SMALL PARAMETER LIMIT FOR DISCRETE-TIME PARTIALLY OBSERVED RISK-SENSITIVE CONTROL PROBLEMS*

FRANCESCA ALBERTINI† AND PAOLO DAI PRA†

Abstract. We show that risk-sensitive control problems and deterministic dynamic games can be connected, under rather mild assumptions, by a small noise limit. In order to control this limit, new techniques are developed to study propagation of large deviations through conditional probabilities.

Key words. risk-sensitive control, dynamics games, large deviations

1. Introduction.

Properties of risk-sensitive control problems and their connections with dynamic games have been widely investigated in recent years [16, 18, 11, 8, 9, 12, 13, 14, 6, 4], in part inspired by seminal results for linear quadratic models contained in [10, 17, 1]. In particular, it has been shown [8, 9, 12, 13, 4] that under a suitable small parameter limit (*small noise limit*) a family of risk-sensitive stochastic control problems becomes equivalent to a deterministic dynamic game. In other words, this means that optimal risk-sensitive control with small noise and suitably rescaled risk parameter is almost equivalent to deterministic robust control (worst-case approach).

Although this result is conceptually natural, its proof usually involves rather sophisticated mathematical techniques, and fairly strong requirements on the model. For continuous-time, totally observable systems a quite satisfactory theory has been developed in [8, 9] by using viscosity solution techniques to analyze the Hamilton–Jacobi equation associated to the optimal control problem. It has been shown, in particular, that the value function of the risk-sensitive control problem converges, as the noise parameter goes to zero, to the upper value function of a related two players, zero-sum differential game.

The analysis of the small parameter limit for nonlinear, partially observed, risk-sensitive control problems has been initiated by P. Whittle [18], whose mostly nonrigorous results have inspired most of the further development. A considerable advancement in the understanding of these models is represented by the results in [12, 13], where the *information state* approach is used. This approach consists in reformulating the partially observed control problem as a completely observed one, in a way that, in a suitable sense, is "preserved" in the small parameter limit. One consequence of this method is that it provides a natural notion of information state for the limiting dynamic game. In [12] the information state approach is applied to discrete-time systems. The result obtained is parallel to the one given in [8], i.e., the connection with partially observed dynamic game is established in terms of the convergence of the value function of the equivalent totally observed model. This value function is the

†Università di Padova Dipartimento di Matematica Pura e Applicata, Via Belzoni 7, 35131 Padova, Italy (albertin@math.unipd.it, daipra@math.unipd.it).

solution of a dynamic programming equation in an infinite-dimensional space. The small parameter limit of this equation is obtained by using large deviation techniques.

The corresponding result in continuous time has been obtained, at a nonrigorous level, in [13]. In this context, one has to deal with the small parameter limit of a Hamilton–Jacobi equation (Mortensen's equation) with infinite-dimensional state space; the current mathematical understanding of this problem has not allowed a complete proof yet. A different approach to the small parameter limit in continuous time is used in [3], where, rather than the convergence of the value function, it is (*rigorously*) shown the convergence of the *cost functional* for *any* control u in a suitably defined admissible class. This requires considerable work for controlling the small parameter limit of the information state, but avoids the use of Mortensen's equation.

In this paper we consider discrete-time, finite time-horizon partially observed systems, and we develop further some large deviation techniques that were introduced in [4] for totally observed systems. The models for which we can analyze the small parameter limit include those of type

$$\begin{aligned} x_{n+1} &= f_n(x_n, u_n, w_n), \\ y_n &= \phi_n(x_n, v_n) \end{aligned} \tag{1.1}$$

for $n = 0, \dots, N-1$, with $x_n \in \mathcal{X}, u_n \in \mathcal{U}, w_n \in \mathcal{W}, y_n, v_n \in \mathbb{R}^d$, where $\mathcal{X}, \mathcal{W}$ are metric spaces and $\mathcal{U}$ is a compact metric space. Moreover, w_n, v_n are independent random variables, $w_n \sim \mu_n^\epsilon$, $v_n \sim \nu_n^\epsilon$, where $(\mu_n^\epsilon)_{\epsilon>0}$, $(\nu_n^\epsilon)_{\epsilon>0}$ are families of probability measures satisfying a large deviation principle (see section 2). Some further regularity assumptions will be needed for ϕ_n and ν_n^ϵ (see section 4), while f_n is supposed only to be continuous. We associate with (1.1) a cost functional of the form

$$J^\epsilon(\mathbf{u}) = \epsilon \log E\Big\{ \exp\Big[\epsilon^{-1}\Big(\sum_{n=0}^{N-1} g_n(x_n, u_n) + g_N(x_N)\Big)\Big]\Big\} \tag{1.2}$$

defined for the control sequences $\mathbf{u} = (u_0, \dots, u_{N-1})$ that are nonanticipative functions of the output sequence $(y_0, \dots, y_N)$. Note that the parameter ϵ appears both in the noise distribution and in (1.2), where it can be interpreted as a *risk parameter*, a measure of controller's aversion to risk. We show that, as $\epsilon \to 0$, the risk-sensitive control problem (1.1), (1.2) converges, in a suitable sense, to the deterministic game with dynamics (1.1) (where w_n, v_n are thought of as deterministic but unknown disturbances) and cost

$$J(\mathbf{u}) = \sup_{\mathbf{v},\mathbf{w}} \Big[\sum_{n=0}^{N-1} \Big(g_n(x_n, u_n) - h_n(w_n) - k_{n+1}(v_{n+1})\Big) + g_N(x_N)\Big], \tag{1.3}$$

where h_n, k_n are *rate functions* (see section 2) associated with $\mu_n^\epsilon, \nu_n^\epsilon$. This convergence is expressed, similarly to [8] and [12], in terms of the convergence of the value function for an equivalent totally observed problem, so that our result can be seen as a generalization of [12]. In fact, models of type (1.1), (1.2) include the ones studied in [12], but we can deal with fairly more general noise distribution, state-space and dynamical equations. The results of this paper have been, in part, announced in [5], where, however, much stronger conditions were required.

This paper is organized as follows. In sections 2 and 3 we develop some new large deviation techniques that are suitable for the problem we deal with. Section 4, which contains the main results of this paper, is devoted to the analysis of the small parameter limit for risk-sensitive control problems.

2. Preliminary notions. In this section we recall some notions from large deviation theory that will be used throughout the paper, and introduce some new ones. We let $\mathcal{X}$ be a metric space. All measures on $\mathcal{X}$ are intended to be defined on its Borel σ-field.

DEFINITION 2.1. *A family of probability measures* $\{P^\epsilon : \epsilon > 0\}$ *on* $\mathcal{X}$ *is said to satisfy a* large deviation principle (*LDP*) *with rate function* $H : \mathcal{X} \to [0, +\infty]$ *if*

i) H *is lower semicontinuous and* $\{x : H(x) \le l\}$ *is compact for every* $l \ge 0$;

ii) *for every* $A \subset \mathcal{X}$ *measurable*

$$\begin{aligned}-\inf_{x\in\mathring{A}} H(x) &\le \liminf_{\epsilon\to 0} \epsilon \log P^\epsilon(A)\\ &\le \limsup_{\epsilon\to 0} \epsilon \log P^\epsilon(A) \le -\inf_{x\in\bar{A}} H(x),\end{aligned}$$

where $\mathring{A}, \bar{A}$ *denote respectively the interior and the closure of* A.

In [4] a modification of the above definition has been introduced for the case of a family of probability measures depending on a further parameter.

DEFINITION 2.2. *Let* Θ *be a set. A family of probability measures* $\{P^\epsilon(dx;\theta) : \epsilon > 0, \theta \in \Theta\}$ *on* $\mathcal{X}$ *is said to satisfy a* uniform large deviation principle (*ULDP*) *with rate function* $H : \mathcal{X} \times \Theta \to [0, +\infty]$ *if*

i) *for every fixed* $\theta \in T$, $H(\cdot, \theta)$ *is lower semicontinuous and* $\{x : H(x, \theta) \le l\}$ *is compact for every* $l \ge 0$,

ii) *for every* $A \subset \mathcal{X}$ *measurable and* $M > 0$,

$$\limsup_{\epsilon\to 0} \sup_{\theta\in\Theta} \left[\epsilon \log P^\epsilon(A;\theta) + \min\left(M, \inf_{x\in\bar{A}} H(x;\theta)\right)\right] \le 0$$

and

$$\liminf_{\epsilon\to 0} \inf_{\theta\in\Theta} \left[\epsilon \log P^\epsilon(A;\theta) + \inf_{x\in\mathring{A}} H(x;\theta)\right] \ge 0.$$

One of the main consequences of an LDP is the well known Varadhan's lemma [15]. In [4] the following version of Varadhan's lemma has been proved.

LEMMA 2.3. *Suppose the family* $\{P^\epsilon(dx;\theta) : \epsilon > 0, \theta \in \Theta\}$ *satisfies a ULDP. Then for every* $F : \mathcal{X} \to \mathbb{R}$ *bounded and continuous*,

$$\lim_{\epsilon\to 0} \epsilon \log \int e^{\epsilon^{-1}F(x)} P^\epsilon(dx;\theta) = \sup_{x\in X} \left[F(x) - H(x,\theta)\right] \tag{2.1}$$

uniformly for $\theta \in \Theta$.

Remark 2.1. Identity (2.1) is the crucial large deviation property in applications to risk-sensitive control. When Θ is a singleton (and therefore pointwise in θ) it is well known [7, Bryc's theorem] that, under rather mild assumptions (namely, exponential tightness, see definition below), identity (2.1) is equivalent to the LDP. It is natural to ask whether, for general Θ, (2.1) implies the ULDP. The answer is no. A simple counterexample is the following: $\mathcal{X} = \mathbb{R}$, $\Theta = [0, 1]$, $P^\epsilon(dx;\theta) = \frac{1}{2\epsilon}\chi_{[\theta-\epsilon,\theta+\epsilon]}(x)dx$, where χ denotes the characteristic function of a set. As we will see later in Remark 2.3, the family $P^\epsilon(dx;\theta)$ satisfies (2.1) with $H(x;\theta) = +\infty$ for $x \ne \theta$, and $H(\theta, \theta) = 0$. Now take $A = (-\infty, 0]$. If $P^\epsilon(dx;\theta)$ satisfied a ULDP, then $\lim_{\epsilon\to 0} \epsilon \log P^\epsilon(A;\epsilon/2) = -\infty$, since $\inf_{x\in A} H(x;\epsilon/2) = +\infty$ for all $\epsilon > 0$. However it holds that $P^\epsilon(A;\epsilon/2) = 1/4$.

We introduce now a notion which is weaker than the one of ULDF. For the rest of this section we assume Θ to be a metric space.

Definition 2.4. *A family $\{P^\epsilon(dx;\theta) : \epsilon > 0, \theta \in \Theta\}$ of positive finite measures on $\mathcal{X}$ is called a* weakly uniform large deviation family *(WULDF) with rate function $H : \mathcal{X} \times \Theta \to (-\infty, +\infty]$ if*

i) *for every fixed $\theta \in \Theta$, $H(\cdot, \theta)$ is lower semicontinuous and $\{x : H(x,\theta) \leq l\}$ is compact for every $l \in \mathbb{R}$;*

ii) *the map $\theta \to \inf_{x \in X} H(x,\theta)$ is real valued and is bounded on the compact subsets of Θ;*

iii) *for every $F : \mathcal{X} \to \mathbb{R}$ bounded and continuous*

$$\lim_{\epsilon \to 0} \epsilon \log \int e^{\epsilon^{-1}F(x)} P^\epsilon(dx;\theta) = \sup_{x \in X} \Big[F(x) - H(x,\theta)\Big] \tag{2.2}$$

uniformly for θ in the compact subsets of Θ.

Remark 2.2. For reasons that will become apparent later, we have chosen to allow P^ϵ in Definition 2.4 to be a positive finite measure, not necessarily a probability measure. For technical reasons, we will need condition ii) in Definition 2.4, which roughly says that $P^\epsilon(\mathcal{X};\theta)$ does not either go to zero or grow too fast as $\epsilon \to 0$. Indeed, by using ii) and letting $F \equiv 0$ in iii) the following statement is easy to prove: for each $K \subset \Theta$ compact, there exists $M(K) > 0$ such that, for ϵ sufficiently small,

$$e^{-\epsilon^{-1}M(K)} \leq P^\epsilon(\mathcal{X};\theta) \leq e^{\epsilon^{-1}M(K)} \tag{2.3}$$

for all $\theta \in K$. Note that, if all $P^\epsilon(dx;\theta)$ are probability measures, then ii) is automatically satisfied, since $\inf_{x \in \mathcal{X}} H(x,\theta) \equiv 0$ (see [7]).

We now state a proposition that serves both as a technical lemma for later use and as a preliminary justification of the notion of WULDF. Its proof will be given in section 3.

Proposition 2.5. *Let $\mathcal{W}$ be a metric space, $f : \Theta \times \mathcal{W} \to \mathcal{X}$ a continuous map, and $\{\mu^\epsilon : \epsilon > 0\}$ a family of probability measures on $\mathcal{W}$ that satisfy an LDP with rate function $h(w)$. Define $P^\epsilon(dx;\theta)$, a probability measure on X, by*

$$P^\epsilon(A;\theta) = \mu^\epsilon\{w : f(\theta,w) \in A\}. \tag{2.4}$$

Then $\{P^\epsilon(dx;\theta) : \epsilon > 0, \theta \in \Theta\}$ is a WULDF with rate function

$$H(x;\theta) = \inf\{h(w) : f(\theta,w) = x\}. \tag{2.5}$$

Remark 2.3. The family of probability measures in (2.4) does not necessarily satisfy a ULDP, even if Θ is compact. For example, consider $\Theta = [0,1]$, $\mathcal{X} = \mathcal{W} = \mathbb{R}$, $\mu^\epsilon(dw) = \frac{1}{2\epsilon}\chi_{[-\epsilon,\epsilon]}(w)dw$, $f(\theta,w) = \theta + w$, and we end up with the counterexample in Remark 2.1. Note that this shows that the family $P^\epsilon(dx;\theta)$ is a WULDF, since it is easy to prove that $\{\mu^\epsilon(dw) : \epsilon > 0\}$ satisfies an LDP with rate function $H(w) = +\infty$ if $w \neq 0$, and $H(0) = 0$.

We now introduce a further notion that will be useful later.

Definition 2.6. *A family $\{P^\epsilon(dx;\theta) : \epsilon > 0, \theta \in \Theta\}$ of positive finite measure on $\mathcal{X}$ is called* exponentially tight *if, for every $L > 0$ and every $K \subset \Theta$ compact, there exists $C \subset \mathcal{X}$ compact such that*

$$P^\epsilon(C^c;\theta) \leq e^{-\epsilon^{-1}L} \tag{2.6}$$

for all $\theta \in K$ and ϵ sufficiently small, where C^c is the complement of C.

Note that when the measures are probability measures and Θ is a singleton, the above definition reduces to the usual one of exponential tightness of large deviation theory [7].

We conclude this section by stating three easy lemmas that will be used in section 3.

LEMMA 2.7. *Under the assumptions of Proposition* 2.5, *let* $P^\epsilon(dx;\theta)$ *be defined by* (2.4). *If* $\{\mu^\epsilon\}$ *is exponentially tight then so is* $\{P^\epsilon(dx;\theta)\}$.

Proof. The proof is straightforward, since compactness is preserved by continuous mapping. □

LEMMA 2.8. *Suppose that* $\{P^\epsilon(dx;\theta) : \epsilon > 0, \theta \in \Theta\}$ *is a WULDF with rate function* H, *and it is exponentially tight. Then the rate function is* proper, *i.e.*, *for every* $L > 0$ *and every* $K \subset \Theta$ *compact, there exists* $C \subset \mathcal{X}$ *compact such that* $H(x;\theta) \geq L$ *for all* $(x, \theta) \in C^c \times K$.

Proof. Let $L > 0$ be given, $M > L$ and C be a compact subset of $\mathcal{X}$ such that (2.6) holds for all $\theta \in K$. Also, let C_δ denote the δ-neighborhood of C. Consider the bounded continuous function

$$F(x) = \min\left\{\frac{M}{\delta} d(x, C) - M, 0\right\}. \tag{2.7}$$

It is easily seen that $F(x) = -M$ for $x \in C$, $F(x) = 0$ on C_δ^c and $F \leq 0$. By using the definition of WULDF we have, for all $\theta \in K$,

$$\inf_{x \in C_\delta^c} H(x, \theta) \geq -\sup_{x \in \mathcal{X}}[F(x) - H(x, \theta)] = -\lim_{\epsilon \longrightarrow 0} \epsilon \log \int e^{\epsilon^{-1} F(x)} P^\epsilon(dx; \theta)$$

$$= -\lim_{\epsilon \longrightarrow 0} \epsilon \log \left[\int_C e^{\epsilon^{-1} F(x)} P^\epsilon(dx; \theta) + \int_{C^c} e^{\epsilon^{-1} F(x)} P^\epsilon(dx; \theta)\right]$$

$$\geq -\liminf_{\epsilon \longrightarrow 0} \epsilon \log \left[e^{-\epsilon^{-1} M} P^\epsilon(X; \theta) + e^{-\epsilon^{-1} L}\right] = \min\left[M - \inf_{x \in \mathcal{X}} H(x, \theta), L\right].$$

Thus, if we choose M large enough, using ii) of Definition 2.4, we have that, for all $\theta \in K$ and $\delta > 0$

$$\inf_{x \in C_\delta^c} H(x, \theta) \geq L \tag{2.8}$$

that clearly concludes the proof. □

LEMMA 2.9. *Under the assumptions of Lemma* 2.8, *let* $F^\epsilon : \mathcal{X} \to \mathbb{R}$, $\epsilon \geq 0$, *be such that* $\sup_{\epsilon \geq 0} \|F^\epsilon\|_\infty < \infty$, $F^\epsilon \to F^0$ *as* $\epsilon \to 0$ *uniformly on the compact subsets of* $\mathcal{X}$ *and* F^0 *is continuous. Then*

$$\lim_{\epsilon \longrightarrow 0} \epsilon \log \int e^{\epsilon^{-1} F^\epsilon(x)} P^\epsilon(dx; \theta) = \sup_{x \in \mathcal{X}} \left[F^0(x) - H(x, \theta)\right] \tag{2.9}$$

uniformly on the compact subsets of Θ.

Proof. If $F^\epsilon \to F^0$ uniformly in all $\mathcal{X}$ then the conclusion follows by (2.2) and by

$$\left|\epsilon \log \int e^{\epsilon^{-1} F^\epsilon(x)} P^\epsilon(dx; \theta) - \epsilon \log \int e^{\epsilon^{-1} F^0(x)} P^\epsilon(dx; \theta)\right| \leq \|F^\epsilon - F^0\|_\infty. \tag{2.10}$$

By using exponential tightness one easily reduces to this case. □

3. Propagation of WULDFs. In our analysis of the small parameter limit for risk-sensitive control problems the *filtering probabilities* and the *information states* will play a key role. They are both families of positive measures that satisfy recursive relations. To prove that they form WULDFs we show that the property of being a WULDF is preserved under four basic operations, namely, 1. *state augmentation*; 2. *composition*; 3. *contraction*; 4. *conditioning.*

In the rest of this section $\mathcal{X}, \mathcal{Y}$, and Θ are metric spaces.

PROPOSITION 3.1 (state augmentation). *Let $\{P^\epsilon(dx;\theta) : \epsilon > 0, \theta \in \Theta\}$ be an exponentially tight WULDF on $\mathcal{X}$ with rate function $H_P(x;\theta)$. Define the measures on $\mathcal{X} \times \Theta$*

$$Q^\epsilon(dx, d\zeta; \theta) = P^\epsilon(dx;\theta) \otimes \delta_\theta(d\zeta),$$

with δ denoting the Dirac measure. Then $\{Q^\epsilon(dx, d\zeta;\theta) : \epsilon > 0, \theta \in \Theta\}$ is an exponentially tight WULDF with rate function

$$H_Q(x,\zeta;\theta) = \begin{cases} H_P(x;\theta) & \text{if } \zeta = \theta, \\ +\infty & \text{if } \zeta \neq \theta. \end{cases}$$

Proof. First we prove that the measures $Q^\epsilon(dx, d\zeta;\theta)$ form a WULDF. It is easy to see that the function $H_Q(x,\zeta;\theta)$ satisfies properties i) and ii) in Definition 2.4, so we only prove that property iii) holds.

Let $K \subseteq \Theta$ be a compact set, and $F : \mathcal{X} \times \Theta \to \mathbb{R}$ be a continuous and bounded function. Let $L > 0$ be such that $|F(x,\zeta)| \leq L$, and $M(K) = \sup_{\theta \in K} |\inf_x H_P(x;\theta)|$, which is finite by ii) of Definition 2.4. Notice that, by the definition of H_Q, we have

$$\sup_{(x,\zeta)\in\mathcal{X}\times\Theta} \Big[F(x,\zeta) - H_Q(x,\zeta;\theta)\Big] = \sup_{x\in\mathcal{X}} \Big[F(x,\theta) - H_P(x;\theta)\Big].$$

Since H_P is proper (see Lemma 2.8), there exists a compact set $C \subseteq \mathcal{X}$ such that $H_P(x;\theta) \geq 3L + M(K)$ for all $x \in C^c$ and all $\theta \in K$. Moreover, for all $\theta \in K$, we have

$$\sup_{x\in\mathcal{X}} (F(x,\theta) - H_P(x;\theta)) \geq -L - M(K),$$

$$F(x,\theta) - H_P(x;\theta) \leq -2L - M(K) \qquad \text{for all } x \in C^c.$$

Thus

$$\sup_{x\in\mathcal{X}} \Big[F(x,\theta) - H_P(x;\theta)\Big] = \sup_{x\in C} \Big[F(x,\theta) - H_P(x;\theta)\Big]. \tag{3.1}$$

Let $\beta > 2L + 2M(K)$. Since $\{P^\epsilon(dx;\theta)\}$ is exponentially tight, there exists a compact set $C_M \subseteq \mathcal{X}$ such that

$$P^\epsilon(C_M^c;\theta) \leq \exp\{-\epsilon^{-1}\beta\} \tag{3.2}$$

for all $\theta \in K$. Without loss of generality, we may assume that $C \subseteq C_M$ and that for ϵ small enough $P^\epsilon(C_M;\theta) \geq e^{-2\epsilon^{-1}M(K)}$ for all $\theta \in K$ (see (2.3)). We have

$$\begin{aligned}
&\epsilon \log \int \exp\{\epsilon^{-1}F(x,\theta)\} P^\epsilon(dx;\theta) \\
&= \epsilon \log \left(\int_{C_M} \exp\{\epsilon^{-1}F(x,\theta)\} P^\epsilon(dx;\theta) + \int_{C_M^c} \exp\{\epsilon^{-1}F(x,\theta)\} P^\epsilon(dx;\theta) \right) \\
&\leq \epsilon \log \int_{C_M} \exp\{\epsilon^{-1}F(x,\theta)\} P^\epsilon(dx;\theta) + \epsilon \log \left(1 + 2\exp\{\epsilon^{-1}(2L + 2M(K) - \beta)\}\right).
\end{aligned}$$

Now choose an arbitrary $\delta > 0$. Since $2L + 2M(K) - \beta < 0$, there exists ϵ_0 such that, for all $\epsilon \le \epsilon_0$ and for all $\theta \in K$, we have

$$\left|\epsilon \log \int \exp\{\epsilon^{-1}F(x,\theta)\}P^\epsilon(dx;\theta) \;-\; \epsilon \log \int_{C_M} \exp\{\epsilon^{-1}F(x,\theta)\}P^\epsilon(dx;\theta)\right| \le \delta. \tag{3.3}$$

Since $F|_{C_M\times K}$ is uniformly continuous, we have that for each $\theta \in K$ there exists an open neighborhood U_θ of θ such that $|F(x,\theta_1) - F(x,\theta_2)| < \delta$ for all $\theta_1, \theta_2 \in U_\theta$ and all $x \in C_M$. K being compact, there exists $\theta_1, \dots, \theta_n$ such that $K \subseteq \cup_{i=1}^n U_{\theta_i}$.

Let $\theta \in K$; then there exists $\bar{i}$ such that $\theta \in U_{\theta_{\bar{i}}}$. Since $|F(x,\theta) - F(x,\theta_{\bar{i}})| < \delta$ for all $x \in C_M$, we have

$$\left|\epsilon \log \int_{C_M} \exp\{\epsilon^{-1}F(x,\theta)\}P^\epsilon(dx;\theta) - \epsilon \log \int_{C_M} \exp\{\epsilon^{-1}F(x,\theta_{\bar{i}})\}P^\epsilon(dx;\theta)\right| < \delta, \tag{3.4}$$

and

$$\left|\sup_{x\in C_M}[F(x,\theta_{\bar{i}}) - H_P(x;\theta)] - \sup_{x\in C_M}[F(x,\theta) - H_P(x;\theta)]\right| < \delta. \tag{3.5}$$

Moreover, by definition of WULDF, we also have

$$\left|\epsilon \log \int \exp\{\epsilon^{-1}F(x,\theta_{\bar{i}})\}P^\epsilon(dx;\theta) - \sup_{x\in\mathcal{X}}[F(x,\theta_{\bar{i}}) - H_P(x;\theta)]\right| < \lambda_i(\epsilon), \tag{3.6}$$

where $\lim_{\epsilon\to 0}\lambda_i(\epsilon) = 0$.

Now let $\lambda(\epsilon) = \sup_{i=1,\dots,n}\lambda_i(\epsilon)$, and note that $\lim_{\epsilon\to 0}\lambda(\epsilon) = 0$. Using (3.1), (3.3), (3.4), (3.5), and (3.6), for all $\epsilon \le \epsilon_0$, we have

$$\begin{aligned}
&\left|\epsilon \log \int \exp\{\epsilon^{-1}F(x,\zeta)\}Q^\epsilon(dx,d\zeta;\theta) - \sup_{(x,\zeta)\in\mathcal{X}\times\Theta}[F(x,\zeta) - H_Q(x,\zeta;\theta)]\right| \\
&\quad = \left|\epsilon \log \int \exp\{\epsilon^{-1}F(x,\theta)\}P^\epsilon(dx;\theta) - \sup_{x\in\mathcal{X}}[F(x,\theta) - H_P(x;\theta)]\right| \\
&\quad \le \delta + \left|\epsilon \log \int_{C_M} \exp\{\epsilon^{-1}F(x,\theta)\}P^\epsilon(dx;\theta) - \sup_{x\in C_M}[F(x,\theta) - H_P(x;\theta)]\right| \\
&\quad \le \delta + \left|\epsilon \log \int_{C_M} \exp\{\epsilon^{-1}F(x,\theta)\}P^\epsilon(dx;\theta) - \epsilon \log \int_{C_M} \exp\{\epsilon^{-1}F(x,\theta_{\bar{i}})\}P^\epsilon(dx;\theta)\right| \\
&\qquad + \left|\epsilon \log \int \exp\{\epsilon^{-1}F(x,\theta_{\bar{i}})\}P^\epsilon(dx;\theta) - \epsilon \log \int_{C_M} \exp\{\epsilon^{-1}F(x,\theta_{\bar{i}})\}P^\epsilon(dx;\theta)\right| \\
&\qquad + \left|\epsilon \log \int \exp\{\epsilon^{-1}F(x,\theta_{\bar{i}})\}P^\epsilon(dx;\theta) - \sup_{x\in\mathcal{X}}[F(x,\theta_{\bar{i}}) - H_P(x;\theta)]\right| \\
&\qquad + \left|\sup_{x\in C_M}[F(x,\theta_{\bar{i}}) - H_P(x;\theta)] - \sup_{x\in C_M}[F(x,\theta) - H_P(x;\theta)]\right| \\
&\quad \le \delta + \delta + \delta + \lambda(\epsilon) + \delta.
\end{aligned}$$

Note that to get the last inequality we used the fact that equation (3.3) still holds when we replace $F(x,\theta)$ by $F(x,\theta_{\bar{i}})$. Thus

$$\begin{aligned}
\limsup_{\epsilon\to 0}\sup_{\theta\in K}\Big|\ &\epsilon \log {\textstyle\int} \exp\{\epsilon^{-1}F(x,\zeta)\}Q^\epsilon(dx,d\zeta;\theta) \\
&- \sup_{(x,\zeta)\in\mathcal{X}\times\Theta}\big[F(x,\zeta) - H_Q(x,\zeta;\theta)\big]\Big| \le 4\delta.
\end{aligned}$$

Since δ is arbitrary, the previous limit must be zero. Thus we have proved that the measures $Q^\epsilon(dx, d\zeta;\theta)$ form a WULDF. It remains to show that this family is also exponentially tight. Let $K \subseteq \Theta$ be a compact set. Since P^ϵ is exponentially tight, for every $L > 0$ there exists $C \subseteq \mathcal{X}$ compact such that

$$P^\epsilon(C^c;\theta) \leq e^{-\epsilon^{-1}L}$$

for every $\theta \in K$. Let $\tilde{C} = C \times K$. Clearly $\tilde{C} \subseteq \mathcal{X} \times \Theta$ is compact, and

$$Q^\epsilon(\tilde{C}^c;\theta) = P^\epsilon(C^c;\theta).$$

The exponential tightness is therefore easily proved. □

The next corollary restates in a different but equivalent way the result of the previous proposition. We give it explicitly for further reference.

Corollary 3.2. *Let $\{P^\epsilon(dx;y,\theta) : \epsilon > 0, (y,\theta) \in \mathcal{Y} \times \Theta\}$ be an exponentially tight WULDF on $\mathcal{X}$ with rate function $H_P(x;y,\theta)$. Define the measures on $\mathcal{X} \times \mathcal{Y}$, $Q^\epsilon(dx, dz; y, \theta) = P^\epsilon(dx; y, \theta) \otimes \delta_y(dz)$, with δ denoting the Dirac measure. Then $\{Q^\epsilon(dx, dz; y, \theta) : \epsilon > 0, (y, \theta) \in \mathcal{Y} \times \Theta\}$ is an exponentially tight WULDF with rate function*

$$H_Q(x, z; y, \theta) = \begin{cases} H_P(x;y,\theta) & \text{if } z = y, \\ +\infty & \text{if } z \neq y. \end{cases}$$

As a simple application of Proposition 3.1, we give the proof of Proposition 2.5.

Proof of Proposition 2.5. By Proposition 3.1 the following identities are easily obtained:

$$\begin{aligned}\lim_{\epsilon\to 0} \epsilon \log \int e^{\epsilon^{-1}F(x)} P^\epsilon(dx;\theta) &= \lim_{\epsilon\to 0} \epsilon \log \int e^{\epsilon^{-1}F(f(\theta,w))} \mu^\epsilon(dw) \\ &= \lim_{\epsilon\to 0} \epsilon \log \int e^{\epsilon^{-1}F(f(\gamma,w))} \mu^\epsilon \otimes \delta_\theta(dw, d\gamma) \\ &= \sup_{w\in\mathcal{W}} \Big[F(f(\theta,w)) - h(w)\Big] = \sup_{x\in\mathcal{X}} \Big[F(x) - H(x;\theta)\Big],\end{aligned}$$

where the limit is uniform in the compact subsets of Θ. Moreover, property i) of Definition 2.4 is easily shown for $H(x;\theta)$, while property ii) comes automatically from the fact that the P^ϵ are probability measures. □

The next lemma presents an easy technical fact that we will need in the proof of Proposition 3.4.

Lemma 3.3. *Let $F : \mathcal{X} \times \Theta \to \mathbb{R}$ be a continuous and bounded map, and $H : \mathcal{X} \times \Theta \to \mathbb{R}^+$ be the rate function of an exponentially tight WULDF whose elements are probability measures. Moreover, suppose H satisfies the following properties.*

(i) *Let $A = \{(x,\theta) : H(x;\theta) < +\infty\}$. Then for every $(x,\theta) \in A$ and every sequence $\theta_n \to \theta$ there exists a sequence $x_n \to x$ such that $H(x_n;\theta_n) \to H(x;\theta)$.*

(ii) *H is lower semicontinuous as a function of (x,θ).*

Then

$$G(\theta) = \sup_{x\in\mathcal{X}} [F(x,\theta) - H(x;\theta)] \tag{3.7}$$

is a bounded and continuous function.

Proof. Assume that $|F(x,\theta)| \leq L$ for all (x,θ). Since H is the rate function for a family of probability measures, we have (see Remark 2.2) $\inf_x H(x,\theta) = 0$ for all $\theta \in T$. This easily implies $|G(\theta)| \leq L$ for all $t \in \Theta$.

We now show that G is upper semicontinuous. First of all we note that, for any $\theta \in \Theta$, there exists $x \in \mathcal{X}$ such that $G(\theta) = F(x,\theta) - H(x,\theta)$, i.e., the supremum in (3.7) is attained. In fact, that supremum can be equivalently taken for $x \in C$, where $C = \{x : H(x,\theta) \leq 3L\}$. Since C is compact and $F - H$ is upper semicontinuous, then it follows that $F(\cdot,\theta) - H(\cdot,\theta)$ has maximum in C. Now let $\theta_n \to \theta$, and x_n be such that $G(\theta_n) = F(x_n,\theta_n) - H(x_n,\theta_n)$. We have to prove that

$$\limsup G(\theta_n) \leq G(\theta). \tag{3.8}$$

Since the lim sup is the limit along a subsequence, we can assume, without loss of generality, that the sequence $G(\theta_n)$ has a limit. Due to the fact that $\{\theta_n : n \geq 0\} \cup \{\theta\}$ is compact, and the properness of H, it follows that the sequence x_n is relatively compact, so it has a convergent subsequence $x_{n_k} \to x$. Thus

$$\lim G(\theta_n) = \lim G(\theta_{n_k}) = \lim \Big[F(x_{n_k},\theta_{n_k}) - H(x_{n_k},\theta_{n_k})\Big]$$

$$\leq F(x,\theta) - H(x,\theta) \leq G(\theta),$$

where we have used the (joint) upper semicontinuity of $F - H$.

Now we prove lower semicontinuity, i.e., that $\liminf G(\theta_n) \geq G(\theta)$. Let x be such that $G(\theta) = F(x,\theta) - H(x;\theta)$. By property (i), there exists a sequence $x_n \to x$, with $H(x_n;\theta_n) \to H(x,\theta)$. So we get

$$\liminf G(\theta_n) \geq \liminf\, [F(x_n,\theta_n) - H(x_n;\theta_n)] = G(\theta). \qquad \square$$

PROPOSITION 3.4 (composition). *Let* $\{P^\epsilon(dx;y,\theta) : \epsilon > 0, (y,\theta) \in \mathcal{Y} \times \Theta\}$ *and* $\{Q^\epsilon(dy;\theta) : \epsilon > 0, \theta \in \Theta\}$ *be two exponentially tight WULDF in* $\mathcal{X}$ *and* $\mathcal{Y}$, *respectively, with rate functions* $H_P(x;y,\theta)$ *and* $H_Q(y;\theta)$. *Assume that the measures* P^ϵ *are all probability measures. Moreover, assume that the rate function* $H_P(x;y,\theta)$ *satisfies assumptions* (i)–(ii) *of Lemma* 3.3 (*with* $\mathcal{Y} \times \Theta$ *in place of* Θ). *Then* $\{R^\epsilon(dx,dy;\theta) : \epsilon > 0, \theta \in \Theta\}$ *defined by*

$$\int f(x,y) R^\epsilon(dx,dy;\theta) = \int \left[\int f(x,y) P^\epsilon(dx;y,\theta)\right] Q^\epsilon(dy;\theta)$$

is an exponentially tight WULDF with rate function

$$H_R(x,y;\theta) = H_P(x;y,\theta) + H_Q(y;\theta).$$

Proof. First we prove that R^ϵ is a WULDF. Since $H_P(\cdot;y,\theta)$ is positive and has minimum zero, property ii) of Definition 2.4 for H_R is easily derived from the corresponding property for H_Q. We now show that i) of Definition 2.4 holds. Since lower semicontinuity is obvious, we need only to prove that for all $L \in \mathbb{R}$ and for each θ, the set $Z = \{(x,y) \,|\, H_R(x,y;\theta) \leq L\}$ is compact. Notice that if $(x,y) \in Z$ then $y \in W = \{y \,|\, H_Q(y;\theta) \leq L\}$, and W is compact. Since H_P is proper, there exists a compact set $V \subseteq \mathcal{X}$ such that $H_P(x;y,\theta) \geq L + 1$ for all $x \in V^c$ and all $y \in W$ (note that $W \times \{\theta\}$ is compact). Thus we have that

$$Z \subseteq V \times W,$$

and so Z is compact, as desired.

Now we must show that also iii) of Definition 2.4 holds for R^ϵ. Let $F(x,y)$ be a continuous and bounded function, and let $K \subseteq \Theta$ be compact. We need to prove that

$$\lim_{\epsilon \to 0} \sup_{\theta \in K} \left[\epsilon \log \int \exp\{\epsilon^{-1} F(x,y)\} R^\epsilon(dx, dy; \theta) - \sup_{(x,y) \in \mathcal{X} \times \mathcal{Y}} [F(x,y) - H_R(x,y;\theta)] \right] = 0. \tag{3.9}$$

Notice that

$$\int \exp\{\epsilon^{-1} F(x,y)\} R^\epsilon(dx, dy; \theta) \;=\; \int \exp\{\epsilon^{-1} G^\epsilon(y,\theta)\} Q^\epsilon(dy, \theta),$$

where

$$G^\epsilon(y,\theta) \;=\; \epsilon \log \int \exp\{\epsilon^{-1} F(x,y)\} P^\epsilon(dx; y, \theta).$$

Clearly, the functions G^ϵ are uniformly bounded. By Corollary 3.2

$$G^\epsilon(y,\theta) \to G(y,\theta) \equiv \sup_{x \in \mathcal{X}} [F(x,y) - H_P(x; y, \theta)]$$

uniformly on the compact subsets of $Y \times \Theta$. Moreover, by Lemma 3.3, G is a bounded continuous function. Thus (3.9) follows as an application of Lemma 2.9 and Proposition 3.1.

It remains to show that the family R^ϵ is exponentially tight. Let $K \subseteq \Theta$ be a compact set, and $M > 0$. Since Q^ϵ is exponentially tight, there exists a compact set $C_1 \subseteq \mathcal{Y}$ such that for all $\theta \in K$ and for all ϵ small enough,

$$Q^\epsilon(C_1^c; \theta) \leq \frac{e^{-\epsilon^{-1} M}}{2}.$$

Moreover, since $P^\epsilon(dx; y, \theta)$ is also exponentially tight, there exists a compact set $C_2 \subseteq \mathcal{X}$ such that

$$P^\epsilon(C_2^c; y, \theta) \leq \frac{e^{-\epsilon^{-1} M}}{2}$$

for all $(y, \theta) \in C_1 \times K$ and for all ϵ small enough. Let $C = C_1 \times C_2$. Then

$$R^\epsilon(C^c; \theta) \leq R^\epsilon(C_2^c \times C_1; \theta) + R^\epsilon(C_2 \times C_1^c; \theta) \leq \sup_{y \in C_1} P^\epsilon(C_2^c; y, \theta) + Q^\epsilon(C_1^c; \theta).$$

Thus, for all ϵ small enough, and for all $\theta \in K$, we get

$$R^\epsilon(C^c; \theta) \leq e^{-\epsilon^{-1} M},$$

which completes the proof. □

Lemma 3.5. *Let $\{P^\epsilon(dx; \theta) : \epsilon > 0, \theta \in \Theta\}$ be a WULDF, with rate function $H(x; \theta)$, and $f : \mathcal{X} \to \mathcal{Y}$ be a continuous function. Then $\{P_f^\epsilon(dy; \theta) : \epsilon > 0, \theta \in \Theta\}$ defined by*

$$P_f^\epsilon(B; \theta) = P^\epsilon(f^{-1}(B); \theta), \quad B \subseteq \mathcal{Y},$$

is again a WULDF with rate function

$$H_f(y;\theta) \;=\; \inf\{H(x;\theta) :\; f(x) = y\}.$$

Moreover if the family $P^\epsilon(dx;\theta)$ is exponentially tight then also the family $P^\epsilon_f(dy;\theta)$ is exponentially tight.

The proof of Lemma 3.5 is easy, and is omitted. From Lemma 3.5 the following Proposition follows.

PROPOSITION 3.6 (contraction). *Let $\{R^\epsilon(dx,dy;\theta) : \epsilon > 0, \theta \in \Theta\}$ be a WULDF on $\mathcal{X} \times \mathcal{Y}$ with rate function $H_R(x,y;\theta)$. Then $\{P^\epsilon(dx;\theta) : \epsilon > 0, \theta \in \Theta\}$, defined by:*

$$P^\epsilon(A;\theta) \;:=\; R^\epsilon(A \times \mathcal{Y};\theta),$$

is a WULDF with rate function

$$H_P(x;\theta) \;=\; \inf_{y\in\mathcal{Y}} H_R(x,y;\theta).$$

Moreover if the family $R^\epsilon(dx,dy;\theta)$ is exponentially tight then also the family $P^\epsilon(dx;\theta)$ is exponentially tight.

PROPOSITION 3.7 (conditioning). *Let $\{P^\epsilon(dx;\theta) : \epsilon > 0, \theta \in \Theta\}$ and $\{Q^\epsilon(dy;x) : \epsilon > 0, x \in \mathcal{X}\}$ be two exponentially tight WULDF's on $\mathcal{X}$ and $\mathcal{Y}$, respectively, with rate functions $H_P(x;\theta)$ and $H_Q(y;x)$. Assume that the measures $Q^\epsilon(dy;x)$ are all probability measures and that both families of kernels are exponentially tight. Moreover assume that the rate function $H_Q(y;x)$ is always finite and continuous, and that the following properties hold.*

1. *The measure $Q^\epsilon(dy;x)$ is of the form*

   $$Q^\epsilon(dy;x) \;=\; q^\epsilon(y;x)\alpha(dy),$$

   where $q^\epsilon(y;x) > 0$ and the measure $\alpha(dy)$ satisfies

   $$\inf_{y\in K} \alpha\left(B(y,\gamma)\right) > 0$$

   for every $K \subset \mathcal{Y}$ compact and $\gamma > 0$, where $B(y,\gamma)$ is the ball centered at y with radius γ.
2. *For any compact sets $K \subseteq \mathcal{Y}$, $C \subseteq \mathcal{X}$ and any $\delta > 0$ there exist $\delta_1 > 0$ and $\epsilon(\delta)$ such that*

   $$|\epsilon \log q^\epsilon(y_1;x) \;-\; \epsilon \log q^\epsilon(y_2;x)| \;<\; \delta$$

   for all y_1, $y_2 \in K$ such that $d(y_1,y_2) < \delta_1$, for all $\epsilon \le \epsilon(\delta)$, and for all $x \in C$.
3. *For any compact sets $K \subseteq \mathcal{Y}$, $C \subseteq \mathcal{X}$ there exists $n_{K,C} > 0$ such that*

   $$\epsilon \log q^\epsilon(y;x) \ge -n_{K,C}$$

   for all $y \in K$, $x \in C$, and $\epsilon > 0$.
4. *For any compact set $K \subseteq \mathcal{Y}$, there exists $N_K > 0$ such that*

   $$\epsilon \log q^\epsilon(y;x) \le N_K$$

   for all $y \in K$, for all $x \in \mathcal{X}$, and for all $\epsilon > 0$.

Then the measures on $\mathcal{X}$

$$R^\epsilon(dx; y, \theta) \;=\; q^\epsilon(y;x) P^\epsilon(dx;\theta)$$

form an exponentially tight WULDF with rate function

$$H_R(x;y,\theta) \;=\; H_Q(y;x) + H_P(x;\theta).$$

Proof. First we prove that the family R^ϵ is exponentially tight. Let $\tilde{K} \subseteq \mathcal{Y} \times \Theta$ be a compact set, and denote by K_1 and K_2 its projection on Y and Θ respectively. By property 4 there exists a constant N_{K_1} such that $q^\epsilon(y;x) \leq e^{\epsilon^{-1} N_{K_1}}$ for all $y \in K_1$, all $x \in \mathcal{X}$, and all $\epsilon > 0$. Given any $M > 0$, since P^ϵ is exponentially tight, there exists a compact set $C \subseteq \mathcal{X}$ such that

$$\sup_{\theta \in K_2} P^\epsilon(C^c;\theta) \;\leq\; e^{-\epsilon^{-1}(M + N_{K_1})}.$$

We have

$$\begin{aligned}\sup_{(y,\theta)\in\tilde{K}} R^\epsilon(C^c;y,\theta) &= \sup_{(y,\theta)\in\tilde{K}} \int_{C^c} q^\epsilon(y;x) P^\epsilon(dx;\theta) \\ &\leq e^{\epsilon^{-1} N_{K_1}} \sup_{\theta\in K_2} P^\epsilon(C^c;\theta) \leq e^{-\epsilon^{-1} M},\end{aligned}$$

which proves exponential tightness. To show that the family $\{R^\epsilon(dx;y,\theta)\}$ is a WULDF with rate function H_R, we define

$$M^P_\theta \;=\; \inf_{x \in X} H_P(x;\theta).$$

Notice that, since the measures $Q^\epsilon(dy;x)$ are all probability measures, it holds that $H_Q(y;x) \geq 0$. Then it is clear that $H_R(x;y,\theta) \geq M^P_\theta$, so the map H_R satisfies property ii) of Definition 2.4. Moreover, since

$$\{\, x \mid H_R(x;y,\theta) \leq L \,\} \subseteq \{\, x \mid H_P(x,\theta) \leq L \,\},$$

property i) of Definition 2.4 holds also.

Now we need to establish property iii) of Definition 2.4. First we prove an intermediate step, which consists of approximating the density $q^\epsilon(y;x)$ with an average on the form

$$\frac{1}{\alpha(B(y,\delta_1))} \int_Y e^{\epsilon^{-1} h(\eta)} q^\epsilon(\eta;x) \alpha(d\eta),$$

$h(\eta)$ being a function suitably concentrated about $\eta = y$.

For any $y \in \mathcal{Y}$, $\delta > 0$, $0 < \tilde{\delta} < \delta$, and $M > 0$, let $g_{y,\delta,\tilde{\delta},M}(\eta)$ be a continuous and bounded function such that

1. $g_{y,\delta,\tilde{\delta},M}(\eta) \leq 0$ for all $\eta \in \mathcal{Y}$, and $g_{y,\delta,\tilde{\delta},M}(\eta) = 0$ for all $\eta \in B(y,\tilde{\delta})$;
2. $g_{y,\delta,\tilde{\delta},M}(\eta) = -M$ if $\eta \notin B(y,\delta)$.

For each given $y \in \mathcal{Y}$, $0 < \tilde{\delta} < \delta$, and $M > 0$, the existence of a function $g_{y,\delta,\tilde{\delta},M}(\cdot)$ satisfying the previous requirements is easily proved. For example one may take

$$g_{y,\delta,\tilde{\delta},M}(\eta) = -\frac{M}{\delta - \tilde{\delta}} \left(\min\{\mathrm{dist}(\eta, B(y,\tilde{\delta})), \delta - \tilde{\delta}\} \right). \qquad \square$$

Claim 1. *For any $K \subseteq \mathcal{Y}$, and $C \subseteq \mathcal{X}$ compact sets, and any $\delta > 0$, $M > 0$, let $\delta_1 > 0$ and $\epsilon(\delta) > 0$ be such that*

$$q^\epsilon(y;x)e^{-\epsilon^{-1}\delta} \le q^\epsilon(\eta;x) \le q^\epsilon(y;x)e^{\epsilon^{-1}\delta} \tag{3.10}$$

for all $x \in C$, $y, \eta \in K$ such that $\eta \in B(y,\delta_1)$ and for all $\epsilon \le \epsilon(\delta)$ (use property 2). Fix any $\tilde{\delta} < \delta_1$, and let $h(\eta) = g_{y,\delta_1,\tilde{\delta},M}(\eta)$. Then there exists a constant $C(\delta_1) > 0$ such that

$$\begin{aligned} &e^{-\epsilon^{-1}\delta}\big(1 + C(\delta_1)^{-1}e^{-\epsilon^{-1}(M-N_K+\delta)}\big)^{-1}\frac{1}{\alpha(B(y,\delta_1))}\int_{\mathcal{Y}} e^{\epsilon^{-1}h(\eta)}q^\epsilon(\eta;x)\alpha(d\eta) \\ &\qquad \le q^\epsilon(y;x) \le e^{\epsilon^{-1}\delta}\frac{1}{\alpha(B(y,\tilde{\delta}))}\int_{\mathcal{Y}} e^{\epsilon^{-1}h(\eta)}q^\epsilon(\eta;x)\alpha(d\eta) \end{aligned} \tag{3.11}$$

for all $y \in K$, for all $x \in C$, $\forall\, \tilde{\delta} < \delta_1$, and $\forall\, \epsilon \le \epsilon(\delta)$, where N_K is defined in Property 4 in the assumptions.

Proof of the claim. Let $C(\delta_1) = \inf_{y\in K}\alpha(B(y,\delta_1))$. It is easy to see that the following inequalities hold:

$$\int_{\mathcal{Y}} e^{\epsilon^{-1}h(\eta)}q^\epsilon(\eta;x)\alpha(d\eta) \ge \int_{B(y,\tilde{\delta})} e^{-\epsilon^{-1}\delta}q^\epsilon(y;x)\alpha(d\eta) = e^{-\epsilon^{-1}\delta}q^\epsilon(y;x)\alpha\left(B(y,\tilde{\delta})\right),$$

$$\begin{aligned} \int_{\mathcal{Y}} e^{\epsilon^{-1}h(\eta)}q^\epsilon(\eta;x)\alpha(d\eta) &\le \int_{B(y,\delta_1)} e^{\epsilon^{-1}\delta}q^\epsilon(y;x)\alpha(d\eta) \\ &\quad + \int_{B(y,\delta_1)^c} e^{-\epsilon^{-1}M}q^\epsilon(\eta;x)\alpha(d\eta) \\ &\le e^{\epsilon^{-1}\delta}q^\epsilon(y;x)\alpha\left(B(y,\delta_1)\right)\left[1 + C(\delta_1)^{-1}e^{-\epsilon^{-1}(M-N_K+\delta)}\right], \end{aligned}$$

from which (3.11) follows easily. So Claim 1 is proved.

Fix any $K \subseteq \mathcal{Y}$, and $C \subseteq \mathcal{X}$ compact sets, and any $\delta > 0$, $M > 0$. Combining equations (3.11) and (3.10) we get that for all $x \in C$, and all $\tilde{y} \in K$ such that $|\tilde{y} - y| < \delta_1$:

$$\begin{aligned} &e^{-\epsilon^{-1}2\delta}\frac{\gamma(\delta_1)^{-1}}{\alpha(B(y,\delta_1))}\int_{\mathcal{Y}} e^{\epsilon^{-1}h(\eta)}q^\epsilon(\eta;x)\alpha(d\eta) \\ &\qquad \le q^\epsilon(\tilde{y};x) \le e^{\epsilon^{-1}2\delta}\frac{1}{\alpha(B(y,\tilde{\delta}))}\int_{\mathcal{Y}} e^{\epsilon^{-1}h(\eta)}q^\epsilon(\eta;x)\alpha(d\eta) \end{aligned} \tag{3.12}$$

where $h(\eta) = g_{y,\delta_1,\tilde{\delta},M}(\eta)$ and $\gamma(\delta_1) = 1 + \frac{1}{C(\delta_1)}e^{-\epsilon^{-1}(M-N_K+\delta)}$. Since $K \subset \cup_{y\in K}B(y,\delta_1)$ and K is compact, there exist $h_1(\eta),\ldots,h_l(\eta)$ all of the type $g_{y_i,\delta_1,\tilde{\delta},M}(\eta)$ for some $y_i \in K$, such that for all $y \in K$ and for all $x \in C$ there exists an index $i \in \{1,\ldots,l\}$ such that

$$\begin{aligned} &e^{-\epsilon^{-1}2\delta}\frac{\gamma(\delta_1)^{-1}}{\alpha(B(y_i,\delta_1))}\int_{\mathcal{Y}} e^{\epsilon^{-1}h_i(\eta)}q^\epsilon(\eta;x)\alpha(d\eta) \le q^\epsilon(\tilde{y};x) \\ &\qquad \le e^{\epsilon^{-1}2\delta}\frac{1}{\alpha(B(y_i,\tilde{\delta}))}\int_{\mathcal{Y}} e^{\epsilon^{-1}h_i(\eta)}q^\epsilon(\eta;x)\alpha(d\eta), \end{aligned} \tag{3.13}$$

where (3.13) holds for all $\tilde{\delta} < \delta_1$, $\epsilon \le \epsilon(\delta)$.

Now we prove that iii) of Definition 2.4 also holds. Fix a compact set $\tilde{K} \subseteq \mathcal{Y} \times \Theta$. Let $K_1 \subseteq \mathcal{Y}$ be its first projection (i.e., $K_1 = \Pi_1(\tilde{K})$) and $K_2 \subseteq \Theta$ be its second projection. Moreover, let N_{K_1} be the positive constant given by property 4. For any continuous and bounded function $F(x)$, we need to show that

$$\lim_{\epsilon \to 0} \sup_{(y,\theta) \in \tilde{K}} \left[\epsilon \log \int_{\mathcal{X}} e^{\epsilon^{-1} F(x)} R^{\epsilon}(dx; y, \theta) - \sup_{x \in \mathcal{X}} \left(F(x) - H_R(x; y, \theta) \right) \right] = 0.$$

We let

- $|F(x)| \leq L_1$,
- $x_\theta \in \mathcal{X}$ be such that $H^P(x_\theta; \theta) = M^P_\theta = \inf_x H_P(x; \theta)$,
- $M^P(K_2)$ be such that $|M^P_\theta| \leq M^P(K_2)$ for all $\theta \in K_2$,
- $C_1 \subseteq \mathcal{X}$ be a compact set such that $x_\theta \in C_1$ for all $\theta \in K_2$ (such compact set exists by properness of the rate function),
- L_2 be such that $|H_Q(y; x)| \leq L_2$ for all $y \in K_1$ and all $x \in C_1$ (notice that this constant exists since H_Q is continuous).

Now consider a compact set $C_2 \subset \mathcal{X}$ and a constant $\Lambda > 0$ such that, for ϵ sufficiently small,

$$P^{\epsilon}(C_2; \theta) \geq e^{-\epsilon^{-1} \Lambda} \tag{3.14}$$

for every $\theta \in K_2$. Note that this can be done by (2.3) and exponential tightness of P^ϵ. Moreover, by property 3, there is a constant n such that

$$-n \leq \epsilon \log q^{\epsilon}(y; x) \tag{3.15}$$

for all $x \in C_2, y \in K_1$.

Fix any positive constants M, T and $\tilde{M}$ such that:

$$\begin{aligned} &M > 2L_1 + L_2 + 2M^P(K_2) + N_{K_1}, \qquad T > 2L_1 + \Lambda + n, \\ &\tilde{M} > 2L_1 + L_2 + M^P(K_2) + M + \Lambda. \end{aligned} \tag{3.16}$$

Since H_P is proper and P^ϵ, R^ϵ are exponentially tight, we have that there is a compact set $C_3 \subseteq \mathcal{X}$, which satisfies the following inequality for ϵ small enough:

$$H_P(x; \theta) > \tilde{M} \quad \text{for all } x \in C_3^c \text{ and all } \theta \in K_2, \tag{3.17}$$

$$P^{\epsilon}(C_3^c; \theta) \leq e^{-\epsilon^{-1} \tilde{M}} \quad \text{for all } \theta \in K_2, \tag{3.18}$$

$$R^{\epsilon}(C_3^c; y, \theta) \leq e^{-\epsilon^{-1} T} \quad \text{for all } (y, \theta) \in \tilde{K}. \tag{3.19}$$

Notice that without loss of generality, we may assume that $C_1, C_2 \subseteq C_3$. Fix any $\delta > 0$. Let $\delta_2 > 0$ be such that

$$|H_Q(y; x) - H_Q(y'; x')| \leq \delta \tag{3.20}$$

for all x, $x' \in C_3$, and y, $y' \in K_1$, such that $\operatorname{dist}(x, x') < \delta_2$ and $\operatorname{dist}(y, y') < \delta_2$.

Now, fix $(y, \theta) \in \tilde{K}$, $x \in C_3$. We have seen that there exist $\delta_1 \leq \delta$, $\epsilon(\delta) > 0$, $y_1, \ldots, y_l \in K_1$ and $i \in \{1, \ldots, l\}$ such that (3.13) holds for all $x \in C_3$, $y \in K_1$, $\tilde{\delta} \leq \delta_1$, and $\epsilon \leq \epsilon(\delta)$.

Upper bound.

$$\begin{aligned}
&\epsilon \log \int e^{\epsilon^{-1}F(x)} R^\epsilon(dx; y, \theta) \\
&\quad = \epsilon \log \int_{C_3} e^{\epsilon^{-1}F(x)} R^\epsilon(dx; y, \theta) + \epsilon \log \left[1 + \frac{\int_{C_3^c} e^{\epsilon^{-1}F(x)} R^\epsilon(dx; y, \theta)}{\int_{C_3} e^{\epsilon^{-1}F(x)} R^\epsilon(dx; y, \theta)} \right] \\
&\quad \leq \epsilon \log \int_{C_3} e^{\epsilon^{-1}F(x)} R^\epsilon(dx; y, \theta) + \epsilon \log \left(1 + e^{\epsilon^{-1}(2L_1 + \Lambda + n - T)} \right),
\end{aligned}$$

where we have used the inequalities

$$\int_{C_3^c} e^{\epsilon^{-1}F(x)} R^\epsilon(dx; y, \theta) \leq e^{\epsilon^{-1}(L_1 - T)},$$

$$\int_{C_3} e^{\epsilon^{-1}F(x)} R^\epsilon(dx; y, \theta) \geq \int_{C_2} e^{\epsilon^{-1}F(x)} R^\epsilon(dx; y, \theta) \geq e^{-\epsilon^{-1}(L_1 + \Lambda + n)}$$

for every $(y, \theta) \in \tilde{K}$. Therefore, using (3.13),

$$\begin{aligned}
&\epsilon \log \int e^{\epsilon^{-1}F(x)} R^\epsilon(dx; y, \theta) \\
&\quad \leq \epsilon \log \left(1 + e^{\epsilon^{-1}(2L_1 + \Lambda + n - T)} \right) + 2\delta \\
&\qquad - \epsilon \log \alpha(B(y_i, \tilde{\delta})) + \epsilon \log \int_{C_3 \times Y} e^{\epsilon^{-1}(F(x) + h_i(\eta))} Q^\epsilon(d\eta; x) P^\epsilon(dx; \theta) \\
&\quad \leq \epsilon \log \left(1 + e^{\epsilon^{-1}(2L_1 + \Lambda + n - T)} \right) + 2\delta - \epsilon \log C(\tilde{\delta}) \\
&\qquad + \epsilon \log \int_{X \times Y} e^{\epsilon^{-1}(F(x) + h_i(\eta))} Q^\epsilon(d\eta; x) P^\epsilon(dx; \theta) \\
&\quad \leq \epsilon \log \left(1 + e^{\epsilon^{-1}(2L_1 + \Lambda + n - T)} \right) + 2\delta - \epsilon \log C(\tilde{\delta}) \\
&\qquad + \sup_{x \in \mathcal{X}, \eta \in \mathcal{Y}} [F(x) + h_i(\eta) - H_Q(\eta; x) - H_P(x; \theta)] + \lambda_i(\epsilon)
\end{aligned}$$

with $\lambda_i(\epsilon) \to 0$ as $\epsilon \to 0$. Note that for the last inequality Proposition 3.4 has been used. Now observe that

$$\begin{aligned}
&\sup_{x \in \mathcal{X}, \eta \in \mathcal{Y}} \Big[F(x) + h_i(\eta) - H_Q(\eta; x) - H_P(x; \theta) \Big] \\
&\qquad \geq F(x_\theta) + h_i(y_i) - H_Q(y_i; x_\theta) - H_P(x_\theta; \theta) \geq -L_1 - L_2 - M^P(K_2).
\end{aligned} \tag{3.21}$$

On the other hand, for $x \notin C_3$

$$F(x) + h_i(\eta) - H_Q(\eta; x) - H_P(x; \theta) \leq L_1 - \tilde{M}, \tag{3.22}$$

and, for $\operatorname{dist}(\eta, y_i) > \delta_1$,

$$F(x) + h_i(\eta) - H_Q(\eta; x) - H_P(x; \theta) \leq L_1 - M + M^P(K_2). \tag{3.23}$$

By (3.16), it follows that the right-hand side (RHS) of (3.22) and (3.23) are smaller than the RHS of (3.21). Therefore

$$\begin{aligned}
&\sup_{x\in\mathcal{X},\eta\in\mathcal{Y}}\Big[F(x)+h_i(\eta)-H_Q(\eta;x)-H_P(x;\theta)\Big]\\
&\quad=\sup_{x\in C_3,\eta\in B(y_i,\delta_1)}\Big[F(x)+h_i(\eta)-H_Q(\eta;x)-H_P(x;\theta)\Big]\\
&\quad\le\sup_{x\in C_3}\Big[F(x)-H_Q(y;x)-H_P(x;\theta)\Big]+\delta\\
&\quad=\sup_{x\in\mathcal{X}}\Big[F(x)-H_Q(y;x)-H_P(x;\theta)\Big]+\delta
\end{aligned}$$

where the last equality comes from an argument analogous to (3.21)–(3.23). Summing up,

$$\begin{aligned}
&\epsilon\log\int e^{\epsilon^{-1}F(x)}R^\epsilon(dx;y,\theta)\\
&\quad\le\epsilon\log\Big(1+e^{\epsilon^{-1}(2L_1+\Lambda+n-T)}\Big)+2\delta-\epsilon\log C(\tilde\delta)\\
&\qquad+\sup_{x\in\mathcal{X}}\Big[F(x)-H_Q(y;x)-H_P(x;\theta)\Big]+\lambda(\epsilon)
\end{aligned}$$

with $\lambda(\epsilon)=\max_{i=1,\dots,l}\lambda_i(\epsilon)$. By using again (3.16), the last inequality implies

$$\begin{aligned}
&\limsup_{\epsilon\to0}\sup_{(y,\theta)\in\tilde K}\epsilon\log\int e^{\epsilon^{-1}F(x)}R^\epsilon(dx;y,\theta)\\
&\qquad-\sup_{x\in\mathcal{X}}\Big[F(x)-H_Q(y;x)-H_P(x;\theta)\Big]\le0.
\end{aligned}\tag{3.24}$$

Lower bound. By (3.13)

$$\begin{aligned}
\epsilon\log\int e^{\epsilon^{-1}F(x)}R^\epsilon(dx;y,\theta)&\ge\epsilon\log\int_{C_3}e^{\epsilon^{-1}F(x)}R^\epsilon(dx;y,\theta)\\
&\ge-2\delta-\epsilon\log\gamma(\delta_1)-\epsilon\log\alpha(B(y_i,\delta_1))\\
&\quad+\epsilon\log\int_{C_3\times\mathcal{Y}}e^{\epsilon^{-1}(F(x)+h_i(\eta))}Q^\epsilon(d\eta;x)P^\epsilon(dx;\theta).
\end{aligned}\tag{3.25}$$

Note that

$$\int_{C_3^c\times\mathcal{Y}}e^{\epsilon^{-1}(F(x)+h_i(\eta))}Q^\epsilon(d\eta;x)P^\epsilon(dx;\theta)\le e^{\epsilon^{-1}(L_1-\tilde M)}$$

and

$$\int_{\mathcal{X}\times\mathcal{Y}}e^{\epsilon^{-1}(F(x)+h_i(\eta))}Q^\epsilon(d\eta;x)P^\epsilon(dx;\theta)\ge e^{-\epsilon^{-1}(L_1+M+\Lambda)},$$

which implies

$$\begin{aligned}
&\epsilon\log\int_{C_3\times\mathcal{Y}} e^{\epsilon^{-1}(F(x)+h_i(\eta))}Q^\epsilon(d\eta;x)P^\epsilon(dx;\theta)\\
&\quad=\epsilon\log\int_{\mathcal{X}\times\mathcal{Y}} e^{\epsilon^{-1}(F(x)+h_i(\eta))}Q^\epsilon(d\eta;x)P^\epsilon(dx;\theta)\\
&\qquad+\epsilon\log\left[1-\frac{\int_{C_3^c\times\mathcal{Y}} e^{\epsilon^{-1}(F(x)+h_i(\eta))}Q^\epsilon(d\eta;x)P^\epsilon(dx;\theta)}{\int_{\mathcal{X}\times\mathcal{Y}} e^{\epsilon^{-1}(F(x)+h_i(\eta))}Q^\epsilon(d\eta;x)P^\epsilon(dx;\theta)}\right]\\
&\quad\ge\epsilon\log\int_{\mathcal{X}\times\mathcal{Y}} e^{\epsilon^{-1}(F(x)+h_i(\eta))}Q^\epsilon(d\eta;x)P^\epsilon(dx;\theta)\\
&\qquad+\epsilon\log\left[1-e^{\epsilon^{-1}(2L_1+M+\Lambda-\tilde{M})}\right].
\end{aligned}$$

Thus

$$\begin{aligned}
&\epsilon\log\int e^{\epsilon^{-1}F(x)}R^\epsilon(dx;y,\theta)\ge-2\delta-\epsilon\log\gamma(\delta_1)-\epsilon\log\alpha(B(y_i,\delta_1))\\
&\quad+\epsilon\log\int_{\mathcal{X}\times\mathcal{Y}} e^{\epsilon^{-1}(F(x)+h_i(\eta))}Q^\epsilon(d\eta;x)P^\epsilon(dx;\theta)+\epsilon\log\left[1-e^{\epsilon^{-1}(2L_1+M+\Lambda-\tilde{M})}\right].
\end{aligned}$$

After having noticed that, by (3.16), $2L_1+M+\Lambda-\tilde{M}<0$, the proof of the lower bound proceeds by repeating the arguments in the proof of the upper bound, yielding

$$\begin{aligned}
&\liminf_{\epsilon\to0}\inf_{(y,\theta)\in\tilde{K}}\epsilon\log\int e^{\epsilon^{-1}F(x)}R^\epsilon(dx;y,\theta)\\
&\qquad-\sup_{x\in\mathcal{X}}\left[F(x)-H_Q(y;x)-H_P(x;\theta)\right]\ge0,
\end{aligned}\tag{3.26}$$

which, together with (3.24), completes the proof. □

Note that, if in Proposition 3.7 we interpret $q^\epsilon(y;x)\alpha(dy)P^\epsilon(dx;\theta)$ as a measure in $\mathcal{X}\times\mathcal{Y}$, the measure R^ϵ has the meaning of *unnormalized* conditional measure. An analogous statement for the normalized version, whose proof follows easily from Proposition 3.7, is given below.

COROLLARY 3.8. *Under the assumptions of Proposition* 3.7, *define*

$$R^\epsilon(dx;y,\theta)=\frac{q^\epsilon(y;x)P^\epsilon(dx;\theta)}{\int_{\mathcal{X}} q^\epsilon(y;x)P^\epsilon(dx;\theta)}.$$

Then $\{R^\epsilon(dx;y,\theta):\epsilon>0,(y,\theta)\in\mathcal{Y}\times\Theta\}$ *is an exponentially tight WULDF with rate function*

$$H_R(x;y,\theta)\;=\;H_Q(y;x)+H_P(x;\theta)-\inf_{x\in\mathcal{X}}\left[H_Q(y;x)+H_P(x;\theta)\right].$$

4. The small parameter limit for partially observed, risk-sensitive control problems.

4.1. The model. Let $(\Omega,\mathcal{F},P)$ be a probability space, $\mathcal{X},\mathcal{Y}$ metric spaces, and $\mathcal{U}$ a compact metric space. Moreover, let $(\mathcal{F}_n)_{n=0}^N$, $(\mathcal{G}_n)_{n=0}^N$ be given filtrations on $(\Omega,\mathcal{F},P)$. We construct a controlled, partially observed stochastic system with state space $\mathcal{X}$, observation space $\mathcal{Y}$, and control space $\mathcal{U}$. The (discrete) time will vary in $\{0,1,\dots,N\}$.

Now, let $\mathcal{M}_1(\mathcal{X})$ $(\mathcal{M}_1(\mathcal{Y}))$ denote the set of probability measures on $\mathcal{X}$ $(\mathcal{Y})$, provided with the weak topology and the corresponding Borel σ-field. Suppose that, for $n = 0, \dots, N-1$ and $\epsilon > 0$, we are given measurable functions (*probability kernels*)

$$\begin{array}{rcl} \mathcal{X} \times \mathcal{U} & \to & \mathcal{M}_1(\mathcal{X}), \\ (x, u) & \to & P_n^\epsilon(\cdot; x, u), \end{array} \tag{4.1}$$

$$\begin{array}{rcl} \mathcal{X} & \to & \mathcal{M}_1(\mathcal{Y}), \\ x & \to & Q_{n+1}^\epsilon(\,\cdot\,; x). \end{array} \tag{4.2}$$

We assume there exists a σ-finite measure α on $\mathcal{Y}$ such that for all $x \in \mathcal{X}$, $Q_{n+1}^\epsilon(\cdot; x)$ has a density with respect to α,

$$Q_{n+1}^\epsilon(dy; x) = q_{n+1}^\epsilon(y; x)\alpha(dy), \tag{4.3}$$

and we assume $q_{n+1}^\epsilon(y; x)$ to be strictly positive everywhere.

For $n = 0, \dots, N-1$ we let $u_n : \mathcal{Y}^{n+1} \to \mathcal{U}$ be a measurable function. The sequence $(u_0, \dots, u_{N-1})$ will be denoted by $\mathbf{u}$, and the set of such sequences (*admissible controls*) will be denoted by $ad(\mathcal{U})$.

For every given $\mathbf{u} \in ad(\mathcal{U})$ we now define $(X_n^{\epsilon,\mathbf{u}})_{n=0}^N$, $(Y_n^{\epsilon,\mathbf{u}})_{n=0}^N$ to be, respectively, $\mathcal{X}$- and $\mathcal{Y}$-valued stochastic processes, defined on $(\Omega, \mathcal{F}, P)$, having the following properties:

i) $X_n^{\epsilon,\mathbf{u}}$ is $\mathcal{F}_n$-measurable, and $Y_n^{\epsilon,\mathbf{u}}$ is $\mathcal{G}_n$-measurable;

ii) for $n = 0, \dots, N-1$,

$$P\{X_{n+1}^{\epsilon,\mathbf{u}} \in \cdot\, | \mathcal{F}_n \vee \mathcal{G}_n\} = P_n^\epsilon(\,\cdot\,; X_n^{\epsilon,\mathbf{u}}, u_n(Y_0^{\epsilon,\mathbf{u}}, \dots, Y_n^{\epsilon,\mathbf{u}})); \tag{4.4}$$

iii) for $n = 1, \dots, N$,

$$P\{Y_n^{\epsilon,\mathbf{u}} \in \cdot\, | \mathcal{F}_n \vee \mathcal{G}_{n-1}\} = Q_n^\epsilon(\,\cdot\,; X_n^{\epsilon,\mathbf{u}}). \tag{4.5}$$

Note that i), ii), and iii) completely determine the law of the processes $X_n^{\epsilon,\mathbf{u}}$ and $Y_n^{\epsilon,\mathbf{u}}$ up to the initial condition $X_0^{\epsilon,\mathbf{u}}, Y_0^{\epsilon,\mathbf{u}}$. For simplicity, we assume $X_0^{\epsilon,\mathbf{u}} = \xi$, $Y_0^{\epsilon,\mathbf{u}} = \eta$, deterministic and $(\epsilon, \mathbf{u})$-independent. It is clear that for given probability kernels as in (4.1) and (4.2), one can construct on a suitable probability space a stochastic process satisfying i), ii), and iii). The dependence on ϵ of the probability kernels in (4.1)(4.2) will be specified later. From now on, the index $(\epsilon, \mathbf{u})$ in $X_n^{(\epsilon,\mathbf{u})}$ and $Y_n^{(\epsilon,\mathbf{u})}$ will be omitted, and we write u_n for $u_n(Y_0^{\epsilon,\mathbf{u}}, \dots, Y_n^{\epsilon,\mathbf{u}})$.

Now we define the cost functional for the optimal control problem. Suppose we are given bounded measurable functions

$$g_n : \mathcal{X} \times \mathcal{U} \to \mathbb{R}, \quad n = 0, \dots, N-1, \quad g_N : \mathcal{X} \to \mathbb{R}. \tag{4.6}$$

For $\mathbf{u} \in ad(\mathcal{U})$ define

$$J^\epsilon(\mathbf{u}) = \epsilon \log E\Big\{ \exp\Big[\epsilon^{-1}\Big(\sum_{n=0}^{N-1} g_n(X_n, u_n) + g_N(X_N)\Big)\Big]\Big\}. \tag{4.7}$$

The optimal control problem associated with J^ϵ consists in computing $J_*^\epsilon = \inf\{J^\epsilon(\mathbf{u}) : \mathbf{u} \in ad(\mathcal{U})\}$ and determining a $\mathbf{u}^* \in ad(\mathcal{U})$ such that $J^\epsilon(\mathbf{u}^*) = J_*^\epsilon$.

4.2. Information vector, information measure, and dynamic programming. In this section the dependence on ϵ of the objects defined in section 2.1 is not relevant. So the index ϵ will be dropped.

It is a standard procedure in stochastic control to analyze optimal control problems with partial observation through a redefinition of the model as a completely observed one. Let $n = 0, \dots, N$. The *information vector* at time n is defined by

$$Z_n = (Y_0, \dots, Y_n, u_0, \dots, u_{n-1}) \in \mathcal{Y}^{n+1} \times \mathcal{U}^n \equiv \mathcal{Z}_n. \tag{4.8}$$

In the following we often identify Z_{n+1} with the triple (Z_n, u_n, Y_{n+1}).

Note that an admissible control at time n can be thought of as a function of Z_n. The stochastic dynamics of (X_n, Y_n) described in i)–iii) induces the following stochastic dynamics for the information vector:

$$P\{Z_{n+1} \in \cdot \,|\mathcal{G}_n\} = \delta_{Y_0} \otimes \cdots \otimes \delta_{Y_n} \otimes P_n^O(dy_{n+1}; Z_n, u_n) \otimes \delta_{u_0} \otimes \cdots \otimes \delta_{u_n}. \tag{4.9}$$

The probability kernels

$$P_n^O : \mathcal{Z}_n \times \mathcal{U} \to \mathcal{M}_1(\mathcal{Y}) \tag{4.10}$$

can be recursively constructed following the procedure below. We also construct an auxiliary sequence of kernels

$$P_n^f : \mathcal{Z}_n \to \mathcal{M}_1(\mathcal{X}) \quad \text{(filtering probabilities)}. \tag{4.11}$$

a) Initialize $P_0^f = \delta_\xi$.

b) Define P_n^O by

$$P_n^O(A; z_n, u_n) = \int \Big(\int Q_{n+1}(A; x_{n+1}) P_n(dx_{n+1}; x_n, u_n) \Big) P_n^f(dx_n; z_n) \tag{4.12}$$

for $A \subset \mathcal{Y}$ measurable.

c) Define P_{n+1}^f by

$$P_{n+1}^f(B; z_{n+1}) = \frac{\int_{\mathcal{X}} \Big(\int_B q_{n+1}(y_{n+1}, x_{n+1}) P_n(dx_{n+1}; x_n, u_n) \Big) P_n^f(dx_n; z_n)}{\int_{\mathcal{X}} \Big(\int_{\mathcal{X}} q_{n+1}(y_{n+1}, x_{n+1}) P_n(dx_{n+1}; x_n, u_n) \Big) P_n^f(dx_n; z_n)} \tag{4.13}$$

for $B \subset \mathcal{X}$ measurable.

Remark 4.1. Equation (4.13) is the well-known *discrete Zakai equation* for the filtering probability. Indeed, P_n^f is a version of the conditional probability of X_n given Z_n, and P_n^O is a version of the conditional probability of Y_{n+1} given Z_n. We assume implicitly that all integrals in (4.13) are finite; this will be guaranteed by later assumptions on the model (Assumption A, section 4.3) where the function $q_n(y_n; \cdot)$ is assumed to be bounded.

Note that P_{n+1}^O has a density with respect to α given by

$$\begin{aligned} \rho_n(y_{n+1}; z_n, u_n) &= \rho_n(z_{n+1}) \\ &= \int \Big(\int q_{n+1}(y_{n+1}, x_{n+1}) P_n(dx_{n+1}; x_n, u_n) \Big) P_n^f(dx_n; z_n). \end{aligned} \tag{4.14}$$

The next step consists of writing the cost function $J(\mathbf{u})$ in terms of the information vector Z_n. The main tool is provided by what we define to be the *information measure.* The information measure at time n is a map

$$P_n^I : \mathcal{Z}_n \to \mathcal{M}(\mathcal{X}), \tag{4.15}$$

where $\mathcal{M}(\mathcal{X})$ is the space of positive finite measures on $\mathcal{X}$. The maps P_n^I are recursively defined as follows:

$$\begin{aligned} &P_0^I(dx_0) = \delta_\xi, \\ &P_{n+1}^I(A; z_{n+1}) \\ &\quad = \frac{\int_{\mathcal{X}} \Big(\int_A e^{g_n(x_n,u_n)} q_{n+1}(y_{n+1}, x_{n+1}) P_n(dx_{n+1}; x_n, u_n) \Big) P_n^I(dx_n; z_n)}{\rho_n(z_{n+1})}. \end{aligned} \tag{4.16}$$

An important property of the information measure is given in the next lemma.

LEMMA 4.1. *The following identity holds for* $n = 0, \dots, N$, *for any* $f : \mathcal{X} \times \mathcal{Z}_n \to \mathbb{R}$ *bounded and measurable and every* $\mathbf{u} \in \mathcal{U}$:

$$E\Big\{ \int f(x_n, Z_n) P_n^I(dx_n; Z_n) \Big\} = E\Big\{ f(X_n, Z_n) \exp\Big[\sum_{k=0}^{n-1} g_k(X_k, u_k) \Big] \Big\}. \tag{4.17}$$

Proof. For $n = 0$ there is nothing to prove. The inductive step is proved as follows:

(4.18)

$$\begin{aligned} &E\left\{ \int f(x_{n+1}, Z_{n+1}) P_{n+1}^I(dx_{n+1}; Z_{n+1}) \right\} \\ &\quad = E\left\{ E\left\{ \int f(x_{n+1}, Z_{n+1}) P_{n+1}^I(dx_{n+1}; Z_{n+1}) \middle| Z_n, u_n \right\} \right\} \\ &\quad = E\left\{ E\left\{ \int f(x_{n+1}, Z_n, u_n, Y_{n+1}) P_{n+1}^I(dx_{n+1}; Z_n, u_n, Y_{n+1}) \middle| Z_n, u_n \right\} \right\} \\ &\quad = E\Big\{ \int \Big[\int f(x_{n+1}, Z_n, u_n, y_{n+1}) P_{n+1}^I(dx_{n+1}; Z_n, u_n, y_{n+1}) \Big] \\ &\qquad\qquad \times \rho_n(y_{n+1}, Z_n, u_n) \alpha(dy_{n+1}) \Big\} \end{aligned}$$

(by (4.16))

$$\begin{aligned} &\quad = E\Big\{ \int \Big[\int \Big(\int f(x_{n+1}, Z_n, u_n, y_{n+1}) q_{n+1}(y_{n+1}; x_{n+1}) P_n(dx_{n+1}; x_n, u_n) \Big) \\ &\qquad\qquad \times \alpha(dy_{n+1}) \Big] e^{g_n(x_n,u_n)} P_n^I(dx_n; Z_n) \Big\} \end{aligned}$$

(by inductive assumption)

$$\begin{aligned} &\quad = E\Big\{ \int \Big[\int f(x_{n+1}, Z_n, u_n, y_{n+1}) q_{n+1}(y_{n+1}; x_{n+1}) P_n(dx_{n+1}; X_n, u_n) \Big] \alpha(dy_{n+1}) \\ &\qquad\qquad \times \exp\Big[\sum_{k=0}^{n} g_k(X_k, u_k) \Big] \Big\} \\ &\quad = E\Big\{ E\Big\{ f(X_{n+1}, Z_{n+1}) \Big| \mathcal{F}_n \vee \mathcal{G}_n \Big\} \exp\Big[\sum_{k=0}^{n} g_k(X_k, u_k) \Big] \Big\} \\ &\quad = E\Big\{ f(X_{n+1}, Z_{n+1}) \exp\Big[\sum_{k=0}^{n} g_k(X_k, u_k) \Big] \Big\}, \end{aligned}$$

where we have used elementary properties of conditional expectation. □

By using the recursive definition (4.16) it is easily checked that the information measures are indeed finite measures. A bound on $P_n^I(X; z_n)$ which is uniform in z_n will be useful later, and is given in the following lemma.

LEMMA 4.2. *For every $n = 0, \dots, N$ and every $z_n \in \mathbb{Z}_n$ we have*

$$|\log P_n^I(X; z_n)| \leq \sum_{k=0}^{n-1} \|g_k\|_\infty. \tag{4.19}$$

Proof. Since the filtering measures are probability measures, it is enough to show that for any $n = 0, \dots, N$ and every positive measurable function f

$$\begin{aligned} \int f(x_n) P_n^f(dx_n; z_n) e^{-\sum_{k=0}^{n-1} \|g_k\|_\infty} &\leq \int f(x_n) P_n^I(dx_n; z_n) \\ \leq \int f(x_n) P_n^f(dx_n; z_n) e^{\sum_{k=0}^{n-1} \|g_k\|_\infty}. \end{aligned} \tag{4.20}$$

The proof of (4.20) comes from an easy induction and is omitted. □

By using Lemma 4.1, we can rewrite the cost functional $J(\mathbf{u})$ as follows:

$$J(\mathbf{u}) = \log E\Big\{ \exp \Big[G_N(Z_N) \Big] \Big\}, \tag{4.21}$$

where

$$G_N(Z_N) = \log \int e^{g_N(x_N)} P_N^I(dx_N; Z_N). \tag{4.22}$$

The partially observed stochastic control problem described in section 4.1 has now been transformed into a totally observed one, with state variable Z_n and cost functional (4.21). For this system the variables Y_n should be thought of as noise variables.

The *value function* associated with (4.22) is defined by

$$V_n(z_n) = \inf_{\mathbf{u} \in ad(\mathcal{U})} \log E\Big\{ \exp \Big[G_N(Z_N) \Big] \Big| Z_n = z_n \Big\}. \tag{4.23}$$

It can be shown (see, e.g., [2]) that V_n satisfies the following recursion:

$$\begin{aligned} V_N(z_N) &= G_N(z_N), \\ V_n(z_n) &= \inf_{u \in \mathcal{U}} \log \int \exp[V_{n+1}(y_{n+1}, z_n, u)] P_n^O(dy_{n+1}; z_n, u). \end{aligned} \tag{4.24}$$

Remark 4.2. By using (4.24) and Lemma 4.2 it is easily seen that the functions V_n are bounded.

Remark 4.3. The stochastic control problem (4.21)–(4.22) is somewhat implicitly stated, since the cost function is given in terms of the solution of the recursion (4.16). Indeed, the cost functional $J(\mathbf{u})$ can be written only in terms of the measures (P_n^f, P_n^I). To see this, consider the stochastic dynamics on $\mathcal{M}_1(X) \times \mathcal{M}(\mathcal{X})$ given by

$$P_{n+1}^f(B) = \frac{\int_{\mathcal{X}} \Big(\int_B q_{n+1}(Y_{n+1}, x_{n+1}) P_n(dx_{n+1}; x_n, u_n) \Big) P_n^f(dx_n)}{\int_{\mathcal{X}} \Big(\int_{\mathcal{X}} q_{n+1}(Y_{n+1}, x_{n+1}) P_n(dx_{n+1}; x_n, u_n) \Big) P_n^f(dx_n)}, \tag{4.25}$$

$$P^I_{n+1}(A) = \frac{\int_{\mathcal{X}} \Big(\int_A e^{g_n(x_n,u_n)} q_{n+1}(Y_{n+1}, x_{n+1}) P_n(dx_{n+1}; x_n, u_n)\Big) P^I_n(dx_n)}{\int_{\mathcal{X}} \Big(\int_{\mathcal{X}} q_{n+1}(Y_{n+1}, x_{n+1}) P_n(dx_{n+1}; x_n, u_n)\Big) P^f_n(dx_n)}, \tag{4.26}$$

or, in short,

$$(P^f_{n+1}, P^I_{n+1}) = F(P^f_n, P^I_n, u_n, Y_{n+1}). \tag{4.27}$$

In (4.27) the Y_n's play the role of disturbances, whose distribution is determined by

$$\begin{aligned} &P(Y_{n+1} \in A | u_0, \dots, u_n, Y_0, \dots, Y_n) \\ &\quad = \int \Big(\int Q_{n+1}(A; x_{n+1}) P_n(dx_{n+1}; x_n, u_n)\Big) P^f_n(dx_n). \end{aligned} \tag{4.28}$$

If we define the cost functional

$$K(\mathbf{u}) = \log E\left\{ e^{g_N(x)} P^I_N(dx)\right\} \tag{4.29}$$

then we have that $K(\mathbf{u}) = J(\mathbf{u})$ for every $\mathbf{u} \in ad(\mathcal{U})$. This shows that, in a very precise sense, the pair (P^f_n, P^I_n) is a sufficient statistic for the risk-sensitive control problem or, in terms more commonly used in control theory, it is an *information state.*

As a consequence, it follows that the value function V_n can be thought of as a function of the information state. In [12, Theorem 3.2], the $\epsilon \to 0$ limit of the value function is studied by looking at the value function as a function of the information state (which is not the same as here, see Remark 4.4 below). In the generality of our model a statement of the type of Theorem 3.2 in [12] does not seem to make sense, and so we prefer to analyze the value function as a function of the information vector. In our construction the information state is only an auxiliary object that allows us to express the cost functional $J(\mathbf{u})$ in terms of the information vector.

Remark 4.4. The information state for risk-sensitive control problems, which is a rather recent achievement in stochastic control theory, was first introduced in [1] and is usually defined (see [12]) through a measure transformation that decouples the observation from the state. The notion of information state in [12] has the advantage, among others, that in the $\epsilon \to 0$ limit it induces a quite natural notion of information state for the limit dynamic game. However, when the partially observed control problem is transformed into a totally observed one by means of the information state in [12] one gets a value function which is, in general, unbounded. In order to use large deviation techniques to control the $\epsilon \to 0$ limit of the value function, some growth bounds are needed, and these bounds come from assumptions on the dynamics of the model. The assumptions that will be given in section 4.3 would not imply any growth bound. Our construction guarantees boundedness of the value function, and appears to be more robust in terms of assumptions on the model.

4.3. Small parameter limit. In this section we investigate the limit of the value function in (4.23) as $\epsilon \to 0$. We first introduce the basic assumptions on the model that are needed to study the small parameter limit.

Assumption A.

1. For $n = 0, \dots, N-1$ the families of probability measures $\{P^\epsilon_n(dx_{n+1}; x_n, u_n) : \epsilon > 0, (x_n, u_n) \in \mathcal{X} \times \mathcal{U}\}$ are WULDF's with rate functions $H^P_n(x_{n+1}; x_n, u_n)$, and they are exponentially tight. In addition, the map $(x_n, u_n) \to P^\epsilon_n(dx_{n+1}; x_n, u_n)$ is weakly continuous.

2. Let $A_n = \{(x, \xi, u) \in \mathcal{X} \times \mathcal{X} \times \mathcal{U} : H_n^P(x, \xi, u) < +\infty\}$. Then for every sequence $(\xi_n, u_n) \to (\xi, u)$ there exists a corresponding sequence $x_n \to x$ such that $H_n^P(x_n, \xi_n, u_n) \to H_n^P(x, \xi, u)$.
3. H_n^P is jointly lower semicontinuous in (x_{n+1}, x_n, u_n).
4. For $n = 1, \ldots, N$ the families of probability measures $\{Q_n^\epsilon(dy_n; x_n) : \epsilon > 0, x_n \in \mathcal{X}\}$ are WULDFs with finite and continuous rate functions $H_n^Q(y_n; x_n)$, and they are exponentially tight.
5. The reference measure α on $\mathcal{Y}$ such that $Q_n^\epsilon(dy_n; x_n) = q_n^\epsilon(y_n; x_n)\alpha(dy_n)$ satisfies
$$\inf_{y \in K} \alpha\left(B(y, \gamma)\right) > 0,$$
for every $K \subset \mathcal{Y}$ compact and $\gamma > 0$, where $B(y, \gamma)$ is the ball centered at y with radius γ. Moreover the density $q_n^\epsilon(y_n; x_n)$ is jointly continuous in $(y_n; x_n)$.
6. For every $K \subset \mathcal{Y}$ compact, $C \subset \mathcal{X}$ compact and every $\delta > 0$ there exist $\delta' > 0$ and $\epsilon' > 0$ such that if $y, y' \in K$ and $d(y, y') < \delta'$ then $|\epsilon \log q_n^\epsilon(y, x) - \epsilon \log q_n^\epsilon(y', x)| < \delta$ for all $x \in C$ and $\epsilon < \epsilon'$.
7. For every $K \subset \mathcal{Y}$, $C \subset \mathcal{X}$ compact the functions $\epsilon \log q_n^\epsilon(y, x)$ are uniformly bounded from above on $K \times \mathcal{X}$ and uniformly bounded from below on $K \times C$ (uniformly means that the bound is independent of ϵ).
8. The functions g_n appearing in the cost functional $J(\mathbf{u})$ are continuous and bounded.

Note that conditions 2–3 and 5–7 correspond to the assumptions of Propositions 3.4 and 3.7 respectively.

A sufficient condition for Assumption A to hold is provided by the following.

Assumption B.

1. Let $\mathcal{W}$ be a metric space. For $n = 0, \ldots, N-1$ let $f_n : \mathcal{X} \times \mathcal{U} \times \mathcal{W} \to \mathcal{X}$ be continuous functions and $\{\mu_n^\epsilon : \epsilon > 0\}$ be an exponentially tight family of probability measures on $\mathcal{W}$ satisfying an LDP with rate function $h_n(w)$. The probability measures $P_n^\epsilon(dx_{n+1}; x_n, u_n)$ are defined by
$$P_n^\epsilon(A; x_n, u_n) = \mu_n^\epsilon\{w : f_n(x_n, u_n, w_n) \in A\}.$$
2. Let $\mathcal{Y} = \mathbb{R}^d$, and, for $n = 1, \ldots, N$, let $\phi_n : \mathcal{X} \times \mathbb{R}^d \to \mathbb{R}^d$ be continuous functions. Moreover, let $\{\nu_n^\epsilon : \epsilon > 0\}$, $n = 1, \ldots, N$, be exponentially tight families of probability measures satisfying an LDP with rate function $k_n(v)$, that is finite and continuous. Suppose the following conditions are satisfied:
a) for every fixed $x \in \mathcal{X}$ the map $v \to \phi_n(x, v)$ is a diffeomorphism in $\mathbb{R}^d$. Moreover the inverse map $\phi_n^{-1}(x, y)$ and $D_y\phi_n^{-1}(x, y)$ are continuous on $\mathcal{X} \times \mathbb{R}^d$, where D_y denotes differentiation with respect to y.
b) For every $K \subset \mathbb{R}^d$ compact, the map $\det(D_y\phi_n^{-1})$ is bounded on $\mathcal{X} \times K$.
c) $\nu_n^\epsilon \ll dv$, and $\{\epsilon \log \frac{d\nu_n^\epsilon}{dv} : \epsilon > 0\}$ is a family of functions that, when restricted to any compact subset of $\mathbb{R}^d$, are equicontinuous and uniformly bounded from below, and are uniformly bounded from above on all $\mathbb{R}^d$.
The probability measures $Q_n^\epsilon(dy_n; x_n)$ are defined by
$$Q_n^\epsilon(B; x_n) = \nu_n^\epsilon\{v : \phi_n(x_n, v) \in B\}.$$
3. The functions g_n appearing in the cost functional $J(\mathbf{u})$ are continuous and bounded.

Note that, under Assumption B, the dynamics for X_n, Y_n have the form

$$\begin{aligned} X_{n+1} &= f_n(X_n, u_n, W_n), \\ Y_n &= \phi_n(X_n, V_n), \end{aligned}$$

where $\{W_0, \dots, W_{N-1}, V_1, \dots, V_N\}$ are independent random variables with $W_n \sim \mu_n^\epsilon$ and $V_n \sim \nu_n^\epsilon$.

The following fact will be proved in the Appendix.

PROPOSITION 4.3. *Assumption B implies Assumption A.*

Example 4.5.

1. We give first some examples where Assumption B holds. Assume $\mathcal{W} = \mathbb{R}^m$. Suppose also that, for $n = 0, 1, \dots, N-1$, we are given Borel measurable functions $\tilde{h}_n : \mathbb{R}^m \to \mathbb{R}$, $\tilde{k}_n : \mathbb{R}^d \to \mathbb{R}$ such that
   i) $\tilde{h}_n(w), \tilde{k}_n(v) \to +\infty$ as $\|w\| \to +\infty, \|v\| \to +\infty$;
   ii) $e^{-\tilde{h}_n}$, $e^{-\tilde{k}_n}$ are integrable with respect to the Lebesgue measure;
   iii) $\tilde{h}_n$ is almost everywhere (a.e.) bounded from below, and $\tilde{k}_n$ is continuous.
   Then we can define

   $$\mu_n^\epsilon(dw) = \frac{e^{-\epsilon^{-1}\tilde{h}_n(w)}dw}{\int e^{-\epsilon^{-1}\tilde{h}_n(w)}dw}, \quad \nu_n^\epsilon(dw) = \frac{e^{-\epsilon^{-1}\tilde{k}_n(v)}dv}{\int e^{-\epsilon^{-1}\tilde{k}_n(v)}dv}.$$

   Then $\mu_n^\epsilon, \nu_n^\epsilon$ satisfy the requirements given in Assumption B, with corresponding rate functions $h_n(w) = \tilde{h}_n(w) - \inf \tilde{h}_n$, $k_n(v) = \tilde{k}_n(v) - \inf \tilde{k}_n$. Note that this example includes the Gaussian noise considered in [12].

   To complete the description of the model we can assign any continuous functions $f_n : \mathcal{X} \times \mathcal{U} \times \mathcal{W} \to \mathcal{X}$ for the state dynamic equations, while examples of output functions ϕ_n satisfying Assumption B are provided by functions of type

   $$\phi_n(x, v) = \beta_n(x) + \gamma_n(x)v,$$

   where $\beta_n : \mathcal{X} \to \mathbb{R}^d$, $\gamma_n : \mathcal{X} \to \mathcal{L}(\mathbb{R}^d, \mathbb{R}^d)$ are continuous functions and, for all $v \in \mathbb{R}^d$, the inequality $\|\gamma_n(x)v\|^2 \geq \delta\|v\|^2$ holds for a constant δ independent of $x \in \mathcal{X}$. Note that no boundedness or growth assumptions on β_n are required.
2. Assumption A has the advantage of being more general than Assumption B, and somewhat more directly usable in the proofs. Besides technical convenience, the description of the model in terms of transition probabilities, rather than difference equations with noise, may be more natural in some contexts, e.g., when $\mathcal{X}$ and/or $\mathcal{Y}$ are finite sets. For instance, in the case of $\mathcal{X}$ finite, one may consider transition probabilities of the form

   $$P_n^\epsilon(x_{n+1}; x_n, u_n) = \frac{e^{-\epsilon^{-1}H_n^P(x_{n+1}; x_n, u_n)}}{\sum_{z \in \mathcal{X}} e^{-\epsilon^{-1}H_n^P(z; x_n, u_n)}}. \tag{4.30}$$

   If H_n^P is finite and continuous in u_n, then (4.30) automatically satisfies 1–3 of Assumption A. A similar transition mechanism can be defined for the output, when $\mathcal{Y}$ is finite; if $\mathcal{X}$ and $\mathcal{Y}$ are both finite, conditions 4–7 of Assumption A are trivially satisfied.

   Dynamics of type (4.30) appear naturally in statistical mechanical models of particle systems; in that context ϵ is a temperature parameter, while the control u_n may be seen as an external field perturbing some "free" evolution.

In what follows we will use objects defined in section 4.2. We find convenient to give a list of all identities we are going to use, showing explicitly the dependence on ϵ:

$$P^{f,\epsilon}_{n+1}(B;z_{n+1}) = \frac{\int_{\mathcal{X}}\Big(\int_B q^\epsilon_{n+1}(y_{n+1},x_{n+1})P^\epsilon_n(dx_{n+1};x_n,u_n)\Big)P^{f,\epsilon}_n(dx_n;z_n)}{\int_{\mathcal{X}}\Big(\int_{\mathcal{X}} q^\epsilon_{n+1}(y_{n+1},x_{n+1})P^\epsilon_n(dx_{n+1};x_n,u_n)\Big)P^{f,\epsilon}_n(dx_n;z_n)}, \tag{4.31}$$

$$\rho^\epsilon_n(z_{n+1}) = \int\Big(\int q^\epsilon_{n+1}(y_{n+1},x_{n+1})P^\epsilon_n(dx_{n+1};x_n,u_n)\Big)P^{f,\epsilon}_n(dx_n;z_n), \tag{4.32}$$

$$\begin{aligned} &P^{I,\epsilon}_{n+1}(A;z_{n+1}) \\ &= \frac{\int_{\mathcal{X}}\Big(\int_A e^{\epsilon^{-1}g_n(x_n,u_n)}q^\epsilon_{n+1}(y_{n+1},x_{n+1})P^\epsilon_n(dx_{n+1};x_n,u_n)\Big)P^{I,\epsilon}_n(dx_n;z_n)}{\rho^\epsilon_n(z_{n+1})}, \end{aligned} \tag{4.33}$$

$$J^\epsilon(\mathbf{u}) = \epsilon\log E\Big\{\exp\epsilon^{-1}\Big[G^\epsilon_N(z_N)\Big]\Big\}, \tag{4.34}$$

$$G^\epsilon_N(z_N) = \epsilon\log\int e^{\epsilon^{-1}g_N(x_N)}P^{I,\epsilon}_N(dx_N;z_N), \tag{4.35}$$

$$V^\epsilon_n(z_n) = \inf_{u\in\mathcal{U}}\epsilon\log\int\exp\epsilon^{-1}[V^\epsilon_{n+1}(z_n,u,y_{n+1})]P^{O,\epsilon}_{n+1}(y_{n+1};z_n,u). \tag{4.36}$$

Remark 4.6. By using Assumption B one checks by rather standard arguments that the value functions $V^\epsilon_n(z_n)$ are continuous. By Remark 4.2 we know that they are also bounded, and it is clear that the bound does not depend on ϵ.

We now give the main result of this section.

THEOREM 4.4. *There are functions $V_n : \mathcal{Z}_n \to \mathbb{R}$, for $n = 0,\dots,N$, such that $V^\epsilon_n \to V_n$ uniformly on the compact subsets of $\mathcal{Z}_n$. Moreover the functions V_n satisfy the following recursion.*

$$\begin{aligned} V_N(z_N) &= \sup_x\Big[g_N(x) - H^I_N(x;z_N)\Big], \\ V_n(z_n) &= \inf_{u_n}\sup_{y_{n+1}}\Big[V_{n+1}(z_n,u_n,y_{n+1}) - H^O_n(y_{n+1};z_n,u_n)\Big], \end{aligned} \tag{4.37}$$

where H^I_N, H^O_n are determined by the following recursions:

$$H^I_0(x) = H^f_0(x)\begin{cases} 0 & \text{if } x = \xi, \\ +\infty & \text{otherwise,}\end{cases}$$

$$\begin{aligned} H^O_n(y_{n+1};z_n,u_n) = \inf_{x_{n+1},x_n}\Big[&H^Q_{n+1}(y_{n+1};x_{n+1}) + H^P_n(x_{n+1};x_n,u_n) \\ &+H^f_n(x_n;z_n)\Big], \end{aligned} \tag{4.38}$$

$$\begin{aligned}H^f_{n+1}(x_{n+1};z_{n+1}) = H^Q_{n+1}(y_{n+1};x_{n+1}) \\ + \inf_{x_n}\Big[H^P_n(x_{n+1};x_n,u_n) + H^f_n(x_n;z_n)\Big] \\ - H^O_n(y_{n+1};z_n,u_n),\end{aligned}\tag{4.39}$$

$$\begin{aligned}H^I_{n+1}(x;z_{n+1}) = H^Q_{n+1}(y_{n+1};x) \\ + \inf_{\eta\in\mathcal{X}}\Big[H^P_n(x,\eta,u_n) + H^I_n(\eta,z_n) - g_n(\eta,u_n)\Big] \\ - H^O_n(y_{n+1};z_n,u_n).\end{aligned}\tag{4.40}$$

Remark 4.7. We have observed above that the functions V^ϵ_n are continuous and bounded. It follows by Theorem 4.4 that also the functions V_n are continuous and bounded. Indeed, in any metric space, uniform convergence on compact subsets preserves continuity.

The proof of Theorem 4.4 is based on the following result, whose proof is given at the end of this section.

PROPOSITION 4.5. *The three families* $\{P^{O,\epsilon}_n(dy_{n+1};z_n,u_n)\}$, $n=0,\dots,N-1$, $\{P^{f,\epsilon}_n(dx_n;z_n)\}$, *and* $\{P^{I,\epsilon}_n(dx_n,z_n)\}$, $n=0,\dots,N$, *are WULDF with rate functions* H^O_n, H^f_n, H^I_n, *respectively.*

In the proof of Theorem 4.4 we also use the following technical result, which we prove in the appendix.

LEMMA 4.6. *Let E be a metric space, F be a compact metric space, and $f^\epsilon : E\times F\to\mathbb{R}$, $\epsilon\geq 0$, be a family of continuous functions such that $f^\epsilon\to f^0$ uniformly on the compact subsets of $E\times F$. Define $g^\epsilon : E\to\mathbb{R}$ by*

$$g^\epsilon(x) = \inf_{y\in F} f^\epsilon(x,y).$$

Then $g^\epsilon\to g^0$ uniformly on the compact subsets of E.

Proof of Theorem 4.4. We prove the convergence $V^\epsilon_n\to V_n$ by backward induction on n. For $n=N$ the claim is an immediate consequence of (4.35) and Proposition 4.5. We now prove the inductive step. Define

$$T^\epsilon_n(z_n,u) = \epsilon\log\int\exp\epsilon^{-1}[V^\epsilon_{n+1}(z_n,u,y_{n+1})]P^{O,\epsilon}_{n+1}(y_{n+1};z_n,u),\tag{4.41}$$

so that

$$V^\epsilon_n(z_n) = \inf_{u\in\mathcal{U}} T^\epsilon_n(z_n,u).\tag{4.42}$$

By inductive assumption $V^\epsilon_{n+1}(z_n,u,y_{n+1})\to V_{n+1}(z_{n+1})$ uniformly on the compact subsets of $\mathcal{Z}_{n+1}$. Thus, by using Lemma 2.9 and Proposition 4.5,

$$T^\epsilon_n(z_n,u)\to\sup_{y_{n+1}\in\mathcal{Y}}\Big[V_{n+1}(z_n,u,y_{n+1}) - H^O_n(y_{n+1};z_n,u_n)\Big].\tag{4.43}$$

By (4.42) and Lemma 4.6 the conclusion follows. □

Proof of Proposition 4.5. We prove by induction that H^I_n and H^f_n are the rate functions for $P^{I,\epsilon}_n$ and $P^{f,\epsilon}_n$, respectively. The $n=0$ case is clear, since the singleton $\{\delta_\xi\}$ is a WULDF with rate function $H^I_0 = H^f_0$. The inductive step, in both cases, is a simple application of (4.31), (4.33), and Propositions 3.4 and 3.7. The fact that H^O_n is the rate function for $P^{O,\epsilon}_n$ also follows for (4.12) and Proposition 3.4. □

4.4. Interpretation of the limit value function. In this section we show that the limit value function V_n can be interpreted as the value function for a partially observed dynamic game. Although this would not be necessary, for conceptual simplicity Assumption B will be assumed throughout this section. Thus, the stochastic dynamics for the risk-sensitive control problem are given, in short, by

$$\left\{ \begin{array}{rcl} x_{n+1} & = & f_n(x_n, u_n, w_n), \\ y_n & = & \phi_n(x_n, v_n) \end{array} \right. \tag{4.44}$$

with $w_n \sim \mu_n^\epsilon$ and $v_n \sim \nu_n^\epsilon$. Now, consider the deterministic, zero-sum dynamic game with dynamics given by (4.44) and cost functional

$$J(\mathbf{u}) = \sup_{\mathbf{v},\mathbf{w}} \left[\sum_{n=0}^{N-1} \Big(g_n(x_n, u_n) - h_n(w_n) - k_{n+1}(v_{n+1}) \Big) + g_N(x_N) \right] \tag{4.45}$$

defined for $\mathbf{u} \in ad(\mathcal{U})$. The supremum in (4.45) is over all sequences $\mathbf{w} = (w_0, \dots, w_{N-1}) \in \mathcal{W}^N$, $\mathbf{v} = (v_1, \dots, v_N) \in (\mathbb{R}^d)^N$. Note that, for $\mathbf{u} \in ad(\mathcal{U})$ fixed, the expression in (4.45) within square brackets is a function of $\mathbf{w}$, $\mathbf{v}$.

PROPOSITION 4.7. *The following identity holds for $n = 0, \dots, N-1$:*

$$\begin{aligned} \sup\Bigg[\sum_{l=0}^{n} \Big(g_l(x_l, u_l) - h_l(w_l) - k_{l+1}(v_{l+1}) \Big) &: (4.44) \text{ holds, and} \\ w_0, \dots, w_n, v_1, \dots, v_{n+1} &\textit{ are such that} \\ (y_0, \dots, y_{n+1}, u_0, \dots, u_n) &= z_{n+1}, x_{n+1} = x \Bigg] \\ = -H^I_{n+1}(x; z_{n+1}) &- \sum_{k=0}^{n} H^O_k(y_{k+1}; z_k, u_k). \end{aligned} \tag{4.46}$$

Proof. Under Assumption B, we can rewrite (4.40) as

$$\begin{aligned} H^I_{n+1}(x; z_{n+1}) = \inf_{\eta \in \mathcal{X}} \inf_{w \in \mathcal{W}} \inf_{v \in \mathbb{R}^d} \Big[& k_{n+1}(v) + h_n(w) + H^I_n(\eta, z_n) - g_n(\eta, u_n) \\ & : f_n(\eta, u_n, w) = x, \phi_{n+1}(x, v) = y_{n+1} \Big] - H^O_n(y_{n+1}; z_n, u_n). \end{aligned} \tag{4.47}$$

We prove (4.46) by induction on n. For $n = 0$ the claim follows using (4.47). Otherwise, by using the inductive assumption and (4.47), we get

$$\begin{aligned} & \sup\Bigg[\sum_{l=0}^{n} \Big(g_l(x_l, u_l) - h_l(v_l) - k_{l+1}(v_{l+1}) \Big) : \text{ (4.44) holds, and} \\ & w_0, \dots, w_n, v_1, \dots, v_{n+1} \text{ are such that } (y_0, \dots, y_{n+1}, u_0, \dots, u_n) = z_{n+1}, x_{n+1} = x \Bigg] \\ & = \sup_{\eta \in \mathcal{X}} \sup_{w \in \mathcal{W}} \sup_{v \in \mathbb{R}^d} \Big[g_n(\eta, u_n) - k_{n+1}(v) - h_n(w) - H^I_n(\eta, z_n) : f_n(\eta, u_n, w) = x, \\ & \qquad \phi_{n+1}(x, v) = y_{n+1} \Big] \\ & \qquad - \sum_{k=0}^{n-1} H^O_k(y_{k+1}; z_k, u_k) \\ & = -H^I_{n+1}(x; z_{n+1}) - \sum_{k=0}^{n} H^O_k(y_{k+1}; z_k, u_k). \qquad \square \end{aligned} \tag{4.48}$$

Proposition 4.7 allows us to transform the dynamic game (4.44), (4.45) into a totally observed one, in terms of the information vector

$$z_{n+1} = (z_n, u_n, y_{n+1}), \tag{4.49}$$

$$J(\mathbf{u}) = \sup_{\mathbf{y}} \left[\sum_{n=0}^{N-1} G_n(z_n, u_n, y_{n+1}) + G_N(z_N) \right] \tag{4.50}$$

with

$$G_N(z_N) = \sup_{x \in \mathcal{X}} \Big[g_N(x) - H_N^I(x; z_N) \Big], \tag{4.51}$$

$$G_n(z_n, u_n, y_{n+1}) = -H_n^O(y_{n+1}; z_n, u_n), \tag{4.52}$$

and where the supremum in (4.50) is over all sequences $\mathbf{y} = (y_1, \dots, y_N) \in \mathcal{Y}^N$. We recall that the standard definition of the upper value function $V_n(z_n)$ for the dynamic game (4.49), (4.50) is the infimum of

$$\sup_{y_{n+1}, \cdots, y_N} \sum_{k=n}^{N-1} G_k(z_k, u_k, y_{k+1}) + G_N(z_N)$$

over $\mathbf{u} \in ad(\mathcal{U})$ where the dynamics (4.49) start at time n from z_n. A simple dynamic programming argument yields the following.

Proposition 4.8. *The upper value function V_n for the zero-sum, two-player dynamic game* (4.49), (4.50) *is given by* (4.37).

Remark 4.8. We have seen that the pair $(P_n^{f,\epsilon}, P_n^{I,\epsilon})$ is an information state for the risk-sensitive control problem. The corresponding pair (H_n^f, H_n^I) can be interpreted as an information state for the limit dynamic game. In fact, the following totally observed dynamic game with state variables (H_n^f, H_n^I) is equivalent to (4.49), (4.50):

$$\begin{aligned} H_{n+1}^f(x) &= H_{n+1}^Q(y_{n+1}; x) + \inf_{\eta} \Big[H_n^P(x_{n+1}; \eta, u_n) + H_n^f(\eta) \Big] \\ &\quad - \inf_x \Big\{ H_{n+1}^Q(y_{n+1}; x) + \inf_{\xi} \Big[H_n^P(x_{n+1}; \xi, u_n) + H_n^f(\xi) \Big] \Big\}, \end{aligned} \tag{4.53}$$

$$\begin{aligned} H_{n+1}^I(x) &= H_{n+1}^Q(y_{n+1}; x) + \inf_{\eta \in \mathcal{X}} \Big[H_n^P(x, \eta, u_n) + H_n^I(\eta) - g_n(\eta, u_n) \Big] \\ &\quad - \inf_x \Big\{ H_{n+1}^Q(y_{n+1}; x) + \inf_{\xi} \Big[H_n^P(x_{n+1}; \xi, u_n) + H_n^f(\xi) \Big] \Big\}, \end{aligned} \tag{4.54}$$

$$\begin{aligned} J(\mathbf{u}) = \sup_{\mathbf{y}} \Bigg\{ - \sum_{n=0}^{N-1} \inf_x \Big\{ H_{n+1}^Q(y_{n+1}; x) + \inf_{\xi} \Big[H_n^P(x_{n+1}; \xi, u_n) + H_n^f(\xi) \Big] \Big\} \\ + \sup_{x \in \mathcal{X}} \Big[g_N(x) - H_N^I(x) \Big] \Bigg\}. \end{aligned} \tag{4.55}$$

It should be noticed that there is a simpler notion of information state for the dynamic game (4.44)–(4.45), given by the real valued function $K_n : \mathcal{X} \to \mathbb{R}$, evolving according to the equation

$$K_{n+1}(x) = H^Q_{n+1}(y_{n+1};x) + \inf_{\eta\in\mathcal{X}} \Big[H^P_n(x,\eta,u_n) + K_n(\eta) - g_n(\eta,u_n)\Big]. \tag{4.56}$$

It can be shown that

$$J(\mathbf{u}) = \sup_{\mathbf{y}} \sup_{x\in\mathcal{X}} \Big[g_N(x) - K_N(x)\Big]. \tag{4.57}$$

It can be proved that the function $K_n(x)$ is the rate function of a WULDF that is recursively defined as in (4.33) where the denominator ρ^ϵ_n is dropped. The measure obtained in this way is closely related to the information state in [12]; the use of this measure in place of P^I_n gives rise to an unbounded value function, posing serious difficulty to the small parameter analysis.

Example 4.9. In the case $\mathcal{X} = \mathbb{R}^p$,

$$\mu^\epsilon_n(dw) = \frac{1}{(2\pi\epsilon)^{p/2}} e^{-\frac{1}{2\epsilon}||w||^2} dw, \qquad \text{and} \qquad \nu^\epsilon_n(dv) = \frac{1}{(2\pi\epsilon)^{d/2}} e^{-\frac{1}{2\epsilon}||v||^2} dv,$$

we have $h_n(w) = \frac{1}{2}||w||^2$ and $k_n(w) = \frac{1}{2}||v||^2$, and we recover the model in [12], but with much more general equations for the dynamics.

5. The completely observed case. The risk-sensitive control problems satisfying Assumption A do not include the completely observed case ($Y_n = X_n$). It is clear, however, that the method used in this paper can easily be directly applied to the dynamic programming equation of a completely observed problem.

Consider a probability space $(\Omega,\mathcal{F},P)$ with a filtration $(\mathcal{F}_n)_{n=0}^N$. Define $ad(\mathcal{U})$, the set of admissible controls, to be the set of the $\mathcal{F}_n$-adapted $\mathcal{U}$-valued processes. For $\mathbf{u} \in ad(\mathcal{U})$, we let $X^{\epsilon,\mathbf{u}}_n$ be the $\mathcal{F}_n$-adapted $\mathcal{X}$-valued process such that

$$P\{X^{\epsilon,\mathbf{u}}_{n+1} \in \cdot\,|\mathcal{F}_n\} = P^\epsilon_n(\cdot\,; X^{\epsilon,\mathbf{u}}_n, u_n).$$

The cost functional is as in (4.7), but defined in this new set of admissible controls. Consider the value function

$$V^\epsilon_n(x) \;=\; \inf_{\mathbf{u}\in\, ad(\mathcal{U})} \epsilon \log E\bigg\{\exp\bigg[\epsilon^{-1}\bigg(\sum_{k=n}^{N-1} g_k(X_n,u_n) + g_N(X_N)\bigg)\bigg]\bigg\}.$$

The following result is proved by induction as in Theorem 4.4. Note that the assumptions needed are much weaker than those of a similar result given in [4].

THEOREM 5.1. *Assume that part* 1 *of either Assumption A or B holds. Then there are functions V_n such that $V^\epsilon_n \to V_n$ as $\epsilon \to 0$, uniformly on compact subsets of $\mathcal{X}$.*

Moreover, if part 1 *of Assumption B holds, then V_n is the upper value function for the deterministic dynamic game with dynamic given by*

$$x_{n+1} \;=\; f_n(x_n,u_n,w_n),$$

and with cost functionals given by

$$J(\mathbf{u}) = \sup_{\mathbf{w}} \Bigg[\sum_{n=0}^{N-1} \Big(g_n(x_n,u_n) - h_n(w_n)\Big) + g_N(x_N)\Bigg].$$

6. Appendix.

6.1. Proof of Proposition 4.3. Properties 1 and 4 of Assumption A follow from Proposition 2.5 and Lemma 2.7.

In the rest of the proof we drop the index n everywhere.

Proof of property 2. Suppose $(x, \xi, u) \in A$, i.e., $H^P(x; \xi, u) < \infty$. First note that since the set $\{w : f(\xi, u, w) = x\}$ is closed, then there is $w \in \mathcal{W}$ such that $f(\xi, u, w) = x$ and $h(w) = H^P(x; \xi, u)$.

Suppose now that we have a sequence $(\xi_k, u_k) \to (\xi, u)$. We construct a sequence $x_k \to x$ such that $H^P(x_k; \xi_k, u_k) \to H^P(x; \xi, u)$. Define $x_k = f(\xi_k, u_k, w)$. By continuity of f, we have that $x_k \to x$. Then let w_k be such that $x_k = f(\xi_k, u_k, w_k)$ and $h(w_k) = H^P(x_k; \xi_k, u_k)$. Clearly $h(w_k) \leq h(w)$, and therefore the sequence w_k has a convergent subsequence $w_{n_k} \to w'$. By lower semicontinuity of h we have

$$h(w') \leq \liminf h(w_{n_k}) \leq h(w). \tag{6.1}$$

But, again by continuity of f, we also have $x = f(\xi, x, w')$, and therefore

$$h(w') \geq h(w). \tag{6.2}$$

By (6.1) and (6.2) we have

$$\lim_k h(w_k) = h(w)$$

as desired.

Proof of property 3. Consider a sequence $(x_k, \xi_k, u_k) \to (x, \xi, u)$. We must show that

$$\liminf H^P(x_k; \xi_k, u_k) \geq H^P(x; \xi, u). \tag{6.3}$$

It is enough to prove this statement: Suppose there is a subsequence $(x_{n_k}, \xi_{n_k}, u_{n_k})$ such that

$$\lim_k H^P(x_{n_k}; \xi_{n_k}, u_{n_k}) = l < \infty; \tag{6.4}$$

then $l \geq H^P(x; \xi, u)$.

To prove this, let w_{n_k} be such that $x_{n_k} = f(\xi_{n_k}, u_{n_k}, w_{n_k})$ and $h(w_{n_k}) = H^P(x_{n_k}; \xi_{n_k}, u_{n_k})$. By (6.4), the sequence w_{n_k} has a limit point w. By continuity of f, $f(\xi, u, w) = x$, and therefore $h(w) \geq H^P(x; \xi, u)$. Finally, by lower semicontinuity of h,

$$l = \lim_k h(w_{n_k}) \geq h(w) \geq H^P(x; \xi, u)$$

which completes the proof of property 3.

Proof of properties 5 *and* 6. Letting

$$\rho^\epsilon = \frac{d\nu^\epsilon}{dv}$$

we easily get

$$\epsilon \log q^\epsilon(y; x) = \epsilon \log \rho^\epsilon(\phi^{-1}(x, y)) + \epsilon \log \left| \det\Big(D_y \phi^{-1}(x, y)\Big) \right|. \tag{6.5}$$

Property 5 follows from (6.5), equicontinuity of $\epsilon \log \rho^\epsilon$, continuity of ϕ^{-1}, and the fact that the function $\log|\det(D_y\phi^{-1})|$, being continuous, is bounded on the compact subsets of $\mathcal{X} \times \mathbb{R}^d$. Property 6 follows from (6.5) and boundedness of $\epsilon \log \rho^\epsilon$ and $\det(D_y\phi^{-1})$.

The only things left to prove are the finiteness and continuity of the rate function H^Q. This follows from finiteness and continuity of k and the identity

$$H^Q(y;x) = k(\phi^{-1}(x,y)).$$

6.2. Proof of Lemma 4.6. We first show that, for $\epsilon \geq 0$, g^ϵ is continuous. We omit the index ϵ in this part of the proof. Upper semicontinuity is obvious. To prove lower semicontinuity, observe that, due to the compactness of F, for every $x \in E$ there is a "minimizer" $y \in F$ such that $g(x) = f(x,y)$. So let $x_n \to x$, and y_n be the corresponding sequence of minimizers. We have to show that

$$\liminf g(x_n) \geq g(x).$$

To do so, it is not restrictive to assume that the sequence $g(x_n)$ has limit. Moreover, let y be a limit point of $\{y_n\}$. We have:

$$\lim g(x_n) = \lim f(x_n, y_n) = f(x,y) \geq g(x).$$

Thus the functions g^ϵ, $\epsilon \geq 0$, are continuous.

Now, let $K \subset E$ be compact. Let $\delta > 0$ be arbitrary, and let $\epsilon' > 0$ be such that for every $\epsilon < \epsilon'$

$$\left|f^\epsilon(x,y) - f^0(x,y)\right| < \delta \tag{6.6}$$

for any $x \in K, y \in F$. Given $x \in K$, let y^ϵ be such that $g^\epsilon(x) = f^\epsilon(x, y^\epsilon)$. By (6.6), for $\epsilon < \epsilon'$ and $x \in K$,

$$g^\epsilon(x) = f^\epsilon(x,y^\epsilon) \geq f^0(x,y^\epsilon) - \delta \geq g^0(x) - \delta.$$

To complete the proof we have to show that there exists ϵ'' such that for any $\epsilon < \epsilon''$

$$g^\epsilon(x) \leq g^0(x) + \delta \tag{6.7}$$

for all $x \in K$. Suppose, by contradiction, that there is no such ϵ''. Then there is a sequence $\epsilon_n \to 0$ and a corresponding sequence x_n in K such that

$$g^{\epsilon_n}(x_n) > g^0(x_n) + \delta \tag{6.8}$$

for all n. Denote by x a limit point of $\{x_n\}$ and by y a limit point of the sequence of minimizers $y_n^{\epsilon_n}$. By possibly passing to subsequences, we may assume that $\{x_n\} \to x$ and $y_n^{\epsilon_n} \to y$. Thus

$$\lim_n g^{\epsilon_n}(x_n) = \lim_n f^{\epsilon_n}(x_n, y_n^{\epsilon_n}) = f^0(x,y). \tag{6.9}$$

On the other hand, by continuity of g^0,

$$\lim_n g^0(x_n) = g^0(x). \tag{6.10}$$

Thus, by (6.8), (6.9), and (6.10) we have $f^0(x,y) \geq g^0(x) + \delta$. Therefore, there is a y' with $f^0(x,y) \geq f^0(x,y') + \delta$. This implies

$$\lim_n \left[f^{\epsilon_n}(x_n, y_n^{\epsilon_n}) - f^{\epsilon_n}(x_n, y')\right] \geq \delta,$$

which is impossible since $f^{\epsilon_n}(x_n, y_n^{\epsilon_n}) = \inf_z f^{\epsilon_n}(x_n, z)$.

HIGH-ORDER APPROXIMATIONS AND GENERALIZED NECESSARY CONDITIONS FOR OPTIMALITY[*]

URSZULA LEDZEWICZ[†] AND HEINZ SCHÄTTLER[‡]

Abstract. In this paper we derive generalized necessary conditions for optimality for an optimization problem with equality and inequality constraints in a Banach space. The equality constraints are given in operator form as $Q = \{x \in X : F(x) = 0\}$ where $F : X \to Y$ is an operator between Banach spaces; the inequality constraints are given by smooth functionals or by closed convex sets. Models of this type are common in the optimal control problem. The paper addresses the case when the Fréchet-derivative $F'(x_*)$ is not onto and hence the classical Lyusternik theorem does not apply to describe the tangent space to Q. In this case the classical Euler–Lagrange type necessary conditions are trivially satisfied, generating abnormal cases. A high-order generalization of the Lyusternik theorem derived earlier [U. Ledzewicz and H. Schättler, *Nonlinear Anal.,* 34 (1998), pp. 793–815] is used to calculate high-order tangent cones to the equality constraint at points $x_* \in Q$ where $F'(x_*)$ is not onto. Combining these with high-order approximating cones related to the other constraints of the problem (feasible cones respectively cones of decrease) a high-order generalization of the Dubovitskii–Milyutin theorem is given and then applied to derive *generalized* necessary conditions for optimality. These conditions reduce to classical conditions for normal cases, but they give new and nontrivial conditions for abnormal cases.

1. Introduction.

We consider the problem of minimizing a functional $I : X \to \mathbb{R}$ in a Banach space X under both equality and inequality constraints. The inequality constraints are of two types, described by smooth functionals $f : X \to \mathbb{R}$ as $P = \{x \in X : f(x) \leq 0\}$ or described by closed convex sets C. The equality constraints are given in operator form as $Q = \{x \in X : F(x) = 0\}$ where $F : X \to Y$ is an operator between Banach spaces. Lagrange multiplier type necessary conditions for optimality at the point x_* in the form of an Euler–Lagrange equation,

$$\lambda_0 I'(x_*) + \sum_{j=1}^{m} \lambda_j f_j'(x_*) + F'^*(x_*)y^* = 0, \tag{1.1}$$

while not all of the multipliers $\lambda_0, \dots, \lambda_m, y^*$ are zero, can be derived (see, for instance, [8, 11]) from approximations to the equality constraints (tangent sets, respectively, tangent cones), the inequality constraints (feasible sets/cones) and the directions of decrease for the functional to be minimized (sets/cones of decrease). However this necessary condition can be satisfied in a trivial way for any point $x_* \in Q$, where the equality constraints are not regular in the sense that $F'(x_*)$ is not onto. Assuming that $\operatorname{Im} F'(x_*)$ is closed, then it is possible simply to choose a nontrivial multiplier

which annihilates $\operatorname{Im} F'(x_*)$ and set all other multipliers to zero, and this choice will satisfy the Euler–Lagrange equation. But clearly this describes only the equality constraint degeneration without any relation to optimality.

One method to overcome the difficulty of abnormality known as "weakening equality constraints" was introduced by Milyutin in [20] and was investigated further by Dmitruk in [7]. In this method, which applies to extremum problems where the degenerate part of the operator F has a finite-dimensional image, a penalty-type approach is pursued where the degenerate equality constraints are replaced by inequality constraints. Here we pursue a different approach based on a p-order generalization of the Lyusternik theorem derived earlier [16] which determines the precise structure of polynomial approximations to Q at x_* when the surjectivity condition on $F'(x_*)$ is not satisfied but when instead a certain operator G_p which takes into account all derivatives up to and including order p is onto. The order p can be arbitrary, and it will be chosen precisely as the minimum number for which the operator G_p becomes onto. If G_p is onto, then the precise structure of q-order polynomial approximations to Q at x_* for any $q \geq p$ can be determined. Thus our result can be used in connection with appropriate approximations to inequality constraints and directions of decrease for the functional I to derive generalized necessary conditions for optimality based on expansions of increasing orders q. In this paper we describe this framework and the relevant structures for $q = p$. Extensions to $q \geq p$ are rather straightforward and will not be pursued here.

First results of this type have been obtained in the work of Avakov [3, 4, 5] and in our own work [13, 14] for the case of $p = 2$. Some of these conditions have been analyzed further by Arutyunov [1, 2]. The paper by Izmailov [12] also analyzes the case $p = 2$, but for inequality constraints. In our own previous work we have embedded Avakov's results into a second order Dubovitskii–Milyutin theory within the framework of second-order approximating cones [14]. This was achieved by introducing a reparametrization variable. However, this approach does not directly generalize to an arbitrary order p. In this paper we present a different approach which for any order p generates approximating cones in the extended state-space $X \times \mathbb{R}$ and is equivalent to the reparametrization for $p = 2$. Based on these p-order approximating cones we then formulate a p-order version of the Dubovitskii–Milyutin theorem, which we use to derive necessary conditions for optimality. These conditions for optimality are nontrivial also for nonregular constraints or abnormal processes due to the use of the p-order generalization of the Lyusternik theorem proved in [16]. Although derived by means of general p-order approximations, the conditions generalize the classical Euler–Lagrange equation and provide a nonnegativity condition to distinguish between minimizing and maximizing extremals. We therefore call them *generalized* necessary conditions for optimality rather than high-order conditions. They reduce to classical conditions for normal cases, but they are generalized in the sense that they give new and nontrivial conditions for abnormal cases.

The paper is organized as follows: In section 2 we define p-order approximating sets and cones. The definitions of p-order approximations are by standard polynomial expansions and are similar to the variational sets of order p defined in [9] or to its nonsmooth extensions considered in [21]. Our idea is to embed them into a conical structure which has the advantage that classical and well-known results can be used in the calculation of dual and polar cones thus simplifying the analysis. In this section we also give a p-order version of the Dubovitskii–Milyutin theorem [8] which we use to derive the necessary conditions for optimality. In section 3 we describe p-order tangent cones for nonregular equality constraints while we analyze p-order sets and cones of decrease in section 4. In section 5 we include a brief derivation of the generalized necessary conditions for optimality for a minimization problem in a Banach space with smooth operator equality constraints. For this problem there is an equivalence between the occurrence of abnormal points and points at which the equality constraint is nonregular. Also this derivation does not use the Dubovitskii–Milyutin framework, but is based on the geometry of the approximations and thus gives insight into the geometric meaning of the necessary conditions. In section 6 we then consider p-order feasible sets and cones to inequality constraints. We include the cases of inequality constraints described both by smooth functionals as well as inequality constraints given by closed convex sets to create a model which can be applied to the optimal control problem.

Then in section 7 we implement all these results on p-order approximating cones into the Dubovitskii–Milyutin framework and formulate generalized necessary conditions for optimality for our problem. Our results differ from existing first- and second-order necessary conditions for optimality like, for instance, those in [6, 9, 10, 19, 21, 22, 23] by giving conditions which are nontrivial for both regular and nonregular cases. Probably the closest results to ours among the long list of publications which derive necessary conditions for extremum problems assuming regularity of the equality constraints are the maximum principles of pth order by Hoffmann and Kornstaedt in [9, Theorems 5.1 and 5.2]. These results are also derived using p-order approximations, but they become trivial in the case of nonregular constraints. Our results developed here give a general (i.e., p-order) version of our results in [14] which were based on second-order approximations. Like this earlier version, the new results directly apply to the optimal control problem [15], but this formulation will be pursued elsewhere [17].

2. A high-order formulation of the Dubovitskii–Milyutin theorem.

In this paper we derive generalized necessary conditions for optimality based on general p-order approximations for smooth extremum problems in Banach spaces with operator equality constraints and inequality constraints given both by functionals and closed convex sets. We recall that a constraint is called an inequality constraint if the set of admissible points has nonempty interior, while it is called an equality constraint otherwise. In this section we formulate a version of the Dubovitskii–Milyutin theorem which gives general abstract necessary conditions for optimality based on high-order approximations and corresponding high-order approximating cones to the constraints and to the objective. The motivation is to consider p-order polynomial approximations along a given $(p-1)$-order polynomial approximating curve for which the necessary conditions were still inconclusive or even trivially satisfied as for abnormal points. The order p itself can be arbitrary.

Let X and Y be Banach spaces, let $I : X \to \mathbb{R}$ be a functional, $F : X \to Y$ an operator, $f_j : X \to \mathbb{R}$, $j = 1, \dots, m$, functionals and let $C \subset X$ be a closed convex set with nonempty interior. We assume that I, the functionals f_j, and the operator F are sufficiently often continuously Fréchet-differentiable and consider the following problem.

Problem (M).

Minimize I over all $x \in X$ which satisfy

· the inequality constraints $x \in P_j = \{x \in X : \ f_j(x) \leq 0\}$ for $j = 1, \dots, m$,

· the equality constraint $x \in Q = \{x \in X : \ F(x) = 0\}$, and

· the convex inequality constraint $x \in C$.

The set $A = \cap_{j=1}^{m} P_j \cap Q \cap C$ is called the admissible domain. We investigate the structure of high-order polynomial approximations to A. We denote sequences $(h_1, \dots, h_k) \in X^k$ by H_k with the subscript giving the length of the sequence. The following definition is standard (see, for instance, [9]).

Definition 2.1. *Let $H_{p-1} = (h_1, \dots, h_{p-1}) \in X^{p-1}$ and set $x(\varepsilon) \doteq x_* + \sum_{i=1}^{p-1} \varepsilon^i h_i$. We call H_{p-1} a $(p-1)$-order approximating sequence to a set $S \subseteq X$ at $x_* \in Clos\, S$; respectively, we call $x : \varepsilon \longmapsto x(\varepsilon)$ a $(p-1)$-order approximating curve if there exist an $\varepsilon_0 > 0$ and a function r defined on $[0, \varepsilon_0]$ with values in X, $r : [0, \varepsilon_0] \to X$, with the property that for $\varepsilon > 0$*

$$x(\varepsilon) + r(\varepsilon) = x_* + \sum_{i=1}^{p-1} \varepsilon^i h_i + r(\varepsilon) \in S \tag{2.1}$$

and

$$\lim_{\varepsilon \to 0} \frac{||r(\varepsilon)||}{\varepsilon^{p-1}} = 0. \tag{2.2}$$

Using the standard Landau notation we say that the function r is of order $o(\varepsilon^{p-1})$ as $\varepsilon \to 0$. Also, we call a $(p-1)$-order approximating sequence/curve $(p-1)$-*order feasible* if S is an inequality constraint (respectively, $(p-1)$-*order tangent* if S is an equality constraint).

Let $x_* \in F$ and assume as given a $(p-1)$-order approximating sequence $H_{p-1} = (h_1, \dots, h_{p-1}) \in X^{p-1}$ with corresponding $(p-1)$-order approximation $x(\varepsilon) \doteq x_* + \sum_{i=1}^{p-1} \varepsilon^i h_i$. It is implicitly assumed that x_* has not been ruled out for optimality. (For instance, since the functional I was decreasing along the corresponding $(p-1)$-order approximating curve or simply by using other approximating sequences.) Then we would like to extend the existing $(p-1)$-order approximations to p-order approximations and derive the corresponding necessary conditions for optimality. In this section we give the general definitions and formulate these ideas precisely. In the following sections we will describe how these extensions are done. The following definitions are direct generalizations of standard existing definitions as can be found in [8], for instance.

Definition 2.2. *We call v_0 a p-order vector of decrease for a functional $I : X \to \mathbb{R}$ at $x_* \in X$ in the direction of the sequence $H_{p-1} = (h_1, \dots, h_{p-1}) \in X^{p-1}$ if there exist a neighborhood V of v_0 and a number $\alpha < 0$ so that for all $v \in V$ we have*

$$I\left(x_* + \sum_{i=1}^{p-1} \varepsilon^i h_i + \varepsilon^p v\right) = I(x(\varepsilon) + \varepsilon^p v) \leq I(x_*) + \alpha \varepsilon^p. \tag{2.3}$$

The collection of all p-order vectors of decrease for I at x_* in the direction of the sequence H_{p-1} will be called the p-order set of decrease to I at x_* in the direction of the sequence H_{p-1} and will be denoted by $DS^{(p)}(I; x_*, H_{p-1})$.

