbol{C}\|\,\gamma}{n}\frac{l(l+1)}{2}.$$

It follows that

$$\langle \boldsymbol{x}_n, \boldsymbol{M}_l \boldsymbol{x}_n \rangle \to 0 \quad (n \to \infty)$$

and since $\boldsymbol{M}_l > \boldsymbol{0}$ we see that $\|\boldsymbol{x}_n\|_2 \to 0$, which contradicts the assumption that $\boldsymbol{x}_n$ is an almost eigenvector. □

The next result shows that the converse is also true.

LEMMA 4.8. *If there are no almost eigenvalues of $\mathcal{A}$ for which the corresponding almost eigenvector $\boldsymbol{x}_n$ satisfies $\|\boldsymbol{C}\boldsymbol{x}_n\|_2 \to 0$ as $n \to \infty$, then the pair $(\boldsymbol{C}, \boldsymbol{A})$ is uniformly observable.*

Proof. Suppose that $\mathcal{A}$ has no almost eigenvalues for which the corresponding eigenvector satisfies $\|\boldsymbol{C}\boldsymbol{x}_n\|_2 \to 0$ as $n \to \infty$. Then

$$(\exists \gamma > 0)(\forall \lambda \in \mathbb{C})(\forall \|\boldsymbol{x}\|_2 = 1) \qquad \|\mathcal{A}\boldsymbol{x} - \lambda \boldsymbol{x}\|_2^2 + \|\boldsymbol{C}\boldsymbol{x}\|_2^2 \geq \gamma.$$

This implies that the same statement is also true for all $\boldsymbol{x}$ with $\|\boldsymbol{x}\|_2 \geq 1$. Therefore

$$\|\mathcal{A}\boldsymbol{x} - \lambda \boldsymbol{x}\|_2^2 + \|\boldsymbol{C}\boldsymbol{x}\|_2^2 < \gamma \Longrightarrow \|\boldsymbol{x}\|_2 < 1.$$

Define $\delta := \gamma/2 > 0$. Then for every λ

$$\left.\begin{array}{rcl} \|\mathcal{A}\boldsymbol{x} - \lambda \boldsymbol{x}\|_2^2 & < & \delta \\ \|\boldsymbol{C}\boldsymbol{x}\|_2^2 & < & \delta \end{array}\right\} \Rightarrow \|\boldsymbol{x}\|_2^2 < 1. \tag{4.2}$$

Now, assume that the pair $(\boldsymbol{C}, \boldsymbol{A})$ is not uniformly observable. Then

$$(\forall l \in \mathbb{N})(\forall \epsilon > 0)(\exists k_0, |x_{k_0}| = 1) \qquad \sum_{k=k_0}^{k_0+l-1} |y_k|^2 < \epsilon. \tag{4.3}$$

For $l \in \mathbb{N}$, define $\epsilon_l := \delta l^{-2(l-1)}$. According to (4.3) we find a sequence $k_0(l)$ and $|x_{k_0(l)}| = 1$. Similar to the proof of Lemma 3.3, we define the sequence

$$r_l := \min \left\{ |A_{k_0(l)+l-1} \cdots A_{k_0(l)} x_{k_0(l)}|^{-1/l}, l \right\},$$

where $r_l := l$ if the inverse is not well defined. With this notation we define the sequence

$$(\boldsymbol{x}_l)_k := \left\{ \begin{array}{cl} x_{k_0(l)} & \text{for } k = k_0(l), \\ r_l^{k-k_0(l)} A_{k-1} \cdots A_{k_0(l)} x_{k_0(l)} & \text{for } k = k_0(l)+1, \cdots, k_0(l)+l-1, \\ 0 & \text{elsewhere} \end{array} \right.$$

and $\bar{\boldsymbol{x}}_l := \boldsymbol{x}_l / \|\boldsymbol{x}_l\|_2$. For the sequence $\bar{\boldsymbol{x}}_l$ we will compute the norms in (4.2). Obviously $r_l > 0 \ \forall \ l \in \mathbb{N}$, and it is easy to get

$$\begin{aligned} \left\| \mathcal{A}\bar{\boldsymbol{x}}_l - \frac{1}{r_l}\bar{\boldsymbol{x}}_l \right\|_2^2 &= \frac{1}{r_l^2} \frac{|x_{k_0(l)}|^2}{\|\boldsymbol{x}_l\|_2^2} + \frac{r_l^{2(l-1)}}{\|\boldsymbol{x}_l\|_2^2} |A_{k_0(l)+l-1} \cdots A_{k_0(l)} x_{k_0(l)}|^2 \\ &= \frac{1}{r_l^2 \|\boldsymbol{x}_l\|_2^2} \left(1 + r_l^{2l} |A_{k_0(l)+l-1} \cdots A_{k_0(l)} x_{k_0(l)}|^2\right), \\ &\leq \frac{2}{r_l^2 \|\boldsymbol{x}_l\|_2^2}, \end{aligned} \tag{4.4}$$

where the inequality follows by definition of r_l.

We consider two distinct possibilities. Suppose that there exists an $l^2 > 2/\delta$ for which $r_l = l$. It follows that the bound in (4.4) yields

$$\left\| \mathcal{A}\bar{\boldsymbol{x}}_l - \frac{1}{r_l}\bar{\boldsymbol{x}}_l \right\|_2^2 < \delta$$

since $\|\boldsymbol{x}_l\|_2^2 \geq |x_{k_0(l)}|^2 = 1$.

Now, suppose that no such l exists equivalently, that

$$r_l = |A_{k_0(l)+l-1} \cdots A_{k_0(l)} x_{k_0(l)}|^{-1/l} < l$$

$\forall$ l large enough. As in the proof of Lemma 3.3 we get that $r_l > 1/\alpha$, where $\|A_k\| < \alpha \; \forall \; k$. Hence, in (4.4) we have

$$\left\| \mathcal{A}\bar{\boldsymbol{x}}_l - \frac{1}{r_l}\bar{\boldsymbol{x}}_l \right\|_2^2 < \frac{2\alpha^2}{\|\boldsymbol{x}_l\|_2^2}.$$

However, with this solution for r_l, it follows by construction of the sequence $\boldsymbol{x}_l$ and the boundedness of $\boldsymbol{A}$ that $\|\boldsymbol{x}_l\|_2 \to \infty$ as $l \to \infty$ (see the proof of Lemma 3.3). Thus there exists an l such that $\|\boldsymbol{x}_l\|_2^2 > 2\alpha^2/\delta$, ensuring that (4.4) is bounded above by δ. Furthermore,

$$\begin{aligned} \|\boldsymbol{C}\bar{\boldsymbol{x}}_l\|_2^2 &= \sum_{k=k_0(l)}^{k_0(l)+l-1} \frac{r_l^{2(k-k_0(l))}}{\|\boldsymbol{x}_l\|_2^2} |y_k|^2 \\ &\leq \frac{\max\{1, r_l^{2(l-1)}\}}{\|\boldsymbol{x}_l\|_2^2} \sum_{k=k_0(l)}^{k_0(l)+l-1} |y_k|^2. \end{aligned}$$

Since $|x_{k_0(l)}| = 1$, we have that $\|\boldsymbol{x}_l\|_2^2 \geq 1$, and using the construction of ϵ_l we get

$$\begin{aligned} \|\boldsymbol{C}\bar{\boldsymbol{x}}_l\|_2^2 &< \max\left\{1, r_l^{2(l-1)}\right\} \epsilon_l \\ &= \max\left\{1, r_l^{2(l-1)}\right\} \delta l^{-2(l-1)} \\ &\leq \delta, \end{aligned}$$

where the last step follows since $r_l \leq l$. Thus we have found $l \in \mathbb{N}$ such that $\|\mathcal{A}\bar{\boldsymbol{x}}_l - \frac{1}{r_l}\bar{\boldsymbol{x}}_l\|_2^2 < \delta$ and $\|\boldsymbol{C}\bar{\boldsymbol{x}}_l\|_2^2 < \delta$. On the other hand, however, we know that $\|\bar{\boldsymbol{x}}_l\|_2^2 = 1$, contradicting (4.2). □

Remark. We see that, by letting δ tend to zero, the construction in the proof of Lemma 4.8 leads to an almost eigenvalue of $\mathcal{A}$ which is real and nonnegative; namely $\lambda = 1/r$, where $r_l \to r$ for a subsequence of l for which this limit exists. (Note that if $r_l = l$ for l large enough, this corresponds to an almost eigenvalue $\lambda = 0$.) We have seen this in Lemma 3.4, where we showed that we have to consider only real nonnegative almost eigenvalues of $\mathcal{A}$ for checking uniform exponential stability of $\boldsymbol{A}$. Following the construction of real almost eigenvectors in the proof of Lemma 3.4, we see that $\|\mathrm{Re}(\tilde{\boldsymbol{x}}_n)\|_2^2 + \|\mathrm{Im}(\tilde{\boldsymbol{x}}_n)\|_2^2 = 1$. Hence, one of these two has a squared norm larger than or equal to 1/2. By choosing this one, it is immediate that the resulting $\boldsymbol{z}_n$ satisfies

$$\|\boldsymbol{C}\boldsymbol{z}_n\|_2^2 \leq 2\|\boldsymbol{C}\boldsymbol{x}_n\|_2^2.$$

This shows that, in the PBH test stated in the previous lemmas, it is sufficient to consider real nonnegative almost eigenvalues only.

Summarizing, we have the following theorem.

THEOREM 4.9. *The following statements are equivalent:*

(i) *The pair $(\boldsymbol{C}, \boldsymbol{A})$ is uniformly observable.*

(ii) *There exists $l \in \mathbb{N}$ such that $\boldsymbol{M}_l > \boldsymbol{0}$.*

(iii) *There exists no almost eigenvalue of $\mathcal{A}$ for which the corresponding almost eigenvector $\boldsymbol{x}_n$ satisfies $\|\boldsymbol{C}\boldsymbol{x}_n\|_2 \to 0$ as $n \to \infty$.*

It can be shown that if the pair $(\boldsymbol{C}, \boldsymbol{A})$ is uniformly observable, there exists a bounded memoryless operator $\boldsymbol{H}$ such that $\boldsymbol{A} + \boldsymbol{H}\boldsymbol{C}$ is UES.

LEMMA 4.10 (see [6]). *If the pair $(\boldsymbol{C}, \boldsymbol{A})$ is uniformly observable, then the operator*

$$\boldsymbol{H} := -\boldsymbol{A}\mathcal{A}^l \boldsymbol{M}_{l+1}^{-1} (\mathcal{A}^*)^l \boldsymbol{C}^*,$$

where l is such that (ii) *in Theorem* 4.9 *is satisfied, guarantees that $\boldsymbol{A}_H := \boldsymbol{A} + \boldsymbol{H}\boldsymbol{C}$ is UES.*

Next we will discuss the concept of uniform detectability, which is less restrictive than uniform observability.

5. Uniform detectability. For uniform detectability, the requirement that different inputs result in significantly different outputs will be restricted to those initial states for which the state itself does not decay fast enough. Formally, this yields the definition as introduced in [1, 3].

DEFINITION 5.1. *The pair $(\boldsymbol{C}, \boldsymbol{A})$ is called uniformly detectable if there exist $l, p \in \mathbb{N}$ and constants $\gamma \in [0, 1)$ and $\epsilon > 0$ such that, whenever*

$$|x_{k_0+p}| \geq \gamma |x_{k_0}|$$

for some k_0 and x_{k_0}, then

$$\sum_{k=k_0}^{k_0+l-1} |y_k|^2 \geq \epsilon |x_{k_0}|^2.$$

The idea is that, when a zero-input trajectory starting at x_{k_0} fails to converge much toward the origin, then x_{k_0} should be observable to a minimum level.

In terms of the observability Gramian (4.1), this definition can be rewritten as

$$x_{k_0}^T \left((\mathcal{A}^*)^p \mathcal{A}^p \right)_{k_0} x_{k_0} \geq \gamma |x_{k_0}|^2 \quad \Longrightarrow \quad x_{k_0}^T (\boldsymbol{M}_l)_{k_0} x_{k_0} \geq \epsilon |x_{k_0}|^2.$$

If the pair $(\boldsymbol{C}, \boldsymbol{A})$ is uniformly observable, then $\boldsymbol{M}_l > \boldsymbol{0}$ for some $l \in \mathbb{N}$ (see Lemma 4.5). Hence, we immediately have the following lemma.

LEMMA 5.2. *If the pair $(\boldsymbol{C}, \boldsymbol{A})$ is uniformly observable, then the pair $(\boldsymbol{C}, \boldsymbol{A})$ is also uniformly detectable.*

The concept of uniform detectability has been well investigated [1, 3]. A result that will prove to be useful is the following.

LEMMA 5.3 (see [1]). *The pair $(\boldsymbol{C}, \boldsymbol{A})$ is uniformly detectable if and only if there exists an operator $\boldsymbol{H} \in \mathcal{M}$ for which $\boldsymbol{A} + \boldsymbol{H}\boldsymbol{C}$ is UES.*

Remark. In case the pair $(\boldsymbol{C}, \boldsymbol{A})$ is uniformly observable, it is possible to define an operator $\boldsymbol{H}$ guaranteeing that $\boldsymbol{A} + \boldsymbol{H}\boldsymbol{C}$ is UES in terms of the observability Gramian (see Lemma 4.10). In the case of uniform detectability, however, a Riccati operator equation has to be solved to find a stabilizing feedback (see [3]), which is much less appealing of course.

For LTI systems, the matrix pair (C, A) is defined to be detectable if there exists a matrix H such that $A + HC$ is stable. Hence, the following is an immediate result from Lemma 5.3.

COROLLARY 5.4. *For an LTI system the pair* (C, A) *is detectable if and only if the corresponding pair* $(\boldsymbol{C}, \boldsymbol{A})$ *is uniformly detectable.*

Now, we are interested in testing uniform detectability of a system in terms of the almost eigenvalues of the block-weighted shift $\mathcal{A}$. For LTI systems the PBH test is given by the following result.

LEMMA 5.5. *An LTI system is detectable if and only if* $\forall\, |\lambda| \geq 1$

$$\left.\begin{array}{ll} Ax & = \lambda x \\ Cx & = 0 \end{array}\right\} \Longrightarrow x = 0.$$

That is, A has no unobservable eigenvalues with magnitude greater than or equal to 1.

For time-varying systems we find similar results.

LEMMA 5.6. *If the pair* $(\boldsymbol{C}, \boldsymbol{A})$ *is uniformly detectable, then* $\mathcal{A}$ *has no almost eigenvalues with magnitude greater than or equal to* 1, *for which the corresponding eigenvector* $\boldsymbol{x}_n$ *satisfies* $\|\boldsymbol{C}\boldsymbol{x}_n\|_2 \to 0$ *as* $n \to \infty$.

Proof. Suppose that the pair $(\boldsymbol{C}, \boldsymbol{A})$ is uniformly detectable. According to Lemma 5.3 there exists an operator $\boldsymbol{H}$ such that $\boldsymbol{A}_H := \boldsymbol{A} + \boldsymbol{H}\boldsymbol{C}$ is UES. Now, let λ be any almost eigenvalue of $\mathcal{A}$, with corresponding eigenvector $\boldsymbol{x}_n$ with $\|\boldsymbol{x}_n\|_2 = 1$. Suppose that $\|\boldsymbol{C}\boldsymbol{x}_n\|_2 \to 0$ as $n \to \infty$. Then

$$\begin{aligned} \|\mathcal{A}_H \boldsymbol{x}_n - \lambda \boldsymbol{x}_n\|_2 &= \|\mathcal{A}\boldsymbol{x}_n - \lambda \boldsymbol{x}_n + \boldsymbol{Z}^* \boldsymbol{H}\boldsymbol{C}\boldsymbol{x}_n\|_2 \\ &\leq \|\mathcal{A}\boldsymbol{x}_n - \lambda \boldsymbol{x}_n\|_2 + \|\boldsymbol{Z}^* \boldsymbol{H}\boldsymbol{C}\boldsymbol{x}_n\|_2 \\ &\leq \|\mathcal{A}\boldsymbol{x}_n - \lambda \boldsymbol{x}_n\|_2 + \|\boldsymbol{H}\|\|\boldsymbol{C}\boldsymbol{x}_n\|_2, \end{aligned}$$

since $\|\boldsymbol{Z}^*\| = 1$. We know that λ is an almost eigenvector of $\mathcal{A}$, $\boldsymbol{H}$ is bounded and $\|\boldsymbol{C}\boldsymbol{x}_n\|_2 \to 0$ as $n \to \infty$; hence, it follows that this expression goes to zero as n goes to infinity. Thus λ is an almost eigenvalue of $\mathcal{A}_H$, and since $\boldsymbol{A}_H$ is UES, it follows from Lemma 3.2 that λ has magnitude less than 1. □

LEMMA 5.7. *If* $\mathcal{A}$ *has no almost eigenvalues with magnitude greater than or equal to* 1 *for which the corresponding eigenvector* $\boldsymbol{x}_n$ *satisfies* $\|\boldsymbol{C}\boldsymbol{x}_n\|_2 \to 0$ *as* $n \to \infty$, *then the pair* $(\boldsymbol{C}, \boldsymbol{A})$ *is uniformly detectable.*

Proof. The proof is a combination of the proofs of Lemmas 3.3 and 4.8. Suppose that $\mathcal{A}$ has no almost eigenvalues with magnitude larger than or equal to 1 for which the corresponding eigenvector satisfies $\|\boldsymbol{C}\boldsymbol{x}_n\|_2 \to 0$ as $n \to \infty$. Then, as in Lemma 4.8, there exists $\delta > 0$ such that for every $|\lambda| \geq 1$

$$\left.\begin{array}{rcl} \|\mathcal{A}\boldsymbol{x} - \lambda \boldsymbol{x}\|_2^2 & < & \delta \\ \|\boldsymbol{C}\boldsymbol{x}\|_2^2 & < & \delta \end{array}\right\} \Longrightarrow \|\boldsymbol{x}\|_2^2 < 1. \tag{5.1}$$

Now, assume that the pair $(\boldsymbol{C}, \boldsymbol{A})$ is not uniformly detectable. Then

(5.2)

$$(\forall l, p \in \mathbb{N})(\forall \gamma \in [0, 1))(\forall \epsilon > 0)(\exists k_0, |x_{k_0}| = 1) \qquad |x_{k_0+p}| \geq \gamma \quad \text{and} \quad \sum_{k=k_0}^{k_0+l-1} |y_k|^2 < \epsilon.$$

For $l \in \mathbb{N}$, define $\epsilon_l := \delta(1-1/l)^{2(l-1)}$ and $\gamma_l := (1-1/l)^l$ and take $p = l$. According to (5.2) we find a sequence $k_0(l)$ and $|x_{k_0(l)}| = 1$. Again we define the sequence

$$r_l := |A_{k_0(l)+l-1} \cdots A_{k_0(l)} x_{k_0(l)}|^{-1/l},$$

which is well defined with $r_l < 1/(1-1/l)$. With this notation we define the sequence

$$(\boldsymbol{x}_l)_k := \begin{cases} x_{k_0(l)} & \text{for } k = k_0(l), \\ r_l^{k-k_0(l)} A_{k-1} \cdots A_{k_0(l)} x_{k_0(l)} & \text{for } k = k_0(l)+1, \ldots, k_0(l)+l-1, \\ 0 & \text{elsewhere} \end{cases}$$

and $\bar{\boldsymbol{x}}_l := \boldsymbol{x}_l / \|\boldsymbol{x}_l\|_2$. For the sequence $\bar{\boldsymbol{x}}_l$ we will compute the norms in (5.1). As in the proof of Lemma 3.3 we can compute

$$\left\| \mathcal{A}\bar{\boldsymbol{x}}_l - \frac{1}{r_l}\bar{\boldsymbol{x}}_l \right\|_2^2 = \frac{2}{r_l^2 \|\boldsymbol{x}_l\|_2^2} < \frac{2\alpha^2}{\|\boldsymbol{x}_l\|_2^2}, \tag{5.3}$$

where the inequality follows by definition of r_l, where $\|A_k\| < \alpha \ \forall\ k$.

Using construction of the sequence $\boldsymbol{x}_l$ and the boundedness of $\boldsymbol{A}$ it can be shown that $\|\boldsymbol{x}_l\|_2 \to \infty$ as $l \to \infty$ (see the proof of Lemma 3.3). Thus there exists an $L \in \mathbb{N}$ such that $\forall\ l > L$ the right-hand side of (5.3) is bounded above by δ. Furthermore, as in the proof of Lemma 4.8, we can show that

$$\|\boldsymbol{C}\bar{\boldsymbol{x}}_l\|_2^2 \le \frac{\max\{1, r_l^{2(l-1)}\}}{\|\boldsymbol{x}_l\|_2^2} \sum_{k=k_0(l)}^{k_0(l)+l-1} |y_k|^2.$$

Since $|x_{k_0(l)}| = 1$, we have that $\|\boldsymbol{x}_l\|_2^2 \ge 1$, and using the construction of ϵ_l, we get

$$\begin{aligned} \|\boldsymbol{C}\bar{\boldsymbol{x}}_l\|_2^2 &< \max\left\{1, r_l^{2(l-1)}\right\} \epsilon_l \\ &= \max\left\{1, r_l^{2(l-1)}\right\} \delta(1-1/l)^{2(l-1)} \\ &\le \delta, \end{aligned}$$

where the last step follows since $r_l < (1-1/l)^{-1}$. Thus we have found $L \in \mathbb{N}$ such that $\forall\ l > L$ we have that $\|\mathcal{A}\bar{\boldsymbol{x}}_l - \frac{1}{r_l}\bar{\boldsymbol{x}}_l\|_2^2 < \delta$ and $\|\boldsymbol{C}\bar{\boldsymbol{x}}_l\|_2^2 < \delta$. Since r_l is bounded, we can take a subsequence of $l \in \mathbb{N}$ for which r_l converges, say $r_l \to r$ as $l \to \infty$. Since $1/r_l < 1 - 1/l$, we have $1/r \ge 1$. Hence we have

$$\begin{aligned} \|\mathcal{A}\boldsymbol{x}_l - \tfrac{1}{r}\boldsymbol{x}_l\|_2^2 &< \delta, \\ \|\boldsymbol{C}\boldsymbol{x}_l\|_2^2 &< \delta \end{aligned}$$

for l large enough. But on the other hand we know that $\|\bar{\boldsymbol{x}}_l\|_2^2 = 1$, contradicting (5.1). □

Notice that again it suffices to only consider real nonnegative almost eigenvalues. Summarizing, we have the following theorem.

THEOREM 5.8. *The following statements are equivalent*:

(i) *The pair* $(\boldsymbol{C}, \boldsymbol{A})$ *is uniformly detectable.*

(ii) *There exists an operator* $\boldsymbol{H} \in \mathcal{M}$ *for which* $\boldsymbol{A} + \boldsymbol{HC}$ *is UES.*

(iii) *There exists no almost eigenvalue of* $\mathcal{A}$ *with magnitude greater than or equal to* 1 *for which the corresponding almost eigenvector* $\boldsymbol{x}_n$ *satisfies* $\|\boldsymbol{C}\boldsymbol{x}_n\|_2 \to 0$ *as* $n \to \infty$.

In the next section we will shortly outline the results for the dual properties of uniform observability (resp., uniform detectability), namely uniform reachability (resp., uniform stabilizability).

6. Uniform reachability and uniform stabilizability. In this section, we consider systems of the form

$$x_{k+1} = A_k x_k + B_k u_k.$$

For the concept of uniform reachability we use the definition in [9].

DEFINITION 6.1. *The pair $(\boldsymbol{A}, \boldsymbol{B})$ is called uniformly reachable if there exists $l \in \mathbb{N}$ such that for every k_0, ξ, there exists a uniformly bounded (with respect to $|\xi|$) input $u_{k_0}, \dots, u_{k_0+l-1}$ such that $x_{k_0+l} = \xi$ where we start at $x_{k_0} = 0$.*

Since $x_{k_0} = 0$, we have

$$x_{k_0+l} = \sum_{j=k_0}^{k_0+l-1} A_{k_0+l-1} \cdots A_{j+1} B_j u_j.$$

It is easy to see that the matrix

$$R(k_0, l) := \left[\begin{array}{cccc} B_{k_0+l-1} & A_{k_0+l-1} B_{k_0+l-2} & \cdots & A_{k_0+l-1} \cdots A_{k_0+1} B_{k_0} \end{array} \right]$$

has to be right-invertible, and this right-inverse has to be uniformly bounded in k_0.

Define the l-step reachability Gramian operator as the block-diagonal operator

$$\boldsymbol{W}_l := \sum_{j=0}^{l-1} \mathcal{A}^j \mathcal{B} \mathcal{B}^* (\mathcal{A}^*)^j.$$

Since

$$R(k_0, l) R(k_0, l)^T = (\boldsymbol{W}_l)_{k_0+l}$$

we have the following.

COROLLARY 6.2. *The pair $(\boldsymbol{A}, \boldsymbol{B})$ is uniformly (l-step) reachable if and only if $\boldsymbol{W}_l > \boldsymbol{0}$.*

Define the time-reverse operator Ω as [4]

$$(\Omega \boldsymbol{x})_k = x_{-k}.$$

It is straightforward to check that $(\Omega \boldsymbol{T} \Omega)_{i,j} = T^T_{-j,-i}$ for any operator $\boldsymbol{T}$. It is also easy to see that $\Omega = \Omega^*$, $\Omega^2 = \boldsymbol{I}$ and that the shift operator satisfies $\Omega \boldsymbol{Z} = \boldsymbol{Z}^* \Omega$. An important property of this time-reverse operator is that $\boldsymbol{A}$ is UES if and only if $\Omega \boldsymbol{A}^* \Omega$ is UES [4, 7]. Since

$$\boldsymbol{W}_l = \boldsymbol{Z}^* \Omega \left(\sum_{j=0}^{l-1} (\Omega \boldsymbol{A} \Omega \boldsymbol{Z})^j (\Omega \boldsymbol{B} \Omega)(\Omega \boldsymbol{B}^* \Omega)(\boldsymbol{Z}^* \Omega \boldsymbol{A}^* \Omega)^j \right) \Omega \boldsymbol{Z},$$

we can compare this with the observability Gramian (4.1). With $\Omega^2 = \boldsymbol{Z}^* \boldsymbol{Z} = \boldsymbol{I}$ it is immediate that the pair $(\boldsymbol{A}, \boldsymbol{B})$ is uniformly reachable if and only if the pair $(\Omega \boldsymbol{B}^* \Omega, \Omega \boldsymbol{A}^* \Omega)$ is uniformly observable. Going through the details we can show the following equivalences.

THEOREM 6.3. *The following statements are equivalent:*

(i) *The pair $(\boldsymbol{A}, \boldsymbol{B})$ is uniformly reachable.*

(ii) *There exists $l \in \mathbb{N}$ such that $\boldsymbol{W}_l > \boldsymbol{0}$.*

(iii) *There exists no almost eigenvalue of* $\boldsymbol{Z}\boldsymbol{A}^*$ *for which the corresponding almost eigenvector* $\boldsymbol{x}_n$ *satisfies* $\|\boldsymbol{B}^*\boldsymbol{x}_n\|_2 \to 0$ *as* $n \to \infty$.

Moreover, if the pair $(\boldsymbol{A}, \boldsymbol{B})$ *is uniformly reachable, then the operator*

$$\boldsymbol{F} := -\mathcal{B}^*(\mathcal{A}^*)^l \boldsymbol{W}_{l+1}^{-1} \mathcal{A}^{l+1},$$

where l *is such that* (ii) *is satisfied, guarantees that* $\boldsymbol{A} + \boldsymbol{B}\boldsymbol{F}$ *is UES.*

For the concept of uniform stabilizability we use the definition in [1, 3].

Definition 6.4. *The pair* $(\boldsymbol{A}, \boldsymbol{B})$ *is called uniformly stabilizable if there exist* $l, p \in \mathbb{N}$ *and constants* $\gamma \in [0, 1)$ *and* $\epsilon > 0$ *such that, whenever*

$$|x_{k_0+p}| \geq \gamma |x_{k_0}|$$

for some k_0 *and* x_{k_0}, *then*

$$x_{k_0}^T (\boldsymbol{W}_l)_{k_0+l} x_{k_0} \geq \epsilon |x_{k_0}|^2.$$

The idea is that, when a zero-input trajectory starting at x_{k_0} fails to converge much toward the origin, there exists a bounded input steering the state toward the origin. Note that this mimics the LTI case, where stabilizability is equivalent to the requirement that any uncontrollable mode be asymptotically stable. Also, it is easily seen that uniform reachability implies uniform stabilizability.

Again, using the time-reverse operator Ω, it can be shown that the pair $(\boldsymbol{A}, \boldsymbol{B})$ is uniformly stabilizable if and only if the pair $(\Omega \boldsymbol{B}^* \Omega, \Omega \boldsymbol{A}^* \Omega)$ is uniformly detectable (see also [1]). Hence we find the following equivalences.

Theorem 6.5. *The following statements are equivalent:*

(i) *The pair* $(\boldsymbol{A}, \boldsymbol{B})$ *is uniformly stabilizable.*

(ii) *There exists an operator* $\boldsymbol{F} \in \mathcal{M}$ *for which* $\boldsymbol{A} + \boldsymbol{B}\boldsymbol{F}$ *is UES.*

(iii) *There exists no almost eigenvalue of* $\boldsymbol{Z}\boldsymbol{A}^*$ *with magnitude greater than or equal to* 1 *for which the corresponding almost eigenvector* $\boldsymbol{x}_n$ *satisfies* $\|\boldsymbol{B}^*\boldsymbol{x}_n\|_2 \to 0$ *as* $n \to \infty$.

7. Conclusions.

The work of [5, 8] was the first to show spectral characterizations of key properties of LTV systems could be formulated, which were the direct analogues of the LTI characterizations, provided that one works with the block-weighted shift $\mathcal{A}$. In this paper we have shown that one need work only with the subset of this spectrum, consisting of the almost eigenvalues of $\mathcal{A}$.

We have also shown that this allows one to consider spectral tests for observability and detectability and their duals, reachability and stabilizability, for linear discrete-time time-varying systems. These tests are the natural generalization of the PBH tests known in the LTI setting.

As was mentioned in the text, computation of the almost eigenvalues/eigenvectors will be difficult in most general cases. Nevertheless, we believe that the real use of the PBH test, even for time-invariant systems, lies not in the numerical determination of controllability/observability, but in its use in theoretical derivations. The characterizations of observability and detectability found in this paper should prove to be similarly useful.

PARAMETRIZED FAMILIES OF EXTREMALS AND SINGULARITIES IN SOLUTIONS TO THE HAMILTON–JACOBI–BELLMAN EQUATION*

MATTHEW KIEFER† AND HEINZ SCHÄTTLER†

Abstract. We analyze the effect which a fold and simple cusp singularity in the flow of a parametrized family of extremal trajectories of an optimal control problem has on the corresponding parametrized cost or value function. A fold singularity in the flow of extremals generates an edge of regression of the value implying the well-known results that trajectories stay strongly locally optimal until the fold-locus is reached, but lose optimality beyond. Thus fold points correspond to conjugate points. A simple cusp point in the parametrized flow of extremals generates a swallowtail in the parametrized value. More specifically, there exists a region in the state space which is covered 3:1 with both locally minimizing and maximizing branches. The changes from the locally minimizing to the maximizing branch occur at the fold-loci and there trajectories lose strong local optimality. However, the branches intersect and generate a cut-locus which limits the optimality of close-by trajectories and eliminates these trajectories from optimality near the cusp point *prior* to the conjugate point. In the language of partial differential equations, a simple cusp point generates a shock in the solutions to the Hamilton–Jacobi–Bellman equation while fold points will not be part of the synthesis of optimal controls near the simple cusp point.

1. Introduction.

We study singularities in solutions to the Hamilton–Jacobi–Bellman equation for the value-function of an optimal control problem for ordinary differential equations. It is well known (see, for instance, [3]) that the necessary conditions for optimality given in the Pontryagin maximum principle [28] also give the characteristic equations for the Hamilton–Jacobi–Bellman equation. Thus, if the flow of extremals (trajectories which satisfy the necessary conditions of the Pontryagin maximum principle) covers an open region R of the state-space diffeomorphically, then a smooth solution to the Hamilton–Jacobi–Bellman equation can be constructed on R by the method of characteristics. In general, however, except for special problems like the linear-quadratic regulator, the value function is typically not smooth. The difficulties in finding solutions to optimal control problems or, equivalently, in finding solutions to the Hamilton–Jacobi–Bellman equation, precisely lie in analyzing the singularities.

There is a large body of literature on singularities of solutions to the Hamilton–Jacobi–Bellman equation. Most of these papers deal with general topological properties of the singular set or try to establish smoothness of solutions. In [17] Fleming proves that the singular set is closed and of Hausdorff dimension at most equal to the dimension of the state space. Dafermos [16] analyzes singular sets for more general hyperbolic conservation laws, but only in dimension one. Cannarsa and Soner [11] analyze the local structure of the singular set for viscosity solutions which satisfy cer-

tain Lipschitz-type conditions. This literature typically addresses the problem from a PDE point of view. Few papers deal with the optimal control problems directly. Cannarsa and Frankowska [11] show that smoothness of the value-function at a point of a trajectory implies smoothness at all later times along the trajectory. Byrnes and Frankowska [9] and Byrnes and Jhemi [10] use convexity properties of the Hamiltonian of the optimal control problem to obtain special structures for the Hamilton–Jacobi–Bellman equation as a Riccati-type PDE and they give conditions for the absence of shocks, i.e., for smooth solutions. In most of these papers, establishing the differentiability of the value-function or of solutions to the Hamilton–Jacobi–Bellman equation is the main interest; it is not to analyze the structure of singularities in more detail.

A different approach to solve optimal control problems is the theory of regular synthesis. Here the value function is only derived indirectly. Instead the optimal control is synthesized as a feedback control. The original paper by Boltyanskii [5] gives conditions which allow to construct the value-function despite singularities and to prove the optimality of the corresponding trajectories. These conditions have been weakened considerably since then by Brunovsky [7] and Sussmann [33] and by Sussmann and Piccoli [27]. General results about the existence of a regular synthesis have been proven by Brunovsky [7]. Detailed results which establish regular syntheses exist in low dimensions. Piccoli [26] analyzed the generic singularities for time-optimal control for two-dimensional systems based on Sussmann's results [34, 35, 36]. In dimension three, Krener and Schättler [22] and Schättler and Jankovic [**?**] construct a regular synthesis for time-optimal control problems under codimension 0 and 1 conditions. In these results the precise structure of the singularities of the value-function is established under generic assumptions. Naturally it is quite difficult if not impossible to obtain precise results under general conditions. Kupka [23] analyzes the least degenerate singularities for extremals in the cotangent bundle, i.e., together with the corresponding multipliers. However, projections into the state space still need to be taken to construct a regular synthesis.

In this paper we describe a framework which aims to analyze and explain singularities in solutions to the Hamilton–Jacobi–Bellman equation through the behavior of the extremal trajectories of the optimal control problem. The starting point for our analysis is *smoothly parametrized families of extremals* (see section 3). In our view this is a natural concept which simply formalizes the notion of integrating extremals of the control problem backward from the terminal manifold without imposing that the flow is a diffeomorphism, i.e., is a field. Yet the relevant identities for the corresponding parametrized cost can be established ("shadow prices") which, when coupled with injectivity of the flow, allow us to prove that the cost is the value function and hence that controls are optimal. While the global existence of these smooth parametrizations depends on the nature of the problem, they generically exist locally around a reference extremal and thus this concept is well suited to study strong local optimality. These parametrizations can typically be obtained in a rather straightforward way near reference extremals which are sufficiently regular finite concatenations of continuous controls (like bang-bang extremals or more general concatenations with singular arcs) by taking the terminal point(s) and/or switching times along the arcs as parameters [24].

Given a smoothly parametrized family of extremals, well-known results from the singularity theory of functions [20] can be applied. In this paper we analyze the effect which the occurrence of the two least degenerate singularities, the so-called fold and simple cusp catastrophes [37, 38], in the flow of extremals have on the structure of the value-function. For the fold singularity these results, or rather their formulations which give the implications on the structure of optimal controls, are classical. Fold points in smooth parametrizations of the extremals generate "edges of regression" [2] in the corresponding value function. It follows that the fold generates the well-known behavior of trajectories which stay strongly locally optimal until the fold-locus is reached but lose optimality beyond. Hence fold singularities correspond to conjugate points. Numerous formulations of related statements exist in the literature ranging from early engineering texts [8] to modern formulations [14]. For instance, Caroff and Frankowska [14] analyze the characteristics of the Hamilton–Jacobi–Bellman equation and formulate necessary conditions for a weak minimum and sufficient conditions for a strong minimum in terms of conjugate points. The closest formulation to ours is the one given by Agrachev and Gamkrelidze in terms of concepts from symplectic geometry. It has been shown [1, Theorem 3.1] that extremals lose optimality as the corresponding extremal lifts (which form Lagrangian manifolds in the cotangent bundle) pass a fold. The details, however, are beyond the scope of this article and we strongly recommend the reader consult the expository article [1]. For the sake of completion, and to set the stage, in this paper we include a brief section on the fold singularity, which states the result in the framework of parametrized families of extremals; we refer the reader to [21] for the proof.

Our focus in this paper is on the effect which a simple cusp singularity in the flow of extremals has on the value function. Indeed, the behavior of optimal trajectories implied by the fold singularity is seldom seen in a regular synthesis of optimal trajectories, i.e., although these trajectories stay locally optimal up to the conjugate point, they are no longer optimal globally prior to the conjugate point. This is explained by the behavior of extremals near a simple cusp point. The simple cusp point generates a region in the state space which is covered 3:1 by both locally minimizing and locally maximizing branches of the corresponding value function. Away from the simple cusp point the changes from the locally minimizing to the maximizing branches occur at the fold-loci and there trajectories lose strong local optimality. However, the two minimizing (maximizing) branches intersect and generate a cut-locus which limits the optimality of the close-by trajectories and indeed eliminates these trajectories from optimality near the cusp point prior to the conjugate point. An analogous behavior of optimal trajectories can already be seen in the classical calculus of variations. For the problem of finding surfaces of revolution of minimum surface area, smooth solutions correspond to the catenaries and cease to be locally optimal at the conjugate point which is the fold point in the parametrization [4, 15]. However, the Goldschmidt solutions (which correspond to broken extremals) are better already for points prior to the conjugate point in the catenaries and the optimal solution is determined by the cut-locus between these two families of trajectories [15, pp. 143–148]. Exactly the same behavior is described in [22] for the three-dimensional time-optimal control problem to an equilibrium point for the generic nonlinear system.

Our result can also be interpreted in terms of the classification of Lagrangian singularities. If the parametrized flow of extremals undergoes a simple cusp singularity, then the corresponding value exhibits a swallow-tail singularity [2]; respectively, in the terminology of [20], its graph looks like the singular set of a swallow-tail singularity. This connection, which implies all the statements about the optimal trajectories made above, will be proven by elementary means in this paper. In particular, verifiable conditions for the existence of a simple cusp in the parametrization of the extremals allow us to determine the occurrence of the swallow-tail singularity in the parametrized value. In summary, our main result implies that *the simple cusp catastrophe generates a shock* (a point for which there exist multiple characteristics) *in the solutions to the Hamilton–Jacobi–Bellman equation while fold catastrophes near a simple cusp will not be part of the solution or synthesis of optimal controls near the simple cusp point.*

In section 2 we formulate the optimal control problem and review the conditions of the maximum principle and the Hamilton–Jacobi–Bellman equation. Section 3 contains a formulation of the method of characteristics for the Hamilton–Jacobi–Bellman equation. This material is classical and is based on ideas from field theory [13, 39, 3, 25]. These results are included since we are not aware of a published reference which would treat the subject in the form as we need it in the sense that our presentation emphasizes the parametrization aspect. The proofs which are based on [30] are only indicated. In section 4 we discuss the normal forms for local coordinates for the fold and simple cusp points and the corresponding changes of coordinates. Normal coordinates will then be used in sections 5 and 6 to analyze the local behavior of the parametrized cost when a parametrized family of extremals undergoes a fold or a simple cusp singularity.

2. Problem formulation. Let U be a subset of $\mathbb{R}^m$, the *control set*, and denote by $\mathcal{U}$ the class of all locally bounded Lebesgue measurable maps defined on some interval $I \subset \mathbb{R}$ with values in U, $u : I \to U$, the *space of (admissible) controls.* Suppose

$$f : \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n, \quad (t, x, u) \mapsto f(t, x, u),$$

the dynamics of the control system, is a continuous map which for fixed $t \in \mathbb{R}$ is r-times continuously differentiable in (x, u). Let N be a k-dimensional embedded C^{r+1}-submanifold of (t, x)-space $\mathbb{R} \times \mathbb{R}^n$, the *terminal manifold.* Thus, near every point $q \in N$, there exists an open set $\Omega \subset \mathbb{R} \times \mathbb{R}^n$ containing q and a C^{r+1}-map $\Psi : \Omega \to \mathbb{R}\times\mathbb{R}^n$ with components ψ_i, $i = 0, \dots , n-k$, which have linearly independent gradients $\nabla\psi_i$ and satisfy $N \cap \Omega = \{(t, x) \in \Omega : \psi_i(t, x) = 0, \quad i = 0, \dots , n-k\}$. Also let $\varphi : N \to \mathbb{R}$ be a C^{r+1}-function. We consider the problem to minimize over $\mathcal{U}$ a cost functional given in Bolza form as

$$\mathcal{J}(u; \tau, \xi) = \int_\tau^T L(s, x, u)ds + \varphi(T, x(T)) \tag{2.1}$$

subject to the dynamics $\dot{x} = f(t, x, u)$ with initial condition $x(\tau) = \xi$ and terminal condition $(T, x(T)) \in N$. The terminal time T is free. (A fixed terminal time would be included as a constraint in N.)

The maximum principle gives necessary conditions for a controlled trajectory (x, u) to be optimal. In our notation we distinguish between tangent vectors which we write as column vectors (such as x, $f(t, x, u)$ etc.) and cotangent vectors which we write as row vectors (like the multipliers λ and ν in the statement of the Maximum principle below). We denote the space of n-dimensional row vectors by $(\mathbb{R}^n)^*$. Define the Hamiltonian function H,

$$H : \mathbb{R} \times [0, \infty) \times (\mathbb{R}^n)^* \times \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}$$

as

$$H(t, \lambda_0, \lambda, x, u) = \lambda_0 L(t, x, u) + \lambda f(t, x, u) \tag{2.2}$$

Theorem 2.1 (Pontryagin maximum principle [28]). *Suppose the controlled trajectory (x,u) defined over the interval $[\tau,T]$ is optimal. Then there exist a constant $\lambda_0 \geq 0$, a covector $\nu \in (\mathbb{R}^{n+1-k})^*$, and an absolutely continuous function $\lambda : [\tau,T] \to (\mathbb{R}^n)^*$, the adjoint variable, such that $(\lambda_0,\lambda(t)) \neq 0$ for all $t \in [\tau,T]$ and the following conditions are satisfied:*

1. *Adjoint equation: almost everywhere in* $[\tau,T]$

$$\dot{\lambda}(t) = -\lambda_0 L_x(t,x(t),u(t)) - \lambda(t) f_x(t,x(t),u(t)), \tag{2.3}$$

2. *Minimum condition: almost everywhere in* $[\tau,T]$

$$H(t,\lambda_0,\lambda(t),x(t),u(t)) = \min_{v\in U} H(t,\lambda_0,\lambda,x,v) \tag{2.4}$$

3. *Transversality condition: the vector $(H+\lambda_0\varphi_t, -\lambda+\lambda_0\varphi_x)$ is orthogonal to the terminal constraint in the endpoint, i.e., at the terminal time T we have that*

$$0 = \lambda_0\varphi_t + \nu D_t\Psi + H, \qquad \lambda = \lambda_0\varphi_x + \nu D_x\Psi. \tag{2.5}$$

We call controlled trajectories (x,u) for which there exist multipliers λ_0, λ, and ν such that the conditions of the maximum principle are satisfied *extremals* and sometimes we refer to the triple (λ,x,u) as an *extremal lift.* Note that the conditions are linear in the multipliers (λ_0,λ,ν) and thus it is possible to normalize this vector. In particular, if $\lambda_0 > 0$, then we can divide by λ_0 and thus assume $\lambda_0 = 1$. These kinds of extremals are called *normal* while extremals with $\lambda_0 = 0$ are called *abnormal.* The existence of optimal abnormal extremals can in general not be ruled out.

Sufficient conditions for optimality center around feedback controls, Hamilton–Jacobi theory, and the related notions of fields of extremals and the value-function. Define the *value-function* V on some open subset R of the state-space, $V : R \to \mathbb{R}$, as

$$V(t,x) = \inf_{u\in\mathcal{U}} \mathcal{J}(u;t,x), \tag{2.6}$$

i.e., as the infimum over all $u \in \mathcal{U}$ of the values of the cost functional $\mathcal{J}(u;t,x)$ if the initial conditions of the dynamics are given by (t,x). It is elementary to see [19] that if the value-function V is differentiable at (t,x), then V satisfies the inequality

$$V_t(t,x) + V_x(t,x)f(t,x,u) + L(t,x,u) \geq 0 \tag{2.7}$$

for all $u \in U$ and equality holds for a (sufficiently regular) optimal control. Conversely, if V is any continuously differentiable function and $u^* = u^*(t,x)$ is an admissible feedback control which, together, satisfy the so-called Hamilton–Jacobi–Bellman equation on an open connected set R containing N, i.e.,

$$V_t(t,x) + \min_{u\in U}\{V_x(t,x)f(t,x,u) + L(t,x,u)\} \equiv 0. \tag{2.8}$$

$$V(t,x) = \varphi(t,x) \quad \text{for } (t,x) \in N, \tag{2.9}$$

then it is well known (and completely elementary under these differentiability conditions) that the feedback control u^* is optimal on R (i.e., with respect to any other controlled trajectory which entirely lies in R) and that V is the corresponding value-function. In particular, each of the extremals in the associated field is a strong local minimum over the set R.

3. The method of characteristics in optimal control. In this section we show how a solution to the Hamilton–Jacobi–Bellman equation can be constructed from a parametrized family of normal extremals which satisfy the maximum principle and cover a set R injectively. The construction below formulates the method of characteristics adapted to the optimal control problem and is a refinement of arguments in [30] which are based on notes by Knobloch. In sections 4 and 5 we use this particular local construction to relate corank 1 singularities in the parametrization to singularities in solutions to the Hamilton–Jacobi–Bellman equation.

Definition 3.1. *A C^r-parametrized family $\mathcal{E}$ of extremals is an 8-tuple $(P; \mathcal{T} = (t_0, t_f); \xi, \nu; x, u, \lambda_0, \lambda)$ consisting of*

- *an open set P in some n-dimensional manifold and a pair $\mathcal{T} = (t_0, t_f)$ of r times continuously differentiable functions $t_0 : P \to \mathbb{R}$ and $t_f : P \to \mathbb{R}$ defined on P which satisfy $t_0(p) < t_f(p)$ for all $p \in P$. They define the domain of the parametrization as $D = \{(t,p) : p \in P,\ t \in I_p = [t_0(p), t_f(p)]\}$. The functions t_0 and t_f define the (compact) intervals of definition for the controlled trajectories with t_f denoting the terminal time.*
- *an r-times continuously differentiable function $\xi : P \to N$ which parametrizes the terminal conditions for the states.*
- *extremal lifts consisting of controlled trajectories $(x,u) : D \to \mathbb{R}^n \times U$, corresponding adjoint vectors $\lambda_0 : P \to [0,\infty)$ and $\lambda : D \to (\mathbb{R}^n)^*$, and a row vector $\nu : P \to (\mathbb{R}^{n+1-k})^*$ which parametrizes the terminal conditions for the costates. Specifically, we assume*
  1. *the multipliers $(\lambda_0(p), \lambda(t,p))$ are nontrivial for all $t \in I_p$,*
  2. *the controls $u = u(\cdot,p)$, $p \in P$, parametrize admissible controls which are continuous in (t,p) and for t fixed depend r-times continuously differentiable on p with the derivatives continuous in (t,p),*
  3. *the trajectories $x = x(t,p)$ solve the terminal value problems for the dynamics*

     $$\dot{x}(t,p) = f(t, x(t,p), u(t,p)), \quad x(t_f(p), p) = \xi(p), \tag{3.1}$$

  4. *the costate $\lambda = \lambda(t,p)$ solves the corresponding adjoint equation*

     $$\dot{\lambda}(t,p) = -\lambda_0(p) L_x(t, x(t,p), u(t,p)) - \lambda(t,p) f_x(t, x(t,p), u(t,p)), \tag{3.2}$$

     with terminal conditions

     $$\lambda(t_f(p), p) = \lambda_0(p)\varphi_x(t_f(p), \xi(p)) + \nu(p) D_x \Psi(t_f(p), \xi(p)), \tag{3.3}$$

  5. *the controls solve the minimization problem*

     $$H(t, \lambda_0(p), \lambda(t,p), x(t,p), u(t,p)) = \min_{v \in U} H(t, \lambda_0(p), \lambda(t,p), x(t,p), v), \tag{3.4}$$

  6. *the transversality condition on the terminal time,*

     $$\begin{aligned} &H(t_f(p), \lambda_0(p), \lambda(t_f(p),p), x(t_f(p),p), u(t_f(p),p)) \\ &\qquad + \lambda_0(p)\varphi_t(t_f(p), \xi(p)) + \nu(p) D_t \Psi(t_f(p), \xi(p)) = 0, \end{aligned} \tag{3.5}$$

     holds.

This notion of a C^r-parametrized family of extremals is a natural concept to formalize an approach which tries to construct a field of extremals by integrating the system and adjoint equations backward from the terminal manifold while maintaining the minimum condition (3.4) without requiring that the flow is a diffeomorphism. No injectivity assumptions are made.

It follows from standard results about differentiable dependence on parameters of solutions to ordinary differential equations that the trajectories $x = x(t,p)$ (and their time-derivatives $\dot{x}(t,p)$) are r-times continuously differentiable in p for fixed t and that these derivatives are continuous jointly in (t,p). We denote this class of functions by $C^{1,r}$. These partial derivatives can be calculated as solutions to the corresponding variational equations which are obtained by interchanging the time-derivative with the p-derivatives. At the moment we do not impose regularity conditions on λ_0 and ν. Consequently $\lambda(t,p)$ need not be differentiable in p. However, if λ_0 and ν are r-times continuously differentiable, then the costate λ has the same smoothness properties as the state x. In this case we call $\mathcal{E}$ a *nicely* C^r-parametrized family of extremals.

Modifications of the definitions for the time-invariant case are straightforward with the one exception that we then want the control to lie in $C^{r-1,r}$. This guarantees that $x(t,p)$ has the desired differentiability properties.

Example. Consider the optimal control problem to minimize

$$J(u) = \frac{1}{2}\int_0^T ||u||_2^2 dt + \varphi(x(T)) \tag{3.6}$$

subject to

$$\dot{x} = f(x) + \sum_{i=1}^{m} g_i(x)u_i, \qquad u_i \in \mathbb{R}, \tag{3.7}$$

where f and the g_i are C^r vector fields on $\mathbb{R}^n$, φ is C^{r+1}, and the terminal time T is fixed. It is easy to see that extremals for this problem are normal and thus, without loss of generality, we may normalize $\lambda_0 \equiv 1$. The Hamiltonian

$$H = \frac{1}{2}\sum_{i=1}^{m} u_i^2 + \lambda\left(f(x) + \sum_{i=1}^{m} g_i(x)u_i\right) \tag{3.8}$$

is strictly convex in u with the unique minimum given by $u_i = -\lambda g_i(x)$. Substituting this relation into the dynamics and adjoint equation gives the following system of $2n$ ordinary differential equations

$$\dot{x} = f(x) - \sum_{i=1}^{m} g_i(x)g_i(x)^T\lambda^T \tag{3.9}$$

$$\dot{\lambda} = -\lambda\left(Df(x) - \sum_{i=1}^{m} Dg_i(x)g_i(x)^T\lambda^T\right). \tag{3.10}$$

If we take as parameter space $P = \mathbb{R}^n$ and integrate these differential equations backward with terminal conditions

$$x(T,p) = p, \qquad \lambda(T,p) = \varphi_x(T,p), \tag{3.11}$$

then the solutions $x = x(t,p)$ and $\lambda = \lambda(t,p)$ exist on a maximal interval $I_p = (t_0(p), T]$ and these solutions are C^r functions of t and p. In particular, the controls

$$u_i(t,p) = -\lambda(t,p)g_i(x(t,p)) \tag{3.12}$$

are also $C^{r,r}$. Thus this generates a nicely C^r parametrized family of extremals.

More generally, if a terminal manifold N is given with free terminal time, then extremals will be parametrized through their endpoints in the terminal manifold N (k-dimensional) and the vector ν in the transversality condition which gives the terminal condition for the multiplier λ ($(n+1-k)$-dimensional). However, we also need to enforce the transversality condition (3.5) on H which pins down the terminal time. Hence the parameter space is n-dimensional.

While the procedure is straightforward, clearly the smoothness conditions required in the parametrizations need not be satisfied in general. But the definition of a C^r-parametrized family of extremals and the shadow price lemma given below generalize to parametrized families of *broken* extremals which have discontinuities on manifolds described by C^r functions $t = t(p)$. For instance, a family of bang-bang trajectories can easily be parametrized using the switching times as parameters. In this paper, however, we consider only parametrized families where the control is continuous (respectively, $C^{r-1,r}$ in the time-invariant case) since we want to study singularities as they arise in smooth parametrizations and study their effect on the parametrized value-function. In our view these parametrizations are no artefact, but arise naturally. Particularly this holds if the parameter set P is restricted to some small neighborhood of some reference value respective to reference trajectory. Then our results have immediate implications on the strong local optimality of the reference trajectory.

On D we define the cost $C : D \to \mathbb{R}$ along a C^r-parametrized family $\mathcal{E}$ of extremals as

$$C(t,p) = \int_t^{t_f(p)} L(s, x(s,p), u(s,p))ds + \varphi(t_f(p), \xi(p)), \tag{3.13}$$

i.e., $C(t,p)$ denotes the cost for the optimal control problem with initial condition $(t,x) = (t, x(t,p))$ corresponding to the control $u = u(t,p)$. It follows from our assumptions and the above smoothness properties that C is continuously differentiable in t with time-derivative

$$\frac{\partial C}{\partial t} = -L(t, x(t,p), u(t,p)) \tag{3.14}$$

and that both C and its time-derivative $\frac{\partial C}{\partial t}$ are r-times continuously differentiable in p.

Notation. For a function like C we denote the gradient with respect to p (which we consider a row vector) by $\frac{\partial C}{\partial p}$. Consequently, for a column vector like $x = (x_1, \ldots, x_n)^T$ we denote by $\frac{\partial x}{\partial p}$ the matrix whose rows are given by the gradients of the components of x, i.e., $\frac{\partial x}{\partial p} = \left(\frac{\partial x_i}{\partial p_j}\right)_{1 \le i,j \le n}$ with row index i and column index j. However, to be consistent, for a row-vector like $\lambda = (\lambda_1, \ldots, \lambda_n)$ we denote the matrix of the partial derivatives $\left(\frac{\partial \lambda j}{\partial p_i}\right)_{1 \le i,j \le n}$ with row index i and column index j by $\frac{\partial \lambda}{\partial p}$. In this sense, we have $\frac{\partial \lambda}{\partial p} = \left(\frac{\partial \lambda^T}{\partial p}\right)^T$. This will allow us to write most formulas without having to use transposes. Finally we denote by $\frac{\partial^2 C}{\partial p^2}$ the Hessian matrix of the second derivatives of a function C.

The following relation is crucial to the whole construction:

LEMMA 3.1 (shadow prices). *Let $\mathcal{E}$ be a C^1-parametrized family of extremals. Then we have that*

$$\lambda_0(p)\frac{\partial C}{\partial p}(t,p) = \lambda(t,p)\frac{\partial x}{\partial p}(t,p). \tag{3.15}$$

Proof (*sketch*). For p fixed both sides of (3.15) are continuously differentiable functions in t. It therefore suffices to show that both sides have the same t-derivative with identical values at the terminal time $t_f(p)$. The latter can be shown by adjoining the terminal condition with multiplier $\nu = \nu(p)$ to C and then using the transversality conditions (2.5) after differentiating in p. Furthermore, using the adjoint equation and the variational equation for $\frac{\partial x}{\partial p}$, it follows that

$$\frac{d}{dt}\left\{\lambda(t,p)\frac{\partial x}{\partial p}(t,p)\right\} = \lambda_0(p)\frac{\partial^2 C}{\partial t \partial p}(t,p) + H_u\frac{\partial u}{\partial p}(t,p),$$

where H_u is evaluated along the parametrized extremal. But

$$H_u(t,\lambda_0(p),\lambda(t,p),x(t,p),u(t,p))\frac{\partial u}{\partial p}(t,p) \equiv 0 \qquad \text{on } D \tag{3.16}$$

follows from the minimization property of the extremal control $u(t,p)$. □

If the parametrization of the extremals covers the state-space diffeomorphically, then the shadow price lemma provides the bridge between the necessary conditions for optimality of the maximum principle and the sufficient conditions of the Hamilton–Jacobi theory. Theorem 3.1 below formalizes this. In its essential contents the statement is classical and can be found in many books on optimal control such as [3, 18]. It is included here since it also gives a means to calculate the singularities in a parametrized flow of extremals.

THEOREM 3.1. *Let $\mathcal{E}$ be a C^r-parametrized family of normal extremals, $r \geq 1$, and suppose the map*

$$\sigma : D \to \mathbb{R}\times\mathbb{R}^n, \qquad (t,p) \mapsto (t,x(t,p)) \tag{3.17}$$

is a C^1-diffeomorphism from some open subset $O \subset \operatorname{int} D$ onto an open subset $R \subset \mathbb{R}\times\mathbb{R}^n$ of the state-space (i.e., the map is bijective and has an everywhere nonvanishing Jacobian). Then the function $V : R \to \mathbb{R}, V = C\circ\sigma^{-1}$, is continuously differentiable in t and r-times continuously differentiable in x on S. The function $u^* : R \to \mathbb{R}, u^* = u\circ\sigma^{-1}$ is an admissible feedback-control which is continuous in t and r-times continuously differentiable in x. Together the pair (V,u^*) solves the Hamilton–Jacobi–Bellman equation

$$V_t(t,x) + \min_{u\in U}\{V_x(t,x)f(t,x,u) + L(t,x,u)\} \equiv 0 \tag{3.18}$$

on R. Furthermore, the following identities hold in the parameter space on O:

$$V_t(t,x(t,p)) = -H(t,\lambda(t,p),x(t,p),u(t,p)) \tag{3.19}$$

$$V_x(t,x(t,p)) = \lambda(t,p). \tag{3.20}$$

If $\mathcal{E}$ is nicely C^r-parametrized, then V is $(r+1)$-times continuously differentiable in x on R and we also have

$$V_{xx}(t,x(t,p)) = \frac{\partial \lambda^T}{\partial p}(t,p)\left(\frac{\partial x}{\partial p}(t,p)\right)^{-1}. \tag{3.21}$$

Proof (*sketch*). By assumption σ is injective with $C^{1,r}$ inverse. Thus V and u^* are well defined and a priori $V \in C^{1,r}$. Since $C = V \circ \sigma$, we have that

$$\frac{\partial C}{\partial p}(t,p) = V_x(t,x(t,p))\frac{\partial x}{\partial p}(t,p),$$

and thus, in view of Lemma 3.1 and the fact that $\frac{\partial x}{\partial p}$ is nonsingular (3.20) follows. Equations (3.18) and (3.19) then follow directly from the conditions of the maximum principle. If $\mathcal{E}$ is nicely C^r parametrized, then λ is C^r in p, and thus we still have $V_x \in C^{1,r}$ since $V_x = \lambda \circ \sigma^{-1}$ on R. In particular, differentiating (3.20) with respect to p and observing that we need to take a transpose in λ to keep the notation consistent, we get (3.21). □

The relation (3.21) can be used to calculate singularities in the map x. Under the assumptions of Theorem 3.1 the function

$$Q(t,p) = V_{xx}(t,x(t,p)) = \frac{\partial \lambda^T}{\partial p}(t,p)\left(\frac{\partial x}{\partial p}(t,p)\right)^{-1} \tag{3.22}$$

satisfies the differential equation

$$\dot{Q} = -Qf_x - f_x^T Q - H_{xx} - (Qf_u + H_{xu})\frac{\partial u}{\partial p}\left(\frac{\partial x}{\partial p}\right)^{-1}, \tag{3.23}$$

where the partial derivatives of f and H are evaluated along the extremal corresponding to the parameter p. This follows by direct differentiation. In particular, if the gradient H_u vanishes identically and the matrix H_{uu} is positive definite along (λ, x, u) on I, then

$$\frac{\partial u}{\partial p} = -H_{uu}^{-1}\left(H_{ux}\frac{\partial x}{\partial p} + f_u^T\frac{\partial \lambda^T}{\partial p}\right), \tag{3.24}$$

and we can eliminate the control-term from (3.23) to get the customary Riccati-equation for the second derivatives V_{xx} [8]:

$$\dot{Q} = -Qf_x - f_x^T Q - H_{xx} + (Qf_u + H_{xu})H_{uu}^{-1}\left(H_{ux} + f_u^T Q\right). \tag{3.25}$$

In this case singularities in $\frac{\partial x}{\partial p}$ therefore relate to the explosion times of the Riccati-equation. It is clear from (3.21) that explosion times in the Riccati-equation can only occur as $\frac{\partial x}{\partial p}$ becomes singular and conversely

COROLLARY 3.1. *Suppose*

$$\frac{\partial x}{\partial p}(t_0,p_0)v_0 = 0 \qquad \text{and} \qquad w_0 = v_0^T\frac{\partial \lambda}{\partial p}(t_0,p_0) \neq 0.$$

Then the solution $Q(\cdot,p_0)$ to the Riccati-equation (3.25) *has a finite explosion time at $t = t_0$.*

Proof. We have $\lim_{t\to t_0} Q(t,p_0)\frac{\partial x}{\partial p}(t,p_0)v_0 = \lim_{t\to t_0} \frac{\partial \lambda^T}{\partial p}(t,p_0)v_0 = \frac{\partial \lambda^T}{\partial p}(t_0,p_0)v_0 = w_0^T \neq 0$. Since also $\lim_{t\to t_0} \frac{\partial x}{\partial p}(t,p_0)v_0 = \frac{\partial x}{\partial p}(t_0,p_0)v_0 = 0$, it follows that $Q(\cdot,p_0)$ has a finite explosion time at t_0. □

In particular, it is well known, and commercial software exists on how to calculate these points numerically. The next corollary, which follows by differentiating (3.15) with respect to p, relates left- and right-eigenvectors at singular points of the flow map. This will be needed to interpret the transversality conditions from singularity theory for the parametrized flow.

COROLLARY 3.2. *Let $\mathcal{E}$ be a C^2-parametrized family of normal extremals. Then the matrix*

$$\Xi(t,p) = \frac{\partial \lambda}{\partial p}(t,p)\frac{\partial x}{\partial p}(t,p) \tag{3.26}$$

is symmetric.

COROLLARY 3.3. *Let $\mathcal{E}$ be a C^2-parametrized family of normal extremals. Suppose*

$$\frac{\partial x}{\partial p}(t_0,p_0)v_0 = 0 \qquad \text{and} \qquad w_0 = v_0^T\frac{\partial \lambda}{\partial p}(t_0,p_0) \neq 0.$$

Then w_0 is a left-eigenvector for eigenvalue 0 to $\frac{\partial x}{\partial p}(t_0,p_0)$,

$$w_0\frac{\partial x}{\partial p}(t_0,p_0) = 0. \tag{3.27}$$

Proof. We have for all $z \in \mathbb{R}^n$ that

$$w_0\frac{\partial x}{\partial p}(t_0,p_0)z = v_0^T\frac{\partial \lambda}{\partial p}(t_0,p_0)\frac{\partial x}{\partial p}(t_0,p_0)z = z^T\frac{\partial \lambda}{\partial p}(t_0,p_0)\frac{\partial x}{\partial p}(t_0,p_0)v_0 = 0$$

and thus $w_0\frac{\partial x}{\partial p}(t_0,p_0) = 0$. □

4. Normal forms for functions near singularities.

In this section we recall the normal forms for folds and cusps for C^r maps $F : \mathbb{R}^n \mapsto \mathbb{R}^n$ and present the required equations for the changes of coordinates. The normal forms are classical and go back to fundamental papers by Whitney [38] and Thom [37]. We include a brief exposition following the presentation in [20]. However, in view of our applications to the optimal control problem, we formulate the results already for the map $\sigma : (t,p) \mapsto (t,x(t,p))$, where t plays the role of a bifurcation parameter. The singular set, S, of σ or equivalently of x, is given as $S = \{(t,p) \in D : \text{rank}\frac{\partial x}{\partial p}(t,p) < n\}$ and the corank 1 singularities, S_1, are where $\frac{\partial x}{\partial p}$ has rank $n-1$. If $(t_0,p_0) \in S_1$, then $\frac{\partial x}{\partial p}(t_0,p_0)$ has a simple eigenvalue zero. We will denote the corresponding left- and right-eigenvectors by w_0 and v_0, respectively. By choosing a sufficiently small open neighborhood D of (p_0,t_0) we may assume that σ has only corank 1 singularities on D. Furthermore, it is a mere consequence of the rank assumption [6, Chap. II.7] that there exist local changes of coordinates in the parameter space $\Phi : D \to D', (t,p) \mapsto (\tau,\xi) = \Phi(t,p) = (t-t_0,\ \xi(t,p))$ and in the state-space $\Psi : R \to R', (t,x) \mapsto (\tau,\eta) = \Psi(t,x) = (t-t_0,\ \eta(t,x))$, such that the map σ has the following form in the new coordinates:

$$k: \quad D' \to R', \qquad (\tau,\xi) = \begin{pmatrix} \tau \\ \xi_1 \\ \vdots \\ \xi_n \end{pmatrix} \mapsto k(\tau,\xi) = \begin{pmatrix} \tau \\ \xi_1 \\ \vdots \\ \xi_{n-1} \\ h(\tau,\xi) \end{pmatrix} \tag{4.1}$$

for some function $h \in C^{1,r}$ (i.e., h is continuously differentiable in τ and r times continuously differentiable in ξ.) Furthermore, $h(0,0) = 0$ and $\frac{\partial h}{\partial \xi_n}(0,0) = 0$. In particular, if the gradient of $\frac{\partial h}{\partial \xi_n}$ does not vanish at (t_0, p_0), then S_1 is an $(n-1)$-dimensional embedded submanifold near (t_0, p_0). The transversality conditions which determine the normal forms at the singular points are best expressed in the coordinates for k and we first give the required formulas for this change of coordinates. However, having the change of coordinates into normal form in mind we already allow more general changes of coordinates Φ and Ψ in which the time variable may be changed according to $\tau = \tau(t,p)$ and $\bar{\tau} = \bar{\tau}(t,x)$. The structure of the map k is retained.

In the new coordinates the singular set is given by

$$S' = \left\{ (\tau,\xi) \in D' : \frac{\partial h}{\partial \xi_n}(\tau,\xi) = 0 \right\} \tag{4.2}$$

and the right-eigenvector to eigenvalue 0 is given by the coordinate vector field $(0, e_n')^T = (0, \frac{\partial}{\partial \xi_n})^T$. Let $(\rho, v)^T$ be the image of $(0, \frac{\partial}{\partial \xi_n})^T$ under this coordinate change, i.e.,

$$\begin{pmatrix} 0 \\ e_n' \end{pmatrix} = D\Phi(t,p) \begin{pmatrix} \rho(t,p) \\ v(t,p) \end{pmatrix}. \tag{4.3}$$

Since $\Psi \circ \sigma = k \circ \Phi$, it follows that

$$D\Psi(t,x) D\sigma(t,p) \begin{pmatrix} \rho(t,p) \\ v(t,p) \end{pmatrix} = \frac{\partial h}{\partial \xi_n}(\tau,\xi) \begin{pmatrix} 0 \\ e_n' \end{pmatrix} \tag{4.4}$$

and thus for $(t,p) \in S$, we have

$$0 = D\sigma(t,p) \begin{pmatrix} \rho(t,p) \\ v(t,p) \end{pmatrix} = \begin{pmatrix} \rho(t,p) \\ \frac{\partial x}{\partial p}(t,p) v(t,p) \end{pmatrix}. \tag{4.5}$$

Hence, v defines a $C^{1,r}$ time-varying vector field on D which gives the right-eigenvector to eigenvalue 0 in the singular set S. Analogously, we can define a $C^{1,r}$ time-varying covector field on D which gives the left-eigenvector w through the change of coordinates in the range applied to the left-eigenvector

$$\varpi(\tau,\xi) = \left(-\frac{\partial h}{\partial \tau}(\tau,\xi), \dots, -\frac{\partial h}{\partial \xi_{n-1}}(\tau,\xi), 1 \right) \tag{4.6}$$

for $Dk(\tau,\xi)$. Here we define

$$(\pi(t,p), w(t,p)) = \varpi(\bar{\tau},\eta) D\Psi(t, x(t,p)) \tag{4.7}$$

and obtain

$$w(t,p)\frac{\partial x}{\partial p}(t,p) = \frac{\partial h}{\partial \xi_n}(\tau,\xi)\frac{\partial \xi_n}{\partial p}(t,p). \tag{4.8}$$

Using these changes of coordinates it is possible to relate the transversality conditions in the different coordinate systems.

LEMMA 4.1. *If $\tau = t - t_0$, then for $(\tau,\xi) = \Phi(t,p) \in S'$ we have that*

$$\frac{\partial^2 h}{\partial \xi_n^2}(\tau,\xi) = w(t,p)\frac{\partial^2 x}{\partial p^2}(t,p)(v(t,p),v(t,p)), \tag{4.9}$$

$$\begin{aligned}\frac{\partial^3 h}{\partial \xi_n^3}(\tau,\xi) = w(t,p)\bigg(&\frac{\partial^3 x}{\partial p^3}(t,p)(v(t,p),v(t,p),v(t,p))\\ &+3\frac{\partial^2 x}{\partial p^2}(t,p)\left(\frac{\partial v}{\partial p}(t,p)v(t,p),v(t,p)\right)\bigg),\end{aligned} \tag{4.10}$$

$$\frac{\partial^2 h}{\partial \tau \partial \xi_n}(\tau,\xi) = w(t,p)\frac{\partial^2 x}{\partial t \partial p}(t,p)v(t,p). \tag{4.11}$$

This lemma is proved by direct calculations which are given in detail in [21]. Note that the assumption about the translation $\tau = t - t_0$ is sufficient to formulate the transversality conditions which then allow the transformation into the normal form. However, this transformation will require more general changes of coordinates in τ.

We now describe the normal forms for *fold* and *cusp* points, respectively. The map σ, respectively, x, has a *fold*-singularity at (t_0,p_0) if and only if the vector $(0,v_0)$ does not lie in the tangent space to S_1 at p_0, $(0,v_0)\notin T_{(t_0,p_0)}S_1$. Equivalently, S_1 and the kernel of $\frac{\partial x}{\partial p}(t_0,p_0)$ are transversal. In the coordinates on D' this is characterized by

$$\frac{\partial^2 h}{\partial \xi_n^2}(0,0) = \left(\frac{\partial^2 h}{\partial \tau \partial \xi_n}(0,0), \frac{\partial^2 h}{\partial \xi \partial \xi_n}(0,0)\right)\cdot\begin{pmatrix} 0 \\ e_n' \end{pmatrix} \neq 0 \tag{4.12}$$

or by

$$w_0\frac{\partial^2 x}{\partial p^2}(t_0,p_0)(v_0,v_0) \neq 0 \tag{4.13}$$

in the original coordinates. It follows from Whitney's results (see, for instance [20, Chap. III, Thm. 4.5]) that we can change the last coordinate on R' so that σ is given by the normal form

$$n : (\tau,\xi_1,\dots,\xi_n) \mapsto (\tau,\xi_1,\dots,\xi_{n-1},\xi_n^2), \tag{4.14}$$

i.e., $h(\tau,\xi) = \xi_n^2$.

The map σ has a *cusp*-singularity at (t_0,p_0) if and only if the eigenvector $(0,v_0)$ lies in the tangent space to S_1 at p_0, $(0,v_0) \in T_{(t_0,p_0)}S_1$, which is equivalent to the geometric fact that the (one-dimensional) kernel of $\frac{\partial x}{\partial p}(t_0,p_0)$ is tangent to S_1. Thus,

$$\frac{\partial^2 h}{\partial \xi_n^2}(0,0) = w_0\frac{\partial^2 x}{\partial p^2}(t_0,p_0)(v_0,v_0) = 0. \tag{4.15}$$

In this case the precise normal form of the function h is determined by the order of contact between the kernel of $\frac{\partial x}{\partial p}(t_0,p_0)$ and S_1. This leads to a further classification

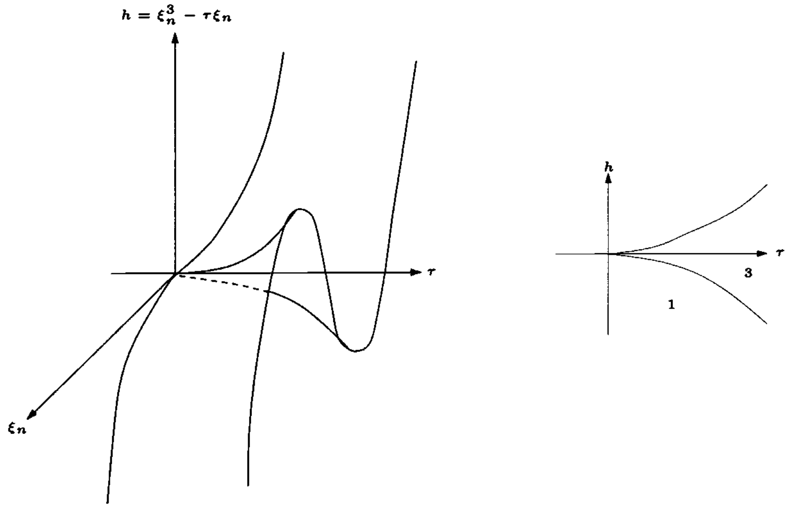

FIG. 4.1. *Simple cusp.*

of these singularities of S_1 into subclasses S_{1_k}, called *Morin*-singularities. Here we are interested only in the case when this order of contact is one, the so-called simple cusp. Even more specifically, we assume that the map σ takes on the singularity transversely in the following sense:

$$\frac{\partial^2 h}{\partial\tau\partial\xi_n}(0,0) \neq 0 \qquad \text{and} \qquad \frac{\partial^3 h}{\partial\xi_n^3}(0,0) \neq 0, \tag{4.16}$$

i.e.,

$$0 \neq w_0 \frac{\partial^2 x}{\partial t \partial p}(t_0, p_0)(v_0, v_0), \tag{4.17}$$

$$0 \neq w_0 \left(\frac{\partial^3 x}{\partial p^3}(t_0, p_0)(v_0, v_0, v_0) + 3\frac{\partial^2 x}{\partial p^2}(t_0, p_0)\left(\frac{\partial v}{\partial p}(t_0, p_0)v_0, v_0 \right) \right). \tag{4.18}$$

Condition (4.17) implies that S_1 is an $(n-1)$-dimensional manifold near (t_0, p_0), while (4.18) states that the order of contact between S_1 and $\ker\frac{\partial x}{\partial p}(t_0, p_0)$ is one. Here [20, Chap. VII, Thm. 4.1.] one can change the last coordinate on R' so that σ is indeed given by the normal form with function $h(\tau, \xi) = \xi_n^3 - \tau\xi_n$:

$$n : (\tau, \xi_1, \dots, \xi_n) \mapsto (\tau, \xi_1, \dots, \xi_{n-1}, \xi_n^3 - \tau\xi_n)). \tag{4.19}$$

Figure 4.1 gives the well-known picture of the simple cusp. It consists of a family of cubic polynomials in ξ_n parametrized by τ. These polynomials have only the real root $\xi_n = 0$ for $\tau < 0$, but three real roots for $\tau > 0$ and, correspondingly, a local minimum and maximum which generate a region where the polynomial is 3:1. Figure 4.1(a) shows the graph of the function h projected into the (τ, ξ_n, h) subspace while Figure 4.1(b) identifies the multiplicities of the images in the (ξ_n, h)-plane. Notice that the image of the singular set in the (ξ_n, h)-plane is a cusp which separates a region where the map is 1:1 from the region where the map is 3:1. On the singular set itself the map is 2:1.

5. The fold singularity in optimal control: Conjugate points. We now describe the structure of the value-function in the state-space for a parametrized flow of extremals near a fold point and its implications on the structures of optimal trajectories. The shadow price lemma allows us to relate the singularity in the flow of extremals to a singularity in the value-function for the corresponding parametrized flow. These considerations are in the sense that we analyze only the given parametrized flow, but do not analyze possible other flows of extremals which can overlap in the same region in the state-space. The theoretical considerations here provide what corresponds to small pieces of a puzzle which gives the required local (in a neighborhood of a reference *point*) structures which then can be pieced together to effect a *regular synthesis.*

We assume that

(A) The matrix $\frac{\partial x}{\partial p}(t_0, p_0)$ has a simple eigenvalue 0 with right-eigen-vector v_0 and left-eigenvector $w_0 = v_0^T \frac{\partial \lambda}{\partial p}(t_0, p_0) \neq 0$.

(F) The transversality condition

$$w_0 \frac{\partial^2 x}{\partial p^2}(t_0, p_0)(v_0, v_0) \neq 0 \tag{5.1}$$

holds.

THEOREM 5.1. *Suppose conditions* (A) *and* (F) *are met at* (t_0, p_0) *for a* $C^{1,3}$ *parametrized flow of normal extremals. Then there exist (open) neighborhoods* D *of* (t_0, p_0) *and* R *of* $(t_0, x_0) = (t_0, x(t_0, p_0))$ *with the following properties:*

(a) *The singular set* S *restricted to* D *is an embedded* n*-dimensional submanifold of fold points which splits* D *into two connected components* D_+ *and* D_-, $D = D_- \cup S \cup D_+$.

(b) *The map* $\sigma : D \to R$, $(t, p) \longmapsto (t, x(t, p))$, *restricted to* D_+ *or* D_- *is a* $C^{1,3}$ *diffeomorphism and both restrictions map* D_+, *respectively,* D_- *onto a region* $R_+ \subset R$,

$$\sigma(D_+) = R_+ = \sigma(D_-). \tag{5.2}$$

Thus, away from the singular set the map σ *is* 2:1 *on* D.

(c) *Let* $\sigma_\pm^{-1} : R_+ \to D_\pm$, *denote the inverses to the restriction of* σ *to* $D_\pm$ *and define the corresponding sections of the value-function for the parametrized flow by*

$$V_\pm : R_+ \to \mathbb{R}, \qquad V_\pm = C \circ \sigma_\pm^{-1}. \tag{5.3}$$

These functions and their gradients can be extended continuously to the fold $F = \sigma(S)$. *The graphs of* V_+ *and* V_- *are tangent on* F *but do not intersect otherwise over* R_+.

Thus the corresponding graphs of V^+ and V^- over R_+ do not intersect near (t_0, x_0), $x_0 = x(t_0, p_0)$, other than on the fold-locus. In other words, V^+ entirely lies to one side of V^-. The structure of the parametrized flow of extremals and the corresponding value-function is summarized in Figure 5.1.

Theorem 5.1 gives a geometric interpretation for what is essentially a classical result. For if the flow of the parametrized extremals is a diffeomorphism until the fold points are encountered, this structure implies the well-known results about strong local extrema of extremal trajectories and conjugate points. In this case a smooth solution to the Hamilton–Jacobi–Bellman equation is obtained in the state-space up to

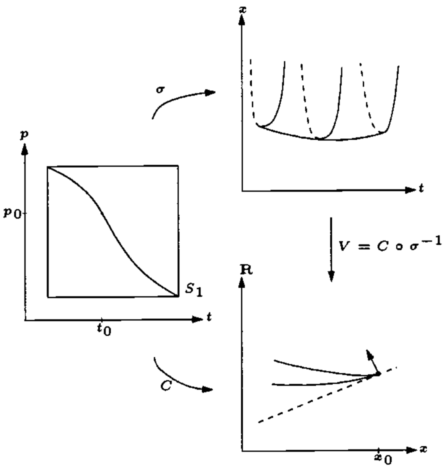

FIG. 5.1. *Value near a fold.*

the hypersurface F defined by the image of the fold-locus. Each of the parametrized extremals is optimal with respect to any other trajectory which lies in the region covered by the parametrized flow of extremals, hence is a *strong local extremum* in the sense of the calculus of variations. At the fold-points optimality ceases. Thus *the fold-points correspond to conjugate points* in the sense of the classical results for strong local optimality. This is exactly the structure as it is already encountered in the calculus of variations in the problem of minimum surfaces of revolution for smooth extremals, the catenaries [4]. As discussed in the introduction, in optimal control numerous formulations of similar results are well known, ranging from engineering textbooks [8] to modern geometric formulations expressed in terms of symplectic geometry [1]. Theorem 5.1 is included here for the sake of completeness since it describes the behavior for the least degenerate singularity and thus the most common degenerate behavior. Its proof within our framework of parametrized extremals is elementary, yet cleverly uses direct calculations in normal form. Its proof, which can be found in [21], is omitted here since the result itself is classical. Instead we illustrate Theorem 5.1 for a simple but instructive example.

Example. Consider the one-dimensional control problem to minimize

$$J(u) = \frac{1}{2}\int_0^T u^2 dt + \frac{1}{3}x(T)^3, \tag{5.4}$$

subject to $\dot{x} = u$, $u \in \mathbb{R}$. The minimum condition implies that $u = -\lambda$ and thus, taking $p = x(T)$, a smoothly parametrized family of extremals is given by

$$x(t,p) = p + (T-t)p^2, \quad u(t,p) = -p^2, \quad \lambda(t,p) = p^2. \tag{5.5}$$

Hence

$$S = \{(t,p) \in [0,T] \times \mathbb{R} : 2(T-t)p + 1 = 0\} \tag{5.6}$$

and all points in S are fold points.

6. The simple cusp singularity in optimal control: Cut-loci. In a regular synthesis, however, the picture of trajectories which stay optimal up to a surface of conjugate points or to a fold-singularity is not a familiar one. The reason lies in the presence of simple-cusp points which, as will be seen now, determine the local behavior of optimal trajectories in a neighborhood of the cusp point.

As above, we make the corank 1 singular point assumption (A). In particular, it follows from the discussions in section 4 that there exists a $C^{1,r}$ time-varying vector field v defined near (t_0, p_0) with the property that v is a right-eigenvector to eigenvalue 0 in the singular set. We now assume that

(C) If v_0 denotes the value at (t_0, p_0) of v, then

$$w_0 \frac{\partial^2 x}{\partial p^2}(t_0, p_0)(v_0, v_0) = 0 \tag{6.1}$$

and the following transversality conditions hold:

$$0 \neq w_0 \frac{\partial^2 x}{\partial t \partial p}(t_0, p_0) v_0, \tag{6.2}$$

$$0 \neq w_0 \left(\frac{\partial^3 x}{\partial p^3}(t_0, p_0)(v_0, v_0, v_0) + 3 \frac{\partial^2 x}{\partial p^2}(t_0, p_0)(\frac{\partial v}{\partial p}(t_0, p_0) v_0, v_0) \right). \tag{6.3}$$

We first summarize the mapping properties of the map σ near (t_0, p_0). The notion of stratifications and compatible maps provides a precise formulation to describe the multiplicities of the map σ near (t_0, p_0).

Definition 6.1. *Let M be a C^r manifold. A C^r stratification $\mathcal{S}$ of M is a locally finite decomposition of M into pairwise disjoint connected embedded C^r manifolds S_i, $i \in I$, which satisfies the so-called frontier-axiom, i.e., if S is an element of $\mathcal{S}$, then the frontier of S, Fron $S = (Clos\, S) \backslash S$, is a union of other elements of $\mathcal{S}$ which have lower dimension. The elements of $\mathcal{S}$ are called strata.*

Definition 6.2. *Let M be a C^r manifold and let N be an embedded C^r submanifold. A C^r stratification $\mathcal{S}$ of M is said to be compatible with N if N is a union of strata.*

Definition 6.3. *Let M and N be C^r manifold and let $F : M \to N$ be a C^r map. Let $\mathcal{S}$ and $\mathcal{T}$ be C^r stratifications of M and N, respectively. We say the stratifications $\mathcal{S}$ and $\mathcal{T}$ are compatible with the map F if for every $S \in \mathcal{S}$ there exists a $T \in \mathcal{T}$ such that the restriction of F to S is a C^r diffeomorphism onto T.*

We summarize the crucial mapping properties of σ near a simple cusp point in terms of these definitions.

Proposition 6.1. *Suppose conditions* (A) *and* (C) *hold at (t_0, p_0) for a $C^{1,4}$ parametrized flow of normal extremals. Then there exist (open) neighborhoods D of (t_0, p_0) and R of $(t_0, x_0) = (t_0, x(t_0, p_0))$ such that there exist stratifications $\mathcal{D}$ of D compatible with the singular set S, and $\mathcal{R}$ of R which are compatible with the map σ. Precisely, on D we have that*

(a) *The singular set S restricted to D is an n-dimensional embedded submanifold of corank 1 singular points which splits D into two connected components D_0 and $\widetilde{D_1}$. There exists an $(n-1)$-dimensional submanifold S_0 embedded into S which consists of simple cusp points and splits S into two connected components $S_\pm$ which consist of fold points.*

(b) *There exists an n-dimensional embedded submanifold T which is tangent to S at S_0 such that S_0 splits T into two connected components T_+ and T_- which are contained in $\widetilde{D_1}$. The map σ is* 1:1 *on the submanifolds S_0, $S_\pm$ and $T_\pm$ with images*

$$\sigma(S_0) =: J_0 \qquad \sigma(S_\pm) = \sigma(T_\pm) =: J_\pm. \tag{6.4}$$

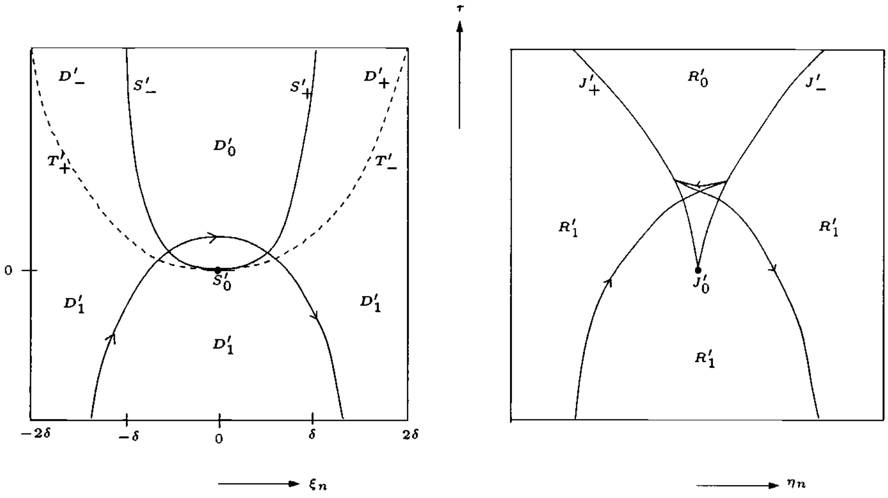

FIG. 6.1. *Compatible stratification for the simple-cusp.*

The submanifold T stratifies $\widetilde{D_1}$ into three connected components D_1, D_+, and D_-; σ restricted to each of the open submanifolds D_0, D_1, D_+, and D_- is a $C^{1,4}$ diffeomorphism with the following images

$$(6.5) \qquad \sigma(D_+) = \sigma(D_0) = \sigma(D_-) =: R_0 \qquad \sigma(D_1) =: R_1.$$

The sets J_0, $J_\pm$, R_0, and R_1 define the stratification $\mathcal{R}$ of R.

Thus the map σ is 1:1 on D_1 and S_0 onto R_1 and J_0, 2:1 on $T_\pm \cup S_\pm$ onto $J_\pm$, and 3:1 from $D_- \cup D_0 \cup D_+$ onto R_0. The structure of the stratifications for the domain and range for the map σ are illustrated in Figure 6.1.

The mapping properties of σ near a simple-cusp point are well known and hence the proof is omitted. The nontrivial aspect of the construction lies in relating them to the mapping properties of the parametrized value-function near the simple-cusp.

THEOREM 6.1. *Suppose conditions* (A) *and* (C) *hold at* (t_0,p_0) *for a* $C^{1,4}$ *parametrized flow of normal extremals and let $\mathcal{D}$ and $\mathcal{R}$, respectively, be the stratifications of the (open) neighborhoods D of (t_0,p_0) and R of $(t_0,x_0) = (t_0,x(t_0,p_0))$ constructed in Proposition* 6.1. *Let $\sigma_\kappa^{-1} : R_+ \to D_\kappa$, $\kappa \in \{-1,0,1\}$, denote the inverses to the restriction of σ to D_κ and define the corresponding sections of the value-function for the parametrized flow by*

$$(6.6) \qquad V_\kappa : R_+ \to \mathbb{R}, \qquad V_\kappa = C \circ \sigma_\kappa^{-1}.$$

These functions and their gradients can be extended continuously to the fold submanifolds $J_\pm$ in the respective domains and the graphs of $V_\pm$ and V_0 are tangent on $J_\pm$, but do not intersect otherwise over R_+. However, V_+ and V_- intersect in a cut-locus Γ which is an n-dimensional embedded submanifold with J_0 in its frontier.

The parametrized value-function is shown in Figure 6.2.

Proof: Since the frontier strata $J_\pm$ of R_0 consist of fold points, the statements about continuous extensions of V_κ and the corresponding gradients onto $J_\pm$ follow from Theorem 5.1. We need to analyze the values $V_\kappa(t,x)$ for a point $(t,x) \in R_0$. Let

$$(6.7) \qquad (t,x) = \sigma_\kappa(t,p_\kappa), \qquad (\tau,\xi_\kappa) = \Phi(t,p_\kappa).$$

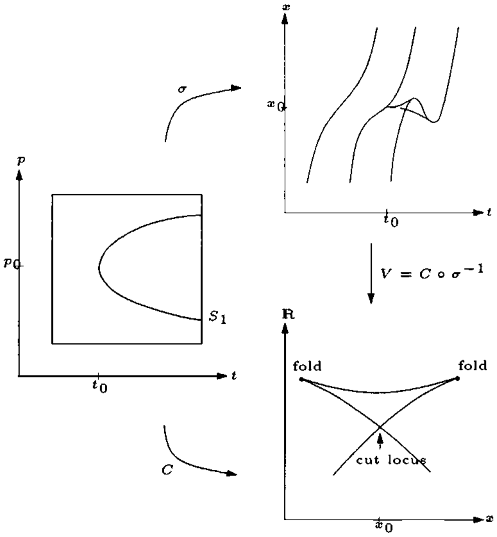

FIG. 6.2. *Value near a simple cusp point.*

Then, for $C' = C \circ \sigma^{-1}$ and $i, j \in \{-1, 0, 1\}$ we have

$$V_i(t,x) - V_j(t,x) = C(t,p_i) - C(t,p_j) = C'(\tau,\xi_i) - C'(\tau,\xi_j) \tag{6.8}$$

and we will analyze the cost in normal coordinates. We first establish the values of the derivatives of $x' = x \circ \sigma^{-1}$ and C' on the cusp surface S_0'. Lemmas 6.1 through 6.3 follow by direct calculations making the necessary change of coordinates into normal form. We only indicate the proofs. Full details can be found in [21].

LEMMA 6.1. *For $(\tau,\xi) \in S'$ we have*

$$\frac{\partial x'}{\partial \xi_n}(\tau,\xi) = 0, \quad \frac{\partial t'}{\partial \xi_n}(\tau,\xi) = 0. \tag{6.9}$$

On the cusp surface S_0' we have

$$\frac{\partial^2 x'}{\partial \xi_n^2}(\tau,\xi) = 0, \quad \frac{\partial^2 t'}{\partial \xi_n^2}(\tau,\xi) = 0, \tag{6.10}$$

$$\frac{\partial^4 x'}{\partial \xi_n^4}(\tau,\xi) = 0, \quad \frac{\partial^4 t'}{\partial \xi_n^4}(\tau,\xi) = 0, \tag{6.11}$$

$$6\frac{\partial^2 x'}{\partial \tau \partial \xi_n}(\tau,\xi) + \frac{\partial^3 x'}{\partial \xi_n^3}(\tau,\xi) = 0, \tag{6.12}$$

$$6\frac{\partial^2 t'}{\partial \tau \partial \xi_n}(\tau,\xi) + \frac{\partial^3 t'}{\partial \xi_n^3}(\tau,\xi) = 0. \tag{6.13}$$

Proof. Let $\sigma' = \sigma \circ \Phi^{-1}$. Then $t' = t(\tau,\xi)$ and $\Psi \circ \sigma' = n$ implies that

$$D\Psi(t,x)\begin{pmatrix} \frac{\partial t'}{\partial \xi_n}(\tau,\xi) \\ \frac{\partial x'}{\partial \xi_n}(\tau,\xi) \end{pmatrix} = \frac{\partial h}{\partial \xi_n}(\tau,\xi)\begin{pmatrix} 0 \\ e_n' \end{pmatrix}, \tag{6.14}$$

which for $(\tau, \xi) \in S'$ gives (6.9). The other relations follow by differentiating (6.14). □

In order to evaluate the derivatives of the cost C' on S'_0 we need to account for the fact that the change into normal form for the simple-cusp also requires that we change the time variable as well, $\tau = \tau(t, p)$. In the new coordinates, the shadow price lemma transforms as follows.

Lemma 6.2.

$$\frac{\partial C'}{\partial \xi_n}(\tau, \xi) = \lambda'(\tau, \xi) \frac{\partial x'}{\partial \xi_n}(\tau, \xi) - H'(\tau, \xi) \frac{\partial t'}{\partial \xi_n}(\tau, \xi), \tag{6.15}$$

where

$$H'(\tau, \xi) = H(\tau, \lambda'(\tau, \xi), x'(\tau, \xi), u'(\tau, \xi)).$$

Proof. Differentiating $C' = C \circ \Phi^{-1}$ we obtain

$$\frac{\partial C'}{\partial \xi_n}(\tau, \xi) = \frac{\partial C}{\partial t}(t, p) \frac{\partial t}{\partial \xi_n}(\tau, \xi) + \frac{\partial C}{\partial p}(t, p) \frac{\partial p}{\partial \xi_n}(\tau, \xi). \tag{6.16}$$

Using Lemma 3.1 and the analogous formula for $\frac{\partial x'}{\partial \xi_n}(\tau, \xi)$, (6.15) follows. □

Lemma 6.2 allows us to evaluate the derivatives of C' on this singular set. By (6.9) we have

$$\frac{\partial C'}{\partial \xi_n}(\tau, \xi) = 0 \quad \text{for } (\tau, \xi) \in S'. \tag{6.17}$$

Lemma 6.3. *For $(\tau, \xi) \in S'_0$ we have*

$$\frac{\partial^2 C'}{\partial \xi_n^2}(\tau, \xi) = 0, \tag{6.18}$$

$$6 \frac{\partial^2 C'}{\partial \tau \partial \xi_n}(\tau, \xi) + \frac{\partial^3 C'}{\partial \xi_n^3}(\tau, \xi) = 0, \tag{6.19}$$

$$18 \frac{\partial^3 C'}{\partial \tau \partial \xi_n^2}(\tau, \xi) + \frac{\partial^4 C'}{\partial \xi_n^4}(\tau, \xi) = 0. \tag{6.20}$$

Proof. These relations follow by differentiating (6.16) and using Lemma 6.2 to evaluate the derivatives on S'_0. □

Having these basic relations available, we now evaluate the differences in the cost. First we blow up coordinates to desingularize the singular set near the cusp point via

$$\begin{aligned} \Theta : (-1, 1) \times (0, \delta) \ &\to \ (0, 3\delta^2) \times (-\delta, \delta), \\ (\alpha, \beta) &\longmapsto (\tau, \xi_n) = (3\beta^2, \alpha\beta). \end{aligned} \tag{6.21}$$

In these coordinates h is given by

$$\widetilde{h}(\alpha, \beta) = (\alpha\beta)^3 - 3\beta^2 \cdot \alpha\beta = \beta^3(\alpha^3 - 3\alpha)$$

and therefore the preimages of a point $(t,x) = \sigma'(\tau,\xi) \in R_0$ are given by the solutions to the cubic polynomial

$$0 = \mu^3 - 3\beta^2\mu - \beta^3(\alpha^3 - 3\alpha).$$

Using another blow-up $\mu = \beta h$, we can eliminate β and obtain the reduced equation

$$0 = h^3 - 3h - (\alpha^3 - 3\alpha) = (h-\alpha)(h^2 + \alpha h + \alpha^2 - 3). \tag{6.22}$$

The solutions can therefore be analyzed in time-slices $\tau = const$ and are given by the trivial root $h_0(\alpha) = \alpha$ corresponding to the preimage in D_0' and the two zeroes

$$h_\pm(\alpha) = -\frac{\alpha}{2} \pm \sqrt{3}\sqrt{1 - \left(\frac{\alpha}{2}\right)^2} \tag{6.23}$$

corresponding to roots in $D_\mp'$ (note the reversal of signs). The properties of the solutions h_κ, $\kappa \in \{-1,0,1\}$ given in the following lemma follow directly from the definition or are immediately verified.

Lemma 6.4.

$$h_\pm^2(\alpha) + \alpha h_\pm(\alpha) + \alpha^2 \equiv 3, \tag{6.24}$$

$$h_+^2(\alpha) + h_+(\alpha)h_-(\alpha) + h_-^2(\alpha) \equiv 3, \tag{6.25}$$

$$h_+(\alpha) + h_-(\alpha) + \alpha = 0. \tag{6.26}$$

We now compare the values of the functions V_κ, $\kappa \in \{-1,0,1\}$.

Proposition 6.2. *Let $(t,x) = \sigma_0'(\tau,\xi)$ and $(\tau,\xi_n) = (3\beta^2, \alpha\beta)$. Then*

$$\begin{aligned} V_0(t,x) - V_\pm(t,x) &= C'(3\beta^2,\alpha\beta) - C'(3\beta^2, h_\pm(\alpha)\beta) \\ &= \frac{1}{72}\frac{\partial^4 C'}{\partial \xi_n^4}(0,0)\left(\alpha - h_\pm(\alpha)\right)^3, \beta^4\left(\alpha + h_\pm(\alpha) + r_\pm(\alpha,\beta)\right), \end{aligned} \tag{6.27}$$

where $r_\pm(\alpha,\beta)$ is of order $o(1)$ uniformly for all $\alpha \in [-1,1]$, i.e., $\lim_{\beta\to 0+} r_\pm(\alpha,\beta) = 0$ uniformly in α over $[-1,1]$.

Proposition 6.3. *Let $(t,x) = \sigma_0'(\tau,\xi)$ and $(\tau,\xi_n) = (3\beta^2, \alpha\beta)$. Then*

$$\begin{aligned} V_+(t,x) - V_-(t,x) &= C'(3\beta^2, h_+(\alpha)\beta) - C'(3\beta^2, h_-(\alpha)\beta) \\ &= \frac{1}{72}\frac{\partial^4 C'}{\partial \xi_n^4}(0,0)\left(h_+(\alpha) - h_-(\alpha)\right)^3 \\ &\qquad \beta^4\left(h_+(\alpha) + h_-(\alpha) + r_0(\alpha,\beta)\right) \end{aligned} \tag{6.28}$$

where $r_0(\alpha,\beta)$ is of order $o(1)$ uniformly for all $\alpha \in [-1,1]$, i.e., $\lim_{\beta\to 0+} r_0(\alpha,\beta) = 0$ uniformly in α over $[-1,1]$.

The proofs of these propositions are similar and we prove only Proposition 6.3. Note the symmetry in the formulas which are identical if the roots are interchanged.

Proof. Writing C' as integral over its ξ_n derivative, we obtain

$$\begin{aligned} \Delta_0(\alpha,\beta) = V_+(t,x) - V_-(t,x) &= C'(3\beta^2, h_+(\alpha)\beta) - C'(3\beta^2, h_-(\alpha)\beta) \\ &= \frac{1}{2}\left(\int_{-1}^{1} \frac{\partial C'}{\partial \xi_n}(3\beta^2, \beta\gamma_0(\alpha,s))ds\right)(h_+(\alpha) - h_-(\alpha))\beta, \end{aligned}$$

where

$$\gamma_0(\alpha,s)=\frac{1}{2}(1+s)h_+(\alpha)+\frac{1}{2}(1-s)h_-(\alpha)=-\frac{\alpha}{2}+s\sqrt{3}\sqrt{1-\left(\frac{\alpha}{2}\right)^2}.$$

We now expand the integrand around $\beta=0$. Using Lemma 6.3 it follows that

$$\begin{aligned}\Delta_0(\alpha,\beta)=\frac{1}{2}\int_{-1}^{1}\Bigg\{&\left(3\frac{\partial^2 C'}{\partial\tau\partial\xi_n}(0,0)+\frac{1}{2}\frac{\partial^3 C'}{\partial\xi_n^3}(0,0)\gamma_0(\alpha,s)^2\right)\beta^2+\Bigg(3\frac{\partial^3 C'}{\partial\tau\partial\xi_n^2}(0,0)\gamma_0(\alpha,s)\\&+\frac{1}{6}\frac{\partial^4 C'}{\partial\xi_n^4}(0,0)\gamma_0(\alpha,s)^3\Bigg)\beta^3+o(\beta^3)ds\Bigg\}(h_+(\alpha)-h_-(\alpha))\beta\\=\frac{1}{2}\int_{-1}^{1}\Bigg\{&\frac{1}{2}\frac{\partial^3 C'}{\partial\xi_n^3}(0,0)\beta^2\left[\gamma_0(\alpha,s)^2-1\right]\\&+\frac{1}{6}\frac{\partial^4 C'}{\partial\xi_n^4}(0,0)\beta^3\left[-\gamma_0(\alpha,s)+\gamma_0(\alpha,s)^3\right]+o(\beta^3)ds\Bigg\}(h_+(\alpha)-h_-(\alpha))\beta.\end{aligned}$$

Now

$$\begin{aligned}\int_{-1}^{1}(\gamma_0(\alpha,s)^2-1)ds&=\int_{-1}^{1}\left[\frac{1}{4}\left(h_+(\alpha)+h_-(\alpha)+s(h_+(\alpha)-h_-(\alpha))\right)^2-1\right]ds\\&=-2+\frac{1}{2}\left(h_+(\alpha)+h_-(\alpha)\right)^2+\frac{1}{6}\left(h_+(\alpha)-h_-(\alpha)\right)^2\\&=-2+\frac{2}{3}\left(h_+(\alpha)^2+h_+(\alpha)h_-(\alpha)+h_-(\alpha)^2\right)=0\end{aligned}$$

and

$$\begin{aligned}\int_{-1}^{1}\gamma_0(\alpha,s)(\gamma_0(\alpha,s)^2-1)ds&=\frac{1}{2}\left(h_+(\alpha)-h_-(\alpha)\right)\int_{-1}^{1}s(\gamma_0(\alpha,s)^2-1)ds\\&=\frac{1}{2}\left(h_+(\alpha)-h_-(\alpha)\right)^2\left(h_+(\alpha)+h_-(\alpha)\right)\int_{-1}^{1}\frac{1}{2}s^2ds\\&=\frac{1}{6}\left(h_+(\alpha)-h_-(\alpha)\right)^2\left(h_+(\alpha)+h_-(\alpha)\right).\end{aligned}$$

Since $h_+(\alpha)-h_-(\alpha)=2\sqrt{3}\sqrt{1-\left(\frac{\alpha}{2}\right)^2}\geq 3$ for $\alpha\in[-1,1]$, (6.28) follows. This proves the proposition. □

For $\alpha\in[-1,1]$ we have $\alpha+h_+(\alpha)\in[1,2]$ and $\alpha+h_-(\alpha)\in[-2,-1]$. Since $h_-(\alpha)<\alpha<h_+(\alpha)$ on the open interval $(-1,1)$, it follows that $\Delta_\pm(\alpha,\beta)$ has constant sign on $(-1,1)\times(0,\delta)$ for δ sufficiently small. Since the sign of $(\alpha+h_\pm(\alpha))$ is given by ±1, this sign is given by the *nonzero* sign of $-\frac{\partial^4 C'}{\partial\xi_n^4}(0,0)$. To see this, note that for $(\tau,\xi)\in S_0'$

$$\frac{\partial^4 C'}{\partial\xi_n^4}(\tau,\xi)=3\frac{\partial\lambda'}{\partial\xi_n}(\tau,\xi)\frac{\partial^3 x'}{\partial\xi_n^3}(\tau,\xi)-3\frac{\partial H'}{\partial\xi_n}(\tau,\xi)\frac{\partial^3 t}{\partial\xi_n^3}(\tau,\xi)\tag{6.29}$$

and

$$\frac{\partial H'}{\partial\xi_n}(\tau,\xi)=\frac{\partial\lambda'}{\partial\xi_n}(\tau,\xi)\frac{\partial H'}{\partial\lambda'}(\tau,\xi)+\frac{\partial H'}{\partial x'}(\tau,\xi)\frac{\partial x'}{\partial\xi_n}(\tau,\xi)+\frac{\partial H'}{\partial u'}(\tau,\xi)\frac{\partial u'}{\partial\xi_n}(\tau,\xi).\tag{6.30}$$

But for $(\tau,\xi)\in S'$

$$\frac{\partial H'}{\partial u'}(\tau,\xi)\frac{\partial u'}{\partial \xi_n}(\tau,\xi)=\frac{\partial H}{\partial u}(t,p)\left(\frac{\partial u}{\partial t}(t,p)\frac{\partial t}{\partial \xi_n}(\tau,\xi)+\frac{\partial u}{\partial p}(t,p)\frac{\partial p}{\partial \xi_n}(\tau,\xi)\right)=0$$

since $\frac{\partial t}{\partial \xi_n}(\tau,\xi)=0$ and in general $\frac{\partial H}{\partial u}(t,p)\frac{\partial u}{\partial p}(t,p)\equiv 0$ by (3.16). In addition, since $\frac{\partial x'}{\partial \xi_n}(\tau,\xi)=0$ on S' we have that

$$\frac{\partial H'}{\partial \xi_n}(\tau,\xi)=\frac{\partial \lambda'}{\partial \xi_n}(\tau,\xi)f(\tau,x'(\tau,\xi),u'(\tau,\xi)). \tag{6.31}$$

Combining this with

$$\frac{\partial^3 x'}{\partial \xi_n^3}(\tau,\xi)=\frac{\partial x}{\partial t}(t,p)\frac{\partial^3 t}{\partial \xi_n^3}(\tau,\xi)+\frac{\partial^3 x}{\partial p^3}(t,p)\left(\frac{\partial p}{\partial \xi_n}(\tau,\xi),\frac{\partial p}{\partial \xi_n}(\tau,\xi),\frac{\partial p}{\partial \xi_n}(\tau,\xi)\right) \tag{6.32}$$

$$+3\frac{\partial^2 x}{\partial p^2}(t,p)\left(\frac{\partial p}{\partial \xi_n}(\tau,\xi),\frac{\partial^2 p}{\partial \xi_n^2}(\tau,\xi)\right)+\frac{\partial x}{\partial p}(t,p)\frac{\partial^3 p}{\partial \xi_n^3}(\tau,\xi), \tag{6.33}$$

it follows that for $(\tau,\xi)\in S_0'$

$$\frac{\partial^4 C'}{\partial \xi_n^4}(\tau,\xi)=3v^T(t,p)\frac{\partial \lambda}{\partial p}(t,p)\left[\frac{\partial^3 x}{\partial p^3}(t,p)\cdot(v(t,p),v(t,p),v(t,p))\right.$$

$$\left.+3\frac{\partial^2 x}{\partial p^2}(t,p)\cdot\left(\frac{\partial v}{\partial p}(t,p)v(t,p),v(t,p)\right)\right], \tag{6.34}$$

which is nonzero by the transversality condition (6.3).

Proposition 6.2 therefore implies that, away from the submanifolds $S_\pm$—where the graphs of V_0 and $V_\pm$ are tangent—the graphs of $V_\pm$ lie either below or above the graph of V_0 depending on the sign in the transversality condition (6.3). Proposition 6.3 allows us to compare V_+ and V_-. It follows from this proposition and the identity (6.26) that V_+ and V_- intersect if and only if

$$\delta(\alpha,\beta)=\alpha-r_0(\alpha,\beta)=0. \tag{6.35}$$

Since $\lim_{\beta\searrow 0^+} r_0(\alpha,\beta)=0$, it follows that the only solution in the limit $\beta\searrow 0$ is $\alpha=0$. Furthermore, $\lim_{\beta\searrow 0^+}\delta(1,\beta)=1$ and $\lim_{\beta\searrow 0^+}\delta(-1,\beta)=-1$ so that we have for some sufficiently small $\beta_0>0$

$$\delta(1,\beta)>0 \quad\text{and}\quad \delta(-1,\beta)<0,\quad 0<\beta<\beta_0. \tag{6.36}$$

Hence, by the mean-value theorem there exists a zero in $\alpha\in(-1,1)$ for all $\beta\in(0,\beta_0]$. But

$$\frac{\partial \delta}{\partial \alpha}(\alpha,\beta)=1-\frac{\partial r_0}{\partial \alpha}(\alpha,\beta) \tag{6.37}$$

and the limiting properties of $r_0(\alpha,\beta)$ extend to $\frac{\partial r_0}{\partial \alpha}(\alpha,\beta)$, since $r_0(\alpha,\beta)$ is C^4 in α on $[-1,1]$. Thus, $\frac{\partial \delta}{\partial \alpha}(\cdot,\beta)$ is positive and hence, $\delta(\cdot,\beta)$ is strictly increasing over $[-1,1]$. The unique zero $\alpha=A(\beta)$ defines the cut-locus in the normal coordinates. By the implicit function theorem the map $\beta\mapsto A(\beta)$ is C^1 on $(0,\beta_0)$. The curve $\alpha=A(\beta)$ separates $[-1,1]\times(0,\beta_0)$ into the open subsets $\{\alpha<A(\beta)\}$ and $\{\alpha>A(\beta)\}$ and on each one of these $\Delta_0(\alpha,\beta)$ has a constant sign. The diffeomorphic image of the n-dimensional embedded submanifold

$$(\beta, \xi_1, \dots, \xi_{n-1}) \mapsto (3\beta^2, \xi_1, \dots, \xi_{n-1}, A(\beta)\beta) \tag{6.38}$$

under the map $\sigma' = \sigma \circ \Phi^{-1}$ defines the cut-locus Γ in R or (t,x)-space. This proves Theorem 6.1.

This structure has several interesting and important implications on the structure of an optimal synthesis near the image (t_0, x_0) of a simple-cusp point (t_0, p_0). Trajectories $x(\cdot, p)$ different from $x(\cdot, p_0)$ lose optimality in a neighborhood V of (t_0, x_0) at the cut-locus prior to reaching the conjugate point at the fold-locus. Even though these trajectories are strong local extrema until they reach the fold-locus, the portion after the cut-locus will not be part of any optimal synthesis. These portions are no longer optimal since there are better trajectories (namely the ones coming from $D_\pm$ if the original trajectories are from $D_\mp$) which, however, are not close to the original trajectories in the sense of a calculus of variations. This feature and the structure of optimal trajectories are exactly the same, as it has been developed in [22] and is described in detail in [32], for the codimension 0 case of time-optimal control to an equilibrium point in $\mathbb{R}^3$.

Also note that it follows from Proposition 6.2 that the graph of V_0 lies above the graphs of V_+ and V_- if and only if

$$\frac{\partial^4 C'}{\partial \xi_n^4}(0,0) < 0, \tag{6.39}$$

and in this case, the minimizing branches generate a viscosity solution to the Hamilton–Jacobi–Bellman equation. If $\frac{\partial^4 C'}{\partial \xi_n^4}(0,0) > 0$, then this solution will be discontinuous. However, since we consider only one parametrized flow of extremals and not the optimal control problem per se, it is not a priori possible to connect the second case to the value function of the optimal control problem.

Example (see [10]). Consider the one-dimensional control problem to minimize

$$J(u) = \frac{1}{2}\int_0^T u^2 dt + \frac{1}{2}\left(x(T)^4 - x(T)^2\right) \tag{6.40}$$

subject to $\dot{x} = u$, $u \in \mathbb{R}$. As before, $u = -\lambda$, and now with $p = x(T)$, a smoothly parametrized family of extremals is given by

$$x(t,p) = p - (T-t)(p - 2p^3), \quad u(t,p) = p - 2p^3 = -\lambda(t,p). \tag{6.41}$$

Hence,

$$S = \{(t,p) \in (-\infty, T] \times \mathbb{R} : 6(T-t)p^2 - (T-t) + 1 = 0\}. \tag{6.42}$$

Here x_{pp} vanishes for $p = 0$ while x_{tp} and x_{ppp} are nonzero at $p = 0$. Thus the point $(T-1, 0)$ is a simple cusp point while all other singular points are fold points.

7. Conclusion.

This structure of the parametrized value near a simple-cusp point is interesting since it confirms that it is the more degenerate singularity, the simple-cusp, which dominates the local behavior at the point over the less degenerate fold-points nearby. Indeed the fold points become irrelevant and are not part of an optimal (regular) synthesis. This, of course, immediately raises the question about the roles of even more degenerate singularities. The results of [22, 32] verify, however, that in dimension three the structure as it was described here is the typical one (under codimension 0 assumptions on the Lie-brackets) also for time-optimal control to an equilibrium point for a nonlinear system. This is consistent with the fact that the fold and simple cusp singularities are the only generic singularities for maps between two-dimensional manifolds (with time generating the third dimension in the parametrization). For higher-dimensional systems, however, this suggests that the more degenerate singularities will play the decisive role. Naturally, the more degenerate the singularities are, the more difficult they are to analyze. Still, an analysis of the Morin-singularities [20, Chap. VII, Thm. 4.1] does not appear to be impossible and the geometry of some of the more degenerate ones like the swallowtail- or butterfly-catastrophe seems to be well understood [29]. Furthermore, generically the most degenerate singularities occur only in isolated points and thus, having the construction of a regular synthesis in mind, it may only be necessary to construct a few local syntheses near reference points. However, in order to analyze higher-dimensional systems, one probably needs to come up with the general structure relating singularities in the parametrized flow of extremals to the corresponding local solutions of the Hamilton–Jacobi–Bellman equation. Looking at the results of this paper, such a relation may indeed exist. Both for the fold and the simple-cusp singularity, the graph of the parametrized value exhibits the structure of the singular set of the next degenerate singularity, i.e., of a cusp for the fold and of a swallow-tail for the simple-cusp. Whether this is a mere coincidence or part of a general pattern which generally holds for transversal S_{1_k} singularities remains to be seen.

ON PARAMETER ESTIMATION USING LEVEL SETS*

JORDAN M. BERG† AND KENNETH HOLMSTRÖM‡

Abstract. Consider the problem of selecting the member of a parametrized family of curves that best matches a given curve. This is a key step in determining proper values for adjustable parameters in low-order plasma etching and deposition models. Level set methods offer several attractive features for treating such problems. This paper presents a parameter estimation scheme that exploits the level set formulation. The method is completely geometric; there is no need to introduce an arbitrary coordinate system for the curves. Analytic results necessary for the application of gradient descent algorithms are derived, and some preliminary numerical results are presented.

Key words. curve evolution, parameter estimation, level set methods, process modeling, semiconductor manufacturing

1. Introduction.

This work is motivated by the need for accurate low-order phenomenological models of thin film etching and deposition processes. These processes are central to the manufacture of microelectronic devices. Phenomenological models are necessary because of the complexity of the surface chemistry and the plasma-surface interactions. Typically these models lump together numerous unknown rate constants into relatively few parameters [8, 14, 20, 21]. Reliable use of these models for simulation or control then depends on the ability of the user to choose the values of these parameters correctly. The parameter values may be selected based on surface evolution data from scanning electron micrographs. To our knowledge, only one study has investigated methods to optimize this process [8]. That work, while successful, used a nongeometric cost function that requires the user to select points in one-to-one correspondence on the actual and estimated surfaces. This selection introduces an arbitrary component of unknown significance into the procedure and places an undesirable burden on the user. In the following sections we introduce a completely coordinate-free cost function that eliminates this arbitrary element.

In a recent series of papers Sethian and Adalsteinsson apply level set methods to the simulation of feature development in a variety of semiconductor manufacturing applications [1, 18, 19]. Level set methods provide a flexible framework for surface evolution problems. String methods are the main alternatives to level set methods. Here the surface is defined by points, which are advanced according to the surface velocity. Two problems may occur if corners appear in the surface. First, if the surface points are allowed to "bunch up" at a corner, the Courant–Friedrichs–Lewy condition may be violated. Second, points on the surface may move past each other, necessitating "delooping." The level set framework is inherently immune to these

problems. String methods may also become unwieldy when topological transitions occur, as during merging or splitting of surfaces. Again, these transitions are handled automatically using level sets. For a detailed discussion and a survey of the literature see [18]. Both corner formation and topological transition occur in etching and deposition, making this a promising area for the application of level set methods.

Although we are motivated by plasma etching and deposition applications, as described above, the problem we address here is more narrow in scope. We describe a geometric cost function based on level set descriptions of both the curve to be matched and the parametrized family. We then construct derivatives of the cost function in terms of the parameters. This allows us to apply the gradient descent class of minimization methods. A simple example is presented, and the tasks remaining before the results can be applied to the full problem are discussed. Several important properties of the cost function are discussed.

Level set methods have been used in identification. Approaches to real-time estimates of evolving features in plasma etching based on level sets have been put forth in [2, 3, 4, 5]. Santosa devises a level set approach to reconstruct the shape of an unknown object from a discrete set of measurements [16]. This is somewhat different from our situation. In this paper we treat the case where the shape of the object is itself the measurement.

2. Level sets. The approach presented here is general, but in this paper we restrict our attention to curves in the plane. In the level set formulation, an oriented curve $\mathcal{C}$ is represented by the zero level set (ZLS) of a level set function (LSF) $\Phi(x)$, that is, $\mathcal{C} = \{x \in R^2 : \Phi(x) = 0\}$. Clearly the choice of Φ is not unique. To remove this nonuniqueness one may think of $\mathcal{C}$ as defining an equivalence class of LSFs on the plane, where two such functions Φ and Ψ are defined to be equivalent if they have the same signature, that is, if Φ and Ψ have the same sign (or are simultaneously zero) at every point in R^2. As usual when dealing with equivalence classes, it is convenient to choose a canonical element. A good choice here is the *signed distance function.* For any curve in the plane, and given some choice of norm, the magnitude of the signed distance function at a point is the shortest distance (as defined by the norm) to the curve. The signed distance function is negative if the point is inside the curve and positive if the point is outside the curve. The choice of which component is inside and which is outside is essentially arbitrary. In situations with physical meaning the proper choice is generally obvious. Efficient algorithms exist for generating the signed distance function given an arbitrary LSF, particularly when allowed freedom in the choice of norms.

The real importance of the level set approach comes when considering *evolving* curves. Here $\mathcal{C} : [0, 1] \times [0, t_f] \to R^2$ is a parametrized curve evolving in time according to the equation

$$\frac{\partial \mathcal{C}}{\partial t} = \tilde{\beta}(s, t, \ldots)\nu, \tag{1}$$

where ν is the outward pointing unit normal to $\mathcal{C}$. The *speed function* $\tilde{\beta}$ describes the outward normal velocity of $\mathcal{C}$ and may depend on independent variables, on local properties of the curve, or on global considerations [13]. In (1), $\tilde{\beta}$ is defined only on the curve. Now the LSF too is time-dependent. The evolution of the LSF according to (1) is governed by the following PDE:

$$\Phi_t + \beta(x, t, \ldots)\|\nabla\Phi\| = 0. \tag{2}$$

This PDE is derived as follows: The curve $\mathcal{C}(s,t)$ is represented by the ZLS of a function $\Phi : R^2 \times [0,\tau) \to R$. Assume that Φ is negative in the interior and positive in the exterior of the zero level set. We consider the zero level set, defined by

$$\left\{X(t) \in R^2 \,:\, \Phi(X,t) = 0\right\}. \tag{3}$$

We have to find an evolution equation of Φ, such that the evolving curve $\mathcal{C}(t)$ is given by the evolving zero level $X(t)$, i.e., $\mathcal{C}(t) \equiv X(t)$. By differentiating $\Phi(X(t),t) = 0$ we obtain

$$\nabla\Phi(X,t) \cdot X_t + \Phi_t(X,t) = 0. \tag{4}$$

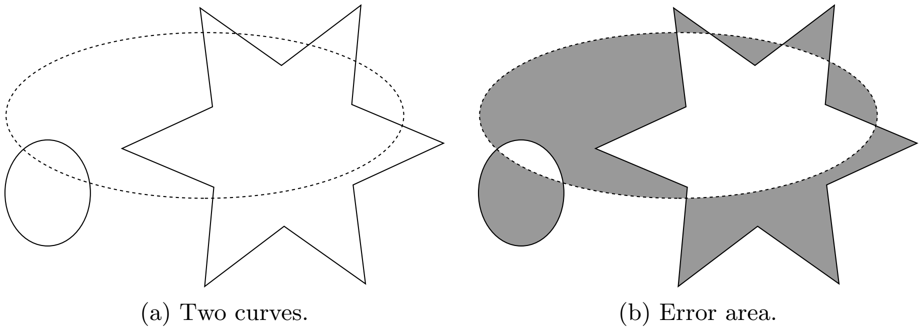
For any level set, the following relation holds:

$$\frac{\nabla\Phi}{\parallel \nabla\Phi \parallel} = \nu. \tag{5}$$

Substituting (5) into (1) to eliminate ν, then placing the resulting expression for $\mathcal{C}_t$ into (4), in place of X_t, gives (2). For more detail on the meaning of (2) when the LSF fails to be differentiable everywhere in space, and for numerical approaches to solving such cases, see [18] and the references therein.

All LSFs in the equivalence class must satisfy an equation like (2). Here β is a function defined everywhere in the plane. Different choices for β are possible, but at any instant they must all coincide on the ZLS itself, and there be equal to $\tilde{\beta}$. We will call any β satisfying this condition *admissible.* To remove the nonuniqueness in the definition of (2) we again turn to equivalence. Any admissible β will map a member of the equivalence class of LSFs at time t_0 into the proper equivalence class at time t. The canonical signed distance function can be recovered from any other member of the class as desired. This process is often referred to as *renormalization.* Note that the evolution (2) will not, in general, preserve the signed distance function.

3. A metric for level set functions. The process of parameter identification will require that we find the parameter values that give, in some sense, the closest match to an observed evolution. To make this rigorous, we must define a metric for LSFs that formalizes the idea of "distance." We turn now to the construction of a suitable function. Our main objective is to avoid the need to parametrize the curves. Such parametrizations are intrinsically arbitrary, and place a burden on the experience and expertise of the end user. This is the motivation for defining a geometric (by which we mean *coordinate-free*) cost function. The idea is presented in Figure 3.1. Figure 3.1(a) shows two closed curves, one consisting of a single connected component, the other consisting of two connected components. In all cases "inside" is taken to be the bounded component of the plane defined by the curves. Since the two curves are not identical, there should be a positive distance between them. We define this distance to be the area of the region between the two curves. This area is shaded light gray in Figure 3.1(b). The example shown in Figure 3.1 is abstract. A geometry that might occur in thin film deposition into a trench or via is shown in Figure 3.2. Here the points contained inside both curves are shaded dark, the points outside both curves are unshaded, and the points inside one curve but not the other—that set of points whose measure defines the distance—are shaded a light gray. That is, given a pair of simple closed curves, $\mathcal{C}_1$ and $\mathcal{C}_2$, let the distance from $\mathcal{C}_1$ to $\mathcal{C}_2$, denoted $\rho(\mathcal{C}_1, \mathcal{C}_2)$, be the total area of points enclosed by either one curve or the other, but



(a) Two curves. (b) Error area.

Fig. 3.1. *Two curves. One* (*dashed*) *is a large ellipse. The other* (*solid*) *consists of two simply connected components, a star and a small ellipse. The distance between the curves is found by summing the areas of the shaded regions.*

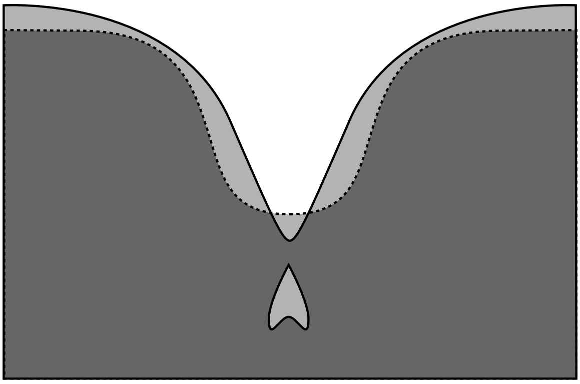


Fig. 3.2. *The estimate* (*dashed*) *differs from the measurement* (*solid*). *The associated cost is then the area between the two curves* (*light gray*).

not both. In three dimensions or higher area is replaced by volume, etc. The definition is extended to any curve defined by a LSF on a compact domain by including appropriate portions of the boundary.

Formally, let A and B be sets. Define the function $\rho(A, B)$ on sets to be the Lebesgue outer measure of the symmetric difference: $\rho(A, B) = \mu^*(S(A, B))$, where $S(A, B) := (A \setminus B) \cup (B \setminus A)$. The symbol $\setminus$ denotes the usual set difference. Unfortunately this is not a metric on sets, because sets that differ only by a set of measure zero will have a distance zero from each other, but are not equal. This problem can be resolved by defining two sets to be equivalent if ρ is zero. Then ρ is a metric on the resulting quotient space [15]. This operation is justified physically in our application since closed curves containing no area can be neglected, at least in terms of the gross structure. Whether these curves have some physical significance at a smaller length scale, or in terms of electrical or mechanical properties of the material, is an interesting question, but beyond the scope of this paper. Having defined $\rho(A, B)$ to be a metric on sets in the above sense, we extend it to closed curves as follows: If I_1 is the interior of curve $\mathcal{C}_1$, and I_2 is the interior of curve $\mathcal{C}_2$, then $\rho(\mathcal{C}_1, \mathcal{C}_2) = \rho(I_1, I_2)$. Finally we overload the notation still further, and extend the metric to LSFs, as fol-

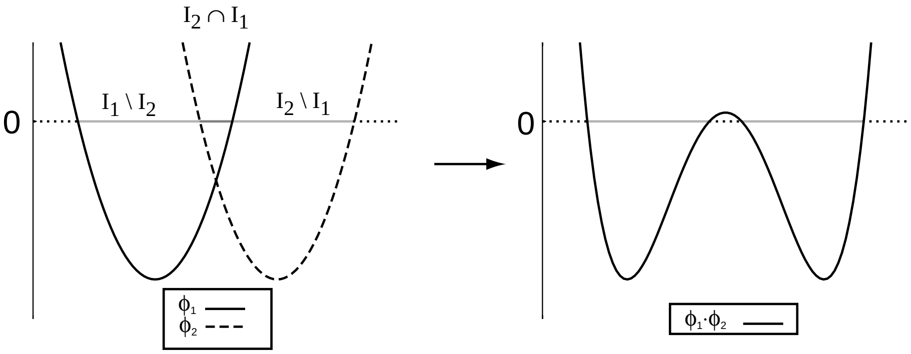

FIG. 3.3. *Product method for constructing error area from level sets.*

lows: If $\mathcal{C}_1$ is the ZLS of Φ and $\mathcal{C}_2$ is the ZLS of Ψ, then $\rho(\Psi, \Phi) = \rho(\mathcal{C}_1, \mathcal{C}_2)$. For the last extension, it is again necessary to consider a quotient space of the set of all LSFs. Here the equivalence relation defined earlier is weakened slightly to $\Phi(x) \sim \Psi(x)$ if $\text{sign}(\Phi) = \text{sign}(\Psi)$ *almost everywhere.* In the context of this paper these are technical details, and do not affect the computations. We refer to the metrics thus defined on plane curves and LSFs as the *area metric*, and refer to its value as the *error area.*

The *Hausdorff metric* is often used to compare curves in the plane. The "asymmetric Hausdorff metric" between curves $\mathcal{C}_1$ and $\mathcal{C}_2$ is defined, given some norm, by placing spheres of radius ϵ on each point of $\mathcal{C}_1$. The infimal value of ϵ for which the union of these spheres contains every point of $\mathcal{C}_2$ is the asymmetric Hausdorff metric from $\mathcal{C}_1$ to $\mathcal{C}_2$. The (symmetric) Hausdorff metric is the larger of the two asymmetric Hausdorff metrics. This paper is not intended as a comparison of the two metrics—only the area metric will be considered below. Much of the development can be accomplished using the Hausdorff metric in place of the area metric. In the context of the etching and deposition problems that motivate this work, the Hausdorff metric has advantages and disadvantages. For example, consider a case where the estimated curve agrees with the measured curve, except for the presence of a tiny bubble far from the free surface. The error according to the Hausdorff metric will be large, even though the bubble would most likely have little physical significance. The area metric would give a small error in this case. On the other hand, given two voids, the area metric does not distinguish between the situation where they are almost touching, and the situation where they are far apart. This potentially troublesome behavior does not occur with the Hausdorff metric.

3.1. The product method. When the estimate and the measurement curve are both characterized by LSFs, the area metric is easy to calculate. If the two LSFs are multiplied pointwise, the result is a new LSF, which we call the *product LSF.* The ZLS of the product LSF defines a curve, and the area of the interior of this curve is exactly the desired value. To see this, let $\mathcal{C}_1$ be the ZLS of Φ and $\mathcal{C}_2$ be the ZLS of Ψ. Recall that the distance between $\mathcal{C}_1$ and $\mathcal{C}_2$ is the measure of the symmetric difference between their interiors. That is, in terms of the LSFs, the measure of the set of points for which one LSF takes a positive value, while the other takes a negative value. If we form $\Gamma(x) = \Phi\Psi$, we see that $\rho(\mathcal{C}_1, \mathcal{C}_2)$ is just the area of the interior of the ZLS corresponding to Γ. Figure 3.3 is a graphical depiction of this construction in one dimension. To calculate the area we generate $\mathcal{C}_3$—the contour corresponding to the ZLS of $\Gamma(x)$ (note that the contour is now composed of *oriented curves* and is no longer just a set)—and apply Green's theorem:

$$\rho = \frac{1}{2}\int_{\mathcal{C}_3} \langle \mathcal{C}_3, \nu \rangle \, ds, \tag{6}$$

where $\langle \cdot, \cdot \rangle$ is the vector inner product. Here, as elsewhere in this paper, s stands for the arc length parameter [9]. Note that it is necessary to assign an LSF to the measurement.

In the procedure above, generating the contour corresponding to the ZLS of Γ is a key step. A geometric algorithm to accomplish this has been developed by Siddiqi, Kimia, and Wang, and is presented in [17].

3.2. The symmetric difference method. In the preceding section the product LSF was used to define the error area. In this section we present an alternative that has better numerical properties. Consider the interior of the ZLS as a set, and note the following relationships between operations on LSFs and set operations on the interiors.

1. Given a LSF Φ, and denoting the interior of the ZLS of Φ as $\mathrm{int}(\Phi)$, then $\mathrm{int}(-\Phi) = \mathrm{int}(\Phi)^c$. That is, the interior of the negative of the ZLS is the *complement* of the interior of the ZLS.
2. Given two LSFs, Φ and Ψ, then $\mathrm{int}(\max(\Phi,\Psi)) = \mathrm{int}(\Phi) \cap \mathrm{int}(\Psi)$.
3. Given two LSFs, Φ and Ψ, then $\mathrm{int}(\min(\Phi,\Psi)) = \mathrm{int}(\Phi) \cup \mathrm{int}(\Psi)$.

The symmetric difference between sets A and B is defined as $S(A,B) = (A \cap B^c) \cup (B \cap A^c)$. It can be shown that $S(A,B) = (A \cup B) \cap (A \cap B)^c$. Identifying A with $\mathrm{int}(\Phi)$ and B with $\mathrm{int}(\Psi)$, we define

$$\Theta \; = \; \max(\underline{\theta}, -\overline{\theta}), \tag{7}$$

where,

$$\underline{\theta} \; = \; \min(\Phi, \Psi), \tag{8}$$

$$\overline{\theta} \; = \; \max(\Phi, \Psi). \tag{9}$$

And it is seen that the error area is the Lebesgue measure of the interior of Θ. We refer to Θ as the symmetric difference LSF.

This formulation is numerically preferable to that of the previous section because if the gradients of the LSFs are near unity everywhere, then the gradient of the symmetric difference LSF will be also. In contrast, the gradients of the product LSF are not preserved. However, even for the symmetric difference method, away from the ZLS the signed distance function is not preserved. To see this, consider the case of the two LSFs, $\Phi(x,y) = x$ and $\Psi(x,y) = y$, whose interiors are the left half-plane and lower half-plane, respectively. These LSFs correspond to the signed distance function in the 1-norm or 2-norm. The union of their interiors is the interior of the level set function $\Theta = \min(\Phi,\Psi)$. The gradient of Θ has unity magnitude everywhere on the ZLS, except at the corner at the origin. To see that the signed distance function is not preserved, consider the point $(-1,-1)$. Although its distance from the ZLS is 2 (in the 1-norm) or $\sqrt{2}$ (in the 2-norm), the value of Θ at $(-1,-1)$ is -1.

4. Parametrized level sets. Ultimately we wish to parametrize the speed function β. In this paper however, we consider the simpler case of a parametrized level set. For the present we suppress also the time dependence of the curves. Our objective then is as follows: We are given a *measured* curve, $\mathcal{M}$, which is the ZLS of $\Phi(x)$. We also have a parametrized family of level set functions, $\Psi(x;\lambda)$. Let $\mathcal{L}(\lambda)$ be the ZLS of $\Psi(x;\lambda)$. We wish to find the value of the parameter vector λ such that $\mathcal{L}(\lambda)$ is closest to $\mathcal{M}$.

One way to proceed is to treat the metric as a cost function and seek to minimize

$$J(\lambda) = \rho(\mathcal{M}, \mathcal{L}(\lambda)) \tag{10}$$

or, in terms of Green's theorem, to minimize

$$J(\lambda) = \frac{1}{2}\int_{\mathcal{E}} \langle \mathcal{E}, \nu \rangle \, ds, \tag{11}$$

where $\mathcal{E}$ is the ZLS of

$$\Gamma(x;\lambda) := \Phi(x)\Psi(x;\lambda). \tag{12}$$

We wish to apply gradient descent methods to accomplish this minimization. To do this, we need to calculate the gradient ρ_i, where we denote partial differentiation with respect to λ_i by a subscript i.

For the smooth segments of the curve we have

$$\rho_i(\lambda) = \int_{\mathcal{E}} \langle \mathcal{E}_i, \nu \rangle \, ds. \tag{13}$$

Equation (13) is derived as follows: Let θ parametrize the curve and take values from 0 to 2π regardless of the value of λ. Of course, this parameter is, in general, no longer the arc length. Now, writing $\mathcal{E}$ explicitly as (x, y), the tangent vector explicitly as $(x_\theta, y_\theta)/\sqrt{x_\theta^2 + y_\theta^2}$, the outward normal ν as $(-y_\theta, x_\theta)/\sqrt{x_\theta^2 + y_\theta^2}$, and recalling that $ds = \sqrt{x_\theta^2 + y_\theta^2}\, d\theta$,

$$\rho = \frac{1}{2}\int_0^{L(\lambda)} \langle \mathcal{E}, \nu \rangle \, ds \tag{14}$$

$$= \frac{1}{2}\int_0^{2\pi} \langle \mathcal{E}, (-y_\theta, x_\theta) \rangle \, d\theta. \tag{15}$$

Differentiating inside the integral, and using the fact that the limits of integration no longer depend on λ,

$$\rho_\lambda = \frac{1}{2}\int_{\mathcal{E}} \langle \mathcal{E}_\lambda, \nu \rangle \, ds + \frac{1}{2}\int_0^{2\pi} \langle \mathcal{E}, (-y_{\theta\lambda}, x_{\theta\lambda}) \rangle \, d\theta. \tag{16}$$

Differentiation by λ and by θ commute. Integration of the second term by parts gives

$$\frac{1}{2}\int_0^{2\pi} \langle \mathcal{E}, (-y_{\theta\lambda}, x_{\theta\lambda}) \rangle \, d\theta = \langle \mathcal{E}, (-y_\lambda, x_\lambda) \rangle |_0^{2\pi} - \frac{1}{2}\int_0^{2\pi} \langle \mathcal{E}_\theta, (-y_\lambda, x_\lambda) \rangle \, d\theta. \tag{17}$$

The leading term in this expression is zero because the curve is closed. To evaluate the remaining term, write the vectors explicitly.

$$-\frac{1}{2}\int_0^{2\pi} \langle \mathcal{E}_\theta, (-y_\lambda, x_\lambda) \rangle \, d\theta \;=\; -\frac{1}{2}\int_0^{2\pi} \langle (x_\theta, y_\theta), (-y_\lambda, x_\lambda) \rangle \, d\theta \tag{18}$$

$$= -\frac{1}{2}\int_0^{2\pi} (-x_\theta y_\lambda + x_\lambda y_\theta)\, d\theta \tag{19}$$

$$= \frac{1}{2}\int_0^{2\pi} \langle (x_\lambda, y_\lambda), (-y_\theta, x_\theta)\rangle\, d\theta \tag{20}$$

$$= \frac{1}{2}\int_{\mathcal{E}} \langle \mathcal{E}_\lambda, \nu\rangle\, ds. \tag{21}$$

Substituting this result into (16) gives (13).

Now consider the change in $\mathcal{E}$ corresponding to a change in the ith parameter λ_i. We write $\Gamma(X(s;\lambda);\lambda) = 0$. So, $\Gamma_i + \langle \nabla\Gamma, \mathcal{E}_i\rangle = 0$. In fact, differentiation with respect to a parameter gives the same form we found when we derived the evolution equation (2), namely $\Gamma_i + \langle \mathcal{E}_i, \nu\rangle \|\nabla\Gamma\| = 0$. This time, however, we arrange the terms as follows:

$$\langle \mathcal{E}_i, \nu\rangle = -\frac{\Gamma_i}{\|\nabla\Gamma\|}. \tag{22}$$

Now, substituting (22) into (13), we obtain

$$\rho_i = -\int_{\mathcal{E}} \Gamma_i/\|\nabla\Gamma\|\, ds. \tag{23}$$

The derivatives of Γ are replaced by $\Gamma_i = \Phi\Psi_i$, and $\nabla\Gamma = \Phi\nabla\Psi + \Psi\nabla\Phi$. Since $\Phi = 0$ on $\mathcal{M}$ and $\Psi = 0$ on $\mathcal{L}$,

$$\rho_i = -\int_{\mathcal{M}\cup\mathcal{L}} \Phi\Psi_i/\|(\Phi\nabla\Psi + \Psi\nabla\Phi)\|\, ds \tag{24}$$

$$= -\int_{\mathcal{L}} \Phi\Psi_i/\|\Phi\nabla\Psi\|\, ds \tag{25}$$

$$= -\int_{\mathcal{L}} \operatorname{sign}(\Phi)\Psi_i/\|\nabla\Psi\|\, ds. \tag{26}$$

5. Corner effects. The formulas (13) and (26) of the previous section apply only to the smooth portion of the curves, and the contours will fail to be smooth at a finite number of corners. If the original curves are smooth, which we assume here for convenience, then the error contours defined by the ZLS of the product LSF will have corners only where the original curves intersect. It is now shown that, to first order, the contribution at each of these corners is zero.

Let $\mathcal{M}$ be the measured curve, $\mathcal{L}$ be the original estimated curve, corresponding to some nominal value for the parameter vector, and $\mathcal{L}'$ be the estimated curve at some new parameter vector, obtained by varying only the element λ_i by $\Delta\lambda_i$. The change in the curve along the outward normal ν, denoted δ_i, will be

$$\delta_i = \langle (\partial\mathcal{L}/\partial\lambda_i)\Delta\lambda_i, \nu\rangle \tag{27}$$

$$= \langle \mathcal{L}_i, \nu\rangle \Delta\lambda_i. \tag{28}$$

We assume that $\mathcal{L}_i$ is continuous. Now consider some neighborhood of each corner point, small enough that $\langle \mathcal{L}_i, \nu\rangle$ may be treated as approximately constant inside that neighborhood and constructed so as to intersect every curve in the family $\mathcal{L} + \langle \mathcal{L}_i, \nu\rangle t,\ t \in [0, \Delta\lambda_i]$, at a right angle. We also choose the neighborhood sufficiently small that the segments of $\mathcal{M}$ and $\mathcal{L}$ contained within it may be approximated

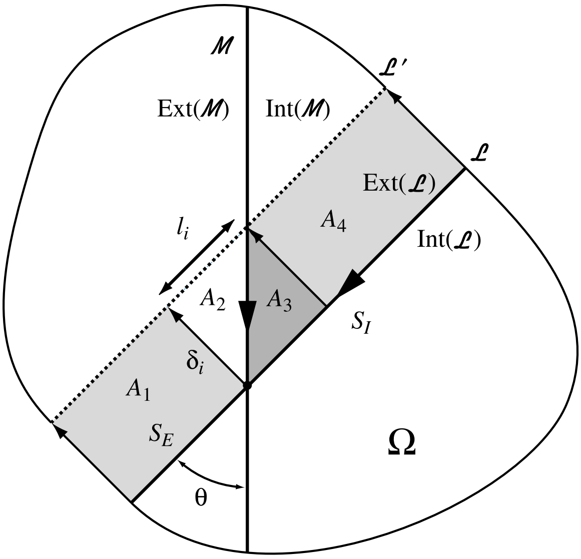

FIG. 5.1. *Close-up of corner effects.*

arbitrarily closely by straight lines. Figure 5.1 shows one such neighborhood, which we denote as Ω. Outside of these neighborhoods (13) holds; we now calculate the difference in one such neighborhood between ρ_i as predicted by (13) and the actual ρ_i. The sum of all such terms will give the total value required to correct the smooth approximation to ρ_i. Denote the length of the curve $\mathcal{L}$ that lies in both Ω and the interior of $\mathcal{M}$ by S_I, and the length of $\mathcal{L}$ in Ω but outside of $\mathcal{M}$ by S_E. The neighborhood is chosen small enough that $\langle \mathcal{L}_i, \nu \rangle$ is approximated arbitrarily well by a constant value. Hence, inside Ω, (13) becomes

$$\rho_i^s = (S_E - S_I)\langle \mathcal{L}_i, \nu \rangle, \tag{29}$$

where we use the fact that the outward normal to $\mathcal{L}$ coincides with the outward normal to the ZLS of the product LSF on the exterior of $\mathcal{M}$ and is opposite to it on the interior of $\mathcal{M}$. The superscript s indicates that this is the smooth approximation. Then

$$\Delta\rho^s = \rho_i^s \Delta\lambda_i = S_E\delta_i - S_I\delta_i. \tag{30}$$

Or, in terms of the regions shown in Figure 5.1,

$$\Delta\rho^s = A_1 - (A_2 + A_3 + A_4). \tag{31}$$

However, in terms of the regions shown in Figure 5.1, the actual change in the area metric is

$$\Delta\rho^a = A_1 + A_2 - (A_3 + A_4). \tag{32}$$

So the corrected expression for $\Delta\rho^a$ is

$$\Delta\rho^a = \Delta\rho^s + 2A_2 = \Delta\rho^s + \delta_i l_i. \tag{33}$$

Dividing through by $\Delta\lambda_i$ gives

$$\frac{\Delta\rho^a}{\Delta\lambda_i} = \frac{\Delta\rho^s}{\Delta\lambda_i} + \langle \mathcal{L}_i, \nu\rangle l_i. \tag{34}$$

As $\Delta\lambda_j$ goes to zero this becomes

$$\frac{\partial\rho^a}{\partial\lambda_i} = \frac{\partial\rho^s}{\partial\lambda_i} + \langle \mathcal{L}_i, \nu\rangle l_i. \tag{35}$$

So $\langle \mathcal{L}_i, \nu\rangle l_i$ is the correction term that must be applied to (13) or (26) to account for the corner. Writing l_i in terms of the corner angle, θ, we see that $l_i = \delta_i / \tan\theta = \langle \mathcal{L}_i, \nu\rangle \Delta\lambda_i / \tan\theta$. Thus, as $\Delta\lambda_i$ goes to zero, the correction term $\langle \mathcal{L}_i, \nu\rangle^2 \Delta\lambda_i / \tan\theta$ vanishes, and so the corners do not affect the calculation of the first derivative. On the other hand, it is clear that for small angles of intersection, the region for which a first-order approximation to the area metric is accurate will be very small. Therefore we anticipate that such geometries will cause significant numerical difficulties in minimization.

For the case in which the curve itself has corners, the gradients calculated by (26) will require correction. We will not consider such curves in the present paper. For a treatment of corners in a related context see [3].

5.1. Gradients by the symmetric difference method. To derive the gradient using the symmetric difference method we replace the product LSF Γ in (12) with the symmetric difference LSF Θ from (7). This substitution does not affect the calculation until (23). There we find

$$\Theta_i = \begin{cases} \Psi_i, & \Psi = 0, \Phi > 0, \\ -\Psi_i, & \Psi = 0, \Phi < 0, \\ 0 & \text{otherwise}, \end{cases} \tag{36}$$

where the case that both Φ and Ψ are zero along a measurable portion of the curve is neglected. This corresponds to a degenerate LSF, and the numerical scheme will typically not detect such a segment, since no sign change occurs. To see that (36) is correct, note that almost everywhere on the ZLS of the symmetric difference LSF either Φ or Ψ, but not both, is zero. When Φ is zero then the ZLS is locally determined only by Φ. Since Φ has no dependence on parameters, Φ_i, and so Θ_i, is zero. When $\Psi = 0$ the ZLS is locally determined only by Ψ. Then

$$\underline{\theta} = \min(\Phi, \Psi) = \begin{cases} \Phi, & \Phi < 0, \\ \Psi, & \Phi > 0. \end{cases} \tag{37}$$

$$\overline{\theta} = \max(\Phi, \Psi) = \begin{cases} \Psi, & \Phi < 0, \\ \Phi, & \Phi > 0. \end{cases} \tag{38}$$

And so,

$$\Theta = \max(\underline{\theta}, -\overline{\theta}) = \begin{cases} \max(\Phi, -\Psi), & \Phi < 0, \\ \max(\Psi, -\Phi), & \Phi > 0. \end{cases} \tag{39}$$

$$= \begin{cases} -\Psi, & \Phi < 0, \\ \Psi, & \Phi > 0. \end{cases} \tag{40}$$

Taking the gradient gives

$$\nabla\Theta = \begin{cases} -\nabla\Psi, & \Phi < 0, \\ \nabla\Psi, & \Phi > 0. \end{cases} \tag{41}$$

So the final expression for $\partial\rho/\partial\lambda_i$ becomes

$$\rho_i = -\int_{\mathcal{L}} \operatorname{sign}(\Phi)\Psi_i/\|\nabla\Psi\|\, ds. \tag{42}$$

That is, the expression for the gradient is the same for both the product LSF and the symmetric difference LSF. Since the area metric and its gradient are the same in both methods, it is natural to ask why one differs from the other. The answer is that the numerical implementation of the contour tracing algorithm will give different results. In the case where both LSFs are signed-distance functions, the symmetric difference method results in a LSF whose intersection with any grid line is piecewise linear. Therefore the interpolation routines used to locate the zeros will give better results for this case. However the gradient calculation is an integral over the ZLS of the estimate only. Therefore the method chosen does not affect the computation of the gradient.

6. Examples.

Here we consider two simple examples. In the first, the measured curve $\mathcal{M}$ is a circle of radius R, centered on (x_0, y_0). Choosing the canonical LSF to represent the curve, we write $\Phi(x,y) = \sqrt{(x-x_0)^2 + (y-y_0)^2} - R$. As a parametrized LSF we also choose a circle, parametrized by the position of its center, and its radius:

$$\Psi(x,y;x_c,y_c,\Pi) = \sqrt{(x-x_c)^2 + (y-y_c)^2} - \Pi. \tag{43}$$

Note that $\|\nabla\Psi\| = \|\nabla\Phi\| = 1$. The derivatives of the estimated LSF with respect to the parameters are calculated exactly, as follows:

$$\Psi_{x_c} = -\frac{(x-x_c)}{\sqrt{(x-x_c)^2 + (y-y_c)^2}}, \tag{44}$$

$$\Psi_{y_c} = -\frac{(y-y_c)}{\sqrt{(x-x_c)^2 + (y-y_c)^2}}, \tag{45}$$

$$\Psi_{\Pi} = -1. \tag{46}$$

In the optimal solution the curves match exactly, and the cost function is zero.

For the second example the parametrized level set is unchanged, but the measured curve is taken as an ellipse, that is, the ZLS of $\Phi(x,y) = \sqrt{((x-x_0)/a)^2 + ((y-y_0)/b)^2} - 1$. This leaves the calculations unchanged, but the optimal estimate no longer gives a perfect match.

6.1. Area metric and derivative computation.

The computation of the area metric and its gradient to parameter variation was checked using five static circular geometries; see Figure 6.1. In the first, the estimated curve is a circle completely contained within the measured circle. In this case the area metric is the difference in the areas, the gradient terms ρ_{x_c} and ρ_{y_c} are zero, and ρ_{Π} is the negative of the circumference. In the second case, the positions are reversed, with the measurement contained in the estimate. The only difference between this and Case I is the sign of

the gradient term corresponding to the radius. In Cases III–V the estimated circle lies on the measured circle in such a way that half the boundary of the estimate lies inside the measured circle and half outside. This should result in $\rho_\Pi = 0$. In Case III the center of the estimated circle is displaced from the center of the measurement only in the x direction, in Case IV, only in the y direction, and in Case V, in both x and y. The gridsize was 0.5 in both the x and y directions for all calculations. Table 6.1 compares the computed results to the theoretical values. Because the gradient calculations depend only on the ZLS of the estimated LSF, the gradients are the same for the two calculation methods. However, the symmetric difference method appears to be the more accurate way to calculate the cost function itself.

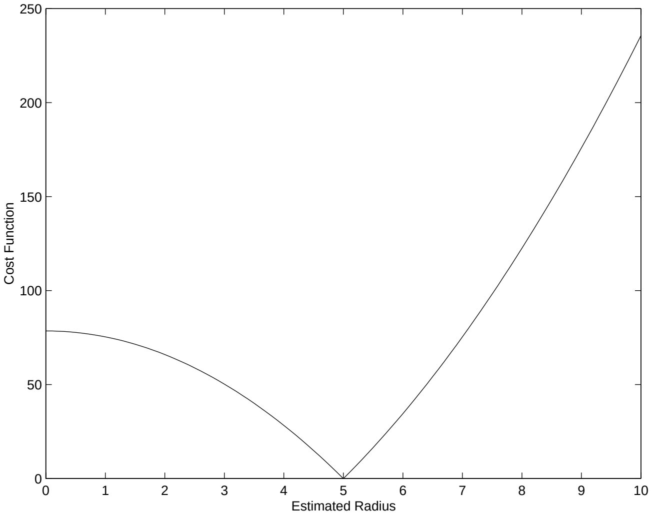

FIG. 6.3. *The cost function $\rho = \pi|R^2 - \Pi^2|$ for $R = 5$.*

6.2. Contour tracing. The error calculation becomes more difficult as the estimate approaches the true value. The reason is that the contour defining the error area becomes difficult to trace accurately. In this section, we examine this behavior more closely and compare the results from the product method with the results from the symmetric difference method. The test case is a circle centered at (2,2) with a radius of 4. Figures 6.2(a) and 6.2(b) show the true curve compared to a series of progressively closer estimates (both true and estimated curves are dotted) with the computed contours as calculated by the product method. Figures 6.2(c) and 6.2(d) show the same test using the symmetric difference method. Again, the gridsize in both the x and y directions is 0.5. Although both methods struggle with the contour as the curves become close, the symmetric difference method does a better job—as is evident from the plots and the computed values of ρ. The contour tracing algorithm implemented here is crude. Linear interpolation is used to locate zero crossings on the computational grid, and those points are connected to form contours. No shock placement logic is currently used. Improving the error calculation further requires either a smaller gridsize or a higher order interpolation method for contour tracing.

6.3. Numerical properties. The first example, in which both the measured and estimated curves are circles, gives several useful insights into the numerical properties of this problem. Consider the case in which the circles are concentric, and the only free parameter is the estimated radius, Π. Then the cost function is $\rho = \pi|R^2 - \Pi^2|$, where R is the true radius. Figure 6.3 shows this cost function. The function is nonsmooth and is not well approximated by a quadratic at the optimal point. The gradient is $\rho_\Pi = (2\pi)\,\mathrm{sign}(\Pi - R)\,\Pi$. The first derivative is undefined at the optimal point, and the magnitude of the gradient does not go to zero at the optimum.

Because of the presence of the absolute value in the area metric, we refer to direct minimization of this cost function as minimizing the 1-norm in the following discussion. The differentiability problem can be partially addressed by forming the cost function

$$J = \tfrac{1}{2}\rho(\mathcal{M}, \mathcal{L}(\lambda))^2. \tag{47}$$

We refer to this cost function as the 2-norm. The 2-norm and its derivatives, $J_i = \rho\rho_i$, are evaluated using the formulas derived above. Using this cost function, the case shown above becomes differentiable everywhere with zero gradient at the optimal point; in general we expect the 2-norm to be smoother than the 1-norm, but cannot guarantee differentiability. Both optimization strategies are illustrated in the example.

For either formulation, when the interiors of the two curves are disjoint, the estimate will converge to a local minimum. Namely, the estimated curve will simply decrease in radius until it vanishes (unless the parameter values are constrained). This observation holds true in general, and care must be taken to avoid either starting the minimization with disjoint interiors, or allowing such a situation during the minimization process.

In the case of a circular estimated curve, it is easy to prevent the interior of the initial guess from being disjoint with the interior of the measured curve. To do so it is sufficient to center the estimate at the origin, and then pick the initial radius sufficiently large. This may seem to be special to the example, but it is not. Consider the c-level set, $\{x \in R^2 : \Psi(x,t) = c\}$. If we use the signed distance function for Ψ, when c is sufficiently large, the measured curve must be contained in the interior of the estimate. So we replace $\Psi(x;\lambda)$ by $\tilde{\Psi}(x;\tilde{\lambda})$, where $\tilde{\Psi} = \Psi - c$, and $\tilde{\lambda} = (\lambda, c)$. Of course, this does not guarantee that subsequent iterations will not cause the interiors to become disjoint.

6.4. Numerical minimization results. The 2-norm is expected to be smoother than the 1-norm. Reflecting this difference, two different methods were chosen for the minimization. The 2-norm was minimized using the Broyden–Fletcher–Goldfarb–Shanno (BFGS) method [10]. This method makes a quadratic approximation to the cost function. The 1-norm, for which a quadratic approximation is expected to be poor near the optimum, was minimized using the method of steepest descent. In both cases the line search used was the one described by Fletcher [10, p. 34], with standard choice of parameters $\rho = 0.01$, $\tau_1 = 9$, and cubic interpolation. The line search accuracy parameter σ was set to 0.9 for the BFGS algorithm (inexact line search), and 0.1 for the steepest descent algorithm (exact line search). The specific implementation of these algorithms was the TOMLAB optimization environment package in Matlab. For more information see [11, 12].

To get some feel for the effects of discretization, the minimizations were carried out first with the true curve centered on a grid point (the origin) and concentric with the initial estimated circle, and next with the center of the true curve not on a grid point, and with the true curve not concentric with the initial estimated circle. In the cases where the true curve is circular the actual optimal estimate is obvious; in the cases where the true curve is elliptical it is necessary to calculate the optimal estimate. Assuming that the optimal estimate is concentric with the true ellipse, this calculation is quite easy. Under this assumption only one parameter is free—the radius of the estimated circle. Then $\langle \mathcal{E}_\Pi, \nu \rangle$ is unity everywhere on the curve, so (26) reduces to $\rho_\Pi = S_I - S_E$, where S_I and S_E are the total length of the arcs of the estimated circle inside and outside the ellipse, respectively. There are two such arcs inside the ellipse, which by symmetry are of equal length. Likewise there are two arcs of equal length outside the ellipse. Setting $\rho_\Pi = 0$ at the optimal point, we see that all four arcs

	2-norm	2.448	-4.128	7.110	78.40	11	33

must have the same arc length. Therefore the angle defined by each arc must be $\pi/2$. Writing the equation for the ellipse in polar form $r = r(\theta)$, in a coordinate system with origin on the center point of the ellipse, we see that the optimal radius $\Pi^\star$ of the estimated circle is just given by $\Pi^\star = r(\pi/4)$. For the ellipse $(x/a)^2 + (y/b)^2 = 1$ used in the examples, where $a = 5\sqrt{5}$ and $b = a/2$, that gives $\Pi^\star = 5\sqrt{2} \approx 7.071$. Once this value has been obtained, the corresponding error area may be calculated by direct integration. In the cases considered below the optimal value is approximately 80.44.

All cases used the symmetric difference method to calculate the area metric, and the gridsize was 0.5 in the x and y directions. That is, the computational grid was 61 by 61 points square. The value of Π was constrained to be greater than the gridsize h. The first line search presented a problem, as the steps taken were much too large, and the first estimate often had an interior disjoint with the true curve. This situation leads to convergence to a nonglobal minimum. The problem was prevented by using the normalized gradient, rather than the gradient itself, for the first line search only.

Three tests for convergence were applied. Convergence condition 1 is an absolute change of less than 10^{-10} in the norm of the difference of sequential estimates of the parameter vector. Convergence condition 2 is a relative reduction in the cost function of less than 10^{-10} in ten consecutive iterations. Convergence condition 3 is that the calculated cost is less than or equal to a specified lower limit (zero in this case). Convergence condition 4, used only for the BFGS method, is that the norm of the gradient is less than 10^{-1}.

In all cases except the first the algorithms stopped because of convergence condition 1. However, this test does not always indicate small search steps. When the accuracy of the function and gradient computation is not sufficient or when we have an ill-conditioned problem the convergence may be due to a zero or close-to-zero step length. The directed derivative is negative but very small and the line search cannot reduce the objective function. In such cases the optimization algorithm terminates too early, and a separate analysis is needed to determine how far from the local optimum we are. We get these premature stops for our last three test examples, but as we know the true answer it is clear that the result is acceptable. One reason for premature termination may be the lost accuracy in the contour tracing algorithm. As has been previously stated, our implementation is crude and may be improved.

The results are summarized in Table 6.2. There the optimal parameter estimates are compared with the true values. The number of iterations required for conver-

gence, N_I, is listed, as are the total number of function evaluations, N_f (which for our test cases is also the total number of gradient evaluations), and the computed area metric of the final solution. Note that the computed values can be less than the true minimum because of errors associated with discretization and contour tracing.

In the case of the centered circle, both the steepest descent minimization of the

1-norm and the BFGS minimization of the 2-norm converge immediately to the optimal solution with very little error on the first line search. The results of the two methods are identical. This is expected, since the gradients are normalized on the first line search, and these methods are using the same search step in the first iteration. The true curves, starting curves, final estimate, and intermediate curves for the remaining cases are shown in Figures 6.4–6.6. The steepest descent minimization of the 1-norm does fairly well for the skewed circle. The relatively poor performance of the BFGS minimization of the 2-norm is partly due to the inaccurate line search for the first normalized gradient step. Away from the optimum the gradient of the 2-norm is very large. This leads to a very large second step that hits the lower constraint on Π, overshoots the minimum, and changes the center of the approximating circle too much. This suggests a two-phase algorithm, with one or more normalized gradient steps with accurate line search, before switching to the BFGS method. Possibly the 1-norm should be used as the objective function for the first phase and the 2-norm for the second.

Another possible contribution to errors when using the BFGS method is due to the extremely small angle (approaching zero as the method converges) between the estimated and true curves. The BFGS method approximates the Hessian based on gradient information, and, as shown in section 5, the error in the first-order estimates may be very large when this angle is small. This conjecture is supported by the results of the skewed ellipse case. Here the angles at the corner between the estimated and true curves are much less acute, and the BFGS method produces a result of comparable accuracy to steepest descent, while converging much more rapidly.

It is not the purpose of this paper to compare the two minimization formulations. Rather, these computations are intended to show that either of the cost functions

developed above are feasible choices for the deposition and etching application. We believe that the results support this conclusion. On the other hand, the results of this section do suggest that the particular numerical formulation used will be an important consideration when applying this technique to practical problems. Many modifications to the numerical formulation are possible—including second-order correction terms at the corners, for example—which may significantly improve performance.

7. Parametrized speed functions. This work is motivated by applications to curve evolution problems. In such cases, the initial curve is assumed known, as is the measured shape at one or more subsequent times. The cost function corresponding to the 1-norm is then

$$J(\lambda) = \sum_k \rho(\mathcal{M}_k, \mathcal{L}(t_k; \lambda)), \tag{48}$$

and the cost function corresponding to the 2-norm is

$$J(\lambda) = \frac{1}{2} \sum_k \rho(\mathcal{M}_k, \mathcal{L}(t_k; \lambda))^2, \tag{49}$$

where $\mathcal{M}_k$ is the kth measured curve, t_k is the time corresponding to the kth measurement, and $\mathcal{L}(t_k; \lambda)$ is the curve obtained by propagating the estimate, with parameter vector λ, to $t = t_k$. The calculation of ρ and ρ_i, and so J and J_i, proceeds exactly as has already been described, with one important difference. The Ψ_i term that appears in (26) is no longer given explicitly by the parametrization. Rather, the λ dependence of $\Psi(x; \lambda)$ arises from the variation of β with λ in the evolution equation

$$\Psi_t + \beta(\,\cdot\,; \lambda)\|\nabla\Psi\| = 0. \tag{50}$$

Thus we will need to determine Ψ_i from β_i instead of writing it directly.

One way to accomplish this is to differentiate both sides of (50) with respect to the ith parameter. The result is a PDE for the gradient, coupled to the original evolution equation. This type of *sensitivity equation* approach is described further in [6, 7]. For the level set evolution equation, assuming only space and time dependence of the speed function, the result of the differentiation is as follows:

$$\Psi_{ti} + \beta_i\|\nabla\Psi\| + \frac{\beta}{\|\nabla\Psi\|}\,(\Psi_x\Psi_{xi} + \Psi_y\Psi_{yi}) = 0. \tag{51}$$

Exchanging the order of differentiation gives

$$\Psi_{it} + \beta_i\|\nabla\Psi\| + \frac{\beta}{\|\nabla\Psi\|}\,(\Psi_x\Psi_{xi} + \Psi_y\Psi_{yi}) = 0. \tag{52}$$

Finally, denote the appropriate gradient term by $S^{(i)} := \Psi_i$ and write

$$S_t^{(i)} + \beta_i\|\nabla\Psi\| + \frac{\beta}{\|\nabla\Psi\|}\,(\Psi_x S_x^{(i)} + \Psi_y S_y^{(i)}) = 0 \tag{53}$$

or

$$S_t^{(i)} + \beta\langle \nu, \nabla S^{(i)}\rangle = -\beta_i\|\nabla\Psi\|, \tag{54}$$

where ν is the outward pointing unit normal to the estimated level set. Once (50) is solved, $\nabla\Psi$ can be computed. Since β is known, and β_i can be computed, (54) is a linear first-order PDE. Initially the various $S^{(i)}$ are everywhere zero, since the starting curve for the model is exactly the true starting curve and does not depend on the speed function β. Boundary conditions are not needed as long as the estimated curve evolves outward everywhere on the boundary. If this is not the case, periodic boundary conditions may be applied [18]. Important behavior, such as curvature or orientation dependence of the speed function, will require additional terms in (54). Once (54) is solved, the computed value for Ψ_i (that is, $S^{(i)}$) is substituted into (26). Because only the values on the estimated curve are required, it would be highly desirable to implement a local solution method, such as the narrowband techniques of Sethian [18]. We note again that in all other ways, computation in the time-dependent evolutionary case will follow the procedures developed in this paper.

LACK OF TIME-DELAY ROBUSTNESS FOR STABILIZATION OF A STRUCTURAL ACOUSTICS MODEL[*]

GEORGE AVALOS[†], IRENA LASIECKA[‡], AND RICHARD REBARBER[§]

Abstract. In this paper we consider a natural robustness question for a model for structural acoustics. This model, which has been of great interest in recent years, is represented by a wave equation in $\mathbb{R}^2$ coupled to a Kelvin–Voigt beam; the coupling is natural physically, and is represented mathematically by highly unbounded operators. We assume that the observation consists of point evaluation of the beam position, the beam velocity, and the wave velocity. We are interested in the effect of arbitrarily small delays in the feedback loop on a controller that uses these observations. We show that it is not possible to construct a dynamic stabilizer of a very general form—including static feedback—such that the stabilization is robust with respect to delays in the feedback loop. In order to do this we need to carefully analyze the input-to-output map. Finally, we relate these results to already existing numerical results obtained for a Galerkin approximation of the system.

Key words. time delays, robust stabilization, coupled partial differential equations, transfer functions, dynamic stabilization, structural acoustics

1. Introduction.

In this paper we consider a natural robustness question for a model for structural acoustics. This model has been of great interest in recent years (see Banks et al. [6, 7, 8, 9, 10, 11, 12] and the references therein, Avalos [1], and Avalos and Lasiecka [2, 3]). In this introduction we roughly describe the problem and our results, and we leave the precise problem description and technical details for later sections.

Most of the mathematical analysis of this structural acoustics model has been done with a two-dimensional approximation; see [6, 7, 12] for details about the modeling for this system. We represent an acoustic cavity by a rectangular region in $\mathbb{R}^2$ and we consider one side of the boundary to be a flexible beam and the other three sides to be hard walls. Sound waves inside the cavity are described by a wave equation. The displacement of the flexible beam, which we call the active boundary, is described by a beam equation with Kelvin–Voigt damping. The coupling of these two equations is natural physically and is represented mathematically by highly unbounded operators. In the references above the control is formed by using piezoceramic patches on the active boundary, which produce moment forces when a voltage is applied. The control goal we consider here is stabilization of the system, in particular the attenuation of the acoustic pressure in the cavity. This attenuation might be described by exponential stability of an appropriate state space model, or by input-output stability of an appropriate input-output model.

In this paper we assume that the full state of the system is not available for use by the controller and that we have access to the following observations of the system: point evaluation of the beam displacement at some point or points on the beam, point evaluation of the beam velocity at some point or points on the beam, and point evaluation of the acoustic pressure at some points in the cavity. We consider controls determined by a dynamic compensator that uses these observations as its input.

We are interested in the effect of arbitrarily small delays in the feedback loop on the stability of the closed-loop system. Roughly speaking, we say that feedback stabilization of a system is *robust with respect to delays* if delays introduced into the feedback loop do not destroy the stability provided that the delays are sufficiently small. In this paper we answer the following question: *Is it possible to construct a dynamic stabilizer (or a static feedback) for this structural acoustics systems such that the stabilization is robust with respect to small delays in the feedback loop?*

For a large class of dynamic stabilizers and static feedbacks we show that the answer to this question is negative, since we find that there exists a sequence of delays $\{\varepsilon_j\}$ such that $\varepsilon_j \to 0$ and the closed-loop system with delay ε_j has an unstable transfer function pole. See section 5 for precise statements of the relevant results. In Banks, Demetriou, and Smith [8] the effect of delays on an H^∞ dynamic compensator for this system is studied numerically. In particular, in [8] delays are inserted in three places in the feedback loop, and the robustness with respect to these delays is studied for a Galerkin approximation of the closed-loop system. In section 6 we adapt our results to the setup in [8] and give a heuristic explanation for the results in [8] based on a frequency domain analysis.

The approach we use for these lack-of-robustness results is systems theoretic in the sense that we first show that our system is in a particular class of systems and then appeal to theorems about this class. The class in question is the class of *regular* systems, which is a very general class whose basic properties were developed by Weiss in [25] and [26], and for which there is now a substantial amount of control machinery; see for instance [17, 18, 19, 21, 22, 23, 27, 29]. In order to show that our system is regular when the observation includes point observations of the beam displacement and velocity, but does not include point observations of the acoustic pressure, we rely heavily on results by Avalos and Lasiecka [2] and Avalos [1]. When the observation includes point evaluation of acoustic pressure, proving regularity involves a careful analysis of the map from control to observation. This regularity is of interest independent of robustness questions, since many other control questions, e.g., adaptive control [18], stability radii [19], or dynamic stabilization [27], can be studied in the regular systems framework.

In the case when the observation does not include point evaluation of acoustic pressure, we have a natural (A, B, C, D) state space realization for the system, and our results can be stated in terms of exponential stability. In the case where the observation includes point evaluation of acoustic pressure, the state space that accommodates both the control and observation does not coincide with the basic energy space—it requires $(1/2)$ more derivatives in the wave variable—so we present our results in input-output form.

The paper is organized as follows. In section 2 we present the controlled, observed structural acoustics system. In section 3 we show that when the observation is point evaluation of acoustic pressure, then the input-to-output map is well posed, that is, for any $T > 0$ this map is in $\mathcal{L}(L^2[0, T; U], L^2[0, T; Y])$, where U is the control space and Y is the observation space. In section 4 we prove regularity of the system. In section 5 we discuss some results on robustness and lack of robustness with respect to delays, which can be immediately applied to our system. In section 6 we relate and compare our results to the numerical studies in [8]. In all the sections except section 3, we allow the acoustic cavity to be either a rectangle or any region in $\mathbb{R}^2$ with a smooth boundary. In section 3 we require the cavity to be a rectangle. In [5] the results in section 3 are obtained, using very different techniques, when Ω is a region in $\mathbb{R}^2$ or $\mathbb{R}^3$ with smooth boundary.

2. The controlled, observed structural acoustics system. In this section we present and analyze the partial differential equation model. This model is based on the one in [9, 12], but we will use a scaled, slightly abstracted version. Let Ω be either a rectangular region in $\mathbb{R}^2$ or a region in $\mathbb{R}^2$ with Lipschitz boundary Γ. Let Γ_0 be a smooth (C^2) segment of Γ with endpoints a and b. Let $z = z(t,x)$ for $t \in [0,\infty)$ and $x \in \Omega$, let $v = v(t,\xi)$ for $t \in [0,\infty)$ and $\xi \in \Gamma_0$, and let $\partial/\partial\nu$ denote the outward normal derivative. Let $U = \mathbb{R}^r$ and $B \in \mathcal{L}(U, H^{-\alpha}(\Gamma_0))$, where α will be specified throughout to be

$$\begin{aligned} &\alpha = \frac{7}{4} \text{ when } \Omega \text{ is rectangular} \\ &\text{and } \alpha = \frac{5}{3} \text{ when } \Omega \text{ has a smooth boundary.} \end{aligned} \tag{2.1}$$

We refer to the following as the *structural acoustics model*:

$$\begin{aligned} z_{tt} &= \Delta z \text{ on } [0,\infty) \times \Omega, \\ \frac{\partial z}{\partial \nu} &= v_t \text{ on } [0,\infty) \times \Gamma_0, \\ \frac{\partial z}{\partial \nu} &= 0 \text{ on } [0,\infty) \times \Gamma \setminus \Gamma_0, \\ v_{tt} &= -\Delta^2 v - \Delta^2 v_t - z_t + Bu \text{ on } [0,\infty) \times \Gamma_0, \\ v(a,t) = v_t(b,t) &= \frac{\partial v(a,t)}{\partial x} = \frac{\partial v(b,t)}{\partial x} = 0 \quad \forall\, t \in [0,\infty). \end{aligned} \tag{2.2}$$

The model discussed in [6, 7, 8, 9, 10, 11, 12], suitably scaled, is a special case of (2.2): in this case Ω is a rectangular region, Γ_0 is the bottom side of the rectangle, and B is of the form

$$B = \sum_{i=1}^{r} \alpha_i \delta'(\eta_i),$$

where $\delta'(\eta_i)$ are derivatives of delta functions evaluated at $\eta_i \in \Gamma_0$ and $\alpha_i \in \mathbb{R}$. The physical interpretation for this particular control operator is that its control action is realized by the strategic placement of piezoelectric ceramic patches on the (flexible) boundary Γ_0; a voltage is subsequently applied through these patches and the resulting bending moments can be interpreted as derivatives of delta functions.

The observation $y(t)$ considered in [6] and [8] is a vector with components of the form $v(t,\xi_0)$ for $\xi_0 \in \Gamma_0$, $v_t(t,\xi_0)$ for $\xi_0 \in \Gamma_0$, and $z_t(t,x_0)$ for $x_0 \in \overline{\Omega}$; these observations are chosen because they are likely to be physically observable. The acoustic pressure is proportional to z_t, so we often refer to an observation of z_t as an observation of acoustic pressure.

In [1], [2] the control system (2.2) was put into the following state-space form. Define the operator $A : L^2(\Omega) \supset \mathcal{D}(A) \to L^2(\Omega)$ by $A = -\Delta$ with

$$\mathcal{D}(A) = \left\{ z \in L^2(\Omega)/\mathbb{R} \cap H^2(\Omega) \middle| \frac{\partial z}{\partial \nu} = 0 \text{ on } \Gamma \right\},$$

where $L^2(\Omega)/\mathbb{R} = \{f \in L^2(\Omega) \mid \int_\Omega f = 0\}$; viz, $L^2(\Omega)/\mathbb{R}$ is the orthogonal complement of the space of constant functions in $L^2(\Omega)$. A is symmetric positive definite on $L^2(\Omega)$, so fractional powers of A are well defined. In particular, from [14] we have

$$\mathcal{D}(A^{\beta/2}) = L^2(\Omega)/\mathbb{R} \cap H^\beta(\Omega) \quad \text{for } \beta \in \left[0, \frac{3}{2}\right). \tag{2.3}$$

Define $\mathring{\mathbf{A}} : L^2(\Gamma_0) \supset \mathcal{D}(\mathring{\mathbf{A}}) \to L^2(\Gamma_0)$ by $\mathring{\mathbf{A}} = \Delta^2$ with

$$\mathcal{D}(\mathring{\mathbf{A}}) = H^4(\Gamma_0) \cap H_0^2(\Gamma_0).$$

$\mathring{\mathbf{A}}$ is symmetric positive definite on $L^2(\Gamma_0)$, so its fractional powers are well defined. In particular, by [14] we have

$$\mathcal{D}\left(\mathring{\mathbf{A}}^{\beta/4}\right) = H_0^\beta(\Gamma_0) \quad \text{for } \beta \in \left[0, \frac{5}{2}\right). \tag{2.4}$$

Since $\mathring{\mathbf{A}}$ is symmetric positive definite on a Hilbert space and the dual space of H_0^β is $H^{-\beta}$, we see that

$$\mathcal{D}\left(\mathring{\mathbf{A}}^{\beta/4}\right)' = H^{-\beta}(\Gamma_0) \quad \text{for } \beta \in \left[0, \frac{5}{2}\right). \tag{2.5}$$

Define

$$H_1 = \mathcal{D}(A^{\frac{1}{2}}) \times L^2(\Omega) = \left(L^2(\Omega)/\mathbb{R} \cap H^1(\Omega)\right) \times L^2(\Omega) \tag{2.6}$$

and

$$H_0 = \mathcal{D}\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right) \times L^2(\Gamma_0) = H_0^2(\Gamma_0) \times L^2(\Gamma_0).$$

Let $A_1 : H_1 \supset \mathcal{D}(A_1) \to H_1$ and $A_0 : H_0 \supset \mathcal{D}(A_0) \to H_0$ be defined by

$$\begin{aligned} A_1 &:= \begin{bmatrix} 0 & I \\ -A & 0 \end{bmatrix} \quad \text{with} \\ D(A_1) &= \{[z_1, z_2]^T \in D(A) \times D(A^{\frac{1}{2}})\} \end{aligned}$$

and

$$\begin{aligned} A_0 &:= \begin{bmatrix} 0 & I \\ -\mathring{\mathbf{A}} & -\mathring{\mathbf{A}} \end{bmatrix} \quad \text{with} \\ D(A_0) &= \left\{ [v_1, v_2]^T \in \left[D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)\right]^2 \ni v_1 + v_2 \in D\left(\mathring{\mathbf{A}}\right) \right\}. \end{aligned}$$

We define the Neumann map N on $H^s(\Gamma)$ for $s > -1/2$ by setting $Ng := z$ for $g \in H^s(\Gamma)$, where z is the unique solution in $L^2(\Omega)/\mathbb{R}$ of the equation

$$\langle Az, v\rangle_{[D(A^{\frac{1}{2}})]' \times D(A^{\frac{1}{2}})} = \int_\Omega \nabla z \cdot \nabla v = \langle g, v\rangle_{H^s(\Gamma)\times[H^s(\Gamma)]'}$$

for all $v \in D(A^{\frac{1}{2}})$. From [14], we have that

$$N \in \mathcal{L}\left(L^2(\Gamma_0), \mathcal{D}(A^{\frac{3}{4}-\epsilon})\right) \text{ for arbitrary } \epsilon > 0,$$

and this boundedness further implies that

$$AN \in \mathcal{L}\left(L^2(\Gamma_0), [\mathcal{D}(A^{\frac{1}{4}+\epsilon})]'\right) \text{ for arbitrary } \epsilon > 0. \tag{2.7}$$

We also define $\gamma : H^1(\Omega) \to H^{\frac{1}{2}}(\Gamma_0)$ by $\gamma(z) = z|_{\Gamma_0}$ and

$$C = \begin{bmatrix} 0 & 0 \\ 0 & \gamma^* \end{bmatrix},$$

so $C \in \mathcal{L}(H_0, \{0\} \times [D(A^{\frac{1}{2}})]')$. Let $\mathcal{X} = H_1 \times H_0$; we refer to the usual product norm on $\mathcal{X}$ by $\|\cdot\|$, and other norms will be indicated by an appropriate subscript. Now define $\mathcal{A} : \mathcal{D}(\mathcal{A}) \supset \mathcal{X} \to \mathcal{X}$ by

$$\mathcal{A} := \begin{bmatrix} A_1 & C \\ -C^* & A_0 \end{bmatrix}$$

with

$$\begin{aligned} D(\mathcal{A}) \quad = \quad & \{[z_1, z_2, v_1, v_2]^T \in [D(A^{\frac{1}{2}})]^2 \times \left[D\left(\mathring{\mathbf{A}}^{\frac{1}{2}}\right)\right]^2 \text{ such that} \\ & -z_1 + Nv_2 \in D(A) \text{ and such that } v_1 + v_2 \in D\left(\mathring{\mathbf{A}}\right) \Big\}. \end{aligned}$$

Let

$$X(t) = [z(t), z_t(t), v(t), v_t(t)]^T. \tag{2.8}$$

If $u(t) \equiv 0$, then (2.2) is formally equivalent to

$$\dot{X}(t) = \mathcal{A}X(t). \tag{2.9}$$

It is shown in Theorem 1.1 in [1] that $\mathcal{A}$ is the generator of a strongly continuous semigroup $S(t)$ on $\mathcal{X}$; see also Banks and Smith [11].

Let $R(s, \mathcal{A}) = (sI - \mathcal{A})^{-1}$. For $\alpha \in \mathbb{R}$, let $\mathbb{C}_\alpha := \{s \in \mathbb{C} \mid \mathbf{Re}(s) > \alpha\}$. The system under consideration in this paper differs from the system in [3] in that the wave equation here has Neumann conditions on $\Gamma \setminus \Gamma_0$, while the wave equation in [3] has Dirichlet conditions. The arguments in [3] can be easily modified to show that $S(t)$ is not exponentially stable, so Proposition 2 in Prüss [20] implies that

$$\sup_{s \in \mathbb{C}_0} \|R(s, \mathcal{A})\|_{\mathcal{L}(\mathcal{X})} = \infty. \tag{2.10}$$

The arguments in [3] can also be modified to show that $S(t)$ is strongly stable and that

$$\sigma(\mathcal{A}) \cap i\mathbb{R} = \emptyset, \tag{2.11}$$

where $\sigma(\mathcal{A})$ is the spectrum of $\mathcal{A}$. Let $s \in i\mathbb{R}$. If $\{s_n\} \subset \overline{\mathbb{C}}_0$, $s = \lim_{n\to\infty} s_n$, and $\{\|R(s_n, \mathcal{A})\|\}$ is unbounded, then $s \in \sigma(\mathcal{A})$, which is in contradiction to (2.11). Hence the only way (2.10) can be true is if

$$\limsup_{|s|\to\infty, s\in\mathbb{C}_0} \|R(s, \mathcal{A})\|_{\mathcal{L}(\mathcal{X})} = \infty. \tag{2.12}$$

Condition (2.12) is important for our lack-of-robustness results.

Let

$$\mathcal{B} = [0, 0, 0, B]^T \in \mathcal{L}\left(U, \{0\}^3 \times H^{-\alpha}(\Gamma_0)\right).$$

Then (2.2) is formally equivalent to

$$\dot{X}(t) = \mathcal{A}X(t) + \mathcal{B}u(t), \tag{2.13}$$

which holds pointwise in time in

$$X_{-1} := [\mathcal{D}(\mathcal{A}^*)]'. \tag{2.14}$$

$S(t)$ extends to a semigroup on $[\mathcal{D}(\mathcal{A}^*)]'$ and (2.2) is also formally equivalent to

$$z_{tt} = -Az + ANv_t, \tag{2.15}$$

$$v_{tt} + \mathring{\mathbf{A}}v_t + \mathring{\mathbf{A}}v = -N^*Az_t + Bu, \tag{2.16}$$

which holds pointwise in time in $[\mathcal{D}(A)]'$ and $[\mathcal{D}(\mathring{\mathbf{A}})]'$, respectively.

We now discuss the observations of this system. Let C_η be a point evaluation at η; we will use the same notation when $\eta \in \Gamma_0$ or when $\eta \in \overline{\Omega}$. Let $\xi_0 \in \Gamma_0$ and $x_0 \in \overline{\Omega}$. We define the following operators on $\mathcal{X}$ by

$$\mathcal{C}_1 := [0, 0, C_{\xi_0}, 0], \qquad \mathcal{C}_2 := [0, 0, 0, C_{\xi_0}], \qquad \mathcal{C}_3 := [0, C_{x_0}, 0, 0]. \tag{2.17}$$

We are ultimately interested in observations that contain several terms of this type, but it is most convenient to analyze these separately; in particular, our analysis of $\mathcal{C}_3$ necessarily will be much different (and more difficult) than our analysis of $\mathcal{C}_1$ or $\mathcal{C}_2$.

We wish to show that (2.2) with any of these observations is a *regular* system. For a detailed discussion of regular systems, see Weiss [25, 26]. Definition 2.1 given below for a *well-posed*, controlled, observed system is not as detailed as that given in [25], but it is equivalent when the system is given by a boundary-controlled partial differential equation of the type we are currently considering.

Definition 2.1. *Let $\mathcal{X}, Y$, and U be Hilbert spaces. A system with state $X(t) \in \mathcal{X}$, input $u(t) \in U$, and observation $y(t) \in Y$ is well posed if for some (and hence all) $T > 0$,*

(1) *$X(t) = S(t)X(0)$ for a strongly continuous semigroup $S(t)$ when $u(t) \equiv 0$;*
(2) *The map $u(\cdot) \to X(T)$ is bounded from $L^2[0, T; U]$ into $\mathcal{X}$;*
(3) *The map $X(0) \to y(\cdot)$ is bounded from $\mathcal{X}$ into $L^2[0, T; Y]$ when $u(t) \equiv 0$;*

(4) *The map* $\mathcal{T} : u(\cdot) \to y(\cdot)$ *with* $X(0) = 0$ *is bounded from* $L^2[0,T;U]$ *into* $L^2[0,T;Y]$.

For many purposes we need only be concerned with the input-output map $\mathcal{T}$.

DEFINITION 2.2. *If an input-output map* $\mathcal{T}$ *satisfies condition* (4)*, we say that it is a well-posed input-output system.*

If the controlled system is formally represented by (2.13) and condition (2) of Definition 2.1 is satisfied, then we say that $\mathcal{B}$ is an *admissible control (input) operator* for $S(t)$. If the uncontrolled system with observation is formally represented by (2.9) and

$$y(t) = \mathcal{C}X(t) \tag{2.18}$$

and condition (3) of Definition 2.1 is satisfied, then we say that $\mathcal{C}$ is an *admissible observation (output) operator* for $S(t)$. From Proposition 3.2 in [25], condition (4) in Definition 2.1 implies that if

$$L^2_\alpha[0,\infty,U] := \left\{ f \in L^2_{\mathrm{loc}}[0,\infty;U] \mid \int_0^\infty \|f(t)\|^2_U e^{-2\alpha t}\,dt < \infty \right\},$$

then there exists $\beta \in \mathbb{R}$ such that

$$\mathcal{T} \in \mathcal{L}(L^2_\beta[0,\infty;U), L^2_\beta[0,\infty;Y)). \tag{2.19}$$

While the well-posedness of the system with the observation operator $\mathcal{C}_1$ follows from basic Sobolev embeddings and the interior smoothness guaranteed by the state-space topology, this is not the case for the observation operators $\mathcal{C}_2$ and $\mathcal{C}_3$. Indeed, the topology generated by the state space $\mathcal{X}$ allows for point evaluation of the v component, but it does not allow us to define a pointwise evaluation of v_t—roughly speaking, $1/2+\varepsilon$ derivatives are missing. In order to handle this difficulty in the case of $\mathcal{C}_2$, we shall use "additional" smoothness results developed for structural acoustic problems in [2], which say that v_t has greater smoothness than the state space guarantees; in particular, $v_t \in L^2(0,T;H^2(\Gamma_0))$. This allows us to use Sobolev's imbeddings to obtain the well-posedness with the $\mathcal{C}_2$ observation.

In the case of the observation operator $\mathcal{C}_3$, the situation is much more delicate. The state space guarantees L^2 smoothness of z_t in the cavity. However, in order to use a Sobolev's imbedding one would need to have $z_t \in H^{3/2+\varepsilon}(\Omega)$, so $3/2+\varepsilon$ derivatives are missing. It can be shown (even for the one-dimensional example) that $L^2(0,T;H^2(\Gamma_0))$ tangential smoothness of the boundary input v_t does not produce sufficient interior smoothness for the variable z_t to make Sobolev embeddings useful for interior-point evaluation. In fact, one could show (with additional nontrivial work) that the maximal internal smoothness of z_t is $H^{1/2}(\Omega)$, but even this does not suffice to take pointwise evaluation in two dimensions. To cope with this difficulty, we resort to completely different arguments, which are based on microlocal analysis for the general smooth domains, and on very delicate calculations involving harmonic analysis when Ω is a rectangle. The rectangular case is dealt with in section 3, while the smooth domain case is treated in [5].

PROPOSITION 2.3. *The system* (2.2) *with observation* $y(t) = \mathcal{C}_1X(t)$ *or observation* $y(t) = \mathcal{C}_2X(t)$ *is well posed.*

Proof. Condition (1) in Definition 2.1 has already been established in [2]. Condition (2) follows immediately from Lemma 2.1 in [2]. To verify condition (3), first note that $\mathcal{C}_1$ is bounded on $\mathcal{X}$, hence is an admissible observation operator for any semigroup on $\mathcal{X}$. Now let the projections P_0 and P_1 be defined by

$$P_0[z_1, z_2, v_1, v_2]^T = [v_1, v_2]^T,$$
$$P_1[z_1, z_2, v_1, v_2]^T = [z_1, z_2]^T.$$

Theorem 1.1 in [2] shows that for any $X_0 \in \mathcal{X}$ and $T > 0$,

$$P_0 S(\cdot) X_0 \in L^2\left(0, T; \mathcal{D}(\mathring{\mathbf{A}}^{\frac{1}{2}}) \times \mathcal{D}(\mathring{\mathbf{A}}^{\frac{1}{2}})\right).$$

Let $X_0 \in \mathcal{X}$ and $X(t) = S(t)X_0$ be of the form (2.8). Using the Sobolev embedding theorem and the fact that $\mathcal{D}(\mathring{\mathbf{A}}^{1/2}) = H_0^2(\Gamma_0)$, we see that $\mathcal{C}_2 S(\cdot) X_0 = v_t(\cdot, \xi_0) \in L^2(0,T)$. By the principle of uniform boundedness, $\mathcal{C}_2$ is an admissible observation operator for $S(t)$.

To verify condition (4), note that Proposition 2.3 in [2] shows that for any $T > 0$ and $u \in L^2[0, T; U]$,

$$P_0 \int_0^{\cdot} S(\cdot - \tau) \mathcal{B} u(\tau)\, d\tau \in L^2\left(0, T; \mathcal{D}(\mathring{\mathbf{A}}^{\frac{1}{2}}) \times \mathcal{D}(\mathring{\mathbf{A}}^{\frac{1}{2}})\right).$$

Using the same reasoning as we used for the admissibility of $\mathcal{C}_1$ and $\mathcal{C}_2$, we see that (2.2) with this observation is well posed. □

If Z is a Banach space, define $H_\alpha^\infty(Z)$ to be all analytic Z-valued functions $\mathbf{H}(s)$ for which there exists $M > 0$ such that $\|\mathbf{H}(s)\| < M$ for all $s \in \mathbb{C}_\alpha$. If $\alpha = 0$ and if Z is clear from the context, we denote $H_\alpha^\infty(Z)$ by H^∞. Let $y(t)$ be the observation of a system resulting from a given u and zero initial conditions. If we denote the Laplace transform of y by $\hat{y}$ and if

$$\hat{y}(s) = \mathbf{H}(s)\hat{u}(s),$$

then we say that $\mathbf{H}(s)$ is the *transfer function* of the system. From Proposition 3.2 in [25], (2.19) is equivalent to $\mathbf{H} \in H_\beta^\infty(\mathcal{L}(U, Y))$, leading to the following definition.

DEFINITION 2.4. *A transfer function $\mathbf{H}(s)$ is well posed if $\mathbf{H} \in H_\beta^\infty(\mathcal{L}(U, Y))$ for some $\beta \in \mathbb{R}$.*

DEFINITION 2.5. *A transfer function $\mathbf{H}$ (or, equivalently, an input-output map $\mathcal{T}$) is* input-output stable *if*

$$\mathbf{H} \in H^\infty(\mathcal{L}(U, Y)) \text{ (or, equivalently, if } \mathcal{T} \in \mathcal{L}(L^2[0, \infty; U), L^2[0, \infty; Y))).$$

DEFINITION 2.6. *A system is* regular *if it is well posed and if the following condition is satisfied by its transfer function $\mathbf{H}(s)$:*

(5) $\lim_{s \to \infty, s \in \mathbb{R}} \mathbf{H}(s) =: D \in \mathcal{L}(U, Y)$ *exists.*

In this case we say that D is the feedthrough of the transfer function and of the system.

DEFINITION 2.7. *If an input-output system is well posed and the transfer function satisfies condition* (5)*, then we say that the input-output system is regular and that its transfer function is regular.*

It is shown in [25] that if a controlled, observed system with semigroup generator $\mathcal{A}$, input operator $\mathcal{B}$, and observation operator $\mathcal{C}$ is regular, it has the following state space representation, with state space $\mathcal{X}$:

$$\begin{aligned} \dot{X}(t) &= \mathcal{A} X(t) + \mathcal{B} u(t), \\ y(t) &= \mathcal{C}_\Lambda X(t) + D u(t), \end{aligned} \tag{2.20}$$

where $\mathcal{C}_\Lambda$ is the *Lebesgue extension* of $\mathcal{C}$; see [25].

Remark 2.8. If a controlled, observed system is well posed but not regular, it has a state space representation, but the abstract form of the observation (when the control is present) is much more complicated (and less analogous to finite dimensional systems) than that in (2.20) (see Salamon [24]).

Since $\mathcal{B}$ is an admissible input operator and $\mathcal{C}_1$ is a bounded observation operator, we get the following simple result, which follows immediately from [25].

PROPOSITION 2.9. *The system* (2.2) *with observation* $\mathcal{C}_1 X(t)$ *is regular.*

3. Observation of acoustic pressure. In the case where the observation operator is $\mathcal{C}_3$ (given in (2.17)) the well-posedness of the system is a much more delicate issue than the case treated by Proposition 2.3. This observation is *not* an admissible observation for $S(t)$ when the state space is $\mathcal{X}$. However, we will see in Corollary 3.4 that when Ω is a rectangular region, the input-output system is well posed. In Theorem 4.8 we see that the transfer function for (2.2) with this observation is regular, i.e., it also satisfies condition (5) in Definition 2.6.

Let $T > 0$ and let Ω be a rectangular domain in $\mathbb{R}^2$ with boundary Γ. Let $[z(t), z_t(t)]^T$ be the solution of the wave equation

$$\begin{aligned} &z_{tt}(t,x,y) = \Delta z(t,x,y) \quad \text{on } (0,T)\times\Omega, \\ &\frac{\partial z}{\partial\nu}(t,\zeta) = \mu(t,\zeta) \quad \text{on } (0,T)\times\Gamma, \qquad (3.1) \\ &z(0,x,y) = z_t(0,x,y) = 0 \quad \text{on } \Omega. \end{aligned}$$

With boundary data $\mu \in L^2(0,T;H^{5/4}(\Gamma))$, we already know from Avalos [4] that

$$[z, z_t] \in C\left([0,T]; H^1(\Omega)\times L^2(\Omega)\right).$$

We assume that $\mu(t,\cdot) = 0$ for $t > T$. We now prove the following "trace" result, which allows for pointwise evaluation of the velocity z_t at a point in $\overline{\Omega}$.

THEOREM 3.1. *For every fixed* $(x_0,y_0)\in\overline{\Omega}$, *the mapping* $\mu \to z_t(\cdot,x_0,y_0)$ *is in*

$$\mathcal{L}(L^2(0,T;H^{5/4}(\Gamma)), L^2(0,T)).$$

In particular, there exists $M > 0$, *independent of* (x_0,y_0), *such that for every* $\mu \in L^2(0,T;H^{5/4}(\Gamma))$,

$$\|z_t(\cdot,x_0,y_0)\|_{L^2(0,T)} \le M\,\|\mu\|_{L^2\left(0,T;H^{\frac{5}{4}}(\Gamma)\right)}. \qquad (3.2)$$

Remark 3.2. Note that this result *does not* follow from a direct application of the classical Sobolev embedding theorem.

Proof. Without loss of generality, we can set $\Omega := \{(x,y)\in\mathbb{R}^2 \mid 0 < x,y < \pi\}$, and since the mapping of concern here is linear, we can set $u \equiv 0$ except on the side $\{y = 0, 0 \le x \le \pi\}$. Fix $(x_0,y_0)\in\overline{\Omega}$. Let $\{\lambda_{mn},\Phi_{mn}\}_{m,n=1}^{\infty}$ denote, respectively, the eigenvalues and orthonormalized eigenfunctions of the operator A defined in section 2. These are given explicitly by

$$\begin{aligned} &\lambda_{mn} = n^2 + m^2 \quad \text{for } m,n = 1,2,\dots, \\ &\Phi_{mn}(x,y) = \tfrac{2}{\pi}\cos nx\cos my \quad \text{for } m,n = 1,2,\dots. \end{aligned}$$

We can explicitly write out the solution $[z, z_t]$ of (3.1)—this is done in [4] and [16]—as

$$z(t,x,y) = \sum_{m,n=1}^{\infty} \left\{ \frac{1}{\sqrt{n^2+m^2}} \int_0^t \sin\sqrt{n^2+m^2}(t-\tau)\mu_n(\tau)d\tau \right\} \Phi_{mn}(x,y);$$

$$\text{(3.3)} \quad z_t(t,x,y) = \sum_{m,n=1}^{\infty} \left\{ \int_0^t \cos\sqrt{n^2+m^2}(t-\tau)\mu_n(\tau)d\tau \right\} \Phi_{mn}(x,y),$$

where

$$\mu_n(t) := \frac{2}{\pi} \int_0^{\pi} \mu(t,\xi)\cos(n\xi)\,d\xi.$$

We now need the following proposition.

PROPOSITION 3.3. *For arbitrary $y_0 \in [0,\pi]$, the map $\mu \to z_t(\cdot,\cdot,y=y_0)$ is in*

$$\mathcal{L}(L^2(0,T;H^{\frac{5}{4}}(0,\pi)), L^2(0,T;H^{\frac{3}{4}}(0,\pi))).$$

In particular, there exists $M > 0$, independent of $y_0 \in [0,\pi]$, such that for all $\mu \in L^2(0,T;H^{\frac{5}{4}}(0,\pi))$,

$$\|z_t(\cdot,\cdot,y=y_0)\|_{L^2(0,T;H^{\frac{3}{4}}(0,\pi))} \le M\,\|\mu\|_{L^2(0,T;H^{\frac{5}{4}}(0,\pi))}.$$

Proof of Proposition 3.3. Define the operator $A_\Pi : L^2(0,\pi) \to L^2(0,\pi)$ by

$$A_\Pi = -\frac{d^2}{dx^2} \quad \text{with } \mathcal{D}(A_\Pi) = \left\{ g \in H^2(0,\pi) \middle| \frac{\partial g(\pi)}{\partial x} = \frac{\partial g(0)}{\partial x} = 0 \right\}.$$

A_Π is self-adjoint, positive semidefinite, so its positive fractional powers are well defined. Its respective eigenvalues and orthonormalized eigenvectors $\{\lambda_n, \Phi_n\}_{n=0}^{\infty}$ are given explicitly by

$$\text{(3.4)} \qquad \lambda_n = n^2 \quad \text{and } \Phi_n(x) = \frac{2}{\pi}\cos nx.$$

Then, for g in $L^2(0,\pi)$ and $\eta \ge 0$,

$$A_\Pi^{\frac{\eta}{2}} g = A_\Pi^{\frac{\eta}{2}} \sum_{n=1}^{\infty} (g,\Phi_n)\,\Phi_n = \sum_{n=1}^{\infty} (g,\Phi_n)\,n^\eta \Phi_n$$

with the L^2-convergence of the series on the right-hand side occurring if and only if $g \in D(A_\Pi^{\frac{\eta}{2}})$. Using this equality and the explicit representation of z_t in (3.3), we obtain

(3.5)
$$A_\Pi^{\frac{\eta}{2}} z_t(t,\cdot,y=y_0) = \sum_{m,n=1}^{\infty} n^\eta \left\{ \int_0^t \cos\sqrt{n^2+m^2}(t-\tau)\mu_n(\tau)d\tau \right\} \Phi_n(\cdot)\cos my_0.$$

Furthermore, from [14], for all $g \in H^\eta(0,\pi)$, $0 \le \eta < 3/2$, we can take

$$\text{(3.6)} \qquad \|g\|^2_{H^\eta(0,\pi)} = \left\| A_\Pi^{\frac{\eta}{2}} g \right\|^2_{L^2(0,\pi)}.$$

Using this and the orthonormality of $\{\Phi_n\}$, we have that for every $g \in H^\eta(0,\pi)$, $0 \le \eta \le 3/2$,

$$\|g\|^2_{H^\eta(0,\pi)} = \sum_{n=1}^{\infty} |(g,\Phi_n)|^2\, n^{2\eta}. \tag{3.7}$$

Extending the boundary input μ by zero outside the interval $[0,T]$, we take the Laplace transform in time of both sides of (3.5) with transform variable

$$\lambda = \gamma + i\omega$$

to thereby obtain

$$\widehat{A_\Pi^{\frac{\eta}{2}} z_t}(\lambda,\cdot,y=y_0) = \sum_{m,n=1}^{\infty} \frac{\lambda n^\eta}{\lambda^2+\lambda_{mn}} \widehat{\mu_n}(\lambda)\Phi_n(\cdot)\cos my_0. \tag{3.8}$$

Therefore, we can use the generalized Parseval's relation (see [13, p. 212]), (3.6), (3.8), and (3.7) to obtain for fixed $\eta \in [0,3/2]$ and any $\gamma \ge 0$

$$2\pi \int_0^\infty e^{-2\gamma t} \|z_t(t,\cdot,y=y_0)\|^2_{H^\eta(0,\pi)}\,dt = 2\pi \int_0^\infty e^{-2\gamma t} \left\| A_\Pi^{\frac{\eta}{2}} z_t(t,\cdot,y=y_0)\right\|^2_{L^2(0,\pi)} dt$$

$$= \int_{-\infty}^{\infty} \left\| \widehat{A_\Pi^{\frac{\eta}{2}} z_t}(\gamma+i\omega,\cdot,y=y_0)\right\|^2_{L^2(0,\pi)} d\omega$$

$$= \int_{-\infty}^{\infty} \sum_{n=1}^{\infty} \left| \sum_{m=1}^{\infty} \frac{\lambda}{\lambda^2+\lambda_{mn}} \cos my_0 \right|^2 |\widehat{\mu_n}(\lambda)|^2\, n^{2\eta} d\omega. \tag{3.9}$$

We now fix $\gamma > 0$ and specify that $\eta \in [0,5/4]$. Suppose we can find some $\theta \in [0, 5/4-\eta]$ and some positive constant $C_0 > 0$ such that

$$\frac{1}{n^\theta} \left| \sum_{m=1}^{\infty} \frac{\lambda}{\lambda^2+\lambda_{mn}} \cos my_0 \right| < C_0, \tag{3.10}$$

where C_0 does not depend on $\omega \in \mathbb{R}$ or $n = 1, 2, \ldots$. Then (3.9) is equal to

$$\int_{-\infty}^{\infty} \sum_{n=1}^{\infty} \left| \sum_{m=1}^{\infty} \frac{\lambda n^{-\theta}}{\lambda^2+\lambda_{mn}} \cos my_0 \right|^2 |\widehat{\mu_n}(\lambda)|^2\, n^{2(\eta+\theta)} d\omega$$

$$\le C_0 \int_{-\infty}^{\infty} \sum_{n=1}^{\infty} |\widehat{\mu_n}(\lambda)|^2\, n^{2(\eta+\theta)} d\omega = C_0 \int_{-\infty}^{\infty} \left\| \widehat{A_\Pi^{\frac{\eta+\theta}{2}} \mu}(\gamma+i\omega) \right\|^2_{L^2(0,\pi)} d\omega$$

$$= 2\pi C_0 \int_0^T e^{-2\gamma t} \|\mu(t)\|^2_{H^{\eta+\theta}(0,\pi)}\,dt \le 2\pi C_0 \int_0^T \|\mu(t)\|^2_{H^{\frac{5}{4}}(0,\pi)}\,dt. \tag{3.11}$$

Hence, if we can verify (3.10) for some $\theta \in [0, 5/4-\eta]$, then (3.9) and (3.11) imply that there exists C_1 such that

$$\int_0^T \|z_t(t,\cdot,y=y_0)\|^2_{H^\eta(0,\pi)}\,dt \le C_1 \int_0^T \|\mu(t)\|^2_{H^{5/4}(0,\pi)}. \tag{3.12}$$

To attain the sought-after estimate (3.10), it suffices to ascertain the convergence of each of the following sums for some value of $\theta \in [0, 5/4 - \eta]$, with each convergence being again independent of $\omega \in \mathbb{R}$ and $n \in \mathbb{N}$:

(i) $\frac{1}{n^\theta} \left| \sum_{m=1}^{\infty} \frac{2\gamma\omega^2}{(\gamma^2 - \omega^2 + m^2 + n^2)^2 + 4\gamma^2\omega^2} \right|$,

(ii) $\frac{1}{n^\theta} \left| \sum_{m=1}^{\infty} \frac{\omega(\gamma^2 - \omega^2 + m^2 + n^2)}{(\gamma^2 - \omega^2 + m^2 + n^2)^2 + 4\gamma^2\omega^2} \right|$.

In fact, the absolute convergence of these sums, independent of ω and n, has already been shown in [4] for $\theta = 1/2$ (see in particular equations (3.19), (3.33), (3.55), and (3.76) in [4]). With the estimate (3.10) being established for $\theta = 1/2$, we see that (3.12) is true for any η such that $\theta = 1/2 \in [0, 5/4 - \eta]$ and so in particular for $\eta = 3/4$. □

Conclusion of the proof of Theorem 3.1. Now upon the use of the Sobolev embedding theorem in one dimension and Proposition 3.3, we have that for any $(x_0, y_0) \in [0, \pi] \times [0, \pi]$, there exists $M, \tilde{M} > 0$ such that

$$\int_0^T |z_t(t, x = x_0, y = y_0)|^2 \, dt \le \tilde{M} \int_0^T \|z_t(t, \cdot, y = y_0)\|^2_{H^{\frac{3}{4}}(0,\pi)} \, dt$$
$$\le M \|\mu\|^2_{L^2(0,T;H^{\frac{5}{4}}(0,\pi))} .$$

This finishes the proof of Theorem 3.1. □

COROLLARY 3.4. *The system* (2.2) *with observation* $y(t) = \mathcal{C}_3 X(t)$ *is input-output well posed.*

Proof. The first three equations in (2.2) are of the same form as the wave equation (3.1) when $\mu = 0$ on $\Gamma \setminus \Gamma_0$ and $\mu = v_t$ on Γ_0. Theorem 1.1 in [2] implies that there exists $M_1 > 0$ such that

$$\|v_t\|_{L^2(0,T;H^2(\Gamma_0))} \le M_1 \|u\|_{L^2(0,T;U)} . \tag{3.13}$$

Combining this with (3.2) and the fact that $\|\cdot\|_{H^{5/4}(\Gamma_0)} \le \|\cdot\|_{H^2(\Gamma_0)}$, we see that there exists $M_2 > 0$ such that

$$\|z_t(\cdot, x_0, y_0)\|_{L^2(0,T)} \le M_2 \|u\|_{L^2(0,T;U)} ,$$

so the input-output map from $u \in L^2(0,T;U)$ into $\mathcal{C}_3 X = z_t(\cdot, x_0, y_0) \in L^2(0,T)$ is well posed. □

4. Regularity results. In this section we show that when the observation is $\mathcal{C}_2 X(t)$ the system is regular, and when the observation is $\mathcal{C}_3 X(t)$ the system is input-output regular. Since we have shown that the system is well posed in the former case and input-output well posed in the latter case, it suffices to show in both of these cases that the transfer function satisfies condition (5) in Definition 2.6. We first need a few technical lemmas.

Let $\alpha > 0$—we will eventually specialize to α as in (2.1), but all the following lemmas are true for more general α. For $s > 0$, let $\mathbf{T}(s)$ be defined on $\mathcal{D}(\mathring{\mathbf{A}}^{\alpha/4})'$ by

$$\mathbf{T}(s) := \left[\frac{s^2}{s+1} + \mathring{\mathbf{A}} \right]^{-1} . \tag{4.1}$$

Lemma 4.1. *For*

$$0 \leq \theta < 4 - \alpha,$$

there exists $M > 0$ such that for all $s > 0$,

$$\|\mathbf{T}(s)\|_{\mathcal{L}\mathcal{D}\left(\mathring{\mathbf{A}}^{\alpha/4}\right)',\mathcal{D}\left(\mathring{\mathbf{A}}^{\theta/4}\right)} \leq \frac{M}{\left(1+\frac{s^2}{s+1}\right)^{1-\frac{1}{4}(\theta+\alpha)}}. \tag{4.2}$$

Proof. For θ in the prescribed range and $w \in \mathcal{D}(\mathring{\mathbf{A}}^{\alpha/4})'$, we have

$$\|\mathbf{T}(s)w\|_{\mathcal{D}\left(\mathring{\mathbf{A}}^{\theta/4}\right)} = \left\|\left[\frac{s^2}{s+1}+\mathring{\mathbf{A}}\right]^{-1} w\right\|_{\mathcal{D}\left(\mathring{\mathbf{A}}^{\theta/4}\right)}$$

$$= \left\|\mathring{\mathbf{A}}^{\frac{\theta}{4}}\left[\frac{s^2}{s+1}+\mathring{\mathbf{A}}\right]^{-1} w\right\|_{L^2(\Gamma_0)} = \left\|\mathring{\mathbf{A}}^{\frac{\theta}{4}}\left[\frac{s^2}{s+1}+\mathring{\mathbf{A}}\right]^{-1} \mathring{\mathbf{A}}^{\frac{\alpha}{4}}\mathring{\mathbf{A}}^{-\frac{\alpha}{4}} w\right\|_{L^2(\Gamma_0)}.$$

Using Krein [15, Eq. (5.15), p. 115] and (2.4), we see that if $s > 0$, there exists $M > 0$ such that

$$\|\mathbf{T}(s)w\|_{\mathcal{D}\left(\mathring{\mathbf{A}}^{\theta/4}\right)} \leq \frac{M}{\left[1+\frac{s^2}{s+1}\right]^{1-\frac{1}{4}(\theta+\alpha)}}\left\|\mathring{\mathbf{A}}^{-\frac{\alpha}{4}} w\right\|_{L^2(\Gamma_0)}$$

$$= \frac{M}{\left[1+\frac{s^2}{s+1}\right]^{1-\frac{1}{4}(\theta+\alpha)}}\|w\|_{\mathcal{D}\left(\mathring{\mathbf{A}}^{\alpha/4}\right)'}. \qquad \square$$

Remark 4.2. The same type of estimate could be obtained using the fact that $\mathring{\mathbf{A}}$ generates an analytic semigroup, but we did not use analyticity here.

Lemma 4.3. *For large enough $s > 0$ the operator*

$$I + \frac{s^2}{s+1}\mathbf{T}(s)N^*A(s^2+A)^{-1}AN$$

is boundedly invertible on $\mathcal{L}(\mathcal{D}(\mathring{\mathbf{A}}^{\theta/4}))$ for $\theta \in [0, 4-\alpha)$. In particular, there exists $M > 0$ such that for large enough $s > 0$,

$$\left\|\left(I + \frac{s^2}{s+1}\mathbf{T}(s)N^*A(s^2+A)^{-1}AN\right)^{-1}\right\|_{\mathcal{L}\left(\mathcal{D}\left(\mathring{\mathbf{A}}^{\theta/4}\right)\right)} \leq M. \tag{4.3}$$

Proof. We prove this result by considering the Neumann series for

$$\left(I + \frac{s^2}{s+1}\mathbf{T}(s)N^*A(s^2+A)^{-1}AN\right)^{-1};$$

in particular, we show that

$$\lim_{s\to\infty}\left\|\frac{s^2}{s+1}\mathbf{T}(s)N^*A(s^2+A)^{-1}AN\right\|_{\mathcal{L}\left(\mathcal{D}\left(\mathring{\mathbf{A}}^{\theta/4}\right)\right)} = 0. \tag{4.4}$$

Let $w \in \mathcal{D}(\mathring{\mathbf{A}}^{\theta/4})$. From (2.7), $N^*A \in \mathcal{L}(\mathcal{D}(A^{\frac{1}{4}+\epsilon}), L^2(\Gamma_0))$, where $\epsilon > 0$ is arbitrarily small, so there exists $M > 0$ such that

$$\begin{aligned}
\left\|N^*A(s^2+A)^{-1}ANw\right\|_{\mathcal{D}\left(\mathring{\mathbf{A}}^{\alpha/4}\right)'} &\le \left\|N^*A(s^2+A)^{-1}ANw\right\|_{L^2(\Gamma_0)} \\
&\le M\left\|(s^2+A)^{-1}ANw\right\|_{D\left(A^{\frac{1}{4}+\epsilon}\right)} \\
&= M\left\|A^{\frac{1}{4}+\epsilon}(s^2+A)^{-1}ANw\right\|_{L^2(\Omega)} \\
&= M\left\|A^{\frac{1}{2}+2\epsilon}(s^2+A)^{-1}A^{\frac{3}{4}-\epsilon}Nw\right\|_{L^2(\Omega)}. \qquad (4.5)
\end{aligned}$$

Using equation (5.15) on page 115 in [15] and (2.7), we see that

$$(4.5) \le \frac{M}{(1+s^2)^{\frac{1}{2}-2\epsilon}}\left\|A^{\frac{3}{4}-\epsilon}Nw\right\|_{L^2(\Omega)} \le \frac{M}{(1+s^2)^{\frac{1}{2}-2\epsilon}}\|w\|_{L^2(\Gamma_0)}$$

and therefore

$$\left\|N^*A(s^2+A)^{-1}ANw\right\|_{\mathcal{D}\left(\mathring{\mathbf{A}}^{\alpha/4}\right)'} \le \frac{M}{(1+s^2)^{\frac{1}{2}-2\epsilon}}\|w\|_{L^2(\Gamma_0)}. \tag{4.6}$$

Since $\theta > 0$, using (4.6) with (4.2) yields for large $s > 0$

$$\frac{s^2}{s+1}\left\|\mathbf{T}(s)N^*A(s^2+A)^{-1}ANw\right\|_{\mathcal{L}\left(\mathcal{D}\left(\mathring{\mathbf{A}}^{\theta/4}\right)\right)} = \mathcal{O}\left(\frac{1}{s^{1-\frac{1}{4}(\theta+\alpha)-4\epsilon}}\right).$$

Since $\theta+\alpha < 4$ by hypothesis, for $\epsilon > 0$ small enough the equation above implies that (4.4) is true. Hence

$$\begin{aligned}
&\left\|\left(I+\frac{s^2}{s+1}\mathbf{T}(s)N^*A(s^2+A)^{-1}AN\right)^{-1}\right\|_{\mathcal{L}\left(\mathcal{D}\left(\mathring{\mathbf{A}}^{\theta/4}\right)\right)} \\
&\qquad \le \frac{1}{1-\frac{s^2}{s+1}\left\|\mathbf{T}(s)N^*A(s^2+A)^{-1}ANw\right\|_{\mathcal{L}\left(\mathcal{D}\left(\mathring{\mathbf{A}}^{\theta/4}\right)\right)}}
\end{aligned}$$

for $s > 0$ large enough, which finishes the proof of Lemma 4.3. □

For $s > 0$, let

$$\mathbf{H}^1(s) := \left\{I+\frac{s^2}{s+1}\mathbf{T}(s)N^*A(s^2+A)^{-1}AN\right\}^{-1}\frac{s}{s+1}\mathbf{T}(s)B. \tag{4.7}$$

Now let α be as in (2.1), and recall that $B \in \mathcal{L}(U, H^{-\alpha}(\Gamma_0))$. Since $\mathcal{D}(\mathring{\mathbf{A}}^{\eta/4}) = H^{\eta}{}_0(\Gamma_0)$ for $\eta \in [0, 5/2)$, we see that $B \in \mathcal{L}(U, \mathcal{D}(\mathring{\mathbf{A}}^{\alpha/4})')$. Combining Lemmas 4.1 and 4.3 we immediately obtain the following result for the operator $\mathbf{H}^1(s)$.

Lemma 4.4. *$\mathbf{H}^1(s)$ is an element of $\mathcal{L}(U, H^{\theta}(\Gamma_0))$ for $s > 0$ large enough and $\theta \in [0, 4-\alpha)$ and for every θ there exists $M > 0$ such that*

$$\left\|\mathbf{H}^1(s)\right\|_{\mathcal{L}\left(U,\mathcal{D}\left(\mathring{\mathbf{A}}^{\theta/4}\right)\right)} \le \frac{M}{\left[1+\frac{s^2}{s+1}\right]^{1-\frac{1}{4}(\theta+\alpha)}}.$$

We now use these lemmas to prove the regularity of the system (2.2) with observation $\mathcal{C}_2 X(t)$. We first need to show that $\mathbf{H}^1$ is the transfer function from u to v_t.

Lemma 4.5. *Let the solution of* (2.2) *be of the form* (2.8) *with* $u \in L^2_\gamma(0,\infty;U)$ *for some* $\gamma \in \mathbb{R}$ *and with* $X(0) = 0$. *Then, for sufficiently large* $s > 0$,

$$\widehat{v_t}(s) = \mathbf{H}^1(s)\widehat{u}(s). \tag{4.8}$$

Proof. Applying the Laplace transform (in time t) to (2.15), (2.16) for $s \in \mathbb{C}_\beta$, we have, formally,

$$\begin{cases} s^2\widehat{z} = -A\widehat{z} + sAN\widehat{v} \iff \widehat{z} = s(s^2+A)^{-1}AN\widehat{v}, \\ \\ s^2\widehat{v} + \mathring{\mathbf{A}}\widehat{v} + s\mathring{\mathbf{A}}\widehat{v} = -sN^*A\widehat{z} + B\widehat{u}. \end{cases}$$

Substituting the first equation above into the second then yields

$$\left(s^2 + (s+1)\mathring{\mathbf{A}} + s^2N^*A(s^2+A)^{-1}AN\right)\widehat{v} = B\widehat{u}. \tag{4.9}$$

To deal with this equation, we will use the relation

$$(s^2 + (\tilde{A} + \tilde{B}))^{-1} = [I + (s^2+\tilde{A})^{-1}\tilde{B}]^{-1}(s^2+\tilde{A})^{-1}$$

for any operators $\tilde{A}$ and $\tilde{B}$ and scalars s for which all the inverses in the relation exist. Letting $\tilde{A} = (s+1)\mathring{\mathbf{A}}$ and $\tilde{B} = s^2N^*A(s^2+A)^{-1}AN$, we obtain formally

$$\begin{aligned} &\left(s^2 + (s+1)\mathring{\mathbf{A}} + s^2N^*A(s^2+A)^{-1}AN\right)^{-1} \\ &= \left(I + \left(s^2+(s+1)\mathring{\mathbf{A}}\right)^{-1} s^2N^*A(s^2+A)^{-1}AN\right)^{-1}\left(s^2+(s+1)\mathring{\mathbf{A}}\right)^{-1} \\ &= \left(I + \frac{s^2}{s+1}\mathbf{T}(s)N^*A(s^2+A)^{-1}AN\right)^{-1}\frac{1}{s+1}\mathbf{T}(s). \end{aligned} \tag{4.10}$$

Using Lemma 4.3, we see that (4.10) is indeed valid for sufficiently large real s. Using (4.10) in (4.9), we get

$$\widehat{v}(s) = \left(I + \frac{s^2}{s+1}\mathbf{T}(s)N^*A(s^2+A)^{-1}AN\right)^{-1}\frac{1}{s+1}\mathbf{T}(s)B\widehat{u}(s)$$

or

$$\widehat{v_t}(s) = s\hat{v}(s) = \mathbf{H}^1(s)\widehat{u}(s),$$

which finishes the lemma. □

It follows from Lemma 4.5 that for sufficiently large real s the transfer function from $u(t)$ to $y = \mathcal{C}_2X(t)$ is

$$\mathbf{H}_1(s) := C_{\xi_0}\mathbf{H}^1(s)$$

(where we recall that C_{ξ_0} is the point evaluation at $\xi_0 \in \Gamma_0$). Since the system (2.2) with this observation is well posed, there exists $\beta \in \mathbb{R}$ such that $\mathbf{H}_1 \in H^\infty_\beta(\mathcal{L}(U,Y))$; hence this transfer function can be extended analytically for $s \in \mathbb{C}_\beta$.

THEOREM 4.6. $\mathbf{H}_1(s)$ *is a regular transfer function with feedthrough* 0.

Proof. The theorem is proved if we can show that

$$\lim_{s\to\infty, s\in\mathbb{R}} \left\|C_{\xi_0}\mathbf{H}^1(s)\right\|_{\mathcal{L}(U,\mathbb{R})} = 0. \tag{4.11}$$

For $1/2 < \theta < 4-\alpha$, Lemma 4.4 and the Sobolev embedding theorem imply that there exists $M > 0$ such that

$$\left\|C_{\xi_0}\mathbf{H}^1(s)\right\|_{\mathcal{L}(U,\mathbb{R})} \le M\left\|\mathbf{H}^1(s)\right\|_{\mathcal{L}(U,H^\theta(\Gamma_0))} \le \frac{M}{\left[1+\frac{s^2}{s+1}\right]^{1-\frac{1}{4}(\theta+\alpha)}}.$$

Taking the limit as $s \to \infty$ along the real axis finishes the proof of Theorem 4.6. □

We now turn to the transfer function $\mathbf{H}_2(s)$ for (2.2) with the observation $\mathcal{C}_3X(t)$. In the previous section it is proved that this transfer function is well posed, so there exists $\beta \in \mathbb{R}$ such that $\mathbf{H}_2 \in H^\infty_\beta(\mathcal{L}(U,Y))$. We will show that this transfer function is also regular with feedthrough 0. Let

$$\mathbf{H}^2(s) = s(s^2+A)^{-1}AN\mathbf{H}^1(s).$$

We first show that $\mathbf{H}^2$ is the transfer function from u into the velocity z_t of the wave component.

LEMMA 4.7. *Let the solution of* (2.2) *be of the form* (2.8) *with* $u \in L^2_\beta(0,\infty;U)$ *and* $X(0) = 0$. *Then, for sufficiently large real* s,

$$\widehat{z_t}(s) = \mathbf{H}^2(s)\widehat{u}(s). \tag{4.12}$$

Proof. Applying the Laplace transform in time to (2.15), we obtain

$$s^2\widehat{z}(s) = -A\widehat{z}s + AN\widehat{v_t}(s)$$

or, equivalently, using (4.8),

$$\widehat{z} = (s^2+A)^{-1}AN\widehat{v_t} = (s^2+A)^{-1}AN\mathbf{H}^1(s)\widehat{u}(s);$$

(4.12) follows immediately from this. □

It follows from Lemma 4.7 that for sufficiently large real s the transfer function from $u(t)$ to $y(t) = \mathcal{C}_3X(t)$ is

$$\mathbf{H}_2(s) := C_{x_0}\mathbf{H}^2(s).$$

THEOREM 4.8. $\mathbf{H}_2(s)$ *is a regular transfer function with feedthrough* 0.

Proof. Since $\alpha/8 < 1/4$, we can choose $\varepsilon \in (0, 1/4-\alpha/8)$. Using the Sobolev embedding theorem and (2.3), there exist $M_1, M_2 > 0$ such that for $s > 0$,

$$\begin{aligned}\|\mathbf{H}_2(s)\|_{\mathcal{L}(U,\mathbb{R})} &= \left\|C_{x_0}\mathbf{H}^2(s)\right\|_{\mathcal{L}(U,\mathbb{R})} \le M_1\left\|\mathbf{H}^2(s)\right\|_{\mathcal{L}(U,H^{1+\varepsilon}(\Omega)\cap L^2(\Omega)/\mathbb{R})}\\ &= M_2\left\|\mathbf{H}^2(s)\right\|_{\mathcal{L}(U,\mathcal{D}(A^{(1+\varepsilon)/2}))}.\end{aligned} \tag{4.13}$$

The right side of (4.13) is equal to

$$\begin{aligned}&M_2s\left\|A^{\frac{1}{2}+\frac{\varepsilon}{2}}(s^2+A)^{-1}AN\mathbf{H}^1(s)\right\|_{\mathcal{L}(U,L^2(\Omega))}\\ &\quad= M_2s\left\|A^{\frac{3}{4}+\varepsilon}(s^2+A)^{-1}A^{\frac{3}{4}-\frac{\varepsilon}{2}}N\mathbf{H}^1(s)\right\|_{\mathcal{L}(U,L^2(\Omega))}\\ &\quad\le \frac{sM_2}{(1+s^2)^{\frac{1}{4}-\varepsilon}}\left\|A^{\frac{3}{4}-\frac{\varepsilon}{2}}N\mathbf{H}^1(s)\right\|_{\mathcal{L}(U,L^2(\Omega))} \le \frac{sM_3}{(1+s^2)^{\frac{1}{4}-\varepsilon}}\left\|\mathbf{H}^1(s)\right\|_{\mathcal{L}(U,L^2(\Gamma_0))}\end{aligned} \tag{4.14}$$

for some $M_3 > 0$, where we use equation (5.15) in [15] for the second-to-last inequality and (2.7) for the last inequality. Using Lemma 4.4 with $\theta = 0$, the right side of (4.14) is

$$\leq \frac{sM_3}{(1+s^2)^{\frac{1}{4}-\varepsilon}\left(1+\frac{s^2}{s+1}\right)^{1-\frac{\alpha}{4}}}.$$

This shows that

$$\|\mathbf{H}_2(s)\|_{\mathcal{L}(U,\mathbb{R})} = \mathcal{O}\left(s^{-\frac{1}{2}+2\varepsilon+\frac{\alpha}{4}}\right).$$

By our choice of ε, we see that $-1/2 + 2\varepsilon + \alpha/4 < 0$, so

$$\lim_{s\to\infty, s\in\mathbb{R}} \|\mathbf{H}_2(s)\|_{\mathcal{L}(U,\mathbb{R})} = 0.$$

5. Lack of robustness for dynamic stabilization of regular systems.

In this section we present results from the literature on lack of robustness with respect to delays. These results can be easily applied to the structural acoustics system in this paper, or in fact any regular system that satisfies (2.12) and has $R(s, A)$ analytic on $\mathbb{C}_0$ and continuous on $\overline{\mathbb{C}_0}$. We first need to discuss dynamic stabilization in this setting. In the definitions and theorems in this section we deal with generic regular systems, and not just the structural acoustics system in section 2.

Let X, X_c, U, and Y be Hilbert spaces, and recall that X_{-1} is defined as in (2.14). Let Σ_p be a regular system represented by

$$\dot{x}_p = Ax_p + Bu_p, \tag{5.1}$$

$$y_p = C_\Lambda x_p + Du_p, \tag{5.2}$$

where A generates a semigroup on X, $B : U \to X_{-1}$, $C : \mathcal{D}(A) \to Y$, and $D : U \to Y$, where we recall that C_Λ is the Lebesgue extension of C; see [25]. The subscript p stands for *plant*, the system we wish to stabilize. The transfer function for (5.1), (5.2) is $\mathbf{H}(s) := C_\Lambda R(s, A)B + D$.

Let Σ_c be a regular system represented by

$$\dot{x}_c = A^c x_c + B^c u_c, \tag{5.3}$$

$$y_c = C^c_\Lambda x_c + D^c u_c, \tag{5.4}$$

where A^c generates a semigroup on the Hilbert space X_c, $B^c : Y \to (X_c)_{-1}$, $C^c : \mathcal{D}(A^c) \to U$, and $D^c : Y \to U$. The subscript c stands for *controller*. The transfer function for (5.3), (5.4) is $\mathbf{H}^c(s) := C^c_\Lambda R(s, A^c)B^c + D^c$.

We can formally form a closed loop of Σ_p and Σ_c by letting

$$u_p = y_c + v_p, \tag{5.5}$$

$$u_c = y_p + v_c, \tag{5.6}$$

where we assume that the dimension of u_p is equal to the dimension of y_c and the dimension of u_c is equal to the dimension of y_p. This closed loop is illustrated in Figure 5.1 (when $\varepsilon = 0$).

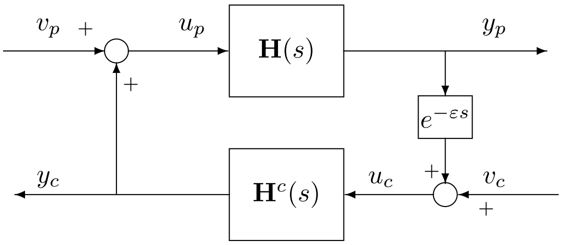

FIG. 5.1. *The closed loop of* Σ_p *and* Σ_c*.*

There are several difficulties associated with making the connections (5.5) and (5.6); these are covered in detail in Weiss and Curtain [27]. Briefly, we assume that $\mathbf{H}^c$ is an *admissible feedback transfer function* for $\mathbf{H}$, which means that $I-\mathbf{H}^c(s)\mathbf{H}(s)$ is invertible for all s in some right half plane, and its inverse is a well posed $\mathcal{L}(U)$-valued transfer function. This condition guarantees that the parallel connection of Σ_p and Σ_c is a well-posed linear system $\Sigma_{p,c}$ with state $[x_p, x_c]^T \in X \times X_c$, input $[v_p, v_c]^T \in U \times Y$, and output $[y_p, y_c]^T \in Y \times U$. If we assume in addition that $I - D^cD$ is invertible in $\mathcal{L}(U)$, then it is shown in [27] that $\Sigma_{p,c}$ is regular as well, with generating operator

$$A_{p,c} := \begin{bmatrix} A + B(I - D^cD)^{-1}D^cC_\Lambda & B(I - D^cD)^{-1}C^c_\Lambda \\ B^c(I - DD^c)^{-1}C_\Lambda & A^c + B^c(I - CC^c)^{-1}DC^c_\Lambda \end{bmatrix} \tag{5.7}$$

on its natural domain.

DEFINITION 5.1. *The regular system* Σ_c *is a regular stabilizing controller for* Σ_p *if* $\mathbf{H}^c$ *is an admissible feedback transfer function for* $\mathbf{H}$*,* $I-D^cD$ *is invertible in* $\mathcal{L}(U)$*, and* $A_{p,c}$ *generates an exponentially stable semigroup on* $X \times X_c$*.*

Remark 5.2. The above definition of a regular stabilizing controller includes static feedback as a special case, since a regular controller can be of the form $y = D^cu$. In this case $A_{p,c}$ generates an exponentially stable semigroup if and only if $A + B(I - D^cD)^{-1}D^cC_\Lambda$ does.

We now consider the effect of a time delay in the plant output. Let $\varepsilon > 0$ and suppose that (5.6) is replaced by

$$u_c(t) = y_p(t - \varepsilon) + v_c(t), \tag{5.8}$$

which is illustrated in Figure 5.1. The transfer function for this system is

$$\mathbf{F}^\varepsilon(\mathbf{H}, \mathbf{H}^c) := \begin{bmatrix} \mathbf{H}(I - e^{-\varepsilon\cdot}\mathbf{H}^c\mathbf{H})^{-1} & \mathbf{H}\mathbf{H}^c(I - e^{-\varepsilon\cdot}\mathbf{H}\mathbf{H}^c)^{-1} \\ e^{-\varepsilon\cdot}\mathbf{H}^c\mathbf{H}(I - e^{-\varepsilon\cdot}\mathbf{H}^c\mathbf{H})^{-1} & \mathbf{H}^c(I - e^{-\varepsilon\cdot}\mathbf{H}\mathbf{H}^c)^{-1} \end{bmatrix},$$

that is,

$$[\hat{v}_p, \hat{v}_c]^T = \mathbf{F}^\varepsilon[\hat{y}_p, \hat{y}_c]^T.$$

DEFINITION 5.3. *Suppose* $\mathbf{F}^0(\mathbf{H}, \mathbf{H}^c)$ *is input-output stable (see Definition* 2.5*). Then we say that the input-output stability of* $\mathbf{F}^0(\mathbf{H}, \mathbf{H}^c)$ *is robust with respect to delays if there exists* $\varepsilon^* > 0$ *such that* $\mathbf{F}^\varepsilon(\mathbf{H}, \mathbf{H}^c)$ *is input-output stable for all* $\varepsilon \in [0, \varepsilon^*)$*.*

Remark 5.4. In the case where the controller is static, it is easy to show that $\mathbf{F}^{\varepsilon}(\mathbf{H}, \mathbf{H}^c)$ is input-output stable if and only if $(I - e^{-\varepsilon \cdot}\mathbf{H}\mathbf{H}^c)^{-1}$ is input-output stable. Hence in this case the input-output stability of $\mathbf{F}^0(\mathbf{H}, \mathbf{H}^c)$ is robust with respect to delays if there exists $\varepsilon^* > 0$ such that $(I - e^{-\varepsilon \cdot}\mathbf{H}D^c)^{-1}$ is input-output stable for all $\varepsilon \in [0, \varepsilon^*)$, and we say that the input-output stability of $(I - \mathbf{H}D)^{-1}$ is robust with respect to delays.

Remark 5.5. If a regular system is exponentially stable (i.e., the semigroup is exponentially stable), then it is input-output stable; see Weiss [25]. Hence, if a regular transfer function is not stable, no regular realization of it is going to be exponentially stable. On the other hand, input-output stability does not necessarily imply exponential stability of the underlying semigroup generator, or even strong stability. Hence, even if we do not identify a state space realization for $\mathbf{F}^{\varepsilon}(\mathbf{H}, \mathbf{H}^c)$, a lack of robustness of the input-output stability of $\mathbf{F}^0(\mathbf{H}, \mathbf{H}^c)$ with respect to delays is quite strong.

We now present results about lack of robustness with respect to delays, and apply these results to our structural acoustics model. These results are simple corollaries of the following frequency domain theorem from [17].

THEOREM 5.6 ([17, Thm. 8.5]). *Suppose U and Y are finite dimensional,* $\mathbf{H}\mathbf{H}^c$ *is regular, and* $\mathbf{F}^0(\mathbf{H}, \mathbf{H}^c)$ *is input-output stable. If*

$$\limsup_{|s| \in \mathbb{C}_0, s \to \infty} \|\mathbf{H}(s)\|_{\mathcal{L}(U,Y)} = \infty, \tag{5.9}$$

then the input-output stability of $\mathbf{F}^0(\mathbf{H}, \mathbf{H}^c)$ *is not robust with respect to delays. In particular, there exist sequences* $\{\varepsilon_n\}$ *and* $\{p_n\}$ *with*

$$\varepsilon_n > 0, \qquad \varepsilon_n \to 0, \qquad p_n \in \mathbb{C}_0, \qquad |\mathrm{Im}(p_n)| \to \infty,$$

such that for any $n \in \mathbb{N}$, p_n *is a pole of* $\mathbf{H}\mathbf{H}^c(I - e^{-\varepsilon_n \cdot}\mathbf{H}\mathbf{H}^c)^{-1}$ *and hence of the overall closed-loop transfer function* $\mathbf{F}^e(\mathbf{H}, \mathbf{H}^c)$.

The following two corollaries will be useful for the system under consideration in this paper.

COROLLARY 5.7. *Suppose U and Y are finite dimensional,* $\Sigma_p = (A, B, C)$ *is a regular system,* $R(s, A)$ *is analytic on* $\mathbb{C}_0$ *and continuous on* $\overline{C_0}$, *and*

$$\limsup_{|s| \to \infty, s \in \mathbb{C}_0} \|R(s, A)\|_{\mathcal{L}(X)} = \infty. \tag{5.10}$$

If there exists a regular stabilizing controller Σ_c *for* Σ_p, *then the input-output stability of* $\mathbf{F}^0(\mathbf{H}, \mathbf{H}^c)$ *is not robust with respect to delays. In particular, the conclusions in Theorem* 5.6 *hold.*

Proof. In Weiss and Rebarber [28] it is shown that if there exists a regular stabilizing controller for Σ_p, then (5.9) holds if and only if (5.10) holds, so we can apply Theorem 5.6. □

As a special case of Corollary 5.7, we consider the static feedback case. We do not need the analyticity of $R(s, A)$ in $\mathbb{C}_0$ here, since we use the results in [21] instead of the results in [28].

COROLLARY 5.8. *Suppose U and Y are finite dimensional,* $\Sigma_p = (A, B, C)$ *is a regular system, and* (5.10) *holds. If there exists* $K \in \mathcal{L}(Y, U)$ *such that the closed-loop generator* $A + BKC_\Lambda$ *generates an exponentially stable semigroup, then the stability of* $(I - \mathbf{H}K)^{-1}$ *is not robust with respect to delays. In particular, the conclusions in Theorem* 5.6 *hold for the poles of* $(I + e^{\varepsilon_n \cdot}\mathbf{H}DK)^{-1}$.

We now turn to the structural acoustics model we have analyzed in previous sections. Since this system satisfies the conditions in Corollary 5.7, we can immediately apply Corollaries 5.7 and 5.8.

Case 1. Suppose the observation is given by

$$\mathcal{C}X(t) = [v(\alpha_1), \ldots , v(\alpha_j), v_t(\beta_1), \ldots , v_t(\beta_k)]^T \tag{5.11}$$

for $\{\alpha_i\}_{i=1}^{j}, \{\beta_i\}_{i=1}^{k} \subset \Gamma_0$. In particular, we assume in this case that the observation does not include any point evaluations of acoustic pressure. Then, by Proposition 2.3 and Theorem 4.6, the system (2.2) with this observation is a regular system, which can be represented by (2.20). Since this system satisfies (2.12), Corollary 5.7 applies to this system, and we obtain the following result.

THEOREM 5.9. *There is no regular dynamic controller using an observation of the form* (5.11) *that stabilizes the structural acoustics model robustly with respect to delays.*

COROLLARY 5.10. *Let $\mathcal{A}$ and $\mathcal{B}$ be as in sections* 2, 3, *and* 4, *and $\mathcal{C}$ be any observation of the form* (5.11). *Then there does not exist $K \in \mathcal{L}(Y, U)$ such that $\mathcal{A} + \mathcal{B}K\mathcal{C}$ generates a C_0-semigroup in a way that is robustly stable with respect to delays.*

Remark 5.11. Note that we have not made any claims about whether one can find an exponentially stabilizing regular dynamic controller in the case where the observation is only taken along the beam and not inside the cavity. We believe that it is unlikely that there is such a stabilizing dynamic controller, but proving this might be difficult: most such lack-of-stabilizability results require either the input operator or observation operator to be bounded, which is not the case here. However, if the control design anticipates small but uncertain delays, then this result shows that no dynamic stabilizer can do the job.

Case 2. Suppose the observation is given by

$$\mathcal{C}X(t) = [v(\alpha_1), \ldots , v(\alpha_j), v_t(\beta_1), \ldots , v_t(\beta_k), z_t(x_i), \ldots , z_t(x_l)]^T \tag{5.12}$$

for $\{\alpha_i\}_{i=1}^{j}, \{\beta_i\}_{i=1}^{k} \subset \Gamma_0$ and $\{x_i\}_{i=1}^{l} \subset \overline{\Omega}$.

As discussed in section 1, since this observation includes point evaluation of acoustic pressure, there is no natural and convenient state space realization; hence we state our results in terms of transfer functions and input-output stabilization. Since $\mathbf{H}(s) = \mathcal{C}_\Lambda R(s, A)\mathcal{B}$ and (5.10) holds, it is possible that $\mathbf{H}$ is unstable, but this is not guaranteed, since there might be many pole-zero cancellations. We will take the point of view that if $\mathbf{H}(s)$ is stable, then it can be robustly stabilized by the zero feedback, and focus our attention on the case where $\mathbf{H}$ is unstable.

THEOREM 5.12. *Suppose the transfer function* $\mathbf{H}$ *for the system* (2.2) *with observation* (5.12) *is not stable. Suppose further that* $\mathbf{H}^c$ *is well posed and is such that* $\mathbf{F}^0(\mathbf{H}, \mathbf{H}^c)$ *is stable (see Definition* 2.5*). Then the stability of* $\mathbf{F}^0(\mathbf{H}, \mathbf{H}^c)$ *is not robust with respect to delays. In particular, the conclusions in Theorem* 5.6 *hold.*

Proof. By Theorems 4.6 and 4.8, $\mathbf{H}$ is regular with feedthrough 0. Since $\mathbf{H}^c$ is well posed, $\mathbf{H}\mathbf{H}^c$ is regular with feedthrough 0. Since $\mathbf{H}$ is analytic in $\overline{\mathbb{C}_0}$, the only way it can be unstable is if (5.9) is satisfied. The conclusion follows from Theorem 5.6. □

Remark 5.13. The above results will still be true if $\mathcal{C}$ is replaced by any observation operator such that the open-loop system is regular. We focus on the particular observations (5.11) and (5.12) because point observation of the beam displacement, beam velocity, and acoustic pressure are well motivated physically.

6. Comparison with numerical results.

The feedback control we considered in the previous section (see Figure 5.1) is not the same as the control discussed in [8]. In [8] a noise term $\eta(t)$ and an exogenous forcing function $f(t)$ are included in the plant, and the feedback compensator includes a tracking term. In that paper numerical studies are done on a (necessarily finite dimensional) Galerkin approximation to the system and controller. Among these studies is a look at the effect of delays introduced in three places in the feedback loop for this finite dimensional model. In this section we give some results about the effect of these delays on the full infinite-dimensional model for this system. We then give some heuristic explanations for the numerical results obtained in [8] for the finite dimensional model, using a frequency domain analysis.

In [8] the fourth equation in (2.2) is replaced by

$$v_{tt}(\xi,t) = -\Delta^2 v(\xi,t) - \Delta^2 v_t(\xi,t) - z_t(\xi,t) + Bu(t) + b(\xi)f(t), \qquad \xi\in\Gamma_0, \quad t\in[0,\infty), \tag{6.1}$$

where b represents the spatial distribution of the forcing term. In [8] $b(\zeta)\equiv 1$, that is, the forcing term acts the same on all points of the active boundary. We further include the noise term $\mathcal{E}\eta(t)$ in the model, where $\eta(t)\in W$, a Hilbert space, and $\mathcal{E}\in\mathcal{L}(W,\mathcal{X})$. Therefore (2.13) is augmented to

$$\dot{X}(t) = \mathcal{A}X(t) + \mathcal{B}u(t) + \mathcal{B}_1 f(t) + \mathcal{E}\eta(t), \tag{6.2}$$

where

$$\mathcal{B}_1 = [0,0,0,b]^T \in \mathcal{X}.$$

Let $\mathcal{C}$ be of the form (5.11) or (5.12), let p be the dimension of the range of $\mathcal{C}$, and let $Y=\mathbb{R}^p$. The observation for (6.2) will be formally given by

$$y(t) = \mathcal{C}_\Lambda X(t) + E\eta(t), \tag{6.3}$$

where $E\in\mathcal{L}(W,Y)$. We do not worry here about the admissibility of $\mathcal{C}$ for $S(t)$, since we will be doing our robustness analysis in the frequency domain, and that analysis is justified by the work in sections 3 and 4. Also, we do not have a feedthrough term $Du(t)$ in the observation (6.3) because, as shown in section 4, the feedthrough is zero.

If the initial condition is $X(0)=X_0$, the system (6.2), (6.3) can be described in input-output terms as

$$\hat{y}(s) = \mathbf{H}(s)\hat{u}(s) + \mathbf{H}_1(s)\hat{f}(s) + \mathbf{H}_2(s)\hat{\eta}(s) + \hat{\nu}(s); \tag{6.4}$$

here ν is the observation of the system, depending on the initial data X_0, but with $u\equiv 0$, $\eta\equiv 0$, and $f\equiv 0$. $\mathbf{H}$ is the transfer function from u to y (analyzed in detail in sections 3 and 4), $\mathbf{H}_1$ is the transfer function from f to y, and $\mathbf{H}_2$ is the transfer function from η to y. If the observation $\mathcal{C}$ does not contain point observations of acoustic pressure, we can write

$$\hat{\nu}(s) = \mathcal{C}_\Lambda R(s,\mathcal{A})X_0, \qquad \mathbf{H}(s) = \mathcal{C}_\Lambda R(s,\mathcal{A})\mathcal{B}, \tag{6.5}$$

$$\mathbf{H}_1(s) = \mathcal{C}_\Lambda R(s,\mathcal{A})\mathcal{B}_1, \qquad \mathbf{H}_2(s) = \mathcal{C}_\Lambda R(s,\mathcal{A})\mathcal{E} + E. \tag{6.6}$$

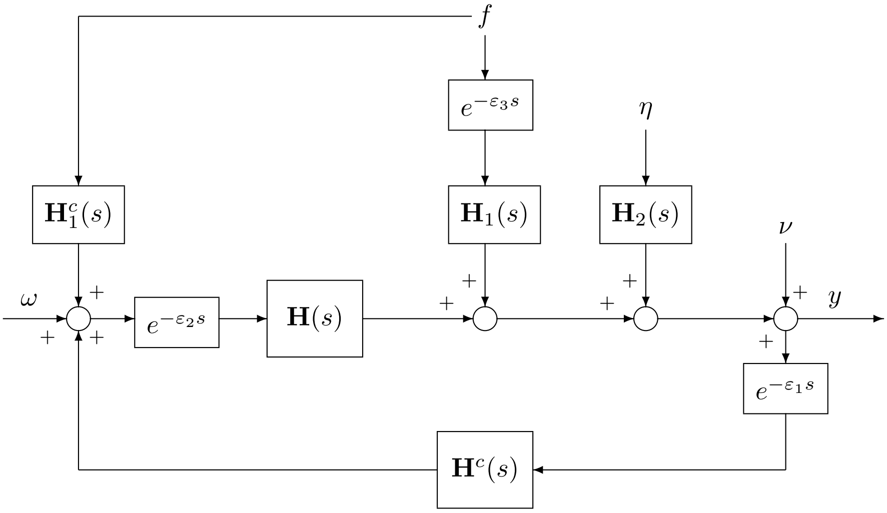

FIG. 6.1. *Controller with tracking and delays.*

If $\mathcal{C}$ does contain point observations of acoustic pressure, results in sections 3 and 4 show that $\mathbf{H}_1$ is regular with feedthrough 0. In this case, since $\mathcal{C}$ is not even bounded on $\mathcal{D}(\mathcal{A})$, the other transfer functions in (6.5), (6.6) are regular only if X_0 and $\mathcal{E}$ are sufficiently smooth. We will assume in this section that this is the case.

We will not be concerned about the exact nature of the feedback here, but we will insist that the controller be of the following form in the frequency domain:

$$\hat{u}(s) = \mathbf{H}^c(s)\hat{y}(s) + \mathbf{H}_1^c(s)\hat{f}(s) + \hat{\omega}(s), \tag{6.7}$$

where $\mathbf{H}^c$ and $\mathbf{H}_1^c$ are well-posed transfer functions, $\mathbf{H}_1^c$ contains any tracking terms, and $\hat{\omega}$ contains initial state information for the compensator. The feedback control in [8] is of this form if the solutions to two algebraic Riccati equations exist and are of sufficient smoothness; it is also of this form if it is a finite dimensional controller computed using the Galerkin approximation to the system. The closed-loop system is shown in Figure 6.1, ignoring the delay blocks.

Solving for $\hat{y}$ in (6.4) and (6.7), we obtain

(6.8)
$$\hat{y} = (I - \mathbf{H}\mathbf{H}^c)^{-1}\mathbf{H}_2\hat{\eta} + (I - \mathbf{H}\mathbf{H}^c)^{-1}(\mathbf{H}_1 + \mathbf{H}\mathbf{H}_1^c)\hat{f} + (I - \mathbf{H}\mathbf{H}^c)^{-1}(\mathbf{H}\hat{w} + \hat{\nu}).$$

An obvious design goal for the compensator is to make the transfer function from ω to y and the transfer function from ν to y stable, so we assume that $\mathbf{H}^c$ has been chosen so that

$$(I - \mathbf{H}\mathbf{H}^c)^{-1} \in H^\infty \qquad \text{and} \qquad (I - \mathbf{H}\mathbf{H}^c)^{-1}\mathbf{H} \in H^\infty. \tag{6.9}$$

As in [8], we consider delays in three places in the feedback loop:
(1) A delay $\varepsilon_1 \geq 0$ in the plant output $y(t)$;
(2) A delay $\varepsilon_2 \geq 0$ in the input voltage $u(t)$; and
(3) A delay $\varepsilon_3 \geq 0$ in the forcing signal $f(t)$.

These three delays are shown in Figure 6.1. When these delays are taken into account, (6.8) becomes

$$\hat{y} = (I - e^{-(\varepsilon_1+\varepsilon_2)\cdot}\mathbf{H}\mathbf{H}^c)^{-1}\mathbf{H}_2\hat{\eta} + (I - e^{-(\varepsilon_1+\varepsilon_2)\cdot}\mathbf{H}\mathbf{H}^c)^{-1}(\mathbf{H}\hat{w} + \hat{\nu})$$

$$+ (I - e^{-(\varepsilon_1+\varepsilon_2)\cdot}\mathbf{H}\mathbf{H}^c)^{-1}(\varepsilon^{-\varepsilon_3\cdot}\mathbf{H}_1 + \varepsilon^{-\varepsilon_2\cdot}\mathbf{H}\mathbf{H}_1^c)\hat{f}. \tag{6.10}$$

In the following results, when we write ε_n, we assume that it is not ε_1, ε_2, or ε_3 as defined above.

PROPOSITION 6.1. *Suppose* (6.9) *holds and* $\mathbf{H}$ *is not stable. Then there exist sequences* $\{\varepsilon_n\}$ *and* $\{p_n\}$ *with*

$$\varepsilon_n > 0, \qquad \varepsilon_n \to 0, \qquad p_n \in \mathbb{C}_0, \qquad |\mathrm{Im}(p_n)| \to \infty$$

such that for any $n \in \mathbb{N}$, p_n *is a pole of* $(I - e^{-(\varepsilon_1+\varepsilon_2)\cdot}\mathbf{H}\mathbf{H}^c)^{-1}$ *when* $\varepsilon_1 + \varepsilon_2 = \varepsilon_n$.

Proof. In sections 3 and 4 we showed that $\mathbf{H}$ is regular with feedthrough 0. Since $\mathbf{H}^c$ is well posed, $\mathbf{H}\mathbf{H}^c$ is regular with feedthrough 0. We first need to show that

$$\limsup_{s\in\mathbb{C}_0, |s|\to\infty} \|\mathbf{H}(s)\mathbf{H}^c(s)\|_{\mathcal{L}(Y)} = \infty. \tag{6.11}$$

Suppose (6.11) is not true. Then there exist $R, M > 0$ such that

$$\|I - \mathbf{H}(s)\mathbf{H}^c(s)\|_{\mathcal{L}(Y)} \le M \quad \text{for } s \in \mathbb{C}_0 \cap \{|s| > R\}. \tag{6.12}$$

Note that

$$\mathbf{H} = (I - \mathbf{H}\mathbf{H}^c)(I - \mathbf{H}\mathbf{H}^c)^{-1}\mathbf{H},$$

so (6.12) and the second equation in (6.9) imply that $\|\mathbf{H}(s)\|_{\mathcal{L}(U,Y)}$ is bounded for $s \in \mathbb{C}_0 \cap \{|s| > R\}$, which contradicts the hypothesis that $\mathbf{H}$ is unstable and the fact that $\mathbf{H}$ is analytic in $\mathbb{C}_0$. Hence (6.11) must be true. Using Lemma 6.3 in [17], we get

$$\limsup_{s\in\mathbb{C}_0, |s|\to\infty} r(\mathbf{H}(s)\mathbf{H}^c(s)) = \infty,$$

where r denotes the spectral radius. Theorem 5.3 in [17] now implies that there exist sequences $\{\varepsilon_n\}$ and $\{p_n\}$ with

$$\varepsilon_n > 0, \qquad \varepsilon_n \to 0, \qquad p_n \in \mathbb{C}_0, \qquad |\mathrm{Im}(p_n)| \to \infty,$$

such that for any $n \in \mathbb{N}$, p_n is a pole of $(I - e^{-(\varepsilon_1+\varepsilon_2)\cdot}\mathbf{H}\mathbf{H}^c)^{-1}\mathbf{H}\mathbf{H}^c$ when $\varepsilon_1 + \varepsilon_2 = \varepsilon_n$. The proposition now follows from the fact that

$$(I - e^{-(\varepsilon_1+\varepsilon_2)\cdot}\mathbf{H}\mathbf{H}^c)^{-1} = e^{-(\varepsilon_1+\varepsilon_2)\cdot}(I - e^{-(\varepsilon_1+\varepsilon_2)\cdot}\mathbf{H}\mathbf{H}^c)^{-1}\mathbf{H}\mathbf{H}^c + I. \qquad \square$$

In [8], numerical tests imply that the stability of the closed-loop system can handle small delays ε_3 in the forcing function $f(t)$, can tolerate very small delays ε_1 in $y(t)$, and becomes unstable for any delays ε_2 in $u(t)$. Direct comparison of the lack-of-robustness results in Proposition 6.1 with the results in [8] is difficult, since our results are for the full infinite dimensional system and controller, and the results in [8] are for a finite dimensional approximation of the system and controller, and also because the results in [8] are for only one initial state. Nonetheless, we can use our framework to give heuristic explanations for the results from [8].

Since in the envisioned applications $f(t)$ will be periodic, we cannot necessarily expect that $y(t)$ defined by (6.10) is in $L^2[0,\infty;Y]$, even if the transfer functions are stable. However, we will assume that the tracking component of the controller is chosen to minimize the effect of f on y. In particular, we assume that $\mathbf{H}_1^c$, which contains the tracking component of the controller, is chosen so that the term $(\mathbf{H}_1 + \mathbf{H}\mathbf{H}_1^c)$ in (6.8) has relatively small H^∞-norm. First suppose that $\varepsilon_3 = 0$. Both ε_1 and ε_2 effect $(I - e^{-(\varepsilon_1+\varepsilon_2)\cdot}\mathbf{H}\mathbf{H}^c)^{-1}$, and ε_2 also effects the term $(\mathbf{H}_1 + e^{-\varepsilon_2\cdot}\mathbf{H}\mathbf{H}_1^c)$ in (6.10). Since $e^{-\varepsilon_2 s}$ can be far from 1 when s is on the imaginary axis and $|s|$ is large, small ε_2 could easily counteract the minimizing effect of $\mathbf{H}_1^c$ on $\|\mathbf{H}_1(s) + e^{-\varepsilon_2 s}\mathbf{H}(s)\mathbf{H}_1^c(s)\|$. Thus, ε_2 should have a stronger destabilizing effect on the closed-loop system than ε_1, which has exactly the same effect on $(I - e^{-(\varepsilon_1+\varepsilon_2)\cdot}\mathbf{H}\mathbf{H}^c)^{-1}$ as ε_2 does.

Now suppose that $\varepsilon_1 = \varepsilon_2 = 0$. The delay ε_3 only effects the term $(e^{-\varepsilon_3\cdot}\mathbf{H}_1 + \mathbf{H}\mathbf{H}_1^c)$ in (6.10), and can easily counteract the effect of $\mathbf{H}_1^c$ on $\|(e^{-\varepsilon_3 s}\mathbf{H}_1(s) + \mathbf{H}(s)\mathbf{H}_1^c(s))\|$ for s on the imaginary axis. However, since $\mathcal{B}_1$ is quite smooth—for instance, in [8] it is $[0,0,0,1]^T$—it is possible that $\mathbf{H}_1(s) = \mathcal{C}R(s,\mathcal{A})\mathcal{B}_1$ is not large when s is on the imaginary axis and $|s|$ is large. This would mitigate the effect of ε_3 on $(e^{-\varepsilon_3\cdot}\mathbf{H}_1 + \mathbf{H}\mathbf{H}_1^c)$.

7. Conclusions. To obtain the results in this paper, we used a combination of techniques. As we have seen in sections 5 and 6, the effect of small delays on feedback control is best handled using a frequency domain approach. In order to use this approach we first must show that the structural acoustics system under consideration is in the class of *regular* systems; we can then readily apply results in [17] about delay robustness for regular systems. It is often a challenge to show that a given system is regular. For the structural acoustic model in a rectangular cavity, to prove regularity we used sharp PDE estimates from [1, 2, 3, 4], C_0-semigroup results from [15], and delicate estimates involving harmonic analysis; for nonrectangular cavities, microlocal analysis is required (see [5]).

Since there is extensive literature on control design for regular systems, the implications of regularity go beyond the study of robustness with respect to delays. For instance, it might be possible to use the regular systems framework to study the effect of additive perturbations on output feedback stabilization [19], to design adaptive control [18], to give Youla parametrizations for stabilizing controllers [27], or to study the relationship between input-output stabilization and exponential stabilization [21, 22].

EQUIVALENT CONDITIONS FOR STABILIZABILITY OF INFINITE-DIMENSIONAL SYSTEMS WITH ADMISSIBLE CONTROL OPERATORS[*]

BIRGIT JACOB[†] AND HANS ZWART[‡]

Abstract. In this paper we study the optimizability of infinite-dimensional systems with admissible control operators. We show that under a weak condition such a system is optimizable if and only if the system can be split into an exponentially stable subsystem and an unstable subsystem that is exactly controllable in finite time. The state space of the unstable subsystem equals the span of all unstable (generalized) eigenvectors of the original system. This subsystem can be infinite-dimensional. Furthermore, the unstable poles satisfy a summability condition. The state space of the exponentially stable subsystem is given by all vectors for which the action of the original C_0-semigroup is stable.

Key words. infinite-dimensional systems, stabilizability, optimizability, controllability

1. Introduction.

This paper is concerned with the stabilization of infinite-dimensional systems with a finite-dimensional input space described by the following abstract differential equation:

$$\begin{aligned} \dot{x}(t) &= Ax(t) + Bu(t), \quad t \geq 0 \\ x(0) &= x_0, \end{aligned} \tag{1}$$

where A is the infinitesimal generator of the C_0-semigroup $T(t)$ on the separable Hilbert space H and B is the control operator.

Since the early days of infinite-dimensional systems theory, researchers have tried to characterize conditions under which (1) is stabilizable; see, e.g., the survey articles by Pritchard and Zabczyk [23] and by Russell [29]. In the early 1970s Datko [4] found a characterization in terms of the cost functional

$$J(x_0, u) := \int_0^\infty \|x(t)\|^2 + \|u(t)\|^2 \, dt. \tag{2}$$

He proved that if B is a bounded operator, then there exists a bounded feedback F such that $A + BF$ generates an exponentially stable semigroup if and only if for every $x_0 \in H$ there exists an input u such that $J(x_0, u) < \infty$.

It was only in the mid-1980s that for the class of bounded control operators other necessary and sufficient conditions were found; see Desch and Schappacher [5], Jacobson and Nett [17], and Nefedov and Sholokhovich [20]. Independently of each other, they showed the following result. Here $\mathcal{L}(X_1, X_2)$ denotes the class of linear, bounded operators from X_1 to X_2.

THEOREM 1.1. *Consider the system* (1) *with* $B \in \mathcal{L}(\mathbb{C}^m, H)$. *Then the following conditions are equivalent.*

1. *There exists an* $F \in \mathcal{L}(H, \mathbb{C}^m)$ *such that* $A + BF$ *generates an exponentially stable* C_0*-semigroup.*
2. *It is possible to split the state space as* $H = H_u \oplus H_s$ *such that* $T(t)|_{H_s}$ *is exponentially stable,* H_u *is finite-dimensional and the restriction of* (1) *to* H_u *is exactly controllable in finite time.*

Looking at the proof of this theorem, we observe that from the fact that B and F are bounded, finite-rank operators it was obtained that there are only finitely many unstable eigenvalues. Furthermore, H_u is the span over the eigenspaces corresponding to these eigenvalues.

In the eighties the first results for unbounded control operators were found. In general, the class of unbounded control operators consists of those operators B for which

$$\int_0^{t_1} T(t_1 - \rho) B u(\rho)\, d\rho$$

defines a bounded linear operator from $\boldsymbol{L}_2(0, t_1; \mathbb{C}^m)$ to H. Following Weiss [32], we call B an *admissible control operator for* $T(t)$. If B is such an admissible control operator for $T(t)$, then for every x_0 and for every $u \in \boldsymbol{L}_2^{loc}(0, \infty; \mathbb{C}^m)$, (1) has a unique solution $x(\cdot)$ which lies in H and is continuous; see Weiss [33].

Flandoli, Lasiecka, and Triggiani [8] extended the result of Datko to the class of admissible control operators for $T(t)$. Among others, they showed the following.

THEOREM 1.2. *Consider the system* (1), *where the operator* B *is an admissible control operator for* $T(t)$. *Then the following conditions are equivalent.*

1. *System* (1) *is* optimizable*; i.e., for every element* $x_0 \in H$ *there exists an input* $u \in \boldsymbol{L}_2(0, \infty; \mathbb{C}^m)$ *such that the cost functional* $J(x_0, u)$*, given by* (2), *is finite.*
2. *There exist an exponentially stable semigroup* $T_F(t)$ *with infinitesimal generator* $A_F : D(A_F) \to H$, *and an* $F \in \mathcal{L}(D(A_F), \mathbb{C}^m)$ *such that*
   (a) $FT_F(\cdot) : D(A_F) \to \boldsymbol{L}_2(0, \infty; \mathbb{C}^m)$ *extends to a bounded linear operator from* H *to* $\boldsymbol{L}_2(0, \infty; \mathbb{C}^m)$*;*
   (b) *For every* $t > 0$ *and* $x_0 \in H$ *there holds*

$$T_F(t)x_0 = T(t)x_0 + \int_0^t T(t - \rho) BFT_F(\rho) x_0\, d\rho. \tag{3}$$

The extension of Theorem 1.1 for the case that B is an admissible control operator for $T(t)$ and F is a bounded operator can be found in Rebarber [25]. The aim of this paper is to show that Theorem 1.1 can be extended to admissible control operators for $T(t)$ and to feedback operators satisfying condition 2 of Theorem 1.2. The implication part 2 to part 1 is relatively easy, so we will concentrate on the other direction.

Before we summarize our results, we have to introduce some notation. We say that the generator A of a C_0-semigroup satisfies the *spectrum decomposition assumption (SDA) at* g, $g \in \mathbb{R}$, if there exist real numbers $g_1 < g < g_2$ such that there is no spectrum of A with real part between g_1 and g_2. In particular, we say that A satisfies the SDA if A satisfies SDA at 0. Hence the SDA states that the spectrum can be split into a "stable" and an "unstable" part. The main result that we prove in this paper is the following.

THEOREM 1.3. *Consider the system* (1), *where the operator* B *is an admissible finite-rank control operator for* $T(t)$. *If the system is optimizable and* A *satisfies the SDA, then it is possible to split the state space as* $H = H_s \oplus H_u$, *where*

$$\begin{aligned} H_s &= \{x_0 \in H \mid T(t)x_0 \in \boldsymbol{L}_2(0,\infty;H)\}, \\ H_u &= \overline{\operatorname*{span}_{\lambda\in\sigma(A) with\ Re(\lambda)\geq 0} P_\lambda H}. \end{aligned}$$

Here $P_\lambda H$ *denotes the spectral subspace corresponding to the eigenvalue* λ.

Moreover, H_s *as well as* H_u *is a* $T(t)$*-invariant subspace,* $T(t)|_{H_s}$ *is exponentially stable,* $T(t)|_{H_u}$ *is a group and the restriction of* (1) *to* H_u *is exactly controllable in finite time.*

A result similar to those of Theorem 1.3 holds if the system $(A + gI, B)$ is optimizable and if $A + gI$ satisfies the SDA. So one sees that the only difference between bounded and unbounded control operators lies in the fact that H_u may be infinite-dimensional and that we have to assume the SDA.

One may interpret this theorem as follows. If the system is optimizable and the spectrum can be split into a stable and unstable part, then the state space can be split in the corresponding way. Note that for general infinite-dimensional systems such a splitting of the state space is not always possible, even if one can split the spectrum. There exist infinitesimal generators whose spectrum lies in the left-half plane and is bounded away from the imaginary axis, but they generate an unstable semigroup; see, e.g., Zabczyk [39].

It may seem that the spectrum decomposition assumption is very strong. However, in Rebarber and Zwart [28, Theorem 2.11] the following result can be found.

THEOREM 1.4. *Assume that system* (1) *is optimizable where the operator* B *is an admissible finite-rank control operator for* $T(t)$. *Then there exists an* $\varepsilon > 0$ *such that all elements in the spectrum of* A *with real part larger than* $-\varepsilon$ *are eigenvalues of* A *with finite algebraic multiplicity and all accumulation points of the spectrum of* A *have real part less than or equal to* $-\varepsilon$.

Hence this result gives a necessary condition for the system (1) to be optimizable. Looking now at the class of systems that satisfies this necessary condition, i.e., in the closed right-half plane there is only point spectrum, it is much harder to find an example that does not satisfy the SDA. All delay and partial differential equations that satisfy the necessary condition on its spectrum also satisfy the SDA at $-\varepsilon$ for some $\varepsilon > 0$.

We construct an example that is optimizable, but it is not possible to split the state space in a direct sum as given in Theorem 1.3. The generator does not satisfy the SDA at any negative number.

If A is a Riesz-spectral operator, then we are able to prove Theorem 1.3 without assuming that A satisfies SDA. The SDA at $-\varepsilon$, for some $\varepsilon > 0$, will automatically be satisfied if the system is stabilizable by a bounded feedback BF, since then there can only be finitely many eigenvalues with real part larger than $-\varepsilon$ for some $\varepsilon > 0$.

From Rebarber and Zwart [28] we have that the unstable part of the spectrum is pure point spectrum; see Theorem 1.4. Here we show an extra property concerning the distribution of this point spectrum.

THEOREM 1.5. *Assume that system* (1) *is optimizable where the operator* B *is an admissible finite-rank control operator for* $T(t)$. *Let* $\{\lambda_n\}$ *denote the set of eigenvalues with real part greater than* 0 *and let* $m_a(\lambda_n, A)$ *denote the algebraic multiplicity of* λ_n.

Then we have

$$\sum_{n\in\mathbb{N}} \frac{m_a(\lambda_n, A)}{|\lambda_n|^2} < \infty.$$

From Theorem 1.3 we obtain some consequences as easy corollaries. For instance, if the spectrum of A lies in the left-half plane and is bounded away from the imaginary axis, but A generates an unstable semigroup, then it is never optimizable, for any admissible finite-rank control operator for $T(t)$. Thus these systems will never be exactly controllable in finite time either. Examples of such generators can be found in, e.g., Zabczyk [39] and Greiner, Voigt, and Wolff [11]. This result can be found in [28] for the case of one-dimensional, not necessarily admissible, input operators.

Another consequence is the following. Suppose that A generates a C_0-group. If (1) is exactly controllable in finite time for some B where B is an admissible finite-rank control operator for $T(t)$, then the (generalized) eigenfunctions of A must span H. This follows easily from Theorem 1.3 by using the fact that $A + \gamma I$ is exactly controllable in finite time for every $\gamma \in \mathbb{R}$. Now choose γ so large that the corresponding "stable" subspace H_s is empty, which is possible since A generates a C_0-group.

A third consequence is the following. Suppose that A generates a completely unstable C_0-semigroup, that $\Sigma(A, B)$ is optimizable, and that B is an admissible finite-rank control operator for $T(t)$. Then A generates a C_0-group, and $\Sigma(A, B)$ is exactly controllable in finite time. This is an extension of the result found by Russell in [29]. Reversing the argument gives that the right-shift semigroup on $\boldsymbol{L}_2(0, \infty)$ will never be optimizable nor exactly controllable in finite time by a finite-rank admissible control operator for $T(t)$. The reason is that the right-shift semigroup is completely unstable, but it is not a C_0-group.

The organization of the paper is as follows. In the next two sections we introduce the necessary background and notation. In section 4, we show that if the state space can be split into two $T(t)$-invariant subspaces, then we can write the system (1) into two corresponding subsystems. Theorem 1.3 will be proved in section 5, apart from the characterization of H_s and H_u. That will be done in section 7. Theorem 1.5 will be the subject of section 6. Finally, in section 8 we present an example that is optimizable, but it is not possible to split the state space of this example in a direct sum as given in Theorem 1.3.

2. System description. In this section, we describe the general class of systems discussed in this paper. First we need to introduce some notation.

$\mathbb{C}_\alpha^+$	$\{z \in \mathbb{C} : \mathrm{Re}(z) > \alpha\}$, $\alpha \in \mathbb{R}$,
$\mathbb{C}_\alpha^-$	$\{z \in \mathbb{C} : \mathrm{Re}(z) < \alpha\}$, $\alpha \in \mathbb{R}$,
H	separable, complex Hilbert space,
$\sigma(A)$	spectrum of A,
$\sigma_\alpha^+(A)$	$\sigma(A) \cap \mathbb{C}_\alpha^+$,
$\sigma_p(A)$	point spectrum of A,
$\rho(A)$	resolvent set of A,
$\rho_\infty(A)$	largest connected subset of $\rho(A)$ that contains an interval of the form $[r, \infty)$,
$N(A)$	$\{x \in D(A) \mid Ax = 0\}$,

$\mathrm{Im}(A)$	$\{x \in H \mid \exists y \in D(A) : Ay = x\}$,
$\boldsymbol{H}_\infty(\mathbb{C}_\alpha^+; H)$	set of holomorphic and bounded functions from $\mathbb{C}_\alpha^+$ to H,
$\boldsymbol{H}_2(\mathbb{C}_\alpha^+; H)$	set of holomorphic functions $f : \mathbb{C}_\alpha^+ \to H$ with $\sup_{x>\alpha} \left(\int_{-\infty}^{\infty} \|f(x+iy)\|^2 dy \right)^{1/2} < \infty.$

We deal with infinite-dimensional, time-invariant systems of the following kind:

$$\dot{x}(t) = Ax(t) + Bu(t). \tag{4}$$

Here $A : D(A) \to H$ is the generator of a C_0-semigroup $T(t)$ on the separable, complex Hilbert space H, and B will be our (unbounded) control operator. The input function u is assumed to be in $\boldsymbol{L}_2^{loc}(0, \infty; \mathbb{C}^m)$.

In order to define our class of control operators we have to introduce some notation. We define the space H_{-1} to be the completion of H with respect to the norm

$$\|x\|_{-1} := \|(\beta I - A)^{-1} x\|$$

and the space H_1 to be $D(A)$ with the norm

$$\|x\|_1 := \|(\beta I - A)x\|,$$

where $\beta \in \rho(A)$, the resolvent set of A. It is easy to verify that H_{-1} and H_1 do not depend on $\beta \in \rho(A)$. Moreover, $\| \cdot \|_1$ is equivalent to the graph norm on $D(A)$, so H_1 is complete. In Weiss [33, Remark 3.4] it is shown that $T(t)$ has a restriction to a C_0-semigroup on H_1 whose generator is the restriction of A to $D(A)$, and $T(t)$ can be extended to a C_0-semigroup on H_{-1} whose generator is an extension of A with domain H. Therefore we get

$$A \in \mathcal{L}(H_1, H) \quad \text{and} \quad A \in \mathcal{L}(H, H_{-1}).$$

H_{-1} equals the dual of $D(A^*)$, where we have equipped $D(A^*)$ with the graph norm (see [33]). Following [33] we introduce admissible control operators for $T(t)$.

Definition 2.1. *Let $B \in \mathcal{L}(\mathbb{C}^m, H_{-1})$. For $t \geq 0$ we define the operator $\mathcal{B}_t : \boldsymbol{L}_2(0, \infty; \mathbb{C}^m) \to H_{-1}$ by*

$$\mathcal{B}_t u := \int_0^t T(t-\rho) B u(\rho) \, d\rho.$$

Then B is called an admissible control operator for $T(t)$, *if for some (and hence any) $t > 0$, $\mathcal{B}_t \in \mathcal{L}(\boldsymbol{L}_2(0, \infty; \mathbb{C}^m), H)$.*

By a solution of (4) with initial condition $x(0) = x_0 \in H$ we mean the function defined by the variation of parameters formula

$$x(t) = T(t)x_0 + \int_0^t T(t-\rho) B u(\rho) \, d\rho, \qquad t \geq 0.$$

Note that the admissibility of B guarantees $x(t) \in H$ for $t \geq 0$ and in [33] it is shown that x is continuous. We will denote system (4) by $\Sigma(A, B)$.

In the following the concept of admissible observation operators for $T(t)$ also will be needed (see also Weiss [34]).

DEFINITION 2.2. *Let $C \in \mathcal{L}(H_1, \mathbb{C}^p)$. Then C is called an* admissible observation operator for $T(t)$*, if for some (and hence any) $t > 0$, there is some $K > 0$ such that*

$$\|CT(\cdot)x\|_{\boldsymbol{L}_2(0,t;\mathbb{C}^p)} \leq K\|x\|, \quad x \in D(A).$$

If the semigroup $T(t)$ is exponentially stable, then the constant K does not depend on $t \geq 0$ (see Grabowski and Callier [10]). We end this section with some simple properties of admissible control and observation operators for $T(t)$.

REMARK 2.3. *B is an admissible control operator for the C_0-semigroup $T_\tau(t)$ given by*

$$T_\tau(t) := e^{\tau t}T(t)$$

where $\tau \in \mathbb{R}$ is arbitrary. Moreover, if the operator $C \in \mathcal{L}(H_1, \mathbb{C}^p)$ is an admissible observation operator for $T(t)$, then C also is an admissible observation operator for $T_\tau(t)$.

3. Optimizability, LQ-stabilizing feedbacks, and exact controllability. In this section we introduce the notions of optimizability, LQ-stabilizing feedbacks, and exact controllability. Furthermore, we investigate relationships between these notions. With the system $\Sigma(A, B)$ we associate the cost functional

$$J(x_0, u) := \int_0^\infty \|x(t)\|^2 + \|u(t)\|^2 \, dt. \tag{5}$$

DEFINITION 3.1. *We call the system $\Sigma(A, B)$* g-optimizable*, $g \in \mathbb{R}$, if for every $x_0 \in H$ there exists an input $u \in \boldsymbol{L}_2^{loc}(0, \infty; \mathbb{C}^m)$ such that*

$$J^g(x_0, u) := \int_0^\infty \left[\|e^{-gt}x(t)\|^2 + \|e^{-gt}u(t)\|^2\right] \, dt < \infty. \tag{6}$$

In particular, we call the system $\Sigma(A, B)$ optimizable*, if it is 0-optimizable.*

Thus the system $\Sigma(A, B)$ is optimizable if for every $x_0 \in H$ there exists an input $u \in \boldsymbol{L}_2(0, \infty; \mathbb{C}^m)$ such that the cost functional $J(x_0, u)$ is finite. Optimizability is also known as the *finite cost condition*. Note further that if the system $\Sigma(A, B)$ is g-optimizable for some $g \in \mathbb{R}$, then the system is g'-optimizable for every $g' \geq g$.

DEFINITION 3.2. *Let $F : D(F) \mapsto \mathbb{C}^m$. We call F an* LQ-stabilizing feedback at *g for the system $\Sigma(A, B)$ if there exists a C_0-semigroup $T_F(t)$ on H with generator $A_F : D(A_F) \to H$ such that $F \in \mathcal{L}(D(A_F), \mathbb{C}^m)$, F is an admissible observation operator for $T_F(t)$,*

$$T_F(t)x_0 = T(t)x_0 + \int_0^t T(t-\rho)BFT_F(\rho)x_0 \, d\rho \tag{7}$$

for every $t \geq 0$ and any $x_0 \in H$, and $\|T_F(t)\| \leq Me^{(g-\delta)t}$ for all $t \geq 0$ and some $M, \delta > 0$. We call the feedback F LQ-stabilizing*, if it is LQ-stabilizing at zero.*

Since F is assumed to be an admissible observation operator for $T_F(t)$, we have that $FT_F(\cdot)x \in \boldsymbol{L}_2^{loc}(0, \infty; \mathbb{C}^m)$ for all $x \in H$. Thus the integral in (7) is well-defined.

If an operator F is stabilizing in the sense given in Rebarber [26] and Weiss and Curtain [37], then it is easy to see that it is also an LQ-stabilizing feedback. The difference between their definition and our Definition 3.2 is that we do not assume that F is an admissible observation operator for $T(t)$. Therefore, in general we do not have the second perturbation equation

$$T_F(t)x = T(t)x + \int_0^t T_F(t-\rho)BFT(\rho)x\,d\rho, \quad t \geq 0, x \in H,$$

which holds if F is stabilizing in their sense; see Weiss [36]. At the present it is unknown whether LQ-stabilizing feedbacks and stabilizing feedbacks in the sense of Rebarber are equivalent.

The following theorem shows that in our situation the system $\Sigma(A,B)$ is g-optimizable if and only if there exists a feedback which is LQ-stabilizing at g. So, we have equivalence between the boundedness of the LQ-cost functional (5) and our notion of stability. This inspired us to call our notion "LQ-stabilizing."

THEOREM 3.3. *The following statements are equivalent.*

(1) *The system $\Sigma(A,B)$ is g-optimizable.*

(2) *There exists a feedback which is LQ-stabilizing at g for the system $\Sigma(A,B)$.*

Proof. By choosing $u(t) = FT_F(t)x_0$ it is easy to see that part (2) implies part (1). Thus it remains to prove that part (1) implies part (2). For g equals zero, this implication is proved in Flandoli, Lasiecka, and Triggiani [8, Corollary 4.3 and Theorem 4.4]; see also Zwart [41]. For general $g \in \mathbb{R}$, it is easy to see that the cost $J^g(x_0,u)$ for the system $\Sigma(A,B)$ equals the cost $J(x_0, e^{-g\cdot}u)$ for the system $\Sigma(A-gI,B)$. Hence, the system $\Sigma(A,B)$ is g-optimizable if and only if the system $\Sigma(A-gI,B)$ is optimizable. For the system $\Sigma(A-gI,B)$ we use the result that we already have, and thus there exist an exponentially stable C_0-semigroup $T_F(t)$ and an admissible observation operator F for $T_F(t)$ such that

$$\begin{aligned} T_F(t)x_0 &= e^{-gt}T(t)x_0 + \int_0^t e^{-g(t-\rho)}T(t-\rho)BFT_F(\rho)\,d\rho \\ &= e^{-gt}\left[T(t)x_0 + \int_0^t T(t-\rho)BFe^{g\rho}T_F(\rho)\,d\rho\right]. \end{aligned}$$

This proves that F is an LQ-stabilizing feedback at g for the system $\Sigma(A,B)$. □

For a C_0-semigroup $T(t)$ we define by $g_b(T)$ the *growth bound* of $T(t)$, i.e.,

$$g_b(T) := \lim_{t\to\infty} \frac{1}{t}\log\|T(t)\|.$$

If the system $\Sigma(A,B)$ is LQ-stabilizable, then we have the existence of an exponentially stable C_0-semigroup $T_F(t)$. The growth bound of this semigroup is denoted by g_b^F, i.e.,

$$g_b^F := g_b(T_F). \tag{8}$$

We call g_b^F the *closed-loop growth bound* of the LQ-stabilizing feedback. If the system is optimizable, then g_b^F depends on the LQ-stabilizing feedback F. However, g_b^F will always be negative, and this is the essential property of the closed-loop growth bound that we will use in the following.

PROPOSITION 3.4. *Assume that F is an LQ-stabilizing feedback for the system $\Sigma(A,B)$, and let g_b^F be the corresponding closed-loop growth bound. Then we have the following.*

(1) *For every $\varepsilon \in [0, -g_b^F)$ the feedback F is LQ-stabilizing for the system $\Sigma(A + \varepsilon I, B)$.*

(2) *For every $\varepsilon \in [0, -g_b^F)$ the feedback F is LQ-stabilizing at $-\varepsilon$ for the system $\Sigma(A, B)$.*

Proof. Let $\varepsilon \in [0, -g_b^F)$. By Remark 2.3 B is an admissible control operator for $e^{\varepsilon t}T(t)$. Let F and $T^F(t)$ be as in Definition 3.2. Then Remark 2.3 implies that F is an admissible observation operator for $e^{\varepsilon t}T^F(t)$. By the definition of g_b^F, the C_0-semigroup $T_\varepsilon^F(t) := e^{\varepsilon t}T^F(t)$ is exponentially stable.

1. From (7) we have that

$$\begin{aligned} T_\varepsilon^F(t)x_0 &= e^{\varepsilon t}T_F(t)x_0 \\ &= e^{\varepsilon t}T(t)x_0 + \int_0^t e^{\varepsilon(t-\rho)}T(t-\rho)BFe^{\varepsilon\rho}T_F(\rho)\,d\rho \\ &= e^{\varepsilon t}T(t)x_0 + \int_0^t e^{\varepsilon(t-\rho)}T(t-\rho)BFT_\varepsilon^F(\rho)\,d\rho. \end{aligned}$$

Since $A + \varepsilon I$ is the infinitesimal generator of the C_0-semigroup $e^{\varepsilon t}T(t)$, we see that F is LQ-stabilizing for the system $\Sigma(A + \varepsilon I, B)$;

2. For all $\gamma > 0$, there exists a $M_\gamma > 0$ such that

$$\|T_F(t)\| \le M_\gamma e^{(g_b^F+\gamma)t}.$$

We choose $\gamma > 0$ such that $g_b^F + \gamma < -\varepsilon$ holds, and we define $\delta := -\varepsilon - g_b^F - \gamma$. Then $\delta > 0$ and $g_b^F + \gamma = -\varepsilon - \delta$, and hence by Definition 3.2 the feedback F is LQ-stabilizing at $-\varepsilon$ for the system $\Sigma(A, B)$. □

Next, we show that the spectral subset $\sigma^+_{g_b^F}(A)$ is of a special form if F is a LQ-stabilizing feedback.

Proposition 3.5. *Assume that F is an LQ-stabilizing feedback for the system $\Sigma(A, B)$, and let g_b^F be the closed-loop growth bound. Then the spectral subset $\sigma^+_{g_b^F}(A)$ consists only of point spectrum with finite algebraic multiplicity, and the possible finite accumulation points of the set $\sigma^+_{g_b^F}(A)$ must lie on the line with real part equal to g_b^F.*

Proof. Let $\tau \in (g_b^F, 0)$ and $\varepsilon \in (-\tau, -g_b^F)$. Then Proposition 3.4 and Theorem 3.3 imply that system $\Sigma(A, B)$ is ε-optimizable. Now Rebarber and Zwart [28, Theorem 2.11] imply that the spectral subset $\sigma^+_\tau(A)$ consists only of point spectrum with finite algebraic multiplicity and contains no finite accumulation point. Since $\tau \in (g_b^F, 0)$ is arbitrary, this implies the statement. □

Note that it is possible that the spectrum of A possesses an accumulation point λ_0 with $\mathrm{Re}(\lambda_0) = g_b^F$.

In the following proposition we rewrite LQ-stabilizability in an equivalent way in the frequency domain. We show that LQ-stabilizability implies a useful representation of $x_0 \in H$, the so-called (ξ, ω)-representation. This was introduced for finite-dimensional systems by Hautus [12] and for infinite-dimensional systems by Zwart [40].

Proposition 3.6.

1. *If for every $x_0 \in H$ there exist $\xi \in \boldsymbol{H}_2(\mathbb{C}_0^+; H)$ and $\omega \in \boldsymbol{H}_2(\mathbb{C}_0^+; \mathbb{C}^m)$ such that*

$$x_0 = (sI - A)\xi(s) - B\omega(s), \qquad s \in \mathbb{C}_0^+, \tag{9}$$

then the system $\Sigma(A,B)$ is optimizable, and hence there exists an LQ-stabilizing feedback.

2. *Assume that there exists an LQ-stabilizing feedback for the system $\Sigma(A,B)$, and let g_b^F be its closed-loop growth bound. Then for every $\sigma \in (g_b^F, 0)$ there exists a constant $C > 0$ such that for every $x_0 \in H$ there exist $\xi \in \boldsymbol{H}_\infty(\mathbb{C}_\sigma^+; H) \cap \boldsymbol{H}_2(\mathbb{C}_\sigma^+; H)$ and $\omega \in \boldsymbol{H}_\infty(\mathbb{C}_\sigma^+; \mathbb{C}^m) \cap \boldsymbol{H}_2(\mathbb{C}_\sigma^+; \mathbb{C}^m)$ with*

$$x_0 = (sI - A)\xi(s) - B\omega(s), \qquad s \in \mathbb{C}_\sigma^+, \tag{10}$$

and

$$\max\{\|\xi\|_{\boldsymbol{H}_\infty(\mathbb{C}_\sigma^+;H)}, \|\xi\|_{\boldsymbol{H}_2(\mathbb{C}_\sigma^+;H)}, \|\omega\|_{\boldsymbol{H}_\infty(\mathbb{C}_\sigma^+;\mathbb{C}^m)}, \|\omega\|_{\boldsymbol{H}_2(\mathbb{C}_\sigma^+;\mathbb{C}^m)}\} \leq C\|x_0\|_H.$$

Proof. By [33, Remark 3.12] it follows that for every $u \in \boldsymbol{L}_2(0,\infty;\mathbb{C}^m)$ the function $\Phi_u(t) := \int_0^t T(t-\rho)Bu(\rho)\,d\rho$ is Laplace-transformable with Laplace transform

$$\hat{\Phi}_u(s) = (sI - A)^{-1}B\omega(s), \qquad \mathrm{Re}(s) \geq r \text{ for some } r \in \mathbb{R},$$

where ω is the Laplace transform of u.

1. Let $x_0 \in H$ be arbitrary. Since $\xi \in \boldsymbol{H}_2(\mathbb{C}_0^+; H)$ and $\omega \in \boldsymbol{H}_2(\mathbb{C}_0^+; \mathbb{C}^m)$, by the Paley–Wiener theorem (see, e.g., [3, Theorem A.6.21]) there exist unique $u \in \boldsymbol{L}_2(0,\infty;\mathbb{C}^m)$ and $x \in \boldsymbol{L}_2(0,\infty;H)$ such that ω is the Laplace transform of u and ξ is the Laplace transform of x. Applying Laplace transforms to the function

$$T(t)x_0 + \int_0^t T(t-\rho)Bu(\rho)\,d\rho, \qquad t \geq 0,$$

we get

$$(sI - A)^{-1}x_0 + (sI - A)^{-1}B\omega(s), \qquad \mathrm{Re}(s) \geq r \text{ for some } r \in \mathbb{R}.$$

Since $\xi(s) = (sI-A)^{-1}x_0 + (sI-A)^{-1}B\omega(s)$, $\mathrm{Re}(s) > \max\{r, 0\}$, the uniqueness of the Laplace transform implies

$$x(t) = T(t)x_0 + \int_0^t T(t-\rho)Bu(\rho)\,d\rho.$$

This proves that x is the state trajectory corresponding to x_0 and u and thus the system $\Sigma(A,B)$ is optimizable. By Theorem 3.3 we have the existence of an LQ-stabilizing feedback.

2. Let F be a LQ-stabilizing feedback from Definition 3.2. Taking the Laplace transform of (7), we get

$$(sI - A_F)^{-1}x_0 = (sI - A)^{-1}x_0 + (sI - A)^{-1}BF(sI - A_F)^{-1}x_0. \tag{11}$$

Since $T_F(t)$ has growth bound g_b^F, it is easy to see that

$$\|(sI - A_F)^{-1}x_0\|_{\boldsymbol{H}_\infty(\mathbb{C}_\sigma^+;H)} \leq C_1\|x_0\|_H,$$

and by using the Paley–Wiener theorem [3, Theorem A.6.21] we get

$$\|(sI - A_F)^{-1}x_0\|_{\boldsymbol{H}_2(\mathbb{C}_\sigma^+;H)} \leq C_2\|x_0\|_H.$$

Since F is an admissible observation operator for $T_F(t)$, similar results hold for $F(sI-A_F)^{-1}x_0$. Define $\xi(s) := (sI-A_F)^{-1}x_0$ and $\omega(s) := F(sI-A_F)^{-1}x_0$. Multiplying (11) with $(sI-A)$ and using the definition of ξ and ω, we obtain (10). ◻

We end this section with the definition and some simple properties of exact controllability in finite time.

DEFINITION 3.7. *The system $\Sigma(A, B)$ is called* exactly controllable in finite time *if there exists a time $t_0 \in (0, \infty)$ such that for every $x \in H$ we can find an input $u \in \boldsymbol{L}_2(0, t_0; \mathbb{C}^m)$ such that*

$$x = \int_0^{t_0} T(t_0 - \rho) B u(\rho) \, d\rho.$$

LEMMA 3.8. *Assume that the system $\Sigma(A, B)$ is exactly controllable in finite time. Then for every $\tau \in \mathbb{R}$ the system $\Sigma(A + \tau I, B)$ also is exactly controllable in finite time.*

The following proposition shows that exact controllability in finite time implies g-optimizability for every $g \in \mathbb{R}$.

PROPOSITION 3.9. *If the system $\Sigma(A, B)$ is exactly controllable in finite time, then it also is g-optimizable for every $g \in \mathbb{R}$.*

The proof of Lemma 3.8 and Proposition 3.9 is quite easy and left to the reader. We conclude this section by proving that the spectrum of an exactly controllable system is of a very special form.

THEOREM 3.10. *If the system $\Sigma(A, B)$ is exactly controllable in finite time, then the spectrum of A is pure point spectrum and it contains no (finite) accumulation point.*

Proof. Let $\gamma \in \mathbb{R}$ be arbitrary. Then by Lemma 3.8 we see that the system $\Sigma(A + \gamma I, B)$ is exactly controllable in finite time as well. Proposition 3.9 implies that $\Sigma(A + \gamma I, B)$ is optimizable. Now from Theorem 3.3 and Proposition 3.5 we obtain that $\sigma_0^+(A + \gamma I)$ consists only of point spectrum with no finite accumulation point. Since $\sigma_{-\gamma}^+(A) = \sigma_0^+(A + \gamma I)$, and since γ is arbitrary, the assertion follows. □

4. Decompositions of C_0-semigroups.

For the formulation of Theorem 5.3 we need to write our system into two subsystems. Properties of such a decomposition are given next.

DEFINITION 4.1. *We call a closed subspace V of H $T(t)$*-invariant, *if $T(t)V \subset V$, for all $t \geq 0$.*

In Kurtz [19] it is shown that a closed subspace V is $T(t)$-invariant if and only if $(\lambda I - A)^{-1} V \subset V$ for all $\lambda \in \rho_\infty(A)$; see also Curtain and Zwart [3, Lemma 2.5.6].

LEMMA 4.2. *Let V be a $T(t)$-invariant subspace of H and let $P_V \in \mathcal{L}(H)$ be a projection from H onto V. Define $W := N(P_V)$ and $P_W := I - P_V$. Then the following hold:*

1. *The operator*

$$T_V(t)x := T(t)x, \qquad t \geq 0, x \in V,$$

defines a C_0-semigroup on V with its generator A_V given by

$$A_V x := Ax, \qquad x \in D(A_V) := D(A) \cap V.$$

Furthermore, $\rho_\infty(A) \subset \rho(A_V)$, and for every $v \in V$ and $s \in \rho_\infty(A)$ we have $(sI - A_V)^{-1} v = (sI - A)^{-1} v$.

2. *Let V_{-1} be the completion of V with respect to the norm $\|(\beta I - A_V)^{-1} \cdot \|_V$. Then $V_{-1} \subset H_{-1}$ and $\|v\|_{V_{-1}} = \|v\|_{H_{-1}}$ for every $v \in V_{-1}$.*

3. *The operator*

$$T_W(t)x := P_W T(t)x, \qquad t \geq 0, x \in W,$$

defines a C_0-semigroup on W.

Proof.

1. Follows immediately from Pazy [22, page 123] and [19].
2. From the first part it follows that $\|(sI - A_V)^{-1}v\| = \|(sI - A)^{-1}v\|$ for every $v \in V$. Now the definition of a completion of a normed vector space shows that $V_{-1} \subset H_{-1}$ and $\|v\|_{V_{-1}} = \|v\|_{H_{-1}}$ for every $v \in V_{-1}$.
3. It is easy to see that $T_W(0) = I_W$ holds. Since V is a $T(t)$-invariant subspace, we have $P_W T(t) P_V = 0$. Thus, for $t, s \geq 0$ and $x \in W$ we obtain

$$\begin{aligned} T_W(t)T_W(s)x = P_W T(t) P_W T(s)x &= P_W T(t)T(s)x - P_W T(t)(I - P_W)T(s)x \\ &= P_W T(t+s)x - P_W T(t) P_V T(s)x = T_W(s+t)x. \end{aligned}$$

Since the strong continuity of $T(t)$ immediately implies that $T_W(t)$ is strongly continuous, $T_W(t)$ is a C_0-semigroup on W. □

LEMMA 4.3. *Let V be a $T(t)$-invariant subspace of H, and let $P_V \in \mathcal{L}(H)$ be a projection from H onto V. Define $W := N(P_V)$ and $P_W := I - P_V$. Then there exists a unique admissible control operator $B_W \in \mathcal{L}(\mathbb{C}^m, W_{-1})$ for $T_W(t)$ on W, where $T_W(t)x := P_W T(t)x$ for $t \geq 0$ and $x \in W$, with the property that*

$$\int_0^t T_W(t-\rho) B_W u(\rho)\, d\rho = P_W \int_0^t T(t-\rho) B u(\rho)\, d\rho \tag{12}$$

for every $t \geq 0$ and $u \in \boldsymbol{L}_2(0, t; \mathbb{C}^m)$. This unique operator B_W is given by

$$B_W u := \lim_{\tau \to 0} \frac{1}{\tau} P_W \int_0^\tau T(\tau - \rho) B u\, d\rho, \qquad u \in \mathbb{C}^m, \tag{13}$$

where the limit is taken in W_{-1}.

Additionally, if $\Sigma(A, B)$ is exactly controllable in finite time, then $\Sigma(A_W, B_W)$ also is exactly controllable in finite time. Here A_W is the generator of the C_0-semigroup $T_W(t)$.

Proof. Let $\mathcal{B}_t \in \mathcal{L}(\boldsymbol{L}_2(0, \infty; \mathbb{C}^m), H)$ be the operator as introduced in Definition 2.1. For $u, v \in L_2(0, \infty; \mathbb{C}^m)$ we define $u \underset{\tau}{\diamond} v$ as

$$(u \underset{\tau}{\diamond} v)(t) = \begin{cases} u(t), & t \in [0, \tau], \\ v(t - \tau), & t > \tau. \end{cases}$$

The admissibility of B for the C_0-semigroup $T(t)$ implies (see [33]) that

$$\mathcal{B}_{\tau + t}(u \underset{\tau}{\diamond} v) = T(t)\mathcal{B}_\tau u + \mathcal{B}_t v.$$

Define $\mathcal{B}_t^W \in \mathcal{L}(\boldsymbol{L}_2(0, \infty; \mathbb{C}^m), W)$, $t \geq 0$, by

$$\mathcal{B}_t^W := P_W \mathcal{B}_t.$$

Since V is a $T(t)$-invariant subspace of H, we have that $P_W T(t) P_V = 0$, $t \geq 0$. Thus for every $\tau, t \geq 0$ and every $u, v \in \boldsymbol{L}_2(0, \infty; \mathbb{C}^m)$ we obtain

$$\begin{aligned} \mathcal{B}_{\tau+t}^W(u \underset{\tau}{\diamond} v) = P_W \mathcal{B}_{\tau+t}(u \underset{\tau}{\diamond} v) &= P_W T(t)\mathcal{B}_\tau u + P_W \mathcal{B}_t v = P_W T(t)\mathcal{B}_\tau u + \mathcal{B}_t^W v \\ &= P_W T(t) P_W \mathcal{B}_\tau u + P_W T(t) P_V \mathcal{B}_\tau u + \mathcal{B}_t^W v = T_W(t)\mathcal{B}_\tau^W u + \mathcal{B}_t^W v. \end{aligned}$$

Now [33, Theorem 3.9] implies that there exists a unique $B_W \in \mathcal{L}(\mathbb{C}^m, W_{-1})$ such that

$$\mathcal{B}_t^W u = \int_0^t T_W(t-\rho) B_W u(\rho)\, d\rho,$$

for $t \geq 0$ and $u \in \boldsymbol{L}_2(0, \infty; \mathbb{C}^m)$, and this unique operator B_W is given by (13). Thus B_W is an admissible control operator for $T_W(t)$ and (12) holds.

If $\Sigma(A, B)$ is exactly controllable in finite time, then there exists a time $t_0 > 0$ such that for every $x \in W$ there is an input $u \in \boldsymbol{L}_2(0, t_0; \mathbb{C}^m)$ such that

$$x = \int_0^{t_0} T(t_0 - \rho) B u(\rho)\, d\rho.$$

From (12) it follows directly that the system $\Sigma(A_W, B_W)$ is exactly controllable in finite time as well. □

If P is a projection that commutes with the C_0-semigroup $T(t)$, we have $H = N(P) \oplus \mathrm{Im}(P)$ and both $N(P)$ and $\mathrm{Im}(P)$ are closed $T(t)$-invariant subspaces. In the following we denote by $T_u(t)$ and $T_s(t)$ the restricted C_0-semigroups on $H_u := N(P)$ and $H_s := \mathrm{Im}(P)$, respectively. Moreover, the generators of the C_0-semigroups $T_u(t)$ and $T_s(t)$ are denoted by A_u and A_s. By $[H_s]_{-1}$ ($[H_u]_{-1}$) we denote the completion of H_s (H_u) with respect to the norm $\|(\beta I - A_s)^{-1} \cdot \|_{H_s}$ ($\|(\beta I - A_u)^{-1} \cdot \|_{H_u}$).

The existence of such a projection P is very helpful since it reduces the semigroup into two (possibly simpler) semigroups $T_s(t)$ and $T_u(t)$.

LEMMA 4.4. *Let $T(t)$ be a C_0-semigroup on H and $B \in \mathcal{L}(\mathbb{C}^m, H_{-1})$ an admissible control operator for $T(t)$. Moreover, let $P \in \mathcal{L}(H)$ be a projection that commutes with $T(t)$, $t \geq 0$. Then we have the following.*

1. *P has a unique continuous extension $\tilde{P}$ in $\mathcal{L}(H_{-1})$ with $\mathrm{Im}(\tilde{P}) = [H_s]_{-1}$ and $N(\tilde{P}) = [H_u]_{-1}$. Moreover, $\tilde{P}$ is a projection and $\tilde{P}$ commutes with $T(t)$ and A.*
2. *$\tilde{P}B \in \mathcal{L}(\mathbb{C}^m, [H_s]_{-1})$ is an admissible control operator for $T_s(t)$ on H_s with the property*

$$\int_0^t T_s(t-\rho) \tilde{P} B u(\rho)\, d\rho = P \int_0^t T(t-\rho) B u(\rho)\, d\rho, \tag{14}$$

for $t \geq 0$ and $u \in \boldsymbol{L}_2(0, t; \mathbb{C}^m)$.

3. *$(I - \tilde{P})B \in \mathcal{L}(\mathbb{C}^m, [H_u]_{-1})$ is an admissible control operator for $T_u(t)$ on H_u with the property*

$$\int_0^t T_u(t-\rho)(I - \tilde{P}) B u(\rho)\, d\rho = (I - P) \int_0^t T(t-\rho) B u(\rho)\, d\rho, \tag{15}$$

for $t \geq 0$ and $u \in \boldsymbol{L}_2(0, t; \mathbb{C}^m)$.

Proof.

1. Choose $\beta \in \rho(A)$ with $\mathrm{Re}\,\beta > g_b(T)$, where $g_b(T)$ is the growth bound of $T(t)$. Then we have

$$(\beta I - A)^{-1} x = \int_0^\infty e^{-\beta t} T(t) x\, dt.$$

Thus P commutes with $(\beta I - A)^{-1}$, and hence also with A. Now [33, Proposition 3.3] shows that P has a unique continuous extension $\tilde{P}$ in $\mathcal{L}(H_{-1})$ and that $\tilde{P}$ commutes with $T(t)$ and A. It is now easy to see that $\tilde{P}$ again is a projection.

In order to prove $\operatorname{Im}(\tilde{P}) = [H_s]_{-1}$, we first choose $x \in [H_s]_{-1}$. Then there exists a sequence $\{x_n\}_n \subset H_s$ with $x_n \to x$, as $n \to \infty$, in $[H_s]_{-1}$. Since $\tilde{P}$ is continuous, we get $\tilde{P}x_n \to \tilde{P}x$. On the other hand, $\tilde{P}x_n = Px_n = x_n \to x$, and thus $x \in \operatorname{Im}(\tilde{P})$. Conversely, we choose $x \in \operatorname{Im}(\tilde{P})$. Then there exists an element $z \in H_{-1}$ with $\tilde{P}z = x$ and a sequence $\{z_n\}_n \subset H$ with $z_n \to z$, as $n \to \infty$, in H_{-1}. Since $Pz_n \in H_s$ and $Pz_n = \tilde{P}z_n \to \tilde{P}z = x$, we get $x \in [H_s]_{-1}$. This proves $\operatorname{Im}(\tilde{P}) = [H_s]_{-1}$. Finally, $N(\tilde{P}) = [H_u]_{-1}$ can be proved in a similar manner.

2. By Lemma 4.3 there is a unique admissible control operator $B_s \in \mathcal{L}(\mathbb{C}^m, [H_s]_{-1})$ for $T_s(t)$ with the property that

$$\int_0^t T_s(t-\rho)B_s u(\rho)\,d\rho = P\int_0^t T(t-\rho)Bu(\rho)\,d\rho, \tag{16}$$

for every $t \geq 0$ and $u \in \boldsymbol{L}_2(0,t;\mathbb{C}^m)$. Using [33], we see that B is given by

$$Bu = \lim_{\tau\to\infty}\frac{1}{\tau}\int_0^t T(t-\rho)Bu\,d\rho, \qquad u \in \mathbb{C}^m,$$

where the limit is taken in H_{-1}. Since $\tilde{P} \in \mathcal{L}(H_{-1})$, we get

$$\tilde{P}Bu = \lim_{\tau\to\infty}\frac{1}{\tau}P\int_0^t T(t-\rho)Bu\,d\rho, \qquad u \in \mathbb{C}^m.$$

By Lemma 4.2, $[H_s]_{-1} \subset H_{-1}$ and the norms coincide. Now by Lemma 4.3 we get $B_s = \tilde{P}B$, which completes the proof.

3. The proof for $T_u(t)$ is similar to the proof of part 2. □

5. Equivalent conditions for optimizability. In this section, we develop equivalent conditions for optimizability. We will see that under a weak assumption the system $\Sigma(A,B)$ is optimizable if and only if we can split it into a part that is exponentially stable and a part that is exactly controllable in finite time. This sufficient condition of optimizability was obtained fairly early in 1975 by Triggiani [31] for infinite-dimensional systems with a bounded control operator, under the extra assumption of finitely many unstable eigenvalues. We now show that this holds for admissible control operators for $T(t)$.

THEOREM 5.1. *Assume that there exists a projection $P \in \mathcal{L}(H)$ such that*

(1) *P commutes with the semigroup $T(t)$;*

(2) *$T_s(t) := PT(t)$ is an exponentially stable C_0-semigroup on $H_s := \operatorname{Im}(P)$;*

(3) *$\Sigma(A_u, (I-\tilde{P})B)$ is exactly controllable in finite time. Here A_u is the generator of the C_0-semigroup $T_u(t) := (I-P)T(t)$ on $H_u := N(P)$.*

Then the system $\Sigma(A,B)$ is optimizable.

Proof. Let $x_0 \in H$ be arbitrary. Since $\Sigma(A_u,(I-\tilde{P})B)$ is exactly controllable in finite time there exist a number $t_0 > 0$ and an input $\tilde{u} \in \boldsymbol{L}_2(0,t_0;\mathbb{C}^m)$ such that

$$-T_u(t_0)(I-P)x_0 = \int_0^{t_0} T_u(t_0-\rho)(I-\tilde{P})B\tilde{u}(\rho)\,d\rho. \tag{17}$$

Define $u \in \boldsymbol{L}_2(0,\infty;\mathbb{C}^m)$ by

$$u(s) := \begin{cases} \tilde{u}(s), & s \leq t_0, \\ 0, & s > t_0. \end{cases}$$

Then for $t \geq t_0$ the state trajectory corresponding to the initial state x_0 and the input function u satisfies

$$\begin{aligned} x(t) \quad &= \quad T(t)x_0 + \int_0^t T(t-\rho)Bu(\rho)\,d\rho \\ &\overset{(14)\text{ and }(15)}{=} T_u(t)(I-P)x_0 + T_s(t)Px_0 \\ &\quad + \int_0^t T_u(t-\rho)(I-\tilde{P})Bu(\rho)\,d\rho + \int_0^t T_s(t-\rho)\tilde{P}Bu(\rho)\,d\rho \\ &= \quad T_u(t-t_0)T_u(t_0)(I-P)x_0 + T_s(t)Px_0 \\ &\quad + T_u(t-t_0)\int_0^{t_0} T_u(t_0-\rho)(I-\tilde{P})B\tilde{u}(\rho)\,d\rho \\ &\quad + T_s(t-t_0)\int_0^{t_0} T_s(t_0-\rho)\tilde{P}B\tilde{u}(\rho)\,d\rho \\ &\overset{(17)}{=} \quad T_s(t)Px_0 + T_s(t-t_0)\int_0^{t_0} T_s(t_0-\rho)\tilde{P}B\tilde{u}(\rho)\,d\rho. \end{aligned}$$

Now the exponential stability of $T_s(t)$ implies $x \in \boldsymbol{L}_2(0,\infty;H)$, and thus the system $\Sigma(A,B)$ is optimizable. □

To show that the converse of Theorem 5.1 holds, we need an extra assumption.

Definition 5.2. *We say that the operator A satisfies the* spectrum decomposition assumption at g (SDA(g)), *if there exist numbers $g_1 < g < g_2$ such that*

$$\mathbb{C}^+_{g_1} \cap \mathbb{C}^-_{g_2} \subset \rho(A). \tag{18}$$

We say that A satisfies the SDA, if it satisfies SDA(0).

If an operator A satisfies the SDA(g) in the sense given in Curtain and Zwart [3], then A satisfies the SDA at g in the sense of Definition 5.2. The difference between their definition and Definition 5.2 is that we do not assume that $\sigma^+_g(A)$ is compact.

The result that we want to prove in this section is the following.

Theorem 5.3. *Assume that the system $\Sigma(A,B)$ is optimizable and that A satisfies SDA. Then there exists a projection P such that*

(1) *P commutes with the semigroup $T(t)$,*
(2) *$T_s(t) := PT(t)$ is an exponentially stable C_0-semigroup on $H_s := \mathrm{Im}(P)$,*
(3) *$T_u(t) := (I-P)T(t)$ is a C_0-group on $H_u := N(P)$,*
(4) *$-A_u$ generates an exponentially stable C_0-semigroup,*
(5) *$\Sigma(A_u,(I-\tilde{P})B)$ is exactly controllable in finite time.*

Remark 5.4. *There are examples of optimizable systems $\Sigma(A,B)$ for which A does not satisfy the SDA, but for every $g < 0$ there exists an $\varepsilon \in (0,-g)$ such that A satisfies the SDA at $-\varepsilon$. If this is the case, then using Theorem* 3.3, *Proposition* 3.4, *and Theorem* 5.3, *we get a result similar to that in Theorem* 5.3; *namely, there exists a projection P such that* 1–3 *and* 5 *of Theorem* 5.3 *are satisfied and additionally $-A_u - \varepsilon I$ generates an exponentially stable C_0-semigroup.*

A projection $P \in \mathcal{L}(H)$ satisfying properties (1)–(4) of Theorem 5.3 is also known as dichotomic projection; see [24]. The proof of Theorem 5.3 is given at the end of this section.

Desch and Schappacher [5], Jacobson and Nett [17] and Nefedov and Sholokhovich [20] have proved Theorem 5.3 for bounded control operators B, i.e., $B \in \mathcal{L}(\mathbb{C}^m, H)$. In this situation, for every (LQ)-stabilizing feedback F, the spectral subset $\sigma^+_{g^F_b}(A)$

consists only of finitely many points. Hence, the SDA is satisfied or at least SDA(g) is satisfied for g arbitrarily close to zero. Example 5.11 shows that the assumptions made in Theorem 5.1 do not imply that A satisfies the SDA at g for some $g \leq 0$. In the following we will see that the assumption that A satisfies the SDA is not very restrictive, because there are a lot of situations where this assumption holds automatically; see Proposition 5.9.

Definition 5.5. *We call the C_0-semigroup $T(t)$* completely unstable *if*

$$\{x \in H : T(\cdot)x \in \boldsymbol{L}_2(0,\infty;H)\} = \{0\}.$$

For example, if A generates a C_0-group $T(t)$ and $-A$ generates a bounded C_0-semigroup, then $T(t)$ is completely unstable.

As a corollary of Theorem 5.3 we show that under the assumption that A generates a completely unstable C_0-semigroup, the system $\Sigma(A,B)$ is optimizable if and only if the system $\Sigma(A,B)$ is exactly controllable in finite time.

Corollary 5.6. *If A generates a completely unstable C_0-semigroup, then the following statements are equivalent.*

(1) *The system $\Sigma(A,B)$ is optimizable.*

(2) *There exists an LQ-stabilizing feedback for the system $\Sigma(A,B)$.*

(3) *The system $\Sigma(A,B)$ is exactly controllable in finite time.*

Moreover, if one of these statements holds, then $T(t)$ is a C_0-group on H, and A satisfies the SDA at any point between the closed-loop growth bound and zero.

Proof. The equivalence between part 1 and part 2 is proved in Theorem 3.3. Proposition 3.9 shows that part 3 implies part 1. We now prove that part 2 implies part 3. Let F be an LQ-stabilizing feedback for the system $\Sigma(A,B)$. Proposition 3.5 implies that the spectral subset $\sigma^+_{g_b^F}(A)$ consists only of point spectrum. Let us assume that there is a $\lambda \in \mathbb{C}^+_{g_b^F} \cap \mathbb{C}^-_0 \cap \sigma(A)$ and x_λ a corresponding eigenvector. In [22, p. 46] it is shown that $e^{\lambda t}$ is an eigenvalue of $T(t)$ with eigenvector x_λ. This implies that $T(\cdot)x_\lambda = e^{\lambda t}x_\lambda \in \boldsymbol{L}_2(0,\infty;H)$, which is in contradiction with the fact that $T(t)$ is completely unstable. Thus $\mathbb{C}^+_{g_b^F} \cap \mathbb{C}^-_0 \subset \rho(A)$ and so A satisfies the SDA($-\varepsilon$) for any $\varepsilon \in (0, -g_b^F)$. Remark 5.4 now implies the existence of a projection P such that 1–3 and 5 of Theorem 5.3 are satisfied. Since $T_s(t) = PT(t) = T(t)P$, we get $T(\cdot)x \in L_2(0,\infty;H)$ for every $x \in H_s$. Using the complete instability of our system this can only happen if $H_s = 0$. Therefore, $H_u = H$ and $T(t)$ equals $T_u(t)$ which implies that $T(t)$ is a C_0-group and that the system $\Sigma(A,B)$ is exactly controllable in finite time. □

The result presented in the previous corollary is closely related to Russell's principle on exact controllability. Russell [29] proved exact controllability for a system governed by the wave equation by showing that the system was stabilizable and backwards stabilizable. The definition of stabilizability used in [29] is stronger than the definition used in this paper. Rebarber and Weiss [27] extended Russell's result to our notion of stabilizability. Their result is closely related to the corollary above, but it is neither a consequence nor a generalization of our result.

Example 5.7. *Consider the right-shift semigroup $T(t)$ on $\boldsymbol{L}_2(0,\infty)$ with generator A. This semigroup satisfies $\|T(t)x_0\| = \|x_0\|$ for every $x_0 \in \boldsymbol{L}_2(0,\infty)$. Hence the right shift semigroup on $\boldsymbol{L}_2(0,\infty)$ is completely unstable. Since this C_0-semigroup is not a C_0-group, Corollary* 5.6 *implies that there cannot exist an admissible finite-rank control operator B for $T(t)$ such that the system $\Sigma(A,B)$ is optimizable.*

Definition 5.8. *We call a C_0-semigroup $T(t)$* eventually norm continuous *if there exists a constant $t' \geq 0$ such that the function $t \to T(t)$ from (t', ∞) into $\mathcal{L}(H)$ is operator-norm continuous.*

Examples for eventually norm continuous C_0-semigroups are holomorphic, differentiable, norm continuous, and compact C_0-semigroups; see Arendt et al. [1, p. 41].

Proposition 5.9. *Assume that F is an LQ-stabilizing feedback for the system $\Sigma(A, B)$, and let g_b^F be its closed-loop growth bound. If the C_0-semigroup $T(t)$ is eventually norm continuous, then for every $\tau \in (g_b^F, 0)$, the set $\sigma_\tau^+(A)$ contains only finitely many points, and thus A satisfies SDA(g) for all but finitely many $g > g_b^F$.*

Proof. By Proposition 3.5 the spectral subset $\sigma_{g_b^F}^+(A)$ contains no finite accumulation point. Let $\tau \in (g_b^F, 0)$. Since by [1, A-II Theorem 1.20] the set $\{\lambda \in \sigma(A) | \mathrm{Re}(\lambda) \geq \tau\}$ is bounded, we have that $\sigma_\tau^+(A)$ contains only finitely many points. Thus the assertion follows. □

In the special case where A is a Riesz-spectral operator we are able to prove Theorem 5.3 without the assumption that A satisfies the SDA. For the definition of a Riesz-spectral operator we refer the reader to [3, Definition 2.3.4].

Theorem 5.10. *Assume that F is an LQ-stabilizing feedback for the system $\Sigma(A, B)$ and that A is a Riesz-spectral operator. Let g be negative and larger than the closed-loop growth bound. Then there exists a projection $P \in \mathcal{L}(H)$ such that* 1–3 *and* 5 *of Theorem* 5.3 *are satisfied and additionally the growth bound of the C_0-semigroup generated by $-A_u$ is at most $-g$.*

Proof. By the definition of a Riesz-spectral operator, there exist sequences $(\lambda_n)_n \subset \mathbb{C}$, $(\phi_n)_n \subset H$, and $(\psi_n)_n \subset H$, with $\langle \phi_n, \psi_m \rangle = \delta_{n,m}$, such that

$$Az := \sum_{n \in \mathbb{N}} \lambda_n \langle z, \psi_n \rangle \phi_n, \qquad z \in H,$$

$$D(A) := \left\{ z \in H | \sum_{n \in \mathbb{N}} |\lambda_n|^2 |\langle z, \psi_n \rangle|^2 < \infty \right\}.$$

Let $T_F(t)$ and F be the operators given by Definition 3.2. Defining $S := \{n \in \mathbb{N} \mid \mathrm{Re}(\lambda_n) \leq g\}$, it is easy to see that

$$Pz := \sum_{n \in S} \langle z, \psi_n \rangle \phi_n$$

is a projection operator on H which commutes with A and $T(t)$, $t \geq 0$. Moreover, by [3, Theorem 2.3.5] we get that

(1) $T_s(t) := PT(t)$ is an exponentially stable C_0-semigroup on $H_s := \mathrm{Im}(P)$,

(2) $T_u(t) := (I - P)T(t)$ is a C_0-group on $H_u := N(P)$,

(3) $\|T_u(t)x\| \leq Me^{gt}\|x\|$ for all $x \in H_u$, $t \leq 0$,

where $M > 0$ is independent of x and t. Lemma 4.4 now shows that $(I - \tilde{P})B$ is an admissible control operator for $T_u(t)$. Thus it remains to prove that $\Sigma(A_u, (I - \tilde{P})B)$ is exactly controllable in finite time. Since $T_{-g}^F(t) := e^{-gt}T_F(t)$ is exponentially stable and $T_u(t)$ satisfies the inequality in outcome (3), the operator $T_u(-t)(I-P)T_F(t)|_{H_u} \in \mathcal{L}(H_u)$ satisfies the estimate

$$\|T_u(-t)(I - P)T_F(t)|_{H_u}\| = \|e^{gt}T_u(-t)(I - P)T_{-g}^F(t)|_{H_u}\| \leq Ce^{-\tau t}, \qquad t \geq 0,$$

for some constants $\tau > 0$ and $C > 0$, which are independent of t. Using the positivity of τ, we can choose a $t_0 > 0$ (sufficiently large) such that $\|T_u(-t_0)(I-P)T_F(t_0)|_{H_u}\| <$

1, and thus the operator $I|_{H_u} - T_u(-t_0)(I-P)T_F(t_0)|_{H_u}$ is invertible in $\mathcal{L}(H_u)$. Let $x_0 \in H_u$ be arbitrary and define

$$\begin{aligned} z_0 &:= \left[I - T_u(-t_0)(I-P)T_F(t_0)|_{H_u}\right]^{-1} T_u(-t_0)x_0, \\ u(\rho) &:= -FT_F(\rho)z_0. \end{aligned}$$

Thus $u \in \boldsymbol{L}_2(0,t_0;\mathbb{C}^m)$. By (7) and (15) we get

$$\begin{aligned} (I-P)T_F(t_0)z_0 &= T_u(t_0)z_0 - (I-P)\int_0^{t_0} T(t_0-\rho)Bu(\rho)\,d\rho \\ &= T_u(t_0)z_0 - \int_0^{t_0} T_u(t_0-\rho)(I-\tilde{P})Bu(\rho)\,d\rho, \end{aligned}$$

which is equivalent to

$$T_u(t_0)\left[z_0 - T_u(-t_0)(I-P)T_F(t_0)z_0\right] = \int_0^{t_0} T_u(t_0-\rho)(I-\tilde{P})Bu(\rho)\,d\rho$$

and thus

$$x_0 = \int_0^{t_0} T_u(t_0-\rho)(I-\tilde{P})Bu(\rho)\,d\rho.$$

Consequently, $\Sigma(A_u,(I-\tilde{P})B)$ is exactly controllable in finite time. □

The following example shows that there exist optimizable systems $\Sigma(A,B)$ for which A does not satisfy SDA(g) at any $g \le 0$, but there is a projection P that fulfills (1)–(3) of Theorem 5.1.

Example 5.11. Let $\{e_n\}_{n\in\mathbb{Z}} \cup \{f_n\}_{n\in\mathbb{Z}}$ be an orthonormal basis of ℓ_2, $\{\alpha_n\}_{n\in\mathbb{Z}} = \mathbb{Q}\cap[-1,0)$, $\{\beta_n\}_{n\in\mathbb{Z}} = \mathbb{Q}\cap(-\infty,-1)$, $\mu_n := \alpha_n + in$ and $\nu_n := \beta_n + in$, $n\in\mathbb{Z}$. We define $A : D(A) \to H$ by

$$\begin{aligned} A &:= \sum_{n\in\mathbb{Z}} \mu_n\langle\cdot,e_n\rangle e_n + \sum_{n\in\mathbb{Z}} \nu_n\langle\cdot,f_n\rangle f_n, \\ D(A) &:= \{x\in H |\sum_{n\in\mathbb{Z}} |\mu_n|^2|\langle x,e_n\rangle|^2 + \sum_{n\in\mathbb{Z}} |\nu_n|^2|\langle x,f_n\rangle|^2 < \infty\} \end{aligned}$$

and $B : \mathbb{C} \to H_{-1}$ by

$$B := \sum_{n\in\mathbb{Z}} e_n.$$

Clearly, A is a Riesz-spectral operator, and A does not satisfy SDA(g) for any $g \le 0$.

A is the generator of the C_0-semigroup $T(t)$ given by

$$T(t) := \sum_{n\in\mathbb{Z}} e^{\mu_n t}\langle\cdot,e_n\rangle e_n + \sum_{n\in\mathbb{Z}} e^{\nu_n t}\langle\cdot,f_n\rangle f_n.$$

Weiss [32] shows that B is an admissible control operator for $T(t)$. It is easy to see that

$$Pz := \sum_{n\in\mathbb{Z}} \langle z,f_n\rangle f_n$$

is a projection operator on H which commutes with A and $T(t)$, $t \ge 0$. Moreover, by [3, Theorem 2.3.5] we get that

(1) $T_s(t) := PT(t)$ is an exponentially stable C_0-semigroup on $H_s := \mathrm{Im}(P)$,
(2) $T_u(t) := (I - P)T(t)$ is a C_0-group on $H_u := N(P)$,
(3) $\|T_u(t)x\| \leq Me^{-t}\|x\|$ for all $x \in H_u$, $t \leq 0$,
where $M > 0$ is independent of x and t. Lemma 4.4 now shows that $(I - \tilde{P})B$ is an admissible control operator for $T_u(t)$.

Next we prove that $\Sigma(A_u, (I - \tilde{P})B)$ is exactly controllable in finite time. By Young [38, Corollary 2, p. 196] we get that $\{e^{\mu_n t}\}_{n\in\mathbb{Z}}$ forms a Riesz basis of $\boldsymbol{L}_2(-\pi, \pi)$, and thus it is easy to show that $\{e^{\mu_n t}\}_{n\in\mathbb{Z}}$ forms a Riesz basis for $\boldsymbol{L}_2(0, 2\pi)$. This implies that $\{g_n\}_{n\in\mathbb{Z}}$, $g_n(t) := e^{\mu_n(2\pi - t)}$ is a Riesz basis for $\boldsymbol{L}_2(0, 2\pi)$ as well. Let $\{h_n\}_{n\in\mathbb{Z}}$ be the biorthogonal sequence of $\{g_n\}_{n\in\mathbb{Z}}$ in $\boldsymbol{L}_2(0, 2\pi)$ [38, p. 29], which again is a Riesz basis of $\boldsymbol{L}_2(0, 2\pi)$ [38, p. 36]. By definition, the biorthogonality of $\{g_n\}_{n\in\mathbb{Z}}$ and $\{h_n\}_{n\in\mathbb{Z}}$ implies that

$$\int_0^{2\pi} g_m(t)\overline{h_n(t)}\,dt = \delta_{nm}, \qquad n, m \in \mathbb{Z}.$$

Thus we get

$$\begin{aligned}\int_0^{2\pi} T_u(2\pi - \rho)B\overline{h_n(\rho)}\,d\rho &= \int_0^{2\pi} \sum_{m\in\mathbb{Z}} e^{\mu_m(2\pi-\rho)}\overline{h_n(\rho)}e_m\,d\rho \\ &= \sum_{m\in\mathbb{Z}} \int_0^{2\pi} g_m(\rho)\overline{h_n(\rho)}\,d\rho\, e_m \qquad (19) \\ &= e_n.\end{aligned}$$

Let $x \in H_u$ be arbitrary. Then $x = \sum_{n\in\mathbb{Z}} \langle x, e_n\rangle e_n$ and $\{\langle x, e_n\rangle\}_{n\in\mathbb{Z}} \in \ell_2$. Defining $u \in \boldsymbol{L}_2(0, 2\pi)$ by

$$u := \sum_{n\in\mathbb{Z}} \langle x, e_n\rangle \overline{h_n},$$

(19) implies that

$$\int_0^{2\pi} T(2\pi - \rho)Bu(\rho)\,d\rho = x.$$

This shows that system $\Sigma(A_u, (I - \tilde{P})B)$ is exactly controllable in finite time. Finally, Theorem 5.1 implies that system $\Sigma(A, B)$ is optimizable.

For the proof of Theorem 5.3 we need the following lemma.

LEMMA 5.12. *Assume that system $\Sigma(A, B)$ is optimizable. Let $(s_n)_n$ be a sequence in $\rho(A) \cap \overline{\mathbb{C}_0^+}$ and $\delta > 0$ be a constant such that*

$$\{s \in \mathbb{C} \mid |s - s_n| < \delta\} \subset \rho(A) \tag{20}$$

for every $n \in \mathbb{N}$. Then

$$\sup_{n\in\mathbb{N}} \|(s_n I - A)^{-1}B\| < \infty \qquad \text{and} \qquad \sup_{n\in\mathbb{N}} \|(s_n I - A)^{-1}\| < \infty.$$

Proof. First we prove that $\sup_{n\in\mathbb{N}} \|(s_n I - A)^{-1}B\| < \infty$ holds. Since the system is optimizable, there exists an LQ-stabilizing feedback F. Let g_b^F be the (negative) closed-loop growth bound, let $\sigma \in (g_b^F, 0)$, and define $\tau := \frac{1}{2}\min\{-\sigma, \delta\}$. If

$\sup_{n\in\mathbb{N}} \|(s_nI-A)^{-1}B\| = \infty$, then the principle of uniform boundedness implies that there exist a vector $u \in \mathbb{C}^m$ and an element $y \in H$ such that

$$\sup_{n\in\mathbb{N}} |\langle (s_nI-A)^{-1}Bu, y\rangle| = \infty. \tag{21}$$

Since B is an admissible control operator for $T(t)$, there exists a constant $\gamma > \tau$ such that

$$(\cdot I-A)^{-1}B \in \boldsymbol{H}_\infty(\mathbb{C}^+_\gamma; H) \tag{22}$$

[35, Proposition 2.3]. Since $s_n \in \overline{\mathbb{C}^+_0}$, we get $s_n + 2\gamma \in \mathbb{C}^+_\gamma$.

We write B as $[b_1,\dots,b_m]$. By Proposition 3.6, for every $n \in \mathbb{N}$ and all $k \in \{1,\dots,m\}$ there exist $\xi_{s_n,k} \in \boldsymbol{H}^\infty(\mathbb{C}^+_\sigma; H)$ and $\omega_{s_n,k} \in \boldsymbol{H}^\infty(\mathbb{C}^+_\sigma; \mathbb{C}^m)$ such that

$$((s_n+2\gamma)I-A)^{-1}b_k = (sI-A)\xi_{s_n,k}(s) - B\omega_{s_n,k}(s), \qquad s \in \mathbb{C}^+_\sigma.$$

Moreover, using (22) and Proposition 3.6, the functions $\xi_{s_n,k}$ and $\omega_{s_n,k}$ can be chosen in such a way that there exists a constant $M > 0$ with

$$\|\xi_{s_n,k}\|_{\boldsymbol{H}_\infty(\mathbb{C}^+_\sigma;H)} \le M \qquad \text{and} \qquad \|\omega_{s_n,k}\|_{\boldsymbol{H}_\infty(\mathbb{C}^+_\sigma;\mathbb{C}^m)} \le M$$

for $n \in \mathbb{N}$ and $k \in \{1,\dots,m\}$. Defining $\Xi_{s_n}(s) := [\xi_{s_n,1}(s),\dots,\xi_{s_n,m}(s)]$ and $\Omega_{s_n}(s) := [\omega_{s_n,1}(s),\dots,\omega_{s_n,m}(s)]$, we obtain

$$((s_n+2\gamma)I-A)^{-1}B = (sI-A)\Xi_{s_n}(s) - B\Omega_{s_n}(s), \qquad s \in \mathbb{C}^+_\sigma. \tag{23}$$

The functions Ξ_{s_n} and Ω_{s_n} also are holomorphic on $\mathbb{C}^+_\sigma$ and there exists a number $\tilde{M} > 0$ with

$$\|\Xi_{s_n}\|_{\boldsymbol{H}_\infty(\mathbb{C}^+_\sigma;H^m)} \le \tilde{M} \qquad \text{and} \qquad \|\Omega_{s_n}\|_{\boldsymbol{H}_\infty(\mathbb{C}^+_\sigma;\mathbb{C}^{m\times m})} \le \tilde{M}. \tag{24}$$

Now for $s \in \mathbb{C}^+_\sigma$, we define the functions

$$\widetilde{\Xi}_{s_n}(s) := \Xi_{s_n}(s_n+s) \qquad \text{and} \qquad \widetilde{\Omega}_{s_n}(s) := \Omega_{s_n}(s_n+s).$$

Since $\mathrm{Re}(s_n) \ge 0$, the functions $\widetilde{\Xi}_{s_n}$ and $\widetilde{\Omega}_{s_n}$ also are holomorphic and bounded (with the same estimates) on $\mathbb{C}^+_\sigma$. Multiplying equation (23) (with $s_n + s$ instead of s) by $((s_n+s)I-A)^{-1}$, $|s| < \tau$, and using the resolvent identity, we get

$$((s_n+s)I-A)^{-1}B\left[\widetilde{\Omega}_{s_n}(s) - \frac{I}{s-2\gamma}\right] = \widetilde{\Xi}_{s_n}(s) - \frac{1}{s-2\gamma}((s_n+2\gamma)I-A)^{-1}B. \tag{25}$$

Note that the existence of $((s_n+s)I-A)^{-1}$, $|s| < \tau$, is guaranteed by (20). Since $\{\widetilde{\Omega}_{s_n}\}_n$ is a uniformly bounded set in $\boldsymbol{H}_\infty(\mathbb{C}^+_\sigma;\mathbb{C}^{m\times m})$, there exists a subsequence $\{\widetilde{\Omega}_{s_{n_j}}\}_j$ of $\{\widetilde{\Omega}_{s_n}\}_n$ which converges uniformly on compact subsets of $\mathbb{C}^+_\sigma$ to a holomorphic function $\widetilde{\Omega} \in \boldsymbol{H}_\infty(\mathbb{C}^+_\sigma;\mathbb{C}^{m\times m})$ (see Hille and Phillips [13, Theorem 3.14.2]). We denote this subsequence again by $\{\widetilde{\Omega}_{s_n}\}_n$.

For $\beta \in (0,\tau]$ we define $B(\beta) := \{s \in \mathbb{C} : |s| \le \beta\}$. We now prove that there exists a number $\tilde{\tau} \in (0,\tau]$ such that

$$\det\left(\widetilde{\Omega}(s) - \frac{I}{s-2\gamma}\right) \neq 0$$

for all $s \in B(\tilde{\tau})\backslash\{0\}$. If it were not true, then there would exist a sequence $(\delta_n)_n \subset B(\tau)\backslash\{0\}$, tending to 0 as n tends to ∞, such that

$$\det\left(\widetilde{\Omega}(\delta_n) - \frac{I}{\delta_n - 2\gamma}\right) = 0, \quad n \in \mathbb{N}.$$

Now

$$\det\left(\widetilde{\Omega}(\delta_n) - \frac{I}{\delta_n - 2\gamma}\right) = \det\Big((\delta_n - 2\gamma)\widetilde{\Omega}(\delta_n) - I\Big)\det\left(\frac{I}{\delta_n - 2\gamma}\right)$$

implies that

$$\det\Big((\delta_n - 2\gamma)\widetilde{\Omega}(\delta_n) - I\Big) = 0, \qquad n \in \mathbb{N}.$$

In other words, $\det((s-2\gamma)\widetilde{\Omega}(s) - I)$ would have a converging sequence of zeros in $B(\tau)$. By the holomorphicity of $\widetilde{\Omega}$ on $\mathbb{C}_\sigma^+$ and of the determinant on $\mathbb{C}^{m\times m}$, we get that $\det((s-2\gamma)\widetilde{\Omega}(s) - I)$ is holomorphic on $\mathbb{C}_\sigma^+$. Since $-\tau > \sigma$, this would imply that the function $\det((s-2\gamma)\widetilde{\Omega}(s) - I)$ would be equal to zero everywhere on $\mathbb{C}_\sigma^+$. Taking $s = 2\gamma$ (note that $2\gamma \in \mathbb{C}_\sigma^+$), we get a contradiction. Therefore, there exists a number $\tilde{\tau} \in (0, \tau]$ such that

$$\det\left(\widetilde{\Omega}(s) - \frac{I}{s - 2\gamma}\right) \neq 0 \qquad \text{for all } s \in B(\tilde{\tau})\backslash\{0\}. \tag{26}$$

On $B(\tilde{\tau})$ we now define the functions

$$f_n(s) := \langle((s+s_n)I - A)^{-1}Bu, y\rangle, \qquad n \in \mathbb{N},$$

where u and y are the vectors from (21). Since $\tilde{\tau} < \delta$, we get by (20) that f_n is holomorphic, and so by the maximum principle there exists a number $\theta_n \in [0, 2\pi)$ such that

$$|f_n(\tilde{\tau}e^{i\theta_n})| \geq |f_n(0)|. \tag{27}$$

Since (by (21)) $\sup_{n\in\mathbb{N}} |f_n(0)| = \infty$, equation (27) implies

$$\sup_{n\in\mathbb{N}} |f_n(\tilde{\tau}e^{i\theta_n})| = \infty. \tag{28}$$

There now exists a subsequence of $\{\theta_n\}_{n=1}^\infty$ which converges to $\theta \in [0, 2\pi]$. Again we rename the subsequence $\{\theta_n\}_{n=1}^\infty$. By the choice of $\tilde{\tau}$, we have that

$$\det\left(\widetilde{\Omega}(\tilde{\tau}e^{i\theta}) - \frac{I}{\tilde{\tau}e^{i\theta} - 2\gamma}\right) \neq 0.$$

The set of invertible matrices is open and $\widetilde{\Omega}_{s_n}(\tilde{\tau}e^{i\theta_n}) - \frac{I}{\tilde{\tau}e^{i\theta_n} - 2\gamma}$ converges to $\widetilde{\Omega}(\tilde{\tau}e^{i\theta}) - \frac{I}{\tilde{\tau}e^{i\theta} - 2\gamma}$. Thus there exists a number $N \in \mathbb{N}$ such that

$$\det\left(\widetilde{\Omega}_{s_n}(\tilde{\tau}e^{i\theta_n}) - \frac{I}{\tilde{\tau}e^{i\theta_n} - 2\gamma}\right) \neq 0, \qquad n \geq N.$$

Multiplying (25) (with $s := \tilde{\tau} e^{i\theta_n}$) by $[\widetilde{\Omega}_{s_n}(\tilde{\tau} e^{i\theta_n}) - \frac{I}{\tilde{\tau} e^{i\theta_n} - 2\gamma}]^{-1} u$ and taking the inner product with y, we obtain

$$\begin{aligned} f_n(\tilde{\tau} e^{i\theta_n}) = \Bigg\langle & \left[\widetilde{\Xi}_{s_n}(\tilde{\tau} e^{i\theta_n}) - \frac{1}{\tilde{\tau} e^{i\theta_n} - 2\gamma} ((s_n + 2\gamma) I - A)^{-1} B \right] \\ & \cdot \left[\widetilde{\Omega}_{s_n}(\tilde{\tau} e^{i\theta_n}) - \frac{I}{\tilde{\tau} e^{i\theta_n} - 2\gamma} \right]^{-1} u, y \Bigg\rangle . \end{aligned} \tag{29}$$

Now $[\widetilde{\Omega}_{s_n}(\tilde{\tau} e^{i\theta_n}) - \frac{I}{\tilde{\tau} e^{i\theta_n} - 2\gamma}]^{-1}$ converges to $[\widetilde{\Omega}(\tilde{\tau} e^{i\theta}) - \frac{I}{\tilde{\tau} e^{i\theta} - 2\gamma}]^{-1}$. Thus using (22) and (24), we see that the right-hand side of (29) is bounded. However, this is in contradiction with (28) and so

$$\sup_{n \in \mathbb{N}} \|(s_n I - A)^{-1} B\| < \infty. \tag{30}$$

It now remains to prove that $\sup_{n \in \mathbb{N}} \|(s_n I - A)^{-1}\| < \infty$. Assume that $\sup_{n \in \mathbb{N}} \|(s_n I - A)^{-1}\| = \infty$. By the principle of uniform boundedness there exists a $z \in H$ such that

$$\sup_{n \in \mathbb{N}} \|(s_n I - A)^{-1} z\| = \infty. \tag{31}$$

By Proposition 3.6 there exist $\omega_z \in \boldsymbol{H}_\infty(\mathbb{C}_\sigma^+; \mathbb{C}^m)$ and $\xi_z \in \boldsymbol{H}_\infty(\mathbb{C}_\sigma^+; H)$ such that we have

$$\xi_z(s_n) = (s_n I - A)^{-1} z + (s_n I - A)^{-1} B \omega_z(s_n), \qquad n \in \mathbb{N}.$$

Since $\{\|\xi_z(s_n)\|\}_n$ and $\{\|\omega_z(s_n)\|\}_n$ are bounded sets, it follows with (31) that

$$\sup_{n \in \mathbb{N}} \|(s_n I - A)^{-1} B\| = \infty$$

which is in contradiction with (30). This completes the proof. □

COROLLARY 5.13. *Assume that* $\Sigma(A, B)$ *is optimizable and let* A *satisfy the SDA. Then*

$$(\cdot I - A)^{-1} \in \boldsymbol{L}_\infty(i\mathbb{R}; \mathcal{L}(H)) \quad \text{ and } \quad (\cdot I - A)^{-1} B \in \boldsymbol{L}_\infty(i\mathbb{R}; \mathcal{L}(\mathbb{C}^m, H)).$$

Proof. Since A satisfies the SDA, there exists a $\delta > 0$ such that $\mathbb{C}_{-\delta}^+ \cap \mathbb{C}_\delta^- \subset \rho(A)$. Now it is easy to see that $(\cdot I - A)^{-1} : i\mathbb{R} \to \mathcal{L}(H)$ and $(\cdot I - A)^{-1} B : i\mathbb{R} \to \mathcal{L}(\mathbb{C}^m, H)$ are continuous. If the statement does not hold, then there exists a sequence $(s_n)_n \in i\mathbb{R}$ such that

$$\lim_{n \to \infty} \|(s_n I - A)^{-1}\| = \infty \quad \text{ or } \quad \lim_{n \to \infty} \|(s_n I - A)^{-1} B\| = \infty,$$

which is in contradiction with Lemma 5.12. □

By $g_{\sigma_p}(A)$ we denote the *bound for the point spectrum of* A, i.e.,

$$g_{\sigma_p}(A) := \sup\{\operatorname{Re}(\lambda) \mid \lambda \in \sigma_p(A)\}.$$

It is easy to see that $g_{\sigma_p}(A) \le g_b(T)$. The following theorem shows that for an optimizable system $\Sigma(A, B)$ we cannot have $g_{\sigma_p}(A) < 0 \le g_b(T)$. For one-dimensional control operators this result also can be found in [28].

THEOREM 5.14. *Assume that $\Sigma(A, B)$ is optimizable and that $\sigma_p(A) \subset \mathbb{C}^-_{-\tau}$ for some $\tau > 0$. Then $T(t)$ is exponentially stable.*

Proof. If $T(t)$ is not exponentially stable, then Huang [14] shows that $\|(sI-A)^{-1}\|$ is not bounded in $\mathbb{C}^+_0$. Therefore, there exists a sequence $(s_n)_n \subset \mathbb{C}^+_0$ such that

$$\lim_{n\to\infty} \|(s_nI - A)^{-1}\| = \infty. \tag{32}$$

Since $\Sigma(A, B)$ is optimizable, by Theorem 3.3 there exists an LQ-stabilizing feedback F. By Proposition 3.5 we get that $\sigma^+_{g^F_b}(A)$ consists of only point spectrum. Thus, for $-\delta := \max\{-\tau, g^F_b\}$ we obtain $\sigma^+_{-\delta}(A) = \emptyset$. From the fact $\sigma^+_{-\delta}(A) = \emptyset$, we see that the sequence $(s_n)_n$ satisfies equation (20). Hence equation (32) is in contradiction with the result of Lemma 5.12. □

REMARK 5.15. *There are many cases where a generator satisfies $g_{\sigma_p}(A) < 0$ and $g_b(T) \geq 0$. This can happen, for example, when the spectrum consists solely of eigenvalues, but the multiplicity of the eigenvalues is not bounded* (*see Zabczyk* [39]) *or for certain shift semigroups* (*see Greiner, Voigt, and Wolff* [11] *or Curtain and Zwart* [3, *Example* 5.1.4]). *This means that for such generators A there exists no admissible finite-rank control operator B for $T(t)$ such that the system $\Sigma(A, B)$ is optimizable.*

We are now going to prove the main result of this section.

Proof of Theorem 5.3. Since $\Sigma(A, B)$ is optimizable, we have from Theorem 3.3 the existence of an LQ-stabilizing feedback F. Let $T_F(t)$ be as in Definition 3.2, and let g^F_b be the (negative) growth bound of $T_F(t)$. By the SDA we have the existence of $g_1 < 0 < g_2$ such that (18) holds. Since (18) remains valid if we increase g_1 (g_1 must remain negative), without loss of generality we may assume that $g^F_b < g_1$ holds. Let $g \in (g_1, g_2)$ be arbitrary. By Theorem 3.3 and Proposition 3.4 the system $\Sigma(A-gI, B)$ is optimizable. The choice of g implies the existence of $\delta > 0$ such that

$$\mathbb{C}^+_{-\delta} \cap \mathbb{C}^-_{\delta} \subset \rho(A - gI),$$

and thus Corollary 5.13 shows

$$((\cdot + g)I - A)^{-1} \in \boldsymbol{L}_\infty(i\mathbb{R}; \mathcal{L}(H)).$$

Therefore Prüss [24, Corollary 5] shows that

$$\{\lambda \in \mathbb{C} \mid |\lambda| = e^g\} \subset \rho(T(1))$$

holds. Since $g \in (g_1, g_2)$ is arbitrary, this implies

$$\{\lambda \in \mathbb{C} \mid e^{g_1} < |\lambda| < e^{g_2}\} \subset \rho(T(1)).$$

Let $c \in (g_1, g_2)$ be arbitrary and define $P \in \mathcal{L}(H)$ by

$$P := \int_{|s|=e^c} (sI - T(1))^{-1}\, ds.$$

It is easy to see that $P^2 = P$ holds, i.e., P is a projection, and that P commutes with the C_0-semigroup $T(t)$. Thus part (1) is satisfied. Define $H_s := \operatorname{Im}(P)$ and $H_u := N(P)$. Then the spectrum of the C_0-semigroup $T_s(t) := PT(t)$ on H_s satisfies

$$\sigma(T_s(1)) \subset \{\lambda \in \mathbb{C} \mid |\lambda| < e^{g_1}\},$$

and thus we get that the spectral radius of $T_s(1)$ is less than 1. Therefore, $T_s(t)$ is an exponentially stable C_0-semigroup on H_s, which proves part 2. Similarly, the spectrum of the C_0-semigroup $T_u(t) := (I-P)T(t)$ on H_u satisfies

$$\sigma(T_u(1)) \subset \{\lambda \in \mathbb{C} \mid e^{g_2} < |\lambda|\},$$

and thus $0 \notin \sigma(T_u(1))$. Then Pazy [22, Theorem 6.5] shows that $T_u(t)$ can be embedded in a C_0-group, and so part 3 follows. Since

$$\sigma(T_u(-1)) = \sigma((T_u(1))^{-1}) \subset \{\lambda \in \mathbb{C} \mid |\lambda| < e^{-g_2}\},$$

we get that the spectral radius of $T_u(-1)$ is less than 1. Thus $-A_u$ generates an exponentially stable C_0-semigroup on H_u, and so part 4 follows.

Lemma 4.4 now shows that $(I-\tilde{P})B$ is an admissible control operator for $T_u(t)$. Thus it remains to prove that $\Sigma(A_u, (I-\tilde{P})B)$ is exactly controllable in finite time. Since $T_F(t)$ and $T_u(-t)$ are exponentially stable, the operator $T_u(-t)(I-P)T_F(t)|_{H_u} \in \mathcal{L}(H_u)$ satisfies the estimate

$$\|T_u(-t)(I-P)T_F(t)|_{H_u}\| \leq Ce^{-\tau t}, \quad t \geq 0,$$

for some $C, \tau > 0$. The proof that $\Sigma(A_u, (I-\tilde{P})B)$ is exactly controllable in finite time now exactly follows the proof of Theorem 5.10. □

6. More information on the spectrum of A.

In this section, we show that the spectrum of the generator A has to be of a special form for the system $\Sigma(A,B)$ to be optimizable. In Proposition 3.5 we saw already that for any LQ-stabilizing feedback F, the spectrum of A in the right-half plane $\mathbb{C}^+_{g_b^F}$ consists only of point spectrum with finite multiplicity and contains no finite accumulation point. We now prove that the eigenvalues cannot go too slowly to infinity if the system $\Sigma(A,B)$ is optimizable.

Let λ_0 be an isolated point of $\sigma(A)$ and an eigenvalue of A. Then $P_{\lambda_0} \in \mathcal{L}(H)$, given by

$$P_{\lambda_0}x := \frac{1}{2\pi i}\int_\Gamma (\lambda I - A)^{-1}x\, d\lambda,$$

where Γ is a simple closed contour in $\mathbb{C}$ with λ_0 the only point of $\sigma(A)$ in its interior and no points of $\sigma(A)$ on Γ, is a projection onto the spectral subspace corresponding to λ_0; see [3, Lemma 2.5.7]. The dimension of $P_{\lambda_0}H$ is called the *algebraic multiplicity*, denoted by $m_a(\lambda_0, A)$, and the *geometric multiplicity* is given by $m_g(\lambda_0, A) := \dim(N(\lambda_0 I - A))$. If there exists a number $p(\lambda_0, A) > 0$ such that $(A - \lambda_0 I)^{p(\lambda_0,A)-1}P_{\lambda_0} \neq 0$, while $(A-\lambda_0 I)^p P_{\lambda_0} = 0$ for all $p \geq p(\lambda_0, A)$, then the point λ_0 is called *pole of* $(\cdot I - A)^{-1}$ *of order* $p(\lambda_0, A)$. In [1, p. 73] it is shown that

$$\max\{m_g(\lambda_0,A), p(\lambda_0,A)\} \leq m_a(\lambda_0,A) \leq p(\lambda_0,A)m_g(\lambda_0,A) \tag{33}$$

holds. The main result of this section is the following theorem.

THEOREM 6.1. *Assume that the system $\Sigma(A,B)$ is optimizable. Then for any LQ-stabilizing feedback F, the spectral subset $\sigma^+_{g_b^F}(A) = \{\lambda_n\}_{n\in\mathbb{N}}$ satisfies*

$$m_g(\lambda_n, A) \leq m, \qquad n \in \mathbb{N},$$

where m is the dimension of the input space, and for every $g > g_b^F$ we have

$$\sum_{n\in\mathbb{N},\mathrm{Re}(\lambda_n)>g} \frac{m_a(\lambda_n, A)}{|\lambda_n - g|^2} < \infty. \tag{34}$$

Moreover, the finite-dimensional systems $\Sigma(A\,|_{P_{\lambda_n}H}, \tilde{P}_{\lambda_n}B)$ are controllable.

In [7], Fattorini proved a result that is similar to equation (34). He considers systems $\Sigma(A, B)$ with bounded control operators and assumes that there exists a nonzero holomorphic function f, being the Laplace transform of a function with compact support, such that for every $x \in \mathrm{Im}\,(f(A))$ there exists an input u, which may be a σ-additive measure with compact support, such that

$$x = \int_0^t T(t-\rho)Bu(d\rho).$$

In this situation Fattorini proved that

$$\sum_{\lambda\in\sigma(A)} \frac{m_a(\lambda, A)\mathrm{Re}(\lambda)}{1+|\lambda|^2} < \infty.$$

For the proof of Theorem 6.1 we need the following lemma.

Lemma 6.2. *Let λ be an isolated point of $\sigma(A)$ and an eigenvalue of A. Then $\overline{\lambda}$ is an isolated point of $\sigma(A^*)$ and an eigenvalue of A^* with $m_g(\overline{\lambda}, A^*) = m_g(\lambda, A)$, $m_a(\overline{\lambda}, A^*) = m_a(\lambda, A)$, and $p(\overline{\lambda}, A^*) = p(\lambda, A)$.*

Proof. The proof follows directly from Kato [18, Remark III 6.23]. □

Proof of Theorem 6.1. In Proposition 3.5 it is shown that $\sigma^+_{g_b^F}(A)$ consists only of point spectrum with finite multiplicity and contains no finite accumulation point in $\sigma^+_{g_b^F}(A)$. Thus we can write $\sigma^+_{g_b^F}(A)$ as $\{\lambda_n\}_{n\in\mathbb{N}}$. That the finite-dimensional systems $\Sigma(A\,|_{P_{\lambda_n}H}, \tilde{P}_{\lambda_n}B)$ are controllable follows directly from [28].

1. We prove that $m_g(\lambda_n, A) \le m$ for all $n \in \mathbb{N}$. Let $n \in \mathbb{N}$. By Proposition 3.6, for every $x_0 \in H$ there exist a vector $\xi \in H$ and $\omega \in \mathbb{C}^m$ such that

$$x_0 = (\lambda_n I - A)\xi - B\omega.$$

Since $\tilde{P}_{\lambda_n}$ commutes with A, this implies

$$P_{\lambda_n}x_0 = (\lambda_n I - A)P_{\lambda_n}\xi - \tilde{P}_{\lambda_n}B\omega$$

and therefore $(\lambda_n I - A)P_{\lambda_n}H + \tilde{P}_{\lambda_n}B\mathbb{C}^m \supset P_{\lambda_n}H$. Thus we have

$$\begin{aligned} m_a(\lambda_n, A) &= \dim(P_{\lambda_n}H) \\ &\le \dim((\lambda_n I - A)P_{\lambda_n}H) + \dim(\tilde{P}_{\lambda_n}B\mathbb{C}^m) \\ &\le m_a(\lambda_n, A) - m_g(\lambda_n, A) + m, \end{aligned}$$

which shows $m_g(\lambda_n, A) \le m$.

2. We prove

$$\sum_{n\in\mathbb{N},\mathrm{Re}(\lambda_n)>g} \frac{m_a(\lambda_n, A)(\mathrm{Re}(\lambda_n) - g)}{1+|\lambda_n - g|^2} < \infty$$

for every $g > g_b^F$. Let $g > g_b^F$ and $\tau \in (g_b^F, g)$. Then there exists $\alpha \in \rho(A)$ with $\mathrm{Re}(\alpha) \in (\tau, g)$. We write B as $B = [b_1, \dots, b_m]$. By Proposition 3.6, for every $k \in \{1, \dots, m\}$ there exist $\xi_k \in \boldsymbol{H}_\infty(\mathbb{C}_\tau^+; H)$ and $\omega_k \in \boldsymbol{H}_\infty(\mathbb{C}_\tau^+; \mathbb{C}^m)$ such that

$$(\alpha I - A)^{-1} b_k = (sI - A)\xi_k(s) - B\omega_k(s), \qquad s \in \mathbb{C}_\tau^+.$$

Defining $\Xi(s) := [\xi_1(s), \dots, \xi_m(s)]$ and $\Omega(s) := [\omega_1(s), \dots, \omega_m(s)]$ we obtain

$$(\alpha I - A)^{-1} B = (sI - A)\Xi(s) - B\Omega(s), \qquad s \in \mathbb{C}_\tau^+. \tag{35}$$

The functions Ξ and Ω also are holomorphic and bounded on $\mathbb{C}_\tau^+$.
Multiplying (35) by $(sI - A)^{-1}$ and using the resolvent identity, we obtain

$$\frac{1}{s-\alpha}(\alpha I - A)^{-1} B = \Xi(s) - (sI - A)^{-1} B \left[\Omega(s) - \frac{1}{s-\alpha} I\right], \qquad s \in \mathbb{C}_g^+ \backslash \sigma(A).$$

Since the term on the left-hand side and the first term of the right-hand side are holomorphic on $\mathbb{C}_g^+$, the function $(sI - A)^{-1} B[\Omega(s) - \frac{1}{s-\alpha} I]$ also is holomorphic on $\mathbb{C}_g^+$. Defining

$$F(s) := \left[\Omega(s) - \frac{1}{s-\alpha} I\right], \qquad s \in \mathbb{C}_g^+, \tag{36}$$

it is easy to see that $F(s)^{-1} \det(F(s))$ is holomorphic on $\mathbb{C}_g^+$. Thus

$$\begin{aligned} G(s) &:= (sI - A)^{-1} B \det(F(s)) \\ &= (sI - A)^{-1} B \left[\Omega(s) - \frac{1}{s-\alpha} I\right] \cdot F(s)^{-1} \det(F(s)) \end{aligned}$$

is holomorphic on $\mathbb{C}_g^+$.
Next we show that every $\lambda \in \sigma_g^+(A)$ is a zero of $\det(F(s))$ with order at least $p(\lambda, A)$. Let us assume that this is not true. Then there is one $\lambda_0 \in \sigma_g^+(A)$ such that λ_0 is no zero of $\det(F(s))$ or λ_0 is a zero of $\det(F(s))$, but the order of λ_0 as zero of $\det(F(s))$ is less than $p := p(\lambda_0, A)$. By $f^{(i)}$ we denote the ith derivative of f. Let $k_0 \in \{0, \dots, p-1\}$ be such that $\det(F(\lambda_0))^{(i)} = 0$, $i = 0, \dots, k_0 - 1$, while $\det(F(\lambda_0))^{(k_0)} \neq 0$ and let $\delta > 0$ be such that $B(\lambda_0) := \{s \in \mathbb{C} \mid 0 < |s - \lambda_0| < \delta\} \subset \rho(A)$. Since $\tilde{P}_{\lambda_0}$ commutes with the resolvent $(\cdot I - A)^{-1}$, by Lemma 4.2 we obtain that

$$\begin{aligned} G_{\lambda_0}(s) &:= P_{\lambda_0} G(s) \\ &= (sI - A|_{P_{\lambda_0} H})^{-1} \tilde{P}_{\lambda_0} B \det(F(s)) \end{aligned}$$

is holomorphic on $\mathbb{C}_g^+$. Since $(sI - A|_{P_{\lambda_0} H})^{-1} = (sI - A)^{-1}$ on $P_{\lambda_0} H$ (see Lemma 4.2), we get $p = p(\lambda_0, A|_{P_{\lambda_0} H})$. Expressing $(\cdot I - A|_{P_{\lambda_0} H})^{-1}$ in its Laurent series, we obtain

$$G_{\lambda_0}(s) = \tilde{G}_{\lambda_0}(s) + \sum_{k=0}^{p-1} \frac{\det(F(s))}{(s - \lambda_0)^{k+1}} (\lambda_0 I - A|_{P_{\lambda_0} H})^k \tilde{P}_{\lambda_0} B, \qquad s \in B(\lambda_0),$$

where $\tilde{G}_{\lambda_0}(s)$ is a holomorphic function on $B(\lambda_0) \cup \{\lambda_0\}$. Since λ_0 is a zero of $\det(F(s))$ with order k_0, we get

$$\sum_{k=0}^{k_0-1} \frac{\det(F(s))}{(s-\lambda_0)^{k+1}} (\lambda_0 I - A|_{P_{\lambda_0}H})^k \tilde{P}_{\lambda_0} B$$

is holomorphic at λ_0. Since $G_{\lambda_0}(s)$ is holomorphic at λ_0, this would imply that

$$\sum_{k=k_0}^{p-1} \frac{\det(F(s))}{(s-\lambda_0)^{k+1}} (\lambda_0 I - A|_{P_{\lambda_0}H})^k \tilde{P}_{\lambda_0} B$$

is holomorphic on $\mathbb{C}_g^+$. Thus using the definition of a pole, we get that

$$\begin{aligned}&(\lambda_0 I - A|_{P_{\lambda_0}H})^{p-k_0-1} \sum_{k=k_0}^{p-1} \frac{\det(F(s))}{(s-\lambda_0)^{k+1}} (\lambda_0 I - A|_{P_{\lambda_0}H})^k \tilde{P}_{\lambda_0} B \\ &= \frac{\det(F(s))}{(s-\lambda_0)^{k_0+1}} (\lambda_0 I - A|_{P_{\lambda_0}H})^{p-1} \tilde{P}_{\lambda_0} B\end{aligned}$$

is holomorphic at λ_0. However, this can only happen if $(\lambda_0 I - A|_{P_{\lambda_0}H})^{p-1}\tilde{P}_{\lambda_0}B = 0$. By the definition of a pole there is a $x \in P_{\lambda_0}H$ such that $(\lambda_0 I - A|_{P_{\lambda_0}H})^{p-1}x \neq 0$. The optimizability of system $\Sigma(A,B)$ implies that there are elements $y \in H$ and $u \in \mathbb{C}^m$ such that

$$x = (\lambda_0 I - A)y - Bu.$$

Since $x \in P_{\lambda_0}H$, this implies $x = (\lambda_0 I - A|_{P_{\lambda_0}H})P_{\lambda_0}y - \tilde{P}_{\lambda_0}Bu$. Multiplying both sides with $(\lambda_0 I - A|_{P_{\lambda_0}H})^{p-1}$, we get

$$0 \neq (\lambda_0 I - A|_{P_{\lambda_0}H})^{p-1}x = (\lambda_0 I - A|_{P_{\lambda_0}H})^{p}y - (\lambda_0 I - A|_{P_{\lambda_0}H})^{p-1}\tilde{P}_{\lambda_0}Bu = 0,$$

which is a contradiction. Thus

$$f(s) := \det(F(s)), \quad s \in \mathbb{C}_g^+, \tag{37}$$

is holomorphic and bounded on $\mathbb{C}_g^+$ and every $\lambda \in \mathbb{C}_g^+ \cap \sigma(A)$ is a zero of f with order at least $p(\lambda, A)$.

Next we show that f is not identically zero. Assume that f is identical to zero on $\mathbb{C}_g^+$. Using (36), (37),

$$f(s) = \det\left((s-\alpha)\Omega(s) - I\right) \det\left(\frac{1}{s-\alpha} I\right), \quad s \in \mathbb{C}_g^+,$$

it would imply that

$$\det\left((s-\alpha)\Omega(s) - I\right) = 0, \quad s \in \mathbb{C}_g^+.$$

Now the holomorphicity of $\det\left((s-\alpha)\Omega(s) - I\right)$ on $\mathbb{C}_\tau^+$ implies

$$0 = \det\left((\alpha-\alpha)\Omega(\alpha) - I\right) = \det(I) = 1,$$

which is a contradiction. Thus $f \not\equiv 0$ on $\mathbb{C}_g^+$.
Applying now Duren [6, Theorem 11.3] to $f \in \boldsymbol{H}_\infty(\mathbb{C}_g^+)$ shows

$$\sum_{n\in\mathbb{N},\mathrm{Re}(\lambda_n)>g} \frac{p(\lambda_n, A)(\mathrm{Re}(\lambda_n) - g)}{1 + |\lambda_n - g|^2} < \infty.$$

Therefore, using (33) and $m_g(\lambda_n, A) \leq m$, we get

$$\sum_{n\in\mathbb{N},\mathrm{Re}(\lambda_n)>g} \frac{m_a(\lambda_n, A)(\mathrm{Re}(\lambda_n) - g)}{1 + |\lambda_n - g|^2} < \infty.$$

3. It remains to prove that

$$\sum_{n\in\mathbb{N},\mathrm{Re}(\lambda_n)>g} \frac{m_a(\lambda_n, A)}{|\lambda_n - g|^2} < \infty$$

for every $g > g_b^F$. Let $k_n := m_a(\lambda_n, A)$, $g > g_b^F$ and $\tilde{g} \in (g_b^F, g)$. By part (2), we have

$$\sum_{n\in\mathbb{N},\mathrm{Re}(\lambda_n)>g} \frac{k_n(\mathrm{Re}(\lambda_n) - g)}{1 + |\lambda_n - g|^2} < \infty \quad \text{and} \quad \sum_{n\in\mathbb{N},\mathrm{Re}(\lambda_n)>g} \frac{k_n(\mathrm{Re}(\lambda_n) - \tilde{g})}{1 + |\lambda_n - \tilde{g}|^2} < \infty.$$

For any $\lambda \in \mathbb{C}$ with $|\lambda - g| \geq 1$ we get

$$\begin{aligned}
&\frac{1}{1 + |\lambda - g|^2} \\
&= \frac{1}{1 + |\lambda - \tilde{g}|^2} \frac{1 + |\lambda - \tilde{g}|^2}{1 + |\lambda - g|^2} \leq \frac{1}{1 + |\lambda - \tilde{g}|^2} \frac{1 + (|\lambda - g| + |g - \tilde{g}|)^2}{1 + |\lambda - g|^2} \\
&\leq \frac{1}{1 + |\lambda - \tilde{g}|^2} \frac{1 + |\lambda - g|^2(1 + g - \tilde{g})^2}{1 + |\lambda - g|^2} = \frac{(1 + g - \tilde{g})^2}{1 + |\lambda - \tilde{g}|^2}.
\end{aligned} \tag{38}$$

Let $J_1 := \{n \in \mathbb{N} \mid \lambda_n \in \sigma_g^+(A) \text{ and } |\lambda_n - g| \geq 1\}$ and $J_2 := \{n \in \mathbb{N} \mid \lambda_n \in \sigma_g^+(A) \text{ and } |\lambda_n - g| < 1\}$. Since J_2 consists only of finitely many points, we get

$$\sum_{n\in J_2} \frac{k_n}{|\lambda_n - g|^2} < \infty.$$

Thus the statement follows directly from the calculation

$$\begin{aligned}
&\sum_{n\in J_1} \frac{k_n}{|\lambda_n - g|^2} \\
&\leq 2 \sum_{n\in J_1} \frac{k_n}{1 + |\lambda_n - g|^2} \\
&= \frac{2}{g - \tilde{g}} \left[\sum_{n\in J_1} k_n \frac{\mathrm{Re}(\lambda_n - \tilde{g})}{1 + |\lambda_n - g|^2} - \sum_{n\in J_1} k_n \frac{\mathrm{Re}(\lambda_n - g)}{1 + |\lambda_n - g|^2} \right] \\
&\overset{(38)}{\leq} \frac{2(1 + g - \tilde{g})^2}{g - \tilde{g}} \sum_{n\in J_1} k_n \frac{\mathrm{Re}(\lambda_n - \tilde{g})}{1 + |\lambda_n - \tilde{g}|^2} - \frac{2}{g - \tilde{g}} \sum_{n\in J_1} k_n \frac{\mathrm{Re}(\lambda_n - g)}{1 + |\lambda_n - g|^2} \\
&< \infty. \qquad \square
\end{aligned}$$

The next proposition gives a simple necessary condition for optimizability of a system $\Sigma(A,B)$.

PROPOSITION 6.3. *Assume that the system $\Sigma(A,B)$ is optimizable, and let F be an LQ-stabilizing feedback. Then for every $g > g_b^F$ there exist constants $M_1, M_2 > 0$ such that*

$$M_1 \leq \|B^*\psi\| \leq M_2$$

for every $\psi \in N(\overline{\lambda}I - A^*)$ with $\|\psi\| = 1$, where λ is an eigenvalue of A with $\mathrm{Re}(\lambda) > g$.

Proof. Let $g > g_b^F$. Using Proposition 3.6 there exists $M_1' > 0$, such that for every $\psi \in H$ with $\|\psi\| = 1$ and every $\lambda \in \mathbb{C}_g^+$ there is a $\xi_\psi \in H$ and $\omega_\psi \in \mathbb{C}^m$ such that

$$\psi = (\lambda I - A)\xi_\psi - B\omega_\psi \tag{39}$$

and $\|\xi_\psi\|_H, \|\omega_\psi\| \leq M_1'$. We now choose $\psi \in N(\overline{\lambda}I - A^*)$ with $\|\psi\| = 1$, where λ is an eigenvalue of A with $\mathrm{Re}(\lambda) > g$. Note that by Lemma 6.2 there exists such a ψ. Taking the inner product of (39) with ψ, we obtain

$$1 = \langle \xi_\psi, (\overline{\lambda}I - A^*)\psi\rangle - \langle B\omega_\psi, \psi\rangle = -\langle \omega_\psi, B^*\psi\rangle$$

and thus

$$1 \leq M_1'\|B^*\psi\|.$$

Next we prove that there exists a constant $M_2 > 0$ such that $\|B^*\psi\| \leq M_2$. Since B is an admissible control operator for $T(t)$, there exist $t_1 > 0$ and $M > 0$ such that

$$\left\| \int_0^{t_1} T(t_1 - \rho)Bu(\rho)\, d\rho \right\| \leq M\|u\|_{\boldsymbol{L}_2(0,t_1;\mathbb{C}^m)}$$

for every $u \in \boldsymbol{L}_2(0,t_1;\mathbb{C}^m)$. Let $K := \sup_{\lambda\in\sigma(A)} \mathrm{Re}(\lambda) < \infty$ and define

$$f(\mu) := \begin{cases} \frac{1-e^{-2\mu t_1}}{2\mu}, & \mu \in [g,K]\backslash\{0\}, \\ t_1, & \mu = 0. \end{cases}$$

By l'Hôspital's rule, f is continuous on $[g,K]$ and so

$$\sup_{\mu\in[g,K]} |f(\mu)| < \infty.$$

Let $\psi \in N(\overline{\lambda}I - A^*)$ with $\|\psi\| = 1$, where λ is an eigenvalue of A with $\mathrm{Re}(\lambda) > g$. We define $u_\lambda \in \boldsymbol{L}_2(0,t_1;\mathbb{C})$ by

$$u_\lambda(\rho) := \frac{1}{t_1}e^{-\lambda(t_1-\rho)}, \qquad \rho \in [0,t_1].$$

This implies

$$\begin{aligned}\|B^*\psi\| &= \sup_{\|u\|=1} |\langle u, B^*\psi\rangle| = \sup_{\|u\|=1} |\langle Bu, \psi\rangle| = \sup_{\|u\|=1} \left| \int_0^{t_1} u_\lambda(\rho)e^{\lambda(t_1-\rho)}\, d\rho \langle Bu, \psi\rangle \right| \\ &= \sup_{\|u\|=1} \left| \int_0^{t_1} \langle Buu_\lambda(\rho), e^{\overline{\lambda}(t_1-\rho)}\psi\rangle\, d\rho \right| = \sup_{\|u\|=1} \left| \int_0^{t_1} \langle Buu_\lambda(\rho), T^*(t_1-\rho)\psi\rangle\, d\rho \right|\end{aligned}$$

$$
\begin{aligned}
&= \sup_{\|u\|=1} \left| \int_0^{t_1} \langle T(t_1-\rho)Buu_\lambda(\rho), \psi\rangle \, d\rho \right| = \sup_{\|u\|=1} \left| \left\langle \int_0^{t_1} T(t_1-\rho)Buu_\lambda(\rho)\, d\rho, \psi \right\rangle \right| \\
&\le \sup_{\|u\|=1} \left\| \int_0^{t_1} T(t_1-\rho)Buu_\lambda(\rho)\, d\rho \right\| \le \sup_{\|u\|=1} M\|uu_\lambda\|_{\boldsymbol{L}_2(0,t_1;\mathbb{C}^m)} \\
&\le \frac{M}{t_1} f(\mathrm{Re}(\lambda))^{1/2} \le \frac{M}{t_1} \sup_{\mu\in[g,K]} |f(\mu)|^{1/2} := M_2. \qquad \square
\end{aligned}
$$

7. More information on the spaces $\boldsymbol{H_u}$ and $\boldsymbol{H_s}$. In Theorem 5.3 we saw that every optimizable system $\Sigma(A,B)$ with A satisfying SDA can be split into an exponentially stable part and an exactly controllable part. We now give a precise description of the spaces H_u and H_s appearing in Theorem 5.3. Note that by the definition of H_u and H_s we have $H = H_u \oplus H_s$. The main result of this section is the following theorem.

THEOREM 7.1. *Suppose $\Sigma(A,B)$ is optimizable and let A satisfy the SDA. Then the spaces H_u and H_s in Theorem* 5.3 *are given by*

$$
\begin{aligned}
H_u &= \overline{\mathrm{span}_{n\in\mathbb{N}} P_{\lambda_n} H}, \\
H_s &= \{x \in H | T(\cdot)x \in \boldsymbol{L}_2(0,\infty;H)\},
\end{aligned}
$$

where $\sigma(A)\cap\mathbb{C}_0^+ = \{\lambda_n\}_{n\in\mathbb{N}}$ (see Theorem 6.1).

In order to prove this theorem we need a series of lemmas.

LEMMA 7.2. *Suppose that $\Sigma(A,B)$ is optimizable and let A satisfy the SDA. Then there exists a constant $C>0$ such that*

$$\|(\cdot I - A)^{-1}x\|_{\boldsymbol{L}_2(i\mathbb{R};H)} \le C\|x\|$$

for every $x\in H$.

Proof. Let F be an LQ-stabilizing feedback, and choose a negative σ larger than g_b^F. Then by Proposition 3.6 there exists a constant $\tilde{C}>0$ such that for every $x\in H$ there exist $\xi_x \in \boldsymbol{H}_2(\mathbb{C}_\sigma^+, H)$ and $\omega_x \in \boldsymbol{H}_2(\mathbb{C}_\sigma^+, \mathbb{C}^m)$ such that

$$(itI-A)^{-1}x = \xi_x(it) - (itI-A)^{-1}B\omega_x(it), \quad t\in\mathbb{R}, \tag{40}$$

$\|\xi_x\|_{\boldsymbol{H}_2(\mathbb{C}_\sigma^+,H)} \le \tilde{C}\|x\|_H$ and $\|\omega_x\|_{\boldsymbol{H}_2(\mathbb{C}_\sigma^+,\mathbb{C}^m)} \le \tilde{C}\|x\|_H$. Using Corollary 5.13, we obtain $(\cdot I-A)^{-1}B \in \boldsymbol{L}_\infty(i\mathbb{R};\mathcal{L}(\mathbb{C}^m,H))$ and thus for $x\in H$ (40) implies

$$
\begin{aligned}
&\|(\cdot I - A)^{-1}x\|_{\boldsymbol{L}_2(i\mathbb{R};H)} \\
&\le \|\xi_x(\cdot)\|_{\boldsymbol{L}_2(i\mathbb{R};H)} + \|(\cdot I-A)^{-1}B\|_{\boldsymbol{L}_\infty(i\mathbb{R};\mathcal{L}(U,H))}\|\omega_x(\cdot)\|_{\boldsymbol{L}_2(i\mathbb{R};\mathbb{C}^m)} \\
&\le C\|x\|_H
\end{aligned}
$$

for some $C>0$ independent of x. $\square$

LEMMA 7.3. *Suppose that $\Sigma(A,B)$ is exactly controllable in finite time and that A generates a C_0-group $T(t)$ on H. Then*

$$H = \overline{\mathrm{span}_{n\in\mathbb{N}} P_{\lambda_n} H},$$

where λ_n are the eigenvalues of A.

Proof. For a C_0-group there is a real constant γ such that $-A+\gamma I$ generates an exponentially stable C_0-semigroup. Since the assumptions made in the theorem also hold for $A-\gamma I$, we may without loss of generality assume that $-A$ generates an exponentially stable C_0-semigroup. By Theorem 3.10 we have that the spectrum of A is purely point spectrum without (finite) accumulation points. We denote this spectrum by $\{\lambda_n\}$.

Define $V := \overline{\operatorname{span}_{n\in\mathbb{N}} P_{\lambda_n} H}$ and $W := V^\perp$, and assume that $W \neq \emptyset$. It is easy to see that V is $T(t)$-invariant. By Lemmas 4.2 and 4.3 we obtain that the system $\Sigma(A_W, B_W)$ is exactly controllable in finite time. The corresponding C_0-semigroup on W is given by

$$T_W(t)x = P_W T(t)x, \qquad x \in W. \tag{41}$$

Since W is the orthogonal complement of V, it follows that W is $T(t)^*$-invariant, and

$$T_W(t)^* x = T(t)^* x, \qquad x \in W.$$

The generator of $T_W(t)$ is given by $A_W^* := A^*|_W$. From the fact that the spectrum of A consists of only point spectrum with finite multiplicity and without an accumulation point, it follows that $\sigma(A^*) = \{\bar{\lambda}_n\}_n$, and $\rho_\infty(A^*) = \rho(A^*)$. Using part (1) of Lemma 4.2 and (41), we have that

$$\sigma(A_W^*) \subset \sigma(A^*) = \{\bar{\lambda}_n\}_n.$$

Let $\varepsilon > 0$ be arbitrary. If $\sigma_{-\varepsilon}^+(A_W^*) \neq \emptyset$, then there exist a $x \in W$ and an $n \in \mathbb{N}$ such that $(\cdot I - A_W^*)^{-1}x$ is not holomorphic at $\overline{\lambda}_n$ [18, p. 174]. Since $(sI - A_W^*)^{-1}x = (sI - A^*)^{-1}x$, $s \in \rho(A^*)$, we get $(\cdot I - A^*)^{-1}x$ is not holomorphic at $\overline{\lambda}_n$. This implies that

$$\int_\Gamma (sI - A^*)^{-1} x \, ds \neq 0,$$

where Γ is a simple closed contour in $\mathbb{C}$ with only one point of $\sigma(A^*)$ in its interior, namely $\overline{\lambda}_n$, and no points of $\sigma(A^*)$ on Γ. Now there is a $y \in H$ such that

$$\langle P_{\lambda_n} y, x\rangle = \left\langle y, \int_\Gamma (sI - A^*)^{-1} x \, ds \right\rangle \neq 0.$$

This is in contradiction with $P_{\lambda_n} y \in V$ and $x \in W = V^\perp$. Thus $\sigma_{-\varepsilon}^+(A_W^*) = \emptyset$, and therefore $\sigma_{-\varepsilon}^+(A_W) = \emptyset$. Since $\Sigma(A_W, B_W)$ is exactly controllable in finite time it is LQ-stabilizable as well. Thus Theorem 5.14 shows that there is a constant $M > 0$ such that

$$\|T_W(t)\| \leq M, \qquad t \geq 0.$$

This implies

$$\|T(-t)\| \geq \|T_W(-t)\| \geq \frac{1}{\|T_W(t)\|} \geq M^{-1}, \qquad t \geq 0,$$

which is in contradiction with the exponential stability of $-A$. Thus the assumption $W \neq \emptyset$ does not hold, and so we get $H = \overline{\operatorname{span}_{n\in\mathbb{N}} P_{\lambda_n} H}$. □

Since $\boldsymbol{H}_2(\mathbb{C}_0^+; H)$ is a closed subset of $\boldsymbol{L}_2(i\mathbb{R}; H)$, we can write

$$\boldsymbol{L}_2(i\mathbb{R}; H) = \boldsymbol{H}_2(\mathbb{C}_0^+; H) \oplus \boldsymbol{H}_2(\mathbb{C}_0^+; H)^\perp, \tag{42}$$

where $\boldsymbol{H}_2(\mathbb{C}_0^+;H)^\perp$ is the orthogonal complement in $\boldsymbol{L}_2(i\mathbb{R};H)$ of $\boldsymbol{H}_2(\mathbb{C}_0^+;H)$. In [3, Theorem A.6.22] it is shown that

$$\boldsymbol{H}_2(\mathbb{C}_0^+;H)^\perp = \left\{f : \mathbb{C}_0^- \to H | f(\,-\,\cdot) \in \boldsymbol{H}_2(\mathbb{C}_0^+;H)\right\}. \tag{43}$$

Proof of Theorem 7.1. By Theorem 5.3 there exists a projection $P \in \mathcal{L}(H)$ such that (1)–(5) of Theorem 5.3 are satisfied. Lemma 7.2 shows that $(\cdot I - A)^{-1}x \in \boldsymbol{L}_2(i\mathbb{R};H)$ for every $x \in H$. If we define

$$\tilde{H}_s = \{x \in H \mid (\cdot I - A)^{-1}x \in \boldsymbol{H}_2(\mathbb{C}_0^+;H)\} \quad \text{and}$$
$$\tilde{H}_u = \{x \in H \mid (\cdot I - A)^{-1}x \in \boldsymbol{H}_2(\mathbb{C}_0^+;H)^\perp\},$$

then (42) shows that

$$\tilde{H}_s \cap \tilde{H}_u = \{0\}.$$

1. We now prove that $\tilde{H}_s$ and $\tilde{H}_u$ are closed, linear subspaces of H. We will prove this result only for $\tilde{H}_s$, as the proof for $\tilde{H}_u$ is very similar. That $\tilde{H}_s$ is a linear subspace of H follows immediately from the fact that $\boldsymbol{H}_2(\mathbb{C}_0^+,H)$ is a linear vector space. In order to prove the closedness we choose a sequence $\{z_n\}_n$ in $\tilde{H}_s$ which converges to $z \in H$. By Lemma 7.2 we get

$$\lim_{n\to\infty} \|(\cdot I - A)^{-1}z_n - (\cdot I - A)^{-1}z\|_{\boldsymbol{L}_2(i\mathbb{R},H)} \le C \lim_{n\to\infty} \|z_n - z\|_H = 0.$$

Since $\boldsymbol{H}_2(\mathbb{C}_0^+;H)$ is a closed subspace of $\boldsymbol{L}_2(i\mathbb{R},H)$, this implies that $(\cdot I - A)^{-1}z \in \boldsymbol{H}_2(\mathbb{C}_0^+;H)$, and so $\tilde{H}_s$ is closed.
2. We now prove that $H_u \subset \tilde{H}_u$. Since $\sigma^+_{g_b^F}(A)$ consists only of point spectrum with no (finite) accumulation point, we have that

$$\rho_\infty(A) \cap \mathbb{C}^+_{g_b^F} = \rho(A) \cap \mathbb{C}^+_{g_b^F}.$$

Since the imaginary axis is in the resolvent set, by Lemma 4.2 we have for all $t \in \mathbb{R}$ and $x \in H_u$

$$(itI - A)^{-1}x = (itI - A_u)^{-1}. \tag{44}$$

The operator $-A_u$ generates an exponentially stable semigroup on H_u, and hence for $x \in H_u$ we get that $(itI - A_u)^{-1}x$ is the Fourier transform of $-T_u(t)x$, $t \in (-\infty,0)$. This last function is in $\boldsymbol{L}_2(-\infty,0;H)$. By the Paley–Wiener theorem [3, Theorem A.6.21], (43), and (44), this implies that $(\cdot I - A)^{-1}x \in \boldsymbol{H}_2(\mathbb{C}_0^+;H)^\perp$, and thus $x \in \tilde{H}_u$.
3. We now prove that $H_s \subset \tilde{H}_s$. Let $x \in H_s$ arbitrary. Then $T(\cdot)x \in \boldsymbol{L}_2(0,\infty;H)$ and thus the Paley–Wiener theorem [3, Theorem A.6.21] implies that its Laplace transform $(\cdot I - A)^{-1}x$ is in $\boldsymbol{H}_2(\mathbb{C}_0^+;H)$. Thus $x \in \tilde{H}_s$.
4. We now prove $H_u = \tilde{H}_u$ and $H_s = \tilde{H}_s$. We prove this result only for $\tilde{H}_s$, as the proof for $\tilde{H}_u$ is very similar. Assume that $H_s = \tilde{H}_s$ does not hold. Then there exists an element $x \in \tilde{H}_s \backslash H_s$. We can write x as $x = x_u + x_s$ with $x_u \in H_u$ and $x_s \in H_s$. Since $x_u = x - x_s \in \tilde{H}_s$, we obtain $x_u \in H_u \cap \tilde{H}_s \subset \tilde{H}_u \cap \tilde{H}_s = \{0\}$, which is in contradiction with $x \in \tilde{H}_s \backslash H_s$.

5. We now prove that $V \subset H_u$, where
$$V := \overline{\operatorname{span}_{n\in\mathbb{N}} P_{\lambda_n} H},$$
and $\{\lambda_n\}_n = \sigma(A) \cap \mathbb{C}_0^+$. First of all we choose $x \in P_{\lambda_n} H$ for some $n \in \mathbb{N}$. Then in [3, p. 99] it has been proven that
$$(itI - A)^{-1}x = \sum_{j=0}^{m_a(\lambda_n,A)} (-1)^j \frac{(\lambda_n I - A)^j x}{(it-\lambda_n)^{j+1}}, \qquad t \in \mathbb{R},$$
where $m_a(\lambda_n, A)$ is the algebraic multiplicity of the eigenvalue λ_n. Since $\mathrm{Re}(\lambda_n) > 0$, we have
$$\frac{1}{(\cdot - \lambda_n)^j} \in \boldsymbol{H}_2(\mathbb{C}_0^+; H)^\perp,$$
and so we obtain that $x \in \tilde{H}_u$. Now $H_u = \tilde{H}_u$ and V are closed, linear subspaces of H and thus the statement is proved.
6. In order to prove the theorem it now remains to show that $V = H_u$ holds. The system $\Sigma(A_u, (I - \tilde{P})B)$ is exactly controllable in finite time. Thus Lemma 7.3 proves $V = H_u$. □

8. An example. We now construct an example that is optimizable, but it is not possible to split the state space in a direct sum as given in Theorem 1.3. The generator in this example does not satisfy the SDA at any negative number. For the construction of this example the following lemmas will be useful. For background information on Carleson measures we refer to Garnett [9, p. 31].

LEMMA 8.1. *Let* $\{q_n\}_{n\in\mathbb{N}} = \mathbb{Q} \cap (\frac{1}{2}, \infty)$ *be chosen such that*
$$q_{k+\frac{l(l-1)}{2}} \in [k-1, k], \qquad l \in \mathbb{N}, k \in \{1, \dots, l\},$$
and define $\{\gamma_n\}_{n\in\mathbb{N}} \subset \mathbb{C}_0^+$ *by*
$$\gamma_n := q_n + in^4, \qquad n \in \mathbb{N}.$$
Then $\mu := \sum_{n\in\mathbb{N}} \mathrm{Re}\gamma_n \delta_{\gamma_n}$ *is a Carleson measure.*

Proof. In order to prove this we define
$$S(h, y_0) := \{z \in \mathbb{C}_0^+ \mid 0 < \mathrm{Re} z < h,\ y_0 < \mathrm{Im}\, z < y_0 + h\}, \qquad h > 0, y_0 \in \mathbb{R}.$$
Now μ is a Carleson measure if and only if there exists a constant $A > 0$ such that $\mu(S(h, y_0)) \le Ah$ for every $h > 0$ and all $y_0 \in \mathbb{R}$ (see, for example, [9, p. 31]).

Clearly, $\mu(S(h, y_0)) = 0$ if $h \in [0, \frac{1}{2}]$. For $h > \frac{1}{2}$ and $y_0 < -h$, we have that $\mu(S(h, y_0)) = 0$ as well.

We now consider the situation $h > \frac{1}{2}$ and $y_0 \ge h^2$. Then for every $n \in \mathbb{N}$ with $y_0 < n^4 < y_0 + h$, we get
$$(n+1)^4 > n^4 + n^2 > y_0 + \sqrt{y_0} \ge y_0 + h.$$
Thus $\#\{\{\gamma_n\}_{n\in\mathbb{N}} \cap S(h, y_0)\} \le 1$. Combining this with the fact that if $\gamma_n \in S(h, y_0)$, then q_n is less than h, shows that $\mu(S(h, y_0)) \le h$.

Finally, we have to consider the situation $h > \frac{1}{2}$, $y_0 \in (-h, h^2)$. Then

$$S(h, y_0) \subset R(h) := \left\{z \in \mathbb{C}_0^+ \mid 0 < \mathrm{Re} z < h,\ -h < \mathrm{Im}\, z < h^2 + h\right\}.$$

Using $h > \frac{1}{2}$, we see that

$$h^2 + h \leq h^2 + 2h^2 < 16h^2.$$

From this we get $\#\{\{\gamma_n\}_{n\in\mathbb{N}} \cap R(h)\} \leq 2\sqrt{h}$. We now choose $l_h \in \mathbb{N}$ such that

$$\frac{l_h(l_h-1)}{2} < 2\sqrt{h} < \frac{l_h(l_h+1)}{2}.$$

This implies immediately

$$l_h \leq 1 + 4h^{1/4} < 6h^{1/4},$$

where we have used that $h > \frac{1}{2}$. Thus

$$\mu(S(h, y_0)) \leq \mu(R(h)) \leq \sum_{n=1}^{[2\sqrt{h}]} q_n \leq \sum_{l=1}^{l_h} \sum_{k=1}^{l} k = \frac{1}{6} l_h(l_h+1)(l_h+2) \leq Ah^{3/4},$$

where $A > 0$ is independent of h. Thus μ is a Carleson measure. □

Lemma 8.2. *Let* $\{q_n\}_{n\in\mathbb{N}} = \mathbb{Q} \cap (\frac{1}{2}, \infty)$ *be chosen as in Lemma* 8.1 *and define* $\{\beta_n\}_{n\in\mathbb{N}}$ *by*

$$\beta_{2n} := \gamma_n, \qquad \beta_{2n-1} := \gamma_n + \frac{1}{n}, \qquad n \in \mathbb{N}.$$

Moreover, let $\Theta \in \boldsymbol{H}_\infty(\mathbb{C}_0^+)$ *be the Blaschke product corresponding to the zeros* $\{\beta_n\}$, *i.e.,*

$$\Theta(s) := \prod_{n=1}^{\infty} \frac{|1-\beta_n^2|}{1-\beta_n^2} \frac{s-\beta_n}{s+\bar{\beta}_n}, \quad s \in \mathbb{C}_0^+.$$

Then

$$\sup_{0<\mathrm{Re}s<1/4} |\Theta^{-1}(s)| < \infty. \tag{45}$$

Proof. For $x \in (0, \frac{1}{4})$, $y \in \mathbb{R}$, we get

$$\begin{aligned}|\Theta(x+iy)^{-2}| &= \prod_{n\in\mathbb{N}} \frac{(x+\mathrm{Re}\beta_n)^2 + (y-\mathrm{Im}\,\beta_n)^2}{(x-\mathrm{Re}\beta_n)^2 + (y-\mathrm{Im}\,\beta_n)^2} \\ &= \prod_{n\in\mathbb{N}} \left(1 + \frac{4x\mathrm{Re}\beta_n}{(x-\mathrm{Re}\beta_n)^2 + (y-\mathrm{Im}\,\beta_n)^2}\right).\end{aligned}$$

Thus (45) is equivalent to

$$\sup_{x\in(0,\frac{1}{4})} \sup_{y\in\mathbb{R}} \sum_{n\in\mathbb{N}} \ln\left(1 + \frac{4x\mathrm{Re}\beta_n}{(x-\mathrm{Re}\beta_n)^2 + (y-\mathrm{Im}\,\beta_n)^2}\right) < \infty. \tag{46}$$

Using $\ln(1+z) \leq z$, $z \geq 0$, and

$$0 \leq \frac{4x\mathrm{Re}\beta_n}{(x-\mathrm{Re}\beta_n)^2 + (y - \mathrm{Im}\,\beta_n)^2},$$

it is easy to see that

$$\sup_{x\in(0,\frac{1}{4})} \sup_{y\in\mathbb{R}} \sum_{n\in\mathbb{N}} \frac{x\mathrm{Re}\beta_n}{(x-\mathrm{Re}\beta_n)^2 + (y - \mathrm{Im}\,\beta_n)^2} < \infty \tag{47}$$

implies (46). Thus it remains to prove that

$$h(x,y) := \sum_{n\in\mathbb{N}} \frac{x\mathrm{Re}\beta_n}{(x-\mathrm{Re}\beta_n)^2 + (y - \mathrm{Im}\,\beta_n)^2}$$

is uniformly bounded on $\mathbb{C}_0^+ \cap \mathbb{C}_{1/4}^-$.

Let $x + iy \in \mathbb{C}_0^+ \cap \mathbb{C}_{1/4}^-$ be arbitrary. Define $z := \frac{1}{3} - x$. From $\mathrm{Re}\beta_n > \frac{1}{2}$, we get

$$\begin{aligned} h(x,y) &= \sum_{n\in\mathbb{N}} \frac{(\frac{1}{3}-z)\mathrm{Re}\beta_n}{(\frac{1}{3}-z-\mathrm{Re}\beta_n)^2 + (y - \mathrm{Im}\,\beta_n)^2} \\ &\leq 3 \sum_{n\in\mathbb{N}} \frac{(\frac{1}{3}-z)(\mathrm{Re}\beta_n - \frac{1}{3})}{(\frac{1}{3}-z-\mathrm{Re}\beta_n)^2 + (y - \mathrm{Im}\,\beta_n)^2} \\ &\leq 3 \sum_{n\in\mathbb{N}} \mathrm{Re}\gamma_n |g_{z,y}(\gamma_n)|^2, \end{aligned}$$

where $\gamma_n := \beta_n - \frac{1}{3} \in \mathbb{C}_0^+$ and

$$g_{z,y}(s) = \frac{\sqrt{\frac{1}{3}-z}}{s+z-iy} \in \boldsymbol{H}_2(\mathbb{C}_0^+).$$

By Lemma 8.1 $\sum_{n\in\mathbb{N}} \mathrm{Re}\beta_{2n}\delta_{\beta_{2n}}$ is a Carleson measure. Similarly, it can be shown that $\sum_{n\in\mathbb{N}} \mathrm{Re}\beta_{2n+1}\delta_{\beta_{2n+1}}$ is a Carleson measure. From this it follows easily that $\sum_{n\in\mathbb{N}} \mathrm{Re}\gamma_n\delta_{\gamma_n}$ also is a Carleson measure. Hence, Avdonin and Ivanov [2, p. 56] or Garnett [9, Theorem 3.9] implies

$$h(x,y) \leq C\|g_{z,y}\|^2_{\boldsymbol{H}_2(\mathbb{C}_0^+)} = C\left\| e^{-(z-iy)\cdot}\sqrt{\frac{1}{3}-z}\right\|^2_{\boldsymbol{L}_2(0,\infty)} = \frac{C}{2}\frac{x}{\frac{1}{3}-x} \leq \frac{3C}{2}.$$

Thus $|\Theta(s)^{-1}|$ is uniformly bounded on $\mathbb{C}_0^+ \cap \mathbb{C}_{1/4}^-$. □

The following realization result can be found in Salamon [30] and in Ober and Wu [21]. The proof in the notation of this paper is documented in Jacob and Zwart [16].

Lemma 8.3. *Let Θ be given as in Lemma 8.2. Then there exist a Hilbert space V, an exponentially stable C_0-semigroup $T(t)$ on V with generator A, and an admissible control operator B for $T(t)$ such that the system $\Sigma(A,B)$ is exactly controllable in finite time, every $-\overline{\beta}_n$, $n \in \mathbb{N}$, is an eigenvalue of A, and the function $x_n(s) := \frac{1}{s+\overline{\beta}_n}$ is a corresponding eigenvector.*

EXAMPLE 8.4. We now consider the system $\Sigma(A,B)$ given as in Lemma 8.3. Since $\Sigma(A,B)$ is exactly controllable in finite time, by Lemma 3.8 and Proposition 3.9 the system $\Sigma(A+I,B)$ is optimizable. Lemma 8.3 shows that $\{\lambda_n\}_{n\in\mathbb{N}} \subseteq \sigma(A+I)$ holds, where $\lambda_n := -\bar{\beta}_n + 1$, and $x_{\lambda_n}(s) := \frac{1}{s-\lambda_n}$ is an eigenvector corresponding to the eigenvalue λ_n. Thus the spectrum of $A+I$ does not satisfy the SDA at any negative number.

Next, we show that it is not possible to decompose the state space V as $V = V_s \oplus V_u$, where

$$\begin{aligned} V_s &:= \{x_0 \in V \mid e^{-g\cdot}T(\cdot)x_0 \in \boldsymbol{L}_2(0,\infty;V)\},\\ V_u &:= \overline{\operatorname*{span}_{\lambda\in\sigma(A+I) \text{ with } \mathrm{Re}(\lambda)\geq g} P_\lambda V} \end{aligned}$$

for some $g<0$. Let $g<0$ be arbitrary. It is easy to see that $x_{\lambda_n} \in V_u$ if $\mathrm{Re}(\lambda_n) \geq g$. Next, we show that $x_{\lambda_n} \in V_s$ holds if $\mathrm{Re}(\lambda_n) < g$. Let $n \in \mathbb{N}$ with $\mathrm{Re}(\lambda_n) < g$ be arbitrary. Since x_{λ_n} is an eigenvector of A with eigenvalue λ_n, we have that

$$T(t)x_{\lambda_n} = e^{\lambda_n t}x_{\lambda_n}.$$

This shows $e^{-g\cdot}T(\cdot)x_{\lambda_n} \in \boldsymbol{L}_2(0,\infty;V)$.

By the construction of the sequence $\{\beta_n\}_{n\in\mathbb{N}}$ there now exist subsequences $\{\mu_n\}_{n\in\mathbb{N}}$, $\{\nu_n\}_{n\in\mathbb{N}} \subseteq \{\lambda_n\}_{n\in\mathbb{N}}$ such that

(1) $\mathrm{Re}\mu_n < g < \mathrm{Re}\nu_n$, $n \in \mathbb{N}$,

(2) $\nu_n = \mu_n + \alpha_n$, $n \in \mathbb{N}$, with $\alpha_n > 0$ and $\lim_{n\to\infty} \alpha_n = 0$,

(3) $\lim_{n\to\infty} \mathrm{Re}\mu_n = g$ and $\lim_{n\to\infty} \mathrm{Im}\,\mu_n = \infty$.

Thus $x_{\mu_n} \in V_s$ and $x_{\nu_n} \in V_u$ for every $n \in \mathbb{N}$. It is now easy to see that

$$\|x_{\nu_n}\|^2 = \frac{\pi}{|\mathrm{Re}\nu_n|}, \qquad n \in \mathbb{N},$$

and

$$\lim_{n\to\infty} \|x_{\mu_n} - x_{\nu_n}\| = 0.$$

Let us now assume that $V = V_s \oplus V_u$ is satisfied. Then there would exist a projection $P \in \mathcal{L}(V)$ with $\ker P = V_s$ and $\mathrm{Im}\,P = V_u$. Thus

$$\begin{aligned} \frac{\pi}{|g|} = \lim_{n\to\infty} \|x_{\nu_n}\|^2 = \lim_{n\to\infty} \|Px_{\nu_n}\|^2 &= \lim_{n\to\infty} \|P(x_{\nu_n} - x_{\mu_n})\|^2 \\ &\leq \|P\|^2 \lim_{n\to\infty} \|x_{\nu_n} - x_{\mu_n}\|^2 = 0, \end{aligned}$$

which is a contradiction. Hence $V = V_s \oplus V_u$ is not satisfied.

9. Conclusion. For an infinite-dimensional optimizable system with a finite-rank admissible control operator we showed that the system can be decomposed into an exponentially stable subsystem and an exactly controllable subsystem. For the proof we needed the spectrum to be able to be decomposed into a stable and an unstable part. The example in section 8 shows that without this SDA Theorem 1.3 does not hold. Since this example is very technical, we feel that every optimizable system encountered in practice satisfies the SDA. Note that Theorem 1.4 already shows that the unstable part of the spectrum of an optimizable system consists of isolated points.

We gave characterizations of the state spaces of the subsystems. The state space of the unstable part equals the span of all unstable (generalized) eigenvectors and the state space of the exponentially stable part is given by all vectors for which the action of the original semigroup is stable.

From our results we derived easy necessary conditions for a system to be optimizable; see, e.g., Example 5.7, Theorem 6.1, and Proposition 6.3 or Jacob and Zwart [15].

ASYMPTOTIC BEHAVIOR OF A MARKOVIAN STOCHASTIC ALGORITHM WITH CONSTANT STEP*

JEAN-CLAUDE FORT† AND GILLES PAGÈS‡

Abstract. We first derive from abstract results on Feller transition kernels that, under some mild assumptions, a Markov stochastic algorithm with constant step size ε usually has a tight family of invariant distributions ν^ε, $\varepsilon \in (0, \varepsilon_0]$, whose weak limiting distributions as $\varepsilon \downarrow 0$ are all flow-invariant for its ODE. Then the main part of the paper deals with a kind of converse: what are the possible limiting distributions among all flow-invariant distributions of the ODE? We first show that no repulsive invariant (thin) set can belong to their supports. When the ODE is a stochastic pseudogradient descent, these supports cannot contain saddle or spurious equilibrium points either, so that they are eventually supported by the set of local minima of their potential. Such results require only the random perturbation to lie in L^2. Various examples are treated, showing that these results yield some weak convergence results for the ν^ε's, sometimes toward a saddle point when the algorithm is not a pseudogradient.

Key words. stochastic algorithm, stationary distribution, Markov chain, gradient descent, saddle point

Introduction. The use of recursive stochastic algorithms is widespread for solving optimization problems. This is due to the new simulation facilities brought by modern scientific computation. Stochastic algorithms are especially encountered in situations where some on-line parameter estimation has to be performed. Such algorithms are recursive, the current estimate being updated at every new observation of a process according to some time-varying deterministic (or predictable) parameter ε_t called *step* or *gain* parameter. In most practical situations, this parameter is gradually decreased so as to finally reach some lower bound ε_∞. Generally ε_∞ is nonzero to prevent any "freezing" of the algorithm at some metastable state or to track some possible slow change of the target.

Hence, this work addresses constant step algorithms, i.e., $\varepsilon_t = \varepsilon_\infty > 0$.

On the other hand, partially because of the recent developments of artificial neural network procedures, it turns out that many learning algorithms share the same features: a "gentle" white noise perturbing the "sophisticated" dynamics of a deterministic "average" differential system $ODE_h \equiv \dot{x} = -h(x)$ (known as the *ordinary differential equation* of the system) so that it reads

$$X^{t+1} = X^t - \varepsilon H(X^t, \omega^{t+1}),\ X^t \in \mathbb{R}^d,$$
$$\omega^t \text{ independently and identically distributed (i.i.d.)},\quad h(x) := \mathbb{E}(H(x, \omega^1)).$$

In such a framework, an algorithm proves to be a homogeneous Markov chain parametrized by its step ε. Under some reasonable conditions, for every small enough

ε the chain owns (at least) one invariant distribution ν^ε. Let $\mathcal{I}_\varepsilon$ be the set of invariant distributions of the algorithm with step ε. The set $\cup_{\varepsilon \in (0,\varepsilon_0]} \mathcal{I}_\varepsilon$ is tight for small enough $\varepsilon_0 > 0$, i.e., weakly relatively compact. On the other hand, the differential system ODE_h being a (deterministic) homogeneous Markov chain, usually owns some invariant distribution(s) as well, characterized by a flow-invariance property. Let $\mathcal{I}_h$ be the set of such flow-invariant distributions. Actually, in most practical situations, $\mathcal{I}_h$ is infinite: whenever ODE_h has two equilibrium points x_1^* and x_2^*, any combination $\alpha\delta_{x_1^*} + (1-\alpha)\delta_{x_2^*}$ is an invariant distribution. The set $\mathcal{I}_h$ can be much more sophisticated: for instance, an attracting cycle surrounding a repulsive equilibrium, etc.

It is a rather classical result that the set $\mathcal{I}_{0^+} := \cap_{\varepsilon\to 0}\overline{\cup_{0<\eta\le\varepsilon}\mathcal{I}_\eta}$ of the *possible weak limiting distributions* of $\nu^\varepsilon \in \mathcal{I}_\varepsilon$ as $\varepsilon \downarrow 0$ is contained in $\mathcal{I}_h$ (see [15] in one dimension, [20], [29] in the case of a unique attracting equilibrium x^* or, more recently, [18] in the slightly different framework of perturbed dynamical systems ; see also [9] for similar results for abstract continuous-time Markov processes).

However, whenever $\mathcal{I}_h \neq \{\delta_{x^*}\}$, the inclusion generally does not hold as an equality: not any flow-invariant distribution $\nu \in \mathcal{I}_h$ is a limiting value of $\nu^{\varepsilon_p} \in \mathcal{I}_{\varepsilon_p}$ as $\varepsilon_p \downarrow 0$. Thus, it seems quite natural that a repulsive equilibrium of ODE_h cannot be asymptotically weighted by any invariant distribution ν^ε of the algorithm when $\varepsilon \downarrow 0$, provided that there is noise enough at this point to push it away. Indeed, similar problems have been investigated in the decreasing step setting, see, e.g., [7], [21], or [28], for repulsive or saddle points leading to the conclusion that such points cannot be limit points for the algorithm. The question is to state whether or not such results still hold in the constant step setting.

These problems are deeply connected to the field of randomly perturbed systems which has been extensively investigated by several authors. Freidlin and Wentzell [13] deal with an ordinary differential equation perturbed by a vanishing standard Brownian motion. They show, using large deviations techniques, that such a diffusion converges in probability to some absolute minima of a suitably defined potential function. Y. Kifer, in several papers and in his book (see, e.g., [18, Chap. 2]), treats the case of randomly perturbed discrete dynamical systems when the perturbation fades. He obtains some general results, still based on a large deviation approach, that prove that the only possible limiting distributions for the invariant distributions ν^ε as $\varepsilon \downarrow 0$ are supported by "quasi-attractors" which turn out to be classical attractors under some natural assumptions. In fact, these works are more in connection with algorithms with decreasing step, since in all cases the perturbation fades as time goes by. In the field of Markov stochastic algorithms with constant step, new results by large deviation techniques have been obtained by M. Benaïm in [3]. This work, carried out independently from ours, was originally motivated by urn processes where the random perturbation term is naturally bounded.

Our aim in this paper is of the same sort but with different techniques. It consists, still within this Markov framework, of investigating the set $\mathcal{I}_{0^+}$ but under some low moment assumption on the random perturbation term (essentially L^2). Thus, a comparison shows what results are or are not moment dependent. Our methods rely on the local or global existence of a smooth Lyapunov function for the algorithm. We show, by twisting this function somewhat, that the distributions in $\mathcal{I}_{0^+}$ never weight the repulsive equilibrium points or the *thin* invariant repelling sets provided that they are excited enough by the noise. Furthermore, in the *pseudogradient* setting, i.e., when there exists a *global* Lyapunov function V such that $(\nabla V|h) \ge 0$ and

$\{(\nabla V|h) = 0\} = \{\nabla V = 0\}$, the whole set $\mathcal{I}_{0^+}$ is supported by the local minima of V if other critical points are excited enough. The case of *spurious* points is also investigated (x^* is spurious if $h(x^*) = 0$, whereas $\nabla V(x^*) \neq 0$).

The paper is organized as follows. In section 1 some existence and tightness results for invariant distributions of Feller homogeneous Markov chains are recalled; these yield some tractable criteria for constant gain stochastic algorithms. The aim is to show that our framework is quite realistic from a practical point of view. We do not care about the possible uniqueness of the invariant distribution for a given positive step ε as this question seems not to interfere with the asymptotic behavior of these distributions.

Section 2 is essentially devoted to the flow-invariance theorem and its first applications. This theorem proves that, under a mild uniform integrability assumption, $\mathcal{I}_{0^+} \subset \mathcal{I}_h$. An additional result is provided when the existence of the flow fails, provided there is some global Lyapunov function. In these two sections, we give only some very short proofs, along with references for the classical technical points.

Section 3 is the main part of the work. It relies on a second-order Taylor expansion in ε of the homogeneous Markov transitions $P^\varepsilon(x, dy)$. First, this yields that no excited enough repulsive critical point of the average function h can be asymptotically weighted by the invariant distributions of the algorithm as $\varepsilon \downarrow 0$. This result extends to repulsive *thin invariant sets.* Two subsections deal with important examples: the Lemniscate example and the periodic/quasi-cycle example, which illustrate both the apparent dissimilarity between the constant and the decreasing step versions of the same stochastic algorithm.

Second, the case of excited enough saddle points of ODE_h is investigated. It is first pointed out that such critical points can be asymptotically weighted when the algorithm is not a stochastic pseudogradient. The Lemniscate example stresses this situation: all the mass of the ν^ε concentrates at some saddle point of h. At this stage, a whole subsection is devoted to stochastic pseudogradient algorithms under the classical assumption in differential geometry that all saddle points are of Morse type. Finally, some further types of critical points are eliminated: the spurious equilibrium points. This latter result solves the case of inflection points in one dimension. Several examples illustrate these results.

Notation.

- $|\,.\,|$ denotes the canonical Euclidean norm on any $\mathbb{R}^d$ space unless noted otherwise;
- $(.|.)$ denotes the canonical inner product;
- $B(x, r)$ denotes the Euclidean open ball with center x and radius $r > 0$;
- $\mathcal{C}(0; 1)$ denotes the unit circle;
- $u \in \mathbb{R}^d$ denotes a row vector and ${}^t u$ denotes its (horizontal) transpose;
- $C_b(\mathbb{R}^d, \mathbb{R}) := \{f : \mathbb{R}^d \longrightarrow \mathbb{R},$ continuous and bounded$\}$;
- $C_0(\mathbb{R}^d, \mathbb{R}) := \{f : \mathbb{R}^d \longrightarrow \mathbb{R},$ continuous subject to (s.t.) $\lim_{|x|\to+\infty} f(x) = 0\}$;
- $\overset{(\mathcal{T})}{\Longrightarrow}$ denotes the weak convergence of probability measures on the topological space X endowed with the topology $\mathcal{T}$; when this topology is obvious (e.g., on $X = \mathbb{R}^d$) the notation $\overset{(X)}{\Longrightarrow}$ will be preferred;
- The letter ν—with or without superscript—always denotes a *probability* measure.

1. Background: Existence and tightness of the invariant distributions of a family of Markov chains.

1.1. General results. Let $(P^\varepsilon(x, dy))_{x\in\mathbb{R}^d}$, $\varepsilon \in (0, \varepsilon_0]$ be a family of Markov transitions on $(\mathbb{R}^d, \mathcal{B}(\mathbb{R}^d))$. We propose in Theorem 1.1 below several criteria for the existence and tightness of a family of stationary distributions in a Feller setting.

A distribution ν^ε is P^ε stationary (or P^ε invariant) if it satisfies $\nu^\varepsilon P^\varepsilon = \nu^\varepsilon$, i.e., $\int \nu^\varepsilon(dx)P^\varepsilon(x,A) = \nu^\varepsilon(A)$ for every Borel set $A \in \mathcal{B}(\mathbb{R}^d)$.

A probability transition $P(x,dy)$ is Feller if $P(f)(x) := \int f(y)P(x,dy)$ maps $C_b(\mathbb{R}^d,\mathbb{R})$ into itself.

These criteria are based on the existence of a Lyapunov function. They are adapted from classical criteria mentioned, e.g., in [9] or [25]. They turn out to be especially well fitted for stochastic approximation with constant step.

THEOREM 1.1. *Let $(P^\varepsilon)_{\varepsilon\in(0,\varepsilon_0]}$ be a family of transitions.*

A. PAKES–HAS'MINSKII SETTING. *Assume that $(P^\varepsilon)_{\varepsilon\in(0,\varepsilon_0]}$ satisfies the Pakes–Has'minskii assumption*

$$(H_b) \equiv \exists\, V : \mathbb{R}^d \to \mathbb{R}_+,\ \psi : \mathbb{R}^d \to \mathbb{R}\ s.t. \begin{cases} \text{(a)}\ \ \psi \le C\ \ and\ \lim\limits_{|x|\to+\infty} \psi(x) = -\infty, \\ \text{(b)}\ \ \begin{cases} \forall\,\varepsilon \in (0,\varepsilon_0],\ \exists\,\lambda(\varepsilon) > 0,\ \mu(\varepsilon) \in \mathbb{R} \\ s.t.\ P^\varepsilon V - V \le \lambda(\varepsilon)\psi + \mu(\varepsilon). \end{cases} \end{cases}$$

(a) *If the transitions $P^\varepsilon(x,dy)$ are Feller for every $\varepsilon \in (0,\varepsilon_0]$, there exists a family $(\nu^\varepsilon)_{\varepsilon\in(0,\varepsilon_0]}$ of P^ε-invariant distributions.*

(b) *If $\sup_{\varepsilon\in(0,\varepsilon_0]} \frac{\mu(\varepsilon)}{\lambda(\varepsilon)} < +\infty$, then the set of invariant distributions $\{\nu^\varepsilon \,/\, \nu^\varepsilon P^\varepsilon = \nu^\varepsilon,\ \varepsilon \in (0,\varepsilon_0]\}$ is tight.*

The function V is called a Lyapunov function for the family.

B. HAJEK SETTING. *Assume that $(P^\varepsilon)_{\varepsilon\in(0,\varepsilon_0]}$ satisfies the Hajek assumption*

$$(H_c) \equiv \exists\, V : \mathbb{R}^d \to \mathbb{R}_+,\ \ s.t. \begin{cases} \text{(a)}\quad \lim\limits_{|x|\to+\infty} V(x) = +\infty, \\ \text{(b)}\quad \begin{cases} \forall\,\varepsilon \in (0,\varepsilon_0],\ \exists\,\alpha(\varepsilon) \in (0,1),\ \exists\,\beta(\varepsilon) \in \mathbb{R}_+ \\ s.t. \quad P^\varepsilon V \le \alpha(\varepsilon)V + \beta(\varepsilon). \end{cases} \end{cases}$$

Then, (H_b) is fulfilled with $\lambda(\varepsilon) := 1-\alpha(\varepsilon)$, $\mu(\varepsilon) := \beta(\varepsilon)$, and $\psi := -V$. If, moreover,

$$L := \sup_{\varepsilon\in(0,\varepsilon_0]} \frac{\beta(\varepsilon)}{1-\alpha(\varepsilon)} < +\infty,\ \textit{then}\ \sup\{\nu^\varepsilon(V),\ \nu^\varepsilon P^\varepsilon = \nu^\varepsilon,\ \varepsilon \in (0,\varepsilon_0]\} \le L.$$

Proof (sketch). Setting A is a parametrized version of a classical criterion of existence of a stationary distribution for Feller–Markov chains (see, e.g., [9, p. 272]). The boundedness of the $\nu^\varepsilon(V)$'s in setting B derives from the following inequalities:

$$\begin{aligned} \frac{1}{n}\sum_{k=0}^{n-1} P^{\varepsilon,k}(V \wedge K)(x) &\le \left(\frac{1}{n}\sum_{k=0}^{n-1} P^{\varepsilon,k}(V)(x)\right) \wedge K \\ &\le \left(\frac{\beta(\varepsilon)}{1-\alpha(\varepsilon)} + \alpha(\varepsilon)^n V(x)\right) \wedge K. \end{aligned}$$

Then, integrating with respect to ν^ε, letting first n go to $+\infty$ and then K, completes the proof. □

This theorem is well suited for stochastic algorithms with constant step (see subsection 1.2 below). It is important for applications to emphasize two features of these criteria: the tightness conclusion holds for the *whole set* $\{\nu^\varepsilon \,/\, \nu^\varepsilon P^\varepsilon = \nu^\varepsilon,\ \varepsilon \in (0,\varepsilon_0]\}$

- without a uniqueness assumption of the invariant distribution at a given ε (such a property is not always true and is usually difficult to fulfill even when it holds);
- without a Feller assumption, once the existence of a family $(\nu^\varepsilon)_{\varepsilon\in(0,\varepsilon_0]}$ is granted.

Remarks. Note that (H_b) implies that the Lyapunov function V satisfies

$$\lim_{|x|\to+\infty} V(x) = +\infty.$$

Following, e.g., [8], the Hajek setting implies, for every $\varepsilon \in (0, \varepsilon_0]$, the stability of the chain $(X^{\varepsilon,t})_{t\in\mathbb{N}}$ in the following sense: for every starting value $x \in \mathbb{R}^d$, $\mathbb{P}_x$-almost surely (a.s.), the sequence of empirical distributions $(\frac{1}{t}\sum_{0\le s\le t-1}\delta_{X^{\varepsilon,s}})_{t\ge1}$ is tight and all its weak limiting distributions are P^ε-invariant.

If $P^\varepsilon(x,dy) = p_\varepsilon(x,y)\theta(dy)$ where $\theta(dy)$ denotes a σ-finite nonnegative measure on $(\mathbb{R}^d, \mathcal{B}(\mathbb{R}^d))$ and $p^\varepsilon(x,y) > 0$, $\theta(dy)$-almost everywhere (a.e.) for every x, then uniqueness of the invariant distributions ν^ε holds (see, e.g., [8]). So, in the Hajek setting, $\mathbb{P}_x$-a.s., the empirical distribution weakly converges to this invariant distribution ν^ε.

1.2. The case of stochastic algorithms with constant gain. In this paper, a stochastic algorithm with constant gain parameter is a family of homogeneous Markov chains, depending on a parameter $\varepsilon > 0$, satisfying the general recursive equation

$$X^{\varepsilon,t+1} = X^{\varepsilon,t} - \varepsilon H(X^{\varepsilon,t}, \omega^{t+1}), \tag{1.1}$$

where $H : \mathbb{R}^d \times E \longrightarrow \mathbb{R}^d$ is a Borel function, $(\omega^t)_{t\ge1}$ is an i.i.d. sequence with common distribution μ on a measurable space $(E, \mathcal{B}(E))$ and ε is a positive real number. The transition $(P^\varepsilon(x,dy))_{x\in\mathbb{R}^d}$ is obviously defined on nonnegative or bounded Borel functions

$$P^\varepsilon(f)(x) := \int f\left(x - \varepsilon H(x,\omega)\right)\mu(d\omega).$$

The first assumption to be made ensures that the above transitions are Feller: There exists some $\rho \in (0,1]$ s.t.

$$(C^\mu_\rho) \equiv \left\{\begin{array}{ll} \text{(i)} & \forall x \in \mathbb{R}^d,\ y \mapsto H(y,\omega) \text{ is } \mu(d\omega)\text{-a.s. continuous at } x, \\ \text{(ii)} & \left\{\begin{array}{l} \forall x \in \mathbb{R}^d,\ \omega \mapsto H(x,\omega) \text{ belongs to } L^{1+\rho}(\mu) \text{ and} \\ x \mapsto \displaystyle\int |H(x,\omega)|^{1+\rho}\mu(d\omega) \text{ is bounded on compact sets.} \end{array}\right. \end{array}\right.$$

Note that if (C^μ_ρ) holds for some $\rho \in (0,1]$, the so-called mean function $h(x) := \int H(x,\omega)\mu(d\omega)$ of the algorithm is continuous (due to uniform integrability).

Most Lyapunov functions V that will be used further on fulfill the following smoothness assumption:

$$(L_\rho) \equiv\ V \in \mathcal{C}^1(\mathbb{R}^d, \mathbb{R}_+) \text{ and } \nabla V \text{ is } \rho\text{-Hölder with coefficient } [\nabla V]_\rho.$$

Of course, some nonnegativity assumption on $(\nabla V|h)$ will be added when necessary throughout the text. From a practical point of view, finding a function V that satisfies assumption (L_ρ) for some $\rho \in (0,1)$, instead of (L_1), allows a decrease in the integrability requirement on the noise.

Theorem 1.1 applied to Markov stochastic algorithms with constant step straightforwardly yields the following global existence and tightness result for the P^ε-invariant distributions ν^ε.

Proposition 1.2. A. Pakes–Has'minskii setting. *Let $\rho \in (0,1]$ and $V : \mathbb{R}^d \to \mathbb{R}_+$. Assume that*

$$(1.2) \quad (Has)_\rho \equiv \begin{cases} \text{(a)} & \textit{the function } H \textit{ satisfies} \\ & (C^\mu_\rho) \textit{ and } \textit{ the function } V \textit{ satisfies } (L_\rho), \\ \text{(b)} & \exists\, A > 0 \textit{ s.t.} \\ & \displaystyle\lim_{|x|\to+\infty}\left((\nabla V|h)(x) - \frac{1}{A}\int |H(x,\omega)|^{1+\rho}\mu(d\omega)\right) = +\infty; \end{cases}$$

then assumption (H_b) holds.

B. Hajek setting. *Assume that there is some $\rho \in (0,1]$ such that*

$$(1.3) \quad (Haj)_\rho \equiv \begin{cases} \text{(a)} & \textit{the function } H \textit{ satisfies } C^\mu_\rho, \\ \text{(b)} & \textit{the function } V \textit{ satisfies } (L_\rho) \textit{ and } \displaystyle\lim_{|x|\to+\infty} V(x) = +\infty, \\ \text{(c)} & \exists\, A > 0 \textit{ s.t.} \\ & \displaystyle V(x) + \int |H(x,\omega)|^{1+\rho}\mu(d\omega) \le A((\nabla V|h)(x) + 1). \end{cases}$$

Then assumption H_c is fulfilled.

B$'$. *Sometimes, rather than the above assumption $(Haj)_\rho$(c), it may be more convenient to check the slightly more stringent*

$$(1.4) \quad (\widetilde{Haj})_\rho \equiv \begin{cases} \text{(a), (b),} \\ \text{(c)} \;\; \exists\, \tilde{A} > 0, \\ \qquad \displaystyle\frac{1}{\tilde{A}}\int |H(x,\omega)|^{1+\rho}\mu(d\omega) \le V(x) + 1 \le \tilde{A}((\nabla V|h)(x) + 1). \end{cases}$$

Proof (sketch). Both settings rely on the following inequality, derived from the bounded increment formula

$$\forall\, x \in \mathbb{R}^d, \quad V\big(x - \varepsilon H(x,\omega)\big) \le V(x) - \varepsilon\big(\nabla V(x)|H(x,\omega)\big) + \varepsilon^{1+\rho}[\nabla V]_\rho |H(x,\omega)|^{1+\rho}.$$

Hence, $V(x - \varepsilon H(x,\omega)) \in L^1(\mu(d\omega))$, and integrating with respect to $\mu(d\omega)$ yields

$$\forall x \in \mathbb{R}^d, \; (P^\varepsilon V - V)(x) \le -\varepsilon\,(\nabla V|h)\,(x) + \varepsilon^{1+\rho}[\nabla V]_\rho \int |H(x,\omega)|^{1+\rho}\mu(d\omega).$$

A. Pakes–Has'minskii setting. One concludes by setting

$$\psi(x) := \frac{1}{A}\int |H(x,\omega)|^{1+\rho}\mu(d\omega) - (\nabla V|h)(x), \; \lambda(\varepsilon) = \varepsilon, \; \mu(\varepsilon) := 0,$$

$\varepsilon_0 < \frac{1}{(A[\nabla V]_\rho)^{\frac{1}{\rho}}}$, and $C := \sup_{x\in\mathbb{R}^d} \psi(x)$. ($\psi$ is bounded by (C^μ_ρ) (ii) and 1.2(b).)

B. Hajek setting. One concludes by setting

$$\alpha(\varepsilon) := \left(1 - \frac{1}{A}\varepsilon(1 - \varepsilon^\rho A[\nabla V]_\rho)\right), \; \beta(\varepsilon) = \varepsilon^{1+\rho}[\nabla V]_\rho A + (1 - \alpha(\varepsilon)) \sup_{(\nabla V|h)\ge\frac{1}{2A}} V(x),$$

and

$$\varepsilon_0 < \min\left(A, \frac{1}{(A[\nabla V]_\rho)^{\frac{1}{\rho}}}\right). \qquad \square$$

About other natural settings. A simpler setting that is commonly encountered in applications is the case of compact valued stochastic algorithms like the Kohonen algorithm (see, e.g., [5] or [6]) and the normalized Benzecri–Oja algorithm (see [26]). Thus, assume that for $\varepsilon \in (0, \varepsilon_0]$ and every x^0 lying in a compact set K, the algorithm defined by (1.1) a.s. lies in K. It is straightforward that, whenever the algorithm is Feller on K (with an obvious definition), every transition P^ε has at least one invariant distribution and $\{\nu^\varepsilon \,/\, \nu^\varepsilon P^\varepsilon = \nu^\varepsilon\}$ is tight. Furthermore, all the results below remain valid for such K-valued Feller algorithms with the straightforward adaptations: a function V is Lyapunov on K if $V \in \mathcal{C}^1(\overset{\circ}{K})$, ∇V continuously extends to K, $(\nabla V | h) \geq 0$, etc. Such an extension will work out for the Benzecri–Oja algorithm that lives in the unit d-dimensional sphere, or some special cases of the Kohonen algorithm (uniform stimuli and 0 neighbor setting).

When the algorithm is not Feller, another family of methods based on ergodicity and recurrence is available (see [22] or [8]) for the existence and tightness of the invariant distributions. Once this point is solved, similar studies to those carried out below can be done; thus, in [6], after proving the existence of the invariant distributions ν^ε by a Doeblin recurrence approach for the Kohonen algorithm with 0 neighbor, a localization of the support of the limiting distribution is carried out. This is done by specific methods since this algorithm is a stochastic gradient descent whose gradient function is not even continuous (see also [27]).

2. Asymptotics of ν^ε as $\varepsilon \downarrow 0$. This section is devoted to the location of the support of any weak limiting value of a tight family $(\nu^\varepsilon)_{\varepsilon \in (0, \varepsilon_0]}$ of P^ε-stationary probability measures. The results mentioned in the first subsection call upon some functional results on stochastic processes and need some more stringent hypothesis on the average function h through ODE_h $\dot{x} = -h(x)$. In the second subsection, we give some applications of the flow-invariance theorem. In the third subsection, we provide some results and examples requiring less regularity on h in the spirit of section 1.

2.1. A flow-invariance theorem for the ν^ε's. In this section we deal with a flow-invariance result for any tight family $(\nu^\varepsilon)_{\varepsilon \in (0, \varepsilon_0]}$ of P^ε-invariant distributions. This version for Markov stochastic algorithms can appear as the constant step version of the ODE method developed by Ljung, Kushner, and Clark. It looks like a variant of the old seminal averaging principle by Has'minskii (see [15] or [18]) for perturbed deterministic dynamical systems. Let us mention, too, for diffusion approximation, the work by Norman on limit theorems for stationary sequences (see [24]) and the synthetic result that can be found in ([9, p. 244]).

The following assumption will hold throughout this section:

$$H_{\text{ODE}} \equiv \begin{cases} \text{(a)} \quad h \text{ is continuous,} \\ \text{(b)} \quad \begin{cases} \text{for every } x_0 \in \mathbb{R}^d \text{ there exists a } \textit{unique } \Phi(x_0, .) \in \mathcal{C}^1(\mathbb{R}_+, \mathbb{R}^d) \\ \text{s.t.} \Phi(x_0, u) = x_0 - \displaystyle\int_0^u h(\Phi(x_0, v)) dv. \end{cases} \end{cases}$$

Uniqueness is generally provided by a local Lipschitz assumption on h.

Let $\varepsilon > 0$, $x_0 \in \mathbb{R}^d$. Set

$$X_0^{(\varepsilon, x_0)} := x_0 \quad \text{and} \quad X_u^{(\varepsilon, x_0)} := X^{(\varepsilon, x_0), t} \text{ if } u \in [t\varepsilon, (t+1)\varepsilon),$$

where $(X^{(\varepsilon, x_0), t})_{t \in \mathbb{N}}$ denotes the algorithm with constant step ε starting at x_0 as defined by (1.1). A straightforward computation shows that $X_u^{(\varepsilon,x_0)}$ satisfies

$$\forall\, u \in \mathbb{R}_+,\ X_u^{(\varepsilon,x_0)} = x_0 - \int_0^u h(X_v^{(\varepsilon,x_0)})dv + \varepsilon M^{\varepsilon,x_0,[\frac{u}{\varepsilon}]} + \int_{\varepsilon[\frac{u}{\varepsilon}]}^u h(X_v^{(\varepsilon,x_0)})dv, \tag{2.1}$$

$$\text{where } M^{\varepsilon,x_0,t} = \sum_{s=0}^{t-1} h(X^{(\varepsilon,x_0),s}) - H(X^{(\varepsilon,x_0),s},\omega^{s+1}), \quad M^{\varepsilon,x_0,0} = 0, \tag{2.2}$$

and u denotes the integral part of $u \in \mathbb{R}_+$. The sequence $(M^{\varepsilon,x_0,t})_{t\in\mathbb{N}}$ is a martingale with respect to its natural filtration under mild integrability assumptions.

Proposition 2.1. (a) *For every sequence $\varepsilon_p \downarrow 0$,*

$$\forall\, K > 0,\ \forall\, T \in \mathbb{R}_+,\ \sup_{u\in[0,T]} \sup_{|x_0|\le K} |X_u^{(\varepsilon_p,x_0)} - \Phi(x_0,u)| \xrightarrow[p\to\infty]{\mathbb{P}} 0.$$

(b) *In particular, for any function $f \in \mathcal{C}_b(\mathbb{R}^d,\mathbb{R}_+)$ s.t. $f(0) = 0$,*

$$\forall\, K > 0,\ \forall u \in \mathbb{R}_+, \qquad \sup_{|x_0|\le K} \mathbb{E}\left(f\left(X_u^{(\varepsilon,x_0)} - \Phi(x_0,u)\right)\right) \longrightarrow 0 \qquad \textit{as } \varepsilon \to 0.$$

Item (b) is an obvious corollary of item (a). Item (a) reads as follows in a sequential form: for any sequences $\varepsilon_p \downarrow 0$, $x_0^p \to x_0^\infty$,

$$\forall\, K > 0,\ \forall\, T \in \mathbb{R}_+,\ \sup_{u\in[0,T]} |X_u^{(\varepsilon_p,x_0^p)} - \Phi(x_0^\infty,u)| \xrightarrow[p\to\infty]{\mathbb{P}} 0.$$

One easily derives this convergence (in distribution) from some abstract weak functional convergence theorems for semimartingales (see, e.g., [17, Thm. 3.39, p. 510] for a comprehensive approach). A direct and self-contained proof is available in [10] (when the function h is not bounded, the proof involves some localization techniques relying on the Sk-regularity for stopped processes).

Theorem 2.2. *Assume that the family $(\nu^\varepsilon)_{\varepsilon\in(0,\varepsilon_0]}$ of P^ε-invariant distributions is tight and that both H_{ODE} and*

$$(UI)_{loc} \equiv \forall\, K \subset \mathbb{R}^d,\ \textit{compact set},\ (|H(x,\omega)|)_{x\in K} \textit{ is } \mu(d\omega)\textit{-uniformly integrable} \tag{2.3}$$

hold. Then, every limiting distribution ν^0 of ν^ε as $\varepsilon \downarrow 0$ satisfies

$$\forall u \in \mathbb{R}_+, \quad \Phi(\nu^0,u) = \nu^0. \tag{2.4}$$

Consequently, if the flow is uniquely ergodic, i.e., exactly one flow-invariant distribution ν^0 exists, then $\nu^\varepsilon \Rightarrow \nu^0$ as $\varepsilon \downarrow 0$.

Note that as a practical matter, $(UI)_{loc}$ always holds when $(\widetilde{Haj})_1$ does.

Proof of Theorem (2.2). Let $u \in \mathbb{R}_+$ and let f be a bounded Lipschitz function, with Lipschitz coefficient $[f]$. $\mathbb{E}(\,.\,)$ will denote the $\mathbb{P}$-expectation on the probability space $(\Omega,\mathcal{A},\mathbb{P})$ on which the innovations ω^t are defined. We have

$$\begin{aligned}
&\left|\int f(\Phi(x_0,u))\nu^\varepsilon(dx_0) - \int f(x_0)\nu^\varepsilon(dx_0)\right| \\
&\qquad = \left|\int \left(f(\Phi(x_0,u)) - P^{[\frac{u}{\varepsilon}]}f(x_0)\right)\nu^\varepsilon(dx_0)\right| \\
&\qquad = \left|\int \left(f(\Phi(x_0,u)) - \mathbb{E}\left(f(X_u^{(\varepsilon,x_0)})\right)\right)\nu^\varepsilon(dx_0)\right| \\
&\qquad \le \int \nu^\varepsilon(dx_0)\mathbb{E}\left(\left|f(X_u^{(\varepsilon,x_0)}) - f(\Phi(x_0,u))\right|\right).
\end{aligned}$$

Let $\varepsilon_p \to 0$ and $\eta > 0$. Since the sequence $(\nu^{\varepsilon_p})_{p\geq 0}$ is tight, there exists a compact set K_η such that

$$\nu^{\varepsilon_p}(K_\eta) \geq 1 - \frac{\eta}{2\|f\|_\infty}$$

for every $p \geq 1$. Hence, integrating separately on K_η and ${}^cK_\eta$ yields

$$\begin{aligned}&\left|\int f(\Phi(x_0,u))\nu^{\varepsilon_p}(dx_0) - \int f(x_0)\nu^{\varepsilon_p}(dx_0)\right| \\ &\qquad \leq \frac{2\|f\|_\infty}{2\|f\|_\infty}\eta + \sup_{x_0\in K_\eta} \mathbb{E}\left(2\|f\|_\infty \wedge ([f]|X_u^{(\varepsilon_p,x_0)} - \Phi(x_0,u)|)\right).\end{aligned}$$

Let $\varphi(x) := 2\|f\|_\infty \wedge ([f]|x|)$. $\varphi(0) = 0$ and $\varphi \in \mathcal{C}_b(\mathbb{R}^d, \mathbb{R}_+)$. Since the flow $\Phi(x_0,u)$ is continuous in x_0, Proposition 2.1(b) yields

$$\forall\, u \in \mathbb{R}_+, \quad \forall \eta > 0, \quad \overline{\lim_p}\left|\int f(x(x_0,u))\nu^{\varepsilon_p}(dx_0) - \int f(x_0)\nu^{\varepsilon_p}(dx_0)\right| \leq \eta,$$

hence

$$\forall\, u \in \mathbb{R}_+, \quad \int f(\Phi(x_0,u))\nu^0(dx_0) = \int f(x_0)\nu^0(dx_0)$$

as $\nu^\varepsilon \Rightarrow \nu^0$. This completes the proof. □

A similar flow-invariance theorem was obtained independently in [3], in the context of urn processes, which, roughly speaking, corresponds to the case where $H(x,\omega)$ is globally bounded.

The first consequence of the flow-invariance theorem above relies on the celebrated Poincaré recurrence theorem (see, e.g., [19, Thm. 3.1, p. 16]) for invariant distributions of a dynamical system. In our setting, it reads as follows.

PROPOSITION 2.3. *The* support *of any flow-invariant distribution ν^0 of ODE_h is contained in the Birkhoff's center $B(\Phi)$ of Φ (the set $B(\Phi)$ is defined as the closure of $\{x \in \mathbb{R}^d \,/\, \exists\, u_n \to +\infty$ with $\Phi(x,u_n) \to x\}$).*

2.2. Some first consequences and examples. The examples below are illustrations of Proposition 2.3.

PROPOSITION 2.4 (Discrete part of ν^0). *Let ν_p^0 denote the purely discrete part of ν^0. Then supp$(\nu_p^0) \subset \{h = 0\}$.*

Proof. Let $x^* \in \operatorname{supp}(\nu_p^0)$. The ν^0-invariance of the flow implies that, for every $u > 0$, $\nu^0(\{\Phi(x^*,u)\}) = \nu^0(\{x^*\}) > 0$. Hence $\{\Phi(x^*,u),\, u > 0\}$ is a path connected countable set containing x^*, that is, $\Phi(x^*,.) \equiv x^*$. Subsequently $h(x^*) = 0$. □

PROPOSITION 2.5 (pseudogradient case). *If V is differentiable on $\mathbb{R}^d$, and $(\nabla V|h) \geq 0$, then*

$$supp(\nu^0) \subset \{(\nabla V|h) = 0\}.$$

Proof. For every $x_0 \in \mathbb{R}^d$, the function $u \mapsto (\nabla V|h)(\Phi(x_0,u))$ converges to 0 as $u \to +\infty$. For every $p \in \mathbb{N}$, let $\varphi_p : \mathbb{R}_+ \to \mathbb{R}_+$ be a continuous nondecreasing function such that

$$\varphi_p(x) := \begin{cases} x, & \text{if } x \in [0,p], \\ p+1, & \text{if } x \geq p+1. \end{cases}$$

One readily checks using the flow-invariance theorem that

$$\forall\, p \in \mathbb{N}, \int \underbrace{\frac{\varphi_p(V(x_0)) - \varphi_p(V(\Phi(x_0,u)))}{u}}_{\geq 0} \nu^0(dx_0) = 0.$$

Letting u go to 0, it follows from Fatou's lemma that $\int \varphi_p'(V)(\nabla V|h)(x_0)\nu^0(dx_0) = 0$ for every $p \in \mathbb{N}$. Letting p go to infinity completes the proof since $\varphi_p' \to \mathbf{1}$. □

We will see below that this result admits an extension to the case where the existence of the flow fails. The next result is a straightforward application of Proposition 2.3.

PROPOSITION 2.6. (a) *Converging dynamics. If ODE_h has a converging flow, i.e., any solution of the ODE_h converges toward (a connected component of) $\{h = 0\}$, then*

$$supp(\nu^0) \subset \{h = 0\}.$$

(b) *Cascade converging dynamics. Assume that there exists a decreasing sequence $(A_n)_{n\in\mathbb{N}}$ of closed subset of $\mathbb{R}^d$ such that $A_1 := \mathbb{R}^d$ and that ODE_h satisfies*

$$\forall\, k \in \mathbb{N},\ \forall\, x_0 \in A_k, \quad \mathrm{dist}(\Phi(x_0,u), A_{k+1}) \to 0 \ \textit{as}\ u \to +\infty.$$

Then $\mathrm{supp}(\nu^0) \subset \cap_n A_n$.

Actually, we do not know any example of an *infinite* cascade of A_n in $\mathbb{R}^d$; for an example of a finite sequence see (2.9) and Proposition 3.5. Several criteria ensure the convergence of the flow without using a Lyapunov function, like the celebrated two-dimensional Poincaré–Bendixson theorem or the Bendixson–Dulac criterion for functions h having a never zero divergence. (See [1] or [11] for some applications to stochastic approximation.) One must mention, too, the cooperative irreducible differential systems introduced by Hirsch in [16]: when the equilibrium set $\{h = 0\}$ is reduced to a single point, the flow of such differential equations is converging. An application to the Kohonen algorithm is carried out in [4].

The Lemniscate example. The algorithm defined by (2.5) below is a typical example, where the decreasing and the constant step algorithms *seem* to behave differently. We will come back to that question further on.

Let $L : \mathbb{R}^2 \to \mathbb{R}$ be the Lemniscate function—$\{L = 0\}$ is a Lemniscate—defined by

$$\forall\, x := (x_1,x_2) \in \mathbb{R}^2, \qquad L(x) := \frac{(x_1^2 + x_2^2)^2}{16} - x_1x_2.$$

Then, set for every $x \in \mathbb{R}^2$

$$V := \frac{L^2}{2(1+L^2)^{\frac{3}{4}}} \text{ and } \theta := \mathcal{H}\left(\frac{L}{(1+L^2)^{\frac{3}{8}}}\right) \left(\mathcal{H}(f) := \begin{pmatrix} \frac{\partial f}{\partial y} \\ -\frac{\partial f}{\partial x} \end{pmatrix} \text{is for Hamiltonian}\right),$$

$$\nabla V(x) = \frac{(L^2+4)}{4(1+L^2)^{\frac{7}{4}}} L(x) \begin{pmatrix} x_1\frac{x_1^2+x_2^2}{4} - x_2 \\ x_2\frac{x_1^2+x_2^2}{4} - x_1 \end{pmatrix},$$

and

$$\theta(x) = \frac{L^2+4}{4(1+L^2)^{\frac{11}{8}}}(x) \begin{pmatrix} x_2\frac{x_1^2+x_2^2}{4} - x_1 \\ -x_1\frac{x_1^2+x_2^2}{4} + x_2 \end{pmatrix}.$$

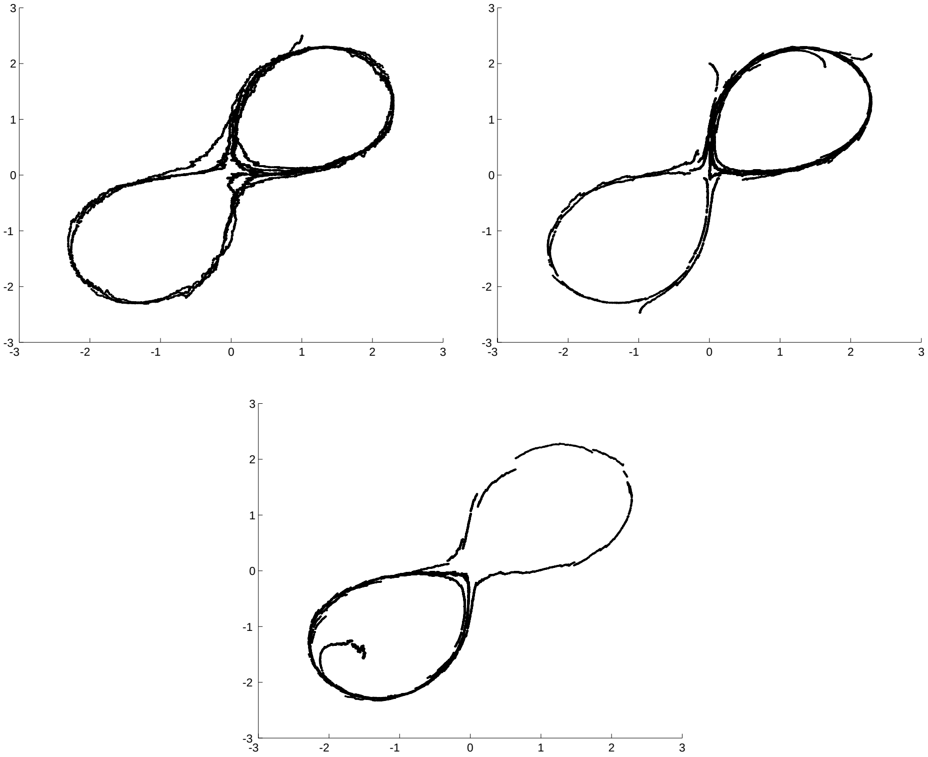

FIG. 1. *Trajectories of the stochastic algorithm* (2.5): $t = 1, \ldots, 10^4$ *and* $\epsilon := 1.5\ 10^{-3}$.

The algorithm (see a simulated path in Figure 1) is defined by

$$(2.5) \qquad h := \nabla V + \theta, \qquad \mu(d\omega) := \frac{d\omega}{(1+|\omega|)^3 \ln^2(2+|\omega|)},$$

$$X^{t+1} := X^t - \varepsilon\left(\underbrace{(I_2 + \varphi(\omega^{t+1}))\,h(X^t) + \mathrm{Diag}[1,\ 0.2]\,\omega^{t+1}}_{:=\,H(X^t,\,\omega^{t+1})}\right),\ \omega^t \overset{\mathcal{L}}{\sim} \mu,$$

where φ is a μ-square integrable and centered 2×2-matrix valued function. In Figure 1 are plotted trajectories of the stochastic algorithm for $t \in \{1, \ldots, 10^4\}$ and $\varepsilon := 1.5 \times 10^{-3}$.

One readily checks that assumption $(\widetilde{Haj})_1$ holds; hence, one derives from Proposition 1.2B the existence of a tight family of invariant distributions $(\nu^{\varepsilon})_{\varepsilon \in (0,\varepsilon_0]}$.

Now, since h is locally Lipschitz, (H_{ODE}) is fulfilled. So is $(UI)_{loc}$ due to $(\widetilde{Haj})_1$. Then one readily checks the following facts:

$$\bullet\ \{(\nabla V | h) = 0\} = \{\nabla V = 0\} = \{L = 0\} \cup \{\nabla L = 0\}$$
$$= \{\nabla V = 0\} = \{L = 0\} \cup \{(-\sqrt{2}; -\sqrt{2}),\ (\sqrt{2}; \sqrt{2})\};$$

• $\{L = 0\} = \{V = 0\}$ is flow-invariant since $V \geq 0$ and, for every $x \in \{L = 0\}$, $\Phi(x, u) \to (0, 0)$ as $u \to +\infty$ (set $x_1 := s$, $x_2 := ts$).

Now applying Proposition 2.6(b) yields the (partial) result

$$\mathrm{supp}(\nu^0) \subset \{(0; 0),\ (-\sqrt{2}; -\sqrt{2}),\ (\sqrt{2}; \sqrt{2})\}.$$

At this stage, a straightforward computation shows that these critical points are of different natures: $(0;0)$ is a saddle point while both $(-\sqrt{2};-\sqrt{2})$, $(\sqrt{2};\sqrt{2})$ are repulsive points as

$$\nabla h(0;0)=\begin{bmatrix}-1 & 0\\ 0 & 1\end{bmatrix},\ \nabla h(\sqrt{2};\sqrt{2})=\nabla h(-\sqrt{2};-\sqrt{2})=\frac{1}{2^{\frac{11}{4}}}\begin{bmatrix}-5 & 2^{-\frac{3}{8}}\\ -2^{-\frac{3}{8}} & -5\end{bmatrix}.$$

The aim of this paper is to investigate whether such repulsive or saddle points can be weighted by ν^0. The answer will be negative for repulsive critical points.

2.3. Location without the ODE. It is possible to get location results for ν^0 even if (H_{ODE}) fails, provided that a global Lyapunov function does exist. As in this paragraph the existence of a *tight* P^ε-invariant family of distributions $(\nu^\varepsilon)_{\varepsilon\in(0,\varepsilon_0]}$ is assumed, assumption (C^μ_ρ) can be relaxed into

$$(C^\mu_{0_+})\equiv\left\{\begin{array}{ll}\text{(i)} & \forall x\in\mathbb{R}^d,\ y\mapsto H(y,\omega)\text{ is }\mu(d\omega)\text{-a.s. continuous at }x,\\ \text{(ii)} & \forall K\subset\mathbb{R}^d,\text{ compact set, }(H(x,\omega))_{x\in K}\text{ is }\mu(d\omega)\text{-uniformly integrable.}\end{array}\right.$$

Note that

$$(\exists\,\rho\in(0,1],\ (C^\mu_\rho))\Longrightarrow(C^\mu_{0_+})\Longrightarrow\left\{\begin{array}{ll}\bullet & P^\varepsilon\text{ is Feller, }\varepsilon\in(0,\varepsilon_0],\\ \bullet & h\text{ is continuous.}\end{array}\right.$$

PROPOSITION 2.7 (Feller setting). *Let* $V:\mathbb{R}^d\xrightarrow{\mathcal{C}^1}\mathbb{R}_+$, *and let* ν^0 *be a weak limiting distribution of* ν^ε *as* $\varepsilon\downarrow 0$. *Assume that the function*

$$\text{(a)}\quad V\textit{ satisfies}\left\{\begin{array}{ll}\text{(i)} & (\nabla V|h)\geq 0,\\ \text{(ii)} & \nabla V\textit{ is bounded or }\lim\limits_{|x|\to+\infty}V(x)=+\infty,\end{array}\right.$$

$$\text{(b)}\quad H\textit{ satisfies }(C^\mu_{0_+})\textit{ and }\int|H(x,\omega)|\mu(d\omega)\textit{ is }(\nu^\varepsilon)_{\varepsilon\in(0,\varepsilon_0]}\textit{-uniformly integrable.}$$

(2.6)

Then, $\mathrm{supp}(\nu^0)\subset\{(\nabla V|h)=0\}$.

The proof of this result relies on a first-order Taylor expansion of the transition $P^\varepsilon(V)(x)$ (see, e.g., [10]). We provide here no further details since a similar method, but with a second-order Taylor expansion of $P^\varepsilon(V)$, will be used in section 3 to treat the case of unstable equilibrium points.

Proposition 2.7 yields the corollary below, which is more tractable for applications.

COROLLARY 2.8. A. PAKES–HAS'MINSKII SETTING. *If* H, h, V, *and the tight family of all the* P^ε*-invariant distributions* ν^ε, $\varepsilon\in(0,\varepsilon_0]$, *satisfy, for some* $\rho\in(0,1]$,

$$(2.7)\quad (Has)_\rho\equiv(\nabla V|h)\geq 0\ \textit{ and }\ (\nabla V|h)^{\frac{1}{1+\rho}}\ \textit{ is }\ (\nu^\varepsilon)_{\varepsilon\in(0,\varepsilon_0]}\textit{-uniformly integrable,}$$

then any weak limiting value ν^0 *of* ν^ε *as* $\varepsilon\downarrow 0$ *satisfies* $\mathrm{supp}(\nu^0)\subset\{(\nabla V|h)=0\}$.

B. HAJEK SETTING. *If* H, h, *and* V *satisfy for some* $\rho\in(0,1]$

$$(2.8)\qquad (\widetilde{Haj})_\rho\ \textit{ and }\ (\nabla V|h)\geq 0,$$

then the same conclusion as in A holds.

The periodic/quasi-cycle example. Consider the linearly perturbed algorithm $H(x,\omega):=h(x)+\omega$ defined by its vector field

$$(2.9)\ \forall\,x:=(x_1,x_2)\in\mathbb{R}^2,\ H(x,\omega):=h(x)+\omega,\ h(x):=\frac{|x|^2-1}{|x|^2+1}x+\varphi(x)\begin{pmatrix}-x_2\\ x_1\end{pmatrix},$$

where φ is a *bounded* continuous function and $(\omega^t)_{t\geq 1}$ is a $(1+\rho)$-integrable two-dimensional white noise. One readily checks that this algorithm is a pseudogradient related to the Lyapunov function

$$V(x) := \frac{1}{1+\rho}\left(|x|^{1+\rho} - 2\ln(1+|x|^{1+\rho})\right).$$

Furthermore, the Hajek criterion $(\widetilde{Haj})_\rho$ is fulfilled using V. Hence, it follows from Proposition 1.2B$'$ and Corollary 2.8 that the set $\{\nu^\varepsilon \,/\, \nu^\varepsilon P^\varepsilon = \nu^\varepsilon,\ \varepsilon\in(0,\varepsilon_0]\}$ is tight for some $\varepsilon_0>0$ and

$$\operatorname{supp}(\nu^0)\subset\{\nabla V|h)=0\}=\mathcal{C}(0;1)\cup\{(0,0)\},$$

where $\mathcal{C}(0;1)$ denotes the unit circle.

If no further assumption is made on the function φ, the existence of the flow of ODE_h may fail, which prevents the use of the flow-invariance theorem. The second feature to be noticed is that the origin $(0,0)$ is a repulsive point for the ODE_h as it is a local maximum of its Lyapunov function V. As in the Lemniscate example, one expects $(0,0)$ not to be weighted by a limiting distribution ν^0 since the random perturbation $H((0,0),\omega)=\omega$ is nonzero at this point.

The asymptotic behavior of this algorithm will be described in subsection 3.1.5 once the case of repulsive points and sets has been treated.

Proposition 2.7 admits a non-Feller version in which the regularity requirements on V are slightly strengthened. Namely, assumption (2.6) then becomes

$$(2.6')\qquad \exists\,\rho\in(0,1]\ \textit{such that}\ \left\{\begin{array}{ll} (\mathrm{a}') & \left\{\begin{array}{ll} (\mathrm{i}) & (\nabla V|h)\geq 0\ \textit{and is lower semi-}\\ & \textit{continuous,}\\ (\mathrm{ii}) & \nabla V \text{ is bounded or}\\ & \displaystyle\lim_{|x|\to+\infty} V(x)=+\infty,\\ (\mathrm{iii}) & \nabla V\ \textit{is}\ \rho'\textit{-Hölder on compact}\\ & \textit{sets for some}\ \rho'\geq\rho,\end{array}\right.\\ (\mathrm{b}') & \textit{the function}\ x\mapsto \displaystyle\int|H(x,\omega)|^{1+\rho}\mu(d\omega)\\ & \textit{is}\ L^1(\nu^\varepsilon)\textit{-bounded as}\ \varepsilon\downarrow 0.\end{array}\right.$$

3. About the support of ν^ε as $\varepsilon\downarrow 0$ near an unstable equilibrium point of the ODE. In the previous section the support of any limiting value ν^0 of ν^ε as $\varepsilon\downarrow 0$ was located under some reasonable assumptions. For instance, when ODE_h has a converging flow (resp., when there exists a global Lyapunov function V), it was shown that $\operatorname{supp}(\nu^0)\subset\{h=0\}$ (resp., $\operatorname{supp}(\nu^0)\subset\{(\nabla V|h)=0\}$). We know (see [7], [21]) that under suitable assumptions on the (decreasing) steps and on the variance function of $H(x,\omega)$, the corresponding algorithm a.s. cannot converge toward an unstable stationary point of ODE_h (i.e., to some maximum or saddle point of V).

The aim of this section is to try to obtain the same type of result. However, we will see further on that the global dependency of ν^ε with respect to the *global* behavior of the solutions of ODE_h does not lead to the same results.

The key of this section is a proposition based on a second-order Taylor expansion of the transition.

PROPOSITION 3.1. *Let $(\nu^\varepsilon)_{\varepsilon\in(0,\varepsilon_0]}$ be a tight family of $(P^\varepsilon)_{\varepsilon\in(0,\varepsilon_0]}$-stationary* *distributions and let ν^0 be one of its limiting distributions as $\varepsilon \downarrow 0$. Assume that*

$$\text{(a)}\ (C^{\mu}_{1_+}) \equiv \left\{ \begin{array}{ll} \text{(i)} & \forall\, x \in \operatorname{supp}(\nu^0),\ y \mapsto H(y,\omega) \textit{ is } \mu(d\omega)\textit{-a.s. continuous at } x, \\ \text{(ii)} & \left\{ \begin{array}{l} \forall\, K \subset \mathbb{R}^d,\ K \textit{ compact set, } (|H(x,\omega)|^2)_{x\in K} \textit{ is} \\ \mu(d\omega)\textit{-uniformly integrable,} \end{array} \right. \end{array} \right.$$

$$\text{(b)}\ x \mapsto \int |H(x,\omega)|^2 \mu(d\omega) \textit{ is } (\nu^{\varepsilon})_{\varepsilon\in(0,\varepsilon_0]} \textit{ uniformly integrable.}$$

Then, for every $f \in \mathcal{C}^2(\mathbb{R}^d,\mathbb{R})$ such that f and $\nabla^2 f$ are bounded and for every sequence $\nu^{\varepsilon_p} \Rightarrow \nu^0$, $\int(\nabla f|h)d\nu^0 = 0$ and

$$\lim_p \int (\nabla f|h)\frac{d\nu^{\varepsilon_p}}{\varepsilon_p} = \frac{1}{2}\int \nu^0(dx)\left(\int \mu(d\omega)\, {}^tH(x,\omega)\nabla^2 f(x) H(x,\omega)\right).$$

Remark. Assumption $(C^{\mu}_{1_+})$ is fulfilled whenever $C^{\mu}_{1+\rho}$(i) holds and

$$\sup_{x\in K}\int |H(x,\omega)|^{2+\rho}\mu(d\omega) < +\infty \text{ for every compact set } K \text{ of } \mathbb{R}^d.$$

Proof. Using a second-order Taylor–Lagrange expansion of the bounded $\mathcal{C}^2$ function f between x and $x - \varepsilon H(x,\omega)$ and successively integrating with respect to μ and ν^{ε} leads to

$$\begin{aligned} \Lambda_{\varepsilon} &:= \left| \varepsilon \int \nu^{\varepsilon}(dx)(\nabla f|h)(x) - \frac{\varepsilon^2}{2}\int \nu^{\varepsilon}(dx)\left(\int \mu(d\omega)\, {}^tH(x,\omega)\nabla^2 f(x)H(x,\omega)\right)\right| \\ &\le \frac{\varepsilon^2}{2}\int \nu^{\varepsilon}(dx)G^{(2)}_{\varepsilon}(x), \end{aligned}$$

where $G^{(2)}_{\varepsilon}(x) := \int \mu(d\omega)|H(x,\omega)|^2 \left(w(\nabla^2 f, x, \varepsilon|H(x,\omega)|) \wedge \|\nabla^2 f\|_{\infty}\right)$ and $w(g,x,.)$ denotes the continuity modulus of g at x.

We note that $G^{(2)}_{\varepsilon}(x)$ is nondecreasing as a function of ε; hence,

$$\forall\, \eta \ge \varepsilon > 0, \qquad \frac{\Lambda_{\varepsilon}}{\varepsilon^2} \le \int \nu^{\varepsilon}(dx)G^{(2)}_{\varepsilon}(x) \le \int \nu^{\varepsilon}(dx)G^{(2)}_{\eta}(x).$$

Assumption $(C^{\mu}_{1_+})$ ensures that $G^{(2)}_{\eta}$ is ν^{ε}-uniformly integrable. Assuming without loss of generality that $\nu^{\varepsilon} \Rightarrow \nu^0$, it follows that

$$\forall\, \eta > 0, \qquad \lim_{\varepsilon\to 0}\int \nu^{\varepsilon}(dx)G^{(2)}_{\eta}(x) = \int \nu^0(dx)G^{(2)}_{\eta}(x).$$

The Lebesgue-dominated convergence theorem yields $\lim_{\eta\to 0}\int \nu^0(dx)G^{(2)}_{\eta}(x) = 0$. This completes the proof of the first equality. The second straightforwardly follows. □

3.1. The case of repulsive equilibrium points of the ODE.

3.1.1. The pointwise result. The next theorem agrees with the intuition that generally speaking no excited enough repulsive point can be weighted when $\varepsilon \downarrow 0$.

THEOREM 3.2. *Let $(\nu^{\varepsilon})_{\varepsilon\in(0,\varepsilon_0]}$ be a tight family of $(P^{\varepsilon})_{\varepsilon\in(0,\varepsilon_0]}$-stationary distributions, and let ν^0 be one of its limiting distributions. Let $x^* \in \mathbb{R}^d$. Assume that the* *assumptions of Proposition* 3.1 *hold and that there exists an open neighborhood* $\mathcal{V}^*$ *of* x^* *and a local Lyapunov function* $V \in \mathcal{C}^2(\mathcal{V}^*, \mathbb{R})$ *such that*

(a) $\forall x \in \mathcal{V}^* \setminus \{x^*\}$, $(\nabla V|h)(x) > 0$ *and* $V(x) < V(x^*)$ (*hence* $\nabla V(x^*) = 0$),
(b) *there exists* $u \in (\mathrm{Ker}\nabla^2 V(x^*))^\perp$, *such that* $\int \mu(d\omega)(H(x^*,\omega)|u)^2 > 0$.

(Assertion (b) *means that the noise has a positive variance in the direction* u*). Then,*

$$\nu^0(\{x^*\}) = 0.$$

Remark. Assumption (b) is equivalent to $\int \mu(d\omega)|\pi(H(x^*,\omega))|^2 > 0$, where π denotes the orthogonal projection on $(\mathrm{Ker}\nabla^2 V(x^*))^\perp$. One may assume without loss of generality that $|u| = 1$. Then let $(e^1, \dots, e^d)$ be an orthonormal basis of $\mathbb{R}^d$ such that $e^1 = u$ and $\langle e^1, \dots, e^p\rangle = (\mathrm{Ker}\nabla^2 V(x^*))^\perp$. Then $\int \mu(d\omega)|\pi(H(x^*,\omega))|^2 = \sum_{i=1}^p \int \mu(d\omega)(H(x^*,\omega)|e^i)^2$.

Proof. The idea is to build a function f, whose support is contained in $\mathcal{V}^*$, that satisfies the assumptions of Proposition 3.1 and for which x^* is also a local maximum. Let $\alpha > 0$ be such that $\overline{B}(x^*, \alpha) \subset \mathcal{V}^*$ and set $K_\alpha := \sup\{V(x),\ \frac{\alpha}{2} \le \|x - x^*\| \le \alpha\}$. Assumption (a) implies $V(x^*) > K_\alpha$. Let $\varphi \in \mathcal{C}^\infty(\mathbb{R}^d, [0,1])$ such that

$$\forall x \in \overline{B}\left(x^*, \frac{\alpha}{2}\right), \quad \varphi(x) := 1 \ \text{ and } \ \forall x \in {}^c B(x^*, \alpha), \quad \varphi(x) := 0.$$

Set for every $x \in \mathbb{R}^d$, $f(x) := (V(x) - K_\alpha)_+^3 \varphi(x)$, where $y_+ := \max(y, 0)$. The function f is clearly $\mathcal{C}^2$ and nonnegative since $y \mapsto (y - K_\alpha)_+^3$ is. Furthermore

$$\nabla f(x) = 3(V(x) - K_\alpha)_+^2 \varphi(x) \nabla V(x) + \underbrace{(V(x) - K_\alpha)_+^3 \nabla \varphi(x)}_{\equiv 0}.$$

Consequently ∇f and $\nabla^2 f$ satisfy

$$(\nabla f|h)(x) = 3(V(x) - K_\alpha)_+^2 \varphi(x)(\nabla V|h)(x) \begin{cases} \ge 0 \text{ everywhere,} \\ > 0 \text{ on } B(x^*, \frac{\alpha}{2}) \setminus \{x^*\}. \end{cases}$$

$$\begin{aligned}\nabla^2 f(x) &= 6(V(x) - K_\alpha)_+ \varphi(x) \nabla V(x)\, {}^t\nabla V(x) + \underbrace{3(V(x) - K_\alpha)_+^2 \nabla V(x)\, {}^t\nabla\varphi(x)}_{\equiv 0} \\ &\quad +3(V(x) - K_\alpha)_+^2 \varphi(x) \nabla^2 V(x) \\ &= 6\big(V(x) - K_\alpha\big)_+ \varphi(x) \nabla V(x)^t \nabla V(x) + 3\big(V(x) - K_\alpha\big)_+^2 \varphi(x) \nabla^2 V(x).\end{aligned}$$

Applying Proposition 3.1 to the above function f first yields

$$\int \nu^0(dx)(V(x) - K_\alpha)_+^2 \varphi(x)(\nabla V|h)(x) = 0.$$

Hence, $\mathrm{supp}(\nu^0) \cap B(x^*, \frac{\alpha}{2}) \subset \{x^*\}$. Consequently,

$$\frac{1}{2}\nu^0(\{x^*\}) \int \mu(d\omega)^t H(x^*,\omega) \nabla^2 f(x^*) H(x^*,\omega) = \lim_p \frac{1}{\varepsilon_p} \int (\nabla f|h)(x) \nu^{\varepsilon_p}(dx) \ge 0.$$

Since $\nabla V(x^*) = 0$ and $V(x^*) > K_\alpha$, it follows that

$$\nu^0(\{x^*\}) \int \mu(d\omega)^t H(x^*,\omega) \nabla^2 V(x^*) H(x^*,\omega) \ge 0.$$

We may assume without loss of generality that the vector $u \in E_- := (\mathrm{Ker}\nabla^2 V(x^*))^\perp$ in assumption (b) satisfies $|u| = 1$. x^* being a strict local maximum of V, $\nabla^2 V(x^*)$ is at least nonpositive (i.e., ${}^tu\nabla^2 V(x^*)u \leq 0$). Set $|\lambda|_{\min} := \min\{|\lambda|,\ \lambda \neq 0,\ \lambda$ eigenvalue of $\nabla^2 V(x^*)\}$. One gets

$$\begin{aligned}{}^tH(x^*,\omega)\nabla^2 V(x^*)H(x^*,\omega) &= {}^t\pi^\perp_{E_-}(H(x^*,\omega))\nabla^2 V(x^*)\pi^\perp_{E_-}(H(x^*,\omega))\\ &\leq -|\lambda|_{\min}|\pi^\perp_{E_-}(H(x^*,\omega))|^2 \leq -|\lambda|_{\min}(H(x^*,\omega)|u)^2,\end{aligned}$$

where $\pi^\perp_{E_-}$ denotes the orthogonal projection on E_-. In turn these inequalities yield

$$\int \mu(d\omega)\,{}^tH(x^*,\omega)\nabla^2 V(x^*)H(x^*,\omega) \leq -|\lambda|_{\min}\int \mu(d\omega)(H(x^*,\omega)|u)^2 < 0,$$

implying that $\nu^0(\{x^*\}) = 0$. □

Remark. The assumptions of Theorem 3.2(a) do not imply that $h(x^*)$ is zero but only that $h(x^*)$ belongs to $\mathrm{Ker}\nabla^2 V(x^*)$. However, if $h(x^*) \neq 0$—and if the assumptions of the flow-invariance theorem (Theorem 2.2) are fulfilled by h—then $\nu^0(\{x^*\}) = 0$ *whatever the noise is*: the discrete part of ν^0 necessarily lies in $\{h = 0\}$ by Proposition 2.4.

A first application. If $x^* \in \{h = 0\}$, h is differentiable at x^*, and all eigenvalues of $\nabla h(x^*)$ have negative real part, then $\nu^0(\{x^*\}) = 0$.

This follows from the quite classical construction (see, e.g., [1]) of an appropriate local Lyapunov function defined by $V(x) := 1 - \int_0^{+\infty} |e^{s\nabla h(x^*)}(x - x^*)|^2 ds$.

3.1.2. The case of higher-order strict local maxima. Theorem 3.2 seems not to be powerful enough to treat the case where the noise exclusively lies in the direction of $(\mathrm{Ker}\nabla^2 V(x^*))^\perp$. This is the case, e.g., for a stochastic algorithm having, near $(0,0)$, $V(x,y) = 1 - (x^2 + y^4)$ as a (local) Lyapunov function. Actually, this question can be solved by simply changing the Lyapunov function.

DEFINITION 3.3. *Let $V : \mathbb{R}^d \to \mathbb{R}_+$ be a function having a (strict) local maximum at $x^* \in \mathbb{R}^d$. The function V has a polynomial local maximum at x^* of order $2p$, $p \in \mathbb{N}^*$, if V is $2p$-differentiable at x^* and*

$$\exists\, \alpha > 0,\ \forall\, u \in \overline{B}(0,\alpha) \setminus \{0\},\quad \sum_{k=2}^{2p} \frac{\nabla^k V(x^*)}{(k-1)!}.u^{(k)} < 0. \tag{3.1}$$

Remark. $\nabla V(x^*)$ is necessarily 0 and it is meaningless to stop at some odd order.

For such maxima, it turns out that $1 - |x - x^*|^2$ is locally a Lyapunov function around x^*.

PROPOSITION 3.4. *Assume that $V : \mathbb{R}^d \to \mathbb{R}_+$ is a local Lyapunov function for h near x^*. If*

(i). *x^* is a strict polynomial local maximum of V whose degree is $2p$,*

(ii). *$h(x) - \nabla V(x) = |x - x^*|^{2p-1}\eta(x)$, $\lim_{x\to x^*}\eta(x) = 0$ (this is fulfilled, e.g., when $h = \nabla V$ near x^*),*
then, $x \mapsto 1 - \frac{1}{2}|x - x^*|^2$ is a Lyapunov function near x^*.

Note that assumption (i) *with $p = 1$ amounts to $\nabla^2 V(x^*)$ being positive.*

Combining this result and Theorem 3.2 straightforwardly solves the following example.

Example. Set $H(x,\omega) := (-\frac{x}{1+|x|^{\frac{5}{2}}}, -y^3(1 + \sqrt{|x|})) + \omega$ and $\omega^t := (0, \omega_2^t)$, $\omega_2^t \sim \mathcal{N}(0,1)$. One readily observes that $V(x,y) := 1 - (x^2 + y^4)$ is a Lyapunov function locally around $(0,0)$, $(0,0)$ being a polynomial maximum of degree 4. Moreover, the noise has its support in $\mathrm{Ker}\nabla^2 V(0,0) := \mathbb{R}(0,1)$. So Theorem 3.2 fails when applied directly but succeeds when passing through Proposition 3.4.

Proof. The Taylor–Young formula applied at x^* to ∇V reads

$$\nabla V(x) = \sum_{k=1}^{2p-1} \frac{\nabla^{k+1}V(x^*)}{k!}.(x-x^*)^{(k)} + |x-x^*|^{2p-1}\varepsilon(x) \quad \textit{with} \quad \lim_{x\to x^*}\varepsilon(x) = 0,$$

hence

$$\begin{aligned} -(x-x^*|h(x)) &= -(x-x^*|\nabla V(x)) + o(|x-x^*|^{2p}) \\ &= \underbrace{-\sum_{k=1}^{2p-1} \frac{\nabla^{k+1}V(x^*)}{k!}.(x-x^*)^{(k+1)}}_{<0 \text{ if } |x-x^*|\le\alpha} + o(|x-x^*|^{2p}). \end{aligned}$$

Finally, it follows that $\exists\, \alpha^* \in (0,\alpha]$ and $\rho^* > 0$ s.t.

$$\forall\, x \in B(x^*,\alpha^*), \qquad -(x-x^*|h(x)) \ge \rho^*|x-x^*|^{2p}. \qquad \square$$

Further comments. One must keep in mind that the square Euclidean norm may be a local Lyapunov function near an obviously nonpolynomial strict local maximum of a function V. This is the case, e.g., when (in any dimension d) $h(x) = V(x) := 1 - \exp(-\frac{1}{|x|^2})$. One readily checks that all the derivatives of V at 0 are 0 and that $1 - \frac{1}{2}|x|^2$ is a strict Lyapunov function for h near 0.

Conversely, the square Euclidean norm is not always a Lyapunov function! Indeed, if

$$V(x) := -\left(\frac{1+\sqrt{2}}{2} + \sin\frac{1}{|x|^2}\right)\exp\left(-\frac{1}{|x|^2}\right) \qquad \text{and} \qquad h := \nabla V,$$

V is a C^∞ function whose all derivatives are bounded on $\mathbb{R}^d$, having a local/global maximum at 0. However,

$$(h(x)|x) = -\left(1+\sqrt{2}+2\sqrt{2}\cos\left(\frac{1}{|x|^2}-\frac{\pi}{4}\right)\right)|x|^{-2}\exp\left(-\frac{1}{|x|^2}\right)$$

whose sign is obviously not constant near 0. In fact, the only way to make up such an example is to choose functions V having infinitely many *undulations* arbitrarily close to its local maximum.

3.1.3. Extension to thin zero sets. A straightforward generalization of Theorem 3.2 is obtained by considering a compact connected set χ^*, instead of an isolated point x^*, provided that χ^* is *thin*, i.e., $\chi^* = \partial\chi^*$.

Assume that there exists a neighborhood $\mathcal{V}^*$ of χ^* and $V \in \mathcal{C}^2(\mathcal{V}^*,\mathbb{R}_+)$ such that

$$\forall\, x \in \chi^*,\ V(x) = v^* \ \text{ and } \ \forall\, x \in \mathcal{V}^* \setminus \chi^*,\ (\nabla V|h)(x) > 0 \text{ and } V(x) < v^*.$$

If, for every $x^* \in \chi^*$, there exists $u(x^*)$ such that

$$\text{(3.2)} \qquad u(x^*) \in \left(\mathrm{Ker}\nabla^2 V(x^*)\right)^\perp \quad \text{and} \quad \int (H(x^*,\omega)|u(x^*))^2\mu(d\omega) > 0,$$

then

$$\nu^0(\chi^*) = 0.$$

Example. Following the notations of subsection 2.2, let

$$h(x) = -\frac{|x|^2 - 1}{|x|^2 + 1}\psi(x) + \varphi(x)\begin{pmatrix} -x_2 \\ x_1 \end{pmatrix},$$

where $\psi : \mathbb{R}^2 \to \mathbb{R}^2$ is $\mathcal{C}^2$, $\psi(x) = x + o(|x| - 1)$ near the unit circle $\mathcal{C}(0;1)$, and $\psi(x) = x + o(|x|)$ when $|x| \to +\infty$. Then $\mathcal{C}(0;1)$ is a repulsive cycle and the above extension of Theorem 3 applies.

3.1.4. The Lemniscate example: Continuation. It was shown in the former Lemniscate example (section 2.2) that any weak limiting value ν^0 of the invariant distributions of the algorithm defined by (2.5) satisfies

$$\operatorname{supp}(\nu^0) \subset \{(0;0),\, (\sqrt{2};\sqrt{2}),\, (-\sqrt{2};-\sqrt{2})\},$$

where the last two points are repulsive stationary points for $ODE_h \equiv \dot{x} = -h(x)$. Following Theorem 3.2, namely assumption (b)(ii) in Proposition 3.1, one derives that

$$\varphi \in L^\infty(\mu) \implies \nu^0(\{(\sqrt{2};\sqrt{2}),\, (-\sqrt{2};-\sqrt{2})\}) = 0.$$

Consequently, $\operatorname{supp}(\nu^0) = \{(0;0)\}$, i.e.,

$$\nu^\varepsilon \overset{(\mathbb{R}^d)}{\Longrightarrow} \delta_{(0;0)} \quad \text{although } (0;0) \text{ is an unstable point.} \tag{3.3}$$

This result stresses the fact that the asymptotic behavior of ν^ε near an unstable point x^* as $\varepsilon \downarrow 0$ depends on the global behavior of the deterministic underlying flow of the dynamical system and on the local properties of the random perturbation term $H(x^*,\omega) - h(x^*) = H(x^*,\omega)$ at x^*.

For instance, in Figure 2 are plotted three histograms of $|X(t)|$ for $t \in \{1,\dots,2\times 10^5\}$, with $\varepsilon := 1.5 \times 10^{-4}$, $\varepsilon := 0.75 \times 10^{-4}$, and $\varepsilon := 0.3 \times 10^{-4}$. ν^ε clearly concentrates at $(0;0)$.

Comparison with the algorithm with decreasing step. The same algorithm, implemented with a regular decreasing step, will a.s. not converge. As a matter of fact, following, e.g., [11] or [2], one derives that, a.s., its limiting value set $\mathcal{X}^\infty$ makes up a flow-invariant compact connected subset of the Lemniscate $\{L = 0\}$ (hence containing $(0;0)$). Then calling upon [7] or [21] implies that it cannot converge to $(0;0)$ as it is a point at which the noise is not degenerate. So $\mathcal{X}^\infty$ is one of the two loops, or the whole Lemniscate $\{L = 0\}$ depending on the noise structure at $(0;0)$.

Actually, the constant step algorithm behaves the same way. What the convergence in (3.3) says is that the algorithm spends infinitely more time in any neighborhood of the origin than anywhere else.

3.1.5. The periodic/quasi-cycle example: Continuation. Let us come back to algorithm (2.9). We saw using the nonfunctional approach that whenever the function φ is continuous and bounded, if $\mathbb{E}(|\omega|^{1+\rho}) < +\infty$, then $\operatorname{supp}(\nu^0) \subset \mathcal{C}(0;1) \cup \{(0;0)\}$.

If, moreover, $0 < \mathbb{E}(|\omega|^2) < +\infty$, then Theorem 3.2 implies that $\nu^0((0;0)) = 0$ as $(0;0)$ is an isolated local maximum of the Lyapunov function V_2 whose Hessian is $\nabla^2 V_2(0;0) = I_2$.

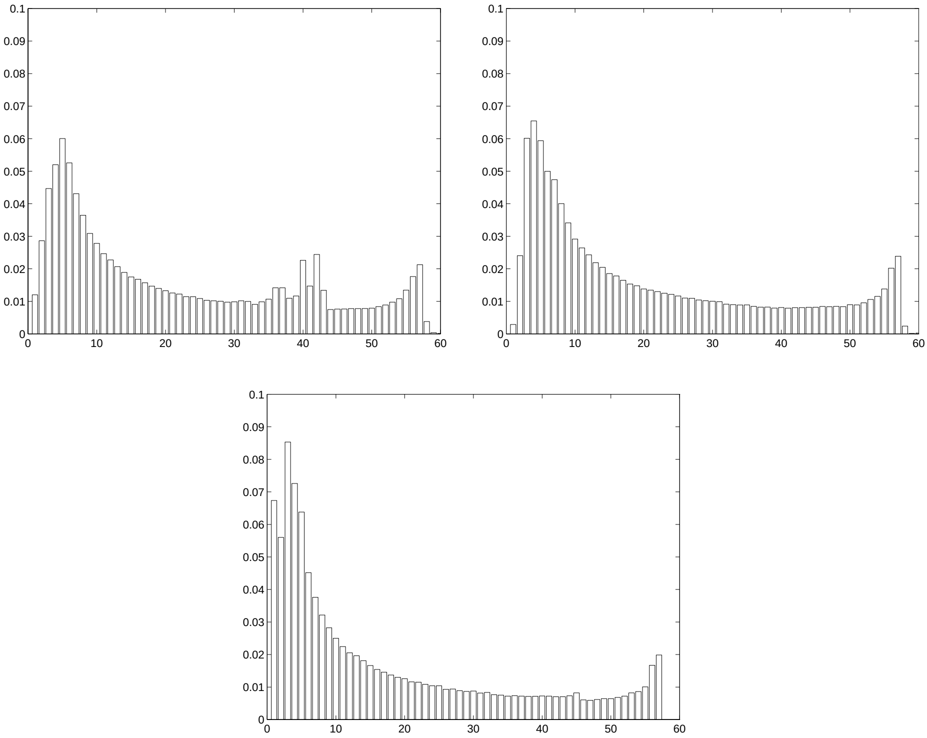

FIG. 2. *Histograms of time spent in* $\{5\times 10^{-2}k \le\mid x \mid\le 5\times 10^{-2}(k+1)\}, 0\le k\le 59$ *with time* $t\in\{1,\dots,2\times 10^5\}$*, and for* $\epsilon := 1.5\times 10^{-4}, \epsilon := 0.75\times 10^{-4}, \epsilon := 0.3\times 10^{-4}$.

PROPOSITION 3.5. *Assume that* φ *is continuous and bounded and if* $0<\mathbb{E}(|\omega|^2)<+\infty$*, then either*

(a) *if* φ *is never* 0 *on* $\mathcal{C}(0;1)$*, then*

$$\nu^\varepsilon \overset{(\mathbb{R}^d)}{\Longrightarrow} \nu^0 := \frac{\frac{1}{\varphi}(e^{i\theta_0})}{\int_0^{2\pi}\frac{1}{\varphi}(e^{i\theta})d\theta}\mathbf{1}_{[0,2\pi[}(\theta_0)d\theta_0, \quad \textit{or}$$

(b) *if* $\int_0^{2\pi}\frac{1}{\varphi}(e^{i\theta})d\theta=+\infty$ *then* $\operatorname{supp}(\nu^0)\subset\{\varphi_{|\mathcal{C}(0;1)}=0\}$.

Proof. (a) Assumption $(UI)_{loc}$ is obviously fulfilled by the algorithm. On the other hand, $ODE_h \equiv \dot{x}=-h(x)$ reads in polar coordinates $((x_1,x_2):=(r\cos\theta, r\sin\theta))$:

$$\dot{r}=-r\frac{r^2-1}{r^2+1} \qquad \text{and} \qquad \dot{\theta}=-\varphi(re^{i\theta}).$$

The unit circle $\mathcal{C}(0;1)$ is flow-invariant for ODE_h, on which the flow is well defined since φ is never 0 on $\mathcal{C}(0;1)$ and the differential equation $ODE_\theta\equiv\dot{\theta}=-\varphi(e^{i\theta})$ is scalar. A straightforward extension of Theorem 2.2 shows that ν^0 is still flow-invariant. Now, it is known that ODE_θ is uniquely ergodic with invariant distribution

$$\nu^0(d\theta_0)=\mathbf{1}_{[0,2\pi)}\frac{\frac{1}{\varphi}(e^{i\theta_0})d\theta_0}{\int_0^{2\pi}\frac{1}{\varphi}(e^{i\theta_0})d\theta_0}.$$

The proof is reproduced for the reader's convenience: let $T > 0$ and $v \in [0,T]$. The invariance property yields, for every $n \in \mathbb{N}^*$,

$$\begin{aligned}\int_0^{2\pi} e^{in\theta_0}\varphi(e^{i\theta_0})\nu^0(d\theta_0) &= \int_0^{2\pi} e^{in\theta(\theta_0,v)}\varphi(e^{i\theta(\theta_0,v)})\nu^0(d\theta_0)\\ &= \int_0^{2\pi}\frac{1}{T}\int_0^T e^{in\theta(\theta_0,v)}\varphi(e^{i\theta(\theta_0,v)})dv\,\nu^0(d\theta_0)\\ &= \int_0^{2\pi}\frac{1}{T}\frac{e^{in\theta(\theta_0,T)}-e^{in\theta(\theta_0,0)}}{-in}\nu^0(d\theta_0)\overset{T\to+\infty}{\longrightarrow} 0.\end{aligned}$$

The Fourier transform being one to one, $\varphi(e^{i\theta_0})\nu^0(d\theta_0) = c\lambda_{|[0,2\pi)}(d\theta_0)$, i.e.,

$$\nu^0(d\theta_0) = \mathbf{1}_{[0,2\pi)}\frac{\frac{1}{\varphi}(e^{i\theta_0})d\theta_0}{\int_0^{2\pi}\frac{1}{\varphi}(e^{i\theta_0})d\theta_0}.$$

Conversely, ν^0 actually is flow-invariant.

(b) Since φ does have zeros on $\mathcal{C}(0;1)$, the flow $\Phi(\theta,u)$ of ODE_θ is well defined and it converges to some zero of φ. Once again, it is straightforward to show that the flow invariance of ν^0 still holds in the following way: for every Borel set A and every $u \geq 0$, $\nu^0(A) = \Phi(\nu^0,u)(A)$. As any limiting distribution of $\Phi(\nu^0,u)$ is supported by $\{\varphi_{|\mathcal{C}(0;1)} = 0\}$, it follows that $\nu^0(A) = 0$, i.e., $\mathrm{supp}(\nu^0) \subset \{\varphi_{|\mathcal{C}(0;1)} = 0\}$. □

Remark. If $\varphi \geq 0$ does have zeros on $\mathcal{C}(0;1)$ while the integral

$$C_\varphi := \int_0^{2\pi}\frac{1}{\varphi}(e^{i\theta_0})d\theta_0 < +\infty, the probability measure \quad \frac{1}{C_\varphi}\frac{1}{\varphi(e^{i\theta_0})}\mathbf{1}_{[0,2\pi[}(\theta_0)\,d\theta_0$$

is still an invariant distribution of ODE_θ.

Some further investigations can be carried out by studying the nature of the critical points of $\{h_{|\mathcal{C}(0;1)} = 0\}$. Furthermore, if the distribution of the white noise is known and admits moments enough (Gaussian, etc.), one may restrict again the support (see, e.g., [23] in a continuous time-diffusion setting) using, e.g., some large deviation methods.

3.2. Saddle points of a stochastic pseudogradient. It was emphasized in section 3.1.4 that a saddle critical point x^* of the mean function h can be weighted by a limiting distribution ν^0 even if the random perturbation does not fade at x^*. The aim of this section is to show that, in many situations, this cannot occur—namely, when the algorithm is a *stochastic pseudogradient* with a $\mathcal{C}^2$ Lyapunov function V satisfying $\{(\nabla V|h) = 0\} = \{h = 0\}$ and x^* is a saddle point of V. Many learning algorithms issued from neural networks are stochastic pseudogradient descents. They are often performed with a (small) constant step (Boltzmann machine, back-propagation algorithm for the multilayer perceptron, and others) precisely to avoid false convergence phenomena to metastable critical points.

The fact that an algorithm is a stochastic pseudogradient provides the information about the *global behavior* of the flow of its ODE_h. For the sake of simplicity, we will assume that there is no spurious equilibrium (see section 3.3). The case of possible spurious points will be investigated later.

Before getting into the technicalities let us explain the method developed in this section. Basically, it consists once again in modifying the global Lyapunov function V near some critical points. Namely, we will flatten V at the local minima and nearly pull down to zero the positive part of the spectra of the Hessian of V near the saddle points. To this end we need to write V locally as a quadratic form up to some $\mathcal{C}^2$-diffeomorphic change of coordinates. The Morse lemma (see, e.g., [14]) will be called upon to ensure this is possible.

Proposition 3.6 (Morse). *Let $g \in \mathcal{C}^3(\mathcal{V}^*, \mathbb{R})$, where $\mathcal{V}^*$ is a neighborhood of x^*. Assume that $g(x^*) = 0$, $\nabla g(x^*) = 0$, and $\nabla^2 g(x^*)$ is invertible. Then there exist $\varepsilon_0 > 0$ and $u \in \mathcal{C}^2(B(x^*, \varepsilon_0), \mathbb{R}^d)$ such that*

$$u(x^*) = 0, \quad u'(x^*) = I_d, \qquad \textit{and} \qquad \forall x \in B(x^*, \varepsilon_0),\ g(x) = \frac{1}{2}\,{}^t u(x) \nabla^2 g(x^*) u(x).$$

Notation. From now on, $E_x^{\pm}$ will denote the vector spaces respectively spanned by eigenvectors of $\nabla^2 V(x)$ with positive and nonpositive eigenvalue.

Theorem 3.7. *Let $(\nu^\varepsilon)_{\varepsilon \in (0, \varepsilon_0]}$ be a tight family of $(P^\varepsilon)_{\varepsilon \in (0,\varepsilon_0]}$-stationary distributions, and let ν^0 be one of its limiting distributions as $\varepsilon \downarrow 0$.*

Assume that H, μ, and the ν^ε's fulfill assumptions (a) *and* (b) *of Proposition* 3.1 *and that there exists a global $\mathcal{C}^2$ Lyapunov function $V : \mathbb{R}^d \to \mathbb{R}_+$ satisfying*

$$(\mathcal{L}) \equiv \begin{cases} \text{(i)} & (\nabla V | h) \geq 0 \ \textit{ and } \ \{(\nabla V | h) = 0\} = \{\nabla V = 0\}, \\ \text{(ii)} & \forall\, K > 0,\ \sup_{\{V \leq K\}} |\nabla V|^2 + \|\nabla^2 V\|^2 + |h|^2 < +\infty. \end{cases}$$

(a) Local result. *Let $x_0^* \in \{\nabla V = 0\}$ and $v_0^* := V(x_0^*)$. Assume that there is some $\eta_0^* > 0$ such that*

(i) *the set $\mathcal{C}_0^* := \{\nabla V = 0\} \cap \{V \in (v_0^* - \eta_0^*, v_0^* + \eta_0^*)\}$ is finite;*

(ii) *for every $x^* \in \mathcal{C}_0^*$, x^* is*

$$\begin{cases} (\alpha) & \textit{a local maximum of } V, \\ (\beta) & \textit{or a local minimum of } V, \\ (\gamma) & \textit{or} \begin{cases} \textit{a } \mathcal{C}^3\textit{-Morse saddle point } (V \textit{ is locally } \mathcal{C}^3,\ \nabla^2 V(x^*) \textit{ is invertible}) \\ \textit{satisfying } (\nabla V | h)(x) \geq c_* |\nabla V|^2(x) \textit{ for some } c_* > 0 \\ \textit{and } \theta(x) := h(x) - \frac{(\nabla V|h)}{|\nabla V|^2}(x) \nabla V(x) = O(|x - x^*|^{1+a_*}) \textit{ for some } a_* > 0; \end{cases} \end{cases}$$

(iii) *there is some $v \in E^-_{x_0^*}$ such that $\int (H(x_0^*, \omega) | v)^2 \mu(d\omega) > 0$ (which implies that x_0^* is not a local minimum);*
then, $\nu^0(\{x_0^*\}) = 0$.

(b) Global result. *Assume that $\{\nabla V = 0\}$ is V-locally finite (i.e., for every $v > 0$, $\{\nabla V = 0\} \cap \{V \leq v\}$ is finite) and that, furthermore, it is made up exclusively of points of type (α), (β), and (γ). If every local maximum satisfies the assumption of Theorem* 3.2 *(possibly with a modified local Lyapunov function) and if the above assumption* (iii) *holds at every saddle point, then*

$$\operatorname{supp}(\nu^0) \subset \{\text{local minima of } V\}.$$

Remark. Actually, a fourth category of points could have been added in the above results (a) or (b) made up of all the points that can be "rejected" by any appropriate method: this category contains, e.g., the excited *thin* sets or the spurious points that satisfy the assumptions of Proposition 3.8 below.

Proof. Step 1 (*flattening of the local minima of $\mathcal{C}_0^*$*). Let $x_0^* \in \mathcal{C}_0^*$ be a local minimum. Being isolated, there is some $\delta_* > 0$ such that $V(x) > V(x^*)$ for every $x \in B(x^*, \delta_*) \setminus \{x^*\}$.

Let $m_* := \min\{V(x),\, x \in \partial B(x^*, \delta_*)\}$, $K_* \in (V(x^*), m_*)$, and let φ^* be a nonnegative increasing C^2 function defined on $[V(x^*), +\infty)$ satisfying

$$(\varphi^*)'(V(x^*)) = 0, \quad (\varphi^*)'(v) > 0 \text{ if } v > V(x^*), \qquad \text{and} \qquad \varphi^*_{|[K_*,+\infty)}(v) = v.$$

Then, we set

$$V^*(x) := \left\{ \begin{array}{ll} \varphi^*(V(x)) & \text{if } x \in B(x^*, \delta_*), \\ V(x) & \text{if } x \notin B(x^*, \delta_*). \end{array} \right.$$

One may assume without loss of generality that this modification is carried out around every local minimum contained in $\mathcal{C}_0^*$ so that the different (closed) balls $\overline{B}(x^*, \delta_*)$ remain pairwise distinct and meet no other critical point of V. The function V^* is then C^2, V^* and V have the same critical points and, for every one of them,

$$\left\{ \begin{array}{ll} \nabla^2 V^*(x^*) = (\varphi^*)'(V(x^*))\nabla^2 V(x^*) = 0 & \text{if } x^* \text{ is a local minimum in } \mathcal{C}_0^*, \\ \nabla^2 V^*(x^*) = \nabla^2 V(x^*) & \text{either.} \end{array} \right.$$

Step 2 (*lowering of the positive part of the spectrum of Morse saddle points of* $\mathcal{C}_0^*$). Let $x^* \in \mathcal{C}_0^*$ be a Morse saddle point. Set $A := \nabla^2 V(x^*)$, $A^{\pm} := \pm \pi_{E^{\pm}_{x^*}} A \, \pi_{E^{\pm}_{x^*}}$, $|\lambda|^* := \max\{|\lambda|,\, \lambda \text{ eigenvalue of } A\} = \|A\|$, $|\lambda|_* := \min\{|\lambda|,\, \lambda \text{ eigenvalue of } A\}$, and $|x|_*^2 := (x|(A^+ + A^-)x)$. $|\,.\,|_*^2$ defines an Euclidean norm.

It follows from the Morse lemma that there is some $\delta_* > 0$ and a C^2-diffeomorphism u: $B(x^*, \delta_*) \to \mathcal{N}_0$, $\mathcal{N}_0$ open neighborhood of 0, such that

$$\forall\, x \in B(x^*, \delta_*),\ V(x) = V(x^*) + \frac{1}{2}(Au(x)|u(x)),\ u(x^*) = 0 \ \text{ and } \ u'(x^*) = I_d. \tag{3.4}$$

Furthermore, by properly lowering δ_*, one may assume that there is some $K > 0$ satisfying

$$\begin{array}{l} u' \text{ is } K\text{-Lipschitz on } B(x^*, \delta_*) \text{ with } K\delta_* < 1/4, \\ \forall\, x \in B(x^*, \delta_*),\ |x - x^*|/2 \le |u(x)|_* \le 2|x - x^*|, \\ \forall\, x \in B(x^*, \delta_*),\ |\theta(x)| \le K|x - x^*|^{1+a_*} \text{ and } (\nabla V|h)(x) \ge c_* |\nabla V|^2(x), \\ \text{assuming without loss of generality that } a_* \in (0, 1]. \end{array} \tag{3.5}$$

Now, let

$$\gamma \in \left(0, \left(\frac{\delta_*}{4}\right)^{a_*} \times \frac{4(1 + K\delta_*)\left(2Kc_*(\frac{\delta_*}{4})^{1-a_*} + \frac{2^{1+a_*}}{|\lambda|_*}\right)}{c_*(\frac{1}{2} - K\delta_*)}\right]$$

and $\rho_* : \mathbb{R}_+ \to \mathbb{R}_+$ be a nonincreasing, nonnegative C^∞ function satisfying $\rho_*(0) := \frac{1-\gamma/2}{1-\gamma}$, $\rho^{(k)}(1) = 0$, $k \in \mathbb{N}$, and $\int_0^1 \rho_* = 1$. Then, the function φ_* defined by $\varphi_*(v) = \gamma + (1 - \gamma)\int_0^v \rho_*(u)du$ satisfies $\varphi_*(0) = \gamma$, $\varphi_*(1) = 1$, $\varphi_*^{(k)}(1) = 0$, $k \ge 1$, and $\|\varphi_*'\|_\infty = \frac{1-\gamma/2}{1-\gamma}$. Now, we are in the position to modify V^* around x^* by setting

$$V^*_\gamma(x) \\ = \begin{cases} V(x^*) + \frac{1}{2}\varphi_*\left(\frac{|u(x)|_*^2}{\alpha_*^2}\right)(A^+u|u)(x) - (A^-u|u)(x) & \text{if } |x - x^*| \le \delta_*,\ |u(x)|_* \le \alpha_*, \\ V^*(x) & \text{if } |u(x)|_* \ge \alpha_* \text{ or } |x - x^*| \ge \delta_*, \end{cases}$$

where

$$\alpha_* := \left(\gamma \frac{c_*(\frac{1}{2} - K\delta_*)}{4(1+K\delta_*)\left(2Kc_*(\frac{\delta_*}{4})^{1-a_*} + \frac{2^{1+a_*}}{|\lambda|_*}\right)}\right)^{\frac{1}{a_*}}.$$

As $\alpha_* \le \frac{\delta_*}{4}$ by construction, it follows that $\{x \,/\, |u(x)|_* \le \alpha_*\} \subset B(x^*, \delta_*/2)$, which ensures that the function V^*_γ is well defined as a C^2 function. Next point to be checked is the global Lyapunov property of V^*_γ.

Set for every $x \in B(x^*, \delta_*)$, $M(x) :=^t u'(x) - I_d$. u' being K-Lipschitz, one gets $\|M(x)\| \le K|x - x^*|$. Then, a little algebra on derivatives yields, still for every $x \in B(x^*, \delta_*)$,

$$\text{(3.6)} \qquad \left\{ \begin{array}{lcl} \nabla V(x) &=& (I_d + M(x))(A^+u(x) - A^-u(x)), \\ \nabla V^*_\gamma(x) &=& (I_d + M(x))(a_+(x)A^+u(x) - a_-(x)A^-u(x)), \end{array} \right.$$

with

$$\left\{ \begin{array}{ll} a_+(x) & := \varphi_*\left(\frac{|u(x)|^2_*}{\alpha^2_*}\right) + \frac{(A^+u|u)(x)}{\alpha^2_*}\varphi'_*\left(\frac{|u(x)|^2_*}{\alpha^2_*}\right), \\ a_-(x) & := 1 - \frac{(A^+u|u)(x)}{\alpha^2_*}\varphi'_*\left(\frac{|u(x)|^2_*}{\alpha^2_*}\right). \end{array} \right.$$

One readily sees that $a_+(x) + a_-(x) \le 2$, $a_+(x) \ge \gamma$, and $a_-(x) \ge 1 - (1-\gamma)\rho_*(0) = \frac{\gamma}{2}$, hence $\min(a_+, a_-) \ge \frac{\gamma}{2}$.

Then, it follows from formula (3.6) and the orthogonality relation $(A^+u(x)|A^-u(x)) = 0$ that, whenever $|u(x)|_* \le \alpha_*$,

$$\begin{aligned} (\nabla V^*_\gamma|\nabla V)(x) &\ge |Au(x)|^2\left(\frac{\gamma}{2}(1 - 2\|M(x)\|) - 2\|M(x)\|(1 + \|M(x)\|)\right) \\ &\ge |Au(x)|^2\left(\frac{\gamma}{2}(1 - 2K\delta_*) - 2K(1+K\delta_*)|x - x^*|\right) \\ &\ge |Au(x)|^2\left(\frac{\gamma}{2}(1 - 2K\delta_*) - 4K(1+K\delta_*)\alpha_*\right) \end{aligned}$$

and

$$\begin{aligned} |(\nabla V^*_\gamma|\theta)|(x) &\le |\nabla V^*_\gamma(x)||\theta(x)| \\ &\le (1 + \|M(x)\|)|a_+(x)A^+u(x) - a_-(x)A^-u(x)|\, K|x - x^*|^{1+a_*} \\ &\le 4(1+K\delta_*)|Au(x)|^2\frac{K}{|\lambda|_*}(2\alpha_*)^{a_*}. \end{aligned}$$

Finally, whenever $|u(x)|_* \le \alpha_*$,

$$\begin{aligned} &(\nabla V^*_\gamma|h)(x) \\ &\quad = \frac{(\nabla V|h)}{|\nabla V|^2}(x)(\nabla V^*_\gamma|\nabla V)(x) + (\nabla V^*_\gamma|\theta)(x) \\ &\quad \ge |Au(x)|^2\left(c_*\left(\frac{\gamma}{2}(1 - 2K\delta_*) - 4K(1+K\delta_*)\alpha_*\right) - 4(1+K\delta_*)\frac{(2\alpha_*)^{a_*}}{|\lambda|_*}\right) \\ &\quad \ge |Au(x)|^2\left(c_*\frac{\gamma}{2}(1 - 2K\delta_*) - 2(1+K\delta_*)\left(2Kc_*\left(\frac{\delta_*}{4}\right)^{1-a_*} + \frac{2^{1+a_*}}{|\lambda|_*}\right)\alpha_*^{a_*}\right) \\ &\quad \ge |Au(x)|^2 c_*\frac{\gamma}{4}(1 - 2K\delta_*) \ge 0. \end{aligned}$$

Hence $(\nabla V^*_\gamma | h) \geq 0$ everywhere since $V^* = V^*_\gamma$ when $|u(x)|_* > \alpha_*$. Furthermore

$$\nabla^2 V^*_\gamma(x^*) = \gamma A^+ - A^-.$$

As for the local minima, one may assume that this modification is made at every Morse saddle point of $\mathcal{C}^*_0$ and that all the closed balls $\overline{B}(x^*, \delta_*)$ provided by these first two steps have a pairwise empty intersection.

Step 3 (*localization*). Let $\psi : \mathbb{R}_+ \to \mathbb{R}_+$ be a $\mathcal{C}^\infty$ nondecreasing function whose derivative has exactly $[v^*_0 - \eta^*_0, v^*_0 + \eta^*_0]$ as its support. Set $W^*_\gamma := \psi \circ V^*_\gamma$. Then

$$\nabla W^*_\gamma = \psi'(V^*_\gamma)\nabla V^*_\gamma \quad \text{and} \quad \nabla^2 W^*_\gamma = \psi''(V^*_\gamma)(\nabla V^*_\gamma)\,{}^t(\nabla V^*_\gamma) + \psi'(V^*_\gamma)\nabla^2 V^*_\gamma.$$

It follows from assumption $(\mathcal{L})$ that W^*_γ meets the following properties:

$(\nabla W^*_\gamma | h)$ is nonnegative and bounded,
$\nabla^2 W^*_\gamma$ is bounded,
$\{(\nabla W^*_\gamma | h) = 0\} \cap \{V \in (v^*_0 - \eta^*_0, v^*_0 + \eta^*_0)\} = \mathcal{C}^*_0$ and $\nabla^2 W^*_\gamma = \underbrace{\psi'(V^*_\gamma)}_{>0} \nabla^2 V^*_\gamma$ on $\mathcal{C}^*_0$.

Step 4 (*fading*). Applying Proposition 3.1 to W^*_γ yields, as $\nu^{\varepsilon_p} \Rightarrow \nu^0$,

$$\int_{\mathbb{R}^d} \nu^0(dx) \left[\int {}^tH(x,u)\nabla^2 W^*_\gamma(x) H(x,u)\mu(du)\right] \geq 0.$$

Since $\nabla^2 W^*_\gamma = 0$ outside $\{V \in (v^*_0 - \eta^*_0, v^*_0 + \eta^*_0)\}$, one gets

$$\begin{aligned}
&\sum_{\substack{x^* \in \mathcal{C}^*_0 \\ x^* \text{ local max}}} \nu^0(x^*) \underbrace{\text{“nonpositive term”}}_{\text{as } \nabla^2 W^*_\gamma \leq 0} \\
&+ \sum_{\substack{x^* \in \mathcal{C}^*_0 \\ x^* \text{ local min}}} \nu^0(x^*) \int {}^tH(x^*,u) \underbrace{\nabla W^*_\gamma(x^*)}_{=0 \text{ by step } 1} H(x^*,u)\mu(du) \\
&+ \sum_{\substack{x^* \in \mathcal{C}^*_0 \\ x^* \text{ saddle point}}} \nu^0(x^*)\psi'(V(x^*)) \left(\gamma \int {}^tH(x^*,u) A^+_{x^*} H(x^*,u)\mu(du)\right. \\
&\qquad\qquad\left. - \int {}^tH(x^*,u) A^-_{x^*} H(x^*,u)\mu(du)\right) \geq 0.
\end{aligned}$$

Letting γ go to 0 eventually leads to

$$\sum_{\substack{x^* \in \mathcal{C}^*_0 \\ x^* \text{ saddle point}}} \nu^0(x^*) \underbrace{\psi'(V(x^*))}_{>0} \underbrace{\int {}^tH(x^*,u) A^-_{x^*} H(x^*,u)\mu(du)}_{\geq 0 \text{ and } > 0 \text{ if } x^* = x^*_0} \leq 0.$$

This completes the proof of item (a). Item (b) is obvious. □

3.3. Spurious zeros of a function *h*. One may consider the situation where the mean function h of a stochastic pseudogradient algorithm related to a global Lyapunov function V has some spurious equilibrium points x^* in the following sense:

$$(\nabla V | h)(x^*) = 0 \text{ with } \nabla V(x^*) \neq 0.$$

We will show that, if this spurious equilibrium is excited in the direction of $\nabla V(x^*)$, that is,

$$(\nabla V|h)(x^*) = 0 \text{ and } \int \mu(d\omega)|(\nabla V(x^*)|H(x,\omega))|^2 > 0,$$

then x^* is not in the support of ν^0. Let $\mathcal{P}^*$ be the set of spurious excited equilibrium.

PROPOSITION 3.8. *Assume that V is a C^2 function and that H satisfies the assumptions of Proposition* 3.1. *If x^* is an excited spurious equilibrium point at level v^* and if there is $\eta^* > 0$ such that $\{(\nabla V|h) = 0\}\cap\{V \in [v^*-\eta^*, v^*+\eta^*]\} \subset \{V = v^*\}$, then, for any limiting distribution ν^0 of $(\nu^\varepsilon)_{\varepsilon\in(0,\varepsilon_0]}$, $\nu^0(\{x^*\}) = 0$.*

Proof. Let L be a positive real number and let x^* be an excited spurious equilibrium of h. Let $\varphi_{_L}$ be a nondecreasing function satisfying $\varphi_{_L}(v) := v - L(v-v^*)^2$ if v lies in a small enough neighborhood $[v^*-\alpha^*(L), v^*+\alpha^*(L)]$ of v^*, $\varphi_{_L}(v^*\pm\alpha^*(L)) = v^*\pm\alpha^*(L)$, $\varphi_{_L}$ is constant on both sides of ${}^c[v^*-\eta^*, v^*+\eta^*]$, and $\varphi'_{_L}$ is nonnegative.

Set $W_{_L} := \varphi_{_L}(V)$. The inner product $(\nabla W_{_L}|\nabla V)$ is nonnegative and, for every $x \in \{V = v^*\}$, $\nabla^2 W_{_L}(x) := -2L\nabla V\, {}^t\nabla V(x) + \nabla^2 V(x)$. Subsequently Proposition 3.1 yields

$$-2L\int_{\mathcal{P}^*\cap\{V=v^*\}} \nu^0(dx^*)\int \mu(d\omega)|(\nabla V(x)|H(x,\omega))|^2 + C^* \geq 0,$$

where C^* is a fixed real number. Consequently, as L goes to infinity,

$$\int_{\mathcal{P}^*\cap\{V=v^*\}} \nu^0(dx)\int \mu(d\omega)|(\nabla V(x)|H(x,\omega))|^2$$

needs to be 0. A continuity argument yields that $\nu^0(x^*) = 0$. □

Application to inflection points in one dimension. This a typical example of an excited spurious equilibrium point. As a matter of fact, assume that the mean function h satisfies

$$h(x^*) = 0 \text{ and } h \text{ has constant sign on } [x^*-\alpha^*, x^*+\alpha^*]$$

for some $\alpha^* > 0$. Then, x^* is a spurious critical point for any C^2 nondecreasing function V satisfying

$$V(x) := x - x^* \text{ if } x \in [x^*-\alpha^*/2, x^*+\alpha^*/2], \quad V'(x) = 0 \text{ if } x \notin [x^*-\alpha^*, x^*+\alpha^*].$$

All the results of this section rely on a second-order Taylor expansion of the probability transition P^ε as $\varepsilon \downarrow 0$ (see the proof of Proposition 3.1). That is the main reason why they require a rather low integrability assumption on the noise $(2+\varepsilon)$. In [3], the noise $H(x,\omega) - h(x)$ is bounded in the original urn model that motivated the work. So, the assumption that the Legendre transform of the noise has a uniform quadratic bound is quite natural in that setting. An equivalence between the chain-transitive relationship and the large deviation zero-cost relationship is established under a dimensionality condition (chaining number of unstable attractors less than 2). Then, some large deviation estimates à la Freidlin–Wentzell of the invariant distribution yield some precise results on the possible supports for the limiting invariant distributions. Thus, the case of an isolated unstable (saddle) cycle can be excluded from the possible supports using such methods in a more general context than that, e.g., proposed in the *local result* item of Theorem 3.7.

4. Conclusion. We have seen that the asymptotic behavior of a constant step stochastic algorithm, when the step goes to 0, is almost the same as that of the corresponding decreasing step stochastic algorithm. They share many properties: concentration near the equilibrium points of ODE_h, convergence to the invariant measure in the case of an attracting limit cycle of ODE_h, avoiding of repulsive equilibrium points or cycles in general and of the saddle points in the case of stochastic pseudogradient with isolated singular points. Only one difference seems to occur: a saddle point can be asymptotically weighted when ODE_h is not a stochastic pseudogradient with isolated singular points (see the Lemniscate example) or, more generally, with some unstable equilibrium points (see the periodic/quasi-cycle example when h does have zeros on the cycle). This happens when the algorithm is trapped into a quasi-cycle of singular points. In fact, this dissimilarity is an illusion: the asymptotics of the invariant measures ν^ε essentially take into account the time spent by the algorithm near some points and there is no contradiction between spending *almost* all the time at some place and not converging to it. This is exactly what happens, e.g., in the Lemniscate example. By the way, this illuminates the result obtained by several authors ([7], [21], [28]) that states that a stochastic algorithm $(X^t)_{t\in\mathbb{N}}$ with decreasing step cannot converge toward an excited unstable equilibrium point x^*. Actually several behaviors are hidden under this nonconvergence: when x^* is a repeller or a saddle point of a global Lyapunov function, it means that $\underline{\lim}_t|X^t - x^*| > \varepsilon_0 > 0$. When x^* is a saddle point trapped in a quasi-cycle as in the Lemniscate example, it just means that $\overline{\lim}_t|X^t - x^*| > \varepsilon_0 > 0$. It is the same for the unstable equilibrium points in the quasi-cycle example (setting (b) of Proposition 3.5). In this latter example, if the step is decreasing at the right rate (fast enough indeed), it has been shown by using some shadowing techniques (see [2]) that the algorithm may still converge to such unstable equilibrium (which are not saddle points, which makes this result consistent with those mentioned above). Actually, these results obtained with constant step lead us to think that it would be more appropriate to describe the behavior of a stochastic algorithm with decreasing step in terms of time spent near the singular points, even when the step approaches 0 too slowly to get some a.s. convergence properties. This can be carried out by studying the weighted empirical measures of the algorithm itself (see [12]).

STABILITY OF PIECEWISE-DETERMINISTIC MARKOV PROCESSES*

FRANÇOIS DUFOUR† AND OSWALDO L. V. COSTA‡

Abstract. In this paper, we study a form of stability for a general family of nondiffusion Markov processes known in the literature as piecewise-deterministic Markov process (PDMP). By stability here we mean the existence of an invariant probability measure for the PDMP. It is shown that the existence of such an invariant probability measure is equivalent to the existence of a σ-finite invariant measure for a Markov kernel G linked to the resolvent operator U of the PDMP, satisfying a boundedness condition or, equivalently, a Radon–Nikodým derivative. Here we generalize existing results of the literature [O. Costa, *J. Appl. Prob.*, 27, (1990), pp. 60–73; M. Davis, *Markov Models and Optimization*, Chapman and Hall, 1993] since we do not require any additional assumptions to establish this equivalence. Moreover, we give sufficient conditions to ensure the existence of such a σ-finite measure satisfying the boundedness condition. They are mainly based on a modified Foster–Lyapunov criterion for the case in which the Markov chain generated by G is either recurrent or weak Feller. To emphasize the relevance of our results, we study three examples and in particular, we are able to generalize the results obtained by Costa and Davis on the capacity expansion model.

Key words. piecewise-deterministic Markov process, invariant measure, Markov chain

1. Introduction.

Piecewise-deterministic Markov processes (PDMPs) were introduced by Davis [3] as a general family of nondiffusion stochastic models suitable for formulating many optimization problems in several areas of applications. The motion of a PDMP $\{x_t\}$ in a state space E depends on three parameters, namely, the flow Φ, the jump rate λ, and the transition probability measure Q. Starting from a point x in E, the motion of the process follows the flow $\Phi(x,t)$ until the first jump time T_1. This jump time occurs either when the flow hits the boundary of the state space E or in a Poisson-like fashion with rate $\lambda(\Phi(x,t))$. The location Z_1 of the process at the jump time T_1 is selected by the measure $Q(\Phi(x,T_1),.)$ and the motion restarts from this new point Z_1 as before. This gives a piecewise-deterministic trajectory for the PDMP $\{x_t\}$ with jump times $\{T_1,T_2,\ldots\}$ and postjump location $\{Z_1,Z_2,\ldots\}$. By a suitable choice of the state space E and the parameters Φ, λ, and Q it is possible to virtually model all nondiffusion processes found in the international literature. The reader can find in [4] a complete and updated description of the theory of PDMPs as well as several important applications.

A problem of great importance in the theory of stochastic processes that has been

in evidence for over the last decades is to obtain conditions for the following problem.

$\mathbf{P}_1$. Existence of an invariant probability measure for a stochastic process.

The existence of such a measure corresponds to an important form of stochastic stability and it is the first step toward an ergodic analysis of the process. For a small sample of the huge theory available today on this subject, see [9, 8, 11, 12, 15, 13]. In general it is not a simple matter to determine whether a given process in a general state space has an invariant probability measure and, if so, whether it is unique. For discrete-time stochastic processes there is available in [14] a rather complete treatment of this subject.

The main goal of [2] (see also [4]) was to derive conditions for the existence of an invariant probability measure for a PDMP $\{x_t\}$. Associated with the PDMP $\{x_t\}$ there is a Markov chain given by the postjump location $\{Z_1, Z_2, \ldots\}$ with kernel $\overline{G}$ (see (8) for its definition). It is natural to ask then if it is possible to link the invariant probability measures associated with the Markov chain $\{Z_1, Z_2, \ldots\}$ and the invariant probability measures associated with the PDMP $\{x_t\}$. Since the conditions for existence and uniqueness of an invariant probability measure are more easily stated in the discrete-time setting, this connection provides a way of analyzing $\mathbf{P}_1$ for a PDMP $\{x_t\}$ without relying on the general continuous-time theory. It was shown in [2] that, under some technical assumptions, there is a one-to-one mapping between the invariant probability measures for the PDMP $\{x_t\}$ and the invariant probability measures of the Markov chain $\{Z_1, Z_2, \ldots\}$. However, this result is not entirely satisfactory since the technical assumptions in [2] require that, roughly speaking, the jump rate λ must be strictly positive and bounded. Important applications presented in [4] show that if these conditions are violated then there may exist an invariant probability measure for the PDMP $\{x_t\}$ but not for the associated Markov chain $\{Z_1, Z_2, \ldots\}$, and vice versa.

In the first part of this paper the problem $\mathbf{P}_1$ for a PDMP $\{x_t\}$ is revisited under a new approach that removes the assumptions made in [2]. Instead of using the kernel $\overline{G}$ associated with the Markov chain $\{Z_1, Z_2, \ldots\}$, we introduce a new kernel G (for its definition, see (4)), related to the resolvent kernel U of the PDMP $\{x_t\}$, and show that $\mathbf{P}_1$ for a PDMP $\{x_t\}$ is equivalent to the next problem.

$\mathbf{P}_2$. Existence of an invariant σ-finite measure for the Markov chain associated with the kernel G satisfying a boundedness condition.

It is important to stress that this equivalence requires no extra conditions than those usually imposed on the definition of the PDMP $\{x_t\}$, being therefore a significant improvement with respect to those results presented in [2]. Notice that $\mathbf{P}_2$ is related to an invariant σ-finite measure and therefore it is not necessarily finite. As will be seen in section 3, the boundedness condition in $\mathbf{P}_2$ can also be characterized as a condition in terms of the Radon–Nikodým derivative of the invariant σ-finite measure for G and a certain probability measure. As in [2], a one-to-one mapping between the invariant probability measures for the PDMP $\{x_t\}$ and the invariant σ-finite measures for the Markov chain associated with the kernel G is established. The examples in [4] are revisited under this new framework and, of course, the problems found in [4] are eliminated with our approach.

It is well known that $\mathbf{P}_1$ is equivalent to the problem of the existence of an invariant probability measure for the resolvent kernel associated to the transition function of the stochastic process (see [1]). It is important to point out that such a direct approach to our problem is in vain due to the fact that both the transition function of a general PDMP $\{x_t\}$ as well as its associated resolvent kernel cannot be explicitly calculated. Here our strategy is to use the special structure of the PDMP to provide a tractable answer to the problem $\mathbf{P}_1$.

In the second part of this paper we give weak sufficient conditions for ensuring that $\mathbf{P}_2$ admits a solution. These conditions are based on a modified Foster–Lyapunov criterion for the case in which the kernel G is either recurrent or weak Feller and, we believe, significantly improve previous results presented in [2, 4] for $\mathbf{P}_1$ for a PDMP $\{x_t\}$. Indeed, an interesting property of the PDMPs is that under weak conditions (see Proposition 4.9) they generate weak Feller kernels G and U although the PDMPs themselves are generally not weak Feller Markov processes. Our results are related to those in Meyn and Tweedie [15, 13], Lin [10], and Foguel [7]. Moreover, it is shown that an invariant probability measure always exists for the PDMP $\{x_t\}$ when G is weak Feller and the union of the state space of $\{x_t\}$ and the boundary Γ^+ (for its definition, see section 2) is a compact set. To illustrate the usefulness of our new conditions, the capacity expansion problem (see [4]) is revisited in a more general setup. A sufficient condition for the existence of an invariant measure is obtained, generalizing previous results in the literature.

The paper is organized in the following way. In section 2 we describe the model and introduce the notation. The equivalence between $\mathbf{P}_1$ for PDMP and $\mathbf{P}_2$ is established in section 3. In section 4 we derive sufficient conditions for checking $\mathbf{P}_2$. Illustrative examples are given in section 5. We conclude the paper in section 6 with some final remarks.

2. Model of piecewise deterministic Markov processes. Let E^0 be an open subset of $\mathbb{R}^n$ and ∂E^0 its boundary. As originally defined by Davis [3, 4], a PDMP is determined by its local characteristics $(\mathfrak{X}, \lambda, Q)$, where $\mathfrak{X}, \lambda, \text{and}\, Q$ are defined as follows.

(a) $\mathfrak{X}$ is a locally Lipschitz continuous vector field in E^0 with flow $\Phi(x,t)$.

Now define

$$\Gamma^+ \doteq \{x \in \partial E^0 : x = \Phi(y,t), y \in E^0, t > 0\}$$

and

$$\Gamma^- \doteq \{x \in \partial E^0 : x = \Phi(y,-t), y \in E^0, t > 0\}.$$

$\Gamma^+ \subset \partial E^0$ represents the boundary points at which the flow exits from E^0. $\Gamma^- \subset \partial E^0$ is characterized by the fact that the flow starting from a point in Γ^- will not leave E^0 immediately. Therefore it is natural to define the state space for the PDMP by

$$E \doteq E^0 \cup \Gamma^- - \Gamma^- \cap \Gamma^+.$$

$\mathcal{E}$ will denote the Borel σ-field of E.

Let us denote by $t_*(x) \doteq \inf\{t > 0 : \Phi(x,t) \in \partial E^0\}$ $\forall$ x in E. If this set is empty, then $t_*(x) = \infty$.

Assume that the explosion time of the flow Φ is equal to infinity when $t_*(x) = \infty$.

(b) $\lambda : E \to \mathbb{R}^+$ is the jump rate. It is assumed that this function is measurable and $(\forall x \in E)$ $(\exists \varepsilon > 0)$ such that $\int_0^\varepsilon \lambda(\Phi(x,s))ds$ exists.

(c) $Q : E \cup \Gamma^+ \times \mathcal{E} \to [0,1]$ is the transition measure satisfying the following property: $(\forall x \in E \cup \Gamma^+)$ $Q(x, E - \{x\}) = 1$.

It is shown in [3, 4] that there exists a probability space $(\Omega, \mathcal{F}_t, \mathcal{F}, P_x)$ on which the motion of the PDMP $\{x_t\}$ is defined as follows. Starting from x, the first jump time T_1 of the process is given by

$$P_x(T_1 > t) \doteq I_{\{t<t_*(x)\}} \exp\left\{-\int_0^t \lambda(\Phi(x,s))ds\right\}.$$

Then

$$(\forall t \in [0, T_1)) \qquad x_t = \Phi(x,t) \qquad \text{and} \qquad x_{T_1} = Z_1,$$

where Z_1 is the random variable having as distribution $Q(\Phi(x,T_1),.)$. Now the process follows the path $\Phi(x_{T_1}, t - T_1)$ up to another jump time T_2, where it jumps to the state $x_{T_2} = Z_2$. The interjump time $T_2 - T_1$ and the postjump random variable Z_2 are defined similarly.

It will be assumed that $(\forall (t,x) \in \mathbb{R}_+ \times E)$, $E_x[\sum_k I_{\{t \geq T_k\}}] < \infty$.

For a more general definition of PDMP the reader is referred to Davis [4, section 29]. However, our results are still valid in this setting.

Notation. Let us denote by μ_{Leb} the Lebesgue measure on $\mathbb{R}$ and $\overline{\mathbb{R}}_+ = \mathbb{R}_+ \cup \{\infty\}$.

Let $B(E)$ be the space of real-valued bounded Borel-measurable functions on E.

$C_b(E)$ ($C_c(E)$, respectively) denotes the space of bounded real-valued continuous functions on E (with compact support, respectively).

$\forall A \in \mathcal{E}$, $A^c \doteq E - A$ and $\overline{A}$ is the closure of A.

Let ρ be a metric on E; then $\forall\ x \in E$ and $A \in \mathcal{E}$, $d(x, A) \doteq \inf y \in A \rho(x,y)$.

Let X be a metric space and $\mathcal{B}(X)$ its Borel σ-field.

$\mathcal{M}(X)$ ($\mathcal{M}_b(X)$, respectively) denotes the set of all σ-finite (finite, respectively) measures defined on $(X, \mathcal{B}(X))$.

Finally, we recall the following classical notations: let K_1 and K_2 be two kernels mapping $(E, \mathcal{E})$ into $\mathbb{R}_+$. Then

$$(\forall \mu \in \mathcal{M}(E)),\ (\forall A \in \mathcal{E}), \quad \mu K_1(A) \doteq \int_E K_1(x,A)\mu(dx),$$

$$(\forall f \in B(E)),\ (\forall x \in E), \quad K_1 f(x) \doteq \int_E f(y) K_1(x,dy),$$

$$(\forall x \in E),\ (\forall A \in \mathcal{E}), \quad K_1K_2(x,A) \doteq \int_E K_2(y,A)K_1(x,dy),$$

provided that the right members exist (see [17, Chapter 1, Definitions 1.2 and 1.5]).

3. Invariant probability measure. The main goal of this section is to show that $\mathbf{P}_1$ for a PDMP is equivalent to $\mathbf{P}_2$ (see Theorem 3.5). This new result represents a significant improvement with respect to those of Costa [2] and Davis [4]. Indeed, unlike [2, 4] this equivalence is established without any additional conditions. The key idea is to use a connection between the resolvent kernel U (see (6)) and the kernel G (see (4)) which comes from Lemma 3.2.

Moreover, in order to provide a complete comparison with the results obtained by Costa and Davis (see, for example, Proposition (34.36) in [4]), we derive transformations which link the invariant probability measures for $\{x_t\}$ and the stochastic kernel G (see Corollary 3.6).

For notational convenience, let us define for $x \in E$ and $t \in [0, t_*(x)[$

$$\Lambda(x,t) \doteq \int_0^t \lambda(\Phi(x,s))ds \tag{1}$$

and the following kernels mapping $(E, \mathcal{E})$ into $[0,1]$:

$$L(x,A) \doteq \int_0^{t_*(x)} \exp -\{s + \Lambda(x,s)\} I_A(\Phi(x,s))ds, \tag{2}$$

$$\begin{aligned} K(x,A) \doteq& \int_0^{t_*(x)} \lambda(\Phi(x,s)) \exp -\{s + \Lambda(x,s)\} Q(\Phi(x,s), A)ds \\ &+ \exp -\{t_*(x) + \Lambda(x, t_*(x))\} Q(\Phi(x, t_*(x)), A), \end{aligned} \tag{3}$$

$$G(x,A) \doteq K(x,A) + L(x,A), \tag{4}$$

$$L_n(x,A) \doteq \sum_{i=0}^{n-1} K^i L(x,A), \tag{5}$$

$$U(x,A) \doteq E_x \int_0^{\infty} I_A(x_t) \exp\{-t\} dt, \tag{6}$$

$$S(x,A) \doteq L(x,E) I_A(x), \tag{7}$$

$$\begin{aligned} \overline{G}(x,A) \doteq& \int_0^{t_*(x)} \lambda(\Phi(x,s)) \exp\{-\Lambda(x,s)\} Q(\Phi(x,s), A)ds \\ &+ \exp\{-\Lambda(x, t_*(x))\} Q(\Phi(x, t_*(x)), A). \end{aligned} \tag{8}$$

In the terminology used by Nummelin [16], the kernels G, U, $\overline{G}$ are stochastic kernels because $\forall\ x \in E$, $G(x,E) = U(x,E) = \overline{G}(x,E) = 1$. $\overline{G}$ is the stochastic kernel for the Markov chain $\{Z_1, Z_2, \ldots\}$. U is the resolvent kernel associated with $\{x_t\}$.

REMARK 3.1. *Note that* $\forall\ x \in E$, $0 < L(x,E) < 1$ *and that* G *is a stochastic kernel. Indeed,* $\forall\ x \in E$,

$$L(x,E) + K(x,E) = 1. \tag{9}$$

Therefore, we can define the kernel $R : E \times \mathcal{E} \longrightarrow \mathbb{R}_+$ such that

$$R(x,A) \doteq \frac{I_A(x)}{L(x,E)} \cdot \tag{10}$$

The following result establishes a connection between the kernels K, L and the resolvent U.

LEMMA 3.2.

$$\forall x \in E, \quad \forall A \in \mathcal{E}, \qquad KU(x,A) + L(x,A) = U(x,A). \tag{11}$$

Proof. From section 32.2 and Proposition 32.34 in Davis [4] and the definition of L_n (see (5)), it is easy to obtain

$$\forall x \in E, \quad \forall A \in \mathcal{E}, \qquad \lim_{n \to \infty} \uparrow L_n(x,A) = U(x,A) \tag{12}$$

and

$$\forall x \in E, \quad \forall A \in \mathcal{E}, \qquad KL_n(x,A) + L(x,A) = L_{n+1}(x,A).$$

Now using the monotone convergence theorem, the result follows. □

REMARK 3.3. *Let us introduce the kernel* $J : E \times \mathcal{E} \longrightarrow \mathbb{R}_+$ *such that*

$$J(x, A) \doteq \sum_{j=0}^{\infty} \int_A L(y, E) K^j(x, dy) \cdot \tag{13}$$

Using (12) *and the definition of* J *we have that* $\forall\ x \in E$, $J(x, E) = U(x, E) = 1$. *Therefore* J *is a stochastic kernel.*

Before presenting the first main result of this section, let us derive the following technical lemma.

LEMMA 3.4. *Let* α *be a* σ*-finite measure defined on* $(E, \mathcal{E})$. *Then assertions* (i) *and* (ii) *are equivalent.*

(i) α *is such that* $\alpha = c\nu R$, *where* ν *is a probability measure and* c *a constant in* $(0, \infty)$.

(ii) α *is such that* $\alpha S(E) < \infty$.

Proof. (i) ⇒ (ii). The proof is obvious.

(ii) ⇒ (i). Define the probability measure $\nu \doteq \frac{\alpha S}{\alpha S(E)}$. Then clearly $\alpha = c\nu R$ with $c = \alpha S(E)$. □

The next theorem establishes the connection between $\mathbf{P}_1$ and $\mathbf{P}_2$.

THEOREM 3.5. *The following assertions are equivalent.*

(i) *There exists an invariant probability measure* μ *for* $\{x_t\}$.

(ii) *There exists a probability measure* ν *such that the positive* σ*-finite measure* $\pi = \nu R$ *is invariant for the stochastic kernel* G.

(iii) *There exists a positive* σ*-finite measure* π *invariant for the stochastic kernel* G *such that* $\pi S(E) < \infty$.

Proof. (ii) ⇒ (i). Assume that there exists a probability measure ν such that $\pi \doteq \nu R$ is invariant for G and define the measure $\mu \doteq \pi L$. Note that $\forall\ A \in \mathcal{E}$, $\mu(A) = \int_E \frac{L(y,A)}{L(y,E)} \nu(dy)$. Therefore μ is a probability measure. Since π is a positive σ-finite measure, there exists a partition $\{E_i\}$ of E such that $\pi(E_i) < \infty$. Recalling that $L = G - K$ (see (4)) and $\pi = \pi G$ we have that $\forall\ A \in \mathcal{E}$,

$$\begin{aligned} \mu U(A) &= \sum_i \int_{E_i} U(x, A) \pi L(dx) \\ &= \sum_i \int_{E_i} U(x, A) \pi (I - K)(dx). \end{aligned}$$

Now, using Lemma 3.2, it follows that

$$\begin{aligned} \mu U(A) &= \sum_i \int_{E_i} \{U(x, A) - KU(x, A)\} \pi(dx) \\ &= \sum_i \int_{E_i} L(x, A) \pi(dx) \\ &= \mu(A). \end{aligned}$$

Therefore from Lemma 1 in [1], μ is an invariant measure for $\{x_t\}$.

(i) ⇒ (ii). Let μ be an invariant probability measure for the process $\{x_t\}$. Then $\mu U = \mu$ (see [1]). Let us define the measure ν by $\nu \doteq \mu J$ with J defined in (13). The measure so defined is a probability since $\mu J(E) = \mu U(E) = \mu(E) = 1$ (see Remark 3.3). Let us introduce $\pi \doteq \nu R$ (see (10)). Then, from (10) and (13) we obtain

$$\pi = \sum_{j=0}^{\infty} \mu K^j. \tag{14}$$

From (14) and (12) and Lemma 3.2, it is easy to obtain that $\pi L = \mu$ and $\pi K + \mu = \pi$.

Consequently $\pi G = \pi(K + L) = \pi K + \mu = \pi$.

(ii) $\Leftrightarrow$ (iii). Using Lemma 3.4 the equivalence is straightforward.

This completes the proof. □

As mentioned in the introduction, the condition on the σ-finite invariant measure π for the Markov chain associated with G can be written in terms of the boundedness of $\pi S(E)$ ((iii) in the theorem) or in terms of the Radon–Nikodým derivative $L(x, E)^{-1}$ of π with respect to a probability measure ν ((ii) in the theorem).

The next result gives explicitly the links between ν and μ using an approach that differs from Costa [2] and Davis [4]. In particular, we avoid introducing the so-called boundary measure associated with the invariant probability measure of $\{x_t\}$ (see, for example, [4, pp. 116–118]). Our approach directly uses the kernels J, L, and R. Moreover, it is shown that these mappings are one to one, providing a complete comparison with results known in the literature (see, for example, Proposition (34.36) in Davis, [4]).

COROLLARY 3.6. (i). *If μ is an invariant probability measure for $\{x_t\}$, then the σ-finite measure μJR is invariant for G and $\mu JRL = \mu$.*

(ii). *If ν is a probability measure such that νR is invariant for G, then the probability measure νRL is invariant for $\{x_t\}$ and $\nu RLJ = \nu$.*

Proof. (i) and the first part of (ii) are easy consequences of Theorem 3.5.

In order to show that if ν is a probability measure such that νR is invariant for G, then $\nu RLJ = \nu$, let us first note that

$$\forall x \in E, \quad \forall A \in \mathcal{E}, \qquad J(x, A) - KJ(x, A) = I_A(x)L(x, E). \tag{15}$$

Since νR is a positive σ-finite measure, there exists a partition $\{E_i\}$ of E such that $\nu R(E_i) < \infty$. Moreover, using the fact that $\nu RK + \nu RL = \nu R$ and (15), we have

$$\begin{aligned} \nu RLJ(A) &= \sum_i \int_{E_i} J(x, A)\nu RL(dx) \\ &= \sum_i \int_{E_i} I_A(x)L(x, E)\nu(dx) \\ &= \nu(A). \end{aligned}$$

This completes the proof. □

The following result shows that if λ is bounded, then $\mathbf{P}_1$ is equivalent to the existence of a finite invariant measure for G. In what follows, we set (see [4, sections 24 and 26])

$$\begin{aligned} N_t &\doteq \sum_{i=1}^{\infty} I_{\{t \geq T_i\}}, \\ p^*(t) &\doteq \sum_{i=1}^{\infty} I_{\{t \geq T_i\}} I_{\{x_{T_i-} \in \Gamma+\}}. \end{aligned}$$

Note that $\{N_t\}$ and $\{p^*(t)\}$ are counting processes, N_t being the number of jumps of the process $\{x_t\}$ in the time interval $[0,t]$ and $p^*(t)$ counting the number of jumps from the boundary up to time t.

PROPOSITION 3.7. *Let μ be an invariant probability measure for the process $\{x_t\}$ with $E_\mu[N_t] < \infty \ \forall \ t \in \mathbb{R}$, and define $\pi \doteq \mu JR$. Then the following assertions are equivalent:*

(i) $\pi(E) < \infty$.

(ii) $\int_E \lambda(x)\mu(dx) < \infty$.

Proof. By repeating the same arguments as in Proposition 34.13 and Theorem 34.15 in Davis [4, pp. 116–117] and using the fact that $E_\mu[N_t] < \infty \ \forall \ t \in \mathbb{R}$, we obtain that

$$E_\mu\left[\int_0^t \exp\{-s\}dp^*(s)\right] = (1-\exp\{-t\})\sigma(\Gamma^+),$$

where σ is a finite measure defined on $(\Gamma^+, \mathcal{B}(\Gamma^+))$ by Theorem 34.15 in Davis (see [4, p. 117]).

From the monotone convergence theorem, it follows that

$$E_\mu\left[\int_0^\infty \exp\{-s\}dp^*(s)\right] = \sigma(\Gamma^+). \tag{16}$$

Consequently, we can define:

$$\Psi_n \doteq E_\mu\left[\int_0^\infty \exp\{-s\}\lambda_n(x_s)ds + \int_0^\infty \exp\{-s\}dp^*(s)\right], \tag{17}$$

where

$$\lambda_n(x) \doteq \begin{cases} \lambda(x) & \text{if } \lambda(x) < n, \\ n & \text{otherwise.} \end{cases}$$

Using Fubini's theorem and the fact that μ is an invariant probability measure for $\{x_t\}$, we get that

$$E_\mu\left[\int_0^t \exp\{-s\}\lambda_n(x_s)ds\right] = (1-\exp\{-t\})\int_E \lambda_n(x)\mu(dx)$$

and again from the monotone convergence theorem,

$$E_\mu\left[\int_0^\infty \exp\{-s\}\lambda_n(x_s)ds\right] = \int_E \lambda_n(x)\mu(dx). \tag{18}$$

Therefore, combining (16), (17), and (18), we have

$$\Psi_n = \int_E \lambda_n(x)\mu(dx) + \sigma(\Gamma^+).$$

Now using the monotone convergence theorem, we obtain

$$\lim_{n\to\infty} \Psi_n = \int_E \lambda(x)\mu(dx) + \sigma(\Gamma^+). \tag{19}$$

On the other hand, it is easy to show from section 32.2 and Proposition 32.34 of Davis [4] that Ψ_n can be written as

$$\Psi_n = \mu \sum_{i=0}^{\infty} K^i \phi_n, \tag{20}$$

where

$$\phi_n = \int_0^{t_*(x)} \lambda_n(\Phi(x,s)) \exp -\{s + \Lambda(x,s)\} ds + \exp -\{t_*(x) + \Lambda(x, t_*(x))\}.$$

Recalling the definition of the stochastic kernel K (see (3)) and from the monotone convergence theorem, it follows that

$$\lim_{n\to\infty} \uparrow \phi_n = K(x, E).$$

Therefore, using (20), we have

$$\lim_{n\to\infty} \Psi_n = \mu \sum_{i=1}^{\infty} K^i(E).$$

Now, with (19) and the previous one, it follows that

$$\mu \sum_{i=0}^{\infty} K^i(E) = 1 + \mu \sum_{i=1}^{\infty} K^i(E) = 1 + \int_E \lambda(x)\mu(dx) + \sigma(\Gamma^+). \tag{21}$$

However, recalling the definitions of the stochastic kernels J and R (see (13) and (10)), we have

$$\mu JR(E) = \mu \sum_{i=0}^{\infty} K^i(E).$$

Thus, combining the previous equation with (21), we obtain the result. □

REMARK 3.8. *It is clear that if $\lambda(.)$ is bounded, then $\pi(E) < \infty$. Therefore, if $\lambda(.)$ is bounded, there exists an invariant probability measure for $\{x_t\}$ if and only if there exists an invariant probability measure for the stochastic kernel G. Assuming, moreover, that G is weak Feller, necessary and sufficient conditions can be given to ensure that $\{x_t\}$ has an invariant measure (see, for example,* [10, 7, 9, 8]). *However, these conditions are difficult to check in practice since they need the limit of the sum of iterations of G.*

4. Sufficient conditions. The aim of this section is to give simple sufficient conditions to check if $\mathbf{P}_2$ (and therefore $\mathbf{P}_1$) has a solution. Such test criteria are based on Foster–Lyapunov inequalities. It has been proven in Meyn and Tweedie [14] that this test function implies the existence of an invariant probability measure for a class of Markov chain. In our case the problem is different since we have to find a σ-finite measure π for G that satisfies the condition $\pi S(E) < \infty$. Following the line of Meyn and Tweedie [14], Lin [10], and Foguel [7], we are able to show that modified drift criteria ensure such a property for the case in which the Markov chain generated by G is either recurrent or weak Feller. Moreover, it is shown that an invariant probability measure always exists for the PDMP $\{x_t\}$ when G is weak Feller and the union of the state space of $\{x_t\}$ and the boundary Γ^+ (for its definition, see section 2) is a compact set.

First we recall some classical definitions related to Markov chains. For a complete exposition on the subject, the reader is referred to the book by Meyn and Tweedie [14].

Notation. We shall denote by $\{Y_n\}$ the Markov chain generated by the stochastic kernel G.

DEFINITION 4.1. *$\{Y_n\}$ is φ-irreducible if there exists a measure φ on $(E, \mathcal{E})$ such that, whenever $\varphi(A) > 0$, it follows that $P_x(\tau_A < \infty) > 0 \ \forall \ x \in E$, where $\tau_A = \inf\{n \geq 1 : Y_n \in A\}$.*

If $\{Y_n\}$ is φ-irreducible, then $\psi = \sum_{n=0}^{\infty} \left(\frac{1}{2}\right)^{n+1} \varphi G^n$ is a maximal irreducibility measure (see [14, Proposition 4.2.2, p. 88]). In the following, we will use ψ to denote a maximal irreducibility measure for $\{Y_n\}$. Associated with a maximal irreducibility measure for $\{Y_n\}$, we define

$$\mathcal{E}^+ \doteq \{A \in \mathcal{E} : \psi(A) > 0\}.$$

DEFINITION 4.2. *$\{Y_n\}$ is called recurrent if it is ψ-irreducible and*

$$\sum_{n=1}^{\infty} G^n(x, A) = \infty \ \forall \ x \in E \text{ and } A \in \mathcal{E}^+$$

.

DEFINITION 4.3. *A set $C \in \mathcal{E}$ is called ν_a-petite if there exists a nontrivial measure ν_a on $(E, \mathcal{E})$ such that*

$$(\forall x \in C), \ (\forall B \in \mathcal{E}) \quad \sum_{n=1}^{\infty} a(n) G^n(x, B) \geq \nu_a(B),$$

where the positive sequence $\{a(n)\}$, satisfies $\sum_{n=0}^{\infty} a(n) = 1$.

Following similar ideas as in Proposition 14.1.1 in the book by Meyn and Tweedie [14, p. 333], we can now establish a sufficient condition for the existence and uniqueness of an invariant probability measure for the PDMP $\{x_t\}$ based on the associated Markov chain $\{Y_n\}$. Note, however, that, unlike in Proposition 14.1.1 in [14], it cannot be claimed that the invariant measure for the Markov chain $\{Y_n\}$ is finite, since $L(Y_n, E) < 1$.

THEOREM 4.4. *Suppose that $\{Y_n\}$ is recurrent and for a petite set $C \in \mathcal{E}^+$ we have*

$$\sup_{x \in C} E_x \left[\sum_{n=1}^{\tau_C} L(Y_n, E) \right] < \infty, \tag{22}$$

where $\tau_C = \inf\{n \geq 1 : Y_n \in C\}$.

Then there exists a unique invariant probability measure for the PDMP $\{x_t\}$.

Proof. Since $\{Y_n\}$ is recurrent it admits a unique (up to constant multiples) σ-finite invariant measure π. From Proposition 10.1.2 in [14, p. 232], it follows that $\pi(C) < \infty$. Although here the function $L(., E) < 1$, the rest of the proof is the same as in Proposition 14.1.1 in [14, p. 232] and we obtain the result. □

The condition given by (22) can be replaced by the following one, which may be easier to check, and is inspired from condition $(V3)$ of Meyn and Tweedie [14, p. 337].

Condition $(\mathcal{D})$. For some set $C \in \mathcal{E}$, some constant $b < \infty$, and an extended real-valued function $V : E \to [0, \infty]$, we have

$$(\forall x \in E) \quad GV(x) - V(x) \leq -L(x, E) + bI_C(x).$$

This condition is of the same form as the drift or the Foster–Lyapunov criterion which is often used in the literature (see [13, 14] and references therein). However, we want to point out the fact that condition $(\mathcal{D})$ is weaker than conditions $(V2)$, $(V3)$ of the book by Meyn and Tweedie [14] due to the fact that $L(., E) < 1$. Therefore, direct application of their results are not straightforward. Note in particular that, unlike Theorem 11.3.4 in [14, p. 265], condition $(\mathcal{D})$ does not guarantee that $E_x[\tau_C] \leq V(x) + bI_C(x)$, since $L(Y_n, E) < 1$ (see (23) in the proof of Corollary 4.5). The next corollary gives the first way to ensure that there exists an invariant probability measure for $\{x_t\}$. It will be used in the next section to show that the pathologies found in the approach of Costa [2] and Davis (see section 34 in [4]) do not exist with our method.

COROLLARY 4.5. *Suppose that* $\{Y_n\}$ *is recurrent and that condition* $(\mathcal{D})$ *is satisfied for a function* V *bounded in a petite set* $C \in \mathcal{E}^+$. *Then there exists a unique invariant probability measure for the PDMP* $\{x_t\}$.

Proof. Applying Proposition 11.3.3 in [14, p. 264] with $Z_k = V(Y_k)$, $\varepsilon_k(x) = L(x, E)$, and $c = 1$, we obtain that

$$E_x\left[\sum_{n=1}^{\tau_C - 1} L(Y_n, E)\right] \leq \begin{cases} L(x, E) + GV(x), & x \in C, \\ V(x) \quad \text{otherwise.} \end{cases}$$

Recall that $\forall\ x \in C$, we have $GV(x) - V(x) \leq -L(x, E) + bI_C(x)$.

Therefore,

$$\begin{aligned} (\forall x \in E) \quad E_x\left[\sum_{n=1}^{\tau_C} L(Y_n, E)\right] &\leq E_x\left[\sum_{n=0}^{\tau_C - 1} L(Y_n, E)\right] + 1 \\ &\leq V(x) + 1 + bI_C(x). \end{aligned} \tag{23}$$

Then, $\sup_{x \in C} E_x[\sum_{n=1}^{\tau_C} L(Y_n, E)] < \infty$ and the result follows by using Theorem 4.4. ☐

In the case where the stochastic kernel G is weak Feller, the next result gives a sufficient condition to check if $\{x_t\}$ has an invariant measure. Before presenting the result, we need the following definition of norm-like functions (see [14, p. 214]).

DEFINITION 4.6. *A function* V *is a norm-like function if it is a positive real-valued function such that* $\lim_{n\to\infty} \inf_{x \notin K_n} V(x) = \infty$, *where* K_n *is an increasing sequence of compact sets satisfying* $\lim_{n\to\infty} \uparrow K_n = E$.

THEOREM 4.7. *Suppose that the Markov chain* $\{Y_n\}$ *is weak Feller,* $L(., E)$ *is a continuous function, and condition* $(\mathcal{D})$ *is satisfied with a compact set* C *and a positive norm-like function* V *which is finite at least at one* $x \in E$. *Then an invariant probability measure exists for the PDMP* $\{x_t\}$.

Proof. If there exists $x \in E$ such that $P_x(\tau_C < \infty) < 1$, then following the last part of the derivation of Theorem 12.3.3 in [14, p. 296] and using the fact that V is a norm-like function, there exists an invariant probability measure π for G. So, $\pi S(E) < \infty$, and using Theorem 3.5 the result follows.

Now if $P_x(\tau_C < \infty) = 1 \ \forall \ x \in E$, then using Proposition 9.1.1 in [14, p. 202], we have that

$$(\forall x \in E) \quad \sum_{n=0}^{\infty} G^n(x, C) = \infty.$$

Let us define the function $g(x) \in C_c(E)$ by

$$g(x) \doteq \frac{d(x, O_1^c)}{d(x, O_1^c) + d(x, \overline{O}_2)},$$

where O_1, O_2 are open sets with compact closure for which $C \subset O_2 \subset \overline{O}_2 \subset O_1$ and $d(.,.)$ is as defined in section 2. Then, we have

$$(\forall x \in E) \quad \sum_{n=0}^{\infty} G^n g(x) = \infty,$$

since $I_C(x) \leq g(x)$.

Therefore, applying Theorem 5.1 in [10], there exists an invariant σ-finite measure π for the stochastic kernel G defined by

$$(\forall f \in C_c(E)) \quad \int_E f(x)\pi(dx) = \underset{N}{\text{bLIM}} \frac{\sum_{n=0}^{N} \eta G^n f}{\sum_{n=0}^{N} \eta G^n g},$$

where η is a positive finite measure on $(E, \mathcal{E})$ and bLIM denotes the Banach limit [18].

Using the hypothesis, we have

$$L(x, E) + GV(x) \leq V(x) + bg(x).$$

Consequently,

$$\frac{\sum_{n=0}^{N} \eta G^n L(E)}{\sum_{n=0}^{N} \eta G^n g} \leq b + \frac{V(x)}{\sum_{n=0}^{N} \eta G^n g}. \tag{24}$$

By hypothesis, $L(., E) \in C_b(E)$, so there exists a sequence $\{f_i\}$ in $C_c(E)$ such that for all $x \in E$, $\lim_{n\to\infty} \uparrow f_i(x) = L(x, E)$. Therefore, with (24) we obtain

$$(\forall i \in \mathbb{N}) \quad \int_E f_i(y)\pi(dy) \leq b.$$

Now using the monotone convergence theorem, it follows that $\int_E L(y, E)\pi(dy) \leq b$.

So $\pi S(E) < \infty$ and with Theorem 3.5 the result follows. □

REMARK 4.8. *In the proof of Theorem* 4.7, *we need only that V is a norm-like function for the case in which $P_x(\tau_C < \infty) < 1$. Therefore, if the condition $P_x(\tau_C < \infty) = 1 \ \forall \ x \in E$ can be directly checked, then the norm-like function assumption can be removed from theorem* 4.7.

Let us introduce the following weak assumptions that will be used in Proposition 4.9 to show that the chain $\{Y_n\}$ is weak Feller.

(A1) The function $t_* : E \to (0, \infty]$ is continuous.

(A2) For any x in E, $\lambda(\Phi(y, t))I_{\{t<t_*(y)\}} \to \lambda(\Phi(x, t))I_{\{t<t_*(x)\}}$ when $y \to x$, μ_{Leb} a.s. on $(0, t_*(x))$.

(A3) For any x in E, there exists a neighborhood $\mathcal{N}(x)$ of x and a function $B_x(.) : \mathbb{R}_+ \to \overline{\mathbb{R}}_+$ such that $\forall\ y \in \mathcal{N}(x)$, $I_{\{t<t_*(y)\}}\lambda(\Phi(y,t)) \leq B_x(t)$, μ_{Leb} a.s. on $(0, t_*(x))$. If $\Lambda(x, t_*(x)) < \infty$, then $\int_0^{t_*(x)} B_x(s)ds < \infty$, otherwise $\int_0^t B_x(s)ds < \infty\ \forall\ t \in (0, t_*(x))$.

(A4) For any x in E, there exists a neighborhood $\mathcal{N}(x)$ of x and a constant $M_x > 0$ such that $\forall\ y \in \mathcal{N}(x)$, $\lambda(\Phi(y,t)) \exp\{-\Lambda(y,t)\} < M_x$.

(A5) For any open sets A in $\mathcal{E}$ and x in E,

$$Q(\Phi(y,t), A)I_{\{t<t_*(y)\}} \to Q(\Phi(x,t), A)I_{\{t<t_*(x)\}}$$

when $y \to x$, μ_{Leb} a.s. on $(0, t_*(x))$.

(A6) For any open sets A in $\mathcal{E}$ and x in E, $Q(\Phi(y, t_*(y)), A) \to Q(\Phi(x, t_*(x)), A)$, when $y \to x$.

Proposition 4.9. (i) *Suppose* (A1)–(A6)*. Then the stochastic kernel G and U are weak Feller and $L(., E) \in C_b(E)$.*

Proof. Let x and $t \in (0, t_*(x))$ be arbitrary fixed. Using assumptions (A2), (A3), and the bounded convergence theorem, we obtain that

$$\int_0^t \lambda(\Phi(y,s))I_{\{s<t_*(y)\}}ds \to \int_0^t \lambda(\Phi(x,s))I_{\{s<t_*(x)\}}ds \tag{25}$$

when $y \to x$. With (A5) it follows that for all open sets A in $\mathcal{E}$,

$$I_{\{t<t_*(y)\}}Q(\Phi(y,t), A)\lambda(\Phi(y,t)) \exp -\{t + \Lambda(y,t)\}$$

tends to

$$I_{\{t<t_*(x)\}}Q(\Phi(x,t), A)\lambda(\Phi(x,t)) \exp -\{t + \Lambda(x,t)\}$$

when $y \to x$, μ_{Leb} a.s. on $(0, t_*(x))$. Combining (A4) and the bounded convergence theorem, we have that

$$\int_0^{t_*(y)} Q(\Phi(y,t), A)\lambda(\Phi(y,t)) \exp -\{t + \Lambda(y,t)\}dt$$

tends to

$$\int_0^{t_*(x)} Q(\Phi(x,t), A)\lambda(\Phi(x,t)) \exp -\{t + \Lambda(x,t)\}dt$$

when $y \to x$.

If $\Lambda(x, t_*(x)) < \infty$, it is easy to deduce from (A3) that

$$\Lambda(y, t_*(y)) \to \Lambda(x, t_*(x))$$

when $y \to x$.

Now, if $\Lambda(x, t_*(x)) = \infty$, and $t_*(x) < \infty$ then

$$(\forall \varepsilon > 0), \quad (\exists \eta > 0) \quad \text{such that} \quad (\forall t \in [t_*(x) - \eta, t_*(x)]) \qquad \Lambda(x,t) > \frac{3\varepsilon}{2}. \tag{26}$$

Using (A1), there exists a neighborhood $\mathcal{N}_1(x)$ of x such that

$$(\forall y \in \mathcal{N}_1(x)) \qquad t_*(y) \in \left[t_*(x) - \frac{\eta}{2}, t_*(x) + \frac{\eta}{2}\right].$$

Therefore $t_*(x) - \eta < t_*(y)$.

So from (25), it follows that there exists a neighborhood $\mathcal{N}_2(x)$ of x such that

$$(\forall y \in \mathcal{N}_2(x)) \qquad |\Lambda(x, t_*(x) - \eta) - \Lambda(y, t_*(x) - \eta)| < \frac{\varepsilon}{2}. \tag{27}$$

Combining (26) and (27)

$$(\forall \varepsilon > 0), \quad (\forall y \in \mathcal{N}_1(x) \cap \mathcal{N}_2(x)), \qquad \Lambda(y, t_*(y)) > \varepsilon,$$

since $\forall\ x \in E$, $\Lambda(x, .)$ is increasing on $[0, t_*(x)]$.

The same result can be obtained for the case where $\Lambda(x, t_*(x)) = \infty$ and $t_*(x) = \infty$.

In conclusion,

$$\Lambda(y, t_*(y)) \to \Lambda(x, t_*(x))$$

when $y \to x$.

Using (A6), we obtain that for any open sets A in $\mathcal{E}$ and x in E, $K(y, A) \to K(x, A)$ when $y \to x$. Similarly, it can be shown that for any $f \in C_b(E)$, $Lf(y) \to Lf(x)$ when $y \to x$.

Consequently, it is straightforward with Proposition 6.1.1 in [14] to conclude that the stochastic kernel G is weak Feller.

Now using (12) and the result (12.7.7) in [6], it follows that for any positive function f in $C_b(E)$, Uf is a lower semicontinuous function. Since U is a stochastic kernel, Uf is continuous. Indeed, let $M_1 > 0$ be such that $f(x) < M_1$. Applying the previous result it follows that $U(M_1 - f)$ is lower semicontinuous. So Uf is upper semicontinuous and U is weak Feller. □

Therefore, the combination of Theorem 4.7 and Proposition 4.9 provides a second easy way of determining if there exists an invariant probability measure for $\{x_t\}$, as it will be shown in Example 1 of the next section.

REMARK 4.10. *An interesting property of the PDMPs is that under the weak conditions of Proposition* 4.9 *they generate weak Feller kernels G and U although the PDMPs themselves are generally not weak Feller Markov processes.*

Indeed, it was shown in [4, Example (27.5)] that the PDMP defined by $E = [0, 1[$, $\Phi(x, t) = x + t$, $\lambda(x) = 0$, and $Q(1, A) = I_A(0)$ is not a weak Feller process but it is easy to see that G and U are weak Feller kernels.

The results of this section have been developed considering the stochastic kernel G defined on $(E, \mathcal{E})$. It may be convenient in some applications to consider the extended state space $E \cup \Gamma^+$ instead of E, with the stochastic kernel G extended to include the points in Γ^+. Let us define the kernel H on $(E, \mathcal{B}(E \cup \Gamma^+))$ (corresponding to an extension of G) by $(\forall x \in E \cup \Gamma^+)$, $(\forall A \in \mathcal{B}(E \cup \Gamma^+))$:

$$H(x, A) \doteq I_E(x) G(x, A \cap E) + I_{\Gamma^+}(x) Q(x, A \cap E). \tag{28}$$

It is easy to see that H is a stochastic kernel on $(E, \mathcal{B}(E \cup \Gamma^+))$. Moreover, it has the following important properties:

(i) if π is a σ-finite invariant measure for H, then $\pi(\Gamma^+) = 0$.

(ii) a σ-finite measure is invariant for G if and only if it is invariant for H.

Therefore, all the results of the previous sections remain true if the kernel G is replaced by H.

It will be shown in the next section (see Example 1), that it may be useful to use H instead of G. Another possible illustration of the usefulness for introducing H is the following result.

COROLLARY 4.11. *Suppose* (A1)–(A6) and that $E \cup \Gamma^+$ is compact. Then there exists an invariant probability measure for the PDMP $\{x_t\}$.

Proof. As in Proposition 4.9, it can be shown that H is a weak Feller kernel. Now using the fact that $E \cup \Gamma^+$ is compact and Theorem 3.1 in [9], it follows that H has an invariant probability measure. Therefore, using the above properties of H and Theorem 3.5, we have the result. □

5. Examples. In this section we apply the results of sections 3 and 4 to three examples to emphasize the relevance of our approach. In the first one, we generalize Proposition (34.46) in [4] and Proposition 8 in [2]. The last two examples are taken from Davis [4]. They show that the equivalence between $\mathbf{P}_1$ and $\mathbf{P}_2$ with $\overline{G}$ replacing G may fail if some conditions are not satisfied. Due to its generality we are able to show that this kind of "counterexample" does not exist with our approach.

Example 1. This example is based on the capacity expansion model (see [2, section 7] and [4, Example (34.45)]. Capacity expansions are general processes of adding facilities to meet a rising demand. For a complete description of these models, the reader is referred to [5]. The demand for some utility is modeled as a random point process, i.e., it increases by one unit at random times. This demand is met by consecutive construction of expansion projects. Each project meets K_i units of demand when completed, where i corresponds the present level of excess demand. We assume that if there is an excess demand of at least p units, then the construction of a new project is started at a rate r_i per unit of time and it is completed after a lead time of $\mathcal{L}_i$ units of time. If the excess demand is less than p, then no construction takes place. New demand occurs with rate $\lambda_i(u)$ where u is the time spent by the current project. This problem can be modelled as a PDMP $\{x_t\}$ with state space

$$E \doteq \{\{p-K_p,\dots,p-1\}\times\{0\}\} \cup \bigcup_{n=p}^{\infty} \{n, [0,\mathcal{L}_n[\} , \tag{29}$$

where p and K_i are integers, $\mathcal{L}_i$ are strictly positive real numbers, and $\mathbb{N}_p$ denotes the set of integers greater than or equal to p. The local characteristics are given by

$$\lambda((i,u)) \doteq \lambda_i(u), \tag{30}$$

$$\Phi(t,(i,u)) = \begin{cases} (i,0) & \text{for } i \in \{p-K_p,\dots,p-1\}, \\ (i,u+r_i t) & \text{for } i \geq p, \end{cases} \tag{31}$$

$$Q((i,u),\{(i+1,u)\}) = 1 \quad \text{and} \quad Q((i,\mathcal{L}_i),\{(i-K_i,0)\}) = 1. \tag{32}$$

Unlike [2, 4], we allow here that the rate r_i, K_i, $\mathcal{L}_i$ can vary according to the excess demand i and that $\lambda_i(u)$ can vary according to the excess demand and to the time spent to complete the projects.

Using (30)–(32), it is easy to show that for a bounded real-valued function $W(.)$ defined on $E \cup \Gamma^+$ we have for $i \geq p$ and $u \in [0,\mathcal{L}_i]$

$$\begin{aligned} HW((i,u)) = &\int_0^{\frac{\mathcal{L}_i-u}{r_i}} \exp -\{s+\Lambda_i(u,s)\}\lambda_i(u+r_is)W((1+i,u+r_is))ds \\ &+\int_0^{\frac{\mathcal{L}_i-u}{r_i}} \exp -\{s+\Lambda_i(u,s)\}W((i,u+r_is))ds \\ &+\exp -\left\{\frac{\mathcal{L}_i-u}{r_i}+\Lambda_i\left(u,\frac{\mathcal{L}_i-u}{r_i}\right)\right\}W((i-K_i,0)), \end{aligned} \tag{33}$$

where $\Lambda_i(u,s) = \int_0^s \lambda_i(u + r_i v)dv$.

Let us introduce the following assumptions:

(H1) There exists $r > 0$ such that $\forall\ i$, $r_i \geq r$.

(H2) For $i \geq p$, $i - K_i \geq p - K_p > 0$ and $\lim_{i\to\infty} i - K_i = \infty$.

(H3) There exists an integer i_0 such that $\forall\ i \geq i_0$, $\frac{K_i}{\mathcal{L}_i} \leq \frac{K_{i+1}}{\mathcal{L}_{i+1}}$.

(H4) For $i \geq p$, $\lambda_i(u)$ is a continuous real-valued function on $[0, \mathcal{L}_i]$.

(H5) For $i \in \{p - K_p, \ldots, p-1\}$, $\lambda_i > 0$.

(H6) $\limsup_{i\to\infty} \frac{\mathcal{L}_i}{K_i r_i} \max_{u\in[0,\mathcal{L}_i]} \lambda_i(u) < 1$.

We have the following result.

Proposition 5.1. *Assume* (H1)–(H6). *Then there exists a unique invariant probability measure for the PDMP* $\{x_t\}$.

Proof. Let us introduce the real-valued function defined on $E \cup \Gamma^+$ by

$$V((i,u)) = i - \frac{K_i}{\mathcal{L}_i} u.$$

With (H2), it follows that the function V is positive norm-like function. Moreover, using (H1), (H3), and (H6), we have that there exists $\varepsilon > 0$ and $k_0 \geq \max\{p, i_0\}$ such that

$$(\forall i \geq k_0), \quad (\varepsilon + \lambda_i(u))\frac{\mathcal{L}_i}{K_i r_i} \leq 1. \tag{34}$$

Using (33) and the previous definition of $V(.)$, we obtain that

$$\begin{aligned} HV(i,u) - V(i,u) \leq & \int_0^{\frac{\mathcal{L}_i - u}{r_i}} \lambda_i(u + r_i s) \exp -\{s + \Lambda_i(u,s)\}ds \\ & -\frac{r_i K_i}{\mathcal{L}_i} \left\{ \int_0^{\frac{\mathcal{L}_i - u}{r_i}} s(1 + \lambda_i(u + r_i s)) \exp -\{s + \Lambda_i(u,s)\}ds \right. \\ & \left. + \frac{\mathcal{L}_i - u}{r_i} \exp - \left\{ \frac{\mathcal{L}_i - u}{r_i} + \Lambda_i\left(u, \frac{\mathcal{L}_i - u}{r_i}\right) \right\} \right\} \\ \leq & \int_0^{\frac{\mathcal{L}_i - u}{r_i}} \left(\lambda_i(u + r_i s) - \frac{r_i K_i}{\mathcal{L}_i} \right) \exp -\{s + \Lambda_i(u,s)\}ds. \end{aligned}$$

Using (34) and the fact that for (i,u) in $E \cup \Gamma^+$,

$$L((i,u),E) = \int_0^{\frac{\mathcal{L}_i - u}{r_i}} \exp -\{s + \Lambda_i(u,s)\}ds,$$

we obtain that there exists a constant b and a compact set

$$C \doteq \{\{p - K_p, \ldots, p-1\} \times \{0\}\} \cup \bigcup_{n=p}^{k_0} \{n, [0, \mathcal{L}_n]\}$$

such that

$$HV(i,u) - V(i,u) \leq -\varepsilon L((i,u),E)) + bI_C((i,u)).$$

It is easy to check that assumptions (A1)–(A6) are satisfied for this process. So, $L(.,E)$ is a continuous function and the stochastic kernel H is weak Feller. Applying Theorem 4.7, the result follows. □

Remark 5.2. *The previous proposition generalizes the result of Costa* [2] *and Davis* [4] *since here K_i, r_i, $\mathcal{L}_i$, and λ_i (as functions of i) may be unbounded, or $\lambda_i(u)$ may depend on the time u spent to complete the project.*

Example 2 (see [4, Example (34.28)]). This example was designed in [4] to point out the fact that the PDMP $\{x_t\}$ may have an invariant probability measure but the associated Markov chain $\{Z_1, Z_2, \ldots\}$ may not. Indeed, the approach developed by Costa [2] suffers from the fact that if μ is an invariant probability measure for $\{x_t\}$, then the associated Markov chain $\{Z_1, Z_2, \ldots\}$ will have an invariant probability measure if the following boundedness condition is satisfied: $\int_E \lambda(x)\mu(dx) < \infty$. Let us show, however, that in our case there exists a σ-finite invariant measure π for the stochastic kernel G as claimed in Theorem 3.5 such that $\pi S(E) < \infty$.

In this case $E = \mathbb{Z}$ and $\forall\ x \in E$, $\Phi(x,t) = x$, $Q(x, \{x+1\}) = Q(x, \{x-1\}) = \frac{1}{2}$ with $\lambda(x)$ satisfying the condition

$$\sum_{x=-\infty}^{\infty} \frac{1}{\lambda(x)} < \infty.$$

It was shown in [4] that $\{x_t\}$ has a unique invariant probability measure μ such that

$$(\forall x \in \mathbb{Z}) \quad \mu(\{x\}) = \frac{1}{\lambda(x)} \sum_{y=-\infty}^{\infty} \frac{1}{\lambda(y)}.$$

Now it is easy to obtain that

$$(\forall x \in \mathbb{Z}) \quad G(x, \{y\}) = \begin{cases} \frac{1}{2}\frac{\lambda(x)}{1+\lambda(x)} & \text{for } y = x+1 \text{ or } y = x-1, \\ \frac{1}{1+\lambda(x)} & \text{for } y = x, \\ 0 & \text{otherwise.} \end{cases} \tag{35}$$

It is easy to verify that $\forall\ x \in \mathbb{Z}$ the measure π defined by

$$(\forall x \in \mathbb{Z}) \quad \pi(\{x\}) = \frac{1+\lambda(x)}{\lambda(x)} \sum_{y=-\infty}^{\infty} \frac{1}{\lambda(y)}$$

is invariant for G.

Indeed,

$$\begin{aligned} \sum_{y=-\infty}^{\infty} G(y, \{x\})\pi(\{y\}) &= G(x-1, \{x\})\pi(\{x-1\}) + G(x, \{x\})\pi(\{x\}) \\ &\quad + G(x+1, \{x\})\pi(\{x+1\}) \\ &= \pi(\{x\}). \end{aligned}$$

Moreover, using the fact that $S(x, \mathbb{Z}) = \frac{1}{1+\lambda(x)}$, it is easy to prove that $\pi S(\mathbb{Z}) < \infty$. Therefore as claimed by Theorem 3.5, if there exists a solution to $\mathbf{P}_1$, then there exists one to $\mathbf{P}_2$.

For this example the fact that $\{x_t\}$ has an invariant probability measure had been established by direct calculation (see [4]). We want now to illustrate the use of the weak conditions of Theorem 4.5 for a suitable choice of function $V(.)$ and petite set C and recover this known result. Indeed, it is straightforward to prove that the Markov chain $\{Y_n\}$ associated with the kernel G is φ-irreducible for $\varphi(\{x\}) = \frac{1}{2^{|x|}}$. Then $\forall$ $x \in E$ we have $\psi(\{x\}) = \sum_{n=0}^{\infty} \left(\frac{1}{2}\right)^{n+1} \varphi G^n(\{x\}) > 0$. Therefore $\mathcal{E} = \mathcal{E}^+$.

Let us show that $\{x\}$ is a petite set for all $x \in \mathcal{E}$. Define

$$\nu(\{y\}) = \begin{cases} \frac{1}{1+\lambda(x)} & \text{for } y = x, \\ \frac{1}{2}\frac{\lambda(x)}{1+\lambda(x)} & \text{for } y = x+1 \text{ or } y = x-1, \\ 0 & \text{otherwise.} \end{cases}$$

So, we have $(\forall B \in \mathcal{E})$, $G(x,B) \geq \nu(B)$, and the claim follows.

Now let us prove that $\{Y_n\}$ is recurrent. Define the function $V_1(i)$ for $i \in \mathbb{Z}$ by

$$V_1(i) = 2\sum_{l=0}^{i}\sum_{j=l}^{\infty} \frac{1}{(j+1)^2} \quad \text{for } i \geq 0,$$

$$V_1(i) = 2\sum_{l=i}^{-1}\sum_{j=-\infty}^{l} \frac{1}{(|j|+1)^2} \quad \text{for } i \leq -1.$$

Then, for $i \geq 1$ and using (35), we have

$$\begin{aligned} GV_1(i) - V_1(i) &= \frac{\lambda(i)}{1+\lambda(i)}\left\{\frac{1}{2}V_1(i+1) + \frac{1}{2}V_1(i-1) - V_1(i)\right\} \\ &= \sum_{j=i+1}^{\infty}\frac{1}{(j+1)^2} - \sum_{j=i}^{\infty}\frac{1}{(j+1)^2} \quad = -\frac{1}{(i+1)^2}. \end{aligned}$$

Similarly, for $i \leq -2$, we obtain

$$GV_1(i) - V_1(i) = -\frac{1}{(|i|+1)^2}.$$

Therefore, the norm-like function $V_1(.)$ satisfies condition $(\mathcal{D})$ in [14, p. 190] for $C = \{-1, 0\}$. Moreover, it is clear that this function is unbounded off petite sets and that $C = \{-1, 0\}$ is a petite since it is a finite set. Consequently, using Theorem 8.4.3 in [14, p. 191], we obtain that $\{Y_n\}$ is recurrent.

In order to show that condition $(\mathcal{D})$ is satisfied for the petite set $C = \{-1, 0\}$, let us introduce the function $V_2(i)$ for $i \in \mathbb{Z}$ by

$$V_2(i) = 2\sum_{l=0}^{i}\sum_{j=l}^{\infty} \frac{1}{\lambda(j)} \quad \text{for } i \geq 0,$$

$$V_2(i) = 2\sum_{l=i}^{-1}\sum_{j=-\infty}^{l} \frac{1}{\lambda(j)} \quad \text{for } i \leq -1.$$

Using (35), we obtain

$$\begin{aligned} GV_2(i) - V_2(i) &= -\frac{1}{1+\lambda(i)} \\ &= -L(i, \mathbb{Z}) \end{aligned}$$

for $i \in \mathbb{Z} - C$.

Therefore, the function $V_2(.)$ satisfies condition $(\mathcal{D})$ for a suitable constant b. From Corollary 4.5, we conclude that there exists a unique invariant probability measure for the PDMP $\{x_t\}$.

Example 3 (see [4, Example (34.33)]). This example shows that the inverse problem as described in the previous example may happen. Indeed, if there exists an invariant probability measure (labeled π) for the stochastic kernel $\overline{G}$, then an invariant probability measure for the PDMP $\{x_t\}$ will exist if the following condition is satisfied: $\int_E \int_0^{t_*(x)} \exp\{-\Lambda(x,s)\} ds \pi(dx) < \infty$. Davis studied the following case: $E = \mathbb{N}$, $\Phi(x,t) = x$, $Q(x, \{x+1\}) = p$, $Q(x, \{x-1\}) = q$, $Q(0, \{1\}) = p$, $Q(0, \{0\}) = q$ with $q = 1 - p$, $p < \frac{1}{2}$. $\lambda(x)$ is bounded. He has shown that there exists an invariant probability measure for $\{x_t\}$ if and only if

$$\sum_{y=0}^{\infty} \frac{1}{\lambda(y)} \left(\frac{p}{q}\right)^y < \infty. \tag{36}$$

Therefore, for the choice of $\lambda(x) = \left(\frac{p}{q}\right)^x$, $\{x_t\}$ has no invariant probability measure although the birth and death process generated by $\overline{G}$ has one. However, we show that there exists an invariant probability measure for the stochastic kernel G if and only if there exists one for $\{x_t\}$, according to the fact that $\lambda(.)$ is bounded and Remark 3.8. By direct calculations, it is easy to show that $(\forall x \in \mathbb{N})$, $G(x, \{y\}) = 0$ if $y \notin \{x-1, x, x+1\}$, and for $x \geq 1$, $G(x, \{x\}) = \frac{1}{1+\lambda(x)}$, $G(x, \{x+1\}) = \frac{p\lambda(x)}{1+\lambda(x)}$, $G(x, \{x-1\}) = \frac{q\lambda(x)}{1+\lambda(x)}$, and $G(0, \{0\}) = \frac{1+q\lambda(0)}{1+\lambda(0)}$, $G(0, \{1\}) = \frac{p\lambda(0)}{1+\lambda(0)}$.