Definition 2.3. *We call v_0 a p-order feasible vector for an inequality constraint P at $x_* \in X$ in direction of H_{p-1} if there exist an $\varepsilon_0 > 0$ and a neighborhood V of v_0 so that for all $0 < \varepsilon \leq \varepsilon_0$*

$$x_* + \sum_{i=1}^{p-1} \varepsilon^i h_i + \varepsilon^p V = x(\varepsilon) + \varepsilon^p V \subset P. \tag{2.4}$$

The collection of all p-order feasible vectors v_0 for P at x_* in the direction of the sequence H_{p-1} will be called the p-order feasible set to P at x_* in the direction of the sequence H_{p-1} and will be denoted by $FS^{(p)}(P; x_*, H_{p-1})$.

Note that by definition the p-order set of decrease to I and the p-order feasible set to P, both at x_* in direction of the sequence H_{p-1}, are open.

DEFINITION 2.4. *We call h_p a p-order tangent vector to an equality constraint Q at x_* in the direction of the sequence H_{p-1} if $H_p = (h_1, \dots, h_{p-1}, h_p) \in X^p$ is a p-order approximating sequence to the set Q at $x_* \in Q$. The collection of all p-order tangent vectors to Q at x_* in the direction of the sequence H_{p-1} will be called the p-order tangent set to Q at x_* in the direction of the sequence H_{p-1} and will be denoted by $TS^{(p)}(Q; x_*, H_{p-1})$.*

Rather than working with approximating sets as is done for instance by Ben-Tal and Zowe in [6], we prefer to embed these approximating sets into cones in the extended state-space $X \times \mathbb{R}$. This has the advantage that many classical results like the Minkowski–Farkas lemma or the annihilator lemma can be directly applied in calculating dual cones (see also [14]). Let us generally refer to p-order sets of decrease, feasible sets and tangent sets as p-order approximating sets and denote them by $AS^{(p)}(Z; x_*, H_{p-1})$. Then we define the corresponding approximating cones as follows.

DEFINITION 2.5. *Given a p-order approximating set $AS^{(p)}(Z; x_*, H_{p-1})$ to a set $Z \subset X$ at x_* in direction of the sequence H_{p-1}, the p-order approximating cone to Z at x_* in direction of H_{p-1}, $AC^{(p)}(Z; x_*, H_{p-1})$, is the cone in $X \times \mathbb{R}$ generated by the vectors $(v, 1) \in AS^{(p)}(Z; x_*, H_{p-1}) \times \mathbb{R}$, i.e.,*

$$AC^{(p)}(Z; x_*, H_{p-1}) = \bigcup_{\gamma > 0} \gamma \left(AS^{(p)}(Z; x_*, H_{p-1}) \times \{1\} \right). \tag{2.5}$$

Thus we talk of the p-order cone of decrease for the functional I, p-order feasible cones for inequality constraints and p-order tangent cones for equality constraints, all at x_* in direction of the sequence H_{p-1}.

DEFINITION 2.6 (see [8]). *Let $C \subseteq Z$ be a cone in a Banach space Z with apex at 0. The dual (or polar) cone to C consists of all continuous linear functionals $\lambda \in Z^*$ which are nonnegative on C, i.e.,*

$$C^* = \{\lambda \in Z^* : \ \langle \lambda, v \rangle \geq 0 \text{ for all } v \in C\}. \tag{2.6}$$

We are now ready to state and prove a general p-order formulation of the classical Dubovitskii–Milyutin theorem [8, Lemma 5.11].

THEOREM 2.7. *Suppose the functional I attains a local minimum for problem (M) at $x_* \in A$. Let $H_{p-1} = (h_1, \dots, h_{p-1}) \in X^{p-1}$ be a $(p-1)$-order approximating sequence such that the p-order cone of decrease for the functional I, the p-order feasible cones for the inequality constraints P_j, $j = 1, \dots, m$, and C, and the p-order tangent cone to the equality constraint Q, all at x_* in direction of the sequence H_{p-1}, are nonempty and convex. Then there exist continuous linear functionals*

$$\Psi_0 = (\lambda_0, \mu_0) \in \left(DC^{(p)}(I; x_*, H_{p-1}) \right)^*, \tag{2.7}$$

$$\Psi_j = (\lambda_j, \mu_j) \in \left(FC^{(p)}(f_j; x_*, H_{p-1}) \right)^*, \qquad j = 1, \dots, m, \tag{2.8}$$

$$\Omega = (\lambda_{m+1}, \mu_{m+1}) \in \left(FC^{(p)}(C; x_*, H_{p-1}) \right)^* \tag{2.9}$$

and

$$\Phi = (\lambda_{m+2}, \mu_{m+2}) \in \left(TC^{(p)}(Q; x_*, H_{p-1})\right)^*, \tag{2.10}$$

all depending on H_{p-1}, such that the generalized Euler–Lagrange equation

$$\sum_{j=0}^{m+2} \lambda_j \equiv 0 \tag{2.11}$$

and the condition

$$\sum_{j=0}^{m+2} \mu_j \equiv 0 \tag{2.12}$$

hold. Furthermore, not all the λ_j, $j = 0, 1, \dots, m+2$, vanish identically.

Proof. By assumption all p-order approximating cones at x_* in direction of the sequence H_{p-1} are nonempty and convex. Since x_* is optimal, the intersection of these cones must be empty. For, if (w, γ) lies in this intersection, then setting $v = \frac{w}{\gamma}$ we have in particular that $H = (h_1, \dots, h_{p-1,}v)$ is a p-order approximating sequence to the equality constraint Q at $x_* \in Q$. Hence there exists an $\varepsilon_0 > 0$ and a function r defined on $[0, \varepsilon_0]$ with values in X, $r : [0, \varepsilon_0] \to X$, which is of order $o(\varepsilon^p)$ as $\varepsilon \to 0$, with the property that $\gamma(\varepsilon) \doteq x_* + \sum_{i=1}^{p-1} \varepsilon^i h_i + \varepsilon^p v + r(\varepsilon) \in Q$. But this curve is admissible for problem (P) since it also satisfies the inequality constraints and the functional I decreases along the curve $\gamma(\varepsilon)$. This contradicts the optimality of x_*.

Since by definition the p-order cones of decrease for I, $DC^{(p)}(I; x_*, H_{p-1})$, the p-order feasible cones $FC^{(p)}(P_j; x_*, H_{p-1})$ for $j = 1, \dots, p$, and the p-order feasible cone $FC^{(p)}(C; x_*, H_{p-1})$ are open, it therefore follows from the classical Dubovitskii–Milyutin lemma [8, Lemma 5.11] that there exist linear functionals in the respective dual cones $\Psi_0 \in \left(DC^{(p)}(I; x_*, H_{p-1})\right)^*$, $\Psi_j \in \left(FC^{(p)}(f_j; x_*, H_{p-1})\right)^*$, $j = 1, \dots, m$, $\Omega \in \left(FS^{(p)}(C; x_*, H_{p-1})\right)^*$ and $\Phi \in \left(TC^{(p)}(Q; x_*, H_{p-1})\right)^*$, which are not all identically zero, so that

$$\Psi_0 + \sum_{j=1}^{m} \Psi_j + \Omega + \Phi \equiv 0. \tag{2.13}$$

Writing $\Psi_j = (\lambda_j, \mu_j)$, $j = 0, 1, \dots, m$, $\Omega = (\lambda_{m+1}, \mu_{m+1})$, and $\Phi = (\lambda_{m+2}, \mu_{m+2})$, (2.11) and (2.12) follow. Furthermore, the nontriviality of the multipliers Ψ_j, $j = 0, \dots, m$, Ω, and Φ is actually equivalent to the nontriviality of the multipliers λ_j, $j = 0, 1, \dots, m+2$. For, if λ_j vanishes identically, then $\mu_j \geq 0$ since (λ_j, μ_j) lies in the dual to a cone in $X \times \mathbb{R}_+$. Thus, if all the λ_j, $j = 0, \dots, m+2$, vanish identically, then $\mu_j \geq 0$ for all $j = 0, \dots, m+2$. But by (2.12) also $\sum_{j=0}^{m+2} \mu_j \equiv 0$, and thus all μ_j are zero as well contradicting the nontriviality of the multipliers Ψ_j, $j = 0, \dots, m$, Ω and Φ. □

This theorem provides the general mechanism to derive generalized necessary conditions for optimality. In the next sections we derive the structure of general p-order approximating cones and their duals, starting in section 3 with the most difficult construction, p-order tangent cones.

3. High-order approximations for equality constraints.

3.1. A high-order generalization of the Lyusternik theorem. We briefly recall the p-order Lyusternik theorem [16] and the required notation: X and Y are Banach spaces, $F : X \to Y$ is an operator, and $Q = \{x \in X : F(x) = F(x_*)\}$. Assuming that $F : X \to Y$ is sufficiently often continuously Fréchet differentiable in a neighborhood of x_*, we consider the Taylor expansion of F along a curve $\gamma(\varepsilon) = x_* + \sum_{i=1}^m \varepsilon^i h_i$. We have

$$F(x_* + \sum_{i=1}^{m} \varepsilon^i h_i) = F\,(x_*) + \sum_{i=1}^{m} \varepsilon^i \nabla^i F(x_*)(h_1, \dots, h_i) + \widetilde{r}(\varepsilon), \tag{3.1}$$

where

$$\nabla^i F(x_*)(h_1, \dots, h_i) \doteq \sum_{r=1}^{i} \frac{1}{r!} \left(\sum_{j_1 + \ldots + j_r = i} F^{(r)}(x_*)(h_{j_1}, \dots, h_{j_r}) \right) \tag{3.2}$$

and $\widetilde{r}(\varepsilon)$ is a function of order $o(\varepsilon^m)$ as $\varepsilon \to 0$. We call the quantities the ith-*order* directional derivatives along the sequence $H_i = (h_1 \dots, h_i)$, $1 \le i \le m$. The higher-order directional derivative no longer acts linearly, but $\nabla^i F(x_*)$ is homogeneous of degree i in the sense that

$$\nabla^i F(x_*)(\varepsilon h_1, \dots, \varepsilon^i h_i) = \varepsilon^i \nabla^i F(x_*)(h_1, \dots, h_i).$$

In particular, no indices $j_1$and j_2 with $j_1 + j_2 > i$ can occur together as arguments in any of the terms in $\nabla^i F(x_*)$. Thus all the vectors h_j whose index satisfies $2j > i$ appear linearly and in separate terms. There are linear operators $G_k = G_k[F](x_*; H_{k-1})$, $k \in \mathbb{N}$, depending on the derivatives up to order k of F in the point x_* (i.e., the k-jet of F in x_*) and the vectors $H_{k-1} = (h_1, \dots, h_{k-1})$, which describe the contributions of these components. In fact, for $k \in \mathbb{N}$ we have $G_k = G_k[F](x_*; H_{k-1}) : X \to Y,\ v \longmapsto G_k(v)$, defined by

$$G_k[F](x_*; H_{k-1})(v) = \sum_{r=0}^{k-1} \frac{1}{r!} \left(\sum_{j_1 + \ldots + j_r = k-1} F^{(r+1)}(x_*)(h_{j_1}, \dots, h_{j_r}, v) \right). \tag{3.3}$$

For simplicity of notation we often suppress the arguments. For example, we write

$$G_1\,(v) = F'(x_*)v, \qquad G_2\,(v) = F''(x_*)(h_1, v),$$
$$G_3(v) = F''(x_*)(h_2, v) + \frac{1}{2} F'''(x_*)(h_1, h_1, v).$$

Given an order p we can therefore separate the linear contributions of the vectors $h_p, \dots, h_{2p-1}$ in derivatives of orders p through $2p-1$ and have for $i = 1, \dots, p$ that

$$\begin{aligned} \nabla^{p-1+i} F(x_*)(h_1, \dots, h_{p-1+i}) = &\left(\sum_{k=1}^{i} G_k[F](x_*; H_{k-1})(h_{p+i-k}) \right) \\ &+ R_{p-1,i}[F](x_*; H_{p-1}). \end{aligned} \tag{3.4}$$

Here the sum gives all the terms which contain a vector $h_p, \dots, h_{p-1+i}$, and the remainder R combines all the remaining terms which only include vectors of index

$\leq p-1$. Similar to the operators G_k the remainders R depend on the $(p-1+i)$-jet of the operator F at x_*, but if the map is clear we omit it in the notation. The general structure of these remainders is given by

$$R_{\ell,i}[F](x_*;H_\ell) = \sum_{r=2}^{\ell+i} \frac{1}{r!} \left(\sum_{\substack{j_1+\cdots+j_r=\ell+i \\ 1\leq j_k\leq \ell,\ 1\leq k\leq r}} F^{(r)}(x_*)(h_{j_1},\dots,h_{j_r}) \right). \tag{3.5}$$

Thus $R_{\ell,i}$ consists of the terms which are homogeneous of degree $\ell+i$, but only involve vectors from H_ℓ. In particular, the remainders only have contributions from derivatives of at least order two. In our applications $\ell = p-1$ and $i = 1,\dots,p$, but the structure above is general.

Definition 3.1. *We say the operator F is p-regular at x_* in direction of the sequence $H_{p-1} \in X^{p-1}$if the following conditions are satisfied:*

(A1) *$F: X \to Y$ is $(2p-1)$-times continuously Fréchet differentiable in a neighborhood of x_*.*

(A2) *The subspaces Y_i, $i = 1,\dots,p$,*

$$Y_i = \sum_{k=1}^{i} \operatorname{Im} G_k = \sum_{k=1}^{i} \operatorname{Im} G_k[F](x_*;H_{k-1})$$

are closed. Also let $Y_0 = \{0\}$.

(A3) *The map $\mathcal{G}_p = \mathcal{G}_p[F](x_*;H_{p-1})$*

$$\begin{aligned} \mathcal{G}_p \ &: \ X \to Z \doteq Y_1 \times Y_2/Y_1 \times \cdots \times Y/Y_{p-1}, \\ v &\mapsto \mathcal{G}_p(v) = (G_1(v), \pi_1 G_2(v), \dots, \pi_{p-1} G_p(v)), \end{aligned} \tag{3.6}$$

where the $\pi_i : Y_{i+1} \to Y_{i+1}/Y_i$ denote the canonical projections into the quotient space, is onto.

In the sense of this definition 1-regularity then corresponds to the classical Lyusternik condition, while 2-regularity is similar to Avakov's definition [3].

The p-order Lyusternik theorem proven in [16] gives a precise description of the p-order approximating sequences for a p-regular operator.

Theorem 3.2 (p-order Lyusternik theorem). *Let $H_{p-1} = (h_1,\dots,h_{p-1}) \in X^{p-1}$ be given such that the ith directional derivatives of F vanish along H_i for $i = 1,\dots,p-1$,*

$$\nabla^i F(x_*)(H_i) = 0 \text{ for } i = 1,\dots,p-1, \tag{3.7}$$

and suppose the operator F is p-regular at x_* in direction of the sequence H_{p-1}. Then $H_p = (h_1,\dots,h_p) \in X^p$ is a p-order approximating sequence to the set Q at $x_* \in Q$ if and only if the following conditions hold for $i = 1,\dots,p$:

$$G_i[F](x_*;H_{i-1})h_p + R_{p-1,i}[F](x_*;H_{p-1}) \in Y_{i-1}. \tag{3.8}$$

We include a brief motivation of Theorem 3.2 and an outline of its proof. Full details are given in [16]. The conditions can be understood by looking at the Taylor expansion of F along a curve $x(\varepsilon) = x_* + \varepsilon h_1 + \varepsilon^2 h_2 + \cdots$. For reasons of simplicity, we consider the case $p = 2$:

$$\begin{aligned} F(x(\varepsilon)) = F(x_*) + \varepsilon F'(x_*)h_1 + \varepsilon^2(F'(x_*)h_2 + \frac{1}{2}F''(x_*)(h_1, h_1)) \\ +\varepsilon^3(F'(x_*)h_3 + F''(x_*)(h_1, h_2) + \frac{1}{6}F'''(x_*)(h_1, h_1, h_1)) + o(\varepsilon^3). \end{aligned}$$

Clearly we must have $F'(x_*)h_1 = 0$. This term cannot be affected by choosing higher-order directions and therefore must vanish generating (3.7). But if F is not regular at x_*, then $F'(x_*)h_1 = 0$ is no longer sufficient for h_1 to be a tangent vector to Q at x_*. For, if $F''(x_*)(h_1, h_1) \notin \operatorname{Im} F'(x_*)$, then it is not possible to choose h_2 to make the term at ε^2 vanish. Even stronger, we need to be able to choose h_2 so that it simultaneously cancels the quadratic term and reduces the cubic term to a vector which lies in $\operatorname{Im} F'(x_*)$. Only then it is possible to choose h_3 to make the term at ε^3 zero. This generates the two conditions in (3.8). The necessity of the conditions in Theorem 3.2 follows along these lines in general.

In order to prove sufficiency if F is p-regular at x_* in direction of the sequence H_{p-1}, we construct the remainder term r in the definition of p-order approximating sequences using Newton's method. This is the essential step of the argument and we briefly outline how it is done.

By (A2) the spaces Y_i, $i = 1, \dots, p-1$, are closed and therefore are Banach spaces. So then are the quotient spaces Y_{i+1}/Y_i, $i = 1, \dots, p-1$, and their product $Z \doteq Y_1 \times Y_2/Y_1 \times \cdots \times Y/Y_{p-1}$. By (A3) the linear and continuous operator $\mathcal{G}_p : X \to Z$ has a bounded right inverse $\mathcal{H}_p : Z \to X$, i.e., $\mathcal{G}_p(x_*, H_{p-1}) \circ \mathcal{H}_p = id_Z$, and there exists a constant C such that $||\mathcal{H}_p(z)|| \le C||z||$ for all $z \in Z$. Let $U = \{x \in X : ||x - x_*|| < \delta\}$ be a sufficiently small neighborhood of x_* so that F is p-times continuously differentiable on U. By choosing ε_0 sufficiently small the entire curve $x(\varepsilon) = x_* + \sum_{i=1}^{p} \varepsilon^i h_i$, $0 \le \varepsilon \le \varepsilon_0$ lies in U. Henceforth we consider one point $x(\varepsilon)$ on this curve; i.e., ε will be fixed. The desired function r is found by constructing a solution to the equation $F(x) = F(x_*)$ using Newton's method. To this end set $x_0 = x(\varepsilon)$, $z_0^{(i)} = \varepsilon^{p+i} y_i$, for $i = 1, \dots, p-1$, and then define

$$\varsigma_0 = z_0^{(p)} = F(x_0) - F(x_*) - \sum_{i=1}^{p-1} z_0^{(i)}. \tag{3.9}$$

It is convenient to have a separate label ς for the pth component and we use $z_n^{(p)}$ and ς_n interchangeably. Then inductively define sequences $\{x_n\}_{n\in\mathbb{N}} \subset X$, and $\{z_n^{(i)}\}_{n\in\mathbb{N}} \subset Y_i$, $i = 1, \dots, p$, as

$$x_n \doteq x_{n-1} - \mathcal{H}_p\left(z_{n-1}^{(1)}, \frac{\pi_1\left(z_{n-1}^{(2)}\right)}{\varepsilon}, \frac{\pi_2\left(z_{n-1}^{(3)}\right)}{\varepsilon^2}, \cdots, \frac{\pi_p\left(z_{n-1}^{(p)}\right)}{\varepsilon^{p-1}}\right), \tag{3.10}$$

and for $i = 1, \dots, p-1$ define

$$z_n^{(i)} \doteq z_{n-1}^{(i+1)} + \varepsilon^i G_{i+1}(x_n - x_{n-1}) \tag{3.11}$$

while

$$\varsigma_n = z_n^{(p)} \doteq F(x_n) - F(x_*) - \sum_{i=1}^{p-1} z_n^{(i)}. \tag{3.12}$$

Note that these sequences are well defined: applying the operator $\mathcal{G}_p$ to (3.10) we get that

$$G_1(x_n - x_{n-1}) = F'(x_*)(x_n - x_{n-1}) = -z_{n-1}^{(1)} \tag{3.13}$$

and for $i = 1, \dots, p-1$ that

$$\varepsilon^i \pi_i \left(G_{i+1}(x_n - x_{n-1})\right) = -\pi_i z_{n-1}^{(i+1)}. \tag{3.14}$$

Thus we have $\pi_i\left(z_n^{(i)}\right) = 0$, so that $z_n^{(i)} \in Y_i$ for all $i = 1, \dots, p-1$.

In the proof [16] the following inequalities are shown by induction for all $n \geq 0$ and $i = 1, \dots, p-1$:

$$||z_n^{(i)}|| \leq M \left(\frac{1}{2}\right)^n \varepsilon^{p+i} \tag{3.15}$$

and

$$||\varsigma_n|| \leq M \left(\frac{1}{2}\right)^n \varepsilon^{2p-1}\alpha(\varepsilon), \tag{3.16}$$

$$||x_{n+1} - x_n|| \leq pMC \left(\frac{1}{2}\right)^n \varepsilon^p \alpha(\varepsilon), \tag{3.17}$$

where $M = \max(1, ||y_i||,\ i = 1, \dots, p)$ and α is a fixed function of order $o(1)$ as $\varepsilon \to 0$. Therefore the sequences $\{z_n^{(i)}\}_{n\in\mathbb{N}},\ i = 1, \dots, p$, all converge to 0 and $\{x_n\}_{n\in\mathbb{N}}$ is Cauchy and hence convergent to some limit, which we call $l(\varepsilon)$. By the continuity of F in x_* and (3.12) it follows that

$$F(l(\varepsilon)) = \lim_{n\to\infty} F(x_n) = F(x_*).$$

Defining

$$r(\varepsilon) = l(\varepsilon) - x(\varepsilon) = \left(\lim_{n\to\infty} x_n\right) - x_0,$$

we therefore have

$$F(x_*) = F\left(x(\varepsilon) + r(\varepsilon)\right)$$

and

$$||r(\varepsilon)|| = \left\|\sum_{n=1}^{\infty}(x_n - x_{n-1})\right\| \leq pMC\sum_{n=1}^{\infty}\left(\frac{1}{2}\right)^{n-1}\varepsilon^p\alpha(\varepsilon) = pMC\varepsilon^p\alpha(\varepsilon)$$

is of order $o(\varepsilon^p)$ as $\varepsilon \to 0$. This verifies the theorem.

3.2. High-order tangent cones. Note that (3.8) implies as necessary condition for the existence of a p-order approximating sequence along H_{p-1} that for $i = 1, \dots, p-1$, we have the following *compatability conditions*:

$$R_{p-1,i}[F](x_*; H_{p-1}) \in Y_i. \tag{3.18}$$

For $i = p$ this condition is satisfied under our assumption that $\mathcal{G}_p$ is onto. We can therefore restate Theorem 3.2 as follows.

COROLLARY 3.3. *Let H_{p-1} be a sequence so that $\nabla^i F(x_*)(H_i) = 0$ for $i = 1, \dots, p-1$, and suppose the operator F is p-regular at x_* in direction of H_{p-1}. Then $TS^{(p)}(Q; x_*, H_{p-1})$ is nonempty if and only if for $i = 1, \dots, p-1$ we have*

$$R_{p-1,i}[F](x_*; H_{p-1}) \in Y_i. \tag{3.19}$$

In this case $TS^{(p)}(Q; x_*, H_{p-1})$ is the closed affine subspace of X given by the solutions to the linear equation

$$\mathcal{G}_p[F](x_*; H_{p-1})(v) + \mathcal{R}_{p-1}[F](x_*, H_{p-1}) = 0, \tag{3.20}$$

where $\mathcal{R}_{p-1}[F](x_*, H_{p-1}) \in Z$ is the point with components

$$(R_{p-1,1}[F](x_*; H_{p-1}), \pi_1 R_{p-1,2}[F](x_*; H_{p-1}), \dots, \pi_{p-1} R_{p-1,p}[F](x_*; H_{p-1})) . \tag{3.21}$$

This formulation of the result clearly brings out the geometric structure of the p-order tangent sets as closed affine linear subspaces of X generated by the kernel of $\mathcal{G}_p$, $\ker \mathcal{G}_p$.

COROLLARY 3.4. *Let H_{p-1} be a sequence such that the operator F is p-regular at x_* in direction of H_{p-1}, that the first $(p-1)$ directional derivatives $\nabla^i F(x_*)(H_i)$ vanish for $i = 1, \dots, p-1$, and that the compatability conditions $R_{p-1,i}[F](x_*; H_{p-1}) \in Y_i$ are satisfied for $i = 1, \dots, p$. Then the p-order tangent cone to $Q = \{x \in X : F(x) = F(x_*)\}$ at x_* in direction of H_{p-1}, $TC^{(p)}(Q; x_*, H_{p-1})$, consists of all solutions $(w, \gamma) \in X \times \mathbb{R}_+$ (i.e., $\gamma > 0$) of the linear equation*

$$\mathcal{G}_p[F](w) + \gamma \mathcal{R}_{p-1}[F](x_*, H_{p-1}) = 0. \tag{3.22}$$

For applications to optimization problems we need the subspace of continuous linear functionals which annihilate $\ker \mathcal{G}_p$. Since the operator $\mathcal{G}_p$ is onto by assumption (A3), it follows by the annihilator lemma or the closed-range theorem [11] that

$$(\ker \mathcal{G}_p)^{\perp} = \operatorname{Im}\left(\mathcal{G}_p^*\right), \tag{3.23}$$

where

$$\mathcal{G}_p^* : Z^* = Y_1^* \times (Y_2/Y_1)^* \times \cdots \times (Y/Y_{p-1})^* \to X^*$$

denotes the adjoint map. Let

$$\tau_i : (Y_{i+1}/Y_i)^* \to Y_i^{\perp_{i+1}} \tag{3.24}$$

denote the canonical isomorphism. Here $\perp_{i+1}$ denotes the annihilator in Y_{i+1}, i.e.,

$$Y_i^{\perp_{i+1}} = \{z^* \in Y_{i+1}^* : \langle z^*, v\rangle = 0 \ \forall \ v \in Y_i\},$$

and we formally set $Y_0 = \{0\}$, so that $Y_0^{\perp_1} \cong Y_1^*$. Then, more specifically, we get the following.

PROPOSITION 3.5. *A functional $\lambda \in X^*$ lies in $(\ker \mathcal{G}_p)^{\perp}$ if and only if it can be represented in the form*

$$\lambda = \sum_{i=1}^{p} G_i^*[F](x_*; H_{i-1}) y_i^* \tag{3.25}$$

for some functionals $y_i^* \in Y_{i-1}^{\perp_i}$, $i = 1, \dots, p$.

Proof. By the annihilator lemma, $\lambda \in (\ker \mathcal{G}_p)^{\perp}$ if and only if there exists a continuous linear functional $\widetilde{y}^* = (\widetilde{y}_1^*, \dots .\widetilde{y}_p^*) \in Z^*$, i.e., $\widetilde{y}_i^* \in (Y_i/Y_{i-1})^*$, so that

$$\lambda = \mathcal{G}_p^* \widetilde{y}^* = \mathcal{G}_p^* \left(\widetilde{y}_1^*, \widetilde{y}_2^*, \dots , \widetilde{y}_p^*\right). \tag{3.26}$$

Thus we have for every $v \in \ker \mathcal{G}_p$

$$\begin{aligned} 0 = \langle \lambda, v\rangle &= \left\langle \mathcal{G}_p^* \widetilde{y}^*, v\right\rangle = \langle \widetilde{y}^*, \mathcal{G}_p v\rangle \\ &= \left\langle \left(\widetilde{y}_1^*, \widetilde{y}_2^*, \dots , \widetilde{y}_p^*\right), \left(G_1(v), \pi_1 G_2(v), \dots , \pi_{p-1} G_p(v)\right)\right\rangle \\ &= \sum_{i=1}^{p} \langle \widetilde{y}_i^*, \pi_{i-1} G_i(v)\rangle . \end{aligned}$$

Define $y_1^* \doteq \widetilde{y}_1^*$ and $y_i^* \doteq \tau_{i-1} \circ \widetilde{y}_i^*$ for $i = 2, \dots , p$. Since $\tau_{i-1} : (Y_i/Y_{i-1})^* \to Y_{i-1}^{\perp_i}$ is the canonical isomorphism, we have that $\tau_{i-1} \circ\, z^* = z^* \circ \pi_{i-1}$ for every $z^* \in Y_i$. Hence

$$\sum_{i=1}^{p} \langle \widetilde{y}_i^*, \pi_{i-1} G_i(v)\rangle = \sum_{i=1}^{p} \langle y_i^*, G_i(v)\rangle = \sum_{i=1}^{p} \langle G_i^* y_i^*, v\rangle .$$

Since this holds for all $v \in \ker \mathcal{G}_p$, (3.25) follows. □

PROPOSITION 3.6. *The dual or polar p-order tangent cone consists of all linear functionals $(\lambda, \mu) \in X^* \times \mathbb{R}$ which can be represented in the following form: There exist functionals $y_i^* \in Y_{i-1}^{\perp_i}$, $i = 1, \dots , p$, and a number $r \geq 0$ such that*

$$\lambda = \sum_{i=1}^{p} G_i^*[F](x_*; H_{i-1}) y_i^* \ , \tag{3.27}$$

$$\mu = \sum_{i=1}^{p} \langle y_i^*, R_{p-1,i}[F](x_*; H_{p-1})\rangle + r. \tag{3.28}$$

Proof. This proof is analogous to the proof of [14, Theorem 2.2] and thus we indicate only the main steps. Define the operator

$$\begin{aligned} \mathcal{K} \ &: \ X \times \mathbb{R} \to Z = Y_1 \times Y_2/Y_1 \times \cdots \times Y/Y_{p-1}, \\ (w, \gamma) &\mapsto \mathcal{K}(w, \gamma) = \mathcal{G}_p[F](w) + \gamma \mathcal{R}_{p-1}[F](x_*, H_{p-1}). \end{aligned}$$

Then

$$TC^{(p)}(Q; x_*, H_{p-1}) = \ker \mathcal{K}(w, \gamma) \cap \{(w, \gamma) \in X \times \mathbb{R} : \ \gamma > 0\}$$

and thus

$$\left(TC^{(p)}(Q; x_*, H_{p-1})\right)^* = (\ker \mathcal{K})^* + \{0\} \times \{r \in \mathbb{R} : \ r \geq 0\}.$$

Since $\ker \mathcal{K}$ is a linear space, the continuous functionals which are nonnegative on $\ker \mathcal{K}$ are given by $(\ker \mathcal{K})^{\perp}$ and by the annihilator lemma

$$(\ker \mathcal{K})^{\perp} = \operatorname{Im} \mathcal{K}^*.$$

Now the result follows analogously as in the proof of Proposition 3.5. □

4. High-order cones of decrease. In this section we determine the p-order sets of decrease of a functional $I : X \to \mathbb{R}$. These results also apply to p-order feasible sets to inequality constraints defined by smooth functionals. We assume as given a $(p-1)$-order sequence H_{p-1} and we calculate the p-order set of decrease of I at x_* along H_{p-1}. Trivial cases arise if there exists a first non-zero directional derivative $\nabla^i I(x_*)(H_i)$ of I with $i \le p-1$. In this case we have either $DS^{(p)}(I; x_*, H_{p-1}) = \emptyset$ if $\nabla^i I(x_*)(H_i) > 0$ or $DS^{(p)}(I; x_*, H_{p-1}) = X$ if $\nabla^i I(x_*)(H_i) < 0$. In the first case the sequence H_{p-1} cannot be used to exclude optimality of x_* since indeed x_* is a local minimum along the approximating curve generated by H_{p-1}. In the second case h_i is an ith-order direction of decrease along H_{i-1} and thus every vector $v \in X$ is admissible as a pth-order component. The only nontrivial case arises if $\nabla^i I(x_*)(H_i) = 0$ for all i with $i \le p-1$ and if $I'(x_*) \ne 0$. Then replacing the operator F with the functional I in (3.4) for $i = 1$, it follows that $DS^{(p)}(I; x_*, H_{p-1})$ consists of all vectors $v \in X$ which satisfy

$$\nabla^p I(x_*)(H_{p-1}, v) = I'(x_*)v + R_{p-1,1}[I](x_*; H_{p-1}) < 0.$$

Here we indicate in the notation that the operator $R_{p-1,1}$ is taken for the functional I. If $I'(x_*) = 0$, then $DS^{(p)}(I; x_*, H_{p-1})$ is still the full space or empty set depending on whether $R_{p-1,1}[I](x_*; H_{p-1})$ is negative or positive. Thus, if $I'(x_*) \ne 0$, then $DS^{(p)}(I; x_*, H_{p-1})$ is an open half-space with normal vector $I'(x_*)$. Summarizing we have (see also [14, Proposition 3.1])

PROPOSITION 4.1. *Suppose $I'(x_*) \ne 0$ and $\nabla^i I(x_*)(H_i) = 0$ for all i with $i \le p-1$. Then the p-order cone of decrease for the functional I at x_* in direction of H_{p-1}, $DC^{(p)}(I; x_*, H_{p-1})$, is given by*

$$\begin{aligned} DC^{(p)}(I; x_*, H_{p-1}) = \{(w, \gamma) \in X \times \mathbb{R} : \gamma > 0, \\ I'(x_*)w + \gamma R_{p-1,1}[I](x_*; H_{p-1}) < 0\}. \end{aligned} \tag{4.1}$$

Thus $DC^{(p)}(I; x_*, H_{p-1})$ is nonempty, open, and convex. The dual or polar cone to $DC^{(p)}(I; x_*, H_{p-1})$ can easily be calculated using the Minkowski–Farkas lemma [8].

PROPOSITION 4.2. *Suppose $I'(x_*) \ne 0$ and $\nabla^i I(x_*)(H_i) = 0$ for all i with $i \le p-1$. Then*

$$\begin{aligned} \left(DC^{(p)}(I; x_*, H_{p-1})\right)^* = \Bigg\{ &(\lambda, \mu) \in X^* \times \mathbb{R} : \ \exists\ \alpha_1 \le 0,\ \alpha_2 \ge 0 \text{ such that} \\ &\begin{pmatrix} \lambda \\ \mu \end{pmatrix} = \begin{pmatrix} I'(x_*) & 0 \\ R_{p-1,1}[I](x_*; H_{p-1}) & 1 \end{pmatrix} \begin{pmatrix} \alpha_1 \\ \alpha_2 \end{pmatrix} \Bigg\}. \end{aligned} \tag{4.2}$$

Proof. Define a linear operator $H : X \times \mathbb{R} \to \mathbb{R}^2$ by

$$H(w, \gamma) = \begin{pmatrix} I'(x_*) & R_{p-1,1}[I](x_*; H_{p-1}) \\ 0 & 1 \end{pmatrix} \begin{pmatrix} w \\ \gamma \end{pmatrix}$$

and let K denote the open cone $K = \{(\alpha_1, \alpha_2) \in \mathbb{R}^2 : \ \alpha_1 < 0,\ \alpha_2 > 0\}$. The polar cone K^* can be identified with the closure of K. Then

$$DC^{(p)}(I; x_*, H_{p-1}) = \{(v, \gamma) \in X \times \mathbb{R} : \ H(w, \gamma) \in K\}.$$

This cone is nonempty and open. Hence it follows by the Minkowski–Farkas lemma [8, Thm. 10.4(a)] that

$$\left(DC^{(p)}(I; x_*, H_{p-1})\right)^* = H^* K^* \cong H^* \ Clos\, K.$$

This proves the proposition. □

Remark. The formulas give the general formulations of well-known formulas for the cone of decrease [8] or the expressions for second-order cones of decrease derived in [14].

5. Generalized necessary conditions for optimality for a problem with equality constraints. We include a brief derivation of the generalized necessary conditions for optimality for the minimization problem under equality constraints which does not use the Dubovitskii–Milyutin framework of Theorem 2.7. Instead this argument is based on the geometry of p-order tangent sets/cones and clearly brings out the geometric meaning of the necessary conditions. Also for this problem nonregularity of the equality constraint is equivalent to the occurrence of abnormal points.

Consider the problem (E) to minimize a functional $I : X \to \mathbb{R}$ over the set $Q = \{x \in X : \ F(x) = 0\}$ where $F : X \to Y$ is an operator between Banach spaces. We assume the following:

(B0) $x_* \in Q$ is a local minimum for problem (E).

(B1) The functional I and the operator F are sufficiently often continuously Fréchet differentiable in a neighborhood of x_*.

Naturally, a p-order approximation along $H_{p-1} = (h_1, \dots , h_{p-1}) \in X^{p-1}$ would be considered only if a $(p-1)$-order approximation remained inconclusive. Thus we also assume as given a sequence $H_{p-1} = (h_1, \dots , h_{p-1}) \in X^{p-1}$ with the following properties:

(B2) The first $p-1$ directional derivatives of F along H_{p-1} vanish,

$$\nabla^i F(x_*)(H_i) = 0 \text{ for all } \ i = 1, \dots , p-1.$$

(B3) The compatability conditions are satisfied for $i = 1, \dots , p$

$$R_{p-1,i}(x_*; H_{p-1}) \in Y_i.$$

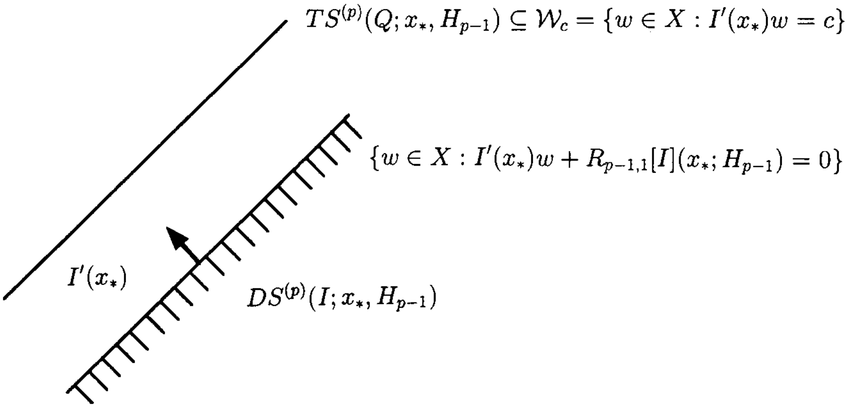
(B4) The operator F is p-regular at x_* in direction of the sequence H_{p-1}.

(B5) $\nabla^i I(x_*)(H_i) = 0$ for all $i = 1, \dots , p-1$.

Remark. By Theorem 3.2 and assumptions (B2)–(B4) there exist vectors $v \in X$ such that $H = (h_1, \dots , h_{p-1}, v)$ is a p-order approximating sequence to the set Q at $x_* \in Q$. Hence there exists an $\varepsilon_0 > 0$ and a function r defined on $[0, \varepsilon_0]$ with values in X, $r : [0, \varepsilon_0] \to X$, which is of order $o(\varepsilon^p)$ as $\varepsilon \to 0$ with the property that $x(\varepsilon) \doteq x_* + \sum_{i=1}^{p-1} \varepsilon^i h_i + \varepsilon^p v + r(\varepsilon) \in Q$. By assumption (B0) the function φ: $[0, \varepsilon_0] \to X$, $\varepsilon \to \varphi(\varepsilon) = I(x(\varepsilon))$, has a local minimum at $\varepsilon = 0$ and by assumption (B1) φ is p-times differentiable at $\varepsilon = 0$ from the right. Modulo a factorial multiplicative constant these derivatives are precisely the ith-order directional derivatives $\nabla^i I(x_*)(H_i)$ of I along the sequence H_i, $1 \le i \le p$. The first $(p-1)$ derivatives only depend on the sequence $H_{p-1} = (h_1, \dots , h_{p-1})$ and do not involve the p-order approximating vector v. Since x_* is optimal for problem (E), the first nonvanishing derivative must be positive. If this happens for a derivative $i < p$, then the necessary condition for minimality along $H = (h_1, \dots , h_{p-1}, v)$ is satisfied and indeed x_* is the minimum of I along $x(\varepsilon)$ for $\varepsilon > 0$ small enough. No further information can then be gained by considering a p-order approximating sequence along H_{p-1}. The only nontrivial situation therefore arises under assumption (B5).

Also suppose that $I'(x_*) \neq 0$. It then follows from Proposition 4.1 that the p-order set of decrease $DS^{(p)}(I; x_*, H_{p-1})$ consists of all vectors $v \in X$ which satisfy

$$I'(x_*)v + R_{p-1,1}[I](x_*; H_{p-1}) < 0 \tag{5.1}$$



$TS^{(p)}(Q;x_*,H_{p-1}) \subseteq \mathcal{W}_c = \{w \in X : I'(x_*)w = c\}$
$\{w \in X : I'(x_*)w + R_{p-1,1}[I](x_*;H_{p-1}) = 0\}$
$I'(x_*)$
$DS^{(p)}(I;x_*,H_{p-1})$

FIG. 5.1. *Geometry of the p-order tangent set and p-order set of decrease.*

and thus is a half-space with normal vector $I'(x_*)$. As in the proof of Theorem 2.7 the optimality of x_* implies that

$$DS^{(p)}(I;x_*,H_{p-1}) \cap TS^{(p)}(Q;x_*,H_{p-1}) = \emptyset, \tag{5.2}$$

where $TS^{(p)}(Q;x_*,H_{p-1})$denotes the p-order tangent set to Q at x_* in direction of the sequence H_{p-1}.

Let $\mathcal{W}_c = \{w \in X : I'(x_*)w = c\}$, $c \in \mathbb{R}$, denote the family of hyperplanes in X parallel to $\ker I'(x_*)$. The empty intersection property (5.2) is then geometrically equivalent to the fact that there exists a $c \in \mathbb{R}$ such that

$$TS^{(p)}(Q;x_*,H_{p-1}) \subseteq \mathcal{W}_c \tag{5.3}$$

and

$$c + R_{p-1,1}[I](H_{p-1}) \geq 0. \tag{5.4}$$

Condition (5.3) states that $TS^{(p)}(Q;x_*,H_{p-1})$ is contained in a parallel translation of the boundary hyperplane of $DS^{(p)}(I;x_*,H_{p-1})$, while (5.4) enforces that $TS^{(p)}(Q;x_*,H_{p-1})$ lies to the right side of $DS^{(p)}(I;x_*,H_{p-1})$ (see Fig. 5.1).

Analytically, (5.3) is equivalent to

$$\ker \mathcal{G}_p \subseteq \ker I'(x_*) = \mathcal{W}_0 \tag{5.5}$$

and thus

$$I'(x_*) \in (\ker \mathcal{G}_p)^{\perp}. \tag{5.6}$$

Hence there exist multipliers $y_i^* \in Y_{i-1}^{\perp_i}$, $i = 1, \ldots, p$, so that

$$I'(x_*) + \sum_{i=1}^{p} G_i^* y_i^* \equiv 0. \tag{5.7}$$

Furthermore, we can evaluate the constant c by substituting an arbitrary vector $v \in TS^{(p)}(Q;x_*,H_{p-1})$. Using the same notation as in the proof of Proposition 3.5, we obtain

$$\begin{aligned} c &= \langle I'(x_*), v\rangle = -\left\langle \mathcal{G}_p^* \widetilde{y}^*, v\right\rangle = -\left\langle \widetilde{y}^*, \mathcal{G}_p v\right\rangle \\ &= \langle \widetilde{y}^*, \mathcal{R}_{p-1}[F](x_*; H_{p-1})\rangle \\ &= \sum_{i=1}^{p} \langle \widetilde{y}_i^*, \pi_{i-1} R_{p-1,i}[F](x_*; H_{p-1})\rangle \\ &= \sum_{i=1}^{p} \langle y_i^*, R_{p-1,i}[F](x_*; H_{p-1})\rangle \,. \end{aligned} \tag{5.8}$$

Thus we have proven the following result.

THEOREM 5.1. *Suppose assumptions* (B0)–(B5) *are satisfied and* $I'(x_*) \neq 0$. *Then there exist multipliers* $y_i^* \in Y_{i-1}^{\perp_i}$, $i = 1, \dots, p$, *so that the following* generalized Euler–Lagrange *equation and inequality condition are satisfied*:

$$0 \equiv I'(x_*) + \sum_{i=1}^{p} G_i^* y_i^*, \tag{5.9}$$

$$0 \leq R_{p-1,1}[I](x_*; H_{p-1}) + \sum_{i=1}^{p} \langle y_i^*, R_{p-1,i}[F](x_*; H_{p-1})\rangle \,. \tag{5.10}$$

The case when $I'(x_*) = 0$ is trivial in the sense that the necessary conditions are either trivially satisfied or violated.

6. High-order feasible cones.

6.1. High-order feasible cones to inequality constraints given by smooth functionals. In this section we calculate the form of the p-order feasible cones, $FC^{(p)}(P; x_*, H_{p-1})$, introduced in section 2, for inequality constraints P described by smooth functionals

$$P = \{x \in X : f(x) \leq 0\}.$$

As with sets of decrease, if there exists a first index $i \leq p-1$ such that $\nabla^i f(x_*)(H_i) \neq 0$, then the constraint will either be satisfied for any p-order vector $v \in X$ if $\nabla^i f(x_*)(H_i) < 0$ or it will be violated if $\nabla^i f(x_*)(H_i) > 0$. This leads to the definition of p-order active constraints.

DEFINITION 6.1. *The inequality constraint P is said to be* p-order active *along the sequence H_{p-1} if for all i, $i = 1, \dots, p-1$, we have $\nabla^i f(x_*)(H_i) = 0$.*

Only p-order active constraints enter the necessary conditions for optimality derived via p-order approximations along an admissible sequence H_{p-1}; p-order inactive constraints generate zero multipliers since $DS^{(p)}(P; x_*, H_{p-1}) = X$ (p-order complementary slackness conditions). If the constraint $P = \{x \in X : f(x) \leq 0\}$ is p-order active along the sequence H_{p-1}, then v is a p-order feasible vector for P at x_* in the direction of H_{p-1}, $v \in FS^{(p)}(P; x_*, H_{p-1})$, if and only if

$$\nabla^p f(x_*)(h_1, \dots, h_{p-1}, v) = f'(x_*)v + R_{p-1,1}[f](x_*; H_{p-1}) < 0. \tag{6.1}$$

Correspondingly the p-order feasible cone, $FC^{(p)}(P; x_*, H_{p-1})$, consists of all vectors $(w, \gamma) \in X \times \mathbb{R}_+$ which satisfy

$$f'(x_*)w + \gamma R_{p-1,1}[f](x_*; H_{p-1}) < 0. \tag{6.2}$$

Thus, if $f'(x_*) \neq 0$, then

$$FC^{(p)}(P; x_*, H_{p-1}) = \{(w, \gamma) \in X \times \mathbb{R} : \gamma > 0, \quad f'(x_*)w + \gamma R_{p-1,1}[f](x_*; H_{p-1}) < 0\} \tag{6.3}$$

and thus $FC^{(p)}(P; x_*, H_{p-1})$ is nonempty, open, and convex.

6.2. High-order feasible cones to closed convex inequality constraints. We also incorporate nonoperator inequality constraints described by closed convex sets with nonempty interior into the problem formulation. This is needed for instance for the application of the results to optimal control problems.

Let $C \subset X$ be a closed convex set with nonempty interior. Again we assume that H_{p-1} is a $(p-1)$-order feasible sequence. Note that it follows from Definition 2.3 that $FS^{(p)}(C; x_*, H_{p-1})$ is open (since any vector in the neighborhood V of v also lies in $FS^{(p)}(C; x_*, H_{p-1})$). It is also clear that $FS^{(p)}(C; x_*, H_{p-1})$ is convex, since C is. Thus $FC^{(p)}(C; x_*, H_{p-1})$ is an open, convex cone. Furthermore, if there exists an integer $j < p$ so that $h_j \in FS^{(j)}(C; x_*, H_{j-1})$, then any vector v is allowed as a p-order feasible direction and thus trivially $FS^{(p)}(C; x_*, H_{p-1}) = X$, i.e., the convex constraint $x \in C$ is not p-order active. In this case the necessary conditions for optimality along H_{p-1} are exactly the same as without C.

The dual or polar cone $FC^{(p)}(C; x_*, H_{p-1})^*$ can be identified with all supporting hyperplanes to $FS^{(p)}(C; x_*, H_{p-1})$ at x_*. More precisely, we have

$$FC^{(p)}(C; x_*, H_{p-1})^* = \{(\lambda, \mu) \in X^* \times \mathbb{R} : \langle \lambda, v\rangle + \mu \geq 0 \ \forall\, v \in FS^{(p)}(C; x_*, H_{p-1})\}.$$

An important property of p-order feasible sets to convex sets relates them to the classical feasible cones as they are defined in [8]: Given a set $S \subset X$ with nonempty interior, a vector $w \in X$ is called a feasible direction to S at x_* if there exist an $\varepsilon_0 > 0$ and a neighborhood W of w so that for all $0 < \varepsilon \leq \varepsilon_0$

$$x_* + \varepsilon W \subset S. \tag{6.4}$$

It is clear that the set of feasible directions to S at x_* is a cone, called the feasible cone to S at x_* and denoted by $FC(S; x_*)$.

Proposition 6.2. *Let $C \subset X$ be a closed convex set with nonempty interior, and let H_{p-1}be a $(p-1)$-order feasible sequence. If $FS^{(p)}(C; x_*, H_{p-1})$ is nonempty, then we have that*

$$FC(C; x_*) + FS^{(p)}(C; x_*, H_{p-1}) \subseteq FS^{(p)}(C; x_*, H_{p-1}) \tag{6.5}$$

and

$$FC(C; x_*) \times \{0\} \subseteq \mathit{Clos}\ FC^{(p)}(C; x_*, H_{p-1}). \tag{6.6}$$

Proof. Both statements hold trivially if $FC(C; x_*)$ is empty. Otherwise, let $w \in FC(C; x_*)$ and take any $v \in FS^{(p)}(C; x_*, H_{p-1})$. Since $FC(C; x_*)$ is a cone, given λ, $0 \leq \lambda < 1$, also $\frac{1}{1-\lambda} w \in FC(C; x_*)$. Thus it is possible to choose $\varepsilon_0 > 0$ and a neighborhood V of v so that for all $0 < \varepsilon \leq \varepsilon_0$ we have

$$x_* + \sum_{i=1}^{p-1} \varepsilon^i h_i + \varepsilon^p V \subset \operatorname{int} C$$

and

$$x_* + \varepsilon^p \frac{1}{1-\lambda} w \in C. \tag{6.7}$$

Here we use the fact that without loss of generality we can rescale ε as ε^p in the definition of feasible directions. Since C is convex, we therefore get that

$$x_* + \lambda \sum_{i=1}^{p-1} \varepsilon^i h_i + \varepsilon^p(\lambda V + w) \subset \operatorname{int} C. \tag{6.8}$$

This holds for all λ, $0 \le \lambda < 1$, and thus taking the limit as $\lambda \to 1$ we obtain $v + w \in FS^{(p)}(C; x_*, H_{p-1})$.

Since $FC(C; x_*)$ is a cone, we thus have for all $\rho > 0$ that

$$(\rho w + v, 1) \in FC^{(p)}(C; x_*, H_{p-1}). \tag{6.9}$$

Equivalently,

$$\left(w + \frac{1}{\rho} v, \frac{1}{\rho} \right) \in FC^{(p)}(C; x_*, H_{p-1})$$

and taking the limit $\rho \to \infty$

$$(w, 0) \in Clos\ FC^{(p)}(C; x_*, H_{p-1}). \qquad \Box$$

COROLLARY 6.3. *Let $C \subset X$ be a closed convex set with nonempty interior and suppose the p-order feasible set $FS^{(p)}(C; x_*, H_{p-1})$ is nonempty. If $(\lambda, \mu) \in FC^{(p)}(C; x_*, H_{p-1})^*$, then $\lambda \in FC(C; x_*)^*$ and thus λ is a supporting hyperplane to C at x_*.*

Proof. If $(\lambda, \mu) \in FC^{(p)}(C; x_*, H_{p-1})^*$, then for all $w \in FC(C; x_*)$

$$0 \le \left\langle (\lambda, \mu), \begin{pmatrix} w \\ 0 \end{pmatrix} \right\rangle = \langle \lambda, w \rangle$$

and thus $\lambda \in FC(C; x_*)^*$. $\Box$

7. Generalized necessary conditions for optimality. In this section we give generalized first- and second-order necessary conditions for optimality for problem (P) based on general p-order approximations. We assume as given a sequence $H_{p-1} = (h_1, \dots, h_{p-1}) \in X^{p-1}$ with the following properties:

(P1) The first $p-1$ directional derivatives of F along H_{p-1} vanish,

$$\nabla^i F(x_*)(H_i) = 0 \text{ for all } i = 1, \dots, p-1,$$

the compatability conditions

$$R_{p-1,i}[F](x_*; H_{p-1}) \in Y_i$$

are satisfied for $i = 1, \dots, p-1$, and the operator F is p-regular at x_* in direction of the sequence H_{p-1}.

(P2) Either the first nonvanishing derivative $\nabla^i I(x_*)(H_i)$ is negative or

$$\nabla^i I(x_*)(H_i) = 0 \quad \text{for} \quad i = 1, \dots, p-1.$$

(P3) If the jth constraint is not p-order active, then the first nonzero derivative $\nabla^i f(x_*)(H_i)$ is negative.

(P4) $FS^{(p)}(C; x_*, H_{p-1})$ is nonempty.

These conditions guarantee respectively that the corresponding p-order approximating cones to the constraints or the functional I are nonempty and convex. The next theorem is a generalization of results in [14] for $p = 2$ to a general order p. It gives a generalized version of the classical first-order necessary conditions for optimality for a mathematical programming problem with convex inequality constraints [8, Thm. 11.4].

THEOREM 7.1. *If x_* is optimal for problem* (P), *then given any sequence $H_{p-1} = (h_1, \dots, h_{p-1}) \in X^{p-1}$ for which conditions* (P1)–(P4) *are satisfied, there exist Lagrange multipliers $\nu_i \geq 0$, $i = 0, 1, \dots, m$, functionals $y_i^* \in Y_{i-1}^{\perp_i}$, $i = 1, \dots, p$, and a supporting hyperplane $\langle \lambda, v \rangle + \mu \geq 0$ for all $v \in FS^{(p)}(C; x_*, H_{p-1})$, all depending on the sequence H_{p-1}, such that the multipliers ν_i, $i = 0, 1, \dots, m$, and λ do not all vanish, and*

$$\lambda \equiv \nu_0 I'(x_*) + \sum_{j=1}^{m} \nu_j f_j'(x_*) + \sum_{i=1}^{p} G_i^* y_i^*, \tag{7.1}$$

$$\begin{aligned} \mu \leq \nu_0 R_{p-1,1}[I](x_*; H_{p-1}) &+ \sum_{j=1}^{m} \nu_j R_{p-1,1}[f_j](x_*; H_{p-1}) \\ &+ \sum_{i=1}^{p} \langle y_i^*, R_{p-1,i}[F](H_{p-1}) \rangle \,. \end{aligned} \tag{7.2}$$

Furthermore, the following p-order complementary slackness conditions hold:

· $\nu_0 = 0$ *if* $DS^{(p)}(I; x_*, H_{p-1}) = X$,

· $\nu_j = 0$ *if* $FS^{(p)}(P_j; x_*, H_{p-1}) = X$ *for* $j = 1, \dots, m$,

· $\lambda = 0$ *if* $FS^{(p)}(C; x_*, H_{p-1}) = X$.

Proof. Let $H_{p-1} = (h_1, \dots, h_{p-1}) \in X^{p-1}$ be a sequence for which conditions (P1)-(P4) are satisfied. We first take care of some special cases. For simplicity of notation set $I = f_0$ and suppose that $f_j'(x_*) = 0$ for some index $j \in \{0, 1, \dots, m\}$. If also $R_{p-1,1}[f_j](x_*; H_{p-1}) \geq 0$, then the conditions of the theorem can trivially be satisfied by taking $\nu_j = 1$ and setting all other multipliers equal to zero. On the other hand, if $R_{p-1,1}[f_j](x_*; H_{p-1}) < 0$, then the corresponding p-order feasible cone (respectively cone of decrease) will be the full space (with dual cone given by $C^* = \{0\}$). Since this will not put any restrictions on admissible p-order directions we may drop the corresponding constraint along with all the inactive constraints. The corresponding multipliers must be zero and this already implies the p-order complementary slackness conditions.

Without loss of generality (or after dropping the inactive constraints) we may therefore assume that all the constraints are p-order active and that none of the gradients $f_j'(x_*)$, $j = 0, 1, \dots, m$, vanishes. In this case the p-order cone of decrease is open, nonempty and convex given by Proposition 4.1 with dual given by Proposition 4.2. These formulas also describe the p-order feasible cones and their duals for the constraints $j = 1, \dots, m$. Furthermore, under assumption (P1) the p-order tangent cone is a closed nonempty subspace described in Corollary 3.4 with dual given in Proposition 3.6.

The assertions of the theorem therefore follow from Theorem 2.7 using the specific forms of the functionals given in these results: Using Propositions 3.6 and 4.2 it follows that there exist nonnegative constants ν_j and ζ_j, $j = 0, 1, \dots, m$, functionals $y_i^* \in Y_{i-1}^{\perp_i}$, $i = 1, \dots, p$, a constant $r \geq 0$, and a functional $(\lambda, \mu) \in FC^{(p)}(C; x_*, H_{p-1})^*$ such that

$$0 = -\nu_0 I'(x_*) - \sum_{j=1}^{m} \nu_j f_j'(x_*) - \sum_{i=1}^{p} G_i^* y_i^* + \lambda \tag{7.3}$$

and

$$\begin{aligned} 0 = &-\nu_0 R_{p-1,1}[I](x_*; H_{p-1}) + \zeta_0 - \sum_{j=1}^{m} (\nu_j R_{p-1,1}[f_j](x_*; H_{p-1}) + \zeta_j) \\ &- \sum_{i=1}^{p} \langle y_i^*, R_{p-1,i}[F](H_{p-1}) \rangle + r + \mu. \end{aligned} \tag{7.4}$$

The first equation gives the generalized Euler–Lagrange equation (7.1) and the inequality condition (7.2) is obtained by dropping the nonnegative terms arising in the $\mathbb{R}$-components of the functionals in the duals to the feasible cones and the tangent cone.

It remains to verify the nontriviality of the multipliers ν_j, $j = 0, 1, \dots, m$, and λ. If all of these vanish, then by (7.1) $\sum_{i=1}^{p} G_i^* y_i^* \equiv 0$. It follows from the proof of Proposition 3.5 that there exists a $\widetilde{y}^* = (\widetilde{y}_1^*, \dots .\widetilde{y}_p^*) \in Z^*$ such that with $y_1^* \doteq \widetilde{y}_1^*$ and $y_i^* \doteq \tau_{i-1} \circ \widetilde{y}_i^*$ for $i = 2, \dots, p$, we have for all $v \in X$ that

$$\langle \widetilde{y}^*, \mathcal{G}_p v \rangle = \sum_{i=1}^{p} \langle G_i^* y_i^*, v \rangle = 0.$$

Under assumption (P1) the operator $\mathcal{G}_p$ is onto and thus $\widetilde{y}^* = 0$ and consequently also $y_i^* = 0$ for $i = 1, \dots, p$. But this contradicts the statement about the nontriviality of the multipliers λ_j in Theorem 2.7. □

Remark. Theorem 2.7 gives the formulation for the case which is *nondegenerate* in the sense that the operator $\mathcal{G}_p$ is onto. If $\mathcal{G}_p$ is not onto, but still closed, while all the other conditions of Theorem 7.1 remain in effect, then a degenerate version of this theorem can easily be obtained by choosing a nontrivial multiplier $\widetilde{y}^* \in (\operatorname{Im} \mathcal{G}_p)^\perp$ which then gives rise to nontrivial multipliers $y_i^* \in Y_{i-1}^{\perp_i}$ which have the property that $\sum_{i=1}^{p} G_i^* y_i^* \equiv 0$. Thus (7.1) still holds if we set $\nu_j = 0$ for $j = 0, 1, \dots, m$, and $\lambda = 0$. Thus the difference is that it can only be asserted that not all of the multipliers ν_j, $j = 0, 1, \dots, m$, $y_i^* \in Y_{i-1}^{\perp_i}$, $i = 1, \dots, p$, and λ do vanish.

Remark. It follows from Corollary 6.3 that λ is also a supporting functional to C at x_*. However, this is weaker than the statement that (λ, μ) defines a supporting hyperplane to $FS^{(p)}(C; x_*, H_{p-1})$.

8. Conclusion. In this paper we derived necessary conditions for optimality for extremum problems in the presence of nonregular equality constraints. Our results are based on a generalized version of the Lyusternik Theorem which describes the structure of p-order approximating sequences if the operator $\mathcal{G}_p$ is onto. Coupled with p-order approximations to inequality constraints, the Dubovitskii–Milyutin framework was then used to derive the results. In this paper we present only the result for the general mathematical programming problem with inequality constraints described by smooth functionals, but we also include inequality constraints described by convex sets. This allows us to apply these results to the optimal control problem. For the case of second-order approximations this is done in [15]; for the general case this is outlined in [17, 18].

ON REPRESENTATIONS AND INTEGRABILITY OF MATHEMATICAL STRUCTURES IN ENERGY-CONSERVING PHYSICAL SYSTEMS[*]

MORTEN DALSMO[†] AND ARJAN VAN DER SCHAFT[‡]

Abstract. In the present paper we elaborate on the underlying Hamiltonian structure of interconnected energy-conserving physical systems. It is shown that a power-conserving interconnection of port-controlled generalized Hamiltonian systems leads to an implicit generalized Hamiltonian system, and a power-conserving partial interconnection to an implicit port-controlled Hamiltonian system. The crucial concept is the notion of a (generalized) Dirac structure, defined on the space of energy-variables or on the product of the space of energy-variables and the space of flow-variables in the port-controlled case. Three natural representations of generalized Dirac structures are treated. Necessary and sufficient conditions for closedness (or integrability) of Dirac structures in all three representations are obtained. The theory is applied to implicit port-controlled generalized Hamiltonian systems, and it is shown that the closedness condition for the Dirac structure leads to strong conditions on the input vector fields.

Key words. Hamiltonian systems, Dirac structures, implicit systems, external variables, integrability, actuated mechanical systems, kinematic constraints, interconnections

1. Introduction.

Most of the current modelling and simulation approaches to (complex) physical systems (e.g., multibody systems) are based on some sort of *network representation*, where the physical system under consideration is seen as the interconnection of a (possible large) number of simple subsystems. This way of modelling has several advantages. From a physical point of view it is usually natural to regard the system as composed of subsystems, possibly from different domains (mechanical, electrical, and so on). The knowledge about subsystems can be stored in libraries, and is reusable for later occasions. Because of the modularity the modelling process can be performed in an "iterative" manner, gradually refining—if necessary—the model by adding other subsystems. Further, the approach is suited to general control design where the overall behavior of the system is sought to be improved by the addition of other subsystems or controlling devices. From a system-theoretic point of view this modular approach naturally emphasizes the need for models of systems *with* external variables, e.g., inputs and outputs.

In this paper we concentrate on the mathematical description of network representations of (lumped-parameter) *energy-conserving* physical systems. In our previous work we have shown how energy-conserving physical systems with *independent* energy variables can be naturally described as generalized Hamiltonian systems (with external variables). However, a general power-conserving interconnection of such systems will lead to a system described by differential *and* algebraic equations, that is, an *implicit* dynamical system, which can no longer be directly described as an explicit

generalized Hamiltonian system. This motivates the definition of *implicit* generalized Hamiltonian systems, as introduced in [SM2, SM3]. The main ingredient in this definition is that of a (generalized) *Dirac structure*. The relevance of Dirac structures in the Hamiltonian modelling of electrical LC-circuits with dependent storage elements (a clear example of interconnected energy-conserving systems) was already recognized in [C2].

The notion of Dirac structures was introduced by Courant and Weinstein [CW] and further investigated by Courant in [C1] as a generalization of Poisson *and* (pre)-symplectic structures. Dorfman [D1, D2] developed an algebraic theory of Dirac structures in the context of the study of completely integrable systems of partial differential equations, with the aim of describing within a Hamiltonian framework certain sets of PDEs which do not admit an easy Hamiltonian formulation in terms of Poisson or symplectic structures, due to nonlocality of the involved operators. The conceptual novelty in the approach initiated in [C2, SM2, SM3] is to use Dirac structures for the direct Hamiltonian description of differential-algebraic equations resulting from the interconnection of energy-conserving systems, including constrained systems. Although the terminology Dirac structure is derived from the "Dirac bracket" introduced by Dirac in his study of *constrained* Hamiltonian systems arising from degenerate Lagrangians [D3], our use of Dirac structures determining, together with the stored energy (Hamiltonian), the algebraic constraints as well as the dynamical equations of motion seems to be new. Furthermore, we stress the "physical" relevance of Dirac structures as naturally capturing the geometric structure of the system as arising from the *interconnection* of subsystems (see e.g., Proposition 2.2).

In Courant and Dorfman [C1, D2] the definition of a Dirac structure includes a *closedness* (or integrability) condition generalizing the Jacobi-identity for Poisson brackets or the closedness of two-forms defining symplectic structures. This condition is naturally satisfied for *constant* Dirac structures (as in the case of LC-circuits) and for Dirac structures arising from holonomic kinematic constraints in mechanical systems, but *not* for the *generalized* Dirac structures arising from nonholonomic kinematic constraints [SM1, SM3] or from general kinematic pairs in multibody systems [M2].

The structure of this paper is as follows. In section 2 we will recall the definitions of a (generalized) Dirac structure and of an implicit Hamiltonian system, and we will show how the power-conserving interconnection of port-controlled (explicit) Hamiltonian systems leads to such an implicit Hamiltonian system. In section 3 we will investigate various useful ways of representing generalized Dirac structures and consequently of representing implicit Hamiltonian systems, and we will study their relationship. Then in section 4 the closedness (or integrability) condition for Dirac structures will be worked out for the three different representations obtained. Both sections 3 and 4 use extensively techniques and results from the work of Courant and Dorfman, although the emphasis is rather different. The results of sections 3 and 4 are applied in section 5 to Dirac structures as arising in implicit generalized Hamiltonian systems with external variables. In particular it is shown that the closedness condition translates into strong conditions on the input vector fields.

A main motivation for the Hamiltonian modelling of interconnected energy-conserving physical systems is, apart from the clear motivation from a general modelling and simulation point of view, the generalization of the theory of "passivity-based control" to complex interconnected physical systems. Key concepts in this theory (see, e.g., [TA, OS, S]) are the use of the internal energy as candidate Lyapunov function, the shaping of the internal energy via state feedback, and the injection of "damping" in order to achieve asymptotic stability. This approach has shown to be very powerful in the robust and/or adaptive control of physical systems described by Euler–Lagrange or Hamiltonian equations of motion (such as robot manipulators, mobile robots, and electrical machines) and can be expected to be equally powerful for interconnected physical systems. Although it is not the topic of the present paper to demonstrate this, we indicate at the end of section 4 how the usual stability theory of Hamiltonian systems based on the Hessian matrix of the Hamiltonian can be naturally extended to implicit Hamiltonian systems. Moreover, at the end of section 5 we show the link between results in this paper and "passivity-based control" of actuated mechanical systems with kinematic constraints.

In the control design of interconnected physical systems also the system-theoretic properties (such as controllability and observability) of implicit port-controlled Hamiltonian systems will prove to be instrumental (e.g., in the analysis how much damping injection is needed for asymptotic stabilization). For explicit port-controlled generalized Hamiltonian systems some of these topics already have been studied in our previous work [SM2, MS1, MS2]. Section 5 provides only a basic framework for a study of these issues. Apart from "passivity-based control", the further exploitation of the structure of symmetries and conservation laws also has a great potential (see, e.g., [BKMM] for related developments). All this is a large area for further research.

2. Generalized Hamiltonian modelling of interconnected systems. In our previous work [MS1, MS2, MBS, MSB1, MSB2, SM1, SM2, SM3] we have argued that the basic dynamic building blocks in the network representation of energy-conserving physical systems are systems of the form

$$\begin{aligned} \dot{x} &= J(x)\tfrac{\partial H}{\partial x}(x) + g(x)f, \\ e &= g^T(x)\tfrac{\partial H}{\partial x}(x). \end{aligned} \tag{2.1}$$

Here $x = (x_1, \dots, x_n)$ denotes the vector of (independent) energy variables, defining local coordinates for the state space manifold $\mathcal{X}$, $H(x_1, \dots, x_n)$ is the total stored energy in the system, with $\frac{\partial H}{\partial x}(x)$ denoting the column-vector of partial derivatives of H, and the $n \times n$ *skew-symmetric* structure matrix $J(x)$ is associated with the network topology of the system. The columns $g_j(x)$, $j = 1, \dots, m$, of the matrix $g(x)$ define the (state modulated) transformers describing the influence of the external *flow* sources (or *inputs*) f_j, $j = 1, \dots, m$. The components e_j of e are the corresponding conjugated (with respect to the power) *efforts* (or *outputs*). Since the matrix $J(x)$ is skew-symmetric we immediately obtain the energy balance

$$\frac{\mathrm{d}}{\mathrm{dt}} H = e^T f \tag{2.2}$$

expressing that the increase in energy equals the externally supplied *power* ($e_j f_j$ is the power of the jth source). Thus (2.1) describes an energy-conserving physical system with *internal* variables $x_1, \dots, x_n$ (associated with energy storage) and *external* (or *port*) variables $f_1, \dots, f_m, e_1, \dots, e_m$ (associated with power), which can be regarded, respectively, as input and output variables.

The system (2.1) is called a port-controlled generalized *Hamiltonian* system because of the following. We may define a generalized *Poisson bracket* operation on the real functions on $\mathcal{X}$ as

$$\{F, G\}(x) = \left[\frac{\partial F}{\partial x}(x)\right]^T J(x)\, \frac{\partial G}{\partial x}(x), \quad F, G : \mathcal{X} \to \mathbb{R}, \tag{2.3}$$

Clearly, this bracket is skew-symmetric and satisfies the Leibniz identity

$$\{F, G_1G_2\}(x) = \{F, G_1\}(x)G_2(x) + G_1(x)\{F, G_2\}(x) \text{ for all } F, G_1, G_2 : \mathcal{X} \to \mathbb{R} \tag{2.4}$$

and thus $\dot{x} = J(x)\frac{\partial H}{\partial x}(x)$ can be seen as the *generalized* Hamiltonian vector field corresponding to H and the generalized Poisson bracket $\{\, ,\, \}$. This generalized Poisson bracket is a true Poisson bracket if additionally the *Jacobi-identity* is satisfied, that is,

$$\{F, \{G, K\}\} + \{G, \{K, F\}\} + \{K, \{F, G\}\} = 0 \quad \text{for all } F, G, K : \mathcal{X} \to \mathbb{R}. \tag{2.5}$$

If (and only if) the Jacobi-identity holds, there exist in a neighborhood of every point $x_0 \in \mathcal{X}$ where $J(x)$ has constant rank local *canonical* coordinates $(q, p, r) = (q_1, \dots, q_k, p_1, \dots, p_k, r_1, \dots, r_l)$ for $\mathcal{X}$ in which $J(x)$ takes the form (see e.g., [O])

$$J(q, p, r) = \begin{bmatrix} 0 & I_k & 0 \\ -I_k & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \tag{2.6}$$

implying that the Hamiltonian vector field $\dot{x} = J(x)\frac{\partial H}{\partial x}(x)$ takes the form

$$\begin{array}{rcl} \dot{q} & = & \frac{\partial H}{\partial p}(q, p, r), \\ \dot{p} & = & -\frac{\partial H}{\partial q}(q, p, r), \\ \dot{r} & = & 0 \end{array} \tag{2.7}$$

which are almost the standard Hamiltonian equations of motion except for the appearance of the conserved quantities $r_1, \dots, r_l$. Although in many cases of interest the Jacobi-identity is satisfied, there are clear examples where it is not satisfied (e.g., mechanical systems with nonholonomic kinematic constraints; see [SM1]).

The overall energy-conserving physical system is now obtained by interconnecting the various port-controlled generalized Hamiltonian subsystems as above in a power-continuous fashion (e.g., by using Kirchhoff's laws). In general this will result in a *mixed* set of differential and algebraic equations, which nevertheless is expected to be again Hamiltonian in some sense. Indeed, it can be seen that it is an *implicit* generalized Hamiltonian system, as defined in [SM2, SM3]. The key concept in the definition of an implicit generalized Hamiltonian system is the notion of a generalized Dirac structure, as introduced (in a rather different context) in [C1, D2].

First we concentrate on interconnected energy-conserving physical systems without any remaining external sources; see section 5 for the general case. In this case the Dirac structure for the interconnected system is defined solely on the space of energy-variables. Let $\mathcal{X}$ be an n-dimensional manifold with tangent bundle $T\mathcal{X}$ and cotangent bundle $T^*\mathcal{X}$. We define $T\mathcal{X} \oplus T^*\mathcal{X}$ as the smooth vector bundle over $\mathcal{X}$ with fiber at each $x \in \mathcal{X}$ given by $T_x\mathcal{X} \times T_x^*\mathcal{X}$. Let X be a smooth vector field and α a smooth one-form on $\mathcal{X}$ respectively. Then we say that the pair (X, α) belongs to a smooth vector subbundle $\mathcal{D} \subset T\mathcal{X} \oplus T^*\mathcal{X}$ (denoted $(X, \alpha) \in \mathcal{D}$) if $(X(x), \alpha(x)) \in \mathcal{D}(x)$ for every $x \in \mathcal{X}$. Furthermore for a smooth vector subbundle $\mathcal{D} \subset T\mathcal{X} \oplus T^*\mathcal{X}$ we define the smooth vector subbundle $D^\perp \subset T\mathcal{X} \oplus T^*\mathcal{X}$ as

$$\mathcal{D}^\perp = \{(X, \alpha) \in T\mathcal{X} \oplus T^*\mathcal{X} \mid \langle \alpha \mid \hat{X} \rangle + \langle \hat{\alpha} \mid X \rangle = 0, \text{ for all } (\hat{X}, \hat{\alpha}) \in \mathcal{D}\} \tag{2.8}$$

with $\langle \mid \rangle$ denoting the natural pairing between a one-form and a vector field. In (2.8) and throughout in the sequel the pairs $(X, \alpha), (\hat{X}, \hat{\alpha})$ are assumed to be pairs of smooth vector fields and smooth one-forms.

DEFINITION 2.1 (see [C1, D2]). *A generalized Dirac structure on an n-dimensional manifold $\mathcal{X}$ is a smooth vector subbundle $\mathcal{D} \subset T\mathcal{X} \oplus T^*\mathcal{X}$ such that $\mathcal{D}^\perp = \mathcal{D}$.*

If $\mathcal{D}$ satisfies an additional *closedness* (or integrability) condition, then $\mathcal{D}$ defines a Dirac structure; see section 4. Later on we will see that the *dimension* of the fibers of a generalized Dirac structure on an n-dimensional manifold is equal to n. By taking $\hat{\alpha} = \alpha$, $\hat{X} = X$ in (2.8) we obtain

$$\langle \alpha \,|\, X \rangle = 0 \quad \text{for all } (X, \alpha) \in \mathcal{D}. \tag{2.9}$$

Conversely, if (2.9) holds, then for every $(X, \alpha), (\hat{X}, \hat{\alpha}) \in \mathcal{D}$

$$\begin{aligned} 0 = \langle \alpha + \hat{\alpha} \,|\, X + \hat{X} \rangle &= \langle \alpha \,|\, X \rangle + \langle \alpha \,|\, \hat{X} \rangle + \langle \hat{\alpha} \,|\, X \rangle + \langle \hat{\alpha} \,|\, \hat{X} \rangle \\ &= \langle \alpha \,|\, \hat{X} \rangle + \langle \hat{\alpha} \,|\, X \rangle, \end{aligned} \tag{2.10}$$

and thus $\mathcal{D} \subset \mathcal{D}^\perp$. Hence a Dirac structure is a smooth vector subbundle of $T\mathcal{X} \oplus T^*\mathcal{X}$ which is *maximal* with respect to property (2.10) or (2.9).

Let now $\mathcal{X}$ be an n-dimensional manifold with a generalized Dirac structure $\mathcal{D}$, and let $H : \mathcal{X} \to \mathbb{R}$ be a Hamiltonian (energy function). Then the *implicit* generalized Hamiltonian system on $\mathcal{X}$ corresponding to $\mathcal{D}$ and H is given by the specification (see [SM2])

$$\left(\dot{x}, \frac{\partial H}{\partial x}(x) \right) \in \mathcal{D}(x). \tag{2.11}$$

By (2.9) we immediately obtain the energy conservation property $\frac{dH}{dt} = \langle \frac{\partial H}{\partial x}(x) | \dot{x} \rangle = 0$. Note that in general the specification (2.11) puts algebraic constraints on $\mathcal{X}$, since in general there will not exist for every $x \in \mathcal{X}$ a tangent vector $\dot{x} \in T_x\mathcal{X}$ such that (2.11) is satisfied. Thus (2.11) is in general a set of differential algebraic equations (DAEs). It can be seen that (2.11) generalizes the notion of an (explicit) generalized Hamiltonian system

$$\dot{x} = J(x) \frac{\partial H}{\partial x}(x), \quad J(x) = -J^T(x), \tag{2.12}$$

by noting that

$$\mathcal{D} = \{ (X, \alpha) \in T\mathcal{X} \oplus T^*\mathcal{X} \,|\, X(x) = J(x)\alpha(x),\ x \in \mathcal{X} \}$$

defines a generalized Dirac structure. (If $\alpha^T(x)J(x)\hat{\alpha}(x) + \hat{\alpha}^T(x)X(x) = 0$ for all $\hat{\alpha}$, then $X(x) = J(x)\alpha(x)$.)

A special case of a Dirac structure is that of a *constant* Dirac structure on a *linear* space.

DEFINITION 2.2. *A constant Dirac structure on a linear n-dimensional space $\mathcal{V}$ is a linear subspace $\mathcal{D} \subset \mathcal{V} \times \mathcal{V}^*$ with the property that $\mathcal{D}^\perp = \mathcal{D}$, where*

$$\mathcal{D}^\perp = \{ (v, v^*) \in \mathcal{V} \times \mathcal{V}^* \,|\, \langle v^* \,|\, \hat{v} \rangle + \langle \hat{v}^* \,|\, v \rangle = 0 \textit{ for all } (\hat{v}, \hat{v}^*) \in \mathcal{D} \}$$

where $\langle \mid \rangle$ denotes the natural pairing between $\mathcal{V}$ and $\mathcal{V}^*$.

The following proposition is derived straightforwardly.

PROPOSITION 2.1. *Let $\mathcal{V}$ be an n-dimensional linear space. A linear subspace $\mathcal{D} \subset \mathcal{V} \times \mathcal{V}^*$ defines a constant Dirac structure if and only if* $\dim \mathcal{D} = n$ *and*

$$\langle v^* \mid v \rangle = 0 \quad \textit{for all } (v, v^*) \in \mathcal{D}. \tag{2.13}$$

Proof. (Sketch; see [SM3] for details.) As in (2.9) and (2.10) we see that if $\mathcal{D}$ defines a constant Dirac structure, then (2.13) holds, while if (2.13) holds, then equivalently

$$\langle v^* \mid \hat{v} \rangle + \langle \hat{v}^* \mid v \rangle = 0 \quad \text{for all } (\hat{v}, \hat{v}^*) \in \mathcal{D}. \tag{2.14}$$

Furthermore, a subspace $\mathcal{D}$ of $\mathcal{V} \times \mathcal{V}^*$ defines a Dirac structure if it is *maximal* with respect to property (2.14), which is equivalent (see [C1]) to the property $\dim \mathcal{D} = n$. □

Now let us consider k port-controlled generalized Hamiltonian systems as in (2.1), i.e., for $i = 1, \ldots, k$

$$\begin{aligned} \dot{x}_i &= J_i(x_i)\tfrac{\partial H_i}{\partial x_i}(x_i) + g_i(x_i) f_i, \\ e_i &= g_i^T(x_i)\tfrac{\partial H_i}{\partial x_i}(x_i), \\ x_i &\in \mathcal{X}_i,\ f_i \in \mathcal{F}_i := \mathbb{R}^{m_i},\ e_i \in \mathcal{E}_i := \mathcal{F}_i^* = \mathbb{R}^{m_i}, \end{aligned} \tag{2.15}$$

with $\mathcal{X}_i$ an n_i-dimensional state space. Consider a general *power-conserving interconnection* of these systems given by an $(m_1 + \ldots + m_k)$-dimensional subspace (possibly parametrized by $x_1, \ldots, x_k$)

$$I(x_1, \ldots, x_k) \subset \mathcal{F}_1 \times \cdots \times \mathcal{F}_k \times \mathcal{E}_1 \times \cdots \times \mathcal{E}_k \tag{2.16}$$

with the property

$$(f_1, \ldots, f_k, e_1, \ldots, e_k) \in I(x_1, \ldots, x_k) \ \Rightarrow \sum_{i=1}^{k} e_i^T f_i = 0. \tag{2.17}$$

REMARK 2.1. *By Proposition* 2.1 *it follows that $I(x_1, \ldots, x_k)$ defines a constant Dirac structure on $\mathcal{F}_1 \times \ldots \times \mathcal{F}_k$, parameterized by $(x_1, \ldots, x_k)$.*

PROPOSITION 2.2. *Consider k port-controlled generalized Hamiltonian systems* (2.15) *subject to an interconnection* (2.16) *satisfying* (2.17)*. Then the resulting interconnected system is an implicit generalized Hamiltonian system with state space $\mathcal{X} := \mathcal{X}_1 \times \cdots \times \mathcal{X}_k$, Hamiltonian $H(x_1, \ldots, x_k) := H_1(x_1) + \cdots + H_k(x_k)$, and generalized Dirac structure $\mathcal{D}$ on $\mathcal{X}$ given as*

$$\begin{aligned} &(X, \alpha) = (X_1, \ldots, X_k, \alpha_1, \ldots, \alpha_k) \in \mathcal{D} \iff \\ &\textit{for all } x_i \in \mathcal{X}_i,\ \ i = 1, \ldots, k,\ \ \exists (f_1, \ldots, f_k, e_1, \ldots, e_k) \in I(x_1, \ldots, x_k) \textit{ such that} \\ &X_i(x_i) = J_i(x_i)\alpha_i(x_i) + g_i(x_i) f_i, \\ &e_i = g_i^T(x_i)\alpha_i(x_i). \end{aligned} \tag{2.18}$$

Proof. The main point is in proving that $\mathcal{D}$ given by (2.18) defines a generalized Dirac structure. Let $(X,\alpha)=(X_1,\dots,X_k,\alpha_1,\dots,\alpha_k)$ be in $\mathcal{D}^\perp$, that is, $\langle\hat\alpha\,|\,X\rangle+\langle\alpha\,|\,\hat X\rangle=0$ for all $(\hat X,\hat\alpha)=(\hat X_1,\dots,\hat X_k,\hat\alpha_1,\dots,\hat\alpha_k)$ satisfying (2.18). This means

$$\begin{aligned}
0&=\sum_{i=1}^k\Big[\hat\alpha_i^T(x_i)X_i(x_i)+\alpha_i^T(x_i)\hat X_i(x_i)\Big]\\
&=\sum_{i=1}^k\Big[\hat\alpha_i^T(x_i)X_i(x_i)+\alpha_i^T(x_i)J_i(x_i)\hat\alpha_i(x_i)+\alpha_i^T(x_i)g_i(x_i)\hat f_i\Big]\\
&=\sum_{i=1}^k\Big(\hat\alpha_i^T(x_i)\left[X_i(x_i)-J_i(x_i)\alpha_i(x_i)\right]+\alpha_i^T(x_i)g_i(x_i)\hat f_i\Big) \qquad (2.19)
\end{aligned}$$

for all $\hat\alpha_i,\hat f_i$ such that $\hat e_i=g_i^T(x_i)\hat\alpha_i(x_i)$ satisfies $(\hat f_1,\dots,\hat f_k,\hat e_1,\dots,\hat e_k)\in I(x_1,\dots,x_k)$. Letting first $\hat f_i=0$ and $\hat e_i=0$, we obtain

$$\sum_{i=1}^k\hat\alpha_i^T(x_i)\left[X_i(x_i)-J_i(x_i)\alpha_i(x_i)\right]=0 \qquad (2.20)$$

for all $\hat\alpha_i(x_i)$ such that $g_i^T(x_i)\hat\alpha_i(x_i)=0$. This means that there exist vectors $f_1,\dots,f_k$ such that

$$X_i(x_i)=J_i(x_i)\alpha_i(x_i)+g_i(x_i)f_i. \qquad (2.21)$$

Substitution into (2.19) yields

$$\begin{aligned}
0&=\sum_{i=1}^k\Big(\hat\alpha_i^T(x_i)g_i(x_i)f_i+\alpha_i^T(x_i)g_i(x_i)\hat f_i\Big)\\
&=\sum_{i=1}^k\Big(\hat e_i^Tf_i+e_i^T\hat f_i\Big) \qquad (2.22)
\end{aligned}$$

for all $\hat f_i$ and $\hat e_i=g_i^T(x_i)\hat\alpha_i(x_i)$ satisfying $(\hat f_1,\dots,\hat f_k,\hat e_1,\dots,\hat e_k)\in I(x_1,\dots,x_k)$. If $g_i^T(x_i)$ is surjective for all $i=1,\dots,k$, this means that (2.22) is satisfied for all $(\hat f_1,\dots,\hat f_k,\hat e_1,\dots,\hat e_k)\in I(x_1,\dots,x_k)$, and by Proposition 2.1 and Remark 2.1 this implies that $(f_1,\dots,f_k,e_1,\dots,e_k)\in I(x_1,\dots,x_k)$ and thus $(X,\alpha)\in\mathcal{D}$. In general we proceed as follows. Define the space of achievable flows and efforts

$$C(x_1,\dots,x_k):=\{(\hat f_1,\dots,\hat f_k,\hat e_1,\dots,\hat e_k)\,|\,\hat f_i\in\mathcal{F}_i,\ \hat e_i\in\operatorname{Im}g_i^T(x_i),\ i=1,\dots,k\}.$$

Then (2.22) implies that

$$\begin{aligned}
(f_1,\dots,f_k,e_1,\dots,e_k)&\in\left(I(x_1,\dots,x_k)\cap C(x_1,\dots,x_k)\right)^\perp\\
&=I^\perp(x_1,\dots,x_k)+C^\perp(x_1,\dots,x_k)
\end{aligned}$$

where $\perp$ denotes orthogonal complement with respect to property (2.22). By Proposition 2.1 it follows that $I^\perp(x_1,\dots,x_k)=I(x_1,\dots,x_k)$, while $C^\perp(x_1,\dots,x_k)$ is seen to be given as

$$C^\perp(x_1,\dots,x_k)=\{(f_1,\dots,f_k,e_1,\dots,e_k)\,|\,f_i\in\ker\,g_i(x_i),\ e_i=0,\ i=1,\dots,k\}.$$

Thus there exist flow vectors $f'_1, \dots, f'_k$ such that $(f'_1, \dots, f'_k, e_1, \dots, e_k) \in I(x_1, \dots, x_k)$, with $X_i(x_i) = J_i(x_i)\alpha_i(x_i) + g_i(x_i)f'_i$, $e_i = g_i^T(x_i)\alpha_i(x_i)$, showing that $(X, \alpha) \in \mathcal{D}$. Hence $\mathcal{D}^\perp \subset \mathcal{D}$. Since it is easily seen that $\mathcal{D} \subset \mathcal{D}^\perp$, this shows that $\mathcal{D}$ defines a Dirac structure. $\square$

We note that the definition of a power-conserving interconnection is very general and for example includes Kirchhoff's laws for electrical systems, the interconnection relations for generalized velocities and forces for interconnected mechanical systems (Newton's third law), as well as transformers in electrical circuits and kinematic pairs in multibody systems.

From a classical control point of view an important example of a power-conserving interconnection is the standard *feedback interconnection.*

EXAMPLE 2.1. *Consider two input-state-output systems* ("*plant*" *and* "*controller*")

$$\begin{aligned} \dot{x}_i &= g_i(x_i, u_i), \\ y_i &= h_i(x_i), \quad u_i, y_i \in \mathbb{R}^m, \quad i = 1, 2, \end{aligned} \tag{2.23}$$

and impose the (*negative*) *feedback interconnection*

$$\begin{aligned} u_2 &= y_1, \\ u_1 &= -y_2, \end{aligned} \tag{2.24}$$

leading to the explicit system

$$\begin{aligned} \dot{x}_1 &= g_1(x_1, -h_2(x_2)), \\ \dot{x}_2 &= g_2(x_2, h_1(x_1)). \end{aligned} \tag{2.25}$$

If we equate the input vectors u_i with flow vectors, and the output vectors y_i with effort vectors, then (2.24) *is a power-conserving interconnection. Proposition* 2.2 *applied to this particular case says that if both systems in* (2.23) *are Hamiltonian, then also* (2.25) *is Hamiltonian. This can be regarded as a special instance of the* passivity theorem *in input-output stability theory.*

3. Representations of generalized Dirac structures and implicit generalized Hamiltonian systems. There are different ways of representing generalized Dirac structures, and consequently of writing the equations of an implicit generalized Hamiltonian system. These representations each have their own advantages and are connected to different but equivalent ways of mathematically modelling the energy-conserving physical systems.

Before going into these representations we first note that a generalized Dirac structure $\mathcal{D}$ on an n-dimensional manifold $\mathcal{X}$ defines the smooth distributions

$$\begin{aligned} G_0 &= \{X \in T\mathcal{X} \mid (X, 0) \in \mathcal{D}\}, \\ G_1 &= \{X \in T\mathcal{X} \mid \exists \alpha \in T^*\mathcal{X} \text{ s.t. } (X, \alpha) \in \mathcal{D}\} \end{aligned} \tag{3.1}$$

and the smooth codistributions

$$\begin{aligned} P_0 &= \{\alpha \in T^*\mathcal{X} \mid (0, \alpha) \in \mathcal{D}\}, \\ P_1 &= \{\alpha \in T^*\mathcal{X} \mid \exists X \in T\mathcal{X} \text{ s.t. } (X, \alpha) \in \mathcal{D}\}. \end{aligned} \tag{3.2}$$

Define for any smooth distribution G the smooth codistribution $\operatorname{ann} G$ as

$$\operatorname{ann} G = \{\alpha \in T^*\mathcal{X} \mid \langle \alpha \mid X \rangle = 0 \text{ for all } X \in G\} \tag{3.3}$$

and for any smooth codistribution P the smooth distribution ker P as

$$\ker P = \{X \in T\mathcal{X} \mid \langle \alpha \mid X \rangle = 0 \text{ for all } \alpha \in P\}. \tag{3.4}$$

The smooth (co)distributions G_0, G_1 and P_0, P_1 are related as follows.

Proposition 3.1. *Let $\mathcal{D}$ be a generalized Dirac structure on $\mathcal{X}$ and define G_0, G_1, P_0, P_1 as in* (3.1), (3.2). *Then*

1. $G_0 = \ker P_1$, $P_0 = \operatorname{ann} G_1$;
2. $P_1 \subset \operatorname{ann} G_0$, $G_1 \subset \ker P_0$, *with equality if G_1, respectively, P_1, is constant-dimensional.*

Proof.

1. $Z \in G_0$ if and only if $(Z, 0) \in \mathcal{D}$, if and only if

$$\langle 0 \mid X \rangle + \langle \alpha \mid Z \rangle = 0 \text{ for all } (X, \alpha) \in \mathcal{D}$$

or equivalently $\langle \alpha \mid Z \rangle = 0$ for all $\alpha \in P_1$. Thus $G_0 = \ker P_1$. Similarly $\beta \in P_0$ if and only if $(0, \beta) \in \mathcal{D}$, if and only if $\langle \beta \mid X \rangle = 0$ for all $X \in G_1$, which implies $P_0 = \operatorname{ann} G_1$.

2. This follows from property 1 and the inequalities $P \subset \operatorname{ann} \ker P$, $G \subset \ker \operatorname{ann} G$, for any smooth (co)distribution P and G, with equality if P and G are constant-dimensional [NS]. □

Remark 3.1. *The distribution G_1 and the co-distribution P_1 have the following interpretation. Consider the implicit generalized Hamiltonian system* (2.11) *corresponding to a generalized Dirac structure $\mathcal{D}$ and a Hamiltonian H. Then the distribution G_1 describes the set of admissible flows $\dot{x}$. In particular, if G_1 is constant-dimensional and involutive then there are $(n - \dim G_1)$ independent conserved quantities for* (2.11). *Dually the codistribution P_1 describes the set of algebraic constraints of* (2.11), *i.e.*,

$$\frac{\partial H}{\partial x}(x) \in P_1(x). \tag{3.5}$$

Definition 3.1. *A point $x \in \mathcal{X}$ is a regular point for the Dirac structure $\mathcal{D}$ on $\mathcal{X}$ if the dimension of G_1 and P_1 (and hence, see Proposition* 3.1, *of G_0, P_0) is constant in a neighborhood of x.*

At every regular point $x \in X$ we have

$$\mathcal{D}^{\perp}(x) = \{(v, v^*) \in T_x\mathcal{X} \times T_x^*\mathcal{X} \mid \langle v^* \mid \hat{v} \rangle + \langle \hat{v}^* \mid v \rangle = 0 \text{ for all } (\hat{v}, \hat{v}^*) \in \mathcal{D}(x)\}, \tag{3.6}$$

and since $\mathcal{D}^{\perp}(x) = \mathcal{D}(x)$, we may regard $\mathcal{D}(x) \subset T_x\mathcal{X} \times T_x^*\mathcal{X}$ as a *constant* Dirac structure on $T_x\mathcal{X}$ (see Definition 2.2). Invoking Proposition 2.1 we deduce that $\dim \mathcal{D}(x) = n$ for every regular point $x \in \mathcal{X}$. Since the set of regular points is open and dense in $\mathcal{X}$, and $\mathcal{D}$ is a vector subbundle, it thus follows that

$$\dim \mathcal{D}(x) = n \quad \text{for all } x \in \mathcal{X}, \tag{3.7}$$

and therefore we may regard $\mathcal{D}(x) \subset T_x\mathcal{X} \times T_x^*\mathcal{X}$ as a constant Dirac structure on $T_x\mathcal{X}$ for *every* $x \in \mathcal{X}$. In particular it follows, since $\mathcal{D}$ is a smooth vector subbundle, that locally about every point in $\mathcal{X}$ we may find $n \times n$ matrices $E(x)$ and $F(x)$, depending smoothly on x, such that locally

$$\begin{aligned} &\mathcal{D}(x) = \{(v, v^*) \in T_x\mathcal{X} \times T_x^*\mathcal{X} \mid F(x)v = E(x)v^*\}, \\ &\operatorname{rank}[F(x) \ : \ -E(x)] = n. \end{aligned} \tag{3.8}$$

Furthermore, because $\mathcal{D} = \mathcal{D}^{\perp}$ necessarily (see [SM2])

$$E(x)F^T(x) + F(x)E^T(x) = 0. \tag{3.9}$$

We will refer to this *local* representation (3.8), (3.9) of a Dirac structure as *representation* I. Given a Hamiltonian $H : \mathcal{X} \to \mathbb{R}$ the corresponding implicit generalized Hamiltonian system in representation I is locally given as

$$F(x)\dot{x} = E(x)\frac{\partial H}{\partial x}(x). \tag{3.10}$$

Example 3.1 ([SM2]; see also [MSB2]). *An LC-circuit is composed of a set of* (*multiport*) *inductors and capacitors interconnected through their ports by the network graph. An n-port inductor is defined by flux linkage variables* $\phi \in \mathbb{R}^n$ (*the energy variables*) *and an energy function* $H_L(\phi)$. *The port variables are the voltages* $v_L \in \mathbb{R}^n$ *and the currents* $i_L \in \mathbb{R}^n$ *defined as*

$$v_L = \dot{\phi}, \;\; i_L = \frac{\partial H_L}{\partial \phi}. \tag{3.11}$$

Similarly, an n-port capacitor is defined by charge variables $q \in \mathbb{R}^n$ *and energy function* $H_C(q)$, *with port variables the currents* $i_C \in \mathbb{R}^n$ *and voltages* $v_C \in \mathbb{R}^n$ *defined as*

$$i_C = \dot{q}, \;\; v_C = \frac{\partial H_C}{\partial q}. \tag{3.12}$$

By Kirchhoff's laws we obtain $n_L + n_C$ *independent equations*

$$F_C i_C + E_C i_L = 0, \;\; F_L v_L + E_L v_C = 0 \tag{3.13}$$

for certain matrices F_C, F_L, E_C, *and* E_L *satisfying (Tellegen's theorem)*

$$E_C F_L^T + F_C E_L^T = 0. \tag{3.14}$$

Using (3.11), (3.12) *and defining the total energy* $H(q, \phi) = H_L(\phi) + H_C(q)$, *we may rewrite* (3.13) *as the implicit generalized Hamiltonian system*

$$\underbrace{\begin{bmatrix} F_C & 0 \\ 0 & F_L \end{bmatrix}}_{F} \begin{bmatrix} \dot{q} \\ \dot{\phi} \end{bmatrix} = \underbrace{\begin{bmatrix} 0 & -E_C \\ -E_L & 0 \end{bmatrix}}_{E} \begin{bmatrix} \frac{\partial H}{\partial q} \\ \frac{\partial H}{\partial \phi} \end{bmatrix}, \tag{3.15}$$

where $EF^T + FE^T = 0$ *by* (3.14).

Two other useful types of representations of generalized Dirac structures, which admit a *global* and *coordinate-free* definition, can be given provided an extra regularity condition is satisfied. We will denote them as representation II and representation III, respectively.

Theorem 3.1 (representation II). *Let* $\mathcal{X}$ *be an n-dimensional manifold. Let* G *be a constant-dimensional distribution on* $\mathcal{X}$, *and* $J(x) : T_x^*\mathcal{X} \to T_x\mathcal{X}$, $x \in \mathcal{X}$, *a skew-symmetric vector bundle map. Then*

$$\mathcal{D} = \{(X, \alpha) \in T\mathcal{X} \oplus T^*\mathcal{X} \mid X(x) - J(x)\alpha(x) \in G(x), x \in \mathcal{X}, \alpha \in \operatorname{ann} G\} \tag{3.16}$$

defines a generalized Dirac structure. Conversely, let $\mathcal{D}$ *be any generalized Dirac structure having the property that the codistribution* P_1 (*see* (3.2)) *is constant-dimensional.*

Then there exists a skew-symmetric vector bundle map $J(x) : P_1(x) \to (P_1(x))^*$, $x \in \mathcal{X}$, *which locally can be extended to a skew-symmetric vector bundle map* $J(x) : T_x^*\mathcal{X} \to T_x\mathcal{X}$, $x \in \mathcal{X}$, *such that* $\mathcal{D}$ *is given by* (3.16) *with* $G := \ker P_1$.

Proof (see also [C1] for the constant case). Let $\mathcal{D}$ be given by (3.16). We have to show that $\mathcal{D}^\perp = \mathcal{D}$.

1. Take $(X, \alpha) = (J\alpha + Z, \alpha) \in \mathcal{D}$, with $Z \in G$. Then for all $(\hat{X}, \hat{\alpha}) = (J\hat{\alpha} + \hat{Z}, \hat{\alpha}) \in \mathcal{D}$, $\hat{Z} \in G$

$$\langle \alpha \,|\, \hat{X} \rangle + \langle \hat{\alpha} \,|\, X \rangle = \langle \alpha \,|\, J\hat{\alpha} \rangle + \langle \hat{\alpha} \,|\, J\alpha \rangle + \langle \alpha \,|\, \hat{Z} \rangle + \langle \hat{\alpha} \,|\, Z \rangle = 0$$

because $J(x)$ is skew-symmetric, and $\alpha, \hat{\alpha} \in \operatorname{ann} G$.

2. Take $(X, \alpha) \in \mathcal{D}^\perp$, that is for all $(\hat{X}, \hat{\alpha}) = (J\hat{\alpha} + \hat{Z}, \hat{\alpha}) \in \mathcal{D}$, $\hat{Z} \in G$, $\hat{\alpha} \in \operatorname{ann} G$

$$0 = \langle \alpha \,|\, \hat{X} \rangle + \langle \hat{\alpha} \,|\, X \rangle = \langle \alpha \,|\, J\hat{\alpha} \rangle + \langle \alpha \,|\, \hat{Z} \rangle + \langle \hat{\alpha} \,|\, X \rangle$$

First let $\hat{Z} = 0$. Then

$$0 = \langle \alpha \,|\, J\hat{\alpha} \rangle + \langle \hat{\alpha} \,|\, X \rangle = \langle \hat{\alpha} \,|\, X - J\alpha \rangle$$

for all $\hat{\alpha} \in \operatorname{ann} G$, implying that $X - J\alpha \in \ker \operatorname{ann} G = G$, since G is constant-dimensional. Now let $\hat{\alpha} = 0$. Then

$$0 = \langle \alpha \,|\, \hat{Z} \rangle$$

for all $\hat{Z} \in G$, implying that $\alpha \in \operatorname{ann} G$.

Conversely, let $\mathcal{D}$ be a generalized Dirac structure on $\mathcal{X}$, with P_1 constant-dimensional. Then we define for every $x \in \mathcal{X}$ a linear map

$$J(x) : P_1(x) \subset T_x^*\mathcal{X} \to (P_1(x))^* \subset T_x\mathcal{X}$$

as follows. Let $v^* \in P_1(x)$, that is, there exists $v \in T_x\mathcal{X}$ such that $(v, v^*) \in \mathcal{D}(x)$. Then define

$$J(x)v^* = v \in (P_1(x))^*. \tag{3.17}$$

To see that $J(x)$ is well-defined, let also $(\hat{v}, v^*) \in \mathcal{D}(x)$. Then $(v - \hat{v}, 0) \in \mathcal{D}(x)$, which means $v - \hat{v} \in G_0(x) = \ker P_1(x)$, and thus v and $\hat{v}$ define the same linear function on $P_1(x)$. Skew-symmetry of the map $J(x) : P_1(x) \to (P_1(x))^*$ follows from

$$\langle \hat{v}^* \,|\, v \rangle + \langle v^* \,|\, \hat{v} \rangle = 0.$$

for all $(v, v^*), (\hat{v}, \hat{v}^*) \in \mathcal{D}(x)$. Finally we may locally *extend* $J(x)$ to a skew-symmetric map from $T_x\mathcal{X}$ to $T_x^*\mathcal{X}$. Now, let $(v, v^*) \in \mathcal{D}(x)$. Then by (3.17) $v = J(x)v^*$ modulo $G(x) := \ker P_1(x)$, while $v^* \in P_1(x)$, and thus $\mathcal{D}$ is indeed given by (3.16). □

REMARK 3.2. *Note* (*see* (3.17)) *that the kernel of* $J(x) : P_1(x) \to (P_1(x))^*$ *is given by* $P_0(x)$.

Given a Hamiltonian $H : \mathcal{X} \to \mathbb{R}$ the equations of the implicit generalized Hamiltonian system corresponding to representation II now take the form

$$\begin{array}{rcl} \dot{x} &=& J(x)\frac{\partial H}{\partial x}(x) + g(x)\lambda, \\ 0 &=& g^T(x)\frac{\partial H}{\partial x}(x), \end{array} \tag{3.18}$$

where $g(x)$ is any full rank matrix such that $\operatorname{Im} g(x) = G(x)$. The variables λ can be seen as Lagrange multipliers, required to keep the constraint equations $g^T(x)\frac{\partial H}{\partial x}(x) = 0$ to be satisfied for all time. Note that (3.18) can be also interpreted as a port-controlled generalized Hamiltonian system (see section 2) with the efforts (or outputs) e set equal to zero.

"Dualizing" representation II we obtain the following.

THEOREM 3.2 (representation III). *Let $\mathcal{X}$ be an n-dimensional manifold. Let P be a constant-dimensional codistribution on $\mathcal{X}$, and $\omega(x) : T_x\mathcal{X} \to T_x^*\mathcal{X}$, $x \in \mathcal{X}$, a skew-symmetric vector bundle map. Then*

$$\mathcal{D} = \{(X, \alpha) \in T\mathcal{X} \oplus T^*\mathcal{X} \mid \alpha(x) - \omega(x)X(x) \in P(x), x \in \mathcal{X}, X \in \ker P\} \tag{3.19}$$

defines a generalized Dirac structure. Conversely, let $\mathcal{D}$ be any generalized Dirac structure having the property that the distribution G_1 (*see* (3.1)) *is constant-dimensional. Then there exists a skew-symmetric vector bundle map $\omega(x) : G_1(x) \to (G_1(x))^*$, $x \in \mathcal{X}$, which locally can be extended to a skew-symmetric vector bundle map $\omega(x) : T_x\mathcal{X} \to T_x^*\mathcal{X}$, $x \in \mathcal{X}$, such that $\mathcal{D}$ is given by* (3.19) *with $P := \operatorname{ann} G_1$.*

Proof. The proof is completely dual to the proof of Theorem 3.1 □

REMARK 3.3 (see Remark 3.2). *The kernel of $\omega(x) : G_1(x) \to (G_1(x))^*$ is given by $G_0(x)$.*

The equations of an implicit generalized Hamiltonian system corresponding to Representation III and a Hamiltonian H take the form

$$\begin{aligned} \frac{\partial H}{\partial x}(x) &= \omega(x)\dot{x} + p^T(x)\lambda, \\ 0 &= p(x)\dot{x}, \end{aligned} \tag{3.20}$$

where $p(x)$ is any full rank matrix such that $\operatorname{Im} p(x) = P(x)$. A main feature of (3.20) in comparison with (3.18) is that in (3.20) the *flow constraints* $p^T(x)\dot{x} = 0$ are made explicit, while in (3.18) the algebraic constraints $g^T(x)\frac{\partial H}{\partial x}(x) = 0$ are distinguished.

EXAMPLE 3.2. *Let Q be an n-dimensional configuration manifold of a mechanical system. Classical* (*kinematic*) *constraints are given in local coordinates $q = (q_1, \dots, q_n)$ for Q as*

$$A^T(q)\dot{q} = 0 \tag{3.21}$$

with $A(q)$ an $n \times k$ matrix, $k \leq n$, with entries depending smoothly on q. We will assume that $A(q)$ has rank equal to k everywhere. The constrained Hamiltonian equations on T^*Q are classically given as (*see, e.g.,* [SM1])

$$\begin{aligned} \begin{bmatrix} \dot{q} \\ \dot{p} \end{bmatrix} &= \underbrace{\begin{bmatrix} 0 & I_n \\ -I_n & 0 \end{bmatrix}}_{J} \begin{bmatrix} \frac{\partial H}{\partial q}(q,p) \\ \frac{\partial H}{\partial p}(q,p) \end{bmatrix} + \begin{bmatrix} 0 \\ A(q) \end{bmatrix} \lambda, \\ 0 &= \begin{bmatrix} 0 & A^T(q) \end{bmatrix} \begin{bmatrix} \frac{\partial H}{\partial q}(q,p) \\ \frac{\partial H}{\partial p}(q,p) \end{bmatrix}. \end{aligned} \tag{3.22}$$

Here the constraint forces $A(q)\lambda$, with $\lambda \in \mathbb{R}^k$, are uniquely determined by the requirement that the constraints (3.21) *have to be satisfied for all time. It is straightforward* *to see that an equivalent description of the equations* (3.22) *is given as follows*

$$\begin{aligned}\begin{bmatrix}\frac{\partial H}{\partial q}(q,p)\\ \frac{\partial H}{\partial p}(q,p)\end{bmatrix} &= \underbrace{\begin{bmatrix}0 & -I_n\\ I_n & 0\end{bmatrix}}_{\omega}\begin{bmatrix}\dot q\\ \dot p\end{bmatrix} + \begin{bmatrix}A(q)\\ 0\end{bmatrix}\lambda,\\ 0 &= \begin{bmatrix}A^T(q) & 0\end{bmatrix}\begin{bmatrix}\dot q\\ \dot p\end{bmatrix}.\end{aligned}\tag{3.23}$$

Let G and P be the distribution and the codistribution, respectively, on T^*Q spanned by the columns of the matrix $\left[\begin{smallmatrix}0\\ A(q)\end{smallmatrix}\right]$ and the rows of the matrix $[A^T(q) \quad 0]$, respectively. Then, since both J and ω are skew-symmetric, it follows from Theorems 3.1 *and* 3.2 *that the pairs (J, G) and (ω, P) define representation* II *and representation* III, *respectively, of the same generalized Dirac structure. We will refer to this generalized Dirac structure as $\mathcal{D}_A$.*

As the last part of this section we will now briefly show how we can directly go from representation I to a local version of representation II or III, and vice versa. This is particularly useful in analysis, where some aspects may be more easily studied in one representation, while others are easier to address in a different representation. The transformation from representation II or III to I is direct and consists of eliminating the Lagrange multipliers λ. Indeed, consider the implicit generalized Hamiltonian system (3.18) corresponding to representation II. Since $\operatorname{rank} g(x) = k$ for all $x \in \mathcal{X}$, we can locally find an $(n-k)\times n$ matrix $s(x)$ of constant rank $n-k$ such that $s(x)g(x) = 0$. Premultiplying the first n equations of (3.18) by $s(x)$ then transforms (3.18) into the following n equations:

$$\begin{bmatrix}s(x)\\ 0\end{bmatrix}\dot x = \begin{bmatrix}s(x)J(x)\\ g^T(x)\end{bmatrix}\frac{\partial H}{\partial x}(x),\tag{3.24}$$

which is easily seen to be of the form (3.10) with $F(x) = \left[\begin{smallmatrix}s(x)\\ 0\end{smallmatrix}\right]$ and $E(x) = \left[\begin{smallmatrix}s(x)J(x)\\ g^T(x)\end{smallmatrix}\right]$ satisfying (3.8), (3.9). The transformation from Representation III to I is completely similar.

Example 3.3. *Consider again the mechanical system with kinematic constraints in Example* 3.2. *Since* $\operatorname{rank} A(q) = k$ *for all $q \in Q$, we can locally find an $(n-k)\times n$ matrix $S(q)$ of constant* rank $n-k$ *such that $S(q)A(q) = 0$. Premultiplying the first $2n$ equations of* (3.22) *by the $(2n-k)\times 2n$ matrix*

$$\begin{bmatrix}I_n & 0\\ 0 & S(q)\end{bmatrix}\tag{3.25}$$

of constant rank $2n-k$ *then transforms* (3.22) *into the following $2n$ equations*:

$$\begin{bmatrix}I_n & 0\\ 0 & S(q)\\ 0 & 0\end{bmatrix}\begin{bmatrix}\dot q\\ \dot p\end{bmatrix} = \begin{bmatrix}0 & I_n\\ -S(q) & 0\\ 0 & A^T(q)\end{bmatrix}\begin{bmatrix}\frac{\partial H}{\partial q}(q,p)\\ \frac{\partial H}{\partial p}(q,p)\end{bmatrix}.\tag{3.26}$$

The transformation from representation I to II or III is more substantial. Consider representation I as given by (3.8), (3.9). Since

$$\ker\,[F(x) \ : \ -E(x)] = \operatorname{Im}\begin{bmatrix}E^T(x)\\ -F^T(x)\end{bmatrix}\tag{3.27}$$

we deduce that locally

$$G_1(x) = \operatorname{Im} E^T(x), \quad P_1(x) = \operatorname{Im} F^T(x) \tag{3.28}$$

(while $G_0(x) = \ker F(x)$, $P_0(x) = \ker E(x)$ if $F(x)$ (respectively, $E(x)$) has constant rank). In order to obtain representation II we need to assume that P_1 has constant dimension (see Theorem 3.1), or equivalently by (3.28), $F(x)$ *has constant rank.* Then we may always locally transform the equations $F(x)v = E(x)v^*$ into the form

$$\begin{bmatrix} F_1(x) \\ 0 \end{bmatrix} v = \begin{bmatrix} E_1(x) \\ E_2(x) \end{bmatrix} v^*, \tag{3.29}$$

where $F_1(x)$ has full row rank for every x in this neighborhood. Since

$$0 = E(x)F^T(x) + F(x)E^T(x) = \begin{bmatrix} E_1(x)F_1^T(x) + F_1(x)E_1^T(x) & F_1(x)E_2^T(x) \\ E_2(x)F_1^T(x) & 0 \end{bmatrix} \tag{3.30}$$

it follows that

$$E_1(x)F_1^T(x) + F_1(x)E_1^T(x) = 0 \tag{3.31}$$

and $E_2^T(x)F_1(x) = 0$, or actually since rank $[F(x) \ : \ -E(x)] = n$

$$\ker F_1(x) = \operatorname{Im} E_2^T(x). \tag{3.32}$$

By injectivity of $F_1^T(x)$ it follows that there exists an $n \times n$ matrix $J(x)$ satisfying $J(x)F_1^T(x) = -E_1^T(x)$, which is by (3.31) skew-symmetric on $\operatorname{Im} F_1^T(x)$, and extendable to a skew-symmetric matrix on $\mathbb{R}^n$. Thus the equations (3.29) can be written as

$$\begin{aligned} &v - J(x)v^* \in \ker F_1(x) = \operatorname{Im} E_2^T(x), \\ &0 = E_2(x)v^* \end{aligned} \tag{3.33}$$

or equivalently, defining the constant rank matrix $g(x) := E_2^T(x)$,

$$\begin{aligned} v &= J(x)v^* + g(x)\lambda, \\ 0 &= g^T(x)v^* \end{aligned} \tag{3.34}$$

which is representation II. Representation III can be obtained similarly by manipulating instead of $F(x)$ the constant rank matrix $E(x)$.

4. Closedness of generalized Dirac structures. The Dirac structures $\mathcal{D}$ of Definition 2.1 are called *generalized* because they do not necessarily satisfy the following *closedness* (or *integrability*) condition.

Definition 4.1 (see [D2]). *A generalized Dirac structure $\mathcal{D}$ on $\mathcal{X}$ is called closed* (*or simply a Dirac structure*) *if for arbitrary* (X_1, α_1), (X_2, α_2), *and* $(X_3, \alpha_3) \in \mathcal{D}$ *there holds*

$$\langle L_{X_1}\alpha_2 \,|\, X_3\rangle + \langle L_{X_2}\alpha_3 \,|\, X_1\rangle + \langle L_{X_3}\alpha_1 \,|\, X_2\rangle = 0. \tag{4.1}$$

The following theorem gives a very useful characterization of closedness of a generalized Dirac structure.

Theorem 4.1 (cf. [D2, Theorem 2.1]; see also [C1]). *$\mathcal{D}$ is closed if and only if*

$$([X_1, X_2], \mathbf{i}_{X_1}\mathbf{d}\alpha_2 - \mathbf{i}_{X_2}\mathbf{d}\alpha_1 + \mathbf{d}\langle \alpha_2 \,|\, X_1\rangle) \in \mathcal{D} \quad \text{for all } (X_1, \alpha_1),\ (X_2, \alpha_2) \in \mathcal{D}. \tag{4.2}$$

Proof. First note that the identities (see, e.g., [AMR])

$$L_X\alpha = \mathbf{d}\mathbf{i}_X\alpha + \mathbf{i}_X\mathbf{d}\alpha, \tag{4.3}$$

$$\mathbf{i}_{[X,Y]}\alpha = L_X\mathbf{i}_Y\alpha - \mathbf{i}_Y L_X\alpha \tag{4.4}$$

are satisfied for all vector fields X, Y and k-forms α on $\mathcal{X}$. (The formula (4.3) is also known as *Cartan's magic formula.*) Hence,

$$\langle L_X\alpha \,|\, Y\rangle = \langle \mathbf{d}\langle \alpha \,|\, X\rangle \,|\, Y\rangle + \mathbf{d}\alpha(X,Y), \tag{4.5}$$

$$\langle \alpha \,|\, [X,Y]\rangle = -\langle \mathbf{d}\langle \alpha \,|\, X\rangle \,|\, Y\rangle + \langle L_Y\alpha \,|\, X\rangle \tag{4.6}$$

for all vector fields X, Y and one-forms α on $\mathcal{X}$.

Now take arbitrary $(X_1,\alpha_1), (X_2,\alpha_2), (X_3,\alpha_3) \in \mathcal{D}$. Then

$$\begin{aligned}
&\langle \mathbf{i}_{X_1}\mathbf{d}\alpha_2 - \mathbf{i}_{X_2}\mathbf{d}\alpha_1 + \mathbf{d}\langle \alpha_2 \,|\, X_1\rangle \,|\, X_3\rangle + \langle \alpha_3 \,|\, [X_1,X_2]\rangle \\
&\quad = \langle \mathbf{i}_{X_1}\mathbf{d}\alpha_2 \,|\, X_3\rangle - \langle \mathbf{i}_{X_2}\mathbf{d}\alpha_1 \,|\, X_3\rangle + \langle \mathbf{d}\langle \alpha_2 \,|\, X_1\rangle \,|\, X_3\rangle + \langle \alpha_3 \,|\, [X_1,X_2]\rangle \\
&\quad = \mathbf{d}\alpha_2(X_1,X_3) + \langle \mathbf{d}\langle \alpha_2 \,|\, X_1\rangle \,|\, X_3\rangle - \mathbf{d}\alpha_1(X_2,X_3) + \langle \alpha_3 \,|\, [X_1,X_2]\rangle \\
&\quad = \langle L_{X_1}\alpha_2 \,|\, X_3\rangle + \mathbf{d}\alpha_1(X_3,X_2) + \langle L_{X_2}\alpha_3 \,|\, X_1\rangle - \langle \mathbf{d}\langle \alpha_3 \,|\, X_1\rangle \,|\, X_2\rangle \\
&\quad = \langle L_{X_1}\alpha_2 \,|\, X_3\rangle + \langle L_{X_2}\alpha_3 \,|\, X_1\rangle + \langle L_{X_3}\alpha_1 \,|\, X_2\rangle \qquad (4.7)
\end{aligned}$$

since $\mathbf{d}\alpha_1(X_2,X_3) = -\mathbf{d}\alpha_1(X_3,X_2)$, and $\mathbf{d}\langle \alpha_3 \,|\, X_1\rangle + \mathbf{d}\langle \alpha_1 \,|\, X_3\rangle = 0$ because (X_1,α_1), $(X_3,\alpha_3) \in \mathcal{D}$. Thus,

$$\begin{gathered}
\mathcal{D} \text{ is closed} \\
\Updownarrow \\
\langle L_{X_1}\alpha_2 \,|\, X_3\rangle + \langle L_{X_2}\alpha_3 \,|\, X_1\rangle + \langle L_{X_3}\alpha_1 \,|\, X_2\rangle = 0 \\
\text{for all } (X_1,\alpha_1), (X_2,\alpha_2), (X_3,\alpha_3) \in \mathcal{D} \\
\Updownarrow \\
\langle \mathbf{i}_{X_1}\mathbf{d}\alpha_2 - \mathbf{i}_{X_2}\mathbf{d}\alpha_1 + \mathbf{d}\langle \alpha_2 \,|\, X_1\rangle \,|\, X_3\rangle + \langle \alpha_3 \,|\, [X_1,X_2]\rangle = 0 \\
\text{for all } (X_1,\alpha_1), (X_2,\alpha_2), (X_3,\alpha_3) \in \mathcal{D} \\
\Updownarrow \\
([X_1,X_2], \mathbf{i}_{X_1}\mathbf{d}\alpha_2 - \mathbf{i}_{X_2}\mathbf{d}\alpha_1 + \mathbf{d}\langle \alpha_2 \,|\, X_1\rangle) \in \mathcal{D} \\
\text{for all } (X_1,\alpha_1), (X_2,\alpha_2) \in \mathcal{D},
\end{gathered}$$

where the last equivalence follows from the fact that $\mathcal{D} = \mathcal{D}^{\perp}$. □

Remark 4.1. *Courant* [C1] *uses property* (4.2) *as the definition of closedness* (*or integrability*) *of a generalized Dirac structure.*

Closedness needs only to be checked on a set of pairs (X_i,α_i) which span the generalized Dirac structure $\mathcal{D}$, as follows from the following lemma.

Lemma 4.1. *Consider a generalized Dirac structure $\mathcal{D}$ on a manifold $\mathcal{X}$. Let*

$$(X_1,\alpha_1), \dots, (X_n,\alpha_n) \in \mathcal{D}$$

and suppose that

$$\big([X_i,X_j], \mathbf{i}_{X_i}\mathbf{d}\alpha_j - \mathbf{i}_{X_j}\mathbf{d}\alpha_i + \mathbf{d}\langle \alpha_j \,|\, X_i\rangle\big) \in \mathcal{D}, \quad i,j = 1,\dots,n. \tag{4.8}$$

Then also $([X,Y], \mathbf{i}_X\mathbf{d}\beta - \mathbf{i}_Y\mathbf{d}\alpha + \mathbf{d}\langle \beta \,|\, X\rangle) \in \mathcal{D}$, *where*

$$(X,\alpha) = \sum_{i=1}^{n}\zeta_i(X_i,\alpha_i), \quad (Y,\beta) = \sum_{i=1}^{n}\eta_i(X_i,\alpha_i) \tag{4.9}$$

for arbitrary $\zeta_i, \eta_i \in C^\infty(\mathcal{X})$, $i = 1,\dots,n$.

Proof. Let $\gamma = \mathbf{i}_X\mathbf{d}\beta - \mathbf{i}_Y\mathbf{d}\alpha + \mathbf{d}\langle\beta \,|\, X\rangle$. A straightforward calculation then gives

$$[X, Y] = \sum_{i,j=1}^{n} [\zeta_i X_i(\eta_j)X_j + \zeta_i\eta_j[X_i, X_j] - \eta_j X_j(\zeta_i)X_i], \tag{4.10}$$

$$\gamma = \sum_{i,j=1}^{n} [\zeta_i X_i(\eta_j)\alpha_j + \zeta_i\eta_j(\mathbf{i}_{X_i}\mathbf{d}\alpha_j - \mathbf{i}_{X_j}\mathbf{d}\alpha_i + \mathbf{d}\langle\alpha_j \,|\, X_i\rangle) - \eta_j X_j(\zeta_i)\alpha_i]. \tag{4.11}$$

Thus, from (4.8) it follows that $([X, Y], \gamma) \in \mathcal{D}$. □

A smooth function $H \in C^\infty(\mathcal{X})$ is said to be *admissible* (see [C1]) if there exists a (smooth) vector field X such that $(X, \mathbf{d}H) \in \mathcal{D}$. From the definition of the codistribution P_1 in (3.2) we see that the space of all admissible functions is given by

$$\mathcal{A}_\mathcal{D} = \{H \in C^\infty(\mathcal{X}) \,|\, \mathbf{d}H \in P_1\}. \tag{4.12}$$

There is a well-defined generalized Poisson bracket on $\mathcal{A}_\mathcal{D}$ given by the formula

$$\{H_1, H_2\}_\mathcal{D} = \langle\mathbf{d}H_1 \,|\, X_2\rangle = -\langle\mathbf{d}H_2 \,|\, X_1\rangle, \tag{4.13}$$

where $(X_1, \mathbf{d}H_1), (X_2, \mathbf{d}H_2) \in \mathcal{D}$. To show that $\{\,,\,\}_\mathcal{D}$ as defined in (4.13) is a generalized Poisson bracket is straightforward. Bilinearity of $\{\,,\,\}_\mathcal{D}$ follows from bilinearity of $\langle\ |\ \rangle$. Skew-symmetry is a consequence of (4.13). Finally, take arbitrary $(X_1, \mathbf{d}H_1), (X_2, \mathbf{d}H_2), (X_3, \mathbf{d}H_3) \in \mathcal{D}$. Then

$$\begin{aligned}\{H_1, H_2H_3\}_D &= -\langle\mathbf{d}(H_2H_3) \,|\, X_1\rangle = -\langle H_3\mathbf{d}H_2 + H_2\mathbf{d}H_3 \,|\, X_1\rangle \\ &= H_3\{H_1, H_2\}_\mathcal{D} + H_2\{H_1, H_3\}_\mathcal{D}\end{aligned} \tag{4.14}$$

so $\{\,,\,\}_\mathcal{D}$ also satisfies the Leibniz identity. For a Dirac structure given by representation II (see Theorem 3.1), $\{\,,\,\}_\mathcal{D}$ is given as follows:

$$\{H_1, H_2\}_\mathcal{D}(x) = \left[\frac{\partial H_1}{\partial x}(x)\right]^T J(x)\, \frac{\partial H_2}{\partial x}(x), \quad H_1, H_2 \in \mathcal{A}_\mathcal{D}. \tag{4.15}$$

We will now characterize closedness of a generalized Dirac structure $\mathcal{D}$ in terms of the bracket $\{\,,\,\}_\mathcal{D}$ and the admissible functions $\mathcal{A}_\mathcal{D}$. The following necessary conditions for closedness follow from Theorem 4.1.

Corollary 4.1 (cf. [C1, D2]). *If $\mathcal{D}$ is closed, then*

1. *G_0 and G_1 are involutive distributions*;
2. $\{H_1, H_2\}_D \in \mathcal{A}_\mathcal{D}$;
3. $\{H_1, \{H_2, H_3\}_\mathcal{D}\}_D + \{H_2, \{H_3, H_1\}_\mathcal{D}\}_D + \{H_3, \{H_1, H_2\}_\mathcal{D}\}_D = 0$

for all $H_1, H_2, H_3 \in \mathcal{A}_\mathcal{D}$.

Proof.

1. Let $X_1, X_2 \in G_0$, i.e., $(X_1, 0), (X_2, 0) \in \mathcal{D}$. Then by Theorem 4.1 $([X_1, X_2], 0) \in \mathcal{D}$, which means that $[X_1, X_2] \in G_0$. Involutivity of G_1 also follows directly from Theorem 4.1.
2. Take $H_1, H_2 \in \mathcal{A}_\mathcal{D}$ so that $(X_1, \mathbf{d}H_1), (X_2, \mathbf{d}H_2) \in \mathcal{D}$. Then we have $([X_1, X_2], \mathbf{d}\langle\mathbf{d}H_2 \,|\, X_1\rangle) \in \mathcal{D}$, which means that

$$\mathbf{d}\langle\mathbf{d}H_2 \,|\, X_1\rangle = \mathbf{d}\{H_2, H_1\}_\mathcal{D} \in P_1 \;\; \Rightarrow \;\; \{H_1, H_2\}_\mathcal{D} \in \mathcal{A}_\mathcal{D}. \tag{4.16}$$

3. Take $H_1, H_2, H_3 \in \mathcal{A}_{\mathcal{D}}$ so that $(X_1, \mathbf{d}H_1), (X_2, \mathbf{d}H_2), (X_3, \mathbf{d}H_3) \in \mathcal{D}$. Then

$$\begin{aligned} 0 &= \langle L_{X_1}\mathbf{d}H_2 \,|\, X_3\rangle + \langle L_{X_2}\mathbf{d}H_3 \,|\, X_1\rangle + \langle L_{X_3}\mathbf{d}H_1 \,|\, X_2\rangle \\ &= \langle \mathbf{d}\langle \mathbf{d}H_2 \,|\, X_1\rangle \,|\, X_3\rangle + \langle \mathbf{d}\langle \mathbf{d}H_3 \,|\, X_2\rangle \,|\, X_1\rangle + \langle \mathbf{d}\langle \mathbf{d}H_1 \,|\, X_3\rangle \,|\, X_2\rangle \\ &= \langle \mathbf{d}\{H_2, H_1\}_{\mathcal{D}} \,|\, X_3\rangle + \langle \mathbf{d}\{H_3, H_2\}_{\mathcal{D}} \,|\, X_1\rangle + \langle \mathbf{d}\{H_1, H_3\}_{\mathcal{D}} \,|\, X_2\rangle \qquad (4.17) \\ &= \{\{H_2, H_1\}_{\mathcal{D}}, H_3\}_{\mathcal{D}} + \{\{H_3, H_2\}_{\mathcal{D}}, H_1\}_{\mathcal{D}} + \{\{H_1, H_3\}_{\mathcal{D}}, H_2\}_{\mathcal{D}} \\ &= \{H_1, \{H_2, H_3\}_{\mathcal{D}}\}_{\mathcal{D}} + \{H_2, \{H_3, H_1\}_{\mathcal{D}}\}_{\mathcal{D}} + \{H_3, \{H_1, H_2\}_{\mathcal{D}}\}_{\mathcal{D}}. \qquad \square \end{aligned}$$

If in addition the codistribution P_1 (see (3.2)) is constant-dimensional, the following theorem gives necessary *and* sufficient conditions for closedness in terms of $\{\,,\,\}_{\mathcal{D}}$ and $\mathcal{A}_{\mathcal{D}}$.

THEOREM 4.2. *Consider a generalized Dirac structure $\mathcal{D}$ on a manifold $\mathcal{X}$. Let P_1 denote the codistribution on $\mathcal{X}$ defined by* (3.2). *Assume that P_1 is constant-dimensional. Then $\mathcal{D}$ is closed if and only if the following three conditions are satisfied*:

1. $G_0 = \ker P_1$ *is involutive*;
2. $\{H_1, H_2\}_{\mathcal{D}} \in \mathcal{A}_{\mathcal{D}}$;
3. $\{H_1, \{H_2, H_3\}_{\mathcal{D}}\}_D + \{H_2, \{H_3, H_1\}_{\mathcal{D}}\}_D + \{H_3, \{H_1, H_2\}_{\mathcal{D}}\}_D = 0$

for all $H_1, H_2, H_3 \in \mathcal{A}_{\mathcal{D}}$.

Proof. The necessity of these three conditions follows from Corollary 4.1 so we have to show only the sufficiency part here. First note that by using Proposition 3.1 we have that $P_1 = \operatorname{ann} G_0$. Since $G_0 = \ker P_1$ is involutive and P_1 is constant-dimensional, by Frobenius's theorem in a neighborhood of any point $x_0 \in \mathcal{X}$ there exist local coordinates $x = (x_1, \dots, x_n)$ such that

$$P_1 = \operatorname{ann} G_0 = \operatorname{span}\{\mathbf{d}x_1, \dots, \mathbf{d}x_{n-m}\}, \qquad (4.18)$$

where $m = \dim \ker P_1$ $(= \dim G_0)$. In the following, every computation is done in such a neighborhood using local coordinates.

Take now arbitrary $(X_1, \alpha_1), (X_2, \alpha_2) \in \mathcal{D}$. Then, since $\alpha_1, \alpha_2 \in P_1$, we have that

$$\alpha_1 = \sum_{i=1}^{n-m} \zeta_i \mathbf{d}x_i, \qquad (4.19)$$

$$\alpha_2 = \sum_{i=1}^{n-m} \eta_i \mathbf{d}x_i, \qquad (4.20)$$

where ζ_i, η_i are smooth functions. Now, let the vector fields $Y_1, \dots, Y_{n-m}$ be such that

$$(Y_i, \mathbf{d}x_i) \in \mathcal{D}, \quad 1 \le i \le n-m. \qquad (4.21)$$

Since also $(X_1, \alpha_1) \in \mathcal{D}$ it follows that

$$\langle \mathbf{d}x_k \,|\, X_1\rangle + \left\langle \sum_{i=1}^{n-m} \zeta_i \mathbf{d}x_i \,\middle|\, Y_k \right\rangle = 0 \qquad (4.22)$$

so

$$\langle \mathbf{d}x_k \,|\, X_1\rangle = -\sum_{i=1}^{n-m} \zeta_i \{x_i, x_k\}_{\mathcal{D}} \qquad (4.23)$$

for $1 \leq k \leq n-m$. Define the vector fields Z_1, Z_2 as

$$Z_1 = X_1 - \sum_{i=1}^{n-m} \zeta_i Y_i, \tag{4.24}$$

$$Z_2 = X_2 - \sum_{i=1}^{n-m} \eta_i Y_i. \tag{4.25}$$

Then

$$\begin{aligned}
\langle \mathbf{d}x_k \,|\, Z_1 \rangle &= \left\langle \mathbf{d}x_k \middle| X_1 - \sum_{i=1}^{n-m} \zeta_i Y_i \right\rangle \\
&= -\sum_{i=1}^{n-m} \zeta_i \{x_i, x_k\}_{\mathcal{D}} - \sum_{i=1}^{n-m} \zeta_i \{x_k, x_i\}_{\mathcal{D}} \\
&= 0 \qquad (4.26)
\end{aligned}$$

for all $1 \leq k \leq n-m$ since $\{x_i, x_k\}_{\mathcal{D}} = -\{x_k, x_i\}_{\mathcal{D}}$. This means that $Z_1 \in \ker P_1 = G_0$ and

$$X_1 = \sum_{i=1}^{n-m} \zeta_i Y_i + Z_1, \tag{4.27}$$

$$X_2 = \sum_{i=1}^{n-m} \eta_i Y_i + Z_2, \tag{4.28}$$

where $Z_1, Z_2 \in G_0$.