If π is an invariant measure for $\{x_t\}$, it must satisfy the following equations: $(\forall x \geq 1)$,

$$\pi(\{x\}) = G(x-1, \{x\})\pi(\{x-1\}) + G(x, \{x\})\pi(\{x\}) + G(x+1, \{x\})\pi(\{x+1\})$$

and

$$\pi(\{0\}) = G(0, \{0\})\pi(\{0\}) + G(1, \{0\})\pi(\{1\}).$$

Therefore,

$$(\forall x \geq 1), \quad pc(x-1) + qc(x+1) - c(x) = 0$$

and

$$-pc(0) + qc(1) = 0$$

with $c(x) \doteq \frac{\lambda(x)}{1+\lambda(x)}\pi(\{x\})$. The unique positive solution of the previous equations is

$$(\forall x \in \mathbb{N}), \quad c(x) = c(0)\left(\frac{p}{q}\right)^x.$$

So, there exists an invariant probability measure for the stochastic kernel G if and only if

$$\sum_{y=0}^{\infty} \pi(\{y\}) < \infty,$$

that is, if and only if

$$\sum_{y=0}^{\infty} \frac{1}{\lambda(y)} \left(\frac{p}{q}\right)^{y} < \infty,$$

which is the same necessary and sufficient condition for the PDMP (see (36)) in agreement with Theorem 3.5.

6. Conclusion. In this paper, we have shown that the existence of an invariant probability measure for a general PDMP is equivalent to the existence of a σ-finite invariant measure for the stochastic kernel G satisfying a boundedness condition or equivalently a Radon–Nikodým derivative. Here we generalize existing results of the literature [2, 4] since we do not require any additional assumptions to establish this equivalence. Moreover, we give sufficient conditions to ensure the existence of such a σ-finite measure satisfying the boundedness condition. They are based mainly on a modified Foster–Lyapunov criterion. To emphasize the relevance of our results, we studied three examples and in particular, we are able to generalize the results obtained by Costa and Davis on the capacity expansion model.

A BACKSTEPPING CONTROLLER FOR A NONLINEAR PARTIAL DIFFERENTIAL EQUATION MODEL OF COMPRESSION SYSTEM INSTABILITIES*

ANDRZEJ BANASZUK†, HÖSKULDUR ARI HAUKSSON‡, AND IGOR MEZIĆ§

Abstract. We prove the existence and uniqueness of solutions in Sobolev spaces for the Moore–Greitzer nonlinear partial differential equation (PDE) model for compression system instabilities with mild conditions on the shape of the compressor characteristic and on the throttle control. To achieve this, the model is reformulated as an evolution equation on a Banach space. Using this new representation, we design a backstepping control of the model. Global stabilization of any axisymmetric equilibrium to the right of the peak of the compressor characteristic is achieved. We also prove that the dynamics can be restricted to the small neighborhood of the point on the left of the peak of the compressor characteristic. Thus, it is possible to restrict the magnitude of stall to arbitrary small values. In addition, finite-dimensional Galerkin projections of the partial differential equation model are studied. It is shown that truncated control laws stabilize truncated models. Numerical simulations of the model with and without control are presented.

Key words. control of partial differential equations, backstepping control of nonlinear differential equations, control of stall and surge in aeroengines, existence and uniqueness of solutions of partial differential equations

1. Introduction.

Surge and stall instabilities that occur in compression systems of jet engines are the topic of much research effort these days for two reasons: efficiency and safety. In particular, jet engines are currently forced to operate in nonoptimal conditions (relatively large mass flow) in order to stay clear of the aforementioned instabilities. Surge is an oscillatory instability of the mean mass flow: upon the onset of surge the air in the compression system of a jet engine starts oscillating back and forth, thus severely impairing its performance. Stall is characterized by the appearance of the so-called *stall cells*—regions of decreased pressure rise and reversed mass flow—at isolated locations around the rim of the compressor. A simplified model of these instabilities has been proposed by Moore and Greitzer [15], and it is this model (sometimes called the *full Moore–Greitzer model*) that is the topic of the present paper. The model consists of a linear PDE governing the behavior of disturbances in the inlet region of the compression system, with nonlocal and nonlinear boundary conditions which describe the coupling of disturbances with the mean flow behavior. Since such a system is hard to analyze, most of the research has been directed toward establishing properties of low-order Galerkin truncations (see [15], [11]). The simplest

approximate model used for bifurcation analysis (see [12]) and control (see [3], [6], [8], [9], [10], [16], [1]) called MG3 used only the first Fourier mode of the nonaxisymmetric flow disturbance (stall variable).

The Moore–Greitzer model deals with a simple compression system in which the air enters the compressor (with one or more rotor/stator stages), goes to a plenum, and exits through a throttle. Stationary operating points for the compressor correspond to a constant pressure rise across the compressor and a constant, circumferentially uniform mass flow through the compressor. The pressure rise versus mass flow curve representing the stationary operating points is called the compressor characteristic. For a given throttle opening the mass flow through the throttle is determined by the pressure drop across the throttle. The corresponding static relationship can be represented by the curve called the throttle characteristic. In a stationary condition the pressure rise across the compressor is balanced by the pressure drop across the throttle and the mass flow through the compressor and through the throttle are equal. Therefore, the intersection of the compressor characteristic and the throttle characteristic determines the operating point of the compressor. The operating point can be changed by adjusting the throttle opening.

The dynamic model for compression systems derived by Moore and Greitzer [15] describes the evolution of the mass flow and the pressure in plenum in a nonstationary condition. When the pressure rise across the compressor is not balanced by the pressure drop across the throttle, the resulting pressure difference is proportional to the rate of change of mass flow (i.e., mass acceleration). Similarly, if the mass flow through the compressor is not balanced by the mass flow through the throttle, the resulting difference is proportional to the rate of pressure rise in the plenum.

In terms of the dynamic model of a compression system, the stationary operating points are represented by the axisymmetric equilibria, surge corresponds to a limit cycle involving pressure rise and mass flow, while rotating stall is represented by a travelling wave of nonaxisymmetric mass flow around the compressor annulus with a constant low value of pressure rise.

From the point of view of efficiency, the desired operating points for the compressor should have high value of pressure rise and low mass flow that is uniform around the compressor annulus. However, the analysis of the dynamic model shows that the corresponding equilibria of the dynamic model have small domains of attraction that are shrinking as the pressure rise increases. A small disturbance is likely to force a transition of the compression system state to either rotating stall or surge.

In the present paper we study *stabilization* of a given axisymmetric equilibrium using the throttle opening as a control variable. The throttle opening is considered to be some function of the state of the system chosen so that the corresponding new dynamic model has a unique globally stable equilibrium at the prescribed location. While bounded disturbances would force the state of the system to evolve in some neighborhood of the desired equilibrium, after they disappear, the state would eventually return to an arbitrary small neighborhood of the equilibrium. Physically, the control would be implemented by varying the throttle opening in the way that prevents transition into rotating stall or surge.

After some manipulation, the dynamic model of compression system will be represented as an evolution equation in a Banach space. Stabilization of the desired equilibrium will be achieved by constructing a Lyapunov function for this equilibrium. A special pure feedback structure of the evolution equation will allow us to use *backstepping* for construction of a Lyapunov function. This technique has been introduced in [7] and applied to many systems described by nonlinear ordinary differential equations (ODEs) with pure feedback structure, including a reduced-order model of compressor dynamics, MG3, in [8] and [1].

Experimental observations of the nonaxisymmetric flow disturbance (stall) behavior indicate that its shape is often far from sinusoidal [2]. Our investigations of the full Moore–Greitzer model show that the resulting nonlinear behavior of the compressor is well represented by the model [14]. It is then natural to ask what can be said about the control of stall and surge using the PDE model. In this paper we show that a global stabilization of the full Moore–Greitzer model is possible. We present a conceptually simple but not necessarily optimal way of constructing a globally stabilizing controller using backstepping control design [7]. To our knowledge, the present paper presents the first successful attempt to globally stabilize a nonlinear PDE using backstepping. We concentrate on a specific model here, but the methods that we develop can be used more broadly. A variety of evolution equation problems with a pure feedback structure can be treated in a way similar to that presented here. The backstepping method presents a powerful tool even in the context of PDEs.

The paper is organized as follows. In section 2 we introduce some notation and represent the full Moore–Greitzer model as an evolution equation in a Banach space, using an operator that is an infinite-dimensional version of that studied by Mansoux, Gyrling, Statiawan, and Paduaro in [11]. In section 3 we prove global existence and uniqueness of solutions of this evolution equation by a simple application of the contraction mapping principle. We present some a priori estimates which, together with the existence of a unique local solution, guarantee the existence of a unique global solution. In section 4 we design a backstepping controller for the full Moore–Greitzer model. We show that the peak and any axisymmetric equilibrium to the right of the peak can be globally asymptotically stabilized.

In the case when the set-point parameter in the controller is such that there is no stable axisymmetric equilibrium we can still guarantee that the dynamics of the closed-loop system are confined to a ball, whose radius can be made arbitrarily small by choosing sufficiently high gains in the controller.

In section 5 we prove that the truncated feedback controller globally stabilizes the system of $2n+2$ ODEs consisting of the Galerkin projection of the PDE describing the stall dynamics onto its first n-modes and the two ODEs describing the surge dynamics. The results are valid for a general compressor characteristic.

2. Preliminaries.

2.1. The Moore–Greitzer model. The full Moore–Greitzer model is described by the following equations (cf. [15])

$$l_c \frac{d\Phi}{d\xi} = -\Psi(\xi) + \frac{1}{2\pi}\int_0^{2\pi} \Psi_c(\Phi + \phi'_\eta|_{\eta=0})d\theta, \tag{1}$$

$$l_c \frac{d\Psi}{d\xi} = \frac{1}{4B^2}(\Phi(\xi) - K_T(\Psi, u)), \tag{2}$$

where ϕ' solves Laplace's equation

$$\phi'_{\eta\eta} + \phi'_{\theta\theta} = 0 \tag{3}$$

for $(\eta, \theta) \in [0, 2\pi] \times (-\infty, 0)$. The boundary conditions are periodic in θ,

$$\frac{\partial}{\partial\xi}(m\phi' + \frac{1}{a}\phi'_\eta) - \left(\Psi_c(\Phi + \phi'_\eta) - \frac{1}{2\pi}\int_0^{2\pi} \Psi_c(\Phi + \phi'_\eta)d\theta - \frac{1}{2a}\phi'_{\theta\eta}\right) = 0 \tag{4}$$

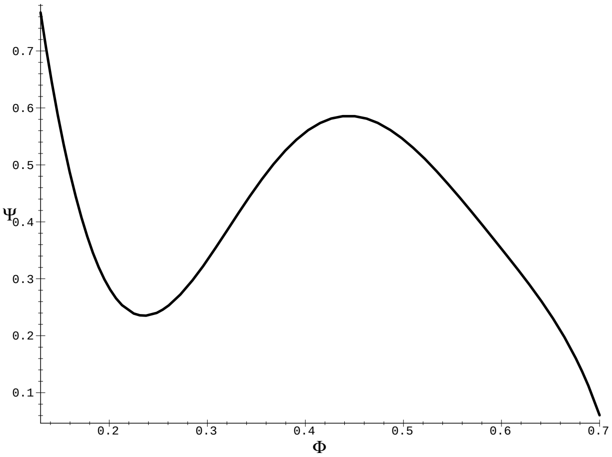

FIG. 1. C_3' *compressor characteristic.*

at $\eta = 0$. At $\eta = -\infty$ we have

$$\phi' = 0. \tag{5}$$

(Note that we try to keep our notation consistent with that of the original paper by Moore and Greitzer [15]. In particular, following [15] we use ξ to denote a nondimensional time variable and η to denote a nondimensional axial distance variable.) The state variables of this model are Φ, the nondimensionalized annulus averaged mass flow coefficient through the compressor; Ψ, the nondimensionalized annulus averaged pressure rise coefficient across the compressor; and ϕ', the disturbance velocity potential. (Note that the prime symbol in ϕ' *does not* refer to differentiation.) The function $\Psi_c(\phi)$ is called the compressor characteristic and is found empirically. It gives the local pressure rise when the local mass flow is ϕ. For most compressors it has an S shape as seen in Figure 1. The parameters a, m, l_c, and B are determined by the geometry of the compressor and the throttle parameter $K_T(\Psi, u)$ is the fraction of the throttle opening. Since the throttle parameter can be varied, it will be used as the control. We assume that we can modify $K_T(\Psi, u)$ at will by a choice of the control function u.

We assume that the compressor characteristic $\Psi_c(\Phi)$ is a general S-shaped curve. In particular, we assume that the following characteristics hold.

1. The characteristic $\Psi_c(\Phi)$ is twice continuously differentiable.

2. The characteristic has one peak (Φ_0, Ψ_0) and, to the left of the peak, one well. The characteristic is strictly decreasing to the right of the peak and to the left of the well; it is strictly increasing between the well and the peak.

3. The characteristic has exactly one inflection point $(\Phi_{infl}, \Psi_{infl})$ between the well and the peak. One has $\Psi_c''(\Phi) < 0$ for $\Phi > \Phi_{infl}$, and $\Psi_c''(\Phi)$ is bounded away from zero on any interval $[\Gamma, +\infty)$ for $\Gamma > \Phi_{infl}$.

Figure 1 shows a typical compressor characteristic $\Psi_c(\phi)$.

Let us give here a physical interpretation for the shape of the compressor characteristic. The desired possible stationary operating points of the compressor lie on the decreasing part of the characteristic to the right of the peak. The lower the value of the axial component of the mass flow entering compressor, the more flow turning is achieved by the blades. Consequently, more work is done on the air by the compressor blades and the pressure rise is higher. However, there is a limit to the value of pressure rise that can be achieved. When the axial component of the incoming air velocity is small relative to the rotor velocity, so that the air is approaching the blade at a high angle of attack, the flow separates on the suction side of a compressor blade; i.e., the blade *stalls*. When a blade stalls, the pressure rise at that blade drops significantly. The pressure rise of a stalled blade is represented by the part of the characteristic between the well and the peak. The peak represents the *stall inception point*: the maximum pressure rise is obtained by a blade that is just about to stall. When the flow is reversed, the air at the suction side of the blade is attached again and the pressure starts to rise. This is represented by the part of the characteristic to the left of the well, called the back-flow part of the characteristic.

The physical mechanism for rotating stall and surge inception can now be explained. When a blade stalls, the pressure in the plenum is usually greater than the local pressure rise produced by the compressor, so that the incoming air at the stalled blade faces a negative pressure gradient and hence has a negative acceleration. The mass flow at the stalled blade passage is locally reduced. There are several possible scenarios of how the situation will evolve. The extreme ones are a transition to a surge or rotating stall condition.

In surge the pressure in the plenum does not drop fast enough, and all the blades stall at the same time. The flow eventually reverses, as the only mechanism to balance the high pressure in the plenum at the stalled blades is for the mass flow to reach the back-flow part of the characteristic. This transition from the neighborhood of the stall inception point to the back-flow characteristic is very fast. The pressure in the plenum is now dropping, as the air escapes from the plenum both through the throttle and through the compressor. The pressure in the plenum eventually drops below the value of the pressure rise on the back-flow part of the characteristic and the pressure gradient becomes positive. The air accelerates slowly until zero mass flow is reached. The plenum pressure is now below the well value. The compressor starts to deliver more pressure rise while the pressure in plenum is about the well level, so the mass flow accelerates fast. Past the value corresponding to the peak the flow at the blades becomes attached. When the flow through compressor becomes bigger than the flow through the throttle, the pressure starts to rise and becomes bigger than the one produced by the compressor. The flow starts to decrease. When the flow reaches the value corresponding to the peak, pressure in the plenum is about the peak value, which is the condition of a stall inception. One full surge cycle is now completed and the next one is about to start.

When rotating stall occurs, one or several blades stall. Locally, the flow is redirected to the neighboring unstalled blades. On one side of the region of stalled blades, the angle of attack of the air flow will increase, causing more blades to stall. On the other side the angle of attack will decrease, making the blades on that side less susceptible to stalling. The air is coming to the blades in the direction of spinning rotor at high angle of attack. These blades are likely to stall. At the same time the blades neighboring the stalled ones in the direction opposite to the spinning rotor accept air at the lower angle of attack than the stalled ones so they are not likely to stall. More air coming through these blades may lower the angle of attack on the first stalled blade, which will result in more local pressure rise. If the pressure in plenum drops fast enough, the pressure gradient on some of the stalled blades will become positive and these blades will unstall. A stable rotating stall condition may develop when some of the blades operate in a stalled condition and the rest are not stalled. The cells of stalled air travel around the compressor so that each blade periodically becomes stalled and unstalled. Note that in a rotating stall condition the average pressure rise delivered by the compressor is low, as the stalled blades barely do any work on the air. Note also that in a stable rotating stall condition the air mass flow in the stalled blade passages is reversed, as the stalled blades cannot deliver enough pressure rise to balance the pressure in the plenum.

At this point the physical mechanism for the stabilization of the operating point close to the peak of the characteristic by varying the throttle opening can be explained. In both stall and surge inception the mechanism of instability is the same: a stalled blade cannot deliver enough pressure rise to balance the high pressure in the plenum and the resulting negative pressure gradient decelerates and eventually reverses the flow at some (stall) or all (surge) blade passages. The control action basically amounts to opening the throttle fast enough so that the pressure in the plenum drops faster than the pressure at a stalled blade. This produces the positive pressure gradient that accelerates the flow to the desired value. After this value is reached, the throttle is closed again.

2.2. Some function spaces. Let $\mathcal{L}^2$ be the space of square integrable functions on the circle $[0, 2\pi]$ and denote the norm by $\|\cdot\|_{\mathcal{L}^2}$. Let L^2, L^∞, and H^k, for $k = 1, 2, \dots$, denote the subspaces of $\mathcal{L}^2$ with zero average and norms $\|\cdot\|_{L^2}$, $\|\cdot\|_{L^\infty}$, $\|\cdot\|_{H^k}$. These norms are given by

$$\begin{aligned}
\|g\|_{L^2} &:= (\textstyle\int_0^{2\pi} g^2 d\theta)^{\frac{1}{2}} = (\pi \sum_{p=1}^{\infty} A_p(\xi)^2)^{\frac{1}{2}},\\
\|g\|_{H^k} &:= (\textstyle\int_0^{2\pi} (\frac{\partial^k g}{\partial \theta^k})^2 d\theta)^{\frac{1}{2}} = (\pi \sum_{p=1}^{\infty} (p^k A_p(\xi))^2)^{\frac{1}{2}},\\
\|g\|_{L^\infty} &:= \operatorname{esssup}_{\theta\in[0,2\pi]} g.
\end{aligned}$$

Here, the A_p's represent the magnitudes of the complex Fourier coefficients of g,

$$g = \sum_{p=1}^{\infty} A_p(\xi) \sin(p\theta + r_p(\xi)).$$

We denote by $\langle \cdot, \cdot \rangle$ the inner product of L^2:

$$\langle g_1, g_2 \rangle = \int_0^{2\pi} g_1 g_2 d\theta = \pi \sum_{p=1}^{\infty} A_p B_p.$$

Here, the A_p's and the B_p's represent the Fourier coefficients of the functions g_1 and g_2, respectively.

Let C^0 denote the space of continuous functions on the circle $[0, 2\pi]$ with zero average, with the norm

$$\|g\|_{C^0} := \max_{\theta\in[0,2\pi]} g.$$

Note that for $g \in C^0$ one has $\|g\|_{C^0} = \|g\|_{L^\infty}$. Thus, to avoid using too many symbols we will use $\|g\|_{L^\infty}$ to denote the norm of C^0 functions.

For future reference, we collect here some inequalities in the following lemma.

LEMMA 2.1. *One has* $H^1 \hookrightarrow C^0 \hookrightarrow L^\infty \hookrightarrow L^2$ *and*

$$\begin{aligned} \|g\|_{L^2} &\leq \sqrt{2\pi}\|g\|_{L^\infty}, \\ \|g\|_{L^\infty} &\leq \tfrac{\sqrt{\pi}}{\sqrt{6}}\|g\|_{H^1}, \\ \|g\|_{L^2} &\leq \|g\|_{H^1}. \end{aligned}$$

Proof. We first prove the inequalities. The first inequality is clear. The second one follows from $\|g\|_{L^\infty} \leq \sum_{p=1}^\infty |A_p(\xi)| \leq (\sum_{p=1}^\infty (\frac{1}{p^2}))^{\frac{1}{2}} (\sum_{p=1}^\infty (pA_p(\xi))^2)^{\frac{1}{2}} = \frac{\sqrt{\pi}}{\sqrt{6}}\|g\|_{H^1}$. The third one is the Poincaré inequality. $H^1 \hookrightarrow C^0$ is the Sobolev embedding of H^1 into C^0 in spatial dimension one. The other embeddings follow from the inequalities. □

Assume for now that ϕ' can be represented as

$$\phi' = \sum_{p=1}^\infty \mathrm{e}^{p\eta}\alpha_p(\xi)\sin(p\theta + r_p(\xi)), \tag{6}$$

where α_p and r_p are real functions.

Let $g := \phi'_\eta|_{\eta=0}$; then

$$g = \sum_{p=1}^\infty p\alpha_p(\xi)\sin(p\theta + r_p(\xi)) =: \sum_{p=1}^\infty A_p(\xi)\sin(p\theta + r_p(\xi)).$$

Equation (4) can therefore be written as

$$\frac{\partial}{\partial\xi}Kg = a\left(\Psi_c(\Phi + g) - \frac{1}{2\pi}\int_0^{2\pi} \Psi_c(\Phi + g)d\theta - \frac{1}{2}\frac{\partial g}{\partial\theta}\right), \tag{7}$$

where the operator K is defined as follows:

$$K\sum_{p=1}^\infty \alpha_p(\xi)\sin(p\theta + r_p(\xi)) = \sum_{p=1}^\infty \left(1 + \frac{am}{p}\right)\alpha_p(\xi)\sin(p\theta + r_p(\xi)). \tag{8}$$

The operator K is an infinite-dimensional analogue of the operator introduced in [11] for a study of finite-dimensional truncations of the full Moore–Greitzer model.

Remark 2.1. Suppose that we can show that the system (1), (2), and (7) has a unique solution such that $g \in H^1$. Then from the Fourier series representation of g we can calculate the corresponding potential ϕ'. Since $g \in H^1$, it follows that on the cylinder $[0, 2\pi] \times (-\infty, 0)$ the potential ϕ' is in the Sobolev space $H^2([0, 2\pi] \times (-\infty, 0))$. In particular, the partial derivatives $\phi'_{\eta\eta}$ and $\phi'_{\theta\theta}$ are in $L^2([0, 2\pi] \times (-\infty, 0))$. Note also that from (6) it follows that ϕ' satisfies the Laplace equation (3) and the boundary conditions (4) and (5). The existence of solutions of the full Moore–Greitzer model follows. The uniqueness follows from the uniqueness of g. It therefore suffices to prove the existence and uniqueness of solutions for the system (1), (2), and (7) to obtain the existence and uniqueness of solutions of the full Moore–Greitzer model.

The variable g represents the nonaxisymmetric mass flow disturbance, i.e., the stall. We shall refer to g as the *stall variable.*

PROPOSITION 2.1. *Let* $Z = L^2$ *or* H^k*, for* $k = 1, 2, \ldots$. $K : Z \mapsto Z$ *is a bounded, self-adjoint, positive definite operator with a bounded inverse. One has* $\|K\|_Z = 1{+}am$*, and* $\|K^{-1}\|_Z = 1$*. Moreover,* K*,* $\frac{\partial}{\partial\xi}$*, and* $\frac{\partial}{\partial\theta}$ *commute.*

Proof. We have $\|Kg\|_Z \leq (1 + \frac{am}{1})\|g\|_Z$ so K is bounded with $\|K\|_Z = 1 + am$. Similarly, K^{-1} is bounded with $\|K^{-1}\|_Z = 1$. Furthermore, $\langle g, Kg\rangle \geq \|g\|_Z$, so K is positive definite and bounded away from zero. It is easy to see that K is self-adjoint.

On their domains the operators $\frac{\partial}{\partial \xi}$, $\frac{\partial}{\partial \theta}$, and K all commute. This is clear by letting them operate termwise on the Fourier series. □

For future reference, we note that the inverse of K is

$$K^{-1}\left(\sum_{p=1}^{\infty} A_p(\xi)\sin(p\theta + r_p(\xi))\right) := \sum_{p=1}^{\infty}\left(\frac{p}{p+am}\right)A_p(\xi)(\sin(p\theta + r_p(\xi))).$$

Using K we can define weighted L^2 and H^k norms as follows:

$$\begin{aligned} \|g\|_{L^2_K} &:= \sqrt{\langle g, Kg\rangle}, \\ \|g\|_{H^k_K} &:= \sqrt{\langle \tfrac{\partial^k g}{\partial \theta^k}, K\tfrac{\partial^k g}{\partial \theta^k}\rangle}. \end{aligned}$$

Note that L^2 and H^k norms are equivalent with their weighted counterparts. In fact, one has Lemma 2.2.

LEMMA 2.2. *We have that*

$$\|g\|_{L^2} \leq \|g\|_{L^2_K} \leq \sqrt{1+am}\|g\|_{L^2},$$

$$\|g\|_{H^k} \leq \|g\|_{H^k_K} \leq \sqrt{1+am}\|g\|_{H^k}.$$

We define

$$\overline{\Psi_c} := \frac{1}{2\pi}\int_0^{2\pi} \Psi_c(\Phi + g(\xi,\theta))d\theta.$$

Then we can rewrite the model (4), (1), and (2) as

$$\frac{\partial}{\partial \xi}g(\xi,\theta) = K^{-1}\left(a(\Psi_c(\Phi(\xi) + g(\xi,\theta)) - \overline{\Psi_c}) - \frac{1}{2}\frac{\partial g(\xi,\theta)}{\partial \theta}\right), \tag{9}$$

$$\frac{d\Phi}{d\xi} = \frac{1}{l_c}(\overline{\Psi_c} - \Psi(\xi)), \tag{10}$$

$$\frac{d\Psi}{d\xi} = \frac{1}{4l_cB^2}(\Phi(\xi) - K_T(\Psi, u)). \tag{11}$$

We will frequently use a formula for a difference of values of a C^1 function at two points.

LEMMA 2.3. *Let f be a C^1 function. Then*

$$f(x+\Delta x) - f(x) = \left(\int_0^1 f'(x + s\Delta x)ds\right)\Delta x.$$

3. Existence and uniqueness of solutions.

3.1. Moore–Greitzer model as an evolution equation on a Banach space. To prove the existence and uniqueness of solutions of the full Moore–Greitzer model we represent the model as an evolution equation of the form

$$\frac{dx}{d\xi} = Ax + f(x), \tag{12}$$

where x belongs to a Banach space X, A is an unbounded operator in X, and f is a nonlinear operator.

Let X be a Banach space. We define the following two spaces:

$$C(0,T;X) := \{x(\cdot) : [0,T] \to X \text{ is strongly continuous in } \|\cdot\|_X \text{ norm}\},$$

$$C^1(0,T;X) := \{x(\cdot) : [0,T] \to X \text{ is continuously differentiable in } \|\cdot\|_X \text{ norm}\}$$

with corresponding norms

$$\|x\|_{C(0,T;X)} = \sup_{\xi\in[0,T]} \|x(\xi)\|_X,$$

$$\|x\|_{C^1(0,T;X)} = \sup_{\xi\in[0,T]} \|x(\xi)\|_X + \sup_{\xi\in[0,T]} \|\frac{d}{d\xi}x(\xi)\|_X.$$

We are going to use the following corollary from Kato's theorem [4], [5].

Theorem 3.1. *Let X be a Banach space, and let A be a generator of a strongly continuous semigroup on X. Let Y be the domain of A. Suppose that $f(\cdot)$ satisfies the conditions*

$$\|f(x)\|_Y \le C_{bdd}(\|x\|_Y) \tag{13}$$

and

$$\|f(x_1) - f(x_2)\|_X \le C_{Lip}(\|x_1\|_X, \|x_2\|_X, \|Ax_1\|_X, \|Ax_2\|_X)\|x_1 - x_2\|_X, \tag{14}$$

where functions C_{bdd} and C_{Lip} are bounded on bounded sets. Then for all $x_0 \in Y$ there exists a unique local strong solution of

$$\frac{dx}{d\xi} = Ax + f(x) \tag{15}$$

such that

$$x \in C(0,\delta;Y) \cap C^1(0,\delta;X), \quad x(0) = x_0 \tag{16}$$

for some $\delta > 0$.

Proof. See Theorem 10 of [4]. □

Define, for $k = 0, 1, \ldots$, the spaces

$$X^k := H_K^k \times \mathbf{R}^2$$

(with $H_K^0 := L_K^2$). The norms on X^k are defined by

$$\|(g, \Phi, \Psi)\|_{X^k}^2 = \|g\|_{H_K^k}^2 + |\Phi|^2 + |\Psi|^2.$$

In this paper we will apply Theorem 3.1 with $X = X^{k-1}$ and $Y = X^k$.

3.2. Local existence and uniqueness. With suitable conditions on the compressor characteristic, Ψ_c, the local existence of X^k solutions becomes rather elementary. In an attempt to appeal to a larger audience, here we will present a detailed proof of the local existence and uniqueness of X^1 solutions. We then state a theorem which gives local existence and uniqueness in X^k and outline the proof.

We are going to apply Theorem 3.1 with

$$X = X^0 = L^2_K \times \mathbf{R}^2, \quad Y = X^1 = H^1_K \times \mathbf{R}^2,$$

with the norms

$$\|(g, \Phi, \Psi)\|^2_{X^1} = \|g\|^2_{H^1_K} + |\Phi|^2 + |\Psi|^2,$$

$$\|(g, \Phi, \Psi)\|^2_{X^0} = \|g\|^2_{L^2_K} + |\Phi|^2 + |\Psi|^2.$$

These spaces are both Hilbert spaces, X^1 is continuously embedded in X^0, and X^1 is dense in X^0. We now define the operator $A : X^1 \to X^0$ as follows:

$$A(g, \Phi, \Psi) := \left(-\frac{1}{2} K^{-1} \frac{\partial g}{\partial \theta}, 0, 0 \right). \tag{17}$$

This operator is closed and, as we will show, it is an infinitesimal generator of a strongly continuous unitary semigroup on X^0. We define

$$f(g, \Phi, \Psi) := (aK^{-1}(\Psi_c(\Phi + g) - \bar{\Psi_c}), \frac{1}{l_c}(\bar{\Psi_c} - \Psi), \frac{1}{4 l_c B^2}(\Phi - K_T(\Psi, u)). \tag{18}$$

Remark 3.1. Using a square throttle characteristic and constant throttle control u (cf. [15]) will cause K_T not to be Lipschitz on the hyperplane defined by $\Psi = 0$. However, if we use a feedback control of the form $u = u(g, \Phi, \Psi)$, $K_T(\Psi, u)$ (and hence also $f(g, \Phi, \Psi)$) becomes a function of all the state variables. We assume that the feedback was chosen such that $K_T(\Psi, u)$ is Lipschitz on bounded subsets of $\mathbf{R}$.

Having defined the function spaces, the operator A, and the nonlinear operator f, we can prove the local existence and uniqueness of solutions of the full Moore–Greitzer model. For this, we will show in the following two lemmas that A given by (17) and $f(g, \Phi, \Psi)$ given by (18) satisfy the conditions of Theorem 3.1.

LEMMA 3.1. *The operator A given by* (17) *is a generator of a strongly continuous unitary semigroup on X^0.*

Proof. Using the fact that K is self-adjoint and integration by parts one can prove that $A^* = -A$; i.e., A is a skew-adjoint operator. Thus, A generates a strongly continuous unitary semigroup on X^0 (cf. Theorem 8 of [4]). □

LEMMA 3.2. *Suppose that $\Psi_c \in C^1(\mathbf{R})$. We also assume that $K_T(\Psi, u)$ is bounded from X^1 to $\mathbf{R}$ and X^0-Lipschitz on X^1-bounded sets, i.e., for all $x_i = (g_i, \Phi_i, \Psi_i) \in X^1$, $i = 1, 2$, $K_T(\Psi, u)$ satisfies*

$$|K_T(\Psi_1, u(x_1)) - K_T(\Psi_2, u(x_2))| \leq C_K \|x_1 - x_2\|_{X^0},$$

where C_K is a function of X^1 norms of x_i, $i = 1, 2$, which is bounded on bounded sets in X^1. Then the function $f(g, \Phi, \Psi)$ given by (18) *satisfies conditions* (13) *and* (14) *of Theorem* 3.1.

Proof. Let $\mathcal{M}$ be a bounded subset of X^1 and let $(g, \Phi, \Psi) \in \mathcal{M}$ be arbitrary. Then, because of embedding $H^1 \hookrightarrow C^0$, for every θ, $\Phi + g(\theta)$ belongs to a bounded interval $I_{\mathcal{M}} \subset \mathbf{R}$. (Note that $I_{\mathcal{M}}$ depends only on $\mathcal{M}$.) Thus, $|\Psi_c'(\Phi+g)| \leq \sup_{\phi\in I_{\mathcal{M}}} |\Psi_c'(\phi)|$. Therefore,

$$\begin{aligned}\|aK^{-1}(\Psi_c(\Phi+g)-\bar{\Psi}_c)\|^2_{H^1_K} &\leq a^2\|K^{-1}\| \left\| \frac{\partial}{\partial\theta}\Psi_c(\Phi+g)\right\|^2_{L^2} \\ &\leq a^2\|K^{-1}\| \sup_{\phi\in I_{\mathcal{M}}} |\Psi_c'(\phi)|^2 \|g\|^2_{H^1} \\ &\leq a^2 \sup_{\phi\in I_{\mathcal{M}}} |\Psi_c'(\phi)|^2\|g\|^2_{H^1_K}. \end{aligned} \tag{19}$$

We also have

$$|\bar{\Psi}_c| = \left|\int_0^{2\pi} \Psi_c(\Phi+g)d\theta\right| \leq \sup_{\phi\in I_{\mathcal{M}}} \Psi_c(\phi). \tag{20}$$

Using (19) and (20), we easily show that $f(g,\Phi,\Psi)$ satisfies (13).

To show that $f(g,\Phi,\Psi)$ satisfies (14), let $x_1 = (g_1,\Phi_1,\Psi_1) \in \mathcal{M}$ and $x_2 = (g_2,\Phi_2,\Psi_2) \in \mathcal{M}$ be arbitrary. To simplify notation, let us denote $F_i := \Psi_c(\Phi_i + g_i)$ for $i = 1, 2$. Recall that $\overline{F_i}$ denotes the average value of F_i. We have

$$\begin{aligned}&\|f(x_1)-f(x_2)\|^2_{X^0} \\ &= a^2\langle K^{-1}((F_1-F_2)-\overline{(F_1-F_2)}),(F_1-F_2)-\overline{(F_1-F_2)}\rangle \\ &\quad + \frac{1}{l_c^2}|\overline{(F_1-F_2)}-(\Psi_1-\Psi_2)|^2 \\ &\quad + \frac{1}{(4l_cB^2)^2}|(\Phi_1-\Phi_2)-(K_T(\Psi_1,u(x_1))-K_T(\Psi_2,u(x_2)))|^2 \\ &\leq a^2\|K^{-1}\|_{L^2}\|(F_1-F_2)-\overline{(F_1-F_2)}\|^2_{L^2} \\ &\quad + \frac{2}{l_c^2}|\overline{(F_1-F_2)}|^2 + \frac{2}{l_c^2}|(\Psi_1-\Psi_2)|^2 \\ &\quad + \frac{2}{(4l_cB^2)^2}|(\Phi_1-\Phi_2)|^2 + \frac{2C_K^2}{(4l_cB^2)^2}\|x_1-x_2\|^2_{X^0}.\end{aligned}$$

Note that $\|K^{-1}\|_{L^2} = 1$ and

$$\|F_1-F_2\|^2_{\mathcal{L}^2} = \|(F_1-F_2)-\overline{(F_1-F_2)}\|^2_{L^2} + 2\pi|\overline{(F_1-F_2)}|^2.$$

Hence,

$$\begin{aligned}&\|f(x_1)-f(x_2)\|^2_{X^0} \\ &\leq C_1\|F_1-F_2\|^2_{\mathcal{L}^2} + C_2\|x_1-x_2\|^2_{X^0},\end{aligned}$$

where $C_1 := a^2 + \frac{2}{l_c^2}$ and $C_2 := \frac{2}{l_c^2} + \frac{2}{(4l_cB^2)^2} + \frac{2C_K^2}{(4l_cB^2)^2}$. We will show that

$$\|(F_1-F_2)\|^2_{\mathcal{L}^2} \leq C_3\|x_1-x_2\|^2_{X^0}, \tag{21}$$

where C_3 is a function of X^1 norms of (g_i,Φ_i,Ψ_i), $i = 1, 2$, which is bounded on bounded sets in X^1. For this, note that by Lemma 2.3

$$\|F_1-F_2\|^2_{\mathcal{L}^2} = \left\|\left(\int_0^1 \Psi_c'(\Phi_2+g_2+s(\Phi_1+g_1-\Phi_2-g_2))ds\right)(\Phi_1-\Phi_2+g_1-g_2)\right\|^2_{\mathcal{L}^2}$$

$$\leq 2 \sup_{\phi \in I_{\mathcal{M}}} |\Psi_c'(\phi)|^2 (|\Phi_1 - \Phi_2|^2 + \|g_1 - g_2\|^2_{L^2_K})$$

$$\leq 2 \sup_{\phi \in I_{\mathcal{M}}} |\Psi_c'(\phi)|^2 \|x_1 - x_2\|^2_{X^0}.$$

Therefore, (21) holds with $C_3 := 2 \sup_{\phi \in I_{\mathcal{M}}} |\Psi_c'(\phi)|^2$. Note that C_3 is bounded on bounded sets in X^1. Thus,

$$\|f(x_1) - f(x_2)\|^2_{X^0} \leq C_4 \|x_1 - x_2\|^2_{X^0},$$

where $C_4 := C_1 C_3 + C_2$. Note that C_4 is bounded on bounded sets in X^1. Therefore, $f(g, \Phi, \Psi)$ satisfies (14). □

Therefore, we can state the following result.

Theorem 3.2. *Assume that Ψ_c is a C^1 function. Then the Cauchy problem*

$$\frac{dx}{d\xi} = Ax + f(x, u), \quad x(0) = x_0 \in X^1 \tag{22}$$

has a unique solution $x \in C(0, \delta; X^1) \cap C^1(0, \delta; X^0)$, such that $x(0) = x_0$, for sufficiently small δ (depending on x_0).

We now state a theorem which gives the local existence and uniqueness of X^k solutions for $k = 1, 2, \ldots$.

Theorem 3.3. *Suppose that $\Psi_c \in C^{k+1}(\mathbf{R})$. We assume that $K_T(\Psi, u)$ is bounded from X^k to $\mathbf{R}$ and X^{k-1}-Lipschitz on X^K-bounded sets, i.e., for all $x_i = (g_i, \Phi_i, \Psi_i) \in X^K$, $i = 1, 2$, $K_T(\Psi, u)$ satisfies*

$$|K_T(\Psi_1, u(x_1)) - K_T(\Psi_2, u(x_2))| \leq C_K \|x_1 - x_2\|_{X^{k-1}},$$

where C_K is a function of X^k norms of x_i, $i = 1, 2$, which is bounded on bounded sets in X^k.

Then the Cauchy problem

$$\frac{dx}{d\xi} = Ax + f(x, u), \quad x(0) = x_0 \in X^k$$

has a unique solution $x \in C(0, \delta; X^k) \cap C^1(0, \delta; X^{k-1})$, such that $x(0) = x_0$, for sufficiently small δ (depending on x_0).

Proof. We only outline the proof.

Since $\Psi_c \in C^{k+1}$ and the underlying space has only one dimension, it follows from the Sobolev embedding theorem that for $\Phi \in \mathbf{R}$ we have that the mapping

$$\Psi_c(\cdot) - \overline{\Psi_c(\cdot)} : \mathcal{H}^k \to H^k$$

is C^1 for $k > \frac{1}{2}$. (See McOwen, [13, p. 221].) (Here, $\mathcal{H}^k$ denotes the usual Sobolev space on the unit circle.) In particular, this mapping is locally X^{k-1}-Lipschitz X^k-bounded sets and because of

$$\begin{aligned} \|f(x)\|^2_{X^k} &\leq \|f(0)\|^2_{X^k} + \|f(x) - f(0)\|^2_{X^k}, \\ &\leq \|f(0)\|^2_{X^k} + C_L \|x\|^2_{X^k} \end{aligned}$$

it is also bounded on bounded sets. The result follows. □

3.3. A priori estimates for X^1 solutions. We have Proposition 3.1.

PROPOSITION 3.1. *Assume that Ψ_c is a C^2 function. Let X^1, X^0, f, and A be as in section* 3.2, *and let $x = (g, \Phi, \Psi) \in C(0, \delta; X^1) \cap C^1(0, \delta; X^0)$ be a solution to* (22) *for some $\delta > 0$. Then*

$$\frac{d}{d\xi}\frac{1}{2}\|g\|^2_{H^1_K} = a\int_0^{2\pi} \Psi_c'(\Phi + g)\left(\frac{\partial g}{\partial \theta}\right)^2 d\theta. \tag{23}$$

Proof. In the proof we will deal with the expression $\frac{\partial^2 g}{\partial \theta^2}$ which is not in L^2 for all X^1 functions. Therefore, we first need to prove that (23) holds on a dense subset of X^1 solutions of (22) for which $\frac{\partial^2 g}{\partial \theta^2}$ makes sense. For this subset we choose X^2 solutions of (22).

Assume that $x = (g, \Phi, \Psi) \in C(0, \delta; X^2) \cap C^1(0, \delta; X^1)$ is a solution to (22) for some $\delta > 0$. Then

$$\frac{d}{d\xi}\frac{1}{2}\|g\|^2_{H^1_K} = \frac{1}{2}\left(\left\langle \frac{d}{d\xi}\frac{\partial g}{\partial \theta}, K\frac{\partial g}{\partial \theta}\right\rangle + \left\langle \frac{\partial g}{\partial \theta}, \frac{d}{d\xi}K\frac{\partial g}{\partial \theta}\right\rangle\right).$$

Since K is self-adjoint and $\frac{d}{d\xi}$, K, and $\frac{\partial}{\partial \theta}$ commute, we have

$$\frac{d}{d\xi}\frac{1}{2}\|g\|^2_{H^1_K} = \left\langle \frac{\partial g}{\partial \theta}, \frac{\partial}{\partial \theta}K\frac{d}{d\xi}g\right\rangle.$$

Thus we have by (9),

$$\frac{d}{d\xi}\frac{1}{2}\|g\|^2_{H^1_K} = a\left\langle \frac{\partial \Psi_c(\Phi + g)}{\partial \theta}, \frac{\partial g}{\partial \theta}\right\rangle - a\left\langle \frac{\partial \overline{\Psi_c}}{\partial \theta}, \frac{\partial g}{\partial \theta}\right\rangle - \frac{1}{2}\left\langle \frac{\partial^2 g}{\partial \theta^2}, \frac{\partial g}{\partial \theta}\right\rangle.$$

One has $\frac{\partial \overline{\Psi_c}}{\partial \theta} = 0$. Moreover,

$$\frac{1}{2}\left\langle \frac{\partial^2 g}{\partial \theta^2}, \frac{\partial g}{\partial \theta}\right\rangle = \int_0^{2\pi} \frac{\partial}{\partial \theta}\left(\frac{\partial g}{\partial \theta}\right)^2 d\theta = 0.$$

Thus,

$$\begin{array}{rcl} \frac{d}{d\xi}\frac{1}{2}\|g\|^2_{H^1_K} & = & a\langle \frac{\partial \Psi_c(\Phi+g)}{\partial \theta}, \frac{\partial g}{\partial \theta}\rangle \\ & = & a\int_0^{2\pi} \Psi_c'(\Phi + g)(\frac{\partial g}{\partial \theta})^2 d\theta \end{array}$$

for $x \in X^2$. Since X^2 local solutions of (22) are dense in the set of X^1 local solutions of (22), if we can show that the right-hand side of (23) is X^1 continuous, then (23) will hold for all X^1 solutions of (22). Let $\mathcal{M}$ be a bounded subset of X^1 and let $x_1 = (g_1, \Phi_1, \Psi_1) \in \mathcal{M}$ and $x_2 = (g_2, \Phi_2, \Psi_2) \in \mathcal{M}$ be arbitrary. Then, by Lemma 2.1, for every θ, $\Phi_1 + g_1(\theta)$ and $\Phi_2 + g_2(\theta)$ belong to a bounded interval $I_{\mathcal{M}} \subset \mathbf{R}$. Therefore, using Lemma 2.3 one obtains

$$\begin{aligned} &|\Psi_c'(\Phi_1 + g_1) - \Psi_c'(\Phi_2 + g_2)| \\ &\qquad \leq |\textstyle\int_0^1 \Psi_c''(\Phi_2 + g_2 + s(\Phi_1 - \Phi_2 + g_1 - g_2))ds(\Phi_1 - \Phi_2 + g_1 - g_2)| \\ &\qquad \leq \sup_{\phi \in I_{\mathcal{M}}} |\Psi_c''(\phi)|(|\Phi_1 - \Phi_2| + \|g_1 - g_2\|_{L^\infty}) \\ &\qquad \leq \sup_{\phi \in I_{\mathcal{M}}} |\Psi_c''(\phi)|(|\Phi_1 - \Phi_2| + \tfrac{\sqrt{\pi}}{\sqrt{6}}\|g_1 - g_2\|_{H^1_K}) \\ &\qquad \leq \sup_{\phi \in I_{\mathcal{M}}} |\Psi_c''(\phi)|\|x_1 - x_2\|_{X^1}. \end{aligned}$$

We can now use this to show that the right-hand side of (23) is continuous in X^1:

$$\begin{aligned} &\left|\textstyle\int_0^{2\pi}\Psi_c'(\Phi_1+g_1)(\frac{\partial g_1}{\partial\theta})^2d\theta-\int_0^{2\pi}\Psi_c'(\Phi_2+g_2)(\frac{\partial g_2}{\partial\theta})^2d\theta\right|\\ \leq\;&\textstyle\int_0^{2\pi}\left|\Psi_c'(\Phi_1+g_1)\left((\frac{\partial g_1}{\partial\theta})^2-(\frac{\partial g_2}{\partial\theta})^2\right)\right|+|\Psi_c'(\Phi_1+g_1)-\Psi_c'(\Phi_2+g_2)|\,(\frac{\partial g_2}{\partial\theta})^2d\theta\\ \leq\;&\sup_{\phi\in I_{\mathcal{M}}}|\Psi_c'(\phi)|(\|g_1\|_{H^1}^2-\|g_2\|_{H^1}^2)+\sup_{\phi\in I_{\mathcal{M}}}|\Psi_c''(\phi)|\|x_1-x_2\|_{X^1}\|g_2\|_{H^1}\\ \leq\;&(\sup_{\phi\in I_{\mathcal{M}}}|\Psi_c'(\phi)|(\|g_1\|_{H^1_K}+\|g_2\|_{H^1_K})+\sup_{\phi\in I_{\mathcal{M}}}|\Psi_c''(\phi)|\|g_2\|_{H^1_K})\|x_1-x_2\|_{X^1}. \end{aligned}$$

Thus (23) holds for all X^1 solutions of (22). □

COROLLARY 3.1. *H^1_K solutions of* (9) *grow at most exponentially; i.e., there is no finite-time blow-up of H^1_K solutions of* (9). *In particular, one has*

$$\frac{d}{d\xi}\|g\|^2_{H^1_K}\leq a\sup_{\phi\in\mathbf{R}}\Psi_c'(\phi)\|g\|^2_{H^1_K} \tag{24}$$

and

$$\frac{d}{d\xi}\|g\|_{H^1_K}\leq a\sup_{\phi\in\mathbf{R}}\Psi_c'(\phi)\|g\|_{H^1_K}. \tag{25}$$

Proof. Observe that it follows from our assumptions that Ψ_c' is bounded from above. Now, using Proposition 3.1 and Lemma 2.2 one obtains

$$\frac{d}{d\xi}\|g\|^2_{H^1_K}\leq a\sup_{\phi\in\mathbf{R}}\Psi_c'(\phi)\|g\|^2_{H^1_K}.$$

Observe that $\frac{\partial}{\partial\xi}\frac{1}{2}\|g\|^2_{H^1_K}=\|g\|_{H^1_K}\frac{\partial}{\partial\xi}\|g\|_{H^1_K}$ so upon dividing (24) by $\|g\|_{H^1_K}$ we get (25).

By Grönwall's lemma we get that the solutions grow at most exponentially. □

3.4. Global existence and uniqueness of X^1 solutions. In section 4 we will construct a globally stabilizing feedback control u for the system (9), (10), and (11). As a consequence, the *global* existence of solutions of the system (9), (10), and (11) will be established. The main condition on characteristic Ψ_c is

$$\sup_{\phi\in\mathbf{R}}\Psi_c'(\phi)<+\infty;$$

i.e., the *positive* slopes of the characteristic are bounded. Note that this condition follows from our assumptions about the characteristic stated in the beginning of section 2.1.

THEOREM 3.4. *Assume that X^1, X^0, f, and A are as before. Assume that*

$$\sup_{\phi\in\mathbf{R}}\Psi_c'(\phi)<\infty$$

and there exist constants N_1, N_2 such that $|K_T(\Psi,u(x))|\leq N_1+N_2\|x\|_{X^1}$. Then for any $T>0$ the Cauchy problem

$$\frac{dx}{d\xi}=Ax+f(x),\quad x(0)=x_0\in X^1 \tag{26}$$

has a unique solution $x\in C(0,T;X^1)\cap C^1(0,T;X^0)$ such that $x(0)=x_0$.

Proof. Since the derivative of the characteristic is bounded from above, there exist positive constants L_1, L_2 such that $\Psi_c(\phi) > -L_1 - L_2|\phi|$ when $\phi < 0$ and $\Psi_c(\phi) < L_1 + L_2\phi$ for $\phi > 0$. We now get

$$\begin{array}{rcl}
\Phi\overline{\Psi_c} & = & \frac{1}{2\pi}\int_0^{2\pi} \Phi\Psi_c(\Phi+g)d\theta \\
& \leq & |\Phi|(L_1 + L_2(|\Phi| + \|g\|_{L^\infty})) \\
& \leq & L_1(1+|\Phi|^2) + L_2|\Phi|^2 + L_2|\Phi|\|g\|_{L^\infty} \\
& \leq & L_1(1+|\Phi|^2) + L_2|\Phi|^2 + L_2\frac{\sqrt{\pi}}{\sqrt{6}}\frac{1}{2}(\|g\|^2_{H^1} + |\Phi|^2).
\end{array}$$

Therefore,

$$\Phi\overline{\Psi_c} \leq L_1 + \left(L_1 + L_2\left(1 + \frac{\sqrt{\pi}}{\sqrt{6}}\frac{1}{2}\right)\right)\|x\|^2_{X^1}. \tag{27}$$

Now by Corollary 3.1 we have

$$\begin{array}{rcl}
\frac{d}{d\xi}\frac{1}{2}\|x\|^2_{X^1} & \leq & a\sup_{\mathbf{R}}\Psi'_c\|g\|^2_{H^1_K} + \Phi\frac{d}{d\xi}\Phi + \Psi\frac{d}{d\xi}\Psi \\
& = & a\sup_{\phi\in\mathbf{R}}\Psi'_c(\phi)\|g\|^2_{H^1_K} + \frac{1}{l_c}\Phi\overline{\Psi_c} - \frac{1}{l_c}\Phi\Psi + \frac{1}{4l_cB^2}\Phi\Psi \\
& - & \frac{1}{4l_cB^2}\Psi K_T(\Psi, u(x)) \\
& \leq & a\sup_{\phi\in\mathbf{R}}\Psi'_c(\phi)\|g\|^2_{H^1_K} + L_1 + \left(L_1 + L_2(1 + \frac{\sqrt{\pi}}{\sqrt{6}}\frac{1}{2})\right)\|x\|^2_{X^1} \\
& + & (\frac{1}{l_c} + \frac{1}{4l_cB^2})\frac{1}{2}(|\Phi|^2 + |\Psi|^2) + \frac{1}{4l_cB^2}|\Psi K_T(\Psi, u(x))| \\
& \leq & a\sup_{\phi\in\mathbf{R}}\Psi'_c(\phi)\|g\|^2_{H^1_K} + L_1 + \left(L_1 + L_2(1 + \frac{\sqrt{\pi}}{\sqrt{6}}\frac{1}{2})\right)\|x\|^2_{X^1} \\
& + & (\frac{1}{l_c} + \frac{1}{4l_cB^2})\frac{1}{2}(|\Phi|^2 + |\Psi|^2) + \frac{1}{4l_cB^2}(N_1 + (N_1+N_2)\|x\|^2_{X^1}).
\end{array}$$

Therefore, we obtain

$$\frac{d}{d\xi}\frac{1}{2}\|x\|^2_{X^1} \leq C_1 + C_2\|x\|^2_{X^1}. \tag{28}$$

Here

$$\begin{array}{rcl}
C_1 & = & \frac{1}{4l_cB^2}N_1 + L_1, \\
C_2 & = & a\sup_{\phi\in\mathbf{R}}\Psi'_c(\phi) + L_1 + L_2(1 + \frac{\sqrt{\pi}}{\sqrt{6}}\frac{1}{2}) + \left(\frac{1}{l_c} + \frac{1}{4l_cB^2}\right)\frac{1}{2} + \frac{N_1+N_2}{4l_cB^2}.
\end{array}$$

By Grönwall's lemma we now get

$$\|x\|^2_{X^1}(\xi) \leq \left(\|x\|^2_{X^1}(0) + \frac{C_1}{C_2}\right)e^{C_2\xi} - \frac{C_1}{C_2}. \tag{29}$$

We therefore see that solutions of (22) are bounded for all finite times and thus we have a global solution. ◻

Because of the embedding $H^1 \hookrightarrow L^\infty$, this means that L^∞ norms of H^1 solutions do not blow up in finite time either.

Global existence and uniqueness of H^1_K solutions of the full Moore–Greitzer model and the corresponding a priori estimates allow us to construct a controller that globally stabilizes the peak or any axisymmetric equilibrium to the right of the peak. The controller will have a similar form to a controller for an MG3 model with the H^1_K norm of the stall variable replacing the magnitude of the first Fourier mode of the stall cell.

4. H^1 backstepping. We are going to construct a feedback controller stabilizing the peak or any axisymmetric equilibrium to the right of the peak of the characteristic for the full Moore–Greitzer model. The feedback is constructed by the following backstepping procedure. In the first step we define a positive definite function $V_1(g)$ and construct a function $\widehat{\Phi}(\|g\|)$ such that for $\Phi = \widehat{\Phi}(\|g\|)$ $V_1(g)$ is a Lyapunov function for (9). $V_1(g)$ is called a *control Lyapunov function* and $\widehat{\Phi}(\|g\|)$ is called a *virtual control* for (9). In the second step we define a control Lyapunov function $V_2(\Phi, g)$ and a virtual control $\Psi = \widehat{\Psi}(\|g\|, \Phi)$ for (9) and (10). In the third (and last) step we construct the control Lyapunov function for the full system (9), (10), and (11) with the throttle function u being the control variable. We will refer to this procedure as H^1 backstepping. The obtained feedback control law u uses the H^1_K norm of a stall cell and resembles familiar control laws for MG3 (see [3], [8], [9], [10], [16], [1]) with A_1 replaced with the H^1_K norm of g. In terms of the Fourier coefficients A_i of g, this norm is $(\sum_{p=1}^{\infty}(1+\frac{am}{i})(iA_i)^2)^{\frac{1}{2}}$. To simplify notation, let us from now on denote the norm $\|\cdot\|_{H^1_K}$ by $\|\cdot\|$.

4.1. H^1 backstepping: Step 1. As a control Lyapunov function for (9) we will use the H^1_K norm of g. Let

$$V_1(g) := \frac{1}{2}\|g\|^2.$$

We will show that $\frac{d}{d\xi}V_1(g)$ can be made negative definite by a virtual control of the form

$$\Phi = \widehat{\Phi}(\|g\|) = \Gamma + \overline{c}_g\|g\| \tag{30}$$

for $\Gamma \geq \Phi_0$ and sufficiently large positive $\overline{c}_g$. (Φ_0 denotes the value of the mass flow coefficient at the peak.) In this paper we assume that $\overline{c}_g \geq 0$. We will need the following result.

LEMMA 4.1. *For every $\theta \in [0, 2\pi]$,*

$$\left(\overline{c}_g - \frac{\sqrt{\pi}}{\sqrt{6}}\right)\|g\| \leq \overline{c}_g\|g\| + g \leq \left(\overline{c}_g + \frac{\sqrt{\pi}}{\sqrt{6}}\right)\|g\|.$$

Proof. Note that $\overline{c}_g\|g\| + g \geq \overline{c}_g\|g\| - \|g\|_{L^\infty} \geq (\overline{c}_g - \frac{\sqrt{\pi}}{\sqrt{6}})\|g\|$ by Lemmas 2.1 and 2.2. □

Let

$$e_\Phi := \Phi - \widehat{\Phi}(\|g\|) = \Phi - \Gamma - \overline{c}_g\|g\|.$$

It follows from Proposition 3.1 and Lemma 2.3 that one can represent $\frac{d}{d\xi}V_1(g)$ as

$$\begin{aligned}
\tfrac{d}{d\xi}V_1(g) &= a\textstyle\int_0^{2\pi}\Psi_c'(\widehat{\Phi}(\|g\|) + g)(\frac{\partial g}{\partial\theta})^2 d\theta \\
&+ a(\textstyle\int_0^{2\pi}(\int_0^1 \Psi_c''(\widehat{\Phi}(\|g\|) + se_\Phi + g)ds)(\frac{\partial g}{\partial\theta})^2 d\theta)e_\Phi.
\end{aligned}$$

Using Lemma 2.3 again, one obtains

$$\begin{aligned}
\tfrac{d}{d\xi}V_1(g) &= a\textstyle\int_0^{2\pi}(\Psi_c'(\Gamma) + \int_0^1 \Psi_c''(\Gamma + s(\overline{c}_g\|g\| + g))ds(\overline{c}_g\|g\| + g))(\frac{\partial g}{\partial\theta})^2 d\theta \\
&+ a(\textstyle\int_0^{2\pi}(\int_0^1 \Psi_c''(\widehat{\Phi}(\|g\|) + se_\Phi + g)ds)(\frac{\partial g}{\partial\theta})^2 d\theta)e_\Phi \\
&= a\Psi_c'(\Gamma)\|g\|^2_{H^1} \\
&+ a\textstyle\int_0^{2\pi}(\int_0^1 \Psi_c''(\Gamma + s(\overline{c}_g\|g\| + g))ds(\overline{c}_g\|g\| + g))(\frac{\partial g}{\partial\theta})^2 d\theta \\
&+ a(\textstyle\int_0^{2\pi}(\int_0^1 \Psi_c''(\widehat{\Phi}(\|g\|) + se_\Phi + g)ds)(\frac{\partial g}{\partial\theta})^2 d\theta)e_\Phi.
\end{aligned}$$

Note that if $\Gamma > \Phi_{infl}$ then $\int_0^1 \Psi_c''(\Gamma + s(\overline{c}_g\|g\| + g))ds$ can be bounded from above by a negative constant that depends only on Γ. Namely,

$$\int_0^1 \Psi_c''(\Gamma + s(\overline{c}_g\|g\| + g))ds \le \sup_{\Gamma \le \phi} \Psi_c''(\phi) < 0. \tag{31}$$

Define

$$c_1 := \frac{a}{1+am}(\overline{c}_g - \frac{\sqrt{\pi}}{\sqrt{6}}) \sup_{\Gamma \le \phi} \Psi_c''(\phi),$$

$$c_2(\Phi, \|g\|) := a \sup_{\min(\widehat{\Phi}(\|g\|),\Phi) - \|g\|_{L^\infty} \le \phi \le \max(\widehat{\Phi}(\|g\|),\Phi) + \|g\|_{L^\infty}} |\Psi_c''(\phi)|.$$

PROPOSITION 4.1. *Assume that* $\Gamma \ge \Phi_0$ *and* $\overline{c}_g > \frac{\sqrt{\pi}}{\sqrt{6}}$. *Then* $\Psi_c'(\Gamma) \le 0$, $c_1 < 0$,

$$\begin{aligned} \tfrac{d}{d\xi}V_1(g) &\le (\tfrac{a}{1+am}\Psi_c'(\Gamma) + c_1\|g\|)\|g\|^2 \\ &+ c_2(\Phi, \|g\|)\|g\|^2|e_\Phi|, \end{aligned} \tag{32}$$

and

$$\begin{aligned} \tfrac{d}{d\xi}\|g\| &\le (\tfrac{a}{1+am}\Psi_c'(\Gamma) + c_1\|g\|)\|g\| \\ &+ c_2(\Phi, \|g\|)\|g\||e_\Phi|. \end{aligned} \tag{33}$$

Proof. Note that it follows from Lemma 4.1 that $\overline{c}_g\|g\| + g \ge (\overline{c}_g - \frac{\sqrt{\pi}}{\sqrt{6}})\|g\|$. Moreover, since $\Gamma > \Phi_{infl}$, (31) holds. Therefore,

$$\begin{aligned} \tfrac{d}{d\xi}V_1(g) &\le (a\Psi_c'(\Gamma) + a(\overline{c}_g - \tfrac{\sqrt{\pi}}{\sqrt{6}})\sup\nolimits_{\Gamma \le \phi} \Psi_c''(\phi)\|g\|)\|g\|_{H^1}^2 \\ &+ c_2(\Phi, \|g\|)\|g\|_{H^1}^2|e_\Phi|. \end{aligned}$$

The first term is nonpositive; the last one is positive. Therefore, the inequality (32) follows from Lemma 2.2. Now the inequality (33) follows from (32). □

Proposition 4.1 is the most important result. It allows us to carry out the backstepping procedure for an infinite-dimensional system (9), (10), and (11) without the necessity of working with its infinite-dimensional part (9). What we have done here is a *replacement of an infinite-dimensional evolution equation* (9) with two *finite-dimensional differential inequalities* (32) and (33). As we shall see this replacement makes the next two backsteps quite standard.

In particular, for $\Phi = \widehat{\Phi}(\|g\|)$ one obtains

$$\frac{d}{d\xi}V_1(g) \le \left(\frac{a}{1+am}\Psi_c'(\Gamma) + c_1\|g\|\right)\|g\|^2.$$

If $\Gamma \ge \Phi_0$ then $\Psi_c'(\Gamma) \le 0$, $c_1 < 0$, and hence for $\Phi = \widehat{\Phi}(\|g\|)$ $\frac{d}{d\xi}V_1(g)$ is negative definite. For $\|g\|$ small, if $\Gamma > \Phi_0$ then $\Psi_c'(\Gamma) < 0$ and $\frac{d}{d\xi}V_1(g)$ depends quadratically on $\|g\|$, whereas for $\Gamma = \Phi_0$ one has $\Psi_c'(\Gamma) = 0$ and therefore the dependence of $\frac{d}{d\xi}V_1(g)$ on $\|g\|$ is cubic.

Remark 4.1. Note that the essential property of the virtual control (30) that allows us to make the time derivative of the control Lyapunov function negative was the ability of moving the stall cell "over the top," so that the whole mass flow $\widehat{\Phi}(\|g\|)+g$ is to the right of the peak, where the slope of the characteristic is negative. The Sobolev embedding was used to guarantee that property. A natural question is why did we not use the L^∞ norm of the stall cell or its minimum value instead of the H^1_K norm. The reason is that in the next step of the backstepping procedure we will need a bound on the time derivative of whatever norm of the stall cell we use in the first step. We have such information about the time derivative of the H^1_K norm, but we do not yet have the information about the L^∞ norm of the stall cell. We are currently working on the design that uses L^∞ norm of the stall cell or its minimum in the first step of backstepping.

4.2. $\boldsymbol{H_1}$ backstepping: Step 2. As a control Lyapunov function for (9) and (10) we will use

$$V_2(\Phi, g) := \frac{1}{2}\|g\|^2 + \frac{1}{2}e_\Phi^2.$$

We will show that $\frac{d}{d\xi}V_2(\Phi, g)$ can be made negative definite by a virtual control of the form

$$\begin{aligned} \Psi &= \widehat{\Psi}(\|g\|, \Phi) \\ &= \Psi_c(\Gamma) + \overline{c}_\Phi(\|g\|, \Phi)e_\Phi \end{aligned}$$

for sufficiently large $\overline{c}_\Phi(\|g\|, \Phi)$. (For semiglobal stabilization $\overline{c}_\Phi(\|g\|, \Phi)$ can be chosen to be a constant depending on the desired region of operation.)

Let

$$\begin{aligned} e_\Psi &:= \Psi - \widehat{\Psi}(\|g\|, \Phi) \\ &= \Psi - \Psi_c(\Gamma) - \overline{c}_\Phi(\|g\|, \Phi)e_\Phi. \end{aligned}$$

To calculate $\frac{d}{d\xi}V_2(\Phi, g)$ we will need to express $\frac{d}{d\xi}e_\Phi$ in terms of e_Φ, e_Ψ, and g. For this, note that

$$\begin{aligned} \tfrac{d}{d\xi}e_\Phi &= \tfrac{d}{d\xi}\Phi - \tfrac{d}{d\xi}\widehat{\Phi}(\|g\|) \\ &= \tfrac{1}{l_c}(\overline{\Psi_c(\Phi+g)} - \Psi) - \overline{c}_g\tfrac{d}{d\xi}\|g\|. \end{aligned}$$

Applying Lemma 2.3 twice, one obtains

$$\begin{aligned} \tfrac{d}{d\xi}e_\Phi &= \tfrac{1}{l_c}(\Psi_c(\Gamma) + \textstyle\int_0^{2\pi}(\int_0^1 \Psi_c'(\Gamma + s(\overline{c}_g\|g\| + g))ds)(\overline{c}_g\|g\| + g)d\theta \\ &+ (\textstyle\int_0^{2\pi}(\int_0^1 \Psi_c'(\widehat{\Phi}(\|g\|) + se_\Phi + g)ds)d\theta)e_\Phi \\ &- \widehat{\Psi}(\|g\|, \Phi) - e_\Psi) - \overline{c}_g\tfrac{d}{d\xi}\|g\| \\ &= \tfrac{1}{l_c}(\textstyle\int_0^{2\pi}(\int_0^1 \Psi_c'(\Gamma + s(\overline{c}_g\|g\| + g))ds)(\overline{c}_g\|g\| + g)d\theta \\ &+ (\textstyle\int_0^{2\pi}(\int_0^1 \Psi_c'(\widehat{\Phi}(\|g\|) + se_\Phi + g)ds)d\theta)e_\Phi \\ &- \overline{c}_\Phi(\|g\|, \Phi)e_\Phi - e_\Psi) - \overline{c}_g\tfrac{d}{d\xi}\|g\|. \end{aligned}$$

To simplify calculations, we introduce the following notation:

$$\begin{aligned} &c_0 := \tfrac{a}{1+am}\Psi_c'(\Gamma), \\ &c_3(g) := |(\overline{c}_g + 1)\textstyle\int_0^{2\pi}\int_0^1 \Psi_c'(\Gamma + s(\overline{c}_g\|g\| + g))dsd\theta|, \\ &c_4(\Phi, g) := \textstyle\int_0^{2\pi}\int_0^1 \Psi_c'(\widehat{\Phi}(\|g\|) + se_\Phi + g)dsd\theta. \end{aligned}$$

Note that $c_3(g)$ and $c_4(\Phi, g)$ can be bounded by functions of $\|g\|$. For clarity, in the following calculations we use notation c_i instead of $c_i(g)$, etc.

Lemma 4.2. *Assume that* $\Gamma \geq \Phi_0$ *and* $\overline{c}_g > \frac{\sqrt{\pi}}{\sqrt{6}}$. *Then*

$$\begin{array}{rcl} |\frac{d}{d\xi}e_\Phi| & \leq & \frac{1}{l_c}(c_3\|g\| + (|c_4 - \overline{c}_\Phi|)|e_\Phi| + |e_\Psi|) \\ & + & \overline{c}_g(|(c_0 + c_1\|g\||)\|g\| + c_2\|g\||e_\Phi|). \end{array}$$

and

$$\begin{array}{rcl} e_\Phi\frac{d}{d\xi}e_\Phi & \leq & \frac{1}{l_c}(c_3\|g\||e_\Phi| + (c_4 - \overline{c}_\Phi)e_\Phi^2 + |e_\Phi e_\Psi|) \\ & + & \overline{c}_g(|(c_0 + c_1\|g\|)|\|g\||e_\Phi| + c_2\|g\|e_\Phi^2). \end{array}$$

Therefore, assuming $\Gamma \geq \Phi_0$ and $\overline{c}_g > \frac{\sqrt{\pi}}{\sqrt{6}}$ one has

$$\begin{array}{rcl} \frac{d}{d\xi}V_2(\Phi, g) & = & \frac{d}{d\xi}V_1(g) + e_\Phi\frac{d}{d\xi}e_\Phi \\ & \leq & (c_0 + c_1\|g\|)\|g\|^2 + c_2\|g\|^2|e_\Phi| \\ & + & \frac{1}{l_c}(c_3\|g\||e_\Phi| + (c_4 - \overline{c}_\Phi)e_\Phi^2 + |e_\Phi e_\Psi|) \\ & + & \overline{c}_g(|(c_0 + c_1\|g\|)|\|g\||e_\Phi| + c_2\|g\|e_\Phi^2) \\ & \leq & (c_0 + c_1\|g\|)\|g\|^2 \\ & + & (c_2\|g\| + \frac{1}{l_c}c_3 + \overline{c}_g|(c_0 + c_1\|g\|)|)\|g\||e_\Phi| \\ & + & (\frac{1}{l_c}(c_4 - \overline{c}_\Phi) + \overline{c}_g c_2\|g\|)e_\Phi^2 + \frac{1}{l_c}|e_\Phi e_\Psi|. \end{array}$$

Define

$$c_5 := (\overline{c}_g + 1)|\Psi_c'(\Gamma)|,$$
$$c_6(g) := (\overline{c}_g + 1)|\int_0^{2\pi}\int_0^1\int_0^1 \Psi_c''(\Gamma + s_1 s_2(\overline{c}_g\|g\| + g))ds_1 ds_2 d\theta|.$$

Note that $c_6(g)$ can be bounded by functions of $\|g\|$. It follows from Lemma 2.3 that

$$c_3 \leq c_5 + c_6\|g\|.$$

Therefore, one obtains

$$\begin{array}{rcl} \frac{d}{d\xi}V_2(\Phi, g) & \leq & (c_0 + c_1\|g\|)\|g\|^2 \\ & + & (c_2\|g\| + \frac{1}{l_c}(c_5 + c_6\|g\|) + \overline{c}_g|(c_0 + c_1\|g\|)|)\|g\||e_\Phi| \\ & + & (\frac{1}{l_c}c_4 + \overline{c}_g c_2\|g\| - \frac{1}{l_c}\overline{c}_\Phi)e_\Phi^2 + \frac{1}{l_c}|e_\Phi e_\Psi|. \end{array}$$

Hence, we have the following result.

Proposition 4.2. *Assume that* $\Gamma \geq \Phi_0$ *and* $\overline{c}_g > \frac{\sqrt{\pi}}{\sqrt{6}}$. *Then*

$$\begin{array}{rcl} \frac{d}{d\xi}V_2(\Phi, g) & \leq & (c_0 + c_1\|g\|)\|g\|^2 \\ & + & (\overline{c}_g|c_0| + \frac{1}{l_c}c_5 + (c_2 + \frac{1}{l_c}c_6 + \overline{c}_g|c_1|)\|g\|)\|g\||e_\Phi| \\ & + & (\frac{1}{l_c}(c_4 - \overline{c}_\Phi) + \overline{c}_g c_2\|g\|)e_\Phi^2 + \frac{1}{l_c}|e_\Phi e_\Psi|. \end{array}$$

Assume that $\Gamma \geq \Phi_0$ and $\overline{c}_g > \frac{\sqrt{\pi}}{\sqrt{6}}$. Observe that if $\Psi = \widehat{\Psi}(\|g\|, \Phi)$ then

$$\begin{array}{rcl} \frac{d}{d\xi}V_2(\Phi, g) & \leq & (c_0 + c_1\|g\|)\|g\|^2 \\ & + & (\overline{c}_g|c_0| + \frac{1}{l_c}c_5 + (c_2 + \frac{1}{l_c}c_6 + \overline{c}_g|c_1|)\|g\|)\|g\||e_\Phi| \\ & + & (\frac{1}{l_c}(c_4 - \overline{c}_\Phi) + \overline{c}_g c_2\|g\|)e_\Phi^2 \\ & = & c_{11}\|g\|^2 + 2c_{12}\|g\|e_\Phi + c_{22}e_\Phi^2, \end{array} \tag{34}$$

where

$$\begin{aligned} c_{11} &:= (c_0 + c_1\|g\|),\\ c_{12} &:= \tfrac{1}{2}(\bar{c}_g|c_0| + \tfrac{1}{l_c}c_5 + (c_2 + \tfrac{1}{l_c}c_6 + \bar{c}_g|c_1|)\|g\|),\\ c_{22} &:= (\tfrac{1}{l_c}(c_4 - \bar{c}_\Phi) + \bar{c}_g c_2\|g\|). \end{aligned}$$

Note that the right-hand side of (34) is a quadratic form in $\|g\|$ and e_Φ (with coefficients being functions of $\|g\|$ and e_Φ). This quadratic form can be made negative definite by choosing sufficiently large $\bar{c}_\Phi$. A sufficient condition for $\frac{d}{d\xi}V_2(\Phi, g)$ to be negative definite for $\Psi = \widehat{\Psi}(\|g\|, \Phi)$ is

$$\begin{aligned} \Delta_1 &:= c_{11} < 0,\\ \Delta_2 &:= c_{11}c_{22} - c_{12}^2 > 0, \end{aligned}$$

which is satisfied if

$$\bar{c}_\Phi \geq c_4 + l_c\bar{c}_g c_2\|g\| + l_c\frac{(\bar{c}_g|c_0| + \frac{1}{l_c}c_5 + (c_2 + \frac{1}{l_c}c_6 + \bar{c}_g|c_1|)\|g\|)^2}{4|c_0 + c_1\|g\||}. \tag{35}$$

Observe that $\Gamma = \Phi_0$ implies that $c_0 = 0$, so that it may seem that the gain function $\bar{c}_\Phi$ blows up when $g = 0$. However, this is not the case. Note that $\Gamma = \Phi_0$ also implies that $\bar{c}_g|c_0| + \frac{1}{l_c}c_5 = 0$. Therefore, for $\Gamma = \Phi_0$ the right-hand side of the inequality (35) becomes

$$c_4 + l_c\bar{c}_g c_2\|g\| + l_c\frac{(c_2 + \frac{1}{l_c}c_6 + \bar{c}_g|c_1|)^2\|g\|^2}{4|c_1|\|g\|}.$$

For $\|g\| = 0$ this quantity is not defined. However, it has a finite limit c_4 at $\|g\| = 0$. Hence, one can conclude that $V_2(\Phi, g)$ is a valid control Lyapunov function also for $\Gamma = \Phi_0$.

4.3. H^1 backstepping: Step 3.

As a control Lyapunov function for full model (9), (10), and (11) we will use

$$V_3(\Phi, \Psi, g) := \frac{1}{2}\|g\|^2 + \frac{1}{2}e_\Phi^2 + \frac{4l_cB^2}{2}e_\Psi^2.$$

We will show that $\frac{d}{d\xi}V_3(\Phi, \Psi, g)$ can be made negative definite by a throttle control of the form

$$K_T(\Psi, u) = \Phi + \bar{c}_\Psi(\|g\|, \Phi)e_\Psi \tag{36}$$

for sufficiently large $\bar{c}_\Psi(\|g\|, \Phi)$. (For semiglobal stabilization $\bar{c}_\Psi(\|g\|, \Phi)$ can be chosen to be a constant depending on the desired region of operation.)

To calculate $\frac{d}{d\xi}V_3(\Phi, \Psi, g)$ we will need to express $\frac{d}{d\xi}e_\Psi$ in terms of e_Φ, e_Ψ, and g. (Throughout the paper, for simplicity, we skip the arguments of functions.) One has

$$\begin{aligned} \tfrac{d}{d\xi}e_\Psi &= \tfrac{d}{d\xi}\Psi - \tfrac{d}{d\xi}\widehat{\Psi}\\ &= \tfrac{1}{4l_cB^2}(-\bar{c}_\Psi e_\Psi) - e_\Phi\tfrac{d}{d\xi}\bar{c}_\Phi - \bar{c}_\Phi\tfrac{d}{d\xi}e_\Phi\\ &= \tfrac{1}{4l_cB^2}(-\bar{c}_\Psi e_\Psi) - \tfrac{\partial\bar{c}_\Phi}{\partial\|g\|}\tfrac{d}{d\xi}\|g\| - \tfrac{\partial\bar{c}_\Phi}{\partial\Phi}\tfrac{d}{d\xi}\Phi - \bar{c}_\Phi\tfrac{d}{d\xi}e_\Phi. \end{aligned}$$

Thus, using Proposition 4.1 and Lemma 4.2 one obtains

$$\begin{aligned}
4l_cB^2e_\Psi\tfrac{d}{d\xi}e_\Psi &\leq -\overline{c}_\Psi e_\Psi^2\\
&+ 4l_cB^2(|\tfrac{\partial\overline{c}_\Phi}{\partial\|g\|}|(((|(c_0+c_1\|g\|)|)\|g\||e_\Psi|+c_2\|g\||e_\Phi e_\Psi|)\\
&+ |\tfrac{\partial\overline{c}_\Phi}{\partial\Phi}|(\tfrac{1}{l_c}(c_3\|g\||e_\Psi|+|(c_4-\overline{c}_\Phi)||e_\Phi e_\Psi|+e_\Psi^2)\\
&+ \overline{c}_\Phi(\tfrac{1}{l_c}(c_3\|g\||e_\Psi|+(|c_4-\overline{c}_\Phi|)|e_\Phi e_\Psi|+e_\Psi^2)\\
&+ \overline{c}_g(|(c_0+c_1\|g\|)|)\|g\||e_\Psi|+c_2\|g\||e_\Phi e_\Psi|))).
\end{aligned}\tag{37}$$

Hence, using Proposition 4.2 and (37) one obtains

$$\begin{aligned}
\tfrac{d}{d\xi}V_3(\Phi,\Psi,g) \leq{}& (c_0+c_1\|g\|)\|g\|^2\\
&+ (\overline{c}_g|c_0|+\tfrac{1}{l_c}c_5+(c_2+\tfrac{1}{l_c}c_6+\overline{c}_g|c_1|)\|g\|)\|g\||e_\Phi|\\
&+ (\tfrac{1}{l_c}(c_4-\overline{c}_\Phi)+\overline{c}_gc_2\|g\|)e_\Phi^2+\tfrac{1}{l_c}|e_\Phi e_\Psi|\\
&- \overline{c}_\Psi e_\Psi^2\\
&+ 4l_cB^2(|\tfrac{\partial\overline{c}_\Phi}{\partial\|g\|}|(((|(c_0+c_1\|g\|)|)\|g\||e_\Psi|+c_2\|g\||e_\Phi e_\Psi|)\\
&+ |\tfrac{\partial\overline{c}_\Phi}{\partial\Phi}|(\tfrac{1}{l_c}(c_3\|g\||e_\Psi|+|(c_4-\overline{c}_\Phi)||e_\Phi e_\Psi|+e_\Psi^2)\\
&+ \overline{c}_\Phi(\tfrac{1}{l_c}(c_3\|g\||e_\Psi|+(|c_4-\overline{c}_\Phi|)|e_\Phi e_\Psi|+e_\Psi^2)\\
&+ \overline{c}_g(|(c_0+c_1\|g\|)|)\|g\||e_\Psi|+c_2\|g\||e_\Phi e_\Psi|)))\\
&= c_{11}\|g\|^2+2c_{12}\|g\||e_\Phi|+2c_{13}\|g\||e_\Psi|+c_{22}e_\Phi^2+2c_{23}|e_\Phi||e_\Psi|+c_{33}e_\Psi^2,
\end{aligned}\tag{38}$$

where

$$\begin{aligned}
c_{11} &= (c_0+c_1\|g\|),\\
c_{12} &= \tfrac{1}{2}(\overline{c}_g|c_0|+\tfrac{1}{l_c}c_5+(c_2+\tfrac{1}{l_c}c_6+\overline{c}_g|c_1|)\|g\|),\\
c_{22} &= (\tfrac{1}{l_c}(c_4-\overline{c}_\Phi)+\overline{c}_gc_2\|g\|),\\
c_{13} &:= \tfrac{1}{2}(4l_cB^2|\tfrac{\partial\overline{c}_\Phi}{\partial\|g\|}|(((|(c_0+c_1\|g\|)|)\\
&\quad +4B^2|\tfrac{\partial\overline{c}_\Phi}{\partial\Phi}|c_3+4B^2\overline{c}_\Phi c_3+4l_cB^2\overline{c}_\Phi\overline{c}_g(|(c_0+c_1\|g\|)|),\\
c_{23} &:= \tfrac{1}{2}(\tfrac{1}{l_c}+4l_cB^2c_2\|g\|+4B^2|\tfrac{\partial\overline{c}_\Phi}{\partial\Phi}||(c_4-\overline{c}_\Phi)|\\
&\quad +4B^2\overline{c}_\Phi|c_4-\overline{c}_\Phi|+4l_cB^2\overline{c}_\Phi\overline{c}_gc_2\|g\|),\\
c_{33} &:= -\overline{c}_\Psi+4B^2|\tfrac{\partial\overline{c}_\Phi}{\partial\Phi}|+4B^2\overline{c}_\Phi.
\end{aligned}$$

Note that the right-hand side of (38) is a quadratic form in $\|g\|$, $|e_\Phi|$, and $|e_\Psi|$ (with coefficients being functions of g and e_Φ that can be bounded by functions of $\|g\|$ and e_Φ. Assuming that $\overline{c}_g > \frac{\sqrt{\pi}}{\sqrt{6}}$ and $\overline{c}_\Phi$ satisfies (35), we can make this quadratic form negative definite by choosing sufficiently large $\overline{c}_\Psi$. Sufficient conditions for $\frac{d}{d\xi}V_3(\Phi,\Psi,g)$ to be negative definite everywhere are

$$\begin{aligned}
\Delta_1 &= c_{11}<0,\\
\Delta_2 &= c_{11}c_{22}-c_{12}^2>0,\\
\Delta_3 &:= c_{33}\Delta_2+2c_{12}c_{13}c_{23}-c_{22}c_{13}^2-c_{11}c_{23}^2<0.
\end{aligned}$$

The condition $\Delta_1 < 0$ is obviously satisfied (see Step 1). To enforce the condition $\Delta_2 > 0$ one should choose $\overline{c}_\Phi$ that satisfies (35) (see Step 2). Finally, once $\overline{c}_\Phi$ satisfies the inequality (35), to assure that $\Delta_3 < 0$, at each point, the gain $\overline{c}_\Psi$ should satisfy the inequality

$$\overline{c}_\Psi > 4B^2 \left|\frac{\partial \overline{c}_\Phi}{\partial \Phi}\right| + 4B^2 \overline{c}_\Phi + \frac{2c_{12}c_{13}c_{23} - c_{22}c_{13}^2 - c_{11}c_{23}^2}{\Delta_2}. \tag{39}$$

If $\Gamma > \Phi_0$ then $\Delta_2 > 0$ holds everywhere and hence the right-hand side of the inequality (39) is defined for everywhere (see Step 2).

However, $\Gamma = \Phi_0$ implies that $c_0 = 0$, and thus Δ_2 vanishes if $g = 0$. Therefore, it may seem that the gain function $\overline{c}_\Psi$ blows up when $g = 0$. However, this is not the case. One can show that the quantity $2c_{12}c_{13}c_{23} - c_{22}c_{13}^2 - c_{11}c_{23}^2$ also vanishes if $g = 0$ and $\frac{2c_{12}c_{13}c_{23} - c_{22}c_{13}^2 - c_{11}c_{23}^2}{\Delta_2}$ has a finite limit as $\|g\|$ goes to zero. Hence, one can conclude that $V_3(\Phi, \Psi, g)$ is a valid control Lyapunov function also for $\Gamma = \Phi_0$. (See similar remarks at the end of section 4.2.)

4.4. The case $\Gamma < \Phi_0$. If the position of the peak is unknown or if the characteristic shifts from its nominal position (because of disturbance, etc.), it may happen that $\Gamma < \Phi_0$. In that case it follows from Proposition 3.1 that $(\Phi, \Psi, g) = (\Gamma, \Psi_c(\Gamma), 0)$ is an unstable equilibrium that cannot be stabilized by the virtual control (30). However, one can prove that the controller of the form (36) will guarantee that the dynamics of the closed-loop system are confined to a ball containing $(\Gamma, \Psi_c(\Gamma), 0)$. The radius of the ball can be made arbitrarily small if one can use arbitrarily high gains in the controller. This modification of the gains in the controller in comparison with the case $\Gamma \geq \Phi_0$ is to be expected, as the controller gains proposed for the case $\Gamma \geq \Phi_0$ were not designed to work also in the case $\Gamma < \Phi_0$.

What we present below is a simple, but not necessarily optimal, way of constructing a controller that confines the dynamics to a ball. Our goal was to provide a simple proof that this is possible, not to actually design a controller that is optimal in any sense.

Assume that $\Phi_{infl} < \Gamma < \Phi_0$. We are going to use notation of the previous sections. We need to introduce two new symbols:

$$\overline{c}_0 := a\Psi_c'(\Gamma),$$

$$\overline{c}_{11} := \overline{c}_0 + c_1\|g\|.$$

These quantities will replace c_0 and c_{11}, respectively. One can show that

$$\frac{d}{d\xi}V_3(\Phi, \Psi, g) \leq \overline{c}_{11}\|g\|^2 + 2c_{12}\|g\||e_\Phi| + 2c_{13}\|g\||e_\Psi| + c_{22}e_\Phi^2 + 2c_{23}|e_\Phi||e_\Psi| + c_{33}e_\Psi^2.$$

Observe that we had to replace c_0 and c_{11} with $\overline{c}_0$ and $\overline{c}_{11}$ since now $\Psi_c'(\Gamma) > 0$.

It will be also useful to introduce the following notation. Let

$$\overline{DV}_2(\Phi, g) := \overline{c}_{11}\|g\|^2 + 2c_{12}\|g\||e_\Phi| + c_{22}e_\Phi^2.$$

Then

$$\frac{d}{d\xi}V_3(\Phi, \Psi, g) \leq \overline{DV}_2(\Phi, g) + 2c_{13}\|g\||e_\Psi| + 2c_{23}|e_\Phi||e_\Psi| + c_{33}e_\Psi^2.$$

Note that $\overline{c}_0 > 0$ and $c_1 < 0$. Therefore, the upper bound on $\frac{d}{d\xi}V_3(\Phi, \Psi, g)$ cannot be made negative everywhere; as for $e_\Phi = e_\Psi = 0$ and $0 < \|g\| < \frac{-\overline{c}_0}{c_1}$ one has

$\overline{c}_{11} > 0$. However, we will show that one can arbitrarily reduce the size of the set where $\frac{d}{d\xi}V_3(\Phi,\Psi,g) > 0$ by using high gains in the controller. This can be accomplished as follows. First, one can arbitrarily reduce the interval on which $\overline{c}_{11} > 0$ by using a high gain $\overline{c}_g$, which makes c_1 big negative. Second, one can use high gains $\overline{c}_\Phi$ and $\overline{c}_\Psi$, which make c_{22} and c_{33} big negative.

Let ϵ be an arbitrary positive number. We are going to show that by using sufficiently high gains $\overline{c}_g$, $\overline{c}_\Phi$, and $\overline{c}_\Psi$ one can guarantee that $\frac{d}{d\xi}V_3(\Phi,\Psi,g) < 0$ outside the set $\mathcal{M}_\epsilon := \{(\Phi,\Psi,g) : \|g\| < \epsilon,\ |e_\Phi| < \epsilon,\ |e_\Psi| < \epsilon\}$.

Step 1. Choose $\overline{c}_g$ such that for $\|g\| \geq \epsilon$ one has $\overline{c}_{11} \leq -3$.

Step 2. Choose $\overline{c}_\Phi$ such that the following conditions (2a) and (2b) are satisfied:

(2a) For $\|g\| \geq \epsilon$ one has $c_{22} \leq \frac{c_{12}^2}{\overline{c}_{11}+2}$.

Note that for a fixed $\|g\|$, $\overline{DV}_2(\Phi,g)$ can be viewed as a quadratic function of $|e_\Phi|$. One can show using some elementary algebra that our choice of $\overline{c}_\Phi$ guarantees that for $\|g\| \geq \epsilon$ one has $\overline{DV}_2(\Phi,g) \leq -2\epsilon^2$.

(2b) For $\|g\| < \epsilon$ one has $\frac{-2c_{12}}{c_{22}} + \sqrt{|\frac{c_{11}}{c_{22}}|} + \sqrt{|\frac{2}{c_{22}}|} < 1$.

One can show using some elementary algebra that this choice guarantees that for $\|g\| < \epsilon$ and $|e_\Phi| \geq \epsilon$ one has $\overline{DV}_2(\Phi,g) \leq -2\epsilon^2$.

Step 3. Choose $\overline{c}_\Psi$ so that the following conditions (3a) and (3b) are satisfied:

(3a) For $\|g\| \geq \epsilon$ or $|e_\Phi| \geq \epsilon$ one has $c_{33} \leq \frac{(c_{13}\|g\|+c_{23}|e_\Phi|)^2}{\overline{DV}_2(\Phi,g)+\epsilon^2}$.

Note that c_{33} is bounded, as the choice of $\overline{c}_\Phi$ in Step 2 guarantees that for $\|g\| \geq \epsilon$ or $|e_\Phi| \geq \epsilon$ one has $\overline{DV}_2(\Phi,g) + \epsilon^2 \leq -\epsilon^2$.

One can show that this choice of $\overline{c}_\Psi$ guarantees that for $\|g\| \geq \epsilon$ or $|e_\Phi| \geq \epsilon$ one has $\frac{d}{d\xi}V_3(\Phi,\Psi,g) \leq -\epsilon^2$.

(3b) For $\|g\| < \epsilon$ and $|e_\Phi| < \epsilon$ one has $\frac{-2c_{13}-2c_{23}}{c_{33}} + \sqrt{\frac{|c_{11}|+|c_{22}|+2c_{12}+1}{|c_{33}|}} < 1$.

One can show that this choice guarantees that for $\|g\| < \epsilon$ and $|e_\Phi| < \epsilon$, but for $|e_\Psi| \geq \epsilon$ one has $\frac{d}{d\xi}V_3(\Phi,\Psi,g) \leq -\epsilon^2$.

Therefore, we have the following result.

PROPOSITION 4.3. *Let the gains $\overline{c}_g$, $\overline{c}_\Phi$, and $\overline{c}_\Psi$ satisfy the conditions stated in Steps 1–3 above. Then outside the set $\mathcal{M}_\epsilon = \{(\Phi,\Psi,g) : \|g\| < \epsilon,\ |e_\Phi| < \epsilon,\ |e_\Psi| < \epsilon\}$ one has*

$$\frac{d}{d\xi}V_3(\Phi,\Psi,g) < -\epsilon^2.$$

Therefore, the state of the closed-loop system enters in a finite time the set

$$\mathcal{N}_\epsilon := \left\{(\Phi,\Psi,g) : V_3(\Phi,\Psi,g) < \frac{4l_cB^2}{2(1+4l_cB^2)}\epsilon^2\right\}.$$

Note that the high gains of the controller presented in this section are required if one wants to reduce the size of the dynamics and in particular of the stall cell, not to stabilize a small stall cell. If one just wants to confine the dynamics to a ball, high gains are not required.

It is not clear at the moment what are the dynamics of the closed-loop system inside the absorbing set $\mathcal{N}_\epsilon$. This issue is currently under investigation.

5. Controllers for Galerkin projections of the full model. In section 4 we constructed a feedback controller stabilizing a peak or any axisymmetric equilibrium to the right of the peak for the full Moore–Greitzer PDE model. The feedback law is given by (36) and has a general form

$$K_T(\Psi, u) = K_T(\|g\|_{H^1_K}, \Phi, \Psi).$$

In terms of the magnitudes A_p of the Fourier modes of a stall cell g the control law looks like familiar backstepping control laws for MG3 with A_1 replaced with $(\sum_{p=1}^{\infty}(1+\frac{am}{p})(pA_p)^2)^{\frac{1}{2}}$. An implementation of this control law would require access to an infinite number of modes of a stall cell g, which is practically impossible.

Remark 5.1. The following was communicated to the authors by Richard Murray from Caltech.

The number of accessible modes depends on the number of pressure sensors used to detect a nonaxisymmetric pressure distribution and their distance from the compressor face. Since it requires $2n+1$ sensors to instantaneously detect the first n modes (by fitting a linear combination of spatial sinusoids), the number of sensors gets somewhat large for higher modes. In addition, with the minimal number of sensors, the last mode is pretty noisy.

The Caltech compressor rig has six sensors so that a measurement of up to second mode magnitude is possible. The rig has enough ports to use 16 sensors, which would make it possible to measure the magnitudes of up to the seventh mode.

Another factor is the distance back from the compressor face. Recall that the magnitudes of the Fourier modes of a stall cell fall off by $e^{-\eta n}$ where η is the nondimensional distance from the compressor face. For the Caltech rig, η is about 0.5, so beyond the third or fourth mode one would not be able to pick out the signal from the noise.

Remark 5.2. An alternative to an instantaneous detection of the first n modes by using $2n+1$ sensors would be using fewer sensors and an observer to reconstruct the modes. If the speed of rotation of the stall cell is known, then one can easily verify that the first few modes are observable (even from a single sensor). The fast decay of the higher modes because of the distance of the sensors from the compressor face makes the observability of these modes poor and therefore is still a limiting factor in the number of detectable modes.

If n modes are accessible, a practical implementation of the controller could use $(\sum_{p=1}^{n}(1+\frac{am}{p})(pA_p)^2)^{\frac{1}{2}}$, i.e., a truncation of the infinite series $(\sum_{p=1}^{\infty}(1+\frac{am}{p})(pA_p)^2)^{\frac{1}{2}}$ representing the H^1_K norm of the stall cell g. A natural question arises: what can we say about the controller of the form (36) that uses first n modes of the stall cell g? In this section we will show that this controller *stabilizes the Galerkin projection of the full Moore–Greitzer PDE model onto its first* n *modes.*

It is easy to show that the ODEs describing evolution of the pth mode of g are

$$\dot{a}_p = \frac{p}{p+am}\left(\frac{a}{\pi}\int_0^{2\pi} \Psi_c(\Phi+g)\sin(p\theta)d\theta + \frac{1}{2}pb_p\right),$$

$$\dot{b}_p = \frac{p}{p+am}\left(\frac{a}{\pi}\int_0^{2\pi} \Psi_c(\Phi+g)\cos(p\theta)d\theta - \frac{1}{2}pa_p\right)$$

or, equivalently,

$$\dot{A}_p = \frac{p}{p+am}\left(\frac{a}{\pi}\int_0^{2\pi} \Psi_c(\Phi+g)\sin(p\theta+r_p)d\theta\right),$$

$$\dot{r}_p = \frac{p}{p+am}\left(-\frac{1}{2}p + \frac{a}{\pi A_p}\int_0^{2\pi}\Psi_c(\Phi+g)\cos(p\theta+r_p)d\theta\right),$$

where g is represented as

$$g = \sum_{p=1}^{\infty}(a_p\sin(p\theta)+b_p\cos(p\theta)) = \sum_{p=1}^{\infty}A_p\sin(p\theta+r_p).$$

A Galerkin projection of the stall PDE with n modes would be the set of $2n$ ODEs as above with g replaced with

$$g_n := \sum_{p=1}^{n}A_p\sin(p\theta+r_p).$$

Hence, an approximate model would consist of equations

$$\dot{A}_p = \frac{p}{p+am}\left(\frac{a}{\pi}\int_0^{2\pi}\Psi_c(\Phi+g_n)\sin(p\theta+r_p)d\theta\right), \tag{40}$$

$$\dot{r}_p = \frac{p}{p+am}\left(-\frac{1}{2}p + \frac{a}{\pi A_p}\int_0^{2\pi}\Psi_c(\Phi+g_n)\cos(p\theta+r_p)d\theta\right) \tag{41}$$

for $p = 1,\dots,n$ and (10) and (11).

One can prove the following result.

THEOREM 5.1. *The controller of the form* (36) *that uses first* n *modes of the stall stabilizes the system of* $2n+2$ *ODEs consisting of the Galerkin projection of* (9) *onto first* n*-modes of* g *and* (10) *and* (11).

Proof. We are going to use a backstepping controller design, almost identical to the one used for the full model.

Step 1. As a control Lyapunov function for (40) and (41) one uses

$$V_1^n(\Phi,\Psi,g_n) := \frac{1}{2}\|g_n\|_{H_K^1}^2 = \frac{1}{2}\sum_{p=1}^{n}\left(1+\frac{am}{p}\right)(pA_p)^2.$$

One has

$$\frac{d}{d\xi}V_1^n(\Phi,\Psi,g_n) = \sum_{p=1}^{n}\left(1+\frac{am}{p}\right)\left(p^2A_p\frac{d}{d\xi}A_p\right),$$
$$\frac{a}{\pi}\int_0^{2\pi}\left(\Psi_c(\Phi+g_n)\sum_{p=1}^{n}p^2A_p\sin(p\theta+r_p)d\theta\right).$$

Integrating by parts, one gets

$$\begin{aligned}\frac{d}{d\xi}V_1^n(\Phi,\Psi,g_n) &= \frac{a}{\pi}\int_0^{2\pi}\left(\Psi_c'(\Phi+g_n)\frac{dg_n}{d\theta}\sum_{p=1}^{n}pA_p\cos(p\theta+r_p)d\theta\right)\\ &= \frac{a}{\pi}\int_0^{2\pi}\Psi_c'(\Phi+g_n)\left(\frac{dg_n}{d\theta}\right)^2 d\theta.\end{aligned}$$

Steps 2 and 3 of the backstepping procedure are exactly the same as in the case of the full model (with g replaced with g_n). $\square$

Simulations. In this section we illustrate the action of a truncated H^1-controller with some simulations. The full Moore–Greitzer model has been simulated using 64 Fourier modes (128 states) to represent the stall cell dynamics. The compressor characteristics are assumed to be a cubic function [15]

$$\Psi_c(\phi) := \psi_0 + H\left(1 + \frac{3}{2}\left(\frac{\phi}{W} - 1\right) - \frac{1}{2}\left(\frac{\phi}{W} - 1\right)^3\right).$$

The coefficients ψ_0, H, and W represent, respectively, the shut-off pressure rise, semiheight, and semiwidth of the characteristic. The parameters ψ_0, H, W, a, m, l_c, and B determine the compressor model. The Greitzer B parameter determines if the compressor is likely to stall or surge. Stalling compressors are characterized by a low value of the B parameter, while surging compresssors are characterized by a high value of the B parameter. We simulated a low B compressor and a high B compressor. We initialized both models with the initial condition for the surge dynamics near the peak of the compressor characteristic. The initial shape of the stall cell was a pure first mode.

Figures 2 and 3 show that, as expected, the state of the uncontrolled low B compressor settled at a rotating stall condition with a significant pressure drop.

The simulations of uncontrolled dynamics are followed by simulations of the dynamics controlled with a truncated H^1-controller using first four Fourier modes of the stall variable and constant gains. The control function was saturated at 0 to avoid using negative values of the throttle coefficient. We see the state of the low B compressor after a transient period of growing the stall variable and a drop in pressure settled at the desired axisymmetric equilibria near the peak of the compressor characteristic. Figures 4 and 5 show the state evolution.

Figures 6 and 7 show the evolution of the state of the uncontrolled high B compressor. The stall cell initially grows fast, but after the mean mass flow reaches the reverse flow part of the characteristic, it decays. The state of the system undergoes a deep surge cycle.

Figures 8 and 9 show the evolution of the state of the controlled high B compressor. The controller opens the throttle and prevents a transition into a deep surge cycle. Note that the mean flow spends more time in the interval between the well and the peak than in the uncontrolled case. This causes the stall variable to grow and stay large. The stall variable starts to decay only after the mean mass flow becomes bigger than the value corresponding to the peak of the compressor characteristic. This explains why the stall variable decays faster in the uncontrolled case than in the controlled one.

Conclusion. We have constructed a feedback controller stabilizing a peak or any axisymmetric equilibrium to the right of the peak of the compressor characteristic for the full Moore–Greitzer model. The control law resembles control laws for a one-mode truncation of the full model. In the case when the set-point parameter in the controller is such that there is no stable axisymmetric equilibrium we can still guarantee that the dynamics of the closed-loop system are confined to a ball, whose radius can be made arbitrarily small by choosing sufficiently high gains in the controller.

A practical implementation of the H^1_K-controller would use a finite sum $(\sum_{p=1}^{n}(1+\frac{am}{p})(pA_p)^2)^{\frac{1}{2}}$. We proved that this truncated feedback controller actually globally stabilizes the system of $2n+2$ ODEs consisting of the Galerkin projection of the PDE describing the stall onto its first n-modes and two ODEs describing the surge dynamics.

While one may argue that the necessity of finding the magnitudes of the Fourier modes of a stall cell for a feedback requires complicated implementation, let us observe that such information would be necessary anyway for any feedback law based on a Galerkin approximation of a Moore–Greitzer PDE model with a finite number of modes.

One feature of the H^1-controller is not desirable. Namely, its gain increases for higher order modes of the stall cell. This does not seem to be necessary (see Remark 4.1). We conjecture that one can replace the H^1_K norm of g with the L^∞ norm of g or with the minimum of g in the controller and have the same stabilizability property without using a higher gain for higher order modes of the stall cell. We are currently working on the proof of this conjecture.

Although we have concentrated on a specific model here, the methods developed in this paper can be used, with slight variations, in a variety of problems involving evolution equations.

Acknowledgments. The authors would like to thank Petar Kokotovic for initiating their collaboration on analysis and control of the full Moore–Greitzer model. The authors acknowledge input from Richard Murray on the stall cell measurements. The second author would also like to thank Björn Birnir and Tom Sideris for helpful discussions.

TWO-DIMENSIONAL PROPER RATIONAL MATRICES AND CAUSAL INPUT/OUTPUT REPRESENTATIONS OF TWO-DIMENSIONAL BEHAVIORAL SYSTEMS*

MARIATERESA NAPOLI† AND SANDRO ZAMPIERI‡

Abstract. The concept of proper rational matrix is strictly connected with the representation of causal transfer matrices. In the two-dimensional (2D) case there is much freedom in defining proper rational matrices. This freedom is connected to the fact that past and future in the 2D case can be determined by a 2D cone. In this way the concept of rational matrix which is proper with respect to a cone can be introduced. Moreover, an algorithm that checks the properness of a rational matrix is proposed. Finally, this algorithm is used for determining all possible causal input/output (I/O) representations of a behavior given by a kernel representation.

Key words. two-dimensional, behavioral approach, input/output representation, proper rational matrices, causality, cones

1. Introduction.

In the behavioral approach, a dynamical system is essentially described through the set of its admissible trajectories, without making any a priori distinction between input and output variables and without setting any causality relation between them.

This distinction, which is the characteristic feature of input/output (I/O) models, can be performed a posteriori, introducing the concept of free variables that are called in this way because their value can be arbitrarily assigned. As a consequence we have that, at least for the class of autoregressive (AR) systems, we can extract an I/O description [12, 9, 15, 13], starting from a behavioral model.

The first question that naturally arises when dealing with I/O descriptions is how to define causality. In case of discrete two-dimensional (2D) systems, which is the one we are interested in, the matter is complex, since the plane $\mathbb{Z}^2$ lacks a natural total ordering. As a consequence, the choice of the causality cone $\mathcal{C}$ is not as straightforward as in the one-dimensional (1D) case. In the classical I/O approach [4], the only admissible causality cone is $\mathcal{C} = \mathbb{N}^2$, so that causality is synonymous with quarter plane causality. In this paper we consider an extension of this notion of causality by assuming that $\mathcal{C}$ is an arbitrary cone in $\mathbb{Z}^2$.

The characterization of causality of 2D systems is based on the concept of the 2D proper rational matrix. This concept has been introduced and analyzed for a particular class of cones in [14, 3]. The characterization of 2D proper rational matrices allowed us to obtain some interesting existence results regarding causal I/O representations of 2D behavioral systems. The aim of this paper is to investigate the causal I/O representation of 2D behavioral systems in another direction. More precisely, starting from the kernel representation of a 2D behavioral system, we want to obtain

an efficient method for determining all the causal relations between the variables of the system, given in terms of the set of all causality cones. This result provides a full characterization of the causality structure of the behavioral system. This problem is solved by extending the concept of the 2D proper rational matrix to general cones and by finding a suitable characterization of this class of rational matrices.

2. 1D proper rational matrices.

In this section we will recall some basic definitions and results on proper rational matrices in the 1D case (see [7, 6]).

In this paper we will consider only polynomials having real coefficients. Notice, however, that all the results we will present hold true for any field. A polynomial $p(z)$, in which we allow also negative powers of the indeterminates, is called a Laurent polynomial and can always be written as

$$p(z) = \sum_{i=n}^{N} p_i z^i,$$

where $n \leq N$ are suitable integers. The coefficient p_0 is called zero-degree coefficient of the polynomial p. The set of all the Laurent polynomials has a ring structure with respect to the usual addition and multiplication and it is denoted by the symbol $\mathbb{R}[z, z^{-1}]$. The rings $\mathbb{R}[z]$ and $\mathbb{R}[z^{-1}]$ are both subrings of $\mathbb{R}[z, z^{-1}]$. Consider, moreover, the ring $\mathbb{R}[[z]]$ of formal power series

$$s(z) = \sum_{i=0}^{+\infty} s_i z^i,$$

and define finally the field of rational functions

$$\mathbb{R}(z) := \left\{ \frac{q(z)}{p(z)} : q(z), p(z) \in \mathbb{R}[z] \text{ and } p(z) \neq 0 \right\},$$

which is the field of fractions of $\mathbb{R}[z]$ (see [1]). It is easy to verify that, up to isomorphism, $\mathbb{R}(z)$ coincides with the field of fractions of $\mathbb{R}[z, z^{-1}]$.

Definition 1. *A rational function $h \in \mathbb{R}(z)$ is said to be proper if there exist $p, q \in \mathbb{R}[z]$ such that $h = q/p$ and the zero-degree coefficient of p is nonzero.*

Notice, moreover, that in this paper the role of the indeterminates z and z^{-1} is inverted with respect to the standard notation used in most system theory books (see [6]). We prefer to follow the less standard notation proposed in [7, 5], because it is more convenient in the 2D case as we will see below (see also [4]).

We give now a theorem providing several equivalent characterizations of proper rational functions. The equivalence of these characterizations is easy to verify (see the first part of Chapter 2 in [7]).

Theorem 2. *Let $h \in \mathbb{R}(z)$. The following facts are equivalent:*

1. *h is proper.*

2. *There exists a unique formal power series $y \in \mathbb{R}[[z]]$ such that for all $p, q \in \mathbb{R}[z]$ such that $h = q/p$ we have that*

$$py = q.$$

3. *Let $p, q \in \mathbb{R}[z, z^{-1}]$ be coprime polynomials such that $h = q/p$. Then there exists $n \in \mathbb{Z}$ such that*

(a) $\hat{p} := z^n p, \quad \hat{q} := z^n q \in \mathbb{R}[z]$.

(b) *The zero-degree coefficient of $\hat{p}$ is nonzero.*

4. *Let $p, q \in \mathbb{R}[z]$ coprime in $\mathbb{R}[z]$ be such that $h = q/p$. Then the zero-degree coefficient of p is nonzero.*

Remarks. Notice that condition 1, which corresponds to the definition of a proper rational function, is an existence statement and thus does not give an algorithmic check of properness. Condition 2 connects proper rational functions with formal power series and so with causal impulse responses. Conditions 3 and 4 provide algorithmic checks of properness in the different rings $\mathbb{R}[z, z^{-1}]$ and $\mathbb{R}[z]$, which in this case are slightly different. The distinction between these two properties will be useful in the 2D case.

Now we consider the matrix case. A polynomial matrix P can be considered both as a matrix with polynomial entries and as a polynomial having matrix coefficients. This is the reason why it makes sense to introduce the concept of the degree-zero coefficient of a polynomial matrix that is in this case a matrix.

Definition 3. *A rational matrix $H \in \mathbb{R}(z)^{h \times m}$ is said to be proper if its entries are proper rational functions.*

We give also in the matrix case a theorem that is similar to the previous one and that provides several equivalent characterizations of a proper rational matrix. The characterization of properness for 1D rational matrices is usually given in terms of row proper matrix fractions (see [6]). The characterization that we will give below is based on coprime matrix fractions. This characterization is known [7], but it is less classical and for this reason we will give a brief proof of this result. The convenience of this characterization compared with the characterization in terms of the row proper matrix fractions is motivated by the fact that the extension of the concept of the row proper matrix fraction to the 2D polynomial matrices is rather involved, while the extension of the concept of coprime matrix fraction to the 2D case is straightforward [8].

Theorem 4. *Let $H \in \mathbb{R}(z)^{h \times m}$. The following facts are equivalent:*

1. *H is proper.*

2. *There exist $P \in \mathbb{R}[z]^{h \times h}$ and $Q \in \mathbb{R}[z]^{h \times m}$ such that $H = P^{-1}Q$ and such that the degree-zero coefficient of P is an invertible square matrix.*

3. *There exists a unique formal power series $Y \in \mathbb{R}[[z]]^{h \times m}$ such that for all $P \in \mathbb{R}[z]^{h \times h}$ and $Q \in \mathbb{R}[z]^{h \times m}$ such that $H = P^{-1}Q$ we have that*

$$PY = Q.$$

4. *Let $P \in \mathbb{R}[z]^{h \times h}$ and $Q \in \mathbb{R}[z]^{h \times m}$ be left coprime polynomial matrices such that $H = P^{-1}Q$. Then the degree-zero coefficient of P is an invertible square matrix.*

Proof. ($1 \Rightarrow 3$) By definition and by Theorem 2, condition 2, we know that if for $i = 1, \dots, h$ and $j = 1, \dots, m$ the polynomials $f_{ij}, g_{ij} \in \mathbb{R}[z]$ are such that $H = [p_{ij}/q_{ij}]$, then there exist $y_{ij} \in \mathbb{R}[[z]]$ such that $p_{ij} y_{ij} = q_{ij}$. Let $p := \prod p_{ij}$ and let $\bar{Q} := [p q_{ij}/p_{ij}] \in \mathbb{R}[z]^{h \times m}$ so that $H = \bar{Q}/p$. Let $P \in \mathbb{R}[z]^{h \times h}$ and $Q \in \mathbb{R}[z]^{h \times m}$ be such that $H = P^{-1}Q$. Then we have that

$$pQ = P\bar{Q} = pPY,$$

which, from the fact that $\mathbb{R}[[z]]$ is a domain, implies that $Q = PY$. We show finally the uniqueness of Y. Suppose that there exist $\hat{P} \in \mathbb{R}[z]^{h \times h}$, $\hat{Q} \in \mathbb{R}[z]^{h \times m}$, and $\hat{Y} \in \mathbb{R}[[z]]^{h \times m}$ such that $\hat{P}\hat{Y} = \hat{Q}$ and $\hat{P}^{-1}\hat{Q} = H = P^{-1}Q$. Since $H = \bar{Q}/p$, we have that

$$\hat{P}\bar{Q} = p\hat{Q} = p\hat{P}\hat{Y}.$$

Notice, moreover, that $\bar{Q} = pY$ implies $\hat{P}\bar{Q} = p\hat{P}Y$ and so $p\hat{P}\hat{Y} = p\hat{P}Y$. Since $\hat{P}$ is nonsingular, this implies that $\hat{Y} = Y$.

($3 \Rightarrow 4$) Let $P \in \mathbb{R}[z]^{h\times h}$ and $Q \in \mathbb{R}[z]^{h\times m}$ be left coprime polynomial matrices such that $H = P^{-1}Q$. Then by condition 3 there exists $Y \in \mathbb{R}[[z]]^{h\times m}$ such that $PY = Q$. Moreover, coprimeness ensures the existence of polynomial matrices $A \in \mathbb{R}[z]^{h\times h}$ and $B \in \mathbb{R}[z]^{m\times h}$, which satisfy the Bezout identity $PA + QB = I$. This implies that $P(A + YB) = I$ and hence that the degree-zero coefficient of P must be an invertible matrix.

($4 \Rightarrow 2$) This is trivial.

($2 \Rightarrow 1$) This follows from the fact that $H = \mathrm{adj}(P)Q/\det(P)$ and from the fact that the degree-zero coefficient of $\det(P)$ is nonzero. □

Notice that the only condition that was valid in the scalar case and that is not valid any more in the matrix case is the one involving the primeness of Laurent polynomials. Condition 4 still provides an algorithmic check of properness in the matrix case together with condition 1 (the definition), which, translating matrix properness into scalar properness, shows another way to verify whether a rational matrix is proper or not.

3. Cones and 2D proper rational matrices.

In this section we will extend the notions of proper rational function and matrix to the 2D case. Some results in this direction can be found also in [14].

Before giving the definition of properness in the 2D case we need to introduce the notion of cone and of regular cone in $\mathbb{Z}^2$.

DEFINITION 5. *A cone $\mathcal{C}$ is a subset of $\mathbb{Z}^2$ such that there exists a pair of elements $d_1, d_2 \in \mathbb{Z}^2$ satisfying*

$$\mathcal{C} = \mathbb{Z}^2 \cap \{\alpha d_1 + \beta d_2 \in \mathbb{R}^2 \ : \ \alpha, \beta \in \mathbb{R},\ \alpha, \beta \geq 0\},$$

and such that the matrix $D \in \mathbb{Z}^{2\times 2}$, whose columns coincide with d_1 and d_2, is nonsingular, i.e., $\det(D) \neq 0$*. A cone $\mathcal{C}$ is said to be* regular *if there exists a pair of elements $d_1, d_2 \in \mathbb{Z}^2$ such that*

$$\mathcal{C} = \{\alpha d_1 + \beta d_2 : \alpha, \beta \in \mathbb{N}\}$$

and such that $\det(D) = \pm 1$*, where D is the matrix defined from d_1, d_2 as above.*

It can be shown that a regular cone $\mathcal{C}$ is always isomorphic to $\mathbb{N}^2$; i.e., it is possible to perform a change of coordinates in such a way that $\mathcal{C}$ coincides with $\mathbb{N}^2$. Moreover, given a cone $\mathcal{C}$, there is always a regular cone $\mathcal{C}_r$ containing $\mathcal{C}$. Actually, it is easy to prove that, up to a change of coordinates, there is no loss of generality not only in assuming that any cone is contained in $\mathbb{N}^2$, but also in supposing that it is specified as

$$\mathcal{C} = \{(i,j) \in \mathbb{N}^2 \ : \ j \leq mi\}, \tag{1}$$

where m is a suitable positive rational number.

Given a Laurent polynomial in two indeterminates

$$p(z_1, z_2) = \sum_{(i,j)\in S} p_{ij} z_1^i z_2^j,$$

where S is a finite subset of $\mathbb{Z}^2$, by $\mathrm{supp}(p)$ we mean the set of points $(i,j) \in \mathbb{Z}^2$ corresponding to nonzero coefficients of $p(z_1, z_2)$

$$\mathrm{supp}(p) = \{(i,j) \in \mathbb{Z}^2 \ : \ p_{ij} \neq 0\}.$$

Let $\mathcal{C}$ be a cone. With the symbol $\mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]_{\mathcal{C}}$ we mean the ring of polynomials whose support is contained in $\mathcal{C}$. Similar definitions can be immediately extended to polynomial matrices and power series. More precisely, with the symbol $\mathbb{R}[[z_1, z_2, z_1^{-1}, z_2^{-1}]]_{\mathcal{C}}$ we mean the ring of formal power series

$$s(z_1, z_2) = \sum_{(i,j)\in\mathcal{C}} s_{ij} z_1^i z_2^j.$$

Notice that $\mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]_{\mathcal{C}}$ is always a ring, but unless $\mathcal{C}$ is regular, this ring lacks many of the properties usually possessed by polynomial rings. (It can be seen, for instance, that it is not, in general, a unique factorization domain.)

For the sake of simplicity, from now on we will denote by $\mathbf{z}$ the pair (z_1, z_2). Consequently, we will use the following shorthand notations:

$$\mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]_{\mathcal{C}} := \mathbb{R}[z_1, z_2, z_1^{-1}, z_2^{-1}]_{\mathcal{C}}, \tag{2}$$

$$\mathbb{R}[[\mathbf{z}, \mathbf{z}^{-1}]]_{\mathcal{C}} := \mathbb{R}[[z_1, z_2, z_1^{-1}, z_2^{-1}]]_{\mathcal{C}}, \tag{3}$$

$$\mathbb{R}(\mathbf{z}) := \mathbb{R}(z_1, z_2), \tag{4}$$

where the last notation denotes the field of rational functions in two indeterminates.

If we think of a polynomial matrix $A(z_1, z_2) \in \mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]^{h\times m}$ as a polynomial with matrix coefficients, we can write it as

$$A(z_1, z_2) = \sum_{(i,j)\in S} A_{ij} z_1^i z_2^j, \tag{5}$$

where $A_{ij} \in \mathbb{R}^{h\times m}$ and S is a finite subset of $\mathbb{Z}^2$. By degree-zero coefficient of $A(z_1, z_2)$ we mean the matrix A_{00}.

Definition 6. *A* 2D *rational function $h \in \mathbb{R}(\mathbf{z})$ is said to be proper with respect to a cone $\mathcal{C}$ if there exist $p, q \in \mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]_{\mathcal{C}}$ such that $h = q/p$ and the zero-degree coefficient of p is nonzero.*

Now we give a theorem providing several equivalent characterizations of 2D proper rational functions. These characterizations provide the extension to the 2D case of the analogous results valid in the 1D case presented in Theorem 2. Observe, moreover, that the theorem that follows has already been proved for regular cones in [14, Lemma 3].

Theorem 7. *Let $h \in \mathbb{R}(\mathbf{z})$ and let $\mathcal{C}$ be any cone in $\mathbb{Z}^2$. The following facts are equivalent:*

1. *h is proper with respect to $\mathcal{C}$.*
2. *There exists a unique formal power series $y \in \mathbb{R}[[\mathbf{z}, \mathbf{z}^{-1}]]_{\mathcal{C}}$ such that for all $p, q \in \mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]_{\mathcal{C}}$ such that $h = q/p$ we have that*

$$py = q.$$

3. *Let $p, q \in \mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]$ be coprime polynomials such that $h = q/p$. Then there exists $n_1, n_2 \in \mathbb{Z}$ such that*
   (a) $\hat{p} := z_1^{n_1} z_2^{n_2} p, \quad \hat{q} := z_1^{n_1} z_2^{n_2} q \in \mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]_{\mathcal{C}}$.
   (b) *The zero-degree coefficient of $\hat{p}$ is nonzero.*

Proof. ($3 \Rightarrow 1$) It is sufficient to notice that $h = \hat{q}/\hat{p}$, which, by the properties imposed on $\hat{p}$ and $\hat{q}$, implies that h is proper with respect to $\mathcal{C}$.

($1 \Rightarrow 2$) If h is proper with respect to $\mathcal{C}$, then there exist polynomials

$$\hat{p} = \sum_{(i,j)\in\mathcal{C}} \hat{p}_{ij} z_1^i z_2^j, \quad \hat{q} = \sum_{(i,j)\in\mathcal{C}} \hat{q}_{ij} z_1^i z_2^j$$

such that $h = \hat{q}/\hat{p}$ and such that $\hat{p}_{00} \neq 0$. It is not restrictive to assume $\hat{p}_{00} = 1$. Let $y \in \mathbb{R}[[\mathbf{z}, \mathbf{z}^{-1}]]_{\mathcal{C}}$ be defined recursively as follows:

$$y_{hk} = -\sum_{\substack{(i,j)\in\mathcal{C}\\(i,j)\neq(0,0)}} \hat{p}_{ij} y(h-i, k-j) + \hat{q}_{hk}.$$

This equation implies that $\hat{p}y = \hat{q}$. Now let $p, q \in \mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]_{\mathcal{C}}$ be such that $h = q/p$. Then we have $\hat{p}q = \hat{q}p = \hat{p}py$ and so, since $\mathbb{R}[[\mathbf{z}, \mathbf{z}^{-1}]]_{\mathcal{C}}$ is a domain, we can argue that $py = q$.

($2 \Rightarrow 3$) In the proof, we will explicitly suppose our cone to be specified as

$$\mathcal{C} = \left\{ (i,j) \in \mathbb{N}^2 \;:\; j \leq \frac{m_1}{m_2} i \right\},$$

where m_1, m_2 are coprime positive integers. This can be done without loss of generality.

Let $p, q \in \mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]$ be coprime polynomials such that $h = q/p$. Then there exist $r_1, r_2 \in \mathbb{Z}$ such that $\hat{p} := z_1^{r_1} z_2^{r_2} p$, $\hat{q} := z_1^{r_1} z_2^{r_2} q \in \mathbb{R}[\mathbf{z}]$ and such that $\hat{p}, \hat{q}$ are coprime in $\mathbb{R}[\mathbf{z}]$. Using the fact that the thesis is true for regular cones [14, Lemma 3], we can argue that

$$\hat{p}y = \hat{q} \tag{6}$$

and $y \in \mathbb{R}[[\mathbf{z}]]$ imply that the zero-degree coefficient of $\hat{p}$ is nonzero. We want to show now that $\hat{p}, \hat{q} \in \mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]_{\mathcal{C}}$.

Let $\bar{\mathcal{C}}$ be the smallest cone containing both $\mathcal{C}$ and the support of $\hat{p}$ (see Figure 1), and let $\bar{m}_1, \bar{m}_2$ be coprime positive integers such that

$$\bar{\mathcal{C}} = \left\{ (i,j) \in \mathbb{N}^2 \;:\; j \leq \frac{\bar{m}_1}{\bar{m}_2} i \right\}.$$

If we show that $\bar{\mathcal{C}} = \mathcal{C}$ or, equivalently, that $(m_1, m_2) = (\bar{m}_1, \bar{m}_2)$, then we are done. Let $\mathcal{C}_1$ and $\mathcal{C}_2$ be two regular cones such that

$$\mathcal{C}_1 \cap \mathcal{C}_2 = \bar{\mathcal{C}}.$$

We can take (see Figure 2) $\mathcal{C}_1 = \mathbb{N}^2$ and $\mathcal{C}_2 = \{\alpha(\bar{m}_1, \bar{m}_2) + \beta(\bar{l}_1, \bar{l}_2) \;:\; \alpha, \beta \in \mathbb{N}\}$, where $\bar{l}_1 = l_1 - k\bar{m}_1, \bar{l}_2 = l_2 - k\bar{m}_2$ and where $l_2\bar{m}_1 - l_1\bar{m}_2 = -1$ and k is a big enough positive integer. Observe that, since $\mathcal{C}_2$ contains the supports of both $\hat{p}$ and y, $\mathcal{C}_2$ contains also the support of $\hat{q}$.

Perform a change of coordinates transforming $\mathcal{C}_2$ into $\mathbb{N}^2$. After this change of coordinates $\hat{p}, \hat{q}$ are still coprime polynomials in $\mathbb{R}[\mathbf{z}]$ and y is still in $\mathbb{R}[[\mathbf{z}]]$. Since $\hat{p}, \hat{q}$ are coprime in $\mathbb{R}[\mathbf{z}]$, there exists [8] $a, b \in \mathbb{R}[\mathbf{z}]$ such that $a\hat{p} + b\hat{q} = \psi \in \mathbb{R}[z_1]$. This fact together with (6) yields $\hat{p}\hat{y} = \psi$, where $\hat{y} := a + by \in \mathbb{R}[[\mathbf{z}]]$. Observe that, if we consider $\hat{p}, a, b, y, \hat{y}$ as polynomials or power series in z_1 having polynomials or power series in z_2 as coefficients, we have that

$$\hat{y} = \sum \hat{y}_h(z_2) z_1^h = \sum a_h(z_2) z_1^h + \left(\sum y_i(z_2) z_1^i\right)\left(\sum b_j(z_2) z_1^j\right),$$

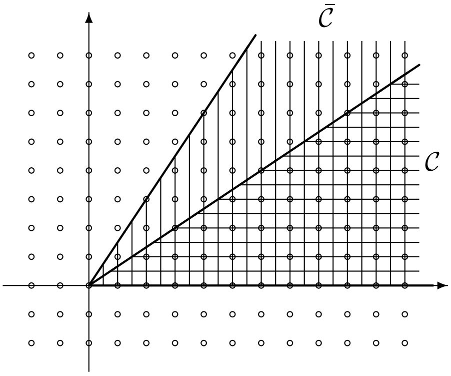

FIG. 1

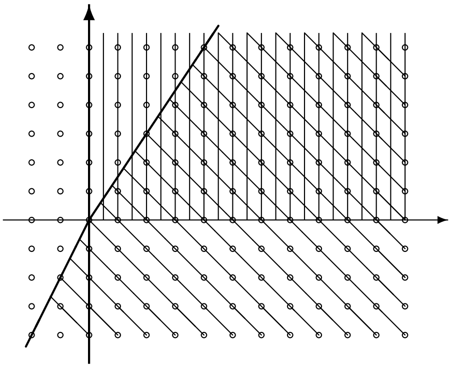

FIG. 2

and so we realize that

$$\hat{y}_h(z_2) = a_h(z_2) + \sum y_{h-i}(z_2) b_i(z_2).$$

This implies that

$$\left(\sum \hat{p}_i(z_2) z_1^i\right)\left(\sum \hat{y}_j(z_2) z_1^j\right) = \sum_{k=l}^{L} \psi_k z_1^k,$$

where $\psi_k \in \mathbb{R}$ and where we can assume that $l \in \mathbb{N}$ is such that $\psi_l \neq 0$. Now, by observing that $\hat{p}_0(z_2) \neq 0$, we can argue that

$$\hat{p}_0(z_2)\hat{y}_l(z_2) = \psi_l \in \mathbb{R} \setminus \{0\}. \tag{7}$$

Assume now by contradiction that $\bar{\mathcal{C}} \neq \mathcal{C}$. This has two consequences. On one hand this implies that the support of $\hat{p}_0(z_2)$ includes at least two points; on the other hand we have that all the coefficients $y_i(z_2)$ of the power series y and consequently also all the coefficients $\hat{y}_i(z_2)$ of the power series $\hat{y}$ are polynomials in z_2. These facts are in contradiction with (7). □

Remark. Notice that condition 4 of Theorem 2 does not extend to the 2D case for general cones in $\mathbb{Z}^2$. It can be seen that [14, Lemma 3] this extension holds true when the cone is regular. Consequently, for general cones we have that condition 3 provides the only way to check algorithmically the properness of a 2D rational function.

Notice, moreover, that the proof of the previous theorem is more difficult than the proof of the analogous result for regular cones. The reason is that for regular cones the ring $\mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]_{\mathcal{C}}$ is isomorphic to the ring $\mathbb{R}[\mathbf{z}]$ of polynomials in two variables, which has many nice properties such as a Bezout equation-like condition for coprimeness. When the cone $\mathcal{C}$ is not regular, the ring $\mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]_{\mathcal{C}}$ does not possess such properties any more. (It is not a unique factorization domain, and even the concept of coprime polynomials is not well defined.) The key idea in the proof of the previous theorem is that any cone is the intersection of two regular cones. In this way we can use the results that are known for regular cones for proving this theorem.

We consider now the matrix case.

DEFINITION 8. *A* 2D *rational matrix $H \in \mathbb{R}(\mathbf{z})^{h \times m}$ is said to be proper with respect to a cone $\mathcal{C}$ if its entries are* 2D *rational functions that are proper with respect to $\mathcal{C}$.*

We give also in this case a theorem providing several equivalent characterizations of a 2D proper rational matrix.

THEOREM 9. *Let $H \in \mathbb{R}(\mathbf{z})^{h\times m}$. The following facts are equivalent:*

1. *H is proper with respect to a cone $\mathcal{C}$.*
2. *There exist $P \in \mathbb{R}[\mathbf{z},\mathbf{z}^{-1}]_{\mathcal{C}}^{h\times h}$ and $Q \in \mathbb{R}[\mathbf{z},\mathbf{z}^{-1}]_{\mathcal{C}}^{h\times m}$ such that $H = P^{-1}Q$ and such that the degree-zero coefficient of P is an invertible square matrix.*
3. *There exists a unique formal power series $Y \in \mathbb{R}[[\mathbf{z},\mathbf{z}^{-1}]]_{\mathcal{C}}^{h\times m}$ such that for all $P \in \mathbb{R}[\mathbf{z},\mathbf{z}^{-1}]_{\mathcal{C}}^{h\times h}$ and $Q \in \mathbb{R}[\mathbf{z},\mathbf{z}^{-1}]_{\mathcal{C}}^{h\times m}$ such that $H = P^{-1}Q$ we have that*

$$PY = Q.$$

Proof. ($2 \Rightarrow 1 \Rightarrow 3$) These implications can be shown in the same way as we proved the same implications in Theorem 4. Notice that uniqueness again follows from the fact that $\mathbb{R}[\mathbf{z},\mathbf{z}^{-1}]_{\mathcal{C}}$ is a domain.

($3 \Rightarrow 2$) Let $P \in \mathbb{R}[\mathbf{z},\mathbf{z}^{-1}]_{\mathcal{C}}^{h\times h}$ and $Q \in \mathbb{R}[\mathbf{z},\mathbf{z}^{-1}]_{\mathcal{C}}^{h\times m}$ be such that $H = P^{-1}Q$. Then condition 3 ensures the existence of $Y \in \mathbb{R}[[\mathbf{z},\mathbf{z}^{-1}]]_{\mathcal{C}}^{h\times m}$ such that $PY = Q$. If $Y = [y_{ij}]$ and if we denote $p := \det(P)$ and $\bar{Q} := \operatorname{adj}(P)Q = [\bar{q}_{ij}]$, then we have that $py_{ij} = \bar{q}_{ij}$ and so, by Theorem 7, we argue that $h_{ij} = \bar{q}_{ij}/p$ is proper and hence that H is proper with respect to $\mathcal{C}$. □

The definition of 2D properness, by translating matrix properness into scalar properness, provides in this case the only way to verify algorithmically whether a rational matrix is proper or not. An efficient algorithmic check can be done as follows.

ALGORITHM. Given a rational matrix $H \in \mathbb{R}(\mathbf{z})^{h\times m}$.

Step 1. Represent it as $H = [q_{ij}/p_{ij}]$, where $q_{ij}, p_{ij} \in \mathbb{R}[\mathbf{z},\mathbf{z}^{-1}]$ are coprime.

Step 2. Let p be the least common multiple of the p_{ij} and let $\bar{q}_{ij} := q_{ij}p/p_{ij}$ so that $H = [\bar{q}_{ij}/p]$.

Step 3. We have that H is proper with respect to a cone $\mathcal{C}$ if and only if there exists $n_1, n_2 \in \mathbb{Z}$ such that

(a) $\hat{p} := z_1^{n_1} z_2^{n_2} p,\quad \hat{q}_{ij} := z_1^{n_1} z_2^{n_2} \bar{q}_{ij} \in \mathbb{R}[\mathbf{z},\mathbf{z}^{-1}]_{\mathcal{C}}$.

(b) The zero-degree coefficient of $\hat{p}$ is nonzero.

Proof of the algorithm. One direction of the proof is easy. Suppose conversely that H is proper. This implies that there exist monomials m_{ij} in z_1, z_2 such that $m_{ij}p_{ij}, m_{ij}q_{ij} \in \mathbb{R}[\mathbf{z},\mathbf{z}^{-1}]_{\mathcal{C}}$ and the zero-degree coefficients of $m_{ij}p_{ij}$ are nonzero. This implies that the polynomials p_{ij} belong to the set

$$\begin{aligned}\mathbf{U} \quad := \quad & \{g \in \mathbb{R}[\mathbf{z},\mathbf{z}^{-1}] \ : \ \exists\ h_1, h_2 \in \mathbb{Z}, z_1^{h_1} z_2^{h_2} g \in \mathbb{R}[\mathbf{z},\mathbf{z}^{-1}]_{\mathcal{C}} \\ & \qquad \text{and zero-degree coefficient of } z_1^{h_1} z_2^{h_2} g \text{ is nonzero}\}.\end{aligned}$$

It is easy to see that this set is a multiplicative set. It is less straightforward to show that it is saturated so that we have $p, q \in \mathbf{U}$ if and only if $pq \in \mathbf{U}$ [1]. This implies that the least common multiple p of p_{ij} is still in $\mathbf{U}$ and so there exists $n_1, n_2 \in \mathbb{Z}$ such that $\hat{p} := z_1^{n_1} z_2^{n_2} p$ and the zero-degree coefficient of $\hat{p}$ is nonzero. Observe finally that $m_{ij}p_{ij}$ divides $\hat{p}$ and that $\hat{p}/m_{ij}p_{ij} \in \mathbb{R}[\mathbf{z},\mathbf{z}^{-1}]_{\mathcal{C}}$. This implies that

$$\hat{q}_{ij} = z_1^{n_1} z_1^{n_2} \bar{q}_{ij} = \hat{p}\frac{q_{ij}}{p_{ij}} = \hat{p}\frac{m_{ij}q_{ij}}{m_{ij}p_{ij}} \in \mathbb{R}[\mathbf{z},\mathbf{z}^{-1}]_{\mathcal{C}}.$$

Remark. In Step 2 we can take as polynomial p any common multiple of the p_{ij} as, for instance, $p = \prod p_{ij}$. Notice, however, that in general the least common multiple is more convenient since often it has smaller support and, moreover, it can be computed efficiently (see [2]).

4. 2D systems in the behavioral approach.

In the remaining part of the paper we want to use the characterization of 2D proper rational matrices given in the previous section for the analysis of the causality structure of a 2D behavioral system given through a kernel representation. We start by giving a short introduction to the theory of 2D systems in the behavioral approach.

It is known that, given a dynamical system, we can associate with it different mathematical models, according to the aim the model was constructed for and to the theoretical approach that has been chosen. When using behavioral models, a dynamical system is characterized by the set of trajectories that constitute the so-called behavior of the system. More precisely, in this setup a dynamical system is described by a triple

$$\Sigma = (T, W, \mathcal{B}),$$

where T is the time domain, W is the signal alphabet, and $\mathcal{B} \subset W^T$, the *behavior*, is the set of admissible trajectories. For 2D systems we assume that $T = \mathbb{Z}^2$ and $W = \mathbb{R}^q$. We refer the interested reader to [9, 10, 11] for a more complete introduction to 2D behavioral systems theory.

An important subclass of 2D systems is constituted by the so-called AR 2D systems. They are 2D systems whose behavior is given by the set of solutions $w \in (\mathbb{R}^q)^{\mathbb{Z}^2}$ (set of all q-dimensional signals defined on $\mathbb{Z}^2$) of a linear difference equation of the following kind:

$$\sum_{(i,j)\in S} R_{ij} w(h+i, k+j) = 0 \qquad \forall (h,k) \in \mathbb{Z}^2, \tag{8}$$

where $R_{ij} \in \mathbb{R}^{l\times q}$ and S is a finite subset of $\mathbb{Z}^2$. Notice that any polynomial matrix

$$R = \sum_{(i,j)\in S} R_{ij} z_1^i z_2^j \in \mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]^{l\times q}$$

naturally induces a polynomial linear operator

$$R(\sigma_1, \sigma_2) \ : \ (\mathbb{R}^q)^{\mathbb{Z}^2} \longrightarrow (\mathbb{R}^l)^{\mathbb{Z}^2}$$

in the following way:

$$(R(\sigma_1, \sigma_2) w)(h,k) = \sum R_{ij} w(h+i, k+j) \qquad \forall (h,k) \in \mathbb{Z}^2.$$

In this way we have that the behavior $\mathcal{B}$ determined by the difference equation (8) coincides with $\ker R(\sigma_1, \sigma_2)$ and that the behavior of an AR system can always be represented as the kernel of a polynomial linear operator, which is called *kernel representation.*

5. Passing from kernel to I/O representations.

Given a behavioral model of a dynamical system, we could wonder whether an I/O representation of the same system can be obtained or not. By answering this question we can check whether there exists a cause-effect relation between the components of the signal.

Roughly speaking, if the constraints imposed by (8) are few with respect to the number of components of the signal, some of them can be considered as inputs. In fact, under this assumption, their value is arbitrarily assignable and determines the value of the remaining components.

The mathematical translation of this intuitive consideration is a rank condition on the polynomial matrix R providing the kernel representation of the system. It can be proved (see [9, 13, 15]) that if

$$\operatorname{rank} R(z_1, z_2) = h,$$

then it is possible to split the components of w in $m := q - h$ inputs (free variables) and h outputs (nonfree variables). More precisely, if S is any permutation matrix such that

$$RS = [P| - Q],$$

where $P \in \mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]^{l\times h}$, $Q \in \mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]^{l\times(q-h)}$, and rank $P = h$, then we say that the pair of matrices (P, Q) provides an I/O representation of the system because they satisfy the properties of the following definition.

Definition 10 (see [9, 14]). *Given a* 2D *AR system* $\Sigma(\mathbb{Z}^2, \mathbb{R}^q, \ker R(\sigma_1, \sigma_2))$, *the difference equation*

$$P(\sigma_1, \sigma_2)y = Q(\sigma_1, \sigma_2)u, \tag{9}$$

where $h + m = q$, $P \in \mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]^{l\times h}$, $Q \in \mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]^{l\times m}$, *and where* $y \in (\mathbb{R}^h)^{\mathbb{Z}^2}$ *and* $u \in (\mathbb{R}^m)^{\mathbb{Z}^2}$, *is an* I/O representation *of* Σ *if*

1. $\mathcal{B} = \{S[\begin{smallmatrix} y \\ u \end{smallmatrix}] : P(\sigma_1, \sigma_2)y = Q(\sigma_1, \sigma_2)u\}$, *where* S *is a suitable* $q\times q$ *permutation matrix;*
2. *u is free, i.e., for all* $u \in (\mathbb{R}^m)^{\mathbb{Z}^2}$ *there exists* $y \in (\mathbb{R}^h)^{\mathbb{Z}^2}$ *such that* (9) *holds;*
3. *no other component in y is free.*

We often use the shorthand notation (P, Q) to denote the I/O representation (9). Observe that, starting from an AR behavioral model, it is possible to extract finitely many different I/O descriptions. They are obtained by choosing different permutation matrices S that satisfy only the rank condition. In other words, they are obtained selecting in different ways the inputs and the outputs among the components of w.

The concept of causality is strictly related to I/O representations. In the 2D case its definition is more involved than for 1D systems, since there are different possible ways to order the time domain $T = \mathbb{Z}^2$. As a consequence, there is more freedom in the choice of the causality cone. Given a cone $\mathcal{C}$, by the symbol $(\mathbb{R}^m)^{\mathbb{Z}^2}_{\mathcal{C}}$ we mean the set of all m-dimensional signals defined on $\mathbb{Z}^2$ and supported in $\mathcal{C}$.

Definition 11. *The I/O representation* (9) *is said to be causal with respect to the cone* $\mathcal{C}$ *if for any* $u \in (\mathbb{R}^m)^{\mathbb{Z}^2}_{\mathcal{C}}$ *there exists* $y \in (\mathbb{R}^h)^{\mathbb{Z}^2}_{\mathcal{C}}$ *such that* (9) *holds.*

Notice that the definition above suggests that the influence of u on y is causal with respect to $\mathcal{C}$. In can be shown, moreover, [14, Lemma 1] that y in the previous definition is uniquely determined from u.

6. Characterization of causal I/O representations. In [14], a characterization of causal I/O representations with respect to regular cones has been given. Our aim here is to extend and generalize those results to general cones. Some of these results can be generalized in a straightforward way. This is the case for Proposition 3 [14], which will be used next. This proposition, stated for regular cones, guarantees that the causality of an I/O representation

$$P(\sigma_1, \sigma_2)y = Q(\sigma_1, \sigma_2)u \tag{10}$$

depends only on a coprime representation of the polynomial matrices specifying the system. Thus, if $\bar{P} \in \mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]^{h\times h}$ and $\bar{Q} \in \mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]^{h\times m}$ are coprime polynomial matrices such that

$$P = F\bar{P}, \quad Q = F\bar{Q},$$

with F a full column rank polynomial matrix of suitable dimensions, then (10) is causal with respect to a regular cone $\mathcal{C}_r$ if and only if

$$\bar{P}(\sigma_1, \sigma_2)y = \bar{Q}(\sigma_1, \sigma_2)u$$

is causal with respect to it. It is easy to see that the proof still holds if we consider general cones.

Let (P, Q) be an I/O representation of a 2D AR system that is causal with respect to a cone $\mathcal{C}$. Define the inputs $\delta^{(i)}$, $i = 1, \ldots, m$, as

$$\delta^{(i)}(t) := \begin{cases} e_i, & t = (0,0), \\ 0 & \text{otherwise}, \end{cases}$$

where e_i is the ith vector of the canonical base in $\mathbb{R}^m$. If $y^{(i)} \in (\mathbb{R}^h)^{\mathbb{Z}^2}_{\mathcal{C}}$ is the corresponding output, namely,

$$P(\sigma_1, \sigma_2)y^{(i)} = Q(\sigma_1, \sigma_2)\delta^{(i)}, \tag{11}$$

we define the impulse response of the 2D system to be the matrix-valued sequence

$$Y := [y^{(1)} \ldots y^{(m)}] \in (\mathbb{R}^{h\times m})^{\mathbb{Z}^2}_{\mathcal{C}}.$$

It is worth pointing out that, as shown in [14], the causality of an I/O representation is equivalent to the existence of the impulse response, since the impulse response determines the way in which the system maps input signals supported in $\mathcal{C}$ into output y by the convolution

$$y(h, k) := \sum_{(i,j)\in\mathbb{Z}^2} Y(h - i, k - j)u(i, j).$$

Notice that, since u and Y are both supported in $\mathcal{C}$, the sum is always finite and, moreover, also the support of y is included in $\mathcal{C}$.

Now we are in a position to state the following theorem, which allows us to characterize the causality structure of a 2D AR system.

THEOREM 12. *Let*

$$P(\sigma_1, \sigma_2)y = Q(\sigma_1, \sigma_2)u, \tag{12}$$

with $P \in \mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]^{l\times h}$ *and* $Q \in \mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]^{l\times m}$, *be an I/O representation of a* 2D *AR system. Then* (12) *is causal with respect to a cone* $\mathcal{C}$ *if and only if the rational matrix* $H \in \mathbb{R}(\mathbf{z})^{h\times m}$ *such that* $Q = PH$ *is proper with respect to the cone* $-\mathcal{C}$.

Proof. Let $\bar{P} \in \mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]^{h\times h}$ and $\bar{Q} \in \mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]^{h\times m}$ be coprime polynomial matrices such that $P = F\bar{P}, Q = F\bar{Q}$, where F is a full column rank polynomial matrix of suitable dimensions, then, as mentioned above, (12) is causal with respect to $\mathcal{C}$ if and only if

$$\bar{P}(\sigma_1, \sigma_2)y = \bar{Q}(\sigma_1, \sigma_2)u \tag{13}$$

is causal with respect to $\mathcal{C}$. Observe that $H = \bar{P}^{-1}\bar{Q}$ and that, moreover, it is not restrictive to assume that $\bar{P}, \bar{Q}$ have entries in $\mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]_{-\mathcal{C}}$. Notice that (13) is causal with respect to $\mathcal{C}$ if and only if there exists the impulse response, which is a matrix-valued sequence $Y \in (\mathbb{R}^{h\times m})^{\mathbb{Z}}_{\mathcal{C}}$ satisfying the matrix difference equation

$$\sum_{ij} \bar{P}_{ij} Y(h+i, k+j) = \bar{Q}_{-h,-k} \quad \forall (h,k) \in \mathbb{Z}^2.$$

If we define the power series $\bar{Y} := \sum_{ij} Y(i,j) z_1^{-i} z_2^{-j} \in \mathbb{R}[[\mathbf{z}, \mathbf{z}^{-1}]]^{h\times m}_{-\mathcal{C}}$, then we have that $\bar{Q} = \bar{P}\bar{Y}$. By Theorem 9 this is equivalent to the fact that H is proper with respect to $-\mathcal{C}$. □

Remarks. Notice that by using Theorem 9 the proof of the previous theorem is more direct than the proof of the analogous result [14, Theorem 1] for regular cones. In both cases the main idea is to characterize properness of a rational matrix in terms of the existence of a power expansion that is supported in the cone. For regular cones this has been done by using the properties of coprime matrix fraction descriptions of rational matrices. However, this method works only for regular cones. This difficulty has been overcome in Theorem 9 simply by using the definition of proper rational matrices, which is in terms of the properness of its scalar entries. This method, which obviously works also for regular cones, is simpler and more natural than the technique used in [14, Theorem 1].

7. Minimal causality cones and parametrization of causal I/O representations. Consider an I/O representation (P, Q). The theorem we proved in the previous section allows us to determine the set of all cones $\mathcal{C}$ such that (P, Q) is causal with respect to $\mathcal{C}$. These cones are called *causality cones* for the I/O representation. Notice that, if $\mathcal{C}$ is a causality cone and $\mathcal{C}' \supseteq \mathcal{C}$, then also $\mathcal{C}'$ is a causality cone. Therefore, the set of causality cones is completely determined by its finite subset $\mathcal{M}(P, Q)$ constituted by the *minimal* causality cones.

In practice the construction of this set reduces to a simple procedure based on the previous theorem. Let $H \in \mathbb{R}(\mathbf{z})^{h\times m}$ be the rational matrix such that $Q = HP$ and represent it as $H = [q_{ij}/p_{ij}]$, where $q_{ij}, p_{ij} \in \mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]$ are coprime. Let p be the least common multiple of p_{ij} and $\bar{q}_{ij} := q_{ij}p/p_{ij}$ so that $H = [\bar{q}_{ij}/p]$. As suggested in the algorithmic check of properness proposed above, H is proper with respect to a cone $\mathcal{C}$ if and only if there exist $n_1, n_2 \in \mathbb{Z}$ such that $\hat{p} := z_1^{n_1} z_2^{n_2} p$, $\hat{q}_{ij} := z_1^{n_1} z_2^{n_2} \bar{q}_{ij} \in \mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]_{\mathcal{C}}$ and the zero-degree coefficient of $\hat{p}$ is nonzero. For this reason the finite set of minimal causality cones can be obtained from the polynomials p and $\bar{q}_{ij}$ in the following way:

Step 1. Determine the convex hull of supp (p) and from this the finite set $V = \{v_1, \ldots, v_k\}$ of the vertices of this convex hull.

Step 2. For each $v_i \in V$ consider the following set of cones:

$$\mathcal{C}(v_i) = \left\{ \mathcal{C} \ : \ v_i - \mathcal{C} \supseteq \text{supp } (p) \cup \bigcup_{ij} \text{supp } (\bar{q}_{ij}) \right\}.$$

Step 3. It is clear that, when the set $\mathcal{C}(v_i)$ is nonempty, it contains a cone $\hat{\mathcal{C}}_i$ that is smaller than every other cone in $\mathcal{C}(v_i)$. Then by Theorem 12 the set $\mathcal{M}(P, Q)$ of the minimal causality cones for the I/O representation (P, Q) coincides with the set of all the cones $\hat{\mathcal{C}}_i$.

It may happen that, for a given I/O representation (P, Q), the set $\mathcal{M}(P, Q)$ is empty. However, there exists a certain freedom in constructing an I/O representation

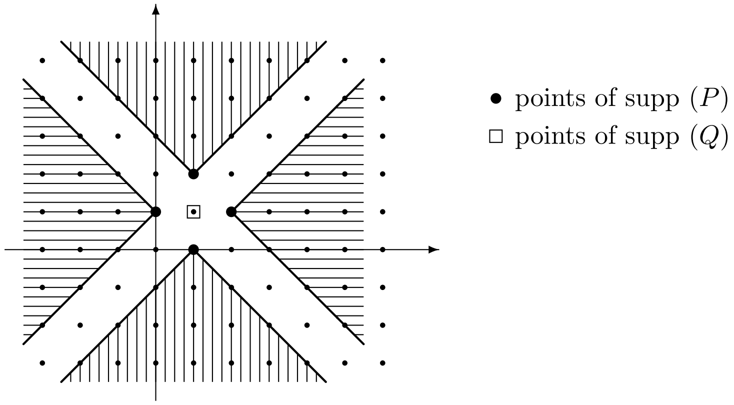

FIG. 3

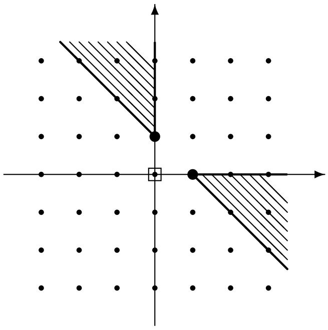

FIG. 4

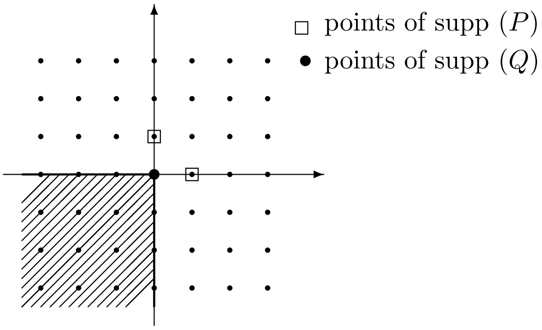

FIG. 5

from a kernel representation, which corresponds to the freedom that there exists in the choice of h linearly independent columns in a rank h polynomial matrix $R \in \mathbb{R}[\mathbf{z}, \mathbf{z}^{-1}]^{l \times q}$ providing the kernel representation of the AR system. The family of the sets $\mathcal{M}(P, Q)$, when (P, Q) varies in the set of all possible I/O representations of the AR system, provides a complete description of its causality structure. It is important to notice that, as a direct consequence of [14, Theorem 2], we have that there always exists an I/O representation (P, Q) such that $\mathcal{M}(P, Q)$ is nonempty.

Example 1. Let Σ be a 2D AR system whose behavior is the kernel of the polynomial matrix

$$R = [z_1 z_2 \mid -z_1 - z_2 - z_1^2 z_2 - z_1 z_2^2].$$

We can consider two I/O representations of Σ. If we let $P = z_1 z_2$ and $Q = z_1 + z_2 + z_1^2 z_2 + z_1 z_2^2$, we have that $\mathcal{M}(P, Q) = \emptyset$. If, conversely, we let $P = z_1 + z_2 + z_1^2 z_2 + z_1 z_2^2$ and $Q = z_1 z_2$, we obtain easily that $\mathcal{M}(P, Q)$ is constituted by four cones as shown in Figure 3. For convenience in this figure and in the figures relative to the example that follow the minimal causality cones are translated in such a way that their vertices coincide with the vertices of the convex hull of p.

Example 2. Let Σ be a 2D AR system whose behavior is the kernel of the polynomial matrix

$$R = [z_1 - z_2 \mid 1].$$

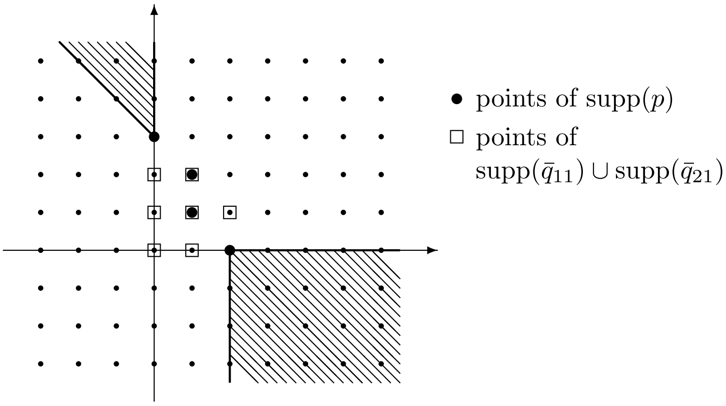

Fig. 6

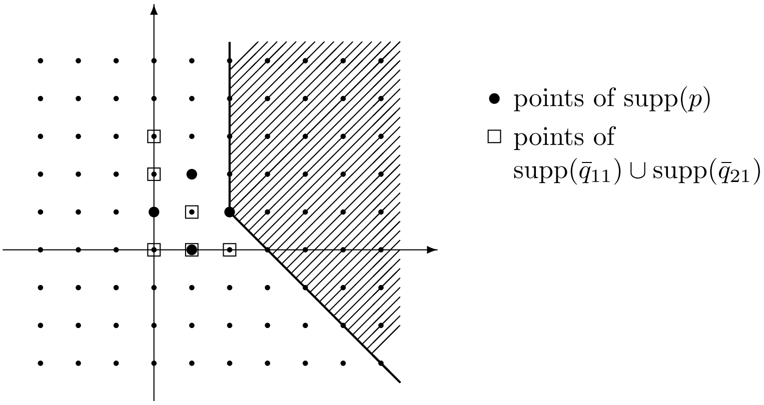

Fig. 7

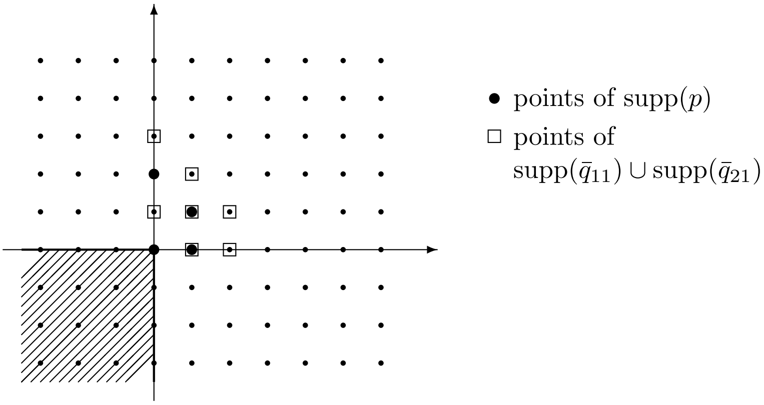

Fig. 8

This is the same 2D AR system considered in Example 1 in [14]. We can consider two I/O representations of Σ. If we let $P = z_1 - z_2$ and $Q = -1$, the set $\mathcal{M}(P,Q)$ contains the cones shown in Figure 4, while if we let $P = -1$ and $Q = z_1 - z_2$, we obtain easily that $\mathcal{M}(P,Q)$ is constituted by only one cone as shown in Figure 5.

Example 3. Let Σ be a 2D AR system whose behavior is the kernel of the polynomial matrix

$$R = \begin{bmatrix} z_1 - z_2^2 & 0 & 2z_1z_2 - 1 \\ 1 & z_1 - z_2 & 1 \end{bmatrix}.$$

This is the same 2D AR system considered in Example 2 in [14]. We can consider three I/O representations of Σ. If we let

$$P = \begin{bmatrix} z_1 - z_2^2 & 0 \\ 1 & z_1 - z_2 \end{bmatrix}, \qquad Q = \begin{bmatrix} 2z_1z_2 - 1 \\ 1 \end{bmatrix},$$

then following the algorithm presented above, we obtain that $p = z_1^2 - z_1z_2 - z_1z_2^2 + z_2^3$, $\bar{q}_{11} = -z_1 + z_2 + 2z_1^2z_2 - 2z_1z_2^2$, and $\bar{q}_{21} = 1 - 2z_1z_2 + z_1 - z_2^2$, and so, as shown in Figure 6, we see that the set $\mathcal{M}(P,Q)$ contains two cones.

Finally, if we consider the other two remaining I/O representations, we obtain the sets of minimal causality cones shown in Figures 7 and 8.

STABILITY OF AN ADAPTIVE REGULATOR FOR PARTIALLY KNOWN NONLINEAR STOCHASTIC SYSTEMS[*]

A. BROCKWELL[†], K. BOROVKOV[†], AND R. EVANS[‡]

Abstract. We investigate the properties of a fast-identification style of control algorithm applied to a class of stochastic dynamical systems in continuous time which are sampled at a constant rate. The algorithm does not assume that the system dynamics are known and estimates them using a simple filter. Under a mild smoothness condition on the system dynamics, we show that when the sampling rate is sufficiently fast, the control algorithm stabilizes the system in the sense that the sampled closed-loop system becomes an ergodic Markov chain. Moreover, an explicit bound is given for the expected deviation of the system state from the origin. The result is also adapted for the case where state-measurement is subject to random noise.

1. Introduction.

Suppose that we have a continuous-time dynamical system given by

$$dx^{(p-1)}(t) = f(x^{(p-1)}(t), \dots, \dot{x}(t), x(t))dt + u(t)dt + \sigma dw(t), \tag{1.1}$$

where $x^{(k)} = \frac{d^k}{dt^k}x(t)$, $x(t) \in \mathbb{R}$, and $w(t)$ is a standard Brownian motion process. The real-valued control term $u(t)$ takes constant values on each time interval $t \in [j\delta, (j+1)\delta)$, $j = 0, 1, 2, \dots$, and can depend only on observed values of x and its derivatives at sampling points in time given by $\{k\delta,\ k = 0, 1, 2, \dots;\ k\delta \le t\}$, where $\delta > 0$ is a fixed sampling interval length which is to be specified in advance. Thus the control can be defined by the sequence $\{u_j\}$ with $u_j = u(t)$, $j\delta \le t < (j+1)\delta$. The function $f : \mathbb{R}^p \to \mathbb{R}$ is not known to the controller, but satisfies the global Lipschitz condition

$$|f(a) - f(b)| \le \beta \|a - b\| \tag{1.2}$$

for some $\beta < \infty$, $\|a\| = (aa^T)^{1/2}$ being the Euclidean norm for row vectors a.

Our objective is to make the sequence of vectors

$$\{\boldsymbol{x}(j\delta)\} := \{(x^{(p-1)}(j\delta), \dots, \dot{x}(j\delta), x(j\delta))\}, \quad j = 0, 1, 2, \dots,$$

behave in some desired fashion. We do this by choosing the (nonanticipative) control sequence $\{u_j, j = 0, 1, 2, \dots\}$ so as to make the system mimic as closely as possible a prespecified reference system. This type of approach is commonly used for adaptive control problems (see, e.g., [6]). In order to match the system dynamics to those of the reference system, the controller will need to estimate the values of the unknown function $f(\cdot)$ on each sampling interval. In fact, it will turn out that as the class

of possible systems to be controlled becomes larger (i.e., β increases), the sampling rate required to guarantee closed-loop stability also increases. Further aspects of this fast-sampling approach will be discussed below.

In this paper, we consider only the regulation problem, i.e., we choose reference systems which are stable around the origin. However, the results can be adapted for other types of problems.

There are relatively few results pertaining to the stability of control laws applied to nonlinear stochastic systems. In fact, to the authors' knowledge, this is the only current result which establishes closed-loop stability of a control law applied to an unknown nonlinear stochastic system. Florchinger [4] has obtained results which apply in the case where noise intensity vanishes as the system state approaches the origin, and Meyn and Guo [7] have obtained results on stability of control laws applied to linear time-varying stochastic systems (see also [2]). In this paper, we consider the case where the system dynamics are nonlinear and the noise intensity does not necessarily approach zero as the state approaches the origin.

The discrete-time system

$$\boldsymbol{y}_t := (y_t^{[1]}, y_t^{[2]}, \dots, y_t^{[p]}) \in \mathbb{R}^p$$

which matches the continuous-time system at the sampling points (in the sense that $\boldsymbol{y}_t = \boldsymbol{x}(t\delta)$) is governed by the system of nonlinear equations

$$\begin{aligned} y_{t+1}^{[1]} &= y_t^{[1]} + \delta(f(\boldsymbol{y}_t) + u_t) + \epsilon_{t+1} + d_{t+1}^{[1]}, \\ y_{t+1}^{[2]} &= y_t^{[2]} + \delta y_t^{[1]} + d_{t+1}^{[2]}, \\ &\cdots \\ y_{t+1}^{[p]} &= y_t^{[p]} + \delta y_t^{[p-1]} + d_{t+1}^{[p]}, \end{aligned} \tag{1.3}$$

where the noise terms ϵ_t are given by

$$\epsilon_t = \sigma(w(t\delta) - w((t-1)\delta)),$$

$w(t)$ being the standard Brownian motion generating the white noise in our original system, and the terms $\boldsymbol{d}_t := (d_t^{[1]}, d_t^{[2]}, \dots, d_t^{[p]})$ are "discretization-correction" terms clearly given by

$$\begin{aligned} d_{t+1}^{[1]} &= \int_{t\delta}^{(t+1)\delta} [f(\boldsymbol{x}(s)) - f(\boldsymbol{x}(t\delta))]\, ds, \\ d_{t+1}^{[2]} &= \int_{t\delta}^{(t+1)\delta} \left[x^{(p-1)}(s) - x^{(p-1)}(t\delta)\right] ds, \\ &\cdots \\ d_{t+1}^{[p]} &= \int_{t\delta}^{(t+1)\delta} [\dot{x}(s) - \dot{x}(t\delta)]\, ds. \end{aligned} \tag{1.4}$$

This choice of $\boldsymbol{d}_{t+1}$ ensures that the discrete-time system does in fact match the continuous time system at the sampling points. To simplify the expressions which follow, we will often refer to the quantities $y_t^{[1]}$ and $d_t^{[1]}$ simply as y_t and d_t, respectively. Note also that $\{\epsilon_t\}$ forms a sequence of independent identically distributed normal random variables, with first absolute moment $\gamma := \mathbf{E}[|\epsilon_t|] = \sigma\sqrt{2\delta/\pi}$.

The system (1.3) can be written more concisely in vector notation as

$$\boldsymbol{y}_{t+1} = \boldsymbol{y}_t(I + \delta B) + (\delta f(\boldsymbol{y}_t) + \delta u_t + \epsilon_{t+1})\boldsymbol{e}_1 + \boldsymbol{d}_{t+1}, \tag{1.5}$$

where B is the $p \times p$ shift matrix

$$B = \begin{bmatrix} 0 & 1 & 0 & \dots & 0 \\ 0 & 0 & 1 & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & 0 & \dots & 1 \\ 0 & 0 & 0 & \dots & 0 \end{bmatrix}$$

and $\boldsymbol{e}_1$ is the row vector $(1, 0, \dots, 0)$.

To control our system, we will use a reference model specified by the linear relation

$$\boldsymbol{z}_{t+1} = \boldsymbol{z}_t L, \quad L = I + \delta H, \tag{1.6}$$

where

$$H = \begin{bmatrix} h_1 & 1 & 0 & \dots & 0 \\ h_2 & 0 & 1 & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots \\ h_{p-1} & 0 & 0 & \dots & 1 \\ h_p & 0 & 0 & \dots & 0 \end{bmatrix}. \tag{1.7}$$

Note that the structure of the reference system (1.6) matches that of the discrete-time system (1.5), i.e., there always exists some $u_t \in \mathbb{R}$ such that (1.5) is equivalent to $\boldsymbol{y}_{t+1} = \boldsymbol{y}_t L + \boldsymbol{d}_{t+1}$. The reference system is in fact an Euler approximation to the continuous-time linear phase-space system $\dot{\boldsymbol{z}} = H\boldsymbol{z}$. Clearly, in order for it to be stable, the continuous-time system must also be stable; i.e., all eigenvalues of H must have negative real parts. Furthermore, δ must be sufficiently small (so that the approximation is "reasonably" good). We establish the maximal value of δ for which stability of (1.6) is guaranteed, along with a bound on the spectral radius of L, as follows.

Let $\{\lambda_i^L\}$ and $\{\lambda_i^H\}$ denote the sets of eigenvalues of L and H, respectively. It is easily seen that λ_i^H is an eigenvalue of H if and only if $1 + \delta\lambda_i^H$ is an eigenvalue of L. Let

$$c = \min_i \frac{|\mathrm{Re}(\lambda_i^H)|}{|\lambda_i^H|} > 0, \quad \delta_0 = \frac{c}{\max_i |\lambda_i^H|}, \tag{1.8}$$

and

$$h = \min_i \frac{|\lambda_i^H|(|\lambda_i^H| - |\mathrm{Im}(\lambda_i^H)|)}{|\mathrm{Re}(\lambda_i^H)|}. \tag{1.9}$$

It can then be shown, using an elementary geometric argument, that for all δ such that $0 \le \delta \le \delta_0$ and for each eigenvalue $\lambda_i^L = 1 + \delta\lambda_i^H$,

$$|\lambda_i^L| \le \rho := 1 - h\delta. \tag{1.10}$$

One possible choice of the quantities $\{h_j\}$ is

$$h_j = -\binom{p}{j} h^j, \quad j = 1, \dots, p,$$

for some $h > 0$. In this case, a direct computation shows that $\det(L - \lambda I) = (1 - \delta h - \lambda)^p$, so that L has a single eigenvalue $\lambda = 1 - \delta h$, with multiplicity p.

Our next step is to choose a control which will match the system dynamics (1.5) to the reference dynamics (1.6). If these were to be matched exactly, we would need to choose u_t so that

$$\delta f(\boldsymbol{y}_t) + \delta u_t + \epsilon_{t+1} + d_{t+1} = \delta h(\boldsymbol{y}_t)$$

or

$$u_t = h(\boldsymbol{y_t}) - f(\boldsymbol{y}_t) - (\epsilon_{t+1} + d_{t+1})/\delta. \tag{1.11}$$

Unfortunately, one cannot choose u_t in this manner. It must depend only on current and past observations of the system, and in (1.11) above, $f(\boldsymbol{y_t})$, ϵ_{t+1}, and d_{t+1} are unobservable at time t. We therefore use a simple filter to obtain an estimate of $f(\boldsymbol{y_t})$. Rather than making any assumptions on the form of $f(\cdot)$ and estimating parameters, we directly estimate the value of $f(\boldsymbol{y}_t)$ itself. Taking into account the fact that $\mathbf{E}\left[\epsilon_t\right] = 0$ and ignoring the presence of the discretization-correction terms $\boldsymbol{d}_t$, we can obtain from (1.3) an estimate ζ_{t-1} of $f(\boldsymbol{y}_{t-1})$ of the form

$$\zeta_{t-1} = (y_t - y_{t-1})/\delta - u_{t-1}$$

(recall that $y_t = y_t^{[1]}$). Since this filter is operating with a lag, we cannot compute ζ_t until time $t+1$. Hence, for control purposes, we rely on the continuity of $f(\cdot)$ and use ζ_{t-1} as an estimate of $f(\boldsymbol{y}_t)$.

Substituting our estimate into (1.11), and again replacing the terms ϵ_{t+1} and d_{t+1} with 0, we obtain the control law

$$u_t = h(\boldsymbol{y}_t) - \zeta_{t-1} = h(\boldsymbol{y}_t) - (y_t - y_{t-1})/\delta + u_{t-1}. \tag{1.12}$$

In terms of our original process (1.1), this control law takes the form

$$u_t = h(\boldsymbol{x}(t\delta)) - \left[x^{(p-1)}(t\delta) - x^{(p-1)}((t-1)\delta)\right]/\delta + u_{t-1}. \tag{1.13}$$

Since we cannot use this control law at time $t = 0$, we initialize the system by setting $u_0 = 0$.

This controller can be thought of as trying to eliminate any "external forces" (which are specified by the function $f(\cdot)$) and replacing them with the force which would be applied by the stable reference system were it at the current point of the phase space. With this in mind, we hope that the system will tend to "imitate" the behavior of the reference system. In particular, we could expect it to be stable around the origin.

The dynamics of our system (using this control law) are now given by the closed-loop equation (substituting (1.12) back into (1.5))

$$\begin{aligned}\boldsymbol{y}_{t+1} &= \boldsymbol{y}_t(I + \delta B) + (\delta f(\boldsymbol{y}_t) - \delta\zeta_{t-1})\boldsymbol{e}_1 + (\delta h(\boldsymbol{y}_t) + \epsilon_{t+1})\boldsymbol{e}_1 + \boldsymbol{d}_{t+1} \\ &= \boldsymbol{y}_t L + \delta(f(\boldsymbol{y}_t) - f(\boldsymbol{y}_{t-1}))\boldsymbol{e}_1 + (\epsilon_{t+1} - \epsilon_t)\boldsymbol{e}_1 + \boldsymbol{d}_{t+1} - d_t\boldsymbol{e}_1.\end{aligned} \tag{1.14}$$

The sequence $\{\boldsymbol{y}_t\}$ is not a Markov chain. However, it is easily seen (from (1.5) and (1.12)) that the sequence of vectors

$$Z_t = (\boldsymbol{y}_t, u_t) = (y_t, y_t^{[2]}, \ldots, y_t^{[p]}, u_t) \tag{1.15}$$

forms a (time-homogeneous) Markov chain.

2. The main result. Before stating the main result of this paper, we will require the following definitions.

Suppose that $\{X_t\}$ is a time-homogeneous Markov chain which takes values on the space $\mathbb{R}^q$. Let $\mathcal{B}(\mathbb{R}^q)$ denote the family of Borel sets in $\mathbb{R}^q$. Let $P^k(z, A)$ denote the k-step transition function of the Markov chain $\{X_t\}$, $P(z, A) = P^1(z, A)$. The Markov chain $\{X_t\}$ on $\mathbb{R}^q$ is said to be *ergodic* if there exists an invariant probability measure π on $\mathcal{B}(\mathbb{R}^q)$, that is,

$$\pi(A) = \int_{x\in\mathbb{R}^q} \pi(dx)P(x, A) \quad \text{for all } A \in \mathcal{B}(\mathbb{R}^q),$$

such that

$$\lim_{n\to\infty} \|P^n(x, \cdot) - \pi(\cdot)\|_{TV} = 0 \quad \text{for all } x \in \mathbb{R}^q,$$

where $\|\cdot\|_{TV}$ represents the total variation norm on signed measures on $\mathcal{B}(\mathbb{R}^q)$.

Our main result is the following theorem.

THEOREM 2.1. *Assume that the system* (1.1) *satisfies condition* (1.2), *and take any vector* $(h_1, \ldots, h_p)$ *such that all eigenvalues of the matrix* H *given by* (1.7) *have negative real parts. Suppose that the sampling interval* δ *is no greater than the quantity* δ_0 *given by* (1.8) *and satisfies the inequalities*

$$k_1(\delta) := \frac{\exp\{(\beta+1)\delta\} - 1 - (\beta+1)\delta}{(\beta+1)\delta} < 1 \tag{2.1}$$

and

$$\alpha := \delta\beta + \delta^2\beta\|H\|\varrho + \frac{2\varrho(k_4(\delta) + k_5(\delta))}{1 - k_1(\delta)} < 1, \tag{2.2}$$

where the quantities $k_4(\delta)$, $k_5(\delta)$, *and* ϱ *are given by*

$$k_4(\delta) = \delta k_1(\delta)(\|H\| + \beta), \quad k_5(\delta) = \delta k_1(\delta)\beta$$

and

$$\varrho = \frac{1}{\delta}\left(\frac{1}{h} + \frac{w_h}{h^2} + \cdots + \frac{w_h^{p-1}}{h^p}\right)$$

with

$$w_h = \sqrt{2}\left(\frac{p^3 - p}{3}\right)^{1/4}\left(p - 1 + \sum_{i=1}^{p} h_i^2\right)^{1/2}. \tag{2.3}$$

Then

(i) *the Markov chain* $\{Z_t\}$ *with control law* u_t *specified by* (1.12) *is ergodic and*

(ii) *under this control law, the continuous-time process* $\{\boldsymbol{x}(t)\}$ *satisfies*

$$\limsup_{t\to\infty} \mathbf{E}\left[\|\boldsymbol{x}(t)\|\right] \le k_7(\delta)\eta + k_8(\delta),$$

where

$$\eta = (1-\alpha)^{-1}\left((\sigma\sqrt{2\delta/\pi} + \delta|f(0)|)(1 + \delta\|H\|\varrho) + \frac{2k_6(\delta)\varrho}{1 - k_1(\delta)}\right),$$

$$k_6(\delta) = k_1(\delta)\sigma\sqrt{2\delta/\pi} + k_2(\delta),$$

$$k_7(\delta) = 1 + \frac{1+k_1(\delta)}{1-k_1(\delta)}\left(\delta(\|H\| + 2\beta)\right),$$

$$k_8(\delta) = \sigma\sqrt{8\delta/\pi} + k_2(\delta) + \frac{1+k_1(\delta)}{1-k_1(\delta)}(\sigma\sqrt{2\delta/\pi} + k_2(\delta)),$$

and

$$k_2(\delta) = \sqrt{8/(9\pi)}(\beta+1)\sigma\delta^{3/2}\exp\{(\beta+1)\delta\}.$$

Remark 1. The first part of Theorem 2.1 states that when the discrete-time controller (1.12) is applied to the continous-time system (1.1) with sampling interval δ, the state of the continuous-time system (and the controller) at the sampling times will approach a limiting distribution as time increases. The second part of the theorem places bounds on the deviation of the continuous-time system from the origin, thereby ensuring that the system will not behave "badly" in between the sampling times (this seems clear intuitively due to the smoothness of $f(\cdot)$).

Remark 2. The condition (2.1) will be satisfied if

$$\delta(\beta+1) < 1.2564. \tag{2.4}$$

By choosing a sufficiently small sampling interval δ, conditions (2.1) and (2.2) can always be met. Although this is a fast-sampling approach to control, which has some inherent disadvantages, the compromise between the level of accuracy of plant-knowledge and the sampling rate required for stability is an interesting issue which, to the authors' knowledge, is not well understood. We will not address this issue in this paper. However, the results obtained, in particular the required relationship between δ and β given by (2.4), suggest that this compromise is an issue worthy of further consideration.

Remark 3. The result can be extended to the case of noisy (but still complete) state measurements. Suppose that the controller only observes $\boldsymbol{y}'_t = \boldsymbol{y}_t + \boldsymbol{n}_t$, where $\{\boldsymbol{n}_t\}$ is a sequence of independently and indentically distributed (i.i.d.) random variables with covariance matrix $Q > 0$. Using the same control law (1.12), with $\boldsymbol{y}_t$ replaced by $\boldsymbol{y}'_t$, the sequence $\{Z_t = (\boldsymbol{y}_t, u_t, \boldsymbol{n}_t)\}$ is a Markov chain. If the quantities η, $k_6(\delta)$, and $k_8(\delta)$ are replaced with

$$\eta = (1-\alpha)^{-1}\Big[(\sigma\sqrt{2\delta/\pi} + \sqrt{\mathrm{tr}\ Q} + \delta|f(0)|)(1 + \delta\|H\|\varrho) + \frac{2k_6(\delta)\varrho}{1-k_1(\delta)} + \delta\|H\|\varrho\sqrt{\mathrm{tr}\ Q}\Big],$$

$$k_6(\delta) = k_1(\delta)\sigma\sqrt{2\delta/\pi} + k_2(\delta) + (2 + \delta\|H\|)k_1(\delta)\sqrt{\mathrm{tr}\ Q},$$

and

$$k_8(\delta) = \sigma\sqrt{8\delta/\pi} + k_2(\delta) + \frac{1+k_1(\delta)}{1-k_1(\delta)}\left(\sigma\sqrt{2\delta/\pi} + k_2(\delta) + 2\sqrt{\mathrm{tr}\ Q}\right),$$

then the results of Theorem 2.1 still hold. This means that the conditions for stability of the closed-loop system remain the same, but the bounds on the first absolute moment of the Markov chain (and on the first absolute moment of the continuous-time process) increase.

Remark 4. The result can also be extended to the multidimensional case where $y_t^{[i]} \in \mathbb{R}^q$, $u_t \in \mathbb{R}^q$, and $w(t)$ is a q-dimensional Brownian motion.

3. Proofs. First we bound $\mathbf{E}\left[\|\boldsymbol{d}_t\|\right]$ as a function of δ. Using this bound we will find a limiting upper bound for $\eta_t := \mathbf{E}\left[\|\boldsymbol{y}_t\|\right]$. This is a form of stability in itself. Then we will show that the Markov chain (1.15) is irreducible and aperiodic and has the (weak) Feller property. This allows us to use results from [8] to strengthen the stability result by establishing ergodicity of the chain.

3.1. Bounds on moments. In order to study the behavior of the discretization-correction terms $\boldsymbol{d}_t$, we establish a bound on the first absolute moment of the difference between processes $\boldsymbol{v}(t)$ and $\boldsymbol{n}(t)$ (starting at the same point $\boldsymbol{v}(0) = \boldsymbol{n}(0)$) which satisfy the equations

$$d\boldsymbol{v}(t) = G(\boldsymbol{v}(t))dt + \sigma\boldsymbol{e}_1 dw(t) \tag{3.1}$$

and

$$\boldsymbol{n}(t) - \boldsymbol{n}(0) = G(\boldsymbol{n}(0))t + \sigma\boldsymbol{e}_1 w(t), \tag{3.2}$$

where $G(\cdot)$ satisfies the global Lipschitz condition $\|G(a) - G(b)\| \leq \kappa\|a - b\|$ and $w(t)$ is a standard Brownian motion. We examine the error $\boldsymbol{v}(t) - \boldsymbol{n}(t)$ by integrating (3.1) and subtracting (3.2) to obtain

$$v(t) - n(t) = \int_0^t \left(G(\boldsymbol{v}(s)) - G(\boldsymbol{n}(s)) + G(\boldsymbol{n}(s)) - G(\boldsymbol{n}(0))\right) ds.$$

Taking norms and expectations, defining $Q(t) = \mathbf{E}\left[\sup_{0\leq s\leq t} \|\boldsymbol{v}(s) - \boldsymbol{n}(s)\|\right]$, and using the Lipschitz property of the function $G(\cdot)$, we obtain

$$\begin{aligned} Q(t) &\leq \kappa \int_0^t \mathbf{E}\left[\sup_{0\leq u\leq s} \|\boldsymbol{v}(s) - \boldsymbol{n}(s)\|\right] ds + \kappa\mathbf{E}\left[\sup_{0\leq u\leq t} \int_0^u \|sG(\boldsymbol{v}(0)) + \sigma\boldsymbol{e}_1 w(s)\| ds\right] \\ &= \kappa \int_0^t Q(s)ds + \frac{\kappa t^2}{2}\|G(\boldsymbol{v}(0))\| + \kappa\sigma \int_0^t \mathbf{E}\left[|w(s)|\right] ds \\ &= \kappa \int_0^t Q(s)ds + \frac{\kappa t^2}{2}\|G(\boldsymbol{v}(0))\| + \sqrt{\frac{8}{9\pi}}\kappa\sigma t^{3/2}. \end{aligned}$$

Using the Gronwall–Bellman inequality (see, e.g., [3]), we obtain the bound

$$Q(t) \leq \kappa\|G(\boldsymbol{v}_0)\| \left(\frac{\exp^{\kappa t} - 1 - \kappa t}{\kappa^2}\right) + \sqrt{\frac{8}{9\pi}}\kappa\sigma t^{3/2} \exp\{\kappa t\}. \tag{3.3}$$

Applying this result to our original process (1.1) and its discretization (1.3) (with $G(\boldsymbol{y}_t) = \boldsymbol{y}_t B + (f(\boldsymbol{y}_t) + u_t)\boldsymbol{e}_1$ so that $\kappa = \beta + 1$), we obtain the bound on the conditional expectation $\mathbf{E}\left[\|\boldsymbol{d}_{t+1}\| \mid \boldsymbol{y}_t, u_t\right]$ given by

$$\mathbf{E}\left[\|\boldsymbol{d}_{t+1}\| \mid \boldsymbol{y}_t, u_t\right] \leq k_1(\delta)\delta\|\boldsymbol{y}_t B + f(\boldsymbol{y}_t)\boldsymbol{e}_1 + u_t\boldsymbol{e}_1\| + k_2(\delta), \tag{3.4}$$

where the quantities $k_1(\delta)$ and $k_2(\delta)$ are defined in Theorem 2.1. For the sake of brevity, we will subsequently suppress the explicit reference to δ in the quantities $k_j(\delta)$, so that, for instance, when we refer to k_1 we really mean $k_1(\delta)$. Substituting the control (1.12) into (3.4), we obtain

$$\begin{aligned} \mathbf{E}\left[\|\boldsymbol{d}_{t+1}\| \mid \boldsymbol{y}_t, u_t\right] &\leq \delta k_1\|\boldsymbol{y}_t B + (f(\boldsymbol{y}_t) + h(\boldsymbol{y}_t) - \zeta_{t-1})\boldsymbol{e}_1\| + k_2 \\ &= \delta k_1\|\boldsymbol{y}_t H + (f(\boldsymbol{y}_t) - f(\boldsymbol{y}_{t-1}) + f(\boldsymbol{y}_{t-1}) - \zeta_{t-1})\boldsymbol{e}_1\| + k_2 \\ &= \delta k_1\|\boldsymbol{y}_t H + (f(\boldsymbol{y}_t) - f(\boldsymbol{y}_{t-1}))\boldsymbol{e}_1\| + k_1\|(\epsilon_t + d_t)\boldsymbol{e}_1\| + k_2. \end{aligned}$$

We now take expectations to get (recall that $\eta_t = \mathbf{E}\left[\|\boldsymbol{y}_t\|\right]$)

$$\begin{aligned}\mathbf{E}\left[\|\boldsymbol{d}_{t+1}\|\right] &\leq \delta k_1\big(\|H\|\mathbf{E}\left[\|\boldsymbol{y}_t\|\right] + \beta\mathbf{E}\left[\|\boldsymbol{y}_t - \boldsymbol{y}_{t-1}\|\right]\big) + k_1\gamma + k_1\mathbf{E}\left[\|\boldsymbol{d}_t\|\right] + k_2 \\ &\leq \delta k_1((\|H\| + \beta)\eta_t + \beta\eta_{t-1}) + k_1\gamma + k_1\mathbf{E}\left[\|\boldsymbol{d}_t\|\right] + k_2 \\ &\leq k_4\eta_t + k_5\eta_{t-1} + k_6 + k_1\mathbf{E}\left[\|\boldsymbol{d}_t\|\right], \qquad (3.5)\end{aligned}$$

where k_4, k_5, and k_6 are the quantities defined in Theorem 2.1 (note their dependence on δ).

Iterating the inequality (3.5), we find that

$$\mathbf{E}\left[\|\boldsymbol{d}_{t+1}\|\right] \leq k_1^t\mathbf{E}\left[\|\boldsymbol{d}_1\|\right] + \sum_{j=0}^{t-1} k_1^j[k_4\eta_{t-j} + k_5\eta_{t-j-1} + k_6]. \qquad (3.6)$$

We now set $r_t = \delta f(\boldsymbol{y}_{t-1})\boldsymbol{e}_1 + \epsilon_t\boldsymbol{e}_1$ and iterate the closed-loop system equation (1.14) to obtain

$$\begin{aligned}\boldsymbol{y}_{t+1} &= \boldsymbol{y}_1 L^t + \sum_{j=0}^{t-1}(r_{t+1-j} - r_{t-j} + \boldsymbol{d}_{t+1-j} - d_{t-j}^{[1]}\boldsymbol{e}_1)L^j \\ &= \left(\sum_{j=1}^{t-1} r_{t+1-j}L^{j-1}L - \sum_{j=1}^{t-1} r_{t+1-j}L^{j-1}\right) \\ &\qquad + \boldsymbol{y}_1 L^t + r_{t+1} - r_1 L^{t-1} + \sum_{j=0}^{t-1}(\boldsymbol{d}_{t+1-j} - d_{t-j}^{[1]}\boldsymbol{e}_1)L^j \\ &= \boldsymbol{y}_1 L^t + r_{t+1} - r_1 L^{t-1} + \delta H\sum_{j=1}^{t-1} r_{t+1-j}L^{j-1} + \sum_{j=0}^{t-1}(\boldsymbol{d}_{t+1-j} - d_{t-j}^{[1]}\boldsymbol{e}_1)L^j. \qquad (3.7)\end{aligned}$$

Using the inequality (3.5), we can bound the first absolute moment of the last sum on the right-hand side of (3.7) as follows (setting $\eta_{-1} = 0$):

$$\begin{aligned}\mathbf{E}\left[\left\|\sum_{j=0}^{t-1}(\boldsymbol{d}_{t+1-j} - d_{t-j}^{[1]}\boldsymbol{e}_1)L^j\right\|\right] &\leq \sum_{j=0}^{t-1}\|L^j\|\left(\mathbf{E}\left[\|\boldsymbol{d}_{t+1-j}\|\right] + \mathbf{E}\left[\|\boldsymbol{d}_{t-j}\|\right]\right) \\ &\leq \sum_{k=0}^{t-1-j} k_1^k[k_4\eta_{t-j-k} + (k_4 + k_5)\eta_{t-j-k-1} + k_5\eta_{t-j-k-2} + 2k_6] \\ &\quad + \sum_{j=0}^{t-1}\|L^j\|\left((k_1^{t-j} + k_1^{t-j-1})\mathbf{E}\left[\|\boldsymbol{d}_1\|\right]\right). \qquad (3.8)\end{aligned}$$

Recall that $u_0 = 0$, so it follows from inequality (3.4) that

$$\mathbf{E}\left[\|\boldsymbol{d}_1\|\right] \leq \delta k_1(\eta_0(1 + \beta) + \omega) + k_2, \qquad (3.9)$$

where $\omega = |f(0)|$. Taking norms and expectations on both sides of (3.7) and substituting (3.8) and (3.9), we have

$$\eta_{t+1} \leq \eta_1\|L^t\| + \delta\beta\eta_t + (\delta\beta\eta_0 + \gamma + \delta\omega)\|L^{t-1}\| + \gamma + \delta\omega$$

$$
\begin{aligned}
&+\delta\|H\|\sum_{j=0}^{t-1}\|L^{j-1}\|(\delta\beta\eta_{t-j}+\gamma+\delta\omega)\\
&+\sum_{j=0}^{t-1}\|L^j\|(k_1^{t-j}+k_1^{t-j-1})(k_1\delta(\eta_0(1+\beta)+\omega)+k_2)\\
&+\sum_{j=0}^{t-1}\|L^j\|\sum_{k=0}^{t-1-j}k_1^k[k_4\eta_{t-j-k}+(k_4+k_5)\eta_{t-j-k-1}+k_5\eta_{t-j-k-2}+2k_6]. \qquad (3.10)
\end{aligned}
$$

Now we need to bound the norms of L^k, $k=0,1,2,\ldots$. If the matrix L were normal (i.e., $LL^*=L^*L$, where L^* is the conjugate-transpose of L), then we would have $\|L^k\|\le\rho^k$, ρ being the spectral radius (maximum of magnitudes of eigenvalues) of L bounded by (1.10). Unfortunately, the matrix $L=I+\delta H$ is not normal, so we will have to make use of a different bound.

If UTU^* is a Schur decomposition of L (i.e., T is upper triangular and U is unitary), then the matrix T can be expressed as the sum of a diagonal matrix and a strictly upper triangular matrix : $T=D+M$. Let $\mathcal{M}$ be the set of matrices M obtained from every possible Schur decomposition of L. The quantity $\Delta(L)=\inf_{M\in\mathcal{M}}\|M\|$ can be used as a measure of nonnormality of the matrix M. Let $\|A\|_\epsilon$ denote the Euclidean norm of the matrix $A=[a_{i,j}]$ defined by

$$\|A\|_\epsilon=\left(\sum_{i,j}a_{i,j}^2\right)^{1/2}.$$

Then $\Delta(L)$ satisfies (see [5, Theorem 1])

$$
\begin{aligned}
\Delta(L)&\le\left(\frac{p^3-p}{12}\right)^{1/4}\sqrt{\|L^*L-LL^*\|_\epsilon}=\left(\frac{p^3-p}{12}\right)^{1/4}\sqrt{\delta^2\|HH^*-H^*H\|_\epsilon}\\
&\le\left(\frac{p^3-p}{12}\right)^{1/4}\delta\sqrt{2\|H\|_\epsilon^2}=\left(\frac{p^3-p}{3}\right)^{1/4}\delta\sqrt{2}\left(p-1+\sum_{i=1}^p h_i^2\right)^{1/2}\le\delta w_h,
\end{aligned}
$$

where w_h is defined by (2.3).

As a direct consequence of Theorem 2 of [5], we have the following lemma.

LEMMA 3.1. *Let $m=w_h\delta$, with w_h defined by* (2.3). *Then for all integers $k\ge1$, we have $\|L^k\|\le\varrho_k$, where*

$$\varrho_k=\rho^k+\binom{k}{1}\rho^{k-1}m+\cdots+\binom{k}{p-1}\rho^{k-p+1}m^{p-1} \qquad (3.11)$$

and ρ is the bound on the spectral radius of L defined by (1.10).

Summing the inequality (3.11), we obtain the bound

$$
\begin{aligned}
\sum_{k=0}^\infty\|L^k\|\le\varrho:=\sum_{k=0}^\infty\varrho_k&=\frac{1}{1-\rho}+m\frac{d}{d\rho}\left(\frac{1}{1-\rho}\right)+\cdots+\frac{m^{p-1}}{(p-1)!}\frac{d^{p-1}}{d\rho^{p-1}}\left(\frac{1}{1-\rho}\right)\\
&\le\frac{1}{\delta h}+\frac{\delta w_h}{(\delta h)^2}+\cdots+\frac{(\delta w_h)^{p-1}}{(\delta h)^p}=\frac{1}{\delta}\left(\frac{1}{h}+\frac{w_h}{h^2}+\cdots+\frac{w_h^{p-1}}{h^p}\right).
\end{aligned}
$$

In order to bound the behavior of η_t, we will also make use of the following version of the discrete-time Gronwall–Bellman lemma.

LEMMA 3.2. *Suppose that* $\{b_t, t = 0, 1, \ldots\}$, $\{\alpha_t, t = 0, 1, \ldots\}$, *and* $\{g_t, t = 0, 1, \ldots\}$ *are sequences of nonnegative real values such that*

$$b_{t+1} \leq \sum_{j=0}^{t} \alpha_j b_{t-j} + g_t, \tag{3.12}$$

with $\sum_{j=0}^{\infty} \alpha_j \leq 1 - \epsilon < 1$. *If* $\{g_t\}$ *is a bounded sequence and* $\lim_{t\to\infty} g_t = g$, *then*

$$\limsup_{t\to\infty} b_t \leq \frac{g}{\epsilon}.$$

It is easily shown that the inequality (3.10) can be expressed in the form (3.12) with

$$g_t = (\gamma + \delta\omega) + (\delta\beta\eta_0 + \gamma + \delta\omega)\|L^{t-1}\| + \eta_1\|L^t\| + \delta\|H\|\varrho(\gamma + \delta\omega) + \frac{2k_6\varrho}{1 - k_1}$$
$$+ \sum_{j=0}^{t-1} \|L^j\|(k_1^{t-j} + k_1^{t-j-1})(k_1\delta(\eta_0(1 + \beta) + \omega) + k_2)$$

so that

$$\lim_{t\to\infty} g_t = g := (\gamma + \delta\omega)(1 + \delta\|H\|\varrho) + \frac{2k_6\varrho}{1 - k_1}.$$

We can sum the coefficients $\{\alpha_j,\ j = 0, 1, \ldots\}$ of $\{\eta_{t-j},\ j = 0, 1, \ldots\}$ in (3.10) to obtain the bound (using (3.12))

$$\sum_{j=0}^{t} \alpha_j \leq \delta\beta + \delta^2\|H\|\beta \sum_{j=0}^{t-2} \|L^j\| + \sum_{j=0}^{t-1} \|L^j\| \sum_{k=0}^{t-1-j} k_1^k(2k_4 + 2k_5)$$
$$\leq \delta\beta + \delta^2\|H\|\beta\varrho + \frac{2\varrho(k_4 + k_5)}{1 - k_1} = \alpha, \tag{3.13}$$

where α is defined in the statement of Theorem 2.1.

Applying Lemma 3.2, we have, if $\alpha < 1$,

$$\mathbf{E}\left[\|\boldsymbol{y}_t\|\right] \leq b_t,$$

with

$$\limsup_{t\to\infty} b_t = \eta := \frac{g}{1 - \alpha}. \tag{3.14}$$

In addition, we can rewrite (1.3) to get

$$u_t = \delta^{-1}(y_{t+1} - y_t - f(\boldsymbol{y}_t)\delta - \epsilon_{t+1} - d_{t+1}).$$

It follows directly from this representation of u_t, the Lipschitz property of $f(\cdot)$, and representation (1.4) that if $\mathbf{E}\left[\|\boldsymbol{y}_t\|\right]$ is bounded, then so is $\mathbf{E}\left[\|u_t\|\right]$. Consequently, if $\alpha < 1$, then $\mathbf{E}\left[\|Z_t\|\right] \leq \mathbf{E}\left[\|\boldsymbol{y}_t\|\right] + \mathbf{E}\left[\|u_t\|\right]$ is bounded.

3.2. Bounds for the continuous-time process. In the previous subsection we established bounds on the first absolute moments of the Markov chain $\{Z_t\}$. Clearly, the behavior of the continuous-time process $\{\boldsymbol{x}(t)\}$ at times other than the sampling instants $\{k\delta,\ k = 0, 1, 2, \ldots\}$ is also of importance. Intuitively, one might expect that due to the smoothness of $f(\cdot)$, the process will not be "badly" behaved in these time intervals. We construct a bound as follows.

Let us consider the process $\boldsymbol{x}(t)$ restricted to the interval $\mathcal{T}_k := [k\delta, (k+1)\delta)$. For all $t \in \mathcal{T}_k$, we have the integral representation

$$\begin{aligned}\boldsymbol{x}(t) &= \boldsymbol{x}(k\delta) + \int_{k\delta}^{t} G_k(\boldsymbol{x}(s))ds + (w(t) - w(k\delta))\boldsymbol{e}_1 \\ &= \boldsymbol{x}(k\delta) + (t - k\delta)G_k(\boldsymbol{x}(k\delta)) + \sigma(w(t) - w(k\delta))\boldsymbol{e}_1 + E(t),\end{aligned}$$

where

$$G_k(\boldsymbol{x}) = \boldsymbol{x}B + (f(\boldsymbol{x}) + u_k)\boldsymbol{e}_1 \tag{3.15}$$

and $E(t)$ is the correction term. Taking norms, suprema over the interval $\mathcal{T}_k$, and expectations, we obtain

$$\begin{aligned}\mathbf{E}\left[\sup_{t\in\mathcal{T}_k} \|\boldsymbol{x}(t)\|\right] \le \mathbf{E}\left[\|\boldsymbol{x}(k\delta)\|\right] + \delta\mathbf{E}\left[\|G_k(\boldsymbol{x}(k\delta))\|\right] + \sigma\mathbf{E}\left[\sup_{t\in\mathcal{T}_k} |w(t) - w(k\delta)|\right] \\ +\mathbf{E}\left[\sup_{t\in\mathcal{T}_k} \|E(t)\|\right].\end{aligned}$$

From (3.3) (with $Q(t) = \mathbf{E}\left[\sup \|E(t)\|\right]$) we have

$$\mathbf{E}\left[\sup_{t\in\mathcal{T}_k} \|E(t)\|\right] \le \delta k_1 \mathbf{E}\left[\|G_k(\boldsymbol{x}(k\delta))\|\right] + k_2,$$

and using the standard argument based on the reflection principle, it can be shown that

$$\mathbf{E}\left[\sup_{t\in\mathcal{T}_k} |w(t) - w(k\delta)|\right] \le \sqrt{8\delta/\pi}.$$

Hence,

$$\begin{aligned}\mathbf{E}\left[\sup_{t\in\mathcal{T}_k} \|\boldsymbol{x}(t)\|\right] \le \mathbf{E}\left[\|\boldsymbol{x}(k\delta)\|\right] + \delta\mathbf{E}\left[\|G_k(\boldsymbol{x}(k\delta))\|\right] + \sigma\sqrt{8\delta/\pi} \\ +\delta k_1\mathbf{E}\left[\|G_k(\boldsymbol{x}(k\delta)\|\right] + k_2.\end{aligned} \tag{3.16}$$

Substituting the equation

$$u_k = h(\boldsymbol{x}(k\delta)) - f(\boldsymbol{x}((k-1)\delta)) - (\epsilon_k + d_k)/\delta$$

into (3.15) and using (3.4), we have (recalling that $\eta_k = \mathbf{E}\left[\|\boldsymbol{x}(k\delta)\|\right]$)

$$\begin{aligned}\mathbf{E}\left[\|G_k(\boldsymbol{x}(k\delta))\|\right] &= \mathbf{E}[\|\boldsymbol{x}(k\delta)B + f(\boldsymbol{x}(k\delta))\boldsymbol{e}_1 - f(\boldsymbol{x}((k-1)\delta))\boldsymbol{e}_1 \\ &\quad +h(\boldsymbol{x}(k\delta))\boldsymbol{e}_1 - (\epsilon_k + d_k)\boldsymbol{e}_1/\delta\|] \\ &\le \|H\|\eta_k + \beta\eta_k + \beta\eta_{k-1} + \sigma\sqrt{2/(\pi\delta)} + \mathbf{E}\left[|d_k|\right]/\delta \\ &\le (\|H\| + \beta)\eta_k + \beta\eta_{k-1} + \sigma\sqrt{2/(\pi\delta)} \\ &\quad +k_1\mathbf{E}\left[\|G_{k-1}(\boldsymbol{x}((k-1)\delta))\|\right] + k_2/\delta.\end{aligned}$$

Multiplying by δ and taking the limit superior on both sides (using (3.14)), we have

$$\limsup_{k\to\infty} \delta\mathbf{E}\left[\|G_k(\boldsymbol{x}(k\delta))\|\right] \le (1-k_1)^{-1}(\delta(\|H\|+2\beta)\eta+\sigma\sqrt{2\delta/\pi}+k_2).$$

Substituting this expression into (3.16) and again taking limits superior on both sides, we find that

$$\begin{aligned}\limsup_{k\to\infty}\mathbf{E}\left[\sup_{t\in\mathcal{T}_k}\|\boldsymbol{x}(t)\|\right] &\le \eta+\sigma\sqrt{8\delta/\pi}+k_2\\ &+\frac{1+k_1}{1-k_1}\left(\delta(\|H\|+2\beta)\eta+\sigma\sqrt{2\delta/\pi}+k_2\right)=k_7\eta+k_8.\end{aligned}$$

As one might expect, this quantity approaches η (cf. (3.14)) as δ approaches 0. This is consistent with the intuitive argument that as the sampling intervals shorten, within each interval the continuous-time process has less time to deviate from the starting point.

The second part of Theorem 2.1 follows from the fact that

$$\limsup_{t\to\infty}\mathbf{E}\left[\|\boldsymbol{x}(t)\|\right] \le \limsup_{k\to\infty}\sup_{t\in\mathcal{T}_k}\mathbf{E}\left[\|\boldsymbol{x}(t)\|\right] \le \limsup_{k\to\infty}\mathbf{E}\left[\sup_{t\in\mathcal{T}_k}\|\boldsymbol{x}(t)\|\right].$$

3.3. Ergodicity. To prove that the chain (1.15) is ergodic, we first need to establish several further properties of the chain.

It is a well-known fact that solutions of stochastic differential equations for which the coefficients satisfy the Lipschitz condition (1.2) also satisfy the Feller property (see, for instance, [9, p. 126]). It is a relatively simple matter to establish the (weak) Feller property for the chain (1.15), since the first p elements of the chain are simply successive samplings of the solution of a stochastic differential equation, and the distribution of the last element (the control term) at time $(t+1)$ depends continuously on the state of the chain at time t.

We will also show that the chain $\{Z_t\}$ is irreducible with respect to μ^{p+1}, the $(p+1)$-dimensional Lebesgue measure, that is,

$$\text{(3.17)}\quad \mu^{p+1}(A)>0 \Rightarrow \sum_{k=1}^{\infty}P^k(x,A)>0 \qquad \text{for all } x\in\mathbb{R}^q, \text{for all } A\in\mathcal{B}(\mathbb{R}^{p+1}),$$

and that the chain is aperiodic. The following lemma will assist us in doing this.

LEMMA 3.3. *Let $\{X_t,\ t=0,1,2,\dots\}$ be a time-homogeneous Markov chain taking values in $\mathbb{R}^q$. Suppose that for some $k>0$ and for each initial value $X_0\in\mathbb{R}^q$, X_k has a probability density which is positive everywhere in $\mathbb{R}^q$. Then the chain is μ^q-irreducible and aperiodic.*

Proof. Relation (3.17) clearly holds for $\phi=\mu^q$ since $P^k(x,\cdot)$ has a positive density. Aperiodicity follows from the observation that, for any $y\in\mathbb{R}^q$, $P^{k+1}(y,\cdot)$ has the same property due to the Chapman–Kolmogorov equation, and hence $P^k(y,\cdot)$ and $P^{k+1}(y,\cdot)$ are equivalent measures, which precludes any periodic behavior. □

In order to use this lemma, first note that $\boldsymbol{y}_1$ has a conditional probability density everywhere-positive in $\mathbb{R}^p$ (for each $Z_0=(\boldsymbol{y}_0,u_0)$). To see this, recall that $\boldsymbol{y}_1=\boldsymbol{x}(\delta)$ is simply the solution of the stochastic differential equation (1.1) at the fixed time $t=\delta$. By Girsanov's theorem (see, e.g., [9]), the distribution of this solution (in the space $C_p[0,\delta]$ of $\mathbb{R}^p$-valued continuous functions) is equivalent to that of the solution $\tilde{\boldsymbol{x}}(t)$ of the system

$$\begin{aligned} d\tilde{x}_1(t) &= \sigma dw(t), \\ d\tilde{x}_j(t) &= \tilde{x}_{j-1}(t)dt, \qquad j = 2, \dots, p. \end{aligned}$$

Therefore the distributions of $\boldsymbol{y}_1$ and $\tilde{\boldsymbol{x}}(\delta)$ are also equivalent, being the projections of equivalent measures. Furthermore, it can be shown (see, e.g., Lemma 3.2 of [10]) that $\tilde{\boldsymbol{x}}(t)$ has a nondegenerate p-variate Gaussian distribution, and hence has a density which is positive everywhere. It is then a direct consequence of the Radon–Nikodym theorem (see, e.g., [1]) that the density of $\boldsymbol{y}_1$ has the same property.

Now we will show that the two-step transition probabilities of the chain (1.15) have everywhere-positive densities in $\mathbb{R}^{p+1}$ (in fact the one-step transition functions are degenerate). From the control law (1.12), we know that given any $(\boldsymbol{y}_0, u_0)$, u_1 is a linear function of $\boldsymbol{y}_1$. This implies that, given any $(\boldsymbol{y}_0, u_0)$, the conditional distribution of $(\boldsymbol{y}_1, u_1)$ is concentrated on the hyperplane

$$u = \boldsymbol{a} \cdot \boldsymbol{y} + \delta^{-1}\boldsymbol{e}_1 \cdot \boldsymbol{y}_0 + u_0,$$

$$\boldsymbol{a} = (h_1 - \delta^{-1}, h_2, \dots, h_p)$$

and has an everywhere-positive density with respect to the respective p-dimensional volume measure on this hyperplane. Hence the random variable $v_1 = \delta^{-1}\boldsymbol{e}_1 \cdot \boldsymbol{y}_1 + u_1$ also has a (conditional) density ν_{y_0,u_0} which is positive everywhere on the real line.

The same argument shows that the conditional distribution of $(\boldsymbol{y}_2, u_2)$ given $(\boldsymbol{y}_1, u_1)$ is concentrated on the hyperplane $u = \boldsymbol{a} \cdot \boldsymbol{y} + v_1$ and also has a density on this hyperplane which is everywhere positive. Hence the conditional distribution of $(\boldsymbol{y}_2, u_2)$ given v_1, being a mixture of such distributions, also has a density $f_{v_1}(\boldsymbol{y}, u)$ which is positive everywhere on the hyperplane. From this it follows that the joint conditional distribution of $(\boldsymbol{y}_2, u_2)$ given the initial state $(\boldsymbol{y}_0, u_0)$ has a density (with respect to μ^{p+1}) which is proportional to the product $f_v(\boldsymbol{y}, u)\nu_{y_0,u_0}(v)$, with $v = \delta^{-1}\boldsymbol{e}_1 \cdot \boldsymbol{y} + u$. This density is clearly positive everywhere in $\mathbb{R}^{p+1}$.

Applying Lemma 3.3 (with $k = 2$), we see that the chain (1.15) is irreducible and aperiodic.

In addition, we have already seen that the first absolute moments $\mathbf{E}[\|Z_t\|]$ are bounded. It follows then from Chebyshev's inequality that the chain must be bounded in probability, that is, its transition probability functions are tight: for any $\epsilon > 0$ and any $x \in \mathbb{R}^q$, there exists a compact set C such that

$$\liminf_{k\to\infty} P^k(x, C) \geq 1 - \epsilon.$$

Finally, having established that the chain $\{Z_t\}$ is an irreducible, aperiodic Feller chain which is bounded in probability, we can apply Theorems 6.0.1 (iii) and 18.0.2 (i) of [8] to see that the chain is ergodic. This completes the proof of Theorem 2.1.

4. Simulation. To illustrate our results, we simulate the control of a particle subjected to a force (in one dimension). This force consists of a constant component, a frictional component which is proportional to velocity, a nonlinearity, and an external control. More precisely, we consider the second order ($p = 2$) system specified by

$$f(x, \dot{x}) = 2 - 0.5\dot{x} + 10\max(0, (1 - |x - 6|)),$$

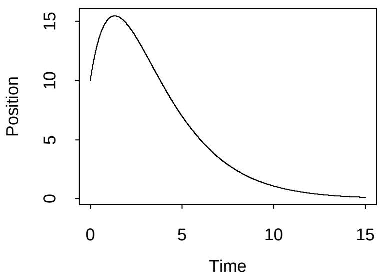

FIG. 4.1. *Position vs. time.*

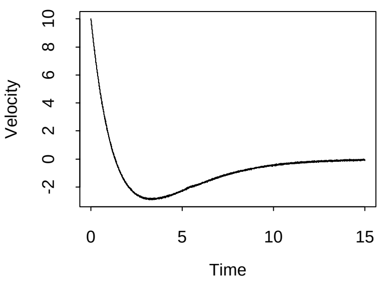

FIG. 4.2. *Velocity vs. time.*

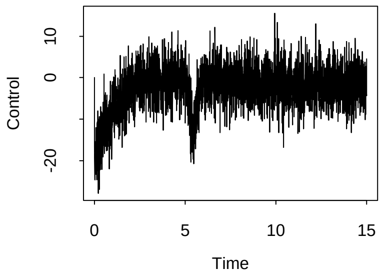

FIG. 4.3. *Control vs. time.*

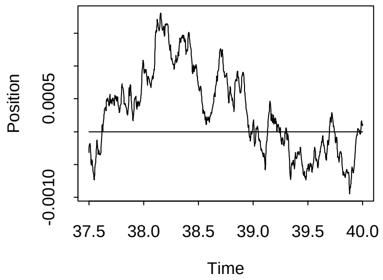

FIG. 4.4. *Position vs. time (small-scale).*

with noise intensity $\sigma = 0.3$ and sampling interval $\delta = 0.005$. The sharp nonlinearity around the point $x = 6$ is included so as to test the adaptive behavior of the controller and to verify stability of the closed-loop system in the presence of such irregularities (recall that the only information available to the controller is the order of the system and a Lipschitz constant associated with the function $f(\cdot,\cdot)$). We use the reference system specified by

$$h(x, \dot{x}) = -\dot{x} - x/4,$$

so that the matrix H has one eigenvalue $\lambda_H = -1/2$ with multiplicity two, and $\|H\| \simeq 1.4254$. This choice of reference system is arbitrary (subject to its stability, of course). Clearly, by choosing a reference system with different eigenvalues, our closed-loop system could be made to exhibit different characteristics, such as a different rate of convergence to the stable regime, more or less control effort expended, etc. It is easily verified that the system and reference system satisfy the conditions of Theorem 2.1, with $\beta = 10$, $k_1(\delta) \simeq 0.3332$, $\delta_0 = 2$, and $h = 1/2$. Figures 4.1 and 4.2 display position and velocity as a function of time for a particular realization of the controlled system. The "settling down" behavior which becomes apparent as time increases is exactly what Theorem 2.1 leads us to expect.

Figure 4.3 illustrates the control action (specified by (1.12)) used to stabilize the system. The adaptive action of the controller becomes apparent just after the time $t = 5$, when the state enters the region $5 \le x \le 7$. The small-scale plot of position for $37.5 \le t \le 40$ given in Figure 4.4 shows that the controller does indeed restrict the system to a narrow neighborhood around the origin as time increases.

The result appears to be quite conservative, since the sampling rate requirements can be relaxed significantly without destabilizing the system. In the example above, the maximal value of δ which satisfies the condition (2.2) is approximately 0.0056.

However, simulations indicate that the critical value of δ for which the system becomes unstable is between 1.5 and 1.6. In part, this could be explained by the fact that the system only spends a minimal amount of time in the region of the nonlinearity ($5 \leq x \leq 7$), so the "effective Lipschitz constant" could be much smaller than 10. For systems in which $f(\cdot)$ varies more around 0, we could expect a smaller discrepancy between the critical value of δ determined by (2.2) and the critical value indicated by simulation.

Acknowledgment. The first author is grateful to Kais Hamza for valuable discussions and guidance during the early stages of this research.

ON THE OBSERVABILITY INEQUALITIES FOR EXACT CONTROLLABILITY OF WAVE EQUATIONS WITH VARIABLE COEFFICIENTS*

PENG-FEI YAO†

Abstract. This paper deals with boundary exact controllability for the dynamics governed by the wave equation with nonconstant coefficients in the principal part, subject to Dirichlet or Neumann boundary controls. The observability inequalities are established by the Riemannian geometry method under some geometric condition for the Dirichlet problem and for the Neumann problem, respectively. Next, a number of nontrivial examples are presented to verify the observability inequality. In particular, a counterexample is given without boundary exact controllability, where the control is exerted on the whole boundary.

Key words. wave equation, exact controllability, Riemannian manifold, Hessian comparison theorem, geometric optics

1. Introduction.

Let Ω be a bounded domain in R^n with smooth boundary $\partial\Omega{=}\Gamma$. It is assumed that Γ consists of two parts: Γ_0 and Γ_1, $\Gamma_0\cup\Gamma_1{=}\Gamma$, with Γ_0 nonempty and relatively open in Γ. In the cylinder $\Omega\times(0,T)$, we consider the exact controllability for the mixed problem

$$\begin{cases} y_{tt}-\displaystyle\sum_{ij=1}^{n}\frac{\partial}{\partial x_i}\left(a_{ij}(x)\frac{\partial y}{\partial x_j}\right)=0 \quad \text{in} \quad \Omega\times(0,T),\\ y(x,0)=y^0(x), \quad y_t(x,0)=y^1(x) \quad \text{in} \quad \Omega, \end{cases} \tag{1.1}$$

$$y=0 \quad \text{in} \quad \Gamma_1\times(0,T), \qquad y=v \quad \text{in} \quad \Gamma_0\times(0,T), \tag{1.1a}$$

where y_{tt} stands for $\partial^2y/\partial t^2$, $a_{ij}=a_{ji}$ are C^∞ functions in $\mathbb{R}^n$, and

$$\sum_{ij=1}^{n}a_{ij}(x)\xi_i\xi_j\geq a\sum_{i=1}^{n}\xi_i^2, \quad x\in\Omega, \tag{1.2}$$

for some constant $a>0$.

We ask whether there is some constant $T_0>0$ such that if $T>T_0$, the following steering property of (1.1) and (1.1a) holds true: for all initial data y^0, y^1 in $L^2(\Omega)\times H^{-1}(\Omega)$, there exists a suitable control function v in $L^2(0,T;L^2(\Gamma_0))$, whose corresponding solution of (1.1), (1.1a) satisfies

$$y(\cdot,T)\equiv y_t(\cdot,T)\equiv 0. \tag{1.3}$$

When the answer is in the affirmative, we then say that the dynamics (1.1) and (1.1a) is exactly controllable in the interval $[0,T]$ on $L^2(\Omega)\times H^{-1}(\Omega)$ by means of the Dirichlet control function $v\in L^2(0,T;L^2(\Gamma_0))$.

Exact controllability problems are best handled by duality or transposition, rather than directly.

Set

$$\mathcal{A}u = -\sum_{ij=1}^{n} \frac{\partial}{\partial x_i}\left(a_{ij}(x)\frac{\partial u}{\partial x_j}\right)$$

and consider the corresponding homogeneous problem

$$\text{(1.4)} \qquad \begin{cases} \phi_{tt} + \mathcal{A}\phi = 0 \quad \text{in} \quad \Omega \times (0,T), \\ \phi(0) = \varphi^0, \quad \phi_t(0) = \varphi^1 \quad \text{in} \quad \Omega, \\ \phi = 0 \quad \text{on} \quad \Gamma \times (0,T). \end{cases}$$

Given $\varphi^0 \in H_0^1(\Omega)$, $\varphi^1 \in L^2(\Omega)$, (1.4) admits a unique solution $\{\,\phi,\, \phi_t\,\} \in C([0,T]; H_0^1(\Omega) \times L^2(\Omega))$ satisfying the trace regularity $\frac{\partial \phi}{\partial v_{\mathcal{A}}} \in L^2(0,T;L^2(\Gamma))$ (Lasiecka, Lions, and Triggiani [9]); i.e., more precisely, for all $T > 0$,

$$\text{(1.5)} \qquad \int_0^T \int_{\Gamma_0} \left(\frac{\partial \phi}{\partial v_{\mathcal{A}}}\right)^2 d\sigma dt \le cT\left(\|\varphi^0\|^2_{H_0^1(\Omega)} + \|\varphi^1\|^2_{L^2(\Omega)}\right),$$

where

$$\frac{\partial \phi}{\partial v_{\mathcal{A}}} = \sum_{ij=1}^{n} a_{ij}\frac{\partial \phi}{\partial x_j} v_i$$

is the conormal derivative, $v = (v_1, v_2, \ldots, v_n)$ is the unit normal of Γ pointing towards the exterior of Ω, and $d\sigma$ is the Euclidean surface element on Γ.

Let ψ be the solution of the following problem:

$$\text{(1.6)} \qquad \begin{cases} \psi_{tt} + \mathcal{A}\psi = 0 \quad \text{in} \quad \Omega \times (0,T), \\ \psi(T) = \psi_t(T) = 0 \quad \text{in} \quad \Omega, \\ \psi|_{\Gamma_1} = 0, \qquad 0 < t < T, \\ \psi|_{\Gamma_0} = \dfrac{\partial \phi}{\partial v_{\mathcal{A}}}, \qquad 0 < t < T, \end{cases}$$

with $\frac{\partial \phi}{\partial v_{\mathcal{A}}}$ produced by (1.4). Given $\varphi^0 \in H_0^1(\Omega)$ and $\varphi^1 \in L^2(\Omega)$, we have defined, in a unique fashion, $\Lambda : H_0^1(\Omega) \times L^2(\Omega) \longrightarrow H^{-1}(\Omega) \times L^2(\Omega)$ by

$$\text{(1.7)} \qquad \Lambda \begin{pmatrix} \varphi^0 \\ \varphi^1 \end{pmatrix} = \begin{pmatrix} \psi_t(0) \\ -\psi(0) \end{pmatrix}.$$

A formal use of Green's formula gives, after we multiply (1.6) by ϕ and integrate by parts,

$$\text{(1.8)} \qquad \left\langle \Lambda \begin{pmatrix} \varphi^0 \\ \varphi^1 \end{pmatrix}, \begin{pmatrix} \varphi^0 \\ \varphi^1 \end{pmatrix} \right\rangle = \int_0^T \int_{\Gamma_0} \left(\frac{\partial \phi}{\partial v_{\mathcal{A}}}\right)^2 d\sigma dt,$$

where $\langle \cdot, \cdot \rangle$ denotes the inner product over $L^2(\Omega) \times L^2(\Omega)$.

By (1.4)–(1.8), getting the exact controllability for (1.1) and (1.1a) over space $L^2(\Omega) \times H^{-1}(\Omega)$ is equivalent to showing that there are constants c, $T_0 > 0$ such that the following observability inequality holds true for $T > T_0$:

$$\text{(1.9)} \qquad \int_0^T \int_{\Gamma_0} \left(\frac{\partial \phi}{\partial v_{\mathcal{A}}}\right)^2 d\sigma dt \ge c\left(\|\varphi^0\|^2_{H_0^1(\Omega)} + \|\varphi^1\|^2_{L^2(\Omega)}\right)$$

for all $\varphi^0 \in H_0^1(\Omega)$, $\varphi^1 \in L^2(\Omega)$, where ϕ solves problem (1.4).

This problem has received considerable attention in the literature, with numerous contributions achieved over the past several years. For the constant coefficient case, see Chen [3], Lagnese [7, 8], Lions [12], and Triggiani [18]. For the variable coefficient case, the observability inequalities were obtained in Bardos, Lebeau, and Rauch [1] and in Tataru [15, 16, 17]. In [1], the observability inequality is established subject to some geometric optics conditions that are almost necessary conditions for the exact controllability. However, as explicitly recognized by the authors, for $a_{ij}(x)$, Ω given, except for the constant coefficient case, it is not an easy matter to verify the (sharp) condition that all rays hit Γ_0 at a nondiffractive point since rays are solutions of a system of nonlinear ordinary equations (Hamilton). In Tataru [15, 16, 17], the observability inequality is obtained by the Carleman estimate, subject to the existence of a pseudoconvex function. Both works above succeed in handling arbitrary first-order terms (energy level) as well as time-dependent coefficients.

We note here that nontrivial examples have not been available in the literature until now.

In the present paper, we consider observability inequality (1.9) by the Riemannian geometry method, subject to a different geometric condition (1.16), which is motivated by geometric multiplier identities. Several multiplier identities, which have been built for constant coefficient wave equation (Lions [12]), are generalized to the variable coefficient case by some computational techniques in Riemannian geometry so that observability inequality (1.9) is derived from those identities. The situation here is very similar to that in the constant coefficient case.

If there is a strictly convex function ϕ on $\overline{\Omega}$, then vector field $H = D\phi$ meets condition (1.16), where D is a connection that will be specified later. At the same time, since $\phi - ct^2$ is pseudoconvex for some constant c, Tataru's work can be applied so that some of the examples, given in section 3, can be derived from Tataru's work. However, in general, vector field H is not the covariant differential of a function (for instance, see Example 3.4).

An interesting problem for exact controllability is to give the time T_0 that the control needs. Similar to the case of constant coefficients, our estimates present an explicit formula for T_0. In addition, our approach also works well for the Euler–Bernoulli equation (Yao [20]) and is available for some nonlinear boundary feedback problems.

The sufficient and necessary conditions, given by Bardos, Lebeau, and Rauch [1], show that if Γ_0 is "small," the exact controllability may not hold true. Such a counterexample is presented by Ralston [13] for the constant coefficient case. It is, however, well known that in the case of constant coefficients one can always find Γ_0 ("large" enough) such that the exact controllability holds true. The situation is very different in the case of variable coefficients. Indeed, by a combination of Riemannian geometry and geometric optics, section 4 presents a counterexample without exact controllability, where the control is exerted on the whole boundary; that is, there exists a ray that never hits the boundary.

We note that for the case $n = 1$ the exact controllability always holds true without geometric condition; that is, the one-dimensional problem (space dependent) fits all the theories above. We give a sketch of the proof for the case $n = 1$ in the appendix at the end of this paper.

Now we are back to our main problem and we focus on observability inequality (1.9), or equivalently, on the following question, raised by Lions [12]. Set

$$F_{T,\Gamma_0} = \left\{ (\varphi^0, \varphi^1) \,|\, (\varphi^0, \varphi^1) \in H_0^1(\Omega) \times L^2(\Omega), \int_0^T \int_{\Gamma_0} \left(\frac{\partial \phi}{\partial v_{\mathcal{A}}} \right)^2 dx dt < \infty \right\}. \tag{1.10}$$

Open question. How can we characterize the Hilbert space F_{T,Γ_0}? Is F_{T,Γ_0} always equal to $H_0^1(\Omega) \times L^2(\Omega)$?

We introduce some notation. Suppose that

$$\sum_{ij=1}^{n} a_{ij}(x)\xi_i\xi_j > 0 \quad \forall\, x \in \mathbb{R}^n, \quad \xi = (\xi_1, \xi_2, \ldots, \xi_n)^\tau \in \mathbb{R}^n, \quad \xi \neq 0. \tag{1.11}$$

Set

$$A(x) = (a_{ij}(x)), \tag{1.12}$$

$$G(x) = (g_{ij}(x)) = A(x)^{-1}. \tag{1.13}$$

Let $\mathbb{R}^n$ have the usual topology and $x = (x_1, x_2, \ldots, x_n)$ be the natural coordinate system. For each $x \in \mathbb{R}^n$, define the inner product and norm over the tangent space $\mathbb{R}^n_x = \mathbb{R}^n$ by

$$g\,(X,\, Y) = \langle X,\, Y \rangle_g = \sum_{ij=1}^{n} g_{ij}(x)\alpha_i\beta_j, \tag{1.14}$$

$$|X|_g = \langle X,\, X \rangle_g^{1/2} \quad \forall \quad X = \sum_{i=1}^{n} \alpha_i \frac{\partial}{\partial x_i}, \quad Y = \sum_{i=1}^{n} \beta_i \frac{\partial}{\partial x_i} \in \mathbb{R}^n_x.$$

It is easily checked from (1.11) that $(\mathbb{R}^n, g)$ is a Riemannian manifold with Riemannian metric g. Denote the Levi–Civita connection in metric g by D. Let H be a vector field on $(\mathbb{R}^n, g)$. The covariant differential DH of H determines a bilinear form on $\mathbb{R}^n_x \times \mathbb{R}^n_x$, for each $x \in \mathbb{R}^n$, by

$$DH\,(X,\, Y) = \langle D_X H,\, Y \rangle_g \quad \forall\; X, Y \in \mathbb{R}^n_x,$$

where $D_X H$ is the covariant derivative of vector field H with respect to X.

For each $x \in \mathbb{R}^n$, denote

$$X \cdot Y = \sum_{i=1}^{n} \alpha_i\beta_i, \quad |X|_0 = (X \cdot X)^{1/2} \quad \forall\, X = \sum_{i=1}^{n} \alpha_i \frac{\partial}{\partial x_i}, \quad Y = \sum_{i=1}^{n} \beta_i \frac{\partial}{\partial x_i} \in \mathbb{R}^n_x,$$

the usual dot product over $\mathbb{R}^n$. For $x \in \mathbb{R}^n$, set

$$A(x)X = \sum_{i=1}^{n} \left(\sum_{j=1}^{n} a_{ij}(x)\alpha_j \right) \frac{\partial}{\partial x_i} \quad \forall \quad X = \sum_{i=1}^{n} \alpha_i \frac{\partial}{\partial x_i} \in \mathbb{R}^n_x. \tag{1.15}$$

Let

$$X = \sum_{i=1}^{n} \alpha_i(x) \frac{\partial}{x_i}$$

be a vector field on $\mathbb{R}^n$. Denote the divergence of X in the Euclidean metric by $\operatorname{div}_0(X)$. Then

$$\operatorname{div}_0(X) = \sum_{i=1}^{n} \frac{\partial \alpha_i(x)}{\partial x_i}.$$

For $f \in C^1(\overline{\Omega})$, denote the gradients of f by ∇_0 and ∇_g in the Euclidean metric and in Riemannian metric g, respectively.

Let $x^0 \in \mathbb{R}^n$. Let r: $(0,\infty) \to \mathbb{R}^n$ be a geodesic with $r(0) = x^0$ parameterized by arc length in the Riemannian metric g. Denote the distance on $(\mathbb{R}^n, g)$ by d_g. For sufficiently small $t > 0$, we know that $d_g(r(t), x^0) = t$, since the exponential map $\exp_{x^0}$: $\mathbb{R}^n_{x^0} \to \mathbb{R}^n$ is injective on a sufficiently small ball in $(\mathbb{R}^n, g)$. We recall that $r(t_0)$ is called the cut point of r with respect to x^0, if $t_0 > 0$ is such that $d_g(r(t), x^0) = t$, $0 \le t < t_0$, and $d_g(r(t), x^0) < t$ for all $t > t_0$ (Cheeger and Ebin [2]). The union of all cut points is called the cut locus of x^0 and is denoted by $cut(x^0)$. For any $X \in \mathbb{R}^n_{x^0}$, $|X|_g = 1$, there is at most one cut point on the geodesic $\exp_{x^0} tX$ $(t \ge 0)$. Thus $cut(x^0)$ is the image of the exponential map on some closed subset of S^{n-1} and the n-dimensional measure of $cut(x^0)$ is zero. Set $\mu(X) = d_g(x^0, r(t_0))$ if $r(t_0)$ is the cut point of x^0 along $r(t) = \exp_{x^0} tX$; set $\mu(X) = \infty$ when there is no cut point of x^0 along r, where $X \in S^{n-1} \subset \mathbb{R}^n_{x^0}$. We define

$$E = \left\{ tX \,|\, 0 \le t < \mu(X),\ X \in S^{n-1} \subset \mathbb{R}^n_{x^0} \right\}.$$

Then $\exp_{x^0}$: $E \to \exp_{x^0}(E)$ is a diffeomorphism. It is obvious that $\exp_{x^0}(E)$ is a star domain and

$$\mathbb{R}^n = \exp_{x^0}(E) \cup cut(x^0).$$

Now we are in a position to state our main results.

THEOREM 1.1. *Let H be a vector field on Riemannian manifold $(\mathbb{R}^n, g)$ such that*

$$\langle D_X H,\, X\rangle_g \ge a|X|_g^2 \quad \forall\, X \in \mathbb{R}^n_x, \quad x \in \Omega, \tag{1.16}$$

for some constant $a > 0$. Then there exists $T_0 > 0$ such that for any $T > T_0$,

$$F_{T,\Gamma_0} = H_0^1(\Omega) \times L^2(\Omega),$$

where

$$\Gamma_0 = \left\{ x \;\middle|\; x \in \Gamma,\ H(x)\cdot \upsilon(x) > 0 \right\}, \tag{1.17}$$

$$T_0 = \frac{2}{a} \sup_{x \in \overline{\Omega}} |H|_g(x). \tag{1.18}$$

Remark 1.1. In the case of constant coefficients, where $a_{ij}(x) = \delta_{ij}$, the above results were obtained by Lions [12] for the radial field $H = x - x_0$. Komornik [6] improved the estimate T_0.

In general, it is not easy to find a vector field H verifying condition (1.16). In the following, we relate the existence of such a vector field to sectional curvature by several corollaries that are useful for the examples in section 3.

If $(\mathbb{R}^n, g)$ is a noncompact complete Riemannian manifold of everywhere positive sectional curvature, there exists a C^∞ strictly convex function h on (R^n, g) by Greene and Wu [4]. All the eigenvalues of its second covariant differential are everywhere positive. Take $H = Dh$, and we have

$$DH\,(X,\,X) = D^2h\,(X,\,X) > 0 \quad \forall \quad X \in \mathbb{R}^n_x, \quad x \in \mathbb{R}^n,$$

where D^2h is the Hessian of h in Riemannian metric g. There is a constant $a > 0$ such that inequality (1.16) holds true, since $\overline{\Omega}$ is compact.

COROLLARY 1.1. *Let $(\mathbb{R}^n, g)$ be noncompact complete and of everywhere positive sectional curvature. h is a C^∞ strictly convex function on $(\mathbb{R}^n, g)$. Then vector field $H = Dh$ meets condition* (1.16) *for any $\Omega \subset \mathbb{R}^n$.*

For $x \in \mathbb{R}^n$, let $\Pi \subset \mathbb{R}^n_x$ be a two-dimensional subspace. Denote the sectional curvature by $K_x(\Pi)$. Let $B(x^0, \gamma)$ be a geodesic ball in $(\mathbb{R}^n, g)$ with the center at x^0 and the radius $\gamma > 0$. Set

$$k_B = \sup_{x \in B(x^0,\gamma),\, \Pi \subset \mathbb{R}^n_x} K_x(\Pi). \tag{1.19}$$

For $x^0 \in \mathbb{R}^n$, set $\rho(x) = d_g(x^0, x)$ $\forall x \in \mathbb{R}^n$.

COROLLARY 1.2. *Let $x^0 \in \mathbb{R}^n$. Let $\gamma > 0$ be such that $B(x^0, \gamma) \subset \exp_{x^0}(E)$. If $\Omega \subset B(x^0, \gamma)$ such that $4\gamma^2 k_B < \pi^2$, then vector field $H = \rho D\rho$ meets condition* (1.16) *with $a = \sqrt{k_B}\gamma cot(\sqrt{k_B}\gamma)$ if $k_B > 0$ and with $a = 1$ when $k_B \leq 0$.*

Remark 1.2. This corollary is a global result. For any a_{ij}, however, we can derive local boundary exact controllability from it since, for any $x^0 \in \mathbb{R}^n$, there exists a $\gamma > 0$ such that $B(x^0, \gamma) \subset \exp_{x^0}(E)$ (Cheeger and Ebin [2]). In addition, if g, defined by (1.14), is the usual dot product of $\mathbb{R}^n$, it is easily checked that

$$H = \rho D\rho = x - x^0.$$

If $(\mathbb{R}^n, g)$ is of everywhere nonpositive sectional curvature, then, for all $x^0 \in \mathbb{R}^n$, $\exp_{x^0}(E) = \mathbb{R}^n$ and $k_B \leq 0$ (see Spivak [14]). The following corollary is immediate from Corollary 1.2.

COROLLARY 1.3. *Let $(\mathbb{R}^n, g)$ be of nonpositive sectional curvature. For any $x^0 \in \mathbb{R}^n$, vector field $H = \rho D\rho$ satisfies condition* (1.16) *for any $\Omega \subset \mathbb{R}^n$ where $a = 1$.*

COROLLARY 1.4. *Assume that*

$$K \geq \sup_{x \in \mathbb{R}^n,\, \pi \subset \mathbb{R}^n_x} K_x(\pi) \geq \inf_{x \in \mathbb{R}^n,\, \pi \subset \mathbb{R}^n_x} K_x(\pi) > 0. \tag{1.20}$$

By the Bonnet theorem (Cheeger and Ebin [2]*), the completion $(\mathbb{R}^n \cup \{\infty\}, g)$ of $(\mathbb{R}^n, g)$ is a compact Riemannian manifold.*

Set

$$d_g(\Omega) = \sup_{x,y \in \Omega} d_g(x, y).$$

If

$$d_g(\Omega) < \frac{1}{2} \min \left\{ \frac{\pi}{\sqrt{K}}, \right.$$

$$\left. \textit{half the length of the shortest closed geodesic in } \mathbb{R}^n \right\}, \tag{1.21}$$

then vector field $H = \rho D\rho$ meets condition (1.16).

Here we turn to the Neumann action problem and examine problem (1.1) with, instead of the Dirichlet action in (1.1a), the Neumann action

$$\frac{\partial y}{\partial v_{\mathcal{A}}} = v \quad \text{on} \quad \Gamma \times (0,T). \tag{1.1b}$$

We say that the dynamic (1.1), (1.1b) is exactly controllable in the interval $[0,T]$ by means of control function v with Neumann action if, for φ^0, φ^1 in some Hilbert spaces, one can find v such that the solution of (1.1) and (1.1b) satisfies (1.3).

Theorem 1.2. *Let H be a vector field on Riemannian manifold* $(\mathbb{R}^n, g)$ *such that inequality* (1.16) *holds true. Let T_0 be given by* (1.18) *and $T > T_0$. Then, for any $\varphi^0 \in L^2(\Omega)$, $\varphi^1 \in (H^1(\Omega))'$, one can find v on $\Gamma \times (0,T)$ such that the solution of* (1.1) *and* (1.1b) *satisfies* (1.3)*. The control v has the following structure:*

$$v = \begin{cases} v_0 + \dfrac{\partial v_1}{\partial t} & on \quad \Gamma_0 \times (0,T), \\ v_2 & on \quad \Gamma_1 \times (0,T), \end{cases} \tag{1.22}$$

where

$$\begin{aligned} &v_0,\, v_1 \in L^2(\Gamma_0 \times (0,T)), \\ &v_2 \in L^2(0,T; (H^1(\Gamma_1))'). \end{aligned}$$

Similar to Lions [12], if Ω and H are subject to the geometrical conditions

$$H(x) \cdot v(x) \geq 0 \quad \forall\, x \in \Gamma, \tag{1.23}$$

then the control v can be taken in $L^2(\Gamma \times (0,T))$.

Theorem 1.3. *Let H be a vector field on Riemannian manifold* $(\mathbb{R}^n, g)$ *such that conditions* (1.16) *and* (1.23) *hold true. Let T_0 be given in* (1.18) *and $T > T_0$. Then, for any $\varphi^0 \in H^1(\Omega)$, $\varphi^1 \in L^2(\Omega)$, one can find $v \in L^2(\Gamma \times (0,T))$ such that the solution of* (1.1) *and* (1.1b) *satisfies* (1.3).

Finally, we consider the exact controllability problem for

$$\begin{cases} y_{tt} + \mathcal{A}y = 0 \quad \text{in} \quad \Omega \times (0,T), \\ y(0) = y^0, \quad y_t(0) = y^1, \\ y = 0 \quad \text{in } \Gamma_1, \quad \dfrac{\partial y}{\partial v_{\mathcal{A}}} = v \quad \text{on } \Gamma_0. \end{cases} \tag{1.24}$$

We have the Dirichlet condition (no action) on Γ_1 and a Neumann action on Γ_0. Set

$$H^1_{\Gamma_1}(\Omega) = \{\, u \,|\, u \in H^1(\Omega),\, u|_{\Gamma_1} = 0 \,\}.$$

In this case, the preceding approach leads to the following result. For the case of the Laplace $\mathcal{A} = -\Delta$, the same result was obtained by Lions [12] and Lasiecka and Triggiani [10]. It is mentioned that, unlike the Dirichlet case (see (1.5)), the corresponding regularity inequality does not hold true for dimension $\Omega \geq 2$.

Theorem 1.4. *Let H be a vector field on Riemannian manifold* $(\mathbb{R}^n, g)$ *such that condition* (1.16) *holds true. Let T_0 be given in* (1.18)*. Then, for any $T > T_0$, $y^0 \in L^2(\Omega)$, $y^1 \in (H^1_{\Gamma_1}(\Omega))'$, we can find v such that the solution y of problem* (1.24) *satisfies* (1.3)*, where*

$$v = v_0 + \frac{\partial v_1}{\partial t}, \quad v_0,\, v_1 \in L^2(\Gamma_0 \times (0,T)).$$

2. The proof of the results.

2.1. Multiplier identities. To estimate the observability inequality (1.9), we need some multiplier identities which have been built for the classical wave equations, where $a_{ij} = \delta_{ij}$ (Lions [12], Komornik [6], Lasiecka and Triggiani [10]). We now consider their generalizations in the variable coefficient situations.

With two metrics on $\mathbb{R}^n$ in mind, one the Euclidean metric and the other Riemannian metric g, we have to deal with various notations carefully.

We recall that $E_1, E_2, \dots, E_n$ is a frame field normal at x (Wu, Shen, and Yu [19]) on Riemannian manifold $(\mathbb{R}^n, g)$ if and only if it is a local basis for vector fields with $\langle E_i, E_j\rangle_g = \delta_{ij}$ in some neighborhood of x and with $(D_{E_i}E_j)(x) = 0$ for $1 \le i, j \le n$. Let H be a vector field on $\mathbb{R}^n$ and $f \in C^1(\overline{\Omega})$. We have the formulae for divergence in the Euclidean metric

$$\operatorname{div}_0(fH) = f\operatorname{div}_0(H) + H(f) \tag{2.1}$$

and

$$\int_\Omega \operatorname{div}_0(H)\,dx = \int_\Gamma H\cdot v\,d\sigma. \tag{2.2}$$

We shall write $(\phi,\, \psi)$ for $\int_\Omega \phi\psi\,dx$ and $\|\phi\|$ for $(\phi,\, \phi)^{1/2}$.

LEMMA 2.1. *Let $x = (x_1, x_2, \dots, x_n)$ be the natural coordinate system in $\mathbb{R}^n$, f, $h \in C^1(\overline{\Omega})$, and H, X vector fields. Then*

(1)

$$\langle H(x),\, A(x)X(x)\rangle_g = H(x)\cdot X(x), \quad x \in \mathbb{R}^n; \tag{2.3}$$

(2)

$$\nabla_g f(x) = \sum_{i=1}^n \left(\sum_{j=1}^n a_{ij}(x)\frac{\partial f}{\partial x_j}\right)\frac{\partial}{\partial x_i}, \quad x \in \mathbb{R}^n; \tag{2.4}$$

(3)

$$\langle \nabla_g f,\, \nabla_g h\rangle_g = \nabla_g f(h) = \nabla_0 f\cdot A(x)\nabla_0 h, \quad x\in\mathbb{R}^n; \tag{2.5}$$

(4)

$$\begin{aligned}\langle \nabla_g f,\, \nabla_g(H(f))\rangle_g(x) &= DH(\nabla_g f,\, \nabla_g f)(x) + \frac{1}{2}\operatorname{div}_0\left(|\nabla_g f|_g^2 H\right)(x)\\ &\quad -\frac{1}{2}|\nabla_g f|_g^2(x) div_0(H)(x) \quad \forall\, x\in\mathbb{R}^n,\end{aligned} \tag{2.6}$$

where $A(x)$ is given by (1.12).

Proof. Set

$$H(x) = \sum_{i=1}^n h_i\frac{\partial}{\partial x_i} \quad \text{and} \quad X(x) = \sum_{i=1}^n f_i\frac{\partial}{\partial x_i}.$$

It follows from (1.15) that

$$\langle H(x),\, A(x)X(x)\rangle_g = \sum_{ij=1}^n\sum_{k=1}^n a_{ik}f_k h_j g_{ij} = \sum_{k=1}^n f_k h_k = H(x)\cdot X(x), \tag{2.7}$$

where

$$g_{ij} = \left\langle \frac{\partial}{\partial x_i}, \frac{\partial}{\partial x_j} \right\rangle_g .$$

Set

$$\nabla_g x_i = \sum_{j=1}^n x_{ij} \frac{\partial}{\partial x_j}, \quad 1 \le i \le n, \tag{2.8}$$

$$C(x) = (x_{ij}(x)), \quad x \in \mathbb{R}^n, \tag{2.9}$$

an $n \times n$ matrix. It follows from (2.8) that

$$x_{ij} = \nabla_g x_i(x_j) = \langle \nabla_g x_i, \nabla_g x_j \rangle_g = \sum_{k,l=1}^n g_{kl} x_{ik} x_{jl}, \quad 1 \le i, j \le n. \tag{2.10}$$

Equation (2.10) gives

$$C(x) = C(x)^\tau G(x) C(x), \quad x \in \mathbb{R}^n,$$

where $C(x)^\tau$ is the transpose of the matrix $C(x)$ and $G(x)$ is defined by (1.13); that is,

$$C(x) = G^{-1}(x) = A(x), \quad x \in \mathbb{R}^n. \tag{2.11}$$

From (2.8) and (2.11), we obtain

$$\nabla_g f = \sum_{i=1}^n \nabla_g f(x_i) \frac{\partial}{\partial x_i} = \sum_{i=1}^n \nabla_g x_i(f) \frac{\partial}{\partial x_i} = \sum_{i=1}^n \left(\sum_{j=1}^n a_{ij} \frac{\partial f}{\partial x_j} \right) \frac{\partial}{\partial x_i}, \quad x \in \mathbb{R}^n.$$

This yields

$$\langle \nabla_g f, \nabla_g h \rangle_g = \nabla_g f(h) = \sum_{ij=1}^n a_{ij} \frac{\partial f}{\partial x_i} \frac{\partial h}{\partial x_j} = \nabla_0 f(x) \cdot A(x) \nabla_0 h(x), \quad x \in \mathbb{R}^n.$$

We now prove part 4. Let $x \in \mathbb{R}^n$. Let $E_1, E_2, \ldots, E_n$ be a frame field normal at x. There are functions $h_1, h_2, \ldots, h_n$ on some neighborhood of x such that $H = \sum_{i=1}^n h_i E_i$. In addition, we have

$$H(f) = \sum_{i=1}^n h_i E_i(f), \tag{2.12}$$

$$\nabla_g f = \sum_{i=1}^n E_i(f) E_i, \quad \text{and} \quad |\nabla_g f|_g^2 = \sum_{j=1}^n (E_j(f))^2, \tag{2.13}$$

where $E_i(f)$ are the covariant differential of f with regard to E_i in Riemannian metric g. For the covariant differential of vector field H, we obtain

$$\begin{aligned} DH(E_i, E_j)(x) &= \langle D_{E_i} H(x), E_j(x) \rangle_g \\ &= \sum_{k=1}^n \langle E_i(h_k) E_k + h_k D_{E_i} E_k, E_j \rangle_g \\ &= E_i(h_j)(x), \end{aligned} \tag{2.14}$$

since $\langle E_k, E_j\rangle_g = \delta_{kj}$ and $D_{E_i}E_k(x) = 0$. It follows from (2.12)–(2.14) and (2.1) that

$$\begin{aligned}\langle \nabla_g f,\, \nabla_g (H(f))\rangle_g (x) &= \sum_{j=1}^n E_j(f) E_j(H(f))\\ &= \sum_{j=1}^n E_j(f)\left(\sum_{i=1}^n E_j(h_i)E_i(f) + \sum_{i=1}^n h_i E_j E_i(f)\right)\\ &= \sum_{ij=1}^n E_j(h_i)E_i(f)E_j(f) + \sum_{i=1}^n h_i\left(\sum_{j=1}^n E_j(f)E_iE_j(f)\right)\\ &= DH(\nabla_g f,\, \nabla_g f) + \frac{1}{2}H\left(|\nabla_g f|_g^2\right)\\ &= DH(\nabla_g f,\, \nabla_g f)(x) + \frac{1}{2}\mathrm{div}_0\left(|\nabla_g f|_g^2 H\right)(x)\\ &\qquad - \frac{1}{2}|\nabla_g f|_g^2(x)\mathrm{div}_0(H)(x) \quad \forall\, x \in \mathbb{R}^n,\end{aligned}$$

where $E_iE_j(f)(x) = E_jE_i(f)(x)$ are the second covariant differential of f. □

PROPOSITION 2.1. *Let ϕ solve problem*

$$\phi_{tt} + \mathcal{A}\phi = 0 \quad on \quad \Omega \times (0, T). \tag{2.15}$$

Suppose that H is a vector field on $\overline{\Omega}$. Then

(1)

$$\begin{aligned}&\int_0^T\int_\Gamma \frac{\partial\phi}{\partial\upsilon_{\mathcal{A}}}H(\phi)\,d\sigma dt + \frac{1}{2}\int_0^T\int_\Gamma\left(\phi_t^2 - |\nabla_g\phi|_g^2\right)H\cdot\nu\,d\sigma dt\\ &= (\phi_t,\, H(\phi))\Big|_0^T + \int_0^T\int_\Omega DH(\nabla_g\phi,\, \nabla_g\phi)\,dxdt\\ &+\frac{1}{2}\int_0^T\int_\Omega\left(\phi_t^2 - |\nabla_g\phi|_g^2\right)\mathrm{div}_0(H)\,dxdt.\end{aligned} \tag{2.16}$$

(2) *Let $P \in C^2(\overline{\Omega})$. Then*

$$\begin{aligned}&\int_0^T\int_\Omega P\left(\phi_t^2 - |\nabla_g\phi|_g^2\right)\,dxdt\\ &= (\phi_t,\, \phi P)\Big|_0^T + \frac{1}{2}\int_0^T\int_\Omega \phi^2\mathcal{A}P\,dxdt + \frac{1}{2}\int_0^T\int_\Gamma \phi^2\nabla_g P\cdot v\,d\sigma dt\\ &-\int_0^T\int_\Gamma\frac{\partial\phi}{\partial\upsilon_{\mathcal{A}}}\phi P d\sigma dt.\end{aligned} \tag{2.17}$$

Proof. (1) We multiply (2.15) by $H(\phi)$ and integrate by parts. Using Green's formula and Lemma 2.1, parts 2–4, we find that

$$\begin{aligned}\int_\Omega \mathcal{A}\phi H(\phi)\,dx &= \int_\Omega\sum_{ij=1}^n a_{ij}(x)\frac{\partial\phi}{\partial x_j}\frac{\partial}{x_i}(H(\phi))\,dx - \int_\Gamma\frac{\partial\phi}{\partial\upsilon_{\mathcal{A}}}H(\phi)\,d\sigma\\ &= \int_\Omega \nabla_g\phi\,(H(\phi))\,dx - \int_\Gamma\frac{\partial\phi}{\partial\upsilon_{\mathcal{A}}}H(\phi)\,d\sigma\end{aligned}$$

$$
\begin{aligned}
&= \int_\Omega \langle \nabla_g \phi,\, \nabla_g\,(H(\phi))\rangle_g\,dx - \int_\Gamma \frac{\partial \phi}{\partial v_{\mathcal{A}}} H(\phi)\,d\sigma \\
&= \int_0^T \int_\Omega DH\,(\nabla_g \phi,\, \nabla_g \phi)\;dxdt + \frac{1}{2}\int_0^T \int_\Gamma |\nabla_g \phi|_g^2 H\cdot v\,d\sigma dt \\
&- \frac{1}{2}\int_0^T \int_\Omega |\nabla_g \phi|_g^2 \mathrm{div}_0(H)\,dxdt - \int_\Gamma \frac{\partial \phi}{\partial v_{\mathcal{A}}} H(\phi)\,d\sigma. \qquad (2.18)
\end{aligned}
$$

On the other hand, we obtain from integration by parts and (2.1)

$$
\begin{aligned}
&\int_0^T \int_\Omega \phi_{tt} H(\phi)\,dxdt \\
&= \int_\Omega \phi_t H(\phi)\,\Big|_0^T\,dx - \int_\Omega \int_0^T \phi_t H(\phi_t)\,dtdx \\
&= (\phi_t,\, H(\phi))\,\Big|_0^T - \frac{1}{2}\int_0^T \int_\Omega H(\phi_t^2)\,dxdt \\
&= (\phi_t,\, H(\phi))\,\Big|_0^T + \frac{1}{2}\int_0^T \int_\Omega \phi_t^2 \mathrm{div}_0(H)\,dxdt - \frac{1}{2}\int_0^T \int_\Gamma \phi_t^2 H\cdot v\,d\sigma dt. \qquad (2.19)
\end{aligned}
$$

Equations (2.19) and (2.18), together with (2.15), yield (2.16).

(2) Lemma 2.1, part 2, gives

$$
\mathcal{A}P = -\sum_{ij=1}^n \frac{\partial}{\partial x_i}\left(a_{ij}(x)\frac{\partial P}{\partial x_j}\right) = -\mathrm{div}_0(\nabla_g P). \qquad (2.20)
$$

From (2.20) and formula (2.1), we thus obtain

$$
\begin{aligned}
\langle \nabla_g \phi,\, \nabla_g (P\phi)\rangle_g(x) &= P|\nabla_g \phi|_g^2(x) + \phi\langle \nabla_g \phi, \nabla_g P\rangle_g(x) \\
&= P|\nabla_g \phi|_g^2 + \frac{1}{2}\nabla_g P(\phi^2) \\
&= P|\nabla_g \phi|_g^2 + \frac{1}{2}\mathrm{div}_0(\phi^2 \nabla_g P) + \frac{1}{2}\phi^2 \mathcal{A}P \quad \forall x\in\Omega. \qquad (2.21)
\end{aligned}
$$

It follows from (2.15), (2.21), (2.2), and Green's formula that

$$
\begin{aligned}
&(\phi_t,\, \phi P)\,\Big|_0^T = \int_0^T [(\phi_{tt}, \phi P) + (\phi_t, \phi_t P)]\,dt \\
&= \int_0^T \int_\Omega \Big[-\langle \nabla_g \phi,\, \nabla_g(\phi P)\rangle_g + \phi_t^2 P\Big]\,dxdt + \int_0^T \int_\Gamma \frac{\partial \phi}{\partial v_{\mathcal{A}}}\phi P\,d\sigma dt \\
&= \int_0^T \int_\Omega P\left(\phi_t^2 - |\nabla_g \phi|_g^2\right)dxdt - \frac{1}{2}\int_0^T \int_\Gamma \phi^2 \nabla_g P\cdot v\,d\sigma dt \\
&- \frac{1}{2}\int_0^T \int_\Omega \phi^2 \mathcal{A}P\,dxdt + \int_0^T \int_\Gamma \frac{\partial \phi}{\partial v_{\mathcal{A}}}\phi P\,d\sigma dt. \qquad (2.22)
\end{aligned}
$$

Equation (2.17) follows from (2.22). □

2.2. The proofs of the results. Now we derive some inequalities that will be used later on.

Let H be a vector field on $(\mathbb{R}^n, g)$ satisfying condition (1.16) and a, which is given by (1.16). Set

$$b = \sup_{x\in\overline{\Omega}} |H|_g(x), \qquad P = \mathrm{div}_0 H - a, \tag{2.23}$$

$$c = \sup_{x\in\overline{\Omega}} |(\mathrm{div}_0 H)^2 - a^2 + 2H(P)|. \tag{2.24}$$

LEMMA 2.2. *Let ϕ solve* (1.4). *Then*

$$\left|\left(\phi_t,\, H(\phi) + \frac{1}{2}P\phi\right)\right| \le bE(0) + \frac{\sqrt{c}}{2}\|\phi_t\|\|\phi\|, \tag{2.25}$$

where

$$E(t) = \frac{1}{2}\int_\Omega (\phi_t^2 + |\nabla_g\phi|_g^2)\,dx = E(0) = \frac{1}{2}(\||\nabla_g\varphi^0|_g\|^2 + \|\varphi^1\|^2). \tag{2.26}$$

Proof. We use a technique given in Komornik [6]. Applications of divergence formulae (2.1) and (2.2) yield

$$\begin{aligned}\left\|H(\phi) + \frac{1}{2}P\phi\right\|^2 &= \|H(\phi)\|^2 + (H(\phi),\, P\phi) + \frac{1}{4}\|P\phi\|^2\\ &= \|H(\phi)\|^2 + \frac{1}{2}\int_\Omega PH(\phi^2)\,dx + \frac{1}{4}\|P\phi\|^2\\ &= \|H(\phi)\|^2 - \frac{1}{4}\int_\Omega \phi^2[(\mathrm{div}_0 H)^2 - a^2 + 2H(P)]\,dx\\ &\le \|H(\phi)\|^2 + \frac{c}{4}\|\phi\|^2, \qquad (2.27)\end{aligned}$$

since $\phi|_\Gamma = 0$. It follows from (2.27) and (2.26) that

$$\begin{aligned}\left|\left(\phi_t,\, H(\phi) + \frac{1}{2}P\phi\right)\right| &\le \|\phi_t\|\left\|H(\phi) + \frac{1}{2}P\phi\right\|\\ &\le \|\phi_t\|\left(\|H(\phi)\| + \sqrt{\frac{c}{4}}\|\phi\|\right)\\ &\le bE(0) + \frac{\sqrt{c}}{2}\|\phi_t\|\|\phi\|. \qquad \Box\end{aligned}$$

Consider the operator $\mathcal{A}$ on $L^2(\Omega)$, given by

$$\mathcal{D}(\mathcal{A}) = \{\, u \,|\, u \in H^2(\Omega),\, u|_\Gamma = 0\,\},$$

$$\mathcal{A}u = -\sum_{ij=1}^n \frac{\partial}{\partial x_i}\left(a_{ij}(x)\frac{\partial u}{\partial x_j}\right), \quad u \in \mathcal{D}(\mathcal{A}). \tag{2.28}$$

It is well known that the spectrum of positive self-adjoint $\mathcal{A}$ consists of eigenvalues

$$0 < \lambda_1 < \lambda_2 < \cdots < \lambda_k < \cdots,$$

with $\lim_{k\to\infty}\lambda_k = \infty$. Denote by Z_k the eigenspaces of $\mathcal{A}$ corresponding to λ_k for $k = 1, 2, \ldots$.

The crux of the proof of Theorem 1.1 is the following.

LEMMA 2.3. *Set*

$$\vartheta = \sup_{x\in\Gamma_0}\left[(H\cdot\upsilon)/|\upsilon_{\mathcal{A}}|_g^2\right] \quad \textit{and} \quad d = \sup_{x\in\Omega}|\mathcal{A}(\mathrm{div}_0 H)|. \tag{2.29}$$

Then

$$\int_0^T\int_{\Gamma_0}\left(\frac{\partial\phi}{\partial\upsilon_{\mathcal{A}}}\right)^2 d\sigma dt \geq \frac{2}{\vartheta}\left[aT - 2b - \sqrt{\frac{c}{\lambda_m}} - \frac{d}{2\lambda_m}T\right]E(0)$$

$$\begin{gathered}\forall T > 0, \quad \varphi^0 \in H_0^1(\Omega), \quad \varphi^1 \in L^2(\Omega),\\ \varphi^0,\, \varphi^1 \perp Z_k, \quad 1 \leq k \leq m-1, \quad m = 1, 2, \ldots,\end{gathered} \tag{2.30}$$

where ϕ solves (1.4) *for initial data* (φ^0, φ^1).

Proof. First, we deal with the values of $|\nabla_g\phi|^2$ and $H(\phi)$ on boundary Γ, respectively. Let $x \in \Gamma$. We decompose $\nabla_g\phi$ into a direct sum in $(\mathbb{R}^n_x, g(x))$:

$$\nabla_g\phi(x) = \left\langle\nabla_g\phi(x),\, \frac{\upsilon_{\mathcal{A}}(x)}{|\upsilon_{\mathcal{A}}|_g}\right\rangle_g\frac{\upsilon_{\mathcal{A}}(x)}{|\upsilon_{\mathcal{A}}|_g} + Y(x), \tag{2.31}$$

where $Y(x) \in \mathbb{R}^n_x$ with $\langle Y(x),\, \upsilon_{\mathcal{A}}(x)\rangle_g = 0$. Lemma 2.1, part 1, and (2.31) yield

$$Y(x)\cdot\upsilon(x) = \langle Y(x),\, \upsilon_{\mathcal{A}}(x)\rangle_g = 0, \tag{2.32}$$

that is, $Y(x) \in \Gamma_x$, the tangent space of Γ at x. It follows from (2.31) and (2.32) that

$$\begin{aligned}|\nabla_g\phi|_g^2 = \nabla_g\phi(\phi) &= \frac{1}{|\upsilon_{\mathcal{A}}(x)|_g^2}\langle\nabla_g\phi(x),\, \upsilon_{\mathcal{A}}(x)\rangle_g^2 + Y(\phi)\\ &= \frac{1}{|\upsilon_{\mathcal{A}}|_g^2}\left(\frac{\partial\phi}{\partial\upsilon_{\mathcal{A}}}\right)^2,\end{aligned} \tag{2.33}$$

since $\phi|_\Gamma = 0$. Similarly, H can be decomposed into a direct sum

$$H = \left\langle H(x),\, \frac{\upsilon_{\mathcal{A}}(x)}{|\upsilon_{\mathcal{A}}(x)|_g}\right\rangle_g\frac{\upsilon_{\mathcal{A}}(x)}{|\upsilon_{\mathcal{A}}(x)|_g} + Z(x), \tag{2.34}$$

where $Z(x) \in \Gamma_x$. Formula (2.34) and Lemma 2.1, part 1, give

$$H(\phi)(x) = \frac{\langle H(x),\, \upsilon_{\mathcal{A}}(x)\rangle_g}{|\upsilon_{\mathcal{A}}(x)|_g^2}\left(\frac{\partial\phi}{\partial\upsilon_{\mathcal{A}}}\right) = \frac{H(x)\cdot\upsilon(x)}{|\upsilon_{\mathcal{A}}(x)|_g^2}\left(\frac{\partial\phi}{\partial\upsilon_{\mathcal{A}}}\right). \tag{2.35}$$

By Proposition 2.1, parts 1 and 2, (1.17), (1.16), (2.33), (2.35), and Lemma 2.2, we find that

$$\begin{aligned}&\frac{\vartheta}{2}\int_0^T\int_{\Gamma_0}\left(\frac{\partial\phi}{\partial\upsilon_{\mathcal{A}}}\right)^2 d\sigma dt \geq \frac{1}{2}\int_0^T\int_\Gamma\left(\frac{\partial\phi}{\partial\upsilon_{\mathcal{A}}}\right)^2\frac{H\cdot\upsilon}{|\upsilon_{\mathcal{A}}|_g^2}\,d\sigma dt\\ &= (\phi_t,\, H(\phi))\Big|_0^T + \int_0^T\int_\Omega\langle D_{\nabla_g\phi}H,\, \nabla_g\phi\rangle_g\,dxdt + \frac{1}{2}\int_0^T\int_\Omega(\phi_t^2 - |\nabla_g\phi|_g^2)\mathrm{div}_0(H)\,dxdt\end{aligned}$$

$$
\begin{aligned}
&= \frac{a}{2}\int_0^T\int_\Omega(\phi_t^2+|\nabla_g\phi|_g^2)\,dxdt+\int_0^T\int_\Omega\langle D_{\nabla_g\phi}H,\,\nabla_g\phi\rangle\,dxdt\\
&-a\int_0^T\int_\Omega|\nabla_g\phi|_g^2\,dxdt+(\phi_t,\,H(\phi))\Big|_0^T+\frac{1}{2}\int_0^T\int_\Omega(\phi_t^2-|\nabla_g\phi|_g^2)P\,dxdt\\
&\geq aTE(0)+\left(\phi_t,\,H(\phi)+\frac{1}{2}P\phi\right)\Big|_0^T+\frac{1}{4}\int_0^T\int_\Omega\phi^2\mathcal{A}(\mathrm{div}_0H)\,dxdt\\
&\geq aTE(0)-2bE(0)-\sqrt{c}\|\phi_t\|\|\phi\|-\frac{d}{4}\int_0^T\|\phi\|^2\,dt\\
&\geq aTE(0)-2bE(0)-\sqrt{\frac{c}{\lambda_m}}\|\phi_t\|\||\nabla_g\phi|_g\|-\frac{d}{4\lambda_m}\int_0^T\||\nabla_g\phi|_g\|^2\,dt\\
&\geq\left[aT-2b-\sqrt{\frac{c}{\lambda_m}}-\frac{d}{2\lambda_m}T\right]E(0),
\end{aligned}
$$

where inequalities

$$\|\phi\|^2\leq\frac{1}{\lambda_m}\||\nabla_g\phi|_g\|^2$$

$$\forall\,\varphi_0\in H_0^1(\Omega),\quad\varphi_1\in L^2(\Omega),\quad\varphi^0,\varphi^1\ \perp Z_k,\quad 1\leq k\leq m-1$$

are used. This completes the proof. □

Consider the operator $\mathcal{A}_0$ on $L^2(\Omega)$, defined by

$$\mathcal{D}(\mathcal{A}_0)=\left\{u\ \Big|\ u\in H^2(\Omega),\ \frac{\partial u}{\partial v_{\mathcal{A}}}\Big|_\Gamma=0\right\},$$

$$\mathcal{A}_0u=-\sum_{ij=1}^n\frac{\partial}{\partial x_i}\left(a_{ij}(x)\frac{\partial u}{\partial x_j}\right),\quad u\in\mathcal{D}(\mathcal{A}_0).\tag{2.36}$$

It is well known that $\mathcal{A}_0$ is nonnegative, self-adjoint on $L^2(\Omega)$ and that its spectrum consists of eigenvalues

$$0=\gamma_1<\gamma_2<\cdots<\gamma_k<\cdots$$

with $\lim_{k\to\infty}\gamma_k=\infty$. Denote by Z_k^0 the eigenspaces of $\mathcal{A}_0$ corresponding to γ_k for $k=1,2,\ldots$.

LEMMA 2.4. *Let $m\geq 2$ be a positive integer, with P and d as given in* (2.23) *and* (2.29), *respectively. Set*

$$e=\sup_{x\in\Omega}|P|.\tag{2.37}$$

Suppose that ϕ solves problem

$$\begin{cases}\phi_{tt}+\mathcal{A}\phi=0\quad in\quad\Omega\times(0,T),\\ \phi(0)=\varphi^0,\quad\phi_t(0)=\varphi^1\quad in\quad\Omega,\\ \dfrac{\partial\phi}{\partial v_{\mathcal{A}}}=0\quad on\quad\Gamma\times(0,T).\end{cases}\tag{2.38}$$

Then

$$\int_0^T\int_{\Gamma_0}\phi_t^2 H\cdot \upsilon\, d\sigma dt-\int_0^T\int_{\Gamma_1}|\nabla_g\phi|_g^2 H\cdot\upsilon\, d\sigma dt-\frac{1}{2}\int_0^T\int_{\Gamma}\phi^2\nabla_g(\mathrm{div}_0(H))\cdot\upsilon\, d\sigma dt$$

$$\geq 2\left[aT-2b-\frac{e}{\sqrt{\gamma_m}}-\frac{Td}{2\gamma_m}\right]E(0)\quad \forall T>0, \tag{2.39}$$

for all $(\varphi^0,\,\varphi^1)\in H^1(\Omega)\times L^2(\Omega)$ *with* $\varphi^0,\,\varphi^1\ \perp Z_k^0$, $1\leq k\leq m-1$, *for which the left-hand side of* (2.39) *is finite, where this time*

$$E(0)=\frac{1}{2}(\|\varphi^0\|^2_{H^1(\Omega)}+\|\varphi^1\|^2). \tag{2.40}$$

Proof. Since $\frac{\partial\phi}{\partial\upsilon_{\mathcal{A}}}|_\Gamma=0$ and $H(x)\cdot\upsilon(x)\leq 0$ for $x\in\Gamma_1$, we have, from parts 1 and 2 of Proposition 2.1, that

$$\begin{aligned}&\int_0^T\int_{\Gamma_0}\phi_t^2 H\cdot\upsilon\, d\sigma dt-\int_0^T\int_{\Gamma_1}|\nabla_g\phi|_g^2 H\cdot\upsilon\, d\sigma dt-\frac{1}{2}\int_0^T\int_\Gamma\phi^2\nabla_g P\cdot\upsilon\, d\sigma dt\\&=2aTE(0)-\int_0^T\int_{\Gamma_1}\phi_t^2 H\cdot\upsilon\, d\sigma dt+\int_0^T\int_{\Gamma_0}|\nabla_g\phi|_g^2 H\cdot\upsilon\, d\sigma dt+2(\phi_t,\,H(\phi))\Big|_0^T\\&+2\int_0^T\int_\Omega\langle D_{\nabla_g\phi}H,\,\nabla_g\phi\rangle_g\, dxdt-2a\int_0^T\int_\Omega|\nabla_g\phi|_g^2\, dxdt+(\phi_t,\,\phi P)\Big|_0^T\\&+\frac{1}{2}\int_0^T\int_\Omega\phi^2\mathcal{A}P\, dxdt\\&\geq 2aTE(0)-4\|\phi_t\|\|H(\phi)\|-2\|\phi_t\|\|\phi P\|-\frac{d}{2}\int_0^T\int_\Omega\phi^2\, dxdt\\&\geq 2\left[aT-2b-\frac{e}{\sqrt{\gamma_m}}-\frac{Td}{2\gamma_m}\right]E(0)\quad\forall T>0,\end{aligned}$$

for all $(\varphi^0,\,\varphi^1)\in H^1(\Omega)\times L^2(\Omega)$ with $\varphi^0,\,\varphi^1\ \perp Z_k^0$, $1\leq k\leq m-1$, for which the left-hand side of (2.39) is finite, where inequalities

$$\|\phi\|^2\leq\frac{1}{\gamma_m}\||\nabla_g\phi|_g\|^2\quad\forall\,(\varphi^0,\varphi^1)\in H^1(\Omega)\times L^2(\Omega),$$

$$\varphi^0,\,\varphi^1\ \perp Z_k^0,\ 1\leq k\leq m-1$$

are used. □

Consider the operator $\mathcal{A}_{\Gamma_1}$ on $L^2(\Omega)$:

$$\mathcal{D}(A_{\Gamma_1})=\left\{u\ \Big|\ u\in H^2(\Omega),\,\frac{\partial u}{\partial\upsilon_{\mathcal{A}}}\Big|_{\Gamma_0}=0,\,u|_{\Gamma_1}=0\right\},$$

$$A_{\Gamma_1}u=-\sum_{ij=1}^n\frac{\partial}{\partial x_i}\left(a_{ij}(x)\frac{\partial u}{\partial x_j}\right),\quad u\in\mathcal{D}(A_{\Gamma_1}). \tag{2.41}$$

The spectrum of $\mathcal{A}_{\Gamma_1}$ consists of eigenvalues

$$0\leq\beta_1<\beta_2<\cdots<\beta_k<\cdots$$

with $\lim_{k\to\infty}\beta_k=\infty$. Denote by $Z_k^{\Gamma_1}$ the eigenspaces of $\mathcal{A}_{\Gamma_1}$ corresponding to β_k for $k=1,2,\ldots$.

Lemma 2.5. *Let m be a positive integer and e, d the same as those in Lemma 2.4. Let ϕ solve problem*

$$\begin{cases} \phi_{tt}+\mathcal{A}\phi=0 \quad \textit{in} \quad \Omega\times(0,T), \\ \phi(0)=\varphi^0, \quad \phi_t(0)=\varphi^1 \quad \textit{in} \quad \Omega, \\ \dfrac{\partial\phi}{\partial\upsilon_{\mathcal{A}}}=0 \quad \textit{on} \quad \Gamma_0, \quad \phi=0 \quad \textit{on} \quad \Gamma_1. \end{cases} \tag{2.42}$$

Then

$$\begin{aligned} &\int_0^T\int_{\Gamma_0}\phi_t^2 H\cdot\upsilon\, d\sigma dt-\frac{1}{2}\int_0^T\int_{\Gamma_0}\phi^2\nabla_g(\mathrm{div}_0(H))\cdot\upsilon\, d\sigma dt \\ &\qquad\geq 2\left[aT-2b-\frac{e}{\sqrt{\beta_m}}-\frac{Td}{2\beta_m}\right]E(0) \quad \forall\, T>0, \end{aligned} \tag{2.43}$$

for all $(\varphi^0,\varphi^1)\in H^1_{\Gamma_1}(\Omega)\times L^2(\Omega)$ with φ^0, $\varphi^1 \perp Z_k^{\Gamma_1}$, $1\leq k\leq m-1$, for which the left-hand side of (2.43) *is finite, where*

$$E(0)=\frac{1}{2}(\|\varphi^0\|^2_{H^1_{\Gamma_1}(\Omega)}+\|\varphi^1\|^2). \tag{2.44}$$

Proof. Since $\frac{\partial\phi}{\partial\upsilon_{\mathcal{A}}}|_{\Gamma_0}=0$ and $\phi|_{\Gamma_1}=0$, we obtain, from (2.33), (2.35), and Proposition 2.1, parts 1 and 2, that

$$\begin{aligned} &\int_0^T\int_{\Gamma_0}\phi_t^2 H\cdot\upsilon\, d\sigma dt-\frac{1}{2}\int_0^T\int_{\Gamma_0}\phi^2\nabla_g(\mathrm{div}_0(H))\cdot\upsilon\, d\sigma dt=\int_0^T\int_{\Gamma_0}|\nabla_g\phi|_g^2 H\cdot\upsilon\, d\sigma dt \\ &-\int_0^T\int_{\Gamma_1}\left(\frac{\partial\phi}{\upsilon_{\mathcal{A}}}\right)^2\frac{H\cdot\upsilon}{|\upsilon_{\mathcal{A}}|_g^2}\, d\sigma dt+2aTE(0)+2\int_0^T\int_\Omega\langle D_{\nabla_g\phi}H,\ \nabla_g\phi\rangle_g\, d\sigma dt \\ &-2a\int_0^T\int_\Omega|\nabla_g\phi|_g^2\, d\sigma dt+2(\phi_t,\ H(\phi))\Big|_0^T+(\phi_t,\ \phi P)\Big|_0^T+\frac{1}{2}\int_0^T\int_\Omega\phi^2\mathcal{A}P\, dxdt \\ &\geq 2aTE(0)-4\|\phi_t\|\|H(\phi)\|-2\|\phi_t\|\|\phi P\|-\frac{d}{2}\int_0^T\int_\Omega\phi^2\, dxdt \\ &\geq 2\left[aT-2b-\frac{e}{\sqrt{\beta_m}}-\frac{Td}{2\beta_m}\right]E(0) \quad \forall\, T>0, \end{aligned} \tag{2.45}$$

for all $(\varphi^0,\ \varphi^1)\in H^1_{\Gamma_1}(\Omega)\times L^2(\Omega)$ with φ^0, $\varphi^1 \perp Z_k^{\Gamma_1}$, $1\leq k\leq m-1$, for which the left-hand side of (2.45) is finite, where this time inequalities

$$\|\phi\|^2\leq\frac{1}{\beta_m}\||\nabla_g\phi|_g\|^2 \quad \forall\,(\varphi^0,\ \varphi^1)\in H^1_{\Gamma_1}(\Omega)\times L^2(\Omega),$$

$$\varphi^0,\ \varphi^1 \perp Z_k^{\Gamma_1}, \qquad 1\leq k\leq m-1$$

are used. □

Proof of Theorem 1.1. Let T_0 be as defined in (1.18). Let $T>T_0$. Let m be given large enough such that

$$T-T_0-\frac{1}{a}\sqrt{\frac{c}{\lambda_m}}-\frac{Td}{2a\lambda_m}>0. \tag{2.46}$$

Lemma 2.3 yields the following inequality:

$$\int_0^T \int_{\Gamma_0} \left(\frac{\partial \phi}{\partial v_{\mathcal{A}}}\right)^2 d\sigma dt \geq c(T) E(0)$$

$$\forall\, \varphi^0 \in H_0^1(\Omega), \quad \varphi^1 \in L^2(\Omega), \quad \varphi^0,\, \varphi^1 \perp Z_k, \quad 1 \leq k \leq m-1, \tag{2.47}$$

where ϕ solves (1.4) for initial data (φ^0, φ^1) and

$$c(T) = \frac{2}{\vartheta} a \left(T - T_0 - \frac{1}{a}\sqrt{\frac{c}{\lambda_m}} - \frac{Td}{2a\lambda_m}\right) > 0.$$

Inequalities (1.5) and (2.47), together with Komornik [6, Thm. 5.2], give Theorem 1.1. $\square$

Proof of Corollary 1.2. We show that vector field $H = \rho \nabla_g \rho$ verifies condition (1.16) under the assumption of Corollary 1.2.

Let M be a space form of constant curvature k_B with Riemannian metric $\langle \cdot, \cdot \rangle_M$ and let $\widetilde{D}$ be the Levi–Civita connection on M. Let $p \in M$. Let $\widetilde{\rho}(q)$ be the distance function on M from p to $q \in M$. For convenience, we introduce a calculation of $\widetilde{D}^2 \widetilde{\rho}$ which is presented in Wu, Shen, and Yu [19]. Let $\widetilde{r} : [0, b] \to M$ be a normal geodesic from p to q such that there is no point conjugate to p on $\widetilde{r}$. Then $\widetilde{\rho}(q) = b$. Let $\widetilde{X} \in M_q$ such that $\langle X, \widetilde{r}'(b)\rangle_M = 0$ and $|\widetilde{X}|_M = 1$. Let $J(t)$ be a proper Jacobi field along $\widetilde{r}$ such that $J(0) = 0$ and $J(b) = \widetilde{X}$. Since M is of constant curvature, $J(t)$ is an almost parallel field along $\widetilde{r}$. Let $E(t)$ be a unit parallel field such that $E(b) = \widetilde{X}$. Then $J(t) = f(t)E(t)$, where f solves problem

$$\begin{cases} f''(t) + k_B f(t) = 0, \quad 0 < t < b, \\ f(0) = 0, \quad f(b) = 1. \end{cases} \tag{2.48}$$

Expression (2.48) gives

$$f(t) = \begin{cases} \dfrac{t}{b}, \quad k_B = 0, \\ \dfrac{\sin\sqrt{k_B}t}{\sin\sqrt{k_B}b}, \quad k_B > 0, \\ \dfrac{\sinh\sqrt{-k_B}t}{\sinh\sqrt{-k_B}b}, \quad k_B < 0. \end{cases} \tag{2.49}$$

Denote the unit sphere in M_p by S. Suppose that $\sigma : [0, \epsilon] \to S$ is a curve such that $\sigma(0) = \widetilde{r}'(0)$ and such that the transversal vector field of $\{\widetilde{r}_s\}$ is J, where $\widetilde{r}_s(t) = \exp_p t\sigma(s)$. Let $F : [0, b] \times [0, \epsilon] \to M$ be defined by $F(t, s) = \widetilde{r}_s(t)$. Set $T = dF(\frac{\partial}{\partial t})$ and $U = dF(\frac{\partial}{\partial s})$. Then $U(\widetilde{r}(t)) = J(t)$ and $T(\widetilde{r}(t)) = \widetilde{r}'(t) = \frac{\partial}{\partial \widetilde{\rho}}(\widetilde{r}(t))$. From (2.49), we then obtain

$$\begin{aligned} \widetilde{D}^2 \widetilde{\rho}(q)(\widetilde{X}, \widetilde{X}) &= UU\widetilde{\rho} - (\widetilde{D}_U)U\widetilde{\rho} \\ &= U\left\langle U, \frac{\partial}{\partial \widetilde{\rho}}\right\rangle_M - \left\langle \widetilde{D}_U U, \frac{\partial}{\partial \widetilde{\rho}}\right\rangle_M \\ &= U\langle U, T\rangle_M - \langle \widetilde{D}_U U, T\rangle_M \\ &= \langle U, \widetilde{D}_U T\rangle_M = \langle U, \widetilde{D}_T U\rangle_M = \langle J(b), J'(b)\rangle_M = f'(b) \\ &= \begin{cases} \dfrac{1}{b}, \quad k_B = 0, \\ \sqrt{k_B}\cot(\sqrt{k_B}b), \quad k_B > 0, \\ \sqrt{-k_B}\coth(\sqrt{-k_B}b), \quad k_B < 0, \end{cases} \end{aligned} \tag{2.50}$$

where $UT = TU$ is used.

Let $x \in \Omega$. Let $r : [0,\, b] \to B(x^0, \gamma)$ be a normal minimal geodesic from x^0 to x. Then $b = \rho(x)$. Let $X \in \mathbb{R}^n_x$ such that $\langle X,\, r'(b)\rangle_g = 0$. Since $\Omega \subset B(x^0, \gamma)$ and $B(x^0, \gamma) \subset \exp_x(E)$, $\rho(x) = d_g(x^0, x)$ is smooth on $\Omega/\{x^0\}$. We obtain from the Hessian comparison theorem (Greene and Wu [5]) and (2.50) that

$$D^2\rho(X,\, X)(x) = |X|_g^2 D^2\rho\left(\frac{X}{|X|_g},\, \frac{X}{|X|_g}\right) \geq |X|_g^2 \widetilde{D}^2\widetilde{\rho}(\widetilde{X},\, \widetilde{X})$$

$$= \begin{cases} \dfrac{1}{\rho(x)}|X|_g^2, \quad k_B = 0, \\ \sqrt{k_B}\cot(\sqrt{k_B}\rho(x))|X|_g^2, \quad k_B > 0, \\ \sqrt{-k_B}\coth(\sqrt{-k_B}\rho(x))|X|_g^2, \quad k_B < 0, \end{cases}$$

$$\geq \begin{cases} \dfrac{1}{\gamma}|X|_g^2, \quad k_B = 0, \\ \sqrt{k_B}\cot(\sqrt{k_B}\gamma)|X|_g^2, \quad k_B > 0 \quad \forall x \in \Omega, \\ \dfrac{1}{\gamma}|X|_g^2, \quad k_B < 0, \end{cases} \tag{2.51}$$

where inequality

$$\sqrt{-k_B}\rho\left(e^{\sqrt{-k_B}\rho} + e^{-\sqrt{-k_B}\rho}\right) \geq e^{\sqrt{-k_B}\rho} - e^{-\sqrt{-k_B}\rho}, \quad k_B < 0,\, \rho > 0,$$

is used.

Set

$$a = \begin{cases} 1, \quad K_B \leq 0, \\ \sqrt{k_B}\gamma\cot(\sqrt{k_B}\gamma), \qquad K_B > 0. \end{cases} \tag{2.52}$$

It is easily checked that the function $t\sqrt{k_B}\cot(\sqrt{k_B}t)$ is monotonically decreasing in $t \in (0, \infty)$ and

$$t\sqrt{k_B}\cot(\sqrt{k_B}t) \leq 1 \qquad \forall\, t \in (0, \infty). \tag{2.53}$$

We thus obtain from (2.51), (2.52), and (2.53), for any $Y \in \mathbb{R}^n_x$, that

$$\begin{aligned} DH(Y,\, Y)(x) =& \rho D^2\rho(Y,\, Y) + \langle Y,\, r'(b)\rangle_g^2 \\ &= \rho D^2\rho(X,\, X) + \langle Y,\, r'(b)\rangle_g^2 \\ &\geq a\left(|X|_g^2 + \langle Y,\, r'(b)\rangle_g^2\right) = a|Y|_g^2 \quad \forall\, x \in \Omega, \end{aligned} \tag{2.54}$$

where $H = \rho\nabla_g\rho$, $Y = X + \langle Y,\, r'(b)\rangle_g r'(b)$, and $\langle X,\, r'(b)\rangle_g = 0$. □

Proof of Corollary 1.4. Set

$$\gamma_0 = \min\left\{\frac{\pi}{\sqrt{K}},\right.$$

$$\left.\text{half the length of the shortest closed geodesic in } \mathbb{R}^n\right\}.$$

Let $x^0 \in \Omega$. Then $\Omega \subset B(x^0, \frac{\gamma_0}{2})$ since $d_g(\Omega) < \frac{\gamma_0}{2}$. By the Klingenberg theorem (Cheeger and Ebin [2, Cor. 5.7]), we have

$$B\left(x^0, \frac{\gamma_0}{2}\right) \subset \exp_{x^0}(E).$$

Since

$$4\left(\frac{\gamma_0}{2}\right)^2 K = \gamma_0^2 K < \pi^2,$$

Corollary 1.2 completes our proof. □

Proof of Theorem 1.2. It is well known that Γ is a submanifold of Riemannian manifold $(\mathbb{R}^n, g)$ with the induced Riemannian metric g_Γ in $(\mathbb{R}^n, g)$. Denote gradient, divergence, and the Laplace operator on (Γ, g_Γ) by ∇_Γ, div_Γ, and Δ_Γ, respectively. Set $\mathcal{G}(x) = \det G(x)$ for $x \in \mathbb{R}^n$. Let Δ_g be the Laplace operator on $\mathbb{R}^n$ in Riemannian metric g. Then, in the natural system $x = (x_1, x_2, \dots, x_n)$,

$$(2.55)\quad \Delta_g f = \frac{1}{\sqrt{\mathcal{G}(x)}} \sum_{ij=1}^{n} \frac{\partial}{\partial x_i}\left(\sqrt{\mathcal{G}(x)} a_{ij}(x) \frac{\partial f}{\partial x_j}\right) \quad \forall f \in C^2(\mathbb{R}^n), \quad x \in \mathbb{R}^n.$$

By the formula of divergence in Riemannian metric g and from part 1 of Lemma 2.1, we have

$$(2.56)\quad \int_\Omega \Delta_g f\, d\Omega_g = \int_\Gamma \left\langle \nabla_g f, \frac{\upsilon_{\mathcal{A}}}{|\upsilon_{\mathcal{A}}|_g}\right\rangle_g d\sigma_\Gamma = \int_\Gamma \frac{1}{|\upsilon_{\mathcal{A}}|_g} \nabla_g f \cdot \upsilon d\sigma_\Gamma \quad \forall f \in C^2(\overline{\Omega}),$$

where Ω_g and $d\sigma_\Gamma$ are the metric volume element and the metric surface element in Riemannian metric g, respectively. It is easily checked that $d\Omega_g = \sqrt{\mathcal{G}(x)} dx$. We thus obtain from (2.55) and part 2 of Lemma 2.1 that

$$(2.57)\quad \int_\Omega \Delta_g f\, d\Omega_g = \int_\Omega \mathrm{div}_0(\sqrt{\mathcal{G}(x)} \nabla_g f)\, dx = \int_\Gamma \sqrt{\mathcal{G}(x)} \nabla_g f \cdot \upsilon\, d\sigma \quad \forall f \in C^2(\overline{\Omega}).$$

Formulae (2.57) and (2.56) give

$$(2.58)\qquad d\sigma_\Gamma = |\upsilon_{\mathcal{A}}|_g \sqrt{\mathcal{G}(x)} d\sigma.$$

In addition, by the Stokes theorem for Riemannian manifold (Γ, g_Γ), we have

$$(2.59)\qquad -\int_\Gamma f \Delta_\Gamma f\, d\sigma_\Gamma = \int_\Gamma |\nabla_\Gamma f|_g^2\, d\sigma_\Gamma$$

for any $f \in H^1(\Gamma)$.

In the following, let ϕ solve problem (2.38) for initial data (φ^0, φ^1). Then

$$(2.60)\qquad |\nabla_g \phi|_g^2 = \left(\frac{\partial \phi}{\partial \upsilon_{\mathcal{A}}}\right)^2 + |\nabla_\Gamma \phi|_g^2 = |\nabla_\Gamma \phi|_g^2 \quad \forall x \in \Gamma,$$

since $\frac{\partial \phi}{\upsilon_{\mathcal{A}}} = 0$ on Γ.

We define ψ by

$$(2.61)\qquad \begin{cases} \psi_{tt} + \mathcal{A}\psi = 0 \quad \text{in} \quad \Omega \times (0,T), \\ \psi(T) = \psi_t(T) = 0, \\ \dfrac{\partial \psi}{\partial \upsilon_{\mathcal{A}}} = \begin{cases} (\phi_{tt} - \phi)|\upsilon_{\mathcal{A}}|_g \sqrt{\mathcal{G}(x)} & \text{on} \quad \Gamma_0 \times (0,T), \\ (\Delta_\Gamma \phi - \phi)|\upsilon_{\mathcal{A}}|_g \sqrt{\mathcal{G}(x)} & \text{on} \quad \Gamma_1 \times (0,T). \end{cases} \end{cases}$$

The solution of (2.61) is a weak solution, defined by transposition. Therefore, given φ^0, φ^1, we have defined, in a unique fashion,

$$(2.62)\qquad \Lambda_1(\varphi^0, \varphi^1) = (\psi_t(0), -\psi(0)).$$

Then, from (2.38), (2.61), (2.60), and (2.58), we obtain, in the sense of distribution,

$$\langle \Lambda_1(\varphi^0,\, \varphi^1),\, (\varphi^0,\, \varphi^1)\rangle = \int_0^T \int_{\Gamma_0} (\phi^2 + \phi_t^2)\, d\sigma_\Gamma dt + \int_0^T \int_{\Gamma_1} (\phi^2 + |\nabla_\Gamma \phi|_g^2)\, d\sigma_\Gamma dt. \tag{2.63}$$

We define on initial data (φ_0, φ^1)

$$\|(\varphi_0, \varphi^1)\|_F = \left(\int_0^T \int_{\Gamma_0} (\phi^2 + \phi_t^2)\, d\sigma_\Gamma dt + \int_0^T \int_{\Gamma_1} (\phi^2 + |\nabla_\Gamma \phi|_g^2)\, d\sigma_\Gamma dt \right)^{1/2}. \tag{2.64}$$

Set

$$\mathcal{X}(T) = \left\{ (\varphi^0, \varphi^1) \;\middle|\; (\varphi^0, \varphi^1) \in H^1(\Omega) \times L^2(\Omega),\, \|(\varphi^0, \varphi^1)\|_F < \infty \right\}. \tag{2.65}$$

Then $\mathcal{X}(T) \subset F$. It is easily checked that $\|\cdot\|_F$ is a seminorm on $\mathcal{X}(T)$.

Let T_0 be given in (1.18). Let $T > T_0$. Suppose that m is given large enough such that

$$T - T_0 - \frac{e}{a\sqrt{\gamma_m}} - \frac{Td}{2a\gamma_m} > 0. \tag{2.66}$$

Set

$$\varepsilon = \max \left(\sup_{x \in \Gamma} \frac{|H \cdot v|}{|v_{\mathcal{A}}|_g \sqrt{\mathcal{G}}},\, \sup_{x \in \Gamma} \frac{|\nabla_g (\mathrm{div}_0 H) \cdot v|}{2|v_{\mathcal{A}}|_g \sqrt{\mathcal{G}}} \right), \tag{2.67}$$

$$c_m = \frac{2a}{\varepsilon} \left(T - T_0 - \frac{e}{a\sqrt{\gamma_m}} - \frac{Td}{2a\gamma_m} \right). \tag{2.68}$$

Lemma 2.4, (2.58), (2.67), and (2.68) then yield the following:

$$\int_0^T \int_{\Gamma_0} (\phi^2 + \phi_t^2)\, d\sigma_\Gamma dt + \int_0^T \int_{\Gamma_1} (\phi^2 + |\nabla_\Gamma \phi|_g^2)\, d\sigma_\Gamma dt \geq c_m E(0)$$

$$\forall\, (\varphi^0, \varphi^1) \in \mathcal{X}(T), \quad \varphi^0,\, \varphi^1 \;\perp\; Z_k^0, \quad 1 \leq k \leq m - 1. \tag{2.69}$$

By the compactness-uniqueness argument, we now show that there is a $c(T) > 0$ such that

$$\|(\varphi_0, \varphi^1)\|_F^2 \geq c(T) E(0) \quad \forall\, (\varphi^0, \varphi^1) \in \mathcal{X}(T). \tag{2.70}$$

Suppose that inequality (2.70) does not hold true. There is a sequence $\{(\varphi_k^0, \varphi_k^1)\} \subset H^1(\Omega) \times L^2(\Omega)$ with

$$E_k(0) = \frac{1}{2}(\|\varphi_k^0\|_{H^1(\Omega)}^2 + \|\varphi_k^1\|^2) = 1 \tag{2.71}$$

for all $k \geq 1$ such that

$$\|(\varphi_k^0, \varphi_k^1)\|_F \leq \frac{1}{k}, \quad k = 1, 2, \ldots. \tag{2.72}$$

Let $H^1(\Omega)\times L^2(\Omega)$ be decomposed into a direct sum:

$$H^1(\Omega)\times L^2(\Omega)=\big((\oplus_{k=1}^{m-1}Z_k^0)\times(\oplus_{k=1}^{m-1}Z_k^0)\big)\oplus\widetilde{W}. \tag{2.73}$$

It is easily checked that

$$\dim\big((\oplus_{k=1}^{m-1}Z_k^0)\times(\oplus_{k=1}^{m-1}Z_k^0)\big)<\infty. \tag{2.74}$$

Set

$$(\varphi_k^0,\varphi_k^1)=\widetilde{u}_k+\widetilde{w}_k,\quad k=1,2,\dots, \tag{2.75}$$

where $\widetilde{u}_k\in(\oplus_{k=1}^{m-1}Z_k^0)\times(\oplus_{k=1}^{m-1}Z_k^0)$ and $\widetilde{w}_k\in\widetilde{W}$. From (2.74), we can assume that

$$\widetilde{u}_k\to\widetilde{u}_0\in\mathcal{X}(T)\quad\text{in}\quad\|\cdot\|_F,\quad\text{as}\quad k\to\infty. \tag{2.76}$$

Since $\|\cdot\|_F$ is a seminorm on $\mathcal{X}(T)$, we obtain from (2.40), (2.69), (2.72), and (2.75) that

$$\sqrt{c_m}\|\widetilde{w}_k-\widetilde{w}_j\|_{H^1(\Omega)\times L^2(\Omega)}\le\|\widetilde{w}_k-\widetilde{w}_j\|_F\le\left(\frac{1}{k}+\frac{1}{j}\right)+\|\widetilde{u}_k-\widetilde{u}_j\|_F\quad\forall\, k\ge1,\ j\ge1.$$

This means that by (2.76),

$$(\varphi_k^0,\varphi_k^1)\to(u^0,u^1)\quad\text{in}\quad H^1(\Omega)\times L^2(\Omega)\quad\text{as}\quad k\to\infty. \tag{2.77}$$

It follows from (2.71) and (2.77) that

$$\|(u^0,u^1)\|_{H^1(\Omega)\times L^2(\Omega)}=1. \tag{2.78}$$

Let ϕ^0 solve problem (2.38) for $(\varphi^0,\varphi^1)=(u^0,u^1)$. Then $\frac{\partial\phi^0}{\partial v_{\mathcal{A}}}|_\Gamma=0$. In addition, by the trace theorem of Sobolev spaces, (2.64), and (2.72), we know that there is a constant $\beta>0$ such that

$$\begin{aligned}\int_0^T\|\phi^0\|_{L^2(\Gamma)}^2\,dt&\le\int_0^T\|\phi^0-\phi^k\|_{L^2(\Gamma)}^2\,dt+\int_0^T\|\phi^k\|_{L^2(\Gamma)}^2\,dt\\&\le\beta\int_0^T\|\phi^0-\phi^k\|_{H^1(\Omega)}^2dt+\|(\varphi_k^0,\varphi_k^1)\|_F^2\\&\le\beta T\|(u^0,u^1)-(\varphi_k^0,\varphi_k^1)\|_{H^1(\Omega)\times L^2(\Omega)}^2+\frac{1}{k^2},\end{aligned} \tag{2.79}$$

where ϕ^k solve problems (2.38) with initial data $(\varphi^0,\varphi^1)=(\varphi_k^0,\varphi_k^1)$ for $k=1,2,\dots$. Expressions (2.77) and (2.79) give

$$\phi^0|_\Gamma=0. \tag{2.80}$$

From (2.80), we may apply observability inequality (1.9) to ϕ^0 and obtain

$$(u^0,u^1)=0,$$

contradicting (2.78).

The inequality in (2.70) gives

$$F\subset H^1(\Omega)\times L^2(\Omega),\quad T>T_0.$$

It follows that

$$(H^1(\Omega))' \times L^2(\Omega) \subset F',$$

so that, if $y^0 \in L^2(\Omega)$, $y^1 \in (H^1(\Omega))'$, we can derive the system in (1.1) and (1.1b) to rest at T by the control function v given by

$$v = \begin{cases} (-\phi + \phi_{tt})|\upsilon_{\mathcal{A}}|_g \sqrt{\mathcal{G}(x)} & \text{on} \quad \Gamma_0 \times (0,T), \\ (-\phi + \Delta_\Gamma \phi)|\upsilon_{\mathcal{A}}|_g \sqrt{\mathcal{G}(x)} & \text{on} \quad \Gamma_1 \times (0,T). \end{cases}$$

This completes the proof of Theorem 1.2. □

Proof of Theorem 1.3. Let T_0 be given in (1.18) and $T > T_0$. Since $\Gamma_1 = \{\, x \,|\, x \in \Gamma,\ H(x) \cdot \upsilon(x) = 0 \,\}$, by starting with Lemma 2.4 and following the proof of Theorem 1.2, we can get the following inequality:

$$\int_0^T \int_\Gamma (\phi^2 + \phi_t^2)\, d\sigma dt \geq c_T E(0), \tag{2.81}$$

where $c_T > 0$ is a constant. This time we define a norm on initial data (φ^0, φ^1) by

$$\|(\varphi^0, \varphi^1)\|_F = \left(\int_0^T \int_\Gamma \phi^2 \, d\sigma dt \right)^{1/2}.$$

From (2.81), a technical argument similar to Lions [12] gives

$$\int_0^T \int_\Gamma \phi^2 \, d\sigma dt \geq c'_T E(0).$$

This completes our proof. □

Proof of Theorem 1.4. Let T_0 be given in (1.18) and $T > T_0$. Let ϕ solve problem (2.42). From Lemma 2.5 and by following the proof of Theorem 1.3, we can obtain $c_T > 0$, satisfying

$$\int_0^T \int_{\Gamma_0} (\phi^2 + \phi_t^2) \geq c_T E(0) \tag{2.82}$$

for all $(\varphi^0,\, \varphi^1) \in H^1_{\Gamma_1}(\Omega) \times L^2(\Omega)$, for which the left-hand side of (2.82) is finite.

On the initial data (φ^0, φ^1), we define the norm by

$$\|(\varphi^0, \varphi^1)\|_F = \left(\int_0^T \int_{\Gamma_0} (\phi^2 + \phi_t^2)\, d\sigma dt \right)^{1/2}.$$

From (2.82), we have

$$F \subset H^1_{\Gamma_1}(\Omega) \times L^2(\Omega).$$

Then

$$F' \supset (H^1_{\Gamma_1}(\Omega))' \times L^2(\Omega).$$

This completes our proof, where we take

$$v = -\phi + \phi_{tt} \quad \text{in} \quad \Gamma_0. \qquad \square$$

3. Examples.

Example 3.1. Let (a_{ij}) be a positive, symmetric constant matrix. Consider the operator $\mathcal{A}$ on $\mathbb{R}^n$, given by

$$\mathcal{A}u = -\sum_{ij=1}^{n} a_{ij}\frac{\partial^2 u}{\partial x_i \partial x_j}.$$

It is easily verified that Riemannian manifold $(\mathbb{R}^n, g)$ is of zero sectional curvature, where

$$g = \sum_{ij}^{n} g_{ij}dx_i dx_j \quad \text{and} \quad (g_{ij}) = (a_{ij})^{-1}. \tag{3.1}$$

By Corollary 1.2,

$$a = 1. \tag{3.2}$$

Let $x^0 \in \mathbb{R}^n$. The distance function ρ satisfies

$$\rho^2(x) = d_g^2(x^0, x) = \sum_{ij=1}^{n} g_{ij}(x_i - x_i^0)(x_j - x_j^0) \quad \forall\ x \in \mathbb{R}^n. \tag{3.3}$$

We obtain

$$\frac{\partial h}{\partial x_k} = \sum_{j=1}^{n} g_{kj}(x_j - x_j^0), \tag{3.4}$$

where $h = \frac{1}{2}\rho^2(x)$. It follows from (3.4) and part 2 of Lemma 2.1 that

$$\nabla_g h = \sum_{i=1}^{n}\left(\sum_{k=1}^{n} a_{ik}\frac{\partial h}{\partial x_k}\right)\frac{\partial}{\partial x_i} = \sum_{i=1}^{n}(x_i - x_i^0)\frac{\partial}{\partial x_i}. \tag{3.5}$$

This gives

$$\sup_{x\in\Omega} |\nabla_g h|_g(x) = \sup_{x\in\Omega} \rho(x), \tag{3.6}$$

so that vector field $H = \nabla_g h$ meets condition (1.16) with $T_0 = 2\sup_{x\in\Omega}\rho(x)$ for any $\Omega \subset \mathbb{R}^n$. This coincides with the result in Komornik [6], where $a_{ij} = \delta_{ij}$. □

LEMMA 3.1. *Let $a_1, a_2, \ldots, a_n$ be positive numbers and M be the hypersurface of $\mathbb{R}^{n+1}$ given by*

$$M = \left\{ (x_1, x_2, \ldots, x_n, x_{n+1}) \;\Big|\; x_{n+1} = \frac{1}{2}\sum_{i=1}^{n} a_i x_i^2 \right\} \tag{3.7}$$

with the induced Riemannian metric in $\mathbb{R}^{n+1}$. Then M is of everywhere positive sectional curvature.

Proof. Let $p = (x_1, x_2, \ldots, x_{n+1}) \in M$. Then

$$M_p = \left\{ X \;\Big|\; X = \sum_{i=1}^{n+1} \alpha_i \frac{\partial}{\partial x_i},\ \alpha_{n+1} = \sum_{i=1}^{n} a_i x_i \alpha_i \right\}. \tag{3.8}$$

Set

$$Z=\sum_{i=1}^{n}a_ix_i\frac{\partial}{\partial x_i}-\frac{\partial}{\partial x_{n+1}}. \tag{3.9}$$

Then $v(p)=\frac{Z}{|Z|_0}$ is a unit normal vector field on M. Denote the connection of the usual flat metric of $\mathbb{R}^{n+1}$ by D^0. Let X, Y be vector fields on M. Then the second fundamental form of M is

$$S(X,Y)=-\left[(D^0_XY)\cdot v\right]v. \tag{3.10}$$

Set

$$X_i=\frac{\partial}{\partial x_i}+a_ix_i\frac{\partial}{\partial x_{n+1}},\quad i=1,2,\dots,n. \tag{3.11}$$

Then $X_1,X_2,\dots,X_n$ is a vector field basis of M. Since $D^0_{\frac{\partial}{\partial x_k}}\frac{\partial}{\partial x_l}=0$ for $1\le k,\,l\le n+1$, we obtain from (3.11)

$$D^0_{X_i}X_j=X_i(a_jx_j)\frac{\partial}{\partial x_{n+1}}=\frac{\partial}{\partial x_i}(a_jx_j)\frac{\partial}{\partial x_{n+1}}=\delta_{ij}a_j\frac{\partial}{\partial x_{n+1}},\quad 1\le i,\,j\le n. \tag{3.12}$$

It follows from (3.10) and (3.12) that

$$S(X_i,\,X_j)=\frac{\delta_{ij}a_j}{|Z|_0}v,\quad 1\le i,\,j\le n. \tag{3.13}$$

Denote the curvature tensor of the Riemannian metric of M by $\mathbb{R}$. Let $\pi\subset M_p$ be a two-dimensional subspace and X, Y be a basis of π, where

$$X=\sum_{i=1}^{n}\alpha_iX_i\quad\text{and}\quad Y=\sum_{i=1}^{n}\beta_iX_i.$$

From (3.13) and the Gauss equation (Wu, Shen, and Yu [19]), we have

$$\begin{aligned}\mathbb{R}(X,\,Y,\,X,\,Y)&=S(X,\,X)\cdot S(Y,\,Y)-|S(X,\,Y)|_0^2\\&=\frac{1}{|Z|_0}\left[\left(\sum_{i=1}^{n}a_i\alpha_i^2\right)\left(\sum_{i=1}^{n}a_i\beta_i^2\right)-\sum_{i=1}^{n}a_i\alpha_i\beta_i\right]>0,\end{aligned} \tag{3.14}$$

since X, Y are linearly independent. Equation (3.14) completes the proof. □

Example 3.2. Let $a_i>0$ be constants, with $i=1,2,\dots,n$. Consider the operator on $\mathbb{R}^n$:

$$\mathcal{A}u=-\sum_{i=1}^{n}\frac{\partial}{\partial x_i}\left(\frac{1+\sum\limits_{j\ne i}^{n}a_j^2x_j^2}{1+\sum\limits_{k=1}^{n}a_k^2x_k^2}\frac{\partial u}{\partial x_i}\right)+\sum_{i\ne j}\frac{\partial}{\partial x_i}\left(\frac{a_ia_jx_ix_j}{1+\sum\limits_{k=1}^{n}a_k^2x_k^2}\frac{\partial u}{\partial x_j}\right).$$

Set

$$A(x) = \frac{1}{1+\sum\limits_{k=1}^{n} a_k^2x_k^2}\begin{pmatrix} 1+\sum\limits_{i=2}^{n} a_i^2x_i^2 & -a_1a_2x_1x_2 & \cdots & -a_1a_nx_1x_n \\ -a_2a_nx_1x_n & 1+\sum\limits_{i\neq 2} a_i^2x_i^2 & \cdots & -a_2a_nx_2x_n \\ \cdots & \cdots & \cdots & \cdots \\ -a_na_1x_nx_1 & -a_na_2x_nx_2 & \cdots & 1+\sum\limits_{i=1}^{n-1} a_i^2x_i^2 \end{pmatrix}. \tag{3.15}$$

Then

$$G(x) = A^{-1}(x) = \begin{pmatrix} 1+a_1^2x_1^2 & a_1a_2x_1x_2 & \cdots & a_1a_nx_1x_n \\ a_2a_nx_1x_n & 1+a_2^2x_2^2 & \cdots & a_2a_nx_2x_n \\ \cdots & \cdots & \cdots & \cdots \\ a_na_1x_nx_1 & a_na_2x_nx_2 & \cdots & 1+a_n^2x_n^2 \end{pmatrix}. \tag{3.16}$$

Consider Riemannian manifold $(\mathbb{R}^n, g)$, where Riemannian metric g is determined in the natural coordinate system $x = (x_1, x_2, \ldots, x_n)$ by

$$g = \sum_{i,j=1}^{n} (\delta_{ij} + a_ia_jx_ix_j)\, dx_idx_j. \tag{3.17}$$

Then

$$\sum_{i,j=1}^{n} (\delta_{ij} + a_ia_jx_ix_j)\, \xi_i\xi_j \geq |\xi|_0^2 \quad \forall\, x,\, \xi = (\xi_1, \xi_2, \ldots, \xi_n) \in \mathbb{R}^n. \tag{3.18}$$

It is easily checked from (3.18) that $(\mathbb{R}^n, g)$ is a complete noncompact Riemannian manifold.

Let M be the hypersurface of $\mathbb{R}^{n+1}$ given by Lemma 3.1 with the induced Riemannian metric in $\mathbb{R}^{n+1}$. It is easily verified from (3.17) and (3.8) that map $\Phi : M \to (\mathbb{R}^n, g)$, defined by

$$\Phi(p) = x \quad \forall\, p = (x_1, x_2, \ldots, x_{n+1}) \in M \tag{3.19}$$

is an isometry. By Lemma 3.1, $(\mathbb{R}^n, g)$ is of everywhere positive sectional curvature. By Corollary 1.1, $H = Dh$ verifies condition (1.16) for any $\Omega \subset \mathbb{R}^n$, where h is a strictly convex function over $(\mathbb{R}^n, g)$. $\square$

Example 3.3. Let $\mathcal{A}$ be defined by

$$\begin{aligned} \mathcal{A}u = &-\frac{\partial}{\partial x}\left(\frac{1+y^6}{1+x^2+y^6}\frac{\partial u}{\partial x}\right) - \frac{\partial}{\partial x}\left(\frac{xy^3}{1+x^2+y^6}\frac{\partial u}{\partial y}\right) \\ &- \frac{\partial}{\partial y}\left(\frac{xy^3}{1+x^2+y^6}\frac{\partial u}{\partial x}\right) - \frac{\partial}{\partial y}\left(\frac{1+x^2}{1+x^2+y^6}\frac{\partial u}{\partial y}\right). \end{aligned} \tag{3.20}$$

Set

$$A(x,y) = \begin{pmatrix} \dfrac{1+y^6}{1+x^2+y^6} & \dfrac{xy^3}{1+x^2+y^6} \\ \dfrac{xy^3}{1+x^2+y^6} & \dfrac{1+x^2}{1+x^2+y^6} \end{pmatrix}. \tag{3.21}$$

Then

$$G(x,y) = (g_{ij}) = A^{-1}(x,y) = \begin{pmatrix} 1+x^2 & -xy^3 \\ -xy^3 & 1+y^6 \end{pmatrix}. \tag{3.22}$$

Consider Riemannian manifold $(\mathbb{R}^2, g)$, where Riemannian metric g is defined in the natural coordinate system (x,y) by

$$g = (1+x^2)dxdx - xy^3dxdy - xy^3dydx + (1+y^6)dydy. \tag{3.23}$$

Let surface M in $\mathbb{R}^3$ be given by

$$M = \left\{ (x,y,z) \;\middle|\; z = \frac{1}{2}x^2 - \frac{1}{4}y^4 \right\}$$

with the induced Riemannian metric in $\mathbb{R}^3$. Then the map $\Phi(x,y,z) = (x,y)$, for any $(x,y,z) \in M$, determines an isometry from M to $(\mathbb{R}^2, g)$. We obtain the Gaussian curvature of $(\mathbb{R}^2, g)$ at (x,y):

$$\begin{aligned} k(x,y) &= \text{the Gaussian curvature of } M \text{ at } (x,y,z) \\ &= \frac{-3y^2}{(1+x^2+y^6)^2} \le 0 \quad \forall\, (x,y) \in \mathbb{R}^2. \end{aligned}$$

Let $(x^0, y^0) \in \mathbb{R}^2$. By Corollary 1.3, vector field $H = \rho D\rho$ satisfies condition (1.16) for any $\Omega \subset \mathbb{R}^2$ with $a = 1$, where ρ is the distance function from (x^0, y^0) to (x,y) in metric g. □

It is not an easy task to calculate the sectional curvature of a Riemannian manifold in general. For convenience, we give a lemma.

Lemma 3.2. *Let* $\mathbb{R}^2$ *have the metric*

$$g = g_1 dxdx + g_2 dydy,$$

where $g_1 > 0$, $g_2 > 0$ *are* C^∞ *functions on* $\mathbb{R}^2$. *Then the Gaussian curvature is*

$$\begin{aligned} k = \frac{1}{4g_1^2g_2^2}\Bigg[& g_2 \frac{\partial g_1}{\partial x}\frac{\partial g_2}{\partial x} + g_1 \frac{\partial g_1}{\partial y}\frac{\partial g_2}{\partial y} \\ & + g_1\left(\frac{\partial g_2}{\partial x}\right)^2 + g_2\left(\frac{\partial g_1}{\partial y}\right)^2 - 2g_1g_2\left(\frac{\partial^2 g_1}{\partial y^2} + \frac{\partial^2 g_2}{\partial x^2}\right)\Bigg]. \end{aligned} \tag{3.24}$$

Proof. Set

$$X = \frac{1}{\sqrt{g_1}}\frac{\partial}{\partial x}, \quad Y = \frac{1}{\sqrt{g_2}}\frac{\partial}{\partial y}.$$

Then X, Y is an orthonormal frame on $(\mathbb{R}^2, g)$. We thus have

$$k = \langle R_{XY}X, Y\rangle = \frac{1}{g_1g_2}\left\langle R_{\frac{\partial}{\partial x}\frac{\partial}{\partial y}}\frac{\partial}{\partial x}, \frac{\partial}{\partial y}\right\rangle, \tag{3.25}$$

where $R_{XY}X = -D_XD_YX + D_YD_XX + D_{[X,Y]}X$ and R is the curvature tensor. Let Γ_{ij}^k be the coefficients of connection D. Then

$$\Gamma_{12}^1 = \frac{1}{2g_1}\frac{\partial g_1}{\partial y}, \quad \Gamma_{11}^2 = -\frac{1}{2g_2}\frac{\partial g_1}{\partial y}, \quad \Gamma_{12}^2 = \frac{1}{2g_2}\frac{\partial g_2}{\partial x}.$$

From the properties of connection, we have

$$\begin{aligned} D_{\frac{\partial}{\partial x}} D_{\frac{\partial}{\partial y}} \frac{\partial}{\partial x} &= D_{\frac{\partial}{\partial x}} \left(\Gamma_{12}^1 \frac{\partial}{\partial x} + \Gamma_{12}^2 \frac{\partial}{\partial y} \right) \\ &= (\cdots) \frac{\partial}{\partial x} + \Gamma_{12}^1 D_{\frac{\partial}{\partial x}} \frac{\partial}{\partial x} + \frac{\partial \Gamma_{12}^2}{\partial x} \frac{\partial}{\partial y} + \Gamma_{12}^2 D_{\frac{\partial}{\partial x}} \frac{\partial}{\partial y} \\ &= (\cdots) \frac{\partial}{\partial x} + \left(\Gamma_{12}^1 \Gamma_{11}^2 + \frac{\partial \Gamma_{12}^2}{\partial x} + \Gamma_{12}^2 \Gamma_{12}^2 \right) \frac{\partial}{\partial y}. \end{aligned} \tag{3.26}$$

Thus

$$\begin{aligned} \left\langle D_{\frac{\partial}{\partial x}} D_{\frac{\partial}{\partial y}} \frac{\partial}{\partial x},\ \frac{\partial}{\partial y} \right\rangle_g &= \left(\Gamma_{12}^1 \Gamma_{11}^2 + \frac{\partial \Gamma_{12}^2}{\partial x} + \Gamma_{12}^2 \Gamma_{12}^2 \right) g_2 \\ &= \frac{1}{2} \frac{\partial^2 g_2}{\partial x^2} - \frac{1}{4 g_1} \left(\frac{\partial g_1}{\partial y} \right)^2 - \frac{1}{4 g_2} \left(\frac{\partial g_2}{\partial x} \right)^2, \end{aligned} \tag{3.27}$$

since $\langle \frac{\partial}{\partial x},\ \frac{\partial}{\partial y} \rangle_g = 0$. A calculation similar to (3.27) gives

$$\left\langle D_{\frac{\partial}{\partial y}} D_{\frac{\partial}{\partial x}} \frac{\partial}{\partial x},\ \frac{\partial}{\partial y} \right\rangle_g = -\frac{1}{2} \frac{\partial^2 g_1}{\partial y^2} + \frac{1}{4 g_1} \frac{\partial g_1}{\partial x} \frac{\partial g_2}{\partial x} + \frac{1}{4 g_2} \frac{\partial g_1}{\partial y} \frac{\partial g_2}{\partial y}. \tag{3.28}$$

Equations (3.27) and (3.28), together with (3.25), yield (3.24). □

Example 3.4. Let $\mathcal{A}$ be the operator

$$\mathcal{A} u = -\frac{\partial}{\partial x} \left(e^{x^3 + y^3} \frac{\partial u}{\partial x} \right) - \frac{\partial}{\partial y} \left(e^{x^3 + y^3} \frac{\partial u}{\partial y} \right). \tag{3.29}$$

Then Riemannian manifold $(\mathbb{R}^2, g)$ is with a metric

$$g = e^{-x^3 - y^3} (dx^2 + dy^2). \tag{3.30}$$

By Lemma 3.2, we have

$$k(x, y) = 3(x + y) e^{x^3 + y^3}, \quad (x, y) \in \mathbb{R}^2. \tag{3.31}$$

By (3.31), we obtain

$$\sup_{(x,y) \in \mathbb{R}^2} K(x, y) = \infty.$$

Take

$$H = -e^{-x} \frac{\partial}{\partial x} - e^{-y} \frac{\partial}{\partial y}, \tag{3.32}$$

and we obtain by calculation

$$\langle D_X H,\ X \rangle_g = \sum_{i,j=1}^{2} h_{ij} X_i X_j \quad \forall\, X = X_1 \frac{\partial}{\partial x} + X_2 \frac{\partial}{\partial y}, \tag{3.33}$$

where

$$(h_{ij}) = \begin{pmatrix} h e^{-x} + \frac{3}{2}(x^2 h e^{-x} + y^2 h e^{-y}) & \frac{3}{2}(x^2 e^{-y} - y^2 e^{-x}) h \\ \frac{3}{2}(y^2 e^{-x} - x^2 e^{-y}) h & h e^{-y} + \frac{3}{2}(x^2 h e^{-x} + y^2 h e^{-y}) \end{pmatrix}, \tag{3.34}$$

$$h = e^{-x^3-y^3}.$$

It follows from (3.33) and (3.34) that

$$\begin{aligned}\langle D_X H,\, X\rangle_g &= \left[he^{-x} + \frac{3}{2}(x^2he^{-x} + y^2he^{-y})\right]X_1^2 + \left[he^{-y} + \frac{3}{2}(x^2he^{-x} + y^2he^{-y})\right]X_2^2 \\ &\geq ah(X_1^2 + X_2^2) = a|X|_g^2, \quad X = X_1\frac{\partial}{\partial x} + X_2\frac{\partial}{\partial y} \in R^2_{(x,y)},\ (x,y) \in \overline{\Omega},\end{aligned}$$

where

$$a = \min_{x\in\overline{\Omega}} \left\{ e^{-x} + \frac{3}{2}(x^2e^{-x} + y^2e^{-y}),\ e^{-y} + \frac{3}{2}(x^2e^{-x} + y^2e^{-y}) \right\}.$$

Then vector field H, given by (3.32), meets condition (1.16) for any $\Omega \subset \mathbb{R}^2$.

Moreover, H is not the Hessian of any function on $\mathbb{R}^2$ in Riemannian metric g since matrix (h_{ij}), given by (3.34), is not symmetric. □

Example 3.5. Let $\mathcal{A}$ be given by

$$\mathcal{A}u = -\frac{\partial}{\partial x}\left(e^{x+y}\frac{\partial u}{\partial x}\right) - \frac{\partial}{\partial y}\left(e^{x+y}\frac{\partial u}{\partial y}\right). \tag{3.35}$$

Riemannian manifold $(\mathbb{R}^2,\, g)$ has a metric

$$g = e^{-x-y}dxdx + e^{-x-y}dydy. \tag{3.36}$$

We obtain from Lemma 3.2 that $k(x,y) = 0$ for any $(x,y) \in \mathbb{R}^2$; that is, $(\mathbb{R}^2, g)$ is of zero curvature. By Corollary 1.3, vector field $H = \rho D\rho$ is satisfied with condition (1.16) with $a = 1$ for any $\Omega \subset \mathbb{R}^2$, where ρ is the distance function over Riemannian manifold $(\mathbb{R}^2, g)$. □

Example 3.6. Consider the operator

$$\mathcal{A}u = -\frac{\partial}{\partial x}\left(e^{x+y}\frac{\partial u}{\partial x}\right) - \frac{\partial}{\partial y}\left(e^{-x-y}\frac{\partial u}{\partial y}\right).$$

Riemannian manifold $(\mathbb{R}^2,\, g)$ has the metric

$$g = e^{x+y}dxdx + e^{-x-y}dydy.$$

By Lemma 3.2 we obtain $k(x,y) = -\frac{1}{2}(e^{-x-y} + e^{x+y}) < 0$ for any $(x,y) \in \mathbb{R}^2$. $(\mathbb{R}^2, g)$ is of everywhere negative curvature. Corollary 1.3 can be applied. □

4. Necessary conditions for exact controllability and counterexamples. Given the linear partial differential operator P,

$$Pu = \frac{\partial^2 u}{\partial t^2} - \mathcal{A}u, \tag{4.1}$$

acting on functions, one sets $f_\alpha = e^{i\alpha(x\cdot\zeta + t\tau)}$ and

$$p(x,t,\zeta,\tau) = \lim_{\alpha\wr\infty}[\overline{f}_\alpha P(f_\alpha)](x,t) = \sum_{ij=1}^{n} a_{ij}(x)\zeta_i\zeta_j - \tau^2. \tag{4.2}$$

Function p is the principal symbol of P.

Given $(x_0, t_0, \zeta_0) \in \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^n/0$, $(x(s), t(s), \zeta(s), \tau(s))$ is a null bicharacteristic curve through (x_0, t_0, ζ_0) if it satisfies the (Hamiltonian) system of ordinary differential equations

$$x' = \frac{1}{2}\frac{\partial p}{\partial \zeta}, \quad t' = \frac{1}{2}\frac{\partial p}{\partial \tau}, \quad \zeta' = -\frac{1}{2}\frac{\partial p}{\partial x}, \quad \text{and} \quad \tau' = -\frac{1}{2}\frac{\partial p}{\partial t} \tag{4.3}$$

with $(x(0), t(0), \zeta(0)) = (x_0, t_0, \zeta_0)$ and $\tau(0)$ chosen so that $p(x_0, t_0, \zeta_0, \tau(0)) = 0$. To abbreviate the terminology, the projection of a bicharacteristic curve is called a ray.

Lemma 4.1. *Let $x(t)$ be a geodesic on Riemannian manifold $(\mathbb{R}^n, g)$ with $x(0) = x_0$ parameterized by arc length. Then*

$$(x(t), \pm t, \zeta(t), \mp 1) \tag{4.4}$$

are bicharacteristic curves through $(x_0, 0, \zeta_0)$, where

$$\zeta(t) = \sum_{i=1}^n \left[\sum_{j=1}^n g_{ij}(x(t))x_j'(t)\right] \frac{\partial}{\partial x_i}, \quad \zeta_0 = \zeta(0). \tag{4.5}$$

Proof. It will suffice to verify (4.3). From (4.5), we obtain

$$x_i'(t) = \sum_{j=1}^n a_{ij}(x(t))\zeta_j(t). \tag{4.6}$$

It follows from (4.2) and (4.6) that

$$x'(t) = \frac{1}{2}\frac{\partial p}{\zeta}. \tag{4.7}$$

In addition, we obtain

$$\sum_{l=1}^n \frac{\partial g_{lp}}{\partial x_i} a_{lk} = -\sum_{l=1}^n g_{lp}\frac{\partial a_{lk}}{\partial x_i}, \tag{4.8}$$

since $\sum_{l=1}^n g_{lp}a_{lk} = \delta_{pk}$.

Since $x(t)$ is a geodesic, we have

$$x_i'' + \sum_{lp=1}^n \Gamma_{lp}^i x_l' x_p' = 0, \tag{4.9}$$

where Γ_{lp}^i are the coefficients of the Levi–Civita connection, given by

$$\Gamma_{lp}^i = \frac{1}{2}\sum_{h=1}^n a_{ih}\left(\frac{\partial g_{hl}}{\partial x_p} + \frac{\partial g_{hp}}{\partial x_l} - \frac{\partial g_{lp}}{\partial x_h}\right). \tag{4.10}$$

It follows from (4.5), (4.9), (4.10), and (4.8) that

$$\zeta_i'(t) = \left(\sum_{j=1}^n g_{ij}(x(t))x_j'(t)\right)'$$

$$\begin{aligned}
&= \sum_{kj=1}^{n} \frac{\partial g_{ij}}{\partial x_k} x_k' x_j' + \sum_{j=1}^{n} g_{ij}(x(t)) x_j''(t) \\
&= \sum_{kj=1}^{n} \frac{\partial g_{ij}}{\partial x_k} x_k' x_j' - \sum_{jlp} g_{ij} \Gamma_{lp}^{j} x_l' x_p' \\
&= \frac{1}{2} \sum_{lp} \frac{\partial g_{lp}}{\partial x_i} x_l' x_p' \\
&= \frac{1}{2} \sum_{lpkj} g_{lp} \frac{\partial a_{lk}}{\partial x_i} a_{pj} \zeta_k \zeta_j = -\frac{1}{2} \sum_{kj} \frac{\partial a_{jk}}{\partial x_i} \zeta_k \zeta_j = -\frac{1}{2} \frac{\partial p}{\partial x_i};
\end{aligned}$$

that is,

$$\zeta'(t) = -\frac{1}{2} \frac{\partial p}{\partial x}.$$

Furthermore, (4.5) and (4.2) yield also

$$p(x(t), \pm t, \zeta(t), \mp 1) = \sum_{ijkl} a_{ij} g_{ik} g_{jl} x_k' x_l' - 1 = \sum_{kl} g_{kl} x_k' x_l' - 1 = 0,$$

since $x(t)$ is parameterized by arc length. This completes our proof. □

By Lemma 4.1 and Bardos, Lebeau, and Rauch [1, Thm. 3.2], the following result is immediate.

THEOREM 4.1. *If there is a closed geodesic that is contained in Ω, then the system in* (1.1), (1.1a) *has no exact controllability where $\Gamma_0 = \Gamma$; that is, for any $T > 0$,*

$$F_{T,\Gamma} \neq H_0^1(\Omega) \times L^2(\Omega).$$

Example 4.1. Consider the operator

$$\mathcal{A}u = -\frac{\partial}{\partial x}\left((1 + x^2 + y^2)^2 \frac{\partial u}{\partial x}\right) - \frac{\partial}{\partial y}\left((1 + x^2 + y^2)^2 \frac{\partial u}{\partial y}\right). \tag{4.11}$$

The Riemannian metric g on $\mathbb{R}^2$ is

$$g = \frac{dxdx + dydy}{(1 + x^2 + y^2)^2}. \tag{4.12}$$

Set

$$B_1 = \{ (x, y) \,|\, x^2 + y^2 < 1 \}, \quad S = \{ (x, y) \,| x^2 + y^2 = 1 \}.$$

We have the following conclusions:

(1) If $\overline{\Omega} \subset B_1$ or $\overline{\Omega} \subset \mathbb{R}^2 - B_1 \bigcup S$, then Theorem 1.1 holds true.

(2) If $S \subset \Omega$, then the system in (1.1), (1.1a) has no exact controllability; that is for any $T > 0$,

$$F_{T,\Gamma} \neq H_0^1(\Omega) \times L^2(\Omega).$$

Proof. From Lemma 3.2, we obtain $k(x, y) = 4$ for any $(x, y) \in \mathbb{R}^2$. $(\mathbb{R}^2, g)$ is then a space form of constant curvature 4. Let M be the sphere of radius $\frac{1}{2}$ and center $(0, 0, \frac{1}{2})$ in $\mathbb{R}^3$, given by

$$M = \{ (x_1, x_2, x_3) \,|\, x_1^2 + x_2^2 + x_3^2 = x_3 \} \tag{4.13}$$

with the induced Riemannian metric in $\mathbb{R}^3$. Then $(\mathbb{R}^2 \cup \{\infty\},\, g)$ is isometric to M with isometry $\Phi : M \to (\mathbb{R}^2 \cup \{\infty\},\, g)$ defined by

$$\Phi(x_1, x_2, x_3) = \left(\frac{x_1}{1 - x_3},\ \frac{x_2}{1 - x_3}\right) \quad \forall \quad (x_1, x_2, x_3) \in M. \tag{4.14}$$

It is easily checked that

$$\sup_{(x,y)\in\mathbb{R}^2} d_g(0, (x, y)) = \frac{\pi}{2}, \qquad \sup_{x^2+y^2=1} d_g(0, (x, y)) = \frac{\pi}{4}.$$

This shows that we can obtain a geodesic ball $B((x^0, y^0), \gamma)$ in $(\mathbb{R}^2 \cup \{\infty\},\, g)$ such that

$$\overline{\Omega} \subset B((x^0, y^0), \gamma) \quad \text{and} \quad \gamma < \frac{\pi}{4}$$

when $\overline{\Omega} \subset B_1$ or $\overline{\Omega} \subset \mathbb{R}^2 - B_1 \bigcup S$. Part 1 then follows from Corollary 1.2.

In order to prove part 2 it will suffice from Theorem 4.1 to prove that the unit circle S is a closed geodesic on $(\mathbb{R}^2, g)$. It is well known that the big circle $C = \{\, (x_1, x_2, \frac{1}{2}) \mid x_1^2 + x_2^2 = \frac{1}{4}\,\}$ is a closed geodesic on the sphere M. In addition, it is easily checked that

$$S = \Phi(C),$$

where Φ is given by (4.14). This gives our desired result since Φ is an isometry from M to $(\mathbb{R}^2, g)$.

Appendix. A sketch of the proof of Theorem 1.1 for the case $n = 1$. Let $l > 0$ and $a(\cdot) \in C^1[0, 1]$, $a(x) > 0$ for any $x \in [0, l]$.

For system

$$\begin{cases} \phi_{tt} = (a(x)\phi_x)_x, & 0 < t < T, \quad 0 < x < l, \\ \phi(t, 0) = \phi(t, l) = 0, & 0 < t < T, \\ \phi(0, x) = \varphi_0(x), \quad \phi_t(0, x) = \varphi_1(x), & 0 < x < l, \end{cases} \tag{A.1}$$

we use multiplier $h\phi_x$, where h is a function on the interval $[0, l]$, and we obtain

$$\begin{aligned} \frac{1}{2}\int_0^T\int_0^l (ah\phi_x^2)_x dxdt = (\phi_t, h\phi_x)\Big|_0^T &+ \frac{1}{2}\int_0^T\int_0^l h_x(\phi_t^2 + a(x)\phi_x^2)\, dxdt \\ &- \frac{1}{2}\int_0^T\int_0^l a_x h\phi_x^2\, dxdt. \end{aligned} \tag{A.2}$$

Let h be the solution of the following problem:

$$\begin{cases} h_x = \dfrac{b}{a}h + 1, \\ h(0) = 0, \end{cases} \tag{A.3}$$

where $b(x) = \max(a_x, 0)$, e.g.,

$$h(x) = e^{\int_0^x \frac{b}{a} dx} \int_0^x e^{-\int_0^s \frac{b}{a} d\tau} ds, \qquad 0 \le x \le l. \tag{A.4}$$

We may obtain, when h, defined by (A.4), enters (A.2),

$$a(l)h(l)\int_0^T \phi_x^2(t, l)\, dt \ge 2TE(0) + 2(\phi_t, h\phi_x)\Big|_0^T, \qquad T > 0, \tag{A.5}$$

where $E(0) = \frac{1}{2}\int_0^l (\phi_t^2 + a\phi_x^2)\, dx$. Inequality (A.5) yields our desired result.

Acknowledgments. I would like to express my thanks to Professors D. X. Feng, I. Lasiecka, and J. L. Lions for their valuable advice. Special thanks go to Professor R. Triggiani for his valuable advice and kindly help.

AVERAGING METHOD FOR ONE-SIDED LIPSCHITZ DIFFERENTIAL INCLUSIONS WITH GENERALIZED SOLUTIONS[*]

TZANKO DONCHEV[†] AND IORDAN SLAVOV[‡]

Abstract. We investigate the convergence of the solution set for singularly perturbed differential inclusions using an averaging technique. The limits of the fast solutions are considered as generalized solutions (i.e., Radon probability measures) of the degenerate system. Exploiting in addition the one-sided Lipschitz condition we prove the existence of a limit of the solution set in an appropriate topology.

Key words. differential inclusion, singular perturbation, one-sided Lipschitz, generalized solution, averaging method

1. Introduction.

Consider the following singularly perturbed multivalued Cauchy problem:

$$\begin{pmatrix} \dot{x}(t) \\ \varepsilon\dot{y}(t) \end{pmatrix} \in H(t, x(t), y(t)), \quad x(0) = x^0, y(0) = y^0. \tag{1.1}$$

The real parameter $\varepsilon > 0$ represents the singular perturbation. Here $x \in \mathbf{R}^n, y \in \mathbf{R}^m$, while $H : I(:= [0,1]) \times \mathbf{R}^n \times \mathbf{R}^m \Longrightarrow \mathbf{R}^{n+m}$ is a multifunction. The variable x is commonly called a “slow” variable, while y is called a “fast” variable. The solution set $Z(\varepsilon), \varepsilon > 0$ of (1.1) consists of all absolutely continuous (AC) functions (x, y) satisfying (1.1) for almost everywhere (a.e.) $t \in I$. For $\varepsilon = 0^+$ it is natural to mean by $Z(0)$ the set of all pairs (x, y) with x-AC and y-integrable on I, satisfying for a.e. $t \in I$

$$\begin{pmatrix} \dot{x}(t) \\ 0 \end{pmatrix} \in H(t, x(t), y(t)), \quad x(0) = x^0. \tag{1.2}$$

The connection between the inclusions (1.1) and (1.2) has been investigated in many papers [5], [6], [7], [16], [17]. For example, in [6] the upper semicontinuity (USC) of the map $\varepsilon \to Z(\varepsilon)$ at $\varepsilon = 0^+$ in $C(I, \mathbf{R}^n) \times (L^2(I, \mathbf{R}^m)$-weak) topology is shown. The lower semicontinuity (LSC) is proved first in [16] and afterwards for more general systems in [4]. However, the question of the continuity (USC plus LSC in one and the same topology) of $Z(\varepsilon)$ at $\varepsilon = 0^+$ has no satisfactory answer. The limit of the solution set is evaluated in some simple cases and is not equal to $Z(0)$ (see [7]) which also makes the problem so complicated.

Our aim is to find conditions and “reasonable” topology in which $Z(\varepsilon)$ has a limit when $\varepsilon \to 0^+$. We consider reasonable any topology implying the continuity of an

integral cost minimized over $Z(\varepsilon)$, i.e., the trajectories of (1). Here we combine the averaging technique elaborated in [14], [12], [9], [10], [11] with the notion of generalized solutions (Radon probability measures) to obtain the existence of the limit of $Z(\varepsilon)$ at $\varepsilon = 0^+$. Let us note that our settings are more general and assumptions are weaker than those in [11] where a similar problem is investigated.

We consider the next particular case of (1.1):

$$\begin{aligned} &\dot{x}(t) \in F(t, x, y, u(t)), \quad x(0) = x^0, \\ &\varepsilon \dot{y}(t) \in G(x, y, u(t)), \quad y(0) = y^0. \end{aligned} \tag{1.3}$$

Here $u(t) \in U$, $u(\cdot)$ is measurable and U is a compact subset of a complete metric space. We will call all such functions *admissible controls.*

The choice of the above special form of (1.1) is dictated by the use of averaging techniques in our proofs. Note also that (1.3) is more general than a system of two differential inclusions (just fix the measurable function $u(\cdot)$ in (1.3)) and than a control system as well (in this case F and G are single-valued for every $u(\cdot)$). These are the cases studied many times using the method of averaging; see references [9], [10], [14]. For the general system (1.1) we do not know any relevant results. On the other hand, (1.3) also covers the case of singularly perturbed control systems with additional uncertainties or disturbances different than the control.

The fundamental theorem of Tikhonov [15] states that for single-valued H under appropriate conditions the unique solution of (1.1) converges as $\varepsilon \to 0$ to a special solution of (1.2) in $C(I, \mathbf{R}^n) \times C([\delta, 1], \mathbf{R}^m)$, for every $0 < \delta < 1$. While the LSC of the solution set of (1.1), (1.2) in Tikhonov's topology is not difficult to prove, the USC is. This problem is solved partially in [14], [17] under restrictive assumptions. Here, we suppose that the y-part of the solution set is embedded in the space of all Radon probability measures $\Re$, i.e., we consider y-variables as additional controls which are called, in optimal control theory, relaxed. Thus we pay special attention to the influence of the solutions of (1.1) with rapidly oscillating y-parts on the limit behavior of the whole solution set. First, we prove for (1.1) that $Z(\varepsilon)$ is USC at $\varepsilon = 0^+$ where in y we use the $[L^1(I, C(K))]^*$-weak* topology (K is the compact set defined after Lemma 3.1 which contains all y-parts of $Z(\varepsilon)$). This topology induces a convergence which is equivalent to the well-known weak convergence of measures in $\Re$.

This way we follow the ideas of [19] which very recently were developed for systems of singularly perturbed ODEs and control systems in [2], [18]. The class of measures considered in the cited papers is narrower, namely measures *invariant* with respect to the flow generated by the *associated* system (see below). Further attempt to apply the same approach is made in [1], where invariant measures for differential inclusions are introduced (see next section for details).

As mentioned above, the object we investigate is more general. Moreover, Example 1 in this paper tells us that the class of invariant measures still is not narrow enough to ensure LSC of $Z(\varepsilon)$ at $\varepsilon = 0^+$. Thus some additional conditions (e.g., additional restrictions on the class of measures used) should be imposed to describe the limit set.

We continue with a brief description of the averaging technique. Fix $t \in I$ and consider the following *associated* system:

$$\begin{aligned} &x = \text{const.}, \\ &\dot{y}(\tau) \in G(x, y(\tau), u(\tau)), \quad y(0) \in Q \subset \mathbf{R}^m, \quad u(\tau) \in U, \quad \tau \geq 0. \end{aligned} \tag{1.4}$$

For given x and t, denote (using Aumann's integral)

$$\bar{V}(t,x,S,Q) = \mathrm{cl}\left\{ \frac{1}{S}\int_0^S F(t,x,Y(\tau,x,S,Q),u(\tau))\,d\tau : u(\tau) \in U \right\},$$

where $Y(\tau,x,S,Q)$ is the solution set on the interval $[0,S]$ of (1.4) and **cl** denotes the closed hull. In the third section of the paper, following the scheme of [9], we show the existence of the nondepending on Q limit (in the Hausdorff metric)

$$\bar{V}(t,x) = \lim_{S\to\infty} \bar{V}(t,x,S,Q).$$

Then exploiting further the one-sided Lipschitz property (see section 3) we prove that the "slow part," that is, the projection of $Z(\varepsilon)$ on $\mathbf{R}^n$, converges in the C-topology to the solution set of the averaged inclusion

$$\dot{x}(t) \in \bar{V}(t,x), \quad x(0) = x^0, \quad t \in I. \tag{1.5}$$

The above-mentioned one-sided Lipschitz (OSL) condition plays a central role in our considerations. Postponing the exact definition until the third section we would like to illustrate the essential difference between OSL and Lipschitz conditions. Suppose $f(t,\cdot)$ (for a.e. $t \in I$) and $g(\cdot)$ are Lipschitz and consider the control system

$$\begin{aligned} \dot{x}(t) &= f(t,x,y,u(t)) + \phi(x), \quad x(0) = x^0,\\ \varepsilon\dot{y}(t) &= g(x,y,u(t)) + \psi(y), \quad y(0) = y^0. \end{aligned}$$

We assume $\phi(\cdot)$ and $\psi(\cdot)$ OSL are continuous (for example, $\phi(x) = -\sqrt[3]{x}$, $\psi(y) = -\sqrt[3]{y}$). Then the right-hand side of the system is OSL but it is not Lipschitz. So, adding very natural and simple functions to a Lipschitz right-hand side we could violate the conditions in [9]. Nevertheless we show here that the averaging technique will still work if the OSL condition is met (as in the system above).

Using the possibility to approximate $Z(\varepsilon)$ (for (1.3)) with the solution set of (1.5), we prove in Theorem 3.3 that $Z(\varepsilon)$ has a Kuratowski limit (the definition is given in the last section). Our proof is not constructive as in [7]. We just benefit from the fact that the set $Z(0)$ is extended with (generalized) functions equivalent in some sense to measures.

We finish the introduction with some notations and definitions. For $A \subset R^{n+m}$, we denote by $\hat{A}$ the projection of A on $\mathbf{R}^n$ and by $\tilde{A}$ the projection of A on $\mathbf{R}^m$. Throughout the paper, $\langle\cdot,\cdot\rangle$ is the scalar product, and $|.|$ is the norm. For a set A denote by $\sigma(x,A) := \sup_{y\in A}\langle x,y\rangle$ its support function and by $D_H(A,B)$ the Hausdorff distance between the sets A, B. Recall that $C(X,Y)$, resp., $L^1(X,Y)$, is the space of all continuous functions, resp., all Lebesgue integrable functions defined on X (equipped with the Lebesgue measure) with values in Y. The multifunction F from the topological space X into the topological space Y is said to be USC (resp., LSC) at $x \in X$ when to every open $V \supset F(x)$ ($V \bigcap F(x) \neq \emptyset$) there exists a neighborhood $W \ni x$ such that $V \supset F(y)$ ($V \bigcap F(y) \neq \emptyset$) for $y \in W$. When X and Y are metrizable (metric) spaces and F is compact valued then F is USC iff it admits a compact graph restricted to a compact subset of X. Furthermore F is LSC at x iff for every $x_i \to x$, $z \in F(x)$ there exist $z_i \in F(x_i)$ with $z_i \to z$ as $i \to +\infty$.

All the concepts not discussed in detail in the following can be found in [3] or in [19].

2. Generalized (relaxed) solutions. In this section we consider (1.1), (1.2) with respect to a topology in which USC at $\varepsilon = 0^+$ of $Z(\varepsilon)$ is easy to obtain but the LSC does not hold in general. Nevertheless in the next section we prove that $\lim_{\varepsilon\to 0^+} Z(\varepsilon)$ (in the Kuratowski sense) exists in the considered topology.

First, start with the following assumptions on the right-hand-side H of (1.1).

A1. H has nonempty, convex, compact values and is bounded on bounded sets. There exist $a, b, \mu > 0$ such that

$$\sigma(x, \hat{H}(t,x,y)) \le a(1+|x|^2+|y|^2),$$
$$\sigma(y, \tilde{H}(t,x,y)) \le b(1+|x|^2) - \mu|y|^2.$$

A2. $H(\cdot,\cdot,\cdot)$ is almost continuous, i.e., for every $\delta > 0$ there exists $I_\delta \subset I$ with measure greater than $1-\delta$ such that H is continuous on $I_\delta \times \mathbf{R}^{n+m}$.

The following statement is a consequence from a result proved in [4].

LEMMA 2.1. *Under* A1 *and* A2 *the solution set* $Z(\varepsilon)$ *of* (1.1) *is nonempty, every solution* $(x,y) \in Z(\varepsilon)$ *exists on the whole* I, *and there exist constants* $M, N > 0$ *such that* $|x(t)| + |y(t)| \le M$ *and* $|H(t,x(t),y(t))| \le N$ *for every* $t \in I$ *and* $\varepsilon > 0$.

This result allows us to consider the "fast" y-parts of $Z(\varepsilon)$ as measures over the *compact* set $K = \{y \in \mathbf{R}^m : |y| \le M\}$. To this end let $\Re(K)$ be the set of all Radon probability measures on K equipped with the weak convergence topology and define the set of functions

$$\wp := \{\nu : I \to \Re(K) \mid \nu(\cdot) \text{ is measurable}\}.$$

Then if every point $y \in K$ is considered as the Dirac measure δ_y concentrated at the point y (i.e., $\delta_y(\{y\}) = 1$) we can represent every measurable function $y : I \to K$ as $\bar{\nu}(\cdot) = \delta_{y(\cdot)}$ which is an element of $\wp$.

DEFINITION 2.1. *The pair* (x,ν) *of AC function* x *and* $\nu \in \wp$ *is said to be a generalized (relaxed) solution of the degenerate inclusion* (1.2) *when* $x(0) = x^0$ *and for a.e.* $t \in I$

$$\begin{pmatrix} \dot{x}(t) \\ 0 \end{pmatrix} \in \int_K H(t,x(t),y)\nu(t)\,(dy),$$

where dy *indicates that the integration is done with respect to* y. *Denote the set of the generalized solutions of* (1.2) *by* Z_G.

Let E^m be the space of all Carathéodory functions $f(\cdot,\cdot)$ on $I \times K$ with values in $\mathbf{R}^m$, i.e., $f(\cdot,y)$ is measurable, $f(t,\cdot)$ is continuous and integrally bounded. Then E^m is isometrically isomorphic to $L^1(I, C(K,\mathbf{R}^m))$ (see [19, Theorem I.5.25]). Moreover, from the Dunford–Pettis theorem ([19, Theorem IV.1.8]) we know that $\wp$ with the weak norm topology is isomorphic to the space $[L^1(I, C(K,\mathbf{R}^m))]^*$ equipped with the weak$*$ topology. Then $\nu_i \to \nu$ for $\nu_i, \nu \in \wp$ and $i = 1,2,\dots$ iff

$$\int_I \left(\int_K f(t,y)\nu_i(t)\,(dy)\right) dt \to \int_I \left(\int_K f(t,y)\nu(t)\,(dy)\right) dt, \quad \text{for every } f \in E^m,$$

which means that $y_i(\cdot) \in L^1(I,\mathbf{R}^m)$ converges to $\nu(\cdot)$ in $L^1(I, C(K,\mathbf{R}^m))^*$-weak* iff

$$\lim_{i\to\infty} \int_I f(t,y_i(t))\,dt = \int_I \left(\int_K f(t,y)\nu(t)\,(dy)\right) dt \tag{2.1}$$

for every $f \in E^m$.

From [19, Chapter IV], we know that $[L^1(I, C(K, \mathbf{R}^m))]^*$-weak* is separable and every closed bounded ball is metrizable. Furthermore, the set $\mathcal{B} = \{g \in L^1(I, C(K, \mathbf{R}^m)) : g(\cdot,\cdot) \text{ is Lipschitz}\}$ is a dense subset of $L^1(I, C(K, \mathbf{R}^m))$. Therefore to prove that $\{y_\varepsilon\}_{\varepsilon>0}$ converges to ν as $\varepsilon \to 0$ it is sufficient to show that $\{y_\varepsilon\}_{\varepsilon>0}$ is bounded and that (2.1) holds for any f_j, where $\mathcal{F} = \{f_j\}_{j=1}^\infty$ is dense in $\mathcal{B}$. We will use only the elements of $\mathcal{F}$ to check (2.1) in the proof of Theorem 3.3.

THEOREM 2.1. *Under the conditions* A1 *and* A2 *the map* $\varepsilon \to Z(\varepsilon)$ *is USC at* $\varepsilon = 0^+$ *in* $C(I, \mathbf{R}^n) \times [(L^1(I, C(K, \mathbf{R}^m))]^*$*-weak* topology.*

Proof. Suppose $\varepsilon_i \to 0$ and $(x_i, y_i) \in Z(\varepsilon_i)$ for every $i = 1, 2, \ldots$. The sequence $\{x_i(\cdot)\}_{i=1}^\infty$ is $C(I, \mathbf{R}^n)$ precompact due to Lemma 2.1 and to the Arzelà–Ascoli theorem. We know that $\{y_i(\cdot)\}_{i=1}^\infty$ is $[L^1(I, C(K, R^m))]^*$-weak* precompact (Theorem IV.2.1 of [19]). Therefore passing to subsequences if necessary (x_i, y_i) converges to (x_0, ν_0) and $(\dot{x}_i, \varepsilon_i \dot{y}_i)$ converges to $(\dot{x}_0, 0)$ in $L^1(I, \mathbf{R}^{m+n})$-weak. The second assertion is standard in singular perturbation theory; see, e.g., [6]. Now we will show that $(x_0, \nu_0) \in Z_G$.

Let $r \in \mathbf{R}^{n+m}$ be arbitrary and let $[s, t] \subset I$. For every i one has

$$\Big\langle r, (x_i(t) - x_i(s), \varepsilon_i(y_i(t) - y_i(s)))\Big\rangle \le \int_s^t \sigma(r, H(\tau, x_i(\tau), y_i(\tau)))\, d\tau.$$

By A2 and Lemma 2.1 we get $\sigma(r, H(\cdot, x, \cdot)) \in E^1$. Due to Theorem IV.2.9 of [19],

$$\lim_{i\to\infty} \int_s^t \sigma(r, H(\tau, x_i(\tau), y_i(\tau)))\, d\tau = \int_s^t \left\{ \int_K \sigma(r, H(\tau, x_0(\tau), y))\nu_0(\tau)\,(dy) \right\} d\tau.$$

Combining the above two inequalities we obtain

$$\Big\langle r, (x^0(t) - x^0(s), 0)\Big\rangle \le \int_s^t \left\{ \int_K \sigma(r, H(\tau, x_0(\tau), y))\nu_0(\tau)\,(dy) \right\} d\tau$$

for every $t \ge s \in I$. Consequently $x_0(0) = x^0$ and

$$\begin{pmatrix} \dot{x}(t) \\ 0 \end{pmatrix} \in \int_K H(t, x(t), y)\nu_0(t)\,(dy).$$

Hence $\varepsilon \to Z(\varepsilon)$ has $C(I, \mathbf{R}^n) \times [L^1(I, C(K, \mathbf{R}^m))]^*$ -weak* compact graph. $\square$

Remark 2.1. The result is also valid if instead of almost continuity we suppose almost USC, i.e., if we replace "continuous" by "USC" in A2.

Using the notion of invariant measures for ordinary differential inclusions introduced recently in [1] and the construction of the cited paper one can prove that Theorem 2.1 holds true if we restrict $\nu(t)$ to be an invariant measure for a.e. $t \in I$ of the associated differential inclusion

$$\dot{y}(\tau) \in \tilde{H}(\tau, x(t), y), \quad \tau \in [t, \infty).$$

Artstein defines in [1] invariant measures as limits of convex combinations of the so-called individual invariant measures. Not entering into details (exact definitions and the corresponding theory for flows can be found, e.g., in [13]), we will use the last characterization to show that restricting to invariant measures is still not sufficient to achieve LSC of $Z(\varepsilon)$ in the topology of Theorem 2.1. Consider the following example.

Example 2.1. The system

$$\begin{aligned}&\dot{x} = x + y + u(t), \quad x(0) = 0,\\ &\varepsilon\dot{y} = -y + \sqrt[3]{y}, \quad y(0) = 0, \quad u(t) \in [-1,1], \quad t \in I,\end{aligned}$$

satisfies conditions A1 and A2. Rewriting the second equation as $dy/d\tau = -y + \sqrt[3]{y}, \tau \in [0,\infty)$, it is not difficult to see that $y = -1$ and $y = 1$ are its stable resting points. Hence the Dirac measures δ_{-1} and δ_1 concentrated at -1 and 1, respectively, are *individual* invariant measures of the associated system. Then $\nu = (1/3)\delta_{-1} + (2/3)\delta_1$ is invariant measure of the associated system in the terminology of [1]. But there is no solution $(x_\varepsilon, y_\varepsilon)$ of the singularly perturbed system such that its "fast" part y_ε approaches ν in the topology considered.

3. Approximation of the solution set. In this section we consider the system (1.3) and show that $\bar{V}(t,x) = \lim_{S\to\infty} \bar{V}(t,x,S,Q)$ exists and does not depend on $Q \subset P$ where $P = \{y \in \mathbf{R}^m : |y| \le M\}$. The constant M will be determined in Lemma 3.1. Introduce the main condition.

B1. There exist positive constants A, B, D, μ such that

$$\begin{aligned}\sigma(x_1 - x_2, F(t,x_1,y_1,u)) - \sigma(x_1 - x_2, F(t,x_2,y_2,u)) &\le A|x_1 - x_2|^2 + B|y_1 - y_2|^2,\\ \sigma(y_1 - y_2, G(x_1,y_1,u)) - \sigma(y_1 - y_2, G(x_2,y_2,u)) &\le D|x_1 - x_2|^2 - \mu|y_1 - y_2|^2,\end{aligned}$$

uniformly in $u \in U$. F is almost continuous and G is continuous. They have nonempty, convex, and compact values and are bounded on bounded sets.

Condition B1 is the so-called OSL condition. Here we use the negative constant $-\mu$ in order to introduce some stability requirement on the "fast" variables y. But even with positive constants the above condition is "viable." For example, one can extend Theorem 2.1 of averaging of differential inclusions of [11] for system (1.3) replacing the Lipschitz condition used there by OSL plus continuity conditions.

Note also that

$$\begin{aligned}\sigma(x, F(t,x,y,u)) &\le \sigma(x, F(t,0,0,u)) + A|x|^2 + B|y|^2,\\ \sigma(y, G(x,y,u)) &\le \sigma(y, G(0,0,u)) + D|x|^2 - \mu|y|^2,\end{aligned}$$

i.e., if $H \equiv (F,G)$, then A1 and A2 follow from B1. Then we can prove the next lemma; see [4].

Lemma 3.1. *Under* B1 *the solution set* $Z(\varepsilon)$ *of* (1.3) *is nonempty, every solution* $(x,y) \in Z(\varepsilon)$ *exists on the whole* I*, and there exist constants* $M, N > 0$ *such that* $|x(t)| + |y(t)| \le M$ *and* $|F(t,x(t),y(t),u(t))| + |G(x(t),y(t),u(t))| \le N$ *for every* $t \in I, \varepsilon > 0$ *and* $u(\cdot)$*-admissible.*

Remark 3.1. Clearly M and N determined in Lemma 2.1 and in the last lemma are different. However, we do not distinguish them since this causes no confusion.

Lemma 3.2. *Given* $y^1, y^2 \in P$*, under* B1 *for every solution* $y_1(\cdot)$ *of* (1.4) *with* $y_1(0) = y^1$ *there exists a solution* $y_2(\cdot)$ *of* (1.4) *with* $y_2(0) = y^2$ *such that* $|y_1(\tau) - y_2(\tau)| \le \exp(-\mu\tau)|y^1 - y^2|, \tau \ge 0$.

Proof. Let $u(\cdot)$ correspond to $y_1(\cdot)$ in (1.4). Fix $u(\cdot)$ and consider the map

$$\Gamma(\tau, v) = \{w \in G(x, v, u(\tau)) : \langle y_1(\tau) - v, \dot{y}_1(\tau) - w\rangle \le -\mu|y_1(\tau) - v|^2\}.$$

Using the fashion of the proof of Theorem 1 in [16] (see also Theorem 3.2 in [4]) one can show that $\Gamma(\cdot,\cdot)$ is nonempty, convex, compact valued, and almost USC (for the last notion, see Remark 2.1). Therefore, there exists a solution $y_2(\cdot)$ of

$$\dot{z}(\tau) \in \Gamma(\tau, z(\tau)), \quad z(0) = y^2.$$

Obviously $\langle y_1(\tau)-y_2(\tau),\dot{y}_1(\tau)-\dot{y}_2(\tau)\rangle \le -\mu|y_1(\tau)-y_2(\tau)|^2$ and therefore $|y_1(\tau)-y_2(\tau)|\le m(\tau)$, where $\dot{m}\le -\mu m,\ \ m(0)=|y^1-y^2|$. □

The modulus of continuity of a multifunction is defined as follows.

Definition 3.1. *For* $\Gamma : I\times \mathbf{R}^p \Longrightarrow \mathbf{R}^q$*,* $\mathcal{A}\subset I, \mathcal{A}$ *compact, and* $\delta, a>0$ *we let*

$$\omega_\Gamma(\delta,\mathcal{A};a)=\sup\{D_H(\Gamma(t,z_1),\Gamma(s,z_2)) : |t-s|\le\delta,\ \ t,s\in\mathcal{A},\\ |z_1-z_2|\le a,\ \ |z_i|\le M\}.$$

Here M *is from Lemma* 3.1*. Clearly if* $\Gamma(\cdot,\cdot)$ *is continuous on* $\mathcal{A}\times\{z\in\mathbf{R}^p : |z|\le M\}$ *then* $\omega_\Gamma(\delta,\mathcal{A};a)\to 0$ *as* $\delta,a\to 0$*.*

In case we want to stress the dependence of the modulus on some parts of the phase variables we will put additional arguments, e.g., for $F(t,x,y,u)$ we denote the modulus by $\omega_F(\delta,\mathcal{A};a,b,c)$ for $b,c>0$.

B2. Let $f(\tau)=\omega_F(0,I;0,M\exp(-\mu\tau),0)$ and suppose that

$$\int_0^\infty f(\tau)\,d\tau = L_1<\infty.$$

Remark 3.2. The above condition holds, for example, if $F(t,x,\cdot,u)$ is Hölderian, i.e., there exist C and α such that $D_H(F(t,x,v,u),F(t,x,w,u))\le C(|v-w|^\alpha+|v-w|^{1+\alpha})$. It is easy to see that in this case $L_1=C(M^\alpha/\mu\alpha+M^{1+\alpha}/(1+\alpha)\mu)$. Furthermore, if $g(\cdot,x,\cdot)\in\mathcal{B}$, then g satisfies B2.

The following statement is an obvious consequence of Lemma 3.2.

Lemma 3.3. *Given* $y^1,y^2\in P$*, under* B1 *and* B2 *for every solution* $y_1(\cdot)$ *of* (1.4) *with* $y_1(0)=y^1$*, there exists a solution* $y_2(\cdot)$ *of* (1.4) *with* $y_2(0)=y^2$ *such that*

$$\frac{1}{S}\int_0^S D_H(F(t,x,y_1(\tau),u(\tau)),F(t,x,y_2(\tau),u(\tau)))\,d\tau\le\frac{L_1}{S}$$

for every $S>0$ *and every* $t\in I$*. Here* L_1 *is the constant from* B2*.*

Repeating with minor modifcations the reasons (not so short) in [8] we can derive the following.

Theorem 3.1. *Under the assumptions* B1 *and* B2 $\lim_{S\to\infty}\bar{V}(t,x,S,Q)=\bar{V}(t,x)$ *exists and does not depend on* $Q\subset P$*, and* $\bar{V}(t,x)$ *is closed and convex. Moreover,* $D_H(\bar{V}(t,x,S,Q),\bar{V}(t,x))\le L_2/\sqrt{S}; L_2=\text{const.}$*, for* S *sufficiently large.*

Here we deal with (1.3) under the OSL condition B1 in contrast to [8], [9], [10] where control systems under Lipschitz conditions are considered. Although B1 is weaker it enables us to derive more directly the closeness of $Z(\varepsilon)$ to the solution set of (1.5).

Lemma 3.4. $\bar{V}(\cdot,\cdot)$ *is almost continuous and OSL, i.e., there exists a constant* $\tilde{L}$ *such that*

$$\sigma(x_1-x_2,\bar{V}(t,x_1))-\sigma(x_1-x_2,\bar{V}(t,x_2))\le\tilde{L}|x_1-x_2|^2.$$

Proof. The almost continuity of $\bar{V}$ follows from the almost continuity of F and the continuity of G. Now, let $S>0$ and denote by $y(\cdot,x,u)$ any solution of (1.4) corresponding to x and admissible control $u(\cdot)$. Then fix one particular $y(\cdot,x_1,u)$ and consider

$$K=\sigma\left(x_1-x_2,\frac{1}{S}\int_0^S F(t,x_1,y(\tau,x_1,u),u(\tau))\,d\tau\right)\\ -\sigma\left(x_1-x_2,\frac{1}{S}\int_0^S F(t,x_2,y(\tau,x_2,u),u(\tau))\,d\tau\right),$$

where $y(\cdot, x_2, u)$ will be chosen later. By virtue of B1 one has

$$\begin{aligned}K &= \frac{1}{S}\int_0^S \big\{\sigma(x_1 - x_2, F(t, x_1, y(\tau, x_1, u), u(\tau)))\\ &\quad -\sigma(x_1 - x_2, F(t, x_2, y(\tau, x_2, u), u(\tau)))\big\}\, d\tau\\ &\le \frac{1}{S}\int_0^S \big(A|x_1 - x_2|^2 + B|y(\tau, x_1, u) - y(\tau, x_2, u)|^2\big)\, d\tau\\ &= A|x_1 - x_2|^2 + \frac{B}{S}\int_0^S |y(\tau, x_1, u) - y(\tau, x_2, u)|^2\, d\tau.\end{aligned}$$

Consider the map

$$\begin{aligned}&\Gamma(\tau, v) = \big\{w \in G(x_2, v, u(\tau)) : \ \langle y(\tau, x_1, u) - v, \dot{y}(\tau, x_1, u) - w\rangle\\ &\le \sigma(y(\tau, x_1, u) - v, G(x_1, y(\tau, x_1, u), u(\tau))) - \sigma(y(\tau, x_1, u) - v, G(x_2, v, u(\tau)))\big\}.\end{aligned}$$

By B1 we have

$$\langle y(\tau, x_1, u) - v, \dot{y}(\tau, x_1, u) - w\rangle \le D|x_1 - x_2|^2 - \mu|y(\tau, x_1, u) - v|^2.$$

Then Γ has nonempty, convex, and compact values and is almost USC (see the proof of Theorem 3.3 in [4]). Therefore the differential inclusion

$$\dot{v}(\tau) \in \Gamma(\tau, v(\tau)), \quad v(0) = y^0,$$

has a solution $y(\tau, x_2, u)$ for which

$$|y(\tau, x_1, u) - y(\tau, x_2, u)|^2 \le r(\tau) \text{ where } \dot{r} \le 2D|x_1 - x_2|^2 - 2\mu r, \ \ r(0) = 0.$$

Consequently

$$r(\tau) \le \exp(-2\mu\tau)\int_0^\tau 2D|x_1 - x_2|^2 \exp(2\mu s)\, ds \le \frac{D}{\mu}|x_1 - x_2|^2. \tag{3.1}$$

Hence $K \le (A + \frac{BD}{\mu})|x_1 - x_2|^2$. Now it is straightforward to prove that

$$\sigma\big(x_1 - x_2, \bar{V}(t, x_1)\big) - \sigma\big(x_1 - x_2, \bar{V}(t, x_2)\big) \le \tilde{L}|x_1 - x_2|^2,$$

where $\tilde{L} = A + BD/\mu$. □

COROLLARY 3.1. *Let $x(\cdot)$ be AC-function such that dist$(\dot{x}(t), \bar{V}(t, x(t))) = q(t)$, $t \in [0, 1]$ and $x(0) = x^0$. Then there exists a solution $z(\cdot)$ of* (1.5) *such that $|x(t) - z(t)| \le \exp(\tilde{L})\int_0^t q(s)\, ds$.*

Proof. We can argue as in the proof of Lemma 3.2, introducing the map

$$\hat{\Gamma}(t, v) = \big\{w \in \bar{V}(t, v) : \ \langle x(t) - v, \dot{x}(t) - w\rangle \le \tilde{L}|x(t) - v|^2 + |x(t) - v|q(t)\big\}. \qquad \square$$

The following two lemmas actually are the proof of the theorem of averaging of (1.3). Their proofs are similar to the corresponding results in [10], [11] but are modified to reflect the fact that some of our conditions are weaker.

LEMMA 3.5. *There exists a function $\alpha(\cdot)$ with $\lim_{\varepsilon\to 0}\alpha(\varepsilon) = 0$ such that for every solution $(x_\varepsilon, y_\varepsilon)$ of* (1.3) *there exists a solution z_ε of* (1.5) *such that $|x_\varepsilon(t) - z_\varepsilon(t)| \le \alpha(\varepsilon)$ on* $[0, 1]$.

Proof. Suppose that $\lim_{\varepsilon\to 0} S_\varepsilon = +\infty$ and $\lim_{\varepsilon\to 0} \varepsilon S_\varepsilon = 0$. Then substitute $t_j = j\varepsilon S_\varepsilon, \tau_j = jS_\varepsilon, x_j = x_\varepsilon(t_j)$ for $j = 0, 1, \dots, N_\varepsilon$ where $N_\varepsilon = [(\varepsilon S_\varepsilon)^{-1}]$ and $[s]$ is the integer part of s. Set also $t_{N_\varepsilon+1} = 1$.

Define the map

$$\begin{aligned}&P_\varepsilon(t, v, w) = \{g \in G(v, w, u_\varepsilon(t)) :\\ &\langle y_\varepsilon(t) - w, \varepsilon\dot{y}_\varepsilon(t) - g\rangle \le D|x_j - v|^2 - \mu|y_\varepsilon(t) - w|^2 + \eta(t)|y_\varepsilon(t) - w|\}.\end{aligned}$$

Here $y_\varepsilon, u_\varepsilon$ correspond to x_ε in (1.3) and $\eta(t) = dist(\varepsilon\dot{y}_\varepsilon(t), G(x_j, y_\varepsilon(t), u_\varepsilon(t)))$. It is easy to show using B1 that P_ε is nonempty, convex, and compact valued and almost USC. Define $y_z(t)$ as a solution on $[t_j, t_{j+1}], j = 0, 1, \dots, N_\varepsilon$ of the differential inclusion

$$\varepsilon\dot{y}(t) \in P_\varepsilon(t, x_j, y(t)), \quad y(t_j) = y_j \overset{def}{=} \lim_{t\to t_j^-} y(t)$$

and satisfying $y_z(0) = y^0$. Obviously $\bar{y}_z(\tau) = y_z(\varepsilon(\tau + \tau_j))$ is a solution of the associated system (1.4) with $\bar{y}_z(0) = y_j$ on the interval $[0, S_\varepsilon]$. It is easy to see that $|y_z(t) - y_\varepsilon(t)| \le r(t)$, where

$$\varepsilon\dot{r}(t) = -\mu r(t) + dist(\varepsilon\dot{y}_\varepsilon(t), G(x_j, y_\varepsilon(t), u_\varepsilon(t))), \quad r(t_j) = |y_z(t_j) - y_\varepsilon(t_j)|.$$

Thus

$$r(t) \le \exp\left(-\frac{\mu t}{\varepsilon}\right)\left\{r(t_j) + \frac{1}{\varepsilon}\int_{t_j}^{t} \exp\left(\frac{\mu s}{\varepsilon}\right) dist(\varepsilon\dot{y}_\varepsilon(s), G(x_j, y_\varepsilon(s), u_\varepsilon(s)))\, ds\right\}.$$

Due to Lemma 3.1, $x_\varepsilon(\cdot)$ is N-Lipschitz. Thus $|x_\varepsilon(t + \varepsilon S_\varepsilon) - x_\varepsilon(t)| \le \varepsilon S_\varepsilon N$. Denote $\lambda(\varepsilon) = \sup\{D_H(G(x_j, y_\varepsilon(t), u_\varepsilon(t)), G(x_\varepsilon(t), y_\varepsilon(t), u_\varepsilon(t))) : t \in [t_j, t_{j+1}]\}$. Then $\lambda(\varepsilon) \to 0$ as $\varepsilon \to 0$ since G is continuous. For $t \in [t_j, t_{j+1}]$, we have

$$r(t) \le \exp\left(-\frac{\mu t}{\varepsilon}\right)\left(\exp\left(\frac{\mu t}{\varepsilon}\right) - \exp\left(\frac{\mu t_j}{\varepsilon}\right)\right)\frac{\lambda(\varepsilon)}{\mu} + \exp\left(-\frac{\mu t}{\varepsilon}\right) r(t_j).$$

Then

$$\begin{aligned}&r(t)\\ &\le \frac{\lambda(\varepsilon)}{\mu}\exp\left(-\frac{\mu t}{\varepsilon}\right)\left(\sum_{i=0}^{j-1}\left(\exp\left(\frac{\mu t}{\varepsilon}\right) - \exp\left(\frac{\mu t_j}{\varepsilon}\right)\right) + \left(\exp\left(\frac{\mu t}{\varepsilon}\right) - \exp\left(\frac{\mu t_j}{\varepsilon}\right)\right)\right)\\ &= \frac{\lambda(\varepsilon)}{\mu}\left(1 - \exp\left(-\frac{\mu t}{\varepsilon}\right)\right) \le \frac{\lambda(\varepsilon)}{\mu}.\end{aligned}$$

By B1 for $\delta > 0$ there exists a compact set $I_\delta \subset I$ with measure greater than $1 - \delta$ such that F is continuous on $I_\delta \times \mathbf{R}^{n+m}$. Let $\delta > 0$ be so small that

$$\int_{A_\delta}\left(\sup_{|x|+|y|\le M}(|F(t, x, y)| + |\bar{V}(t, x)|)\right)^2 dt \le \frac{\varepsilon}{2},$$

where $A_\delta = I \setminus I_\delta$ and M is the constant from Lemma 3.1. Introduce the function

$$\rho_\delta(t) = \begin{cases} \sup_{|x|+|y|\le M}(|F(t, x, y)| + |\bar{V}(t, x)|), & t \in A_\delta,\\ 0 & \text{elsewhere.}\end{cases}$$

It is obvious that $\int_I \rho_\delta^2(t)\,dt < \varepsilon/2$ and $\int_I \rho_\delta(t)\,dt < (\delta\varepsilon)/2$.

For $t \in [t_j, t_{j+1}], j = 0, 1, \dots, N_\varepsilon$, define the following multifunction:

$$R_\varepsilon(t, v) = \{w \in F(t_j, x_j, y_z(t), u_\varepsilon(t)) : \langle x_\varepsilon(t) - v, \dot{x}_\varepsilon(t) - w\rangle \le A|x_\varepsilon(t) - v|^2 \\ +B|y_\varepsilon(t) - y_z(t)|^2 + \rho_\delta^2(t) + \omega_F^2(\varepsilon S_\varepsilon + \delta, I_\delta; 0)\}.$$

It is not difficult to show that $R_\varepsilon(\cdot,\cdot)$ is almost USC with nonempty, convex, and compact values. Hence there exists AC-function $\xi(\cdot)$ with

$$\dot{\xi}(t) \in R_\varepsilon(t, \xi(t)), \quad \xi(t_j) = \lim_{t \to t_j^-} \xi(t),$$

and $\xi(0) = x^0$. Therefore

$$\langle \xi(t) - x_\varepsilon(t), \dot{\xi}(t) - \dot{x}_\varepsilon(t)\rangle \le A|x_\varepsilon(t) - \xi(t)|^2 + B|y_\varepsilon(t) - y_z(t)|^2 \\ +\rho_\delta^2(t) + \omega_F^2(\varepsilon S_\varepsilon + \delta, I_\delta; 0).$$

Since $|y_\varepsilon(t) - y_z(t)| = r(t) \le \lambda(\varepsilon)/\mu$, after some standard calculations we get

$$|\xi(t) - x_\varepsilon(t)| \le C\left(\bar{\lambda}(\varepsilon) + \int_I \rho_\delta^2(t)\,dt\right) \le C(\bar{\lambda}(\varepsilon) + \varepsilon). \tag{3.2}$$

Here C is an appropriate constant and $\bar{\lambda}(\varepsilon) \to 0$ as $\varepsilon \to 0$. From Theorem 3.1 one can conclude that there exists $v_j \in \bar{V}(t_j, x_j)$, $j = 1, 2, \dots, N_\varepsilon - 1$, such that

$$\left|\frac{1}{S_\varepsilon}\int_{\tau_j}^{\tau_{j+1}} \dot{\xi}(\varepsilon\tau)\,d\tau - v_j\right| \le \frac{L_2}{\sqrt{S_\varepsilon}}.$$

Set $\psi(t) = \psi(t_j) + v_j(t - t_j)$ for $t \in [t_j, t_{j+1}], j = 0, 1, \dots, N_\varepsilon$, where $\psi(0) = x^0$. Therefore

$$|\psi(t) - \xi(t)| \le \frac{L_2}{\sqrt{S_\varepsilon}} \tag{3.3}$$

for every $t \in [0, 1]$. We have that

$$\mathit{dist}(\dot{\psi}(t), \bar{V}(t, \psi(t))) \le \mathit{dist}(\dot{\psi}(t), \bar{V}(t_j, x_j)) + D_H(\bar{V}(t_j, x_j), \bar{V}(t_j, \psi(t_j))) \\ + D_H(\bar{V}(t_j, \psi(t_j)), \bar{V}(t_j, \psi(t))) + D_H(\bar{V}(t_j, \psi(t)), \bar{V}(t, \psi(t))) \\ \le D_H(\bar{V}(t_j, x_j), \bar{V}(t_j, \psi(t_j))) + \omega_{\bar{V}}(0, I_\delta; N\varepsilon S_\varepsilon) \\ + \omega_{\bar{V}}(\varepsilon S_\varepsilon, I_\delta; 0) + 2\rho_\delta(t).$$

By (3.2) we get $|\psi(t_j) - x_j| \le |\psi(t_j) - \xi(t_j)| + |\xi(t_j) - x_\varepsilon(t_j)| \le 2M\varepsilon S_\varepsilon + 2C(\lambda(\varepsilon) + \rho_\delta(t))$. Therefore $\mathit{dist}(\dot{\psi}(t), \bar{V}(t, \psi(t))) \le \nu(\varepsilon)$ where by Definition 3.1 $\lim_{\varepsilon\to 0} \nu(\varepsilon) = 0$. Thus from Corollary 3.1 there exists a solution $z_\varepsilon(\cdot)$ of (1.5), such that $|\psi(t) - z_\varepsilon(t)| \le \exp(\tilde{L})\nu(\varepsilon)$. Using the triangle inequality, (3.2), and (3.3) we obtain the proof. □

Lemma 3.6. *There exists a function* $\alpha(\cdot)$ *tending to zero as* $\varepsilon \to 0$ *such that for every solution* z *of* (1.5) *there exists a solution* $(x_\varepsilon, y_\varepsilon)$ *of* (1.3) *such that* $|x_\varepsilon(t) - z(t)| \le \alpha(\varepsilon)$ *on* $[0, 1]$.

Proof. We will use the same partition of I and notations as in the previous proof. Let $z(\cdot)$ be a solution of (1.5). Then for $t \in [t_j, t_{j+1}], j = 0, 1, \dots, N_\varepsilon$, we have

$$\dot{z}(t) \in \bar{V}(t_j, z(t_j)) + \theta(\varepsilon)B_1(0),$$

where $\theta(\varepsilon, t)\overset{def}{=}\omega_{\bar{V}}(\varepsilon S_\varepsilon, I_\delta; C\varepsilon S_\varepsilon)+\rho_\delta(t)$. By Definition 3.1 and the definition of $\rho_\delta(t)$, we have $\int_I \theta^2(\varepsilon, t)dt \to 0$ as $\varepsilon \to 0$.

For $[t_j, t_{j+1}], j = 0, 1, \dots, N_\varepsilon$, define successively the function $w(\cdot)$ and the map

$$W(t,p) = \{v \in \bar{V}(t_j, w(t_j)) : \langle z(t) - p, \dot{z}(t) - v\rangle \le (\tilde{L} + 1)|z(t) - w(t_j)|^2 + \theta^2(\varepsilon)\},$$

where $\tilde{L} \le A + BD/\mu$ is determined in Lemma 3.3. For $j = 0$ we set $w(t_0) = w(0) = x^0$. Then $W(t,p) \ne \emptyset$ thanks to Lemma 3.1 and it is clear that $W(\cdot,\cdot)$ is compact, convex valued, and almost USC. Therefore the differential inclusion

$$\dot{w}(t) \in W(t, w), \quad w(t_j) = \lim_{t\to t_j^-} w(t)$$

admits a solution $w(t)$ on $[t_j, t_{j+1}]$. Then $|w(t) - z(t)|^2 \le r(t)$, where

$$\dot{r}(t) = (\tilde{L} + 1)r + \theta^2(\varepsilon, t), \quad r(0) = 0,$$

i.e., $r(t) \le \exp(C(t - t_j)) \int_I \theta^2(\varepsilon, s)\, ds$ for $t \in [t_j, t_{j+1})$. Here and below C is an arbitrary and sufficiently large constant.

Let $\Delta = \varepsilon S_\varepsilon$ and z_j be the projection of $\Delta^{-1} \int_{t_j}^{t_{j+1}} \dot{w}(t)\, dt$ on $\bar{V}(t_j, z(t_j))$, i.e., $z_j \in \bar{V}(t_j, z(t_j))$ and $|z_j - \Delta^{-1} \int_{t_j}^{t_{j+1}} \dot{w}(t)\, dt| = dist(\Delta^{-1} \int_{t_j}^{t_{j+1}} \dot{w}(t)\, dt, \bar{V}(t_j, z(t_j)))$. On the interval $(t_j, t_{j+1}]$ we define the control $u(t)$ to satisfy the inequality

$$dist\left(z_j, \frac{1}{\Delta}\int_{t_j}^{t_{j+1}} F(t_j, w(t_j), y_w(t), u(t))\, dt\right) \le \frac{2}{S_\varepsilon}.$$

Here $y_w(t) = \tilde{y}_w(t/\varepsilon)$ where $\tilde{y}_w(\tau)$ is a solution on $[\tau_j, \tau_{j+1}] = [jS_\varepsilon, (j + 1)S_\varepsilon]$ of

$$\dot{y}(\tau) \in G(v(\tau_j), y(\tau), u(\tau)), \quad y(\tau_j) = y_\varepsilon(\tau_j).$$

Such control exists thanks to Theorem 3.1 and the definition of $\bar{V}$. Let $(x_\varepsilon(\cdot), y_\varepsilon(\cdot))$ be a solution of

$$\begin{aligned} &\dot{x}(t) \in \tilde{F}(t, x(t), y(t), u(t)), \quad x(0) = x^0,\\ &\varepsilon\dot{y}(t) \in \tilde{G}(t, x(t), y(t), u(t)), \quad y(0) = y^0, \end{aligned}$$

where $\tilde{F}$ and $\tilde{G}$ are defined on $[t_j, t_{j+1}], j = 0, 1, \dots, N_\varepsilon$, as follows:

$$\begin{aligned} &\tilde{F}(t, \alpha, \beta, u(t)) = \{p \in F(t, \alpha, \beta, u(t)) :\\ &\langle p - z_j, \alpha - w(t)\rangle \le A|\alpha - w(t)|^2 + B|\beta - y_w(t)|^2 + 4\Delta^2 + |z_j - w(t)|^2\},\\ &\tilde{G}(t, \alpha, \beta, u(t)) = \{q \in G(\alpha, \beta, u(t)) : \langle q - \varepsilon\dot{y}_w(t), \beta - y_w(t)\rangle\\ &\le D|\alpha - w(t)|^2 - \mu|\beta - y_w(t)|^2 + 4\Delta^2 + |z_j - w(t)|^2\}. \end{aligned}$$

Thus $|x_\varepsilon(t) - z(t)|^2 \le m(t),\ |y_\varepsilon(t) - y_v(t)|^2 \le s(t)$, where

$$\begin{aligned} &\dot{m}(t) \le Am + Bs + 4\Delta^2 + r(t), \quad m(0) = 0,\\ &\varepsilon\dot{s}(t) \le Dm - \mu s + 4\Delta^2 + r(t), \quad s(0) = 0. \end{aligned}$$

Therefore, integrating by parts one obtains

$$s(t) \le \exp\left(-\frac{\mu t}{\varepsilon}\right)\int_0^t (Dm(\lambda)+4\Delta^2+r(\lambda)) \exp\left(\frac{\mu\lambda}{\varepsilon}\right) d\left(\frac{\lambda}{\varepsilon}\right) \le \frac{D}{\mu}m(t)+\frac{4\Delta^2 t}{\mu}, +\frac{r(t)}{\mu},$$

since $\dot{m}(t) \geq 0, \dot{r}(t) \geq 0$. Consequently

$$\dot{m}(t) \leq Am + \frac{BD}{\mu}m + 4\frac{\Delta^2 B}{\mu} + r(t)\frac{B}{\mu} + 4\Delta^2 + r(t).$$

That is,

$$m(t) \leq \exp\left\{\left(A + \frac{BD}{\mu}\right)t\right\}\left(4\frac{\Delta^2 B}{\mu}t + \left(\frac{B}{\mu} + 1\right)\int_0^t r(\lambda)d\,\lambda + 4\Delta^2 t\right),$$

where $t \in [0, \Delta]$. Thus

$$m(t) \leq \exp(C)\left(4\frac{\Delta^2 B}{\mu} + 4\Delta^2 + \Delta\right) \leq C\varepsilon S_\varepsilon. \qquad \square$$

Now the first principal result in this section follows from Lemma 3.5 and Lemma 3.6. Namely, the projection $X(\varepsilon) = \hat{Z}(\varepsilon)$ can be approximated by the solution set of the averaged inclusion (1.5).

THEOREM 3.2. *Under the conditions* B1 *and* B2 *there exists* $\alpha(\cdot)$ *such that* $\lim_{\varepsilon\to 0^+} \alpha(\varepsilon) = 0$ *and* $D_H(X(\varepsilon), X_0) = \alpha(\varepsilon)$, *where* $X(\varepsilon)$ *is the "slow" part of the solution set of* (1.3) *and* X_0 *is the solution set of* (1.5).

Now we are able to prove the main result in the paper, namely that the solution set of (1.3) (denote it again by $Z(\varepsilon)$) possesses a limit in topology $\mathcal{T} = C(I, \mathbf{R}^n) \times [L^1(I, C(K, \mathbf{R}^m))]^*$-weak*.

DEFINITION 3.2. *We will say that* $Z_0 = \lim_{\varepsilon\to 0^+} Z(\varepsilon)$ *in* $\mathcal{T}$ *iff*

(a) $Z_0 \subset \liminf_{\varepsilon\to 0^+} Z(\varepsilon)$, *i.e., for every* $(x_0, \nu_0) \in Z_0$ *there exists* $(x_\varepsilon, y_\varepsilon) \in Z(\varepsilon), \varepsilon > 0$ *such that* $(x_\varepsilon, y_\varepsilon) \to (x_0, y_0)$ *in* $\mathcal{T}$;

(b) $\limsup_{\varepsilon\to 0^+} Z(\varepsilon) \subset Z_0$, *i.e., all cluster points in* $\mathcal{T}$ *of every* $\{(x_\varepsilon, y_\varepsilon)\}_{\varepsilon>0}$ *with* $(x_\varepsilon, y_\varepsilon) \in Z(\varepsilon)$ *are contained in* Z_0.

Since $\mathcal{T}$ is metrizable we consider only countable subsequences.

THEOREM 3.3. *Suppose* B1 *and* B2 *are fulfilled. Then there exists the limit* $Z_0 = \lim_{\varepsilon\to 0^+} Z(\varepsilon) \subset Z_G$ *in* $C(I, \mathbf{R}^n) \times [L^1(I, C(K, \mathbf{R}^m))]^*$*-weak* topology.*

Proof. By Theorem 2.1 it follows that $\limsup_{\varepsilon\to 0^+} Z(\varepsilon) \neq \emptyset$ (in $\mathcal{T}$) and is included in Z_G. To finish the proof we have to show that $\limsup_{\varepsilon\to 0^+} Z(\varepsilon) \subset \liminf_{\varepsilon\to 0^+} Z(\varepsilon)$ (the opposite inclusion is always satisfied).

Let $(x_0, \nu_0) \in \limsup_{\varepsilon\to 0^+} Z(\varepsilon)$. Then there are $(x_\varepsilon, y_\varepsilon) \in Z(\varepsilon), \varepsilon > 0$ such that (x_0, ν_0) is a cluster point of $\{(x_\varepsilon, y_\varepsilon)\}_{\varepsilon>0}$ in $\mathcal{T}$. Denote

$$\begin{aligned} w_j^\varepsilon(t) &= \int_0^t f_j(s, y_\varepsilon(s))\,ds, \\ w_j^0 &= \int_I \left(\int_K f_j(t, y)\nu_0(t)\,(dy)\right) dt, j = 1, 2, \ldots, \end{aligned} \tag{3.4}$$

where $f_j \in \mathcal{F}$. Recall that the set of Lipschitz functions $\mathcal{F} = \{f_j(\cdot, \cdot)\}_{j=1}^\infty$ is dense in $L^1(I, C(K, \mathbf{R}^m))$.

There exist subsequences $x_i = x_{\varepsilon_i}, y_i = y_{\varepsilon_i}, \varepsilon_i \to 0, i = 1, 2, \ldots$, such that

$$\begin{aligned} &x_i \to x_0 \text{ in } C(I, \mathbf{R}^n), \\ &w_j^i(1) = \int_I f_j(t, y_i(t))\,dt \to w_j^0 \text{ for } j = 1, 2, \ldots. \end{aligned} \tag{3.5}$$

We have that $(x_i, w_i, y_i) = (x_i, w_1^i, w_2^i, \dots, w_k^i, y_i)$ is a solution of the following system:

$$\begin{aligned} \dot{x}(t) &\in F(t, x(t), y(t), u(t)), \quad x(0) = x^0, \\ \dot{w}_1(t) &= f_1(t, y(t)), \quad w_1(0) = 0, \\ &\vdots \\ \dot{w}_k(t) &= f_k(t, y(t)), \quad w_k(0) = 0, \\ \varepsilon \dot{y}(t) &\in G(x(t), y(t), u(t)), \quad y(0) = y^0, \end{aligned} \tag{3.6}$$

where $\varepsilon = \varepsilon_i, i = 1, 2, \dots$. On the other hand, (x_i, w_i) has a cluster point $(x_0, \tilde{w}_0)$ in $C(I, \mathbf{R}^{n+k})$ due to Lemma 2.1 and the Arzelà–Ascoli theorem, and by (3.5) $w_i(1) \to \tilde{w}_0(1) = (w_1^0, w_2^0, \dots, w_k^0)$.

So $(x_0, \tilde{w}_0) \in \limsup_{\varepsilon \to 0^+} S(\varepsilon)$ where $S(\varepsilon)$ is the "slow" part of the solution set of (3.6). Since $f_j \in \mathcal{F}$, system (3.6) satisfies the conditions of Theorem 3.2, hence $(x_0, \tilde{w}_0) \in \liminf_{\varepsilon \to 0^+} S(\varepsilon)$. This means that for every $\varepsilon > 0$ there is a solution $(\tilde{x}_\varepsilon, \tilde{w}_\varepsilon, \tilde{y}_\varepsilon)$ of (3.6) such that $(\tilde{x}_\varepsilon, \tilde{w}_\varepsilon) \to (x_0, \tilde{w}_0)$ in $C(I, \mathbf{R}^{n+k})$. Consequently

$$\tilde{x}_\varepsilon \to x_0 \text{ in } C(I, \mathbf{R}^n), \tag{3.7}$$

$$\int_I f_j(t, \tilde{y}_\varepsilon(t))\, dt \to \int_I \left(\int_K f_j(t, y) \nu_0(t)\, (dy) \right) dt \text{ for } f_j \in \mathcal{F}, j = 1, 2, \dots, k. \tag{3.8}$$

The second relation follows by $\tilde{w}_\varepsilon(1) \to \tilde{w}_0(1) = (w_1^0, w_2^0, \dots, w_k^0)$ and (3.4).

Fix the natural number k and denote for every $\varepsilon > 0$

$$Z_\varepsilon^k = \{(\tilde{x}_\varepsilon, \tilde{y}_\varepsilon) \in Z(\varepsilon) : \text{ (3.7) and (3.8) are fulfilled}\}.$$

For every $0 < \varepsilon < 1$ we have that $Z_\varepsilon^{k+1} \subset Z_\varepsilon^k \neq \emptyset$ and Z_ε^k is $C(I, \mathbf{R}^{n+m})$ compact. Therefore $Z_\varepsilon^\infty = \bigcap_{k=1}^\infty Z_\varepsilon^k$ is not empty. Then if $(\tilde{x}_\varepsilon, \tilde{y}_\varepsilon) \in Z_\varepsilon^\infty, \varepsilon > 0$, relation (3.8) holds for any $f_j \in \mathcal{F}$; consequently $(\tilde{x}_\varepsilon, \tilde{y}_\varepsilon) \to (x_0, \nu_0)$ in $\mathcal{T}$. □

COROLLARY 3.2. *Consider the optimization problem*

$$\int_I h(t, x_\varepsilon(t), y_\varepsilon(t))\, dt \to \inf,$$

where the functional is minimized over the solutions of (1.3). *Suppose* $h(\cdot, x, y)$ *is measurable on* I, $h(t, \cdot, \cdot)$ *is continuous on* $\mathbf{R}^{n+m}$, *and* B1, B2 *are fulfilled. Denote by* $J(\varepsilon), \varepsilon > 0$, *the corresponding optimal value. Then* $\lim_{\varepsilon \to 0} J(\varepsilon)$ *exists.*

Proof. In system (3.6) we add the equation

$$\dot{w}_0(t) = h(t, x(t), y(t)), \quad w_0(0) = 0.$$

All the arguments in the proof of Theorem 3.3 will be valid having in mind that

$$\int_I h(t, x_\varepsilon(t), y_\varepsilon(t))\, dt \to \int_I \left(\int_K h(t, x_0(t), y) \nu_0(t)\, (dy) \right) dt, \varepsilon \to 0$$

when $(x_\varepsilon, y_\varepsilon) \to (y_0, \nu_0)$ in the considered topology (see [19]). □

Acknowledgments. We wish to thank the anonymous referees for their valuable comments and suggestions, which contributed much to improve the paper.

FINITE-DIMENSIONAL COMPENSATORS FOR THE H^∞-OPTIMAL CONTROL OF INFINITE-DIMENSIONAL SYSTEMS VIA A GALERKIN-TYPE APPROXIMATION*

MINGQING XIAO† AND TAMER BAŞAR‡

Abstract. We study the existence of general finite-dimensional compensators in connection with the H^∞-optimal control of linear time-invariant systems on a Hilbert space with noisy output feedback. The approach adopted uses a Galerkin-type approximation, where there is no requirement for the system operator to have a complete set of eigenvectors. We show that if there exists an infinite-dimensional compensator delivering a specific level of attenuation, then a finite-dimensional compensator exists and achieves the same level of disturbance attenuation. In this connection, we provide a complete analysis of the approximation of infinite-dimensional generalized Riccati equations by a sequence of finite-dimensional Riccati equations. As an illustration of the theory developed here, we provide a general procedure for constructing finite-dimensional compensators for robust control of flexible structures.

Key words. H^∞-optimal control, finite-dimensional compensators, infinite-dimensional systems, Riccati equations, flexible structures

1. Introduction.

Let X, U, W be real, separable Hilbert spaces, and let $\mathcal{L}(X;U)$, $\mathcal{L}(X;W)$ be the class of linear bounded operators from, respectively, X to U and X to W. Consider the uncertain evolution equation on X:

$$\begin{aligned} \dot{x}(t) &= Ax(t) + Bu(t) + Dw(t), \\ x(0) &= x_0, \end{aligned} \tag{1.1}$$

where $B \in \mathcal{L}(X;U)$, $D \in \mathcal{L}(X;W)$; u is the control and w is an unknown deterministic disturbance, with $u(t) \in U$ and $w(t) \in W$. The operator A is the infinitesimal generator of a strongly continuous semigroup $T(t)$ on X, which we will henceforth refer to as the structure operator for system (1.1). The *partial observation* (also called noise-corrupted measurement) is given by

$$y(t) = Cx(t) + \eta(t), \tag{1.2}$$

where $C \in \mathcal{L}(X;Y)$, Y being a Hilbert space, called the space of measurements, and $\eta \in W_1$ being another disturbance, modeling the measurement error. The controller is allowed to be only a causal function of the observation y. For symmetry purposes, we write the performance index in terms of a second output

$$y_1(t) = Hx(t) + D_{12}u(t), \tag{1.3}$$

where $y_1 \in Y_1$, with Y_1 a real Hilbert space, $H \in \mathcal{L}(X;Y_1)$, and $D_{12} \in \mathcal{L}(U;Y_1)$ satisfying the following standard hypotheses:

$$D_{12}^* D_{12} = I, \qquad D_{12}^* H = 0. \tag{1.4}$$

Let the cost function corresponding to the output y_1 be

$$K_{x_0}(u,w) = \int_0^\infty \|y_1(t)\|_{Y_1}^2 dt \equiv \int_0^\infty (\|Hx(t)\|_{Y_1}^2 + \|u(t)\|_U^2) dt. \tag{1.5}$$

A natural class of infinite-dimensional compensators for (1.1) and (1.2), characterized by three maps $L \in \mathcal{L}(X;U)$, $M \in \mathcal{L}(X;X)$, $G \in \mathcal{L}(Y;X)$, is the following one:

$$\begin{aligned} u(t) &= Lz(t), \\ \dot{z}(t) &= (A+M)z(t) + Gy(t). \end{aligned} \tag{1.6}$$

Here we do not lump A and M into a single operator, because A is unbounded while M is bounded. Let $w \in L^2(0,\infty;W)$ and $\eta \in L^2(0,\infty;W_1)$, where $L^2(0,\infty;W)$ is the Hilbert space of Lebesgue square integrable functions on $(0,\infty)$, with values in W. The H^∞-optimal design problem for (1.1), under (1.2) and (1.6), and with the cost function (1.5) is the following: Given $\gamma > 0$, find L, M, and G such that

$$\sup_{w,\eta} \frac{K_0(u,w)}{\displaystyle\int_0^\infty (\|w(t)\|_W^2 + \|\eta(t)\|_{W_1}^2) dt} < \gamma^2. \tag{1.7}$$

More precisely, we have the following definition.

Definition 1.1. *The γ-attenuation level is attained for system* (1.1), *with observation* (1.2) *and cost function* (1.5), *if there exist L, M, and G in* (1.6) *such that* (1.7) *holds.*

It is well known [1] that in the finite-dimensional case, and when the dimension of the compensator is the same as the dimension of the state (i.e., $\dim(z) = \dim(x)$), under some stabilizability and detectability conditions an explicit solution can be obtained for the triple L, M, G, in terms of two Riccati equations coupled through a spectral radius condition. This result was subsequently generalized to infinite-dimensional spaces by Bensoussan and Bernhard [3]. Before stating this extension, let us introduce the two associated infinite-dimensional Riccati equations:

$$\begin{aligned} &\Pi A + A^*\Pi - \Pi\left(BB^* - \frac{1}{\gamma^2}DD^*\right)\Pi + H^*H = 0, \\ &\Pi = \Pi^* \geq 0, \\ &A - \left(BB^* - \frac{1}{\gamma^2}DD^*\right)\Pi \text{ exponentially stable,} \end{aligned} \tag{1.8}$$

and

$$\begin{aligned} &\Sigma A^* + A\Sigma - \Sigma\left(C^*C - \frac{1}{\gamma^2}H^*H\right)\Sigma + DD^* = 0, \\ &\Sigma = \Sigma^* \geq 0, \\ &A^* - \left(C^*C - \frac{1}{\gamma^2}H^*H\right)\Sigma \text{ exponentially stable.} \end{aligned} \tag{1.9}$$

Then we have [3] as follows.

THEOREM 1.1 (Bensoussan and Bernhard [3]). *Assume that the pair* (A, B) *is stabilizable and the pair* (A, H) *is detectable. Then the* γ*-attenuation level is attained for system* (1.1), *with observation* (1.2) *and under cost function* $K_0(u, w)$*, iff the Riccati equation* (1.8) *admits a solution* Π*, and* (1.9) *admits a solution* Σ*, and furthermore*

$$(1.10) \qquad I - \frac{1}{\gamma^2}\Pi\Sigma \text{ is invertible, or equivalently } \Sigma\left(I - \frac{1}{\gamma^2}\Pi\Sigma\right)^{-1} \geq 0.$$

An infinite-dimensional compensator that achieves the bound γ^2 *in* (1.7) *is given by* (1.6) *where*

$$(1.11) \qquad L = -B^*\Pi, \quad M = -\left(BB^* - \frac{1}{\gamma^2}DD^*\right)\Pi - \Gamma C^* C, \quad G = \Gamma C^*$$

and

$$\Gamma = \Sigma\left(I - \frac{1}{\gamma^2}\Pi\Sigma\right)^{-1}.$$

Even though this is a complete solution for the problem at hand, the fact that the compensator is infinite dimensional renders it impractical. There is therefore a need to develop a theory that will deliver finite-dimensional stabilizing compensators, which achieve a given level of disturbance attenuation. We will address this problem here when the measurement y is finite-dimensional.

The existence of finite-dimensional compensators for infinite-dimensional linear quadratic regulator (LQR) problems or for linear quadratic Gaussian (LQG) problems has been established in [8], [25], and [26] provided that the structure operator of the underlying system has a complete set of generalized eigenvectors; their construction is based on the eigenvectors of either the structure operator or the closed-loop structure operator obtained under state feedback. Gibson [12], [13], Gibson and Adamian [14], and Ito [15] have established the existence of finite-dimensional compensators for LQR problems by using Galerkin-type approximations in which independent basis elements were used instead of the complete set of eigenvectors, making it possible for the results to be applied to general parabolic systems, hereditary differential systems, and flexible structures.

The existence and design of general finite-dimensional compensators for infinite-dimensional systems in an H^∞ framework was one of the open problems in H^∞-optimal control, as posed by Curtain and Salamon in 1990 [7]. Özbay [20], Özbay and Tannenbaum [21], [22], and Curtain and Zhou [10] have obtained a number of results on finite-dimensional H^∞ controllers by using frequency domain techniques under appropriate assumptions. Banks, Demetriou, and Smith [2] studied a two-dimensional structural acoustic model by using H^∞ periodic control, which was approximated by a finite-dimensional compensator: piezoceramic actuators. Ito and Morris [16] developed an approximation scheme when the *full output measurement* is available. However, the problem of finding finite-dimensional H^∞ controllers from state-space approximations in complete generality was an unsolved problem. Thus one of the objectives of this paper is to fill this gap. In the present paper, we establish a general existence result for finite-dimensional H^∞-optimal compensators (1.6) for (1.1) with finite-dimensional measurement (1.2), such that the γ-attenuation level (1.7) is achieved. More precisely, we study the evolution system

$$\dot{x}(t) = Ax(t) + Bu(t) + Dw(t), \qquad x(0) = x_0 \in X \tag{1.12}$$

along with the partial observation

$$y(t) = Cx(t) + \eta(t) \tag{1.13}$$

with finite-dimensional compensator

$$\begin{aligned} u(t) &= L_c z(t), \\ \dot{z}(t) &= (A_c + M_c)z(t) + G_c y(t), \end{aligned} \tag{1.14}$$

where $u(t)$ is an $\mathbb{R}^m$-valued control function, the measurement space is $\mathbb{R}^p$, and $C \in \mathcal{L}(X, \mathbb{R}^p)$, $z(t) \in Z = \mathbb{R}^{n_c}$, and A_c, M_c, G_c, L_c are matrices belonging to appropriate spaces. The cost function is still expressed as

$$K_{x_0}(u, w) = \int_0^\infty (\|Hx(t)\|_{Y_1}^2 + \|u(t)\|_{\mathbb{R}^m}^2)dt. \tag{1.15}$$

We will show that there exists a finite-dimensional compensator (1.14) which stabilizes the infinite-dimensional system (1.12) with noise measurement output (1.13), and a γ-attenuation level is achieved, i.e.,

$$\sup_{w,\eta} \frac{K_0(u,w)}{\displaystyle\int_0^\infty (\|w(t)\|_W^2 + \|\eta(t)\|_{W_1}^2)dt} < \gamma^2 \tag{1.16}$$

provided that this level of attenuation level is achieved under the infinite-dimensional compensator (1.6).

The rest of this paper is organized as follows. Section 2 provides assumptions and some preliminary results on asymptotic behavior and approximation of Riccati equations, proofs of which have been included in Appendix II. Results obtained in Appendix II can be viewed as independent from the main body of the paper and can be read as such. The existence of finite-dimensional compensators for the infinite-dimensional problem is proven in section 3. Section 4 presents an important application of this theory to the control of flexible structures. Section 5 includes some concluding remarks, and Appendix I contains a duality theorem which is needed in section 3.

2. Assumptions and some preliminaries.

Let $\{X^N\}$ be a sequence of finite-dimensional subspaces of X, and let P^N denote the orthogonal projection[1] of X onto X^N. Throughout this paper, the following notation and conventions will be adopted, unless otherwise indicated: $\langle \cdot, \cdot \rangle$ denotes the inner-product on X, $\mathcal{L}(X)$ denotes the space of all bounded linear operators on X, and A^* denotes the adjoint of the linear operator A,

$$\Sigma(X) = \{T \in \mathcal{L}(X) : \ T \text{ is Hermitian}\}$$

$$\Sigma^+(X) = \{T \in \Sigma(X) : \quad \langle Tx, x \rangle \ \geq 0 \ \forall x \in X\}.$$

[1] Orthogonal projection means that the range and the null spaces of the projection are orthogonal.

We next introduce a sequence of operators, which will be used in the main body of the paper. Let $A^N \in \mathcal{L}(X^N)$, $B^N = P^N B \in \mathcal{L}(U, X^N)$, $D^N = P^N D \in \mathcal{L}(W, X^N)$, and C^N and H^N represent the restrictions of C and H onto X^N, respectively, and $\Pi^N, \Sigma^N \in \mathcal{L}(X^N)$.

Definition 2.1. *A sequence $\{x_N \in X^N\}$ converges to $x \in X$ if*

$$\|P^N x - x_N\|_{X^N} \to 0 \textit{ as } N \to \infty.$$

Definition 2.2. *Let X, Y be two Banach spaces. A sequence of linear operators $A^N : X^N \to Y^N$ converges to an operator $A : D(A) \subset X \to Y$ if*

$$\mathcal{D} = \{x : P^N x \in D(A^N), A^N P^N x \textit{ converges in } Y^N\}$$

and

$$Ax = \lim_{N\to\infty} A^N P^N x \quad \textit{for} \quad x \in \mathcal{D} \cap D(A).$$

We will denote this type of convergence by $A^N \to\!\!\to A$.

Definition 2.3. *We say that the Riccati equation*

$$\Pi A + A^*\Pi - \Pi\left(BB^* - \frac{1}{\gamma^2}DD^*\right)\Pi + H^*H = 0$$

admits a solution Π, if $\Pi \in \Sigma^+(X)$ and $\forall x, y \in D(A)$ the following holds:

$$\langle \Pi x, Ay\rangle + \langle Ax, \Pi y\rangle - \left\langle \Pi\left(BB^* - \frac{1}{\gamma^2}DD^*\right)\Pi x, y\right\rangle + \langle H^*Hx, y\rangle = 0.$$

A similar definition applies to the Riccati equation

$$\Sigma A^* + A\Sigma - \Sigma\left(C^*C - \frac{1}{\gamma^2}H^*H\right)\Sigma + DD^* = 0.$$

Definition 2.4. *The pair (A, B) in* (1.1) *is stabilizable if there exists an operator $F \in \mathcal{L}(X, U)$ such that $A + BF$ is exponentially stable.*

Definition 2.5. *The pair (A, H) (A in* (1.1), *H in* (1.15)*) is detectable if there exists an operator $G \in \mathcal{L}(Y_1, X)$ such that $A + GH$ is exponentially stable.*

Assumptions.

(A1) For every $x \in X$, $e^{A^N t}P^N x$ converges strongly to $T(t)x$, $e^{A^{N*} t}P^N x$ converges strongly to $T^*(t)x$, and the convergence is uniform in t on bounded intervals of $[0, \infty[$. Here $T(t)$ is the C_0 semigroup generated by A, and P^N is the orthogonal projection of X onto a finite-dimensional space X^N.

(A2) For each integer $N > 0$, $A^N - (B^N B^{N*} - \frac{1}{\gamma^2}D^N D^{N*})\Pi^N$ generates an exponentially stable semigroup on X^N, and

$$\|e^{(A^N - (B^N B^{N*} - \frac{1}{\gamma^2}D^N D^{N*})\Pi^N)t}P^N\|_{\mathcal{L}(X,X^N)} \le M_1 e^{-\omega_1 t}, \qquad t \in [0, \infty[,$$

for some $M_1 \ge 1$ and $\omega_1 > 0$, independent of N.

(A3) For each integer $N > 0$, $A^{N*} - (C^{N*}C^N - \frac{1}{\gamma^2}H^{N*}H^N)\Sigma^N$ generates an exponentially stable C_0 semigroup on X^N, and

$$\|e^{(A^{N*} - (C^{N*}C^N - \frac{1}{\gamma^2}H^{N*}H^N)\Sigma^N)t}P^N\|_{\mathcal{L}(X,X^N)} \le M_2 e^{-\omega_2 t}, \qquad t \in [0, \infty[,$$

for some $M_2 \ge 1$ and $\omega_2 > 0$, independent of N.

(A4) For each $N > 0$, the operator matrix

$$\mathcal{A}_p^N = \begin{bmatrix} A + \frac{1}{\gamma^2} DD^*\Pi & BL^N \\ G^N C & A^N + M^N \end{bmatrix}$$

satisfies the spectrum-determined growth condition,[2] where

$$L^N = -B^{N*}\Pi^N, \quad G^N = \Gamma^N C^{N^*}, \quad \Gamma^N = \Sigma^N \left(I - \frac{1}{\gamma^2} \Pi^N \Sigma^N \right)^{-1}$$

and

$$M^N = -\left(B^N B^{N^*} - \frac{1}{\gamma^2} D^N D^{N*} \right) \Pi^N - \Gamma^N C^{N*} C^N.$$

Remark 1. (1) In (A1), $e^{A^N t} P^N x$ converges strongly to $T(t)x$ means that

$$\| P^N T(t) x - e^{A^N t} P^N x \|_{X^N} \to 0 \quad \text{as } N \to \infty.$$

For $t = 0$, assumption (A1) implies that $P^N x \to x$ for each $x \in X$; thus we have the result that the subspace X^N approximates X.

(2) According to (A1) we have for each $u \in U$, $B^N u \to Bu$ and for each $x \in X$, $C^N x \to Cx$ as $N \to \infty$. Moreover, since both B and C are compact operators, principle of uniform boundedness [27] implies that

$$B^N \to B, \qquad C^N \to C \qquad \text{as} \quad N \to \infty$$

where the convergences are in the corresponding operator norms.

(3) From assumption (A2), we know that the resolvent set of matrix

$$A^N - \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*} \right) \Pi^N$$

contains the ray (ω_1, ∞) and

$$\left\| \left[\lambda I - \left(A^N - \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*} \right) \Pi^N \right) \right]^{-1} \right\|_{\mathcal{L}(X^N)} \leq M_1 / (\lambda + \omega_1)$$
$$\text{for } \mathrm{Re}\lambda > -\omega_1.$$

A similar corresponding statement follows from assumption (A3).

The proof of the following two lemmas can be found in Appendix II.

LEMMA 2.1. *Suppose that for a given $\gamma > 0$ the Riccati equation*

$$\Pi A + A^* \Pi - \Pi \left(BB^* - \frac{1}{\gamma^2} DD^* \right) \Pi + H^* H = 0 \tag{2.1}$$

[2] Spectrum-determined growth condition means that

$$\sup\{ \mathrm{Re}\lambda : \lambda \in \sigma(\mathcal{A}_p) \} = \lim_{t \to \infty} \frac{1}{t} \ln \| e^{\mathcal{A}_p t} \|,$$

where $\sigma(A)$ denotes the spectrum of A.

admits a solution $\Pi \in \Sigma^+(X)$ *such that* $A - BB^* - \frac{1}{\gamma^2}DD^*\Pi$ *is exponentially stable, and for each* N

$$\Pi^N A^N + A^{N*}\Pi^N - \Pi^N \left(B^N B^{N*} - \frac{1}{\gamma^2}D^N D^{N*}\right)\Pi^N + H^{N*}H^N = 0 \tag{2.2}$$

admits a solution $\Pi^N \in \Sigma^+(X^N)$ *which satisfies assumption* (A2). *Then, under assumption* (A1), *we have* $\Pi^N \to\!\!\to \Pi$ *as* $N \to \infty$.

Lemma 2.2. *Suppose that for a given* $\gamma > 0$, *the Riccati equation*

$$\Sigma A^* + A\Sigma - \Sigma\left(C^*C - \frac{1}{\gamma^2}H^*H\right)\Sigma + DD^* = 0 \tag{2.3}$$

admits a solution $\Sigma \in \Sigma^+(X)$ *such that* $A^* - (C^*C - \frac{1}{\gamma^2}H^*H)\Sigma$ *is exponentially stable, and*

$$\Sigma^N A^{N*} + A^N\Sigma^N - \Sigma^N\left(C^{N*}C^N - \frac{1}{\gamma^2}H^{N*}H^N\right)\Sigma^N + D^N D^{N*} = 0 \tag{2.4}$$

admits a solution $\Sigma^N \in \Sigma^+(X)$ *which satisfies assumption* (A3). *Then, under assumption* (A1), *we have* $\Sigma^N \to\!\!\to \Sigma$ *as* $N \to \infty$.

The following lemma now provides some properties of Riccati equations provided that for the given $\gamma > 0$, the γ-attenuation level is achieved. The proof can be found in [3].

Lemma 2.3. *Assume that* (A, B) *is stabilizable and that* (A, H) *is detectable, and the* γ*-attenuation level holds for system* (1.12) *with measurement* (1.13) *and cost function* K_0. *Then, we have*

(1) $A - BB^*\Pi$ *is exponentially stable, where* Π *is a solution of* (1.8);

(2) $A^* + \frac{1}{\gamma^2}\Pi DD^* - (C^*C - \frac{1}{\gamma^2}\Pi BB^*\Pi)\Gamma$ *is exponentially stable, where*

$$\Gamma = \Sigma\left(I - \frac{1}{\gamma^2}\Pi\Sigma\right)^{-1}$$

and Σ *is the solution of* (1.9);

(3) $A^* + \frac{1}{\gamma^2}\Pi DD^* - C^*C\Gamma$ *is exponentially stable;*

(4) Γ *is the unique solution of the following Riccati equation*

$$\Gamma\left(A^* + \frac{1}{\gamma^2}\Pi DD^*\right) + \left(A + \frac{1}{\gamma^2}DD^*\Pi\right)\Gamma - \Gamma\left(C^*C - \frac{1}{\gamma^2}\Pi BB^*\Pi\right)\Gamma + DD^* = 0; \tag{2.5}$$

(5) *the system*

$$\begin{aligned} \dot{x} &= \left(A^* + \frac{1}{\gamma^2}\Pi DD^*\right)x + C^*v + \Pi B\mu, \qquad x(0) = 0, \\ z &= D^*x \end{aligned} \tag{2.6}$$

with cost function

$$K_0(v,\mu) = \int_0^\infty (\|z\|_W^2 + \|v\|_Y^2)dt \tag{2.7}$$

achieves the γ-attenuation level; i.e., there exists $\hat{v} \in Y$ such that

$$\sup_{\mu} \frac{\int_0^\infty (\|z\|^2 + \|\hat{v}\|^2)dt}{\int_0^\infty \|\mu\|^2 dt} < \gamma^2. \tag{2.8}$$

3. Main existence result and its proof.

MAIN THEOREM. *Consider the uncertain evolution system* (1.1) *along with finite-dimensional measurement* (1.13) *and cost function K_{x_0} given by* (1.15). *Assume that (A, B) is stabilizable and (A, H) is detectable, and there exists an infinite-dimensional compensator for* (1.12) *such that the γ-attenuation level is achieved with the measurement* (1.13). *Then, under assumptions* (A1)–(A4), *there exists a finite-dimensional compensator-based controller*

$$\begin{aligned} u(t) &= L^N z(t), \\ \dot{z}(t) &= (A^N + M^N)z(t) + G^N y(t) \end{aligned}$$

which stabilizes the uncertain system (1.12), *and the γ-attenuation level is achieved under the same measurement* (1.13) *and cost function* (1.15).

We prove the result using a sequence of lemmas and theorems. First let us introduce

$$\mathcal{A}^N := \begin{bmatrix} A & BL^N \\ G^N C & A^N + M^N \end{bmatrix}$$

where

$$L^N = -B^{N*}\Pi^N, \quad G^N = \Gamma^N C^{N^*}, \quad \Gamma^N = \Sigma^N \left(I - \frac{1}{\gamma^2}\Pi^N\Sigma^N \right)^{-1}$$

and

$$M^N = -\left(B^N B^{N^*} - \frac{1}{\gamma^2} D^N D^{N*} \right) \Pi^N - \Gamma^N C^{N*} C^N.$$

One goal here is to show that there exists a sufficiently large N such that $\mathcal{A}^N$ is exponentially stable on $X \times X^N$.

LEMMA 3.1. *Assume that assumptions* (A1) *and* (A2) *are satisfied. Then for each N, $L^N = -B^{N*}\Pi^N \in \mathcal{L}(X^N, \mathbb{R}^m)$ and $L^N P^N$ converges $L = -B^*\Pi$ in its operator norm as $N \to \infty$. Furthermore, there exists an integer N_1 such that if $N \geq N_1$ and $Re\lambda > -\omega_3$*

$$\left(\lambda I - \left(A + \frac{1}{\gamma^2} DD^*\Pi + BL^N P^N \right) \right)^{-1} \in \mathcal{L}(X)$$

and

$$e^{(\lambda I - (A + \frac{1}{\gamma^2} DD^*\Pi + BL^N P^N))t} \to e^{(\lambda I - (A + \frac{1}{\gamma^2} DD^*\Pi + BL))t} \quad \textit{as} \quad N \to \infty$$

where the convergence is uniform on bounded t-intervals.

Proof. Since B is a compact operator, so is B^*. By assumption (A1) we know that $B^{N*} \to B^*$ in norm, and by Lemma 2.1 we have $\Pi^N \to\to \Pi$. Thus the first conclusion follows. For the second assertion, let $S^N(t)$ be the C_0 semigroup generated by the operator $A+\frac{1}{\gamma^2}DD^*\Pi+BL^NP^N$, and let $S(t)$ be the C_0 semigroup generated by the operator $A+\frac{1}{\gamma^2}DD^*\Pi+BL$. Since

$$A+\frac{1}{\gamma^2}DD^*\Pi+BL^NP^N=A+\frac{1}{\gamma^2}DD^*\Pi+BL+B(L^NP^N-L),$$

in view of the "Perturbation Theorem" of [9], we have

$$S^N(t)=S(t)+\int_0^t S(t-s)B(L^NP^N-L)S^N(s)ds. \tag{3.1}$$

Since $A+\frac{1}{\gamma^2}DD^*\Pi+BL$ is exponentially stable, there exist $M_3\geq 1$ and $\omega\geq 0$ such that

$$\|S(t)\|\leq M_3e^{-\omega t}.$$

Thus we have

$$\|S^N(t)\|\leq M_3e^{-\omega t}+\int_0^t M_3e^{-\omega(t-s)}\|B\|\|L-L^NP^N\|\|S^N(s)\|ds, \tag{3.2}$$

and Gronwall's lemma implies that

$$\|S^N(t)\|\leq M_3e^{(-\omega+M_3\|B\|\|L-L^NP^N\|)t},\qquad t\geq 0. \tag{3.3}$$

Since $L^NP^N\to L$, by the Hille–Yosida theorem (see Theorem 1.5.3 of [24]) we know that there exists $N_1>0$ such that when $N>N_1$, $(\lambda I-(A+\frac{1}{\gamma^2}DD^*\Pi+BL^N))^{-1}$ is bounded in $\mathcal{L}(X)$. This yields the second statement. To conclude the proof, note that

$$\begin{aligned}&\left(\lambda I-\left(A+\frac{1}{\gamma^2}DD^*\Pi+BL^NP^N\right)\right)^{-1}-\left(\lambda I-\left(A+\frac{1}{\gamma^2}DD^*\Pi+BL\right)\right)^{-1}\\&\quad=\left(\lambda I-\left(A+\frac{1}{\gamma^2}DD^*\Pi+BL^NP^N\right)\right)^{-1}\\&\qquad\times B(L^NP^N-L)\left(\lambda I-\left(A+\frac{1}{\gamma^2}DD^*\Pi+BL\right)\right)^{-1}\end{aligned}$$

and $L^N\to\to L$, which lead to

$$\left(\lambda I-\left(A+\frac{1}{\gamma^2}DD^*\Pi+BL^NP^N\right)\right)^{-1}\to\left(\lambda I-\left(A+\frac{1}{\gamma^2}DD^*\Pi+BL\right)\right)^{-1}\quad\text{as } N\to\infty.$$

By the Trotter–Kato theorem (see Theorem 3.4.4 of [24]), the proof of Lemma 3.1 is complete. □

Remark 2. Clearly, from (3.3) there exist $\omega_3\geq 0$ and $N_3>0$ such that when $N>N_3$, we have

$$\|S^N(t)\|\leq M_3e^{-\omega_3 t},\qquad t\geq 0,$$

where both ω_3 and M_3 are independent of N.

Lemma 3.2. *Let A^N, B^N, C^N, D^N, and Π^N satisfy* (A1), (A2), *and* (A3) *for each $N > 0$. Then for every $x \in X$,*

$$e^{(A^N - (B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*})\Pi^N)t} P^N x \to T_1(t)x$$

uniformly on bounded intervals with respect to t, where $T_1(t)$ is the C_0 semigroup generated by $A - (BB^* - \frac{1}{\gamma^2} DD^*)\Pi$.

Proof. According to the Trotter–Kato theorem and Remark 1, part 3, we need to show that

$$\begin{aligned}&\left[\lambda I - \left(A^N - \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*}\right)\Pi^N\right)\right]^{-1} P^N x\\ &\qquad \to \left[\lambda I - \left(A - \left(BB^* - \frac{1}{\gamma^2} DD^*\right)\Pi\right)\right]^{-1} x\end{aligned}$$

holds for any $x \in X$. Since

$$\begin{aligned}&\left[I - \left(A^N - \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*}\right)\Pi^N\right)\right]^{-1} P^N - (\lambda I - A^N)^{-1}\\ &\quad = -\left[I - \left(A^N - \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*}\right)\Pi^N\right)\right]^{-1}\\ &\qquad \times \left[\left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*}\right)\Pi^N\right](\lambda I - A^N)^{-1}\end{aligned}$$

and

$$\begin{aligned}&\left[\lambda I - \left(A - \left(BB^* - \frac{1}{\gamma^2} DD^*\right)\Pi\right)\right]^{-1} - (\lambda I - A)^{-1}\\ &\quad = -\left[\lambda I - \left(A - \left(BB^* - \frac{1}{\gamma^2} DD^*\right)\Pi\right)\right]^{-1}\left[\left(BB^* - \frac{1}{\gamma^2} DD^*\right)\Pi\right](\lambda I - A)^{-1},\end{aligned}$$

it can then be verified that

$$\begin{aligned}&\left[\lambda I - \left(A^N - \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*}\right)\Pi^N\right)\right]^{-1} P^N\\ &\quad - \left[\lambda I - \left(A - \left(BB^* - \frac{1}{\gamma^2} DD^*\right)\Pi\right)\right]^{-1}\\ &= \Bigg\{\Bigg[I - \left[\lambda I - \left(A^N - \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*}\right)\Pi^N\right)\right]^{-1}\\ &\quad \times \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*}\right)\Pi^N P^N\Bigg]\left[(\lambda I - A^N)^{-1} P^N - (\lambda I - A)^{-1}\right]\\ &\quad + \left[\lambda I - \left(A^N - \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*}\right)\Pi^N\right)\right]^{-1}\\ &\quad \times \left[\left(BB^* - \frac{1}{\gamma^2} DD^*\right)\Pi - \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*}\right)\Pi^N P^N\right](\lambda I - A)^{-1}\Bigg\}(\lambda I - A)\\ &\quad \times \left[\lambda I - \left(A - \left(BB^* - \frac{1}{\gamma^2} DD^*\right)\Pi\right)\right]^{-1}.\end{aligned}$$

According to assumptions (A1), (A2), and Lemma 2.1, we have

$$(\lambda I - A^N)^{-1} \to\to (\lambda I - A)^{-1}, \ \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*}\right) \Pi^N \to\to \left(BB^* - \frac{1}{\gamma^2} DD^*\right) \Pi$$

as $N \to \infty$. Note that

$$\left[\lambda I - \left(A - \left(BB^* - \frac{1}{\gamma^2} DD^*\right) \Pi\right)\right]^{-1} : X \to D(A),$$

and hence the closed graph theorem implies that the operator

$$(\lambda I - A) \left[\lambda I - \left(A - \left(BB^* - \frac{1}{\gamma^2} DD^*\right) \Pi\right)\right]^{-1}$$

is bounded. Thus we have the desired result. □

THEOREM 3.3. *Let* A^N, B^N, C^N, D^N, *and* Π^N *satisfy* (A1) *and* (A2), *and introduce*

$$\mathcal{A}_p^N := \begin{bmatrix} A + \frac{1}{\gamma^2} DD^* \Pi & BL^N \\ G^N C & A^N + M^N \end{bmatrix},$$

where Π *is the solution of* (1.8). *Then, for sufficiently large* N, *there exists* $\epsilon > 0$ *which is independent of* N *such that*

$$\sigma(\mathcal{A}_p^N) \subseteq (-\infty, -\epsilon]$$

where $\sigma(\mathcal{A}_p)$ *is the spectrum*[3] *of* $\mathcal{A}_p$.

Proof. For a given $(h_1, h_2) \in X \times X^N$, consider the equation

$$(\lambda I - \mathcal{A}_p^N) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} h_1 \\ h_2 \end{bmatrix}, \tag{3.4}$$

which is equivalent to

$$\lambda v_1 - \left(A v_1 + \frac{1}{\gamma^2} DD^* \Pi v_1 + BL^N v_2\right) = h_1 \tag{3.5}$$

and

$$\lambda v_2 - [G^N C v_1 + (A^N + M^N) v_2] = h_2. \tag{3.6}$$

What we now show is that for any given $(h_1, h_2) \in X \times X^N$, when N is sufficiently large, (3.5)–(3.6) admits a solution (v_1, v_2) which is also in $X \times X^N$.

According to Lemma 3.1, there exists an integer $N_1 > 0$ such that when $\mathrm{Re}\lambda > -\omega_3$, $(\lambda I - (A + \frac{1}{\gamma^2} DD^* \Pi + BL^N))^{-1}$ is well defined. Hence, (3.5) can be written as

$$v_1 = \left[\lambda I - \left(A + \frac{1}{\gamma^2} DD^* \Pi + BL^N\right)\right]^{-1} [BL^N (v_2 - v_1) + h_1]. \tag{3.7}$$

[3] The spectrum of an operator consists of three mutually exclusive parts: the point spectrum, the continuous spectrum, and the residual spectrum; for more details, see Kato [18].

Similarly, since $A^N - (B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*})\Pi^N$ generates an exponentially stable semigroup by the hypothesis of the theorem and in view of Lemma 2.1, there exists λ, with $\mathrm{Re}\lambda > -\omega_1$, for which (3.6) becomes

$$(3.8)\quad v_2 = \left[\lambda I - \left(A^N - \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*}\right)\right)\Pi^N\right]^{-1} [G^N C(v_1 - v_2) + h_2].$$

Thus, if $\mathrm{Re}\lambda > -\min(\omega_1, \omega_3)$ and $N > N_1$ we have

$$\begin{aligned} v_1 - v_2 &= \left[\lambda I - \left(A + \frac{1}{\gamma^2} DD^*\Pi + BL^N\right)\right]^{-1} [BL^N(v_2 - v_1) + h_1] \\ &\quad - \left[\lambda I - \left(A^N - \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*}\right)\right)\Pi^N\right]^{-1} [G^N C(v_1 - v_2) + h_2]. \end{aligned}$$

We next show that the above equation admits a unique solution. By some manipulations, we arrive at

$$\begin{aligned} (3.9)\qquad & \left[\lambda I - \left(A^N + \frac{1}{\gamma^2} D^N D^{N*}\Pi^N - G^N C^N\right)\right](v_1 - v_2) \\ &= \left[\lambda I - \left(A^N - \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*}\right)\Pi^N\right)\right](v_1 - v_2) + (B^N L^N + G^N C^N)(v_1 - v_2) \\ &= \left[\lambda I - \left(A^N - \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*}\right)\Pi^N\right)\right] \\ &\quad \times \left(-\left[\lambda I - \left(A + \frac{1}{\gamma^2} DD^*\Pi + BL^N\right)\right]^{-1} BL^N\right. \\ &\quad\quad \left. + \left[\lambda I - \left(A^N - \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*}\right)\Pi^N\right)\right]^{-1} B^N L^N\right)(v_1 - v_2) \\ &+ \left[\lambda I - \left(A^N - \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*}\right)\Pi^N\right)\right]\left(\left[\lambda I - \left(A + \frac{1}{\gamma^2} DD^*\Pi + BL^N\right)\right]^{-1} h_1\right. \\ &\left. - \left[\lambda I - \left(A^N - \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*}\right)\Pi^N\right)\right]^{-1} P^N h_1\right) \\ &+ P^N h_1 - h_2 + G^N(C^N - C)(v_1 - v_2). \end{aligned}$$

By Lemma 2.3, part 3, for all λ such that $\mathrm{Re}\lambda > -\omega_2$, the matrix $[\lambda I - (A^N + \frac{1}{\gamma^2} D^N D^{N*}\Pi^N - G^N C^N)]$ is invertible, in view of which the following equality holds:

$$\begin{aligned} &\left[\lambda I - \left(A^N + \frac{1}{\gamma^2} D^N D^{N*}\Pi^N - G^N C^N\right)\right]^{-1} \\ &\quad \times \left[\lambda I - \left(A^N - \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*}\right)\Pi^N\right)\right] \\ &= I + \left[\lambda I - \left(A^N + \frac{1}{\gamma^2} D^N D^{N*}\Pi^N - G^N C^N\right)\right]^{-1} (B^N B^{N*}\Pi^N - G^N C^N). \end{aligned}$$

Thus for $\mathrm{Re}\lambda > -\min(\omega_1, \omega_2, \omega_3) := -\omega$ and $N > N_1$, (3.9) can be written as

$$\begin{aligned}(3.10)\qquad &(v_1 - v_2) - \varphi^N BL^N(v_1 - v_2)\\ &\quad + \left[\lambda I - \left(A^N + \frac{1}{\gamma^2} D^N D^{N*}\Pi^N - G^N C^N\right)\right]^{-1} G^N(C - C^N)(v_1 - v_2)\\ &\quad = \left[\lambda I - \left(A^N + \frac{1}{\gamma^2} D^N D^{N*}\Pi^N - G^N C^N\right)\right]^{-1} (P^N h_1 - h_2) - \varphi^N h_1,\end{aligned}$$

where φ^N is

$$\begin{aligned}\varphi^N = &\left\{ I + \left[\lambda I - \left(A^N + \frac{1}{\gamma^2} D^N D^{N*}\Pi^N - G^N C^N\right)\right]^{-1} (B^N B^{N*}\Pi^N - G^N C^N) \right\}\\ &\times \left\{ - \left[\lambda I - \left(A + \frac{1}{\gamma^2} DD^*\Pi + BL^N\right)\right]^{-1} \right.\\ &\qquad \left. + \left[\lambda I - \left(A^N - \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*}\right)\right)\Pi^N\right]^{-1} P^N \right\}.\end{aligned}$$

We show next that there exists N' such that if $N > N'$,

$$(3.11)\quad \left\| \varphi^N BL^N + \left[\lambda I - \left(A^N + \frac{1}{\gamma^2} D^N D^{N*}\Pi^N - G^N C^N\right)\right]^{-1} G^N(C - C^N) \right\|_{\mathcal{L}(X)} < 1,$$

which then says that (3.5), (3.6) are solvable for $\mathrm{Re}\lambda \geq 0$ according to (3.7) and (3.8).

Again we denote by S^N the C_0 semigroup generated by operator $A + \frac{1}{\gamma^2} DD^*\Pi + BL^N$. Since both

$$\left[\lambda I - \left(A + \frac{1}{\gamma^2} DD^*\Pi + BL^N\right)\right]^{-1} B = \int_0^\infty e^{-\lambda t} S^N(t) B dt$$

and

$$\begin{aligned}&\left[\lambda I - \left(A^N + \frac{1}{\gamma^2} D^N D^{N*}\Pi^N - B^N B^{N*}\Pi^N\right)\right]^{-1} P^N B\\ &\qquad = \int_0^\infty e^{-\lambda t} e^{(A^N + \frac{1}{\gamma^2} D^N D^{N*}\Pi^N - B^N B^{N*}\Pi^N)t} P^N B dt\end{aligned}$$

hold for $\mathrm{Re}\lambda \geq -\omega$, for any $T > 0$ we have

$$\begin{aligned}&\left\| \left[\lambda I - \left(A + \frac{1}{\gamma^2} DD^*\Pi + BL^N\right)\right]^{-1} B \right.\\ &\qquad \left. - \left[\lambda I - \left(A^N + \frac{1}{\gamma^2} D^N D^{N*}\Pi^N - B^N B^{N*}\Pi^N\right)\right]^{-1} P^N B \right\|\\ &\qquad \leq \int_0^T e^{-\mathrm{Re}\lambda t} \| e^{(A^N + \frac{1}{\gamma^2} D^N D^{N*}\Pi^N - B^N B^{N*}\Pi^N)t} P^N B - S^N B \| dt\\ &\qquad\quad + \left(M_1 \frac{e^{-(\mathrm{Re}\lambda + \omega_1)T}}{\mathrm{Re}\lambda + \omega_1} + M_3 \frac{e^{-(\mathrm{Re}\lambda + \omega_3)T}}{\mathrm{Re}\lambda + \omega_3} \right) \|B\|.\end{aligned}$$

By Lemma 2.3, part 3, and the principle of uniform boundedness [27], for $\mathrm{Re}\lambda \geq -\omega$ there is a constant $c > 0$ independent of N such that

$$\left\| I + \left[\lambda I - \left(A^N + \frac{1}{\gamma^2} D^N D^{N*}\Pi^N - G^N C^N\right)\right]^{-1} (B^N B^{N*} P^N - G^N C^N)\right\| \leq c.$$

Let $c_L := \max_N \|L^N\|$ and choose $T > 0$ such that for $\mathrm{Re}\lambda > -\omega$

$$c_L c \left(M_1 \frac{e^{-(\mathrm{Re}\lambda + \omega_1)T}}{\mathrm{Re}\lambda + \omega_1} + M_3 \frac{e^{-(\mathrm{Re}\lambda + \omega_3)T}}{\mathrm{Re}\lambda + \omega_3}\right) \|B\| \leq \frac{1}{4}.$$

On the other hand, as $N \to \infty$ we have

$$\begin{aligned} &e^{(A^N + \frac{1}{\gamma^2} D^N D^{N*}\Pi^N - B^N B^{N*}\Pi^N)t} P^N B \to S(t)B \qquad \text{strongly},\\ &S^N(t)B \rightarrow\rightarrow S(t)B \end{aligned}$$

uniformly on $[0, T]$. Thus there exists $N'' > 0$ such that when $N \geq N''$, the following holds:

$$\int_0^T e^{-\mathrm{Re}\lambda t} \| e^{(A^N + \frac{1}{\gamma^2} D^N D^{N*}\Pi^N - B^N B^{N*}\Pi^N)t} P^N B - S^N B\| dt \leq \frac{1}{4 c c_L}$$

by noting that B is compact. It then follows that for $N \geq \max(N', N'') := \hat{N}$, $\|\varphi^N B L^N\| \leq \frac{1}{2}$. Note that $C^N \to C$ as $N \to \infty$, and there exists $\overline{N} > 0$ such that when $N > \overline{N}$

$$\left\| \left[\lambda I - \left(A^N + \frac{1}{\gamma^2} D^N D^{N*} P^N - G^N C^N\right)\right]^{-1} G^N (C - C^N)\right\|_{\mathcal{L}(X)} < \frac{1}{2}.$$

Therefore, for $N > \max(\hat{N}, \overline{N})$, (3.11) holds, and (3.5), (3.6) are solvable for sufficiently large N when $\mathrm{Re}\lambda \geq -\omega$, which yields the conclusion. □

THEOREM 3.4. *Under the assumptions of Theorem* 3.3, *let* $\mathcal{A}_p^N$ *be given. Let*

$$\mathcal{A} = \begin{bmatrix} A + \frac{1}{\gamma^2} DD^*\Pi & -BB^*\Pi \\ \Gamma C^* C & A - (BB^* - \frac{1}{\gamma^2} DD^*)\Pi - \Gamma C^* C \end{bmatrix}$$

and $\mathcal{S}(t)$ *be the* C_0 *semigroup generated by* $\mathcal{A}$ *on* $X \times X$ *with* $D(\mathcal{A}) = D(A) \times D(A)$. *If there exists a* λ *such that the operator* $[\lambda I - \mathcal{A}_p^N]^{-1}$ *is uniformly bounded for all N, then*

$$\mathcal{S}^N(t) \rightarrow\rightarrow \mathcal{S}(t) \qquad \textit{uniformly on bounded } t\textit{-intervals as } N \to \infty,$$

where $\mathcal{S}^N(t)$ *is the* C_0 *semigroup generated by* $\mathcal{A}_p^N$ *on* $X \times X$ *with* $D(\mathcal{A}_p^N) = D(A) \times X^N$.

Proof. Introduce

$$Q^N = \begin{bmatrix} \frac{1}{\gamma^2} DD^*\Pi & -BB^{N*}\Pi^N \\ \Gamma^N C^{N*} C & -(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*})\Pi^N - \Gamma^N C^{N*} C^N \end{bmatrix}$$

and

$$Q = \begin{bmatrix} \frac{1}{\gamma^2} DD^*\Pi & -BB^*\Pi \\ \Gamma C^* C & -(BB^* - \frac{1}{\gamma^2} DD^*)\Pi - \Gamma C^* C \end{bmatrix}.$$

Let $\mathcal{A} = \mathcal{A}_1 + Q$ and $\mathcal{A}_p^N = \mathcal{A}_{p1}^N + Q^N$. To show $S^N(t) \to\to S(t)$ for $t \geq 0$ is equivalent to proving that for $\mathrm{Re}\lambda > -\omega$

$$R(\lambda : \mathcal{A}_p^N) \to\to R(\lambda : \mathcal{A}), \tag{3.12}$$

i.e.,

$$R(\lambda : \mathcal{A}_p^N)\overline{P}^N x \to R(\lambda : \mathcal{A})x \qquad \forall x \in X,$$

where $\overline{P}^N : X \times X \to X \times X^N$ is given by

$$\overline{P}^N = \begin{bmatrix} I & 0 \\ 0 & P^N \end{bmatrix}.$$

Hence we next claim (3.12). First, it is not difficult to verify that

$$\begin{aligned}[\lambda I - (\mathcal{A}_{p1}^N + Q^N)]^{-1} - &[\lambda I - \mathcal{A}_{p1}^N]^{-1} \\ &= [\lambda I - (\mathcal{A}_{p1}^N + Q^N)]^{-1} Q^N [\lambda I - \mathcal{A}_{p1}^N]^{-1}\end{aligned}$$

and

$$[\lambda I - (\mathcal{A}_1 + Q)]^{-1} - [\lambda I - \mathcal{A}_1]^{-1} = [\lambda I - (\mathcal{A}_1 + Q)]^{-1} Q [\lambda I - \mathcal{A}_1]^{-1}.$$

Hence we have

$$\begin{aligned}[\lambda I - &(\mathcal{A}_{p1}^N + Q^N)]^{-1}\overline{P}^N - [\lambda I - (\mathcal{A}_1 + Q)]^{-1} \\ &= [\lambda I - (\mathcal{A}_{p1}^N + Q^N)]^{-1} Q^N \big([\lambda I - \mathcal{A}_{p1}^N]^{-1}\overline{P}^N - [\lambda I - \mathcal{A}_1]^{-1}\big) \\ &\qquad - [\lambda I - (A_{p1}^N + Q^N)]^{-1}(\overline{P}^N Q - Q^N)[\lambda I - \mathcal{A}_1]^{-1} \\ &\qquad + \big([\lambda I - (\mathcal{A}_{p1}^N + Q^N)]^{-1}\overline{P}^N - [\lambda I - \mathcal{A}_1 + Q)]^{-1}\big) Q [\lambda I - \mathcal{A}_1]^{-1} \\ &\qquad + [\lambda I - \mathcal{A}_{p1}^N]^{-1}\overline{P}^N - [\lambda I - \mathcal{A}_1]^{-1}.\end{aligned} \tag{3.13}$$

Reorganizing (3.13) yields

$$\begin{aligned}\Big([\lambda I - &(\mathcal{A}_{p1}^N + Q^N)]^{-1}\overline{P}^N - [\lambda I - (\mathcal{A}_1 + Q)]^{-1}\Big)(I - Q[\lambda I - \mathcal{A}_1]^{-1}) \\ &= \Big(I + [\lambda I - (\mathcal{A}_{p1}^N + Q^N)]^{-1} Q^N\Big)\Big([\lambda I - \mathcal{A}_{p1}^N]^{-1}\overline{P}^N - [\lambda I - \mathcal{A}_1]^{-1}\Big) \\ &\qquad - [\lambda I - (\mathcal{A}_{p1}^N + Q^N)]^{-1}(\overline{P}^N Q - Q^N)[\lambda I - \mathcal{A}_1]^{-1}.\end{aligned}$$

Since

$$[I - Q(\lambda I - \mathcal{A}_1)^{-1}]^{-1} = [\lambda I - \mathcal{A}_1][\lambda I - (\mathcal{A}_1 + Q)]^{-1},$$

we know that $[I + Q(\lambda I - \mathcal{A}_1)^{-1}]^{-1}$ is bounded by the closed graph theorem (see [27]). Therefore, we arrive at

$$\begin{aligned}&[\lambda I - (\mathcal{A}_{p1}^N + Q^N)]^{-1}\overline{P}^N - [\lambda I - (\mathcal{A}_1 + Q)]^{-1} \\ &= \Big\{\Big(I - [\lambda I - (\mathcal{A}_{p1}^N + Q^N)]^{-1} Q^N\Big)\Big([\lambda I - \mathcal{A}_{p1}^N]^{-1}\overline{P}^N - [\lambda I - \mathcal{A}_1]^{-1}\Big) \\ &\qquad - [\lambda I - (\mathcal{A}_{p1}^N + Q^N)]^{-1}(\overline{P}^N Q - Q^N)[\lambda I - \mathcal{A}_1]^{-1}\Big\}[\lambda I - \mathcal{A}_1][\lambda I - (\mathcal{A}_1 + Q)]^{-1}.\end{aligned}$$

By assumption (A1), we have

$$[\lambda I - \mathcal{A}_{p1}^N]^{-1}\overline{P}^N \to [\lambda I - \mathcal{A}_1]^{-1}, \qquad \overline{P}^N Q - Q^N \to 0 \qquad \text{strongly as } N \to \infty.$$

Therefore, (3.12) holds as $N \to \infty$, thus completing the proof. □

Remark 3. One sufficient condition for $[\lambda I - \mathcal{A}_p^N]^{-1}$ to be uniformly bounded in N is assumption (A4). Clearly if A is an analytic C_0 semigroup, $[\lambda I - \mathcal{A}_p^N]^{-1}$ is uniformly bounded in N according to Theorem 3.3.

THEOREM 3.5. *Under the assumptions of Theorem* 3.3, *let $\mathcal{A}_p^N$ be given. Recall that*

$$\mathcal{A}^N = \begin{bmatrix} A & BL^N \\ G^N C & A^N + M^N \end{bmatrix}.$$

If $\mathcal{A}_p^N$ generates a stable semigroup, then $\mathcal{A}^N$ also generates a stable semigroup on $X \times X^N$.

Proof. *Step* 1. Consider the system

$$\begin{aligned}\dot{x_h} &= \left(A + \frac{1}{\gamma^2}DD^*\Pi\right)x_h - BB^{N*}\Pi^N p_k^N + Dw,\\ \dot{p_k^N} &= \left(A^N - \left(B^N B^{N*} - \frac{1}{\gamma^2}D^N D^{N*}\right)\Pi^N - \Gamma^N C^{N*}C^N\right)p_k^N\\ &\qquad + \Gamma^N C^{N*}Cx_h + \Gamma^N C^{N*}\eta,\\ x_h(0) &= h,\\ p_k^N(0) &= k.\end{aligned} \tag{3.14}$$

We claim that for a given $\delta > 0$, $0 < \delta < \gamma$, there exists $N_\delta > 0$ such that when $N \geq N_\delta$ the following estimate holds:

$$\begin{aligned}&\int_0^\infty \left(\|Hx_h\|^2 + \|B^{N*}\Pi^N p_k^N\|^2 - \gamma^2\left(\left\|w + \frac{1}{\gamma^2}D^*\Pi x_h\right\|^2 + \|\eta\|^2\right)\right)dt\\ &\qquad \leq -\delta^2\int_0^\infty (\|w\|^2 + \|\eta\|^2)dt + C_0(\|h\|^2 + \|k\|^2),\end{aligned} \tag{3.15}$$

where C_0 is some positive constant. First we denote the solution of (3.14) with initial condition $(0,0)$ by (x_0, p_0^N). It is easy to see that by evaluating $\frac{d}{dt}(\Pi x_0, x_0)$ and integrating from 0 to ∞, we have the following identity:

$$\begin{aligned}&\int_0^\infty \Bigg(\|Hx_0\|^2 + \|B^{N*}\Pi^N p_0^N\|^2 - \|B^*\Pi x_0 - B^{N*}\Pi^N p_0^N\|^2\\ &\qquad + \gamma^2\left(\|w\|^2 - \left\|w + \frac{1}{\gamma^2}D^*\Pi x_0\right\|^2\right)\Bigg)dt = 0.\end{aligned} \tag{3.16}$$

We then consider the following coupled (optimal) system:

$$\begin{aligned}\dot{\overline{x}} &= \left(A + \frac{1}{\gamma^2}DD^*\Pi\right)\overline{x} - BB^*\Pi\overline{p} + Dw,\\ \dot{\overline{p}} &= \left(A - \left(BB^* - \frac{1}{\gamma^2}DD^*\right)\Pi - \Gamma C^*C\right)\overline{p} + \Gamma C^*C\overline{x} + \Gamma C^*\eta,\\ \overline{x}(0) &= 0,\\ \overline{p}(0) &= 0.\end{aligned} \tag{3.17}$$

Letting $\xi = \overline{x} - \overline{p}$, we have

$$\dot{\xi} = \left(A + \frac{1}{\gamma^2} DD^*\Pi - \Gamma C^* C\right)\xi + Dw - \Gamma C^*\eta, \qquad \xi(0) = 0. \tag{3.18}$$

Note that (3.17) is in fact the dual system of (2.6) in Lemma 2.3, and thus by the duality theorem (see Appendix I) we have

$$\gamma_1^2 := \sup_{w,\eta} \frac{\int_0^\infty \|B^*\xi\|^2 dt}{\int_0^\infty (\|w\|^2 + \|\eta\|^2)dt} = \sup_{w,\eta} \frac{\int_0^\infty \|B^*\Pi(\overline{x}(t) - \overline{p}(t))\|^2 dt}{\int_0^\infty (\|w\|^2 + \|\eta\|^2)dt} < \gamma^2.$$

Since $(x_h, p_k^N) \in L^2(0,\infty; X) \times L^2(0,\infty; X^N)$ and $(x,p) \in L^2(0,\infty;X) \times L^2(0,\infty;X)$, according to Theorem 3.4, letting $\varepsilon = (\gamma^2 - \gamma_1^2)/2$, there exists $N' > 0$ such that when $N > N'$

$$\int_0^\infty \|B^*\Pi x_0 - B^*\Pi\overline{x}\|^2 dt < \varepsilon, \qquad \int_0^\infty \|B^*\Pi p - B^{N*}\Pi^N p^N\|^2 dt < \varepsilon,$$

which implies that when $N > N'$,

$$\sup_{w,\eta} \frac{\int_0^\infty \|B^*\Pi x_0(t) - B^{N*}\Pi^N p_0^N(t)\|^2 dt}{\int_0^\infty (\|w\|^2 + \|\eta\|^2)dt} < \gamma^2.$$

Hence we can find $\delta < \gamma$ and $N_\delta > N'$ such that for $N \geq N_\delta$ we have

$$\sup_{w,\eta} \frac{\int_0^\infty \|B^*\Pi x_0(t) - B^{N*}\Pi^N p_0^N(t)\|^2 dt}{\int_0^\infty (\|w\|^2 + \|\eta\|^2)dt} \leq \gamma^2 - \delta^2. \tag{3.19}$$

Hence (3.15), (3.19) yield

$$\begin{aligned}\int_0^\infty \left(\|Hx_0\|^2 + \|B^{N*}\Pi^N p_0^N\|^2 - \gamma^2\left(\left\|w + \frac{1}{\gamma^2}D^*\Pi x_0\right\|^2 + \|\eta\|^2\right)\right) \\ \leq -\delta^2 \int_0^\infty (\|w\|^2 + \|\eta\|^2)dt.\end{aligned} \tag{3.20}$$

Let $x_1 := x_h - x_0$, $p_1^N := p_k^N - p_0^N$. Note that (x_1, p_1^N) depends only on h, k and not on w, η, and clearly for some positive constants c_1 and c_2:

$$\|x_1\| \leq c_1\|h\|, \qquad \|p_1^N\| \leq c_2\|k\|.$$

Therefore, replacing (x_0, p_0^N) by $(x_h - x_1, p_k^N - p_1^N)$ in (3.20), we arrive at (3.15).

Step 2. Introduce the system

(3.21)

$$\begin{aligned}
&\dot{\hat{x}}_h = A\hat{x}_h - BB^{N*}\Pi^N\hat{p}_k^N,\\
&\dot{\hat{p}}_k^N = \left(A^N - \left(B^N B^{N*} - \frac{1}{\gamma^2}D^N D^{N*}\right)\Pi^N - \Gamma^N C^{N*}C^N\right)\hat{p}_k^N + \Gamma^N C^{N*} C\hat{x}_h,\\
&\hat{x}_h(0) = h,\\
&\hat{p}_k^N(0) = k.
\end{aligned}$$

We shall prove that there exists $N_1 > 0$ such that for $N \geq N_1$ we have

$$\hat{x}_h, \hat{p}_k^N \in L^2(0, +\infty; X).$$

For any $T > 0$, we define

$$x_T(t) = \begin{cases} \hat{x}_h(t) & \text{if } t \leq T, \\ x_{\hat{x}_T, \hat{p}_T^N}(t - T) & \text{if } t > T \end{cases}$$

and

$$p_T^N(t) = \begin{cases} \hat{p}_k^N(t) & \text{if } t \leq T, \\ p^N_{\hat{x}_T, \hat{p}_T^N}(t - T) & \text{if } t > T, \end{cases}$$

where $(x_{\hat{x}_T, \hat{p}_T^N}, p^N_{\hat{x}_T, \hat{p}_T^N})$ is the solution of

(3.22)
$$\begin{aligned} &\dot{x} = \left(A + \frac{1}{\gamma^2} DD^*\Pi\right) x - BB^{N*}\Pi^N p^N, \\ &\dot{p^N} = \left(A^N - \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*}\right)\Pi^N - \Gamma^N C^{N*} C^N\right) p^N + \Gamma^N C^{N*} Cx, \\ &x(T) = \hat{x}_h(T), \\ &p^N(T) = \hat{p}_k^N(T). \end{aligned}$$

If we let

$$w_T(t) = \begin{cases} -\gamma^{-2} D^*\Pi\hat{x}_h(t) & \text{if } t \leq T, \\ 0 & \text{if } t > T, \end{cases}$$

we can see that the pair $(x_T(\cdot), p_T^N(\cdot))$ is the solution of the system (3.14) corresponding to the perturbation $w(\cdot) = w_T(\cdot)$ and $\eta = 0$. Hence for $N \geq N_\delta$, by applying (3.15) we have

$$\begin{aligned} &\int_0^\infty \left(\|Hx_T\|^2 + \|B^{N*}\Pi^N p_T^N\|^2 - \gamma^2 \left\| w_T + \frac{1}{\gamma^2} D^*\Pi x_T \right\|^2 \right) dt \\ &\qquad \leq -\delta^2 \int_0^\infty \|w\|^2 dt + C_0(\|h\|^2 + \|k\|^2). \end{aligned} \tag{3.23}$$

Note that by the definition of w_T we have

$$\begin{aligned} &\int_T^\infty \left(\|Hx_T\|^2 + \|B^{N*}\Pi^N p_T^N\|^2 - \gamma^2 \left\| w_T + \frac{1}{\gamma^2} D^*\Pi x_T \right\|^2 \right) dt \\ &\qquad = \int_T^\infty \left(\|Hx_{\hat{x}_T, \hat{p}_T^N}\|^2 + \|B^{N*}\Pi^N p^N_{\hat{x}_T, \hat{p}_T^N}\|^2 - \gamma^2 \left\| \frac{1}{\gamma^2} D^* p^N_{\hat{x}_T, \hat{p}_T^N} \right\|^2 \right) dt. \end{aligned}$$

On the other hand, making use of Riccati equation (1.8) yields

$$\begin{aligned} &\int_T^\infty \left(\|Hx_T\|^2 + \|B^{N*}\Pi^N p_T^N\|^2 - \gamma^2 \left\| w_T + \frac{1}{\gamma^2} D^*\Pi x_T \right\|^2 \right) dt \\ &\qquad = (\Pi\hat{x}_T, \hat{x}_T) + \int_T^\infty \|B^*\Pi x_{\hat{x}_T, \hat{p}_T^N} - B^{N*}\Pi^N p^N_{\hat{x}_T, \hat{p}_T^N}\|^2 dt. \end{aligned} \tag{3.24}$$

Therefore we deduce from (3.23) and (3.24) the estimate

$$\begin{aligned}
&\int_0^\infty \left(\|Hx_T\|^2 + \|B^{N*}\Pi^N p_T^N\|^2 - \gamma^2 \left\| w_T + \frac{1}{\gamma^2} D^*\Pi x_T \right\|^2 \right) dt \\
&= \int_0^T (\|Hx_T\|^2 + \|B^{N*}\Pi^N p_T^N\|^2) dt + (\Pi \hat{x}_T, \hat{x}_T) \\
&\qquad + \int_T^\infty \|B^* \Pi x_{\hat{x}_T, \hat{p}_T^N} - B^{N*}\Pi^N p^N_{\hat{x}_T, \hat{p}_T^N}\|^2 dt \\
&< -\delta^2 \int_0^\infty \|w_T\|^2 dt + C_0(\|h\|^2 + \|k\|^2),
\end{aligned} \tag{3.25}$$

which yields (with c_1 some positive constant):

$$\int_0^T \|D^*\Pi \hat{x}_h\|^2 dt \leq C_1(\|h\|^2 + \|k\|^2).$$

By letting $T \to \infty$, we have $D^*\Pi\hat{x}_h \in L^2(0, +\infty; W)$. Note that $(\hat{x}_h, \hat{p}_k^N)$ appears as the solution of (3.14) with

$$w = -\frac{1}{\gamma^2} D^*\Pi\hat{x}_h \text{ and } \eta = 0.$$

Thus we have $\hat{x}_h, \hat{p}_k^N \in L^2(0, +\infty; X)$, and according to a theorem due to Datko (see [11]) $\mathcal{A}^N$ is exponentially stable. This completes the proof of Theorem 3.5. □

COROLLARY 3.6. *For any choice of the matrices A^N, L^N, G^N, M^N, if $\mathcal{A}_p^N$ defined in Theorem* 3.3 *satisfies the spectrum-determined growth condition, then there exists $N' > 0$ such that when $N > N'$, $\mathcal{A}^N$ which is defined in Theorem* 3.5 *generates an exponentially stable semigroup.*

Proof. The proof is quite straightforward. Note that according to Theorem 3.3, there exists an $N' > 0$ such that when $N > N'$ we have

$$\sigma(\mathcal{A}_p^N) \subseteq (-\infty, -\varepsilon]$$

for some $\varepsilon > 0$ which is independent of N, and $\mathcal{A}_p^N$ satisfies the spectrum-determined growth condition. Thus the growth constant ω_p,

$$\omega_p = \lim_{t\to\infty} \frac{1}{t} \ln \|e^{\mathcal{A}_p^N t}\|,$$

is negative, and hence $\mathcal{A}_p^N$ generates an exponentially stable C_0 semigroup. By Theorem 3.5, we have that when $N > N'$, $\mathcal{A}^N$ is exponentially stable. □

Equipped with all the results above, we are now in a position to prove the main theorem stated at the beginning of this section.

Proof of the main theorem. Let us view the system and its finite-dimensional compensator together as a coupled system, i.e.,

$$\begin{aligned}
&(3.26) \\
&\dot{x} = Ax - BB^{N*}\Pi^N p + Dw, \\
&\dot{p}^N = \left(A^N - \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*}\right)\Pi^N - \Gamma^N C^{N*} C^N\right) p^N + \Gamma^N C^{N*} C x + \Gamma^N C^{N*}\eta, \\
&x(0) = 0, \\
&p^N(0) = 0.
\end{aligned}$$

By Corollary 3.6, there exists $N_1 > 0$ such that when $N > N_1$, the matrix operator

$$\mathcal{A}^N = \begin{bmatrix} A & BL^N \\ G^N C & A^N + M^N \end{bmatrix}$$

generates an exponentially stable C_0 semigroup; thus the coupled system (3.26) is an exponentially stable system. Let $\hat{w} = w - \frac{1}{\gamma^2} D^* \Pi x$, $w \in L^2(0, \infty; W)$; then there exists N_2 such that (x, p^N) satisfies (3.15) with $h = 0, k = 0$ for $N > N_2$, i.e.,

$$\begin{aligned} \int_0^\infty \Big(\|Hx\|^2 + \|B^{N*}\Pi^N p^N\|^2 - \gamma^2(\|\hat{w}\|^2 + \|\eta\|^2) \Big) dt \\ \leq -\delta^2 \int_0^\infty \left(\left\| \hat{w} + \frac{1}{\gamma^2} D^* \Pi x \right\|^2 + \|\eta\|^2 \right) dt, \end{aligned} \tag{3.27}$$

which is equivalent to

$$\begin{aligned} \sup_{\hat{w},\eta} \frac{\int_0^\infty (\|Hx\|^2 + \|B^{N*}\Pi^N p^N\|^2) dt}{\int_0^\infty (\|\hat{w}\|^2 + \|\eta\|^2) dt} \\ \leq \gamma^2 - \delta^2 \inf_{\hat{w},\eta} \frac{\int_0^\infty (\|\eta\|^2 + \|\hat{w} + \frac{1}{\gamma^2} D^* \Pi x\|^2) dt}{\int_0^\infty (\|\hat{w}\|^2 + \|\eta\|^2) dt}. \end{aligned}$$

Since $\mathcal{A}_p^N$ is exponentially stable, we immediately have

$$\inf_{w,\eta} \frac{\int_0^\infty (\|\eta\|^2 + \|w - \frac{1}{\gamma^2} D^* \Pi x\|^2) dt}{\int_0^\infty (\|w\|^2 + \|\eta\|^2) dt} > 0.$$

Therefore (1.16) holds and the proof is complete. □

4. An application: Robust control of flexible structures. As an illustration of the theory developed in the previous section, we consider here the problem of robust control of flexible structures and provide a general computational scheme for a finite-dimensional compensator design, which can be used for numerical implementation of the full-order controller for particular structures such as the Euler–Bernoulli beam with the Kelvin–Voigt damping.

A typical class of flexible structures can be generically described by a system of partial differential equations:

$$M(\xi) \frac{\partial^2}{\partial t^2} z(\xi, t) + d_0 \frac{\partial}{\partial t} z(\xi, t) + A_0 z(\xi, t) = B_0 u(\xi, t) + D_0 w(\xi, t), \qquad t > 0, \tag{4.1}$$

where $z(\xi, t)$ is a vector of displacements of the structure (denoted by Ω) off its equilibrium position, as a function of space variable ξ and time t; $M(\xi)$ is the mass density; A_0 is a linear, time-invariant, self-adjoint, and positive differential operator; the domain $D(A_0)$ consists of all smooth functions satisfying (4.1) with appropriate boundary conditions and is dense in $L^2(\Omega)$; d_0 represents the inherent damping operators; $B_0 u$ denotes the control forces, while $D_0 w$ represents the external disturbance forces on the structure.

In most cases, the operator A_0, attributed to stiffness, is assumed to have a compact resolvent and thus the eigenvalues $\{\lambda_i\}$ form an infinitely increasing sequence of nonnegative real numbers. This can be expressed as the eigenproblem: $A_0 \phi_i =$

$\lambda_i \phi_i$, where $\{\sqrt{\lambda_i}\}$ are called the *vibration mode frequencies*, and $\{\phi_i(\xi)\}$ are the corresponding *vibration mode shapes*. Possible disturbances result from atmospheric effects, meteorite collisions, as well as pumps and motors. The objective of designing a (finite-dimensional) H^∞-optimal compensator for flexible structures is to maintain the attitude of each mode as close as possible to the desired attitude in the presence of disturbances acting on the structure (system) and corrupting the measurements.

Under the assumption that M is a bounded, self-adjoint, and coercive linear operator on $L^2(\Omega)$, without loss of any generality, (4.1) can be transformed into an evolution equation on $L^2(\Omega)$ in the form

$$\ddot{z}(t) + \tilde{d}_0 \dot{z}(t) + \tilde{A}_0 z(t) = \tilde{B}_0 u(t) + \tilde{D}_0 w(t), \qquad t > 0.$$

Let $H_0 = L^2(\Omega)$, and let V be the Hilbert space which is the completion of $D(\tilde{A}_0)$ with respect to the inner product $\langle v_1, v_2 \rangle_V := \langle \tilde{A}_0 v_1, v_2 \rangle_{H_0}$, that is, $V = D(\tilde{A}_0^{1/2})$. In this case the following embedding holds:

$$V \subset H_0 = H_0' \subset V'$$

where H_0' and V' represent the dual spaces of H_0 and V, respectively, with the injection from V into H_0 and from H_0 into V' being continuous with dense ranges. The total energy space is defined as $X = V \times H_0$ with inner product given by

$$\langle [v_1, h_1], [v_2, h_2] \rangle_X = \langle v_1, v_2 \rangle_V + \langle h_1, h_2 \rangle_{H_0}.$$

The state-space formulation of (4.1) is then

$$\dot{x}(t) = Ax(t) + Bu(t) + Dw(t),$$

where

$$A = \begin{bmatrix} 0 & I \\ -\tilde{A}_0 & -\tilde{d}_0 \end{bmatrix}, \qquad B = \begin{bmatrix} 0 \\ \tilde{B}_0 \end{bmatrix}, \qquad D = \begin{bmatrix} 0 \\ \tilde{D}_0 \end{bmatrix}, \qquad x = \begin{bmatrix} z \\ \dot{z} \end{bmatrix}.$$

Let $\mathcal{V} := V \times V$ and $\mathcal{H} := H_0 \times H_0$. In view of the nature of flexible structures and the above discussion, we can assume that $\tilde{d}_0 \in \mathcal{L}(V)$ and the operator $A \in \mathcal{L}(\mathcal{V}, \mathcal{V}')$ is generated by the bilinear continuous form on $\mathcal{V}$,

$$\langle -Ax, v \rangle_{\mathcal{V}' \times \mathcal{V}} = a(x, v) \qquad \text{for } x, v \in \mathcal{V},$$

where $a(\cdot, \cdot)$ is symmetric, and V-H_0 coercive:

$$\exists \alpha > 0, \quad \exists \lambda \in \mathbb{R}, \quad a(x, x) + \lambda \|x\|_{\mathcal{V}}^2 \geq \alpha \|x\|_{\mathcal{H}}^2.$$

Thus A generates an *analytic* semigroup e^{At} on $\mathcal{H}$ (see Theorem 2.12 of [6]). Moreover, if $0 \in \rho(A)$, then e^{At} is a compact C_0 semigroup of contraction. Let V^N be the span of N linearly independent vectors e_j, which is the orthogonal projection of V by operator P_{V^N}. Furthermore, we define the Hilbert space $X^N = V^N \times V^N$, whose inner product is the same as X. Let

$$A^N = \begin{bmatrix} 0 & I \\ -\mathcal{M}^{-\mathcal{N}} \mathcal{K}^{\mathcal{N}} & -\mathcal{M}^{-\mathcal{N}} \lceil_\infty^{\mathcal{N}} \end{bmatrix}_{2N \times 2N},$$

where $\mathcal{M}^N = [\langle e_i, e_j \rangle_{H_0}]_{N \times N}$, $\mathcal{K}^N = [\langle \tilde{A}_0^{1/2} e_i, \tilde{A}_0^{1/2} e_j \rangle_{H_0}]_{N \times N}$, $d_1^N = [\langle d_0 e_i, e_j \rangle]_{N \times N}$. Then the semigroups $e^{A^N t}$ and $e^{A^{N*} t}$ satisfy assumption (A1) of section 2.

Proposition 4.1. *Assume that the projection operator $P_{V^N} : V \to V^N$ is the V-projection onto V^N, which is a sequence of finite-dimensional subspaces, and $v_N = P_{V^N} v \in V^N$ converges to v for any $v \in V$. Let*

$$P^N = \begin{bmatrix} P_{V^N} & 0 \\ 0 & P_{H^N} \end{bmatrix},$$

where P_{H^N} is the H-projection onto V^N. Then, we have the following:

(a) *$e^{A^N t} P^N$ converges strongly to e^{At}, uniformly in t for t in bounded intervals;*

(b) *$e^{A^{N*} t} P^N$ converges strongly to $e^{A^* t}$, uniformly in t for t in bounded intervals.*

Outline of the proof. Since the embedding $V \subset H_0$ is compact, a direct calculation leads to the result that $(\lambda I - A^N)^{-1}$ strongly converges to $(\lambda I - A)^{-1}$ when $\lambda > 0$. Then application of the Trotter–Kato theorem yields (a), and the proof of (b) is similar. □

We assume that the control forces are implemented through m actuators. Thus there exist m vectors $b_i \in H_0, 1 \leq i \leq m$, such that

$$\tilde{B}_0 u = \sum_{i=1}^{m} b_i u_i, \quad \text{where} \quad u = [u_1, u_2, \ldots, u_m]^T \in \mathbb{R}^m,$$

where u_i are called the *actuator amplitudes* and b_i are referred to as the *actuator influence functions* in H_0. The adjoint of $\tilde{B}_0$ is thus given by

$$\tilde{B}_0^* h = [\langle b_1, h\rangle H_0, \langle b_2, h\rangle_{H_0}, \ldots, \langle b_m, h\rangle_{H_0}]^T, \quad \text{where} \quad h \in H_0.$$

Recall that the performance index is given by (1.15). Here we define $Q := H^* H$. Since $Q = Q^* \in \mathcal{L}(X)$ and $X = V \times H_0$, Q can be written as

$$Q = \begin{bmatrix} Q_{11} & Q_{12} \\ Q_{12}^* & Q_{22} \end{bmatrix},$$

where $Q_{11} = Q_{11}^* \in \mathcal{L}(V), Q_{12} \in \mathcal{L}(H_0, V)$, and $Q_{22} = Q_{22}^* \in \mathcal{L}(H_0)$.

Let the measurement be produced by p sensors

$$y(t) = C_0 z(t) + E_0 \dot{z}(t) + \eta(t),$$

where $C_0, E_0 \in \mathcal{L}(H_0, \mathbb{R}^p), y_i(t) = (c_i, z)_{H_0} + (v_i, \dot{z})_{H_0} + \eta_i, c_i, v_i \in H_0, \eta_i \in W_1, i = 1, 2, \ldots, p$. Functions $\{c_i\}$ are the position sensors, and functions $\{v_i\}$ are the velocity sensors in H_0. If we introduce $C = [C_0, E_0]$, then the partial observation can be written as $y(t) = Cx(t) + \eta(t)$.

Next we let

$$\hat{Q}^N = \begin{bmatrix} [\langle e_i, Q_{11} e_j\rangle]_V & [\langle e_i, Q_{12} e_j\rangle]_V \\ [\langle e_i, Q_{12} e_j\rangle]_V^T & [\langle e_i, Q_{22} e_j\rangle]_{H_0} \end{bmatrix}_{2N \times 2N}, \quad C^N = \begin{bmatrix} [\langle e_i, c_j\rangle]_{H_0} \\ [\langle e_i, v_j\rangle]_{H_0} \end{bmatrix}_{2N \times p}^T,$$

$$B^N = \begin{bmatrix} 0 \\ \mathcal{M}^{-N} \mathcal{B}^N \end{bmatrix}_{2N \times m}, \quad d^N = \begin{bmatrix} 0 \\ \mathcal{M}^{-N} d_1^N \end{bmatrix}_{2N \times N}, \quad D^N = \begin{bmatrix} 0 \\ \mathcal{M}^{-N} \mathcal{D}^N \end{bmatrix}_{2N \times 1},$$

and

$$\mathcal{B}^N = [\langle e_i, b_j\rangle]_{N \times m}, \quad \mathcal{D}^N = [\langle e_i, P_{H^N} D\cdot\rangle_H]_{N \times 1}.$$

Straightforward calculations lead to the following two propositions.

PROPOSITION 4.2. *Let P^N, B^N, C^N, and D^N be given as above. Then we have*

$$(1)\ B^N = P^N B; \quad (2)\ C^N = P^N C\big|_{X^N}; \quad (3)\ D^N = P^N D; \quad (4)\ Q^N = P^N Q\big|_{X^N};$$

$$(5)\ D^N D^{N*} = \begin{bmatrix} 0 & 0 \\ 0 & [\langle P_{H_0^N} D D^* P^*_{H^N} e_i, e_j \rangle_{H_0}]_{N\times N} \end{bmatrix}_{2N\times 2N},$$

where $C\big|_{X^N}$ represents the restriction of operator C onto X^N, and so does $Q\big|_{X^N}$.

PROPOSITION 4.3. *Let $\mathcal{G}^N$ be the Gramian matrix defined as*

$$\mathcal{G}^N = \begin{bmatrix} [(e_i, e_j)]_V & 0 \\ 0 & [(e_i, e_j)]_{H_0} \end{bmatrix}_{2N\times 2N}.$$

Then we have (1) $A^{N*} = \mathcal{G}^{-N}(A^N)^T \mathcal{G}^N$; (2) $B^{N*} = (B^N)^T \mathcal{G}^N$; (3) $Q^N = \mathcal{G}^{-N}\hat{Q}^N$.

Hence we have provided the complete matrix representations of the Riccati equations:

$$\Pi^N A^N + A^{N*}\Pi^N - \Pi^N \left(B^N B^{N*} - \frac{1}{\gamma^2} D^N D^{N*} \right) \Pi^N + Q^N = 0 \tag{4.2}$$

and

$$\Sigma A^{N*} + A^N \Sigma^N - \Sigma^N \left(C^{N*} C^N - \frac{1}{\gamma^2} Q^N \right) \Sigma^N + D^N D^{N*} = 0 \tag{4.3}$$

through Propositions 4.2 and 4.3. Let γ^{Π}_{Nc} (respectively, γ^{Σ}_{Nc}) be the optimum attenuation level associated with (4.2) (respectively, (4.3)), that is, for $\gamma > \gamma^{\Pi}_{Nc}$ (respectively, $\gamma > \gamma^{\Sigma}_{Nc}$) (4.2) (respectively, (4.3)) admits a nonnegative solution Π^N (respectively, Σ^N), which satisfies assumption (A2) (respectively, (A3)), and for $\gamma < \gamma^{\Pi}_{Nc}$ (respectively, $\gamma < \gamma^{\Sigma}_{Nc}$) there will be no such solution. We use similar notations γ^{Π}_c and γ^{Σ}_c to represent the optimum attenuation level associated with Riccati equations (1.8), (1.9), respectively. Now we are interested in the question of whether we can have

$$\gamma^{\Pi}_{Nc} \to \gamma^{\Pi}_c, \qquad \gamma^{\Sigma}_{Nc} \to \gamma^{\Sigma}_c \qquad \text{as } N \to \infty$$

which is equivalent to the question of whether the performance of the system can be made arbitrarily close to that obtained under the infinite-dimensional controller. According to [30], γ^{Π}_{Nc} has a closed-form representation in terms of the norm of an operator, denoted by $\mathcal{S}_{N\Pi} \in \mathcal{L}(X^N)$. That is, $\gamma^{\Pi}_{Nc} = \|\mathcal{S}_{\mathcal{N}\Pi}\|_{\mathcal{L}(\mathcal{X}^{\mathcal{N}})}$, and so does $\gamma^{\Pi}_c = \|\mathcal{S}_{\Pi}\|_{\mathcal{L}(X)}$. Thus to require $\gamma^{\Pi}_{Nc} \to \gamma^{\Pi}_c$ is equivalent to requiring

$$\|\mathcal{S}_{N\Pi}\|_{\mathcal{L}(X^N)} \to \|\mathcal{S}_{\Pi}\|_{\mathcal{L}(X)}. \tag{4.4}$$

However, we generally have only

$$\mathcal{S}_{N\Pi} \to\to \mathcal{S}_{\Pi}.$$

Hence it will be necessary to impose additional restrictions on the system for the approximation. One can verify that a sufficient condition for (4.4), by the closed-form of γ^{Π}_c, is that either the semigroup e^{At} or operator D be compact, since in this case operator $\mathcal{S}_{\Pi}$ would be a compact operator. Similar results hold for the Riccati equation (4.3). Let the matrix Π^N

$$\Pi^N = \begin{bmatrix} \Pi^N_{11} & \Pi^N_{12} \\ \Pi^{N*}_{12} & \Pi^N_{22} \end{bmatrix}_{2N\times 2N}$$

be the solution of (4.2). Then the finite-dimensional compensator in X^N can be constructed as

$$\begin{aligned} u_c(t) &= -\tilde{B}_0^*[\Pi_{11}^{N*} z_{N1}(t) + \Pi_{22}^N \dot{z}_{2N}(t)], \\ \dot{z}_N(t) &= \left(A^N - \left(B^N B^{N*} + \frac{1}{\gamma^2} D^N D^{N*}\right)\Pi^N\right) z_N(t) \\ &\quad + \Sigma^N \left(I - \frac{1}{\gamma^2}\Pi^N \Sigma^N\right)^{-1} C^{N*} y(t), \end{aligned} \tag{4.5}$$

where $z_N = (z_{N1}, z_{2N}) \in X^N$. We summarize the above discussion in the following theorem.

THEOREM 4.4. *Assume that* (A, B) *is stabilizable,* (A, H) *is detectable, and either* $0 \in \rho(A)$ *or both* D *and* H *are compact. If a* γ*-attenuation level is achieved by an infinite-dimensional compensator, then*

(1) *for sufficiently large* N*, Riccati equation* (4.2) *admits a nonnegative solution* $\Pi^N \in \Sigma^+(X^N)$ *which satisfies assumption* (A2);

(2) *for sufficiently large* N*, Riccati equation* (4.3) *admits a nonnegative solution* $\Sigma^N \in \Sigma^+(X^N)$ *which satisfies assumption* (A3);

(3) *the finite-dimensional compensator given in* (4.5) *achieves the same attenuation level by choosing an appropriate* N*; that is, when* $x_0 = 0$ *we have*

$$\sup_{w,\eta} \frac{\displaystyle\int_0^\infty (\|Hx(t)\|_{Y_1}^2 + \|u_c(t)\|_{\mathbb{R}^m}^2)dt}{\displaystyle\int_0^\infty (\|w(t)\|_W^2 + \|\eta(t)\|_{W_1}^2)dt} < \gamma^2.$$

5. Concluding remarks. In this paper we have established the existence of finite-dimensional compensators in the H^∞-optimal control of infinite-dimensional systems by using a Galerkin-type approximation. This result readily covers the case when the system structure operator A has a complete set of generalized eigenvectors, such as A being a Riesz-spectral operator.[4] In order to construct such a finite-dimensional compensator, we required that there exist an infinite-dimensional compensator achieving a γ-attenuation level. This is quite natural because one cannot expect a finite-dimensional compensator to be able to achieve the γ-attenuation level if there is no infinite-dimensional compensator to do so. From the proofs we can see that the finite-dimensional controller in fact converges to the infinite-dimensional controller as its order increases. The order of the finite-dimensional controller depends on how much error the system can tolerate, which is measured by the difference between γ and γ_c, where γ_c is the optimum level of disturbance attenuation for the system, which can be defined in a similar way as in the finite-dimensional case (see [30]).

The approach used in this paper can be extended to the case when the finite-dimensional controller is only allowed to act on the boundary. Such an extension as well as results of some numerical experiments will be reported elsewhere.

[4] A is a Riesz-spectral operator means that it has simple eigenvalues and the corresponding eigenvectors form a Riesz basis: a sequence of vectors $\{\phi_n, n \geq 1\}$ in a Hilbert space X such that (1) $\overline{span\{\phi_n\}} = X$, (2) there exist constants m, M such that for all N

$$m \sum_{n=1}^N |\alpha_n|^2 \leq \left\| \sum_{n=1}^N \phi_n \right\|^2 \leq M \sum_{n=1}^N |\alpha_n|^2.$$

Appendix I. The following theorem is from [3].

DUALITY THEOREM. *Consider Hilbert spaces X, Y, Z, identified with their duals. Let $\mathcal{A}$ be the infinitesimal generator of a C_0 semigroup in X, and $\mathcal{B} \in \mathcal{L}(Y, X), \mathcal{C} \in \mathcal{L}(X, Z)$. With the triple $(\mathcal{A}, \mathcal{B}, \mathcal{C})$, associate a linear system*

$$\dot{x} = \mathcal{A}x + \mathcal{B}u, \quad x(0) = 0$$

and a corresponding observation $\mathcal{C}x$. The system dual to this is defined as

$$\dot{\xi} = \mathcal{A}^*\xi + \mathcal{C}^*v, \quad \xi(0) = 0,$$

with a corresponding observation $\mathcal{B}^*\xi$. Assume that $\mathcal{A}$ is exponentially stable. Then we have

$$\sup_u \frac{\int_0^\infty |\mathcal{C}x|^2 dt}{\int_0^\infty |u|^2 dt} = \sup_v \frac{\int_0^\infty |\mathcal{B}^*\xi|^2 dt}{\int_0^\infty |v|^2 dt}.$$

Appendix II. We provide here a proof for Lemma 2.1, which is in the form of a sequence of propositions.

PROPOSITION A.1. *The Riccati equation*

$$\Pi A + A^*\Pi - \Pi\left(BB^* - \frac{1}{\gamma^2}DD^*\right)\Pi + H^*H = 0 \tag{A2.1}$$

has at most one solution $\Pi \in \Sigma^+(X)$ such that $A - (BB^* - \frac{1}{\gamma^2}DD^*)\Pi$ is exponentially stable.

Proof. Let $\Pi_1, \Pi_2 \in \Sigma^+(X)$ be two solutions of (A2.1) such that both $A - (BB^* - \frac{1}{\gamma^2}DD^*)\Pi_1$ and $A - (BB^* - \frac{1}{\gamma^2}DD^*)\Pi_2$ are exponentially stable. Consider the system

$$\dot{x} = Ax + Bu + Dw, \qquad x(0) = x_0.$$

Since Π_1, Π_2 satisfy (A2.1), we have

$$\begin{aligned}&\frac{d}{dt}\langle(\Pi_1 - \Pi_2)x, x\rangle \\ &= \gamma^2\left(\left\|w - \frac{1}{\gamma^2}D^*\Pi_2 x\right\|^2 - \left\|w - \frac{1}{\gamma^2}D^*\Pi_1 x\right\|^2\right) + \|u + B^*\Pi_2 x\|^2 - \|u + B^*\Pi_1 x\|^2.\end{aligned}$$

By integrating this between 0 and T, we obtain

$$\begin{aligned}&\langle(\Pi_1 - \Pi_2)x(T), x(T)\rangle - \langle(\Pi_1 - \Pi_2)x_0, x_0\rangle \\ &\quad = \int_0^T \left\{\gamma^2\left(\left\|w - \frac{1}{\gamma^2}D^*\Pi_1 x\right\|^2 - \left\|w - \frac{1}{\gamma^2}D^*\Pi_2 x\right\|^2\right)\right. \\ &\qquad\qquad \left. + \|u + B^*\Pi_2 x\|^2 - \|u + B^*\Pi_1 x\|^2\right\} dt.\end{aligned}$$

Setting $u = -B^*(\frac{\Pi_1+\Pi_2}{2})x, w = \gamma^{-2}D^*(\frac{\Pi_1+\Pi_2}{2})x$, we have

$$\langle(\Pi_1 - \Pi_2)x_0, x_0\rangle = \langle(\Pi_1 - \Pi_2)x(T), x(T)\rangle. \tag{A2.2}$$

Next we claim that the system

$$\dot{x} = Ax - BB^*\left(\frac{\Pi_1+\Pi_2}{2}\right)x + \frac{1}{\gamma^2}DD^*\left(\frac{\Pi_1+\Pi_2}{2}\right)x, \qquad x(0)=x_0 \tag{A2.3}$$

is exponentially stable. Let $\mathcal{A}_1 = \frac{1}{2}(A - BB^*\Pi_1 + \frac{1}{\gamma^2}DD^*\Pi_1), \mathcal{A}_2 = \frac{1}{2}(A - BB^*\Pi_2 + \frac{1}{\gamma^2}DD^*\Pi_2)$. Note that both $\mathcal{A}_1$ and $\mathcal{A}_2$ are exponentially stable according to the assumption at the beginning. Thus by the generalized Lyapunov's theorem [11] there exist two (unique) self-adjoint, positive definite, bounded operators $P_1, P_2 \in \mathcal{L}(X)$ such that

$$\langle P_1\mathcal{A}_1x, x\rangle + \langle x, P_1\mathcal{A}_1x\rangle = -\langle x, x\rangle \qquad \forall x \in D(A)$$

and

$$\langle P_2\mathcal{A}_1x, x\rangle + \langle x, P_2\mathcal{A}_1x\rangle = -\langle x, x\rangle \qquad \forall x \in D(A).$$

It is known that $\langle x, y\rangle_{e_1} := \langle x, P_1y\rangle, \langle x, y\rangle_{e_2} := \langle x, P_2y\rangle$ define two equivalent inner products on X such that

$$\begin{aligned} \alpha_1\|x\|_X^2 \le \|x\|_{e_1}^2 \le \beta_1\|x\|_X^2, \qquad \alpha_1 > 0,\\ \alpha_2\|x\|_X^2 \le \|x\|_{e_2}^2 \le \beta_2\|x\|_X^2, \qquad \alpha_2 > 0. \end{aligned}$$

Thus from (A2.3), for $x_0 \in D(A)$, we have

$$\begin{aligned} &\frac{d}{dt}\|x\|^2 = \langle \dot{x}, x\rangle + \langle x, \dot{x}\rangle \\ &= \langle \mathcal{A}_1x, x\rangle + \langle x, \mathcal{A}_1x\rangle + \langle \mathcal{A}_2x, x\rangle + \langle x, \mathcal{A}_2x\rangle \\ &\le \alpha_1^{-1}(\langle \mathcal{A}_1x, x\rangle_{e_1} + \langle x, \mathcal{A}_1x\rangle_{e_1}) + \alpha_2^{-1}(\langle \mathcal{A}_2x, x\rangle_{e_2} + \langle x, \mathcal{A}_2x\rangle_{e_2}) \\ &= -(\alpha_1^{-1} + \alpha_2^{-1})\langle x, x\rangle, \end{aligned}$$

which implies that $x \in L^2(0,\infty; X)$. Hence (A2.2) is exponentially stable.

Now in (A2.2), letting $T \to \infty$ yields

$$\langle (\Pi_1 - \Pi_2)x_0, x_0\rangle = 0 \qquad \forall x_0 \in X,$$

which implies $\Pi_1 = \Pi_2$. □

Reasoning similar to that given above leads to the next proposition.

PROPOSITION A.2. *The Riccati equation*

$$\Sigma A^* + A\Sigma - \Sigma\left(C^*C - \frac{1}{\gamma^2}H^*H\right)\Sigma + DD^* = 0$$

has at most one positive solution $\Sigma \in \Sigma^+(X)$ such that $A^* - (C^*C - \frac{1}{\gamma^2}H^*H)\Sigma$ is exponentially stable.

PROPOSITION A.3. *Suppose that the Riccati equation*

$$\Pi A + A^*\Pi - \Pi\left(BB^* - \frac{1}{\gamma^2}DD^*\right)\Pi + H^*H = 0 \tag{A2.4}$$

has a solution $\Pi \in \Sigma^+(X)$ *such that* $A - (BB^* - \frac{1}{\gamma^2}DD^*)\Pi$ *is exponentially stable and that* (A, H) *is detectable. Then, for any* $t_f > 0$*, the Riccati equation*

$$\begin{aligned}&\dot{\Pi}(t) + \Pi(t)A + A^*\Pi(t) - \Pi(t)\left(BB^* - \frac{1}{\gamma^2}DD^*\right)\Pi(t) + H^*H = 0,\\ &\Pi(t_f) = 0,\end{aligned} \tag{A2.5}$$

has a unique solution $\Pi(t; t_f) \in \Sigma^+(X)$ *on* $[0, t_f]$ *with the property that* $\Pi(t; t_f) \leq \Pi$ *and for all* $x \in X$ *the limit*

$$\Pi x = \lim_{t_f \to \infty} \Pi(t; t_f)x$$

exists.

Proof. Consider the following optimization problem:

$$\varphi(s, x_0) = \sup_w \inf_u J_\gamma(x_0; u, w) = \sup_w \inf_u \int_s^{t_f} (\|Hx\|^2 + \|Bu\|^2 - \gamma^2\|w\|)dt,$$

where x is subject to

$$\dot{x}(s) = Ax(s) + Bu(s) + Dw(s), \quad x(t) = x_0. \tag{A2.6}$$

Note that the conditions of this proposition guarantee that $\varphi(t, x_0)$ is finite. According to Theorem 2.1 of [29], we have that

$$\varphi(t, x_0) = J_\gamma(x_0; u^*, w^*), \tag{A2.7}$$

where $u^* = B^*p,\ w^* = -\frac{1}{\gamma^2}D^*p$, and p is generated by

$$\begin{aligned}\dot{x} &= Ax + BB^*p - \frac{1}{\gamma^2}DD^*p, \quad x(t) = x_0,\\ \dot{p} &= -A^*p + H^*Hx, \quad p(t_f) = 0.\end{aligned} \tag{A2.8}$$

Thus the operator $x_0 \to -p = \partial\varphi(t, x_0)$ is linear and therefore self-adjoint on X (see example 2 in Chapter 2 of [5]). Moreover,

$$\varphi(t, x) = \langle P(t)x, x\rangle \quad \text{for} \quad x \in X, P(t) = \partial\varphi(t). \tag{A2.9}$$

Making use of (A2.6) and (A2.9), we have

$$\begin{aligned}\frac{d}{ds}\langle P(s)x(s), x(s)\rangle =& -\langle H^*Hx(s), x(s)\rangle - \langle P(s)BB^*P(s)x(s), x(s)\rangle\\ &+ \frac{1}{\gamma^2}\langle DD^*P(s)x(s), x(s)\rangle.\end{aligned}$$

Alternatively, from (A2.8),

$$\begin{aligned}&\frac{d}{ds}\langle P(s)x(s), x(s)\rangle\\ &= \langle \dot{P}(s)x(s), x(s)\rangle + \langle Ax(s), x(s)\rangle + \langle A^*x(s), x(s)\rangle\\ &\qquad + 2\langle P(s)BB^*P(s)x(s), x(s)\rangle - \frac{2}{\gamma^2}\langle DD^*P(s)x(s), x(s)\rangle.\end{aligned}$$

Therefore, from the last two equalities we obtain

$$\begin{aligned}&\dot{P}(t) + P(t)A + A^*P(t) - P(t)\left(BB^* - \frac{1}{\gamma^2}DD^*\right)P(t) + H^*H = 0,\\ &P(t_f) = 0.\end{aligned} \tag{A2.10}$$

Thus, $P(t)$ solves (A2.5). Let $\Pi(t;t_f) = P(t)$. From the above discussion we have

$$\langle \Pi(t;t_f)x_0, x_0\rangle = \sup_w \inf_u J_\gamma^{t_f}(x_0;u,w).$$

Note that $\langle \Pi(t;t_f)x_0, x_0\rangle$ is monotonically nondecreasing with increasing t_f, since the lower value of the game $J^{t_f}(x_0;\cdot,\cdot)$ defined on $[t,t_f]$ cannot be larger than that of the one defined on a longer interval, $[t,t_{f'}]$, $t_{f'} > t_f$, as the maximizing player can always play zero control on the subinterval $[t_f, t_{f'}]$. Let $\hat{w} \in \mathcal{W}$ be picked to be zero beyond $t = t_f$. Denoting all admissible feedback controls for (A2.6) by $\mathcal{M}$, we have the following estimate:

$$\begin{aligned}\langle \Pi(t;t_f)x_0, x_0\rangle &= \sup_w \inf_u J_\gamma^{t_f}(x_0;u,w)\\ &\le \inf_{\mu\in\mathcal{M}} \sup_w J_\gamma^\infty(x_0;u,\hat{w})\\ &\le \inf_{\mu\in\mathcal{M}} \sup_w J_\gamma^\infty(x_0;u,w) = \langle \Pi x_0, x_0\rangle.\end{aligned}$$

By the parallelogram law in a Hilbert space, we have that $\lim_{t\to\infty}\langle \Pi(t;t_f)x, y\rangle$ exists for any $x, y \in X$. Thus we can define $R \in \Sigma^+(X)$ such that

$$\lim_{t\to\infty}\langle \Pi(t;t_f)x, y\rangle = \langle Rx, y\rangle.$$

It can be verified by employing the standard argument (cf. [6]) that R in fact solves (A2.4).

Next we claim that $R = \Pi$, i.e., $\Pi(t;t_f)x \to \Pi x$ $\forall x \in X$: Since $A - (BB^* - \frac{1}{\gamma^2}DD^*)\Pi := K$ is exponentially stable, there exist $M > 0, \beta > 0$ such that

$$\|e^{Kt}\| \le Me^{-\beta t}.$$

Set $\Xi(t) = \Pi - \Pi(t;t_f)$; then Ξ is the mild solution to the Riccati equation

$$\begin{aligned}&\dot{\Xi} + K^*\Xi + \Xi K + \Xi\left(BB^* - \frac{1}{\gamma^2}DD^*\right)\Xi = 0,\\ &\Xi(t_f) = \Pi,\end{aligned} \tag{A2.11}$$

which is equivalent to the equation

$$\begin{aligned}(\Pi - \Pi(t;t_f))x =& e^{(t_f-t)K^*}\Pi e^{(t_f-t)K}\\ &+ \int_t^{t_f} e^{(s-t)K^*}\Xi(s)\left(BB^* - \frac{1}{\gamma^2}DD^*\right)\Xi(s)e^{(s-t)K}x ds\end{aligned} \tag{A2.12}$$

for any $x \in X$. Since for any $x \in X$, $\{\Pi(t;t_f)x\}$ is bounded, there exists a $C > 0$ such that

$$\|\Pi(t;t_f)\| \le C \qquad \text{for} \quad 0 \le t \le t_f \le \infty \tag{A2.13}$$

by the principle of uniform boundedness. Therefore (A2.12) and (A2.13) give

$$\begin{aligned}\|(\Pi - \Pi(t;t_f))x\| &\leq M^2 e^{-2\beta(t_f-t)}\|\Pi\|\|x\| \\ &\quad + M^2 \int_t^{t_f} e^{-\beta(s-t)}\|(\Pi - \Pi(t;t_f))x\| \left\|BB^* - \frac{1}{\gamma^2}DD^*\right\| (\|\Pi\| + C)e^{-\beta(s-t)}ds.\end{aligned}$$

By employing Gronwall's inequality, we obtain

$$\begin{aligned}&\|(\Pi - \Pi(t;t_f))x\| \\ &\quad\leq M^2 e^{-2\beta(t_f-t)}\|\Pi\|\|x\| \exp\left(M^2 \int_t^{t_f} \left\|BB^* - \frac{1}{\gamma^2}DD^*\right\| (\|\Pi\| + C)e^{-\beta(s-t)}ds\right) \\ &\quad\leq M^2 e^{-2\beta(t_f-t)}\|\Pi\|\|x\| \exp\left(M^2 \left\|BB^* - \frac{1}{\gamma^2}DD^*\right\| (\|\Pi\| + C)/\beta\right),\end{aligned}$$

which completes the proof. □

Similarly, we have the following.

PROPOSITION A.4. *Suppose that the Riccati equation*

$$\Pi^N A^N + A^{N*}\Pi^N - \Pi^N \left(B^N B^{N*} - \frac{1}{\gamma^2}D^N D^{N*}\right)\Pi^N + H^{N*}H^N = 0 \tag{A2.14}$$

has a positive definite solution Π^N *such that* $A^N - B^N B^{N*} + \frac{1}{\gamma^2}D^N D^{N*}$ *is exponentially stable. Then, for any* $t_f > 0$*, the Riccati equation*

(A2.15)
$$\begin{aligned}&\dot{\Pi}^N + \Pi^N A^N + A^{N*}\Pi^N - \Pi^N \left(B^N B^{N*} - \frac{1}{\gamma^2}D^N D^{N*}\right)\Pi^N + H^{N*}H^N = 0, \\ &\Pi^N(t_f;t_f) = 0,\end{aligned}$$

has a unique positive definite solution $\Pi^N(t;t_f)$ *with the property that* $\Pi^N(t;t_f) \leq \Pi$ *for* $t \in [0,\infty)$*, and for all* $x \in X$ *the limit*

$$\Pi^N x = \lim_{t_f\to\infty} \Pi^N(t;t_f)x$$

exists.

PROPOSITION A.5. *Suppose that both Riccati equations*

(A2.16)
$$\Pi^N A^N + A^{N*}\Pi^N - \Pi^N \left(B^N B^{N*} - \frac{1}{\gamma^2}D^N D^{N*}\right)\Pi^N + H^{N*}H^N = 0, \quad N = 1,2,\ldots,$$

and

$$\Pi A + A^*\Pi - \Pi\left(BB^* - \frac{1}{\gamma^2}DD^*\right)\Pi + H^*H = 0 \tag{A2.17}$$

have solutions $\Pi^N \in \Sigma^+(X^N)$, $\Pi \in \Sigma^+(X)$*, such that* $A^N - (B^N B^{N*} - \frac{1}{\gamma^2}D^N D^{N*})\Pi^N$ *and* $A - (BB^* - \frac{1}{\gamma^2}DD^*)\Pi$ *are both exponentially stable. For any* $t_f > 0$*, let* $\Pi^N(t;t_f)$*,* $\Pi(t;t_f)$ *be the solutions of the Riccati equations*

$$\begin{aligned}&\dot{\Pi}^N(t) + \Pi^N(t)A^N + A^{N*}\Pi^N(t) - \Pi^N(t)\left(B^N B^{N*} - \frac{1}{\gamma^2}D^N D^{N*}\right)\Pi^N(t) \\ &\qquad + H^{N*}H^N = 0, \\ &\Pi^N(t_f) = 0, \quad N = 1,2,\ldots,\end{aligned}$$

and

$$\begin{aligned}&\dot{\Pi}(t) + \Pi(t)A + A^*\Pi(t) - \Pi(t)\left(BB^* - \frac{1}{\gamma^2}DD^*\right)\Pi(t) + H^*H = 0,\\ &\Pi(t_f) = 0,\end{aligned}$$

respectively, where for convenience we suppress the dependence on the terminal time t_f. Then, for each $t_f > 0$,

$$\Pi^N(t;t_f) \to\!\!\to \Pi(t;t_f) \quad \textit{uniformly in } t \textit{ on} \quad [0,t_f] \quad \textit{as} \quad N \to \infty.$$

Proof. Consider the optimization problem

$$\sup_w \inf_u J_\gamma^N(x_0^N;u,w) = \sup_w \inf_u \int_\tau^{t_f} (\|H^N x^N\|^2 + \|u\|^2 - \gamma^2\|w\|^2)dt,$$

where x^N is subject to

$$\begin{aligned}\dot{x}^N &= A^N x + B^N u + D^N w,\\ x^N(\tau) &= x_0^N,\end{aligned} \tag{A2.18}$$

which is equivalent to

$$x^N(t) = e^{A^N(t-\tau)}x_0^N + \int_\tau^t e^{A^N(t-s)}\big(B^N u(s) + D^N w(s)\big)ds.$$

Let us denote $L_2(0,t_f;X^N)$ by $\mathcal{X}^N$, $L_2(0,t_f;U)$ by $\mathcal{U}$, and $L_2(0,t_f;W)$ by $\mathcal{W}$. Define $\mathcal{F}^N \in \mathcal{L}(\mathcal{X}^N,\mathcal{X}^N)$ by

$$(\mathcal{F}^N\phi)(s) = \int_\tau^t e^{A^N(t-s)}\phi(s)ds, \qquad \phi \in \mathcal{X}^N.$$

By identifying X^N, U with respective duals, it is easy to verify that

$$(\mathcal{F}^{N*}\phi)(s) = \int_t^{t_f} e^{A^{N*}(s-t)}\phi(s)ds, \qquad \phi \in \mathcal{X}^N,$$

where $\mathcal{F}^{N*} \in \mathcal{L}(\mathcal{X}^N,\mathcal{X}^N)$. Next we write the cost function J_γ^N as

(A2.19)
$$J_\gamma^N(x_0^N;u,w) = \|H^N(e^{A^N\cdot}x_0^N + \mathcal{F}^N(B^N u + D^N w))\|_{\mathcal{X}^N}^2 + \|u\|_{\mathcal{U}}^2 - \gamma^2\|w\|_{\mathcal{W}}^2.$$

For arbitrary but fixed $w \in \mathcal{W}$, there exists a unique u which minimizes J_γ^N, which further is the unique solution of

$$\delta_u J_\gamma^N(x_0^N;u,w)(v) = 0 \quad \forall v \in \mathcal{U}, \tag{A2.20}$$

where $\delta_u J_\gamma^N(x_0^N;u,w)(v)$ stands for the Gâteaux derivative of J_γ^N at u, applied to v. From (A2.19), we have

$$\begin{aligned}&\delta J_\gamma^N(x_0^N;u,w)(v)\\ &\quad = 2\langle H^{N*}H^N\big(e^{A^N\cdot}x_0^N + \mathcal{F}(B^N u + D^N w)\big), \mathcal{F}B^N v\rangle_{\mathcal{X}^N} + 2\langle u,v\rangle_{\mathcal{U}}\\ &\quad = 2\langle T_1^N u + T_2^N w + T_3^{N*}x_0^N, v\rangle,\end{aligned}$$

where

$$T_1^N = I + B^{N*}\mathcal{F}^{N*}H^{N*}H^N\mathcal{F}^N B^N \in \mathcal{L}(\mathcal{U},\mathcal{U}),$$

$$T_2^N = B^{N*}\mathcal{F}^{N*}H^{N*}H^N\mathcal{F}^N D^N \in \mathcal{L}(\mathcal{W},\mathcal{U}),$$

and

$$T_3^{N*} = B^{N*}\mathcal{F}^{N*}H^{N*}H^N e^{A^N\cdot} \in \mathcal{L}(X^N,\mathcal{U}).$$

According to (A2.20), a necessary and sufficient condition for u to be optimal for a fixed w is that

$$u^w(t) = -\big(T_1^{-N}(T_3^{N*}x_0^N + T_2^N w)\big)(t) \quad \text{a.e. in } [0,t_f],$$

where we define $T_1^{-N} = (T_1^N)^{-1}$. Hence we have

(A2.21)
$$\begin{aligned} &J_\gamma^N(x_0^N;u^w,w)\\ &= \|H^N\big(e^{A^N\cdot}x_0^N - \mathcal{F}^N B^N T_1^{-N}T_3^{N*}x_0^N + \mathcal{F}^N((-B^N T_1^{-N}T_2^N + D^N)w)\big)\|^2_{\mathcal{X}^\mathcal{N}}\\ &\quad + \|T_1^{-N}(T_3^{N*}x_0^N + T_2^N w)\|^2_{\mathcal{U}} - \gamma^2\|w\|^2_{\mathcal{W}}. \end{aligned}$$

We now study the problem of maximizing the expression $J_\gamma^N(x_0^N;u^w,w)$ for $w \in \mathcal{W}$. Note that although we have a linear quadratic problem, the concavity is not verified a priori. However, the Riccati equation (A2.16) provides the γ-attenuation level for system (A2.18) with cost function J_γ^N, and one can show that $w \to J_\gamma^N(x_0^N;u^w,w)$ is strictly concave. Thus the maximizer w will satisfy the equation

$$\delta_w J_\gamma^N(x_0^N;u^w,w)(m) = 0 \quad \forall m \in \mathcal{W}. \tag{A2.22}$$

Direct calculation results in

$$\delta_w J_\gamma^N(x_0^N;u^w,w)(m) = 2\langle \mathcal{T}_1^N w + \mathcal{T}_2^N x_0^N, m\rangle \qquad \forall m \in \mathcal{W}, \tag{A2.23}$$

where $\mathcal{T}_1^N \in \mathcal{L}(\mathcal{W},\mathcal{W})$ is given by

$$\begin{aligned} \mathcal{T}_1^N &= [\mathcal{F}^N(-B^N T_1^{-N}T_2^N + D^N)]^* H^{N*}H^N[\mathcal{F}^\mathcal{N}(-B^N T_1^{-N}T_2^N + D^N)]\\ &\quad + T_2^{N*}T_1^{-N*}T_1^{-N}T_2^N - \gamma^2 I \end{aligned}$$

and $\mathcal{T}_2^N \in \mathcal{L}(\mathcal{X}^N,\mathcal{W})$ is given by

$$\begin{aligned} \mathcal{T}_2^N &= [\mathcal{F}^N(-B^N T_1^{-N}T_2^N + D^N)]^* H^{N*}H^N(e^{A^N\cdot} - \mathcal{F}^N B^N T_1^{-N}T_3^{N*})\\ &\quad + T_3^N T_1^{-N*}T_1^{-N}T_3^{N*}. \end{aligned}$$

Recalling the proof of the first part of Proposition A.3, we know that

$$\langle \Pi^N(\tau)x_0^N, x_0^N\rangle = \sup_w \inf_u J_\gamma^N(x_0^N;u,w).$$

Thus, letting $x_0^N = 0$, we have

$$\sup_w \inf_u J_\gamma^N(0;u,w) = 0.$$

From (A2.21) we have

$$J_\gamma^N(0; u^w, w) = \langle \mathcal{T}_1^N w, w\rangle.$$

Since $w \to J_\gamma^N(0; u^w, w)$ is strictly concave, $w = 0$ is the only maximizer of the differential game $J_\gamma^N(0; u^w, w)$, which implies that $-\mathcal{T}_1^N$ is a positive definite operator of $\mathcal{L}(\mathcal{W}, \mathcal{W})$. Thus from (A2.19) we have

$$w = (-\mathcal{T}_1^N)^{-1}\mathcal{T}_2 x_0^N. \tag{A2.24}$$

Hence by (A2.20), (A2.21), and (A2.24), we have

$$\sup_w J_\gamma^N(x_0^N; u^w, w) = \langle (\mathcal{K}^{N*}\mathcal{K}^N + T_3^N T_1^{-N*} T_1^{-N} T_3^{N*} + \mathcal{T}_2^{N*}(-\mathcal{T}_1)^{-N}\mathcal{T}_2^N)x_0^N . x_0^N\rangle_{\mathcal{X}^N},$$

where

$$\mathcal{K}^N = H^N(e^{A^N\cdot} - \mathcal{F}^N B^N T_1^{-N} T_3^{N*}).$$

In view of this, we obtain

$$\Pi^N(\tau)x_0^N = (\mathcal{K}^{N*}\mathcal{K}^N + T_3^N T_1^{-N*} T_1^{-N} T_3^{N*} + \mathcal{T}_2^{N*}(-\mathcal{T}_1)^{-N}\mathcal{T}_2^N)x_0^N. \tag{A2.25}$$

Define $\mathcal{F}$, T_1, T_2, T_3 by

$$\begin{aligned}
&(\mathcal{F}\phi)(s) = \int_0^t e^{A(t-s)}\phi(s)ds, \qquad \phi \in \mathcal{X},\\
&T_1 = I + B^*\mathcal{F}^*H^*H\mathcal{F}B \in \mathcal{L}(\mathcal{U},\mathcal{U}),\\
&T_2 = B^*\mathcal{F}^*H^*H\mathcal{F}D \in \mathcal{L}(\mathcal{W},\mathcal{U}),\\
&T_3^* = B^*\mathcal{F}^*H^*He^{A\cdot} \in \mathcal{L}(X,\mathcal{U})
\end{aligned}$$

and $\mathcal{T}_1 \in \mathcal{L}(\mathcal{W}, \mathcal{W})$ and $\mathcal{T}_2 \in \mathcal{L}(\mathcal{X}, \mathcal{W})$, respectively, by

$$\begin{aligned}
\mathcal{T}_1 = {} & [\mathcal{F}(-BT_1^{-1}T_2 + D)]^*H^*H[\mathcal{F}(-BT_1^{-1}T_2 + D)]\\
& + T_2^*T_1^{-1*}T_1^{-1}T_2 - \gamma^2 I,
\end{aligned}$$

$$\begin{aligned}
\mathcal{T}_2 = {} & [\mathcal{F}(-BT_1^{-1}T_2 + D)]^*H^*H(e^{A\cdot} - \mathcal{F}BT_1^{-1}T_3^*)\\
& + T_3T_1^{-*}T_1^{-1}T_3^*.
\end{aligned}$$

Consider the optimization problem

$$J_\gamma(x_0; u, w) = \sup_w \inf_u \int_\tau^{t_f} (\|x\|^2 + \|u\|^2 - \gamma^2\|w\|^2)dt,$$

where x is generated by

$$\dot{x} = Ax + Bu + Dw, \qquad x(\tau) = x_0.$$

Then, following a discussion similar to the one that led to (A2.25),

$$\Pi(0)x_0 = (\mathcal{K}^*\mathcal{K} + T_3(T_1^{-1})^*T_1^{-1}T_3^* + \mathcal{T}_2^*(-\mathcal{T}_1)^{-1}\mathcal{T}_2)x_0,$$

where

$$\mathcal{K} = H(e^{A\cdot} - \mathcal{F}BT_1^{-1}T_3^*).$$

By assumptions (A1)–(A4), as $N \to \infty$ we have

$$\begin{aligned}
&e^{A^N t} \rightarrow\rightarrow e^{At} \qquad \text{uniformly on} \qquad [0, t_f],\\
&e^{A^{N*} t} \rightarrow\rightarrow e^{A^* t} \qquad \text{uniformly on} \quad [0, t_f],\\
&B^N \to B \qquad \text{strongly},\\
&D^N \to D \qquad \text{strongly},\\
&H^N \to H \qquad \text{strongly}.
\end{aligned}$$

Letting $x_0^N := P^N x_0$, the above discussion indicates that

$$\Pi^N(\tau) P^N x_0 \to \Pi(\tau) x_0 \quad \forall x_0 \in X \qquad \text{as} \quad N \to \infty,$$

and this completes the proof of Proposition A.5. □

Proof of Lemma 2.1. For each $\varepsilon > 0$ and $x \in X$, according to Propositions A.3 and A.4 there exists $t_f > 0$ such that

$$\begin{aligned}
&\|\Pi(0; t_f)x - \Pi x\| < \varepsilon,\\
&\|\Pi^N(0, t_f)P^N - \Pi^N P^N\| < \varepsilon \qquad \text{for each} \quad N = 1, 2, \dots .
\end{aligned}$$

Note that

$$\begin{aligned}
\|\Pi^N P^N x - \Pi x\| \le &\|\Pi^N P^N x - \Pi(0; t_f)^N P^N x\| + \|\Pi(0; t_f)^N P^N x - \Pi^N(0; t_f)x\|,\\
&\|\Pi^N(0; t_f)x - \Pi(0; t_f)x\| + \|\Pi(0; t_f)x - \Pi x\|\\
&\le \varepsilon\|x\| + \|\Pi^N(0; t_f)\|\|P^N x - x\| + \|\Pi^N(0; t_f)x - \Pi(0; t_f)x\| + \varepsilon.
\end{aligned}$$

Since $\|\Pi^N(0; t_f)\|$ is uniformly bounded in N by uniform boundedness theorem, and $\Pi^N(0; t_f)x \to \Pi(0; t_f)x$ by Proposition A.5, we thus have

$$\Pi^N \rightarrow\rightarrow \Pi \qquad \text{as} \quad N \to \infty,$$

and this completes the proof of Lemma 2.1. □

By using the duality theorem, Lemma 2.2 can be proven similarly.

DYNAMIC DOMAIN DECOMPOSITION OF OPTIMAL CONTROL PROBLEMS FOR NETWORKS OF STRINGS AND TIMOSHENKO BEAMS*

G. LEUGERING†

Abstract. We consider general networks of strings and/or Timoshenko beams. We apply controls at boundary nodes of the network and want to minimize some cost function along (part of) the structure. Optimality systems for the entire structure are far too complex to compute in reasonable time. In particular, in real-time applications one wants to reduce the size of the problem. Thus, dynamic decomposition into its physical elements appears to be a natural approach. We show how to iteratively decompose the global optimality system into a system related to a substructure. Then we interpret the local system as an optimality system corresponding to an optimal control problem for the substructure and finally we show convergence of the "outer" iteration.

Key words. dynamic domain decomposition, networks of strings and beams, saddle-point iteration, relaxation

1. Introduction.

We consider a connected network of smooth curves in $\mathbb{R}^3$ indexed by $i = 1 : n_e$. The curves are joined together at vertices $\{v_J, v_M, \dots\} = V$ and are representative of the physical location of strings or of centerlines of beams in their reference configuration. Each of those curves will undergo deformations which we describe by $r_i(x,t) : [0,l_i] \times [0,T] \longrightarrow \mathbb{R}^{p_i}$. Let v_J be a vertex and d_J the number of arcs adjacent to v_J, and let $\mathcal{E}_J$ be the set of indices corresponding to adjacent arcs at v_J, i.e., $d_J = |\mathcal{E}_J|$. In particular, we consider directed graphs, such that an edge with label i joining vertices v_J and v_M in the direction $v_J \ \to v_M$ is parametrized in such a way that $x = 0$ corresponds to the vertex v_J, while $x = \ell_i$ corresponds to v_M. For the sake of convenience, however, we will write $r_i(v_J,t)$ instead of $r_i(0,t)$ or $r_i(\sigma_i(0),t)$, where σ_i is the mapping from $[0,\ell_i]$ onto the edge e_i. With this convention in mind we define the edge-node incidence relation ϵ as

$$\epsilon_{iJ} = \begin{cases} -1 & \text{if } e_i \text{ starts at } v_J, \\ 1 & \text{if } e_i \text{ ends at } v_J, \\ 0 & \text{if } e_i \text{ is not incident at } v_J. \end{cases}$$

At a given vertex v_J the deformation $r_i(v_J,t)$ of arc i has $p_i \in \mathbb{N}$ degrees of freedom. At a given vertex v_J, such that arc i is adjacent to v_J, we suppose that $q_J (q_J \leq p_i)$ of these variables are geometrically constrained. At simple nodes, where $d_J = 1$, we always have $q_J = p_i$ (for $\epsilon_{iJ} \neq 0$). At multiple nodes, where $d_J > 1$, we assume that we have surjective linear mappings $C_{iJ} : \mathbb{R}^{p_i} \to \mathbb{R}^{q_J}$ $(p_i \geq q_J)$ such that

$$\lambda_J(t) := C_{iJ} r_i(v_J,t) = C_{jJ} r_j(v_J,t) \qquad \forall\, i,j \in \mathcal{E}_J,\ t \in (0,T).$$

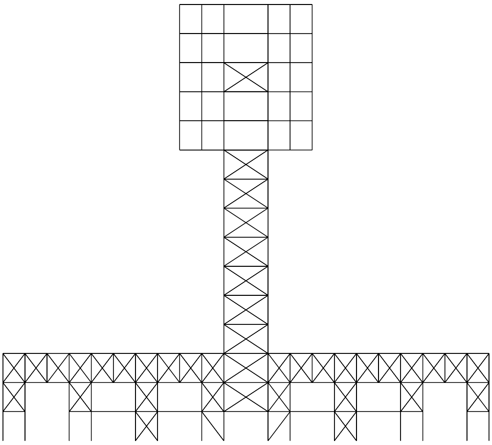

FIG. 1.1. *A typical multibay frame.*

Note that each arc carries along a local base so that C_{iJ} can be expressed as a matrix with respect to these bases. This requirement says that some (combinations of) variables are continuous across the joint v_J. For example, if $C_{iJ} = I \in \mathbb{R}^{p_i \times p_i}$, then all displacements are continuous across v_J, which for beams signifies a rigid joint. In particular, if one considers for simplicity a planar beam network with u_i, w_i, ψ_i as longitudinal, vertical, and shear displacements, then projecting with C_{iJ} onto the first two variables at v_J describes a pin joint, whereas $C_{iJ} = I_{3\times 3}$ describes a rigid joint. We refer the reader to [14], [15] (see also [27], [28] for "scalar" networks). As C_{iJ} has rank q_J, there is a right inverse C_{iJ}^+ such that $C_{iJ}C_{iJ}^+ = I$. Let Π_{iJ} denote the orthogonal projection onto the kernel of C_{iJ} and $\Pi_{iJ}^\perp$ the orthogonal projection onto $(\mathrm{ker} C_{iJ})^\perp = \mathrm{Im}\, C_{iJ}^T$, i.e., $C_{iJ}^+ C_{iJ} = \Pi_{iJ}^\perp$.

A typical situation is shown on a qualitative level in Figure 1.1. The graph shown there might be regarded as a part of a more complex space structure. Rather than decompose such a (sub-)structure into each individual element, one would use homogenization in order to replace the periodic substructures by dynamically equivalent homogenous elements and apply the decomposition principle to the structure composed of those homogenized structural elements. It is important to note that by this procedure one can deal with systems having local joint dynamics, where substructures interfere at common nodes. We might therefore include rigid bodies at those joints, as well as dry friction. Also it is possible and natural to decompose trusses, that is, structures with pin joints. Those situations cannot be handled with models obtained from three-dimensional elasticity by asymptotic analysis. See Saint Jean Paulin and Vanninathan [34] as an exemplary paper in this direction.

We introduce a mass matrix M_i, a stiffness matrix K_i, structural matrices R_i, S_i such that M_i, K_i, S_i are symmetric and positive definite (S_i is either positive definite or equal to zero). All matrices are sufficiently smooth with respect to x along arc i. With this notation one can define a kinetic and potential energy as well as a work functional as follows:

$$\mathcal{K}(t) := \frac{1}{2}\sum_{i=1}^{n_e} \int_0^{l_i} M_i(x)\dot r_i(x,t)\cdot \dot r_i(x,t)\,dx, \tag{1.1}$$

$$\mathcal{U}(t) := \frac{1}{2}\sum_{i=1}^{n_e}\int_0^{l_i}[K_i(x)(r_i'(x,t) + R_i(x)r_i(x,t)) \\ \cdot (r_i'(x,t) + R_i(x)r_i(x,t)) + S_i(x)r_i(x,t)\cdot r_i(x,t)]\,dx, \tag{1.2}$$

$$\mathcal{W}(t) := \sum_{i=1}^{n_e}\int_0^{l_i} F_i(x,t)r_i(x,t)\,dx + \sum_{v_J\in V} f_J(t)\lambda_J(t) \tag{1.3}$$

(dot and prime represent time and space derivatives, respectively). F_i and f_J are distributed body and nodal forces, respectively. The Lagrangian then is defined as

$$\mathcal{L}(r) := \int_0^T [\mathcal{K}(t) + \mathcal{W}(t) - \mathcal{U}(t)]\,dt. \tag{1.4}$$

Before we proceed to write down the equations of motion as in [14] we would like to indicate the range of applications of the formulation (1.1)–(1.3). For more details see [14].

Examples.

1. *Three-dimensional string networks.* $p_i = q_i = 3$, $C_{iJ} = I_{3\times 3}$,

$$R_i = S_i = 0,\ M_i = \rho_i I,\ S_i = 0,$$
$$K_i = Eh_i\left[\left(1 - \frac{1}{s_i}\right)I_{3\times 3} + \frac{1}{s_i}e_ie_i^T\right],$$

where e_i is the unit vector along the straight arc i, $s_i > 1$ is a stretching factor, E is Young's modulus, h_i is the thickness, and ρ_i is the density. The matrix K_i may also depend on x. This is the case when the original nonlinear problem is linearized around an equilibrium corresponding to a preloading of the network.

2. *Two-dimensional Timoshenko beam networks.* We have $e_i, e_i^\perp$ as above and n (orthogonal to the common $e_i - e_i^\perp$-plane). $M_i = \mathrm{diag}(\rho_i, \rho_i, \rho_i I_i)$,

$$K_i = \mathrm{diag}(Eh_i, Gh_i, EI_i),\ R_{i23} = 1,\ R_{ij} = 0 \text{ else},\ S_i = 0.$$

In this case the potential energy (1.2) reduces to

$$\mathcal{U}(t) = \frac{1}{2}\sum_{i=1}^{n_e}[Eh_i {u'}_i^2 + Gh_i({w'}_i + \psi_i)^2 + EI_i{\psi'}_i^2]\,dx,$$

where we have identified $r_i = (u_i, w_i, \psi_i)^T$ such that u_i, w_i denote longitudinal and vertical displacement, while ψ_i represents the shear deformation. $\mathcal{K}(t)$ and $\mathcal{W}(t)$ are obvious. In addition to the physical quantities introduced above, EI_i denotes the flexural rigidity, Eh_i the longitudinal stiffness, G_i the shear modulus, and I_i the moment of the cross section. The setup is seen to reproduce exactly the Timoshenko beam theory. For rigid joints $C_{iJ} = (e_i, e_i^\perp, n)$, for pin joints

$$C_{iJ} = (e_i, e_i^\perp)^T(e_i, e_i^\perp, n) \in \mathbb{R}^{2\times 3}.$$

3. *Three-dimensional Timoshenko beam networks.* This is analogous to Example 2; see [14].
4. *Networks of strings and beams.* See [14].

5. *Two-dimensional precurved Timoshenko beam (Bresse beam) networks.* This case is as in (1.2) but with

$$R_i = \begin{pmatrix} 0 & -\kappa_i & 0 \\ \kappa_i & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix},$$

where $\kappa_i(x)$ is the curvature of arc i in the $e_i - e_i^\perp$ plane.

Once the formulation (1.1)–(1.4) is seen to be sufficiently general, we proceed to write down the equations of motion, which are derived from (1.1)–(1.4) by standard variational principles.

$$\text{(1.5)} \qquad M_i\ddot{r}_i = [K_i(r_i' + R_i r_i)]' - R_i^T K_i(r_i' + R_i r_i) - S_i r_i + F_i, \qquad (x,t) \in (0,l_i) \times (0,T),$$

$$\text{(1.6)} \qquad r_i(v_D) = 0,\ \epsilon_{iD} \neq 0,\ v_D \in V_D,\ i \in \mathcal{E}_D,\ t \in (0,T),$$

$$\text{(1.7)} \qquad C_{iJ} r_i(v_J) = C_{kJ} r_k(v_J) =: \lambda_J,\ \forall\, i,k \in \mathcal{E}_J,\ v_J \in V_M,\ t \in (0,T),$$

$$\text{(1.8)} \qquad \sum_{i\in\mathcal{E}_J} \epsilon_{iJ}(C_{iJ}^+)^T [K_i(r_i' + R_i r_i)](v_J) = f_J - M_J\ddot{\lambda}_J, \qquad v_J \in V_M \cup V_N \cup V_C,\ t \in (0,T),$$

$$\text{(1.9)} \qquad \epsilon_{iJ}\Pi_{iJ}[K_i(r_i' + R_i r_i)](v_J) = 0,\ v_J \in V_M \cup V_N \cup V_C,\ t \in (0,T),$$

$$\text{(1.10)} \qquad r_i(\cdot,0) = r_{i0},\ \dot{r}_i(\cdot,0) = r_{i1}, \quad x \in (0,l_i).$$

Here we have denoted by V_M, V_S the sets of multiple and simple nodes such that $V = V_M \dot\cup V_S$ and $V_S = V_N \dot\cup V_D \dot\cup V_C$ (disjoint union) separates into free Neumann nodes, fully clamped (Dirichlet) nodes, and controlled Neumann nodes. One can of course also consider partially clamped nodes. The control forces f_J are set to zero for $v_J \in V_N \cup V_M$. The matrix M_J represents mass and rotatory inertia of a rigid body at node v_J. In this paper, however, we will consider $M_J = 0$ and return to the more general case in some remarks below.

It should be noted that one might include nonlinear coupling dynamics in (1.8) and (1.9) such as dry friction, plasticity, obstacles, Winkler supports, etc..

The standing assumption throughout the paper is that

$$\text{(A)} \begin{cases} & \text{either} \\ \text{(i)} & \text{every } S_i \text{ is positive definite} \\ & \text{or} \\ \text{(ii)} & V_D \neq \emptyset \text{ and for each node there is a path to a node} \\ & \text{in } V_D \text{ along which all joints are rigid.} \end{cases}$$

The standard case is (Aii), which simply states that, in engineering terms, the structure is not a mechanism; in other words no part can perform rigid rotations, or the structure is statically determined. Its mathematical significance is revealed after defining appropriate spaces, as in [14]:

$$\text{(1.11)} \qquad \mathbf{H} = \prod_{i=1}^{n_e} L^2(0,l_i,\mathbb{R}^{p_i}),$$

$$\text{(1.12)} \qquad \mathbf{V} = \left\{ r \in \prod_{i=1}^{n_e} H^1(0,l_i,\mathbb{R}^{p_i}) | r_i \text{ satisfies (1.6), (1.7)} \right\}.$$

We define the inner products

$$(r,\hat r)_{\mathbf{H}} = \frac{1}{2}\sum_{i=1}^{n_e}\int_0^{l_i} M_i r_i \hat r_i \, dx, \tag{1.13}$$

$$(r,\hat r)_{\mathbf{V}} = \frac{1}{2}\sum_{i=1}^{n_e}\int_0^{l_i} [K_i(r_i' + R_i r_i)(\hat r_i' + R_i \hat r_i) + (S_i + I) r_i \hat r_i] \, dx. \tag{1.14}$$

By Lemma 3.1, Chapter IV of [14], we find that under assumption (A) the norm $\|r\|_{\mathbf{V}} = (r,r)_{\mathbf{V}}^{1/2}$, even without the term I, is equivalent to

$$\|r\| := \left(\sum_{i=1}^{n_e}\int_0^{l_i} [|r_i|^2 + |r_i'|^2] \, dx\right)^{1/2}. \tag{1.15}$$

We also cite Theorem 3.1, Chapter IV from [14]. We denote by $\mathbf{V}^*$ the dual of $\mathbf{V}$.

THEOREM 1.1. *Let* $(r_0, r_1) \in \mathbf{V}\times\mathbf{H}$*,* $f \in L^2(0,T,\mathbf{H})$*,* $M_J = 0\,\forall j$*,* $f_J \in L^2(0,T,\mathbb{R}^{q_J})$*,* $J : v_J \in V_C$*. Let* (A) *be satisfied. Then there exists a unique mild solution* r *of* (1.5)–(1.10) *with regularity* $r \in C(0,T,\mathbf{V}) \cap C^1(0,T,\mathbf{H}) \cap C^2(0,T,\mathbf{V}^*)$*.*

2. Control problems.

In [14] and other related work we asked the question as to whether networks described by (1.5)–(1.10) are controllable. In particular, given initial data $(r_0, r_1) \in \mathbf{V}\times\mathbf{H}$, $F \equiv 0$, is it possible to find controls $f_J \in L^2(0,T,\mathbb{R}^{q_J})$, $v_J \in V_C$, such that after time $T > 0$, reasonably large, the final values $r(\cdot,T)$, $\dot r(\cdot,T)$ are either exactly zero (or prescribed) or in an ϵ-ball around zero?

The first case is known as exact controllability (reachability), while the second case for $\epsilon > 0$ (arbitrary) is referred to as approximate controllability.

We have been able to give affirmative answers only for tree networks with $|V_D| = 1$ and $V_S = V_C$. See Theorem 5.1, Chapter IV of [14], and [36]. For string trees with $|V_D| = 1$, $V_S \supset V_C$ (and possibly joint masses) we have some positive results [18], but the picture is more complicated. If, however, the network contains circuits and if it is completely homogenous, then even approximate controllability fails to hold. On the other side positive results can be expected to hold whenever the individual optical lengths of the strings are rationally independent, even though this has not yet been rigorously investigated. All relevant results can be translated as well into the context of stabilizability.

Given this complex picture, one is tempted to rather look into *optimal* control problems related to such networks. Indeed, in many circumstances one does not want to exactly (approximately) control the entire structure. Rather, one wants to protect some substructure against vibrational energy. This can be achieved by minimizing the energy in that subregion or, alternatively, by steering the flux of energy away from the subregion. In order not to overload the presentation we choose the first case, since the second case would necessitate a different analysis.

We will consider the cost functional

$$J(f) := \frac{1}{2}\sum_{J\in V_C}\int_0^T |f_J|^2 \, dt + \frac{k}{2}\left\{\|r(T) - z_0\|_{\mathbf{V}}^2 + \|\dot r(T) - z_1\|_{\mathbf{H}}^2\right\}. \tag{2.1}$$

One might also take the $\mathbf{V}\times\mathbf{H}$ topology induced on the subgraph associated with a subset $\mathcal{C}$ of the edge set. If k grows large in (2.1), one comes close to controllability problems described above.

There are other reasonable choices for the cost function. In particular, one can work in the shifted energy norm and consider

$$J(f) := \frac{1}{2}\sum_{J\in V_C}\int_0^T |f_J|^2\,dt + \frac{k}{2}\left\{\|r(T)-z_0\|_{\mathbf{H}}^2 + \|\dot r(T)-z_1\|_{\mathbf{V}^*}^2\right\}. \tag{2.2}$$

One can also include $\int_0^T \|r\|_{\mathbf{H}}^2\,dt$, $\int_0^T \|r\|_{\mathbf{V}}^2\,dt$, or the total energy integrated over the time interval $[0,T]$, and, if the network is known to be exactly controllable, a general $L-Q-R$ infinite horizon problem would be of interest. The problem we discuss here is the following:

$$\min_{(f_J)_{J\in V_C}} J((f_J)) \text{ subject to (1.5)–(1.10)}, \tag{2.3}$$

with $J(\cdot)$ given by (2.1).

3. Global optimality conditions. It is a matter of applying standard arguments to derive the optimality system corresponding to the optimization problem (2.3). We introduce an adjoint state p localized to arc i as p_i, which then satisfies the adjoint "backward running" system

$$M_i\ddot p_i = [K_i(p_i'+R_ip_i)]' - R_i^TK_i(p_i'+R_ip_i) - S_ip_i, \qquad (x,t)\in(0,\ell_i)\times(0,T), \tag{3.1}$$

$$p_i(v_D)=0,\ \epsilon_{iD}\neq 0,\ v_D\in V_D,\ i\in\mathcal{E}_D, t\in(0,T), \tag{3.2}$$

$$C_{iJ}p_i(v_J) = C_{kJ}p_k(v_J) =: \Theta_J\ \forall\, i,k\in\mathcal{E}_J,\ v_J\in V_M, t\in(0,T), \tag{3.3}$$

$$\sum_{i\in\mathcal{E}_J}\epsilon_{iJ}(C_{iJ}^+)^T[K_i(p_i'+R_ip_i)](v_J)=0,\ v_J\in V_M\cup V_N\cup V_C,\ t\in(0,T), \tag{3.4}$$

$$\epsilon_{iJ}\Pi_{iJ}[K_i(p_i'+R_ip_i)](v_J)=0,\ v_J\in V_M\cup V_N\cup V_C,\ t\in(0,T), \tag{3.5}$$

$$p(T)=k(\dot r(T)-z_1),\ \dot p(T) = -kA(r(T)-z_0), \tag{3.6}$$

$$f_J = -p_{i_J},\ J: v_J\in V_C,\ i\in\mathcal{E}_J\ t\in(0,T). \tag{3.7}$$

The operator A in (3.6) is the Riesz isomorphism between $\mathbf{V}$ and $\mathbf{V}^*$. It is obvious from (3.6) that, because of the regularity of $r(T)\in\mathbf{V}$ and $\dot r(T)\in\mathbf{H}$, the final values of p have the regularity $p(T)\in\mathbf{H}$ and $\dot p(T)\in\mathbf{V}^*$. However, by the regularity result of Theorem 1.1, we know that the operator taking L^2-in-time Neumann data at external (simple) nodes into the final values of the solution is bounded with respect to the total energy. The adjoint of that operator selects the Dirichlet traces of the solutions of the homogenous problem at those external nodes. Hence, by transposition, the traces of p at nodes in V_C are L^2-in-time. The solution p satisfies (3.1)–(3.7) in the sense of transposition, as in Nicaise [29, Theorem 5.1]. It is also possible to derive the required regularity of traces directly using "direct" inequalities for the nonharmonic Fourier series associated with networks. We have the following theorem.

THEOREM 3.1. *Let the assumptions of Theorem* 1.1 *be satisfied. Then the optimality system* (1.1)–(1.10), (3.1)–(3.7) *has a unique solution* r, p *such that*

$$r\in C(0,T,\mathbf{V})\cap C^1(0,T,\mathbf{H})\cap C^2(0,T,\mathbf{V}^*),$$
$$p\in C(0,T,\mathbf{H})\cap C^1(0,T,\mathbf{V}^*)\cap C^2(0,T,D(A)^*).$$

In addition, we have $p_{iJ}(v_J,\dot{)}\in L^2(0,T)$ *for* $v_J\in V_C$, $i\in\mathcal{E}_J$.

Remark 3.1. If we consider data (r_0, r_1), $(z_0, z_1) \in \mathbf{D}(\mathbf{A}) \times \mathbf{V}$, then the adjoint state satisfies $p \in C(0, T, \mathbf{V}) \cap C^1(0, T, \mathbf{H})$, too.

This is seen as follows: we start with final data $(p_T, \dot{p}_T) \in \mathbf{V} \times \mathbf{H}$. We solve the adjoint system backward in time and take Dirichlet traces at controlled nodes which have $H^1(0, T; \mathbf{R}^{q_J})$ regularity. These traces are used as Neumann inputs to the forward running system, according to the optimality conditions. These inputs, together with the assumed regularity of the initial data, produce a solution r that has $C(0, T; \mathbf{D}(\mathbf{A})) \cap C^1(0, T, \mathbf{V})$ regularity. That regularity is shared by the final data $(r(T), \dot{r}(T))$. Since we assume the same regularity for the target, we have $(-\dot{r}(T),\ Ar(T)) := \Lambda(p_T, \dot{p}_T) \in \mathbf{V} \times \mathbf{H}$. Indeed, this process is precisely the one described in [12], [13]. It amounts to solving $\Lambda(p_T, \dot{p}_T) + \frac{1}{k} M(p_T, \dot{p}_T) = (-z_1, Az_0)$. It is plain that the parameter k serves as a Tychonov regularization of the Hilbert uniqueness method (HUM) operator Λ. The last equation can be uniquely solved in the finite energy space.

The main point of the paper is to provide an iterative procedure in order to solve (1.5)–(1.10), (3.1)–(3.7) based on decoupled subproblems. The reason for this is that the system (1.5)–(1.10), (3.1)–(3.7) is extremely large if the network is complex and the states are discretized by finite difference (FD), finite element (FEM) methods or wavelet approximations. Another important reason is that one arc might represent a string while another one represents a beam, so that different numerical approximations apply. It would, therefore, be extremely useful to be able to restrict calculations to a single element (arc), perform those *in parallel*, and communicate mutual results after the iteration step is completed.

For homogenous planar two-dimensional problems such a procedure has been derived by Benamou [1], [2], [3], and [4]. The procedure was inspired by Lions [25], who discussed an iterative nonoverlapping Schwarz decomposition for a static (elliptic) problem. It is straightforward to apply that technique to dynamic, parabolic, or hyperbolic problems and it was then realized by Benamou that the resulting dynamic domain decomposition (d^3m) method could be applied to optimality systems. However, it was by no means clear how to obtain such decoupling in the case of networks as discussed above.

In this respect, an observation made by Glowinski and Le Tallec [11] turned out to be very useful. Namely, they showed that Lions's method was equivalent to an augmented Lagrangian approach combined with a standard saddle-point iteration. We used the latter approach to derive dynamic domain decomposition methods for both simulation purposes and, more important for this paper, for optimal control problems for planar networks of strings and Euler–Bernoulli beams (with constant coefficients) [19], [23]. While in the case of string networks we worked with the cost analogous to (2.1), and we used the entire state throughout $(0, T)$ for Euler–Bernoulli beams. Note that the full state cost is easier to handle. Full state cost is the one used throughout in [1], [2], [3]. We have also looked into another possibility based on so-called Dirichlet–Neumann iterations as in [8] and [35]; see [18].

4. Dynamic domain decomposition.

Instead of (1.7), (1.8) and (3.3), (3.4) we consider, at multiple nodes v_J, the following mixed Robin-type boundary conditions for r_i^{n+1}, p_i^{n+1}, where n is the iteration index:

$$\begin{aligned}
&\epsilon_{iJ}(C_{iJ}^{+})^T[K_i((r_i^{n+1})' + R_i r_i^{n+1})](v_J) + \beta C_{iJ} p_i^{n+1}(v_J) \\
&= \beta\left(\frac{2}{d_J}\sum_{j\in\mathcal{E}_J} C_{jJ} p_j^n(v_J) - C_{iJ} p_i^n(v_J)\right)
\end{aligned} \tag{4.1}$$

$$-\left(\frac{2}{d_J}\sum_{j\in\mathcal{E}_J}\epsilon_{jJ}(C_{jJ}^{+})^T[K_j({r_j^n}'+R_jr_j^n)](v_J)\right.$$
$$\left.-\epsilon_{iJ}(C_{iJ}^{+})^T[K_i({r_i^n}'+R_ir_i^n)](v_J)\right)=:\lambda_{iJ}^n,$$

$$\begin{aligned}&\epsilon_{iJ}(C_{iJ}^{+})^T[K_i((p_i^{n+1})'+R_ip_i^{n+1})](v_J)-\beta C_{iJ}r_i^{n+1}(v_J)\\ &=-\beta\left(\frac{2}{d_J}\sum_{j\in\mathcal{E}_J}C_{jJ}r_j^n(v_J)-C_{iJ}r_i^n(v_J)\right)\\ &\quad-\left(\frac{2}{d_J}\sum_{j\in\mathcal{E}_J}\epsilon_{jJ}(C_{jJ}^{+})^T[K_j({p_j^n}'+R_jp_j^n)](v_J)\right.\\ &\quad\left.-\epsilon_{iJ}(C_{iJ}^{+})^T[K_i({p_i^n}'+R_ip_i^n)](v_J)\right)=:\mu_{iJ}^n\end{aligned}\tag{4.2}$$

for all $v_J\in V_M,\ t\in(0,T)$. The parameter $\beta>0$, which can be interpreted as an additional stiffness at the vertex v_J, turns out to be useful in the numerical simulations. Tuning β allows us to vary essentially between Dirichlet conditions ($\beta\to\infty$) and Neumann conditions ($\beta\to 0$).

The other conditions (1.5), (1.6), (1.8) at nodes in $V_N\cup V_C$, (1.9), (1.10) and (3.1), (3.2), (3.4) at nodes in $V_N\cup V_C$ (3.5)–(3.7) are kept unchanged.

Let us assume for a moment that the sequence (r_i^n,p_i^n) starting at some given (r_i^0,p_i^0) converges. We would like to check whether (4.1), (4.2) lead to the transmission conditions (1.6), (1.7), (1.8) and (3.2), (3.3), (3.4). Indeed, (4.1), (4.2) with the index n dropped amount to

$$\begin{aligned}0&=2\beta\left(\frac{1}{d_J}\sum_{j\in\mathcal{E}_J}C_{jJ}p_j(v_J)-C_{iJ}p_i(v_J)\right)\\ &\quad-\frac{2}{d_J}\sum_{j\in\mathcal{E}_J}\epsilon_{jJ}(C_{jJ}^{+})^T[K_j({r_j}'+R_jr_j)](v_J),\end{aligned}\tag{4.3}$$

$$\begin{aligned}0&=-2\beta\left(\frac{1}{d_J}\sum_{j\in\mathcal{E}_J}C_{jJ}r_j(v_J)-C_{iJ}r_i(v_J)\right)\\ &\quad-\frac{2}{d_J}\sum_{j\in\mathcal{E}_J}\epsilon_{jJ}(C_{jJ}^{+})^T[K_j({p_j}'+R_jp_j)](v_J).\end{aligned}\tag{4.4}$$

Upon summing (4.3), (4.4) over all arcs incident at v_J, we obtain

$$\begin{aligned}\sum_{j\in\mathcal{E}_J}\epsilon_{iJ}(C_{jJ}^{+})^T[K_i({r_i}'+R_ir_i)](v_J)&=0,\\ \sum_{j\in\mathcal{E}_J}\epsilon_{iJ}(C_{iJ}^{+})^T[K_i({p_i}'+R_ip_i)](v_J)&=0,\end{aligned}\tag{4.5}$$

which is (1.8), (3.4) at $v_J \in V_M$. If we now use (4.5) in (4.3), (4.4) we arrive at

$$\begin{aligned} C_{iJ}p_i(v_J) &= \frac{1}{d_J}\sum_{j\in\mathcal{E}_J} C_{jJ}p_j(v_J), \\ C_{iJ}r_i(v_J) &= \frac{1}{d_J}\sum_{j\in\mathcal{E}_J} C_{jJ}r_j(v_J) \end{aligned} \tag{4.6}$$

at v_J and for all $i \in \mathcal{E}_J$. But that implies

$$C_{iJ}p_i(v_J),\ C_{iJ}r_i(v_J) \text{ are independent of } i \in \mathcal{E}_J. \tag{4.7}$$

We thus see that, once the sequence (r_i^n, p_i^n) converges, the limiting (r, p) satisfies all boundary and transmission conditions in addition to the local balance equations (1.5) and (3.1). That is, in the limit, the global optimality conditions are satisfied. Note that this argument is independent of the choice of β.

We also consider some variants of the domain decomposition below:

- Instead of (4.1), (4.2) we can take into account the knowledge of those new iterates that have already been computed. While (4.1), (4.2) can be regarded as a Jacobi-type iteration, the latter strategy would be more in the spirit of a Gauss–Seidel-type iteration. One expects, and actually numerically confirms, faster convergence. However, with the latter strategy one sacrifices the inherent parallelism to some extent.
- A second extension utilizes another standard technique, namely, relaxation. This means that we reuse the old information on the actual edge with an underrelaxation parameter $\lambda \in [0, 1)$ as follows:

$$\begin{aligned} &\epsilon_{iJ}(C_{iJ}^{+})^T[K_i((r_i^{n+1})' + R_i r_i^{n+1})](v_J) + \beta C_{iJ}p_i^{n+1}(v_J) \\ &= (1-\lambda)\Bigg(\beta\Bigg(\frac{2}{d_J}\sum_{j\in\mathcal{E}_J} C_{jJ}p_j^n(v_J) - C_{iJ}p_i^n(v_J)\Bigg) \\ &\quad -\Bigg(\frac{2}{d_J}\sum_{j\in\mathcal{E}_J}\epsilon_{jJ}(C_{jJ}^{+})^T[K_j(r_j^{n\prime} + R_j r_j^n)](v_J) \\ &\qquad - \epsilon_{iJ}(C_{iJ}^{+})^T[K_i(r_i^{n\prime} + R_i r_i^n)](v_J)\Bigg)\Bigg) \\ &\quad + \lambda\Bigg(\epsilon_{iJ}(C_{iJ}^{+})^T[K_i((r_i^n)' + R_i r_i^n)](v_J) + C_{iJ}p_i^n(v_J)\Bigg), \end{aligned} \tag{4.8}$$

$$\begin{aligned} &\epsilon_{iJ}(C_{iJ}^{+})^T[K_i((p_i^{n+1})' + R_i p_i^{n+1})](v_J) - \beta C_{iJ}r_i^{n+1}(v_J) \\ &= (1-\lambda)\Bigg(-\beta\Bigg(\frac{2}{d_J}\sum_{j\in\mathcal{E}_J} C_{jJ}r_j^n(v_J) - C_{iJ}r_i^n(v_J)\Bigg) \\ &\quad -\Bigg(\frac{2}{d_J}\sum_{j\in\mathcal{E}_J}\epsilon_{jJ}(C_{jJ}^{+})^T[K_j(p_j^{n\prime} + R_j p_j^n)](v_J) \\ &\qquad - \epsilon_{iJ}(C_{iJ}^{+})^T[K_i(p_i^{n\prime} + R_i p_i^n)](v_J)\Bigg)\Bigg) \\ &\quad + \lambda\Bigg(\epsilon_{iJ}(C_{iJ}^{+})^T[K_i((p_i^n)' + R_i p_i^n)](v_J) - C_{iJ}r_i^n(v_J)\Bigg) \end{aligned} \tag{4.9}$$

for all $v_J \in V_M,\ t \in (0,T)$.

- A third variant, which is the extension to networks of an algorithm described by Deng [6] for planar elliptic problems, can be written as follows:

$$\begin{aligned} &\epsilon_{iJ}(C_{iJ}^{+})^T[K_i((r_i^{n+1})' + R_i r_i^{n+1})](v_J) + \beta C_{iJ} p_i^{n+1}(v_J) =: g_{iJ}^{n+1} \\ &= 2\beta\left(\frac{2}{d_J}\sum_{j\in\mathcal{E}_J} C_{jJ} p_j^n(v_J) - C_{iJ} p_i^n(v_J)\right) \\ &\qquad -\left(\frac{2}{d_J}\sum_{j\in\mathcal{E}_J} g_{jJ}^n - g_{iJ}^n\right), \end{aligned} \tag{4.10}$$

$$\begin{aligned} &\epsilon_{iJ}(C_{iJ}^{+})^T[K_i((p_i^{n+1})' + R_i p_i^{n+1})](v_J) - \beta C_{iJ} r_i^{n+1}(v_J) =: h_{iJ}^{n+1} \\ &= -2\beta\left(\frac{2}{d_J}\sum_{j\in\mathcal{E}_J} C_{jJ} r_j^n(v_J) - C_{iJ} r_i^n(v_J)\right) \\ &\qquad -\left(\frac{2}{d_J}\sum_{j\in\mathcal{E}_J} h_{jJ}^n - h_{iJ}^n\right) \end{aligned} \tag{4.11}$$

for all $v_J \in V_M,\ t \in (0,T)$. Reducing the iteration index in the defining equations (4.10), (4.11) to n and summing over all incident edges, it is easy to see that this variant is equivalent to the original conditions (4.1), (4.2). One can then also introduce a relaxation parameter into this variant. We conclude this discussion of alternative constructions with the remark that the last approach, even though equivalent to the first, is easier to implement, as no derivatives have to be computed for the update.

Let us, for the sake of easier reference, collect the conditions for the decoupled system (r_i^{n+1}, p_i^{n+1})

$$\begin{cases} M_i \ddot{r}_i^{n+1} = [K_i((r_i^{n+1})' + R_i r_i^{n+1})]' & - R_i^T K_i(r_i^{n+1\prime} + R_i r_i^{n+1}) - S_i r_i^{n+1}, \\ M_i \ddot{p}_i^{n+1} = [K_i((p_i^{n+1})' + R_i p_i^{n+1})]' & - R_i^T K_i(p_i^{n+1\prime} + R_i p_i^{n+1}) - S_i p_i^{n+1}, \\ & \qquad (x,t) \in (0,\ell_i) \times (0,T), \end{cases} \tag{4.12}$$

$$r_i(v_D) = 0,\ p_i(v_D) = 0,\ \epsilon_{iD} \neq 0,\ v_D \in V_D,\ t \in (0,T), \tag{4.13}$$

$$\begin{cases} \epsilon_{iC}[K_i((r_i^{n+1})' + R_i r_i^{n+1})](v_C) &= -p_i^{n+1}(v_C), \\ \epsilon_{iC}[K_i((p_i^{n+1})' + R_i p_i^{n+1})](v_C) &= 0,\ v_C \in V_C,\ t \in (0,T), \end{cases} \tag{4.14}$$

$$\begin{cases} \epsilon_{iN}[K_i((r_i^{n+1})' + R_i r_i^{n+1})](v_N) &= 0, \\ \epsilon_{iN}[K_i((p_i^{n+1})' + R_i p_i^{n+1})](v_N) &= 0,\ v_N \in V_N,\ t \in (0,T), \end{cases} \tag{4.15}$$

$$\begin{cases} \epsilon_{iJ}\Pi_{iJ}[K_i((r_i^{n+1})' + R_i r_i^{n+1})](v_J) &= 0, \\ \epsilon_{iJ}\Pi_{iJ}[K_i((p_i^{n+1})' + R_i p_i^{n+1})](v_J) &= 0,\ v_J \in V_M,\ t \in (0,T), \end{cases} \tag{4.16}$$

$$r_i^{n+1}, p_i^{n+1} \text{ satisfies (4.1), (4.2) (or (4.8), (4.9)) at } v_J \in V_M,\ t \in (0,T), \tag{4.17}$$

$$\begin{cases} r^{n+1}(\cdot,0) &= r_0,\ \dot{r}^{n+1}(\cdot,0) = r_1, \\ p^{n+1}(\cdot,T) &= k(\dot{r}^{n+1}(\cdot,T) - z_1), \\ \dot{p}^{n+1}(\cdot,T) &= -kA(r^{n+1}(\cdot,T) - z_0),\ x \in (0,l_i). \end{cases} \tag{4.18}$$

In order to discuss problems (4.12)–(4.18) for each individual $i = 1 : n_e$, we have to distinguish four cases:

(i) $\epsilon_{iC}, \epsilon_{iJ} \neq 0$ for $v_C \in V_C$, $v_J \in V_M$,

(ii) $\epsilon_{iJ}, \epsilon_{iM} \neq 0$ for $v_J, v_M \in V_M$,

(iii) $\epsilon_{iD}, \epsilon_{iD} \neq 0$ for $v_D \in V_D$, $v_J \in V_M$,

(iv) $\epsilon_{iN}, \epsilon_{iJ} \neq 0$ for $v_N \in V_N$, $v_J \in V_M$.

The single edge network $\epsilon_{iD}, \epsilon_{iB} \neq 0$ $v_D, v_B \in V_S$ is trivial. The most complicated case is (i), which we will consider below. The other cases then follow similarly. Now, as (4.1), (4.2) are known boundary inputs λ_{iJ}^n and μ_{iJ}^n, respectively, one can look at the system (4.12)–(4.18) as an optimality system corresponding to an optimal control problem on the individual arc i as follows:

$$
\begin{aligned}
&\min_{f_J, f_C} \frac{k}{2} \left\{ \|r_i^{n+1}(T) - z_i^0\|_{H^1(0,\ell_i)^{p_i}}^2 + \|\dot r_i^{n+1}(T) - z_i^1\|_{L^2(0,\ell_i)^{p_i}}^2 \right\} \\
&\qquad + \frac{1}{2} \int_0^T \left\{ \frac{1}{\beta} |f_J|^2 + |f_C|^2 \right\} dt \\
&\qquad + \frac{\beta}{2} \int_0^T \left| C_{iJ} r_i^{n+1}(v_J) + \frac{1}{\beta} \mu_{iJ}^n \right|^2 dt,
\end{aligned} \tag{4.19}
$$

$$
\begin{aligned}
&M_i \ddot r_i^{n+1} = [K_i((r_i^{n+1})' + R_i r_i^{n+1})]' - R_i^T K_i((r_i^{n+1})' + R_i r_i^{n+1}) - S_i r_i^{n+1}, \\
&\qquad\qquad\qquad\qquad (x,t) \in (0,l_i) \times (0,T), \\
&\epsilon_{iC}[K_i((r_i^{n+1})' + R_i r_i^{n+1})](v_C) = f_C,\ t \in (0,T), \\
&\epsilon_{iJ}(C_{iJ}^+)^T [K_i((r_i^{n+1})' + R_i r_i^{n+1})](v_J) = f_J + \lambda_{iJ}^n,\ t \in (0,T), \\
&\epsilon_{iJ} \Pi_{iJ} [K_i((r_i^{n+1})' + R_i r_i^{n+1})](v_J) = 0,\ t \in (0,T), \\
&r_i^{n+1}(0) = r_{i0},\ \dot r_i^{n+1}(0) = r_{i1},\ x \in (0,\ell_i).
\end{aligned} \tag{4.20}
$$

The proof that (4.19), (4.20) is actually the corresponding optimal control problem is done by standard variational arguments. Now, regularity theory in [14, Chapter IV] yields Theorem 4.1.

THEOREM 4.1. *Let* $(r_{i0}, r_{i1}) \in H^1(0,l_i) \times L^2(0,l_i)$, $\lambda_{iJ}^n, \mu_{iJ}^n \in L^2(0,T,\mathbb{R}^{q_J})$. *Then problem* (4.19), (4.20) *has unique minimizers* $f_C \in L^2(0,T,\mathbb{R}^{p_i})$, $f_J \in L^2(0,T,\mathbb{R}^{q_J})$. *The necessary optimality conditions are given by* (4.12)–(4.18).

Note that a similar result holds for the relaxed algorithm, where the λ_{iJ}^n, μ_{iJ}^n now depend on the relaxation parameter λ as in (4.8), (4.9).

Remark 4.1. The same arguments as in Remark 3.1 apply to the local optimality system. Hence, working with the local regularity $H^2(0,\ell_i) \times H^1(0,\ell_i)$ for initial and target data, and assuming in addition $\lambda_{iJ}^n, \in H^1(0,T,\mathbb{R}^{q_J})$, then the adjoint system has local finite-energy regularity.

5. Convergence of the algorithm.

Let us denote the unique solution of (4.12)–(4.18) by $(\hat r_i, \hat p_i)$ and by (r_i, p_i) the local restrictions of the solution (r,p) of the global optimality system (1.5)–(1.10) (with $F_i, M_J = 0$), (3.1)–(3.7). We then introduce the errors $\tilde r_i^n := r_i - \hat r_i^n$, $\tilde p_i^n := p_i - \hat p_i^n$. Now, observe that p_i, r_i also satisfy (4.1), (4.2), and, of course also the other conditions (4.12)–(4.16), (4.18) for the decoupled system.

This shows that $\tilde r_i^{n+1}, \tilde p_i^{n+1}$ satisfy (4.12)–(4.18), where (4.18) is changed to

$$\begin{cases} \tilde r_i^{n+1}(0) &= 0,\ \dot{\tilde r}_i^{n+1}(0) = 0, \\ \tilde p_i^{n+1}(T) &= k\dot{\tilde r}_i^{n+1}(T), \\ \dot{\tilde p}_i^{n+1}(T) &= -kA_i \tilde r_i^{n+1}(T), \end{cases} \tag{5.1}$$

and A_i, defined by $(Ar)_i =: A_i r_i$, is the restriction of A to the edge with index i. The same is true for all other cases (ii)–(iv). We proceed to show that the errors $\tilde r_i^n$, $\tilde p_i^n$ converge to zero in a natural energy sense.

The main work involves the condition (4.1), (4.2). For the sake of simplicity, we take $\beta = 1$, the arguments being valid for general $\beta > 0$. We multiply (4.1), (4.2) by $C_{iJ}\tilde p_i^{n+1}(v_J)$, $C_{iJ}\tilde r_i^{n+1}(v_J)$, respectively, and then sum over all incident arcs.

$$\begin{aligned} &\sum_{i\in\mathcal{E}_J} \epsilon_{iJ} (C_{iJ}^+)^T [K_i((\tilde r_i^{n+1})' + R_i \tilde r_i^{n+1})](v_J) \cdot C_{iJ}\tilde p_i^{n+1}(v_J) + \sum_{i\in\mathcal{E}_J} |C_{iJ}\tilde p^{n+1}(v_J)|^2 \\ &= \frac{2}{d_J} \sum_{j\in\mathcal{E}_J} C_{jJ}\tilde p_j^n(v_J) \sum_{i\in\mathcal{E}_J} C_{iJ}\tilde p_i^{n+1}(v_J) - \sum_{i\in\mathcal{E}_J} C_{iJ}\tilde p_i^n(v_J) C_{iJ}\tilde p_i^{n+1}(v_J) \\ &\quad -\Bigg(\frac{2}{d_J} \sum_{j\in\mathcal{E}_J} \epsilon_{jJ} (C_{jJ}^+)^T [K_j(\tilde r_j^{n\prime} + R_j \tilde r_j^n)](v_J) \sum_{i\in\mathcal{E}_J} C_{iJ}\tilde p_i^{n+1}(v_J) \\ &\qquad - \sum_{i\in\mathcal{E}_J} \epsilon_{iJ} (C_{iJ}^+)^T [K_i(\tilde r_i^{n\prime} + R_i \tilde r_i^n)](v_J) \cdot C_{iJ}\tilde p_i^{n+1}(v_J) \Bigg), \end{aligned} \tag{5.2}$$

$$\begin{aligned} &\sum_{i\in\mathcal{E}_J} \epsilon_{iJ} (C_{iJ}^+)^T [K_i((\tilde p_i^{n+1})' + R_i \tilde p_i^{n+1})](v_J) C_{iJ}\tilde r_i^{n+1}(v_J) - \sum_{i\in\mathcal{E}_J} |C_{iJ}\tilde r_i^{n+1}(v_J)|^2 \\ &= -\Bigg(\frac{2}{d_J} \sum_{j\in\mathcal{E}_J} C_{jJ}\tilde r_j^n(v_J) \sum_{i\in\mathcal{E}_J} C_{iJ}\tilde r_i^{n+1}(v_J) - \sum_{i\in\mathcal{E}_J} C_{iJ}\tilde r_i^n(v_J) C_{iJ}\tilde r_i^{n+1}(v_J) \Bigg) \\ &\quad -\Bigg(\frac{2}{d_J} \sum_{j\in\mathcal{E}_J} \epsilon_{jJ} (C_{jJ}^+)^T [K_j(\tilde p_j^{n\prime} + R_j \tilde p_j^n)](v_J) \sum_{i\in\mathcal{E}_J} C_{iJ}\tilde r_i^{n+1}(v_J) \\ &\qquad - \sum_{i\in\mathcal{E}_J} \epsilon_{iJ} C_{iJ}^+ [K_i(\tilde p_i^{n\prime} + R_i \tilde p_i^n)](v_J) C_{iJ}\tilde r_i^{n+1}(v_J) \Bigg). \end{aligned} \tag{5.3}$$

On the other hand, taking squares in (4.1), (4.2) we obtain

$$\begin{aligned} &|(C_{iJ}^+)^T [K_i((\tilde r_i^{n+1})' + R_i \tilde r_i^{n+1})](v_J)|^2 = |C_{iJ}\tilde p_i^{n+1}(v_J)|^2 \\ &+ |(C_{iJ}^+)^T [K_i(\tilde r_i^{n\prime} + R_i \tilde r_i^n)](v_J)|^2 \\ &- 2C_{iJ}\tilde p_i^{n+1}(v_J) \Bigg(\frac{2}{d_J} \sum_{j\in\mathcal{E}_J} C_{jJ}\tilde p_j^n(v_J) - C_{iJ}\tilde p_i^n(v_J) \Bigg) \\ &-\Bigg(\frac{2}{d_J} \sum_{j\in\mathcal{E}_J} \epsilon_{jJ} (C_{jJ}^+)^T [K_j(\tilde r_j^{n\prime} + R_j \tilde r_j^n)](v_J) \\ &\qquad - \epsilon_{iJ} (C_{iJ}^+)^T [K_i(\tilde r_i^{n\prime} + R_i \tilde r_i^n)](v_J) \Bigg) \end{aligned} \tag{5.4}$$

$$
\begin{aligned}
&+\frac{4}{d_J^2}\left|\sum_{j\in\mathcal{E}_J} C_{jJ}\tilde{p}_j^n(v_J)\right|^2 + \left|C_{iJ}\tilde{p}_i^n(v_J)\right|^2\\
&-\frac{4}{d_J}\sum_{j\in\mathcal{E}_J} C_{jJ}\tilde{p}_j^n(v_J)C_{iJ}\tilde{p}_i^n(v_J)\\
&+\frac{4}{d_J^2}|\sum_{j\in\mathcal{E}_J}\epsilon_{jJ}(C_{jJ}^+)^T[K_j(\tilde{r}_j^{n\prime}+R_j\tilde{r}_j^n)](v_J)\big|^2\\
&-\frac{4}{d_J^2}\sum_{j\in\mathcal{E}_J}\epsilon_{jJ}(C_{jJ}^+)^T[K_j(\tilde{r}_j^{n\prime}+R_j\tilde{r}_j)](v_J)\\
&\qquad\qquad -\epsilon_{iJ}(C_{iJ}^+)^T[K_i(\tilde{r}_i^{n\prime}+R_i\tilde{r}_i^n)](v_J)\\
&-2\left(\frac{2}{d_J}\sum_{j\in\mathcal{E}_J} C_{jJ}\tilde{p}_j^n(v_J)-\tilde{p}_i^n(v_J)\right)\\
&\qquad\qquad -\left(\frac{2}{d_J}\sum_{j\in\mathcal{E}_J}\epsilon_{jJ}(C_{jJ}^+)^T[K_j(\tilde{r}_j^{n\prime}+R_j\tilde{r}_j^n)](v_J)\right.\\
&\qquad\qquad\qquad \left.-\epsilon_{iJ}(C_{iJ}^+)^T[K_i(\tilde{r}_i^{n\prime}+R_i\tilde{r}_i^n)](v_J)\right).
\end{aligned}
$$

A similar expression holds for the $\tilde{p}_i^n$-variable. We sum (5.4) over incident edges and obtain

$$
\begin{aligned}
&\sum_{i\in\mathcal{E}_J}|(C_{iJ}^+)^T[K_i((\tilde{r}_i^{n+1})'+R_i\tilde{r}_i^{n+1})](v_J)|^2\\
&\quad=\sum_{i\in\mathcal{E}_J}|C_{iJ}\tilde{p}_i^{n+1}(v_J)|^2+\sum_{i\in\mathcal{E}_J}|C_{iJ}\tilde{p}_i^n(v_J)|^2\\
&\qquad+\sum_{i\in\mathcal{E}_J}|(C_{iJ}^+)^T[K_i(\tilde{r}_i^{n\prime}+R_i\tilde{r}_i^n(v_J))]|^2\\
&\quad+2\Bigg[-\sum_{i\in\mathcal{E}_J}C_{iJ}\tilde{p}_i^{n+1}(v_J)\frac{2}{d_J}\sum_{j\in\mathcal{E}_J}C_{jJ}\tilde{p}_j^n(v_J)\\
&\qquad+\sum_{i\in\mathcal{E}_J}C_{iJ}\tilde{p}_i^{n+1}(v_J)C_{iJ}\tilde{p}_i^n(v_J)\\
&\qquad+\frac{2}{d_J}\sum_{i\in\mathcal{E}_J}C_{iJ}\tilde{p}_i^{n+1}(v_J)\sum_{j\in\mathcal{E}_J}\epsilon_{jJ}(C_{jJ}^+)^T[K_j(\tilde{r}_j^{n\prime}+R_j\tilde{r}_j^n)](v_J)\\
&\qquad+\sum_{i\in\mathcal{E}_J}\epsilon_{iJ}(C_{iJ}^+)^T[K_i(\tilde{r}_i^{n\prime}+R_i\tilde{r}_i^n)](v_J)C_{iJ}\tilde{p}_i^{n+1}(v_J)\Bigg]\\
&\quad-2\sum_{i\in\mathcal{E}_J}\left(\frac{2}{d_J}\sum_{j\in\mathcal{E}_J}C_{jJ}\tilde{p}_j^n(v_J)-C_{iJ}\tilde{p}_i^n(v_J)\right)\\
&\quad-\left(\frac{2}{d_J}\sum_{j\in\mathcal{E}_J}\epsilon_{jJ}(C_{jJ}^+)^T[K_j(\tilde{r}_j^{n\prime}+R_i\tilde{r}_j^n)](v_J)-\epsilon_{iJ}(C_{iJ}^+)^T[K_i(\tilde{r}_i^{n\prime}+R_i\tilde{r}_i^n)](v_J)\right).
\end{aligned}
\tag{5.5}
$$

Again, a similar expression can be derived for the adjoint variable. Factoring the last term in (5.5), we see that it reduces to

$$-2\sum_{i\in\mathcal{E}_J}\left\{\epsilon_{iJ}(C_{jJ}^{+})^T[K_i(\tilde{r}_i^{n\prime}+R_i\tilde{r}_i^n)](v_J)C_{iJ}\tilde{p}_i^n(v_J)\right\}\,.$$

Furthermore, the bracketed term in (5.5) is minus the right-hand side of (5.2). Therefore, we arrive at

$$\begin{aligned}
&\sum_{i\in\mathcal{E}_J}|(C_{iJ}^{+})^T[K_i((\tilde{r}_i^{n+1})'+R_i\tilde{r}_i^{n+1})](v_J)|^2+\sum_{i\in\mathcal{E}_J}|C_{iJ}\tilde{p}_i^{n+1}(v_J)|^2\\
&=-2\sum_{i\in\mathcal{E}_J}\epsilon_{iJ}(C_{iJ}^{+})^T[K_i((\tilde{r}_i^{n+1})'+R_i\tilde{r}_i^{n+1})](v_J)C_{iJ}\tilde{p}_i^{n+1}(v_J)\\
&-2\sum_{i\in\mathcal{E}_J}\epsilon_{iJ}(C_{iJ}^{+})^T[K_i(\tilde{r}_i^{n\prime}+R_i\tilde{r}_i^n)](v_J)C_{iJ}\tilde{p}_i^n(v_J)\\
&+\sum_{i\in\mathcal{E}_J}\left|(C_{iJ}^{+})^T[K_i(\tilde{r}_i^{n\prime}+R_i\tilde{r}_i^n)](v_J)\right|^2+\sum_{i\in\mathcal{E}_J}\left|C_{iJ}\tilde{p}_i^n(v_J)\right|^2.
\end{aligned}\tag{5.6}$$

An analogous relation holds for the adjoint variable, but with the opposite signs at the mixed terms. We sum up (5.6) and its counterpart and integrate with respect to time. We obtain for $v_J\in V_M$,

$$\begin{aligned}
\tilde{E}_J^{n+1}:=\int_0^T\sum_{i\in\mathcal{E}_J}\Big\{&|(C_{iJ}^{+})^T[K_i((\tilde{r}_i^{n+1})'+R_i\tilde{r}_i^{n+1})](v_J)|^2\\
&+|(C_{iJ}^{+})^T[K_i((\tilde{p}_i^{n+1})'+R_i\tilde{p}_i^{n+1})](v_J)|^2\\
&+|C_{iJ}\tilde{r}_i^{n+1}(v_J)|^2+|C_{iJ}\tilde{p}_i^{n+1}(v_J)|^2\Big\}\,dt=\tilde{E}_J^n\\
+2\int_0^T\sum_{i\in\mathcal{E}_J}\big[&\epsilon_{iJ}(C_{iJ}^{+})^T[K_i((\tilde{p}_i^{n+1})'+R_i\tilde{p}_i^{n+1})](v_J)C_{iJ}\tilde{r}_i^{n+1}(v_J)\\
&-\epsilon_{iJ}(C_{iJ}^{+})^T[K_i((\tilde{r}_i^{n+1})'+R_i\tilde{r}_i^{n+1})](v_J)C_{iJ}\tilde{p}_i^{n+1}(v_J)\big]\,dt\\
+\,2\int_0^T\sum_{i\in\mathcal{E}_J}\big[&\epsilon_{iJ}(C_{iJ}^{+})^T[K_i(\tilde{p}_i^{n\prime}+R_i\tilde{p}_i^{n+1})](v_J)C_{iJ}\tilde{r}_i^n(v_J)\\
&-\epsilon_{iJ}(C_{iJ}^{+})^T[K_i(\tilde{r}_i^{n\prime}+R_i\tilde{r}_i^n)](v_J)C_{iJ}\tilde{p}_i^n(v_J)\big]\,dt.
\end{aligned}\tag{5.7}$$

We first note that $C_{iJ}^{+}\,(C_{iJ}^{+})^T$ is symmetric and positive definite, and so is K_i. Hence, $\tilde{E}_J^n$ is equivalent to the "energy trace" at v_J

$$\begin{aligned}
E_J^n:=\int_0^T\sum_{i\in\mathcal{E}_J}\Big\{&K_i(\tilde{r}_i^{n\prime}+R_i\tilde{r}_i)(v_J)\cdot(\tilde{r}_i^{n\prime}+R_i\tilde{r}_i^n)(v_J)\\
&+K_i(\tilde{p}_i^{n\prime}+R_i\tilde{p}_i^n)(v_J)\cdot(\tilde{p}_i^{n\prime}+R_i\tilde{p}_i^n)(v_J)\\
&+|C_{iJ}\tilde{r}_i^n(v_J)|^2+|C_{iJ}\tilde{p}_i^n(v_J)|^2\Big\}\,dt.
\end{aligned}\tag{5.8}$$

Let us now recall that the total energy associated with (1.1), (1.2) is

$$\begin{aligned}\mathcal{E}(r,t) &:= \frac{1}{2}\sum_{i=1}^{n_e}\int_0^{l_i}\left[M_i\dot r_i\cdot\dot r_i + K_i(r_i'+R_ir_i)\cdot(r_i'+R_ir_i)+S_ir_i\cdot r_i\right]dx \\ &=: \sum_{i=1}^{n_e}\mathcal{E}_i(r_i,t)\ .\end{aligned}\tag{5.9}$$

Now, according to [14, Lemma 3.2, Chapter IV], there is a constant C such that

$$\begin{aligned}&\int_0^T\left[M_i\dot r_i\cdot\dot r_i + K_i(r_i'+R_ir_i)\cdot(r_i'+R_ir_i)+S_ir_i\cdot r_i\right](v_J)\,dt \\ &\leq C\left\{\int_0^t \mathcal{E}(r_i,s)ds + \mathcal{E}_i(r_i,0)+\mathcal{E}_i(r_i,t)\right\}\end{aligned}\tag{5.10}$$

for sufficiently regular solutions of (1.5). Moreover, for solutions r_i of (1.5) satisfying (1.9) and with the understanding that $C_{iJ}=I$ for $v_J\in V_S$ ($\epsilon_{iJ}\neq 0$),

$$\begin{aligned}\frac{d}{dt}\mathcal{E}(r,t) &= \sum_J\sum_{i\in\mathcal{E}_J}\epsilon_{iJ}(C_{iJ}^+)^T[K_i(r_i'+R_ir_i)](v_J)C_{iJ}\dot r_i(v_J) \\ &\leq \sum_J\sum_{i\in\mathcal{E}_J}\left\{\frac{1}{4\epsilon}|(C_{iJ}^+)^T[K_i(r_i'+R_ir_i)](v_J)|^2+\epsilon|C_{iJ}\dot r_i(v_J)|^2\right\}.\end{aligned}\tag{5.11}$$

Upon integration, (5.11) leads to

$$\begin{aligned}\mathcal{E}(r,t)\leq \mathcal{E}(r,0)+\int_0^t\sum_J\sum_{i\in\mathcal{E}_J}\Bigg\{&\frac{1}{4\epsilon}|(C_{iJ}^+)^T[K_i(r_i'+R_ir_i)](v_J)|^2 \\ &+\epsilon|C_{iJ}\dot r_i(v_J)|^2\Bigg\}\,ds,\end{aligned}$$

which by (5.10) yields

$$\begin{aligned}\mathcal{E}(r,t)\leq \mathcal{E}(r,0)+\frac{1}{4\epsilon}\int_0^t\sum_J\sum_{i\in\mathcal{E}_J}&|(C_{iJ}^+)^T[K_i(r_i'+R_ir_i)](v_J)|^2\,dt \\ &+\epsilon C\left\{\int_0^t\mathcal{E}(r,s)\,ds+\mathcal{E}(r,0)+\mathcal{E}(r,t)\right\}\ .\end{aligned}\tag{5.12}$$

Now, absorbing $\epsilon C\,\mathcal{E}(r,t)$ into the left side of (5.12) and using Gronwall's inequality we obtain

$$\mathcal{E}(r,t)\leq C\left\{\mathcal{E}(r,0)+\int_0^t\sum_J\sum_{i\in\mathcal{E}_J}|(C_{iJ}^+)^T[K_i(r_i'+R_ir_i)](v_J)|^2\,dt\right\}\tag{5.13}$$

with a generic constant $C>0$. We may apply the energy estimate to our local solutions $\tilde r_i^n,\tilde p_i^n$, as no coupling conditions have been used to derive (5.13). Even though, by Remark 4.1, we can achieve energy-space regularity for the local adjoint system, if we assume $H^1(0,T)$-regularity of λ_{iJ}, we want to derive energy estimates in the shifted energy space, as we want to deal with $\lambda's$ being in L^2. The application of estimate (5.13) to $\tilde{p}_i^n$ is done as follows. Assuming, as always, L^2-regularity of the data μ_{iJ}^n (see (5.21) below for the justification), and using the fact that $\tilde{r}_i^n(v_J)$ is also L^2-in-time, we have a Neumann-type problem for $\tilde{p}_i^n$with L^2-boundary inputs and final data in the shifted energy space. By transposition, we obtain the estimate (5.13) with $\mathcal{E}(r,t)$ and $\mathcal{E}(r,0)$ replaced by $\mathcal{E}^*(p,t)$ and $\mathcal{E}^*(p,T)$, respectively. However, because $\|v\|_{\mathbf{V}^*} = \|A^{-1}v\|_{\mathbf{V}}$ we have that $\mathcal{E}^*(\tilde{p}^n,T) := \|\tilde{p}^n(T)\|_{\mathbf{H}} + \|\dot{\tilde{p}}^n(T)\|_{\mathbf{V}^*}$ and $k^2\mathcal{E}(\tilde{r}^n,T)$ are equivalent. Since $\mathcal{E}(\tilde{r}^n,0)=0$, we therefore obtain

$$\begin{aligned}\mathcal{E}^*(\tilde{p}^n,t) \le C\int_0^T \sum_J \sum_{i\in\mathcal{E}_J} \Bigg\{ &|(C_{iJ}^+)^T[K_i(\tilde{p}_i^{n\prime}+R_i\tilde{p}_i^n)](v_J)|^2 \\ &+|(C_{iJ}^+)^T[K_i(\tilde{r}_i^{n\prime}+R_i\tilde{r}_i^n)](v_J)|^2 \Bigg\}\, dt\ ,\end{aligned} \tag{5.14}$$

whenever the right-hand side is defined. Note that the summation is taken over all joint indices J such that $v_J \in V_M \cup V_N \cup V_C$. Therefore, (5.14) can be rewritten as

$$\begin{aligned}\mathcal{E}^*(\tilde{p}^n,t) \le C\int_0^T \sum_{v_J\in V_M} \sum_{i\in\mathcal{E}_J} \Bigg\{ &|(C_{iJ}^+)^T[K_i(\tilde{p}_i^{n\prime}+R_i\tilde{p}_i^n)](v_J)|^2 \\ &+ |(C_{iJ}^+)^T[K_i(\tilde{r}_i^{n\prime}+R_i\tilde{r}_i^n)](v_J)|^2 \Bigg\}\, dt \\ + C\int_0^T \sum_{v_C\in V_C} &|(\tilde{p}_{i_C}^n(v_C))|^2\, dt \qquad (\mathcal{E}_C=\{i_C\}).\end{aligned} \tag{5.15}$$

By applying the same argument to $(\tilde{r}_i^n)$ and denoting $\tilde{E}^n = \sum_J \tilde{E}_J^n$, $J : v_J \in V_M$, we obtain

$$\mathcal{E}(\tilde{r}^n,t) + \mathcal{E}^*(\tilde{p}^n,t) \le C\left(\tilde{E}^n + \int_0^T \sum_{v_C\in V_C} |\tilde{p}_{i_C}^n(v_C)|^2\, dt\right). \tag{5.16}$$

Again, this estimate holds as long as the right-hand side is finite. This will turn out to be true in the following.