Now we want to calculate the term

$$\alpha_{12} = \mathbf{i}_{X_1} \mathbf{d}\alpha_2 - \mathbf{i}_{X_2} \mathbf{d}\alpha_1 + \mathbf{d}\langle \alpha_2 \,|\, X_1 \rangle. \tag{4.29}$$

We have $\mathbf{d}\alpha_2 = \mathbf{d}(\sum_{i=1}^{n-m} \eta_i \mathbf{d}x_i) = \sum_{i=1}^{n-m} \mathbf{d}\eta_i \wedge \mathbf{d}x_i$, so

$$\begin{aligned}
\mathbf{i}_{X_1} \mathbf{d}\alpha_2 &= \mathbf{i}_{X_1} \left(\sum_{i=1}^{n-m} \mathbf{d}\eta_i \wedge \mathbf{d}x_i \right) \\
&= \sum_{i=1}^{n-m} \left[\mathbf{i}_{X_1} \mathbf{d}\eta_i \wedge \mathbf{d}x_i - \mathbf{d}\eta_i \wedge \mathbf{i}_{X_1} \mathbf{d}x_i \right] \\
&= \sum_{i=1}^{n-m} \left[\left\langle \mathbf{d}\eta_i \middle| \sum_{j=1}^{n-m} \zeta_j Y_j + Z_1 \right\rangle \mathbf{d}x_i - \left\langle \mathbf{d}x_i \middle| \sum_{j=1}^{n-m} \zeta_j Y_j + Z_1 \right\rangle \mathbf{d}\eta_i \right] \\
&= \sum_{i,j=1}^{n-m} \left[\zeta_j Y_j(\eta_i) \mathbf{d}x_i - \zeta_j \{x_i, x_j\}_D \mathbf{d}\eta_i \right] + \sum_{i=1}^{n-m} Z_1(\eta_i) \mathbf{d}x_i, \qquad (4.30)
\end{aligned}$$

where we used the fact that $\langle \mathbf{d}x_i \,|\, Z_1 \rangle = 0$ since $\mathbf{d}x_i \in \operatorname{ann} G_0$. Similarly we obtain

$$\mathbf{i}_{X_2} \mathbf{d}\alpha_1 = \sum_{i,j=1}^{n-m} [\eta_j Y_j(\zeta_i) \mathbf{d}x_i - \eta_j \{x_i, x_j\}_{\mathcal{D}} \mathbf{d}\zeta_i] + \sum_{i=1}^{n-m} Z_2(\zeta_i) \mathbf{d}x_i. \tag{4.31}$$

Moreover,

$$\begin{aligned}\mathbf{d}\langle \alpha_2 \,|\, X_1\rangle &= \mathbf{d}\left\langle \sum_{i=1}^{n-m} \eta_i \mathbf{d}x_i \,\middle|\, \sum_{j=1}^{n-m} \zeta_j Y_j + Z_1 \right\rangle \\ &= \mathbf{d}\left[\sum_{i,j=1}^{n-m} \eta_i \zeta_j \left\langle \mathbf{d}x_i \,|\, Y_j \right\rangle\right] \\ &= \mathbf{d}\left[\sum_{i,j=1}^{n-m} \eta_i \zeta_j \{x_i, x_j\}_{\mathcal{D}}\right] \\ &= \sum_{i,j=1}^{n-m} [\eta_i \zeta_j \mathbf{d}\{x_i, x_j\}_{\mathcal{D}} + \{x_i, x_j\}_{\mathcal{D}}(\zeta_j \mathbf{d}\eta_i + \eta_i \mathbf{d}\zeta_j)] \\ &= \sum_{i,j=1}^{n-m} [\eta_i \zeta_j \mathbf{d}\{x_i, x_j\}_{\mathcal{D}} + \{x_i, x_j\}_{\mathcal{D}}(\zeta_j \mathbf{d}\eta_i - \eta_j \mathbf{d}\zeta_i)], \qquad (4.32)\end{aligned}$$

where the last equation follows from skew-symmetry of $\{\,,\,\}_{\mathcal{D}}$. Inserting (4.30), (4.31), and (4.32) in (4.29) gives

$$\begin{aligned}\alpha_{12} &= \mathbf{i}_{X_1}\mathbf{d}\alpha_2 - \mathbf{i}_{X_2}\mathbf{d}\alpha_1 + \mathbf{d}\langle \alpha_2 \,|\, X_1\rangle \\ &= \sum_{i,j=1}^{n-m} [(\zeta_j Y_j(\eta_i) - \eta_j Y_j(\zeta_i))\mathbf{d}x_i + \eta_i \zeta_j \mathbf{d}\{x_i, x_j\}_{\mathcal{D}}] \\ &\quad + \sum_{i=1}^{n-m} (Z_1(\eta_i) - Z_2(\zeta_i))\mathbf{d}x_i. \qquad (4.33)\end{aligned}$$

From (4.33) we immediately see that $\alpha_{12} \in P_1$ since $\mathbf{d}\{x_i, x_j\}_{\mathcal{D}} \in P_1$ when $1 \le i, j \le n - m$.

Now we have to take a closer look at the term $[X_1, X_2]$. A direct calculation yields

$$\begin{aligned}[X_1, X_2] &= \left[\sum_{i=1}^{n-m} \zeta_i Y_i + Z_1, \sum_{j=1}^{n-m} \eta_j Y_j + Z_2\right] \qquad (4.34) \\ &= \sum_{i,j=1}^{n-m} \{(\zeta_j Y_j(\eta_i) - \eta_j Y_j(\zeta_i))Y_i + \eta_i \zeta_j [Y_j, Y_i]\} + \sum_{i=1}^{n-m} (Z_1(\eta_i) - Z_2(\zeta_i))Y_i + Z_{12},\end{aligned}$$

where the vector field Z_{12} is given by

$$Z_{12} = \sum_{i=1}^{n-m} (\zeta_i [Y_i, Z_2] - \eta_i [Y_i, Z_1]) + [Z_1, Z_2]. \qquad (4.35)$$

Now take arbitrary $Z \in G_0$ and consider $\mathbf{d}\{x_i, x_j\}_{\mathcal{D}} \in \operatorname{ann} G_0$ for $1 \le i, j \le n - m$.

Then

$$\begin{aligned} 0 &= \langle \mathbf{d}\{x_i, x_j\}_{\mathcal{D}} \,|\, Z\rangle \\ &= -Z(\{x_j, x_i\}_D) \\ &= -Z(Y_i(x_j)) \\ &= -Y_i(Z(x_j)) + [Y_i, Z](x_j) \\ &= \langle \mathbf{d}x_j \,|\, [Y_i, Z]\rangle \end{aligned} \tag{4.36}$$

for all $1 \le i, j \le n-m$, which means that $[Y_i, Z] \in \ker P_1 = G_0$ for all $1 \le i \le n-m$. Since G_0 is involutive we immediately see from (4.35) that also $Z_{12} \in G_0$.

Now we want to show that $([Y_j, Y_i], \mathbf{d}\{x_i, x_j\}_{\mathcal{D}}) \in \mathcal{D}$. We know that $\{x_i, x_j\}_{\mathcal{D}} \in \mathcal{A}_{\mathcal{D}}$, which means that there exist vector fields Y_{ij} such that $(Y_{ij}, \mathbf{d}\{x_i, x_j\}_{\mathcal{D}}) \in \mathcal{D}$, $i, j = 1, \ldots, n-m$. Then

$$\begin{aligned} \langle \mathbf{d}x_k \,|\, [Y_j, Y_i] - Y_{ij}\rangle &= [Y_j, Y_i](x_k) - Y_{ij}(x_k) \\ &= Y_j(\langle \mathbf{d}x_k \,|\, Y_i\rangle) - Y_i(\langle \mathbf{d}x_k \,|\, Y_j\rangle) - \langle \mathbf{d}x_k \,|\, Y_{ij}\rangle \\ &= \langle \mathbf{d}\{x_k, x_i\}_{\mathcal{D}} \,|\, Y_j\rangle - \langle \mathbf{d}\{x_k, x_j\}_{\mathcal{D}} \,|\, Y_i\rangle - \{x_k, \{x_i, x_j\}_{\mathcal{D}}\}_{\mathcal{D}} \\ &= \{\{x_k, x_i\}_{\mathcal{D}}, x_j\}_{\mathcal{D}} - \{\{x_k, x_j\}_{\mathcal{D}}, x_i\}_{\mathcal{D}} - \{x_k, \{x_i, x_j\}_{\mathcal{D}}\}_{\mathcal{D}} \\ &= \{x_j, \{x_i, x_k\}_{\mathcal{D}}\}_{\mathcal{D}} + \{x_i, \{x_k, x_j\}_{\mathcal{D}}\}_{\mathcal{D}} + \{x_k, \{x_j, x_i\}_{\mathcal{D}}\}_{\mathcal{D}} \\ &= 0 \end{aligned} \tag{4.37}$$

when $1 \le i, j, k \le n-m$, which means that $[Y_j, Y_i] - Y_{ij} \in \ker P_1 = G_0$. Thus,

$$([Y_j, Y_i], \mathbf{d}\{x_i, x_j\}) \in \mathcal{D}, \quad i, j = 1, \ldots, n-m, \tag{4.38}$$

and by inspection of (4.33) and (4.34) we see that $([X_1, X_2], \alpha_{12}) \in \mathcal{D}$, and closedness of $\mathcal{D}$ follows from Theorem 4.1. □

In the following we will explicitly characterize closedness in the three different *representations* of a Dirac structure.

THEOREM 4.3 (representation I). *Consider a generalized Dirac structure $\mathcal{D}$ on a manifold $\mathcal{X}$ given locally in representation* I (*see* (3.8), (3.9)). *Define $(X_i, \alpha_i) \in \mathcal{D}$ in local coordinates by*

$$X_i = E_i^T(x), \tag{4.39}$$

$$\alpha_i = -F_i^T(x), \tag{4.40}$$

*where $E_i^T(x)$ and $F_i^T(x)$ denote the i*th *column of the matrices $E^T(x)$ and $F^T(x)$, respectively. Then $\mathcal{D}$ is closed if and only if*

$$\big([X_i, X_j], \mathbf{i}_{X_i}\mathbf{d}\alpha_j - \mathbf{i}_{X_j}\mathbf{d}\alpha_i + \mathbf{d}\langle \alpha_j \,|\, X_i\rangle\big) \in \mathcal{D}(x) \tag{4.41}$$

for all $x \in \mathcal{X}$, $i, j = 1, \ldots, n$.

Proof. The proof follows from (3.27), Theorem 4.1, and Lemma 4.1. □

THEOREM 4.4 (representation II). *Let $\mathcal{X}$ be an n-dimensional manifold. Let G be a constant-dimensional distribution on $\mathcal{X}$, and $J(x) : T_x^*\mathcal{X} \to T_x\mathcal{X}$, $x \in \mathcal{X}$, be a skew-symmetric vector bundle map. Moreover, let $\{\,,\,\}$ denote the generalized Poisson bracket corresponding to J. Then the generalized Dirac structure given by* (*see Theorem* 3.1)

$$\mathcal{D} = \{(X, \alpha) \in T\mathcal{X} \oplus T^*\mathcal{X} \,|\, X(x) - J(x)\alpha(x) \in G(x), x \in \mathcal{X}, \alpha \in \text{ann}\, G\} \tag{4.42}$$

is closed if and only if

1. *G is involutive*;
2. $\{H_1, H_2\} \in \mathcal{A}_\mathcal{D}$;
3. $\{H_1, \{H_2, H_3\}\} + \{H_2, \{H_3, H_1\}\} + \{H_3, \{H_1, H_2\}\} = 0$

for all $H_1, H_2, H_3 \in \mathcal{A}_\mathcal{D} = \{H \in C^\infty(\mathcal{X}) \mid \mathbf{d}H \in \operatorname{ann} G\}$.

Proof. The result follows from Theorem 4.2 using the facts that $G_0 = G$ and that $\{H_1, H_2\}_\mathcal{D} = \{H_1, H_2\}$ for all $H_1, H_2 \in \mathcal{A}_\mathcal{D}$. □

THEOREM 4.5 (representation III). *Let $\mathcal{X}$ be an n-dimensional manifold. Let P be a constant-dimensional codistribution on $\mathcal{X}$, and $\omega(x) : T_x\mathcal{X} \to T_x^*\mathcal{X}$, $x \in \mathcal{X}$, be a skew-symmetric vector bundle map. Then the generalized Dirac structure given by* (*see Theorem* 3.2)

$$\mathcal{D} = \{(X, \alpha) \in T\mathcal{X} \oplus T^*\mathcal{X} \mid \alpha(x) - \omega(x)X(x) \in P(x), x \in \mathcal{X}, X \in \ker\, P\} \tag{4.43}$$

is closed if and only if

1. *$\mathit{ker} P$ is involutive*;
2. $\mathbf{d}\omega(X_1, X_2, X_3) = 0$ *for all* $X_1, X_2, X_3 \in \mathit{ker} P$.

Proof. Let $(X_1, \alpha_1), (X_2, \alpha_2) \in \mathcal{D}$, i.e.,

$$\alpha_i = \mathbf{i}_{X_i}\omega + p_i, \quad p_i \in P,\ X_i \in \ker P, \quad i = 1, 2. \tag{4.44}$$

Define as in (4.29) the one-form $\alpha_{12} = \mathbf{i}_{X_1}\mathbf{d}\alpha_2 - \mathbf{i}_{X_2}\mathbf{d}\alpha_1 + \mathbf{d}\langle\alpha_2 \mid X_1\rangle$. Now, using Cartan's magic formula, we get

$$\mathbf{d}\mathbf{i}_{X_1}\omega = L_{X_1}\omega - \mathbf{i}_{X_1}\mathbf{d}\omega, \tag{4.45}$$

$$\mathbf{d}\mathbf{i}_{X_1}\mathbf{i}_{X_2}\omega = L_{X_1}\mathbf{i}_{X_2}\omega - \mathbf{i}_{X_1}L_{X_2}\omega + \mathbf{i}_{X_1}\mathbf{i}_{X_2}\mathbf{d}\omega \tag{4.46}$$

for all vector fields X_1, X_2 on $\mathcal{X}$. Hence

$$\begin{aligned} \alpha_{12} &= \mathbf{i}_{X_1}\mathbf{d}\alpha_2 - \mathbf{i}_{X_2}\mathbf{d}\alpha_1 + \mathbf{d}\langle\alpha_2 \mid X_1\rangle \\ &= \mathbf{i}_{X_1}\mathbf{d}(\mathbf{i}_{X_2}\omega + p_2) - \mathbf{i}_{X_2}\mathbf{d}(\mathbf{i}_{X_1}\omega + p_1) + \mathbf{d}\mathbf{i}_{X_1}(\mathbf{i}_{X_2}\omega + p_2) \\ &= \mathbf{i}_{X_1}\mathbf{d}\mathbf{i}_{X_2}\omega + \mathbf{i}_{X_1}\mathbf{d}p_2 - \mathbf{i}_{X_2}\mathbf{d}\mathbf{i}_{X_1}\omega - \mathbf{i}_{X_2}\mathbf{d}p_1 + \mathbf{d}\mathbf{i}_{X_1}\mathbf{i}_{X_2}\omega + \mathbf{d}\mathbf{i}_{X_1}p_2 \\ &= -\mathbf{i}_{X_2}L_{X_1}\omega + L_{X_1}\mathbf{i}_{X_2}\omega + \mathbf{i}_{X_1}\mathbf{d}p_2 - \mathbf{i}_{X_2}\mathbf{d}p_1 + \mathbf{i}_{X_2}\mathbf{i}_{X_1}\mathbf{d}\omega \\ &= \mathbf{i}_{[X_1,X_2]}\omega + \mathbf{i}_{X_1}\mathbf{d}p_2 - \mathbf{i}_{X_2}\mathbf{d}p_1 + \mathbf{i}_{X_2}\mathbf{i}_{X_1}\mathbf{d}\omega \qquad (4.47) \end{aligned}$$

since $\mathbf{i}_{[X_1,X_2]}\omega = L_{X_1}\mathbf{i}_{X_2}\omega - \mathbf{i}_{X_2}L_{X_1}\omega$. Thus, using Theorem 4.1 and the definition of $\mathcal{D}$, we have that

$$\begin{gathered} \mathcal{D} \text{ is closed} \\ \Updownarrow \\ ([X_1, X_2], \mathbf{i}_{[X_1,X_2]}\omega + \mathbf{i}_{X_1}\mathbf{d}p_2 - \mathbf{i}_{X_2}\mathbf{d}p_1 + \mathbf{i}_{X_2}\mathbf{i}_{X_1}\mathbf{d}\omega) \in \mathcal{D} \\ \text{for all } p_1, p_2 \in P, \text{ for all } X_1, X_2 \in \ker P. \\ \Updownarrow \\ \left.\begin{array}{l} [X_1, X_2] \in \ker P \\ \mathbf{i}_{X_1}\mathbf{d}p_2 - \mathbf{i}_{X_2}\mathbf{d}p_1 + \mathbf{i}_{X_2}\mathbf{i}_{X_1}\mathbf{d}\omega \in P \end{array}\right\} \text{ for all } p_1, p_2 \in P, \text{ for all } X_1, X_2 \in \ker P. \end{gathered}$$

Now, if P is a constant-dimensional codistribution and $\ker P$ is involutive, it follows that for every $p \in P$ there exists $\bar{p} \in P$ and a one-form η such that $\mathbf{d}p = \eta \wedge \bar{p}$. Thus, $\mathbf{i}_X\mathbf{d}p = \eta(X)\bar{p} \in P$ for all $X \in \ker P$. Moreover, $\mathbf{i}_{X_2}\mathbf{i}_{X_1}\mathbf{d}\omega(X_3) = \mathbf{d}\omega(X_1, X_2, X_3)$ which means that $\mathbf{i}_{X_2}\mathbf{i}_{X_1}\mathbf{d}\omega \in P$ if and only if $\mathbf{d}\omega(X_1, X_2, X_3) = 0$ for all $X_3 \in \ker\, P$ since P is constant-dimensional. □

Remark 4.2. *In* [C1] *it is shown that closedness of D implies condition* 2 *in Theorem* 4.5.

We will now apply the above theory to mechanical systems with kinematic constraints (see Example 3.2).

Proposition 4.1. *Consider the mechanical system with kinematic constraints $A^T(q)\dot{q} = 0$ as given in Example* 3.2. *Let $\{\, , \,\}$ denote the Poisson bracket defined (locally) by the structure matrix J. Then the following statements are equivalent*:

1. *$\mathcal{D}_A$ is closed*;
2. *the constraints* (3.21) *are holonomic*;
3. *$\mathbf{d}\{H_1, H_2\} \in \operatorname{ann} G$ for all H_1, H_2 such that $\mathbf{d}H_1, \mathbf{d}H_2 \in \operatorname{ann} G$.*

Proof. $1 \Leftrightarrow 2$: From Theorem 4.5 it follows that $\mathcal{D}_A$ is closed if and only if $\ker P$ is involutive which is equivalent to the constraints (3.21) being holonomic. $1 \Leftrightarrow 3$: This follows from Theorem 4.4 since G is involutive and $\{\, , \,\}$ satisfies the Jacobi identity in this case. □

The next proposition gives an interesting interpretation of closedness of generalized Dirac structures that come up in connection with Lie-Poisson structures.

Proposition 4.2. *Let G be any n-dimensional Lie group* (*e.g.*, $SE(3)$), *with Lie algebra g, and the dual Lie algebra g^* with the Lie-Poisson bracket $\{\, , \,\}$. Consider a constant distribution on g^*, that is a linear subspace $\mathcal{V} \subset g^*$. Define the Dirac structure $\mathcal{D}$ on g^* as*

$$\mathcal{D} = \{(X, \alpha) \in Tg^* \oplus T^*g^* \mid X(x) - J(x)\alpha(x) \in \mathcal{V},\ \alpha(x) \in \mathcal{V}^\perp,\ x \in g^*\}, \tag{4.48}$$

where $J(x)$ is the structure matrix of the Lie-Poisson bracket $\{\, , \,\}$. Then $\mathcal{D}$ is closed if and only if $\mathcal{V}^\perp \subset g$ is a subalgebra.

Proof. The proof follows more or less directly from results obtained in [MR, p. 287]. □

Example 4.1 ($\mathcal{X} = se^*(3) \backsimeq \mathbb{R}^6$). *The motion of a rigid body with respect to a body-fixed rotation reference frame in the center of mass is given* (*in the absence of gravity*) *by*

$$M\dot{\omega} + \omega \times M\omega = \tau, \tag{4.49}$$

$$m\dot{v} + \omega \times mv = F, \tag{4.50}$$

where $v, \omega \in \mathbb{R}^3$ are, respectively, the linear and the angular velocities, M is the inertia tensor, and $\tau, F \in \mathbb{R}^3$ are, respectively, the torques and the forces. By defining $\Pi, p \in \mathbb{R}^3$ as

$$\Pi = M\omega,\ \ \Pi = [\Pi_x, \Pi_y, \Pi_z]^T, \tag{4.51}$$

$$p = mv,\ \ p = [p_x, p_y, p_z]^T \tag{4.52}$$

and the Hamiltonian $H(\Pi, p)$ as

$$H(\Pi, p) = \frac{1}{2}\Pi^T M^{-1}\Pi + \frac{1}{2m}p^T p, \tag{4.53}$$

it follows that (4.49) *and* (4.50) *can be written as*

$$\begin{bmatrix} \dot{\Pi} \\ \dot{p} \end{bmatrix} = \underbrace{\begin{bmatrix} S(\Pi) & S(p) \\ S(p) & 0 \end{bmatrix}}_{J(\Pi,p)} \begin{bmatrix} \frac{\partial H}{\partial \Pi} \\ \frac{\partial H}{\partial p} \end{bmatrix} + \begin{bmatrix} \tau \\ F \end{bmatrix}. \tag{4.54}$$

Here $\Pi = [\Pi_x, \Pi_y, \Pi_z]^T$ *and* $p = [p_x, p_y, p_z]^T$ *are the body angular and linear momentum, respectively.* $S(\,\cdot\,)$ *is defined by* $S(a)b = a \times b$ *for* $a, b \in \mathbb{R}^3$*.* $J(\Pi, p)$ *is the structure matrix of the Lie-Poisson bracket on* $\mathcal{X} = se^*(3) \simeq \mathbb{R}^6$*.*

Assume that the following constraints are imposed on the system:

$$p_y = p_z = 0. \tag{4.55}$$

Let $e_x = [1\;0\;0]^T$, $e_y = [0\;1\;0]^T$, $e_z = [0\;0\;1]^T$*. Then*

$$\mathcal{V}^\perp = \ker \begin{bmatrix} 0 & 0 \\ e_y & e_z \end{bmatrix}, \tag{4.56}$$

which is not a subalgebra of $se(3) \simeq \mathbb{R}^6$ (*see, e.g.,* [MR])*. Hence, the corresponding generalized Dirac structure is not closed in this case. However, if the additional constraint* $p_x = 0$ *is imposed on the system* (*fixed center of mass*)*, it is easy to see that closedness of the corresponding generalized Dirac structure follows.*

Similarly to the case when the Jacobi-identity is satisfied for a generalized Poisson structure, one can show that if the closedness condition (4.1) is satisfied for a generalized Dirac structure then there exist local canonical coordinates around any *regular* point in which the geometric picture simplifies considerably (see Proposition 4.1.2 in [C1]). In our context (i.e., for generalized Dirac structures arising from physical systems) constant-dimensionality of the codistribution P_1 is often a reasonable assumption. Thus, in the next proposition we will draw attention to the existence and construction of canonical coordinates for Dirac structures that may be given in representation II (cf. Theorem 3.1). In essence, the proof of this proposition comes down to using Frobenius's theorem and a generalized version of Darboux's theorem and proceeds along the same general line as the proof of Proposition 4.1.2 in [C1]. However, we show directly how local canonical coordinates may be found for a Dirac structure in representation II. In addition, we show more explicitly where the three necessary conditions in Corollary 4.1 come into play which is interesting in itself.

Proposition 4.3. *Let* $\mathcal{D}$ *be a generalized Dirac structure on an* n*-dimensional manifold* $\mathcal{X}$*. Assume that the codistribution* P_1 (*see* (3.2)) *is constant-dimensional so that* $\mathcal{D}$ *can always be given in representation* II *as follows*:

$$\mathcal{D} = \{(X, \alpha) \in T\mathcal{X} \oplus T^*\mathcal{X} \mid X(x) - J(x)\alpha(x) \in G_0(x), x \in \mathcal{X}, \alpha \in \operatorname{ann} G_0\}, \tag{4.57}$$

where $J(x) : T_x^*\mathcal{X} \to T_x\mathcal{X}$, $x \in \mathcal{X}$, *is a skew-symmetric vector bundle map. Then, if* $\mathcal{D}$ *is closed, there exist around every regular point* $x_0 \in \mathcal{X}$ *local canonical coordinates*

$$(q, p, r, s) = (q_1, \ldots, q_k, p_1, \ldots, p_k, r_1, \ldots, r_l, s_1, \ldots, s_m), \quad 2k + l + m = n$$

for $\mathcal{X}$ *in which* $J(x)$ *and* G_0 *take the simple form*

$$J(x) = \begin{bmatrix} 0 & I_k & 0 & * \\ -I_k & 0 & 0 & * \\ 0 & 0 & 0 & * \\ * & * & * & * \end{bmatrix}, \quad G_0 = span\left\{\frac{\partial}{\partial s_1}, \ldots, \frac{\partial}{\partial s_m}\right\}, \tag{4.58}$$

where $*$ *denotes unspecified elements,* $m = n - \dim P_1$ *and* $l = n - \dim G_1(x_0)$*.*

Conversely, if $\mathcal{D}$ *is given by* (4.57), (4.58) *in a neighborhood of* $x_0 \in \mathcal{X}$*, then* $\mathcal{D}$ *is closed in this neighborhood.*

Proof. If $\mathcal{D}$ is closed, it follows from condition 1 in Corollary 4.1 that G_0 is involutive. Since $P_1 = \operatorname{ann} G_0$ is constant-dimensional, also G_0 is constant-dimensional with dimension equal to m. Thus, by Frobenius' theorem in a neighborhood N_{x_0} of any point $x_0 \in \mathcal{X}$ there exist local coordinates $(y, s) = (y_1, \dots, y_{n-m}, s_1, \dots, s_m)$, such that

$$G_0 = \operatorname{span}\left\{\frac{\partial}{\partial s_1}, \dots, \frac{\partial}{\partial s_m}\right\} \tag{4.59}$$

and

$$P_1 = \operatorname{ann} G_0 = \operatorname{span}\left\{\mathbf{d}y_1, \dots, \mathbf{d}y_{n-m}\right\}. \tag{4.60}$$

Now, $\{\,,\,\}_{\mathcal{D}}$ is given in terms of $J(x)$ as follows:

$$\{F, G\}_{\mathcal{D}}(x) = \left[\frac{\partial F}{\partial x}(x)\right]^T J(x)\,\frac{\partial G}{\partial x}(x) \tag{4.61}$$

for all $F, G \in C^\infty(\mathcal{X})$ such that $\mathbf{d}F, \mathbf{d}G \in \operatorname{ann} G_0$. Moreover, since $\mathcal{D}$ is closed, it follows from condition 2 in Corollary 4.1 that

$$\mathbf{d}\{y_i, y_j\}_{\mathcal{D}} \in \operatorname{ann} G_0, \quad i, j = 1, \dots, n-m, \tag{4.62}$$

which means that

$$\frac{\partial\{y_i, y_j\}_D}{\partial s_k} = 0, \quad k = 1, \dots, m,\ i, j = 1, \dots, n-m. \tag{4.63}$$

Hence, $J(x)$ takes the following form in the local coordinates (y, s):

$$J(y, s) = \begin{bmatrix} \bar{J}(y) & * \\ * & * \end{bmatrix} \tag{4.64}$$

where $\bar{J}(y) = [\{y_i, y_j\}_{\mathcal{D}}]$ is the $(n-m) \times (n-m)$ upper-left submatrix of $J(y, s)$. In addition, the distribution G_1 is given locally in the coordinates (y, s) as

$$G_1(y, s) = \operatorname{Im}\begin{bmatrix} \bar{J}(y) & 0 \\ 0 & I_m \end{bmatrix}. \tag{4.65}$$

If $x_0 \in \mathcal{X}$ is a regular point, then G_1 is by definition constant-dimensional in a neighborhood of x_0 which implies that $\bar{J}(y)$ has constant rank $2k = n - (l + m)$ in a neighborhood $\hat{N}_{x_0} \subset N_{x_0}$ of x_0. Define (without loss of generality) the submanifold $\mathcal{Y} \subset \mathcal{X}$ as

$$\mathcal{Y} = \{(y, s) \in \hat{N}_{x_0} \mid s = s(x_0)\}. \tag{4.66}$$

$y = (y_1, \dots, y_{n-m})$ are local coordinates for $\mathcal{Y}$ around $y_0 = y(x_0)$. Since $\mathcal{D}$ is closed, it follows from condition 3 in Corollary 4.1 that $\{\,,\,\}_{\mathcal{D}}$ defines a Poisson structure on $\mathcal{Y}$ with structure matrix $\bar{J}(y)$. Now, using the fact that $\bar{J}(y)$ has constant rank $2k \leq n - m$ for all $y \in \mathcal{Y}$, it follows from Theorem 6.22 in [O] (called the generalized Darboux's theorem; see also [W]), that around $y_0 \in \mathcal{Y}$ there exist local coordinates $(q, p, r) = (q_1, \dots, q_k, p_1, \dots, p_k, r_1, \dots, r_l)$ in which $\bar{J}(y)$ takes the form

$$\bar{J}(p, q, r) = \begin{bmatrix} 0 & I_k & 0 \\ -I_k & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}. \tag{4.67}$$

Now (q,p,r,s) are local coordinates for $\mathcal{X}$ around $x_0 \in \mathcal{X}$ in which $J(x)$ and G_0 take the simple form (4.58).

Conversely, it is easy to check that a generalized Dirac structure given by (4.57), (4.58) in a neighborhood of $x_0 \in \mathcal{X}$, satisfies the sufficient conditions for closedness as given in Theorem 4.2 in this neighborhood. □

The equations of an implicit generalized Hamiltonian system corresponding to the local representation (4.57), (4.58) and a Hamiltonian H take the form

$$\begin{array}{rcl} \dot{q} &=& \frac{\partial H}{\partial p}(q,p,r,s), \\ \dot{p} &=& -\frac{\partial H}{\partial q}(q,p,r,s), \\ \dot{r} &=& 0, \\ 0 &=& \frac{\partial H}{\partial s}(q,p,r,s). \end{array} \tag{4.68}$$

Comparing (4.68) with (2.7) we see that while (2.7) makes explicit the conserved quantities, (4.68) also makes explicit the algebraic *constraints*

$$\begin{array}{rcl} 0 &=& \frac{\partial H}{\partial s_1}(q,p,r,s), \\ & \vdots & \\ 0 &=& \frac{\partial H}{\partial s_m}(q,p,r,s). \end{array} \tag{4.69}$$

If H is nondegenerate in the energy-variables $s_1, \dots, s_m$, that is,

$$\operatorname{rank} \left[\frac{\partial^2 H}{\partial s_i \partial s_j} \right] = m, \tag{4.70}$$

then by the implicit function theorem one may locally express the variables $s_1, \dots, s_m$ as functions of $q,p,r,$ i.e., $s_i = s_i(q,p,r),\ i = 1, \dots, m.$ Defining the *constrained* Hamiltonian

$$H_c(q,p,r) := H(q,p,r,s(q,p,r)) \tag{4.71}$$

it follows that (4.68) reduces to the same format as (2.7):

$$\begin{array}{rcl} \dot{q} &=& \frac{\partial H_c}{\partial p}(q,p,r), \\ \dot{p} &=& -\frac{\partial H_c}{\partial q}(q,p,r), \\ \dot{r} &=& 0, \end{array} \tag{4.72}$$

which is an explicit Hamiltonian dynamics on the constrained state space $\mathcal{X}_c = \{(q,p,r,s) \mid \frac{\partial H}{\partial s_i}(q,p,r,s) = 0,\ i = 1, \cdots, m\}$. Also note that while under the assumption (4.70) the variables $s_1, \dots, s_m$ together with the Hamiltonian H define a (constraint) submanifold $\mathcal{X}_c$ of $\mathcal{X}$, dually the level sets of the variables $r_1, \dots, r_\ell$ define a *foliation* of $\mathcal{X}$. Both the constraint submanifold $\mathcal{X}_c$ and the foliation are *invariant* for the Hamiltonian dynamics. However, as shown in this section, there are cases of interest where the generalized Dirac structure does *not* satisfy the closedness condition (e.g., mechanical systems with *nonholonomic* constraints). Furthermore, also if the closedness condition is satisfied the actual *construction* of the canonical coordinates $q_i, p_i, r_i, s_i,$ may be very involved, and preferably should be avoided.

We remark that the representation (4.68) of an implicit Hamiltonian system with regard to a closed Dirac structure is quite amenable for *stability analysis*, at least when the nondegeneracy condition (4.70) is satisfied. Indeed, let (q_0, p_0, r_0, s_0) be an equilibrium of (4.68), that is,

$$\frac{\partial H}{\partial q}(q_0, p_0, r_0, s_0) = 0,\ \frac{\partial H}{\partial p}(q_0, p_0, r_0, s_0) = 0,\ \frac{\partial H}{\partial s}(q_0, p_0, r_0, s_0) = 0, \tag{4.73}$$

and let us also assume that $\frac{\partial H}{\partial r}(q_0, p_0, r_0, s_0) = 0$ (see later). Under the nondegeneracy condition (4.70) the implicit function theorem allows us to express the variables s locally around q_0, p_0, r_0, s_0 as functions of q, p, r leading as above to the explicit Hamiltonian dynamics (4.72). Note that in general the implicit function theorem only provides an *existence* result, and that finding the *actual* expression of s as function of q, p, r is in general not possible or preferably should be avoided.

Now, if the Hessian matrix of H_c at (q_0, p_0, r_0) is positive (or negative) definite it follows that (q_0, p_0, r_0) is a *stable* equilibrium of (4.72) (see, e.g., [MR]). On the other hand, this Hessian matrix of H_c can be easily expressed in the *original* Hamiltonian H as

$$\begin{bmatrix} \frac{\partial^2 H}{\partial q^2} & \frac{\partial^2 H}{\partial q \partial p} & \frac{\partial^2 H}{\partial q \partial r} \\ \frac{\partial^2 H}{\partial p \partial q} & \frac{\partial^2 H}{\partial p^2} & \frac{\partial^2 H}{\partial p \partial r} \\ \frac{\partial^2 H}{\partial r \partial q} & \frac{\partial^2 H}{\partial r \partial p} & \frac{\partial^2 H}{\partial r^2} \end{bmatrix} - \begin{bmatrix} \frac{\partial^2 H}{\partial q \partial s} \\ \frac{\partial^2 H}{\partial p \partial s} \\ \frac{\partial^2 H}{\partial r \partial s} \end{bmatrix} \left[\frac{\partial^2 H}{\partial s^2}\right]^{-1} \begin{bmatrix} \frac{\partial^2 H}{\partial s \partial q} & \frac{\partial^2 H}{\partial s \partial p} & \frac{\partial^2 H}{\partial s \partial r} \end{bmatrix} \tag{4.74}$$

evaluated at (q_0, p_0, r_0, s_0). Thus this way of checking stability can be performed *without* the actual computation of H_c. Furthermore, note that for checking definiteness of (4.74) only the variables s need to be explicitly computed; we may use other coordinates instead of q, p, r.

Since the variables $r_1, \ldots, r_l$ are invariants (or *Casimirs*) we may also replace in the stability analysis the constrained Hamiltonian H_c by $H_c(q, p, r) + \Phi(r)$, with Φ any function of $r = (r_1, \ldots, r_l)$. Hence we may also replace $H(q, p, r, s)$ with

$$\bar{H}_\Phi(q, p, r, s) := H(q, p, r, s) + \Phi(r) \tag{4.75}$$

and substitute $\bar{H}_\Phi$ into (4.74) in order to check definiteness. (The addition of a function $\Phi(r)$ to H_c when checking the definiteness of the Hessian is known as the energy-Casimir method; see, e.g., [MR].)

5. Implicit port-controlled generalized Hamiltonian systems.

As already alluded to in section 2, if we interconnect port-controlled Hamiltonian systems (2.1) in such a way that some of the external variables remain free port variables, then we will end up with an implicit generalized Hamiltonian system *with* external (or port) variables. In order to make this precise we give the following definition (see [SM2]).

DEFINITION 5.1. *Let $\mathcal{X}$ be an n-dimensional manifold of energy variables, and let $H : \mathcal{X} \to \mathbb{R}$ be a Hamiltonian. Furthermore, let $\mathcal{F}$ be the linear space $\mathbb{R}^m$ of external flows f, with dual the space $\mathcal{F}^*$ of external efforts e. Consider a Dirac structure on the product space $\mathcal{X} \times \mathcal{F}$, only depending on x. The implicit port-controlled generalized Hamiltonian system corresponding to $\mathcal{X}$, H, $\mathcal{D}$, and $\mathcal{F}$ is defined by the specification*

$$\left(\dot{x}, f, \frac{\partial H}{\partial x}(x), -e\right) \in \mathcal{D}(x). \tag{5.1}$$

REMARK 5.1. *The minus sign in front of the effort e comes from the natural identification $(\alpha, e) \in T^*\mathcal{X} \times \mathcal{F}^* \to (\alpha, -e) \in (T\mathcal{X} \times \mathcal{F})^*$. Physically this means that the ingoing power is counted positively.*

Since by definition of a Dirac structure (cf. (2.9)) $\langle \alpha \,|\, X\rangle - \langle e \,|\, f\rangle = 0$ for all $(X, f, \alpha, -e) \in \mathcal{D}$, it follows that an implicit port-controlled Hamiltonian system satisfies the energy balance

$$\frac{dH}{dt} = e^T f. \tag{5.2}$$

Definition 5.1 generalizes the notion of an (explicit) port-controlled generalized Hamiltonian system (2.1) by noting that in this case the Dirac structure $\mathcal{D}$ on $\mathcal{X} \times \mathcal{F}$ is given by the specification $(X, f, \alpha, -e) \in \mathcal{D}$ iff

$$\begin{aligned} X(x) &= J(x)\alpha(x) + g(x)f, \\ e &= g^T(x)\alpha(x), \quad x \in \mathcal{X}. \end{aligned} \tag{5.3}$$

Indeed, let $(X, f, \alpha, -e) \in \mathcal{D}^\perp$; that is,

$$\langle \hat{\alpha} \,|\, X\rangle + \langle \alpha \,|\, \hat{X}\rangle - \langle \hat{e} \,|\, f\rangle - \langle e \,|\, \hat{f}\rangle = 0 \tag{5.4}$$

for all $(\hat{X}, \hat{f}, \hat{\alpha}, -\hat{e})$ satisfying (5.3). By first taking $\hat{f} = 0$ we obtain

$$\hat{\alpha}^T(x)X(x) + \alpha^T(x)J(x)\hat{\alpha}(x) - \hat{\alpha}^T(x)g(x)f = 0 \tag{5.5}$$

for all $\hat{\alpha}$, and thus $X(x) = J(x)\alpha(x) + g(x)f$, and substitution in (5.4) yields

$$\hat{\alpha}^T(x)g(x)f + \alpha^T(x)g(x)\hat{f} - \hat{\alpha}^T(x)g(x)f - e^T\hat{f} = 0 \tag{5.6}$$

for all $\hat{f}$, implying that $e = g^T(x)\alpha(x)$, and thus that $(X, f, \alpha, -e) \in \mathcal{D}$.

Now let us consider, as in section 2, k port-controlled generalized Hamiltonian systems, see (2.15), with $\mathcal{E}_j = \mathcal{F}_j^*$, $j = 1, \dots, k$. A power-conserving *partial* interconnection is obtained by writing a direct sum decomposition

$$\mathcal{F}_1 \times \cdots \times \mathcal{F}_k = \mathcal{F}^i \oplus \mathcal{F}^p \tag{5.7}$$

with the subspace $\mathcal{F}^i$ denoting the flows to be interconnected, and $\mathcal{F}^p$ the remaining flows at the external ports of the partially interconnected system. By defining $\mathcal{E}^i := (\mathcal{F}^p)^\perp$ and $\mathcal{E}^p := (\mathcal{F}^i)^\perp$ we obtain the dual direct sum decomposition

$$\mathcal{E}_1 \times \cdots \times \mathcal{E}_k = \mathcal{E}^i \oplus \mathcal{E}^p. \tag{5.8}$$

Proposition 5.1. *Consider as in* (2.15) *k port-controlled generalized Hamiltonian systems, with direct sum decomposition* (5.7), (5.8). *Consider a power-conserving partial interconnection given by a subspace* (*possibly parametrized by $x_1, \dots, x_k$*)

$$I(x_1, \dots, x_k) \subset \mathcal{F}^i \times \mathcal{E}^i \tag{5.9}$$

with $\dim I(x_1, \dots, x_k) = \dim \mathcal{F}^{\mathrm{i}}$, *having the property*

$$(f^i, e^i) \in I(x_1, \dots, x_k) \;\Rightarrow\; \langle e^i \,|\, f^i\rangle = 0. \tag{5.10}$$

Then the resulting partially interconnected system is an implicit port-controlled generalized Hamiltonian system with state space $\mathcal{X} := \mathcal{X}_1 \times \cdots \times \mathcal{X}_k$, Hamiltonian

$H(x_1,\dots,x_k) := H_1(x_1) + \cdots + H_k(x_k)$, and generalized Dirac structure on $\mathcal{X} \times \mathcal{F}^p$ given as

$$\begin{aligned}
&(X, f^p, \alpha, -e^p) = (X_1,\dots,X_k, f^p, \alpha_1,\dots,\alpha_k, -e^p) \in \mathcal{D} \iff \\
&X_j(x_j) = J_j(x_j)\alpha_j(x_j) + g_j(x_j) f_j, \\
&e_j = g_j^T(x_j)\alpha_j(x_j), \quad x_j \in \mathcal{X}_j,\ j = 1,\dots,k, \\
&(f_1,\dots,f_k, e_1,\dots,e_k) = (f^i, f^p, e^i, e^p) \text{ such that } (f^i, e^i) \in I(x_1,\dots,x_k).
\end{aligned} \tag{5.11}$$

Proof. The proof is very similar to the proof of Proposition 2.2. Let $(X, f^p, \alpha, -e^p)$ be in $\mathcal{D}^\perp$, that is,

$$\langle \hat{\alpha} \,|\, X \rangle + \langle \alpha \,|\, \hat{X} \rangle - \langle \hat{e}^p \,|\, f^p \rangle - \langle e^p \,|\, \hat{f}^p \rangle = 0 \tag{5.12}$$

for all $(\hat{X}, \hat{f}^p, \hat{\alpha}, -\hat{e}^p)$ satisfying (5.11). First, letting $\hat{f}_j = \hat{e}_j = 0$ for all $j = 1,\dots,k$ we obtain (2.21), and by substitution in (5.12) we obtain, similar to (2.22),

$$0 = \sum_{j=1}^{k} \left(\hat{e}_j^T f_j + e_j^T \hat{f}_j \right) - \langle \hat{e}^p \,|\, f^p \rangle - \langle e^p \,|\, \hat{f}^p \rangle = \langle \hat{e}^i \,|\, f^i \rangle + \langle e^i \,|\, \hat{f}^i \rangle \tag{5.13}$$

for all $\hat{f}^i, \hat{e}^i$. By definition of $I(x_1,\dots,x_k)$ in (5.10) this implies, as in Proposition 2.2 (adding if necessary flow vectors in the kernel of $g_j(x_i)$) that $(f^i, e^i) \in I(x_1,\dots,x_k)$, and thus $(X, f^p, \alpha, -e^p) \in \mathcal{D}$. Since it is readily seen that $\mathcal{D} \subset \mathcal{D}^\perp$ it follows that $\mathcal{D}$ defines a Dirac structure. □

REMARK 5.2. *An interesting open problem is the* variational *interpretation of Proposition* 5.1 (*and Proposition* 2.2). *Indeed, if all the Hamiltonian subsystems admit a variational characterization* (*as Euler–Lagrange equations*) *one could conjecture that also the* (*partially*) *interconnected Hamiltonian system admits "some kind of" variational characterization. It is to be expected, however, that the closedness conditions as treated in this and the previous section will play an important role in such a characterization, since already for classical mechanical systems with kinematic constraints it is known* (*see e.g.,* [AKN, BC]) *that they cannot be formulated as standard Euler–Lagrange equations in case the constraints are* nonholonomic. *Also, the formulation* (4.68) *of an implicit Hamiltonian system satisfying the closedness condition suggests a connection with variational principles via the first-order condition of Pontryagin's maximum principle. In the case of electrical circuits, where the interconnections are defined by Kirchhoff's laws and the closedness conditions are trivially satisfied* (*see Example* 3.1), *some important work concerning a variational formulation of Kirchhoff's laws and the resulting variational characterization of the overall circuit has been done* (*see, e.g.,* [JE, M1]), *and it seems of interest to extend these ideas to the general situation considered in Proposition* 5.1.

In the rest of this section we will not elaborate on general implicit port-controlled Hamiltonian systems and their different representations, but instead concentrate on a special subclass which arises naturally in the control of mechanical systems. Consider the following port-controlled generalized Hamiltonian system *with constraints* given by

$$\begin{aligned} \dot{x} &= J(x)\tfrac{\partial H}{\partial x}(x) + g(x)f + b(x)\lambda, \\ e &= g^T(x)\tfrac{\partial H}{\partial x}(x), \\ 0 &= b^T(x)\tfrac{\partial H}{\partial x}(x), \end{aligned} \tag{5.14}$$

where $x \in \mathcal{X}$, $f \in \mathcal{F} := \mathbb{R}^m$ and $g(x) = [g_1(x) \dots g_m(x)]$ is the $n \times m$ matrix of input vector fields g_j. $b(x) = [b_1(x) \dots b_k(x)]$ is the $n \times k$ matrix of constraint vector fields. Throughout this section we will assume that $b(x)$ has rank equal to k everywhere. It is easily seen that, e.g., an *actuated* mechanical system with kinematic constraints will fit into the description (5.14). By rewriting (5.14) as

$$\begin{aligned} \begin{bmatrix} \dot{x} \\ f \end{bmatrix} &= \underbrace{\begin{bmatrix} J(x) & 0 \\ 0 & 0 \end{bmatrix}}_{\tilde{J}(x)} \begin{bmatrix} \frac{\partial H}{\partial x}(x) \\ -e \end{bmatrix} + \begin{bmatrix} g(x) & b(x) \\ I_m & 0 \end{bmatrix} \tilde{\lambda}, \\ 0 &= \begin{bmatrix} g^T(x) & I_m \\ b^T(x) & 0 \end{bmatrix} \begin{bmatrix} \frac{\partial H}{\partial x}(x) \\ -e \end{bmatrix}, \end{aligned} \tag{5.15}$$

where $\tilde{\lambda} \in \mathbb{R}^{m+k}$, it follows from Theorem 3.1 that (5.15) defines representation II of a generalized Dirac structure $\mathcal{D}$ on $\mathcal{X} \times \mathcal{F}$. Thus (5.14) is an implicit port-controlled generalized Hamiltonian system.

We will now study $\mathcal{D}$ further as given in representation (5.15). In what follows we will use $\{\,,\,\}$ and $\{\,,\,\}_{\mathcal{X}\times\mathcal{F}}$ to denote the generalized Poisson brackets on $\mathcal{X}$ and $\mathcal{X} \times \mathcal{F}$, respectively, with structure matrices $J(x)$ and $\tilde{J}(x)$ (see (5.15)), respectively. In addition we will let B denote the constant-dimensional distribution on $\mathcal{X}$ given by

$$B(x) = \operatorname{Im} b(x), \quad x \in \mathcal{X}. \tag{5.16}$$

From (5.15) we immediately see that the distribution G_0 on $\mathcal{X} \times \mathcal{F}$ defined by $\mathcal{D}$ (see (3.1)) is given by

$$G_0(x,y) = \operatorname{Im} \begin{bmatrix} g(x) & b(x) \\ I_m & 0 \end{bmatrix}, \quad (x,y) \in \mathcal{X} \times \mathcal{F}. \tag{5.17}$$

Note that G_0 is constant-dimensional with dimension equal to $m+k$ since $\operatorname{rank} b(x) = k$ for all $x \in \mathcal{X}$. The following lemma, for which a proof is straightforward, gives necessary and sufficient conditions for G_0 being involutive.

LEMMA 5.1. *G_0 is involutive if and only if $[X,Y] \in B$ for all $X,Y \in \{g_1,\dots,g_m,b_1,\dots,b_k\}$.*

The next lemma gives three necessary conditions for the closedness of $\mathcal{D}$.

LEMMA 5.2. *If the generalized Dirac structure $\mathcal{D}$ on $\mathcal{X} \times \mathcal{F}$ is closed, then*

1. $\{H_1,\{H_2,H_3\}\} + \{H_2,\{H_3,H_1\}\} + \{H_3,\{H_1,H_2\}\} = 0$;
2. $L_{g_j}\{H_1,H_2\} = \{L_{g_j}H_1,H_2\} + \{H_1,L_{g_j}H_2\}$, $j = 1,\dots,m$;
3. $\mathbf{d}\{H_1,H_2\} \in \operatorname{ann} B$

for all $H_1,H_2,H_3 \in C^\infty(\mathcal{X})$ such that $\mathbf{d}H_1, \mathbf{d}H_2, \mathbf{d}H_3 \in \operatorname{ann} B$.

Proof. Assume that $\mathcal{D}$ is closed, i.e., satisfies (4.1). Using *Cartan's magic formula*, the closedness condition (4.1) can be written as

$$\begin{aligned} &\langle \mathbf{d}\langle \alpha_2 \,|\, X_1\rangle \,|\, X_3\rangle + \langle \mathbf{d}\langle \alpha_3 \,|\, X_2\rangle \,|\, X_1\rangle + \langle \mathbf{d}\langle \alpha_1 \,|\, X_3\rangle \,|\, X_2\rangle \\ &\qquad + \mathbf{d}\alpha_2(X_1,X_3) + \mathbf{d}\alpha_3(X_2,X_1) + \mathbf{d}\alpha_1(X_3,X_2) = 0. \end{aligned} \tag{5.18}$$

Consider H_1, H_2, and $H_3 \in C^\infty(\mathcal{X})$, where $\mathbf{d}H_i \in \operatorname{ann} B$, $i = 1,2,3$. Let $j \in \{1,\dots,m\}$ and define

$$X_1(x,y) = \begin{bmatrix} X_{H_1}(x) \\ 0 \end{bmatrix}, \qquad \alpha_1(x,y) = \begin{bmatrix} \frac{\partial H_1}{\partial x}(x) \\ -L_g^T H_1(x) \end{bmatrix}, \tag{5.19}$$

$$X_2(x,y) = \begin{bmatrix} X_{H_2}(x) \\ 0 \end{bmatrix}, \qquad \alpha_2(x,y) = \begin{bmatrix} \frac{\partial H_2}{\partial x}(x) \\ -L_g^T H_2(x) \end{bmatrix}, \tag{5.20}$$

$$X_3(x,y) = \begin{bmatrix} X_{H_3}(x) + \rho g_j(x) \\ \rho Y_j \end{bmatrix}, \quad \alpha_3(x,y) = \begin{bmatrix} \frac{\partial H_3}{\partial x}(x) \\ -L_g^T H_3(x) \end{bmatrix} \tag{5.21}$$

for $(x,y) \in \mathcal{X} \times \mathcal{F}$, where $Y_j = \frac{\partial}{\partial y_j}$, $\rho \in \mathbb{R}$ and

$$X_{H_i}(x) = J(x)\frac{\partial H_i}{\partial x}(x), \; L_g^T H_i(x) = g^T(x)\frac{\partial H_i}{\partial x}(x). \tag{5.22}$$

Thus, $(X_i, \alpha_i) \in \mathcal{D}$, $i = 1,2,3$. Now, it is easy to see that $\langle \alpha_i \,|\, X_j \rangle = \{H_i, H_j\}$, $i,j = 1,2,3$, which implies that

$$\langle \mathbf{d}\langle \alpha_2 \,|\, X_1 \rangle \,|\, X_3 \rangle = \{\{H_2, H_1\}, H_3\} + \rho L_{g_j}\{H_2, H_1\}, \tag{5.23}$$

$$\langle \mathbf{d}\langle \alpha_3 \,|\, X_2 \rangle \,|\, X_1 \rangle = \{\{H_3, H_2\}, H_1\}, \tag{5.24}$$

$$\langle \mathbf{d}\langle \alpha_1 \,|\, X_3 \rangle \,|\, X_2 \rangle = \{\{H_1, H_3\}, H_2\}. \tag{5.25}$$

Moreover, we have that

$$\alpha_i = \frac{\partial H_i}{\partial x_1}\mathbf{d}x_1 + \cdots + \frac{\partial H_i}{\partial x_n}\mathbf{d}x_n - L_{g_1}H_i\mathbf{d}y_1 - \cdots - L_{g_m}H_i\mathbf{d}y_m, \quad i = 1,\dots,3, \tag{5.26}$$

which means that

$$\mathbf{d}\alpha_i = -\sum_{l=1}^{m}\sum_{k=1}^{n} \frac{\partial L_{g_l}H_i}{\partial x_k}\mathbf{d}x_k \wedge \mathbf{d}y_l, \quad i = 1,\dots,3. \tag{5.27}$$

Hence,

$$\mathbf{d}\alpha_2(X_1, X_3) \quad = \quad -\rho\left[\frac{\partial L_{g_j}H_2}{\partial x}\right]^T X_{H_1} \quad = \quad -\rho\{L_{g_j}H_2, H_1\} \tag{5.28}$$

and similarly

$$\mathbf{d}\alpha_1(X_3, X_2) \quad = \quad -\mathbf{d}\alpha_1(X_2, X_3) \quad = \quad \rho\{L_{g_j}H_1, H_2\} \quad = \quad -\rho\{H_2, L_{g_j}H_1\}. \tag{5.29}$$

In addition, it follows that $\mathbf{d}\alpha_3(X_2, X_1) = 0$. Therefore, from the integrability condition (5.18) we have that

$$\begin{aligned} &\{\{H_2, H_1\}, H_3\} + \{\{H_3, H_2\}, H_1\} + \{\{H_1, H_3\}, H_2\} \\ &\qquad + \rho\left(L_{g_j}\{H_2, H_1\} - \{L_{g_j}H_2, H_1\} - \{H_2, L_{g_j}H_1\}\right) = 0 \end{aligned} \tag{5.30}$$

for all $\rho \in \mathbb{R}$, implying condition 1 for $\rho = 0$ and condition 2 for $\rho = 1$.

Now, a direct calculation yields

$$\begin{aligned}\alpha_{12} &= \mathbf{i}_{X_2}\mathbf{d}\alpha_1 - \mathbf{i}_{X_1}\mathbf{d}\alpha_2 + \mathbf{d}\langle \alpha_1 \mid X_2\rangle \\ &= -\sum_{l=1}^{m}(\{L_{g_l}H_1, H_2\} + \{H_1, L_{g_l}H_2\})\,\mathbf{d}y_l + \sum_{k=1}^{n}\frac{\partial\{H_1,H_2\}}{\partial x_k}\mathbf{d}x_k,\end{aligned} \tag{5.31}$$

from which condition 3 (and condition 2) follows directly since $\alpha_{12} \in \operatorname{ann} G_0$ (see Theorem 4.1). □

Before being able to give the sufficient and necessary conditions for $\mathcal{D}$ being closed, we also need the following result.

LEMMA 5.3. *If for arbitrary $H_1, H_2 \in C^\infty(\mathcal{X})$ such that $\mathbf{d}H_1, \mathbf{d}H_2 \in \operatorname{ann} B$ there holds*

1. $L_{g_j}\{H_1, H_2\} = \{L_{g_j}H_1, H_2\} + \{H_1, L_{g_j}H_2\}$, $j = 1, \ldots, m$,
2. $\mathbf{d}\{H_1, H_2\} \in \operatorname{ann} B$,

then $\{\tilde{H}_1, \tilde{H}_2\}_{\mathcal{X}\times\mathcal{F}} \in \mathcal{A}_{\mathcal{D}}$ for all $\tilde{H}_1, \tilde{H}_2 \in \mathcal{A}_{\mathcal{D}}$.

Proof. Take arbitrary $\tilde{H}_2, \tilde{H}_2 \in \mathcal{A}_{\mathcal{D}}$. From (5.17) we see that this is equivalent to

$$0 = b^T(x)\frac{\partial \tilde{H}_i}{\partial x}(x,y), \tag{5.32}$$

$$\frac{\partial \tilde{H}_i}{\partial y}(x,y) = -g^T(x)\frac{\partial \tilde{H}_i}{\partial x}(x,y) \tag{5.33}$$

for $i = 1, 2$. Let $j \in \{1, \ldots, m\}$ and define

$$\hat{g}_j(x,y) = \begin{bmatrix} g_j(x) \\ 0 \end{bmatrix}. \tag{5.34}$$

Then (5.33) can be written as

$$\frac{\partial \tilde{H}_i}{\partial y_k} = -L_{\hat{g}_k}\tilde{H}_i, \quad k = 1, \ldots, m, \tag{5.35}$$

for $i = 1, 2$. Now,

$$\{\tilde{H}_1, \tilde{H}_2\}_{\mathcal{X}\times\mathcal{F}} = \sum_{k,l=1}^{n} J_{kl}(x)\frac{\partial \tilde{H}_1}{\partial x_k}\frac{\partial \tilde{H}_2}{\partial x_l}, \tag{5.36}$$

so

$$\frac{\partial\{\tilde{H}_1, \tilde{H}_2\}_{\mathcal{X}\times\mathcal{F}}}{\partial y_j} = -\,\{L_{\hat{g}_j}\tilde{H}_1, \tilde{H}_2\}_{\mathcal{X}\times\mathcal{F}} - \{\tilde{H}_1, L_{\hat{g}_j}\tilde{H}_2\}_{\mathcal{X}\times\mathcal{F}}. \tag{5.37}$$

Since

$$\{H_1, H_2\} = \sum_{k,l=1}^{n} J_{kl}(x)\frac{\partial H_1}{\partial x_k}\frac{\partial H_2}{\partial x_l}, \quad H_1, H_2 \in C^\infty(\mathcal{X}), \tag{5.38}$$

it follows from condition 1 that

$$L_{\hat{g}_j}\{\tilde{H}_1, \tilde{H}_2\}_{\mathcal{X}\times\mathcal{F}} = \{L_{\hat{g}_j}\tilde{H}_1, \tilde{H}_2\}_{\mathcal{X}\times\mathcal{F}} + \{\tilde{H}_1, L_{\hat{g}_j}\tilde{H}_2\}_{\mathcal{X}\times\mathcal{F}}, \tag{5.39}$$

which inserted in (5.37) yields

$$\frac{\partial\{\tilde{H}_1,\tilde{H}_2\}_{\mathcal{X}\times\mathcal{F}}}{\partial y_j} = -L_{\hat{g}_j}\{\tilde{H}_1,\tilde{H}_2\}_{\mathcal{X}\times\mathcal{F}}. \tag{5.40}$$

Moreover, from condition 2 it follows that

$$b^T(x)\frac{\partial\{\tilde{H}_1,\tilde{H}_2\}_{\mathcal{X}\times\mathcal{F}}}{\partial x} = 0. \tag{5.41}$$

Thus, from (5.40) and (5.41) we see that $\{\tilde{H}_1,\tilde{H}_2\}_{\mathcal{X}\times\mathcal{F}} \in \mathcal{A}_{\mathcal{D}}$. □

We are now ready to present the necessary and sufficient conditions for (5.15) defining a Dirac structure on $\mathcal{X}\times\mathcal{F}$.

THEOREM 5.1. *The generalized Dirac structure $\mathcal{D}$ on $\mathcal{X}\times\mathcal{F}$ as defined by* (5.15) *is closed if and only if*

1. $[X,Y]\in B$ *for all vector fields* $X,Y\in\{g_1,\dots,g_m,b_1,\dots,b_k\}$;
2. $L_{g_j}\{H_1,H_2\} = \{L_{g_j}H_1,H_2\}+\{H_1,L_{g_j}H_2\}$, $j=1,\dots,m$;
3. $\mathbf{d}\{H_1,H_2\}\in \operatorname{ann} B$;
4. $\{H_1,\{H_2,H_3\}\}+\{H_2,\{H_3,H_1\}\}+\{H_3,\{H_1,H_2\}\}=0$

for all $H_1,H_2,H_3\in C^\infty(\mathcal{X})$ *such that* $\mathbf{d}H_1,\mathbf{d}H_2,\mathbf{d}H_3\in\operatorname{ann} B$.

Proof. The necessary and sufficient conditions for closedness of $\mathcal{D}$ follows immediately by combining the results in Lemma 5.1, Lemma 5.2, Lemma 5.3 and then using Theorem 4.4. □

COROLLARY 5.1 ($B=0$). *Let* $b(x)=0$ (*no constraints*) *in* (5.14). *Then the generalized Dirac structure $\mathcal{D}$ on $\mathcal{X}\times\mathcal{F}$ as defined by* (5.15) (*with* $b(x)=0$) *is closed if and only if*

1. $[g_i,g_j]=0$, $i,j=1,\dots,m$;
2. $L_{g_j}\{H_1,H_2\} = \{L_{g_j}H_1,H_2\}+\{H_1,L_{g_j}H_2\}$ *for all* $H_1,H_2\in C^\infty(\mathcal{X})$, $j=1,\dots,m$;
3. $\{\,,\,\}$ *satisfies the Jacobi identity.*

Hence, the closedness condition (4.1) for the generalized Dirac structure on $\mathcal{X}\times\mathcal{F}$ arising from the constrained port-controlled Hamiltonian system (5.14) translates (among other things) into strong conditions on the input vector fields g_j.

Conditions 2–4 in Theorem 5.1 may be succinctly expressed by requiring that the generalized Poisson bracket $\{\,,\,\}$ of $F,G\in C^\infty(\mathcal{X})$ where $\mathbf{d}F$, $\mathbf{d}G\in\operatorname{ann}B$ is preserved by the dynamics of (5.14) for *every* choice of internal energy H such that $\mathbf{d}H\in\operatorname{ann}B$ and for every $f\in\mathcal{F}$. Indeed, requiring that

$$\frac{d}{dt}\{F,G\} = \left\{\frac{d}{dt}F,G\right\}+\left\{F,\frac{d}{dt}G\right\} \tag{5.42}$$

for all $F,G\in C^\infty(\mathcal{X})$ such that $\mathbf{d}F,\mathbf{d}G\in\operatorname{ann}B$, where $\frac{d}{dt}$ denotes the time-derivative along (5.14), is equivalent to

$$\begin{aligned}\{\{F,G\},H\}&+L_g\{F,G\}f+L_b\{F,G\}\lambda\\ &=\{\{F,H\},G\}+\{(L_gF)f,G\}+\{F,\{G,H\}\}+\{F,(L_gG)f\}\end{aligned} \tag{5.43}$$

for all $H\in C^\infty(\mathcal{X})$ such that $\mathbf{d}H\in\operatorname{ann}B$ and $f\in\mathcal{F}$. Letting $H=0$ and $f=0$, we obtain

$$L_b\{F,G\}\lambda = 0 \quad \text{for all } \lambda\in\mathbb{R}^k, \tag{5.44}$$

which means that $\mathbf{d}\{F, G\} \in \operatorname{ann} B$. Moreover, letting $f = 0$ leads to

$$\{\{F, G\}, H\} = \{\{F, H\}, G\} + \{F, \{G, H\}\}, \tag{5.45}$$

which is none other than the Jacobi-identity. Thus, (5.43) amounts to

$$L_g\{F, G\}f = \{(L_g F)f, G\} + \{F, (L_g G)f\} \quad \text{for all } f \in \mathcal{F}, \tag{5.46}$$

which is equivalent to

$$L_{g_j}\{F, G\} = \{L_{g_j} F, G\} + \{F, L_{g_j} G\}, \quad j = 1, \dots, m. \tag{5.47}$$

The next example should give an idea of what the conditions in Theorem 5.1 imply for the (local) mathematical structure of system (5.14).

Example 5.1. *Consider the port-controlled generalized Hamiltonian system with constraints given in* (5.14). *Assume that conditions* 1–4 *in Theorem* 5.1 *are all satisfied. By condition* 1 *it follows that the constant-dimensional distribution B is involutive. Hence, by Frobenius' theorem in a neighborhood of any point $x_0 \in \mathcal{X}$ there exist local coordinates $(y, s) = (y_1, \dots, y_{n-k}, s_1, \dots, s_k)$, such that*

$$\operatorname{ann} B = \operatorname{span}\{\mathbf{d}y_1, \dots, \mathbf{d}y_{n-k}\} \tag{5.48}$$

and

$$B = \operatorname{span}\left\{\frac{\partial}{\partial s_1}, \dots, \frac{\partial}{\partial s_k}\right\}. \tag{5.49}$$

Condition 3 *implies that*

$$\frac{\partial\{y_i, y_j\}}{\partial s_l} = 0, \quad l = 1, \dots, k, \ i, j = 1, \dots, n - k. \tag{5.50}$$

Hence, $J(x)$ takes the following form in the local coordinates (y, s):

$$J(y, s) = \begin{bmatrix} J_{yy}(y) & * \\ * & * \end{bmatrix}, \tag{5.51}$$

where $J_{yy}(y) = [\{y_i, y_j\}]$ is the $(n - k) \times (n - k)$ upper-left submatrix of $J(y, s)$. From condition 1 *it also follows that $[b_i, g_j] \in B$ which implies that in the coordinates (y, s) the matrix of input vector fields takes the form*

$$g(x, y) = \begin{bmatrix} g_y(y) \\ g_s(y, s) \end{bmatrix}. \tag{5.52}$$

Furthermore, since

$$[g_i, g_j](y, s) = \begin{bmatrix} [g_{y_i}, g_{y_j}](y) \\ * \end{bmatrix} \tag{5.53}$$

while $[g_i, g_j] \in B$, it follows that $[g_{y_i}, g_{y_j}] = 0$, $i, j = 1, \dots, m$. Assume additionally that the distribution $B + G$ is constant-dimensional with dimension equal to $m + k$. Then the submatrix $g_y(y)$ of $g(x, y)$ has constant rank equal to $m \leq n - k$. Thus *(see e.g., Theorem* 2.36 *in* [NS]), *there exists a local transformation* $(y_1, \dots, y_{n-k}) \to (\tilde{y}_1, \dots, \tilde{y}_{n-k})$ *such that*

$$g_{y_j} = \frac{\partial}{\partial \tilde{y}_j}, \quad j = 1, \dots m. \tag{5.54}$$

In these coordinates condition 2 *amounts to*

$$\frac{\partial \{\tilde{y}_i, \tilde{y}_j\}}{\partial \tilde{y}_l} = \left\{\frac{\partial \tilde{y}_i}{\partial \tilde{y}_l}, \tilde{y}_j\right\} + \left\{\tilde{y}_i, \frac{\partial \tilde{y}_j}{\partial \tilde{y}_l}\right\} = 0, \quad l = 1, \dots, m, \ i, j = 1, \dots n-k, \tag{5.55}$$

which means that $\{\tilde{y}_i, \tilde{y}_j\}$ *is independent of the first* m *local coordinates* $\tilde{y}_1, \dots, \tilde{y}_m$*. Let now* $z = (\tilde{y}_{m+1}, \dots, \tilde{y}_{n-k})$ *and* $w = (\tilde{y}_1, \dots, \tilde{y}_m)$*. Then from the discussion above we can conclude that* (z, w, s) *are local coordinates for* $\mathcal{X}$ *around* x_0 *in which* (5.14) *takes the form*

$$\begin{aligned} \begin{bmatrix} \dot{z} \\ \dot{w} \end{bmatrix} &= \begin{bmatrix} J_{zz}(z) & J_{zw}(z) \\ -J_{zw}^T(z) & J_{ww}(z) \end{bmatrix} \begin{bmatrix} \frac{\partial H}{\partial z}(z, w, s) \\ \frac{\partial H}{\partial w}(z, w, s) \end{bmatrix} + \begin{bmatrix} 0 \\ I_m \end{bmatrix} f, \\ \dot{s} &= J_{sz}(z, w, s)\tfrac{\partial H}{\partial z}(z, w, s) + J_{sw}(z, w, s)\tfrac{\partial H}{\partial w}(z, w, s) \\ &\quad + g_s(z, w, s)f + b_s(z, w, s)\lambda, \\ e &= \tfrac{\partial H}{\partial w}(z, w, s), \\ 0 &= \tfrac{\partial H}{\partial s}(z, w, s), \end{aligned} \tag{5.56}$$

where the last equation follows from the fact that the $k \times k$ *matrix* $b_s(z, w, s)$ *has full rank. Note that the equation for* $\dot{s}$ *can be* left out *from* (5.56) *because it is needed only to determine the Lagrange multipliers* $\lambda \in \mathbb{R}^k$*. Finally from condition* 4 *it follows that the matrix*

$$\begin{bmatrix} J_{zz}(z) & J_{zw}(z) \\ -J_{zw}^T(z) & J_{ww}(z) \end{bmatrix} \tag{5.57}$$

satisfies the Jacobi-identity (*in the* (*z,w*)*-coordinates*).

Finally, in the next example we will relate the results in this paper (in particular this section) to "passivity-based control" of actuated mechanical systems with kinematic constraints.

Example 5.2. *Consider a mechanical system with kinematic constraints* $A^T(q)\dot{q} = 0$ *as in Example* 3.2. *Additionally, let the system be actuated by generalized external forces* $u = (u_1, \dots, u_m)$ *corresponding to generalized configuration coordinates* $C_1(q), \dots, C_m(q)$*. The dynamical equations of motion are given as*

(5.58)

$$\begin{aligned} \begin{bmatrix} \dot{q} \\ \dot{p} \end{bmatrix} &= \begin{bmatrix} 0 & I_n \\ -I_n & 0 \end{bmatrix} \begin{bmatrix} \frac{\partial H}{\partial q}(q,p) \\ \frac{\partial H}{\partial p}(q,p) \end{bmatrix} + \textstyle\sum_{i=1}^m \begin{bmatrix} 0 \\ \frac{\partial C_i}{\partial q}(q) \end{bmatrix} u_i + \begin{bmatrix} 0 \\ A(q) \end{bmatrix} \lambda, \\ y_i &= \left[\tfrac{\partial C_i}{\partial q}(q)\right]^T \tfrac{\partial H}{\partial p}(q,p) \ \left(= \tfrac{dC_i}{dt}(q)\right), \quad i = 1, \dots, m, \\ 0 &= A^T(q)\tfrac{\partial H}{\partial p}(q,p) \ (= A^T(q)\dot{q}). \end{aligned}$$

This is a port-controlled generalized Hamiltonian system with constraints as in (5.14) *with external flows the vector* $(u_1, \ldots, u_m)$ *of external forces, and external efforts the vector* $(y_1, \ldots, y_m)$ *of corresponding generalized velocities. It can be verified, as in Proposition* 4.1, *that the underlying generalized Dirac structure satisfies the conditions of Theorem* 5.1 (*that is, is closed*) *if and only if the kinematic constraints* $A^T(q)\dot{q} = 0$ *are* holonomic.

Now, consider an additional port-controlled Hamiltonian system (*the* "*controller*")

$$\begin{aligned} \dot{\xi} &= u_c, \\ y_c &= \tfrac{\partial P}{\partial \xi}(\xi), \quad \xi, u_c, y_c \in \mathbb{R}^m, \end{aligned} \tag{5.59}$$

with Hamiltonian P. (*Note that this is of the type* (2.1) *with* $J = 0$, $g =$ *identity matrix*, $x = \xi$, $f = u_c$, *and* $e = y_c$.) *Feedback interconnection as in Example* 2.1 *leads to the implicit generalized Hamiltonian system*

$$\begin{aligned} \begin{bmatrix} \dot{q} \\ \dot{p} \\ \dot{\xi} \end{bmatrix} &= \begin{bmatrix} 0 & I_n & 0 \\ -I_n & 0 & -\frac{\partial C}{\partial q}(q) \\ 0 & \frac{\partial^T C}{\partial q}(q) & 0 \end{bmatrix} \begin{bmatrix} \frac{\partial H}{\partial q}(q,p) \\ \frac{\partial H}{\partial p}(q,p) \\ \frac{\partial P}{\partial \xi}(\xi) \end{bmatrix} + \begin{bmatrix} 0 \\ A(q) \\ 0 \end{bmatrix} \lambda, \\ 0 &= A^T(q)\tfrac{\partial H}{\partial p}(q,p), \end{aligned} \tag{5.60}$$

with $\frac{\partial C}{\partial q}(q)$ *denoting the matrix with ith column* $\frac{\partial C_i}{\partial q}(q)$. *The codistribution* P_0 *of the underlying generalized Dirac structure can be readily seen to be given as*

$$P_0 = \operatorname{span}\{\mathbf{d}C_i - \mathbf{d}\xi_i \mid i = 1, \ldots, m\} \tag{5.61}$$

expressing the fact (*see also Remark* 3.1) *that the functions*

$$C_i(q) - \xi_i, \quad i = 1, \ldots, m, \tag{5.62}$$

are independent conserved quantities for the closed-loop dynamics (5.60). *It follows that along* (5.60)

$$\xi_i(t) = C_i(q(t)) + c_i, \quad \textit{for all } t, \quad i = 1, \ldots, m, \tag{5.63}$$

with the constants c_i *solely depending on the initial conditions of the* "*controller*" (5.59).

Substituting (5.63) *into* (5.60) *and noting that*

$$\frac{\partial C}{\partial q}(q)\frac{\partial P}{\partial \xi}(C_1(q) + c_1, \ldots, C_m(q) + c_m) = \frac{\partial P}{\partial q}(C_1(q) + c_1, \ldots, C_m(q) + c_m), \tag{5.64}$$

it follows that the dynamics of the (q,p)*-part of* (5.60) (*the original mechanical system*) *are given as*

$$\begin{aligned} \begin{bmatrix} \dot{q} \\ \dot{p} \end{bmatrix} &= \begin{bmatrix} 0 & I_n \\ -I_n & 0 \end{bmatrix} \begin{bmatrix} \frac{\partial H_{new}}{\partial q}(q,p) \\ \frac{\partial H_{new}}{\partial p}(q,p) \end{bmatrix} + \begin{bmatrix} 0 \\ A(q) \end{bmatrix} \lambda, \\ 0 &= A^T(q)\tfrac{\partial H_{new}}{\partial p}(q,p), \end{aligned} \tag{5.65}$$

where H_{new} is the "new" Hamiltonian defined by

$$H_{new}(q,p) = H(q,p) + P(C_1(q) + c_1, \dots, C_m(q) + c_m). \tag{5.66}$$

Thus by appropriately choosing the Hamiltonian $P(\xi)$ of the "controller sub-system" (5.59), *we may* shape *the Hamiltonian $H(q,p)$ of the constrained mechanical system* (5.58) *by addition of the* potential energy $P(C_1(q) + c_1, \dots, C_m(q) + c_m)$, *with $c_1, \dots, c_m$ only depending on the initial condition of* (5.59) (*that is*, *with properly initialization we may set $c_1 = \dots = c_m = 0$*). *This idea of shaping the internal energy is one of the main ideas of "passivity-based control." We have thus demonstrated that this can be accomplished by power-conserving* (*in fact*, *feedback*) *interconnection of* (5.58) *with a controller sub-system* (5.59).

In particular, *if H and $C_1, \dots, C_m$ are such that P can be chosen in such a manner that H_{new} as defined by* (5.66) *has a strict minimum at some desired equilibrium point (q_0, p_0)*, *then (q_0, p_0) will be a* (*Lyapunov*) *stable equilibrium of* (5.65) (*and*, *because of* (5.63), *also the ξ-dynamics will be stable*). *To be more precise we only need the function H_{new}* restricted *to the constraint manifold $\{(q,p) \mid A^T(q)\frac{\partial H_{new}}{\partial p}(q,p) = 0\}$ to have a strict minimum at (q_0, p_0).*

It can be verified that the underlying generalized Dirac structure of (5.60) *is closed if and only if the kinematic constraints $A^T(q)\dot{q} = 0$ are* holonomic. *If this happens to be the case then checking that H_{new} restricted to the constraint manifold has a strict minimum may be performed as indicated at the end of section* 4.

Within the same philosophy one may pursue asymptotic *stability by adding*, *apart from the energy-shaping Hamiltonian controller* (2.24), *energy-dissipating elements to the system. In particular*, *one may replace the feedback interconnection $u_c = y$, $u = -y_c$ as above by the power-conserving* partial *interconnection* (*with free external flow v and external effort y*)

$$\begin{array}{rcl} u_c & = & y, \\ u & = & -y_c + v, \end{array} \tag{5.67}$$

and then terminate *this port by an energy-dissipating element*

$$v = -\frac{\partial R}{\partial y}(y) \tag{5.68}$$

for some (*Rayleigh*) *dissipation function R. For the asymptotic stability analysis of the resulting closed-loop system one again must distinguish between holonomic and nonholonomic kinematic constraints $A^T(q)\dot{q} = 0$.* (*In fact*, *in the nonholonomic case there is a fundamental obstruction to asymptotic stabilization*, *since Brockett's necessary conditions are not satisfied*; *see*, *e.g.*, [MS3] *for the references.*)

6. Conclusions. It has been shown that a power-conserving interconnection of port-controlled generalized Hamiltonian systems leads to an implicit generalized Hamiltonian system, and a power-conserving partial interconnection to an implicit port-controlled Hamiltonian system. The crucial concept is the notion of a (generalized) Dirac structure, defined on the space of energy-variables or on the product of the space of energy-variables and the space of flow-variables in the port-controlled case. Three natural representations of generalized Dirac structures have been treated. Necessary and sufficient conditions for closedness of a Dirac structure in all three representations have been obtained. This has been illustrated on mechanical systems with kinematic constraints and constrained systems on dual Lie algebras. Canonical coordinates for (closed) Dirac structures have been discussed, as well as their use for stability analysis of implicit Hamiltonian systems. Finally the theory has been applied to implicit port-controlled generalized Hamiltonian systems, such as actuated mechanical systems with kinematic constraints, and it has been shown in particular that the closedness condition for the Dirac structure leads to strong conditions on the input vector fields.

Acknowledgments. We would like to thank Bernhard Maschke (Conservatoire National des Arts et Métiers, Paris) for stimulating discussions. We also thank Peter Crouch (Arizona State University) and Tony Bloch (University of Michigan) for pointing out to the second author the relevance of Dirac structures.

BOUNDED POWER SIGNAL SPACES FOR ROBUST CONTROL AND MODELING[*]

P. M. MÄKILÄ[†], J. R. PARTINGTON[‡], AND T. NORLANDER[§]

Abstract. The nonlinear space of signals allowing Wiener's generalized harmonic analysis (GHA), the linear bounded power signal spaces of Beurling, Marcinkiewicz, and Wiener, and a new linear bounded power space are studied from a control and systems theory perspective. Specifically, it is shown that the system power gain is given by the H_∞ norm of the system transfer function in each of these spaces for a large class of (power) stable finite and infinite dimensional systems. The GHA setup is shown to possess several limitations for the purpose of robustness analysis which motivates the use of the other more general (nonstationary) signal spaces. The natural double-sided time axis versions of bounded power signal spaces are shown to break the symmetry between Hardy space H_∞ methods and bounded power operators; e.g., the system transfer function being in H_∞ does not imply that a causal-linear time-invariant (LTI) system is bounded as an operator on any of the double-sided versions of the studied bounded power signal spaces.

Key words. bounded power signals, generalized harmonic analysis, robust control, infinite dimensional systems, H_∞

1. Introduction.

It is popular to use bounded power signals (Boyd and Barratt (1991); Doyle, Francis, and Tannenbaum (1992); Zhou, Doyle, and Glover (1996); Gardner (1988)) as a physically well-motivated persistent signal setup in control and system identification studies. These provide also an alternative to finite energy L_2 signal spaces for introducing robust H_∞ control (Zames (1981)). Unfortunately, the most common definitions of the set of signals with bounded power do not result in a linear vector space setup as pointed out by Mari (1996). It is possible to eliminate this problem by considering some appropriate subset of the set of all bounded power signals, such as periodic or almost periodic signals; (see, e.g., Mäkilä (1990), Partington and Mäkilä (1996)). In this way, however, some generality is lost. An attractive alternative is to generalize the usual definition of the power size measure of a signal. It turns out that several interesting generalizations are possible and have in fact been treated in the functional analytic literature by famous mathematicians, such as Marcinkiewicz and Beurling (see Chen and Lau (1989) for some historical background). It is the purpose of this paper to treat both the standard setup and some of the generalizations of bounded power signals from a control and systems perspective.

A milestone in the development of rich nonprobabilistic signal models is the work of Wiener on GHA summarized in his book (Wiener (1933)); see also Wiener (1979). In his work the now standard definition of bounded power signals for the continuous-time case is given using the notion of autocorrelation function. This work generalizes essentially the Fourier integral to a large class of persistent signals in a rigorous way

and gives a functional analytic basis for spectral analysis. In Wiener (1927) GHA is considered for sequences (i.e., the discrete-time case is covered). It was well known to Wiener that the set of bounded power signals as introduced by him (the set S in Wiener (1933)) is not a linear space; see, e.g., his treatment of so-called coherency issues (Wiener, (1930), (1949)). Wiener's work on GHA has inspired Gardner (1988) to develop a complete nonprobabilistic paradigm for spectral analysis.

Robust H_∞ control is fundamental to modern feedback control theory and control engineering. Due to mathematical difficulties with standard bounded power signal setups, robust H_∞ control and estimation theory have been developed mostly based on a finite energy L_2 (ℓ_2) signal space setting, although much of the engineering motivation for robust disturbance rejection and estimation comes from persistent bounded power–like (stationary and nonstationary) signal settings; see, e.g., the seminal paper by Zames (1981). Several recent books and papers (Boyd and Barratt (1991); Doyle, Francis, and Tannenbaum (1992); Zhou et al. (1994); Zhou, Doyle, and Glover (1996)) on robust control emphasize the importance of persistent bounded power signal setups for robust control but give only results for finite dimensional systems using some subset of the set of signals allowing GHA. In the present paper we generalize, among other things, system gain results to full GHA setups and beyond to Marcinkiewicz and related spaces for large classes of stable finite dimensional and infinite dimensional systems. Furthermore, we introduce a new bounded power–like signal space. The equivalency between the Hardy space H_∞ of bounded analytic transfer functions and spaces of power stable causal LTI operators is lost in the double-sided time axis case.

The paper is organized as follows. In section 2 GHA methods are studied. Several results are proved here on discrete- and continuous-time GHA analysis, including Theorems 2.1–2.4. Technical difficulties restricting the generality of GHA methods in, e.g., robustness analysis are demonstrated. More general bounded power signal spaces are studied in section 3. Specifically, bounded power signal spaces that can be traced back to Marcinkiewicz, Wiener, and Beurling are studied here. It is shown that for a large class of stable, causal, LTI finite and infinite dimensional systems, the system power gain is given by the H_∞ norm of the system transfer function in each of the considered generalized bounded power signal spaces. Conclusions are drawn in section 4.

2. The average power setup—autocorrelation function.

2.1. Discrete-time case. Consider now the standard form of the bounded power signal setup, which is based on an average power measure. A (real or complex) sequence $x = \{x_k\}_{k=-\infty}^{\infty}$ is said to have average (symmetric) bounded power if

$$\|x\|_A = \left(\lim_{n\to\infty} \frac{1}{2n+1} \sum_{k=-n}^{n} |x_k|^2 \right)^{1/2} < \infty. \tag{2.1}$$

This is the discrete analogue of the continuous-time definition in Doyle, Francis, and Tannenbaum (1992); Zhou, Doyle, and Glover (1996). It has been recently pointed out in a control context in Mari (1996) that the set of all finite power signals is not a linear vector space in the continuous-time case. The same is true in the discrete case (Mäkilä and Partington (1996)), even if it is required that the allowable signals must, in addition, have bounded amplitude (i.e., must belong to ℓ_∞) and be such that they possess a well-defined autocorrelation function.

A well-motivated starting point for a reexamination of such issues is to study Wiener's GHA (Wiener (1927), (1930), (1933)). It is appropriate to start by stating some results related to GHA but which actually apply under more general assumptions than those used in GHA. To do this we introduce a seminorm which coincides with the seminorm $\|u\|_A$ given in (2.1), whenever that exists. Furthermore, we introduce a norm which will turn out to be most useful later. Let $\{u_k\}$ denote a real or complex sequence. Introduce the seminorm

$$\|u\|_B = \left(\limsup_{n\to\infty} \frac{1}{2n+1} \sum_{k=-n}^{n} |u_k|^2 \right)^{1/2} \tag{2.2}$$

and the norm

$$\|u\|_{BP} = \left(\sup_{n} \frac{1}{2n+1} \sum_{k=-n}^{n} |u_k|^2 \right)^{1/2} . \tag{2.3}$$

We use the notations u_k and $u(k)$ to denote the general element of the sequence $u = \{u_k\} = \{u(k)\}$.

Note that the seminorm $\|u\|_B$ is finite if and only if the norm $\|u\|_{BP}$ is finite. Usually, in the single-sided time axis case, it will be more natural to replace $2n+1$ with $n+1$ in the above definitions, since we take summation from 0 to n (see Mäkilä and Partington (1996), where this was done for *BP*). The new seminorms are uniformly equivalent to the corresponding old ones.

In a certain sense, a more appropriate seminorm to take on the space of bounded power signals would be

$$\|u\|_{BL} = \left(\mathrm{Blim}_{n\to\infty} \frac{1}{2n+1} \sum_{k=-n}^{n} |u_k|^2 \right)^{1/2} , \tag{2.4}$$

where Blim denotes any Banach or generalized limit (see Rudin (1973)). However, the existence of such limits is not constructive, and this definition would be useless for most practical purposes, so we reject it.

THEOREM 2.1. *Let $u = \{u_k\}$ be a (double-sided) sequence of complex (or real) numbers.*

(a) *If $\|u\|_{BP} < \infty$, then*

$$|u(0)|^2 + \sum_{k\neq 0} \frac{|u(k)|^2}{k^2} \leq 6\|u\|_{BP}^2 . \tag{2.5}$$

(b) *If $\|u\|_B < \infty$, then*

$$|u(0)|^2 + \sum_{k\neq 0} \frac{|u(k)|^2}{k^2} < \infty . \tag{2.6}$$

Furthermore, there does not exist any bound of the form

$$|u(0)|^2 + \sum_{k\neq 0} \frac{|u(k)|^2}{k^2} \leq C\|u\|_B^2 \tag{2.7}$$

for some constant $C > 0$.

Proof. Consider part (a). Write

$$|u(0)|^2 + \sum_{k=-n,k\neq 0}^{n} \frac{|u(k)|^2}{k^2} = \sum_{k=1}^{n} \frac{|u(k)|^2 + |u(-k)|^2 + \delta(k-1)|u(0)|^2}{k^2}, \tag{2.8}$$

where $\delta(\cdot)$ is the Kronecker function, i.e., $\delta(i) = 1$ if $i = 0$, and $\delta(i) = 0$ otherwise. Now apply Abel's partial summation formula (Apostol (1967)). This gives

$$\begin{aligned} &|u(0)|^2 + \sum_{k=-n,k\neq 0}^{n} \frac{|u(k)|^2}{k^2} \\ &\quad = \frac{1}{(n+1)^2} \sum_{k=-n}^{n} |u(k)|^2 + \sum_{k=1}^{n} \sum_{l=-k}^{k} |u(l)|^2 \left(\frac{1}{k^2} - \frac{1}{(k+1)^2} \right) \\ &\quad \leq \frac{2n+1}{(n+1)^2} \frac{1}{2n+1} \sum_{k=-n}^{n} |u(k)|^2 + \sum_{k=1}^{n} \left(\frac{1}{2k+1} \sum_{l=-k}^{k} |u(l)|^2 \right) \frac{2(2k+1)}{k(k+1)^2} \\ &\quad \leq \frac{2n+1}{(n+1)^2} \|u\|_B^2 + 2 \left(\sum_{k=1}^{n} \frac{2k+1}{k(k+1)^2} \right) \|u\|_B^2 \leq 6\|u\|_B^2 \end{aligned} \tag{2.9}$$

for sufficiently large n. This proves part (a). We could prove part (b) by first noting that $\|u\|_B < \infty$ implies that $\|u\|_{BP} < \infty$ and then rely on part (a). Or, independently of this, we could split the sum

$$|u(0)|^2 + \sum_{k=-n,k\neq 0}^{n} \frac{|u(k)|^2}{k^2} \tag{2.10}$$

into two parts, the latter part being

$$\sum_{m<|k|\leq n} \frac{|u(k)|^2}{k^2}, \tag{2.11}$$

choosing n and m sufficiently large, applying Abel's partial summation formula to the latter part, so that one does not need a uniform bound on

$$\frac{1}{2n+1} \sum_{k=-n}^{n} |u_k|^2, \tag{2.12}$$

and estimate terms otherwise in an analogous manner to part (a). This idea of proof makes it plausible that no bound analogous to the bound in part (a) can be found. In fact, as we can find u with $u(0) \neq 0$ but $\|u\|_B = 0$, it follows that the latter claim of part (b) is true. This completes the proof of the theorem.

Wiener (1927) gives a weaker form of part (a) of the above result. Using this result it follows that if $\{u_k\}$ satisfies the condition $\|u\|_B < \infty$ (or $\|u\|_{BP} < \infty$), then

$$\{u_0, u(\pm 1)/(\pm 1), u(\pm 2)/(\pm 2), \ldots, u(\pm k)/(\pm k), \ldots\} \tag{2.13}$$

is a square summable sequence, and hence the function $s(\omega)$ defined by

$$s(\omega) = \frac{1}{2\pi} u(0)\omega + \frac{1}{2\pi} \sum_{k\neq 0} \frac{u(k)}{-ik} e^{-ik\omega}, \qquad \omega \in [-\pi, \pi] \tag{2.14}$$

is square integrable on $[-\pi,\pi]$, i.e., $s \in L_2(-\pi,\pi)$. Note that (2.14) also defines s outside the interval $[-\pi,\pi]$.

We have the following result. (Wiener (1949) mentions this result in a more general form without proof. We add here a proof for completeness.)

THEOREM 2.2. *Let $u = \{u_k\}$ be such that $\|u\|_A < \infty$. Then*

$$\|u\|_A^2 = \lim_{\epsilon \to 0} \frac{1}{2\epsilon} \int_{-\pi}^{\pi} |s(\omega+\epsilon) - s(\omega-\epsilon)|^2 \, d\omega. \tag{2.15}$$

Proof. We have that

$$s(\omega+\epsilon) - s(\omega-\epsilon) = \frac{1}{\pi} u(0)\epsilon - \frac{i}{\pi} \sum_{k \neq 0} u(k) e^{-ik\omega} \frac{\sin k\epsilon}{k}. \tag{2.16}$$

By Parseval's theorem

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} |s(\omega+\epsilon) - s(\omega-\epsilon)|^2 d\omega = \left(\frac{1}{\pi} u(0)\epsilon\right)^2 + \left(\frac{1}{\pi}\right)^2 \sum_{k \neq 0} |u(k)|^2 \left(\frac{\sin k\epsilon}{k}\right)^2. \tag{2.17}$$

Define the continuous-time signal $u(t)$ as $u(t) = u([t])$, where $[t]$ denotes the largest integer satisfying $[t] \leq t$. We now proceed to show that

$$\lim_{\epsilon \to 0} \frac{1}{\epsilon} \sum_{k \neq 0} |u(k)|^2 \left(\frac{\sin k\epsilon}{k}\right)^2 = \lim_{\epsilon \to 0} \frac{1}{\epsilon} \int_{-\infty}^{\infty} |u(t)|^2 \left(\frac{\sin \epsilon t}{t}\right)^2 dt. \tag{2.18}$$

Note that we can neglect here in the left-hand side (LHS) sum the terms corresponding to $k = -1, 0$, and in the right-hand side (RHS) integral the part $\int_{-1}^{1}$, as these tend to zero when $\epsilon \to 0$. We thus need to estimate (taking $\epsilon > 0$ to simplify the notation)

$$\begin{aligned}
&\left| \frac{1}{\epsilon} \sum_{k \neq -1,0} |u(k)|^2 \left(\frac{\sin k\epsilon}{k}\right)^2 - \frac{1}{\epsilon} \int_{|t|>1} |u(t)|^2 \left(\frac{\sin \epsilon t}{t}\right)^2 dt \right| \\
&\leq \frac{1}{\epsilon} \sum_{k \neq -1,0} |u(k)|^2 \int_k^{k+1} \left| \left(\frac{\sin \epsilon k}{k}\right)^2 - \left(\frac{\sin \epsilon t}{t}\right)^2 \right| dt \\
&\leq \frac{1}{\epsilon} \sum_{k \neq -1,0}^{-n \leq k \leq n} |u(k)|^2 \int_k^{k+1} + \frac{1}{\epsilon} \sum_{|k|>n} |u(k)|^2 \int_k^{k+1},
\end{aligned} \tag{2.19}$$

where $n > 1$ and the RHS expression is divided into two separate parts to facilitate the remaining size estimation. Substitute in the integrals above $t = k + x$, $0 \leq x \leq 1$. It is convenient to estimate (for $k \neq -1, 0$)

$$\begin{aligned}
&\int_k^{k+1} \left| \left(\frac{\sin \epsilon k}{k}\right)^2 - \left(\frac{\sin \epsilon t}{t}\right)^2 \right| dt \\
&= \int_0^1 \frac{|(k+x)^2 \sin^2 k\epsilon - k^2 \sin(k+x)\epsilon|}{k^2(k+x)^2} dx \\
&\leq \int_0^1 \frac{(x^2 + 2kx) \sin^2 k\epsilon}{k^2(k+x)^2} dx + \int_0^1 \frac{\sin^2 x\epsilon \sin^2 k\epsilon}{(k+x)^2} dx \\
&\quad + \frac{1}{2} \int_0^1 \frac{|\sin 2k\epsilon \sin 2x\epsilon|}{(k+x)^2} dx + \int_0^1 \frac{\cos^2 k\epsilon \sin^2 x\epsilon}{(k+x)^2} dx.
\end{aligned} \tag{2.20}$$

Now we continue estimating terms in (2.19). Consider first the term with $|k| \leq n$. Using (2.20) and the relationships $|\sin y| \leq |y|$ (for any real y) and $|k+x| \geq 1$, we then get

$$\frac{1}{\epsilon} \sum_{k \neq -1,0}^{-n \leq k \leq n} |u(k)|^2 \int_k^{k+1} \left| \left(\frac{\sin \epsilon k}{k} \right)^2 - \left(\frac{\sin \epsilon t}{t} \right)^2 \right| dt$$

$$\leq \epsilon \left[\frac{1}{3} + n + n^2 + \frac{1}{2} n + \frac{1}{3} \right] \sum_{k=-n}^{n} |u(k)|^2. \tag{2.21}$$

Similarly, we get for the term with $|k| > n$ in (2.19), taking $n > 10$

$$\frac{1}{\epsilon} \sum_{|k|>n} |u(k)|^2 \int_k^{k+1} \left| \left(\frac{\sin \epsilon k}{k} \right)^2 - \left(\frac{\sin \epsilon t}{t} \right)^2 \right| dt \leq (2+\epsilon) \sum_{|k|>n} \frac{|u(k)|^2}{k^2} \to 0 \tag{2.22}$$

when $n \to \infty$ by Theorem 2.1. Hence this, (2.21), and (2.19) imply the relationship (2.18). Observe that

$$\lim_{T \to \infty} \frac{1}{2T} \int_{-T}^{T} |u(t)|^2 \, dt = \lim_{n \to \infty} \frac{1}{2n+1} \sum_{k=-n}^{n} |u(k)|^2 \tag{2.23}$$

by construction. Hence the RHS integral in (2.18) is equal to $\pi/2$ times $\|u\|_A^2$ by an application of Theorem 21 in Wiener (1933). The result then follows by (2.18).

Let us assume for the moment that the sequence $u = \{u_k\}$ is such that the autocorrelation function (or covariance sequence) defined by

$$R_{uu}(\nu) = \lim_{n \to \infty} \frac{1}{2n+1} \sum_{k=-n}^{n} u(k+\nu)\overline{u(k)} \tag{2.24}$$

exists for any $\nu = 0, \pm 1, \pm 2, \ldots$. (This is not always the case, as Example 2.2 below shows.) Note that this is essentially the same definition as used in Wiener (1927).

We shall state here for later reference a necessary condition for the existence of the limit defining $R_{uu}(0)$.

Proposition 2.1. *A necessary condition for $R_{uu}(0)$ to exist is that*

$$\lim_{n \to \pm\infty} \frac{|u(n)|^2}{n} = 0. \tag{2.25}$$

Proof. This is easy, as a necessary condition for the existence of the required limit is given by

$$\lim_{n \to \infty} \left(\frac{1}{2n+3} \sum_{k=-n-1}^{n+1} |u(k)|^2 - \frac{1}{2n+1} \sum_{k=-n}^{n} |u(k)|^2 \right) = 0. \tag{2.26}$$

The result then follows readily.

Let S_A denote the set of all sequences having an autocorrelation function. Note that $R_{uu}(0) = \|u\|_A^2$. Furthermore, let the notation P_X mean the set defined by

$$P_X = \{u \,|\, \|u\|_X < \infty\}, \tag{2.27}$$

where X denotes a signal size symbol, e.g., $X = B$ in the case of the seminorm (2.2). Therefore we have the set inclusions $S_A \subset P_A \subset P_B = P_{BP}$. Note that the space P_B is the discrete analogue of the Marcinkiewicz space (Chen and Lau (1989)); see also section 2.2. Furthermore, P_{BP} is the discrete analogue of an important Banach space usually credited (Chen and Lau (1989)) to Beurling (1964); see also section 2.2.

Introduce for $u \in S_A$ the function

$$F_u(\omega) = \frac{1}{2\pi} R_{uu}(0)\omega + \frac{1}{2\pi} \sum_{k \neq 0} \frac{R_{uu}(k)}{-ik} e^{-ik\omega}, \qquad \omega \in [-\pi, \pi]. \tag{2.28}$$

(Again this is essentially the same definition as used in Wiener (1927).) It is easily seen that $|R_{uu}(k)| \leq R_{uu}(0)$ (using Schwarz's inequality). Hence $\{R_{uu}(k)\}$ is a bounded sequence. It therefore follows that $F_u(\omega)$ is a square integrable function, i.e., $F_u(\omega) \in L_2(-\pi, \pi)$. Following Wiener's terminology (Wiener (1927), (1930), (1933)), F_u will be called the spectrum of u. (The term *spectral distribution function* is often used instead, especially in the stochastic literature.) We just state some fairly standard properties of R_{uu} and F_u.

FACT 2.1. *Let* $u \in S_A$. *Then*

(a) $R_{uu}(-\nu) = \overline{R_{uu}(\nu)}$.

(b) R_{uu} *is positive semidefinite*; *i.e., for any complex sequence* $\{x_i\}$

$$\sum_{i=1}^{n} \sum_{j=1}^{n} x_i \bar{x}_j R_{uu}(i-j) \geq 0, \qquad n = 1, 2, \dots . \tag{2.29}$$

(c) F_u *is real-valued.*

It can be shown (Wiener (1927)) that F_u can be defined to be a nondecreasing function (note that our choice of interval of definition for F_u from $-\pi$ to π means that F_u can obtain both negative and positive values) so that

$$R_{uu}(\nu) = \int_{-\pi}^{\pi} e^{i\nu\omega} dF_u(\omega) \tag{2.30}$$

holds. Then furthermore,

$$R_{uu}(0) = F_u(\pi) - F_u(-\pi). \tag{2.31}$$

Note that the essential property for the existence of the spectrum, i.e., of a nondecreasing function satisfying (2.30), is the positive semidefiniteness of the covariance sequence. This is the same property that shows up in spectral analysis of stationary stochastic processes (Caines (1988)). Hence Herglotz's theorem (Caines (1988)) in the theory of positive semidefinite sequences proves the existence of the spectrum (spectral distribution).

Now (2.31) shows that it is possible to recover the signal size $\|u\|_A$ from the spectrum in the discrete case (the continuous case is more difficult). However, it is common to use the so-called spectral density function $f_u(\omega)$ introduced as

$$f_u(\omega) = \frac{1}{2\pi} \sum_{k=-\infty}^{\infty} R_{uu}(k) e^{-ik\omega}, \qquad -\pi \leq \omega \leq \pi \tag{2.32}$$

in spectral analysis. The recovery of the signal size $\|u\|_A$ from the spectral density function f_u is, however, a rather technical issue. The fact below illustrates that smoothness of the spectral density function guarantees recovery of the signal size $\|u\|_A$ from f_u.

FACT 2.2. *Let $u \in S_A$. If $\sum_{k=-\infty}^{\infty} |R_{uu}(k)| < \infty$, then the spectral density $f_u(\omega)$ is a continuous function and*

$$\int_{-\pi}^{\pi} f_u(\omega) d\omega = R_{uu}(0). \tag{2.33}$$

Unfortunately, in general

$$R_{uu}(0) = F_u(\pi) - F_u(-\pi) \geq \int_{-\pi}^{\pi} f_u(\omega) d\omega, \tag{2.34}$$

where strict inequality applies if F_u contains a singular part (i.e., a part that is continuous but has vanishing derivative almost everywhere) (Kolmogorov and Fomin (1970), Wiener (1927)), even if jumps in F_u are accounted for in f_u by allowing f_u to include impulses (Dirac delta functions).

We thus see that it need not be possible to recover the signal size correctly ($R_{uu}(0)$ is equal to $\|u\|_A^2$) from the spectral density f_u. This provides yet another motivation for studying alternative formulations of bounded power–like signals.

Input-output analysis for LTI (causal) systems is the topic of the next result with S_A as the signal set.

THEOREM 2.3. *Let G be a causal LTI system with (unit) impulse response $\{g(k)\}_{k \geq 0}$. Let $y = Gu$ denote the output of G to the input u defined by $y(t) = \sum_{k \geq 0} g(k) u(t-k)$. Let $u \in S_A$ and suppose that*

$$\sum_{k \geq 0} k^{1/2} |g(k)| < \infty. \tag{2.35}$$

Then $y \in S_A$, and the covariance sequence of the output y is given by

$$R_{yy}(\nu) = \sum_{k \geq 0, l \geq 0} g(k) \overline{g(l)} R_{uu}(\nu - k + l), \qquad \nu = 0, \pm 1, \pm 2, \dots . \tag{2.36}$$

Furthermore, $R_{yy}(\nu)$ can be expressed in terms of the spectrum F_u of u as

$$R_{yy}(\nu) = \int_{-\pi}^{\pi} e^{i\nu\omega} |G(e^{-i\omega})|^2 \, dF_u(\omega), \tag{2.37}$$

where $G(z) = \sum_{k \geq 0} g(k) z^k$.

Remark 2.1. Note that it is easy to see that condition (2.35) cannot be relaxed here to $\sum_{k \geq 0} |g(k)| < \infty$; cf. Mäkilä and Partington (1996). The condition of *strict stability*, i.e.,

$$\sum_{k \geq 0} k |g(k)| < \infty \tag{2.38}$$

(see Ljung (1987) for the terminology) would at first inspection appear more natural than condition (2.35) here because we get for an arbitrary $u \in S_A$, by an application of Schwarz's inequality,

$$\begin{aligned} |y(t)| &\leq \sum_{k \geq 0} |g(k)| |u(t-k)| \\ &\leq |g(0)||u(t)| + \left(\sum_{k \geq 1} k^2 |g(k)|^2 \right)^{1/2} \left(\sum_{k \geq 1} \frac{|u(t-k)|^2}{k^2} \right)^{1/2}, \end{aligned} \tag{2.39}$$

where the RHS is finite by Theorem 2.1 and by (2.38) (this is easy to verify). Hence strict stability guarantees that the output y is well defined. Obviously strict stability implies (2.35). Note that strict stability implies that the frequency response $G(e^{i\theta})$ of the system is continuously differentiable, while (2.35) does not even imply differentiability of $G(e^{i\theta})$.

Proof of Theorem 2.3. Introduce the quantity

$$r_{yy}(\nu) = \sum_{k\geq 0, l\geq 0} g(k)\overline{g(l)} R_{uu}(\nu - k + l), \qquad \nu = 0, \pm 1, \pm 2, \dots . \tag{2.40}$$

Now $r_{yy}(\nu)$ clearly exists for any ν as $\{g(k)\}$ is absolutely summable and $\{R_{uu}(\tau)\}$ is a bounded sequence. We now show that the output covariance sequence $\{R_{yy}(\nu)\}$ is given by $\{r_{yy}(\nu)\}$ when (2.35) holds. We can take

$$\|G\|_1 \equiv \sum_{k\geq 0} |g(k)| > 0, \tag{2.41}$$

as otherwise there is nothing to prove. We estimate

$$\begin{aligned}
&\left| \frac{1}{2n+1} \sum_{t=-n}^{n} y(t+\nu)\overline{y(t)} - r_{yy}(\nu) \right| \\
&\quad = \left| \sum_{k\geq 0, l\geq 0} g(k)\overline{g(l)} \left[\frac{1}{2n+1} \sum_{t=-n}^{n} u(t+\nu-k)\overline{u(t-l)} - R_{uu}(\nu-k+l) \right] \right| \\
&\quad \leq \left| \sum_{k=0,l=0}^{k=N,l=N} g(k)\overline{g(l)} \left[\frac{1}{2n+1} \sum_{t=-n}^{n} u(t+\nu-k)\overline{u(t-l)} - R_{uu}(\nu-k+l) \right] \right| \\
&\quad + \left| \sum_{\max(k,l)>N} g(k)\overline{g(l)} \left[\frac{1}{2n+1} \sum_{t=-n}^{n} u(t+\nu-k)\overline{u(t-l)} - R_{uu}(\nu-k+l) \right] \right| .
\end{aligned} \tag{2.42}$$

Consider the last term in (2.42). Clearly

$$\sum_{\max(k,l)>N} g(k)\overline{g(l)} R_{uu}(\nu-k+l) \to 0 \tag{2.43}$$

when $N \to \infty$ (recall that $|R_{uu}(\nu-k+l)| \leq R_{uu}(0)$). Furthermore, by Schwarz's inequality

$$\begin{aligned}
&\left| \sum_{\max(k,l)>N} g(k)\overline{g(l)} \frac{1}{2n+1} \sum_{t=-n}^{n} u(t+\nu-k)\overline{u(t-l)} \right| \\
&\quad \leq \sum_{\max(k,l)>N} |g(k)||g(l)| \left(\frac{1}{2n+1} \sum_{t=-n}^{n} |u(t+\nu-k)|^2 \right)^{1/2} \\
&\quad \times \left(\frac{1}{2n+1} \sum_{t=-n}^{n} |u(t-l)|^2 \right)^{1/2}
\end{aligned}$$

$$\leq \sum_{\max(k,l)>N} |g(k)||g(l)| \left(\frac{2(n+|\nu|+k)+1}{2n+1}\right)^{1/2} \left(\frac{2(n+l)+1}{2n+1}\right)^{1/2}$$

$$\times \left(\frac{1}{2(n+|\nu|+k)+1} \sum_{t=-n-|\nu|-k}^{n+|\nu|+k} |u(t)|^2\right)^{1/2}$$

$$\times \left(\frac{1}{2(n+l)+1} \sum_{t=-n-l}^{n+l} |u(t)|^2\right)^{1/2}. \tag{2.44}$$

Now the RHS of the last inequality above tends to zero when $N \to \infty$ by (2.35) and as

$$\frac{1}{2n+1} \sum_{t=-n}^{n} |u(t)|^2 \tag{2.45}$$

tends to $R_{uu}(0)$ (i.e., to a finite limit) when $n \to \infty$.

It therefore remains only to show that the first term on the RHS of the inequality (2.42) tends to zero when n tends to infinity for any finite N, for the first part of the theorem to follow. Hence we need to estimate

$$\left| \sum_{k=0,l=0}^{k=N,l=N} g(k)\overline{g(l)} \left[\frac{1}{2n+1} \sum_{t=-n}^{n} u(t+\nu-k)\overline{u(t-l)} - R_{uu}(\nu-k+l) \right] \right|$$

$$\leq \left| \sum_{k,l=0}^{k,l=N} g(k)\overline{g(l)} \left[\frac{1}{2n+1} \left(\sum_{t=-n}^{n} u(t+\nu-k)\overline{u(t-l)} \right.\right.\right.$$

$$\left.\left.\left. - \sum_{\tau=-n}^{n} u(\tau+\nu-k+l)\overline{u(\tau)} \right) \right] \right|$$

$$+ \left| \sum_{k,l=0}^{k,l=N} g(k)\overline{g(l)} \left[\frac{1}{2n+1} \sum_{t=-n}^{n} u(t+\nu-k+l)\overline{u(t)} - R_{uu}(\nu-k+l) \right] \right|. \tag{2.46}$$

Consider the last term above. Let $\epsilon > 0$ be given. As $u \in S_A$ it follows that there exists a positive integer $n(\epsilon, N, \nu)$ such that

$$\left| \frac{1}{2n+1} \sum_{t=-n}^{n} u(t+\nu-k+l)\overline{u(t)} - R_{uu}(\nu-k+l) \right|$$

$$\leq \epsilon/(2\|G\|_1^2), \quad 0 \leq k, l \leq N, \tag{2.47}$$

for any $n \geq n(\epsilon, N, \nu)$. Letting $n \geq n(\epsilon, N, \nu)$ we thus get

$$\left| \sum_{k,l=0}^{k,l=N} g(k)\overline{g(l)} \left[\frac{1}{2n+1} \sum_{t=-n}^{n} u(t+\nu-k+l)\overline{u(t)} - R_{uu}(\nu-k+l) \right] \right|$$

$$\leq \sum_{k,l=0}^{k,l=N} |g(k)||g(l)|\epsilon/(2\|G\|_1^2) \leq \epsilon/2. \tag{2.48}$$

Consider now the first term on the RHS of the inequality (2.46). Take $n_1 > \min[N + |\nu|, n(\epsilon, N, \nu)]$ such that

$$|u(n)|^2 \leq \frac{\epsilon\, n}{2\|G\|_1^2 N(N+|\nu|)} \tag{2.49}$$

for any $n \geq n_1$. This is possible by Proposition 2.1. Take $n \geq n_1$. Then

$$\begin{aligned}&\left|\sum_{t=-n}^{n} u(t+\nu-k)\overline{u(t-l)} - \sum_{\tau=-n}^{n} u(\tau+\nu-k+l)\overline{u(\tau)}\right| \\ &\qquad \leq l\,\{\epsilon[n+|\nu|+\max(k,l)]\}/[2\|G\|_1^2 N(N+|\nu|)].\end{aligned} \tag{2.50}$$

Therefore, finally,

$$\begin{aligned}&\left|\sum_{k,l=0}^{k,l=N} g(k)\overline{g(l)}\left[\frac{1}{2n+1}\left(\sum_{t=-n}^{n} u(t+\nu-k)\overline{u(t-l)} - \sum_{\tau=-n}^{n} u(\tau+\nu-k+l)\overline{u(\tau)}\right)\right]\right| \\ &\qquad \leq \sum_{k,l=0}^{k,l=N} |g(k)||g(l)|[\epsilon\, N(n+|\nu|+N)]/[2\|G\|_1^2 N(N+|\nu|)(2n+1)] \\ &\qquad \leq \|G\|_1^2[\epsilon\, N(|\nu|+N)]/[2\|G\|_1^2 N(N+|\nu|)] \leq \epsilon/2.\end{aligned} \tag{2.51}$$

As $\epsilon > 0$ is arbitrary, it follows that it is possible to make the RHS of the inequality in (2.46) as small as one likes by choosing n large enough. As this conclusion holds for any N, this concludes the proof of the first part of the theorem; i.e.,

$$R_{yy}(\nu) = \lim_{n\to\infty} \frac{1}{2n+1}\sum_{t=-n}^{n} y(t+\nu)\overline{y(t)} \tag{2.52}$$

exists and is given by $r_{yy}(\nu)$. The latter part of the theorem, i.e., (2.37), follows readily by properties of Lebesgue–Stieltjes integrals by directly computing

$$\begin{aligned}\int_{-\pi}^{\pi} e^{i\nu\omega}|G(e^{-i\omega})|^2 dF_u &= \int_{-\pi}^{\pi} e^{i\nu\omega}\sum_{k,l\geq 0} g(k)\overline{g(l)}e^{-ik\omega}e^{il\omega}dF_u \\ &= \sum_{k,l\geq 0} g(k)\overline{g(l)}\int_{-\pi}^{\pi} e^{i(\nu-k+l)\omega}\,dF_u \\ &= \sum_{k,l\geq 0} g(k)\overline{g(l)}R_{uu}(\nu-k+l) = R_{yy}(\nu),\end{aligned} \tag{2.53}$$

where we have used absolute summability of $\{g(k)\}$, which implies continuity of the transfer function $G(e^{-i\omega})$, (2.30), and finally (2.36).

Theorem 2.3 shows that it is the set S_A, not the larger set P_A, that is natural in input-output analysis when the limit operation is used in the signal set definition. Note that if we restrict the input to the intersection $S_A \cap \ell_\infty(\mathbb{Z})$, the condition of strict stability can be relaxed to the condition $\sum_{k\geq 0}|g(k)| < \infty$. This we see easily following the steps of the proof above; cf. also Theorem 2.2 in Ljung (1987). Ljung (1987) defines a setup of quasi-stationary signals which reduces to the single-sided time axis variant of $S_A \cap \ell_\infty(\mathbb{Z})$ (Ljung (1987) considers the single-sided time axis case) when deterministic signal modeling is used only.

Theorem 2.3 has the following important corollary.

COROLLARY 2.1. *Let the conditions of Theorem* 2.3 *hold. Then*

$$\|G\|_{S_A} \equiv \sup_{u \in S_A, \|u\|_A \neq 0} \frac{\|Gu\|_A}{\|u\|_A} = \|G\|_\infty, \tag{2.54}$$

where $\|G\|_\infty = \sup_\omega |G(e^{-i\omega})|$.

This result is obvious from Theorem 2.3. It guarantees that the H_∞ norm of the system transfer function gives the induced system gain in S_A under mild assumptions, e.g., for strictly stable systems and hence for exponentially stable systems specifically. Note that this result is obtained with the help of the machinery of Lebesgue–Stieltjes integrals. In the literature (Boyd and Barratt (1991); Doyle, Francis, and Tannenbaum (1992); Zhou et al. (1994)) similar results have been derived for stable finite dimensional systems in some subset of S_A only, e.g., for signals such that $R_{uu}(0) = \int_{-\pi}^{\pi} f_u(\omega)\, d\omega$.

Remark 2.2. An equivalent problem to that of determining the $\|\cdot\|_A$ gain is the following. Let $v_m = [g(0), \ldots, g(m)]^T$ and consider the optimization problem

$$\sup_T \frac{v_m^H T v_m}{T_{11}}, \tag{2.55}$$

where the symbol H denotes complex conjugate transpose and where the supremum is taken over all positive semidefinite Hermitian Toeplitz matrices with $T_{11} > 0$. This supremum is given by the square of the H_∞ norm of $G_m(z) = \sum_{k=0}^{m} g(k) z^k$, since the supremization problem is equivalent to the problem of determining $\|G_m\|_A^2$. (It suffices to observe that a finite segment of the covariance sequence of $u \in S_A$ generates a positive semidefinite Hermitian Toeplitz matrix and to each such positive semidefinite Hermitian Toeplitz matrix there corresponds a $\tilde{u} \in S_A$, e.g., by standard results from the theory of stationary stochastic processes (Karlin and Taylor (1975)).)

Let us now study whether we could get linear vector space setups by changing from a quadratic norm to some other norm (as we observed that in the quadratic case we needed cross-correlations (i.e., generalizations, R_{uv}, of the autocorrelation function R_{uu} to signal pairs u and v in a natural way) to exist to get a subset of S_A, which is a linear vector space).

We get the following result.

PROPOSITION 2.2. *Consider signals* $u = \{u_k\}$ *satisfying*

$$\lim_{n\to\infty} \frac{1}{2n+1} \sum_{k=-n}^{n} |u(k)| < \infty. \tag{2.56}$$

There exist signals u *and* v *satisfying* (2.56) *whose sum* $u + v$ *does not have a limit of the form in* (2.56). *Hence, the set defined by condition* (2.56) *is not a linear vector space.*

Proof. Define the sequence $u \in S_A$ as $u(k) = +1$ for all k, and the sequence $v \in S_A$ as $v(0) = -1$, $v(k) = +1$ for $|k| = 2^1 - 1$ to $2(2^1 - 1)$, $v(k) = -1$ for $|k| = 2^2 - 1$ to $2(2^2 - 1)$, $v(k) = +1$ for $|k| = 2^3 - 1$ to $2(2^3 - 1)$, etc. Evaluating

$$s_n(u,v) = \frac{1}{2n+1} \sum_{k=-n}^{n} |u(k) + v(k)| \tag{2.57}$$

for different n, we see that the generated s_n has two points of accumulation (4/3 and 2/3), and so s_n does not tend to any limit when $n \to \infty$. The result follows.

It is easy to generalize this result to other ℓ_p norms. Our conclusion is that the problem is in the use of the limit operation in the definition of the signal set, so the natural remedy is to study more general operations on signals.

The lack of linear vector space structure is a disturbing property of formulations of bounded power signals using the limit operation, and there are some other difficulties as well.

Let $y = Gu$ denote the output of the system G to the input $u = [u_1, \ldots, u_m]^T$ (each u_i is a complex (or real) sequence). Furthermore, let the size of u be measured by some function $\|u\|$ of $\|u_i\|_A$, $i = 1, \ldots, m$, with the property that in the single-variable case this function reduces to the $\| \cdot \|_A$ function. Let the size of y be measured with the same function as u.

FACT 2.3. *There is a causal, stable, finite dimensional, LTI multivariable system G for which $\|u\| < \infty$ does not imply that $\|y\|$ exists, where $y = Gu$.*

To get an example of such a multivariable system it suffices to consider the two-input and one-output system $G = [1, 1]$. The output $y = Gu$ is then given by $y = u_1 + u_2$. Hence the claim of the fact follows as S_A is not a linear vector space.

Note that this result is true for any function $\| \cdot \|$ as defined above. The only way to get around this property would be to require that in order that u be an admissible input signal, the cross-covariances of the elements of u must exist. However, there does not seem to be any good physical reason to make such a restriction. Anyway, in the standard GHA formulation for the multivariable case (Wiener (1949)) the existence of the covariance matrix sequence

$$R_{uu}(\nu) = \lim_{n \to \infty} \frac{1}{2n+1} \sum_{k=-n}^{n} u(k+\nu)\overline{u(k)}^T, \qquad \nu = 0, \pm 1, \pm 2, \ldots \tag{2.58}$$

is required. This is, however, somewhat counterintuitive as a basis for a signal set for robustness analysis, e.g., as the existence of cross-covariances between the components of an input vector means that different components must know what the other components are for them to be admissible (which is not a very natural requirement in many applications, although technically not very restrictive). For example, if $m = 2$ (i.e., the input is two-dimensional) and we take $u_1 = 0$ and $u_2 = v$, where v is defined in the proof of Proposition 2.2, then $u = [u_1, u_2]$ has a covariance matrix sequence, but if $u_1 = 1$ and $u_2 = v$, then u has not, and so this input is not admissible from the GHA point of view.

We shall now consider an example demonstrating that a more serious shortcoming of the standard GHA signal setup for robustness analysis is that, in general, it is not appropriate for non-LTI systems or when non-LTI system perturbations are present.

Example 2.1. Consider the causal linear time-varying system

$$y(t) = \sum_{k \geq 0} g(t,k) u(t-k). \tag{2.59}$$

Let $u \in S_A$ have the constant value 1. Define $g(0,0) = 1$, $g(t,0) = 0$ for $|t| = 2^1 - 1$ to $2(2^1 - 1)$, $g(t,0) = 1$ for $|t| = 2^2 - 1$ to $2(2^2 - 1)$, $g(t,0) = 0$ for $|t| = 2^3 - 1$ to $2(2^3 - 1)$, etc. Let $g(t,k) = 0$ for any $k > 0$ and any t. (Obviously, $g(t,k) = 0$ for

$k < 0$ by causality.) Then the sequence

$$s_n(y) = \frac{1}{2n+1} \sum_{t=-n}^{n} y(t)\overline{y(t)} \tag{2.60}$$

has two points of accumulation (1/3 and 2/3), and so y does not belong to S_A.

2.2. Continuous-time case. Let u denote a real- or complex-valued signal which is locally square integrable on the real axis. Let us specify two signal norms as follows:

$$\|u\|_S = \left(\sup_{T>0} \frac{1}{2T} \int_{-T}^{T} |u(t)|^2 \, dt \right)^{1/2}, \tag{2.61}$$

$$\|u\|_{BP} = \left(\sup_{T\geq 1} \frac{1}{2T} \int_{-T}^{T} |u(t)|^2 \, dt \right)^{1/2}, \tag{2.62}$$

and the seminorm

$$\|u\|_B = \left(\limsup_{T\to\infty} \frac{1}{2T} \int_{-T}^{T} |u(t)|^2 \, dt \right)^{1/2}. \tag{2.63}$$

As in the discrete case, a further seminorm could be defined using Banach limits, but it would not be of practical use.

Wiener (1933) gave several results related to GHA in terms of a boundedness condition on $\| \cdot \|_S$. Using an analogous notation as in the discrete-time case, we let P_X mean the set defined by

$$P_X = \{u \in L^2_{loc}(R) \mid \|u\|_X < \infty\}, \tag{2.64}$$

where X denotes a signal size symbol and $L^2_{loc}(R)$ the set of all locally square integrable functions on the real axis. P_S and P_{BP} are Banach spaces. Many functional analytic results related to these spaces are given in Beurling (1964) and Chen and Lau (1989).

The continuous-time analogue of the B-seminorm, i.e., $\|u\|_B$ as defined above, is discussed in Wiener (1979, p. 334), where Masani refers to the vector space that it defines as the *Marcinkiewicz vector space.* It is worth noting that taking the completion of the space of almost periodic functions under $\| \cdot \|_B$, which is a norm on it, produces some objects which are not functions in the usual sense (cf. Jacob, Larsen, and Zwart (1996); Larsen (1996)). See also Chen and Lau (1989) for further historical remarks and additional references.

The following set inclusions are clearly valid: $P_S \subset P_{BP} = P_B$. We get the following result.

THEOREM 2.4. *Let u be a locally square integrable function on the real axis.*

(a) *If $\|u\|_S < \infty$, then*

$$\int_{-\infty}^{\infty} \frac{|u(t)|^2}{1+t^2} \, dt \leq \pi \|u\|_S^2. \tag{2.65}$$

(b) *If $\|u\|_{BP} < \infty$, then*

$$\int_{-\infty}^{\infty} \frac{|u(t)|^2}{1+t^2} \, dt \leq \left(2 + \frac{\pi}{2}\right) \|u\|_{BP}^2. \tag{2.66}$$

(c) *If* $\|u\|_B < \infty$, *then*

$$\int_{-\infty}^{\infty} \frac{|u(t)|^2}{1+t^2}\, dt < \infty. \tag{2.67}$$

Furthermore, there does not exist any bound of the form

$$\int_{-\infty}^{\infty} \frac{|u(t)|^2}{1+t^2}\, dt \leq C\|u\|_B^2 \tag{2.68}$$

for some constant $C > 0$.

Proof. Note that part (a) above is Theorem 20 in Wiener (1933) with a somewhat tighter bound. Integration by parts gives

$$\int_{-A}^{A} \frac{|u(t)|^2}{1+t^2}\, dt = \frac{1}{1+A^2}\int_{-A}^{A} |u(t)|^2\, dt + \int_0^A \frac{2t}{(1+t^2)^2}\, dt \int_{-t}^{t} |u(\tau)|^2\, d\tau. \tag{2.69}$$

Hence

$$\int_{-A}^{A} \frac{|u(t)|^2}{1+t^2}\, dt \leq \left(\frac{2A}{1+A^2} + \int_0^A \left(\frac{2t}{1+t^2}\right)^2 dt\right)\|u\|_S^2 = 2(\arctan A)\|u\|_S^2 \leq \pi\|u\|_S^2. \tag{2.70}$$

To prove part (b) we partition the interval of integration in the last term in (2.69) into two intervals as follows:

$$\int_0^A \frac{2t}{(1+t^2)^2}\, dt \int_{-t}^{t} |u(\tau)|^2\, d\tau = \int_0^1 + \int_1^A \tag{2.71}$$

for $A > 1$. Then we notice that

$$\int_{-t}^{t} |u(\tau)|^2\, d\tau \leq 2\|u\|_{BP}^2 \tag{2.72}$$

for $0 \leq t \leq 1$. Inserting these relationships in (2.69) and proceeding otherwise as in part (a) gives

$$\int_{-A}^{A} \frac{|u(t)|^2}{1+t^2}\, dt \leq \left(\frac{2A}{1+A^2} + 2 - \frac{\pi}{2} + 2\arctan A - \frac{2A}{1+A^2}\right)\|u\|_{BP}^2 \tag{2.73}$$

from which part (b) follows. Part (c) follows in a rather analogous manner, so we omit the proof here. The nonexistence of a bound of the form indicated follows as there are nontrivial signals with $\|u\|_B = 0$, while the integral on the LHS of the bound is greater than zero.

Introduce the autocovariance function (Wiener (1933)) of u by

$$R_{uu}(\tau) = \lim_{T\to\infty} \frac{1}{2T}\int_{-T}^{T} u(t+\tau)\overline{u(t)}dt. \tag{2.74}$$

when the indicated limit exists. Let S_A denote the set of all signals u for which $R_{uu}(\tau)$ exists for all real τ. Wiener (1933) has shown that $|R_{uu}(\tau)| \leq R_{uu}(0)$ for all τ for any $u \in S_A$. Let us define the average power signal measure in analogy with the discrete-time case by $\|u\|_A = \sqrt{R_{uu}(0)}$. The following example shows that there exist signals u which have a bounded average power but for which the autocovariance function is not always well defined.

Example 2.2. Let $u(t)$ be constructed to be real and to take the constant value $\epsilon_k = \pm 1$ on each interval of the form $(k, k+1)$, $k \in \mathbb{Z}$, where $\epsilon_{-1} = \epsilon_0 = \epsilon_1 = 1$ and ϵ_k is defined by induction on $|k|$ to satisfy

$$\epsilon_k \epsilon_{k+1} = \begin{cases} +1 & \text{if } 3^{2n} \leq |k| < 3^{2n+1}, \\ -1 & \text{if } 3^{2n+1} \leq |k| < 3^{2n+2} \end{cases} \tag{2.75}$$

for each $n \geq 0$. It is easily checked that u has unit average power but that if $R_{uu}(1)$ existed it would be given by

$$R_{uu}(1) = \lim_{N \to \infty} \frac{1}{2N} \sum_{k=-N}^{N-1} \epsilon_k \epsilon_{k+1}. \tag{2.76}$$

However, this limit does not exist.

This example can clearly be adapted to hold in the discrete-time case as well.

Wiener (1933) has shown that there exists for any $u \in S_A$ a nondecreasing function $\sigma_u(\omega)$ of bounded variation such that almost everywhere

$$R_{uu}(\tau) = \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{i\omega\tau} d\sigma_u(\omega), \tag{2.77}$$

where the integral should be interpreted as a Lebesgue–Stieltjes integral. (It is worth noting here that the validity of this result does not require that $\|u\|_S < \infty$; it is enough to assume that $\|u\|_B < \infty$. This is important as S_A is not a subset of P_S.) This result follows also by Bochner's theory for positive semidefinite functions (Bochner (1959)). The function σ_u is called the spectrum of u.

It is also possible to introduce the spectral density f_u of $u \in S_A$ by

$$f_u(\omega) = \int_{-\infty}^{\infty} R_{uu}(\tau) e^{-i\omega\tau} d\tau, \qquad \omega \in R. \tag{2.78}$$

The correct interpretation of f_u is a bit technical in the general case but can be given in terms of generalized functions or distributions. Under certain conditions it can simply be interpreted as the derivative of the spectrum $\sigma_u(\omega)$.

The problem of recovery of the average power of a signal in S_A from its spectrum or from its spectral density is highly nontrivial. However, a fairly complete answer has been given by Wiener (1933). We state Wiener's results on this below. Let T_A denote the subset of S_A consisting of those signals having a continuous autocorrelation function. (Wiener (1933) shows that the autocorrelation function is continuous for all τ if it is continuous for $\tau = 0$, a remarkable result!)

FACT 2.4 (Wiener (1933)).

(a) *If $u \in S_A$, then*

$$\sigma_u(\infty) - \sigma_u(-\infty) \leq R_{uu}(0). \tag{2.79}$$

(b) *Let $u \in S_A$. Then*

$$\sigma_u(\infty) - \sigma_u(-\infty) = R_{uu}(0) \tag{2.80}$$

if and only if $u \in T_A$.

Conditions for recovery of the average power of a signal from the power density function are even trickier than those given above. Note that, e.g., in Zhou et al. (1994), it is suggested that one could use the formula

$$R_{uu}(0) = \frac{1}{2\pi}\int_{-\infty}^{\infty} f_u(\omega)d\omega, \tag{2.81}$$

but unfortunately Fact 2.4 shows that this formula does not apply when the autocorrelation function of R_{uu} lacks continuity.

The problem in general is that the spectrum and the spectral density have smoothed out certain information about the signal u. Let us provide an example of this phenomenon.

Example 2.3. Consider the static nonlinearity $y = G(u) = |u|$. Introduce the system gain by

$$\|G\| = \sup_{u\in S_A, \|u\|_A \neq 0} \frac{\|G(u)\|_A}{\|u\|_A}. \tag{2.82}$$

Clearly $\|G\| = 1$. Now consider what one could conclude by applying formula (2.81). Let us choose the signal $u(t) = e^{it^2} \in S_A$. The autocorrelation function of u is given by (Wiener (1933)) $R_{uu}(0) = 1$, $R_{uu}(\tau) = 0$, elsewhere. But formula (2.81) gives erroneously that $R_{uu}(0) = 0$ as the spectral density function is identical to zero (the same result is obtained by evaluating the total variation of the spectrum). However, $y = G(u)$ is now the constant signal $y(t) = 1$, so its spectrum has a jump of 1 at $\omega = 0$ and its spectral density is the Dirac delta function (i.e., a generalized function). So now both the total variation of the spectrum and formula (2.81) give the correct value 1 for the average power of the output. Hence one could erroneously conclude that the system gain for the static nonlinearity must be unbounded!

We would now like to determine the induced system gain in a GHA (S_A) setup for some fairly large class of continuous-time LTI systems; cf. Corollary 2.1 for the discrete-time case. One such result is as follows. Let G map S_A into S_A. Define the induced system gain

$$\|G\|_{S_A} = \sup_{u\in S_A, \|u\|_A \neq 0} \frac{\|Gu\|_A}{\|u\|_A}. \tag{2.83}$$

Note that we use here (for simplicity) the same notation as in the discrete-time case.

THEOREM 2.5 (Mäkilä (1990)). *Let G be a causal LTI system given by convolution with a* (*unit*) *impulse response function $g(t)$, such that $tg(t)$ is absolutely integrable* (*on the nonnegative reals*) *and such that $(1+t)g(t)$ is square integrable* (*on the nonnegative reals*). *Then*

$$\|G\|_{S_A} = \|G\|_\infty, \tag{2.84}$$

where $\|G\|_\infty = \sup_{Re\, s\geq 0} |G(s)|$ denotes the H_∞ norm of the transfer function $G(s)$ of the system, the latter being defined by

$$G(s) = \int_0^\infty e^{-st} g(t)\, dt. \tag{2.85}$$

Proof. The proof of this result was sketched in Mäkilä (1990). We shall give a slightly more detailed proof here. This result follows from some important results in Wiener (1933). The output y of the system G to the input $u \in S_A$ is defined by

$$y(t) = \int_0^\infty g(\tau)u(t-\tau)\,d\tau. \tag{2.86}$$

By Lemma 29_6 in Wiener (1933), it follows by the assumptions on G that the output y has a continuous autocorrelation function; i.e., it belongs to T_A. This means that the autocorrelation function of y can be exactly recovered from the spectrum σ_y of y, and in particular that $\sigma_y(\infty) - \sigma_y(-\infty) = \|y\|_A^2$. Thus by Fact 2.4 and Theorems 30 and 31 in Wiener (1933)

$$\|G\|_{S_A}^2 \le \sup_{\sigma_u(\infty)-\sigma_u(-\infty)>0} \frac{\int_{-\infty}^{\infty} |G(j\omega)|^2\,d\sigma_u}{\int_{-\infty}^{\infty} d\sigma_u}, \tag{2.87}$$

where $\sigma_u(\omega)$ denotes the spectrum of u. (Note that we can take the supremum here over signals u with spectra having nonzero total variation; as for signals with $\|u\|_A \neq 0$ but having zero spectrum, the signal amplification is zero, i.e., then $\|y\|_A = 0$ under the assumptions of the theorem.) Here the integrals are Lebesgue–Stieltjes integrals. To see how (2.87) can be utilized, observe that, by the Schwarz inequality,

$$\int_0^\infty |g(t)|\,dt \le \left(\int_0^\infty |g(t)|^2(1+t)^2\,dt\right)^{1/2} \left(\int_0^\infty \frac{1}{(1+t)^2}\,dt\right)^{1/2} < \infty. \tag{2.88}$$

Hence g is absolutely integrable on the nonnegative reals, i.e., belongs to $L_1(R_+)$. It follows that the frequency response $G(j\omega)$ is a continuous function tending to zero when $|\omega| \to \infty$ (by the Riemann–Lebesgue lemma). We see then readily that the RHS of (2.87) is bounded from above by the square of the H_∞ norm of the transfer function of G. As there exists a periodic signal u in S_A, with frequency equal to a finite frequency at which $|G(j\omega)|$ attains its maximum, having the signal gain amplification ratio $\|Gu\|_A/\|u\|_A = \|G\|_\infty$, the proof of the theorem is completed.

Remark 2.3. Note that it is not possible to relax the conditions on G to absolute integrability of g on the nonnegative reals. This is seen easily by a counterexample analogous to the discrete-time example given in Mäkilä and Partington (1996). The above result means that the induced system gain in an S_A setup is given by the H_∞ norm of the system transfer function for a large class of systems, including, e.g., LTI systems having an exponentially decaying impulse response function.

3. Generalized bounded power signal setups. In this section we shall consider several generalized bounded power signal setups. There are several subtle issues when analyzing bounded power signals and corresponding induced input-output norms for LTI causal systems. Some of these subtle issues are related to differences between the two-sided (double-sided) time axis case and the single-sided time axis case.