We go back to (5.7) and evaluate the mixed terms on the right-hand side:

$$\begin{aligned}0 &= \int_0^T\int_0^{l_i} [M_i\ddot{\tilde{p}}_i^n - (K_i((\tilde{p}_i^n)' + R_i\tilde{p}^n))' + R_i^T(K_i(\tilde{p}_i^{n\prime}+R_i\tilde{p}_i^n)) \\ &\qquad\qquad + S_i\tilde{p}_i^n]\tilde{r}_i^n\, dx\, dt \\ &= \int_0^{l_i} (M_i\dot{\tilde{p}}_i^n\tilde{r}_i^n - M_i\tilde{p}_i^n\dot{\tilde{r}}_i^n)|_0^T\, dx \\ &\quad + \int_0^T\int_0^{l_i} \tilde{p}_i^n M_i\ddot{\tilde{r}}_i^n\, dx\, dt - \sum_J \int_0^T \epsilon_{iJ}K_i(\tilde{p}_i^{n\prime}+R_i\tilde{p}_i^n)(v_J)\tilde{r}_i^n(v_J)\, dt \\ &\quad + \int_0^T\int_0^{l_i} (\tilde{p}_i^{n\prime}+R_i\tilde{p}_i^n)K_i\tilde{r}_i^{n\prime}\, dx\, dt\end{aligned}$$

$$\begin{aligned}
&+\sum_J \epsilon_{iJ}\int_0^T \tilde p_i^n(v_J)(K_iR_i\tilde r_i^n)(v_J)\,dt - \int_0^T\int_0^{l_i}\tilde p_i^n(K_iR_i\tilde r^n)'\,dx\,dt\\
&+\int_0^T\int_0^{l_i}\tilde p_i^n(R_i^TK_iR_i\tilde r_i^n + S_i\tilde r_i^n)\,dx\,dt\\
=&\int_0^T\sum_J\epsilon_{iJ}[K_i(\tilde r_i^{n\prime}+R_i\tilde r_i^n)](v_J)\tilde p_i^n(v_J)\,dt\\
&-\int_0^T\sum_J\epsilon_{iJ}[K_i(\tilde p_i^{n\prime}+R_i\tilde p_i^n)](v_J)\tilde r_i^n(v_J)\,dt\\
&-k\|\tilde r_i^n(T)\|^2_{\mathbf{V}_i} - k\|\dot{\tilde r}_i^n(T)\|^2_{\mathbf{H_i}}\ ,
\end{aligned}\tag{5.17}$$

where $\mathbf{V}_i := H^1(0,\ell_i)^{p_i}$ and $\mathbf{H}_i := L^2(0,\ell_i)^{p_i}$. As $(Ar)_i =: A_ir_i$, A_i is the Riesz isomorphism between V_i and V_i^* with respect to the norm

$$\|r_i\|^2_{\mathbf{V_i}} = \int_0^{l_i}[K_i(r_i'+R_ir_i)(r_i'+R_ir_i)+(S_i+I)r_ir_i]\,dx.$$

Now

$$\begin{aligned}
\tilde p_i^n(v_J) &= \Pi_{iJ}^{\perp}\tilde p_i^n(v_J) + \Pi_{iJ}\tilde p_i^n(v_J)\\
&= C_{iJ}^{+}C_{iJ}\tilde p_i^n(v_J) + \Pi_{iJ}\tilde p_i^n(v_J),
\end{aligned}$$

and hence, by (1.9)

$$\begin{aligned}
&\epsilon_{iJ}[K_i(\tilde r_i^{n\prime}+R_i\tilde r_i^n)](v_J)\tilde p_i^n(v_J)\\
&=\epsilon_{iJ}(C_{iJ}^{+})^T[K_i(\tilde r_i^{n\prime}+R_i\tilde r_i^n)](v_J)C_{iJ}\tilde p_i^n(v_J)\\
&\qquad+\epsilon_{iJ}\Pi_{iJ}[K_i(\tilde r_i^{n\prime}+R_i\tilde r_i^n)](v_J)\tilde p_i^n(v_J)\\
&=\epsilon_{iJ}(C_{iJ}^{+})^T[K_i(\tilde r_i^{n\prime}+R_i\tilde r_i^n)](v_J)C_{iJ}\tilde p_i^n(v_J).
\end{aligned}\tag{5.18}$$

The same holds for the other terms in (5.17). We thus have by (5.17), (5.18)

$$\begin{aligned}
&\int_0^T\sum_{v_J\in V_M}\epsilon_{iJ}(C_{iJ}^{+})^T[K_i(\tilde r_i^{n\prime}+R_i\tilde r_i^n)](v_J)C_{iJ}\tilde p_i^n(v_J)\,dt\\
&-\int_0^T\sum_{v_J\in V_M}\epsilon_{iJ}(C_{iJ}^{+})^T[K_i(\tilde p_i^{n\prime}+R_i\tilde p_i^n)](v_J)C_{iJ}\tilde r_i^n(v_J)\,dt\\
&= k\left\{\|\tilde r_i^n(T)\|^2_{\mathbf{V}_i}+\|\tilde r_i^n(T)\|^2_{\mathbf{H_i}}\right\}+\sum_{v_C\in V_C}\int_0^T|\tilde p_{i_C}^n(v_C)|^2\,dt.
\end{aligned}\tag{5.19}$$

Upon using (5.19) in (5.7) we obtain

$$\begin{aligned}
\tilde E^{n+1} = \tilde E^n &- 2k\big\{\|\tilde r^n(T)\|^2_{\mathbf V}+\|\dot{\tilde r}^n(T)\|^2_{\mathbf H}\\
&\qquad +\|\tilde r^{n+1}(T)\|^2_{\mathbf V}+\|\dot{\tilde r}^{n+1}(T)\|^2_{\mathbf H}\big\}\\
&-2\Bigg\{\int_0^T\sum_{V_C\in V_C}|\tilde p_{i_C}^n(v_C)|^2\,dt\\
&\qquad+\int_0^T\sum_{V_C\in V_C}|\tilde p_{i_C}^{n+1}(v_C)|^2\,dt\Bigg\}.
\end{aligned}\tag{5.20}$$

Taking the initial data to be zero, we iterate the recursion (5.20) down to the index zero:

$$
\begin{aligned}
\tilde{E}^{n+1} = \tilde{E}^0 &- 4k \sum_{k=0}^{n+1}{}' \big\{ \|\tilde{r}^k(T)\|^2_{\mathbf{V}} + \|\dot{\tilde{r}}^k(T)\|^2_{\mathbf{H}} \big\} \\
&- 4k \sum_{k=0}^{n+1}{}' \sum_{v_C \in V_C} \int_0^T |\tilde{p}^k_{i_C}(v_C)|^2 \, dt,
\end{aligned}
\tag{5.21}
$$

where $\sum_{i=0}^{n}{}' a_i := \frac{1}{2} a_0 + \frac{1}{2} a_n + \sum_{j=1}^{n-1} a_j$. Letting n tend to infinity we conclude

$$
\begin{cases}
\displaystyle\sum_{k=0}^{\infty} & \big\{ \|\tilde{r}^k(T)\|^2_{\mathbf{V}} + \|\dot{\tilde{r}}^k(T)\|^2_{\mathbf{H}} \big\} < \infty, \\
\displaystyle\sum_{k=0}^{\infty} \sum_{v_C \in V_C} & \displaystyle\int_0^T |\tilde{p}^k_{i_C}(v_C)|^2 \, dt < \infty, \\
 & \tilde{E}^n \text{ bounded,}
\end{cases}
\tag{5.22}
$$

whenever E^0 is finite. This can be achieved by properly choosing the initial guess for the iterates $\hat{r}^0_i$, $\hat{p}^0_i$ and taking initial and target data of the global system to be in $\mathbf{D}(\mathbf{A}) \times \mathbf{V}$.

Going back to (4.10), (4.11) (with $\beta = 1$ for simplicity) it is easily seen that the recursion (5.20) takes the equivalent form:

$$
\begin{aligned}
\int_0^T \sum_{J \in V_M, i \in \mathcal{E}_J} \|(\tilde{g}^{n+1}_{ij}, \tilde{h}^{n+1}_{iJ})\|^2 dt &= \int_0^T \sum_{J \in V_M, i \in \mathcal{E}_J} \|(\tilde{g}^{n}_{ij}, \tilde{h}^{n}_{iJ})\|^2 dt \\
-2k\big\{ \|\tilde{r}^n(T)\|^2_{\mathbf{V}} + \|\dot{\tilde{r}}^n(T)\|^2_{\mathbf{H}} &+ \|\tilde{r}^{n+1}(T)\|^2_{\mathbf{V}} + \|\dot{\tilde{r}}^{n+1}(T)\|^2_{\mathbf{H}} \big\} \\
- 2 \left\{ \int_0^T \sum_{V_C \in V_C} |\tilde{p}^n_{i_C}(v_C)|^2 \, dt \right. &+ \left. \int_0^T \sum_{V_C \in V_C} |\tilde{p}^{n+1}_{i_C}(v_C)|^2 \, dt \right\}.
\end{aligned}
\tag{5.23}
$$

Of course, the analogue of (5.21) and the conclusion that the $L^2(0,T)$-norm of $(\tilde{g}, \tilde{h})_{J \in V_M, i \in \mathcal{E}_J}$ remains bounded also hold.

We conclude from (5.22) that

$$
\begin{aligned}
&(\tilde{r}^n(T), \dot{\tilde{r}}^n(T)) \longrightarrow 0 \text{ in } \mathbf{V} \times \mathbf{H}, \\
&\tilde{p}^n_{i_C}(v_C) \longrightarrow 0 \text{ in } L^2(0,T).
\end{aligned}
\tag{5.24}
$$

But, as $\tilde{E}^n$ is bounded in n by (5.22), we obtain from (5.24) and (5.16) that

$$
\mathcal{E}_i(\tilde{r}^n_i, t), \; \mathcal{E}^*_i(\tilde{p}^n_i, t) \le C \qquad \forall\, i, n, t.
\tag{5.25}
$$

Thus, on subsequences

$$
\begin{cases}
(\tilde{r}^n_i, \dot{\tilde{r}}^n_i) \longrightarrow (\eta_i, \dot{\eta}_i), & w - \star - \text{in } L^\infty(0, T, \mathbf{V}_i \times \mathbf{H}_i), \\
(\tilde{p}^n_i, \dot{\tilde{p}}^n_i) \longrightarrow (\mu_i, \dot{\mu}_i), & w - \star - \text{in } L^\infty(0, T, \mathbf{H}_i \times \mathbf{V}^*_i),
\end{cases}
\tag{5.26}
$$

$$
\begin{cases}
C_{iJ} \tilde{r}^n_i(v_J) \longrightarrow \alpha_{iJ}, \; C_{iJ} \tilde{p}^n_{ij}(v_J) \longrightarrow \gamma_{iJ}, \\
(C^+_{iJ})^T [K_i(\tilde{r}^{n\prime}_i + R_i \tilde{r}^n_i)](v_J) \longrightarrow \beta_{iJ}, \\
(C^+_{iJ})^T [K_i(\tilde{p}^{n\prime}_i + R_i \tilde{p}^n_i)](v_J) \longrightarrow \delta_{iJ}, \qquad w - \text{in } L^2(0,T).
\end{cases}
\tag{5.27}
$$

However, as only a subsequence is involved, we cannot use (4.1), (4.2) directly in order to conclude convergence to the global solutions. We therefore resort to a result given by Opial [33] as follows.

We consider the map taking $(\tilde{g}_{iJ},\ \tilde{h}_{iJ})$ of (4.10) and (4.11) into the right-hand sides of those equations (for the errors), where we delete the iteration index n. That is, given $(\tilde{g}_{iJ},\ \tilde{h}_{iJ})$ we solve the local error system with mixed Robin conditions (4.10), (4.11) and inhomogeneities $(\tilde{g}_{iJ},\ \tilde{h}_{iJ})$ for $\tilde{r}_j,\ \tilde{p}_j$, and then compute all the traces appearing in (4.10), (4.11) on the right-hand side (again with the iteration index n deleted). To be precise, we introduce a map S_J by

$$(S_J(z))_i := \frac{2}{d_J} \sum_{j \in \mathcal{E}_J} z_{jJ} - z_{iJ}.$$

Note that this map satisfies $S_J^2 = I$. We identify network quantities, such as $C_{iJ}\tilde{r}_i(V_J)$, with $\tilde{r}_{iJ}$. With this notation, (4.10), (4.11) can be written briefly as

$$(\tilde{g}_{iJ}^{n+1}, \tilde{h}_{iJ}^{n+1}) = ((S_J(2\tilde{p}^n - \tilde{g}^n))_i, S_J(-2\tilde{r}^n - \tilde{h}^n)_i).$$

In an obvious way we can collect all the components into single vectors $\tilde{g}, \tilde{h}, \tilde{p}, \tilde{r}$. We extend the map S_J to all multiple nodes and denote it by S. Now, we define the map $\mathcal{T}$ by

$$\mathcal{T}(\tilde{g}, \tilde{h}) := S(2(\tilde{p}, -\tilde{r}) - (\tilde{g}, \tilde{h})). \tag{5.28}$$

Speaking in terms of our iteration (involving either (4.1), (4.2) or (4.10), (4.11) (with $\beta = 1$)), the new boundary terms $\tilde{g}_{iJ}^{n+1}, \tilde{h}_{iJ}^{n+1}$ are obtained from the previous ones by applying $\mathcal{T}$; i.e., with $x := (\tilde{g}, \tilde{h})$ we have a fixed point iteration

$$x^{n+1} = \mathcal{T}(x^n). \tag{5.29}$$

If $\beta > 0$ we have instead $\mathcal{T}(\tilde{g}, \tilde{h}) := S(2\beta(\tilde{p}, -\tilde{r}) - (\tilde{g}, \tilde{h}))$.

Now, the existence of a fixed-point is guaranteed by the existence (and in fact uniqueness) of solutions to the global optimality system. It is apparent from (5.23) (or equivalently (5.20)) that the mapping $\mathcal{T}$ is nonexpansive, i.e., $\|\mathcal{T}(x)\| \le \|x\|$. We are going to show that the map $\mathcal{T}$ is asymptotically regular in the sense of Opial [33], i.e., $\mathcal{T}^{n+1}x - \mathcal{T}^n x = \mathcal{T}^n(\mathcal{T} - I)x \to 0$. Then, according to Opial [33, Theorem 2], the sequence defined by (5.29) converges weakly to a (in fact the unique) fixed point. Now, with $(\bar{\tilde{g}}, \bar{\tilde{h}}) := \mathcal{T}(\tilde{g}, \tilde{h})$ we obtain by (5.23)

$$\begin{aligned} \|(\bar{\tilde{g}}, \bar{\tilde{h}})\|^2_{L^2(0,T;\mathbf{R}^{ne \times \# V_M})} &= \|(T(\tilde{g}, \tilde{h}))\|^2_{L^2} \\ &= \|(\tilde{g}, \tilde{h})\|^2_{L^2} - 2k\big\{\|\tilde{r}(T)\|^2_{\mathbf{V}} + \|\dot{\tilde{r}}(T)\|^2_{\mathbf{H}} \\ &\qquad + \|\bar{\tilde{r}}(T)\|^2_{\mathbf{V}} + \|\dot{\bar{\tilde{r}}}(T)\|^2_{\mathbf{H}}\big\} \\ &\quad - 2\left\{ \int_0^T \sum_{V_C \in V_C} |\tilde{p}_{i_C}(v_C)|^2 \, dt + \int_0^T \sum_{V_C \in V_C} |\bar{\tilde{p}}_{i_C}(v_C)|^2 \, dt \right\}. \end{aligned} \tag{5.30}$$

Assume that λ is an eigenvalue of $\mathcal{T}$ corresponding to the eigenpair (g, h). Then

$$
\begin{aligned}
(5.31)\qquad \|T(\tilde g, \tilde h)\|^2 &= |\lambda|^2 \|(\tilde g, \tilde h)\|^2\\
&= \|(\tilde g, \tilde h)\|^2 - 2k\big\{\|\tilde r(T)\|^2_{\mathbf{V}} + \|\dot{\tilde r}(T)\|^2_{\mathbf{H}}\\
&\qquad\qquad + \|\bar{\tilde r}(T)\|^2_{\mathbf{V}} + \|\dot{\bar{\tilde r}}(T)\|^2_{\mathbf{H}}\big\}\\
&\quad - 2\left\{\int_0^T \sum_{V_C \in V_C} |\tilde p_{i_C}(v_C)|^2 \, dt\right.\\
&\qquad\qquad \left. + \int_0^T \sum_{V_C \in V_C} |\bar{\tilde p}_{i_C}(v_C)|^2 \, dt\right\}.
\end{aligned}
$$

Dividing by $\|(\tilde g, \tilde h)\|^2 \neq 0$, we see that $|\lambda| \leq 1$. Assume now that $\lambda = 1$. Then equality (5.31) immediately gives

$$\tilde r(T) = \dot{\tilde r}(T) = \bar{\tilde r}(T) = \dot{\bar{\tilde r}}(T) = 0,\ \tilde p_{i_C}(v_C) = \bar{\tilde p}_{i_C}(v_C) = 0.$$

As shown above this implies that $\tilde r = \tilde p = \bar{\tilde r} = \bar{\tilde p} = 0$. Hence, all eigenvalues of $\mathcal{T}$ have modulus less than 1. We recall the structure of T given by (5.28). Up to the isomorphism S this map is the identity shifted by a map that takes appropriate traces of $\tilde r, \tilde p$ at all multiple nodes. Now, by our "energy inequalities" (5.20), (5.21), we know that even the Neumann traces at those nodes are L^2 in time. However, $\tilde r, \tilde p$ solve hyperbolic equations on each edge. Interchanging the space and time variables (as usual in one-dimensional problems) one obtains the same regularity for the velocities at multiple nodes. Therefore, picking Dirichlet data is a compact operation. Hence, the map $\mathcal{T}$ is—up to an isomorphism—the identity plus a compact operator K. Therefore, K and hence the entire map $\mathcal{T}$ is completely determined by its point spectrum and the essential spectrum at $\lambda = 1$. In terms of asymptotic regularity, the worst that can happen is that $x = \lim_{k\to\infty} x_k$, where x_k is the eigenelement $(= (\tilde g_k, \tilde h_k))$ corresponding to $\lambda_k \to 1$. On this sequence we have $\|\mathcal{T}^n(\mathcal{T} - I)x_k\| = |\lambda_k^n(\lambda_k - 1)| \to 0$. Thus, $\mathcal{T}$ is asymptotically regular and Opial's result applies.

We conclude by the same argument as in (4.3)–(4.6) that, in a weak-L^2 sense, all boundary and transmission conditions are satisfied in the limit. In fact, as seen above, the convergence of traces at multiple nodes takes place in the strong sense, and going back to the original iteration, we infer strong convergence of Neumann traces there. Therefore, we have strong convergence of the solutions $\tilde r_i^n$ in $C(0, T; H^1(0, \ell_i)) \cap C^1(0, T; L^2(0, \ell_i))$, and $\tilde p_i^n$ in $C(0, T; L^2(0, \ell_i)) \cap C^1(0, T; (H^1(0, \ell_i))^*)$. On the other hand by (5.24) all global and, hence, local final conditions for the adjoint system strongly tend to zero, and so do the traces at controlled nodes. The strong limits $\tilde r_i$ and $\tilde p_i$ of the local solutions thus correspond to zero initial and final data, respectively. Also, in the limit the global transmission conditions are satisfied in the strong sense. By uniqueness, the limits have to be equal to zero. We obtain Theorem 5.1.

THEOREM 5.1. *Let* (r_0, r_1), $(z_0, z_1) \in \mathbf{D}(\mathbf{A}) \times \mathbf{V}$ *and assumption* (A) *be satisfied. Then the sequence* $(r_i^n, p_i^n)_i$, $i = 1 : n_e$, $n \in \mathbb{N}_0$, *defined by the solution to* (4.12)–(4.18) *(or* (4.19), (4.20)*) converges to* (r_i, p_i), $i = 1 : n_e$ *in* $C(0, T; V \times H) \cap C^1(0, T; H \times V^*)$, *where* $(r, p) = (r_i, p_i)_{i=1}^{n_e}$ *solves the global optimality system* (1.5)–(1.10), (3.1)–(3.7).

This result can be extended to the relaxed version (4.8), (4.9) of (4.1), (4.2) as well as to the relaxed version of (4.10), (4.11). The point is that by underrelaxation the iteration mapping $\mathcal{T}_\lambda := \lambda I + (1 - \lambda)\mathcal{T}$ has the same set of fixed points as the original map $\mathcal{T}$, and, according to Opial [33, Theorem 3], the map $\mathcal{T}_\lambda$ is asymptotically regular. Hence for each $\lambda \in (0,1)$ and for any initial data, the fixed point sequence converges weakly in L^2 to the unique fixed point of $\mathcal{T}$. Therefore, independently of λ, the transmission conditions are satisfied in the weak limit and, by the argument given above, also in the strong limit. Now, in order to conclude convergence of the relaxed scheme, one needs to extend the basic recursion relation (5.20) to the relaxed scheme, as one has to use the fact that the final values and the traces at controlled nodes tend to zero also for the sequence generated by the relaxed scheme. This extension is tedious but nevertheless possible.

6. Remarks on other cost functionals. One might consider functions different from (2.1). In particular, we might want to optimize the flux of energy, rather than to dissipate energy. This is of interest in real-time applications where one wants to protect certain subregions from perturbations. Without going into details, we mention that in the string case the flux at a given vertex v_J in the direction e_i of edge i is given by

$$\begin{aligned} &-\epsilon_{iJ}K_i r_i'(v_J)\dot{r}_i(v_J) \\ &\quad = \frac{1}{4}\left\{|\epsilon_{iJ}K_i r_i'(v_J) - \dot{r}_i(v_J)|^2 - |\epsilon_{iJ}K_i r_i'(v_J) + \dot{r}_i(v_J)|^2\right\}, \end{aligned}$$

so that maximizing the flux of energy at v_J in that direction comes down to minimizing the quadratic cost

$$\frac{k}{2}\int_0^T |\epsilon_{iJ}K_i r_i'(v_J) + \dot{r}_i(v_J)|^2\, dt.$$

It is apparent that upon letting k grow large the optimal control would have the tendency to install an absorbing condition at v_J. More on this issue can be found in [17]. The complete analysis of the corresponding domain decomposition is yet to be done. Similar cost criteria apply also to the Timoshenko beam case.

Another cost function, which is much simpler and more classical, is provided by the full-state cost

$$J(f) = \frac{1}{2}\sum_{v_J \in V_C}\int_0^T |f_J|^2\, dt + \frac{1}{2}\int_0^T \sum_{i=1}^{n_e} |r_i|^2\, dx\, dt. \tag{6.1}$$

This is the kind of cost function that has been frequently used by Benamou [1], [2], etc.. The point is that recursions similar to (5.21) involve the error with respect to the entire state, so that convergence follows without the necessity of applying energy estimates. In our present situation, we are able to show that in the case of (6.1), (5.21) changes to

$$\begin{aligned} \tilde{E}^{n+1} = \tilde{E}^0 - 4\sum_{k=0}^{n+1'}\sum_{i=1}^{n_e}\int_0^T\int_0^{l_i} |\tilde{r}_i^k|^2\, dx\, dt \\ -4\sum_{k=0}^{n+1'}\sum_{v_C \in V_C}\int_0^T |\tilde{p}_{iC}^k(v_C)|^2\, dt. \end{aligned} \tag{6.2}$$

In this case it is obvious that we obtain convergence in $L^2(0,T,H)$ of the corresponding errors directly. We note that, by standard arguments, the coupling in the local and global optimality systems is much simpler then, as the full state r_i appears as distributed input in the adjoint equation.

As for cost function (2.2), we remark that results similar to those corresponding to cost function (2.1) can be shown. We refer the reader to Lagnese and Leugering [16], where transmission problems in higher dimensions are discussed. See also Leugering [19] for a discussion of this problem in the context of networks of strings.

We also remark that it is possible to show similar results—in the case of full state cost—for networks of Rayleigh beams. This can be done by letting the shear stiffness of each member tend to infinity; see Example 2. The analysis, however, goes beyond the scope of this paper. We shall consider this problem in a forthcoming publication.

7. Numerical simulations. We consider only networks of strings. For Timoshenko beams the simulations are very similar. As an example we take a tripod (divining rod) consisting of one-dimensional elastic material. We put Neumann boundary controls at the south node and the northwest node, whereas the northeast node is clamped. This system is known to be exactly controllable in $T \geq 4$ time units *in general*, that is, for *general* initial conditions [14]. We have picked $T = 3$ as final time because this particular example shows that controls can be applied successfully in a shorter time interval for a particular choice of the initial data. However, as is obvious, a control time of one time unit is not sufficient to steer the system to rest. This is verified numerically in Figure 7.1. Figures 7.2 and 7.3 show a rectangular tripod with the south vertex controlled in the Neumann condition. In Figure 7.2 the west node is clamped, while the east node is subjected to a free Neumann condition. That system is also known to be controllable [18]. Here it really takes 4 time units (a shorter time duration is not sufficient in this configuration; we have only one control) to control the configuration to rest. In Figure 7.3, however, the east and west nodes are clamped. This situation is known to be uncontrollable [18] in any time interval by Neumann controls at the south node. The underlying phenomenon is exactly as in the midspan control case for a string clamped at its boundaries. Figure 7.4 clearly shows that the upright element does not absorb any energy from the horizontal members, simply because a zero node deflection occurs at the multiple node. The initial data are chosen as eigenelements in an obvious way. There is no longitudinal component in the initial data; therefore, the upright element performs no vertical deflection, which is in complete agreement with the theory.

The final experiment concerns the problem of controlling networks with circuits. It has been shown in [14] that homogenous networks of strings, i.e., the network contains a circuit and all physical constants are equal, are not even approximately controllable. It was further demonstrated in [14] that upon using completely absorbing boundary controls at simple nodes, a residual motion settles in such a circuit that has zero displacements (and velocities) at the nodes constituting the closed path. Furthermore, it has also been remarked in [14] that exact controllability is obtained for string networks, once the prestretching factors (which in turn determine the "optical length" of an individual string) are rational independent. However, rational independence is a matter that is hard to realize (with finitely many machine numbers). We take a square with two strings attached to it. The simple nodes of the string network are controlled in the Neumann conditions. Instead of taking an eigenmode on the square with zero nodal values that would give a picture similar to Figure 7.4, we decided to produce a canonical short range input (bump) as before; see Figure 7.5. The pictures clearly show that only very minor (literally "invisible") oscillations are left after the canonical timespan.

The numerical experiments were done using a Newmark-(1/2,1/4) scheme for the forward and backward wave equations appearing in the optimality conditions.

We worked out also the discrete optimality conditions for the discretized problem and implemented the corresponding scheme, which is slightly different from the one obtained by first deriving the optimality condition on the partial differential equation level and then discretizing. In fact, this is an important and well-known observation: control and discretization do not commute in general.

The physical constants are always put to unity for easier reference. We used 20 discretization points in space for each member. The outer iterations were terminated usually after 10 iterations to yield 10^{-4} accuracy. In order to be close to controllability phenomena, we have chosen the penalty parameter k to be in the range of 10^4.

We applied several variations of the algorithms and also different discretizations of the equations and costs; however, we do not have the space to dwell on this and refer to a forthcoming publication where the numerical part will be made more explicit.

Acknowledgment. We gratefully acknowledge Ralf Hundhammer's work on the implementation.

NECESSARY CONDITIONS OF OPTIMIZATION FOR PARTIALLY OBSERVED CONTROLLED DIFFUSIONS[*]

CHARALAMBOS D. CHARALAMBOUS[†] AND JOSEPH L. HIBEY[‡]

Abstract. Necessary conditions are derived for stochastic partially observed control problems when the control enters the drift coefficient and correlation between signal and observation noise is allowed. The problem is formulated as one of complete information, but instead of considering directly the equation satisfied by the unnormalized conditional density of nonlinear filtering, measure-valued decompositions are used to decompose it into two processes. The minimum principle and the stochastic partial differential equation satisfied by the adjoint process are then derived, and the optimality conditions are shown to be the exact necessary conditions derived by Bensoussan [*Maximum principle and dynamic programming approaches of the optimal control of partially observed diffusions*, Stochastics, 9 (1983), pp. 169–222; *Stochastic Control of Partially Observable Systems*, Cambridge University Press, Cambridge, UK, 1992] when the correlation is zero.

Key words. stochastic control, minimum principle, partially observable diffusions, nonlinear filtering, measure-valued decompositions

1. Introduction.

The stochastic control problem under consideration is

$$\min\{J(u); u \in U_{ad}\}, \tag{1.1}$$

$$J(u) = E^u \left\{ \int_0^T \pi(t, x_t, u_t)dt + \kappa(x_T) \right\}, \tag{1.2}$$

$$dx_t = f(t, x_t, u_t)dt + \sigma(t, x_t)dw_t, \; x_0 = x, \tag{1.3}$$

$$dy_t = h(t, x_t)dt + g(t)dw_t + \hat{g}(t)db_t, \; y_0 = 0, \tag{1.4}$$

where, assuming $\{w_s; 0 \leq s \leq t\}, \{b_s; 0 \leq s \leq t\}$ are uncorrelated Wiener processes, the correlation between the signal process and the observation process is

$$\langle x, y \rangle_t = \int_0^t \sigma(s, x_s)g(s)^T ds. \tag{1.5}$$

The set of all admissible controls, denoted by U_{ad}, may depend on the observations $\{y_s; 0 \leq s \leq t\}$, thereby describing a strict-sense control problem (output feedback) rather than a wide-sense one which requires additional dependence of U_{ad} on the previous controls (see, for example, Fleming and Nisio [3]). Recent approaches addressing this problem with output feedback when the correlation between the signal

process and the observation process is zero (i.e., $g = 0$) are based on strong and weak variations, and can be found in Bensoussan [1, 2], Haussmann [4], Baras, Elliott, and Kohlmann [5], and Elliott and Yang [6]. A stochastic partial differential equation satisfied by the adjoint process is given by Bensoussan [1, 2] when $g = 0$ and $\sigma(t, x)$ is degenerate, whereas the other authors above provide an explicit representation for the adjoint process in terms of a conditional expectation. The derivations found in Bensoussan [1] and Haussmann [4] are based on the robust version of the unnormalized conditional density equation which does not exist when the correlation considered here is present (due to h_i, h_j being noncommutative). Bensoussan [2] introduced a new approach in solving the problem by applying the variational methods of partial differential equations, weak control variations, and using Galerkin's approximations for Sobolev spaces to approximate the adjoint process through a finite-dimensional basis.

Here, for the stochastic control problem (1.1)–(1.4), we shall derive optimality conditions that are generalizations of the optimality conditions derived in Bensoussan [1, 2]. The main idea of our methodology is the use of measure-valued decompositions as discussed by Kunita [7, 8], whereby the unnormalized conditional density ρ_t is written as a composition of two measure-valued processes such that $\rho_t = \nu_t\mu_t$. In Kunita [7, 8], this decomposition is used to obtain necessary and sufficient conditions for the smoothness of ρ_t. Here we recognize that ν_t satisfies a parabolic partial differential equation containing the Kolmogorov operator, and hence the explicit dependence on the control, while μ_t satisfies a stochastic partial differential equation containing the observations and, therefore, has no explicit dependence on the control. Therefore, in the control situation, this decomposition serves as a separation argument similar to the separation principle given by Wonham [9] because any control variation affects explicitly only the measure-valued process ν_t. A similar approach in deriving necessary conditions of optimization for state-valued processes satisfying the separation principle of Wonham [9] is given by Bensoussan [10].

In section 2, we state our main assumptions and give a summary of the results from filtering theory and Kunita's [7, 8] decomposition which will be used throughout. In section 3, we formulate the stochastic control problem by expressing the performance index in terms of the measure-valued processes ν_t, μ_t. In addition, we present our separation argument and relate the perturbed process $\rho_t^{\mathcal{B}}$ of Bensoussan [1, 2] to our perturbed processes z_t which are, respectively, the byproducts of applying weak variations to the equations satisfied by ρ_t, ν_t. In section 4, we derive the minimum principle using the interplay between Euclidean variational methods and variational methods for measure-valued processes. We also derive the stochastic partial differential equation satisfied by the adjoint process using a generalization of the martingale representation theorem. In section 5, we show that the minimum principle established by Bensoussan [1, 2] is a special case of Theorem 4.3, and that the stochastic partial differential equation satisfied by the adjoint process found in Bensoussan [1, equation (2.66)] is related to the adjoint process equation given by (4.10) (in fact, Bensoussan's adjoint process equation is again a special case of the adjoint process given by (4.10)).

2. Problem formulation.

The control parameter u will take values in a compact, convex subset U of some Euclidean space R^k. We shall make the following assumptions.

2.1. Assumptions.

(A1) $f : [0, T] \times R^n \times U \to R^n$, bounded continuous in t, continuous in u, C^∞ in

x, with bounded derivatives of any order in x, bounded first derivatives in u, with a constant k_1 such that

$$|f(t,x,u) - f(t,z,u)| \leq k_1|x-z|;$$

(A2) $\sigma : [0,T] \times R^n \to R^n \otimes R^m$, bounded continuous in t, C^∞ in x, with bounded derivatives of any order in x, and a constant k_2 such that

$$||\sigma(t,x) - \sigma(t,z)|| \leq k_2|x-z|;$$

(A3) $h : [0,T] \times R^n \to R^d$, bounded continuous in t, C^∞ in x, with bounded derivatives of any order in x;

(A4) $g : [0,T] \to R^d \otimes R^m$, $\hat{g} : [0,T] \to R^d \otimes R^d$, continuous, with constants $\beta_1, \beta_2 > 0$, such that

$$g(t)g(t)^T + \hat{g}(t)\hat{g}(t)^T \geq \beta_1 I_d, \; \hat{g}(t)\hat{g}(t)^T \geq \beta_2 I_d,$$

where I_d denotes the $d \times d$ identity matrix;

(A5) $\pi : [0,T] \times R^n \times U \to R$, bounded, with bounded L^2-norm independent of u, continuous in u, and satisfying

$$\pi(.,.,u) \in L^2([0,T] \times R^n), \; \left|\frac{\partial}{\partial u}\pi(t,x,u)\right| \leq \gamma(x), \; \gamma(\cdot) \in L^2(R^n);$$

(A6) $\kappa : R^n \to R$, Borel bounded with $\kappa(\cdot) \in L^2(R^n)$;

(A7) $x_0 = x$ is assumed to be known. If x_0 is random, then $p_0 \in L^2(R^n)$ is the density of x_0 and is assumed to be independent of $\{w_s, b_s; 0 \leq s \leq t\}$.

2.2. Evolution of unnormalized conditional density equation. We start with a reference probability space $(\Omega, \mathcal{F}, \mathcal{P})$ with a complete filtration $\{\mathcal{F}_t; t \in [0,T]\}$, two adapted Wiener processes, $\{w(t); t \in [0,T]\}$, $\{b(t); t \in [0,T]\}$, and an $\mathcal{F}_0$ measurable random variable x_0 such that

$w : [0,T] \times \Omega \to R^n$ is a standard Wiener process independent of $b(\cdot)$,
$b : [0,T] \times \Omega \to R^d$ is a standard Wiener process independent of $w(\cdot)$,
$x(0) : \Omega \to R^n$ is a random variable independent of $w(\cdot), b(\cdot)$.

Furthermore, suppose an observation process $y(\cdot)$ is given by

$$dy_t = g(t)dw_t + \hat{g}(t)db_t, \; y_0 = 0. \tag{2.1}$$

We write $\{\mathcal{F}_t^y; t \in [0,T]\}$ for the complete filtration generated by the observation σ-algebra $\sigma\{y_s; 0 \leq s \leq t \leq T\}$, and we denote by E^u (resp., E) the expectation with respect to measure $\mathcal{P}^u$ (resp., $\mathcal{P}$).

Definition 2.1. *Denote by $L_y^2([0,T]; R^k)$ the set of square integrable stochastic processes adapted to $\{\mathcal{F}_t^y; t \in [0,T]\}$ with values in R^k. The set of admissible controls, denoted by U_{ad}, is defined as*

$$U_{ad} \stackrel{\triangle}{=} \{u(\cdot) \in L_y^2([0,T]; R^k) u(t,y) \in U, (a.e. \text{ on } [0,T]), \mathcal{P} \; a.s.\}.$$

Given the system $(\Omega, \mathcal{F}, \mathcal{P}; \mathcal{F}_t)$ and a $u \in U_{ad}$, consider the diffusion process $x(\cdot)$ satisfying the Ito equation

$$dx_t = f(t,x_t,u_t)dt - \sigma(t,x_t)g(t)^T k(t,x_t)dt + \sigma(t,x_t)dw_t, \; x_0 \in R^n, \tag{2.2}$$

where the $d \times 1$ vector $k(t, x_t)$ is defined by

$$k(t, x_t) \triangleq (g(t)g(t)^T + \hat{g}(t)\hat{g}(t)^T)^{-1} h(t, x_t). \tag{2.3}$$

By assumptions (A3) and (A4), $k(t, x)$ is a well-defined bounded vector. Furthermore, by assumptions (A1)–(A3) and (A7), there exists a unique solution (see Bensoussan [2]) such that

$$x(.) \in L^2(\Omega, \mathcal{F}_T, \mathcal{P}; C([0, T]; R^n)).$$

Define the martingale $\{m_t; t \in [0, T]\}$ with respect to $(\{\mathcal{F}_t; t \in [0, T]\}, \mathcal{P})$ by

$$m_T \triangleq \int_0^T k(s, x_s)^T (g(s)dw_s + \hat{g}(s)db_s),$$

and introduce a new probability measure through the likelihood-ratio Λ_T^u defined as

$$\Lambda_T^u \triangleq E\left[\frac{d\mathcal{P}^u}{d\mathcal{P}} | \mathcal{F}_T\right] = \exp\left\{m_T - \frac{1}{2}\langle m, m\rangle_T\right\}. \tag{2.4}$$

On this new probability measure $\mathcal{P}^u$ (and after incorporating the martingale translation theorem) the processes $\{x_s, y_s; 0 \le s \le t\}$ become for the system $(\Omega, \mathcal{F}_t, \mathcal{P}^u), t \in [0, T]$, the weak solutions of (1.3), (1.4), which are unique in probability law.

Given any $\tilde{f} \in C_b^\infty(R^n)$ (space of continuous, real-valued, infinitely continuously differentiable functions with bounded derivatives), we obtain from Bayes formula (see Bensoussan [2] and Kunita [11], assuming existence of a conditional distribution which is also absolutely continuous with respect to Lebesque measure)

(2.5)

$$E^u[\tilde{f}(x_t)|\mathcal{F}_t^y] = \frac{E[\tilde{f}(x_t)\Lambda_t^u|\mathcal{F}_t^y]}{E[\Lambda_t^u|\mathcal{F}_t^y]} = \frac{\int_{R^n} \tilde{f}(z)\rho_t(dz)}{\int_{R^n} \rho_t(dz)} = \frac{\rho_t(\tilde{f})}{\rho_t(1)} = \frac{\langle \tilde{f}(z), \rho_t(z)\rangle}{\langle 1, \rho_t(z)\rangle},$$

where ρ_t is the unnormalized conditional density of x_t given the information $\mathcal{F}_t^y$.

THEOREM 2.2. *For any $\tilde{f} \in C_b^\infty(R^n)$, $\rho_t(\tilde{f})$ is the solution of*

$$\rho_t(\tilde{f}) = p_0(\tilde{f}) + \int_0^t \rho_s(A^u(s)\tilde{f})ds + \int_0^t \rho_s(M(s)\tilde{f})d\tilde{y}_s, \tag{2.6}$$

where p_0 is a delta measure δ_x and

$$A^u(t) = \sum_{i=1}^n f^i(t, x, u)\frac{\partial}{\partial x^i} + \frac{1}{2}\sum_{i,j=1}^n a^{ij}(t, x)\frac{\partial^2}{\partial x^i \partial x^j}, \ a(t, x) = \sigma(t, x)\sigma(t, x)^T, \tag{2.7}$$

$$M_k(t) = \sum_{i=1}^d (\tilde{k}(t)^{-1/2})^{ik} h^i(t, x) + \sum_{i=1}^n (\sigma(t, x)g(t)^T \tilde{k}(t)^{-1/2})^{ik}\frac{\partial}{\partial x^i}, \ 1 \le k \le d, \tag{2.8}$$

$$\tilde{k}(t) = g(t)g(t)^T + \hat{g}(t)\hat{g}(t)^T, \tag{2.9}$$

with $(\cdot)^{i,j}$ the (i, j)th component of a matrix, $(\cdot)^i$ the ith component of a vector, and $\{\tilde{y}_s; 0 \le s \le t\}$ a standard Wiener process.

Proof. See Pardoux [12]. □

Remark 2.1. Notice that (2.6) is a degenerate version of the equation presented by Pardoux [12, equation (4.3), pp. 206–216] in the case when no control is present, $g(t) \in R^d \otimes R^n, \sigma(t,x) \in R^n \otimes R^n$, and $\tilde{k}(t) = I_d$. A similar equation is derived by Kunita [8, pp. 154–167] using the interplay between Kushner's equation for the normalized conditional density and the unnormalized conditional density when no control is present, $\hat{g} = I_d, g = 0$, and a martingale $\tilde{g}(t)db_t$ is added to the right side of (1.3). Different proofs of (2.6), when $\sigma(t,x) \in R^n \otimes R^n$ and $g(t) \in R^d \otimes R^n$, are also found in Bensoussan [2]. It is important to note that the case when g depends on x still remains open. For reasons of simplicity, and without loss of generality, we shall assume that $\tilde{k}(t) = I_d$ so that $\{y_s; 0 \leq s \leq t\}$ is the standard Wiener process described by (2.1).

2.3. Decomposition and representations of unnormalized conditional density. Suppose the operators $A^u(t), M_k(t)$ are defined by

$$A^u(t) \triangleq \frac{1}{2}\sum_{j=1}^{m} X_j(t)^2 + X_0^u(t);\ M_k(t) \triangleq h_k(t) + Y_k(t),\ 1 \leq k \leq d, \tag{2.10}$$

where

$$X_0^u(t) \triangleq X_0(t,x,u) = \sum_{i=1}^{n}\left(f^i(t,x,u) - \frac{1}{2}\sum_{k=1}^{m}\sum_{j=1}^{n}\sigma^{jk}(t,x)\frac{\partial}{\partial x^j}\sigma^{ik}(t,x)\right)\frac{\partial}{\partial x^i},$$

$$X_j(t) \triangleq X_j(t,x) = \sum_{i=1}^{n}\sigma^{ij}(t,x)\frac{\partial}{\partial x^i},\ 1 \leq j \leq m,$$

$$Y_k(t) \triangleq Y_k(t,x) = \sum_{j=1}^{m}\gamma(t)^{kj}X_j(t),\ h_k(t) = h^k(t,x),\ 1 \leq k \leq d,$$

and γ^{ij} are components of $g(t)$. Writing the stochastic integral of (2.6) in terms of the Stratonovich integral and defining

$$L^u(t) \triangleq A^u(t) - \frac{1}{2}\sum_{k=1}^{d} M_k(t)^2 = \frac{1}{2}\sum_{j=1}^{m}\tilde{X}_j(t)^2 + \tilde{X}_0^u(t) + \tilde{h}_0(t), \tag{2.11}$$

then (2.6) is equivalent to

$$\rho_t(\tilde{f}) = p_0(\tilde{f}) + \int_0^t \rho_r(L^u(r)\tilde{f})dr + \sum_{k=1}^{d}\int_0^t \rho_r(M_k(r)\tilde{f}) \circ dy_r^k. \tag{2.12}$$

Here, "∘" denotes the Stratonovich integral. Furthermore,

$$\tilde{X}_0^u(t) \triangleq \tilde{X}^u(t,x) = X_0^u(t) - \sum_{k=1}^{d} h_k(t)Y_k(t),\ \tilde{X}_j(t) \triangleq \tilde{X}_j(t,x) = \sum_{k=1}^{m}\theta^{ik}(t)X_k(t),\ 1 \leq j \leq m, \tag{2.13}$$

$$M_k(t) = h_k(t) + Y_k(t),\ \tilde{h}_0(t) = -\frac{1}{2}\sum_{k=1}^{d}(h_k(t)^2 + Y_k(t)h_k(t)), \tag{2.14}$$

and $\theta^{ij}(t)$ are the components of the positive definite matrix $\theta(t)$, satisfying $\theta(t)^T\theta(t) = I_m(t) - g(t)^T g(t)$.

At this point, we invoke the representation results of stochastic partial differential equations given by Kunita [8, 7]. Write the space $(\Omega, \mathcal{F}_T, \mathcal{P})$ as a product of two probability spaces as follows:

$$\Omega = \Omega^y \otimes \Omega^w = C([0,T]; R^d) \otimes C([0,T]; R^m),$$

$$\mathcal{F}_T = \mathcal{F}_T^y \otimes \mathcal{F}_T^w,\ \mathcal{P}(dy, dw) = \mathcal{P}^y(dy) \otimes \mathcal{P}^w(dw),$$

where $\mathcal{F}_T^y, \mathcal{F}_T^w$ are the Borel σ-algebras on $C([0,T]; R^d), C([0,T]; R^m)$ (spaces of continuous functions), respectively. Here $\mathcal{P}^y, \mathcal{P}^w$ denote the Wiener measures $\mu_w^d(dy), \mu_w^m(dw)$ on $C([0,T]; R^d), C([0,T]; R^m)$, respectively. For $u \in U_{ad}$ consider the process $\xi_{0,t} = \xi_{0,t}(x, y, w)$ starting at $\xi_{0,0} = x$ and described by the stochastic differential equation

$$(\Omega^y \otimes \Omega^w, \mathcal{F}_t^y \otimes \mathcal{F}_t^w, \mathcal{P}^y \otimes \mathcal{P}^w):$$

$$d\xi_{0,t} = \tilde{X}^u(t, \xi_{0,t})dt + \sum_{j=1}^{m}\tilde{X}_j(t, \xi_{0,t}) \circ dw_t^j + \sum_{k=1}^{d} Y_k(t, \xi_{0,t}) \circ dy_t^k. \tag{2.15}$$

Since the coefficients of (2.15) are of C^∞-class and their derivatives are bounded, by Kunita [13, Theorem 2.3], the solution map $\xi_{0,t}(\cdot, y, w) : R^n \to R^n$ is a.s., for each $y \in C([0,T]; R^d)$ (which specifies the control function at a fixed time t), a C^∞-diffeomorphism in x for any t. Define $\phi_{0,t} \overset{\triangle}{=} \phi_{0,t}(x, y, w)$ by

$$\phi_{0,t} \overset{\triangle}{=} \exp\left\{\sum_{k=1}^{d}\int_0^t h_k(r, \xi_{0,r}(x)) \circ dy_r^k + \int_0^t \tilde{h}_0(r, \xi_{0,r})(x)dr\right\}. \tag{2.16}$$

Then (see Kunita [8, 7]) the solution of (2.12) can be represented by

$$\rho_t(\tilde{f})(x, y) = E_{\mathcal{P}^w}[\tilde{f}(\xi_{0,t}(x, y, \cdot))\phi_{0,t}(x, y, \cdot)]. \tag{2.17}$$

Also, since $u(t, .)$ is measurable with respect to t and $\{y_s; 0 \leq s \leq t\}$, the results of Kunita [14] extend easily and show that $\rho_t(\tilde{f})$ of (2.12) satisfies $E_{\mathcal{P}}|\rho_t(\tilde{f})(x)|^2 < \infty$ for all t and x.

Remark 2.2. Notice that if the initial state $x = x_0$ is random, then (2.19) is given by

$$\rho_t(\tilde{f})(\tilde{w}) = \int_{R^n} E_{\mathcal{P}^w}[\tilde{f}(\xi_{0,t}(x, \tilde{w}, .))\phi_{0,t}(x, \tilde{w}, .)]p_0(dx);$$

thus an additional integration with respect to p_0 is required, which is also consistent with the derivation of (2.6), where $x_0 = x$ is assumed to be deterministic; see Kunita [8, 11].

A different representation describing the solution of (2.12), which also constitutes our main tool in deriving the stochastic minimum principle, is given in Kunita [8] by treating the second term on the right side of (2.12) as the principal part and the last term as the perturbation part. Using this approach, which also holds in the controlled case as well, the solution to (2.12) can be expressed as $\rho_t = \nu_t \mu_t$, where

$$d\mu_t(\tilde{f})(x,y) = \sum_{k=1}^{d} \mu_t(M_k(t)\tilde{f})(x,y) \circ dy_t^k, \ \lim_{t \downarrow 0} \mu_t(\tilde{f}) = \tilde{f}(x), \tag{2.18}$$

$$\frac{\partial}{\partial t}\nu_t(\tilde{f})(x,y) = \nu_t(\mu_t L^u(t)\mu_t^{-1}\tilde{f})(x,y), \ \lim_{t \downarrow 0} \nu_t(\tilde{f}) = \tilde{f}(x), \tag{2.19}$$

with $\mu_t L^u(t)\mu_t^{-1}$ a second-order differential operator of parabolic type (see Kunita [8], [11, Chapter 6]). In fact, if we let $n_{0,t}(x,y)$ correspond to the solution of

$$dn_{0,t} = \sum_{k=1}^{d} Y_k(t, n_{0,t}) \circ dy_t^k, \ n_{0,0} = x, \tag{2.20}$$

which is also the solution to (2.15) when $\tilde{X}_j(t) = 0, \ 0 \leq j \leq m$, then the solution to (2.18) can be represented as

$$\mu_t(\tilde{f})(x,y) = \tilde{f}(n_{0,t}(x,y)) \exp\left\{ \sum_{k=1}^{d} \int_0^t h_k(r, n_{0,r}(x,y)) \circ dy_r^k \right\}. \tag{2.21}$$

By the assumptions on $Y_1, \ldots, Y_d$ the solution map $n_{0,t}(.,y) : R^n \to R^d$ is, a.s., one-to-one, onto, and C^∞ in x for each t. The representation (2.21) can be shown easily by an application of Ito's formula. Similarly, a representation for $\nu_t(\tilde{f})(x,y)$ is given in Kunita [7, 13].

Remark 2.3. For the uncontrolled case, and assuming $L(t)$ is hypoelliptic, it was shown by Kunita [7] that the solution measure $\rho_t(x,y,dz)$ of (2.6) has C^∞-density function for almost all $y \in C([0,T];R^d)$ by first showing that the solution measure $\nu_t(x,y,dz)$ of (2.19) has a C^∞-density function (because $\rho_t = \nu_t\mu_t$ and $\mu_t(.,y) \in C_b^\infty(R^n)$ is a one-to-one and onto map). Also, since for each t, $u(t,.)$ depends on $\{y_s; 0 \leq s \leq t\}$, the result of Kunita [7] can be applied to our problem by assuming that the Lie algebra generated by the vector fields of the diffusion coefficient of (1.3) is, a.s., of dimension n for all $t \in [0,T], x \in R^d$.

Remark 2.4. Notice that the measure-valued process μ_t satisfying (2.18) does not explicitly depend on the control u, as is easily seen in (2.14); only the measure-valued process ν_t satisfying (2.19) depends on u. This is the separation argument we shall concentrate on in our analysis.

2.4. Variational methods applied to the information state. Introduce the Hilbert space $H(R^n) = L^2(R^n)$ with scalar product denoted by $(\cdot,\cdot)$. Define the Sobolev space

$$H^1(R^n) \triangleq \left\{ \hat{u} \in L^2(R^n), \frac{\partial \hat{u}}{\partial x^i} \in L^2(R^n), 1 \leq i \leq n \right\}.$$

Let $H^{-1}(R^n)$ be the dual of $H^1(R^n)$. The norm in $H(R^n)$ is denoted by $|\cdot|$ while the norm in $H^1(R^n)$ is denoted by $||\cdot||$, that is,

$$|| \hat{u} ||^2 = | \hat{u} |^2 + \sum_{i=1}^{n} \left| \frac{\partial}{\partial x^i} \hat{u} \right|^2 .$$

The norm in $H^{-1}(R^n)$ is denoted by $||\cdot||_*$. The pairing between $H^1(R^n)$ and $H^{-1}(R^n)$ is denoted by $\langle \cdot, \cdot \rangle$. Define

$$\begin{aligned} &L_y^2((0,T);H^1) \overset{\triangle}{=} \\ &\{\hat{u} \in L^2(\Omega^y, \mathcal{F}_t^y, \mathcal{P}^y; L^2((0,T);H^1)); \text{a.e. on } [0,\mathrm{T}], \hat{u}(t) \in L^2(\Omega^y, \mathcal{F}_t^y, \mathcal{P}^y; H^1)\}. \end{aligned}$$

Integrating (2.19) by parts, we get the equation

$$\frac{\partial}{\partial t}\nu_t = L_{w^y}^u(t)^* \nu_t, \;\; \nu_0 = \delta_x \tag{2.22}$$

written in strong form, where $L_{w^y}^u(t)^*$ is the formal adjoint of $L_{w^y}^u(t) = \mu_t L^u(t) \mu_t^{-1}$, which can be represented by

$$L_{w^y}^u(t) = \frac{1}{2}\sum_{i,j=1}^n \alpha_{w^y}^{ij}(t,x)\frac{\partial^2}{\partial x^i \partial x^j} + \sum_i^n b_{w^y}^i(t,x,u)\frac{\partial}{\partial x^i} + d_{w^y}(t,x,u).$$

Lemma 2.3. *Suppose* $u \in U_{ad}$, (A1)–(A7) *hold, and* (A8) $w_t \in R^n, \exists \beta_3 > 0$ *such that*

$$\sigma(t,x)\sigma^T(t,x) \geq \beta_3 I_n > 0 \; \forall t \geq 0, \forall x \in R^n.$$

Then

$$-A^u(\cdot), A^u(\cdot)^* \in L^\infty((0,T); \mathcal{L}(H^1(R^n); H^{-1}(R^n))),$$

$$M(\cdot), M(\cdot)^* \in L^\infty((0,T); \mathcal{L}(H^1(R^n); H^d(R^n))),$$

the coercivity condition associated with the strong form of (2.6) *holds, that is, for some* $\lambda_1, \lambda_2 > 0$,

$$-2\langle A^u(t), \hat{u}, \hat{u}\rangle + \lambda_1 | \hat{u} |^2 \geq \lambda_2 || \hat{u} ||^2 + \sum_{k=1}^d |M_k(t)^* \hat{u} |^2$$

and for each $y(\cdot) \in C([0,T]; R^d)$, *there exists a unique solution of* (2.22) *in the space*

$$\nu(\cdot) \in L_y^2((0,T); H^1(R^n)), \frac{\partial}{\partial t}\nu(\cdot) \in L_y^2((0,T); H^{-1}(R^n)).$$

Proof. The coercivity condition is a direct consequence of (A1)–(A4) and (A8) (see Bensoussan [2]). For each $u \in U_{ad}$, define

$$A_{w^y}^u(t) f \overset{\triangle}{=} \mu_t(A^u(t)\mu_t^{-1}) f = \mu_t\left(\left[L^u(t) + \frac{1}{2}\sum_{k=1}^d M_k(t)^2\right]\mu_t^{-1}\right) f.$$

The operators $L_{w^y}^u(t)$ and $A_{w^y}^u$ are for almost all $w^y \in \Omega^y$ second-order linear parabolic partial differential operators. By assumptions (A1)–(A4) and (A8), the random functions $\alpha_{w^y}^{i,j}, b_{w^y}^i, d_{w^y}$ are a.s. smooth and bounded. Therefore, for any $w^y \in C([0,T]; R^d)$, (2.22) can be viewed as a deterministic partial differential equation. Using the standard theory of these equations, there is one and only one solution of (2.22) as specified. □

Next, consider the strong form of (2.6):

$$\rho_t = p_0 + \int_0^t A^u(s)\rho_s ds + \sum_{i=1}^d \int_0^t M_k(s)\rho_s dy_s^i. \tag{2.23}$$

The previous lemma enables us to obtain the following results.

Theorem 2.4. *Suppose* $u \in U_{ad}$ *and* (A1)–(A8) *hold. Then there exists one and only one solution to* (2.23) *in the space*

$$\rho(\cdot) \in L_y^2((0,T); H^1(R^n)) \cap L^2(\Omega^y, \mathcal{F}_t^y, \mathcal{P}^y; C((0,T); H)).$$

Proof. This follows from Lemma 2.3 and the representation $\rho_t = \nu_t \mu_t$. Alternatively, we can employ the energy equality

$$|\rho_t|^2 = |p_0|^2 + 2\int_0^t \langle A^u(r)\rho_r, \rho_r\rangle dr + \sum_{k=1}^d \int_0^t |M_k(r)\rho_r|^2 dr + 2\sum_{k=1}^d \int_0^t (M_k(r)\rho_r, \rho_r) dy_r^k$$

and the coercivity condition of Lemma 2.3, and then proceed as in Bensoussan [2]. □

3. Decomposed control problem. With the aid of (2.4), the expected cost (1.2) can be written as

$$J(u) = E\left\{\Lambda_T \left[\kappa(x_T) + \int_0^T \pi(r, x_r, u_r) dr\right]\right\}.$$

In addition, by (2.5), the above cost is equivalent to

$$J(u) = E_{\mathcal{P}}\left\{\langle \kappa, \rho_T\rangle + \int_0^T \langle \pi(r, ., u_r), \rho_r\rangle dr\right\}. \tag{3.1}$$

Since $\rho_t = \nu_t \mu_t$, we also have the representation

$$J(u) = E_{\mathcal{P}}\left\{\nu_T \mu_T(\kappa) + \int_0^T \nu_r \mu_r(\pi^u(r)) dr\right\}, \tag{3.2}$$

where $\pi^u(t) \overset{\triangle}{=} \pi(t, x, u)$.

Suppose $u^* \in U_{ad}$ is an optimal control. For any other control $u \in U_{ad}$ and for $\epsilon \in [0,1]$, we know that

$$u_t^\epsilon = u_t^* + \epsilon(u_t - u_t^*) \in U$$

and

$$J(u^\epsilon) \geq J(u^*).$$

In addition, if the Gâteaux derivative of $J(u)$ as a functional on the Hilbert space $L_y^2((0,T); R^k)$ is well defined, then by differentiating with respect to ϵ we obtain

$$\frac{d}{d\epsilon} J(u^\epsilon)|_{\epsilon=0} \geq 0 \ \forall u \in U_{ad}.$$

In the following, we assume for convenience that $u \in U_{ad}$ is such that

$$u^\delta = u^* + \delta u \in U_{ad}, \ \ \delta \in [0, \alpha].$$

As a result of the decomposition (2.18) and (2.19), any control variation $u^\delta \in U_{ad}$ would affect only the measure-valued process ν_t. Indeed, it is clear that the right side of (2.18) does not contain the control variable because $M_k(t), 1 \leq k \leq d$, as defined by (2.14), is independent of u. Thus the solution measure μ_t of (2.18) is not affected by control variations (see Kunita [13, 15] and Bensoussan [2]).

Let us now introduce the equation

$$\rho_t^{\mathcal{B}}(\tilde{f}) = \int_0^t \rho_r \left(\frac{\partial}{\partial u} L^{u^*}(r) u_r \tilde{f} \right) dr + \int_0^t \rho_r^{\mathcal{B}}(L^{u^*}(r)\tilde{f}) dr + \sum_{k=1}^d \int_0^t \rho_r^{\mathcal{B}}(M_k(r)\tilde{f}) \circ dy_r^k, \tag{3.3}$$

which is obtained by formally considering weak control variations of (2.12). Next, we shall show that the solution $\rho_t^{\mathcal{B}}$ of (3.3) can also be represented by the composition $\rho_t^{\mathcal{B}} = z_t \mu_t$, where z is given by (3.4).

LEMMA 3.1. *Let $\mu_t^{-1}(\cdot)(x, y)$ be the inverse operator of $\mu_t(\cdot)(x, y)$. Then $\rho_t^{\mathcal{B}}$ is the solution to* (3.3) *if and only if*

$$z_t(\tilde{f}) = \rho_t^{\mathcal{B}}(\mu_t^{-1}(\tilde{f}))$$

is the solution of

$$\frac{\partial}{\partial t} z_t(\tilde{f}) = z_t(\mu_t L^{u^*}(t) \mu_t^{-1} \tilde{f}) + \nu_t \left(\mu_t \frac{\partial}{\partial u} L^{u^*}(t) u_t \mu_t^{-1} \tilde{f} \right), \quad \lim_{t \downarrow 0} z_t = 0. \tag{3.4}$$

Proof. Suppose $\rho_t^{\mathcal{B}}$ is the solution to (3.3). We shall show that $z_t(\tilde{f}) = \rho_t^{\mathcal{B}}(\mu_t^{-1}(\tilde{f}))$ is a solution to (3.4). By (2.21), the inverse operator $\mu_{s,t}^{-1}$ is given by

$$\mu_{s,t}^{-1}(\tilde{f}) = \tilde{f}(n_{s,t}^{-1}(x)) \exp \left\{ - \sum_{k=1}^d \int_s^t h_k(r, n_{r,t}^{-1}(x)) \circ \hat{d}\, y_r^k \right\}, \tag{3.5}$$

where $n_{s,t}^{-1}$ (which is one-to-one and onto, and $C^\infty(R^n)$ a.s. for each t) is the inverse process of $n_{s,t}$ which is the solution of (2.20) starting at $n_{s,s} = x$. Letting $\tilde{n}_{s,t}, s \in [0, t]$, be the solution of the backward stochastic differential equation

$$d\tilde{n}_{s,t} = \sum_{k=1}^d Y_k(s, \tilde{n}_{s,t}) \circ \hat{d}\, y_s^k, \ \ \tilde{n}_{t,t} = x,$$

from Kunita [13, 15] we have $n_{s,t}^{-1} = \tilde{n}_{s,t}$. Applying the Ito differential rule to $\tilde{f}(\tilde{n}_{s,t}(x))\phi_{s,t}^{-1}(x)$, which is the right side of (3.5), it follows that

$$\begin{aligned} \tilde{f}(\tilde{n}_{s,t}(x))\phi_{s,t}^{-1}(x) = \tilde{f}(x) &- \sum_{k=1}^d \int_s^t Y_k(r) \tilde{f}(\tilde{n}_{r,t}(x)) \phi_{r,t}^{-1}(x) \circ \hat{d} y_r^k \\ &- \sum_{k=1}^d \int_s^t h_k(r) \tilde{f}(\tilde{n}_{r,t}(x)) \phi_{r,t}^{-1}(x) \circ \hat{d} y_r^k. \end{aligned}$$

Interchanging the forward and backward variables of integration (see Kunita [8, Part II]) and setting $s = 0, \tilde{n}_t = \tilde{n}_{0,t}$ we arrive at

$$\mu_t^{-1}(\tilde{f}) = \tilde{f}(x) - \sum_{k=1}^{d} \int_0^t M_k(r)\mu_r^{-1}(\tilde{f}) \circ dy_r^k. \tag{3.6}$$

Applying the result of Kunita [11, Lemma 6.2.7, Theorem 6.2.8, pp. 312–313] to $\tilde{z}_t(\tilde{f}) = \rho_t^{\mathcal{B}}(\mu_t^{-1}(\tilde{f}))$, we have

$$\begin{aligned} d\tilde{z}_t(\tilde{f}) &= d[\rho_t^{\mathcal{B}}(\mu_t^{-1}(\tilde{f}))] \\ &= \rho_t\left(\frac{\partial}{\partial u} L^{u^*}(t) u_t \mu_t^{-1}\tilde{f}\right) dt + \rho_t^{\mathcal{B}}(L^{u^*}(t)\mu_t^{-1}\tilde{f})dt \\ &\quad + \sum_{k=1}^{d} \rho_t^{\mathcal{B}}(M_k(t)\mu_t^{-1}\tilde{f}) \circ dy_t^k - \sum_{k=1}^{d} \rho_t^{\mathcal{B}}(M_k(t)\mu_t^{-1}\tilde{f}) \circ dy_t^k \\ &= \nu_t\mu_t\left(\frac{\partial}{\partial u} L^{u^*}(t) u_t \mu_t^{-1}\tilde{f}\right) dt + \tilde{z}_t(\mu_t L^{u^*}(t)\mu_t^{-1}\tilde{f})dt, \end{aligned}$$

where the second equality follows by substituting $\nu_t\mu_t$ for ρ_t and using the fact that μ_t is a one-to-one and onto map. The sufficiency can be shown similarly by letting $z_t(\tilde{f})$ be the solution of (3.4) and applying Ito's extended formula to the composition $\tilde{\rho}_t^{\mathcal{B}} = z_t\mu_t(\tilde{f})$, where $\mu_t(\tilde{f})$ is the solution to (2.18). □

Write (3.4) in the strong form (by integrating by parts):

$$\frac{\partial}{\partial t} z_t = L_{w^y}^{u^*}(t)^* z_t + \frac{\partial}{\partial u} L_{w^y}^{u^*}(t)^* \nu_t u_t, \ \lim_{t\downarrow 0} z_t = 0. \tag{3.7}$$

From (2.10), (2.11) we obtain

$$\frac{\partial}{\partial u} L^u(t)^*\tilde{f} = -\sum_{i=1}^{n} \frac{\partial}{\partial x_i}\left(\frac{\partial}{\partial u} f^i(t,x,u)\tilde{f}\right).$$

Since $\frac{\partial}{\partial u} f^i(t,x,u)$ is bounded and continuous in u, then for $\tilde{f} \in H(R^n)$ we have

$$\frac{\partial}{\partial u} L^u(t)^*\tilde{f} \in \mathcal{L}(R^k; \mathcal{L}(H(R^n); H^{-1}(R^n))).$$

In addition, since U is compact, we also have

$$\frac{\partial}{\partial u} L^u(t)^*\rho_t u_t \in L_y((0,T); H^{-1}(R^n)).$$

Recall that $L_{w^y}^u(t)$ can be represented by

$$L_{w^y}^u(t) = \frac{1}{2}\sum_{i,j=1}^{n} \alpha_{w^y}^{i,j}(t,x)\frac{\partial^2}{\partial x^i \partial x^j} + \sum_{i=1}^{n} b_{w^y}^i(t,x,u)\frac{\partial}{\partial x^i} + d_{w^y}(t,x,u),$$

where the coefficients are a.s. smooth and bounded. Consequently,

$$\frac{\partial}{\partial u} L_{w^y}^u(t)\tilde{f} = \frac{\partial}{\partial u}\left(\sum_{i=1}^{n} b_{w^y}^i(t,x,u)\frac{\partial}{\partial x^i} + d_{w^y}(t,x,u)\right)\tilde{f},$$

and by Lemma 2.3 we deduce that for any w^y,

$$\frac{\partial}{\partial u} L_{w^y}^{u^*}(t)^* \nu_t u_t \in L^2((0,T); H^{-1}(R^n)).$$

Thus, by Lemma 2.3, we conclude that for each w^y there exists one and only one solution to (3.7) in the space

$$z(\cdot) \in L_y^2((0,T); H^1(R^n)),\ \frac{\partial}{\partial t} z(\cdot) \in L_y^2((0,T); H^{-1}(R^n)).$$

In view of Lemma 3.1 we also conclude existence and uniqueness of solutions $\rho_t^{\mathcal{B}}$ corresponding to (3.3).

Lemma 3.2. *Suppose u^*, u are admissible. Then there exists one and only one solution of* (3.3) *(in the strong sense) in the space*

$$\rho^{\mathcal{B}} \in L_y^2((0,T); H^1(R^n)) \cap L^2(\Omega^y, \mathcal{F}_t^y, \mathcal{P}^y; C((0,T); H(R^n))).$$

Proof. The proof follows from the above construction and Lemma 3.1, or by applying the variational methods to (3.3) using the compactness of U. □

Lemma 3.3. *Suppose ν_t^δ denotes the solution to* (2.19) *when control u^δ is used and ν_t denotes its solution when control u^* is used. Then*

$$\sup_{0 \le t \le T} E_{\mathcal{P}^y} \left| \frac{\nu_t^\delta - \nu_t}{\delta} - z_t \right|^2 \to 0 \ as\ \delta \to 0.$$

Proof. Set $\tilde{\nu}_t^\delta = \frac{\nu_t^\delta - \nu_t}{\delta} - z_t$, where ν_t^δ, ν_t, z_t are solutions of the corresponding equations expressed in strong form. Clearly, the proof is complete if we can show that

$$\sup_{0 \le t \le T} E_{\mathcal{P}^y} |\tilde{\nu}_t^\delta|^2 \to 0 \ as\ \delta \to 0,$$

and thus it is sufficient to show that

$$\sup_{0 \le t \le T} E_{\mathcal{P}^y} |\tilde{\nu}_t^\delta \mu_t|^2 \to 0 \ as\ \delta \to 0.$$

From the above definition of $\tilde{\nu}_t^\delta$ we also have

$$\tilde{\nu}_t^\delta(\tilde{f}) = \frac{\nu_t^\delta(\tilde{f}) - \nu_t(\tilde{f})}{\delta} - z_t(\tilde{f}),$$

and, as a direct consequence, we obtain

$$\tilde{\nu}_t^\delta(\tilde{f}) = \int_0^t \tilde{\nu}_r^\delta(\mu_r L^{u^*+\delta u}(r) \mu_r^{-1} \tilde{f}) dr + \int_0^t z_r(\mu_r [L^{u^*+\delta u}(r) - L^{u^*}(r)] \mu_r^{-1} \tilde{f}) dr$$
$$+ \delta \int_0^t \nu_r \left(\mu_r \left[L^{u^*+\delta u}(r) - L^{u^*}(r) - \delta \frac{\partial}{\partial u} L^{u^*}(r) u_r \right] \mu_r^{-1} \tilde{f} \right) dr.$$

Integration by parts yields

$$\tilde{\nu}_t^\delta(\tilde{f}) = \int_0^t \tilde{\nu}_r^\delta(\mu_r L^{u^*+\delta u}(r) \mu_r^{-1} \tilde{f}) dr$$
$$+ \int_0^t \int_0^1 d\lambda \nu_r \left(\mu_r \left[\frac{\partial}{\partial u} L^{u^*+\lambda\delta u}(r) - \frac{\partial}{\partial u} L^{u^*}(r) \right] \mu_t^{-1} \tilde{f} \right) u_r dr$$
$$+ \delta \int_0^t \int_0^1 d\lambda z_r \left(\mu_r \frac{\partial}{\partial u} L^{u^*+\lambda\delta u}(r) \mu_r^{-1} \tilde{f} \right) u_r dr.$$

Denote by $\rho_t^\delta(\tilde{f})$ the solution to (2.12) corresponding to control $u^\delta \in U_{ad}$. From section 2.3 and Lemma 3.1, we now have

$$\rho_t^\delta = \nu_t^\delta \mu_t,\ \tilde{\rho}_t^\delta = \tilde{\nu}_t^\delta \mu_t,\ \tilde{\nu}_t^\delta \mu_t = \frac{\nu_t^\delta \mu_t - \nu_t \mu_t}{\delta} - z_t \mu_t.$$

Thus

$$\tilde{\rho}_t^\delta(\tilde{f}) = \int_{R^n} \tilde{f}(z)\tilde{\rho}_t^\delta(x,z)dz = \int_{R^n} \tilde{\nu}_t^\delta(x,z)\tilde{f}(n_{0,t}(z))\phi_{0,t}(z)dz,$$

where $\phi_{0,t}$ is the exponential term in (2.21). It is now a matter of simple algebra to show that

$$\begin{aligned} d\tilde{\rho}_t^\delta = L^{u^*+\delta u}(t)^* \tilde{\rho}_t^\delta dt &+ \int_0^1 d\lambda \left[\frac{\partial}{\partial u} L^{u^*+\lambda\delta u}(t)^* - \frac{\partial}{\partial u} L^{u^*}(t)^* \right] \rho_t u_t dt \\ &+ \delta \int_0^1 d\lambda \frac{\partial}{\partial u} L^{u^*+\lambda\delta u}(t)^* \rho_t^{\mathcal{B}} u_t dt + \sum_{k=1}^d M_k(t)^* \tilde{\rho}_t^\delta \circ dy_t^k. \end{aligned}$$

Rewriting the Stratonovich stochastic integral in terms of the Ito stochastic integral and using the equality

$$\frac{\partial}{\partial u} L^{u^*+\lambda\delta u}(t) = \frac{\partial}{\partial u}\left(A^{u^*+\lambda\delta u}(t) - \frac{1}{2}M_k(t)^2 \right) = \frac{\partial}{\partial u} A^{u^*+\lambda\delta u}(t),$$

we now obtain

$$\begin{aligned} d\tilde{\rho}_t^\delta = A^{u^*+\delta u}(t)^* \tilde{\rho}_t^\delta dt &+ \int_0^1 d\lambda \left[\frac{\partial}{\partial u} A^{u^*+\lambda\delta u}(t)^* - \frac{\partial}{\partial u} A^{u^*}(t)^* \right] \rho_t u_t dt \\ &+ \delta \int_0^1 d\lambda \frac{\partial}{\partial u} A^{u^*+\lambda\delta u}(t)^* \rho_t^{\mathcal{B}} u_t dt + \sum_{k=1}^d M_k(t)^* \tilde{\rho}_t^\delta dy_t^k. \end{aligned}$$

Applying the Ito differential rule to $|\tilde{\rho}_t^\delta|^2$ we deduce the energy equation

$$\begin{aligned} |\tilde{\rho}_t^\delta|^2 = 2 &\int_0^t \langle A^{u^*+\delta u}(r)\tilde{\rho}_r^\delta, \tilde{\rho}_r^\delta \rangle dr \\ &+ 2\int_0^t \left\langle \tilde{\rho}_r^\delta, \int_0^1 d\lambda \left[\frac{\partial}{\partial u} A^{u^*+\lambda\delta u}(r)^* - \frac{\partial}{\partial u} A^{u^*}(r)^* \right] \rho_r \right\rangle u_r dr \\ &+ 2\delta \int_0^t \left\langle \tilde{\rho}_r^\delta, \int_0^1 d\lambda \frac{\partial}{\partial u} A^{u^*+\lambda\delta u}(r)^* \rho_r^{\mathcal{B}} \right\rangle u_r dr \\ &+ \sum_{k=1}^d \int_0^t |M_k(r)^* \tilde{\rho}_r^\delta|^2 dr + \sum_{k=1}^d \int_0^t (\tilde{\rho}_r^\delta, M_k(r)^* \tilde{\rho}_r^\delta) dy_r^k. \end{aligned}$$

Using the coercivity condition (assumption (A8)) in the above equation and proceeding as in Bensoussan [2, Lemma 8.2.1], we deduce the estimate

$$\sup_{0\le t\le T} E_{\mathcal{P}^y} |\tilde{\rho}_t^\delta|^2 \to 0 \ as\ \delta \to 0.$$

Finally, since $\tilde{\rho}_t^\delta = \tilde{\nu}_t^\delta \mu_t$, we have the desired results. □

The next step is to establish the differentiability of $J(u)$ as a function on the Hilbert space $L^2_y([0,T];R^k)$.

LEMMA 3.4. *The cost function $J(u)$ is Gâteaux differentiable and*

$$\begin{aligned}(3.8)\quad J^{u^\delta} &\triangleq \frac{d}{d\delta}J(u^*+\delta u)|_{\delta=0}\\ &= E_{\mathcal{P}^y}\left\{z_T\mu_T(\kappa(x))+\int_0^T\left[z_r\mu_r(\pi^{u^*}(r))+\nu_r\mu_r\left(\frac{\partial}{\partial u}\pi^{u^*}(r)u_r\right)\right]dr\right\}.\end{aligned}$$

Proof. Suppose we set $\hat{J}$ to be equal to the right side of (3.8), and $\nu^\delta_t=\delta\tilde{\nu}^\delta_t+\delta z_t+\nu_t$; then

$$\begin{aligned}\frac{1}{\delta}\{J(u^*+\delta u)-J(u^*)\} &= E_{\mathcal{P}^y}\int_0^T\left\{\tilde{\nu}^\delta_r\mu_r\left(\pi^{u^*+\delta u}(r)-\pi^{u^*}(r)-\delta\frac{\partial}{\partial u}\pi^{u^*}(r)u(r)\right)\right\}dr\\ &\quad+E_{\mathcal{P}^y}\int_0^T\{z_r\mu_r(\pi^{u^*+\delta u}(r)-\pi^{u^*}(r))\}dr\\ &\quad+E_{\mathcal{P}^y}\int_0^T\tilde{\nu}^\delta_r\mu_r(\pi^{u^*+\delta u}(r))dr.\end{aligned}$$

Letting δ tend to zero, we notice that the first and second terms of the right side of the previous expression tend to zero due to assumption (A5). The last term also tends to zero by Lemma 3.3. □

4. Necessary conditions.

The perturbed process z_t satisfying (3.4) and the variational cost (3.8) can be viewed as the analogue of the deterministic variational problem given by Fleming and Rishel [16, Theorem 10.2, p. 38 and Theorem 11.1, p. 41] as follows. Suppose we introduce the new equation

$$(4.1)\quad \frac{\partial}{\partial t}P_t(x)=-(\mu_tL^{u^*}(t)\mu_t^{-1})P_t(x)-\mu_t(\pi^{u^*}(t))(x),\ \lim_{t\uparrow T}P_t(x)=\mu_T(\kappa)(x),$$

where $\mu_t(\pi^{u^*}(t))$ corresponds to the integral cost and $\mu_T(\kappa)$ corresponds to the terminal cost.

LEMMA 4.1. *Let $\mu_t^{-1}(\cdot)(x,y)$ be the inverse operator of $\mu_t(\cdot)(x,y)$. Then $\tilde{q}_t=\mu_t^{-1}P_t$ is a solution of*

$$d\tilde{q}_t=-L^{u^*}(t)\tilde{q}_tdt-\pi^{u^*}(t)dt-\sum_{k=1}^d M_k(t)\tilde{q}_t\circ dy^k_t,\lim_{t\uparrow T}\tilde{q}_t=\kappa.$$

Moreover, there exists one and only one solution

$$\tilde{q}_t(\cdot)\in L^2_y((0,T);H^1(R^n))\cap L^2(\Omega,\mathcal{F}_{0,t},\mathcal{P};C((0,T);H))$$

such that the preceding equation holds.

Proof. The first part is obtained as in Lemma 3.1, using (3.6). The second part follows from the variational methods of section 2.4. □

If $\pi^{u^*}(t)$ is set to zero, the evaluation of $z_T(P_T)$, using (4.1) and the homogeneous part of (3.4) (e.g., with the second term on the right side of (3.4) set to zero), yields $z_T\mu_T(\kappa)$ (see Kunita [11, Lemma 6.2.7, p. 312]). Comparing (3.4) and (4.1), we have the following result by an application of Kunita [11, Lemma 6.2.7, Theorem 6.2.8, pp. 312–313].

LEMMA 4.2. *The variational cost of Lemma* 3.4 *is given by*

$$J^{u^\delta} = E_{\mathcal{P}^y}\left\{\sum_{j=1}^{k}\int_0^T u_t^j \int_{R^n}\left[\frac{\partial}{\partial u^j}L^{u^*}(t)\tilde{P}_t(x) + \frac{\partial}{\partial u^j}\pi^{u^*}(t)\right]\rho_t(x)dxdt\right\}, \tag{4.2}$$

where $\tilde{P}_t(x) \overset{\triangle}{=} \mu_t^{-1}P_t(x)$.

Proof. Applying the Ito formula given by Kunita [11, Lemma 6.2.7, Theorem 6.2.8, pp. 312–313] to $z_t(P_t)$ gives

$$\begin{aligned} z_T(P_T) &= z_0(P_0) + \int_0^T z_t(\mu_t L^{u^*}(t)\mu_t^{-1}P_t)dt + \int_0^T \nu_t\left(\mu_t\frac{\partial}{\partial u}L^{u^*}(t)u_t\mu_t^{-1}P_t\right)dt \\ &\quad - \int_0^T z_t(\mu_t L^{u^*}(t)\mu_t^{-1}P_t)dt - \int_0^T z_t(\mu_t\pi^{u^*}(t))dt \\ &= \int_0^T\left[\nu_t\mu_t\left(\frac{\partial}{\partial u}L^{u^*}(t)u_t\mu_t^{-1}P_t\right) - z_t(\mu_t\pi^{u^*}(t))\right]dt. \end{aligned} \tag{4.3}$$

Substituting (4.3) into the variational cost of Lemma 3.4 (using $z_T(P_T) = z_T(\mu_T\kappa(x))$) gives

$$J^{u^\delta} = E_{\mathcal{P}^y}\left\{\int_0^T\left[\nu_t\left(\mu_t\frac{\partial}{\partial u}L^{u^*}(t)u_t\mu_t^{-1}P_t\right) + \nu_t\mu_t\left(\frac{\partial}{\partial u}\pi^{u^*}(t)u_t\right)\right]dt\right\}.$$

Replacing $\nu_t\mu_t$ by ρ_t, and setting $\tilde{P}_t = \mu_t^{-1}P_t$, we recover (4.2) (since for each $t \in [0,T], u_t$ is $\mathcal{F}_t^y$-measurable). □

We now have the following necessary conditions of optimality.

THEOREM 4.3. *Suppose* u_t^* *is optimal for the control problem with cost function* (3.1) *and state* ρ_t *satisfying* (2.12). *Then there exists a process* $\overset{\wedge}{P_t}(x)$ *such that the condition*

$$\sum_{j=1}^{k}(u_t^j - u_t^{*j})\left\{\int_{R^n}\left[\frac{\partial}{\partial u^j}\pi(t,x,u_t^*) + \frac{\partial}{\partial u^j}L^{u^*}(t)\overset{\wedge}{P_t}(x)\right]\rho_t(x)dx\right\} \geq 0 \tag{4.4}$$

holds for all $u \in U_{ad}$ *a.e., on* $t \in [0,T]$ *a.s., where* $\overset{\wedge}{P_t}(x) = \mu_t^{-1}E_{\mathcal{P}^w}(P_t(x))$. *The Hamiltonian* $H_t(\rho_t, \overset{\wedge}{P_t}, u_t)$ *is given by*

$$\frac{\partial}{\partial u}H_t(\rho_t,\overset{\wedge}{P_t},u_t) = \frac{\partial}{\partial u}\int_{R^n}[\pi(t,x,u_t) + \tilde{X}^u(t)\overset{\wedge}{P_t}(x)]\rho_t(x)dx.$$

Proof. We start by using the conditional optimality given by Striebel [17, Chapter 4] which states that whenever $u \in U_{ad}$ is conditionally optimal, it is also optimal; see Bensoussan and van Schuppen [18, Definition 2.1]. Thus, by Lemma 4.2,

$$J^{u^\delta} = E_{\mathcal{P}^y}\left\{\int_0^T\int_{R^n}\left[\frac{\partial}{\partial u}L^{u^*}(t)\mu_t^{-1}P_t(x) + \frac{\partial}{\partial u}\pi^{u^*}(t)\right]\rho_t(x)dxu_tdt\right\}$$

and, by reconditioning on $\mathcal{F}_t^y$,

$$J^{u^\delta} = E_{\mathcal{P}^y}\left\{E_{\mathcal{P}^w}\int_0^T\int_{R^n}\left[\frac{\partial}{\partial u}L^{u^*}(t)\mu_t^{-1}P_t(x) + \frac{\partial}{\partial u}\pi^{u^*}(t,x)\right]\rho_t(x)dxu_tdt\right\},$$

where $E_{\mathcal{P}^w}$ is nothing more than the conditional expectation $E(\cdot|\mathcal{F}_t^y)$. However, since ρ_t and μ_t^{-1} are $\mathcal{F}_t^y$-adapted, we apply the result in Kunita [7, Lemma 4] twice and obtain

$$J^{u^\delta} = E_{\mathcal{P}^y}\left\{\int_0^T\int_{R^n}\left[\frac{\partial}{\partial u}L^{u^*}(t)\mu_t^{-1}E_{\mathcal{P}^w}(P_t(x)) + \frac{\partial}{\partial u}\pi^{u^*}(t)\right]\rho_t(x)dxu_tdt\right\}.$$

Since u^* is optimal and admissible for any other control $u \in U_{ad}$ and $\epsilon \in [0,1]$, we have $u_t^* + \epsilon(u_t - u_t^*) \in U$ (i.e., admissible) and, therefore,

$$J(u^* + \epsilon(u-u^*)) \geq J(u^*).$$

Thus, by the Gâteaux differentiability of $J(u)$ (as a function on the Hilbert space $L_y^2([0,T];R^k)$),

$$\begin{aligned}&\frac{d}{d\epsilon}J(u^* + \epsilon(u-u^*))|_{\epsilon=0}\\ &= E_{\mathcal{P}^y}\left\{\sum_{j=1}^d\int_0^T(u_t^j - u_t^{*j})\int_{R^n}\left[\frac{\partial}{\partial u^j}L^{u^*}(t)\mu_t^{-1}E_{\mathcal{P}^w}(P_t(x)) + \frac{\partial}{\partial u^j}\pi^{u^*}(t)\right]\rho_t(x)dxdt\right\}.\end{aligned}$$

Following the derivations presented in Fleming and Rishel [16, Theorem 11.2, p. 41], Bensoussan [10, Chapter VI, Theorem 1.2, pp. 232–234], or Bensoussan [1, Theorem 2.1], we deduce (4.4). □

Remark 4.1. Notice that the necessary condition of optimality established in Theorem 4.3 has as a special case the one given by Bensoussan [1, Theorem 2.1, equation (2.22)] or [2, Theorem 8.2.1, p. 279].

The next step is to determine a stochastic partial differential equation satisfied by the costate process $\overset{\wedge}{P_t}(x)$ identified in Theorem 4.3. To do so, we appeal to the martingale representation results of Bensoussan [1, Lemma 2.6]. Therefore, taking the expectation of (4.1) with respect to measure $\mathcal{P}^w$, we obtain

$$E_{\mathcal{P}^w}\frac{\partial}{\partial t}P_t(x) = E_{\mathcal{P}^w}\{-(\mu_tL^{u^*}(t)\mu_t^{-1})P_t(x) - \mu_t(\pi^{u^*}(t))\}.$$

But $E_{\mathcal{P}^w}[\mu_t(\pi^{u^*}(t))]$ is just $\mu_t(\pi^{u^*}(t))$, which follows from the representation

$$\mu_t\pi^{u^*}(t) = \pi(t, n_{0,t}(x), u_t^*)\exp\left\{\sum_{k=1}^d\int_0^t h_k(r, n_{0,r}(x))\circ dy_r^k\right\},$$

because $n_t(x)$ is the solution to (2.20) and is $\mathcal{F}_{0,t}^y$ measurable. Hence, one deduces

$$E_{\mathcal{P}^w}\frac{\partial}{\partial t}P_t(x) = -(\mu_tL^{u^*}(t)\mu_t^{-1})E_{\mathcal{P}^w}P_t(x) - \mu_t(\pi^{u^*}(t)). \tag{4.5}$$

Define $\bar{P}_t(x) = E_{\mathcal{P}^w}(P_t(x))$; from the martingale representation theorem given in Bensoussan [1, Lemma 2.6],

$$d\bar{P}_t(x) = [-(\mu_t L^{u^*}(t)\mu_t^{-1})\bar{P}_t(x) - \mu_t(\pi^{u^*}(t))]dt - \sum_{k=1}^{d} r_t^k dy_t^k, \tag{4.6}$$

where $\{r_s^k, 0 \leq s \leq t\}, 1 \leq k \leq d$, is a square integrable $\mathcal{F}_t^y$-adapted process. However, since μ_t is a one-to-one and onto map, we can define a new process $\tilde{r}_t^k \overset{\triangle}{=} \mu_t^{-1} r_t^k, 1 \leq k \leq d$, so that the martingale term in (4.6) can be written as

$$\sum_{k=1}^{d} r_t^k dy_t^k = \sum_{k=1}^{d} \mu_t(\tilde{r}_t^k) dy_t^k.$$

Suppose $\tilde{r}_t^k$ is in the domain of $M_k(t), 1 \leq k \leq d$, and that $\tilde{r}_t^k$ is absolutely continuous with respect to t, $1 \leq k \leq d$. Then we can represent the Ito stochastic integral in terms of the Stratonovich stochastic integral

$$\sum_{k=1}^{d} \mu_t(\tilde{r}_t^k) dy_t^k = \sum_{k=1}^{d} \mu_t(\tilde{r}_t^k) \circ dy_t^k - \frac{1}{2}\sum_{k=1}^{d} \mu_t(M_k(t)\tilde{r}_t^k)dt.$$

Therefore, (4.6) becomes

$$d\bar{P}_t(x) = -(\mu_t L^{u^*}(t)\mu_t^{-1})\bar{P}_t(x)dt - \mu_t(\pi^{u^*}(t))dt + \frac{1}{2}\sum_{k=1}^{d} \mu_t(M_k(t)\tilde{r}_t^k)dt - \sum_{k=1}^{d} \mu_t(\tilde{r}_t^k) \circ dy_t^k. \tag{4.7}$$

LEMMA 4.4. *Suppose $\tilde{r}_t^k$ is in the domain of $M_k(t), 1 \leq k \leq d$, and that $\tilde{r}_t^k$ is absolutely continuous with respect to t, $1 \leq k \leq d$. $(\overset{\wedge}{P_t}(x), \{\tilde{r}_t^k\}_{k=1}^d)$ is a solution to*

$$\begin{aligned} d\overset{\wedge}{P_t}(x) = -L^{u^*}(t)\overset{\wedge}{P_t}(x)dt - \pi^{u^*}(t)dt - \sum_{k=1}^{d} \tilde{r}_t^k \circ dy_t^k + \frac{1}{2}\sum_{k=1}^{d} M_k(t)\tilde{r}_t^k dt \\ - \sum_{k=1}^{d} M_k(t)\overset{\wedge}{P_t}(x) \circ dy_t, \end{aligned} \tag{4.8}$$

$$\lim_{t \uparrow T} \overset{\wedge}{P_t}(x) = \kappa(x), \tag{4.9}$$

if and only if $\bar{P}_t'(x) = \mu_t \overset{\wedge}{P_t}(x)$ is a solution of (4.7).

Proof. Here we shall follow the proof given by Kunita [11, Lemma 6.2.3, p. 307]. First set $\bar{P}_t' = \mu_t \overset{\wedge}{P_t}$, where $\overset{\wedge}{P_t}$ is the solution to (4.8). From (2.18),

$$\bar{P}_t'(x) = \overset{\wedge}{P_t}(n_{0,t}(x))\phi_{0,t}(x), \ \phi_{0,t}(x) = \exp\left\{\sum_{k=1}^{d}\int_0^t h_k(r, n_{0,r}(x)) \circ dy_r^k\right\},$$

where n_t is the solution to (2.20). By the Stratonovich version of the extended Ito formula

$$d[\overset{\wedge}{P_t}(n_{0,t}(x))\phi_{0,t}(x)] = \Bigg\{ - L^{u^*}(t)\overset{\wedge}{P_t}(n_{0,t}(x))dt - \pi^{u^*}(t, n_{0,t}(x))dt$$

$$
\begin{aligned}
&-\sum_{k=1}^{d}\tilde{r}_t^k(n_{0,t}(x))\circ dy_t^k\\
&+\frac{1}{2}\sum_{k=1}^{d}M_k(t)\tilde{r}_t^k(n_{0,t}(x))dt-\sum_{k=1}^{d}M_k(t)\hat{P}_t(n_{0,t}(x))\circ dy_t^k\\
&+\sum_{i=1}^{n}\frac{\partial}{\partial x^i}\hat{P}_t(n_{0,t}(x))\circ dn_{0,t}^i(x)\\
&+\hat{P}_t(n_{0,t}(x))\sum_{k=1}^{d}h_k(t,n_{0,t}(x))\circ dy_t^k\Bigg\}\phi_{0,t}(x).
\end{aligned}
$$

Substituting

$$
\sum_{i=1}^{n}\frac{\partial}{\partial x^i}\hat{P}_t(n_{0,t}(x))\circ dn_{0,t}^i(x)=\sum_{k=1}^{d}\sum_{i=1}^{n}Y_k^i(t,n_{0,t}(x))\frac{\partial}{\partial x^i}\hat{P}_t(n_{0,t}(x))\circ dy_t^k
$$

into the previous equation, the fifth term cancels the sixth and seventh terms. As a consequence,

$$
\begin{aligned}
d[\hat{P}_t(n_{0,t}(x))\phi_{0,t}(x)]&=d\bar{P}_t'(x)\\
&=\Bigg\{-L^{u^*}(t)\hat{P}_t(n_{0,t}(x))dt-\pi^{u^*}(t,n_{0,t}(x))dt\\
&\quad-\sum_{k=1}^{d}\tilde{r}_t^k(n_{0,t}(x))\circ dy_t^k+\frac{1}{2}\sum_{k=1}^{d}M_k(t)\tilde{r}_t^k(n_{0,t}(x))dt\Bigg\}\phi_{0,t}(x)\\
&=-(\mu_tL^{u^*}(t)\mu_t^{-1})\bar{P}_t'(x)dt-\mu(\pi^{u^*}(t))dt\\
&\quad-\sum_{k=1}^{d}\mu_t(\tilde{r}_t^k)\circ dy_t^k+\frac{1}{2}\sum_{k=1}^{d}\mu_t(M_k(t)\tilde{r}_t^k)dt.
\end{aligned}
$$

Therefore, $\bar{P}_t'(x)$ satisfies (4.7). Conversely, suppose $\bar{P}_t'(x)$ is a solution to (4.7). We can show similarly that

$$
\begin{aligned}
d[\mu_t^{-1}(\bar{P}_t')]=&-\sum_{k=1}^{d}M_k(t)\mu_t^{-1}(\bar{P}_t')\circ dy_t^k-L^{u^*}(t)\mu_t^{-1}(\bar{P}_t')dt-\pi^{u^*}(t)dt\\
&+\frac{1}{2}\sum_{k=1}^{d}M_k(t)\tilde{r}_t^kdt-\sum_{k=1}^{d}\tilde{r}_t^k\circ dy_t^k,
\end{aligned}
$$

and so $\mu_t^{-1}\bar{P}_t'(x)$ satisfies (4.8). □

We shall next derive the equation satisfied by the costate process $\hat{P}_t(x)$ when the stochastic integral is expressed in terms of an Ito stochastic integral, starting with (4.6), avoiding the transformation of Ito integrals to Stratonovich integrals, and using the assumptions of Lemma 4.4.

THEOREM 4.5. *The pair* $(\hat{P}_t(x),\{\tilde{r}_t^k\}_{k=1}^d)$ *describes the costate process which is a solution of the Ito equation*

$$
d\hat{P}_t(x)=-A^{u^*}(t)\hat{P}_t(x)dt+\sum_{k=1}^{d}M_k(t)^2\hat{P}_t(x)dt-\pi^{u^*}(t)dt+\sum_{k=1}^{d}M_k(t)\tilde{r}_t^kdt
$$

$$-\sum_{k=1}^{d} M_k(t) \hat{P}_t (x) dy_t^k - \sum_{k=1}^{d} \tilde{r}_t^k dy_t^k, \ \lim_{t \uparrow T} \hat{P}_t (x) = \kappa(x). \tag{4.10}$$

Furthermore, there exists one and only one pair

$$\hat{P} (\cdot) \in L_y^2((0,T); H^1(R^n)) \cap L^2(\Omega, \mathcal{F}_{0,t}, \mathcal{P}^y; C((0,T); H)),$$

$$\tilde{r}_t \in (L_y^2((0,T); H^{-1}(R^n)))^d,$$

such that (4.10) *holds.*

Proof. Using the definition of the adjoint process as given in Theorem 4.3, one way to show the validity of (4.10) is to apply the extended Ito formula to the composition $\mu_t \hat{P}_t (x)$, where $\hat{P}_t (x)$ satisfies (4.10), to show that (4.6) is recovered. Since the correlated case requires substantial algebra, let us first consider the uncorrelated case. Thus

$$\mu_t \hat{P}_t (x) = \exp \left\{ \sum_{k=1}^{d} \int_0^t h_k(s) dy_s^k \right\} \hat{P}_t (x),$$

where $\hat{P}_t$ is the solution to (4.10) when M_k is replaced by h_k. But the differential rule yields

$$\begin{aligned} d(\mu_t \hat{P}_t)(x) = \Bigg\{ & \left[-L^{u^*}(t) \hat{P}_t (x) + \frac{1}{2} \sum_{k=1}^{d} h_k(t)^2 \hat{P}_t (x) - \pi^{u^*}(t) + \sum_{k=1}^{d} h_k(t) \tilde{r}_t^k \right] dt \\ & - \sum_{k=1}^{d} h_k(t) \hat{P}_t \, dy_t^k - \sum_{k=1}^{d} \tilde{r}_t^k dy_t^k \\ & + \left[\sum_{k=1}^{d} h_k(t) dy_t^k \hat{P}_t (x) + \frac{1}{2} \sum_{k=1}^{d} h_k(t)^2 \hat{P}_t (x) \right] \\ & + \left[- \sum_{k=1}^{d} h_k(t)^2 \hat{P}_t (x) - \sum_{k=1}^{d} \tilde{r}_t^k h_k(t) \right] \Bigg\} \mu_t \end{aligned}$$

and, after cancellations, we obtain

$$d(\mu_t \hat{P}_t)(x) = -\mu_t (L^{u^*}(t) \hat{P}_t (x) - \pi^{u^*}(t)) dt - \sum_{k=1}^{d} \mu_t \tilde{r}_t^k dy_t^k.$$

Replacing $\hat{P}_t$ by $\mu_t^{-1} P_t$ and using $\tilde{r}_t^k = \mu_t^{-1} r_t^k$ we recover (4.6).

For the correlated case, notice also that μ_t satisfies the stochastic partial differential equation

$$d\mu_t(\tilde{f}) = \sum_{k=1}^{d} \mu_t(M_k(t)\tilde{f}) dy_t^k + \frac{1}{2} \sum_{k=1}^{d} \mu_t(M_k(t)^2 \tilde{f}) dt, \ \lim_{t \downarrow 0} \mu_t(\tilde{f}) = \tilde{f}(x),$$

which is the Ito form of (2.18). The solution of the above equation can be represented as

$$\begin{aligned}\mu_t(\tilde{f}) &= \tilde{f}(n_{0,t}(x)) \exp\left\{\sum_{k=1}^{d}\int_0^t h_k(r, n_{0,r}(x))dy_r^k + \frac{1}{2}\sum_{k=1}^{d}\int_0^t Y_k(r)h_k(r, n_{0,r}(x))dr\right\}\\ &= \tilde{f}(n_{0,t}(x))\phi_{0,t},\end{aligned}$$

where $n_{0,t}$ corresponds to the solution of

$$dn_t = \sum_{k=1}^{d} Y_k(t)dy_t^k + \sum_{k=1}^{d}\sum_{i=1}^{n} Y_k^i(t)\frac{\partial}{\partial x^i}Y_k(t)dt,\ n_0 = x.$$

Therefore,

$$\begin{aligned}d[\mu_t \hat{P}_t (x)] &= d[\hat{P}_t (n_{0,t}(x))\phi_{0,t}]\\ &= d \hat{P}_t (n_{0,t}(x))\phi_{0,t}+ \hat{P}_t (n_{0,t}(x))d\phi_{0,t} + d\langle \hat{P} (n(x)), \phi\rangle_t\\ &= \Bigg\{-A^{u^*}(t) \hat{P}_t (n_{0,t}(x))dt + \sum_{k=1}^{d} M_k(t)^2 \hat{P}_t (n_{0,t}(x))dt - \pi^{u^*}(t, n_{0,t}(x))dt\\ &\quad + \sum_{k=1}^{d} M_k(t)\tilde{r}_t^k(n_{0,t}(x))dt - \sum_{k=1}^{d} M_k(t) \hat{P}_t (n_{0,t}(x))dy_t^k\\ &\quad - \sum_{k=1}^{d} \tilde{r}_t^k(n_{0,t}(x))dy_t^k + \sum_{i=1}^{n}\frac{\partial}{\partial x^i} \hat{P}_t (n_{0,t}(x))dn_{0,t}^i(x)\\ &\quad + \frac{1}{2}\sum_{i,j=1}^{n}\frac{\partial^2}{\partial x^i\partial x^j} \hat{P}_t (n_{0,t}(x))d\langle n^i(x), n^j(x)\rangle_t\\ &\quad + \sum_{j=1}^{n} d\left\langle \frac{\partial}{\partial x^j} \hat{P} (n(x)), n^j(x)\right\rangle\Bigg\}\phi_{0,t}\\ &\quad + \Bigg\{\sum_{k=1}^{d} h_k(t) \hat{P}_t (n_{0,t}(x))dy_t^k + \frac{1}{2}\sum_{k=1}^{d} h_k(t)^2 \hat{P}_t (n_{0,t}(x))dt\\ &\qquad + \frac{1}{2}\sum_{k=1}^{d} Y_k(t)h_k(t) \hat{P}_t (n_{0,t}(x))dt\Bigg\}\phi_{0,t} + d\langle \hat{P} (n(x)), \phi\rangle_t.\end{aligned}$$

Furthermore,

$$A^{u^*}(t) = L^{u^*}(t) + \frac{1}{2}\sum_{k=1}^{d} M_k(t)^2,\ M_k(t)^2 = Y_k(t)^2 + h_k(t)^2 + Y_k(t)h_k(t) + 2h_k(t)Y_k(t),$$

$$\begin{aligned}&\sum_{i=1}^{n}\frac{\partial}{\partial x^i} \hat{P}_t (n_{0,t}(x))dn_{0,t}^i(x)\\ &\quad = \sum_{k=1}^{d}\left(Y_k(t) \hat{P}_t (n_{0,t}(x))dy_t^k + \frac{1}{2}\sum_{i,j=1}^{n} Y_k^i(t)\frac{\partial}{\partial x^i} \hat{P}_t (n_{0,t}(x))\frac{\partial}{\partial x^j}Y_k^j(t)dt\right),\end{aligned}$$

$$\frac{1}{2}\sum_{i,j=1}^{n}\frac{\partial^2}{\partial x^i \partial x^j}\overset{\wedge}{P_t}(n_{0,t}(x))d\langle n^i(x), n^j(x)\rangle_t$$

$$=\frac{1}{2}\sum_{k=1}^{d}\sum_{i,j=1}^{n}Y_k^i(t)Y_k^j(t)\frac{\partial^2}{\partial x^i \partial x^j}\overset{\wedge}{P_t}(n_{0,t}(x))dt,$$

$$\sum_{j=1}^{n}d\left\langle\frac{\partial}{\partial x^j}\hat{P}(n(x)), n^j(x)\right\rangle_t=-\sum_{k=1}^{d}Y_k(t)\tilde{r}_t^k(n_{0,t}(x))dt$$

$$-\sum_{k=1}^{d}(Y_k(t)^2+h_k(t)Y_k(t)+Y_k(t)h_k(t))\overset{\wedge}{P_t}(n_{0,t}(x))dt,$$

$$\phi_{0,t}^{-1}d\langle\hat{P}(n(x)),\phi\rangle_t=-\sum_{k=1}^{d}h_k(t)M_k(t)\overset{\wedge}{P_t}(n_{0,t}(x))dt$$

$$-\sum_{k=1}^{d}h_k(t)\tilde{r}_t^k(n_{0,t}(x))dt+\sum_{k=1}^{d}h_k(t)Y_k(t)\overset{\wedge}{P_t}(n_{0,t}(x))dt,$$

and, after some cancellations, we obtain

$$d[\overset{\wedge}{P_t}(n_{0,t}(x))\phi_{0,t}]=\left\{-L^{u^*}(t)\overset{\wedge}{P_t}(n_{0,t}(x))dt-\pi^{u^*}(t,n_{0,t}(x))dt\right.$$
$$\left.-\sum_{k=1}^{d}\tilde{r}_t^k(n_{0,t}(x))dy_t^k\right\}\phi_{0,t}$$
$$=-(\mu_t L^{u^*}(t)\mu_t^{-1})\bar{P}_t(x)dt-\mu_t\pi^{u^*}(t)dt-\sum_{k=1}^{d}\mu_t(\tilde{r}_t^k)dy_t^k.$$

Finally, by the definition of $\tilde{r}_t^k$, $\mu_t\tilde{r}_t^k=\mu_t\mu_t^{-1}r_t^k=r_t^k$, we arrive at (4.6) as desired. Uniqueness of the processes $\overset{\wedge}{P_t}$ and $\tilde{r}_t^k, 1\le k\le d$, follows if, with the help of the inner product $\langle\overset{\wedge}{P_t},\rho_t^{\mathcal{B}}\rangle$, the variational cost of Lemma 3.4 can be expressed as in (4.4); for a proof, see Bensoussan [2, Theorem 8.2.3]. □

Remark 4.2. Notice that the minimum principle given in Theorem 4.3 and the stochastic partial differential equation given in Theorem 4.5 ((4.10), costate equation) can be obtained through a more simplified approach that does not require the conditional optimality of Striebel [17, Chapter 20] and the martingale representation results of Bensoussan [1, Lemma 2.6]. To see this, suppose the process defined in (4.1) is replaced by q_t satisfying

$$dq_t(x)=-(\mu_t L^{u^*}(t)\mu_t^{-1})q_t(x)dt-\mu_t(\pi^{u^*}(t))dt-\sum_{k=1}^{d}\mu_t(\tilde{r}_t^k)dy_t^k,\ \lim_{t\uparrow T}q_t(\kappa(x))=\mu_T\kappa(x),$$
(4.11)

where, as before, $\bar{r}_t^k, 1 \leq k \leq d$, is an $\mathcal{F}_t^y$-adapted process. Similarly, as in (4.7), we can rewrite (4.11) in terms of the Stratonovich integral, which in differential form becomes

$$dq_t(x) = (\mu_t L^{u^*}(t)\mu_t^{-1})q_t(x)dt - \mu_t(\pi^{u^*}(t))dt - \sum_{k=1}^{d} \mu_t(\bar{r}_t^k) \circ dy_t^k + \frac{1}{2}\sum_{k=1}^{d} \mu_t(M_k(t)\bar{r}_t^k)dt \tag{4.12}$$

and is the same as (4.7). Therefore, if we define $\overset{\wedge}{q_t}(x) \triangleq \mu_t^{-1}(q_t)(x)$, then $\overset{\wedge}{q_t}(x)$ satisfies (4.8). It remains to show that if $\overset{\wedge}{q_t}(x)$ rather than $\overset{\wedge}{P_t}(x)$ is used in (4.4), the minimum principle of Theorem 4.3 can be established, thus implying that $\overset{\wedge}{q_t}(x)$ is the costate process. By the Ito formula,

$$\begin{aligned} z_T(q_T(x)) &= z_T\mu_T(\kappa(x)) \\ &= \int_0^T \left[\nu_t\mu_t\left(\frac{\partial}{\partial u}L^{u^*}(t)u_t\mu_t^{-1}q_t\right)dt - z_t\mu_t\pi^{u^*}(t)dt - \sum_{k=1}^{d} z_t\mu_t(\bar{r}_t^k)\circ dy_t^k \right. \\ &\qquad \left. + \frac{1}{2}\sum_{k=1}^{d} z_t\mu_t(M_k(t)\bar{r}_t^k)dt\right], \end{aligned}$$

and by substituting the above expression into the variational cost of Lemma 3.4, we obtain

$$\begin{aligned} J^{u^\delta} = E_{\mathcal{P}^y}\Bigg\{&\int_0^T \left[\nu_t\mu_t\left(\frac{\partial}{\partial u}L^{u^*}(t)u_t\mu_t^{-1}q_t\right) + \nu_t\mu_t\left(\frac{\partial}{\partial u}\pi^{u^*}(t)u_t\right)\right]dt \\ &+ \sum_{k=1}^{d}\int_0^T\left[-z_t\mu_t(\bar{r}_t^k)\circ dy_t^k + \frac{1}{2}\sum_{k=1}^{d} z_t\mu_t(M_k(t)\bar{r}_t^k)dt\right]\Bigg\}. \end{aligned}$$

Since $\rho_t^{\mathcal{B}} = z_t\mu_t$, then, by (3.3), the last two components of the right side of the previous expression correspond to an Ito integral; hence, using $\overset{\wedge}{q_t}(x) \triangleq \mu_t^{-1}q_t(x)$ and $\rho_t = \nu_t\mu_t$,

$$J^{u^\delta} = E_{\mathcal{P}^y}\left\{\int_0^T \left[\rho_t\left(\frac{\partial}{\partial u}L^{u^*}(t)u_t\overset{\wedge}{q_t}\right) + \rho_t\left(\frac{\partial}{\partial u}\pi^{u^*}(t)u_t\right)\right]dt - \sum_{k=1}^{d}\int_0^T \rho_t^{\mathcal{B}}(\bar{r}_t^k)dy_t^k\right\}.$$

But the martingale term of J^{u^δ} has zero expectation with respect to measure $\mathcal{P}^y$; therefore,

$$J^{u^\delta} = E_{\mathcal{P}^y}\left\{\int_0^T \left[\left\langle\frac{\partial}{\partial u}L^{u^*}(t)\overset{\wedge}{q_t}(x), \rho_t(x)\right\rangle + \left\langle\frac{\partial}{\partial u}\pi^{u^*}(t), \rho_t(x)\right\rangle\right]u_t dt\right\}. \tag{4.13}$$

However, from (4.12), the optimality condition (4.4) can be established, and the relation between $\bar{r}_t^k$ and r_t^k is given by $\bar{r}_t^k = \tilde{r}_t^k = \mu_t^{-1}r_t^k, 1 \leq k \leq d$.

5. Relation to previous work. Let us consider the stochastic control problem investigated by Bensoussan [1, 2], where $\sigma(x) \in R^n \otimes R^n, M_k = h_k, 1 \leq k \leq d$; that is, no correlation between the observation process and state process is allowed. Thus, the stochastic equation describing the unnormalized conditional density of nonlinear filtering becomes

$$d\rho_t + A_0 \rho_t dt = B^{u^*} \rho_t dt + \sum_{k=1}^{d} \rho_t h_k dy_t^k, \tag{5.1}$$

where

$$A_0 \tilde{f} = \frac{1}{2} \sum_{i,j=1}^{n} \frac{\partial}{\partial x^i} \left(a^{ij}(x) \frac{\partial \tilde{f}}{\partial x^j} \right),$$

$$B^{u^*} \tilde{f} = \sum_{i=1}^{n} \frac{\partial}{\partial x^i} (\alpha^i(x, u^*) \tilde{f}), \ \alpha^i(x, u^*) = -f^i(x, u^*) + \frac{1}{2} \sum_{j=1}^{n} \frac{\partial}{\partial x^j} a^{ij}(x).$$

It is easily seen that

$$L^{u^*,*} \tilde{f} = B^{u^*} \tilde{f} - A_0 \tilde{f} - \frac{1}{2} \sum_{k=1}^{d} h_k^2 \tilde{f}$$

and

$$\begin{aligned} \left\langle \overset{\wedge}{P_t} (x), \frac{\partial}{\partial u} L^{u^*,*} \rho_t(x) \right\rangle &= \left\langle \overset{\wedge}{P_t} (x), - \sum_{i=1}^{n} \frac{\partial}{\partial x^i} \left(\frac{\partial}{\partial u} f^i(x, u^*) \rho_t \right) \right\rangle \\ &= \left\langle \sum_{i=1}^{n} \frac{\partial}{\partial x^i} \overset{\wedge}{P_t} (x) \frac{\partial}{\partial u} f^i(x, u^*), \rho_t(x) \right\rangle, \end{aligned} \tag{5.2}$$

which implies the following.

THEOREM 5.1. *If the unnormalized conditional density of nonlinear filtering satisfies* (5.1)*, then the minimum principle of Theorem* 4.3 *is given by*

$$\sum_{j=1}^{k} (u_t^j - u_t^{*j}) \left\{ \int_{R^n} \left[\frac{\partial}{\partial u^j} \pi(x, u_t^*) + \sum_{i=1}^{n} \frac{\partial}{\partial x^i} \overset{\wedge}{P_t} (x) \frac{\partial}{\partial u^j} f^i(x, u_t^*) \right] \rho_t(x) dx \right\} \geq 0,$$

which is exactly the minimum principle presented in Bensoussan [1, *Theorem* 2.1]; [2, *Theorem* 8.2.1, *p.* 279].

Proof. The proof follows from (5.1), (5.2), and the result of Theorem 4.3. □

There is also a connection between the costate process of (4.10) and the costate process given in Bensoussan [1, Theorem 2.2], which is recognized as follows. Suppose we set $\tilde{r}_t^k = -\exp\{-\sum_{j=1}^{d} y_t^j h_j\} \hat{r}_t^k$; then by Lemma 4.4, we have the following.

THEOREM 5.2. *If the unnormalized conditional density of nonlinear filtering satisfies* (5.1)*, then the costate process identified in Theorem* 4.3 *satisfies* (4.10) *and solves*

$$d \overset{\wedge}{P_t} (x) = A_0 \overset{\wedge}{P_T} (x) dt + \sum_{i=1}^{n} a^i(x, u^*) \frac{\partial}{\partial x^i} \overset{\wedge}{P_t} (x) dt - \pi^{u^*} dt + \sum_{k=1}^{d} h_k^2 \overset{\wedge}{P_t} (x) dt$$

$$
+\exp\left\{-\sum_{j=1}^{d} y_t^j h_j\right\}\hat{r}_t^k h_k dt-\sum_{k=1}^{d} h_k \hat{P}_t\,(x)dy_t^k
$$
$$
+\sum_{k=1}^{d}\exp\left\{-\sum_{j=1}^{d} y_t^j h_j\right\}\hat{r}_t^k dy_t^k,\ \lim_{t\uparrow T}\hat{P}_t\,(x)=k(x),
$$

which is exactly the equation satisfied by the costate process established in Bensoussan [1, *Theorem* 2.2].

Proof. Using (5.2) and substituting $\tilde{r}_t^k = -\exp\{-\sum_{j=1}^{d} y_t^j h_j\}\hat{r}_t^k, 1 \le k \le d$, in the costate equation of Lemma 4.4, the result follows. □

6. Conclusion. In this paper we have presented a new approach based on measure-valued decompositions to derive necessary conditions of optimality for partially observed stochastic control problems when correlation between the state process and observation process is present. Let us also note that our approach can be applied to the case when the correlation is zero, but the control appears in both the drift and the diffusion coefficients of the state process. However, in this case, the validity of Lemma 3.3 and Lemma 3.4 must be established. The approach discussed in this paper was first published in [19].

SIMULTANEOUS STABILIZATION OF LINEAR AND NONLINEAR SYSTEMS BY MEANS OF NONLINEAR STATE FEEDBACK*

BERTINA HO-MOCK-QAI† AND WIJESURIYA P. DAYAWANSA‡

Abstract. The simultaneous stabilization (resp., asymptotic stabilization) of a countable family of control systems consists of finding a control which stabilizes (resp., asymptotically stabilizes) all the systems in the family. In this paper, we introduce a new method which enables us to show that, given any countable family of *stabilizable nonlinear* systems, there exists a continuous state feedback law which simultaneously stabilizes (not asymptotically) the family. Then, by enriching this method, we prove that any finite family of stabilizable linear time invariant (LTI) systems can be simultaneously exponentially stabilized by means of nonlinear time-varying state feedback. We also derive sufficient conditions for the simultaneous asymptotic stabilizability of countably infinite families of LTI systems. Finally, sufficient conditions for the simultaneous asymptotic stabilizability of finite families of *nonlinear* systems are provided and used for the simultaneous asymptotic stabilization of certain pairs of nonlinear homogeneous systems.

Key words. simultaneous stabilization, linear systems, nonlinear systems, continuous state feedback, time-varying state feedback

1. Introduction.

To the best of our knowledge, the simultaneous asymptotic stabilization of *countably infinite* families of systems and of families of *nonlinear* systems has never been directly addressed in the literature. Actually, *finite families of linear time invariant (LTI) systems* have been the main focus of the literature related to simultaneous stabilization.

Although the simultaneous asymptotic stabilization of two LTI systems by means of LTI feedback has been completely solved for almost 15 years [13, 14], the simultaneous asymptotic stabilization of more than two LTI systems by LTI feedback laws remains a challenging issue. Indeed, necessary and sufficient conditions for the simultaneous asymptotic stabilizability of three LTI systems are provided in Blondel et al. [3], Ghosh and Byrnes [4], and Vidyasagar and Viswanadham [14], but none of them yields an algorithm to decide whether three LTI systems can be simultaneously stabilized by means of LTI feedback. It is therefore not clear whether the simultaneous stabilizability of more than two LTI systems by means of LTI feedback can be computationally decided, and investigation on this matter continues [1, 2].

To overcome the limitations of LTI controllers, the use of time-varying feedback laws and merely continuous feedback laws for simultaneous stabilization has been investigated: Kabamba and Yang [9] established the simultaneous asymptotic stabilizability of finite families of LTI systems by means of time-varying feedback laws which involve both the sampled output of the system and a periodic function of time.

On the other hand, Zhang and Blondel [16] obtained sufficient conditions for the simultaneous asymptotic stabilizability of such families by controllers based on LTI feedback laws combined with zeroth order hold functions and samplers. While both of these design procedures are based on some discretization strategy, Khargonekar, Pascoal, and Ravi [10] introduced a method that does not involve any discretization scheme and proved that any finite family of stabilizable LTI systems can be simultaneously asymptotically stabilized by a periodic linear time-varying feedback law which is *piecewise continuous*. Finally, Petersen [11] derived a necessary and sufficient condition for the simultaneous quadratic asymptotic stabilizability of single-input LTI systems by means of continuous nonlinear feedback.

We stress that to the best of our knowledge, there do not exist any published results on the simultaneous stabilization of *nonlinear systems*, and our goal in this paper is to address this issue. In order to achieve this goal, we are led to solve several intermediate problems.

First, by introducing a new method to interpolate feedback laws, we prove that given any *countable* family of general nonlinear systems, there exists a merely continuous state feedback law which simultaneously stabilizes (not asymptotically) the family if each system of the family is asymptotically stabilizable by means of *continuous* state feedback. We actually find two feedback laws that solve the simultaneous stabilization problem. Although the first law cannot really be used in practical problems, it yields more insight into the construction than the second; however, the second law is more explicit and is used to prove further results. We then show that if each system of the family is globally asymptotically stabilizable, then there exists a continuous state feedback law which not only simultaneously stabilizes the family but also yields boundedness of all the solutions of the corresponding closed-loop systems. Finally, if the systems of the family are LTI and asymptotically stabilizable by means of LTI feedback, we provide a simple procedure to construct a simultaneous stabilizer.

Next, we introduce *time-varying* state feedback laws and we modify the construction used to derive the previous results. We then prove that given any *finite* family of LTI systems that are individually stabilizable by means of LTI state feedback, there exists a nonlinear time-varying state feedback law which is continuous and which simultaneously globally exponentially stabilizes the family. Because our approach does not involve any discretization strategy as in [9, 16], it should be compared to that of Khargonekar, Pascoal, and Ravi [10]. Our approach is actually very different from that of Khargonekar, Pascoal, and Ravi, and the controller that we derive is *nonlinear* and *continuous*, while theirs is *linear* and *piecewise continuous*. We also provide sufficient conditions for the simultaneous asymptotic stabilizability of countably infinite families of LTI systems.

Finally, by extending the previous approach to the nonlinear setting, we are able to derive sufficient conditions for the simultaneous local and global asymptotic stabilizability of finite families of *nonlinear* systems by means of continuous time-varying state feedback laws. We then use these conditions in order to establish the simultaneous asymptotic stabilizability of certain pairs of homogeneous nonlinear control systems.

The paper is organized as follows. In section 2, we review some definitions. We discuss the simultaneous stabilization of countable families of nonlinear systems in section 3. The simultaneous asymptotic stabilization of LTI systems is then discussed in section 4. We provide, in section 5, some sufficient conditions for the simultaneous asymptotic stabilization of nonlinear systems. These sufficient conditions are used in section 6 for the simultaneous asymptotic stabilization of certain pairs of homogeneous systems in $\mathbb{R}^n$. Finally, section 7 contains our conclusions.

2. Definitions.

Before introducing our results, we need some definitions and notation. Let X be a subset of $\mathbb{R}^n$ containing the origin, and let k be a positive integer. A mapping $u : X \to \mathbb{R}^m$ is said to be almost C^k on X, if it is C^k on $X\backslash\{0\}$. Further, $\|\cdot\|$ denotes the Euclidean norm on $\mathbb{R}^k$, and for r positive $B_r(0)$ denotes the set $B_r(0) \triangleq \{x \in \mathbb{R}^k,\ \|x\| < r\}$. Let S denote an autonomous (resp., a time-varying) system $\dot{x} = f(x)$ (resp., $\dot{x} = f(t,x)$), where x lies in $\mathbb{R}^n$. We let $x(\cdot, x_0)$ (resp., $x(\cdot, x_0, t_0)$) denote any one of the solutions of S that starts at x_0 (resp., at x_0 at time t_0), for each x_0 in $\mathbb{R}^n$ and each $t_0 \geq 0$. We will adopt the usual convention that the infimum of a real-valued mapping over the empty set is $+\infty$. Finally, for a given symmetric positive definite matrix P, we let $\lambda_{min}(P)$ and $\lambda_{max}(P)$ denote, resp., the smallest and largest eigenvalues of P.

Definition 2.1 (stability of time-varying systems). *Let $f : [0,\infty) \times \mathbb{R}^n \to \mathbb{R}^n$ be a continuous mapping such that $f(t,0) = 0$ for each $t \geq 0$. The system $S : \dot{x} = f(t,x)$ is*

(i) *stable, if for each $\varepsilon > 0$ and each $t_0 \geq 0$, there exists $\delta(\varepsilon, t_0) > 0$ such that we have $\|x(t, x_0, t_0)\| < \varepsilon$ for each $t \geq t_0$ and each x_0 in $B_{\delta(\varepsilon,t_0)}(0)$;*

(ii) *locally asymptotically stable if it is stable according to case* (i) *and for each $t_0 \geq 0$, there exists $\bar{\delta}(t_0) > 0$ such that* $\lim_{t\to+\infty} x(t, x_0, t_0) = 0$*, for each x_0 in $B_{\bar{\delta}(t_0)}(0)$;*

(iii) *locally exponentially stable if there exist some positive reals γ, $\bar{\delta}$, and L such that*

$$\|x(t, x_0, t_0)\| \ \leq\ L\|x_0\|e^{-\gamma(t-t_0)}, \quad t \geq t_0, \quad t_0 \geq 0, \quad x_0 \in B_{\bar{\delta}}(0);$$

(iv) *locally uniformly stable with exponential (uniform in t_0) convergence if there exist some positive reals γ and $\bar{\delta}$, and a mapping $h : (0,\infty) \to (0,\infty)$ such that* $\lim_{r\to0^+} h(r) = 0$ *and*

$$\|x(t, x_0, t_0)\| \ \leq\ h(\|x_0\|)e^{-\gamma(t-t_0)}, \quad t \geq t_0, \quad t_0 \geq 0, \quad x_0 \in B_{\bar{\delta}}(0).$$

Note that whenever the mapping f does not explicitly depend on t, the positive reals δ and $\bar{\delta}$ that appear in cases (i) *and* (ii) *are independent of t_0.*

Definition 2.1, case (iv) is more general than that of exponential stability but reduces to this concept if the mapping h satisfies $h(r) \leq \alpha r$ for some constant $\alpha > 0$ and for each $r > 0$ close to 0. Although we allow general mappings h, the fundamental idea of uniform (in t_0) exponential convergence is preserved. Furthermore, it is plain that the requirement $\lim_{r\to0^+} h(r) = 0$ yields uniform stability.

Throughout this paper, the words *stable* and *stabilize* are used in the basic sense and refer to the concept of stability as given in Definition 2.1, case (i), while in the control theory literature they usually refer to the concept of *asymptotic stability* according to Definition 2.1, case (ii). Further, we will often omit the term *locally* and unless otherwise stated *asymptotically stable* will mean *locally asymptotically stable.*

Finally, a feedback law *simultaneously* stabilizes (resp., asymptotically stabilizes) a countable family of control systems if it stabilizes (resp., asymptotically stabilizes) *all* the systems in the family.

Definition 2.2. *Let D be a neighborhood of the origin in $\mathbb{R}^n$, and let $f : D \to \mathbb{R}^n$ be continuous. A positive definite mapping $V : D \to [0,\infty)$ is a Lyapunov function* *for the system $\dot{x} = f(x)$ if V is C^0 on D, C^1 on $D\backslash\{0\}$, and*

$$\nabla V(x) f(x) \;\equiv\; \left[\frac{\partial V(x)}{\partial x_1}, \cdots, \frac{\partial V(x)}{\partial x_n}\right] f(x) \;<\; 0, \quad x \in D\backslash\{0\}.$$

Definition 2.3. *Let $\{x_m\}_{m\in\mathbb{Z}}$ be a sequence of positive integers. Further, for each $i = 1, \dots, x_n$ and each n in $\mathbb{Z}$, let Q_i^n belong to a given class of mathematical objects. Then, $\{Q_i^n,\ i = 1, \dots, x_n\}_{n=1}^{\infty}$, $\{Q_i^n,\ i = 1, \dots, x_n\}_{n=-1}^{-}\infty$, and $\{Q_i^n,\ i = 1, \dots, x_n\}_{n\in\mathbb{Z}}$ denote, resp., the three sequences*

$$\{Q_1^1, \dots, Q_{x_1}^1, Q_1^2, \dots, Q_{x_2}^2, Q_1^3, \dots\},$$
$$\{\dots, Q_{x_{-3}}^{-3}, Q_1^{-2}, \dots, Q_{x_{-2}}^{-2}, Q_1^{-1}, \dots, Q_{x_{-1}}^{-1}\},$$
$$\{\dots, Q_1^{-1}, \dots, Q_{x_{-1}}^{-1}, Q_1^0, \dots, Q_{x_0}^0, Q_1^1, \dots, Q_{x_1}^1, \dots\}.$$

3. Simultaneous stabilization.

Throughout this section, we consider a countable family $\{S_i,\ i \in \mathcal{I}\}$ of systems

$$S_i: \quad \dot{x} \;=\; f_i(x, u), \quad i \in \mathcal{I}, \tag{1}$$

where the set $\mathcal{I}$ contains more than one element, the state x lies in $\mathbb{R}^n$, the input u belongs to $\mathbb{R}^m$, and for each i in $\mathcal{I}$ the mapping $f_i : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$ is continuous on a neighborhood of the origin with $f_i(0, 0) = 0$.

Under these assumptions, we show that if each system S_i can be asymptotically stabilized then there exists a continuous feedback law which simultaneously stabilizes (not asymptotically) the family $\{S_i,\ i \in \mathcal{I}\}$.

3.1. Main result.

In this subsection, we establish the following theorem.

Theorem 3.1. *Let k be in $\{0, 1, \dots\}$. Assume that for each i in $\mathcal{I}$, there exists a state feedback law $u_i : \mathbb{R}^n \to \mathbb{R}^m$ such that $u_i(0) = 0$, u_i is continuous and almost C^k on some neighborhood of the origin, and u_i locally asymptotically stabilizes the system S_i. Then, there exists a state feedback law $v : \mathbb{R}^n \to \mathbb{R}^m$, such that $v(0) = 0$, v is continuous and almost C^k on some neighborhood of the origin, and v simultaneously stabilizes (not asymptotically) the family $\{S_i,\ i \in \mathcal{I}\}$.*

We prove the theorem in the case where the set $\mathcal{I}$ is countably infinite. Thus, we may assume that $\mathcal{I} = \{1, 2, \dots\}$. The result for finite families of systems will clearly follow from the fact that simultaneous stabilizability of the countable family $\{S_1, S_2, \dots\}$ yields simultaneous stabilizability of any finite family $\{S_1, \dots, S_n\}$.

The main lines of the proof are as follows: For each $i = 1, 2, \dots$, we let V_i denote a Lyapunov function for the system $\dot{x} = f_i(x, u_i(x))$. We define a sequence of neighborhoods of the origin $\{U_i^n, i = 1, 2, \dots\}_{n=i}^{\infty}$ such that for each $i = 1, 2, \dots$ the boundaries of the sets U_i^n, $n = i, i + 1, \dots$, are level sets of V_i. We then design a continuous feedback law v which is equal to u_i on the boundaries of the sets U_i^n, $n = i, i + 1, \dots$, for each $i = 1, 2, \dots$. It follows that for each $i = 1, 2, \dots$ and each $n = 1, 2, \dots$, the set $\overline{U}_i^n$ is invariant with respect to the system $\dot{x} = f_i(x, v(x))$. We conclude that for each $i = 1, 2, \dots$, the feedback law v stabilizes S_i upon noting that the family $\{U_i^n\}_{n=i}^{\infty}$ is a topological base at the origin.

Proof. Throughout the proof, we assume that the set $\mathcal{I}$ is equal to $\{1, 2, \dots\}$. For each $i = 1, 2, \dots$, we let D_i be a bounded neighborhood of the origin and $V_i : \overline{D}_i \to [0, \infty)$ be a Lyapunov function such that the mappings u_i and $f_i(\cdot, u_i(\cdot))$ are continuous on $\overline{D}_i$, the mapping u_i is almost C^k on $\overline{D}_i$, and

$$\nabla V_i(x)\, f_i(x, u_i(x)) \;<\; 0, \quad x \in \overline{D}_i\backslash\{0\}. \tag{2}$$

For each $i = 1, 2, \ldots$, we let W_i^β denote the set $W_i^\beta \triangleq \{x \in D_i : V_i(x) < \beta\}$ for each $\beta > 0$, and we define the mapping $\bar{u}_i : D_1 \to \mathbb{R}^m$ by setting

$$\bar{u}_i(x) = \begin{cases} u_i(x), & x \in D_1 \cap D_i, \\ 0, & x \in D_1 \backslash D_i. \end{cases}$$

Let $\theta > 0$. Using the continuity of the mapping u_i on D_i and the fact that $u_i(0) = 0$ for each $i = 1, 2, \ldots$, it is not hard to construct a sequence of positive reals $\{\beta_i^n,\ i = 1, \ldots, n\}_{n=1}^\infty$ [5, Lemma 3.3, p. 51] such that

$$\beta_n^n < \inf_{x \in \partial D_n} V_n(x), \quad n = 1, 2, \ldots,$$

$$\beta_i^n \to 0 \text{ as } n \to \infty, \quad i = 1, 2, \ldots, \tag{3}$$

$$D_n \supset W_{n-1}^{\beta_{n-1}^{n-1}} \supset \overline{W}_1^{\beta_1^n}, \quad n = 2, 3, \ldots, \tag{4}$$

$$W_{i-1}^{\beta_{i-1}^n} \supset \overline{W}_i^{\beta_i^n}, \ i = 2, \ldots, n, \quad n = 2, 3, \ldots, \tag{5}$$

and

$$\|u_k(x)\| < \frac{\theta}{n}, \quad x \in D_k \cap W_n^{\beta_n^n}, \quad k = 1, \ldots, n+2, \quad n = 1, 2, \ldots. \tag{6}$$

Next, we set $U_i^n \triangleq W_i^{\beta_i^n}$ for each $i = 1, \ldots, n$ and each $n = 1, 2, \ldots$. From the inequality $\beta_1^1 < \inf_{x \in \partial D_1} V_1(x)$, we get the inclusion $D_1 \supset U_1^1$. Thus, (4) and (5) yield a sequence of nested neighborhoods

$$\begin{array}{ccccccc} D_1 & \supset & U_1^1 & \supset & & & \\ & & U_1^2 & \supset & U_2^2 & \supset & \\ & & U_1^3 & \supset & U_2^3 & \supset & U_3^3 \quad \supset \\ & & U_1^4 & \supset & \ldots & \ldots & \ldots \\ & & \vdots & \vdots & & \vdots & \end{array} \tag{7}$$

such that each neighborhood contains the closure of the neighborhood that follows.

For each $n = 1, 2, \ldots$ and each $i = 1, \ldots, n$, we define the sets Δ_i^n by setting

$$\Delta_1^1 \triangleq D_1 \backslash \overline{U}_1^2, \qquad \text{with} \qquad \Delta_1^n \triangleq U_{n-1}^{n-1} \backslash \overline{U}_2^n, \quad n = 2, 3, \ldots,$$
$$\Delta_i^n \triangleq U_{i-1}^n \backslash \overline{U}_{i+1}^n, \quad i = 2, \ldots, n-1, \ n = 3, 4, \ldots,$$
$$\Delta_n^n \triangleq U_{n-1}^n \backslash \overline{U}_1^{n+1}, \quad n = 2, 3, \ldots.$$

Because the family $\{U_i^n,\ i = 1, \ldots, n\}_{n=1}^\infty$ is a topological base at the origin (this follows from (3)), we obtain from (7) that the family $\{\Delta_i^n,\ i = 1, \ldots, n\}_{n=1}^\infty$ is an open cover of $D_1 \backslash \{0\}$. We let $\{q_i^n,\ i = 1, \ldots, n\}_{n=1}^\infty$ be a partition of unity subordinate to $\{\Delta_i^n,\ i = 1, \ldots, n\}_{n=1}^\infty$, such that the support of q_i^n is included in Δ_i^n for each $i = 1, \ldots, n$ and each $n = 1, 2, \ldots$ [15, p. 10]. Finally, we define the feedback law $v : D_1 \to \mathbb{R}^m$ by setting

$$v(x) = \begin{cases} 0, & x = 0, \\ \displaystyle\sum_{n=1}^\infty \sum_{i=1}^n \bar{u}_i(x)\, q_i^n(x), & x \in D_1 \backslash \{0\}. \end{cases}$$

The mapping v is almost C^k. Let x be in $D_1\backslash\{0\}$ and let r be in $(0, \|x\|)$ with $\overline{B_r(0)} \subset D_1$. Because $\{U_i^n,\ i = 1, \dots, n\}_{n=1}^{\infty}$ is a topological base at the origin composed of nested neighborhoods, there exists an integer N such that

$$U_N^N \cup \{U_i^n,\ i = 1, \dots, n\}_{n=N+1}^{\infty} \ \subset\ \overline{B_r(0)}.$$

This and the fact that the support of each mapping q_i^n is included in Δ_i^n yield

$$v(y) = \sum_{n=1}^{N} \sum_{i=1}^{n} \bar{u}_i(y) q_i^n(y), \quad y \in D_1\backslash\overline{B_r(0)}. \tag{8}$$

We now show that v is C^k on the neighborhood $D_1\backslash\overline{B_r(0)}$ of x by proving that the mapping $\bar{u}_i\, q_i^n : D_1\backslash\{0\} \to \mathbb{R}^m$ is C^k on $D_1\backslash\{0\}$ for each $i = 1, \dots, n$ and each $n = 1, 2, \dots$.

We fix $n = 2, 3, \dots$ and $i = 1, \dots, n$. By definition of $\bar{u}_i$ we have $\bar{u}_i = u_i$ on D_i, so that

$$\bar{u}_i(y)\, q_i^n(y) \ = \ u_i(y)\, q_i^n(y), \quad y \in (D_1 \cap D_i)\backslash\{0\}. \tag{9}$$

Further, as the support of q_i^n is included in Δ_i^n, we get

$$\bar{u}_i(y)\, q_i^n(y) \ = \ 0, \quad y \in \left(D_1\backslash\overline{\Delta}_i^n\right)\backslash\{0\}. \tag{10}$$

Because q_i^n is smooth on $D_1\backslash\{0\}$ and u_i is C^k on $D_i\backslash\{0\}$, it follows from (9) and (10) that $\bar{u}_i\, q_i^n$ is C^k on

$$\left(\left(D_1\backslash\overline{\Delta}_i^n\right) \cup (D_1 \cap D_i)\right)\backslash\{0\}. \tag{11}$$

Next, by combining the definition of the sets Δ_i^n with (4) and (7), we obtain for each $n = 2, 3, \dots$ the inclusions

$$\begin{aligned}
&\overline{\Delta}_1^n \subset \overline{U}_{n-1}^{n-1} \ \subset\ D_1, \\
&\overline{\Delta}_i^n \subset \overline{U}_{i-1}^{n} \ \subset\ U_i^{n-1} \ \subset\ D_i, \quad i = 1, \dots, n-1\,, \\
&\overline{\Delta}_n^n \subset \overline{U}_{n-1}^{n} \ \subset\ D_n \qquad\qquad \text{(follows from (4))},
\end{aligned}$$

and because we also have $\overline{\Delta}_i^n \subset D_1\backslash\{0\}$, we get $\overline{\Delta}_i^n \ \subset\ (D_1 \cap D_i)\backslash\{0\}$. This implies that the set in (11) is equal to $D_1\backslash\{0\}$, and it follows that the mapping $\bar{u}_i\, q_i^n$ is C^k on $D_1\backslash\{0\}$. Furthermore, the mapping $\bar{u}_1 q_1^1$ is C^k on $D_1\backslash\{0\}$, since by definition of $\bar{u}_1$ we have $\bar{u}_1 q_1^1 = u_1 q_1^1$ on $D_1\backslash\{0\}$. In view of (8), we conclude that for each x in $D_1\backslash\{0\}$, there exists a neighborhood U_x of x included in $D_1\backslash\{0\}$ such that the mapping v is C^k on U_x. In short, the mapping v is C^k on $D_1\backslash\{0\}$.

Continuity of v. We fix $n = 2, 3, \dots$. From the definition of the sets Δ_j^m, it is easily checked that for each $m = n+2, n+3, \dots$, we have

$$\left(U_{n-1}^{n-1}\backslash\overline{U}_{n+1}^{n+1}\right) \cap \Delta_j^m = \emptyset, \quad j = 1, \dots, m\,,$$

and because the support of each function q_j^m is included in Δ_j^m, we get

$$v(x) \ = \ \sum_{m=1}^{n+1} \ \sum_{j=1}^{m} \bar{u}_j(x)\, q_j^m(x), \quad x \in U_{n-1}^{n-1}\backslash\overline{U}_{n+1}^{n+1}.$$

As the functions of $\{q_i^n, i = 1, \ldots, n\}_{n=1}^{\infty}$ sum up to 1, the previous equality implies that

$$\|v(x)\| \;\le\; \max(\|\bar{u}_1(x)\|, \ldots, \|\bar{u}_{n+1}(x)\|), \quad x \in U_{n-1}^{n-1} \backslash \overline{U}_{n+1}^{n+1},$$

so that (6) combined with the definition of the mappings $\bar{u}_i,\ i = 1, 2, \ldots,$ yield

$$\|v(x)\| \;<\; \frac{\theta}{n-1}, \quad x \in U_{n-1}^{n-1} \backslash \overline{U}_{n+1}^{n+1}. \tag{12}$$

Further, upon noting that the family $\{U_l^l\}_{l=1}^{\infty}$ is a topological base at the origin composed of nested neighborhoods such that each neighborhood contains the closure of the neighborhood that follows, we deduce that

$$U_{l-1}^{l-1} \backslash \{0\} \;=\; \bigcup_{n=l}^{\infty} \left(U_{n-1}^{n-1} \backslash \overline{U}_{n+1}^{n+1} \right), \quad l = 2, 3, \ldots,$$

and (12) implies that

$$\|v(x)\| \;\le\; \frac{\theta}{l-1}, \quad x \in U_{l-1}^{l-1} \backslash \{0\}, \quad l = 2, 3, \ldots.$$

Because $\frac{\theta}{l-1} \to 0 \;\; as \;\; l \to \infty$, continuity of v at the origin follows.

Simultaneous stability. From the definitions of the sets U_i^n and Δ_i^n, it is not hard to see that for each $i = 1, 2, \ldots$ and each $n = 1, 2, \ldots$, the boundary ∂U_i^n is included in Δ_i^n and does not intersect with any other set Δ_j^m. Thus, because the support of the mapping q_i^n is included in Δ_i^n for each $i = 1, 2, \ldots$ and each $n = 1, 2, \ldots$, it follows from the definition of v that

$$v(x) = u_i(x), \quad x \in \partial U_i^n, \quad i = 1, \ldots, I, \quad n = 1, 2, \ldots.$$

This, together with (2) and the fact that the sets $\overline{U}_i^n$ are included in D, yields

$$\nabla V_i(x)\, f_i(x, v(x)) \;<\; 0, \quad x \in \partial U_i^n, \quad i = 1, \ldots, I, \quad n = 1, 2, \ldots. \tag{13}$$

For each $i = 1, \ldots, I$ and each $n = 1, 2, \ldots$, by combining (13) with Lemma 8.1 applied with $D,\ V = V_i,\ f(\cdot, \cdot) = f_i(\cdot, v(\cdot))$, and $b(\cdot) \equiv \beta_i^n$, we obtain that the set $\overline{U}_i^n$ is invariant with respect to the system $\dot{x} = f_i(x, v(x))$. Thus, for each $i = 1, \ldots, I$, the family $\{U_i^n\}_{n=1}^{\infty}$ is a topological base at the origin such that $\overline{U}_i^n$ is positively invariant with respect to the system $\dot{x} = f_i(x, v(x))$ for each $n = 1, 2, \ldots$. It follows that v stabilizes (not asymptotically) the system S_i for each $i = 1, \ldots, I$. □

3.2. A more explicit simultaneous stabilizer. In this subsection, we show that we can circumvent the computation of the partition of unity that appears in the expression of the previous simultaneous stabilizer, and we provide a more explicit simultaneous stabilizer which can actually be used in *practical* problems. Although this simultaneous stabilizer is more explicit than the one presented in the previous subsection, it somehow yields less insight into the construction. Furthermore, we will use this more explicit stabilizer, in this paper, to prove further results.

For the sake of simplicity, we assume throughout this subsection that the set $\mathcal{I}$ is finite and equal to $\{1, \ldots, I\}$ (with $I \ge 2$). However, the construction that we provide can be easily transposed to the case of a countably infinite family of systems (see [5, p. 40] for further details).

In that case, a simpler proof of Theorem 3.1 may be given (we refer the interested reader to [8] for a proof). The main difference between this proof and the one presented in the previous subsection lies in the structure of the topological base that is considered. We actually define a sequence of neighborhoods of the origin $\{U_i^n, i = 1, \ldots, I\}_{n=1}^\infty$ such that for each $i = 1, \ldots, I$ the boundaries of the sets U_i^n, $n = 1, 2, \ldots$ are level sets of V_i. Using a partition of unity $\{q_i^n,\ i = 1, \ldots, n\}_{n=1}^\infty$ subordinate to $\{U_i^n, i = 1, \ldots, I\}_{n=1}^\infty$, we then design a continuous feedback law v which is equal to u_i on the boundaries of the sets U_i^n, $n = 1, 2, \ldots,$ for each $i = 1, 2, \ldots$. By using an argument similar to that used in the proof of Theorem 3.1, we obtain that v stabilizes the system S_i for each $i = 1, \ldots, I$.

We now show that we can circumvent the computation of the partition of unity $\{q_i^n, i = 1, \ldots, I\}_{n=1}^\infty$ that appears in the expression of the obtained simultaneous stabilizer.

Derivation of a more explicit simultaneous stabilizer. Under the enforced assumptions, there exist a bounded neighborhood of the origin D and a C^k (where $k \geq 0$ is an integer) Lyapunov function $V_i : \overline{D} \to [0, \infty)$ such that

$$\nabla V_i(x)\, f_i(x, u_i(x)) \ < \ 0, \quad x \in \overline{D} \backslash \{0\}, \tag{14}$$

for each $i = 1, \ldots, I$. Without loss of generality, we may assume that for each $i = 1, \ldots, I$, the mappings $f_i(\cdot, u_i(\cdot))$ and u_i are continuous on $\overline{D}$ with u_i almost C^k on $\overline{D}$.

For each $i = 1, \ldots, I$, and each $\beta > 0$, we set $W_i^\beta \ \triangleq \ D \cap V_i^{-1}(\,[0, \beta)\,)$. It is not hard to obtain [5, Lemma 2.5, p. 32] three sequences of positive reals $\{\alpha_i^n,\ i = 1, \ldots, I\}_{n=1}^\infty$, $\{\beta_i^n,\ i = 1, \ldots, I\}_{n=1}^\infty$, and $\{\gamma_i^n,\ i = 1, \ldots, I\}_{n=1}^\infty$ converging to the origin, such that for each $n = 1, 2, \ldots$, we have

$$\inf_{x \in \partial D} V_i(x) \ > \ \gamma_i^n \ > \ \beta_i^n \ > \ \alpha_i^n, \quad i = 1, \ldots, I, \tag{15}$$

$$W_I^{\alpha_I^n} \ \supset \ \overline{W_1^{\gamma_1^{n+1}}} \qquad \text{and} \qquad W_{i-1}^{\alpha_{i-1}^n} \ \supset \ \overline{W_i^{\gamma_i^n}}, \quad i = 2, \ldots, I. \tag{16}$$

For each $i = 1, \ldots, I$ and each $n = 1, 2, \ldots,$ we define the mappings $\overline{q}_i^n : D \to [0, 1]$ by setting

$$\overline{q}_i^n(x) = \begin{cases} e^{\frac{\left(V_i(x) - \beta_i^n\right)^2}{\left(V_i(x) - \beta_i^n\right)^2 - \left(\beta_i^n - \alpha_i^n\right)^2}} & \text{if } \ V_i(x) \in (\alpha_i^n, \beta_i^n), \\ e^{\frac{(V_i(x) - \beta_i^n)^2}{\left(V_i(x) - \beta_i^n\right)^2 - \left(\gamma_i^n - \beta_i^n\right)^2}} & \text{if } \ V_i(x) \in [\beta_i^n, \gamma_i^n), \\ 0 & \text{otherwise} \end{cases} \tag{17}$$

for each x in D. It can be checked [5, Lemma B.6, p. 159] that the mapping $\overline{q}_i^n$ is C^k on D for each $i = 1, \ldots, I$ and each $n = 1, 2, \ldots$. Finally, we let $\bar{v} : D \to \mathbb{R}^m$ be given by

$$\bar{v}(x) \ = \ \sum_{n=1}^{\infty} \sum_{i=1}^{I} \overline{q}_i^n(x) u_i(x), \quad x \in D. \tag{18}$$

PROPOSITION 3.2. *The state feedback law $\bar{v}$ as given in* (18) *is continuous and almost C^k on D and simultaneously stabilizes (not asymptotically) the family $\{S_i,\ i = 1, \ldots, I\}$.*

Proof. First, we note that (15) combined with (16) yields a sequence of nested neighborhoods

$$D \supset W_1^{\gamma_1^1} \supset W_1^{\beta_1^1} \supset W_1^{\alpha_1^1} \supset W_2^{\gamma_2^1} \supset \cdots \supset W_I^{\alpha_I^1} \supset W_1^{\gamma_1^2} \supset \cdots \tag{19}$$

such that each neighborhood contains the closure of the neighborhood that follows. It is not hard to see from the definition of the mappings $\overline{q}_i^n$ that

$$\{x \in D : \overline{q}_i^n(x) \neq 0\} \;=\; W_i^{\gamma_i^n} \backslash \overline{W}_i^{\alpha_i^n}, \quad i = 1, \ldots, I, \quad n = 1, 2, \ldots, \tag{20}$$

so that these sets are disjoint. Now, let x be in $D\backslash\{0\}$ and let r be in $(0, \|x\|)$ such that $\overline{B_r(0)} \subset D$. Further, let the integer n_r be such that $W_1^{\gamma_1^n} \subset \overline{B_r(0)}$, $n = n_r + 1, n_r + 2, \ldots$. It follows from the definition of $\bar{v}$, together with (20), that

$$\bar{v}(y) \;=\; \sum_{n=1}^{n_r} \sum_{i=1}^{I} u_i(y)\overline{q}_i^n(y), \quad y \in D\backslash\overline{B_r(0)}. \tag{21}$$

Because the mappings u_i and $\overline{q}_i^n$ are C^k on $D\backslash\{0\}$ for each $i = 1, \ldots, I$ and each $n = 1, 2, \ldots$ (see [5, Lemma B.6, p. 159] for further details), we easily obtain from (21) that $\bar{v}$ is C^k on $D\backslash\{0\}$. Furthermore, (20) implies that

$$\|\bar{v}(x)\| \;\leq\; \max\left(\|u_1(x)\|, \ldots, \|u_I(x)\|\right), \quad x \in D,$$

and continuity of $\bar{v}$ at the origin follows from that of the mappings $u_i, i = 1, \ldots, I$.

Simultaneous stability. From (20) and the definition of the mappings $\overline{q}_i^n$, we deduce that for each $i = 1, \ldots, I$ and each $n = 1, 2, \ldots$, we have

$$\overline{q}_i^n(x) \;=\; 1 \quad \text{with} \quad \overline{q}_j^m(x) \;=\; 0, \quad x \in \partial W_i^{\beta_i^n}, \quad (j, m) \neq (i, n),$$

and the definition of $\bar{v}$ yields $\bar{v}(x) = u_i(x)$, $x \in \partial W_i^{\beta_i^n}$. By an argument similar to that used in the proof of Theorem 3.1 to establish simultaneous stability, it follows from (14) and Lemma 8.1 that for each $i = 1, \ldots, I$ the mapping $\bar{v}$ stabilizes S_i, which completes the proof. □

We now assume that there exists a continuous and almost C^k feedback law $u_i : \mathbb{R}^n \to \mathbb{R}^m$ which *globally* asymptotically stabilizes S_i and that the mapping $f_i(\cdot, u_i(\cdot))$ is continuous on $\mathbb{R}^n$ for each $i = 1, \ldots, I$. In that case, the previous construction can be slightly modified in order to yield a feedback law $\widehat{v}$ that simultaneously stabilizes the family $\{S_i,\ i = 1, \ldots, I\}$ and in such a way that all the solutions of the closed-loop system $\dot{x} = f_i(x, \widehat{v}(x))$ are bounded for each $i = 1, \ldots, I$.

Indeed, we may assume that the Lyapunov function V_i is radially unbounded for all $i = 1, \ldots, I$. It can easily be seen [5, Lemma 2.2, p. 28] that there exist some two-sided sequences of positive reals $\{\alpha_i^n,\ i = 1, \ldots, I\}_{n\in\mathbb{Z}}$, $\{\beta_i^n,\ i = 1, \ldots, I\}_{n\in\mathbb{Z}}$, and $\{\gamma_i^n,\ i = 1, \ldots, I\}_{n\in\mathbb{Z}}$ converging to 0 and $+\infty$ as n tends to $+\infty$ and $-\infty$, resp., and satisfying

$$W_I^{\alpha_I^n} \supset \overline{W}_1^{\gamma_1^{n+1}} \qquad \text{and} \qquad W_{i-1}^{\alpha_{i-1}^n} \supset \overline{W}_i^{\gamma_i^n}, \quad i = 2, \ldots, I, \quad n \in \mathbb{Z}. \tag{22}$$

For each $i = 1, \ldots, I$ and each n in $\mathbb{Z}$, we let the mapping $\overline{q}_i^n : \mathbb{R}^n \to [0, 1]$ be given by the formula (17) with α_i^n, β_i^n, and γ_i^n as defined here, and we let the mapping $\widehat{v} : \mathbb{R}^n \to \mathbb{R}^m$ be given by

$$\widehat{v}(x) \;=\; \sum_{n\in\mathbb{Z}} \sum_{i=1}^{I} \overline{q}_i^n(x) u_i(x), \quad x \in \mathbb{R}^n. \tag{23}$$

By arguments similar to those used in the proof of Proposition 3.2, it can be shown that $\widehat{v}$ is continuous on $\mathbb{R}^n$, C^k on $\mathbb{R}^n \backslash \{0\}$, and that for each $i = 1, \dots, I$ and each n in $\mathbb{Z}$, the solutions of $\dot{x} = f_i(x, \widehat{v}(x))$ starting in $\overline{W}_i^{\beta_i^n}$ remain in this set forever. As $\{W_i^{\beta_i^n}\}_{n \in \mathbb{Z}}$ covers $\mathbb{R}^n$ for each $i = 1, \dots, I$, we obtain the following proposition.

PROPOSITION 3.3. *The state feedback law $\widehat{v}$ as given in* (23) *is continuous and almost C^k on $\mathbb{R}^n$ and simultaneously stabilizes (not asymptotically) the family $\{S_i,\ i = 1, \dots, I\}$. Further, the solutions of the system $\dot{x} = f_i(x, \widehat{v}(x))$, starting at x_0, are bounded for each x_0 in $\mathbb{R}^n$ and each $i = 1, \dots, I$.*

In order to obtain three sequences $\{\gamma_i^n,\ i = 1, \dots, I\}_{n \in \mathbb{Z}}$, $\{\beta_i^n,\ i = 1, \dots, I\}_{n \in \mathbb{Z}}$, and $\{\alpha_i^n,\ i = 1, \dots, I\}_{n \in \mathbb{Z}}$, one actually needs to find a condition on the two positive reals α and β that yields the inclusion $D \cap V_{i-1}^{-1}([0, \alpha)) \supset D \cap V_i^{-1}([0, \beta])$, for each $i = 2, \dots, I$, as well as a condition for the inclusion $D \cap V_I^{-1}([0, \alpha)) \supset D \cap V_1^{-1}([0, \beta])$ to be satisfied. In the case where the system S_i and the feedback law u_i are linear for all $i = 1, \dots, I$, these conditions are well known and we provide, in the following paragraph, a simple procedure that yields the desired sequences of reals. We will then use these sequences in section 4.

3.3. Application to families of linear systems.

We now consider a countable family $\{S_i,\ i \in \mathcal{I}\}$ of LTI systems

$$S_i: \quad \dot{x} \;=\; A_i x \;+\; B_i u, \quad i \in \mathcal{I}, \tag{24}$$

where the state x lies in $\mathbb{R}^n$, the input u is in $\mathbb{R}^m$, and for each $i \in \mathcal{I}$, the matrices A_i and B_i belong to $\mathbb{R}^{n \times n}$ and $\mathbb{R}^{n \times m}$, respectively. Finally, for each $i \in \mathcal{I}$, we assume that there exists K_i in $\mathbb{R}^{n \times m}$ such that the linear feedback law $u_i : \mathbb{R}^n \to \mathbb{R}^m$ given by $u_i(x) = K_i x,\ x \in \mathbb{R}^n$, asymptotically stabilizes S_i.

For the sake of simplicity, we assume that $\mathcal{I}$ is finite and equal to $\{1, \dots, I\}$ where $I \geq 2$ is an integer. However, the construction that we provide below can be transposed easily to the case of countably infinite families of LTI systems (see [5, Chapter 3] for further details).

We now let $V_i : \mathbb{R}^n \to [0, \infty)$ be a Lyapunov function for the system $\dot{x} = f_i(x, u_i(x))$ given by $V_i(x) = x^t P_i x,\ x \in \mathbb{R}^n$, where P_i is a positive definite matrix. As u_i globally asymptotically stabilizes the system S_i for each $i = 1, \dots, I$, a simultaneous stabilizer for the family $\{S_i, i = 1, \dots, I\}$ may be given by the formula (23). In this particular case, the sequences of real $\{\alpha_i^n,\ i = 1, \dots, I\}_{n \in \mathbb{Z}}$, $\{\beta_i^n,\ i = 1, \dots, I\}_{n \in \mathbb{Z}}$, and $\{\gamma_i^n,\ i = 1, \dots, I\}_{n \in \mathbb{Z}}$, used in the expression of the mappings $\overline{q}_i^n$, can be defined as follows: We let π_1 be in $(0, \lambda_{min}(P_1)/\lambda_{max}(P_I))$ and π_i be in $(0, \lambda_{min}(P_i)/\lambda_{max}(P_{i-1}))$ for each $i = 2, \dots, I$. Further, we let θ_i in $(0, 1)$ for each $i = 1, \dots, I$ be such that

$$(\pi_1 \cdots \pi_I)\,(\theta_1^2 \cdots \theta_I^2) \;<\; 1, \tag{25}$$

and we let $\widehat{\gamma}_1^0$ be an arbitrary positive real. Finally, we let the sequences of positive reals $\{\alpha_i^n,\ i = 1, \dots, I\}_{n \in \mathbb{Z}}$, $\{\beta_i^n,\ i = 1, \dots, I\}_{n \in \mathbb{Z}}$, and $\{\gamma_i^n,\ i = 1, \dots, I\}_{n \in \mathbb{Z}}$ be defined by setting, on one hand,

$$\gamma_1^0 = \widehat{\gamma}_1^0, \quad \beta_i^n \;=\; \theta_i \gamma_i^n, \quad \alpha_i^n \;=\; \theta_i \beta_i^n, \quad i = 1, \dots, I, \quad n = 0, 1, \dots \tag{26}$$

with

$$\gamma_1^{n+1} \;=\; \pi_1 \alpha_I^n \quad \text{and} \quad \gamma_i^n = \pi_i \alpha_{i-1}^n, \quad i = 2, \dots, I, \quad n = 0, 1, \dots, \tag{27}$$

and, on the other hand,

$$(28)\qquad \alpha_I^n = \frac{\gamma_1^{n+1}}{\pi_1} \quad \text{and} \quad \alpha_i^n = \frac{\gamma_{i+1}^n}{\pi_{i+1}}, \quad i = I-1, \dots, 1, \quad n = -1, -2, \dots$$

with

$$(29)\qquad \beta_i^n = \frac{\alpha_i^n}{\theta_i} \quad \text{and} \quad \gamma_i^n = \frac{\beta_i^n}{\theta_i}, \quad i = I, \dots, 1, \quad n = -1, -2, \dots.$$

It is plain that the obtained sequences of reals converge to 0 (resp., $+\infty$) as n tends to $+\infty$ (resp., $-\infty$), and satisfy (22) for each n in $\mathbb{Z}$. Thus, these sequences can be used in the expression of the mappings q_i^n as given in (17) in order to produce a feedback law $\widehat{v}$ [given by (23)] which simultaneously stabilizes $\{S_i,\ i = 1, \dots, I\}$.

4. Simultaneous asymptotic stabilization of LTI systems. The results of the previous section are primarily derived using a stability criterion based on the positive invariance of sets. In order to construct feedback laws which achieve asymptotic stability, we now enrich this criterion and introduce time-varying feedback laws. We obtain an invariance criterion for time-varying sets that we use for the simultaneous *asymptotic* stabilization of families of LTI systems.

Throughout this section, we consider a countable family $\{S_i,\ i \in \mathcal{I}\}$ of LTI systems as defined in (24). Further, for each i in $\mathcal{I}$, we assume that there exists K_i in $\mathbb{R}^{n\times m}$ such that the linear feedback law $u_i : \mathbb{R}^n \to \mathbb{R}^m$ given by $u_i(x) = K_i x$ asymptotically stabilizes S_i.

Further, for each i in $\mathcal{I}$, we let $V_i : \mathbb{R}^n \to [0, \infty)$ denote a Lyapunov function for the system $\dot{x} = (A_i + B_i K_i)\, x$ given by $V_i(x) = x^t\, P_i\, x$ for each x in $\mathbb{R}^n$, where P_i is a positive definite matrix in $\mathbb{R}^{n\times n}$. Finally, we let Q_i be the positive definite matrix defined by

$$\nabla V_i(x)\, ((A_i + B_i K_i)\, x) \;=\; -\, x^t Q_i x, \quad x \in \mathbb{R}^n, \quad i \in \mathcal{I}.$$

The main result of this section is the following theorem.

THEOREM 4.1. *Assume that, in addition to the enforced assumptions, the set $\mathcal{I}$ is finite with $\mathcal{I} = \{1, \dots, I\}$ and $I \geq 2$. Then, there exists a time-varying state feedback law $v : [0,\infty) \times \mathbb{R}^n \to \mathbb{R}^m$, continuous on $[0,\infty) \times \mathbb{R}^n$ and C^∞ on $[0,\infty) \times (\mathbb{R}^n \backslash \{0\})$, which simultaneously globally exponentially stabilizes the family $\{S_i,\ i = 1, \dots, I\}$.*

The general lines of the proof of this theorem are as follows: We introduce a sequence $\{b_i^n(\cdot),\ i = 1, \dots, I\}_{n\in\mathbb{Z}}$ of mappings defined from $[0,\infty)$ into $(0,+\infty)$, decreasing to 0 as t tends to $+\infty$, and such that for each $t \geq 0$, the sequence of neighborhoods $\{V_i^{-1}([0, b_i^n(t)))\}_{n\in\mathbb{Z}}$ is a topological base at the origin. We then design a time-varying feedback law $v(t,x)$ such that for each $t \geq 0$, each $i = 1, \dots, I$, and each n in $\mathbb{Z}$, we have $v(t,x) = u_i(x)$ for all x in $V_i^{-1}(b_i^n(t))$. Finally, we show that for each $t_0 \geq 0$, each $i = 1, \dots, I$, and each n in $\mathbb{Z}$, each solution of the system $\dot{x} = f_i(x, v(t,x))$, which starts in the set $V_i^{-1}([0, b_i^n(t_0)])$ at time t_0, remains in the set $V_i^{-1}([0, b_i^n(t)])$ for all $t \geq t_0$. For each $i = 1, \dots, I$, we conclude that v asymptotically stabilizes the system S_i, upon noting that the mapping b_i^n converges to 0 as t tends to $+\infty$ for each n in $\mathbb{Z}$.

Proof. For each $i = 1, \dots, I$ and each $\beta > 0$, we let W_i^β denote the set $W_i^\beta \triangleq V_i^{-1}(\,[0, \beta)\,)$. We then define three sequences of positive reals $\{\alpha_i^n,\ i = 1, \dots, I\}_{n\in\mathbb{Z}}$, $\{\beta_i^n,\ i = 1, \dots, I\}_{n\in\mathbb{Z}}$, and $\{\gamma_i^n,\ i = 1, \dots, I\}_{n\in\mathbb{Z}}$ exactly as we did in subsection 3.3. In other words, we let π_1 be in $(0, \lambda_{min}(P_1)/\lambda_{max}(P_I))$ and π_i be in $(0, \lambda_{min}(P_i)/\lambda_{max}(P_{i-1}))$ for each $i = 2, \dots, I$. Further, we let $\widehat{\gamma}_1^0$ be an arbitrary positive real, and we let θ_i in $(0,1)$ for each $i = 1,\ldots,I$ be such that (25) holds. Finally, we apply the formulas (26), (27), (28), and (29).

Construction of the simultaneous stabilizer. We now seek a C^1 mapping $h : [0,\infty) \to (0,\infty)$ such that the mapping $b_i^n : [0,\infty) \to (0,\infty)$, given by

$$b_i^n(t) \;=\; \beta_i^n\, h(t), \quad t \geq 0,$$

satisfies

$$\nabla V_i(x)\,(\,A_i x + B_i u_i(x)\,) \;<\; \dot{b}_i^n(t), \quad x \in V_i^{-1}(b_i^n(t)), \quad t \geq 0, \tag{30}$$

or, equivalently,

$$-x^t Q_i\, x \;<\; \dot{b}_i^n(t), \quad x \in V_i^{-1}(b_i^n(t)), \quad t \geq 0, \tag{31}$$

for each $i = 1,\ldots,I$ and each n in $\mathbb{Z}$. In what follows, we fix $i = 1,\ldots,I$, n in $\mathbb{Z}$, and $t \geq 0$. Let x be such that $x^t P_i\, x = b_i^n(t)$. Then, by elementary linear algebra, we get $-x^t x \leq -b_i^n(t)/\lambda_{max}(P_i)$, and because we also have $-x^t Q_i\, x \leq -\lambda_{min}(Q_i)\, x^t x$, inequality (31) will be satisfied if

$$-\frac{\lambda_{min}(Q_i)}{\lambda_{max}(P_i)}\, b_i^n(t) \;<\; \dot{b}_i^n(t). \tag{32}$$

Because we require that $h(t) > 0$ and $b_i^n(t) = \beta_i^n h(t)$, inequality (32) will hold if

$$\frac{\dot{h}(t)}{h(t)} \;>\; -\,\frac{\lambda_{min}(Q_i)}{\lambda_{max}(P_i)}. \tag{33}$$

We now set $\rho \triangleq \min_{i=1,\ldots,I}\,(\lambda_{min}(Q_i)/\lambda_{max}(P_i))$ and we deduce from (33) that the desired assertion (30) will be satisfied for each $i = 1,\ldots,I$ and each n in $\mathbb{Z}$, if

$$\frac{\dot{h}(t)}{h(t)} \;>\; -\,\rho, \quad t \geq 0. \tag{34}$$

Let η be a fixed constant in $(1,\infty)$, and let the mapping $h : [0,\infty) \to (0,\infty)$ be given by

$$h(t) \;=\; e^{-\frac{\rho}{\eta}t}, \quad t \geq 0.$$

It is plain that h satisfies (34) so that for each $i = 1,\ldots,I$ and each n in $\mathbb{Z}$, the mapping $b_i^n : [0,\infty) \to (0,\infty)$ given by

$$b_i^n(t) \;=\; \beta_i^n h(t) \;=\; \beta_i^n e^{-\frac{\rho}{\eta}t}, \quad t \geq 0,$$

satisfies the desired assertion (30).

Next, for each $i = 1,\ldots,I$ and each n in $\mathbb{Z}$, we define the mappings $a_i^n, c_i^n : [0,\infty) \to (0,\infty)$ by setting

$$c_i^n(t) \;=\; \gamma_i^n\, h(t) \quad \text{and} \quad a_i^n(t) \;=\; \alpha_i^n\, h(t), \quad t \geq 0.$$

Because we have

$$b_i^n(t) \;=\; \theta_i c_i^n(t) \quad \text{with} \quad a_i^n(t) \;=\; \theta_i b_i^n(t), \quad t \geq 0, \quad i = 1,\ldots,I, \quad n \in \mathbb{Z},$$

and

$$c_1^{n+1}(t) \;=\; \pi_1 a_I^n(t) \quad \text{with} \quad c_i^n(t) \;=\; \pi_i a_{i-1}^n(t), \quad t \geq 0, \quad i = 2, \dots, I, \quad n \in \mathbb{Z},$$

it follows from the definition of θ_i and π_i for each $i = 1, \dots, I$ that for each $t \geq 0$, we have a two-sided sequence of neighborhoods

$$\begin{array}{cccccccccccc}
\vdots & & & & & & & & & & & \vdots \\
W_1^{c_1^{-1}(t)} & \supset & & & \cdots & & & & & & W_I^{a_I^{-1}(t)} & \supset \\
W_1^{c_1^{0}(t)} & \supset & W_1^{b_1^{0}(t)} & \supset & W_1^{a_1^{0}(t)} & \supset & W_2^{c_2^{0}(t)} & \supset & \cdots & \supset & W_I^{a_I^{0}(t)} & \supset \\
W_1^{c_1^{1}(t)} & \supset & W_1^{b_1^{1}(t)} & \supset & W_1^{a_1^{1}(t)} & \supset & W_2^{c_2^{1}(t)} & \supset & \cdots & \supset & W_I^{a_I^{1}(t)} & \supset \\
\vdots & & & & & & \vdots & & & & \vdots &
\end{array} \tag{35}$$

such that each neighborhood contains the closure of the neighborhood that follows. Next, for each $i = 1, \dots, I$ and each n in $\mathbb{Z}$, we define the mapping $q_i^n : [0, \infty) \times \mathbb{R}^n \to [0, 1]$ by setting

$$q_i^n(t, x) = \begin{cases} e^{\frac{(V_i(x) - b_i^n(t))^2}{\left(V_i(x) - b_i^n(t)\right)^2 - \left(b_i^n(t) - a_i^n(t)\right)^2}} & \text{if } V_i(x) \in (a_i^n(t), b_i^n(t)], \\ e^{\frac{\left(V_i(x) - b_i^n(t)\right)^2}{\left(V_i(x) - b_i^n(t)\right)^2 - (c_i^n(t) - b_i^n(t))^2}} & \text{if } V_i(x) \in (b_i^n(t), c_i^n(t)), \\ 0 & \text{otherwise} \end{cases} \tag{36}$$

for each (t, x) in $[0, \infty) \times \mathbb{R}^n$, and we let the mapping $v : [0, \infty) \times \mathbb{R}^n \to \mathbb{R}^m$ be given by

$$v(t, x) = \sum_{i=1}^{I} \sum_{n \in \mathbb{Z}} u_i(x) q_i^n(t, x), \quad (t, x) \in [0, \infty) \times \mathbb{R}^n.$$

The feedback law v is continuous on $[0, \infty) \times \mathbb{R}^n$ and C^∞ on $[0, \infty) \times (\mathbb{R}^n \backslash \{0\})$. Let (t, x) be in $[0, \infty) \times \mathbb{R}^n \backslash \{0\}$. It is easily checked from (35) combined with the continuity of the mappings V_j, a_j^m, and c_j^m for each (j, m) in $\{1, \dots, I\} \times \mathbb{Z}$ that there exist a neighborhood U of (t, x) in $[0, \infty) \times (\mathbb{R}^n \backslash \{0\})$ and a pair (i, n) in $\{1, \dots, I\} \times \mathbb{Z}$ such that

$$v(\tau, y) \;=\; u_i(y)\, q_i^n(\tau, y), \quad (\tau, y) \in U. \tag{37}$$

Because q_i^n is C^∞ on $[0, \infty) \times \mathbb{R}^n$ [5, Lemma B.6, p. 159] and u_i is C^∞ on $\mathbb{R}^n$ for each $i = 1, \dots, I$ and each n in $\mathbb{Z}$, the equality (37) implies that v is C^∞ on $[0, \infty) \times \mathbb{R}^n \backslash \{0\}$. Further, because the mappings q_i^n take values in $[0, 1]$, the equality (37) yields

$$\|v(t, x)\| \;\leq\; \max\left(\|u_1(x)\|, \dots, \|u_I(x)\|\right), \quad (t, x) \in [0, \infty) \times \mathbb{R}^n,$$

and continuity of u_i for each $i = 1, \dots, I$ combined with the fact that $v(t, 0) = 0,\ t \geq 0$ implies that v is continuous at each point $(t, 0), t \geq 0$. Therefore, v is continuous on $[0, \infty) \times \mathbb{R}^n$.

Global exponential stability. Throughout the rest of the proof, we fix $i = 1, \dots, I$. From the definition of v, it is not hard to see that

$$v(t, x) = u_i(x), \quad t \geq 0, \quad x \in V_i^{-1}(\, b_i^n(t)\,), \quad n \in \mathbb{Z}.$$

Therefore, from (30) we get

$$\nabla V_i(x)\,(A_i\,x + B_i v(t,x)) \;<\; \dot{b}_i^n(t), \quad x \in V_i^{-1}(b_i^n(t)), \quad t \geq 0, \quad n \in \mathbb{Z},$$

and because we have $\partial W_i^\beta = V_i^{-1}(\beta)$ and $\overline{W}_i^\beta = V_i^{-1}([0,\beta])$ for each $\beta > 0$, Lemma 8.1 implies that for each $t_0 \geq 0$ and each n in $\mathbb{Z}$, the solution $x(\cdot, x_0, t_0)$ of $\dot{x} = A_i x + B_i v(t,x)$ starting from x_0 at time t_0 satisfies

$$V_i(x(t,x_0,t_0)) \;\leq\; b_i^n(t), \quad t \geq t_0, \quad x_0 \in \overline{W}_i^{b_i^n(t_0)}. \tag{38}$$

From the definition of the sequence $\{\beta_i^n\}_{n\in\mathbb{Z}}$, it is easily seen that we have

$$\beta_i^{n+k} \;=\; (\pi_1 \cdots \pi_I\, \theta_1^2 \cdots \theta_I^2)^k \beta_i^n, \quad n \in \mathbb{Z}, \quad k = 0, 1, \ldots.$$

Upon setting $T \triangleq -\frac{\eta}{\rho}\,\log(\pi_1 \ldots \pi_I\, \theta_1^2 \ldots \theta_I^2)$, the previous equality translates to

$$\beta_i^n e^{-\frac{\rho}{\eta}kT} \;=\; \beta_i^{n+k}, \quad n \in \mathbb{Z}, \quad k = 0, 1, \ldots, \tag{39}$$

which in turn easily yields

$$b_i^n(t + kT) \;=\; b_i^{n+k}(t), \quad t \geq 0, \quad n \in \mathbb{Z}, \quad k = 0, 1, \ldots. \tag{40}$$

Let x_0 be in $\mathbb{R}^n$. As the sequence $\{b_i^n(0) = \beta_i^n\}_{n\in\mathbb{Z}}$ is strictly decreasing and converges to 0 and $+\infty$ as n tends to $+\infty$ and $-\infty$, resp., there exists an integer $\bar{n}$ such that

$$b_i^{\bar{n}+1}(0) \;<\; V_i(x_0) \;\leq\; b_i^{\bar{n}}(0). \tag{41}$$

Fix $t_0 \geq 0$, and let the integer k and t_0' in $[0,T)$ be such that $t_0 = kT + t_0'$. By combining (40) with the fact that the mapping b_i^n is decreasing for each n in $\mathbb{Z}$, we get

$$b_i^{\bar{n}}(0) \;=\; b_i^{\bar{n}-k-1}((k+1)T) \;\leq\; b_i^{\bar{n}-k-1}(t_0),$$

so that (41) yields $x_0 \in V_i^{-1}(\,[0, b_i^{\bar{n}-k-1}(t_0)]\,)$. Thus, the inequality (38) implies that

$$V_i(x(t,x_0,t_0)) \;\leq\; b_i^{\bar{n}-k-1}(t), \quad t \geq t_0,$$

and from the expression of $b_i^{\bar{n}-k-1}(t)$ we obtain that

$$V_i(x(t,x_0,t_0)) \;\leq\; \beta_i^{\bar{n}-k-1}\, e^{-\frac{\rho}{\eta}(t-t_0+t_0'+kT)}, \quad t \geq t_0. \tag{42}$$

Next, by combining (39) with the fact that $t_0' \geq 0$, we obtain from (42) that

$$V_i(x(t,x_0,t_0)) \;\leq\; \beta_i^{\bar{n}-1}\, e^{-\frac{\rho}{\eta}(t-t_0+t_0')} \;\leq\; \beta_i^{\bar{n}-1}\, e^{-\frac{\rho}{\eta}(t-t_0)}, \quad t \geq t_0. \tag{43}$$

The identity (39) yields $\beta_i^{\bar{n}-1} = e^{\frac{2\rho}{\eta}T}\beta_i^{\bar{n}+1}$, so that the inequality $\beta_i^{\bar{n}-1} < e^{\frac{2\rho}{\eta}T}V_i(x_0)$ follows from (41). Thus, (43) implies that

$$\sqrt{V_i(x(t,x_0,t_0))} \;\leq\; e^{\frac{\rho}{\eta}T}\sqrt{V_i(x_0)}\; e^{-\frac{\rho}{2\eta}(t-t_0)}, \quad t \geq t_0.$$

Because $e^{\frac{\rho}{\eta}T}$ is a constant and the mapping $x \mapsto \sqrt{V_i(x)}$ is a norm on $\mathbb{R}^n$, we obtain from the equivalence of all norms on $\mathbb{R}^n$ that v globally exponentially stabilizes S_i

with the rate of convergence $\frac{\rho}{2\eta}$. The proof of the theorem is complete upon noting that the previous argument holds for each $i = 1, \ldots, I$. $\square$

In case the set $\mathcal{I}$ is countably infinite, we obtain the following sufficient conditions for simultaneous asymptotic stabilizability.

THEOREM 4.2. *Assume that, in addition to the enforced assumptions, the set $\mathcal{I}$ is countably infinite and equal to $\{1, 2, \ldots\}$ and that the following statements hold.*

(i) *There exists a positive real M such that $\|K_i\| \leq M,\ i = 1, 2, \ldots.$*

(ii) *The real $\rho \triangleq \inf_{i=1,2,\ldots}(\frac{\lambda_{min}(Q_i)}{\lambda_{max}(P_i)})$ is strictly positive.*

Then, there exists a time-varying state feedback law $v : [0, \infty) \times \mathbb{R}^n \to \mathbb{R}^m$, continuous on $[0, \infty) \times \mathbb{R}^n$ and C^∞ on $[0, \infty) \times (\mathbb{R}^n \backslash \{0\})$, which simultaneously globally asymptotically stabilizes the family $\{S_i,\ i = 1, 2, \ldots\}$.

We omit the proof of this theorem as it is based on arguments similar to those used for Theorem 4.1 (we refer the interested reader to [5, p. 65] or [7] for a proof).

5. Simultaneous asymptotic stabilization of nonlinear systems.

Because the asymptotic criterion introduced in the previous section is nonlinear we are now able to use it for the simultaneous stabilization of nonlinear systems. We actually obtain the following sufficient conditions for simultaneous stabilizability.

THEOREM 5.1. *Let $k \geq 0$ and $k' \geq 1$ be two integers and set $k'' \triangleq \min(k, k')$. Let D be a neighborhood of the origin, and assume that there exists a continuous and almost C^k state feedback law $u_i : D \to \mathbb{R}^m$ which locally asymptotically stabilizes S_i for each $i = 1, \ldots, I$. Further, assume that for each $i = 1, \ldots, I$, the mapping $f_i(\cdot, u_i(\cdot))$ is continuous on D and let $V_i : \overline{D} \to [0, \infty)$ be a $C^{k'}$ Lyapunov function, satisfying*

$$\nabla V_i(x)\, f_i(x, u_i(x)) \ < \ 0, \quad x \in D \backslash \{0\}.$$

(a) *Assume that there exists a sequence $\{b_i^n,\ i = 1, \ldots, I\}_{n=1}^\infty$ of $C^{k'}$ mappings $b_i^n : [0, \infty) \to (0, \infty)$, such that the following assertions hold.*

(i) $\sup_{t \geq t_0} b_i^n(t) \ \to\ 0$ *as* $n \to \infty, \quad i = 1, \ldots, I, \quad t_0 \geq 0.$

(ii) $b_i^n(t) < \inf_{x \in \partial D} V_i(x), \quad t \geq 0, \quad i = 1, \ldots, I, \quad n = 1, 2, \ldots.$

(iii) $b_i^n(t) \ \to\ 0$ *as* $t \to \infty, \quad i = 1, \ldots, I, \quad n = 1, 2, \ldots.$

(iv) *For each $n = 1, 2, \ldots,$ we have*

$$D \cap V_I^{-1}(\,[0, b_I^n(t))\,) \ \supset\ D \cap V_1^{-1}(\,[0, b_1^{n+1}(t)]\,), \quad t \geq 0, \tag{44}$$

and for each $n = 1, 2, \ldots$ and each $i = 1, \ldots, I - 1$ we have

$$D \cap V_i^{-1}(\,[0, b_i^n(t)]\,) \ \supset\ D \cap V_{i+1}^{-1}(\,[0, b_{i+1}^n(t))\,), \quad t \geq 0. \tag{45}$$

(v) *For each $n = 1, 2, \ldots$ and each $i = 1, \ldots, I$, we have*

$$\nabla V_i(x)\, f_i(x, u_i(x)) \ < \ \dot{b}_i^n(t), \quad x \in D \cap V_i^{-1}(b_i^n(t)), \quad t \geq 0.$$

Then, there exists a time-varying state feedback law $v : [0, \infty) \times D \to \mathbb{R}^m$, continuous on $[0, \infty) \times D$ and $C^{k''}$ on $[0, \infty) \times (D \backslash \{0\})$, which simultaneously locally asymptotically stabilizes the family $\{S_i,\ i = 1, \ldots, I\}$.

(b) *Now, assume that for each $i = 1, \ldots, I$, the feedback law u_i globally asymptotically stabilizes S_i and that V_i is a radially unbounded Lyapunov function, so that we may set $D \triangleq \mathbb{R}^n$. Further, assume that there exists a sequence $\{b_i^n,\ i = 1, \ldots, I\}_{n \in \mathbb{Z}}$*

of $C^{k'}$ *mappings* $b_i^n : [0,\infty) \to (0,\infty)$*, such that on one hand, assertion* (i) *holds and, on the other hand, assertions* (ii), (iii), (iv), and (v) *hold for each* n *in* $\mathbb{Z}$*. Finally, assume that we have*

$$b_i^n(t_0) \to +\infty \quad as \quad n \to -\infty, \quad i = 1, \ldots, I, \quad t_0 \geq 0. \tag{46}$$

Then there exists a time-varying state feedback law $v : [0,\infty) \times \mathbb{R}^n \to \mathbb{R}^m$*, continuous on* $[0,\infty) \times \mathbb{R}^n$ *and* $C^{k''}$ *on* $[0,\infty) \times (\mathbb{R}^n \backslash \{0\})$*, which simultaneously globally asymptotically stabilizes the family* $\{S_i,\ i = 1, \ldots, I\}$*.*

Proof. As the proof of assumption (b) is similar to that of assumption (a), we prove only (a) (see [5, p. 83] for further details). Further, because the main lines of the proof of assumption (a) are similar to those of the proof of Theorem 4.1, we will merely outline the main differences between these two proofs. For each $i = 1, \ldots, I$ and each $\beta > 0$, we set $W_i^\beta \triangleq \{x \in D : V_i(x) < \beta\}$.

We first construct two sequences $\{a_i^n,\ i = 1, \ldots, I\}_{n=1}^\infty$ and $\{c_i^n,\ i = 1, \ldots, I\}_{n=1}^\infty$ of mappings $a_i^n, b_i^n : [0,\infty) \to (0,\infty)$, satisfying for each $n = 1, 2, \ldots$

$$\inf_{x \in \partial D} V_i(x) \ > \ c_i^n(t) \ > \ b_i^n(t) \ > \ a_i^n(t) \ > \ 0, \quad t \geq 0, \quad i = 1, \ldots, I, \tag{47}$$

with

$$W_I^{a_I^n(t)} \supset \overline{W}_1^{c_1^{n+1}(t)}, \qquad \text{and} \qquad W_i^{a_i^n(t)} \supset \overline{W}_{i+1}^{c_{i+1}^n(t)}, \quad i = 1, \ldots, I-1, \tag{48}$$

for each $t \geq 0$ as follows: We define $c_1^1 : [0,\infty) \to (0,\infty)$ by setting

$$c_1^1(t) \ = \ \frac{b_1^1(t) + \inf\limits_{x \in \partial D} V_1(x)}{2}, \quad t \geq 0.$$

Then, for each $n = 1, 2, \ldots$ and each $i = 1, \ldots, I-1$, we define two C^∞ mappings $a_i^n, c_{i+1}^n : [0,\infty) \to (0,\infty)$ from b_i^n and b_{i+1}^n by applying Lemma 8.2 with $b_1 = b_i^n$, $b_2 = b_{i+1}^n$, and (45). Finally, for each $n = 1, 2, \ldots$, we define two C^∞ mappings $a_I^n, c_1^{n+1} : [0,\infty) \to (0,\infty)$ by applying Lemma 8.2 with $b_1 = b_I^n$, $b_2 = b_1^{n+1}$, and the inequality (44).

Next, for each $n = 1, 2, \ldots$ and each $i = 1, \ldots, I$, we define the mapping $q_i^n : [0,\infty) \times D \to [0,1]$ by applying the formula (36) for each (t,x) in $[0,\infty) \times D$ (with V_i, a_i^n, b_i^n, c_i^n as defined here). Finally, we define the feedback law $v : [0,\infty) \times D \to \mathbb{R}^m$ by setting

$$v(t,x) = \sum_{n=1}^{\infty} \sum_{i=1}^{I} u_i(x) q_i^n(t,x), \quad (t,x) \in [0,\infty) \times D. \tag{49}$$

Using an argument similar to that used in the proof of Theorem 4.1, it is not hard to check that v is continuous on $[0,\infty) \times D$ and $C^{k''}$ on $[0,\infty) \times (D \backslash \{0\})$.

We now fix $i = 1, \ldots, I$ and $n = 1, 2, \ldots$. Because $\partial W_i^{b_i^n(t)} = D \cap V_i^{-1}(b_i^n(t))$ and $q_i^n(t,x) = 1$ for each x in $V_i^{-1}(b_i^n(t))$ and each $t \geq 0$, we obtain that $v(t,x) = u_i(x)$ for each x in $\partial W_i^{b_i^n(t)}$ and each $t \geq 0$. It follows from the assumption v that

$$\nabla V_i(x)\, f_i(x, v(t,x)) \ = \ \nabla V_i(x)\, f_i(x, u_i(x)) \ < \ \dot{b}_i^n(t), \quad x \in \partial W_i^{b_i^n(t)}, \quad t \geq 0.$$

Thus, by an argument similar to that used in the proof of Theorem 4.2 to prove asymptotic stability, it can be shown that v simultaneously asymptotically stabilizes the family $\{S_i,\ i = 1, \ldots, I\}$. □

We are now going to use these sufficient conditions for the simultaneous stabilization of certain homogeneous systems.

6. Simultaneous asymptotic stabilization of homogeneous systems. In this section, we consider a pair of control systems,

$$S_1 : \ \dot{x} = f(x) - g(x)u \qquad \text{and} \qquad S_2 : \ \dot{x} = f(x) + g(x)u, \tag{50}$$

where the state x lies in $\mathbb{R}^n$ and the input u lies in $\mathbb{R}^m$. We assume that the mappings $f : \mathbb{R}^n \to \mathbb{R}^n$ and $g : \mathbb{R}^n \to \mathbb{R}^{n\times m}$ are continuous with $f(0) = 0$ and that there exists a continuous state feedback law $u : \mathbb{R}^n \to \mathbb{R}^m$ which locally asymptotically stabilizes S_2, so that $-u$ locally asymptotically stabilizes S_1. We define the mapping $F : \mathbb{R}^n \to \mathbb{R}^n$ by setting

$$F(x) \ = \ f(x) \ + \ g(x)\, u(x), \quad x \in \mathbb{R}^n, \tag{51}$$

and we assume that F is homogeneous, i.e., there exists s in $\mathbb{R}$ and $(r_1, \dots, r_n)$ in $(0, +\infty)^n$ such that for each x in $\mathbb{R}^n \backslash \{0\}$ and each $\lambda > 0$, we have

$$F(\lambda^{r_1} x_1, \dots, \lambda^{r_n} x_n) \ = \ \begin{pmatrix} \lambda^{s+r_1} F_1(x) \\ \vdots \\ \lambda^{s+r_n} F_n(x) \end{pmatrix}, \tag{52}$$

where F_i is the ith coordinate mapping of F for each $i = 1, \dots, n$ (note that this assumption clearly holds if the control system S_1 and the feedback law u are homogeneous). As we shall see in the following proposition, it turns out that there *always* exists a time-varying state feedback law which simultaneously stabilizes S_1 and S_2.

PROPOSITION 6.1. *Let the systems S_1 and S_2 and the mapping $F : \mathbb{R}^n \to \mathbb{R}^n$ satisfy the assumptions* (50), (51), *and* (52). *Then, the following hold.*

(i) *If $s = 0$, then there exists a continuous time-varying state feedback law $v : [0, \infty) \times \mathbb{R}^n \to \mathbb{R}^m$ which simultaneously globally uniformly asymptotically stabilizes S_1 and S_2, with uniform exponential convergence of the corresponding closed-loop systems* (*according to Definition* 2.1 (iv)).

(ii) *If $s > 0$, then there exists a continuous time-varying state feedback law $v : [0, \infty) \times \mathbb{R}^n \to \mathbb{R}^m$ which simultaneously globally asymptotically stabilizes S_1 and S_2.*

(iii) *If $s < 0$, then there exists a continuous time-varying state feedback law $v : [0, \infty) \times \mathbb{R}^n \to \mathbb{R}^m$ which simultaneously locally asymptotically stabilizes S_1 and S_2.*

Proof. The main idea of the proof is to construct some sequences of mappings b_i^n satisfying the assumptions of Theorem 5.1. To this end, we first define a mapping $h_\beta : [0, \infty) \to (0, \infty)$ for each β in some subset of $(0, \infty)$ as follows.

We let $p = 1$ and we choose k satisfying

$$k \ \geq \ \max_{i=1,\dots,n} (r_i) \qquad \text{and} \qquad 1 + \frac{s}{k} > 0.$$

By Theorem 2 in Rosier [12], there exists a C^1 radially unbounded homogeneous Lyapunov function $V : \mathbb{R}^n \to [0, \infty)$ such that

$$\nabla V(x)\, F(x) \ < \ 0, \quad x \in \mathbb{R}^n \backslash \{0\}, \tag{53}$$

and

$$V(\lambda^{r_1} x_1, \dots, \lambda^{r_n} x_n) = \lambda^k V(x), \quad x \in \mathbb{R}^n \backslash \{0\}, \tag{54}$$

for each $\lambda > 0$. We stress that (53) implies that the system $\dot{x} = F(x)$ is globally asymptotically stable. Further, as mentioned in [12, p. 470], the identities (52) and (54) yield

$$\nabla V(\lambda^{r_1}x_1,\dots,\lambda^{r_n}x_n)\,F(\lambda^{r_1}x_1,\dots,\lambda^{r_n}x_n) \;=\; \lambda^{s+k}\,\nabla V(x)\,F(x)$$

for all x in $\mathbb{R}^n\backslash\{0\}$ and all $\lambda > 0$. Furthermore, from the homogeneity of V and F it can be checked [5, Lemma 5.1, p. 87] that there exists $\theta > 0$ such that we have

$$\nabla V(x)\,F(x) \;<\; -\,\theta\rho^{1+\frac{s}{k}}, \quad x \in V^{-1}(\rho), \quad \rho > 0. \tag{55}$$

If $s = 0$, then for each $\beta > 0$ we define $h_\beta : [0,\infty) \to (0,\infty)$ by setting

$$h_\beta(t) \;=\; \beta e^{-\theta t}, \quad t \ge 0. \tag{56}$$

If $s > 0$, then for each $\beta > 0$ we let $h_\beta : [0,\infty) \to (0,\infty)$ be given by

$$h_\beta(t) \;=\; \frac{1}{\left(\beta^{-\frac{s}{k}} + \dfrac{s}{k}\theta t\right)^{\frac{k}{s}}}, \quad t \ge 0. \tag{57}$$

Finally, if $s < 0$, we set

$$\bar{\beta} \;\triangleq\; \left[\theta\left(\frac{-s}{2k}\right)^{\frac{1}{2}} e^{\frac{1}{2}}\right]^{-\frac{k}{s}} \tag{58}$$

and for each β in $(0,\bar{\beta}]$ we define $h_\beta : [0,\infty) \to (0,\infty)$ by setting

$$h_\beta(t) \;=\; \begin{cases} \beta, & t \le \dfrac{\beta^{\frac{-s}{k}}}{\theta}, \\ \beta e^{-\left(t - \frac{\beta^{\frac{-s}{k}}}{\theta}\right)^2}, & t > \dfrac{\beta^{\frac{-s}{k}}}{\theta}. \end{cases} \tag{59}$$

It is not hard to check [5, Lemma B.13, p. 164] that for each β in $(0,\bar{\beta}]$ (resp., $\beta > 0$) the mapping h_β as defined in (59) (resp., (56) or (57)), satisfies $h_\beta(0) = \beta$ together with

$$-\theta h_\beta(t)^{1+\frac{s}{k}} \;\le\; \dot{h}_\beta(t), \quad t \ge 0. \tag{60}$$

If $s < 0$ (resp., $s \ge 0$), we fix β in $(0,\bar{\beta}]$ (resp., in $(0,\infty)$). Because the mapping h_β given by the formula (59) (resp., (56) or (57)) satisfies the inequality (60), it follows from (55) that

$$\nabla V(x)\,F(x) \;<\; \dot{h}_\beta(t), \quad x \in V^{-1}(h_\beta(t)), \quad t \ge 0. \tag{61}$$

Furthermore, it is plain that for each β in $(0,\bar{\beta}]$ (resp., in $(0,\infty)$), the mapping h_β is nonincreasing and converges to 0 as t tends to $+\infty$. Finally, for each β and each γ in $(0,\bar{\beta}]$ (resp., in $(0,\infty)$) with $\beta < \gamma$, we have $h_\beta(t) < h_\gamma(t)$ for all $t \ge 0$.

Simultaneous asymptotic stabilization in the case $s \ge 0$.

Throughout this paragraph, we assume $s \ge 0$. We fix $\widehat{\beta}$ in $(0,1)$, and we define the sequence of positive reals $\{\beta_i^n,\ i = 1,2\}_{n\in\mathbb{Z}}$ by setting

$$\beta_1^n \;\triangleq\; (\widehat{\beta})^{2n-1} \qquad \text{and} \qquad \beta_2^n \;\triangleq\; (\widehat{\beta})^{2n}, \quad n \in \mathbb{Z}.$$

Next, we choose the sequences of positive reals $\{\alpha_i^n,\ i = 1, 2, \}_{n\in\mathbb{Z}}$ and $\{\beta_i^n,\ i = 1, 2\}_{n\in\mathbb{Z}}$ such that we have

$$\gamma_1^n \ > \ \beta_1^n \ > \ \alpha_1^n \ > \ \gamma_2^n \ > \ \beta_2^n \ > \ \alpha_2^n \ > \ \gamma_1^{n+1}, \quad n \in \mathbb{Z},$$

and we define the mappings $a_i^n,\ b_i^n,\ c_i^n : [0,\infty) \to (0,\infty)$ by setting

$$a_i^n(t) \ = \ h_{\alpha_i^n}(t), \quad b_i^n(t) \ = \ h_{\beta_i^n}(t), \quad c_i^n(t) \ = \ h_{\gamma_i^n}(t)$$

for each $t \geq 0$, with h_β given by (56) if $s = 0$ and (57) if $s > 0$. Because h_β satisfies (61), it follows that

$$\nabla V(x)\, F(x) \ < \ \dot{b_i^n}(t), \quad x \in V^{-1}(b_i^n(t)), \quad t \geq 0, \tag{62}$$

for each $i = 1, 2$ and each n in $\mathbb{Z}$. For each $i = 1, 2$, and each n in $\mathbb{Z}$, we let the mapping $q_i^n : [0,\infty) \times \mathbb{R}^n \to [0, 1]$ be given by the formula (36) for each (t, x) in $[0,\infty) \times \mathbb{R}^n$, after substituting V for V_i, with a_i^n, b_i^n, and c_i^n as given here. It can be checked that the sequence of mappings $\{b_i^n,\ i = 1, 2, \}_{n\in\mathbb{Z}}$ satisfies each one of the assumptions of Theorem 5.1(b), and from the proof of this theorem we see that the mapping $v : [0,\infty) \times \mathbb{R}^n \to \mathbb{R}^m$ given by

$$v(t,x) = -\sum_{n\in\mathbb{Z}} u(x)\, q_1^n(t,x) \ + \ \sum_{n\in\mathbb{Z}} u(x)\, q_2^n(t,x), \quad (t,x) \in [0,\infty) \times \mathbb{R}^n, \tag{63}$$

simultaneously *globally* asymptotically stabilizes S_1 and S_2. In the case $s = 0$ we now show that the feedback law v uniformly stabilizes with exponential convergence both S_1 and S_2.

Exponential convergence in the case $s = 0$. Throughout this paragraph, we assume that $s = 0$, so that we have

$$b_1^n(t) \ = \ (\widehat{\beta})^{2n-1}\, e^{-\theta t}, \quad \text{and} \quad b_2^n(t) \ = \ (\widehat{\beta})^{2n}\, e^{-\theta t}, \quad t \geq 0, \quad n \in \mathbb{Z}.$$

Upon setting $T \triangleq -\frac{1}{\theta}\ln(\beta^2)$, these definitions yield

$$b_i^n(t + kT) \ = \ b_i^{n+k}(t), \quad t \geq 0, \quad i = 1, 2, \quad n \in \mathbb{Z}, \quad k = 0, 1, \ldots. \tag{64}$$

We now fix $i = 1, 2$ and we let x_0 be in $\mathbb{R}^n$. Because the sequence $\{b_i^n(0)\}_{n\in\mathbb{Z}}$ is strictly decreasing and converges to $+\infty$ and 0 as n tends to $-\infty$ and $+\infty$, resp., there exists $\bar{n}(x_0)$ in $\mathbb{Z}$ (for the sake of brevity, we will let $\bar{n}$ denote $\bar{n}(x_0)$) such that

$$b_i^{\bar{n}+1}(0) \ < \ V(x_0) \ \leq \ b_i^{\bar{n}}(0). \tag{65}$$

We fix $t_0 \geq 0$ and let the integer k and the real t_0' in $[0, T)$ be such that $t_0 = kT + t_0'$. By combining (64) with the fact that the mapping b_i^n is decreasing for each n in $\mathbb{Z}$, we get

$$b_i^{\bar{n}}(0) \ = \ b_i^{\bar{n}-k-1}((k+1)T) \ \leq \ b_i^{\bar{n}-k-1}(t_0),$$

so that (65) yields $V(x_0) \leq b_i^{\bar{n}-k-1}(t_0)$. Therefore, Lemma 8.1 combined with (62) implies that

$$V(x(t, x_0, t_0)) \ \leq \ b_i^{\bar{n}-k-1}(t), \quad t \geq t_0. \tag{66}$$

Next, for x in $\mathbb{R}^n$, Lemma 1 in [12] yields the existence of $(\lambda_x) > 0$ and y in $S^{n-1} \triangleq \{x \in \mathbb{R}^n : \|x\| = 1\}$ satisfying $x = (\,(\lambda_x)^{r_1} y_1, \dots, (\lambda_x)^{r_n} y_n\,)$, and upon setting $m_V = \min_{y \in S^{n-1}} V(y)$, we get

$$V(x) \;=\; (\lambda_x)^k\, V(y) \;\geq\; m_V (\lambda_x)^k. \tag{67}$$

We now define r and R by setting $r \triangleq \min_{i=1,\dots,n} r_i$ and $R \triangleq \max_{i=1,\dots,n} r_i$, and we obtain

$$\|x\|^2 \;=\; (\lambda_x)^{2r_1} y_1^2 + \cdots + (\lambda_x)^{2r_n} y_n^2 \;\leq\; \begin{cases} (\lambda_x)^{2R} & \text{if} \quad (\lambda_x) \geq 1, \\ (\lambda_x)^{2r} & \text{if} \quad (\lambda_x) < 1. \end{cases}$$

Thus, for each $t \geq t_0$, the inequalities (66) and (67) together with the expression of $b_i^{\bar{n}-k-1}(t)$ yield

$$\begin{aligned} \|x(t, x_0, t_0)\|^{\frac{k}{R}} \;&\leq\; \frac{\beta_i^{\bar{n}-1-k}}{m_V} e^{-\theta t} \quad \text{if } (\lambda_{x(t,x_0,t_0)}) \geq 1, \\ \|x(t, x_0, t_0)\|^{\frac{k}{r}} \;&\leq\; \frac{\beta_i^{\bar{n}-1-k}}{m_V} e^{-\theta t} \quad \text{if } (\lambda_{x(t,x_0,t_0)}) < 1. \end{aligned}$$

Because $t_0 = kT + t_0'$ with $t_0' \geq 0$, it is easily seen from (64) that we have

$$\begin{aligned} \|x(t, x_0, t_0)\| \;&\leq\; \left(\frac{\beta_i^{\bar{n}-1}}{m_V}\right)^{\frac{R}{k}} e^{-\theta \frac{R}{k}(t-t_0)} \quad \text{if } (\lambda_{x(t,x_0,t_0)}) \geq 1, \\ \|x(t, x_0, t_0)\| \;&\leq\; \left(\frac{\beta_i^{\bar{n}-1}}{m_V}\right)^{\frac{r}{k}} e^{-\theta \frac{r}{k}(t-t_0)} \quad \text{if } (\lambda_{x(t,x_0,t_0)}) < 1 \end{aligned}$$

for each $t \geq t_0$. Thus, we get

$$\|x(t, x_0, t_0)\| \;\leq\; \max \left[\left(\frac{\beta_i^{\bar{n}-1}}{m_V}\right)^{\frac{R}{k}}, \left(\frac{\beta_i^{\bar{n}-1}}{m_V}\right)^{\frac{r}{k}} \right] e^{-\theta \frac{r}{k}(t-t_0)}, \quad t \geq t_0.$$

We note that the real

$$\max \left[\left(\frac{\beta_i^{\bar{n}-1}}{m_V}\right)^{\frac{R}{k}}, \left(\frac{\beta_i^{\bar{n}-1}}{m_V}\right)^{\frac{r}{k}} \right]$$

depends solely on $\|x_0\|$ (uniformly in t_0). Further, by definition, the integer $\bar{n}(x_0)$ converges to $+\infty$ as $\|x_0\|$ tends to 0, so that $\beta_i^{\bar{n}}$ converges to 0 as $\|x_0\|$ tends to 0. We therefore obtain that v globally uniformly asymptotically stabilizes with exponential convergence the systems S_1 and S_2 (according to Definition 2.1 (iv)).

Simultaneous local asymptotic stabilization in the case $s < 0$.

We let

$$\beta_1^n \;\triangleq\; \frac{\bar{\beta}}{2n-1} \qquad \text{and} \qquad \beta_2^n \;\triangleq\; \frac{\bar{\beta}}{2n}, \quad n = 1, 2, \dots,$$

with $\bar{\beta}$ as given in (58), and we define $b_i^n : [0, \infty) \to (0, \infty)$ by setting $b_i^n(t) = h_{\beta_i^n}(t)$ for each $t \geq 0$, each $i = 1, 2$, and each $n = 1, 2, \dots$, with h_β as given in (59). It can easily be checked that the mappings b_i^n satisfy the assumptions of Theorem 5.1(a). Thus, there exists a continuous time-varying state feedback law $v : [0, \infty) \times V^{-1}(\,[0, \bar{\beta}{+}1)\,) \to \mathbb{R}^m$ which simultaneously locally asymptotically stabilizes S_1 and S_2. $\square$

7. Conclusion. In this paper, merely continuous and time-varying nonlinear state feedback have proved very useful for simultaneous stabilization of countable families of linear and nonlinear systems. We believe that the use of such feedback for robust stabilization of *uncountable* families of systems also should yield interesting results; we continue our investigation in that direction [6].

8. Appendix. The following lemma is the key argument in establishing the results of this paper. It is either implicitly or explicitly used in the proofs of all the theorems and propositions of this paper.

LEMMA 8.1. *Let D be a bounded neighborhood of the origin in $\mathbb{R}^n$ (resp., $D = \mathbb{R}^n$) and let $V : \overline{D} \to (0, \infty)$ be a Lyapunov function (resp., a radially unbounded Lyapunov function). Further, let the mapping $f : [0, \infty) \times \overline{D} \to \mathbb{R}^n$ be continuous and let the mapping $b : [0, \infty) \to (0, \inf_{x \in \partial D} V(x))$ be C^1. Finally, set $W^\beta \triangleq \{x \in D : \; V(x) < \beta\}$ for each $\beta > 0$, and assume that*

$$\nabla V(x)\, f(t, x) \; < \; \dot{b}(t), \quad x \in \partial W^{b(t)}, \quad t \geq 0. \tag{68}$$

Then, for each $t_0 \geq 0$ and each x_0 in $\overline{W}^{b(t_0)}$, each solution $x(\cdot, x_0, t_0)$ of $\dot{x} = f(t, x)$ satisfies

$$x(t, x_0, t_0) \; \in \; \overline{W}^{b(t)}, \quad t \geq t_0.$$

Proof. Fix $t_0 \geq 0$ and x_0 in $\overline{W}^{b(t_0)}$ and let $x(\cdot, x_0, t_0)$ denote the solution of $\dot{x} = f(t, x)$ that starts from x_0 at time t_0. In order to prove the lemma, the next two claims will be needed.

CLAIM 1. *Let $t_3 > t_0$ be such that $x(t, x_0, t_0)$ lies in D for each t in $[t_0, t_3)$. Then we have the inequality $V(x(t, x_0, t_0)) \leq b(t)$, $t \in [t_0, t_3)$.*

Assume that Claim 1 does not hold. Then there exists t_2 in $[t_0, t_3)$ such that we have $V(x(t_2, x_0, t_0)) > b(t_2)$. Because we have $V(x(t_0, x_0, t_0)) - b(t_0) \leq 0$, continuity of the mapping $V(x(\cdot, x_0, t_0)) - b(\cdot)$ yields the existence of t_1 in $[t_0, t_2)$ and h_1 in $(0, t_3 - t_1)$ such that

$$V(x(t_1, x_0, t_0)) - b(t_1) = 0, \tag{69}$$

and

$$V(x(t_1 + h, x_0, t_0)) - b(t_1 + h) > 0, \quad h \in (0, h_1). \tag{70}$$

By assumption $x(t_1, x_0, t_0)$ belongs to D, and we obtain from (69) that $x(t_1, x_0, t_0)$ lies in $\partial W^{b(t_1)}$. Thus, assumption (68) yields

$$\frac{d}{dt}|_{t=t_1} V(x(t, x_0, t_0)) = \nabla V(x(t_1, x_0, t_0))\, f(\, t_1, x(t_1, x_0, t_0)\,) \; < \; \dot{b}(t_1),$$

and from the continuity of the mappings $\nabla V(\cdot)$, $f(\cdot, \cdot)$, and $\dot{b}(\cdot)$, combined with (69) we get

$$V(x(t_1 + h, x_0, t_0)) \; < \; b(t_1 + h) \quad \text{for} \quad h > 0 \quad \text{small enough,}$$

which is a contradiction of (70). The proof of Claim 1 is thus complete.

CLAIM 2. *$x(t, x_0, t_0)$ lies in D for each $t \geq t_0$.*

Since Claim 2 clearly holds if $D = \mathbb{R}^n$, we assume that D is bounded. Suppose that the claim does not hold. Because x_0 belongs to D, it is easily seen [5, Lemma B.2.iii, p. 152] that there exists $t_1 > t_0$ such that

$$x(t_1, x_0, t_0) \in \partial D, \qquad \text{and} \qquad x(t, x_0, t_0) \in D, \quad t \in [t_0, t_1). \tag{71}$$

Thus, Claim 1 yields

$$V(x(t, x_0, t_0)) \leq b(t), \quad t \in [t_0, t_1). \tag{72}$$

Further, from (71) combined with the definition of b, we obtain

$$V(x(t_1, x_0, t_0)) \geq \inf_{x \in \partial D} V(x) > b(t_1),$$

and continuity of the mapping $V(x(\cdot, x_0, t_0)) - b(\cdot)$ at t_1 yields the existence of h_1 in $(0, t_1 - t_0)$ satisfying

$$V(x(t_1 - h, x_0, t_0)) > b(t_1 - h), \quad h \in (0, h_1),$$

which contradicts (72). Hence, we have Claim 2.

We now let $t_3 > t_0$. By Claim 2, the point $x(t, x_0, t_0)$ lies in D for each $t \geq t_0$, so that Claim 1 applied with t_3 yields

$$V(x(t, x_0, t_0)) \leq b(t), \quad t \in [t_0, t_3).$$

The proof of the lemma is completed upon noting that this last argument holds for all $t_3 > t_0$, all x_0 in $\overline{W}^{b(t_0)}$, and all $t_0 \geq 0$. □

The following lemma is used in the proof of Theorem 5.1 in order to establish robust asymptotic stabilizability of certain families of nonlinear systems.

LEMMA 8.2. *Let D_1 and D_2 be two bounded neighborhoods of the origin (resp., Let $D_1 = D_2 = \mathbb{R}^n$), and let $V_1 : \overline{D}_1 \to [0, \infty)$ and $V_2 : \overline{D}_2 \to [0, \infty)$ be two Lyapunov functions (resp., two radially unbounded Lyapunov functions). Further, let b_1 and b_2 be two continuous mappings from $[0, \infty)$ into $(0, \inf_{x \in \partial D_1} V_1(x))$ and $(0, \inf_{x \in \partial D_2} V_2(x))$, resp., such that*

$$D_1 \cap V_1^{-1}([0, b_1(t))) \supset D_2 \cap V_2^{-1}([0, b_2(t)]), \quad t \geq 0. \tag{73}$$

Then, there exist two C^∞ mappings $a_1 : [0, \infty) \to (0, \inf_{x \in \partial D_1} V_1(x))$ and $c_2 : [0, \infty) \to (0, \inf_{x \in \partial D_2} V_2(x))$ such that for each $t \geq 0$ we have

$$b_1(t) > a_1(t) \qquad \text{and} \qquad c_2(t) > b_2(t), \tag{74}$$

together with

$$D_1 \cap V_1^{-1}([0, a_1(t))) \supset D_2 \cap V_2^{-1}([0, c_2(t)]). \tag{75}$$

Proof. For each $t \geq 0$ and each δ_t, either in $(0, t)$ if $t > 0$ or in $(0, \infty)$ if $t = 0$, we set

$$I(t, \delta_t) \triangleq \begin{cases} (t - \delta_t, t + \delta_t) & \text{if} \quad t > 0, \\ [0, \delta_t) & \text{if} \quad t = 0. \end{cases}$$

As usual, $\overline{I}(t, \delta_t)$ denotes the closure of $I(t, \delta_t)$. We first construct a mapping $a_1 : [0, \infty) \to (0, \inf_{x \in \partial D_1} V_1(x))$ such that $b_1(t) > a_1(t)$ for each $t \geq 0$ and

$$D_1 \cap V_1^{-1}([0, a_1(t))) \supset D_2 \cap V_2^{-1}([0, b_2(t)]), \quad t \geq 0. \tag{76}$$

Construction of a_1. Fix t in $[0,\infty)$. The continuity of the mapping b_1 and b_2 combined with (73) yields the existence of $\delta_t > 0$ (with δ_t in $(0,t)$ if $t>0$) [5, Lemma B.12, p. 163] such that

$$D_1 \cap V_1^{-1}\left(\left[0, \min_{\tau\in\bar{I}(t,\delta_t)} b_1(\tau)\right)\right) \supset D_2 \cap V_2^{-1}\left(\left[0, \max_{\tau\in\bar{I}(t,\delta_t)} b_2(\tau)\right]\right).$$

It is easily seen that there exists α_t satisfying

$$\alpha_t \in \left(0, \min_{\tau\in\bar{I}(t,\delta_t)} b_1(\tau)\right) \tag{77}$$

and

$$D_1 \cap V_1^{-1}([0,\alpha_t)) \supset D_2 \cap V_2^{-1}\left(\left[0, \max_{\tau\in\bar{I}(t,\delta_t)} b_2(\tau)\right]\right). \tag{78}$$

We now extract from the family $\{I(t,\delta_t)\}_{t\in[0,\infty)}$ a countable subcover $\{I(t_k,\delta_{t_k})\}_{k=0}^{\infty}$ such that $t_k < t_{k+1}$ for all $k=0,1,\dots$. We let δ'_{t_k} and δ''_{t_k} in $(0,\delta_{t_k}]$ be such that the sets

$$I_0 \triangleq [0,\delta_0) \qquad \text{and} \qquad I_k \triangleq (t_k-\delta'_{t_k}, t_k+\delta''_{t_k}), \quad k=1,2,\dots,$$

form an open cover of $[0,\infty)$ and any t in $[0,\infty)$ lies in at most two successive sets I_k and I_{k+1}. We let $\{\bar{p}_k\}_{k=0}^{\infty}$ be a partition of unity subordinate to $\{I_k\}_{k=0}^{\infty}\backslash\{0\}$ such that for each $k=1,2,\dots$, the support of $\bar{p}_k$ is included in I_k and the support of $\bar{p}_0$ is included in $(0,\delta t_0)$ [15, p. 10]. For each $k=0,1,\dots$, we define the C^∞ mapping $p_k : [0,\infty) \to [0,1]$ by setting

$$\begin{aligned} &p_k(t) = \bar{p}_k(t), \quad t>0, \quad k=0,1,\dots,\\ &p_0(0)=1 \qquad \text{and} \qquad p_k(0)=0, \quad k=1,2,\dots. \end{aligned}$$

Next, we let the mapping $a_1 : [0,\infty) \to (0,\infty)$ be given by

$$a_1(t) = \sum_{k=0}^{\infty} \alpha_{t_k} p_k(t), \quad t\geq 0.$$

Let t be in $[0,\infty)$. Then, there exists an open neighborhood U_t of t in $[0,\infty)$ that intersects with at most two sets I_k and I_{k+1} of the family $\{I_k\}_{k=0}^{\infty}$. It follows that we have $a_1(\tau) = \alpha_{t_k}p_k(\tau) + \alpha_{t_{k+1}}p_{k+1}(\tau)$ for each τ in U_t. Thus, a_1 is C^∞ on $[0,\infty)$. Further, in view of (77), we get that $0 < a_1(t) < b_1(t)$ for each $t \geq 0$.

We now show that (76) holds. Let t be in $[0,\infty)$. If t lies in a unique set I_k, we get $a_1(t) = \alpha_{t_k}$, so that the inclusion (76) follows from (78). On the other hand, if t lies in two sets I_k and I_{k+1}, we get

$$a_1(t) = \alpha_{t_k} p_k(t) + \alpha_{t_{k+1}} p_{k+1}(t). \tag{79}$$

As (78) yields

$$D_1 \cap V_1^{-1}([0,\alpha_{t_j})) \supset D_2 \cap V_2^{-1}([0,b_2(t)]), \quad j=k,k+1,$$

and since we have $a_1(t) \geq \min(\alpha_{t_k},\alpha_{t_{k+1}})$ (this follows from (79)), we obtain (76).

Construction of c_2. The construction of a mapping c_2 satisfying (74) and (75) is similar to that of a_1. From the continuity of the mappings a_1 and b_2, we obtain from (76) a real $\delta_t > 0$ [5, Lemma B.12, p. 163] such that

$$D_1 \cap V_1^{-1}\left(\left[0, \min_{\tau \in \overline{I}(t,\delta_t)} a_1(\tau)\right)\right) \supset D_2 \cap V_2^{-1}\left(\left[0, \max_{\tau \in \overline{I}(t,\delta_t)} b_2(\tau)\right]\right).$$

Thus, there exists γ_t [5, Lemma B.11, p. 162] satisfying

$$\gamma_t \in \left(\max_{\tau \in \overline{I}(t,\delta_t)} b_2(\tau), \inf_{x \in \partial D_2} V_2(x) \right)$$

and

$$D_1 \cap V_1^{-1}\left(\left[0, \min_{\tau \in \overline{I}(t,\delta_t)} a(\tau)\right)\right) \supset D_2 \cap V_2^{-1}([0, \gamma_t]).$$

From the new family $\{I(t,\delta_t)\}_{t \geq 0}$, we construct some sequences of sets $\{I(t_k, \delta_{t_k})\}_{k=0}^{\infty}$ and $\{I_k\}_{k=0}^{\infty}$, and a family of mappings $\{p_k\}_{k=0}^{\infty}$ exactly as we did in the construction of a_1. Next, we let the mapping $c_2 : [0,\infty) \to (0,\infty)$ be given by

$$c_2(t) = \sum_{k=0}^{\infty} \gamma_{t_k}\, p_k(t), \quad t \geq 0.$$

Using arguments similar to those used for a_1, it can be shown that c_2 is C^∞ on $[0,\infty)$, and that both (74) and (75) hold. Hence, we have the lemma. □

OPTIMAL CONTROL PROBLEMS WITH PARTIALLY POLYHEDRIC CONSTRAINTS[*]

J. FRÉDÉRIC BONNANS[†] AND HOUSNAA ZIDANI[‡]

Abstract. This paper discusses a class of state constrained optimal control problems, for which it is possible to formulate second-order necessary or sufficient conditions for local optimality or quadratic growth that do not involve all curvature terms for the constraints. This kind of result is classical in the case of polyhedric control constraints. Our theory of optimization problems with partially polyhedric constraints allows to extend these results to the case when the control constraints are polyhedric, in the presence of state constraints satisfying some specific hypotheses. The analysis is based on the assumption that some strict semilinearized qualification condition is satisfied. We apply the theory to some optimal control problems of elliptic equations with state and control constraints.

1. Introduction.

This paper discusses a class of optimal control problems that have local control constraints and a finite number of state constraints. The problem was considered recently in [15], where second-order necessary optimality conditions were obtained. The aim of this paper is to generalize this type of result to more general optimal control problems that have two types of constraints, the first of them being polyhedric. We also prove that this type of second-order condition allows us to state second-order sufficient conditions, and in fact that they allow us to characterize quadratic growth. Our basic tools are the second-order necessary conditions based on second-order tangent sets and polyhedricity theory.

The approach of second-order necessary conditions based on second-order tangent sets was renewed in [22], where the computation of the contribution of the curvature of the feasible set to second-order necessary conditions was done in the case of nonnegative continuous functions of time. This approach was extended in [16, 20, 21, 31] for abstract optimization problems and more recently in [29, 30] for optimal control problems.

Polyhedricity theory for convex sets is a classical tool for obtaining formulas for the directional derivative of the projection over a convex set [18, 28], was applied to nonlinear control problems [36, 26], and has been linked to the recent work on sensitivity analysis for abstract optimization problems [6, 8, 10].

The paper is organized as follows. Section 2 presents a theory of second-order necessary or sufficient optimality conditions for abstract optimization problems that satisfy the strict semilinearized qualification condition. In the case corresponding to an optimal control problem with polyhedric control constraints and a finite number of additional inequality constraints, the theory is complete in the sense that there is no gap between the necessary and sufficient conditions. More precisely, we obtain a

characterization of the quadratic growth condition.

In section 3, assuming a weak second-order sufficient condition and the strict semilinearized qualification condition, we provide a formula for computing the directional derivative of the optimal control (as well as a second-order expansion of the value function) with respect to a perturbation.

Section 4 discusses the application of the previous results to some optimal control problems of elliptic equations. We consider the case of nonnegative control subject to a finite number of state constraints.

Notations. Let (P) be an optimization problem. By $F(\mathrm{P})$, ε-$S(\mathrm{P})$, and val(P), we denote the feasible set, set of ε solutions, and value of problem (P), respectively.

2. Second-order abstract optimality conditions.

In this section we discuss the theory of second-order optimality conditions for optimization problems of the following type:

$$\text{(AP)} \qquad \mathrm{Min}_x f(x);\ x \in K_X;\ G(x) \in K_Y.$$

Here X and Y are Banach spaces, K_X and K_Y are closed convex subsets of X and Y, respectively, and f and G are twice continuously differentiable mappings from X into $\mathbb{R}$ and Y. We note that, if $\mathcal{K}$ is a convex subset of a Banach space $\mathcal{X}$ and $x \in \mathcal{K}$, then the tangent and normal cones $T_{\mathcal{K}}$ and $N_{\mathcal{K}}$ and the cone of feasible directions $\mathcal{R}_{\mathcal{K}}$ are defined as

$$\begin{aligned} T_{\mathcal{K}}(x) &:= \{y \in \mathcal{X};\ \exists\, x(\sigma) = x + \sigma y + o(\sigma) \in \mathcal{K},\ \sigma \geq 0\},\\ N_{\mathcal{K}}(x) &:= \{x^* \in \mathcal{X}^*;\ \langle x^*, y\rangle \leq 0, \forall y \in T_{\mathcal{K}}(x)\},\\ \mathcal{R}_{\mathcal{K}}(x) &:= \{y \in \mathcal{X};\ \exists\, t > 0;\ x + ty \in \mathcal{K}\}, \end{aligned}$$

with the convention that these sets are empty if $x \notin \mathcal{K}$. An interesting case is when K_X is *polyhedric* in the following sense [28, 18].

DEFINITION 2.1. *Let $x_0 \in K_X$ and $x^* \in N_{K_X}(x_0)$. We say that K_X is polyhedric at x_0 for the direction x^* if*

$$T_{K_X}(x_0) \cap (x^*)^{\perp} = \overline{\mathcal{R}_{K_X}(x_0) \cap (x^*)^{\perp}}. \tag{2.1}$$

If K_X is polyhedric at each $x_0 \in K_X$ $\forall$ $x^* \in N_{K_X}(x_0)$, we say that K_X is polyhedric.

By setting

$$\mathcal{K} := K_X \times K_Y, \quad \mathcal{Y} := X \times Y, \quad \mathcal{G}(x) := (x, G(x)),$$

we can write the abstract optimization problem (AP) under the form

$$\text{(AP2)} \qquad \mathrm{Min}_x f(x)(\text{such that})\mathcal{G}(x) \in \mathcal{K},$$

with $\mathcal{G}(x)$, twice continuously differentiable mapping from X into $\mathcal{Y}$, and $\mathcal{K}$ closed convex subset of $\mathcal{Y}$. We will use the relationship between the two formats several times, in order to use the results that were derived for problem (AP2). For instance, the standard constraint qualification condition for $x_0 \in F(\mathrm{AP2})$, due to Robinson [32], is as follows:

$$0 \in \ \mathrm{int}\{D\mathcal{G}(x_0)X - (\mathcal{K} - \mathcal{G}(x_0))\}. \tag{2.2}$$

LEMMA 2.2 (Robinson [32]). *Let $x_0 \in F(\mathrm{AP2})$ satisfy (2.2). Then the following metric regularity property holds. There exist $\varepsilon > 0$ and $\alpha > 0$ such that $\forall$ $x \in B(x_0, \varepsilon)$ $\exists$ $\hat{x} \in \mathcal{G}^{-1}(\mathcal{K})$ satisfying*

$$\|\hat{x} - x\| \leq \alpha \mathrm{dist}(\mathcal{G}(x), \mathcal{K}).$$

It is easy to show (e.g., [10]) that the qualification condition for a problem of the form (AP) (after it has been put under the form (AP2)) is equivalent to

$$0 \in \operatorname{int}\{DG(x_0)(K_X - x_0) - (K_Y - G(x_0))\}. \tag{2.3}$$

The *critical cone* at $x_0 \in F(\mathrm{AP})$ is defined as the set of directions of nonincrease of the cost function that are tangent to the feasible set. More precisely,

$$C(x_0) := \{h \in T_{K_X}(x_0); Df(x_0)h \le 0;\ DG(x_0)h \in T_{K_Y}[G(x_0)]\}.$$

The Lagrangian function and the set of Lagrange multipliers are defined as

$$\begin{aligned}\mathcal{L}(x,\lambda) &:= f(x) + \langle \lambda, G(x)\rangle,\\ \Lambda(x) &:= \{(q,\lambda) \in N_{K_X}(x) \times N_{K_Y}[G(x)];\ D_x\mathcal{L}(x,\lambda) + q = 0\}.\end{aligned}$$

LEMMA 2.3 (Zowe and Kurcyusz [37]). *Let x_0 be a local solution of* (AP) *satisfying the qualification hypothesis* (2.3)*. Then with x_0 is associated a nonempty and bounded set of Lagrange multipliers.*

It is convenient to use the following well-known characterization of the critical cone.

LEMMA 2.4. *Let $\Lambda(x) \neq \emptyset$, say contains (q,λ). Then $Df(x)h = 0$ whenever $h \in C(x)$, and*

$$C(x) = \{h \in T_{K_X}(x) \cap q^\perp;\ DG(x)h \in T_{K_Y}[G(x)] \cap \lambda^\perp\}. \tag{2.4}$$

Proof. Let $h \in X$ be tangent to the feasible set of (AP), in the sense that $h \in T_{K_X}(x)$ and $DG(x)h \in T_{K_Y}[G(x)]$. By definition of $\Lambda(x)$, we have

$$0 = \langle D_x\mathcal{L}(x,\lambda) + q, h\rangle = Df(x)h + \langle \lambda, DG(x)h\rangle + \langle q, h\rangle.$$

Since the last two terms are nonpositive, we have $Df(x)h \ge 0$, and $Df(x)h \le 0$ iff the last two terms are zero. The result follows. □

Let $x \in F(\mathrm{AP})$. Using the above lemma, we may view the critical cone as a linearization of the following set:

$$A(q,\lambda) := \{h \in (K_X - x) \cap q^\perp;\ DG(x)h \in T_{K_Y}[G(x)] \cap \lambda^\perp\}. \tag{2.5}$$

Note that in this expression we chose to "linearize" the constraint $G(x) \in K_Y$ but not the relation $x \in K_X$. The set $A(q,\lambda)$ is the inverse image, through the linear continuous mapping $h \to (h, DG(x)h)$, of the closed convex set

$$\left((K_X - x) \cap q^\perp\right) \times \left(T_{K_Y}[G(x)] \cap \lambda^\perp\right).$$

We will use the associated qualification condition which we will call the *strict semilinearized qualification condition* (we justify this terminology below). From the above discussion, it follows that the expression of the strict semilinearized qualification condition is

$$0 \in \operatorname{int}\left\{DG(x)\left((K_X - x) \cap q^\perp\right) - T_{K_Y}[G(x)] \cap \lambda^\perp\right\}. \tag{CQA}$$

We may compare this condition to the more classical *strict qualification condition*, introduced in [34] (see also [4]), whose expression for problem (AP) is

$$0 \in \operatorname{int}\left\{DG(x)\left((K_X - x) \cap q^\perp\right) - (K_Y - G(x)) \cap \lambda^\perp\right\}. \tag{2.6}$$

LEMMA 2.5. (i) *Condition* (2.6) *implies* (CQA), *and both conditions are equivalent if K_Y is a polyhedron in the Banach space Y.*

(ii) *Assume that the standard constraint qualification* (2.3) *holds. Then condition* (CQA) *implies existence and uniqueness of the Lagrange multiplier.*

Proof. (i) Since $(K_Y - G(x)) \subset T_{K_Y}(G(x))$, we obviously have that (2.6) implies (CQA). Assume now that K_Y is a polyhedron in Y and that (CQA) holds. Since $\mathbb{R}_+(K_Y - G(x)) = \mathcal{R}_{K_Y}(x)$ is equal to $T_{K_Y}(G(x))$, conditions (CQA) and (2.6) are obviously equivalent.

(ii) It is known that the strict qualification condition (2.6) implies existence and uniqueness of the Lagrange multiplier, see [34]. Since (CQA) is nothing but the strict qualification condition after linearization of the second constraint (that leaves invariant the set of Lagrange multipliers), we obtain that the set of Lagrange multipliers that by (2.2) is nonempty is in fact a singleton. □

It is possible to express a second-order necessary optimality condition for problem (AP), using the result of [16], in terms of the *second-order tangent set* to $K_Y \subset Y$ at $y \in K_Y$ in direction $z \in T_{K_Y}(y)$ that is defined as

$$T^2_{K_Y}(y,z) := \left\{ w \in Y;\ y + tz + \frac{t^2}{2}w + o(t^2) \in K_Y, t \geq 0 \right\}.$$

Let x_0 be a local minimum of (AP) satisfying (2.3). Set

$$\mathcal{T}(h) := T^2_{K_Y}[G(x_0), DG(x_0)h].$$

In all that follows, we shall use this definition of a support function.

DEFINITION 2.6. *Let $\mathcal{K}$ a subset of a Banach space $\mathcal{X}$, and let x^* be in $\mathcal{X}^*$. The support function of $\mathcal{K}$ at x^* is $\sigma(x^*, \mathcal{K}) := \sup\{\langle x^*, x\rangle \ :\ x \in \mathcal{K}\}$.*

The following theorem is obtained by combining the result of [16] with some polyhedricity properties. Note that if $\mathcal{T}(h) = \emptyset$, then $\sigma(\cdot, \mathcal{T}(h))$ is identically equal to $-\infty$; therefore, in that case, the conclusion of case (i) of Lemma 2.5 is trivially satisfied.

THEOREM 2.7. *Assume that K_X is polyhedric. Let x_0 be a local minimum of* (AP) *satisfying* (2.3) *and the strict semilinearized qualification condition* (CQA). *Then*

(i) *$C(x_0) \cap \mathcal{R}_{K_X}(x_0)$ is a dense subset of $C(x_0)$, and each $h \in C(x_0) \cap \mathcal{R}_{K_X}(x_0)$ satisfies*

$$D^2_{x^2}\mathcal{L}(x_0, \lambda)(h,h) - \sigma(\lambda, \mathcal{T}(h)) \geq 0, \tag{2.7}$$

where λ is the Lagrange multiplier.

(ii) *If in addition $h \to \sigma(\lambda, \mathcal{T}(h))$ is lower semicontinuous over $C(x_0)$, then* (2.7) *holds for all critical direction h.*

(iii) *If K_Y is a polyhedron, then for all critical direction h we have*

$$D^2_{x^2}\mathcal{L}(x_0, \lambda)(h,h) \geq 0. \tag{2.8}$$

Proof. (i), step a. We claim that $C(x_0) \cap \mathcal{R}_{K_X}(x_0)$ is a dense subset of $C(x_0)$. Let $h \in C(x_0)$, and fix $\varepsilon > 0$. Since K_X is polyhedric, $\exists\ \hat{h}_\varepsilon \in \mathcal{R}_{K_X}(x_0) \cap q^\perp$ such that $\|\hat{h}_\varepsilon - h\| \leq \varepsilon$. Let $t_\varepsilon > 0$ be such that $x_0 + t_\varepsilon \hat{h}_\varepsilon \in K_X$. We use the metric regularity property that, by Lemma 2.2, follows from (CQA):

$\exists\ \gamma > 0$ and $\alpha > 0$ such that, if $\hat{w} \in X$, and $\|\hat{w}\| \leq \gamma$,
then $\exists\ w \in (K_X - x_0) \cap q^\perp$ such that
$DG(x_0)w \in T_{K_Y}[G(x_0)] \cap \lambda^\perp$, and
$\|w - \hat{w}\| \leq \alpha[\mathrm{dist}(\hat{w}, (K_X - x_0) \cap q^\perp) + \mathrm{dist}(DG(x_0)\hat{w}, T_{K_Y}[G(x_0)] \cap \lambda^\perp)]$.

Reducing t_ε if necessary, we have that $\hat{w}_\varepsilon := t_\varepsilon \hat{h}_\varepsilon$ is such that $\|\hat{w}_\varepsilon\| \le \gamma$ and $\hat{w}_\varepsilon \in (K_X - x_0) \cap q^\perp$. Since

$$\operatorname{dist}(DG(x_0)\hat{w}_\varepsilon, T_{K_Y}[G(x_0)] \cap \lambda^\perp) = O(\varepsilon t_\varepsilon),$$

it follows that $\exists\ w_\varepsilon \in (K_X - x_0) \cap q^\perp$ such that

$$\begin{aligned} &DG(x)w_\varepsilon \in T_{K_Y}[G(x_0)] \cap \lambda^\perp, \\ &\|w_\varepsilon - \hat{w}_\varepsilon\| = \alpha \operatorname{dist}(DG(x_0)\hat{w}_\varepsilon, T_{K_Y}[G(x_0)] \cap \lambda^\perp) = O(t_\varepsilon \varepsilon). \end{aligned}$$

Set $h_\varepsilon := t_\varepsilon^{-1} w_\varepsilon$. Then $h_\varepsilon \in C(x_0) \cap \mathcal{R}_{K_X}(x_0)$, and $\|h_\varepsilon - h\| = O(\varepsilon)$. This proves our claim.

(i), step b. Since x_0 is a qualified local solution of (AP) and the Lagrange multiplier is unique, by [16, Thm. 4.2] the following second-order necessary condition holds. For any critical direction h, we have

$$D^2_{x^2}\mathcal{L}(x_0, \lambda)(h, h) - \sigma(q, T^2_{K_X}(x_0, h)) - \sigma(\lambda, \mathcal{T}(h)) \ge 0. \tag{2.9}$$

Note that we have used here the fact that the support function of a set in product form is the sum of the corresponding support function.

On the other hand, since $q \in N_{K_X}(x_0)$, we have $\sigma(q, T^2_{K_X}(x_0, h)) \le 0$ [16, Sect. 4]. If $h \in \mathcal{R}_{K_X}(x_0)$, then $0 \in T^2_{K_X}(x_0, h)$, so that $\sigma(q, T^2_{K_X}(x_0, h)) = 0$. Point (i) follows.

(ii) Let $h \in C(x_0)$. By (i) $\exists\ h_k \to h$, $h_k \in C(x_0) \cap \mathcal{R}_{K_X}(x_0)$, and

$$D^2_{x^2}\mathcal{L}(x_0, \lambda)(h_k, h_k) \ge \sigma(\lambda, \mathcal{T}(h_k)).$$

Since the right-hand side is lower semicontinuous (l.s.c.) by hypothesis, and $D^2_{x^2}\mathcal{L}(x_0, \lambda)(\cdot, \cdot)$ is a continuous function, we may pass to the limit in this inequality. Point (ii) follows.

(iii) If K_Y is a polyhedron, then it is well known that $0 \in \mathcal{T}(h)$ (e.g., [10]), whence $\sigma(\lambda, \mathcal{T}(h)) = 0$ for all critical direction h. The result then follows from (ii). □

In order to formulate second-order sufficient conditions, we need the following concept.

Definition 2.8 (see, e.g., [19]). *We say that a quadratic form Q on a Hilbert space X is a Legendre form if Q is weakly l.s.c. and, whenever a sequence $\{x_k\} \subset X$ satisfies $x_k \xrightarrow{w} x$ and $Q(x_k) \to Q(x)$, then $x_k \to x$.*

The function $x \to \|x\|^2$ is the simplest example of a Legendre form. More generally, if $N > 0$ and Q is a weakly continuous quadratic form, it is easy to check that $x \to N\|x\|^2 + Q(x)$ is a Legendre form; see, e.g., [11].

Definition 2.9. *We say that x_0 is a local solution of* (AP) *satisfying the* quadratic growth condition *if*

$$\exists \alpha > 0; \quad f(x) \ge f(x_0) + \alpha\|x - x_0\|^2 + o(\|x - x_0\|^2) \quad \forall x \in F(\text{AP}), \tag{2.10}$$

where F(AP) *is the feasible set of the problem* (AP).

Theorem 2.10. *Assume that K_X is a polyhedric subset of the Hilbert space X. Let x_0 be a qualified local minimum of* (AP) *satisfying the strict semilinearized qualification condition* (CQA)*, and let (q_0, λ_0) be the unique associated Lagrange multiplier. If $Q_0(h) := D^2_{x^2}\mathcal{L}(x_0, \lambda_0)(h, h)$ is a Legendre form and K_Y is a polyhedron, then the following condition is necessary and sufficient for quadratic growth:*

$$D^2_{x^2}\mathcal{L}(x_0, \lambda_0)(h, h) > 0 \quad \forall\ h \in C(x_0)\backslash\{0\}. \tag{2.11}$$

Proof. Let x_0 satisfy the quadratic growth condition. Then $\exists\ \alpha > 0$ such that x_0 is a local solution of the problem

$$(\mathrm{AP}_\alpha) \qquad \mathrm{Min}_x f(x) - \frac{\alpha}{2}\|x - x_0\|^2;\ x \in K_X;\ G(x) \in K_Y.$$

Since K_Y is a polyhedron, and therefore $\sigma(\lambda, \mathcal{T}(h)) = 0$, (2.11) follows from Theorem 2.7.

Conversely, assume that (2.11) holds, while the quadratic growth condition is not satisfied. Then $\exists\ x_k \to x_0$ such that

$$(2.12) \qquad f(x_k) \leq f(x_0) + o(\|x_k - x_0\|^2).$$

Set $t_k := \|x_k - x_0\|$. Extracting a subsequence if necessary, we may assume that $x_k = x_0 + t_k h_k$, $\|h_k\| = 1$, and $h_k \overset{w}{\to} \bar{h}$. Also $\bar{h} \in T_{K_X}(x_0)$ since $h_k \in \mathcal{R}_{K_X}(x_0)$, (2.12) implies that $Df(x_0)\bar{h} \leq 0$, and from $G(x_k) \in K_Y$ we deduce that $DG(x_0)\bar{h} \in T_{K_Y}(G(x_0))$. It follows that $\bar{h}$ is a critical direction.

By the first-order optimality condition we have

$$\langle q_0, x_k - x_0\rangle \leq 0 \text{ and } \langle \lambda_0, G(x_k) - G(x_0)\rangle \leq 0.$$

Combining with $D_x\mathcal{L}(x_0, \lambda_0) + q_0 = 0$, we deduce that

$$\begin{aligned} f(x_k) - f(x_0) &\geq \mathcal{L}(x_k, \lambda_0) - \mathcal{L}(x_0, \lambda_0) + \langle q_0, x_k - x_0\rangle \\ &= \frac{t_k^2}{2} Q_0(h_k) + o(t_k^2). \end{aligned}$$

Combining with (2.12), it follows that $Q_0(h_k) \leq o(1)$. Since $Q_0(\cdot)$ is l.s.c., we have $Q_0(\bar{h}) \leq 0$. Since $\bar{h}$ is critical, with (2.11) this implies that $\bar{h} = 0$. It follows that $Q_0(h_k) \to Q_0(\bar{h})$. Due to $\|h_k\| = 1$ and $\bar{h} = 0$, this contradicts the fact that $Q_0(h_k)$ is a Legendre form. □

3. Abstract sensitivity analysis.

This section is devoted to the study of the family of perturbed optimization problems

$$(\mathrm{AP}_u) \qquad \mathrm{Min}_x f(x, u) \text{ s.t. } x \in K_X;\ \ G(x, u) \in K_Y.$$

Here u belongs to a Banach space U, K_X is a closed convex subset of the Hilbert space X, K_Y is a polyhedron included in the finite dimensional space Y, so that (CQA) is equivalent to the strict qualification condition (2.6), f and G are twice continuously differentiable mappings from $X \times U$ into $\mathbb{R}$ and Y. The Lagrangian of this problem is

$$\mathcal{L}(x, \lambda, u) := f(x, u) + \langle \lambda, G(x, u)\rangle.$$

We perform a sensitivity analysis along a path of perturbation variables of the form

$$u(t) := u_0 + tu_1 + \frac{t^2}{2}u_2 + o(t^2) \quad \text{with } u_i(t) \in U, i = 0, 1, 2.$$

Let x_0 be a local solution of (AP_{u_0}). The following problems may be interpreted as the linearization and the second-order expansion of problem (AP_u) at (x_0, u_0) along the path $u(t)$, respectively:

$$(\mathrm{LP}) \qquad \begin{aligned} \mathrm{Min}_{h \in X} Df(x_0, u_0)(h, u_1) \text{ s.t. } h \in T_{K_X}(x_0);& \\ DG(x_0, u_0)(h, u_1) \in T_{K_Y}[G(x_0, u_0)],& \end{aligned}$$

and, (q_0, λ_0) being the Lagrange multiplier associated with x_0:

$$\text{(SP)} \qquad \text{Min}_{h \in S(LP)} D_u \mathcal{L}(x_0, \lambda_0, u_0)u_2 + D^2_{(x,u)^2}\mathcal{L}(x_0, \lambda_0, u_0)((h, u_1), (h, u_1)).$$

LEMMA 3.1. *Let x_0 satisfy* (CQA). *Then*

(i) S(LP) *is nonempty, and*

$$\text{val (LP)} = D_u \mathcal{L}(x_0, \lambda_0, u_0)u_1, \tag{3.1}$$

where (q_0, λ_0) is the unique Lagrange multiplier associated with x_0,

(ii) *The set* $S(\text{LP}) \cap \mathcal{R}_{K_X}(x_0)$ *is a dense subset of* S(LP).

Proof. (i) The dual, in the sense of convex analysis, to the linearized problem (LP), is known to be (e.g., [8])

$$\text{(LD)} \qquad \text{Max}_{(q,\lambda)} D_u \mathcal{L}(x_0, \lambda, u_0)u_1; \quad (q, \lambda) \in \Lambda(x_0).$$

By Lemma 2.5, we know that there exists a unique Lagrange multiplier (q_0, λ_0), and that the primal and dual values are equal. This proves (3.1). It follows that $h \in X$ is a solution of (LP) iff $h \in F$(LP) and the complementarity conditions

$$\langle q_0, h \rangle = \langle \lambda_0, DG(x_0, u_0)(h, u_1) \rangle = 0$$

are satisfied. In other words, $h \in S$(LP) iff

$$h \in T_{K_X}(x_0) \cap (q_0)^\perp; \quad DG(x_0, u_0)(h, u_1) \in T_{K_Y}[G(x_0, u_0)] \cap (\lambda_0)^\perp.$$

By (CQA) the set of such h is not empty; hence S(LP) is not empty.

(ii) This is a consequence of Theorem 2.7(i) applied to problem (LP), once we have checked that problem (LP) itself satisfies the strict semilinearized qualification condition. The expression of the latter (for problem (LP)) is

$$0 \in \text{ int} \left\{ DG(x)[(T_{K_X(x_0)} - h) \cap q_0^\perp] - (T_{T_{K_Y}[G(x_0)]} DG(x_0)h) \cap \lambda_0^\perp \right\}.$$

Since $(K_X - x_0) \subset T_{K_X(x_0)} - h$ and $T_{K_Y}[G(x_0)] \subset T_{T_{K_Y}[G(x_0)]} DG(x_0)h$, this is an obvious consequence of (CQA). □

THEOREM 3.2. *Assume that*

(i) *For small enough $t > 0$, $\exists\, x(t)$, $o(t^2)$-solution of* $(\text{AP}_{u(t)})$ *such that $x(t) \to x_0$.*

(ii) *The point x_0 is the unique solution of* (AP_{u_0}) *and satisfies* (CQA) *and the second-order sufficient optimality condition* (2.11),

(iii) *The Hessian $Q_0(h) := D^2_{x^2}\mathcal{L}(x_0, \lambda_0, u_0)(h, h)$ is a Legendre form over the Hilbert space X.*

Then

(a) *The following expansion for the value function of* $(\text{AP}_{u(t)})$ *holds:*

$$\text{val } (\text{AP}_{u(t)}) = \text{val } (\text{AP}_{u_0}) + t\text{val (LP)} + \frac{t^2}{2}\text{val (SP)} + o(t^2). \tag{3.2}$$

(b) *One has $x(t) = x_0 + O(t)$. Any weak limit-point of $t^{-1}(x(t) - x_0)$ is a strong limit-point and is a solution of* (SP). *In particular, if* (SP) *has a unique solution $\bar{h}$, then $x(t) = x_0 + t\bar{h} + o(t)$.*

Proof. (a) Let $Q_{u_1}(h) := D^2_{x^2}\mathcal{L}(x_0, \lambda_0)((h, u_1), (h, u_1))$. (Note that this notation is coherent with the definition of $Q_0(\cdot)$ given before.) Consider the subproblem

$$(\text{SP}_\sigma) \qquad \text{Min}_{h \in S(\text{LP})} D_u \mathcal{L}(x_0, \lambda, u_0)u_2 + Q_{u_1}(h) - \sigma(q_0, T^2_{K_X}(x_0, h)).$$

Since K_Y is a polyhedron, we have $\sigma(\lambda_0, T^2_{K_Y}[G(x_0,u_0), DG(x_0,u_0)(h,u_1)]) = 0$. It follows from [8, Prop. 2.1] that

$$\mathrm{val}(\mathrm{AP}_{u(t)}) \le \mathrm{val}(\mathrm{AP}_{u_0}) + t\mathrm{val}(\mathrm{LP}) + \frac{t^2}{2}\mathrm{val}(\mathrm{SP}_\sigma) + o(t^2),$$

while [8, Prop. 4.3] implies that the right-hand side of (3.2) is a lower estimate of $\mathrm{val}(\mathrm{AP}_{u(t)})$. We now prove (3.2) by checking that $\mathrm{val}(\mathrm{SP}) \ge \mathrm{val}(\mathrm{SP}_\sigma)$. By Lemma 3.1, the set $S(\mathrm{LP}) \cap \mathcal{R}_{K_X}(x_0)$ is a dense subset of $S(\mathrm{LP})$. Also on $S(\mathrm{LP}) \cap \mathcal{R}_{K_X}(x_0)$ the cost functions of (SP) and (SP_σ) coincide. Since $\sigma(q_0, T^2_{K_X}(x_0,h)) \le 0$, it follows that

$$\begin{aligned}\mathrm{val}(\mathrm{SP}) &= \inf_{h\in S(\mathrm{LP})\cap\mathcal{R}_{K_X}(x_0)} \{D_u\mathcal{L}(x_0,\lambda_0,u_0)u_2 + Q_{u_1}(h)\}\\ &= \inf_{h\in S(\mathrm{LP})\cap\mathcal{R}_{K_X}(x_0)} \{D_u\mathcal{L}(x_0,\lambda_0,u_0)u_2 + Q_{u_1}(h) - \sigma(q_0, T^2_{K_X}(x_0,h))\}\\ &\ge \mathrm{val}(\mathrm{SP}_\sigma),\end{aligned}$$

as was to be proved.

(b) By [8, Prop 5.3], we have $x(t) = x_0 + O(t)$. Let us prove that any weak limit-point of $t^{-1}(x(t) - x_0)$ is a strong limit-point. Let $t_k \to 0^+$, $x_k := x(t_k)$, and $h_k := t_k^{-1}(x_k - x_0)$ be such that $h_k \overset{w}{\to} \bar{h}$. By [8, Prop. 5.3], we know that

$$Q_{u_1}(h_k) \to Q_{u_1}(\bar{h}).$$

Since $Q_0(\cdot)$ is a Legendre form, we have $h_k \to \bar{h}$, as was to be proved. Finally if (SP) has a unique solution $\bar{h}$, it follows that $t^{-1}(x(t) - x_0)$ converges to $\bar{h}$. The conclusion follows. □

4. Application to state constrained optimal control problems.

4.1. General results.

In this section we apply the results of the previous sections to some optimal control problems for semilinear elliptic equations. In the rest of this paper, we denote by Ω a bounded open subset of $\mathbb{R}^n$ $(n \le 3)$ with Lipschitz boundary Γ. Given a function $u \in L^2(\Omega)$ (we take in this section the standard notations for optimal control problems), we consider the following boundary value problem:

$$-\Delta y + \phi(x,y) = u \ \text{ in } \Omega, \qquad y(x) = 0 \ \text{ on } \Gamma, \tag{4.1}$$

where $\phi : \overline{\Omega} \times \mathbb{R} \longrightarrow \mathbb{R}$ is a continuous function which is of class C^2 and such that $\phi'_y(x,\cdot) \ge 0 \ \forall\, x \in \Omega$.

From now on, the weak solution of (4.1) associated with u will be denoted y_u. Under the above assumption, we can prove the existence and uniqueness of a solution of (4.1).

THEOREM 4.1. *For every $u \in L^2(\Omega)$, (4.1) admits a unique weak solution y_u in $H^1_0(\Omega) \cap C(\overline{\Omega})$, which is Hölder continuous, and we have*

$$\|y_u\|_{C(\overline{\Omega})} \le C_1(1 + \|u\|_{L^2(\Omega)})$$

where $C_1 = C_1(\Omega)$ is independent of u. Moreover, if we denote by $\mathcal{A} : L^2(\Omega) \longrightarrow C(\overline{\Omega})$ the mapping which associates with every control u the weak solution y_u of (4.1), then

$\mathcal{A}$ is twice continuously Fréchet differentiable, and for every $u, h \in L^2(\Omega)$, if we denote $y_u = \mathcal{A}(u)$ and $z_h = \mathcal{A}'(u)h$, then z_h is the weak solution of

$$-\Delta z_h + \phi'_y(x, y_u) z_h = h \quad in\ \Omega, \qquad z_h = 0 \quad on\ \Gamma. \tag{4.2}$$

Proof. The above theorem is a collection of known results for semilinear elliptic equations (see [7, 6, 15] and the general references [1, 2, 5]). □

Consider the following control constraints:

$$L^2_+(\Omega) := \{u \in L^2(\Omega) \mid u(x) \geq 0 \text{ almost everywhere (a.e.) on } x \in \Omega\}.$$

Let us also consider a family of functions G_j of class $C^2 : L^2(\Omega) \to \mathbb{R}$ for $1 \leq j \leq m$. We consider the following optimal control problem:

$$\text{Min}\{F(u) \mid u \in L^2_+(\Omega),\ G_j(u) \leq 0 \text{ for } 1 \leq j \leq m\} \tag{$\mathcal{P}$}$$

where

$$F(u) := \frac{1}{2}\int_\Omega (y_u(x) - y_d(x))^2\, dx + \frac{N}{2}\int_\Omega u(x)^2\, dx, \tag{4.3}$$

with y_d is a given function in $L^2(\Omega)$, and $N > 0$. The adjoint state p^0_u associated with u is defined as the unique solution in $H^2(\Omega)$ of the system

$$-\Delta p^0_u + \phi'_y(x, y_u)p^0_u = y_u - y_d \ \text{ in } \Omega, \quad p^0_u = 0 \ \text{ on } \Gamma.$$

It is known that $u \to F(u)$ is a C^2 mapping with derivative

$$DF(u) = Nu + p^0_u.$$

We will detail later the cases when $G_j(u)$ are some punctual or integral functions of the state.

Let $\bar{u}$ be an optimal solution of problem $(\mathcal{P})$. Set

$$\begin{aligned} J_+ &= \{j \in \{1, \dots, m\} \mid G_j(\bar{u}) < 0\}, \\ J_0 &= \{j \in \{1, \dots, m\} \mid G_j(\bar{u}) = 0\}, \\ J_- &= \{j \in \{1, \dots, m\} \mid G_j(\bar{u}) = 0,\ \bar{\lambda}_j > 0\}. \end{aligned}$$

Then $J_0 \cup J_- \cup J_+ = \{1, \dots, m\}$. Problem $(\mathcal{P})$ can be written as

$$\text{Min}\{F(u) \mid u \in L^2_+(\Omega), G(u) \in \mathbb{R}^m_-\}.$$

In addition (see, e.g., [10, 3]), Robinson's constraint qualification assumption is equivalent to

$$\exists v \in L^2_+(\Omega), \quad G_j(\bar{u}) + DG_j(\bar{u})(v - \bar{u}) < 0. \tag{4.4}$$

Therefore we obtain the following (classical) expression of the first order optimality system.

THEOREM 4.2. *Assume that $\bar{u}$ is a local solution of* (P) *satisfying* (4.4). *Denote by $\bar{y}$ and $\bar{p}$ the state and adjoint state associated with $\bar{u}$. Then there exist Lagrange multipliers $(\bar{q}, \bar{\lambda}) \in L^2(\Omega) \times \mathbb{R}^m$ such that*

$$\bar{\lambda}_j \geq 0,\ 1 \leq j \leq m,\ \textit{and } \bar{\lambda}_j = 0 \qquad \textit{if } G_j(\bar{u}) < 0, \tag{4.5}$$

$$N\bar{u} + \bar{p} + \sum_{j=1}^m \bar{\lambda}_j DG_j(\bar{u}) + \bar{q} = 0; \qquad \langle \bar{q}, u - \bar{u}\rangle \leq 0 \ \ \forall u \in L^2_+(\Omega). \tag{4.6}$$

Since $L^2_+(\Omega)$ is polyhedric in $L^2(\Omega)$ (see, e.g., [18, 28]), $(\mathcal{P})$ is of the form (AP) with

$$X = L^2(\Omega), \quad Y = \mathbb{R}^m, \quad K_X = L^2_+(\Omega), \quad K_Y = \mathbb{R}^m_-.$$

We now discuss the strict semilinearized qualification condition (CQA). We need a notation for the contact set of $\bar{u}$ and its complement (defined up to a null measure set):

$$\Omega_-(\bar{u}) := \{x \in \Omega;\ \bar{q}(x) < 0\}, \qquad \Omega_0(\bar{u}) := \{x \in \Omega;\ \bar{u}(x) = 0\},$$

$$\Omega_+(\bar{u}) := \{x \in \Omega;\ \bar{u}(x) > 0\}.$$

Since $\Omega_-(\bar{u}) \subset \Omega_0(\bar{u})$, we have

$$T_{L^2_+(\Omega)}(\bar{u}) \cap \bar{q}^\perp = \left\{h \in L^2(\Omega);\ h \geq 0 \ \text{ on } \ \Omega_0(\bar{u});\ \ h = 0 \ \text{ on } \ \Omega_-(\bar{u})\right\}.$$

Therefore, the strict qualification condition is identical to the qualification condition of the problem

$$\operatorname{Min}\{F(u) \mid u \in L^2(\Omega),\ u = 0 \text{ on } \Omega_-(\bar{u}),\ G_j(u) = 0 \text{ for } j \in J_-\}.$$

Lemma 4.3. *Let $\bar{u} \in F(\mathcal{P})$, with associated Lagrange multiplier $(\bar{q}, \bar{\lambda})$. Then the three conditions below are equivalent:*

(i) *The strict semilinearized qualification condition* (CQA) *is satisfied.*

(ii) *The following conditions hold:*

$$\left\{\begin{array}{l} \text{(a)}\ \ \{DG_i(\bar{u})h;\ \ i \in J_-;\ \ h \in (T_{L^2_+(\Omega)}(\bar{u}) \cap \bar{q}^\perp)\} \textit{ is onto,} \\ \text{(b)}\ \ \exists h \in (\mathcal{R}_{L^2_+(\Omega)}(\bar{u}) \cap \bar{q}^\perp);\ DG_i(\bar{u})h = 0, i \in J_-;\ DG_i(\bar{u})h < 0, i \in J_0 \backslash J_-. \end{array}\right. \tag{4.7}$$

(iii) *There exists no $(\tilde{q}, \tilde{\lambda}) \in L^2(\Omega) \times \mathbb{R}^m$ with $\tilde{\lambda} \neq 0$, satisfying the following relations:*

$$\left\{\begin{array}{l} \text{(a)}\ \ \tilde{\lambda}_i = 0, \qquad i \in J_+; \qquad \tilde{\lambda}_i \geq 0, \qquad i \in J_0 \backslash J_-, \\ \text{(b)}\ \ \tilde{q}(x) = 0 \quad \textit{on } \Omega_+(\bar{u}), \quad \tilde{q}(x) \leq 0 \quad \textit{on } \Omega_0(\bar{u}) \backslash \Omega_-(\bar{u}); \\ \text{(c)}\ \ \tilde{q} + \sum_{1 \leq i \leq m} \tilde{\lambda}_i DG_i(\bar{u}) = 0. \end{array}\right. \tag{4.8}$$

Proof. By the definition, (CQA) holds iff for any $z \in \mathbb{R}^m$ close enough to 0, $\exists$ $h \in \left(L^2_+(\Omega) - \bar{u}\right) \cap \bar{q}^\perp$ satisfying the following relations:

$$\text{(i)}\ \ DG_i(\bar{u})h = z_i,\ i \in J_-; \quad \text{(ii)}\ \ DG_i(\bar{u})h \leq z_i,\ i \in J_0 \backslash J_-. \tag{4.9}$$

It follows from (4.9(i)) that the set

$$\{DG_i(\bar{u})h;\ \ i \in J_-;\ \ h \in (\mathcal{R}_{L^2_+(\Omega)}(\bar{u}) \cap \bar{q}^\perp)\} \text{ is onto.}$$

This implies that (4.7(i)) is a necessary condition for (CQA). Then taking $z_i = 0$, $i \in J_-$, and $z_i < 0$, $i \in J_0 \backslash J_-$, we deduce that (4.7) is a necessary condition for (CQA), i.e., (CQA) $\Rightarrow$ (4.7). We end the proof by showing that (4.7)$\Rightarrow$(4.8)$\Rightarrow$(CQA).

Assume that (CQA) does not hold. Then the convex cone

$$E := \left\{DG(\bar{u})h - z;\ h \in \mathcal{R}_{L^2_+(\Omega)}(\bar{u}) \cap \bar{q}^\perp;\ \ z_i \leq 0, i \in J_0;\ z_i = 0, i \in J_-\right\}$$

is not equal to $\mathbb{R}^m$. Since the latter is a finite dimensional space, the closure of E is not equal to $\mathbb{R}^m$. By the Hahn–Banach theorem, since E is a cone, $\exists\, \tilde\lambda \in \mathbb{R}^m$, $\tilde\lambda \neq 0$, such that $\langle \tilde\lambda, y\rangle \geq 0\ \forall y \in E$. It follows that (4.8(i)) holds, while $\tilde q$ defined by (4.8(iii)) is such that

$$-\langle \tilde\lambda, DG(\bar u)h\rangle = \int_\Omega \tilde q(x)h(x)dx \leq 0 \quad \forall h \in (L^2_+(\Omega) - \bar u) \cap \bar q^\perp. \tag{4.10}$$

Since the polar of the intersection of two closed convex cones is the closure of the sum of their polar cones, we have that

$$\tilde q \in \left(\left(L^2_+(\Omega) - \bar u\right) \cap \bar q^\perp\right)^- = \overline{(L^2_+(\Omega) - \bar u)^- + \mathbb{R}\bar q}.$$

Relation (4.8(ii)) follows.

Finally, suppose that (4.7) holds, but (4.8) does not hold. Let $(\tilde q, \tilde\lambda)$ satisfy (4.8). Then (4.10) holds. It follows that for each $h \in \mathcal{R}_{L^2_+(\Omega)}(\bar u) \cap \bar q^\perp$,

$$0 \leq -\int_\Omega \tilde q(x)h(x)dx = \sum_{1\leq i\leq m} \tilde\lambda_i DG_i(\bar u)h.$$

This and (4.7(ii)) imply $\tilde\lambda_i = 0\ \forall i \in J_0 \backslash J_-$. Then, since $L^2_+(\Omega)$ is polyhedric, with (4.7(i)) we obtain $\tilde\lambda_i = 0\ \forall i \in J_-$, in contradiction with the fact that $\tilde\lambda \neq 0$. □

Denote by $L^2(\Omega_+(\bar u))$ the Hilbert space of functions of $L^2(\Omega)$ that are a.e. null outside $\Omega_+(\bar u)$. From the above lemma, we deduce the following corollary, similar to [15, Thm. 5.2].

Corollary 4.4. *A sufficient condition for* (CQA) *is that the restriction of $DG(\bar u)$ to $L^2(\Omega_+(\bar u))$, with image space $\mathbb{R}^m$, is onto.*

We now discuss second-order optimality conditions. Since $Q_0(\cdot)$ is a Legendre form, we have the following result which is an immediate consequence of Theorem 2.10. Note that the assumption, that the Hessians $D^2G(\bar u)$ are weakly continuous, is typically satisfied if G represents state constraints, as will be the case in the examples to be seen later. The expression of the Lagrangian for problem $(\mathcal{P})$ is

$$\mathcal{L}(u, \lambda) := F(u) + \sum_{i=1}^m \lambda_i G_i(u).$$

Theorem 4.5. *Let $\bar u$ be an optimal solution of $(\mathcal{P})$, with associated Lagrange multiplier $(\bar q, \bar\lambda)$, satisfying condition* (CQA). *Assume that the Hessians $D^2G_i(\bar u)$ (for $i = 1, \ldots, m$) are weakly continuous. Then $\bar u$ satisfies the quadratic growth condition iff*

$$D^2_{uu}\mathcal{L}(\bar u, \bar\lambda)(h, h) > 0\ \ \forall h \in C(\bar u), \quad h \neq 0.$$

4.2. Problems with finitely many punctual state constraints. We consider in this subsection the case when the functions G_j, $1 \leq j \leq m$, are defined by

$$G_j(u) = y_u(x_j) - b_j.$$

Here $b \in \mathbb{R}^m$ and $x_j \in \Omega$, $1 \leq j \leq m$, are given. We denote $\bar y := y_{\bar u}$. A simple consequence of Lemma 4.3 follows.

LEMMA 4.6. *Assume that* $\Omega_+(\bar{u})$ *has a nonempty interior. Then the strict semi-linearized qualification condition* (CQA) *is satisfied.*

Proof. If the conclusion does not hold, then by Lemma 4.3, $\exists\ (\tilde{q}, \tilde{\lambda}) \in L^2(\Omega) \times \mathbb{R}^m$ with $\tilde{\lambda} \neq 0$, satisfying (4.8). It is a classical result (see, e.g., [12]) that $\tilde{q} \in L^2(\Omega) \cap W^{1,s}(\Omega)$, $\forall\ s < n/(n-1)$ and is the unique solution in $W^{1,1}(\Omega)$ of

$$-\Delta\tilde{q} + \phi'_y(x, \bar{y})\tilde{q} = -\textstyle\sum_{1\leq i\leq m} \lambda_i \delta(x_i) \text{ in } \Omega, \quad \tilde{q} = 0 \text{ on } \Gamma. \tag{4.11}$$

Here $\delta(x_i)$ stands for the Dirac measure at point x_i. Since $\tilde{q} = 0$ on the interior of Ω_+, and the latter is nonempty, we have by the unique extension theorem [35] that $\tilde{q} = 0$ over Ω except perhaps at the points x_j. But this implies $\tilde{\lambda} = 0$, in contradiction to the hypothesis. □

We now state the characterization of quadratic growth. By z_h we denote the solution of the linearized equation (4.2) with $y_u = \bar{y}$ and right-hand side h. As a consequence of Theorem 4.5, we have the following.

THEOREM 4.7. *Let* $\bar{u}$ *be a feasible point of* $(\mathcal{P})$, *with associated Lagrange multiplier* $(\bar{q}, \bar{\lambda})$, *and assume that the interior of* Ω_+ *is nonempty. Then* $\bar{u}$ *satisfies the quadratic growth condition iff* $\exists\ \bar{p} \in W^{1,s}(\Omega)\ \forall\ s < n/(n-1)$, *such that*

$$\bar{\lambda}_j \geq 0,\ 1 \leq j \leq m,\ \textit{and } \bar{\lambda}_j = 0 \qquad \textit{if } G_j(\bar{u}) < 0, \tag{4.12}$$

$$-\Delta\bar{p} + \phi'_y(x, \bar{y})\bar{p} = \bar{y} - y_d + \sum_{j=1}^{m} \bar{\lambda}_j \delta(x_j) \ \ \textit{in } \Omega, \quad \bar{p} = 0 \ \ \textit{on } \Gamma, \tag{4.13}$$

$$\int_\Omega (N\bar{u}(x) + \bar{p}(x))(u(x) - \bar{u}(x))\,dx \geq 0 \ \ \forall u \in L^2_+(\Omega), \tag{4.14}$$

and such that, $\forall\ h \in C(\bar{u})$, $h \neq 0$, *and* z_h *solution of* (4.2) *(in which* $\bar{y} = y_{\bar{u}}$*),*

$$\int_\Omega (Nh(x)^2 + z_h^2(x)^2 - \bar{p}(x)\phi''_y(x, \bar{y})z_h(x)^2)\,dx > 0. \tag{4.15}$$

We now discuss sensitivity of the solution of the optimal control problem with respect to the target y_d. Therefore we denote

$$F(u, y_d) := \frac{1}{2}\int_\Omega (y_u(x) - y_d(x))^2\,dx + \frac{N}{2}\int_\Omega u(x)^2\,dx.$$

Consider a target path, where $t \geq 0$,

$$y_d(t) = y_{d0} + ty_{d1} + \frac{t^2}{2}y_{d2} + o(t^2).$$

Note that

$$D_{y_d}F(u, y_{d0})y_{d1} = -\int_\Omega (\bar{y} - y_{d0})(x)y_{d1}(x)dx.$$

The subproblems to be considered here, corresponding to (LP) and (SP), are

$$\begin{array}{c}\text{Min}_{h\in L^2(\Omega)} \displaystyle\int_\Omega (N\bar{u} + \bar{p})(x)h(x)dx - \int_\Omega (\bar{y} - y_{d0})(x)y_{d1}(x)dx \\ \text{s.t. } h \geq 0 \text{ on } \Omega_0(\bar{u}); z_h(x_i) \leq 0,\ i \in J_0,\end{array} \tag{$\overline{\text{LP}}$}$$

and, denoting by z_h the solution of (4.2) (in which $y_u = \bar{y}$),

$$(\overline{\mathrm{SP}}) \qquad \mathrm{Min}_{h\in S(\overline{\mathrm{LP}})} D^2F(\bar{u}, y_{d0})((h, y_{d1}), (h, y_{d1})) - \int_\Omega (\bar{y} - y_{d0})(x) y_{d2}(x)dx.$$

(An expression of the Hessian of F in term of $\bar{p}$ and z_h is given in [6].)

Theorem 4.8. *Assume that $\bar{u}$ is the unique solution of* (AP) *and satisfies* (CQA) *as well as the second-order sufficient optimality condition* (4.15)*. Then*

(a) *The following expansion for the value function of* $(AP_{u(t)})$ *holds:*

$$\mathrm{val}\,(\mathrm{AP}_{u(t)}) = \mathrm{val}\,(\mathrm{AP}_{\bar{u}}) + t\mathrm{val}\,(\overline{\mathrm{LP}}) + \frac{t^2}{2}\mathrm{val}\,(\overline{\mathrm{SP}}) + o(t^2). \tag{4.16}$$

(b) *Let $u(t)$ be a path of $o(t^2)$-solutions. Then one has $u(t) = \bar{u} + O(t)$. Any weak limit-point of $t^{-1}(u(t) - \bar{u})$ is a strong limit-point and is a solution of* $(\overline{\mathrm{SP}})$*. In particular, if* $(\overline{\mathrm{SP}})$ *has a unique solution $\bar{h}$, then $u(t) = \bar{u} + t\bar{h} + o(t)$.*

Proof. It is easy to check that the solutions of the perturbed problem are uniformly bounded and that they strongly converge in $L^2(\Omega)$ to $\bar{u}$; see, e.g., [6]. In addition the Hessian of the Lagrangian, which is equal to the Hessian of the cost, is a Legendre form. Therefore the conclusion is a consequence of Theorem 3.2. □

4.3. Problems with integral state constraints. We consider in this subsection the case when the functions $G_j(u)$, $1 \le j \le m$, are defined by

$$G_j(u) = \int_\Omega g_j(y_u(x), x)\, dx.$$

The functions $g_j(u)$ are assumed to be twice continuously differentiable functions $\mathbb{R} \times \bar{\Omega} \to \mathbb{R}$. Then $G(\cdot)$ is itself a C^2 mapping. We know that the derivative of $u \to G_j(u)$, viewed as a function $L^2(\Omega) \to \mathbb{R}$, is $p_j(u) \in H^2(\Omega)$ solution of

$$-\Delta p_j + \phi'_y(x, y_u)p_j = D_y g_j(y_u(x), x) \ \text{ in } \Omega, \quad p_j = 0 \ \text{ on } \Gamma.$$

A simple consequence of Lemma 4.3 follows.

Lemma 4.9. *The strict qualification condition* (CQA) *is satisfied iff the following system has no solution $(\tilde{q}, \tilde{\lambda}) \in W^{1,s}(\Omega) \times \mathbb{R}^m$:*

$$\begin{array}{l} -\Delta\tilde{q} + \phi'_y(x, \bar{y})\tilde{q} = -\sum_{1\le i\le m} \lambda_i D_y g_j(\bar{y}(x), x) \quad in\ \Omega, \quad \tilde{q} = 0 \quad on\ \Gamma, \\ \tilde{q}(x) = 0 \qquad on\ \Omega_+(\bar{u}), \qquad \tilde{q}(x) \ge 0 \quad on\ \Omega_0(\bar{u})\backslash\Omega_-(\bar{u}), \\ \lambda \ne 0; \quad \lambda_i = 0, i \in J_+, \quad \lambda_i \ge 0, \qquad i \in J_0\backslash J_-. \end{array} \tag{4.17}$$

Let us give an example of such integral constraints for which condition (CQA) can be checked. Let $b \in \mathbb{R}^m$ and $a_j \in C(\overline{\Omega})$ for $1 \le j \le m$, with $a_j(x)$ of constant sign over its support $\Omega_j := \mathrm{supp}(a_j)$. Assume that these supports satisfy the following geometric relation:

$$\Omega_i \cap \Omega_j = \emptyset \text{ for } i \ne j; \quad \Omega \setminus (\cup_{1\le j\le m}\Omega_j) \ \text{ is connected.} \tag{4.18}$$

We consider the case when

$$g_j(u) := \int_\Omega a_j(x)y_u(x)dx - b_j.$$

We also assume the following:

$$\exists\ \Omega_*, \text{ open subset of } \Omega_+(u), \text{ s.t. } \Omega_* \cap \Omega_j = \emptyset, \qquad 1 \leq j \leq m. \tag{4.19}$$

LEMMA 4.10. *Under the above hypotheses, the strict qualification condition* (CQA) *is satisfied.*

Proof. If the conclusion does not hold, then $\exists\ (\tilde{q}, \tilde{\lambda})$ satisfying the condition of Lemma 4.9, and in particular

$$-\Delta\tilde{q} + \phi'_y(x,\bar{y})\tilde{q} = -\sum_{j \in J_0 \cup J_-} \tilde{\lambda}_j a_j \ \text{ in } \Omega, \quad \tilde{q} = 0 \ \text{ on } \Gamma, \tag{4.20}$$

as well as $\tilde{q} = 0$ on Ω_*. Set $A := \Omega \setminus (\cup_{1 \leq j \leq m} \Omega_j)$. Then A is a connected open set that contains Ω_*. Since Ω_* is open, and $\tilde{q} = 0$ on A, by the unique extension theorem [35] we obtain $\tilde{q} = 0$ on A, hence on $\partial\Omega_j$, $\forall\ 1 \leq j \leq m$. Let j be such that $\tilde{\lambda}_j \neq 0$. Let A_j be the interior of Ω_j, $1 \leq j \leq m$, and let

$$B_j := \{x \in \Omega;\ \text{dist}(x, A_j) \leq \varepsilon\}.$$

Take $\varepsilon > 0$ so small that $B_j \backslash A_j$ does not intersect Ω_i for $i \neq j$. Then $\tilde{q}$ satisfies

$$-\Delta\tilde{q} + \phi'_y(x, y_u)\tilde{q} = -\tilde{\lambda}_j a_j \ \text{ in } B_j, \quad \tilde{q} = 0 \text{ on } \partial B_j.$$

This equation has a unique solution in $H^1_0(B_j)$. Since a_j is of constant sign, $\tilde{q}$ is nonzero over the interior of B_j. But this is impossible, since the latter contains a nonempty open set included in A. □

Whenever (CQA) holds, we can state a characterization of quadratic growth. We omit the statement since it is similar to Theorem 4.2.

5. Conclusion and possible extensions. Our theoretical results extend those in [6], which discuss problems with polyhedric control constraints only. We were able to give an application of these results for control and state constrained optimal control problems when the number of state constraints is finite.

For technical reasons we discussed only the case when the space dimension n is less than or equal to 3. Extension of these results in the case $n > 3$ seems possible by combining the technique of this paper with the two norms approach [6, 25]. The latter would also allow our results to extend to the case of boundary control or to problems with a parabolic state equation.

It seems also possible to extend our results to the case when K_Y is not a polyhedron, taking advantage of the results in [9]. For instance, the set of semi definite positive matrices is a closed convex set that satisfies hypothesis (ii) of Theorem 2.7. On the other hand, the case of a punctual state constraint at every point of the domain Ω seems out of reach, since the strict qualification condition is probably not satisfied in that case.

Acknowledgments. The authors thank the two referees for their useful remarks.

AVERAGE $\mathcal{H}_2$ PERFORMANCE AND MAXIMAL PARAMETER PERTURBATION RADIUS FOR UNCERTAIN SYSTEMS*

KE-YOU ZHAO[†], MICHAEL J. GRIMBLE[‡], AND JAKOB STOUSTRUP[§]

Abstract. In this paper, methods are presented for calculating the maximal parameter perturbation bounds under $\mathcal{H}_2$ performance constraints for a family of uncertain systems and for calculating the average $\mathcal{H}_2$ performance under such parameter variations. The uncertain systems are described by state space models with nonlinear (polynomial) dependencies on real uncertain parameters. All results obtained are based on necessary and sufficient conditions. As a special virtue of the approach, the proposed algorithms for stability analysis and for performance analysis turn out to have exactly the same algebraic structure. An example illustrates the results and the algorithms.

Key words. $\mathcal{H}_2$ performance, stability, robustness, nonlinear perturbation, state space methods

1. Introduction.

Robust performance analysis for uncertain control systems, which is now receiving a great deal of attention (see [4, 9] and references therein), is a relatively new area in comparison with robust stability analysis. For linear time-invariant systems, the $\mathcal{H}_2$ performance metric arises naturally in a number of different physically meaningful situations; see [4, 6, 3]. The $\mathcal{H}_2$ performance of a linear time-invariant system is measured via the $\mathcal{H}_2$ norm of its transfer matrix. As long as this $\mathcal{H}_2$ norm is less than a given upper bound, the design can stop, and there is usually no need to seek the minimal norm and/or this might not be advisable due to robustness considerations.

Suppose now that the $\mathcal{H}_2$ norm of a nominal (stable) system is less than a given upper bound. Then the question is whether the norm is still less than this upper bound after suffering a parameter perturbation, or alternatively, how to find the maximal domain for perturbation parameters under stability and $\mathcal{H}_2$ norm constraints.

This paper will consider the latter problem and calculate the maximal perturbation interval or radius in perturbation parameter space. The results obtained are not only sufficient but also necessary. The paper is different from most previously published papers which deal with a fixed parameter domain and affine perturbations. One of our motivations comes from [4], which computed the supremum of the $\mathcal{H}_2$ norm in the case of an affine perturbation with perturbation parameter $q \in [0, 1]$. Also in similarity with that paper we shall compute not only the maximal perturbation radii subject to stability and performance constraints but also the average performance over a fixed perturbation set.

The notation used throughout the paper is as follows. Denote the real number set by $\mathbf{R}$ and the complex plane (the complex open left half plane) by $\mathbf{C}$ ($\mathbf{C}^-$). Let **cs**: $\mathbf{R^{m\times n}} \to \mathbf{R^{mn}}$ be the column stacking operator on a matrix and $\oplus$: $\mathbf{R^{n\times n}} \times \mathbf{R^{m\times m}} \to \mathbf{R^{mn\times mn}}$ be the standard matrix Kronecker sum defined in [2]. Finally, let $\lambda_k(\cdot)$ be the kth eigenvalue of a square matrix.

2. Problem formulation. Consider a linear time-invariant system

$$\begin{aligned} \dot{x}(t) &= A(q)x(t) + B(q)w(t), \\ z(t) &= C(q)x(t), \end{aligned} \tag{2.1}$$

where $x \in \mathbf{R^n}$, $w \in \mathbf{R^m}$, and $z \in \mathbf{R^p}$ are state, disturbance, and performance vectors, respectively; $A(q)$, $B(q)$, and $C(q)$ are (of compatible dimension) continuous matrix functions of the perturbation parameter vector $q = [q_1, q_2, \ldots, q_l]^T \in \mathbf{R^l}$. The transfer function matrix from w to z can be expressed as $T(s,q) = C(q)(sI - A(q))^{-1}B(q)$. A square constant matrix is called stable if all of its eigenvalues lie in $\mathbf{C}^-$. The corresponding transfer function $T(s,q)$ is said to be stable for a given q if $A(q)$ is stable and its $\mathcal{H}_2$ norm is defined by

$$\|T(s,q)\|_2 \doteq \left\{ \frac{1}{2\pi} \int_{-\infty}^{+\infty} \mathbf{trace}\,[T(j\omega,q)T^*(j\omega,q)]\, d\omega \right\}^{1/2}, \tag{2.2}$$

where $T^*(s,q) \doteq T'(-s,q)$ and $(\cdot)'$ denotes transpose.

We shall make the following standing assumptions on the nominal system—given by $(A(0), B(0), C(0))$—and on the parameter dependence:

AS1. $A(0)$ is stable.

AS2. $\|T(s,0)\|_2^2 < \gamma$.

AS3. The system matrices may be parameterized as

$$\begin{aligned} A(q) &\doteq A_0 + qA_1 + \cdots + q^{m_1}A_{m_1}, \\ B(q) &\doteq B_0 + qB_1 + \cdots + q^{m_2}B_{m_2}, \\ C(q) &\doteq C_0 + qC_1 + \cdots + q^{m_3}C_{m_3}, \end{aligned}$$

where all of A_k, B_k, and C_k are given constant matrices.

Here, γ is a given positive constant which reflects the tolerance of the system as measured by the $\mathcal{H}_2$ performance (for instance, an acceptable output variance of (2.1) to a white noise signal w). The goal is to find the "maximal domain" in $\mathbf{R^l}$ so that $\|T(s,q)\|_2^2 < \gamma$ for every q in the domain. A prerequisite for doing this is that $A(q)$ must be stable for all q in this domain. This means that the robust stability analysis must be completed first (see relevant results in [1, 5, 7, 8]).

The relevant problems will in this paper only be considered for the single parameter case, i.e., $l = 1$. The two parameter case, $l = 2$, can at least in principle be handled by the approach described below applying a line search. However, for medium or large scale problems, computational issues will limit the practical use of this.

To formulate the problem of determining the maximal perturbation radius, first define

$$r_s^- \doteq \inf\{r < 0 : A(q) \text{ is stable } \forall q \in (r,0)\}, \tag{2.3}$$

$$r_s^+ \doteq \sup\{r > 0 : A(q) \text{ is stable } \forall q \in (0,r)\}, \tag{2.4}$$

$$r_2^- \doteq \inf\{r < 0 : A(q) \text{ is stable and } \|T(s,q)\|_2^2 < \gamma\ \forall q \in (r,0)\}, \tag{2.5}$$

$$r_2^+ \doteq \sup\{r > 0 : A(q) \text{ is stable and } \|T(s,q)\|_2^2 < \gamma\ \forall q \in (0,r)\}. \tag{2.6}$$

Then (r_s^-, r_s^+) is the maximal perturbation interval of q while keeping the stability of $A(q)$, and (r_2^-, r_2^+) is the maximal perturbation interval of q while keeping $\|T(s,q)\|_2^2 < \gamma$.

PROBLEM 2.1. *Suppose that system* (2.1) *satisfies* AS1, AS2, *and* AS3.

(a) *Find* r_s^- *and* r_s^+.

(b) *Find* r_2^- *and* r_2^+.

Remark 2.2. Obviously, $(r_2^-, r_2^+) \subset (r_s^-, r_s^+)$.

The notion of average performance can be defined in terms of the following problem.

PROBLEM 2.3. *Suppose that system* (2.1) *satisfies* AS1, AS2, *and* AS3 *and that two numbers* $\underline{q}$ *and* $\overline{q}$ *are given, where* $r_s^- < \underline{q} < \overline{q} < r_s^+$.

Find $\frac{1}{\overline{q} - \underline{q}} \int_{\underline{q}}^{\overline{q}} \|T(s,q)\|_2^2 \, dq.$

This definition follows the convention in [4]. It can be argued that an alternative problem formulation similar to Problem 2.3 but without the square would be interesting as well. That problem also admits a solution but not one which is as easy to interpret in terms of the problem parameters as the one given for Problem 2.3 below.

Remark 2.4. The integral boundaries of Problem 2.3 have been chosen to be strictly inside the stability interval (not on the closure). This is because, usually, the integral would become unbounded on the stability boundary.

3. Preliminaries.

The main idea in this paper is to transform functions that are rational in the independent variable (the uncertain parameter) into a matrix version of the companion form, utilizing the fact that the "denominator" is based on a matrix valued polynomial map. In what follows, we shall provide a matrix result which will prove useful in this respect.

Let $M(r) = M_0 + rM_1 + \cdots + r^m M_m$, where all of the M_k's are $n \times n$ constant matrices, and $|M_0| \neq 0$ ($|\cdot|$ denotes the determinant). Let

$$r^- \doteq \sup\{r < 0 : |M(r)| = 0\}, \tag{3.1}$$

$$r^+ \doteq \inf\{r > 0 : |M(r)| = 0\} \tag{3.2}$$

be the maximal perturbation bounds for nonsingularity of matrices. By simple operations on the matrix and its determinant (see [8]), it can be shown that

$$r^- = \frac{1}{\lambda_{min}^-(\mathbf{M})}, \tag{3.3}$$

$$r^+ = \frac{1}{\lambda_{max}^+(\mathbf{M})}, \tag{3.4}$$

where $\mathbf{M}$ is an $mn \times mn$ matrix given by

$$\mathbf{M} \doteq - \begin{pmatrix} \mathbf{O} & -\mathbf{I} & \mathbf{O} & \cdots & \mathbf{O} \\ \mathbf{O} & \mathbf{O} & -\mathbf{I} & \cdots & \mathbf{O} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathbf{O} & \mathbf{O} & \mathbf{O} & \cdots & -\mathbf{I} \\ M_0^{-1}M_m & M_0^{-1}M_{m-1} & M_0^{-1}M_{m-2} & \cdots & M_0^{-1}M_1 \end{pmatrix}, \tag{3.5}$$

$\lambda_{min}^-(\cdot)$ stands for the minimal value of the negative real eigenvalues (let $\lambda_{min}^-(\cdot) = 0^-$ if there exist no negative real eigenvalues) and $\lambda_{max}^+(\cdot)$ stands for the maximal value of the positive real eigenvalues (let $\lambda^+_{max}(\cdot) = 0^+$ if no positive real eigenvalues), respectively.

Formulae (3.3) and (3.4) suggest the following algorithm.

ALGORITHM 3.1 (the maximal perturbation bounds for nonsingularity of matrices).

Step 1. *Input M_k, $k = 0, 1, \ldots, m$, where $|M_0| \neq 0$;*

Step 2. *Define* $\mathbf{M}$ *as in* (3.5);

Step 3. *Calculate all the eigenvalues of* $\mathbf{M}$;

Step 4. *Find r^- and r^+ based on* (3.3) *and* (3.4)*, then output.*

Algorithm 3.1 will be one of the cornerstones below in solving Problems 2.1 and 2.3. Algorithm 3.1 is conceptually clear and easy to implement, although, admittedly, the numerical aspects can be quite involved for large scale problems, since the relevant matrices will be of very high order. Hence, the main applications for the results below will be in terms of small or medium scale problems.

The following lemma helps us to transform Problem 2.1(a) into that of the maximal perturbation bounds for the nonsingularity of matrices.

LEMMA 3.2. *Suppose that*

(1) *Q is a singly connected domain in $\mathbf{R}^1$, and $0 \in Q$,*

(2) *$A(0)$ is stable.*

Then $A(q)$ are stable $\forall q \in Q$ if and only if $|A(q) \oplus A(q)| \neq 0 \, \forall q \in Q$.

Proof. Recall the continuity of $A(q)$, $B(q)$, $C(q)$ in q and that

$$\lambda_k(A(q) \oplus A(q)) = \lambda_i(A(q)) + \lambda_j(A(q)), \qquad k = 1, \ldots, n^2;\ i, j = 1, \ldots, n.$$

From this observation the lemma becomes obvious. □

By using Lemma 3.2 it follows that

$$r_s^- = \sup\{q < 0 : |A(q) \oplus A(q)| = 0\} \qquad \text{(scalar case)}, \tag{3.6}$$

$$r_s^+ = \inf\{q > 0 : |A(q) \oplus A(q)| = 0\} \qquad \text{(scalar case)}, \tag{3.7}$$

$$r_s = \inf\{r : |A(q) \oplus A(q)| = 0 \quad \text{for some } q,\ \|q\| \leq r\} \qquad \text{(multiparameter case)}. \tag{3.8}$$

Instead of (2.2) in the frequency domain, use the state space approach to compute

$$\|T(s, q)\|_2^2 = \mathbf{trace}\{C'(q)C(q)Q(q)\},$$

where $Q(q) = Q(q)'$ satisfies

$$A(q)Q(q) + Q(q)A(q)' + B(q)B(q)' = 0.$$

It is easy to show the following compact formula (or see [4]):

$$\|T(s, q)\|_2^2 = -\mathbf{cs}[C'(q)C(q)]' \cdot [A(q) \oplus A(q)]^{-1} \cdot \mathbf{cs}[B(q)B'(q)]. \tag{3.9}$$

Going one step from (3.9), the following result is obtained, which helps transform Problem 2.1(b) into that of the maximal perturbation bounds for nonsingularity of matrices.