3.1. Discrete-time case. Let F be a causal LTI operator mapping sequences $\{u(k)\}_{k\ge0}$ to $\{y(k)\}_{k\ge0}$.

THEOREM 3.1. *An operator F as above has finite gain with respect to the seminorm $\|\cdot\|_B$ if and only if it is bounded with respect to the BP norm; this happens if and only if F is ℓ_2 bounded and thus corresponds to a transfer function in H_∞.*

Proof. If F is ℓ_2 bounded, then it has finite $\|\cdot\|_B$ gain, since, as in Mäkilä and Partington (1996),

$$\frac{1}{n+1}\sum_{k=0}^{n}|y(k)|^2 \le \|F\|_2^2\frac{1}{n+1}\sum_{k=0}^{n}|u(k)|^2, \tag{3.1}$$

and the result follows on taking the limit superior of each side as $n \to \infty$.

For the converse we show the following "automatic continuity" result. *Any causal LTI operator that maps each one-sided sequence in BP into a sequence in BP is bounded as an operator on the one-sided BP space.* This will give the result, since, if F is $\|\cdot\|_B$ bounded, then F maps BP into BP; then, by Mäkilä and Partington (1996), F is ℓ_2 bounded. The method we use is a standard one and similar to the proof of Theorem 1 of Loy (1974).

Suppose to the contrary that there exist $u^{(n)}$ with $\|u^{(n)}\|_{BP}=1$ but $\|y^{(n)}\|_{BP}\ge n$. We shall establish a contradiction by constructing an input u with bounded power mapping to an output y with unbounded power, so we can certainly assume that each $y^{(n)}$ has bounded power.

We write S for the right shift so that $S(a_0,a_1,a_2,\dots)=(0,a_1,a_2,\dots)$, and consider $u^{(2)}$. There will be a constant K_1 such that the corresponding output y satisfies

$$\left(\frac{1}{K_1}\sum_{k=0}^{K_1-1}|y_k|^2\right)^{1/2} > 1. \tag{3.2}$$

We express this by saying that the power at time K_1-1 is greater than 1.

Now let $N_1>2$, consider $u^{(2)}+S^{K_1}u^{(N_1)}/2$, and estimate the power of the corresponding output y. It is the same as before at time K_1-1, and at time K_1+n it is

$$\left(\frac{1}{K_1+n+1}\sum_{k=0}^{K_1+n}|y_k|^2\right)^{1/2} \ge -p_1+q, \tag{3.3}$$

where p_1 is the output power due to the first input and q is that due to the second one. We assumed that p_1 was finite and we can make $q-p_1>2$ by choosing N_1 large since it requires

$$\left(\frac{n+1}{K_1+n+1}\right)^{1/2}\frac{N_1}{2} > p_1+2, \tag{3.4}$$

which holds, whatever n is, once $(1/(K_1+1))^{1/2}N_1/2 > p_1+2$.

So let K_2 be such that, with input $u^{(2)}+S^{K_1}u^{(N_1)}/2$ the corresponding output has power at least 2 by time K_2-1. Repeat, and now consider $u^{(2)}+S^{K_1}u^{(N_1)}/2+S^{K_2}u^{(N_2)}/4$, where N_2 is large enough that the inequality $(1/(K_2+1))^{1/2}N_2/4 > p_2+3$, where p_2 is the maximum output power due to the first two inputs.

Repeating this way we obtain an input $u^{(2)}+\sum_{j=1}^{\infty}S^{K_j}u^{(N_j)}/2^j$, whose power is bounded but which gives an output with unbounded power. This completes the proof.

Remark 3.1. A natural question here is whether for some $C>0$ there holds an inequality of the form $\|F\|_{BP\to BP}\le C\|F\|_{B\to B}$. For systems with ℓ_1 impulse responses, this is easily seen to be the case, since they map periodic sequences of the form $(u, u, u, u, \ldots)$, where u is a finite-length vector, into sequences of the form $(y_1, y_1 + y_2, y_1 + y_2 + y_3, \ldots)$, where each y_k is a vector of the same length as u and where $\sum \|y_k\|_2 < \infty$. The gain of F with respect to $\| \cdot \|_B$ is now at least

$$\frac{\|y_1\|_2 - \sum_{k=2}^{\infty} \|y_k\|_2}{\|u\|_2}, \tag{3.5}$$

which can be made arbitrarily close to the H_∞ norm of the transfer function corresponding to F, by a suitable choice of u. In general, however, such an inequality is not known to hold, and it is not possible to use the closed graph theorem (cf. Kolmogorov and Fomin (1970)) to deduce the existence of a constant, because the norm $\|F\|_{B \to B}$ is not known to be complete.

We now consider the two-sided case, where our inputs and outputs are defined on $\mathbb{Z}$. Let us define a signal size measure as follows. Let $u = \{u(k)\}$ denote an arbitrary (real or complex) sequence. Consider the set of all signals u defined by the condition

$$\|u\|_C^2 = \limsup_{n \to \infty} \left[\sup_{t_0} \frac{1}{2n+1} \sum_{k=-n+t_0}^{n+t_0} |u(k)|^2 \right] < \infty. \tag{3.6}$$

Introduce the notation $P_C = \{u \mid \|u\|_C < \infty\}$. Our first observation is that the definition in (3.6) can be simplified.

Proposition 3.1. *Whenever the norm $\|u\|_C$ is finite, then the limit superior in the defining equation* (3.6) *can be replaced by an infimum over $n \geq 0$ or a limit as $n \to \infty$.*

Proof. Suppose that $n \geq 0$ and let

$$A = \sup_{t_0} \frac{1}{2n+1} \sum_{k=-n+t_0}^{n+t_0} |u(k)|^2. \tag{3.7}$$

Then, for $m > n$ we can write $2m + 1 = q(2n + 1) + r$, where q and r are integers with $q \geq 1$ and $0 \leq r < 2n + 1$. Now for any $t \in \mathbb{Z}$ we have

$$\frac{1}{2m+1} \sum_{k=-m+t}^{m+t} |u(k)|^2 \leq (q+1) \frac{2n+1}{2m+1} \sup_{t_0} \frac{1}{2n+1} \sum_{k=-n+t_0}^{n+t_0} |u(k)|^2, \tag{3.8}$$

as we see by splitting the block of $2m + 1$ terms into at most $q + 1$ blocks of length $2n + 1$. Thus

$$\begin{aligned} \limsup_{m \to \infty} \left[\sup_{t} \frac{1}{2m+1} \sum_{k=-m+t}^{m+t} |u(k)|^2 \right] &\leq \limsup_{m \to \infty} (q+1) A \frac{2n+1}{2m+1} \\ &\leq \limsup_{q \to \infty} (q+1) A / q = A. \end{aligned}$$

Hence we have "lim sup ≤ inf," and since we always have "inf ≤ lim inf ≤ lim sup," the limit exists and equals the infimum, as required.

We are now ready for the following result.

Theorem 3.2. *The set P_C is a linear vector space, on which $\| \cdot \|_C$ is a seminorm. Furthermore, $u \in P_C$ if and only if $u \in \ell_\infty(\mathbb{Z})$. One has $\|u\|_C = \|u\|_A$ whenever u is periodic.*

Proof. We shall show that $\|\cdot\|_C$ satisfies the triangle inequality in P_C. This is the only nontrivial part to establish that P_C is a linear vector space and that $\|\cdot\|_C$ is a seminorm. Thus we estimate by Schwarz's inequality

(3.9)

$$\begin{aligned}
\|u+v\|_C^2 &= \limsup_{n\to\infty} \sup_{t_0} \frac{1}{2n+1} \sum_{k=-n+t_0}^{n+t_0} |u(k)+v(k)|^2 \\
&\le \limsup_{n\to\infty} \sup_{t_0} \frac{1}{2n+1} \left[\sum_{k=-n+t_0}^{n+t_0} |u(k)|^2 + \sum_{k=-n+t_0}^{n+t_0} |v(k)|^2 + 2 \sum_{k=-n+t_0}^{n+t_0} |u(k)||v(k)| \right] \\
&\le \limsup_{n\to\infty} \left[\sup_{t_0} \frac{1}{2n+1} \sum_{k=-n+t_0}^{n+t_0} |u(k)|^2 + \sup_{t_0} \frac{1}{2n+1} \sum_{k=-n+t_0}^{n+t_0} |v(k)|^2 \right. \\
&\qquad \left. + 2 \sup_{t_0} \frac{1}{2n+1} \left(\sum_{k=-n+t_0}^{n+t_0} |u(k)|^2 \right)^{1/2} \left(\sum_{k=-n+t_0}^{n+t_0} |v(k)|^2 \right)^{1/2} \right] \\
&\le \|u\|_C^2 + \|v\|_C^2 + 2 \limsup_{n\to\infty} \left[\sup_{t_0} \left(\frac{1}{2n+1} \sum_{k=-n+t_0}^{n+t_0} |u(k)|^2 \right)^{1/2} \right. \\
&\qquad \left. \times \sup_{t_0} \left(\frac{1}{2n+1} \sum_{k=-n+t_0}^{n+t_0} |v(k)|^2 \right)^{1/2} \right] \\
&\le \|u\|_C^2 + \|v\|_C^2 + 2\|u\|_C \|v\|_C = \left(\|u\|_C + \|v\|_C \right)^2 .
\end{aligned}$$

Hence P_C is a linear vector space on which $\|\cdot\|_C$ is a seminorm. The validity of the latter part of the theorem is seen as follows. Clearly if $u \in \ell_\infty(\mathbb{Z})$, then $u \in P_C$ as $\|u\|_C \le \|u\|_\infty$ $(= \sup_t |u(t)|)$ for any $u \in \ell_\infty(\mathbb{Z})$. Suppose now that $u \in P_C$ but that $u \notin \ell_\infty(\mathbb{Z})$. Clearly if $u \notin \ell_\infty(\mathbb{Z})$, then

$$\sup_{t_0} \frac{1}{2n+1} \sum_{k=-n+t_0}^{n+t_0} |u(k)|^2 = \infty \tag{3.10}$$

so that $u \notin P_C$, which is a contradiction. Hence $u \in P_C$ must imply that $u \in \ell_\infty(\mathbb{Z})$.

Finally, let u be a periodic signal, with period p, say. Then it is easily seen that

$$\|u\|_A^2 = \frac{1}{p} \sum_{j=1}^{p} |u(j)|^2. \tag{3.11}$$

Suppose now that $2n+1 = pq + r$, where q and r are nonnegative integers with $0 \le r < p$. Then summing any $2n+1$ consecutive values $|u(k)|^2$ gives a total of at least $q \sum_{j=1}^{p} |u(j)|^2$ and at most $(q+1) \sum_{k=1}^{p} |u(k)|^2$. Thus

$$\frac{q}{2n+1} \sum_{j=1}^{p} |u(j)|^2 \le \sup_{t_0} \frac{1}{2n+1} \sum_{k=-n+t_0}^{n+t_0} |u(k)|^2 \le \frac{q+1}{2n+1} \sum_{j=1}^{p} |u(j)|^2. \tag{3.12}$$

The result now follows, since $q/(2n+1)$ and $(q+1)/(2n+1)$ both tend to $1/p$ as $n \to \infty$.

If G takes P_C into P_C we may introduce the system gain, induced by $\|\cdot\|_C$, as follows:

$$\|G\|_C = \sup_{u \in P_C, \|u\|_C \neq 0} \frac{\|Gu\|_C}{\|u\|_C} \tag{3.13}$$

when it exists.

It is known (see Loy (1974), Maté (1989)) that any shift-invariant linear system on $\mathbb{Z}_+$ that takes bounded inputs to bounded outputs is automatically continuous as an operator on ℓ_∞, and hence it has an impulse response in ℓ_1. For systems on $\mathbb{Z}$, such an automatic continuity result does not hold, even for causal operators. We have not found this stated explicitly anywhere in the literature, but it follows from the observation that the closure of the set of all vectors of the form $u - Su$ in $\ell_\infty(\mathbb{Z}_+)$ is a subspace Y of infinite codimension which contains $c_0(\mathbb{Z}_+)$. The quotient space $X = \ell_\infty(\mathbb{Z}_+)/Y$ therefore supports a discontinuous linear functional ϕ, and then defining $(Fu)(k) = \phi(P_X Ru)$, where

$$(Ru)(k) = \begin{cases} u(-k) & \text{if } k \geq 0, \\ 0 & \text{if } k < 0 \end{cases} \tag{3.14}$$

and $P_X : \ell_\infty(\mathbb{Z}_+) \to X$ is the projection, produces a discontinuous operator which is easily seen to be causal since it is zero on all sequences u such that $u(k) \to 0$ as $k \to -\infty$. Similar ideas can be found in the book of Sinclair (1976).

Returning to P_C we consider the case with signals defined on $\mathbb{Z}$. Let G be a bounded input bounded output stable, causal, LTI system. To avoid pathological situations such as those given above we shall assume now that G is defined by a convolution kernel such that $\|G\|_1 \equiv \sum_{k\geq 0} |g(k)| < \infty$. Consider G as an operator from P_C into P_C. (Here $g = \{g(k)\}$ denotes the unit impulse response of G.) Then

$$\|G\|_\infty \leq \|G\|_C \leq \|G\|_1, \tag{3.15}$$

where $\|G\|_\infty$ denotes the H_∞ norm of the transfer function $G(z) = \sum_{k\geq 0} g(k) z^k$ of G, i.e., $\|G\|_\infty = \sup_{|z|<1} |G(z)|$.

This is seen as follows. Let $u \in P_C$. Let $y = Gu$. We estimate, using Schwarz's inequality,

(3.16)

$$\begin{aligned} \frac{1}{2n+1} \sum_{t=-n+t_0}^{n+t_0} |y(t)|^2 &= \frac{1}{2n+1} \sum_{t=-n+t_0}^{n+t_0} \left| \sum_{k\geq 0} g(k) u(t-k) \right|^2 \\ &\leq \frac{1}{2n+1} \sum_{k,l\geq 0} |g(k)\overline{g(l)}| \sum_{t=-n+t_0}^{n+t_0} |u(t-k)\overline{u(t-l)}| \\ &\leq \sum_{k,l\geq 0} |g(k)||g(l)| \left(\frac{1}{2n{+}1} \sum_{t=-n+t_0}^{n+t_0} |u(t{-}k)|^2 \right)^{1/2} \left(\frac{1}{2n{+}1} \sum_{t=-n+t_0}^{n+t_0} |u(t{-}l)|^2 \right)^{1/2}. \end{aligned}$$

This gives

$$\begin{aligned} \|y\|_C^2 &\leq \limsup_{n\to\infty} \sum_{k,l\geq 0} |g(k)||g(l)| \\ &\qquad \times \left[\sup_{t_0} \left(\frac{1}{2n+1} \sum_{t=-n+t_0}^{n+t_0} |u(t)|^2 \right)^{1/2} \sup_{t_0} \left(\frac{1}{2n+1} \sum_{t=-n+t_0}^{n+t_0} |u(t)|^2 \right)^{1/2} \right] \\ &= \|G\|_1^2 \|u\|_C^2. \end{aligned} \tag{3.17}$$

This in turn gives the RHS inequality in (3.15). The LHS inequality in (3.15) is obtained by observing that $y(t) = G(e^{-i\omega})u(t)$ for $u(t) = e^{i\omega t}$ so that $\|G\|_C \geq \|G\|_\infty$.

A further argument is needed to establish the following important improvement of (3.15).

THEOREM 3.3. *Let G be a causal LTI system defined by a convolution kernel, satisfying $\|G\|_1 < \infty$. Consider G as an operator from P_C into P_C. Then*

$$\|G\|_C = \|G\|_\infty. \tag{3.18}$$

Proof. Suppose that G has a finite impulse response $(g(0), \ldots, g(m), 0, 0, \ldots)$, say, so that

$$y(t) = \sum_{k=0}^{m} g(k)u(t-k) \tag{3.19}$$

for $t \in \mathbb{Z}$. It will be notationally convenient to suppose that m is even—say, $m = 2p$. For each $t_0 \in \mathbb{Z}$ we have

$$\sum_{k=t_0-n}^{t_0+n} |y(t)|^2 \leq \|G\|_\infty^2 \sum_{k=t_0-n-m}^{t_0+n} |u(k)|^2, \tag{3.20}$$

since the output that would result from the input $u(t_0-n-m), \ldots, u(t_0+n)$ includes the terms $y(t_0-n), \ldots, y(t_0+n)$. Thus

(3.21)

$$\sup_{t_0} \frac{1}{2n+1} \sum_{k=-n+t_0}^{n+t_0} |y(k)|^2 \leq \frac{2n+1+2p}{2n+1} \|G\|_\infty^2 \sup_{t_1} \frac{1}{2n+1+2p} \sum_{k=t_1-(n+p)}^{t_1+n+p} |u(k)|^2,$$

where $t_1 = t_0 - p$. Now, taking limit superiors of both sides of (3.22), as n and $n+p$ go to infinity, we obtain $\|y\|_C^2 \leq \|G\|_\infty^2 \|u\|_C^2$. The general case now follows, since we can approximate the general convolution kernel G by finite impulse response kernels $G^{(m)}$ and then use (3.15) to show that for each input u the corresponding sequence $y^{(m)}$ of outputs converges in the seminorm $\|\cdot\|_C$.

An alternative proof of the above result can also be given, based on Remark 2.2.

Note that in the double-sided axis case the assumption $\|G\|_1 < \infty$ is necessary as otherwise the output $y(t)$ may become infinite even for finite t.

3.2. Continuous-time case. Let F be a causal time-invariant operator mapping functions on $(0, \infty)$ to functions on $(0, \infty)$. The following result is the analogue of the discrete-time theorem proven in Mäkilä and Partington (1996), and the proof is the same.

THEOREM 3.4. *For an operator F as above there is a constant $K > 0$ such that $\|Fu\|_{BP} \leq K\|u\|_{BP}$ for all u such that $\|u\|_{BP} < \infty$, if and only if F is a bounded operator on $L_2(0, \infty)$ and thus corresponds to a transfer function in $H_\infty(\mathbb{C}_+)$. Moreover $\|F\|$ is the same whether we consider F as acting on the space BP or $L_2(0, \infty)$.*

It will also be noted that the proof goes through to yield the similar result for $\|\cdot\|_S$.

The continuous-time version of Theorem 3.1 is also valid, and we state it here for completeness.

THEOREM 3.5. *An operator F as above has finite gain with respect to the seminorm $\| \cdot \|_B$ if and only if it is bounded with respect to the BP norm; this happens if and only if F is L_2 bounded and thus corresponds to a transfer function in $H_\infty(\mathbb{C}_+)$.*

Proof. The proof is the same as that of Theorem 3.1, replacing sums by integrals. For example, if F is L_2 bounded, then

$$\frac{1}{T}\int_0^T |y(t)|^2\,dt \le \|F\|_2^2 \frac{1}{T}\int_0^T |u(t)|^2\,dt, \tag{3.22}$$

and thus F has finite $\| \cdot \|_B$ gain, as we see on taking limit superiors as $T \to \infty$.

Conversely, the automatic continuity result stated in the proof of Theorem 3.1 (*any causal LTI operator that maps each one-sided sequence in BP into a sequence in BP is bounded as an operator on the one-sided BP space*) still holds in continuous time. The same proof holds, with the obvious replacement of sums by integrals. Theorem 3.4 then completes the proof of the equivalence of finite B-gain and finite L_2-gain.

Some recent work on the representation of shift-invariant operators on function spaces on $(0, \infty)$ by transfer functions can be found in Partington and Ünalmış (1997).

Remark 3.2. For systems with L_1 impulse responses we again have the identity

$$\|F\|_{BP\to BP} = \|F\|_{B\to B}, \tag{3.23}$$

as in Remark 3.1. This is because periodic functions of the form $u + S_T u + S_T^2 u + \cdots$, where $u \in L_2(0,T)$ and S_T denotes the right shift by an amount T, are mapped to functions of the form $y_1 + S_T(y_1+y_2) + S_T^2(y_1+y_2+y_3) + \cdots$, where each $y_k \in L_2(0,T)$ and $\sum_{k=1}^\infty \|y_k\|_2 < \infty$. The gain of F with respect to $\| \cdot \|_B$ is now at least

$$\frac{\|y_1\|_2 - \sum_{k=2}^\infty \|y_k\|_2}{\|u\|_2}, \tag{3.24}$$

which can be made arbitrarily close to the H_∞ norm of the transfer function corresponding to T, by a suitable choice of u. Alternatively one could base a proof on the lemma of Amerio and Prouse (1971, p. 72), which asserts that an L_1 convolution kernel maps almost periodic functions to almost periodic functions, and gives a representation of the operator in terms of the corresponding transfer function.

Similarly for the case of signals defined on the whole of $\mathbb{R}$, we can define a seminorm $\|u\|_C$ in continuous time, analogously to equation (3.6). Namely, for locally L_2 functions for which the quantity below is finite, we define

$$\|u\|_C^2 = \limsup_{T\to\infty}\left[\sup_{t_0} \frac{1}{2T}\int_{k=-T+t_0}^{T+t_0} |u(t)|^2\,dt\right]. \tag{3.25}$$

Again the limit superior is actually a limit and equals the infimum over $T > 0$. There is one difference here from the discrete-time case, in that for any function which is in $L_2(\mathbb{R})$, including ones not in $L_\infty(\mathbb{R})$, the quantity given in (3.25) will still be finite.

The proof of (3.15) can be extended in the obvious way to show that in this case operators defined by convolution with L_1 impulse responses give systems with finite gain. It can also be shown, by methods analogous to those used in the proof of Theorem 3.3, that in this case the $\| \cdot \|_C$ gain is equal to the H_∞ norm of the Laplace transform of the impulse response.

4. Conclusions. Bounded power signal spaces due to Wiener, Marcinkiewicz, and Beurling have been studied from a control and systems perspective. Furthermore, a new bounded power signal space has been introduced. Specifically, it has been shown that for a large class of stable finite and infinite dimensional systems, the system power gain is given by the H_∞ norm of the system transfer function. This means that robust H_∞ control can be rigorously motivated based on very general, physically attractive, persistent signal spaces, which allow both stationary and nonstationary signals (nonstationarity meaning here signals with time-dependent spectral properties).

In the double-sided time axis case some care must be taken when using H_∞ methods to analyze robust control and estimation for bounded power signals. It follows from our results that, e.g., in the double-sided time axis case, the causal LTI system G with the H_∞ transfer function $G(z) = z\exp[-(1+z)/(1-z)]$ is not power stable (actually not even stabilizable by any controller with transfer function of the form $C(z) = X(z)/Y(z)$, where $Y \neq 0$ and X and Y are transfer functions of power stable causal LTI systems, by an application of a result in Partington and Mäkilä (1994). It is believed that the bounded power signal spaces studied here will turn out to be important in the active research area of system identification for robust control (see, e.g., Partington (1997)), as they allow for very rich and realistic nonprobabilistic signal models.

Acknowledgments. The authors would like to thank H. G. Dales for helpful discussions on automatic continuity theory.

EQUIVALENCE OF NONLINEAR SYSTEMS TO PRIME SYSTEMS UNDER GENERALIZED OUTPUT TRANSFORMATIONS*

E. ARANDA-BRICAIRE† AND R. M. HIRSCHORN‡

Abstract. Within a linear algebraic framework, we present a new characterization of the class of nonlinear systems which are equivalent to a prime system. We then introduce a class of generalized output transformations that can be thought of as a generalization to the nonlinear setting of a unimodular transformation in the output space. Our main result gives necessary and sufficient conditions for equivalence to a prime system under a certain group of transformations that includes generalized output transformations.

Key words. nonlinear systems, output transformation, prime systems, differential forms

1. Introduction.

The problem of characterizing the class of linear systems that are equivalent to prime systems was first posed and solved by Morse [12]. The group of transformations considered in [12] included, besides state space change of coordinates and linear state feedback, output space change of coordinates. Marino, Respondek, and van der Schaft [10] generalized this result to the nonlinear case. They showed that the class of smooth affine nonlinear systems that are locally equivalent to prime systems can be characterized by the properties of two families of involutive distributions defined on the state manifold.

In this paper we consider the problem of equivalence to a prime system under a group of transformations that consist of state space diffeomorphism, regular static state feedback, and generalized output transformation (GOT). In the case where we restrict ourselves to the output space change of coordinates used by Marino, Respondek, and van der Schaft [10], we obtain a new and simpler characterization for the class of nonlinear systems which are (locally) equivalent to prime systems. We then introduce the notion of GOT to identify a larger class of systems equivalent to prime systems. We proceed in two steps. First, we enlarge the output space by considering a finite number of the time derivatives of the output as coordinates of new output space. Then we define a new set of outputs on this enlarged space. This transformation is invertible in the sense that the new outputs can be expressed as functions of a finite number of the time derivatives of the original output, and vice versa. That is, we can recover the original output without any integration. By analogy with the linear case, these transformations could be called unimodular, in the sense that their inverse belongs to the same class of transformations. This approach finds a natural application in control problems such as output tracking and output regulation.

The goal of this paper is to develop a framework and sound theory to study this

new group of transformations and then identify those systems which are equivalent to a prime system under this group of transformations.

Of course, a necessary condition for this equivalence is that the system be linearizable by static state feedback. It will be shown that the crucial step is the requirement that certain linear forms on the extended output space can be constructed such that their *pull-back* under the output map coincide with some suitable forms on the state space. In that respect, it is worth mentioning that the pull-back of a form is *always* a well-defined object, as opposed to the *push-forward* of a distribution, which may fail to be well defined. Therefore, one completely avoids the projectability-type conditions as stated in [10].

We present our results within the linear algebraic framework introduced by Di Benedetto, Grizzle, and Moog [6]. However, it will be shown that our results can be given a meaningful geometric interpretation in terms of jet bundles [15]. Finally, let us mention that this work was partially motivated by some results previously obtained for discrete-time systems [1]. One advantage of our formalism is that it allows a completely parallel treatment of both the continuous- and the discrete-time cases.

The paper is organized as follows. In section 2 we recall some basic definitions from the so-called linear algebraic approach [2, 6]. Our main results are contained in section 3. In subsection 3.1 we obtain new necessary and sufficient conditions for equivalence to prime system under regular static state feedback, state space diffeomorphism, and output space diffeomorphism. In subsection 3.2 we introduce the notion of GOT and study some of its properties. In subsection 3.3 we derive necessary and sufficient conditions for equivalence to prime system under regular static state feedback, state space diffeomorphism, and GOT. Finally, some conclusions and final remarks are offered in section 4.

2. Linear algebraic framework. To begin with, we recall some basic definitions from [2, 6]. Consider a nonlinear system Σ, described by equations of the form

$$\Sigma : \begin{cases} \dot{x} &= f(x) + \sum_{i=1}^{m} u_i g_i(x) = f(x) + g(x)u, \\ y &= h(x), \end{cases} \tag{1}$$

where the state $x \in M$, an open and connected subset of $\mathbb{R}^n$, the control $u \in \mathbb{R}^m$, and the output $y \in Y$, an open and connected subset of $\mathbb{R}^m$. Throughout the paper the following standing assumptions are made:

A1. The vector fields $f(x)$ and $g_i(x)$ and the mapping $h(x)$ are real analytic.

A2. For almost all $x \in M$, $\operatorname{rank} g(x) = \operatorname{rank} \mathrm{d}h(x) = m$.

Let $\mathcal{K}$ denote the field of meromorphic functions of a finite number of the variables $\{x, u^{(j)},\ j \geq 0\}$. The time derivative of a function $\varphi \in \mathcal{K}$ is defined by

$$\dot{\varphi} = \frac{d}{dt}\varphi = \frac{\partial \varphi}{\partial x}[f(x) + g(x)u] + \sum_{j \geq 0} \frac{\partial \varphi}{\partial u^{(j)}} u^{(j+1)}. \tag{2}$$

Notice that the sum in (2) involves only finitely many terms. Let $\mathcal{E}$ denote the $\mathcal{K}$-vector space spanned by $\{\mathrm{d}x, \mathrm{d}u^{(j)},\ j \geq 0\}$, where $\mathrm{d}x$ and $\mathrm{d}u^{(j)}$ stand, respectively, for $\{\mathrm{d}x_1, \ldots, \mathrm{d}x_n\}$ and $\{\mathrm{d}u_1^{(j)}, \ldots, \mathrm{d}u_m^{(j)}\}$. The elements of $\mathcal{E}$ are *differential forms* of degree one, or simply *one-forms*. The operator $\frac{d}{dt} : \mathcal{K} \to \mathcal{K}$ induces a derivation in $\mathcal{E}$ by

$$\omega = \sum_j a_j \mathrm{d}v_j \mapsto \dot{\omega} = \sum_j (\dot{a}_j \mathrm{d}v_j + a_j \mathrm{d}\dot{v}_j).$$

The *relative degree* r of a one-form $\omega \in \mathcal{E}$ is defined to be the least integer such that $\omega^{(r)} \not\in \operatorname{span}_{\mathcal{K}}\{\mathrm{d}x\}$. If such an integer does not exist, set $r = \infty$.

Introduce a sequence of subspaces $\{\mathcal{H}_k\}$ of $\mathcal{E}$ by

$$\begin{array}{rcl} \mathcal{H}_1 & = & \operatorname{span}_{\mathcal{K}}\{\mathrm{d}x\}, \\ \mathcal{H}_{k+1} & = & \operatorname{span}_{\mathcal{K}}\{\omega \in \mathcal{H}_k \mid \dot{\omega} \in \mathcal{H}_k\},\ k \geq 1. \end{array} \tag{3}$$

This sequence of subspaces was first introduced in [2, 3] to address the dynamic feedback linearization problem. It is clear that the sequence (3) is decreasing. Denote by k^* the least integer such that

$$\mathcal{H}_1 \supset \mathcal{H}_2 \supset \cdots \supset \mathcal{H}_{k^*} \supset \mathcal{H}_{k^*+1} = \mathcal{H}_{k^*+2} = \cdots =: \mathcal{H}_\infty. \tag{4}$$

Assume that $\mathcal{H}_\infty = 0$. We shall explain below the significance of this assumption. In [2] it was proven that there exists a set of one-forms $\mathcal{W} = \{\omega_1, \ldots, w_m\}$ and a list of integers $\{r_1, \ldots, r_m\}$ such that, for $1 \leq k \leq k^*$,

$$\mathcal{H}_k = \operatorname{span}_{\mathcal{K}}\{\omega_i^{(j)}, \mid r_i \geq k,\ 0 \leq j \leq r_i - k\}. \tag{5}$$

The integer r_i associated to the one-form w_i coincides with its relative degree. A set of one-forms satisfying (5) is called a system of *linearizing one-forms.*

According to (2), define

$$\begin{aligned} h^{(1)} &= h^{(1)}(x, u) \\ &= \frac{\partial h}{\partial x}[f(x) + g(x)u], \\ h^{(k+1)} &= h^{(k+1)}(x, u, \ldots, u^{(k)}) \\ &= \frac{\partial h^{(k)}}{\partial x}[f(x) + g(x)u] + \sum_{i=0}^{k-1} \frac{\partial h^{(k)}}{\partial u^{(i)}} u^{(i+1)}. \end{aligned}$$

Therefore, associated to the system Σ, we can define two sequences of subspaces $\{\mathcal{E}_k\}$ and $\{\mathcal{F}_k\}$ of $\mathcal{E}$ defined by

$$\begin{array}{rcl} \mathcal{E}_k & = & \operatorname{span}_{\mathcal{K}}\{\mathrm{d}x, \mathrm{d}h, \ldots, \mathrm{d}h^{(k)}\},\ k \geq 0, \\ \mathcal{F}_k & = & \operatorname{span}_{\mathcal{K}}\{\mathrm{d}h, \ldots, \mathrm{d}h^{(k)}\},\ k \geq 0. \end{array}$$

These two sequences of subspaces were first introduced in [6] to unify different notions of invertibility for nonlinear systems. The number $\rho^* = \dim \mathcal{E}_n - \dim \mathcal{E}_{n-1}$ is called the *rank of the system* Σ. It can be shown [6] that $\rho^* = \dim \mathcal{E}_n - \dim \mathcal{E}_{n-1} = \dim \mathcal{F}_n - \dim \mathcal{F}_{n-1}$. This characterization of rank was introduced in [6] and agrees with Fliess's definition [7]. Finally, for notational convenience, define $\mathcal{X} = \operatorname{span}_{\mathcal{K}}\{\mathrm{d}x\}$.

Remark 2.1. In paper [6] the notation $y^{(k+1)}(x, u, \ldots, u^{(k)})$ was used instead of $h^{(k+1)}(x, u, \ldots, u^{(k)})$. We use the latter notation because, in the next section, the $y_j^{(k)}$ will be used to denote the canonical system of coordinates of the extended output space. □

Remark 2.2. Throughout the paper we use the notion of pull-back of a differential form, as well as the differential forms version of Frobenius theorem. For details, the reader is referred to [4]. □

3. Main results.

3.1. Equivalence to prime systems. In this section we present new necessary and sufficient conditions for equivalence to prime system under state diffeomorphism, regular static state feedback, and output space diffeomorphism. In a sense, this result is a particular case of the more general notion of equivalence that we introduce below and provides a new linear algebraic characterization of the class of systems already identified in [10].

Definition 3.1. *A system* Π *is said to be a* prime system *if it is of the form*

$$\Pi \ : \left\{ \begin{array}{rcl} \dot{z}_{i1} & = & z_{i2}, \\ & \vdots & \\ \dot{z}_{i\kappa_i} & = & v_i, \\ \tilde{y}_i & = & z_{i1}, \ \ 1 \le i \le m, \end{array} \right. \tag{6}$$

where $z = (z_{11}, \dots, z_{1\kappa_1}, \dots, z_{m1}, \dots, z_{m\kappa_m}) \in \mathbb{R}^n$ *and* $n = \sum_{i=1}^{m} \kappa_i$ *for some integers* $\{\kappa_i\}_{i=1}^{m}$.

Definition 3.2. *The system* Σ *is said to be* equivalent to the prime system Π *if there exist*

(i) *A state diffeomorphism*

$$\begin{array}{rcl} \phi : M & \to & \mathbb{R}^n, \\ x & \mapsto & z = \phi(x); \end{array}$$

(ii) *a regular static state feedback* $u = \alpha(x) + \beta(x)v$*; that is,* $\beta(x)$ *is a square nonsingular matrix;*

(iii) *an output space diffeomorphism*

$$\begin{array}{rcl} \psi : Y & \to & \mathbb{R}^m, \\ y & \mapsto & \tilde{y} = \psi(y) \end{array}$$

such that the transformation of Σ *under* $(\phi, (\alpha, \beta), \psi)$ *equals* Π.

In order to state our first result, we need to introduce some notation. First define $\dot{\mathcal{H}}_k = \operatorname{span}_{\mathcal{K}}\{\dot{\omega} \mid \omega \in \mathcal{H}_k\}$. If $\{\omega_1, \dots, \omega_s\}$ is a basis of $\mathcal{H}_k$, it is easy to check that $\dot{\mathcal{H}}_k = \operatorname{span}_{\mathcal{K}}\{\omega_1, \dots, \omega_s, \dot{\omega}_1, \dots, \dot{\omega}_s\}$. However, in general, $\{\omega_1, \dots, \omega_s, \dot{\omega}_1, \dots, \dot{\omega}_s\}$ is not a basis of $\dot{\mathcal{H}}_k$, because it may happen that the latter set is not linearly independent. Also, recall that $\mathcal{F}_0 = \operatorname{span}_{\mathcal{K}}\{\mathrm{d}h(x)\}$.

Theorem 3.3. *Consider the square nonlinear system* Σ *and suppose that it satisfies* A1 *and* A2. *Then* Σ *is equivalent to prime system* Π *if and only if the following conditions are satisfied:*

(i) $\mathcal{H}_\infty = 0$;

(ii) *for* $k = 1, \dots, k^*$, $\mathcal{H}_k$ *is completely integrable;*

(iii) *for* $k = 1, \dots, k^*$, $\mathcal{H}_k = \dot{\mathcal{H}}_{k+1} \oplus \operatorname{span}_{\mathcal{K}}\{\mathcal{W}_k\}$, *where* $\mathcal{W}_k \subset \mathcal{F}_0$;

(iv) *for* $k = 1, \dots, k^*$, $\mathcal{H}_k \cap \mathcal{F}_0$ *is completely integrable.*

Remark 3.4. Theorem 3.3 can be seen as a dual version of Theorem 4 in [10]. In particular, conditions (i), (ii), and (iv) of Theorem 3.3 are equivalent, respectively, to conditions (ii), (i), and (iv) of Theorem 4 in [10]. Also, notice that our conditions require the construction of a single sequence of subspaces or codistributions. □

Remark 3.5. In [2, 3] it has been shown that conditions (i) and (ii) are the necessary and sufficient conditions for the system Σ without outputs to be linearizable by state diffeomorphism and regular static state feedback. In particular, condition (i) is a necessary and sufficient condition for strong accessibility. □

Remark 3.6. In the event that the conditions of Theorem 3.3 are satisfied, the *decoupling matrix* [9, p. 263], [13, p. 254] of the *transformed* output $\tilde{y} = \psi(y)$ has full rank m. Therefore, the problem of asymptotically tracking a desired output y_d is transformed into the problem of asymptotically tracking the desired output $\tilde{y}_d = \psi(y_d)$, which is a *linear* problem in the transformed coordinates. □

Proof of Theorem 3.3. *Necessity.* First notice that the subspaces $\mathcal{H}_k$ are invariant under state diffeomorphism and under regular static state feedback [2, 3]. Moreover, they are independent of the output map. Next we show that the subspace $\mathcal{F}_0 \subset \mathcal{X}$ is invariant under output space diffeomorphism. Suppose that $\tilde{y} = \tilde{h}(x) = \psi \circ h(x)$. By the chain rule, we have

$$\mathrm{d}\tilde{h}(x) = \left.\frac{\partial \psi}{\partial y}\right|_{y=h(x)} \mathrm{d}h(x).$$

This shows that $\operatorname{span}_{\mathcal{K}}\{\mathrm{d}\tilde{h}(x)\} \subset \operatorname{span}_{\mathcal{K}}\{\mathrm{d}h(x)\}$. Since $y \mapsto \psi(y)$ is a diffeomorphism, a similar argument shows that $\operatorname{span}_{\mathcal{K}}\{\mathrm{d}h(x)\} \subset \operatorname{span}_{\mathcal{K}}\{\mathrm{d}\tilde{h}(x)\}$, and hence $\operatorname{span}_{\mathcal{K}}\{\mathrm{d}\tilde{h}(x)\} = \operatorname{span}_{\mathcal{K}}\{\mathrm{d}h(x)\}$. In a similar manner, one can show that $\mathcal{F}_0$ is invariant under state space diffeomorphism. Finally, it is clear that $\mathcal{F}_0$ remains unchanged under state feedback. Thus conditions (i)–(iv) are invariant under all the considered transformations.

An easy computation shows that conditions (i)–(iv) are satisfied for a prime system Π. Therefore, if system Σ is equivalent to a prime system Π, conditions (i)–(iv) necessarily hold true.

Sufficiency. We proceed by induction, going down from $k = k^*$ to $k = 1$. First notice that $\mathcal{H}_{k^*+1} = \mathcal{H}_\infty = 0$, and hence $\dot{\mathcal{H}}_{k^*+1} = 0$. Therefore, when $k = k^*$, condition (iii) means that $\mathcal{H}_{k^*} = \operatorname{span}_{\mathcal{K}}\{\mathcal{W}_{k^*}\}$, where

$$\mathcal{W}_{k^*} = \{\omega_{k^*1}, \ldots, \omega_{k^*\rho_{k^*}}\} \subset \mathcal{F}_0. \tag{7}$$

Moreover, by condition (iv) we can assume without loss of generality that the forms ω_{k^*i} are exact, say $\omega_{k^*i} = \mathrm{d}\varphi_{k^*i}$. By (7), the forms ω_{k^*i} can also be written as follows:

$$\omega_{k^*i} = \mathrm{d}\varphi_{k^*i} = \sum_{j=1}^{m} a_{ij}\mathrm{d}h_j(x), \tag{8}$$

where $a_{ij} \in \mathcal{K}$.

Even though the forms ω_{k^*i} are linear combinations of the differentials $\mathrm{d}h_j(x)$, it is not possible to assert a priori that they are the pull-back of some forms on the output space. This assertion holds true if and only if the coefficients a_{ij} can be expressed as functions of the scalar outputs y_j. The following lemma states that this is the case indeed.

LEMMA 3.7. *The coefficients a_{ij}, for $1 \leq i \leq \rho_{k^*}$, $1 \leq j \leq m$, in* (8) *can be expressed as functions of $y_1, \ldots, y_m$ only; that is, $a_{ij} = a_{ij}(y) = a_{ij} \circ h(x)$.*

Proof. Since the forms ω_{k^*i} are exact, we have that

$$\mathrm{d}\omega_{k^*i} = \sum_{j=1}^{m} \mathrm{d}a_{ij} \wedge \mathrm{d}h_j(x) = 0, \; i = 1, \ldots, \rho_{k^*}. \tag{9}$$

Now, taking the exterior product of (9) with the $(m-1)$-form $\mathrm{d}h_1(x)\wedge\cdots\widehat{\mathrm{d}h_j(x)}\cdots\wedge \mathrm{d}h_m(x)$, where $\widehat{\mathrm{d}h_j(x)}$ means that that factor is omitted, yields

$$\text{(10)}\quad \mathrm{d}a_{ij}\wedge \mathrm{d}h_1(x)\wedge\cdots\wedge \mathrm{d}h_j(x)\wedge\cdots\wedge \mathrm{d}h_m(x)=0,\ 1\le i\le \rho_{k^*},\ 1\le j\le m.$$

Since $\operatorname{rank}\mathrm{d}h(x)=m$, it follows that the linear forms $\mathrm{d}h_j(x)$ are independent. Consequently, (10) implies that $\mathrm{d}a_{ij}\in \operatorname{span}_{\mathcal{K}}\{\mathrm{d}h(x)\}$. The latter means that a_{ij} are constant on each submanifold $h^{-1}(K)$, $K\in\mathbb{R}^m$. Again, since $\operatorname{rank}\mathrm{d}h(x)=m$, there are coordinates $(y_1,\ldots,y_m,q_1,\ldots,q_{n-m})$ of M such that $h:M\to Y$ becomes the canonical submersion $(y,q)\mapsto(y)$. Therefore,

$$a_{ij}(x)=a_{ij}(y,q)=a_{ij}(y,0)=a_{ij}(y).\qquad \square$$

By Lemma 3.7, we can define ρ_{k^*} forms on the output space Y by $\eta_{k^*i}=\sum_{j=1}^m a_{ij}(y)\mathrm{d}y_j$, $i=1,\ldots,\rho_{k^*}$. Then it is clear that the pull-back (see [4]) of the form η_{k^*i} under the map $h:M\to Y$ coincides precisely with the form ω_{k^*i}; that is,

$$\text{(11)}\qquad \omega_{k^*i}=h^*(\eta_{k^*i}),\ i=1,\ldots,\rho_{k^*}.$$

Now suppose that through steps $\ell=k^*$ to $\ell=k+1$ we have constructed sets of forms $\mathcal{W}_\ell=\{\omega_{\ell 1},\ldots,\omega_{\ell\rho_\ell}\}$ (some of them possibly empty) such that $\omega_{ij}=h^*(\eta_{ij})$ and

$$\mathcal{H}_{k+1}=\operatorname{span}_{\mathcal{K}}\{\mathcal{W}_i^{(j)},\ k+1\le i\le k^*,\ 0\le j\le i-k-1\},$$

where the notation $\mathcal{W}_i^{(j)}$ should be understood elementwise. Therefore, by condition (iii), we can choose a set of forms $\mathcal{W}_k=\{\omega_{k1},\ldots,\omega_{k\rho_k}\}\subset\mathcal{F}_0$ such that

$$\mathcal{H}_k=\operatorname{span}_{\mathcal{K}}\{\mathcal{W}_i^{(j)},\ k\le i\le k^*,\ 0\le j\le i-k\}.$$

Moreover, condition (iv) means that we can assume, without loss of generality, that ω_{ki} are exact, say $\omega_{ki}=\mathrm{d}\varphi_{ki}$, and that there are forms η_{ki} defined on the output space such that, for $i=1,\ldots,\rho_k$, $\omega_{ki}=h^*(\eta_{ki})$.

Repeat the above construction from $k=k^*$ to $k=1$, and let $\mathcal{W}=\cup_{i=1}^{k^*}\mathcal{W}_i=\{\omega_1,\ldots,\omega_s\}$ and $r_i=\{k\mid \omega_i\in\mathcal{W}_k\}$. Notice that, by construction, each ω_i belongs to one and only one set $\mathcal{W}_k$, whence the integer r_i is well-defined. Therefore, $\mathcal{W}=\{\omega_1,\ldots,\omega_s\}$ is a system of linearizing forms whose list of relative degrees is $\{r_1,\ldots,r_s\}$. As a matter of fact, it can be shown (see, e.g., [2, 3]) that $s=m$ and that $\sum_{i=1}^m r_i=n$. Recall that, by construction, the forms ω_i are exact, say $\omega_i=\mathrm{d}\varphi_i(x)$. Define

$$z_{ij}=\phi_{ij}(x)=\varphi_i^{(j-1)}(x),\ 1\le i\le m,\ 1\le j\le r_i.$$

It follows that the map $x\mapsto\phi(x)$ is a diffeomorphism. In coordinates z_{ij}, system Σ becomes

$$\begin{aligned}\dot z_{i1}&=z_{i2},\\ &\ \ \vdots\\ \dot z_{ir_i}&=a_i(z)+b_i(z)u,\ 1\le i\le m,\\ y&=h\circ\phi^{-1}(z).\end{aligned}$$

The fact that the forms $\omega_i^{(j)}$ are independent implies that the matrix $B(z)$, whose rows are $b_i(z)$, has full rank. Therefore, the static state feedback $u = [B(z)]^{-1}[v - a(z)]$ is well defined and yields

$$\begin{array}{rcl} \dot{z}_{i1} & = & z_{i2}, \\ & \vdots & \\ \dot{z}_{ir_i} & = & v_i, \ 1 \le i \le m, \\ y & = & h \circ \phi^{-1}(z). \end{array} \tag{12}$$

To conclude the proof, we just need to construct a suitable output space diffeomorphism. In order to do so, we need the following result.

LEMMA 3.8. *Let $\{\eta_1, \ldots, \eta_m\}$ be the collection of forms defined on the output space which satisfy $\omega_i = h^*(\eta_i)$. Then, for $i = 1, \ldots, m$, $\mathrm{d}\eta_i = 0$.*

Proof. As in the proof of Lemma 3.7, it is possible to choose a coordinates system $(y_1, \ldots, y_m, q_1, \ldots, q_{n-m})$, so that $h : M \to Y$ becomes the canonical projection $(y, q) \mapsto y$. Let $w_i = \sum_{j=1}^m a_{ij}\mathrm{d}h_j$. We have already shown that the a_{ij} can be expressed as functions of y_j only. Since $\omega_i = h^*(\eta_i)$, we have that necessarily $\eta_i = \sum_{j=1}^m a_{ij}\mathrm{d}y_j$. Define $\tau^i_{jk} = \frac{\partial a_{ik}}{\partial y_j} - \frac{\partial a_{ij}}{\partial y_k}$. Then, the two-form $\mathrm{d}\eta_i$ can be written as $\mathrm{d}\eta_i = \sum_{j<k} \tau^i_{jk}\mathrm{d}y_j \wedge \mathrm{d}y_k$. Now, recall that $\mathrm{d}\omega_i = \sum_{j=1}^m \mathrm{d}a_{ij} \wedge \mathrm{d}h_j$ so that, in coordinates (y, q), the two-form $\mathrm{d}\omega_i$ becomes $\mathrm{d}\omega_i = \sum_{j<k} \tau^i_{jk}\mathrm{d}y_j \wedge \mathrm{d}y_k$. By construction, the forms ω_i are exact, so that $\mathrm{d}\omega_i \equiv 0$. Therefore, the coefficients τ^i_{jk} must be identically zero. □

By virtue of Lemma 3.8, we can assume, without loss of generality, that, for $i = 1, \ldots, m$, $\eta_i = \mathrm{d}\psi_i(y)$. Finally, define the output space diffeomorphism $y \mapsto \psi(y)$. In coordinates $\tilde{y} = \psi(y)$, the system (12) is in prime form. □

Example 3.9 (see [10]). Consider the system

$$\begin{array}{rcl} \dot{x}_1 & = & u_1, \\ \dot{x}_2 & = & x_3, \\ \dot{x}_3 & = & u_2, \\ \dot{x}_4 & = & x_5, \\ \dot{x}_5 & = & x_6, \\ \dot{x}_6 & = & u_3, \end{array} \qquad \begin{array}{rcl} y_1 & = & x_1, \\ y_2 & = & x_2 + x_1x_5, \\ y_3 & = & x_4, \end{array} \tag{13}$$

defined on $M = \mathbb{R}^6$, $Y = \mathbb{R}^3$. For system (13) we easily compute

$$\begin{array}{rcl} \mathcal{H}_2 & = & \mathrm{span}_{\mathcal{K}}\{\mathrm{d}x_2, \mathrm{d}x_4, \mathrm{d}x_5\}, \\ \mathcal{H}_3 & = & \mathrm{span}_{\mathcal{K}}\{\mathrm{d}x_4\}, \\ \mathcal{H}_\infty & = & 0. \end{array}$$

Therefore, conditions (i) and (ii) of Theorem 3.3 are satisfied. Moreover, if we choose $\mathcal{W}_1 = \{\mathrm{d}x_1\}$, $\mathcal{W}_2 = \{\mathrm{d}x_2 + x_1\mathrm{d}x_5\}$, and $\mathcal{W}_3 = \{\mathrm{d}x_4\}$ we see also that condition (iii) is satisfied. However, $\mathrm{span}_{\mathcal{K}}\{\mathcal{W}_2\} = \mathcal{H}_2 \cap \mathcal{F}_0$ is not completely integrable. Therefore, system (13) is not equivalent to prime system. □

3.2. Generalized output transformations. Next we introduce the notion of GOT. As we point out below, the notion of equivalence studied in the previous section is a particular case of this new class of transformations.

DEFINITION 3.10. *Given two finite nonnegative integers d and d', a GOT consists of two smooth maps $\psi : Y \times (\mathbb{R}^m)^d \to \mathbb{R}^m$ and $\chi : \mathbb{R}^m \times (\mathbb{R}^m)^{d'} \to Y$ such that*

$$\tilde{y} = \psi(y, \dot{y}, \ldots, y^{(d)}), \tag{14}$$

$$y = \chi(\tilde{y}, \dot{\tilde{y}}, \ldots, \tilde{y}^{(d')}). \tag{15}$$

Even though $y = h(x)$, in general we have $\tilde{y} = \tilde{h}(x, u, \dots, u^{(d-1)})$. A GOT is called proper *if $\tilde{h}$ is a function of x only; i.e., $\tilde{y} = \tilde{h}(x)$.*

In the case when $d = d' = 0$, the GOT (14)–(15) reduces to an output space diffeomorphism. Notice, however, that in general $d \neq d'$.

Example 3.11. Let $Y = \mathbb{R}^3$, and let $y = (y_1, y_2, y_3)$ and $z = (z_1, z_2, z_3)$ be two systems of coordinates of $\mathbb{R}^3$. Consider the maps

$$\begin{array}{rcl} \psi : Y \times \mathbb{R}^3 & \rightarrow & \mathbb{R}^3, \\ (y, \dot{y}) & \mapsto & (y_1, y_2 + y_1\dot{y}_1, y_3 + \dot{y}_2), \\ \chi : \mathbb{R}^3 \times (\mathbb{R}^3)^2 & \rightarrow & Y, \\ (z, \dot{z}, \ddot{z}) & \mapsto & (z_1, z_2 - z_1\dot{z}_1, z_3 - \dot{z}_2 + z_1\ddot{z}_1 + \dot{z}_1^2). \end{array}$$

It is easy to verify that the pair (ψ, χ) is a GOT with $d = 1$ and $d' = 2$. □

Remark 3.12. Parallel to the algebraic definition of GOT given by Definition 3.10, a more geometric interpretation of this class of transformations can be given in terms of jet bundles (see, e.g., [15]). Consider the output $y \in Y$ as a function of time and assume that it is of class C^∞. Then, every trajectory $y(t)$ in the output space defines a section of the d-jet bundle $J^d(\mathbb{R}, Y)$ by $t \mapsto j_t^d = (t, y(t), \dot{y}, \dots, y^{(d)}(t))$. Similarly, every smooth curve $z(t)$ on $\mathbb{R}^m$ defines a section of the d'-jet bundle $J^{d'}(\mathbb{R}, \mathbb{R}^m)$. Therefore, the maps ψ and χ can be interpreted as bundle maps such that the following diagrams commute:

$$\begin{tikzcd} J^d(\mathbb{R}, Y) \arrow[r, "\psi"] \arrow[d, "\pi"'] & J^0(\mathbb{R}, \mathbb{R}^m) \arrow[d, "\pi"] \\ \mathbb{R} \arrow[r, "\mathrm{id}_{\mathbb{R}}"'] & \mathbb{R} \end{tikzcd} \qquad \begin{tikzcd} J^{d'}(\mathbb{R}, \mathbb{R}^m) \arrow[r, "\chi"] \arrow[d, "\pi"'] & J^0(\mathbb{R}, Y) \arrow[d, "\pi"] \\ \mathbb{R} \arrow[r, "\mathrm{id}_{\mathbb{R}}"'] & \mathbb{R} \end{tikzcd}$$

where $\pi : J^k(\mathbb{R}, N) \to \mathbb{R}$ is the source map and $\mathrm{id}_{\mathbb{R}}$ is the identity map. Roughly speaking, this means that to every smooth trajectory $y(t) \in Y$ corresponds one and only one trajectory $z(t) \in \mathbb{R}^m$. □

Several types of invariants have been associated with the input-output map of the system Σ, e.g., the *relative degrees* [9, 13], the *structure at infinity* [11], the *essential orders* [8], and the *rank of the system* [6, 7]. Among them, the most fundamental is, without doubt, the rank ρ^* (see section 2). Theorem 3.13 below states that the rank is invariant under proper GOTs.

THEOREM 3.13. *Let (ψ, χ) be a proper GOT, and let ρ^* and $\tilde{\rho}^*$ denote, respectively, the rank of the system Σ with respect to the output $y = h(x)$ and with respect to the new output $\tilde{y} = \psi(y, \dot{y}, \dots, y^{(d)}) = \tilde{h}(x)$. Then $\tilde{\rho}^* = \rho^*$.*

Proof. Let $\{\mathcal{F}_k\}$ and $\{\tilde{\mathcal{F}}_k\}$ denote, respectively, the sequences of subspaces associated to the system Σ with the output $y = h(x)$ and with the new output $\tilde{y} = \tilde{h}(x)$. Next note that, according to Definition 3.10, we have

$$\dot{\tilde{h}}_i = \sum_{k=1}^{m} \sum_{\ell=0}^{d} \left. \frac{\partial \psi_i}{\partial y_k^{(\ell)}} \right|_{h_k^{(\ell)}} h_k^{(\ell+1)},$$

$$\tilde{h}_i^{(j+1)} = \sum_{k=1}^{m} \sum_{\ell=0}^{d+j} \frac{\partial \tilde{h}_i^{(j)}}{\partial h_k^{(\ell)}} h_k^{(\ell+1)}, \qquad j \geq 1. \tag{16}$$

Pick an arbitrary form $\omega \in \tilde{\mathcal{F}}_k$, say $\omega = \sum_{i=1}^{m} \sum_{j=0}^{k} \tilde{a}_{ij} \mathrm{d}\tilde{h}_i^{(j)}$. By (16), it follows that there are coefficients a_{ij} such that $\omega = \sum_{i=1}^{m} \sum_{j=0}^{k+d} a_{ij} \mathrm{d}h_i^{(j)}$. This shows that, for every integer $k \geq 0$, we have $\tilde{\mathcal{F}}_k \subset \mathcal{F}_{k+d}$. Similarly, it is easily seen that, for $k \geq 0$, $\mathcal{F}_k \subset \tilde{\mathcal{F}}_{k+d'}$. Let $s = \max\{d, d'\}$. Then the subspaces $\{\mathcal{F}_k\}$ and $\{\tilde{\mathcal{F}}_k\}$ satisfy

$$\tilde{\mathcal{F}}_k \subset \mathcal{F}_{k+s} \subset \tilde{\mathcal{F}}_{k+2s} \subset \mathcal{F}_{k+3s} \subset \cdots . \tag{17}$$

Now suppose that $\tilde{\rho}^* < \rho^*$, say $\rho^* = \tilde{\rho}^* + r$, for some integer $r > 0$. We will show that this leads to contradiction. First note that, for every $k \geq n$, we have

$$\begin{array}{rcl} \dim \mathcal{F}_k - \dim \mathcal{F}_{k-1} & = & \rho^* = \tilde{\rho}^* + r, \\ \dim \tilde{\mathcal{F}}_k - \dim \tilde{\mathcal{F}}_{k-1} & = & \tilde{\rho}^*. \end{array} \tag{18}$$

Next let $\Theta_i = \{\theta_i^j,\ j = 1, \ldots, \ell_i\}$ denote some sets of linear forms such that Θ_0 is a basis of $\tilde{\mathcal{F}}_n$, $\Theta_0 \cup \Theta_1$ is a basis of $\mathcal{F}_{n+s}$, $\Theta_0 \cup \Theta_1 \cup \Theta_2$ is a basis of $\tilde{\mathcal{F}}_{n+2s}$, etc. Note that, by construction, $\ell_i \geq 0$ for every integer $i \geq 1$.

By definition of the sets Θ_i and by (18), we have that

$$\begin{array}{rclcl} \dim \mathcal{F}_{n+(2k+1)s} & = & \sum_{i=0}^{2k+1} \ell_i & = & \ell_0 + \ell_1 + 2ks\rho^* = \ell_0 + \ell_1 + 2ks\tilde{\rho}^* + 2ksr, \\ \dim \tilde{\mathcal{F}}_{n+(2k+2)s} & = & \sum_{i=0}^{2k+2} \ell_i & = & \ell_0 + (2k+2)s\tilde{\rho}^*. \end{array}$$

Solving for ℓ_{2k+2} we obtain

$$\ell_{2k+2} = 2s\tilde{\rho}^* - \ell_1 - 2ksr. \tag{19}$$

By (19), ℓ_{2k+2} becomes negative for k large enough, which is a contradiction. This concludes the proof. □

3.3. Equivalence under generalized transformations.

Definition 3.14. *The system Σ is said to be* equivalent to the prime system Π under proper GOT *if there exist*

(i) *a state diffeomorphism*

$$\begin{array}{rcl} \phi : M & \rightarrow & \mathbb{R}^n, \\ x & \mapsto & z = \phi(x); \end{array}$$

(ii) *a regular static state feedback $u = \alpha(x) + \beta(x)v$;*

(iii) *a proper GOT (ψ, χ)*

such that the transformation of Σ under $(\phi, (\alpha, \beta), (\psi, \chi))$ equals Π.

Remark 3.15. We restrict ourselves to proper GOTs because we are studying equivalence to prime systems, for which the output is a function of the state only. □

Theorem 3.16. *Consider the square nonlinear system Σ and suppose that it satisfies* A1 *and* A2. *Then Σ is equivalent to prime system Π under proper GOT if and only if the following conditions are satisfied:*

(i) $\mathcal{H}_\infty = 0$;

(ii) *for $k = 1, \ldots, k^*$, $\mathcal{H}_k$ is completely integrable;*

(iii) $\mathcal{X} \cap \mathcal{F}_{n-1} = \mathcal{X}$*;*

(iv) $\rho^* = m$.

Remark 3.17. A system which satisfies the hypothesis of Theorem 3.3 (and hence is equivalent to prime system Π) also satisfies conditions (i)–(iv) above. Clearly, conditions (i)–(ii) hold. Next, note that condition (iii) of Theorem 3.3 implies $\mathcal{H}_{k^*} \subset \mathcal{F}_0$, $\mathcal{H}_{k^*-1} \subset \mathcal{F}_1$, etc., and thus $\mathcal{X} = \mathcal{H}_1 \subset \mathcal{F}_{k^*-1} \subset \mathcal{F}_{n-1}$. Therefore condition (iii) holds. Finally, from Remark 3.6 we can see that condition (iv) holds as well. □

In order to prove Theorem 3.16, we need to introduce some notation. For a given nonnegative integer d, the extended state space, extended output space, and extended output map are defined, respectively, by $M^d = M \times (\mathbb{R}^m)^{d+1}$, $Y^d = Y \times (\mathbb{R}^m)^d$, and

$$\begin{array}{rcl} h_e : M \times (\mathbb{R}^m)^{(d+1)} & \to & Y \times (\mathbb{R}^m)^d, \\ (x, u, \dots, u^{(d)}) & \mapsto & (y, \dots, y^{(d)}) = (h(x), \dots, h^{(d)}(x, \dots, u^{(d-1)})). \end{array}$$

Also, we will need the following technical result.

PROPOSITION 3.18. *The rank ρ^* of the system Σ is equal to m if and only if, for every integer $N > 0$,* $\dim \mathcal{F}_N = mN$*.*

Proof. First suppose that $\rho^* = m$ but that for some integer N we have $\dim \mathcal{F}_N < mN$. Then, necessarily, there is a form $\mathrm{d}h_i^{(N)}$ and coefficients c_{ij}^k such that

$$\mathrm{d}h_i^{(N)} = \sum_{j=1}^{m} \sum_{k=0}^{(N-1)} c_{ij}^k \mathrm{d}h_j^{(k)} + \sum_{j \neq i} c_{ij}^N \mathrm{d}h_j^{(N)}.$$

The latter implies that for every integer $\bar{N} > N$ we have

$$\mathrm{d}h_i^{(\bar{N})} = \sum_{j=1}^{m} \sum_{k=0}^{(\bar{N}-1)} \bar{c}_{ij}^k \mathrm{d}h_j^{(k)} + \sum_{j \neq i} \bar{c}_{ij}^{\bar{N}} \mathrm{d}h_j^{(\bar{N})}. \tag{20}$$

Let us recall [6] that, for $N > n$, $\dim \mathcal{E}_N - \dim \mathcal{E}_{N-1} = \dim \mathcal{F}_N - \dim \mathcal{F}_{N-1}$. Thus, (20) implies that $\dim\, \mathcal{E}_{\bar{N}} - \dim\, \mathcal{E}_{\bar{N}-1} < m$. In particular, if we choose $\bar{N} > n$, we have that $\rho^* = \dim\, \mathcal{E}_{\bar{N}} - \dim\, \mathcal{E}_{\bar{N}-1} < m$, which is a contradiction. The converse is obvious. □

Proof of Theorem 3.16. *Necessity.* It is clear that conditions (i)–(iv) are satisfied for a system in prime form. Moreover, conditions (i)–(ii) are invariant under state diffeomorphism and regular static state feedback. On the other hand, Theorem 3.13 states that the rank ρ^* is invariant under proper GOTs. It remains to prove that condition (iii) is also invariant under proper GOTs. This part of the proof will be broken down into two lemmas.

LEMMA 3.19. *Let* $\mathcal{F}_\infty = \mathrm{span}_\mathcal{K}\{\mathrm{d}h_i^{(j)},\ 1 \le i \le m,\ j \ge 0\}$*. Then we have* $\mathcal{X} \cap \mathcal{F}_\infty = \mathcal{X} \cap \mathcal{F}_{n-1}$*.*

Proof. Pick an arbitrary linear form $\omega \in \mathcal{X} \cap \mathcal{F}_\infty$. Then there are coefficients b_{ij} and an integer $N \ge 0$ such that

$$\omega = \sum_{i=1}^{m} \sum_{j=0}^{N} b_{ij} \mathrm{d}h_i^{(j)}.$$

Next note that, by Proposition 3.18, the forms $\{\mathrm{d}h_i^{(j)},\ 1 \le i \le m,\ 0 \le j \le N\}$ are linearly independent. Then, necessarily, $\mathrm{d}h_i^{(j)} \notin \mathcal{X}$ for $j > n-1$. Since $\omega \in \mathcal{X}$, one concludes that $N < n-1$, whence $\omega \in \mathcal{X} \cap \mathcal{F}_{n-1}$. We have shown that $\mathcal{X} \cap \mathcal{F}_\infty \subset \mathcal{X} \cap \mathcal{F}_{n-1}$. On the other hand, it is obvious that $\mathcal{X} \cap \mathcal{F}_{n-1} \subset \mathcal{X} \cap \mathcal{F}_\infty$. □

LEMMA 3.20. *Let (ψ, χ) be a proper GOT, and let $\{\mathcal{F}_k\}$ and $\{\tilde{\mathcal{F}}_k\}$ denote, respectively, the sequences of subspaces associated with the system Σ with the output $y = h(x)$ and with the new output $\tilde{y} = \psi(y, \dot{y}, \dots, y^{(d)}) = \tilde{h}(x)$. Then $\tilde{\mathcal{F}}_{n-1} \cap \mathcal{X} = \mathcal{F}_{n-1} \cap \mathcal{X}$.*

Proof. In the proof of Theorem 3.13 we have shown that, for every integer $k \geq 0$, we have $\tilde{\mathcal{F}}_k \subset \mathcal{F}_{k+d}$. Pick an arbitrary form $\omega \in \tilde{\mathcal{F}}_{n-1} \cap \mathcal{X}$. Lemma 3.19 implies that

$$\omega \in \mathcal{F}_{n+d-1} \cap \mathcal{X} \subset \mathcal{F}_\infty \cap \mathcal{X} = \mathcal{F}_{n-1} \cap \mathcal{X}.$$

This proves that $\tilde{\mathcal{F}}_{n-1} \cap \mathcal{X} \subset \mathcal{F}_{n-1} \cap \mathcal{X}$. Since (ψ, χ) is a GOT, a symmetric argument shows that $\mathcal{F}_{n-1} \cap \mathcal{X} \subset \tilde{\mathcal{F}}_{n-1} \cap \mathcal{X}$. □

Sufficiency. Conditions (i)–(ii) imply that the system Σ is linearizable by regular static state feedback. Therefore, we can assume, without loss of generality, that Σ is in the form (12). Next notice that condition (iii) implies that, for $i = 1, \ldots, m$,

$$\mathrm{d}z_{i1} = \mathrm{d}\phi_{i1}(x) = \sum_{j=1}^{m} \sum_{k=0}^{d} a_{ij}^{k} \mathrm{d}h_j^{(k)}, \tag{21}$$

where $0 \leq d \leq n-1$.

LEMMA 3.21. *The coefficients a_{ij}^k appearing in* (21) *can be expressed as functions of* $\{y_i^{(j)},\ 1 \leq i \leq m,\ 0 \leq j \leq d\}$ *only.*

Proof. By Proposition 3.18, the forms $\{\mathrm{d}h_i^{(j)},\ 1 \leq i \leq m,\ 0 \leq j \leq d\}$ are independent. Therefore, a similar argument to that used in Lemma 3.7 can be used to conclude the proof. □

By Lemma 3.21, we can define m one-forms on the extended output space Y^d by

$$\eta_i = \sum_{j=1}^{m} \sum_{k=0}^{d} a_{ij}^{k} \mathrm{d}y_j^{(k)}.$$

Then it is clear that the pull-back of the forms η_i under the extended output map $h_e : M^d \to Y^d$ coincides precisely with the forms $\mathrm{d}z_{i1}$; that is, $\mathrm{d}z_{i1} = h_e^*(\eta_i)$.

LEMMA 3.22. *Let $\{\eta_1, \ldots, \eta_m\}$ be the collection of forms defined on the extended output space Y^d which satisfy $\mathrm{d}z_{i1} = h_e^*(\eta_i)$. Then, for $i = 1, \ldots, m$, $\mathrm{d}\eta_i = 0$.*

Proof. By Proposition 3.18, the extended output map $h_e : M^d \to Y^d$ has full rank equal to $m(d+1)$. Therefore, there exists a system of coordinates of the extended state space M^d such that $h_e : M^d \to Y^d$ becomes the canonical projection. A similar construction as in Lemma 3.8 shows then that $\mathrm{d}\eta_i = 0$. □

By virtue of Lemma 3.22, we can assume, without loss of generality, that, for $i = 1, \ldots, m$, $\eta_i = \mathrm{d}\psi_i(y, \dot{y}, \ldots, y^{(d)})$. Finally define a new output function $\tilde{y}$ by $\tilde{y}_i = \psi_i(y, \dot{y}, \ldots, y^{(d)})$. With this change of output variables, system (12) is in prime form. It remains to prove that there is an inverse map $y = \chi(\tilde{y}, \ldots, \tilde{y}^{(d')})$. Notice that $y = h(x) = h \circ \phi^{-1}(z)$ and that, by construction, $z_{ij} = \tilde{y}_i^{(j-1)}$. Therefore, it follows that necessarily

$$y = h \circ \phi^{-1}(z) = \chi(\tilde{y}, \ldots, \tilde{y}^{(d')})$$

for some integer $d' \geq 0$. □

Example 3.23 (Example 3.9, continued). We have shown that system (13) is not equivalent to a prime system under standard output space transformations, i.e., output space diffeomorphism. We shall show that system (13) is equivalent to prime system under proper GOTs. We have already shown that conditions (i)–(ii) are satisfied. It is easy to check that

$$\begin{aligned}
\mathcal{F}_0 &= \mathrm{span}_{\mathcal{K}}\{\mathrm{d}x_1, \mathrm{d}x_2 + x_1\mathrm{d}x_5, \mathrm{d}x_4\}, \\
\mathcal{F}_1 &= \mathrm{span}_{\mathcal{K}}\{\mathrm{d}x_1, \mathrm{d}x_2, \mathrm{d}x_3 + x_1\mathrm{d}x_6, \mathrm{d}x_4, \mathrm{d}x_5, \mathrm{d}u_1\}, \\
\mathcal{F}_2 &= \mathrm{span}_{\mathcal{K}}\{\mathrm{d}x_1, \mathrm{d}x_2, \mathrm{d}x_3, \mathrm{d}x_4, \mathrm{d}x_5, \mathrm{d}x_6, \mathrm{d}u_1, \mathrm{d}\dot{u}_1, \mathrm{d}u_2 + x_1\mathrm{d}u_3\}.
\end{aligned}$$

Note that $\mathcal{X} \subset \mathcal{F}_2$ and, since $\mathcal{F}_2 \subset \mathcal{F}_5$, we have $\mathcal{X} \cap \mathcal{F}_5 = \mathcal{X}$, and thus condition (iii) is also satisfied. Finally, lengthy but straightforward computations show that $\rho^* = \dim \mathcal{F}_6 - \dim \mathcal{F}_5 = 3$. Consequently, system (13) is equivalent to prime system.

Since the state equations are already in the form (1), in order to transform system (13) into prime form, we just need to find a suitable GOT. This can be accomplished as follows: first note that

$$\begin{array}{lclcl} \mathrm{d}x_1 & = & \mathrm{d}h_1 & = & h_e^*(\mathrm{d}y_1), \\ \mathrm{d}x_2 & = & \mathrm{d}h_2 - x_5\mathrm{d}h_1 - x_1\mathrm{d}\dot{h}_3 & = & h_e^*(\mathrm{d}y_2 - \dot{y}_3\mathrm{d}y_1 - y_1\mathrm{d}\dot{y}_3), \\ \mathrm{d}x_4 & = & \mathrm{d}h_3 & = & h_e^*(\mathrm{d}y_3). \end{array} \tag{22}$$

By integrating the right sides of (22), we find the GOT $(y, \dot{y}) \mapsto \tilde{y} = (y_1, y_2 - y_1\dot{y}_3, y_3)$. In coordinates $(\tilde{y}_1, \tilde{y}_2, \tilde{y}_3)$, system (13) is in prime form. The inverse output transformation is obviously given by $(\tilde{y}, \dot{\tilde{y}}) \mapsto y = (\tilde{y}_1, \tilde{y}_2 + \tilde{y}_1\dot{\tilde{y}}_3, \tilde{y}_3)$. □

As pointed out before, one immediate application of Theorems 3.3 and 3.16 is the possibility of (asymptotically or exactly) tracking a desired output trajectory $y_d(t)$. This is best illustrated by the following example.

Example 3.24 (Example 3.23, continued). The decoupling matrix [9, 13] associated with the original output $y = h(x)$ of system (13) is given by

$$B(x) = \begin{bmatrix} 1 & 0 & 0 \\ x_5 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

Since $\operatorname{rank} B(x) = 2$, noninteracting control cannot be achieved by regular static state feedback.

On the other hand, the output functions which bring system (13) to prime form are given, as functions of x, by

$$\begin{array}{lcl} \tilde{y}_1 & = & y_1 = x_1, \\ \tilde{y}_2 & = & y_2 - y_1\dot{y}_3 = x_2, \\ \tilde{y}_3 & = & y_3 = x_4. \end{array}$$

The decoupling matrix $\tilde{B}(x)$ associated with the output $\tilde{y} = \tilde{h}(x)$ is simply $\tilde{B}(x) = I_3$. Therefore the *standard noninteracting feedback* [9, 13] can be used to decouple the scalar output components $\tilde{y}_i$, $i = 1, \dots, 3$. Now suppose that we want to asymptotically track a smooth output trajectory $y_d(t) = (y_{d1}(t), y_{d2}(t), y_{d3}(t))$ for system (13). Such trajectory is transformed in the new coordinates into $\tilde{y}_d(t) = (y_{d1}(t), y_{d2}(t) - y_{d1}(t)\dot{y}_{d3}(t), y_{d3}(t))$. Since (13) has been transformed into a prime system, the asymptotic output tracking problem is solved by *linear* state feedback in the transformed coordinates, namely

$$\begin{array}{lcl} u_1 & = & \dot{\tilde{y}}_{d1} - k_0^1(x_1 - \tilde{y}_{d1}), \\ u_2 & = & \ddot{\tilde{y}}_{d2} - k_1^2(x_3 - \dot{\tilde{y}}_{d2}) - k_0^2(x_2 - \tilde{y}_{d2}), \\ u_3 & = & \tilde{y}_{d3}^{(3)} - k_2^3(x_6 - \ddot{\tilde{y}}_{d3}) - k_1^3(x_5 - \dot{\tilde{y}}_{d3}) - k_0^3(x_4 - \tilde{y}_{d3}), \end{array}$$

where $s + k_0^1$, $s^2 + k_1^2 s + k_0^2$ and $s^3 + k_2^3 s^2 + k_1^3 s + k_0^3$ are Hurwitz polynomials. □

4. Conclusion and final remarks. We have introduced the notion of GOT for nonlinear systems and have shown that the linear algebraic framework introduced by Di Benedetto, Grizzle, and Moog [6] provides a rather convenient tool to study their properties. In particular, it has been shown that the rank of a system remains unchanged under such transformations.

It is worth mentioning that the class of GOT that we have introduced can be seen as the "dual" transformation of the class of generalized state feedbacks introduced in [14] and studied from the differential algebraic viewpoint in [5], where they were called *quasi–static* state feedbacks.

As an important application of this new class of transformations, a larger class of systems which are equivalent to prime systems has been identified. In turn, this result is applicable to control problems where output transformations are naturally allowed, such as output tracking and output regulation.

Of course, the conditions of Theorems 3.3 and 3.16 imply that the system Σ is *invertible* [6, 7], and hence noninteracting control can be achieved by dynamic state feedback. In that respect, Theorems 3.3 and 3.16 avoid the addition of extra dynamics to the system, as pointed out in [10].

An open issue for further research is the study of the notion of equivalence of nonlinear systems under GOTs, not necessarily proper.

QUADRATIC OPTIMAL CONTROL OF WELL-POSED LINEAR SYSTEMS*

OLOF J. STAFFANS†

Abstract. We study the infinite horizon quadratic cost minimization problem for a well-posed linear system in the sense of Salamon and Weiss. The quadratic cost function that we seek to minimize need not be positive, but it is convex and bounded from below. We assume the system to be jointly stabilizable and detectable and give a feedback solution to the cost minimization problem. Moreover, we connect this solution to the computation of either a (J, S)-inner or an S-normalized coprime factorization of the transfer function, depending on how the problem is formulated. We apply the general theory to get factorization versions of the bounded and positive real lemmas. In the case where the system is regular it is possible to show that the feedback operator can be expressed in terms of the Riccati operator and that the Riccati operator is a stabilizing self-adjoint solution of an algebraic Riccati equation. This Riccati equation is nonstandard in the sense that the weighting operator in the quadratic term differs from the expected one, and the computation of the correct weighting operator is a nontrivial task.

1. Introduction.

This work treats the infinite horizon quadratic cost minimization problem for a time-invariant well-posed linear control system in the sense of Salamon and Weiss and extends the results presented in [23] to unstable systems. The approach is the same as in [22]: we first employ a preliminary state feedback to stabilize the system, and then we apply the theory developed in [23] to solve the quadratic cost minimization problem for the stable system. Working backwards we then obtain a solution to the original problem.

We consider two different types of cost functions. In the standard case both the control and the observation are equally penalized; we show that this leads to a problem that is equivalent to the computation of a normalized coprime factorization of the transfer function (see Corollary 4.9). It is possible to embed this type of problem into a more general class of problem where there is no cost on the control itself, only on the observation. In this setting the problem of quadratic cost minimization becomes equivalent to the computation of an inner coprime factorization of the transfer function, i.e., a coprime factorization with an inner numerator (see Theorem 4.4).

The infinite horizon quadratic cost minimization problem is also associated with an algebraic Riccati equation. Indeed, we show that in the case where the optimally controlled system and its adjoint are regular in the sense of Weiss, the Riccati operator satisfies an algebraic Riccati equation, and the feedback operator can be computed from the Riccati operator. However, in this connection we encounter a very interesting phenomenon: the weighting operator in the quadratic term of the Riccati equation differs from the expected one, and the computation of the correct weighting operator is a nontrivial task. The same operator is present in the formula that connects the

†Åbo Akademi University, Department of Mathematics, FIN-20500 Åbo, Finland (Olof.Staffans@abo.fi, http://www.abo.fi/~staffans/).

Riccati operator to the feedback operator. This phenomenon was first reported in [18] in a stable setting for a more restricted class of transfer functions. Examples where this phenomenon occurs are given in [21], [22], [30], and [33].

We have based the discussion above on transfer functions rather than input/output maps since we believe that the former concept is more familiar to most readers. However, in the main body of the text we phrase our results in terms of input/output maps instead. In our opinion, this formulation is both easier and more intuitive than the transfer function formulation, and it has the advantage that generalizations to nonlinear and time-dependent systems are more immediate.

For a more detailed account of the existing Riccati equation theory for various classes of systems we refer the reader to [14] (and its forthcoming new version) and to the review [13]. However, we have to mention the very interesting paper by Flandoli, Lasiecka, and Triggiani [5]. In that paper the observation operator is bounded, but the authors have told us that the results of that paper can be extended to some classes of unbounded observation operators. Their approach is quite different from ours. They do not assume that the system is stabilizable and detectable. On the other hand, they also do not prove that the optimal system is well posed in our sense. They make no study of the input/output behavior of the closed loop system, and in particular, they do not mention the all-pass property of the optimal closed loop system (see Remark 2.8). In our opinion, this is the most characteristic property of the closed loop system.

The results presented here were originally obtained in the spring of 1995, and they were circulated in the form of two preprints [18, 19] with the titles "Coprime factorizations and optimal control of abstract linear systems" and "The nonstandard quadratic cost minimization problem for abstract linear systems." The former preprint treated the "standard" cost minimization problem and the latter a "nonstandard" cost minimization problem, where the cost function contains a possibly indefinite weighting operator but is still bounded from below. The latter was a straightforward modification of the former, and it was not included in the original submission to SIAM. However, later work on the H^∞ minimax problem has proved that the inclusion of the indefinite weighting operator would improve the future reference value of this work significantly.[1] This was one of the reasons for a major revision that was carried out in late 1996.[2] In the meantime we received preprints of [32] and [33], which overlap our section 2. The problem studied in [33] is essentially the same as in [23], summarized here in section 2, plus a Riccati equation theory for stable systems. However, neither paper fully contains the other.

This work is very closely related to [24]; in fact, they were both part of the same original submission to SIAM. We expect the reader to have access to [24] and refer freely to results in that paper. In particular, we send the reader to [24] for a short presentation of the basic theory of well-posed linear systems.

We use the following notation:

$\mathcal{L}(U;Y)$, $\mathcal{L}(U)$: The set of bounded linear operators from U into Y or from U into itself, respectively.

I: The identity operator.

A^*: The (Hilbert space) adjoint of the operator A.

[1] This is due to the fact that it makes the formulae look identical to those that are valid in the H^∞-case, although the underlying assumptions are different. See [25] and [26].

[2] At the same time [24] was separated into an independent paper.

$A \geq 0$: A is (self-adjoint and) positive definite.

$A \gg 0$: $A \geq \epsilon I$ for some $\epsilon > 0$, hence A is invertible.

$\mathrm{dom}(A)$: The domain of the (unbounded) operator A.

$\mathrm{range}(A)$: The range of the operator A.

$\mathbf{R}$, $\mathbf{R}^+$, $\mathbf{R}^-$: $\mathbf{R} = (-\infty, \infty)$, $\mathbf{R}^+ = [0, \infty)$, and $\mathbf{R}^- = (-\infty, 0]$.

$L^2(J;U)$: The set of U-valued L^2-functions on the interval J.

$L^2_\omega(J;U)$: $L^2_\omega(J;U) = \left\{ u \in L^2_{\mathrm{loc}}(J;U) \mid (t \mapsto \mathrm{e}^{-\omega t} u(t)) \in L^2(J;U) \right\}$.

$H^\infty_\omega(U;Y)$: The set of $\mathcal{L}(U;Y)$-valued H^∞ functions over the half-plane $\Re z > \omega$.

$TI_\omega(U;Y)$, $TI_\omega(U)$: The set of bounded linear time-invariant operators from $L^2_\omega(\mathbf{R};U)$ into $L^2_\omega(\mathbf{R};Y)$ or from $L^2_\omega(\mathbf{R};U)$ into itself.

$TIC_\omega(U;Y)$, $TIC_\omega(U)$: The set of causal operators in $TI_\omega(U;Y)$ or $TI_\omega(U)$.

$TIC(U;Y)$, $TIC(U)$: $TIC(U;Y) = TIC_0(U;Y)$ and $TIC(U) = TIC_0(U)$.

$\langle \cdot, \cdot \rangle_H$: The inner product in the Hilbert space H.

$\tau(t)$: The time-shift group $\tau(t)u(s) = u(t+s)$ (this is a left shift when $t > 0$ and a right shift when $t < 0$).

π_J: $(\pi_J u)(s) = u(s)$ if $s \in J$ and $(\pi_J u)(s) = 0$ if $s \notin J$. Here $J \subset \mathbf{R}$.

π_+, π_-: $\pi_+ = \pi_{\mathbf{R}^+}$ and $\pi_- = \pi_{\mathbf{R}^-}$.

We extend a L^2_ω-function u defined on a subinterval J of $\mathbf{R}$ to the whole real line by requiring u to be zero outside of J, and we denote the extended function by $\pi_J u$. We use the same symbol π_J both for the embedding operator $L^2_\omega(J) \to L^2_\omega(\mathbf{R})$ and for the corresponding projection operator $L^2_\omega(\mathbf{R}) \to L^2_\omega(J)$. With this interpretation, $\pi_J L^2_\omega(\mathbf{R};U) = L^2_\omega(J;U) \subset L^2_\omega(\mathbf{R};U)$ for each interval $J \subset \mathbf{R}$.

2. The stable quadratic cost minimization problem. Before looking at the general quadratic cost minimization problem for unstable systems, let us recall some basic results valid for stable systems.

Definition 2.1. *Let $\Psi = \left[\begin{smallmatrix} \mathcal{A} & \mathcal{B} \\ \mathcal{C} & \mathcal{D} \end{smallmatrix}\right]$ be a stable well-posed linear system on (U,H,Y)* [23, Definition 1], *and let $J = J^* \in \mathcal{L}(Y)$. The quadratic cost minimization problem for Ψ with cost operator J consists of finding, for each $x_0 \in H$, the infimum over all $u \in L^2(\mathbf{R}^+;U)$ of the cost*

$$Q(x_0, u) = \langle y, Jy \rangle_{L^2(\mathbf{R}^+;Y)}, \tag{2.1}$$

where $y = \mathcal{C}x_0 + \mathcal{D}\pi_+ u$ is the observation of Ψ with initial value $x_0 \in H$ and control $u \in L^2(\mathbf{R}^+;U)$. If there exists an operator $\Pi = \Pi^* \in \mathcal{L}(H)$ such that the optimal cost is given by

$$\inf_{u \in L^2(\mathbf{R}^+;U)} Q(x_0, u) = \langle x_0, \Pi x_0 \rangle_H,$$

then Π is called the Riccati operator of Ψ with cost operator J.

We have studied this problem in [23], but unfortunately, at that time we took the operator J to be the identity operator throughout. If J is positive definite, then it is possible to reduce J to the identity by a simple change of variable in the output space Y, but many applications, such as the positive (real) lemma and the bounded (real) lemma, require the use of a nondefinite J.[3] Fortunately, it turns out that the results

[3] We shall return elsewhere to the H^∞ theory which requires both a nondefinite cost operator J and a nondefinite sensitivity operator S.

presented in [23] remain valid with trivial modifications as long as the input/output map $\mathcal{D}$ of Ψ is J-coercive in the following sense:

DEFINITION 2.2. *Let $J = J^* \in \mathcal{L}(Y)$.*

(i) *The operator $\mathcal{D} \in TIC(U;Y)$ is J-coercive iff $\mathcal{D}^* J\mathcal{D} \gg 0$, that is, $\langle \mathcal{D}u, J\mathcal{D}u\rangle_{L^2(\mathbf{R};Y)} \geq \epsilon \|u\|^2_{L^2(\mathbf{R};U)}$ for all $u \in L^2(\mathbf{R};U)$ and some $\epsilon > 0$.*

(ii) *A stable well-posed linear system $\Psi = \left[\begin{smallmatrix} \mathcal{A} & \mathcal{B} \\ \mathcal{C} & \mathcal{D}\end{smallmatrix}\right]$ is J-coercive iff its input-output map $\mathcal{D}$ is J-coercive.*

Indeed, this is the case that is important in the applications to the bounded and positive (real) lemmas in section 8.

Since the solution to the cost minimization problem in the stable J-coercive case is almost identical to the one in [23] we simply present this solution below, leaving the proofs to the reader (it is done by inserting the operator J or S after each adjoint operator defined on Y or U, respectively).

DEFINITION 2.3 (see [23, Definitions 16 and 17]). *Let $J = J^* \in \mathcal{L}(Y)$, and let $S = S^* \in \mathcal{L}(U)$.*

(i) *The operator $\mathcal{N} \in TIC(U;Y)$ is (J,S)-inner iff $\mathcal{N}^* J \mathcal{N} = S$.*

(ii) *An operator $\mathcal{X} \in TIC(U;Y)$ is outer if the image of $L^2(\mathbf{R}^+;U)$ under $\mathcal{X}\pi_+$ is dense in $L^2(\mathbf{R}^+;Y)$.*

(iii) *An operator $\mathcal{X} \in TIC(U)$ is an (invertible) S-spectral factor of $\mathcal{D}^* J\mathcal{D} \in TI(U)$ iff $\mathcal{X}$ is invertible in $TIC(U)$ and $\mathcal{D}^* J \mathcal{D} = \mathcal{X}^* S \mathcal{X}$.*

(iv) *The factorization $\mathcal{D} = \mathcal{N}\mathcal{X}$ is a (J,S)-inner-outer factorization of $\mathcal{D} \in TIC(U;Y)$ if $\mathcal{N} \in TIC(U;Y)$ is (J,S)-inner and $\mathcal{X} \in TIC(U)$ is outer.*

(v) *In each case S is called the sensitivity operator of $\mathcal{N}$ or of the factorization.*

LEMMA 2.4 (see [23, Lemmas 13 and 18]). *Let $\mathcal{D} \in TIC(U;Y)$, $J = J^* \in \mathcal{L}(Y)$, $S \in \mathcal{L}(U)$, $S \gg 0$, $\widetilde{S} \in \mathcal{L}(U)$, and $\widetilde{S} \gg 0$.*

(i) *$\mathcal{D}^* J \mathcal{D}$ has an S-spectral factor $\mathcal{X}$ iff $\mathcal{D}$ is J-coercive.*

(ii) *If $\mathcal{X}$ is an S-spectral factor of $\mathcal{D}^* J\mathcal{D}$, then $\mathcal{N}\mathcal{X} = \left(\mathcal{D}\mathcal{X}^{-1}\right)\mathcal{X}$ is a (J,S)-inner-outer factorization of $\mathcal{D}$. Conversely, if $\mathcal{D}$ is J-coercive and $\mathcal{N}\mathcal{X}$ is a (J,S)-inner-outer factorization of $\mathcal{D}$, then $\mathcal{X}$ is an S-spectral factor of $\mathcal{D}^* J\mathcal{D}$.*

(iii) *The set of all possible S-spectral factors $\mathcal{X}$ of $\mathcal{D}^* J \mathcal{D}$ can be parameterized as $\mathcal{X} = E^{-1}\widetilde{\mathcal{X}}$ and $S = E^* \widetilde{S} E$, where $\widetilde{\mathcal{X}}$ is a fixed $\widetilde{S}$-spectral factor and $E \in \mathcal{L}(U)$ is an arbitrary invertible operator.*

(iv) *If $\mathcal{D}$ is J-coercive, then the Toeplitz operator $\pi_+\mathcal{D}^* J\mathcal{D}\pi_+$ is invertible, and its inverse can be written in the form $(\pi_+\mathcal{D}^* J \mathcal{D}\pi_+)^{-1} = \mathcal{X}^{-1}S^{-1}\pi_+(\mathcal{X}^*)^{-1}$. Here $\mathcal{X}$ is an arbitrary S-spectral factor of $\mathcal{D}^* J\mathcal{D}$. ($\mathcal{X}^{-1}S^{-1}\pi_+(\mathcal{X}^*)^{-1}$ does not depend on the particular factorization, only on $\mathcal{D}$ and J.)*

LEMMA 2.5 (see [23, Lemma 13 and Theorem 27]). *Let $J = J^* \in \mathcal{L}(Y)$, and let $\Psi = \left[\begin{smallmatrix} \mathcal{A} & \mathcal{B} \\ \mathcal{C} & \mathcal{D}\end{smallmatrix}\right]$ be a stable J-coercive well-posed linear system on (U,H,Y). Then, for each $x_0 \in H$, there is a unique control $u^{\mathrm{opt}}(x_0) \in L^2(\mathbf{R}^+;U)$ that minimizes the cost function $Q(x_0,u)$ in Definition 2.1. This control u^{opt} is given by*

$$u^{\mathrm{opt}}(x_0) = -\mathcal{X}^{-1}S^{-1}\pi_+\mathcal{N}^* J\mathcal{C}x_0,$$

where $\mathcal{N}\mathcal{X}$ is an arbitrary (J,S)-inner-outer factorization of $\mathcal{D}$ (cf. Lemma 2.4). The corresponding state $x^{\mathrm{opt}}(x_0)$, output $y^{\mathrm{opt}}(x_0)$, and the minimum $Q(x_0,u^{\mathrm{opt}}(x_0))$ of the cost function are given by

$$\begin{aligned} x^{\mathrm{opt}}(x_0) &= \mathcal{A}x_0 - \mathcal{B}\mathcal{X}^{-1}\tau S^{-1}\pi_+\mathcal{N}^* J\mathcal{C}x_0, \\ y^{\mathrm{opt}}(x_0) &= (I-P)\mathcal{C}x_0, \\ Q(x_0,u^{\mathrm{opt}}(x_0)) &= \langle x_0, \mathcal{C}^* J\,(I-P)\,\mathcal{C}x_0\rangle_H\,, \end{aligned}$$

where

$$P = \mathcal{D}\pi_+(\pi_+\mathcal{D}^* J\mathcal{D}\pi_+)^{-1}\pi_+\mathcal{D}^* J = I - \mathcal{N}S^{-1}\pi_+\mathcal{N}^* J$$

is the projection onto the range of $\mathcal{D}\pi_+$ *along the null space of* $\pi_+\mathcal{D}^* J$. *In particular,* Ψ *has a Riccati operator, namely*

$$\Pi = \mathcal{C}^* J\,(I - P)\,\mathcal{C},$$

and $y^{\mathrm{opt}}(x_0)$ *belongs to the null space of the projection* P, *i.e.,*

$$\pi_+\mathcal{D}^* J y^{\mathrm{opt}}(x_0) = \pi_+\mathcal{D}^* J\left(\mathcal{C}x_0 + \mathcal{D}\pi_+ u^{\mathrm{opt}}(x_0)\right) = 0.$$

We remark that, although the factorization $\mathcal{D} = \mathcal{N}\mathcal{X}$ and the operator S are not unique, the formulas given above produce the same result independently of how the factorization is chosen. This follows from Lemma 2.4 (see, in particular, part (iv)).

THEOREM 2.6 (see [23, Theorem 27]). *Let* $J = J^* \in \mathcal{L}(Y)$, *and let* $\Psi = \left[\begin{smallmatrix}\mathcal{A} & \mathcal{B}\\ \mathcal{C} & \mathcal{D}\end{smallmatrix}\right]$ *be a stable J-coercive well-posed linear system on* (U, H, Y). *Let* $x_0 \in H$, *let* $x^{\mathrm{opt}}(x_0)$, $y^{\mathrm{opt}}(x_0)$, *and* $u^{\mathrm{opt}}(x_0)$ *be the optimal state, output, and control for the quadratic cost minimization problem, and let* Π *be the corresponding Riccati operator* (*see Lemma* 2.5).

(i) *Let* $\mathcal{D} = \mathcal{N}\mathcal{X}$ *be a* (J,S)*-inner-outer factorization of* $\mathcal{D}$, *and define* $\mathcal{M} = \mathcal{X}^{-1}$. *Then*

$$\begin{bmatrix}\mathcal{K} & \mathcal{F}\end{bmatrix} = \begin{bmatrix}-S^{-1}\pi_+\mathcal{N}^* J\mathcal{C} & (I - \mathcal{X})\end{bmatrix}$$

is a stable and stabilizing state feedback pair for Ψ [23, *Definition* 22] *and*

$$\begin{aligned}\begin{bmatrix}x^{\mathrm{opt}}(t,x_0)\\ y^{\mathrm{opt}}(x_0)\\ u^{\mathrm{opt}}(x_0)\end{bmatrix} &= \begin{bmatrix}\mathcal{A}_{\circlearrowleft}(t)\\ \mathcal{C}_{\circlearrowleft}\\ \mathcal{K}_{\circlearrowleft}\end{bmatrix} x_0 = \begin{bmatrix}\mathcal{A}(t) + \mathcal{B}\mathcal{M}\tau(t)\mathcal{K}\\ \mathcal{C} + \mathcal{N}\mathcal{K}\\ \mathcal{M}\mathcal{K}\end{bmatrix} x_0\\ &= \begin{bmatrix}\mathcal{A}(t)\\ \mathcal{C}\\ 0\end{bmatrix} x_0 - \begin{bmatrix}\mathcal{B}\mathcal{M}\tau(t)\\ \mathcal{N}\\ \mathcal{M}\end{bmatrix} S^{-1}\pi_+\mathcal{N}^* J\mathcal{C}x_0\end{aligned}$$

is equal to the state and output of the closed loop system $\Psi_{\circlearrowleft}$ *defined by*

$$\Psi_{\circlearrowleft} = \begin{bmatrix}\mathcal{A}_{\circlearrowleft} & \mathcal{B}_{\circlearrowleft}\\ \begin{bmatrix}\mathcal{C}_{\circlearrowleft}\\ \mathcal{K}_{\circlearrowleft}\end{bmatrix} & \begin{bmatrix}\mathcal{D}_{\circlearrowleft}\\ \mathcal{F}_{\circlearrowleft}\end{bmatrix}\end{bmatrix} = \begin{bmatrix}\mathcal{A} + \mathcal{B}\tau\mathcal{M}\mathcal{K} & \mathcal{B}\mathcal{M}\\ \begin{bmatrix}\mathcal{C} + \mathcal{N}\mathcal{K}\\ \mathcal{M}\mathcal{K}\end{bmatrix} & \begin{bmatrix}\mathcal{N}\\ \mathcal{M} - I\end{bmatrix}\end{bmatrix}$$

with initial value x_0, *initial time zero, and zero control* $u_{\circlearrowleft}$ (*see Figure* 2.1). *The Riccati operator* Π *of* Ψ *can be written in the following alternative forms*:

$$\Pi = \mathcal{C}^* J\mathcal{C} - \mathcal{K}^* S\mathcal{K} = \mathcal{C}^* J\mathcal{C}_{\circlearrowleft} = \mathcal{C}_{\circlearrowleft}^* J\mathcal{C}_{\circlearrowleft} = \mathcal{C}_{\circlearrowleft}^* J\mathcal{C}.$$

(ii) *Conversely, suppose that* $\left[\begin{smallmatrix}y^{\mathrm{opt}}(x_0)\\ u^{\mathrm{opt}}(x_0)\end{smallmatrix}\right]$ *is equal to the observation of some stable state feedback perturbation* $\Psi_{\circlearrowleft}$ *of* Ψ *with initial value* x_0, *initial time zero, zero control* $u_{\circlearrowleft}$, *and some admissible stable state feedback pair* $[\mathcal{K} \quad \mathcal{F}]$. *Then there exists an operator* $S \in \mathcal{L}(U)$, $S \gg 0$, *such that* $\mathcal{N}\mathcal{X}$ *is a* (J,S)*-inner-outer factorization of* $\mathcal{D}$, *where* $\mathcal{N} = \mathcal{D}\,(I - \mathcal{F})^{-1}$ *and* $\mathcal{X} = (I - \mathcal{F})$. *Moreover,* $\mathcal{K}$ *is given by* $\mathcal{K} = -S^{-1}\pi_+\mathcal{N}^* J\mathcal{C}$.

FIG. 2.1. *Optimal state feedback connection* $\Psi_\circlearrowright$ *in Theorem* 2.6.

(iii) *If* $y = \mathcal{C}_\circlearrowright x_0 + \mathcal{D}_\circlearrowright \pi_+ u_\circlearrowright$ *is the first output of the optimal closed loop system* $\Psi_\circlearrowright$ *with initial state* $x_0 \in H$ *and control* $u_\circlearrowright \in L^2(\mathbf{R}^+;U)$ (*see Figure* 2.1), *then the closed loop cost* $Q_\circlearrowright(x_0, u_\circlearrowright)$ *is given by*

$$Q_\circlearrowright(x_0,u_\circlearrowright) = \langle y, Jy\rangle_{L^2(\mathbf{R}^+;Y)} = \langle x_0, \Pi x_0\rangle_H + \langle u_\circlearrowright, S u_\circlearrowright\rangle_{L^2(\mathbf{R}^+;Y)}\,. \tag{2.2}$$

Proof. Only (iii) requires a proof, since this identity is not found in [23]. This proof goes as follows (the last equality follows from Lemma 2.5):

$$\begin{aligned}\langle y, Jy\rangle_{L^2(\mathbf{R}^+;Y)} &= \big\langle (y^{\mathrm{opt}}(x_0) + \mathcal{N}\pi_+u_\circlearrowright)(s), J(y^{\mathrm{opt}}(x_0) + \mathcal{N}\pi_+u_\circlearrowright)(s)\big\rangle_{L^2(\mathbf{R}^+;Y)}\\ &= \big\langle y^{\mathrm{opt}}(x_0), Jy^{\mathrm{opt}}(x_0)\big\rangle_{L^2(\mathbf{R}^+;Y)}\\ &\quad + 2\Re\big\langle \mathcal{X}\pi_+u_\circlearrowright(s), \mathcal{D}^*Jy^{\mathrm{opt}}(x_0)\big\rangle_{L^2(\mathbf{R}^+;U)}\\ &\quad + \langle u_\circlearrowright, \mathcal{N}^*J\mathcal{N}\pi_+u_\circlearrowright\rangle_{L^2(\mathbf{R}^+;U)}\\ &= \langle x_0, \Pi x_0\rangle_H + \langle u_\circlearrowright, Su_\circlearrowright\rangle_{L^2(\mathbf{R}^+;U)}\,. \qquad \square\end{aligned}$$

REMARK 2.7. *This theorem is actually true under weaker stability assumptions. It suffices if* $\mathcal{C}$ *and* $\mathcal{D}$ *are stable, i.e.,* $\mathcal{A}$ *and* $\mathcal{B}$ *need not be stable* [24, *Definition* 2.11]. *Of course, the corresponding closed loop* $\mathcal{A}_\circlearrowright$ *and* $\mathcal{B}_\circlearrowright$ *need not be stable in this case. Stability of* $\mathcal{A}$ *was not assumed in* [23], *and the stability of* $\mathcal{B}$ *was never used in a nontrivial way in the proofs* (*although it was assumed*). *See also* [33] *which requires no stability of* $\mathcal{A}$ *and* $\mathcal{B}$.

REMARK 2.8. *The conclusion of part* (iii) *of Theorem* 2.6 *says that the frequency response of the input/output map from the closed loop control* $u_\circlearrowright$ *in Figure* 2.1 *to the original output is completely flat, i.e., this input/output map is all-pass, with a power amplification level equal to* S. *Thus,* S *measures the sensitivity of the closed loop system with respect to deviations from the optimal strategy. This is the reason why we call* S *the* sensitivity operator *of the closed loop system.*

3. Quadratic cost minimization: Reduction to the stable case.

We are now ready to attack the unstable quadratic cost minimization problem. The definition of the problem is essentially the same as in the stable case.

DEFINITION 3.1. *Let* $\Psi = \left[\begin{smallmatrix}\mathcal{A} & \mathcal{B}\\ \mathcal{C} & \mathcal{D}\end{smallmatrix}\right]$ *be a well-posed linear system on* (U,H,Y), *and let* $J = J^* \in \mathcal{L}(Y)$. *The* (*nonstandard*) *quadratic cost minimization problem for* Ψ *with cost operator* J *consists of finding, for each* $x_0 \in H$, *the infimum of the cost* $Q(x_0,u)$ *defined in* (2.1) *over all those* $u \in L^2(\mathbf{R}^+;U)$ *for which the corresponding observation* $y = \mathcal{C}x_0 + \mathcal{D}\pi_+u$ *of* Ψ *satisfies* $y \in L^2(\mathbf{R}^+;Y)$. *If there exists an operator* $\Pi = \Pi^* \in \mathcal{L}(H)$ *such that the optimal cost is given by*

$$\inf_{u\in L^2(\mathbf{R}^+;U)} Q(x_0,u) = \langle x_0, \Pi x_0\rangle_H\,,$$

then Π *is called the Riccati operator of* Ψ *with cost operator* J.

Clearly, Q is a quadratic, possibly unbounded, function of $u \in L^2(\mathbf{R}^+;U)$ due to the fact that $\mathcal{D}\pi_+$ is a linear, possibly unbounded, operator in $L^2(\mathbf{R}^+;U)$. The latter operator is not bounded on $L^2(\mathbf{R}^+;U)$ unless Ψ is input-output stable, but it is always closed.

LEMMA 3.2. *Let* $\mathcal{D} \in TIC_\alpha(U;Y)$ *for some* $\alpha \geq 0$. *Then the restriction* $\mathcal{D}_0$ *of the Toeplitz operator* $\mathcal{D}\pi_+$ *to the domain*

$$\operatorname{dom}(\mathcal{D}_0) = \left\{ u \in L^2(\mathbf{R}^+;U) \mid \mathcal{D}\pi_+ u \in L^2(\mathbf{R}^+;Y) \right\}$$

is a closed (possibly unbounded) linear operator from $\operatorname{dom}(\mathcal{D}_0) \subset L^2(\mathbf{R}^+;U)$ *into* $L^2(\mathbf{R}^+;Y)$.

Proof. This follows directly from the fact that $L^2(\mathbf{R}^+)$ is continuously imbedded in $L^2_\alpha(\mathbf{R}^+)$. □

We can say something more about how $\mathcal{D}_0$ maps $L^2(\mathbf{R}^+;U)$ into $L^2(\mathbf{R}^+;Y)$ in the case where $\mathcal{D}$ has a right coprime factorization.[4]

LEMMA 3.3. *Let* $\mathcal{D} \in TIC_\alpha(U;Y)$ *for some* $\alpha \geq 0$, *and suppose that* $\mathcal{D}$ *has a right coprime factorization* $(\mathcal{N},\mathcal{M})$ [24, *Definition* 4.2].

(i) *If* $u \in L^2_{\mathrm{loc}}(\mathbf{R}^+;U)$, $u_\flat \in L^2_{\mathrm{loc}}(\mathbf{R}^+;Y)$, *and* $y \in L^2_{\mathrm{loc}}(\mathbf{R}^+;Y)$ *satisfy*

$$u = \mathcal{M}\pi_+ u_\flat \text{ and } y = \mathcal{N}\pi_+ u_\flat,$$

then $u_\flat \in L^2(\mathbf{R}^+;U)$ *iff both* $u \in L^2(\mathbf{R}^+;U)$ *and* $y \in L^2(\mathbf{R}^+;Y)$. *Thus,* $\operatorname{dom}(\mathcal{D}_0)$ *is equal to the image of* $L^2(\mathbf{R}^+;U)$ *under* $\mathcal{M}\pi_+$, *and* $\operatorname{range}(\mathcal{D}_0)$ *is equal to the image of* $L^2(\mathbf{R}^+;U)$ *under* $\mathcal{N}\pi_+$. *In particular,* $\operatorname{dom}(\mathcal{D}_0)$ *is dense in* $L^2(\mathbf{R}^+;U)$ *iff* $\mathcal{M}$ *is outer.*

(ii) *With* u, $u_\flat$, *and* y *as above, there exist strictly positive constants* ϵ *and* M *such that*

$$\begin{aligned}\epsilon\left(\|u\|^2_{L^2(\mathbf{R}^+;U)} + \|y\|^2_{L^2(\mathbf{R}^+;Y)}\right) &\leq \|u_\flat\|^2_{L^2(\mathbf{R}^+;U)} \\ &\leq M\left(\|u\|^2_{L^2(\mathbf{R}^+;U)} + \|y\|^2_{L^2(\mathbf{R}^+;Y)}\right).\end{aligned}$$

Proof. Clearly, if $u_\flat \in L^2(\mathbf{R}^+;U)$, then both $u \in L^2(\mathbf{R}^+;U)$ and $y \in L^2(\mathbf{R}^+;Y)$. Conversely, if both $u \in L^2(\mathbf{R}^+;U)$ and $y \in L^2(\mathbf{R}^+;Y)$, then we can use the right coprimeness of $\mathcal{N}$ and $\mathcal{M}$ to write

$$u_\flat = \left(\widetilde{\mathcal{Y}}\mathcal{N} + \widetilde{\mathcal{X}}\mathcal{M}\right)\pi_+ u_\flat = \widetilde{\mathcal{Y}}y + \widetilde{\mathcal{X}}u,$$

and this implies that $u_\flat \in L^2(\mathbf{R}^+;U)$. The claims about the domain and range of $\mathcal{D}_0$ follow immediately, and so does claim (ii). □

As a special case of this result (take $\mathcal{N} = \mathcal{D}$ and $\mathcal{M} = I$) we get the following (trivial) estimate.

LEMMA 3.4. *For each* $\mathcal{D} \in TIC(U;Y)$ *there exist strictly positive constants* ϵ *and* M *such that, for all* $u \in L^2(\mathbf{R};U)$,

$$\epsilon\left(\|u\|^2_{L^2(\mathbf{R};U)} + \|\mathcal{D}u\|^2_{L^2(\mathbf{R};Y)}\right) \leq \|u\|^2_{L^2(\mathbf{R};U)} \leq \|u\|^2_{L^2(\mathbf{R};U)} + \|\mathcal{D}u\|^2_{L^2(\mathbf{R};Y)}.$$

A necessary and sufficient condition for the existence of a finite infimum for the nonstandard quadratic cost minimization problem is that the cost function Q is bounded from below as a function of u. This should be true for each fixed $x_0 \in H$. We shall actually impose a slightly stronger condition on Q which implies that not only does the infimum exist, but it is in fact a minimum.[5] However, before intro-

[4] This is true, e.g., when $\mathcal{D}$ is the input-output map of a jointly stabilizable and detectable well-posed linear system. See [24, Theorem 4.4].

[5] See Lemma 3.9.

ducing this condition, let us make the following simple observation about the stable case.

LEMMA 3.5. *Let $J = J^* \in \mathcal{L}(Y)$. The operator $\mathcal{D} \in TIC(U;Y)$ is J-coercive iff $\mathcal{D}^*J\mathcal{D} \geq \epsilon(\mathcal{D}^*\mathcal{D} + I)$ for some $\epsilon > 0$, i.e., $\langle \mathcal{D}u, J\mathcal{D}u\rangle_{L^2(\mathbf{R};Y)} \geq \epsilon\big(\|u\|^2_{L^2(\mathbf{R};U)} + \|\mathcal{D}u\|^2_{L^2(\mathbf{R};U)}\big)$ for all $u \in L^2(\mathbf{R};U)$.*

Proof. This follows from Definition 2.2 and Corollary 3.4. □

In the unstable case we turn the characterization of J-coercivity given in this lemma into a definition.

DEFINITION 3.6. *Let $J = J^* \in \mathcal{L}(Y)$, and let $\alpha \geq 0$.*

(i) *The operator $\mathcal{D} \in TIC_\alpha(U;Y)$ is J-coercive iff there exists a constant $\epsilon > 0$ such that*

$$\langle \mathcal{D}\pi_+u, J\mathcal{D}\pi_+u\rangle_{L^2(\mathbf{R}^+;Y)} \geq \epsilon\left(\|u\|^2_{L^2(\mathbf{R}^+;U)} + \|\mathcal{D}\pi_+u\|^2_{L^2(\mathbf{R}^+;Y)}\right)$$

for all those $u \in L^2(\mathbf{R}^+;U)$ for which $\mathcal{D}\pi_+u \in L^2(\mathbf{R}^+;Y)$.

(ii) *The system $\Psi = \left[\begin{smallmatrix}\mathcal{A} & \mathcal{B}\\ \mathcal{C} & \mathcal{D}\end{smallmatrix}\right]$ on (U,H,Y) is J-coercive if there exist constants $M > 0$ and $\epsilon > 0$ such that the cost function Q defined in* (2.1) *satisfies*

$$Q(x_0,u) \geq \epsilon\left(\|u\|^2_{L^2(\mathbf{R}^+;U)} + \|y\|^2_{L^2(\mathbf{R}^+;Y)}\right) - M\,\|x_0\|^2_H \tag{3.1}$$

for all those $x_0 \in H$ and $u \in L^2(\mathbf{R}^+;U)$ for which $y = \mathcal{C}x_0 + \mathcal{D}\pi_+u \in L^2(\mathbf{R}^+;Y)$.

By Lemma 3.5, part (i) of Definition 2.2 is consistent with part (i) of Definition 3.6. That the second half of these definitions is also consistent follows from the next lemma.

LEMMA 3.7. *A stable system is J-coercive in the sense of Definition* 3.6 *iff its input-output map is J-coercive.*[6]

Proof. Trivially, the J-coercivity of an arbitrary system (stable or not) implies that its input-output map is J-coercive (take $x_0 = 0$).

Conversely, suppose that $\mathcal{D}$ is J-coercive, e.g., in the sense of Definition 2.2. For each $u \in L^2(\mathbf{R}^+;U)$ we have

$$\begin{aligned}&\langle \mathcal{D}\pi_+u + \mathcal{C}x_0, J(\mathcal{D}\pi_+u + \mathcal{C}x_0)\rangle_Y\\ &\qquad \geq \langle \mathcal{D}\pi_+u, J(\mathcal{D}\pi_+u)\rangle_Y - 2\,\|J\|\,\|\mathcal{D}\|\,\|\mathcal{C}\|\,\|u\|\,\|x_0\| - \|J\|\,\|\mathcal{C}\|^2\,\|x_0\|^2.\end{aligned}$$

Combining this with Lemma 3.5 and with the fact that for all positive constants a, b, and δ it is true that $2ab \leq \delta a^2 + (1/\delta)b^2$, we find that for some sufficiently large constant M, independent of u and x_0,

$$\langle \mathcal{D}\pi_+u + \mathcal{C}x_0, J(\mathcal{D}\pi_+u + \mathcal{C}x_0)\rangle_Y \geq \epsilon/2(\|u\|^2 + \|y\|^2) - M\,\|x_0\|^2.$$

Thus, the system is J-coercive in the sense of Definition 3.6. □

LEMMA 3.8. *Let $J = J^* \in \mathcal{L}(U;Y)$, and let $\mathcal{D} \in TIC_\alpha(U;Y)$ for some $\alpha \geq 0$. If $\mathcal{D}$ has a right coprime factorization $(\mathcal{N},\mathcal{M})$, then $\mathcal{D}$ is J-coercive iff $\mathcal{N}$ is J-coercive.*

Proof. This follows from Lemmas 3.3 and 3.5 and Definition 3.6. □

Our approach to the quadratic cost minimization problem is to first use a preliminary stabilizing feedback and to then minimize the stabilized problem. It is based on the following result.

[6] The same statement is actually true for all jointly stabilizable and detectable systems. See Lemma 3.9(iii).

LEMMA 3.9. *Let $J = J^* \in \mathcal{L}(Y)$, and let $\Psi = \left[\begin{smallmatrix}\mathcal{A} & \mathcal{B}\\ \mathcal{C} & \mathcal{D}\end{smallmatrix}\right]$ be a well-posed linear system on (U, H, Y) with jointly stabilizing feedback and output injection pairs $[\mathcal{K}^1 \quad \mathcal{F}^1]$ and $\left[\begin{smallmatrix}\mathcal{H}\\ \mathcal{G}\end{smallmatrix}\right]$* [24, *Definition* 3.15]. *Let*

$$\begin{aligned}\Psi_\flat &= \begin{bmatrix} \mathcal{A}_\flat & \mathcal{B}_\flat \\ \begin{bmatrix}\mathcal{C}_\flat \\ \mathcal{K}^1_\flat\end{bmatrix} & \begin{bmatrix}\mathcal{D}_\flat \\ \mathcal{F}^1_\flat\end{bmatrix}\end{bmatrix} \\ &= \begin{bmatrix} \mathcal{A} + \mathcal{B}\tau\left(I - \mathcal{F}^1\right)^{-1}\mathcal{K}^1 & \mathcal{B}\left(I - \mathcal{F}^1\right)^{-1} \\ \begin{bmatrix}\mathcal{C} + \mathcal{D}\left(I - \mathcal{F}^1\right)^{-1}\mathcal{K}^1 \\ \left(I - \mathcal{F}^1\right)^{-1}\mathcal{K}^1\end{bmatrix} & \begin{bmatrix}\mathcal{D}\left(I - \mathcal{F}^1\right)^{-1} \\ \left(I - \mathcal{F}^1\right)^{-1} - I\end{bmatrix}\end{bmatrix}\end{aligned}$$

be the state feedback perturbed version of Ψ [24, *Lemma* 3.13] *with feedback pair $[\mathcal{K}^1 \quad \mathcal{F}^1]$.*

(i) *The output $y = \mathcal{C}x_0 + \mathcal{D}\pi_+ u$ of Ψ with initial value $x_0 \in H$ and control $u \in L^2_{\text{loc}}(\mathbf{R}^+; U)$ is equal to the first output $y = \mathcal{C}_\flat x_0 + \mathcal{D}_\flat \pi_+ u_\flat$ of $\Psi_\flat$ with the same initial value $x_0 \in H$ and control $u_\flat \in L^2_{\text{loc}}(\mathbf{R}^+; U)$ if we choose u and $u_\flat$ to satisfy*

$$u = \left(I - \mathcal{F}^1\right)^{-1}\left(\mathcal{K}^1 x_0 + \pi_+ u_\flat\right) = \mathcal{K}^1_\flat x_0 + \left(I + \mathcal{F}^1_\flat\right)\pi_+ u_\flat, \tag{3.2}$$

or equivalently,[7]

$$u_\flat = -\mathcal{K}^1 x_0 + \left(I - \mathcal{F}^1\right)\pi_+ u.$$

With this choice of u and $u_\flat$, the states $x(t) = \mathcal{A}(t)x_0 + \mathcal{B}\tau(t)\pi_+ u$ and $x(t) = \mathcal{A}_\flat(t)x_0 + \mathcal{B}_\flat\tau(t)\pi_+ u_\flat$ of the two systems are also equal for all $t \in \mathbf{R}^+$. Moreover, $u_\flat \in L^2(\mathbf{R}^+; U)$ iff both $y \in L^2(\mathbf{R}^+; Y)$ and $u \in L^2(\mathbf{R}^+; U)$, and there exists a constant M (independent of x_0, u, and $u_\flat$) such that

$$\begin{aligned}\|u\|^2_{L^2(\mathbf{R}^+;U)} &\le M\left(\|x_0\|^2_H + \|u_\flat\|^2_{L^2(\mathbf{R}^+;U)}\right), \\ \|u_\flat\|^2_{L^2(\mathbf{R}^+;U)} &\le M\left(\|x_0\|^2_H + \|y\|^2_{L^2(\mathbf{R}^+;Y)} + \|u\|^2_{L^2(\mathbf{R}^+;U)}\right).\end{aligned}$$

(ii) *The original system Ψ is J-coercive iff the feedback stabilized system $\Psi_\flat$ is so.*

(iii) *The original system Ψ is J-coercive iff its input/output map $\mathcal{D}$ is J-coercive.*

(iv) *If either (hence both) of the two systems is J-coercive, then the controls $u \in L^2(\mathbf{R}^+; U)$ of Ψ and $u_\flat \in L^2(\mathbf{R}^+; U)$ of $\Psi_\flat$ are uniquely determined by the initial state x_0 and the (first) output y. In particular, if the output $y = \mathcal{C}x_0 + \mathcal{D}\pi_+ u$ of Ψ with initial value x_0 and control $u \in L^2(\mathbf{R}^+; U)$ is equal to the first output $\mathcal{C}_\flat x_0 + \mathcal{D}_\flat \pi_+ u_\flat$ of $\Psi_\flat$ with initial value x_0 and control $u_\flat \in L^2(\mathbf{R}^+; U)$, then u and $u_\flat$ must satisfy* (3.2).

Proof. (i) The output of Ψ is given by $y = \mathcal{C}x_0 + \mathcal{D}\pi_+ u$ and the first output of $\Psi_\flat$ is given by $y = \mathcal{C}_\flat x_0 + \mathcal{D}_\flat u_\flat = (\mathcal{C} + \mathcal{D}(I - \mathcal{F}^1)^{-1}\mathcal{K}^1)x_0 + \mathcal{D}(I - \mathcal{F}^1)^{-1}\pi_+ u_\flat$, so we get the same output if we let u and $u_\flat$ satisfy (3.2). By [24, Theorem 4.4], $(\mathcal{D}_\flat, (I + \mathcal{F}^1_\flat))$ is a right coprime factorization of $\mathcal{D}$. Since it is possible to write the equations connecting u, $u_\flat$, and y in the form

$$\begin{aligned}u &= \left(I + \mathcal{F}^1_\flat\right)\pi_+ u_\flat + \mathcal{K}^1_\flat x_0, \\ y &= \mathcal{D}_\flat \pi_+ u_\flat + \mathcal{C}_\flat x_0,\end{aligned}$$

[7] See the equivalent [24, Figures 3.4 and 3.7].

and since (by the stability of $\Psi_\flat$) $\mathcal{K}_\flat x_0 \in L^2(\mathbf{R}^+;U)$ and $\mathcal{C}_\flat x_0 \in L^2(\mathbf{R}^+;Y)$, it follows from Lemma 3.3 that $u_\flat \in L^2(\mathbf{R}^+;U)$ iff both $y \in L^2(\mathbf{R}^+;Y)$ and $u \in L^2(\mathbf{R}^+;U)$. Moreover, the listed inequalities are true.

(ii) Suppose that Ψ is J-coercive. By the second of the two inequalities in part (i),

$$\epsilon/2 \left\|u\right\|^2_{L^2(\mathbf{R}^+;U)} + \epsilon/2 \left\|y\right\|^2_{L^2(\mathbf{R}^+;Y)} \geq -\epsilon/2 \left\|x_0\right\|^2_H + \epsilon/(2M) \left\|u_\flat\right\|^2_{L^2(\mathbf{R}^+;U)},$$

and this combined with (3.1) implies that $\Psi_\flat$ is J-coercive (replace M by $M + \epsilon/2$ and ϵ by $\min\{\epsilon/2, \epsilon/(2M)\}$). The proof of the converse part is similar but simpler.

(iii) This follows from part (ii) and Lemmas 3.7 and 3.8.

(iv) If the two controls $u^1_\flat$ and $u^2_\flat$ produce the same output $y = \mathcal{C}_\flat x_0 + \mathcal{D}_\flat u^1_\flat = \mathcal{C}_\flat x_0 + \mathcal{D}_\flat u^2_\flat$, then their difference $u^1_\flat - u^2_\flat$ satisfies $\mathcal{D}_\flat \pi_+(u^1_\flat - u^2_\flat) = 0$. As $\mathcal{D}_\flat$ is J-coercive, $\mathcal{D}_\flat \pi_+$ is one-to-one on $L^2(\mathbf{R}^+;U)$, and we find that $\pi_+(u^1_\flat - u^2_\flat) = 0$. Similarly, if the two controls u^1 and u^2 produce the same output $y = \mathcal{C}x_0 + \mathcal{D}\pi_+ u^1 = \mathcal{C}x_0 + \mathcal{D}\pi_+ u^2$, then their difference $u^1 - u^2$ satisfies $\mathcal{D}\pi_+(u^1 - u^2) = 0$. Define $z = (I + \mathcal{F}^1_\flat)^{-1}\pi_+(u^1 - u^2)$. Then $(I + \mathcal{F}^1_\flat)z = u^1 - u^2$ and $\mathcal{D}_\flat z = \mathcal{D}(u^1 - u^2) = 0$. Recall that $(\mathcal{D}_\flat, (I + \mathcal{F}^1_\flat))$ is a right coprime factorization of $\mathcal{D}$ [24, Theorem 4.4]. From Lemma 3.3 we conclude that $z \in L^2(\mathbf{R}^+;U)$, which combined with the J-coercivity of $\mathcal{D}_\flat$ implies that $z = 0$. Thus, $u^1 - u^2 = 0$ also. □

4. The solution to the unstable quadratic cost minimization problem.

Lemma 3.9 gives us the following preliminary solution to the general quadratic cost minimization problem.

LEMMA 4.1. *Let $J = J^* \in \mathcal{L}(Y)$, and let $\Psi = [\begin{smallmatrix}\mathcal{A} & \mathcal{B}\\ \mathcal{C} & \mathcal{D}\end{smallmatrix}]$ be a jointly stabilizable and detectable J-coercive well-posed linear system on (U, H, Y). Then the quadratic cost minimization problem with cost operator J has a unique minimizing solution $u^{\mathrm{opt}}(x_0) \in L^2(\mathbf{R}^+;U)$. This solution can be computed as follows: We first feedback stabilize Ψ as described in Lemma* 3.9, *and we then apply Lemma* 2.5 *with Ψ replaced by the stabilized system $\Psi_\flat$ to get an optimal control $u^{\mathrm{opt}}_\flat(x_0)$, an optimal output $y^{\mathrm{opt}}(x_0)$, and an optimal state trajectory $x^{\mathrm{opt}}(x_0)$ for the stabilized system. The optimal control for the original system Ψ is then given by $u^{\mathrm{opt}}(x_0) = \mathcal{K}^1_\flat x_0 + (I + \mathcal{F}^1_\flat)\pi_+ u^{\mathrm{opt}}_\flat(x_0)$, and the optimal output and state for the original minimization problem is equal to the optimal output $y^{\mathrm{opt}}(x_0)$ and state $x^{\mathrm{opt}}(x_0)$ for the stabilized minimization problem. In particular, the original problem and the stabilized problem have the same Riccati operator.*

The solution given by Lemma 4.1 is not yet complete in the sense that it does not contain the same type of feedback description as Theorem 2.6 does for the stable case. Our next task will be to develop such a feedback description. This description will be given in terms of a right coprime factorization of the input/output map $\mathcal{D}$ with the special property that its numerator is (J, S)-inner. This notion is defined as follows.

DEFINITION 4.2. *Let $J = J^* \in \mathcal{L}(Y)$, let $S = S^* \in \mathcal{L}(U)$ be invertible, let $\mathcal{D} \in TIC_\alpha(U;Y)$ for some $\alpha \geq 0$, and let $(\mathcal{N}, \mathcal{M})$ be a right coprime factorization of $\mathcal{D}$ in TIC.*

(i) *If $\mathcal{N}$ is (J, S)-inner, then $(\mathcal{N}, \mathcal{M})$ is a (J, S)-inner right coprime factorization of $\mathcal{D}$.*

(ii) *If $[\begin{smallmatrix}\mathcal{N}\\ \mathcal{M}\end{smallmatrix}]$ is (I, S)-inner, i.e., if $\mathcal{N}^*\mathcal{N} + \mathcal{M}^*\mathcal{M} = S$, then $(\mathcal{N}, \mathcal{M})$ is an S-normalized right coprime factorization of $\mathcal{D}$.*

LEMMA 4.3. *Let $J = J^* \in \mathcal{L}(Y)$, and let $S \in \mathcal{L}(U)$, $S \gg 0$, $\widetilde{S} \in \mathcal{L}(U)$, and $\widetilde{S} \gg 0$. Let $\mathcal{D} \in TIC_\alpha(U;Y)$ for some $\alpha \geq 0$, and suppose that $\mathcal{D}$ has a right coprime factorization $(\mathcal{N}, \mathcal{M})$ in $TIC(U;Y)$.*

(i) *If $\mathcal{D}$ is stable, then $(\mathcal{N}, \mathcal{M})$ is a (J, S)-inner right coprime factorization of $\mathcal{D}$ iff $\mathcal{N}\mathcal{M}^{-1}$ is a (J, S)-inner-outer factorization of $\mathcal{D}$, or equivalently, iff $\mathcal{M}^{-1}$ is an S-spectral factor of $\mathcal{D}^*J\mathcal{D}$.*

(ii) *$\mathcal{D}$ has a (J, S)-inner right coprime factorization iff $\mathcal{D}$ is J-coercive.*

(iii) *The set of all possible (J, S)-inner right coprime factorizations $(\mathcal{N}, \mathcal{M})$ of $\mathcal{D}$ (where J and $\mathcal{D}$ are fixed while $\mathcal{N}$, $\mathcal{M}$ and S vary) can be parameterized as $\mathcal{N} = \widetilde{\mathcal{N}}E$, $\mathcal{M} = \widetilde{\mathcal{M}}E$, and $S = E^*\widetilde{S}E$, where $(\widetilde{\mathcal{N}}, \widetilde{\mathcal{M}})$ is a fixed $(J, \widetilde{S})$-inner right coprime factorization of $\mathcal{D}$ and $E \in \mathcal{L}(U)$ is an arbitrary invertible operator.*

Proof. (i) It is easy to see that if $\mathcal{X}$ is an S-spectral factor of $\mathcal{D}^*J\mathcal{D}$, and if we define $\mathcal{M} = \mathcal{X}^{-1}$ and $\mathcal{N} = \mathcal{D}\mathcal{X}$, then $(\mathcal{N}, \mathcal{M})$ is a (J, S)-inner right coprime factorization of $\mathcal{D}$ (it is coprime since $\mathcal{M}$ is invertible in $TIC(U)$). Conversely, if $(\mathcal{N}, \mathcal{M})$ is a (J, S)-inner right coprime factorization of $\mathcal{D}$, then $(\mathcal{D}, I)$ is another right coprime factorization of $\mathcal{D}$, and it follows from [24, Lemma 4.3(i)] that $\mathcal{M}$ has an inverse in $TIC(U)$. It is then obvious that $\mathcal{X} = \mathcal{M}^{-1}$ is an S-spectral factor of $\mathcal{D}^*J\mathcal{D}$.

(ii) If $\mathcal{D}$ is J-coercive, then by Lemmas 3.8 and 2.4(i), $\mathcal{N}$ is J-coercive and has a (J, S)-inner-outer factorization $\mathcal{N} = \widetilde{\mathcal{N}}\mathcal{X}$. According to Lemma 2.4(ii), $\mathcal{X}$ is invertible, and by [24, Lemma 4.3(i)], $(\widetilde{\mathcal{N}}, \widetilde{\mathcal{M}}) = (\mathcal{N}\mathcal{X}^{-1}, \mathcal{M}\mathcal{X}^{-1})$ is a (J, S)-inner right coprime factorization of $\mathcal{D}$.

On the other hand, if $\mathcal{D}$ has a (J, S)-inner right coprime factorization $(\mathcal{N}, \mathcal{M})$, then $\mathcal{N}$ is (J, S)-inner, hence J-coercive (since we assume that $S \gg 0$). By Lemma 3.8, $\mathcal{D}$ is J-coercive.

(iii) This follows from [24, Lemma 4.3(i)] and Lemma 2.4(iii). □

The following is our first main result.

THEOREM 4.4. *Let $J = J^* \in \mathcal{L}(Y)$, let $S \in \mathcal{L}(U)$, $S \gg 0$, and let $\Psi = \left[\begin{smallmatrix}\mathcal{A} & \mathcal{B}\\ \mathcal{C} & \mathcal{D}\end{smallmatrix}\right]$ be a J-coercive jointly stabilizable and detectable well-posed linear system on (U, H, Y) [24, Definition 3.16]. Let $x^{\mathrm{opt}}(x_0)$, $y^{\mathrm{opt}}(x_0)$, and $u^{\mathrm{opt}}(x_0)$ be the optimal state, output, and control for the quadratic cost minimization problem for Ψ, and let Π be the corresponding Riccati operator (cf. Lemma 4.1).*

(i) *Let $(\mathcal{N}, \mathcal{M})$ be a (J, S)-inner right coprime factorization of $\mathcal{D}$. Then there is a unique feedback map $\mathcal{K}$ such that $[\mathcal{K} \quad \mathcal{F}] = [\mathcal{K} \quad (I - \mathcal{M}^{-1})]$ is an admissible stabilizing state feedback pair for Ψ and*

$$\begin{bmatrix} x^{\mathrm{opt}}(t, x_0) \\ y^{\mathrm{opt}}(x_0) \\ u^{\mathrm{opt}}(x_0) \end{bmatrix} = \begin{bmatrix} \mathcal{A}_{\circlearrowleft}(t) \\ \mathcal{C}_{\circlearrowleft} \\ \mathcal{K}_{\circlearrowleft} \end{bmatrix} x_0 = \begin{bmatrix} \mathcal{A}(t) + \mathcal{B}\mathcal{M}\tau(t)\mathcal{K} \\ \mathcal{C} + \mathcal{N}\mathcal{K} \\ \mathcal{M}\mathcal{K} \end{bmatrix} x_0$$

is equal to the state and output of the closed loop system $\Psi_{\circlearrowleft}$ defined by

$$\Psi_{\circlearrowleft} = \begin{bmatrix} \mathcal{A}_{\circlearrowleft} & \mathcal{B}_{\circlearrowleft} \\ \begin{bmatrix} \mathcal{C}_{\circlearrowleft} \\ \mathcal{K}_{\circlearrowleft} \end{bmatrix} & \begin{bmatrix} \mathcal{D}_{\circlearrowleft} \\ \mathcal{F}_{\circlearrowleft} \end{bmatrix} \end{bmatrix} = \begin{bmatrix} \mathcal{A} + \mathcal{B}\tau\mathcal{M}\mathcal{K} & \mathcal{B}\mathcal{M} \\ \begin{bmatrix} \mathcal{C} + \mathcal{N}\mathcal{K} \\ \mathcal{M}\mathcal{K} \end{bmatrix} & \begin{bmatrix} \mathcal{N} \\ \mathcal{M} - I \end{bmatrix} \end{bmatrix}$$

with initial value x_0, initial time zero, and zero control $u_{\circlearrowleft}$ (see Figure 2.1). The feedback map $\mathcal{K}$ is uniquely determined by the fact that $\mathcal{C}_{\circlearrowleft} = \mathcal{C} + \mathcal{N}\mathcal{K} \in \mathcal{L}(H; L^2(\mathbf{R}^+; Y))$, $\mathcal{K}_{\circlearrowleft} = \mathcal{M}\mathcal{K} \in \mathcal{L}(H; L^2(\mathbf{R}^+; U))$, and $\pi_+\mathcal{N}^*J\mathcal{C}_{\circlearrowleft} = 0$. Moreover, the Riccati operator of Ψ is given by

$$\Pi = \mathcal{C}_{\circlearrowleft}^* J \mathcal{C}_{\circlearrowleft} = (\mathcal{C} + \mathcal{N}\mathcal{K})^* J (\mathcal{C} + \mathcal{N}\mathcal{K}).$$

(ii) *If* $y = \mathcal{C}_{\circlearrowright}x_0 + \mathcal{D}_{\circlearrowright}\pi_+u_{\circlearrowright}$ *is the first output of the optimal closed loop system* $\Psi_{\circlearrowright}$ *in* (i) *with initial state* $x_0 \in H$ *and control* $u_{\circlearrowright} \in L^2(\mathbf{R}^+;U)$ (*see Figure* 2.1), *then the closed loop cost* $Q_{\circlearrowright}(x_0,u_{\circlearrowright})$ *is given by*

$$Q_{\circlearrowright}(x_0,u_{\circlearrowright}) = \langle y, Jy\rangle_{L^2(\mathbf{R}^+;Y)} = \langle x_0, \Pi x_0\rangle_H + \langle u_{\circlearrowright}, Su_{\circlearrowright}\rangle_{L^2(\mathbf{R}^+;Y)}\,. \tag{4.1}$$

(iii) *If* Ψ *is jointly* ω*-stabilizable and detectable for some* $\omega < 0$ [24, *Definition* 3.16], *and if* $\mathcal{N}$ *and* $\mathcal{M}$ *in* (i) *are right* ω*-coprime* [24, *Definition* 4.1], *then the closed loop system* $\Psi_{\circlearrowright}$ *is* ω*-stable.*

(iv) *If* $(\mathcal{N},\mathcal{M})$ *are given, then the feedback map* $\mathcal{K}$, *the Riccati operator* Π, *the closed loop semigroup* $\mathcal{A}_{\circlearrowright}$, *and the closed loop controllability and feedback maps* $\mathcal{C}_{\circlearrowright}$ *and* $\mathcal{K}_{\circlearrowright}$ *can be computed as follows*: *Choose some arbitrary jointly stabilizing feedback and output injection pairs* $[\mathcal{K}^1 \quad \mathcal{F}^1]$ *and* $\left[\begin{smallmatrix}\mathcal{H}\\ \mathcal{G}\end{smallmatrix}\right]$. *Then*

$$\begin{aligned}
\mathcal{K} &= \mathcal{M}^{-1}\mathcal{K}^1_\flat - S^{-1}\pi_+\mathcal{N}^*J\mathcal{C}_\flat,\\
\begin{bmatrix}\mathcal{A}_{\circlearrowright}\\ \mathcal{C}_{\circlearrowright}\\ \mathcal{K}_{\circlearrowright}\end{bmatrix} &= \begin{bmatrix}\mathcal{A}_\flat\\ \mathcal{C}_\flat\\ \mathcal{K}^1_\flat\end{bmatrix} - \begin{bmatrix}\mathcal{B}\mathcal{M}\tau\\ \mathcal{N}\\ \mathcal{M}\end{bmatrix} S^{-1}\pi_+\mathcal{N}^*J\mathcal{C}_\flat,\\
\Pi &= \mathcal{C}^*_\flat J\mathcal{C}_\flat - \left(\mathcal{K} - \mathcal{M}^{-1}\mathcal{K}^1_\flat\right)^* S\left(\mathcal{K} - \mathcal{M}^{-1}\mathcal{K}^1_\flat\right)\\
&= \mathcal{C}^*_\flat\left(J - J\mathcal{N}S^{-1}\pi_+\mathcal{N}^*J\right)\mathcal{C}_\flat = \mathcal{C}^*_\flat J\mathcal{C}_{\circlearrowright} = \mathcal{C}^*_{\circlearrowright}J\mathcal{C}_\flat,
\end{aligned}$$

where $\mathcal{A}_\flat = \mathcal{A} + \mathcal{B}\tau\mathcal{K}^1_\flat$, $\mathcal{C}_\flat = \mathcal{C} + \mathcal{D}\mathcal{K}^1_\flat$, *and* $\mathcal{K}^1_\flat = (I - \mathcal{F}^1)^{-1}\mathcal{K}^1$. (*If* Ψ *is stable, then we can can take* $\mathcal{K}^1_\flat = 0$, $\mathcal{A}_\flat = \mathcal{A}$, *and* $\mathcal{C}_\flat = \mathcal{C}$ *and get the same formulae as in Theorem* 2.6).