LEMMA 3.3. *Suppose that*

(1) *Q is a singly connected domain in $\mathbf{R}^1$, and $0 \in Q$,*

(2) *$A(q)$ are stable $\forall q \in Q$,*

(3) *$\|T(s, 0)\|_2^2 < \gamma$.*

Then $\|T(s,q)\|_2^2 < \gamma \ \forall\ q \in Q$ *if and only if* $|\mathbf{M}_\gamma(q)| \neq 0 \, \forall q \in Q$, *where*

$$\mathbf{M}_\gamma(q) \doteq A(q) \oplus A(q) + \frac{1}{\gamma}\mathbf{cs}[B(q)B'(q)] \cdot \mathbf{cs}[(C'(q)C(q)]'. \tag{3.10}$$

Proof. $\|T(s,q)\|_2^2 < \gamma \ \forall q \in Q$
$\Leftrightarrow \gamma + \mathbf{cs}[C'(q)C(q)]' \cdot [A(q) \oplus A(q)]^{-1} \cdot \mathbf{cs}[B(q)B'(q)] > 0 \, \forall q \in Q$ (from (3.9));
$\Leftrightarrow |\gamma I + [A(q) \oplus A(q)]^{-1} \cdot \mathbf{cs}[B(q)B'(q)] \cdot \mathbf{cs}[C'(q)C(q)]'| > 0 \, \forall q \in Q$ (use equality $|\gamma I + XY| = |\gamma I + YX|$);
$\Leftrightarrow |\gamma[A(q) \oplus A(q)]^{-1}| \cdot |\mathbf{M}_\gamma(q)| > 0 \, \forall q \in Q$ (from (3.10));
$\Leftrightarrow |\mathbf{M}_\gamma(q)| \neq 0 \, \forall q \in Q$ (due to the continuity of $A(q), B(q), C(q)$ to q, and Lemma 3.2).

The rest of the proof is trivial and thus omitted. □

By using Lemma 3.3 we obtain the following formulae:

$$r_2^- = \sup\{q \in (r_s^-, 0) : |\mathbf{M}_\gamma(q)| = 0\} \qquad \text{(scalar case)}, \tag{3.11}$$

$$r_2^+ = \inf\{q \in (0, r_s^+) : |\mathbf{M}_\gamma(q)| = 0\} \qquad \text{(scalar case)}, \tag{3.12}$$

$$r_2 = \inf\{r : r \leq r_s \text{ and } |\mathbf{M}_\gamma(q)| = 0 \quad \text{for some } q, \|q\| \leq r\} \qquad \text{(multiparameter case)}. \tag{3.13}$$

In section 2 we presented two types of problems. One is the maximal perturbation bounds for system stability; the other is the maximal perturbation bounds for system performance. Lemmas 3.2 and 3.3 help us to transform these two into the maximal perturbation bounds for nonsingularity of matrices. This means that the resulting algorithms will be similar in spirit.

4. Maximal stability and performance radii.

This section will describe the main formulae and algorithms.

By using matrix multiplication and the expressions of $A(q)$, $B(q)$, $C(q)$ in Problem 2.1, it can be seen that

$$A(q) \oplus A(q) = \mathbf{A}_0 + q\mathbf{A}_1 + \cdots + q^{m_1}\mathbf{A}_{m_1}, \tag{4.1}$$

$$\mathbf{cs}[B(q)B'(q)] = \mathbf{b}_0 + q\mathbf{b}_1 + \cdots + q^{2m_2}\mathbf{b}_{2m_2}, \tag{4.2}$$

$$\mathbf{cs}[C'(q)C(q)] = \mathbf{c}_0 + q\mathbf{c}_1 + \cdots + q^{2m_3}\mathbf{c}_{2m_3}, \tag{4.3}$$

where

$$\mathbf{A}_k = A_k \oplus A_k, \ k = 0, 1, \ldots, m_1,$$
$$\mathbf{b}_0 = \mathbf{cs}\left[B_0 B_0'\right], \ \ldots, \mathbf{b}_k = \mathbf{cs}\left[\sum_{i+j=k} B_i B_j'\right], \ldots, \mathbf{b}_{2m_2} = \mathbf{cs}\left[B_{m_2} B_{m_2}'\right],$$
$$\mathbf{c}_0 = \mathbf{cs}\left[C_0' C_0\right], \ \ldots, \mathbf{c}_k = \mathbf{cs}\left[\sum_{i+j=k} C_i' C_j\right], \ldots, \mathbf{c}_{2m_3} = \mathbf{cs}\left[C_{m_3}' C_{m_3}\right].$$

Substituting the above expressions for $A(q)$, $B(q)$, and $C(q)$ in (3.10), it can be written then as

$$\mathbf{M}_\gamma(q) = M_{0\gamma} + qM_{1\gamma} + \cdots + q^m M_{m\gamma}, \tag{4.4}$$

where $m = \max\{m_1, 2(m_2 + m_3)\}$ and

$$M_{0\gamma} = (A_0 \oplus A_0) + \frac{1}{\gamma}\mathbf{cs}\left[B_0 B_0'\right] \cdot \mathbf{cs}\left[C_0' C_0\right]', \tag{4.5}$$

and all of other $M_{k\gamma}$ (the detailed expressions are omitted) depend on $\mathbf{A}_i$, $\mathbf{b}_j$, and $\mathbf{c}_k$ in a similar fashion.

By recalling Algorithm 3.1 and using (3.6), (3.7), and (4.1), the following result is obtained.

THEOREM 4.1. *Assume that the system* (2.1) *satisfies* AS1, AS2, *and* AS3. *Then the following two statements are equivalent:*

(1) *system* (2.1) *is stable* $\forall\ |q| < \delta$*,*

(2) $\min\{-r_s^-, r_s^+\} > \delta$*.*

To compute the maximal perturbation stability bounds, we can devise the following algorithm from the above results.

ALGORITHM 4.2 (the maximal perturbation bounds for Problem 2.1(a)).

Step 1. *Input* A_k*,* $k = 0, 1, \dots, m$*, where* A_0 *must be stable*;

Step 2. *Calculate* $\mathbf{A}_k$*,* $k = 0, 1, \dots, m_1$;

Step 3. *Let* $M_k = \mathbf{A}_k$*, recall Algorithm* 3.1*, then compute* r^- *and* r^+;

Step 4. *Let* $r_s^- = r^-$ *and* $r_s^+ = r^+$*, and output.*

From AS2, Lemma 3.3, and (4.5), it can be shown that $|M_{0\gamma}| \neq 0$. By recalling Algorithm 3.1 and using (3.11), (3.12), and (4.4), the following result is obtained.

THEOREM 4.3. *Assume that the system* (2.1) *satisfies* AS1, AS2, *and* AS3. *Then the following two statements are equivalent:*

(1) $\|T(s,q)\|_2 < \gamma\ \forall\ |q| < \delta$*,*

(2) $\min\{-r_s^-, r_s^+\} > \delta$*.*

Similarly, to compute the maximal perturbation performance bounds, we can devise the following algorithm from the above results.

ALGORITHM 4.4 (the maximal perturbation bounds for Problem 2.1(b)).

Step 1. *Input* A_i*,* B_j*, and* C_k*, where we must have AS*1 *and AS*2;

Step 2. *Calculate* $\mathbf{A}_i$*,* $\mathbf{b}_j$*, and* $\mathbf{C}_k$*, and also* m;

Step 3. *Calculate* $M_{k\gamma}$;

Step 4. *Let* $M_k = M_{k\gamma}$*, and recall Algorithm* 3.1 *to get* r^- *and* r^+;

Step 5. *Output* $r_2^- = \max\{r_s^-, r^-\}$*,* $r_2^+ = \min\{r_s^+, r^+\}$*.*

Remark 4.5. Algorithms 4.2 and 4.4 do not need any iteration.

Reference [5] gave the maximal perturbation bounds for Problem 2.1(a) in the simplest case (affinely linear perturbation of a single parameter).

5. Average $\mathcal{H}_2$ performance.

To compute the average performance we follow the line of approach of [4]. In similarity with that approach we shall further assume that $B(q)$ and $C(q)$ are fixed matrices, i.e., we have the following uncertainty structure.

AS4. The system matrices may be parameterized as

$$\begin{aligned}
&A(q) \doteq A_0 + qA_1 + \cdots + q^{m_1} A_{m_1},\\
&B(q) \doteq B_0,\\
&C(q) \doteq C_0.
\end{aligned}$$

This assumption can be lifted at the cost of more complicated expressions. These, though, can be obtained easily for a specific application, for instance, by the use of a symbolic algebra package, and the more general result is straightforward, following the idea below.

We define the following matrix:

$$\mathbf{A} \doteq \begin{pmatrix} \mathbf{O} & -\mathbf{I} & \mathbf{O} & \cdots & \mathbf{O} \\ \mathbf{O} & \mathbf{O} & -\mathbf{I} & \cdots & \mathbf{O} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathbf{O} & \mathbf{O} & \mathbf{O} & \cdots & -\mathbf{I} \\ \mathbf{A}_0^{-1}\mathbf{A}_{m_1} & \mathbf{A}_0^{-1}\mathbf{A}_{m_1-1} & \mathbf{A}_0^{-1}\mathbf{A}_{m_1-2} & \cdots & \mathbf{A}_0^{-1}\mathbf{A}_1 \end{pmatrix},$$

where, as above, $\mathbf{A}_k = A_k \oplus A_k,\ k = 0, 1, \ldots, m_1$. Note that $\mathbf{A}_0$ is invertible due to assumption AS1. Also define

$$\mathbf{B} \doteq \begin{pmatrix} 0 \\ \vdots \\ \mathbf{A}_0^{-1}\mathbf{cs}(B_0 B_0') \end{pmatrix}.$$

Finally, we need

$$\mathbf{C} \doteq \begin{pmatrix} 0 & \ldots & 0 & \mathbf{cs}\,(C_0' C_0)' \end{pmatrix}.$$

With these definitions, we can obtain the following result for the *average* $\mathcal{H}_2$ performance of the parameter dependent system.

THEOREM 5.1. *Assume $A(q)$, $B(q)$, and $C(q)$ are as described in* AS4 *with $A(0)$ stable. Let $\underline{q}$ and $\overline{q}$ be two real numbers satisfying $r_s^- < \underline{q} < \overline{q} < r_s^+$, where r_s^- and r_s^+ are as defined in* (2.3) *and* (2.4). *Then*

$$\frac{1}{\overline{q} - \underline{q}} \int_{\underline{q}}^{\overline{q}} \|T(s,q)\|_2^2 \, dq = -\frac{1}{\overline{q} - \underline{q}} \mathbf{C}\mathbf{A}^{-1} \left(\log(I + \overline{q}\mathbf{A}) - \log(I + \underline{q}\mathbf{A}) \right) \mathbf{B},$$

where $\log(\cdot)$ *denotes the matrix logarithm, i.e., the inverse of the matrix exponential.*

Proof. It is straightforward using (3.9) to show that

$$\|T(s,q)\|_2^2 = -\mathbf{C}(I + q\mathbf{A})^{-1}\mathbf{B}.$$

Hence,

$$\int \|T(s,q)\|_2^2 \, dq = -\mathbf{C} \left(\int (I + q\mathbf{A})^{-1} \, dq \right) \mathbf{B} = -\mathbf{C} \left(\mathbf{A}^{-1} \log(I + q\mathbf{A}) \right) \mathbf{B}. \tag{5.1}$$

The last equality holds whenever the argument of the logarithm is a nonsingular matrix. This condition, however, is fulfilled in any open subset of (r_s^-, r_s^+) due to (3.6) and (3.7). □

In certain nongeneric cases (where controllability or observability is lost), it might make sense to extend the calculation of average performance to the boundaries of stability. In that case, the integral in (5.1) becomes more involved. Indeed, let T be a nonsingular matrix, such that

$$T^{-1}\mathbf{A}T = \begin{bmatrix} \tilde{\mathbf{A}} & 0 \\ 0 & \mathbf{A}_0 \end{bmatrix},$$

where $\tilde{\mathbf{A}}$ is nonsingular and $\mathbf{A}_0$ is nilpotent of order k. (One possibility is to compose $\tilde{\mathbf{A}}$ and $\mathbf{A}_0$ by Jordan blocks and to choose the columns of T as the corresponding generalized eigenvectors.)

Then it is easy to show that

$$\int \|T(s,q)\|_2^2 \, dq = -\mathbf{C}T \begin{bmatrix} \tilde{\mathbf{A}}^{-1} \log(I + q\tilde{\mathbf{A}}) & 0 \\ 0 & qI + \sum_{i=1}^{k-1} (-1)^i \frac{q^{i+1}}{i+1} \mathbf{A}_0^i \end{bmatrix} T^{-1}\mathbf{B}.$$

6. Example. An example with a single perturbation parameter is cited below. Let

$$A(q) = \begin{bmatrix} -2 & 1 \\ 0 & -1.5 \end{bmatrix} + q \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} + q^2 \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix} + q^3 \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix},$$

$$B(q) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} + q \begin{bmatrix} 1 & 0 \\ 1 & 2 \end{bmatrix}, \; C(q) = \begin{bmatrix} 1 & 1 \end{bmatrix}.$$

It is easy to show that

$$A_0 = \begin{bmatrix} -2 & 1 \\ 0 & -1.5 \end{bmatrix}$$

is stable, that

$$T(s,0) = \begin{bmatrix} \frac{1}{s+2} & \frac{s+3}{(s+2)(s+1.5)} \end{bmatrix},$$

and that $\|T(s,0)\|_2^2 \approx 0.8214 < 1 = \gamma$. In this example it may be shown that

$$A(q) \oplus A(q) = \begin{bmatrix} -4 & 1 & 1 & 0 \\ 0 & -3.5 & 0 & 1 \\ 0 & 0 & -3.5 & 1 \\ 0 & 0 & 0 & -3 \end{bmatrix} + q \begin{bmatrix} 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$
$$+ q^2 \begin{bmatrix} 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 \end{bmatrix} + q^3 \begin{bmatrix} 2 & 1 & 1 & 0 \\ 1 & 1 & 0 & 1 \\ 1 & 0 & 1 & 1 \\ 0 & 1 & 1 & 0 \end{bmatrix},$$

$$\mathbf{cs}[B(q)B'(q)] = \begin{bmatrix} 1 \\ 0 \\ 0 \\ 1 \end{bmatrix} + q \begin{bmatrix} 2 \\ 1 \\ 1 \\ 4 \end{bmatrix} + q^2 \begin{bmatrix} 1 \\ 1 \\ 1 \\ 5 \end{bmatrix},$$

and

$$\mathbf{cs}[C'(q)C(q)] = \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}.$$

Furthermore,

$$\mathbf{M}_\gamma(q) = \begin{bmatrix} -3 & 2 & 2 & 1 \\ 0 & -3.5 & 0 & 1 \\ 0 & 0 & -3.5 & 1 \\ 1 & 1 & 1 & -2 \end{bmatrix} + q \begin{bmatrix} 2 & 3 & 3 & 2 \\ 1 & 1 & 1 & 2 \\ 1 & 1 & 1 & 2 \\ 4 & 4 & 4 & 4 \end{bmatrix}$$
$$+ q^2 \begin{bmatrix} 1 & 1 & 1 & 1 \\ 2 & 1 & 1 & 1 \\ 2 & 1 & 1 & 1 \\ 5 & 6 & 6 & 5 \end{bmatrix} + q^3 \begin{bmatrix} 2 & 1 & 1 & 0 \\ 1 & 1 & 0 & 1 \\ 1 & 0 & 1 & 1 \\ 0 & 1 & 1 & 0 \end{bmatrix}.$$

Finally, $(r_s^-, r_s^+) = (-1.6710, 0.7683)$ can be calculated, which shows that the family $A(q)$ is stable $\forall\ q \in (-1.6710, 0.7683)$, and $(r_2^-, r_2^+) = (-1.5670, 0.0442)$, meaning that $\|T(s,q)\|_2^2 < 1\ \forall\ q \in (-1.5670, 0.0442)$. These two intervals are furthermore the largest intervals with these properties.

If now, in compliance with Assumption AS4, we fix the input matrix

$$B(q) \equiv \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix},$$

we obtain a larger performance interval: $\left(r_2^-, r_2^+\right) = (-1.6668, 0.3182)$, where the $\mathcal{H}_2$ norm is bounded by 1. Moreover, in that interval, the average performance can be expressed in terms of

$$\begin{aligned} \sqrt{\int_{r_2^-}^{r_2^+} \|T(s,q)\|_2^2\, dq} &= \sqrt{-\frac{1}{r_2^+ - r_2^-} \mathbf{C}\mathbf{A}^{-1} \left(\log(I + r_2^+\mathbf{A}) - \log(I + r_2^-\mathbf{A})\right)\mathbf{B}}, \\ &\approx 0.7428 \end{aligned}$$

which for this case is in fact better than the nominal performance, $\|T(s,0)\|_2 \approx 0.9063$!

7. Conclusions. Methods for calculating the maximal parameter-perturbation bounds under $\mathcal{H}_2$ performance constraints for a family of systems described by state space models, with nonlinear dependence on real uncertain parameters, have been presented. The results are not conservative as the information of the system structure is used completely. The algorithms as presented here, for robust performance radii and for stability radii, are algebraically similar in nature. Finally, an explicit expression for average $\mathcal{H}_2$ performance for an uncertainty interval also has been presented.

NONCONVEX VARIATIONAL PROBLEMS RELATED TO A HYPERBOLIC EQUATION*

FABIÁN FLORES-BAZÁN† AND STEFANIA PERROTTA‡

Abstract. We first prove a new Lyapunov-type theorem which will yield existence of solutions to nonconvex minimum problems involving some hyperbolic equations on rectangular domains with Darboux boundary conditions. Some problems with obstacle and bang-bang results are also considered.

Key words. Lyapunov theorem, nonconvex minimum problems, relaxed problem, sequentially weakly lower semicontinuous function, biconjugate function, Darboux boundary conditions

1. Introduction.

The classical Lyapunov theorem on the range of vector-valued measures, as established in [Ce, Chap. 16], has proved, in the absence of any general theory, to be a very important tool in the study of nonconvex minimization problems within the framework of optimal control [Ne], [Ce], [S1], [R1], [R2], [R3], and [R4] and calculus of variations [Ar], [Ce], [C-Co], [Cr], [Cr-M], [Mar], [C-F], [Ma], [Am-C], [Am-Ma], and [F1]. The setting on which the Lyapunov theorem works is as follows. We start by considering an auxiliary minimization problem (P**) associated to the original one (P). Problem (P**) is such that, if J and J^{**} are the functionals associated to problems (P) and (P**), respectively, then

$$J^{**}(u) \le J(u) \quad \forall \text{ u} \qquad \text{and} \qquad \min_u \; J^{**}(u) = J^{**}(\tilde{u}) \in \mathbb{R}.$$

Then, an application of the Lyapunov theorem shows the existence of a function $\bar{u}$ satisfying $J(\bar{u}) = J^{**}(\tilde{u}) = \min_u \; J^{**}(u)$, showing that $\bar{u}$ is a solution to (P). As a consequence, we could also have min (P**) = min (P). This equality suggests we consider J^{**} as the relaxed functional, defined as the greatest sequentially weakly lower semicontinuous functional majorized by J (e.g., [DM]). However, we actually call (P**) the convexified problem since the relaxation procedure requires some additional assumptions on the integrands which are not necessarily imposed in this paper.

The integral functionals treated under this setting have special structure, namely, they can be split into the sum of two integrals: one depending on the derivative of higher order (e.g., gradient, Laplacian, etc.), and the other depending on the state function itself. The former is the nonconvex part.

A multidimensional version of the Lyapunov theorem has been proven in [Br], although a similar result was already published in [A-L]. This version permits us

to deal with nonconvex minimum problems involving some hyperbolic equations on rectangular domains with Darboux conditions on the entire boundary, as shown in [Br-F].

This paper is organized as follows. In section 2, a new Lyapunov-type theorem suitable for our purpose is established. This result involves a "unilateral" condition (see (ii) in Lemma 2.3) and is not valid if the set-valued map considered is not constant, as shown in Remark 2.6. In section 3, we present new classes of nonconvex integrals having minima. In such integrals we consider a monotonicity condition with respect to the state variable which replaces the concavity condition imposed in [Br-F]. Moreover, since our functionals involve a hyperbolic differential operator with Darboux boundary conditions on three sides of the rectangle, we also consider problems with obstacles (Corollary 3.4), unlike [Br-F], where the conditions are given on the entire boundary. The integrands we propose here give rise to integrals that are nondifferentiable and lower semicontinuous only along some special minimizing sequences. In section 4, we also apply the previously mentioned Lyapunov-type result to treat a bang-bang problem for the controlled equation $z_{xy} = u(x, y)$ (Theorems 4.4 and 4.6).

2. A Lyapunov-type result.

Before establishing our Lyapunov-type result, we recall some basic definitions from set-valued analysis. We refer to the book [Au-Fr, Chapter VIII]. In particular, a set-valued map $T : Y \subset \mathbb{R}^m \to \mathbb{R}^n$ is a map from Y to the subsets of $\mathbb{R}^n$. In what follows measurability is with respect to a Lebesgue measure.

Definition 2.1. *Given a measurable set $Y \subset \mathbb{R}^m$, the set-valued map $T : Y \to \mathbb{R}^n$ is called* measurable *if the inverse image of each open set is a measurable set. In other words, if for every open set $V \subset \mathbb{R}^n$, we have that*

$$T^{-1}(V) \doteq \Big\{ y \in Y : \ T(y) \cap V \neq \emptyset \ \Big\}$$

is measurable.

The next proposition will be useful in the proof of our main lemma.

Proposition 2.2. *Let $Y \subset \mathbb{R}^m$ be a closed set, $F : Y \to \mathbb{R}^n$ be a measurable set-valued map with closed and nonempty values, and $\psi : \mathbb{R}^n \times Y \to \mathbb{R}$ be a function such that the map $x \mapsto \psi(x, y)$ is continuous $\forall y \in Y$, $y \mapsto \psi(x, y)$ is measurable on Y $\forall x \in \mathbb{R}^n$. Then, the set-valued map $T : Y \to \mathbb{R}^n$,*

$$T(y) = \Big\{ x \in F(y) : \ \psi(x, y) = 0 \ \Big\},$$

which is supposed to take nonempty values, is measurable with closed values.

Proof. That $T(y)$ is closed follows from the continuity of $\psi(\cdot, y)$ and the closedness of $F(y)$. By virtue of Theorem 8.1.4 in [Au-Fr], we need only verify that the graph of T is measurable. It is defined by Graph $T \doteq \{(x, y) : \ x \in T(y)\}$. The conclusion is then implied by the equality Graph T = Graph $F \cap \psi^{-1}(0)$, which is trivially satisfied. □

In the following, the pair (x, y) with $y = (x_2, x_3, \ldots, x_m)$ denotes a vector in $\mathbb{R}^m$, Q denotes the closed cube in $\mathbb{R}^m$ defined by $Q \doteq \prod_{i=1}^m [a_i, b_i]$, and Q' denotes the closed cube in $\mathbb{R}^{m-1}$ corresponding to the last $m - 1$ components of Q, i.e., $Q' \doteq \prod_{i=2}^m [a_i, b_i] \subset \mathbb{R}^{m-1}$. Given a convex set $K \subset \mathbb{R}^n$, we denote by extr K the set of extreme points of K, that is, the set of such $x \in K$ such that $K \backslash \{x\}$ is convex as well, and by $\langle \cdot, \cdot \rangle$ we denote the scalar product in $\mathbb{R}^n$.

The next result is a variant of Lemma 2.2 in [Am-Ma], suitable for our purpose. We refer to section 4 for a further extension of this result. Applications of it to variational problems arising in economics will appear elsewhere; see [F2] and [F-R].

LEMMA 2.3. *Let $S \subset \mathbb{R}^n$ be a k-dimensional relative open simplex with vertices $c_0, c_1, \dots, c_k$, $E \subset Q \subset \mathbb{R}^m$ be a measurable set, and $v : E \to S$ be a measurable function. Then, there exists a measurable function $w : E \to \operatorname{extr} S$ such that*

(i) *$\int_{a_1}^{b_1} w(x,y)\chi_E(x,y)dx = \int_{a_1}^{b_1} v(x,y)\chi_E(x,y)dx$ for almost all $y \in Q'$;*

(ii) *for every $x \in [a_1, b_1]$, every $\nu \in C_+$, we have*

$$\int_{a_1}^{x} \langle w(r,y), \nu\rangle \chi_E(r,y)dr \geq \int_{a_1}^{x} \langle v(r,y), \nu\rangle \chi_E(r,y)dr \qquad \textit{for almost all } y \in Q'.$$

Here, $C_+ \doteq \{\nu : \langle c_i - c_{i+1}, \nu\rangle \geq 0 \ \ \forall\, i = 0, 1, \dots, k-1\}$.

Proof. A measurable selection theorem allows us to write $v(x,y) = \sum_0^k p_i(x,y)c_i$ for suitable measurable functions $p_i : E \to [0,1]$ satisfying $\sum_0^k p_i \equiv 1$. For any $\nu \in C_+$, we set $\alpha_i = \langle c_i, \nu\rangle$ for $i = 0, \cdots, k$. Thus, $\alpha_0 \geq \alpha_1 \geq \cdots \geq \alpha_k$.

We claim that there exist measurable functions $\delta_i : Q' \to [a_1, b_1]$, $i = 1, \dots, k$, such that $\delta_i(y) \leq \delta_{i+1}(y)$ and, by putting $\delta_0 \equiv a_1$, $\delta_{k+1} \equiv b_1$, one has

$$(2.1) \qquad \int_{\delta_i(y)}^{\delta_{i+1}(y)} \chi_E(x,y)dx = \int_{a_1}^{b_1} p_i(x,y)\chi_E(x,y)dx \qquad \text{for almost all } y \in Q'.$$

To prove (2.1), we proceed recursively as follows. Assuming δ_i is known for $i = 0, \dots, j$, we will define δ_{j+1}. Let us consider the function

$$\psi(x,y) = \int_{a_1}^{x} \chi_E(r,y)dr - \int_{a_1}^{b_1} \sum_{i=0}^{j} p_i(r,y)\chi_E(r,y)dr.$$

This function is such that $x \mapsto \psi(x,y)$ is continuous for almost every (a.e.) y; $y \mapsto \psi(x,y)$ is measurable for every x; $\psi(b_1,y) \geq 0$ since $\sum_0^k p_i \equiv 1$; and

$$\begin{aligned}\psi(\delta_j(y),y) &= \int_{a_1}^{\delta_j(y)} \chi_E(r,y)dr - \sum_{i=0}^{j} \int_{a_1}^{b_1} p_i(r,y)\chi_E(r,y)dr \\ &= -\int_{a_1}^{b_1} p_j(r,y)\chi_E(r,y)dr \leq 0.\end{aligned}$$

Thus, by the previous proposition, the set-valued map $T(y) = \{x \in [\delta_j(y), b_1] : \psi(x,y) = 0\}$, $y \in Q'$, is measurable and then admits at least a measurable selection $\delta_{j+1} : Q' \to [a_1, b_1]$ (see Theorem 8.1.3 in [Au-Fr], for instance). In particular, we have $\delta_{j+1}(y) \geq \delta_j(y)$ and

$$\int_{\delta_j(y)}^{\delta_{j+1}(y)} \chi_E(x,y)dx = \int_{a_1}^{b_1} p_j(x,y)\chi_E(x,y)dx \qquad \text{for almost all } y \in Q'.$$

This proves claim (2.1). A desired function satisfying the requirements of the lemma is given by

$$w(x,y) = \sum_{i=0}^{k} c_i \chi_{E_i(y)\cap E}(x,y) = \sum_{i=0}^{k} c_i \chi_{E_i \cap E}(x,y),$$

where $E_i(y) = [\delta_i(y), \delta_{i+1}(y)[\times Q'$ for $i = 0, \dots, k-1$ and $E_k(y) = [\delta_k(y), b_1] \times Q'$. On the other hand, $E_i = \text{hyp } \delta_{i+1} \setminus \text{hyp } \delta_i$ for $i = 0, \dots, k$. Here hyp δ_i means the hypograph of the function δ_i defined by hyp $\delta_i \doteq \{(y,t) \in Q' \times [a_1, b_1] \ : \ \delta_i(y) \geq t\}$.

Let us now prove part (i).

$$\begin{aligned}\int_{a_1}^{b_1} w(x,y)\chi_E(x,y)dx &= \int_{a_1}^{b_1} \sum_{i=0}^{k} c_i \chi_{E_i(y)\cap E}(x,y)dx = \sum_{i=0}^{k} c_i \int_{\delta_i(y)}^{\delta_{i+1}(y)} \chi_E(x,y)dx \\ &= \sum_{i=0}^{k} c_i \int_{a_1}^{b_1} p_i(x,y)\chi_E(x,y)dx = \int_{a_1}^{b_1} v(x,y)\chi_E(x,y)dx.\end{aligned}$$

It remains only to prove part (ii). Fix any $y \in Q'$ and x such that $\delta_j(y) \leq x \leq \delta_{j+1}(y)$ for $j = 0, \dots, k$. Then

$$\begin{aligned}&\int_{a_1}^{x} \langle w(r,y), \nu\rangle \chi_E(r,y)dr = \int_{a_1}^{x} \sum_{i=0}^{k} \alpha_i \chi_{E_i(y)\cap E}(r,y)dr \\ &= \sum_{i=0}^{j-1} \alpha_i \int_{\delta_i(y)}^{\delta_{i+1}(y)} \chi_E(r,y)dr + \int_{\delta_j(y)}^{x} \alpha_j \chi_E(r,y)dr \\ &= \sum_{i=0}^{j-1} \alpha_i \int_{a_1}^{b_1} p_i(r,y)\chi_E(r,y)dr + \int_{\delta_j(y)}^{x} \alpha_j \chi_E(r,y)dr \\ &= \sum_{i=0}^{j-1} \alpha_i \int_{a_1}^{x} p_i(r,y)\chi_E(r,y)dr + \sum_{i=0}^{j-1} \alpha_i \int_{x}^{b_1} p_i(r,y)\chi_E(r,y)dr \\ &\qquad + \int_{\delta_j(y)}^{x} \alpha_j \chi_E(r,y)dr \\ &\geq \sum_{i=0}^{j-1} \alpha_i \int_{a_1}^{x} p_i(r,y)\chi_E(r,y)dr + \alpha_j \int_{x}^{b_1} \left[1 - \sum_{i=j}^{k} p_i(r,y)\right] \chi_E(r,y)dr \\ &\qquad + \int_{\delta_j(y)}^{x} \alpha_j \chi_E(r,y)dr \\ &= \sum_{i=0}^{j-1} \alpha_i \int_{a_1}^{x} p_i(r,y)\chi_E(r,y)dr + \alpha_j \int_{\delta_j(y)}^{b_1} \chi_E(r,y)dr \\ &\qquad - \alpha_j \int_{x}^{b_1} \sum_{i=j}^{k} p_i(r,y)\chi_E(r,y)dr \\ &= \sum_{i=0}^{j-1} \alpha_i \int_{a_1}^{x} p_i(r,y)\chi_E(r,y)dr + \sum_{i=j}^{k} \alpha_j \int_{a_1}^{x} p_i(r,y)\chi_E(r,y)dr \\ &\geq \int_{a_1}^{x} \sum_{i=0}^{j-1} \alpha_i p_i(r,y)\chi_E(r,y)dr + \int_{a_1}^{x} \sum_{i=j}^{k} \alpha_i p_i(r,y)\chi_E(r,y)dr \\ &= \int_{a_1}^{x} \sum_{i=0}^{k} \alpha_i p_i(r,y)\chi_E(r,y)dr = \int_{a_1}^{x} \langle v(r,y), \nu\rangle \chi_E(r,y)dr.\end{aligned}$$

The latter proves (ii) and the proof of the lemma is concluded. □

Remark 2.4. Under the same assumptions of Lemma 2.3, one can also obtain the existence of another function w satisfying (i) and

For every $x \in [a_1, b_1]$, every $\nu \in C_-$, we have

$$\int_{a_1}^{x} \langle w(r,y), \nu\rangle \chi_E(r,y)dr \leq \int_{a_1}^{x} \langle v(r,y), \nu\rangle \chi_E(r,y)dr \qquad \forall y \in Q'.$$

Here, $C_- \doteq \{\nu : \langle c_i - c_{i+1}, \nu\rangle \leq 0 \ \ \forall\, i = 0, 1, \ldots, k-1\}$.

Remark 2.5. One cannot expect that, in addition to (i) and (ii) in Lemma 2.3, also holds an equality like (i) but integrated with respect to another variable. In other words, assume for simplicity that $n = 1$, $m = 2$, $a_1 = a_2 = 0$, $b_1 = b_2 = 1$, $E = Q \subset \mathbb{R}^2$, and $\nu = 1$. Then one cannot expect that besides satisfying (i) and (ii) in Lemma 2.3, there is also

(iii) $\int_0^1 w(x,y)dy = \int_0^1 v(x,y)dy$ for almost all $x \in \ [0,1]$.

In fact, by integrating (iii) and using the Tonelli–Fubini theorem, one obtains

$$\int_0^1 \Big[\int_0^x w(r,y)dr - \int_0^x v(r,y)dr\Big]dy = 0 \qquad \forall x \in [0,1].$$

Setting $u(x,y) = \int_0^x (w(r,y) - v(r,y))dr$, the above equality becomes $\int_0^1 u(x,y)dy = 0$ $\forall x \in [0,1]$ and, because of (ii), $u(x,y) \geq 0$ $\forall x \in [0,1]$, for a.e. $y \in [0,1]$. Thus, for every $x \in [0,1]$ there exists a null set $N(x) \subset [0,1]$ such that $u(x,y) = 0\ \forall\, y \in [0,1] \setminus N(x)$. It turns out that $u(x,y) = 0\ \forall\, x \in Q_1$, $\forall\, y \in [0,1] \setminus N$ with $N = \bigcup_{x \in Q_1} N(x)$ (independent of x), being a null set, where Q_1 is the set of rational numbers in $[0,1]$. Since $u(\cdot, y)$ is continuous, the latter implies that $u(x,y) = 0$ $\forall x \in [0,1]$, a.e. $y \in [0,1]$. It follows that

$$\int_B [w(r,s) - v(r,s)]dsdr = 0 \qquad \forall \text{ Borel set } B \subset Q.$$

Hence, $w(r,s) = v(r,s)$ for almost all (r,s) in Q. The latter gives a contradiction since v takes values in the open simplex S and w takes values only on its extreme points. In other words, we have shown that one cannot obtain, in Lemma 2.3, an equality like (i) where the integral is respect to one variable and an inequality like (ii) integrated with respect to another variable.

Remark 2.6. The result in Lemma 2.3 is not valid if one considers a set-valued map depending on x. In fact, simply take $n = 2$, $m = 2$, $E = Q = [0,1]^2$, $\nu = (1,0)$, the set-valued map $\Phi(x,y) = \{\lambda(1,x) : \ \lambda \in \ [0,1]\}$ (instead of $\Phi(x,y) \equiv S$), and $v(x,y) = \frac{1}{2}(1,x)$. Then, it is not difficult to show that there exists no function w taking values in $\{(0,0),(1,x)\}$ such that (i) and (ii) continues to be valid (compare with the example in [Am-Ma]).

3. Nonconvex minimum problems involving a hyperbolic equation.

We shall consider, on the rectangle $Q = [a,b] \times [c,d] \subset \mathbb{R}^2$, Darboux-type boundary conditions for the equation

$$z_{xy}(x,y) = u(x,y), \tag{3.1}$$

$$z(x,y) = \psi(x,y), \qquad (x,y) \in \partial_+ Q, \tag{3.2}$$

where $\partial_+ Q = \{a\} \times [c,d] \cup [a,b] \times \{c\} \cup \{b\} \times [c,d]$ and ψ is a continuous function on $\partial_+ Q$ such that the restriction of ψ to each one of the three sides of $\partial_+ Q$ is absolutely continuous with derivative in L^p for $p \in \ ]1, +\infty[$.

We denote by $W^{*,p}(Q,\mathbb{R}^n)$ the space of all functions $z : Q \to \mathbb{R}^n$ in L^p whose distributional derivatives z_x, z_y, z_{xy} are in L^p. This space becomes a Banach space with the norm $\|z\|_* = \|z\|_p + \|z_x\|_p + \|z_y\|_p + \|z_{xy}\|_p$ as shown in [S2]. It is easy to see that the following integral representation for $z \in W^{*,p}$ is valid:

$$z(x,y) = z(x,c) + z(a,y) - z(a,c) + \int_a^x \int_c^y z_{xy}(r,s)dsdr.$$

In particular, given any $u \in L^p$, every solution to (3.1) and (3.2) is in $W^{*,p}(Q,\mathbb{R}^n)$ and satisfies

$$z(x,y) = \psi(x,c) + \psi(a,y) - \psi(a,c) + \int_a^x \int_c^y u(r,s)dsdr. \tag{3.3}$$

In the following $\mathcal{L} \otimes \mathcal{B}_k$ will denote the product of the Lebesgue σ-algebra on Q with the Borel σ-algebra on $\mathbb{R}^k$. We recall that a function $f : Q \times \mathbb{R}^k \to \mathbb{R} \cup \{+\infty\}$ is called $\mathcal{L} \otimes \mathcal{B}_k$-measurable or simply measurable if the inverse image under f of every closed subset of $\overline{\mathbb{R}}$ is in $\mathcal{L} \otimes \mathcal{B}_k$. By h^{**}, we denote the biconjugate (bipolar) function defined as the greatest convex lower semicontinuous function not greater than h. Whenever $\xi \in \mathbb{R}^n$, $|\xi|$ stands, unless otherwise specified, for the Euclidean norm in $\mathbb{R}^n$.

For fixed $\nu \in \mathbb{R}^n$, on the functional $J_1 : W^{*,p}(Q,\mathbb{R}^n) \to \mathbb{R} \cup \{+\infty\}$

$$J_1(z) = \int_a^b \int_c^d h(z_{xy})dydx + \int_a^b \int_c^d g(x,y,\langle z,\nu\rangle)dydx + \int_a^b \int_c^d f(x,y,\langle z_y,\nu\rangle)dydx,$$

to be minimized, we assume the following hypothesis.

Hypothesis H1. We assume $1 < p < +\infty$. The function $f : Q \times \mathbb{R} \to \mathbb{R}$ is such that

(f_1) f is $\mathcal{L} \otimes \mathcal{B}_1$-measurable;

(f_2) the map $\rho \mapsto f(x,y,\rho)$ is convex and nonincreasing for a.e. $(x,y) \in Q$;

(f_3) there exists a constant $\alpha_1 \geq 0$ and a function $\beta_1 \in L^1$ such that

$$f(x,y,\rho) \geq -\alpha_1|\rho|^p - \beta_1(x,y).$$

The function $g : Q \times \mathbb{R} \to \mathbb{R}$ is such that

(g_1) g is $\mathcal{L} \otimes \mathcal{B}_1$-measurable;

(g_2) the map $\eta \mapsto g(x,y,\eta)$ is lower semicontinuous and nonincreasing for a.e. $(x,y) \in Q$;

(g_3) there exists a constant $\alpha_2 \geq 0$ and a function $\beta_2 \in L^1$ such that

$$g(x,y,\eta) \geq -\alpha_2|\eta|^p - \beta_2(x,y).$$

The function $h : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ is such that

(h_1) h is lower semicontinuous;

(h_2) there exist some constants $\alpha_3 > 0$, $\beta_3 \in \mathbb{R}$ such that

$$h(\xi) \geq \alpha_3|\xi|^p - \beta_3;$$

(h_3) setting $K = \{\xi \in \mathbb{R}^n : \ h^{**}(\xi) < h(\xi)\}$, we require that $K \subset \bigcup_{i\in I} S_i$ where I is a countable set and each S_i is a relative open simplex in $\mathbb{R}^n$ such that $h^{**} = h$ on extr S_i and h^{**} is affine on every S_i. Here the sets S_i are supposed to be disjoint. There is no assumption if $n = 1$.

In addition, for fixed $\nu \in \mathbb{R}^n$, we assume

$$\alpha_3 - (\alpha_2(d-c)^p 2^{p-1} + \alpha_1)2^{p-1}(b-a)^p|\nu|^p > 0. \tag{3.4}$$

We are interested in the following minimization problem:

$$\min_{z \in Z} J_1(z), \tag{P$_1$}$$

where

$$Z = \Big\{ z \in W^{*,p}(Q, \mathbb{R}^n) : z \text{ satisfies (3.2)} \Big\}.$$

We are now in a position to state the first main result.

THEOREM 3.1. *Let f, g, h satisfy Hypothesis* H1 *above. Assume the functional J_1 is finite at some $z \in Z$. Then problem* (P$_1$) *admits at least a solution.*

Proof. (a) We first consider the convexified problem associated with (P$_1$):

$$\min_{z \in Z} J_1^{**}(z), \tag{P_1^{**}}$$

where J_1^{**} is obtained from J by replacing h by h^{**}. Because of the assumptions on the integrands, $\lambda \doteq \inf J_1^{**}(z)$ is finite. Take any minimizing sequence (z^k) in Z. Then, by the condition on (3.4), we obtain $\|z^k_{xy}\|_p \leq B$ for some positive constant B. Therefore, there exists a subsequence, still indexed by k, such that $z^k_{xy} \rightharpoonup \xi$ in $L^p(Q, \mathbb{R}^n)$. This implies that $\int_a^x \int_c^y z^k_{xy}(r,s)dsdr \to \int_a^x \int_c^y \xi(r,s)dsdr$ for $(x,y) \in Q$. Therefore, $z^k(x,y) \to \tilde{z}(x,y)$ for $(x,y) \in Q$, where

$$\tilde{z}(x,y) = \psi(x,c) + \psi(a,y) - \psi(a,c) + \int_a^x \int_c^y \xi(r,s)dsdr.$$

This implies that $\tilde{z} \in W^{*,p}(Q, \mathbb{R}^n)$. Since Q is a compact set and z^k and $\tilde{z}$ are continuous, $z^k \to \tilde{z}$ uniformly. Thus $\tilde{z} \in Z$. On the other hand, it is not difficult to prove that $z^k_y \rightharpoonup \tilde{z}_y$ in L^p and $z^k_x \rightharpoonup \tilde{z}_x$ in L^p. Hence $\tilde{z}$ is a minimizer for J_1^{**} since h^{**} and $f(x,y,\cdot)$ are convex functions.

(b) Let $\tilde{z} \in Z$ be any solution to problem (P$_1^{**}$). We set for every $i \in I$, $E_i = \{(x,y) \in Q : \tilde{z}_{xy}(x,y) \in S_i\}$, and apply Lemma 2.3 to obtain a measurable function w_i taking values in extr S_i on E_i, such that, for every $i \in I$,

(i) $\int_a^b w_i(x,y)\chi_{E_i}(x,y)dx = \int_a^b \tilde{z}_{xy}(x,y)\chi_{E_i}(x,y)dx$ for a.e. $y \in [c,d]$, and

(ii) for every $x \in [a,b]$, we have

$$\int_a^x \langle w_i(r,y), \nu\rangle \chi_{E_i}(r,y)dr \geq \int_a^x \langle \tilde{z}_{xy}(r,y), \nu\rangle \chi_{E_i}(r,y)dr \qquad \text{for a.e. } y \in [c,d].$$

Put $E_0 = Q \setminus \bigcup_i E_i$, and define $w : Q \to \mathbb{R}^n$ by

$$w(x,y) = \tilde{z}_{xy}(x,y)\chi_{E_0}(x,y) + \sum_{i \in I} w_i(x,y)\chi_{E_i}(x,y).$$

Clearly, this function is measurable and, because of the growth condition (h_2) and (h_3)—h^{**} is affine in S_i—w is in L^p since the integral $\int\int h^{**}(\tilde{z}_{xy}(x,y))dydx$ is finite. Moreover, by Vitali's convergence theorem, it follows that

$$\int_a^b w(x,y)dx = \int_a^b \tilde{z}_{xy}(x,y)dx \qquad \text{for a.e. } y \in [c,d] \tag{3.5}$$

and for every $x \in [a,b]$

$$\int_a^x \langle w(r,y),\nu\rangle dr \geq \int_a^x \langle \tilde{z}_{xy}(r,y),\nu\rangle dr \qquad \text{for a.e. } y \in [c,d]. \tag{3.6}$$

Thus, the function $z : Q \to \mathbb{R}^n$ given by

$$z(x,y) = \psi(x,c) + \psi(a,y) - \psi(a,c) + \int_a^x \int_c^y w(r,s)dsdr \tag{3.7}$$

is in $W^{*,p}(Q,\mathbb{R}^n)$ and satisfies the boundary condition (3.2). The latter follows from (3.5) and the integral representation for z and $\tilde{z}$.

On the other hand, since h^{**} is affine on each S_i, (3.5) implies

$$\begin{aligned}\int_a^b \int_c^d h(z_{xy}(x,y))dydx &= \int_a^b \int_c^d h^{**}(z_{xy}(x,y))dydx \\ &= \int_a^b \int_c^d h^{**}(\tilde{z}_{xy}(x,y))dydx.\end{aligned} \tag{3.8}$$

It follows from (3.6) that for every $x \in [a,b]$, we have

$$\int_a^x \langle z_{xy}(r,y),\nu\rangle dr \geq \int_a^x \langle \tilde{z}_{xy}(r,y),\nu\rangle dr \qquad \text{for a.e. } y \in [c,d].$$

As a consequence,

$$\langle z_y(x,y),\nu\rangle \geq \langle \tilde{z}_y(x,y),\nu\rangle \quad \text{and} \quad \langle z(x,y),\nu\rangle \geq \langle \tilde{z}(x,y),\nu\rangle \tag{3.9}$$

for a.e. $(x,y) \in Q$, which obviously implies

$$\int_a^b \int_c^d f(x,y,\langle z_y(x,y),\nu\rangle)dydx \leq \int_a^b \int_c^d f(x,y,\langle \tilde{z}_y(x,y),\nu\rangle)dydx, \tag{3.10}$$

$$\int_a^b \int_c^d g(x,y,\langle z(x,y),\nu\rangle)dydx \leq \int_a^b \int_c^d g(x,y,\langle \tilde{z}(x,y),\nu\rangle)dydx. \tag{3.11}$$

Hence, (3.8), together with (3.10) and (3.11), implies that z is a solution to problem (P_1) since $\tilde{z}$ is a solution to (P_1^{**}) and $h^{**} \leq h$. □

Remark 3.2. The assumption $K \subset \bigcup_{i\in I} S_i$, (h_3) in Hypothesis H1, is imposed (instead of an equality) in order to include some cases in which, for instance, the integrand h has rotational symmetry; that is, h is of the form $h(\xi) = \bar{h}(|\xi|)$. This fact is exhibited in the following example. Let us fix $0 < t_1 < t_2$ and consider an even function $\bar{h}$ such that, besides satisfying the superlinear growth condition (h_2), we also assume, for $i = 1,2$, that $\bar{h}(t) = \bar{h}(t_i) = \bar{h}^{**}(t_i)$ if $0 \leq t \leq t_1$, $\bar{h}(t_1) < \bar{h}(t)$ if $t_1 < t < t_2$, and $\bar{h}(t) = \bar{h}^{**}(t)$ $\forall t > t_2$ with $\bar{h}_+^{**\prime}(t_2) > 0$. Setting $h(\xi) = \bar{h}(|\xi|)$, we have $h^{**}(\xi) = \bar{h}^{**}(|\xi|)$ and

$$K \doteq \Big\{ \xi \in \mathbb{R}^n : \bar{h}^{**}(|\xi|) < \bar{h}(|\xi|) \Big\} = \Big\{ \xi \in \mathbb{R}^n : \ t_1 < |\xi| < t_2 \Big\}.$$

Thus, K is not a countable union of simplices but satisfies the inclusion assumption (see Lemma 4.3 later) as required in (h_3) and then the theorem can be applied.

Motivated by the fact that (h_3) is a consequence of (h_2) if $h : \mathbb{R} \to \mathbb{R} \cup \{+\infty\}$, we will establish another existence result whose proof follows the reasoning of the preceding theorem componentwise. Before proceeding, we give some notation. By $\tilde{z} \preceq z$ we mean $\tilde{z}^i \leq z^i$ $\forall i = 1, \dots, n$ and a function $g : \mathbb{R}^n \to \mathbb{R}$ is said to be nondecreasing (nonincreasing) if $\tilde{z} \preceq z$ implies $g(\tilde{z}) \leq g(z)$ $(\geq)$. For fixed $p > 1$, $|\xi| = [\sum_{j=1}^n |\xi^j|^p]^{\frac{1}{p}}$ whenever $\xi = (\xi^1, \dots, \xi^n)$. Thus, if $z \in L^p(Q, \mathbb{R}^n)$, then $\|z\|_p = [\sum_{j=1}^n \int_Q |z^j(x,y)|^p dxdy]^{\frac{1}{p}}$.

Hypothesis H2. We assume $1 < p < +\infty$. The function $f : Q \times \mathbb{R}^n \to \mathbb{R}$ is such that

(f_1) f is $\mathcal{L} \otimes \mathcal{B}_n$-measurable;

(f_2) the map $\rho \mapsto f(x,y,\rho)$ is convex and nonincreasing for a.e. $(x,y) \in Q$;

(f_3) there exists a constant $\alpha_1 \geq 0$ and a function $\beta_1 \in L^1$ such that

$$f(x,y,\rho) \geq -\alpha_1 |\rho|^p - \beta_1(x,y).$$

The function $g : Q \times \mathbb{R}^n \to \mathbb{R}$ is such that

(g_1) g is $\mathcal{L} \otimes \mathcal{B}_n$-measurable;

(g_2) the map $\eta \mapsto g(x,y,\eta)$ is lower semicontinuous and nonincreasing for a.e. $(x,y) \in Q$; (g_3) there exists a constant $\alpha_2 \geq 0$ and a function $\beta_2 \in L^1$ such that

$$g(x,y,\eta) \geq -\alpha_2 |\eta|^p - \beta_2(x,y).$$

The function $h_j : \mathbb{R} \to \mathbb{R} \cup \{+\infty\}$, $j = 1, \dots, n$, is such that

(h_1) h_j is lower semicontinuous;

(h_2) there exist some constants $\alpha_3 > 0$, $\beta_3 \in \mathbb{R}$ such that

$$h_j(\xi) \geq \alpha_3 |\xi|^p - \beta_3.$$

In addition, we assume

$$\alpha_3 - (\alpha_2 (d-c)^p 2^{p-1} + \alpha_1) 2^{p-1} (b-a)^p > 0. \tag{3.12}$$

Now, our purpose is to consider the following minimization problem:

$$\min_{z \in Z} J_2(z), \tag{P$_2$}$$

where $J_2 : Z \to \mathbb{R} \cup \{+\infty\}$ is given by

$$J_2(z) = \int_a^b \int_c^d \sum_{j=1}^n h_j(z_{xy}^j) dydx + \int_a^b \int_c^d g(x,y,z) dydx + \int_a^b \int_c^d f(x,y,z_y) dydx$$

and

$$Z = \Big\{ z \in W^{*,p}(Q, \mathbb{R}^n) : z \text{ satisfies } (3.2) \Big\}.$$

We have the second main theorem.

THEOREM 3.3. *Let f, g, h_j satisfy Hypothesis* H2 *above. Assume the functional J_2 is finite at some $z \in Z$. Then problem* (P$_2$) *admits at least a solution.*

Proof. We start by considering the convexified problem

$$\min_{z \in Z} J_2^{**}(z), \tag{P$_2^{**}$}$$

where J_2^{**} is obtained from J_2 by replacing each h_j with h_j^{**}. We proceed as in the proof (part (a)) of the previous theorem to conclude that problem (P_2^{**}) has at least a solution, say $\tilde{z} = (\tilde{z}^1, \dots, \tilde{z}^n)$. On the other hand, it is well known that under assumption (h_2) in Hypothesis H2, one has

$$\left\{\xi \in \mathbb{R} : h_j^{**}(\xi) < h_j(\xi)\right\} = \bigcup_{i \in I_j} \,]a_i^j, b_i^j[,$$

where the intervals $]a_i^j, b_i^j[$ are disjoint and finite with I_j being a countable set. In this situation each $]a_i^j, b_i^j[$ plays the role of the simplex S_i in Assumption H1. We now reason as in part (b) in the proof of Theorem 3.3. That is, setting

$$E_i^j = \left\{(x, y) \in Q : \ \tilde{z}_{xy}^j(x, y) \in \ ]a_i^j, b_i^j[\ \right\}$$

for every $j = 1, \dots, n$ and every $i \in I_j$, we apply Lemma 2.3 (with $]a_i^j, b_i^j[$ instead of S, E_i^j instead of E and $\nu = 1$) to obtain a measurable function w_i^j taking values in $\{a_i^j, b_i^j\}$ on E_i^j, such that

(i) $\int_a^b w_i^j(x, y)\chi_{E_i^j}(x, y)dx = \int_a^b \tilde{z}_{i,xy}^j(x, y)\chi_{E_i^j}(x, y)dx$ for a.e. $y \in [c, d]$ and

(ii) for every $x \in [a, b]$, we have

$$\int_a^x w_i^j(r, y)\chi_{E_i^j}(r, y)dr \geq \int_a^x \tilde{z}_{i,xy}^j(r, y)\chi_{E_i^j}(r, y)dr \qquad \text{for a.e. } y \in [c, d].$$

Put $E_0^j = Q \setminus \bigcup_{i \in I_j} E_i^j$, and define $z^j : Q \to \mathbb{R}$ by

$$z_{xy}^j(x, y) = \tilde{z}_{xy}^j(x, y)\chi_{E_0^j}(x, y) + \sum_{i \in I_j} w_i^j(x, y)\chi_{E_i^j}(x, y),$$
$$z^j(a, y) = \psi^j(a, y), \ z^j(x, c) = \psi^j(x, c).$$

Exactly as in the proof of the previous theorem, it can be proven that $\tilde{z}^j \in W^{*,p}(Q, \mathbb{R})$ satisfies the boundary condition (3.2),

$$\int_a^b\int_c^d h_j(z_{xy}^j(x, y))dydx = \int_a^b\int_c^d h_j^{**}(z_{xy}^j(x, y))dydx = \int_a^b\int_c^d h_j^{**}(\tilde{z}_{xy}^j(x, y))dydx,$$

and $z_y^j(x, y) \geq \tilde{z}_y^j(x, y)$, $z^j(x, y) \geq \tilde{z}^j(x, y)$ for a.e. (x, y) in Q. Consequently, by setting $z = (z^1, \dots, z^n)$, we obtain

$$\int_a^b\int_c^d \sum_{j=1}^n h_j(z_{xy}^j(x, y))dydx = \int_a^b\int_c^d \sum_{j=1}^n h_j^{**}(\tilde{z}_{xy}^j(x, y))dydx,$$

and by the monotonicity assumption on f and g,

$$\int_a^b\int_c^d f(x, y, z_y(x, y))dydx \leq \int_a^b\int_c^d f(x, y, \tilde{z}_y(x, y))dydx$$

and

$$\int_a^b\int_c^d g(x, y, z(x, y))dydx \leq \int_a^b\int_c^d g(x, y, \tilde{z}(x, y))dydx.$$

These facts show that z is a solution to problem (P_2), since $\tilde{z}$ is a solution to problem (P_2^{**}) and $h_j^{**} \leq h_j$. $\square$

The application of Lemma 2.3 in the proof of Theorems 3.1 and 3.3 allows us to construct a function z from $\tilde{z}$ satisfying

$$\langle z(x,y), \nu \rangle \geq \langle \tilde{z}(x,y), \nu \rangle \quad \text{and} \quad \tilde{z}(x,y) \preceq z(x,y), \tag{3.13}$$

respectively. Therefore, setting

$$Z_1 = \Big\{ z \in W^{*,p}(Q, \mathbb{R}^n) : z \text{ satisfies } (3.2), \langle z, \nu \rangle \geq \varphi_1 \text{ in } Q \Big\},$$

$$Z_2 = \Big\{ z \in W^{*,p}(Q, \mathbb{R}^n) : z \text{ satisfies } (3.2),\ \varphi_2 \preceq z \text{ in } Q \Big\},$$

for given measurable functions $\varphi_1 : Q \to \mathbb{R}$ and $\varphi_2 : Q \to \mathbb{R}^n$, we also obtain the following corollary.

Corollary 3.4. *Assume, in addition to Hypothesis* H1 *or* H2*, that some measurable constraints, as above, are given. Then the problems*

$$\min_{z \in Z_1} J_1(z) \quad \textit{and} \quad \min_{z \in Z_2} J_2(z)$$

admit at least a solution.

Remark 3.5. (i) By Remark 2.4, Theorems 3.1 and 3.3 continue to be valid in case $f(x,y,\cdot)$ and $g(x,y,\cdot)$ are nondecreasing functions. Moreover, under this assumption, the previous corollary also holds with the reverse inequality appearing in the definition of Z_1 and Z_2. In fact, Remark 2.4 asserts the existence (similar to (3.13)) of a function z satisfying

$$\langle z(x,y), \nu \rangle \leq \langle \tilde{z}(x,y), \nu \rangle \quad \text{or} \quad z(x,y) \preceq \tilde{z}(x,y)$$

according to whether we are dealing with problem Z_1 or Z_2, both with the reverse inequalities. Thus, if $\langle \tilde{z}(x,y), \nu \rangle \leq \varphi_1(x,y)$ (respectively, $\tilde{z} \preceq \varphi_2$), then $\langle z(x,y), \nu \rangle \leq \varphi_1(x,y)$ (respectively, $z \preceq \varphi_2$), and hence the conclusion follows since $f(x,y,\cdot)$ and $g(x,y,\cdot)$ are nondecreasing functions.

(ii) As a consequence of the monotonicity of $f(x,y,\cdot)$ and $g(x,y,\cdot)$, together with the fact that z is also a solution to (P_1^{**}) (respectively, (P_2^{**})), one can conclude that for almost all (x,y) in Q,

$$\begin{cases} f(x,y,\langle z_y(x,y), \nu \rangle) = f(x,y,\langle \tilde{z}_y(x,y), \nu \rangle), \\ g(x,y,\langle z(x,y), \nu \rangle) = g(x,y,\langle \tilde{z}(x,y), \nu \rangle) \end{cases}$$

(respectively,

$$\begin{cases} f(x,y,z_y(x,y)) = f(x,y,\tilde{z}_y(x,y)), \\ g(x,y,z(x,y)) = g(x,y,\tilde{z}(x,y))). \end{cases}$$

The last part of the preceding remark yields the following corollary.

Corollary 3.6. *Assume, in addition to the hypothesis of Theorems* 3.1 *or* 3.3*, that $n = 1$ and for almost all $(x,y) \in Q$ one of the functions $f(x,y,\cdot)$ or $g(x,y,\cdot)$ is strictly decreasing in $\mathbb{R}$ and $\nu = 1$. Then every solution to the convexified problem* $(\mathrm{P}_\mathrm{i}^{**})$ $(i = 1,2)$ *is a solution to the original (nonconvex) problem* (P_i) $(i = 1,2)$.

Notice that the previous corollary admits the following variant. Instead of assuming that $f(x,y,\cdot), g(x,y,\cdot)$ are strictly decreasing, one can impose that both functions satisfy $f(x,y,\rho) = f_1(x,y)f_2(\rho)$, $g(x,y,\eta) = g_1(x,y)g_2(\eta)$ with suitable assumptions on f_i, g_i. Here, f_2, g_2 might be piecewise monotone.

Example 3.7. In what follows I_K will denote the indicator function of the set K, i.e., $I_K(\xi) = 0$ if $\xi \in K$ and $I_K(\xi) = +\infty$ otherwise. For fixed $p \geq 1$, let us consider the problem of minimizing

$$J_1(z) = \int_0^1 \int_0^1 I_{\{-1,+1\}}(z_{xy}(x,y))dydx$$

among those functions z in $W^{*,p}([0,1] \times [0,1], \mathbb{R})$ satisfying $z(0,y) = z(x,0) = z(1,y) = 0$ for $x \in [0,1]$, $y \in [0,1]$. We denote this space by Z. Clearly, this problem admits infinitely many solutions. In fact, for every $k \in \mathbb{N}$, it is not difficult to check that the function z^k defined by

$$z^k(x,y) = \begin{cases} -\Big(x - \dfrac{2i-2}{2^k}\Big)y & \text{if } \dfrac{2i-2}{2^k} \leq x \leq \dfrac{2i-1}{2^k}, \\ \Big[-\dfrac{1}{2^k} + \Big(x - \dfrac{2i-1}{2^k}\Big)\Big]y & \text{if } \dfrac{2i-1}{2^k} \leq x \leq \dfrac{2i}{2^k} \end{cases}$$

($i = 1, 2, \dots, 2^{k-1}$) is a minimizer for J_1 in Z. Notice that $z^k \to 0$ uniformly. We now consider the functional J_2,

$$J_2(z) = \int_0^1 \int_0^1 I_{\{-1,+1\}}(z_{xy}(x,y))dydx + \int_0^1 \int_0^1 |z(x,y)|^p dydx,$$

defined on the same space as J_1. One can easily prove that the sequence defined above is minimizing for J_2, i.e., $\lim_k J_2(z^k) = \inf J_2(z) = 0$. However, since every function in $W^{*,p}$ is continuous, the minimum value of J_2 is not attained. Notice that the monotonicity assumption (g_2) in Hypothesis H1 or H2 is not satisfied. The same conclusion also is reached if we consider the functional $J_3 : Z \to \mathbb{R}$,

$$J_3(z) = J_1(z) + \int_0^1 \int_0^1 |z_y(x,y)|^p dydx,$$

since the sequence, as above, continues to be minimizing for J_3 and $z_y^k \to 0$ uniformly. Observe that $z_x^k \rightharpoonup 0$ in L^p.

Remark 3.8. Certainly, because of the analogy of the results in Lemma 2.3, we also obtain existence results for the functional J_1 (or J_2) depending on z_x in place of z_y, but in this case the boundary data have to be given on $\partial^- Q = [a,b] \times \{c\} \cup \{a\} \times [c,d] \cup [a,b] \times \{d\}$. On the other hand, due to the last part of Remark 2.5, our approach cannot be applied to a functional depending on z_x and z_y simultaneously. However, we believe that such a result, in general, is not true even if we were unable to find a concrete example.

4. Some bang-bang theorems for the simplest hyperbolic equation. This section is devoted to prove a *weak* bang-bang theorem for the hyperbolic inclusion

$$z_{xy}(x,y) \in C \qquad \text{for a.e. } (x,y) \in Q \tag{4.1}$$

where C is a compact convex subset of $\mathbb{R}^n$, $z \in W^{*,\infty}(Q, \mathbb{R}^n)$, and all the notations are those introduced in section 3. Some of the topological concepts to be used here have been introduced in section 2. Recall that, given a set E, co E and $\mathrm{aff}(E)$ stand for the convex hull of E and for the smallest affine space containing E, respectively ([Roc]). Moreover, if C is a convex subset of $\mathbb{R}^n$, a face F of C is said to be *exposed* if it is the intersection of C and a supporting hyperplane of C. The normal cone to C at a point $x \in \mathbb{R}^n$ is defined by

$$N_C(x) = \{\xi \in \mathbb{R}^n \,:\, \langle \xi, x-y\rangle \geq 0 \;\forall y \in C\}$$

and the tangent cone

$$T_C(x) = \{\zeta \in \mathbb{R}^n \,:\, \langle \zeta, \xi\rangle \leq 0 \;\forall \xi \in N_C(x)\}\,.$$

Definition 4.1. *Let C be a convex set and e be a point such that $e \notin C$. We say that the supporting hyperplane H to C strictly separates C and e if C is contained in a closed half-space associated with H and e belongs to the opposite open half-space.*

First we prove the following technical proposition.

Proposition 4.2. *Let $P \subset \mathbb{R}^n$ be an n-dimensional convex polytope (see* [Roc]*) and e and x, $e \in \mathbb{R}^n \backslash P$ and $x \in \partial P$, be such that $]x,e] \cap P$ is empty. Then there exists an $(n-1)$-dimensional face F of P such that $x \in F$ and* $\mathrm{aff}(F)$ *strictly separates P and e.*

Proof. Let F_i, $i = 1,\dots,k$, be the $(n-1)$-dimensional faces of P and F_i, $i = 1,\dots,k_x$, be those which contain x. For every $i = 1,\dots,k$ denote by ν_i the exterior normal vector at the face F_i and by π_i the supporting half-space to P at every point of F_i. Thus, for every point $y \in \partial\pi_i$, the tangent and the normal cones to π_i at y are given by $T_{\pi_i}(y) = \pi_i - y$ and $N_{\pi_i}(y) = \mathbb{R}_0^+\nu_i$, respectively. Recalling that $P = \cap_{i=1}^k \pi_i$, by Corollary 23.8.1 in [Roc] (see also [Au-Fr, p. 141]) the normal cone to P at x is given by $N_P(x) = \sum_{i=1}^k N_{\pi_i}(x) = \sum_{i=1}^{k_x} N_{\pi_i}(x)$; hence

$$N_P(x) = \left\{\sum_{i=1}^{k_x} \lambda_i\nu_i \,:\, \lambda_i \geq 0,\; i = 1,\dots k_x\right\}.$$

As a consequence, the tangent cone to P at x is given by

$$T_P(x) = \bigcap_{i=1}^{k_x} T_{\pi_i}(x) = \bigcap_{i=1}^{k_x}(\pi_i - x).$$

Taking into account that every face of P is exposed, from $]x,e] \cap P = \emptyset$ it follows that $(e-x) \notin T_P(x)$. Therefore there exists $i \in \{1,\dots,k_x\}$ such that $e \notin \pi_i$, and the conclusion follows. □

The following result is a sharper version of Lemma 2.3 in [Am-Ma]. We prove that every n-dimensional compact convex set C can be written, up to the boundary, as a union of a countable family of n-dimensional simplices (with pairwise disjoint interior) having their vertices in the set of extreme points of C.

Lemma 4.3. *Let C be an n-dimensional compact convex subset of $\mathbb{R}^n$. Then there exists a countable family $\mathcal{S}$ of n-dimensional simplices such that*

(i) int $C \subset \cup\{S \,:\, S \in \mathcal{S}\}$*;*

(ii) int $S \cap$ int $S' = \emptyset$ *if $S, S' \in \mathcal{S}$ and $S \neq S'$;*

(iii) extr $S \subseteq$ extr C *for every $S \in \mathcal{S}$.*

Proof. If C has only a finite number of extreme points, then it is a polytope and the proof is trivial. Otherwise, let E be a countable dense subset of extr C and set

$E = \{e_i : i \in \mathbb{N}\}$ such that $e_0, e_1, \dots, e_n$ are affinely independent. We are going to construct the family $\mathcal{S}$ by a recursive argument.

At the first step set $S_1^1 = \text{co}\{e_0, \dots, e_n\}$, $C_1 = S_1^1$, and $n_1 = 1$. Obviously, S_1^1 is an n-dimensional simplex. At the second step, consider the point $e_{n+1} \in E$ and denote by F_k^1, $k = 1, \dots, n_2$, the $(n-1)$-dimensional faces of C_1 that satisfy the following property: for every $k = 1, \dots, n_2$ the hyperplane $\text{aff}(F_k^1)$ generated by F_k^1 strictly separates C_1 and e_{n+1}. By Proposition 4.2 the set $\{F_k^1 : k = 1, \dots, n_2\}$ is not empty. For every $k = 1, \dots, n_2$ denote by S_k^2 the n-dimensional simplex given by $S_k^2 = co(F_k^1 \cup \{e_{n+1}\})$. The finite family $\{S_1^1, S_k^2 : k = 1, \dots, n_2\}$ fulfills properties (ii) and (iii) in the statement. Finally, set $C_2 = C_1 \cup \{S_k^2 : k = 1, \dots, n_2\}$. We claim that $C_2 = \text{co}\{e_0, \dots, e_{n+1}\}$.

Obviously $C_2 \subseteq \text{co}\{e_0, \dots, e_{n+1}\}$. In order to prove the opposite inclusion consider $x = \sum_{i=0}^{n+1} \lambda_i e_i$, $0 \le \lambda_i \le 1$, $\sum_{i=0}^{n+1} \lambda_i = 1$. If $\lambda_{n+1} = 0$, then $x \in S_1^1 \subset C_2$. If $\lambda_{n+1} = 1$, then $x = e_{n+1} \in C_2$. Otherwise, if $0 < \lambda_{n+1} < 1$, set $\bar{x} = \sum_{i=0}^{n} \lambda_i/(1 - \lambda_{n+1})e_i$. Then $\bar{x} \in S_1^1$ and $x = (1 - \lambda_{n+1})\bar{x} + \lambda_{n+1}e_{n+1}$. Let $\tilde{x}$ be the *last* point in $[\bar{x}, e_{n+1}] \cap \partial C_1$. By Proposition 4.2 there exists an $(n-1)$-dimensional face F of C_1 such that $\tilde{x} \in F$ and $\text{aff}(F)$ strictly separates C_1 and e_{n+1}. The definition of the simplices S_k^2 implies that the segment whose extreme points are $\tilde{x}$ and e_{n+1} is included in C_2. Hence, the segment $[\bar{x}, e_{n+1}]$ is also included in C_2 and the claim is proven.

Suppose now we have defined $m - 1$ finite families

$$\left\{S_k^h : k = 1, \dots, n_h\right\}, \qquad h = 1, \dots, m-1,$$

of simplices whose interior points are mutually disjoint and whose extreme points are in $\{e_0, \dots, e_{n+m-2}\}$, and $m - 1$ convex sets

$$C_h = C_{h-1} \cup \left(\bigcup_{k=1}^{n_h} S_k^h\right) = \text{co}\{e_0, \dots, e_{n+h-1}\}, \qquad h = 1, \dots, m-1 \quad (C_0 = \emptyset).$$

In particular $C_{m-1} = \cup_{h=1}^{m-1} \cup_{k=1}^{n_h} S_k^h = \text{co}\{e_0, \dots, e_{n+m-2}\}$. Following the same ideas of the second step, denote by $\{F_k^{m-1} : k = 1, \dots n_m\}$ the family of all $(n-1)$-dimensional faces of C_{m-1} such that $\text{aff}(F_k^{m-1})$ strictly separates C_{m-1} and e_{n+m-1}. By Proposition 4.2 this family is not empty. For every $k \in \{1, \dots, n_m\}$, define the simplex $S_k^m = \text{co}(F_k^{m-1} \cup \{e_{n+m-1}\})$. Clearly, the family $\{S_k^h : h = 1, \dots, m, k = 1, \dots, n_h\}$ satisfies items (ii) and (iii) of the statement. Moreover, setting $C_m = C_{m-1} \cup (\cup_{k=1}^{n_m} S_k^m)$, one can prove, as in the previous step, that $C_m = \text{co}\{e_0, \dots, e_{n+m-1}\}$.

Recursively, one obtains the countable family of simplices $\mathcal{S} = \{S_k^h : h \in \mathbb{N}^+, k = 1, \dots, n_h\}$ satisfying (ii) and (iii) and such that, for every $m \ge 1$, $\cup_{h=1}^{m} \cup_{k=1}^{n_h} S_k^h = \text{co}\{e_0, \dots, e_{n+m-1}\} = C_m$. Hence also (i) is fulfilled,

$$\text{int}\, C \subset \text{co}\, E = \bigcup_{m \ge 1} C_m = \bigcup \left\{S : S \in \mathcal{S}\right\},$$

and the lemma is proven. □

We are now in a position to establish our first bang-bang theorem for the inclusion (4.1).

THEOREM 4.4. *Let C be a convex compact subset in $\mathbb{R}^n$, let $\tilde{z}$ be a solution of the inclusion* (4.1). *Then, for every vector $\nu \in \mathbb{R}^n$ there exists a function $z \in W^{*,\infty}(Q, \mathbb{R}^n)$ such that*

(i) $z_{xy}(x,y) \in \partial_r C$ *(the relative boundary of* C*) for a.e.* $(x,y) \in Q$*;*

(ii) $z(x,y) = \tilde{z}(x,y)$ *for every* $(x,y) \in \partial_+ Q$*;*

(iii)$\langle z(x,y), \nu\rangle \geq \langle \tilde{z}(x,y), \nu\rangle$ *for every* $(x,y) \in Q$*.*

Proof. It is not restrictive to assume that C has dimension n. By Lemma 4.3, the interior of C is the union of countably many relative open pairwise disjoint simplices (the faces of the n-dimensional simplices in $\mathcal{S}$). Denote this family by $\{S_k : k \in \mathbb{N}\}$. Then Q can be partitioned as a union of countably many measurable sets, $Q = F \cup (\cup_{k\in\mathbb{N}} E_k)$, where

$$F = \Big\{(x,y) \in Q \, : \, \tilde{z}_{xy}(x,y) \in \partial C\Big\},$$

$$E_k = \Big\{(x,y) \in Q \, : \, \tilde{z}_{xy}(x,y) \in S_k\Big\}, \qquad k \in \mathbb{N}.$$

For every k in $\mathbb{N}$, let w_k be the function obtained by applying Lemma 2.3 for $E = E_k$, $S = S_k$, and $v = \tilde{z}_{xy}$. Let w be the function defined by $w = \tilde{z}_{xy}\chi_F + \sum_{k\in\mathbb{N}} \chi_{E_k}$. Arguing as in the proof of Theorem 3.1, one can prove that the function $z : Q \to \mathbb{R}^n$ given by

$$z(x,y) = \tilde{z}(x,c) + \tilde{z}(a,y) - \tilde{z}(a,c) + \int_a^x \int_c^y w(r,s)dsdr$$

is in $W^{*,\infty}(Q)$ and satisfies (i), (ii), and (iii). □

Remark 4.5. Notice that, if in the previous theorem $\tilde{z}$ is such that $\tilde{z}_{xy} \in \mathrm{ri}\ C$ (the relative interior of C) a.e. in Q, we obtain that $z_{xy} \in \mathrm{extr}\ C$ a.e. in Q. Thus, the previous result allows us to generalize Lemma 2.3 to the case when S is a convex relative open bounded subset of $\mathbb{R}^n$, and also Theorem 3.1 by substituting S_i, in Hypothesis H1, with a convex relative open bounded subset of $\mathbb{R}^n$. Others assumptions on S_i remain valid.

In case $n = 2$ we obtain the following bang-bang theorem in the *strong* form.

THEOREM 4.6. *Let* $\tilde{z}$ *be a solution of the inclusion* (4.1) *where* C *is a compact and convex subset of* $\mathbb{R}^2$*. Then, for every vector* $\nu \in \mathbb{R}^2$ *there exists a function* $z \in W^{*,\infty}(Q, \mathbb{R}^2)$ *such that*

(i) $z_{xy}(x,y) \in \mathrm{extr}\ C$ *for a.e.* $(x,y) \in Q$*;*

(ii) $z(x,y) = \tilde{z}(x,y)$ *for every* $(x,y) \in \partial_+ Q$*;*

(iii) $\langle z(x,y), \nu\rangle \geq \langle \tilde{z}(x,y), \nu\rangle$ *for every* $(x,y) \in Q$*.*

Proof. For $n = 2$ the boundary of C is the union of its extreme points and of its one-dimensional faces. Notice that, since the one-dimensional Hausdorff measure of ∂C is finite, the one-dimensional faces of C are at most countable. Hence, the proof is similar to that of the previous theorem, where we add to the family $\{S_k : k \in \mathbb{N}\}$ the relative interior of the one-dimensional faces of C and we call F the set

$$F = \Big\{(x,y) \in Q \, : \, \tilde{z}_{xy}(x,y) \in \mathrm{extr}\ C\Big\}. \qquad \square$$

STABILIZATION OF HIGH EIGENFREQUENCIES OF A BEAM EQUATION WITH GENERALIZED VISCOUS DAMPING[*]

SHENGJIA LI[†], JINGYUAN YU[‡], ZHANDONG LIANG[†], AND GUANGTIAN ZHU[§]

Abstract. In this paper, using the one-dimensional vibrating beam equation with generalized viscous damping as a model of vibration of flexible robot arms, it is shown that for such a system the high eigenmodes decay at a uniform rate. The proof is obtained by perturbation theory of linear operators [Y. H. Luo, *Acta Math. Sinica*, 32 (1991), pp. 556–563] and asymptotic estimates of eigenvectors based on an earlier work of G. B. Birkhoff and M. H. Stone. Feedback control for this class of system is investigated, and a finite-dimensional controller is presented for an exponentially stable closed-loop system. Our method may be used to study nondissipative systems.

Key words. generalized viscous damping, eigenfrequencies, feedback control, exponential decay

1. Introduction.

In recent years there has been much interest in the topic of control and stabilization of vibrating equations. For example, see [6], [13], [14], and [16] for serially connected beams, [12], [20], [21], [22], [23] for vibrating strings or second order wave equations, and [1], [5], [18] for beam equations with locally distributed damping.

In this article, we consider the beam equation

$$(1.1)\qquad \begin{cases} \dfrac{\partial^2}{\partial t^2}u(x,t) + \dfrac{\partial^4}{\partial x^4}u(x,t) + b(x)\dfrac{\partial}{\partial t}u(x,t) = 0, & 0 < x < \ell, \quad t > 0, \\ u(0,t) = \dfrac{\partial}{\partial x}u(0,t) = \dfrac{\partial^2}{\partial x^2}u(\ell.t) = \dfrac{\partial^3}{\partial x^3}u(\ell,t) = 0, & t \geq 0, \\ u(x,0) = u_0(x), \qquad \frac{\partial}{\partial t}u(x,0) = u_2(x), \quad 0 \leq x \leq \ell, \end{cases}$$

where the viscous damping $b(x)$ is a continuous real function satisfying the hypothesis. Such a perturbing term takes place due to medium impurities, distributed and/or boundary friction, small viscous effects, etc.

It is well known that the analysis of damping is important in the understanding of vibrating system behavior. In [1] and [5], Chen et al. have considered the asymptotic average decay rate for the wave equation with variable coefficient viscous damping based on an earlier work of Birkhoff and Langer. For second order wave equations, a rigorous treatment of the asymptotics of the eigenvalues is given in [21], one of the conjectures in [1] is proven to be wrong in general, and the results in [20] are extended to allow sign-change damping terms, and a sufficient condition for stability in that case is given in [23]. Unfortunately, for the beam equation (1.1) the Birkhoff–Langer technique cannot be applied; information about the asymptotic average decay rate of this equation is still unknown. Whether it is valid or not is an open question [1],

[5]. In this paper, we prove that all high eigenmodes decay at a uniform rate. This result answers the conjecture [1] in the generalized case: there exists an $n_1 > 0$, such that $\text{Re}\lambda_{nj} < -\frac{\delta_0}{2} + \varepsilon$ for $n > n_1$, $j = 1, 2$, where $\varepsilon : 0 < \varepsilon < \frac{\delta_0}{2}$ and $\lambda_{nj} \in \sigma_0(A)$ (the spectrum of A). Finally, in order to stabilize the system exponentially, a finite-dimensional controller is presented. The main difference between the work of this paper and that of [1], [5], and others is that our condition on $b(x)$ is not necessarily dissipative but only "more positive than negative [5]." Our method may be used to study nondissipative systems.

In order to study (1.1), we define the differential operator A_0 as follows:

$$\begin{cases} A_0\phi(x) = \frac{d^4}{dx^4}\phi(x), & \phi(x) \in D(A_0), \\ D(A_0) = \{\phi; \phi \in H^4(0,\ell), & \text{and} \quad \phi(0) = \phi'(0) = \phi''(\ell) = \phi'''(\ell) = 0\}. \end{cases}$$

Obviously A_0 is positive in $L^2(0,\ell)$. By the equivalent transformation $y_1(t) = u(t)$, $y_2(t) = \frac{d}{dt}u(t)$, (1.1) becomes

$$\begin{cases} \dfrac{d}{dt}\begin{pmatrix} y_1(t) \\ y_2(t) \end{pmatrix} = A \begin{pmatrix} y_1(t) \\ y_2(t) \end{pmatrix}, \quad t > 0, \\ \begin{pmatrix} y_1(0) \\ y_2(0) \end{pmatrix} = \begin{pmatrix} u_1 \\ u_2 \end{pmatrix}, \end{cases} \tag{1.2}$$

where $A = \left(\begin{smallmatrix} 0 & I \\ -A_0 & -b(x) \end{smallmatrix}\right)$ and $D(A) = D(A_0) \times D(A_0^{\frac{1}{2}})$. The energy inner product is defined on $D(A)$ by $((\begin{smallmatrix} u_1 \\ u_2 \end{smallmatrix}), (\begin{smallmatrix} v_1 \\ v_2 \end{smallmatrix})) = (A_0^{\frac{1}{2}}u_1, A_0^{\frac{1}{2}}v_1) + (u_2, v_2)$ for $u_1, v_1 \in D(A_0^{\frac{1}{2}})$, $u_2, v_2 \in D(A_0)$, and the Hilbert space $\mathbf{H}$ is defined as the closure of D(A) in this energy inner product.

Hypothesis. We assume that $b(x) \in C[0,\ell]$ and satisfies

$$\int_0^l b(x)|\phi_{nj}(x)|^2 dx \geq \delta_0 > 0, \qquad j = 1, 2, \quad n > n_0, \tag{1.3}$$

where $\delta_0 > 0$ is a constant, n_0 is a positive integer, and ϕ_{nj}, $j = 1, 2$, $n = 1, 2, \ldots,$ are the orthonormalized eigenfunctions of the eigenequation

$$\begin{cases} \dfrac{\partial^2}{\partial t^2}u(x,t) + \dfrac{\partial^4}{\partial x^4}u(x,t) = 0, & 0 < x < \ell, \quad t > 0, \\ u(0,t) = \dfrac{\partial}{\partial x}u(0,t) = \dfrac{\partial^2}{\partial x^2}u(\ell,t) = \dfrac{\partial^3}{\partial x^3}u(\ell,t) = 0, & t \geq 0. \end{cases} \tag{1.1$'$}$$

The assumptions on the damping coefficient $b(x)$ are very weak; the value of $b(x)$ can even be negative on some small parts of the interval $[0,\ell]$.

The organization of this paper is as follows. In section 2 we obtain the asymptotic formula for the eigenvectors of A. In section 3 we get the stronger result that the operator $A = \begin{pmatrix} 0 & I \\ -A_0 & -b(x) \end{pmatrix}$ generates a C_0-semigroup and all generalized eigenvectors of A form an unconditional basis of H. In section 4 we prove that, for a given $\varepsilon : 0 < \varepsilon < \frac{\delta_0}{2}$, there exists an $n_1 > n_0$ such that $\text{Re}\lambda_{nj} < -\frac{\delta_0}{2} + \varepsilon$ for $n > n_1$, where $\lambda_{nj} \in \sigma(A)$. In section 5, a finite-dimensional controller is presented for exponentially stable closed-loop system.

2. Asymptotic estimations of the eigenvectors of $\boldsymbol{A}$. In this section, we will estimate the eigenvectors of A. For convenience, we suppose that $\ell = 1$. The following is obvious.

Lemma 2.1. *The eigenequation of* (1.1) *is equivalent to the eigenequation of* (1.2). *That is, a complex λ satisfies the eigenequation*

$$\begin{cases} \lambda^2\phi(x) + \lambda b(x)\phi(x) + \phi^{(4)}(x) = 0, & x \in (0,1), \\ \phi(0) = \phi'(0) = \phi''(1) = \phi'''(1) = 0, \end{cases} \tag{2.1}$$

if and only if λ satisfies the eigenequation

$$\lambda \begin{pmatrix} \phi_1 \\ \phi_2 \end{pmatrix} = A \begin{pmatrix} \phi_1 \\ \phi_2 \end{pmatrix}.$$

We only need to estimate those of the quadratic eigenfunction (2.1). *For convenience, we divide the complex plane into*

$$S_n = \left\{ \rho;\ \frac{n\pi}{8} \le \arg\rho \le \frac{n+1}{8}\pi \right\}, \quad n = 0,1,2,3,4,5,6,7.$$

Then, for every sector S_n, we can arrange ω_1, ω_2, ω_3, ω_4(the roots of $\omega^4 = -1$), such that

$$\operatorname{Re}(\rho\omega_1) \le \operatorname{Re}(\rho\omega_2) \le \operatorname{Re}(\rho\omega_3) \le \operatorname{Re}(\rho\omega_4) \quad \textit{for } \rho \in S_n. \tag{2.2}$$

In fact, for S_0, we choose $\omega_1 = e^{\frac{3\pi}{4}i}, \omega_2 = e^{\frac{5\pi}{4}i}, \omega_3 = e^{\frac{\pi}{4}i}, \omega_4 = e^{-\frac{\pi}{4}i}$. We can verify that (2.2) *is true for $\rho \in S_0$. Similarly, we can see that* (2.2) *holds for S_n, $1 \le n \le 7$. Let $\lambda = \rho^2$. For* (2.1), *we have a general result.*

Lemma 2.2. *The equation*

$$\phi^{(4)}(x) + \rho^2 b(x)\phi(x) + \rho^4\phi(x) = 0, \quad x \in [0,1],\ \rho \in S_n,\ |\rho| > b_0,\ 0 \le n \le 7, \tag{2.3}$$

has four linearly independent solutions, ϕ_k, $k = 1,2,3,4$, which satisfy

$$\frac{d^j}{dx^j}\phi_k(x,\rho) = \rho^j e^{\rho\omega_k x}\left[\omega_k^j + O\left(\frac{1}{\rho}\right)\right], \quad j = 0,1,2,3, \tag{2.4}$$

where $b_0 = \max|b(x)|$ and ω_k, $k = 1,2,3,4$, are the four roots of the equation $\omega^4 = -1$ satisfying (2.2). *If $b(x) = 0$, then $O(\frac{1}{\rho}) = 0$.*

Proof. Because $e^{\rho\omega_j x}$, $j = 1,2,3,4$, are the basic solutions of the equation $\phi^{(4)} + \lambda^2\phi = 0$, by the method of variation of constants, the solution of (2.3) can be represented as

$$y(x,\rho) = \sum_{j=1}^{4} c_j e^{\rho\omega_j x} + \frac{1}{4\rho}\int_0^x \left(\sum_{j=1}^{4} \omega_j e^{\rho\omega_j(x-\xi)}\right) b(\xi)y(\xi)d\xi, \tag{2.5}$$

where c_j, $j = 1,2,3,4$, are arbitrary constants. For a fixed k, we set

$$\begin{aligned} &c_j' = c_j, && 1 \le j \le k, \\ &c_j' = c_j + \tfrac{1}{4\rho}\textstyle\int_0^1 \omega_j e^{-\rho\omega_j\xi} b(\xi)y(\xi)d\xi, && k+1 \le j \le 4. \end{aligned} \tag{2.6}$$

Then (2.5) can be rewritten as

$$\begin{aligned} y(x,\rho) = \sum_{j=1}^{4} c'_j e^{\rho\omega_j x} + \tfrac{1}{4\rho}\int_0^x \left(\sum_{j=1}^{k}\omega_j e^{\rho\omega_j(x-\xi)}\right) b(\xi)y(\xi)d\xi \\ - \frac{1}{4\rho}\int_x^1 \left(\sum_{j=k+1}^{4}\omega_j e^{\rho\omega_j(x-\xi)}\right) b(\xi)y(\xi)d\xi. \end{aligned} \tag{2.7}$$

Taking $c'_k = 1$, $c'_n = 0$, $n \neq k$, we get

$$\begin{aligned} y_k(x,\rho) = e^{\rho\omega_k x} + \frac{1}{4\rho}\int_0^x \left(\sum_{j=1}^{k}\omega_j e^{\rho\omega_j(x-\xi)}\right) b(\xi)y_k(\xi)d\xi \\ - \frac{1}{4\rho}\int_x^1 \left(\sum_{j=k+1}^{4}\omega_j e^{\rho\omega_j(x-\xi)}\right) b(\xi)y_k(\xi)d\xi\,, \quad k=1,2,3,4. \end{aligned} \tag{2.8}$$

If $y_k(x,\rho), 1 \le k \le 4$, are solutions of (2.2), differentiating y_k with respect to x, we get

$$\begin{aligned} \frac{d^j}{dx^j}y_k(x,\rho) = (\rho\omega_k)^j e^{\rho\omega_k x} + \frac{1}{4\rho}\int_0^x \left(\sum_{\nu=1}^{k}\omega_\nu^{j+1}\rho^j e^{\rho\omega_\nu(x-\xi)}\right) b(\xi)y_k(\xi)d\xi \\ - \frac{1}{4\rho}\int_x^1 \left(\sum_{\nu=k+1}^{4}\omega_\nu^{j+1}\rho^j e^{\rho\omega_\nu(x-\xi)}\right) b(\xi)y_k(\xi)d\xi, \\ k=1,2,3,4,\ j=0,1,2,3. \end{aligned} \tag{2.9}$$

Let

$$\frac{d^j}{dx^j}y_k(x,\rho) = \rho^j e^{\rho\omega_k x} z_{kj}(x,\rho)\,, \quad k=1,2,3,4,\ j=0,1,2,3; \tag{2.10}$$

we get

$$\begin{aligned} z_{kj}(x,\rho) = \omega_k^j + \frac{1}{4\rho}\int_0^x \left(\sum_{\nu=1}^{k}\omega_\nu^{j+1} e^{\rho(\omega_\nu-\omega_k)(x-\xi)}\right) b(\xi)z_{k0}(\xi,\rho)d\xi, \\ - \frac{1}{4\rho}\int_x^1 \left(\sum_{\nu=k+1}^{4}\omega_\nu^{j+1} e^{\rho(\omega_k-\omega_\nu)(\xi-x)}\right) b(\xi)z_{k0}(\xi,\rho)d\xi, \\ k=1,2,3,4,\ j=0,1,2,3. \end{aligned} \tag{2.11}$$

Let

$$K_{kj0}(x,\xi,\rho) = \begin{cases} \dfrac{1}{4}\left(\displaystyle\sum_{\nu=1}^{k}\omega_\nu^{j+1} e^{\rho(\omega_\nu-\omega_k)(x-\xi)}\right) b(\xi)\,, & \xi < x, \\ -\dfrac{1}{4}\left(\displaystyle\sum_{\nu=k+1}^{4}\omega_\nu^{j+1} e^{\rho(\omega_k-\omega_\nu)(\xi-x)}\right) b(\xi)\,, & \xi > x, \end{cases} \tag{2.12}$$

$$k=1,2,3,4,\ j=0,1,2,3.$$

From (2.12), (2.11) can be rewritten as

$$z_{kj}(x,\rho)=\omega_k^j+\frac{1}{\rho}\int_0^1 K_{kj0}(x,\xi,\rho)z_{k0}(\xi,\rho)d\xi\,,\quad k=1,2,3,4,\ j=0,1,2,3. \tag{2.13}$$

From inequality (2.2), we have

$$|e^{-\rho(\omega_k-\omega_\nu)(x-\xi)}|=e^{(x-\xi)^{\mathrm{Re}}(\rho\omega_\nu-\rho\omega_k)}\le 1\quad \text{for}\ \ \nu\le k,\ \xi<x,\ \rho\in S_n,$$

and

$$|e^{-\rho(\omega_k-\omega_\nu)(x-\xi)}|=e^{(x-\xi)^{\mathrm{Re}}(\rho\omega_\nu-\rho\omega_k)}\le 1\quad \text{for}\ \ \nu> k,\ \xi>x,\ \rho\in S_n.$$

So

$$|K_{kj0}(x,\xi,\rho)|\le \max\nolimits_{0\le\xi\le 1}|b(\xi)|=b_0. \tag{2.14}$$

By Picard's iteration, we see that (2.12) has a unique solution

$$z_{kj}(x,\rho)\quad \text{for}\ \ \rho\in S_n \text{ and } |\rho|>b_0,$$

satisfying

$$z_{kj}(x,\xi)=\omega_k^j+O\left(\frac{1}{\rho}\right)\quad \text{as}\ \ \rho\longrightarrow\infty. \tag{2.15}$$

From (2.15), we get (2.4).

Finally, we prove that (2.8) is the solution of (2.3) for $|\rho|$ large enough. For this, in the following, we prove (2.7) is a solution of (2.3) for every (c_1',c_2',c_3',c_4') and $|\rho|>b_0$. Because (2.6) is a linear mapping from (c_1,c_2,c_3,c_4) to (c_1',c_2',c_3',c_4') , we prove only that mapping (2.6) is invertible for $|\rho|>b_0$. Supposing (2.6) had a solution $c_j\neq 0$ for $c_j'=0$, the equation

$$\begin{aligned} y(x,\rho)=&\frac{1}{4\rho}\int_0^x\left(\sum_{\nu=1}^k\omega_\nu e^{\rho\omega_\nu(x-\xi)}\right)b(\xi)y(\xi,\rho)d\xi\\ &-\frac{1}{4\rho}\int_0^x\left(\sum_{\nu=k+1}^4\omega_\nu e^{\rho\omega_\nu(x-\xi)}\right)b(\xi)y(\xi,\rho)d\xi \end{aligned} \tag{2.16}$$

has a nonzero solution. Differentiating (2.16), we get

$$\frac{d^j}{dx^j}y(x,\rho)=\rho^j e^{\rho\omega_k x}z_j(x,\rho)\,,\quad j=0,1,2,3, \tag{2.17}$$

where z_j satisfy

$$\begin{aligned} z_j(x,\rho)=&\frac{1}{4\rho}\int_0^x\left(\sum_{\nu=1}^k\omega_\nu e^{-\rho(\omega_k-\omega_\nu)(x-\xi)}\right)b(\xi)z_0(\xi,\rho)d\xi\\ &-\frac{1}{4\rho}\int_0^x\left(\sum_{\nu=k+1}^4\omega_\nu e^{\rho(\omega_\nu-\omega_k)(x-\xi)}\right)b(\xi)z_0(\xi,\rho)d\xi,\ j=0,1,2,3. \end{aligned} \tag{2.18}$$

Let $M(\rho)=\max_{0\le x\le 1}|z_j(x,\rho)|\,,\, j=0,1,2,3$. We get

$$|z_j(x,\rho)|\le\left[\frac{b_0k}{4|\rho|}+\frac{b_0(4-k)}{4|\rho|}\right]M(\rho)\,,\, j=0,1,2,3. \tag{2.19}$$

That is,

$$M(\rho)\le\frac{b_0}{|\rho|}M(\rho). \tag{2.20}$$

From (2.20), we see that $M(\rho)=0$, and $z_j(x,\rho)=0$ $(j=0,1,2,3)$ for $|\rho|>b_0$. Then $y(x,\rho)=e^{\rho\omega_k x}z_0(x,\rho)=0$ for $|\rho|>b_0$. This is a contradiction with $y(x,\rho)\neq 0$. Therefore mapping (2.7) is the solution of (2.3). The proof is complete. □

In order to get an asymptotic formula for eigenfunctions of (2.1), we first estimate the eigenvalues of (2.1).

Lemma 2.3. *The eigenvalues of* (2.1) *are the following sequences:*

$$\begin{aligned}\lambda_{n1}&=\left(-n+\frac{1}{2}\right)^2\pi^2\left[i+O\left(\frac{1}{n^2}\right)\right], \quad n=1,2,\dots,\\ \lambda_{n2}&=\left(n+\frac{1}{2}\right)^2\pi^2\left[i+O\left(\frac{1}{n^2}\right)\right], \quad n=1,2,\dots.\end{aligned} \tag{2.21}$$

Proof. Let $\rho^4=\lambda^2$ and $S_0=\{\rho\ ;\ \ -\frac{\pi}{4}\le\arg\rho\le 0\}$. Taking $\omega_1=e^{\frac{5\pi i}{4}}$, $\omega_2=e^{\frac{3\pi i}{4}}$, $\omega_3=e^{\frac{7\pi i}{4}}$, $\omega_4=e^{\frac{\pi i}{4}}$, then $\mathrm{Re}\omega_1\rho\le\mathrm{Re}\omega_2\rho\le\mathrm{Re}\omega_3\rho\le\mathrm{Re}\omega_4\rho$ for $\rho\in S_0$, and $e^{\omega_1\rho}\to 0, e^{\omega_4\rho}\to\infty$ $(\rho\to\infty,\rho\in S_0)$ exponentially. By Lemma 2.2 for $\rho\in S_0$ (2.2) has four independent solutions ϕ_1, ϕ_2, ϕ_3, ϕ_4, which satisfy (2.4). By (2.4), we get

$$\begin{aligned}&\phi_k(0)=1+O\left(\frac{1}{\rho}\right), && \phi_k'(0)=\rho\omega_k\left[1+O\left(\frac{1}{\rho}\right)\right],\\ &\phi_k''(1)=\rho^2\omega_k^2e^{\rho\omega_k}\left[1+O\left(\frac{1}{\rho}\right)\right], && \phi_k'''(1)=\rho^3\omega_k^3e^{\rho\omega_k}\left[1+O\left(\frac{1}{\rho}\right)\right],\\ &&& k=1,2,3,4.\end{aligned} \tag{2.22}$$

From this estimation, the eigendeterminant $\Delta(\lambda)=0$ can be represented as

$$\begin{vmatrix}\omega_1[1] & \omega_2[1] & \omega_3[1] & \omega_4[1]\\ [1] & [1] & [1] & [1]\\ (\omega_1)^3e^{\omega_1\rho}[1] & (\omega_2)^3e^{\omega_2\rho}[1] & (\omega_3)^3e^{\omega_3\rho}[1] & (\omega_4)^3e^{\omega_4\rho}[1]\\ (\omega_1)^2e^{\omega_1\rho}[1] & (\omega_2)^2e^{\omega_2\rho}[1] & (\omega_1)^2e^{\omega_3\rho}[1] & (\omega_4)^2e^{\omega_4\rho}[1]\end{vmatrix}, \tag{2.23}$$

where $[1]=1+O(\frac{1}{\rho})$. By computing, we get

$$\Delta(\lambda)=-2(e^{\rho\omega_3}+e^{\rho\omega_2})+e^{\rho\omega_3}O\left(\frac{1}{\rho}\right). \tag{2.24}$$

Noting that $\omega_1=-\omega_4,\omega_2=-\omega_3$, (2.24) becomes

$$e^{\rho\omega_2}\Delta(\lambda)=-2(e^{2\rho\omega_2}+1)+O\left(\frac{1}{\rho}\right). \tag{2.25}$$

Because equations $e^{2\rho\omega_2} + 1 = 0$ have roots

$$\rho_{n1} = \omega_2^{-1}\left(n + \frac{1}{2}\right)\pi i, \quad n = 0, 1, 2, 3, \ldots, \tag{2.26}$$

by Rouche's theorem, we can see that the equation $\Delta(\lambda) = 0$ has a sequence of simple roots represented as

$$\hat{\rho}_{n1} = \rho_{n1} + O\left(\frac{1}{n}\right), \quad n = 1, 2, 3, \ldots. \tag{2.27}$$

From (2.27), we get the second representation of (2.21).

Taking $S_1 = \{\rho\ ;\ 0 \leq \arg\rho \leq \frac{\pi}{4}\}$, $\omega_1 = e^{\frac{3\pi i}{4}}$, $\omega_2 = e^{\frac{5\pi i}{4}}$, $\omega_3 = e^{\frac{\pi i}{4}}$, $\omega_4 = e^{-\frac{\pi i}{4}}$ and using the above method, we can prove the other sequence in (2.21). The proof is complete. □

Corollary 2.4. *The eigenvalues of* (1.1′) *satisfy the following asymptotic formula*

$$\begin{aligned} \lambda_{n1} &= (-n + \tfrac{1}{2})^2\pi^2[i + O_1(\tfrac{1}{n^2})], \quad n = 1, 2, \ldots, \\ \lambda_{n2} &= (n + \tfrac{1}{2})^2\pi^2[i + O_2(\tfrac{1}{n^2})], \qquad n = 1, 2, \ldots. \end{aligned} \tag{2.22′}$$

By Lemmas 2.2 *and* 2.3, *we can get the asymptotic estimate of the eigenvectors of* (2.1).

Lemma 2.5. *There exist eigenvectors of* (2.1) *satisfying the following asymptotic formula:*

$$\begin{gathered} y_{n1}(x) = -\sqrt{2}e^{(-n+\frac{1}{2})\pi ix} - i\sqrt{2}e^{(n-\frac{1}{2})i\pi x} + O(\tfrac{1}{n}), \\ y_{n2}(x) = \sqrt{2}e^{-(n+\frac{1}{2})\pi ix} + i\sqrt{2}e^{(n+\frac{1}{2})\pi ix} + O(\tfrac{1}{n}), \\ n = 1, 2, 3, \ldots, \quad x \in [a, b] \subset (0, 1), \end{gathered} \tag{2.28}$$

where a and b are two arbitrary constants which satisfy $0 < a < b < 1$.

Furthermore, there exists a constant $M > 0$ such that $|y_{nj}(x)| \leq M$ for $x \in [0, 1]$ and $j = 1, 2,\ n = 1, 2, \ldots$.

Proof. Let $\rho^4 = \lambda^2$, $\omega_1 = e^{\frac{3\pi i}{4}}$, $\omega_2 = e^{\frac{5\pi i}{4}}$, $\omega_3 = e^{\frac{\pi i}{4}}$, $\omega_4 = e^{\frac{7\pi i}{4}}$. We consider Lemma 2.4 on the sector $S_0 = \{\rho\ ;\ 0 \leq \arg\rho \leq \frac{\pi}{4}\}$. Because $\phi_j(x, \lambda) = e^{\rho\omega_j x}[1 + O(\frac{1}{\rho})]$, $j = 1, 2, 3, 4$, are the basic solutions of the equation $\phi^{(4)}(x) + \lambda b(x)\phi(x) + \lambda^2\phi(x) = 0$, the eigenvectors corresponding to the eigenvalue $\lambda_{nk}, k = 1, 2, n = 1, 2, \ldots$, are $y_{nk}(x) = y(x, \lambda_{nk}) = \sum_{j=1}^4 c_j\phi_j(x, \lambda_{nk})$, and c_j $(j = 1, 2, 3, 4)$ satisfy the following equations:

$$\begin{cases} \phi_1'(0, \lambda_{nk})c_1 + \phi_2'(0, \lambda_{nk})c_2 + \phi_3'(0, \lambda_{nk})c_3 + \phi_4'(0, \lambda_{nk})c_4 = 0, \\ \phi_1(0, \lambda_{nk})c_1 + \phi_2(0, \lambda_{nk})c_2 + \phi_3(0, \lambda_{nk})c_3 + \phi_4(0, \lambda_{nk})c_4 = 0, \\ \phi_1'''(1, \lambda_{nk})c_1 + \phi_2'''(1, \lambda_{nk})c_2 + \phi_3'''(1, \lambda_{nk})c_3 + \phi_4'''(1, \lambda_{nk})c_4 = 0, \\ \phi_1''(1, \lambda_{nk})c_1 + \phi_2''(1, \lambda_{nk})c_2 + \phi_3''(1, \lambda_{nk})c_3 + \phi_4''(1, \lambda_{nk})c_4 = 0\,. \end{cases} \tag{2.29}$$

By the theory of linear algebra, we obtain

$$y_{nk}(x) = \begin{vmatrix} \phi_1(x, \lambda_{nk}) & \phi_2(x, \lambda_{nk}) & \phi_3(x, \lambda_{nk}) & \phi_4(x, \lambda_{nk}) \\ \phi_1(0, \lambda_{nk}) & \phi_2(0, \lambda_{nk}) & \phi_3(0, \lambda_{nk}) & \phi_4(0, \lambda_{nk}) \\ \phi_1'''(1, \lambda_{nk}) & \phi_2'''(1, \lambda_{nk}) & \phi_3'''(1, \lambda_{nk}) & \phi_4'''(1, \lambda_{nk}) \\ \phi_1''(1, \lambda_{nk}) & \phi_2''(1, \lambda_{nk}) & \phi_3''(1, \lambda_{nk}) & \phi_4''(1, \lambda_{nk}) \end{vmatrix}. \tag{2.30}$$

By the representation of $\phi_{nk}(x)$ for $x \in [a,b]$, $y_{nk}(x)$ can be rewritten as

$$y_{nk}(x) = \begin{vmatrix} e^{\omega_1\rho_{nk}x}[1] & e^{\omega_2\rho_{nk}x}[1] & e^{-\omega_2\rho_{nk}x}[1] & e^{\omega_4\rho_{nk}(x-1)}[1] \\ 1+O(\frac{1}{n}) & 1+O(\frac{1}{n}) & 1+O(\frac{1}{n}) & O(\frac{1}{n}) \\ (\omega_1)^3e^{\omega_1\rho_{nk}}[1] & (\omega_2)^3e^{\omega_2\rho_{nk}}[1] & (\omega_3)^3e^{\omega_3\rho_{nk}}[1] & (\omega_4)^3[1] \\ (\omega_1)^2e^{\omega_1\rho_{nk}}[1] & (\omega_2)^2e^{\omega_2\rho_{nk}}[1] & (\omega_1)^2e^{\omega_3\rho_{nk}}[1] & (\omega_4)^2[1] \end{vmatrix}$$

$$\begin{aligned} &= \begin{vmatrix} e^{\omega_1\rho_{nk}x} & e^{\omega_2\rho_{nk}x} & e^{-\omega_2\rho_{nk}x} & 0 \\ 1 & 1 & 1 & 0 \\ 0 & (\omega_2)^3e^{\omega_2\rho_{nk}} & (\omega_3)^3e^{\omega_3\rho_{nk}} & (\omega_4)^3 \\ 0 & (\omega_2)^2e^{\omega_2\rho_{nk}} & (\omega_3)^2e^{\omega_3\rho_{nk}} & (\omega_4)^2 \end{vmatrix} + O\left(\frac{1}{n}\right) \\ &= e^{\omega_1\rho_{nk}x}\left[\begin{vmatrix} \omega_3 & \omega_4 \\ 1 & 1 \end{vmatrix}\omega_3^2\omega_4^2e^{\omega_3\rho_{nk}} - \begin{vmatrix} \omega_2 & \omega_4 \\ 1 & 1 \end{vmatrix}\omega_2^2\omega_4^2e^{\omega_2\rho_{nk}}\right] \\ &\quad + e^{\omega_2\rho_{nk}}e^{-\omega_2\rho_{nk}x}\begin{vmatrix} \omega_2 & \omega_4 \\ 1 & 1 \end{vmatrix}\omega_2^2\omega_4^2 - e^{-\omega_2\rho_{nk}}e^{\omega_2\rho_{nk}x}\begin{vmatrix} \omega_3 & \omega_4 \\ 1 & 1 \end{vmatrix}\omega_3^2\omega_4^2 \\ &\quad + O\left(\frac{1}{n}\right). \end{aligned} \tag{2.31}$$

Taking $k=1,\ n=1,2,\dots,$ in (2.31) we get

$$y_{n1}(x) = (i+1)\sqrt{2}e^{\omega_1\omega_2^{-1}(-n+\frac{1}{2})\pi ix} - \sqrt{2}e^{(-n+\frac{1}{2})\pi ix} - i\sqrt{2}e^{(n-\frac{1}{2})\pi ix} + O\left(\frac{1}{n}\right). \tag{2.32}$$

Taking $\omega_1 = e^{\frac{5\pi i}{4}}$, $\omega_2 = e^{\frac{3\pi i}{4}}$, $\omega_3 = e^{\frac{7\pi i}{4}}$, $\omega_4 = e^{\frac{1\pi i}{4}}$, we consider Lemma 2.5 on the sector $S_0 = \{\rho\ ;\ -\frac{\pi}{4} \le \arg\rho \le 0\}$. By the above method, we can get

$$y_{n2}(x) = -(i+1)\sqrt{2}e^{\omega_1\omega_2^{-1}(n+\frac{1}{2})\pi ix} + \sqrt{2}e^{-(n+\frac{1}{2})\pi ix} + i\sqrt{2}e^{(n+\frac{1}{2})\pi ix} + O\left(\frac{1}{n}\right). \tag{2.33}$$

The proof is complete. □

By Lemma 2.2 and (2.30), we get the following corollary.

COROLLARY 2.6. *The eigenfunctions of* $(1.1')$ *satisfy the following asymptotic formula:*

$$\begin{gathered} y_{n1}(x) = -\sqrt{2}e^{(-n+\frac{1}{2})\pi ix} - i\sqrt{2}e^{(n-\frac{1}{2})i\pi x} + O_1(\tfrac{1}{n}), \\ y_{n2}(x) = \sqrt{2}e^{-(n+\frac{1}{2})\pi ix} + i\sqrt{2}e^{-(n+\frac{1}{2})\pi ix} + O_2(\tfrac{1}{n}), \\ n = 1,2,3,\dots, \quad x \in [a,b] \subset (0,1), \end{gathered} \tag{2.34}$$

where a and b are two arbitrary constants: $0 < a < b < 1$.

Furthermore, there exists a constant $M > 0$ such that $|y_{nj}(x)| \le M$ for $x \in [0,1]$ and $j = 1,2,\ n = 1,2,\dots.$

3. Properties of operator *A*. In this section, we discuss some properties of A. Let $\{\Psi_{nj}\}$, $j = 1,2$, $n = 1,2,\dots$, be the set of all generalized eigenvectors of A. We have the following result.

THEOREM 3.1. *A is a generator of a C_0-semigroup $T(t)$, and all of the eigenvectors $\{\Psi_{nj}\}$ $(j = 1,2, n = 1,2,\dots)$ of A form an unconditional basis of H.*

Proof. Obviously A generates a C_0-semigroup $T(t)$. By Corollary 2.4, $\mu_{nj} = (\frac{1}{2}+(-1)^j n)^2[i+O_1(\frac{1}{n})]$, $j = 1, 2$, $n = 1, 2, \dots$, are the eigenvalues of $A_1 = \begin{pmatrix} 0 & I \\ -A_0 & 0 \end{pmatrix}$, and the eigenvectors $\begin{pmatrix} \phi_n \\ \mu_{nj}\phi_n \end{pmatrix}$ of A_1 corresponding to μ_{nj}, $j = 1, 2$, $n = 1, 2, \dots$, form an orthogonal basis of H. Then A_1 is a (D)-operator [3]; that is, A_1 has a discrete spectrum and its eigenvectors $\begin{pmatrix} \phi_n \\ \mu_n\phi_n \end{pmatrix}$ form a basis of H. Because

$$\left\| \begin{pmatrix} 0 & 0 \\ 0 & -b(x) \end{pmatrix} \Phi \right\| \le b_0\|\phi_2\| = b_0\|A_1^0\|\|\Phi\|, \qquad \Phi \in D(A_1), \tag{3.1}$$

where $A_1^0 = I$, $\Phi = (\phi_1, \phi_2)^T$, $b_0 = \max_{x\in[0,1]} |b(x)|$, by Corollary 11 [2], A is also a (D)-operator. That is, A has also a discrete spectrum and its generalized eigenvectors $\{\Psi_{nj}\}$ ($j = 1, 2$, $n = 1, 2, \dots$) form a basis of H. □

4. The estimate for the real parts of the eigenvalues of A.

We now estimate the real parts of the eigenvalues of A.

LEMMA 4.1. *Let* $\sigma(A) = \{\mu_{nj};\quad j = 1, 2, n = 1, 2, 3, \dots\}$. *There exists a constant* n_0 *such that* $\mathrm{Re}\mu_{nj} < -\frac{\delta_0}{2} + \varepsilon$ *for* $n > n_0$, *where* $0 < \varepsilon < \frac{\delta_0}{2}$.

Proof. Let $\begin{pmatrix} \phi_{1nj} \\ \phi_{2nj} \end{pmatrix}$, $j = 1, 2, n = 1, 2, \dots$, be the eigenvector of A corresponding to the eigenvalue μ_{nj}. By Lemma 2.1, $\phi_{2nj} = \mu_{nj}\phi_{1nj}$ and ϕ_{1nj} satisfies the equation

$$\begin{cases} \phi_{1nj}^{(4)}(x) + \mu_{nj}b(x)\phi_{1nj}(x) + \mu_{nj}^2\phi_{1nj}(x) = 0, \\ \phi_{1nj}(0) = \phi'_{1nj}(0) = \phi''_{1nj}(1) = \phi'''_{1nj}(1) = 0\,. \end{cases} \tag{4.1}$$

Forming the inner product of (4.1) with ϕ_{1nj}, we obtain

$$\mu_{nj}^2\|\phi_{1nj}\|^2 + \mu_{nj}\int_0^1 b(x)|\phi_{1nj}(x)|^2dx + \|\phi''_{1nj}\|^2 = 0. \tag{4.2}$$

Equation (4.2) is equivalent to

$$2(\mathrm{Re}\mu_{nj})(\mathrm{Im}\mu_{nj})\|\phi_{1nj}\|^2 + (\mathrm{Im}\mu_{nj})\int_0^1 b(x)|\phi_{1nj}(x)|^2dx = 0 \tag{4.3}$$

and

$$((\mathrm{Re}\mu_{nj})^2 - (\mathrm{Im}\mu_{nj})^2)\|\phi_{1nj}\|^2 + (\mathrm{Re}\mu_{nj})\int_0^1 b(x)|\phi_{1nj}|^2dx + \|\phi''_{1nj}\|^2 = 0. \tag{4.4}$$

For convenience, we let $\|\phi_{1nj}\| = 1$. From (4.3) and (4.4) we get

$$\begin{aligned} \mathrm{Re}\mu_{nj} &= -\tfrac{1}{2}\textstyle\int_0^1 b(x)|\phi_{1nj}|^2dx \\ &\quad \pm \tfrac{1}{2}\sqrt{(\textstyle\int_0^1 b(x)|\phi_{1nj}(x)|^2dx)^2 - 4\|\phi''_{1nj}\|^2\|\phi_{1nj}\|^2}, && \text{if } \mathrm{Im}\mu_{nj} = 0, \\ \mathrm{Re}\mu_{nj} &= -\tfrac{1}{2}\textstyle\int_0^1 b(x)|\phi_{1nj}(x)|^2dx, && \text{if } \mathrm{Im}\mu_{nj} \neq 0. \end{aligned} \tag{4.5}$$

Because $|\mu_{nj}| \to \infty$, by (4.5), (2.25), the above corollaries, and the hypothesis, we see that there exists a constant n_0 such that $\mathrm{Re}\mu_{nj} < -\frac{\delta_0}{2} + \epsilon$, for $n \ge n_0$. Therefore the proof is complete. □

From Lemma 4.1, we can get the following decomposition result.

THEOREM 4.2. *The system* (1.2) *can be decomposed into*

$$\tfrac{d}{dt}Y_{n_1}(t) = A_{n_1}Y_{n_1}(t), \quad Y_{n_1} = P_{n_1}Y_0, \quad t > 0, \tag{4.6}$$

$$\frac{d}{dt}Y_r(t) = A_rY_r(t), \quad Y_r = P_rY_0 \quad , t > 0, \tag{4.7}$$

where P_{n_1} is a projection; $P_r = I - P_{n_1}$, $Y_{n_1} = P_{n_1}Y$, $Y_r = P_rY$, $A_{n_1} = P_{n_1}AP_{n_1}$, and $A_r = P_rAP_r$. In addition, A_r generates a semigroup $T_r(t) = P_rT(t)P_r$ with the growth property

$$T_r(t) \leq M_r(\varepsilon)e^{-(\delta_1-\varepsilon)t}, \quad t \geq 0, \quad 0 < \varepsilon < \delta_1 = \frac{\delta_0}{2}, \tag{4.8}$$

where $M_r(\varepsilon) \geq 1$ is a constant with respect to P_r, ε, and δ_0.

Proof. According to Lemma 4.1, there are only $2n_1$ eigenvalues, $\mu_{nj} \in \sigma(A)$, such that Re$\mu_{nj} > -\delta_1 + \epsilon$. We assume that they are $\mu_{11}, \mu_{12}, \ldots, \mu_{n_1 1}, \mu_{n_1 2}$. Let $P_{n_1} = (2i\pi)^{-1}\sum_{n=1}^{n_1}\sum_{j=1}^{2}\oint_{C_{nj}} R(\lambda; A)d\lambda$, where $C_{nj}, j = 1, 2, n = 1, 2, \ldots, n_0$, is a circle, centered at μ_{nj}, such that no other μ_{nj} belongs to its interior. Obviously, $P_r = \sum_{\mu_{nj}\in\sigma_0(A)}(2i\pi)^{-1}\oint_{V_{nj}} R(\lambda; A)d\lambda$, where $\sigma_0(A) = \sigma(A)\backslash\{\mu_{nj}, j = 1, 2; n = 1, 2, \ldots, n_1\}$, V_{nj} is a small circle defined similarly to C_{nj}. Let $Y_{n_1} = P_{n_1}Y$, $Y_r = P_rY$, $A_{n_1} = P_{n_1}AP_{n_1}$, $A_r = P_rAP_r$; we can obtain (4.6) and (4.7). We now prove (4.8). By the definition of P_{n_1} and P_r, we know that $H = (P_{n_1}H)\bigoplus(P_rH)$ and P_rH is an invariant subspace of the semigroup T(t). On P_rH, $T_r(t) = P_rT(t)P_r$ is a C_0-semigroup with generator $A_r = P_rAP_r$. Obviously, A_r is a (D)-operator in P_rH because A is a (D)-operator in H. Therefore, for any $Y_r \in P_rH$,

$$T_r(t)Y_r(t) = \sum_{n=n_1+1}^{N_0}\sum_{j=1}^{2}e^{\mu_{nj}t}\sum_{k=0}^{n(j)}\alpha_{knj}\phi_{knj} + \sum_{j=1}^{2}\sum_{n=N_0+1}^{\infty}\alpha_{nj}e^{\mu_{nj}t}\phi_{nj}, \tag{4.9}$$

where $\{\phi_{knj}\}$ are the generalized unit eigenvectors of A_r, $N_0 > 0$ is a constant, and

$$\begin{aligned}\|T_r(t)Y_r\| &\leq M_0\left(\sum_{j=1}^{2}\sum_{n=n_1+1}^{N_0} e^{2\mathrm{Re}\mu_{nj}t}\sum_{k=0}^{n(j)}|\alpha_{knj}|^2 + \sum_{j=1}^{2}\sum_{n=N_0+1}^{\infty}|\alpha_{nj}|^2e^{2Re\mu_{nj}t}\right)^{\frac{1}{2}}\\ &\leq M_0M_r(\varepsilon)e^{-(\delta_1-\varepsilon)t}\left(\sum_{n=n_1+1}^{N_0}\sum_{j=1}^{2}\sum_{k=0}^{n(j)}|\alpha_{knj}|^2 + \sum_{j=1}^{2}\sum_{k=n_1+1}^{\infty}|\alpha_{nj}|^2\right)^{\frac{1}{2}}\\ &\leq M_0M_r(\varepsilon)M_1e^{-\delta_1t}\|Y_r\|, \end{aligned} \tag{4.10}$$

where M_0 and M_1 are constants relative to the unconditional bases [3]. The proof of (4.8) is complete. □

5. Finite-dimensional state feedback controller. In this section, we design a finite-dimensional state feedback controller such that system (1.1) is stable.

THEOREM 5.1. *For a given ε : $0 < \varepsilon < \delta_1$, let there be no eigenvalue of A on the line $\{\lambda|\ \mathrm{Re}\lambda = -(\delta_1 - \varepsilon)\}$. Then, there exists a bounded linear operator $\hat{\mathcal{C}}_\epsilon$ such that $A + \hat{\mathcal{C}}_\varepsilon$ generates an exponentially stable C_0-semigroup $T_\varepsilon(t)$; that is, there exists a constant $M_\varepsilon \geq 1$ such that*

$$\|T_\epsilon(t)\| \leq M_\epsilon e^{-(\delta_1-\epsilon)t}, \quad t \geq 0. \tag{5.1}$$

Proof. From Theorem 4.2, we know that $A = A_{n_1} + A_r$, where A_{n_1} is invariant on $H_1 = P_{n_1}H$, and A_r is invariant on $H_2 = P_r H$. Because H_1 is a finite-dimensional subspace spanned by the generalized eigenfunctions of A_{n_1}, A_{n_1} is equivalent to a finite matrix A_1. By the theory of lumped parameter systems, we can find a matrix C_1 such that (A_1, C_1) is controllable. Then there exists a matrix K_1 such that all eigenvalues of $A_1 + C_1K_1$ are assigned to the half plane $\{\lambda \mid \mathrm{Re}\lambda < -(\delta_1 - \varepsilon)\}$ and $\sigma(A_1 + C_1K_1) \cap \sigma(A_r) = \emptyset$. Let C_ϵ be the operator on H_1 corresponding to C_1K_1. Let $\hat{\mathcal{C}}_\varepsilon = C_\varepsilon P_{n_0}$. By the finite state feedback $\hat{\mathcal{C}}_\varepsilon$, we get a new system:

$$\begin{cases} \dfrac{d}{dt}Y(t) = (A + \hat{\mathcal{C}}_\varepsilon)Y(t), \\ Y(0) = Y_0 \in H\,. \end{cases} \tag{5.2}$$

By the definition of $\hat{\mathcal{C}}_\epsilon$, we see that $A + \hat{\mathcal{C}}_\epsilon$ generates a C_0 semigroup $T_\epsilon(t)$, $t \geq 0$ on H, and there exists a constant $M_\epsilon \geq 1$ such that $\|T_\varepsilon(t)\| \leq M_\varepsilon e^{-(\delta_1-\varepsilon)t}$, $t \geq 0$. The proof is complete. □

Because system (5.2) is not equivalent to (1.2), the stability result of system (5.2) does not directly imply that of system (1.1). So we will find a control for system (1.1) such that the closed loop system of (1.1) is stable.

For convenience, we write $\hat{\mathcal{C}}_\varepsilon$ in the form of a matrix:

$$\hat{\mathcal{C}}_\varepsilon = \begin{pmatrix} C_{11} & C_{12} \\ C_{21} & C_{22} \end{pmatrix}. \tag{5.3}$$

Lemma 5.2. *Let u(x,t), $\frac{\partial u(x,t)}{\partial t}$, $\frac{\partial u(x,t)}{\partial x}$, and $\frac{\partial^2 u(x,t)}{\partial x^2}$ be continuous. Then the system*

$$\begin{cases} y_1 = u + \displaystyle\int_0^t (1,0)\begin{pmatrix} C_{11} & C_{12} \\ C_{21} & C_{22} \end{pmatrix}\begin{pmatrix} y_1(s) \\ y_2(s) \end{pmatrix} ds, \\ y_2 = \dfrac{du}{dt} \end{cases} \tag{5.4}$$

has a unique solution.

By the theory of Volterra integral equations, the proof of Lemma 5.2 *is simple.*

For system (1.1)*, we take the following control:*

$$f(t) = (0,1)\begin{pmatrix} C_{11} & C_{12} \\ C_{21} & C_{22} \end{pmatrix}\begin{pmatrix} y_1(t) \\ y_2(t) \end{pmatrix} - A_0 \int_0^t (1,0)\begin{pmatrix} C_{11} & C_{12} \\ C_{21} & C_{22} \end{pmatrix}\begin{pmatrix} y_1(s) \\ y_2(s) \end{pmatrix} ds, \tag{5.5}$$

where y_1 and y_2 are defined by (5.4)*. Then system* (1.1) *controlled by $f(t)$ can be written as*

$$\begin{cases} \dfrac{d^2u(t)}{dt^2} + B\dfrac{d}{dt}u(t) + A_0u(t) = f(t)\,, \quad t > 0, \\ u(0) = u_0\,, \quad \dfrac{d}{dt}u(0) = u_1\,, \quad u_0, u_1 \in L^2[0,l], \end{cases} \tag{5.6}$$

where $B = b(x)$. By the transformation

$$\begin{cases} y_1 = u + \int_0^t (1,0)\begin{pmatrix} C_{11} & C_{12} \\ C_{21} & C_{22} \end{pmatrix}\begin{pmatrix} y_1(s) \\ y_2(s) \end{pmatrix} ds, \\ y_2 = \dfrac{du}{dt}, \end{cases} \tag{5.7}$$

system (5.6) *becomes*

$$\left\{\begin{aligned} &\frac{d}{dt}Y(t) = (A + \mathcal{C}_\epsilon)Y(t)\,, \quad t > 0 \\ &Y(0) = \begin{pmatrix} y_1(0) \\ y_2(0) \end{pmatrix} = \begin{pmatrix} u_0 \\ u_1 \end{pmatrix}, \end{aligned}\right. \tag{5.8}$$

where $Y(t) = (y_1(y), y_2(t))^T$. *By Theorem* 5.1, *system* (5.7) *generates an exponentially stable C_0-semigroup.*

THEOREM 5.3. *The solution $u(x,t)$ of closed-loop system* (5.6) *converges exponentially fast to*

$$-\int_0^\infty (1,0)\hat{\mathcal{C}}_\epsilon \begin{pmatrix} y_1(s) \\ y_2(s) \end{pmatrix} ds,$$

where $y = (y_1, y_2)^T$, the solution of (5.8).

Proof. Because $u(x,t_2) - u(x,t_1) = \int_{t_1}^{t_2} \frac{\partial u(x,t)}{\partial t} dt = \int_{t_1}^{t_2} y_2(t)dt$ and

$$\|u(x,t_2) - u(x,t_1)\| \le \int_{t_1}^{t_2} \|y_2(t)\|dt \le \int_{t_1}^{t_2} Me^{-\delta_0 t}dt,$$

we get

$$\lim_{t\to\infty} u(x,t) = u(x,\infty) \in H^2(0,l).$$

Because

$$y_1(t) = u(x,t) + \int_0^t (1,0)\hat{\mathcal{C}}_\epsilon \begin{pmatrix} y_1(s) \\ y_2(s) \end{pmatrix} ds$$

and

$$\|u(x,t) + \int_0^t (1,0)\hat{\mathcal{C}} \begin{pmatrix} y_1(s) \\ y_2(s) \end{pmatrix} ds\| = \|y_1(t)\| \le \|Y(0)\|Me^{-\delta_0 t} \to 0,$$

we have

$$\lim_{t\to\infty} \int_0^t (1,0)\hat{\mathcal{C}}_\epsilon \begin{pmatrix} y_1(s) \\ y_2(s) \end{pmatrix} ds = \int_0^\infty (1,0)\hat{\mathcal{C}}_\epsilon \begin{pmatrix} y_1(s) \\ y_2(s) \end{pmatrix} ds. \qquad \square$$

Remark. For system (1.1), it is still not clear how many eigenvalues have nonnegative real parts.

ADMISSION CONTROL FOR COMBINED GUARANTEED PERFORMANCE AND BEST EFFORT COMMUNICATIONS SYSTEMS UNDER HEAVY TRAFFIC*

EITAN ALTMAN† AND HAROLD J. KUSHNER‡

Abstract. Communications systems often have many types of users. Since the users share the same resource, there is a conflict in their needs. This conflict leads to the imposition of controls on admission or elsewhere. In this paper, there are two types of customers, GP (Guaranteed Performance) and BE (Best Effort). We consider an admission control of GP customer which has two roles. First, to guarantee the performance of the existing GP customers, and second, to regulate the congestion for the BE users. The optimal control problem for the actual physical system is difficult. A heavy traffic approximation is used, with optimal or nearly optimal controls. It is shown that the optimal values for the physical system converge to that for the limit system and that good controls for the limit system are also good for the physical system. This is done for both the discounted and average cost per unit time cost criteria. Additionally, asymptotically, the pathwise average (not mean) costs for the physical system are nearly minimal when good nearly optimal controls for the limit system are used. Numerical data show that the heavy traffic optimal control approach can lead to substantial reductions in waiting time for BE with only quite moderate rejections of GP, under heavy traffic. It also shows that the controls are often linear in the state variables. The approach has many advantages. It is robust, simplifies the analysis (both analytical and numerical), and allows a more convenient study of the parametric dependencies. Even if optimal control is not wanted, the approach is very convenient for a systematic exploration of the possible tradeoffs among the various cost components. This is done by numerically solving a series of problems with different weights on the costs. We can then get the best tradeoffs and the control policies which give them.

Key words. admission control, control of communications systems, control of queueing networks, heavy traffic limits, ergodic control, singular control, weak convergence

1. Introduction.

Broadband-ISDN (integrated services data network) high speed networks allow the possibility of integrating different services into one single telecommunications network. In particular, they handle applications that require guaranteed quality of service (QoS), such as bounded delays, bounded cell loss rates, and a guarantee on the throughput. Such a service is called Guaranteed Performance (GP). On the other hand, they also support more flexible applications, such as data transfer, that are less sensitive to instantaneous variations in available bandwidth, delays, jitter, etc., and which do not require guarantees on throughputs or delays. We call the latter "Best Effort" (BE) traffic. In the context of Asynchronous Transfer Mode (ATM), this corresponds to the Available Bit Rate (ABR) service category [1], which can adapt to the bandwidth unused by the GP service classes. In the context of the Internet, the BE traffic are the TCP/IP connections, which use a congestion avoidance mechanism [17] so as to adapt to the available bandwidth, in contrast with real-time applications that use UDP (UDP is a protocol which does not adapt its transmission

rate to the current congestion state of the system) such as the phone over the Internet [5]. In particular, we suppose that the BE users share the remaining bandwidth, as for example, in the standard Internet. (Note that, unlike ATM, the Internet does not provide performance guarantees for real-time applications. However, in practice, the TCP/IP connections do adapt their transmission rate to the available bandwidth left over after the UDP sessions; see [3].)

Since GP and BE share the same resources of the network, there is a conflict in needs, and the question of admission control arises. The purpose of this paper is to analyze the impact that Connection Admission Control (CAC) performed on GP traffic has on the BE traffic, in order to properly allocate resources in a dynamic manner as well as guarantee QoS.

In ATM networks, a large part of the architecture has been standardized [1]. Implementation of the CAC, however, is not standardized and is left to the network manager. This has motivated much research and a large literature has emerged. Several approaches have been used in designing CACs. The first approach is based on characterizing the input traffic of a source by some simple parameters, such as the effective bandwidth; basically it estimates the bandwidth that should be given to a source to guarantee that the cell loss rate does not exceed (in some asymptotic sense) some small number. Examples of this approach are [10, 15, 13, 18, 19, 31, 32, 37]. A diffusion-based statistical CAC was proposed in [12].

A recent approach to admission control estimates (on-line) the consequence of possible admission, using real-time measures of the network activity [14, 35, 36]. An optimal-control approach for call admission, using a Markov Decision Processes approach, has been used in a number of papers [11, 16, 34]. All the cited papers focus on the impact of admission control on GP traffic. To the best of our knowledge, our paper is the first to consider the optimal design of the CAC for the GP sessions in terms of the performance of both the BE and the GP sessions.

The CAC was not intended to be performed on BE traffic, since BE traffic is sufficiently flexible so as not to deteriorate QoS that is required by GP connections. In particular, the ATM forum has decided [1] that ABR sessions will not be subject to CAC (unless they require from the network a guarantee on minimum cell rate). We shall therefore assume that BE sessions are always admitted into the network, unless some very large limit is reached. This limit might represent the number of sessions that can be handled simultaneously by the switches. This limit will not depend on the available bandwidth.

Quite often, CACs are designed taking into account only the performance requirements of GP sessions. However, as already noted in [2, 4], under appropriate operating conditions in the network (in particular, the heavy-traffic conditions, which correspond to an efficient utilization of the resources) it is possible to improve substantially the performance (delays and throughputs) of the BE sessions by modifying *slightly* the CAC for the GP sessions.

References [2, 4] contain analysis of the performance of GP and BE sessions for given CACs (performed on GP sessions) that take into account also the performance of BE sessions. In this paper, we go one further step and provide a design based on an optimization approach. We consider the *optimal* admission control arising when the number of sessions and the available bandwidth are taken to be large and scaled in an appropriate way so as to perform in the desirable heavy traffic region.

The approach taken is that of optimal control in the heavy traffic regime. In this regime, the system has little spare bandwidth over what is needed to handle the "average load." It is shown that the physical system can be well approximated by a controlled (reflected) diffusion process, and that good controls for this diffusion process are good for the physical system under heavy traffic. The resulting controls are easily implementable (and are often simply linear in the state variables) and can give a significant improvement of the performance of the BE sessions by only a small rejection of GP sessions. The work is a continuation of the past work on the control of communications and queueing systems under heavy traffic conditions [29, 27, 26, 22, 30, 25, 28, 23].

The extensive numerical results in [25] illustrate the power of such an approach. Excellent controls, system performance, and very useful information which would not otherwise be available were obtained. The paper [30], concerned with trunk line problems, also shows the power of the heavy traffic approach for modeling, simplifying and controlling very complex systems.

The control problem for the actual physical model is quite hard, if not impossible to solve. The system is not always Markovian. Even in the Markovian case, the number of states can be extremely large. Additionally, even for an uncontrolled Markovian system, the computation of the steady state overflows (losses) and delays is difficult. The heavy traffic approach provides much analytical and computational simplification. The optimally controlled costs for the physical problem converge to the optimally controlled cost for the limit problem, and a nearly optimal control for the limit problem is also nearly optimal for the physical problem if the traffic is "heavy."

In applications, the traffic is not always heavy. But this regime is one of the crucial ones for design, analogous to the case of the trunk line problem for long distance teletraffic. The analysis illustrates efficient use of resources. In any large system, there are many alternative uses of the resources and continuous tradeoffs among them. Here we can see, for example, the effect of marginal reallocations of bandwidth within a control context. Of course, serious control problems do exist even outside of the heavy traffic regime; for example, even if the system is heavily overbuilt from the heavy traffic perspective, the structure of the burstiness in arrivals can lead to important control problems. In this regard, it is worth noting that, in the numerical study in [25] of controlled multiplexers in the heavy traffic regime, the buffer is empty or nearly empty most of the time, and it is the burstiness of the input which yields the losses and the control problem.

There are many other advantages to the combined heavy traffic and optimal control approach. Under broad conditions, it yields the appropriate dimensioning of the system and shows that good performance can often be achieved with only modestly extra bandwidth (over average requirements). The "limit" variables can be interpreted as "aggregated" states. The analysis takes advantage of the laws of large numbers and central limit theorems that come into play as the size of the system grows. The "limit" or aggregate equations can be used to compute nearly optimal controls for the physical system, and to get good estimates of various measures of performance. The relative simplicity of the form of the heavy traffic limit process facilitates understanding the parametric dependencies. As in [25], we can obtain both qualitative and quantitative information which is often very hard to get. To do so otherwise, one would need to study many particular cases of systems with different parameters and sizes whose relationships would remain obscure. The reference [33] contains examples of other types of applications.

The method allows convenient numerical approximations (see [24, 25]) whose complexity is much less than that of even the physical Markov systems. In fact, the basic Markov chain approximation method of [24] has been coded for problems of this type and is publicly available.[1] The format is robust: bursty data, priorities, time dependence, dependence of arrivals on the system state, and other useful extensions can be readily handled.

An important question concerns the tradeoff between gains in QoS for BE versus losses for GP. The heavy traffic formulation allows a systematic exploration of this. One solves the optimization problem with various weights for the associated losses and costs and computes the values of the individual components of the cost under the optimal controls. This yields the set of possible tradeoffs under good operating policies. One can then choose the control which gets the best performance for one component with a constraint on the others. Usually, optimization for its own sake is not the main interest. But the use of optimizing or optimal control methods for exploration of possibilities is of greater interest and provides a powerful design tool. The value of this approach was amply demonstrated in [25], and the large gains due to the use of feedback control were demonstrated. This is equally valid for the present problem. Indeed, numerical data shows that substantial reductions (say, 30% or even much more) in BE delays can be obtained with only very modest levels of rejection of GP customers. The percent rejected depends on the system parameters and the arrival rates, and it goes to zero as the system grows, for any fixed percentage gain in delay.

The "state space" collapse phenomenon illustrated in section 5, when there are many GP and BE subclasses, allows one to explore the effects on performance and control of complex customer requirements. One can do the numerics for aggregations of several classes as well as for the original problem to get insights into robustness of the model and performance under varying conditions. This would be very hard under any current alternative approach. Indeed, the limit allocations to the different classes are consistent with the (ad hoc) weighted fair-shares for different types of BE customers which were defined by the ATM forum for sharing bandwidth (see [1, section I.3]).

The model in section 4 can be used to study the effects of finite bandwidth constraints on individual users. The multicast problem of section 6 shows how seemingly complex forms of the problem can be put into the context of a general theory.

The structure of the paper is as follows. The basic model is presented in section 2, and the input-output equation is written in a way that is convenient for the heavy traffic analysis. In the basic model, the BE customers share the available bandwidth equally, whatever it is. The general methods used for the analysis of this case also apply with little modification to the subsequent cases. Section 3 deals with the weak convergence of the heavy traffic approximations and the discounted cost function as the traffic intensity approaches unity. Many of the ideas have been used in the references in various ways, despite the difference in the problems considered. Because of this and to save space, we provide detailed outlines with references where possible. There is a new problem with "tightness" of the set of the (singular) controls, but we show that they can be approximated such that they are tight.

Section 4 considers the case where there is an upper limit to the bandwidth that any one of the BE customers can use. This changes the dynamics and the scaling, but the previous analysis can be carried over. In order to illustrate the power and

[1] See the home page of the Lefschetz Center for Dynamical Systems, Brown University Dept. of Applied Mathematics home page http://www.dam.brown.edu/lcds.html. Select the software link to get the documentation and codes.

versatility of the approach, in section 5 we consider extensions where there are several classes of BE customers, which might be allocated bandwidth in class dependent ways. There is a surprising degeneracy, which can be exploited to simplify the analysis and subsequent numerical work.

Section 6 extends the basic model to a multicast case. Here there are two channels (any number could be used), each with its own class of GP customers and its own control. But the BE customers must be transmitted simultaneously on each of the channels. Many variations of the format are possible. The ergodic cost problem is dealt with in section 7. In section 7 we impose a constraint on the rate at which GP arrivals can be rejected, so that previous results on the ergodic cost problem can be exploited. The form of the heavy traffic limit equations implies that this constraint is not very restrictive and this is borne out by numerical data. But in section 8 we show that it is not a restriction.

The optimal mean cost per unit time for the physical system converges to the optimal "ergodic" value for the limit system as the size of the system and time go to infinity in any way at all. Furthermore, the limit of the pathwise (not mean) average costs per unit time cannot be better than the optimal ergodic value for the limit system. The pathwise average costs for the physical system can be made to be arbitrarily close to this ideal limit by using a nice nearly optimal (for the limit system) control on the physical system, under heavy traffic. The pathwise results are important, since in any single application, we have just one sample path, and the mean values are less important than the pathwise values. Furthermore, a "nice" nearly optimal control for the limit system provides nearly optimal values for the physical system, under heavy traffic, in both a mean and pathwise sense.

Some of the development is similar to that in recent works on control under heavy traffic (e.g., [29, 22, 25, 23]), although the exact form of the adaptation is not entirely obvious for the present problem. This is particularly true of the derivation of the basic setup in the first part of section 3. Because of this, we have referred to the literature whenever possible. There remain many new methodological features apart from the novelty of an important application in a broad context: The approximation of the singular controls, both for the discounted and the ergodic problem, the degeneration (or state space collapse) for the multi BE/GP class problem, the adaptation of the formulation to multicast, and other extensions, with state dependent dynamics.

2. Problem 1: The basic setup. In this section, we set up the notation and evolution equations for the *basic problem*. The development for the more complex problem classes is similar. There are two classes of users, which we refer to as class 0 and class 1. Class 0 refers to the BE traffic and class 1 the GP traffic. As usual in the analysis of systems under conditions of heavy traffic, the mean service capacity is slightly greater than the mean demand. The system is parameterized by a parameter N. Both the system capacity, excess capacity (over what is required for the average demands), and demand grow as $N \to \infty$, with the *relative* excess capacity going to zero. This will be formalized below. A consequence of the heavy traffic analysis is that these relationships represent good design in that very good performance can be obtained. A well designed heavy traffic operating regime implies that the system is not overbuilt and can handle the demands placed on it.

In this and in the next section, the bandwidth is normalized so that each member of class 1 requires one unit of bandwidth. The members of class 0 share whatever bandwidth is left. An applications paradigm is that each arrival is the work for a "session," whose work arrives essentially at once, and is buffered on arrival. This models well the more general situation in which the input rate of packets within a session is not less than the transmission rate, so that when we allocate a given bandwidth to a session then this bandwidth is indeed used by it. In section 4 we shall relax this assumption. The channel is time shared, with a guaranteed time going to the class 1 customers, and the time remaining to the class 0 customers. Thus, there is no limitation on the rate at which work can be done on the set of class 0 customers except for the available capacity.

Let $\alpha_l^{i,N}, l = 1, \dots,$ denote the interarrival times for the members of class i, and set $E\alpha_l^{i,N} = \bar{\alpha}^{i,N}$. For a given N, $\{\alpha_l^{i,N}\}_{l=1,\dots,i=0,1}$ are assumed to be mutually independent. To conform with standard usage we also define the normalized mean "rates" $\lambda^{i,N} = 1/N\bar{\alpha}^{i,N}$. The service times for the members of class 1 are exponentially distributed with constant rate $\mu^{1,N}$. Class 1 can be controlled in that any requested admission can be denied by the controller. The system is a "loss" system in that any customer denied admission disappears from the system. For analytic convenience we suppose further that there is a constant $B_+^0 > 0$ such that no class 0 customers are admitted to the system if the current number of class 0 customers in the system is greater than $\sqrt{N}B_+^0$. It follows from the heavy traffic limit theorems (and from the numerical data) that this is inconsequential for large enough B_+^0. In fact, the condition is useful only to simplify some of the analytic details for the ergodic cost criterion, and B_+^0 can be set equal to infinity for the discounted cost function. But we include the finite upper bound here to unify the development. Let $F^{0,N}(t)$ denote $1/\sqrt{N}$ times the number of class 0 customers not admitted by time t.

The time requirements for the members of class 0 are also exponentially distributed. But the rate at which a customer of class 0 departs from the system depends on the (random) resources available to it while it is in the system. The "conditional mean instantaneous departure rate" for a class 0 customer at time t is defined to be $\mu^{0,N}$ times the bandwidth available to that customer at that time; i.e., if at time t, $B(t)$ is the total bandwidth unused by members of class 1, and there are $A(t)$ members of class 0 in the system, then the probability (conditioned on the data up to that time) of a single departure of a member of class 0 in the time interval $[t, t+\delta)$ is $\mu^{0,N}B(t)\delta/A(t) + o(\delta)$, and the probability of more than one departure in that interval is $o(\delta)$. The set of interarrival times and the service times for class 1 are assumed to be mutually independent. This independence of the interarrival times is a good description of reality, since we are working at the session level, where this property has often been observed.[2] Long range dependence in the arrival process is not relevant as it might be at the packet level.

We assume that there is b (parameterizing the "excess capacity," which might be negative) such that the channel capacity is

$$C_N = N\left[\frac{\lambda^{0,N}}{\mu^{0,N}} + \frac{\lambda^{1,N}}{\mu^{1,N}}\right] + b\sqrt{N}. \tag{2.1}$$

Suppose that $\lambda^{i,N} \to \lambda_i$ and $\mu^{i,N} \to \mu_i$, all positive. Thus, the mean arrival rates and the channel capacity are all $O(N)$, and the channel capacity is $O(\sqrt{N})$ greater than the mean requirements. For appropriate b, this will be seen to be sufficient for good

[2] See, e.g., Liu (INRIA, Sophia Antipolis, France), *Measurements over the Web*, private communication, to be submitted.

behavior. We also make the innocuous assumption that

$$\left\{ \left| \alpha_l^{i,N} / \bar{\alpha}^{i,N} \right|^2 ; l, i, N \right\} \text{ is uniformly integrable,} \tag{2.2}$$

and that there are σ_i^2 such that

$$E \left[1 - \frac{\alpha_l^{i,N}}{\bar{\alpha}^{i,N}} \right]^2 \to \sigma_i^2. \tag{2.3}$$

In common cases, the arrival processes are assumed to be Poisson. Then all moments of the terms in (2.2) are uniformly (in i, l, n) bounded. If the interarrival intervals for class i are constant, then $\sigma_i^2 = 0$. If the arrival stream for class i is Poisson, then $\sigma_i^2 = 1$. Define the scaled mean arrival process

$$S^{i,N}(t) = \frac{1}{N} \left[\# \text{ of class } i \text{ arrivals by time } t \right]$$

and the normalized and centered sum

$$W^{i,N}(t) = \frac{1}{\sqrt{N}} \sum_{l=1}^{[Nt]} \left[1 - \frac{\alpha_l^{i,N}}{\bar{\alpha}^{i,N}} \right],$$

where $[Nt]$ denotes the integer part.

As usual in heavy traffic scaling, all of the basic system variables are scaled by $1/\sqrt{N}$. Define $X^{0,N}(t)$ to be $1/\sqrt{N}$ times the number of members of class 0 in the system at time t, and set

$$X^{1,N}(t) = \frac{1}{\sqrt{N}} \left[\# \text{ of class 1 in system at time } t - N \frac{\lambda^{1,N}}{\mu^{1,N}} \right].$$

Thus $X^{1,N}(t)$ is the scaled number of class 1 customers centered about the mean, if there are no rejections and an infinite channel capacity. Define $A^{i,N}(t)$ (resp., $D^{i,N}(t)$) to be $1/\sqrt{N}$ times the number of arrivals (resp., departures) of class i by time t, and $F^{1,N}(t)$ denotes $1/\sqrt{N}$ times the number of arrivals of class 1 up to time t which the controller did not admit. Thus, $A^{i,N}(t) = \sqrt{N} S^{i,N}(t)$. The (nondecreasing) control process $F^{1,N}(\cdot)$ is assumed to be *admissible* in that it is (ω, t) measurable and its value at time t depends only on the data which is available up to time t.

The system balance equations are

$$X^{0,N}(t) = X^{0,N}(0) + A^{0,N}(t) - D^{0,N}(t) - F^{0,N}(t), \tag{2.4a}$$

$$X^{1,N}(t) = X^{1,N}(0) + A^{1,N}(t) - D^{1,N}(t) - F^{1,N}(t) - U^{1,N}(t), \tag{2.4b}$$

where $U^{1,N}(t)$ is $1/\sqrt{N}$ times the number of class 1 customers that could not be admitted due the *entire* channel being occupied by class 1 customers. This last term will disappear in the limit. We will suppose that the set

$$\left\{ X^{1,N}(0), N \right\} \text{ is tight (bounded in probability).} \tag{2.5}$$

If this set is not tight, then there will be a long delay before the heavy traffic regime is entered. The set $\{X^{0,N}(0)\}$ is always tight, since $B_+^0 < \infty$. It is also supposed that the initial condition is independent of the subsequent arrival times and service times for class 1.

In order to simplify the convergence proofs, one needs to put the input and output processes into a more convenient form.

Representation of the input processes. Following a common practice in weak convergence analysis, we decompose the arrival process as

$$\begin{aligned} A^{i,N}(t) &= \frac{1}{\sqrt{N}} \sum_{l=1}^{NS^{i,N}(t)} 1 \\ &= \frac{1}{\sqrt{N}} \sum_{l=1}^{NS^{i,N}(t)} \left[1 - \frac{\alpha_l^{i,N}}{\bar{\alpha}^{i,N}}\right] + \frac{1}{\sqrt{N}} \sum_{l=1}^{NS^{i,N}(t)} \frac{\alpha_l^{i,N}}{\bar{\alpha}^{i,N}}. \end{aligned} \tag{2.6a}$$

Note that

$$\sum_{l=1}^{NS^{i,N}(t)} \alpha_l^{i,N}$$

equals t minus the time since the last arrival before or at t. Thus, by (2.6a),

$$A^{i,N}(t) = W^{i,N}(S^{i,N}(t)) + t\lambda^{i,N}\sqrt{N} - \frac{\rho^{i,N}(t)}{\sqrt{N}}, \tag{2.6b}$$

where $\rho^{i,N}(t)$ is the time since the last arrival before or at t, divided by the mean interarrival interval. The sequence of processes $\rho^{i,N}(\cdot)/\sqrt{N}$ converges weakly to the "zero" process. It does not affect any of the subsequent calculations and for the sake of notational simplicity, it will be *omitted* in all of the subsequent system equations after (2.11).

Representation of the output processes. Because of the exponential distribution of the service time for the class 1 customers, $D^{1,N}(\cdot)$ can be decomposed into the sum of the integral of the *instantaneous conditional mean rate* at which $D^{1,N}(\cdot)$ increases, and a martingale process $\tilde{D}^{i,N}(\cdot)$. To do this, first note that the conditional mean instantaneous rate of increase of $D^{1,N}(\cdot)$ at t is $\mu^{1,N}/\sqrt{N}$ times the number of class 1 customers in the system at t.

We have the decomposition

$$D^{1,N}(t) = \mu^{1,N} \int_0^t \left[X^{1,N}(s) + \sqrt{N}\frac{\lambda^{1,N}}{\mu^{1,N}}\right] ds + \tilde{D}^{1,N}(t). \tag{2.7}$$

The Doob–Meyer increasing process associated with the martingale is just $1/\sqrt{N}$ times the integral in (2.7); namely,

$$\langle \tilde{D}^{1,N} \rangle(t) = \frac{\mu^{1,N}}{\sqrt{N}} \int_0^t \left[X^{1,N}(s) + \sqrt{N}\frac{\lambda^{1,N}}{\mu^{1,N}}\right] ds. \tag{2.8}$$

The factor $1/\sqrt{N}$ appears due to the definition of $D^{i,N}(t)$ as $1/\sqrt{N}$ times the number of departures by time t. Similar decompositions were used in [22, 27].

Let $I^{0,N}(t)$ denote the indicator function of the event that there are class 0 customers in the system at t. The departure process for class 0 is similarly decomposed into the integral of the conditional mean instantaneous rate at which $D^{0,N}(\cdot)$ increases and a martingale $\tilde{D}^{0,N}(\cdot)$. In preparation for this, first note that the available bandwidth per class 0 customer at time t is

$$\frac{C_N - \left[\sqrt{N}X^{1,N}(t) + N\lambda^{1,N}/\mu^{1,N}\right]}{\sqrt{N}X^{0,N}(t)} I^{0,N}(t),$$

which equals

$$\frac{N\lambda^{0,N}/\mu^{0,N} + b\sqrt{N} - \sqrt{N}X^{1,N}(t)}{\sqrt{N}X^{0,N}(t)} I^{0,N}(t).$$

Thus the conditional mean instantaneous rate at which $D^{0,N}(\cdot)$ increases at t is

$$\left[\sqrt{N}\frac{\lambda^{0,N}}{\mu^{0,N}} + b - X^{1,N}(t)\right] I^{0,N}(t).$$

Hence,

$$D^{0,N}(t) = \mu^{0,N} \int_0^t \left[\sqrt{N}\frac{\lambda^{0,N}}{\mu^{0,N}} + b - X^{1,N}(s)\right] I^{0,N}(t)ds + \tilde{D}^{0,N}(t), \tag{2.9a}$$

which we rewrite as

$$D^{0,N}(t) = \mu^{0,N} \int_0^t \left[\sqrt{N}\frac{\lambda^{0,N}}{\mu^{0,N}} + b - X^{1,N}(s)\right] ds + \tilde{D}^{0,N}(t) - Y^{0,N}(t). \tag{2.9b}$$

The term $Y^{0,N}(\cdot)$ is a reflection term; it compensates for the difference in the integrals in (2.9a) and (2.9b), and it can increase only when $X^{0,N}(t) = 0$. The Doob–Meyer increasing process associated with $\tilde{D}^{0,N}(\cdot)$ is

$$\langle \tilde{D}^{0,N} \rangle(t) = \frac{\mu^{0,N}}{\sqrt{N}} \int_0^t \left[\sqrt{N}\frac{\lambda^{0,N}}{\mu^{0,N}} + b - X^{1,N}(s)\right] I^{0,N}(s)ds,$$

which is written more conveniently as

$$\mu^{0,N} \int_0^t \left[\frac{\lambda^{0,N}}{\mu^{0,N}} + \frac{b}{\sqrt{N}} - \frac{X^{1,N}(s)}{\sqrt{N}}\right] I^{0,N}(s)ds. \tag{2.10}$$

Now, putting all of the above representations together and canceling the $\pm\sqrt{N}\lambda^{i,N}$ terms yields the forms:

$$\begin{aligned} X^{0,N}(t) = X^{0,N}(0) + W^{0,N}(S^{0,N}(t)) - \mu^{0,N} \int_0^t g_0(X^N(s))ds \\ - \tilde{D}^{0,N}(t) - F^{0,N}(t) + Y^{0,N}(t) - \frac{\rho^{0,N}(t)}{\sqrt{N}}, \end{aligned} \tag{2.11a}$$

$$\begin{aligned} X^{1,N}(t) = X^{1,N}(0) + W^{1,N}(S^{1,N}(t)) - \mu^{1,N} \int_0^t X^{1,N}(s)ds \\ - \tilde{D}^{1,N}(t) - F^{1,N}(t) - U^{1,N}(t) - \frac{\rho^{1,N}(t)}{\sqrt{N}}, \end{aligned} \tag{2.11b}$$

where we define

$$g_0(x) = b - x^1, \tag{2.12}$$

and the $Y^{0,N}(t)$ term compensates for the fact that there are no departures of class 0 customers at time t if $X^{0,N}(t) = 0$. It assures that $X^{0,N}(t)$ will stay nonnegative.

Comments on weak convergence. The path space for all of the random processes is $D^k[0,\infty)$, the space of functions which are right continuous, have left hand limits, and take values in Euclidean k-space for appropriate integers k. The Skorohod topology is used [6, 9]. This is the most common and convenient choice in heavy traffic analysis. The following is a convenient criterion for tightness in this space. It will be used implicitly. Let $\{Y^n(\cdot)\}$ be a sequence of processes with paths in $D[0,\infty)$, with probability one. Let $\mathcal{T}^n(t)$ denote the stopping times with respect to the filtration engendered by $Y^n(\cdot)$ and which are no larger than t. If

$$\lim_{\delta\to 0} \sup_n \sup_{\tau\in\mathcal{T}^n(t)} E\left(1 \wedge |Y^n(\tau+\delta) - Y^n(\tau)|\right) = 0, \tag{2.13}$$

for each t, and

$$\{Y^n(t) : n, t\} \text{ is tight}, \tag{2.14}$$

then $\{Y^n(\cdot)\}$ is tight [9].

3. Discounted cost function and weak convergence.

The convergence theorem implies that only a bandwidth excess of order $O(\sqrt{N})$ is needed for good performance.

Although the set of applications is new, the setup so far is similar to that of many other problems of control of queues under heavy traffic. See, for example, [29, 22, 25, 23]. The main new questions concern the control functions $F^{1,N}(\cdot)$. We will be concerned with two types of cost functions: the discounted and the average cost per unit time (to be called the ergodic cost function). Until section 7, we concentrate on the discounted problem. Much of the analysis carries over to the ergodic case with little change. Also, analogous procedures are used for the convergence proofs for all of the problem formulations in the following sections.

Let $\beta > 0, c_i > 0$, where β can be as small as we wish, and let $k(\cdot)$ be a nonnegative continuous function with $k(0) = 0$. The discounted cost function is defined by

$$C_\beta^N(x, F^{1,N}) = E\int_0^\infty e^{-\beta s} k(X^{0,N}(s))ds + E\int_0^\infty e^{-\beta s} \sum_i c_i dF^{i,N}(s). \tag{3.1}$$

The second term penalizes the rejections. We do not penalize the loss $U^{1,N}(\cdot)$, since it is zero in the limit as $N \to \infty$ no matter what the controls are. The first term can be quite general. If $k(\cdot)$ is linear, then it simply penalizes the waiting time for class 0 customers. More generally, it can be nonlinear. For example, it might be zero for small values of the argument (if the delays at small values are considered to be unimportant), or it might increase superlinearly to discourage long delays. The allowed generality of the cost function is one of the advantages of the approach. Define $V_\beta^N(x) = \inf_{F^{1,N}} C_\beta^N(x, F^{1.N})$, where the inf is over the admissible controls.

The basic structure of the convergence proofs is similar to those in the cited references to controlled queues in heavy traffic, except for the questions of tightness and approximation of the control functions. After stating the convergence theorems, the proofs will be outlined and references given for many of the details.

Define $B^{i,N}(\cdot) = W^{i,N}(S^{i,N}(\cdot)) - \tilde{D}^{i,N}(\cdot)$.

THEOREM 3.1. *Let $\epsilon > 0$ be small but arbitrary, and let $F^{1,N}(\cdot)$ be ϵ-optimal controls. Suppose that $\{F^{1,N}(\cdot), N\}$ is tight.*[3] *Then the set*

$$\{X^{i,N}(\cdot), B^{i,N}(\cdot), F^{i,N}(\cdot), i = 1, 2; Y^{0,N}(\cdot), N\}$$

is tight. The weak sense limit of any weakly convergent subsequence satisfies

$$X^0(t) = X^0(0) - \mu_0 \int_0^t g_0(X(s))ds + B^0(t) + Y^0(t) - F^0(t), \tag{3.2a}$$

$$X^1(t) = X^1(0) - \mu_1 \int_0^t X^1(s)ds + B^1(t) - F^1(t), \tag{3.2b}$$

where the $B^i(\cdot)$ are mutually independent Wiener processes with variance parameters $\lambda_i(1 + \sigma_i^2)$. $0 \le X^0(t) \le B_+^0$, and $Y^0(\cdot)$ is the reflection term at zero. $F^0(\cdot)$ is the reflection term at the upper bound. The other processes are nonanticipative[4] *with respect to the Wiener processes.*

Comments on the proof. Details for similar results are in [22, 23, 25, 29, 27], and we will only outline the sequence of ideas. First, by the renewal theorem, $S^{i,N}(\cdot)$ converges weakly to the deterministic (limit scaled mean arrival rate) process with values $\lambda_i t$. By Donsker's Theorem [6, 9], $W^{i,N}(\cdot)$ converges weakly to mutually independent Wiener processes with variance parameters σ_i^2. Hence the $W^{i,N}(S^{i,N}(\cdot))$ converges to mutually independent Wiener processes $\tilde{W}^i(\cdot)$ with variance parameters $\lambda_i \sigma_i^2$.

The set of martingales $\{\tilde{D}^{i,N}(\cdot); i, N\}$ can readily be proved to be tight via the criterion (2.14), (2.15). This is done by a direct computation using the fact that their associated Doob–Meyer increasing processes (2.8) and (2.10) are bounded by a constant times t. The fact that the scaled discontinuities go to zero as $N \to \infty$ implies that their weak sense limits have continuous paths with probability one.

With the above tightness results available on the "driving terms" $W^{i,N}(S^{i,N}(\cdot))$, $\tilde{D}^{i,N}(\cdot)$, and the tightness assumption on the control terms, the tightness of $\{X^{1,N}(\cdot)$, $U^{1,N}(\cdot)$, $N\}$ can be readily proved if the $X^{1,N}$ in (2.11b) is replaced by some bounded functions. For the general case, the tightness follows by a standard truncation argument [21]. This tightness implies that the sequence $U^{1,N}(\cdot)$ has "zero" weak sense limits, since the "upper boundary" for $X^{1,N}$ gets pushed to infinity as $N \to \infty$. The tightness of $\{X^{1,N}(\cdot)\}$ also implies the tightness of $\{X^{0,N}(\cdot), Y^{0,N}(\cdot), F^{0,N}(\cdot), N\}$. In fact, the tightness of the $\{F^{0,N}(\cdot)\}$ can be shown even without tightness of the controls, since the controls only decrease $X^{1,N}(\cdot)$ (hence $X^{0,N}(\cdot)$) and $F^{0,N}(\cdot)$ is a reflection process at an upper boundary. Indeed, one can show that $F^{0,N}(\cdot)$ is asymptotically continuous with probability one. If it were not asymptotically continuous, then the asymptotic discontinuity and the properties of the other driving terms for $X^{0,N}(\cdot)$ would imply that asymptotically there is a jump to the interior of $[0, B_+^0]$ from the upper boundary, which is impossible, since the individual steps go to zero as $N \to \infty$ and $F^{0,N}(\cdot)$ can increase only on the boundary. The tightness of $\{Y^{0,N}(\cdot), N\}$ implies that $I^{0,N}(\cdot)$ can be nonzero only on set whose Lebesgue measure goes to zero as $N \to \infty$. Hence, $I^{0,N}(\cdot)$ has no asymptotic influence on the Doob–Meyer increasing process associated with the martingale $\tilde{D}^{0,N}(\cdot)$.

[3] By Theorem 3.3, this tightness assumption entails no loss of generality.

[4] The associated filtration here and in subsequent uses of "nonanticipative" is that generated by all of the processes $(X^i(\cdot), B^i(\cdot), F^i(\cdot), Y^i(\cdot), i = 0, 1)$.

Now, given the tightness, extract a weakly convergent subsequence, with the weak sense limits being denoted by $X^i(\cdot)$, etc. It can be shown that the weak sense limits $\tilde{D}^i(\cdot)$ are mutually independent Wiener processes which are independent of the $\tilde{W}^i(\cdot)$, and have the variance parameters λ_i. The Wiener property of the limits of the $\tilde{D}^{i,N}(\cdot)$ is proved as in [22, Theorem 3.1]. The mutual independence is a consequence of the independence conditions and the definition of "conditional mean instantaneous rate" via a conditional expectation, and an analogous computation is in [22, Theorem 3.1]. The fact that (3.2) holds follows from the weak convergence. The nonanticipativenss properties are proved by standard "martingale" means as in [29, Theorem 5.1], [22, Theorem 3.1], or [23, Theorem 2.1]

Definition. *The discounted cost function for* (3.2) *is*

$$C_\beta(x, F^1) = E\int_0^\infty e^{-\beta s} k(X^0(s))ds + E\int_0^\infty e^{-\beta s}\sum_i c_i dF^i(s). \tag{3.3}$$

Define an *admissible* control $F^1(\cdot)$ for (3.2) to be a nondecreasing process which is nonanticipative with respect to the Wiener processes. If $F^1(\cdot)$ is absolutely continuous, with derivative $u(\cdot)$, then we say that $u(\cdot)$ is admissible if it is nonnegative, measurable, and nonanticipative. Define $V_\beta(x) = \inf_{F^1} C_\beta^N(x, F^1)$, where the inf is over the admissible controls. We say that $F^{1,N}(\cdot)$ has a *derivative* which is bounded by R if for each t and $s > 0$, $F^{1,N}(t+s) - F^{1,N}(t) \leq Rs + 1/\sqrt{N}$. The $1/\sqrt{N}$ term is needed since $F^{1,N}(\cdot)$ is piecewise constant with jumps $1/\sqrt{N}$.

Theorem 3.2 (weak convergence). *Let* $X^N(0) \Rightarrow X(0)$ *Then*

$$V_\beta^N(X^N(0)) \to V_\beta(X(0)). \tag{3.4}$$

Discussion of the proof. By Theorem 3.3, it can be assumed without loss of generality that for each fixed $\epsilon > 0$, there is some set of ϵ-optimal controls for (2.11), (3.2), with uniformly bounded derivatives; hence the set is tight. As a result of the discounting, as noted in the proof of Theorem 3.3, we can suppose that there is $T_\epsilon < \infty$ such that the $F^{1,N}(\cdot)$ do not change after time T_ϵ. It is sufficient to work with this set below.

Given $\epsilon > 0$, let $F^{1,N}(\cdot)$ be a sequence of ϵ-optimal controls. Let $X^N(0) \to X(0)$. By Theorem 3.1, $\{X^{0,N}(\cdot), X^{1,N}(\cdot), F^{1,N}(\cdot)\}$ is tight. Let N_k index a weakly convergent subsequence with weak sense limits $(X^0(\cdot), X^1(\cdot), F^1(\cdot))$. Then, by the weak convergence and Fatou's Lemma

$$\liminf_k V_\beta^{N_k}(X^{N_k}(0)) \geq V_\beta(X(0)).$$

This and the ϵ-optimality of $F^{1,N}(\cdot)$ for each N implies that

$$\begin{aligned} \epsilon + \liminf_N V_\beta^N(X^N(0)) &\geq \liminf_N C_\beta^N(X^N(0), F^{1,N}) \\ &\geq C_\beta(X(0), F^1) \geq V_\beta(X(0)). \end{aligned} \tag{3.5}$$

Since ϵ is arbitrary, (3.5) implies that

$$\liminf_N V_\beta^N(X^N(0)) \geq V_\beta(X(0)). \tag{3.6}$$

Now we prove the reverse inequality to (3.5); namely,

$$\limsup_N V_\beta^N(X^N(0)) \leq V_\beta(X(0)). \tag{3.7}$$

To do this we apply the following widely useful approach. Note that, for each initial condition, the distribution of the limit process $X(\cdot)$ depends on the pair $(F^1(\cdot), B(\cdot))$. For each fixed $\epsilon > 0$, we first find an ϵ-optimal pair $(F^{\epsilon,1}(\cdot), B^{\epsilon}(\cdot))$ for the limit process with the property that there is a sequence of admissible controls $F^{\epsilon,1,N}(\cdot)$ for (2.11) such that (defining $B^{\epsilon,N}(\cdot)$ as $B^N(\cdot)$ was defined but under control $F^{\epsilon,1,N}(\cdot)$) $\{X^N(0), F^{\epsilon,1,N}(\cdot), B^{\epsilon,N}(\cdot))\}$ converges weakly to $(X(0), F^{\epsilon,1}(\cdot), B(\cdot))$ and also that

$$C_\beta^N(X^N(0), F^{\epsilon,1,N}) \to C_\beta(X(0), F^{\epsilon,1}) \leq V_\beta(X(0)) + \epsilon. \tag{3.8}$$

For any $\epsilon > 0$, there is an $F^{\epsilon,1}(\cdot)$ and a sequence of admissible controls $\{F^{\epsilon,1,N}(\cdot)\}$ satisfying the requirement (3.8). See, e.g., [28, section 5]. The sequence of controls given by the reference is admissible and the $F^{\epsilon,1,N}(T_\epsilon)$ are uniformly bounded. It does not necessarily have a bounded derivative, and might not even be tight in the Skorohod topology. (A time transformation method was used in the reference to circumvent the tightness problem. But the method used here is simpler in the current case, since Theorem 3.3 shows how to alter the control sequence (without loss of generality) so that we have bounded derivatives (hence tightness) with (3.8) holding (with perhaps ϵ replaced by 2ϵ).)

Now, (3.8) and the fact that (due to the nonoptimality of $F^{\epsilon,1,N}(\cdot)$)

$$V_\beta^N(X^N(0)) \leq C_\beta^N(X^N(0), F^{\epsilon,1,N})$$

yields (3.4).

Comment on the optimal controls. The comments on the form of the optimal control in section 7 also hold for the discounted cost problem. In particular, numerical data show that there is a piecewise linear or nearly linear switching curve such that the optimal control is to reject above and accept below, with any decision allowed when on the curve. For large N, this control will be nearly optimal for the physical system. These comments on the shape of the switching curves are based on (very consistent) numerical computations, but not on proofs.

Comment on tightness. An ϵ-optimal sequence $\{F^{1,N}(\cdot), N\}$ need not be tight in general. Let $X^{1,N}(t_0) > 0$. Consider the example of a control which rejects until $X^{1,N}(t)$ reaches the value zero, and then stops. Since the required time for $X^{1,N}(\cdot)$ to reach zero is of the order of $X^{1,N}(t_0)/\sqrt{N}$, the control clearly converges to a step function in an obvious way. But, owing to the fact that it increases in small steps (of size $1/\sqrt{N}$), the sequence is not tight in the Skorohod topology. There are many ways of dealing with this problem. We can adapt the time transformation method of [26, 24]. But, because of the relative simplicity of the dynamics and cost function, there is a simpler way, which avoids the extra notation and concepts.

THEOREM 3.3. *It can be supposed that the controls in Theorems* 3.1 *and* 3.2 *are tight. In fact, it can be supposed that they have uniformly bounded derivatives for each* $\epsilon > 0$.

Proof. Fix $\epsilon > 0$. Since $B_+^0 < \infty$, $\{k(X^{0,N}(t)), k(X^0(t)); N, t\}$ is uniformly bounded.[5] Thus, due to the discounting, there is $T_\epsilon < \infty$ and a sequence of $\epsilon/2$-optimal controls which do not change after time T_ϵ. Note that the control which is identically zero has uniformly (in N) bounded costs.

[5] Even if $B_+^0 = \infty$, by imposing a growth rate $k(x^0) = O(|x^0|^{1+\delta})$ for large x^0, $0 \leq \delta < 1$, and assuming that $\sup_N E|X^{0,N}(0)|^2 < \infty$, $Ek(X^{0,N}(t))$ is at most $O(t^2)$ for large t, uniformly in the control (and analogously for the limit system).

The existence of $T_\epsilon < \infty$ can be seen from the following argument. From any time T on, and with no control after that time, the limit cost is

$$E\int_T^\infty e^{-\beta t}k(X^0(t))dt + E\int_T^\infty e^{-\beta t}c_0 dF^0(t).$$

The first term obviously goes to zero as $T \to \infty$, uniformly in the past values of the control. The same thing can be said of the second term, owing to the properties of the solution to (3.2a). A similar argument applies to the physical system and controls $F^{1,N}(\cdot)$. We need only work with controls for which the sequence of costs is uniformly bounded.

For large enough $K < \infty$, the sequence defined by $F_K^{1,N}(\cdot) = F^{1,N}(\cdot) \wedge K$ will be $3\epsilon/4$-optimal, and similarly for $F_K^1(\cdot) = F^1(\cdot) \wedge K$. To see this, note that whatever the controls in the previous paragraph are, the boundedness of the costs imply that

$$\sup_N EF^{1,N}(T_\epsilon) < \infty, \quad EF^1(T_\epsilon) < \infty. \tag{3.9}$$

Furthermore,

$$\begin{aligned} \lim_K \sup_N P\left\{\left[F^{1,N}(T_\epsilon) - F^{1,N}(T_\epsilon) \wedge K\right] \neq 0\right\} = 0, \\ \lim\nolimits_K P\left\{\left[F^1(T_\epsilon) - F^1(T_\epsilon) \wedge K\right] \neq 0\right\} = 0. \end{aligned} \tag{3.10}$$

(3.9) and (3.10) and a straightforward analysis using Fatou's Lemma implies that the costs and systems associated with the use of $F^{i,N}(\cdot) \wedge K$ (resp., $F^i(\cdot) \wedge K$ for the limit system) are asymptotically (as $K \to \infty$) no worse (uniformly in N) than the costs for the original untruncated controls.

Now that we know that there are $3\epsilon/4$-optimal controls $F^{1,N}(\cdot), F^1(\cdot)$ which do not increase after T_ϵ and that are uniformly bounded, we can show that we can bound the derivative as well: More precisely, we can show that there are $R < \infty$ and ϵ-optimal controls which satisfy:

$$F_R^1(t+s) - F_R^1(t) \leq Rs, \tag{3.11}$$

$$F_R^{1,N}(t+s) - F_R^{1,N}(t) \leq Rs + 1/\sqrt{N}, \tag{3.12}$$

for all $t, s > 0$. In particular, let $F_R^1(\cdot)$ denote the largest control which satisfies (3.11), but is no greater than $F^1(\cdot)$, and let $F_R^{1,N}(\cdot)$ be the largest control which satisfies (3.12) and which is no greater than $F^{1,N}(\cdot)$.

Since $K < \infty$ and R is as large as desired, any jump in $F^{1,N}(\cdot)$ can be reached by $F_R^{1,N}(\cdot)$ in an arbitrarily short (uniformly in N and in the realization) time afterwards. Thus, excluding a set of measure which goes to zero (uniformly in N) as $R \to \infty$, $F^{1,N}(t) - F_R^{1,N}(t)$ goes to zero (uniformly in N) as $R \to \infty$. This and the boundedness of the F functions imply that $X^{1,N}(t) - X_R^{1,N}(t)$ is bounded and (excluding sets of arbitrarily small measure) converges to zero uniformly in N. Similar remarks hold for $F^{1,N}(\cdot), F_R^{1,N}(\cdot)$. These results imply that the costs converge as well.

The $1/\sqrt{N}$ term appears in (3.12) since $F^{1,N}(\cdot)$ is piecewise constant with an increment of $1/\sqrt{N}$ at each rejection.

4. Upper limit to the bandwidth for the BE sharing customers. In the model of the previous two sections, the class 0 customers shared the available bandwidth, whatever it was, and used *all* of it. In general, it might not be possible for all of the available bandwidth to be used. For example, there might be local restrictions on the rate at which data can enter the channel buffer (e.g., bounded modem speed, etc.). This possibility changes the problem a little, and we will indicate the few required adjustments. Such examples are further illustrations of the versatility of the approach.

Suppose that the *maximum* bandwidth that any single class 0 customer can use is C_0. The main difference in the development concerns the departure process for class 0 customers and the structure of the appropriate cost function. We now *redefine*

$$X^{0,N}(t) = \frac{\#\text{ of class 0 customers at time } t - N\lambda^{0,N}/(C_0\mu^{0,N})}{\sqrt{N}}.$$

Note that now $X^{0,N}(t)$ is centered around a *mean value,* assuming that each class 0 customer uses exactly C_0 units of bandwidth. In sections 2 and 3, the number of class 0 customers in the system was $O(\sqrt{N})$, and $X^{0,N}(t)$ measured that actual number, scaled by $1/\sqrt{N}$. Now, the number in the system will be $O(N)$, and $X^{0,N}(t)$ measures the deviation from the mean number, scaled by $1/\sqrt{N}$. We suppose that class 0 customers are rejected if $X^{0,N}(t) \geq B^0_+$, where $B^0_+ < \infty$. Theoretical and numerical results show that this will have negligible effect if B^0_+ is large.

The martingale decomposition (2.9) remains valid, but the instantaneous conditional mean departure rate is different, being determined by whether or not the available capacity per class 0 customer is greater than C_0. The conditional mean instantaneous rate at which $D^{0,N}(\cdot)$ increases at time t is

$$\frac{\mu^{0,N}}{\sqrt{N}}[\#\text{ of class 0 in system at } t] \times \min\left[\frac{\text{available BW at } t}{\#\text{ of class 0 in system at } t},\ C_0\right] I^{0,N}(t),$$

which equals

$$\begin{aligned}
&I^{0,N}(t)\frac{\mu^{0,N}}{\sqrt{N}} \times \min\left[\text{available BW at } t,\ C_0(\#\text{ of class 0 in system at } t)\right]\\
&= I^{0,N}(t)\frac{\mu^{0,N}}{\sqrt{N}}\times\\
&\min\left[\frac{N\lambda^{0,N}}{\mu^{0,N}} + b\sqrt{N} - \sqrt{N}X^{1,N}(t),\ C_0\left(\frac{\lambda^{0,N}N}{C_0\mu^{0,N}} + \sqrt{N}X^{0,N}(t)\right)\right]\\
&= I^{0,N}(t)\lambda^{0,N}\sqrt{N} + I^{0,N}(t)\mu^{0,N}g_1(X^N(t)),
\end{aligned} \tag{4.1}$$

where we define

$$g_1(x) = \min\left[b - x^1, C_0x^0\right]. \tag{4.2}$$

Now, analogously to what was done in section 2, we can write the decomposition as

$$D^{0,N}(t) = \lambda^{0,N}\sqrt{N}t + \int_0^t \mu^{0,N}g_1(X^N(s))ds + \tilde{D}^{0,N}(t) - Y^{0,N}(t),$$

where the Doob–Meyer increasing process associated with the martingale $\tilde{D}^{0,N}(\cdot)$ is

$$\langle\tilde{D}^{0,N}\rangle(t) = \int_0^t \left[\lambda^{0,N} + \frac{1}{\sqrt{N}}\mu^{0,N}g_1(X^N(s))\right] I^{0,N}(s)ds.$$

The dynamical equation is (2.11) with (2.11a) replaced by

$$\begin{aligned} X^{0,N}(t) &= X^{0,N}(0) + W^{0,N}(S^{0,N}(t)) \\ &\qquad - \mu^{0,N} \int_0^t g_1(X^N(s))ds - \tilde{D}^{0,N}(t) - F^{0,N}(t) + Y^{0,N}(t), \end{aligned} \tag{4.3}$$

and the limit equation is (3.2) with (3.2a) replaced by

$$X^0(t) = X^0(0) - \mu_0 \int_0^t g_1(X(s))ds + B^0(t) - F^0(t). \tag{4.4}$$

In the cost function (3.1), the function $k(\cdot)$ was assumed to be nonnegative. This made sense since $X^{0,N}(t)$ was nonnegative. Now, since $X^{0,N}(t)$ can take any sign, we suppose that $k(x^0)$ takes the sign of x^0 and is zero if $x^0 = 0$. Note that for large negative x^0, the departure rate is essentially limited by the C_0 limitation, and the control has little effect. Also, suppose that

$$|k(x^0)| = O(|x^0|), \quad \sup_N E\left|X^{0,N}(0)\right|^2 < \infty. \tag{4.5}$$

Under the given conditions Theorems 3.1 to 3.3 hold.

The savings in waiting time for the class 0 customers (for the controlled problem) are of the order of that of the model in sections 2 and 3. But, since there are many more customers in the system at any time, the savings per customer is less. We are essentially concerned with "marginal" savings, at a "marginal" cost.

Comments on the proofs. The proofs outlined in section 3 work here as well, with essentially the same details. The only differences are due to the fact that in the present case the $X^{0,N}(t)$ are not bounded below. But in the proofs, the second moment bound

$$\sup_{N,t,F^{1,N}} E\left|X^{0,N}(t)\right|^2 < \infty \tag{4.6}$$

is used in lieu of the zero lower bound. (4.6) is proved by use of a dominating system. The second moments are bounded by a constant plus the second moments of the following system, which is defined on the interval $(-\infty, 0]$, and the reflection term $F^{0,N}(\cdot)$ now acts at the origin, and keeps the state nonpositive:

$$X^{0,N}(t) = X^{0,N}(0) + W^{0,N}(S^{0,N}(t)) - \mu^{0,N} \int_0^t X^{0,N}(s)ds - \tilde{D}^{0,N}(t) - F^{0,N}(t). \tag{4.7}$$

The proof of (4.6) for the model (4.7) is done by a Liapunov function technique and can be found in [22, p. 771]

5. Extension. Several BE and GP subclasses. The developments in the previous sections can be extended to the case where there are multiple subclasses of any of the classes (and similarly for the models in the subsequent sections). We will illustrate only one of the many possibilities, working with the setup in sections 2 and 3. Suppose that there are now two types of BE (class 0) customers, called class 01 and class 02, with parameters $\lambda^{0i,N}, \mu^{0i,N}, i = 1, 2$. We suppose that the natural analogs of the conditions in sections 2 and 3 hold. There is a surprisng and very useful degeneracy, which simplifies both the analytical problem and the numerical analysis.

Analogous to (2.1), we let the channel capacity be

$$C_N = N\left[\sum_i \frac{\lambda^{0i,N}}{\mu^{0i,N}} + \frac{\lambda^{1,N}}{\mu^{1,N}}\right] + \sqrt{N}b. \tag{5.1}$$

The bandwidth available at time t for both subclasses 01 and 02 is

$$\sum_i N\frac{\lambda^{0i,N}}{\mu^{0i,N}} - \sqrt{N}X^{1,N}(t) + \sqrt{N}b, \quad b > 0.$$

The processes are defined analogously to what was done in section 2; e.g., $D^{0i,N}(\cdot)$ is the number of departures of subclass $0i$ by time t, divided by $\sqrt{N}$.

Until otherwise noted, let us assume that the available bandwidth is shared equally among all class 0 customers, irrespective of the subclass. Then the total conditional mean instantaneous rate at which $D^{0i,N}(\cdot)$ increases at t is (following the idea used in section 2 and assuming that there are class 0 customers in the system)

$$\frac{\mu^{0i,N}}{\sqrt{N}}\,[\text{\# of subclass } 0i \text{ in system at } t]\,\frac{\text{avail BW at } t}{\text{total \# of class 0 in system at } t},$$

which equals

$$\mu^{0i,N}X^{0i,N}(t)\frac{\sum_j N\frac{\lambda^{0j,N}}{\mu^{0j,N}} - \sqrt{N}X^{1,N}(t) + \sqrt{N}b}{\sqrt{N}\sum_j X^{0j,N}(t)}. \tag{5.2}$$

Define

$$\bar{a}^N = \frac{\lambda^{01,N}/\mu^{01,N}}{\sum_j \lambda^{0j,N}/\mu^{0j,N}}, \quad \bar{a} = \lim_N \bar{a}^N. \tag{5.3}$$

The system is degenerate in that if the costs are bounded in N, then the ratios $X^{01,N}(t)/(X^{01,N}(t)+X^{02,N}(t))$ converge to $\bar{a}$ as $N \to \infty$. Thus we need only analyze the system with class 1 and one of the subclasses $0i$. Only an informal argument will be given. We note in passing that this convergence relation is an example of what is called state space collapse in the heavy traffic analysis of queueing systems. It is not the usual type, which is concerned with multiclass queues under the workload formulation.

Let us examine the mean rates of increase of $A^{0i,N}(\cdot)$ and $D^{0i,N}(\cdot)$. The "mean rate" at which $A^{0i,N}(\cdot)$ increases is $\sqrt{N}\lambda^{0i,N}$. Define $B^N = \sum_i[\lambda^{0i,N}/\mu^{0i,N}]$. Set

$$a^N(t) = \frac{X^{01,N}(t)}{X^{01,N}(t) + X^{02,N}(t)}.$$

Using the fact that the available bandwidth is partitioned equally among all the class 0 customers, the conditional mean instantaneous rates at which $D^{0i,N}(\cdot), i = 1, 2$, resp., increase at t are, resp.,

$$\left[\sqrt{N}B^N - X^{1,N}(t) + b\right]\mu^{01,N}a^N(t),$$

$$\left[\sqrt{N}B^N - X^{1,N}(t) + b\right]\mu^{02,N}\left(1 - a^N(t)\right).$$

The differences of the dominant arrival and departure terms for the two subclasses are, resp.,

$$\sqrt{N}\left[\lambda^{01,N} - B^N \mu^{01,N} a^N(t)\right], \tag{5.4a}$$

$$\sqrt{N}\left[\lambda^{02,N} - B^N \mu^{02,N}\left(1 - a^N(t)\right)\right]. \tag{5.4b}$$

For the case of section 2, the analogs of these terms have the value zero.

Let $\epsilon > 0$ be small. If for large N, $a^N(t) \notin [\bar{a} - \epsilon, \bar{a} + \epsilon]$, then (5.4a) implies that there is a large force (of the order of $\sqrt{N}$) returning it to this interval. Similarly, (5.4b) implies that $(1 - \alpha^N(t))$ must be very close to $(1 - \bar{a})$. The contribution of the nondominant terms is relatively small in comparison.

The degeneracy situation is similar if there are more than two subclasses.

Many interesting variations of the multiple subclass problem can be analyzed. For example, we might wish to alter the above formulation to allow each of the $0i$ subclasses a different fraction of the available bandwidth. More concretely, suppose that there are positive numbers k_i such that for each unit of bandwidth allocated to a customer of subclass 01, we allocate k_2/k_1 units of bandwidth to each customer of subclass 02. Then the dominant term in the conditional mean instantaneous rate at which $D^{0i,N}(\cdot)$ increases at t is

$$\mu^{0i,N} k_i X^{0i,N}(t) \frac{B^N N}{\sqrt{N}\left(k_1 X^{01,N}(t) + k_2 X^{02,N}(t)\right)}. \tag{5.5}$$

Redefine $a^N(t)$:

$$a^N(t) = \frac{k_1 X^{01,N}(t)}{\sum_j k_i X^{0i,N}(t)}. \tag{5.6}$$

Then, the difference between the dominant input and output terms is (5.4), but with the new value of $a^N(t)$ used. Thus, we see that the new value of $a^N(t)$ is very close to $\bar{a}$ for large N.

Note that the weighted fair-share for different types of BE customers in the above equations is the one defined by the ATM forum for sharing bandwidth among ABR users (see [1, Section I.3]).

6. Multicast: The limit dynamical equations and the discounted cost function. Now consider the case where there are two channels. There are three classes of customers. Class 0 is as in section 2, but must be transmitted simultaneously and with the same instantaneous rate on both channels. Class i, $i = 1, 2$, is to be transmitted on channel i only. We make the natural analogs of the assumptions of sections 2 and 3, defining $A^{i,N}(\cdot), D^{i,N}(\cdot), X^{i,N}(\cdot), i = 0, 1, 2$, etc., analogously to what was done there. Analogous to (2.1), the capacity of channel i is assumed to be

$$C_N^i = N \sum_i \frac{\lambda^{i,N}}{\mu^{i,N}} + b_i \sqrt{N}, \quad b_i > 0. \tag{6.1}$$

Any number of channels and 0 subclasses could also be used, with an arbitrary assignment of the subclasses to the channels.

At time t, the bandwidth available for class 0 customers on channel i is

$$N \frac{\lambda^{0,N}}{\mu^{0,N}} + b^i \sqrt{N} - X^{i,N}(t)\sqrt{N}.$$

Thus, the conditional mean instantaneous rate at which $D^{0,N}(\cdot)$ increases at t is determined by the channel with the largest available bandwidth and (analogous to what was done in section 2) is

$$\text{(6.2)}\quad \frac{\mu^{0,N}\sqrt{N}X^{0,N}(t)}{\sqrt{N}} \times \min\left[\frac{N\frac{\lambda^{0,N}}{\mu^{0,N}}+b_1\sqrt{N}-X^{1,N}(t)\sqrt{N}}{\sqrt{N}X^{0,N}(t)},\ \frac{N\frac{\lambda^{0,N}}{\mu^{0,N}}+b_2\sqrt{N}-X^{2,N}(t)\sqrt{N}}{\sqrt{N}X^{0,N}(t)}\right] I^{0,N}(t).$$

This equals

$$\left[\sqrt{N}\lambda^{0,N}+\mu^{0,N}g_2(X^N(t))\right] I^{0,N}(t), \tag{6.3}$$

where we define

$$g_2(x)=\min\left[b_1-X^{1,N}(t),\ b_2-X^{2,N}(t)\right]. \tag{6.4}$$

Thus analogous to what was done in section 2, we can write

$$D^{0,N}(t)=\lambda^{0,N}\sqrt{N}t+\int_0^t g_2(X^N(s))ds+\tilde{D}^{0,N}(t)-Y^{0,N}(t),$$

where the Doob–Meyer increasing process associated with the martingale is

$$\langle\tilde{D}^{0,N}\rangle(t)=\int_0^t\left[\lambda^{0,N}+\frac{\mu^{0,N}}{\sqrt{N}}g_2(X^N(s))\right]I^{0,N}(s)ds.$$

The analog of (2.11) is

$$\begin{aligned} X^{0,N}(t)=X^{0,N}(0)+W^{0,N}(S^{0,N}(t))-\mu^{0,N}\int_0^t g_2(X^N(s))ds\\ -\tilde{D}^{0,N}(t)+Y^{0,N}(t)-F^{0,N}(t), \end{aligned} \tag{6.6a}$$

and for $i=1,2$,

$$\begin{aligned} X^{i,N}(t)=X^{i,N}(0)+W^{i,N}(S^{i,N}(t))-\mu^{i,N}\int_0^t X^{i,N}(s)ds\\ -\tilde{D}^{i,N}(t)-F^{i,N}(t)-U^{i,N}(t), \end{aligned} \tag{6.6b}$$

where the $Y^{0,N}(t)$ term compensates for the fact that there are no departures of class 0 customers at time t if $X^{0,N}(t)=0$, and $U^{i,N}(t)$ compensates for the class i arrivals lost due to a full system (when the entire channel is occupied by class i customers).

The discounted cost function is still (3.1), but now the sum has three terms. The analysis given in section 3 holds here in the same way and the limit equations are

$$X^0(t)=X^0(0)-\mu_0\int_0^t g_2(X(s))ds+B^0(t)+Y^0(t)-F^0(t), \tag{6.7a}$$

$$X^i(t)=X^i(0)-\mu_i\int_0^t X^i(s)ds+B^i(t)-F^i(t),\quad i=1,2, \tag{6.7b}$$

where the $B^i(\cdot)$ are mutually independent Wiener processes with variance parameters $\lambda_i(\sigma_i^2+1)$. The associated cost function is (3.3), and we still have

$$V_\beta^N(X^N(0)) \to V_\beta(X(0)), \tag{6.8}$$

if $X^N(0) \Rightarrow X(0)$.

The model of section 4. Now, suppose that each class 0 customer can use at most a bandwidth C_0. Then define $X^{0,N}(t)$ as in section 4, and let $B_+^0 < \infty$. The development is a combination of those of sections 3 and 4. Now, the conditional mean instantaneous rate at which $D^{0,N}(\cdot)$ increases at t is obtained as the minimum of three terms, depending on whether the available capacities in channels 1, 2, or C_0 are the limiting factor. It is

$$\begin{aligned}&\frac{\mu^{0,N}}{\sqrt{N}}[\#\text{ of class 0 in system at } t]\\ &\min\left[\frac{\text{avail BW in ch 1 at } t}{\#\text{ of class 0 in system at } t}, \frac{\text{avail BW in ch 2 at } t}{\#\text{ of class 0 in system at } t}, C_0\right] I^{0,N}(t).\end{aligned} \tag{6.9}$$

Define

$$g_3(x) = \min\left[b_1 - x^1, b_2 - x^2, C_0 x^0\right]. \tag{6.10}$$

Then (6.9) can be written as

$$\left[\sqrt{N}\lambda^{0,N} + \mu^{0,N} g_3(X^N(t))\right] I^{0,N}(t).$$

All of the previous results continue to hold with $g_3(\cdot)$ replacing $g_2(\cdot)$.

7. The ergodic cost function: The basic model: Bounded control rate.

For concreteness, we work with the system model and assumptions of sections 2 and 3, although all of the results hold for all of the other models. In this section, we will suppose that the controls $F^{1,N}(\cdot)$ and $F^1(\cdot)$ (for the limit system) have bounded derivatives in the sense used in Theorem 3.3, as follows: There is a constant R, which can be as large as we wish, such that $\dot{F}^1(t) \le R$ for all t, and for all $t, s > 0$, $F^{1,N}(t+s) - F^{1,N}(t) \le Rs + 1/\sqrt{N}$. Thus, the maximum "rate" of refusing admission to class 1 customers is bounded by $\sqrt{N}R$.

The reasonableness of the bounded derivative assumption is also seen from the form of the limit equation (3.2), which (informally) suggests that one loses very little by bounding the derivative of $F^1(\cdot)$. Furthermore, it is completely borne out by our numerical data. The next section shows that we can make this assumption in the proofs with no loss of generality.

Although useful in applications, the mathematical reason for the assumption of bounded control "derivatives" concerns the mathematics of the ergodic cost problem. Little is known about the ergodic cost problem for the limit system when the control functions are arbitrary right continuous functions. But a great deal is known when they have uniformly bounded derivatives. In that case, for the current nondegenerate model (3.2), there is an optimal feedback control which is time independent and the optimal value $\bar{\gamma}_R(x)$ (defined below) does not depend on x. More importantly, for our purposes, for any $\epsilon > 0$, there is an ϵ-optimal time independent feedback control $u^\epsilon(\cdot)$ such that $u^\epsilon(\cdot) = \dot{F}^{\epsilon,1}(\cdot)$ is arbitrarily smooth, and under which there is a unique stationary measure. The $F^{\epsilon,1}(\cdot)$ plays the role of the $F^{1,\epsilon}(\cdot)$ in Theorem 3.2. The basic convergence results are quite technical. They are in [20] for the unconstrained (no reflecting boundaries) problem, with extensions to the constrained problem being in [22, 23]. Indeed, under our basic setup, the needed convergence results can be obtained from [23] by appropriate identification of terms.

Define the cost functions

$$\mathcal{C}^N(X^N(0),T,F^{1,N}) = \int_0^T k(X^{0,N}(s))ds + \sum_i c_i F^{i,N}(T),$$

$$\bar{\gamma}_R^N(X^N(0),T) = \inf_{F^{1,N}} E\mathcal{C}^N(X^N(0),T,F^{1,N})/T,$$

$$\bar{\gamma}_R^N(X^N(0)) = \limsup_T \bar{\gamma}_R^N(X^N(0),T).$$

For the limit system, define the analogous quantities, with the N dropped. If there is no rate R restriction, we drop the subscript R. We also suppose that (with little loss of generality)

$$\sup_N E|X^{1,N}(0)|^2 < \infty. \tag{7.1}$$

In section 3 it was shown that, for the discounted cost problem and large enough R, we can get as close to optimality as we wish. The proof in Theorem 3.3 used the fact that the discounting implied that we need concern ourselves only with a finite time interval. The proof is more subtle for the ergodic cost problem and is given in the next section.

The results in [23] will apply if we have tightness of the doubly indexed (both t and N are indices now) set of processes

$$\left\{X^N(t+\cdot), B^N(t+\cdot) - B^N(t), F^{1,N}(t+\cdot) - F^{1,N}(t); N, t\right\}. \tag{7.2}$$

The tightness holds for the set of $F^{1,N}(t+\cdot) - F^{1,N}(t)$ processes by the assumption on boundedness of the derivative. The set $\{W^{i,N}(S^{i,N}(t+\cdot)) - W^{i,N}(S^{i,N}(t); N, t\}$ is tight due to the independence properties of the interarrival intervals, (2.2), the weak convergence of the $S^{i,N}(t+\cdot) - S^{i,N}(t)$, as $N \to \infty$ and for any sequence t, and the use of the criterion (2.14), (2.15).

A standard Liapunov function argument (using the Liapunov function $|X^{1,N}|^2$) and the "R-derivative" restrictions on the controls can be used to prove directly that

$$\sup_{t,N,F^{1,N}} E\left|X^{1,N}(t)\right|^2 < \infty. \tag{7.3}$$

Here, the sup is over the $F^{1,N}$ which satisfy the R-derivative restriction. Then, tightness can be shown for the set of $\tilde{D}^{i,N}(t+\cdot) - \tilde{D}^{i,N}(t)$ processes by a direct application of the criterion (2.14), (2.15) and the use of (7.3) to bound the expectation of the Doob–Meyer processes associated with $\tilde{D}^{i,N}(t+\cdot) - \tilde{D}^{i,N}(t)$. The proof of the tightness of the doubly indexed sequence $\{X^{i,N}(t+\cdot); N, t\}$ is then the same as the proof of tightness of $\{X^{i,N}(\cdot), t\}$, where the initial conditions vary over a tight set (the $X^{0,N}(t)$ are bounded by B_0^+).

Given the tightness of (7.2) and the nondegeneracy of the limit system (3.2) (the set of driving Wiener processes is nondegenerate; in fact, the components are mutually independent with positive variances), the following results follow by a direct application of the results and ideas in [23]:

$$\bar{\gamma}_R^N(X^N(0),T) \to \bar{\gamma}_R, \tag{7.4}$$

as $T \to \infty$ and $N \to \infty$ in any way at all, where $\bar{\gamma}_R$ is the infimum of the costs for the limit system over controls with derivatives bounded by R, and it does not depend on the initial condition.

Furthermore, for any $\epsilon > 0$,

$$\lim_{N,T} P\left\{\frac{\mathcal{C}^N(X^N(0),T,F^{1,N})}{T} \le \bar{\gamma}_R - \epsilon\right\} = 0, \tag{7.5}$$

where N, T can go to their limits in any way at all, and $F^{1,N}(\cdot)$ is an arbitrary sequence of controls. There is a converse to (7.5) which says that a good control for the limit system is a good control for the physical system. Given $\epsilon > 0$, let $F^{\epsilon,1}(\cdot)$ be an ϵ-optimal control with smooth derivative $u^\epsilon(\cdot)$ and an adaptation $F^{\epsilon,1,N}(\cdot)$ to the physical system such that

$$\lim_{N,T} P\left\{\frac{\mathcal{C}^N(X^N(0),T,F^{\epsilon,1,N})}{T} \ge \bar{\gamma}_R + 2\epsilon\right\} = 0, \tag{7.6}$$

The results of the next section imply that we can replace $\bar{\gamma}_R$ in (7.5) and (7.6) by $\bar{\gamma}$.

The control $u^\epsilon(\cdot)$ can be adapted for use on the physical system in many ways, for large N. For example, by rejecting an arrival of class 1 at t with probability (conditioned on the past system data) $u^\epsilon(X^N(t))/[\lambda^{1,N}\sqrt{N}]$. Alternatively, we need not have the rejection choices being random, provided that $\sqrt{N}$ times the number rejected when the state is "near" x converges to $u^\epsilon(x)$ as $N \to \infty$.

Comments on the controls. Numerical data show that the derivative $\dot{F}(t) = u(t)$ of the optimal control takes either the value R or zero, with the regions separated by a piecewise linear or nearly linear switching curve. One applies this control to the physical system as in the last paragraph. (This procedure is asymptotically equivalent to rejecting all arrivals when the state is above the switching curve.) Equation (7.6) holds for such discontinuous controls as well. This is important in applications since such controls are easily implemented. Numerical data show that the switching curves converge nicely to piecewise smooth (or even linear) curves as $R \to \infty$. (7.6) holds for this curve a well. Then we reject all arrivals of class 1 when the state is above the switching curve. Analogous remarks hold for the discounted cost problem.

Comment. Note that both (7.5) and (7.6) deal with pathwise average costs, not with average costs. Since any application is a single realization, the convergence of pathwise average costs is more important than the convergence of expectations. The inequalities (7.5) and (7.6) say that for large N, the optimal controls for the physical problem are (asymptotically) only negligibly better than the use of a nice almost optimal control for the limit system.

Finally, we simply note without further comment that the methods in [20, 22, 23] can be adapted to prove that $\lim_{N,\beta\to 0} \beta V_\beta^N(X^N(0)) = \bar{\gamma}$.

8. The ergodic cost problem: The basic model: Arbitrary controls.

Now, return to the problem of bounded derivative controls. We will show that we can approximate any optimal or nearly optimal control by a control which has a "derivative" bounded by R, for large enough R.

THEOREM 8.1.

$$\lim_R [\bar\gamma - \bar\gamma_R] = 0. \tag{8.1a}$$

$$\lim_R \limsup_N \left[\bar\gamma^N(x) - \bar\gamma_R^N(x)\right] = 0. \tag{8.1b}$$

Proof. A detailed outline of the steps will be given. Unlike as in Theorem 3.3, we cannot restrict ourselves to a finite interval. We need to show that for any $\delta > 0$, there is $R_\delta < \infty$ such that there are δ-optimal controls for both the physical and the limit system with bounded rate R_δ.

The development proceeds in several steps. The steps will be outlined (informally to save space) for the physical system. The details are a little simpler for the limit system.

1. Given $\epsilon > 0$, show that there is a $B_\epsilon < \infty$ such that the optimal cost will change by no more than ϵ if we do not reject when $X^{1,N}(t) < -B_\epsilon$.

2. Let $\epsilon > 0$. Allowing only controls which do not reject if $X^{1,N}(t) < -B$, for some given $0 < B < \infty$, show that there is $K_\epsilon < \infty$ such that if we further restrict the controls such that the increments $F^{1,N}(n+1) - F^{1,N}(n)$ are at most K_ϵ for all n, N, then the optimal cost will change by no more than ϵ.

3. Let $\epsilon > 0$. Allowing only controls satisfying the restrictions of the first two steps for some finite B, K, show that there is $R_\epsilon < \infty$ such that the optimal cost will change by at most ϵ if we further restrict the controls to have maximum "derivative" R_ϵ.

Step 1 is the least difficult to accept even without a proof, since it is quite reasonable that there is a $B < \infty$ such that an optimal or nearly optimal control that would not reject if $X^{1,N}(t) \le -B$. The proof is a formalization of the following idea. Given a control $F^{1,N}(\cdot)$ and a $B > 0$, define another control $F_B^{1,N}(t) \le F^{1,N}(t)$, where $F_B^{1,N}(t)$ is as close as possible to $F^{1,N}(t)$, but acts only when $X^{1,N}(t) \ge -B$. For large B, the change in $X^{0,N}(\cdot)$ is slight. To save space, we concentrate on the outline for the other steps.

Thus, we start by supposing that there is $0 < B < \infty$ such that there are no rejections if $X^{1,N}(t) \le -B$. We will show that, given $\epsilon > 0$, there is $K_\epsilon < \infty$, such that we lose less than ϵ in the cost if we restrict the control to satisfy $F^{1,N}(n+1) - F^{1,N}(n) \le K_\epsilon$ for all N, n, ω.

Because we do not reject if $X^{1,N}(t) \le -B$, a Liapunov function argument can be used to get that there is $C < \infty$ such that

$$\sup_{N,t,F^{1,N}} E\left|X^{1,N}(t)\right|^2 \le C. \tag{8.2}$$

Also, the same $-B$ restriction and (8.2) can be used to show that

$$\sup_{n,N,F^{1,N}} E\left[F^{1,N}(n+1) - F^{1,N}(n)\right]^2 < \infty. \tag{8.3}$$

The sup in (8.2) is over all controls satisfying our $-B$ restriction. The proof of (8.3) computes a worst case on each interval, which is a control taking $X^{1,N}(n)$ satisfying only (8.2) to $-B$ as quickly as possible, then keeping it there until the end of the interval, and repeating on the next interval, etc. The uniform mean square boundedness of the part due to keeping $X^{1,N}(\cdot)$ at $-B$ on $[n, n+1]$ follows from the reflection mapping and the mean square bounds on the martingales driving (2.11b). For the reflection mapping and the Lipschitz continuity of the reflection term as a function of the driving processes, see [8], [7, Proposition 2.1].

Given any $F^{1,N}(\cdot)$ satisfying our restriction, we proceed to approximate it by bounding the increments by K. The approximation will be denoted by $F_K^{1,N}(\cdot)$, and the associated processes denoted by $X_K^N(\cdot)$. Define $F_K^{1,N}(\cdot)$ such that it satisfies the restriction $F_K^{1,N}(n+1) - F_K^{1,N}(n) \leq K$, it is no greater than $F^{1,N}(\cdot)$, and tries to keep $X_K^{1,N}(\cdot)$ as close as possible to $X^{1,N}(\cdot)$.

We always have $X_K^{1,N}(t) \geq X^{1,N}(t)$ and hence $X_K^{0,N}(t) \geq X^{0,N}(t)$. It is not hard to see that, for large enough K, $X_K^{1,N}(\cdot)$ will repeatedly catch up to and equal $X^{1,N}(\cdot)$. We can decompose time into successive intervals where $X^{1,N}(t) < X_K^{1,N}(t)$ and where $X^{1,N}(t) = X_K^{1,N}(t)$. The key to the proof of step 2 is the observation that, as $K \to \infty$, a larger percentage of time will be taken up by the latter intervals. More precisely, for any $T_0 < \infty$, it can be shown that

$$\lim_K \limsup_N \sup_{t,F^{1,N}} P\left\{X^{1,N}(s) \neq X_K^{1,N}(s) \text{ for some } s \in [t, t+T_0]\right\} = 0. \tag{8.4}$$

Equation (8.4) follows from the observations made before it. Choose the control $F_K^{1,N}(\cdot)$ as described. Then, starting at time $t-k$ for large k, the probability that $X_K^{1,N}(\cdot)$ catches up to $X^{1,N}(\cdot)$ and equals it on $[t, t+T_0]$ goes to unity as $K \to \infty$.

Note that if $X_K^{0,N}(t) = 0$, then $X^{0,N}(t) = 0$. We next bound the "return times" to the boundary $x^0 = 0$. Indeed, it can be shown that

$$\lim_{T\to\infty} \limsup_N \sup_{t,F_K^{1,N},K} \sup_\omega P\left\{X_K^{0,N}(t+s) \neq 0, \text{ for some } s \leq T \middle| \text{data to } t\right\} = 0. \tag{8.5}$$

This can be shown by a weak convergence argument, using the fact that it holds for the limit process, as follows. The worst case for proving (8.5) is where there is no control since the control only decreases $X^{0,N}(t)$. Thus, suppose that there are $\rho > 0$, t_n and $N_n \to \infty, T_n \to \infty$ such that (no control)

$$\lim_n \sup_\omega P\left\{X^{0,N_n}(t_n+s) \neq 0, \text{ for some } s \leq T_n \middle| \text{data to } t_n\right\} \geq \rho. \tag{8.6a}$$

We will show a contradiction to (8.6a). Actually, it is more direct to show that the assertion

$$\lim_n \sup_\omega P\left\{Y^{0,N_n}(t_n+T_n) - Y^{0,N_n}(t_n) = 0 \middle| \text{data to } t_n\right\} \geq \rho. \tag{8.6b}$$

is false. The falsity of (8.6b) implies the falsity of (8.6a).

A Liapunov function argument using (7.1) and the fact that there is no control can be used to prove that

$$\sup_n E|X^{1,N_n}(t_n)|^2 < \infty. \tag{8.7}$$

Now, extract a weakly convergent subsequence of $X^{N_n}(t_n + \cdot)$, and note that its limit $X(\cdot)$ satisfies (3.2). The distribution of $X^1(0)$ depends on the selected convergent subsequence. But, due to (8.7), $E|X^1(0)|^2$ is bounded uniformly in the selected convergent subsequence. Using this last fact, the properties of (3.2) and the weak convergence now imply that (8.6b) cannot hold unless $\rho = 0$. Now note that (a key point) if $X_K^{0,N}(t) = 0$ and $X^{1,N}(t) = X_K^{1,N}(t)$, then the two processes start again at t with equal initial values.

The above results imply the following. For any $\delta > 0$, with a probability arbitrarily close to one, the fraction of time that $|X^{0,N}(t) - X_K^{0,N}(t)| \geq \delta$ on any time interval goes to zero as $K \to \infty$, uniformly in the time interval and in (large) N. This implies that the change in the $k(\cdot)$ part of the cost can be made as small as desired by making K large enough. By construction, $F^{1,N}(t) \geq F_K^{1,N}(t)$, hence the control cost is no greater for the approximating control. We omit the details of the fact that

$$E[F_K^{0,N}(T) - F^{0,N}(T)]/T$$

can be made as small as desired by making K large. But it can be proved by a weak convergence argument and the facts established above.

Thus for large enough K, we lose as little as desired by restricting $F^{1,N}(\cdot)$ such that $F^{1,N}(n+1) - F^{1,N}(n) \leq K$ for all N, n. This completes step 2.

Now, we turn to step 3 and make a few comments concerning the $k(\cdot)$ component of the cost. Given a control $F^{1,N}(\cdot)$ satisfying the restrictions of steps 1 and 2 (with constants B and K, resp.), find a suitable approximation with a bounded "derivative." Let R denote the derivative bound. Define a control $F_R^{1,N}(\cdot)$ with derivative bounded by R, such that $F_R^{1,N}(t) \leq F^{1,N}(t)$, but where the associated process $X_R^{1,N}(\cdot)$ is allowed to catch up with $X^{1,N}(\cdot)$ when possible. It will catch up repeatedly, for large enough R. This is because the maximum number of rejects on any time interval of unit length is $2K/\sqrt{N}$. Since K is bounded and R large, except for an arbitrarily small time subinterval the number of rejects on any time interval $[n, n+1]$ can be made as close as desired to what is needed, uniformly in N, n. Additionally, $|X^{1,N}(t) - X_R^{1,N}(t)|$ is uniformly (in N, t) bounded. Thus, the values of $X^{1,N}(t)$ and $X_R^{1,N}(t)$ will be arbitrarily close when $X_R^{0,N}(t)$ (hence, $X^{0,N}(t)$) hits zero, or very shortly thereafter (at most a time $K/R + O(1/\sqrt{N})$ later).

Note that the approximation problem is more subtle than in step 2, since we cannot guarantee that $X_R^{1,N}(\cdot)$ will equal $X^{1,N}(\cdot)$ on longer and longer intervals. For example, if $F^{1,N}(\cdot)$ jumps periodically, or if the limit is singular with respect to Lebesgue measure.

The following properties can be proved. First, by a Liapunov function argument, it can be shown that

$$\limsup_N \sup_{t,R,F_R^{1,N}} E\left|X_R^{1,N}(t)\right|^2 < \infty.$$

Using this, it can be shown that

$$\limsup_N \sup_{n,R,F_R^{1,N}} E \sup_{n \leq s \leq n+1} \left|X_R^{1,N}(s)\right|^2 < \infty, \tag{8.8}$$

with a similar estimate holding for the $X^{1,N}(\cdot)$. The above comments imply that

$$\lim_R \limsup_N \sup_\tau E \sup_{t \leq T} \int_\tau^{\tau+t} \left|X^{1,N}(s) - X_R^{1,N}(s)\right| ds = 0, \tag{8.9}$$

for any $T < \infty$, and where τ are stopping times. Now use an argument based on recurrence to $X^{0,N}(\cdot)$ to zero analogous to what was done in step 2 to get that the

$k(\cdot)$-costs are close for large R. Obviously, the component of the cost due to $F_R^{1,N}(\cdot)$ is no greater than that due to $F^{1,N}(\cdot)$. Again, by a weak convergence argument, it can be shown that the overflow costs also converge, and the details are omitted.

9. Data. Some typical data is given in Table 1 below. The cost function is $c_0 EX^0(1) + EF^1(1) + 5EF^0(1)$, all stationary values. $B_+^0 = 6.4$, and larger values made little difference. The individual components of the cost function are tabulated, and we write $EF^0(1) = 0$ if it is less than 10^{-4}. The fraction of lost class 1 customers is $EF^1(1)/[\lambda_1\sqrt{N}]$, so it depends on N. The tables indicate the potential tradeoffs between the time gained for class 0 and the lost class 1 customers.

TABLE 1.
Components of optimal cost for limit system.

Table A: $\mu_1 = .5, \mu_0 = 1, \lambda_1 = 1, \lambda_0 = 1, \sigma_1^2 = 1, \sigma_0^2 = 1, b = 2.5$							
	$EX^0(1)$	$EF^1(1)$	$EF^0(1)$	% savings	% Rejection of class 1		
					N=100	N=10^3	N=10^4
no cont.	.555	0	.0032	na	0	0	0
$c_0 = 5$	.267	.489	0	52%	4.89	1.55	.489
$c_0 = 10$	.184	1.01	0	67%	1.01	.319	.101

Table B: $\mu_1 = .25, \mu_0 = .25, \lambda_1 = .5, \lambda_0 = 1, \sigma_1^2 = 1, \sigma_0^2 = 1, b = 2.5$							
	$EX^0(1)$	$EF^1(1)$	$EF^0(1)$	% savings	% Rejection of class 1		
					N=100	N=10^3	N=10^4
no cont.	1.57	0	.002	na	0	0	0
$c_0 = 5$	.424	1.463	0	73%	1.463	.386	.1463
$c_0 = 10$	.299	2.34	0	81%	2.34	.740	.234

Table C: $\mu_1 = 1, \mu_0 = 1, \lambda_1 = 1, \lambda_0 = 1, \sigma_1^2 = 1, \sigma_0^2 = 3, b = 2.5$							
	$EX^0(1)$	$EF^1(1)$	$EF^0(1)$	% savings	% Rejection of class 1		
					N=100	N=10^3	N=10^4
no cont.	.853	0	.004	na	0	0	0
$c_0 = 5$	.557	.750	0	35%	.750	.237	.0750
$c_0 = 10$	.415	1.77	0	51%	1.77	.316	.177

In the above examples and in all other cases that we tested numerically, a considerable saving in the global performance is obtained. The price paid for this saving is the rejection of class 1 customers. However, the fraction of rejected class 1 customers is acceptable for large N. As is seen in the tables, it is of the order of 1% for $N = 1000$, and less than 0.5% for $N = 10000$. We thus conclude that for large systems operating at a heavy traffic regime, we may gain considerably in overall performance of the system at the cost of rejection of a very small fraction of GP calls.

ON CONCEPTS OF CONTROLLABILITY FOR DETERMINISTIC AND STOCHASTIC SYSTEMS*

AGAMIRZA E. BASHIROV[†] AND NAZIM I. MAHMUDOV[†]

Abstract. The new necessary and sufficient conditions, which are formulated in terms of convergence of a certain sequence of operators involving the resolvent of the negative of the controllability operator, are found for deterministic linear stationary control systems to be completely and approximately controllable, respectively. These conditions are applied to study the S-controllability (a property of attaining an arbitrarily small neighborhood of each point in the state space with a probability arbitrarily close to one) and C-controllability (the S-controllability fortified with some uniformity) of stochastic systems. It is shown that the S-controllability (the C-controllability) of a partially observable linear stationary control system with an additive Gaussian white noise disturbance on all the intervals $[0,T]$ for $T>0$ is equivalent to the approximate (complete) controllability of its deterministic part on all the intervals $[0,T]$ for $T>0$.

Key words. complete controllability, approximate controllability, stochastic controllability, deterministic linear system, partially observable linear system

1. Introduction.

Theory of controllability originates from the famous work [1] done by Kalman. At present this theory is almost complete for deterministic linear control systems (see, for example, Curtain and Pritchard [2]; Curtain and Zwart [3]; Balakrishnan [4]; Bensoussan et al. [5]; Zabczyk [6]).

The natural extension of the complete and approximate controllability concepts to stochastic control systems is meaningless. In Bashirov [7] and Bashirov and Kerimov [8] these concepts were weakened and, for stochastic control systems, the concept of S-controllability was defined. Briefly, an S-controllable stochastic control system is a system attaining an arbitrarily small neighborhood of each point in the state space with a probability arbitrarily close to one. We also found it useful to define the concept of C-controllability for stochastic control systems as S-controllability fortified with some uniformity.

The main results of [7, 8] concern a partially observable linear stationary control system with an additive Gaussian white noise disturbance (the system (S)) and its deterministic part (the system (D)). From the results of [8] (the necessity part of Theorems 4 and 5(b)), it follows that if the system (S) is C-controllable (S-controllable) on the interval $[0,T]$, where $T>0$ is fixed, then the system (D) is completely (approximately) controllable on the same interval $[0,T]$. A sufficient condition of C-controllability (which is a sufficient condition of S-controllability as well) for the system (S) on the fixed interval $[0,T]$ is also found in [8]. This sufficient condition is based on Lemma 7 in [8] which is proved under the complete controllability condition of the system (D) on all the intervals $[0,t]$ for $0<t\le T$. Thus, more precisely than in [8], this sufficient condition is the complete controllability of the system (D) on all the intervals $[0,t]$ for $0<t\le T$.

[†]Department of Mathematics, Eastern Mediterranean University, Gazimagusa, Mersin 10, Turkey, and Institute of Cybernetics, Azerbaijan Academy of Sciences, F. Agayev St. 9, Baku 370141, Azerbaijan (aga.as@mozart.emu.edu.tr, nazim.as@mozart.emu.edu.tr).

A discussion of an example presented in [8] leads us to expect that a weaker sufficient condition of S-controllability on the interval $[0, T]$ for the system (S) could exist as the approximate controllability of the system (D) on all the intervals $[0, t]$ for $0 < t \leq T$. This was conjectured in [7, 8], wherein this conjecture is settled positively.

Discussing the S- and C-controllability concepts, we found the new necessary and sufficient conditions for deterministic linear stationary control systems to be completely and approximately controllable. These conditions are formulated in terms of uniform and strong convergence of a certain sequence of operators involving the resolvent of the negative of the controllability operator and clearly distinguish complete and approximate controllabilities.

Studying sources about theory of controllability, we did not find the analogues of these conditions which prompted us to consider them as new. For convenience, we call the above-mentioned conditions the resolvent conditions of complete and approximate controllabilities.

A verification of the resolvent conditions for a concrete control system requires a computation of the respective resolvent and then studying the convergence of the above-mentioned sequence involving this resolvent. This is illustrated in the examples of controlled one-dimensional heat and wave equations. We expect that the resolvent conditions will play a significant role in theoretical investigations of theory of controllability because after a first application, they have allowed us to settle the conjecture mentioned above.

2. General notations. In this paper X and Y are real separable Hilbert spaces. R^k denotes the k-dimensional real Euclidean space. As usual, $R^1 = R$. The closure of the set D is denoted by $\overline{D}$. The space of all linear bounded operators from X to Y is denoted by $\mathcal{L}(X, Y)$. The brief notation $\mathcal{L}(X) = \mathcal{L}(X, X)$ is used as well. A^* denotes the adjoint of the operator A. The trace of the operator A is denoted by $\operatorname{tr} A$. If $A \in \mathcal{L}(X)$ is self-adjoint and $\langle h, Ah \rangle \geq 0$ (respectively, $\langle h, Ah \rangle \geq c\|h\|^2$, where $c = \text{const.} > 0$) for all $h \in X$, then we write $A \geq 0$ (respectively, $A > 0$), where $\langle \cdot, \cdot \rangle$ is an inner product and $\|\cdot\|$ is a norm. For $A \geq 0$, the square root of A is denoted by $A^{1/2}$. The symbol I denotes an identity operator. Zero operator, zero vector, and the number zero are denoted by 0; it is clear which is meant from the context.

It is always supposed that two time moments are given. The initial time moment is identified with zero and is fixed. The terminal moment is denoted by T $(T > 0)$ and is considered variable. The notation $\mathbf{T}$ is used for the finite time interval $[0, T]$. $L_2(\mathbf{T}, X)$ and $L_2(0, T; X)$ denote the space of equivalence classes of all functions from $\mathbf{T} = [0, T]$ to X that are Lebesgue measurable and square integrable with respect to the Lebesgue measure. As usual, we use the brief notation $L_2(0, T) = L_2(0, T; R)$. The notation $\Delta = \{(t, s) : 0 \leq s \leq t \leq T\}$ is used for the triangular set over $\mathbf{T}$. $B_2(\Delta, \mathcal{L}(X, Y))$ denotes the class of all $\mathcal{L}(X, Y)$-valued functions on Δ that are strongly measurable and square integrable with respect to the Lebesgue measure on Δ (see, for example, [2, 3]).

All integrals of vector-valued functions are considered in the Bochner sense. For probability, expectation, and conditional expectation, the notations $\mathbf{P}$, $\mathbf{E}$, and $\mathbf{E}(\cdot \,|\, \cdot)$, respectively, are used. $\operatorname{cov}(x, y)$ is the covariance operator of the random variables x and y. The brief notation $\operatorname{cov} x = \operatorname{cov}(x, x)$ is used as well. The integrals of operator-valued functions (except stochastic integrals) are in the strong Bochner sense.

3. Main definitions. Consider a control system on $\mathbf{T}$. Let x_t^u be its (random or not) state value at time $t \in \mathbf{T}$ corresponding to the control u taken from the set of the admissible controls U. If the control system under consideration is stochastic, then by $\mathcal{F}^u$ we denote the smallest σ-algebra generated by the observations on the time interval $\mathbf{T}$ corresponding to the control u. Suppose that X is the state space. For $0 \le \varepsilon < \infty$ and for $0 \le p \le 1$, introduce the sets

$$D = \{x_T^u : u \in U\}, \tag{1}$$

$$S(\varepsilon, p) = \big\{h \in X : \exists u \in U\ \mathbf{P}\big(\|\mathbf{E}(x_T^u|\mathcal{F}^u) - h\|^2 > \varepsilon\big) \le 1 - p\big\}, \tag{2}$$

$$C(\varepsilon, p) = \big\{h \in X : \exists u \in U\ h = \mathbf{E}x_T^u,\ \mathbf{P}\big(\|\mathbf{E}(x_T^u|\mathcal{F}^u) - h\|^2 > \varepsilon\big) \le 1 - p\big\}. \tag{3}$$

Definition 1. *A deterministic control system will be called*

(a) D^c-controllable on $\mathbf{T}$ *if* $D = X$;

(b) D^a-controllable on $\mathbf{T}$ *if* $\overline{D} = X$.

It is clear that the D^c- and D^a-controllabilities are the well-known complete and approximate controllabilities for deterministic control systems, respectively. Originally, the D^c-controllability was introduced in Kalman [1] as a concept for finite dimensional deterministic control systems, so the natural extension of this concept is too strong for many infinite dimensional control systems. Therefore, the D^a-controllability was introduced as a weakened version of the D^c-controllability. It is also clear that neither D^c- nor D^a-controllabilities can be a property of stochastic control systems, so there is a need to further weaken these concepts in order to extend them to stochastic control systems.

The following definition will be used as a step in discussing the main concepts of controllability for stochastic systems.

Definition 2. *Given* $\varepsilon \ge 0$ *and* $0 \le p \le 1$, *a control system will be called*

(a) $S^c_{\varepsilon,p}$-controllable on $\mathbf{T}$ *if* $S(\varepsilon, p) = X$;

(b) $S^a_{\varepsilon,p}$-controllable on $\mathbf{T}$ *if* $\overline{S(\varepsilon, p)} = X$;

(c) $C^c_{\varepsilon,p}$-controllable on $\mathbf{T}$ *if* $C(\varepsilon, p) = X$;

(d) $C^a_{\varepsilon,p}$-controllable on $\mathbf{T}$ *if* $\overline{C(\varepsilon, p)} = X$;

(e) $S^0_{\varepsilon,p}$-controllable on $\mathbf{T}$ *if* $0 \in S(\varepsilon, p)$.

The geometric interpretation of the $S^c_{\varepsilon,p}$-controllability ($S^a_{\varepsilon,p}$-controllability) is as follows. If a control system with the initial state x_0 is $S^c_{\varepsilon,p}$-controllable ($S^a_{\varepsilon,p}$-controllable) on $\mathbf{T}$, then with probability not less than p it can pass from x_0 for the time T into the $\sqrt{\varepsilon}$-neighborhood of an arbitrary point in the state space (in a set that is dense in the state space). The geometric interpretation of the $C^c_{\varepsilon,p}$- and $C^a_{\varepsilon,p}$-controllabilities differs from the same of the $S^c_{\varepsilon,p}$- and $S^a_{\varepsilon,p}$-controllabilities since among the controls, with the help of which the $\sqrt{\varepsilon}$-neighborhood of any point h is achieved, there exists one with a property that the expectation of the target state, corresponding to this control, coincides with h. Obviously, a $C^c_{\varepsilon,p}$-controllable ($C^a_{\varepsilon,p}$-controllable) control system is $S^c_{\varepsilon,p}$-controllable ($S^a_{\varepsilon,p}$-controllable), but the converse is not true.

The smaller ε is and the larger p is for a control system, the more controllable it is; i.e., it is possible to hit into a smaller neighborhood with a higher probability. One can observe that all control systems are $S^c_{\varepsilon,p}$-, $S^a_{\varepsilon,p}$-, $C^c_{\varepsilon,p}$-, and $C^a_{\varepsilon,p}$-controllable on any interval with $\varepsilon \ge 0$ and $p = 0$ or $\varepsilon = \infty$ and $0 \le p \le 1$, if we admit ∞ as a value for ε. At the same time, it is clear that a D^c-controllable (D^a-controllable) deterministic system is $S^c_{0,1}$- and $C^c_{0,1}$-controllable ($S^a_{0,1}$- and $C^a_{0,1}$-controllable) with parameters $\varepsilon = 0$ and $p = 1$ since, for deterministic systems, $D = S(0, 1) = C(0, 1)$.

Also, each kind of controllability from Definition 2 with a smaller ε and a greater p implies the same kind of controllability with a greater ε and a smaller p.

Summarizing, we can give the following easy necessary and sufficient conditions for the D^c- and D^a-controllabilities.

PROPOSITION 1. *For a deterministic control system the following three conditions are equivalent*:

(a) D^c*-controllability on* $\mathbf{T}$;

(b) $S^c_{\varepsilon,p}$*-controllability on* $\mathbf{T}$ *for all* $\varepsilon \geq 0$ *and for all* $0 \leq p \leq 1$;

(c) $C^c_{\varepsilon,p}$*-controllability on* $\mathbf{T}$ *for all* $\varepsilon \geq 0$ *and for all* $0 \leq p \leq 1$.

PROPOSITION 2. *For a deterministic control system the following three conditions are equivalent*:

(a) D^a*-controllability on* $\mathbf{T}$;

(b) $S^a_{\varepsilon,p}$*-controllability on* $\mathbf{T}$ *for all* $\varepsilon \geq 0$ *and for all* $0 \leq p \leq 1$;

(c) $C^a_{\varepsilon,p}$*-controllability on* $\mathbf{T}$ *for all* $\varepsilon \geq 0$ *and for all* $0 \leq p \leq 1$.

Excepting the limit values $\varepsilon = 0$ and $p = 1$ from the above-mentioned necessary and sufficient conditions for the D^c- and D^a-controllabilities, one can obtain the weakened versions of these concepts. For a moment call a given stochastic system

(a) S^c*-controllable on* $\mathbf{T}$ if it is $S^c_{\varepsilon,p}$-controllable on $\mathbf{T}$ for all $\varepsilon > 0$ and for all $0 \leq p < 1$;

(b) S^a*-controllable on* $\mathbf{T}$ if it is $S^a_{\varepsilon,p}$-controllable on $\mathbf{T}$ for all $\varepsilon > 0$ and for all $0 \leq p < 1$;

(c) C^c*-controllable on* $\mathbf{T}$ if it is $C^c_{\varepsilon,p}$-controllable on $\mathbf{T}$ for all $\varepsilon > 0$ and for all $0 \leq p < 1$;

(d) C^a*-controllable on* $\mathbf{T}$ if it is $C^a_{\varepsilon,p}$-controllable on $\mathbf{T}$ for all $\varepsilon > 0$ and for all $0 \leq p < 1$.

In [7, 8] it is shown that the concepts of S^c- and S^a-controllabilities are equivalent. It will also be shown that for partially observable linear stationary control systems with additive Gaussian white noise disturbance the C^a-controllability on all the intervals $[0, T]$ with $T > 0$ is equivalent to the S^c-and S^a-controllabilities on all the intervals $[0, T]$ with $T > 0$. Thus, we can define two basic and one additional concepts of controllability for stochastic systems.

DEFINITION 3. *A control system will be called*

(a) S-controllable on $\mathbf{T}$ *if it is* $S^c_{\varepsilon,p}$*-controllable on* $\mathbf{T}$ *or, equivalently,* $S^a_{\varepsilon,p}$*-controllable on* $\mathbf{T}$ *for all* $\varepsilon > 0$ *and for all* $0 \leq p < 1$;

(b) C-controllable on $\mathbf{T}$ *if it is* $C^c_{\varepsilon,p}$*-controllable on* $\mathbf{T}$ *for all* $\varepsilon > 0$ *and for all* $0 \leq p < 1$;

(c) S^0-controllable on $\mathbf{T}$ *if it is* $S^0_{\varepsilon,p}$*-controllable on* $\mathbf{T}$ *for all* $\varepsilon > 0$ *and for all* $0 \leq p < 1$.

Geometrically, the S-controllability can be interpreted as follows: an S-controllable on $\mathbf{T}$ control system can attain for the time T an arbitrarily small neighborhood of each point in the state space with a probability arbitrarily close to one. The C-controllability is the S-controllability fortified with some uniformity. The S^0-controllability is useful in discussing S- and C-controllabilities.

Finally, notice that the abbreviations D, S, C, c, and a in the previously introduced controllability concepts mean deterministic, stochastic, combined, complete, and approximate, respectively.

4. Preliminaries.

In this paper it is always supposed that A is the infinitesimal generator of a strongly continuous semigroup $\mathcal{U}$, $B \in \mathcal{L}(Y, X)$, $C \in \mathcal{L}\big(X, R^k\big)$; x_0 is a Gaussian random variable with $\operatorname{cov} x_0 = P_0$; m and n are X- and R^k-valued Wiener processes, respectively; $n_0 = 0$, $m_0 = 0$, $\mathbf{E}n_t = 0$, $\mathbf{E}m_t = 0$, $\operatorname{cov} n_t = It$, $\operatorname{cov} m_t = Mt$, M is a nuclear operator on X; and x_0, n, m are mutually independent. Let $f \in L_2(\mathbf{T}, X)$ and consider the linear partially observable stochastic control system

$$\begin{cases} dx_t^u = (Ax_t^u + Bu_t + f_t)dt + dm_t, \ 0 < t \le T, \ x_0^u = x_0, \\ d\xi_t^u = Cx_t^u dt + dn_t, \ 0 < t \le T, \ \xi_0^u = 0, \end{cases} \tag{4}$$

where x, u, and ξ are state, control, and observation processes. Under the set U of admissible controls we consider the set of all controls in the linear feedback form

$$u_t = \bar{u}_t + \int_0^t K_{t,s}\, d\xi_s^u,$$

where $K \in B_2\big(\Delta, \mathcal{L}(R^k, Y)\big)$ and $\bar{u} \in L_2(\mathbf{T}, Y)$.

To the system (4) one can associate two control systems. The first is the deterministic control system

$$\frac{d}{dt} y_t^v = Ay_t^v + Bv_t + f_t, \ 0 < t \le T, \ y_0^v = y_0 = \mathbf{E}x_0, \tag{5}$$

where v is a control in $V = L_2(\mathbf{T}, Y)$. The second is the partially observable stochastic control system

$$\begin{cases} dz_t^w = (Az_t^w + Bw_t)dt + dm_t, \ 0 < t \le T, \ z_0^w = z_0 = x_0 - \mathbf{E}x_0, \\ d\eta_t^w = Cz_t^w dt + dn_t, \ 0 < t \le T, \ \eta_0^w = 0, \end{cases} \tag{6}$$

where w is a control in W consisting of all controls in the linear feedback form

$$w_t = \int_0^t K_{t,s}\, d\eta_s^w,$$

where $K \in B_2\big(\Delta, \mathcal{L}(R^k, Y)\big)$.

Note that solutions of the equations in (4), (5), and (6) are meant in the mild sense, i.e.,

$$\begin{aligned} x_t^u &= \mathcal{U}_t x_0 + \int_0^t \mathcal{U}_{t-s}(Bu_s + f_s)\, ds + \int_0^t \mathcal{U}_{t-s}\, dm_s, \ 0 \le t \le T, \\ y_t^v &= \mathcal{U}_t y_0 + \int_0^t \mathcal{U}_{t-s}(Bv_s + f_s)\, ds, \ 0 \le t \le T, \\ z_t^w &= \mathcal{U}_t z_0 + \int_0^t \mathcal{U}_{t-s} Bw_s\, ds + \int_0^t \mathcal{U}_{t-s}\, dm_s, \ 0 \le t \le T. \end{aligned}$$

Denote

$$\Gamma_{T-t} = \int_t^T \mathcal{U}_{T-s} BB^* \mathcal{U}_{T-s}^*\, ds, \ 0 \le t \le T. \tag{7}$$

For $0 \le t < T$, the operator Γ_{T-t} is called a controllability operator. One can see that $\Gamma_{T-t} \ge 0$ and, hence, the resolvent $R(\lambda, -\Gamma_{T-t}) = (\lambda I + \Gamma_{T-t})^{-1}$ is well defined for all $\lambda > 0$ and for all $0 \le t \le T$. If $\Gamma_{T-t} > 0$, then $R(\lambda, -\Gamma_{T-t})$ is defined for $\lambda = 0$ as well.

We will use the following operator Riccati equations:

$$\frac{d}{dt} Q_t + Q_t A + A^* Q_t - \lambda^{-1} Q_t BB^* Q_t = 0, \ 0 \le t < T, \ Q_T = I, \ \lambda > 0, \tag{8}$$

$$\frac{d}{dt}P_t - AP_t - P_tA^* - M + P_tC^*CP_t = 0,\ 0 < t \leq T,\ P_0 = \operatorname{cov} z_0. \tag{9}$$

LEMMA 1. *There exist the unique strongly continuous solutions* (*in scalar product sense*) Q^λ *and* P *of* (8) *and* (9), *respectively, satisfying* $Q_t^\lambda \geq 0$ *and* $P_t \geq 0$ *for all* $t \in \mathbf{T}$. *Moreover, the solution of* (8) *has the explicit form*

$$Q_t^\lambda = \lambda \mathcal{U}_{T-t}^* R(\lambda, -\Gamma_{T-t})\mathcal{U}_{T-t},\ 0 \leq t \leq T,\ \lambda > 0. \tag{10}$$

For the proof of existence and uniqueness part of this lemma, see [2]. For the proof of representation (10), see [8, 9].

Consider the linear regulator problem consisting of minimizing the cost functional

$$J(v) = \|y_T^v - h\|^2 + \lambda \int_0^T \|v_t\|^2\, dt, \tag{11}$$

where y^v is a state process, defined by (5); v is a control in $V = L_2(\mathbf{T}, Y)$; and $h \in X$ and $\lambda > 0$ are parameters.

LEMMA 2. *For given* $h \in X$ *and* $\lambda > 0$, *there exists a unique optimal control* v^λ *in* $L_2(\mathbf{T}, Y)$ *at which the functional* (11) *takes on its minimum value and*

$$v_t^\lambda = -B^*\mathcal{U}_{T-t}^* R(\lambda, -\Gamma_T)(\mathcal{U}_T y_0 - h + g) \textit{ almost everywhere (a.e.) on } \mathbf{T}, \tag{12}$$

$$y_T^{v^\lambda} - h = \lambda R(\lambda, -\Gamma_T)(\mathcal{U}_T y_0 - h + g), \tag{13}$$

where

$$g = \int_0^T \mathcal{U}_{T-t} f_t\, dt.$$

Proof. The existence and the uniqueness of an optimal control follows from a general theorem about linear regulator problems (see [2]). We will prove the formulae (12) and (13). By computing the variation of the functional (11), one can easily obtain

$$v_t^\lambda = -\lambda^{-1} B^* \mathcal{U}_{T-t}^* \left(y_T^{v^\lambda} - h\right) \text{ a.e. on } \mathbf{T}. \tag{14}$$

Using this in (5), we have

$$\begin{aligned} y_T^{v^\lambda} &= \mathcal{U}_T y_0 + \int_0^T \mathcal{U}_{T-t}\left(Bv_t^\lambda + f_t\right) dt \\ &= \mathcal{U}_T y_0 + g - \lambda^{-1} \int_0^T \mathcal{U}_{T-t} BB^* \mathcal{U}_{T-t}^* \left(y_T^{v^\lambda} - h\right) dt \\ &= \mathcal{U}_T y_0 + g - \lambda^{-1} \Gamma_T \left(y_T^{v^\lambda} - h\right). \end{aligned}$$

Hence,

$$\lambda y_T^{v^\lambda} = \lambda(\mathcal{U}_T y_0 + g) - \Gamma_T\left(y_T^{v^\lambda} - h\right),$$

which implies

$$(\lambda I + \Gamma_T) y_T^{v^\lambda} = \lambda(\mathcal{U}_T y_0 + g) + \Gamma_T h$$

and, consequently,

$$\begin{aligned} y_T^{v^\lambda} &= \lambda(\lambda I + \Gamma_T)^{-1}(\mathcal{U}_T y_0 + g) + (\lambda I + \Gamma_T)^{-1}(\lambda I + \Gamma_T - \lambda I)h \\ &= \lambda R(\lambda, -\Gamma_T)(\mathcal{U}_T y_0 + g - h) + h. \end{aligned}$$

Thus, (13) holds. Substituting (13) in (14), we obtain (12). The lemma is proven.

5. Resolvent conditions for D^c- and D^a-controllabilities. In this section, the necessary and sufficient conditions of D^c - and D^a -controllabilities are discussed.

THEOREM 1. *The following statements are equivalent*:

(1a) *the control system* (5) *is D^c-controllable on* $\mathbf{T}$;

(1b) *the complete controllability condition for the system* (5) *holds, i.e.,* $\Gamma_T > 0$;

(1c) $R(\lambda, -\Gamma_T)$ *converges as* $\lambda \to 0$ *in uniform operator topology*;

(1d) $R(\lambda, -\Gamma_T)$ *converges as* $\lambda \to 0$ *in strong operator topology*;

(1e) $R(\lambda, -\Gamma_T)$ *converges as* $\lambda \to 0$ *in weak operator topology*;

(1f) $\lambda R(\lambda, -\Gamma_T)$ *converges to zero operator as* $\lambda \to 0$ *in uniform operator topology.*

Proof. The equivalence (1a) ⇔ (1b) is well known. For the implication (1b) ⇒ (1c), suppose $\Gamma_T > 0$. Then for all $x \in X$ and for all $\lambda \geq 0$,

$$\langle x, (\lambda I + \Gamma_T)x\rangle \geq (\lambda + k)\|x\|^2,$$

where $k > 0$ is a constant. Therefore, for all $\lambda \geq 0$,

$$\|R(\lambda, -\Gamma_T)\| = \left\|(\lambda I + \Gamma_T)^{-1}\right\| \leq \frac{1}{\lambda + k} \leq \frac{1}{k}.$$

We obtain that $\|R(\lambda, -\Gamma_T)\|$ is bounded with respect to $\lambda \geq 0$. Furthermore,

$$\begin{aligned} \left\|R(\lambda, -\Gamma_T) - \Gamma_T^{-1}\right\| &= \left\|(\lambda I + \Gamma_T)^{-1} - \Gamma_T^{-1}\right\| \\ &= \left\|\Gamma_T^{-1}(\Gamma_T - \lambda I - \Gamma_T)(\lambda I + \Gamma_T)^{-1}\right\| \\ &\leq \lambda\left\|\Gamma_T^{-1}\right\| \left\|(\lambda I + \Gamma_T)^{-1}\right\| \\ &\leq \lambda k^{-2}. \end{aligned}$$

Thus, $R(\lambda, -\Gamma_T)$ converges to Γ_T^{-1} as $\lambda \to 0$ in uniform operator topology. The implications (1c) ⇒ (1d) ⇒ (1e) are obvious. The implication (1e) ⇒ (1f) follows from the boundedness of a weakly convergent sequence of operators. For the implication (1f) ⇒ (1b), suppose

$$\lambda\|R(\lambda, -\Gamma_T)\| = \lambda \left\|(\lambda I + \Gamma_T)^{-1}\right\| \to 0, \ \lambda \to 0.$$

Then $\lambda^{1/2} \left\|(\lambda I + \Gamma_T)^{-1/2}\right\| \to 0$ as $\lambda \to 0$. For sufficiently small $\lambda_0 > 0$, we can write

$$\lambda_0^{1/2} \left\|(\lambda_0 I + \Gamma_T)^{-1/2}\right\| \leq 1/\sqrt{2}.$$

Thus, for all $x \in X$ we have

$$\begin{aligned} \|x\|^2 &= \left\|\left(\lambda_0^{1/2}(\lambda_0 I + \Gamma_T)^{-1/2}\right)\left(\lambda_0^{-1/2}(\lambda_0 I + \Gamma_T)^{1/2}\right)x\right\|^2 \\ &\leq \frac{1}{2}\left\|\lambda_0^{-1/2}(\lambda_0 I + \Gamma_T)^{1/2}x\right\|^2 \\ &= \frac{1}{2}\left\langle \lambda_0^{-1}(\lambda_0 I + \Gamma_T)x, x\right\rangle, \end{aligned}$$

which implies

$$\left\langle \lambda_0^{-1}(\lambda_0 I + \Gamma_T)x, x \right\rangle \geq 2\|x\|^2$$

and, consequently,

$$\langle \Gamma_T x, x \rangle \geq \lambda_0 \|x\|^2.$$

Thus, $\Gamma_T > 0$. The theorem is proven.

THEOREM 2. *The following statements are equivalent*:

(2a) *the control system* (5) *is* D^a*-controllable on* $\mathbf{T}$;

(2b) *the approximate controllability condition for the system* (5) *holds, i.e., if* $B^*\mathcal{U}_t^* x = 0$ *for all* $t \in \mathbf{T}$*, then* $x = 0$;

(2c) $\lambda R(\lambda, -\Gamma_T)$ *converges to zero operator as* $\lambda \to 0$ *in strong operator topology*;

(2d) $\lambda R(\lambda, -\Gamma_T)$ *converges to zero operator as* $\lambda \to 0$ *in weak operator topology.*

Proof. The equivalence (2a) ⇔ (2b) is well known. For the implication (2c) ⇒ (2a), suppose $\lambda R(\lambda, -\Gamma_T) \to 0$ as $\lambda \to 0$ in strong operator topology. Consider arbitrary $h \in X$ and the functional (11) with this h. By (13), selecting λ sufficiently small, we can make $y_T^{v^\lambda}$ close to h, so the control system (5) is D^a-controllable. For the implication (2a) ⇒ (2c), let the control system (5) be D^a-controllable. Then for arbitrary $h \in X$, there exists a sequence $\{\bar{v}^i\}$ in $L_2(\mathbf{T}, Y)$ such that $\left\|y_T^{\bar{v}^i} - h\right\| \to 0$ as $i \to \infty$. We have

$$\left\|y_T^{v^\lambda} - h\right\|^2 \leq \left\|y_T^{v^\lambda} - h\right\|^2 + \lambda \int_0^T \left\|v_t^\lambda\right\|^2 dt \leq \left\|y_T^{\bar{v}^i} - h\right\|^2 + \lambda \int_0^T \left\|\bar{v}_t^i\right\|^2 dt,$$

where v^λ is the control at which the functional (11) takes on its minimum value. If $\varepsilon > 0$ is given, then we can make $\|y_T^{\bar{v}^i} - h\| < \varepsilon/\sqrt{2}$ for some sufficiently large i and then we can select $\delta > 0$ to be sufficiently small so that for all $0 < \lambda < \delta$,

$$\lambda \int_0^T \left\|\bar{v}_t^i\right\|^2 dt < \frac{\varepsilon^2}{2}.$$

Thus, $\left\|y_T^{v^\lambda} - h\right\| < \varepsilon$ for all $0 < \lambda < \delta$. By (13) and the arbitrariness of h, the convergence of $\lambda R(\lambda, -\Gamma_T)$ to zero operator is implied as $\lambda \to 0$ in strong operator topology. Finally, the equivalence (2c) ⇔ (2d) is a consequence of $\lambda R(\lambda, -\Gamma_T) \geq 0$. The theorem is proven.

The conditions (1f) and (2c) in Theorems 1 and 2 clearly distinguish the D^c- and D^a-controllabilities of the control system (5) showing that the distinction between them is in a kind of convergence of $\lambda R(\lambda, -\Gamma_T)$ to zero operator as $\lambda \to 0$. We call these conditions the resolvent conditions for the control system (5) to be D^c- and D^a-controllable, respectively.

An application of the resolvent conditions to a concrete system requires a computation of the respective resolvent and then a verification of the respective convergence. These are illustrated below in the examples of controlled one-dimensional heat and wave equations.

Example 1. Consider a controlled one-dimensional heat equation

$$\frac{\partial}{\partial t} y_{t,\theta} = \frac{\partial^2}{\partial \theta^2} y_{t,\theta} + v_{t,\theta},\ 0 \leq \theta \leq 1,\ 0 < t \leq T, \tag{15}$$

with the initial and boundary conditions

$$y_{0,\theta} = y_{t,0} = y_{t,1} = 0,\ 0 \leq \theta \leq 1,\ 0 \leq t \leq T. \tag{16}$$

Let $X = L_2(0,1)$. In the system (15)–(16), the second-order differential operator $d^2/d\theta^2$ stands for the operator A with the domain

$$D(A) = \bigl\{h \in X : \bigl(d^2/d\theta^2\bigr)h \in X,\ h_0 = h_1 = 0\bigr\},$$

and it generates the strongly continuous semigroup $\mathcal{U}$ defined by

$$[\mathcal{U}_t h]_\theta = \sum_{i=1}^{\infty} 2e^{-i^2\pi^2 t}\sin(i\pi\theta)\int_0^1 h_\alpha \sin(i\pi\alpha)\,d\alpha,\ 0 \le \theta \le 1,\ t \ge 0,\ h \in X.$$

If v is considered as a control action taken from the set of admissible controls $V = L_2(\mathbf{T}, X)$, then it is easily shown that $B = B^* = I$ and, since $\mathcal{U}_t$ is self-adjoint,

$$\Gamma_T = \int_0^T \mathcal{U}_{T-s}BB^*\mathcal{U}_{T-s}^*\,ds = \int_0^T \mathcal{U}_{2s}\,ds.$$

Therefore, for $h \in X$,

$$\begin{aligned}
[\Gamma_T h]_\theta &= \left[\int_0^T \mathcal{U}_{2s}h\,ds\right]_\theta \\
&= \sum_{i=1}^{\infty}\int_0^T 2e^{-2i^2\pi^2 s}\sin(i\pi\theta)\int_0^1 h_\alpha \sin(i\pi\alpha)\,d\alpha\,ds \\
&= \sum_{i=1}^{\infty}\frac{1-e^{-2i^2\pi^2 T}}{i^2\pi^2}\sin(i\pi\theta)\int_0^1 h_\alpha\sin(i\pi\alpha)\,d\alpha.
\end{aligned}$$

The half-range Fourier sine expansion of $h \in X$ is

$$h_\theta = \sum_{i=1}^{\infty} 2\sin(i\pi\theta)\int_0^1 h_\alpha\sin(i\pi\alpha)\,d\alpha,\ 0 \le \theta \le 1.$$

Using this, we obtain

$$[(\lambda I + \Gamma_T)h]_\theta = \sum_{i=1}^{\infty}\frac{2i^2\pi^2\lambda + 1 - e^{-2i^2\pi^2 T}}{i^2\pi^2}\sin(i\pi\theta)\int_0^1 h_\alpha\sin(i\pi\alpha)\,d\alpha.$$

Let $(\lambda I + \Gamma_T)h = g$. If we use the half-range Fourier sine expansion of $g \in X$, then

$$\begin{aligned}
&\sum_{i=1}^{\infty}\frac{2i^2\pi^2\lambda + 1 - e^{-2i^2\pi^2 T}}{i^2\pi^2}\sin(i\pi\theta)\int_0^1 h_\alpha\sin(i\pi\alpha)\,d\alpha \\
&\quad = \sum_{i=1}^{\infty} 2\sin(i\pi\theta)\int_0^1 g_\alpha\sin(i\pi\alpha)\,d\alpha,
\end{aligned}$$

which implies

$$\begin{aligned}
&\int_0^1 h_\alpha\sin(i\pi\alpha)\,d\alpha \\
&= \frac{2i^2\pi^2}{2i^2\pi^2\lambda + 1 - e^{-2i^2\pi^2 T}}\int_0^1 g_\alpha\sin(i\pi\alpha)\,d\alpha,\ i = 1, 2, \ldots.
\end{aligned}$$

Therefore,

$$\begin{aligned} h_\theta &= \left[(\lambda I + \Gamma_T)^{-1} g\right]_\theta = [R(\lambda, -\Gamma_T) g]_\theta \\ &= \sum_{i=1}^{\infty} \frac{4i^2\pi^2}{2i^2\pi^2\lambda + 1 - e^{-2i^2\pi^2 T}} \sin(i\pi\theta) \int_0^1 g_\alpha \sin(i\pi\alpha)\, d\alpha. \end{aligned}$$

If $g_\alpha \equiv 1$, then by Parseval's identity,

$$\begin{aligned} \|R(\lambda, -\Gamma_T) g\|_X^2 &= \frac{1}{2} \sum_{i=1}^{\infty} \frac{(4i^2\pi^2)^2}{(2i^2\pi^2\lambda + 1 - e^{-2i^2\pi^2 T})^2} \left(\int_0^1 \sin(i\pi\alpha)\, d\alpha \right)^2 \\ &= \sum_{i=1}^{\infty} \frac{8i^2\pi^2 (1 - (-1)^i)^2}{(2i^2\pi^2\lambda + 1 - e^{-2i^2\pi^2 T})^2} \\ &\geq \sum_{i=1}^{\infty} \frac{8i^2\pi^2 (1 - (-1)^i)^2}{(2i^2\pi^2\lambda + 1)^2} = \sum_{i=1,3,5,\ldots} \frac{32 i^2\pi^2}{(2i^2\pi^2\lambda + 1)^2}. \end{aligned}$$

One can verify that the inequality

$$\frac{i}{2i^2\pi^2\lambda + 1} > \frac{i+1}{2(i+1)^2\pi^2\lambda + 1}$$

holds whenever i is an integer that is greater than the number $1/\sqrt{2\lambda}\pi$. Let N_λ be the smallest odd integer that is greater than $1/\sqrt{2\lambda}\pi$. Then the sequence

$$\left\{ i^2\pi^2 / \left(2i^2\pi^2\lambda + 1\right)^2 \right\}_{i=1,2,\ldots}$$

is decreasing for $i \geq N_\lambda$. The following limits are obvious:

$$N_\lambda \to \infty \text{ and } \lambda N_\lambda^2 \to \frac{1}{2\pi^2} \text{ as } \lambda \to 0.$$

Using these, for $g_\alpha \equiv 1$, we obtain

$$\begin{aligned} \|R(\lambda, -\Gamma_T) g\|_X^2 &\geq \sum_{i=N_\lambda}^{\infty} \frac{16 i^2\pi^2}{(2i^2\pi^2\lambda + 1)^2} \geq \int_{N_\lambda}^{\infty} \frac{16\pi^2 t^2}{(2\pi^2\lambda t^2 + 1)^2}\, dt \\ &\geq \int_{N_\lambda}^{\infty} \frac{4\pi^2 t}{(2\pi^2\lambda t^2 + 1)^2}\, dt = \frac{1}{\lambda(2\pi^2\lambda N_\lambda^2 + 1)} \to \infty \end{aligned}$$

as $\lambda \to 0$. Therefore, by (1a) $\Leftrightarrow$ (1d) in Theorem 1, the system (15)–(16) is not D^c-controllable. At the same time, for all $g \in X$,

$$\begin{aligned} &\|\lambda R(\lambda, -\Gamma_T) g\|_X^2 \\ &= \sum_{i=1}^{\infty} \frac{8 i^4\pi^4\lambda^2}{(2i^2\pi^2\lambda + 1 - e^{-2i^2\pi^2 T})^2} \left(\int_0^1 g_\alpha \sin(i\pi\alpha)\, d\alpha \right)^2 \to 0 \end{aligned}$$

as $\lambda \to 0$ and hence, by (2a) $\Leftrightarrow$ (2c) in Theorem 2, the system (15)–(16) is D^a-controllable.

Example 2. Consider a controlled wave equation

$$\text{(17)} \qquad \frac{\partial^2}{\partial t^2} \xi_{t,\theta} = \frac{\partial^2}{\partial \theta^2} \xi_{t,\theta} + b_\theta v_t, \ 0 \leq \theta \leq 1, \ 0 < t \leq T,$$

with the initial and boundary conditions

$$\xi_{0,\theta} = f_\theta,\ \frac{\partial}{\partial t}\xi_{t,\theta}\Big|_{t=0} = g_\theta,\ \xi_{t,0} = \xi_{t,1} = 0,\ 0 \le \theta \le 1,\ 0 \le t \le T, \tag{18}$$

where v is a control action taken from the set of admissible controls $V = L_2(0,T)$, i.e., $Y = R$. We assume that f, g, and b are functions in $L_2(0,1)$. For these functions, we will use the half-range Fourier sine expansions

$$f_\theta = \sum_{i=1}^{\infty} \alpha_i \sin(i\pi\theta),\ g_\theta = \sum_{i=1}^{\infty} \beta_i \sin(i\pi\theta),\ b_\theta = \sum_{i=1}^{\infty} \gamma_i \sin(i\pi\theta)$$

and suppose that

$$\sum_{i=1}^{\infty} i^2\alpha_i^2 < \infty.$$

Let X be a Hilbert space of all functions

$$h = \begin{bmatrix} f \\ g \end{bmatrix} : [0,1] \to R,$$

where f and g satisfy the above-mentioned conditions endowed with the scalar product

$$\langle h, \tilde{h}\rangle = \left\langle \begin{bmatrix} f \\ g \end{bmatrix}, \begin{bmatrix} \tilde{f} \\ \tilde{g} \end{bmatrix} \right\rangle = \sum_{i=1}^{\infty} \left(i^2\pi^2\alpha_i\tilde{\alpha}_i + \beta_i\tilde{\beta}_i \right),$$

where $\tilde{\alpha}_i$ and $\tilde{\beta}_i$ are the respective Fourier coefficients of $\tilde{f}$ and $\tilde{g}$. This space X is suitable for the problem (17)–(18) (see Curtain and Zwart [3, p. 149] and Zabczyk [6, p. 180]). For the operator

$$A = \begin{bmatrix} 0 & I \\ d^2/d\theta^2 & 0 \end{bmatrix}, \tag{19}$$

where I is the identity operator on $L_2(0,1)$ and $d^2/d\theta^2$ has the domain

$$D\big(d^2/d\theta^2\big) = \big\{\eta \in L_2(0,1) : \big(d^2/d\theta^2\big)\eta \in L_2(0,1),\ \eta_0 = \eta_1 = 0\big\},$$

and for $B \in \mathcal{L}(R, X)$ defined by

$$[Bv]_\theta = \begin{bmatrix} 0 \\ b_\theta v \end{bmatrix},\ 0 \le \theta \le 1,\ v \in R,$$

the problem (17)–(18) can be formulated in the abstract form

$$\frac{d}{dt}y_t = Ay_t + Bv_t,\ t > 0, \tag{20}$$

where

$$[y_t]_\theta = \begin{bmatrix} \xi_{t,\theta} \\ (\partial/\partial t)\xi_{t,\theta} \end{bmatrix}, 0 \le \theta \le 1,\ 0 < t \le T;\ y_0 = \begin{bmatrix} f \\ g \end{bmatrix}.$$

It is known that the operator A defined by (19) generates a continuous group $\mathcal{U}$ (see Curtain and Zwart [3] and Zabczyk [6]) as defined by

$$[\mathcal{U}_t h]_\theta = \sum_{i=1}^{\infty} \begin{bmatrix} \cos(i\pi t) & (i\pi)^{-1}\sin(i\pi t) \\ -i\pi\sin(i\pi t) & \cos(i\pi t) \end{bmatrix} \begin{bmatrix} \alpha_i \\ \beta_i \end{bmatrix} \sin(i\pi\theta),\ 0 \le \theta \le 1,\ t \in R,$$

where

$$h = \begin{bmatrix} f \\ g \end{bmatrix} \in X$$

and α_i and β_i are Fourier coefficients of f and g, respectively. Since $\mathcal{U}$ is a group, we have $\mathcal{U}_t^* = \mathcal{U}_{-t}$. Therefore, the controllability operator Γ_T of the system (20) is

$$\Gamma_T h = \int_0^T \mathcal{U}_{T-t} B B^* \mathcal{U}_{T-t}^* h\, dt = \int_0^T \mathcal{U}_t B B^* \mathcal{U}_{-t} h\, dt,\ h \in X.$$

We have

$$[\mathcal{U}_{-t} h]_\theta = \sum_{i=1}^{\infty} \begin{bmatrix} \alpha_i \cos(i\pi t) - \beta_i (i\pi)^{-1}\sin(i\pi t) \\ \alpha_i i\pi \sin(i\pi t) + \beta_i \cos(i\pi t) \end{bmatrix} \sin(i\pi\theta).$$

One can calculate that

$$B^* h = \sum_{i=1}^{\infty} \gamma_i \beta_i,\ h \in X.$$

Hence,

$$B^* \mathcal{U}_{-t} h = \sum_{i=1}^{\infty} \gamma_i (\alpha_i i\pi \sin(i\pi t) + \beta_i \cos(i\pi t))$$

and, consequently,

$$[\mathcal{U}_t B B^* \mathcal{U}_{-t} h]_\theta = \sum_{i=1}^{\infty} \begin{bmatrix} \gamma_i (i\pi)^{-1}\sin(i\pi t) \\ \gamma_i \cos(i\pi t) \end{bmatrix} \sin(i\pi\theta) \\ \times \sum_{j=1}^{\infty} \gamma_j (\alpha_j j\pi \sin(j\pi t) + \beta_j \cos(j\pi t)).$$

Thus, for $T = 2$,

$$[\Gamma_2 h]_\theta = \int_0^2 [\mathcal{U}_t B B^* \mathcal{U}_{-t} h]_\theta\, dt = \sum_{i=1}^{\infty} \begin{bmatrix} \gamma_i^2 \alpha_i \\ \gamma_i^2 \beta_i \end{bmatrix} \sin(i\pi\theta).$$

We obtain that

$$[(\lambda I + \Gamma_2) h]_\theta = \sum_{i=1}^{\infty} \left(\lambda + \gamma_i^2\right) \begin{bmatrix} \alpha_i \\ \beta_i \end{bmatrix} \sin(i\pi\theta),$$

which implies

$$[R(\lambda, -\Gamma_2) h]_\theta = \left[(\lambda I + \Gamma_2)^{-1} h\right]_\theta = \sum_{i=1}^{\infty} \left(\lambda + \gamma_i^2\right)^{-1} \begin{bmatrix} \alpha_i \\ \beta_i \end{bmatrix} \sin(i\pi\theta).$$

Finally, for all $h \in X$,

$$\|\lambda R(\lambda, -\Gamma_2)h\|^2 = \sum_{i=1}^{\infty} \frac{\lambda^2}{\left(\lambda + \gamma_i^2\right)^2} \left(i^2\pi^2\alpha_i^2 + \beta_i^2\right) \to 0$$

as $\lambda \to 0$ if $\gamma_i \neq 0$ for all $i = 1, 2, \ldots$. Thus, by (2a) $\Leftrightarrow$ (2c) in Theorem 2, we obtain the following sufficient condition for the approximate controllability of the system (17)–(18) which agrees with Theorem 2.10 in Zabczyk [6]: if $T \geq 2$ and b is such that

$$\gamma_i = 2\int_0^1 b_\theta \sin(i\pi\theta)\, d\theta \neq 0,\ i = 1, 2, \ldots,$$

then the system (17)–(18) is D^a-controllable.

6. Necessary and sufficient conditions for C- and S-controllabilities. The following two lemmas are proven in [7, 8].

Lemma 3. *For $\varepsilon > 0$ and for $0 \leq p < 1$, the control system* (4) *is $C^c_{\varepsilon,p}$-controllable* ($C^a_{\varepsilon,p}$*-controllable*) *on* $\mathbf{T}$ *if and only if the control system* (5) *is D^c-controllable* (D^a*-controllable*) *on* $\mathbf{T}$ *and the control system* (6) *is $S^0_{\varepsilon,p}$-controllable on* $\mathbf{T}$.

By this lemma, the study of the $C^c_{\varepsilon,p}$-controllability (the $C^a_{\varepsilon,p}$-controllability) of the control system (4) is separated into the study of the D^c-controllability (D^a-controllability) and the $S^0_{\varepsilon,p}$-controllability of the control systems (5) and (6), respectively.

Lemma 4. *The following statements hold:*

(a) *there exists a finite limit*

$$a_T = \lim_{\lambda \to 0} \int_0^T \operatorname{tr} CP_sQ_s^\lambda P_sC^* ds,$$

where Q^λ and P are solutions of (8) *and* (9)*, respectively*;

(b) *the control system* (6) *is $S^0_{\varepsilon,p}$-controllable on* $\mathbf{T}$ *if $a_T < \varepsilon(1-p)$*;

(c) *the system* (6) *is S^0-controllable on* $\mathbf{T}$ *if $a_T = 0$*.

It turns out that the condition $a_T = 0$, which is sufficient for the system (6) to be S^0-controllable, is weaker than the D^a-controllability (particularly, the D^c-controllability) of the control system (5) on all the intervals $[0, t]$ with $0 < t \leq T$.

Lemma 5. *If the control system* (5) *is D^a-controllable on all the intervals* $[0, t]$ *with $0 < t \leq T$, then $a_T = 0$, where a_T is defined in Lemma* 4(a).

Proof. From (2a) $\Leftrightarrow$ (2c) (see Theorem 2), we obtain that $\lambda R(\lambda, -\Gamma_{T-t})$ strongly converges to zero operator as $\lambda \to 0$ for all $0 \leq t < T$. Hence, by Lemma 1, Q_t^λ strongly converges to zero operator as $\lambda \to 0$ for all $0 \leq t < T$. Furthermore, substituting $h = \lambda^{1/2}(\lambda I + \Gamma_{T-t})^{-1/2}x$ in

$$\left\langle \lambda^{-1}(\lambda I + \Gamma_{T-t})h, h\right\rangle \geq \langle h, h\rangle,$$

we obtain

$$\left\langle \lambda(\lambda I + \Gamma_{T-t})^{-1}x, x\right\rangle \leq \|x\|^2.$$

Thus, $\lambda R(\lambda, -\Gamma_{T-t}) \leq I$ and by Lemma 1, $Q_t^\lambda \leq \mathcal{U}_{T-t}^*\mathcal{U}_{T-t}$ for all $\lambda > 0$ and for all $0 \leq t \leq T$. Hence, we can change the places of limit, integral, and trace in definition of the number a_T in Lemma 4(a) to obtain $a_T = 0$. The lemma is proven.

THEOREM 3. *The control system* (4) *is* C*-controllable on all the intervals* $[0,T]$ *with* $T > 0$ *if and only if the control system* (5) *is* D^c*-controllable on all the intervals* $[0,T]$ *with* $T > 0$.

This follows from Lemmas 3, 4(c), and 5.

THEOREM 4. *The control system* (4) *is* S*-controllable on all the intervals* $[0,T]$ *with* $T > 0$ *if and only if the control system* (5) *is* D^a*-controllable on all the intervals* $[0,T]$ *with* $T > 0$.

The necessity follows from Theorem 5(b) in [8]. The sufficiency follows from Lemmas 3, 4(c), and 5.

COROLLARY 1. *The control system* (4) *is* S*-controllable on all the intervals* $[0,T]$ *with* $T > 0$ *if it is* C^a*-controllable on all the intervals* $[0,T]$ *with* $T > 0$.

Proof. From Lemmas 3 and 5 and Theorem 4, one can see that each of the S- and C^a- controllabilities of the control system (4) on all the intervals $[0,T]$ with $T > 0$ is equivalent to the D^a-controllability of the control system (5) on all the intervals $[0,T]$ with $T > 0$.

Example 3. Consider the control system (4) with the operators A and B as defined in Example 1. It was shown that the deterministic part of this system is D^a-controllable on all the intervals $[0,T]$ with $T > 0$. Hence, this system is S-controllable on all the intervals $[0,T]$ with $T > 0$.

Example 4. Consider the control system (4) with the operators A and B as defined in Example 2. It was shown that the deterministic part of this system is D^a-controllable on all the intervals $[0,T]$ with $T > 2$ if some additional condition holds. However, Theorem 4 does not guarantee the S-controllability of this system.

ASYMPTOTIC EFFICIENCY OF PERTURBATION-ANALYSIS-BASED STOCHASTIC APPROXIMATION WITH AVERAGING[*]

QIAN-YU TANG[†], PIERRE L'ECUYER[†], AND HAN-FU CHEN[‡]

Abstract. Central limit theorems are obtained for the perturbation analysis Robbins–Monro single run (PARMSR) algorithm updated either after every regenerative cycle or after every fixed-length observation period, and with averaging of the iterates, for one-dependent regenerative processes. When the convergence to the optimizer is expressed in terms of the total observation time of the system (or the total computing budget in the case of a simulation), the convergence rate and the limit covariance matrix turn out to be the same for all updating schemes and are optimal within the class of stochastic approximation-algorithms under certain assumptions. A bound on the strong convergence rate of the usual PARMSR algorithm updated after every fixed-length observation period is established using a limit theorem on double array martingales. This is the key step for obtaining central limit theorems for the algorithms with averaging and has interest in its own right.

Key words. perturbation analysis, asymptotic efficiency, central limit theorems, stochastic approximation, recursive estimation, queueing theory

1. Introduction.

Consider a discrete-time stochastic process $\{X_i,\ i \geq 0\}$ which follows the stochastic recurrence

$$X_{i+1} = h(X_i,\ \tilde{\theta}_i,\ U_i) \tag{1.1}$$

with initial state X_0, where h is a measurable function, each $\tilde{\theta}_i \in D$ is a *decision* (or control), D is a compact subset of the l-dimensional real space $\mathbb{R}^l$, and $\{U_i,\ i \geq 0\}$ is a sequence of i.i.d. random vectors defined on a probability space $\{\Omega,\ \mathcal{F},\ P\}$. In the case of a simulation model, $\{U_i,\ i \geq 0\}$ can be interpreted as the sequence of $U(0,1)$ random numbers that drive the simulation. A real-valued *cost process* $\{J_i,\ i \geq 0\}$ is defined by $J_i = \phi(X_i, \tilde{\theta}_i)$ for some measurable mapping ϕ. Denote (X_i, J_i) by $(X_i(\theta), J_i(\theta))$ when the control parameter $\tilde{\theta}_i$ is fixed at θ for all $i \geq 0$. The objective function is the steady-state average cost

$$\overline{J}(\theta) = \lim_{t\to\infty} \frac{1}{t} \sum_{i=1}^{t} \mathsf{E}[J_i(\theta)], \tag{1.2}$$

which is to be minimized with respect to θ for $\theta \in D$.

To insure that (1.2) exists and to prove our results, we assume certain stability conditions on the process $\{J_i,\ i \geq 0\}$, expressed in the form of a regenerative

structure. We suppose (roughly) that this process, as well as its stochastic gradient (perturbation analysis) process, is one-dependent regenerative in an extended sense (see the next section for details). One-dependent regenerative is a weakened version of the classical notion of a regenerative stochastic process and covers a broad class of systems [1, 29, 36]. The weakening is that adjacent regenerative cycles are allowed to be dependent. The stochastic recursion model (1.1) is very general (it suffices to put enough information into the state X_i), and it will permit us to define the perturbation analysis gradient estimators (under some additional conditions).

We assume that no closed-form expression for $\bar{J}$ is available, and we consider a stochastic approximation (SA) approach to find a root of $f(\theta) \overset{\triangle}{=} \overline{J}_\theta(\theta) \overset{\triangle}{=} d\overline{J}(\theta)/d\theta$. (In this paper, a θ subscript means the gradient with respect to θ.) We suppose that the root is the unique optimizer θ^0 of $\overline{J}(\theta)$. The Robbins–Monro [33] SA algorithm has the general form

$$\theta_{n+1} = \Pi_D(\theta_n - a_n f_{n+1}) \tag{1.3}$$

with an initial value θ_0, where $\{a_n,\ n \geq 0\}$ is a deterministic sequence of matrices called the *step sizes*, $f_{n+1} = f(\theta_n) + \varepsilon_{n+1}$ is an unbiased estimator of $f(\theta_n)$, ε_{n+1} is the observation *noise* at the $(n+1)$th step, $\Pi_D : \mathbb{R}^l \to D$ is a projection operator (which would disappear if D was $\mathbb{R}^l$, as in the original Robbins–Monro formulation), and θ_n is the nth estimate for the optimizer θ^0. See, e.g., [7, 22, 24, 28]. It is well known that under certain conditions on the regression function $f(\theta)$, on the noise sequence $\{\varepsilon_n,\ n \geq 1\}$, and on the matrix A^* assuming that $a_n = A^*/n$, $\sqrt{n}(\theta_n - \theta^0)$ is asymptotically $N(0,\ S^*)$, where S^* is a limiting covariance matrix. The trace of S^* is minimized by taking $A^* = M_1^{-1}$, where $M_1 = f_\theta(\theta^0)$ is the Hessian matrix of $\overline{J}(\theta)$ at θ^0. This optimal covariance matrix is $S^* = M_1^{-1}S_0^*(M_1^{-1})'$, where the prime means "transpose" and S_0^* is the asymptotic covariance matrix of $(1/\sqrt{n})\sum_{j=1}^n \varepsilon_j$.

However, since M_1 is generally unknown, this optimal SA scheme is usually impractical. This has motivated the introduction of SA algorithms with averaging of the iterates, using a sequence of step sizes which decreases at a rate slower than $1/n$ (see [3, 5, 24, 31, 32, 43]). One of these algorithms uses (1.3) as usual, then retains the following estimator of θ^0 at step n:

$$\overline{\theta}_n = \frac{1}{n}\sum_{j=1}^n \theta_j = \frac{1}{n}(\theta_n + (n-1)\bar{\theta}_{n-1}). \tag{1.4}$$

Under certain conditions, $\sqrt{n}(\overline{\theta}_n - \theta^0)$ is asymptotically $N(0,\ S^*)$. The major advantage of this averaging algorithm is that there is no need to know M_1^{-1}.

Under appropriate smoothness conditions, *infinitesimal perturbation analysis* (IPA) offers a viable means of estimating $f(\theta)$ by observing a single sample path of the system (see section 2.2 and, e.g., [15, 21, 25] and other references therein). Going one step further, one can simultaneously optimize along that single sample path: At successive epochs along the path, a (generally biased) estimator of $f(\theta)$ for the current θ is put in the SA algorithm to recursively estimate θ^0 while the system is running (either on-line or via simulation). The general idea is as follows: Run the system for a short period of time, say, L_{n+1} steps of (1.1) with θ fixed at θ_n, and use the collected information to compute the estimator f_{n+1} of $f(\theta_n)$; put f_{n+1} in (1.3) to get θ_{n+1}; continue running the system (from its current state) for another L_{n+2} steps with $\theta = \theta_{n+1}$ to compute f_{n+2}; and so on. Denoting $N_n = \sum_{j=1}^n L_j$ (with $N_0 = 0$), one has $\tilde{\theta}_i = \theta_n$ for $N_n \leq i < N_{n+1}$. In [38, 39], this is called the perturbation analysis Robbins–Monro single run (PARMSR) algorithm. Considerable effort has been devoted, in recent years, to studying the convergence of the PARMSR algorithm in the field of discrete event dynamic systems (DEDSs); see, e.g., [8, 9, 10, 14, 23, 26, 27, 40, 41], among others. The convergence rate results mentioned previously for the SA algorithm, however, have been proved under conditions that do not hold in the PARMSR setup.

In this paper we study the convergence rate, in the sense of central limit theorems, for the PARMSR algorithm with averaging. Let N_n represent the cumulative *computing budget* for the first n steps of the PARMSR algorithm. We express the convergence speed of the algorithm in terms of N_n (as done, e.g., in [28]) instead of n. When $\sqrt{N_n}(\overline{\theta}_n - \theta^0)$ is asymptotically $N(0,\ S^*)$, with $S^* = M_1^{-1} S_0^* (M_1^{-1})'$, where S_0^* is the asymptotic covariance matrix of $(1/\sqrt{N_n}) \sum_{j=1}^{n} \varepsilon_j$, we say that the PARMSR algorithm is *asymptotically optimal* (see [3, 5, 43] for similar definitions in terms of n). This must be understood as optimal only within the class of SA algorithms and for the particular gradient estimator that is used. Another type of convergence rate, in the sense of large-deviation bounds on the probability of exit of a neighborhood of θ^0 by the tail process $\{\theta_n,\ n \geq n_0\}$ for large n_0, is studied in [12].

We analyze the following two cases:

- (R) The parameter θ_n is updated after each regenerative cycle of the process $\{J_i,\ i \geq 0\}$ (so L_n is random and represents the length of the nth regenerative cycle). In this regenerative case, we use θ_{n-1} instead of θ_n to obtain f_{n+1}, as explained in section 3.
- (F) θ_n is updated after every L steps of the recurrence (1.1), so $L_n = L$, a positive constant.

For case (R), the limiting behavior is relatively easy to analyze since the main part of the observation noise can be decomposed into two martingale difference sequences. Then, standard SA results are applicable. For case (F), the analysis is more difficult, primarily because the standard conditions on the observation noise, assumed in, e.g., [3, 24, 31, 32, 43], do not hold. These authors require the observation noise to satisfy the properties of martingale differences, or of stationary ϕ-mixing processes, or of the infinite sum of a martingale difference sequence. For the PARMSR algorithm with fixed-length observation period, the observation noise has a very complicated dynamic, as shown in previous convergence studies; see, e.g., [9, 10, 23, 26, 40, 41]. In this paper, we first obtain a bound on the almost sure (a.s.) convergence rate of the usual PARMSR algorithm (without averaging), using a limit theorem on double array martingales borrowed from [6] and [19]. We then apply this result to obtain a central limit theorem showing the asymptotic optimality of the PARMSR algorithm with averaging for the case (F).

Our results imply that the PARMSR algorithm with averaging has the same asymptotic efficiency, i.e., the same convergence rate and the same limiting covariance matrix in terms of N_n, for both (R) and (F). Moreover, for (F), this limit covariance is independent of the updating frequency L. Our emphasis in this paper is on the case (F). This case is more difficult to analyze than (R), but its implementation is much easier, because there is no need to recognize the regeneration points, so the implementation depends much less on the structure of the system. For case (R), the algorithm must identify the regeneration points explicitly, which is usually hard for complex systems. See [34, 35] on the identification of regeneration points for closed and open queueing networks.

A third approach, not considered here, is to have $L_n \to \infty$ with n. This was studied in [28] for decreasing step sizes and in [13] for constant step sizes, without the averaging of the iterates.

The rest of the paper is organized as follows. In the next section we specify the regenerative structure of the model. We also define the IPA estimators and introduce some assumptions to make sure that the IPA process shares a common regenerative structure with the original process and is strongly consistent. The asymptotic efficiency of the PARMSR algorithm with averaging for cases (R) and (F) is analyzed in sections 3 and 4, respectively. All the proofs are collected in the appendix.

2. The model.

2.1. The regenerative structure.

We now expand on the model introduced at the beginning of section 1. The state process $\{X_i,\, i \geq 0\}$ takes values in some Borel space $\mathcal{X}$, and the initial state $X_0 \in \mathcal{X}$ is a random variable. The stochastic process $\{X_i, \tilde{\theta}_i, J_i),\, i \geq 0\}$ is defined on the same probability space $\{\Omega,\, \mathcal{F},\, P\}$ as $\{X_0,\, U_i,\, i \geq 0\}$, via (1.1) and (1.3). Let $\mathcal{F}_i = \sigma(X_0, \ldots, X_i)$, the sigma field generated by $X_0, \ldots, X_i$. We suppose that there is a sequence of integers $0 = k_0 < k_1 < k_2 < \cdots$ such that each k_m is a stopping time with respect to the filtration $\{\mathcal{F}_i,\, i \geq 0\}$ and such that the following condition (A0) is satisfied.

Suppose for a moment that until time k_m, the process is run as usual with $\tilde{\theta}_i$ varying according to the SA algorithm, but that from then on, the parameter is fixed at θ; i.e., $\tilde{\theta}_i = \theta$ for $i \geq k_m$. We denote this modified process starting at time k_m by $\{X_i^{(m+1)}(\theta),\, i \geq 0\}$, that is, $X_i^{(m+1)}(\theta) = X_{k_m+i}$ for $i \geq 0$, and put $J_i^{(m+1)}(\theta) = \phi(X_i^{(m+1)}(\theta), \theta)$ for $i \geq 0$ and $k_r^{(m+1)}(\theta) = k_{m+r} - k_m$ for $r \geq 0$. We also denote $X_i(\theta) = X_i^{(1)}(\theta)$, $J_i(\theta) = J_i^{(1)}(\theta)$, and $k_m(\theta) = k_m^{(1)}(\theta)$, which correspond to a process where θ is fixed from the beginning.

(A0) For any fixed $\theta \in D$ and $m \geq 0$, $\{J_i^{(m+1)}(\theta),\, i \geq 0\}$ and $\{k_r^{(m+1)}(\theta),\, r \geq 0\}$ have the same joint distribution as $\{J_i(\theta),\, i \geq 0\}$ and $\{k_r(\theta),\, r \geq 0\}$ and are independent of $\mathcal{F}_{k_{m-1}-1}$ and k_m.

When this condition (A0) is satisfied, the controlled process $\{J_i,\, i \geq 0\}$ is called (nondelayed) *one-dependent regenerative*. This extends the usual definition found, e.g., in [29, 36]: For the process $\{J_i(\theta),\, i \geq 0\}$, for which θ is fixed from the beginning, we get the usual definition of one-dependent regenerative, which we call in this paper *one-dependent regenerative for fixed* θ. The k_m's are called the *regeneration points*. Denote $\eta_m = k_m - k_{m-1}$, the length of the mth regenerative cycle, $\eta_r^{(m+1)}(\theta) = k_r^{(m+1)}(\theta) - k_{r-1}^{(m+1)}(\theta)$, and $\eta_m(\theta) = k_m(\theta) - k_{m-1}(\theta)$. If (A0) holds with $\mathcal{F}_{k_{m-1}-1}$ replaced by $\mathcal{F}_{k_m-1}$, the process is called *classically regenerative*. From the definition of J_i and by Proposition V.1.1 of [1], if (A0) holds for $\{X_i,\, i \geq 0\}$, it also holds for $\{J_i,\, i \geq 0\}$ with the same regeneration points.

It is well known that Harris-recurrent Markov chains (HRMCs) are one-dependent regenerative processes for fixed θ; this can be seen by applying the splitting technique due to [2]. HRMCs cover a very large class of models. We refer the reader to [1, 29, 30, 36] for appropriate background.

If $\mathsf{E}[\eta_1(\theta)] < \infty$ and $\mathsf{E}[\sum_{i=1}^{\eta_1(\theta)} |J_i(\theta)|] < \infty$ for all $\theta \in D$, then $\overline{J}(\theta)$ in (1.2) is well defined on D and the renewal-reward theorem (see, e.g., [1] and [42]) implies that

$$\overline{J}(\theta) = \frac{1}{\mathsf{E}[\eta_1(\theta)]} \mathsf{E}\left[\sum_{i=1}^{\eta_1(\theta)} J_i(\theta)\right]. \tag{2.1}$$

2.2. Gradient estimation via IPA and the PARMSR algorithm. We now explain how IPA is used to estimate the gradient in this context. For fixed θ, the IPA estimators are constructed from the recurrence

$$\begin{aligned} J_{\theta,i}(\theta) &= \phi_x(X_i(\theta),\theta)X_{\theta,i}(\theta) + \phi_\theta(X_i(\theta),\theta), \\ X_{\theta,i+1}(\theta) &= h_x(X_i(\theta),\theta,U_i)X_{\theta,i}(\theta) + h_\theta(X_i(\theta),\theta,U_i), \end{aligned}$$

for $i \geq 0$, where $X_{\theta,0}(\theta) = 0$, ϕ_x and ϕ_θ denote the partial derivatives of ϕ with respect to its first and second components, and similarly for h. Assuming that these stochastic derivatives exist and under appropriate uniform integrability conditions (see [15, 25]), $J_{\theta,i}(\theta)$ is an unbiased IPA estimator of the gradient of $\mathsf{E}[J_i(\theta)]$.

Suppose now that θ is *not* fixed but takes the successive values $\{\tilde{\theta}_i,\ i \geq 0\}$ as in (1.1). This is what happens when the PARMSR algorithm is applied. We then define the IPA estimator as follows. Let

$$\begin{aligned} J_{\theta,i} &= \phi_x(X_i,\tilde{\theta}_i)X_{\theta,i} + \phi_\theta(X_i,\tilde{\theta}_i), \\ X_{\theta,i+1} &= h_x(X_i,\tilde{\theta}_i,U_i)X_{\theta,i} + h_\theta(X_i,\tilde{\theta}_i,U_i). \end{aligned}$$

The gradient estimator at the nth step of SA has the general form

$$f_{n+1} = K \sum_{i=1}^{L_{n+1}} J_{\theta,N_n+i} \tag{2.2}$$

for some constant K. In our context, we have $L_{n+1} = \eta_{n+1}$ and $K = 1$ for case (R), and $L_{n+1} = L$ and $K = 1/L$ for case (F).

Equations (1.3) and (2.2) give the general form of the PARMSR algorithm. In this paper, we define the projection operator Π_D of (1.3) as

$$\Pi_D(\theta_n - a_n f_{n+1}) = \begin{cases} \theta_n - a_n f_{n+1} & \text{if } \theta_n - a_n f_{n+1} \in D, \\ \\ \theta_n & \text{if } \theta_n - a_n f_{n+1} \notin D. \end{cases}$$

If D is a convex set, we could also define $\Pi_D(x)$ to be the nearest boundary point of D whenever $x \notin D$.

For the analysis of the PARMSR algorithm, we need to assume that $\{J_{\theta,i},\ i \geq 0\}$ is also one-dependent regenerative with the same regeneration points as $\{J_i,\ i \geq 0\}$. Glasserman [15, 16, 17] and Glasserman, Hu, and Strickland [18] give several sets of sufficient conditions for this property to hold for fixed θ, for classically regenerative systems (see, e.g., Theorem 8.3 in [15], Theorem 5.4 in [16], and Theorem 5.6 in [17]). The following conditions ensure, among other things, that the IPA estimators are *strongly consistent* for $f(\theta)$, in the sense that $\lim_{t\to\infty}(1/t)\sum_{i=1}^{t} J_{\theta,i}(\theta) = f(\theta)$ a.s. We denote $J_{\theta,i}^{(m+1)}(\theta) = dJ_i^{(m+1)}(\theta)/d\theta$. Later on, for our theorems, we will require values of ξ_0 larger than 2 in (A3).

(A1) For $i \geq 0$, $J_i(\theta)$ is absolutely continuous with respect to θ on D.

(A2) $\{J_i,\ i \geq 0\}$ and $\{J_{\theta,i},\ i \geq 0\}$ are one-dependent regenerative in the sense of (A0), with common regeneration points $\{k_m,\ m \geq 0\}$.

(A3) There are two sequences of one-dependent and identically distributed random variables (r.v.'s) $\{Z_m,\ m \geq 1\}$ and $\{\eta_m^*,\ m \geq 1\}$, and a constant $\xi_0 \geq 2$, such that $\mathsf{E}[Z_1^{\xi_0}] < \infty$ and $\mathsf{E}\left[(\eta_1^*)^{\xi_0}\right] < \infty$, and such that for all $m \geq 0$, $1 \leq i \leq \eta_{m+1}$, and $\theta \in D$, $\max(\|J_{\theta,k_m+i}\|,\ \|J_{\theta,k_m+i}(\theta)\|,\ \|J_{\theta,i}^{(m+1)}(\theta)\|)$ $\leq Z_{m+1}$ and $\max(\eta_{m+1},\ \eta_{m+1}(\theta),\ \eta_1^{(m+1)}(\theta)) \leq \eta_{m+1}^*$.

A classical example where (A1) to (A3) are verified in the literature is that of the $GI/G/1$ queue considered in [8, 9, 24, 26, 41].

LEMMA 2.1. *If conditions* (A0)–(A3) *hold, then for each* $\theta \in D$, *the IPA derivative estimator is strongly consistent for* $f(\theta)$ *and*

$$f(\theta) = \frac{1}{\mathsf{E}[\eta_1(\theta)]} \mathsf{E}\left[\sum_{i=1}^{\eta_1(\theta)} J_{\theta,i}(\theta)\right]. \tag{2.3}$$

Proof. The proof is along the same lines as in [15, 16, 17, 18]. In fact (A2) and (A3) are needed only for fixed θ (uniformly in θ) to prove this lemma. □

3. The PARMSR algorithm with averaging for case (R).

Since $\eta_1(\theta) \geq 1$, finding a root of $f(\theta)$ is equivalent to finding a root of $f(\theta)\overline{\eta}(\theta)$, where $\overline{\eta}(\theta) = \mathsf{E}[\eta_1(\theta)]$, i.e., to finding a root of the second expectation in (2.3). If regeneration points for the model under consideration can be identified explicitly, one can use the sum of the $J_{\theta,i}(\theta)$ over any regenerative cycle as an unbiased estimator of $f(\theta)\overline{\eta}(\theta)$, where θ is the (fixed) value of the parameter during that cycle. This motivates taking $L_{n+1} = \eta_{n+1}$ and $K = 1$ in (2.2).

The PARMSR algorithm *without averaging* for case (R) is composed of (1.3) and (2.2) (cf. [8, 14, 26, 27]), with $\tilde{\theta}_i = \theta_{n-1}$ for $k_n < i \leq k_{n+1}$, and where $\theta_{-1},\ \theta_0 \in D$ are initial values. Thus, f_{n+1} is viewed as an estimator of $f(\theta_{n-1})\overline{\eta}(\theta_{n-1})$. It is worth noticing that the decision parameter throughout the evolution of the $(n+1)$th regenerative cycle is fixed at θ_{n-1} rather than θ_n. This is because of the one-dependent nature of our model, and it simplifies the convergence analysis.

The *averaging* version of this PARMSR algorithm works the same, but retains $\overline{\theta}_n$ instead of θ_n as an estimator of θ^0. Our aim is to obtain a central limit theorem for $\{\bar{\theta}_n,\ n \geq 1\}$. For this, we introduce the following conditions on the step sizes a_n and the functions f and $\overline{\eta}$.

(A4) There are constants $\overline{a} > 0$ and $\nu \in (1/2,\ 1)$ such that $0 < a_n \leq \overline{a} n^{-\nu}$ for all $n \geq 1$; $a_j = \overline{a}$ for all $j \leq 0$; $\sum_{n=1}^{\infty} a_n = \infty$; $0 \leq a_{n+1}^{-1} - a_n^{-1} \to 0$ as $n \to \infty$

(A5) The set D is compact and convex, and $f(\theta)$ is bounded on D. The optimizer θ^0 is an interior point of D. There are a stable matrix $-M_1$ (all eigenvalues of M_1 have positive real parts) and positive constants r_0 and c_1 such that $\|f(\theta) - M_1(\theta - \theta^0)\| \leq c_1 \|\theta - \theta^0\|^2$, whenever $\|\theta - \theta^0\| \leq r_0$.

(A6) There exists a continuously differentiable function $v : R^l \to R$ such that $v(\theta^0) = 0$ and for all $\Delta_1 > 0$, $\inf\{(f(\theta))' v_\theta(\theta) : \theta \in D,\ \|\theta - \theta^0\| \leq \Delta_1\} > 0$.

(A7) $f(\theta)$ is Lipschitz with modulus B_1 on D; i.e., $\|f(x_1) - f(x_2)\| \leq B_1 \|x_1 - x_2\|\ \forall\ x_1,\ x_2 \in D$.

(A8) $\overline{\eta}(\theta)$ and $H(\theta)$ are continuous at θ^0, where $H(\theta)$ is defined as

$$H(\theta) = \mathsf{E}\left[\left(\sum_{i=1}^{\eta_1(\theta)} J_{\theta,i}(\theta)\right)\left(\sum_{i=1}^{\eta_1(\theta)} J_{\theta,i}(\theta)\right)'\right].$$

Let us comment on conditions (A4)–(A8). Observe that $\nu < 1$ in (A4), so the classical choice of $a_n = O(1/n)$ is not allowed. This (A4) is the usual condition of *slowly decreasing step sizes* (e.g., as in [3, 24, 32]). Conditions (A5) and (A6) are standard in the context of SA. (A5) asks the objective function to be locally quadratic around the optimizer θ^0, while (A6) says that θ^0 should be an attractor point from every other point of D. In the context of queueing systems, for example, the set D may represent a stability region where the standard load conditions are fulfilled. In the case where D is unbounded, an SA procedure with randomly varying truncations can be employed (see, e.g., [3, 4, 5] and [7]). Condition (A7) requires that the regression function $f(\theta)$ is sufficiently smooth. We note that if the model is classically regenerative, then the Lipschitz conditions on $f(\theta)$ and $\overline{\eta}(\theta)$ required in Theorem 3.1 can be dropped since in this situation, $\tilde{\theta}_i = \theta_{n-1}$ can be replaced by $\tilde{\theta}_i = \theta_n$ for $k_n < i \le k_{n+1}$, and we do not need to decompose the noise ε_{n+1} into two parts (see the proof of Theorem 3.1(i)). Condition (A8) requires the continuity of $\overline{\eta}(\theta)$ and $H(\theta)$ at the optimizer θ^0. This is a mild condition. See [26] for the verification in the context of a $GI/G/1$ queue.

The following theorem contains our main results for case (R).

THEOREM 3.1.

(i) *Suppose that the conditions* (A0)–(A7) *hold with* $\xi_0 \ge 4$ *in* (A3) *and that* $\overline{\eta}(\theta)$ *is Lipschitz with modulus* B_2. *Then* $\|\theta_n - \theta^0\| = o(a_n^\delta)$ *a.s. for all* $\delta \in [0,\ 1 - 1/(2\nu))$, *where* ν *is given by condition* (A4).

(ii) *Suppose that conditions* (A0)–(A8) *hold with some* $\xi_0 > 4/\nu$ *and that* $\overline{\eta}(\theta)$ *is Lipschitz on* D. *Then* $(\theta_n - \theta^0)/\sqrt{a_n} \to N(0,\ S_1)$ *in distribution as* $n \to \infty$, *where*

$$S_1 = \int_0^\infty e^{-\overline{\eta}(\theta^0)M_1 t} S e^{-\overline{\eta}(\theta^0)M_1' t} dt, \quad S = H(\theta^0).$$

(iii) *Under the same conditions as in* (ii) *with* $\xi_0 > 4/\nu$ *replaced by* $\xi_0 > 4$, *the PARMSR algorithm with averaging for case* (R) *satisfies* $\sqrt{n}(\overline{\theta}_n - \theta^0) \to N(0,\ S_2)$ *in distribution as* $n \to \infty$, *where* $S_2 = \overline{\eta}(\theta^0)^{-2} M_1^{-1} S (M_1^{-1})'$.

For the first n iterations of the PARMSR algorithm for case (R), the total computing budget is $N_n = k_n = \sum_{i=1}^n \eta_i$. By the continuity of $\overline{\eta}(\theta)$ at θ^0 and the law of large numbers for martingales, it is seen that $N_n/n \to \overline{\eta}(\theta^0)$ a.s. as $n \to \infty$. Combining this with Theorem 3.1, we obtain Corollary 3.1.

COROLLARY 3.1. *Under the assumptions of Theorem* 3.1 (iii), *one has* $\sqrt{N_n}(\overline{\theta}_n - \theta^0) \to N(0,\ S^*)$ *in distribution as* $n \to \infty$, *where* $S^* = \overline{\eta}(\theta^0)^{-1} M_1^{-1} S (M_1^{-1})'$.

4. Convergence of the PARMSR algorithm for case (F).

The PARMSR algorithm *without averaging*, with updating period L, is composed of (1.3) and (2.2) with $L_n = L$, $K = 1/L$, and $\tilde{\theta}_{nL+i} = \theta_n$ for $0 \le i \le L-1$ and $n \ge 0$. For $L = 1$, we have $\tilde{\theta}_i = \theta_i$ for all $i \ge 0$. The *averaging* version uses $\overline{\theta}_n$ as a final estimate of θ^0.

(A9) There exists a sequence of one-dependent and identically distributed r.v.'s $\{Z_{m+1}^{(0)},\ m \ge 0\}$, with $\mathsf{E}[(Z_1^{(0)})^{6/\nu}] < \infty$, such that for all $m \ge 0$ and $1 \le i \le \eta_{m+1}$, $\|J_{\theta,k_m+i} - J_{\theta,i}^{(m+1)}(\tilde{\theta}_{k_m})\| \le a_{k_m} Z_{m+1}^{(0)}$ a.s.

(A10) There are two positive constants α_0 and γ_1 such that

$$P\{\eta_{m+1} \ne k_1^{(m+1)}(\tilde{\theta}_{k_m}) \mid \mathcal{F}_{k_m}\} \le \alpha_0 a_{k_m}^{\gamma_1}.$$

(A11) The constants ξ_0 in (A3) and ν in (A4) satisfy $\xi_0 \ge \max\{2/\zeta,\ 4/\nu,\ 2p_1\}$, where $p_1 > 1$ and $\zeta > 0$ are other constants such that for γ_1 in (A10),

$$\nu\,(1 + \gamma_1(1 - 1/p_1)) > 1,\ 0 < \zeta < \delta'\nu,\ \gamma_1(1 - 1/p_1) \ge 1/2,\ \delta' \in (0,\ 1/2].$$

Chong and Ramadge [10] have checked conditions (A9) and (A10) for certain classically regenerative systems, although the convergence rates of the PARMSR algorithms have not been studied there. For example, (A9) and (A10) have been verified in [9, 10, 40, 41] in the context of a $GI/G/1$ queue, with some conditions on the service time and the interarrival time distributions.

THEOREM 4.1. *For the PARMSR algorithm with fixed updating period $L_n = L$, we have the following:*

(i) *If conditions* (A0)–(A10) *hold with $\xi_0 \geq \max\{4,\ 2p_1\}$ and $\nu(1+\gamma_1(1-1/p_1)) > 1$, where $p_1 > 1$ is some constant and γ_1 is given in* (A10)*, then $\theta_n \to \theta^0$ a.s. as $n \to \infty$.*

(ii) *If* (A0)–(A11) *hold and the constant δ' satisfies* (A11)*, one has $\|\theta_n - \theta^0\| = o(a_n^{1/2-\delta'})$ a.s.*

(iii) *If* (A0)–(A11) *hold with $\nu\gamma_1(1-1/p_1) > 1/2$ and $0 < \delta' < 1/2(1-1/(2\nu))$, then for the algorithm with averaging, one has $\sqrt{n}(\overline{\theta}_n - \theta^0) \to N(0,\ S_3)$ in distribution as $n \to \infty$, where $S_3 = L^{-1}\overline{\eta}(\theta^0)^{-1}M_1^{-1}S(M_1^{-1})'$.*

We note that δ' in Theorem 4.1(ii) is independent of ν. Thus $1/2 - \delta'$ can be arbitrarily close to $1/2$ if condition (A3) is fulfilled with a very large ξ_0. This is different from our Theorem 3.1 and from Theorem 2.2 in [41], where $\|\theta_n - \theta^0\| = o(a_n^\delta)$ a.s. with $\delta \in [0,\ 1-1/(2\nu))$ depending on ν. In the latter setup, if ν is close to $1/2$, δ must be close to zero.

For the first n SA iterations, the total computing budget of the PARMSR algorithm with updating period L is $N_n = nL$. The following corollary provides a central limit theorem in terms of N_n.

COROLLARY 4.1. *Suppose that the conditions of Theorem* 4.1(ii) *are satisfied. Then the PARMSR algorithm with averaging and with updating period L satisfies $\sqrt{N_n}(\overline{\theta}_n - \theta^0) \to N(0,\ S^*)$ in distribution as $n \to \infty$, where S^* is defined in Corollary* 3.1.

It follows from Corollaries 3.1 and 4.1 that the PARMSR algorithms with averaging, updated either after every regenerative cycle or after every L steps of the process $\{J_i,\ i \geq 0\}$, have the same convergence rate and the same limit covariance matrix, for arbitrary $L \geq 1$, as a function of the computing budget. It should be pointed out that the small-sample or transient behavior of these algorithms generally differ. We also recall that our analysis of the asymptotic behavior is based on what happens after no projection of θ_n on D occurs anymore. Thus, our results do not apply if the optimizer θ^0 lies on the boundary of D. If θ^0 is very close to the boundary, it may take a long while before no projection occurs, and this may affect the convergence speed.

The choices of $K = 1$ for (R) and $K = 1/L$ for (F) in (2.2) appear natural but are not necessary for the convergence results to hold. The two theorems and their corollaries are still valid for an arbitrary constant $K > 0$ in (2.2).

5. Appendix.

Proof of Theorem 3.1. We use the notation $\mathcal{F}^{(m)} = \mathcal{F}_{k_m}$ for $m > 0$ and $\mathcal{F}^{(m)} = \sigma\{X_0,\ \theta_0,\ \theta_{-1}\}$ for $m \leq 0$. For case (R), the observation noise is $\varepsilon_{n+1} = f_{n+1} - f(\theta_n)\overline{\eta}(\theta_n)$.

(i) We first decompose ε_{n+1} as $\varepsilon_{n+1} = \varepsilon_{n+1}^{(1)} + \varepsilon_{n+1}^{(2)}$, where

$$\varepsilon_{n+1}^{(1)} = \sum_{i=1}^{\eta_{n+1}} J_{\theta,k_n+i} - f(\theta_{n-1})\overline{\eta}(\theta_{n-1}), \tag{5.1}$$

$$\varepsilon_{n+1}^{(2)} = (f(\theta_{n-1}) - f(\theta_n))\overline{\eta}(\theta_{n-1}) + f(\theta_n)(\overline{\eta}(\theta_{n-1}) - \overline{\eta}(\theta_n)). \tag{5.2}$$

By Lemma 2.1 and the one-dependence assumption, it is seen that $\{\varepsilon_{2n}^{(1)},\ \mathcal{F}^{(2n)},\ n \geq$

$1\}$ and $\{\varepsilon^{(1)}_{2n-1},\, \mathcal{F}^{(2n-1)},\, n \geq 1\}$ are martingale difference sequences. By (5.1) and condition (A3),

$$\|\varepsilon^{(1)}_{n+1}\| \leq \eta^*_{n+1} Z_{n+1} + \sup_{\theta\in D} \|f(\theta)\| \sup_{\theta\in D} \overline{\eta}(\theta), \tag{5.3}$$

which yields

$$\sup_n \mathsf{E}\left[\|\varepsilon^{(1)}_{n+1}\|^2 \mid \mathcal{F}^{(n-1)}\right] < \infty \tag{5.4}$$

by the Schwarz inequality and (A3). Then, using the local convergence theorem of martingales (see, e.g., [6, 20, 37]), it is seen that $\sum_{n=1}^{\infty} a^{(1-\delta)}_{2n-1}\varepsilon^{(1)}_{2n} < \infty$ and $\sum_{n=1}^{\infty} a^{(1-\delta)}_{2n-2}\varepsilon^{(1)}_{2n-1} < \infty$ a.s., which implies that

$$\sum_{i=1}^{\infty} a^{1-\delta}_{i-1}\varepsilon^{(1)}_i < \infty \quad \text{a.s.} \tag{5.5}$$

By Lemma 2 of [40] and condition (A3), one derives

$$a^{(1-\delta)/2}_{n-1} Z_n \xrightarrow[n\,\to\,\infty]{} 0 \text{ and } a^{(1-\delta)/2}_{n-1}\eta^*_n \xrightarrow[n\,\to\,\infty]{} 0 \text{ a.s.} \quad \forall\, \delta \in [0,\, 1 - 1/(2\nu)). \tag{5.6}$$

Using condition (A3) and (5.6), it follows from (1.3) and (2.2) that

$$\|\theta_n - \theta_{n-1}\| \leq a_{n-1}\|f_n\| \leq a^{\delta}_{n-1} a^{1-\delta}_{n-1}\eta^*_n Z_n = o(a^{\delta}_n) \quad \text{a.s.},$$

which gives

$$\begin{aligned} \|\varepsilon^{(2)}_{n+1}\| &\leq \|\theta_n - \theta_{n-1}\| \left(B_1 \sup_{\theta\in D} \overline{\eta}(\theta) + B_2 \sup_{\theta\in D} \|f(\theta)\| \right) \\ &= O(\|\theta_n - \theta_{n-1}\|) = o(a^{\delta}_n) \quad \text{a.s.} \end{aligned} \tag{5.7}$$

via (5.2) and the Lipschitz conditions.

By (5.5) and (5.7), the a.s. convergence of the algorithm follows from Theorem 3.1 in [4] (see also Theorem 2.4.1 in [7]). Note that we are using a projection algorithm in (1.3), rather than a randomly varying truncation procedure as in [4, 7]. But the convergence analysis works the same way, since θ^0 is assumed in (A5) to be in the interior of D. After establishing the convergence, by (5.5), (5.7), and Theorem 3.2.1 of [7], it follows that $\|\theta_n - \theta\| = o(a^{\delta}_n)$ a.s.

(ii) Since $\theta_n \to \theta^0$ a.s. as $n \to \infty$, there is a finite time n_0 (which may depend on the sample path) such that

$$\theta_{n+1} = \theta_n - a_n f_{n+1} \quad \forall\, n \geq n_0. \tag{5.8}$$

Define $\varphi_{0,\,0} = I$, $\varphi_{n,n+1} = I$, and

$$\varphi_{n,\,k} = (I + a_n A_n)\cdots(I + a_k A_k) \quad \forall\, n \geq k, \tag{5.9}$$

where $\{A_n,\ n \geq 0\}$ is a sequence of deterministic matrices such that $\lim_{n\to\infty} A_n = -\overline{\eta}(\theta^0) M_1$. Then it is standard to derive that

$$\|\varphi_{n,\,k}\| \leq c_0 \exp\left(-c\sum_{j=k}^{n} a_j\right) \text{ and } \sup_n \sum_{i=1}^{n} a_i\|\varphi_{n,\,i+1}\|^{r_1} < \infty \quad \forall\, r_1 > 0, \tag{5.10}$$

where c_0 and c are some positive constants. From (5.8) one derives

$$\begin{aligned}(5.11)\quad &\frac{\theta_{n+1}-\theta^0}{\sqrt{a_{n+1}}}\\ &= \varphi_{n,n_0}\frac{\theta_{n_0}-\theta^0}{\sqrt{a_{n_0}}} - \sum_{i=n_0}^{n}\varphi_{n,i+1}\sqrt{a_i}\varepsilon_{i+1}^{(1)} - \sum_{i=n_0}^{n}\varphi_{n,i+1}\sqrt{a_i}\varepsilon_{i+1}^{(2)}\\ &\quad - \sum_{i=n_0}^{n}\varphi_{n,i+1}o(a_i)\sqrt{a_i}\varepsilon_{i+1} - \sum_{i=n_0}^{n}\varphi_{n,i+1}\sqrt{a_i}(1+o(a_i))O(\|\theta_i-\theta^0\|^2).\end{aligned}$$

In the proof of Theorem 2 of [3], it is shown that $\mathsf{E}[\|\theta_n-\theta^0\|^2]=O(a_n)$, so the last term on the right side of (5.11) converges to zero in probability via (5.10). By the conditions (A2), (A3), and Lemma 2 of [40], it is derived that $\sqrt{a_n}\varepsilon_{n+1}\to 0$ a.s. as $n\to\infty$, which yields that the fourth term on the right side of (5.11) converges to zero a.s. Similarly, we can prove that the first and the third terms converge to zero a.s. Then, the result follows from standard martingale arguments.

(iii) To prove (iii), we verify that all conditions of Theorem 2 in [3] are fulfilled. Using (2.9) in [3], it is easy to see that condition (A4) on the step sizes is equivalent to (1.5) and (1.6) in [3]. The condition on the existence of the Lyapunov function $v(\theta)$ is put in (A6), which is weaker than (A1) in [3] but is consistent with (A2) in [4] and (A4.3.3) in [7]. Note that we use a projection algorithm in (1.3) rather than a randomly varying truncation procedure as in [3, 4, 7]. Condition (A2) in [3] is implied by our condition (A5).

We now check conditions (A3) and (A4) in [3], concerning the observation noise $\varepsilon_n=\varepsilon_n^{(1)}+\varepsilon_n^{(2)}$. Letting $\delta=0$ in (5.5), by the Kronecker lemma, we have that as $n\to\infty$, $a_n\sum_{i=1}^n\varepsilon_{i+1}^{(1)}\to 0$ a.s., which is (2.5) in [3]. Since $\{\varepsilon_{2n}^{(1)},\ \mathcal{F}^{(2n)},\ n\ge 1\}$ and $\{\varepsilon_{2n-1}^{(1)},\ \mathcal{F}^{(2n-1)},\ n\ge 1\}$ are martingale difference sequences, by (5.3) and (5.4) it is easy to derive that (2.6) and (2.7) in [3] are satisfied. From (5.7) it follows that $\|\varepsilon_{n+1}^{(2)}\|=O(\|\theta_n-\theta_{n-1}\|)=O(a_{n-1}\|f_n\|)$. Then we derive that $\mathsf{E}[\|\varepsilon_{n+1}^{(2)}\|^2]=O(a_n^2)$, which satisfies (A4) in [3]. Thus we can apply Theorem 2 in [3] and this concludes the proof. □

Proof of Theorem 4.1. For Theorem 4.1, we first give the proof for $L=1$ for simplicity of writing, then extend the results to $L>1$. As in the proof of Theorem 3.1, for the convergence of $\sum_{n=1}^\infty a_n^{1-\delta}\varepsilon_{n+1}^{(1)}$, it suffices to prove the convergence of $\sum_{n=1}^\infty a_{2n-1}^{1-\delta}\varepsilon_{2n}^{(1)}$ and $\sum_{n=1}^\infty a_{2n-2}^{1-\delta}\varepsilon_{2n-1}^{(1)}$, where $\{\varepsilon_{2n}^{(1)},\ \mathcal{F}^{(2n)},\ n\ge 1\}$ and $\{\varepsilon_{2n-1}^{(1)},\ \mathcal{F}^{(2n-1)},\ n\ge 1\}$ are martingale difference sequences. Such a technique is standard when one wants to extend some results on classically regenerative processes to the one-dependent regenerative processes. Hence, no generality is lost by supposing that $\{J_n(\theta),\ n\ge 1\}$ is a classically regenerative process, which we now do for simplicity of writing. We first give two lemmas.

Lemma 5.1. *Suppose that $\{z_i\}$ is a sequence of r.v.'s with the same distribution. Then for any $r>0$, $\mathsf{E}|z_1|^r<\infty$ implies*

$$\lim_{n\to\infty} n^{-1/r}z_n=0\quad a.s.$$

Furthermore, if $\{z_i,\ i\ge 1\}$ are mutually independent, then the converse is true.

Proof. The proof follows from the Borel–Cantelli lemma and Corollary 4.1.3 in [11, pp. 90–91]. See also Lemma 2 in [40]. □

LEMMA 5.2. *Suppose that* $\{z_n, \mathcal{B}_n^*\}$ *is an* l*-dimensional martingale difference sequence satisfying*

$$\sup_n \mathsf{E}[\|z_{n+1}\|^2 | \mathcal{B}_n^*] < \infty, \quad \|z_n\| = o(h(n)) \text{ a.s.}, \; h(n) \le h(n+1) \quad \forall\, n \ge 0,$$

and that $g_{n,i}$ *is a* $\mathcal{B}_i^*$*-measurable* $l \times l$*-dimensional random matrix, for* $1 \le i \le n$*, which satisfies*

$$\sum_{i=1}^{n} \|g_{n,i}\|^2 \le \overline{g} < \infty \quad \text{a.s. } \forall\, n \ge 1,$$

where $h(n)$ *and* $\overline{g}$ *are positive constants. Then, as* $n \to \infty$,

$$\max_{1 \le i \le n} \left\| \sum_{j=1}^{i} g_{n,j} z_{j+1} \right\| = o(h(n+1) \log n) \quad \text{a.s.}$$

Proof. The proof is in Guo, Huang, and Hannan [19]. See also [6]. □

Proof of Theorem 4.1(i) for $\boldsymbol{L = 1}$**.** The key idea lies in verifying that $\sum_{n=1}^{\infty} a_n \varepsilon_{n+1}$ converges a.s. Then the desired result follows from Theorem 3.1 in [4] (see also Theorem 2.4.1 in [7]). Recall that the observation noise here is

$$\varepsilon_{n+1} = f_{n+1} - f(\theta_n). \tag{5.12}$$

Denote $D_{m,i} = J_{\theta,i}^{(m+1)}(\theta_{k_m})$, the value of f_{k_m+i} obtained if θ_{k_m+j} is fixed at θ_{k_m} for $j \ge 0$.

(a) We first show that $\sum_{m=1}^{\infty} \sum_{i=1}^{\eta_{m+1}} a_{k_m+i-1} \varepsilon_{k_m+i}$ converges a.s. From (2.2) and (5.12) it is easy to see that

$$\begin{aligned} &\sum_{m=1}^{\infty} \sum_{i=1}^{\eta_{m+1}} a_{k_m+i-1} \varepsilon_{k_m+i} \\ &= \sum_{m=1}^{\infty} \sum_{i=1}^{\eta_{m+1}} (a_{k_m+i-1} - a_{k_m}) \varepsilon_{k_m+i} + \sum_{m=1}^{\infty} a_{k_m} \sum_{i=1}^{\eta_1^{(m+1)}(\theta_{k_m})} (D_{m,i} - f(\theta_{k_m})) \\ &\quad + \sum_{m=1}^{\infty} a_{k_m} \sum_{i=1}^{\eta_{m+1}} (f(\theta_{k_m}) - f(\theta_{k_m+i-1})) + \sum_{m=1}^{\infty} a_{k_m} \sum_{i=1}^{\eta_{m+1}} (f_{k_m+i} - D_{m,i}) \\ &\quad + \sum_{m=1}^{\infty} a_{k_m} \sum_{i=\eta_1^{(m+1)}(\theta_{k_m})+1}^{\eta_{m+1}} (D_{m,i} - f(\theta_{k_m})) I\{\eta_{m+1} > \eta_1^{(m+1)}(\theta_{k_m})\} \\ &\quad - \sum_{m=1}^{\infty} a_{k_m} \sum_{i=\eta_{m+1}+1}^{\eta_1^{(m+1)}(\theta_{k_m})} (D_{m,i} - f(\theta_{k_m})) I\{\eta_{m+1} < \eta_1^{(m+1)}(\theta_{k_m})\}. \end{aligned} \tag{5.13}$$

As in Lemma 3.4 of [41], we can prove that each term on the right-hand side of (5.13) converges a.s.

(b) From the result of step (a), analogous to Lemma 3.5 of [41], we obtain the a.s. convergence of $\sum_{n=1}^{\infty} a_n \varepsilon_{n+1}$. □

Proof of Theorem 4.1(ii) for $L = 1$. We need the following definitions and lemma. For $n \geq 0$, let

$$\psi_{n,i} = \begin{cases} (I - a_n M_1) \cdots (I - a_i M_1) & \text{for } i \leq n, \\ I & \text{for } i = n+1, \\ 0 & \text{for } i \geq n+2, \end{cases} \tag{5.14}$$

$$\sigma(n) = \max\{m : \quad k_m \leq n\}, \quad \tau(n) = \sigma(n) + 1. \tag{5.15}$$

Lemma 5.3. *If conditions* (A0)–(A11) *are satisfied, with* δ' *satisfying* (A11), *then*

$$a_{n+1}^{\delta'-1/2} \sum_{j=0}^{n} a_j \psi_{n,j+1} \varepsilon_{j+1} \xrightarrow[n \to \infty]{} 0 \quad a.s.$$

Proof. Since $-M_1$ is stable, it is standard to derive that (see, e.g., [3] and [7])

$$\|\psi_{n,i}\| \leq c_0 \exp\left(-c \sum_{j=i}^{n} a_j\right), \quad \frac{a_i}{a_n} = \exp\left(o(1) \sum_{s=i}^{n-1} a_s\right) \quad \forall\, n \geq i, \tag{5.16}$$

$$\sup_n \sum_{i=1}^{n} a_i \exp\left(-rc \sum_{j=i+1}^{n} a_j\right) < \infty, \quad \sup_n \sum_{i=1}^{n} a_i \|\psi_{n,i+1}\|^r < \infty \quad \forall\, r > 0, \tag{5.17}$$

where c_0 and c are some constants and $o(1) \to 0$ as $i \to \infty$.

Using (2.2), (5.12), and (5.15), we have

$$\begin{aligned} &a_{n+1}^{\delta'-1/2} \sum_{j=0}^{n} a_j \psi_{n,j+1} \varepsilon_{j+1} \\ &= a_{n+1}^{\delta'-1/2} \sum_{j=k_{\sigma(n)}+1}^{n} a_j \psi_{n,j+1} \varepsilon_{j+1} \\ &\quad + a_{n+1}^{\delta'-1/2} \sum_{m=0}^{\sigma(n)-1} \sum_{i=1}^{\eta_{m+1}} a_{k_m+i-1} \psi_{n,k_m+i} (f_{k_m+i} - f(\theta_{k_m+i-1})) \\ &= a_{n+1}^{\delta'-1/2} \sum_{j=k_{\sigma(n)}+1}^{n} a_j \psi_{n,j+1} \varepsilon_{j+1} \\ &\quad + a_{n+1}^{\delta'-1/2} \sum_{m=0}^{\sigma(n)-1} \sum_{i=1}^{\eta_{m+1}} a_{k_m+i-1} \psi_{n,k_m+i} (f(\theta_{k_m}) - f(\theta_{k_m+i-1})) \\ &\quad + a_{n+1}^{\delta'-1/2} \sum_{m=0}^{\sigma(n)-1} \sum_{i=1}^{\eta_{m+1}} a_{k_m+i-1} \psi_{n,k_m+i} (f_{k_m+i} - D_{m,i}) \\ &\quad + a_{n+1}^{\delta'-1/2} \sum_{m=0}^{\sigma(n)-1} \sum_{i=1}^{\eta_{m+1}} (a_{k_m+i-1} - a_{k_m}) \psi_{n,k_m+i} (D_{m,i} - f(\theta_{k_m})) \end{aligned} \tag{5.18}$$

$$+a_{n+1}^{\delta'-1/2}\sum_{m=0}^{\sigma(n)-1}\sum_{i=1}^{\eta_{m+1}} a_{k_m}(\psi_{n,k_m+i}-\psi_{n,k_m})(D_{m,i}-f(\theta_{k_m}))$$

$$+a_{n+1}^{\delta'-1/2}\sum_{m=0}^{\sigma(n)-1} a_{k_m}\psi_{n,k_m}w_{m+1}$$

$$+a_{n+1}^{\delta'-1/2}\sum_{m=0}^{\sigma(n)-1} a_{k_m}\psi_{n,k_m}\sum_{i=\eta_1^{(m+1)}(\theta_{k_m})+1}^{\eta_{m+1}}(D_{m,i}-f(\theta_{k_m}))I\{\eta_{m+1}>\eta_1^{(m+1)}(\theta_{k_m})\}$$

$$-a_{n+1}^{\delta'-1/2}\sum_{m=0}^{\sigma(n)-1} a_{k_m}\psi_{n,k_m}\sum_{i=\eta_{m+1}+1}^{\eta_1^{(m+1)}(\theta_{k_m})}(D_{m,i}-f(\theta_{k_m}))I\{\eta_{m+1}<\eta_1^{(m+1)}(\theta_{k_m})\},$$

where

$$w_{m+1}=\sum_{i=1}^{\eta_1^{(m+1)}(\theta_{k_m})}(D_{m,i}-f(\theta_{k_m})). \tag{5.19}$$

We will show that each term on the right-hand side of the second equality in (5.18) converges to zero a.s. Then the desired result follows from (5.18).

(i) By condition (A4), there is a constant α_1 such that

$$\max_{1\le i\le\eta_{m+1}}\left(\frac{a_{k_m}}{a_{k_m+i}}\right)\le 1+\alpha_1 a_{k_m}\eta_{m+1}^* \text{ and } \max_{1\le i\le\eta_{m+1}}|a_{k_m+i}-a_{k_m}|\le\alpha_1 a_{k_m}^2\eta_{m+1}^*. \tag{5.20}$$

Using (A3), it follows from (5.12) that

$$\|\varepsilon_{k_m+i}\|\le W_{m+1}^{(0)}\overset{\triangle}{=}\max_{\theta\in D}\|f(\theta)\|+Z_{m+1}\quad\text{for}\quad 1\le i\le\eta_{m+1}. \tag{5.21}$$

By Lemma 5.1 and conditions (A3) and (A11), one has

$$\frac{1}{\sqrt{m^v}}\eta_{m+1}^*W_{m+1}^{(0)}\xrightarrow[m\to\infty]{}0\quad\text{a.s.}, \tag{5.22}$$

which yields

$$\sqrt{a_{k_{\sigma(n)}}}\eta_{\sigma(n)+1}(\theta^*)W_{\sigma(n)+1}^{(0)}\xrightarrow[n\to\infty]{}0\quad\text{a.s.} \tag{5.23}$$

By (5.16), (5.20), and (5.21), we have

$$\frac{a_{n+1}^{\delta'}}{\sqrt{a_{n+1}}}\left\|\sum_{j=k_{\sigma(n)}+1}^{n}a_j\psi_{n,j+1}\varepsilon_{j+1}\right\|\le\frac{a_{n+1}^{\delta'}}{\sqrt{a_{n+1}}}c_0a_{k_{\sigma(n)}}W_{\sigma(n)+1}^{(0)}\eta_{\sigma(n)+1}(\theta^*)$$

$$\le c_0a_{n+1}^{\delta'}\left(\frac{a_{k_{\sigma(n)}}}{a_{k_{\sigma(n)+1}}}\right)^{1/2}a_{k_{\sigma(n)}}^{1/2}\eta_{\sigma(n)+1}(\theta^*)W_{\sigma(n)+1}^{(0)}$$

$$\le c_0a_{n+1}^{\delta'}(1+\alpha_1a_{k_{\sigma(n)}}\eta_{\sigma(n)+1}(\theta^*))^{1/2}\sqrt{a_{k_{\sigma(n)}}}\eta_{\sigma(n)+1}(\theta^*)W_{\sigma(n)+1}^{(0)}\xrightarrow[n\to\infty]{}0\quad\text{a.s.},$$

which implies that the first term on the right-hand side of the second equality in (5.18) converges to zero as $n \to \infty$ a.s.

(ii) Using (A3), it follows from (1.3) and (2.2) that

$$\|\theta_{k_m+i} - \theta_{k_m}\| \leq \sum_{j=1}^{i} \|\theta_{k_m+j} - \theta_{k_m+j-1}\| \leq a_{k_m} W_{m+1} \quad \text{for } 1 \leq i \leq \eta_{m+1}, \tag{5.24}$$

where $W_{m+1} = \eta^*_{m+1} Z_{m+1}$.

By (A7), (5.20), and (5.24), one has

$$\begin{aligned} & a_{n+1}^{\delta'-1/2} \left\| \sum_{m=0}^{\sigma(n)-1} \sum_{i=1}^{\eta_{m+1}} a_{k_m+i-1} \psi_{n,k_m+i} (f(\theta_{k_m}) - f(\theta_{k_m+i-1})) \right\| \\ & \leq B_1 a_{n+1}^{\delta'} \sum_{m=0}^{\sigma(n)-1} \sum_{i=1}^{\eta_{m+1}} a_{k_m+i-1} \|\psi_{n,k_m+i}\| \frac{1}{\sqrt{a_{n+1}}} a_{k_m} W_{m+1} \\ & \leq B_1 a_{n+1}^{\delta'} \sum_{m=0}^{\sigma(n)-1} \sum_{i=1}^{\eta_{m+1}} a_{k_m+i-1} \|\psi_{n,k_m+i}\| \left(\frac{a_{k_m+i}}{a_{n+1}} \right)^{1/2} \\ & \qquad \cdot \max_{1 \leq i \leq \eta_{m=1}} \left(\frac{a_{k_m}}{a_{k_m+i}} \right)^{1/2} \sqrt{a_{k_m}} W_{m+1} \\ & \leq B_1 c_0 a_{n+1}^{\delta'} \sum_{m=0}^{\sigma(n)-1} \sum_{i=1}^{\eta_{m+1}} a_{k_m+i-1} \exp\left(-c \sum_{j=k_m+i}^{n} a_j \right) \exp\left(o(1) \sum_{j=k_m+i}^{n} a_j \right) \\ & \qquad \cdot (1 + \alpha_1 a_{k_m} \eta^*_{m+1})^{1/2} \sqrt{a_{k_m}} W_{m+1} \\ & \xrightarrow[n \to \infty]{} 0 \quad \text{a.s.,} \end{aligned} \tag{5.25}$$

since by (5.16)–(5.17),

$$\begin{aligned} & \sum_{m=0}^{\sigma(n)-1} \sum_{i=1}^{\eta_{m+1}} a_{k_m+i-1} \exp\left(-c \sum_{j=k_m+i}^{n} a_j \right) \exp\left(o(1) \sum_{j=k_m+i}^{n} a_j \right) \\ & \leq \sum_{i=0}^{n} a_i \exp\left(-c \sum_{j=i+1}^{n} a_j \right) \exp\left(o(1) \sum_{j=i+1}^{n} a_j \right) \;=\; O(1) \quad \text{a.s.,} \end{aligned}$$

and by (5.22)

$$(1 + \alpha_1 a_{k_m} \eta^*_{m+1})^{1/2} \sqrt{a_{k_m}} W_{m+1} \xrightarrow[m \to \infty]{} 0 \quad \text{a.s.}$$

Thus, the second term on the right-hand side of the second equality in (5.18) converges to zero a.s. as $n \to \infty$.

(iii) By condition (A9) one has

$$\|f_{k_m+i} - D_{m,i}\| \leq a_{k_m} Z^{(0)}_{m+1} \quad \text{a.s.} \tag{5.26}$$

for $1 \le i \le \eta_{m+1}$. Similar to (5.22), by Lemma 5.1 it follows that

$$\sqrt{a_{k_m}} Z^{(0)}_{m+1} \xrightarrow[m \to \infty]{} 0 \quad \text{a.s.} \tag{5.27}$$

By the same argument as in (5.25), it is seen that

$$\begin{aligned} & a_{n+1}^{\delta'-1/2} \left\| \sum_{m=0}^{\sigma(n)-1} \sum_{i=1}^{\eta_{m+1}} a_{k_m+i-1} \psi_{n,k_m+i} (f_{k_m+i} - D_{m,i}) \right\| \\ & \le a_{n+1}^{\delta'} \sum_{m=0}^{\sigma(n)-1} \sum_{i=1}^{\eta_{m+1}} a_{k_m+i-1} \|\psi_{n,k_m+i}\| \left(\frac{a_{k_m+i}}{a_{n+1}} \right)^{1/2} \max_{1 \le i \le \eta_{m+1}} \left(\frac{a_{k_m}}{a_{k_m+i}} \right)^{1/2} \\ & \qquad \cdot \sqrt{a_{k_m}} Z^{(0)}_{m+1} \\ & \le c_0 a_{n+1}^{\delta'} \sum_{m=0}^{\sigma(n)-1} \sum_{i=1}^{\eta_{m+1}} a_{k_m+i-1} \exp\left(-c \sum_{j=k_m+i}^{n} a_j \right) \exp\left(o(1) \sum_{j=k_m+i}^{n} a_j \right) \\ & \qquad \cdot (1 + \alpha_1 a_{k_m})^{1/2} \sqrt{a_{k_m}} Z^{(0)}_{m+1} \\ & \xrightarrow[n \to \infty]{} 0 \quad \text{a.s.,} \end{aligned} \tag{5.28}$$

which implies that the third term on the right-hand side of the second inequality in (5.18) converges to zero as $n \to \infty$ a.s.

(iv) Analogous to (5.25), by (5.20) it is derived that the fourth term on the right-hand side of the second inequality in (5.18) converges to zero as $n \to \infty$ a.s.

(v) By the definition (5.14), we have

$$\begin{aligned} \psi_{n,k_m+i} - \psi_{n,k_m} &= \sum_{j=1}^{i} a_{k_m+j-1} \psi_{n,k_m+j} M_1 \\ &= \psi_{n,k_m+i} \sum_{j=1}^{i} a_{k_m+j-1} \psi_{k_m+i-1,k_m+j} M_1. \end{aligned} \tag{5.29}$$

Similar to (5.25), we arrive at the conclusion that the fifth term on the right-hand side of the second inequality in (5.18) converges to zero as $n \to \infty$ a.s.

(vi) We now consider the convergence of the sixth term. First, by the definition (5.14),

$$\sum_{m=0}^{\tau(n)} \psi_{n,k_m} a_{k_m} w_{m+1} = \sum_{m=0}^{n+1} a_{k_m} \psi_{n,k_m} w_{m+1}. \tag{5.30}$$

Let $h(m) = m^\zeta \ \forall \ m \ge 1$, where ζ is some constant satisfying $0 < \zeta < \delta' \nu$. Then by condition (A11) and Lemma 2.1 we have

$$\frac{\|w_{m+1}\|}{h(m)} \le \frac{W^{(0)}_{m+1} \eta^*_{m+1}}{m^\zeta} \xrightarrow[m \to \infty]{} 0 \quad \text{a.s.} \tag{5.31}$$

By (5.16)–(5.17), it is derived that

$$
\begin{aligned}
(5.32)\qquad \frac{1}{a_{n+1}}\sum_{m=0}^{n+1} a_{k_m}^2\|\psi_{n,k_m}\|^2 &\le \frac{1}{a_{n+1}}\sum_{m=0}^{n+1} a_{k_m-1}a_{k_m}\|\psi_{n,k_m}\|^2\\
&\le \frac{1}{a_{n+1}}\sum_{i=0}^{n+1} a_{i-1}\|\psi_{n,i}\|^2 a_i\\
&\le c_0^2\sum_{i=0}^{n+1}\exp\left(-2c\sum_{j=i}^{n}a_j\right)a_{i-1}\exp\left(o(1)\sum_{j=i}^{n}a_j\right)=O(1),
\end{aligned}
$$

which, incorporating with (5.31) and Lemma 5.2, leads to

$$
(5.33)\qquad \frac{1}{\sqrt{a_{n+1}}}\sum_{m=0}^{n+1}\psi_{n,k_m}a_{k_m}w_{m+1}=O(1)+o(h(n)\log n).
$$

By (5.33), it follows from (5.30) that

$$
\begin{aligned}
a_{n+1}^{\delta'-1/2}\sum_{m=0}^{\tau(n)}a_{k_m}\psi_{n,k_m}w_{m+1} &= O(a_{n+1}^{\delta'})+o\left(a_{n+1}^{\delta'}h(n)\log n\right)\\
&= o\left(\frac{1}{n^{\delta'\nu-\zeta}}\log n\right)=o(1)\quad \text{a.s.},
\end{aligned}
$$

which implies that $a_{n+1}^{\delta'-1/2}\sum_{m=0}^{\sigma(n)-1}a_{k_m}\psi_{n,k_m}w_{m+1}\to 0$ a.s. as $n\to\infty$, since by (5.16), (5.20), and (5.22)–(5.23) we have

$$
\begin{aligned}
&\frac{a_{n+1}^{\delta}}{\sqrt{a_{n+1}}}\|\psi_{n,k_{\sigma(n)}}a_{k_{\sigma(n)}}w_{\sigma(n)+1}+\psi_{n,k_{\tau(n)}}a_{k_{\tau(n)}}w_{\tau(n)+1}\|\\
&\le c_0a_{n+1}^{\delta}\Big((1+\alpha_1a_{k_{\sigma(n)}}\eta^*_{\sigma(n)+1})^{1/2}\sqrt{a_{k_{\sigma(n)}}}\eta^*_{\sigma(n)+1}W^{(0)}_{\sigma(n)+1}\\
&\qquad+\left(\frac{a_n}{a_{n+1}}\right)^{1/2}\sqrt{a_{k_{\tau(n)}}}\eta^*_{\tau(n)+1}W^{(0)}_{\tau(n)+1}\Big)\xrightarrow[n\to\infty]{}0\quad\text{a.s.}
\end{aligned}
$$

(vii) Set

$$
V_{m+1}^{(0)}=\sum_{i=\eta_1^{(m+1)}(\theta_{k_m})+1}^{\eta_{m+1}}(D_{m,i}-f(\theta_{k_m}))I\{\eta_{m+1}>\eta_1^{(m+1)}(\theta_{k_m})\}\quad\forall\, m\ge 0.
$$

By (5.31), we get

$$
(5.34)\qquad \frac{V_m^{(0)}-\mathsf{E}[V_m^{(0)}|\mathcal{F}^{(m-1)}]}{h(m)}\xrightarrow[m\to\infty]{}0\quad\text{a.s.},
$$

which incorporating with (5.32) and Lemma 5.2 yields

$$
\begin{aligned}
(5.35)\qquad &\frac{1}{\sqrt{a_{n+1}}}\sum_{m=0}^{n+1}\psi_{n,k_m}a_{k_m}(V_{m+1}^{(0)}-\mathsf{E}[V_{m+1}^{(0)}|\mathcal{F}^{(m)}])\\
&=O(1)+o(h(n)\log n)=o(h(n)\log n)\quad\text{a.s.}
\end{aligned}
$$

By Hölder's inequality and condition (A10) for any $p_1>1$ we have

$$\begin{aligned}(5.36)\qquad &\|\mathsf{E}[V_{m+1}^{(0)}|\mathcal{F}^{(m)}]\|\\ &\leq \mathsf{E}[\eta_{m+1}^{*}W_{m+1}^{(0)}I\{\eta_{m+1}>\eta_1^{(m+1)}(\theta_{k_m})\}|\mathcal{F}^{(m)}]\\ &\leq \left(\mathsf{E}\left[(W_{m+1}^{(0)}\eta_{m+1}^{*})^{p_1}\right]\right)^{1/p_1}P\{\eta_{m+1}>\eta_1^{(m+1)}(\theta_{k_m})|\mathcal{F}^{(m)}\}^{1-1/p_1}\\ &\leq \alpha_0^{1-1/p_1}\left(\mathsf{E}\left[(W_{m+1}^{(0)}\eta_{m+1}^{*})^{p_1}\right]\right)^{1/p_1}a_{k_m}^{\gamma_1(1-1/p_1)},\end{aligned}$$

which leads to

$$\begin{aligned}(5.37)\qquad &\frac{1}{a_{n+1}^{1/2-\delta'}}\left\|\sum_{m=0}^{n+1}\psi_{n,k_m}a_{k_m}\mathsf{E}[V_{m+1}^{(0)}|\mathcal{F}^{(m)}]\right\|\\ &\leq \alpha_0^{1-1/p_1}\sup_m\left\{\left(\mathsf{E}\left[(W_{m+1}^{(0)}\eta_{m+1}^{*})^{p_1}\right]\right)^{1/p_1}\right\}\\ &\cdot\frac{1}{a_{n+1}^{1/2-\delta'}}\sum_{m=0}^{n+1}\|\psi_{n,k_m}\|a_{k_m-1}a_{k_m}^{\gamma_1(1-1/p_1)}\\ &\leq O(1)a_{n+1}^{\delta'}\sum_{i=-1}^{n+1}a_i\exp\left(-c\sum_{j=i+1}^{n}a_j\right)\left(\frac{a_{i+1}}{a_{n+1}}\right)^{1/2}a_{i+1}^{\gamma_1(1-1/p_1)-1/2}\\ &=o(1)\quad\text{a.s.,}\end{aligned}$$

provided that $\gamma_1(1-1/p_1)\geq 1/2$. Combining (5.35) and (5.37) gives

$$\frac{1}{a_{n-1}^{1/2-\delta'}}\left\|\sum_{m=0}^{n+1}\psi_{n,k_m}a_{k_m}V_{m+1}^{(0)}\right\|=o(1)+o(a_{n+1}^{\delta'}h(n)\log n)=o(1)\quad\text{a.s.,}$$

where $0<\zeta<\delta'\nu$.

(viii) In the same way as in (vii), one shows that the last term on the right-hand side of the second equality in (5.18) converges to zero a.s. □

Proof of Theorem 4.1(ii) for $L = 1$. By Theorem 4.1(i), there is an a.s. finite r.v. n_0^* such that no projection occurs after step n_0^*; i.e.,

$$(5.38)\qquad \theta_{n+1}=\theta_n-a_n(f(\theta_n)+\varepsilon_{n+1})\quad\forall\ n\geq n_0^*.$$

Then, for a deterministic integer n_0, on the event $\{n\geq n_0\geq n_0^*\}$, one has

$$\begin{aligned}(5.39)\qquad \frac{\theta_{n+1}-\theta^0}{a_{n+1}^{1/2-\delta'}}&=a_{n+1}^{\delta'-1/2}\psi_{n,n_0}(\theta_{n_0}-\theta^0)-a_{n+1}^{\delta'-1/2}\sum_{j=n_0}^{n}\psi_{n,j+1}a_j\varepsilon_{j+1}\\ &-a_{n+1}^{\delta'-1/2}\sum_{j=n_0}^{n}\psi_{n,j+1}a_j(f(\theta_j)-M_1(\theta_j-\theta^0)).\end{aligned}$$

Let $r\leq r_0$, where r_0 is given by condition (A5). Define

$$(5.40)\qquad \sigma^*=\begin{cases}0 & \text{if }\ \|\theta_{n_0}-\theta^0\|\geq r,\\ \inf\{j:\ \ j>n_0,\ \|\theta_j-\theta^0\|\geq r\} & \text{otherwise.}\end{cases}$$

By (5.16), it is easy to see that

$$\begin{aligned}(5.41)\qquad &\|a_{n+1}^{\delta'-1/2}\psi_{n,n_0}(\theta_{n_0}-\theta^0)\|\\ &\le c_0 a_{n_0}^{\delta'-1/2}\left(\frac{a_{n_0}}{a_{n+1}}\right)^{1/2-\delta'}\exp\left(-c\sum_{j=n_0}^{n}a_j\right)\|\theta_{n_0}-\theta^0\|\\ &\le O(1)\exp\left(-c\sum_{j=n_0}^{n}a_j\right)\exp\left(o(1)\sum_{j=n_0}^{n}a_j\right)\\ &=o(1)\quad\text{as}\quad n\to\infty.\end{aligned}$$

Let c_0^* be a constant such that

$$\sup_{j\ge1}\left\{\left(\frac{a_j}{a_{j+1}}\right)^{1/2-\delta'}\right\}\le c_0^*.$$

By condition (A5) and (5.16), we have

$$\begin{aligned}(5.42)\quad & a_{n+1}^{\delta'-1/2}\left\|\sum_{j=n_0}^{n}\psi_{n,j+1}a_j(f(\theta_j)-M_1(\theta_j-\theta^0))I\{\sigma^*>n+1,\ n_0^*\le n_0\}\right\|\\ &\le c_0c_1a_{n+1}^{\delta'-1/2}\sum_{j=n_0}^{n}\exp\left(-c\sum_{s=j+1}^{n}a_s\right)a_j\|\theta_j-\theta^0\|^2I\{\sigma^*>j,\ n_0^*\le n_0\}\\ &\le c_0c_1r\sum_{j=n_0}^{n}\exp\left(-c\sum_{s=j+1}^{n}a_s\right)a_j\left(\frac{a_j}{a_{n+1}}\right)^{1/2-\delta'}\frac{\|\theta_j-\theta^0\|I\{\sigma^*>j,\ n_0^*\le n_0\}}{a_j^{1/2-\delta'}}\\ &\le c_0^*c_0c_1r\sum_{j=n_0}^{n}\exp\left(-\frac{c}{2}\sum_{s=j+1}^{n}a_s\right)a_j\frac{\|\theta_j-\theta^0\|I\{\sigma^*>j,\ n_0^*\le n_0\}}{a_j^{1/2-\delta'}}\end{aligned}$$

if n_0 is large enough.

By Lemma 5.3 and (5.41)–(5.42), it follows from (5.39) that

$$\begin{aligned}&\|\theta_{n+1}-\theta^0\|I\{\sigma^*>n+1,\ n_0^*\le n_0\}a_{n+1}^{\delta'-1/2}\\ &\le o(1)+c_0^*c_0c_1r\sum_{j=n_0}^{n}\exp\left(-\frac{c}{2}\sum_{s=j+1}^{n}a_s\right)a_j\\ (5.43)\qquad &\cdot\|\theta_j-\theta^0\|^2I\{\sigma^*>j,\ n_0^*\le n_0\}a_j^{\delta'-1/2},\end{aligned}$$

which, incorporating the Bellman–Gronwall inequality, leads to

$$\begin{aligned}(5.44)\qquad &\|\theta_n-\theta^0\|I\{\sigma^*>n,\ n_0^*\le n_0\}a_n^{\delta'-1/2}\\ &\le o(1)+o(1)\sum_{j=n_0}^{n-1}\exp\left(-\frac{c}{2}\sum_{s=j+1}^{n}a_s\right)a_j\exp\left(c_0^*c_0c_1r\sum_{s=j+1}^{n-1}a_s\right)\end{aligned}$$

$$\leq o(1) + o(1) \sum_{j=n_0}^{n-1} a_j \exp\left(-\frac{c}{4} \sum_{s=j+1}^{n-1} a_s \right) \; = \; o(1),$$

where r is sufficiently small such that $c_0^* c_0 c_1 r \leq c/4$. From (5.44), it is readily seen that $\|\theta_n - \theta^0\| = o(a_n^{1/2-\delta'})$ as $n \to \infty$ a.s. □

Proof of Theorem 4.1(iii) for $L = 1$. In order to prove Theorem 4.1(iii), we need several lemmas. From (5.14), we have

$$\psi_{n,j} = \psi_{n-1,j} - a_n M_1 \psi_{n-1,j} = I - M_1 \sum_{i=j}^{n} a_i \psi_{i-1,j},$$

which gives

$$(5.45) \quad a_{j-1} \sum_{i=j}^{n} \psi_{i-1,j} = \sum_{i=j}^{n} a_i \psi_{i-1,j} + \sum_{i=j}^{n} (a_{j-1} - a_i) \psi_{i-1,j} = M_1^{-1} + G_{n,j},$$

where

$$(5.46) \qquad G_{n,j} \overset{\triangle}{=} -M_1^{-1} \psi_{n,j} + \sum_{i=j}^{n} (a_{j-1} - a_i) \psi_{i-1,j} \quad \forall\ n \geq j.$$

LEMMA 5.4. *Let the conditions of Theorem* 4.1(iii) *be satisfied. Then*

$$\lim_{n\to\infty} \frac{1}{\sqrt{n}} \sum_{j=1}^{n-1} (M_1^{-1} + G_{n,j+1})(f(\theta_j) - M_1(\theta_j - \theta^0)) = 0 \quad a.s.$$

Proof. For any $\delta' \in (0,\ 1/2(1 - 1/(2\nu)))$, by condition (A4) and Theorem 4.1(ii) it follows that

$$\sum_{i=1}^{\infty} \frac{1}{\sqrt{i}} \|\theta_i - \theta^0\|^2 = \sum_{i=1}^{\infty} \frac{1}{\sqrt{i}} o(a_i^{1-2\delta'}) = \sum_{i=1}^{\infty} \frac{1}{\sqrt{i}} o\left(\frac{1}{i^{\nu(1-2\delta')}} \right) < \infty \ \text{ a.s.},$$

which gives

$$(5.47) \qquad \lim_{n\to\infty} \frac{1}{\sqrt{n}} \sum_{j=1}^{n-1} \|\theta_j - \theta^0\|^2 = 0 \quad \text{a.s.}$$

via the Kronecker lemma (see, e.g., [11]).

It is shown in [3, Lemma 1] that for all $n \geq j \geq 1$, $G_{n,j}$ defined by (5.46) are bounded. From Theorem 4.1, condition (A5), and (5.47), the lemma follows easily. □

LEMMA 5.5. *Suppose that conditions* (A0)–(A11) *are satisfied. Then we have that* $1/\sqrt{n} \sum_{i=1}^{n} \varepsilon_i \to N(0,\ S_4)$ *in distribution as* $n \to \infty$*, where* $S_4 = \overline{\eta}(\theta^0)^{-1} S$.

Proof. As in (5.13), we decompose

$$
\begin{aligned}
\frac{1}{\sqrt{n}}\sum_{i=1}^{n}\varepsilon_i
&= \frac{1}{\sqrt{n}}\sum_{j=k_{\sigma(n)}+1}^{n}\varepsilon_j + \frac{1}{\sqrt{n}}\sum_{m=0}^{\sigma(n)-1}\sum_{i=1}^{\eta_{m+1}}(f_{k_m+i}-D_{m,i})\\
&\quad+\frac{1}{\sqrt{n}}\sum_{m=0}^{\sigma(n)-1}\sum_{i=1}^{\eta_{m+1}}(f(\theta_{k_m})-f(\theta_{k_m+i-1}))\\
&\quad+\frac{1}{\sqrt{n}}\sum_{m=0}^{\sigma(n)-1}\sum_{i=\eta_1^{(m+1)}(\theta_{k_m})+1}^{\eta_{m+1}}(D_{m,i}-f(\theta_{k_m}))I\{\eta_{m+1}>\eta_1^{(m+1)}(\theta_{k_m})\}\\
&\quad-\frac{1}{\sqrt{n}}\sum_{m=0}^{\sigma(n)-1}\sum_{i=\eta_{m+1}+1}^{\eta_1^{(m+1)}(\theta_{k_m})}(D_{m,i}-f(\theta_{k_m}))I\{\eta_{m+1}<\eta_1^{(m+1)}(\theta_{k_m})\}\\
&\quad+\frac{1}{\sqrt{n}}\sum_{m=0}^{\sigma(n)-1}w_{m+1},
\end{aligned} \tag{5.48}
$$

where $\sigma(n)$ is defined by (5.15) and w_{m+1} is defined by (5.19).

Initially, we show that each of the first five terms on the right-hand side of (5.48) converges to zero a.s. as $n\to\infty$. Then we show that the last term converges to a $N(0,\ S_4)$ in distribution. Hence the desired result follows.

(i) Similar to (5.23), it is easy to show that the first term on the right-hand side of (5.48) converges to zero as $n\to\infty$ a.s.

(ii) By (5.26) it is derived that

$$
\begin{aligned}
\sum_{m=1}^{\infty}\frac{1}{\sqrt{m}}\mathsf{E}\left[\left\|\sum_{i=1}^{\eta_{m+1}}(f_{k_m+i}-D_{m,i})\right\|\,\middle|\mathcal{F}^{(m)}\right] &\le \sum_{m=1}^{\infty}\frac{1}{\sqrt{m}}a_{k_m}\mathsf{E}\left[\eta^*_{m+1}Z^*_{m+1}Z^{(0)}_{m+1}\right]\\
&\le \sum_{m=1}^{\infty}\frac{\overline{a}}{m^{\nu+1/2}}\mathsf{E}\left[\eta^*_{m+1}Z^*_{m+1}Z^{(0)}_{m+1}\right]<\infty \quad \text{a.s.},
\end{aligned}
$$

which implies

$$
\sum_{m=1}^{\infty}\frac{1}{\sqrt{m}}\sum_{i=1}^{\eta_{m+1}}(f_{k_m+i}-D_{m,i})<\infty \quad \text{a.s.} \tag{5.49}
$$

by the local convergence theorem of martingales (see, e.g., [6, 20, 37]). By the Kronecker lemma, it follows from (5.49) that

$$
\lim_{n\to\infty}\frac{1}{\sqrt{n}}\sum_{m=0}^{n}\sum_{i=1}^{\eta_{m+1}}(f_{k_m+i}-D_{m,i})=0 \quad \text{a.s.},
$$

which gives

$$
\lim_{n\to\infty}\frac{1}{\sqrt{n}}\sum_{m=0}^{\sigma(n)-1}\sum_{i=1}^{\eta_{m+1}}(f_{k_m+i}-D_{m,i})=0 \quad \text{a.s.}, \tag{5.50}
$$

since $\sigma(n) \le n \ \forall \ n \ge 1$.

(iii) By (5.24), similar to (5.50) we can prove that the third term on the right-hand side of (5.48) converges to zero as $n \to \infty$ a.s.

(iv) By (5.36) and condition (A4), we derive that

$$\mathsf{E}\left\| \sum_{m=1}^{\infty} \frac{1}{\sqrt{m}} \sum_{i=\eta_1^{(m+1)}(\theta_{k_m})+1}^{\eta_{m+1}} (D_{m,i} - f(\theta_{k_m})) I\{\eta_{m+1} > \eta_1^{(m+1)}(\theta_{k_m})\} \right\| \tag{5.51}$$
$$\le \sum_{m=1}^{\infty} \frac{1}{\sqrt{m}} \alpha_0^{1-1/p_1} \left(\mathsf{E}\left[(W_{m+1}^{(0)} \eta_{m+1}^*)^{p_1} \right] \right)^{1/p_1} \overline{a}^{\gamma_1(1-1/p_1)} m^{-\gamma_1(1-1/p_1)\nu} < \infty$$

if $\nu\gamma_1(1 - 1/p_1) > 1/2$. By (5.51), it is easy to prove that the fourth term on the right-hand side of (5.48) converges to zero as $n \to \infty$ a.s.

(v) Similar to (iv), we can prove that the fifth term on the right-hand side of (5.48) converges to zero a.s. as $n \to \infty$.

(vi) By the central limit theorem for martingales (see, e.g., [11] and [20]),

$$\frac{1}{\sqrt{n}} \sum_{m=0}^{n} w_{m+1} \xrightarrow[n \to \infty]{d} N(0, \ S). \tag{5.52}$$

We now show that

$$\frac{\sigma(n)}{n} \xrightarrow[n \to \infty]{} \frac{1}{\overline{\eta}(\theta^0)} \quad \text{a.s.} \tag{5.53}$$

One can decompose

$$\frac{1}{n}\sum_{i=1}^{n} \eta_i = \frac{1}{n}\sum_{i=1}^{n} (\eta_i - \eta_1^{(i)}(\theta_{k_{i-1}})) + \frac{1}{n}\sum_{i=1}^{n} (\eta_1^{(i)}(\theta_{k_{i-1}}) - \overline{\eta}(\theta_{k_{i-1}})) \tag{5.54}$$
$$+ \frac{1}{n}\sum_{i=1}^{n} (\overline{\eta}(\theta_{k_{i-1}}) - \overline{\eta}(\theta^0)) + \overline{\eta}(\theta^0).$$

By conditions (A9) and (A10), we have

$$\mathsf{E}\left[\sum_{i=1}^{\infty} \frac{1}{i} \|\eta_i - \eta_1^{(i)}(\theta_{k_{i-1}})\| \right] \le \sum_{i=1}^{\infty} \frac{1}{i} \mathsf{E}\left[\eta_i^* I\{\eta_i \ne \eta_1^{(i)}(\theta_{k_{i-1}})\} \right]$$
$$\le \sum_{i=1}^{\infty} \frac{1}{i} \sqrt{\mathsf{E}[(\eta_1^*)^2]} \sqrt{P\{\eta_i \ne \eta_1^{(i)}(\theta_{k_{i-1}})\}} \le O(1) \sum_{i=1}^{\infty} \frac{1}{i} i^{-\gamma_1\nu/2} < \infty,$$

which, combining with the Kronecker lemma, yields $\lim_{n\to\infty} 1/n \sum_{i=1}^{n} (\eta_i - \eta_1^{(i)}(\theta_{k_{i-1}})) < \infty$ a.s. By the local convergence theorem of martingales and the Kronecker lemma, it is derived that $\lim_{n\to\infty} 1/n \sum_{i=1}^{n} (\eta_1^{(i)}(\theta_{k_{i-1}}) - \overline{\eta}(\theta_{k_{i-1}})) = 0$ a.s. By Theorem 3.1, $\theta_n \to \theta^0$ a.s. as $n \to \infty$, which implies $1/n \sum_{i=1}^{n} (\overline{\eta}(\theta_{k_{i-1}}) - \overline{\eta}(\theta^0)) \to 0$ as $n \to \infty$ a.s. via the continuity of $\overline{\eta}(\theta)$ at θ^0. Thus it follows from (5.54) that

$$\frac{1}{n}\sum_{i=1}^{n} \eta_i \xrightarrow[n \to \infty]{} \overline{\eta}(\theta^0) \quad \text{a.s.} \tag{5.55}$$

From the definition (5.15), we have $n < \sum_{i=1}^{\sigma(n)+1} \eta_i \le n + \eta_{\sigma(n)+1}$, which gives

$$1 < \left(\frac{\sigma(n)}{n} + \frac{1}{n}\right) \frac{1}{\sigma(n)+1} \sum_{i=1}^{\sigma(n)+1} \eta_i \le 1 + \frac{\sigma(n)+1}{n} \frac{1}{\sigma(n)+1} \eta^*_{\sigma(n)+1}. \tag{5.56}$$

This yields (5.53) by (5.55) and Lemma 5.1.

To prove

$$\frac{1}{\sqrt{n}} \sum_{m=0}^{\sigma(n)-1} w_{m+1} \xrightarrow[n \to \infty]{} N(0,\ S_4), \tag{5.57}$$

we need a central limit theorem for stopped martingales. We note that if the Kolmogorov inequality is replaced by Doob's inequality (see, e.g., [11]), the proof of Theorem 9.4.1 in [11] goes through for the stopped martingales. Then, by (5.52) and (5.53), (5.57) follows. □

LEMMA 5.6. *If the conditions of Theorem* 4.1(iii) *are fulfilled, then we have that* $1/\sqrt{n}\sum_{j=1}^{n} G_{n,j}\varepsilon_j \to 0$ *in probability as* $n \to \infty$.

Proof. Similar to (5.48), we have

$$\begin{aligned}
\frac{1}{\sqrt{n}} \sum_{j=1}^{n} G_{n,j}\varepsilon_j \\
&= \frac{1}{\sqrt{n}} \sum_{j=k_{\sigma(n)}+1}^{n} G_{n,j}\varepsilon_j + \frac{1}{\sqrt{n}} \sum_{m=0}^{\sigma(n)-1} \sum_{i=1}^{\eta_{m+1}} G_{n,k_m+i}(f_{k_m+i} - D_{m,i}) \\
&\quad + \frac{1}{\sqrt{n}} \sum_{m=0}^{\sigma(n)-1} \sum_{i=1}^{\eta_{m+1}} G_{n,k_m+i}(f(\theta_{k_m}) - f(\theta_{k_m+i-1})) \\
&\quad + \frac{1}{\sqrt{n}} \sum_{m=0}^{\sigma(n)-1} \sum_{i=\eta_1^{(m+1)}(\theta_{k_m})+1}^{\eta_{m+1}} G_{n,k_m+i}(D_{m,i} - f(\theta_{k_m})) I\{\eta_{m+1} > \eta_1^{(m+1)}(\theta_{k_m})\} \\
&\quad - \frac{1}{\sqrt{n}} \sum_{m=0}^{\sigma(n)-1} \sum_{i=\eta_{m+1}+1}^{\eta_1^{(m+1)}(\theta_{k_m})} G_{n,k_m+i}(D_{m,i} - f(\theta_{k_m})) I\{\eta_{m+1} < \eta_1^{(m+1)}(\theta_{k_m})\} \\
&\quad + \frac{1}{\sqrt{n}} \sum_{m=0}^{\sigma(n)-1} \sum_{i=1}^{\eta_1^{(m+1)}(\theta_{k_m})} G_{n,k_m}(D_{m,i} - f(\theta_{k_m})) \\
&\quad + \frac{1}{\sqrt{n}} \sum_{m=0}^{\sigma(n)-1} \sum_{i=1}^{\eta_1^{(m+1)}(\theta_{k_m})} (G_{n,k_m+i} - G_{n,k_m})(D_{m,i} - f(\theta_{k_m})).
\end{aligned} \tag{5.58}$$

Since $G_{n,j}$ is bounded for $n \ge j \ge 1$, it follows from the proof of Lemma 5.5 that each of the first five terms on the right side of (5.58) converges to zero a.s. as $n \to \infty$. In what follows we prove that as $n \to \infty$ the sixth term converges to zero in probability, while the last term converges to zero a.s.

(i) By the definition (5.46), we get

$$\mathsf{E}\left[\left\|\frac{1}{\sqrt{n}}\sum_{m=0}^{\tau(n)} G_{n,k_m} w_{m+1}\right\|^2\right] \le \frac{1}{n}\mathsf{E}\left[\sum_{m=0}^{\tau(n)} \|G_{n,k_m}\|^2 \mathsf{E}[\|w_{m+1}\|^2 | \mathcal{F}^{(m)}]\right] \tag{5.59}$$

$$\le \mathsf{E}\left[(\eta_1^* W_1^{(0)})^2\right] \frac{1}{n}\sum_{i=0}^{n+1} \|G_{n,i}\|^2 \xrightarrow[n\,\to\,\infty]{} 0$$

via Lemma 1 of [3]. By (5.59), it is easy to derive that $1/\sqrt{n}\sum_{m=0}^{\sigma(n)-1} G_{n,k_m} w_{m+1} \to 0$ in probability as $n \to \infty$.

(ii) By (5.14) and (5.45), we have

$$\|G_{n,j} - G_{n,j-1}\| \tag{5.60}$$

$$= \left\|(a_{j-1} - a_{j-2})\sum_{s=j}^{n} \psi_{s-1,j} + a_{j-2}\sum_{s=j}^{n}(\psi_{s-1,j} - \psi_{s-1,j-1}) - a_{j-2}\psi_{j-2,j-1}\right\|$$

$$\le \alpha_1 a_{j-1} a_{j-2} \sum_{s=j}^{n} \|\psi_{s-1,j}\| + a_{j-2}\sum_{s=j}^{n} a_{j-1}\|M_1\| \; \|\psi_{s-1,j}\| + a_{j-2}$$

$$\le a_{j-1}\left((\alpha_1 + \|M_1\|)\sup_j\left\{\frac{a_{j-2}}{a_{j-1}}\right\} \; \sup_j\left\{a_{j-1}\sum_{s=j}^{n}\|\psi_{s-1,j}\|\right\} + \sup_j\left\{\frac{a_{j-2}}{a_{j-1}}\right\}\right)$$

$$\le c_3 a_{j-1} \qquad \forall\; n \ge j \ge 1,$$

where α_1 and c_3 are some constants. By (5.60) and (5.26), it follows that

$$\frac{1}{\sqrt{n}}\left\|\sum_{m=0}^{\sigma(n)-1} \sum_{i=1}^{\eta_1^{(m+1)}(\theta_{k_m})} (G_{n,k_m+i} - G_{n,k_m})(D_{m,i} - f(\theta_{k_m}))\right\|$$

$$\le \frac{1}{\sqrt{n}}\sum_{m=0}^{\sigma(n)-1} \sum_{i=1}^{\eta_1^{(m+1)}(\theta_{k_m})} \left\|\sum_{j=1}^{i}(G_{n,k_m+j} - G_{n,k_m+j-1})\right\| \cdot \|D_{m,i} - f(\theta_{k_m})\|$$

$$\le \frac{c_3}{\sqrt{n}}\sum_{m=0}^{\sigma(n)-1} a_{k_m}(\eta_{m+1}^*)^2 W_{m+1}^{(0)} \xrightarrow[n\,\to\,\infty]{} 0 \quad \text{a.s.}$$

via similar arguments as for (5.50). Thus, the proof of Lemma 5.6 is completed. □

Proof of Theorem 4.1(iii) for $L = 1$. By (5.45), from (5.38) it follows that

$$\sqrt{n}(\overline{\theta}_n - \theta^0) = o(1) + \frac{1}{\sqrt{n}}\sum_{i=n_0^*}^{n}(\theta_i - \theta^0) \tag{5.61}$$

$$= o(1) + \frac{1}{\sqrt{n}}\frac{1}{a_{n_0^*-1}}(M_1^{-1} + G_{n,n_0^*})(\theta_{n_0^*} - \theta^0)$$

$$-\frac{1}{\sqrt{n}}\sum_{j=n_0^*}^{n-1}(M_1^{-1} + G_{n,j+1})(f(\theta_j) - M_1(\theta_j - \theta^0))$$

$$-\frac{M_1^{-1}}{\sqrt{n}}\sum_{j=n_0^*}^{n-1}\varepsilon_{j+1}-\frac{1}{\sqrt{n}}\sum_{j=n_0^*}^{n-1}G_{n,j+1}\varepsilon_{j+1}.$$

Since the $G_{n,j}$ are bounded uniformly for $n \geq j \geq 1$, one has

$$\frac{1}{\sqrt{n}}\frac{1}{a_{n_0^*-1}}(M_1^{-1}+G_{n,n_0^*})(\theta_{n_0^*}-\theta^0)\xrightarrow[n\to\infty]{}0 \quad \text{a.s.} \tag{5.62}$$

By (5.62) and Lemmas 5.4–5.6, the desired result follows from (5.61). □

Proof of Theorem 4.1 for $L > 1$. Let $\widetilde{\varepsilon}_n = \beta_n - f(\widetilde{\theta}_{n-1})$ $\forall$ $n \geq 1$. The proof for the case $L = 1$ applies to the present setting if we replace θ_n, ε_n, f_n by $\widetilde{\theta}_n$, $\widetilde{\varepsilon}_n$, and β_n, respectively (cf. [40] and [41]). We mention only the key point for Theorem 4.1(iii). By the definitions (5.12) and (2.2),

$$\frac{1}{\sqrt{n}}\sum_{i=1}^{n}\varepsilon_i=\frac{1}{\sqrt{n}}\sum_{i=0}^{n}\left(\frac{1}{L}\sum_{j=1}^{L}\beta_{iL+j}-f(\theta_{i-1})\right) \tag{5.63}$$

$$=\frac{1}{L\sqrt{n}}\sum_{i=1}^{(n+1)L}(\beta_i-f(\widetilde{\theta}_{i-1})) \;=\; \frac{1}{L\sqrt{n}}\sum_{i=1}^{(n+1)L}\widetilde{\varepsilon}_i.$$

As in the proof of Lemma 5.5, one can show that $1/\sqrt{n}\sum_{i=1}^{n}\widetilde{\varepsilon}_i \to N(0,\ S_4)$ in distribution as $n\to\infty$. Combined with (5.63), this gives $1/\sqrt{n}\sum_{i=1}^{n}\varepsilon_i \to N(0,\ S_4^*)$ in distribution as $n\to\infty$, where $S_4^* = L^{-1}S_4 = L^{-1}\overline{\eta}(\theta^0)^{-1}S$. The rest of the proof works the same way as for $L = 1$. □

A PASSIVE SYSTEM APPROACH TO FEEDBACK STABILIZATION OF NONLINEAR CONTROL STOCHASTIC SYSTEMS[*]

PATRICK FLORCHINGER[†]

Abstract. The purpose of this paper is to provide sufficient conditions for asymptotic stabilization in probability of nonlinear control stochastic differential systems by means of smooth state feedback laws. In particular, we prove that, as in the case of stochastic differential systems affine in the control, one can compute stabilizing feedback laws provided the unforced stochastic differential system is Lyapunov stable in probability and some rank conditions are fulfilled. Some well-known stabilization results for stochastic differential systems affine in the control proved in the literature are extended to nonaffine nonlinear control stochastic differential systems.

Key words. stability in probability, control stochastic differential equation, smooth state feedback law, passive stochastic system

1. Introduction.

The aim of this paper is to state sufficient conditions for asymptotic stabilization in probability of some nonlinear control stochastic differential systems. In particular, we prove that stabilizing feedback laws can be computed provided the unforced stochastic differential system is stable in probability and some rank conditions are satisfied.

The stabilizability of nonlinear stochastic differential systems affine in the control has been studied in the past years by means of the stochastic Lyapunov machinery developed by Khasminskii [12]. Among several contributions to the subject, we wish to outline those which are more closely related to the work of the present paper.

The pioneering work of Jurdjevic and Quinn [10] on the stabilization of nonlinear deterministic systems affine in the control, the unforced dynamics of which are linear, has been extended to nonlinear stochastic differential systems in [4]. Following the method developed by Kalouptsidis and Tsinias [11] for deterministic systems, Boulanger has given in [1], by using output feedback laws, an extension of the stochastic version of Jurdjevic and Quinn's theorem to stochastic systems, the unforced dynamics of which are stable in probability. Furthermore, the stabilizing feedback laws computed in the latter work are smooth provided restrictive assumptions on the Lyapunov function associated to the unforced dynamics of the system are satisfied. In [5] and [7] the conditions proposed in [4] are weakened and more general sufficient conditions for asymptotic stability in probability of nonlinear stochastic differential systems are given, provided the unforced dynamics are Lyapunov stable in probability and some rank condition is satisfied.

The problem of computing stabilizing state feedback laws for nonlinear stochastic differential systems is much harder (see, for example, [5] or [3] and the references therein). The purpose of this paper is to address this question and provide an easy way to reach this goal in some specific cases.

The notion of "passivity" has been used in order to analyze the stability of some deterministic interconnected nonlinear systems (see [17], for example). In [8] and

[9], Hill and Moylan have combined the methodology of passive systems theory with the Lyapunov stability theory in order to prove stabilization results for nonlinear deterministic systems. Byrnes, Isidori, and Willems [2] have developed a framework for studying the stabilizability of minimum-phase nonlinear deterministic systems, and they have shown by means of techniques of passive systems theory that the stabilization results proved in [10], [11], and [15] for deterministic systems can be deduced from a basic stability property of passive systems affine in the control.

Noticing that passive systems theory has been developed by Willems [18] for nonaffine nonlinear deterministic systems, Lin [16] extends the results proved in [2] to a wider class of systems which are not necessarily affine in the control.

The purpose of this paper is to introduce the notion of "passivity" for nonlinear control stochastic differential systems by using a method close to that developed by Lin [16] in the deterministic case. With this aim, we show that the problem of asymptotic stabilization in probability of nonlinear stochastic differential systems can be solved by means of the stochastic passive systems theory developed in the following. Furthermore, we will see that certain stabilization results proposed in the literature by analytic methods can be recovered from the basic stabilizability property of passive stochastic systems. This shows that a number of stabilization schemes reduce to that of a passive stochastic system subject to pure gain feedback. Hence, the role played by the concept of passivity in order to compute stabilizing state feedback laws leads to the following question: when can a nonlinear stochastic differential system be rendered passive via state feedback law? This question will be solved in this paper in the particular case of interconnected stochastic differential systems.

This paper is divided into six sections and is organized as follows. In section 1, we recall some basic facts concerning the asymptotic stability in probability of the equilibrium solution of a stochastic differential equation proved by Khasminskii [12] and we state the stochastic version of La Salle's theorem proved by Kushner [13]. In section 2, we introduce the class of stochastic differential systems we are dealing with in this paper. In section 3, we introduce the notion of passivity for input/output nonlinear stochastic differential systems and we prove a first stabilization result for such systems and a nonlinear version of the Kalman–Yacubovitch–Popov lemma for stochastic differential systems affine in the control. In section 4, we use the methodology for passive stochastic systems developed in section 3 in order to prove two feedback stabilization results for nonlinear stochastic differential systems. In section 5, we study the particular case of interconnected stochastic differential systems which are feedback equivalent to passive stochastic differential systems. In section 6, we illustrate some results of the paper by design examples.

2. Stochastic stability.

The purpose of this section is to recall the main results concerning the asymptotic stability in probability of the equilibrium solution of a stochastic differential equation that we need in the following as well as the stochastic version of La Salle's theorem.

For a complete presentation of the stochastic stability theory and the stochastic Lyapunov machinery we refer the reader to the book of Khasminskii [12] for examples.

Let $(\Omega, \mathcal{F}, P)$ be a complete probability space and denote by $w = \{w_t \ ; \ t \geq 0\}$ a standard $\mathbb{R}^p$-valued Wiener process defined on this space.

Consider the stochastic process solution $x_t \in \mathbb{R}^n$ of the stochastic differential equation written in the sense of Itô,

$$x_t = x_0 + \int_0^t f(x_s)\, ds + \int_0^t g(x_s)\, dw_s \tag{2.1}$$

where

(1) x_0 is given in $\mathbb{R}^n$,

(2) f and g are Lipschitz functions mapping $\mathbb{R}^n$ into $\mathbb{R}^n$ and $\mathbb{R}^{n\times p}$, respectively, vanishing in the origin, and such that there exists a nonnegative constant K such that for any $x \in \mathbb{R}^n$,

$$|f(x)| + |g(x)| \leq K(1 + |x|). \tag{2.2}$$

If for any $s \geq 0$ and $x \in \mathbb{R}^n$, $x_t^{s,x}$, $t \geq s$, denotes the solution at time t of the stochastic differential equation (2.1) starting from the state x at time s, one can introduce the notion of stability in probability for the equilibrium solution of the stochastic differential equation (2.1) as follows.

Definition 2.1. *The equilibrium solution $x_t \equiv 0$ of the stochastic differential equation* (2.1) *is stable in probability if and only if for any $s \geq 0$ and $\epsilon > 0$,*

$$\lim_{x\to 0} P\left(\sup_{s\leq t} |x_t^{s,x}| > \epsilon\right) = 0.$$

Furthermore, the equilibrium solution of the stochastic differential equation (2.1) is (locally) asymptotically stable in probability if the following property is satisfied.

Definition 2.2. (1) *The equilibrium solution of the stochastic differential equation* (2.1) *is locally asymptotically stable in probability if and only if it is stable in probability and for any $s \geq 0$,*

$$\lim_{x\to 0} P\left(\lim_{t\to +\infty} |x_t^{s,x}| = 0\right) = 1.$$

(2) *The equilibrium solution of the stochastic differential equation* (2.1) *is asymptotically stable in probability if and only if it is stable in probability and for any $s \geq 0$,*

$$P\left(\lim_{t\to +\infty} |x_t^{s,x}| = 0\right) = 1$$

for any $x \in \mathbb{R}^n$.

Denote by L the infinitesimal generator of the stochastic process solution x_t of the stochastic differential equation (2.1). Then, by means of martingale theory arguments, one can prove the following version of the Lyapunov theorem.

Theorem 2.3. *Assume that there exists a Lyapunov function V defined on a bounded open neighborhood D of the origin in $\mathbb{R}^n$ (i.e., a function V in $C^2(D;\mathbb{R})$ which is positive definite) such that*

$$LV(x) \leq 0$$
$$(\textit{respectively},\ LV(x) < 0)$$

for any $x \in D\backslash\{0\}$. Then, the equilibrium solution $x_t \equiv 0$ of the stochastic differential equation (2.1) *is stable (respectively, locally asymptotically stable) in probability.*

Moreover, if $D = \mathbb{R}^n$ and the Lyapunov function V is proper, then the equilibrium solution $x_t \equiv 0$ of the stochastic differential equation (2.1) *is asymptotically stable in probability provided*

$$LV(x) < 0$$

for any $x \in \mathbb{R}^n \setminus \{0\}$.

For a detailed proof of Theorem 2.3 we refer the reader to Khasminskii [12].

The assumptions on the coefficients of the stochastic differential equation (2.1) can be relaxed in the following way provided the equilibrium solution of the system is asymptotically stable in probability (see [12, Theorem 4.1, p. 84]).

THEOREM 2.4. *Suppose that the functions f and g are locally Lipschitz and satisfy inequality* (2.2) *on any ball $B(0,R) = \{x \in \mathbb{R}^n \ / \ ||x|| \le R\}$. Suppose that there exists a proper Lyapunov function V defined on $\mathbb{R}^n$ and a positive constant c such that*

$$LV(x) \le cV(x)$$

for every x in $\mathbb{R}^n$. Then, the stochastic differential equation (2.1) *has a unique solution $(x_t)_{t\ge 0}$ with continuous trajectories.*

To conclude this section, recall the stochastic version of La Salle's theorem proved by Kushner [13] which gives the ω-limit set for a stable in probability equilibrium solution of the stochastic differential equation (2.1).

THEOREM 2.5. *Assume there exists a Lyapunov function V such that*

$$LV(x) \le 0$$

for any $x \in \mathbb{R}^n$. Then, the stochastic process solution x_t of the stochastic differential equation (2.1) *tends in probability to the largest invariant set whose support is contained in the locus $LV(x_t) = 0$ for any $t \ge 0$.*

REMARK 2.6. *If the equilibrium solution $x_t \equiv 0$ of the stochastic differential equation* (2.1) *is stable in probability, then the existence of a Lyapunov function V such that $LV(x) \le 0$ for any $x \in \mathbb{R}^n$ is given by the converse Lyapunov theorem proved by Kushner* [14].

3. Problem setting.

Denote by $(\Omega, \mathcal{F}, P)$ a complete probability space and by $w = \{w_t; t \ge 0\}$ a standard $\mathbb{R}^p$-valued Wiener process defined on this space.

Consider the stochastic differential system in $\mathbb{R}^n$ written in the sense of Itô,

$$x_t = x_0 + \int_0^t f(x_s, u)ds + \int_0^t g(x_s)dw_s \tag{3.1}$$

where

(1) x_0 is given in $\mathbb{R}^n$,

(2) u is an $\mathbb{R}^m$-valued measurable control law,

(3) f and g are Lipschitz functions defined in $C^\infty(\mathbb{R}^n \times \mathbb{R}^m; \mathbb{R}^n)$ and $C^\infty(\mathbb{R}^n; \mathbb{R}^{n\times p})$, respectively, vanishing in the origin, and such that there exists a nonnegative constant K such that for any $x \in \mathbb{R}^n$ and $u \in \mathbb{R}^m$,

$$|f(x,u)| + |g(x)| \le K(1 + |x| + |u|). \tag{3.2}$$

Furthermore, assume that the unforced stochastic differential system deduced from (3.1), that is, the stochastic differential system

$$dx_t = f(x_t, 0)dt + g(x_t)dw_t, \tag{3.3}$$

is such that there exists a Lyapunov function V defined on $\mathbb{R}^n$ satisfying

$$L_0V(x) \le 0 \tag{3.4}$$

for every $x \in \mathbb{R}^n$ where L_0 is the infinitesimal generator of the stochastic differential equation (3.3).

Note that according to the stochastic Lyapunov Theorem (Theorem 2.3) the equilibrium solution $x_t \equiv 0$ of the stochastic differential system (3.3) is stable in probability.

REMARK 3.1. *If one assumes that the equilibrium solution $x_t \equiv 0$ of the stochastic differential system* (3.3) *is stable in probability, the existence of a Lyapunov function V satisfying* (3.4) *is given by the converse Lyapunov theorem proved by Kushner* [14].

The aim of this paper is to state sufficient conditions for the stochastic differential system (3.1) to be (locally) asymptotically stabilizable in probability by means of a smooth state feedback law.

4. Passive stochastic systems. Consider the input/output nonlinear stochastic differential system in $\mathbb{R}^n \times \mathbb{R}^m$ written in the sense of Itô,

$$\left\{\begin{array}{lcl} dx_t & = & f(x_t, u)dt + g(x_t)dw_t, \\ y_t & = & h(x_t, u), \end{array}\right. \tag{4.1}$$

where

(1) $w = \{w_t; t \geq 0\}$ is an $\mathbb{R}^p$-valued standard Wiener process defined on $(\Omega, \mathcal{F}, P)$,
(2) u is an $\mathbb{R}^m$-valued measurable control law,
(3) f, g, and h are smooth functions mapping $\mathbb{R}^n \times \mathbb{R}^m$, $\mathbb{R}^n$, and $\mathbb{R}^n \times \mathbb{R}^m$, respectively, in $\mathbb{R}^n$, $\mathbb{R}^{n\times p}$, and $\mathbb{R}^m$, respectively, vanishing in the origin, and satisfying a linear growth condition similar to (3.2).

First, we introduce the notion of "passivity" for the stochastic differential system (4.1) as follows.

DEFINITION 4.1. *The input/output stochastic differential system* (4.1) *is said to be passive if there exists a Lyapunov function V defined on $\mathbb{R}^n$, called the storage function, such that*

$$LV(x) \leq h(x, u)^\star u \tag{4.2}$$

for every $(x, u) \in \mathbb{R}^n \times \mathbb{R}^m$ where L is the infinitesimal generator of the stochastic process solution of the first equation in (4.1).

Then, necessary conditions for the input/output nonlinear stochastic differential system (4.1) to be passive can be obtained as follows.

PROPOSITION 4.2. *Necessary conditions for the stochastic differential system* (4.1) *to be passive with a storage function V are*

(1) $L_0V(x) \leq 0$ *for every* $x \in \mathbb{R}^n$,
(2) $\sum_{i=1}^n \frac{\partial f_i}{\partial u}(x, 0)\frac{\partial V}{\partial x_i}(x) = h(x, 0)^\star$ *for every* $x \in S_1$,
(3) $\sum_{i=1}^n \frac{\partial^2 f_i}{\partial u^2}(x, 0)\frac{\partial V}{\partial x_i}(x) \leq \frac{\partial h^\star}{\partial u}(x, 0) + \frac{\partial h}{\partial u}(x, 0)$ *for every* $x \in S_1$

where L_0 is, as in the previous section, the infinitesimal generator of the unforced stochastic differential system deduced from the first equation in (4.1) *and* $S_1 = \{x \in \mathbb{R}^n / L_0V(x) = 0\}$.

Proof of Proposition 4.2. Consider the auxiliary function F mapping $\mathbb{R}^n \times \mathbb{R}^m$ into $\mathbb{R}$ defined for every $(x, u) \in \mathbb{R}^n \times \mathbb{R}^m$ by

$$F(x, u) = LV(x) - h(x, u)^\star u.$$

Since the stochastic differential system (4.1) is passive, it is obvious, according to Definition 4.1, that $F(x, u) \leq 0$ for every $(x, u) \in \mathbb{R}^n \times \mathbb{R}^m$ and hence, one gets (2.1) by setting $u = 0$.

Conversely, noticing that for all $x \in S_1$, $F(x,0) = L_0V(x) = 0$, one can deduce that

$$F(x,u) \leq F(x,0)$$

for every $(x,u) \in S_1 \times \mathbb{R}^m$, which implies that the function F achieves its maximum at $u = 0$ on the set S_1.

Therefore, for any $x \in S_1$, it yields

$$\frac{\partial F}{\partial u}(x,0) = 0 \text{ and } \frac{\partial^2 F}{\partial u^2}(x,0) \leq 0$$

which give (2.2) and (3.1) by easy computations similar to those in the proof of Proposition 4.3 in [16]. □

REMARK 4.3. *If the stochastic differential system* (4.1) *is passive, property* (2.1) *in the previous proposition implies, according to the stochastic Lyapunov theorem* (Theorem 2.3)*, that the equilibrium solution $x_t \equiv 0$ of the unforced stochastic differential system* (3.3) *is stable in probability.*

If the stochastic differential system is affine in the control and the function h does not depend on the control, then one can prove that the system is passive provided it satisfies a nonlinear version of the Kalman–Yacubovitch–Popov (KYP) criterion.

DEFINITION 4.4. *The stochastic differential system*

$$\begin{cases} dx_t &= (f(x_t) + \bar{f}(x_t)u)dt + g(x_t)dw_t, \\ y_t &= h(x_t) \end{cases} \tag{4.3}$$

satisfies a KYP property if there exists a Lyapunov function V defined on $\mathbb{R}^n$ such that

$$L_0V(x) \leq 0$$

and

$$\nabla V(x)\bar{f}(x) = h(x)^\star$$

for every $x \in \mathbb{R}^n$.

Then, one can prove the following criterion which extends Proposition 2.12 in [2] (see also [8]) to stochastic differential systems.

PROPOSITION 4.5. *The stochastic differential system* (4.3) *is passive if and only if it satisfies a KYP property.*

Proof of Proposition 4.5. If the stochastic differential system (4.3) is passive, there exists a Lyapunov function V defined on $\mathbb{R}^n$ such that

$$LV(x) \leq h(x)^\star u$$

for every $(x,u) \in \mathbb{R}^n \times \mathbb{R}^m$.

But, since for every $(x,u) \in \mathbb{R}^n \times \mathbb{R}^m$,

$$LV(x) = L_0V(x) + \nabla V(x)\bar{f}(x)u \tag{4.4}$$

one can easily deduce from the above estimates that the KYP property is satisfied by the stochastic differential system (4.3).

Conversely, if the KYP property is satisfied, there exists a Lyapunov function V defined on $\mathbb{R}^n$ such that for every x in $\mathbb{R}^n$,

$$L_0 V(x) \leq 0$$

and

$$\nabla V(x) \bar{f}(x) = h(x)^\star .$$

Then, since for every $(x, u) \in \mathbb{R}^n \times \mathbb{R}^m$, (4.4) holds, one can deduce from the previous estimates that

$$LV(x) \leq h(x)^\star u \tag{4.5}$$

and hence, the stochastic differential system (4.3) is passive. □

Before stating a stabilization result for passive stochastic systems, we introduce the following notations.

Denote by $\bar{f}_i$, $1 \leq i \leq m$, the functions defined on $\mathbb{R}^n$ by

$$\bar{f}_i(x) = \frac{\partial f}{\partial u_i}(x, 0)$$

and, if V is a C^{2r} $(r \geq 1)$ Lyapunov function defined on $\mathbb{R}^n$, introduce the space

$$\Lambda = \operatorname{span}\left\{ \mathrm{ad}_{L_0}^k \bar{f}_i \ / \ 0 \leq k \leq n-1, 1 \leq i \leq m \right\}$$

and the sets Γ and S associated with Λ defined by

$$\Gamma = \left\{ x \in \mathbb{R}^n \ / \ L_0^k V(x) = 0 \ , k = 1, \ldots, r \right\}$$

and

$$S = \left\{ x \in \mathbb{R}^n \ / \ L_0^k Y V(x) = 0, \forall Y \in \Lambda, k = 0, \ldots, r-2 \right\},$$

where YV denotes the Lie derivative of V with respect to Y.

Then, as in the case of stochastic differential systems affine in the control, a non-affine passive stochastic differential system has the following stabilizability property by output feedback.

THEOREM 4.6. *Assume that the stochastic differential system* (4.1) *is passive with a C^{2r} $(r \geq 1)$ storage function V, and let $s : \mathbb{R}^n \to \mathbb{R}^m$ be any first/third sector function (i.e., $y^\star s(y) > 0$ $\forall y \neq 0$ and $s(0) = 0$). Then, the output feedback law*

$$u = -s(y) \tag{4.6}$$

renders the stochastic differential system (4.1) *locally asymptotically stable in probability provided $\Gamma \cap S = \{0\}$.*

Moreover, if the Lyapunov function V is proper, the equilibrium solution of the stochastic differential system (4.1) *is asymptotically stable in probability.*

Proof of Theorem 4.6. The proof of this theorem, which is an extension of Theorem 3.2 in [2] to stochastic differential systems, follows from passive inequality (4.2) with the feedback law (4.6) and the stochastic version of La Salle's theorem (Theorem 2.5).

Indeed, with the feedback law u given by (4.6) one can deduce from the passive inequality (4.2) that

$$LV(x) \leq -h(x, u)^\star s\left(h(x, u)\right) \tag{4.7}$$

for every $(x, u) \in \mathbb{R}^n \times \mathbb{R}^m$ and, since s is a first/third sector function, yields

$$LV(x) \leq 0$$

which implies according to the stochastic Lyapunov theorem (Theorem 2.3) that the equilibrium solution of the stochastic differential system (4.1) is stable in probability.

Furthermore, according to the stochastic version of La Salle's theorem (Theorem 2.5) the equilibrium solution of the stochastic differential system (4.1) tends in probability to the largest invariant set whose support is contained in the locus $LV(x_t) = 0$ for all $t \geq 0$.

But, if $LV(x_t) = 0$ for all $t \geq 0$, one can deduce from (4.7) and the fact that s is a first/third sector function that $y_t = h(x_t, u) = 0$ for all $t \geq 0$ which implies that $L_0V(x_t) = 0$ for all $t \geq 0$.

Therefore, by successive applications of Itô's formula to the stochastic process $LV(x_t)$, one gets that $L_0^kV(x_t) = 0$ $\forall t \geq 0$ and $k \in \{1, \ldots, r\}$ and $L_0^kYV(x_t) = 0$ $\forall t \geq 0$, $Y \in D$, and $k \in \{0, \ldots, r-2\}$ which implies, since $\Gamma \cap S = \{0\}$, that the stochastic process x_t tends in probability to 0.

This proves, by the stochastic version of La Salle's theorem, that the equilibrium solution of the stochastic differential equation (4.1) is locally asymptotically stable in probability.

Moreover, if the Lyapunov function V is proper, the equilibrium solution of the stochastic differential system (4.1) is asymptotically stable in probability. □

The following result, which is an easy consequence of the previous theorem, will enable us to recover well-known results of the stochastic stabilization theory.

COROLLARY 4.7. *Assume that the stochastic differential system* (4.1) *is passive with a proper* C^{2r} $(r \geq 1)$ *storage function* V. *If* $\Gamma \cap S = \{0\}$, *then, for each* $k > 0$, *the feedback law*

$$u = -ky$$

renders the stochastic differential system (4.1) *asymptotically stable in probability.*

REMARK 4.8. *The result of the previous corollary can be interpreted as a generalization of the results proved in* [1], [4], *and* [5] *on the stabilization of stochastic differential systems affine in the control*

$$dx_t = (f(x_t) + \bar{f}(x_t)u)dt + g(x_t)dw_t. \tag{4.8}$$

For example, if the stochastic differential system (4.8) *satisfies the hypotheses stated in* [4], *then Theorem* 3.2 *in* [4] *is a particular case of Corollary* 4.7.

Indeed, by taking the dummy output

$$y_t = \nabla V(x_t)\bar{f}(x_t),$$

one can prove easily that the hypotheses stated in [4] *imply those stated in the previous corollary and hence, the feedback law*

$$u(x) = -\nabla V(x)\bar{f}(x)$$

renders the stochastic differential system (4.8) *asymptotically stable in probability.*

5. The main results. We are now ready to state the main results of the paper on the stabilization of the class of systems introduced previously. The first result is given by the following statement.

Theorem 5.1. *If the stochastic differential system* (3.1) *is such that* $\Gamma \cap S = \{0\}$*, then it is locally asymptotically stabilizable in probability by a local smooth state feedback law* $u = \alpha(x)$*,* $\alpha(0) = 0$*, which can be solved uniquely from the equation*

$$u + \left(\frac{\partial V}{\partial x}(x) k(x,u) \right)^{\star} = 0, \tag{5.1}$$

where k *is the smooth function mapping* $\mathbb{R}^n \times \mathbb{R}^m$ *into* $\mathbb{R}^{n \times m}$ *defined by*

$$f(x,u) - f(x,0) = k(x,u)u.$$

Moreover, if V *is proper and equation* (5.1) *has a solution* $u = \alpha(x)$ *which is well-defined on* $\mathbb{R}^n$*, then the stochastic differential system* (3.1) *is asymptotically stabilizable in probability.*

Proof of Theorem 5.1. Choosing the output y defined by

$$y = h(x,u) = \left(\frac{\partial V}{\partial x}(x) k(x,u) \right)^{\star}, \tag{5.2}$$

one can prove easily that the input/output stochastic differential system (3.1)–(5.2) is passive.

Indeed, for every $(x,u) \in \mathbb{R}^n \times \mathbb{R}^m$,

$$\begin{aligned} LV(x) &= L_0 V(x) + \left(\frac{\partial V}{\partial x}(x) k(x,u) \right) u \\ &\leq h(x,u)^{\star} u. \end{aligned}$$

Therefore, since $\Gamma \cap S = \{0\}$ one can deduce from Theorem 4.6 that the output feedback control law

$$u = -y = -\left(\frac{\partial V}{\partial x}(x) k(x,u) \right)^{\star}$$

renders the stochastic differential system (3.1)–(5.2) locally asymptotically stable in probability.

Hence, the state feedback law $u = \alpha(x)$ renders the equilibrium solution $x_t \equiv 0$ of the stochastic differential equation (3.1) locally asymptotically stable in probability provided that there exists a C^{∞} function α, locally defined on a neighborhood of the origin, such that (5.1) is satisfied.

This is indeed the case since the function H defined on $\mathbb{R}^n \times \mathbb{R}^m$ by

$$H(x,u) = u + \left(\frac{\partial V}{\partial x}(x) k(x,u) \right)^{\star}$$

satisfies the assumptions of the implicit function theorem.

Thus, the equilibrium solution of the stochastic differential equation (3.1) is locally asymptotically stable in probability and, if V is proper and equation (5.1) has a solution defined on all $\mathbb{R}^n$, then the result also holds globally.

This completes the proof of Theorem 5.1. □

Remark 5.2. *In the case of nonlinear stochastic differential systems affine in the control,* (5.1) *reduces to*

$$u = -\left(\sum_{i=1}^{n} \frac{\partial f_i}{\partial u}(x,0) \frac{\partial V}{\partial x_i}(x) \right)^{\star}$$

which implies that it always has a global solution on $\mathbb{R}^n$*. Hence, Theorem* 5.1 *covers the stabilization result proved in* [4]*.*

The second result concerns stochastic differential systems in $\mathbb{R}^n$ written in the sense of Itô in the form

$$x_t = x_0 + \int_0^t \left(f(x_s) + \bar{f}(x_s)u + \sum_{i=1}^m u_i R_i(x_s)u \right) ds + \int_0^t g(x_s)dw_s \tag{5.3}$$

where

(1) x_0 is given in $\mathbb{R}^n$,

(2) u is an $\mathbb{R}^m$-valued measurable control law,

(3) f and g are smooth Lipschitz functions defined in $C^\infty(\mathbb{R}^n;\mathbb{R}^n)$ and $C^\infty(\mathbb{R}^n;\mathbb{R}^{n\times p})$, respectively, vanishing in the origin, and satisfying a linear growth condition similar to (3.2),

(4) $\bar{f}$ and R_i, $1 \leq i \leq m$, are smooth Lipschitz functions defined in $C^\infty(\mathbb{R}^n;\mathbb{R}^{n\times m})$, vanishing in the origin, and satisfying a linear growth condition as in (3.2).

Furthermore, assume that the unforced stochastic differential system deduced from (5.3), that is, the stochastic differential system

$$dx_t = f(x_t)dt + g(x_t)dw_t, \tag{5.4}$$

is such that there exists a Lyapunov function V defined on $\mathbb{R}^n$ satisfying

$$L_0V(x) \leq 0 \tag{5.5}$$

for every $x \in \mathbb{R}^n$, where L_0 is the infinitesimal generator of the stochastic differential equation (5.4).

Note that according to the stochastic Lyapunov theorem (Theorem 2.3) the equilibrium solution $x_t \equiv 0$ of the stochastic differential system (5.4) is stable in probability.

The drift term of the stochastic differential system (5.3) can be regarded as "second degree approximation" of the drift term of the stochastic differential system (3.1).

We are now ready to state the second result of the section.

THEOREM 5.3. *Assume that the stochastic differential system* (5.3) *is such that* $\Gamma \cap S = \{0\}$ *and that for every* $x \in \mathbb{R}^n$*, the matrix* $\Delta(x)$ *defined by*

$$\Delta(x) = Id_{m\times m} + \begin{pmatrix} \nabla V(x)R_1(x) \\ .. \\ .. \\ .. \\ \nabla V(x)R_m(x) \end{pmatrix}^\star$$

is invertible. Then, the stochastic differential system (5.3) *is locally asymptotically stabilizable in probability by the smooth state feedback law u defined by*

$$u(x) = -\left(\Delta(x)\right)^{-1}\left(\nabla V(x)\bar{f}(x)\right)^\star . \tag{5.6}$$

Moreover, if in addition the Lyapunov function V is proper, then the state feedback law u given by (5.6) *renders the stochastic differential system* (5.3) *asymptotically stable in probability.*

Proof of Theorem 5.3. Choosing the output y defined by

$$y = \left(\nabla V(x)\bar{f}(x)\right)^{\star} + \begin{pmatrix} \nabla V(x)R_1(x) \\ .. \\ .. \\ .. \\ \nabla V(x)R_m(x) \end{pmatrix}^{\star} u, \tag{5.7}$$

one can prove easily that the input/output stochastic differential system (5.3)–(5.7) is passive.

Indeed, a straightforward computation gives

$$\begin{aligned} LV(x) &= L_0V(x) + \nabla V(x)\bar{f}(x)u + \sum_{i=1}^{m} u_i \left(\nabla V(x)R_i(x)\right) u \\ &\leq \left(\nabla V(x)\bar{f}(x) + u^{\star} \begin{pmatrix} \nabla V(x)R_1(x) \\ .. \\ .. \\ .. \\ \nabla V(x)R_m(x) \end{pmatrix} \right) u \\ &\leq y^{\star}u. \end{aligned}$$

Therefore, since $\Gamma \cap S = \{0\}$ one can deduce from Theorem 4.6 that the output feedback control law $u = -y$ renders the stochastic differential system (5.3)–(5.7) locally asymptotically stable in probability.

Hence, the state feedback law u given by (5.6) renders the equilibrium solution $x_t \equiv 0$ of the stochastic differential system (5.3) locally asymptotically stable in probability.

If the Lyapunov function V is proper, the global stabilization result of the theorem is obvious.

This completes the proof of Theorem 5.3. □

REMARK 5.4. *Since $\nabla V(0) = 0$, one has $\Delta(0) = Id_{m \times m}$ and hence, the matrix $\Delta(x)$ is always invertible on a neighborhood of the origin in $\mathbb{R}^n$. Therefore, the state feedback law u given by* (5.6) *is locally well-defined and smooth on a neighborhood of the origin.*

In the particular case of a single input, system (5.3) can be written as

$$x_t = x_0 + \int_0^t \left(f(x_s) + \bar{f}(x_s)u + r(x_s)u^2\right) ds + \int_0^t g(x_s)dw_s \tag{5.8}$$

and Theorem 5.3 leads to the following result.

COROLLARY 5.5. *Assume that the stochastic differential system* (5.8) *is such that $\Gamma \cap S = \{0\}$. Then, the smooth state feedback law u defined by*

$$u(x) = -\frac{1}{1 + \nabla V(x)r(x)} \nabla V(x)\bar{f}(x) \tag{5.9}$$

renders the stochastic differential system (5.8) *locally asymptotically stable in probability.*

Moreover, if the Lyapunov function V is proper and $1 + \nabla V(x)r(x) \neq 0$ for every $x \in \mathbb{R}^n$, then the equilibrium solution of the stochastic differential system (5.8) *is asymptotically stabilized in probability by the state feedback law* (5.9).

Remark 5.6. *In the case of stochastic differential systems affine in the control, the matrix $\Delta(x)$ is invertible on all $\mathbb{R}^n$ since $R_i(x) \equiv 0$ for every $i \in \{1, \dots, m\}$. Therefore, the stabilization result proved in* [4] *and* [1] *can be deduced from the result proved in Theorem* 5.3.

6. Interconnected stochastic differential systems.

Consider the input/output interconnected nonlinear stochastic differential system in $\mathbb{R}^q \times \mathbb{R}^n \times \mathbb{R}^m$ written in the sense of Itô,

$$d\xi_t = (\tilde{f}(\xi_t) + \tilde{f}_0(\xi_t, y_t)y_t)dt + \tilde{g}(\xi_t)d\tilde{w}_t, \tag{6.1}$$

$$dx_t = (f(x_t) + \bar{f}(x_t)u)dt + g(x_t)dw_t, \tag{6.2}$$

$$y_t = h(x_t), \tag{6.3}$$

where

(1) $w = \{w_t, t \geq 0\}$ and $\tilde{w} = \{\tilde{w}_t, t \geq 0\}$ are independent standard Wiener processes defined on $(\Omega, \mathcal{F}, P)$ with values in $\mathbb{R}^p$ and $\mathbb{R}^r$, respectively,

(2) u is an $\mathbb{R}^m$-valued measurable control law,

(3) $\tilde{f}$ and $\tilde{g}$ are smooth Lipschitz functions mapping $\mathbb{R}^q$ into $\mathbb{R}^q$ and $\mathbb{R}^{q\times r}$, respectively, vanishing in the origin, and satisfying a linear growth condition similar to (3.2),

(4) $\tilde{f}_0$ is a smooth Lipschitz function mapping $\mathbb{R}^q \times \mathbb{R}^m$ into $\mathbb{R}^{q\times m}$,

(5) f, $\bar{f}$ and g are smooth Lipschitz functions mapping $\mathbb{R}^n$ into $\mathbb{R}^n$, $\mathbb{R}^{n\times m}$, and $\mathbb{R}^{n\times p}$, respectively, vanishing in the origin, and satisfying a linear growth condition similar to (3.2),

(6) h is a smooth function mapping $\mathbb{R}^n$ into $\mathbb{R}^m$.

First, we discuss conditions under which the stochastic differential system (6.1)–(6.3) is feedback equivalent to a passive stochastic differential system.

Proposition 6.1. *Suppose that $\xi_t \equiv 0$ is an asymptotically stable in probability equilibrium solution of the stochastic differential system*

$$d\xi_t = \tilde{f}(\xi_t)dt + \tilde{g}(\xi_t)d\tilde{w}_t, \tag{6.4}$$

for which we know a C^{2r} Lyapunov function U such that

$$\tilde{L}U(\xi) < 0$$

for every ξ in $\mathbb{R}^q$ (here, $\tilde{L}$ denotes the infinitesimal generator of the stochastic process solution of (6.4)*). Suppose that the stochastic differential system* (6.2)*–*(6.3) *is passive with a C^{2r} storage function. Then, the stochastic differential system* (6.1)*–*(6.3) *is feedback equivalent to a passive system with a C^{2r} storage function.*

Proof of Proposition 6.1. Setting $\zeta_t = (\xi_t, x_t)$, the stochastic differential system (6.1)–(6.3) has the form

$$d\zeta_t = (F(\zeta_t) + \bar{F}(\zeta_t)u)dt + G(\zeta_t)d\begin{pmatrix} \tilde{w}_t \\ \\ w_t \end{pmatrix}, \tag{6.5}$$

$$y_t = H(\zeta_t), \tag{6.6}$$

where

$$F(\zeta) = \begin{pmatrix} \tilde{f}(\xi) + \tilde{f}_0(\xi, h(x))h(x) \\ \\ f(x) \end{pmatrix},$$

$$\bar{F}(\zeta) = \begin{pmatrix} 0 \\ \\ \bar{f}(x) \end{pmatrix},$$

$$G(\zeta) = \begin{pmatrix} \tilde{g}(\xi) \\ \\ g(x) \end{pmatrix},$$

and

$$H(\zeta) = h(x).$$

In the following, we prove by means of Proposition 4.5 that the stochastic differential system (6.5)–(6.6) is rendered passive by the feedback law

$$u = -\left(\nabla U(\xi)\tilde{f}_0(\xi, h(x))\right)^{\star} + v. \tag{6.7}$$

Indeed, denoting by W the C^{2r} composite Lyapunov function defined on $\mathbb{R}^q \times \mathbb{R}^n$ by

$$W(\zeta) = U(\xi) + V(x)$$

yields

$$\begin{aligned} \nabla W(\zeta)\bar{F}(\zeta) &= \nabla V(x)\bar{f}(x) \\ &= h(x)^{\star} \\ &= H(\zeta)^{\star}. \end{aligned}$$

Furthermore, denoting by $\mathcal{L}_0$ the infinitesimal generator of the unforced stochastic differential system deduced from (6.5) when u is given by (6.7), one has

$$\begin{aligned} \mathcal{L}_0 W(\zeta) &= \tilde{L}U(\xi) + \nabla U(\xi)\tilde{f}_0(\xi, h(x))h(x) + LV(x) + \nabla V(x)\bar{f}(x)u \\ &= \tilde{L}U(\xi) + LV(x) \\ &\leq 0. \end{aligned}$$

Then, the stochastic differential system deduced from (6.5)–(6.6) when u is given by (6.7) satisfies a KYP property and, according to Proposition 4.5, is passive. □

Now, we apply some of the above results to the problem of asymptotic stabilization in probability of interconnected nonlinear stochastic differential systems.

THEOREM 6.2. *Suppose that the equilibrium solution $\xi_t \equiv 0$ of the stochastic differential system*

$$d\xi_t = \tilde{f}(\xi_t)dt + \tilde{g}(\xi_t)d\tilde{w}_t$$

is asymptotically stable in probability and that we know a C^{2r} Lyapunov function U such that

$$\tilde{L}U(\xi) < 0$$

for every ξ in $\mathbb{R}^q$. Suppose that the stochastic differential system (6.2)–(6.3) *is passive with a C^{2r} storage function and $\Gamma \cap S = \{0\}$. Then, the stochastic differential system* (6.1)–(6.2) *is asymptotically stabilizable in probability by means of a smooth state feedback law.*

Proof of Theorem 6.2. By Proposition 6.1 the stochastic differential system (6.1)–(6.3) is feedback equivalent to a passive stochastic differential system.

Then, setting $v = -s(y)$ where s is a first/third sector function in this stochastic differential system, one gets for every $(\xi, x) \in \mathbb{R}^q \times \mathbb{R}^n$,

$$\mathcal{L}W(\xi, x) \leq -h(x)s(h(x)),$$

where $\mathcal{L}$ is the infinitesimal generator of the closed-loop system.

Therefore, the equilibrium solution $(\xi_t, x_t) \equiv (0,0)$ of the closed-loop system is stable in probability, and according to the stochastic version of La Salle's theorem (Theorem 2.5) it tends in probability to the largest invariant set whose support is contained in the locus $\mathcal{L}W(\xi_t, x_t) = 0 \; \forall t \geq 0$.

Arguing as in the proof of Theorem 4.6, the latter condition implies that $\tilde{L}U(\xi_t) = 0$ and $LV(x_t) = 0 \; \forall t \geq 0$.

Then, since $\xi_t \equiv 0$ is asymptotically stable in probability, the stochastic process ξ_t tends in probability to 0 and, since $\Gamma \cap S = \{0\}$, successive applications of Itô's formula to the process $LV(x_t)$ implies that the stochastic process x_t tends in probability to 0.

This proves that the equilibrium solution $(\xi_t, x_t) \equiv (0,0)$ of the closed-loop system deduced from the equivalent passive system to (6.1)–(6.3) when v is an output feedback law given by a first/third sector function is asymptotically stable in probability. □

Moreover, if (6.2) is linear, one can deduce as a corollary of the previous theorem, the following result originally proven in [6].

Consider the stochastic process $(\xi_t, x_t) \in \mathbb{R}^q \times \mathbb{R}^n$ solution of the interconnected stochastic differential system written in the sense of Itô,

$$d\xi_t = (\tilde{f}(\xi_t) + \tilde{f}_0(\xi_t, x_t)Dx_t)dt + \tilde{g}(\xi_t)d\tilde{w}_t, \tag{6.8}$$

$$dx_t = (Ax_t + Bu)dt + \sum_{k=1}^{p} C_k x_t dw_t^k, \tag{6.9}$$

where

1. $w = \{w_t, t \geq 0\}$ and $\tilde{w} = \{\tilde{w}_t, t \geq 0\}$ are independent standard Wiener processes defined on $(\Omega, \mathcal{F}, P)$ with values in $\mathbb{R}^p$ and $\mathbb{R}^r$, respectively,
2. u is an $\mathbb{R}^m$-valued measurable control law,
3. $\tilde{f}$ and $\tilde{g}$ are smooth Lipschitz functions mapping $\mathbb{R}^q$ into $\mathbb{R}^q$ and $\mathbb{R}^{q \times r}$, respectively, vanishing in the origin, and satisfying a linear growth condition similar to (3.2),
4. $\tilde{f}_0$ is a smooth Lipschitz function mapping $\mathbb{R}^q \times \mathbb{R}^n$ into $\mathbb{R}^{q \times m}$,
5. D is a matrix in $\mathcal{M}_{m \times n}(\mathbb{R})$,
6. A, B, and C_k, $1 \leq k \leq p$, are matrices in $\mathcal{M}_{n \times n}(\mathbb{R})$, $\mathcal{M}_{n \times m}(\mathbb{R})$, and $\mathcal{M}_{n \times n}(\mathbb{R})$, respectively.

Then, one can prove the following stabilization result for the stochastic differential system (6.8)–(6.9).

COROLLARY 6.3. *Assume that $\xi_t \equiv 0$ is an asymptotically stable in probability equilibrium solution of the stochastic differential system*

$$d\xi_t = \tilde{f}(\xi_t)dt + \tilde{g}(\xi_t)d\tilde{w}_t,$$

for which we know a C^{2r} Lyapunov function U such that

$$\tilde{L}U(\xi) < 0$$

for every ξ in $\mathbb{R}^q$. Suppose that there exists a matrix K in $\mathcal{M}_{m\times n}(\mathbb{R})$ and a symmetric and positive definite matrix P in $\mathcal{M}_{n\times n}(\mathbb{R})$ such that

$$(A+BK)^\star P + P(A+BK) + \sum_{k=1}^{p} C_k^\star P C_k < 0$$

and

$$D = 2B^\star P.$$

Then, the stochastic differential system (6.8)–(6.9) *is asymptotically stabilizable in probability by means of a smooth state feedback law.*

Proof. Choosing the output y defined by

$$y_t = Dx_t, \tag{6.10}$$

one can prove easily that the input/output stochastic differential system (6.9)–(6.10) is passive with the storage function V defined on $\mathbb{R}^n$ by $V(x) = \langle Px, x\rangle$ and satisfies $\Gamma \cap S = \{0\}$.

The conclusion follows immediately by application of Theorem 6.2. □

7. Examples. *Example* 1. Consider the stochastic differential system defined on $\mathbb{R}^2$ by

$$\begin{cases} dx_1 &= \left(-\frac{1}{2}x_1 + x_2 + x_2^2u^3\right)dt + x_1 dw_t^1, \\ dx_2 &= \left(-x_1 - \frac{1}{2}x_2 + x_1x_2u\right)dt + x_2 dw_t^2, \end{cases} \tag{7.1}$$

where x_0 is given in $\mathbb{R}^2$.

Then, denoting by V the Lyapunov function defined on $\mathbb{R}^2$ by

$$V(x) = \frac{1}{2}\left(x_1^2 + x_2^2\right),$$

one gets by routine calculations that $L_0V(x) = 0$ for every $x \in \mathbb{R}^2$.

Furthermore,

$$\nabla V(x)\bar{f}(x) = x_1x_2^2,$$

$$\mathrm{ad}_{L_0}\bar{f}V(x) = \frac{3}{2}x_1x_2^2 - 2x_1^2x_2 + x_2^3,$$

and

$$L_0\left(\mathrm{ad}_{L_0}\bar{f}V\right)(x) = -\frac{25}{4}x_1x_2^2 - 6x_1^2x_2 + 2x_1^3 + 3x_2^2.$$

Then, one has $S = \{0\}$ and since $\Gamma = \mathbb{R}^2$ one gets $\Gamma \cap S = \{0\}$.

Hence, by Theorem 5.1, there exists a smooth state feedback law which renders the stochastic differential system (7.1) asymptotically stable in probability.

Example 2. Consider the stochastic differential system with two inputs defined on $\mathbb{R}^3$ by

$$(7.2)\begin{cases} dx_1 = \left(-\frac{1}{2}x_1 + -2x_2\left(x_2^2+x_3^4\right) + \ln\left(x_1^2+1\right)u_1 + \cos(x_2+x_3)u_1u_2\right)dt \\ \qquad + \left(x_1^3u_2^2\right)dt + x_1dw_t, \\ dx_2 = \left(x_1 - 2x_3^3 + x_2u_2 + \sin x_1u_1u_2 - 2x_3^3u_1^2\right)dt, \\ dx_3 = \left(x_2 + x_3u_2 + x_2u_1^2\right)dt, \end{cases}$$

where x_0 is given in $\mathbb{R}^3$.

Then, denoting by V the Lyapunov functional defined on $\mathbb{R}^3$ by

$$V(x) = \frac{1}{2}\left(x_1^2 + \left(x_2^2+x_3^4\right)^2\right),$$

one can prove by routine calculations that the hypothesis of Theorem 5.3 is satisfied and so the stochastic differential system (7.2) can be stabilized by the state feedback law u given by

$$u(x) = -\left(\Delta(x)\right)^{-1}\begin{pmatrix} x_1\ln\left(x_1^2+1\right) \\ \left(2x_2^2+4x_3^4\right)\left(x_2^2+x_3^4\right)\end{pmatrix}.$$

Example 3. Consider the stochastic differential system defined on $\mathbb{R}^2$ by

$$(7.3)\qquad\begin{cases} dx_1 &= \left(-x_1^3 - \frac{3}{2}x_1x_2^2 + x_1\mathrm{e}^{x_2}u^2\right)dt + x_1x_2dw_t^1, \\ dx_2 &= \left(-\frac{3}{2}x_2^3 + x_2^2u\right)dt + x_2^2dw_t^2, \end{cases}$$

where x_0 is given in $\mathbb{R}^2$.

Then, denoting by V the Lyapunov functional defined on $\mathbb{R}^2$ by

$$V(x) = \frac{1}{4}\left(x_1^4 + x_2^4\right),$$

one gets by straightforward computations that $L_0V(x) = -x_1^6$ for every $x \in \mathbb{R}^2$.

Moreover, since for every $x \in \mathbb{R}^2$,

$$\nabla V(x)\bar{f}(x) = x_2^5,$$

one has $\Gamma \cap S = \{0\}$ and, according to Corollary 5.5, the smooth state feedback law u defined by

$$u(x) = -\frac{x_2^5}{1+x_1^4\mathrm{e}^{x_2}}$$

is a global stabilizer for the stochastic differential system (7.3).

SOLUTION OF MIMO $\mathcal{H}_2/\ell_1$ PROBLEM WITHOUT ZERO INTERPOLATION*

MURTI V. SALAPAKA[†], M. KHAMMASH[†], AND M. DAHLEH[‡]

Abstract. In this paper we present a methodology to obtain converging lower and upper bounds to a multiple objective problem where an $\mathcal{H}_2$ performance objective is minimized subject to an ℓ_1 constraint. This methodology gives a computationally efficient synthesis procedure by avoiding many of the problems that are present in methods that employ zero interpolation techniques to characterize achievable closed loop maps.

Key words. robust control, ℓ_1 optimization, discrete time

1. Notation.

$(X, \|\| \cdot \|\|)$	The set X endowed with the norm $\| \cdot \|$.
R	The real number system.
R^n	The n-dimensional Euclidean space.
$\hat{x}(\lambda)$	The λ transform of a right sided real sequence $x = (x(k))_{k=0}^{\infty}$ defined as $\hat{x}(\lambda) := \sum_{k=0}^{\infty} x(k)\lambda^k$.
ℓ	The vector space of sequences.
$\ell^{m\times n}$	The vector space of matrix sequences of size $m \times n$.
ℓ_1	The Banach space of right sided absolutely summable real sequences with the norm given by $\|x\|_1 := \sum_{k=0}^{\infty} \|x(k)\|$.
$\ell_1^{m\times n}$	The Banach space of matrix valued right sided real sequences with the norm $\|x\|_1 := \max_{1\leq i\leq m} \sum_{j=1}^{n} \|x_{ij}\|_1$, where $x \in \ell_1^{m\times n}$ is the matrix (x_{ij}) and each x_{ij} is in ℓ_1.
c_0	The subspace of ℓ_∞ with elements x that satisfy $\lim_{k\to\infty} x(k) = 0$.
ℓ_2	The Banach space of right sided square summable sequences with the norm given by $\|x\|_2 := (\sum_{k=0}^{\infty} x(k)^2)^{1/2}$.
$\mathcal{H}_2$	The isometric isomorphic image of ℓ_2 under the λ transform $\hat{x}(\lambda)$ with the norm given by $\|\hat{x}(\lambda)\|_2 = \|x\|_2$.
P_n	The truncation operator on the space of sequences; $P_n(x(0)x(1)\ldots) = (x(0)\ x(1)\ldots x(n)0\ 0\ldots)$.
X^*	The dual space of the Banach space X. $\langle x, x^*\rangle$ denotes the value of the bounded linear functional x^* at $x \in X$.
$W(X^*, X)$	The weak star topology on X^* induced by X.
$\mathcal{D}$	The closed unit disc in the complex plane.
A'	The transpose of the matrix A.

2. Introduction. Consider Figure 3.1, where a generalized linear time-invariant plant G is depicted with a controller K connected in a feedback arrangement. Also shown are exogenous inputs w_1 and w_2 and regulated variables z_1 and z_2. The controller determines the control effort based on the measured variable y. A number of control objectives can be cast into the setup shown in Figure 3.1. The controller's objective is to stabilize the system and enhance its performance with respect to external inputs. The nature of the exogenous inputs and the particular characteristics of the regulated variables determine the appropriate systems' "measures" that must be used to quantify performance. The $\mathcal{H}_2$, $\mathcal{H}_\infty$, and ℓ_1 measures are frequently used as objectives for control synthesis. The $\mathcal{H}_2$ measure of a system is the variance of the regulated output when the exogenous input is modeled as white noise, whereas the $\mathcal{H}_\infty$ measure is the maximum energy (the ℓ_2 norm) of the regulated variable when the exogenous signal is any signal with unit energy. Another measure of a system is the ℓ_1 measure, which is the maximum magnitude of the regulated variable when the exogenous input is allowed to be any signal with unity maximum magnitude. The design of controllers which minimize these measures have been extensively studied [1].

It is known that performance with respect to a measure (usually the ℓ_1, $\mathcal{H}_2$, or the $\mathcal{H}_\infty$ norm of the closed loop) is not a guarantee of good performance with respect to some other measure. For example, in Figure 3.1 a control design objective may be stated in terms of the ℓ_1 performance between w_1 and z_1 and the minimization of the variance of z_2 with w_2 as white noise. A standard ℓ_1 solution or a standard $\mathcal{H}_2$ solution might fail to address such multiobjective concerns. Motivated by such issues researchers have focused their attention on multiobjective problems that incorporate two or more different measures in their problem definition.

An important class of problems that falls under this category is the one that incorporates time domain objectives and the $\mathcal{H}_2$ objective. In [5] it was shown that the single-input single-output problem of minimizing the ℓ_1 norm of the closed loop subject to an $\mathcal{H}_2$ constraint can be solved via finite-dimensional convex programming. In a related result it was shown in [6] that problems that incorporate the ℓ_1 norm and the $\mathcal{H}_2$ norm of the various transfer functions in a closed loop map of a multiple-input–multiple-output (MIMO) system can be formulated and solved via finite-dimensional quadratic programming. In [2] a method based on positive cones was used to minimize an $\mathcal{H}_2$ measure of the closed loop map subject to an ℓ_1 constraint.

Most approaches that incorporate the ℓ_1 objective characterize the achievability of a closed loop map through a stabilizing controller by using zero interpolation conditions on the closed loop map [1]. Computation of the zeros and the zero directions can be done by finding the nullspaces of certain Toeplitz-like matrices. Once the optimal closed loop map is determined, the task of determining the controller still remains. The closed loop map needs to satisfy the zero interpolation conditions exactly to guarantee that the correct cancellations take place while solving for the controller. However, numerical errors are always present and there exists a need to determine which poles and zeros cancel. These difficulties exist even for the pure MIMO ℓ_1 problem when zero interpolation methods are employed. However, recently in [3] it was shown that converging upper and lower bounds can be determined to the ℓ_1 problem by solving an auxiliary problem that does not require zero interpolation and thus avoids the above mentioned problems.

In this paper we formulate an auxiliary problem to the one given in [6]. We show that converging upper and lower bounds can be computed without zero interpolation

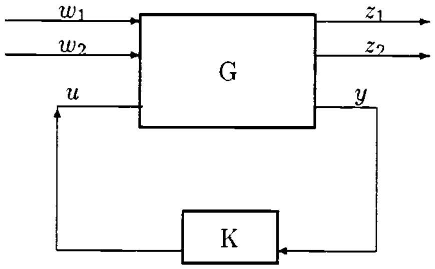

FIG. 3.1. *Closed loop system.*

for the most general MIMO case. This provides an attractive method for solving the problem.

The paper is organized as follows. In section 3 we present the preliminary material. In section 4 we formulate the multiobjective control problem and an auxiliary problem which regularizes it. In section 5 we solve the problem through lower and upper bound approximations. Section 6 contains conclusions and future directions.

3. Preliminaries. In this section we present a brief summary of mathematical and system results that will be utilized later in the paper.

3.1. System preliminaries. Consider the system in Figure 3.1, where $w := (w_1\ w_2)'$ is the exogenous disturbance, $z := (z_1\ z_2)'$ is the regulated output, u is the control input, and y is the measured output. In feedback control design the objective is to design a controller K such that with $u = Ky$ the resulting closed loop map Φ_{zw} from w to z is stable (see Figure 3.1) and satisfies certain performance criteria. In [7] a parametrization of all closed loop maps that are achievable via stabilizing controllers was derived. A good treatment of the issues involved is presented in [1]. Following the notation used in [1] we denote by n_u, n_w, n_z, and n_y the number of control inputs, exogenous inputs, regulated outputs, and measured outputs, respectively, of the plant G. We represent by Θ the set of impulse responses of closed loop maps of the plant G that are achievable through stabilizing controllers. $H \in \ell_1^{n_z \times n_3}$, $U \in \ell_1^{n_z \times n_u}$, and $V \in \ell_1^{n_y \times n_w}$ characterize the Youla parametrization of the plant [7]. The following theorem follows from the Youla parametrization.

THEOREM 3.1. $\Theta = \{\Phi \in \ell_1^{n_z \times n_w}$*: there exists a* $Q \in \ell_1^{n_u \times n_y}$ *with* $\hat{\Phi} = \hat{H} - \hat{U}\hat{Q}\hat{V}\}$*, where* $\hat{f}$ *denotes the* λ *transform* (*see* [1]) *of* f.

If Φ is in Θ we say that Φ is an *achievable* closed loop map. We assume throughout the paper that $\hat{U}$ has normal rank n_u and $\hat{V}$ has normal rank n_y. There is no loss of generality in making this assumption [1].

3.2. Mathematical preliminaries. In this subsection we summarize the mathematical results that are relevant to the paper. An exhaustive treatment of the subject matter of this subsection is given in [4]. The reader may skip this part of the paper and refer to this subsection whenever required.

DEFINITION 3.2 (convex sets). *A subset* Ω *of a vector space* X *is said to be convex if for any two elements* c_1 *and* c_2 *in* Ω *and for a real number* λ *with* $0 < \lambda < 1$ *the element* $\lambda c_1 + (1 - \lambda)c_2 \in \Omega$.

LEMMA 3.3. *Let* Ω *be a convex subset of a Banach space* X *and* $f : \Omega \rightarrow R$ *be strictly convex. If* f *achieves its minimum on* Ω*, then the minimizer is unique.*

THEOREM 3.4 (Banach–Alaoglu). *Let $(X, \|\cdot\|_x)$ be a normed vector space with X^* as its dual. The set*

$$B^* := \{x^* \in X^* : \|x^*\| \leq M\} \tag{3.1}$$

is compact in the weak-star topology for any $M \in R$.

LEMMA 3.5. *Suppose ϕ_k is a sequence in $\ell_2 \phi \in \ell_2$ and $\phi_k(t) \to \phi_0(t)$ for all t. Suppose also that $\|\phi_k\|_2 \nearrow \|\phi_0\|_2$. Then $\|\phi_k - \phi_0\|_2 \to 0$.*

Proof. Given $\epsilon > 0$ choose n such that

$$\|(I - P_n)\phi_0\|_2^2 \leq \min\left\{\frac{\epsilon}{8}, \left(\frac{\epsilon}{8(\|\phi_0\|_2 + 1)}\right)^2\right\}, \tag{3.2}$$

where P_n is the truncation operator. As $\phi_k(t) \to \phi_0(t)$ we can choose K_2 such that

$$k > K_2 \Rightarrow \|P_n(\phi_k - \phi_0)\|_2^2 \leq \frac{\epsilon}{4}. \tag{3.3}$$

We know that $\|P_n(\phi_k)\|_2 \to \|P_n(\phi_0)\|_2$ as $k \to \infty$. From the above and the fact that $\|\phi_k\|_2 \to \|\phi_0\|_2$ it follows that we can choose K_3 such that

$$k > K_3 \Rightarrow |\, \|(I - P_n)\phi_k\|_2^2 - \|(I - P_n)\phi_0\|_2^2 \,| \leq \frac{\epsilon}{4}. \tag{3.4}$$

Let $K \geq \max\{K_2, K_3\}$; then $k > K$ implies

$$\begin{aligned}
\|\phi_k - \phi_0\|_2^2 &= \|P_n(\phi_k - \phi_0)\|_2^2 + \|(I - P_n)(\phi_k - \phi_0)\|_2^2 \\
&\leq \frac{\epsilon}{4} + \|(I - P_n)(\phi_k)\|_2^2 + \|(I - P_n)(\phi_0)\|_2^2 + 2\sum_{t=n+1}^{\infty} |\phi_k(t)|\,|\phi_0(t)| \\
&\leq \frac{\epsilon}{4} + 2\|(I - P_n)(\phi_0)\|_2^2 + \frac{\epsilon}{4} + 2\sum_{t=n+1}^{\infty} |\phi_k(t)|\,|\phi_0(t)| \\
&\leq \frac{\epsilon}{4} + 2\frac{\epsilon}{8} + \frac{\epsilon}{4} + 2\|(I - P_n)\phi_k\|_2\,\|(I - P_n)\phi_0\|_2 \\
&\leq \frac{\epsilon}{4} + 2\frac{\epsilon}{8} + \frac{\epsilon}{4} + 2\|\phi_0\|_2 \frac{\epsilon}{8(\|\phi_0\|_2 + 1)} \\
&\leq \epsilon. \qquad \square
\end{aligned}$$

4. Problem statement. Let H, U, and V in the Youla parametrization be partitioned into submatrices according to the equation

$$H - U * Q * V = \begin{pmatrix} H^{11} & H^{12} \\ H^{21} & H^{22} \end{pmatrix} - \begin{pmatrix} U^1 \\ U^2 \end{pmatrix} * Q * (V^1 \;\; V^2),$$

where $Q \in \ell_2^{n_u \times n_y}$. The problem statement is as follows: *Given a plant G and a positive real number γ solve the problem*

$$\inf_{Q \in \ell_1^{n_u \times n_y}} \|H^{22} - U^2 * Q * V^2\|_2^2$$

subject to

$$\|H^{11} - U^1 * Q * V^1\|_1 \leq \gamma.$$

We denote by μ the optimal value obtained from the above problem.

Now we define an auxiliary problem that is intimately related to the one defined above. The auxiliary problem statement is: *Given a plant G and positive real numbers α and γ solve the problem*

$$\begin{aligned} &\inf_{Q\in\ell_1^{n_u\times n_y}} \|H^{22}-U^2*Q*V^2\|_2^2 \\ \textit{subject to}\quad & \\ &\|H^{11}-U^1*Q*V^1\|_1\leq\gamma, \\ &\|Q\|_1\leq\alpha. \end{aligned} \tag{4.1}$$

The optimal value obtained from the above problem is denoted by ν.

Note that in the problem statement of μ the allowable Youla parameter Q, which is in $\ell_1^{n_u\times n_y}$, needs to satisfy $\|H^{11}-U^1*Q*V^1\|_1\leq\gamma$. Therefore, it follows that $\|U^1*Q*V^1\|_1=\|H^{11}-U^1*Q*V^1-H^{11}\|_1\leq\|H^{11}-U^1*Q*V^1\|_1+\|H^{11}\|_1\leq \|H^{11}\|_1+\gamma$. Suppose $\hat{U}^1$ has more rows than columns and $\hat{V}^1$ has more columns than rows and both have full normal rank. Thus the left inverse of $\hat{U}^1$ exists (given by $(\hat{U}^1)^{-1}$) and the right inverse of $\hat{V}^1$ exists (given by $(\hat{V}^1)^{-r}$). Further, suppose that $\hat{U}^1$ and $\hat{V}^1$ have no zeros on the unit circle. Then it can be shown (see Lemma 4.2 and the discussion below) that there exists a β (which depends only on $(\hat{U}^1)^{-1}$ and $(\hat{V}^1)^{-r}$) such that $\|Q\|_1\leq\beta$. Thus if in the auxiliary problem we choose $\alpha\geq\beta$, then the constraint $\|Q\|_1\leq\alpha$ is redundant in the problem statement of ν and we get $\mu=\nu$. The extra constraint in the problem statement of ν is useful because it regularizes the problem (as will be seen). The following lemma is useful in estimating β.

LEMMA 4.1 (see [1]). *Let* $\operatorname{int}(\mathcal{D})$ *denote the interior of the unit disc in the complex plane. Given a function $\hat{f}(\,.\,)$ of the complex variable λ analytic in* $\operatorname{int}(\mathcal{D})$, *then* $\frac{d^kf}{d\lambda}|_{\lambda_0}=0$ *for $k=0,1,\ldots,(\sigma-1)$ and $\lambda_0\in\operatorname{int}(\mathcal{D})$ if and only if $\hat{f}(\lambda)=(\lambda-\lambda_0)^\sigma\hat{g}(\lambda)$, where $g(\,.\,)$ is analytic in* $\operatorname{int}(\mathcal{D})$.

LEMMA 4.2. *Let ϕ be an element of ℓ_1 such that $\|\phi\|_1\leq\gamma$ for some $\gamma>0$. Let $\hat{\phi}(\lambda)$ be the λ transform of ϕ. Suppose, $\hat{\phi}(\lambda)$ has a zero at $\lambda=a$ with $|a|<1$. If $\hat{\phi}(\lambda)=(\lambda-a)\hat{\psi}(\lambda)$, then $\|\hat{\psi}(\lambda)\|_1\leq\frac{\gamma}{1-|a|}$.*

Proof. As $\|\phi\|_1\leq\gamma$ it follows that $\|(\lambda-a)\hat{\psi}(\lambda)\|_1\leq\gamma$. This implies that $\sum_{t=-\infty}^{\infty}|\psi(t-1)-a\psi(t)|\leq\gamma$. This is true only if $\sum_{t=-\infty}^{\infty}(|\psi(t-1)|-|a|\,|\psi(t)|)\leq\gamma$, which implies that $\|\psi\|_1(1-|a|)\leq\gamma$. Therefore, $\|\psi\|_1\leq\frac{\gamma}{1-|a|}$. □

In the discussion above we have obtained an upper bound on the one norm of $R:=U^1*Q*V^1$ for any $Q\in\ell_1^{n_u\times n_y}$, which satisfies $\|H^{11}-U^1*Q*V^1\|_1\leq\gamma$. As U^1 and V^1 are left and right invertible it follows that $\hat{Q}=(\hat{U}^1)^{-l}\hat{R}(\hat{V}^1)^{-r}$. As Q is in $\ell_1^{n_u\times n_y}$ it is true that $\hat{R}$ interpolates the unstable poles of $(\hat{U}^1)^{-l}$ and $(\hat{V}^1)^{-r}$ none of which are on the unit circle by assumption. Using Lemma 4.2 one can obtain an upper bound on the one norm of Q that depends only on the upper bound of the one norm of R, $(U^1)^{-l}$, and $(V^1)^{-r}$.

The following lemma is a result on the uniqueness of the solution to (4.1).

LEMMA 4.3. *Let $Q^0\in\ell_1^{n_u\times n_y}$ be a solution to* (4.1). *Let $\Phi^0=H-U*Q^0*V$ with $\Phi^{22,o}=H^{22}-U^2*Q^0*V^2$ and $\Phi^{11,o}=H^{11}-U^1*Q^0*V^1$. Then $\Phi^{22,o}$ is unique. Furthermore, if $\hat{U}^2$ and $\hat{V}^2$ have full normal column and row ranks, respectively, then Q^0 is unique.*

Proof. Note that the problem statement of ν given by (4.1) can be recast as

$$\nu=\inf\{\|\Phi^{22}\|_2^2:\Phi^{22}\in A_{al}\}, \tag{4.2}$$

where A_{al} is the following set:

$$\{\Phi^{22} : \text{there exists } Q \in \ell_1^{n_u \times n_y} \text{ with } \Phi^{22} = H^{22} - U^2 * Q * V^2, \\ \|H^{11} - U^1 * Q * V^1\|_1 \leq \gamma, \text{ and } \|Q\|_1 \leq \alpha\}.$$

Its clear that A_{al} is a convex set. It is also true that $\|\,.\,\|_2^2$ is a strictly convex function. It follows from Lemma 3.3 that the minimizer of (4.2) given by $\Phi^{22,o}$, if it exists, is unique. If $\hat{U}^2$ and $\hat{V}^2$ have full column and row ranks, then it follows that

$$\hat{Q}^0 = (\hat{U}^2)^{-l} \hat{\Phi}^{22,o} (\hat{V}^2)^{-r},$$

where $(\hat{U}^2)^{-l}$ and $(\hat{V}^2)^{-r}$ represent the left and the right inverses of $\hat{U}^2$ and $\hat{V}^2$, respectively. Thus $\hat{Q}^0$ is unique. This proves the lemma. □

5. Converging lower and upper bounds.

5.1. Converging lower bounds.

5.1. Converging lower bounds. Let ν_n be defined by

$$(5.1) \qquad \begin{aligned} &\inf_{Q \in \ell_1^{n_u \times n_y}} \|P_n(H^{22} - U^2 * Q * V^2)\|_2^2 \\ \text{subject to} \quad & \\ &\|P_n(H^{11} - V^1 * Q * V^1)\|_1 \leq \gamma, \\ &\|Q\|_1 \leq \alpha. \end{aligned}$$

It is clear that only the parameters of $Q(0), \ldots, Q(n)$ enter into the optimization problem and therefore (5.1) is a finite-dimensional quadratic programming problem. Once optimal $Q(0), \ldots, Q(n)$ are found, $Q = \{Q(0), \ldots, Q(n), 0, \ldots\}$ will be a finite impulse response (FIR) optimal solution to (5.1).

THEOREM 5.1. *Suppose the constraint set in problem* (4.1) *is nonempty. Then problem* (4.1) *always has an optimal solution* $Q^0 \in \ell_1^{n_u \times n_y}$. *Furthermore,*

$$\nu_n \nearrow \nu.$$

Also, if $\Phi^{22,o} := H^{22} - U^2 * Q^0 * V^2$ *and* $\Phi^{22,n} := H^{22} - U^2 * Q^n * V^2$, *where* Q^n *is a solution to* (5.1), *then there exists a subsequence* $\{\Phi^{22,n_m}\}$ *of the sequence* $\{\Phi^{22,n}\}$ *such that*

$$\|\Phi^{22,n_m} - \Phi^{22,o}\|_2 \to 0 \text{ as } m \to \infty.$$

If $\hat{U}^2$ *and* $\hat{V}^2$ *have full normal column and row ranks, respectively, then* Q^0 *is unique and*

$$\|\Phi^{22,n} - \Phi^{22,o}\|_2 \to 0 \text{ as } n \to \infty.$$

Proof. We know that for any $Q \in \ell_1^{n_u \times n_y}$, $\|P_n(H^{11} - U^1 * Q * V^1)\|_1 \leq \|P_{n+1}(H^{11} - U^1 * Q * V^1)\|_1$, and $\|P_n(H^{22} - U^2 * Q * V^2)\|_2^2 \leq \|P_{n+1}(H^{22} - U^2 * Q * V^2)\|_2^2$. Therefore, $\nu_n \leq \nu_{n+1}$ for all $n = 1, 2, \ldots$. Thus $\{\nu_n\}$ forms an increasing sequence. Similarly it can be shown that for all n, $\nu_n \leq \nu$.

For $n = 1, 2, \ldots$, let $\{Q^n\} \in \ell_1^{n_u \times n_y}$ be FIR solutions of (5.1). As the sequence $\{Q^n\}$ is uniformly bounded by α in $\ell_1^{n_u \times n_y}$ it follows from the Banach–Alaoglu theorem that there exists a subsequence $\{Q^{n_m}\}$ of $\{Q^n\}$ and $Q^0 \in \ell_1^{n_u \times n_y}$ such that

$Q_{ij}^{n_m} \to Q_{ij}^0$ in the $W(c_0^*, c_0)$ topology. This implies that $Q^{n_m}(t) \to Q^0(t)$ for all $t = 0, 1, \dots$. Therefore, for all n, $P_n(U * Q^{n_m} * V)$ converges to $P_n(U * Q^0 * V)$ as $m \to \infty$. Now for any $n > 0$ and for any $n_m > n$, $\|P_n(H^{11} - U^1 * Q^{n_m} * V^1)\|_1 \leq \gamma$. This implies that $\|P_n(H^{11} - U^1 * Q^0 * V^1)\|_1 \leq \gamma$. Since n is arbitrary, we have

$$\|H^{11} - U^1 * Q^0 * V^1\|_1 \leq \gamma.$$

Similarly for any $n > 0$ and for any $n_m > n$, $\|P_n(H^{22} - U^2 * Q^{n_m} * V^2)\|_2^2 \leq \nu$. Again, this implies that $\|P_n(H^{22} - U^2 * Q^0 * V^2)\|_2^2 \leq \nu$. Since n is arbitrary, it follows that

$$\|H^{22} - U^2 * Q^0 * V^2\|_2^2 \leq \nu.$$

It follows that Q^0 is an optimal solution for (4.1).

To prove that $\nu_n \nearrow \nu$, we note that

$$\|P_n(H^{22} - U^2 * Q^{n_m} * V^2)\|_2^2 \leq \|P_{n_m}(H^{22} - U^2 * Q^{n_m} * V^2)\|_2^2 = \nu_{n_m} \qquad \forall n > 0,\ \forall n_m > n.$$

Taking the limit as m goes to infinity we have

$$\|P_n(H^{22} - U^2 * Q^0 * V^2)\|_2^2 \leq \lim_{m \to \infty} \nu_{n_m} \ \forall n > 0.$$

It follows that

$$\|H^{22} - U^2 * Q^0 * V^2\|_2^2 \leq \lim_{m \to \infty} \nu_{n_m}.$$

Thus we have shown that $\lim_{m \to \infty} \nu_{n_m} = \nu$. Since ν_n is a monotonically increasing sequence, it follows that $\nu_n \nearrow \nu$.

It is clear from Lemma 4.3 that $\Phi^{22,o} := H^{22} - U^2 * Q^0 * V^2$ is unique. If $\Phi^{22,n} := P_n(H^{22} - U^2 * Q^n * V^2)$, then from the discussion above it follows that $\nu_{n_m} = \|\phi^{22,n_m}\|_2^2$ converges to $\nu = \|\Phi^{22,o}\|_2^2$. Also, $\Phi^{22,n_m}(t)$ converges to $\Phi^{22,o}(t)$. It follows from Lemma 3.5 that

$$\|\Phi^{22,n_m} - \Phi^{22,o}\|_2 \to 0 \text{ as } m \to \infty.$$

From Lemma 4.3 we also have that if $\hat{U}^2$ and $\hat{V}^2$ have full normal column and row ranks, respectively, then Q^0 is unique. From the uniqueness of Q^0 it follows that the original sequence $\{\Phi^{22,n}\}$ converges to $\Phi^{22,o}$ in the two norm. This proves the theorem. □

5.2. Converging upper bounds. Let $\nu^n(\gamma)$ be defined by

$$\begin{aligned} &\inf_{Q \in \ell_1^{n_u \times n_y}} \|H^{22} - U^2 * Q * V^2\|_2^2 \\ &\text{subject to} \\ &\|H^{11} - U^1 * Q * V^1\|_1 \leq \gamma, \\ &\|Q\|_1 \leq \alpha, \\ &Q(k) = 0 \text{ if } k > n. \end{aligned} \tag{5.2}$$

We will assume that γ, which characterizes the ℓ_1 constraint level, is in the interior of the domain of the function ν. The following theorem shows that $\{\nu^n(\gamma)\}$ defines a sequence of upper bounds to $\nu(\gamma)$ which converge to $\nu(\gamma)$.

THEOREM 5.2. *For all n, $\nu^n(\gamma) \geq \nu^{n+1}(\gamma) \geq \nu(\gamma)$. Also*

$$\nu^n(\gamma) \searrow \nu(\gamma).$$

Proof. It is clear that $\nu^n(\gamma) \geq \nu^{n+1}(\gamma)$ because any $Q \in \ell_1^{n_u \times n_y}$ that satisfies the constraints in the problem definition of $\nu^n(\gamma)$ will satisfy the constraints in the problem definition of $\nu^{n+1}(\gamma)$. For the same reason we also have $\nu^n(\gamma) \geq \nu(\gamma)$ for all relevant n.

Thus $\{\nu^n(\gamma)\}$ is a decreasing sequence of real numbers bounded below by $\nu(\gamma)$. It can be shown that $\nu(\gamma)$ is a continuous function of γ (see Theorem 6.5 in [5]).

Given $\epsilon > 0$ choose $\delta > 0$ such that

$$\nu(\gamma - \delta) - \nu(\gamma) < \frac{\epsilon}{2}. \tag{5.3}$$

Such a δ exists from the continuity of $\nu(\gamma)$ in γ. Let $Q^{\gamma-\delta}$ be a solution to the problem $\nu(\gamma - \delta)$, which is guaranteed to exist from Theorem 5.1. Let M be large enough so that $m \geq M$ implies that

$$| \|H^{22} - U^2 * P_m(Q^{\gamma-\delta}) * V^2\|_2^2 - \|H^{22} - U^2 * Q^{\gamma-\delta} * V^2\|_2^2| < \frac{\epsilon}{2} \tag{5.4}$$

and

$$| \|H^{11} - U^1 * P_m(Q^{\gamma-\delta}) * V^1\|_1 - \|H^{11} - U^1 * Q^{\gamma-\delta} * V^1\|_1| < \frac{\delta}{2}. \tag{5.5}$$

As $Q^{\gamma-\delta}$ is a solution to the problem $\nu(\gamma - \delta)$ it is also true that

$$\|H^{22} - U^2 * Q^{\gamma-\delta} * V^2\|_2^2 = \nu(\gamma - \delta),$$
$$\|H^{11} - U^1 * Q^{\gamma-\delta} * V^1\|_1 \leq \gamma - \delta,$$

and

$$\|Q^{\gamma-\delta}\|_1 \leq \alpha.$$

From the above and (5.4), (5.5) it follows that for all $m \geq M$,

$$\|H^{22} - U^2 * P_m(Q^{\gamma-\delta}) * V^2\|_2^2 - \nu(\gamma - \delta) \leq \frac{\epsilon}{2}, \tag{5.6}$$

$$\|H^{11} - U^1 * P_m(Q^{\gamma-\delta}) * V^1\|_1 \leq \gamma, \tag{5.7}$$

and

$$\|P_m(Q^{\gamma-\delta})\|_1 \leq \alpha. \tag{5.8}$$

From (5.3) and the above it follows that for all $m \geq M$, $P_m(Q^{\gamma-\delta})$ satisfies all the constraints of problem $\nu^m(\gamma)$ and

$$\|H^{22} - U^2 * P_m(Q^{\gamma-\delta}) * V^2\|_2^2 - \frac{\epsilon}{2} - \nu(\gamma) \leq \frac{\epsilon}{2}.$$

Thus for all $m \geq M$ it follows that

$$\nu^m(\gamma) - \nu(\gamma) \leq \epsilon.$$

This proves the theorem. □

6. Conclusions. In this paper, we have formulated a problem that incorporates the $\mathcal{H}_2$ performance measure and the ℓ_1 measure. It is shown that converging upper and lower bounds can be obtained via finite-dimensional convex programming problems. This methodology avoids many of the problems of the zero interpolation based methods previously employed.

Ongoing research has indicated that the method developed here can be generalized to solve multiple-objective problems that involve the $\mathcal{H}_2$ measure and various time domain measures (including the ℓ_1 norm). Future research involves implementation of the method developed.

ON THE NULL ASYMPTOTIC STABILIZATION OF THE TWO-DIMENSIONAL INCOMPRESSIBLE EULER EQUATIONS IN A SIMPLY CONNECTED DOMAIN*

JEAN-MICHEL CORON†

Abstract. We study the asymptotic stabilization of the origin for the two-dimensional (2-D) Euler equation of incompressible inviscid fluid in a bounded domain. We assume that the controls act on an arbitrarily small nonempty open subset of the boundary. We prove the null global asymptotic stabilizability by means of explicit feedback laws if the domain is connected and simply connected.

Key words. inviscid fluid, stabilization, nonlinear control

1. Introduction.

In previous papers [2, 3] we have considered the problem of the controllability of the two-dimensional (2-D) Euler equation of incompressible inviscid fluid in a bounded domain. In particular, we have proved that, if the controls act on an arbitrarily small open subset of the boundary which meets every connected component of this boundary, then the 2-D Euler equation is exactly controllable. This result has been extended recently by Glass to the three-dimensional (3-D) Euler equation in [9, 10].

For linear control systems, the exact controllability implies the asymptotic stabilizability by means of feedback laws. This is well known for linear control systems of finite dimension and, by Slemrod [22], J.-L. Lions [17], Lasiecka–Triggiani [16], and Komornik [15], it also holds in infinite dimension in very general cases. But, as pointed out by Sussmann in [24], Sontag–Sussman in [23], and Brockett in [1], this is no longer true for *nonlinear* control systems, even of finite dimension. Let us also notice that, as in the counterexample of [1], the linearized control system of the Euler equation around the origin is not controllable.

Therefore it is natural to ask what is the situation for the asymptotic stabilizability of the origin for the 2-D Euler equation of incompressible inviscid fluid in a bounded domain when the controls act on an arbitrarily small open subset of the boundary which meets any connected component of this boundary. In this paper we prove the null global asymptotic stabilizability by means of feedback laws if the domain is simply connected.

Our paper is organized as follows.

- In section 2, we give explicit feedback laws which globally asymptotically stabilize the origin and state our main results.
- In sections 3 and 4, we give the proofs of our main results.

2. Explicit stabilizing feedbacks.

Let Ω be a nonempty bounded connected and simply connected subset of $\mathbb{R}^2$ of class C^∞ and let γ be a nonempty open subset of the boundary $\partial\Omega$ of Ω. This set γ is the location of the control. Let y be the velocity

field of the inviscid fluid contained in Ω. We assume that the fluid is incompressible, so that

$$\text{div } y = 0. \tag{2.1}$$

Since Ω is simply connected, y is completely characterized by $\omega := \text{curl } y$ and $y \cdot n$ on $\partial\Omega$, where n denotes the unit outward normal to $\partial\Omega$. For the problem of controllability, one does not really need to specify the control and the state: one considers the "Euler control system" as an underdetermined system by requiring $y \cdot n = 0$ on $\partial\Omega \setminus \gamma$ instead of $y \cdot n = 0$ on $\partial\Omega$ as for the uncontrolled usual Euler equation. For the stabilization problem, one needs to specify more precisely the control and the state. In this paper the state is ω. For the control there are at least two natural possibilities:

(a) The control is $y \cdot n$ on γ and the time derivative $\partial\omega/\partial t$ of the vorticity at the points of γ where $y \cdot n < 0$, i.e., at the points where the fluid enters into the domain Ω.

(b) The control is $y \cdot n$ on γ and the vorticity ω at the points where $y \cdot n < 0$.

Let us point out that, by (2.1), in both cases $y \cdot n$ has to satisfy $\int_{\partial\Omega} y \cdot n = 0$.

2.1. Case where one controls the time derivative of the vorticity of the incoming flow.

In this subsection we concentrate on case (a); for case (b), see subsection 2.2.

Let us give our stabilizing feedback laws. Let $g \in C^\infty(\partial\Omega)$ be such that

$$\text{Support } g \subset \gamma, \tag{2.2}$$

$$\gamma_+ := \{g > 0\} \text{ and } \gamma_- := \{g < 0\} \text{ are connected}, \tag{2.3}$$

$$g \neq 0, \tag{2.4}$$

$$\overline{\gamma_+} \cap \overline{\gamma_-} = \emptyset, \tag{2.5}$$

$$\int_{\partial\Omega} g = 0. \tag{2.6}$$

For any compact set K of $\mathbb{R}^q$ and any $f \in C^0(K; \mathbb{R}^m)$, we denote

$$|f|_{0,K} = \text{Max } \{|f(x)|\,; x \in K\}.$$

For simplicity, we write $|f|_0$ instead of $|f|_{0,\overline{\Omega}}$. Our stabilizing feedback laws are

$$y \cdot n = M\, |\omega|_0\, g \text{ on } \gamma,$$

$$\frac{\partial\omega}{\partial t} = -M\, |\omega|_0\, \omega \text{ on } \gamma_- \text{ if } |\omega|_0 \neq 0,$$

where $M > 0$ is large enough. With these feedback laws, a function $\omega : I \times \overline{\Omega} \to \mathbb{R}$, where I is an interval, is a solution of the closed loop system Σ if

$$\frac{\partial\omega}{\partial t} + \text{ div } (\omega y) = 0 \text{ in } \overset{\circ}{I} \times \Omega, \tag{2.7}$$

$$\text{div } y = 0 \text{ in } \overset{\circ}{I} \times \Omega, \tag{2.8}$$

$$\text{curl } y = \omega \text{ in } \overset{\circ}{I} \times \Omega, \tag{2.9}$$

$$y(t) \cdot n = M\, |\omega(t)|_0\, g \text{ on } \partial\Omega\, \forall t \in I, \tag{2.10}$$

$$\frac{\partial\omega}{\partial t} = -M\, |\omega(t)|_0\, \omega \text{ on } \{t;\, \omega(t) \neq 0\} \times \gamma_-, \tag{2.11}$$

where, for $t \in \Omega$, $\omega(t) : \overline{\Omega} \to \mathbb{R}$ and $y(t) : \overline{\Omega} \to \mathbb{R}^2$ are defined by requiring $\omega(t)(x) = \omega(t,x), y(t)(x) = y(t,x), \forall x \in \overline{\Omega}$. More precisely, the definition of a solution of system Σ is as follows.

Definition 2.1. *Let I be an interval. A function $\omega : I \to C^0(\overline{\Omega})$ is a solution of system Σ if*

(i) $\omega \in C^0(I; C^0(\overline{\Omega}))(\cong C^0(I \times \overline{\Omega}))$,

(ii) *for $y \in C^0(I \times \overline{\Omega}; \mathbb{R}^2)$ defined by requiring* (2.8) *and* (2.9) *in the sense of distributions and* (2.10), *one has* (2.7) *in the sense of distributions,*

(iii) *in the sense of distributions on the open manifold $\{t \in \overset{\circ}{I};\ \omega(t) \neq 0\} \times \gamma_-$ one has $\partial\omega/\partial t = -M\,|\omega(t)|_0\,\omega$.*

Our first theorem says that, for M large enough, the Cauchy problem for system Σ has at least one solution defined on $[0,+\infty)$ for any initial data in $C^0(\overline{\Omega})$. More precisely one has the following.

Theorem 2.2. *There exists $M_0 > 0$ such that, for any $M \geqslant M_0$, the following two properties hold:*

(i) *For any $\omega_0 \in C^0(\overline{\Omega})$, there exists a solution of system Σ defined on $[0,+\infty)$ such that $\omega(0) = \omega_0$.*

(ii) *Any maximal solution of system Σ defined at time* 0 *is defined on* $[0,+\infty)$ *(at least).*

Remark 2.3. (a) *In this theorem, property* (i) *is in fact implied by property* (ii) *and Zorn's lemma. We state* (i) *in order to emphasize the existence of a solution to the Cauchy problem for system Σ.* (b) *We do not know if the solution to the Cauchy problem is unique for positive time. (For negative time, one does not have uniqueness since there are solutions ω of system Σ defined on $[0,+\infty)$ such that $\omega(0) \neq 0$ and $\omega(T) = 0$ for $T \in [0,+\infty)$ large enough.) But let us emphasize that, already for control systems in finite dimension, one considers feedback laws which are merely continuous; with these feedback laws, the Cauchy problem for the closed loop system may have many solutions. It turns out that this lack of uniqueness is not a real problem. Indeed, in finite dimension at least, if a point is asymptotically stable for a continuous vector field, then there exists, as in the case of regular vector fields, a (smooth) strict Lyapunov function. This result is due to Kurzweil* [13]. *It is tempting to conjecture that a similar result holds in infinite dimension under reasonable assumptions. The existence of this Lyapunov function ensures some robustness to perturbations. It is precisely this robustness which makes the interest of feedback laws compared to open loop controls. We will see that, for our feedback laws, there exists also a strict Lyapunov—see Proposition* 3.6 *below—and therefore our feedback laws provide some kind of robustness.*

Our next theorem shows that, at least for M large enough, our feedback laws globally and strongly asymptotically stabilize the origin in $C^0(\overline{\Omega})$ for system Σ.

Theorem 2.4. *There exists a positive constant $M_1 \geqslant M_0$ such that, for any $\varepsilon \in (0,1]$, any $M \geqslant M_1/\varepsilon$, and any maximal solution ω of system Σ defined at time* 0,

$$|\omega(t)|_0 \leqslant \text{Min } \left\{|\omega(0)|_0, \frac{\varepsilon}{t}\right\}\ \forall t > 0. \tag{2.12}$$

Remark 2.5. *Due to the term $|\omega(t)|_0$ appearing in* (2.10) *and in* (2.11) *our feedback laws do not depend only on the value of ω on γ. Let us point out that there is no asymptotically stabilizing feedback law depending only on the value of ω on γ such that the origin is asymptotically stable for the closed loop system. In fact, given a nonempty open subset Ω_0 of Ω, there is no feedback law which does not depend on the values of ω on Ω_0. This phenomenon is due to the existence of "phantom vortices":*

there are smooth stationary solutions $\bar{y} : \overline{\Omega} \to \mathbb{R}^2$ *of the* 2*-D Euler equations such that* Support $\bar{y} \subset \Omega_0$ *and* $\bar{\omega} :=$ curl $\bar{y} \neq 0$*; see, e.g.,* [20]*. Then* $\omega(t) = \bar{\omega}$ *is a solution of the closed loop system if the feedback law does not depend on the values of* ω *on* Ω_0 *and vanishes for* $\omega = 0$*.*

Remark 2.6. *Let us emphasize that* (2.12) *implies that*

$$|\omega(t)|_0 \leqslant \varepsilon \quad \forall t \geqslant 1, \tag{2.13}$$

for any maximal solution ω *of system* Σ *defined at time 0 (whatever* $\omega(0)$ *is). It would be interesting to know if one could have a similar result for the* 2*-D Navier–Stokes equations of viscous incompressible flows, that is, if given* $\varepsilon > 0$*, does there exist a feedback law such that* (2.13) *holds for any solution of the closed loop Navier–Stokes control system? Note that* $y = 0$ *on* γ *is a feedback which leads to asymptotic stabilization of the null solution of the Navier–Stokes control system. But this feedback does not have the required property. For recent results on the controllability of the Navier–Stokes control system, see the papers by Imanuvilov and Fursikov* [6, 7, 8] *and the paper by Imanuvilov* [12] *as well as* [4, 5]*.*

2.2. Case where one controls the vorticity of the incoming flow. In this subsection one does no longer control the time-derivative of the vorticity of the incoming flow but the vorticity of the incoming flow itself. Therefore the control is $y \cdot n$ on γ with the constraint $\int_{\partial\Omega} y \cdot n = 0$ (as above) and the vorticity ω at the points where $y \cdot n < 0$. Of course in this new situation one cannot take the state ω in $C^0(\overline{\Omega})$: if the state ω is in $C^0(\overline{\Omega})$, then it will determine part of the control, namely, the vorticity of the incoming flow. It is therefore natural to consider the state ω as being in $L^\infty(\Omega)$.

For any measurable subset B of $\mathbb{R}^q$ and any $f \in L^\infty(B; \mathbb{R}^m)$, we denote by $|f|_{\infty,B}$ the essential supremum of f on B. For simplicity, we write $|f|_\infty$ instead of $|f|_{\infty,\overline{\Omega}}$. Our stabilizing feedback laws are

$$y \cdot n = M\, |\omega|_\infty\, g \text{ on } \gamma, \tag{2.14}$$

$$\omega = 0 \text{ on } \gamma_- \text{ if } |\omega|_\infty \neq 0, \tag{2.15}$$

where, again, $M > 0$ is large enough. With these feedback laws, a function $\omega : I \times \overline{\Omega} \to \mathbb{R}$, where I is an interval, is a solution of the closed loop system that we call Σ_1, if one has (2.7), (2.8), (2.9) and

$$y(t) \cdot n = M\, |\omega(t)|_\infty\, g \text{ on } \partial\Omega \text{ for almost every } t \in I, \tag{2.16}$$

$$\omega = 0 \text{ on } \{t;\, \omega(t) \neq 0\} \times \gamma_-. \tag{2.17}$$

Since $\omega(t)$ is only in $L^\infty(\Omega)$, the meaning of (2.17) has to be specified. As usual, (2.17) has to be understood in a "weak sense," which is obtained by multiplying (2.7) by suitable smooth test functions, integrating on $I \times \Omega$, and performing integration by parts. More precisely, the definition of a solution of system Σ_1 is as follows.

Definition 2.7. *Let* I *be an interval. A function* $\omega : I \to L^\infty(\Omega)$ *is a solution of system* Σ_1 *if*

(i) $\omega \in C^0(I; H^{-1}(\Omega))$,

(ii) $\omega \in L^\infty_{loc}(I; L^\infty(\Omega)) \cong L^\infty_{loc}(I \times \overline{\Omega})$,

(iii) *for any* $\varphi \in C^1(I \times \overline{\Omega})$ *with compact support such that*

$$\text{Support } \varphi \subset \left(\overset{\circ}{I} \times \Omega\right) \cup \left(\{t \in \overset{\circ}{I};\, |\omega(t)|_\infty > 0\} \times \gamma_-\right), \tag{2.18}$$

one has

$$\int_{I\times\Omega}\left(\omega\frac{\partial\varphi}{\partial t}+\omega(y\cdot\nabla)\varphi\right)=0, \tag{2.19}$$

where $y\in L^\infty\left(I;C^0\left(\overline{\Omega}\right)\right)$ *is defined by requiring* (2.16) *and, in the sense of distributions on* $\overset{\circ}{I}\times\Omega$, (2.8) *and* (2.9).

Our first theorem says that, for M large enough, the Cauchy problem for system Σ_1 has at least one solution defined on $[0,+\infty)$ for any initial data in $L^\infty(\Omega)$. More precisely, one has the following.

THEOREM 2.8. *There exists* $M_2\geqslant 0$ *such that, for any* $M\geqslant M_2$, *the following two properties hold.*

(i) *For any* $\omega_0\in L^\infty(\Omega)$, *there exists a solution of system* Σ_1 *defined on* $[0,+\infty)$ *such that* $\omega(0)=\omega_0$.

(ii) *Any maximal solution of system* Σ_1 *defined at time* 0 *is defined on* $[0,+\infty)$ *(at least).*

Our next theorem, which is analogous to Theorem 2.4, tells us that, at least for M large enough, feedbacks laws (2.14) and (2.15) globally and strongly asymptotically stabilize the origin in $L^\infty(\Omega)$ for system Σ_1.

THEOREM 2.9. *There exists a positive constant* $M_3>0$ *such that, for any* $\epsilon\in(0,1]$, *any* $M\geqslant M_3/\varepsilon$, *and any maximal solution of system* Σ_1 *defined at time* 0, *one has*

$$|\omega(t)|_\infty\leqslant \text{ Min }\left\{|\omega(0)|_\infty,\frac{\varepsilon}{t}\right\}\ \forall t>0.$$

The proof of Theorem 2.9 is very similar to the proof of Theorem 2.4 and therefore is omitted. The end of this paper is organized as follows.

- In section 3, we prove Theorems 2.2 and 2.4.
- In section 4, we prove Theorem 2.8.

3. Proof of Theorems 2.2 and 2.4.

3.1. Proof of Theorem 2.2. For a compact subset K and a function $y\in C^0(K;\mathbb{R}^2)$, we let

$$q_K(y):=|y|_0+\sup\{|y(x)-y(x')|/r(|x-x'|);(x,x')\in K^2,x\neq x'\},$$

where

$$r(s)=s+s\ln(1/s)\ \forall s\in(0,1),\ \text{and } r(s)=s\ \forall s\geqslant 1. \tag{3.1}$$

For simplicity, we write q instead of $q_{\overline{\Omega}}$. For technical reasons, it is useful to extend $y\in C^0(\overline{\Omega})$ outside $\overline{\Omega}$. Let $R>0$ be such that

$$\overline{\Omega}\subset B_{R/2}:=\{x\in\mathbb{R}^2;|x|<R/2\}.$$

Let $B_R:=\{x\in\mathbb{R}^2;|x|<R\}$. Let $\mathcal{P}:C^0(\overline{\Omega};\mathbb{R}^2)\to C^0(\overline{B_R};\mathbb{R}^2)$ be a continuous linear map such that

$$\mathcal{P}(y)(x)=y(x)\ \forall x\in\overline{\Omega}\ \forall y\in C^0(\overline{\Omega};\mathbb{R}^2), \tag{3.2}$$

$$\text{Support }\mathcal{P}(y)\subset\overline{B_{R/2}}\ \forall y\in C^0(\overline{\Omega};\mathbb{R}^2), \tag{3.3}$$

and such that, for some $C_0>0$,

$$q_{\overline{B_R}}(\mathcal{P}(y))\leqslant C_0q(y)\,\forall y\in C^0(\overline{\Omega};\mathbb{R}^2). \tag{3.4}$$

Let us recall the following important theorem, due to Wolibner [25] and Yudovich [26] (see also [14, Lemma 2.6]).

THEOREM 3.1 (see Wolibner [25] and Yudovich [26]). *Let T be a positive real number and let $y \in L^\infty\left((0,T);C^0\left(\overline{B_R};\mathbb{R}^2\right)\right)$ be such that*

(3.5)

$$y(t,x) := y(t)(x) = 0 \text{ for almost everywhere (a.e.) } (t,x) \in (0,T) \times \left(B_R \setminus B_{R/2}\right),$$

and, for some constant $K \in (0,+\infty)$,

$$q_{\overline{B_R}}(y(t)) \leqslant K \text{ for a.e. } t \in (0,T). \tag{3.6}$$

Then there exists one and only one map $\Phi^y \in C^0([0,T]\times[0,T]\times\overline{B_R};\overline{B_R})$, $(t,s,x) \to \Phi^y(t,s,x)$ such that

$$\Phi^y(t,s,x) = x + \int_s^t y(t',\Phi^y(t',s,x))dt' \,\forall (t,s,x) \in [0,T]\times[0,T]\times\overline{B_R}.$$

Moreover there exist two constants $C_1 = C_1(K,R,T) > 0$ and $\delta = \delta(K,R,T) > 0$, depending on K,R,T, such that, for any $(x,x') \in \overline{B_R}^2$, for any $(t,t',s,s') \in [0,T]^4$, and for any $y \in L^\infty\left((0,T);C^0\left(\overline{B_R};\mathbb{R}^2\right)\right)$ satisfying (3.5) *and* (3.6),

$$|\Phi^y(t',s',x') - \Phi^y(t,s,x)| \leqslant C_1(|s'-s|^\delta + |t'-t|^\delta + |x'-x|^\delta). \tag{3.7}$$

Our proof of Theorem 2.2 is divided in two parts.

- We first prove the existence of a solution to the Cauchy problem for small positive time.
- Then we prove that any maximal solution to Σ defined at time 0 is defined on $[0,+\infty)$.

So let us first start with the proof of the following proposition.

PROPOSITION 3.2. *There exists $M_0 > 0$ such that, for any $M \geqslant M_0$ and for any $\omega_0 \in C^0(\overline{\Omega})$, there exists $T > 0$ and a solution of system Σ defined on $[0,T]$ such that $\omega(0) = \omega_0$.*

Of course if $\omega_0 = 0$ one can take arbitrary $T > 0$ and choose $\omega = 0$. Therefore we may assume that $\omega_0 \neq 0$. Then there exists a point x^0 in Ω such that

$$\omega_0(x^0) \neq 0. \tag{3.8}$$

Let $M > 0$. Let $C_2 > 0$ (depending on M) be such that

$$|y|_0 \leqslant C_2 \tag{3.9}$$

for any $y \in C^0(\overline{\Omega};\mathbb{R}^2)$ such that

$$|\text{curl } y|_0 \leqslant |\omega_0|_0, \text{ div } y = 0,$$
$$|y \cdot n| \leqslant M|\omega_0|_0|g|_{0,\partial\Omega} \text{ on } \partial\Omega.$$

Let $\rho > 0$ be such that

$$B(x^0,\rho) := \{x \in \mathbb{R}^2; |x - x^0| < \rho\} \subset \Omega \tag{3.10}$$

and let

$$T = \rho/C_2. \tag{3.11}$$

Let us denote by $|\ |_{H^{-1}(\Omega)}$ one of the usual norm of the Sobolev space $H^{-1}(\Omega)$. Let $C_3 > 0$ be such that, for any $f \in L^\infty(\Omega; \mathbb{R}^2)$,

$$|\text{div } f|_{H^{-1}(\Omega)} \leqslant C_3 \, |f|_{L^\infty(\Omega)} \, . \tag{3.12}$$

Let also $C_4 > 0$ be such that, for any divergence free $f \in C^0(\overline{\Omega}; \mathbb{R}^2)$ with a bounded curl,

$$|f|_0 \leqslant C_4 \left(| \text{ curl } f|_{L^\infty(\Omega)} + |f \cdot n|_{0,\partial\Omega} \right) . \tag{3.13}$$

We are going to construct a solution $\omega \in C^0([0,T] \times \overline{\Omega})$ of system Σ satisfying the initial condition $\omega(0) = \omega_0$ as a fixed point of a map $F : X \to X$, where X is the set of functions $\omega \in C^0([0,T] \times \overline{\Omega})$ such that

$$\omega(0) = \omega_0, \tag{3.14}$$

$$t \in [0,T] \to |\omega(t)|_0 \text{ is nonincreasing,} \tag{3.15}$$

$$\left| \frac{\partial \omega}{\partial t} \right|_{L^\infty((0,T);H^{-1}(\Omega))} \leqslant C_3 C_4 |\omega_0|_0^2 \left(M |g|_{0,\partial\Omega} + 1 \right) . \tag{3.16}$$

Note that X is a closed convex subset of $C^0([0,T] \times \overline{\Omega})$ equipped with the sup-norm $|\ |_{0,[0,T]\times\overline{\Omega}}$. Let us define F. For $\omega \in X$, let us define $\tilde{y}_\omega \in C^0([0,T] \times \overline{\Omega}; \mathbb{R}^2)$ by requiring

$$\text{div } \tilde{y}_\omega = 0 \text{ in } (0,T) \times \Omega, \tag{3.17}$$

$$\text{curl } \tilde{y}_\omega = \omega \text{ in } (0,T) \times \Omega, \tag{3.18}$$

$$\tilde{y}_\omega(t,\cdot) \cdot n = M \text{ Max } \{ |\omega(t)|_0, |\omega_0(x^0)| \} g \text{ on } \partial\Omega \ \forall t \in [0,T]. \tag{3.19}$$

Note that, by (3.15), (3.14), (3.17), (3.18), (3.19), and a theorem due to Wolibner [25] (see also [14, Lemma 1.4]), there exists a constant C_5 such that

$$q(\tilde{y}_\omega(t,\cdot)) \leqslant C_5 \, \forall t \in [0,T] \ \forall \omega \in X. \tag{3.20}$$

Let $y_\omega \in C^0([0,T] \times \overline{B_R}; \mathbb{R}^2)$ be defined by

$$y_\omega(t,\cdot) = \mathcal{P}(\tilde{y}_\omega(t,\cdot)) \ \forall t \in [0,T]. \tag{3.21}$$

By (3.4) and (3.20),

$$q_{\overline{B_R}}(y_\omega(t,\cdot) \leqslant C_0 C_5 \ \ \forall \omega \in X. \tag{3.22}$$

In particular, by the Wolibner–Yudovich theorem (Theorem 3.1), there exists a flow Φ^{y_ω} associated with y_ω. For any interval I containing 0 such that $0 = \text{Min} I$ and for any $y \in L^\infty_{\text{loc}} \left(I; C^0 \left(\overline{B_R}; \mathbb{R}^2 \right) \right)$ satisfying (3.5) and such that $q_{\overline{B_R}}(y) \in L^\infty_{\text{loc}}(I)$, let us define $s_y : I \times \overline{\Omega} \to I$ by

$$s_y(t,x) = \text{ Max } \{ t' \in [0,t]; \ \Phi^y(t',t,x) \in \overline{\gamma_-} \}, \tag{3.23}$$

with the convention Max $\emptyset = 0$. Let us also define $a_y : I \times \overline{\Omega} \to \overline{\Omega}$ by

$$a_y(t,x) = \Phi^y(s_y(t,x),t,x). \tag{3.24}$$

With these notations, we can now define our map $F(\omega) : [0,T] \times \overline{\Omega} \to \mathbb{R}$ by

$$F(\omega)(t,x) = \omega_0 \left(a_{y_\omega}(t,x) \right) \exp \left(-M \int_0^{s_{y_\omega}(t,x)} |\omega(t')|_0 \, dt' \right) . \tag{3.25}$$

It follows from our construction of F (recall also (3.17)) that, in the sense of distributions,

$$\frac{\partial F(\omega)}{\partial t} + \text{ div } (F(\omega)y_\omega) = 0 \text{ in } (0,T) \times \Omega. \tag{3.26}$$

Indeed, let $\bar{t} \in (0,T)$ and $\bar{x} \in \Omega$. Then, for (t,x) close enough to $(\bar{t},\bar{x})$, one has

$$s_{y_\omega}(t,\Phi^{y_\omega}(t,\bar{t},x)) = s_{y_\omega}(\bar{t},x),$$
$$a_{y_\omega}(t,\Phi^{y_\omega}(t,\bar{t},x)) = a_{y_\omega}(\bar{t},x),$$

which imply that

$$F(\omega)(t,\Phi^{y_\omega}(t,\bar{t},x)) = F(\omega)(\bar{t},x). \tag{3.27}$$

But (3.27), together with (3.2), (3.17), (3.21), and standard smoothing procedures, gives (3.26) in the sense of distributions.

Let us now check that if $\omega \in X$ is a fixed point of F, then ω is a solution of system Σ which, by (3.14), satisfies the Cauchy initial data $\omega(0) = \omega_0$. Indeed, let ω be a fixed point of F and let $y = \tilde{y}_\omega$. Then, from (3.17) and (3.18), we get (2.8) and (2.9). From (3.26), we get (2.7). Let us also point out that, by (3.23),

$$s_{y_\omega}(t,x) = t \;\; \forall t \in [0,T] \, \forall x \in \gamma_-. \tag{3.28}$$

From (3.24), (3.25), and (3.28), one gets

$$\omega(t,x) = F(\omega)(t,x) = \omega_0(x) \exp\left(-M \int_0^t |\omega(t')|_0 \, dt'\right) \; \forall (t,x) \in [0,T] \times \gamma_-,$$

which implies (2.11). It remains only to verify that (2.10) holds. By (3.19), it suffices to check that

$$\left|\omega_0(x^0)\right| \leqslant |\omega(t)|_0 \;\; \forall t \in [0,T]. \tag{3.29}$$

From the definition of C_2, (3.2), (3.14), (3.15), (3.17), (3.18), (3.19), and (3.21), one gets that $|y_\omega(t)|_0 \leqslant C_2$ for any $t \in [0,T]$, which, with (3.10) and (3.11), gives

$$\Phi^{y_\omega}(t,0,x^0) \in \Omega \;\; \forall t \in [0,T].$$

Therefore $s_{y_\omega}(t,\Phi^{y_\omega}(t,0,x_0)) = 0$ for any $t \in [0,T]$, which implies that

$$F(\omega)(t,\Phi^{y_\omega}(t,0,x^0)) = \omega_0(x^0) \, \forall t \in [0,T]. \tag{3.30}$$

From (3.30), one has

$$(|\omega(t)|_0 =) \, |F(\omega(t))|_0 \geqslant \left|\omega_0(x^0)\right| \; \forall t \in [0,T].$$

Therefore (3.29) holds and the fixed point ω of F is indeed a solution of system Σ.

By the Leray–Schauder fixed point theorem, in order to prove the existence of a fixed point to F, it suffices to check that

$$F(X) \subset X, \tag{3.31}$$

$$F \text{ is continuous,} \tag{3.32}$$

$$F(X) \text{ is relatively compact in } C^0([0,T] \times \overline{\Omega}). \tag{3.33}$$

Let us first check (3.31). Let $\omega \in X$. It follows directly from (3.25) that

$$|F(\omega)|_{L^\infty(\overline{\Omega}\times[0,T])} \leqslant |\omega_0|_0 \,.$$

Clearly

$$F(\omega)(0) = \omega(0) = \omega_0. \tag{3.34}$$

Let us check that

$$t \in [0,T] \to |F(\omega(t))|_0 \text{ is nonincreasing.} \tag{3.35}$$

Let $0 \leqslant t_1 \leqslant t_2 \leqslant T$ and let $x \in \overline{\Omega}$. If $s_{y_\omega}(t_2,x) \leqslant t_1$, one has

$$F(\omega)(t_2,x) = F(\omega)\left(t_1, \Phi^{y_\omega}(t_1,t_2,x)\right).$$

If $s_{y_\omega}(t_2,x) > t_1$, one has

$$F(\omega)(t_2,x) = F(\omega)\left(a_{y_\omega}(t_2,x), t_1\right) \exp - \left(M \int_{t_1}^{s_{y_\omega}(t_2,x)} |\omega(t')|_0 dt' \right).$$

In both cases

$$|F(\omega)(t_2,x)| \leqslant |F(\omega)(t_1)|_0,$$

which shows (3.35). From (3.12), (3.13), (3.17), (3.18), (3.19), (3.26), (3.34), and (3.35), one gets that

$$\left| \frac{\partial F(\omega)}{\partial t} \right|_{L^\infty((0,T);H^{-1}(\Omega))} \leqslant C_3 C_4 |\omega_0|_0^2 \left(M|g|_{0,\partial\Omega} + 1 \right).$$

Therefore, in order to prove (3.31), it suffices to check that $F(\omega)$ is continuous on $[0,T] \times \overline{\Omega}$. From the continuity of Φ^{y_ω} and the definition (3.23) of s_{y_ω}, it is clear that

$$s_{y_\omega} \text{ is upper semicontinuous on } [0,T] \times \overline{\Omega}. \tag{3.36}$$

Since the continuity of s_{y_ω} implies the continuity of F, it remains only to check that

$$s_{y_\omega} \text{ is lower semicontinuous on } [0,T] \times \overline{\Omega}. \tag{3.37}$$

In order to prove this lower semicontinuity, let us assume that the following lemma, proved in Appendix B, holds.

Lemma 3.3. *There exists $M_0 > 0$ such that, for any $T > 0$ and for any $y \in L^\infty\left((0,T); C^0\left(\overline{B_R}; \mathbb{R}^2\right)\right)$ satisfying* (3.5), (3.6) *for some $K > 0$, and for some function $\alpha \in L^\infty((0,T);(0,+\infty))$,*

$$y(t,\cdot)\cdot n = \alpha(t) g \textit{ on } \partial\Omega \textit{ for a.e. } t \in (0,T), \tag{3.38}$$

$$M_0 |\text{curl } y(t)|_{L^\infty(\Omega)} \leqslant \alpha(t) \textit{ for a.e. } t \in (0,T), \tag{3.39}$$

$$\text{div } y = 0 \textit{ in } (0,T) \times \Omega \tag{3.40}$$

for any $(\tilde{t},\tilde{x}) \in (0,T] \times \overline{\gamma_-}$ and for any $\nu \in (0,\tilde{t})$, there exists $t \in (\tilde{t}-\nu,\tilde{t})$, such that

$$\Phi^y\left(t,\tilde{t},\tilde{x}\right) \notin \overline{\Omega}.$$

Let us also point out that, by the definition of γ_-, (3.2), (3.19), (3.21), and (3.22), for any $\tilde{x} \in \overline{\Omega}$, if for $0 \leqslant t' \leqslant t \leqslant T$ $\Phi^{y_\omega}(t',t,\tilde{x})$ is not in $\overline{\Omega}$, then

$$\exists t'' \in [t',t] \text{ such that } \Phi^{y_\omega}(t',t,\tilde{x}) \in \overline{\gamma_-}. \tag{3.41}$$

This is indeed clear if y_ω is smooth enough, for example, locally Lipschitz with respect to x. The case where y is not smooth follows from the main ingredient, due to Wolibner [25], to prove the uniqueness of Φ^y in Theorem 3.1. Let us briefly sketch the proof. Let $W \in C^\infty(\mathbb{R}^2)$ be such that $\{W = 0\} = \partial\Omega$, $W > 0$ in Ω, $W < 0$ in $\mathbb{R}^2 \setminus \overline{\Omega}$ and ∇W does not vanish on $\partial\Omega$. Let $w(s) = W(\Phi^{y_\omega}(s,t,\tilde{x}))$. If (3.41) does not hold one easily sees, using (3.2), (3.19), (3.21), and (3.22), that there exists $C_6 > 0$ such that

$$\frac{\mathrm{d}w}{\mathrm{d}s} \leqslant C_6 r(|w|) \text{ on } [t', t], \tag{3.42}$$

where r is defined in (3.1). Since $w(t') < 0 \leqslant w(t)$, there exists $t_1 \in (t', t]$ such that $w(t_1) = 0$. Then, using (3.42) and the fact that $\int_0^1 /r(s)ds = +\infty$, one gets that $w \geqslant 0$ on $[t', t_1]$, which is in contradiction with the fact that $w(t') < 0$. Hence we have (3.41). Using (3.2), (3.17), (3.18), (3.19), (3.21), and (3.22), one easily sees that $y = y_\omega$ satisfies the assumptions of Lemma 3.3 if $M \geqslant M_0$. From now on we assume that $M \geqslant M_0$ with M_0 as in Lemma 3.3. From the continuity of Φ^{y_ω}, the definition (3.23) of s_{y_ω} and Lemma 3.3, one easily sees that (3.37) holds. Hence we have (3.31). The continuity of F can be proved with the same type of arguments used to prove the continuity of $F(\omega)$. We omit the proof.

Let us now turn to the proof of (3.33). By Wolibner–Yudovich's theorem (Theorem 3.1), (3.22), (3.24), (3.25), and Ascoli's theorem, it suffices to check that

$$s_{y_\omega} \text{ is relatively compact in } C^0([0,T] \times \overline{\Omega}). \tag{3.43}$$

Let $(\omega_k;\, k \in \mathbb{N})$ be a sequence of functions in X. We want to prove the existence of a subsequence of the $(\omega_k;\, k \in \mathbb{N})$ converging in $C^0([0,T] \times \overline{\Omega})$. By Ascoli's theorem and Wolibner–Yudovich's theorem, (Theorem 3.1), the set $\{\Phi^{y_{\omega_k}};\, k \in \mathbb{N}\}$ is relatively compact in $C^0([0,T] \times [0,T] \times \overline{B_R}; \overline{B_R})$. Hence, without loss of generality, we may assume the existence of $\Phi \in C^0([0,T] \times [0,T] \times \overline{B_R}; \overline{B_R})$ such that the sequence $(\Phi^{y_{\omega_k}};\, k \in \mathbb{N})$ is converging to Φ in $C^0([0,T] \times [0,T] \times \overline{B_R}; \overline{B_R})$. Associated with Φ is the function $s : [0,T] \times \overline{\Omega} :\to \mathbb{R}$ defined by (see (3.23))

$$s(t,x) = \text{ Max } \{t' \in [0,t];\, \Phi(t',t,x) \in \overline{\gamma_-}\}.$$

(Let us recall the convention Max $\emptyset$ =0.) Let $(t_k;\, k \in \mathbb{N})$ be a sequence of real numbers in $[0,T]$ converging to some $\bar{t}$ as k goes to $+\infty$. Let $(x_k;\, k \in \mathbb{N})$ be a sequence of points in $\overline{\Omega}$ converging to some $\bar{x}$ as k goes to $+\infty$. It is clear that

$$s(\bar{t},\bar{x}) \geqslant \limsup_{k\to+\infty} s_{y_{\omega_k}}(t_k, x_k). \tag{3.44}$$

Therefore in order to prove (3.43) it suffices to check that

$$s(\bar{t},\bar{x}) \leqslant \liminf_{k\to+\infty} s_{y_{\omega_k}}(t_k, x_k). \tag{3.45}$$

Indeed, from (3.44) and (3.45), one gets that the sequence $(s_{y_{\omega_k}};\, k \in \mathbb{N})$ converges uniformly to s on $[0,T]\times\overline{\Omega}$ as $k \to +\infty$. Let us again point out that Φ has the following property: for any $x \in \overline{\Omega}$, if for $0 \leqslant t' \leqslant t \leqslant T$ $\Phi(t',t,x)$ is not in $\overline{\Omega}$, then there exists $t'' \in [t', t]$ such that $\Phi(t'',t,x) \in \overline{\gamma_-}$. Indeed, it follows from the fact that the $\Phi^{y_{\omega_k}}$ have this property (see above) and converge to Φ in $C^0([0,T] \times [0,T] \times \overline{B_R}; \overline{B_R})$ as k goes to $+\infty$. From this property and the convergence of the $\Phi^{y_{\omega_k}}$ to Φ in $C^0([0,T] \times [0,T] \times \overline{B_R}; \overline{B_R})$ one easily sees, as above, that (3.45) holds if Φ satisfies the following property:

$$\forall 0 < \nu < t \leqslant T\, \forall x \in \overline{\gamma_-},\ \Phi([t-\nu, t], t, x) \not\subset \overline{\Omega}. \tag{3.46}$$

Let us prove this property. Let $\theta \in C^\infty(\overline{\Omega})$ be defined by

$$\Delta\theta = 0 \text{ in } \overline{\Omega}, \tag{3.47}$$

$$\frac{\partial\theta}{\partial n} = g \text{ on } \partial\Omega. \tag{3.48}$$

Let us point out that the existence of θ follows from (2.6). Let us write

$$\tilde{y}_{\omega_k} = \alpha_k(t)\nabla\theta + \tilde{z}_k,$$

where $\alpha_k \in C^0([0,T])$ and $\tilde{z}_k \in C^0([0,T] \times \overline{\Omega}; \mathbb{R}^2)$ are defined by

$$\alpha_k(t) = M \text{ Max } \{|\omega_k(t)|_0, |\omega_0(x^0)|\} \, \forall t \in [0,T], \tag{3.49}$$

$$\text{div } \tilde{z}_k = 0 \text{ in } (0,T) \times \Omega, \tag{3.50}$$

$$\text{curl } \tilde{z}_k = \omega_k \text{ in } (0,T) \times \Omega, \tag{3.51}$$

$$\tilde{z}_k \cdot n = 0 \text{ on } [0,T] \times \partial\Omega. \tag{3.52}$$

Using (3.14) and (3.15) for $\omega = \omega_k$ and using (3.49), one gets

$$M|\omega_0(x^0)| \leqslant \alpha_k(t) \leqslant M|\omega_0|_0, \tag{3.53}$$

$$t \in [0,T] \to \alpha_k(t) \text{ is nonincreasing.} \tag{3.54}$$

From (3.53) and (3.54), we get the existence of $\alpha \in L^\infty(0,T)$ such that, extracting subsequences if necessary, one has

$$0 < M|\omega_0(x^0)| \leqslant \alpha(t) \text{ for a.e. } t \in (0,T), \tag{3.55}$$

$$\alpha_k(t) \to \alpha(t) \text{ as } k \to +\infty \text{ for a.e. } t \in (0,T). \tag{3.56}$$

Let us now turn to the sequence $(\tilde{z}_k; k \in \mathbb{N})$. Let us fix $r \in (2, +\infty)$. Using (3.14), (3.15), and (3.16) with $\omega = \omega_k$, using also (3.50), (3.51), and (3.52), one gets that

$$\tilde{z}_k \text{ is bounded in } C^0([0,T]; W^{1,r}(\Omega; \mathbb{R}^2)), \tag{3.57}$$

$$\frac{\partial\tilde{z}_k}{\partial t} \text{ is bounded in } L^\infty([0,T]; H^{-1}(\Omega; \mathbb{R}^2)). \tag{3.58}$$

Then, by a compactness lemma due to P.-L. Lions [18, Lemma C1, Appendix C] (take, with the notations of [18], $X = W^{1,r}(\Omega; \mathbb{R}^2)$ and $Y = H^{-1}(\Omega; \mathbb{R}^2)$) and by the Rellich–Kondrakov theorem, (3.57) and (3.58) imply that the sequence $(\tilde{z}_k; k \in \mathbb{N})$ is relatively compact in $C^0([0,T] \times \overline{\Omega}; \mathbb{R}^2)$. Hence, extracting subsequences if necessary, we may assume the existence of $\tilde{z} \in C^0([0,T] \times \overline{\Omega}; \mathbb{R}^2)$ such that $\tilde{z}_k$ tends to $\tilde{z}$ in $C^0([0,T] \times \overline{\Omega}; \mathbb{R}^2)$ as k tends to $+\infty$. Let $y : (0,T) \times B_R \to \mathbb{R}^2$ be defined by

$$y(t,\cdot) = \alpha(t)\mathcal{P}(\nabla\theta) + \mathcal{P}(\tilde{z}(t,\cdot)) \, \forall t \in (0,T). \tag{3.59}$$

Let us check that, if $M \geqslant M_0$, y satisfies the assumptions of Lemma 3.3. By (3.3) and (3.59), one has (3.5). It follows easily from (3.22) that

$$q_{\overline{B_R}}(y_\omega(t,\cdot) \leqslant C_0 C_5 \text{ for a.e. } t \in (0,T),$$

which implies (3.5). Passing to the limit in (3.52), one gets $z \cdot n = 0$, which with (3.59) gives (3.38). Finally, if $M \geqslant M_0$, (3.39) follows easily from the fact that

$$|\text{curl } y(t)|_{L^\infty(\Omega)} \leqslant \liminf_{k\to+\infty} |\text{curl } y_k(t)|_{L^\infty(\Omega)}.$$

Hence y satisfies the assumptions of Lemma 3.3, and, by this lemma, we have (3.46) if one has

$$\Phi = \Phi^{y}. \tag{3.60}$$

But, by the definition of $\Phi^{y_{\omega_k}}$,

$$\Phi^{y_{\omega_k}}(t,s,x) = x + \int_s^t y_{\omega_k}(t', \Phi^{y_{\omega_k}}(t',s,x))dt'. \tag{3.61}$$

Letting $k \to +\infty$ in (3.61), we get, by the dominated convergence theorem,

$$\Phi(t,s,x) = x + \int_s^t y(t', \Phi^{y_{\omega_k}}(t',s,x))dt',$$

for any $(t,s,x) \in [0,T] \times [0,T] \times \overline{B_R}$, which implies (3.60). This ends the proof of Proposition 3.2.

Let us now prove the next proposition.

PROPOSITION 3.4. *For any $M \geqslant M_0$, any maximal solution of system Σ defined at time* 0 *is defined on* $[0,+\infty)$ *(at least).*

Let us recall that $\omega : I \to C^0(\overline{\Omega})$ is a *maximal* solution of system Σ if, for any interval J containing I but not equal to I, there exists no solution of system Σ which is equal to ω on the interval I. The existence of a maximal solution follows, as usual, from Zorn's lemma; hence Theorem 2.2 is a corollary of Propositions 3.2 and 3.4.

Until the end of this paper, for any $\omega \in L^\infty(\Omega)$, one defines $\tilde{y}_\omega \in C^0(\overline{\Omega})$ and $y_\omega \in C^0(\overline{B_R})$ by requiring

$$\begin{gathered} \text{div } \tilde{y}_\omega = 0 \text{ and curl } \tilde{y}_\omega = \omega \text{ in } \Omega, \\ \tilde{y}_\omega \cdot n = M|\omega|_{L^\infty(\Omega)} g \text{ on } \partial\Omega, \\ y_\omega = \mathcal{P}(\tilde{y}_\omega). \end{gathered}$$

Of course if, for some interval I, ω is a map from I into $L^\infty(\Omega)$, the above conditions specified at any time in I, give maps $\tilde{y}_\omega : I \to C^0(\overline{\Omega})$ and $y_\omega : I \to C^0(\overline{B_R})$. With these notations, let us start the proof of Proposition 3.4 by the following simple observation.

LEMMA 3.5. *Let $T > 0$ and let $\omega \in C^0([0,T]; C^0(\overline{\Omega}))$ be a solution of system Σ. Then, for any $t \in [0,T]$ and for any $x \in \overline{\Omega}$,*

$$\omega(t,x) = \omega(0, a_{y_\omega}(t,x)) \exp\left(-M \int_0^{s_{y_\omega}(t,x)} |\omega(t')|_0 dt'\right). \tag{3.62}$$

In particular,

$$t \to |\omega(t)|_0 \textit{ is nonincreasing.} \tag{3.63}$$

Indeed, for $t \in (0,T]$ and $x \in \overline{\Omega}$, let $\omega^* : [0,t] \to \mathbb{R}$ be defined by $\omega^*(t') = \omega(t', \Phi^{y_\omega}(t',t,x))$. Using (2.7), (2.8), and standard smoothing procedures, one gets that, in the sense of distributions,

$$\frac{\mathrm{d}\omega^*}{\mathrm{d}t'} = 0 \text{ on } (s_{y_\omega}(t,x), t).$$

In particular,

$$\omega(s_{y_\omega}(t,x), a_{y_\omega}(t,x)) = \omega^*(s_{y_\omega}(t,x)) = \omega^*(t) = \omega(t,x). \tag{3.64}$$

If $s_{y_\omega}(t,x)=0$, this gives (3.62). Let us study the case where $0<s_{y_\omega}(t,x)$. It follows directly from (2.11) that, in the sense of distributions,

$$\frac{\partial\omega}{\partial t'}(t',a)=-M|\omega(t')|_0\omega(t',a) \text{ on } \{t'\in(0,T)\}\,\forall a\in\gamma_-.$$

In particular,

$$\omega^*(s_{y_\omega}(t,x))=\omega(0,a_{y_\omega}(t,x))\exp\left(-M\int_0^{s_{y_\omega}(t,x)}|\omega(t')|_0dt'\right),$$

which, with (3.64), gives again (3.62). Property (3.63) follows from (3.62) (see the proof of (3.35)) or note that, if $0\leqslant t_1\leqslant T$, $t\in[0,T-t_1]\to\omega(t+t_1)$ is a solution of system Σ and apply, for $t=t_2-t_1\in[0,T-t_1]$, (3.62) to this solution.

Let $\omega\in C^0(I\times\overline{\Omega})\cong C^0(I;C^0(\overline{\Omega}))$ be a maximal solution to Σ such that I is an interval containing 0. Let $T=\operatorname{Sup} I$. We want to prove that $T=+\infty$. Let us assume that $T<+\infty$. From Proposition 3.2, it follows that $T>0$ and $T\notin I$. Therefore, in order to get a contradiction with the maximal property of ω, it suffices to check that

$$\omega(t) \text{ converges in } C^0(\overline{\Omega}) \text{ as } t\to T^-. \tag{3.65}$$

Indeed, if (3.65) holds, then $\bar\omega : I\cup\{T\}\to C^0(\overline{\Omega})$ defined by $\bar\omega=\omega$ on I and $\bar\omega(T)=\lim_{t\to T}\omega(t)$ is also a solution to system Σ.

If $|\omega(t)|_0\to 0$ as $t\to T^-$, (3.65) holds. Therefore, by (3.63), we may assume that, for some $\eta>0$,

$$|\omega(t)|_0\geqslant\eta\ \forall t\in[0,T). \tag{3.66}$$

As above, using, in particular, Lemma 3.3 and (3.66), one gets that s_{y_ω} is continuous on $[0,T]\times\overline{\Omega}$. Therefore $F(\omega)$ defined by (3.25) is continuous on $[0,T]\times\overline{\Omega}$. But, by Lemma 3.5, this function is equal to ω on $[0,T)\times\overline{\Omega}$. This proves (3.65) and therefore ends the proof of Theorem 2.2.

3.2. Proof of Theorem 2.4. Let $V : C^0(\overline{\Omega})\to[0,+\infty)$ be defined by

$$V(\omega)=|\omega\exp(-\theta)|_0,$$

where $\theta\in C^\infty(\overline{\Omega})$ satisfies (3.47) and (3.48). Theorem 2.4 is an easy consequence of the following proposition.

PROPOSITION 3.6. *There exists $M_4\geqslant M_0$ and $\mu>0$ such that, for any $M\geqslant M_4$ and any solution $\omega:[0,+\infty)\to C^0(\overline{\Omega})$ of system Σ, one has, for any $t\in[0,+\infty)$,*

$$[-\infty,0]\ni\dot V(t):=\frac{d}{dt^+}V(\omega(t))\leqslant-\mu MV^2(\omega(t)), \tag{3.67}$$

where $d/dt^+V(\omega(t)):=\lim_{\varepsilon\to0^+}(V(\omega(t+\varepsilon))-V(\omega(t)))/\varepsilon$.

Let us check that this proposition indeed implies Theorem 2.4. Let $\omega:[0,+\infty)\to C^0(\overline{\Omega})$ be a solution of system Σ with $\omega(0)\neq0$ and $M\geqslant M_4$. Integrating (3.67), one gets

$$V(\omega(t))\leqslant\frac{V(\omega(0))}{1+\mu MtV(\omega(0))}\,\forall t\geqslant0.$$

In particular,

$$V(\omega(t))\leqslant\frac{1}{\mu Mt}\,\forall t>0. \tag{3.68}$$

But

$$|\omega(t)|_0 \leqslant |\exp(\theta)|_0 V(\omega(t))\, \forall t \geqslant 0,$$

which, with (3.68), gives

$$|\omega(t)|_0 \leqslant \frac{|\exp(\theta)|_0}{\mu M t}\, \forall t > 0.$$

Since, by (3.63), $|\omega(t)|_0 \leqslant |\omega(0)|_0$ for any $t \geqslant 0$, we get (2.12) if one takes $M \geqslant |\exp(\theta)|_0/(\mu\varepsilon)$. Therefore Theorem 2.4 holds with

$$M_1 = \text{ Max } \{M_4, |\exp(\theta)|_0/\mu\}.$$

Let us now turn to the proof of Proposition 3.6. Clearly, since system Σ is autonomous, it suffices to check that (3.67) holds for $t = 0$. Let us also assume that the following lemma, which is proved in Appendix A, holds.

LEMMA 3.7. *For any x in $\overline{\Omega}$,*

$$\nabla\theta(x) \neq 0. \tag{3.69}$$

From this lemma and standard elliptic estimates, we get the existence of $\mu_0 \in (0, 1]$ such that

$$\nabla\theta \cdot (\nabla\theta + z) \geqslant \mu_0 \text{ on } \overline{\Omega} \tag{3.70}$$

for any $z \in C^0(\overline{\Omega}; \mathbb{R}^2)$ such that $\operatorname{div} z = 0$, $|\operatorname{curl} z|_0 \leqslant \mu_0$, and $z \cdot n = 0$ on $\partial\Omega$. For $t \geqslant 0$, let $x(t) \in \overline{\Omega}$ be such that

$$V(\omega(t)) = |\omega(t, x(t))| \exp(-\theta(x(t))).$$

For simplicity, we assume that $\omega(t, x(t)) \geqslant 0$; the case where $\omega(t, x(t)) < 0$ can be treated in a similar way. We have

$$V(\omega(t)) - V(\omega(0)) \leqslant \kappa(t), \tag{3.71}$$

with

(3.72)
$$\begin{aligned}\kappa(t) &= \omega(t, x(t)) \exp(-\theta(x(t))) - \omega(0, a_{y_\omega}(t, x(t))) \exp(-\theta(a_{y_\omega}(t, x(t))))\\ &= V(\omega(t)) \left(1 - \exp\left(\theta(x(t)) - \theta(a_{y_\omega}(t, x(t))) + M \int_0^{s_{y_\omega}(t,x(t))} |\omega(t')|_0 dt'\right)\right).\end{aligned}$$

We choose $M_4 = \text{ Max } \{1/\mu_0, M_0\}$ and take any $M \geqslant M_4$. Let us again decompose y_ω in the following way:

$$y_\omega = M|\omega(t)|_0(\nabla\theta + z), \tag{3.73}$$

with $\operatorname{div} z = 0$, $\operatorname{curl} z = \omega/(M|\omega(t)|_0)$ ($= 0$ if $\omega(t) = 0$), and $z \cdot n = 0$ on $\partial\Omega$. For any x in $\overline{\Omega}$ and for any s in $[s_{y_\omega}(t, x), t]$, one has

$$\frac{\partial}{\partial s}\left(\theta\left(\Phi^{y_\omega}(s, t, x)\right)\right) = \nabla\theta(\Phi^{y_\omega}(s, t, x)) y_\omega\left(s, \Phi^{y_\omega}(s, t, x)\right),$$

which, with (3.70), (3.73), gives

$$\frac{\partial}{\partial s}\left(\theta\left(\Phi^{y_\omega}(s, t, x)\right)\right) \geqslant \mu_0 M |\omega(t)|_0.$$

In particular,

$$\theta(x(t)) - \theta\left(a_{y_\omega}(t, x(t))\right) \geqslant \mu_0 M|\omega(t)|_0(t - s_{y_\omega}(t, x(t))),$$

which, with (3.63) and (3.72), implies that

$$\begin{aligned}\kappa(t) &\leqslant MV(\omega(t))|\omega(t)|_0\left(-\mu_0\left(t - s_{y_\omega}\left(t, x\left(t\right)\right)\right) - s_{y_\omega}\left(t, x\left(t\right)\right)\right)\\ &\leqslant -\mu_0 MV(\omega(t))|\omega(t)|_0 t\\ &\leqslant -\mu_0 M \text{ Min } \{\exp(\theta(x));\ x \in \overline{\Omega}\} V(\omega(t))^2 t\end{aligned}$$

Hence, one gets Proposition 3.6 by taking $\mu = \mu_0$ Min $\{\exp(\theta(x));\ x \in \overline{\Omega}\}$.

4. Proof of Theorem 2.8. Let us first prove (i) of Theorem 2.8. We are going to deduce (i) of Theorem 2.8 from (the proof of) Theorem 2.2. Roughly speaking the idea is that, if we replace (2.11) with

$$\frac{\partial \omega}{\partial t} = -kM\left|\omega(t)\right|_0 \omega \text{ on } \{t;\ \omega(t) \neq 0\} \times \gamma_-,$$

then, as $k \to +\infty$, the solutions of the Cauchy problem for system Σ converge to a solution of the Cauchy problem for system Σ_1.

Reversing time in the proof of Lemma 3.3, one easily gets the following.

LEMMA 4.1. *There exists $M_5 \geqslant M_0$ such that, for any $T > 0$ and for any $y \in L^\infty\left((0,T); C^0\left(\overline{B_R}; \mathbb{R}^2\right)\right)$ satisfying* (3.5), (3.6) *for some $K > 0$, and for some function $\alpha \in L^\infty\left((0,T); (0, +\infty)\right)$,*

$$y(t,\cdot)\cdot n = \alpha(t) g \textit{ on } \partial\Omega \textit{ for a.e. } t \in (0,T), \tag{4.1}$$

$$M_5|\text{ curl } y(t)|_{L^\infty(\Omega)} \leqslant \alpha(t) \textit{ for a.e. } t \in (0,T), \tag{4.2}$$

$$\text{div y} = 0 \textit{ in } (0,T)\times\Omega \tag{4.3}$$

for any $(\tilde{t}, \tilde{x}) \in [0,T) \times \overline{\gamma_+}$ and for any $\nu \in (0, T - \tilde{t})$, there exists $t \in (\tilde{t}, \tilde{t} + \nu)$, such that

$$\Phi^y\left(t, \tilde{t}, \tilde{x}\right) \notin \overline{\Omega}.$$

We choose $M_2 =$ Max $\{M_0, M_5\}$, where M_0 is defined in the proof of Lemma 3.3; see (B.3). Let $M \geqslant M_2$. Let $\omega_0 \in L^\infty(\Omega)$. There exists a sequence $(\omega_{0,k};\ k \in \mathbb{N}^*)$ of functions in $C^0(\overline{\Omega})$ such that

$$|\omega_{0,k}(x)| \leqslant |\omega_0|_{\infty,\Omega\cap B(x,1/k)}\ \forall k \in \mathbb{N}^*\ \forall x \in \overline{\Omega}, \tag{4.4}$$

$$\omega_{0,k}(x) \underset{k\to+\infty}{\longrightarrow} \omega_0(x) \text{ for a.e. } x \in \Omega. \tag{4.5}$$

By (the proof of) Theorem 2.2, there exists a solution $\omega^k \in C^0([0,\infty); C^0(\overline{\Omega}))$ of system Σ, with (2.11) replaced by

$$\frac{\partial \omega_k}{\partial t} = -kM\left|\omega_k(t)\right|_0 \omega_k \text{ on } \{t;\ \omega_k(t) \neq 0\} \times \gamma_-, \tag{4.6}$$

such that $\omega_k(0) = \omega_{0,k}$. Let $\tilde{y}_k = \tilde{y}_{\omega_k} \in C^0([0,+\infty) \times \overline{\Omega}; \mathbb{R}^2)$ and let $y_k = y_{\omega_k} \in C^0([0,+\infty) \times \overline{B_R}; \mathbb{R}^2)$. Let $\alpha_k \in C^0([0,+\infty))$ and $\tilde{z}_k \in C^0([0,+\infty) \times \overline{\Omega}; \mathbb{R}^2)$ be defined by

$$\alpha_k(t) = M|\omega_k(t)|_0\ \forall t \in [0,+\infty), \tag{4.7}$$

$$\text{div } \tilde{z}_k = 0, \quad \text{curl } \tilde{z}_k = \omega_k \text{ in } (0,+\infty)\times\Omega,$$

$$\tilde{z}_k \cdot n = 0 \text{ on } [0,+\infty) \times \partial\Omega.$$

One has $\tilde{y}_k = \alpha_k \nabla\theta + \tilde{z}_k$. As in the proof of (3.43), extracting subsequences if necessary, one gets the existence of ω in $L^\infty((0,+\infty); L^\infty(\Omega)) \cap C^0([0,+\infty); H^{-1}(\Omega))$, of a nonincreasing function α in $L^\infty((0,+\infty),[0,+\infty))$ and of $\tilde{z}$ in $C^0([0,+\infty)\times\overline{\Omega})$ with $t \to q(\tilde{z}(t,\cdot)) \in L^\infty_{\mathrm{loc}}(0,+\infty)$ such that, for any $T \in [0,+\infty)$, one has, as $k \to +\infty$

$$\omega_k \to \omega \text{ in } C^0([0,T]; H^{-1}(\Omega)), \tag{4.8}$$

$$\omega_k \rightharpoonup \omega \text{ in } \sigma(L^1((0,+\infty)\times\Omega), L^\infty((0,+\infty)\times\Omega)), \tag{4.9}$$

$$\tilde{z}_k \to \tilde{z} \text{ in } C^0([0,T]\times\overline{\Omega};\mathbb{R}^2), \tag{4.10}$$

$$\alpha_k(t) \to \alpha(t) \text{ for a.e. } t \in (0,+\infty). \tag{4.11}$$

Let $\tilde{y}(t) = \alpha(t)\nabla\theta + \tilde{z}$. One has (2.8) and (2.9) for $y = \tilde{y}$ and $I = [0,T]$. Let $y \in L^\infty([0,+\infty); C^0(\overline{B_R};\mathbb{R}^2))$ be defined by $y(t,\cdot) = \mathcal{P}(\tilde{y}(t,\cdot))$. Let $\varphi \in C^1((0,+\infty)\times\overline{\Omega})$ with compact support such that

$$\text{Support } \varphi \subset ((0,+\infty)\times\Omega) \cup (\{t \in (0,+\infty)\,;\, \alpha(t) > 0\} \times \gamma_-)\,. \tag{4.12}$$

Let us check that (2.19) holds. Since α_k, $k \in \mathbb{N}^*$, and α are nonincreasing, one gets from (4.11) and (4.12) that, for some $k_0 \in \mathbb{N}^*$, one has, for any $k \geqslant k_0$,

$$\text{Support } \varphi \subset ((0,+\infty)\times\Omega) \times (\{t \in (0,+\infty);\, |\omega_k(t)|_0 > 0\} \times \gamma_-).$$

Hence, for any $k \geqslant k_0$,

$$\int_{(0,+\infty)\times\Omega} \left(\omega_k \frac{\partial\varphi}{\partial t} + \omega(\tilde{y}_k\cdot\nabla)\varphi\right) = \int_{(0,+\infty)\times\Omega} \alpha_k\omega_k g\varphi. \tag{4.13}$$

Let $t_0 > 0$ be such that

$$\alpha(t_0) > 0, \tag{4.14}$$

$$\text{Support } \varphi \subset [0,t_0] \times (\Omega \cup \gamma_-). \tag{4.15}$$

Since α_k, $k \in \mathbb{N}^*$, and α are nonincreasing, it follows again from (4.12) that there exists a positive integer $k_1 \geqslant k_0$ such that, for any $k \geqslant k_1$ and any $t \in [0,t_0]$, $\alpha_k(t) \geqslant \alpha(t_0)/2$. Hence, by (4.4) and (4.6), one has, for any $(t,x) \in [0,t_0]\times\gamma_-$,

$$|\omega_k(t,x)| \leqslant |\omega|_\infty \exp\left(-\frac{k\alpha(t_0)t}{2}\right). \tag{4.16}$$

Hence, letting k go to $+\infty$ in (4.13), and using (4.14), (4.15), and (4.16), one gets (2.19).

It remains to check that

$$M|\omega(t)|_\infty = \alpha(t) \text{ for a.e. } t \in (0,+\infty). \tag{4.17}$$

By (4.7), (4.8), and (4.11),

$$M|\omega(t)|_\infty \leqslant \alpha(t) \text{ for a.e. } t \in (0,+\infty).$$

Hence, in order to prove (4.17), it suffices to check that, if for some $0 < t_1 < t_2$, for some $\chi > 0$, and for some $k_2 > 0$,

$$\alpha_k(t_2) \geqslant \chi\,\forall k \geqslant k_2, \tag{4.18}$$

then

$$M|\omega(t_1)|_\infty \geqslant \chi. \tag{4.19}$$

Let $x_k \in \overline{\Omega}$ be such that

$$M|\omega_k(t_2, x_k)| = \alpha_k(t_2). \tag{4.20}$$

Still extracting subsequences if necessary, we may assume that, for some $x_\infty \in \overline{\Omega}$,

$$x_k \to x_\infty \text{ as } k \to \infty. \tag{4.21}$$

Let $\bar{x}_\infty = \Phi^y(0, t_2, x_\infty)$. Let us assume for the moment that the following lemma holds.

Lemma 4.2. *There exists $\rho > 0$ and $k_3 \geqslant k_2$ such that, for any $k \geqslant k_3$ and for any $t \in [0, t_1]$,*

$$\Phi^{y_k}(t, 0, \bar{x}) \in \overline{\Omega}\, \forall \bar{x} \in \overline{\Omega} \cap B(\bar{x}_\infty, \rho). \tag{4.22}$$

Letting $k \to +\infty$ in (4.22), one gets

$$\Phi^y(t_1, 0, \overline{\Omega} \cap B(\bar{x}_\infty, \rho)) \subset \overline{\Omega}. \tag{4.23}$$

From Lemma 3.3 and (4.22), it follows that, for any $\bar{x} \in \overline{\Omega} \cap B(\bar{x}_\infty, \rho)$ and any $k \geqslant k_3$,

$$s_{\omega_k}(t_1, \Phi^{y_k}(t_1, 0, \bar{x})) = 0,$$

so that, by (3.62),

$$\omega_k(t_1, \Phi^{y_k}(t_1, 0, \bar{x})) = \omega_0(\bar{x}). \tag{4.24}$$

Let us point out that (4.24) implies that

$$\omega(t_1, x) = \omega_0(\Phi^y(0, t_1, x)) \text{ for a.e. } x \in \Phi^y(t_1, 0, \overline{\Omega} \cap B(\bar{x}_\infty, \rho)). \tag{4.25}$$

Indeed, let us first notice that, since $\Phi^y(t, 0, \cdot)$ is a homeomorphism of $\overline{B_R}$—its inverse is $\Phi^y(0, t, \cdot)$—it follows from (4.23) and the invariance of domain theorem (see, e.g., [19, Theorem 3.3.2]) that

$$\Phi^y(t, 0, \Omega \cap B(\bar{x}_\infty, \rho)) \subset \Omega\, \forall t \in [0, t_1]. \tag{4.26}$$

Let $\psi \in C^\infty(\overline{\Omega})$, the support of which is included in the open subset $\Phi^y(t_1, 0, \Omega \cap B(\bar{x}_\infty, \rho)) \subset \Omega$. Then, by (4.8),

$$< \omega(t_1, x), \psi >_{H^{-1}(\Omega), H_0^1(\Omega)} = \lim_{k \to +\infty} I_k, \tag{4.27}$$

with

$$I_k = \int_{\Phi^y(t_1, 0, \Omega \cap B(\bar{x}_\infty, \rho))} \omega_k(t_1, x)\psi(x) dx.$$

Since div $\tilde{y}_k = 0$, one gets, using also (4.22) and (4.24), the existence of $k_4 \geqslant k_3$ such that, for any $k \geqslant k_4$,

$$\begin{aligned} I_k &= \int_{\Phi^{y_k}(t, 0, \Omega \cap B(\bar{x}_\infty, \rho))} \omega_k(t_1, x)\psi(x) dx \\ &= \int_{\Omega \cap B(\bar{x}_\infty, \rho)} \omega_k(t_1, \Phi^{y_k}(t_1, 0, \bar{x})\psi(\Phi^{y_k}(t_1, 0, \bar{x})) d\bar{x} \\ &= \int_{\Omega \cap B(\bar{x}_\infty, \rho)} \omega_0(\bar{x})\psi(\Phi^{y_k}(t_1, 0, \bar{x})) d\bar{x}. \end{aligned}$$

Note that, by (4.26) and the fact that div $y = 0$ in $(0, T) \times \Omega$, $\Phi^y(t_1, 0, \cdot)$ restricted to $\Omega \cap B(\bar{x}_\infty, \rho)$ preserves the Lebesgue measure. Hence

$$\begin{aligned}\lim_{k\to+\infty} I_k &= \int_{\Omega\cap B(\bar{x}_\infty,\rho)} \omega_0(\bar{x})\psi(\Phi^y(t_1, 0, \bar{x}))d\bar{x} \\ &= \int_{\Phi^y(t_1,0,\Omega\cap B(\bar{x}_\infty,\rho))} \omega_0(\Phi^y(0, t_1, x))\psi(x)dx,\end{aligned}$$

which, with (4.27), implies (4.25). From Lemma 3.5, with kM instead of M in (3.62), (4.18), and (4.20), one has

$$\begin{aligned}(4.28)\quad \chi \leqslant M|\omega_k(t_2, x_k)| \leqslant M|\omega_{0,k}(\Phi^{y_k}(s_{y_k}(t_2, x_k), t_2, x_k)| \\ \times (\exp(-kM\chi s_{y_k}(t_2, x_k)))\,.\end{aligned}$$

In particular, by (4.4),

$$s_{y_k}(t_2, x_k) \to 0 \text{ as } k \to +\infty,$$

which, with (4.4), (4.18), (4.20), and (4.28), implies that

$$(4.29)\qquad M|\omega_0|_{\infty,\Omega\cap B(\bar{x}_\infty,\rho)} \geqslant \chi.$$

This inequality, together with (4.25) and the fact that $\Phi^y(t_1, 0, \cdot)$ restricted to $\Omega \cap B(\bar{x}_\infty, \rho)$ preserves the Lebesgue measure, implies that

$$(4.30)\qquad M|\omega(t_1)|_{\infty,\Phi^y(t_1,0,\Omega\cap B(\bar{x}_\infty,\rho))} \geqslant \chi,$$

which gives (4.19).

It remains to prove Lemma 4.2. Let us first point out that

$$(4.31)\qquad \Phi^y(t, t_2, x_\infty) \in \overline{\Omega}\, \forall t \in [0, t_2].$$

Indeed, if (4.31) does not hold, there exists $t_3 \in (0, t_2]$ such that $\Phi^y(t_3, t_2, x_\infty) \notin \overline{\Omega}$. Then, for some $k_5 > 0$,

$$s_{y_k}(t_2, x_k) \geqslant t_3/2\, \forall k \geqslant k_5,$$

which, with (4.4) and (4.6), implies that

$$(4.32)\qquad \chi \leqslant M|\omega_k(t_2, x_k)| \leqslant M|\omega_0|_\infty \exp(-kM\chi t_3/2)\,.$$

Letting k go to $+\infty$ in (4.32), we get a contradiction. This ends the proof of (4.31).

One easily checks that y satisfies the assumption of Lemma 4.1. Since $\Phi^y(t, t_2, x_\infty) = \Phi(t, 0, \bar{x}_\infty)$, Lemma 4.1 and (4.31) give that

$$\Phi^y(t, 0, \bar{x}_\infty) \in \overline{\Omega} \setminus \overline{\gamma_+}\, \forall t \in [0, t_1],$$

which implies Lemma 4.2.

Let us now prove (ii) of Theorem 2.8. One needs the following lemma, which is analogous to Lemma 3.5 but requires a different proof.

LEMMA 4.3. *Let $T > 0$, let $\omega \in C^0([0, T]; H^{-1}(\Omega)) \cap L^\infty([0, T]; L^\infty(\Omega))$ be a solution of system Σ_1, and let $t \in [0, T]$. Then the closed set $S(t) := \{x \in \omega;\ a_{y_\omega}(t, x) \in \partial\Omega$ and $s_{y_\omega}(t, x) = 0\}$ has measure 0 and, for a.e. $x \in \Omega$,*

$$(4.33)\qquad \omega(t, x) = \omega(0, \Phi^{y_\omega}(0, t, x)) \textit{ if } s_{y_\omega}(t, x) = 0,$$

$$(4.34)\qquad \omega(t, x) = 0 \textit{ if } s_{y_\omega}(t, x) > 0,$$

where s_{y_ω} *is defined by* (3.23)*—recall the convention* Max $\emptyset = 0$. *In particular,* (3.62) *again holds (for a.e.* $(t,x) \in (0,T) \times \Omega$*).*

With this lemma, which is proved at the end of this section, one gets easily (ii) of Theorem 2.8. Indeed, let ω be a maximal solution of system Σ_1 defined on an interval I containing 0 and let us assume that $T :=$ Sup $I < +\infty$. Again, it follows from (i) of Theorem 2.8 that

$$T \notin I. \tag{4.35}$$

Using (3.62), which holds by Lemma 4.3, one gets that $|\omega(t)|_\infty \leqslant |\omega(0)|_\infty$ for any t in $[0,T)$. Then, using the fact that $\partial\omega/\partial t = -$ div (ωy), one gets that $\omega \in H^1((0,T); H^{-1}(\Omega))$. Hence

$$\omega(t) \text{ converges in } H^{-1}(\Omega) \text{ as } t \to T^-. \tag{4.36}$$

Then $\bar\omega : I \cup \{T\} \to C^0(\overline{\Omega})$ defined by $\bar\omega = \omega$ on I and $\bar\omega(T) = \lim_{t\to T} \omega(t)$ is also a solution of system Σ_1, a contradiction with the maximal property of ω and (4.35).

Finally, we briefly sketch the proof of Lemma 4.3. Let us first check that $S(t)$ has measure 0. One has

$$S(t) \subset \{\Phi^{y_\omega}(t,0,\bar x);\ \bar x \in \gamma_-,\ \Phi^{y_\omega}(s,0,\bar x) \in \Omega\ \forall s \in (0,T]\}.$$

Hence, since div $y_\omega = 0$ in $(0,T) \times \Omega$, $S(t)$ has measure 0.

Let us now prove (4.33). Let $U = \{(t,x) \in (0,T) \times \Omega;\ a_{y_\omega}(t,x) \in \Omega\}$. Let us consider the *linear* hyperbolic equation that we call $\mathcal{L}$, where $f : U \to \mathbb{R}$ is the unknown,

$$\frac{\partial f}{\partial t} + \text{ div } (f y_\omega) = 0 \text{ in } U, \tag{4.37}$$

$$f(0,\cdot) = \omega(0,\cdot) \text{ on } \{0\} \times \Omega, \tag{4.38}$$

where (4.37) and (4.38) have to be understood in a weak sense. More precisely a function $f : U \to \mathbb{R}$ is a solution of $\mathcal{L}$ if $f \in L^\infty(U)$ and is such that, for any $\psi \in C^1_0(U \cup (\{0\} \times \Omega))$,

$$\int_U f\left(\frac{\partial\psi}{\partial t} + (y_\omega \cdot \nabla)\,\psi\right) = -\int_\Omega \omega(0,\cdot)\psi(0,\cdot).$$

Clearly ω is a solution of $\mathcal{L}$. Moreover $\bar\omega : U \to \mathbb{R}$, defined by

$$\bar\omega(t,x) = \omega(0, \Phi^{y_\omega}(0,t,x))\,\forall (t,x) \in U,$$

is also a solution of $\mathcal{L}$. Hence, in order to prove (4.33), it suffices to check that $\mathcal{L}$ has a unique solution. When y_ω is of class C^1, this is a classical result due to Oleĭnik [21]; see also [11, Theorem 2.2.1]. When $y_\omega \in L^\infty\left([0,T]; C^0\left(\overline{B_R}; \mathbb{R}^2\right)\right)$—satisfying (3.5)—and such that $t \to q_{\overline{B_R}}(y(t,\cdot)) \in L^\infty(0,T)$ one needs a (very slight) modification of the proof since, for example, (2.2.10) in [11] is no longer true. Let us briefly describe the modification. By standard smoothing procedures, one can construct, for $\varepsilon \in (0,1]$, $y^\varepsilon \in C^1([0,T] \times \overline{B_R}; \overline{B_R})$ be such that, for some $C_7 > 0$,

$$|y^\varepsilon - y_\omega|_{0,[0,T]\times\overline{B_R}} \leqslant C_7 \varepsilon^{3/4}\ \forall \varepsilon \in (0,1], \tag{4.39}$$

$$\text{Support } y^\varepsilon \subset [0,T] \times \overline{B_R/2}\ \forall \varepsilon \in (0,1], \tag{4.40}$$

$$|\nabla y^\varepsilon|_{0,[0,T]\times\overline{B_R}} \leqslant C_7 \varepsilon^{-1/4}\ \forall \varepsilon \in (0,1]. \tag{4.41}$$

Let $\varphi \in C^1([0,T] \times \overline{B_R})$, the support of which is included in U. Let, for $\varepsilon \in (0,1]$, $\psi^\varepsilon \in C^1([0,T] \times \overline{B_R})$ be defined by

$$\psi^\varepsilon(t,x) = -\int_t^T \varphi(s, \Phi^{y^\varepsilon}(s,t,x))ds.$$

One has

$$\psi^\varepsilon(T,\cdot) = 0,$$
$$\frac{\partial \psi^\varepsilon}{\partial t} + (y^\varepsilon \cdot \nabla)\psi^\varepsilon = \varphi,$$

and one easily checks that, at least for ε small enough, Support $\psi^\varepsilon \subset U \cup (\{0\} \times \Omega)$. Therefore, at least for ε small enough,

$$\int_U (\omega - \bar{\omega})\varphi = \int_U (\omega - \bar{\omega})((y^\varepsilon - y_\omega) \cdot \nabla)\psi^\varepsilon. \tag{4.42}$$

But, with (4.41), one gets the existence of C_8 such that

$$|\nabla \Phi^{y^\varepsilon}|_{0,[0,T]\times\overline{B_R}\times\overline{B_R}} \leqslant C_8 \varepsilon^{-1/4} \ \forall \varepsilon \in (0,1].$$

This gives the existence of C_9 such that

$$|\nabla \psi^\varepsilon|_{0,[0,T]\times\overline{B_R}} \leqslant C_9 \varepsilon^{-1/4} \ \forall \varepsilon \in (0,1],$$

which, with (4.39), implies that

$$\lim_{\varepsilon \to 0} |((y^\varepsilon - y_\omega) \cdot \nabla)\psi^\varepsilon|_{0,[0,T]\times\overline{B_R}} = 0. \tag{4.43}$$

From (4.42) and (4.43), one gets

$$\int_U (\omega - \bar{\omega})\varphi = 0,$$

and therefore $\omega = \bar{\omega}$ on U. The proof of (4.34) is similar to the proof of (4.33): consider $U' = \{(t,x) \in (0,T) \times \Omega;\ s_{y_\omega}(t,x) > 0\}$ and the linear hyperbolic equation $\mathcal{L}'$ $(\partial f / \partial t) +$ div $(f y_\omega) = 0$ on U' with, instead of (4.38), the boundary condition $f = 0$ on $(0,T) \times \gamma_-$; as above, one shows that this equation $\mathcal{L}'$ has a unique solution; but ω and 0 are solutions of $\mathcal{L}'$ on U', which proves (4.34). We omit the details.

Appendix A. Proof of Lemma 3.7. Since θ is harmonic on $\overline{\Omega}$, which is simply connected, it admits a harmonic conjugate $\psi \in C^\infty(\overline{\Omega})$. One has, with $x = (x_1, x_2)$,

$$\frac{\partial \psi}{\partial x_1} = \frac{\partial \theta}{\partial x_2},\ \frac{\partial \psi}{\partial x_2} = -\frac{\partial \theta}{\partial x_1}. \tag{A.1}$$

Let $\tau \in C^\infty(\partial\Omega; \mathbb{R}^2)$ be the unit tangent vector field on $\partial\Omega$ such that (τ, n) is a direct basis of $\mathbb{R}^2$ at any point of $\partial\Omega$. From (A.1) one gets

$$\frac{\partial \psi}{\partial \tau} = \frac{\partial \theta}{\partial n} \text{ on } \partial\Omega, \tag{A.2}$$

$$\frac{\partial \psi}{\partial n} = -\frac{\partial \theta}{\partial \tau} \text{ on } \partial\Omega. \tag{A.3}$$

By (2.3), the closed set $\partial\Omega \setminus (\gamma_+ \cup \gamma_-)$ has two connected components, that we call Γ_+ and Γ_-. By (3.48) and (A.2), there are two constants C_+ and C_- such that

$$\psi = C_+ \text{ on } \Gamma_+,\ \psi = C_- \text{ on } \Gamma_-. \tag{A.4}$$

Relabeling, if necessary, Γ_+ and Γ_-, we may assume that

$$C_- \leqslant C_+. \tag{A.5}$$

By (3.48) and (A.2),

$$\frac{\partial \psi}{\partial \tau} < 0 \text{ on } \gamma_-, \ \frac{\partial \psi}{\partial \tau} > 0 \text{ on } \gamma_+,$$

which, with (A.4) and (A.5), implies that

$$C_- < C_+, \tag{A.6}$$

$$\psi(x) \in [C_-, C_+] \ \forall x \in \partial\Omega. \tag{A.7}$$

Using (A.4), (A.6), and (A.7), together with the strong maximum principle applied to the harmonic function ψ, one gets that

$$\frac{\partial \psi}{\partial n} < 0 \text{ on } \Gamma_-, \ \frac{\partial \psi}{\partial n} > 0 \text{ on } \Gamma_+, \tag{A.8}$$

which, with (A.3), implies that

$$\frac{\partial \theta}{\partial \tau} > 0 \text{ on } \Gamma_-, \ \frac{\partial \theta}{\partial \tau} < 0 \text{ on } \Gamma_+. \tag{A.9}$$

From (2.3), (3.48), and (A.9), one gets that

$$\nabla\theta(x) \neq 0 \ \forall x \in \partial\Omega, \tag{A.10}$$

$$\text{degree } (\nabla\theta, \Omega, 0) = 0. \tag{A.11}$$

Let $f : \overline{\Omega} \subset \mathbb{R}^2 \cong \mathbb{C} \to \mathbb{C} \cong \mathbb{R}^2$ be defined by

$$f(x_1 + ix_2) = \frac{\partial \theta}{\partial x_1}(x_1, x_2) - i\frac{\partial \theta}{\partial x_2}(x_1, x_2). \tag{A.12}$$

Then f is holomorphic and, by (A.10), does not vanish on $\partial\Omega$; therefore the degree deg $(f, \Omega, 0)$ is well defined and is equal to the number of zeros of f, counted according to their multiplicity. But, by (A.11) and (A.12), degree $(f, \Omega, 0) = -$ degree $(\nabla\theta, \Omega, 0)$ $= 0$. Therefore f does not vanish on $\overline{\Omega}$, which proves Lemma 3.7.

Appendix B. Proof of Lemma 3.3. Let $\tau_- \in C^\infty(\Gamma_+ \cup \Gamma_-; \mathbb{R}^2)$ be defined by requiring

$$\tau_-(x) \in \{\tau(x), -\tau(x)\} \, \forall x \in \Gamma_+ \cup \Gamma_-, \tag{B.1}$$

$$\tau_-(x) \text{ is pointing outside } \Gamma_+ \cup \Gamma_- \, \forall x \in \partial\gamma_-. \tag{B.2}$$

Note that $\partial\gamma_-$ has two elements and is included in $\Gamma_+ \cup \Gamma_-$. It follows from (A.9) that

$$(\nabla\theta(x)) \cdot \tau_-(x) < 0 \ \forall x \in \partial\gamma_-,$$

which, with standard elliptic estimates, implies the existence of $M_0 > 0$ such that, for any $z \in C^0(\overline{\Omega}; \mathbb{R}^2)$ and for any $x \in \Gamma_+ \cup \Gamma_-$ such that dist $(x, \partial\gamma_-) \leqslant 1/M_0$,

$$\left(\begin{cases} z \cdot n = g \text{ on } \partial\Omega \\ \text{div } z = 0 \text{ in } \partial\Omega \\ M_0 | \text{ curl } z|_{L^\infty(\Omega)} \leqslant 1 \end{cases} \right) \Rightarrow \left(z(x) \cdot \tau_-(x) \leqslant -\frac{1}{M_0} \right). \tag{B.3}$$

Finally, let us remark that M_0 has the property required by Lemma 3.3. Indeed, let $y \in L^\infty\left((0,T);C^0\left(\overline{B_R};\mathbb{R}^2\right)\right)$ satisfying (3.5), (3.6) for some $K>0$, (3.38)–(3.39) for some $\alpha \in L^\infty((0,T);(0,+\infty))$, and (3.40). We argue by contradiction and therefore assume the existence of $(\tilde{t},\tilde{x}) \in (0,T] \times \overline{\gamma_-}$, and $\nu \in (0,\tilde{t})$ such that

$$\Phi^y\left(t,\tilde{t},\tilde{x}\right) \in \overline{\Omega}\, \forall t \in (\tilde{t}-\nu,\tilde{t}). \tag{B.4}$$

For $t \in [\tilde{t}-\nu,\tilde{t}]$, let $k(t)=\Phi^y\left(t,\tilde{t},\tilde{x}\right)$. We claim that there exists $\nu_1 \in (0,\nu]$ such that

$$k(t) \in \partial\Omega\, \forall t \in [\tilde{t}-\nu_1,\tilde{t}]. \tag{B.5}$$

Indeed, (B.5) follows easily from (3.38) and (B.4) if y is smooth enough, e.g., locally Lipschitz with respect to x. As in the proof of (3.41), the case where y is not smooth follows from the main ingredient, due to Wolibner [25], to prove the uniqueness of Φ^y in Theorem 3.1; since the proof is very similar to the proof of (3.41) given above, we omit it. From (3.38) and (B.5), we get that

$$k(t) \in \Gamma_+ \cup \Gamma_-\, \forall t \in [\tilde{t}-\nu_1,\tilde{t}]. \tag{B.6}$$

By (3.38), (3.39), (3.40), and (B.3), there exists $\nu_2 \in (0,\nu_1]$ such that

$$\dot{k}(t)\cdot\tau_-(k(t)) \leqslant -\frac{1}{M_0}\alpha(t)\, \forall t \in [\tilde{t}-\nu_2,\tilde{t}]. \tag{B.7}$$

Since $k(\tilde{t}) \in \overline{\gamma_-}$, and $\alpha(t)>0$ for a.e. $t \in (0,T)$, (B.6) and (B.7) are in contradiction—recall (B.2).

SHIFT OPERATOR INDUCED APPROXIMATIONS OF DELAY SYSTEMS*

P. M. MÄKILÄ[†] and J. R. PARTINGTON[‡]

Abstract. Certain shift operator induced finite-dimensional approximations of an important class of delay systems are studied. H_∞, H_2, and L_1 error bounds are given for stable delay systems. Furthermore, a multiple shift formula, generated by a second-order Padé shift, is analyzed further, and an exact asymptotic H_∞ error formula is derived. The studied class of shift operator induced approximations provides an appealing and most transparent approach for determining good finite-dimensional models of delay systems.

Key words. approximation by exponentials, delay systems, Padé shifts, shift operators

1. Introduction.

This paper studies certain shift operator induced approximations of a class of stable delay systems. This belongs to the classic topic of approximation of stable systems by exponentials (i.e., by finite-dimensional systems); see, e.g., Wiener [38], Kautz [15], Horowitz [13], McDonough and Huggins [26], and Kammler [14]. The new approximation approach studied here provides the most transparent approximations of delay systems with minimum effort, which makes it ideally suited for control engineering textbooks and courses. The studied approach should make it possible to reintroduce delay systems as a main type of plant model in modern undergraduate and graduate level control engineering textbooks, as once was the case in classical textbooks on process control.

There are several norms that are of interest as a measure of the approximation accuracy, especially the L_1 norm (see Glover, Curtain, and Partington [7], Mäkilä [19, 20], Partington [28], and Mäkilä [22]), the L_2 norm (see Glover, Curtain, and Partington [7], Glover, Lam, and Partington [10], Mäkilä [20], Wahlberg and Mäkilä [36]), and the H_∞ norm (see Glover, Lam, and Partington [8, 9], Lam [17], Mäkilä [20], Partington [28, 29], and Wahlberg and Mäkilä [36]).

Classically, most of the interest in approximation by exponentials has been associated with certain orthonormal exponential bases, especially exponential Laguerre and Legendre functions (see Szegő [35], Wiener [38], and Horowitz [13]). The classical theory of orthonormal polynomials has been very useful in analyzing Laguerre, Legendre, and Kautz approximations of linear systems, especially of delay systems (see Glader et al. [6], Wahlberg and Mäkilä [36], and Mäkilä [21]).

In the Laplace transform domain the above-mentioned orthonormal basis approximations produce rational approximations with fixed poles. Walsh [37] is a classical reference on fixed pole rational approximation, which has many applications to H_2 and H_∞ approximation and to identification of systems (see Mäkilä and Partington [23], Mäkilä, Partington, and Gustafsson [25], Ninness and Gustafsson [27], and

Heuberger, Van den Hof, and Bosgra [11]).

More recently there has been growing interest in rational approximations based on rational wavelets (see Pati [31], Pati and Krishnaprasad [32], Dudley, Ward, and Partington [2, 3, 4], and Partington [30]), which allow the choice of the pole locations from certain infinite sets. Rational wavelets are examples of redundant, rich, model sets, or dictionaries, which offer the potential for better degree of approximation than expansions in a single orthonormal basis.

Shift operators are very important in operator theory and in its many applications (see Rosenblum and Rovnyak [34]). It turns out that shift operator techniques are also very useful in approximation of linear systems by finite-dimensional systems (see Wahlberg and Mäkilä [36]). This is true partly because many important orthonormal bases, such as Laguerre and Kautz bases, are known to be induced by corresponding shift operators. It is also known that the delay operator is a shift operator. Certain Padé approximations of delay systems are also known to be associated with shift operators (for general material on Padé approximations see, e.g., Petrushev and Popov [33]). Therefore, shift operator techniques carry much potential for the purpose of modeling linear systems. Very detailed and strong results can be derived for certain shift operator approximations of delay systems. In Mäkilä and Partington [24], certain multiple Laguerre and Kautz shift induced approximations were studied in detail. In the present work a more general class of shift operator induced approximations of a class of delay systems is studied. The studied approach allows one to determine good low-order approximations of delay systems in a most transparent manner without any computations. Due to the elegant simplicity of the approximations, their error behavior can be analyzed to an unusual degree of completeness.

The rest of this paper is organized as follows. In section 2 some mathematical background material is reviewed briefly. Section 3 introduces the class of shift operator induced approximations of delay systems that will be studied in the present work. This approximation technique can also be interpreted in terms of all-pass rational approximations of the Laplace domain delay operator. H_∞ and H_2 error bounds for this technique are given here, too. In addition, L_1 error bounds are derived. In section 4 a special case of the general technique is studied in detail, namely, the so-called Padé-2 shift formula. Some very detailed H_∞ error bounds are given here and an asymptotically exact H_∞ error formula is derived. Section 5 provides a numerical example. Finally some conclusions are drawn in section 6.

2. Mathematical preliminaries.

Let H_p denote the Hardy space of functions f, over the real field, which are analytic in the open right half complex plane such that $|f(\sigma + j\omega)|^p$ is integrable for each $\sigma > 0$, and $\sup_{\sigma>0}[\int_{-\infty}^{\infty} |f(\sigma + j\omega)|^p \, d\omega]^{1/p} < \infty$, where $1 \leq p < \infty$. Here f is defined over the real field, meaning that $f(s) = \overline{f(\bar{s})}$ (f has real-valued coefficients only). Of special interest to us are the Hardy spaces H_2 and H_∞. In H_2 we shall use the norm $\|f\|_2 \equiv \sqrt{1/(2\pi)} \sup_{\sigma>0}[\int_{-\infty}^{\infty} |f(\sigma + j\omega)|^2 \, d\omega]^{1/2}$. The choice of the coefficient $\sqrt{1/(2\pi)}$ in the definition of the H_2 norm is convenient as this makes the Laplace transform operator $\mathcal{L}$ an isometry from $L_2(0, \infty)$ onto H_2. Finally, the Hardy space H_∞ of bounded analytic functions f in the right half plane is equipped with the norm $\|f\|_\infty = \sup_{Re\, s>0} |f(s)| < \infty$. (Note that the notation $\| \cdot \|_p$ is used to denote both the L_p norm and the H_p norm.)

Let H be a Hilbert space with inner product $(\cdot, \cdot)$. The norm for $x \in H$ is defined as $\|x\| \equiv (x, x)^{1/2}$. Let A denote a bounded linear operator from the Hilbert space H into H. Let A^* denote the adjoint operator of A, that is, $(Ax, y) = (x, A^* y)$ for all $x, y \in H$. A bounded operator $S : H \to H$ is said to be a *shift operator* if S is an isometry and $S^{*n} \to 0$ strongly (that is, $\|S^{*n}x\| \to 0$ for any x in H). A subspace E of H is called *cyclic* for the bounded operator A if $\bigvee_{k\geq 0} A^k E = H$. (Here $\bigvee$ denotes linear envelope.) The *multiplicity* of a shift operator S is the minimum dimension of a cyclic subspace for S. Multiplicity of a shift operator is important as two shift operators are unitarily equivalent if and only if they have the same multiplicity. (Unitarily equivalent operators are indistinguishable for many purposes.) Rosenblum and Rovnyak [34] give more mathematical background material on shift operators.

An example of a shift operator on H_2 is the so-called *Laguerre shift* S_L, defined by $S_L : G(s) \to G(s)(s-1/2)/(s+1/2)$ for any $G \in H_2$. (This shift is simply the Laplace transform of the (unitarily equivalent) Laguerre shift on $L_2(0, \infty)$; see Rosenblum and Rovnyak [34].) The multiplicity of the Laguerre shift is one as $\bigvee_{k\geq 0} S_L^k 1/(s+1/2) = H_2$ by a classical closure result based on Laguerre functions (see Szegő [35]).

A fundamental shift operator is the delay operator. Let S_h denote the shift operator on H_2, defined by $(S_h f)(s) = e^{-hs} f(s)$, $f \in H_2$. Here $h > 0$ corresponds to the time delay. Therefore, this operator corresponds to multiplication with e^{-hs}. The presence of this operator in most real problems makes control and systems theory a highly nontrivial theory. Note that the multiplicity of the shift S_h on H_2 is infinite.

Thus the delay operator on H_2 is in a certain sense a complex shift operator. The corresponding right shift operator, S_d, defined on the space of square summable sequences ℓ_2 by $S_d(x_1, x_2, \ldots) = (0, x_1, x_2, \ldots)$, for any $x \in \ell_2$, is clearly of multiplicity one and so has mathematically a rather simple structure. It is for this reason that the theory of the shift operator is rather more difficult in continuous time control and systems theory than in discrete time.

More generally it can be shown that any operator of multiplication on H_2 by a nonconstant inner function u gives rise to a shift operator, which has finite multiplicity if and only if u is a Blaschke product. See, for example, [1, Chapter 1].

Finally, the standard notation $s_n = O(f_n)$ means that the nonnegative sequences $\{s_n\}$, $\{f_n\}_{n\geq 1}$ satisfy $s_n \leq C f_n$, for some constant $C > 0$, for n large enough.

3. A general multiple shift formula.

In this section we consider approximation of stable delay systems by certain multiple shift formulas.

Recall that multiplication with e^{-hs} is a shift operator on H_2. Note that the best rational H_∞ approximation, of any degree, of e^{-hs} is the zero function. The transfer function e^{-hs} corresponds to the pure transmission line, the so-called *delay line*, for which many classical approximation methods such as Padé approximations and Bessel approximations have been used (see Kuo [16], Glover, Lam, and Partington [10], and Glader et al. [6]).

We shall study delay systems of the form $G(s) = e^{-hs}R(s)$, where $h > 0$ and $R \neq 0$ is a stable, strictly proper, rational transfer function. Let $m \geq 1$ denote the relative degree of $R(s)$. (Recall that the relative degree of a rational transfer function $R(s)$ is defined as the difference between the degrees of the denominator polynomial and the numerator polynomial of $R(s)$.)

An even simpler approximation technique than the full Padé approximation is based on the relationship

$$e^{-hs} = \lim_{n\to\infty} \left(\frac{1 - \frac{hs}{2n}}{1 + \frac{hs}{2n}} \right)^n . \tag{3.1}$$

Note that the shift operator $S_L^{(n)}$ defined by

$$S_L^{(n)} f \equiv \left(\frac{1 - \frac{hs}{2n}}{1 + \frac{hs}{2n}} \right)^n f,\ f \in H_2, \tag{3.2}$$

is essentially a multiple Laguerre shift of multiplicity n. Thus this approximation procedure involves approximating the shift operator corresponding to multiplication with e^{-hs} by the shift operator $S_L^{(n)}$.

This suggests a Laguerre shift type approximation of a stable delay system of the earlier mentioned form $G(s) = e^{-hs}R(s)$, namely, the approximation $S_L^{(n)}R(s)$. This type of approximation has been studied in Lam [18] and Mäkilä and Partington [24]. Such approximations are easy to compute and also easy to implement using analog filters.

The Laguerre formula is an example of a much more general construction, which we now analyze.

Let $u(s)$ be an inner function (a stable all-pass function) that lies in H_∞ on the right-hand half plane and is analytic in a neighborhood of the origin. For physical reasons we shall assume that $u(\overline{s}) = \overline{u(s)}$, and for the purposes of rational approximation we shall normally require u to be rational. We shall choose the normalization $u(0) = 1$.

One simple way to construct examples of such functions is to write

$$u(s) = \frac{p(-s)}{p(s)}, \tag{3.3}$$

where p is a real polynomial with no zeroes in the closed right-hand half plane. An example analyzed in Mäkilä and Partington [24] is $p(s) = 1 + s/2$; another important example (based on Padé approximation) is $p(s) = 1 + s/2 + s^2/12$. This latter example will be studied in more detail in the next section.

The intention is to approximate an exponential e^{-hs} by the inner function

$$u_n(hs) := (u(hs/n))^n. \tag{3.4}$$

Note first that, using the Taylor expansion, there is an index $k \geq 1$ and constants A, B, and $C > 0$ such that

$$A|\omega|^k \leq \left| e^{-j\omega} - u(j\omega) \right| \leq B|\omega|^k \qquad \text{for} \quad |\omega| \leq C. \tag{3.5}$$

We also have

$$\|e^{-j\omega} - u(j\omega)\|_\infty \leq 2, \tag{3.6}$$

since both functions are inner.

Note that for nonzero $R(s)$ with relative degree $m (\geq 1)$, there exist positive constants D, E, and F, such that

$$E|\omega|^{-m} \leq |R(j\omega)| \leq F|\omega|^{-m} \qquad \text{for } |\omega| \geq D. \tag{3.7}$$

The following lemma shows that dilations of u provide approximations to the exponential function with, in general, improved error bounds.

LEMMA 3.1. *Under the hypotheses above,*

$$|e^{-jh\omega} - u_n(jh\omega)| \leq \min\left(2, B\frac{h^k|\omega|^k}{n^{k-1}}\right) \qquad \textit{for} \quad |\omega| \leq nC/h. \tag{3.8}$$

Proof. We use the formula $(a^n - b^n) = (a-b)(a^{n-1} + a^{n-2}b + \cdots + ab^{n-2} + b^{n-1})$, with $a = e^{-jh\omega/n}$ and $b = u(jh\omega/n)$. Since $|a-b| \le B|h\omega/n|^k$ for $|h\omega/n| \le C$, and $|a| = |b| = 1$, we obtain the result. □

The following general result shows how the dilations of u provide shift operators which converge strongly to the exponential shift. For a function G defined on the right half plane, we define $S_h G$ by $(S_h G)(s) = e^{-hs}G(s)$ and $S_{u,n,h}G$ by $(S_{u,n,h}G)(s) = u_n(hs)G(s)$. We write A_0 for the closed subspace of H_∞ consisting of functions G continuous on the closed right half plane, such that $G(j\omega) \to 0$ as $\omega \to \pm\infty$.

COROLLARY 3.1. *Let u be a rational inner function satisfying* (3.5) *with $k > 1$. Then for every $G \in H_2$ one has $\|S_{u,n,h}G - S_h G\|_2 \to 0$ as $n \to \infty$; and for every $G \in A_0$ one has $\|S_{u,n,h}G - S_h G\|_\infty \to 0$ as $n \to \infty$.*

Proof. By Lemma 3.1 we see that $u_n(jh\omega) \to e^{-jh\omega}$ pointwise as $n \to \infty$, and hence, since e^{-hs} and $u_n(hs)$ are inner, Lebesgue's dominated convergence theorem implies that $\|S_{u,n,h}G - S_h G\|_2 \to 0$ when $G \in H_2$. Moreover the bound in Lemma 3.1 shows that $S_{u,n,h}G$ tends uniformly to $S_h G$ on the imaginary axis, since, if $\epsilon > 0$ is given, there is an M such that $|G(j\omega)| < \epsilon/2$, whenever $|\omega| \ge M$, and hence $|(e^{-jh\omega} - u_n(jh\omega))G(j\omega)| < \epsilon$ if $|\omega| \ge M$. It is now necessary to show only that the same applies for $|\omega| < M$, if n is sufficiently large, and this follows from Lemma 3.1. □

We define ω_n and ω_n^* to be the solutions of the equations

$$Bh^k\omega_n^k/n^{k-1} = 2 \qquad \text{and} \qquad Bh^k{\omega_n^*}^k/n^{k-1} = \sqrt{2}, \tag{3.9}$$

so that ω_n and ω_n^* grow as $n^{(k-1)/k}$.

Let R be a stable rational function satisfying (3.7). We may choose D large enough that $FD^{-m} \le \|R\|_\infty$.

THEOREM 3.1. *Under the hypotheses above, provided that $D \le \omega_n \le Cn/h$, one has*

$$\|R(s)e^{-sh} - R(s)u_n(sh)\|_\infty \le \max\left\{ \|R\|_\infty \frac{Bh^kD^k}{n^{k-1}}, \max_{\omega\in\{D,\omega_n\}} \frac{FBh^k\omega^{k-m}}{n^{k-1}}, 2F\omega_n^{-m} \right\}. \tag{3.10}$$

Proof. This follows by considering the intervals $[0, D]$, $[D, \omega_n]$, and $[\omega_n, \infty)$ separately, using the estimates in Lemma 3.1. □

Similar analyses can be performed for small n, if $D \le \omega_n \le Cn/h$ is no longer satisfied, by considering intervals in the same way. We shall see specific examples of this later.

To establish some lower bounds, we need an estimate corresponding to that in Lemma 3.1.

LEMMA 3.2. *Under the hypotheses above,*

$$|e^{-jh\omega} - u_n(jh\omega)| \ge \frac{2\sqrt{2}A}{\pi}\frac{h^k|\omega|^k}{n^{k-1}}, \qquad \textit{for} \quad |\omega| \le \min\{\omega_n^*, Cn/h\}. \tag{3.11}$$

Proof. Without loss of generality we can take $\omega \ge 0$. We consider the argument of $u_n(jh\omega)$ and use the standard inequalities

$$\frac{2\sqrt{2}}{\pi}|\theta| \le \left|1 - e^{i\theta}\right| \le |\theta| \qquad \text{for } |\theta| \le \pi/2, \tag{3.12}$$

implying that

$$\frac{2\sqrt{2}}{\pi}|\arg z - \arg w| \le |z - w| \le |\arg z - \arg w| \tag{3.13}$$

whenever $|z| = |w| = 1$ and $|\arg z - \arg w| \leq \pi/2$. Hence

$$A\left(\frac{h\omega}{n}\right)^k \leq \left|\arg(u(j\omega h/n)) - \frac{h\omega}{n}\right| \leq \frac{\pi}{2\sqrt{2}} B\left(\frac{h\omega}{n}\right)^k \leq \frac{\pi}{2n} \tag{3.14}$$

for $|h\omega/n| \leq C$ and $|\omega| \leq \omega_n^*$, and hence

$$|\arg(u_n(j\omega h)) - h\omega| \geq nA\left(\frac{h\omega}{n}\right)^k, \tag{3.15}$$

which implies the asserted inequality. □

We can now derive a lower bound, corresponding to the upper bound in Theorem 3.1.

THEOREM 3.2. *Under the hypotheses above, provided that $D \leq \omega_n^* \leq Cn/h$, one has*

$$\|R(s)e^{-sh} - R(s)u_n(sh)\|_\infty \geq \max_{\omega \in \{D, \omega_n^*\}} \frac{2\sqrt{2}AE}{\pi} \frac{h^k \omega^{k-m}}{n^{k-1}}. \tag{3.16}$$

Proof. This follows at once from Lemma 3.2, using (3.7). □

COROLLARY 3.2. *Under the hypotheses of Theorem* 3.1*, the asymptotic rate of H_∞ convergence of $R(s)u_n(sh)$ to $R(s)e^{-sh}$ as $n \to \infty$ is of order exactly $n^{-\lambda}$, where $\lambda = (k-1)\min(1, m/k)$.*

Proof. This follows immediately from Theorems 3.1 and 3.2, on considering the cases $m \leq k$ and $m \geq k$ separately. □

For example, if $k = 3$, which is the case with the function $u(s) = (1 - s/2)/(1 + s/2)$, analyzed in Mäkilä and Partington [24], then the exact H_∞ convergence rates for $m = 1, 2, 3, 4, \ldots$, are of orders $n^{-2/3}$, $n^{-4/3}$, n^{-2}, $n^{-2}, \ldots$.

The bounds given in Theorems 3.1 and 3.2 can also be used to determine the exact H_2 convergence rates.

THEOREM 3.3. *Under the hypotheses of Theorem* 3.1*, the asymptotic rate of H_2 convergence of $R(s)u_n(sh)$ to $R(s)e^{-sh}$ as $n \to \infty$ is of order exactly $n^{-\mu}$, where $\mu = (k-1)\min(1, (2m-1)/(2k))$.*

Proof. Writing $K_1, K_2, \ldots$ for positive constants which we do not need to write down explicitly, we find that the estimates used in Lemma 3.1 and Theorem 3.1 show that the square of an upper H_2 bound is

$$K_1 \int_0^D \frac{\omega^{2k}}{n^{2k-2}}\, d\omega + K_2 \int_D^{\omega_n} \frac{\omega^{2k-2m}}{n^{2k-2}}\, d\omega + K_3 \int_{\omega_n}^\infty \omega^{-2m}\, d\omega, \tag{3.17}$$

which, using the fact that ω_n is of order $n^{(k-1)/k}$, gives three terms, each of order at most the greater of $n^{-(2k-2)}$ or $n^{-(k-1)(2m-1)/k}$.

Likewise a lower bound can be obtained by using the estimates in Lemma 3.2 and Theorem 3.2 and integrating from D to ω_n^*. This gives as the square of a lower bound the quantity

$$K_4 \int_D^{\omega_n^*} \frac{\omega^{2k-2m}}{n^{2k-2}}\, d\omega, \tag{3.18}$$

which, since ω_n^* is of order $n^{(k-1)/k}$, produces a lower bound the same as the upper bound (to within a factor independent of n). □

For example, if $k = 3$, as for the function $u(s) = (1 - s/2)/(1 + s/2)$, discussed above, the exact H_2 convergence rates for $m = 1, 2, 3, 4, 5, \ldots$, are of orders $n^{-1/3}$, n^{-1}, $n^{-5/3}$, n^{-2}, $n^{-2}, \ldots$, which is a result given in Mäkilä and Partington [24].

We now turn our attention to L_1 error bounds for the corresponding impulse response functions. The following lemma shows that they are not very much worse than the H_∞ bounds, and it applies in a very general setting. We let $\mathcal{L}$ denote the Laplace transform operator, which maps $L_1(0,\infty)$ contractively into H_∞.

LEMMA 3.3. *Let $g \in L_1(0,\infty)$ and let (g_n) be any sequence of degree-n approximants in $L_1(0,\infty)$ such that $\|\mathcal{L}g_n - \mathcal{L}g\|_\infty = O(n^{-\lambda})$ as $n \to \infty$, for some $\lambda > 1$. Then $\|g_n - g\|_1 = O(n^{1-\lambda})$ as $n \to \infty$.*

Proof. It is well known (see also Partington [29]) that for functions $f \in L_1$ whose Laplace transforms are rational of degree n the inequality $\|g\|_1 \le 2n\|\mathcal{L}g\|_\infty$ holds. We therefore see that

$$\|g_{2^r} - g_{2^{r+1}}\|_1 \le 2(2^r + 2^{r+1})\|\mathcal{L}g_{2^r} - \mathcal{L}g_{2^{r+1}}\|_\infty = O(2^{r-\lambda r}), \tag{3.19}$$

implying that (g_{2^r}) is a Cauchy sequence in L_1 whose limit must be g. Hence $\|g_{2^r} - g\|_1 = O(2^{r-\lambda r})$. To obtain the result for general n we choose r such that $2^r \le n < 2^{r+1}$ and use the inequality $\|g_n - g_{2^r}\|_1 \le 2(n+2^r)\|\mathcal{L}g_n - \mathcal{L}g_{2^r}\|_\infty = O(n^{1-\lambda})$. □

A rather better bound can be obtained by using the continuous-time version of the Hardy–Littlewood inequality

$$\|g\|_1 \le K_1\|(\mathcal{L}g)'\|_{H_1} \tag{3.20}$$

(see also [5, Ex. 11.3], Hille and Tamarkin [12]). (In this and the following calculation, we shall use K_1, K_2, etc., to denote positive constants that we do not estimate.) To do this, we need to bound the H_1 norm of the derivative of $R(s)(e^{-hs} - u_n(hs))$. Note that it follows from (3.5) that $|-e^{-s} - u'(s)| \le K_2|s|^{k-1}$ for $|s|$ sufficiently small. It is also clear that $u'(s) \in H_\infty$ if u is rational and inner. Moreover we have the following bound: for $n \ge 2$,

$$|e^{-jh\omega(n-1)/n} - u(jh\omega/n)^{n-1}| \le \min\left(2, K_3\frac{h^k|\omega|^k}{n^{k-1}}\right) \quad \text{for } |\omega| \le nK_4/h, \tag{3.21}$$

analogous to Lemma 3.1. Putting these inequalities together and using the inequality

$$|a^n - b^{n-1}c| \le |a^{n-1}(a-c)| + |(a^{n-1} - b^{n-1})c| \tag{3.22}$$

with $a = e^{-jh\omega/n}$, $b = u(jh\omega/n)$, and $c = -u'(jh\omega/n)$, we obtain a bound

$$\begin{aligned} &|-he^{-jh\omega} - hu(jh\omega/n)^{n-1}u'(jh\omega/n)| \\ &\quad \le \min\left(K_5, K_6\frac{h^k|\omega|^{k-1}}{n^{k-1}}\right) + \min\left(K_7, K_8\frac{h^{k+1}|\omega|^k}{n^{k-1}}\right), \end{aligned} \tag{3.23}$$

valid for $|\omega| \le nK_9/h$.

THEOREM 3.4. *Under the hypotheses of Theorem 3.1, provided that m, the relative degree of $R(s)$, is at least 2, then the L_1 errors between the impulse responses corresponding to $R(s)e^{-hs}$ and $R(s)u_n(hs)$ are of order at most $n^{-\nu}$ as $n \to \infty$, where $\nu = (k-1)\min\{1, (m-1)/k\}$.*

Proof. We bound the H_1 norm of the derivative of $Q(s) := R(s)(e^{-hs} - u_n(hs))$, as above. Since the calculation is similar to several others in this section, we shall give only a brief summary of it. Now

$$\|Q'(s)\|_{H_1} \le \|R'(s)(e^{-hs} - u_n(hs))\|_{H_1} + \|R(s)(-he^{-hs} - hu(hs/n)^{n-1}u'(hs/n))\|_{H_1}. \tag{3.24}$$

Note that $R'(s)$ is rational with relative degree $m+1$, since $R(s)$ is rational with relative degree m. For the first term in (3.24), we have pointwise bounds of orders ω^k/n^{k-1}, ω^{k-m-1}/n^{k-1}, and ω^{-m-1}, valid for various eventually overlapping ranges of ω, as in Theorem 3.1 with m replaced by $(m+1)$; for the second they become ω^{k-1}/n^{k-1}, ω^{k-m}/n^{k-1}, and ω^{-m}. Performing the integrals along the imaginary axis, we obtain the H_1 bounds $n^{-\nu_1}$ and $n^{-\nu_2}$, where $\nu_1 = (k-1)\min\{1, m/k\}$ and $\nu_2 = (k-1)\min\{1, (m-1)/k\} \leq \nu_1$. Finally, using (3.20) we obtain the desired result. □

Thus, for the case $k = 3$ discussed above, the L_1 convergence rates when m takes the values $2, 3, 4, 5, \ldots$ are at worst $O(n^{-2/3})$, $O(n^{-4/3})$, $O(n^{-2})$, $O(n^{-2}), \ldots$, which is an improvement on the bounds that one would obtain from Corollary 3.2 and Lemma 3.3.

4. The multiple Padé-2 shift formula. An important shift operator is the Kautz shift, $S_K : H_2 \to H_2$ (see Wahlberg and Mäkilä [36]), defined by

$$S_K f = \left(\frac{s^2 - bs + c}{s^2 + bs + c}\right) f,\ f \in H_2, \tag{4.1}$$

where $b > 0$ and $b^2 - 4c < 0$. This shift operator has multiplicity 2 and corresponds to multiplication by a second-order rational all-pass function with two complex (strictly nonreal) *stable* poles.

Analogous to the Laguerre formula for e^{-hs}, the Kautz shift gives the following (Kautz) formula for e^{-hs}:

$$e^{-hs} = \lim_{n\to\infty} \left(\frac{1 - \frac{hs}{2n} + \frac{1}{3}\left(\frac{hs}{2n}\right)^2}{1 + \frac{hs}{2n} + \frac{1}{3}\left(\frac{hs}{2n}\right)^2}\right)^n . \tag{4.2}$$

The shift operator $S_P^{(n)} : H_2 \to H_2$ defined by

$$S_P^{(n)} f = \left(\frac{1 - \frac{hs}{2n} + \frac{1}{3}\left(\frac{hs}{2n}\right)^2}{1 + \frac{hs}{2n} + \frac{1}{3}\left(\frac{hs}{2n}\right)^2}\right)^n f,\ f \in H_2, \tag{4.3}$$

is a multiple Kautz shift of multiplicity $2n$. As this shift is motivated by the second-order Padé approximation of e^{-hs}, we shall call it *the multiple Padé-2 shift.*

Introduce the monotonically increasing continuous function

$$\varphi_k(\nu) = \sup_{0\leq\omega\leq\nu} \omega^k |R(j\omega)|,\ \nu \geq 0. \tag{4.4}$$

Note that for nonzero $R(s)$ with relative degree $m(\geq 1)$

$$|R(j\omega)| \leq \|R\|_\infty C^m \omega^{-m}, \quad \omega > C, \tag{4.5}$$

for some constant $C > 0$. We shall next study the approximation of $G(s) = e^{-hs}R(s)$ by $S_P^{(n)} R(s)$.

THEOREM 4.1. *Let $G(s) = e^{-hs}R(s)$, where $h > 0$ and $R(s) \not\equiv 0$ is a stable rational transfer function with relative degree $m \geq 1$. Then*

$$\|G - S_P^{(n)} R\|_\infty \geq \frac{h^5}{1080\pi} \varphi_5(\omega_n(h)) \times n^{-4}, \quad n \geq 1, \tag{4.6}$$

where $\omega_n(h) = 2h^{-1}n^{4/5}$ and φ_5 is defined in (4.4).

Hence, for $m = 1, 2, 3, 4$ *if* $n < (Dh/2)^{5/4}$, *and for* $m \geq 5$ *for any* $n \geq 1$,

$$\|G - S_P^{(n)} R\|_\infty \geq \frac{h^5}{1080\pi} \varphi_5(\omega_1(h)) \times n^{-4}. \tag{4.7}$$

Finally, for $m = 1, 2, 3, 4$ *if* $n \geq (Dh/2)^{5/4}$,

$$\|G - S_P^{(n)} R\|_\infty \geq \frac{4}{135\pi} (h/2)^m E \times n^{-(4m/5)}. \tag{4.8}$$

Proof. Clearly,

$$\|G - S_P^{(n)} R\|_\infty = \sup_{\omega \geq 0} |R(j\omega)| \left| e^{-jh\omega} - \left(\frac{1 - \frac{jh\omega}{2n} + \frac{1}{3}\left(\frac{jh\omega}{2n}\right)^2}{1 + \frac{jh\omega}{2n} + \frac{1}{3}\left(\frac{jh\omega}{2n}\right)^2} \right)^n \right|. \tag{4.9}$$

Furthermore,

$$\left(\frac{1 - \frac{jh\omega}{2n} + \frac{1}{3}\left(\frac{jh\omega}{2n}\right)^2}{1 + \frac{jh\omega}{2n} + \frac{1}{3}\left(\frac{jh\omega}{2n}\right)^2} \right)^n = e^{-j2n \arctan \frac{(h\omega/2n)}{1-(1/3)(h\omega/2n)^2}} \tag{4.10}$$

for $(1/3)(h\omega/2n)^2 < 1$, that is, for $(0 \leq)\omega < 2\sqrt{3}h^{-1}n$. (Note that the range of arctan is $(-\pi/2, \pi/2)$.)

It follows immediately from the formula $|e^{j\theta} - 1| = 2|\sin \frac{\theta}{2}|$ that

$$\begin{aligned} &\left| e^{-jh\omega} - e^{-j2n \arctan \frac{(h\omega/2n)}{1-(1/3)(h\omega/2n)^2}} \right| \\ &\quad = 2 \left| \sin \left[\frac{h\omega}{2} - n \arctan \frac{(h\omega/2n)}{1 - (1/3)(h\omega/2n)^2} \right] \right| \end{aligned} \tag{4.11}$$

for $(0 \leq)\omega < 2\sqrt{3}h^{-1}n$.

We shall need the auxiliary inequalities

$$0 \leq y - \arctan\left(\frac{y}{1 - (1/3)y^2} \right) \leq \frac{1}{45} y^5 \text{ for } 0 \leq y < \sqrt{3}. \tag{4.12}$$

To prove the right-hand side inequality consider the function

$$g(y) = y - \arctan \frac{y}{1 - (1/3)y^2} - \gamma y^5. \tag{4.13}$$

Then clearly $g(0) = 0$ and

$$g'(y) = y^4[(1/9) - 5\gamma - (5/3)\gamma y^2 - (5/9)\gamma y^4]/(1 + (1/3)y^2 + (1/9)y^4). \tag{4.14}$$

Hence $\gamma = (1/45)$ is the best (smallest) constant to get $g(y) \geq 0$ for all $y \geq 0$ up to the first discontinuity of g at $y = \sqrt{3}$. The proof of the left-hand inequality follows by using in g above $\gamma = 0$ and noting that then $g'(y) \geq 0$ for $0 \leq y < \sqrt{3}$.

Denote now $y = h\omega/(2n)$. Then

$$\begin{aligned} 2 \left| \sin \left[\frac{h\omega}{2} - n \arctan \frac{(h\omega/2n)}{1 - (1/3)(h\omega/2n)^2} \right] \right| &= 2 \left| \sin n \left(y - \arctan \frac{y}{1 - (1/3)y^2} \right) \right| \\ &\geq 2(2/\pi) n \left[y - \arctan \left(\frac{y}{1 - (1/3)y^2} \right) \right], \end{aligned} \tag{4.15}$$

if $0 \le n[y - \arctan(\frac{y}{1-(1/3)y^2})] \le (\pi/2)$ and $0 \le y < \sqrt{3}$. (The latter condition means that $0 \le \omega < 2\sqrt{3}h^{-1}n$.) By (4.12) it is seen that (4.15) holds if

$$\frac{1}{45}y^5 \le \frac{\pi}{2}\frac{1}{n} \text{ and } 0 \le y < \sqrt{3}. \tag{4.16}$$

That is, (4.15) holds if

$$y \le (45\pi/2)^{1/5} n^{-1/5} \text{ and } 0 \le y < \sqrt{3}. \tag{4.17}$$

Next we show that the auxiliary inequality

$$y - \arctan\left(\frac{y}{1-(1/3)y^2}\right) \ge \frac{1}{135}y^5 \tag{4.18}$$

is valid for $0 \le y < \sqrt{3}$. Consider the function $g(y)$ as above. From the expression of $g'(y)$ we see that $\gamma = 1/135$ is actually the largest constant for which $g'(y) \ge 0$ for $0 \le y < \sqrt{3}$. This proves the inequality (4.18).

Using (4.18) in (4.15) gives that

$$2\left|\sin\left[\frac{h\omega}{2} - n\arctan\frac{(h\omega/2n)}{1-(1/3)(h\omega/2n)^2}\right]\right| \ge 2 \times (2/\pi) \times n \times \frac{1}{135}\left(\frac{h\omega}{2n}\right)^5, \tag{4.19}$$

for any $n \ge 1$ when $0 \le \omega h \le n^{-1/5} \times 2n = 2n^{4/5}$. Therefore

$$\begin{aligned} \|G - S_P^{(n)}R\|_\infty &\ge \frac{h^5}{1080\pi}\sup_{0\le\omega\le\omega_n(h)} \omega^5|R(j\omega)| \times n^{-4} \\ &= \frac{h^5}{1080\pi}\varphi_5(\omega_n(h)) \times n^{-4}, \end{aligned} \tag{4.20}$$

where $\omega_n(h) = 2h^{-1}n^{4/5}$. This proves the first part of the theorem.

Note that, for any $m \ge 1$,

$$\|G - S_P^{(n)}R\|_\infty \ge \frac{h^5}{1080\pi}\varphi_5(\omega_1(h)) \times n^{-5}, \quad n \ge 1, \tag{4.21}$$

by the first part of the theorem. This gives the second bound of the theorem. (Observe that clearly $\varphi_5(\omega_1(h)) > 0$ as R is a nonzero rational function by assumption.) Also, as $\varphi_5(\nu) \to \infty$ when $\nu \to \infty$ for $m = 1, 2, 3, 4$, we can get a tighter bound, at least for large n, in that case, as follows.

By (3.7) we get that

$$\varphi_5(\nu) \ge E\nu^{5-m} \text{ for } \nu \ge D, \tag{4.22}$$

where $E > 0$. Thus $\varphi_5(\nu)$ grows without limit for $m = 1, 2, 3, 4$ when $\nu \to \infty$. Clearly, for $m \ge 5$

$$\lim_{\nu\to\infty}\varphi_5(\nu) < \infty. \tag{4.23}$$

Therefore, for $m \ge 5$, $\varphi_5(\omega_n(h))$ remains finite even for large n and so the order of magnitude n^{-2} is the tightest order we can get here. However, for $m = 1, 2, 3, 4$, we see that when $D \le \omega_n(h)$ then

$$\varphi_5(\omega_n(h)) \ge E\omega_n(h)^{5-m} = (2h^{-1})^{5-m}En^4n^{-(4m/5)}. \tag{4.24}$$

Thus the first part of the theorem now gives the last (third) bound of the theorem with the coefficient $(4/135\pi)(h/2)^m E$ in front of $n^{-(4m/5)}$. This completes the proof of the theorem. □

Next we shall give some upper bounds for the H_∞ error of the Padé-2 formula.

THEOREM 4.2. *Let $G(s) = e^{-hs}R(s)$, where $h > 0$ and $R(s) \not\equiv 0$ is a stable rational transfer function with relative degree $m \geq 1$. Let $C > 0$ be a constant such that* (4.5) *is satisfied. Furthermore, let $n \geq \max\{(2\sqrt{3})^{-1}Ch, 3\}$. Then, for $m = 1,2,3,4$ if $C < 1440^{1/5}h^{-1}n^{4/5}$,*

$$\|G - S_P^{(n)}R\|_\infty \leq 2\left(\frac{Ch}{1440^{1/5}}\right)^m \|R\|_\infty n^{-4m/5}. \tag{4.25}$$

Finally, for $m \geq 5$ if $n \geq [1440(Ch)^{m-5}/(2\sqrt{3})^m]^{1/(m-4)}$, and for $m = 1,2,3,4$ if $C \geq 1440^{1/5}h^{-1}n^{4/5}$,

$$\|G - S_P^{(n)}R\|_\infty \leq \frac{(Ch)^5}{720}\|R\|_\infty n^{-4}. \tag{4.26}$$

Hence,

$$\|G - S_P^{(n)}R\|_\infty = \max\{O(n^{-4m/5}), O(n^{-4})\}. \tag{4.27}$$

Proof. Now

$$\|G - S_P^{(n)}R\|_\infty \leq 2\max\left\{\sup_{0\leq\omega\leq\omega_n}|R(j\omega)s_n(\omega)|, \sup_{\omega>\omega_n}|R(j\omega)s_n(\omega)|\right\} \tag{4.28}$$

where

$$s_n(\omega) = \sin\left(\frac{h\omega}{2} - n\arctan\frac{(h\omega/2n)}{1-(1/3)(h\omega/2n)^2}\right), \tag{4.29}$$

and $C < \omega_n < 2\sqrt{3}h^{-1}n$ is at this point an otherwise unspecified parameter. Clearly,

$$\sup_{\omega>\omega_n}|R(j\omega)s_n(\omega)| \leq \sup_{\omega>\omega_n}|R(j\omega)| \leq \|R\|_\infty C^m\omega_n^{-m}, \tag{4.30}$$

where the last inequality follows by (4.5).

Also by (4.12)

$$\sup_{0\leq\omega\leq\omega_n}|R(j\omega)s_n(\omega)| \leq \sup_{0\leq\omega\leq\omega_n}|R(j\omega)| \times n \times \frac{1}{45}\left(\frac{\omega h}{2n}\right)^5, \tag{4.31}$$

for $\omega_n < 2\sqrt{3}h^{-1}n$. It follows by (4.5) that

$$\sup_{0\leq\omega\leq\omega_n}|R(j\omega)s_n(\omega)| \leq \frac{\|R\|_\infty C^m h^5}{1440}\sup_{C\leq\omega\leq\omega_n}\omega^{-m+5}n^{-4}. \tag{4.32}$$

Then, for $m \geq 5$,

$$\sup_{0\leq\omega\leq\omega_n}|R(j\omega)s_n(\omega)| \leq \frac{\|R\|_\infty C^m h^5}{1440}C^{-m+5}n^{-4}. \tag{4.33}$$

This gives (4.26) for $m \geq 5$ when

$$C^m\omega_n^{-m} \leq \frac{(Ch)^5}{1440}n^{-4}, \tag{4.34}$$

that is, when

$$n \geq \left(\frac{1440(Ch)^{m-5}}{(2\sqrt{3})^m} \right)^{1/(m-4)}. \tag{4.35}$$

Therefore, it remains to consider the case $m = 1, 2, 3, 4$. Then (4.31), (4.28), and (4.30) give that

$$\|G - S_P^{(n)} R\|_\infty \leq 2 \max \left\{ \frac{\|R\|_\infty C^m h^5}{1440} \omega_n^{-m+5} n^{-4}, \|R\|_\infty C^m \omega_n^{-m} \right\}. \tag{4.36}$$

To determine the smallest upper bound, consider

$$\inf_{C<\omega_n<2\sqrt{3}h^{-1}n} \max \left\{ \frac{h^5}{1440} \omega_n^{-m+5} n^{-4}, \omega_n^{-m} \right\}. \tag{4.37}$$

Note that here the first expression is a monotone increasing function of $\omega_n \geq 0$ and the second a monotone decreasing function of $\omega_n \geq 0$. These expressions attain the same value at the unique point $\omega_n^* = (1440^{1/5}/h) n^{4/5}$, which is the global minimizer of the maximum of these two expressions for $C < \omega_n < 2\sqrt{3}h^{-1}n$ if $C < \omega_n^* < 2\sqrt{3}h^{-1}n$. As the case $\omega_n^* \geq 2\sqrt{3}h^{-1}n$ cannot occur for large n, we have treated this case by the condition $n \geq 3$ in the statement of the theorem. (It is easy to check that $n \geq 3$ guarantees that $\omega_n^* < \sqrt{3}h^{-1}n$.) Hence only two cases remain. The first occurs when $\omega_n^* > C$, which gives (4.25). If $\omega_n^* \leq C$, then the infimum above is given by $[(h^5)/1440] C^{-m+5} n^{-4}$, which gives (4.26). This completes the proof of the theorem. □

The above two results mean that the Padé-2 formula achieves the tight order of magnitude $O(n^{-4m/5})$ for $m = 1, 2, 3, 4$, and $O(n^{-4})$ for $m \geq 5$, for H_∞ approximation of delay systems of the form $e^{-hs}R(s)$, where $h > 0$ and $R \neq 0$ is a stable strictly proper rational transfer function with relative degree m. These order of magnitude estimates are easier to derive with the general result from the previous section, but the above bounds have independent interest. The Padé-2 formula has a surprisingly good degree of approximation when compared with the optimal degree of rational approximation $O(n^{-m})$ (see Glover, Lam, and Partington [9]) and noting that the Padé-2 formula involves no computations to get the approximations! Some explicit (but rather complicated) bounds for the error in Padé $(2n, 2n)$ approximation are given by Lam [17]. These are asymptotically optimal, but other methods may be preferred in practice.

THEOREM 4.3. *Let $G(s) = e^{-hs}R(s)$ be as in Theorem 4.2. Let $R(s)$ have relative degree $m \geq 5$. Then*

$$\|G - S_P^{(n)} R\|_\infty \leq \frac{h^5}{720} \lim_{\nu\to\infty} \varphi_5(\nu) \times n^{-4}, \; n \geq 3. \tag{4.38}$$

Furthermore,

$$\lim_{n\to\infty} \|G - S_P^{(n)} R\|_\infty \times n^4 = \frac{h^5}{720} \lim_{\nu\to\infty} \varphi_5(\nu). \tag{4.39}$$

Proof. Clearly,

$$\|G - S_P^{(n)} R\|_\infty \leq 2 \max \left\{ \sup_{0\leq\omega_n} |R(j\omega) s_n(\omega)|, \sup_{\omega>\omega_n} |R(j\omega)| \right\} \tag{4.40}$$

where s_n is defined in (4.29) and $0 < \omega_n < 2\sqrt{3}h^{-1}n$. Clearly, by the definition of φ_5

$$2 \sup_{\omega > \omega_n} |R(j\omega)| \leq \frac{2\varphi_5(\infty)}{\omega_n^5}, \tag{4.41}$$

where $\varphi_5(\infty) = \lim_{\nu \to \infty} \varphi_5(\nu)$. Note that $\varphi_5(\infty)$ is well defined as $m \geq 5$ by assumption.