Proof. Let us first show that the conditions on $\mathcal{K}$ in (i) determine $\mathcal{K}$ uniquely. Suppose that we have two feedback maps $\mathcal{K}^1$ and $\mathcal{K}^2$ such that both $\mathcal{C}+\mathcal{N}\mathcal{K}^1$ and $\mathcal{C}+\mathcal{N}\mathcal{K}^2$ belong to $\mathcal{L}(H;L^2(\mathbf{R}^+;Y))$, both $\mathcal{M}\mathcal{K}^1$ and $\mathcal{M}\mathcal{K}^2$ belong to $\mathcal{L}(H;L^2(\mathbf{R}^+;U))$, and $\pi_+\mathcal{N}^*J(\mathcal{C}+\mathcal{N}\mathcal{K}^1) = \pi_+\mathcal{N}^*J(\mathcal{C}+\mathcal{N}\mathcal{K}^2)$. Then, for each $x \in H$, $\mathcal{N}(\mathcal{K}^1 - \mathcal{K}^2)x \in L^2(\mathbf{R}^+;Y)$, $\mathcal{M}(\mathcal{K}^1 - \mathcal{K}^2)x \in L^2(\mathbf{R}^+;U)$, and $\pi_+\mathcal{N}^*J(\mathcal{N}(\mathcal{K}^1 - \mathcal{K}^2)x) = 0$. By Lemma 3.3, $(\mathcal{K}^1 - \mathcal{K}^2)x \in L^2(\mathbf{R}^+;U)$, hence

$$0 = \pi_+\mathcal{N}^*J(\mathcal{N}(\mathcal{K}^1 - \mathcal{K}^2)x) = \pi_+(\mathcal{N}^*J\mathcal{N})(\mathcal{K}^1 - \mathcal{K}^2)x = S\pi_+(\mathcal{K}^1 - \mathcal{K}^2)x.$$

As $(\mathcal{K}^1 - \mathcal{K}^2)x$ is supported on $\mathbf{R}^+$ and S invertible, we must have $(\mathcal{K}^1 - \mathcal{K}^2)x = 0$ for all $x \in H$.

In order to prove the remainder of (i) we proceed as suggested by (iv); i.e., we choose preliminary jointly stabilizing feedback and output injection pairs $[\mathcal{K}^1 \quad \mathcal{F}^1]$ and $\left[\begin{smallmatrix}\mathcal{H}\\ \mathcal{G}\end{smallmatrix}\right]$ with interaction operator $\mathcal{E}_1$. The output injection pair and the interaction operator $\mathcal{E}_1$ play a very nonsignificant role below; they are only needed so that we can apply [24, Theorem 4.4] in order to show that $(\mathcal{D}(I-\mathcal{F}^1)^{-1}, (I-\mathcal{F}^1)^{-1})$ is a right coprime factorization of $\mathcal{D}$. We shall therefore ignore the output injection part of the system for the rest of this proof, but we return to this question at the end of the section.

We add the state feedback pair $[\mathcal{K}^1 \quad \mathcal{F}^1]$ to the system Ψ and close the state feedback loop as in Lemma 3.9 to get the stable system $\Psi_\flat$ given in that lemma. According to Lemma 4.1, the quadratic cost minimization problems for Ψ and $\Psi_\flat$ have the same optimal state $x^{\mathrm{opt}}(x_0)$ and output $y^{\mathrm{opt}}(x_0)$ and the optimal controls $u^{\mathrm{opt}}(x_0)$ and $u^{\mathrm{opt}}_\flat(x_0)$ are related to each other as in (3.2).

We want to apply Theorem 2.6 to solve the quadratic cost minimization problem for the closed loop system $\Psi_\flat$. By Lemmas 3.7 and 3.9, $\mathcal{D}_\flat$ is coercive. Since both

$(\mathcal{D}_\flat, (I + \mathcal{F}^1_\flat))$ and $(\mathcal{N}, \mathcal{M})$ are right coprime factorizations of $\mathcal{D}$, it follows from [24, Lemma 4.3] that the operator

$$\mathcal{X} = \mathcal{M}^{-1}\left(I + \mathcal{F}^1_\flat\right) = \left(\left(I - \mathcal{F}^1\right)\mathcal{M}\right)^{-1} \tag{4.2}$$

belongs to $TIC(U)$ and is invertible in $TIC(U)$. Thus, $\mathcal{N}\mathcal{X}$ is a (J, S)-inner-outer factorization of $\mathcal{D}_\flat$. By Theorem 2.6, the solution to the quadratic cost minimization problem for $\Psi_\flat$ is of state feedback type. More precisely, the pair

$$\begin{bmatrix} \mathcal{K}_\natural & \mathcal{F}_\natural \end{bmatrix} = \begin{bmatrix} -S^{-1}\pi_+\mathcal{N}^* J \mathcal{C}_\flat & (I - \mathcal{X}) \end{bmatrix}$$

is a stable stabilizing state feedback pair for $\Psi_\flat$, and if we further extended the system $\Psi_\flat$ into

$$\begin{bmatrix} \mathcal{A}_\flat & \mathcal{B}_\flat \\ \begin{bmatrix} \mathcal{C}_\flat \\ \mathcal{K}^1_\flat \\ \mathcal{K}_\natural \end{bmatrix} & \begin{bmatrix} \mathcal{D}_\flat \\ \mathcal{F}^1_\flat \\ \mathcal{F}_\natural \end{bmatrix} \end{bmatrix}$$

by adding the extra state feedback pair, and then close the new state feedback loop to get the stable closed loop system [24, Lemma 4.5]

$$\begin{aligned}
\Psi_{\flat\circlearrowleft} &= \begin{bmatrix} \mathcal{A}_{\flat\circlearrowleft} & \mathcal{B}_{\flat\circlearrowleft} \\ \begin{bmatrix} \mathcal{C}_{\flat\circlearrowleft} \\ \mathcal{K}^1_{\flat\circlearrowleft} \\ \mathcal{K}_{\natural\circlearrowleft} \end{bmatrix} & \begin{bmatrix} \mathcal{D}_{\flat\circlearrowleft} \\ \mathcal{F}^1_{\flat\circlearrowleft} \\ \mathcal{F}_{\natural\circlearrowleft} \end{bmatrix} \end{bmatrix} \\
&= \begin{bmatrix} \mathcal{A}_\flat + \mathcal{B}_\flat \tau \mathcal{X}^{-1}\mathcal{K}_\natural & \mathcal{B}_\flat \mathcal{X}^{-1} \\ \begin{bmatrix} \mathcal{C}_\flat + \mathcal{D}_\flat \mathcal{X}^{-1}\mathcal{K}_\natural \\ \mathcal{K}^1_\flat + \mathcal{F}^1_\flat \mathcal{X}^{-1}\mathcal{K}_\natural \\ \mathcal{X}^{-1}\mathcal{K}_\natural \end{bmatrix} & \begin{bmatrix} \mathcal{D}_\flat \mathcal{X}^{-1} \\ \mathcal{F}^1_\flat \mathcal{X}^{-1} \\ \mathcal{X}^{-1} - I \end{bmatrix} \end{bmatrix} \\
&= \begin{bmatrix} \mathcal{A} + \mathcal{B}\tau\left(\mathcal{K}^1_\flat + \mathcal{M}\mathcal{K}_\natural\right) & \mathcal{B}\mathcal{M} \\ \begin{bmatrix} \mathcal{C} + \mathcal{D}\left(\mathcal{K}^1_\flat + \mathcal{M}\mathcal{K}_\natural\right) \\ \mathcal{K}^1_\flat + \mathcal{F}^1\mathcal{M}\mathcal{K}_\natural \\ \left(I - \mathcal{F}^1\right)\mathcal{M}\mathcal{K}_\natural \end{bmatrix} & \begin{bmatrix} \mathcal{N} \\ \mathcal{F}^1\mathcal{M} \\ \left(I - \mathcal{F}^1\right)\mathcal{M} - I \end{bmatrix} \end{bmatrix},
\end{aligned}$$

then $x^{\mathrm{opt}}(x_0)$, $y^{\mathrm{opt}}(x_0)$, and $u_\flat^{\mathrm{opt}}(x_0)$ are given by

$$\begin{bmatrix} x^{\mathrm{opt}}(x_0) \\ y^{\mathrm{opt}}(x_0) \\ u_\flat^{\mathrm{opt}}(x_0) \end{bmatrix} = \begin{bmatrix} \mathcal{A}_{\flat\circlearrowleft} \\ \mathcal{C}_{\flat\circlearrowleft} \\ \mathcal{K}_{\natural\circlearrowleft} \end{bmatrix} x_0 = \begin{bmatrix} \mathcal{A} + \mathcal{B}\tau\left(\mathcal{K}^1_\flat + \mathcal{M}\mathcal{K}_\natural\right) \\ \mathcal{C} + \mathcal{D}\left(\mathcal{K}^1_\flat + \mathcal{M}\mathcal{K}_\natural\right) \\ \left(I - \mathcal{F}^1\right)\mathcal{M}\mathcal{K}_\natural \end{bmatrix} x_0$$

and $\mathcal{C}_{\flat\circlearrowleft}$ satisfies

$$\mathcal{N}^* J \mathcal{C}_{\flat\circlearrowleft} = 0.$$

From this result we are able to derive the conclusions listed in (i) and (iv). Most of the proof is ready. In particular, the formulae for the Riccati operator Π given in (iv) follow from Lemma 3.9 and the corresponding formulae in Theorem 2.6. It only remains to return to the original system Ψ and the original control $u^{\mathrm{opt}}(x_0)$.

The optimal control $u_\flat^{\mathrm{opt}}(x_0)$ for $\Psi_\flat$ corresponds to the optimal control

$$u^{\mathrm{opt}}(x_0) = \left(I - \mathcal{F}^1\right)^{-1}\left(\mathcal{K}^1 x_0 + u_\flat^{\mathrm{opt}}(x_0)\right) = \left(\mathcal{K}^1_\flat + \mathcal{M}\mathcal{K}_\natural\right) x_0$$

for the original system Ψ. We observe that $u^{\mathrm{opt}}(x_0)$ is equal to the sum of the two last outputs of $\Psi_{\flat\circlearrowright}$ with zero control. Let us add these two rows and combine them into one to get the system

$$\Psi_{\circlearrowright} = \begin{bmatrix} \mathcal{A}_{\circlearrowright} & \mathcal{B}_{\circlearrowright} \\ \begin{bmatrix} \mathcal{C}_{\circlearrowright} \\ \mathcal{K}_{\circlearrowright} \end{bmatrix} & \begin{bmatrix} \mathcal{D}_{\circlearrowright} \\ \mathcal{F}_{\circlearrowright} \end{bmatrix} \end{bmatrix} = \begin{bmatrix} \mathcal{A} + \mathcal{B}\tau\mathcal{M}\mathcal{K} & \mathcal{B}\mathcal{M} \\ \begin{bmatrix} \mathcal{C} + \mathcal{N}\mathcal{K} \\ \mathcal{M}\mathcal{K} \end{bmatrix} & \begin{bmatrix} \mathcal{N} \\ \mathcal{M} - I \end{bmatrix} \end{bmatrix},$$

where $\mathcal{K} = \mathcal{M}^{-1}\mathcal{K}_{\circlearrowright} = \mathcal{K}_{\natural} + \mathcal{M}^{-1}\mathcal{K}^1_{\flat}$. We then have

$$\begin{bmatrix} x^{\mathrm{opt}}(t, x_0) \\ y^{\mathrm{opt}}(x_0) \\ u^{\mathrm{opt}}(x_0) \end{bmatrix} = \begin{bmatrix} \mathcal{A}_{\circlearrowright}(t) \\ \mathcal{C}_{\circlearrowright} \\ \mathcal{K}_{\circlearrowright} \end{bmatrix} x_0 = \begin{bmatrix} \mathcal{A}(t) + \mathcal{B}\mathcal{M}\tau(t)\mathcal{K} \\ \mathcal{C} + \mathcal{N}\mathcal{K} \\ \mathcal{M}\mathcal{K} \end{bmatrix} x_0.$$

Moreover, since $\mathcal{C}_{\circlearrowright} = \mathcal{C}_{\flat\circlearrowright}$, we have $\mathcal{N}^* J \mathcal{C}_{\circlearrowright} = 0$, and $\Psi_{\circlearrowright}$ is the system that we get by closing the state feedback loop in the system

$$\begin{bmatrix} \mathcal{A} & \mathcal{B} \\ \begin{bmatrix} \mathcal{C} \\ \mathcal{K} \end{bmatrix} & \begin{bmatrix} \mathcal{D} \\ \mathcal{F} \end{bmatrix} \end{bmatrix},$$

where $\mathcal{K}$ is the feedback map defined above and $\mathcal{F} = I - \mathcal{M}^{-1}$. This completes the proofs of both (i) and (iv).

The proof of (ii) is identical to the proof of Theorem 2.6(iii).

Finally, let us prove (iii). Under the assumption of (iii) we can throughout work with the notion of ω-stability instead of just plain stability (the latter notion is the same as ω-stability with $\omega = 0$). The only part of the extended optimal system $\Psi_{\flat\circlearrowright}$ whose ω-stability is not obvious is the state feedback map $\mathcal{K}_{\natural}$; all the other parts of the system are bounded linear operators on the correct spaces. Thus, we must show that $\mathcal{K}_{\natural} \in \mathcal{L}(H; L^2_{\omega}(\mathbf{R}^+; U))$. Recalling the definition of $\mathcal{K}_{\natural}$, we realize that it suffices to show that the anticausal operator $\mathcal{N}^*$ belongs to $TI_{\omega}(Y; U)$. Here the duality is with respect to the inner product in the unweighted L^2, so by standard duality theory $\mathcal{N}^* \in TI_{-\omega}(Y; U)$. However, since $\mathcal{N}^*$ is anticausal, this implies that $\mathcal{N}^*$ can be extended to an anticausal operator in $TI_{\beta}(Y; U)$ for all $\beta \leq -\omega$ [24, Lemmas 2.4 and 2.9]. In particular, since $\omega \leq 0$, $\mathcal{N}^* \in TI_{\omega}(Y; U)$. Thus, $\mathcal{K}_{\natural} \in \mathcal{L}(H; L^2_{\omega}(\mathbf{R}^+; U))$, and $\Psi_{\flat\circlearrowright}$ is stable. □

REMARK 4.5. *An inspection of the proof of Theorem* 2.6 *shows that if the system* Ψ *is jointly strongly stabilizable and detectable, then the optimal closed loop system* $\Psi_{\circlearrowright}$ *will be strongly stable, too* [24, *Lemma* 3.5].

Theorem 4.4 does not contain a converse part like the one found in Theorem 2.6(ii), since we have been able to prove only the following partial converse.

THEOREM 4.6. *Make the same hypothesis as in Theorem* 4.4. *Suppose that the solution to the quadratic cost minimization problem is of state feedback type in the sense that* $\left[\begin{smallmatrix} y^{\mathrm{opt}}(x_0) \\ u^{\mathrm{opt}}(x_0) \end{smallmatrix}\right]$ *is equal to the output of the closed loop system* $\Psi_{\circlearrowright}$ *with initial value* x_0, *initial time zero, zero input* $u_{\circlearrowright}$, *and some stabilizing state feedback pair* $[\mathcal{K} \quad \mathcal{F}]$. *Define* $\mathcal{M} = (I - \mathcal{F})^{-1}$ *and* $\mathcal{N} = \mathcal{D}\mathcal{M}$. *Then there exists a positive invertible operator* $S = S^* \in \mathcal{L}(U)$ *such that* $\mathcal{N}$ *is* (J, S)*-inner, and the claim* (ii) *in Theorem* 4.4 *is true for this closed loop system. If, moreover,* $\mathcal{N}$ *and* $\mathcal{M}$ *are right coprime, then* $(\mathcal{N}, \mathcal{M})$ *is a* (J, S)*-inner right coprime factorization of* $\mathcal{D}$. *This is true, in particular, whenever* Ψ *is exponentially stabilizable.*

Proof. We suppose that the solution to the quadratic cost minimization problem for Ψ is of state feedback type and claim that this implies that the solution to the quadratic cost minimization problem for the system $\Psi_\flat$ considered in the proof of Theorem 4.4 is also of state feedback type. The proof of this is based on [24, Lemma 4.5] and Lemma 3.9. We consider the combined system

$$\begin{bmatrix} \mathcal{A} & \mathcal{B} \\ \begin{bmatrix} \mathcal{C} \\ \mathcal{K}^1 \\ \mathcal{K} \end{bmatrix} & \begin{bmatrix} \mathcal{D} \\ \mathcal{F}^1 \\ \mathcal{F} \end{bmatrix} \end{bmatrix},$$

where $(\mathcal{K}^1, \mathcal{F}^1)$ is the same preliminary feedback pair that we used in the proof of Theorem 4.4 and $[\mathcal{K} \quad \mathcal{F}]$ is the optimal feedback pair. By [24, Lemma 4.5], $[\mathcal{K} \quad \mathcal{F}]$ is a stabilizing feedback pair for this combined system (due to the coprimeness of $\mathcal{D}(I - \mathcal{F}^1)^{-1}$ and $(I - \mathcal{F}^1)^{-1}$). Moreover, the pair

$$\begin{bmatrix} \mathcal{K}_\natural & \mathcal{F}_\natural \end{bmatrix} = \begin{bmatrix} \mathcal{K} - (I - \mathcal{F})(I - \mathcal{F}^1)^{-1}\mathcal{K}^1 & I - (I - \mathcal{F})(I - \mathcal{F}^1)^{-1} \end{bmatrix}$$

is a stabilizing feedback pair for $\Psi_\flat$. By combining this fact with Lemma 3.9, we find that the optimal solution to the quadratic cost minimization problem for the system $\Psi_\flat$ is of state feedback type. However, in contrast to the situation covered by the converse part of Theorem 2.6, we do not know that the feedback pair $[\mathcal{K}_\natural \quad \mathcal{F}_\natural]$ itself is stable, and this causes some additional complications and prevents us from applying part (ii) of Theorem 2.6. Instead we argue directly, examining the proof of the converse part of Theorem 2.6 as presented in [23].

We know that $\mathcal{F}_\natural \in TIC_\alpha(U)$ for some $\alpha \geq 0$ (but not necessarily for $\alpha = 0$) and that $(I - \mathcal{F}_\natural)^{-1} \in TIC(U)$. Fortunately, it was the latter property that was important for a major part of the proof of Theorem 2.6(ii). By repeating the argument in [23] we find that if we define $\mathcal{M}_\natural = (I - \mathcal{F}_\natural)^{-1}$, then

$$\mathcal{M}_\natural^* \mathcal{D}_\flat^* J \mathcal{D}_\flat \mathcal{M}_\natural = S$$

for some nonnegative $S = S^* \in \mathcal{L}(U)$. However, the proof given there of the invertibility of S was based on the boundedness of $\mathcal{F}_\natural$, so it does not apply.

Since $\mathcal{M}_\natural$ is invertible in $TIC_\alpha(U)$, we know that $\mathcal{M}_\natural$ is one-to-one. This together with the invertibility of $\mathcal{D}_\flat^* J \mathcal{D}_\flat$ (which is a consequence of the J-coercivity) implies that S is one-to-one. Its inverse S^{-1} is a nonnegative, possibly unbounded, self-adjoint operator which has a nonnegative self-adjoint square root $S^{-1/2}$. Denote the domain of $S^{-1/2}$ by W. Then $\mathcal{M}_\natural S^{-1/2} \in TIC(W; U)$, and it can be extended to an operator on $TIC(U)$ since $S^{-1/2}\mathcal{M}_\natural^* \mathcal{D}_\flat^* J \mathcal{D}_\flat \mathcal{M}_\natural S^{1/2}$ can be extended to the identity operator on $TIC(U)$. We denote this extension of $\mathcal{M}_\natural S^{-1/2}$ by $\widetilde{\mathcal{M}}$. Then $S^{-1/2} = \mathcal{M}_\natural^{-1}\widetilde{\mathcal{M}} \in TIC_\alpha(W; U)$, and it can be extended to an operator in $TIC_\alpha(U)$ since the right-hand side of this equation belongs to $TIC_\alpha(U)$. But this means that $S^{-1/2}$ can be extended to an operator in $\mathcal{L}(U)$, hence $S^{1/2}$ and S must be invertible.

Since $\mathcal{N} = \mathcal{D}\mathcal{M} = \mathcal{D}(I - \mathcal{F})^{-1} = \mathcal{D}_\flat \mathcal{M}_\natural^{-1}$, and since $\mathcal{M}_\natural^* \mathcal{D}_\flat^* J \mathcal{D}_\flat \mathcal{M}_\natural = S$, we find that $\mathcal{N}$ is (J, S)-inner as claimed. The proof of the statement given in part (ii) of Theorem 4.4 remains the same as before.

We have not been able to prove that $\mathcal{N}$ and $\mathcal{M}$ must always be right coprime. This will be true if and only if the feedback pair $[\mathcal{K}^1 \quad \mathcal{F}^1]$ stabilizes the original system extended with the feedback pair $[\mathcal{K} \quad \mathcal{F}]$, cf. [24, Lemma 4.5]. In particular, it is true whenever $[\mathcal{K}^1 \quad \mathcal{F}^1]$ is exponentially stabilizing; see [24, Lemma 3.20]. □

FIG. 4.1. *Externally parameterized optimal state feedback system.*

According to Lemmas 2.4 and 4.3, Theorems 2.6 and 4.4 contain a hidden free invertible parameter $E \in \mathcal L(U)$.[8] For example, the set of all possible (J,S)-inner coprime factorization of $\mathcal D$ in Theorem 4.4 can be parameterized as follows.

PROPOSITION 4.7. *Let $(\widetilde{\mathcal N},\widetilde{\mathcal M})$ be a particular $(J,\widetilde S)$-inner coprime factorization of $\mathcal D$. Then the set of all possible sensitivity operators S and all possible (J,S)-inner coprime factorizations $(\mathcal N,\mathcal M)$ of $\mathcal D$ (where J and $\mathcal D$ are fixed while $\mathcal N$, $\mathcal M$, and S vary) can be parameterized as*

$$S = E^*\widetilde S E, \qquad \mathcal N = \widetilde{\mathcal N}E, \qquad \mathcal M = \widetilde{\mathcal M}E,$$

where E varies over the set of all invertible operators in $\mathcal L(U)$. The corresponding feedback pair $[\mathcal K \quad \mathcal F]$ in Theorem 4.4 is given by

$$\mathcal K = E^{-1}\widetilde{\mathcal K}, \qquad (I-\mathcal F) = E^{-1}(I-\widetilde{\mathcal F}),$$

where $\widetilde{\mathcal K} = -\widetilde S\pi_+\widetilde{\mathcal N}^*J\mathcal C$ and $\widetilde{\mathcal F} = (I-\widetilde{\mathcal M}^{-1})$; i.e., $[\widetilde{\mathcal K} \quad \widetilde{\mathcal F}]$ is the feedback pair in Theorem 4.4 corresponding to the factorization $(\widetilde{\mathcal N},\widetilde{\mathcal M})$. The parameterized version of the formula for the closed loop system in Theorem 4.4 is

$$\Psi_\circlearrowleft = \begin{bmatrix}\mathcal A_\circlearrowleft & \mathcal B_\circlearrowleft\\ \begin{bmatrix}\mathcal C_\circlearrowleft\\ \mathcal K_\circlearrowleft\end{bmatrix} & \begin{bmatrix}\mathcal D_\circlearrowleft\\ \mathcal F_\circlearrowleft\end{bmatrix}\end{bmatrix} = \begin{bmatrix}\mathcal A+\mathcal B\widetilde{\mathcal M}\tau\widetilde{\mathcal K} & \mathcal B\widetilde{\mathcal M}E\\ \begin{bmatrix}\mathcal C+\widetilde{\mathcal N}\widetilde{\mathcal K}\\ \widetilde{\mathcal M}\widetilde{\mathcal K}\end{bmatrix} & \begin{bmatrix}\widetilde{\mathcal N}E\\ \widetilde{\mathcal M}E-I\end{bmatrix}\end{bmatrix}.$$

The first column is independent of E (but the second is not).

This follows from Lemma 4.3.

The operator E has a very simple interpretation: it represents a coordinate change in the input space for the closed loop system.

PROPOSITION 4.8. *Introduce the same notation as in Proposition 4.7. Then the two diagrams drawn in Figures 2.1 and 4.1 are equivalent in the sense that the relationships between all the signals with identical names are identical in the two diagrams (but z differs in general from $\tilde z$.)*

Proof. Clearly, if we can show that the relationships between $u_\circlearrowleft$ and u are the same in both the diagrams, then all the other relationships will be the same, too, since both diagrams say that

$$\begin{aligned} x &= \mathcal A x_0 + \mathcal B\tau u,\\ y &= \mathcal C x_0 + \mathcal D u. \end{aligned}$$

[8] In [23] this parameter was written out explicitly and it was explained why it cannot be avoided: it represents an undetermined feed-forward term inside the feedback loop.

In Figure 2.1 we have

$$u = \mathcal{K}x_0 + \mathcal{F}u + \pi_+ u_\flat,$$

from which we can solve u in the form

$$\begin{aligned} u &= (I - \mathcal{F})^{-1} (\mathcal{K}x_0 + \pi_+ u_\flat) \\ &= (I - \widetilde{\mathcal{F}})^{-1} E \left(E^{-1}\widetilde{\mathcal{K}}x_0 + \pi_+ u_\flat\right) \\ &= (I - \widetilde{\mathcal{F}})^{-1} (\widetilde{\mathcal{K}}x_0 + E\pi_+ u_\flat). \end{aligned}$$

On the other hand, Figure 4.1 says that

$$u = \widetilde{\mathcal{K}}x_0 + \widetilde{\mathcal{F}}u + E\pi_+ u_\flat,$$

and this equation is equivalent to the one above. □

The minimization problem considered in Theorem 4.4 leads to an inner coprime factorization. If instead we use the different cost function

$$Q_1(x_0, u) = \|y\|^2_{L^2(\mathbf{R}^+;Y)} + \|u\|^2_{L^2(\mathbf{R}^+;U)}, \tag{4.3}$$

then we get a normalized coprime factorization.

COROLLARY 4.9. *Let* $\Psi = \left[\begin{smallmatrix} \mathcal{A} & \mathcal{B} \\ \mathcal{C} & \mathcal{D} \end{smallmatrix}\right]$ *be a jointly stabilizable and detectable well-posed linear system on* (U, H, Y). *Let* $x^{\mathrm{opt}}(x_0)$, $y^{\mathrm{opt}}(x_0)$, *and* $u^{\mathrm{opt}}(x_0)$ *be the optimal state, output, and control for the quadratic cost minimization problem described in Definition* 3.1, *but with the cost function* $Q(x_0, u)$ *replaced by the cost function* $Q_1(x_0, u)$ *in* (4.3). *If* $S = S^* \in \mathcal{L}(U)$ *and* $(\mathcal{N}, \mathcal{M})$ *is an* S*-normalized right coprime factorization of* $\mathcal{D}$ (*in the sense of Definition* 4.2), *then there is a unique feedback map* $\mathcal{K}$ *such that* $[\mathcal{K} \quad \mathcal{F}] = [\mathcal{K} \quad (I - \mathcal{M}^{-1})]$ *is an admissible stabilizing state feedback pair for* Ψ *and*

$$\begin{bmatrix} x^{\mathrm{opt}}(t, x_0) \\ y^{\mathrm{opt}}(x_0) \\ u^{\mathrm{opt}}(x_0) \end{bmatrix} = \begin{bmatrix} \mathcal{A}_\circlearrowleft(t) \\ \mathcal{C}_\circlearrowleft \\ \mathcal{K}_\circlearrowleft \end{bmatrix} x_0 = \begin{bmatrix} \mathcal{A}(t) + \mathcal{B}\mathcal{M}\tau(t)\mathcal{K} \\ \mathcal{C} + \mathcal{N}\mathcal{K} \\ \mathcal{M}\mathcal{K} \end{bmatrix} x_0$$

is equal to the state and output of the closed loop system $\Psi_\circlearrowleft$ *defined by*

$$\Psi_\circlearrowleft = \begin{bmatrix} \mathcal{A}_\circlearrowleft & \mathcal{B}_\circlearrowleft \\ \begin{bmatrix} \mathcal{C}_\circlearrowleft \\ \mathcal{K}_\circlearrowleft \end{bmatrix} & \begin{bmatrix} \mathcal{D}_\circlearrowleft \\ \mathcal{F}_\circlearrowleft \end{bmatrix} \end{bmatrix} = \begin{bmatrix} \mathcal{A} + \mathcal{B}\tau\mathcal{M}\mathcal{K} & \mathcal{B}\mathcal{M} \\ \begin{bmatrix} \mathcal{C} + \mathcal{N}\mathcal{K} \\ \mathcal{M}\mathcal{K} \end{bmatrix} & \begin{bmatrix} \mathcal{N} \\ \mathcal{M} - I \end{bmatrix} \end{bmatrix}$$

with initial value x_0, *initial time zero*, *and zero input* $u_\circlearrowleft$ (*see Figure* 2.1). *The feedback map* $\mathcal{K}$ *is uniquely determined by the fact that* $\mathcal{C}_\circlearrowleft = \mathcal{C} + \mathcal{N}\mathcal{K} \in \mathcal{L}(H; L^2(\mathbf{R}^+; Y))$, $\mathcal{K}_\circlearrowleft = \mathcal{M}\mathcal{K} \in \mathcal{L}(H; L^2(\mathbf{R}^+; U))$, *and*

$$\pi_+ (\mathcal{N}^*\mathcal{C}_\circlearrowleft + \mathcal{M}^*\mathcal{K}_\circlearrowleft) = 0.$$

Moreover, *the Riccati operator of* Ψ *is given by*

$$\Pi = \mathcal{C}^*_\circlearrowleft\mathcal{C}_\circlearrowleft + \mathcal{K}^*_\circlearrowleft\mathcal{K}_\circlearrowleft = (\mathcal{C} + \mathcal{N}\mathcal{K})^*(\mathcal{C} + \mathcal{N}\mathcal{K}) + (\mathcal{M}\mathcal{K})^*(\mathcal{M}\mathcal{K}).$$

Proof. Apply Theorem 4.4 with Ψ replaced by the augmented system

$$\Psi_{\mathrm{aug}} = \begin{bmatrix} \mathcal{A} & \mathcal{B} \\ \begin{bmatrix} \mathcal{C} \\ 0 \end{bmatrix} & \begin{bmatrix} \mathcal{D} \\ I \end{bmatrix} \end{bmatrix},$$

and use the fact that $(\mathcal{N}, \mathcal{M})$ is an S-normalized right coprime factorization of $\mathcal{D}$ iff $([\begin{smallmatrix}\mathcal{N}\\ \mathcal{M}\end{smallmatrix}], \mathcal{M})$ is an (I, S)-inner right coprime factorization of $[\begin{smallmatrix}\mathcal{D}\\ I\end{smallmatrix}]$. Also observe that the augmented system is always coercive. The net effect is that throughout one replaces J by I, $\mathcal{D}$ by $[\begin{smallmatrix}\mathcal{D}\\ I\end{smallmatrix}]$, $\mathcal{N}$ by $[\begin{smallmatrix}\mathcal{N}\\ \mathcal{M}\end{smallmatrix}]$, $\mathcal{C}$ by $[\begin{smallmatrix}\mathcal{C}\\ 0\end{smallmatrix}]$, $\mathcal{C}_\flat$ by $[\begin{smallmatrix}\mathcal{C}_\flat\\ \mathcal{K}^1_\flat\end{smallmatrix}]$, and $\mathcal{C}_\circlearrowleft$ by $[\begin{smallmatrix}\mathcal{C}_\circlearrowleft\\ \mathcal{K}_\circlearrowleft\end{smallmatrix}]$ in Theorem 4.4. $\square$

Let us end this section with a discussion of the joint stabilizability and detectability assumption in Theorem 4.4. This assumption was needed so that we could apply [24, Theorem 4.4] and conclude that the preliminary feedback gives us a coprime factorization of the input/output map. The optimal feedback given by Theorem 4.4 gives us another stabilizing feedback pair. However, we are not able to prove that the optimal feedback pair and the original stabilizing output injection pair $[\begin{smallmatrix}\mathcal{H}\\ \mathcal{G}\end{smallmatrix}]$ are jointly stabilizing (and we do not even expect this to be true in full generality). The problem is that these two pairs need not have a well-defined interaction operator $\mathcal{E}$.

By using the fact that the interaction operator $\mathcal{E}$ is determined (modulo a static part) by its Hankel operator $\mathcal{K}\mathcal{H}$, it is possible to construct $\mathcal{E}$ (whenever such an interaction operator exists). To do this we have to take a closer look at the proof of Theorem 4.4. The critical step in the proof is the addition of the state feedback row to the preliminary stabilized system $\Psi_\flat$. Let us redo this part of the proof, restoring the omitted output injection column

$$\begin{bmatrix} \mathcal{H} \\ \mathcal{G} \\ \mathcal{E}_1 \end{bmatrix}$$

to the system Ψ_1; i.e., let us start with the full system

$$\Psi_{\text{ext}} = \begin{bmatrix} \mathcal{A} & \begin{bmatrix} \mathcal{H} & \mathcal{B} \end{bmatrix} \\ \begin{bmatrix} \mathcal{C} \\ \mathcal{K}^1 \end{bmatrix} & \begin{bmatrix} \mathcal{G} & \mathcal{D} \\ \mathcal{E}_1 & \mathcal{F}^1 \end{bmatrix} \end{bmatrix}$$

and close the state feedback loop to get the stable system

$$\begin{aligned}\Psi_\flat &= \begin{bmatrix} \mathcal{A}_\flat & \begin{bmatrix} \mathcal{H}_\flat & \mathcal{B}_\flat \end{bmatrix} \\ \begin{bmatrix} \mathcal{C}_\flat \\ \mathcal{K}^1_\flat \end{bmatrix} & \begin{bmatrix} \mathcal{G}_\flat & \mathcal{D}_\flat \\ \mathcal{E}_{1\flat} & \mathcal{F}^1_\flat \end{bmatrix} \end{bmatrix} \\ &= \begin{bmatrix} \mathcal{A} + \mathcal{B}\tau \left(I - \mathcal{F}^1\right)^{-1} \mathcal{K}^1 & \begin{bmatrix} \mathcal{H} + \mathcal{B}\left(I - \mathcal{F}^1\right)^{-1} \mathcal{E}_1 & \mathcal{B}\left(I - \mathcal{F}^1\right)^{-1} \end{bmatrix} \\ \begin{bmatrix} \mathcal{C} + \mathcal{D}\left(I - \mathcal{F}^1\right)^{-1} \mathcal{K}^1 \\ \left(I - \mathcal{F}^1\right)^{-1} \mathcal{K}^1 \end{bmatrix} & \begin{bmatrix} \mathcal{G} + \mathcal{D}\left(I - \mathcal{F}^1\right)^{-1} \mathcal{E}_1 & \mathcal{D}\left(I - \mathcal{F}^1\right)^{-1} \\ \left(I - \mathcal{F}^1\right)^{-1} \mathcal{E}_1 & \left(I - \mathcal{F}^1\right)^{-1} - I \end{bmatrix} \end{bmatrix}.\end{aligned}$$

To this system we want to add a new state feedback row $[\mathcal{K}_\natural \quad \mathcal{E}_\natural \quad \mathcal{F}_\natural]$. To see how this row should be constructed we examine the feedback pair

$$\begin{bmatrix} \mathcal{K}_\natural & \mathcal{F}_\natural \end{bmatrix} = \begin{bmatrix} -S^{-1}\pi_+\mathcal{N}^* J \mathcal{C}_\flat & (I - \mathcal{X}) \end{bmatrix}$$

that we used in the proof of Theorem 4.4. Since

$$\begin{aligned} \mathcal{X} &= \mathcal{M}^{-1}(I - \mathcal{F}^1)^{-1} = S^{-1}\mathcal{N}^* J \mathcal{N}\mathcal{M}^{-1}(I - \mathcal{F}^1)^{-1} \\ &= S^{-1}\mathcal{N}^* J \mathcal{D}(I - \mathcal{F}^1)^{-1} = S^{-1}\mathcal{N}^* J \mathcal{D}_\flat, \end{aligned}$$

this pair can be rewritten in the alternative form

$$\begin{bmatrix} \mathcal{K}_\natural & \mathcal{F}_\natural \end{bmatrix} = \begin{bmatrix} 0 & I \end{bmatrix} - S^{-1}\begin{bmatrix} \pi_+\mathcal{N}^* J \mathcal{C}_\flat & \mathcal{N}^* J \mathcal{D}_\flat \end{bmatrix},$$

which gives us a clue to the correct definition of $\mathcal{E}_\natural$.

LEMMA 4.10. *Let $\Psi = \left[\begin{smallmatrix}\mathcal{A} & \mathcal{B}\\ \mathcal{C} & \mathcal{D}\end{smallmatrix}\right]$ be a stable well-posed linear system on (U, H, Y), and let $\mathcal{N}^* \in TI(Y; Z)$ be anticausal. Define*

$$\mathcal{K} = \pi_+\mathcal{N}^*\mathcal{C}, \qquad \mathcal{E} = \mathcal{N}^*\mathcal{D}.$$

(i) *The map $\mathcal{K}$ satisfies*

$$\mathcal{K}\mathcal{A}(t) = \pi_+\tau(t)\mathcal{K}, \qquad t \in \mathbf{R}^+,$$

and the Hankel operator of $\mathcal{E}$ is given by

$$\pi_+\mathcal{E}\pi_- = \mathcal{K}\mathcal{B}.$$

(ii) *If $\mathcal{E}$ can be written as a sum $\mathcal{E} = \mathcal{E}_- + \mathcal{E}_+$, where both $\mathcal{E}_-$ and $\mathcal{E}_+$ belong to $TI(Y; Z)$ and $\mathcal{E}_+$ is causal and $\mathcal{E}_-$ anticausal, then*

$$\begin{bmatrix} \mathcal{A} & \mathcal{B} \\ \begin{bmatrix}\mathcal{C}\\ \mathcal{K}\end{bmatrix} & \begin{bmatrix}\mathcal{D}\\ \mathcal{E}_+\end{bmatrix}\end{bmatrix}$$

is a stable well-posed linear system on $(U, H, Y \times Z)$.

(iii) *Conversely, if there exists some $\mathcal{E}_+$ for which the system above is a stable well-posed linear system on $(U, H, Y \times Z)$, then we get a splitting $\mathcal{E} = \mathcal{E}_- + \mathcal{E}_+$ of the type described above by defining $\mathcal{E}_- = \mathcal{E} - \mathcal{E}_+$. This splitting is unique modulo a static operator E.*

Proof. (i) To compute $\mathcal{K}\mathcal{A}(t)$ we use the anticausality and time invariance of $\mathcal{N}^*$ and part (iii) of [24, Definition 2.1] to get

$$\begin{aligned}\mathcal{K}\mathcal{A}(t) &= \pi_+\mathcal{N}^*\mathcal{C}\mathcal{A}(t)\\ &= \pi_+\mathcal{N}^*\pi_+\tau(t)\mathcal{C}\\ &= \pi_+\mathcal{N}^*\tau(t)\mathcal{C}\\ &= \pi_+\tau(t)\mathcal{N}^*\mathcal{C}\\ &= \pi_+\tau(t)\pi_+\mathcal{N}^*\mathcal{C}\\ &= \pi_+\tau(t)\mathcal{K}.\end{aligned}$$

Almost the same argument, but with part (iii) of [24, Definition 2.1] replaced by part (iv), gives

$$\begin{aligned}\pi_+\mathcal{E}\pi_- &= \pi_+\mathcal{N}^*\mathcal{D}\pi_-\\ &= \pi_+\mathcal{N}^*\pi_+\mathcal{D}\pi_-\\ &= \pi_+\mathcal{N}^*\mathcal{C}\mathcal{B}\\ &= \mathcal{K}\mathcal{B}.\end{aligned}$$

(ii) This follows immediately from part (i) and [24, Definition 2.1] (the Hankel operator of $\mathcal{E}_-$ is zero).

(iii) Clearly $\mathcal{E}_-$ is anticausal, since $\mathcal{E}$ and $\mathcal{E}_+$ have the same Hankel operator. The uniqueness statement follows from [23, Lemma 6]. □

By applying this lemma to the crucial step in the proof of Theorem 4.4 (and using [24, Lemma 3.5]) we get the following addition to Theorem 4.4.

Corollary 4.11. *Let* $\left[\begin{smallmatrix}\mathcal{H}\\ \mathcal{G}\end{smallmatrix}\right]$ *and* $\mathcal{E}_1$ *be the output injection pair and the interaction operator used in the proof of Theorem* 4.4. *Then the optimal state feedback pair* $[\mathcal{K}\quad\mathcal{F}]$ *and the output injection pair* $\left[\begin{smallmatrix}\mathcal{H}\\ \mathcal{G}\end{smallmatrix}\right]$ *are jointly stabilizing iff* $\mathcal{N}^*J\mathcal{G}_\flat = \mathcal{N}^*J(\mathcal{G}+(I-\mathcal{F}^1)^{-1}\mathcal{E}_1)$ *can be split into a causal and an anticausal part that both belong to* $TI(Y;U)$.

We shall not need this result here and leave the proof to the reader.

For completeness, let us also mention the following "dual" result, where one uses an anticausal time-invariant operator to construct a new output injection pair for a well-posed linear system. This result is needed in the solution to the "dual" quadratic optimal filtering problem.

Lemma 4.12. *Let* $\Psi = \left[\begin{smallmatrix}\mathcal{A} & \mathcal{B}\\ \mathcal{C} & \mathcal{D}\end{smallmatrix}\right]$ *be a stable well-posed linear system on* (U,H,Y), *and let* $\widetilde{\mathcal{N}}^* \in TI(Z;U)$ *be anticausal. Define*

$$\mathcal{H} = \mathcal{B}\widetilde{\mathcal{N}}^*\pi_-, \qquad \mathcal{E} = \mathcal{D}\widetilde{\mathcal{N}}^*.$$

(i) *The map* $\mathcal{H}$ *satisfies*

$$\mathcal{A}(t)\mathcal{H} = \mathcal{H}\tau(t)\pi_-, \qquad t\in\mathbf{R}^+,$$

and the Hankel operator of $\mathcal{E}$ *is given by*

$$\pi_+\mathcal{E}\pi_- = \mathcal{C}\mathcal{H}.$$

(ii) *If* $\mathcal{E}$ *can be written as a sum* $\mathcal{E} = \mathcal{E}_- + \mathcal{E}_+$, *where both* $\mathcal{E}_-$ *and* $\mathcal{E}_+$ *belong to* $TI(Z;U)$ *and* $\mathcal{E}_+$ *is causal and* $\mathcal{E}_-$ *anticausal, then*

$$\begin{bmatrix}\mathcal{A} & [\mathcal{H} \quad \mathcal{B}]\\ \mathcal{C} & [\mathcal{E}_+ \quad \mathcal{D}]\end{bmatrix}$$

is a stable well-posed linear system on $(Z\times U,H,Y)$.

(iii) *Conversely, if there exists some* $\mathcal{E}_+$ *for which the system above is a stable well-posed linear system on* $(Z\times U,H,Y)$, *then we get a splitting* $\mathcal{E} = \mathcal{E}_- + \mathcal{E}_+$ *of the type described above by defining* $\mathcal{E}_- = \mathcal{E} - \mathcal{E}_+$. *This splitting is unique modulo a static operator* E.

The proof of this lemma is very similar to the proof of Lemma 4.10, and we leave it to the reader.

Remark 4.13. *Theorem* 4.4 *and Corollary* 4.9 *remain true in the case where we minimize* $\langle y, Jy\rangle_{L^2_\beta(\mathbf{R}^+;Y)}$ *instead, where* $\beta\in\mathbf{R}$ *is arbitrary. We must then throughout replace the unweighted space* L^2 *by the weighted space* L^2_β. *In particular, the notion of an inner operator should be redefined so that it refers to the weighted space* L^2_β, *and the adjoints should be computed with respect to the inner product in the weighted space* L^2_β.

Remark 4.14. *The results of this section remain valid if throughout we replace the algebra of time-invariant bounded linear operators from* $L^2(\mathbf{R};U)$ *into* $L^2(\mathbf{R};Y)$ *by various subalgebras, for example, the algebra of convolution operators induced by measures with finite total variation. The main exception is that spectral factorizations and inner-outer factorizations need not exist in all subalgebras. In particular, Theorem* 4.4 *remains valid. In the algebra studied in* [18] *spectral factorizations and inner-outer factorizations do exist and the input/output maps can always be decomposed into causal and anticausal parts, as required by Lemmas* 4.10 *and* 4.12.

5. The optimal problem on a finite time interval. Our next goal is to show that the Riccati operator in Theorem 4.4 satisfies an algebraic Riccati equation involving the generating operators of the system Ψ. Two such algebraic Riccati equations were given in [23], namely the *open loop* and the *closed loop* algebraic Riccati equations. The derivation of the closed loop Riccati equation was based entirely on the properties of the optimal closed loop system, and that argument remains valid since the optimal closed loop system is stable. However, the open loop system can be unstable, and in order to derive the open loop Riccati equation we have to study the behavior of the optimal system on a finite time interval.

LEMMA 5.1. *Make the same assumption and introduce the same notations as in Theorem* 4.4. *Then, for all $x_0 \in H$ and all $t \geq 0$,*

$$\pi_{[0,t]}\left(\mathcal{D}^* J\pi_{[0,t]}\mathcal{C}_{\circlearrowleft} + \tau(-t)\mathcal{B}^*\Pi\mathcal{A}_{\circlearrowleft}(t)\right) = 0, \tag{5.1}$$

$$\pi_{[0,t]}\left(\mathcal{N}^* J\pi_{[0,t]}\mathcal{C}_{\circlearrowleft} + \tau(-t)\mathcal{M}^*\mathcal{B}^*\Pi\mathcal{A}_{\circlearrowleft}(t)\right) = 0, \tag{5.2}$$

$$\mathcal{C}_{\circlearrowleft}^* J\pi_{[0,t]}\mathcal{C}_{\circlearrowleft} + \mathcal{A}_{\circlearrowleft}^*(t)\Pi\mathcal{A}_{\circlearrowleft}(t) = \Pi, \tag{5.3}$$

$$\mathcal{C}^* J\pi_{[0,t]}\mathcal{C}_{\circlearrowleft} + \mathcal{A}^*(t)\Pi\mathcal{A}_{\circlearrowleft}(t) = \Pi. \tag{5.4}$$

Proof. Fix $t \geq 0$. Let us perform the minimization of the cost function $Q(x_0, u)$ separately with respect to $u_1 = \pi_{[0,t]}u$ and $u_2 = \pi_{[t,\infty)}u$. To do this we write $Q(x_0, u)$ in the form

$$Q(x_0, u) = \int_0^t \langle y(s), Jy(s)\rangle_Y \, ds + \int_t^\infty \langle y(s), Jy(s)\rangle_Y \, ds,$$

where y is the output of Ψ with initial time zero, initial value x_0, and control u. Let x be the corresponding state of Ψ. Since

$$\pi_{[0,t]}y = \pi_{[0,t]}\mathcal{C}x_0 + \pi_{[0,t]}\mathcal{D}\pi_{[0,t]}u \text{ and } \pi_{[t,\infty)}y = \tau(-t)\mathcal{C}x(t) + \mathcal{D}\pi_{[t,\infty)}u,$$

we observe that the first term depends only on x_0 and u_1 and the second term only on $x(t)$ and u_2. If we fix u_1 and minimize with respect to u_2, then, because of the time invariance of the problem, the minimum is equal to $\langle x(t), \Pi x(t)\rangle_H$. Thus, we are left with the problem of minimizing the cost function

$$Q(x_0, u) = \int_0^t \langle y(s), Jy(s)\rangle_Y \, ds + \langle x(t), \Pi x(t)\rangle_H \tag{5.5}$$

with respect to u_1, where $\pi_{[0,t]}y$ is the function given above and $x(t) = \mathcal{A}(t)x_0 + \mathcal{B}\tau(t)u_1$. Differentiating (5.5) with respect to u_1 and setting the result to be zero we get (5.1). That also (5.2) holds follows from the time invariance and anticausality of $\mathcal{M}^*$ and the fact that $\mathcal{M}^*\mathcal{D}^* = \mathcal{N}^*$.

By replacing y and x in (5.5) by $y^{\text{opt}}(x_0)$ and $x^{\text{opt}}(x_0)$ we find that

$$\langle x_0, \Pi x_0\rangle_H = \int_0^t \left\langle y^{\text{opt}}(x_0, s), Jy^{\text{opt}}(x_0, s)\right\rangle_Y \, ds + \left\langle x^{\text{opt}}(t, x_0), \Pi x^{\text{opt}}(t, x_0)\right\rangle_Y,$$

from which (5.3) follows since $y^{\text{opt}}(x_0) = \mathcal{C}_{\circlearrowleft}x_0$ and $x^{\text{opt}}(t, x_0) = \mathcal{A}_{\circlearrowleft}(t)x_0$. This

FIG. 5.1. *Primal-dual connection with primal feedback.*

combined with (5.1) implies that for all x_0 and x_1 in H,

$$\begin{aligned}\langle x_1, \Pi x_0\rangle_H &= \int_0^t \langle (\mathcal{C}_\circlearrowleft x_1)(s), J(\mathcal{C}_\circlearrowleft x_0)(s)\rangle_Y \, ds + \langle \mathcal{A}_\circlearrowleft(t)x_1, \Pi\mathcal{A}_\circlearrowleft(t)x_0\rangle_H \\ &= \int_0^t \left\langle (\mathcal{C}x_1 + \mathcal{D}u^{\text{opt}}(x_1))(s), Jy^{\text{opt}}(x_0,s)\right\rangle_Y \, ds \\ &\quad + \left\langle \mathcal{A}(t)x_1 + \mathcal{B}\tau(t)u^{\text{opt}}(x_1), \Pi x^{\text{opt}}(x_0,t)\right\rangle_H \\ &= \int_0^t \langle (\mathcal{C}x_1)(s), J\mathcal{C}_\circlearrowleft x_0(s)\rangle_Y \, ds + \langle \mathcal{A}(t)x_1, \mathcal{A}_\circlearrowleft(t)x_0\rangle_H \,,\end{aligned}$$

which gives us (5.4). □

We remark that Lemma 5.1 has been proved independently by Hans Zwart [35] under weaker assumptions.

The preceding lemma can be interpreted as a result concerning the state and output of the adjoint system Ψ^* if we use the state x multiplied by Π and the output y multiplied by J of the original system as initial value and control for Ψ.

COROLLARY 5.2. *Make the same assumption and introduce the same notations as in Theorem* 4.4. *Let* $x^{\text{opt}}(x_0)$ *and* $y^{\text{opt}}(x_0)$ *denote the optimal state and optimal output in the quadratic cost minimization problem for* Ψ, *and let* x^* *and* u^* *denote the state and output of the adjoint system* Ψ^* *with initial time* $t > 0$, *initial value* $\Pi x^{\text{opt}}(t, x_0)$, *and control* $y^{\text{opt}}(x_0)$ (*see Figure* 5.1 *with* $u_\circlearrowleft = 0$). *Then* $x^*(s) = \Pi x^{\text{opt}}(x_0, s)$ *for all* $s \in [0,t]$ *and* $\pi_{[0,t]}u^* = 0$. *The same formulae are true if instead* x^* *and* u^* *denote the state and output of the optimal adjoint system* $\Psi^*_\circlearrowleft$ *with initial time* $t > 0$, *initial value* $\Pi x^{\text{opt}}(t, x_0)$, *and control* $y^{\text{opt}}(x_0)$.

Proof. Fix $0 \le s \le t$. By the definition of the state of the adjoint system Ψ^*, we have

$$\begin{aligned}x^*(s) &= \mathcal{A}^*(t-s)\Pi x^{\text{opt}}(t,x_0) + \mathcal{C}^*J\tau(s)\pi_{[s,t]}y^{\text{opt}}(x_0) \\ &= \left(\mathcal{A}^*(t-s)\Pi\mathcal{A}_\circlearrowleft(t-s) + \mathcal{C}^*J\tau(s)\pi_{[s,t]}\tau(-s)\mathcal{C}_\circlearrowleft\right) x^{\text{opt}}(x_0,s) \\ &= \left(\mathcal{A}^*(t-s)\Pi\mathcal{A}_\circlearrowleft(t-s) + \mathcal{C}^*J\pi_{[0,t-s]}\mathcal{C}_\circlearrowleft\right) x^{\text{opt}}(x_0,s) \\ &= \Pi x^{\text{opt}}(x_0,s),\end{aligned}$$

where the last equality follows from (5.4). The same computation is valid if we replace Ψ^* by $\Psi^*_\circlearrowleft$.

The restriction of the output of Ψ^* to $[0,t]$ is given by

$$\pi_{[0,t]}u^* = \pi_{[0,t]}\left(\tau(-t)\mathcal{B}^*\Pi x^{\mathrm{opt}}(t,x_0) + \mathcal{D}^* J\pi_{[0,t]}y^{\mathrm{opt}}(x_0)\right),$$

and this is zero according to (5.1). To prove the same result with Ψ^* replaced by the optimal closed loop adjoint system $\Psi^*_{\circlearrowleft}$ we argue in the same way, but replace (5.1) by (5.2). □

REMARK 5.3. *A similar result is true for nonzero inputs $u_{\circlearrowleft}$ to the primal and $Su_{\circlearrowleft}$ to the dual system* (*see Figure* 5.1). *This follows from Corollary* 5.7 *below, since the connection in Figure* 5.3 *becomes identical to the one in Figure* 5.1 *if we replace u in Figure* 5.3 *by $u_{\circlearrowleft} + z$.*

Up to now we have in this section made only marginal use of Theorem 4.4, but the remaining results depend heavily on the characterization of the optimal feedback pair given in that theorem. We begin with the following key lemma.

LEMMA 5.4. *Make the same assumption and introduce the same notations as in Theorem* 4.4. *Then, for all $t \ge 0$,*

$$\pi_+\tau(-t)\mathcal{B}^*_{\circlearrowleft}\Pi\mathcal{B}_{\circlearrowleft}\tau(t)\pi_+ + \pi_{[0,t]}\mathcal{D}^*_{\circlearrowleft}J\pi_{[0,t]}\mathcal{D}_{\circlearrowleft}\pi_{[0,t]} = S\pi_{[0,t]}.$$

Proof. To prove this we compute, using the facts that $\Pi = \mathcal{C}^*_{\circlearrowleft}J\mathcal{C}_{\circlearrowleft}$ and $\pi_+\mathcal{D}_{\circlearrowleft}\pi_- = \pi_+\mathcal{N}\pi_- = \mathcal{C}_{\circlearrowleft}\mathcal{B}_{\circlearrowleft}$,

$$\begin{aligned}
&\pi_+\tau(-t)\mathcal{B}^*_{\circlearrowleft}\Pi\mathcal{B}_{\circlearrowleft}\tau(t)\pi_+ + \pi_{[0,t]}\mathcal{D}^*_{\circlearrowleft}J\pi_{[0,t]}\mathcal{D}_{\circlearrowleft}\pi_{[0,t]}\\
&\quad= \pi_+\tau(-t)\mathcal{B}^*_{\circlearrowleft}\mathcal{C}^*_{\circlearrowleft}J\mathcal{C}_{\circlearrowleft}\mathcal{B}_{\circlearrowleft}\tau(t)\pi_+ + \pi_{[0,t]}\mathcal{D}^*_{\circlearrowleft}J\pi_{[0,t]}\mathcal{D}_{\circlearrowleft}\pi_{[0,t]}\\
&\quad= \pi_{[0,t]}\tau(-t)\pi_-\mathcal{N}^*J\pi_+\mathcal{N}\pi_-\tau(t)\pi_+ + \pi_{[0,t]}\mathcal{D}^*_{\circlearrowleft}J\pi_{[0,t]}\mathcal{D}_{\circlearrowleft}\pi_{[0,t]}.
\end{aligned}$$

The combination of operators in the first term on the last row satisfies

$$\begin{aligned}
\pi_+\mathcal{N}\pi_-\tau(t)\pi_+ &= \pi_+\mathcal{N}\tau(t)\pi_{[0,t]}\\
&= \pi_+\tau(t)\mathcal{N}\pi_{[0,t]}\\
&= \tau(t)\pi_{[t,\infty)}\mathcal{N}\pi_{[0,t]},
\end{aligned}$$

so we can continue the computation above as (recalling that $\mathcal{N}^*J\mathcal{N} = S$)

$$\begin{aligned}
&\pi_+\tau(-t)\mathcal{B}^*_{\circlearrowleft}\Pi\mathcal{B}_{\circlearrowleft}\tau(t)\pi_+ + \pi_{[0,t]}\mathcal{D}^*_{\circlearrowleft}J\pi_{[0,t]}\mathcal{D}_{\circlearrowleft}\pi_{[0,t]}\\
&\quad= \pi_{[0,t]}\mathcal{N}^*J\pi_{[t,\infty)}\tau(-t)\tau(t)\pi_{[t,\infty)}\mathcal{N}\pi_{[0,t]} + \pi_{[0,t]}\mathcal{D}^*_{\circlearrowleft}J\pi_{[0,t]}\mathcal{D}_{\circlearrowleft}\pi_{[0,t]}\\
&\quad= \pi_{[0,t]}\mathcal{N}^*J\pi_{[t,\infty)}\mathcal{N}\pi_{[0,t]} + \pi_{[0,t]}\mathcal{N}^*J\pi_{[0,t]}\mathcal{N}\pi_{[0,t]}\\
&\quad= \pi_{[0,t]}\mathcal{N}^*J\mathcal{N}\pi_{[0,t]}\\
&\quad= S\pi_{[0,t]},
\end{aligned}$$

from which the claim follows. □

LEMMA 5.5. *Make the same assumption and introduce the same notations as in Theorem* 4.4. *Then, for all $t \ge 0$,*

$$\begin{aligned}
&(5.6) & S\pi_{[0,t]}\mathcal{K} &= -\pi_{[0,t]}\left(\mathcal{N}^*J\pi_{[0,t]}\mathcal{C} + \tau(-t)\mathcal{M}^*\mathcal{B}^*\Pi\mathcal{A}(t)\right)\\
&& &= -\pi_{[0,t]}\left(\mathcal{D}^*_{\circlearrowleft}J\pi_{[0,t]}\mathcal{C} + \tau(-t)\mathcal{B}^*_{\circlearrowleft}\Pi\mathcal{A}(t)\right),\\

FIG. 5.2. *Primal-dual connection with dual feedback.*

Proof. Since $y^{\mathrm{opt}}(x_0) = (\mathcal{C} + \mathcal{D}_{\circlearrowleft}\mathcal{K})x_0$ and $x^{\mathrm{opt}}(x_0, t) = (\mathcal{A}(t) + \mathcal{B}_{\circlearrowleft}\tau(t)\mathcal{K})$, we get from (5.2) and Lemma 5.4

$$\begin{aligned}
0 &= \pi_{[0,t]}\mathcal{D}^*_{\circlearrowleft}J\pi_{[0,t]}y^{\mathrm{opt}}(x_0) + \pi_{[0,t]}\tau(-t)\mathcal{B}^*_{\circlearrowleft}\Pi x^{\mathrm{opt}}(x_0, t)\\
&= \pi_{[0,t]}\mathcal{D}^*_{\circlearrowleft}J\pi_{[0,t]}\left(\mathcal{C} + \mathcal{D}_{\circlearrowleft}\mathcal{K}\right)x_0\\
&\quad + \pi_{[0,t]}\tau(-t)\mathcal{B}^*_{\circlearrowleft}\Pi\left(\mathcal{A}(t) + \mathcal{B}_{\circlearrowleft}\tau(t)\mathcal{K}\right)x_0\\
&= \pi_{[0,t]}\mathcal{D}^*_{\circlearrowleft}J\pi_{[0,t]}\mathcal{C}x_0 + \pi_{[0,t]}\tau(-t)\mathcal{B}^*_{\circlearrowleft}\Pi\mathcal{A}(t)x_0\\
&\quad + \pi_{[0,t]}\mathcal{D}^*_{\circlearrowleft}J\pi_{[0,t]}\mathcal{D}_{\circlearrowleft}\mathcal{K}x_0\\
&\quad + \pi_{[0,t]}\tau(-t)\mathcal{B}^*_{\circlearrowleft}\Pi\mathcal{B}_{\circlearrowleft}\tau(t)\mathcal{K}x_0\\
&= \pi_{[0,t]}\mathcal{D}^*_{\circlearrowleft}J\pi_{[0,t]}\mathcal{C}x_0 + \pi_{[0,t]}\tau(-t)\mathcal{B}^*_{\circlearrowleft}\Pi\mathcal{A}(t)x_0\\
&\quad + \pi_{[0,t]}S\mathcal{K}x_0.
\end{aligned}$$

This is (5.6).

The proof of (5.7) is very similar, and we leave it to the reader.

The identity (5.8) follows from (5.4) and (5.6) since they give

$$\begin{aligned}
\Pi &= \mathcal{A}^*_{\circlearrowleft}(t)\Pi\mathcal{A}(t) + \mathcal{C}^*_{\circlearrowleft}J\pi_{[0,t]}\mathcal{C}\\
&= \left(\mathcal{A}^*(t) + \mathcal{K}^*\mathcal{M}^*\tau(-t)\mathcal{B}^*\right)\Pi\mathcal{A}(t) + \left(\mathcal{C}^*J + \mathcal{K}^*\mathcal{N}^*J\right)\pi_{[0,t]}\mathcal{C}\\
&= \mathcal{A}^*(t)\Pi\mathcal{A}(t) + \mathcal{C}^*J\pi_{[0,t]}\mathcal{C} - \mathcal{K}^*S\pi_{[0,t]}\mathcal{K}. \qquad \square
\end{aligned}$$

Lemma 5.5 can be used to derive the following result.

COROLLARY 5.6. *Make the same assumption and introduce the same notations as in Theorem* 4.4. *Let x and y denote the state and output of Ψ with initial time zero, initial state x_0, and control u, and let x^* and u^* denote the state and output of the closed loop optimal adjoint system $\Psi^*_{\circlearrowleft}$ with initial time $t > 0$, initial value $\Pi x(t)$, and control Jy* (*see Figure* 5.2). *Then $x^*(s) = \Pi x(s)$ for all $s \in [0, t]$ and u^* is given by*

$$\pi_{[0,t]}u^* = -S\pi_{[0,t]}\left(\mathcal{K}x_0 - (I - \mathcal{F})\pi_{[0,t]}u\right).$$

Thus, apart from the factor $-S$ and the different feed-through term, this is the same signal that is produced by the optimal state feedback output of Ψ.

We leave the proof of this corollary to the reader since it is essentially the same as the proof of Corollary 5.2, with Lemma 5.1 replaced by Lemma 5.5.

It is possible to reformulate the preceding result in a way that does not involve any feedback, only feed-forward.

FIG. 5.3. *Feed-forward primal-dual connection.*

COROLLARY 5.7. *Make the same assumption and introduce the same notations as in Theorem* 4.4. *Let x, y, and z denote the state, the output, and the state feedback output of Ψ with initial time zero, initial state x_0, and control u, and let x^* and u^* denote the state and output of the adjoint system Ψ^* with initial time $t > 0$, initial value $\Pi x(t)$, control Jy, and output injection signal $S(u - z)$ (see Figure* 5.3). *Then $x^*(s) = \Pi x(s)$ for all $s \in [0, t]$ and u^* is given by*

$$\pi_{[0,t]}u^* = -S\pi_{[0,t]}\left(\mathcal{K}x_0 - (I - \mathcal{F})\pi_{[0,t]}u\right).$$

Proof. This follows from Corollary 5.6, which tells us that all the input signals (and initial states) in Figures 5.2 and 5.3 are identical; hence the outputs are also identical. □

6. The algebraic Riccati equation. With the aid of the formulae in the preceding section we can repeat the computations in [23, Sections 9 and 10] with the following results. (We refer the reader to [2], [23, Sections 7 and 8], and [29] for discussions on the generating operators of well-posed linear systems.)

THEOREM 6.1. *Make the same assumptions and introduce the same notations as in Theorem* 4.4. *Extend the system Ψ into*

$$\Psi = \begin{bmatrix} \mathcal{A} & \mathcal{B} \\ \begin{bmatrix}\mathcal{C}\\\mathcal{K}\end{bmatrix} & \begin{bmatrix}\mathcal{D}\\\mathcal{F}\end{bmatrix} \end{bmatrix}$$

by adding the optimal state feedback pair $(\mathcal{K}, \mathcal{F})$. Let

$$\Psi_{\circlearrowleft} = \begin{bmatrix} \mathcal{A}_{\circlearrowleft} & \mathcal{B}_{\circlearrowleft} \\ \begin{bmatrix}\mathcal{C}_{\circlearrowleft}\\\mathcal{K}_{\circlearrowleft}\end{bmatrix} & \begin{bmatrix}\mathcal{D}_{\circlearrowleft}\\\mathcal{F}_{\circlearrowleft}\end{bmatrix} \end{bmatrix} = \begin{bmatrix} \mathcal{A} + \mathcal{B}\tau\mathcal{M}\mathcal{K} & \mathcal{B}\mathcal{M} \\ \begin{bmatrix}\mathcal{C} + \mathcal{N}\mathcal{K}\\\mathcal{M}\mathcal{K}\end{bmatrix} & \begin{bmatrix}\mathcal{N}\\\mathcal{M} - I\end{bmatrix} \end{bmatrix}$$

be the optimal closed loop system given by Theorem 4.4. *Denote the generating operators of Ψ and $\Psi_{\circlearrowleft}$ by the same letters as the corresponding operators* [23, *Sections* 7 *and* 8].

(i) *The Riccati operator* Π *of* Ψ *satisfies the Lyapunov equations*

$$\begin{aligned}\langle Ax_0, \Pi x_1\rangle_H + \langle x_0, \Pi A x_1\rangle_H &= -\langle Cx_0, JCx_1\rangle_Y + \langle Kx_0, SKx_1\rangle_U\,,\\ &\qquad x_0, x_1 \in \operatorname{dom}(A),\\ \langle Ax_0, \Pi x_1\rangle_H + \langle x_0, \Pi A_{\circlearrowleft} x_1\rangle_H &= -\langle Cx_0, JC_{\circlearrowleft}x_1\rangle_Y\,,\\ &\qquad x_0 \in \operatorname{dom}(A), \quad x_1 \in \operatorname{dom}(A_{\circlearrowleft}),\\ \langle A_{\circlearrowleft}x_0, \Pi x_1\rangle_H + \langle x_0, \Pi A_{\circlearrowleft} x_1\rangle_H &= -\langle C_{\circlearrowleft}x_0, JC_{\circlearrowleft}x_1\rangle_Y\,,\\ &\qquad x_0, x_1 \in \operatorname{dom}(A_{\circlearrowleft}).\end{aligned}$$

(ii) *The Lyapunov equations in* (i) *can be rewritten in the form*

$$\begin{aligned}\Pi Ax &= -\left(A^*\Pi + C^*JC - K^*SK\right)x\\ &= -\left(A_{\circlearrowleft}^*\Pi + C_{\circlearrowleft}^*JC\right)x, \qquad x \in \operatorname{dom}(A),\\ \Pi A_{\circlearrowleft}x &= -\left(A^*\Pi + C^*JC_{\circlearrowleft}\right)x\\ &= -\left(A_{\circlearrowleft}^*\Pi + C_{\circlearrowleft}^*JC_{\circlearrowleft}\right)x, \qquad x \in \operatorname{dom}(A_{\circlearrowleft}).\end{aligned}$$

(iii) *In addition, suppose that the extended system* Ψ *is regular together with its adjoint* [28, *Theorem* 5.8]. *Denote the feed-through operators with the same letters as their corresponding input/output maps* [23, *Sections* 7 *and* 8], *and let an over-line denote the strong Weiss extension of an observation map* (*see* [23, *Proposition* 36], *for example,* $\overline{C}x = \lim_{\lambda\to\infty} C_\lambda x$, *where* $C_\lambda = \lambda C(\lambda I - A)^{-1}$ *is the* "*Yosida approximation*" *of* C). *Then*

$$\begin{bmatrix} A_{\circlearrowleft} & B_{\circlearrowleft}\\ \begin{bmatrix} C_{\circlearrowleft}\\ K_{\circlearrowleft}\end{bmatrix} & \begin{bmatrix} D_{\circlearrowleft}\\ F_{\circlearrowleft}\end{bmatrix}\end{bmatrix} = \begin{bmatrix} A + BM\overline{K} & BM\\ \begin{bmatrix} \overline{C} + N\overline{K}\\ M\overline{K}\end{bmatrix} & \begin{bmatrix} N\\ M - I\end{bmatrix}\end{bmatrix},$$

where the equation for $B_{\circlearrowleft}$ *should be interpreted as* $\overline{B}_{\circlearrowleft}^* = M^*\overline{B}^*$.

(iv) *In the regular case* (iii) *above, the operator* $\overline{B}^*\Pi$ *satisfies the equations*

$$\begin{aligned}SKx &= -M^*\left(\overline{B}^*\Pi + D^*JC\right)x, \quad x \in \operatorname{dom}(A),\\ 0 &= \left(\overline{B}^*\Pi + D^*JC_{\circlearrowleft}\right)x, \quad x \in \operatorname{dom}(A_{\circlearrowleft}).\end{aligned}$$

(v) *In the regular case* (iii) *above, the Riccati operator* Π *satisfies the algebraic Riccati equation*

$$\begin{aligned}&\langle Ax_0, \Pi x_1\rangle_H + \langle x_0, \Pi Ax_1\rangle_H + \langle Cx_0, JCx_1\rangle_Y\\ &\quad = \left\langle M^*\left(\overline{B}^*\Pi + D^*JC\right)x_0, S^{-1}M^*\left(\overline{B}^*\Pi + D^*JC\right)x_1\right\rangle_U,\\ &\qquad x_0, x_1 \in \operatorname{dom}(A).\end{aligned}$$

In particular, if $M = I$,[9] *then*

$$\begin{aligned}&\langle Ax_0, \Pi x_1\rangle_H + \langle x_0, \Pi Ax_1\rangle_H + \langle Cx_0, JCx_1\rangle_Y\\ &\quad = \left\langle\left(\overline{B}^*\Pi + D^*JC\right)x_0, S^{-1}\left(\overline{B}^*\Pi + D^*JC\right)x_1\right\rangle_U,\\ &\qquad x_0, x_1 \in \operatorname{dom}(A).\end{aligned}$$

[9] This means that the feed-through operator of $\mathcal{F}$ is taken to be zero; i.e., there is "no feed-forward term inside the feedback loop." See the discussion after [23, Theorem 27].

Proof. (i) Take x_0 and x_1 in the indicated domains, apply (5.3), (5.4), or (5.8) to x_1, take the inner product with x_0, differentiate with respect to t, and substitute $t = 0$.

(ii) This follows from (i).

(iii) These formulae are found in [23, Sections 7 and 8] and proved in [29].

(iv) Let $x = \mathcal{A}x_0$ and $y = \mathcal{C}x_0$ denote the state and output of Ψ with initial time zero, initial state x_0, and zero control u. Referring to Corollary 5.6, we let $x^* = \Pi x$ and $u^* = -S\mathcal{K}x_0$ be the state and output of the optimal adjoint system $\Psi^*_{\circlearrowleft}$ with initial time $t > 0$, initial value $\Pi x(t)$, and control Jy (restricted to the interval $[0,t]$). Take $x_0 \in \operatorname{dom}(A)$. Then all the inputs and outputs belong to $W^{1,2}([0,t])$, $x(t) \in \operatorname{dom}(A)$, and, for all $s \in [0,t]$,

$$y(s) = Cx(s), \qquad u^*(s) = -SKx(s)$$

(the proofs of these claims are analogous to the proofs of [23, Propositions 29 and 36]). By part (ii), the initial values of the state $x^*(t) = \Pi x(t)$ and control $Jy(t) = JCx(t)$ satisfy

$$A^*_{\circlearrowleft}x^*(t) + C^*_{\circlearrowleft}Jy(t) = (A^*_{\circlearrowleft}\Pi + C^*_{\circlearrowleft}JC)x(t) = \Pi Ax(t) \in H.$$

Thus, by [23, Proposition 36(ii)], the output u^* of $\Psi^*_{\circlearrowleft}$ is related to the input y and the state x^* through the formula

$$u^*(s) = \overline{B}^*_{\circlearrowleft}x^*(s) + D^*_{\circlearrowleft}Jy(s),$$

which combined with (iii) gives us

$$-SKx(s) = u^*(s) = M^*\overline{B}^*\Pi x(s) + N^*JCx(s) = M^*(\overline{B}^*\Pi + D^*JC)x(s).$$

Taking $s = 0$ we get the first formula in (iv). We get the second formula by replacing Corollary 5.6 by Corollary 5.2.

(v) Combine (i) and (iv). □

7. Computation of the sensitivity operator. Looking at the different formulae involving $\overline{B}^*\Pi$ in part (iv) of Theorem 6.1, a natural question to ask is whether it is possible to compute $\overline{B}^*\Pi x$ for all x in the Hilbert space W_B defined in [23, Section 7]. This is the space of all possible initial values x_0 satisfying the equation $Ax_0 + Bu_0 \in H$ for some $u_0 \in U$ [23, Lemma 32]. It is invariant in the sense that the controlled state $x(t)$ of Ψ stays in W_B under the action of a control u in $W^{1,2}(\mathbf{R}^+;U)$, provided the initial values x_0 and $u_0 = u(0)$ satisfy $Ax_0 + Bu_0 \in H$ [23, Remark 34]. Moreover, it contains both the domains $\operatorname{dom}(A)$ and $\operatorname{dom}(A_{\circlearrowleft})$; in fact, it contains all the domains of the generators of any state feedback perturbed version of $\mathcal{A}$ [23, Proposition 37]. Another related question is whether it is possible to write all the different Lyapunov equations given in part (ii) of Theorem 6.1 into one common form. A third related question concerns the crucial sensitivity operator S appearing in Theorem 6.1: is it possible to give a formula for this operator in terms of the original data and the Riccati operator Π? The answers to all these questions are affirmative, as can be shown with the aid of Corollary 5.7.

Theorem 7.1. *Make the same assumptions and introduce the same notations as in Theorem* 4.4. *Denote the generating operators of* Ψ *by the same letters as the corresponding operators* [23, *Section* 7], *and let* $\widehat{\mathcal{D}}$ *and* $\widehat{\mathcal{F}}$ *be the transfer functions of* $\mathcal{D}$ *and* $\mathcal{F}$ [24, *Lemma* 2.9]. *Let* $x_0 \in H$ *and* $u_0 \in U$ *satisfy* $Ax_0 + Bu_0 \in H$.

(i) *If $\alpha \in \mathbf{C}$ has real part bigger than the growth rate of Ψ, then the vectors $y_0 \in Y$ and $w_0 \in U$ defined by*[10]

$$y_0 = C(\alpha I - A)^{-1}(\alpha x_0 - Ax_0 - Bu_0) + \widehat{\mathcal{D}}(\alpha)u_0, \tag{7.1}$$

$$w_0 = -K(\alpha I - A)^{-1}(\alpha x_0 - Ax_0 - Bu_0) + (I - \widehat{\mathcal{F}}(\alpha))u_0 \tag{7.2}$$

are independent of α. Moreover,

$$A^*\Pi x_0 + C^*Jy_0 + K^*Sw_0 = -\Pi\,(Ax_0 + Bu_0) \in H, \tag{7.3}$$

and, for all $\beta \in \mathbf{C}$ with real part bigger than the growth rate of Ψ,

$$(I - \widehat{\mathcal{F}}(\beta))^*Sw_0 = B^*(\overline{\beta}I - A^*)^{-1}\Pi(\overline{\beta}x_0 + Ax_0 + Bu_0) + (\widehat{\mathcal{D}}(\beta))^*Jy_0. \tag{7.4}$$

In particular, Π maps the space W_B defined in [23, *Section* 7] *continuously into the space $V^*_{(C,K)}$ defined in* [23, *Proposition* 39].

(ii) *If Ψ is regular, then* (7.1) *and* (7.2) *can be written in the alternative forms*

$$y_0 = \overline{C}x_0 + Du_0, \tag{7.5}$$

$$w_0 = -\overline{K}x_0 + (I - F)u_0 = -\overline{K}x_0 + Xu_0, \tag{7.6}$$

which substituted into (7.3) *gives*

$$\begin{aligned}(A^*\Pi + C^*J\overline{C} - K^*S\overline{K})x_0 + \Pi(Ax_0 + Bu_0)\\ = -(C^*JD + K^*SX)u_0.\end{aligned} \tag{7.7}$$

(iii) *If Ψ^* is regular, then* (7.4) *can be written in the alternative form*

$$(I - F^*)Sw_0 = X^*Sw_0 = \overline{B}^*\Pi x_0 + D^*Jy_0. \tag{7.8}$$

(iv) *If both Ψ and Ψ^* are regular, then* (7.5) *and* (7.6) *combined with* (7.8) *give*

$$(\overline{B}^*\Pi + D^*J\overline{C} + X^*S\overline{K})\,x_0 = (X^*SX - D^*JD)u_0. \tag{7.9}$$

In particular, if $X = I$ (i.e., $F = 0$ and there is "no feed-forward term inside the feedback loop"), then

$$(\overline{B}^*\Pi + D^*J\overline{C} + S\overline{K})\,x_0 = (S - D^*JD)u_0.$$

A special case of the last formula is found in [18, Formula (60)]. (The setting in [18] is different, and that formula is actually valid in a much larger (Banach) space than W_B.)

Proof. (i) Take some $x_0 \in H$ and $u_0 \in U$ satisfying $Ax_0 + Bu_0 \in H$. Choose some $u \in W^{1,2}([0,t];U)$ with $u(0) = u_0$. Consider the connection described in Corollary 5.7. As in that corollary, we let $x = \mathcal{A}x_0 + \mathcal{B}\tau\pi_+u$, $y = \mathcal{C}x_0 + \mathcal{D}\pi_+u$, and $z = \mathcal{K}x_0 + \mathcal{F}\pi_+u$ denote the state, the output, and the state feedback output of Ψ with initial time zero, initial state x_0, and control u. Furthermore, let $w = (u - z)$. Then, by [23, Proposition 29], all the inputs and and outputs of the extended primal system Ψ

[10] For notational simplicity we have in this theorem replaced $u_\circlearrowleft$ in Figure 5.3 by w. It represents the input to the optimal closed loop system; cf. Figure 5.1.

belong to $W^{1,2}([0,t])$ and the state x is continuously differentiable in H. It follows from, for example, [16, Formula (2.1;2)] combined with [23, Proposition 29] that (7.1) and (7.2) hold with x_0, u_0, y_0, and w_0 replaced by $x(t)$, $u(t)$, $u(t)$, and $w(t)$ for all $t \geq 0$. In particular, defining $y_0 = y(0)$ and $w_0 = w(0)$ we get (7.1) and (7.2).

Let us continue with a discussion of the dual system Ψ^* in Corollary 5.7. We fix some $t > 0$ and let $x^*(s) = \mathcal{A}^*(t-s)\Pi x(t) + \mathcal{C}^* J\tau(s)\pi_{[0,t]}y + \mathcal{K}^* S\tau(s)\pi_{[0,t]}w$, $0 \leq s \leq t$, be the state and $u^* = \tau(-t)\mathcal{B}^*\Pi x(t) + \mathcal{D}^* J\pi_{[0,t]}y + \mathcal{F}^* S\pi_{[0,t]}w$ be the output of Ψ^* with initial time $t > 0$, initial value $\Pi x(t)$, control Jy, and output injection signal Sw (throughout restricting all the functions to the interval $[0,t]$). According to Corollary 5.7, $x^* = \Pi x$ and $u^* = Sw$. The former equation implies that x^* is continuously differentiable in H (since x is continuously differentiable in H). The derivative of x is $x' = Ax + Bu$ (see [23, Proposition 29]), and the derivative of x^* is $(x^*)' = -A^*x^* - C^*Jy - K^*Sw$ (this equation is always true in the larger space W^* defined in [23, Section 7], but this time we know that the derivative actually belongs to the smaller space H). Equating the derivative of x^* with the derivative of Πx we get (7.3). Equation (7.4) is derived in the same way as equations (7.1) and (7.2) were derived above, except that we also have to use the additional fact that $u^* = Sw$ (and we have used (7.3) to slightly simplify the result).

(ii) If Ψ is regular, then (7.5) and (7.6) are the limits of (7.1) and (7.2) as $\alpha \to \infty$.

(iii) If Ψ^* is regular, then (7.8) is the limit of (7.4) as $\beta \to \infty$.

(iv) This is immediate. □

The preceding theorem provides us with the following formula, among others, for the sensitivity operator S.

Corollary 7.2. *In the case where both the extended system Ψ and its adjoint are regular and $X = I$*[11] *the following additional claims are true:*

(i) *For all $u_0 \in U$, we have*

$$Su_0 = D^*JDu_0 + \lim_{\alpha\to\infty} \overline{B}^*\Pi(\alpha I - A)^{-1}Bu_0.$$

In particular, $S = D^*JD$ iff the limit above is zero for all $u_0 \in U$.

(ii) *If for some $u_0 \in U$ it is true that $Bu_0 \in H$, then*

$$Su_0 = D^*JDu_0.$$

(iii) *If $S = D^*JD$, then, for all $x_0 \in W_B$,*

$$\overline{K}x_0 = -S^{-1}\left(\overline{B}^*\Pi + D^*J\overline{C}\right)x_0.$$

Proof. To prove part (i) it suffices to apply (7.9) with $x_0 = (\alpha I - A)^{-1}Bu_0$, let $\alpha \to \infty$, and use the regularity of the system. Part (ii) follows directly from (7.9) with $x_0 = 0$. The final claim is obvious (see (7.9)). □

Remark 7.3. *As we shall prove elsewhere* [25], *the difference $S - D^*JD$ is positive* (*negative*) *definite whenever Π is positive* (*negative*) *definite on the reachable subspace.* (*The proof is a fairly straightforward application of Lemma* 5.4.) *This is related to the fact that the factorization is* (J,S)*-lossless iff Π is positive on the reachable subspace.*

8. Applications: The bounded and positive real lemmas.

By applying the preceding theory we can derive the first available versions of the strict bounded and positive (real) lemmas for general well-posed linear systems.

[11] We lose no generality by assuming that $X = I$; see Proposition 4.7.

In the positive real lemma and the bounded real lemma we need a cost function containing both the output y and the control u. For this reason we do in the same way as in Corollary 4.9 and adjoin a copy of the control to the output; i.e., we study the augmented system

$$\Psi_{\text{aug}} = \begin{bmatrix} \mathcal{A} & \mathcal{B} \\ \begin{bmatrix} \mathcal{C} \\ 0 \end{bmatrix} & \begin{bmatrix} \mathcal{D} \\ I \end{bmatrix} \end{bmatrix}. \tag{8.1}$$

By replacing the identity cost operator in Corollary 4.9 by a more general cost operator J defined on $U \times Y$, we get the following result.

COROLLARY 8.1. *Let $J = J^* = \left[\begin{smallmatrix} Q & L^* \\ L & R \end{smallmatrix}\right] \in \mathcal{L}(Y \times U)$, let $S = S^* \in \mathcal{L}(U)$, $S \gg 0$, and let $\Psi = \left[\begin{smallmatrix} \mathcal{A} & \mathcal{B} \\ \mathcal{C} & \mathcal{D} \end{smallmatrix}\right]$ be a jointly stabilizable and detectable well-posed linear system on (U, H, Y).*

(i) *The extended system Ψ_{aug} in* (8.1) *is J-coercive iff $\mathcal{D}$ has a right coprime factorization $(\mathcal{N}, \mathcal{M})$ for which $\left[\begin{smallmatrix} \mathcal{N} \\ \mathcal{M} \end{smallmatrix}\right]$ is (J, S)-inner.*

(ii) *Assuming J-coercivity, let $x^{\text{opt}}(x_0)$, $y^{\text{opt}}(x_0)$, and $u^{\text{opt}}(x_0)$ be the optimal state, output, and control for the quadratic cost minimization problem described in Definition* 3.1, *but with the original system Ψ replaced by the extended system Ψ_{aug}. Let $(\mathcal{N}, \mathcal{M})$ be a right coprime factorization of $\mathcal{D}$ of the type described in* (i). *Then there is a unique feedback map $\mathcal{K}$ such that $[\mathcal{K} \quad \mathcal{F}] = [\mathcal{K} \quad (I - \mathcal{M}^{-1})]$ is an admissible stabilizing state feedback pair for Ψ and*

$$\begin{bmatrix} x^{\text{opt}}(t, x_0) \\ y^{\text{opt}}(x_0) \\ u^{\text{opt}}(x_0) \end{bmatrix} = \begin{bmatrix} \mathcal{A}_{\circlearrowleft}(t) \\ \mathcal{C}_{\circlearrowleft} \\ \mathcal{K}_{\circlearrowleft} \end{bmatrix} x_0 = \begin{bmatrix} \mathcal{A}(t) + \mathcal{B}\mathcal{M}\tau(t)\mathcal{K} \\ \mathcal{C} + \mathcal{N}\mathcal{K} \\ \mathcal{M}\mathcal{K} \end{bmatrix} x_0$$

is equal to the state and output of the closed loop system $\Psi_{\circlearrowleft}$ defined by

$$\Psi_{\circlearrowleft} = \begin{bmatrix} \mathcal{A}_{\circlearrowleft} & \mathcal{B}_{\circlearrowleft} \\ \begin{bmatrix} \mathcal{C}_{\circlearrowleft} \\ \mathcal{K}_{\circlearrowleft} \end{bmatrix} & \begin{bmatrix} \mathcal{D}_{\circlearrowleft} \\ \mathcal{F}_{\circlearrowleft} \end{bmatrix} \end{bmatrix} = \begin{bmatrix} \mathcal{A} + \mathcal{B}\tau\mathcal{M}\mathcal{K} & \mathcal{B}\mathcal{M} \\ \begin{bmatrix} \mathcal{C} + \mathcal{N}\mathcal{K} \\ \mathcal{M}\mathcal{K} \end{bmatrix} & \begin{bmatrix} \mathcal{N} \\ \mathcal{M} - I \end{bmatrix} \end{bmatrix}$$

with initial value x_0, initial time zero, and zero input $u_{\circlearrowleft}$ (see Figure 2.1). *The feedback map $\mathcal{K}$ is uniquely determined by the fact that $\mathcal{C}_{\circlearrowleft} = \mathcal{C} + \mathcal{N}\mathcal{K} \in \mathcal{L}(H; L^2(\mathbf{R}^+; Y))$, $\mathcal{K}_{\circlearrowleft} = \mathcal{M}\mathcal{K} \in \mathcal{L}(H; L^2(\mathbf{R}^+; U))$, and*

$$\pi_+ \left[\mathcal{N}^* \quad \mathcal{M}^*\right] J \begin{bmatrix} \mathcal{C}_{\circlearrowleft} \\ \mathcal{K}_{\circlearrowleft} \end{bmatrix} = 0.$$

Moreover, the Riccati operator of Ψ is given by

$$\Pi = \left[\mathcal{C}_{\circlearrowleft}^* \quad \mathcal{K}_{\circlearrowleft}^*\right] J \begin{bmatrix} \mathcal{C}_{\circlearrowleft} \\ \mathcal{K}_{\circlearrowleft} \end{bmatrix}.$$

(iii) *If Ψ is stable, then*

$$\mathcal{K} = -S^{-1}\pi_+ \left[\mathcal{N}^* \quad \mathcal{M}^*\right] J \begin{bmatrix} \mathcal{C} \\ 0 \end{bmatrix} = -S^{-1}\pi_+ \left(\mathcal{N}^* Q + \mathcal{M}^* L\right) \mathcal{C}$$

and

$$\Pi = \mathcal{C}^* Q \mathcal{C} - \mathcal{K}^* S \mathcal{K}.$$

(iv) *In the case where the extended system* Ψ *is regular together with its adjoint the formulae connecting* K *and* Π *in Theorem* 6.1(iv)–(v) *become* (*with the normalization* $M = I$)

$$
\begin{gathered}
Kx_0 = -S^{-1}\big(\overline{B}^*\Pi + (D^*Q + L^*)C\big)x_0, \\
\langle Ax_0, \Pi x_1\rangle_H + \langle x_0, \Pi A x_1\rangle_H + \langle Cx_0, QCx_1\rangle_Y = \langle Kx_0, SKx_1\rangle_U\,, \\
x_0, x_1 \in \operatorname{dom}(A)
\end{gathered}
$$

and the sensitivity operator S *is given by the strong limit* (*for each fixed* $u_0 \in U$)

$$
Su_0 = \begin{bmatrix} D^* & I \end{bmatrix} J \begin{bmatrix} D \\ I \end{bmatrix} u_0 + \lim_{\alpha\to\infty} \overline{B}^*\Pi(\alpha I - A)^{-1}Bu_0.
$$

Proof. Part (i) follows from Lemma 4.3(ii). Part (ii) follows from Theorem 4.4 in the same way as Corollary 4.9 does. Part (iii) follows from Theorem 2.6. Part (iv) follows from Theorem 6.1 and Corollary 7.2(i). □

From this result we can obtain a factorization version of the *strict bounded (real) lemma* as follows: We let Ψ be stable and choose J to be

$$
J = \begin{bmatrix} -I & 0 \\ 0 & \gamma^2 I \end{bmatrix},
$$

where γ is a real constant. Then the extended system is J-coercive iff the input/output map $\mathcal{D}$ satisfies

$$
\|\mathcal{D}\|_{TIC(U;Y)} < \gamma. \tag{8.2}
$$

Thus, Corollary 8.1 applies iff (8.2) holds. In this case the formulae in Corollary 8.1(ii)–(iii) become

$$
\begin{gathered}
\mathcal{D} = \mathcal{N}\mathcal{M}^{-1}, \qquad \gamma^2\mathcal{M}^*\mathcal{M} - \mathcal{N}^*\mathcal{N} = S, \\
\mathcal{K} = S^{-1}\pi_+\mathcal{N}^*\mathcal{C}, \qquad \gamma^2\pi_+\mathcal{M}^*\mathcal{K}_{\circlearrowleft} = \pi_+\mathcal{N}^*\mathcal{C}_{\circlearrowleft}, \\
\begin{bmatrix} \mathcal{C}_{\circlearrowleft} \\ \mathcal{K}_{\circlearrowleft} \end{bmatrix} = \begin{bmatrix} \mathcal{C} \\ 0 \end{bmatrix} + \begin{bmatrix} \mathcal{N} \\ \mathcal{M} \end{bmatrix} \mathcal{K} = \begin{bmatrix} \mathcal{C} \\ 0 \end{bmatrix} + \begin{bmatrix} \mathcal{N} \\ \mathcal{M} \end{bmatrix} S^{-1}\pi_+\mathcal{N}^*\mathcal{C}, \\
\Pi = \gamma^2\mathcal{K}_{\circlearrowleft}^*\mathcal{K}_{\circlearrowleft} - \mathcal{C}_{\circlearrowleft}^*\mathcal{C}_{\circlearrowleft} = -\mathcal{C}^*\left(I + \mathcal{N}S^{-1}\pi_+\mathcal{N}^*\right)\mathcal{C}.
\end{gathered}
$$

The connecting and Lyapunov equations in Corollary 8.1(iv) become (for x_0 and $x_1 \in \operatorname{dom}(A)$)

$$
\begin{gathered}
Kx_0 = -S^{-1}\left(\overline{B}^*\Pi - D^*C\right)x_0, \\
\langle Ax_0, \Pi x_1\rangle_H + \langle x_0, \Pi A x_1\rangle_H = \langle Cx_0, Cx_1\rangle_Y + \langle Kx_0, SKx_1\rangle_U\,.
\end{gathered}
$$

Observe that the parameter γ enters these equations only through the sensitivity operator S, which is given by the strong limit (for each fixed $u_0 \in U$)

$$
Su_0 = \left(\gamma^2 I - D^*D\right)u_0 + \lim_{\alpha\to\infty} \overline{B}^*\Pi(\alpha I - A)^{-1}Bu_0.
$$

We remark that in our setting Π is negative definite; to get the standard setting where Π is positive [12, Theorem 3.7.1], we must replace J by $-J$ and maximize instead of minimize. This will replace S by $-S$ and Π by $-\Pi$.

The *strictly positive (real) lemma* is a statement about a stable system $\Psi = \left[\begin{smallmatrix} \mathcal{A} & \mathcal{B} \\ \mathcal{C} & \mathcal{D} \end{smallmatrix}\right]$ on (U, H, U) (i.e., the output space of this system is equal to its input space). The input/output map $\mathcal{D}$ of Ψ is strictly positive iff

$$\int_{\mathbf{R}^+} \left(\langle (\mathcal{D}\pi_+ u)(s), u(s) \rangle_U + \langle u(s), (\mathcal{D}\pi_+ u)(s) \rangle_U \right) \, ds \geq \epsilon \, \|u\|^2_{L^2(\mathbf{R}^+;U)}$$

for all $u \in L^2(\mathbf{R}^+; U)$ and some $\epsilon > 0$. Clearly, $\mathcal{D}$ is strictly positive iff the extended system Ψ_{aug} is J-coercive with respect to the operator

$$J = \begin{bmatrix} 0 & I \\ I & 0 \end{bmatrix}.$$

Thus, Corollary 8.1 applies with this J iff $\mathcal{D}$ is strictly positive. The formulae of Corollary 8.1(ii)–(iii) become in this case

$$\begin{aligned} &\mathcal{D} = \mathcal{N}\mathcal{M}^{-1}, \qquad && \mathcal{M}^*\mathcal{N} + \mathcal{N}^*\mathcal{M} = S, \\ &\mathcal{K} = -S^{-1}\pi_+\mathcal{M}^*\mathcal{C}, \qquad && \pi_+ \left(\mathcal{M}^*\mathcal{C}_{\circlearrowleft} + \mathcal{N}^*\mathcal{K}_{\circlearrowleft} \right) = 0, \end{aligned}$$

$$\begin{bmatrix} \mathcal{C}_{\circlearrowleft} \\ \mathcal{K}_{\circlearrowleft} \end{bmatrix} = \begin{bmatrix} \mathcal{C} \\ 0 \end{bmatrix} + \begin{bmatrix} \mathcal{N} \\ \mathcal{M} \end{bmatrix} \mathcal{K} = \begin{bmatrix} \mathcal{C} \\ 0 \end{bmatrix} - \begin{bmatrix} \mathcal{N} \\ \mathcal{M} \end{bmatrix} S^{-1}\pi_+\mathcal{M}^*\mathcal{C},$$

$$\Pi = \mathcal{K}^*_{\circlearrowleft}\mathcal{C}_{\circlearrowleft} + \mathcal{C}^*_{\circlearrowleft}\mathcal{K}_{\circlearrowleft} = -\mathcal{K}^* S \mathcal{K} = -\mathcal{C}^*\mathcal{M}S^{-1}\pi_+\mathcal{M}^*\mathcal{C}.$$

The connecting and Lyapunov equations in Corollary 8.1(iv) become (for x_0 and $x_1 \in \operatorname{dom}(A)$)

$$\begin{aligned} K x_0 &= -S^{-1} \left(\overline{B}^* \Pi + C \right) x_0, \\ \langle A x_0, \Pi x_1 \rangle_H + \langle x_0, \Pi A x_1 \rangle_H &= \langle K x_0, S K x_1 \rangle_U \end{aligned}$$

and the sensitivity operator S is given by the strong limit (for each fixed $u_0 \in U$)

$$S u_0 = (D + D^*) \, u_0 + \lim_{\alpha \to \infty} \overline{B}^* \Pi (\alpha I - A)^{-1} B u_0.$$

Again Π is negative; to get a positive Π we should change the sign of J and maximize instead of minimize [12, Problem 3.25].

In the Pritchard–Salamon case the applications to the bounded and positive (real) lemmas that we have presented above are found in [31, Remark 4.34].

SUCCESSIVE APPROXIMATIONS OF LINEAR CONTROL MODELS[*]

JOHN R. BIRGE[†] AND SAMER TAKRITI[‡]

Abstract. We present a technique for approximating sequences of linear programs with varying right-hand sides and study the geometric properties of this approximation. Our approximation has an efficiency advantage over optimal solutions. When applied to deterministic control problems, the suggested technique outperforms the linear feedback model and provides accurate results (error of 5.8% in our numerical example). Numerical experience with stochastic models indicates that this approach may outperform the limited lookahead policies while maintaining low computational requirements.

Key words. stochastic programming, linear programming, optimal control, linear feedback control, certainty equivalent control, limited lookahead policies

1. Introduction.

In most stochastic optimal control applications, dynamic programming fails to solve the given model due to the lack of a closed form solution for the cost-to-go problem at each stage (see, for example, chapter 4 of [2]). These models are usually simplified by discretizing the continuous variables and applying the dynamic programming algorithm to the resulting finite-dimensional state and control spaces. Even then, a solution can be obtained only in the cases in which the dimension of the state-space is small. When an on-line solution is required, things become more complicated and one has to settle for an approximation that provides a suboptimal control for the given problem. Many of these approximations, such as certainty equivalent control and open-loop feedback control, require repeated solutions of an optimization model with varying parameters. When the parameters change quickly and the computational cost is large, the computed solution may become obsolete. In such situations, great emphasis is placed on reducing the calculation time. Unfortunately, this may reduce the quality of the solution obtained.

An example of the need for a quick solution is that of controlling the movements of a surface ship in restrained waters [6]. A manual control system places severe demands on the crew's skills, making the use of a more automated control highly desirable. A feedback control continuously measures the state of the vessel (location, velocity, and acceleration) and then makes a decision that maintains optimal or near-optimal performance. The performance of such systems is evaluated using a function of the state variables. In general, the goal is to minimize or maximize that function subject to linear system dynamics. Quantities to be minimized can be time, fuel, cost, etc., while those to be maximized include speed, efficiency, and profit.

With time discretized to simplify the calculations, the model becomes a discrete-time linear system [1, 5]. In this case, the state of the controlled system at stage $i+1$ is assumed to be a linear function of its state at stage i and of the decision made

at that stage. If the performance measure is a linear function of the states and the controls, then a linear program is necessary to find an optimal control. In this linear case, the states can be described using the linear equations

$$x^{i+1} = \mathcal{A}x^i + \mathcal{B}u^i,\ i = 0,\ \ldots,\ T-1.$$

Here, $\mathcal{A}$ is the state-transition matrix, u^i is the control input vector of the system at stage i, and $\mathcal{B}u^i$ represents the contribution of the control variables to the change in the state vector. We compute an optimal control by minimizing a linear function of the states and the decisions over a horizon of T periods. That is,

$$\begin{array}{lrcl} \inf_{x,u} & \sum_{i=0}^{T} c_x^i x^i & + & \sum_{i=0}^{T-1} c_u^i u^i \\ \text{subject to} & x^0 & = & t, \\ & x^{i+1} & = & \mathcal{A}x^i + \mathcal{B}u^i,\ i = 0,\ \ldots,\ T-1, \\ & x & \geq & 0, \end{array} \tag{1}$$

where c_x and c_u are row vectors representing the cost associated with x and u. The vector t is the initial state of the system. One may also impose other linear constraints on the control vector u. Note that when the initial conditions vary, the only difference between the linear programs solved is in the first m' entries of the right-hand side, where m' is the dimension of t. Our intent is to develop fast methods that take advantage of this structure.

Using the right-hand side of (1), we partition the equality constraints into two sets. The first is the set of constraints for which the right-hand side vector varies. In (1), for example, this set is $x^0 = t$. The second is the set of constraints for which the right-hand side is known in advance. In our model, this set is $\mathcal{A}x^i + \mathcal{B}u^i - x^{i+1} = 0,\ i = 0,\ \ldots,\ T-1$. We denote the constraints of the first set by A, the constraints of the second set by B, the right-hand side vectors by t and b, and the objective function by c. Our discussion is general in that we do not make any assumptions regarding the structure of A and B.

To simplify notation, we denote the decision variables—state and control—by x. Therefore, the control problem is to evaluate the mathematical program

$$\begin{array}{rcl} \psi(t) = \inf_x c^T x & & \\ \text{subject to } Ax & = & t, \\ Bx & = & b, \\ x & \geq & 0 \end{array}$$

for different values of t. Generally speaking, the size of these programs is quite large. The time needed to compute an exact solution using classical linear programming techniques is lengthy. The solution obtained may become obsolete, since the state vector that was fed to the control algorithm is very different from the real state vector to which the control is applied. In practice, a linear relation is often assumed between the state vector and the control, so that one can make a decision quickly for any given initial state. This form of linear feedback control may, however, be suboptimal.

This paper presents a technique for quickly evaluating sequences of linear programs with varying right-hand sides. Our method combines features of linear feedback control with the complete optimization procedure to obtain an approach that is both fast and accurate. It is a generalization of the approach developed by Birge and Wets [3, 4]. While Birge and Wets deal with quickly evaluating a function $\phi(t) = \{\inf c^T x : Ax = t, x \geq 0\}$ for a varying $t \in \Re^m$, we allow our right-hand side vector to have a varying component, $t \in \Re^{m'}$, and a known one, $b \in \Re^{m-m'}$. Due to their assumption that all entries in the right-hand side can vary, Birge and Wets deal with a sublinear function. To approximate it, they evaluate $\phi(t)$ at m different points, $t^1, \dots, t^m$, and at $-t^1, \dots, -t^m$. These vectors are chosen so that the square matrix $D = [t^1, \dots, t^m]$ forms a basis for A. When a right-hand side, t, is provided, an upper bound on $\phi(t)$ can be computed as $\sum_{k=1}^m (D_{k.}^{-1}t)^+\phi(t^k) + (D_{k.}^{-1}t)^-\phi(-t^k)$, where $D_{k.}^{-1}$ denotes the kth row of the inverse of D. If $D_{k.}^{-1}t \geq 0$, then $(D_{k.}^{-1}t)^+ = D_{k.}^{-1}t$ and $(D_{k.}^{-1}t)^- = 0$. On the other hand, if $D_{k.}^{-1}t < 0$, then $(D_{k.}^{-1}t)^+ = 0$ and $(D_{k.}^{-1}t)^- = -D_{k.}^{-1}t$.

The rest of this paper is organized as follows. Section 2 describes the mathematical model, its geometric properties, and the polyhedral approximation. We discuss our approximation and related implementation issues in section 3 and then present some numerical results in section 4.

2. Geometric properties.

Mathematically, the linear control problem is equivalent to evaluating

$$\begin{array}{rrcl} \psi(t) = \inf_x c^T x & & & \\ \text{subject to } & Ax & = & t, \\ & Bx & = & b, \\ & x & \geq & 0, \end{array} \tag{2}$$

where $t \in \Re^{m'}$ and $b \in \Re^{m-m'}$ are the random (varying) and deterministic (fixed) parts of the right-hand side vector, respectively, and $A \in \Re^{m' \times n}$ and $B \in \Re^{m-m' \times n}$ are the constraint matrices. We make the assumptions that $[A^T|B^T]^T$ is of full row rank, b is in the nonnegative hull of the column vectors of B, and the set of the dual solutions of (2) is not empty.

PROPOSITION 1. *Under the above assumptions, the function $\psi(t)$ is proper and convex. Furthermore, the set of feasible right-hand sides, t, of the program* (2) *and the epigraph of $\psi(t)$ are convex polyhedra.*

Proof. To show that $\psi(t)$ is proper, consider any feasible solution, x^*, for the linear system $Bx = b$, $x \geq 0$, and the corresponding $t^* = Ax^*$. Then, $\psi(t^*) \leq c^T x^* < \infty$. The set of feasible right-hand sides is a convex polyhedron since it is the intersection of the convex polyhedral cone $\{[y^T, z^T]^T : y = Ax, z = Bx, x \geq 0\}$ (see, for example, [3] for a proof) and the hyperplanes $\{[y^T, z^T]^T : z_i = b_i\}$, $i = m' + 1, \dots, m$. That is, it is the intersection of a finite number of half-spaces. To prove that the set $\text{epi}(\psi)$ is a polyhedron, note that

$$\begin{aligned} \text{epi}(\psi) &= \{[v, t^T]^T : v \geq \psi(t)\} \\ &= \{[v, t^T]^T : v \geq [t^T, b^T][\pi^{k^T}, \mu^{k^T}]^T, k = 1, \dots, K\}, \end{aligned}$$

where $[\pi^{k^T}, \mu^{k^T}]^T$, $k = 1, \dots, K$, is the set of dual solutions corresponding to all dual feasible bases of (2). So, $\text{epi}(\psi)$ is the intersection of a finite number of closed half-spaces; hence, it is a convex polyhedron. □

Since $\text{epi}(\psi)$ is a convex polyhedron, it can be represented as a convex combination of its extreme points and a nonnegative combination of its extreme directions (see

Theorem 18.5 in [10]). Therefore,

$$\text{epi}(\psi) = \left\{ \begin{bmatrix} v \\ t \end{bmatrix} : \begin{bmatrix} v \\ t \end{bmatrix} = \sum_{k=1}^{k'} \mu_k \begin{bmatrix} v_k \\ t^k \end{bmatrix} + \sum_{k=k'+1}^{K} \mu_k \begin{bmatrix} v_k \\ t^k \end{bmatrix},\ \mu_k \geq 0 \right\},$$

where $\sum_{k=1}^{k'} \mu_k = 1$ and the set of vectors $[v_k, {t^k}^T]$ includes all extreme points and directions of epi(ψ).

Proposition 2. *Suppose* $[v_k, {t^k}^T]^T$, $k = 1, \ldots, k'$, *and* $[v_k, {t^k}^T]^T$, $k = k' + 1, \ldots, K$, *is a collection of points and directions in epi*(ψ) $\subset \Re^{m'+1}$. *Then*

$$(3) \qquad \psi(t) \leq \inf \left\{ v : \begin{bmatrix} v \\ t \end{bmatrix} = \sum_{k=1}^{k'} \mu_k \begin{bmatrix} v_k \\ t^k \end{bmatrix} + \sum_{k=k'+1}^{K} \mu_k \begin{bmatrix} v_k \\ t^k \end{bmatrix},\ \mu_k \geq 0 \right\},$$

where $\sum_{k=1}^{k'} \mu_k = 1$.

Proof. This follows directly from Proposition 1 and Jensen's inequality. □

Proposition 2 provides an upper bound on the value of $\psi(t)$ for any given right-hand side t. To implement this approximation, we solve (2) for different right-hand side vectors, t^k, $k = 1, \ldots, k'$, and directions, t^k, $k = k' + 1, \ldots, K$. Then, given a vector t, we write it in terms of t^k by choosing the appropriate values for μ_k. The approximate value of $\psi(t)$ is then $\sum_{k=1}^{K} \mu_k v_k$. Clearly, it is advantageous to select the smallest possible value for v_k for each vector used in the approximation; i.e., $v_k = \psi(t^k)$. We call this approximation polyhedral since it is based on the fact that epi(ψ) is a polyhedron. In the special case of $b = 0$, the function $\psi(t)$ is positively homogeneous and the polyhedral approximation becomes that of Birge and Wets, i.e., a sublinear approximation.

The following proposition states the necessary and sufficient conditions for the polyhedral approximation to be exact.

Proposition 3. *Inequality* (3) *is satisfied as an equality for all* $t \in \Re^{m'}$ *if and only if the set of vectors used in the approximation includes all the extreme points and directions of epi*(ψ).

Proof. If the set of vectors used in the polyhedral approximation includes all extreme points and directions, then

$$\left\{ \sum_{k=1}^{k'} \mu_k \begin{bmatrix} v_k \\ t^k \end{bmatrix} + \sum_{k=k'+1}^{K} \mu_k \begin{bmatrix} v_k \\ t^k \end{bmatrix},\ \sum_{k=1}^{k'} \mu_k = 1,\ \mu_k \geq 0 \right\} = \text{epi}(\psi)$$

by Theorem 18.5 of [10], and the bound is exact. On the other hand, assume that the bound is exact and that an extreme point or direction is not included in the set of approximating vectors. Then, we have a representation of an extreme point or direction in terms of other points and directions in epi(ψ), which leads to a contradiction. □

If the representation, μ, of the given right-hand side, t, is not unique, we can choose the vector μ that provides the lowest upper bound. However, finding the best μ requires solving another linear program of size $m' \times K$. To avoid this difficulty, the set of the representing vectors can be chosen so that the approximation has a unique solution which satisfies the constraint $\sum_{k=1}^{k'} \mu_k = 1$. That is, the vectors t^k form a basis for $\Re^{m'+1}$. The solution vector μ is then found by solving the system of linear equations:

$$\begin{bmatrix} D_p & D_d \\ e^T & 0 \end{bmatrix} \begin{bmatrix} \mu_p \\ \mu_d \end{bmatrix} = \begin{bmatrix} t \\ 1 \end{bmatrix},$$

where $D_p = [t^1, \ldots, t^{k'}]$ and $D_d = [t^{k'+1}, \ldots, t^{m'+1}]$. The objective function value obtained from using the vectors $[D_p, D_d]$ in the approximation is denoted by $\psi_{[D_p,D_d]}$. The problem here is that some components of μ may be negative, in which case the upper bound is assumed to be infinite. One can use a number of bases, D_p^l and D_d^l, $l = 1, \ldots, L$, and choose the solution corresponding to the best bound. Also, using the convex hull of D_p^l plus the nonnegative combination of D_d^l improves the bound obtained.

PROPOSITION 4. *Let D_p^l and D_d^l, $l = 1, \ldots, L$, be a collection of matrices as described above. Then*

$$\psi(t) \leq \psi_{con(D_p^l)+pos(D_d^l)}(t) \leq \inf_l \psi_{[D_p^l,D_d^l]},$$

where

$$\psi_{con(D_p^l)+pos(D_d^l)}(t) = \inf \left\{ v : \begin{bmatrix} v \\ t \end{bmatrix} = \sum_{l=1}^{L} \sum_{i=1}^{k_l'} \mu_i^l \begin{bmatrix} v_i^l \\ t_i^l \end{bmatrix} + \sum_{l=1}^{L} \sum_{i=k_l'+1}^{m'+1} \mu_i^l \begin{bmatrix} v_i^l \\ t_i^l \end{bmatrix} \right\},$$

$\sum_{l=1}^{L} \sum_{i=1}^{k_l'} \mu_i^l = 1$, *and* $\mu_i^l \geq 0$, $i = 1, \ldots, m'+1$, $l = 1, \ldots, L$.

Proof. Since $\text{epi}(\psi)$ is a convex polyhedron, any convex combination of vectors in $\text{epi}(\psi)$, such as the column vectors of D_p^l, $l = 1, \ldots, L$, plus a nonnegative combination of directions in $\text{epi}(\psi)$, such as the column vectors of D_d^l, $l = 1, \ldots, L$, is also in $\text{epi}(\psi)$. That is,

$$\text{epi}(\psi_{\text{con}(D_p^l)+\text{pos}(D_d^l)}) \subseteq \text{epi}(\psi).$$

Also, any feasible solution, μ_i^l, for $\text{epi}(\psi_{[D_p^l,D_d^l]})$ can be used to construct a feasible solution for $\text{epi}(\psi_{\text{con}(D_p^l)+\text{pos}(D_d^l)})$. Therefore,

$$\text{epi}(\psi_{[D_p^l,D_d^l]}) \subseteq \text{epi}(\psi_{\text{con}(D_p^l)+\text{pos}(D_d^l)}).$$

The statement of the proposition follows by taking the infimum of the components corresponding to the objective function value, v, over the three polyhedral sets. □

In order to obtain a good approximation, it is clear that one may need to use a large number of bases. Of course, the goal is to have a small number of bases that cover the range of possible t and that provide reasonably accurate results. As an example, consider the following system of linear equations:

$$\begin{array}{cccccl} x_1 & & +x_3 & -x_4 & & = t_1, \\ & x_2 & +x_3 & & -x_5 & = t_2, \\ x_1, & x_2, & x_3, & x_4, & x_5 & \geq 0 \end{array}$$

with the objective function $x_1 + x_2 + x_3 + 100x_4 + 100x_5$. Let us assume that t can only take its values from the first quadrant. If we choose

$$\begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}$$

as an approximating basis, our approximation is exact for all right-hand side vectors such that $t_1 \geq t_2$, but we pay a very large price for vectors of the form $t_1 < t_2$. Also, using the basis

$$\begin{bmatrix} 0 & 1 \\ 1 & 1 \end{bmatrix}$$

results in very large objective function values for vectors that have $t_1 > t_2$. To obtain an exact approximation for all $t \geq 0$, we need to include both of the previous bases in our set of approximating bases. On the other hand, if we use the identity matrix as an approximating basis, we obtain a reasonable approximation for all possible vectors, t, while performing a smaller number of calculations. In other words, one basis that is suboptimal but covers a wide region is better than choosing an optimal basis that may end up very bad if conditions change. To avoid searching for good bases, we suggest using parametric programming in conjunction with our approximation to achieve reasonable bounds while using a single basis. The following section discusses this approach.

3. Using parametric programming. An alternative for the approximation of section 2 is to choose a set of vectors, t^k, and use scalar multiples of these vectors to represent a given right-hand side. In other words, we use the vectors $\lambda_k t^k$, $\lambda_k \in \Re$, to represent any right-hand side, t. Note that the function $\psi(\lambda_k t^k)$ is a piecewise-linear convex function of the parameter λ_k (see, for example, section 8.11 in [9]). The best upper bound is then obtained by solving the following program:

$$\begin{array}{llrcl} & \inf_{\lambda,\mu} & \displaystyle\sum_{k=1}^{K}\mu_k\psi(\lambda_k t^k) & & \\ (4) & \text{subject to} & \displaystyle\sum_{k=1}^{K}\mu_k\lambda_k t^k & = & t, \\ & & \displaystyle\sum_{k=1}^{K}\mu_k & = & 1, \\ & & \mu & \geq & 0. \end{array}$$

Let $\nu_k = \mu_k\lambda_k$. Then, the mathematical program (4) can be written in the form

$$\begin{array}{llrcl} & \inf_{\nu,\mu} & \displaystyle\sum_{k=1}^{K}\mu_k\psi(\frac{\nu_k}{\mu_k} t^k) & & \\ (5) & \text{subject to} & \displaystyle\sum_{k=1}^{K}\nu_k t^k & = & t, \\ & & \displaystyle\sum_{k=1}^{K}\mu_k & = & 1, \\ & & \mu & \geq & 0. \end{array}$$

Note that $\mu_k\psi(\frac{\nu_k}{\mu_k}t^k)$ is convex (see, for example, section 5 in [10]), hence the objective function of (5) is convex. However, the resulting approximation is not linear, and solving it may require more effort than solving the original program (2).

To simplify the calculations, the set of vectors t^k is chosen to form a basis for $\Re^{m'}$. In this case, we can write program (5) as

$$
\begin{array}{lll}
\inf_{\lambda,\mu} & \displaystyle\sum_{k=1}^{m'} \mu_k \psi(\lambda_k t^k) & \\
\text{subject to} & \mu_k \lambda_k = D_{k.}^{-1} t, & \\
 & \displaystyle\sum_{k=1}^{K} \mu_k = 1, & \\
 & \mu \geq 0, &
\end{array}
\tag{6}
$$

where D is the basis formed by taking t^k as its column vectors and $D_{k.}^{-1}$ is the kth row of D^{-1}. Note that in the previous program, the value of each μ_k determines the corresponding λ_k. To look for an approximate solution of (6), one can assume certain values for μ_k, compute the corresponding objective function values, and then take the lowest upper bound as an approximation for the objective function value of (2). The previous operation is not expensive if m' is relatively small.

Since the parametric linear programs, $\psi(\lambda_k t^k)$, $k = 1, \ldots, K$, are solved for all values of λ_k or, at least, for a wide range of positive and negative values, program (6) has an infinite number of feasible solutions for any given vector, t. In this case, a single basis is sufficient to cover the set of all possible right-hand side vectors, $t \in \Re^{m'}$. Here again, we have a generalization of the positive linear bases approach presented by Birge and Wets. They suggest solving the original linear program for each t^k and $-t^k$ to guarantee a representation of any vector t. In our case, we solve parametrically for each t^k and for all possible negative and positive values of the parameter λ_k. Here is an algorithmic description of our approximating procedure.

ALGORITHM. Given the parameters $\lambda_{\min} \leq 0 \leq \lambda_{\max}$, a step size $\Delta > 0$, and a basis, $D = [t^1, \ldots, t^{m'}]$, for A, we use the following procedure to approximate $\psi(t)$.

```
• Initialization. Evaluate $\psi(\lambda t^k)$, $k = 1, \ldots, m'$. The evaluation is performed
  for all values of $\lambda$ in the range $[\lambda_{\min}, \lambda_{\max}]$. Since $\psi$ is a piecewise-linear
  function of the parameter $\lambda$, we only need to evaluate $\psi$ at the break-points.
  Set $v \leftarrow \infty$.
• Compute the inverse $D^{-1}$.
• General step.
  1. Obtain a new right-hand side vector $t$.
  2. Set $\mu_1 = \cdots = \mu_{m'-1} = 0$.
     While $\mu_1 \leq 1$
         While $\mu_2 \leq 1 - \mu_1$
             ...
                 While $\mu_{m'-1} \leq 1 - \sum_{k=1}^{m'-2} \mu_k$
                     Set $\mu_{m'} = 1 - \sum_{k=1}^{m'-1} \mu_k$.
                     For $k = 1$ to $m'$
                         If $\mu_k = 0$, let $\lambda_k = 0$; otherwise, let $\lambda_k = D_{k.}^{-1} t / \mu_k$.
                     If $v > \sum_{k=1}^{m'} \mu_k \psi(\lambda_k t^k)$, then set $v = \sum_{k=1}^{m'} \mu_k \psi(\lambda_k t^k)$.
                 $\mu_{m'-1} \leftarrow \mu_{m'-1} + \Delta$
             ...
         $\mu_2 \leftarrow \mu_2 + \Delta$
     $\mu_1 \leftarrow \mu_1 + \Delta$
  3. The value of $v$ is the best upper bound for $\psi(t)$ using $D$.
```

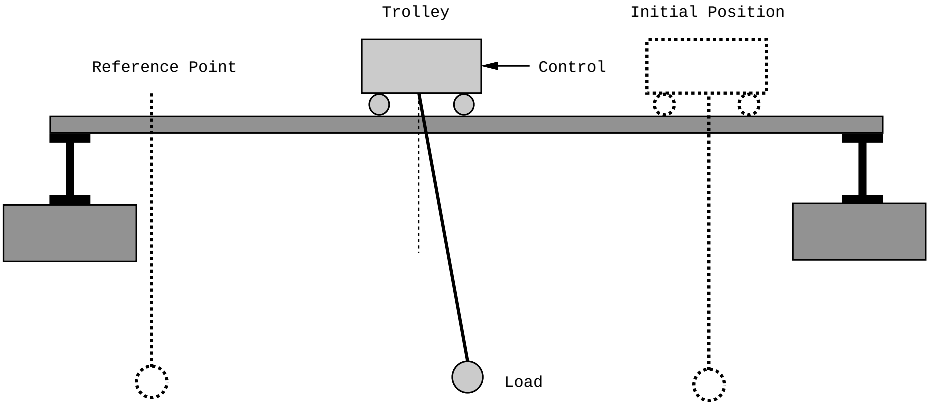

Fig. 1. *A crane control problem.*

4. Go to 1.

In the following section, we test our algorithm by applying it on a crane control problem.

4. Numerical results. To evaluate the procedure of section 3, we consider the feedback control example of [7, 8]. The example, which is depicted in figure 1, is based on a crane with an overhead trolley that runs on frictionless straight rails with its load suspended on an inextensible cable from its center of gravity. The objective is to move the trolley from a given position to a reference point with the load starting and finishing in a stationary position directly beneath the trolley. The state variables, x_1^i, x_2^i, x_3^i, and x_4^i, represent the position of the trolley (from the reference point), its velocity, the angle of the cable, and its angular velocity. The state of the system changes according to the linear equation

$$x^{i+1} = \begin{bmatrix} 1 & 0.3 & 0.036 & 0.0036 \\ & 1 & 0.234 & 0.036 \\ & & 0.92 & 0.292 \\ & & -0.526 & 0.92 \end{bmatrix} x^i + \begin{bmatrix} 0.08 \\ 0.534 \\ -0.08 \\ -0.526 \end{bmatrix} u^i + \alpha\beta w^i, \tag{7}$$

where α and β are scalars and w^i is the random disturbance at stage i. The control variable, u_i, is restricted to the range $[-1, 1]$. Starting at $[-5, 1, 0, 0]^T$ and using a study horizon of $T = 30$, the goal is to be as close as possible to the origin at any point in time. This requirement is approximated by minimizing the expectation over w^i of the function $\sum_{i=1}^{T} \sum_{j=1}^{m'} |x_j^i|$.

Since the size of such a problem may make on-line control practically infeasible, certainty equivalent controllers (CECs) are used to simplify the calculations. CECs apply, at each stage, the control that would be optimal if all uncertain quantities are fixed at their expected values (see, for example, section 4.1 of [2]). That is, given the initial state, x^0, we assume known conditions throughout the study horizon. The state transition equation takes the form $x^{i+1} = \mathcal{A}x^i + \mathcal{B}u^i + \alpha\beta E(w^i),\ i = 0,\ \ldots,\ T-1$, where $E(w^i)$ is the expected value of the noise term at stage i. At each time period, we apply the decision, u^0, obtained from solving the mathematical program

$$\begin{array}{llrl} (8) & \min_{x,u} & \displaystyle\sum_{i=1}^{T}\sum_{j=1}^{m'}|x_j^i| & \\ & \text{subject to} & x^{i+1} = & \mathcal{A}x^i + \mathcal{B}u^i + \alpha\beta E(w^i),\ i = 0,\ \ldots,\ T-1. \end{array}$$

If the resulting problem (8) is still large for an on-line controller, CECs are often combined with limited lookahead policies (see section 4.3 of [2]) to further reduce the size of the problem. The resulting mathematical program is to minimize the cost over the truncated horizon, $\mathcal{T}$,

$$\begin{array}{llrl} (9) & \min_{x,u} & \displaystyle\sum_{i=1}^{\mathcal{T}}\sum_{j=1}^{m'}|x_j^i| & \\ & \text{subject to} & x^{i+1} = & \mathcal{A}x^i + \mathcal{B}u^i + \alpha\beta E(w^i),\ i = 0,\ \ldots,\ \mathcal{T}-1. \end{array}$$

This approach results in significant computational savings at the cost of providing a suboptimal control. In general, the quality of the decision or control tends to improve as the value of $\mathcal{T}$ increases.

Our technique is basically an approximation for (8). The optimization problem (8) is solved parametrically for different right-hand side vectors, t^K, which are used to approximate the optimal value of (8) whenever a new state, x^0, is observed. At each stage, a suboptimal policy is constructed using the optimal policies

$$x^i = \sum_{k=1}^{K} \mu_k X_k^i(\lambda_k), \tag{10}$$

where $X_k^i(\lambda_k)$ is an optimal solution vector for (8) when the initial state of the system is $\lambda_k t^k$. The vectors λ and μ are obtained from solving (6). The error in our approximation is introduced in representing t as a combination of the vectors t^k. Since the effort needed to compute the upper bound of the approximation (6) is independent of the effort needed to approximate $\psi(\lambda_k t^k)$, it is best, at least in the deterministic case, to use the most accurate approximation for $\psi(\lambda_k t^k)$.

Here, we compare our approximation to the limited lookahead policies with horizons, $\mathcal{T}$, between 3 and 30 periods. In order to obtain a quick solution, we use the identity matrix as the approximating basis for (6). That is, the problem in (8) is solved parametrically for the right-hand side vectors $\lambda_k e_i^k$, $i = 1, \ldots, 4$, where λ_k is chosen to be between $\lambda_{\min} = -50$ and $\lambda_{\max} = 50$. The values of μ_i, $i = 1, \ldots, 4$, are varied between 0 and 1 using a step size of $\Delta = 0.2$.

As a third case, we consider a quadratic objective function subject to the constraints of (8) and assume that $T \to \infty$ so that we can derive a stationary linear feedback control. In this case, we assume that the objective function at each stage is to minimize the l_2 norm of the state vector. The resulting quadratic program has a stationary solution in which the optimal control, u^i, at any stage is a linear function of the state of the system

$$u^i = [-(\mathcal{B}^T\mathcal{K}\mathcal{B})^{-1}\mathcal{B}^T\mathcal{K}\mathcal{A}]x^i.$$

Here, $\mathcal{K}$ is the unique solution of the discrete-time Riccati equation

$$\mathcal{K} = \mathcal{A}^T[\mathcal{K} - \mathcal{K}\mathcal{B}(\mathcal{B}^T\mathcal{K}\mathcal{B})^{-1}\mathcal{B}^T\mathcal{K}]\mathcal{A} + I,$$

where I is the identity matrix. For our example, the solution of the Riccati equation is

$$\mathcal{K} = \begin{bmatrix} 7.376 & 5.387 & 0.979 & 4.635 \\ 5.387 & 12.562 & -2.609 & 10.514 \\ 0.979 & -2.609 & 9.347 & -1.531 \\ 4.635 & 10.514 & -1.531 & 10.729 \end{bmatrix},$$

and the resulting control is of the form

$$u^i = [-1.052, -2.329, 1.042, -0.143]x^i.$$

This control law is a rough approximation of an optimal policy for the linear model.

Table 1 compares the policy obtained by applying the parametric programming model of section 3 with both the lookahead policy and the stationary linear feedback policy. The first column in the table, $\mathcal{T}$, contains the number of stages used in the lookahead policy approximation of (9). The second column presents the objective function value of (9) over the full horizon of 50 periods for the deterministic case, $\mu = 0.0$. In general, the accuracy of the lookahead policies improves as the number of stages, $\mathcal{T}$, used in the approximation increases. The row labeled "Quadratic" provides the objective function value for the stationary linear feedback approach, while the row labeled "Polyhedral" provides the objective value if the approximation of section 3 is used. The approximation of section 3 provides a bound of 74.01, compared to a bound of 81.10 for the stationary linear feedback control. The optimal objective value, 69.94, corresponds to the limited lookahead policies when $\mathcal{T} = 30$. Using a lookahead approximation with a horizon smaller than 12 periods yields an inferior solution to the polyhedral approximation. We expect our approximation to improve as more bases are included. The CPU time required to compute the polyhedral approximation is almost the same as that required to solve the linear program (9) with $\mathcal{T} = 3$. The time needed to solve (9) increases as the number of stages considered is increased. The quadratic linear feedback model is 10 times faster than the polyhedral approximation since it only involves matrix multiplication. However, the solution produced by the linear feedback policy is 10.1% worse than that of the polyhedral approximation.

In order to incorporate the effect of random noise into the problem, we assume that the state vector, x^{i+1}, at time $i+1$ is given as a linear function of the state of the system at time i, plus a random noise vector $\alpha\beta w^i$. Each component of w^i is a uniformly distributed random variable over the open interval (–0.5, 0.5). Solving this problem, with an expected value objective as in (7), yields a stochastic program that may be quite difficult to solve in real time. The CEC combined with limited lookaheads is one approach to achieve an approximate solution. In this case, we resolve (9) with the current state, x^i, and expectations for future conditions. Our approximation applies to this problem as well, but here we may benefit by a more robust basis than in limited lookaheads. The linear feedback approximation may also benefit in this case.

We use three values for the coefficient α: 0.01, 0.05, and 0.10. For the limited lookahead strategy of (9), we assume that the value of the coefficient β is a function of the study horizon, $\mathcal{T}$. It grows linearly with the size of the study horizon since the times needed to solve the linear programs involved increase with $\mathcal{T}$. The effect of the number of stages is assumed to be $\beta = \mathcal{T}/3$. The reason for this assumption is that the execution time of the limited lookahead model (9) increases as $\mathcal{T}$ increases, which results in a wider range for the random disturbance. On the other hand, the polyhedral

Table 1
Comparison of different approximations.

$\mathcal{T}$	$\alpha = 0.0$	$\alpha = 0.01$	$\alpha = 0.05$	$\alpha = 0.10$

14	73.59	98.30	322.20	1568.85
15	73.27	100.51	364.31	1807.80
16	73.06	103.95	439.03	2045.91
17	71.36	104.98	499.91	2273.62
18	71.64	103.57	562.90	2506.10
19	71.60	107.28	633.87	2717.86
20	70.06	108.83	737.30	2898.79
25	69.94	120.41	1209.84	4072.42
30	69.94	131.87	1819.55	5248.97
Quadratic	81.10	81.24	82.01	83.34
Polyhedral	74.01	75.20	85.44	100.26

and quadratic approximation times do not increase with the horizon. Therefore, we can consider β fixed for these approximations. Since the polyhedral approximation requires time comparable to a three stage ($\mathcal{T} = 3$) horizon, we use $\beta = 1$ for that method. The linear feedback control from the quadratic model is 10 times faster than our serial polyhedral implementation, so we choose $\beta = 0.1$ in that case.

The results are shown in columns 3, 4, and 5 of Table 1. Note that the best bound provided by the limited lookahead strategy is always higher than that produced by the polyhedral approximation. This is a result of increasing β with the size of the problem that needs to be solved when limited lookahead is used. Our approximation seems to produce reasonable results even when α is set to 0.10. Note that the linear feedback control produces better results for $\alpha = 0.05$ and $\alpha = 0.10$ since the value of β used is relatively small. However, we expect our results to improve if we use parallel computers to cut down the calculation time.

5. Conclusions. We gave an approximate solution method for linear control problems with varying initial state conditions that require rapid solutions. We showed characteristics of the approximation that guarantee bounds on the solution of the linear optimization problem. As shown in an example, our approximation has an efficiency advantage over an optimal policy for deterministic problems with quite accurate results for longer time horizons (error of 5.8%). The corresponding linear feedback controller had an error of 16.0% for the same problem. In addition, our policy was effective in a stochastic system in reducing the error by more than 14.3% over the limited lookahead policies while maintaining low computational requirements.

Acknowledgments. The authors would like to thank the associate editor and the referees for their constructive comments, especially for pointing out that (5) is convex.

A NEW ALGORITHM FOR STATE-CONSTRAINED SEPARATED CONTINUOUS LINEAR PROGRAMS[*]

XIAODONG LUO[†] AND DIMITRIS BERTSIMAS[‡]

Abstract. During the last few decades, significant progress has been made in solving large-scale finite-dimensional and semi-infinite linear programming problems. In contrast, little progress has been made in solving linear programs in infinite-dimensional spaces despite their importance as models in manufacturing and communication systems. Inspired by the research on separated continuous linear programs, we propose a new class of continuous linear programming problems that has a variety of important applications in communications, manufacturing, and urban traffic control. This class of continuous linear programs contains the separated continuous linear programs as a subclass. Using ideas from quadratic programming, we propose an efficient algorithm for solving large-scale problems in this new class under mild assumptions on the form of the problem data. We prove algorithmically the absence of a duality gap for this class of problems without any boundedness assumptions on the solution set. We show this class of problems admits piecewise constant optimal control when the optimal solution exists. We give conditions for the existence of an optimal solution. We also report computational results which illustrate that the new algorithm is effective in solving large-scale realistic problems (with several hundred continuous variables) arising in manufacturing systems.

Key words. continuous linear programming, strong duality, semi-infinite linear programming, nonlinear programming, jobshop scheduling problems

1. Introduction.

Bellman [7, 8] introduced the following optimization problem:

$$
\begin{aligned}
(CLP)\ \text{minimize} & \int_0^T c(t)'x(t)\ dt \\
\text{subject to (s.t.)}\ \ & A(t)x(t) + \int_0^t B(s,t)x(s)\ ds \le b(t), \\
& x(t) \ge 0, \qquad t \in [0,\ T],
\end{aligned}
$$

where $A(t)$ and $B(s,t)$ are matrices depending on time (their entries are bounded measurable functions) and $b(t)$ and $c(t)$ are bounded measurable functions. (CLP) is an instance of a *continuous linear program.*

The problem that has attracted the most attention is the *separated continuous linear programming* problem (SCLP), a subclass of the continuous linear programming problem:

$$
(SCLP)\ \text{minimize} \int_0^T c(t)'u(t)\ dt
$$

$$\text{s.t.} \int_0^t Gu(t)\ dt + y(t) = a(t), \tag{1}$$

$$\begin{aligned} &Hu(t) \leq b(t), \\ &y(t),\ u(t) \geq 0, \qquad t \in [0,\ T], \end{aligned}$$

where $y(t)$ and $a(t)$ are absolutely continuous functions. Note that the variables $u(t)$ and $y(t)$ are linked only through (1), in which $u(t)$ appears only under the integration operator and $y(t)$ does not appear under the integration operator. The problem $(SCLP)$ was first introduced by Anderson [4] in order to model job-shop scheduling problems (see also Avram, Bertsimas, and Ricard [6], Weiss [49]).

In this paper, we examine a larger subclass of continuous linear programs which can be used to model a variety of problems that arise in communications, manufacturing, and urban traffic control (see Luo [32]). The problem we consider is the following:

$$(SCSCLP)\ \text{minimize} \int_0^T (c(t)'u(t) + g(t)'y(t))\ dt$$

$$\text{s.t.} \quad \int_0^t Gu(t)\ dt + Ey(t) = a(t), \tag{2}$$

$$Hu(t) \leq b(t), \tag{3}$$

$$Fy(t) \leq h(t), \tag{4}$$

$$u(t) \geq 0, \qquad t \in [0,\ T],$$

where $b(t)$, $c(t)$, $g(t)$, and $h(t)$ are bounded measurable functions and $a(t)$ is an absolutely continuous function. The dimensions of $b(t)$, $a(t)$, $u(t)$, $y(t)$, and $h(t)$ are n_1, n_2, n_3, n_4, and n_5, respectively. We call $(SCSCLP)$ the *state-constrained separated continuous linear programs.* We call $y(t)$ the state variable and $u(t)$ the control variable. We call (2) the state equation (or sometimes we use the term system dynamics) and call (4) the state constraint. We call (3) the control constraint.

Related literature. The computational study of CLP was initiated by Lehman [26] who attempted to develop a simplex-like algorithm for CLP. Drews [10], Hartberger [20], and Segers [44] later followed him. Perold [37, 38] developed the first simplex-like algorithm for CLP (see also Anderson, Nash, and Perold [1] and Anderson and Philpott [3]. Anstreicher [5] continued Perold's work in his Ph.D. thesis, even though both their algorithms were still incomplete. In the meantime, Russian authors such as Ilyutovich [21, 22] treated the problem using Pontryagin's maximum principle. In addition, Ito, Kelley, and Sachs [23] have developed a primal-dual path, following interior point method for CLP. Anderson and Nash in [2] proposed a convex quadratic programming procedure for $(SCLP)$. The series of papers on SCLP by Pullan [41, 42, 43] deals with solution structure, duality theory, and numerical algorithms and to the best of our knowledge represents the state of the art of this area. Philpott and Craddock [39] later specialized Pullan's work to a network version of SCLP and presented encouraging numerical results.

Objective and contributions. In this paper, we will develop a new algorithm for solving SCSCLP problems under Assumption 1 below. The new algorithm uses discretization. Unlike the algorithms mentioned above, it varies the discretization and control simultaneously. Based on the number of constant pieces allowed in the control, we develop a quadratic program with polyhedral constraints. The quadratic program is generally nonconvex. However, we do not need to solve the quadratic program to optimality. We only need to obtain a KKT point. We use the Frank–Wolfe method (see Martos [33] and Murty [36]) or general matrix-splitting algorithms (see Lin and Pang [28], Eckstein [11], Bertsekas and Tsitsiklis [9], Luo and Tseng [31]) to find a KKT point for the quadratic program. By gradually increasing (and occasionally decreasing) the number of pieces allowed in the control, we can improve upon any nonoptimal KKT solution. We call this the successive quadratic programming method. By a KKT solution structural result of Luo and Tseng [31], we show that the iterates of the algorithm move from one polyhedral set to another, with improved cost. By bounding the size of the quadratic programs we encounter, we bound the number of all such polyhedral sets. We show that the new algorithm converges in finite time. The absence of a duality gap and the existence of certain highly structured optimal solutions for ($SCSCLP$) follow as byproducts. Furthermore, we have implemented our algorithm and report computational results which illustrate that the new algorithm is effective in solving large scale realistic problems (with several hundred continuous variables) arising in manufacturing systems.

Structure of the paper. The remainder of this paper is structured as follows. In section 2, we introduce the dual problem for ($SCSCLP$) (called ($SCSCLP^*$)) and state our assumptions. We also prove weak duality results between ($SCSCLP$) and ($SCSCLP^*$) and introduce some standard definitions and notations. In section 3, we develop a quadratic program with polyhedral constraints. In section 3.1, we review some nonlinear programming techniques for calculating a KKT point of a quadratic program with polyhedral constraints. In section 4, we develop a procedure for removing redundant intervals in a feasible solution for ($SCSCLP$). In section 5, we introduce a new discrete approximation for ($SCSCLP$) which is closely related to the dual problem. From this discrete approximation, we derive a criterion to detect whether a feasible solution is optimal for ($SCSCLP$). If the criterion is not satisfied, we derive a descent direction for the feasible solution to ($SCSCLP$). In section 6, we formally state the new algorithm. In section 7, we prove that the new algorithm converges in finite time. In section 8, we use the new algorithm to prove new duality results and new optimal solution structural results for ($SCSCLP$). In section 9, we report computational results that illustrate the effectiveness of the new algorithm in solving large-scale problems. The reader is advised to first read sections 2 and 6 to obtain a general idea of the problem, the assumptions, and the new algorithm.

2. Definitions and notation. First, we reiterate problem ($SCSCLP$) and state our assumptions. We consider the problem

$$
\begin{aligned}
(SCSCLP)\ \text{minimize} & \int_0^T (c(t)'u(t) + g(t)'y(t))\ dt \\
\text{s.t.} \qquad & \int_0^t Gu(t)\ dt + Ey(t) = a(t), \\
& Hu(t) \le b(t), \\
& Fy(t) \le h(t), \\
& u(t) \ge 0, \qquad t \in [0,\ T],
\end{aligned}
$$

and its dual

$$
(SCSCLP^*)\ \text{maximize} - \int_0^T a(t)'\ d\pi(t) - \int_0^T b(t)'\eta(t)\ dt - \int_0^T h(t)'\ d\xi(t)
$$

$$\begin{aligned} \text{s.t.} \qquad & c(t) - G'\pi(t)\ dt + H'\eta(t) \geq 0, \\ & E'\pi(t) + F'\xi(t) = \int_t^T g(t)\ dt, \\ & \pi(t) \text{ bounded measurable with finite variation,} \\ & \xi(t) \text{ monotonic increasing and right continuous} \\ & \qquad \text{on } [0,\ T] \text{ with } \xi(T) = 0, \quad \pi(T) = 0, \\ & \eta(t) \geq 0, \qquad \text{for } t \in [0,\ T], \end{aligned}$$

under the following assumptions (we will give a formal definition of piecewise linear (constant) functions later in this section).

Assumption 1.

a) *$a(t)$ and $h(t)$ are continuous,*

b) *$a(t)$, $c(t)$, and $h(t)$ are piecewise linear,*

c) *$b(t)$ and $g(t)$ are piecewise constant,*

d) *Problem ($SCSCLP$) is feasible and its objective value is bounded from below.*

We require that $u(t)$, $y(t)$, and $\eta(t)$ are bounded and measurable functions on $[0,\ T]$. We remark that the dual problem ($SCSCLP^*$) reduces to the alternative dual problem for ($SCLP$) introduced by Pullan [41] when the primal problem is an SCLP.

We have the following weak duality results for ($SCSCLP$). For completeness, we give its proof.

Proposition 1. *Weak duality holds between ($SCSCLP$) and ($SCSCLP^*$).*

Proof. Consider any two solutions $(u(t),\ y(t))$ and $(\pi(t),\ \eta(t),\ \xi(t))$ which are feasible to ($SCSCLP$) and ($SCSCLP^*$), respectively. Let $z(t) = b(t) - Hu(t)$ and $\bar{z}(t) = h(t) - Fy(t)$. We have

$$\begin{aligned} & \int_0^T (c(t)'u(t) + g(t)'y(t))\ dt - \left(- \int_0^T a(t)'\ d\pi(t) - \int_0^T b(t)'\eta(t)\ dt - \int_0^T h(t)'\ d\xi(t) \right) \\ & = \int_0^T (c(t)'u(t) + g(t)'y(t))\ dt + \int_0^T a(t)'\ d\pi(t) + \int_0^T b(t)'\eta(t)\ dt + \int_0^T h(t)'\ d\xi(t) \\ & = \int_0^T (c(t)'u(t) + g(t)'y(t))\ dt + \int_0^T \left(\int_0^t Gu(s)\ ds + Ey(t) \right)'\ d\pi(t) \\ & \quad + \int_0^T (Hu(t) + z(t))'\eta(t)\ dt + \int_0^T (Fy(t) + \bar{z}(t))'d\xi(t) \\ & = \int_0^T (c(t)'u(t) + g(t)'y(t))\ dt - \int_0^T \pi(t)'Gu(t)\ dt + \int_0^T (Ey(t))'\ d\pi(t) \\ & \quad + \int_0^T (Hu(t) + z(t))'\eta(t)\ dt + \int_0^T (Fy(t) + \bar{z}(t))'d\xi(t) \\ & = \int_0^T (c(t) - G'\pi(t) + H'\eta(t))'\ u(t)\ dt \\ & \quad + \int_0^T y(t)'\ d\left(E'\pi(t) + F'\xi(t) - \int_t^T g(t)\ dt \right) \\ & \quad + \int_0^T z(t)'\eta(t)\ dt + \int_0^T \bar{z}(t)'d\xi(t) \end{aligned}$$

$$= \int_0^T \left(c(t) - G'\pi(t) + H'\eta(t)\right)' u(t)\ dt + \int_0^T z(t)'\eta(t)\ dt + \int_0^T \bar{z}(t)'d\xi(t)$$
$$\geq 0.$$

Note that in general $\int_0^T (Fy(t))'d\xi(t)$ and $\int_0^T \bar{z}(t)'d\xi(t)$ may not exist since neither $y(t)$ nor $\bar{z}(t)$ needs to be continuous. However, since

$$\int_0^T y(t)'\ d\left(E'\pi(t) + F'\xi(t) - \int_t^T g(t)\ dt\right) = 0,$$

we have

$$\begin{aligned}\int_0^T y(t)'\ dF'\xi(t) &= \int_0^T y(t)'\ d\left(E'\pi(t) + F'\xi(t) - \int_t^T g(t)\ dt\right)\\ &\quad - \int_0^T y(t)'\ d\left(E'\pi(t) - \int_t^T g(t)\ dt\right)\\ &= - \int_0^T y(t)'\ d\left(E'\pi(t) - \int_t^T g(t)\ dt\right),\end{aligned}$$

which implies that $\int_0^T y(t)'\ dF'\xi(t)$ exists. The existence of $\int_0^T \bar{z}(t)'d\xi(t)$ now follows from the existence of both $\int_0^T y(t)'\ dF'\xi(t)$ and $\int_0^T (Fy(t) + \bar{z}(t))'d\xi(t)$ since

$$\int_0^T \bar{z}(t)'d\xi(t) = \int_0^T (Fy(t) + \bar{z}(t))'d\xi(t) - \int_0^T y(t)'\ dF'\xi(t). \qquad \square$$

The requirement that $\pi(t)$ is bounded, measurable, and of finite variation in $(SCSCLP^*)$ is important, as it makes the integration by parts valid in the proof of the above proposition (see also Harrison [19]). As a consequence of the proof, we have the following corollary.

COROLLARY 1. *Strong duality holds between* $(SCSCLP)$ *and* $(SCSCLP^*)$ *if and only if there exist* $(u(t),\ y(t))$ *and* $(\pi(t),\ \eta(t),\ \xi(t))$ *which are feasible to* $(SCSCLP)$ *and* $(SCSCLP^*)$*, respectively, and satisfy the following conditions:*

$$\begin{aligned}&\int_0^T \left(c(t) - G'\pi(t) + H'\eta(t)\right)' u(t)\ dt = 0,\\ &\int_0^T (b(t) - Hu(t))'\eta(t)\ dt = 0,\\ &\int_0^T (h(t) - Fy(t))'d\xi(t) = 0.\end{aligned} \tag{5}$$

We call all three equations in (5) the complementary slackness condition for $(SCSCLP)$ and $(SCSCLP^*)$.

The following are standard definitions and notations which we will use throughout the remainder of the paper.

We call a sequence of time epochs $P = \{t_0, \ldots, t_p\}$ a partition of $[0,\ T]$ if

$$0 = t_0 \leq t_1 \leq \cdots \leq t_p = T.$$

We use $|P|$ to denote the cardinality of P. Note that since our development sometimes treats t_i as a variable, we allow $t_i = t_{i-1}$ for some $i \geq 1$ and always treat t_i and t_{i-1} as two different variables.

We say that a function $f(t)$ is piecewise constant (linear) with a partition $P = \{t_0, \ldots, t_p\}$ if $f(t)$ is constant (linear) on $[t_{i-1},\ t_i)$ for $i = 1, \ldots, p$. We say $f(t)$ is piecewise constant (linear) on $[0,\ T]$ if $f(t)$ is piecewise constant (linear) with some partition of $[0,\ T]$.

Let $P = \{t_0, \ldots, t_p\}$ be a partition of $[0,\ T]$. Throughout this paper, we assume Assumption 1 holds. In particular, we assume that $a(t)$, $h(t)$, and $c(t)$ are piecewise linear and $b(t)$ and $g(t)$ are piecewise constant with partition P. Let $\mathcal{B}$ be the set of breakpoints of $a(t)$, $b(t)$, $c(t)$, $g(t)$, and $h(t)$. For each breakpoint in $\mathcal{B}$, we select one element t_i in P such that its value denotes the same time in $[0,\ T]$ as the breakpoint. We always select $t_0 = 0$ and $t_p = T$. We denote D^P to be the set of selected elements of P excluding t_0 and t_p. Let $D_1^P = D^P \bigcup \{t_0, t_p\}$. We sometimes omit the superscript P when the context is clear.

We say that an interval $[t_{i-1},\ t_i]$ is a subinterval of $[t_l,\ t_m]$, where t_l and t_m are two consecutive breakpoints in D_1^P, if $l \leq i-1 < i \leq m$. In this case, we also say that t_{i-1}, t_i, and $[t_{i-1},\ t_i]$ reside on $[t_l,\ t_m]$.

For a function $f(t)$, we will use the notation

$$f(t-) = \lim_{s \to t-} f(s) \qquad \text{and} \qquad f(t+) = \lim_{s \to t+} f(s),$$

when the above limits exist and t is not equal to any breakpoint in D_1^P. If $[t_{i-1},\ t_i]$ is a zero-length subinterval of $[t_l,\ t_m]$, where t_l and t_m are two consecutive breakpoints in D_1^P, we let

$$f(t_i-) = \begin{cases} \lim_{s \to t_i-} f(s) & \text{if } t_i = t_m, \\ \lim_{s \to t_i+} f(s) & \text{if } t_i = t_l, \end{cases}$$

and let $f(t_{i-1}+) = f(t) = f(t_i-)$. We note that the value of $f(t_i)$ is sensitive to both the value of t_i and its index i.

Given $t_i \neq t_{i-1}$ for $i = 1, \ldots, p$ and a set of $2p$ numbers $\hat{f}(t_0+)$, $\hat{f}(t_1-)$, $\hat{f}(t_1+), \ldots,$ $\hat{f}(t_{p-1}+)$, $\hat{f}(t_p-)$, the function $f(t)$ defined by

$$f(t) = \begin{cases} \hat{f}(t_i+) & \text{if } t = t_0, t_1, \ldots,\ t_{p-1}, \\ 0 & \text{if } t = T, \\ \frac{t_i - t}{t_i - t_{i-1}} \hat{f}(t_{i-1}+) + \frac{t - t_{i-1}}{t_i - t_{i-1}} \hat{f}(t_i-) & \text{for } t \in (t_{i-1},\ t_i),\ i = 1, \ldots, p \end{cases}$$

is called the piecewise-linear extension of these $2p$ numbers; for a set of p numbers $\hat{f}(t_0+)$, $\hat{f}(t_1+)$, $\ldots$, $\hat{f}(t_{p-1}+)$, the function $f(t)$ defined by

$$f(t) = \begin{cases} \hat{f}(t_{p-1}+) & t = T, \\ \hat{f}(t_{i-1}+) & \text{for } t \in [t_{i-1},\ t_i),\ i = 1, \ldots, p \end{cases}$$

is called the piecewise constant extension of these p variables.

For two functions $f(t)$ and $g(t)$, we denote $\int_a^b f(t)\ dg(t)$ as the Lebesgue–Stieltjes integral of $f(t)$ with respect to $g(t)$ from a to b, given that the integral exists, including both a and b. For any mathematical program (LP) we let $V(\text{LP})$ be the optimal value of the objective function, which may not be attained. For any feasible solution x of (LP), we let $V(\text{LP}, x)$ be the solution value of x in (LP). For any n-dimensional

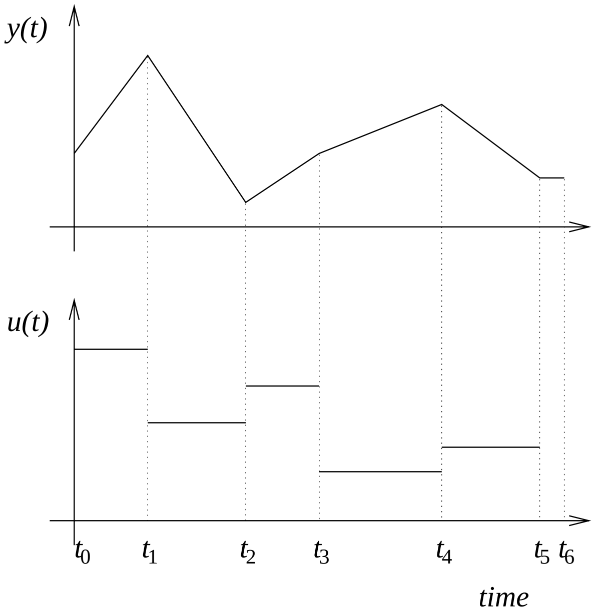

FIG. 1. *A piecewise constant optimal control for* $(SCLP)$.

vector x, we denote by x_i the ith coordinate of x, and, for any nonempty subset $Q \subseteq \{1,\ldots,n\}$, we use x_Q, $[x]_Q$, or $(x)_Q$ to denote the vector with components x_i, $i \in Q$ (with x_i arranged in the same order as in x). For a matrix A, we denote by A_{ij} the jth element of the ith row of matrix A and denote by $A_{i\bullet}$ the ith row of A.

3. A quadratic programming subproblem.

By a result of Pullan [42] (see also Anderson and Nash [2]), there exists an optimal basic feasible solution to $(SCLP)$ whose $u(t)$ is piecewise constant (see Figure 1) when Assumption 1 holds and the solution set to $(SCLP)$ is bounded. We will prove later in the paper that this remains true for $(SCSCLP)$. For any feasible control $u(t)$ that is piecewise constant with respect to a partition P, we have the following standard linear approximation problem (see Pullan [41] and the references therein):

$$
\begin{aligned}
DP(P)\min & \sum_{i=1}^{p}(t_i - t_{i-1})\hat{u}(t_{i-1}+)'c\left(\frac{t_i + t_{i-1}}{2}\right) \\
& + \sum_{i=1}^{p}\frac{t_i - t_{i-1}}{2}(\hat{y}(t_i) + \hat{y}(t_{i-1}))'g(t_{i-1}+) \\
\text{s.t. } & E\hat{y}(t_0) = a(t_0), \\
& (t_i - t_{i-1})G\hat{u}(t_{i-1}+) + E\hat{y}(t_i) - E\hat{y}(t_{i-1}) = a(t_i) - a(t_{i-1}), \\
& \qquad i = 1,\ldots,p, \\
& H\hat{u}(t_{i-1}+) \le b(t_{i-1}+), \qquad i = 1,\ldots,p, \\
& F\hat{y}(t_i) \le h(t_i), \qquad i = 0,\ldots,p, \\
& \hat{u}(t_{i-1}+) \ge 0, \qquad i = 1,\ldots,p,
\end{aligned}
$$

where we have the convention that $c(\frac{t_i+t_{i-1}}{2}) = c(t_i-)$ whenever $t_i = t_{i-1}$. Note that even though it is possible that $t_i = t_{i-1}$ for some $i \geq 1$, we still treat $\hat{u}(t_i+)$ and $\hat{u}(t_{i-1}+)$ as separate variables. If $(\hat{u},\ \hat{y})$ is a feasible solution to $DP(P)$, where partition P satisfies $t_i \neq t_{i-1}$ for all i, the piecewise constant extension of $\hat{u}$, together with the piecewise-linear extension of $\hat{y}$, defines a feasible solution to $(SCSCLP)$ with the same cost, due to Assumption 1. If we fix the partition, $DP(P)$ is a linear programming problem. So, once an optimal partition P is known, an optimal solution can be computed by solving the linear program $DP(P)$.

However, we do not know the optimal partition in advance. The algorithms proposed by Pullan [41] and by Philpott and Craddock [39] alternatively do the following two steps:

1) Improve the control for the current partition.
2) Improve the partition.

In contrast, the algorithm we propose improves both the control and partition at the same time.

By introducing new variables

$$\hat{v}(t_i) = (t_i - t_{i-1})\hat{u}(t_{i-1}+), \tag{6}$$

we can eliminate variable $\hat{u}$ from $DP(P)$ and obtain the following simpler mathematical programming problem in variables $\hat{v}$, $\hat{y}$, and $\hat{t}$, with $\hat{t}$ being the vector of t_i's such that $t_i \notin D_1^P$:

$$\begin{aligned} QP(|P|) \min \sum_{i=1}^{p} \hat{v}(t_i)' c\left(\frac{t_i + t_{i-1}}{2}\right) + \sum_{i=1}^{p} \frac{t_i - t_{i-1}}{2}(\hat{y}(t_i) + \hat{y}(t_{i-1}))' g(t_{i-1}+) \\ \text{s.t. } E\hat{y}(t_0) = a(t_0), \\ G\hat{v}(t_i) + E\hat{y}(t_i) - E\hat{y}(t_{i-1}) = a(t_i) - a(t_{i-1}), \\ i = 1, \dots, p, \\ H\hat{v}(t_i) \leq (t_i - t_{i-1})b(t_{i-1}+), \qquad i = 1, \dots, p, \\ F\hat{y}(t_i) \leq h(t_i), \qquad i = 0, \dots, p, \\ 0 = t_0 \leq t_1 \leq \cdots \leq t_p = T, \\ \hat{v}(t_i) \geq 0, \qquad i = 1, \dots, p, \end{aligned} \tag{7}$$

where $c(\frac{t_i+t_{i-1}}{2}) = c(t_i-)$ whenever $t_i = t_{i-1}$. Note that the breakpoints in D_1^P are fixed and are not variables. We treat both $\hat{v}(t_i)$ and $\hat{y}(t_i)$ as variables. Let t_l and t_m be two consecutive breakpoints in D_1^P. For any $i \in (l,\ m]$, $c(\frac{t_i+t_{i-1}}{2})$, $a(t_i) - a(t_{i-1})$, and $h(t_i)$ are the following linear functions of t_i and t_{i-1} (note that by Assumption 1b, $c(t)$, $a(t)$, and $h(t)$ are piecewise linear and therefore $\dot{c}(t)$, $\dot{a}(t)$, and $\dot{h}(t)$ are piecewise constant):

$$\begin{aligned} c\left(\frac{t_i + t_{i-1}}{2}\right) &= c(t_l) + \frac{t_i + t_{i-1} - 2t_l}{2}\dot{c}(t_l+), \\ a(t_i) - a(t_{i-1}) &= (t_i - t_{i-1})\dot{a}(t_l+), \\ h(t_i) &= h(t_l) + (t_i - t_l)\dot{h}(t_l+), \end{aligned}$$

and $g(t_{i-1}+) = g(t_l)$ and $b(t_{i-1}+) = b(t_l)$ are constant vectors. So, $QP(|P|)$ is a quadratic programming problem with polyhedral constraints.

Given a feasible solution $(\hat{v},\ \hat{y},\ \hat{t})$ to $QP(|P|)$ such that $t_i \neq t_{i-1}$ for all i, we can obtain a feasible solution $(\hat{u}, \hat{y})$ to problem $DP(P)$ with P defined from vector $\hat{t}$ and the breakpoints in D_1^P and $\hat{u}$ defined from

$$\hat{u}(t_{i-1}+) = \frac{\hat{v}(t_i)}{t_i - t_{i-1}}. \tag{8}$$

Equation (6) defines an injective mapping from the solution set to $DP(P)$ to the solution set to $QP(|P|)$. The two related solutions have the same solution value.

However, if $t_i = t_{i-1}$ but $\hat{v}(t_i) \neq 0$ for some i, the right-hand side of (8) is not properly defined, i.e., there may be a solution to $QP(|P|)$ for which the corresponding solution to $DP(P)$ cannot be constructed. We overcome this difficulty by constantly removing redundant zero-length intervals in a feasible solution and by using only the solution $(\hat{v},\ \hat{y},\ \hat{t})$ to $QP(|P|)$ that satisfies

$$t_i \neq t_{i-1} \quad \text{for all} \quad i \geq 1 \tag{9}$$

to construct a feasible solution for $DP(P)$ (and so for $(SCSCLP)$). When some zero-length intervals cannot be removed, we show that there is a series of feasible solutions to $QP(|P|)$ that satisfies (9) whose solution value becomes arbitrarily close to that of the feasible solution to $QP(|P|)$. This is key to understanding the absence of a duality gap result between $(SCSCLP)$ and $(SCSCLP^*)$, as we will see later on.

LEMMA 1. *Suppose $u(t)$ in all feasible solutions to $(SCSCLP)$ is bounded. Let $(\hat{v},\ \hat{y},\ \hat{t})$ be a feasible solution to $QP(|P|)$. Then*

$$\hat{v}(t_i) = 0 \quad \textit{whenever} \quad t_i = t_{i-1}. \tag{10}$$

Proof. Suppose $t_i = t_{i-1}$ for some i, but $\hat{v}(t_i) \neq 0$. Let $[t_l,\ t_m]$ be the interval t_i resides on, where t_l and t_m are two consecutive breakpoints in D_1^P. Without loss of generality, we may assume that there exists a positive-length subinterval of $[t_l,\ t_m]$ that is adjacent to $[t_{i-1},\ t_i]$ (since we can switch the values of $\hat{v}(t_j)$ and $\hat{y}(t_j)$ with adjacent zero-length subintervals on $[t_l,\ t_m]$ and maintain the feasibility of the solution). We assume that the adjacent positive-length subinterval on $[t_l,\ t_m]$ is $[t_{i-2},\ t_{i-1}]$. When the adjacent positive-length subinterval of $[t_l,\ t_m]$ is $[t_i,\ t_{i+1}]$, a similar analysis applies.

For any $\tau \in (0,\ 1)$, it is easy to verify that the following solution is feasible for $QP(|P|)$:

$$\tilde{t}_j^\tau = \begin{cases} t_j & \text{if } j \neq i-1 \text{ and } j \neq i, \\ \tau t_{i-2} + (1-\tau)t_{i-1} & \text{if } j = i-1, \\ t_i & \text{if } j = i, \end{cases}$$

$$\tilde{v}^\tau(\tilde{t}_j^\tau) = \begin{cases} \hat{v}(t_j) & \text{if } j \neq i-1 \text{ and } j \neq i, \\ (1-\tau)\hat{v}(t_{i-1}) & \text{if } j = i-1, \\ \tau\hat{v}(t_{i-1}) + \hat{v}(t_i) & \text{if } j = i, \end{cases}$$

$$\tilde{y}^\tau(\tilde{t}_j^\tau) = \begin{cases} \hat{y}(t_j) & \text{if } j \neq i-1 \text{ and } j \neq i, \\ \tau\hat{y}(t_{i-2}) + (1-\tau)\hat{y}(t_{i-1}) & \text{if } j = i-1, \\ \hat{y}(t_i) & \text{if } j = i. \end{cases}$$

The basic idea is to split interval $[t_{i-2},\ t_{i-1}]$ into two intervals $[t_{i-2},\ \tau t_{i-2}+(1-\tau)t_{i-1}]$ and $[\tau t_{i-2} + (1-\tau)t_{i-1},\ t_{i-1}]$ and combine the second interval with $[t_{i-1},\ t_i]$. It is easy to check that $(\tilde{v}^\tau,\ \tilde{y}^\tau,\ \tilde{t}^\tau)$ is feasible for $QP(|P|)$ and has one less zero-length interval than $(\hat{v},\ \hat{y},\ \hat{t})$. Applying the same process repeatedly, we can eliminate all the zero-length intervals in the solution $(\hat{v},\ \hat{y},\ \hat{t})$.

Let $(\bar{v}^{\tau},\ \bar{y}^{\tau},\ \bar{t}^{\tau})$ be the resulting solution and let Q be the resulting partition. Hence, $(\bar{v}^{\tau},\ \bar{y}^{\tau},\ \bar{t}^{\tau})$ is feasible for $QP(|Q|)$. From this solution, we can construct a feasible solution for $DP(Q)$ (and thus for $(SCSCLP)$) by using (8). However, as τ tends to zero, the corresponding feasible solution to $DP(P)$ is unbounded from above (since the denominator in (8) goes to zero, but the numerator is bounded away from zero). Thus $u(t)$ in $(SCSCLP)$ is unbounded and this creates a contradiction. □

We remark that Lemma 1 implies that if $u(t)$ is bounded and E is an identity matrix (e.g., a bounded and feasible $(SCLP)$), then $\hat{y}(t_{i-1}) = \hat{y}(t_i)$ whenever $t_{i-1} = t_i$. In general, when (10) holds, it is possible that $\hat{y}(t_{i-1}) \neq \hat{y}(t_i)$ even if $t_{i-1} = t_i$. If in addition to (10), $\hat{y}(t_{i-1}) = \hat{y}(t_i)$ for some i such that $t_{i-1} = t_i$, then we can eliminate the zero-length interval $[t_{i-1},\ t_i]$ from $(\hat{v},\ \hat{y},\ \hat{t})$ while maintaining the feasibility and improving the solution value of the solution. This fact will be used later in section 4 to remove redundant intervals.

In general, $u(t)$ may not be bounded in a feasible solution to $(SCSCLP)$. It is possible that there is no feasible solution to $(SCSCLP)$ that is optimal for $(SCSCLP)$. This perhaps is the key difficulty in establishing the absence of a duality gap between $(SCSCLP)$ and $(SCSCLP^*)$ by conventional methods. Hence, we have the following relationship between $(SCSCLP)$ and $QP(|P|)$.

LEMMA 2. *Given any feasible solution* $(\hat{v},\ \hat{y},\ \hat{t})$ *to* $QP(|P|)$, *there exists a series of feasible solutions* $(\hat{v}^k,\ \hat{y}^k,\ \hat{t}^k)$ *to* $QP(|P|)$ *that satisfies* (9) *and whose solution value becomes arbitrarily close to that of* $(\hat{v},\ \hat{y},\ \hat{t})$ *as* k *tends to infinity.*

Proof. By using the same procedure used to prove Lemma 1, we can construct a solution $(\bar{v}^{\tau},\ \bar{y}^{\tau},\ \bar{t}^{\tau})$ which is feasible to $QP(|Q|)$ for some partition Q and satisfies (9). It is easily verified that the solution value of $(\bar{v}^{\tau},\ \bar{y}^{\tau},\ \bar{t}^{\tau})$ to $QP(|Q|)$ becomes arbitrarily close to that of $(\hat{v},\ \hat{y},\ \hat{t})$ as τ goes to zero. □

In fact, we can have $t_i \neq t_{i+1}$ and $t_{i-1} \neq t_{i-2}$ whenever $t_i = t_{i-1}$ in a local optimum for $QP(|P|)$. The existence of $\hat{v}(t_i) \neq 0$ but $t_i = t_{i-1}$ indicates the presence of the Dirac δ function in $u(t)$ at time t_i.

A direct consequence of Lemma 2 is $V((SCSCLP)) \leq V(QP(|P|))$ for all P. This fact enables us to solve $(SCSCLP)$ through solving $QP(|P|)$ for a series of partitions. We note that $V(QP(|P|)) = V(SCSCLP)$ does not imply that there is a feasible solution for $(SCSCLP)$, whose solution value is equal to $V(QP|P|)$, due to the possible presence of zero-length intervals in P.

3.1. Finding a KKT point for $QP(|P|)$.

We do not need to solve the nonconvex quadratic program $QP(|P|)$ to optimality, as we will see in section 6. We only need to compute a series of KKT points (or equivalently, stationary points) of a set of quadratic programs. We use the Frank–Wolfe method (see Martos [33] and Murty [36]) or general matrix-splitting algorithms (see Lin and Pang [28], Eckstein [11], Bertsekas and Tsitsiklis [9], Luo and Tseng [31]) to find a KKT point for the quadratic program. There are other methods for obtaining a KKT point, such as those proposed by Ye [51] and Kojima, Noma, and Yoshise [24].

4. Removing redundant intervals.

After finding a KKT point of $QP(|P|)$, it is possible that some zero-length intervals can be removed, as we noted following Lemma 1. It is also possible that some adjacent intervals can be merged while improving the solution value. The reduction of unnecessary control pieces in the solution is a key feature of the new algorithm. This enables us to prove the convergence of the new algorithm without requiring the norm of the maximal length interval in the discretization to tend to zero (cf. Pullan [41] and Philpott and Craddock [39]).

To do this, let $(\hat{v},\ \hat{y},\ \hat{t})$ be a feasible solution to $QP(|P|)$ and let $[t_{i-1},\ t_i]$ and $[t_i,\ t_{i+1}]$ be two adjacent intervals that reside on $[t_l,\ t_m]$, where t_l and t_m are two consecutive breakpoints in D_1^P. We eliminate t_i from P (or equivalently, combine $[t_{i-1},\ t_i]$ and $[t_i,\ t_{i+1}]$) and define a new feasible solution $(\tilde{v},\ \tilde{y},\ \tilde{t})$ for $QP(|P \setminus \{t_i\}|)$ as follows. Let $\tilde{v}$ be the vector formed by removing $\hat{v}(t_{i+1})$ from $\hat{v}$ and then replacing $\hat{v}(t_i)$ with $\hat{v}(t_i) + \hat{v}(t_{i+1})$, let $\tilde{y}$ be the vector formed by removing $\hat{y}(t_i)$ from $\hat{y}$, and let $\tilde{t}$ be the vector formed by removing t_i from $\hat{t}$.

Lemma 3. *Let $[t_{i-1},\ t_i]$ and $[t_i,\ t_{i+1}]$ be two adjacent intervals that reside on $[t_l,\ t_m]$, where t_l and t_m are two consecutive breakpoints in D_1^P. If*

$$(t_{i+1} - t_i)\hat{v}(t_i)'\dot{c}(t_{i-1}+) + (t_{i+1} - t_i)\hat{y}(t_{i-1})'g(t_{i-1}+) + (t_i - t_{i-1})\hat{y}(t_{i+1})'g(t_{i-1}+)$$

$$\leq (t_i - t_{i-1})\hat{v}(t_{i+1})'\dot{c}(t_{i-1}+) + (t_{i+1} - t_{i-1})\hat{y}(t_i)'g(t_{i-1}+), \tag{11}$$

then we can combine $[t_{i-1},\ t_i]$ and $[t_i,\ t_{i+1}]$ while maintaining the feasibility and improving the solution value of a feasible solution to $QP(|P|)$.

Proof. The difference between the solution value of $(\hat{v},\ \hat{y},\ \hat{t})$ and that of the solution $(\tilde{v},\ \tilde{y},\ \tilde{t})$ is the following:

$$\begin{aligned}
&\hat{v}(t_i)'c\left(\frac{t_i + t_{i-1}}{2}\right) + \hat{v}(t_{i+1})'c\left(\frac{t_{i+1} + t_i}{2}\right) + \frac{t_i - t_{i-1}}{2}(\hat{y}(t_i) + \hat{y}(t_{i-1}))'g(t_{i-1}+)\\
&+ \frac{t_{i+1} - t_i}{2}(\hat{y}(t_{i+1}) + \hat{y}(t_i))'g(t_{i-1}+) - (\hat{v}(t_i) + \hat{v}(t_{i+1}))'c\left(\frac{t_{i+1} + t_{i-1}}{2}\right)\\
&- \frac{t_{i+1} - t_{i-1}}{2}(\hat{y}(t_{i+1}) + \hat{y}(t_{i-1}))'g(t_{i-1}+)\\
= &-\frac{1}{2}\left((t_{i+1} - t_i)\,\hat{v}(t_i)'\dot{c}(t_{i-1}+) + (t_{i+1} - t_i)\hat{y}(t_{i-1})'g(t_{i-1}+)\right.\\
&\left.+ (t_i - t_{i-1})\hat{y}(t_{i+1})'g(t_{i-1}+)\right)\\
&+ \frac{1}{2}\left((t_i - t_{i-1})\hat{v}(t_{i+1})'\dot{c}(t_{i-1}+) + (t_{i+1} - t_{i-1})\hat{y}(t_i)'g(t_{i-1}+)\right).
\end{aligned}$$

We see that the new solution has a smaller solution value if and only if (11) holds. □

A direct corollary to Lemma 3 is the following.

Corollary 2. *Let t_l and t_m be two consecutive breakpoints in D_1^P. We can combine adjacent zero-length intervals in $[t_l,\ t_m]$ while maintaining the feasibility and improving the solution value of a feasible solution to $QP(|P|)$.*

Proof. Let $[t_{i-1},\ t_i]$ and $[t_i,\ t_{i+1}]$ be two adjacent zero-length intervals that reside on $[t_l,\ t_m]$. Since $t_{i-1} = t_i = t_{i+1}$, (11) is trivially satisfied. By Lemma 3, we can combine $[t_{i-1},\ t_i]$ and $[t_i,\ t_{i+1}]$ and maintain the feasibility and improve the solution value of the feasible solution to $QP(|P|)$. □

By Corollary 2, we can combine adjacent zero-length intervals. The following lemma implies that all the zero-length intervals except those at the breakpoints in D_1^P can be eliminated.

Lemma 4. *Let $[t_{i-1},\ t_i]$ be a zero-length interval that resides on $[t_l,\ t_m]$, where t_l and t_m are two consecutive breakpoints in D_1^P. Suppose $[t_{i-2},\ t_{i-1}]$ and $[t_i,\ t_{i+1}]$ are two positive-length intervals that also reside on $[t_l,\ t_m]$. We can either*

(a) *combine $[t_{i-2},\ t_{i-1}]$ and $[t_{i-1},\ t_i]$, or*

(b) *combine $[t_{i-1},\ t_i]$ and $[t_i,\ t_{i+1}]$,* *while maintaining the feasibility and improving the solution value of the feasible solution to* $QP(|P|)$.

Proof. Since $t_{i-1} = t_i$, by Lemma 3, we can combine $[t_{i-2},\ t_{i-1}]$ and $[t_{i-1},\ t_i]$ if the following relation holds:

$$(12)\quad (t_{i-1} - t_{i-2})\hat{y}(t_i)'g(t_{i-2}+) \leq (t_{i-1} - t_{i-2})(\hat{v}(t_i)'\dot{c}(t_{i-2}+) + \hat{y}(t_{i-1})'g(t_{i-2}+)).$$

By Lemma 3 again, we can combine $[t_{i-1},\ t_i]$ and $[t_i,\ t_{i+1}]$ if the following relation holds:

$$(13)\qquad (t_{i+1} - t_i)\hat{y}(t_i)'g(t_i+) \geq (t_{i+1} - t_i)(\hat{v}(t_i)'\dot{c}(t_i+) + \hat{y}(t_{i-1})'g(t_i+)).$$

By assumption, we have $t_{i+1} - t_i > 0$ and $t_{i-1} - t_{i-2} > 0$. Since $c(t)$ is linear and $g(t)$ is constant on $[t_l,\ t_m]$, we have

$$g(t_{i-2}+) = g(t_i+) \quad \text{and} \quad \dot{c}(t_{i-2}+) = \dot{c}(t_i+).$$

So either (12) or (13) is true. This proves the lemma. □

We next propose the following procedure for removing redundant intervals on $[t_l,\ t_m]$, where t_l and t_m are two consecutive breakpoints in D_1^P.

Procedure PURIFY. Repeatedly combine two adjacent intervals $[t_{i-1}, t_i]$ and $[t_i, t_{i+1}]$ in $[t_l,\ t_m]$ if (11) is satisfied.

When more than one pair of adjacent intervals satisfies (11), we can combine them in an arbitrary order, one pair at a time. Let $\tilde{P}$ be the resulting partition of $[0,\ T]$ after we apply the above procedure to P for all consecutive breakpoints in D_1^P. We call $\tilde{P}$ a *purified partition* of $[0,\ T]$. Note that the remaining zero-length intervals are located at the breakpoints in D_1^P and there are at most $2|D_1^P|$ zero-length intervals in P.

5. Improving a nonoptimal solution. One major step of the new algorithm is to calculate a KKT point of the system $QP(|P|)$ for some partition P of $[0,\ T]$. However, the problem $QP(|P|)$ is nonconvex. To obtain a global optimal solution for $(SCSCLP)$, we must be able to improve a solution that is not globally optimal for $(SCSCLP)$. In this section, we give descent directions for solutions that are not globally optimal for $(SCSCLP)$. To do so, we first introduce a new discrete approximation for $(SCSCLP)$ which is closely related to the dual problem $(SCSCLP^*)$. From this new approximation, we derive a criterion that detects whether a solution is globally optimal for $(SCSCLP)$. If this criterion is not satisfied, we give a descent direction for the current solution and thus improve the solution value. We show that instead of using the direction constructed in section 5.3, an algorithm for $(SCSCLP)$ can also use the Frank–Wolfe method or the matrix-splitting algorithm to find a descent direction. We also show that the first iterate of the Frank–Wolfe method provides an upper bound on the current duality gap.

5.1. A new discrete approximation. For partition $P = \{t_0, \ldots, t_p\}$, we let $P' = \left\{t_0, \frac{t_0+t_1}{2}, t_1, \ldots, \frac{t_{p-1}+t_p}{2}, t_p\right\}$ be a refined partition of P. Consider the following new discrete approximation to $(SCSCLP)$, a close variation of the second discretization in Pullan [41]:

$$AP1(P) \quad \min \sum_{i=1}^{p} \frac{t_i - t_{i-1}}{2} \Bigg(c(t_{i-1}+)'\hat{u}(t_{i-1}+) + c(t_i-)'\hat{u}(t_i-)$$

$$+2\hat{y}\left(\frac{t_{i-1}+t_i}{2}\right)' g(t_{i-1}+)\Bigg)$$

$$\text{s.t. } E\hat{y}(t_0) = a(t_0),$$

$$\begin{aligned}
&\left(\frac{t_i - t_{i-1}}{2}\right) G\hat{u}(t_i-) + E\hat{y}(t_i) - E\hat{y}\left(\frac{t_i + t_{i-1}}{2}\right)\\
&= a(t_i) - a\left(\frac{t_i + t_{i-1}}{2}\right), \\
&\qquad\qquad\qquad\qquad\qquad\qquad i = 1, \ldots, p,\\
&\left(\frac{t_i - t_{i-1}}{2}\right) G\hat{u}(t_{i-1}+) + E\hat{y}\left(\frac{t_i + t_{i-1}}{2}\right) - E\hat{y}(t_{i-1})\\
&= a\left(\frac{t_i + t_{i-1}}{2}\right) - a(t_{i-1}),\\
&\qquad\qquad\qquad\qquad\qquad\qquad i = 1, \ldots, p,\\
&H\hat{u}(t_{i-1}+) \le b(t_{i-1}+), \qquad i = 1, \ldots, p,\\
&H\hat{u}(t_i-) \le b(t_i-), \qquad i = 1, \ldots, p,\\
&F\hat{y}(t_i) \le h(t_i), \qquad i = 0, \ldots, p,\\
&F\hat{y}\left(\frac{t_i + t_{i-1}}{2}\right) \le h\left(\frac{t_i + t_{i-1}}{2}\right), \qquad i = 1, \ldots, p,\\
&\hat{u}(t_i-), \hat{u}(t_{i-1}+) \ge 0, \qquad i = 1, \ldots, p.
\end{aligned}$$

Problem $AP1(P)$ is closely related to the dual problem. The linear programming dual of $AP1(P)$ gives rise to feasible solutions for the dual problem $(SCSCLP^*)$. Thus an optimal solution to $AP1(P)$ contains the dual information. We will construct a descent solution for $(SCSCLP)$ based on a solution for $AP(P)$, a closely related linear program, to be defined shortly.

It is clear that the set of feasible solutions to $AP1(P)$ is the same as the set of feasible solutions to $DP(P')$ if we identify $\hat{u}(t_i-)$ in $AP1(P)$ with $\hat{u}((\frac{t_{i-1}+t_i}{2})+)$ in $DP(P')$. There are two differences between $DP(P')$ and $AP1(P)$, both of which reside in the objective function. First, instead of averaging the cost coefficients of $u(t)$ over each subinterval, the instantaneous values of the cost coefficients at the original breakpoints of P are used. Second, instead of using the average values of the state variable $y(t)$ in each subinterval, the values of $y(t)$ at the midpoint of each subinterval of P are used. It can be checked that any feasible solution for $DP(P)$ defines a feasible solution for $DP(P')$ and thus for $AP1(P)$, and these two solutions have the same solution value.

Similar to $QP(|P|)$, we introduce $\hat{v}$ to eliminate $\hat{u}$, where

$$\hat{v}(t_{i-1}+) = \frac{t_i - t_{i-1}}{2}\hat{u}(t_{i-1}+) \quad \text{and} \quad \hat{v}(t_i-) = \frac{t_i - t_{i-1}}{2}\hat{u}(t_i-). \tag{14}$$

Now $AP1(P)$ is transformed into the following linear program in $\hat{v}$ and $\hat{y}$:

$$AP(P) \quad \min \sum_{i=1}^{p} \Bigg(c(t_{i-1}+)'\hat{v}(t_{i-1}+) + c(t_i-)'\hat{v}(t_i-)$$

$$
\begin{aligned}
&\qquad\qquad +(t_i - t_{i-1})\hat{y}\left(\frac{t_{i-1}+t_i}{2}\right)' g(t_{i-1}+)\Bigg) \\
&\qquad \text{s.t. } E\hat{y}(t_0) = a(t_0), \\
&G\hat{v}(t_i-) + E\hat{y}(t_i) - E\hat{y}\left(\frac{t_i+t_{i-1}}{2}\right) = a(t_i) - a\left(\frac{t_i+t_{i-1}}{2}\right), \\
&\qquad\qquad i = 1,\dots,p, \\
&G\hat{v}(t_{i-1}+) + E\hat{y}\left(\frac{t_i+t_{i-1}}{2}\right) - E\hat{y}(t_{i-1}) = a\left(\frac{t_i+t_{i-1}}{2}\right) - a(t_{i-1}), \\
&\qquad\qquad i = 1,\dots,p, \\
&H\hat{v}(t_{i-1}+) \le \left(\frac{t_i-t_{i-1}}{2}\right) b(t_{i-1}+), \qquad i = 1,\dots,p, \\
&H\hat{v}(t_i-) \le \left(\frac{t_i-t_{i-1}}{2}\right) b(t_i-), \qquad i = 1,\dots,p, \\
&F\hat{y}(t_i) \le h(t_i), \qquad i = 0,\dots,p, \\
&F\hat{y}\left(\frac{t_i+t_{i-1}}{2}\right) \le h\left(\frac{t_i+t_{i-1}}{2}\right), \qquad i = 1,\dots,p, \\
&\hat{v}(t_i-),\ \hat{v}(t_{i-1}+) \ge 0, \quad i = 1,\dots,p.
\end{aligned}
$$

Similar to $AP1(P)$ and $DP(P')$, $AP(P)$ and $QP(|P'|)$ have the same feasible solution set if the partition in $QP(|P'|)$ is fixed to P'. We note that the actual value of $\hat{y}(t_0)$ does not affect the objective value of $AP(P)$ as long as $E\hat{y}(t_0) = a(t_0)$ and $F\hat{y}(t_0) \le h(t_0)$ (which is indeed feasible by assumption). The dual problem for $AP(P)$ (after eliminating $\hat{y}(t_0)$) can be written as

$$
\begin{aligned}
AP^*(P) \max\ & \hat{\pi}(t_0+)' a(t_0) \\
&+ \sum_{i=1}^{p} (\hat{\pi}(t_{i-1}+) + \hat{\pi}(t_i-))' \left(a(t_i) - a\left(\frac{t_i+t_{i-1}}{2}\right)\right) \\
&- \sum_{i=1}^{p} \left(\frac{t_i-t_{i-1}}{2}\right) (\hat{\eta}(t_{i-1}+) + \hat{\eta}(t_i-))' b(t_i-) \\
&+ \sum_{i=1}^{p} \left(\hat{\xi}(t_i)' h(t_i) + \hat{\xi}\left(\frac{t_{i-1}+t_i}{2}\right)' h\left(\frac{t_{i-1}+t_i}{2}\right)\right) \\
\text{s.t. } & c(t_i-) - G'\hat{\pi}(t_i-) + H'\hat{\eta}(t_i-) \ge 0, \quad i = 1,\dots,p, \\
& c(t_{i-1}+) - G'\hat{\pi}(t_{i-1}+) + H'\hat{\eta}(t_{i-1}+) \ge 0, \quad i = 1,\dots,p, \\
& E'(-\hat{\pi}(t_i-) + \hat{\pi}(t_{i-1}+)) + F'\hat{\xi}\left(\frac{t_{i-1}+t_i}{2}\right) = (t_i - t_{i-1}) g(t_{i-1}+), \\
& \qquad\qquad i = 1,\dots,p, \\
& E'(-\hat{\pi}(t_i+) + \hat{\pi}(t_i-)) + F'\hat{\xi}(t_i) = 0, \quad i = 1,\dots,p-1, \\
& E'(\hat{\pi}(t_p-)) + F'\hat{\xi}(t_p) = 0, \\
& \hat{\eta}(t_i-), \hat{\eta}(t_{i-1}+) \ge 0, \quad i = 1,\dots,p, \\
& \hat{\xi}(t_i), \hat{\xi}\left(\frac{t_{i-1}+t_i}{2}\right) \le 0, \quad i = 1,\dots,p.
\end{aligned}
$$

Similar to the second discretization in Pullan [41], the importance of $AP(P)$ lies in the fact that feasible solutions for its dual problem $AP^*(P)$ can be used either to define a feasible solution for $(SCSCLP^*)$ with the same solution value or to define a sequence of feasible solutions for $(SCSCLP^*)$ whose solution value converges to that of the original solution to $AP^*(P)$, as shown in the following theorem.

THEOREM 1. *Suppose that P is a purified partition of $[0,\ T]$ (as defined at the end of section 4). Given any feasible solution $(\hat{\pi},\ \hat{\eta},\ \hat{\xi})$ to $AP^*(P)$, if (9) holds for P, then there exists a feasible solution $(\pi(t),\ \eta(t),\ \xi(t))$ to $(SCSCLP^*)$ whose solution value equals that of $(\hat{\pi},\ \hat{\eta},\ \hat{\xi})$. Otherwise, there exists a series of feasible solutions $(\pi^k(t),\ \eta^k(t),\ \xi^k(t))$ to $(SCSCLP^*)$ that are piecewise linear with partition P^k, whose solution value converges to that of $(\hat{\pi},\ \hat{\eta},\ \hat{\xi})$ with P^k satisfying (9).*

Proof. When there are no zero-length intervals in P (i.e., (9) holds), we let

$$\xi(t) = \begin{cases} \sum_{j=i+1}^{p} \left(\hat{\xi}\left(\frac{t_j+t_{j-1}}{2}\right) + \hat{\xi}(t_j)\right) & \text{if } t = t_i,\ i = 0, 1, \dots,\ p-1, \\ 0 & \text{if } t = T. \end{cases}$$

For $t \in (t_{i-1},\ t_i)$, we let

$$\xi(t) = \frac{t_i - t}{t_i - t_{i-1}}\xi(t_{i-1}) + \frac{t - t_{i-1}}{t_i - t_{i-1}}\left(\xi(t_i) + \hat{\xi}(t_i)\right).$$

We note that $\xi(t)$ is monotonically increasing and right continuous (albeit discontinuous). Let $\pi(t)$ and $\eta(t)$ be the piecewise-linear extensions of $\hat{\pi}$ and $\hat{\eta}$, respectively. It can be shown that $(\pi(t),\ \eta(t),\ \xi(t))$ is a feasible solution for $(SCSCLP^*)$ by virtue of the piecewise linearity of the problem data. Now, let us check the relationship between the solution value of the newly constructed solution of $(SCSCLP^*)$ and the original solution of $AP^*(P)$. Through integration by parts, we have

$$\begin{aligned} & -\int_0^T a(t)'\ d\pi(t) \\ &= -a(t)'\pi(t)\ |_0^T + \int_0^T \pi(t)'\ da(t) \\ &= \hat{\pi}(t_0+)'a(t_0) + \sum_{i=1}^{p}\left(\frac{a(t_i) - a(t_{i-1})}{t_i - t_{i-1}}\right)' \int_{t_{i-1}}^{t_i} \pi(t)\ dt \\ &= \hat{\pi}(t_0+)'a(t_0) + \sum_{i=1}^{p}(\hat{\pi}(t_{i-1}+) + \hat{\pi}(t_i-))'\left(a(t_i) - a\left(\frac{t_i + t_{i-1}}{2}\right)\right). \end{aligned} \tag{15}$$

Since $\eta(t)$ is piecewise linear and $b(t)$ is piecewise constant with partition P, we have

$$\int_{t_{i-1}}^{t_i} b(t)'\eta(t)\ dt = \left(\frac{t_i - t_{i-1}}{2}\right)(\hat{\eta}(t_{i-1}+) + \hat{\eta}(t_i-))'b(t_i-), \quad i = 1, \dots, p.$$

So

$$-\int_0^T b(t)'\eta(t)\ dt = -\sum_{i=1}^{p}\left(\frac{t_i - t_{i-1}}{2}\right)(\hat{\eta}(t_{i-1}+) + \hat{\eta}(t_i-))'b(t_i-). \tag{16}$$

Direct calculation gives

$$-\int_0^T h(t)'\ d\xi(t)$$

$$
\begin{aligned}
&= -h(t)'\xi(t)\big|_0^T + \int_0^T \xi(t)'\, dh(t) \\
&= h(t_0)'\xi(t_0) + \sum_{i=1}^{p} \left(\frac{h(t_i) - h(t_{i-1})}{t_i - t_{i-1}} \right)' \int_{t_{i-1}}^{t_i} \xi(t)\, dt \\
&= h(t_0)' \sum_{j=1}^{p} \left(\hat{\xi}\left(\frac{t_j + t_{j-1}}{2} \right) + \hat{\xi}(t_j) \right) \\
&\quad + \sum_{i=1}^{p} \left(\frac{h(t_i) - h(t_{i-1})}{2} \right)' \\
&\quad \times \left(2 \sum_{j=i+1}^{p} \left(\hat{\xi}\left(\frac{t_j + t_{j-1}}{2} \right) + \hat{\xi}(t_j) \right) + \hat{\xi}\left(\frac{t_i + t_{i-1}}{2} \right) + 2\hat{\xi}(t_i) \right)
\end{aligned}
$$

$$
= \sum_{i=1}^{p} \left(\hat{\xi}(t_i)'h(t_i) + \hat{\xi}\left(\frac{t_{i-1} + t_i}{2} \right)' h\left(\frac{t_{i-1} + t_i}{2} \right) \right). \tag{17}
$$

Combining (15), (16), and (17), we see that $(\pi(t),\ \eta(t),\ \xi(t))$ has the same solution value as $(\hat{\pi},\ \hat{\eta},\ \hat{\xi})$. This proves the first part of the theorem.

Now, suppose (9) does not hold for P. Since P is a purified partition, by Corollary 2 and Lemma 4, the zero-length intervals in P can be located only at the breakpoints in D_1^P. So for any zero-length interval $[t_{i-1},\ t_i]$ that resides on $[t_l,\ t_m]$, where t_l and t_m are two consecutive breakpoints in D_1^P, either $t_{i-1} = t_l$ or $t_i = t_m$. Let $\tau \in (0,\ 1)$. We define a new solution $(\tilde{\pi}^\tau,\ \tilde{\eta}^\tau,\ \tilde{\xi}^\tau)$ in the following way.

If $t_{i-1} = t_l$, we let

$$
\begin{aligned}
\tilde{t}_{i-1}^\tau &= t_{i-1}, \\
\tilde{t}_i^\tau &= (1-\tau)t_i + \tau t_{i+1}, \\
\tilde{t}_{i+1}^\tau &= t_{i+1}, \\
\tilde{\pi}^\tau(\tilde{t}_i^\tau -) &= (1-\tau)\hat{\pi}(t_i -) + \tau\hat{\pi}(t_i +), \\
\tilde{\pi}^\tau(\tilde{t}_i^\tau +) &= (1-\tau)\hat{\pi}(t_i +) + \tau\hat{\pi}(t_{i+1} -), \\
\tilde{\eta}^\tau(\tilde{t}_i^\tau -) &= (1-\tau)\hat{\eta}(t_i -) + \tau\hat{\eta}(t_i +), \\
\tilde{\eta}^\tau(\tilde{t}_i^\tau +) &= (1-\tau)\hat{\eta}(t_i +) + \tau\hat{\eta}(t_{i+1} -), \\
\tilde{\xi}^\tau\left(\frac{\tilde{t}_i^\tau + \tilde{t}_{i-1}^\tau}{2} \right) &= (1-\tau)\hat{\xi}\left(\frac{t_i + t_{i-1}}{2} \right) + \tau\hat{\xi}(t_i), \\
\tilde{\xi}^\tau(\tilde{t}_i^\tau) &= (1-\tau)\hat{\xi}(t_i) + \tau\hat{\xi}\left(\frac{t_i + t_{i+1}}{2} \right), \\
\tilde{\xi}^\tau\left(\frac{\tilde{t}_i^\tau + \tilde{t}_{i+1}^\tau}{2} \right) &= (1-\tau)\hat{\xi}\left(\frac{t_i + t_{i+1}}{2} \right).
\end{aligned}
$$

If $t_i = t_m$, we let

$$
\begin{aligned}
\tilde{t}_{i-2}^\tau &= t_{i-2}, \\
\tilde{t}_{i-1}^\tau &= (1-\tau)t_{i-1} + \tau t_{i-2}, \\
\tilde{t}_i^\tau &= t_i, \\
\tilde{\pi}^\tau(\tilde{t}_{i-1}^\tau -) &= (1-\tau)\hat{\pi}(t_{i-1} -) + \tau\hat{\pi}(t_{i-2} +),
\end{aligned}
$$

$$\begin{aligned}
\tilde{\pi}^\tau(\tilde{t}^\tau_{i-1}+) &= (1-\tau)\hat{\pi}(t_{i-1}+) + \tau\hat{\pi}(t_{i-1}-),\\
\tilde{\eta}^\tau(\tilde{t}^\tau_{i-1}-) &= (1-\tau)\hat{\eta}(t_{i-1}-) + \tau\hat{\eta}(t_{i-2}+),\\
\tilde{\eta}^\tau(\tilde{t}^\tau_{i-1}+) &= (1-\tau)\hat{\eta}(t_{i-1}+) + \tau\hat{\eta}(t_{i-1}-),\\
\tilde{\xi}^\tau\left(\frac{\tilde{t}^\tau_i + \tilde{t}^\tau_{i-1}}{2}\right) &= (1-\tau)\hat{\xi}\left(\frac{t_i + t_{i-1}}{2}\right) + \tau\hat{\xi}(t_{i-1}),\\
\tilde{\xi}^\tau(\tilde{t}^\tau_{i-1}) &= (1-\tau)\hat{\xi}(t_{i-1}) + \tau\hat{\xi}\left(\frac{t_{i-1} + t_{i-2}}{2}\right),\\
\tilde{\xi}^\tau\left(\frac{\tilde{t}^\tau_{i-1} + \tilde{t}^\tau_{i-2}}{2}\right) &= (1-\tau)\hat{\xi}\left(\frac{t_{i-1} + t_{i-2}}{2}\right).
\end{aligned}$$

For all the other quantities not defined in the above cases, we let $\tilde{t}^\tau_j = t_j$, $\tilde{\pi}^\tau(\tilde{t}^\tau_j-) = \hat{\pi}(t_j-)$, $\tilde{\pi}^\tau(\tilde{t}^\tau_j+) = \hat{\pi}(t_j+)$, $\tilde{\eta}^\tau(\tilde{t}^\tau_j-) = \hat{\eta}(t_j-)$, $\tilde{\eta}^\tau(\tilde{t}^\tau_j+) = \hat{\eta}(t_j+)$, $\tilde{\xi}^\tau(\tilde{t}^\tau_{j-1}) = \hat{\xi}(t_{j-1})$, and $\tilde{\xi}^\tau\left(\frac{\tilde{t}^\tau_j+\tilde{t}^\tau_{j-1}}{2}\right) = \hat{\xi}\left(\frac{t_j+t_{j-1}}{2}\right)$.

Let P^τ be the partition defined from $\tilde{t}^\tau$. It is easy to check the feasibility of $(\tilde{\pi}^\tau,\ \tilde{\eta}^\tau,\ \tilde{\xi}^\tau)$ to $AP^*(P^\tau)$. Since $(\tilde{\pi}^\tau,\ \tilde{\eta}^\tau,\ \tilde{\xi}^\tau)$ converges to $(\hat{\pi},\ \hat{\eta},\ \hat{\xi})$ and $\tilde{t}^\tau$ converges to $\hat{t}$ as τ tends to zero, we see that the solution value of $(\tilde{\pi}^\tau,\ \tilde{\eta}^\tau,\ \tilde{\xi}^\tau)$ in $AP^*(P^\tau)$ converges to the solution value of $(\hat{\pi},\ \hat{\eta},\ \hat{\xi})$ in $AP^*(P)$. Furthermore, (9) holds for P^τ. Applying the first part of the theorem to P^τ, we conclude that the theorem is true for P. □

We may now summarize the relationship among the values of various discrete approximations in the following theorem (see also Theorem 3.5 in Pullan [41]).

THEOREM 2. *For any partitions P and Q,*

$$V(AP(P)) = V(AP^*(P)) \le V((SCSCLP^*)) \le V((SCSCLP)) \le V(DP(Q)).$$

Proof. By the strong duality result for finite-dimensional linear programming, the value of the optimal solution to $AP(P)$ is the value of the optimal solution to its dual $AP^*(P)$. By Theorem 1, the solution value of this solution can be closely approximated by a sequence of feasible solutions to $(SCSCLP^*)$. It then follows that this value is a lower bound on $V((SCSCLP^*))$, and thus a lower bound on $V((SCSCLP))$ by Proposition 1. The final inequality follows from the definition of $DP(Q)$. □

COROLLARY 3. *For any partitions P and Q, if*

$$V(AP(P)) \ge V(QP(|Q|)),$$

then the optimal solution value of $QP(|Q|)$ gives the optimal solution value to $(SCSCLP)$. In particular, if a solution $(\hat{v},\ \hat{y},\ \hat{t})$ is feasible for $QP(|Q|)$ and has the same cost as the optimal value of $AP(P)$, then $(\hat{v},\ \hat{y},\ \hat{t})$ gives the optimal solution value for $(SCSCLP)$ which can be closely approximated by a sequence of feasible solutions to $(SCSCLP)$.

Proof. By Lemma 2, the solution value of any feasible solution to $QP(|Q|)$ is an upper bound on $V((SCSCLP))$, and the result follows directly from Theorem 2. □

5.2. The doubling of breakpoints. Based on a new discrete approximation of $(SCLP)$ similar to $AP1(P)$, Pullan [41] found a descent solution for $(SCLP)$ (consequently, a descent direction can be constructed) by patching together the current solution and a solution that has a better solution value in $AP1(P)$ than the current solution. The new solution has a strictly improved solution value in $(SCLP)$ but usually has three times as many constant control pieces as the original solution. In the following, we give a construction for a feasible solution to $(SCSCLP)$ that produces, at most, approximately twice as many breakpoints as the original feasible solution.

Let P be a partition of $[0,\ T]$, and define a new partition as follows:

$$\bar{P} = \{t_0, t_0, t_1, t_1, \ldots, t_i, t_i, t_i, \ldots, t_p, t_p\},$$

where each breakpoint in D^P has two duplicates and all the other breakpoints have only one duplicate. Intuitively, we have placed a zero-length interval at the beginning of every breakpoint of P and put a zero-length interval at the end of each breakpoint in D^P. Under this configuration, the set of intervals in $\bar{P}$ is the union of the intervals in P and a set of zero-length intervals. We let $\bar{t}_i$ denote the $(i+1)$th element of $\bar{P}$. $D_1^{\bar{P}}$ is the set of breakpoints in $\bar{P}$ that correspond to the breakpoints in D_1^P. For the ith interval (i.e., $[t_{i-1},\ t_i]$) in P, we have a corresponding interval $[\bar{t}_{j-1},\ \bar{t}_j]$ in $\bar{P}$, where $\bar{t}_{j-1} = t_{i-1}$ and $\bar{t}_j = t_i$. We call this interval in $\bar{P}$ an old interval. All the other intervals in $\bar{P}$ are called new intervals. Note that all the new intervals have zero length but not vice versa.

Given a solution $(\hat{v},\ \hat{y},\ \hat{t})$ to $QP(|P|)$, we first construct a feasible solution $(\bar{v},\ \bar{y},\ \bar{t})$ to $QP(|\bar{P}|)$ and then show a descent direction for this solution in $QP(|\bar{P}|)$. The descent direction will be used in the proof of convergence. We need not use the same direction in the new algorithm, as we will see in the last remark in section 6. This solution has the same solution value in $QP(|\bar{P}|)$ as the current solution in $QP(|P|)$ and has approximately twice as many intervals, fewer than the one constructed by Pullan [41].

Let $(\hat{v},\ \hat{y},\ \hat{t})$ be a feasible solution for $QP(|P|)$. For the ith interval in $\bar{P}$, if it is an old interval, we let interval j be the corresponding interval in P and set

$$\bar{v}(\bar{t}_i) = \hat{v}(t_j), \qquad \bar{y}(\bar{t}_i) = \hat{y}(t_j). \tag{18}$$

We let $\bar{v}(\bar{t}_i) = 0$ if interval i in $\bar{P}$ is a new interval and let $\bar{y}(\bar{t}_i) = \hat{y}(t_j)$, where j is the interval in P that corresponds to the closest old interval in $\bar{P}$ to the left of $[t_{i-1},\ t_i]$ (with the convention that $\bar{y}(\bar{t}_1) = y(t_0)$ and $\bar{y}(\bar{t}_0) = y(t_0)$).

It is easy to verify that $(\bar{v},\ \bar{y},\ \bar{t})$ is feasible for $QP(|\bar{P}|)$ and has the same solution value in $QP(|\bar{P}|)$ as $(\hat{v},\ \hat{y},\ \hat{t})$ in $QP(|P|)$.

5.3. A descent direction.

According to Corollary 3, a feasible solution $(\hat{v},\ \hat{y},\ \hat{t})$ to $QP(|P|)$ gives the optimal solution value of $(SCSCLP)$ if the optimal solution to $AP(P)$ has an equal or larger solution value. If so, we can stop the algorithm. Otherwise, there exists $(\tilde{\bar{v}},\ \tilde{\bar{y}},\ \tilde{\bar{t}})$ feasible for $AP(P)$ and with a strictly smaller solution value in $AP(P)$, i.e., we have

$$\delta \overset{\text{def}}{=} V(AP(P), (\tilde{\bar{v}}, \tilde{\bar{y}}, \tilde{\bar{t}})) - V(QP(|P|), (\hat{v},\ \hat{y},\ \hat{t})) < 0. \tag{19}$$

Note that $|\delta|$ is an upper bound on the duality gap between $(SCSCLP)$ and $(SCSCLP^*)$.

Let $\epsilon \in [0,\ 1]$. For every interval $[t_{i-1},\ t_i]$, we define

$$\epsilon_i = \frac{(t_i - t_{i-1})\epsilon}{2}.$$

We define a new partition P^ϵ of $[0,\ T]$ as follows:

$$P^\epsilon \overset{\text{def}}{=} \{t_0, t_0 + \epsilon_1, t_1 - \epsilon_1, t_1 + \epsilon_2, \ldots, t_i - \epsilon_i, t_i, t_i + \epsilon_{i+1}, \ldots, t_p - \epsilon_p, t_p\},$$

FIG. 2. *The construction of a descent solution where t_l and t_m are two consecutive breakpoints in D_1.*

where we replace the breakpoint t_i in $P \setminus D_1^P$ with two elements $t_i - \epsilon_i$ and $t_i + \epsilon_{i+1}$ and add two elements $t_i - \epsilon_i$ and $t_i + \epsilon_{i+1}$. For breakpoint t_i in D^P, we add $t_0 + \epsilon_1$ and $t_p - \epsilon_p$ for t_0 and t_p, respectively. We define the vector t^ϵ from P^ϵ by mapping t_i^ϵ to the $(i+1)$th element in P^ϵ. We construct a descent solution $(v^\epsilon,\ y^\epsilon,\ t^\epsilon)$ with partition P^ϵ as follows.

When P does not have any zero-length intervals, let $\tilde{\bar{u}}(t)$, $\hat{u}(t)$, and $\hat{\bar{u}}(t)$ be the piecewise constant extensions of $\tilde{\bar{u}}$, $\hat{u}$, and $\hat{\bar{u}}$, respectively, where $\tilde{\bar{u}}$ is defined from $\tilde{\bar{v}}$ by

$$\tilde{\bar{u}}(t_{i-1}+) = 2\frac{\tilde{\bar{v}}(t_{i-1}+)}{t_i - t_{i-1}}, \quad \tilde{\bar{u}}(t_i-) = 2\frac{\tilde{\bar{v}}(t_i-)}{t_i - t_{i-1}},$$

$\hat{u}$ is defined from $\hat{v}$ by (8), and $\hat{\bar{u}}$ is defined as

$$\hat{\bar{u}}(t_{i-1}+) = \frac{\tilde{\bar{v}}(t_{i-1}+) + \tilde{\bar{v}}(t_i-)}{t_i - t_{i-1}}.$$

We construct the new control by patching together $\tilde{\bar{u}}(t)$, $\hat{u}(t)$, and $\hat{\bar{u}}(t)$ as follows:

$$(20) \qquad u^\epsilon(t) = \begin{cases} \tilde{\bar{u}}(t), & t \in [t_{i-1},\ t_{i-1} + \epsilon_i) \bigcup [t_i - \epsilon_i,\ t_i),\ t_i \in D^P, \\ \tilde{\bar{u}}(t), & t \in [t_{p-1},\ t_{p-1} + \epsilon_p) \bigcup [t_p - \epsilon_p,\ t_p], \\ \hat{u}(t), & t \in [t_{i-1} + \epsilon_i,\ t_i - \epsilon_i), \\ \hat{\bar{u}}(t), & \text{otherwise.} \end{cases}$$

Having constructed the control, the construction of the state variables for $(SCSCLP)$ is straightforward. Our construction of a descent solution $(v^\epsilon,\ y^\epsilon,\ t^\epsilon)$ for $(\hat{v},\ \hat{y},\ \hat{t})$ is illustrated in Figure 2.

However, if $t_{i-1} = t_i$ for some i, the u variables in the previous paragraph are not properly defined. Fortunately, we can bypass this difficulty by working on the v variables. We define v^ϵ as follows. Let t_l and t_m be two consecutive breakpoints in

D_1^P. Let $[t_i+\epsilon_{i+1},\ t_{i+1}-\epsilon_{i+1}]$ and $[t_{i+1}-\epsilon_{i+1},\ t_{i+1}+\epsilon_{i+2}]$ be two intervals that reside on $[t_l,\ t_m]$. If t_j^ϵ is the breakpoint in P^ϵ that is mapped to $t_{i+1}-\epsilon_{i+1}$, we let

$$\begin{aligned} v^\epsilon(t_j^\epsilon) &= (1-\epsilon)\hat{v}(t_{i+1}),\\ v^\epsilon(t_{j+1}^\epsilon) &= \epsilon(\tilde{\bar{v}}(t_{i+1}-)+\tilde{\bar{v}}(t_{i+1}+)). \end{aligned}\tag{21}$$

If t_j^ϵ is the breakpoint in P^ϵ that is mapped to t_l, we let

$$v^\epsilon(t_{j+1}^\epsilon) = \epsilon\tilde{\bar{v}}(t_l+).\tag{22}$$

If t_j^ϵ is the breakpoint in P^ϵ that is mapped to t_m, we let

$$v^\epsilon(t_j^\epsilon) = \epsilon\tilde{\bar{v}}(t_m-).\tag{23}$$

We define y^ϵ in three different cases as follows. For the breakpoint t_j^ϵ in P^ϵ that is mapped to $t_{i-1}+\epsilon_i$, we let

$$y^\epsilon(t_j^\epsilon) = (1-\epsilon)\hat{y}(t_{i-1}) + \epsilon\tilde{\bar{y}}\left(\frac{t_i+t_{i-1}}{2}\right).\tag{24}$$

For the breakpoint t_j^ϵ in P^ϵ that is mapped to $t_i-\epsilon_i$, we let

$$y^\epsilon(t_j^\epsilon) = (1-\epsilon)\hat{y}(t_i) + \epsilon\tilde{\bar{y}}\left(\frac{t_i+t_{i-1}}{2}\right).\tag{25}$$

For the breakpoint t_j^ϵ in P^ϵ that is mapped to t_i, we let

$$y^\epsilon(t_j^\epsilon) = (1-\epsilon)\hat{y}(t_i) + \epsilon\tilde{\bar{y}}(t_i).\tag{26}$$

When ϵ is small, $(v^\epsilon,\ y^\epsilon,\ t^\epsilon)$ is a descent solution as shown in the following theorem.

THEOREM 3. *If* (19) *holds, then* $(v^\epsilon,\ y^\epsilon,\ t^\epsilon)$ *is a feasible solution to* $QP(|\bar{P}|)$ *and*

$$V(QP(|\bar{P}|),(v^\epsilon,\ y^\epsilon,\ t^\epsilon)) - V(QP(|\bar{P}|),(\bar{v},\ \bar{y},\ \bar{t})) = \epsilon\delta + o(\epsilon),\tag{27}$$

where δ *is defined in* (19). *For* ϵ *small enough,* $(v^\epsilon,\ y^\epsilon,\ t^\epsilon)$ *has a strictly smaller solution value than* $(\bar{v},\ \bar{y},\ \bar{t})$.

Proof. The feasibility of $(v^\epsilon,\ y^\epsilon,\ t^\epsilon)$ follows easily. By definition, we have

$$\begin{aligned} V(QP(|\bar{P}|),(\bar{v},\ \bar{y},\ \bar{t})) &= V(QP(|P|),(\hat{v},\ \hat{y},\ \hat{t}))\\ &= \sum_{i=1}^{p}\hat{v}(t_i)'c\left(\frac{t_i+t_{i-1}}{2}\right) + \sum_{i=1}^{p}\frac{t_i-t_{i-1}}{2}(\hat{y}(t_i)\\ &\quad + \hat{y}(t_{i-1}))'g(t_{i-1}+),\\ V(QP(|\bar{P}|),(v^\epsilon,\ y^\epsilon,\ t^\epsilon)) &= \sum_{i=1}^{|P^\epsilon|-1} c\left(\frac{t_i^\epsilon+t_{i-1}^\epsilon}{2}\right)' v^\epsilon(t_i^\epsilon)\\ &\quad + \sum_{i=1}^{|P^\epsilon|-1}\frac{t_i^\epsilon-t_{i-1}^\epsilon}{2}(y^\epsilon(t_i^\epsilon)+y^\epsilon(t_{i-1}^\epsilon))'g(t_{i-1}^\epsilon+). \end{aligned}$$

Let t_l and t_m be two consecutive breakpoints in D_1^P and let $t_{\bar{l}}^\epsilon$ and $t_{\bar{m}}^\epsilon$ be the corresponding breakpoints in $D_1^{P^\epsilon}$. We have

$$\sum_{i=l+1}^{m}\hat{v}(t_i)'c\left(\frac{t_i+t_{i-1}}{2}\right) - \sum_{i=\bar{l}+1}^{\bar{m}} c\left(\frac{t_i^\epsilon+t_{i-1}^\epsilon}{2}\right)' v^\epsilon(t_i^\epsilon)$$

$$
\begin{aligned}
&= \sum_{i=l+1}^{m} \hat{v}(t_i)'c\left(\frac{t_i+t_{i-1}}{2}\right) - \sum_{i=l+1}^{m}(1-\epsilon)\hat{v}(t_i)'c\left(\frac{t_i+t_{i-1}}{2}\right)\\
&\quad - \sum_{i=l+1}^{m-1}\epsilon(\tilde{\bar{v}}(t_i+)+\tilde{\bar{v}}(t_i-))'c\left(t_i+\frac{\epsilon_{i+1}-\epsilon_i}{2}\right)\\
&\quad - \epsilon\tilde{\bar{v}}(t_l+)'c\left(t_l+\frac{\epsilon_{i+1}}{2}\right) - \epsilon\tilde{\bar{v}}(t_m-)'c\left(t_m-\frac{\epsilon_m}{2}\right)\\
&= \sum_{i=l+1}^{m}\epsilon\left(\hat{v}(t_i)'c\left(\frac{t_i+t_{i-1}}{2}\right) - (\tilde{\bar{v}}(t_{i-1}+)'c(t_{i-1}+) + \ \tilde{\bar{v}}(t_i-)'c(t_i-))\right) + o(\epsilon),
\end{aligned}
$$

(28)

and

$$
\begin{aligned}
&\sum_{i=l+1}^{m}\frac{t_i-t_{i-1}}{2}(\hat{y}(t_i)+\hat{y}(t_{i-1}))'g(t_{i-1}+) - \sum_{i=\bar{l}+1}^{\bar{m}}\frac{t_i^{\epsilon}-t_{i-1}^{\epsilon}}{2}(y^{\epsilon}(t_i^{\epsilon})+y^{\epsilon}(t_{i-1}^{\epsilon}))'g(t_{i-1}^{\epsilon}+)\\

&\quad - \sum_{i=l+1}^{m}\frac{\epsilon_i+\epsilon_{i+1}}{2}\left(2(1-\epsilon)\hat{y}(t_i)+\epsilon\left(\tilde{\bar{y}}\left(\frac{t_i+t_{i-1}}{2}\right)+\tilde{\bar{y}}\left(\frac{t_{i+1}+t_i}{2}\right)\right)\right)'g(t_{i-1}+)\\
&\quad -\frac{\epsilon_{l+1}}{2}\left(2(1-\epsilon)\hat{y}(t_l)+\epsilon\left(\tilde{\bar{y}}(t_l)+\tilde{\bar{y}}\left(\frac{t_{l+1}+t_l}{2}\right)\right)\right)'g(t_l+)\\
&\quad -\frac{\epsilon_m}{2}\left(2(1-\epsilon)\hat{y}(t_m)+\epsilon\left(\tilde{\bar{y}}(t_m)+\tilde{\bar{y}}\left(\frac{t_{m-1}+t_m}{2}\right)\right)\right)'g(t_m-)\\
&= \sum_{i=l+1}^{m}\epsilon\frac{t_i-t_{i-1}}{2}(\hat{y}(t_i)+\hat{y}(t_{i-1}))'g(t_{i-1}+)\\
&\quad - \sum_{i=l+1}^{m}(t_i-t_{i-1})\epsilon\tilde{\bar{y}}\left(\frac{t_i+t_{i-1}}{2}\right)'g(t_{i-1}+)+o(\epsilon).
\end{aligned}
$$

(29)

Summing up (28) and (29) over all pairs of consecutive breakpoints in D_1, we have

$$
\begin{aligned}
&V(QP(|\bar{P}|),(v^{\epsilon},\ y^{\epsilon},\ t^{\epsilon})) - V(QP(|\bar{P}|),(\bar{v},\ \bar{y},\ \bar{t}))\\
&= V(QP(|\bar{P}|),(v^{\epsilon},\ y^{\epsilon},\ t^{\epsilon})) - V(QP(|P|),(\hat{v},\ \hat{y},\ \hat{t}))\\
&= \sum_{i=1}^{p}\epsilon\left(\tilde{\bar{v}}(t_{i-1}+)'c(t_{i-1}+)+\tilde{\bar{v}}(t_i-)'c(t_i-)-\hat{v}(t_i)'c\left(\frac{t_i+t_{i-1}}{2}\right)\right.\\
&\qquad\qquad \left. -\frac{t_i-t_{i-1}}{2}(\hat{y}(t_i)+\hat{y}(t_{i-1}))'g(t_{i-1}+)\right)+o(\epsilon)\\
&= \epsilon(V(AP(P),(\tilde{\bar{v}},\tilde{\bar{y}},\tilde{\bar{t}})) - V(QP(|P|),(\hat{v},\ \hat{y},\ \hat{t}))) + o(\epsilon)\\
&= \epsilon\delta + o(\epsilon).
\end{aligned}
$$

Since $\delta < 0$, when ϵ is small enough, $(v^\epsilon,\ y^\epsilon,\ t^\epsilon)$ is a strictly improved feasible solution to $QP(|\bar{P}|)$. □

Interestingly, the new solution $(v^\epsilon,\ y^\epsilon,\ t^\epsilon)$ gives a descent direction for $(\bar{v},\ \bar{y},\ \bar{t})$ in $QP(|\bar{P}|)$. This solution can also be used to show that the first Frank–Wolfe iterate for $(\bar{v},\ \bar{y},\ \bar{t})$ provides an upper bound on the current duality gap, as we next illustrate.

Let $[t_l,\ t_m]$ be two consecutive breakpoints in D_1^P. We define a new partition $\bar{\bar{P}}$ as follows. The set of breakpoints of $\bar{\bar{P}}$ that resides on $[t_l,\ t_m]$ is $\{t_l,\ \frac{t_l+t_{l+1}}{2},\ \frac{t_l+t_{l+1}}{2}, \dots,\ t_m\}$, i.e., the union of $\{t_l,\ t_m\}$ with the set of midpoints of the intervals in P, and each midpoint appears exactly twice. We construct $(\bar{\bar{v}},\ \bar{\bar{y}},\ \bar{\bar{t}})$ as follows. The set of breakpoints of $(\bar{\bar{v}},\ \bar{\bar{y}},\ \bar{\bar{t}})$ is $\bar{\bar{P}}$. Let

$$\bar{\bar{v}}_j = \begin{cases} \tilde{\bar{v}}(t_{i+1}-) + \tilde{\bar{v}}(t_{i+1}+) & \text{if the } j\text{th interval of } \bar{\bar{P}} \text{ is } [\frac{t_i+t_{i+1}}{2},\ \frac{t_{i+1}+t_{i+2}}{2}], \\ \tilde{\bar{v}}(t_l+) & \text{if the } j\text{th interval of } \bar{\bar{P}} \text{ is } [t_l,\ \frac{t_l+t_{l+1}}{2}], \\ \tilde{\bar{v}}(t_m-) & \text{if the } j\text{th interval of } \bar{\bar{P}} \text{ is } [\frac{t_{m-1}+t_m}{2},\ t_m], \\ 0 & \text{otherwise,} \end{cases}$$

$\bar{\bar{y}}(\bar{\bar{t}}_0) = y(t_0)$, and

$$\bar{\bar{y}}(\bar{\bar{t}}_j) = \begin{cases} \tilde{\bar{y}}\left(\frac{t_{i+1}+t_{i+2}}{2}\right) & \text{if the } j\text{th interval of } \bar{\bar{P}} \text{ is } [\frac{t_i+t_{i+1}}{2},\ \frac{t_{i+1}+t_{i+2}}{2}], \\ \tilde{\bar{y}}\left(\frac{t_l+t_{l+1}}{2}\right) & \text{if the } j\text{th interval of } \bar{\bar{P}} \text{ is } [t_l,\ \frac{t_l+t_{l+1}}{2}], \\ \tilde{\bar{y}}(t_m) & \text{if the } j\text{th interval of } \bar{\bar{P}} \text{ is } [\frac{t_{m-1}+t_m}{2},\ t_m], \\ \tilde{\bar{y}}\left(\frac{t_{i+1}+t_i}{2}\right) & \text{if the } j\text{-th interval of } \bar{\bar{P}} \text{ is } [\frac{t_i+t_{i+1}}{2},\ \frac{t_i+t_{i+1}}{2}]. \end{cases}$$

THEOREM 4. *For $\epsilon \in [0,\ 1]$, let t^ϵ be defined by P^ϵ. Let $(v^\epsilon,\ y^\epsilon,\ t^\epsilon)$ be the solution to $QP(|\bar{P}|)$ defined by* (21)–(26). *We have*

$$\begin{aligned} v^\epsilon &= \epsilon\bar{\bar{v}} + (1-\epsilon)\,\bar{v}, \\ y^\epsilon &= \epsilon\bar{\bar{y}} + (1-\epsilon)\,\bar{y}, \\ t^\epsilon &= \epsilon\bar{\bar{t}} + (1-\epsilon)\,\bar{t}, \end{aligned}$$

and $(\bar{\bar{v}},\ \bar{\bar{y}},\ \bar{\bar{t}})$ is feasible for $QP(|\bar{P}|)$.

Proof. Theorem 4 obtains the direct consequence of the definition of $(v^\epsilon,\ y^\epsilon,\ t^\epsilon)$ and $(\bar{\bar{v}},\ \bar{\bar{y}},\ \bar{\bar{t}})$. □

If we pick $(\tilde{\bar{v}}, \tilde{\bar{y}},\ \tilde{\bar{t}})$ introduced in (19) as an optimal solution for $AP(P)$, then by Theorem 2, $|\delta|$ is an upper bound on the current duality gap. By (27) and Theorem 4, the negative objective value of the first Frank–Wolfe iterate for $(\bar{v},\ \bar{y},\ \bar{t})$ gives an upper bound on the current duality gap.

6. A new algorithm for $(SCSCLP)$.

In this section, we give a generic successive quadratic programming algorithm for $(SCSCLP)$.

```
Algorithm $\mathcal{A}$ $(E, F, G, H, a(t), b(t), c(t), g(t), h(t), T, \beta)$.
Let $k = 0$. Let $d$ be the current duality gap initially set to infinity.
Let $(v^k,\ y^k,\ t^k)$ be a feasible solution to $QP(|P^0|)$. Let $P^0$ be a partition on $[0,\ T]$,
such that $a(t)$, $c(t)$, and $h(t)$ are piecewise linear with $P^0$ and $b(t)$ and $g(t)$ are
piecewise constant with $P^0$.
while $d > \beta$ do
    1. Calculate a KKT point of $QP(|P^k|)$ which has an equal or better solution
       value than $(v^k,\ y^k,\ t^k)$.
```

2. Recursively remove redundant intervals in P^k as follows.
   Apply Procedure $PURIFY$ to all pairs of consecutive breakpoints in $D_1^{P^k}$. Let $(\tilde{v}^k,\ \tilde{y}^k,\ \tilde{t}^k)$ be the resulting solution and let Q be the resulting partition. If $(\tilde{v}^k,\ \tilde{y}^k,\ \tilde{t}^k)$ is not a KKT point of $QP(|Q|)$, let $(v^k,\ y^k,\ t^k) = (\tilde{v}^k,\ \tilde{y}^k,\ \tilde{t}^k)$ and $P^k = Q$ and go to Step 1. Otherwise, we denote the resulting purified partition as $\tilde{P}^k = \{t_0, t_1, \dots, t_p\}$.
3. Double the number of intervals. Define P^{k+1} as
   $$P^{k+1} = \{t_0, t_0, t_1, t_1, \dots, t_i, t_i, t_i, \dots, t_p, t_p\},$$
   where each breakpoint in D has two duplicates and all the other breakpoints have only one duplicate. Construct a feasible solution $(\bar{v}^{k+1},\ \bar{y}^{k+1},\ \bar{t}^{k+1})$ for $QP(|P^{k+1}|)$ as in (18).
4. Calculate the current duality gap d. If the solution value of $(\tilde{v}^k,\ \tilde{y}^k,\ \tilde{t}^k)$ is the same as the optimal value of $AP(\tilde{P}^k)$, stop the algorithm. Otherwise go to Step 5.
5. Get a strictly improved solution $(v^{k+1},\ y^{k+1},\ t^{k+1})$ from $(\bar{v}^{k+1},\ \bar{y}^{k+1},\ \bar{t}^{k+1})$ for $QP(|P^{k+1}|)$.
6. Let $k = k + 1$.

end while

Remarks.

1. In Step 1 of Algorithm $\mathcal{A}$, we can use the Frank–Wolfe method or general matrix-splitting algorithms to compute a KKT point of $QP(|P^k|)$.
2. Algorithm $\mathcal{A}$ will not loop between Step 1 and Step 2 forever, because every time Algorithm $\mathcal{A}$ goes from Step 2 to Step 1, the cardinality of P^k is reduced at least by 1.
3. In Step 4 of Algorithm $\mathcal{A}$, we can let $d = V(QP(|\tilde{P}^k|)) - V(AP(\tilde{P}^k))$. We can also let d be the negative objective value of the first Frank–Wolfe iterate for $(\bar{v},\ \bar{y},\ \bar{t})$ and so, instead of checking whether the solution value of $(\tilde{v}^k,\ \tilde{y}^k,\ \tilde{t}^k)$ is the same as the optimal value of $AP(\tilde{P}^k)$, we can check whether the objective value of the first Frank–Wolfe iterate for $(\bar{v},\ \bar{y},\ \bar{t})$ is zero.
4. In Step 5 of Algorithm $\mathcal{A}$, we can use the direction constructed in section 5.3 (cf. $(v^\epsilon,\ y^\epsilon,\ t^\epsilon)$). We can also use the Frank–Wolfe method or general matrix-splitting algorithms to find a descent direction for $(\bar{v}^{k+1},\ \bar{y}^{k+1},\ \bar{t}^{k+1})$. By Theorem 3, we are guaranteed to find a descent direction.

7. Convergence of the new algorithm. In this section we prove that the new algorithm converges. We first describe the argument we will use to show the convergence informally. We use the Frank–Wolfe method or general matrix-splitting algorithms to compute a series of KKT points to a series of generally nonconvex quadratic programs. These KKT points have nondecreasing solution values. By Corollary 3, we can detect whether a KKT point gives an optimal solution to $(SCSCLP)$. If it does, we terminate the algorithm. If not, by Theorem 3, we can find a new solution with approximately twice as many constant control pieces as the current solution but with a strictly improved cost. Since there is only a finite number of different solution values for the KKT points of every quadratic program constructed, and there is an upper bound on the size of the quadratic programs we encounter (see Corollary 4 below), a finite convergence result follows readily. Based on the primal solution, we can compute an optimal dual solution for $(SCSCLP^*)$.

Contrary to the convergence analysis of a variety of algorithms for $(SCLP)$, we do not need to let the norm of the maximal length interval in the discretization tend to zero (as in Pullan [41]). Moreover, neither do we need the explicit knowledge of all the extreme points of a certain set of finite-dimensional linear programs (as in Anderson and Nash [2]). Most importantly, we prove the absence of a duality gap result as a byproduct of the new algorithm, even when there is no optimal solution for $(SCSCLP)$.

In the following, we give upper bounds on the cardinality of $\tilde{P}^k$, the purified partition in Step 2 of Algorithm $\mathcal{A}$. Since by Lemma 4 and Corollary 2 we know that the total number of zero-length intervals in $\tilde{P}^k$ is at most $2|D_1^{\tilde{P}^k}|$, we need only to bound the number of positive-length intervals in $\tilde{P}^k$. We map each positive-length interval of $\tilde{P}^k$ to an extreme point of a certain set of linear programs and then show that the mapping is injective. Before doing so, we give some more notation and several useful lemmas.

Let t_l and t_m be two consecutive breakpoints in $D_1^{\tilde{P}^k}$. By definition, $a(t)$, $c(t)$, and $h(t)$ are linear and $b(t)$ and $g(t)$ are constant on $[t_l,\ t_m)$. Let $[\tilde{t}_{i-1},\ \tilde{t}_i]$ and $[\tilde{t}_i,\ \tilde{t}_{i+1}]$ be two adjacent positive-length intervals in partition $\tilde{P}^k$ such that $[\tilde{t}_{i-1},\ \tilde{t}_{i+1}] \subseteq [t_l,\ t_m]$. Let $\Delta t_i = \tilde{t}_i - \tilde{t}_{i-1}$ and $\Delta t_{i+1} = \tilde{t}_{i+1} - \tilde{t}_i$. We have $\Delta t_i > 0$ and $\Delta t_{i+1} > 0$ by assumption. Let $(\tilde{v}^k, \tilde{y}^k, \tilde{t}^k)$ be the resulting solution in Step 2 of Algorithm $\mathcal{A}$. Let J_i be the set of indices of the constraints in $F\tilde{y}^k(\tilde{t}_i) \le h(\tilde{t}_i)$ that are binding. Let

$$\tilde{u}^k(\tilde{t}_{i-1}+) = \frac{\tilde{v}^k(\tilde{t}_i)}{\Delta t_i}$$

and

$$\tilde{u}^k(\tilde{t}_i+) = \frac{\tilde{v}^k(\tilde{t}_{i+1})}{\Delta t_{i+1}}.$$

It is obvious that $(\tilde{u}^k(\tilde{t}_i+),\ \frac{\tilde{y}^k(\tilde{t}_{i+1}) - \tilde{y}^k(\tilde{t}_i)}{\Delta t_{i+1}})$ is a feasible solution to the following linear system:

$$\begin{aligned}(SYS_{J_i})\ & G\tilde{u}^k(\tilde{t}_i+) + E\frac{\tilde{y}^k(\tilde{t}_{i+1}) - \tilde{y}^k(\tilde{t}_i)}{\Delta t_{i+1}} = \dot{a}(\tilde{t}_i),\\ & H\tilde{u}^k(\tilde{t}_i+) \le b(\tilde{t}_i),\\ & \left(F\frac{\tilde{y}^k(\tilde{t}_{i+1}) - \tilde{y}^k(\tilde{t}_i)}{\Delta t_{i+1}}\right)_{J_i} \le \dot{h}(\tilde{t}_i),\\ & \tilde{u}^k(\tilde{t}_i+) \ge 0.\end{aligned}$$

By introducing new variables, we can eliminate $\frac{\tilde{y}^k(\tilde{t}_{i+1}) - \tilde{y}^k(\tilde{t}_i)}{\Delta t_{i+1}}$ in (SYS_{J_i}) and transform (SYS_{J_i}) into the following linear system:

$$\begin{aligned}(SYS1_{J_i})\ & G\tilde{u}^k(\tilde{t}_i+) + E(w_{i+1} - w_i) = \dot{a}(\tilde{t}_i),\\ & H\tilde{u}^k(\tilde{t}_i+) + \tilde{z}^k(\tilde{t}_i+) = b(\tilde{t}_i),\\ & (F(w_{i+1} - w_i))_{J_i} + x = \dot{h}(\tilde{t}_i),\\ & x \ge 0, w_{i+1} \ge 0, w_i \ge 0, \tilde{u}^k(\tilde{t}_i+) \ge 0, \tilde{z}^k(\tilde{t}_i+) \ge 0.\end{aligned}$$

Every extreme point of the linear program defined by maximizing some linear function over $(SYS1_{J_i})$ defines a unique feasible solution to (SYS_{J_i}), which is called a generalized extreme point for (SYS_{J_i}). Every extreme ray of this linear program defines a unique ray to (SYS_{J_i}), which is called a generalized extreme ray for (SYS_{J_i}). Since this is a feasible finite-dimensional linear program in standard form, the resolution theorem applies. After translating the result into variables in (SYS_{J_i}), we have the following analogue of the resolution theorem for (SYS_{J_i}).

LEMMA 5. *Every feasible solution of (SYS_{J_i}) can be written as the sum of a convex combination of the generalized extreme points of (SYS_{J_i}) and a linear combination (with nonnegative coefficients) of generalized extreme rays to (SYS_{J_i}).*

By Lemma 5, we have

$$\begin{aligned} \tilde{u}^k(\tilde{t}_i+) &= \sum_{j=1}^{k^{(i)}} \lambda_j^{(i)} s_j^{(i)} + \sum_{j=1}^{q^{(i)}} \mu_j^{(i)} r_j^{(i)}, \\ \frac{\tilde{y}^k(\tilde{t}_{i+1}) - \tilde{y}^k(\tilde{t}_i)}{\Delta t_{i+1}} &= \sum_{j=1}^{k^{(i)}} \lambda_j^{(i)} \bar{s}_j^{(i)} + \sum_{j=1}^{q^{(i)}} \mu_j^{(i)} \bar{r}_j^{(i)} \end{aligned} \tag{30}$$

for some positive $k^{(i)} \geq 1$ and nonnegative $q^{(i)} \geq 0$, where $\lambda_j^{(i)} > 0$, $\sum_{j=1}^{k^{(i)}} \lambda_j^{(i)} = 1$, and $\mu_j^{(i)} > 0$, the $(s_j^{(i)},\ \bar{s}_j^{(i)})$ are generalized extreme points to system (SYS_{J_i}), and the $(r_j^{(i)},\ \bar{r}_j^{(i)})$ are generalized extreme rays to system (SYS_{J_i}). Without loss of generality, assume that we have sorted $(s_j^{(i)},\ \bar{s}_j^{(i)})$ in the following order:

$$\dot{c}(\tilde{t}_i)' s_j^{(i)} - g(t_l+)' \bar{s}_j^{(i)} \geq \dot{c}(\tilde{t}_i)' s_{j+1}^{(i)} - g(t_l+)' \bar{s}_{j+1}^{(i)} \qquad \text{for all } j. \tag{31}$$

We have the following result on $(\tilde{v}^k,\ \tilde{y}^k,\ \tilde{t}^k)$.

LEMMA 6.

$$V(QP(|\tilde{P}^k|), (\tilde{v}^k,\ \tilde{y}^k,\ \tilde{t}^k)) \leq V(QP(|P^k|), (v^k,\ y^k,\ t^k)).$$

Proof. Since Procedure *PURIFY* does not increase the solution value of the current solution, the result immediately follows. □

LEMMA 7. *Suppose* (30) *and* (31) *hold for $\tilde{u}^k(\tilde{t}_{i-1}+)$ and $\tilde{u}^k(\tilde{t}_i+)$. Furthermore, suppose $[\tilde{t}_{i-1},\ \tilde{t}_i]$ is not the first positive-length interval that resides on $[t_l,\ t_m]$. Then we have*

$$\dot{c}(\tilde{t}_i)' s_1^{(i-1)} - g(t_l+)' \bar{s}_1^{(i-1)} > \dot{c}(\tilde{t}_i)' s_1^{(i)} - g(t_l+)' \bar{s}_1^{(i)}$$

for the two adjacent positive-length intervals $[\tilde{t}_{i-1},\ \tilde{t}_i]$ and $[\tilde{t}_i,\ \tilde{t}_{i+1}]$ that reside on $[t_l,\ t_m]$.

Proof. We first show that

$$\dot{c}(\tilde{t}_i)' r_j^{(i)} - g(t_l+)' \bar{r}_j^{(i)} \leq 0 \tag{32}$$

for every $j \leq q^{(i)}$ without assuming that $[\tilde{t}_{i-1},\ \tilde{t}_i]$ is not the first positive-length interval that resides on $[t_l,\ t_m]$.

Let $\tau \in (0,\ 1)$. Suppose

$$\tilde{u}^k(\tilde{t}_i+) = \tau u_1 + (1-\tau) u_2$$

and

$$\frac{\tilde{y}^k(\tilde{t}_{i+1}) - \tilde{y}^k(\tilde{t}_i)}{\Delta t_{i+1}} = \tau y_1 + (1-\tau) y_2,$$

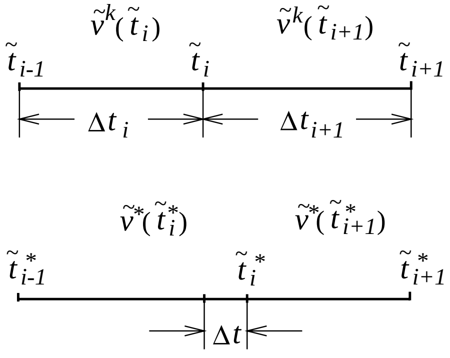

FIG. 3. *Perturbation of the solution.*

where $(u_1,\ y_1)$ and $(u_2,\ y_2)$ are two feasible solutions for (SYS_{J_i}). Let γ be the largest scalar in $(0,\ \tau\Delta t_{i+1}]$ such that $F(\tilde y^k(\tilde t_i) + \gamma y_1) \le h(\tilde t_i)$. Such a γ exists by virtue of the feasibility of $(u_1,\ y_1)$ and $(u_2,\ y_2)$ to system (SYS_{J_i}). For any $\Delta t \in (0,\ \gamma)$, we consider the following perturbation of $(\tilde v^k, \tilde y^k, \tilde t^k)$, as shown in Figure 3:

$$\tilde t_j^* = \begin{cases} \tilde t_i + \Delta t & \text{if } j = i,\\ \tilde t_j & \text{otherwise,} \end{cases}$$

$$\tilde v^*(\tilde t_j^*) = \begin{cases} \tilde v^k(\tilde t_i) + u_1\Delta t & \text{if } j = i,\\ \tilde v^k(\tilde t_j) - u_1\Delta t & \text{if } j = i+1,\\ \tilde v^k(\tilde t_j) & \text{otherwise,} \end{cases}$$

$$\tilde y^*(\tilde t_j^*) = \begin{cases} \tilde y^k(\tilde t_i) + y_1\Delta t & \text{if } j = i,\\ \tilde y^k(\tilde t_j) & \text{otherwise.} \end{cases}$$

We can easily check the feasibility of $(\tilde v^*,\ \tilde y^*,\ \tilde t^*)$ to $QP(|\tilde P|)$. So

$$\begin{aligned}
&\sum_{j=1}^{p} \tilde v^*(\tilde t_j^*)' c\left(\frac{\tilde t_{i-1}^* + \tilde t_i^*}{2}\right) - \sum_{j=1}^{p} \tilde v^k(\tilde t_j)' c\left(\frac{\tilde t_{i-1} + \tilde t_i}{2}\right)\\
&= \left(\frac{c(\tilde t_{i-1}) + c(\tilde t_i^*)}{2}\right)' \tilde v^*(\tilde t_i^*) + \left(\frac{c(\tilde t_i^*) + c(\tilde t_{i+1})}{2}\right)' \tilde v^*(\tilde t_{i+1}^*)\\
&\quad - \left(\frac{c(\tilde t_{i-1}) + c(\tilde t_i)}{2}\right)' \tilde v^k(\tilde t_i) - \left(\frac{c(\tilde t_i) + c(\tilde t_{i+1})}{2}\right)' \tilde v^k(\tilde t_{i+1})\\
&= \left(\frac{c(\tilde t_i^*) - c(\tilde t_i)}{2}\right)' \tilde v^k(\tilde t_i) + \left(\frac{c(\tilde t_i^*) - c(\tilde t_i)}{2}\right)' \tilde v^k(\tilde t_{i+1})\\
&\quad - \frac{\Delta t}{2}(\Delta t_i + \Delta t_{i+1})\dot c(\tilde t_i)' u_1\\
&= \frac{\Delta t \Delta t_i}{2}(\dot c(\tilde t_i)' \tilde u^k(\tilde t_i -) - \dot c(\tilde t_i)' u_1)\\
&\quad + \frac{\Delta t \Delta t_{i+1}}{2}(\dot c(\tilde t_i)' \tilde u^k(\tilde t_i +) - \dot c(\tilde t_i)' u_1).
\end{aligned} \tag{33}$$

Also,

$$\sum_{j=1}^{p} \frac{\tilde t_i^* - \tilde t_{i-1}^*}{2}(\tilde y^*(\tilde t_i^*) + \tilde y^*(\tilde t_{i-1}^*))' g(\tilde t_{i-1}^* +)$$

$$
\begin{aligned}
&-\sum_{j=1}^{p}\frac{\tilde{t}_i-\tilde{t}_{i-1}}{2}(\tilde{y}^k(\tilde{t}_i)+\tilde{y}^k(\tilde{t}_{i-1}))'g(\tilde{t}_{i-1}+)\\
&=\frac{\tilde{t}^*_i-\tilde{t}^*_{i-1}}{2}(\tilde{y}^*(\tilde{t}^*_i)+\tilde{y}^*(\tilde{t}^*_{i-1}))'g(\tilde{t}^*_{i-1}+)\\
&\quad+\frac{\tilde{t}^*_{i+1}-\tilde{t}^*_i}{2}(\tilde{y}^*(\tilde{t}^*_{i+1})+\tilde{y}^*(\tilde{t}^*_i))'g(\tilde{t}^*_i+)\\
&\quad-\frac{\tilde{t}_i-\tilde{t}_{i-1}}{2}(\tilde{y}^k(\tilde{t}_i)+\tilde{y}^k(\tilde{t}_{i-1}))'g(\tilde{t}_{i-1}+)\\
&\quad-\frac{\tilde{t}_{i+1}-\tilde{t}_i}{2}(\tilde{y}^k(\tilde{t}_{i+1})+\tilde{y}^k(\tilde{t}_i))'g(\tilde{t}_i+)\\
&=\frac{\Delta t_i+\Delta t}{2}(\tilde{y}^k(\tilde{t}_i)+\tilde{y}^k(\tilde{t}_{i-1})+\Delta t y_1)'g(\tilde{t}_{i-1}+)\\
&\quad+\frac{\Delta t_{i+1}-\Delta t}{2}(\tilde{y}^k(\tilde{t}_{i+1})+\tilde{y}^k(\tilde{t}_i)+\Delta t y_1)'g(\tilde{t}_i+)\\
&\quad-\frac{\Delta t_i}{2}(\tilde{y}^k(\tilde{t}_i)+\tilde{y}^k(\tilde{t}_{i-1}))'g(\tilde{t}_{i-1}+)-\frac{\Delta t_{i+1}}{2}(\tilde{y}^k(\tilde{t}_{i+1})+\tilde{y}^k(\tilde{t}_i))'g(\tilde{t}_i+)\\
&=\frac{\Delta t}{2}(\tilde{y}^k(\tilde{t}_{i-1})-\tilde{y}^k(\tilde{t}_{i+1})+(\Delta t_i+\Delta t_{i+1})y_1)'g(t_l+). \qquad (34)
\end{aligned}
$$

Combining (33) and (34), we derive

$$
\begin{aligned}
&V(QP(|\tilde{P}^k|),(\tilde{v}^*,\ \tilde{y}^*,\ \tilde{t}^*))-V(QP(|\tilde{P}^k|),(\tilde{v}^k,\ \tilde{y}^k,\ \tilde{t}^k))\\
&=\frac{\Delta t\Delta t_i}{2}\left(\dot{c}(\tilde{t}_i)'\tilde{u}^k(\tilde{t}_i-)-g(\tilde{t}_i+)'\frac{\tilde{y}^k(\tilde{t}_i)-\tilde{y}^k(\tilde{t}_{i-1})}{\Delta t_i}-(\dot{c}(\tilde{t}_i)'u_1-y_1'g(t_l+))\right)\\
&\quad+\frac{\Delta t\Delta t_{i+1}}{2}\left(\dot{c}(\tilde{t}_i)'\tilde{u}^k(\tilde{t}_i+)-g(\tilde{t}_i+)'\frac{\tilde{y}^k(\tilde{t}_{i+1})-\tilde{y}^k(\tilde{t}_i)}{\Delta t_{i+1}}-(\dot{c}(\tilde{t}_i)'u_1-y_1'g(t_l+))\right). \qquad (35)
\end{aligned}
$$

By the definition of a KKT point and the discussion following it in section 3.1, a feasible solution to $QP(|P|)$ is a KKT point if and only if there is no feasible descent direction for this solution. Hence

$$
V(QP(|\tilde{P}^k|),(\tilde{v}^*,\ \tilde{y}^*,\ \tilde{t}^*))-V(QP(|\tilde{P}^k|),(\tilde{v}^k,\ \tilde{y}^k,\ \tilde{t}^k))\geq 0. \qquad (36)
$$

Thus (35) implies that $\dot{c}(\tilde{t}_i)'u_1-y_1'g(t_l+)$ is uniformly bounded from above for any possible choice of (u_1, y_1).

For any $\bar{j}\leq q^{(i)}$ and any $\epsilon\in(0\ ,1)$, we have

$$
\begin{aligned}
\tilde{u}^k(\tilde{t}_i+)&=\epsilon\lambda_1^{(i)}(s_1^{(i)}+\frac{\mu_{\bar{j}}^{(i)}}{\epsilon\lambda_1^{(i)}}r_{\bar{j}}^{(i)})\\
&\quad+(1-\epsilon\lambda_1^{(i)})\left(\sum_{j=2}^{k^{(i)}}\frac{\lambda_j^{(i)}}{1-\epsilon\lambda_1^{(i)}}s_j^{(i)}+\frac{\lambda_1^{(i)}(1-\epsilon)}{1-\epsilon\lambda_1^{(i)}}s_1^{(1)}+\sum_{j=1,j\neq\bar{j}}^{q^{(i)}}\frac{\mu_j^{(i)}}{1-\epsilon\lambda_1^{(i)}}r_j^{(i)}\right)
\end{aligned}
$$

and

$$
\frac{\tilde{y}^k(\tilde{t}_{i+1})-\tilde{y}^k(\tilde{t}_i)}{\Delta t_{i+1}}
$$

$$
\begin{aligned}
&= \epsilon\lambda_1^{(i)}\left(\bar{s}_1^{(i)} + \frac{\mu_{\bar{j}}^{(i)}}{\epsilon\lambda_1^{(i)}}\bar{r}_{\bar{j}}^{(i)}\right)\\
&\quad + (1-\epsilon\lambda_1^{(i)})\left(\sum_{j=2}^{k^{(i)}}\frac{\lambda_j^{(i)}}{1-\epsilon\lambda_1^{(i)}}\bar{s}_j^{(i)} + \frac{\lambda_1^{(i)}(1-\epsilon)}{1-\epsilon\lambda_1^{(i)}}\bar{s}_1^{(1)} + \sum_{j=1,j\neq\bar{j}}^{q^{(i)}}\frac{\mu_j^{(i)}}{1-\epsilon\lambda_1^{(i)}}\bar{r}_j^{(i)}\right).
\end{aligned}
$$

By letting

$$
u_1 = s_1^{(i)} + \frac{\mu_{\bar{j}}^{(i)}}{\epsilon\lambda_1^{(i)}} r_{\bar{j}}^{(i)}, \qquad y_1 = \bar{s}_1^{(i)} + \frac{\mu_{\bar{j}}^{(i)}}{\epsilon\lambda_1^{(i)}}\bar{r}_{\bar{j}}^{(i)},
$$

and letting ϵ tend to zero, the above boundedness result on $\dot{c}(\tilde{t}_i)'u_1^{(i)} - y_1' g(t_l+)$ implies (32). Since $[t_{i-1},\ t_i]$ is not the first positive-length interval that resides on $[t_l,\ t_m]$, we can similarly have

$$
\dot{c}(\tilde{t}_i)' r_j^{(i-1)} - g(t_l+)'\bar{r}_j^{(i-1)} \leq 0 \quad \text{for all } j.
$$

These together with (30) and (31) give

$$
\dot{c}(\tilde{t}_i)' s_1^{(i-1)} - g(t_l+)'\bar{s}_1^{(i-1)} \geq \dot{c}(\tilde{t}_i)'\tilde{u}^k(\tilde{t}_{i-1}+) - g(\tilde{t}_i+)'\frac{\tilde{y}^k(\tilde{t}_i) - \tilde{y}^k(\tilde{t}_{i-1})}{\Delta t_i}. \tag{37}
$$

Similarly,

$$
\dot{c}(\tilde{t}_i)' s_1^{(i)} - g(t_l+)'\bar{s}_1^{(i)} \geq \dot{c}(\tilde{t}_i)'\tilde{u}^k(\tilde{t}_i+) - g(\tilde{t}_i+)'\frac{\tilde{y}^k(\tilde{t}_{i+1}) - \tilde{y}^k(\tilde{t}_i)}{\Delta t_{i+1}}. \tag{38}
$$

Since $\tilde{P}$ is a purified partition, by Procedure *PURIFY*, the opposite of (11) holds, which is equivalent to

$$
\dot{c}(\tilde{t}_i)'\tilde{u}^k(\tilde{t}_{i-1}+) - g(\tilde{t}_i+)'\frac{\tilde{y}^k(\tilde{t}_i) - \tilde{y}^k(\tilde{t}_{i-1})}{\Delta t_i} > \dot{c}(\tilde{t}_i)'\tilde{u}^k(\tilde{t}_i+) - g(\tilde{t}_i+)'\frac{\tilde{y}^k(\tilde{t}_{i+1}) - \tilde{y}^k(\tilde{t}_i)}{\Delta t_{i+1}}. \tag{39}
$$

Now, suppose

$$
\dot{c}(\tilde{t}_i)' s_1^{(i-1)} - g(t_l+)'\bar{s}_1^{(i-1)} \leq \dot{c}(\tilde{t}_i)' s_1^{(i)} - g(t_l+)'\bar{s}_1^{(i)}.
$$

By (37) and (39), we have

$$
\dot{c}(\tilde{t}_i)'\tilde{u}^k(\tilde{t}_i+) - g(\tilde{t}_i+)'\frac{\tilde{y}^k(\tilde{t}_{i+1}) - \tilde{y}^k(\tilde{t}_i)}{\Delta t_{i+1}} < \dot{c}(\tilde{t}_i)' s_1^{(i)} - g(t_l+)'\bar{s}_1^{(i)}
$$

and

$$
\dot{c}(\tilde{t}_i)'\tilde{u}^k(\tilde{t}_{i-1}+) - g(\tilde{t}_i+)'\frac{\tilde{y}^k(\tilde{t}_i) - \tilde{y}^k(\tilde{t}_{i-1})}{\Delta t_i} \leq \dot{c}(\tilde{t}_i)' s_1^{(i)} - g(t_l+)'\bar{s}_1^{(i)}.
$$

Let $u_1 = s_1^{(i)}$ and $y_1 = \bar{s}_1^{(i)}$. Then the above relationship together with (35) gives

$$
V(QP(|\tilde{P}^k|), (\tilde{v}^*,\ \tilde{y}^*,\ \tilde{t}^*)) - V(QP(|\tilde{P}^k|), (\tilde{v}^k,\ \tilde{y}^k,\ \tilde{t}^k)) < 0,
$$

which contradicts that $(\tilde{v}^k,\ \tilde{y}^k,\ \tilde{t}^k)$ is a KKT point for $QP(|\tilde{P}^k|)$ (cf. (36)). □

Since $\dot{c}(\tilde{t}_i)$ is a constant vector over $[t_l,\ t_m]$, as a consequence of Lemma 7, every nonzero-length interval that resides on $[t_l,\ t_m]$ (except the first nonzero-length interval) corresponds to a different generalized extreme point of some system (SYS_{J_i}). Since only a finite number of different systems (SYS_{J_i}) exists, and for each (SYS_{J_i}) there is a finite number of generalized extreme points, we see there is only a finite number of nonzero-length intervals that reside on $[t_l,\ t_m]$. Since the number of zero-length intervals that reside on $[t_l,\ t_m]$ is at most two (one on each end of $[t_l,\ t_m]$), there is also a finite number of breakpoints in $[t_l,\ t_m]$. Thus we have the following corollary.

COROLLARY 4. *There is a finite number of breakpoints in* $\tilde{P}^k$.

There is only a finite number of different solution values for all the KKT points of $QP(|P|)$, as shown in the following lemma.

LEMMA 8. *The KKT points for* $QP(|P|)$ *are the union of a finite number of connected sets. Over each connected component of KKT points of* $QP(|P|)$*, the objective value is a constant. Furthermore, the number of connected sets is bounded from above by a number that depends on* $|P|$ *only.*

Proof. It is easily seen that a solution to $QP(|P|)$ is a KKT point of $QP(|P|)$ if and only if it is a solution to a feasible symmetric affine variational inequality problem whose dimension depends only on $|P|$ (cf. section 3.1). The lemma now follows directly from Lemma 3.1 of Luo and Tseng [31]. □

We now present the main convergence result of the paper.

THEOREM 5. *Algorithm* $\mathcal{A}$ *will terminate after a finite number of iterations.*

Proof. Suppose Algorithm $\mathcal{A}$ does not terminate after a finite number of iterations. It is guaranteed by Theorem 3 that Step 4 of Algorithm $\mathcal{A}$ would produce a strictly improved solution, and thus every iteration of Algorithm $\mathcal{A}$ would give a KKT point of a certain $QP(|P|)$ that has a strictly better solution value. By Lemma 8, the KKT points generated by $QP(|P|)$ should lie on a different connected KKT points component of $QP(|P|)$ for every $|P|$. This means that the cardinality of P is unbounded and contradicts Corollary 4. □

8. New structural and duality results. As a result of Algorithm $\mathcal{A}$ and Theorem 5, we have the following new structural result for $(SCSCLP)$.

THEOREM 6. *Under Assumption* 1*, Algorithm* $\mathcal{A}$ *terminates with a solution to* $QP(|P|)$ *for some* P *that gives the optimal objective value of* $(SCSCLP)$ *and can be closely approximated by a series of piecewise constant controls for* $(SCSCLP)$*. When the solution set for* $(SCSCLP)$ *is bounded and* E *is an identity matrix, Algorithm* $\mathcal{A}$ *terminates with a piecewise constant optimal control with partition* P *such that* $t_i \neq t_{i-1}$ *for all* i*. Furthermore, over each interval* $[t_{i-1},\ t_i)$*,* $(u(t_i+), \frac{y(t_{i+1})-y(t_i)}{t_{i+1}-t_i})$ *is a convex combination of the generalized extreme points of linear system* (SYS_{J_i})*, where* J_i *is a subset of* $\{1, \ldots, n_2\}$.

Proof. The first part of the theorem is a direct consequence of Theorem 5. The second part of the theorem follows from Lemma 5 and the remark following the proof of Lemma 1. □

We remark that when the solution set for $(SCSCLP)$ is unbounded, it is possible that the optimal solution value is not attained. We next derive the following new duality result for $(SCSCLP)$.

THEOREM 7. *Under Assumption* 1*, there is no duality gap between* $(SCSCLP)$ *and* $(SCSCLP^*)$*. There always exists an optimal solution for* $(SCSCLP^*)$ *that is piecewise linear. Furthermore, there exists a bounded measurable optimal solution for* $(SCSCLP)$ *if and only if Algorithm* $\mathcal{A}$ *terminates with such a solution.*

Proof. The first part of the theorem is a direct consequence of Theorem 5.

Denote $\tilde{P}^k$ as the final purified partition when Algorithm $\mathcal{A}$ terminates. To prove the second part of the theorem, we first show that the zero-length intervals in $\tilde{P}^k$ can be eliminated in the dual problem $AP^*(P)$. Let $[t_{i-1},\ t_i]$ be a zero-length interval that resides on $[t_l,\ t_m]$, where t_l and t_m are two consecutive breakpoints in $D_1^{\tilde{P}^k}$. By Lemma 4, the zero-length intervals can be located only at the breakpoints in $D_1^{\tilde{P}^k}$. We assume $t_i = t_m$ (the case $t_{i-1} = t_l$ can be treated similarly).

Let $(\hat{\pi},\ \hat{\eta},\ \hat{\xi})$ be an optimal solution for $AP^*(\tilde{P}^k)$. Then we can construct a new solution $(\tilde{\pi},\ \tilde{\eta},\ \tilde{\xi})$ for $AP^*(\tilde{P}^k)$ in the following way. Let $(\tilde{\pi},\ \tilde{\eta},\ \tilde{\xi})$ equal $(\hat{\pi},\ \hat{\eta},\ \hat{\xi})$ except

$$\begin{aligned}
\tilde{\pi}(t_{i-1}+) &= \hat{\pi}(t_{i-1}-), \quad \tilde{\pi}(t_i-) = \hat{\pi}(t_{i-1}-),\\
\tilde{\eta}(t_{i-1}+) &= \hat{\eta}(t_{i-1}-), \quad \tilde{\eta}(t_i-) = \hat{\eta}(t_{i-1}-),\\
\tilde{\xi}\left(\frac{t_{i-1}+t_i}{2}\right) &= 0, \qquad \tilde{\xi}(t_{i-1}) = 0,\\
\tilde{\xi}(t_i) &= \hat{\xi}\left(\frac{t_{i-1}+t_i}{2}\right) + \hat{\xi}(t_{i-1}) + \hat{\xi}(t_i).
\end{aligned}$$

It is easy to check the feasibility of $(\tilde{\pi},\ \tilde{\eta},\ \tilde{\xi})$. It is a fact that $(\tilde{\pi},\ \tilde{\eta},\ \tilde{\xi})$ and $(\hat{\pi},\ \hat{\eta},\ \hat{\xi})$ have the same solution value in $AP^*(\tilde{P}^k)$. Let $\bar{P}$ be $\tilde{P}^k \setminus \{t_{i-1}\}$. By eliminating the elements $\tilde{\pi}(t_{i-1}-)$, $\tilde{\pi}(t_{i-1}+)$, $\tilde{\eta}(t_{i-1}-)$, $\tilde{\eta}(t_{i-1}+)$, $\tilde{\xi}(t_{i-1})$, and $\tilde{\xi}\left(\frac{t_{i-1}+t_i}{2}\right)$ from $(\tilde{\pi},\ \tilde{\eta},\ \tilde{\xi})$, we can get a feasible solution $(\bar{\pi},\ \bar{\eta},\ \bar{\xi})$ for $AP(\bar{P})$. Also, $(\bar{\pi},\ \bar{\eta},\ \bar{\xi})$ has the same solution value as $(\tilde{\pi},\ \tilde{\eta},\ \tilde{\xi})$.

By repeating this process, we can eliminate all the zero-length intervals in $\tilde{P}^k$ and define a feasible solution for $AP^*(P)$ from the resulting partition P. From this feasible solution, we can construct an optimal solution for $(SCSCLP^*)$ that is piecewise linear. This proves the second part of the theorem.

One direction of the third part of the theorem is quite obvious. The other direction (i.e., if there exists a bounded measurable optimal solution for $(SCSCLP)$, then Algorithm $\mathcal{A}$ will find such a solution) can be shown as follows. Let the bounded measurable solution $(u(t),\ y(t))$ be optimal for $(SCSCLP)$. By the second part of the theorem, there always exists an optimal solution $(\pi(t),\ \eta(t),\ \xi(t))$ for $(SCSCLP^*)$ that is piecewise linear with partition P (defined by removing all the zero-length intervals from $\tilde{P}^K$). By Corollary 1, the complementary slackness condition (5) is satisfied. Let $\bar{u}(t)$ be the piecewise constant extensions of $u(t_0+),\ u(t_1+), \dots, u(t_{p-1}+)$. Let $\bar{y}(t)$ be the piecewise-linear extension of $y(t_0+), y(t_1-)\ y(t_1+), \dots, y(t_{p-1}+), y(t_p-)$. The solution $(\bar{u}(t),\ \bar{y}(t))$ is a feasible solution for $(SCSCLP)$ which together with $(\pi(t),\ \eta(t),\ \xi(t))$ satisfies (5). Therefore, Corollary 1 again, $(\bar{u}(t),\ \bar{y}(t))$ is optimal for $(SCSCLP)$. □

9. Computational results. Algorithm $\mathcal{A}$ has been implemented and tested on a Sparc 10/41. The program is written in *C*. We used the academic version of *LOQO* Version 1.08 by Vanderbei [48]. We call its subroutines to solve intermediate linear programming and quadratic programming subproblems.

The implementation of Algorithm $\mathcal{A}$ consists of four modules: the input data processing module, the output module, the successive quadratic programming module, and the lower bound module. The successive quadratic programming module uses the Frank–Wolfe method to iteratively solve a sequence of quadratic programs, as outlined in Algorithm $\mathcal{A}$. The lower bound module uses the partition generated by

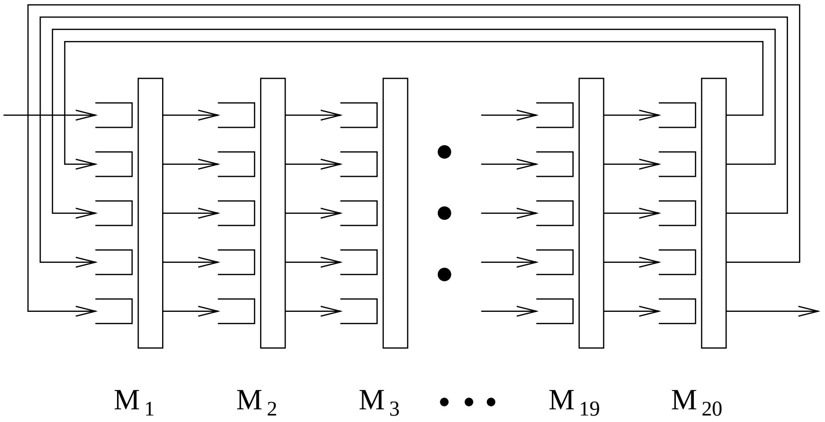

FIG. 4. *The reentrant line for the example.*

the successive quadratic programming module to calculate a dual feasible solution for the problem.

We next give a numerical example that arises in manufacturing systems. The example is a reentrant line, as in Kumar [25]. A reentrant line is a multiclass queuing network with fixed routing.

The reentrant line we consider is shown in Figure 4. We have from left to right n stations (in Figure 4, we have 20 stations), and each station services 5 different classes of customers. There are $5n$ classes of customers in total. Class i customers will be served at machine $\lfloor (i-1)/n + 1 \rfloor$. After class i customer finishes service, it will become class $i+1$ customer if $i < 5n$ and exit the system otherwise. For this system, we assume the exogenous arrival rate for class 1 customer is 1 and is zero for all other classes. We generate randomly the mean service time, the cost per unit time, and the initial number of customers for each class of customers. Our objective is to find an optimal control policy (involving both routing and sequencing decisions) that minimizes the cumulated cost of queuing over a fixed time horizon $[0,\ T]$.

We can formulate the problem as an $(SCSCLP)$. Let $y_i(t)$ be the queue length of class i customers at time t. If class i customers are served at machine j, we let $u_i(t)$ be the proportion of machine capacity of machine j that is devoted to class i customers at time t. The G matrix of the $(SCSCLP)$ is the node-arc incidence matrix for the following line digraph: Node i of the graph corresponds to class i and the edges are $(i,\ i+1)$ for $i = 1, \ldots, 5n-1$. The matrix H is a block diagonal matrix, with each block a row vector of mean service times of the customers served at the same machine. F is a negative identity matrix. $c(t)$ is a zero vector. $g(t)$ is a randomly generated vector. $a(t) = y(0) + e_1 t$ with e_1 the unit vector whose first component is one and all the other components are zero. $b(t)$ is a vector of all ones and $h(t)$ is a zero vector.

The computational sequences are shown in Table 9.1.

When we fix the precision requirement and vary the number of stations in the example, we find that the computational time grows almost quadratically with the problem dimension, as shown in Figure 5. This is due to the fact that the number of control pieces grows almost linearly with the problem dimension and the total number of nonzero elements in the intermediate problems grows almost quadratically with the number of stations. Notice that for the largest example in Figure 5 (25 stations) there are 250 continuous variables.

Table 9.1
Test results for the example.

# Iter.	Obj. Value	# Pieces	Dual obj.	Time in sec.
0	20987.1355	7		
1	5986.7656	7	5956.7923	134.05
2	5965.1006	15	5962.7291	1738.2
3	5963.6674	29	5963.2700	2436.61

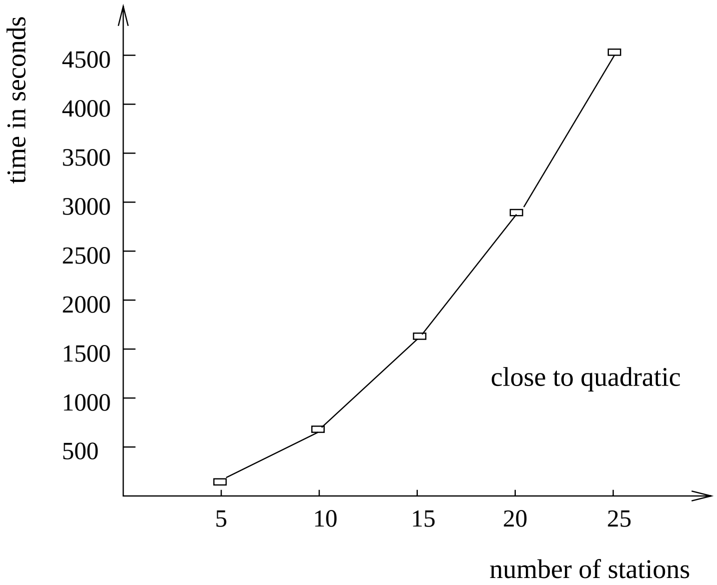

Fig. 5. *Computation time versus the number of stations* (*with precision fixed at* 0.0001).

This problem demonstrates that our algorithm can solve rather large problems. It is our experience that $(SCSCLP)$ is easier to approximate than to solve exactly. The computational time grows almost exponentially with the accuracy requirement. A key feature of Algorithm $\mathcal{A}$ is that it keeps the number of breakpoints as small as possible, which in turn makes the size of intermediate quadratic programming subproblems small. It is this feature that makes the algorithm efficient. We believe that Algorithm $\mathcal{A}$ can be made even more efficient if the special structure of the intermediate quadratic programs is exploited.

A CONVEX OPTIMIZATION APPROACH TO THE RATIONAL COVARIANCE EXTENSION PROBLEM*

CHRISTOPHER I. BYRNES†, SERGEI V. GUSEV‡, AND ANDERS LINDQUIST§

Abstract. In this paper we present a convex optimization problem for solving the rational covariance extension problem. Given a partial covariance sequence and the desired zeros of the modeling filter, the poles are uniquely determined from the unique minimum of the corresponding optimization problem. In this way we obtain an algorithm for solving the covariance extension problem, as well as a constructive proof of Georgiou's seminal existence result and his conjecture, a stronger version of which we have resolved in [Byrnes et al., *IEEE Trans. Automat. Control*, AC-40 (1995), pp. 1841–1857].

Key words. rational covariance extension, partial stochastic realization, trigonometric moment problem, spectral estimation, speech processing, stochastic modeling

1. Introduction.

In [7] a solution to the problem of parameterizing all rational extensions of a given window of covariance data has been given. This problem has a long history, with antecedents going back to potential theory in the work of Carathéodory, Toeplitz, and Schur [9, 10, 31, 30], and continuing in the work of Kalman, Georgiou, Kimura, and others [18, 14, 21]. It has been of more recent interest due to its significant interface with problems in signal processing and speech processing [11, 8, 25, 20] and in stochastic realization theory and system identification [2, 32, 22]. Indeed, the recent solution to this problem, which extended a result by Georgiou and confirmed one of his conjectures [13, 14], has shed some light on the stochastic (partial) realization problem through the development of an associated Riccati-type equation, whose unique positive semidefinite solution has as its rank the minimum dimension of a stochastic linear realization of the given rational covariance extension [6]. In both its form as a complete parameterization of rational extensions to a given covariance sequence and as an indefinite Riccati-type equation, one of the principal problems which remains open is that of developing effective computational methods for the approximate solution of this problem. In this paper, motivated by the effectiveness of interior point methods for solving nonlinear convex optimization problems, we recast the fundamental problem as such an optimization problem.

In section 2 we describe the principal results for the rational covariance extension problem and set notation we shall need throughout. The only solution to this problem for which there have been simple computational procedures is the so-called *maximum entropy* solution, which is the particular solution that maximizes the entropy gain.

In section 3 we demonstrate that the infinite-dimensional optimization problem for determining this solution has a simple finite-dimensional dual. This motivates the introduction in section 4 of a nonlinear, strictly convex functional defined on a closed convex set naturally related to the covariance extension problem. We first show that any solution of the rational covariance extension problem lies in the interior of this convex set and that, conversely, an interior minimum of this convex functional will correspond to the unique solution of the covariance extension problem. Our interest in this convex optimization problem is, therefore, twofold: as a starting point for the computation of an explicit solution and as a means of providing an alternative proof of the rational covariance extension theorem.

Concerning the existence of a minimum, we show that this functional is proper and bounded below, i.e., that the sublevel sets of this functional are compact. From this, it follows that there exists a minimum. Since uniqueness follows from strict convexity of the functional, the central issue which needs to be addressed in order to solve the rational covariance extension problem is whether, in fact, this minimum is an interior point. Indeed, our formulation of the convex functional, which contains a barrier-like term, was inspired by interior point methods. However, in contrast to interior point methods, the barrier function we have introduced does not become infinite on the boundary of our closed convex set. Nonetheless, we are able to show that the gradient, rather than the value, of the convex functional becomes infinite on the boundary. The existence of an interior point which minimizes the functional then follows from this observation.