Also by (4.12)

$$\begin{aligned} 2 \sup_{0 \leq \omega \leq \omega_n} |R(j\omega)s_n(\omega)| &\leq \frac{h^5}{720} \sup_{0 \leq \omega \leq \omega_n} |R(j\omega)|\omega^5 \times n^{-4} \\ &\leq \frac{h^5}{720}\varphi_5(\infty) \times n^{-4}. \end{aligned} \tag{4.42}$$

Take $\omega_n = 2\alpha\sqrt{3}h^{-1}n$, where $0 < \alpha < 1$. Hence if n is such that

$$\frac{h^5}{720}n^{-4} > \frac{2}{(2\alpha\sqrt{3}h^{-1}n)^5}, \tag{4.43}$$

then the upper bound in the theorem follows. This gives $n > 5/(\alpha\sqrt{3})$. But as $\alpha < 1$ can be taken arbitrarily close to 1, we see that the upper bound of the theorem is indeed valid for $n \geq 3$.

To prove the asymptotically exact error formula, it suffices to show that asymptotically the upper bound of the theorem is also a lower bound for the approximation error. Recall the Taylor series expansions

$$y - \arctan \frac{y}{1 - (\frac{1}{3})y^2} = \frac{1}{45}y^5 + \cdots, \tag{4.44}$$

valid for $|y| < 2/(1 + \sqrt{7/3})$(higher order terms in y than y^5 have not been explicitly indicated above), and $\sin x = x+$ (higher order terms in x). Let $M > 0$ and $0 < \beta < 4/5$. Now clearly

$$\begin{aligned} \|G - S_P^{(n)}R\|_\infty \times n^4 &\geq 2 \sup_{0 \leq \omega \leq Mn^\beta} |R(j\omega)| \left| \sin\left(\frac{\omega h}{2} - n \arctan \frac{\frac{\omega h}{2n}}{1 - \left(\frac{1}{3}\right)\left(\frac{\omega h}{2n}\right)^2}\right)\right| \times n^4 \\ &\to \lim_{n \to \infty} 2 \sup_{0 \leq \omega \leq Mn^\beta} |R(j\omega)| \times n \times \frac{1}{45}\left(\frac{\omega h}{2n}\right)^5 \times n^4 = \frac{h^5}{720}\varphi_5(\infty), \end{aligned} \tag{4.45}$$

when $n \to \infty$. (Here we have utilized the fact that, when taking above the supremum over ω, the argument of the sine function as well as of the arctan function both tend to zero when $n \to \infty$. Hence the indicated Taylor series expansions become exact using the first term of both of the series only.) This completes the proof. □

Thus the function φ_5 appears in a fundamental manner in the H_∞ error of the Padé-2 formula for approximating delay systems of the considered form for $m \geq 5$. The asymptotically accurate formula $\|G - S_P^{(n)}R\|_\infty \approx (h^5/720)\varphi_5(\infty) \times n^{-4}$ provides an elegant way to determine what n value suffices to achieve some given approximation accuracy.

5. Numerical example.

We shall consider the linear system with a transfer function given by

$$G(s) = \frac{\exp(-hs)}{(Ts + 1)^5}, \tag{5.1}$$

TABLE 5.1
H_∞ errors (all times 10^{-3}).

Formula/ℓ	1	2	4	6	8	10
Laguerre	15.49	3.874	0.968	0.430	0.242	0.155
Kautz	-	7.747	1.937	0.861	0.484	0.310
Padé-2	-	1.389	0.087	0.017	0.005	0.002

of which one physical example is that of five perfectly mixed identical tanks with transportation delay, all coupled in series. To fix ideas we take $T = 1$ and $h = 1$.

Table 5.1 shows the H_∞ errors as given by the respective asymptotic error formulae produced by approximating the delay e^{-hs} by, respectively, the Laguerre shift formula

$$e^{-hs} \sim \frac{(1 - hs/(2n))^n}{(1 + hs/(2n))^n}, \tag{5.2}$$

the particular Kautz shift formula

$$e^{-hs} \sim \frac{(1 - hs/(2n) + h^2s^2/(8n^2))^n}{(1 + hs/(2n) + h^2s^2/(8n^2))^n}, \tag{5.3}$$

and the Padé-2 based shift formula

$$e^{-hs} \sim \frac{(1 - hs/(2n) + h^2s^2/(12n^2))^n}{(1 + hs/(2n) + h^2s^2/(12n^2))^n}. \tag{5.4}$$

Specifically, we give in Table 5.1 the values for the asymptotic H_∞ error formulas for multiplicity-ℓ Laguerre, Kautz, and Padé-2 shift formulas, so that $\ell = n$ for the Laguerre shift and $\ell = 2n$ for the others. The corresponding approximations of the delay systems have degree $5 + \ell$ as rational functions.

In this example it is easy to determine the asymptotic H_∞ error formulas for the Laguerre, Kautz, and Padé-2 shift formulas. We note that the function $\varphi_5(\nu)$ in (4.4) is now given as $\varphi_5(\nu) = \nu^5|R(j\nu)|$, $\nu \geq 0$, so that $\varphi_5(\infty) = \lim_{\nu\to\infty} \varphi_5(\nu) = 1$. Furthermore, we get that $\varphi_3(\infty) = (2/5) \times (3/5)^{3/2} \approx 0.4648$. Hence the asymptotic H_∞ error formula for the Laguerre shift formula is $\|G - S_L^{(n)}R\|_\infty \approx 15.49 \cdot 10^{-3}n^{-2}$, for the Kautz shift formula $\|G - S_K^{(n)}R\|_\infty \approx 30.99 \cdot 10^{-3}n^{-2}$ (see Mäkilä and Partington [24]), and for the Padé-2 shift formula $\|G - S_P^{(n)}R\|_\infty \approx 1.389 \cdot 10^{-3}n^{-4}$.

Note that in this example the Laguerre formula provides a fairly small H_∞ error even for $\ell = 1$, i.e., the sixth-order approximation of G so obtained might be satisfactory for many practical purposes (e.g., for robust H_∞ control design). The eleventh-order approximation provided by the Padé-2 formula for $\ell = 6$ would most likely be satisfactory for all practical purposes (e.g., even for simulating time responses of the system).

6. Conclusions. Certain shift operator induced finite-dimensional approximations of a class of delay systems have been studied. The studied approach provides the most transparent way of approximating delay systems. H_∞, H_2, and L_1 approximation error bounds have been derived for the studied class of delay systems. A special feature of the studied approximation approach is that the approximations can be written down without any computations and that their H_∞ error behavior can also be often determined reliably by simple hand computations. Hence this approach should provide an ideal technique for the purpose of treating approximate modeling and control of delay systems in control engineering courses and text books. Furthermore, it provides good low-order models for rapid low-order controller design for this important class of delay systems.

It is possible to use the studied approach for general delay systems, not just for the class of delay systems studied here. Certain generalizations of the error analysis made here are obvious; e.g., removing the restriction to a stable (strictly proper) rational part $R(s)$ in the system transfer function $G(s) = e^{-hs}R(s)$ is easy. If $R(s)$ is strictly proper with no poles on the imaginary axis, then it is clear that instead of H_∞ error bounds, one gets completely analogous L_∞ error bounds on the imaginary axis. The approximations have the same number of unstable poles as $G(s)$. Hence, L_∞ convergence of the frequency responses is enough to guarantee convergence of the studied approximations in the gap metric and in the chordal metric. Therefore the studied approach is also most useful for unstable delay systems.

The case of relative degree $m = 1$ is hard for analyzing the L_1 error behavior of the shift operator induced approximation method. This case is known to be difficult for the L_1 error analysis of several other approximation methods as well.

THE VELOCITY TRACKING PROBLEM FOR NAVIER–STOKES FLOWS WITH BOUNDED DISTRIBUTED CONTROLS*

M. D. GUNZBURGER† AND S. MANSERVISI‡

Abstract. We present some systematic approaches to the mathematical analysis and numerical approximation of the time dependent optimal control problem of tracking the velocity for Navier–Stokes flows in bounded two-dimensional domains with bounded distributed controls. We study the existence of optimal solutions and derive an optimality system from which optimal solutions may be determined. We also define and analyze semidiscrete-in-time and fully space-time discrete approximations of the optimality system and a gradient method for the solution of the fully discrete system. The results of some computational experiments are provided.

Key words. optimal control, Navier–Stokes equations, fluid mechanics

1. Introduction.

The possibility of steering a velocity field to a target velocity field over time has a wide range of applications in engineering and science. In the literature, examples are found related to combustion, chemical reacting flows, design problems, reduction of turbulence, controllability, drag reduction, etc.; see, e.g., [5], [7], [17], [27], and [31].

The controls are some physical parameters or functions that can be adjusted in practice, e.g., the velocity at the boundary or the body force in some special settings. Here, we will consider distributed or body force controls $\vec{f}$. One method for effecting such control is through a magnetic field acting on an ionized fluid or on a liquid metal. Although such controls are technologically difficult and sometimes impossible to realize in practice, they are mathematically more tractable and thus serve as a first setting for the study of optimal control problems for the nonlinear Navier–Stokes system.

A common means for effecting the velocity tracking is to monitor the quadratic functional

$$\mathcal{J}(\vec{u}(\vec{f})) = \frac{\alpha}{2}\int_0^T \int_\Omega |\vec{u}-\vec{U}|^2 \, d\vec{x}dt + \frac{\gamma}{2}\int_\Omega \left|\vec{u}(T)-\vec{U}(T)\right|^2 d\vec{x}\,, \tag{1.1}$$

where $\vec{u}$ denotes the velocity field of the flow and $\vec{U}$ the desired velocity field, i.e., the velocity field that we would like to match. Also, Ω denotes the flow domain and $(0,T)$ denotes the time interval over which the tracking is to be affected. The α and γ constants can be chosen to adjust the relative importance of the two terms appearing in (1.1). The first term in (1.1) measures, in the L^2-norm in space and time, the distance between the given target velocity $\vec{U}$ and the state velocity $\vec{u}$ over the interval $(0,T)$. The second term measures this distance, in the $L^2(\Omega)$-norm, at the time $t = T$.

‡Mathematical Institute, University of Oxford, 24-29 St.Giles, Oxford OX1 3LB, UK (manservi@maths.ox.ac.uk).

The inclusion of the second term is found to be useful in practice since otherwise the flow field $\vec{u}$ may be driven far from the target velocity $\vec{U}$ near $t = T$.

The state of the system is described by the velocity-pressure pair $(\vec{u}, p)$, which is the solution of the Navier–Stokes system

$$\left\{\begin{array}{l} \partial_t \vec{u} + (\vec{u}\cdot\nabla)\vec{u} - \nu\Delta\vec{u} + \nabla p = \vec{f} \qquad \text{in } (0,T)\times\Omega\,, \\ \nabla\cdot\vec{u} = 0 \qquad \text{in } (0,T)\times\Omega\,, \\ \vec{u} = \vec{0} \qquad \text{on } (0,T)\times\Gamma\,, \\ \vec{u} = \vec{u}_0 \qquad \text{on } \Omega\,, \\ \displaystyle\int_\Omega p\,d\vec{x} = 0 \qquad \text{on } (0,T)\,, \end{array}\right. \tag{1.2}$$

where Γ denotes the boundary of the flow domain Ω, ∂_t the partial derivative with respect to time, and $\vec{u}_0$ a given initial velocity field. For simplicity, we have chosen homogeneous velocity boundary conditions; our results can be easily extended, with some notational complications, to other boundary conditions. In (1.2), $\vec{f}$ denotes the distributed control; thus, in our study, the distributed control is the body force per unit mass.

The size of the control is limited by technological constraints such as the amount of energy available for controlling the system. The simplest way to define such a constraint on the size of the control is to explicitly require that some norm of the control be bounded by a given constant, e.g., for all t,

$$\left(\int_\Omega |\vec{f}\,|^2\,d\vec{x}\right)^{1/2} \le K\,, \tag{1.3}$$

where the positive constant K represents, e.g., a measure of the maximum power that is available to control the system.

The velocity tracking will be effected by minimizing the cost functional (1.1) subject to the constraints (1.2) and (1.3). In this paper, we present and analyze a precise mathematical formulation of this problem and its numerical approximation for bounded, two-dimensional domains. We prove the existence of optimal controls and states and characterize such optimal solutions by deriving the first-order necessary condition associated with the problem. We formulate and analyze semidiscrete and fully discrete finite element-based approximations of the optimality system and study a gradient method for the solution of the discrete equations. We also present the results of some computational experiments. The results presented in this paper may be extended, with little difficulty, to many other objective functionals; however, the extension to boundary controls is more difficult and will be the subject of a separate paper.

Mathematical theories and approximation techniques for optimal control problems for the Navier–Stokes equations have been developed in various settings; see, e.g., [1], [10], [11], [12], [13], [14], [15], [21], [25], [26], [29], [30], and [32]. Some numerical methods for solving control problems for unsteady flows have been proposed and tested; see, e.g., [21], [24], [25], [26], [28], and [30]. Many of these deal with distributed controls and take a different approach to limiting the size of the control. Instead of imposing the explicit bound (1.3), the size of the control is limited by introducing a penalty term into the functional, e.g., instead of (1.1), a functional such as

$$\mathcal{J}(\vec{u}(\vec{f})) + \frac{\beta}{2}\int_0^T\int_\Omega |\vec{f}\,|^2\,d\vec{x}dt \tag{1.4}$$

is minimized subject to (1.2). Such an approach has been shown to be effective. However, it is obvious that the minimizer of (1.3) does not in general minimize (1.4), which is the real objective. Furthermore, when one minimizes (1.4) one does not know what the actual size of the control will be; one merely knows that by adjusting the constant β relative to α and γ, one can make more or less control available for effecting the velocity tracking; i.e., reducing β allows for more control and vice versa. However, unlike the explicit bound (1.3), one cannot ever be sure that the size of the control will indeed be within the technological constraints. For this reason, the approach taken in this paper is the more practical one; the penalty approach is easier to treat mathematically, which accounts for its popularity in the literature.

2. The optimal control problem for velocity tracking. Let $\Omega \subset \mathbb{R}^2$ be a bounded, open set. We shall use the standard notations for the Sobolev spaces (and their vector-valued, i.e., $\mathbb{R}^2$-valued, counterparts) $H^m(\Omega)$ with norm $\|\cdot\|_m$; we also use the notations $L^2(\Omega) = H^0(\Omega)$ and $\|\cdot\| = \|\cdot\|_0$. Let $H_0^m(\Omega)$ denote the closure of $C_0^\infty(\Omega)$ under the norm $\|\cdot\|_m$ and $H_0^{-m}(\Omega)$ denote the dual space of $H_0^m(\Omega)$. We introduce the solenoidal spaces

$$\begin{aligned}\mathcal{V}(\Omega) &= \{\vec{u} \in C_0^\infty(\Omega) : \nabla\cdot\vec{u} = 0\},\\ V(\Omega) &= \{\vec{u} \in H_0^1(\Omega) : \nabla\cdot\vec{u} = 0\},\\ W(\Omega) &= \{\vec{u} \in L^2(\Omega) : \nabla\cdot\vec{u} = 0\}\,.\end{aligned}$$

The spaces $V(\Omega)$ and $W(\Omega)$ are the closures of $\mathcal{V}(\Omega)$ in $L^2(\Omega)$ and $H^1(\Omega)$, respectively. The dual space of $V(\Omega)$ is denoted by $V(\Omega)^*$ while the dual space of $W(\Omega)$ can be identified with itself. Also, we define

$$L_0^2(\Omega) = \{p \in L^2(\Omega) : \int_\Omega p\, d\vec{x} = 0\}\,.$$

For details about these spaces, see, e.g., [2] and [16]. Given T, we introduce the notation $L^p((0,T); H^m(\Omega))$ for the temporal-spatial function spaces defined on $(0,T)\times\Omega$ with the norm

$$\|\vec{u}\|_{L^p((0,T);X)} = \left(\int_0^T \|\vec{u}\|_X^p\, dt\right)^{1/p}\,.$$

In order to define the weak form of the Navier–Stokes equations we introduce two continuous bilinear forms,

$$a(\vec{u},\vec{v}) = 2\nu \sum_{i,j=1}^n \int_\Omega D_{ij}(\vec{u}) D_{ij}(\vec{v})\, d\vec{x} \qquad \forall\, \vec{u},\vec{v} \in H^1(\Omega)\,, \tag{2.1}$$

$$b(\vec{v},q) = -\int_\Omega q \nabla\cdot\vec{v}\, d\vec{x} \qquad \forall q \in L^2(\Omega), \quad \forall\, \vec{v} \in H^1(\Omega), \tag{2.2}$$

where $D_{ij}(\vec{v}) = \frac{1}{2}(\partial v_i/\partial x_j + \partial v_j/\partial x_i)$ and the continuous trilinear form

$$c(\vec{w};\vec{u},\vec{v}) = \sum_{i,j=1}^n \int_\Omega w_j \left(\frac{\partial u_i}{\partial x_j}\right) v_i d\vec{x} \qquad \forall\, \vec{w},\vec{u},\vec{v} \in H^1(\Omega)\,.$$

We set $\vec{g} = \vec{f}/K$ so that the constraint (1.3) on the control can be written in the form

$$\|\vec{g}\|^2(t) = \int_\Omega |\vec{g}|^2(t)\, d\vec{x} \le 1 \qquad \text{for } t \in [0,T]\,. \tag{2.3}$$

We denote by $\mathcal{B}$ the set of $\vec{g} \in L^2((0,T);L^2(\Omega))$ that satisfies the constraint (2.3) which implies that $\|\vec{g}\|_{L^\infty((0,T);L^2(\Omega))} \leq 1$. The set $\mathcal{B}$ is a convex closed set in $L^2((0,T);L^2(\Omega))$. The constraint choice (2.3) reflects the many practical situations in which at any time one can or must, due to technological constraints, limit the total size of the control.

Other types of constraints can also be handled by the techniques used in this paper. For example, one can choose $\|\vec{g}\|_{L^2((0,T);L^2(\Omega))} \leq K$. However, constraints such as this are not very useful in practice since they allow for forces whose size, at any given time, can exceed technological limits. Also, they reflect a situation similar to that encountered when one seeks optimal controls that minimize the functional (1.4). The regularization parameter β in (1.4) can be interpreted as a Lagrange multiplier corresponding to a constraint such as $\|\vec{g}\|_{L^2((0,T);L^2(\Omega))} \leq K$ with some $K = K(\beta)$. In the context of infinite-dimensional parameter identification problems, this duality is explored by, e.g., [4] and [36]. The effect of using such constraints would be very similar to that for the case in which one optimizes with respect to the penalized functional (1.4), a case that has already been treated in [21]. For these reasons, it seems that the constraint choice (2.3) is more appropriate.

A weak formulation of the Navier–Stokes problem is defined as follows: seek $(\vec{u},p) \in L^2((0,T);H^1_0(\Omega)) \times L^2((0,T);L^2_0(\Omega))$ satisfying

$$\text{(2.4)} \qquad \begin{cases} \langle \partial_t \vec{u}, \vec{v}\rangle + a(\vec{u},\vec{v}) + c(\vec{u};\vec{u},\vec{v}) + b(\vec{u},p) = K\langle \vec{g},\vec{v}\rangle \quad \forall\, \vec{v} \in H^1_0(\Omega), \\ b(\vec{u},p) = 0 \quad \forall\, q \in L^2_0(\Omega), \\ \vec{u}(0,\cdot) = \vec{u}_0(\cdot) \in V(\Omega)\,, \end{cases}$$

where $\langle \cdot,\cdot\rangle$ denotes the duality pairing between $H^{-1}(\Omega)$ and $H^1_0(\Omega)$. The homogeneous boundary conditions for the velocity and the zero-mean condition for the pressure are satisfied due to the choice of spaces in which solutions are sought. For a simulation problem, $\vec{g} \in H^{-1}(\Omega)$ as well as $\vec{u}_0(\cdot)$ are given functions; in our optimal control setting, $\vec{g} \in L^2(\Omega)$ is the control to be determined through the optimization process.

In terms of our current notation, the functional (1.1) can be expressed as

$$\text{(2.5)} \qquad \mathcal{J}(\vec{u}(\vec{g})) = \frac{\alpha}{2}\int_0^T \|\vec{u} - \vec{U}\|^2\, dt + \frac{\gamma}{2}\|\vec{u}(T) - \vec{U}(T)\|^2\,,$$

where $\vec{U}$ is the desired target velocity. The set of all possible target velocities $L^\infty((0,T);L^2(\Omega))$ is denoted by $\mathcal{U}_{ad}$. There are no particular requirements on the target velocity $\vec{U}$ other than the fact that the functional must be bounded. The target velocity field need not be a solution of the Navier–Stokes equations. In particular, nonsolenoidal fields or fields that satisfy initial and boundary conditions different from those in (1.2) can be used as desired target velocities.

Given $K > 0$, $T > 0$, $\vec{u}_0 \in V(\Omega)$, and $\vec{U} \in \mathcal{U}_{ad}$, the set of *admissible states and controls* is defined by

$$\begin{aligned} \mathcal{A}_{ad} = \Big\{ (\vec{u}, \vec{g}) \in L^2((0,T); H_0^1(\Omega)) \times L^2((0,T); L^2(\Omega)) \\ \text{such that } \mathcal{J}(\vec{u}(\vec{g})) < \infty, \text{ (2.3) is satisfied, and} \\ \text{there exists } p \in L^2((0,T); L_0^2(\Omega)) \text{ such that (2.4) is satisfied} \Big\}. \end{aligned}$$

Actually, our notion of optimality will be a local one; i.e., we will have to be content to find optimal solutions $(\vec{u}, \vec{g})$ defined as follows:

$$\begin{aligned} &\text{given } K > 0,\ T > 0,\ \vec{u}_0 \in V(\Omega), \text{ and } \vec{U} \in \mathcal{U}_{ad}, \text{ find } (\vec{u}, \vec{g}) \in \mathcal{A}_{ad} \\ &\text{such that } \ \mathcal{J}(\vec{u}(\vec{g})) \le \mathcal{J}(\vec{w}(\vec{h})) \ \ \forall \ \ (\vec{w}, \vec{h}) \in \mathcal{A}_{ad} \text{ satisfying} \\ &\qquad \|\vec{h} - \vec{g}\|_{L^2((0,T);L^2(\Omega))} \le \epsilon \ \text{ for some } \epsilon > 0. \end{aligned} \tag{2.6}$$

2.1. Existence of the optimal solutions. In the following theorem we prove the existence of solutions for the optimal control problem. First, a few words should be said concerning known results about the unique solvability of the Navier–Stokes system. If Γ is Lipschitz continuous, $\vec{u}_0 \in W(\Omega)$, and $\vec{g} \in L^2((0,T); B(\Omega))$, where $B(\Omega)$ is the closed unit ball in $L^2(\Omega)$, then the unique solution $\vec{u}$ of (2.4) belongs to $C([0,T]; W(\Omega)) \cap L^2((0,T); V(\Omega))$ and $\vec{u}_t \in L^2((0,T); H^{-1}(\Omega))$. Furthermore, if $\Gamma \in C^2$ and $\vec{u}_0 \in V(\Omega)$, then the unique solution belongs to $C([0,T]; V(\Omega)) \cap L^2((0,T); H^2 \cap H_0^1)$ and $\vec{u}_t \in L^2((0,T); W(\Omega))$. See, e.g., [9] or [33].

THEOREM 2.1. *Given $K > 0$, $T > 0$, $\vec{u}_0 \in V(\Omega)$, and $\vec{U} \in \mathcal{U}_{ad}$, there exists a solution $\widehat{g} \in L^2((0,T); B(\Omega))$ and $\widehat{u} \in C([0,T]; W(\Omega)) \cap L^2((0,T); V(\Omega))$ of the optimal control problem* (2.6).

Proof. The admissible set $\mathcal{A}_{ad}$ is bounded and not empty, e.g., the Navier–Stokes system has a solution for $\vec{g} = \vec{0}$. Let $\{\vec{u}_n, \vec{g}_n\}$ be a minimizing sequence in $\mathcal{A}_{ad}$. Let p_n be the corresponding pressure such that $(\vec{u}_n, p_n, \vec{g}_n)$ satisfies (2.4). The sequence $\{\vec{g}_n\}$ is uniformly bounded in $L^2((0,T); L^2(\Omega))$ by T. From well-known theorems for solutions of the two-dimensional, unsteady Navier–Stokes equations (see, e.g., [33]), it follows that the corresponding sequence $\vec{u}_n$ is bounded in $C([0,T]; W(\Omega)) \cap L^2((0,T); V(\Omega))$ and the corresponding sequence p_n is bounded in $L^2((0,T); L_0^2(\Omega))$. Thus, there exist a $(\widehat{u}, \widehat{p}, \widehat{g})$ and a subsequence of $(\vec{u}_n, p_n, \vec{g}_n)$ that converges weakly to $(\widehat{u}, \widehat{p}, \widehat{g})$. We abuse the notation and write again that

$$\begin{array}{lllll} \vec{g}_n & \rightarrow & \widehat{g} & in & L^2((0,T); L^2(\Omega)) \quad \text{weakly}, \\ \vec{u}_n & \rightarrow & \widehat{u} & in & L^2((0,T); V(\Omega)) \quad \text{weakly}, \\ \vec{u}_n & \rightarrow & \widehat{u} & in & L^\infty((0,T); W(\Omega)) \quad \text{*-weakly}, \\ p_n & \rightarrow & \widehat{p} & in & L^2((0,T); L_0^2(\Omega)) \quad \text{weakly}. \end{array}$$

The sequence $\{\vec{g}_n\} \in \mathcal{B}$ converges weakly in the topology of $L^2((0,T); L^2(\Omega))$ to an element of $L^2((0,T); L^2(\Omega))$, and now we must prove that the limit $\widehat{g}$ belongs to $\mathcal{B}$. If we prove that the set $\mathcal{B}$ is weakly closed in the topology of $L^2((0,T); L^2(\Omega))$, then this implies that the sequence $\{\vec{g}_n\}$ converges in $\mathcal{B}$. We recall that every closed convex set is also weakly closed. The set $\mathcal{B}$ is convex and closed in $L^2((0,T); L^2(\Omega))$ and thus is weakly closed in this topology; then we have that $\widehat{g} \in \mathcal{B}$.

Now the pair $(\widehat{u}, \widehat{g})$ satisfies the Navier–Stokes equations (2.4) and minimizes the functional (2.5). In fact, by the lower semicontinuity of the functional (2.5) we have

$$\mathcal{J}(\vec{u}(\widehat{g})) \le \liminf_{n \to \infty} \mathcal{J}(\vec{u}_n(\vec{g}_n)) .$$

Furthermore, a priori estimates (see [9] or [33]) for $\vec{u}$ in a fractional time-order Sobolev space yields in our case that $\vec{u}_n$ converges strongly to $\vec{u} \in L^2((0,T);W(\Omega))$. Now we consider the weak Navier–Stokes system (2.4) with state $(\vec{u}_n, p_n)$ and control $\vec{g}_n$. We let $\vec{v} = \psi(t)\vec{w}$ in that system, where $\vec{w} \in \mathcal{V}(\Omega)$ and $\psi(t)$ is a continuously differentiable function on $(0,T)$ such that $\psi(T) = 0$. We then integrate the result with respect to time over the interval $(0,T)$. Then, integrating by parts with respect to time, we obtain

$$- \int_0^T \langle \vec{u}_n, \psi'(t)\vec{w} \rangle \, dt + \nu \int_0^T a(\vec{u}_n, \psi(t)\vec{w}) \, dt + \int_0^T c(\vec{u}_n; \vec{u}_n, \psi(t)\vec{w}) \, dt \\ + \int_0^T b(\psi(t)\vec{w}, p_n) \, dt = (\vec{u}_0, \psi(0)\vec{w}) + \int_0^T (\vec{g}_n, \psi(t)\vec{w}) \, dt \, .$$

We can pass to the limit inside the linear and the nonlinear terms. In fact, if $\vec{u}_n$ converges to $\widehat{u}$ in $L^2((0,T);V(\Omega))$ weakly and $L^2((0,T);W(\Omega))$ strongly, then for any $\vec{z} \in C^1((0,T);\mathcal{D}(\Omega))$, we have

$$\lim_{n\to\infty} \int_0^T c(\vec{u}_n; \vec{u}_n, \vec{z}(t)) \, dt = \int_0^T c(\widehat{u}; \widehat{u}, \vec{z}(t)) \, dt \, ;$$

see, e.g., [33]. If $\psi \in \mathcal{D}(0,T)$, then $(\widehat{u}, \widehat{p}, \widehat{g})$ satisfies the Navier–Stokes equation (2.4) in the distribution sense. Since $\mathcal{V}(\Omega)$ is dense in $V(\Omega)$, then this is still true for any $\vec{w} \in V(\Omega)$ by a continuity argument. □

We remark that this theorem implies the existence of a global optimal solution but it does not preclude the existence of other local optimal solutions. How such local optimal solutions are determined is discussed in the next section.

2.2. First-order necessary condition. In this section we derive the first-order necessary condition associated with the optimal control problem (2.6). If the Gateaux derivative of the functional exists, then the optimal solution must satisfy this standard first-order necessary condition; see, e.g., [3] or [35].

THEOREM 2.2. *Let $\vec{u}_0 \in V(\Omega)$. If $(\widehat{u}, \widehat{g})$ is an optimal pair and the functional $\mathcal{J}(\vec{u}(\vec{g}))$ is Gateaux differentiable, then the necessary condition for $\widehat{g}$ to be a minimizer of $\mathcal{J}(\vec{u}(\vec{g}))$ is*

$$\left(\frac{d\mathcal{J}(\vec{u}(\widehat{g}))}{d\vec{g}} \cdot (\vec{h} - \widehat{g}) \right) \geq 0 \quad \forall \vec{h} \in \mathcal{B} \, . \tag{2.7}$$

It is clear that the set $\mathcal{B}$ is in $L^\infty((0,T);L^2(\Omega))$; however, it is usual and convenient to work with the standard topology of $L^2((0,T);L^2(\Omega))$ in order to use well-known results. We recall that the solution of the Navier–Stokes system defines a mapping $\vec{u} = \vec{u}(\vec{g})$ from $L^2((0,T);L^2(\Omega))$ to $L^2((0,T);W(\Omega))$ which is Gateaux differentiable, and thus Theorem 2.2 can be applied.

THEOREM 2.3. *Let $\vec{u}_0 \in V(\Omega)$. The mapping $\vec{u} = \vec{u}(\vec{g})$ from $L^2((0,T);L^2(\Omega))$ to $L^2((0,T);V(\Omega))$ has a Gateaux derivative $(d\vec{u}/d\vec{g}) \cdot \vec{z}$ for every $\vec{z}$ in $L^2((0,T);L^2(\Omega))$. Furthermore, $\widetilde{w}(\vec{z}) = (d\vec{u}/d\vec{g}) \cdot \vec{z}$ is the solution of the problem*

$$\begin{cases} \langle \partial_t \widetilde{w}, \vec{v} \rangle + \nu a(\widetilde{w}, \vec{v}) + c(\vec{u}(\vec{g}); \widetilde{w}, \vec{v}) + c(\widetilde{w}, \vec{u}(\vec{g}), \vec{v}) \\ \qquad\qquad + \, b(\widetilde{w}, \widetilde{r}) = K(\vec{z}, \vec{v}) \quad \forall \, \vec{v} \in H_0^1(\Omega) \, , \\ b(\widetilde{w}, q) = 0 \quad \forall \, q \in L_0^2(\Omega) \, , \\ \widetilde{w}(t, \vec{x}) = 0 \quad \text{on } (0,t) \times \Gamma \, , \\ \widetilde{w}(0, \vec{x}) = 0 \quad \text{on } \Omega \end{cases} \tag{2.8}$$

for some $\widetilde{r} \in L^2((0,T); L^2_0(\Omega))$. *Furthermore, we have that* $\widetilde{w} \in L^\infty((0,T); W(\Omega)) \cap L^2((0,T); V(\Omega))$.

Proof. See, e.g., [1] or [21]. □

Of course, $\vec{g} + \mathcal{B} \subset L^2((0,T); L^2(\Omega))$ so that the mapping $\vec{u} = \vec{u}(\vec{g})$ is Gateaux differentiable for all $\vec{h} - \vec{g}$ with $\vec{h}$ in the admissible set $\mathcal{B}$. Note that $\widetilde{r}$ may be interpreted as the derivative $(dp/d\vec{g}) \cdot \vec{z}$ of the pressure $p(\vec{g})$.

In order to characterize optimal solutions, we introduce the adjoint problem to the linearized Navier–Stokes equations.

THEOREM 2.4. *Let* $\vec{u}_0 \in V(\Omega)$ *and let* $(\widehat{u}, \widehat{g})$ *be a solution of the optimal control problem. Let* $\vec{w} \in L^2((0,T), V(\Omega)) \cap L^\infty((0,T), L^2(\Omega))$, *and* $r \in L^2((0,T); L^2_0(\Omega))$ *denote the solution of the adjoint problem*

$$\left\{\begin{array}{l} -\langle \partial_t \vec{w}, \vec{v}\rangle + \nu a(\vec{v}, \vec{w}) + c(\widehat{u}; \vec{v}, \vec{w}) + c(\vec{v}; \widehat{u}, \vec{w}) \\ \qquad\qquad + \, b(\vec{v}, r) = \alpha(\vec{u} - \vec{U}, \vec{v}) \quad \forall\, \vec{v} \in H^1_0(\Omega)\,, \\ b(\vec{w}, q) = 0 \quad \forall\, q \in L^2_0(\Omega)\,, \\ \vec{w}(T, \cdot) = \gamma(\widehat{u}(T,\cdot) - \vec{U}(T,\cdot)) \quad \text{in } \Omega\,, \\ \vec{w} = \vec{0} \quad \text{on } (0,T) \times \Gamma\,. \end{array}\right. \tag{2.9}$$

Let $S \subset (0,T)$ *be the set in which* $\vec{w}$ *is different from zero. Then, we have*

$$\|\vec{w}\|\widehat{g} = -\vec{w} \qquad \text{for } t \in S\,. \tag{2.10}$$

On $(0,T)\backslash S$, $\widehat{u} = \vec{U}$ *and* $\widehat{g}$ *is uniquely determined up to a gradient by* $(1/K)\vec{F}$, *where* $\vec{F} = \partial_t \vec{U} + (\vec{u} \cdot \nabla)\vec{U} - \nu \Delta \vec{U}$.

Proof. Let $(\widehat{u}, \widehat{g})$ be a solution of the optimal control problem. We can compute the Gateaux derivative of the functional $\mathcal{J}(\vec{u}(\widehat{g}))$ in the direction of $\vec{z}$. We have

$$\frac{d\mathcal{J}(\vec{u}(\widehat{g}))}{d\vec{g}} \cdot \vec{z} = \alpha \int_0^T \int_\Omega (\widehat{u} - \vec{U}) \cdot \widetilde{w}\, d\vec{x}dt + \gamma \int_\Omega (\widehat{u}(T) - \vec{U}(T)) \cdot \widetilde{w}(T)\, d\vec{x},$$

where $\widetilde{w} = (d\vec{u}/d\vec{g}) \cdot \vec{z}$. Now, using (2.8) and (2.9) and then integrating the result by parts with respect to time, we obtain

$$\begin{aligned} \frac{d\mathcal{J}(\vec{u}(\widehat{g}))}{d\vec{g}} \cdot \vec{z} = \int_0^T & \Big(-\langle \partial_t \vec{w}, \widetilde{w}\rangle + \nu a(\widetilde{w}, \vec{w}) + c(\widehat{u}; \widetilde{w}, \vec{w}) + c(\widetilde{w}; \widehat{u}, \vec{w})\Big)\, dt \\ & + \int_\Omega \vec{w}\widetilde{w}\, d\vec{x}\Big|_0^T \\ = \int_0^T & \Big(\langle \partial_t \widetilde{w}, \vec{w}\rangle + \nu a(\widetilde{w}, \vec{w}) + c(\widehat{u}; \widetilde{w}, \vec{w}) + c(\widetilde{w}; \widehat{u}, \vec{w})\Big)\, dt\,. \end{aligned}$$

Hence, again using (2.8) and (2.9), we obtain

$$\frac{d\mathcal{J}(\vec{u}(\widehat{g}))}{d\vec{g}} \cdot \vec{z} = K \int_0^T \int_\Omega \vec{w} \cdot \vec{z}\, dt = K(\vec{w}, \vec{z})_{L^2((0,T);L^2(\Omega))}\,, \tag{2.11}$$

where $\vec{w}$ is the solution of the system (2.9).

In order to show (2.10), we use the first-order necessary condition (2.7) which, as a result of (2.11), is equivalent to

$$(\vec{w}, \vec{h} - \widehat{g})_{L^2((0,T);L^2(\Omega))} \geq 0 \quad \forall\, \vec{h} \in \mathcal{B}\,. \tag{2.12}$$

Let $J \subset S$ be the subset on which $\|\widehat{g}\| < 1$. Let

$$\epsilon = \frac{1}{2}\left(\int_\Omega \widehat{g}\frac{\vec{w}}{\|\vec{w}\|}\,d\vec{x} + \sqrt{\left(\int_\Omega \widehat{g}\frac{\vec{w}}{\|\vec{w}\|}\,d\vec{x}\right)^2 + 1 - \|\widehat{g}\|^2}\right) > 0\,.$$

We choose $\vec{h} = -\epsilon(\vec{w}/\|\vec{w}\|) + \widehat{g}$ on J and $\vec{h} = \widehat{g}$ elsewhere. In this case, $\|\vec{h}\| \le 1$ and $(\vec{w}, \vec{h} - \widehat{g})_{L^2((0,T);L^2(\Omega))} = -\epsilon\|\vec{w}\|_{L^2((0,T);L^2)} < 0$, which contradicts the first-order necessary condition (2.12). Thus, the set J has zero measure and $\|\widehat{g}\| = 1$ a.e. on S.

Next, again let $\widehat{g}$ be an optimal control for t almost everywhere (a.e.) in S; we have already determined that $\|\widehat{g}\| = 1$. Let $I \subset S$ be the subset on which $\widehat{g} \neq -\vec{w}/\|\vec{w}\|$. Choosing $\vec{h} = -\vec{w}/\|\vec{w}\|$ in (2.12) implies that

$$-\int_I (\vec{w}, \widehat{g})\,dt \ge \int_I \|\vec{w}\|\,dt\,. \tag{2.13}$$

By contradicting (2.13), we will show that I has zero measure so that $\|\vec{w}\|\widehat{g} = -\vec{w}$ on S.

First, we show that $\widehat{g} \neq \vec{w}/\|\vec{w}\|$ on the set I so that, together with its definition, we conclude that $\widehat{g}$ is *not* proportional to $\vec{w}$ on I. If we set $\vec{h} = 0$ in (2.12) we have that $(\vec{w}, -\widehat{g})_{L^2((0,T);L^2(\Omega))} \ge 0$ and thus $\widehat{g}$ cannot be equal to $\vec{w}/\|\vec{w}\|$. Therefore, the control $\widehat{g}$ is not proportional to $\vec{w}$ on the set I, and thus the strict Schwarz inequality $|(\vec{w}, \widehat{g})| < \|\vec{w}\|$ holds for t a.e. I.

From the strict Schwarz inequality, we then have that

$$-\int_I\int_\Omega \vec{w}\cdot\widehat{g}\,d\vec{x}dt \le \int_I |(\vec{w}, \widehat{g})|\,dt < \int_I \|\vec{w}\|\,dt\,.$$

But this contradicts (2.13) so that the set I must have zero measure. Hence, if $\vec{w} \neq 0$, we have $\|\vec{w}\|\widehat{g} = -\vec{w}$ for t a.e. in S.

On $(0,T)\backslash S$, we need only concern ourselves with sets of positive measure on which $\vec{w} = \vec{0}$, since otherwise we can define $\widehat{g}$ by continuity from neighboring times at which $\vec{w} \neq \vec{0}$. Now $\vec{w} = \vec{0}$ on a set of positive measure in $(0,T)$ if and only if $\widehat{u} = \vec{U}$ a.e. on that set. Consequently, on that set there must exist P (which is not necessarily the same as $\widehat{p}$) such that $\widehat{g} = (1/K)(\vec{F} + \nabla P)$ and $\|\widehat{g}\| \le 1$. □

Remark 2.5. Clearly, even if there exists a measurable set in $(0,T)$ such that there exists a P such that $\|\vec{g}_U\| \le 1$, where $\vec{g}_U = (1/K)(\vec{F} + \nabla P)$, we may not have that $\vec{w} = \vec{0}$ on that set. For this to be true, we also need a requirement on $(\widehat{u} - \vec{U})$ sometime on that set, e.g., $\widehat{u} = \vec{U}$ at some point in that set.

Remark 2.6. It is also clear that it is indeed possible for $\vec{w} = \vec{0}$ on measurable sets. For example, if $\vec{u}_0(\cdot) = \vec{U}(0,\cdot)$ and if there exists a P such that $\|\vec{F} + \nabla P\| \le K$, then we have that $\widehat{u} = \vec{U}$, $\vec{w} = \vec{0}$, and $\widehat{g} = (1/K)(\vec{F} + \nabla P)$ for almost all t.

Remark 2.7. Clearly, a joint rescaling of α and γ does not affect the optimal solution. Indeed, if we multiply both of these parameters by the same positive number, then the adjoint variable $\vec{w}$ is scaled by that same multiple, but, from (2.10), the optimal control $\widehat{g}$ remains unchanged as does, by (2.4), the optimal state $(\widehat{u}, \widehat{p})$. Of course, this is to be expected since multiplying the functional $\mathcal{J}(\vec{u}(\vec{g}))$ of (2.5) by a positive number cannot change its extremal points.

2.3. The optimality system. We have seen that all local optimal solutions are among the solutions of the optimality system (neglecting the possibility of $\vec{w} = \vec{0}$)

$$
\left\{
\begin{aligned}
&\langle \partial_t \widehat{u}, \vec{v}\rangle + \nu a(\widehat{u}, \vec{v}) + c(\widehat{u}; \widehat{u}, \vec{v}) + b(\vec{v}, \widehat{p}) = K(\widehat{g}, \vec{v}) \quad \forall\, v \in H_0^1(\Omega)\,,\\
&b(\widehat{u}, q) = 0 \quad \forall\, q \in L_0^2(\Omega)\\
&-\langle \partial_t \vec{w}, \vec{v}\rangle + \nu a(\vec{w}, \vec{v}) + c(\vec{w}; \widehat{u}, \vec{v}) + c(\widehat{u}; \vec{w}, \vec{v})\\
&\qquad\qquad + b(\vec{v}, r) = \alpha(\widehat{u} - \vec{U}, \vec{v}) \quad \forall\, v \in H_0^1(\Omega)\,,\\
&b(\vec{w}, q) = 0 \quad \forall\, q \in L_0^2(\Omega)\,,\\
&\|\vec{w}\| \vec{g} = -\vec{w} \quad \text{in } (0,T)\times\Omega
\end{aligned}
\right.
\tag{2.14}
$$

with initial velocity $\widehat{u}(0, \vec{x}) = \vec{u}_0(\vec{x})$, final condition $\vec{w}(T, \vec{x}) = \gamma(\widehat{u}(T) - \vec{U}(T))$ on Ω, and homogeneous boundary condition on $(0,T)\times\Gamma$ for both $\widehat{u}$ and $\vec{w}$. The above system of equations is a weak formulation of the system

$$
\left\{
\begin{aligned}
&\partial_t \widehat{u} - \nu\Delta\widehat{u} + (\widehat{u}\cdot\nabla)\widehat{u} + \nabla\widehat{p} = K\widehat{g}\,,\\
&\nabla\cdot\widehat{u} = 0\,,\\
&-\partial_t\vec{w} - \nu\Delta\vec{w} + (\nabla\widehat{u})^T\vec{w} - (\widehat{u}\cdot\nabla)\vec{w} + \nabla r = \alpha(\widehat{u} - \vec{U})\,,\\
&\nabla\cdot\vec{w} = 0\,,\\
&\|\vec{w}\|\widehat{g} = -\vec{w}
\end{aligned}
\right.
$$

in $(0,T)\times\Omega$ with the same initial, final, and boundary conditions.

REMARK 2.8. From a computational standpoint, this is a very difficult system to solve and, among the solutions of the above system, there might be solutions which do not have the property of local optimality. Therefore, how one solves this system and determines an optimal solution is a rather important question. In the following sections, we will discretize in time and then in space-time.

3. Semidiscrete-in-time approximation.

3.1. Formulation of the semidiscrete optimal control problem. Let $\sigma_N = \{t_n\}_{n=0}^N$ be a partition of $[0,T]$ into equal intervals of duration $\Delta t = T/N$ with $t_0 = 0$ and $t_N = T$. We will denote by $\mathbf{q}$ the vector $(q^{(1)}, q^{(2)}, \ldots, q^{(N)})$ of functions belonging to $\mathbf{X} = X^N$ and defined discretely with respect to time. Note that only the time levels t_n, $n = 1, 2, \ldots, N$, enter into this definition. The associated continuous, piecewise (with respect to t) linear function $q_N = q_N(t, \vec{x})$ is defined by the interpolating conditions $q_N(t_n, \vec{x}) = q^{(n)}(\vec{x})$ for $n = 1, 2, \ldots, N$. For each fixed Δt (or N) and for every function $\psi(t, \cdot)$ defined over $(0,T)$, we can associate the corresponding set $\{\psi^{(n)}(\cdot)\}_{n=1}^N$, where $\psi^{(n)}(\vec{x}) = \psi(t_n, \vec{x})$. Thus, we may define, for example, $\vec{U}_N$ to be a continuous, piecewise linear function with respect to t defined by $\vec{U}_N(t_n, \vec{x}) = \vec{U}^{(n)}(\vec{x}) = \vec{U}(t_n, \vec{x})$ for all $n = 1, 2, \ldots, N$.

The vector $\mathbf{r}$ of functions in the dual space $\mathbf{X}^*$ are defined with respect to the dual grid t_n, $n = 0, 1, \ldots, N-1$, i.e., $\mathbf{r} = (r^{(0)}, r^{(1)}, \ldots, r^{(N-1)})$. $\langle \mathbf{r}, \mathbf{p}\rangle = \sum_{n=1}^N \langle r^{(n-1)}, p^{(n)}\rangle$ denotes a duality pairing between elements of the spaces $\mathbf{X}$ and its dual $\mathbf{X}^*$ defined with respect to the discrete-time grid.

The state variables $\vec{u}^{(n)} \in H_0^1(\Omega)$ and $p^{(n)} \in L_0^2(\Omega)$ are constrained to satisfy the semidiscrete Navier–Stokes equations,

$$
\left\{
\begin{aligned}
&\frac{1}{\Delta t}(\vec{u}^{(n)} - \vec{u}^{(n-1)}, \vec{v}) + \nu a(\vec{u}^{(n)}, \vec{v}) + c(\vec{u}^{(n)}; \vec{u}^{(n)}, \vec{v})\\
&\qquad\qquad + b(\vec{v}, p^{(n)}) = K(\vec{g}^{(n)}, \vec{v}) \quad \forall\, \vec{v} \in H_0^1(\Omega), \quad \text{for } n = 1, 2, \ldots, N\,,\\
&b(\vec{u}^{(n)}, q) = 0 \quad \forall\, q \in L_0^2(\Omega), \quad \text{for } n = 1, 2, \ldots, N\,,\\
&\vec{u}^{(n)} = 0 \quad \text{on } \Gamma, \quad \text{for } n = 1, 2, \ldots, N\,,\\
&\vec{u}^{(0)} = \vec{u}_0(\vec{x}) \in V(\Omega),
\end{aligned}
\right. \tag{3.1}
$$

obtained from (1.2) by a backward Euler discretization in time.

Since we are requiring the exact control $\vec{f}$ to be bounded in norm by a real positive number K, we again require that

$$\|\vec{g}^{(n)}\| \le 1 \qquad \text{for } n = 1, 2, \ldots, N\,. \tag{3.2}$$

If we denote the unit ball of $\mathbf{L}^2(\Omega)$ by $\mathbf{B}$, then the above constraint simply implies that $\mathbf{g} \in \mathbf{B}$.

Optimization is achieved by means of the minimization of the discretized-in-time functional

$$\mathcal{J}^N(\mathbf{u}(\mathbf{g})) = \frac{\alpha \Delta t}{2} \sum_{n=1}^{N} \|\vec{u}^{(n)} - \vec{U}^{(n)}\|^2 + \frac{\gamma}{2}\|\vec{u}^{(N)} - \vec{U}^{(N)}\|^2\,. \tag{3.3}$$

This functional results from applying the right-point discretization rule in time to the continuous functional (2.5). We also introduce the admissibility set

$$
\begin{aligned}
\mathcal{A}_{ad}^N = \Big\{ &(\mathbf{u}, \mathbf{g}) \in \mathbf{H}_0^1(\Omega)) \times \mathbf{L}^2(\Omega)) \text{ such that } \mathcal{J}^N(\mathbf{u}(\mathbf{g})) < \infty, \ \mathbf{g} \in \mathbf{B},\\
&\qquad \text{and there exists } \mathbf{p} \in \mathbf{L}_0^2(\Omega)) \text{ such that (3.1) is satisfied} \Big\}.
\end{aligned}
$$

The formulation of the *semidiscrete-in-time optimal control problem* is then given by

> given $K > 0$, $T > 0$, $\vec{u}_0 \in V(\Omega)$, $\vec{U} \in \mathcal{U}_{ad}$, and N, find $(\mathbf{u}, \mathbf{g}) \in \mathcal{A}_{ad}^N$ such that the functional (3.3) is minimized.

Of course, we really seek local minimizers of the functional (3.3) in the same sense as (2.6).

The value of $\vec{g}^{(0)}$ is not defined by this formulation; it can be arbitrarily chosen. For example, one could simply set $\vec{g}^{(0)} = \vec{g}^{(1)}$ or use some other extension of the continuous, piecewise linear (with respect to time) function $\vec{g}_N$ in $C((0, T); L^2(\Omega))$. More complicated discretizations of the functional can explicitly involve the value $\vec{g}^{(0)}$. Note that this is exactly the same situation as is encountered for the pressure in the backward Euler semidiscretization of the Navier–Stokes equations, i.e., $p^{(0)}$ is not defined by (3.1).

3.2. Existence and first-order necessary condition. Now we state and prove the existence of solutions of the semidiscrete optimal control problem in an open, bounded, two-dimensional domain Ω with Lipschitz-continuous boundary Γ.

THEOREM 3.1. *Given $K > 0$, $T > 0$, $\Delta t = T/N$, $\vec{u}_0 \in V(\Omega)$, and $\vec{U} \in \mathcal{U}_{ad}$, there exists at least one solution, $(\widehat{\mathbf{u}}, \widehat{\mathbf{g}}) \in \mathbf{V}(\Omega) \times \mathbf{L}^2(\Omega)$, of the semidiscrete-in-time optimal control problem.*

Proof. Given N, let $\{\mathbf{g}_k\}_{k=1}^{\infty}$ be a minimizing sequence. Each component of the minimizing sequence is uniformly bounded by 1, and the corresponding solution $\vec{\mathbf{u}}_k$ is uniformly bounded in $\mathbf{V}(\Omega)$. Now we can proceed with a weakly convergent subsequence for each component and show that these subsequences converge to the solution of the optimal control problem in the semidiscrete approximation. Using the fact that the injection of $V(\Omega)$ into $L^2(\Omega)$ is compact, the subsequence $\mathbf{u}_k$ converges strongly. This allows us to pass to the limit in the semidiscrete Navier–Stokes equation, and the proof follows as in the continuous case. The components of $\mathbf{g}_k$ are bounded in the unit ball, and so the weak limit satisfies the bound imposed on the control. □

In the rest of this section we derive the first-order necessary condition that optimal solutions of the semidiscrete-in-time optimal control problem must satisfy. We will follow standard procedures. First, we introduce auxiliary variables that allow us to transform the inequality constraints into equalities and then invoke well-known derivations for equality constrained minimization problems; see, e.g., [3] or [35].

We begin by replacing (3.2) with

$$\|\vec{g}^{(n)}\|^2 - 1 + (s^{(n)})^2 = 0 \qquad \text{for } n = 1, 2, \ldots, N\,, \tag{3.4}$$

for some $\mathbf{s} \in \mathbb{R} = \mathbb{R}^N$. Clearly, if (3.4) is satisfied, so is (3.2). Then, the constraints in the semidiscrete-in-time optimal control problem are all equality constraints and are given by (3.1) and (3.4). Also, note that if $(\widehat{\mathbf{u}}, \widehat{\mathbf{p}}, \widehat{\mathbf{g}})$ is a solution of the semidiscrete-in-time optimal control problem, then there exists $\widehat{\mathbf{s}}$ such that $\widehat{\mathbf{g}}$ and $\widehat{\mathbf{s}}$ satisfy (3.4).

REMARK 3.2. It is worthwhile pointing out that the variables $s^{(n)}$ are introduced only as a theoretical tool and not for computational purposes. Computationally, these variables are known to be a poor tool since they may introduce many local minima.

Let $\mathbf{B}_1 = \mathbf{H}_0^1(\Omega) \times \mathbf{L}_0^2(\Omega) \times \mathbf{L}^2(\Omega) \times \mathbb{R}$ and $\mathbf{B}_2 = \mathbf{H}^{-1}(\Omega) \times \mathbf{L}_0^2(\Omega) \times \mathbb{R}$. We equip these product spaces with the usual graph norms. We define the nonlinear mapping $M : \mathbf{B}_1 \to \mathbf{B}_2$ by $M(\mathbf{u}, \mathbf{p}, \mathbf{g}, \mathbf{s}) = (\mathbf{f}, \mathbf{z}, \mathbf{l})$ for $(\mathbf{u}, \mathbf{p}, \mathbf{g}, \mathbf{s}) \in \mathbf{B}_1$ and $(\mathbf{f}, \mathbf{z}, \mathbf{l}) \in \mathbf{B}_2$ if and only if

$$\left\{\begin{array}{l} \dfrac{1}{\Delta t}(\vec{u}^{(n)} - \vec{u}^{(n-1)}, \vec{v}) + \nu a(\vec{u}^{(n)}, \vec{v}) + c(\vec{u}^{(n)}, \vec{u}^{(n)}, \vec{v}) + b(\vec{v}, p^{(n)}) \\ \qquad\qquad -K(\vec{g}^{(n)}, \vec{v}) = (\vec{f}^{(n)}, \vec{v}) \quad \forall\, \vec{v} \in H_0^1(\Omega)\,, \quad \text{for } n = 1, 2, \ldots, N\,, \\ b(\vec{u}^{(n)}, q) = (z^{(n)}, q) \quad \forall\, q \in L_0^2(\Omega)\,, \quad \text{for } n = 1, 2, \ldots, N\,, \\ \frac{1}{2}[(\vec{g}^{(n)}, \vec{g}^{(n)}) - 1 + (s^{(n)})^2] = l^{(n)}, \quad \text{for } n = 1, 2, \ldots, N\,, \\ \vec{u}^{(n)} = 0 \quad \text{on } \Gamma\,, \quad \text{for } n = 1, 2, \ldots, N\,, \\ \vec{u}^{(0)} = \vec{u}_0(\vec{x}) \in V(\Omega)\,. \end{array}\right. \tag{3.5}$$

Thus, the constraint equations (3.1) and (3.4) in the semidiscrete-in-time optimal control problem can be expressed as $M(\mathbf{u}, \mathbf{p}, \mathbf{g}, \mathbf{s}) = (\mathbf{0}, \mathbf{0}, \mathbf{0})$.

For any fixed $\widehat{\mathbf{g}} \in \mathbf{L}^2(\Omega)$ and $\mathbf{u}(\widehat{\mathbf{g}}) \in \mathbf{H}_0^1(\Omega)$, we define another nonlinear mapping $Q : \mathbf{B}_1 \to \mathbb{R} \times \mathbf{B}_2$ by $Q(\mathbf{u}, \mathbf{p}, \mathbf{g}, \mathbf{s}) = (a, \mathbf{f}, \mathbf{z}, \mathbf{l})$ if and only if

$$\begin{pmatrix} \mathcal{J}^N(\mathbf{u}(\mathbf{g})) - \mathcal{J}^N(\mathbf{u}(\widehat{\mathbf{g}})) \\ M(\mathbf{u}, \mathbf{p}, \mathbf{g}, \mathbf{s}) \end{pmatrix} = \begin{pmatrix} a \\ (\mathbf{f}, \mathbf{z}, \mathbf{l}) \end{pmatrix}. \tag{3.6}$$

These mappings are strictly differentiable, as is shown in the following lemma. We recall the notion of a strict differentiability, which is a slightly stronger concept than Frechet differentiability; see [35]. Let X and Y denote Banach spaces, and let the mapping $\varphi(x) : X \to Y$ be Frechet differentiable at x. Denote its Frechet derivative by D; of course, D is a bounded, linear mapping from X to Y. Then, $\varphi(x)$ is strictly differentiable at $x \in X$ if for any $\epsilon > 0$ there exists a $\delta > 0$ such that whenever $\|x - x_1\|_X < \delta$ and $\|x - x_2\|_X < \delta$ for $x_1, x_2 \in X$,

$$\|\varphi(x_1) - \varphi(x_2) - D(x_1 - x_2)\|_Y \le \epsilon \|x_1 - x_2\|_X \,.$$

The strict derivative D at the point $x \in X$, if it exists, will often be denoted by $D = \varphi'(x)$. The value of this mapping on an element $\widetilde{x} \in X$ will often be denoted by $\varphi'(x) \cdot \widetilde{x}$.

Lemma 3.3. *Let the nonlinear mappings $M : \mathbf{B}_1 \to \mathbf{B}_2$ and $Q : \mathbf{B}_1 \to \mathbb{R} \times \mathbf{B}_2$ be defined by* (3.5) *and* (3.6), *respectively. Then, these mappings are strictly differentiable on all of $\mathbf{B}_1$. Furthermore, the strict derivative of M at a point $(\mathbf{u}, \mathbf{p}, \mathbf{g}, \mathbf{s}) \in \mathbf{B}_1$ is given by the bounded linear operator $M'(\mathbf{u}, \mathbf{p}, \mathbf{g}, \mathbf{s}) : \mathbf{B}_1 \to \mathbf{B}_2$, where $M'(\mathbf{u}, \mathbf{p}, \mathbf{g}, \mathbf{s}) \cdot (\widetilde{\mathbf{w}}, \widetilde{\mathbf{r}}, \widetilde{\mathbf{h}}, \widetilde{\mathbf{s}}) = (\overline{\mathbf{f}}, \overline{\mathbf{z}}, \overline{\mathbf{l}})$ for $(\widetilde{\mathbf{w}}, \widetilde{\mathbf{r}}, \widetilde{\mathbf{h}}, \widetilde{\mathbf{s}}) \in \mathbf{B}_1$ and $(\overline{\mathbf{f}}, \overline{\mathbf{z}}, \overline{\mathbf{l}}) \in \mathbf{B}_2$ if and only if*

$$(3.7) \qquad \begin{cases} \dfrac{1}{\Delta t}(\widetilde{\vec{w}}^{(n)} - \widetilde{\vec{w}}^{(n-1)}, \vec{v}) + \nu a(\widetilde{\vec{w}}^{(n)}, \vec{v}) + c(\widetilde{\vec{w}}^{(n)}, \vec{u}^{(n)}, \vec{v}) \\ \qquad\qquad + c(\vec{u}^{(n)}, \widetilde{\vec{w}}^{(n)}, \vec{v}) + b(\vec{v}, \widetilde{r}^{(n)}) - K(\widetilde{\vec{h}}^{(n)}, \vec{v}) = (\overline{\vec{f}}^{(n)}, \vec{v}) \\ \qquad\qquad\qquad\qquad \forall\, \vec{v} \in H^1_0(\Omega)\,, \quad \textit{for } n = 1, 2, \ldots, N\,, \\ b(\widetilde{\vec{w}}^{(n)}, q) = (\overline{z}^{(n)}, q) \quad \forall\, q \in L^2_0(\Omega)\,, \quad \textit{for } n = 1, 2, \ldots, N\,, \\ 2(\widetilde{\vec{h}}^{(n)}, \vec{g}^{(n)}) + 2s^{(n)}\widetilde{s}^{(n)} = \overline{l}^{(n)}, \quad \textit{for } n = 1, 2, \ldots, N\,, \\ \widetilde{\vec{w}}^{(n)} = \vec{0} \quad \textit{on } \Gamma\,, \quad \textit{for } n = 1, 2, \ldots, N\,, \\ \widetilde{\vec{w}}^{(0)} = \vec{0} \quad \textit{on } \Omega\,. \end{cases}$$

Moreover, the strict derivative of Q at a point $(\mathbf{u}, \mathbf{p}, \mathbf{g}, \mathbf{s}) \in \mathbf{B}_1$ is given by the bounded linear operator $Q'(\mathbf{u}, \mathbf{p}, \mathbf{g}, \mathbf{s}) : \mathbf{B}_1 \to \mathbb{R} \times \mathbf{B}_2$, where $Q'(\mathbf{u}, \mathbf{p}, \mathbf{g}, \mathbf{s}) \cdot (\widetilde{\mathbf{w}}, \widetilde{\mathbf{r}}, \widetilde{\mathbf{h}}, \widetilde{\mathbf{s}}) = (\overline{a}, \overline{\mathbf{f}}, \overline{\mathbf{z}}, \overline{\mathbf{l}})$ for $(\widetilde{\mathbf{w}}, \widetilde{\mathbf{r}}, \widetilde{\mathbf{h}}, \widetilde{\mathbf{s}}) \in \mathbf{B}_1$ and $(\overline{a}, \overline{\mathbf{f}}, \overline{\mathbf{z}}, \overline{\mathbf{l}}) \in \mathbb{R} \times \mathbf{B}_2$ if and only if

$$(3.8) \qquad \begin{pmatrix} (\mathcal{J}^N)'(\mathbf{u}(\widehat{\mathbf{g}})) \cdot (\widetilde{\mathbf{w}}, \widetilde{\mathbf{r}}, \widetilde{\mathbf{h}}, \widetilde{\mathbf{s}}) \\ M'(\mathbf{u}, \mathbf{p}, \mathbf{g}, \mathbf{s}) \cdot (\widetilde{\mathbf{w}}, \widetilde{\mathbf{r}}, \widetilde{\mathbf{h}}, \widetilde{\mathbf{s}}) \end{pmatrix} = \begin{pmatrix} \overline{a} \\ (\overline{\mathbf{f}}, \overline{\mathbf{z}}, \overline{\mathbf{l}}) \end{pmatrix},$$

where

$$(\mathcal{J}^N)'(\mathbf{u}(\widehat{\mathbf{g}})) \cdot (\widetilde{\mathbf{w}}, \widetilde{\mathbf{r}}, \widetilde{\mathbf{h}}, \widetilde{\mathbf{s}}) = \alpha \Delta t \sum_{n=1}^{N} \int_\Omega (\vec{u}^{(n)} - \vec{U}^{(n)}) \cdot \widetilde{\vec{w}}^{(n)} \, d\vec{x} + \gamma \int_\Omega (\vec{u}^{(N)} - \vec{U}^{(N)}) \cdot \widetilde{\vec{w}}^{(N)} \, d\vec{x}.$$

Proof. The linearity of the operator $M'(\mathbf{u}, \mathbf{p}, \mathbf{g}, \mathbf{s})$ is obvious and its boundedness follows easily from the continuity of the forms $a(\cdot, \cdot)$, $b(\cdot, \cdot)$, and $c(\cdot, \cdot, \cdot)$. Likewise, the linearity and boundedness of the operator $Q'(\mathbf{u}, \mathbf{p}, \mathbf{g}, \mathbf{s})$ are obvious.

The fact that $M'(\mathbf{u}, \mathbf{p}, \mathbf{g}, \mathbf{s})$ is the strict derivative of the mapping $M(\mathbf{u}, \mathbf{p}, \mathbf{g}, \mathbf{s})$ follows also from the continuity of the trilinear form $c(\cdot, \cdot, \cdot)$. Indeed, we have that for any $(\mathbf{u},\mathbf{p},\mathbf{g},\mathbf{s}) \in X = \mathbf{B}_1$ and for all $(\mathbf{w},\mathbf{r},\boldsymbol{\beta}) \in \mathbf{B}_2^* = \mathbf{H}_0^1(\Omega) \times \mathbf{L}_0^2(\Omega) \times \mathbb{R}$,

$$\begin{aligned}
&\Big\langle(\mathbf{w},\mathbf{r},\boldsymbol{\beta}), M(\mathbf{u}_1,\mathbf{p}_1,\mathbf{g}_1,\mathbf{s}_1) - M(\mathbf{u}_2,\mathbf{p}_2,\mathbf{g}_2,\mathbf{s}_2)\\
&\qquad\qquad -M'(\mathbf{u},\mathbf{p},\mathbf{g},\mathbf{s}) \cdot (\mathbf{u}_1-\mathbf{u}_2,\mathbf{p}_1-\mathbf{p}_2,\mathbf{g}_1-\mathbf{g}_2,\mathbf{s}_1-\mathbf{s}_2)\Big\rangle\\
&\quad = \sum_{n=1}^{N} \beta^{(n)}\Big((g_1^{(n)},g_1^{(n)}) + (s_1^{(n)})^2 - (g_2^{(n)},g_2^{(n)}) - (s_2^{(n)})^2\\
&\qquad\qquad -2(g^{(n)},g_1^{(n)}-g_2^{(n)}) - 2s^{(n)}(s_1^{(n)}-s_2^{(n)})\Big)\\
&\qquad + \sum_{n=1}^{N}\Big(c(\vec{u}_1^{(n)},\vec{u}_1^{(n)},\vec{w}^{(n)}) - c(\vec{u}_2^{(n)},\vec{u}_2^{(n)},\vec{w}^{(n)})\\
&\qquad\qquad -c(\vec{u}_1^{(n)}-\vec{u}_2^{(n)},\vec{u}^{(n)},\vec{w}^{(n)}) - c(\vec{u}^{(n)},\vec{u}_1^{(n)}-\vec{u}_2^{(n)},\vec{w}^{(n)})\Big)\\
&\quad = -\sum_{n=1}^{N}\Big(c(\vec{u}_1^{(n)}-\vec{u}_2^{(n)},\vec{u}^{(n)}-\vec{u}_1^{(n)},\vec{w}^{(n)}) + c(\vec{u}^{(n)}-\vec{u}_2^{(n)},\vec{u}_1^{(n)}-\vec{u}_2^{(n)},\vec{w}^{(n)})\Big)\\
&\qquad - \sum_{n=1}^{N}\beta^{(n)}\Big((g_1^{(n)}-g_2^{(n)},g^{(n)}-g_1^{(n)}) + (g_1^{(n)}-g_2^{(n)},g^{(n)}-g_2^{(n)})\\
&\qquad\qquad +(s_1^{(n)}-s_2^{(n)})(s^{(n)}-s_1^{(n)}) + (s_1^{(n)}-s_2^{(n)})(s^{(n)}-s_2^{(n)})\Big),
\end{aligned}$$

so that using the continuity of the form $c(\cdot,\cdot,\cdot)$, we have, for some constants $C_1, C_2 > 0$,

$$\begin{aligned}
&\|M(\mathbf{u}_1,\mathbf{p}_1,\mathbf{g}_1,\mathbf{s}_1) - M(\mathbf{u}_2,\mathbf{p}_2,\mathbf{g}_2,\mathbf{s}_2)\\
&\qquad -M'(\mathbf{u},\mathbf{p},\mathbf{g},\mathbf{s}) \cdot (\mathbf{u}_1-\mathbf{u}_2,\mathbf{p}_1-\mathbf{p}_2,\mathbf{g}_1-\mathbf{g}_2,\mathbf{s}_1-\mathbf{s}_2)\|_{\mathbf{B}_2}\\
&\quad \le C_1\Big(\|\mathbf{u}_1-\mathbf{u}_2\|_1(\|\mathbf{u}-\mathbf{u}_1\|_1 + \|\mathbf{u}-\mathbf{u}_2\|_1)\\
&\qquad +\|\mathbf{g}_1-\mathbf{g}_2\|(\|\mathbf{g}-\mathbf{g}_1\| + \|\mathbf{g}-\mathbf{g}_2\|)\\
&\qquad +|\mathbf{s}_1-\mathbf{s}_2|(|\mathbf{s}-\mathbf{s}_1| + |\mathbf{s}-\mathbf{s}_2|)\Big)\\
&\quad \le C_2\|(\mathbf{u}_1-\mathbf{u}_2,\mathbf{p}_1-\mathbf{p}_2,\mathbf{g}_1-\mathbf{g}_2,\mathbf{s}_1-\mathbf{s}_2)\|_{\mathbf{B}_1}\\
&\qquad \Big(\|(\mathbf{u}-\mathbf{u}_1,\mathbf{p}-\mathbf{p}_1,\mathbf{g}-\mathbf{g}_1,\mathbf{s}-\mathbf{s}_1)\|_{\mathbf{B}_1}\\
&\qquad +\|(\mathbf{u}-\mathbf{u}_2,\mathbf{p}-\mathbf{p}_2,\mathbf{g}-\mathbf{g}_2,\mathbf{s}-\mathbf{s}_2)\|_{\mathbf{B}_1}\Big)\,.
\end{aligned}$$

Then, for any $\epsilon > 0$, by choosing $\delta = \epsilon/(2C_2)$ we have that whenever $\|(\mathbf{u}-\mathbf{u}_1,\mathbf{p}-\mathbf{p}_1,\mathbf{g}-\mathbf{g}_1,\mathbf{s}-\mathbf{s}_1)\|_{\mathbf{B}_1} < \delta$ and $\|(\mathbf{u}-\mathbf{u}_2,\mathbf{p}-\mathbf{p}_2,\mathbf{g}-\mathbf{g}_2,\mathbf{s}-\mathbf{s}_2)\|_{\mathbf{B}_1} < \delta$,

$$\begin{aligned}
&\|M(\mathbf{u}_1,\mathbf{p}_1,\mathbf{g}_1,\mathbf{s}_1) - M(\mathbf{u}_2,\mathbf{p}_2,\mathbf{g}_2,\mathbf{s}_2)\\
&\qquad -M'(\mathbf{u},\mathbf{p},\mathbf{g},\mathbf{s}) \cdot (\mathbf{u}_1-\mathbf{u}_2,\mathbf{p}_1-\mathbf{p}_2,\mathbf{g}_1-\mathbf{g}_2,\mathbf{s}_1-\mathbf{s}_2)\|_{\mathbf{B}_2}\\
&\quad \le \epsilon\|(\mathbf{u}_1-\mathbf{u}_2,\mathbf{p}_1-\mathbf{p}_2,\mathbf{g}_1-\mathbf{g}_2,\mathbf{s}_1-\mathbf{s}_2)\|_{\mathbf{B}_1}\,.
\end{aligned}$$

Thus, the mapping M is strictly differentiable on all of $\mathbf{B}_1$ and its strict derivative is given by M'.

Using the strict differentiability of the mapping M, it is then easy to show that the mapping Q is also strictly differentiable and that its strict derivative is given by Q'. □

Next, we prove some further properties of the derivatives of the mappings M and Q. We will be assuming that the optimal control does not vanish, i.e., that $\widehat{g}^{(n)} \neq 0$ for all $n = 1, \dots, N$. This is permissible since if $\widehat{g}^{(n)} = 0$ for some n, then it is clear that the constraint $\|\widehat{g}^{(n)}\| \le 1$ is satisfied everywhere in a neighborhood of $\widehat{g}^{(n)} \in L^2(\Omega)$. Since in any case our notion of an optimal control is a local one, see, e.g., (2.6), we can delete that constraint since it is automatically satisfied.

LEMMA 3.4. *Given $T > 0$, $K > 0$, $\Delta t = T/N$ for $N > 0$, $\vec{u}_0 \in V(\Omega)$, and $\vec{U} \in \mathcal{U}_{ad}$. Let $(\widehat{\mathbf{u}}, \widehat{\mathbf{p}}, \widehat{\mathbf{g}}, \widehat{\mathbf{s}}) \in \mathbf{B}_1$ denote a solution of the semidiscrete-in-time optimal control problem. Then, if $\widehat{g}^{(n)} \neq 0$ for all $n = 1, \dots, N$, we have*

(i) *the operator $M'(\widehat{\mathbf{u}}, \widehat{\mathbf{p}}, \widehat{\mathbf{g}}, \widehat{\mathbf{s}})$ has closed range in $\mathbf{B}_2$;*

(ii) *the operator $Q'(\widehat{\mathbf{u}}, \widehat{\mathbf{p}}, \widehat{\mathbf{g}}, \widehat{\mathbf{s}})$ has closed range in $\mathbb{R} \times \mathbf{B}_2$;*

(iii) *the operator $Q'(\widehat{\mathbf{u}}, \widehat{\mathbf{p}}, \widehat{\mathbf{g}}, \widehat{\mathbf{s}})$ is not onto $\mathbb{R} \times \mathbf{B}_2$;*

(iv) *for Δt sufficiently small the operator $M'(\widehat{\mathbf{u}}, \widehat{\mathbf{p}}, \widehat{\mathbf{g}}, \widehat{\mathbf{s}})$ is onto $\mathbf{B}_2$.*

Proof. Let the bounded linear operator $S : \mathbf{B}_1 \to \mathbf{B}_2$ be defined as follows: $S \cdot (\widetilde{\mathbf{w}}, \widetilde{\mathbf{r}}, \widetilde{\mathbf{h}}, \widetilde{\mathbf{s}}) = (\overline{\mathbf{f}}, \overline{\mathbf{z}}, \overline{\mathbf{l}})$ for $(\widetilde{\mathbf{w}}, \widetilde{\mathbf{r}}, \widetilde{\mathbf{h}}, \widetilde{\mathbf{s}}) \in \mathbf{B}_1$ and $(\overline{\mathbf{f}}, \overline{\mathbf{z}}, \overline{\mathbf{l}}) \in \mathbf{B}_2$ if and only if

$$(3.9)\quad \begin{cases} \dfrac{1}{\Delta t}(\widetilde{w}^{(n)} - \widetilde{w}^{(n-1)}, \vec{v}) + \nu a(\widetilde{w}^{(n)}, \vec{v}) \\ \qquad\qquad + b(\vec{v}, \widetilde{r}^{(n)}) - K(\widetilde{h}^{(n)}, \vec{v}) = (\overline{f}^{(n)}, \vec{v}) \\ \qquad\qquad\qquad\qquad \forall\, \vec{v} \in H_0^1(\Omega)\,, \quad \text{for } n = 1, 2, \dots, N\,, \\ b(\widetilde{w}^{(n)}, q) = (\overline{z}^{(n)}, q) \quad \forall\, q \in L_0^2(\Omega)\,, \quad \text{for } n = 1, 2, \dots, N\,, \\ 2(\widetilde{h}^{(n)}, \widehat{g}^{(n)}) + 2\widetilde{s}^{(n)}\widehat{s}^{(n)} = \overline{l}^{(n)}, \quad \text{for } n = 1, 2, \dots, N\,, \\ \widetilde{w}^{(n)} = \vec{0} \quad \text{on } \Gamma\,, \quad \text{for } n = 1, 2, \dots, N\,, \\ \widetilde{w}^{(0)} = \vec{0} \quad \text{on } \Omega\,. \end{cases}$$

The third equation poses no difficulty. In fact, for all $n = 1, 2, \dots, N$, we may choose $\widetilde{s}^{(n)} = 0$ and $\widetilde{h}^{(n)} = \overline{l}^{(n)}\widehat{g}^{(n)}/(2\|\widehat{g}^{(n)}\|^2)$ which is permissible since, by hypothesis, $\|\widehat{g}^{(n)}\| \neq 0$. Then the third equation in (3.9) is satisfied for any choice of $\overline{l}^{(n)} \in \mathbb{R}$. Thus, the question of the closeness of the range of the operator $S : \mathbf{B}_1 \to \mathbf{B}_2$ reduces to the like question for the inhomogeneous semidiscrete-in-time Stokes operator $\widetilde{S} : \mathbf{H}_0^1(\Omega) \times \mathbf{L}_0^2(\Omega) \to \mathbf{H}^{-1}(\Omega) \times \mathbf{L}_0^2(\Omega)$ defined as follows: $\widetilde{S} \cdot (\widetilde{\mathbf{w}}, \widetilde{\mathbf{r}}) = (\widetilde{\mathbf{f}}, \overline{\mathbf{r}})$ for $(\widetilde{\mathbf{w}}, \widetilde{\mathbf{r}}) \in \mathbf{H}_0^1(\Omega) \times \mathbf{L}_0^2(\Omega)$ and $(\widetilde{\mathbf{f}}, \overline{\mathbf{r}}) \in \mathbf{H}^{-1}(\Omega) \times \mathbf{L}_0^2(\Omega)$ if and only if

$$\begin{cases} \dfrac{1}{\Delta t}(\widetilde{w}^{(n)} - \widetilde{w}^{(n-1)}, \vec{v}) + \nu a(\widetilde{w}^{(n)}, \vec{v}) + b(\vec{v}, \widetilde{r}^{(n)}) \\ \qquad\qquad = (\widetilde{f}^{(n)}, \vec{v}) \qquad \forall\, \vec{v} \in H_0^1(\Omega)\,, \quad \text{for } n = 1, 2, \dots, N\,, \\ b(\widetilde{w}^{(n)}, q) = (\overline{z}^{(n)}, q) \quad \forall\, q \in L_0^2(\Omega)\,, \quad \text{for } n = 1, 2, \dots, N\,, \\ \widetilde{w}^{(n)} = \vec{0} \quad \text{on } \Gamma\,, \quad \text{for } n = 1, 2, \dots, N\,, \\ \widetilde{w}^{(0)} = \vec{0} \quad \text{on } \Omega\,. \end{cases}$$

The fact that the operator $\widetilde{S}$ has closed range in $\mathbf{H}^{-1}(\Omega) \times \mathbf{L}_0^2(\Omega)$ follows easily form well-known results for the semidiscrete-in-time Stokes equations; see, e.g., [33]. We can then conclude that the operator S has closed range in $\mathbf{B}_2$, and since the operator $M'(\widehat{\mathbf{u}}, \widehat{\mathbf{p}}, \widehat{\mathbf{g}}, \widehat{\mathbf{s}})$ is a compact perturbation of the operator S, we have, from the Fredholm theory, that $M'(\widehat{\mathbf{u}}, \widehat{\mathbf{p}}, \widehat{\mathbf{g}}, \widehat{\mathbf{s}})$ itself has closed range in $\mathbf{B}_2$.

Starting from (i), the proof of (ii) and (iii) can be found in [18], [19], or [20].

For (iv), we must show that (3.7), with $(\mathbf{u}, \mathbf{p}, \mathbf{g}, \mathbf{s}) = (\widehat{\mathbf{u}}, \widehat{\mathbf{p}}, \widehat{\mathbf{g}}, \widehat{\mathbf{s}})$, has a solution $(\widetilde{\mathbf{w}}, \widetilde{\mathbf{r}}, \widetilde{\mathbf{h}}, \widetilde{\mathbf{s}}) \in \mathbf{B_1}$ for all $(\overline{\mathbf{f}}, \overline{\mathbf{z}}, \overline{\mathbf{l}}) \in \mathbf{B}_2$. Since by (i) we have that $Ran(M'(\widehat{\mathbf{u}}, \widehat{\mathbf{p}}, \widehat{\mathbf{g}}, \widehat{\mathbf{s}}))$

is closed in $\mathbf{B}_2$ and since then $Ran(M'(\widehat{\mathbf{u}},\widehat{\mathbf{p}},\widehat{\mathbf{g}},\widehat{\mathbf{s}})) = \mathrm{Ker}(M'^*(\widehat{\mathbf{u}},\widehat{\mathbf{p}},\widehat{\mathbf{g}},\widehat{\mathbf{s}}))^\perp$, we can instead show that $\mathrm{Ker}(M'^*(\widehat{\mathbf{u}},\widehat{\mathbf{p}},\widehat{\mathbf{g}},\widehat{\mathbf{s}})) = \{0\}$, i.e., that $(\mathbf{w},\mathbf{r},\boldsymbol{\beta}) = (\mathbf{0},\mathbf{0},\mathbf{0})$ is the only solution of

$$(3.10)\qquad \begin{cases} -\dfrac{1}{\Delta t}(\vec{w}^{(n)} - \vec{w}^{(n-1)},\vec{v}) + \nu a(\vec{w}^{(n-1)},\vec{v}) + c(\vec{w}^{(n-1)},\widehat{u}^{(n)},\vec{v}) \\ \qquad\qquad + c(\widehat{u}^{(n)},\vec{w}^{(n-1)},\vec{v}) + b(\vec{v},r^{(n-1)}) = 0 \\ \qquad\qquad\qquad\qquad \forall\,\vec{v}\in H^1_0(\Omega)\,, \quad \text{for } n=1,2,\ldots,N\,, \\ b(\vec{w}^{(n-1)},q) = 0 \quad \forall\, q\in L^2_0(\Omega)\,, \quad \text{for } n=1,2,\ldots,N\,, \\ \beta^{(n-1)}(\widehat{g}^{(n)},h) - K(\vec{w}^{(n-1)},h) = 0 \\ \qquad\qquad\qquad\qquad \forall\, h\in L^2(\Omega)\,, \quad \text{for } n=1,2,\ldots,N\,, \\ \widehat{s}^{(n)}\beta^{(n-1)} = 0, \quad \text{for } n=1,2,\ldots,N\,, \\ \vec{w}^{(n-1)} = \vec{0} \quad \text{on } \Gamma\,, \quad \text{for } n=1,2,\ldots,N\,, \\ \vec{w}^{(N)} = \vec{0} \quad \text{on } \Omega\,. \end{cases}$$

It is well known (see, e.g., [34]) that in two dimensions, the trilinear form $c(\cdot,\cdot,\cdot)$ satisfies, for some constant $K>0$ depending only on Ω,

$$c(\vec{w},\vec{u},\vec{v}) \le K\|\vec{u}\|_1\|\vec{w}\|^{1/2}\|\vec{w}\|_1^{1/2}\|\vec{v}\|^{1/2}\|\vec{v}\|_1^{1/2} \qquad \forall\,\vec{w},\vec{u},\vec{v}\in H^1(\Omega)\,.$$

Then, from (3.10), one obtains, for $n=1,2,\ldots,N$,

$$(3.11)\quad \left(1-\frac{K^2\Delta t}{\epsilon}\|\widehat{u}^{(n)}\|_1^2\right)\|\vec{w}^{(n-1)}\|^2 - \|\vec{w}^{(n)}\|^2 + (2\nu-\epsilon)\Delta t\|\vec{w}^{(n-1)}\|_1^2 \le 0\,.$$

Let

$$G^{(n)} = 1 - \Delta t\left(\frac{K^2}{\epsilon}\|\widehat{u}^{(n)}\|_1^2\right)$$

so that (3.11) yields that

$$(3.12)\qquad G^{(n)}\|\vec{w}^{(n-1)}\|^2 + (2\nu-\epsilon)\Delta t\|\vec{w}^{(n-1)}\|_1^2 \le \|\vec{w}^{(n)}\|^2\,.$$

We choose ϵ sufficiently small so that $(2\nu-\epsilon)>0$. Now, if

$$(3.13)\qquad \Delta t \le \frac{\epsilon}{K^2\|\widehat{u}^{(n)}\|_1^2} \qquad \text{for } n=1,2,\ldots,N\,,$$

then $G^{(n)}>0$ and thus, from (3.12) and $\vec{w}^{(N)} = \vec{0}$, we have that $\|\vec{w}^{(n-1)}\| = 0$ for $n=1,2,\ldots,N$. Then, it follows that $\boldsymbol{\beta}$ and $\mathbf{r}$ must also vanish so that $\mathrm{Ker}(M'^*(\widehat{\mathbf{u}},\widehat{\mathbf{p}},\widehat{\mathbf{g}},\widehat{\mathbf{s}}))^\perp = 0$, and thus the operator $M'(\widehat{\mathbf{u}},\widehat{\mathbf{p}},\widehat{\mathbf{g}},\widehat{\mathbf{s}})$ is onto $\mathbf{B}_2$. □

The first-order necessary condition follows easily from the fact that the operator $Q'(\widehat{\mathbf{u}},\widehat{\mathbf{p}},\widehat{\mathbf{g}},\widehat{\mathbf{s}})$ is not onto $\mathbb{R}\times\mathbf{B}_2$; see, e.g., [18], [19], or [20].

THEOREM 3.5. *Given $T>0$, $K>0$, $\Delta t = T/N$ for $N>0$, $\vec{u}_0\in V(\Omega)$, and $\vec{U}\in\mathcal{U}_{ad}$. If $(\widehat{\mathbf{u}},\widehat{\mathbf{p}},\widehat{\mathbf{g}},\widehat{\mathbf{s}})\in\mathbf{B}_1$ is a solution of the semidiscrete-in-time optimal control problem, then if $\widehat{g}^{(n)}\neq 0$ for all $n=1,\ldots,N$, we have that*

(i) *there exists a nonzero Lagrange multiplier $(\lambda,\mathbf{w},\mathbf{r},\boldsymbol{\beta})\in\mathbb{R}\times\mathbf{H}^1_0(\Omega)\times\mathbf{L}^2_0(\Omega)\times\mathbb{R}$ satisfying the Euler equations*

$$(3.14)\quad \begin{aligned} &\lambda\,(\mathcal{J}^N)'(\widehat{\mathbf{u}})\cdot(\widetilde{\mathbf{w}},\widetilde{\mathbf{r}},\widetilde{\mathbf{h}},\widetilde{\mathbf{s}}) + \Big\langle(\mathbf{w},\mathbf{r},\boldsymbol{\beta}), M'(\widehat{\mathbf{u}},\widehat{\mathbf{p}},\widehat{\mathbf{g}},\widehat{\mathbf{s}})\cdot(\widetilde{\mathbf{w}},\widetilde{\mathbf{r}},\widetilde{\mathbf{h}},\widetilde{\mathbf{s}})\Big\rangle = 0 \\ &\qquad\qquad\qquad\qquad\qquad\qquad \forall\,(\widetilde{\mathbf{w}},\widetilde{\mathbf{r}},\widetilde{\mathbf{h}},\widetilde{\mathbf{s}})\in\mathbf{B}_1\,, \end{aligned}$$

where $\langle\cdot,\cdot\rangle$ denotes the duality pairing between $\mathbf{B}_2$ and $\mathbf{B}_2^*$;

(ii) *if* $(M'(\widehat{\mathbf{u}},\widehat{\mathbf{p}},\widehat{\mathbf{g}},\widehat{\mathbf{s}}))$ *is onto* $\mathbf{B}_2$*, e.g., if* Δt *is sufficiently small so that* (3.13) *holds, then* $\lambda \neq 0$*.*

Remark 3.6. If $\lambda \neq 0$, then it is clear that we may assign an arbitrary value to it.

Remark 3.7. If $\lambda = 0$, then we have, from (3.14), that $M'^*(\widehat{\mathbf{u}},\widehat{\mathbf{p}},\widehat{\mathbf{g}},\widehat{\mathbf{s}})\cdot(\mathbf{w},\mathbf{r},\boldsymbol{\beta}) = 0$; i.e., $0 \neq (\mathbf{w},\mathbf{r},\boldsymbol{\beta}) \in \operatorname{Ker}(M'^*(\widehat{\mathbf{u}},\widehat{\mathbf{p}},\widehat{\mathbf{g}},\widehat{\mathbf{s}}))$.

3.3. The optimality system. Next, we examine the first-order necessary condition (3.14) to derive an optimality system from which semidiscrete-in-time optimal states and controls may be determined. We will find, as in the continuous case, that the optimal control $\widehat{\mathbf{g}}$ is proportional to the solution of an adjoint system of equations.

Theorem 3.8. *Given* $T > 0$*,* $K > 0$*,* $\Delta t = T/N$ *for* $N > 0$*,* $\vec{u}_0 \in V(\Omega)$*, and* $\vec{U} \in \mathcal{U}_{ad}$*. Let* $(\widehat{\mathbf{u}},\widehat{\mathbf{p}},\widehat{\mathbf{g}},\widehat{\mathbf{s}}) \in \mathbf{B}_1$ *denote a solution of the semidiscrete-in-time optimal control problem. Assume that* $\widehat{g}^{(n)} \neq 0$ *for all* $n = 1,\dots,N$ *and* $\operatorname{Ker}(M'^*(\widehat{\mathbf{u}},\widehat{\mathbf{p}},\widehat{\mathbf{g}},\widehat{\mathbf{s}})) = 0$*. Then, if* $\vec{w}^{(n-1)} \neq \vec{0}$*,*

$$\|\vec{w}^{(n-1)}\|\widehat{g}^{(n)} = -\vec{w}^{(n-1)} \quad \textit{for } n = 1,2,\dots,N\,, \tag{3.15}$$

where $(\mathbf{w},\mathbf{r}) \in \mathbf{H}^1_0(\Omega) \times \mathbf{L}^2_0(\Omega)$ *satisfies the adjoint problem*

$$\begin{cases} -\dfrac{1}{\Delta t}(\vec{w}^{(n)} - \vec{w}^{(n-1)},\vec{v}) + \nu a(\vec{v},\vec{w}^{(n-1)}) + c(\vec{v},\widehat{u}^{(n)},\vec{w}^{(n-1)}) \\ \qquad + c(\widehat{u}^{(n)},\vec{v},\vec{w}^{(n-1)}) + b(\vec{v},r^{(n-1)}) = \alpha(\widehat{u}^{(n)} - \vec{U}^{(n)},\vec{v}) \\ \qquad\qquad \forall\, \vec{v} \in H^1_0(\Omega)\,, \quad \textit{for } n = 1,,\dots,N\,, \\ b(\vec{w}^{(n-1)},q) = 0 \quad \forall\, q \in L^2_0(\Omega)\,, \quad \textit{for } n = 1,\dots,N\,, \\ \vec{w}^{(n-1)} = \vec{0} \quad \text{on } \Gamma\,, \quad \textit{for } n = 1,\dots,N\,, \\ \vec{w}^{(N)} = \gamma(\vec{u}^{(N)} - \vec{U}^{(N)}) \quad \text{in } \Omega\,. \end{cases} \tag{3.16}$$

Proof. The first-order necessary condition (3.14) is equivalent to

$$\begin{aligned} &\lambda\left(\alpha\Delta t\sum_{n=1}^{N}\left((\widehat{u}^{(n)} - \vec{U}^{(n)}),\widetilde{w}^{(n)}\right) + \gamma\left((\widehat{u}^{(N)} - \vec{U}^{(N)}),\widetilde{w}^{(N)}\right)\right) \\ &\quad + \Delta t\sum_{n=1}^{N}\beta^{(n-1)}\left[\left(\widehat{g}^{(n)},\widetilde{h}^{(n)}\right) + \widehat{s}^{(n)}\widetilde{s}^{(n)}\right] + \Delta t\sum_{n=1}^{N}\Big[\frac{1}{\Delta t}(\widetilde{w}^{(n)} - \widetilde{w}^{(n-1)},\vec{w}^{(n-1)}) \\ &\qquad + \nu a(\widetilde{w}^{(n)},\vec{w}^{(n-1)}) + c(\widetilde{w}^{(n)},\widehat{u}^{(n)},\vec{w}^{(n-1)}) + c(\widehat{u}^{(n)},\widetilde{w}^{(n)},\vec{w}^{(n-1)}) \\ &\qquad + b(\vec{w}^{(n-1)},\widetilde{r}^{(n)}) - K(\widetilde{h}^{(n)},\vec{w}^{(n-1)}) + b(\widetilde{w}^{(n)},r^{(n-1)})\Big] = 0 \end{aligned}$$

for all $(\widetilde{\mathbf{w}},\widetilde{\mathbf{r}},\widetilde{\mathbf{h}},\widetilde{\mathbf{s}}) \in \mathbf{B}_1$. Since (iv) of Lemma 3.4 holds, we have, by Theorem 3.5, that $\lambda \neq 0$. We are free to choose $\lambda = -1$ (see Remark 3.6.)

Choosing $\widetilde{w}^{(n)} = 0$, $\widetilde{s}^{(n)} = 0$, and $\widetilde{h}^{(n)} = 0$ for all n in the first-order necessary condition yields, since $\widetilde{r}^{(n)}$ is arbitrary in $L^2_0(\Omega)$, the second equation in (3.16).

Choosing $\widetilde{w}^{(0)} = \vec{0}$, we have that

$$\sum_{n=1}^{N}(\widetilde{w}^{(n)} - \widetilde{w}^{(n-1)},\vec{w}^{(n-1)}) = -\sum_{n=1}^{N}(\widetilde{w}^{(n)},\vec{w}^{(n)} - \vec{w}^{(n-1)}) + (\widetilde{w}^{(N)},\vec{w}^{(N)})$$

so that choosing $\widetilde{r}^{(n)} = 0$, $\widetilde{s}^{(n)} = 0$, and $\widetilde{h}^{(n)} = 0$ for all n in the first-order necessary condition yields (recalling that $\lambda = -1$), for all $n = 1, 2, \dots, N$,

$$\begin{aligned}&\Big(-\gamma(\widehat{u}^{(N)} - \vec{U}^{(N)}) + \vec{w}^{(N)}, \widetilde{w}^{(N)}\Big)\\ &\quad -\Delta t \sum_{n=1}^{N} \Big[-\frac{1}{\Delta t}(\widetilde{w}^{(n)}, \vec{w}^{(n)} - \vec{w}^{(n-1)}) + \nu a(\widetilde{w}^{(n)}, \vec{w}^{(n-1)}) + c(\widetilde{w}^{(n)}, \widehat{u}^{(n)}, \vec{w}^{(n-1)})\\ &\quad + c(\widehat{u}^{(n)}, \widetilde{w}^{(n)}, \vec{w}^{(n-1)}) + b(\widetilde{w}^{(n)}, r^{(n-1)}) - \alpha\left((\widehat{u}^{(n)} - \vec{U}^{(n)}), \widetilde{w}^{(n)}\right)\Big] = 0\end{aligned}$$

from which the first and last equations in (3.16) follow. The third equation in (3.16) holds trivially since $\mathbf{w} \in \mathbf{H}_0^1(\Omega)$. Thus, we have shown that (3.16) holds.

Choosing $\widetilde{w}^{(n)} = 0$, $\widetilde{r}^{(n)} = 0$, and $\widetilde{h}^{(n)} = 0$ for all n in the first-order necessary condition yields, since $\widetilde{s}^{(n)}$ is arbitrary in $\mathbb{R}$,

$$\beta^{(n-1)}\widehat{s}^{(n)} = 0 \qquad \text{for } n = 1, 2, \dots, N\,. \tag{3.17}$$

Choosing $\widetilde{w}^{(n)} = 0$, $\widetilde{r}^{(n)} = 0$, and $\widetilde{s}^{(n)} = 0$ in the first-order necessary condition yields, since $\widetilde{h}^{(n)}$ is arbitrary in $\mathbf{L}^2(\Omega)$,

$$\beta^{(n-1)}\widehat{g}^{(n)} = K\vec{w}^{(n-1)} \qquad \text{for } n = 1, 2, \dots, N\,. \tag{3.18}$$

If $\vec{w}^{n-1} \neq \vec{0}$, then (3.18) requires that $\beta^{(n-1)} \neq 0$ (since $\widehat{g}^{(n)} \neq \vec{0}$) and then (3.17) yields $\widehat{s}(n) = 0$. Then the third equation in (3.5) yields that $\|\widehat{g}^{(n)}\| = 1$ and then (3.18) yields $|\beta^{(n-1)}| = K\|\vec{w}^{(n-1)}\|$, i.e., $\widehat{g}^{(n)} = \pm\,\vec{w}^{(n-1)}/\|\vec{w}^{(n-1)}\|$. The first-order necessary condition cannot determine the sign since one corresponds to a local maximum and the other to a local minimum. To determine the sign, we examine the functional $\mathcal{J}^N(\mathbf{u}(\mathbf{g}))$ in the neighborhood of an optimal point $\widehat{\mathbf{g}}$. Let $\mathbf{g} = \widehat{\mathbf{g}} + \epsilon\widetilde{\mathbf{h}}$ for $\epsilon > 0$, where $\widetilde{\mathbf{h}} \in \mathbf{L}^2(\Omega)$ is an arbitrary admissible variation. Since the admissible states and controls satisfy the discretized Navier–Stokes equations, we must have that the corresponding variations, i.e., the sensitivities, $(\widetilde{\mathbf{w}}, \widetilde{\mathbf{r}})$ satisfy

$$\begin{cases} \dfrac{1}{\Delta t}(\widetilde{w}^{(n)} - \widetilde{w}^{(n-1)}, \vec{v}) + \nu a(\widetilde{w}^{(n)}, \vec{v}) + c(\widetilde{w}^{(n)}, \widehat{u}^{(n)}, \vec{v})\\ \qquad + c(\widehat{u}^{(n)}, \widetilde{w}^{(n)}, \vec{v}) + b(\vec{v}, \widetilde{r}^{(n)}) = K(\widetilde{h}^{(n)}, \vec{v})\\ \qquad\qquad \forall\, \vec{v} \in H_0^1(\Omega)\,, \quad \text{for } n = 1, 2, \dots, N\,,\\ b(\widetilde{w}^{(n)}, q) = 0 \quad \forall\, q \in L_0^2(\Omega)\,, \quad \text{for } n = 1, 2, \dots, N\,,\\ \widetilde{w}^{(n)} = \vec{0} \quad \text{on } \Gamma\,, \quad \text{for } n = 1, 2, \dots, N\,,\\ \widetilde{w}^{(0)} = \vec{0} \quad \text{on } \Omega\,. \end{cases} \tag{3.19}$$

Note that so far we have not imposed the requirement that admissible variations $\widetilde{\mathbf{h}}$ keep $\mathbf{g} = \widehat{\mathbf{g}} + \epsilon\widetilde{\mathbf{h}}$ within the constraint set $\|\mathbf{g}\| \leq 1$. The gradient of the functional $\mathcal{J}^N(\mathbf{u}(\widehat{\mathbf{g}}))$ in the direction of $\widetilde{\mathbf{h}}$ is then given by

$$\begin{aligned}(\mathcal{J}^N)'(\mathbf{u}(\widehat{\mathbf{g}})) \cdot \widetilde{\mathbf{h}} = \alpha\Delta t \sum_{n=1}^{N} \int_\Omega (\widehat{u}^{(n)} - \vec{U}^{(n)}) \cdot \widetilde{w}^{(n)}\, d\vec{x}\\ + \gamma \int_\Omega (\widehat{u}^{(N)} - \vec{U}^{(N)}) \cdot \widetilde{w}^{(N)}\, d\vec{x}\,.\end{aligned} \tag{3.20}$$

Combining (3.16), (3.19), and (3.20) yields

$$(\mathcal{J}^N)'(\mathbf{u}(\widehat{\mathbf{g}})) \cdot \widetilde{\mathbf{h}} = K\langle \mathbf{w}, \widetilde{\mathbf{h}} \rangle \,. \tag{3.21}$$

Now, choose $\widetilde{h}^{(j)} = -\widehat{g}^{(j)}$ for some j such that $\vec{w}^{(j-1)} \neq \vec{0}$ and $\widetilde{h}^{(n)} = \vec{0}$ for $n \neq j$ so that, since $\|\widehat{g}^{(j)}\| = 1$, for ϵ small enough we have that if $\vec{g}^{(j)} = \widehat{g}^{(j)} + \epsilon \widetilde{h}^{(j)}$, then $\|\vec{g}^{(j)}\| \leq 1$ so that $\vec{g}^{(j)}$ is admissible. (Note that $\widetilde{h}^{(j)} = \widehat{g}^{(j)}$ would take us out of the constraint set so that we need not consider that case here.) With $\widetilde{h}^{(j)} = -\widehat{g}^{(j)}$ and $\widetilde{h}^{(n)} = \vec{0}$ otherwise, we have from (3.18) and (3.21), that

$$\begin{aligned}(\mathcal{J}^N)'(\mathbf{u}(\widehat{\mathbf{g}}) \cdot \widetilde{\mathbf{h}} = K\langle \mathbf{w}, \widetilde{\mathbf{h}} \rangle = K \sum_{n=1}^{N} (\vec{w}^{(n-1)}, \widetilde{h}^{(n)}) \\ = -K(\vec{w}^{(j-1)}, \widehat{g}^{(j)}) = -\beta^{(j-1))} \|\widehat{g}^{(j)}\|^2 = -\beta^{(j-1)} \,.\end{aligned}$$

But, since we are entering the admissibility set from the optimal solution $\widehat{g}^{(j)}$, we must have that $(\mathcal{J}^N)'(\mathbf{u}(\widehat{\mathbf{g}})) \cdot \widetilde{\mathbf{h}} \geq 0$ for this choice of $\widetilde{\mathbf{h}}$ so that $\beta^{(j-1)} < 0$ and therefore $\widehat{g}^{(j)} = -\vec{w}^{(j-1)}/\|\vec{w}^{(j-1)}\|$. Since j is arbitrary such that $\vec{w}^{(j-1)} \neq 0$, we have that (3.15) holds. □

REMARK 3.9. If $\vec{w}^{(n-1)} = \vec{0}$ and $\vec{w}^{(n)} = \vec{0}$ for some n, then $\widehat{u}^{(n)} = \vec{U}^{(n)}$ and we can determine $\widehat{g}^{(n)}$ from the semidiscrete Navier–Stokes equations, i.e., there must exist a $P^{(n)}$ such that $(\vec{U}^{(n)}, P^{(n)})$ satisfy (3.1) for that particular value of n. If $\vec{w}^{(n-1)} = \vec{0}$ and $\vec{w}^{(n)} \neq \vec{0}$, then $\widehat{u}^{(n)} \neq \vec{U}^{(n)}$ and we can extend the control from the right and set $\widehat{g}^{(n)} = \widehat{g}^{(n+1)}$ or, if $n = N$, $\widehat{g}^{(N)} = -\vec{w}^{(N)}/\|\vec{w}^{(N)}\|$.

REMARK 3.10. Again, a joint rescaling of α and γ does not affect the solution of the semidiscrete-in-time optimal control problem.

We have seen that one may obtain a solution of the semidiscrete-in-time optimal control problem by solving the coupled system (if $\vec{w}^{(n-1)} \neq \vec{0}$ for $n = 1, 2, \ldots, N$)

$$\left\{ \begin{aligned}
&\frac{1}{\Delta t}(\widehat{u}^{(n)} - \widehat{u}^{(n-1)}, \vec{v}) + \nu a(\widehat{u}^{(n)}, \vec{v}) + c(\widehat{u}^{(n)}, \widehat{u}^{(n)}, \vec{v}) + b(\vec{v}, \widehat{p}^{(n)}) \\
&\qquad\qquad = K(\widehat{g}^{(n)}, \vec{v}) \quad \forall\, \vec{v} \in H_0^1(\Omega)\,, \qquad \text{for } n = 1, 2, \ldots, N\,, \\
&b(\widehat{u}^{(n)}, q) = 0 \quad \forall\, q \in L_0^2(\Omega)\,, \qquad \text{for } n = 1, 2, \ldots, N\,, \\
&\widehat{u}^{(n)} = 0 \quad \text{on } \Gamma\,, \qquad \text{for } n = 1, 2, \ldots, N\,, \\
&\widehat{u}^{(0)} = \widehat{u}_0(\vec{x}) \in V(\Omega)\,, \\
&\|\vec{w}^{(n-1)}\| \widehat{g}^{(n)} = -\vec{w}^{(n-1)} \quad \text{in } \Omega\,, \quad \text{for } n = 1, 2, \ldots, N\,, \\
&-\frac{1}{\Delta t}(\vec{w}^{(n)} - \vec{w}^{(n-1)}, \vec{v}) + \nu a(\vec{v}, \vec{w}^{(n-1)}) + c(\vec{v}, \widehat{u}^{(n)}, \vec{w}^{(n-1)}) \\
&\qquad + c(\widehat{u}^{(n)}, \vec{v}, \vec{w}^{(n-1)}) + b(\vec{v}, r^{(n-1)}) = \alpha(\widehat{u}^{(n)} - \vec{U}^{(n)}, \vec{v}) \\
&\qquad\qquad\qquad \forall\, \vec{v} \in H_0^1(\Omega)\,, \quad \text{for } n = 1, \ldots, N\,, \\
&b(\vec{w}^{(n-1)}, q) = 0 \quad \forall\, q \in L_0^2(\Omega)\,, \quad \text{for } n = 1, \ldots, N\,, \\
&\vec{w}^{(n-1)} = \vec{0} \quad \text{on } \Gamma\,, \quad \text{for } n = 1, \ldots, N\,, \\
&\vec{w}^{(N)} = \gamma(\widehat{u}^{(N)} - \vec{U}^{(N)}) \quad \text{in } \Omega\,.
\end{aligned} \right. \tag{3.22}$$

The above system of equations is a weak formulation of the system

$$\begin{cases} \dfrac{1}{\Delta t}(\widehat{u}^{(n)} - \widehat{u}^{(n-1)}) + (\widehat{u}^{(n)} \cdot \nabla)\widehat{u}^{(n)} - \nu\Delta\widehat{u}^{(n)} + \nabla\widehat{p}^{(n)} \\ \qquad\qquad\qquad = K\widehat{g}^{(n)} \quad \text{in } \Omega\,, \quad \text{for } n = 1, 2, \dots, N\,, \\ \nabla \cdot \widehat{u} = 0 \quad \text{in } \Omega\,, \quad \text{for } n = 1, 2, \dots, N\,, \\ \widehat{u}^{(n)} = 0 \quad \text{on } \Gamma\,, \quad \text{for } n = 1, 2, \dots, N\,, \\ \widehat{u}^{(0)} = \widehat{u}_0 \quad \text{in } \Omega\,, \\ \|\vec{w}^{(n-1)}\|\widehat{g}^{(n)} = -\vec{w}^{(n-1)} \quad \text{in } \Omega\,, \quad \text{for } n = 1, 2, \dots, N\,, \\ -\dfrac{1}{\Delta t}(\vec{w}^{(n)} - \vec{w}^{(n-1)}) - \nu\Delta\vec{w}^{(n-1)} + (\nabla\widehat{u}^{(n)})^T\vec{w}^{(n-1)} - (\widehat{u}^{(n)} \cdot \nabla)\vec{w}^{(n-1)} \\ \qquad\qquad +\nabla r^{(n-1)} = \alpha(\widehat{u}^{(n)} - \vec{U}^{(n)}) \quad \text{in } \Omega\,, \quad \text{for } n = 1, 2, \dots, N\,, \\ \nabla \cdot \vec{w}^{(n-1)} = 0 \quad \text{in } \Omega\,, \quad \text{for } n = 1, 2, \dots, N\,, \\ \vec{w}^{(n-1)} = \vec{0} \quad \text{on } \Gamma\,, \quad \text{for } n = 1, \dots, N\,, \\ \vec{w}^{(N)} = \gamma(\widehat{u}^{(N)} - \vec{U}^{(N)}) \quad \text{in } \Omega\,. \end{cases}$$

Remark 3.11. If $\lambda = 0$, then (3.15) still holds where $\vec{\mathbf{w}}$ is any nontrivial solution of the homogeneous system

$$\begin{cases} -\dfrac{1}{\Delta t}(\vec{w}^{(n)} - \vec{w}^{(n-1)}, \vec{v}) + \nu a(\vec{v}, \vec{w}^{(n-1)}) + c(\vec{v}, \widehat{u}^{(n)}, \vec{w}^{(n-1)}) \\ \qquad\qquad + c(\widehat{u}^{(n)}, \vec{v}, \vec{w}^{(n-1)}) + b(\vec{v}, r^{(n-1)}) = \vec{0} \\ \qquad\qquad\qquad\qquad \forall\, \vec{v} \in H_0^1(\Omega)\,, \quad \text{for } n = 1,, \dots, N\,, \\ b(\vec{w}^{(n-1)}, q) = 0 \quad \forall\, q \in L_0^2(\Omega)\,, \quad \text{for } n = 1, \dots, N\,, \\ \vec{w}^{(n-1)} = \vec{0} \quad \text{on } \Gamma\,, \quad \text{for } n = 1, \dots, N\,, \\ \vec{w}^{(N)} = \vec{0} \quad \text{in } \Omega\,; \end{cases}$$

see Remark (3.7).

We now examine the convergence of solutions of the semidiscrete-in-time optimal control system.

Theorem 3.12. *Given $K > 0$, $T > 0$, $\Delta t = T/N$, $\vec{u}_0 \in V(\Omega)$, and $\vec{U} \in \mathcal{U}_{ad}$. Then, for $\Delta T \to 0$, i.e., $N \to \infty$, the solution $\{(\widehat{u}^{(n)}, \widehat{g}^{(n)})\}_{n=1}^N$ of the system* (3.22) *converges to the solution $(\widehat{u}, \widehat{g})$ of the system* (2.14).

Proof. Let $\Delta t = T/N$, and let $\vec{u}\,'^N$ denote the piecewise linear function such that $\vec{u}\,'^{(n)} = (\vec{u}^{(n)} - \vec{u}^{(n-1)})/\Delta t$ for $n = 1, 2, \dots, N$. From the well-known theory on semidiscrete-in-time approximations of the Navier–Stokes equations (see, e.g., [33]), the sequences $\{\widehat{u}^N\}_{N=1}^\infty$, $\{\widehat{g}^N\}_{N=1}^\infty$, and $\{\widehat{u}\,'^N\}_{N=1}^\infty$ are uniformly bounded in $L^2((0,T); V(\Omega)) \cap L^\infty((0,T); W(\Omega))$, $\mathcal{B}$, and $L^2((0,T); V^*(\Omega))$, respectively. Then we can extract subsequences, which we again denote by $\{\widehat{u}^N\}$ and $\{\widehat{g}^N\}$ such that

$$\begin{cases} \widehat{u}^N \to \vec{u} & L^2(0, T, V(\Omega)) \text{ weakly}\,, \\ \widehat{u}^N \to \vec{u} & L^\infty(0, T, H(\Omega)) \text{ *-weakly}\,, \\ \widehat{g}^N \to \vec{g} & L^2(0, T, B(\Omega)) \text{ weakly}\,, \\ \widehat{u}\,'^N \to \vec{u}\,' & \quad L^2(0, T, V^*(\Omega)) \text{ weakly}\,. \end{cases}$$

The set $\mathcal{B}$ is a convex, closed set and thus weakly closed so that the limit $\vec{g}$ satisfies the bound $\|\vec{g}\| \leq 1$ a.e on $(0,T)$. Let $\mathcal{H}((0,T);n,m;V,V^*) = \{\vec{v} \in L^n((0,T);V) : \vec{v}\,' \in L^m((0,T);V^*)\}$. We have that $V(\Omega) \subset W(\Omega) \subset V^*(\Omega)$, where V and V^* are reflexive, the injections are continuous, and, from the Sobolev imbedding theorem, the imbedding $V(\Omega) \to W(\Omega)$ is compact. Then, the injection from $\mathcal{H}((0,T);2,2,V,V^*)$ into $L^2((0,T);W)$ is compact. We note that if the sequence $\vec{u}_k$ converges weakly in $L^2((0,T);V(\Omega))$ and the sequence $\vec{u}\,'_k$ converges weakly in $L^2((0,T);V^*(\Omega))$, then the sequence $\vec{u}_k$ converges strongly in $L^2((0,T);W(\Omega))$. (A proof of this result can be found in, e.g., [33].) As a consequence, the sequence $\widehat{u}^N$ converges strongly in $L^2((0,T);W(\Omega))$. Now we can pass to the limit in the system of equations and in the functional using standard techniques. The fact that the sequence $\widehat{u}^N$ converges weakly in $L^2((0,T);V(\Omega))$ and strongly in $L^2((0,T);W(\Omega))$ allows us to pass to the limit in the nonlinear term and thus show that the limit $(\vec{u},\vec{g})$ is a solution of the continuous optimal control problem. Thus, as $N \to \infty$, the solution of the semidiscrete optimal control problem converges to the corresponding solution of the continuous optimal control problem. □

4. Fully discrete time-space approximation.

4.1. Preliminaries. We consider only conforming finite element approximations. Let $X^h \subset H^1(\Omega)$ and $S^h \subset L^2(\Omega)$ be two families of finite dimensional subspaces parameterized by h that tends to zero. We also denote $X_0^h = X^h \cap H_0^1(\Omega)$, $S_0^h = S^h \cap L_0^2(\Omega)$, and $S_B^h = S^h \cap B(\Omega)$. We make the following assumptions on X^h and S^h.

Approximation hypotheses: there exist an integer l and a constant C, independent of h, $\vec{u}$, and p, such that for $1 \leq k \leq l$ we have

$$\inf_{\vec{u}_h \in X_0^h} \|\vec{u}_h - \vec{u}\|_1 \leq C h^k \|\vec{u}\|_{k+1} \quad \forall \vec{u} \in H^{k+1}(\Omega) \cap H_0^1(\Omega)\,, \tag{4.1}$$

$$\inf_{p_h \in S_0^h} \|p - p_h\| \leq C h^k \|p\|_k \qquad \forall p \in H^k(\Omega) \cap L_0^2(\Omega)\,. \tag{4.2}$$

The inf-sup condition or LBB condition: there exists a constant C', independent of h, such that

$$\inf_{0 \neq q_h \in S_0^h} \; \sup_{0 \neq \vec{u}_h \in X_0^h} \frac{\int_\Omega q_h \nabla \cdot \vec{u}_h}{\|\vec{u}_h\|_1 \|q_h\|} \geq C' > 0\,. \tag{4.3}$$

This condition assures the stability of the Navier–Stokes discrete solutions.

To preserve the antisymmetry of the trilinear form $c(\vec{u};\vec{v},\vec{w})$ on the finite element spaces we introduce the modified trilinear form (see [33])

$$\widetilde{c}(\vec{u};\vec{v},\vec{w}) = \frac{1}{2}\{c(\vec{u};\vec{v},\vec{w}) - c(\vec{u};\vec{w},\vec{v})\} \qquad \forall \vec{u},\vec{v},\vec{w} \in H_0^1(\Omega).$$

We can recall some useful formulas and inequalities that hold in a two-dimensional domain Ω :

$$\left.\begin{aligned} &\widetilde{c}(\vec{u};\vec{v},\vec{w}) = -\widetilde{c}(\vec{u};\vec{w},\vec{v})\,, \\ &\widetilde{c}(\vec{u};\vec{v},\vec{v}) = 0 \end{aligned}\right\} \quad \forall\, \vec{u};\vec{v},\vec{w} \in H^1(\Omega)$$

and (see, e.g., [33])

$$\left.\begin{aligned} &|\widetilde{c}(\vec{u};\vec{v},\vec{w})| \leq K_1 \|\nabla \vec{u}\| \cdot \|\vec{v}\|_{L^4(\Omega)} \|\nabla \vec{w}^{(n)}\|\,, \\ &|\widetilde{c}(\vec{u};\vec{v},\vec{w})| \leq K_2 \|\vec{u}\|^{\frac{1}{2}} \|\nabla \vec{u}\|^{\frac{1}{2}} \|\nabla \vec{v}\| \cdot \|\vec{w}\|^{\frac{1}{2}} \|\nabla \vec{w}\|^{\frac{1}{2}} \end{aligned}\right\} \quad \forall\, \vec{u};\vec{v},\vec{w} \in H^1(\Omega)\,.$$

We remark that the last inequality is true in the framework of the conforming finite element approximation and only in the two-dimensional case; see [33].

4.2. Formulation of the fully discrete optimal control approximation. Let $\sigma_N = \{t_n\}_{n=0}^N$ be a partition of $[0, T]$ into equal intervals $\Delta t = T/N$ with $t_0 = 0$ and $t_N = T$. On the finite element spaces $X_0^h \subset H_0^1(\Omega)$ and $S_0^h \subset L_0^2(\Omega)$ we assume that the hypotheses (4.1)–(4.3) hold. For each fixed Δt (or N) and for every involved quantity $q(t, \vec{x})$ we associate the corresponding set $\{q_h^{(n)}\}_{n=1}^N$ and a continuous linear function $\vec{q}_h^N(t, \vec{x})$ such that $\vec{q}_h^N(t_n, \vec{x}) = q_h(t_n, \vec{x})$ for all $n = 1, 2, \ldots, N$. We denote by $\mathbf{q}$ the vector $(q^{(1)}, q^{(2)}, \ldots, q^{(N)})$ of the discrete-time components. We assume that the control $\vec{f}_h^{(n)}$ is bounded by K so that $\|\vec{g}_h^{(n)}\| \leq 1$ for all $n = 1, 2, \ldots, N$.

Given $\Delta t = T/N$, $\{\vec{g}_h^{(n)}\}_{n=1}^N \in \mathbf{B}(\Omega)$, and $\vec{u}_0 \in V(\Omega)$, then $(\vec{\mathbf{u}}_h, \mathbf{p}_h) \in (\mathbf{X}_0^h \times \mathbf{S}_0^h)$ is said to be generalized solution for the fully discrete time-space approximation of the Navier–Stokes equations if $(u_h^{(n)}, p_h^{(n)})$ satisfies

$$(4.4)\qquad \begin{cases} \dfrac{1}{\Delta t}(\vec{u}_h^{(n)} - \vec{u}_h^{(n-1)}, \vec{v}_h) + \nu a(\vec{u}_h^{(n)}, \vec{v}_h) + \widetilde{c}(\vec{u}_h^{(n)}; \vec{u}_h^{(n)}, \vec{v}_h) \\ \qquad\qquad + \, b(\vec{v}_h, p^{(n)}) = K(\vec{g}_h^{(n)}, \vec{v}_h) \quad \forall \vec{v}_h \in X_0^h(\Omega)\,, \\ b(\vec{v}_h^{(n)}, q_h) = 0 \quad \forall q_h \in S_0^h(\Omega) \end{cases}$$

for $n = 1, 2, \ldots, N$ with initial velocity $\vec{u}_h^{(0)} = \Pi^h \vec{u}_0(\vec{x})$, where Π^h denotes the projection of the initial data $\vec{u}_0$ onto X^h.

The fully discretized functional is given by

$$(4.5)\qquad \mathcal{J}_h^N(\mathbf{u}_h(\mathbf{g})) = \frac{\alpha}{2}\Delta t \sum_{n=1}^N \|\vec{u}_h^{(n)} - \vec{U}^{(n)}\|^2 + \frac{\gamma}{2}\|\vec{u}_h^{(N)} - \vec{U}^{(N)}\|^2 \,.$$

The formulation of the optimal problem in the fully discrete approximation is then given by

> *given $\Delta t = T/N$, $\vec{u}_0 \in V(\Omega)$, and $\vec{U} \in U_{ad}$, find $(\mathbf{u}_h, \mathbf{p}_h, \mathbf{g}_h)$, a sequence in $(\mathbf{X}_0^h(\Omega) \times \mathbf{S}_0^h(\Omega) \times \mathbf{S}_B^h(\Omega))$, such that $(\mathbf{u}_h, \mathbf{p}_h)$ is the solution of* (4.4) *and minimizes the cost function in* (4.5).

The existence and convergence of the solution of the fully discrete optimal control problem can be proved in the same way as for semidiscrete-in-time case if we limit our analysis to conforming finite element methods. We can state that the fully discrete optimal solution $(\widehat{\mathbf{u}}_h, \widehat{g}_h)$ converges to the optimal solution $(\widehat{u}, \widehat{g})$ of the continuous problem as $\Delta t \to 0$, i.e., as $N \to \infty$ and $h \to 0$. The well-known corresponding theorems on fully discrete approximations of the Navier–Stokes equations can be found in, e.g., [33]. The optimal necessary condition can be found using the same techniques that were used for the semidiscrete-in-time case. Finally for completeness we can state the theorem that gives the control as a solution of the adjoint equation

THEOREM 4.1. *Let $\vec{u}_0 \in V(\Omega)$, $\vec{U} \in \mathcal{U}_{ad}$, and $\Delta t = T/N$. If $(\widehat{\mathbf{u}}_h, \widehat{\mathbf{g}}_h)$ is a solution of the fully discrete optimal control problem, then, if Δt is sufficiently small and if $\vec{w}_h^{(n-1)} \neq 0$ or all $n = 1, 2, \ldots, N$, we have that $\|\vec{w}_h^{(n-1)}\|\vec{g}_h^{(n)} = -\vec{w}_h^{(n-1)}$ for all $n = 1, 2, \ldots, N$, where, for $n = 1, 2 \ldots, N$, the functions $\vec{w}_h^{(n-1)} \in X_0^h$ are the solution* *of the discrete adjoint problem*

$$(4.6)\qquad \begin{cases} -\dfrac{1}{\Delta t}(\vec{w}_h^{(n)} - \vec{w}_h^{(n-1)}, \vec{v}_h) + \nu a(\vec{v}_h, \vec{w}_h^{(n-1)}) + \widetilde{c}(\vec{v}_h; \widehat{u}_h^{(n)}, \vec{w}_h^{(n-1)}) \\ \qquad\qquad + \ \widetilde{c}(\widehat{u}_h^{(n)}; \vec{v}_h, \vec{w}_h^{(n-1)}) + b(\vec{v}_h, r_h^{(n-1)}) \\ \qquad\qquad\qquad = \alpha(\widehat{u}_h^{(n)} - \vec{U}^{(n)}, \vec{v}_h) \quad \forall \vec{v}_h \in X_0^h(\Omega) \\ b(\vec{w}_h^{(n-1)}, q_h) = 0 \quad \forall q_h \in S_0^h(\Omega) \end{cases}$$

for $n = 1, 2, \ldots, N$ along with the terminal condition $\vec{w}_h^{(N)} = \gamma(\widehat{u}_h^{(N)} - \vec{U}^{(N)})$.

5. A projected gradient method. An approximation to the optimal control, state, and adjoint variable may be obtained by solving the fully discrete optimality system which consists of the following (after dropping the $\widehat{(\cdot)}$ notation to denote the optimal solution):

The discrete Navier–Stokes system

$$(5.1)\qquad \begin{cases} \dfrac{1}{\Delta t}(\vec{u}_h^{(n)} - \vec{u}_h^{(n-1)}, \vec{v}_h) + \nu a(\vec{u}_h^{(n)}, \vec{v}_h) + c(\vec{u}_h^{(n)}; \vec{u}_h^{(n)}, \vec{v}_h) \\ \qquad\qquad\qquad + \ b(\vec{v}_h, p_h^{(n)}) = K(\vec{g}_h^{(n)}, \vec{v}_h) \qquad \forall\, \vec{v}_h \in X_0^h(\Omega)\,, \\ b(\vec{u}_h^{(n)}, q_h) = 0 \qquad \forall\, q_h \in S_0^h(\Omega) \end{cases}$$

for $n = 1, 2, \ldots, N$, with initial velocity $\vec{u}_h^{(0)} = \pi^h \vec{u}_0$ and homogeneous boundary condition.

The discrete adjoint system

$$(5.2)\qquad \begin{cases} -\dfrac{1}{\Delta t}(\vec{w}_h^{(n)} - \vec{w}_h^{(n-1)}, \vec{v}_h) + \nu a(\vec{w}_h^{(n-1)}, \vec{v}_h) \\ \qquad\qquad + \ c(\vec{u}_h^{(n)}; \vec{v}_h, \vec{w}_h^{(n-1)}) + c(\vec{v}_h; \vec{u}_h^{(n)}; \vec{w}_h^{(n-1)}) \\ \qquad\qquad + \ b(\vec{v}_h, r_h^{(n-1)}) = \alpha(\vec{u}_h^{(n)} - \vec{U}^{(n)}, \vec{v}_h) \quad \forall\, \vec{v}_h \in X_0^h(\Omega)\,, \\ b(\vec{w}_h^{(n-1)}, q_h) = 0 \qquad \forall\, q_h \in S_0^h(\Omega) \end{cases}$$

for $n = 1, 2, \ldots, N$, with final condition $\vec{w}_h^{(N)} = \gamma(\vec{u}_h^{(N)} - \pi^h \vec{U}^{(N)})$ and homogeneous boundary condition.

The discrete optimality condition

$$(5.3)\qquad \|\vec{w}_h^{(n-1)}\| \vec{g}_h^{(n)} = -\vec{w}_h^{(n-1)}$$

for $n = 1, 2, \ldots, N$.

In practice, one cannot solve the systems (5.1)–(5.3) simultaneously; note that not only are all three systems coupled to each other, but the discrete Navier–Stokes system (5.1) marches *forward* in time starting from an initial condition, while the adjoint system (5.2) marches *backward* in time starting from a terminal condition.

We now consider a *gradient method* for the solution of the discrete optimality system (5.1)–(5.3). At each iteration the method requires the sequential solution of (5.1) and (5.2).

Let $\mathcal{J}_h^N(k) = \mathcal{J}_h^N(\mathbf{u}_h(\mathbf{g}_h(k)))$, where $\mathcal{J}_h^N(\cdot,\cdot)$ is given by (4.5), k is the iteration counter of the gradient algorithm, and $\mathbf{g}_h(k)$ is the kth iterate for the optimal control. In the algorithm, τ will denote a prescribed tolerance used to test for the convergence of the functional. The gradient algorithm proceeds as follows.

```
(a) initialization:
    (i) choose $\tau$ and $\vec{\mathbf{g}}_h(0)$; set $k = 0$ and $\epsilon = 1$;
    (ii) solve for the starting velocity field $\mathbf{u}_h(0)$ from (5.1) with $\mathbf{g}_h = \mathbf{g}_h(0)$;
    (iii) evaluate $\mathcal{J}_h^N(0)$;.
(b) main loop:
    (iv) set $k = k + 1$;
    (v) solve for $\mathbf{w}_h(k)$ from (5.2) with $\mathbf{u}_h = \mathbf{u}_h(k-1)$;
    (vi) for $n = 1, 2, \dots, N$,
        – set $\vec{q} = \vec{g}_h^{(n)}(k-1) - \epsilon \dfrac{\vec{w}_h^{(n-1)}(k)}{\|\vec{w}_h^{(n-1)}(k)\|}$;
        – if $\|\vec{g}_h^{(n)}(k)\| \le 1$, set $\vec{g}_h^{(n)}(k) = \vec{q}$ ;
        – if $\|\vec{g}_h^{(n)}(k)\| > 1$, set $\vec{g}_h^{(n)}(k) = \dfrac{\vec{q}}{\|\vec{q}\|}$;
    (vii) solve for $\mathbf{u}_h(k)$ from (5.1) with $\mathbf{g}_h = \mathbf{g}_h(k)$;
    (viii) evaluate $\mathcal{J}_h^N(k)$;
    (ix) if $\mathcal{J}_h^N(k) \ge \mathcal{J}_h^N(k-1)$, set $\epsilon = .5\epsilon$ and go to (vi); otherwise continue;
    (x) if $|\mathcal{J}_h^N(k) - \mathcal{J}_h^N(k-1)|/|\mathcal{J}_h^N(k)| > \tau$, set $\epsilon = 1.5\epsilon$ and go to (iv);
        otherwise stop.
```

REMARK 5.1. The bulk of the computational costs are found in the backward-in-time solution of the discrete adjoint system in step (v) and the forward-in-time solution of the discrete state system in step (vii).

REMARK 5.2. The gradient of the fully discrete functional (4.5) is given by, for $n = 1, 2, \dots, N$,

$$\frac{d\mathcal{J}_h^N}{d\vec{g}_h^{(n)}}\bigg|_{\mathbf{g}_h} = K\vec{w}_h^{(n-1)} \,;$$

this follows from the equation analogous to (3.21) for the semidiscrete functional. Then it is clear that the above algorithm is based on the iteration

$$\vec{g}_h^{(n)}(k+1) = \Pi_B \left(\vec{g}_h^{(n)}(k) - \rho_k \frac{d\mathcal{J}_h^N}{d\vec{g}_h^{(n)}}\bigg|_{\mathbf{g}_h(k)} \right) \tag{5.4}$$

for $n = 1, 2, \dots, N$, where Π_B denotes the projection onto the unit ball in X_h, viewed as a subspace of $L^2(\Omega)$.

The convergence property of the projected gradient algorithm is given in the following result.

THEOREM 5.3. *Let* $(\mathbf{u}_h(k), \mathbf{w}_h(k), \mathbf{p}_h(k), \mathbf{r}_h(k), \mathbf{g}_h(k))$ *denote the kth iterate of the projected gradient algorithm, and let* $(\widehat{\mathbf{u}}_h, \widehat{\mathbf{w}}_h, \widehat{\mathbf{p}}_h, \widehat{\mathbf{r}}_h, \widehat{\mathbf{g}}_h)$ *denote a solution of the fully discrete optimality system* (5.1)–(5.3). *Let* $\mathbf{B}_h = (B_h)^N$, *where* B_h *denotes the unit ball in* X_h (*with respect to* $L^2(\Omega)$.) *Then, for* Δt *sufficiently small,* K *sufficiently large, and any* $\mathbf{g}_h(0) \in \mathbf{B}_h$,

$$(\mathbf{u}_h(k), \mathbf{w}_h(k), \mathbf{p}_h(k), \mathbf{r}_h(k), \mathbf{g}_h(k)) \to (\widehat{\mathbf{u}}_h, \widehat{\mathbf{w}}_h, \widehat{\mathbf{p}}_h, \widehat{\mathbf{r}}_h, \widehat{\mathbf{g}}_h) \quad \text{as } k \to \infty\,.$$

Proof. We will make use of the following classical result; see, e.g., [1], [6], [22], or [8]. Let X be a Hilbert space with norm $\|\cdot\|$, and let $\mathcal{K}(\cdot)$ be a real-valued functional on X. Suppose that $\mathcal{K}(\cdot)$ is of class C^2; suppose that $\widehat{x}$ is a local minimizer of $\mathcal{K}(\cdot)$; suppose that there exists a ball B of X, centered at $\widehat{x}$, such that there exist two real numbers c_1 and c_2 such that for all $\widetilde{g} \in B$ and all $\delta x_1, \delta x_2 \in X$,

$$\mathcal{J}''(\widetilde{x})(\delta x_1, \delta x_2) \le c_1 \|\delta x_1\| \|\delta x_2\| \qquad \text{and} \qquad c_2 \|\delta x_1\|^2 \le \mathcal{J}''(\widetilde{x})(\delta x_1, \delta x_1)\,, \tag{5.5}$$

where $\mathcal{J}''(\widetilde{x})(\delta x_1, \delta x_2)$ is the bilinear form associated with the second derivatives of $\mathcal{J}(\cdot)$; and suppose that ρ_k is chosen so that

$$0 < a \le \rho_k \le b < \frac{2c_2}{c_1} \qquad \text{for all } k \tag{5.6}$$

for some positive numbers a and b. Then the iterates of the gradient algorithm

$$x(k+1) = x(k) - \rho_k \nabla\mathcal{K}(x(k)) \quad k = 0, 1, 2, \dots,$$

converge to $\widehat{x}$ for any initial iterate $x(0) \in B$.

For our setting, let $\Delta t = T/N$ and let

$$\mathcal{K}_h^N(\mathbf{u}, \mathbf{g}, \boldsymbol{\beta}, \mathbf{s}) = \mathcal{J}_h^N(\mathbf{u}) - \sum_{n=1}^{N} \frac{\beta^{(n)}}{2} \left(\|\vec{g}_h^{(n)}\|^2 - 1 + (s^{(n)})^2 \right).$$

The functional $\mathcal{K}_h^N$ could have more minimizers than $\mathcal{J}_h^N$, but every optimal solution of our problem is also a minimizer of $\mathcal{K}_h^N$. If $(\widehat{u}_h^{(n)}, \widehat{g}_h^{(n)})$ is an optimal solution, then it minimizes $\mathcal{J}_h^N$ with $\|\widehat{g}_h^{(n)}\| = 1$, $\widehat{\beta}^{(n)} = (\widehat{g}_h^{(n)}, \widehat{w}_h^{(n-1)}) = -K\|\widehat{w}_h^{(n-1)}\|$, and $\widehat{s}^{(n)} = 0$ for all $n = 1, \dots, N$ and $\mathcal{K}_h^N = \mathcal{J}_h^N$ so that the optimal solution minimizes $\mathcal{K}_h^N$. Since we are looking for a minimum point, we search for $\beta^{(n)} \le 0$. The first variation of $\mathcal{K}_h^N$ can be written as

$$D\mathcal{K}_h^N(\mathbf{u}_h(\mathbf{g}_h), \mathbf{g}_h, \boldsymbol{\beta}, \mathbf{s})(\delta\mathbf{g}_h, \delta\boldsymbol{\beta}, \delta\mathbf{s}) = \Delta t \sum_{n=1}^{N} \int_\Omega (K\vec{w}_h^{(n-1)} - \beta^{(n)}\vec{g}_h^{(n)}) \cdot \delta\vec{g}_h^{(n)} \, d\vec{x}$$

$$-\Delta t \sum_{n=1}^{N} \left(\beta^{(n)} s^{(n)} \delta s^{(n)} + \left(\|\vec{g}_h^{(n)}\|^2 - 1 + (s^{(n)})^2\right)\delta\beta^{(n)} \right). \tag{5.7}$$

The search could be in the $\mathbf{g}, \boldsymbol{\beta}$, and $\mathbf{s}$ direction with the gradient given by

$$\begin{aligned} \left.\frac{d\mathcal{K}_h^N}{d\vec{g}_h^{(n)}}\right|_{(\mathbf{g}_h, \boldsymbol{\beta}, \mathbf{s})} &= K\vec{w}_h^{(n-1)} - \beta^{(n)}\vec{g}_h^{(n)}, \\ \left.\frac{d\mathcal{K}_h^N}{d\beta^{(n)}}\right|_{(\mathbf{g}_h, \boldsymbol{\beta}, \mathbf{s})} &= \|\vec{g}_h^{(n)}\|^2 - 1 + (s^{(n)})^2, \\ \left.\frac{d\mathcal{K}_h^N}{ds^{(n)}}\right|_{(\mathbf{g}_h, \boldsymbol{\beta}, \mathbf{s})} &= \beta^{(n)} s^{(n)} \end{aligned}$$

for $n = 1, 2, \dots, N$. We can reduce the number of the directions to only one if we set $\|\vec{g}^{(n)}(k)\|^2 - 1 + s^{2(n)}(k) = 0$ and $s^{(n)}(k) = 0$ if $\|\widetilde{g}^{(n)}(k-1)\|^2 \ge 1$ or $\beta^{(n)}(k) = 0$ if $\|\widetilde{g}^{(n)}\|^2(k-1) < 1$, where k is the kth iteration of the gradient algorithm. If $s^{(n)}(k) = 0$, we can fix $\beta^{(n)}(k)$ equal to $(\vec{g}_h^{(n)}(k), \vec{w}_h^{(n)}(k))$, assuming that $\vec{g}_h^{(n)}(k)$ is orthogonal to the gradient direction $d\mathcal{K}_h^N/d\vec{g}_h^{(n)}$. The variation $\delta\mathbf{g}_h$ can be set proportional to the adjoint solution and $\mathcal{K}_h^N$ decreases for all iterations.

Now the gradient algorithm can be applied to $\mathcal{K}_h^N$ only in the $\mathbf{g}$ direction. For each $\widetilde{\mathbf{g}}_h \in L^2((0,T); \mathbf{X}^h)$, the nonvanishing terms of the second Frechet derivative of $\mathcal{K}_h^N(\widetilde{\mathbf{u}}_h(\widetilde{\mathbf{g}}_h), \widetilde{\mathbf{g}}_h)$ are given by

$$D^2\mathcal{K}_h^N(\widetilde{\mathbf{u}}_h(\widetilde{\mathbf{g}}_h), \widetilde{\mathbf{g}}_h)(\delta\mathbf{g}_{1h}, \delta\mathbf{g}_{2h}) = -\Delta t \sum_{n=1}^{N} \widetilde{\beta}^{(n)} \int_\Omega \delta\vec{g}_{1h}^{(n)} \cdot \delta\vec{g}_{2h}^{(n)} d\vec{x},$$

$$\begin{aligned}&\alpha\Delta t\sum_{n=1}^{N}\int_\Omega \widetilde{w}_{1h}^{(n)}\cdot\widetilde{w}_{2h}^{(n)}\,d\vec{x}+\gamma\int_\Omega \widetilde{w}_{1h}^{(N)}\cdot\widetilde{w}_{2h}^{(N)}d\vec{x}\\ &+\alpha\Delta t\sum_{n=1}^{N}\int_\Omega(\vec{u}_h^{(n)}-\vec{U}_h^{(n)})\cdot\widetilde{z}_h^{(n)}\,d\vec{x}+\gamma\int_\Omega(\vec{u}_h^{(N)}-\vec{U}_h^{(N)})\cdot\widetilde{z}_h^{(N)}\,d\vec{x}\,,\end{aligned}\tag{5.8}$$

where $\widetilde{w}_h^{(n)}\in X_0^h$, $\widetilde{u}_h^{(n)}\in X_0^h$, $\widetilde{w}_{ih}^{(n)}\in X_0^h$, and $\widetilde{z}_h^{(n)}\in X_0^h$ are the solution of the adjoint equations, the solution of the Navier–Stokes equations, and the first and the second variation of $\vec{u}_h^{(n)}$, respectively. By following arguments similar to those used in [21], we have that, for some constants $C_1, C_2 > 0$,

$$\begin{aligned}&|D^2\mathcal{K}_h^N(\widetilde{\mathbf{u}}_h(\widetilde{\mathbf{g}}_h),\widetilde{\mathbf{g}}_h)(\delta\mathbf{g}_{1h},\delta\mathbf{g}_{2h})|\\ &\quad\le\Big(\alpha f_2(\|\widetilde{\mathbf{g}}_h-\widehat{\mathbf{g}}_h\|)\\ &\qquad+\big(\alpha+\gamma+\alpha C_1 f_2(\|\widetilde{\mathbf{g}}_h-\widehat{\mathbf{g}}_h\|)\big)f_1^2(\|\widetilde{\mathbf{g}}_h-\widehat{\mathbf{g}}_h\|)\Big)\|\delta\mathbf{g}_{1h}\|\|\delta\mathbf{g}_{2h}\|\end{aligned}\tag{5.9}$$

and

$$\begin{aligned}&|D^2\mathcal{K}_h^N(\widetilde{\mathbf{u}}_h(\widetilde{\mathbf{g}}_h),\widetilde{\mathbf{g}}_h)(\delta\mathbf{g}_{1h},\delta\mathbf{g}_{1h})|\\ &\quad\ge\Delta t\sum_{n=1}^{N}\Big(-\widetilde{\beta}^{(n)}-C_2\alpha f_2(\|\widetilde{\mathbf{g}}_h-\widehat{\mathbf{g}}_h\|)f_1^2(\|\widetilde{\mathbf{g}}_h-\widehat{\mathbf{g}}_h\|)\Big)\|\delta\mathbf{g}_{1h}\|^2\,,\end{aligned}\tag{5.10}$$

where $f_1(\cdot)$ and $f_1(\cdot)$ are continuous functions. Equation (5.10) can give the correct estimate only if $\widehat{\beta}^{(n)}\neq 0$, which means $\widehat{s}^{(n)}=0$ and $\|\widehat{g}^{(n)}\|=1$. Hence, let $\widehat{w}^{(n-1)}$ be different from zero for all $n=1,\dots,N$ and define $\eta=\min\{\|\widehat{w}^{(n-1)}\| : n=1,\dots,N\}$. We can write

$$\widetilde{\beta}^{(n)}=(\widetilde{g}_h^{(n)},\widetilde{w}_h^{(n-1)})=\widehat{\beta}^{(n)}-(\widehat{g}_h^{(n)}-\widetilde{g}_h^{(n)},\widehat{w}_h^{(n-1)})-(\widetilde{g}_h^{(n)},\widehat{w}_h^{(n-1)}-\widetilde{w}_h^{(n-1)}),$$

and, for K large enough, the estimate

$$|\widetilde{\beta}^{(n)}|\ge K\eta-\alpha(f_2(0)\|\widetilde{\mathbf{g}}_h-\widehat{\mathbf{g}}_h\|+f_2(\|\widetilde{\mathbf{g}}_h-\widehat{\mathbf{g}}_h\|)+f_2(0))\,.$$

Now, assume that $\|\widehat{\mathbf{g}}_h-\widetilde{\mathbf{g}}_h\|\le\xi$ so that, consequently, $f_1(\|\widehat{\mathbf{g}}_h-\widetilde{\mathbf{g}}_h\|)\le\xi_1$ and $\alpha f_2(\|\widehat{\mathbf{g}}_h-\widetilde{\mathbf{g}}_h\|)\le\xi_2$ for some $\xi_1,\xi_2\le\infty$ and choose K large enough. Then, we may choose

$$c_1=\xi_2+(\alpha+\gamma+\alpha C_1\xi_2)\xi_1^2 \qquad\text{and}\qquad c_2=K\eta-\xi_2\xi-2\xi_2-C_2\xi_2\xi_1^2. \qquad \square$$

REMARK 5.4. Steps (ix) and (x) of the algorithm automate the choice of ρ_k satisfying (5.6).

REMARK 5.5. Under the hypotheses of Theorem 5.3 one can also prove that an appropriately defined conjugate gradient algorithm converges.

6. Computational examples. The optimality system presents a formidable computational challenge even for relatively simple geometries and relatively coarse grids. It involves the forward-in-time Navier–Stokes system coupled to the backward-in-time adjoint system.

One can split the optimality system into its two constituent systems of equations. At any step of the iteration, the Navier–Stokes system can be solved by marching forward in time from the initial condition; at any time, the body force must be determined, through the gradient algorithm, from the adjoint solution obtained in the previous step. At every time step, the nonlinearity of the Navier–Stokes system is treated with a modified Newton–Raphson method. The adjoint equations can then be solved marching backward in time, starting from the final condition, which along with the right-hand side and coefficients, are determined from the Navier–Stokes solution. Thus, both the state and adjoint variables must be available and stored over the entire space-time domain. The iterative procedure, i.e., the forward Navier–Stokes sweeps followed by the backward adjoint sweeps, is repeated until convergence is achieved. The projected gradient algorithm with variable step, described in the previous section, is a slowly convergent method and many iterations are necessary, even for the simple test cases discussed below.

The solution globally consists of eight fields: three for the state of the fluid, three for the adjoint state, and two for the control. As was mentioned above, this solution must be available over the whole time-space domain and cannot be stored in the computer memory, even for simple test cases that use a 20×20 spatial mesh and 100 time steps. Therefore, these fields must be stored out of core and be accessible during the matrix and right-hand side assemblies.

The scheme employed for solving linear systems is the frontal method described in [23]. The implementation of the method we use employs out-of-core storage. Since there are not limitations on the storage of the solver matrix with this method, many engineering problems can be adequate treated. The primary disadvantage of the frontal method is the effort necessary to access and store the matrix.

Of course, our solution strategy and its implementation is a straightforward one. Other more sophisticated strategies and implementations can be devised that require less storage and perhaps less central processing resources. This is a subject that is currently of substantial interest to us and the flow control community.

6.1. Test 1. We consider a unit square domain $(0,1) \times (0,1) \subset \mathbb{R}^2$. We assume that the time interval [0,1] is divided into equal intervals of duration $\Delta t = 1/N$. The finite element spaces are chosen to be continuous piecewise biquadratic polynomials for the velocity and continuous piecewise bilinear polynomials for the pressure, i.e., the Taylor–Hood finite element pair, with respect to a rectangular mesh. The mesh size is denoted by h, and calculations with varying mesh sizes have been performed. In this first test we are interested in the convergence history with respect to the parameters involved, so a simple stationary target velocity $\vec{U}(x,y) = (U(x,y), V(x,y))$ is chosen; e.g.,

$$U = 10\frac{d}{dy}\Big(\phi(0.4,x)\phi(0.4,y)\Big) \quad \text{and} \quad V = -10\frac{d}{dx}\Big(\phi(0.4,x)\phi(0.4,y)\Big)\,, \tag{6.1}$$

where

$$\phi(t,z) = (1-z)^2\big(1 - cos(2\pi t z)\big)\,.$$

Velocity tracking evolution. For the first example we choose the initial velocity

$$u_0(x,y) = -U(x,y) \qquad \text{and} \qquad v_0(x,y) = -V(x,y)$$

so that the initial flow rotates in an opposite sense from the target flow. The flow evolution is given in Figure 6.1. The controlled fluid is on the left, and the desired flow is on the right. (In the figures, all values are normalized by the maximum value.) Figure 6.2 shows the error $\|\widehat{u} - \vec{U}\|$ between the optimally controlled flow $\widehat{u}$ and the

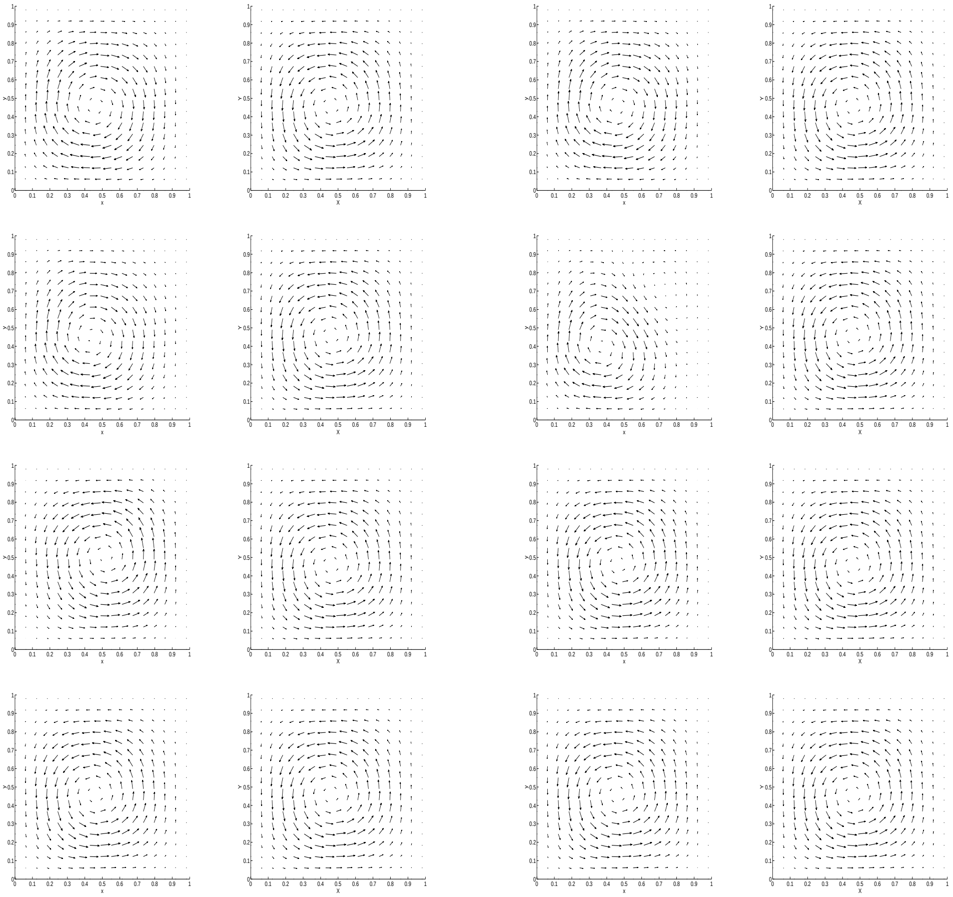

FIG. 6.1. *Test* 1. *Controlled (left) and target (right) flows at* $t = 0, .05, .1, .125, .135, .2, .5, 1$.

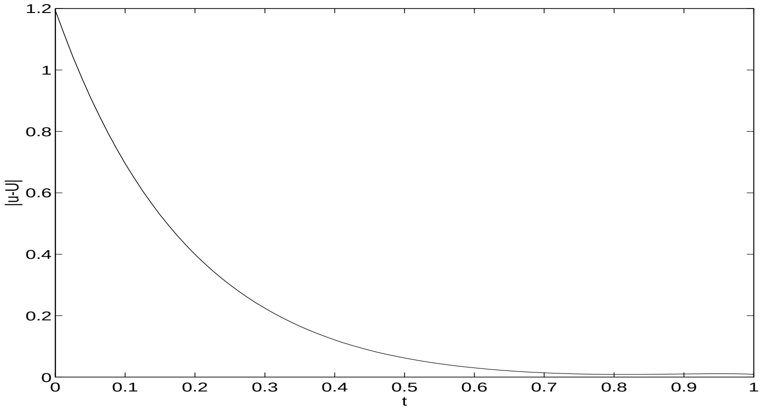

FIG. 6.2. *Test* 1. *Error* $\|\widehat{u} - \vec{U}\|$ *vs. time.*

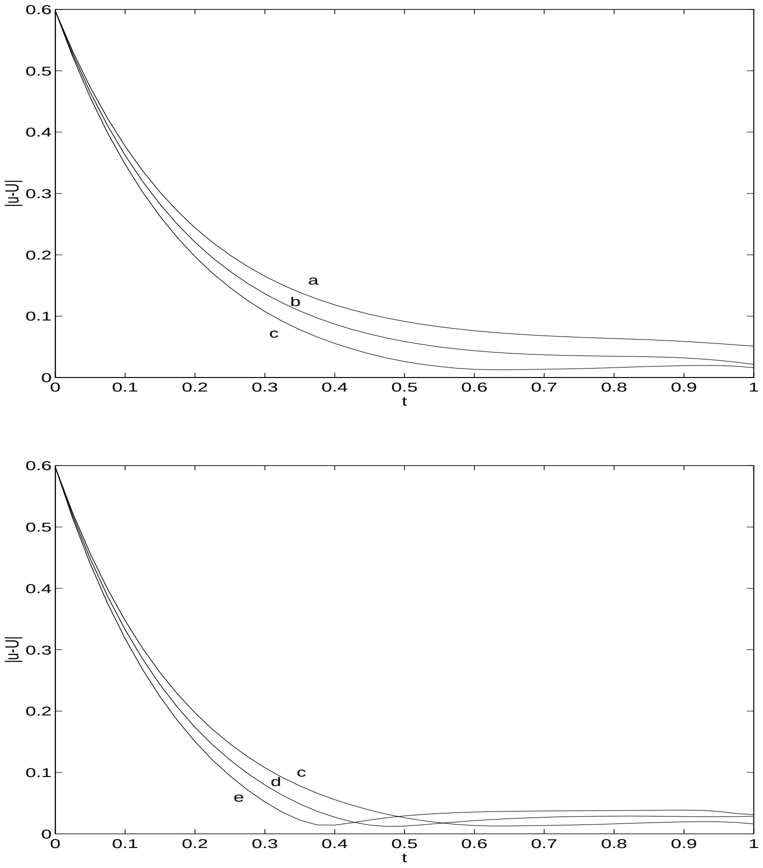

FIG. 6.3. *Test* 1. *Error* $\|\widehat{u} - \vec{U}\|$ *vs. time for different values of the bound* K *for the control;* $K = 3.0$ (a), 3.2 (b), 3.4 (c), 3.6 (d), 3.8 (e).

target flow $\vec{U}$. As we can see, the error does not go to zero very rapidly due to the fact that we have a bounded control. For this calculation, by $t = 0.15$ we achieve a match in shape of the flow and at $t = 0.6$ we achieve a match in magnitude as well. For this calculation, $\Delta t = 0.025$, $h = 1/16$, $\alpha = 1$, $\gamma = 0.5$, and $K = 3.2$.

Velocity tracking with different control norm. We want to analyze what happens if we change K, the a priori bound for the norm of control $\vec{f}$. The values $\Delta t = 0.025$, $h = 1/16$, $\alpha = 1$, and $\gamma = 0.5$ are used in all cases. We now set the initial velocity of the controlled flow to zero and the target flow is still given by (6.1). In Figure 6.3, we give the error $\|\widehat{u} - \vec{U}\|$ between the controlled flow $\widehat{u}$ and the target flow $\vec{U}$ for different value of K. (We are really giving information about the solution of the fully discrete optimal control problem.) We have $K = 3.0$ (a), 3.2 (b), 3.4 (c) and 3.4 (c), 3.6 (d), 3.8 (e), respectively. We observe that for $K \leq 3.4$, as K increases, the controlled flow matches better over the whole time interval. However, for $K > 3.4$, there is a better match only up to some time $t^* < T = 1$, but for $t > t^*$, the performance of the controlled flow gets worse as K increases. Of course, we are minimizing the functional (4.5) that involves a sum over the time steps; it does not follow that the error $\|\widehat{u} - \vec{U}\|$ necessarily decreases with increasing K at every time step. The norm

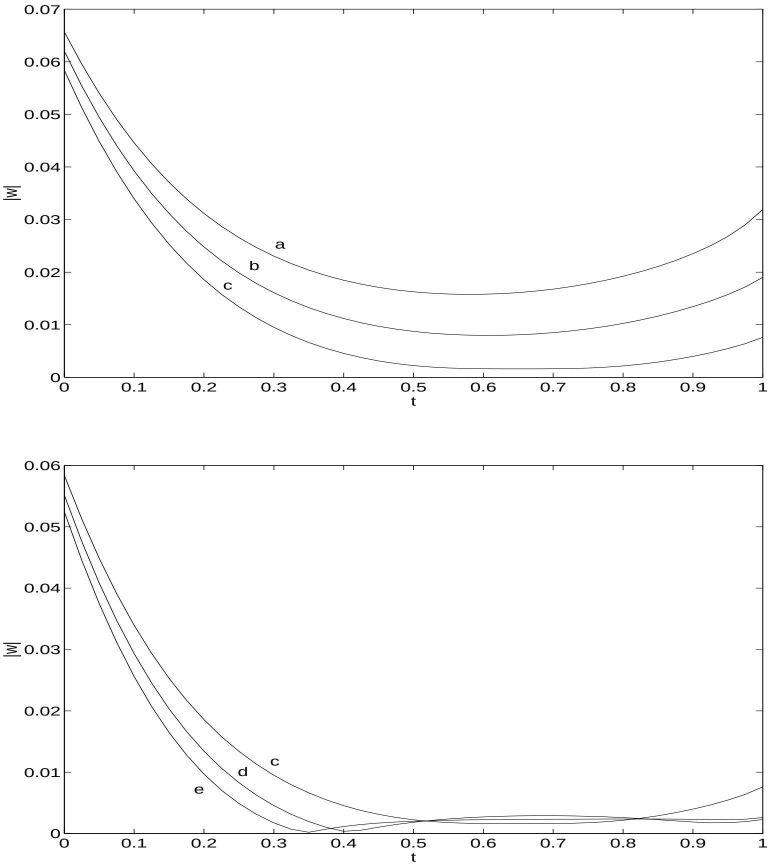

FIG. 6.4. *Test* 1. *Adjoint function norm $\|\vec{w}\|$ vs. time for different values of the bound K for the control;* $K = 3.0$ (a), 3.2 (b), 3.4 (c), 3.6 (d), 3.8 (e).

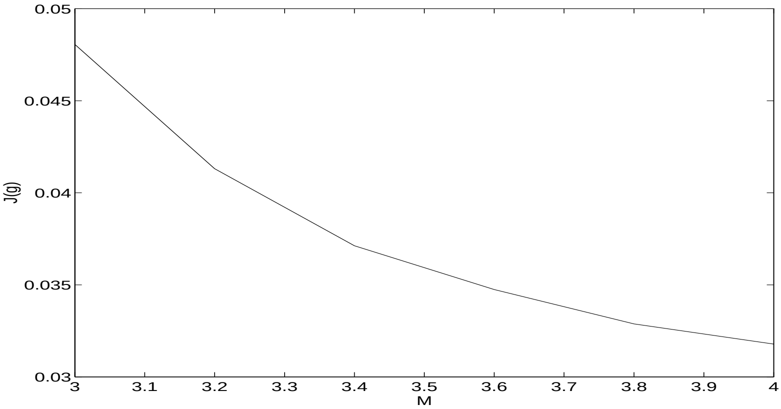

FIG. 6.5. *Test* 1. *Value of the functional vs. the bound $K = M$ for the control.*

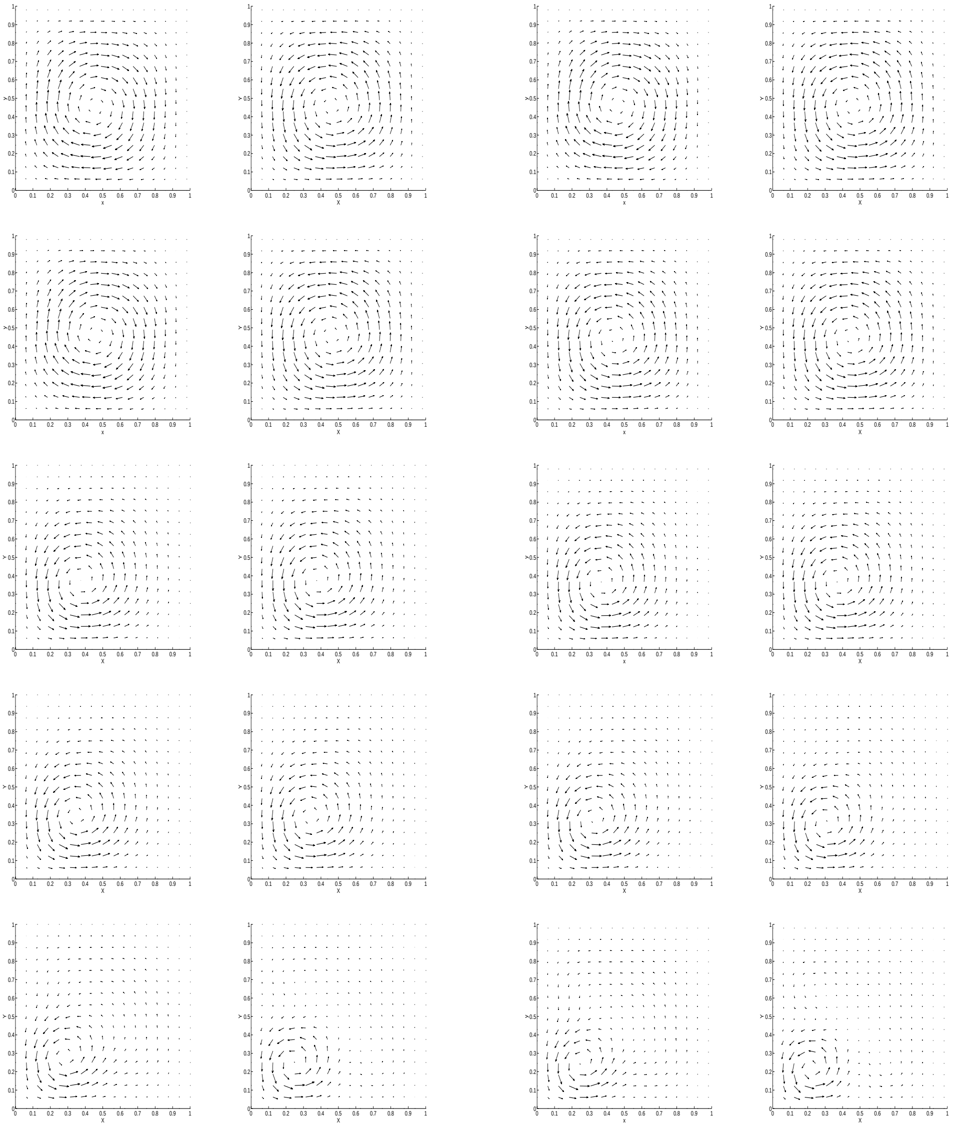

FIG. 6.6. *Test 2. Controlled (left) and target (right) flows at* $t = .1, .2, .3, .4, .5, .6, .7, .8, .9, 1$.

$\|\vec{w}\|$ of the adjoint variable agrees with the intuitive behavior of the error between the controlled and target flows. That norm is given in Figure 6.4 for the different values of K. In Figure 6.5, we display the value of the functional (4.5), evaluated at the optimal solution, vs. K. As is expected, the functional decreases as K increases.

6.2. Test 2. We consider a unit square domain $(0,1) \times (0,1) \subset \mathbb{R}^2$. We assume that the time interval [0,1] is divided in equal intervals of time $\Delta t = 1/N$. The Taylor–Hood finite element pair is used with respect to a rectangular mesh. We report only results for $h = 1/16$; however, calculations with varying mesh sizes have

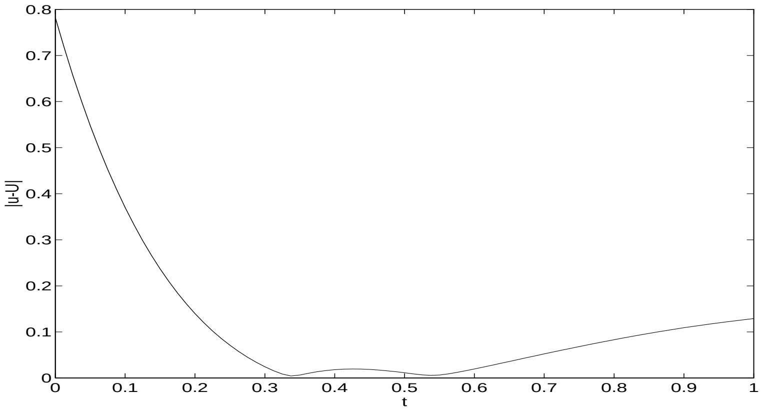

FIG. 6.7. *Test 2. Error* $\|\widehat{u} - \vec{U}\|$ *vs. time.*

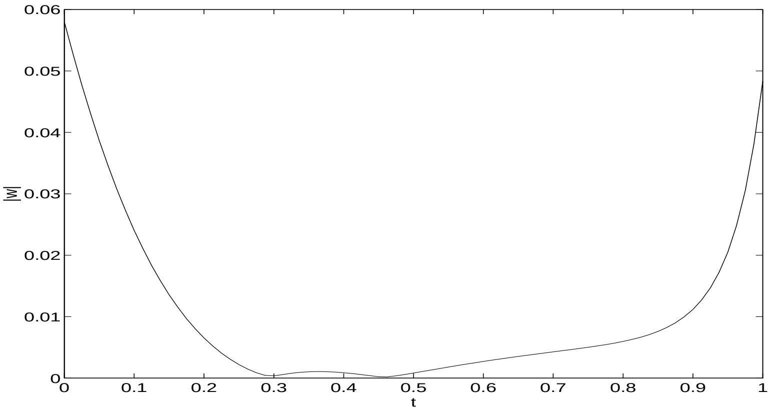

FIG. 6.8. *Test 2. Adjoint function norm* $\|\vec{w}\|$ *vs. time.*

been performed. The target velocity $\vec{U}(x, y)$ is chosen to be

$$U(x, y) = a(1, .4, x, y) + a(2, t, x, y)/(4\pi t + 1),$$
$$V(x, y) = b(1, .4, x, y) + b(2, t, x, y)/(4\pi t + 1)\,,$$

where

$$\phi(k, t, z) = (1 - zt)^2\big(1 - cos(2k\pi tz)\big),$$
$$a(k, t, x, y) = \frac{d}{dy}\Big(\phi(k, t, x)\phi(k, t, y)\Big),$$
$$b(k, t, x, y) = -\frac{d}{dx}\Big(\phi(k, t, x)\phi(k, t, y)\Big)\,.$$

This velocity field is a superposition of two flows, one having a vortex at the center of the domain and another flow with four vortices. Each of these flows prevails at different times of the evolution. The initial velocity for the controlled flow is chosen to be

$$u_0(x,y) = -8U(1/4,x,y) \qquad \text{and} \qquad v_0(x,y) = -8V(1/4,x,y)$$

so that it has an opposite rotational sense and magnitude from that of the target flow. For this computation, $\alpha = 1$, $\gamma = 0.5$, and $K = 1.6$. The evolutionary history is given in Figure 6.6. The controlled fluid is on the right, the desired flow is on the left, and all the pictures are normalized. We can see that by $t = 0.3$, the controlled flow looks very much like the desired flow. Figure 6.7 shows the error $\|\widehat{u} - \vec{U}\|$ between the controlled flow $\widehat{u}$ and the target flow $\vec{U}$. At the beginning, the error rapidly decreases but after this initial interval of time the error increases due to changes in the desired flow which cannot be followed well by a control with the bound we have chosen. The norm of the control is forced to be less then 1.6. Evidently, this does not allow enough power to well-match the time evolution of the desired flow. For the same flow, Figure 6.8 shows the values of the norm of the adjoint variable $\vec{w}$.

APPROXIMATION AND LIMIT RESULTS FOR NONLINEAR FILTERS OVER AN INFINITE TIME INTERVAL*

AMARJIT BUDHIRAJA[†] AND HAROLD J. KUSHNER[‡]

Abstract. This paper is concerned with approximations to nonlinear filtering problems that are of interest over a very long time interval. Since the optimal filter can rarely be constructed, one needs to compute with numerically feasible approximations. The signal model can be a jump-diffusion or just a process that is approximated by a jump-diffusion. The observation noise can be either white or of wide bandwidth. The observations can be taken in either discrete or continuous time. The cost of interest is the pathwise error per unit time over a long time interval. It is shown under quite reasonable conditions on the approximating filter and the signal and noise processes that (as time, bandwidth, process, and filter approximation, etc.) go to their limit in any way at all, the limit of the pathwise average costs per unit time is just what one would get if the approximating processes were replaced by their ideal values and the optimal filter were used. Analogous results are obtained (with appropriate scaling) if the observations are taken in discrete time, and the sampling interval also goes to zero. For these cases, the approximating filter is a numerical approximation to the optimal filter for the presumed limit (signal, observation noise) problem.

Key words. nonlinear filters, approximations to nonlinear filters, infinite time filtering, occupation measures, pathwise average error criteria

1. Introduction.

This paper is concerned with approximations to nonlinear filtering problems that are of interest over a very long time interval. Consider the simplest such problem where the observation is a function of the state of a diffusion process and either or both the function or the process is nonlinear. Then, except in a few cases which on the whole are not of much practical value, it is not feasible to compute the truly optimal filter. Then one must approximate in some way.

Suppose that the approximation is parameterized by a parameter h such that as $h \to 0$, the approximation converges to the true filter in the sense that the computed expectations of any bounded and continuous function converge to the true conditional expectation; equivalently, the computed approximating conditional distribution converges weakly to the true conditional distribution. Now suppose that the filter is of interest over an arbitrarily large interval T and the errors of concern are the *pathwise average* (not the mean value) "prediction" errors per unit time for some rather arbitrary definition of prediction. Pathwise errors are a main item of interest in many such applications since we work with only one long path, and the law of large numbers argument which justifies the use of mean values is inappropriate.

Now there are two parameters: h and T. The convergence of the filter over any fixed finite interval says nothing about the behavior of the pathwise average errors as $h \to 0$ and $T \to \infty$ arbitrarily. We will show that, under quite reasonable conditions,

the pathwise errors converge in probability to an optimal deterministic limit in a very natural sense. This limit is what one would get if one used the true optimal filter and not an approximation. In fact, the limit is also what one would get for the true optimal filter if the expectation of the pathwise average replaced the pathwise average. The convergence is independent of how $h \to 0$ or $T \to \infty$. The error function is quite general and can even be an (appropriate) path functional. This is quite a strong result. Note that it is important that we allow $h \to 0$ and $T \to \infty$ in an arbitrary way. If, for example, we required that the time required to get a good approximation by the "ergodic limit" depends on h, for small h, then the approximating filter would not be good for large time, since the better the filter is (i.e., the smaller h is), the more time is required for the pathwise average to be well approximated by the ergodic limit.

Actually, our interest is in more general problems as well. We let the signal process be replaced by a "pre-jump-diffusion," which is only approximated by a jump-diffusion. The discrete time case is also treated. Also, we allow wide bandwidth observation noise. Much (perhaps most) of the theoretical work in nonlinear filtering is in continuous time, and white observation noise is the usual one. But most applications are in discrete time. If the interval between observations becomes small so that one is tempted to use a continuous time model, then one is confronted with the very real presence of wide bandwidth and not white noise. One usually constructs a numerical approximation to a filter which assumes white observation noise and a diffusion model. Then the wide bandwidth observation noise, combined with all of the other approximations, can conceivably lead to serious errors when T is large.

The last part of the paper deals with this general problem. The observations are in discrete time with a small time interval between the observations, the observation noise is wide bandwidth, the signal is only approximated by a sampled diffusion, and the pathwise average errors over a long time interval T are of interest. Under reasonable conditions we show that the desired limit result holds here as well, as all the parameters go to their limits simultaneously (observation interval, observation noise bandwidth, h, the signal converging to a jump-diffusion, T, etc.). This is a true justification of filtering work in continuous time.

Some work on this problem was done in [21], where the pathwise average error was replaced by an expectation of the pathwise average error, and which contains much additional material on the wide bandwidth observation noise problem. In [12], the asymptotics of the filter alone was dealt with, and it was presumed that the filter was the true optimal filter, not an approximation. The approach taken here uses an adaptation of the occupation measure approach which was used successfully on a variety of control and limit problems in [19, 22].

2. Problem formulation and occupation measures.

Let h parameterize the approximating filter. Until section 5, we work with observations in continuous time. Let $X(\cdot)$ denote the basic signal process, which is the solution to an Itô equation. The process can be a jump-diffusion with time independent coefficient functions, with only notational changes required in the development. But for notational simplicity, we work with a simple diffusion, which takes values in a compact set in $\mathbb{R}^r$, Euclidean r-space. Where continuity is used in the current proof, for the jump-diffusion case it is replaced by the fact that we have continuity at each time with probability one, and uniform (in t) right continuity in probability. Similarly, under appropriate conditions on the boundary and reflection directions, the results hold for a reflected jump-diffusion. Our basic condition on the signal process is the following.

ASSUMPTION 2.1. *$X(\cdot)$ takes values in a compact subset G of $\mathbb{R}^r$ for all $X(0) \in G$ and satisfies the Itô equation*

$$dX = p(X)dt + \sigma(X)dW, \tag{2.1}$$

where $W(\cdot)$ is a standard vector-valued Wiener process and $p(\cdot)$ and $\sigma(\cdot)$ are continuous. The solution of the above Itô equation is unique in the weak sense for each initial condition.

The uniqueness assumption imposes rather mild requirements on $p(\cdot)$ and $\sigma(\cdot)$, while the compactness of the state space will hold if, say, $\sigma(\cdot)$ vanishes outside a compact set and 0 is a global attractor for the deterministic equation obtained by substituting $\sigma = 0$ in (2.1). Alternatively, compactness of the state space can be achieved by constraining a diffusion in a bounded region by appropriately reflecting it at the boundary. Then the model is represented as the solution to the Skorohod problem, and the techniques of the current paper can be used to cover this case as well. In many applications, the state spaces are inherently compact; for example, where the state is the phase of a signal. Additionally, unbounded signal models are often used for mathematical convenience, while the true process does take values in a compact set.

The observation process is $Y(\cdot)$, defined by

$$Y(t) = \int_0^t g(X(s))ds + B(t), \tag{2.2}$$

where $g(\cdot)$ is a continuous vector-valued function and $B(\cdot)$ is a standard vector-valued Wiener process, independent of $W(\cdot)$ and $X(0)$.

Unless otherwise stated all statements of the form, "with probability one (w.p.1)," "almost surely (a.s.)", "convergence in probability," etc., will correspond to the basic probability space which supports $X(\cdot), Y(\cdot), W(\cdot), B(\cdot)$.

The optimal filter process. We will use the representation of the optimal filter as it was originally developed in [15]. This is most convenient for our purposes and it is completely equivalent to the forms used later, as in [8, 11, 23]. Let $\tilde{X}(\cdot)$ be a process satisfying (2.1), and one which (loosely speaking) is conditionally independent of $(X(\cdot), W(\cdot), B(\cdot))$ given its initial condition. We formalize this as follows: $\tilde{X}(\cdot)$ is a process satisfying (2.1) such that there exists a (possibly random) probability measure Π^* on $\mathbb{R}^r$ with the properties that conditioned on Π^*, $\tilde{X}(\cdot)$ is independent of $(X(\cdot), W(\cdot), B(\cdot))$, and the conditional distribution of $\tilde{X}(0)$ given Π^* is Π^*. We will call Π^* the "random initial distribution" of $\tilde{X}(\cdot)$ (i.e., the distribution of $\tilde{X}(0)$). It will vary depending on the need and will be specified when needed.

Let $Y_{a,b}, a < b$, denote the values of $Y(\cdot) - Y(a)$ in the time interval $[a, b]$. Until further notice, let $\Pi(0)$ denote the distribution of $X(0)$ and $\Pi(t)$ the distribution of $X(t)$, given the data $Y_{0,t}$ and $\Pi(0)$. Let $\tilde{X}_{0,a}$ denote the values of $\tilde{X}(\cdot)$ in the time interval $[0, a]$. Define the function

$$R(\tilde{X}_{0,t}, Y_{0,t}) = \exp\left[\int_0^t g'(\tilde{X}(s))dY(s) - \frac{1}{2}\int_0^t \left|g(\tilde{X}(s))\right|^2 ds\right]. \tag{2.3}$$

Let $E_Z f$ denote the expectation of a function f given the data Z. Then the optimal filter $\Pi(\cdot)$ satisfies the following relation (which defines the inner product notation). For each bounded and measurable real-valued function $\phi(\cdot)$

$$\int \phi(x)\Pi(t, dx) \equiv \langle \Pi(t), \phi \rangle = \frac{E_{\{\Pi(0), Y_{0,t}\}}\left[\phi(\tilde{X}(t))R(\tilde{X}_{0,t}, Y_{0,t})\right]}{E_{\{\Pi(0), Y_{0,t}\}}R(\tilde{X}_{0,t}, Y_{0,t})}, \tag{2.4}$$

where $\Pi(0)$ is the distribution of the initial condition $\tilde{X}(0)$.

Owing to the Markov property of $X(\cdot)$, the optimal filter defined by (2.4) satisfies the following semigroup relation: For $0 < s < t$

$$\langle \Pi(t), \phi \rangle = \frac{E_{\{\Pi(t-s), Y_{t-s,t}\}} \left[\phi(\tilde{X}(s)) R(\tilde{X}_{0,s}, Y_{t-s,t}) \right]}{E_{\{\Pi(t-s), Y_{t-s,t}\}} R(\tilde{X}_{0,s}, Y_{t-s,t})}. \tag{2.5}$$

In (2.5), $\Pi(t-s)$ is the (possibly random) distribution of the initial condition $\tilde{X}(0)$. Throughout the paper, we use the notation $E_{\{\Pi(a), Y_{a,b}\}} F(\tilde{X}_{0,s}, Y_{a,b})$ for the conditional expectation, given the data $Y_{a,b}$ and where the random initial distribution for $\tilde{X}(\cdot)$ is $\Pi(a)$. The analogous notation will be used when approximations to $\tilde{X}(\cdot)$ are used.

Since $\Pi(t)$ is nearly always hard (if not impossible) to compute for nonlinear problems, in applications one uses various approximations. Let $\Pi^h(\cdot)$ denote the actual measure-valued process, to be specified more precisely below (see (2.7)), which is the "numerical" filter used in the application. Thus, $\Pi^h(t)$ (with values $\Pi^h(t, dx)$) is the approximation at time t.

As discussed earlier, $\Pi(0)$ and $\Pi^h(0)$, which represent the initial condition of the auxiliary process used in the filter formula, will be allowed to be random (i.e., they can be measure-valued random variables, although always nonanticipative with respect to the Wiener processes. In this case, we can still write $P_{\Pi(0)}\{X(0) \in A\} = \Pi(0, A)$, random or not.

Defining $\Pi(0)$ arbitrarily. Equation (2.4) defines a measure-valued process $\Pi(\cdot)$, with initial condition $\Pi(0)$. This process $\Pi(\cdot)$ is well defined even if $\Pi(0)$ is not the distribution of $X(0)$, although it would not then be the optimal filter. Keep in mind the following important fact: *In what follows, we allow* $\Pi(0)$ *to be arbitrary but with support in G, and we will note it explicitly if it is the distribution of* $X(0)$. Then, the semigroup property in equation (2.5) shows that the pair $(X(\cdot), \Pi(\cdot))$ is Markov.

An approximating auxiliary process and approximate filter. A common way to approximate the optimal filter is to find a process which suitably approximates $X(\cdot)$ but for which the optimal filter is feasible. We then construct the optimal filter for the approximating process but use the actual observations (2.2). This was the motivation for the Markov chain approximation filter in [16, 20]. The approximating filter $\Pi^h(\cdot)$, which will be defined later in this section, will be constructed by replacing the auxiliary process $\tilde{X}(\cdot)$ in (2.4) by $\tilde{X}^h(\cdot)$, where $\tilde{X}^h(\cdot)$ approximates the auxiliary process $\tilde{X}(\cdot)$ but is "simpler" than it. Thus, this filter is built under the assumption that the true signal process is $\tilde{X}^h(\cdot)$, not $X(\cdot)$. The process $\tilde{X}^h(\cdot)$ might be Markov; for example, a continuous time Markov chain on a finite state space. More commonly, it is an interpolation of a discrete parameter process; i.e, there is $\delta_h > 0$ and which goes to zero as $h \to 0$ such that $\tilde{X}^h(\cdot)$ is constant on the intervals $[n\delta_h, n\delta_h + \delta_h)$ and $\tilde{X}^h(n\delta_h), n = 0, \ldots,$ is Markov. When the signal process is defined in continuous time, we always assume that $\tilde{X}^h(\cdot)$ is of one of these two forms. Furthermore, we always suppose (without loss of generality) that $\tilde{X}^h(t)$ takes values in G.

To quantify the sense in which $\tilde{X}^h(\cdot)$ approximates $\tilde{X}(\cdot)$, we will assume the following basic consistency condition.

ASSUMPTION 2.2. *For any sequence $\{\Pi^h\}$ of probability measures converging weakly to some probability measure Π, $\tilde{X}^h(\cdot)$ with the initial distribution Π^h converges weakly to $\tilde{X}(\cdot)$ with the initial distribution Π.*

This is a very weak assumption on the approximating filter. It holds, for example, when $\tilde{X}^h(\cdot)$ is a finite state Markov chain, which is "asymptotically consistent" with

$X(\cdot)$, as defined in [16, 20]. Indeed, the convergence (as $h \to 0$ and for an arbitrary finite time) of filters based on this approximating model has been proved in [16, 20], and the approximation performs well if the state dimension is not higher than four. Another possibility is to use an appropriate discrete time approximation to $\tilde{X}(\cdot)$. One might discretize time, but not space, provided that the computation is feasible. In either case, Assumption 2.2 will be satisfied if the approximating process satisfies the minimal consistency conditions in [16, 20].

Similar to the construction of $\tilde{X}(\cdot)$, we will take $\tilde{X}^h(\cdot)$ to be independent of $(X(\cdot), W(\cdot), B(\cdot))$, given the initial condition. The distribution of the initial condition $\tilde{X}^h(0)$ will be a measure-valued random variable, analogous to what was done in (2.4) and (2.5), when $\tilde{X}(\cdot)$ was used. Define

$$R(\tilde{X}^h_{0,t}, Y_{0,t}) = \exp\left[\int_0^t g'(\tilde{X}^h(s))dY(s) - \frac{1}{2}\int_0^t \left|g(\tilde{X}^h(s))\right|^2 ds\right]. \tag{2.6}$$

For Markov $\tilde{X}^h(\cdot)$, the approximating filter $\Pi^h(\cdot)$ is defined by

$$\langle \Pi^h(t), \phi\rangle = \frac{E_{\{\Pi^h(0),Y_{0,t}\}}\left[\phi(\tilde{X}^h(t))R(\tilde{X}^h_{0,t}, Y_{0,t})\right]}{E_{\{\Pi^h(0),Y_{0,t}\}}R(\tilde{X}^h_{0,t}, Y_{0,t})} \tag{2.7}$$

and $\Pi^h(\cdot)$ satisfies the semigroup equation

$$\langle \Pi^h(t+s), \phi\rangle = \frac{E_{\{\Pi^h(t),Y_{t,t+s}\}}\left[\phi(\tilde{X}^h(s))R(\tilde{X}^h_{0,s}, Y_{t,t+s})\right]}{E_{\{\Pi^h(t),Y_{t,t+s}\}}R(\tilde{X}^h_{0,s}, Y_{t,t+s})}, \quad s > 0,\ t \geq 0. \tag{2.8}$$

According to our standard notation, the initial distribution of $\tilde{X}^h(\cdot)$ in (2.7) is $\Pi^h(0)$ and in (2.8) it is $\Pi^h(t)$.

When $\tilde{X}^h(\cdot)$ is piecewise constant with $\{\tilde{X}^h(n\delta_h); n \geq 1\}$ being Markov, then the approximating filter is defined by (2.7) and (2.8), but where t and s are integral multiples of δ_h and $\Pi^h(\cdot)$ is constant on the intervals $[n\delta_h, n\delta_h + \delta_h)$. Thus, the evolution of $\Pi^h(\cdot)$ can be written in recursive form in general.

From the Feller–Markov property of $X(\cdot)$, it follows easily that the pair $(X(\cdot), \Pi(\cdot))$ is Feller–Markov. Since $X(t)$ takes values in a compact set G, and the samples of $\Pi(t)$ are measures with support in G, we have at least one invariant measure for the Markov family determined by $(X(\cdot), \Pi(\cdot))$. When initialized at this measure, the process $(X(\cdot), \Pi(\cdot))$ is stationary; i.e., the distribution of

$$(X(t+\cdot), \Pi(t+\cdot))$$

does not depend on t. Let $\bar{Q}(\cdot)$ denote the measure of the joint process

$$\Psi(\cdot) = (X(\cdot), \Pi(\cdot), Y(\cdot), B(\cdot), W(\cdot)),$$

where $(X(\cdot), \Pi(\cdot))$ is stationary. Let $\bar{Q}_f(\cdot)$ denote the measure of the stationary joint process $(X(\cdot), \Pi(\cdot))$. We will make the following fundamental assumption throughout this paper.

ASSUMPTION 2.3. *There is a unique invariant measure for* $(X(\cdot), \Pi(\cdot))$.

In section 7 we provide conditions for the uniqueness of the invariant measure to hold and provide some examples for which these conditions can be verified. The critical importance of the uniqueness of the stationary joint process was first raised in [21].

The stationary process and associated measure will be given a filtering interpretation later in this section.

In the following, lower case letters $x(\cdot), \pi(\cdot)$, etc., are used for the canonical sample paths. Letters such as $x, y, \ldots$ are used to denote vectors such as $x(t), y(t)$, etc. Define $\psi_f(\cdot) = (x(\cdot), \pi(\cdot))$, $\Psi_f(\cdot) = (X(\cdot), \Pi(\cdot))$, and $\psi(\cdot) = (x(\cdot), \pi(\cdot), y(\cdot), b(\cdot), w(\cdot))$, although we will not always need the component $w(\cdot)$.

For each $t \geq 0$, define the process

$$\Psi^h(t, \cdot) = \left(X(t + \cdot), \Pi^h(t + \cdot), Y(t + \cdot) - Y(t), B(t + \cdot) - B(t), W(t + \cdot) - W(t)\right).$$

Define $\Psi_f^h(t, \cdot)$ similarly. In sections 4 and 6 in which we consider more general approximate filtering problems, we will consider modifications to the $\Psi^h(t, \cdot)$ process by replacing $X(\cdot), Y(\cdot), B(\cdot)$ with h-parametrized processes $X^h(\cdot), Y^h(\cdot), B^h(\cdot)$.

The path spaces. The path space $D[\mathbb{R}^k; 0, \infty)$ of $\mathbb{R}^k$-valued functions which are right continuous and have left hand limits (CADLAG), endowed with the Skorohod topology [3, 9], will be used for the vector-valued processes such as $X(\cdot), Y(\cdot), B(\cdot), \tilde{X}(\cdot)$, etc., for the appropriate value of k. Let $\mathcal{M}(G)$ denote the space of measures on G with the weak topology. Let $m_n(\cdot)$ and $m(\cdot)$ be in $\mathcal{M}(G)$. Recall that $m_n(\cdot)$ converges weakly to $m(\cdot)$ if for each bounded and continuous function $\phi(\cdot)$ on G, $\langle m_n, \phi\rangle \to \langle m, \phi\rangle$. Equivalently, for a set of continuous functions $\{\phi_i(\cdot)\}$ which are dense (in the topology of uniform convergence) in the set of bounded and continuous functions on G, we have the metric

$$d(m_n, m) = \sum_i 2^{-i} |\langle m_n - m, \phi_i\rangle| \to 0.$$

Owing to the fact that the values of $X(t)$ and $\tilde{X}^h(t)$ are in G, the samples of the $\Pi(t)$ and its approximations $\Pi^h(\cdot)$ take values in $\mathcal{M}(G)$. The path $\Pi(\cdot)$ and its approximations will take values in the CADLAG space $D[\mathcal{M}(G); 0, \infty)$, also with the Skorohod topology used. The measure-valued random variables $Q^{h,T}(\cdot)$ defined by (2.9) below take values in the space of measures on the product path space

$$\mathcal{M}\left(D[\mathbb{R}^k; 0, \infty) \times D[\mathcal{M}(G); 0, \infty)\right)$$

for the appropriate value of k (which is the sum of the dimensions of x, y, b, w).

A "prediction error" function. We start with a special case of the error or performance function in order to fix ideas. Let $\phi(\cdot)$ be a bounded, continuous, and real-valued function of x and consider the pathwise average error per unit time

$$G^{h,T}(\phi) \equiv \frac{1}{T} \int_0^T \left[\langle \Pi^h(t), \phi\rangle - \phi(X(t))\right]^2 dt. \tag{2.9}$$

We will show that, under quite broad conditions on the approximate filter,

$$G^{h,T}(\phi) \to \int \left[\langle \pi(0), \phi\rangle - \phi(x(0))\right]^2 \bar{Q}_f(d\psi_f(\cdot)) \tag{2.10}$$

in the sense of probability, as $h \to 0$ and $T \to \infty$, in any way at all. Later in this section, it will be seen that the right side of (2.10) is what one would also get as the limit if the true optimal filter were used and not the approximation. In this sense there is pathwise asymptotic optimality. The result will actually be much more general. The errors will be written in terms of the following occupation measure.

The occupation measures. For a random variable Z and set A, let $I_A(Z)$ denote the indicator function of the event that $Z \in A$. Let C and C' be measurable sets in the product path spaces of $\Psi^h(t,\cdot)$ and $\Psi^h_f(t,\cdot)$, resp. Define the occupation measures $Q^{h,T}(\cdot)$ and $Q^{h,T}_f(\cdot)$ as

$$Q^{h,T}(C) = \frac{1}{T}\int_0^T I_C(\Psi^h(t,\cdot))dt \tag{2.11}$$

and

$$Q^{h,T}_f(C') = \frac{1}{T}\int_0^T I_{C'}(\Psi^h_f(t,\cdot))dt. \tag{2.12}$$

We can write (2.9), in terms of $Q^{h,T}_f(\cdot)$, as

$$G^{h,T}(\phi) = \int [\langle \pi(0), \phi\rangle - \phi(x(0))]^2\, Q^{h,T}_f(d\psi_f(\cdot)). \tag{2.13}$$

A more general error or performance function. It will be shown that for any (bounded, measurable, and continuous w.p.1 with respect to the measure $\bar{Q}_f(\cdot)$) real-valued function $F(\cdot)$

$$\frac{1}{T}\int_0^T F(\Psi^h_f(t))dt = \int F(\psi_f(\cdot))Q^{h,T}_f(d\psi_f(\cdot)) \to \int F(\psi_f(\cdot))\bar{Q}_f(d\psi(\cdot)) \tag{2.14}$$

in probability. This says that sample mean errors of many types (see the example in the next paragraph) will converge to the stationary value, which is the same value that one would get if the true optimal filter were used, and the pathwise occupation measure replaced by its expected value. The convergence is in the sense of probability, and holds as $T \to \infty$ and $h \to 0$ in any way at all. The arbitrariness of the way that $T \to \infty$ and $h \to 0$ is crucial in applications. It is important that the approximation is good for all small h, not depending on T, if T is large enough. Results such as (2.14) are the main contributions of this paper.

The function $F(\cdot)$ can be quite general. In (2.10), $F(\psi_f(\cdot))$ depends only on $\psi_f(0)$, since it equals $|\langle \pi(0), \phi\rangle - \phi(x(0))|^2$. But, $F(\cdot)$ might have a more complex dependence on $\psi_f(\cdot)$. For example, consider the case where we are interested in

$$\frac{1}{T}\int_0^T \left[\max_{s\in[t-1,t]} \left|\phi(X(s)) - \langle \Pi^h(s), \phi\rangle\right|\right] dt.$$

Here

$$F(\psi_f(\cdot)) = \max_{s\le 1} |\phi(x(s)) - \langle \pi(s), \phi\rangle|.$$

Comment on the stationary process. Let us deviate a little and discuss the meaning of a stationary process $(X(\cdot), \Pi(\cdot))$. Recall that we assume that the measure $\bar{Q}_f(\cdot)$ of the *stationary pair* $(X(\cdot), \Pi(\cdot))$ is unique. Now, consider the *correctly initialized* filter, i.e., the true optimal filter, which we denote by $\Pi_0(\cdot)$, i.e., $\Pi_0(B) = P\{X(0) \in B\}$ for each Borel set $B \in \mathbb{R}^r$. Define the mean occupation measure $Q^T_f(\cdot)$ by

$$Q^T_f(C) = \frac{1}{T}\int_0^T P\left((X(t+\cdot), \Pi_0(t+\cdot)) \in C\right) dt, \tag{2.15}$$

for measurable sets C in the product path space. Note that $Q_f^T(\cdot)$ is a measure but it is not random. It follows from the proofs of Theorems 3.1 and 3.2 that $\{Q_f^T(\cdot); T < \infty\}$ is tight and converges to $\bar{Q}_f(\cdot)$, the measure of the unique stationary process. Thus, the limit in (2.14) is the same as if the optimal filter were used (with probability one) and the pathwise occupation measure were replaced by the mean occupation measure.

Note that the integrand in (2.14) is the measure of the (system, filter) pair on the time interval $[t, \infty)$, and the integral is equivalent to choosing t at random in $[0, T]$. This gives a loose interpretation of $\bar{Q}_f(\cdot)$ in terms of a random initial time.

3. Tightness and weak convergence.

The following lemma will be used in the tightness arguments to follow.

LEMMA 3.1 (see [14, Theorem 2.7b]). *Let $Z_{n,s}(\cdot)$, $n = 1, 2, \ldots; s > 0$ be a family of processes with paths in the Skorohod space $D[S_0; 0, \infty)$, where S_0 is a complete and separable metric space with metric $\gamma(\cdot)$. For each $\delta > 0$ and each t in a dense set, let there be a compact set $S_{\delta,t} \subset S_0$ such that*

$$\sup_{n,s} P\{Z_{n,s}(t) \notin S_{\delta,t}\} \leq \delta. \tag{3.1}$$

Let $\mathcal{F}_t^{n,s}$ denote the minimal σ-algebra which measures $\{Z_{n,s}(u), u \leq t\}$, and $\mathcal{T}_{n,s}(T)$ the set of $\mathcal{F}_t^{n,s}$-stopping times which are less than $T > 0$. Suppose that for each T

$$\lim_{\delta \to 0} \limsup_n \sup_s \sup_{\tau \in \mathcal{T}_n(T)} E\left[\gamma\left(Z_{n,s}(\tau + \delta), Z_{n,s}(\tau)\right) \wedge 1\right] = 0. \tag{3.2}$$

Then to every $\epsilon > 0$ there exists a compact set K_ϵ such that

$$\limsup_n \sup_s P(Z_{n,s}(\cdot) \in K_\epsilon) > 1 - \epsilon.$$

We will apply the above theorem for the doubly parametrized process $\{\Pi^h(t + \cdot); h > 0, t > 0\}$. Condition (3.1) will hold trivially due to the compactness of the space and we will concentrate on verifying (3.2).

THEOREM 3.1. *Assume that Assumptions 2.1, 2.2, and 2.3 hold. Then*

$$\{X(t + \cdot); t \geq 0\} \text{ is tight,} \tag{3.3a}$$

$$\left\{\tilde{X}^h(\cdot); h, \text{ all possible initial conditions}\right\} \text{ is tight.} \tag{3.3b}$$

To every $\epsilon > 0$ there exists a compact set K_ϵ such that

$$\limsup_{h \to 0} \sup_t P(\Pi^h(t + \cdot) \in K_\epsilon) > 1 - \epsilon. \tag{3.3c}$$

Also for every sequence $h_k \to 0$, $T_k \to \infty$,

$$\left\{Q^{h_k, T_k}(\cdot); k \geq 1\right\} \text{ is tight.} \tag{3.4}$$

Let $Q(\cdot)$ denote a weak sense limit of the set in (3.4), as $k \to \infty$. Let ω be the canonical variable on the probability space on which $Q(\cdot)$ is defined, and denote the samples by $Q^\omega(\cdot)$. Then, for each ω, $Q^\omega(\cdot)$ is a measure on the product path space $D[\mathbb{R}^k; 0, \infty) \times D[\mathcal{M}(G); 0, \infty)$ for appropriate k. It induces a process

$$\Psi^\omega(\cdot) = (X^\omega(\cdot), \Pi^\omega(\cdot), Y^\omega(\cdot), B^\omega(\cdot), W^\omega(\cdot)). \tag{3.5}$$

For almost all ω, $(X^\omega(\cdot), \Pi^\omega(\cdot))$ is stationary.

Proof. The set $\{X(t+\cdot), t \geq 0\}$ is tight, by the fact that the set of "initial conditions" $\{X(t), t > 0\}$ are confined to a compact set and the properties of the diffusion (2.1). The set in (3.3b) is tight by the assumptions on $\tilde{X}^h(\cdot)$ concerning weak convergence, which (using the fact that the possible values of $\tilde{X}^h(0)$ are confined to some compact set) implies that every subsequence of the set in (3.3b) has a further subsequence which converges weakly.

To prove (3.3c) we will apply Lemma 3.1. For a real number $\rho > 0$ and each fixed h and t, let $\mathcal{T}^{h,t}(\rho)$ denote the set of stopping times with respect to the filtration $\sigma\{\Pi^h(t+s) : s \leq u\}_{u \geq 0}$, bounded by ρ. Then, by Lemma 3.1, it is sufficient to show that

$$\lim_{\delta\to 0} \sup_{h\to 0} \sup_{t} \sup_{\tau\in\mathcal{T}^{h,t}(\rho)} E\left|\langle \Pi^h(t+\tau+\delta), \phi\rangle - \langle \Pi^h(t+\tau), \phi\rangle\right| = 0 \tag{3.6}$$

for each continuous, bounded, and real-valued $\phi(\cdot)$. Define the function

$$K(h,t,\tau,\delta) = \frac{E_{\{\Pi^h(t+\tau), Y_{t+\tau,t+\tau+\delta}\}}\left[\phi(\tilde{X}^h(\delta)) R(\tilde{X}^h_{0,\delta}, Y_{t+\tau,t+\tau+\delta})\right]}{E_{\{\Pi^h(t+\tau), Y_{t+\tau,t+\tau+\delta}\}} R(\tilde{X}^h_{0,\delta}, Y_{t+\tau,t+\tau+\delta})}.$$

Owing to the use of the weak topology, the boundedness of $\phi(\cdot)$, and the semigroup property (2.18), proving that (3.6) is equivalent to proving that

$$\lim_{\delta\to 0} \sup_{h\to 0} \sup_{t} \sup_{\tau\in\mathcal{T}^{h,t}(\rho)} E\left|K(h,t,\tau,\delta) - \langle \Pi^h(t+\tau), \phi\rangle\right| = 0.$$

But showing this is straightforward, owing to the convergence to unity of the exponential function $R(\tilde{X}^h_{0,\delta}, Y_{t+\tau,t+\tau+\delta})$ as $\delta \to 0$. In particular, it is sufficient to show that (where d_s denoted the differential with respect to the s variable)

$$\begin{aligned} &E_{\{\Pi^h(t+\tau), Y_{t+\tau,t+\tau+\delta}\}} \phi(\tilde{X}^h(\delta)) \\ &\quad \times \left\{ \exp\left[\int_0^\delta g'(\tilde{X}^h(s)) d_s Y(t+\tau+s) - \frac{1}{2}\int_0^\delta \left| g(\tilde{X}^h(s))\right|^2 ds \right] - 1 \right\} \end{aligned}$$

goes to zero in mean as $\delta \to 0$, uniformly in (h,t,τ), for each bounded and continuous function $\phi(\cdot)$. But this follows from the boundedness of $g(\cdot)$. This proves (3.3c).

Since

$$\{B(t+\cdot) - B(t), W(t+\cdot) - W(t), Y(t+\cdot) - Y(t), t > 0\}$$

is always tight, (3.3c) implies that to every $\epsilon > 0$ there exists a compact set K_ϵ such that

$$\lim_{h} \sup_{t} \sup P(\Psi^h(t+\cdot) \in K_\epsilon) > 1 - \epsilon.$$

Now standard arguments show that the family in (3.4) is tight; for more detail see [19, Chapter 1, section 6] or [22, section 5], where there are general results on getting the tightness of occupation measures from the tightness of the set of time shifted processes.

The proofs in [22, Theorem 6.3, part 2] or in [19, Chapter 5, Theorem 2.2] can be adapted to show the stationarity. We work with the marginals $Q_f^{h,T}(\cdot)$ and a subsequence (h, T) such that $\{Q_f^{h,T}(\cdot)\}$ converges weakly. Let H be a Borel set in the product $(x(\cdot), \pi(\cdot))$ path space. For $c > 0$, define the left shift H_c by $H_c = \{\psi_f(\cdot) : \psi_f(c, \cdot) \in H\}$. Then

$$Q_f^{h,T}(H_c) = \frac{1}{T}\int_0^T I_{H_c}(\Psi_f^h(t, \cdot))dt = \frac{1}{T}\int_0^T I_H(\Psi_f^h(t + c, \cdot))dt,$$

$$Q_f^{h,T}(H_c) - Q_f^{h,T}(H) = \frac{1}{T}\int_T^{T+c} I_H(\Psi_f^h(t, \cdot))dt - \frac{1}{T}\int_0^c I_H(\Psi_f^h(t, \cdot))dt. \tag{3.7}$$

The difference goes to zero as $T \to \infty$ for all ω, c, h, and H. This and the weak convergence yields the stationarity of the limit processes $(X^\omega(\cdot), \Pi^\omega(\cdot))$ for almost all ω. □

We now need to identify the processes associated with the limits of the occupation measures and prove the main result (2.10).

Theorem 3.2. *Assume that Assumptions* 2.1, 2.2, *and* 2.3 *hold. Then, for almost all* ω, *the following hold.*

(i) $(B^\omega(\cdot), W^\omega(\cdot))$ *are standard Wiener processes, with respect to which* $(X^\omega(\cdot)$, $\Pi^\omega(\cdot)$, $Y^\omega(\cdot))$ *are nonanticipative.*

(ii)

$$dY^\omega = g(X^\omega)dt + dB^\omega, \tag{3.8}$$

(iii)

$$dX^\omega = p(X^\omega)dt + \sigma(X^\omega)dW^\omega. \tag{3.9}$$

(iv) *For each bounded and measurable real-valued function* $\phi(\cdot)$

$$\langle \Pi^\omega(t), \phi\rangle = \frac{E_{\{\Pi^\omega(0), Y_{0,t}^\omega\}}\left[\phi(\tilde{X}(t))R(\tilde{X}_{0,t}, Y_{0,t}^\omega)\right]}{E_{\{\Pi^\omega(0), Y_{0,t}^\omega\}}R(\tilde{X}_{0,t}, Y_{0,t}^\omega)}. \tag{3.10}$$

(v) $(X^\omega(\cdot), \Pi^\omega(\cdot))$ *is the unique stationary process, and hence its distribution does not depend on* ω.

Finally, for any bounded and measurable real-valued function $F(\cdot)$ *which is continuous almost everywhere with respect to the unique measure* $\bar{Q}_f(\cdot)$ *of the stationary process,*

$$\frac{1}{T}\int_0^T F(\Psi_f^h(t + \cdot))dt \to \int F(\psi_f(\cdot))\bar{Q}_f(d\psi_f(\cdot)) \tag{3.11}$$

in probability as $h \to 0$ *and* $T \to \infty$ *in any way at all.*

Proof. Let $h_k \to 0, T_k \to \infty$. Fix a weakly convergent subsequence of $\{Q^{h_k,T_k}(\cdot)\}_{k\geq 1}$, and index it by h_k, T_k also, abusing the notation. It will turn out that all convergent subsequences have the same limit.

The processes $B^\omega(\cdot), W^\omega(\cdot)$. Let us demonstrate the Wiener and mutual independence properties (for almost all ω). Let $f_i(\cdot)$ and $q(\cdot)$ be real-valued and continuous functions of their arguments and with compact support, with the $f_i(\cdot)$ being twice continuously differentiable. Let $\phi_j(\cdot)$ be an arbitrary finite collection of bounded and continuous real-valued functions. Let ρ and τ be arbitrary nonnegative numbers, and let $u_i \leq \rho$ be (a finite collection of) arbitrary nonnegative real numbers. Define the function

$$\begin{aligned} F(\psi(\cdot)) &= q(x(u_i), \langle \pi(u_i), \phi_j \rangle, b(u_i), w(u_i); i, j) \\ &\times \left[f_1(b(\rho+\tau)) f_2(w(\rho+\tau)) - f_1(b(\rho)) f_2(w(\rho)) - \int_\rho^{\rho+\tau} A_0 f_1(b(s)) f_2(w(s))) ds \right], \end{aligned}$$

where $A_0 = (1/2)\left[\sum_i \partial^2/\partial b_i^2 + \sum_i \partial^2/\partial w_i^2\right]$. The b_i (resp., w_i) are the scalar components of b (resp., w).

We will show that

$$\int Q^\omega(d\psi(\cdot))F(\psi(\cdot)) = 0 \tag{3.12}$$

for almost all ω. The arbitrariness of the functions and of $\rho, \tau, u_i \leq \rho$ and (3.12) imply that $W^\omega(\cdot)$ and $B^\omega(\cdot)$ are standard vector-valued and independent Wiener processes, and martingales with respect to the filtration generated by $\{\Psi^h(s), s \leq t\}$, hence the nonanticipativity.

To get (3.12), we will show that the mean square value

$$E\left[\int Q^{h_k,T_k}(d\psi(\cdot))F(\psi(\cdot))\right]^2 \tag{3.13}$$

goes to zero as h, T go to their limits. This and the weak convergence imply (3.12) since they imply that $E\left[\int Q(d\psi(\cdot))F(\psi(\cdot))\right]^2 = 0$. (An analogous calculation for a queueing problem is in [22].) By the definition of the occupation measure, the expression

$$\int Q^{h_k,T_k}(d\psi(\cdot))F(\psi(\cdot)) \tag{3.14a}$$

equals

$$\frac{1}{T_k}\int_0^{T_k} F_1(t)dt, \tag{3.14b}$$

where $F_1(t)$ equals $F_2(t)F_3(t)$, and where

$$F_2(t) = q\left(X(t+u_i), \langle \Pi^{h_k}(t+u_i), \phi_j \rangle, B(t+u_i) - B(t), W(t+u_i) - W(t); i, j\right),$$

$$\begin{aligned} F_3(t) = \Bigg[& f_1(B(t+\rho+\tau) - B(t)) f_2(W(t+\rho+\tau) - W(t)) \\ & - f_1(B(t+\rho) - B(t)) f_2(W(t+\rho) - W(t)) \\ & - \int_{t+\rho}^{t+\rho+\tau} A_0 f_1(B(t+s) - B(t)) f_2(W(t+s) - W(t))) ds \Bigg]. \end{aligned}$$

The mean square value of (3.14b) equals

$$\frac{1}{T_k^2}\int_0^{T_k}\int_0^{T_k} EF_2(t)F_2(v)F_3(t)F_3(v)dtdv. \tag{3.15}$$

Now, using the fact that (the martingale property)

$$E\left[F_3(v)|W(u),B(u),u\le t+\rho\right]=0 \quad \text{for } v\ge t, \tag{3.16}$$

we see that (3.15) is of the order of $O(1/T_k)$, which yields the desired result.

Identifying the limits $X^\omega(\cdot), Y^\omega(\cdot)$. For a vector z, define $|z|_1^2=|z|^2\wedge 1$. To identify the $Y^\omega(\cdot)$ process, we will prove that

$$E\int Q^\omega(d\psi(\cdot))\left|y(s)-\int_0^s g(x(u))du-b(s)\right|_1^2=0 \tag{3.17}$$

for each s. This is equivalent to

$$EE^\omega\left|Y^\omega(s)-\int_0^s g(X^\omega(u))du-B^\omega(s)\right|_1^2=0,$$

which implies (3.8) for almost all ω.

Equation (3.17) is shown by using the definition of the occupation measure and the weak convergence, i.e., by using the fact that (2.2) implies

$$\begin{aligned}&E\int Q^{h_k,T_k}(d\psi(\cdot))\left|y(s)-\int_0^s g(x(u))du-b(s)\right|_1^2\\&\quad=E\frac{1}{T_k}\int_0^{T_k}\left|Y(t+s)-Y(t)-\int_t^{t+s}g(X(u))du-(B(t+s)-B(t))\right|_1^2dt=0.\end{aligned}$$

Now use the weak convergence and the fact that the integrand in the first integral is a bounded and continuous function of $\psi(\cdot)$.

We deal with $X(\cdot)$ by a process approximation method. Recall the definitions of $p(\cdot)$ and $\sigma(\cdot)$ from (2.1). For each $\epsilon>0$ and $t\ge 0$, there is $\Delta_0>0$ such that for $\Delta\le\Delta_0$ we have (uniformly in $u\ge 0$)

$$\begin{aligned}E\Bigg|&X(u+t)-X(u)-\int_u^{u+t}p(X(s))ds\\&-\sum_{i:i\Delta<t}\sigma(X(u+i\Delta))\left[W(u+i\Delta+\Delta)-W(u+i\Delta)\right]\Bigg|^2=O(\epsilon).\end{aligned} \tag{3.18}$$

We have shown above that $(W^\omega(\cdot),B^\omega(\cdot))$ are Wiener processes, and that $(X^\omega(\cdot),\Pi^\omega(\cdot))$ is nonanticipative with respect to them. Suppose that we can show that for each $\epsilon>0$ and $t\ge 0$ there is $\Delta_\epsilon>0$ such that for $\Delta\le\Delta_\epsilon$,

$$\begin{aligned}E\int\Bigg[&x(t)-x(0)-\int_0^t p(x(s))ds\\&-\sum_{i:i\Delta<t}\sigma(x(i\Delta))[w(i\Delta+\Delta)-w(i\Delta)]\Bigg]_1^2Q^\omega(d\psi(\cdot))=O(\epsilon).\end{aligned} \tag{3.19}$$

Then, analogous to what was done for $Y^\omega(\cdot)$ above, we have, for almost all ω,

$$X^\omega(t)=X^\omega(0)+\int_0^t p(X^\omega(s))ds+\sum_{i:i\Delta<t}\sigma(X^\omega(i\Delta))[W^\omega(i\Delta+\Delta)-W^\omega(i\Delta)]$$

modulo $O(\epsilon)$ in mean square. This and the arbitrariness of ϵ and Δ imply (3.9). The reason for using the finite sum approximation to the stochastic integral is that now the integrand in (3.19) is a bounded and continuous function of $\psi(\cdot)$, w.p.1 for each ω, since the $Q^\omega(\cdot)$ must induce continuous processes. (If $X(\cdot)$ is jump-diffusion, the continuity w.p.1 still holds since the probability that a jump occurs at any given (nonrandom) time point is zero.) Thus, the weak convergence can be used.

Consider now

$$E\int \left| x(t) - x(0) - \int_0^t p(x(s))ds - \sum_{i:i\Delta<t} \sigma(x(i\Delta))[w(i\Delta+\Delta) - w(i\Delta)] \right|_1^2 Q^{h_k,T_k}(d\psi(\cdot)).$$

The h index is irrelevant in this calculation. By the definition of the occupation measure, the above expression is equivalent to

$$E\frac{1}{T_k}\int_0^{T_k} \left| X(t+u) - X(u) - \int_u^{t+u} p(X(s))ds \right.$$
$$\left. - \sum_{i:i\Delta<t} \sigma(X(u+i\Delta))[W(u+i\Delta+\Delta) - W(u+i\Delta)] \right|_1^2 du.$$

But, (3.18) implies that, for small enough $\Delta > 0$, the expectation of this is $O(\epsilon)$ uniformly in T. This and the weak convergence of $Q^{h,T}(\cdot)$ to $Q(\cdot)$ imply (3.19).

The $\Pi^\omega(\cdot)$ component. Now we turn our attention to $\Pi^h(\cdot)$ and the sample value $\Pi^\omega(\cdot)$ component of the weak sense limit. For small $\Delta > 0$, define $R^\Delta(\tilde{X}^h_{0,s}, Y_{0,s})$ by approximating the stochastic integral $\int_0^s g'(\tilde{X}^h(u))dY(u)$ in the exponent by the sum

$$\sum_{i:i\Delta<s} g'(\tilde{X}^h(i\Delta))\,[Y(i\Delta+\Delta) - Y(i\Delta)]$$

analogously to what was done in (3.18). For arbitrary t define $R^\Delta(\tilde{X}^h_{0,s}, Y_{t,t+s})$ analogously. For each h, t, define the difference $\hat{Z}^{h,\Delta}(t,\cdot)$ by

$$\hat{Z}^{h,\Delta}(t,s) = \frac{E_{\{\Pi^h(t),Y_{t,t+s}\}}\left[\phi(\tilde{X}^h(s))R(\tilde{X}^h_{0,s}, Y_{t,t+s})\right]}{E_{\{\Pi^h(t),Y_{t,t+s}\}}R(\tilde{X}^h_{0,s}, Y_{t,t+s})}$$
$$- \frac{E_{\{\Pi^h(t),Y_{t,t+s}\}}\left[\phi(\tilde{X}^h(s))R^\Delta(\tilde{X}^h_{0,s}, Y_{t,t+s})\right]}{E_{\{\Pi^h(t),Y_{t,t+s}\}}R^\Delta(\tilde{X}^h_{0,s}, Y_{t,t+s})}.$$

We note that $\{\tilde{X}^h(\cdot)\}$ is equicontinuous in probability in the following sense. For each positive ρ and t, there is $h_0 > 0$ and $\alpha > 0$ such that

$$\sup_{h\le h_0} P\left\{ \sup_{u\le\alpha,\ s\le t} \left|\tilde{X}^h(s+u) - \tilde{X}^h(s)\right| \ge \rho \right\} \le \rho.$$

By the properties of the approximation of the stochastic integral by a sum, for each $\epsilon' > 0$ and $\epsilon'' > 0$, there is Δ_0 such that for $\Delta < \Delta_0$, and small $h > 0$, we have

$$\sup_{\Pi^h(t),t} P\left\{ \left|\hat{Z}^{h,\Delta}(t,s)\right| \ge \epsilon' \right\} \le \epsilon''. \tag{3.20}$$

This is due to the just-cited equicontinuity in probability, keeping in mind that the state space is compact, and where the sup is over all possible values. Next we verify that (3.10) holds. We would like to show that, for each s,

$$E\int Q^{\omega}(d\psi(\cdot))\left|\langle\pi(s),\phi\rangle-\frac{E_{\{\pi(0),y_{0,s}\}}\left[\phi(\tilde{X}(s))R(\tilde{X}_{0,s},y_{0,s})\right]}{E_{\{\pi(0),y_{0,s}\}}R(\tilde{X}_{0,s},y_{0,s})}\right|_1^2=0. \tag{3.21}$$

But the integrand function is not well defined, since $y(\cdot)$ is an arbitrary path function and the stochastic integral in $R(\cdot)$ in (3.21) is not defined. The problem is resolved by working with an approximation.

It will actually be shown that

$$E\int Q^{\omega}(d\psi(\cdot))\left|\langle\pi(s),\phi\rangle-\frac{E_{\{\pi(0),y_{0,s}\}}\left[\phi(\tilde{X}(s))R^{\Delta}(\tilde{X}_{0,s},y_{0,s})\right]}{E_{\{\pi(0),y_{0,s}\}}R^{\Delta}(\tilde{X}_{0,s},y_{0,s})}\right|_1^2 \tag{3.22}$$

goes to zero as $\Delta\to 0$, which implies (3.10). Here the $\tilde{X}(\cdot)$ is a process with initial distribution $\pi(0)$ and the law of evolution of $X(\cdot)$. Note that the integrand function in (3.22) does not depend on this process, only on its initial condition. Also it is bounded and continuous w.p.1 (with respect to $Q^{\omega}(\cdot)$) for almost all ω.

By the weak convergence, (3.22) is the limit of

$$E\int Q^{h_k,T_k}(d\psi(\cdot))\left|\langle\pi(s),\phi\rangle-\frac{E_{\{\pi(0),y_{0,s}\}}\left[\phi(\tilde{X}^{h_k}(s))R^{\Delta}(\tilde{X}^{h_k}_{0,s},y_{0,s})\right]}{E_{\{\pi(0),y_{0,s}\}}R^{\Delta}(\tilde{X}^{h_k}_{0,s},y_{0,s})}\right|_1^2.$$

Thus, we need only show that, for each $s>0$ and each bounded and continuous function $\phi(\cdot)$, this expression is small for small $\Delta>0, h_k>0$ and large $T_k<\infty$. By the definition of the measure $Q^{h,T}(\cdot)$, this expression equals

$$E\frac{1}{T_k}\int_0^{T_k}\left|\hat{Z}^{h_k,\Delta}(t,s)\right|_1^2 dt. \tag{3.23}$$

Now, the fact that (3.23) is small for small h_k,Δ follows from (3.20).

Theorem 3.1 yields the stationarity of $(X^{\omega}(\cdot),\Pi^{\omega}(\cdot))$ for almost all ω. The measure $\bar{Q}_f(\cdot)$ of the stationary $(X^{\omega}(\cdot),\Pi^{\omega}(\cdot))$ process is unique by assumption. Thus $Q_f^{h_k,T_k}(\cdot)$ converges weakly to $\bar{Q}_f(\cdot)$ along the chosen subsequence. The uniqueness also implies that the subsequence is irrelevant and that $Q_f^{h,T}(\cdot)$ converges weakly to $\bar{Q}_f(\cdot)$ along any (h,T) subsequence. This implies (3.11). $\square$

4. Non-Markov signal processes. In actual physical applications, the signal process would not generally be a diffusion or jump-diffusion, but rather some non-Markov process which is only approximated by a diffusion or jump-diffusion. For example, the physical process might be a dynamical system which is driven by a wide bandwidth noise process and not a Wiener process. To quantify the connection, we need to parameterize the physical process, and suppose that it converges weakly to some "ideal" signal process, a diffusion or jump-diffusion, as the approximation parameter h goes to its limit. We would construct an approximation to the optimal filter for the ideal signal process, but use the physical observations. Thus, we are concerned with the convergence of the pathwise average errors as the time interval goes to its infinite limit; the physical process is better and better approximated by its ideal limit and the filter approximation converges to the optimal filter for that ideal limit. Thus, we have a physical process $X^h(\cdot)$, with values on the same compact range space G and which is approximated by the diffusion $X(\cdot)$, defined by (2.1), and a filter $\Pi^h(\cdot)$ which is a numerical approximation to the optimal filter for (2.1) with observations (2.2), but where the actual physical observations defined by

$$dY^h = g(X^h(t))dt + dB \tag{4.1}$$

are used. We could use another parameter rather than h to index the "prediffusion" process and then let this go to its limit together with h, T, but there is no loss of generality in using h to index this process as well.

The filter to be built is as in section 2. This would be a filter constructed under the assumption that the system is (2.1) and observations (2.2). But, with (4.1) actually used. The approximating filter uses the auxiliary process $\tilde{X}^h(\cdot)$, which satisfies (A2.2). Thus the approximating filter takes the form (2.7), but with $Y^h(\cdot)$ replacing $Y(\cdot)$. The process $X^h(\cdot)$ is not to be confused with $\tilde{X}^h(\cdot)$. The former is the actual physical signal process. The latter continues to play the role that it had in the previous sections; i.e., it is an approximation to the ideal limit, which is used only to get a numerical approximation to the optimal filter for (2.1) and (2.2). The following is the basic assumption on the physical process $X^h(\cdot)$.

ASSUMPTION 4.1. *$X^h(t) \in G$ for all $t, h > 0$. The family $\{X^h(t+\cdot); h > 0, t \geq 0\}$ is tight and whenever for some subsequence $(h_k, t_k)_{k\geq 1}$, where $h_k \to 0$ as $k \to \infty$, the distribution of $X^{h_k}(t_k)$ converges weakly to some measure* Π *and the sequence $\{X^{h_k}(t_k + \cdot)\}_{k\geq 1}$ is weakly convergent, then the limit of the latter is $X(\cdot)$ with initial distribution* Π.

If the filter is to operate over some fixed finite time interval, then convergence results are relatively easy to obtain, since the criteria of interest in that case are mean values. Many such results are in [21]. In the definition of $\Psi^h(\cdot)$, drop the W-component and replace $X(\cdot), Y(\cdot)$, by $X^h(\cdot), Y^h(\cdot)$, resp. Redefine the $\Psi(\cdot), \psi(\cdot)$, $Q^{h,T}(\cdot)$ analogously. In Theorem 4.1 we obtain the analog of Theorems 3.1 and 3.2 for this approximate filtering problem. Theorem 3.1 continues to hold, with the same proof. In the proof of the analog of Theorem 3.2, there is no new problem with the identification of the limit processes $Y^\omega(\cdot)$ and $\Pi^\omega(\cdot)$. But there is a problem in the identification of the limit $X^\omega(\cdot)$. The assumption of weak convergence on $X^h(t + \cdot)$ made above is not enough. The problem is that the $Q^{h,T}(\cdot)$ are occupation measures, whose values depend on the *samples* of the paths. Owing to this we need to make a (quite unrestrictive) assumption so that a martingale type method can be used to identify $X^\omega(\cdot)$. Theorem 3.2 can be viewed as an ergodic theorem or weak law of large numbers, and it works partly due to the ergodic properties of $X(\cdot)$, as reflected in the uniqueness of the stationary process. But the assumed weak convergence of $X^h(t+\cdot)$ is not enough in itself to get such a weak law of large numbers. It says little about "long range dependence." This is the main issue that we will need to deal with.

A note on the martingale problem method. In order to motivate the assumptions to be used, we first recall the classical martingale problem formulation of the existence of a solution to (2.1). Let $\phi_j(\cdot)$, $q(\cdot)$ and $\rho, \tau, u_i \leq \rho$, satisfy the conditions above (3.12) and let $f(\cdot)$ be real-valued with compact support and with partial derivatives up to third order being continuous. Let A denote the differential generator of $X(\cdot)$. To identify the process $X^\omega(\cdot)$ as that satisfying (3.9) for an appropriate Wiener process

$W^\omega(\cdot)$, it is sufficient to show that $X(\cdot)$ solves the martingale problem of Stroock and Varadhan; namely, for all such $f(\cdot), q(\cdot)$, etc.,

$$\begin{aligned}\int Q^\omega(d\psi(\cdot))q(x(u_i), \langle \pi(u_i), \phi_j\rangle, b(u_i); i, j)\\ \times \left[f(x(\rho+\tau)) - f(x(\rho)) - \int_\rho^{\rho+\tau} Af(x(s))ds\right] = 0.\end{aligned} \tag{4.2}$$

To show (4.2), it is natural to try to evaluate

$$\begin{aligned}E\Bigg[\int Q^{h,T}(d\psi(\cdot))q(x(u_i), \langle \pi(u_i, \phi_j\rangle, b(u_i); i, j,)\\ \times\left[f(x(\rho+\tau)) - f(x(\rho)) - \int_\rho^{\rho+\tau} Af(x(s))ds\right]\Bigg]_1^2\end{aligned} \tag{4.3}$$

and show that it goes to zero as h, T go to their limits, analogous to the procedure used in connection with (3.12) and (3.13). This and the weak convergence imply (4.2); equivalently, there exists $X^\omega(\cdot)$ and $W^\omega(\cdot)$, with $X^\omega(\cdot)$ nonanticipative, satisfying (3.9) for almost all ω.

It is hard to show (4.3) directly. We take an approach which has been one of the most powerful tools to date for functional limit theorems for convergence to diffusion type processes, namely, the perturbed test function method [5, 13, 17, 18, 19, 26]. This method uses a perturbation $f^h(\cdot)$ to the test function $f(\cdot)$ in (4.2). To simplify the development, and preserve the generality of the results, we will simply assume that a suitable perturbation exists, but methods for constructing it in many important cases are in the references.

The perturbed test function method. Given a test function $f(\cdot)$, which is three times continuously differentiable and with compact support, we seek a process $f^h(\cdot)$ which is close to $f(X^h(\cdot))$ and an extension $\hat{A}^h$ of the operator A such that, loosely speaking,

$$f^h(\cdot) - f(X^h(\cdot)) \to 0,$$

$$\hat{A}^h f^h(\cdot) - Af(X^h(\cdot)) \to 0.$$

With such perturbed test functions $f^\gamma(\cdot)$ available, simple adaptations of the martingale method can be used to identify $X^\omega(\cdot)$.

The operator $\hat{A}^h$. Let $\mathcal{F}_t^h$ be a filtration on the probability space, where $\mathcal{F}_t^h$ measures at least $\{\Psi^h(s), s \le t\}$, and where $\Psi^h(s) = (X^h(s), \Pi^h(s), Y^h(s), B(s))$. Let $u(\cdot)$ and $v(\cdot)$ denote measurable processes which are $\mathcal{F}_t^h$-adapted and progressively measurable and satisfy the following conditions:

$$\sup_t E|u(t)| < \infty, \quad \sup_t E|v(t)| < \infty,$$

$$\sup_{0<\delta,t} \frac{E|E[u(t+\delta)|\mathcal{F}_t^h] - u(t)|}{\delta} < \infty, \tag{4.4}$$

$$\lim_{\delta\to 0} E\left|\frac{E[u(t+\delta)|\mathcal{F}_t^h] - u(t)}{\delta} - v(t)\right| = 0 \text{ almost all } t.$$

Then we say that $u(\cdot) \in \mathcal{D}(\hat{A}^h)$, the *domain of the operator* $\hat{A}^h$, and write $\hat{A}^h u = v$. This operator was introduced originally in [13, 27]. The most important property of the operator $\hat{A}^h$ is given by Lemma 4.1.

The usefulness of the operator $\hat{A}^h$ for proving weak convergence depends on the choice of the conditioning σ-algebra $\mathcal{F}_t^h$. Suppose that $X^h(\cdot)$ is driven by a wide bandwidth noise process $\xi^h(\cdot)$. Then, we would normally set $\mathcal{F}_t^h$ to be the minimal σ-algebra which measures $\{\Psi^h(s), \xi^h(s),\ s \le t\}$. See the references for more detail.

LEMMA 4.1 (see [13; 18, section 3.2; 19, section 7.2]). *Let $u(\cdot) \in \mathcal{D}(\hat{A}^h)$. Then the process defined by*

$$M_u(t) = u(t) - \int_0^t \hat{A}^h u(s) ds \tag{4.5a}$$

*is an $\mathcal{F}_t^h$-martingale and, w.p.*1,

$$E[u(t+s)|\mathcal{F}_t^h] = u(t) + \int_t^{t+s} E[\hat{A}^h u(r)|\mathcal{F}_t^h] dr. \tag{4.5b}$$

Equation (4.5) *continues to hold if the t and $t+s$ are replaced by any bounded stopping times τ_1 and τ_2 with $\tau_1 \le \tau_2$, and which take countably many values. If $u(\cdot)$ is right continuous, then the τ_i can be any bounded stopping times with $\tau_1 \le \tau_2$.*

In order to apply the perturbed test function method we need that the domain of the operator $\hat{A}^h$ is sufficiently rich and as $h \to 0$ the operator $\hat{A}^h$ is consistent with A. This is made precise in the following assumption.

ASSUMPTION 4.2. *For every continuous real-valued function $f(\cdot)$, with compact support and whose partial derivatives up to third order are continuous, there exists $f^h(\cdot) \in \mathcal{D}(\hat{A}^h)$ which is right continuous w.p.*1 *and which satisfies* (4.6) *and* (4.7) *for each $T_1 > 0$:*

$$\lim_h \sup_t E|f^h(t) - f(X^h(t))| = 0, \tag{4.6}$$

$$\lim_h \sup_t \sup_{\tau \le T_1} E \left| \int_t^{t+\tau} \left[\hat{A}^h f^h(s) - Af(X^h(s)) \right] ds \right| = 0. \tag{4.7}$$

General methods of construction of $f^h(\cdot)$ are in [18] under quite broad conditions on the processes involved, and the reader is referred to that reference for more information. See also [19]. The key result for applications is the following lemma.

LEMMA 4.2 (see [18]). *Let the sequence $\{X^h(\cdot), h > 0\}$ converge weakly in $D[\mathbb{R}^r; 0, \infty)$ to a process $X(\cdot)$. Assume that Assumption* 4.2 *holds. Then, $X(\cdot)$ solves the martingale problem for operator A.*

The following theorem essentially says that under the above assumptions Theorems 3.1 and 3.2 continue to hold for this approximate filtering problem.

THEOREM 4.1. *Assume that Assumptions* 2.1, 2.2, 2.3, 4.1, *and* 4.2 *hold. Then* (3.3a) *holds with $X(\cdot)$ replaced by $X^h(\cdot)$. Also,* (3.3b), (3.3c), *and* (3.4) *continue to hold with the modified definitions of $\Pi^h(\cdot)$ and $Q^{h,T}(\cdot)$ stated at the beginning of this section.*

Let Q be a weak limit as in Theorem 3.1*; then Q^ω induces a process*

$$\Psi^\omega(\cdot) = (X^\omega(\cdot), \Pi^\omega(\cdot), Y^\omega(\cdot), B^\omega(\cdot)).$$

For almost all ω the following hold.

(i) *The pair* $(X^{\omega}(\cdot), \Pi^{\omega}(\cdot))$ *is stationary.*

(ii) *There exists a Wiener process* W^{ω} *for which statements* (i) *through* (v) *in Theorem* 3.2 *hold.*

Finally the last conclusion of Theorem 3.2 *also holds; i.e.,* (3.11) *is true.*

Comment on the proof. The only difference from the proofs of Theorems 3.1 and 3.2 concern the proof of (4.2). As noted, this is to be done by showing that (4.3) goes to zero as h, T go to their limits. Thus, we confine our remarks to an evaluation of (4.3).

Let $h \to 0, T \to \infty$ index a weakly convergent subsequence. The expression

$$\begin{aligned} &\int Q^{h,T}(d\psi(\cdot)) q(x(u_i), \langle \pi(u_i), \phi_j \rangle, b(u_i); i, j) \\ &\qquad \times \left[f(x(\rho+\tau)) - f(x(\rho)) - \int_{\rho}^{\rho+\tau} Af(x(s))ds \right] \end{aligned} \tag{4.8}$$

equals

$$\begin{aligned} &\frac{1}{T}\int_0^T q(X^h(t+u_i), \langle \Pi^h(t+u_i), \phi_j \rangle, B(t+u_i) - B(t); i, j) \\ &\qquad \times \left[f(X^h(t+\tau+\rho)) - f(X^h(t+\rho)) - \int_{t+\rho}^{t+\rho+\tau} Af(X^h(s))ds \right] dt. \end{aligned} \tag{4.9}$$

Define

$$M_f^h(t) = f^h(t) - \int_0^t \hat{A}^h f^h(s) ds.$$

Rewrite the bracketed term in (4.9) as

$$\left[M_f^h(t+\tau+\rho) - M_f^h(t+\rho) \right] + [V^h(t+\tau+\rho) - V^h(t+\rho)],$$

where

$$V^h(t) = [f(X^h(t)) - f^h(t)] - \int_0^t [Af(X^h(s)) - \hat{A}^h f^h(s)] ds.$$

By (4.6) and (4.7), $\lim_h \sup_t E|V^h(t+\tau+\rho) - V^h(t+\rho)| = 0$. The weak sense limits of (4.9) are then the same as those of

$$\frac{1}{T}\int_0^T q(X^h(t+u_i), \langle \Pi^h(t+u_i), \phi_j \rangle, B(t+u_i) - B(t); i, j) \left[M_f^h(t+\tau+\rho) - M_f^h(t+\tau) \right] dt. \tag{4.10}$$

Now, square (4.10), take expectations and use the martingale properties of $M_f^h(\cdot)$ to get that the mean square value is $O(1/T)$. This and the weak convergence imply (4.2). □

5. Discrete time observations.

5.1. A Markov signal process. Now, let all processes be defined in discrete time. The idea is fully analogous to what was done in the continuous time case. The following is the basic assumption on the signal process.

ASSUMPTION 5.1. *The signal process $X(\cdot) = \{X(n), n < \infty\}$ is Feller–Markov and takes values in a compact subset G of $\mathbb{R}^r$.*

The observations are defined by $Y(0) = 0$ and

$$Y(n) - Y(n-1) = g(X(n)) + \xi(n),\ n = 1, \ldots, \tag{5.1}$$

where $\{\xi(n)\}$ are mutually independent $(0, I)$ Gaussian random variables which are independent of $X(\cdot)$, and $g(\cdot)$ is continuous.

The Bayes' rule formula for the true conditional distribution of $X(n)$ given $Y_{0,n}$ can be represented in terms of an auxiliary process $\tilde{X}(\cdot)$ as in section 2, where $\tilde{X}(\cdot)$ has the probability law of $X(\cdot)$ but, conditioned on its (possibly random) initial condition, is independent of all the other processes. Analogous to the notation used for the continuous time problem, let $Y_{0,n}$ denote the set $\{Y(i); i \leq n\}$. Define

$$R(\tilde{X}_{0,n}, Y_{0,n}) = \exp\left[\sum_{i=1}^{n} g'(\tilde{X}(i))[Y(i) - Y(i-1)] - \frac{1}{2}\sum_{i=1}^{n}\left|g(\tilde{X}(i))\right|^2\right].$$

Then as in section 2, the optimal filter $\Pi(\cdot)$ can be defined by its moments:

$$\langle \Pi(n), \phi\rangle = \frac{E_{\{\Pi(0),Y_{0,n}\}}\left[\phi(\tilde{X}(n))R(\tilde{X}_{0,n}, Y_{0,n})\right]}{E_{\{\Pi(0),Y_{0,n}\}}R(\tilde{X}_{0,n}, Y_{0,n})}, \tag{5.2}$$

where $\Pi(0)$ is the distribution of $X(0)$ and $\tilde{X}(0)$. As before $(X(\cdot), \Pi(\cdot))$ is Feller–Markov. Henceforth, as in the previous sections, when discussing $\Pi(\cdot)$, we allow $\Pi(0)$ to be arbitrary, and not necessarily the distribution of $X(0)$.

Analogous to the case in section 2, it is generally necessary to approximate the optimal filter in some way. For example, the sequence $X(\cdot)$ might be samples of a diffusion process taken at discrete instants, and the transition function must then be computed approximately. In order to approximate the transition function we might try to solve the corresponding Fokker–Planck equation on $[0, 1]$ by the Markov chain approximation method and also appropriately approximate the initial condition. Or we might try to solve it by some other numerical method (e.g., finite elements, spectral method, etc.) which yields approximations to the one step transition density (assuming that there is a density) which converge in L_2 to the true transition density as the approximation parameter goes to its limit. If this approximation is not nonnegative, we can take its positive part and renormalize to get a transition probability. Finally, even if the original processes were given in discrete time, i.e., no approximations of a p.d.e. were needed, it might be too hard to perform the integrations with the true transition function and we might have to use an appropriate approximation instead. These considerations lead to a formulation analogous to what led to the approximating form (2.7), which we now develop.

Analogous to for the continuous time case, the approximating filter can often be represented in terms of a discrete parameter auxiliary Markov process $\tilde{X}^h(\cdot)$, with values in a compact subset of $\mathbb{R}^r$, and which is independent of the other processes, given its initial condition. As in the continuous time case we will assume the following condition on the auxiliary process.

ASSUMPTION 5.2. *If $\tilde{X}^h(0)$ converges weakly (for any subsequence of values of $h \to 0$) with limit distribution $\Pi(0)$, then the sequence $\tilde{X}^h(\cdot)$ converges weakly to $X(\cdot)$ with initial distribution $\Pi(0)$.*

Define, for $n = 1, \ldots,$

$$R(\tilde{X}^h_{0,n}, Y_{0,n}) = \exp\left[\sum_{i=1}^{n} g'(\tilde{X}^h(i))[Y(i) - Y(i-1)] - \frac{1}{2}\sum_{i=1}^{n}\left|g(\tilde{X}^h(i))\right|^2\right].$$

Again, define the approximating filter $\Pi^h(\cdot)$ by its moments as follows:

$$\langle \Pi^h(n), \phi\rangle = \frac{E_{\{\Pi^h(0), Y_{0,n}\}}\left[\phi(\tilde{X}^h(n))R(\tilde{X}^h_{0,n}, Y_{0,n})\right]}{E_{\{\Pi^h(0), Y_{0,n}\}}R(\tilde{X}^h_{0,n}, Y_{0,n})}. \tag{5.3}$$

Equation (5.3) is just the Bayes' rule formula for the filter for the signal process $\tilde{X}^h(\cdot)$, but with the actual observations $Y(n) - Y(n-1)$ used.

The analog of the semigroup relation (2.8) holds, but where time is discrete. The semigroup property stems from the fact that the filter is that for the discrete parameter Markov process $\tilde{X}^h(\cdot)$, but with the actual physical observations used.

Define the sequences $B(n) = \sum_{i=1}^{n} \xi^i$ and

$$\Psi^h(n, \cdot) = \left\{X(n + \cdot), \Pi^h(n + \cdot), B(n + \cdot) - B(n), Y(n + \cdot) - Y(n)\right\},$$

$$\Psi^h_f(n, \cdot) = \{X(n + \cdot), \Pi^h(n + \cdot)\}$$

. Define $\psi(\cdot)$ and $\psi_f(\cdot)$ analogously.

The Skorohod topology is replaced by a "sequence" topology as follows: The $\Pi^h(n)$ still take values in $\mathcal{M}(G)$ and the weak topology is still used on this space. Let $d^\pi(\cdot)$ and $d^k(\cdot)$ denote the metrics on the space of measures and on Euclidean-k space, resp., where k is the sum of the dimensions of $Y(n), B(n)$, and $X(n)$. Let $d_0(\cdot)$ denote the product metric. Then the metric on the product path (sequence) space is

$$d(a(\cdot), b(\cdot)) = \sum_{n=0}^{\infty} 2^{-n}\left[d_0(a(n), b(n)) \wedge 1\right].$$

Define the occupation measure $Q^{h,N}(\cdot)$ by: For a Borel set C in the product sequence space,

$$Q^{h,N}(C) = \frac{1}{N}\sum_{n=1}^{N} I_C(\Psi^h(n, \cdot)). \tag{5.4}$$

Finally we impose the following basic condition.

ASSUMPTION 5.3. *There is a unique stationary measure $\bar{Q}_f(\cdot)$ of the $\Psi_f(\cdot) = (X(\cdot), \Pi(\cdot))$ process.*

Let $F(\cdot)$ be a real-valued bounded and continuous (w.p.1 with respect to $\bar{Q}_f(\cdot)$) function of $\psi_f(\cdot)$. Then, analogous to (2.10) and (2.14), we are concerned with the convergence (in probability)

$$\frac{1}{N}\sum_{n=1}^{N} F(\Psi^h_f(n + \cdot)) \to \int F(\psi_f(\cdot))\bar{Q}_f(d\psi_f(\cdot)), \tag{5.5}$$

where $h \to 0$ and $N \to \infty$ in any way at all.

The analogs of Theorems 3.1 and 3.2 hold, and the proof is close to those proofs. But owing to the discrete time some of the details are simpler, and others slightly different.

THEOREM 5.1. *Assume that Assumptions* 5.1, 5.2, *and* 5.3 *hold. Then* $\{Q^{h,N}(\cdot); h > 0, N > 0\}$ *is tight. Let* $Q(\cdot)$ *denote a weak sense limit, always as* $h \to 0$ *and* $N \to \infty$. *Let* ω *be the canonical variable on the probability space on which* $Q(\cdot)$ *is defined, and denote the sample values by* $Q^{\omega}(\cdot)$. *Then, for each* ω, $Q^{\omega}(\cdot)$ *is a measure on the product path* (*sequence*) *space. It induces a process*

$$\Psi^{\omega}(\cdot) = (X^{\omega}(\cdot), \Pi^{\omega}(\cdot), Y^{\omega}(\cdot), B^{\omega}(\cdot)) .$$

For almost all ω, *the following hold:*

(i) $(X^{\omega}(\cdot), \Pi^{\omega}(\cdot))$ *is stationary.*

(ii) $B^{\omega}(\cdot)$ *is the sum if mutually independent* $N(0, I)$ *random variables* $\{\xi^{\omega}(n)\}$ *which are independent of* $X^{\omega}(\cdot)$.

(iii)

$$Y^{\omega}(n) - Y^{\omega}(n-1) = g(X^{\omega}(n)) + \xi^{\omega}(n).$$

(iv) $X^{\omega}(\cdot)$ *has the transition function of* $X(\cdot)$.

Finally, for each integer n *and each bounded and measurable real-valued function* $\phi(\cdot)$,

$$\langle \Pi^{\omega}(n), \phi \rangle = \frac{E_{\{\Pi^{\omega}(0), Y^{\omega}_{0,n}\}} \left[\phi(\tilde{X}(n)) R(\tilde{X}_{0,n}, Y^{\omega}_{0,n}) \right]}{E_{\{\Pi^{\omega}(0), Y^{\omega}_{0,n}\}} R(\tilde{X}_{0,n}, Y^{\omega}_{0,n})}.$$

Remark on the proof. The details are essentially the same as those of the proofs of Theorems 3.1 and 3.2 and are omitted. We note only two differences. First, owing to the use of discrete time, the martingale method cannot be used to characterize $B^{\omega}(\cdot)$, as done in the first part of the proof of Theorem 3.2. But an analogous method, using a direct computation of the (conditional) characteristic function, can be used instead, as follows. Replace the expression $F(\cdot)$ defined above (3.12) by the following. For arbitrary integers m, n, k, let $u_i \le m$ and $v_p; p \le n$, be arbitrary integers. Let ν_i be vectors (with the dimension of $\xi(n)$), and replace the expression by

$$\begin{aligned} F(\psi(\cdot)) &= q(x(v_p), \langle \pi(u_i), \phi_j \rangle, b(u_i); i \le m, p \le n, j) \\ &\times \left[\exp\left[\sum_{l=m}^{m+k} \nu_l' [b(l+1) - b(l)] \right] - \exp\left[\sum_{l=m}^{m+k} |\nu_l|^2/2 \right] \right] \end{aligned}$$

We need to show that, for almost all ω,

$$\int F(\psi(\cdot)) Q^{\omega}(d\psi(\cdot)) = 0, \tag{5.6a}$$

which will imply that

$$\begin{aligned} &\int Q^{\omega}(d\psi(\cdot)) q(x(v_p), \langle \pi(u_i), \phi_j \rangle, b(u_i); i \le m, p \le n, j) e^{\sum_{l=m}^{m+k} \nu_l' [b(l+1) - b(l)]} \\ &\quad = \int Q^{\omega}(d\psi(\cdot)) q(x(v_p), \langle \pi(u_i), \phi_j \rangle, b(u_i); i \le m, p \le n, j) e^{\sum_{l=m}^{m+k} |\nu_l|^2/2}. \end{aligned} \tag{5.6b}$$

This, in turn, implies that (for almost all ω) the $\xi^\omega(l)$ are mutually independent, normally distributed with mean zero and with the covariance being the identity matrix, and are independent of the $X^\omega(\cdot)$ and of the "past" of the $\Pi^\omega(\cdot)$ process. The proof of (5.6a) is analogous to the arguments below (3.12), and the details are omitted.

We need to characterize $X^\omega(\cdot)$. In particular, we need to show that it is Markov with the transition function of $X(\cdot)$. A characteristic function and "weak law of large numbers type" argument can be used. The goal is to show that, for any integer m, any bounded and continuous real-valued function $q(\cdot)$, and any vector λ,

$$\int Q^\omega(d\psi(\cdot))q(x(u_j); u_j \leq m)\left[e^{\lambda' x(m+1)} - \int e^{i\lambda' v} P(dv, 1|x(m))\right] = 0, \tag{5.7}$$

where $P(dv, 1|x)$ is the one step transition function of $X(\cdot)$. Equation (5.7) says that $X^\omega(\cdot)$ is Markov with the transition function of $X(\cdot)$ since it says that the conditional expectation of $e^{i\lambda' X^\omega(m+1)}$, given the "past" and the current state, can be computed by use of the transition function.

Rewrite (5.7) as the weak sense limit of

$$\frac{1}{N}\sum_{n=1}^{N} q(X(n+u_j); u_j \leq m)\left[e^{i\lambda' X(n+m+1)} - \int e^{i\lambda' v} P(dv, 1|X(n+m))\right]. \tag{5.8}$$

Note that by the Markov property the expectation of the nth summand (conditioned on the data to time $n+m$) in (5.8) is zero. Now, use this last fact to show that the mean square value is $O(1/N)$. The rest of the details are as in the proofs of Theorems 3.1 and 3.2. □

5.2. A non-Markov signal process. Recall the model of section 4, where the underlying signal process, called $X^h(\cdot)$ there, was not Markov. We supposed that it converged weakly to the process of section 2 as $h \to 0$. We can do a similar analysis in the discrete time case, and it is worthwhile since the actual signal process will not usually be Markov and it is not a priori obvious that even small errors per step will not lead to large errors as the time interval goes to infinity. As noted in section 4, we could use a symbol other than h to index this process, but there is no loss of generality in using h. In lieu of the perturbed test function method introduced in section 4, we will follow the procedure of the previous subsection as closely as possible. We keep the assumptions on $\tilde{X}^h(\cdot)$ and the filter form (5.3), which uses instead of $Y(\cdot)$ the following modified observation process:

$$Y^h(n) - Y^h(n-1) = g(X^h(n)) + \xi(n).$$

The main new problem is the identification of the $X^\omega(\cdot)$. We concentrate on that and make the assumptions of the last subsection.

Some assumption on the convergence of $X^h(\cdot)$ to $X(\cdot)$ is needed. The procedure of the last subsection requires that we show that

$$\frac{1}{N}\sum_{n=1}^{N} q(X^h(n+u_j); u_j \leq m)\left[e^{i\lambda' X^h(n+m+1)} - \int e^{i\lambda' v} P(dv, 1|X^h(n+m))\right] \tag{5.9}$$

converges to zero in probability as $N \to \infty$. The convergence in (5.9) is not guaranteed by the weak convergence of $X^h(\cdot)$ to $X(\cdot)$, since the property (5.9) involves the "long range dependencies" of the $X^h(\cdot)$ processes. We will take an approach that is quite flexible and whose conditions are not stringent.

We make the following assumptions. Define the process $X(\cdot|x)$ to have the law of evolution of $X(\cdot)$, but with initial condition x.

ASSUMPTION 5.4. *For an arbitrary integer m and any bounded and continuous real-valued function $f(\cdot)$ of m arguments,*

$$\lim_h \sup_n \left[Ef(X^h(n+u_j); u_j \le m) - E\left[f(X(u_j|X^h(n)); u_j \le m) \right] \right] = 0. \tag{5.10}$$

ASSUMPTION 5.5. *For an arbitrary integer m and any bounded and continuous real-valued function $f(\cdot)$ of m arguments and any $\mu > 0$, there is $m_\mu < \infty$ such that*

$$\begin{aligned} \limsup_h \sup_{|n-\nu|\ge m_\mu} & E\left(\left[f(X^h(n+u_j); u_j \le m) - Ef(X^h(n+u_j); u_j \le m) \right] \right. \\ & \times \left. \left[f(X^h(\nu+u_j); u_j \le m) - Ef(X^h(\nu+u_j); u_j \le m) \right] \right) \le \mu. \end{aligned} \tag{5.11}$$

Condition (5.10) can be interpreted as follows: It is equivalent to saying that if for any sequence n_h, $X^h(n_h)$ converges weakly to a random variable $\hat{X}(0)$ as $h \to 0$, then $\{X^h(n_h + \cdot)\}$ converges weakly to $X(\cdot)$ with initial condition $\hat{X}(0)$. It is unrestrictive since the usual choices for $X^h(\cdot)$ are Markov with time independent transition functions. Condition (5.11) deals with long-range dependence. It basically says that if we take increments of the $X^h(\cdot)$ process which are separated by a large time interval which does not depend on h), then their correlation is small for small h. This does not appear to be restrictive. It is guaranteed by appropriate mixing conditions [9]. Actually, (5.11) is needed only for the types of functions which appear in (5.9). In the definition of $\Psi^h(\cdot)$ replace $X(\cdot), Y(\cdot)$ by $X^h(\cdot), Y^h(\cdot)$, resp. Redefine $\Pi^h(\cdot)$ by replacing $Y(\cdot)$ by $Y^h(\cdot)$ in (5.3). Modify the definitions of $\Psi^h_f(\cdot)$ and $Q^{h,N}(\cdot)$ in a similar manner.

THEOREM 5.2. *Assume that Assumptions* 5.1, 5.2, 5.3, 5.4, *and* 5.5 *hold. Then the conclusions of Theorem* 5.1 *hold with the above modified definitions of* $\Pi^h(\cdot)$ *and* $Q^{h,N}(\cdot)$.

Comments on the proof. All of the details are as in Theorem 5.1, except for the characterization of $X^\omega(\cdot)$ and we concentrate on this. Return to the proof of (5.7) via an evaluation of the limit of (5.9). For a bounded and continuous function $q(\cdot)$, define

$$q_1(x(u_j), x(m+1); u_j \le m) = q(x(u_j); u_j \le m) e^{i\lambda' x(m+1)},$$

$$q_2(x(u_j); u_j \le m) = q(x(u_j); u_j \le m) \int e^{i\lambda' v} P(dv, 1|x(m)).$$

We will show that

$$\left| \int Q^{N,h}(d\psi(\cdot)) \left[q_1(x(u_j), x(m+1); u_j \le m) - q_2(x(u_j); u_j \le m) \right] \right| \to 0 \tag{5.12}$$

in mean as $N \to \infty$ and $h \to 0$. This, together with the weak convergence, yields (5.7) for almost all ω. Evaluate the integral in (5.12) by first rewriting it as

$$\frac{1}{N} \sum_{n=1}^{N} \left[q_1(X^h(n+u_j), X^h(n+m+1); u_j \le m) - q_2(X^h(n+u_j); u_j \le m) \right]. \tag{5.13}$$

Now, split (5.13) into the difference of the two sums

$$\begin{aligned}\frac{1}{N}\sum_{n=1}^{N} \big[&q_1(X^h(n+u_j), X^h(n+m+1); u_j \le m) \\ &-Eq_1(X^h(n+u_j), X^h(n+m+1); u_j \le m)\big]\end{aligned} \tag{5.14}$$

and

$$\begin{aligned}\frac{1}{N}\sum_{n=1}^{N} \big[&q_2(X^h(n+u_j), X^h(n+m+1); u_j \le m) \\ &-Eq_1(X^h(n+u_j), X^h(n+m+1); u_j \le m)\big].\end{aligned} \tag{5.15}$$

By Assumption 5.5, (5.14) goes to zero in mean square as $N \to \infty$ and $h \to 0$. By Assumption 5.4, the term $Eq_1(X^h(n+u_j), X^h(n+m+1); u_j \le m)$ in (5.15) can be replaced by $Eq_1(X(u_j|X^h(n)), X(m+1|X^h(n)); u_j \le m)$ in the sense that the mean square limits as $N \to \infty$ and $h \to 0$ are the same. By the Markov property of $X(\cdot)$, for any initial condition

$$Eq_1(X(u_j), X(m+1); u_j \le m) = Eq_2(X(u_j); u_j \le m).$$

By the last two sentences, we can replace the expected value in (5.15) by

$$Eq_2(X(u_j|X^h(n)); u_j \le m)$$

without changing the limits. Using Assumption 5.4 again, we can replace $Eq_2(X(u_j|X^h(n));$ $u_j \le m)$ by $Eq_2(X^h(n+u_j); u_j \le m)$ in (5.15) in that the mean square limits are the same. Now, use Assumption 5.5 again to get that the mean square limit of (5.15) with this last replacement is zero. We have shown that the mean square limit of (5.13) is zero, as $N \to \infty$ and $h \to 0$, which implies (5.7). □

6. Discrete to continuous time: White or wideband observation noise.

The most appropriate justification of the classical continuous time filter is as an approximation to the discrete time model for small sampling intervals. Quite often, one has wide bandwidth rather than white noise and the signal is not a diffusion but only an approximation to a diffusion. One still might wish to use some sort of ideal filter, which is built on the assumption that the signal is a particular diffusion and that the observation noise is white. If the filter is to be used for a very long time interval and one is interested in pathwise prediction errors or other performance measures (see section 2 for an example), questions arise concerning the asymptotic quality, as the time, the bandwidth of the observation noise, the parameter in the diffusion approximation to the actual signal process, etc., all go to their respective limits. We will see that the previous robustness results continue to hold under reasonable conditions.

Asymptotic, large time results were obtained in [21] for mean value criteria. Depending on how the filter with wide bandwidth observation noise is constructed, there might be the so-called correction terms [21]. In the present context, we suppose that either the basic Bayes' rule formulas such as (2.7) or its later analogs are used or that the constructed filter is equivalent to these formulas, at least asymptotically. There is no need to introduce correction terms into the Bayes' rule formulas as written here.

The problem formulation. The signal process $X^h(\cdot)$ is assumed to satisfy the conditions used in Theorem 4.1 and is sampled at intervals of width $\Delta_h \to 0$. The observation noise is wide bandwidth in the sense to be made precise below. There is a process $B^h(\cdot)$ satisfying Assumptions 6.1, 6.2, and 6.3 below, such that the observation process, $\{Y^h(n\Delta_h); n \geq 0\}$ satisfies the equation

$$Y^h(n\Delta_h) - Y^h(n\Delta_h - \Delta_h) = \Delta_h g(X^h(n\Delta_h)) + B^h(n\Delta_h) - B^h(n\Delta_h - \Delta_h). \tag{6.1}$$

The assumptions on the process $B^h(\cdot)$ are as follows.

Assumption 6.1. *The process $B^h(\cdot)$ is independent of $X^h(\cdot)$. The set*

$$\{B^h(t + \cdot) - B^h(t); h > 0, t \geq 0\} \tag{6.2}$$

is tight and any weakly convergent subsequence of the form $\{B^{h_k}(t_k + \cdot) - B^{h_k}(t_k)\}_{k\geq 1}$, such that $h_k \to 0$ as $k \to \infty$ converges to the standard Wiener process $B(\cdot)$ as $k \to \infty$.

Assumption 6.2. *For every family of random variables of the form $\{\mu_n^{\Delta,h}, n \geq 1, h > 0, \Delta > 0\}$ which satisfies* (i)–(iii) *below, we have that for each $T > 0$ and $\epsilon > 0$,*

$$\lim_{\Delta\to 0} \limsup_h \sup_n P\left\{ \sup_{s\leq T} \left| \sum_{i=n}^{n+s/\Delta_h} \mu_i^{\Delta,h} \left[B^h(i\Delta_h + \Delta_h) - B^h(i\Delta_h)\right] \right| \geq \epsilon \right\} = 0. \tag{6.3}$$

(i) $\mu_n^{\Delta,h}$ *is bounded uniformly in n, Δ, and h.*

(ii) *For each fixed h and Δ, the family $\{\mu_n^{\Delta,h}, n < \infty\}$ is independent of $B^h(\cdot)$.*

(iii)

$$\lim_{\Delta\to 0} \limsup_h \sup_n P\left\{ \sup_{n\leq i\leq n+T/\Delta_h} \left|\mu_i^{\Delta,h}\right| \geq \delta \right\} = 0, \text{ for each } \delta > 0. \tag{6.4}$$

The requirement (6.3) is mainly a condition on how fast the conditional dependence of the "future," given the "past," goes to zero. Owing to the independence of $\{\mu_n^h, n < \infty\}$ and $B^h(\cdot)$, the condition is not stringent. Various sufficient conditions for (A6.2) to hold will be given at the end of the section.

Now for the final assumption.

Assumption 6.3. *For every positive integer m, real numbers $\rho > 0$, $u_j \leq \rho, j \leq m$, and real-valued bounded and continuous function $f(\cdot)$*

$$\begin{aligned} &Ef(B^h(t + u_j) - B^h(t); j)f(B^h(s + u_j) - B^h(s); j) \\ &\quad -Ef(B^h(t + u_j) - B^h(t); j)Ef(B^h(s + u_j) - B^h(s); j) \to 0 \end{aligned} \tag{6.5}$$

as $h \to 0$, uniformly in (s, t), such that $s > t + \rho + 1$.

This condition essentially says that the correlation between intervals that are separated in time by at least some constant goes to zero as $h \to 0$, uniformly in time.

The process $B^h(\cdot)$ could be white, but not necessarily Gaussian. In this case, the verification of the conditions in Assumptions 6.2 and 6.3 is usually trivial.

We define $Y^h(s) = B^h(s) = 0$ for $s < 0$. The filter is denoted by $\{\Pi^h(n\Delta_h)\}$, and we define the continuous time interpolations $Y^h(\cdot), B^h(\cdot), \Pi^h(\cdot)$, and $\tilde{X}^h(\cdot)$ so that they are constant on the intervals $[n\Delta_h, n\Delta_h + \Delta_h)$.

In what follows, we use the convention that if a limit of summation is not an integer, take the integer part. We represent the filter as in the previous sections, in terms of an auxiliary process $\tilde{X}^h(\cdot)$ which satisfies the assumptions imposed on it in section 2. At the sampling times, the filter takes the form

$$\langle \Pi^h(n\Delta_h), \phi\rangle = \frac{E_{\{\Pi^h(0), Y^h_{0,n\Delta_h}\}}\left[\phi(\tilde{X}^h(n\Delta_h))R(\tilde{X}^h_{0,n\Delta_h}, Y^h_{0,n\Delta_h})\right]}{E_{\{\Pi^h(0), Y^h_{0,n\Delta_h}\}}R(\tilde{X}^h_{0,n\Delta_h}, Y^h_{0,n\Delta_h})}, \tag{6.6}$$

where we use the definition

$$R(\tilde{X}^h_{0,n\Delta_h}, Y^h_{k\Delta_h,(n+k)\Delta_h}) = e^Z, \tag{6.7}$$

where Z is defined by

(6.8)
$$\sum_{i=1}^{n} g'(\tilde{X}^h(i\Delta_h))[Y^h(k\Delta_h + i\Delta_h) - Y^h(k\Delta_h + i\Delta_h - \Delta_h)] - \frac{\Delta_h}{2}\sum_{i=1}^{n}\left|g(\tilde{X}^h(i\Delta_h)\right|^2.$$

The definition (6.6), with (6.8) used, satisfies the semigroup property over the discrete time mesh: $\{n\Delta_h; n \geq 1\}$.

Instead of constant interpolation of $\Pi^h(\cdot)$ over the interval $[n\Delta_h, n\Delta_h + \Delta_h)$, one may use the following different definition for the approximate filter.

$$\langle \Pi^h(t), \phi\rangle = \frac{E_{\{\Pi^h(0), Y^h_{0,t}\}}\left[\phi(\tilde{X}^h(t))R(\tilde{X}^h_{0,t}, Y^h_{0,t})\right]}{E_{\{\Pi^h(0), Y^h_{0,t}\}}R(\tilde{X}^h_{0,t}, Y^h_{0,t})}. \tag{6.9}$$

The forms (6.6) and (6.9) are equal at the sampling times. Theorem 6.1 continues to hold for the form of filter in (6.9); however, for the sake of brevity we will only prove the constant interpolation case.

Define $\Psi^h(\cdot) = \big(X^h(\cdot), \Pi^h(\cdot), Y^h(\cdot), B^h(\cdot)\big)$, $\Psi^h_f(\cdot) = \big(X^h(\cdot), \Pi^h(\cdot)\big)$, and define $Q^{h,T}$, $\psi(\cdot)$ and $\psi_f(\cdot)$ analogously.

THEOREM 6.1. *Assume that Assumptions* 2.1, 2.2, 2.3, 4.1, 4.2, 6.1, 6.2, *and* 6.3 *hold. Then all the conclusions of Theorem* 4.1 *hold with the above modified definitions of* $\Pi^h(\cdot)$ *(see* (6.6)*) and* $Q^{h,T}(\cdot)$.

Comments on the proof. The proof is similar to those of Theorems 3.1, 3.2, and 4.1. The main differences concern the characterization of the limit $X^\omega(\cdot)$, the proof for (3.3c), the proof that $B^\omega(\cdot)$ is a standard Wiener process which is independent of $X^\omega(\cdot)$, and the proof of the representation of $\Pi^\omega(\cdot)$.

The characterization of $X^\omega(\cdot)$ as $X(\cdot)$, with the appropriate initial condition, is analogous to what was done in section 4, with only minor notational differences, which are due to the replacement of $B(\cdot)$ by $B^h(\cdot)$, and so we omit the details.

Proof of (3.3c). It is difficult to prove (3.3c) directly. We will actually prove the tightness of an approximation to the family $\{\Pi^h(t+\cdot); h > 0, t > 0\}$ and use the following useful fact. Let the sequence $\{Z_n(\cdot)\}$ have paths in some Skorohod space with metric denoted by $d(\cdot,\cdot)$. Suppose that for each positive real numbers ϵ_1, ϵ_2 and T_0, there is a process $Z_n^{\epsilon_1,\epsilon_2,T_0}(\cdot)$ such that

$$\limsup_n P\left\{\sup_{s\leq T_0} d(Z_n(s), Z_n^{\epsilon_1,\epsilon_2,T_0}(s)) \geq \epsilon_1\right\} \leq \epsilon_2, \tag{6.10}$$

and $\{Z_n^{\epsilon_1,\epsilon_2,T_0}(\cdot), n < \infty\}$ is tight for each $\epsilon_1, \epsilon_2, T_0$. Then $\{Z_n(\cdot)\}$ is tight. The approximations generally simplify the characterization of the weak sense limits as well.

Note that for our case the process index is the pair (h,t) instead of n. Pursuing this idea, let $\epsilon_1, \epsilon_2, T_0$ be as above. Then, for each h and t, we seek a process $\hat{\Pi}^h(t,\cdot)$ (dropping the affixes $\epsilon_1, \epsilon_2, T_0$) such that

$$\limsup_h \sup_t P\left\{ \sup_{s\le T_0} \left| \langle \Pi^h(t+s), \phi\rangle - < \hat{\Pi}^h(t,s), \phi > \right| \ge \epsilon_1 \right\} \le \epsilon_2 \tag{6.11}$$

and $\{\hat{\Pi}^h(t,\cdot); h>0, t\ge 0\}$ is tight. If we can find such processes, then (3.3c) holds. We now show (6.11). We can work with each $\phi(\cdot)$ separately due to the definition of the weak topology.

Keep in mind that we can have a different modification for each (h,t). We first consider the case where $t = n\Delta_h$ for some n. Fix $\phi(\cdot)$. Let $\Delta > 0$ be small but fixed. Assume that h is small enough such that $\Delta >> \Delta_h$. The idea is to break the sum

$$\sum_{j=1}^{s/\Delta_h} g'(\tilde{X}^h(j\Delta_h)) \left[Y^h(t+j\Delta_h) - Y^h(t+j\Delta_h-\Delta_h)\right] \tag{6.12}$$

in (6.8) as a sum of

$$\sum_{i=0}^{s/\Delta-1} g'(\tilde{X}^h(i\Delta)) \left[Y^h(t+i\Delta+\Delta) - Y^h(t+i\Delta)\right] \tag{6.13}$$

and the "error"

$$\begin{aligned} V^{h,\Delta}(t,s) = \sum_{i=0}^{s/\Delta-1} & \sum_{j=i\Delta/\Delta_h+1}^{(i+1)\Delta/\Delta_h \wedge s/\Delta_h} \\ & \left[g'(\tilde{X}^h(j\Delta_h)) - g'(\tilde{X}^h(i\Delta))\right] \left[Y^h(t+j\Delta_h) - Y^h(t+j\Delta_h-\Delta_h)\right]. \end{aligned} \tag{6.14}$$

Note that if we concatenate the sums in (6.14), we get

$$\sum_{i=n}^{n+s/\Delta_h} \mu_i^{h,\Delta} \left[Y^h(i\Delta_h+\Delta_h) - Y^h(i\Delta_h)\right]$$

for an obvious definition of $\mu_i^{h,\Delta}$, which clearly satisfies (i), (ii), and (iii) in Assumption 6.2, in view of weak convergence properties of $\tilde{X}^h(\cdot)$. The case where t/Δ_h is not an integer is dealt with in a completely analogous way and we omit the details. Now we use Assumption 6.2 for the family $\{\mu_i^{h,\Delta}; h, \Delta, i\}$. For an arbitrary small $\epsilon_3 > 0$, define $\tau^{h,\Delta,t} = \min\{s : |V^{h,\Delta}(t,s)| \ge \epsilon_3\}$. Then Assumption 6.2 yields that, for small $\epsilon > 0$ and small enough $\epsilon_3 > 0$,

$$\lim_{\Delta\to 0} \limsup_h \sup_t P\left\{ P_{\{\Pi^h(0), Y^h_{t,t+s}\}} \left\{ \tau^{h,\Delta,t} < T_0 \right\} \ge \epsilon \right\} = 0. \tag{6.15}$$

Define $\hat{R}^{h,\Delta}(\tilde{X}^h_{0,s}, Y^h_{t,t+s})$ to be $R(\tilde{X}^h_{0,s}, Y^h_{t,t+s})$ with (6.13) replacing (6.12). Now define $\hat{\Pi}^h(t,\cdot)$ by

$$\langle \hat{\Pi}^h(t,s), \phi\rangle = \frac{E_{\{\Pi^h(0), Y^h_{0,t}\}} \left[\phi(\tilde{X}^h(t)) \hat{R}^{h,\Delta}(\tilde{X}^h_{0,s}, Y^h_{0,s})\right]}{E_{\{\Pi^h(0), Y^h_{0,t}\}} \hat{R}^{h,\Delta}(\tilde{X}^h_{0,s}, Y^h_{0,s})}. \tag{6.16}$$

We have

$$\hat{R}^{h,\Delta}(\tilde{X}^h_{0,s}, Y^h_{t,t+s})e^{V^h(t,s)} = R(\tilde{X}^h_{0,s}, Y^h_{t,t+s})$$

and, except on as a (h, t-dependent) set of arbitrarily small measure, $\tau^{h,\Delta,t} \geq T_0$ for small h and Δ. Hence, we can suppose that, asymptotically, $|e^{V^h(t,s)} - 1| \leq \epsilon_4$, arbitrary. Thus, (6.11) holds.

The tightness of the set $\{\hat{\Pi}^h(t,\cdot); h, t\}$ for each $\Delta > 0$ is clear. This follows by noting that the exponential contains the sum (6.13), hence $\hat{\Pi}^h(t,\cdot)$ contains only simple discontinuities at deterministic times $i\Delta$. This proves (3.3c). Thus in view of the tightness assumptions on the set $\{X^h(t+\cdot), B^h(t+\cdot) - B^h(t); h > 0, t\}$, we have that (3.4) holds. We can extract a weakly convergent subsequence of the set in (3.4), indexed again by (h, t), and with limit denoted by $Q(\cdot)$, with sample values $Q^\omega(\cdot)$.

The independence of $B^\omega(\cdot)$ and $X^\omega(\cdot)$. We will only do a simple calculation to illustrate the general procedure. Let $f_i(\cdot)$ be bounded and continuous real-valued functions of their arguments, and with compact support. We wish to show that, for almost all ω and any nonnegative u, v,

$$\int Q^\omega(d\psi(\cdot))f_1(b(v))f_2(x(u)) = \int Q^\omega(d\psi(\cdot))f_1(b(v)) \int Q^\omega(d\psi(\cdot))f_2(x(u)).$$

Write the prelimit forms of the difference between the two sides:

$$\begin{aligned} &\frac{1}{T}\int_0^T f_1(B^h(t+v) - B^h(t))f_2(X^h(t+u))dt \\ &\quad -\frac{1}{T^2}\int_0^T f_1(B^h(t+v) - B^h(t))dt \int_0^T f_2(X^h(s+u))ds. \end{aligned} \tag{6.17}$$

The rest of the procedure is to square, take expectations, and use the fact that $B^h(\cdot)$ is independent of $X^h(\cdot)$ and Assumption 6.3 to show that the difference goes to zero in mean square as $h \to 0, T \to \infty$. Define $C = Ef_1(B(v))$. Let us first evaluate the expectation of the square of the first term; namely, evaluate

$$\frac{1}{T^2}\int_0^T\int_0^T Ef_1(B^h(t+v)-B^h(t))f_2(X^h(t+u))f_1(B^h(s+v)-B^h(s))f_2(X^h(s+u))dtds.$$

Now, use Assumption 6.3, the weak convergence of $B^h(t+\cdot) - B^h(t)$, and the independence of $B^h(\cdot)$ and $X^h(\cdot)$ to show that the limits are the same as those of

$$C^2\frac{1}{T^2}\int_0^T\int_0^T Ef_2(X^h(t+u))f_2(X^h(s+u))dtds.$$

A similar procedure shows that the limits of the expectation of the square of the second term and of the product of the first and second terms in (6.17) is also the same. Thus, the limit is zero, as desired. The same procedure works if the functions $f_i(\cdot)$ depend on the processes at an arbitrary finite number of times. Hence the independence of $X^\omega(\cdot)$ and $B^\omega(\cdot)$.

The Wiener property of $B^\omega(\cdot)$ for almost all ω. The proof is similar to what was done to prove the independence of the $X^\omega(\cdot)$ and $B^\omega(\cdot)$. We need to show characteristic function results such as the following. Let λ_q be arbitrary vectors (of the dimension of b). Show that, for almost all ω,

$$\begin{aligned}&\int Q^\omega(d\psi(\cdot))e^{i\lambda_1'(b(u+s)-b(u))}e^{i\lambda_2'b(u)}\\ &\quad= \int Q^\omega(d\psi(\cdot))e^{i\lambda_1'(b(u+s)-b(u))}\int Q^\omega(d\psi(\cdot))e^{i\lambda_2'b(u)}\\ &\quad= e^{-s|\lambda_1|^2/2}e^{-u|\lambda_2|^2/2}.\end{aligned}$$

To show this, work with the difference of the prelimit forms of the two sides:

$$\frac{1}{T}\int_0^T \left[e^{i\lambda_1'(B^h(t+u+s)-B^h(t+u))}e^{i\lambda_2 B^h(t+u)-B^h(t))}\right]dt - e^{-s|\lambda_1|^2/2}e^{-u|\lambda_2|^2/2}.$$

Square, take expectations, and use the weak convergence and Assumption 6.3, analogous to what was done to show the independence property.

Characterization of the process $\boldsymbol{\Pi^\omega(\cdot)}$. Given the tightness of $\{\Pi^h(\cdot)\}$ and the discussion in that section, the fact that (3.10) holds is essentially a property of the asymptotic smoothness of $\tilde{X}^h(\cdot)$. It can be proved by working with $\hat{\Pi}^h(t,\cdot)$ in lieu of $\Pi^h(t+\cdot)$, and then letting $\Delta \to 0$, and the details are omitted. □

Sufficient conditions for Assumption 6.2 to hold. Define $\xi_i^h = B^h(i\Delta_h + \Delta_h) - B^h(i\Delta_h)$. The simplest case satisfying (6.3) is where the ξ_i^h are martingale differences with variances bounded by some constant times Δ_h), i.e., where the observation noise is white but not necessarily Gaussian.

Correlated noise can be treated by the perturbed test function method [18] of the type introduced in section 4. Here we will construct a particular perturbation which serves our present purposes. Let E_n denote the expectation conditioned on $\{\mu_i^{h,\Delta}, \xi_i^h, i \le n\}$. Fix $T > 0$. Define

$$S_i^{h,\Delta,n} = \sum_{j=n}^{n+i} \mu_j^{h,\Delta}\xi_j^h,\ i \le T/\Delta_h.$$

Assume that

$$\sup_{i,h} E\left|\xi_i^h\right|^2 < \infty. \tag{6.18}$$

Define the “perturbation”

$$\delta S_i^{h,\Delta,n,T} = \sum_{j=n+i}^{n+T/\Delta_h-1} E_{n+i}\mu_{j+1}^{h,\Delta}\xi_{j+1}^h,\ i \le T/\Delta_h. \tag{6.19}$$

Suppose that

$$\sum_{j=n+i}^{n+T/\Delta_h} E\left|E_{n+i}\xi_{j+1}^h\right| = O(\Delta_h), \tag{6.20}$$

where $O(\Delta_h)$ is uniform in i, and that

$$\limsup_h \sup_n E\sum_{i=n}^{n+T/\Delta_h}|\xi_i^h|^2 + \left|\sum_{i=n}^{n+T/\Delta_h}\sum_{j=i+1}^{n+T/\Delta_h} E\xi_i^h\xi_j^h\right| < \infty. \tag{6.21}$$

These conditions are rather mild. They would be satisfied, for example, if $B^h(\cdot)$ were a sufficiently "nonanticipatively smoothed" Wiener process; e.g., $B^h(t) = \int_{-\infty}^t q_h(t-s)B(s)ds$ for an appropriate kernel $q_h(\cdot)$ which converges to a delta function as $h \to 0$.

Noting that the index i is in the upper limit in (6.8) and in the lower limit in (6.9), we have

$$E_{n+i}\left[S_{i+1}^{h,\Delta,n} - S_i^{h,\Delta,n}\right] = E_{n+i}\mu_{n+i+1}^{h,\Delta}\xi_{n+i+1}^h,$$

$$E_{n+i}\left[\delta S_{i+1}^{h,\Delta,n,T} - \delta S_i^{h,\Delta,n,T}\right] = -E_{n+i}\mu_{n+i+1}^{h,\Delta}\xi_{n+i+1}^h.$$

Thus the perturbed function

$$\tilde{S}_i^{h,\Delta,n,T} = S_i^{h,\Delta,n} + \delta S_i^{h,\Delta,n,T}$$

is a martingale, and martingale inequalities can be used to get (6.3). The desire to get this martingale property is the key motivation behind the way the perturbation $\delta S_i^{h,\Delta,n,T}$ was constructed. It was constructed specifically to effect the desired cancellation.

Recall that if M_i is a square integrable martingale, then

$$P\left\{\sup_{i\le N}|M_i| \ge \epsilon\right\} \le \frac{EM_N^2}{\epsilon^2}. \tag{6.22}$$

Condition (6.20) and the fact that the $\mu_i^{h,\Delta}$ can be taken to be arbitrarily small implies that, for any $\epsilon > 0$,

$$\lim_{\Delta\to 0}\limsup_h \sup_n P\left\{\sup_{i\le T/\Delta_h}\left|\delta S_i^{h,\Delta,n,T}\right| \ge \epsilon\right\} = 0. \tag{6.23}$$

This is a consequence of the facts that the μ-terms are bounded and small in probability and independent of the ξ terms, and that (6.20) implies that

$$\sum_{i\le T/\Delta_h} E\left|\delta S_i^{h,\Delta,n,T}\right| = O(1).$$

Since $\delta S_{T/\Delta_h}^{h,\Delta,n,T} = 0$,

$$E|\tilde{S}_{T/\Delta_h}^{h,\Delta,n,T}|^2 = E|S_{T/\Delta_h}^{h,\Delta,n}|^2.$$

Also, a direct computation using (6.21), (6.22), and the boundedness and smallness in probability of the μ-terms (and their independence of the ξ) yields

$$\lim_{\Delta\to 0}\limsup_h \sup_n E|S_{T/\Delta_h}^{h,\Delta,n}|^2 = 0.$$

The last two equations and (6.22) yield

$$\lim_{\Delta\to 0}\limsup_h \sup_n P\left\{\sup_{i\le T/\Delta_h}\left|\tilde{S}_i^{h,\Delta,n,T}\right| \ge \epsilon\right\} = 0. \tag{6.24}$$

This and (6.23) imply (6.3).

7. Uniqueness of the invariant measure of $(X(\cdot),\Pi(\cdot))$. In this section we address the question of uniqueness of the invariant measure for the pair $(X(\cdot),\Pi(\cdot))$. It is known from Kunita [12] that if $X(\cdot)$ is a time homogeneous Feller–Markov process with a compact state space, such that it admits a unique invariant measure and the corresponding stationary flow is purely nondeterministic, then the true optimal filtering process $\Pi(\cdot)$ taken by itself has a unique invariant measure. The results in [12], however, do not provide any information concerning the uniqueness of the stationary joint distribution of $(X(\cdot),\Pi(\cdot))$. Uniqueness for the joint problem is considerably harder to prove and to date the only known result, excepting the linear filtering case, is for a discrete time filtering problem where the signal is a finite state Markov chain (see also Stettner [28]). We provide in Theorem 7.1 a sufficient condition under which the uniqueness for the joint problem holds. The theorem roughly says that if the signal process has a unique invariant measure and the filter "forgets its initial condition," in the sense to be made precise below, then the pair $(X(\cdot),\Pi(\cdot))$ has at most one invariant measure. We refer the reader to [1, 2, 6, 7, 10, 24, 25] for some recent results on forgetting of the initial condition. Finally, we discuss some examples in which the sufficient condition can be seen to hold.

Let $(S,\mathcal{S})$ be a Polish space, $\mathcal{S}$ being the Borel sigma-field on S. Let $X(\cdot)$ be an S-valued Markov process with0 CADLAG paths and $Y(\cdot)$ be given via (2.2), where, as before, $B(\cdot)$ is independent of $X(\cdot)$. As in section 2, we will consider the process $(X(\cdot),Y(\cdot))$ on the path space, $D(S\times\mathbb{R}^m;0,\infty)$, where m denotes the dimension of the observation vector. Let P_μ be the probability measure on the path space of $(X(\cdot),Y(\cdot))$ under which $X(0)$ has the distribution μ. With an abuse of notation, we will use the notation P_x when μ is a point mass concentrated at $x\in S$. If the filter is initialized at $\Pi(0)=\nu$ (whether or not it is the distribution of $X(0)$), we denote the process by $\Pi^\nu(\cdot)$. Following the notation of section 2, $\Pi^\nu(\cdot)$ is defined by

$$\langle\Pi^\nu(t),\phi\rangle=\frac{E_{\nu,Y_{0,t}}\left[\phi(\tilde X(t))R(\tilde X_{0,t},Y_{0,t})\right]}{E_{\nu,Y_{0,t}}\left[R(\tilde X_{0,t},Y_{0,t})\right]},$$

where $\phi(\cdot)$ is a bounded and measurable real-valued function, and $\tilde X(\cdot)$ is as in section 2. Recall that $\Pi^\nu(0)=\nu$ is the distribution of $\tilde X(0)$.

Definition 7.1. *We say that the "filter forgets its initial condition" if for all $\nu_1,\nu_2\in\mathcal{M}(S)$, for all $x\in S$ and continuous bounded real valued functions $\phi(\cdot)$ on S:*

$$|\langle\Pi^{\nu_1}(t),\phi\rangle-\langle\Pi^{\nu_2}(t),\phi\rangle|$$

converges to zero in P_x-probability as $t\to\infty$.

Theorem 7.1. *Suppose that $X(t)$ has a unique invariant measure and the filter forgets its initial condition. Then the pair $(X(\cdot),\Pi(\cdot))$ has at most one invariant measure.*

Proof. Suppose ρ_1 and ρ_2 are two invariant measures for the pair $(X(\cdot),\Pi(\cdot))$. We will show that for all continuous and bounded functions f on $S\times\mathcal{M}(S)$

$$\int f(x,\alpha)\rho_1(dx,d\alpha)=\int f(x,\alpha)\rho_2(dx,d\alpha), \tag{7.1}$$

where (x,α) denotes a generic element of $S\times\mathcal{M}(S)$. Let μ denote the unique invariant measure of $X(\cdot)$ and let μ_1,μ_2 be regular conditional probability functions such that

$\rho_i(dx, d\alpha) = \mu_i(x, d\alpha)\mu(dx)$; $i = 1, 2$. The left side of (7.1) equals, for all $t > 0$,

$$\int \left[\int E_x \left[f(X(t), \Pi^\alpha(t)) \right] \mu_1(x, d\alpha) \right] \mu(dx),$$

while the right hand side of (7.1) equals, for all $t > 0$,

$$\int \left[\int E_x \left[f(X(t), \Pi^\beta(t)) \right] \mu_2(x, d\beta) \right] \mu(dx).$$

Thus

$$\begin{aligned} &\left| \int f(x,\alpha)\rho_1(dx,d\alpha) - \int f(x,\alpha)\rho_2(dx,d\alpha) \right| \\ &\quad \le \int \int \int E_x \left| f(X(t), \Pi^\alpha(t)) - f(X(t), \Pi^\beta(t)) \right| \mu_1(x, d\alpha)\mu_2(x, d\beta)\mu(dx). \end{aligned} \tag{7.2}$$

The assumption on forgetting the initial condition implies that for all $x \in S$ and $\alpha, \beta \in \mathcal{M}(S)$, as $t \to \infty$,

$$E_x \left| f(X(t), \Pi^\alpha(t)) - f(X(t), \Pi^\beta(t)) \right| \to 0.$$

Now an application of dominated convergence theorem shows that the right side of (7.2) converges to 0 as $t \to \infty$. This proves (7.1). □

Remark. Although we have stated and proved the above theorem for a signal evolving continuously in time and observations taken continuously, the result holds for discrete time models such as in section 5, where the signal can evolve either continuously or discretely in time, but the observations are taken at discrete time instants. (The paper [6] also allowed a point process observation model.) The proof, excepting some minor notational changes, remains unchanged.

We now give some examples, in the following two theorems, where the sufficient condition in the above theorem is seen to hold. The theorems below are fairly straightforward consequences of the results proved in Atar and Zeitouni [2] and LeGland [10], in view of which details of the proofs are omitted.

THEOREM 7.2. *Let the signal $X(\cdot)$ (indexed either by a continuous or discrete time parameter) be a Feller time homogeneous Markov process taking values in a compact Polish space S. Suppose that the observations are in discrete time and given by* (5.1)*, Suppose that there exists a finite measure μ on $(S, \mathcal{S})$ and an integer $n \geq 1$ such that for all $x \in S$:*

$$c_1\mu(d\chi) \le P(d\chi, n|x) \le c_2\mu(d\chi), \tag{7.2}$$

where $P(d\chi, n|x)$ is the n-step transition probability function for $X(\cdot)$ and c_1, c_2 are some finite positive constants. Then the process $\{X(k), \Pi(k), k < \infty\}$ has at most one stationary measure.

Remarks on the Proof. The proof is based on the properties of Hilbert's projective metric (see [4]) on the space of finite measures. It can be shown that for x, ν_1, ν_2 as in the beginning of the section, the Hilbert distance between $\Pi^{\nu_1}(m)$ and $\Pi^{\nu_2}(m)$ converges to zero a.s. P_x as $m \to \infty$. This fact is proved for $n = 1$ in [2] and for $n \geq 1$, in the special case of finite state Markov chains in [10]. The case of general compact state space follows by similar arguments. The convergence in the Hilbert metric implies the convergence in total variation norm which in turn implies the property of the filter forgetting its initial condition in the sense of Definition 7.1.

Since $X(\cdot)$ is Feller with a compact state space, it has at least one invariant measure. Finally, if μ_1, μ_2 are two such invariant measures, we have, using the properties of Hilbert metric and (7.2), that the Hilbert distance between $\int P(\cdot, n|x)\mu_1(dx)$ and $\int P(\cdot, n|x)\mu_2(dx)$ converges to zero as $n \to \infty$. This implies that $\mu_1 = \mu_2$ and therefore Theorem 7.1 can be applied.

Theorem 7.3. *Let the signal be given via* (2.1) *and suppose that it takes values in a compact Riemannian manifold. Suppose that* $p(\cdot)$ *and* $\sigma(\cdot)$ *are Lipschitz continuous and that the generator of the Markov process is strictly elliptic. Assume that the observation process is given via* (2.2) *with* $g(\cdot)$ *a twice continuously differentiable real-valued function. Then* $(X(\cdot), \Pi(\cdot))$ *has a unique stationary measure.*

Remarks on the Proof. Arguments as in Theorems 3.1 and 3.2 show that $(X(\cdot), \Pi(\cdot))$ has at least one invariant measure. Furthermore, upper and lower bounds on the transition probability kernel of a Markov diffusion process on a compact manifold (see [2]) yield that if μ_1 and μ_2 are two invariant measures for $X(\cdot)$, then the Hilbert distance between $\int P(\cdot, t|x)\mu_1(dx)$ and $\int P(\cdot, t|x)\mu_2(dx)$ converges to 0 as $t \to \infty$, where $P(\cdot, t|x)$ is the transition probability kernel of $X(\cdot)$. This proves the uniqueness of the invariant measure for $X(\cdot)$. Let $h(\cdot)$ denote the Hilbert distance between the measures. Next, the results in [2] show that, for the additive white noise corrupted observation case, where x, ν_1, ν_2 are as in the beginning of this section and satisfy $h(\nu_1, \nu_2) < \infty$, a.s. P_x, we have that $h(\Pi^{\nu_1}(t), \Pi^{\nu_2}(t))$ converges to zero a.s. P_x as $t \to \infty$. The constraint, $h(\nu_1, \nu_2) < \infty$, can be removed using techniques similar to those of [7, Theorem 3.2] on first proving that the P_x-probability of the event, $h(\Pi^{\nu_1}(t), \Pi^{\nu_2}(t)) < \infty$ for some t, is one.