In section 5, we apply these convex minimization techniques to the rational covariance extension problem, noting that, as hinted above, we obtain a new proof of Georgiou's conjecture. Moreover, this proof, unlike our previous proof [7] and the existence proof of Georgiou [14], is constructive. Consequently, we have also obtained an algorithmic procedure for solving the rational covariance extension problem. In section 6 we report some computational results and present some simulations.

2. The rational covariance extension problem.

It is well known that the spectral density $\Phi(z)$ of a purely nondeterministic stationary random process $\{y(t)\}$ is given by the Fourier expansion

$$\Phi(e^{i\theta}) = \sum_{-\infty}^{\infty} c_k e^{ik\theta} \tag{2.1}$$

on the unit circle, where the covariance lags

$$c_k = \mathrm{E}\{y_{t+k}y_t\}, \quad k = 0, 1, 2, \dots \tag{2.2}$$

play the role of the Fourier coefficients

$$c_k = \frac{1}{2\pi}\int_{-\pi}^{\pi} e^{ik\theta}\Phi(e^{i\theta})d\theta. \tag{2.3}$$

In spectral estimation [8], identification [2, 22, 32], speech processing [11, 25, 24, 29], and several other applications in signal processing and systems and control, we are faced with the inverse problem of finding a spectral density which is *coercive*, i.e., positive on the unit circle, given only

$$c = (c_0, c_1, \dots, c_n), \tag{2.4}$$

which is a *partial covariance sequence* positive in the sense that

$$T_n = \begin{bmatrix} c_0 & c_1 & \cdots & c_n \\ c_1 & c_0 & \cdots & c_{n-1} \\ \vdots & \vdots & \ddots & \vdots \\ c_n & c_{n-1} & \cdots & c_0 \end{bmatrix} > 0, \tag{2.5}$$

i.e., the Toeplitz matrix T_n is positive definite.

In fact, the covariance lags (2.2) are usually estimated from an approximation

$$\frac{1}{N-k+1} \sum_{t=0}^{N-k} y_{t+k} y_t$$

of the ergodic limit

$$c_k = \lim_{T \to \infty} \frac{1}{T} \sum_{t=0}^{T} y_{t+k} y_t,$$

since only a finite string

$$y_0, y_1, y_2, y_3, \dots, y_N$$

of observations of the process $\{y(t)\}$ is available, and therefore we can only estimate a finite partial covariance (2.4), where $n << N$.

The corresponding inverse problem is a version of the *trigonometric moment problem* [1, 16]: Given a sequence (2.4) of real numbers satisfying the positivity condition (2.5), find a coercive spectral density $\Phi(z)$ such that (2.3) is satisfied for $k = 0, 1, 2, \dots, n$. Of course there are infinitely many such solutions, and we shall shortly specify some additional properties which we would like the solution to have.

The trigonometric moment problem, as stated above, is equivalent to the *Carathéodory extension problem* to determine an extension

$$c_{n+1}, c_{n+2}, c_{n+3}, \dots, \tag{2.6}$$

with the property that the function

$$v(z) = \frac{1}{2} c_0 + c_1 z^{-1} + c_2 z^{-2} + \cdots \tag{2.7}$$

is *strictly positive real*, i.e., is analytic on and outside the unit circle (so that the Laurent expansion (2.7) holds for all $|z| \geq 1$) and satisfies

$$v(z) + v(z^{-1}) > 0 \quad \text{on the unit circle.} \tag{2.8}$$

In fact, given such a $v(z)$,

$$\Phi(z) = v(z) + v(z^{-1}) \tag{2.9}$$

is a solution to the trigonometric moment problem. Conversely, any coercive spectral density $\Phi(z)$ uniquely defines a strictly positive real function $v(z)$ via (2.9).

These problems are classical and go back to Carathéodory [9, 10], Toeplitz [31], and Schur [30]. In fact, Schur parameterized all solutions in terms of what are now known as the *Schur parameters*, or, more commonly in the circuits and systems literature, as *reflection coefficients*, and which are easily determined from the covariance lags via the Levinson algorithm [27]. More precisely, modulo the choice of c_0, there is a one-to-one correspondence between infinite covariance sequences $c_0, c_1, c_2, \dots$ and Schur parameters $\gamma_0, \gamma_1, \dots$ such that

$$|\gamma_t| < 1 \quad \text{for } t = 0, 1, 2, \dots, \tag{2.10}$$

under which partial sequences (2.4) correspond to partial sequences $\gamma_0, \gamma_1, \dots, \gamma_{n-1}$ of Schur parameters. Therefore, covariance extension (2.6) amounts precisely to finding a continuation

$$\gamma_n, \gamma_{n+1}, \gamma_{n+2}, \dots \tag{2.11}$$

of Schur parameters satisfying (2.10). Each such solution is only guaranteed to yield a $v(z)$ which is meromorphic.

In circuits and systems theory, however, we are generally only interested in solutions which yield a rational $v(z)$ of at most degree n, or, equivalently, a rational spectral density $\Phi(z)$ of at most degree $2n$. Then the unique rational, stable, minimum-phase function $w(z)$ having the same degree as $v(z)$ and satisfying

$$w(z)w(z^{-1}) = \Phi(z) \tag{2.12}$$

is the transfer function of a *modeling filter*, which shapes white noise into a random process with the first $n+1$ covariance lags given by (2.4); see, e.g., [7, 6] for more details.

Setting all free Schur parameters (2.11) equal to zero, which clearly satisfies the condition (2.10), yields a rational solution

$$\Phi(z) = \frac{1}{a(z)a(z^{-1})}, \tag{2.13}$$

where $a(z)$ is a polynomial given by

$$a(z) = a_0 z^n + a_1 z^{n-1} + \cdots + a_n \quad (a_0 > 0), \tag{2.14}$$

which is easily computed via the Levinson algorithm [27]. This so-called *maximum entropy solution* is an all-pole or AR solution, and the corresponding modeling filter

$$w(z) = \frac{z^n}{a(z)} \tag{2.15}$$

has all its zeros at the origin.

However, in many applications a wider variety in the choice of zeros is required in the spectral density $\Phi(z)$. To illustrate this point, consider in Figure 2.1 a spectral density in the form of a periodogram determined from a speech signal sampled over 20 milliseconds (in which time interval it represents a stationary process) together with a maximum entropy solution corresponding to $n = 6$. As can be seen, the latter yields a rather flat spectrum which is unable to approximate the valleys or the "notches" in the speech spectrum, and therefore in speech synthesis, the maximum entropy solution results in artificial speech which sounds quite flat. This is a manifestation of the fact that all the zeros of the maximum entropy filter (2.15) are located at the origin and thus do not give rise to a frequency where the power spectrum vanishes. However,

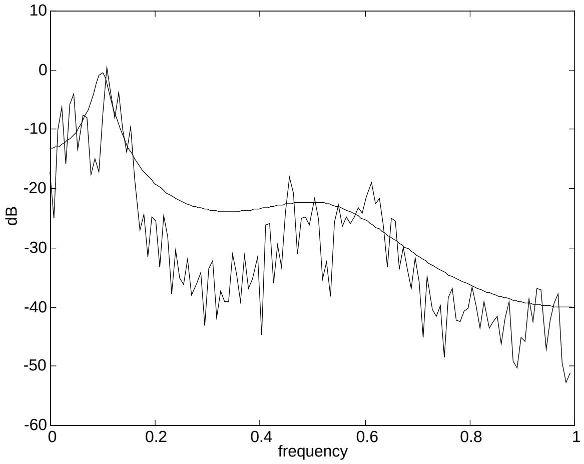

FIG. 2.1. *Spectral envelope of a maximum entropy solution.*

were we able to place some zeros of the modeling filter reasonably close to the unit circle, these would produce notches in the spectrum at approximately the frequency of the arguments of those zeros.

For this reason, it is widely appreciated in the signal and speech processing community that regeneration of human speech requires the design of filters having nontrivial zeros [3, p. 1726], [24, pp. 271–272], [29, pp. 76–78]. Indeed, while all-pole filters can reproduce many human speech sounds, the acoustic theory teaches that nasals and fricatives require both zeros and poles [24, pp. 271–272], [29, p. 105].

Therefore, we are interested in modeling filters

$$w(z) = \frac{\sigma(z)}{a(z)}, \tag{2.16}$$

for which (2.14) and

$$\sigma(z) = z^n + \sigma_1 z^{n-1} + \cdots + \sigma_n \tag{2.17}$$

are *Schur polynomials*, i.e., polynomials with all roots in the open unit disc. In this context, the maximum entropy solution corresponds to the choice $\sigma(z) = z^n$.

An important mathematical question, therefore, is to what extent it is possible to assign desired zeros and still satisfy the interpolation condition that the partial covariance sequence (2.4) is as prescribed. In [13] (see also [14]), Georgiou proved that for any prescribed zero polynomial $\sigma(z)$ there exists a modeling filter $w(z)$ and conjectured that this correspondence would yield a complete parameterization of all rational solutions of at most degree n, i.e., that the correspondence between v and a choice of positive sequence (2.4) and a choice of Schur polynomial (2.14) would be a bijection. This is a nontrivial and highly nonlinear problem, since generally there is no method to see which choices of free Schur parameters will yield rational solutions. In [7] we resolved this long-standing conjecture by proving the following theorem as a corollary of a more general theorem on complementary foliations of the space of all rational positive real functions of degree at most n.

THEOREM 2.1 (see [7]). *Given any partial covariance sequence* (2.4) *and Schur polynomial* (2.17)*, there exists a unique Schur polynomial* (2.14) *such that* (2.16) *is* *a minimum-phase spectral factor of a spectral density* $\Phi(z)$ *satisfying*

$$\Phi(z) = c_0 + \sum_{k=1}^{\infty} \hat{c}_k (z^k + z^{-k}),$$

where

$$\hat{c}_k = c_k \quad \textit{for} \quad i = 1, 2, \dots, n.$$

In particular, the solutions of the rational positive extension problem are in one-to-one correspondence with self-conjugate sets of n points (counted with multiplicity) lying in the open unit disc, i.e., with all possible zero structures of modeling filters. Moreover, this correspondence is bianalytic.

Consequently, we not only proved Georgiou's conjecture that the family of all rational covariance extensions of (2.4) of degree at most n is completely parameterized in terms of the zeros of the corresponding modeling filters $w(z)$, but also that the modeling filter $w(z)$ depends analytically on the covariance data and the choice of zeros, a strong form of well-posedness increasing the likelihood of finding a numerical algorithm.

In fact, both Georgiou's existence proof and our proof of Theorem 2.1 are nonconstructive. However, in this paper we present for the first time an algorithm which, given the partial covariance sequence (2.4) and the desired zero polynomial (2.17), computes the unique pole polynomial (2.14). This is done via the convex optimization problem to minimize the value of the function $\varphi : \mathbb{R}^{n+1} \to \mathbb{R}$, defined by

$$\begin{aligned} \varphi(q_0, q_1, \dots, q_n) &= c_0 q_0 + c_1 q_1 + \cdots + c_n q_n \\ &\quad - \frac{1}{2\pi} \int_{-\pi}^{\pi} \log Q(e^{i\theta}) |\sigma(e^{i\theta})|^2 d\theta \end{aligned} \tag{2.18}$$

over all $q_0, q_1, \dots, q_n$ such that

$$Q(e^{i\theta}) = q_0 + q_1 \cos\theta + q_2 \cos 2\theta + \cdots + q_n \cos n\theta > 0 \quad \text{for all } \theta. \tag{2.19}$$

In sections 4 and 5 we show this problem has a unique minimum. In this way we shall also provide a new and constructive proof of the weaker form of Theorem 2.1 conjectured by Georgiou.

Using this convex optimization problem, a sixth-degree modeling filter with zeros at the appropriate frequencies can be constructed for the speech segment represented by the periodogram of Figure 2.1. In fact, Figure 2.2 illustrates the same periodogram together with the spectral density of such a filter. As can be seen, this filter yields a much better description of the notches than does the maximum entropy filter.

Before turning to the main topic of this paper, the convex optimization problem for solving the rational covariance extension problem for arbitrarily assigned zeros, we shall provide a motivation for this approach in terms of the maximum entropy solution.

3. The maximum entropy solution. As a preliminary we shall first consider the maximum entropy solution discussed in section 2. The reason for this is that, as indicated by its name, this particular solution corresponds to an optimization problem. Hence, this section will be devoted to clarifying the relation between this particular optimization problem and the class of problems solving the general problem. Thus

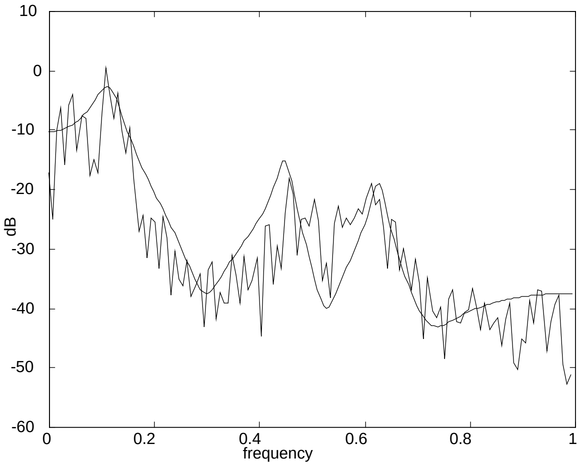

FIG. 2.2. *Spectral envelope obtained with appropriate choice of zeros.*

our interest is not in the maximum entropy solution per se, but in showing that it can be determined from a constrained convex minimization problem in $\mathbb{R}^{n+1}$, which naturally is generalized to a problem with arbitrary prescribed zeros.

Let us briefly recall the problem at hand. Given the partial covariance sequence

$$c_0, c_1, \dots, c_n,$$

determine a coercive, rational spectral density

$$\Phi(z) = \hat{c}_0 + \sum_{k=1}^{\infty} \hat{c}_k (z^k + z^{-k}) \tag{3.1}$$

of degree at most $2n$ such that

$$\hat{c}_k = c_k \quad \text{for} \quad i = 1, 2, \dots, n. \tag{3.2}$$

Of course there are many solutions to this problem, and it is well known that the maximum entropy solution is the one which maximizes the entropy gain

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} \log \Phi(e^{i\theta}) d\theta \tag{3.3}$$

(see, e.g., [19]), and we shall now consider this constrained optimization problem.

We begin by setting up the appropriate spaces. Recall from classical realization theory that a rational function

$$v(z) = \frac{1}{2}\hat{c}_0 + \hat{c}_1 z^{-1} + \hat{c}_2 z^{-2} + \cdots$$

of degree n has a representation

$$\hat{c}_k = h' F^{k-1} g \quad k = 1, 2, 3, \dots$$

for some choice of $(F, g, h) \in \mathbb{R}^{n \times n} \times \mathbb{R}^n \times \mathbb{R}^n$. Therefore, if in addition $v(z)$ is strictly positive real, implying that all eigenvalues of F are less than one in modulus, $\hat{c}_k$ tends exponentially to zero as $k \to \infty$. Hence, in particular,

$$\hat{c} := (\hat{c}_0, \hat{c}_1, \hat{c}_2, \dots)$$

must belong to ℓ_1. Moreover, the requirement that (3.1) be a coercive spectral density adds another constraint, namely that $\hat{c}$ belongs to the set

$$\mathcal{F} := \left\{ \hat{c} \in \ell_1 \mid \hat{c}_0 + \sum_{k=1}^{\infty} \hat{c}_k (e^{ik\theta} + e^{-ik\theta}) > 0 \right\}. \tag{3.4}$$

Now, let

$$\psi(\hat{c}) = -\frac{1}{2\pi} \int_{-\pi}^{\pi} \log \left[\hat{c}_0 + \sum_{k=1}^{\infty} \hat{c}_k (e^{ik\theta} + e^{-ik\theta}) \right] d\theta \tag{3.5}$$

be a functional $\mathcal{F} \to \mathbb{R}$, and consider the infinite-dimensional convex constrained optimization problem to minimize $\psi(\hat{c})$ over $\mathcal{F}$ given the finite number of constraints (3.2). Thus we have relaxed the optimization problem to allow also for nonrational spectral densities.

Since the optimization problem is convex, the Lagrange function

$$L(\hat{c}, \lambda) = \psi(\hat{c}) + \sum_{k=0}^{n} \lambda_k (\hat{c}_k - c_k) \tag{3.6}$$

has a saddle point [26, p. 458] provided the stationary point lies in the interior of $\mathcal{F}$, and, in this case, the optimal Lagrange vector $\lambda = (\lambda_0, \lambda_1, \dots, \lambda_n) \in \mathbb{R}^{n+1}$ can be determined by solving the *dual problem* to maximize

$$\rho(\lambda) = \min_{\hat{c} \in \mathcal{F}} L(\hat{c}, \lambda). \tag{3.7}$$

To this end, first note that

$$\frac{\partial L}{\partial \hat{c}_k} = -\frac{1}{2\pi} \int_{-\pi}^{\pi} (e^{ik\theta} + e^{-ik\theta}) \Phi^{-1}(e^{i\theta}) d\theta + \lambda_k \quad \text{for } k = 0, 1, 2, \dots, n, \tag{3.8}$$

and that

$$\frac{\partial L}{\partial \hat{c}_k} = -\frac{1}{2\pi} \int_{-\pi}^{\pi} (e^{ik\theta} + e^{-ik\theta}) \Phi^{-1}(e^{i\theta}) d\theta \quad \text{for } k = n+1, n+2, \dots. \tag{3.9}$$

Then, setting the gradient equal to zero, we obtain from (3.9) that

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} (e^{ik\theta} + e^{-ik\theta}) \Phi^{-1}(e^{i\theta}) d\theta = 0 \quad \text{for } |k| > n,$$

from which it follows that Φ^{-1} must be a pseudopolynomial

$$Q(z) = q_0 + \frac{1}{2} q_1 (z + z^{-1}) + \cdots + \frac{1}{2} q_n (z^n + z^{-n}) \tag{3.10}$$

of degree at most n, i.e.,

$$\Phi^{-1}(z) = Q(z), \tag{3.11}$$

yielding a spectral density Φ which is rational and of at most degree $2n$, and thus belongs to the original (nonrelaxed) class of spectral densities. Likewise we obtain from (3.8) that

$$\lambda_k = \frac{1}{2\pi} \int_{-\pi}^{\pi} (e^{ik\theta} + e^{-ik\theta}) \Phi^{-1}(e^{i\theta}) d\theta \tag{3.12}$$

for $k = 0, 1, 2, \dots, n$, which together with (3.11) yields

$$\lambda_k = q_k \quad \text{for } k = 0, 1, 2, \dots, n. \tag{3.13}$$

However, the minimizing $\hat{c}$ is given by

$$\hat{c}_k = \frac{1}{2\pi}\int_{-\pi}^{\pi} \frac{1}{2}(e^{ik\theta} + e^{-ik\theta})Q(e^{i\theta})^{-1}d\theta \tag{3.14}$$

and consequently

$$\sum_{k=0}^{n} q_k\hat{c}_k = \frac{1}{2\pi}\int_{-\pi}^{\pi} Q(e^{i\theta})Q(e^{i\theta})^{-1}d\theta = 1. \tag{3.15}$$

To determine the optimal (saddle point) Lagrange multipliers we turn to the dual problem. In view of (3.11), (3.13), and (3.15), the dual function is

$$\rho(q) = \frac{1}{2\pi}\int_{-\pi}^{\pi} \log Q(e^{i\theta})d\theta + 1 - c'q,$$

where $c \in \mathbb{R}^{n+1}$ is the vector with components $c_0, c_1, \dots, c_n$. Consequently, the dual problem is equivalent to minimizing

$$\varphi(q) = c'q - \frac{1}{2\pi}\int_{-\pi}^{\pi} \log Q(e^{i\theta})d\theta \tag{3.16}$$

over all $q \in \mathbb{R}^{n+1}$ such that the pseudopolynomial (3.10) is nonnegative on the unit circle, i.e.,

$$Q(e^{i\theta}) > 0 \quad \text{for all } \theta, \tag{3.17}$$

and, if the dual problem has an optimal solution satisfying (3.17), the optimal Q solves the primal problem when inserted into (3.11).

The dual problem to minimize (3.16) given (3.17) is a finite-dimensional convex optimization problem, which is simpler than the original (primal) problem. Clearly it is a special case of the optimization problem (2.18)–(2.19), obtained by setting $|\sigma(e^{i\theta})|^2 = 1$ as required for the maximum entropy solution. Figure 3.1 depicts a typical cost function φ in the case $n = 1$. As can be seen, it is convex and attains its optimum in an interior point so that the spectral density Φ has all its poles in the open unit disc as required. That this is the case in general will be proven in section 5.

We stress again that the purpose of this section is not primarily to derive an algorithm for the maximum entropy solution, for which we already have the simple Levinson algorithm, but to motivate an algorithm for the case with prescribed zeros in the spectral density. This is the topic of the next two sections.

4. The general convex optimization problem. Given a partial covariance sequence $c = (c_0, c_1, \dots, c_n)'$ and a Schur polynomial $\sigma(z)$, we know from section 2 that there exists a Schur polynomial

$$a(z) = a_0z^n + a_1z^{n-1} + \cdots + a_n \quad (a_0 > 0)$$

such that

$$\Phi(z) = \frac{\sigma(z)\sigma(z^{-1})}{a(z)a(z^{-1})} = c_0 + \sum_{k=1}^{\infty} \hat{c}_k(z^k + z^{-k}), \tag{4.1}$$

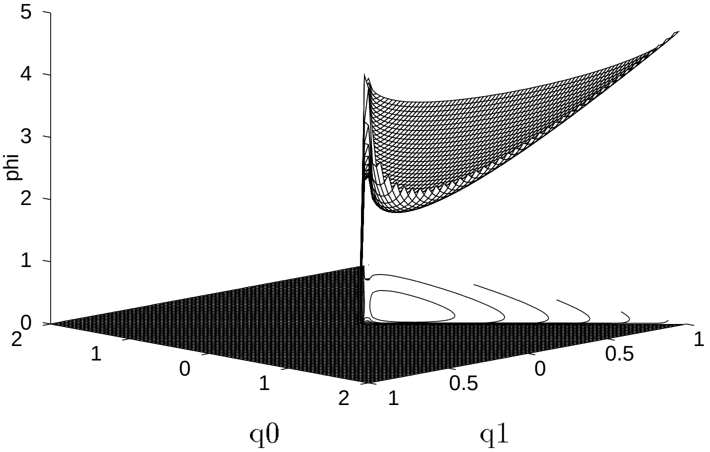

FIG. 3.1. *A typical cost function $\varphi(q)$ in the case $n = 1$.*

where

$$\hat{c}_k = c_k \quad \text{for } k = 1, 2, \dots, n. \tag{4.2}$$

The question now is: How do we find $a(z)$? In this section, we shall construct a nonlinear, strictly convex functional on a closed convex domain. In the next section, we shall show that this functional always has a unique minimum and that if such a minimum occurs as an interior point, it gives rise to $a(z)$.

As seen from (2.3), the interpolation condition (4.2) may be written

$$c_k = \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{ik\theta} \frac{|\sigma(e^{i\theta})|^2}{Q(e^{i\theta})} d\theta \quad \text{for } k = 0, 1, \dots, n, \tag{4.3}$$

where

$$Q(z) = a(z)a(z^{-1}), \tag{4.4}$$

so the problem is reduced to determining the variables

$$q = \begin{bmatrix} q_0 \\ q_1 \\ \vdots \\ q_n \end{bmatrix} \in \mathbb{R}^{n+1} \tag{4.5}$$

in the pseudopolynomial

$$Q(z) = q_0 + \frac{1}{2} q_1 (z + z^{-1}) + \frac{1}{2} q_2 (z^2 + z^{-2}) + \cdots + \frac{1}{2} q_n (z^n + z^{-n}) \tag{4.6}$$

so that the conditions (4.3) and

$$Q(e^{i\theta}) > 0 \quad \text{for all } \theta \in [-\pi, \pi] \tag{4.7}$$

are satisfied.

Now, consider the convex functional $\varphi(q) : \mathbb{R}^{n+1} \to \mathbb{R}$ defined by

$$\varphi(q) = c'q - \frac{1}{2\pi}\int_{-\pi}^{\pi} \log Q(e^{i\theta})|\sigma(e^{i\theta})|^2 d\theta. \tag{4.8}$$

Our motivation in defining $\varphi(q)$ comes in part from the desire to introduce a barrier-like term, as is done in interior point methods, and in part from our analysis of the maximum entropy method in the previous section. As it turns out, by a theorem of Szegö the logarithmic integrand is in fact integrable for nonzero Q having zeros on the boundary of the unit circle, so that $\varphi(q)$ does not become infinite on the boundary of the convex set. On the other hand, $\varphi(q)$ is a natural generalization of the functional (3.16) in section 3, since it specializes to (3.16) when $|\sigma(e^{i\theta})|^2 \equiv 1$ as for the maximum entropy solution. As we shall see, minimizing (4.8) yields precisely via (4.4) the unique $a(z)$ which corresponds to $\sigma(z)$.

It is clear that if $q \in \mathcal{D}_n^+$, where

$$\mathcal{D}_n^+ = \{q \in \mathbb{R}^{n+1} \mid Q(z) > 0 \quad \text{for } |z| = 1\}, \tag{4.9}$$

then $\varphi(q)$ is finite. Moreover, $\varphi(q)$ is also finite when $Q(z)$ has finitely many zeros on the unit circle, as can be seen from the following lemma.

LEMMA 4.1. *The functional $\varphi(q)$ is finite and continuous at any $q \in \overline{\mathcal{D}_n^+}$ except at zero. The functional is infinite, but continuous, at $q = 0$. Moreover, φ is a C^∞ function on $\mathcal{D}_n^+$.*

Proof. We want to prove that $\varphi(q)$ is finite when $q \neq 0$. Then the rest follows by inspection. Clearly, $\varphi(q)$ cannot take the value $-\infty$; hence, it remains to prove that $\varphi(q) < \infty$. Since $q \neq 0$,

$$\mu := \max_\theta Q(e^{i\theta}) > 0.$$

Then setting $P(z) := \mu^{-1}Q(z)$,

$$\log P(e^{i\theta}) \leq 0 \tag{4.10}$$

and

$$\varphi(q) = c'q - \frac{1}{2\pi}\log\mu \int_{-\pi}^{\pi} |\sigma(e^{i\theta})|^2 d\theta - \frac{1}{2\pi}\int_{-\pi}^{\pi} \log P(e^{i\theta})|\sigma(e^{i\theta})|^2 d\theta,$$

and hence, the question of whether $\varphi(q) < \infty$ is reduced to determining whether

$$-\int_{-\pi}^{\pi} \log P(e^{i\theta})|\sigma(e^{i\theta})|^2 d\theta < \infty.$$

However, since $|\sigma(e^{i\theta})|^2 \leq M$ for some bound M, this follows from

$$\int_{-\pi}^{\pi} \log P(e^{i\theta}) d\theta > -\infty, \tag{4.11}$$

which is the well-known Szegö condition: (4.11) is a necessary and sufficient condition for $P(e^{i\theta})$ to have a stable spectral factor [17]. However, since $P(z)$ is a symmetric pseudopolynomial which is nonnegative on the unit circle, there is a polynomial $\pi(z)$ such that $\pi(z)\pi(z^{-1}) = P(z)$. But then $w(z) = \frac{\pi(z)}{z^n}$ is a stable spectral factor, and hence (4.11) holds. $\square$

Lemma 4.2. *The functional $\varphi(q)$ is strictly convex and defined on a closed, convex domain.*

Proof. We first note that $q = 0$ is an extreme point, but it can never be a minimum of φ since $\varphi(0)$ is infinite. In particular, in order to check the strict inequality

$$\varphi(\lambda q^{(1)} + (1-\lambda)q^{(2)}) < \lambda\varphi(q^{(1)}) + (1-\lambda)\varphi(q^{(2)}), \tag{4.12}$$

where one of the arguments is zero, we need only consider the case that either $q^{(1)}$ or $q^{(2)}$ is zero, in which case the strict inequality holds. We can now assume that none of the arguments is zero, in which case the strict inequality in (4.12) follows from the strict concavity of the logarithm. Finally, it is clear that $\overline{\mathcal{D}_n^+}$ is a closed convex subset. □

Lemma 4.3. *Let $q \in \overline{\mathcal{D}_n^+}$, and suppose $q \neq 0$. Then $c'q > 0$.*

Proof. Consider an arbitrary covariance extension of c such as, for example, the maximum entropy extension, and let $\Phi(z)$ be the corresponding spectral density (2.9). Then c is given by (2.3), which may also be written

$$c_k = \frac{1}{2\pi}\int_{-\pi}^{\pi} \frac{1}{2}(e^{ik\theta} + e^{-ik\theta})\Phi(e^{i\theta})d\theta, \quad k = 0, 1, \dots, n.$$

Therefore, in view of (4.6),

$$c'q = \frac{1}{2\pi}\int_{-\pi}^{\pi} Q(e^{ik\theta})\Phi(e^{i\theta})d\theta, \tag{4.13}$$

which is positive whenever $Q(z) \geq 0$ on the unit circle and $q \neq 0$. □

Proposition 4.4. *For all $r \in \mathbb{R}$, $\varphi^{-1}(-\infty, r]$ is compact. Thus φ is proper (i.e., $\varphi^{-1}(K)$ is compact whenever K is compact) and bounded from below.*

Proof. Suppose $q^{(k)}$ is a sequence in $M_r := \varphi^{-1}(-\infty, r]$. It suffices to show that $q^{(k)}$ has a convergent subsequence. Each $Q^{(k)}$ may be factored as

$$Q^{(k)}(z) = \lambda_k \bar{a}^{(k)}(z)\bar{a}^{(k)}(z^{-1}) = \lambda_k \bar{Q}^{(k)}(z),$$

where λ_k is positive and $\bar{a}^{(k)}(z)$ is a monic polynomial, all of whose roots lie in the closed unit disc. The corresponding sequence of the (unordered) set of n roots of each $\bar{a}^{(k)}(z)$ has a convergent subsequence, since all (unordered) sets of roots lie in the closed unit disc. Denote by $\bar{a}(z)$ the monic polynomial of degree n which vanishes at this limit set of roots. By reordering the sequence if necessary, we may assume the sequence $a^{(k)}(z)$ tends to $\bar{a}(z)$. Therefore, the sequence $q^{(k)}$ has a convergent subsequence if and only if the sequence λ_k does, which will be the case provided the sequence λ_k is bounded from above and from below away from zero. Before proving this, we note that the sequences $c'\bar{q}^{(k)}$, where $\bar{q}^{(k)}$ is the vector corresponding to the pseudopolynomial $\bar{Q}^{(k)}$, and

$$\frac{1}{2\pi}\int_{-\pi}^{\pi} \log \bar{Q}^{(k)}(e^{i\theta})|\sigma(e^{i\theta})|^2 d\theta \tag{4.14}$$

are both bounded from above and from below, respectively, away from zero and $-\infty$. The upper bounds come from the fact that $\{\bar{a}^{(k)}(z)\}$ are Schur polynomials and hence have their coefficients in the bounded Schur region. As for the lower bound of $c'\bar{q}^{(k)}$, note that $c'\bar{q}^{(k)} > 0$ for all k (Lemma 4.3) and $c'\bar{q}^{(k)} \to \alpha > 0$. In fact, $\bar{Q}^{(k)}(e^{i\theta}) \to |\bar{a}(e^{i\theta})|^2$, where $\bar{a}(z)$ has all its zeros in the closed unit disc, and hence it follows from (4.13) that $\alpha > 0$. Then, since $\varphi(q) < \infty$ for all $q \in \overline{\mathcal{D}_n^+}$ except $q = 0$ (Lemma 4.1), (4.14) is bounded away from $-\infty$. Next, observe that

$$\varphi(q^{(k)}) = \lambda_k c' \bar{q}^{(k)} - \frac{1}{2\pi} \log \lambda_k \int_{-\pi}^{\pi} |\sigma(e^{i\theta})|^2 d\theta - \frac{1}{2\pi} \int_{-\pi}^{\pi} \log \bar{Q}^{(k)}(e^{i\theta}) |\sigma(e^{i\theta})|^2 d\theta.$$

From this we can see that if a subsequence of λ_k were to tend to zero, then $\varphi(q^{(k)})$ would exceed r. Likewise, if a subsequence of λ_k were to tend to infinity, φ would exceed r, since linear growth dominates logarithmic growth. □

5. Interior critical points and solutions of the rational covariance extension problem. In the previous section, we showed that φ has compact sublevel sets in $\overline{\mathcal{D}_n^+}$, so that φ achieves a minimum. Moreover, since φ is strictly convex and $\overline{\mathcal{D}_n^+}$ is convex, such a minimum is unique. We record these observations in the following statement.

PROPOSITION 5.1. *For each partial covariance sequence c and each Schur polynomial $\sigma(z)$, the functional φ has a unique minimum on $\overline{\mathcal{D}_n^+}$.*

In this paper we consider a question which is of independent interest: whether φ achieves its minimum at an interior point. The next result describes an interesting systems-theoretic consequence of the existence of such interior minima.

THEOREM 5.2. *Fix a partial covariance sequence c and a Schur polynomial $\sigma(z)$. If $\hat{q} \in \mathcal{D}_n^+$ is a minimum for φ, then*

$$\hat{Q}(z) = a(z)a(z^{-1}), \tag{5.1}$$

where $a(z)$ is the solution of the rational covariance extension problem.

Proof. Suppose that $\hat{q} \in \mathcal{D}_n^+$ is a minimum for φ. Then

$$\frac{\partial \varphi}{\partial q_k}(\hat{q}) = 0 \quad \text{for } k = 0, 1, 2, \ldots, n. \tag{5.2}$$

Differentiating inside the integral, which is allowed due to uniform convergence, (5.2) yields

$$c_k - \frac{1}{2\pi} \int_{-\pi}^{\pi} \frac{1}{2}(e^{ik\theta} + e^{-ik\theta}) \frac{|\sigma(e^{i\theta})|^2}{\hat{Q}(e^{i\theta})} d\theta = 0 \quad \text{for } k = 0, 1, \ldots, n,$$

where $\hat{Q}(z)$ is the pseudopolynomial (4.6) corresponding to $\hat{q}$, or, equivalently,

$$c_k = \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{ik\theta} \frac{|\sigma(e^{i\theta})|^2}{\hat{Q}(e^{i\theta})} d\theta \quad \text{for } k = 0, 1, \ldots, n, \tag{5.3}$$

which is precisely the interpolation condition (4.3)–(4.4), provided (5.1) holds. □

As a corollary of this theorem, we have that the gradient of φ at *any* $\tilde{q} \in \mathcal{D}_n^+$ is given by

$$\frac{\partial \varphi}{\partial q_k}(\tilde{q}) = c_k - \tilde{c}_k, \tag{5.4}$$

where

$$\tilde{c}_k = \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{ik\theta} \frac{|\sigma(e^{i\theta})|^2}{\tilde{Q}(e^{i\theta})} d\theta, \quad k = 0, 1, 2, \ldots, n \tag{5.5}$$

is the partial covariance sequence corresponding to a process with spectral density

$$\tilde{\Phi}(e^{i\theta}) = \frac{|\sigma(e^{i\theta})|^2}{\tilde{Q}(e^{i\theta})},$$

where $\tilde{Q}(z)$ is the pseudopolynomial corresponding to $\tilde{q}$. The gradient is thus the difference between the true and calculated partial covariance sequences.

We now state the converse result, underscoring our interest in this particular convex optimization problem.

THEOREM 5.3. *For each partial covariance sequence c and each Schur polynomial $\sigma(z)$, suppose that $a(z)$ gives a solution to the rational covariance extension problem. If*

$$\hat{Q}(z) = a(z)a(z^{-1}), \tag{5.6}$$

then the corresponding $(n+1)$-vector $\hat{q}$ lies in $\mathcal{D}_n^+$ and is a unique minimum for φ.

Proof. Let $a(z)$ be the solution of the rational covariance extension problem corresponding to c and $\sigma(z)$, and let $\hat{Q}(z)$ be given by (5.6). Then c satisfies the interpolation condition (5.3), which is equivalent to (5.2), as seen from the proof of Theorem 5.2. However, since $a(z)$ is a Schur polynomial, $\hat{Q}(z) > 0$ on the unit circle, and thus $\hat{q} \in \mathcal{D}_n^+$. Since φ is strictly convex on $\mathcal{D}_n^+$, (5.3) implies that $\hat{q}$ is a unique minimum for φ. □

Since the existence of a solution to the rational covariance extension problem has been established in [14] (see also [7]), we do in fact know the existence of interior minima for this convex optimization problem. On the other hand, we know from Proposition 5.1 that φ has a minimum for some $\hat{q} \in \overline{\mathcal{D}_n^+}$, so to show that φ has a minimum in the interior $\mathcal{D}_n^+$ it remains to prove the following lemma.

LEMMA 5.4. *The functional φ never attains a minimum on the boundary $\partial\mathcal{D}_n^+$.*

Proof. Denoting by $D_p\varphi(q)$ the directional derivative of φ at q in the direction p, it is easy to see that

$$D_p\varphi(q) := \lim_{\epsilon\to 0} \frac{\varphi(q+\epsilon p) - \varphi(q)}{\epsilon} \tag{5.7}$$

$$= c'p - \frac{1}{2\pi}\int_{-\pi}^{\pi} \frac{P(e^{i\theta})}{Q(e^{i\theta})}|\sigma(e^{i\theta})|^2 d\theta, \tag{5.8}$$

where $P(z)$ is the pseudopolynomial

$$P(z) = p_0 + \frac{1}{2}p_1(z+z^{-1}) + \frac{1}{2}p_2(z^2+z^{-2}) + \cdots + \frac{1}{2}p_n(z^n+z^{-n})$$

corresponding to the vector $p \in \mathbb{R}^{n+1}$. In fact,

$$\frac{\log(Q+\epsilon P) - \log Q}{\epsilon} = \frac{P}{Q}\log\left[\left(1+\epsilon\frac{P}{Q}\right)^{\frac{1}{\epsilon}\frac{Q}{P}}\right] \to \frac{P}{Q}$$

as $\epsilon \to +0$, and hence (5.7) follows by dominated convergence.

Now, let $q \in \mathcal{D}_n^+$ and $\bar{q} \in \partial\mathcal{D}_n^+$ be arbitrary. Then the corresponding pseudopolynomials Q and $\bar{Q}$ have the properties

$$Q(e^{i\theta}) > 0 \quad \text{for all } \theta \in [-\pi, \pi]$$

and

$$\bar{Q}(e^{i\theta}) \geq 0 \quad \text{for all } \theta \text{ and } \bar{Q}(e^{i\theta_0}) = 0 \text{ for some } \theta_0.$$

Since $q_\lambda := \bar{q} + \lambda(q - \bar{q}) \in \mathcal{D}_n^+$ for $\lambda \in (0,1]$, we also have for $\lambda \in (0,1]$ that

$$Q_\lambda(e^{i\theta}) := \bar{Q}(e^{i\theta}) + \lambda[Q(e^{i\theta}) - \bar{Q}(e^{i\theta})] > 0 \quad \text{for all } \theta \in [-\pi, \pi],$$

and we may form the directional derivative

$$D_{\bar{q}-q}\varphi(q_\lambda) = c'(\bar{q} - q) + \frac{1}{2\pi}\int_{-\pi}^{\pi} h_\lambda(\theta)d\theta, \tag{5.9}$$

where

$$h_\lambda(\theta) = \frac{Q(e^{i\theta}) - \bar{Q}(e^{i\theta})}{Q_\lambda(e^{i\theta})}|\sigma(e^{i\theta})|^2.$$

Now,

$$\frac{d}{d\lambda}h_\lambda(\theta) = \frac{[Q(e^{i\theta}) - \bar{Q}(e^{i\theta})]^2}{Q_\lambda(e^{i\theta})^2}|\sigma(e^{i\theta})|^2 \geq 0,$$

and hence $h_\lambda(\theta)$ is a monotonically nondecreasing function of λ for all $\theta \in [-\pi, \pi]$. Consequently, h_λ tends pointwise to h_0 as $\lambda \to 0$. Therefore,

$$\int_{-\pi}^{\pi} h_\lambda(\theta)d\theta \to +\infty \quad \text{as } \lambda \to 0. \tag{5.10}$$

In fact, if

$$\int_{-\pi}^{\pi} h_\lambda(\theta)d\theta \to \alpha < \infty \quad \text{as } \lambda \to 0, \tag{5.11}$$

then $\{h_\lambda\}$ is a Cauchy sequence in $L^1(-\pi, \pi)$ and hence has a limit in $L^1(-\pi, \pi)$ which must equal h_0 almost everywhere. However, h_0, having poles in $[-\pi, \pi]$, is not summable and hence, as claimed, (5.11) cannot hold.

Consequently, by virtue of (5.9),

$$D_{q-\bar{q}}\varphi(q_\lambda) \to +\infty \quad \text{as } \lambda \to 0$$

for all $q \in \mathcal{D}_n^+$ and $\bar{q} \in \partial\mathcal{D}_n^+$, and hence, in view of Lemma 26.2 in [28], φ is essentially smooth. Then it follows from Theorem 26.3 in [28] that the subdifferential of φ is empty on the boundary of $\mathcal{D}_n^+$, and therefore φ cannot have a minimum there. □

Thus we have proven the following result.

THEOREM 5.5. *For each partial covariance sequence c and each Schur polynomial $\sigma(z)$, there exists an $(n+1)$-vector $\hat{q}$ in $\mathcal{D}_n^+$ which is a minimum for φ.*

Consequently, by virtue of Theorem 5.2, there does exist a solution to the rational covariance extension problem for each partial covariance sequence and zero polynomial $\sigma(z)$, and, in view of Theorem 5.3, this solution is unique.

These theorems have the following corollary.

COROLLARY 5.6 (Georgiou's conjecture). *For each partial covariance sequence c and each Schur polynomial $\sigma(z)$, there is a unique Schur polynomial $a(z)$ such that* (4.1) *and* (4.2) *hold.*

Hence, we have given an independent proof of the weaker version of Theorem 2.1 conjectured by Georgiou, but not of the stronger version of [7] which states that the problem is well posed in the sense that the one-to-one correspondence between $\sigma(z)$ and $a(z)$ is a diffeomorphism.

6. Some numerical examples. Given an arbitrary partial covariance sequence $c_0, c_1, \dots, c_n$ and an arbitrary zero polynomial $\sigma(z)$, the constructive proof of Georgiou's conjecture provides algorithmic procedures for computing the corresponding unique modeling filter, which are based on the convex optimization problem to minimize the functional (2.18) over all $q_0, q_1, \dots, q_n$ such that (2.19) holds.

In general such procedures will be based on the gradient of the cost functional φ, which, as we saw in section 5, is given by

$$\frac{\partial \varphi}{\partial q_k}(q_0, q_1, \dots, q_n) = c_k - \bar{c}_k, \tag{6.1}$$

where

$$\bar{c}_k = \frac{1}{2\pi}\int_{-\pi}^{\pi} e^{ik\theta}\frac{|\sigma(e^{i\theta})|^2}{Q(e^{i\theta})}d\theta \quad \text{for } k = 0, 1, 2, \dots, n \tag{6.2}$$

are the covariances corresponding to a process with spectral density

$$\frac{|\sigma(e^{i\theta})|^2}{Q(e^{i\theta})} = \bar{c}_0 + 2\sum_{k=1}^{\infty} \bar{c}_k \cos(k\theta). \tag{6.3}$$

The gradient is thus the difference between the given partial covariance sequence $c_0, c_1, \dots, c_n$ and the partial covariance sequence corresponding to the choice of variables $q_0, q_1, \dots, q_n$ at which the gradient is calculated. The minimum is attained when this difference is zero.

The following simulations have been done by Per Enqvist, using Newton's method (see, e.g., [23, 26]), which of course also requires computing the Hessian (second-derivative matrix) in each iteration. A straightforward calculation shows that the Hessian is the sum of a Toeplitz and a Hankel matrix. More precisely,

$$H_{ij}(q_0, q_1, \dots, q_n) = \frac{1}{2}(d_{i+j} + d_{i-j}), \quad i, j = 0, 1, 2, \dots, n, \tag{6.4}$$

where

$$d_k = \frac{1}{2\pi}\int_{-\pi}^{\pi} e^{ik\theta}\frac{|\sigma(e^{i\theta})|^2}{Q(e^{i\theta})^2}d\theta \quad \text{for } k = 0, 1, 2, \dots, 2n \tag{6.5}$$

and $d_{-k} = d_k$. Moreover, $d_0, d_1, d_2, \dots, d_{2n}$ are the $2n+1$ first Fourier coefficients of the spectral representation

$$\frac{|\sigma(e^{i\theta})|^2}{Q(e^{i\theta})^2} = d_0 + 2\sum_{k=1}^{\infty} d_k \cos(k\theta). \tag{6.6}$$

The gradient and the Hessian can be determined from (6.1) and (6.4), respectively, by applying the inverse Levinson algorithm (see, e.g., [27]) to the appropriate polynomial spectral factors of $Q(z)$ and $Q(z)^2$, respectively, and then solving the resulting linear equations for $\bar{c}_0, \bar{c}_1, \dots, \bar{c}_n$ and $d_0, d_1, d_2, \dots, d_{2n}$; see [12] for details.

To illustrate the procedure, let us again consider the sixth-order spectral envelopes of Figures 2.1 and 2.2 together with the corresponding zeros and poles. Hence, Figure 6.1 illustrates the periodogram for a section of speech data together with the corresponding sixth-order maximum entropy spectrum, which, since it lacks finite zeros,

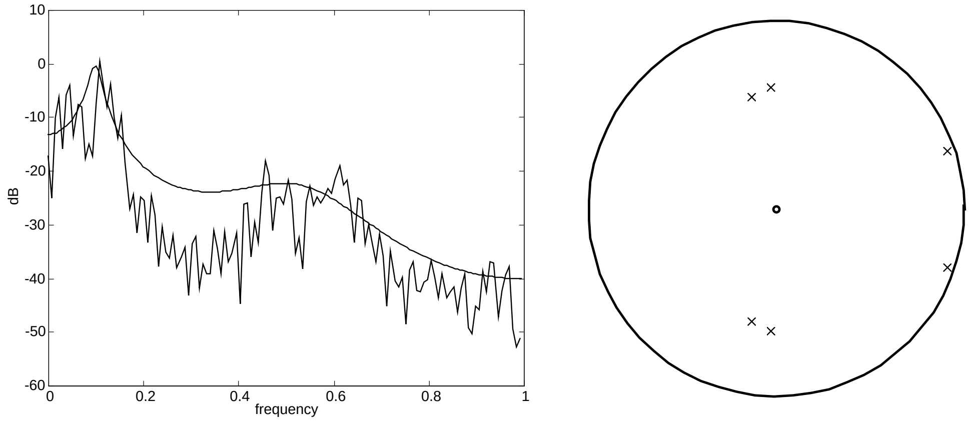

FIG. 6.1.

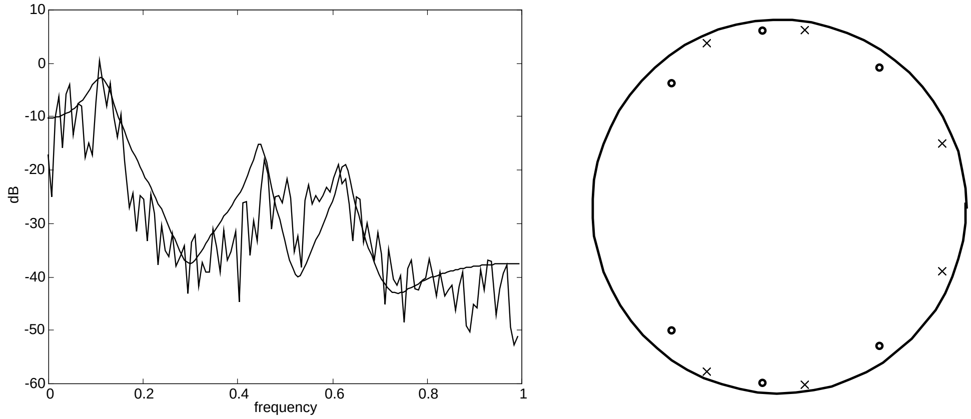

FIG. 6.2.

becomes rather “flat.” The location of the corresponding poles (marked by ×) in the unit circle is shown next to it. The zeros (marked by ∘) of course all lie at the origin.

Now, selecting the zeros appropriately as indicated to the right in Figure 6.2, we obtain the poles as marked, and the corresponding sixth-order modeling filter produces the spectral envelope to the left in Figure 6.2. We see that the second solution has a spectral density that is less flat and provides a better approximation, reflecting the fact that the filter is designed to have transmission zeros near the minima of the periodogram.

7. Conclusions. In [13, 14] Georgiou proved that to each choice of partial covariance sequence and numerator polynomial of the modeling filter there exists a rational covariance extension yielding a pole polynomial for the modeling filter, and he conjectured that this extension is unique so that it provides a complete parameterization of all rational covariance extensions. In [7] we proved this long-standing conjecture in the more general context of a duality between filtering and interpolation and showed that the problem is well posed in a very strong sense. In [6] we connected this solution to a certain Riccati-type matrix equation that sheds further light on the structure of this problem.

However, our proof in [7], as well as the existence proof of Georgiou [14], is nonconstructive. In this paper we presented a constructive proof of Georgiou's conjecture, which, although it is weaker than our result in [7], provides us for the first time with an algorithm for solving the problem of determining the unique pole polynomial corresponding to the given partial covariance sequence and the desired zeros.

This is done by means of a constrained convex optimization problem, which can be solved without explicitly computing the values of the cost function and which has the interesting property that the cost function is finite on the boundary but the gradient is not. In this context, Georgiou's conjecture is equivalent to establishing that there is a unique minimum in the *interior* of the feasible region. Specialized to the maximum entropy solution, this optimization problem was seen to be a dual to the well-known problem of maximizing the entropy gain.

Acknowledgments. We would like to thank Per Enqvist and Massoud Amin for their help with simulations.

ROBUSTNESS WITH RESPECT TO DELAYS FOR EXPONENTIAL STABILITY OF DISTRIBUTED PARAMETER SYSTEMS*

RICHARD REBARBER[†] AND STUART TOWNLEY[‡]

Abstract. In this paper we address the question of whether the open-loop exponential growth rate of a linear system can be improved by a feedback in such a way that this improvement is robust with respect to small delays in the feedback loop. When the input operator is admissible, and the class of possible feedbacks consists of compact operators, we find that if a feedback can improve the exponential growth rate, then it can do so robustly. Furthermore, we find that if the control space is finite dimensional and a bounded feedback cannot be found to improve exponential stability, then a large class of *unbounded* feedbacks cannot improve the exponential growth rate robustly, even if such feedbacks can improve the exponential growth rate in the absence of delays.

1. Introduction.

In this paper we are concerned with robustness of stability with respect to small delays in the feedback loop for distributed parameter systems. This issue has been analyzed a great deal when the stability in question is either input-output stability or modal stability. For a sample see Logemann, Rebarber, and Weiss [10] (for the frequency domain), Logemann and Rebarber [11], Datko, Lagnese, and Polis [3], Datko [4] (for modal stability of partial differential equations), and Logemann and Townley [12] (for modal stability of neutral systems). To our knowledge, there are no results available in the literature on robustness of *state space* stability for distributed parameter systems. If input-output stability is not robust, then in most situations it follows immediately that any state space stability is not robust. However, in general, robustness of input-output stability does not imply robustness of exponential stability, the most useful kind of state space stability. One reason for this is that, in general, input-output stability does not imply exponential stability. A more immediate difficulty is that the state space for the system with delay in the feedback is dependent on the delay.

In this paper we address the question of whether the exponential growth rate of a system can be improved by a feedback in such a way that this improvement is robust with respect to small delays in the feedback loop. When the input operator is admissible, and the class of feedbacks consists of compact operators, we find, in Theorem 3.5, that if a compact feedback can improve the exponential growth rate, then it can do so robustly when a natural state space is chosen for the delayed system. Sometimes it is possible to improve the exponential growth rate with an *unbounded* feedback when it is not possible with a bounded feedback. We find in Theorem 4.1 that if the control space is finite dimensional and a bounded feedback cannot be found

to improve exponential stability, then a large class of unbounded feedbacks cannot improve the exponential growth rate robustly, even if such feedbacks can improve the exponential growth when there are no delays present in the feedback loop.

We consider state space systems of the form

$$\dot{x}(t) = Ax(t) + Bu(t), \tag{1.1}$$

where A is the infinitesimal generator of a strongly continuous semigroup $S(t)$ on X, a Hilbert space with norm $\|\cdot\|$. Let $R(s,A) = (sI-A)^{-1}$. Let

$$\mathbb{C}_\alpha = \{s \in \mathbb{C} \mid \mathrm{Re}\,(s) > \alpha\},$$

and for any Hilbert space X, let $H^\infty_\omega(X)$ be the set of all $\mathcal{B}(X)$-valued functions $f(s)$ which are holomorphic in $\mathbb{C}_\omega$ and for which $\sup_{s\in\mathbb{C}_\omega}\|f(s)\| < \infty$. The growth bound ω_0 of $S(t)$ is given by

$$\omega_0 = \lim_{t\to\infty} \frac{\ln(\|S(t)\|_{\mathcal{B}(X)})}{t} = \inf\{\omega \mid R(s,A) \in H^\infty_\omega(X)\}. \tag{1.2}$$

We let X_{-1} denote the closure of X in the norm $\|x\|_{-1} = \|R(\lambda,A)x\|$ for some λ in the resolvent set of A. The control space is a Hilbert space U with norm $\|\cdot\|_U$, and $B : U \to X_{-1}$ is an *admissible* input operator for $S(t)$; for details about admissibility see Weiss [20, 22]. Two consequences of the admissibility of B are that for every $F \in \mathcal{B}(X,U)$,

- $A - BF$ is the infinitesimal generator of a strongly continuous semigroup $S_F(t)$;
- the function $FR(s,A)B$ is analytic and bounded in $\mathbb{C}_\alpha$ for some $\alpha \in \mathbb{R}$.

For $F \in \mathcal{B}(X,U)$ we associate with (1.1) the observation

$$y(t) = Fx(t)\,. \tag{1.3}$$

Then (1.1) and (1.3) determine a linear open-loop, input-output system with transfer function $\mathbf{H}_F$ given by

$$\mathbf{H}_F(s) = FR(s,A)B\,. \tag{1.4}$$

Note that unity output feedback $u(t) = -y(t)$ for the input-output system (1.1) and (1.3) coincides with state feedback control $u(t) = -Fx(t)$ for (1.1).

We consider the closed-loop system with unity gain and delay ε in the feedback loop, described by Figure 1, equivalently (1.1), (1.3) with feedback control $u(t) = v(t) - Fx(t-\varepsilon)$. The block with transfer function $e^{-\varepsilon s}$ represents a delay by ε, where $\varepsilon \geq 0$. The transfer function $\mathbf{G}^\varepsilon$ for the closed-loop system (i.e., the transfer function from v to y) is given by

$$\mathbf{G}^\varepsilon(s) = \mathbf{H}_F(s)\left(I + e^{-\varepsilon s}\mathbf{H}_F(s)\right)^{-1}. \tag{1.5}$$

In the next section we obtain a sufficient condition for the existence of a feedback which robustly improves stability in a frequency domain sense; see Definition 2.6 and Proposition 2.7. In section 3 we show that the same condition is necessary and sufficient for the existence of a feedback which robustly improves stability in a natural state space setting; see Proposition 3.1, Definition 3.2, and Theorem 3.5. In section 4 we show that the necessary and sufficient condition of section 3 is also necessary and sufficient when a large class of unbounded feedbacks is used; see Theorem 4.1. In section 5 we give examples to illustrate our main results.

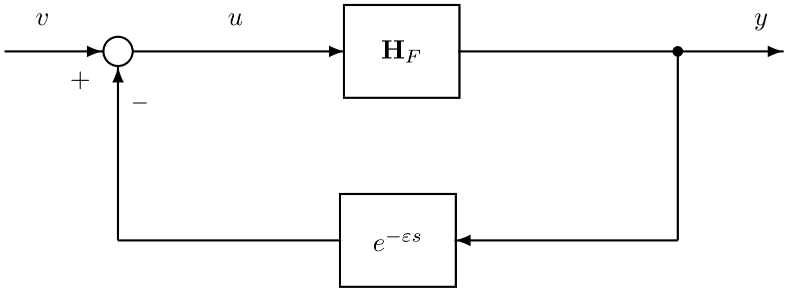

FIG. 1. *Feedback system with delay.*

2. Frequency domain robustness for state space systems. Let $\mathcal{K}(X,U)$ denote the set of compact operators from X into U. For systems of the form (1.1) we use the following definition of exponential stabilizability.

DEFINITION 2.1. *The system* (1.1) *is exponentially α-stabilizable if for every $\nu > \alpha$ there exists a feedback operator $F \in \mathcal{K}(X,U)$ and $M_\nu > 0$ such that*

$$\|S_F(t)\|_{\mathcal{B}(X)} \le M_\nu e^{\nu t}.$$

REMARK 2.2. *When the input space U is finite dimensional, so that $\mathcal{K}(X,U) = \mathcal{B}(X,U)$, Definition* 2.1 *coincides with the usual notion of closed-loop stabilizability* (*see*, *for instance*, *Curtain* [1] *or Jacobson and Nett* [8]). *Infinite dimensional input spaces U might arise in boundary control of partial differential equations in two or more spatial variables. In such cases*, *compact feedback operators arise naturally via integration over the boundary.*

We now summarize from Rebarber [14] necessary conditions for (1.1) to be exponentially α-stabilizable (see [1] or [8] for similar conditions in the case where the input space is finite dimensional). Let $\sigma(A)$ denote the spectrum of A, and suppose there exists $\nu \in \mathbb{R}$ such that

$$\sigma_u(A,\nu) := \{\lambda \mid \lambda \in \sigma(A) \text{ and } \operatorname{Re}(\lambda) \ge \nu\}$$

is bounded and can be isolated from the remaining part $\sigma_s(A,\nu)$ of the spectrum of A by a simple closed contour Γ. Following [9, Theorem 6.17], let

$$P = \int_\Gamma R(s,A)\,ds \qquad \text{and} \qquad N = I - P,$$

so that P is the projection corresponding to $\sigma_u(A,\nu)$ and N is the projection corresponding to $\sigma_s(A,\nu)$. Let $X_u = PX$ and $X_s = NX$, so that X can be represented by $X_u \oplus X_s$. Then (1.1) can be decomposed into the two systems

$$\dot{x}_u(t) = A_u x_u(t) + B_u u(t),$$

$$\dot{x}_s(t) = A_s x_s(t) + B_s u(t),$$

where $A_u = AP$, $A_s = AN$, $B_u = PB$, and $B_s = NB$.

LEMMA 2.3 (see [14, Theorem 1]). *If (A,B) is exponentially α-stabilizable, then for every $\nu > \alpha$, (A,B) has spectrum decomposition at ν in the sense that $\sigma_u(A,\nu)$ is bounded and can be isolated from $\sigma_s(A,\nu)$ by a simple closed contour, and*

(a) *$\sigma_u(A,\nu)$ consists of finitely many eigenvalues of finite multiplicity;*

(b) *A_s generates a strongly continuous semigroup $S_s(t)$ such that $\|S_s(t)\| \leq M_\nu e^{\nu t}$ for some $M_\nu \in \mathbb{R}$;*

(c) *(A_u, B_u) is a controllable pair.*

The following lemma shows that if $F \in \mathcal{K}(X,U)$, then the transfer function $\mathbf{H}_F$, for (1.1) and (1.3), is strictly proper in some right half-plane.

LEMMA 2.4. *Let A be the generator of a semigroup with growth bound ω_0, $B \in \mathcal{B}(U, X_{-1})$ be an admissible input operator for $S(t)$, and $F \in \mathcal{K}(X,U)$. Then for every $\gamma > \omega_0$,*

$$\lim_{\substack{|s|\to\infty \\ s\in\mathbb{C}_\gamma}} \|\mathbf{H}_F(s)\|_{\mathcal{B}(U)} = 0. \tag{2.1}$$

This result was proved in Curtain [1, Lemma 3.7] in the case where the input space U is finite dimensional.

Proof. F is compact if and only if F^* is compact (Schauder's theorem) and B^* is output admissible if B is input admissible (Salamon [17, Lemma 1.3.5]). Therefore, since the growth bound of the semigroup $S^*(t)$ generated by A^* is the same as that of $S(t)$,

$$\|\mathbf{H}_F(s)\|_{\mathcal{B}(U)} = \|FR(s,A)B\|_{\mathcal{B}(U)} = \|B^*R(\overline{s},A^*)F^*\|_{\mathcal{B}(U)}$$

holds for all $s \in \mathbb{C}_{\omega_0}$, where we make the identification between the Hilbert spaces X and U and their duals.

Step 1. We claim that for each $x \in X$ and $\gamma > \omega_0$,

$$\lim_{\substack{|s|\to\infty \\ s\in\mathbb{C}_\gamma}} \|B^*R(s,A^*)x\|_U = 0. \tag{2.2}$$

To see this, fix $x \in X$ and let $\{s_n\}_{n=1}^{\infty} \in \mathbb{C}_\gamma$ and $\lim_{n\to\infty}|s_n| = \infty$. If $\operatorname{Re}(s_n) \to \infty$, then it follows from [21, Proposition 2.3], that

$$\lim_{n\to\infty} \|B^*R(s_n,A^*)x\| = 0.$$

Therefore we assume that $\operatorname{Re}(s_n)$ is bounded, so there exists η such that $\gamma < \operatorname{Re}(s_n) \leq \eta$.

Write $s \in \mathbb{C}_\gamma$ as $a+ib$ for $a,b \in \mathbb{R}$. Then

$$R(s,A^*)x = \int_0^\infty e^{-at}e^{-ibt}S^*(t)x\,dt \tag{2.3}$$

$$= \int_0^{\pi/b} e^{-at}e^{-ibt}S^*(t)x\,dt + \int_{\pi/b}^\infty e^{-at}e^{-ibt}S^*(t)x\,dt. \tag{2.4}$$

By making a change of variable in the second integral in (2.4) and using the semigroup property of $S^*(t)$, we see that (2.4) can be written as

$$R(s,A^*)x = \int_0^{\pi/b} e^{-at}e^{-ibt}S^*(t)x\,dt - \int_0^\infty e^{-at}e^{-ibt}S^*(t)e^{-a\pi/b}S^*(\pi/b)x\,dt. \tag{2.5}$$

Multiplying both (2.3) and (2.5) on the left by $B^*/2$ and adding give

$$\begin{aligned} B^*R(s,A^*)x &= (1/2)\int_0^{\pi/b} e^{-at}e^{-ibt}B^*S^*(t)x\,dt \\ &\quad + (1/2)B^*\int_0^\infty e^{-at}e^{-ibt}S^*(t)[I - e^{-a\pi/b}S^*(\pi/b)]x\,dt. \end{aligned} \tag{2.6}$$

To analyze the first term in (2.6), note that by the output admissibility of B^*,

$$\|B^*S^*(\cdot)x\|_U \in L^2[0,\pi/b].$$

Hence, using Hölder's inequality, there exists M_1 such that

$$\left\|(1/2)\int_0^{\pi/b} e^{-at}e^{-ibt}B^*S^*(t)x\,dt\right\|_U \leq \frac{M_1}{\sqrt{b}} \tag{2.7}$$

for $s \in C_\gamma$.

We can rewrite the second term in (2.6) as

$$(1/2)B^*R(a+ib,A^*)[(I-e^{-a\pi/b}S^*(\pi/b))x].$$

By Proposition 2.3 in [21] we see that $\|B^*R(a+ib,A)\|_{\mathcal{B}(X,U)}$ is uniformly bounded for $a+ib \in \mathbb{C}_\gamma$, so there exists M_2 such that

$$\begin{aligned} &\left\|(1/2)B^*\int_0^{\infty} e^{-at}e^{-ibt}S^*(t)[I-e^{-a\pi/b}S^*(\pi/b)]x\,dt\right\|_U \\ &\leq M_2\|[I-e^{-a\pi/b}S^*(\pi/b)]x\| \end{aligned} \tag{2.8}$$

for $s \in \mathbb{C}_\gamma$. We see from the strong continuity of $S(t)$ that (2.8) → 0 as $|b| \to \infty$.

If we write $s_n = a_n + b_n$, then $\gamma < a_n < \eta$ and $|b_n| \to \infty$. We see from (2.6), (2.7), and (2.8) that $\|B^*R(s_n,A^*)x\|_U \to 0$ as $n \to \infty$.

Step 2. Using Step 1, it is clear that if F^* is of finite rank, then

$$\lim_{\substack{|s|\to\infty \\ s\in\mathbb{C}_\gamma}} \|B^*R(s,A^*)F^*\|_{\mathcal{B}(U)} = 0. \tag{2.9}$$

Step 3. Since any Hilbert space has the finite approximation property, it then follows, by using a standard finite rank approximation of the compact operator F^*, that (2.9) is true if B^* is admissible and F^* is compact. This completes the proof. □

Define

$$\alpha_{\min} = \inf\{\alpha \mid (A,B) \text{ is exponentially } \alpha\text{-stabilizable}\}.$$

The following result, which is of interest in its own right, will be used in the proof of Proposition 2.7.

PROPOSITION 2.5. *Suppose B is admissible and $F \in \mathcal{K}(X,U)$. If $\beta > \alpha_{\min}$, then*

$$\lim_{\substack{|s|\to\infty \\ s\in\mathbb{C}_\beta}} \|\mathbf{H}_F(s)\|_{\mathcal{B}(U)} = 0.$$

Proof. If $\alpha_{\min} < \nu_1 < \beta$, then (A,B) is exponentially ν_1-stabilizable. Let $\nu_1 < \nu_2 < \beta$. Using a spectrum decomposition for (A,B) at ν_2, we see that $\mathbf{H}_F(s) = \mathbf{H}_u(s) + \mathbf{H}_s(s)$, where $\mathbf{H}_u(s) = FR(s,A_u)B_u$ and $\mathbf{H}_s(s) = FR(s,A_s)B_s$. Since A_u has spectrum consisting of finitely many eigenvalues and F and B_u are bounded,

$$\lim_{\substack{|s|\to\infty \\ s\in\mathbb{C}_\beta}} \|\mathbf{H}_u(s)\|_{\mathcal{B}(U)} = 0.$$

Since $\beta > \nu_2$, we see from Lemma 2.4 that

$$\lim_{\substack{|s|\to\infty\\ s\in\mathbb{C}_\beta}} \|\mathbf{H}_s(s)\|_{\mathcal{B}(U)} = 0.$$

This completes the proof. □

We now formulate the notion of *robustly improving stability* in a frequency domain context. Let

$$\alpha_0(\mathbf{H}_F) = \inf\{\alpha \mid \mathbf{H}_F \in H^\infty_\alpha(U)\} \tag{2.10}$$

denote the input-output growth rate of $\mathbf{H}_F$. We are interested in using feedback to improve the stability of (1.1), that is, in finding a feedback F so that the growth rate of $\mathbf{G}^0$ is less than the growth rate of $\mathbf{H}_F$, and in determining whether this improved stability is robust with respect to delays. Because our interest is in improving stability, we emphasize the dependence on the growth rate α in our definitions.

Definition 2.6.

(a) $\mathbf{G}^\varepsilon$ *is* α-stable *if* $\mathbf{G}^\varepsilon \in H^\infty_\alpha(U)$. *It is well known that this property is equivalent to the property: if* $\hat{y} = \mathbf{G}^\varepsilon \hat{v}$ *and* $e^{-\alpha\cdot}v(\cdot) \in L^2([0,\infty),U)$, *then* $e^{-\alpha\cdot}y(\cdot) \in L^2([0,\infty),U)$.

(b) $\mathbf{G}^0$ *is* robustly α-stable with respect to delays *if there is an* $\varepsilon_0 > 0$ *such that for any* $\varepsilon \in [0,\varepsilon_0], \mathbf{G}^\varepsilon$ *is* α*-stable.*

(c) *We say that unity feedback* robustly improves the stability *of* $\mathbf{H}_F$ *if there exists* $\alpha < \alpha_0(\mathbf{H}_F)$ *such that* $\mathbf{G}^0$ *is robustly* α*-stable with respect to delays.*

We can now give a sufficient condition under which we can robustly improve stability in the sense of Definition 2.6.

Proposition 2.7. *If* $\alpha_{\min} < \omega_0$, *then there exists* $F \in \mathcal{K}(U,X)$ *for which unity feedback robustly improves the stability of* $\mathbf{H}_F(s)$.

Proof. By the definition of $\alpha_{\min}$, for any $\alpha \in (\alpha_{\min},\omega_0)$ we can find $F \in \mathcal{K}(X,U)$ so that the semigroup generated by $A - BF$ is α-stable. Hence $\mathbf{G}^0 \in H^\infty_\alpha(U)$, that is, $\mathbf{G}^0$ is α-stable. From Proposition 2.5 we see that for $\alpha \in (\alpha_{\min},\omega_0)$ and $F \in \mathcal{K}(X,U)$,

$$\limsup_{\substack{|s|\to\infty\\ s\in\mathbb{C}_\alpha}} \|\mathbf{H}_F(s)\|_{\mathcal{B}(U)} = 0.$$

Hence there exist $\delta \in (0,1)$ and $m_1 > 0$ such that

$$\|\mathbf{H}_F(s)\|_{\mathcal{B}(U)} < 1 - \delta, \qquad s \in \mathbb{C}_\alpha \cap \{|s| \geq m_1\}.$$

Therefore the Neumann series for $(I + e^{-\varepsilon s}\mathbf{H}_F(s))^{-1}$ converges uniformly in this region, so that $\mathbf{G}^\varepsilon(s)$ is bounded in $\mathbb{C}_\alpha \cap \{|s| \geq m_1\}$. Since $\mathbf{H}_F(s)(I + \mathbf{H}_F(s))^{-1}$ is bounded in the compact set $\mathbb{C}_\alpha \cap \{|s| \leq m_1\}$, a simple perturbation argument then shows that there exists $\varepsilon^* > 0$ such that for any $\varepsilon \in [0,\varepsilon^*]$, $\mathbf{H}_F(s)(I + e^{-\varepsilon s}\mathbf{H}_F(s))^{-1}$ is also bounded in $\mathbb{C}_\alpha \cap \{|s| < m_1\}$. It follows that $\mathbf{H}_F(I + e^{-\varepsilon\cdot}\mathbf{H}_F)^{-1}$ is α-stable for all $\varepsilon \in [0,\varepsilon^*]$ and therefore $\mathbf{G}^0$ is robustly α-stable with respect to delays.

Hence, to show that we have robustly improved the stability, all that remains is to show that we have in fact improved the stability. To do this it suffices to show that $\alpha_0(\mathbf{H}_F) = \omega_0$, which is not a priori guaranteed, since the input-output growth rate α_0 might be less than the exponential growth rate ω_0. Clearly $\alpha_0(\mathbf{H}_F) \leq \omega_0$. Moreover, since $(A - BF)$ is α-stable, $(A - \omega_0 I, B, F)$ is stabilizable and detectable in the sense discussed in Rebarber [15], and so results in [15] guarantee that input-output stability of $(A-\omega_0 I, B, F)$ is equivalent to exponential stability. Hence for $\varepsilon > 0$, exponential $(\omega_0 - \varepsilon)$-stability of $S(t)$ is equivalent to $(\omega_0 - \varepsilon)$-stability of $\mathbf{H}_F$. In particular, if $\mathbf{H}_F \in H^\infty_{\omega_0-\varepsilon}(U)$ for some $\varepsilon > 0$, then $S(t)$ is exponentially $(\omega_0-\varepsilon)$-stable. This would contradict the definition of ω_0, so $\alpha_0(\mathbf{H}_F)$ cannot be less than ω_0, and the proof is complete. □

3. State space robustness. In this section we consider robustness of exponential stability in a natural state space for the closed-loop system with delay in the feedback loop. We make the same assumptions on A, B, and F as in section 2, so that, in particular, B is admissible for $S(t)$ and F is compact. A closed-loop state space realization for the system described by Figure 1 with $v \equiv 0$ is given, formally, by the differential equation

$$\dot{x}(t) = Ax(t) - BFx(t-\varepsilon), \qquad y(t) = Fx(t), \tag{3.1}$$

where $x(t)$ takes values in the original state space X. In order to show that robustly improved stability in an input-output context can be strengthened to the robustly improved exponential stability for (3.1), we must first show that (3.1) is well-posed in some natural state space which takes account of the delay. A natural choice for this state space is $X \times L^2(-\varepsilon, 0; X)$. The well-posedness of (3.1) in this state space is summarized as follows.

PROPOSITION 3.1. *For each $x_0 \in X$ and $\phi_0 \in L^2(-\varepsilon, 0; X)$,*

(a) *there exists a unique $x(\cdot)$ evolving continuously in X which satisfies*

$$x(t) = S(t)x_0 - \int_0^t S(t-\tau)BFx(\tau-\varepsilon)d\tau, \qquad t \geq 0, \tag{3.2}$$

with $x(t) = \phi_0(t)$ for $t \in [-\varepsilon, 0]$. Furthermore, for each $t \geq 0$ there exists $M_1 > 0$ such that

$$\|x(t)\|^2 \leq M_1(\|x_0\|^2 + \|\phi\|^2_{L^2(-\varepsilon,0;X)}); \tag{3.3}$$

(b)

$$\dot{x}(t) = Ax(t) - BFx(t-\varepsilon) \quad \textit{for almost every (a.e.)} \quad t \geq 0, \tag{3.4}$$

holds as an equation in X_{-1};

(c) *let $\Phi(t)$ be defined for $t \geq 0$ by*

$$\Phi(t)(r) = x(t+r), \qquad r \in [-\varepsilon, 0]. \tag{3.5}$$

Then for each $t \geq 0$, $\Phi(t) \in L^2(-\varepsilon, 0; X)$ and there exists $M_2 > 0$ such that

$$\|\Phi(t)\|^2_{L^2(-\varepsilon,0;X)} \leq M_2(\|x_0\|^2_X + \|\phi\|^2_{L^2(-\varepsilon,0;X)}); \tag{3.6}$$

(d) *the formula*

$$\mathcal{T}_{F,\varepsilon}(t)\begin{pmatrix} x_0 \\ \phi_0 \end{pmatrix} = \begin{pmatrix} x(t) \\ \Phi(t) \end{pmatrix}$$

defines a strongly continuous semigroup on $X \times L^2(-\varepsilon, 0; X)$.

Proof. (a) The main step in the proof is the construction of a continuous solution trajectory $x(\cdot)$. This is achieved by piecing together segments on the intervals $[n\varepsilon, (n+1)\varepsilon)$, for $n \in \mathbb{N}$. Indeed, given that

$$x(t) = \phi_0(t) \quad \text{for} \quad t \in [-\varepsilon, 0],$$

we can define

$$x(t) = S(t-n\varepsilon)x(n\varepsilon) - \int_0^{t-n\varepsilon} S(t-n\varepsilon-\tau)BFx(\tau+n\varepsilon-\varepsilon)d\tau, \qquad n\varepsilon \le t \le (n+1)\varepsilon$$

recursively for $n \in \mathbb{N}$. By the admissibility of B, for every $n \in \mathbb{N}$, $x(\cdot)$ is continuous on $[0, (n+1)\varepsilon)$ with values in X and $Fx(\cdot) \in L^2(n\varepsilon, (n+1)\varepsilon; U)$. Using induction, it is easy to verify that $x(\cdot)$ satisfies (3.2) and (3.3) for $t \in [0, n\varepsilon)$ and all $n \in N$, thus proving (a).

(b) Since $x_0 \in X$ and $Fx(\cdot - \tau) \in L^2(0, T; U)$ for all T, this follows immediately from Theorem 3.9 in [20].

(c) This follows from the construction of Φ from $x(\cdot)$.

The proof of (d) is similar to the case when B is bounded (see for example Curtain and Zwart [2]). Indeed, given x_0, ϕ_0, and s, let $g(t) = x(t+s)$. Then

$$g(t) = x(t+s) = S(t+s)x_0 - \int_0^{t+s} S(t+s-\tau)BFx(\tau-\varepsilon)d\tau$$

$$= S(t)x(s) - \int_0^{t} S(t-\sigma)BFx(s+\sigma-\varepsilon)d\sigma\,.$$

Hence $g(\cdot)$ is the solution of (3.2) corresponding to initial conditions $g(0) = x(s)$ and $g(\theta) = x(s+\theta)$ for $\theta \in [-\varepsilon, 0]$. It now follows from the definition of $\mathcal{T}_{F,\varepsilon}(t)$ that

$$\mathcal{T}_{F,\varepsilon}(t+s)\begin{pmatrix} x_0 \\ \phi_0 \end{pmatrix} = \begin{pmatrix} g(t) \\ g(t+\cdot) \end{pmatrix} = \mathcal{T}_{F,\varepsilon}(t)\begin{pmatrix} x(s) \\ x(s+\cdot) \end{pmatrix} = \mathcal{T}_{F,\varepsilon}(t)\mathcal{T}_{F,\varepsilon}(s)\begin{pmatrix} x_0 \\ \phi_0 \end{pmatrix}$$

which is the semigroup property for $\mathcal{T}_{F,\varepsilon}(t)$. Strong continuity of the semigroup $\mathcal{T}_{F,\varepsilon}$ is an easy consequence of continuity of $x(\cdot)$ and the estimates (3.3) and (3.6). □

The following definition is a state space analogue of parts (b) and (c) of Definition 2.6.

Definition 3.2.

(a) *$F \in \mathcal{K}(X, U)$ robustly exponentially α-stabilizes* (1.1) *if there exists $\varepsilon_0 > 0$ such that for any $\varepsilon \in [0, \varepsilon_0]$ the semigroup $\mathcal{T}_{F,\varepsilon}$ is α-stable.*

(b) *F robustly improves the exponential stability of* (1.1) *if F robustly exponentially α-stabilizes* (1.1) *for some $\alpha < \omega_0$ (see* (1.2)*).*

We will show that exponential stabilization of the delay-free system by compact feedback is robust if the corresponding input-output stabilization is robust, in particular if $\alpha_{\min} < \omega_0$. Our approach is to show that the resolvent of the generator of $\mathcal{T}_{F,\varepsilon}(t)$ is bounded in $\overline{\mathbb{C}_\alpha}$, which shows, using Prüss [13, Proposition 2], that the semigroup $\mathcal{T}_{F,\varepsilon}(t)$ is α-stable. Instead of determining the generator of $\mathcal{T}_{F,\varepsilon}$, we use the fact that the resolvent of the generator is the Laplace transform of $\mathcal{T}_{F,\varepsilon}(t)$. To this end we take Laplace transforms of (3.2) and (3.5) which, after some rearrangement, gives

$$\hat{x}(s) = (I + e^{-\varepsilon s}R(s,A)BF)^{-1}R(s,A)\left[x_0 - e^{-\varepsilon s}BF\int_{-\varepsilon}^{0} e^{-st}\phi_0(t)dt\right] \tag{3.7}$$

and, for $r \in [-\varepsilon, 0]$,

$$\hat{\Phi}(s)(r) = e^{-sr}\left(\hat{x}(s) + \int_r^0 e^{-st}\phi_0(t)dt\right). \tag{3.8}$$

If we show that

$$\|(I + e^{-\varepsilon s}R(s,A)BF)^{-1}R(s,A)\|_{\mathcal{B}(X)}$$

and

$$\|(I + e^{-\varepsilon s}R(s,A)BF)^{-1}R(s,A)B\|_{\mathcal{B}(U,X)}$$

are bounded in $\overline{\mathbb{C}_\alpha}$, then it will follow that

$$\left\|\begin{pmatrix} \hat{x}(s) \\ \hat{\Phi}(s) \end{pmatrix}\|_{X\otimes L^2(-\varepsilon,0;X)} \leq M \| \begin{pmatrix} x_0 \\ \phi_0 \end{pmatrix}\right\|_{X\otimes L^2(-\varepsilon,0;X)} \tag{3.9}$$

for some $M > 0$ and all $s \in \overline{\mathbb{C}_\alpha}$ so that $\mathcal{T}_{F,\varepsilon}(t)$ is α-stable.

Lemma 3.3. *If there exists $M > 0$ such that for all $s \in \overline{\mathbb{C}_\alpha}$*

$$\|(I + R(s,A)BF)^{-1}R(s,A)\|_{\mathcal{B}(X)} \leq M, \tag{3.10a}$$

$$\|(I + e^{-\epsilon s}\mathbf{H}_F(s))^{-1}\|_{\mathcal{B}(U)} \leq M, \tag{3.10b}$$

$$\|\mathbf{H}_F(s)(I + e^{-\epsilon s}\mathbf{H}_F(s))^{-1}\|_{\mathcal{B}(U)} \leq M, \tag{3.10c}$$

then there exists $\tilde{M} > 0$ such that

$$\|(I + e^{-\varepsilon s}R(s,A)BF)^{-1}R(s,A)\|_{\mathcal{B}(X)} \leq \tilde{M}, \tag{3.11}$$

$$\|(I + e^{-\varepsilon s}R(s,A)BF)^{-1}R(s,A)B\|_{\mathcal{B}(U,X)} \leq \tilde{M} \tag{3.12}$$

for all $s \in \overline{\mathbb{C}_\alpha}$.

Remark 3.4. *Note that*

$$R(s, A - BF) = (I + R(s,A)BF)^{-1}R(s,A),$$

so (3.10a) *is equivalent to exponential α-stability of the closed-loop delay-free state space system, whilst* (3.10b) *and* (3.10c) *are equivalent to input-output α-stability of the closed-loop system with delay.*

Proof. Since B is admissible for the semigroup generated by A, it is also admissible for the semigroup generated by $A-BF$ (see Salamon [17]), which means that $R(s, A-BF)B$ is bounded in the same half-plane as $R(s, A - BF)$; see [21, Proposition 2.3]. Hence

$$\|(I + R(s,A)BF)^{-1}R(s,A)B\|_{\mathcal{B}(U,X)} \leq M. \tag{3.13}$$

Let

$$\mathbf{I}(s) = (I + R(s,A)BF)^{-1}R(s,A)B\Delta(s)S(s) + (I + R(s,A)BF)^{-1}R(s,A), \tag{3.14}$$

where

$$S(s) = (I + \mathbf{H}_F(s))(I + \mathbf{H}_F(s)e^{-\epsilon s})^{-1}F(I + R(s,A)BF)^{-1}R(s,A)$$

and

$$\Delta(s) = (1 - e^{-\epsilon s}).$$

We will show that

$$(I + e^{-\varepsilon s} R(s, A)BF)^{-1} R(s, A) = \mathbf{I}(s). \tag{3.15}$$

This would verify (3.11), since all the terms on the right side of (3.14) are, by hypothesis, bounded in $\overline{\mathbb{C}_\alpha}$. (3.12) would then follow because

$$(I + e^{-\varepsilon s} R(s, A)BF)^{-1} R(s, A)B = \mathbf{I}(s)B\,,$$

and, using (3.14), $\mathbf{I}(s)B$ is clearly bounded in $\overline{\mathbb{C}_\alpha}$, since the only difficult term is $S(s)B$, which is bounded in $\overline{\mathbb{C}_\alpha}$ by (3.13).

For brevity, we write $R(s, A) = R(s)$. Then

$$(I + e^{-\varepsilon s} R(s)BF)^{-1} R(s) - \mathbf{I}(s)$$

$$= (I + e^{-\varepsilon s} R(s)BF)^{-1}(R(s) - (I + e^{-\varepsilon s} R(s)BF))\mathbf{I}(s).$$

Substituting $\mathbf{I}(s)$ from (3.14) into this expression, we obtain, after a number of straightforward manipulations,

$$\begin{aligned} &(R(s) - (I + e^{-\varepsilon s} R(s)BF))\mathbf{I}(s) \\ &\quad = \big[(I + R(s)BF) - \{(I + e^{-\varepsilon s} R(s)BF) \\ &\qquad \times [(I + R(s)BF)^{-1} R(s)B\Delta(s)(I + \mathbf{H}_F(s))(I + \mathbf{H}_F(s)e^{-\epsilon s})^{-1}F + I]\}\big] \\ &\qquad \times (I + R(s)BF)^{-1} R(s) \\ &\quad = \Delta(s)\{R(s)BF - \big[(I + e^{-\varepsilon s} R(s)BF)(I + R(s)BF)^{-1} R(s)B \\ &\qquad \times\ (I + \mathbf{H}_F(s))(I + \mathbf{H}_F(s)e^{-\epsilon s})^{-1}F\big]\}(I + R(s)BF)^{-1} R(s). \end{aligned} \tag{3.16}$$

Recall that

$$\mathbf{H}_F(s) = FR(s)B\,,$$

$$F(I + R(s)BF)^{-1} R(s)B = \mathbf{H}_F(s)(I - \mathbf{H}_F(s))^{-1},$$

and

$$(I + R(s)BF)^{-1} R(s)B = R(s)B(I + \mathbf{H}_F(s))^{-1}\,.$$

Using these inside the second pair of square brackets in (3.16), expanding, and simplifying, we see that (3.16) is zero. Therefore

$$(I + e^{-\varepsilon s} R(s, A)BF)^{-1} R(s, A) = \mathbf{I}(s)$$

as claimed, and the proof is complete. □

THEOREM 3.5. *It is possible to robustly improve the exponential stability of* (1.1) *in the sense of Definition* 3.2 *if and only if* $\alpha_{\min} < \omega_0$.

Proof. The “only if” part follows immediately from the definition of $\alpha_{\min}$.

For the "if" part, we first show that for any $\alpha \in (\alpha_{\min}, \omega_0)$, there exists ε_1 such that (3.10a), (3.10b), and (3.10c) are true for $\varepsilon \in (0, \varepsilon_1)$. By the definition of $\alpha_{\min}$, for any $\alpha \in (\alpha_{\min}, \omega_0)$ we know that there exists $F \in \mathcal{K}(X, U)$ such that the delay-free closed-loop system is exponentially α-stable, i.e., so that (3.10a) holds for $s \in \overline{\mathbb{C}_\alpha}$. Since $\alpha < \omega_0$, the proof of Proposition 2.7 shows that unity feedback robustly improves the stability of $\mathbf{H}_F$. This establishes the existence of ε_1 such that (3.10b) and (3.10c) are bounded in $\overline{\mathbb{C}_\alpha}$ for any $\varepsilon \in (0, \varepsilon_1)$. Lemma 3.3 now implies that (3.11) and (3.12) are true in $\overline{\mathbb{C}_\alpha}$ for any $\varepsilon \in (0, \varepsilon_1)$. Therefore, (3.9) holds in $\overline{\mathbb{C}_\alpha}$ for some M and for any $\varepsilon \in (0, \varepsilon_1)$. This shows that the resolvent of the semigroup $\mathcal{T}_{F,\varepsilon}(t)$ is bounded in $\overline{\mathbb{C}_\alpha}$, so that $\mathcal{T}_{F,\varepsilon}(t)$ is α-stable. Hence F robustly improves the exponential stability of (1.1) in the sense of Definition 3.2. □

4. Unbounded feedback. We have seen that if B is an admissible input operator for $S(t)$, then we can robustly improve the exponential stability of (1.1) by compact feedback if and only if $\alpha_{\min} < \omega_0$. In [15] a definition of exponential stabilizability (which we call *regular stabilizability*) is given which allows F to be unbounded provided that (A, B, F) is a *regular system* and unity gain is an *admissible feedback*. We refer the reader to Weiss [22] for details about regular systems, and to Weiss [23] for details about admissible feedbacks. We mention here that if the feedback loop is closed with unity gain and unity gain is an admissible feedback for (A, B, F), then the closed-loop generator is $A - BF_L$, where F_L is the Lebesgue extension of F (see [22]), and that the formulas (1.4) and (1.5) hold when F is replaced by F_L. Roughly speaking, we say that (1.1) is regularly stabilizable if $A + BF_L$ generates an exponentially stable semigroup. With this kind of stabilizability it can be possible to improve the exponential stability of (1.1) even if $\alpha_{\min} = \omega_0$. (We should note here that in the definition of $\alpha_{\min}$ we still use the definition of stabilizability by compact F.) However, we will show that whenever the input space U is finite dimensional, any such improvement of stability is not robust with respect to delays.

THEOREM 4.1. *Suppose U is finite dimensional and $\alpha_{\min} = \omega_0$. If (1.1) is regularly μ-stabilizable, where $\mu < \omega_0$, then there exists sequences (ε_n) and (p_n) with*

$$\varepsilon_n > 0\,, \quad \lim_{n\to\infty} \varepsilon_n = 0\,, \quad p_n \in \mathbb{C}_{\omega_0}\,, \quad \lim_{n\to\infty} |\operatorname{Im} p_n| = \infty\,,$$

and such that for any $n \in \mathbb{N}$, p_n is a pole of $\mathbf{G}^{\varepsilon_n}$.

Proof. Suppose (1.1) is regularly μ-stabilizable with $\mu < \omega_0$ with the admissible feedback F. We break the proof up into two cases.

Case 1. Suppose

$$\limsup_{\substack{|s|\to\infty \\ s\in\mathbb{C}_{\omega_0}}} \|R(s, A)\|_{\mathcal{B}(X)} = \infty,$$

or, equivalently,

$$\limsup_{\substack{|s|\to\infty \\ s\in\mathbb{C}_0}} \|R(s, A - \omega_0 I)\|_{\mathcal{B}(X)} = \infty. \tag{4.1}$$

Since $A - BF_L$ is the generator of a semigroup with growth rate μ, $(A - \omega_0 I, B, F)$ is stabilizable and detectable in the sense given in [15]. Combining this with (4.1), we can conclude from (4.1) and Theorem 1.6 in [15] that

$$\limsup_{\substack{|s|\to\infty \\ s\in\mathbb{C}_0}} \|\mathbf{H}_F(s + \omega_0)\|_{\mathcal{B}(U)} = \limsup_{\substack{|s|\to\infty \\ s\in\mathbb{C}_{\omega_0}}} \|\mathbf{H}_F(s)\|_{\mathcal{B}(U)} = \infty. \tag{4.2}$$

By hypothesis, there exists F such that (A, B, F) is a regular system and $A - BF_L$ is μ-exponentially stable. From Proposition 4.1 in Weiss [22] it follows that the closed-loop transfer function $\mathbf{G}^0$ for (A, B, F) with unity gain is μ-stable. Hence, in the terminology of [10], the identity operator I stabilizes $\mathbf{H}_F(s + \omega_0)$, and the conclusion of Theorem 4.1 follows immediately from Lemma 8.5 in [10].

Case 2. Suppose

$$\limsup_{\substack{|s|\to\infty \\ s\in\mathbb{C}_{\omega_0}}} \|R(s, A)\|_{\mathcal{B}(X)} < \infty. \tag{4.3}$$

Since $u(t) = -F_L x(t)$ is such that for any $\alpha \in (\mu, \omega_0)$,

$$\int_0^\infty e^{-\alpha t} \left(\|u(t)\|_U^2 + \|x(t)\|^2\right) dt < \infty,$$

we see that (1.1) is *open-loop α-stabilizable* as defined in Rebarber and Zwart [16]. By Theorem 2.11 in [16], for any $\alpha \in (\mu, \omega_0)$ we have that $\{\lambda \in \sigma(A) \mid \operatorname{Re}\lambda \geq \alpha\}$ contains no finite accumulation point (although ∞ might be an accumulation point) and consists only of point spectrum with finite multiplicity; see also Theorem 3.5 in Zwart [24] for a related result. Using this fact along with (4.3), we see that

$$\sigma_1(A) = \{\lambda \in \sigma(A) \mid \operatorname{Re}\lambda = \omega_0\}$$

consists of finitely many eigenvalues of finite multiplicity. Since $\{\lambda \in \sigma(A) \mid \operatorname{Re}\lambda \geq \alpha\}$ contains no finite accumulation point, $\sigma_1(A)$ can be isolated from the remaining part, $\sigma_2(A)$, of $\sigma(A)$ by a simple closed contour Γ. We proceed as in [9], Theorem 6.17 (see also the development before Lemma 2.3 in this paper) to decompose (1.5) into

$$\dot{x}_1(t) = A_1 x_1(t) + B_1 u(t),$$

$$\dot{x}_2(t) = A_2 x_2(t) + B_2 u(t),$$

where $\sigma(A_1) = \sigma_1(A)$, $\sigma(A_2) = \sigma_2(A)$, and the x_1-subsystem is finite-dimensional. By (4.3) and the fact that A_2 does not have spectrum in $\overline{\mathbb{C}_{\omega_0}}$, $\|R(s, A_2)\|$ is bounded on $\overline{\mathbb{C}_{\omega_0}}$. Using [13, Proposition 2], this shows that A_2 generates an $(\omega_0 - \varepsilon)$-stable semigroup for some $\varepsilon > 0$. It follows that exponential α-stabilizability of (1.1) by bounded feedback is equivalent to α-stabilizability of the pair (A_1, B_1), which in turn is equivalent to controllability of the pair (A_1, B_1). Since $\alpha_{\min} = \omega_0$, (1.1) is not stabilizable by bounded feedback, we conclude that (A_1, B_1) is not controllable. In particular, the (A_1, B_1)-subsystem has an uncontrollable mode λ, with $\operatorname{Re}\lambda = \omega_0$. This implies that (1.5) cannot be regularly α-stabilized for any $\alpha < \omega_0$, which contradicts our hypotheses. Therefore Case 2 cannot hold, so Case 1 holds and the proof is complete. $\square$

5. Examples.

Example 1. To illustrate Theorem 3.5, we consider a heat equation with Neumann boundary control on part of the boundary. Let Ω be a bounded open domain in $\mathbb{R}^n$, $n = 2$ or 3, with Lipschitz boundary Γ, and let Γ_0 be a nonempty simply connected subset of Γ. Let $\langle \cdot, \cdot \rangle$ denote the real inner product in $L^2(\Omega)$, $\dot{w}$ denote differentiation with respect to time $t \geq 0$, $\partial w/\partial\nu$ denote the normal derivative of w on Γ, and Δ be the Laplacian in Ω. Unless otherwise stated, ξ will denote a variable in Ω and ζ will denote a variable in Γ.

We now consider the following heat equation with Neumann boundary control on Γ_0 and Dirichlet data on $\Gamma \setminus \Gamma_0$:

$$\dot{w}(\xi,t) = \Delta w(\xi,t), \qquad \xi \in \Omega, \quad t \geq 0, \tag{4.1a}$$

$$w(\zeta,t) = 0, \qquad \zeta \in \Gamma \setminus \Gamma_0, \quad t \geq 0, \tag{4.1b}$$

$$\frac{\partial w(\zeta,t)}{\partial \nu} = u(\zeta,t), \qquad \zeta \in \Gamma_0, \quad t \geq 0, \tag{4.1c}$$

where $u \in L^2[0,T;U]$, with $U = L^2(\Gamma_0)$.

We wish to represent (4.1a)–(4.1c) as a state space equation in $X = L^2(\Omega)$. Let the operator $A : \mathcal{D}(A) \to L^2(\Omega)$ be defined by

$$Aw = \Delta w, \qquad \mathcal{D}(A) = \left\{ z \in L^2(\Omega) \mid \Delta z \in L^2(\Omega), \ z|_{\Gamma\setminus\Gamma_0} = 0, \ \frac{\partial z}{\partial \nu}|_{\Gamma_0} = 0 \right\}.$$

It is well known that A is negative self-adjoint and has compact resolvent. In particular, for any $\beta \in \mathbb{R}$, $\sigma_u(A,\beta)$ consists of finitely many eigenvalues, each with finite multiplicity.

We define the Neumann map $\mathcal{N}$ as follows: If f is defined on Γ_0, then $\mathcal{N} f = R$ if R is the (distributional) solution to

$$\Delta R(\xi) = 0, \qquad \xi \in \Omega,$$

with boundary conditions

$$R(\zeta) = 0, \qquad \zeta \in \Gamma \setminus \Gamma_0,$$

$$R(\zeta) = f(\zeta), \qquad \zeta \in \Gamma_0,$$

where the boundary values are to be understood in the sense of trace.

It is a standard exercise to show that (4.1a)–(4.1c) can be put into the form (1.1) in X_{-1} (where w is now the dependent variable instead of x) with

$$B = -A\mathcal{N}.$$

In order to apply the results of sections 2 and 3, we need to show that B is admissible for the semigroup $S(t)$ generated by A. Let λ be in the resolvent set of A, and define $X_{-1/2}$ as the completion of X in the norm $\|(\lambda I - A)^{-1/2} \cdot \|$. It follows from Weiss [21] and Hansen and Weiss [7] that if the range of B is contained in $X_{-1/2}$, then B is admissible. From Grisvard [6],

$$\mathcal{D}((-A)^{1/2}) = \{ z \in H^1(\Omega) \mid z = 0 \text{ on } \Gamma \setminus \Gamma_0 \},$$

so from elliptic theory

$$\mathcal{N} \in \mathcal{B}(L^2(\Gamma), \mathcal{D}((-A)^{1/2})).$$

Hence we see that the range of $B = -A\mathcal{N}$ is contained in $X_{-1/2}$, so B is admissible. Therefore the results in sections 2 and 3 show that if $F \in \mathcal{K}(X,U)$ is such that $u(\zeta,t) = Fw(\xi,t)$ is an exponentially α-stabilizing feedback, then this stability is robust in the natural state spaces described in section 3.

As a specific example, let $\Omega = \{(x,y) \mid 0 < x < \pi,\ 0 < y < \pi\} \subset \mathbb{R}_2$ and Γ_0 be $\{0 \leq x \leq \pi\}$. The eigenvalues of A are easily computed to be

$$\lambda_{j,k} = -\left(\left(j + \frac{1}{2}\right)^2 + k^2\right), \qquad j \in \mathbb{N},\ k \in \mathbb{Z}^+,$$

with associated eigenvectors

$$\Phi_{j,k}(x,y) = \sin(kx)\cos((j+1/2)y), \qquad j \in \mathbb{N},\ k \in \mathbb{Z}^+.$$

Since the eigenvalue with the largest real part is $\lambda_{0,1} = -5/4$, the open loop system is exponentially $(-5/4)$-stable. The eigenvalue with the second largest real part is $\lambda_{1,1}$, which is equal to $-13/4$. In order to improve stability to $(-13/4)$-stability, we use a one dimensional bounded feedback of the form

$$F : X \to U, \quad (Fw) = \langle \eta, w \rangle g$$

with $\eta \in X$ and $g \in U$. With this feedback (4.1a)–(4.1c) are equivalent to

$$\dot{w}(t) = Aw(t) + Bgu(t), \qquad u(t) = \langle \eta, w(\cdot, t) \rangle.$$

We can find η so that F of this form exponentially $-13/4$-stabilizes (4.1a)–(4.1c) if and only if (A_u, Bg) is controllable on X_u, which is the closed span of $\Phi_{0,1}$ in X (see Theorem 6.1 in Triggiani [18]). In particular, suppose the trace $\Phi_{0,1}|_{\Gamma_0}$ (which is $\sin x$) is not orthogonal to g in $L^2(\Gamma)$. Then we can use the characterization of the adjoint of $A\mathcal{N}$ found in Triggiani [19] to show that $-A\mathcal{N}g$ is not orthogonal to $\Phi_{0,1}$ in $L^2(\Omega)$, and so (A_u, Bg) is controllable on X_u as required.

Example 2. Let X be a Hilbert space, and let A be a nonnegative self-adjoint operator on X with domain $\mathcal{D}(A)$. To illustrate Theorem 4.1 we consider a large class of hyperbolic systems of the form

$$\ddot{x}(t) + Ax(t) = Bu(t). \tag{4.2}$$

We assume that $B : U \to X_{-1}$, where U is finite dimensional, is admissible for this system in the sense that $\mathcal{B} = [0, B]^T$, is admissible for the semigroup on $H = \mathcal{D}(A^{1/2}) \oplus X$ generated by

$$\mathcal{A} = \begin{bmatrix} 0 & I \\ -A & 0 \end{bmatrix}.$$

The first-order state space equation for (4.2) is

$$\dot{z}(t) = \mathcal{A}x(t) + \mathcal{B}u(t). \tag{4.3}$$

It is easy to see that $\omega_0 = 0$ for this system. Since $\mathcal{A}$ does not have the spectrum decomposition described in Lemma 2.3, (4.3) is not stabilizable by bounded feedback, so $\alpha_{\min} = \omega_0$. Many systems of this form can be exponentially stabilized by regular feedback, for instance, many wave and beam equations in spatial dimension one. However, by Theorem 4.1 this stabilization cannot be robust with respect to small delays in the feedback loop. Related nonrobustness results for this system can be found in Datko and You [5].

Acknowledgments. We would like to thank Uwe Stroinski, George Weiss, and Mohammad Rammaha for several helpful discussions related to the work in this paper.

DETERMINATION OF THE INTERFACE BETWEEN THE FLUIDS IN A HALL–HÉROULT CELL FROM MEASUREMENTS OF ELECTRIC POTENTIALS AND CURRENTS ON THE ELECTRODES[*]

D. J. CEDIO-FENGYA[†], M. V. ROMERIO[‡], AND M. VOGELIUS[§]

Abstract. In this paper we apply the method of electrical impedance tomography to the problem of determining the interface between two fluid layers in a shallow electrolytic cell. We show that any nontrivial set of boundary currents and corresponding boundary voltages suffices to uniquely identify the interface. We propose a very simple reconstruction method that in an essential way uses the fact that the cell is of very small height. Estimates of the accuracy of this method are also provided. Finally we perform a number of computational experiments to demonstrate the efficiency of the method we propose. For the numerical reconstructions we use synthetic data generated from a discretized boundary integral formulation of the underlying conductivity problem.

1. Introduction.

Hall and Héroult are two names commonly associated with the electrolytic cells used for industrial aluminum production. The main components of a Hall–Héroult cell are the electrolytic bath and the liquid aluminum. At the top and the bottom of a cell are the arrays of anode and cathode blocks. The electrolytic bath contains, among other things, cryolite, and it is situated on top of the liquid aluminum layer. There are other less important layers which we disregard. The efficiency of the cell (a measure of the aluminum production) depends strongly on the location of the interface between the electrolytic bath and the aluminum layer. It is thus practically important to be able to control the location of the interface. However, before we can proceed to control the interface location, we need to be able to determine fairly accurately its current state. In industrial plants, cells are operating at a temperature of the order of 970°C. At this temperature the cryolite contained in the bath is chemically very active. Under such conditions measurements of the interface location by mechanical means encounter severe difficulties. In fact, the location cannot be determined accurately with such procedures. It is, on the other hand, very simple to make measurements of the voltages and currents at the top and bottom of the cell (at the anode and cathode blocks). These are exactly the kinds of measurements that are used in so-called electrical impedance tomography to determine the internal conductivity distribution. Since the conductivity properties of the electrolytic bath and the aluminum are fairly well known (and very different), the determination of the

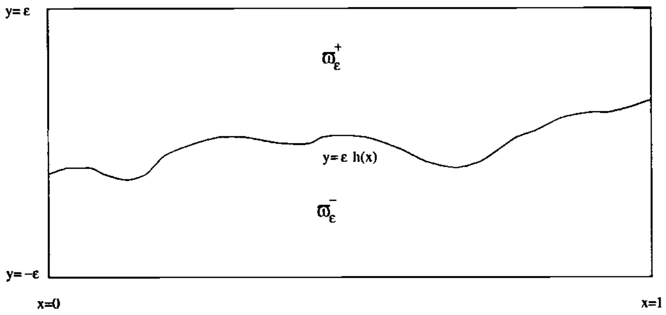

FIG. 1. *The domain Ω_ϵ representing the electrolytic cell.*

conductivity distribution is really equivalent to the determination of the location of the interface.

The purpose of this work is to demonstrate that electrical impedance tomography can be effectively applied to determine the location of an interface between two horizontal layers of different (but known) conductivity. In doing so we shall strongly make use of one geometric characteristic of a Hall–Héroult cell. Such a cell typically has a width of about 1/3 of its length and a height of about 1/50 of its length. Consequently we shall restrict our attention to domains of very small height. In this initial study we also suppose that the properties of the cell are independent of the width variable. We therefore model the cell by the two-dimensional rectangular domain $\Omega_\epsilon = (0,1) \times (-\epsilon, \epsilon)$ of length 1 and height 2ϵ.

As shown in Figure 1 we suppose that the domain Ω_ϵ is separated into two parts, ω_ϵ^+, and ω_ϵ^-, by the curve $y = \epsilon h(x)$. The subdomains $\omega_\epsilon^\pm$ are given by $\omega_\epsilon^+ = \{(x,y) :\ 0 < x < 1,\ \epsilon h(x) < y < \epsilon\}$ and $\omega_\epsilon^- = \{(x,y) :\ 0 < x < 1,\ -\epsilon < y < \epsilon h(x)\}$, respectively. The subdomain ω_ϵ^+ corresponds to the electrolytic bath and the subdomain ω_ϵ^- corresponds to the liquid aluminum layer; these have *different*, known, constant conductivities $a_+ > 0$ and $a_- > 0$ (we note that our theoretical results could very easily be generalized to the case in which a_+ and a_- are known, variable conductivities, with a proper jump across the curve $y = \epsilon h(x)$). We assume that the function $h(\cdot)$ satisfies $-1 < h(x) < 1$, $0 \le x \le 1$; for simplicity we also always (for our theoretical results) assume that $h(\cdot)$ is sufficiently smooth. We model the imposed boundary currents as distributed currents at the top and bottom boundaries. The two vertical boundaries $x = 0, 1$ are assumed to be insulated. The boundary value problem for the voltage potential u_ϵ therefore becomes

$$\nabla \cdot (a_+ \nabla u_\epsilon) = 0 \quad \text{in} \quad \omega_\epsilon^+, \tag{1a}$$

$$\nabla \cdot (a_- \nabla u_\epsilon) = 0 \quad \text{in} \quad \omega_\epsilon^-, \tag{1b}$$

$$\frac{\partial u_\epsilon}{\partial x} = 0 \quad \text{on} \quad x = 0, 1, \tag{1c}$$

$$a_+ \frac{\partial u_\epsilon}{\partial y} = f \text{ on } \ y = \epsilon, \qquad a_- \frac{\partial u_\epsilon}{\partial y} = g \text{ on } \ y = -\epsilon, \tag{1d}$$

with the continuity condition

$$u_\epsilon \text{ is continuous across the interface } y = \epsilon h(x) \tag{1e}$$

and the jump condition

$$\text{(1f)} \qquad a_+ \left(\frac{\partial}{\partial n}\right)_+ u_\epsilon = a_- \left(\frac{\partial}{\partial n}\right)_- u_\epsilon \quad \text{on the interface } y = \epsilon h(x).$$

Here n is a fixed normal direction to the interface $\{y = \epsilon h(x)\}$; $\left(\frac{\partial}{\partial n}\right)_+$ and $\left(\frac{\partial}{\partial n}\right)_-$ denote the derivatives in the direction n as we approach the interface from the top and the bottom, respectively. This boundary value problem has a corresponding weak formulation: find $u_\epsilon \in H^1(\Omega_\epsilon)$ such that

$$\text{(2)} \int_{\Omega_\epsilon} a_\epsilon \nabla u_\epsilon \nabla v \; dxdy = \int_{\partial\Omega_\epsilon \cap \{y=\epsilon\}} f \; v \; dx - \int_{\partial\Omega_\epsilon \cap \{y=-\epsilon\}} g \; v \; dx \quad \forall \; v \in H^1(\Omega_\epsilon).$$

Here the (piecewise-constant) conductivity distribution $a_\epsilon(x,y)$ is given by

$$a_\epsilon(x,y) = a_+ \;\text{ for } \epsilon h(x) < y < \epsilon \;, \;\; a_\epsilon(x,y) = a_- \;\text{ for } -\epsilon < y < \epsilon h(x).$$

Given $f, \, g \in H^{1/2}(0,1)$, with $\int_0^1 f \; dx = \int_0^1 g \; dx$, the weakly formulated boundary value problem (2) has a solution, and this solution is unique up to an additive constant. If the current distributions f and g are in $C^{2,\alpha}([0,1])$ for some $\alpha > 0$, then elliptic regularity theory ensures that u_ϵ is C^∞ inside each of the subdomains $\omega_\epsilon^\pm$ and is twice continuously differentiable up to the smooth parts of the boundaries $\partial\omega_\epsilon^\pm$. Such a smooth, weak solution u_ϵ satisfies (1) in a classical sense.

For our identification problem we suppose that measurements of the voltage potential u_ϵ are available all along the top and bottom boundaries $\{y = \pm\epsilon\}$. The main objective of this paper is to show that the interface $y = \epsilon h(x)$ may be very effectively determined from knowledge of these measurements. The present study may thus be seen as another piece of evidence that electrical impedance tomography is a quite effective method to determine special features of an otherwise known conductor; see also [1, 7, 8, 4, 15] and references therein. The setting we study here is as already mentioned very simplified when compared to the industrial, three-dimensional problem. We do however believe that the simplified setting exhibits many of the key characteristics. The added difficulties of the industrial, three-dimensional problem will be the focus of future work.

2. A two-dimensional identification result. The first question that naturally arises is whether knowledge of u_ϵ at the top and bottom boundaries suffices to identify the location of the interface between the constant conductivities a_+ and $a_-(\neq a_+)$. This question is somewhat analogous to the question of identifiability of an inaccessible boundary part (cf. [2]) and it is therefore not surprising that it is answered in the affirmative by the following theorem.

THEOREM 2.1. *Suppose $h_i \in C^{2,\alpha}([0,1])$, $i = 1,2$, and suppose $f, g \in C^{2,\alpha}([0,1])$ with at least one of these boundary currents not identically zero. Let u_ϵ^i, $i = 1,2$ denote solutions to* (2) (*or* (1)) *corresponding to the two interfaces $y = \epsilon h_i(x)$, $i = 1,2$, but with the same fixed set of boundary currents f, g. Then*

$$u_\epsilon^1 - u_\epsilon^2 = c \text{ (a single constant) } \; on \; \partial\Omega_\epsilon \cap (\{y = \epsilon\} \cup \{y = -\epsilon\})$$
$$\Rightarrow \;\; h_1 = h_2 \;\; on \; [0,1].$$

Proof. By adding the constant c to u_ϵ^2 we get another solution to (2). It therefore suffices to prove that $h_1 = h_2$ on $[0,1]$ whenever we have two solutions with $u_\epsilon^1 = u_\epsilon^2$

on $\partial\Omega_\epsilon \cap (\{y=\epsilon\} \cup \{y=-\epsilon\})$. Let $\tilde{\omega}_\epsilon^+$, $\tilde{\omega}_\epsilon^{int}$, and $\tilde{\omega}_\epsilon^-$ denote the sets

$$\begin{aligned}\tilde{\omega}_\epsilon^+ &= \{(x,y)\ :\ 0<x<1\ ,\ \ \epsilon\max(h_1(x),h_2(x)) < y < \epsilon\},\\ \tilde{\omega}_\epsilon^{int} &= \{(x,y)\ :\ 0<x<1\ ,\ \ \epsilon\min(h_1(x),h_2(x)) < y < \epsilon\max(h_1(x),h_2(x))\},\\ \tilde{\omega}_\epsilon^- &= \{(x,y)\ :\ 0<x<1\ ,\ \ -\epsilon < y < \epsilon\min(h_1(x),h_2(x))\}.\end{aligned}$$

Due to elliptic regularity theory the u_ϵ^i are both smooth solutions to $\triangle u_\epsilon^i = 0$ inside the three sets $\tilde{\omega}_\epsilon^+$, $\tilde{\omega}_\epsilon^{int}$, and $\tilde{\omega}_\epsilon^-$. Due to elliptic regularity theory and the regularity assumptions on f and g it also follows that the u_ϵ^i are C^2 up to (the interior of) the top and bottom boundaries $\{(x,y)\ :\ 0<x<1\ ,\ \ y=\pm\epsilon\}$ and that they satisfy the boundary conditions in a classical sense.

Now consider $v_\epsilon = u_\epsilon^1 - u_\epsilon^2$. Since, by assumption, v_ϵ has zero Cauchy data (v_ϵ and $\frac{\partial}{\partial y}v_\epsilon$ vanish) on the top and bottom boundaries $\{(x,y)\ :\ 0<x<1\ ,\ \ y=\pm\epsilon\}$, and since v_ϵ satisfies $\triangle v_\epsilon = 0$ in $\tilde{\omega}_\epsilon^+ \cup \tilde{\omega}_\epsilon^-$, it follows from unique continuation (Holmgren's uniqueness theorem) that $v_\epsilon \equiv 0$ in $\tilde{\omega}_\epsilon^+ \cup \tilde{\omega}_\epsilon^-$. It is well known that the u_ϵ^i, and thus v_ϵ, are continuous on $\overline{\Omega}_\epsilon$. We therefore get

$$v_\epsilon \equiv 0 \ \text{ on } \overline{\tilde{\omega}_\epsilon^+ \cup \tilde{\omega}_\epsilon^-}\,. \tag{3}$$

Let $\tilde{\omega}$ denote any nonempty, connected component of the open set $\tilde{\omega}_\epsilon^{int}$ (if one exists). Corresponding to $\tilde{\omega}$ we either have $h_1(x) < h_2(x)\ \forall\ (x,y) \in \tilde{\omega}$ or $h_2(x) < h_1(x)\ \forall\ (x,y)\in\tilde{\omega}$. Without loss of generality we suppose that

$$h_1(x) < h_2(x)\ \ \forall\ (x,y)\in\tilde{\omega}\ \ .$$

The set $\tilde{\omega}$ has an open, connected projection on the x-axis, hence there exists an open interval $I \subset (0,1)$ such that

$$\begin{gathered} h_1(x) < h_2(x)\ \ \forall\ x\in I \quad\text{and}\\ \tilde{\omega} = \{(x,y)\ :\ x\in I\ ,\ \ \epsilon h_1(x) < y < \epsilon h_2(x)\}.\end{gathered}$$

The following argument is slightly different depending on whether or not the endpoints of I fall in the interior of the interval $(0,1)$. Let us first consider the case where both endpoints fall in the interior. Afterwards we shall outline the changes necessary if this is not the case. The boundary of $\tilde{\omega}$ is now given by

$$\partial\tilde{\omega} = \{(x,y)\ :\ x\in\overline{I}\ ,\ \ y=\epsilon h_2(x)\} \cup \{(x,y)\ :\ x\in\overline{I}\ ,\ \ y=\epsilon h_1(x)\}. \tag{4}$$

Because of the identity (3) it follows immediately that $v_\epsilon = 0$ on $\partial\tilde{\omega}$. We also have that v_ϵ is continuous on the closure of $\tilde{\omega}$, and satisfies $\triangle v_\epsilon = 0$ in $\tilde{\omega}$. From the maximum principle it now follows that $v_\epsilon \equiv 0$ in $\tilde{\omega}$.

If one (or both) of the endpoints of I lies on the boundary of $[0,1]$, then $\partial\tilde{\omega}$ will generally contain at least one vertical line segment in addition to the curves $y=\epsilon h_i(x)$. If (by chance) there happens to be no such vertical boundary part(s) we proceed just as before to show that $v_\epsilon \equiv 0$ in $\tilde{\omega}$. Now suppose vertical lines form part of the boundary. The classical version of the maximum principle asserts that $v_\epsilon \equiv 0$ in $\tilde{\omega}$ or a nonzero extremal value is attained (in the interior) of one of the vertical boundary parts. As the normal derivative of v_ϵ vanishes along the vertical boundary part(s) the strong version of the maximum principle (Hopf's lemma) implies that we necessarily must have $v_\epsilon \equiv 0$ in $\tilde{\omega}$. In summary we have now verified that v_ϵ always vanishes in $\tilde{\omega}$. Since $\tilde{\omega}$ is any nonempty, connected component of $\tilde{\omega}_\epsilon^{int}$ this immediately shows that one of the following two statements must be true: 1) $v_\epsilon \equiv 0$ on the closure of $\tilde{\omega}_\epsilon^{int}$, or 2) $\tilde{\omega}_\epsilon^{int}$ is the empty set.

Let us now suppose that $\tilde{\omega}_\epsilon^{int} \neq \varnothing$, and therefore $v_\epsilon \equiv 0$ on the closure of $\tilde{\omega}_\epsilon^{int}$. By a combination with (3) this implies that

$$v_\epsilon = u_\epsilon^1 - u_\epsilon^2 = 0 \ \text{ on } \overline{\Omega}_\epsilon.$$

We consider a single, nonempty connected component $\tilde{\omega}$ of the set $\tilde{\omega}_\epsilon^{int}$ (such a component exists since we suppose that $\tilde{\omega}_\epsilon^{int}$ itself is nonempty). We shall analyze the case where the boundary of $\tilde{\omega}$ has the form (4). The case in which there are vertical boundary parts may be treated in a completely analogous manner due to the fact that the normal derivatives of u_ϵ^i, $i = 1, 2$ vanish on these vertical parts. Along the boundary curve $\{(x, y) \ : \ x \in I \ , \ \ y = \epsilon h_2(x)\}$ we have that $[\frac{\partial}{\partial n} u_\epsilon^1] = \left(\frac{\partial}{\partial n}\right)_+ u_\epsilon^1 - \left(\frac{\partial}{\partial n}\right)_- u_\epsilon^1 = 0$ (since u_ϵ^1 satisfies $\triangle u_\epsilon^1 = 0$ across this curve). Along this curve we also have that the conormal derivative of u_ϵ^2 satisfies the jump condition

$$\left[a_\epsilon \frac{\partial}{\partial n} u_\epsilon^2\right] = a_+ \left(\frac{\partial}{\partial n}\right)_+ u_\epsilon^2 - a_- \left(\frac{\partial}{\partial n}\right)_- u_\epsilon^2 = 0. \tag{5}$$

Here n denotes a fixed normal direction to the curve $y = \epsilon h_2(x)$; $\left(\frac{\partial}{\partial n}\right)_+$ and $\left(\frac{\partial}{\partial n}\right)_-$ denote the derivatives in the direction n as we approach the curve from the top and the bottom, respectively. Since $u_\epsilon^1 = u_\epsilon^2$ in all of Ω_ϵ we in particular have that $\left(\frac{\partial}{\partial n}\right)_\pm u_\epsilon^2 = \left(\frac{\partial}{\partial n}\right)_\pm u_\epsilon^1 = \frac{\partial}{\partial n} u_\epsilon^1$ along the curve $\{(x, y) \ : \ x \in I \ , \ \ y = \epsilon h_2(x)\}$. Since $a_+ \neq a_-$, the jump condition (5) therefore yields

$$\left(\frac{\partial}{\partial n}\right)_\pm u_\epsilon^2 = \frac{\partial}{\partial n} u_\epsilon^1 = 0$$

along the curve $\{(x, y) \ : \ x \in I \ , \ \ y = \epsilon h_2(x)\}$. By a completely identical argument we get that

$$\left(\frac{\partial}{\partial n}\right)_\pm u_\epsilon^1 = \frac{\partial}{\partial n} u_\epsilon^2 = 0$$

along the curve $\{(x, y) \ : \ x \in I \ , \ \ y = \epsilon h_1(x)\}$. Consider now the function u_ϵ^1. From the previous two identities we get that

$$\frac{\partial}{\partial n} u_\epsilon^1 = 0$$

along the boundary curves $\{(x, y) \ : \ x \in I \ , \ \ y = \epsilon h_i(x)\}$, $i = 1, 2$, of $\tilde{\omega}$. Since the function u_ϵ^1 also satisfies $\triangle u_\epsilon^1 = 0$ in $\tilde{\omega}$ and since it has finite energy (it is in $H^1(\tilde{\omega})$), it follows that $u_\epsilon^1 =$ constant in $\tilde{\omega}$. Unique continuation (Holmgren's uniqueness theorem) now implies that $u_\epsilon^1 =$ constant in all of Ω_ϵ, which contradicts the fact that the boundary currents f and g are not both identically zero. The assumption that the set $\tilde{\omega}_\epsilon^{int}$ is nonempty has thus led to a contradiction, and as a consequence it must necessarily be empty. This implies that $h_1(x) = h_2(x)$ for all $x \in [0, 1]$, exactly as desired. □

Remark. We note that the proof of Theorem 2.1 carries through virtually without any changes when the h_i are only assumed to be piecewise $C^{2,\alpha}$ and globally Lipschitz. This observation is relevant for interfaces such as the piecewise-linear ones we consider in connection with our numerical experiments. We also note that there is some similarity between the above proof and the proof of Lemma 2.1 in [7].

Theorem 2.1 guarantees the identifiability of h from the overdetermined data $u_\epsilon|_{y=\pm\epsilon}$, but it does not provide an explicit reconstruction formula. The derivation of such a reconstruction formula, in the case when the height of the cell (2ϵ) approaches zero, is the focus of the next two sections.

3. The asymptotic limit as $\boldsymbol{\epsilon \longrightarrow 0}$. In this section we shall study the limit of the voltage potential u_ϵ as $\epsilon \to 0$. Studies of such "thin domain" limits are quite common in continuum mechanics—for instance in connection with the derivation of "dimensionally reduced" equations for beams, plates, or shells (see [5, 14] and references therein). These studies have incorporated sandwich-like structures [13, 14] and they have extended to the modeling of electrolytic cells [3], but to the best of our knowledge distributions of "material properties" such as those encountered here have not previously been rigorously analyzed. Since this analysis is furthermore quite short and elementary we shall, for the convenience of the reader, include it here.

As is frequently the case it is also here preferable to "stretch" the domain Ω_ϵ, by introduction of the new variables $(x,z) = (x, y/\epsilon)$. In these new coordinates the domain becomes $\Omega = (0,1) \times (-1,1)$, and the corresponding voltage potential $v_\epsilon(x,z) = u_\epsilon(x,\epsilon z)$ satisfies the boundary value problem

$$\frac{\partial}{\partial x}\left(a(x,z)\frac{\partial v_\epsilon}{\partial x}\right) + \epsilon^{-2}\frac{\partial}{\partial z}\left(a(x,z)\frac{\partial v_\epsilon}{\partial z}\right) = 0 \quad \text{in} \quad \Omega, \tag{6a}$$

$$\frac{\partial v_\epsilon}{\partial x} = 0 \quad \text{at} \quad x = 0,1, \tag{6b}$$

$$a_+\frac{\partial v_\epsilon}{\partial z} = \epsilon f \ \text{ at } z = 1, \quad a_-\frac{\partial v_\epsilon}{\partial z} = \epsilon g \ \text{ at } z = -1. \tag{6c}$$

Here the conductivity $a(x,z)$ is independent of ϵ and is given by

$$a(x,z) = a_+ \ \text{ for } \ h(x) < z < 1, \quad a(x,z) = a_- \ \text{ for } \ -1 < z < h(x).$$

(6a) is the (customary) shorthand for

$$\frac{\partial}{\partial x}a_+\frac{\partial v_\epsilon}{\partial x} + \epsilon^{-2}\frac{\partial}{\partial z}a_+\frac{\partial v_\epsilon}{\partial z} = 0 \quad \text{for } h(x) < z < 1,$$

$$\frac{\partial}{\partial x}a_-\frac{\partial v_\epsilon}{\partial x} + \epsilon^{-2}\frac{\partial}{\partial z}a_-\frac{\partial v_\epsilon}{\partial z} = 0 \quad \text{for } -1 < z < h(x),$$

with the continuity condition

$$v_\epsilon \text{ is continuous across the interface } z = h(x),$$

and the jump condition

$$\left[a\frac{\partial}{\partial x}v_\epsilon\right]n_x + \epsilon^{-2}\left[a\frac{\partial}{\partial z}v_\epsilon\right]n_z = 0 \quad \text{on the interface } z = h(x).$$

By formally expanding $v_\epsilon(x,z)$ in powers of ϵ and matching terms of equal powers in (6) we obtain

$$v_\epsilon(x,z) = \epsilon^{-1}v^{(-1)}(x,z) + \epsilon v^{(1)}(x,z) + \epsilon^3 v^{(3)}(x,z) + \cdots,$$

where the functions $v^{(i)}$ satisfy the equations

$$\frac{\partial}{\partial x}a\frac{\partial}{\partial x}v^{(i-2)}+\frac{\partial}{\partial z}a\frac{\partial}{\partial z}v^{(i)}=0 \quad \text{in } \Omega, \tag{7}$$

the (vertical) boundary conditions $\frac{\partial}{\partial x}v^{(i)}=0$ at $x=0,1$, and the (horizontal) boundary conditions

$$a_+\frac{\partial}{\partial z}v^{(1)}=f \quad \text{at } z=1, \qquad a_-\frac{\partial}{\partial z}v^{(1)}=g \quad \text{at } z=-1, \tag{8a}$$

$$a_\pm\frac{\partial}{\partial z}v^{(i)}=0 \quad \text{at } z=\pm 1 \quad \text{for } i\neq 1. \tag{8b}$$

We note that as before (7) is to be interpreted in the strong sense in each of the subdomains $\omega^+=\{(x,z)\ :\ 0<x<1,\ h(x)<z<1\}$ and $\omega^-=\{(x,z)\ :\ 0<x<1,\ -1<z<h(x)\}$, but in a weak sense across their interface, i.e., all the $v^{(i)}$ are continuous, and furthermore

$$\left[a\frac{\partial}{\partial x}v^{(i-2)}\right]n_x+\left[a\frac{\partial}{\partial z}v^{(i)}\right]n_z=0 \tag{9}$$

along the interface $z=h(x)$. Here $n=(n_x,n_z)$ denotes a vector field normal to the interface, and $[\cdot]$ indicates, as before, the difference between the values as we approach the interface from above and below. As it turns out, these equations imply that all the v's corresponding to even superscripts vanish and that the first nonvanishing v corresponding to an odd superscript is $v^{(-1)}$. (7) and the boundary condition (8b) corresponding to $i=-1$ now read

$$\frac{\partial}{\partial z}a\frac{\partial}{\partial z}v^{(-1)}=0 \ \text{ in } \Omega, \qquad a_\pm\frac{\partial}{\partial z}v^{(-1)}=0 \quad \text{at } z=\pm 1.$$

This immediately implies that $v^{(-1)}(x,z)=v^{(-1)}(x)$ (a function of x only). We now multiply (7) with $i=1$ by any smooth $\phi(x)$ (a function of x only) and integrate over Ω. After integration by parts (and use of (8a) and (9) for $i=1$) this yields

$$\int_0^1 ((1-h(x))a_+ +(1+h(x))a_-)\,\frac{d}{dx}v^{(-1)}\frac{d}{dx}\phi\ dx=\int_0^1 (f-g)\phi\ dx.$$

In other words, $v^{(-1)}(x)$ is the solution to the two-point boundary value problem

$$\begin{aligned}\frac{d}{dx}\left(((1-h(x))a_+ +(1+h(x))a_-)\,\frac{d}{dx}v^{(-1)}\right)&=-f+g \quad \text{in } \ (0,1),\\ \frac{d}{dx}v^{(-1)}(x)&=0 \quad \text{at } \ x=0,1.\end{aligned} \tag{10}$$

The following proposition translates the previous formal analysis into a completely rigorous convergence statement. The proof of this proposition is based on a variational technique somewhat similar to that used in [12] to derive the beam equation in the constant coefficient case.

PROPOSITION 3.1. *Suppose the function h as well as the boundary currents f,g are in $C^{2,\alpha}([0,1])$ with $\int_0^1 f\ dx=\int_0^1 g\ dx$. Let $u_\epsilon(x,y)$ be a solution to* (1) (*or* (2)) *and let* $v^{(-1)}(x)$ *be a solution to* (10). *There exists a constant* C, *dependent on* f, g, h, *and* $a_{\pm}$ *but independent of the (small) positive parameter* ϵ, *such that*

$$\int_{\Omega_\epsilon} a_\epsilon(x,y)|\nabla(\epsilon u_\epsilon - v^{(-1)})|^2 \, dxdy \leq C\epsilon^3.$$

Proof. The solution u_ϵ has a very simple variational characterization, related to (2). It is a minimizer of the energy expression

$$\frac{1}{2}\int_{\Omega_\epsilon} a_\epsilon |\nabla u|^2 \, dxdy - \int_{\partial\Omega_\epsilon \cap \{y=\epsilon\}} fu \, dx + \int_{\partial\Omega_\epsilon \cap \{y=-\epsilon\}} gu \, dx$$

in the space $H^1(\Omega_\epsilon)$. Selecting as a test function $u = \epsilon^{-1}v^{(-1)}$ we therefore get

$$\begin{aligned}
&\frac{1}{2}\int_{\Omega_\epsilon} a_\epsilon |\nabla u_\epsilon|^2 \, dxdy - \int_{\partial\Omega_\epsilon \cap \{y=\epsilon\}} fu_\epsilon \, dx + \int_{\partial\Omega_\epsilon \cap \{y=-\epsilon\}} gu_\epsilon \, dx \\
&\qquad \leq \frac{1}{2}\epsilon^{-2}\int_{\Omega_\epsilon} a_\epsilon \left|\frac{d}{dx}v^{(-1)}\right|^2 \, dxdy - \epsilon^{-1}\int_0^1 (f-g)v^{(-1)} \, dx \\
&\qquad = \frac{1}{2}\epsilon^{-1}\int_0^1 ((1-h(x))a_+ + (1+h(x))a_-)\left|\frac{d}{dx}v^{(-1)}\right|^2 \, dx \qquad (11)\\
&\qquad -\epsilon^{-1}\int_0^1 (f-g)v^{(-1)} \, dx.
\end{aligned}$$

We note that the last expression is simply ϵ^{-1} times the energy (minimum) associated with the two-point boundary value problem (10). From the natural dual variational principle we get that

$$\begin{aligned}
&\frac{1}{2}\int_{\Omega_\epsilon} a_\epsilon |\nabla u_\epsilon|^2 \, dxdy - \int_{\partial\Omega \cap \{y=\epsilon\}} fu_\epsilon \, dx + \int_{\partial\Omega \cap \{y=-\epsilon\}} gu_\epsilon \, dx \\
&\qquad = \max_{\sigma \in V} -\frac{1}{2}\int_{\Omega_\epsilon} a_\epsilon^{-1}|\sigma|^2 \, dxdy, \qquad (12)
\end{aligned}$$

where the set V is characterized by

$$\begin{aligned}
V = \Bigg\{\sigma = (\sigma_x, \sigma_y) \in \left(L^2(\Omega_\epsilon)\right)^2 \ : \ &\int_{\Omega_\epsilon} \sigma \cdot \nabla v \, dxdy \\
&= \int_{\partial\Omega_\epsilon \cap \{y=\epsilon\}} fv \, dx - \int_{\partial\Omega_\epsilon \cap \{y=-\epsilon\}} gv \, dx \ \ \forall v \in H^1(\Omega_\epsilon)\Bigg\}.
\end{aligned}$$

In terms of the subsets ω_ϵ^+ and ω_ϵ^-, the elements of V are those vector fields that satisfy (in a "weak" distributional sense) the divergence constraints

$$\nabla \cdot \sigma = 0 \text{ in } \omega_\epsilon^+, \ \nabla \cdot \sigma = 0 \text{ in } \omega_\epsilon^-, \qquad (13a)$$

$$[\sigma_x]n_x + [\sigma_y]n_y = [\sigma \cdot n] = 0 \text{ on the interface } y = \epsilon h(x), \qquad (13b)$$

and the boundary conditions

$$\sigma_y = f \text{ at } y = \epsilon, \quad \sigma_y = g \text{ at } y = -\epsilon, \quad \text{and } \sigma_x = 0 \text{ at } x = 0, 1.$$

We note that (13) is just a "piecewise" formulation of the constraint $\nabla \cdot \sigma = 0$ in Ω_ϵ. Now define the test field $\tau = (\tau_x, \tau_y)$ as follows:

$$\tau_x = \epsilon^{-1} a_\epsilon(x,y) \frac{d}{dx} v^{(-1)}(x), \tag{14a}$$

$$\tau_y = -\epsilon^{-1} \frac{\partial}{\partial x} \left(\int_{-\epsilon}^{y} a_\epsilon(x,t)\ dt\ \frac{d}{dx} v^{(-1)}(x) \right) + g(x). \tag{14b}$$

We may alternatively express τ_y in terms of its formulas in the subdomains $\omega_\epsilon^{\pm}$

$$\begin{aligned} \tau_y(x,y) &= h'(x)(a_+ - a_-) \frac{d}{dx} v^{(-1)}(x) \\ &\quad -\epsilon^{-1} \left((y - \epsilon h(x)) a_+ + (\epsilon h(x) + \epsilon) a_- \right) \frac{d^2}{dx^2} v^{(-1)}(x) + g(x) \ \text{ in } \omega_\epsilon^+, \end{aligned} \tag{15a}$$

$$\tau_y(x,y) = -\epsilon^{-1}(y+\epsilon) a_- \frac{d^2}{dx^2} v^{(-1)}(x) + g(x) \ \text{ in } \omega_\epsilon^-. \tag{15b}$$

Due to the regularity assumptions about f, g, and h it follows that $v^{(-1)} \in C^3([0,1])$; τ is thus piecewise C^1 and certainly globally in $(L^2(\Omega_\epsilon))^2$. From the piecewise version of the definition of τ_y in combination with the definition of τ_x we get

$$\begin{aligned} \nabla \cdot \tau = \frac{\partial}{\partial x}\tau_x + \frac{\partial}{\partial y}\tau_y &= \epsilon^{-1} a_\epsilon \frac{d^2}{dx^2} v^{(-1)}(x) - \epsilon^{-1} a_\epsilon \frac{d^2}{dx^2} v^{(-1)}(x) \\ &= 0 \text{ in } \omega_\epsilon^+ \text{ and } \omega_\epsilon^-. \end{aligned} \tag{16}$$

For the same reason it also follows that

$$\begin{aligned} [\tau_x] n_x &= (\tau_x^+ - \tau_x^-) \frac{-\epsilon h'(x)}{\sqrt{1 + \epsilon^2 h'(x)^2}} \\ &= -(a_+ - a_-) \frac{d}{dx} v^{(-1)}(x) \frac{h'(x)}{\sqrt{1 + \epsilon^2 h'(x)^2}} \quad \text{on } y = \epsilon h(x) \text{ and} \\ [\tau_y]\, n_y &= (\tau_y^+ - \tau_y^-) \frac{1}{\sqrt{1 + \epsilon^2 h'(x)^2}} \\ &= \Bigg(h'(x)(a_+ - a_-) \frac{d}{dx} v^{(-1)}(x) \\ &\qquad -\epsilon^{-1} \left((y - \epsilon h(x)) a_+ + (\epsilon h(x) + \epsilon) a_- \right) \frac{d^2}{dx^2} v^{(-1)}(x) + g(x) \\ &\qquad +\epsilon^{-1}(y+\epsilon) a_- \frac{d^2}{dx^2} v^{(-1)}(x) - g(x) \Bigg) \frac{1}{\sqrt{1 + \epsilon^2 h'(x)^2}} \\ &= h'(x)(a_+ - a_-) \frac{d}{dx} v^{(-1)}(x)\ \frac{1}{\sqrt{1 + \epsilon^2 h'(x)^2}} \quad \text{on } y = \epsilon h(x), \end{aligned}$$

so that

$$[\tau_x] n_x + [\tau_y] n_y = 0 \text{ on the interface } y = \epsilon h(x). \tag{17}$$

It is also immediately clear from (10) and (14a) that the field τ satisfies the boundary condition

$$\begin{aligned} \tau_y &= -\frac{d}{dx} \left(((1 - h(x)) a_+ + (1 + h(x)) a_-) \frac{d}{dx} v^{(-1)} \right) + g(x) \\ &= f(x) \ \text{ at } y = \epsilon, \end{aligned} \tag{18a}$$

as well as

$$\tau_y = g(x) \ \text{ at } y=-\epsilon \ , \quad \text{and } \tau_x = 0 \ \text{ at } x=0,1. \tag{18b}$$

The statements (16)–(18) together assert that the field τ, defined by (14), is indeed an element of V. From (15) and the facts that g and h are in $C^{2,\alpha}$ and $v^{(-1)}$ is in C^3, we immediately get

$$\int_{\Omega_\epsilon} a_\epsilon^{-1}|\tau_y|^2 \ dxdy \leq C\epsilon. \tag{19}$$

By inserting τ into the dual variational expression, and using (12) and (19), we now get that

$$\begin{aligned}
&\frac{1}{2}\int_{\Omega_\epsilon} a_\epsilon|\nabla u_\epsilon|^2 \ dxdy - \int_{\partial\Omega_\epsilon\cap\{y=\epsilon\}} fu_\epsilon \ dx + \int_{\partial\Omega_\epsilon\cap\{y=-\epsilon\}} gu_\epsilon \ dx \\
&\quad \geq -\frac{1}{2}\int_{\Omega_\epsilon} a_\epsilon^{-1}|\tau|^2 \ dxdy \\
&\quad = -\frac{1}{2}\int_{\Omega_\epsilon} a_\epsilon^{-1}|\tau_x|^2 \ dxdy + O(\epsilon) \\
&\quad = -\frac{1}{2}\epsilon^{-1}\int_0^1 ((1-h(x))a_+ + (1+h(x))a_-)\left|\frac{d}{dx}v^{(-1)}\right|^2 \ dx + O(\epsilon) \\
&\quad = \frac{1}{2}\epsilon^{-1}\int_0^1 ((1-h(x))a_+ + (1+h(x))a_-)\left|\frac{d}{dx}v^{(-1)}\right|^2 \ dx \\
&\qquad\quad -\epsilon^{-1}\int_0^1 (f-g)v^{(-1)} \ dx \quad + O(\epsilon).
\end{aligned} \tag{20}$$

A combination of the upper bound (11) and the lower bound (20) gives that

$$\begin{aligned}
&\frac{1}{2}\int_{\Omega_\epsilon} a_\epsilon|\nabla u_\epsilon|^2 \ dxdy - \int_{\partial\Omega_\epsilon\cap\{y=\epsilon\}} fu_\epsilon \ dx + \int_{\partial\Omega_\epsilon\cap\{y=-\epsilon\}} gu_\epsilon \ dx \\
&\quad = \frac{1}{2}\epsilon^{-1}\int_0^1 ((1-h(x))a_+ + (1+h(x))a_-)\left|\frac{d}{dx}v^{(-1)}\right|^2 \ dx \\
&\qquad\quad -\epsilon^{-1}\int_0^1 (f-g)v^{(-1)} \ dx + O(\epsilon) \\
&\quad = \frac{1}{2}\int_{\Omega_\epsilon} a_\epsilon|\epsilon^{-1}\nabla v^{(-1)}|^2 \ dxdy \\
&\qquad\quad -\int_{\partial\Omega_\epsilon\cap\{y=\epsilon\}} f\epsilon^{-1}v^{(-1)} \ dx + \int_{\partial\Omega_\epsilon\cap\{y=-\epsilon\}} g\epsilon^{-1}v^{(-1)} \ dx + O(\epsilon).
\end{aligned} \tag{21}$$

It is well known that

$$\begin{aligned}
&\frac{1}{2}\int_{\Omega_\epsilon} a_\epsilon|\nabla(u_\epsilon - v)|^2 \ \ dxdy \\
&\quad = \frac{1}{2}\int_{\Omega_\epsilon} a_\epsilon|\nabla v|^2 \ dxdy - \int_{\partial\Omega_\epsilon\cap\{y=\epsilon\}} fv \ dx + \int_{\partial\Omega_\epsilon\cap\{y=-\epsilon\}} gv \ dx \\
&\quad -\left(\frac{1}{2}\int_{\Omega_\epsilon} a_\epsilon|\nabla u_\epsilon|^2 \ dxdy - \int_{\partial\Omega_\epsilon\cap\{y=\epsilon\}} fu_\epsilon \ dx + \int_{\partial\Omega_\epsilon\cap\{y=-\epsilon\}} gu_\epsilon \ dx\right)
\end{aligned}$$

for any $v \in H^1(\Omega_\epsilon)$. By a combination of this identity and the estimate (21) it follows immediately that

$$\frac{1}{2}\int_{\Omega_\epsilon} a_\epsilon |\nabla(u_\epsilon - \epsilon^{-1}v^{(-1)})|^2 \;\; dxdy = O(\epsilon)$$

or

$$\int_{\Omega_\epsilon} a_\epsilon |\nabla(\epsilon u_\epsilon - v^{(-1)})|^2 \;\; dxdy = O(\epsilon^3),$$

exactly as desired. □

Returning to the "stretched" domain $\Omega = (0,1) \times (-1,1)$ and the function $v_\epsilon(x,z) = u_\epsilon(x,\epsilon z)$, Proposition 3.1 asserts that

$$\text{(22a)} \int_\Omega a(x,z)\left(\left(\frac{\partial}{\partial x}(\epsilon v_\epsilon - v^{(-1)})\right)^2 + \epsilon^{-2}\left(\frac{\partial}{\partial z}(\epsilon v_\epsilon - v^{(-1)})\right)^2\right) \; dxdz \le C\epsilon^2$$

(recall $dxdy = \epsilon dxdz$) from which it also immediately follows that

$$\text{(22b)} \int_\Omega a(x,z)\left(\frac{\partial}{\partial z}v_\epsilon\right)^2 \; dxdz = \epsilon^{-2}\int_\Omega a(x,z)\left(\frac{\partial}{\partial z}(\epsilon v_\epsilon - v^{(-1)})\right)^2 \; dxdz \le C\epsilon^2.$$

The functions u_ϵ, v_ϵ, and $v^{(-1)}$ have so far been defined only up to additive constants. It will be convenient to make a specific choice for these constants. This can for instance be done by assuming that

$$\int_{\partial\Omega} v_\epsilon \; ds = \int_{\partial\Omega} v^{(-1)} \; ds = 0.$$

From (22a) it now follows that

$$\text{(23)} \qquad \int_\Omega \left(\epsilon v_\epsilon - v^{(-1)}\right)^2 \; dxdz \le C\epsilon^2,$$

and therefore

$$\|\epsilon v_\epsilon - v^{(-1)}\|_{H^1(\Omega)} \le C\epsilon.$$

Based on a standard trace estimate we conclude that

$$\text{(24)} \qquad \begin{aligned} \|\epsilon u_\epsilon(\cdot, \pm\epsilon) - v^{(-1)}(\cdot)\|_{H^{1/2}(0,1)} &= \|\epsilon v_\epsilon(\cdot, \pm 1) - v^{(-1)}(\cdot)\|_{H^{1/2}(0,1)} \\ &\le C\|\epsilon v_\epsilon - v^{(-1)}\|_{H^1(\Omega)} \\ &\le C\epsilon. \end{aligned}$$

This estimate of the approximation error in the boundary data, however, is not sufficient for our later analysis. We shall need an estimate of the H^1 approximation error. In order to establish such an estimate we need two a priori estimates of $\epsilon v_\epsilon - v^{(-1)}$ in higher-order norms. These estimates require stricter regularity assumptions about the boundary currents and the "interface" function $h(x)$. From now on we shall assume that $h \in C^{3,\alpha}([0,1])$ and that $f,\ g \in C^{4,\alpha}([0,1])$ with

$$\text{(25)} \qquad f'(x) = f'''(x) = 0 \quad \text{at} \;\; x = 0, 1.$$

Let c be a constant such that $\max_{x\in[0,1]} h(x) < c < 1$. This guarantees that the domain $\omega_c = \{(x,z) \ : \ 0 < x < 1, \quad c < z < 1\}$ lies inside $\omega^+ = \{(x,z) \ : \ 0 < x < 1, \quad h(x) < z < 1\}$. Select a smooth cutoff function $\phi(z)$ with the properties that $\phi \equiv 1$ near $z = 1$, $\phi \equiv 0$ near $z = c$, and $0 \le \phi(z) \le 1$, $c \le z \le 1$, and let w_ϵ denote the function

$$w_\epsilon(x,z) = (\epsilon v_\epsilon(x,z) - v^{(-1)}(x))\phi(z). \tag{26}$$

Our first a priori estimate is the following lemma.

LEMMA 3.2. *Suppose that h is in $C^{3,\alpha}([0,1])$ and suppose that the boundary currents f, g are in $C^{4,\alpha}([0,1])$ with f satisfying* (25). *Let w_ϵ denote the function defined by* (26). *There exists a constant C, dependent on the boundary currents f, g, the function h, and the conductivities $a_\pm$, but independent of $0 < \epsilon < 1$, such that*

$$\int_{\omega_c} \left(\left(\frac{\partial^2}{\partial x^2} w_\epsilon \right)^2 + \epsilon^{-4} \left(\frac{\partial^2}{\partial z^2} w_\epsilon \right)^2 + \epsilon^{-2} \left(\frac{\partial^2}{\partial x \partial z} w_\epsilon \right)^2 \right) \, dxdz \le C\epsilon^{-2}.$$

Proof. Let $\tilde{v}_\epsilon$ denote the even extension of v_ϵ across the boundary line $x = 0$. Since $\frac{\partial}{\partial x} v_\epsilon = 0$ at $x = 0$ it follows immediately that $\tilde{v}_\epsilon$ remains a solution to

$$\left(\frac{\partial^2}{\partial x^2} + \epsilon^{-2} \frac{\partial^2}{\partial z^2} \right) \tilde{v}_\epsilon = 0 \quad \text{in } (-1,1) \times (\max h(x), 1),$$

with

$$a_+ \frac{\partial}{\partial z} \tilde{v}_\epsilon|_{z=1} = \epsilon \tilde{f} \quad \text{on } z = 1, \ -1 < x < 1.$$

Here $\tilde{f}$ denotes the even extension of f across the point $x = 0$. Since $f \in C^{4,\alpha}([0,1])$ with $f'(0) = f'''(0) = 0$ it follows that $\tilde{f}$ is a $C^{4,\alpha}$ function, and consequently elliptic regularity theory gives that $\tilde{v}_\epsilon$ is C^4 on $(-1,1) \times [c,1]$. It immediately follows that v_ϵ is C^4 on the domain $[0,1) \times [c,1]$. By a similar extension argument across the boundary line $x = 1$ we get that v_ϵ is C^4 on the domain $(0,1] \times [c,1]$, and thus

$$v_\epsilon \in C^4([0,1] \times [c,1]) = C^4(\overline{\omega}_c).$$

Since f, g are $C^{4,\alpha}$ and h is $C^{3,\alpha}$, we have

$$v^{(-1)} \in C^4([0,1]).$$

Altogether we therefore conclude that

$$w_\epsilon \in C^4([0,1] \times [c,1]) = C^4(\overline{\omega}_c). \tag{27}$$

Using the definition (26) of w_ϵ we calculate

$$\begin{aligned} &\left(\frac{\partial^2}{\partial x^2} + \epsilon^{-2} \frac{\partial^2}{\partial z^2} \right) w_\epsilon(x,z) \\ &\quad = -\frac{d^2}{dx^2} v^{(-1)}(x)\phi(z) + 2\epsilon^{-1} \frac{\partial}{\partial z} v_\epsilon(x,z) \frac{d}{dz}\phi(z) \\ &\qquad + \epsilon^{-2}(\epsilon v_\epsilon(x,z) - v^{(-1)}(x)) \frac{d^2}{dz^2}\phi(z). \end{aligned}$$

From estimates (22b) and (23) it now immediately follows that, for $0 < \epsilon < 1$,

$$\left\| \left(\frac{\partial^2}{\partial x^2} + \epsilon^{-2} \frac{\partial^2}{\partial z^2} \right) w_\epsilon \right\|_{L^2(\omega_c)} \leq C\epsilon^{-1},$$

which is equivalent to

$$\int_{\omega_c} \left(\left(\frac{\partial^2}{\partial x^2} w_\epsilon \right)^2 + \epsilon^{-4} \left(\frac{\partial^2}{\partial z^2} w_\epsilon \right)^2 + 2\epsilon^{-2} \frac{\partial^2}{\partial x^2} w_\epsilon \frac{\partial^2}{\partial z^2} w_\epsilon \right) \, dxdz = O(\epsilon^{-2}). \tag{28}$$

Let us now for a moment consider the last term of this integral:

$$\begin{aligned} \int_{\omega_c} \frac{\partial^2}{\partial x^2} w_\epsilon \frac{\partial^2}{\partial z^2} w_\epsilon \, dxdz &= -\int_{\omega_c} \frac{\partial}{\partial x} w_\epsilon \frac{\partial}{\partial z} \left(\frac{\partial^2}{\partial x \partial z} w_\epsilon \right) \, dxdz \\ &= \int_{\omega_c} \left(\frac{\partial^2}{\partial x \partial z} w_\epsilon \right)^2 \, dxdz - \int_{\partial\Omega \cap \{z=1\}} \frac{\partial}{\partial x} w_\epsilon \frac{\partial^2}{\partial x \partial z} w_\epsilon \, dx \\ &= \int_{\omega_c} \left(\frac{\partial^2}{\partial x \partial z} w_\epsilon \right)^2 \, dxdz - \epsilon^2 a_+^{-1} \int_{\partial\Omega \cap \{z=1\}} \frac{\partial}{\partial x} w_\epsilon \, f'(x) \, dx. \end{aligned} \tag{29}$$

In the first integration by parts there are no boundary terms coming from the vertical boundaries, since $\frac{\partial}{\partial x} w_\epsilon$ vanishes at $x = 0, 1$. In the second integration by parts there is no boundary term coming from the lower boundary $\{0 < x < 1, \ z = c\}$, due to the fact that ϕ vanishes in a neighborhood of $z = c$. In the last identity we have used that

$$\frac{\partial^2}{\partial x \partial z} w_\epsilon = \frac{\partial^2}{\partial x \partial z} (\epsilon v_\epsilon - v^{(-1)})\phi = \epsilon^2 a_+^{-1} f'(x) \quad \text{at } z = 1.$$

A combination of (28) and (29) gives that

$$\begin{aligned} &\int_{\omega_c} \left(\left(\frac{\partial^2}{\partial x^2} w_\epsilon \right)^2 + \epsilon^{-4} \left(\frac{\partial^2}{\partial z^2} w_\epsilon \right)^2 + 2\epsilon^{-2} \left(\frac{\partial^2}{\partial x \partial z} w_\epsilon \right)^2 \right) \, dxdz \\ &\qquad = 2a_+^{-1} \int_{\partial\Omega \cap \{z=1\}} \frac{\partial}{\partial x} w_\epsilon \, f'(x) \, dx + O(\epsilon^{-2}). \end{aligned} \tag{30}$$

Since $\frac{\partial}{\partial x} w_\epsilon = 0$ at $z = c$,

$$\frac{\partial}{\partial x} w_\epsilon(x, 1) = \int_c^1 \frac{\partial^2}{\partial x \partial z} w_\epsilon(x, z) \, dz,$$

and therefore

$$\int_{\partial\Omega \cap \{z=1\}} \left(\frac{\partial}{\partial x} w_\epsilon \right)^2 \, dx \leq (1 - c) \int_{\omega_c} \left(\frac{\partial^2}{\partial x \partial z} w_\epsilon \right)^2 \, dxdz. \tag{31}$$

This last estimate together with (30) immediately implies that

$$\int_{\omega_c} \left(\left(\frac{\partial^2}{\partial x^2} w_\epsilon \right)^2 + \epsilon^{-4} \left(\frac{\partial^2}{\partial z^2} w_\epsilon \right)^2 + \epsilon^{-2} \left(\frac{\partial^2}{\partial x \partial z} w_\epsilon \right)^2 \right) \, dxdz \leq C\epsilon^{-2},$$

$0 < \epsilon < 1$, as desired. □

Let $c < c_2 < 1$ be chosen sufficiently close to 1 so that $\phi(z) \equiv 1$ for $z \in [c_2, 1]$, and let ϕ_2 denote a second cutoff function with the properties that $\phi_2 \equiv 1$ near $z = 1$, $\phi_2 \equiv 0$ near $z = c_2$, and $0 \leq \phi_2(z) \leq 1$ for $z \in [c_2, 1]$. Let $w_{2,\epsilon}$ denote the function defined by

$$w_{2,\epsilon}(x,z) = w_\epsilon(x,z)\phi_2(z) = (\epsilon v_\epsilon(x,z) - v^{(-1)}(x))\phi_2(z). \tag{32}$$

Our last a priori estimate is the following lemma.

LEMMA 3.3. *Suppose that h is in $C^{3,\alpha}([0,1])$ and suppose that f, g are in $C^{4,\alpha}([0,1])$ with f satisfying* (25). *Let $w_{2,\epsilon}$ denote the function defined by* (32) *and define $Dw_{2,\epsilon} = \frac{\partial}{\partial z} w_{2,\epsilon}$. There exists a constant C, dependent on the boundary currents f, g, the function h, and the conductivities $a_\pm$, but independent of $0 < \epsilon < 1$, such that*

$$\int_{\omega_{c_2}} \left(\left(\frac{\partial^2}{\partial x^2} Dw_{2,\epsilon} \right)^2 + \epsilon^{-4} \left(\frac{\partial^2}{\partial z^2} Dw_{2,\epsilon} \right)^2 + \epsilon^{-2} \left(\frac{\partial^2}{\partial x \partial z} Dw_{2,\epsilon} \right)^2 \right) dxdz \leq C\epsilon^{-2}.$$

Proof. A simple calculation, just as in the previous proof, yields that

$$\begin{aligned} &\left(\frac{\partial^2}{\partial x^2} + \epsilon^{-2} \frac{\partial^2}{\partial z^2} \right) Dw_{2,\epsilon}(x,z) \\ &\quad = -\frac{d^2}{dx^2} v^{(-1)}(x) \frac{d}{dz}\phi_2(z) + 2\epsilon^{-1} \frac{\partial^2}{\partial z^2} v_\epsilon(x,z) \frac{d}{dz}\phi_2(z) \\ &\quad\quad + 3\epsilon^{-1} \frac{\partial}{\partial z} v_\epsilon(x,z) \frac{d^2}{dz^2}\phi_2(z) \\ &\quad\quad + \epsilon^{-2}(\epsilon v_\epsilon(x,z) - v^{(-1)}(x)) \frac{d^3}{dz^3}\phi_2(z). \end{aligned} \tag{33}$$

From the estimate in Lemma 3.2 we have

$$\int_{\omega_c} \left(\frac{\partial^2}{\partial z^2} w_\epsilon \right)^2 dxdz \leq C\epsilon^2.$$

Since $\phi \equiv 1$ on $\omega_{c_2} \subset \omega_c$,

$$\frac{\partial^2}{\partial z^2} w_\epsilon = \frac{\partial^2}{\partial z^2}(\epsilon v_\epsilon - v^{(-1)}) = \epsilon \frac{\partial^2}{\partial z^2} v_\epsilon \quad \text{in } \omega_{c_2}.$$

The previous integral estimate therefore immediately gives

$$\int_{\omega_{c_2}} \left(\frac{\partial^2}{\partial z^2} v_\epsilon \right)^2 dxdz \leq C. \tag{34}$$

A combination of (33) with the estimates (22b), (23), and (34) now leads to

$$\left\| \left(\frac{\partial^2}{\partial x^2} + \epsilon^{-2} \frac{\partial^2}{\partial z^2} \right) Dw_{2,\epsilon} \right\|_{L^2(\omega_{c_2})} \leq C\epsilon^{-1},$$

or equivalently

$$\begin{aligned} \int_{\omega_{c_2}} &\left(\left(\frac{\partial^2}{\partial x^2} Dw_{2,\epsilon} \right)^2 + \epsilon^{-4} \left(\frac{\partial^2}{\partial z^2} Dw_{2,\epsilon} \right)^2 + 2\epsilon^{-2} \frac{\partial^2}{\partial x^2} Dw_{2,\epsilon} \frac{\partial^2}{\partial z^2} Dw_{2,\epsilon} \right) dxdz \\ &= O(\epsilon^{-2}). \end{aligned} \tag{35}$$

As in the proof of Lemma 3.2 let us now for a moment consider the last term of this integral:

$$\begin{aligned}
\int_{\omega_{c_2}} \frac{\partial^2}{\partial x^2} Dw_{2,\epsilon} \frac{\partial^2}{\partial z^2} Dw_{2,\epsilon}\, dxdz &= -\int_{\omega_{c_2}} \frac{\partial}{\partial x} Dw_{2,\epsilon} \frac{\partial}{\partial z}\left(\frac{\partial^2}{\partial x \partial z} Dw_{2,\epsilon}\right) dxdz \\
&= \int_{\omega_{c_2}} \left(\frac{\partial^2}{\partial x \partial z} Dw_{2,\epsilon}\right)^2 dxdz \\
&\quad - \int_{\partial\Omega \cap \{z=1\}} \frac{\partial}{\partial x} Dw_{2,\epsilon} \frac{\partial^2}{\partial x \partial z} Dw_{2,\epsilon}\, dx \\
&= \int_{\omega_{c_2}} \left(\frac{\partial^2}{\partial x \partial z} Dw_{2,\epsilon}\right)^2 dxdz \\
&\quad + \epsilon^5 \int_{\partial\Omega \cap \{z=1\}} f'(x) \frac{\partial^3}{\partial x^3} v_\epsilon\, dx.
\end{aligned} \tag{36}$$

In the first integration by parts there are no boundary terms coming from the vertical boundaries since $\frac{\partial}{\partial x} Dw_{2,\epsilon} = \frac{\partial}{\partial z}\frac{\partial}{\partial x} w_{2,\epsilon}$ vanishes at $x = 0, 1$. In the second integration by parts there is no boundary term coming from the lower boundary $\{0 < x < 1,\ z = c_2\}$, due to the fact that ϕ_2 vanishes in a neighborhood of $z = c_2$. In the last identity we have used that

$$\begin{aligned}
\frac{\partial}{\partial x} Dw_{2,\epsilon} &= \epsilon \frac{\partial}{\partial x}\frac{\partial}{\partial z} v_\epsilon = \epsilon^2 f' \quad \text{at } z = 1 \quad \text{and} \\
\frac{\partial^2}{\partial x \partial z} Dw_{2,\epsilon} &= \epsilon \frac{\partial}{\partial x}\frac{\partial^2}{\partial z^2} v_\epsilon = -\epsilon^3 \frac{\partial^3}{\partial x^3} v_\epsilon \quad \text{at } z = 1.
\end{aligned}$$

The last term in the right-hand side of (36) may be estimated by

$$\begin{aligned}
\left| \epsilon^5 \int_{\partial\Omega \cap \{z=1\}} f'(x) \frac{\partial^3}{\partial x^3} v_\epsilon\, dx \right| &= \left| \epsilon^5 \int_{\partial\Omega \cap \{z=1\}} f'''(x) \frac{\partial}{\partial x} v_\epsilon\, dx \right| \\
&= \left| \epsilon^4 \int_{\partial\Omega \cap \{z=1\}} f'''(x) \frac{\partial}{\partial x} (w_\epsilon + v^{(-1)})\, dx \right| \\
&\leq C\epsilon^4 \left(1 + \left(\int_{\partial\Omega \cap \{z=1\}} \left[\frac{\partial}{\partial x} w_\epsilon\right]^2 dx \right)^{1/2} \right).
\end{aligned}$$

If we now apply the inequality (31) we get

$$\left| \epsilon^5 \int_{\partial\Omega \cap \{z=1\}} f'(x) \frac{\partial^3}{\partial x^3} v_\epsilon\, dx \right| \leq C\epsilon^4 \left(1 + \left(\int_{\omega_c} \left[\frac{\partial^2}{\partial x \partial z} w_\epsilon\right]^2 dxdz \right)^{1/2} \right),$$

which, because of Lemma 3.2, immediately leads to

$$\left| \epsilon^5 \int_{\partial\Omega \cap \{z=1\}} f'(x) \frac{\partial^3}{\partial x^3} v_\epsilon\, dx \right| \leq C\epsilon^4. \tag{37}$$

A combination of (35), (36), and (37) gives

$$\int_{\omega_{c_2}} \left(\left(\frac{\partial^2}{\partial x^2} Dw_{2,\epsilon}\right)^2 + \epsilon^{-4} \left(\frac{\partial^2}{\partial z^2} Dw_{2,\epsilon}\right)^2 + 2\epsilon^{-2} \left(\frac{\partial^2}{\partial x \partial z} Dw_{2,\epsilon}\right)^2 \right) dxdz = O(\epsilon^{-2}),$$

exactly as desired. □

The estimate in Lemma 3.3 immediately implies that

$$\int_{\omega_{c_2}} \left(\frac{\partial}{\partial z}\frac{\partial^2}{\partial x^2} w_{2,\epsilon}\right)^2 \, dxdz \le C\epsilon^{-2}.$$

Proceeding along the lines of the argument that led to (31) we obtain

$$\begin{aligned}\int_0^1 \left(\frac{\partial^2}{\partial x^2}(\epsilon v_\epsilon(x,1) - v^{(-1)}(x))\right)^2 \, dx &= \int_0^1 \left(\frac{\partial^2}{\partial x^2} w_{2,\epsilon}(x,1)\right)^2 \, dx \\ &\le C\int_{\omega_{c_2}} \left(\frac{\partial}{\partial z}\frac{\partial^2}{\partial x^2} w_{2,\epsilon}\right)^2 \, dxdz \\ &\le C\epsilon^{-2}.\end{aligned}$$

Consequently

$$\begin{aligned}\int_0^1 \left(\frac{\partial^2}{\partial x^2}(\epsilon u_\epsilon(x,\epsilon) - v^{(-1)}(x))\right)^2 \, dx &= \int_0^1 \left(\frac{\partial^2}{\partial x^2}(\epsilon v_\epsilon(x,1) - v^{(-1)}(x))\right)^2 \, dx \\ &\le C\epsilon^{-2},\end{aligned}$$

or in combination with the estimate (24)

$$\|\epsilon u_\epsilon(\cdot,\epsilon) - v^{(-1)}(\cdot)\|_{H^2(0,1)} \le C\epsilon^{-1}.$$

If we again combine this estimate with (24) and use the fact that the Sobolev norms are logarithmically convex (with respect to the smoothness index), it follows that

$$\|\epsilon u_\epsilon(\cdot,\epsilon) - v^{(-1)}(\cdot)\|_{H^1(0,1)} \le C\epsilon^{1/3},$$

or in particular

$$\left\|\frac{\partial}{\partial x}(\epsilon u_\epsilon(\cdot,\epsilon) - v^{(-1)}(\cdot))\right\|_{L^2(0,1)} \le C\epsilon^{1/3}.$$

A completely similar argument with the boundary $\partial\Omega \cap \{z = 1\}$ $(\partial\Omega_\epsilon \cap \{y = \epsilon\})$ replaced by $\partial\Omega \cap \{z = -1\}$ $(\partial\Omega_\epsilon \cap \{y = -\epsilon\})$, and f replaced by g would lead to

$$\left\|\frac{\partial}{\partial x}(\epsilon u_\epsilon(\cdot,-\epsilon) - v^{(-1)}(\cdot))\right\|_{L^2(0,1)} \le C\epsilon^{1/3}.$$

In summary we have therefore proven the following result.

THEOREM 3.4. *Suppose that h is in $C^{3,\alpha}([0,1])$ and suppose that the boundary currents f, g are in $C^{4,\alpha}([0,1])$ with both f and g satisfying* (25). *There exists a constant C, dependent on the boundary currents f, g, the function h, and the conductivities $a_\pm$, but independent of $0 < \epsilon < 1$, such that*

$$\left\|\frac{\partial}{\partial x}(\epsilon u_\epsilon(\cdot,\pm\epsilon) - v^{(-1)}(\cdot))\right\|_{L^2(0,1)} \le C\epsilon^{1/3}.$$

By an extension of the arguments above it may be proven that $\frac{\partial}{\partial x}(\epsilon u_\epsilon)(\cdot,\pm\epsilon)$ converge to $\frac{d}{dx}v^{(-1)}(\cdot)$ uniformly. However, for reasons of space we do not present the details here. The above theorem plays a significant role in the derivation of a very accurate and robust reconstruction formula, valid for ϵ sufficiently small. This formula, which is derived in the next section, is conceptually somewhat similar to the linearized formula derived in [9], [10] for the reconstruction of a corroded (inaccessible) surface of a thin structure. However, the formula here is not based on any linearization and furthermore we provide estimates of its accuracy.

4. Reconstruction of the interface. Based on (10) we get that

$$(1-h(x))a_+ + (1+h(x))a_- = \frac{-\int_0^x (f-g)(t)\ dt}{\frac{d}{dx}v^{(-1)}(x)} \tag{38}$$

whenever $\int_0^x (f-g)(t)\ dt \neq 0$. On the right-hand side we know the numerator $-\int_0^1 (f-g)(t)\ dt$, however, we do not know the denominator $\frac{d}{dx}v^{(-1)}(x)$. What we do have access to are the boundary voltage derivatives $\frac{\partial}{\partial x}(\epsilon u_\epsilon)(x, \pm\epsilon)$. Let δ be an arbitrarily small positive number, and let I_δ denote the set

$$I_\delta = \left\{ x \in [0,1] \ : \ \left| \int_0^x (f-g)(t)\ dt \right| \geq 2\delta \max\{a_-, a_+\} \right\}.$$

From (38) we see that

$$2\min\{a_-, a_+\} \leq \frac{-\int_0^x (f-g)(t)\ dt}{\frac{d}{dx}v^{(-1)}(x)} \leq 2\max\{a_-, a_+\}.$$

It therefore immediately follows that

$$\left| \frac{d}{dx}v^{(-1)}(x) \right| \geq \delta \quad \text{for } x \in I_\delta.$$

From (38) we also see that

$$\operatorname{sign}\left(\frac{d}{dx}v^{(-1)}(x) \right) = \operatorname{sign}\left(-\int_0^x (f-g)(t)\ dt \right).$$

We now define approximations to $\frac{d}{dx}v^{(-1)}$:

$$DV_{\pm\epsilon}(x) = \begin{cases} \epsilon \frac{\partial}{\partial x} u_\epsilon(x, \pm\epsilon) & \text{when } |\epsilon \frac{\partial}{\partial x} u_\epsilon(x, \pm\epsilon)| \geq \delta, \\ \delta \ \operatorname{sign}\left(-\int_0^x (f-g)(t)\ dt \right) & \text{otherwise.} \end{cases} \tag{39}$$

We note that since the data $\epsilon \frac{\partial}{\partial x} u_\epsilon(x, \pm\epsilon)$ are at our disposal, the functions $DV_{\pm\epsilon}$ may easily be computed. The two corresponding reconstructed interfaces $h_{\pm\epsilon}$ are then given by

$$(1-h_{\pm\epsilon}(x))a_+ + (1+h_{\pm\epsilon}(x))a_- = \frac{-\int_0^x (f-g)(t)\ dt}{DV_{\pm\epsilon}(x)}, \tag{40}$$

or more explicitly

$$h_{\pm\epsilon}(x) = \frac{-\int_0^x (f-g)(t)\ dt}{(a_- - a_+)DV_{\pm\epsilon}(x)} - \frac{a_- + a_+}{a_- - a_+}. \tag{41}$$

That these formulas do indeed provide good approximations to the true "interface" function on I_δ is guaranteed by the following theorem.

THEOREM 4.1. *Suppose that h is in $C^{3,\alpha}([0,1])$ and that the boundary currents f, g are in $C^{4,\alpha}([0,1])$ with both f and g satisfying* (25). *Let $h_{\pm\epsilon}$ be as defined by* (39) *and* (41) *for some $\delta > 0$. There exists a constant C, dependent on f, g, h, and $a_\pm$ but independent of $0 < \epsilon < 1$ and δ such that*

$$\|h - h_{\pm\epsilon}\|_{L^2(I_\delta)} \leq C\delta^{-2}\epsilon^{1/3}.$$

If the function $x \to \int_0^x (f-g)(t)\ dt$ has only finitely many zeros on $[0,1]$ and if all these zeros are simple, then there exists a constant K such that $|[0,1] \setminus I_\delta| \leq K\delta$.

Proof. For $x \in I_\delta$ we have that

$$|\frac{d}{dx}v^{(-1)}(x)| \geq \delta \quad \text{and} \quad |DV_{\pm\epsilon}(x)| \geq \delta.$$

By subtraction of (40) from (38) it therefore follows that

$$\begin{aligned}
&|h(x) - h_{\pm\epsilon}(x)| \\
&\quad \leq \frac{1}{|a_- - a_+|}\left|\frac{-\int_0^x (f-g)(t)\ dt}{\frac{d}{dx}v^{(-1)}(x)} - \frac{-\int_0^x (f-g)(t)\ dt}{DV_{\pm\epsilon}(x)}\right| \\
&\quad = \frac{\left|\int_0^x (f-g)(t)\ dt\right|}{|a_- - a_+|\left|\frac{d}{dx}v^{(-1)}(x)\right| |DV_{\pm\epsilon}(x)|}\left|DV_{\pm\epsilon}(x) - \frac{d}{dx}v^{(-1)}(x)\right| \qquad (42)\\
&\quad \leq \frac{\|f\|_{L^2(0,1)} + \|g\|_{L^2(0,1)}}{\delta^2|a_- - a_+|}\left|DV_{\pm\epsilon}(x) - \frac{d}{dx}v^{(-1)}(x)\right| \\
&\quad = C\delta^{-2}\left|DV_{\pm\epsilon}(x) - \frac{d}{dx}v^{(-1)}(x)\right| \qquad \text{for } x \in I_\delta.
\end{aligned}$$

The definition of $DV_{\pm\epsilon}$, and the fact that $\frac{d}{dx}v^{(-1)}$ and $-\int_0^x (f-g)(t)\ dt$ have the same sign, guarantee that

$$\left|DV_{\pm\epsilon}(x) - \frac{d}{dx}v^{(-1)}(x)\right| \leq \left|\epsilon\frac{\partial}{\partial x}u_\epsilon(x,\pm\epsilon) - \frac{d}{dx}v^{(-1)}(x)\right| \quad \text{for } x \in I_\delta.$$

From a combination of this estimate with (42) it now immediately follows that

$$|h(x) - h_{\pm\epsilon}(x)|^2 \leq C\delta^{-4}\left|\epsilon\frac{\partial}{\partial x}u_\epsilon(x,\pm\epsilon) - \frac{d}{dx}v^{(-1)}(x)\right|^2 \quad \text{for } x \in I_\delta.$$

Integration over I_δ, extraction of the square root, and use of the estimate in Theorem 3.4 lead to the desired estimate for $\|h - h_{\pm\epsilon}\|_{L^2(I_\delta)}$.

The estimate on the measure of the set $[0,1] \setminus I_\delta$ is obvious, given that $\int_0^x (f - g)(t)\ dt$ is continuously differentiable with only finitely many simple zeros. □

If the function $x \to \int_0^x (f-g)(t)\ dt$ has only finitely many zeros which are all simple, and if we were to change the definition of $h_{\pm\epsilon}$ a little just to make sure that it stays bounded:

$$\tilde{h}_{\pm\epsilon}(x) = \begin{cases} h_{\pm\epsilon}(x) & \text{when } |h_{\pm\epsilon}(x)| \leq 1, \\ \text{sign}(h_{\pm\epsilon}(x)) & \text{otherwise ,} \end{cases}$$

then Theorem 4.1, for the choice $\delta = \epsilon^{2/15}$, immediately implies that

$$\|h - \tilde{h}_{\pm\epsilon}\|_{L^2(0,1)} \leq C(\delta^{-2}\epsilon^{1/3} + \delta^{1/2}) = 2C\epsilon^{1/15}.$$

The above analysis gives no indication of how to proceed if the function $\int_0^x (f - g)(t)\, dt$ vanishes in an entire interval (c, d). We shall now formally find an appropriate approximation to $h(x)$ in this case as well. Since $\int_0^x (f-g)(t)\, dt = 0$ in (c, d) it follows from (10) that $\frac{d}{dx}v^{(-1)} = 0$ in (c, d). We return to the asymptotic expansion at the beginning of section 3 in order to calculate the second (nontrivial) term, corresponding to the function $v^{(1)}(x, z)$. This function satisfies the weak formulation of the equation

$$\frac{\partial}{\partial x} a \frac{\partial}{\partial x} v^{(-1)} + \frac{\partial}{\partial z} a \frac{\partial}{\partial z} v^{(1)} = 0 \quad \text{in } \Omega,$$

with the boundary conditions

$$a_+ \frac{\partial}{\partial z} v^{(1)} = f \quad \text{at } z = 1 \ , \quad a_- \frac{\partial}{\partial z} v^{(1)} = g \quad \text{at } z = -1.$$

By integration of these equations and use of the fact that $\frac{d}{dx}v^{(-1)}(x) = 0$ (and $f(x) = g(x)$) for $x \in (c, d)$ we get that $v^{(1)}(x, z)$, for $x \in (c, d)$, has the form

$$v^{(1)}(x, z) = \begin{cases} \frac{1}{a_+} f(x)(z - h(x)) + b(x) & \text{for } h(x) < z < 1, \\ \frac{1}{a_-} f(x)(z - h(x)) + b(x) & \text{for } -1 < z < h(x), \end{cases}$$

where $b(x)$ is some function of x alone. We now consider the expression $\epsilon^{-1}(u_\epsilon(x, \epsilon) - u_\epsilon(x, -\epsilon))$; from the asymptotic expansion at the beginning of section 3 it formally follows that

$$\begin{aligned} \epsilon^{-1}(u_\epsilon(x, \epsilon) - u_\epsilon(x, -\epsilon)) &= \epsilon^{-1}(v_\epsilon(x, 1) - v_\epsilon(x, -1)) \\ &= \frac{1}{a_+} f(x)(1 - h(x)) + \frac{1}{a_-} f(x)(1 + h(x)) + O(\epsilon^2) \\ &= \left(\frac{1}{a_-} - \frac{1}{a_+}\right) f(x)h(x) + \left(\frac{1}{a_-} + \frac{1}{a_+}\right) f(x) + O(\epsilon^2) \end{aligned}$$

for $x \in (c, d)$. Provided the boundary current f has no zeros in the interval (c, d), we thus arrive at a formula for an approximation to h:

$$h_{1,\epsilon}(x) = \frac{u_\epsilon(x, \epsilon) - u_\epsilon(x, -\epsilon)}{\epsilon f(x) \left(\frac{1}{a_-} - \frac{1}{a_+}\right)} - \frac{a_+ + a_-}{a_+ - a_-}. \tag{43}$$

If f has simple isolated zeros, then a procedure similar to that before could be applied; on the other hand, if f has an entire interval of zeros inside (c, d), then the determination of higher-order terms in the asymptotic expansion for v_ϵ would be required in order to obtain a formula for an approximation to h (in terms of the boundary data).

The derivation of the formula (43) is entirely formal. In order to provide a rigorous justification we would need estimates of how well $\epsilon^{-1}(u_\epsilon(x, \epsilon) - u_\epsilon(x, -\epsilon))$ approximates $v^{(1)}(x, 1) - v^{(1)}(x, -1)$. We are confident that such estimates can be proven along the lines of our proofs in section 3, but we have not carried out this analysis.

Remarks. So far we have assumed that a_+ and a_- are fixed positive constants (i.e., they are bounded away from 0 and ∞). There is one degenerate case that is of high interest in the context of Hall–Héroult cells, namely the case in which a_+ is very small (nearly zero) relative to a_-. The formula we derived for $h_{-\epsilon}$ makes sense even for $a_+/a_- = 0$. In this extreme case it reads

$$h^0_{-\epsilon}(x) = \frac{-\int_0^x (f-g)(t)\ dt}{a_- DV^0_{-\epsilon}(x)} - 1,$$

with

$$a_- DV^0_{-\epsilon}(x) = \begin{cases} a_-\epsilon\frac{\partial}{\partial x}u_\epsilon(x,-\epsilon) & \text{when } |a_-\epsilon\frac{\partial}{\partial x}u_\epsilon(x,-\epsilon)| \geq \delta', \\ \delta' \text{ sign}\left(-\int_0^x (f-g)(t)\ dt\right) & \text{otherwise.} \end{cases}$$

The small parameter δ' has taken the role of δa_- in our earlier notation. We expect this formula to provide an acceptable approximation to $h(x)$, at least for $x \in I^0_\delta = \{x \ :\ |\int_0^x (f-g)(t)\ dt| \geq 2\delta'\}$, an expectation which is confirmed by our numerical experiments. The situation is completely different when it comes to the formula for $h_{+\epsilon}$, since this refers to boundary data of u_ϵ along $y = \epsilon$. In the extreme case, $a_+/a_- = 0$, the top boundary of the domain Ω_ϵ has been completely isolated from the bottom subdomain, ω^+_ϵ, where the limit of the rescaled solutions $(a_- u_\epsilon)$ appears to be well defined. On the top boundary, indications are that $a_- DV_+\epsilon$ becomes infinitely large as a_+/a_- tends to zero, and therefore the formula $h_{+\epsilon}$ does not provide a good approximation to h, rather it converges to -1.

If we multiply by a_+ in both the numerator and the denominator (of the first term) of the right-hand side of (43), then we may formally insert $a_+/a_- = 0$ to get

$$h^0_{1,\epsilon}(x) = -\frac{a_+\epsilon^{-1}(u_\epsilon(x,\epsilon) - u_\epsilon(x,-\epsilon))}{f(x)} + 1.$$

It appears that the rescaled top boundary data $a_+\epsilon^{-1}u_\epsilon(x,\epsilon)$ has a well-defined limit as a_+/a_- tends to zero and that the rescaled bottom data $a_+\epsilon^{-1}u_\epsilon(x,-\epsilon)$ tends to zero as a_+/a_- tends to zero. Our numerical experiments indicate that the limiting formula provides a reliable approximation to h (recall that this corresponds to intervals in which $\int_0^x (f-g)(t)\ dt \equiv 0$).

5. Integral equation formulation. In this section we describe how we numerically approximate the solution u_ϵ of the boundary value problem (1) (the forward problem) by solving a system of integral equations. We use this solution to generate the data needed for the numerical reconstruction of the interface h.

As in the calculation of the asymptotic limit (section 3), it is preferable to introduce the new coordinate $z = y/\epsilon$ and solve the following rescaled problem (the same as (6)) in the ϵ-independent domain $\Omega = (0,1) \times (-1,1)$:

$$\frac{\partial}{\partial x}\left(a(x,z)\frac{\partial v_\epsilon}{\partial x}\right) + \epsilon^{-2}\frac{\partial}{\partial z}\left(a(x,z)\frac{\partial v_\epsilon}{\partial z}\right) = 0 \quad \text{in} \quad \Omega,$$
$$\frac{\partial v_\epsilon}{\partial x} = 0 \quad \text{at} \quad x = 0, 1,$$
$$a_+\frac{\partial v_\epsilon}{\partial z} = \epsilon f \ \text{ at } z = 1, \quad a_-\frac{\partial v_\epsilon}{\partial z} = \epsilon g \ \text{ at } z = -1.$$

Here the conductivity $a(x,z)$ is given by

$$a(x,z) = \begin{cases} a_+, & (x,z) \in \omega^+, \\ a_-, & (x,z) \in \omega^-, \end{cases}$$

with

$$\omega^+ = \{(x,z) :\ 0 < x < 1,\ h(x) < z < 1\},$$
$$\omega^- = \{(x,z) :\ 0 < x < 1,\ -1 < z < h(x)\}.$$

The physical voltage potential u_ϵ is related to v_ϵ by $u_\epsilon(x,y) = v_\epsilon(x, y/\epsilon)$. We note that v_ϵ satisfies

$$\frac{\partial^2}{\partial x^2} v_\epsilon + \frac{1}{\epsilon^2}\frac{\partial^2}{\partial z^2} v_\epsilon = 0 \tag{44}$$

in each of the subdomains ω^+ and ω^-. We also note that the fundamental solution corresponding to the differential operator in (44) is given by

$$N_\epsilon((x,z);(\tilde{x},\tilde{z})) = \frac{\epsilon}{4\pi}\log((\tilde{x}-x)^2 + \epsilon^2(\tilde{z}-z)^2). \tag{45}$$

Unless otherwise specified $n = (n_x, n_z)$ denotes the exterior unit normal associated with each of the subdomains ω^+ and ω^-. Γ_I denotes the interface between ω^+ and ω^-, that is,

$$\Gamma_I = \{(x, h(x)) : 0 \le x \le 1\}.$$

We now derive an integral formulation for the values of v_ϵ along the boundary $\partial\omega^+ \cup \partial\omega^- = \partial\Omega \cup \Gamma_I$. It is convenient to introduce the following operators L and D:

$$Lv = \frac{\partial^2 v}{\partial x^2} + \frac{1}{\epsilon^2}\frac{\partial^2 v}{\partial z^2}, \qquad Dv = \frac{\partial v}{\partial x} n_x + \frac{1}{\epsilon^2}\frac{\partial v}{\partial z} n_z,$$

corresponding to each of the two subdomains ω^+ and ω^-. Then, for $(\tilde{x},\tilde{z}) \in \omega^+$ we have

$$\begin{aligned} v_\epsilon(\tilde{x},\tilde{z}) &= \int_{\omega^+} Lv_\epsilon\ N_\epsilon(\cdot;(\tilde{x},\tilde{z}))\ dxdz - \int_{\omega^+} v_\epsilon\ LN_\epsilon(\cdot;(\tilde{x},\tilde{z}))\ dxdz \\ &= \int_{\partial\omega^+} Dv_\epsilon N_\epsilon(\cdot;(\tilde{x},\tilde{z}))\ ds - \int_{\partial\omega^+} v_\epsilon\ DN_\epsilon(\cdot;(\tilde{x},\tilde{z}))\ ds \end{aligned} \tag{46}$$

and

$$0 \ = \ \int_{\partial\omega^-} Dv_\epsilon\ N_\epsilon(\cdot;(\tilde{x},\tilde{z}))\ ds - \int_{\partial\omega^-} v_\epsilon\ DN_\epsilon(\cdot;(\tilde{x},\tilde{z}))\ ds. \tag{47}$$

Multiplying (46) by a_+ and (47) by a_- and adding we obtain

$$\begin{aligned} a_+ v_\epsilon(\tilde{x},\tilde{z}) + a_+ \int_{\partial\omega^+} v_\epsilon\ DN_\epsilon(\cdot\ ;(\tilde{x},\tilde{z}))\ ds + a_- \int_{\partial\omega^-} v_\epsilon\ DN_\epsilon(\cdot\ ;(\tilde{x},\tilde{z}))\ ds \\ = a_+ \int_{\Gamma_+} Dv_\epsilon\ N_\epsilon(\cdot\ ;(\tilde{x},\tilde{z}))\ ds\ +\ a_- \int_{\Gamma_-} Dv_\epsilon\ N_\epsilon(\cdot\ ;(\tilde{x},\tilde{z}))\ ds \end{aligned} \tag{48}$$

for $(\tilde{x},\tilde{z}) \in \omega^+$. Here Γ_+ and Γ_- are the top and bottom boundaries given by

$$\Gamma_+ = \{(x,1) : 0 \le x \le 1\},$$
$$\Gamma_- = \{(x,-1) : 0 \le x \le 1\}.$$

We have used the conditions

$$\begin{aligned} a_+ \left(Dv_\epsilon\right)^+ &= -a_- \left(Dv_\epsilon\right)^- \quad \text{along } \ \Gamma_I, \\ Dv_\epsilon \ &= 0 \quad \text{along } x = 0 \text{ and } x = 1, \end{aligned}$$

where $(Dv_\epsilon)^+$ and $(Dv_\epsilon)^-$ correspond to the situations in which Γ_I is interpreted as a boundary part of ω^+ and ω^-, respectively (recall that the normals are exterior to the subdomains). Now let $(\tilde{x}, \tilde{z})$ approach $\partial\omega^+ \setminus \Gamma_I$, excluding the top two corner points. (48) then becomes

$$\begin{aligned} a_+ v_\epsilon(\tilde{x},\tilde{z}) + a_+ \int_{\partial\omega^+} v_\epsilon \ DN_\epsilon(\cdot;(\tilde{x},\tilde{z}))ds - \frac{a_+ v_\epsilon(\tilde{x},\tilde{z})}{2} \ + a_- \int_{\partial\omega^-} v_\epsilon \ DN_\epsilon(\cdot;(\tilde{x},\tilde{z}))ds \\ = a_+ \int_{\Gamma_+} N_\epsilon(\cdot;(\tilde{x},\tilde{z})) \ Dv_\epsilon ds \ + \ a_- \int_{\Gamma_-} N_\epsilon(\cdot;(\tilde{x},\tilde{z})) \ Dv_\epsilon ds. \end{aligned}$$

The additional term on the left-hand side reflects the jump associated with the double-layer potential. For $(\tilde{x}, \tilde{z}) \in \partial\omega^+ \setminus \Gamma_I$, excluding the top two corners, we thus have

$$\begin{aligned} & v_\epsilon(\tilde{x},\tilde{z}) + 2\int_{\partial\omega^+} v_\epsilon \ DN_\epsilon(\cdot;(\tilde{x},\tilde{z}))ds + \frac{2a_-}{a_+}\int_{\partial\omega^-} v_\epsilon \ DN_\epsilon(\cdot;(\tilde{x},\tilde{z}))ds \\ & \quad = \frac{2}{a_+}\left(a_+\int_{\Gamma_+} N_\epsilon(\cdot;(\tilde{x},\tilde{z})) \ Dv_\epsilon \ ds \ + \ a_-\int_{\Gamma_-} N_\epsilon(\cdot;(\tilde{x},\tilde{z})) \ Dv_\epsilon ds\right). \end{aligned} \tag{49}$$

Similarly, for $(\tilde{x}, \tilde{z}) \in \omega^- \setminus \Gamma_I$, excluding the bottom two corners, we have

$$\begin{aligned} & v_\epsilon(\tilde{x},\tilde{z}) + \frac{2a_+}{a_-}\int_{\partial\omega^+} v_\epsilon \ DN_\epsilon(\cdot;(\tilde{x},\tilde{z})) \ ds + 2\int_{\partial\omega^-} v_\epsilon \ DN_\epsilon(\cdot;(\tilde{x},\tilde{z})) \ ds \\ & \quad = \frac{2}{a_-}\left(a_+\int_{\Gamma_+} N_\epsilon(\cdot;(\tilde{x},\tilde{z})) \ Dv_\epsilon \ ds \ + \ a_-\int_{\Gamma_-} N_\epsilon(\cdot;(\tilde{x},\tilde{z})) \ Dv_\epsilon \ ds\right). \end{aligned} \tag{50}$$

Next, consider the interior (smooth) points of Γ_I. For such points we arrive at

$$\begin{aligned} & v_\epsilon(\tilde{x},\tilde{z}) + \frac{2a_+}{a_+ + a_-}\int_{\partial\omega^+} v_\epsilon \ DN_\epsilon(\cdot\ ;(\tilde{x},\tilde{z})) \ ds + \frac{2a_-}{a_+ + a_-}\int_{\partial\omega^-} v_\epsilon \ DN_\epsilon(\cdot\ ;(\tilde{x},\tilde{z})) \ ds \\ & \quad = \frac{2}{a_+ + a_-}\left(a_+\int_{\Gamma_+} N_\epsilon(\cdot\ ;(\tilde{x},\tilde{z})) \ Dv_\epsilon \ ds + a_-\int_{\Gamma_-} N_\epsilon(\cdot\ ;(\tilde{x},\tilde{z})) \ Dv_\epsilon \ ds\right). \end{aligned} \tag{51}$$

This equation can be obtained by letting $(\tilde{x}, \tilde{z})$ approach Γ_I from inside ω^+ in (48). It can also be obtained by letting $(\tilde{x}, \tilde{z})$ approach Γ_I from inside ω^- in the equation analogous to (48) for the subdomain ω^-.

We note that at a corner the jump associated with a double-layer potential must be modified. The jump now becomes

$$\frac{1}{2}\delta_{out} \ v_\epsilon \quad \text{and} \quad -\frac{1}{2}\delta_{in} \ v_\epsilon$$

as $(\tilde{x}, \tilde{z})$ approaches the corner, (x_c, z_c), from outside and from inside the domain, respectively. Here

$$\delta_{out} = \frac{\gamma}{\pi} \quad \text{and} \quad \delta_{in} = 2 - \frac{\gamma}{\pi},$$

and γ is the interior angle of the corner. Therefore, letting $(\tilde{x}, \tilde{z}) \to (x_c, z_c)$ in (48) and simplifying we obtain

$$\begin{aligned} v_\epsilon(x_c, z_c) + 4 \int_{\partial\omega^+} v_\epsilon \; DN_\epsilon(\cdot\,; (x_c, z_c)) \; ds + \frac{4a_-}{a_+} \int_{\partial\omega^-} v_\epsilon \; DN_\epsilon(\cdot\,; (x_c, z_c)) \; ds \\ = \frac{4}{a_+} \left(a_+ \int_{\Gamma_+} N_\epsilon(\cdot\,; (x_c, z_c)) \; Dv_\epsilon \; ds + a_- \int_{\Gamma_-} N_\epsilon(\cdot\,; (x_c, z_c)) \; Dv_\epsilon \; ds \right), \end{aligned} \tag{52}$$

where (x_c, z_c) is one of the top two corners of ω^+. Similarly, we can establish the following formula for the bottom two corners of ω^-:

$$\begin{aligned} v_\epsilon(x_c, z_c) + \frac{4a_+}{a_-} \int_{\partial\omega^+} v_\epsilon \; DN_\epsilon(\cdot\,; (x_c, z_c)) \; ds + 4 \int_{\partial\omega^-} v_\epsilon \; DN_\epsilon(\cdot\,; (x_c, z_c)) \; ds \\ = \frac{4}{a_-} \left(a_+ \int_{\Gamma_+} N_\epsilon(\cdot\,; (x_c, z_c)) \; Dv_\epsilon \; ds \; + \; a_- \int_{\Gamma_-} N_\epsilon(\cdot\,; (x_c, z_c)) \; Dv_\epsilon \; ds \right). \end{aligned} \tag{53}$$

We now consider the two endpoints of Γ_I. Letting $(\tilde{x}, \tilde{z}) \to (x_c, z_c)$ in (48) and applying the jump condition above we obtain

$$\begin{aligned} v_\epsilon(x_c, z_c) + \frac{2\pi a_+}{\gamma a_+ + (\pi - \gamma) a_-} \int_{\partial\omega^+} v_\epsilon \; DN_\epsilon(\cdot\,; (x_c, z_c)) \; ds \\ + \frac{2\pi a_-}{\gamma a_+ + (\pi - \gamma) a_-} \int_{\partial\omega^-} v_\epsilon \; DN_\epsilon(\cdot\,; (x_c, z_c)) \; ds \\ = \frac{2\pi}{\gamma a_+ + (\pi - \gamma) a_-} \left(a_+ \int_{\Gamma_+} N_\epsilon(\cdot\,; (x_c, z_c)) \; Dv_\epsilon \; ds \right. \\ \left. + a_- \int_{\Gamma_-} N_\epsilon(\cdot\,; (x_c, z_c)) \; Dv_\epsilon \; ds \right), \end{aligned} \tag{54}$$

where (x_c, z_c) is now one of the endpoints of Γ_I (and γ is the angle interior to ω^+). While we have initially for (most of) our theoretical analysis assumed that h is globally smooth we use a piecewise-linear representation for h in our numerical computations. Since we deliberately avoid placing any collocation points at interior corners of Γ_I it is, however, not necessary to derive the special form of the integral formulation corresponding to such interior corner points. Summarizing (49) through (54) we have

$$\begin{aligned} v_\epsilon(\tilde{x}, \tilde{z}) + k^+(\tilde{x}, \tilde{z}) \int_{\partial\omega^+} v_\epsilon \; DN_\epsilon(\cdot\,; (\tilde{x}, \tilde{z})) \; ds \\ + k^-(\tilde{x}, \tilde{z}) \int_{\partial\omega^-} v_\epsilon \; DN_\epsilon(\cdot\,; (\tilde{x}, \tilde{z})) \; ds \\ = \frac{k^+(\tilde{x}, \tilde{z})}{a_+} \left(a_+ \int_{\Gamma_+} N_\epsilon(\cdot\,; (\tilde{x}, \tilde{z})) \; Dv_\epsilon \; ds \right. \\ \left. + a_- \int_{\Gamma_-} N_\epsilon(\cdot\,; (\tilde{x}, \tilde{z})) \; Dv_\epsilon \; ds \right), \end{aligned}$$

where $(\tilde{x}, \tilde{z})$ denotes any point on the boundary. The coefficients $k^+(\tilde{x}, \tilde{z})$ and $k^-(\tilde{x}, \tilde{z})$ are related by $k^+(\tilde{x}, \tilde{z}) = \frac{a_+}{a_-} k^-(\tilde{x}, \tilde{z})$, and their exact dependence on $(\tilde{x}, \tilde{z})$ is given by (49)–(54). The previous equation may be rewritten

$$v_\epsilon(\tilde{x}, \tilde{z}) + \int_{\partial\Omega \cup \Gamma_I} K(\cdot\,; (\tilde{x}, \tilde{z})) \left(n_x \frac{\partial}{\partial x} + n_z \frac{1}{\epsilon^2} \frac{\partial}{\partial z} \right) N_\epsilon(\cdot\,; (\tilde{x}, \tilde{z})) \; v_\epsilon \; ds \tag{55}$$

$$= \frac{k^+(\tilde{x},\tilde{z})}{\epsilon a_+}\left(\int_{\Gamma_+} f\ N_\epsilon(\cdot\ ; (\tilde{x},\tilde{z}))\ ds - \int_{\Gamma_-} g\ N_\epsilon(\cdot\ ; (\tilde{x},\tilde{z}))\ ds\right),$$

with

$$K((x,z);(\tilde{x},\tilde{z})) = \begin{cases} k^+(\tilde{x},\tilde{z}), & (x,z) \in \partial\omega^+ \setminus \Gamma_I, \\ k^-(\tilde{x},\tilde{z}), & (x,z) \in \partial\omega^- \setminus \Gamma_I, \\ k^+(\tilde{x},\tilde{z}) - k^-(\tilde{x},\tilde{z}), & (x,z) \in \Gamma_I. \end{cases}$$

In the above formula n still denotes the exterior unit normal on $\partial\Omega$. However, along the interface Γ_I, n is now taken to be the exterior unit normal to ω^+. The change in the right-hand side has been obtained by insertion of the formulas

$$a_+ Dv_\epsilon|_{\Gamma_+} = \frac{f}{\epsilon}, \quad a_- Dv_\epsilon|_{\Gamma_-} = -\frac{g}{\epsilon}.$$

The solution v_ϵ (being the solution to a Neumann problem) is only determined up to an additive constant. To remedy this situation we impose the additional condition

$$\int_{\partial\Omega} v_\epsilon\ ds = 0. \tag{56}$$

The equations (55) and (56) are now uniquely solvable.

We shall now briefly describe the collocation method which we use to discretize the system of equations (55)–(56); for more details including an analysis of its convergence properties, see Chapter 13 in [11]. Let $s(t) = (x(t), z(t))\ :\ [0,T] \to \partial\Omega \cup \Gamma_I$ be a parametrization by arclength of the cell boundary and the interface. In our implementation we take $s(0)$ to be the point where Γ_I meets the left vertical boundary, $s(t)$, $t > 0$, then traces the boundary $\partial\Omega$ clockwise until it returns to $s(0)$, at which point it continues along Γ_I finally reaching the point where Γ_I meets the right vertical boundary at $t = T$. We select $p = 7N - 1$ collocation points along $\partial\Omega \cup \Gamma_I$. It is always required that the four corners of $\partial\Omega$ and the endpoints of Γ_I be collocation points. We select $N + 1$ equidistant points along the top side of Ω as well as along the bottom side. $2N + 1$ points are chosen on each of the vertical sides, such as to be approximately equidistant while satisfying the restriction that the endpoints of Γ_I be amongst them. Finally we select $N + 1$ points along the interface Γ_I. These points are again evenly spaced with the following exception. Given an equidistant set of points

$$(x(t_1), y(t_1)), \ldots, (x(t_{N+1}), y(t_{N+1}))$$

along Γ_I we minimally shift those points (if any) that fall at interior corners of Γ_I. This is done to avoid explicitly incorporating the special integral formulation corresponding to such corners. The total number of collocation points is $7N-1$ (as each of the corners of Ω and the endpoints of Γ_I are included twice above). Given the collocation points

$$s(t_j) = (x(t_j), y(t_j)), \qquad 0 < t_1 < t_2 \cdots < t_p < T,$$

we seek an approximate solution $v_\epsilon^{(p)}$ from a finite-dimensional subspace X_p, with $\dim X_p = p = 7N - 1$, by requiring that (55) be satisfied at these points. For our computations, X_p consists of the continuous piecewise-linear functions with nodes at the given collocation points. For convenience we shall sometimes think of $v_\epsilon^{(p)}$ as a function of t through the following natural identification:

$$v_\epsilon^{(p)}(t) = v_\epsilon^{(p)}(s(t)).$$

Let $c = \{c_j\}_{j=1}^{p}$ denote the nodal values of $v_\epsilon^{(p)}$. Then for $t \in [t_j, t_{j+1}]$,

$$v_\epsilon^{(p)}(t) = \frac{c_j(t_{j+1} - t) + c_{j+1}(t - t_j)}{t_{j+1} - t_j}.$$

$v_\epsilon^{(p)}$ also has the representation

$$v_\epsilon^{(p)}(t) = \sum_{j=1}^{p} c_j L_j(t), \quad t_1 < t < t_p, \tag{57}$$

where L_j is the standard piecewise-linear "hat" function with support in $[t_{j-1}, t_{j+1}]$. Upon substitution of (57) into (55) the coefficients $c = \{c_j\}_{j=1}^{p}$ solve the linear system

$$Mc = \varphi, \tag{58}$$

with the "generic" elements of the matrix M defined by

$$m_{ij} = \begin{cases} L_j(t_i) + \int_{t_{j-1}}^{tj+1} K(s(t); s(t_i)) \; L_j(t) \; DN_\epsilon(s(t); s(t_i)) \; dt, & 1 \le i, j \le p, \\ \int_{\partial\Omega} L_j(t) dt, & i = p+1, \;\; 1 \le j \le p, \end{cases}$$

and the right-hand side given by

$$\varphi_i = \frac{k^+(s(t_i))}{\epsilon \; a_+} \left(\int_{\Gamma_+} f \; N_\epsilon(\cdot \; ; s(t_i)) \; ds \; - \; \int_{\Gamma_-} g \; N_\epsilon(\cdot \; ; s(t_i)) \; ds \right).$$

When $0 < t_j < T$ is one of the two parameter values corresponding to the endpoints of Γ_I an extra integral has to be added to the formula for m_{ij}. This integral corresponds to the parameter interval $(0, t_1)$ in the case of the left endpoint and the parameter interval (t_p, T) in the case of the right endpoint. Almost all the (nonzero) integrals in the definition of the matrix m are calculated by means of a Simpson's composite rule. An exception is made when $j = i$ and $s(t_i)$ is a collocation point adjacent to one of the (interior) corners of Γ_I; in this case the integral is calculated using a highly accurate adaptive quadrature routine. We solve the $(p+1) \times p$ system of equations (58) by means of linear least squares. Once we obtain the coefficients c_j, we have an approximation to v_ϵ along $\partial\Omega \cup \Gamma_I$. In order to reconstruct the interface function $h(x)$, we most often also require an approximation to $\epsilon \frac{\partial v_\epsilon}{\partial x}$ along Γ_+ and Γ_-. Having computed the values

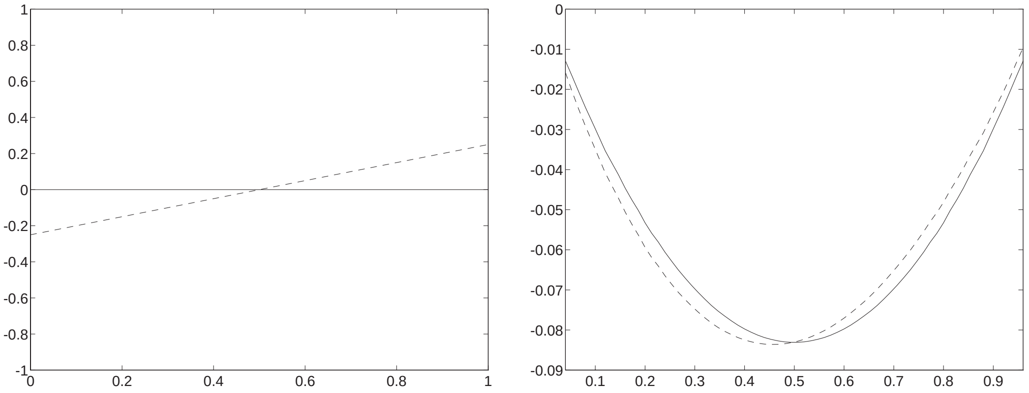
$$v_\epsilon^{(p)}(0,1), \; v_\epsilon^{(p)}\left(\frac{1}{N}, 1\right), \; v_\epsilon^{(p)}\left(\frac{2}{N}, 1\right), \ldots, v_\epsilon^{(p)}(1,1)$$

and

$$v_\epsilon^{(p)}(0,-1), \; v_\epsilon^{(p)}\left(\frac{1}{N}, -1\right), \; v_\epsilon^{(p)}\left(\frac{2}{N}, -1\right), \ldots, v_\epsilon^{(p)}(1,-1)$$

at the $N+1$ equidistant collocation points along Γ_+ and Γ_-, respectively, we approximate $\epsilon \frac{\partial v_\epsilon}{\partial x}$ by numerical differentiation, using the five-point rule

$$\begin{aligned} &\epsilon \frac{\partial v_\epsilon}{\partial x}\left(\frac{i}{N}, \pm 1\right) \\ &\quad \approx \frac{\epsilon}{12} \frac{v_\epsilon^{(p)}(\frac{i-2}{N}, \pm 1) - 8 v_\epsilon^{(p)}(\frac{i-1}{N}, \pm 1) + 8 v_\epsilon^{(p)}(\frac{i+1}{N}, \pm 1) - v_\epsilon^{(p)}(\frac{i+2}{N}, \pm 1)}{\frac{1}{N}}, \end{aligned}$$



(a) (b)

FIG. 2. *Two interfaces* (a) *and the corresponding boundary voltage derivatives* (b).

$i = 2,\dots, N$-2. Figure 2b displays two examples of this approximate, rescaled derivative from the bottom boundary Γ_-. The computations were both done with $\epsilon = 0.01$, $a_+ = 1$, $a_- = 5$, and with boundary currents $f = -2x + 1$, $g = 2x - 1$. Two different h's were used, namely $h(x) = 0$ and $h(x) = \frac{1}{4}x - \frac{1}{8}$, as displayed in Figure 2a. The solid (dashed) interface in Figure 2a corresponds to the solid (dashed) approximate derivative graphed in Figure 2b. Notice that the approximate derivatives are reasonably different except near $x = 0.5$, where the two h's agree.

In the following section approximate values such as these will be used as "synthetic" data in order to establish the effectiveness of the interface reconstruction formulas derived in section 3.

6. Computational results. Before we present our computational results let us first note any restrictions or conditions imposed on our data. In all our computations the boundary currents $f(x)$ and $g(x)$ are piecewise-linear, but not necessarily continuous, functions which satisfy

$$\int_{\Gamma^+} f(x)dx - \int_{\Gamma^-} g(x)dx = 0. \tag{59}$$

The "true" interface function $h(x)$ is a piecewise-linear continuous function, and the conductivities a_+ and a_- are positive constants with $a_+ \neq a_-$. In the examples presented in this section the "synthetic" data have been generated with N between 50 and 150, corresponding to a total number of collocation points between 349 and 1049. A relatively large number of collocation points was used for small ϵ, large conductivity ratios, and very "rough" h's. The reconstructed interface function is given in terms of its computed values at the equidistant points i/N, $2 \leq i \leq N - 2$. Since the formulas used in reconstructing the interface are only valid for "thin domains," we restrict our thickness parameter, ϵ, to the interval between 0 and 1/10. In two of our examples (corresponding to Figures 3b and 8) we select parameters that are directly relevant to Hall–Héroult cells. In our other examples the parameters are chosen simply to test various features of the reconstruction formulas.

We note that in many cases the voltage potential v_ϵ has a singularity at the corners of the domain, Ω, as well as at the points where the interface meets the vertical boundaries. Therefore the approximation we calculate may not be very accurate near these (six) points. Furthermore, the value of $\int_0^x (f-g)(t)dt$ is always very close to zero when x is near 0 or 1, and so the reconstruction formula based on the derivative data degenerates near these points. Recognizing these facts, we cannot expect to recover the interface function $h(x)$ very well for values near 0 or 1. Consequently, we have graphed all the reconstructed interfaces only for $0.05 < x < 0.95$.

In the first example we examine the effect of different conductivity ratios on the reconstructed interface. We use the derivative-based formula (41). Here and in all the following examples the cutoff parameter δ (in the formula for $DV_{\pm\epsilon}$) is chosen very small (so small that δa_- is always of magnitude less than 10^{-5}). We compare the reconstruction results for the following two sets of conductivities: (a) $a_+ = 1,\ a_- = 2$, and (b) $a_+ = 1,\ a_- = 10^4$, with all other data remaining the same. The boundary currents are $f(x) = -x + \frac{1}{2}$ and $g(x) = \ x - \frac{1}{2}$. The interface function, $h(x)$, is defined by

$$h(x) = \begin{cases} 0.50, & 0 \quad \le x \le 0.30, \\ -100x + 30.5, & 0.30 \quad < x < 0.31, \\ -0.50, & 0.31 \quad \le x \le 1, \end{cases}$$

and the thickness parameter used is $\epsilon = 0.02$. Each of the frames in Figure 3 shows two reconstructions of $h(x)$ obtained by using the bottom derivative data (the dot-dashed line) and the top derivative data (the dashed line). As in all the figures to follow the solid line represents the "true" location of the interface. Figure 3a corresponds to the first set of conductivities ($a_+ = 1,\ a_- = 2$) and Figure 3b corresponds to the second set. It is evident that if the conductivities are close in size, either set of data (top or bottom) suffices for the reconstruction. However, if the conductivities are very different in magnitude, as in case (b), the bottom data (from the boundary adjacent to the subdomain with the large conductivity) produces the only acceptable reconstruction of $h(x)$. This is consistent with our remarks at the end of section 4. In the rest of our examples we always use the bottom data to calculate the boundary voltage derivative, unless otherwise stated. We note that there are oscillations present in the (synthetic) boundary derivative data (particularly in that which corresponds to the top boundary and a conductivity ratio $a_+/a_- = 10^{-4}$). These oscillations could be made smaller by use of more collocation points and/or a more sophisticated differentiation strategy. This last comment is only of minor practical interest since "real" measured data will come with a limited accuracy, which we cannot as easily change.

In our next example we analyze the reconstruction results obtained by means of (41) for different ϵ. In each case the boundary currents are given by $f(x) = \frac{x}{2}$ and $g(x) = \frac{x}{4} + \frac{1}{8}$; the interface, $h(x)$, is defined by

$$h(x) = \begin{cases} 0, & 0 \quad \le x < 0.25, \\ 2x - 0.5, & 0.25 \quad \le x < 0.375, \\ -2x + 1, & 0.375 \quad \le x < 0.625, \\ 2x - 1.5, & 0.625 \quad \le x < 0.75, \\ 0, & 0.75 \quad \le x \le 1, \end{cases}$$

and the conductivities are $a_+ = 1$ and $a_- = 5$. We shall compare the results obtained for the following three cases: (a) $\epsilon = 0.10$, (b) $\epsilon = 0.05$, and (c) $\epsilon = 0.01$. Since the performance of the reconstruction formula is based on how well $\epsilon\frac{\partial}{\partial x}u_\epsilon(x, \pm 1)$ approximates $\frac{d}{dx}v^{(-1)}(x)$, $0 \le x \le 1$, we can expect better results for smaller ϵ. On

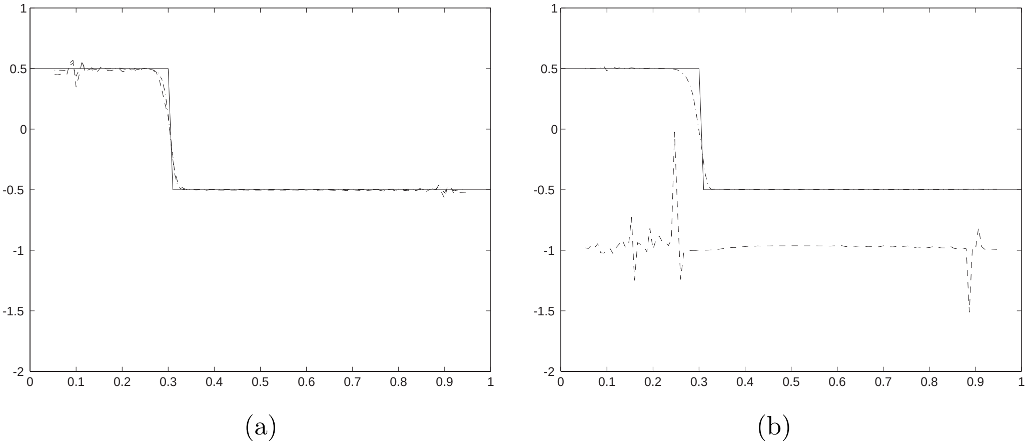


FIG. 3. *Reconstructed interfaces for two different conductivity ratios.* (a) $a_+/a_- = 0.5$, (b) $a_+/a_- = 10^{-4}$.

the other hand we note that as ϵ decreases the solution to (1) becomes increasingly more difficult to approximate; i.e., the quality of our synthetic data declines. Our computational results displayed in Figure 4a–c confirm both of these observations. Figure 4a shows the reconstruction of $h(x)$ for $\epsilon = 0.10$. The smoothness of the reconstruction directly corresponds to the smoothness of our approximation $u_\epsilon^{(p)}$. In this case the approximation is very smooth, but the thickness parameter ϵ is not sufficiently small, resulting in a smooth, but fairly inaccurate, reconstruction. Figure 4b shows the reconstruction with $\epsilon = 0.05$. The improved accuracy and increased irregularity is evident. Figure 4c shows the reconstruction of $h(x)$ for $\epsilon = 0.01$. The effect of decreasing ϵ is clearly displayed. The reconstruction is highly accurate but is also somewhat irregular. We may regularize the reconstructed curve in the following fashion. Let $h_r(x)$ be the originally reconstructed interface function and consider the energy

$$\begin{aligned} E_c(\tilde{h}_r) &= \|\tilde{h}_r - h_r\|^2_{L^2(0,1)} + c\|\tilde{h}'_r\|^2_{L^2(0,1)} \\ &= \quad E_1 \quad + \quad cE_2. \end{aligned}$$

The regularized interface function is an approximate minimizer of this energy. We obtain this approximation by solving a finite difference version of the corresponding Euler–Lagrange equation

$$-c\frac{d^2\tilde{h}_r}{dx^2} + \tilde{h}_r = h_r,$$

with the boundary conditions $\tilde{h}'_r = 0$ at $x = 0, 1$. Our selection of the value of c is based on an L-curve approach. Quite frequently, as c increases up to a particular value, c_{opt}, E_2 rapidly decreases while E_1 slightly increases. Then, for $c > c_{opt}$, E_2 decreases at a declining rate while E_1 rapidly increases. In some sense c_{opt} represents the optimal choice. For our example we examined the results obtained for several values of c. The reconstruction obtained after regularization of the interface in Figure

FIG. 4. *Reconstructions for various values of* ϵ. (a) $\epsilon = 0.1$, (b) $\epsilon = 0.05$, (c) $\epsilon = 0.01$, (d) $\epsilon = 0.01$, *regularized.*

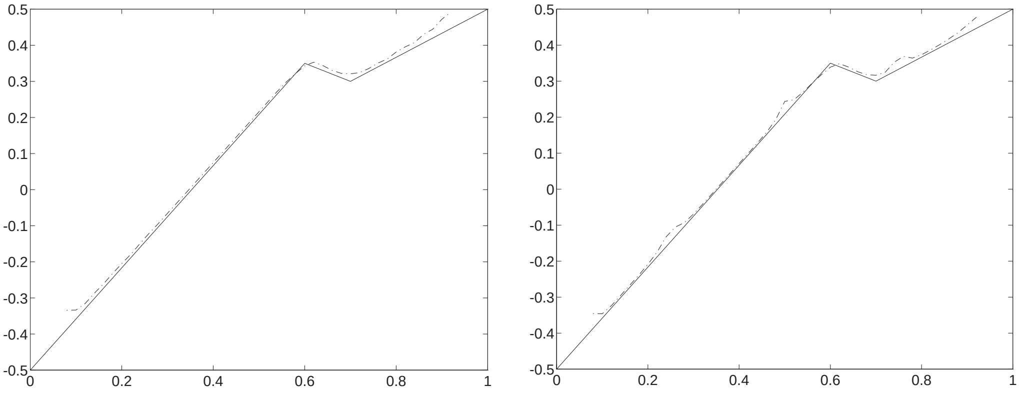
4c is graphed in Figure 4d. For a further discussion of this regularization approach and the selection of c, we refer the reader to [6] and [10].

In our next example we examine the effect of the smoothness of the boundary currents on the reconstructed interface. We again base the reconstruction on (41). For our example we take conductivity values $a_+ = 1$ and $a_- = 5$ and thickness parameter $\epsilon = 0.02$. We compare the computational results for the reconstruction of the interface:

$$h(x) = \begin{cases} \frac{17}{12}x - \frac{1}{2}, & 0 \quad\ \le x < 0.60, \\ -\frac{1}{2}x + \frac{13}{20}, & 0.60 \quad \le x < 0.70, \\ \frac{2}{3}x - \frac{1}{6}, & 0.70 \quad \le x \le 1.00 \end{cases}$$

for the following two sets of boundary currents:

$$\text{(a)} \quad f(x) = x - \frac{1}{2},$$
$$g(x) = 0,$$



(a) (b)

FIG. 5. *The effect of discontinuities in the currents on the reconstruction.*

and

$$\text{(b)} \quad f(x) = \begin{cases} -\frac{3}{8}, & 0 \quad \leq x < 0.25, \\ -\frac{1}{8}, & 0.25 \quad \leq x < 0.50, \\ \frac{1}{8}, & 0.50 \quad \leq x < 0.75, \\ \frac{3}{8}, & 0.75 \quad \leq x \leq 1.00, \end{cases}$$

$$g(x) = 0.$$

The current distribution f in (b) is a very natural piecewise-constant approximation to the continuous distribution in (a). Figure 5a shows the reconstruction corresponding to the smooth f. Away from the endpoints ($x = 0, 1$), the reconstructed interface is uniformly accurate in its approximation of $h(x)$. Figure 5b shows the reconstruction corresponding to the piecewise-constant f. Away from the points of discontinuity of f as well as the endpoints, the reconstructed interface provides an excellent approximation to $h(x)$. This reconstruction is clearly less accurate near the points of discontinuity of f. The local inaccuracy of the reconstruction at these points of discontinuity is caused by two facts: 1) the fact that the boundary voltage derivative $\epsilon\frac{\partial}{\partial x}u_\epsilon$ is a poorer approximation to $\frac{d}{dx}v^{(-1)}$, and 2) the fact that our synthetic data (the approximation of u_ϵ) are less accurate.

In our next example we use model data corresponding to a cell in which both (41) and (43) must be employed to reconstruct $h(x)$. The conductivities are $a_+ = 1$ and $a_- = 2$ and once again we use a thickness parameter of $\epsilon = 0.02$. The "true" interface is given by

$$(60) \qquad h(x) = \begin{cases} -\frac{3}{4}x + \frac{2}{5}, & 0 \quad \leq x < 0.20, \\ x + \frac{1}{20}, & 0.20 \quad \leq x < 0.25, \\ -\frac{3}{4}x + \frac{39}{80}, & 0.25 \quad \leq x < 0.65, \\ x - \frac{13}{20}, & 0.65 \quad \leq x < 0.70, \\ -\frac{3}{4}x + \frac{23}{40}, & 0.70 \quad \leq x \leq 1.00, \end{cases}$$

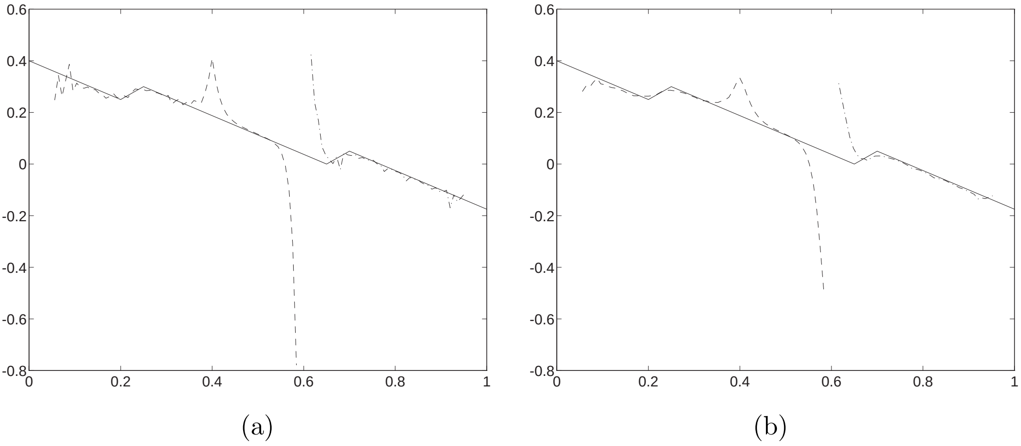


FIG. 6. *Reconstruction using a combination of* (41) *and* (43).

and the boundary currents are defined by

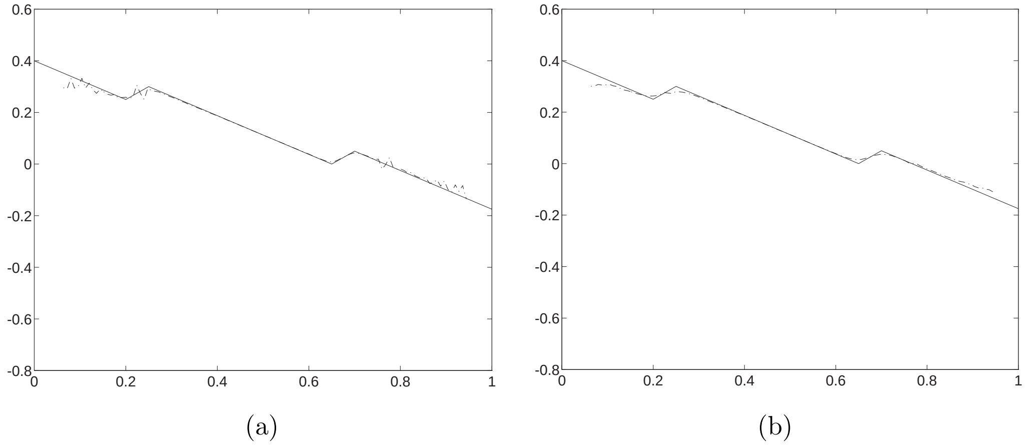
$$f(x) = \begin{cases} 2, & 0 \leq x < 0.40, \\ -1, & 0.40 \leq x < 0.60, \\ 2, & 0.60 \leq x \leq 1.00, \end{cases}$$

$$g(x) = \begin{cases} 1, & 0 \leq x < 0.60, \\ \\ 2, & 0.60 \leq x \leq 1.00. \end{cases}$$

Since $\int_0^x (f(t) - g(t))\, dt \neq 0, \quad 0 < x < 0.60$, (41) is used to reconstruct $h(x)$ for $x < 0.60$. The result is the dashed curve to the left in Figure 6a. Since $\int_0^x (f(t) - g(t))\, dt \equiv 0, \quad 0.60 < x < 1.00$, (43) is used to reconstruct $h(x)$ for $x > 0.60$. The result is the dot-dashed curve to the right in Figure 6a. Away from the endpoints the reconstruction is a quite accurate approximation to $h(x)$ except near the points $x = 0.40$ and $x = 0.60$. Note that $x = 0.40$ is a point of discontinuity for $f(x)$ while $x = 0.60$ is a point of discontinuity for both $f(x)$ and $g(x)$ as well as the point at which the formula used to reconstruct $h(x)$ changes. Even with perfect boundary voltage data we could not expect to reconstruct $h(x)$ with extremely good accuracy near $x = 0.40$ and $x = 0.60$. Since the reconstruction is rather unsmooth we regularize the curves using the process described above. The regularized result is graphed in Figure 6b.

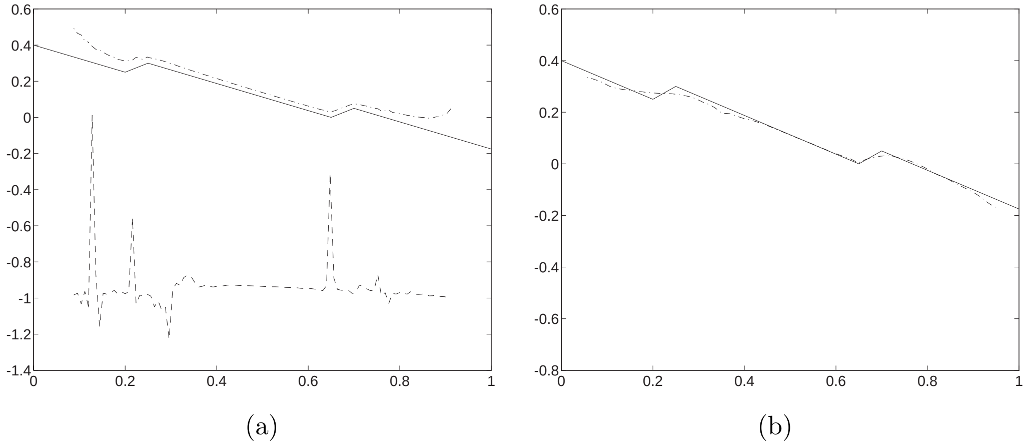
It is not that the interface (60) is particularly difficult to reconstruct. It may be quite accurately reconstructed using smoother (and less degenerate) boundary currents. Figure 7 shows the reconstruction of this interface for conductivities $a_+ = 1$, $a_- = 2$ and thickness parameter $\epsilon = 0.02$ (as before). However, this time we use the boundary currents $f(x) = -2x + 1$ and $g(x) = 2x - 1$. Figure 7a is the reconstruction obtained by use of the derivative-based formula (41); Figure 7b is the same reconstruction, only this time regularized. This example confirms that the inaccuracies in the previous reconstruction were largely a result of the discontinuities and the degeneracy of the applied boundary currents.

In our final example we demonstrate that an interface such as (60) may also be quite accurately reconstructed in the case $a_+ = 1$, $a_- = 10^4$, and $\epsilon = 0.02$. Figure



(a) (b)

FIG. 7. *The same interface and conductivities as in the previous figure, but with smoother, less degenerate boundary currents.*



(a) (b)

FIG. 8. *Same interface as in Figure* 7*, but a conductivity ratio* $a_+/a_- = 10^{-4}$*. Reconstructions based on* (41) *to the left, reconstruction based on* (43) *to the right. The boundary currents for* (a) *and* (b) *differ.*

8a corresponds to applied boundary currents $f(x) = -2x + 1$ and $g(x) = 2x - 1$ and use of (41). The dot-dashed (fairly good) reconstruction corresponds to the use of the bottom derivative data. The dashed (useless) reconstruction is obtained by use of the top derivative data. No regularization was performed on the reconstructions shown in Figure 8a. Figure 8b corresponds to the applied boundary currents $f = g = 1$ and use of (43). This reconstruction has been regularized using the technique described earlier.

CONVEX OPTIMIZATION VIA FEEDBACKS[*]

ARKADII V. KRYAZHIMSKII[†]

Abstract. Three dynamical systems are associated with a problem of convex optimization in a finite-dimensional space. For system trajectories $x(t)$, the ratios $x(t)/t$ are, respectively, (i) solution tracking (staying within the solution set X^0), (ii) solution abandoning (reaching X^0 as time t goes back to the initial instant), and (iii) solution approaching (approaching X^0 as time t goes to infinity). The systems represent a closed control system with appropriate feedbacks. In typical cases, the structure of the trajectories is simple enough. For instance, for a problem of quadratic programming with linear and box constraints, solution-approaching dynamics are described by a piecewise-linear ODE with a finite number of polyhedral domains of linearity. Finding the order of visiting these domains yields an analytic resolution of the original problem; a detailed analysis is given for a particular example. A discrete-time approach is outlined.

Key words. feedback control, differential inclusions, convex programming, linear equality constraints

1. Introduction.

Our goal in this paper is to expose new connections between dynamical systems and static convex optimization problems. The idea of approaching a static optimizer along a trajectory of a continuous-time dynamical system has been exploited in various aspects. Gradient processes shifting the primal and dual variables against the gradients of the Lagrange function so as to attain its saddle point have perhaps the longest history [1]. Gradient-type processes in feasible sets [2], continuous-time gradient projection [3], and continuous-time barrier projection [4] illustrate, among other things, further developments in the gradient approach. The homotopy approach rests on the idea of tracking solutions of time-parametrized problems by smoothly transforming an easily solvable problem into the original one. In this context we mention path-following processes [5] and interior-point homotopy methods [6]. Finally, we refer to continuous-time counterparts of proximal and Newton-type optimization methods (see, e.g., [3]).

In this paper we hold a viewpoint of control theory. We describe three dynamical systems (ODEs) whose state-over-time ratios converge to static optimizers. The ODEs represent a closed control system with appropriate feedbacks. The structure of the feedbacks originates from the method of shifting control [7] and its regularized modifications [8].

The paper has two objectives.

The first objective is qualitative. We show that the dynamical systems corresponding to the *Filippov shifting*, *regularized shifting*, and *penalized shifting* feedbacks converge to an optimizer differently. The Filippov shifting system is fixed on the optimizer. The regularized shifting system reaches the optimizer as time goes back to the initial instant. The penalized shifting system finds the optimizer as time goes to

infinity. Thus, we have solution-tracking dynamics, solution-abandoning dynamics, and solution-approaching dynamics. Up to now, dynamical systems reaching the optimizer at infinity (a prototype of solution approaching) have been considered. Solution tracking and solution abandoning extend the variety of qualitative links between the dynamical systems and the solvers to convex optimization problems.

Our second objective is to outline an analytic optimization approach associated with explicit solutions of the designed ODEs. Generally, these ODEs have multivalued right-hand sides, and nonstandard solution techniques are required. However, if the minimized function is strictly convex, the right-hand sides of the ODEs are single valued (the Filippov shifting system is a single exception). For instance, the penalized shifting system associated with a problem of quadratic programming with linear and box constraints is described by a piecewise-linear ODE with a finite number of polyhedral domains of linearity. System trajectory is represented explicitly in each domain. A problem is to identify the order of visiting the domains. In section 7 we give an example of an analytic resolution of this problem.

We restrict this study to convex optimization problems whose feasible sets are described by inclusions and linear equalities. The linear equality constraints allow us to implement the idea of extremal shifting with minimum modifications (in this paper we deal with a minimum of technical details).

In section 2 we discuss the underlying idea of our method. In sections 3, 4, and 6 we introduce the Filippov shifting system, the regularized shifting system, and the penalized shifting system, and prove their convergence properties. Sections 5 and 7 are devoted to the analytic design of the regularized shifting trajectories and the penalized shifting trajectories for two particular examples. In section 8 we consider discrete-time analogues of the shifting and penalized shifting dynamics.

The study was initiated in [9]. In this paper the method of regularized shifting was used for the justification of a finite approximate optimization algorithm. A preliminary text of the present paper was published in [10]. A family of numerical algorithms for convex optimization adjoining the suggested approach is described in [11].

2. Outline of the method: Definitions. We are concerned with the optimization problem

$$\begin{aligned} &\text{minimize } J(x),\\ &x \in M,\\ &Fx = b. \end{aligned} \tag{2.1}$$

Here J is a convex function on R^n, M is a closed, convex, and bounded set in R^n, F is an $r \times n$ matrix, and $b \in R^r$. As usual, R^k is a k-dimensional Euclidean space of column vectors, x_i is the ith coordinate of $x \in R^n$, x^T stands for x transposed, and $|\cdot|$ denotes the Euclidean norm. A point $x \in R^n$ such that $x \in M$, $Fx = b$ is called feasible in problem (2.1). The collection of all points feasible in (2.1) forms the feasible set of problem (2.1). We assume that the feasible set of problem (2.1) is nonempty. J^0 and X^0 denote the optimal value and the solution set in problem (2.1), respectively. Note that X^0 is nonempty. In what follows, $\operatorname{argmin}\{f(x) : x \in E\}$ stands for the collection of all minimizers of function f in E.

Let us outline informally a method of building a dynamical system tracking the solution set X^0. We begin with an ODE with a fixed (zero) initial state and a variable (controllable) right-hand side $u(t)$:

$$\dot{x}(t) = u(t), \quad x(0) = 0, \tag{2.2}$$

where time t varies between zero and infinity. Impose the constraint $u(t) \in M$. Then, no matter how $u(t)$ is formed, $x(t)/t \in M$ for all $t > 0$; this follows from the convexity of M. In other words, the ratio $x(t)/t$ automatically satisfies the inclusion constraint in problem (2.1). We treat $x(t)/t$ as a candidate for tracking X^0. Let us find a control law ensuring $Fx(t)/t = b$, or, equivalently, $\epsilon(t) = |Fx(t) - bt|^2 = 0$ for all $t \geq 0$. The zero initial condition implies $\epsilon(0) = 0$. So, it is sufficient to have $\dot{\epsilon}(t) \leq 0$. The differentiation yields $\dot{\epsilon}(t) = 2(Fx(t) - bt)^T(Fu(t) - b)$. We get $\dot{\epsilon}(t) \leq 0$ by letting $u(t) \in L^-(t, x(t))$, where

$$L^-(t,x) = \{u \in M : (Fx - bt)^T(Fu - b) \leq 0\}. \tag{2.3}$$

Any $u(t) \in L^-(t, x(t))$ keeps $x(t)/t$ within the feasible set of problem (2.1) for all $t > 0$. We associate this argument with the method of shifting control [7]. Control $u(t) \in L^-(t, x(t))$ shifts discrepancy $\epsilon(t)$ toward zero. Now let $u(t)$ minimize J in $L^-(t, x(t))$, i.e., $u(t) \in U^s(t, x(t))$, where

$$U^s(t,x) = \operatorname{argmin}\{J(u) : u \in L^-(t,x)\}. \tag{2.4}$$

We call $U^s(t, x)$ the *shifting feedback*. We have $Fx^0 - b = 0$, where x^0 is a solution of problem (2.1). Hence $(Fx(t) - bt)^T(Fx^0 - b) = 0$, and $x^0 \in L^-(t, x(t))$. Therefore $J(u(t)) \leq J(x^0) = J^0$ for all $t > 0$. Due to the convexity of J,

$$J\left(\frac{x(t)}{t}\right) \leq \frac{1}{t}\int_0^t J(u(s))ds \leq \frac{1}{t}\int_0^t J^0 = J^0.$$

Now take into account that $x(t)/t$ is feasible in problem (2.1). We immediately get that $x(t)/t$ is a solution of (2.1), or, equivalently, $x(t)/t \in X^0$ for all $t > 0$. We find that $x(t)$, a trajectory of the control system (2.2) under the shifting feedback $U^s(t, x(t))$, tracks the solution set X^0.

Unfortunately, the above argument does not work, for we cannot guarantee the existence of a trajectory under the shifting feedback $U^s(t, x)$. Let us give a simple nonexistence example. We minimize the scalar variable x under the trivial constraints $x \in [-1, 1]$ and $x = 0$. We have $L^-(t, x) = [-1, 0]$ for $x \geq 0$, and $L^-(t, x) = [0, 1]$ for $x < 0$. Hence $U^s(t, x) = \{u^s(t, x)\}$, where

$$u^s(t,x) = \begin{cases} -1, & x \geq 0, \\ 0, & x < 0. \end{cases}$$

The differential equation for system (2.2) closed with feedback $U^s(t, x)$ is

$$\dot{x}(t) = u^s(t, x(t)), \quad x(0) = 0. \tag{2.5}$$

Its right-hand side is discontinuous. Obviously, this equation has neither classical nor Carathéodory solutions.

The paradox disappears if we assume Filippov's definition of solutions. Following [12], we identify a solution of (2.5) with a solution of the differential inclusion

$$\dot{x}(t) \in U^{fs}(t, x(t)), \quad x(0) = 0.$$

Here

$$U^{fs}(t,x) = \begin{cases} \{-1\}, & x > 0, \\ \{0\}, & x < 0, \\ [-1, 0], & x = 0. \end{cases}$$

It is easily seen that $x(t) = 0$ is a single Filippov solution of (2.5) and $x(t)/t \in X^0$ for all $t > 0$ ($X^0 = \{0\}$).

In section 3 the features of the above example will be extended to the general case.

In what follows, we deal with multivalued feedbacks for system (2.2). A (multivalued) *feedback* U is defined to be a map from $R_+ \times R^n$ into the collection of all nonempty sets in M; here $R_+ = [0, \infty]$. A feedback U such that $U(t,x)$ is one-element for all $(t,x) \in E$ is called *single valued on* E; if $E = R_+ \times R^n$, we call U *single valued.* A *trajectory* (of system (2.2)) *under feedback* U is a solution of

$$\dot{x}(t) \in U(t, x(t)), \quad x(0) = 0. \tag{2.6}$$

More accurately, a function $x(\cdot) : R_+ \mapsto R^n$ is called a trajectory under U if $x(\cdot)$ is absolutely continuous on every bounded interval, $x(0) = 0$, and the inclusion in (2.6) holds for almost all $t \geq 0$.

The convexity of M and the fact that the values of feedbacks are contained in M yield the following.

LEMMA 2.1. *Let* $x(\cdot)$ *be a trajectory under an arbitrary feedback. Then* $x(t)/t \in M$ *for all* $t > 0$.

We conclude this section with some known definitions and properties of multivalued maps; they will be referred to in what follows. A multivalued (set-valued) map $\mathcal{F}$ on $E \subset R_+ \times R^n$ associates with every $(t,x) \in E$ a nonempty set $\mathcal{F}(t,x) \subset R^n$; if $E = R_+ \times R^n$, we call $\mathcal{F}$ a multivalued map (without mentioning its set of definition). The continuity, upper semicontinuity, and lower semicontinuity of a multivalued map $\mathcal{F}$ on E at a point are understood in a standard way (see [13, pp. 41, 43]). A multivalued map $\mathcal{F}$ whose restriction to a set E is continuous at every point $(t,x) \in E$ is said to be continuous on E; if $E = R_+ \times R^n$, then $\mathcal{F}$ is called continuous. The same applies for the upper and lower semicontinuity. The next two lemmas follow from standard results of set-valued analysis (see [14, section 1.4]).

LEMMA 2.2. *Let* $\mathcal{F}$ *be a closed and convex-valued multivalued map continuous on* E, *and* f *be a convex function on* R^n. *Then the multivalued map* $(t,x) \mapsto \operatorname{argmin}\{f(u) : u \in \mathcal{F}(t,x)\}$ *is closed and convex valued and upper semicontinuous on* E.

LEMMA 2.3. *Let* $E_1, \ldots, E_m$ *be closed sets in* $R_+ \times R^n$, *and a multivalued map* $\mathcal{F}$ *be upper semicontinuous on each of them. Then* $\mathcal{F}$ *is upper semicontinuous on* $\cup\{E_j : j = 1, \ldots, m\}$.

3. Solution-tracking dynamics. In this section we extend the argument of section 2 to the general case. We state that the trajectories under the shifting feedback are solution tracking but usually do not exist. Next, we introduce the Filippov shifting feedback. We prove that there always exists a trajectory under this feedback, and every such trajectory is solution tracking.

We call a function $x(\cdot) : R_+ \mapsto R^n$ *solution tracking* if $x(t)/t \in X^0$ for all $t > 0$. Let us fix a continuous feedback Q such that $Q(t,x) \cap X^0$ is nonempty for all $(t,x) \in R_+ \times R^n$. The *shifting* feedback U^s is defined by (2.4), where

$$L^-(t,x) = \{u \in Q(t,x) : (Fx - bt)^T(Fu - b) \leq 0\} \tag{3.1}$$

(in (2.3) we have $Q(t,x) = M$). Note that U^s is closed and convex valued.

Let us give a criterion for a function $x(\cdot)$ to be a trajectory under the shifting feedback. We set

$$Q^0(t,x) = \operatorname{argmin}\{J(u) : u \in Q(t,x)\}. \tag{3.2}$$

Lemma 2.3 and the continuity of Q yield the following.

LEMMA 3.1. *Feedback Q^0 (3.2) is upper semicontinuous.*

THEOREM 3.1. *Let $x(\cdot) : R_+ \mapsto R^n$ be absolutely continuous on every bounded interval, and $x(0) = 0$. Then the next statements are equivalent:*

(i) *$x(\cdot)$ is a trajectory under the shifting feedback;*

(ii) *$\dot{x}(t) \in Q^0(t, x(t)) \cap X^0$ for almost all $t \geq 0$.*

Proof. Let (i) hold. By the definition of the shifting feedback (see (2.4)), $\dot{x}(t) \in L^-(t, x(t))$ for almost all t. Hence (see (3.1)), the function $\epsilon(\cdot) : t \mapsto \mid Fx(t) - tb \mid^2$ is nonincreasing. Since $\epsilon(0) = 0$, we have $Fx(t) = tb$ for all $t \geq 0$. Therefore $L^-(t, x(t)) = Q(t, x(t))$ for $t \geq 0$ (see (3.1)). By (3.2) $U^s(t, x(t)) = Q^0(t, x(t))$. Consequently $\dot{x}(t) \in Q^0(t, x(t))$ for almost all $t \geq 0$. In particular $J(\dot{x}(t)) \leq J^0$ for almost all $t \geq 0$. It follows from $Fx(t) = tb$ that $\dot{x}(t)$ is feasible in problem (2.1) for almost all $t \geq 0$. Hence $J(\dot{x}(t)) = J^0$ for almost all $t \geq 0$. Therefore $\dot{x}(t) \in X^0$ for almost all $t \geq 0$.

Let (ii) hold. For almost all t, $\dot{x}(t)$ is simultaneously a minimizer of J in $Q(t, x(t))$ and a minimizer of J in the feasible set of problem (2.1). Since $L^-(t, x(t))$ contains the feasible set of problem (2.1) and is contained in $Q(t, x(t))$, $\dot{x}(t)$ minimizes J in $L^-(t, x(t))$, or, equivalently, $\dot{x}(t) \in U^s(t, x(t))$ for almost all t. □

COROLLARY 3.1. *Every trajectory under the shifting feedback is solution tracking.*

Proof. Let $x(\cdot)$ be a trajectory under the shifting feedback. By Theorem 3.1(ii), $\dot{x}(t) \in X^0$ for almost all $t \geq 0$. Since X^0 is closed and convex, $x(t)/t \in X^0$ for all $t > 0$. □

COROLLARY 3.2. *Let there exist a trajectory under the shifting feedback. Then $\cup\{Q_0(t, x) \cap X^0 : x \in tX^0\}$ is nonempty for all $t \geq 0$.*

Proof. Let $x(\cdot)$ be a trajectory under the shifting feedback. By statement (ii) of Theorem 3.1, $x(t) \in tX^0$ for all $t \geq 0$ and $Q^0(t, x(t)) \cap X^0$ is nonempty for almost all $t \geq 0$. Due to the upper semicontinuity of feedback Q^0 (Lemma 3.1), $Q^0(t, x(t)) \cap X^0$ is nonempty for all $t \geq 0$. □

COROLLARY 3.3. *Let X^0 be one-element. The next statements are equivalent:*

(i) *there exists a trajectory under the shifting feedback;*

(ii) *for all $t \geq 0$ it holds that $x^0 \in Q^0(t, tx^0)$, where x^0 is a single element in X^0.*

Proof. If (i) holds, then (ii) is true by Corollary 3.2. Let (ii) hold. By Theorem 3.1, $x(\cdot) : t \mapsto tx^0$ is a trajectory under the shifting feedback. □

The necessary condition for the existence of a trajectory under the shifting feedback given in Corollary 3.2 is a severe constraint on the problem's data and feedback Q. For instance, if $Q(t, x) = M$ (see section 2), this condition requires that a minimizer in the original problem (2.1) minimizes J in M. The latter situation is degenerate.

To avoid the nonexistence phenomenon, we introduce a Filippov modification of the shifting feedback. In what follows, conv E designates the closure of the convex hull of a set $E \subset R^n$. The *Filippov shifting feedback* U^{fs} is defined by

$$U^{fs}(t, x) = \cap_{\delta > 0} \operatorname{conv} \cup \{U^s(t, y) : |y - x| \leq \delta\}. \tag{3.3}$$

THEOREM 3.2. *There exists a trajectory under the Filippov shifting feedback, and every such trajectory is solution tracking.*

Proof. We can easily verify that the Filippov shifting feedback U^{fs} is upper semicontinuous. Obviously, it is bounded. These properties imply the existence of a trajectory under U^{fs} (see, e.g., [13, Theorem 4, p. 101]). Now let $x(\cdot)$ be a trajectory under U^{fs}. We must prove that $x(\cdot)$ is solution tracking. Take a small $\delta > 0$ and arbitrary $t \geq 0$ such that $\dot{x}(t) \in U^{fs}(t, x)$. By (3.3) there are points $y_1, \ldots, y_k$ in the closed δ-neighborhood of $x(t)$, elements $u_i \in U^s(t, y_i)$ $(i = 1, \ldots, k)$, and coefficients $\beta_i \geq 0$ $(i = 1, \ldots, k)$, $\sum_{i=1}^k \beta_i = 1$, such that

$$\left| \dot{x}(t) - \sum_{i=1}^{k} \beta_i u_i \right| < \delta. \tag{3.4}$$

By the definition of $U^s(t, x)$ (see (2.4)), $u_i \in L^-(t, y_i)$. So, $(Fy_i - tb)^T(Fu_i - b) \leq 0$. Fix an arbitrary $\mu > 0$, and, with no loss of generality, take δ so small that $(Fx(t) - tb)^T(Fu_i - b) \leq \mu$ for all i. Then $(Fx(t) - tb)^T$ $(F \sum_{i=1}^k \beta_i u_i - b) \leq \mu$. Due to (3.4) we can choose δ so small that

$$(Fx(t) - tb)^T(F\dot{x}(t) - b) \leq 2\mu. \tag{3.5}$$

Note that $Q(t, y_i) \cap X^0$ is nonempty for every i. Let $x_i^0 \in Q(t, y_i) \cap X^0$. Obviously, $(Fy_i - tb)^T(Fx_i^0 - b) = 0$. Hence $x_i^0 \in X^0 \cap L^-(t, y_i)$. Consequently $J(u_i) \leq J(x^0) = J^0$ (see (2.4)). By the convexity of J we have $J(\sum_{i=1}^k \beta_i u_i) \leq J^0$. Taking into account (3.4) and (if needed) decreasing δ, we get

$$J(\dot{x}(t)) \leq J^0 + \mu. \tag{3.6}$$

In (3.5) and (3.6) $\mu > 0$ is arbitrary. Omitting μ yields

$$(Fx(t) - tb)^T(F\dot{x}(t) - b) \leq 0, \tag{3.7}$$

$$J(\dot{x}(t)) \leq J^0. \tag{3.8}$$

Recall that t is arbitrary and satisfies $\dot{x}(t) \in U^{fs}(t, x)$. The latter holds for almost all $t \geq 0$. Therefore for almost all $t \geq 0$ estimates (3.7) and (3.8) are valid. Set $\epsilon(t) = |Fx(t) - tb|^2$. Obviously $\epsilon(0) = 0$. By (3.7) $\dot{\epsilon}(t) \leq 0$ for almost all $t \geq 0$. Thus for all $t \geq 0$ we have $\epsilon(t) = 0$, or $Fx(t)/t = b$. So far as $x(t)/t \in M$ (Lemma 2.1), $x(t)/t$ is feasible in problem (2.1) for all $t > 0$. Now integrate (3.8) and use the convexity of J. For arbitrary $t > 0$ we obtain

$$J\left(\frac{x(t)}{t}\right) \leq \frac{1}{t}\int_0^t J(\dot{x}(s))ds \leq \frac{1}{t}\int_0^t J^0 = J^0. \tag{3.9}$$

Since $x(t)/t$ is feasible in problem (2.1), $x(t)/t$ is a minimizer in (2.1). Equivalently, $x(t)/t \in X^0$. Thus trajectory $x(\cdot)$ is solution tracking. □

Note that if J is strictly convex, the shifting feedback U^s is single valued (see (2.4)). This is not true for the Filippov shifting feedback U^{fs}.

THEOREM 3.3. *Let J be strictly convex, and the Filippov shifting feedback be single valued. Then there exists a trajectory under the shifting feedback.*

Proof. Since J is strictly convex, each of the sets X^0 and Q^0 is one-element. We denote by x^0 a single element in X^0 and by $q^0(t, x)$ a single element in $Q^0(t, x)$. Suppose there does not exist a trajectory under the shifting feedback. Then statement (ii) of Corollary 3.3 is untrue; i.e., there is a $\tau \geq 0$ such that $x^0 \neq q$, where $q = q^0(\tau, \tau x^0)$. Then q (lying in M) does not satisfy the equality constraint in problem (2.1), $Fq \neq b$. Take $\epsilon > 0$ and set $y_\epsilon^- = \tau x^0 - (\epsilon q - x^0)$. We have

$$\begin{aligned}(Fy_\epsilon^- - \tau b)^T(Fq - b) &= (F\tau x^0 - \tau b - \epsilon F(q - x^0))^T(Fq - b)\\ &= -\epsilon(Fq - b)^T(Fq - b) < 0.\end{aligned}$$

By Lemma 3.1 the function $(t, x) \mapsto q^0(t, x)$ is continuous. Consequently for sufficiently small $\epsilon > 0$, $(Fy_\epsilon^- - \tau b)^T\ (Fq^0(\tau, y_\epsilon^-) - b) < 0$, or $q^0(\tau, \tau y_\epsilon^-) \in L^-(\tau, y_\epsilon^-)$. Hence for small $\epsilon > 0$, $q^0(\tau, \tau y_\epsilon^-)$ minimizes J in $L^-(\tau, y_\epsilon^-)$, i.e., $q^0(\tau, y_\epsilon^-) \in U^s(\tau, y_\epsilon^-)$. By the definition of the Filippov shifting feedback, $q = \lim_{\epsilon\to+0} q^0(\tau, y_\epsilon^-)$ is contained in $U^{fs}(\tau, \tau x^0)$. Now let

$$y_\epsilon^+ = \tau x^0 + \epsilon(q - x^0),$$

$u_\epsilon^+ \in U^s(\tau, y_\epsilon^+)$, and u^+ be a limit point of the sequence $(u_{1/i}^+)$. By (3.3) $u^+ \in U^{fs}(\tau, \tau x^0)$. Since $u_{1/i}^+ \in L^-(\tau, y_{1/i}^+)$, we have $(Fy_{1/i}^+ - \tau b)^T\ (Fu_{1/i}^+ - b) \le 0$. Dividing by ϵ and using $Fx^0 = b$, we get $(Fq - b)^T\ (Fu_{1/i}^+ - b) \le 0$. Hence $(Fq - b)^T$ $(Fu^+ - b) \le 0$. If $u^+ = q$, then $Fq - b = 0$. The latter does not hold by assumption. Therefore $u^+ \ne q$. Thus $U^{fs}(\tau, \tau x^0)$ contains the two different elements q and u^+. We find that the Filippov shifting feedback U^{fs} is not single valued, which contradicts the assumption. □

4. Solution-abandoning dynamics. The single-validity is a useful property of a feedback. It allows us to design trajectories using standard ODE techniques. Theorem 3.3 says that the Filippov shifting feedback U^{fs} is rarely single valued.

In this section we consider a feedback that is single valued on $(0, \infty) \times R^n$ (provided J is strictly convex) whose trajectories possess a property slightly weaker than solution tracking (we call it solution abandoning). The single-validity on $(0, \infty) \times R^n$, i.e., everywhere except the hyperplane $t = 0$, is less convenient than the single-validity everywhere but still gives a chance for using ODE techniques. The trajectories under a feedback U that is single valued on $(0, \infty) \times R^n$ are governed by an ODE whose right-hand side is well defined everywhere except $t = 0$. If the right-hand side is continuous on $(0, \infty) \times R^n$ (which is the case in this section), the solutions of the ODE are continuable to zero and bounded in its neighborhood. A solution $x(\cdot)$ is a trajectory under U whenever $\lim_{t\to+0} x(t) = 0$.

In what follows, $\operatorname{dist}(x, X)$ stands for the distance from a point $x \in R^n$ to a set $X \subset R^n$. We call a function $x(\cdot) : R_+ \mapsto R^n$ *solution abandoning* if $\operatorname{dist}(x(t)/t, X^0) \to 0$ as $t \to +0$. Define the *regularized shifting* feedback U^{rs} by

$$U^{rs}(t, x) = \begin{cases} (1 - \omega(t, x))U^s(t, x) + \omega(t, x)Q^0(t, x), & t > 0, \\ Q(0, x), & t = 0. \end{cases} \tag{4.1}$$

Here $\omega(\cdot)$ is a continuous *pasting function* defined on $(0, \infty) \times R^n$. It satisfies $\omega(t, x) = 0$ if $|Fx - tb| \ge \rho(t)$, and $\omega(t, x) = 1$ if $|Fx - tb| = 0$. A continuous *barrier function* $\rho(\cdot)$ is defined on R_+, takes positive values everywhere except the origin, vanishes at the origin, and satisfies

$$\lim_{t\to+0} \frac{\rho(t)}{t} = 0. \tag{4.2}$$

If J is strictly convex, then feedbacks U^s (2.4) and Q^0 (3.2) are single valued, hence U^{rs} is single valued on $(0, \infty) \times R^n$. To state the existence of a trajectory under the regularized shifting feedback we need to assume that feedback L^- (3.1) is continuous on

$$E^+ = \{(t, x) : t > 0,\ x \in R^n,\ Fx - tb \ne 0\}. \tag{4.3}$$

Note that the continuity of L^- on E^+ does not imply its continuity on $R_+ \times R^n$. For instance, for problem (2.1) with the trivial constraints $x \in [-1,1]$, $x = 0$, and $Q(t,x) = [-1,1]$, we have $L^-(t,x) = [-1,0]$ if $x > 0$, $L^-(t,x) = [0,1]$ if $x > 0$, and $L^-(t,x) = [-1,1]$ if $x = 0$. We see that L^- is continuous on $E^+ = \{(t,x) : t > 0,\ x \in R^1,\ x \neq 0\}$ and discontinuous at points $(t,0)$.

Let us give a condition sufficient for L^- to be continuous on E^+. We write int E for the interiority of a set $E \subset R^n$.

Lemma 4.1. *Let* int $Q(t,x)$ *intersect the feasible set of problem* (2.1) *for every* $(t,x) \in E^+$. *Then feedback* L^- *is continuous on* E^+.

Proof. Since Q is continuous, L^- is upper semicontinuous. We complete the proof by showing that L^- is lower semicontinuous on E^+. Let $L_0^-(t,x) = \{u \in R^n : (Fx - bt)^T(Fu - b) \leq 0\}$. By (3.1) $L^-(t,x) = \{u \in L_0^-(t,x)\ : u \in Q(t,x)\}$. Then by Proposition 1.5.2 in [15], the next conditions are sufficient for L^- to be lower semicontinuous on E^+:

(i) L_0^- is lower semicontinuous on E^+;

(ii) $Q(t,x)$ is convex;

(iii) the graph of the multivalued map $(t,x) \mapsto \text{int } Q(t,x)$ defined on E^+ is open; and

(iv) $L_0^-(t,x) \cap \text{int } Q(t,x)$ is nonempty for all $(t,x) \in E^+$.

Condition (i) is obviously satisfied. Conditions (ii) and (iv) follow from the assumptions. It remains to prove (iii). Take arbitrary $(t_*,x_*) \in E^+$ and $u_* \in \text{int } Q(t,x)$. Let $\epsilon > 0$ be the radius of a neighborhood of u_* contained in $Q(t_*,x_*)$. Then

$$\Delta(\psi \mid Q(t_*,x_*)) - \epsilon|\psi| \geq \psi^T u_*$$

for all $\psi \in R^n$. Here and in what follows $\Delta(\cdot \mid D)$ is the support function of $D \subset R^n$, i.e., $\Delta(\psi \mid D) = \sup\{\psi^T u : u \in D\}$. By the continuity of Q, if (τ,ξ) is sufficiently close to (t_*,x_*), then

$$\Delta(\psi \mid Q(\tau,\xi)) \geq \Delta(\psi \mid Q(t_*,x_*)) - \frac{\epsilon}{2}|\psi|$$

for all $\psi \in R^n$. Hence for (τ,ξ) close to (t_*,x_*) it holds that

$$\Delta(\psi \mid Q(\tau,\xi)) - \frac{\epsilon}{2}|\psi| \geq \psi^T u_*$$

for all $\psi \in R^n$; equivalently, the $(\epsilon/2)$-neighborhood of u_* is contained in $Q(\tau,\xi)$. Thus, (t_*,x_*,u_*) lies in the interior of the graph of $(t,x) \mapsto \text{int } Q(t,x)$. This graph is therefore open. Condition (iii) is proved. □

Lemma 4.2. *Let feedback* L^- *be continuous on* E^+. *Then the regularized shifting feedback is closed and convex valued and upper semicontinuous.*

Proof. Observing (4.1), we easily see that the regularized shifting feedback U^{rs} is closed and convex valued. We must prove that U^{rs} is upper semicontinuous. Let

$$D^+ = \{(t,x) \in (0,\infty) \times R^n : |Fx - tb| \geq \rho(t)\},$$
$$D^- = \{(t,x) \in (0,\infty) \times R^n : |Fx - tb| \leq \rho(t)\},$$
$$D_0^+ = D^+ \cup (\{0\} \times R^n),$$
$$D_0^- = D^- \cup (\{0\} \times R^n).$$

Obviously D_0^+ and D_0^- are closed, and $D_0^+ \cup D_0^- = R_+ \times R^n$. In view of Lemma 2.3 it is sufficient to prove that U^{rs} is upper semicontinuous on each of these sets. Note that $U^{rs}(t,x) \subset Q(t,x)$ and $U^{rs}(0,x) = Q(0,x)$ (see (4.1)). Since Q is continuous, U^{rs} is upper semicontinuous on $\{0\} \times R^n$. It remains to show that U^{rs} is upper semicontinuous on D^+ and D^-. By assumption L^- is continuous on D^+. Then by Lemma 2.2 the shifting feedback U^s is upper semicontinuous on D^+. On the other hand, U^{rs} and U^s coincide on D^+ (see (4.1)). Thus U^{rs} is upper semicontinuous on D^+. Take arbitrary $(t_*, x_*) \in D^-$ and show that U^{rs} is upper semicontinuous at (t_*, x_*). Let $Fx_* \neq bt_*$. Feedback L^- is continuous at (t_*, x_*). Hence by Lemma 2.2 U^s is upper semicontinuous at (t_*, x_*). By Lemma 3.1 Q^0 is upper semicontinuous at (t_*, x_*). Observe formula (4.1) for $U^{rs}(t,x)$. So far as $\omega(\cdot)$ is continuous, and U^s and Q^0 are upper semicontinuous at (t_*, x_*), U^{rs} is upper semicontinuous at (t_*, x_*). Let $Fx_* = bt_*$. Now formula (4.1) for $U^{rs}(t,x)$ and the facts that Q^0 is upper semicontinuous at (t_*, x_*) and $\omega(t,x) \to 1$ as $(t,x) \to (t_*, x_*)$ yield that $U^{rs}(t,x)$ lies in an arbitrary neighborhood of $U^{rs}(t_*, x_*) = Q^0(t_*, x_*)$ provided (t,x) is sufficiently close to (t_*, x_*). In other words, U^{rs} is upper semicontinuous at (t_*, x_*). We have proved that U^{rs} is upper semicontinuous at every point in D^-. □

A key property of the trajectories under the regularized shifting feedback is as follows.

Lemma 4.3. *Let $x(\cdot)$ be a trajectory under the regularized shifting feedback. Then for all $t > 0$*

$$J\left(\frac{x(t)}{t}\right) \leq J^0, \tag{4.4}$$

$$\left| F\frac{x(t)}{t} - b \right| \leq \frac{\rho(t)}{t}. \tag{4.5}$$

Proof. Take a $t \geq 0$ such that $\dot{x}(t) \in U^{rs}(t, x(t))$. By (4.1) $\dot{x}(t) = (1 - \omega(t,x(t)))u_1(t) + \omega(t,x(t))u_2(t)$, where $u_1(t) \in U^s(t,x(t))$ and $u_2(t) \in Q^0(t,x(t))$. By the definition of $Q^0(t,x(t))$ (see (3.2)), $J(u_2(t)) \leq J^0$. The definition of $U^s(t,x(t))$ (see (2.4)) and the fact that $Q(t,x(t))$ intersects X^0 imply that $J(u_1(t)) \leq J^0$. Then the convexity of J and the inclusion $\omega(t,x(t)) \in [0,1]$ yield

$$J(\dot{x}(t)) \leq (1 - \omega(t,x(t)))J(u_1(t)) + \omega(t,x(t))J(u_1(t)) \leq J^0.$$

We have proved that $J(\dot{x}(t)) \leq J^0$ for almost all $t \geq 0$. Now using the convexity of J, we get (4.4) for all $t > 0$ (a detailed argument is given in (3.9)). Let us prove that (4.5) holds for all $t > 0$. Suppose the contrary, i.e., $\epsilon(t^*) > \rho(t^*)$ for some $t^* \geq 0$, where $\epsilon(t) = |Fx(t) - bt|$. Note that $\epsilon(0) = 0 = \rho(0)$. Hence $t^* > 0$, and there is a $t_* \in (0, t^*)$ such that $\epsilon(t_*) < \epsilon(t^*)$ and $\epsilon(t) > \rho(t)$ for all $t \in [t_*, t^*]$. By the definition of the pasting function $\omega(\cdot)$ we have $\omega(t,x(t)) = 0$ for $t \in [t_*, t^*]$. Therefore $U^{rs}(t,x(t)) = U^s(t,x(t))$ for $t \in [t_*, t^*]$. Hence $\dot{x}(t) \in U^s(t,x(t))$ for almost all $t \in [t_*, t^*]$. Since $U^s(t,x(t)) \subset L^-(t,x(t))$ (see (2.4)), $d\epsilon^2(t)/dt = 2(Fx(t) - bt)^T(F\dot{x}(t) - b) \leq 0$ for almost all $t \in [t_*, t^*]$. Thus $\epsilon(\cdot)$ is nonincreasing on $[t_*, t^*]$, which is not possible, since by supposition $\epsilon(t_*) < \epsilon(t^*)$. The obtained contradiction proves that (4.5) holds for all $t > 0$. □

Theorem 4.1. *Let feedback L^- be continuous on E^+. Then there exists a trajectory under the regularized shifting feedback, and every such trajectory is solution abandoning.*

Proof. By Lemma 4.2 the regularized shifting feedback U^{rs} is upper semicontinuous. Obviously, it is bounded. These properties imply the existence of a trajectory under U^{rs} (see [14, Theorem 4, p. 101]). Let $x(\cdot)$ be a trajectory under the regularized shifting feedback. By Lemma 4.3 the estimates (4.4) and (4.5) hold for all $t > 0$. Estimate (4.5) and the fact that $\rho(\cdot)$ satisfies (4.2) imply that $|Fx(t)/t - b| \to 0$ as $t \to +0$. The latter convergence and the inclusion $x(t)/t \in M$ holding for all $t > 0$ (Lemma 2.1) yield that the distance from $x(t)/t$ to the feasible set in problem (2.1) goes to zero as $t \to +0$. Then in view of (4.4), $\lim_{t\to+0} \operatorname{dist}(x(t)/t, X^0) = 0$, i.e., trajectory $x(\cdot)$ is solution abandoning. □

Lemma 4.3 provides additional information on a solution-abandoning trajectory $x(\cdot)$ under the regularized shifting feedback. In particular, we see that as $t \to +0$, values $J(x(t)/t)$ converge to the optimal value J^0 from below.

5. Solution-abandoning dynamics: Example. Here we give an example of a solution-abandoning trajectory under the regularized shifting feedback.

Consider the problem of finding the projection of a vector $z \in R^n$ onto the hyperplane H orthogonal to a vector $q \in R^n$. This problem is represented in the form (2.1), where $J(x) = |x - z|^2$, $F = q^T$, and M is a closed ball centered at zero and containing z. We assume that $q^T z < 0$ and denote by x^0 the projection of z onto H, i.e., the solution of problem (2.1). Set $Q(t, x) = M$. Note that the zero element is feasible in problem (2.1) and lies in the interior of $Q(t, x)$. Therefore by Lemma 4.1 feedback L^- is continuous on E^+. Hence by Theorem 4.1 there exists a trajectory under the regularized shifting feedback U^{rs}, and every such trajectory is solution abandoning. Let us construct a trajectory under U^{rs}. The shifting feedback U^s (2.4) has the form

$$U^s(t,x) = \begin{cases} \{z\}, & q^T x > 0, \\ \{x^0\}, & q^T x \le 0. \end{cases}$$

We have $Q^0(t, x) = \{x^0\}$ (see (3.2)). Hence the regularized shifting feedback U^{rs} (4.1) is given by

$$U^{rs}(t,x) = \begin{cases} \{u^{rs}(t,x)\}, & t > 0, \\ M, & t = 0, \end{cases}$$

where

$$u^{rs}(t,x) = \begin{cases} z, & q^T x > 0, \\ (1 - \omega(t,x))x^0 + \omega(t,x)z, & -\rho(t) < q^T x \le 0, \\ x^0, & q^T x \le -\rho(t). \end{cases}$$

We take $\rho(t) = t^2$ for the barrier function, and $\omega(t, x) = \max\{0, (1 - |q^T x|)/t^2\}$ for the pasting function. Then a trajectory under U^{rs} is described by the ODE

$$\dot{x}(t) = x^0 + \zeta(t, q^T x(t))(z - x^0), \quad x(0) = 0, \tag{5.1}$$

where

$$\zeta(t,y) = \begin{cases} 1, & y \ge 0, \\ 1 + \frac{y}{t^2}, & -t^2 < y < 0, \\ 0, & y \le -t^2. \end{cases}$$

Let $x(\cdot)$ be a solution of (5.1). Scalar multiplying (5.1) by q, we find that $y(t) = q^T x(t)$ solves

$$\dot{y}(t) = q^T x^0 + \zeta(t, y(t)) q^T (z - x^0), \quad y(0) = 0,$$

or, as long as $q^T x^0 = 0$,

$$\dot{y}(t) = -a\zeta(t, y(t)), \quad y(0) = 0, \tag{5.2}$$

where $a = -q^T z > 0$. The right-hand side in (5.2) is decreasing in the state variable. Hence $y(\cdot)$ is a unique solution of (5.2). We can easily verify that $y(\cdot)$ solves the linear ODE

$$\dot{y}(t) = -a\left(1 + \frac{y(t)}{t^2}\right), \quad y(0) = 0,$$

and is given by

$$y(t) = -a\left(\int_{1/t}^{\infty} \frac{e^{-a\tau}}{\tau^2} d\tau\right) e^{-a/t}$$

for $t > 0$. Obviously $y(t) \leq 0$. Also, we have

$$-y(t) \leq \frac{1}{(1/t)^2} a \left(\int_{1/t}^{\infty} e^{-a\tau} d\tau\right) e^{-a/t} = at^2 \int_0^{\infty} e^{-a\tau} d\tau = t^2.$$

Thus

$$-t^2 \leq y(t) \leq 0. \tag{5.3}$$

Coming back to (5.1) and taking into account (5.2), we find that $x(\cdot)$ solves the equation

$$\dot{x}(t) = x^0 - \frac{\dot{y}(t)}{a}(z - x^0), \quad x(0) = 0.$$

Hence trajectory $x(\cdot)$ is unique and given by

$$x(t) = x^0 t - \frac{y(t)}{a}(z - x^0).$$

Owing to (5.3) we have

$$\left|\frac{x(t)}{t} - x^0\right| \leq \frac{t}{a}|z - x^0|. \tag{5.4}$$

Thus $x(t)/t$ converges to x^0, the solution of problem (2.1), as $t \to +0$. We found a formula for $x(\cdot)$, a (single) trajectory under the regularized shifting feedback, and showed that $x(\cdot)$ is solution abandoning.

6. Solution-approaching dynamics. In this section we introduce a feedback whose trajectories approach the solution set X^0 as time goes to infinity.

We call a function $x(\cdot) : R_+ \mapsto R^n$ *solution approaching* if $\text{dist}(x(t)/t, X^0) \to 0$ as $t \to \infty$. Note that a solution-abandoning trajectory (see section 4) identifies a solution within an arbitrarily short initial time interval. A solution-approaching trajectory finds a solution in infinite time. Thus, solution-approaching trajectories are much slower "solution identifiers" than solution-abandoning trajectories. On the other hand, the structure of the ODEs for solution-approaching trajectories is usually simpler.

We define the *penalized shifting* feedback U^{ps} by

$$U^{ps}(t,x) = \text{argmin}\{2(Fx - tb)^T Fu + \alpha J(u) : u \in Q(t,x)\}, \tag{6.1}$$

where α is a positive *penalty parameter.* A key property of the trajectories under the penalized shifting feedback is as follows.

LEMMA 6.1. *Let $x(\cdot)$ be a trajectory under the penalized shifting feedback. Then for all $t \geq 0$*

$$\lambda(t) \leq 0, \tag{6.2}$$

where

$$\lambda(t) = |Fx(t) - tb|^2 + \alpha \int_0^t J(\dot{x}(\tau))d\tau - \alpha t J^0. \tag{6.3}$$

Proof. For almost all t we have

$$\dot{\lambda}(t) = 2(Fx(t) - tb)^T (F(\dot{x}(t) - b) + \alpha J(\dot{x}(t))) - \alpha J^0.$$

Letting $x^0(t) \in X^0 \cap Q(t, x(t))$ (note that by assumption $Q(t, x(t))$ intersects X^0) and observing that $Fx^0(t) - b = 0$ and $J^0 = J(x^0(t))$, we continue as follows:

$$\begin{aligned}\dot{\lambda}(t) = {} & [2(Fx(t) - tb)^T (F(\dot{x}(t) - b) + \alpha J(\dot{x}(t)))] \\ & -[2(Fx(t) - tb)^T (F(x^0(t) - b) + \alpha J(x^0(t)))].\end{aligned}$$

Now take into account that for almost all $t \geq 0$ we have $\dot{x}(t) \in U^{ps}(t, x(t))$. Owing to (6.1) and the fact that $x^0 \in Q(t, x(t))$ we get $\dot{\lambda}(t) \leq 0$ for almost all $t \geq 0$. Since $\lambda(\cdot)$ is absolutely continuous and $\lambda(0) = 0$, (6.2) holds for all $t \geq 0$. □

The next lemma is a simple corollary of Lemma 6.1.

LEMMA 6.2. *Let $x(\cdot)$ be a trajectory under the penalized shifting feedback. Then for all $t > 0$ we have* (4.4) *and*

$$\left| F\frac{x(t)}{t} - b \right|^2 \leq \frac{\alpha K}{t}, \tag{6.4}$$

where $K = 2\max\{|J(u)| : u \in M\}$.

Proof. Take arbitrary $t > 0$. By Lemma 6.1, $\lambda(t)$ defined by (6.3) satisfies (6.2). Dividing (6.2) by t^2, we get

$$\left| F\frac{x(t)}{t} - b \right|^2 + \frac{1}{t^2}\alpha \int_0^t J(\dot{x}(\tau))d\tau - \frac{1}{t^2}\alpha t J^0 \leq 0. \tag{6.5}$$

Hence

$$\frac{1}{t}\int_0^t J(\dot{x}(\tau))d\tau \le J^0,$$

and we obtain (4.4) due to the convexity of J. Noticing that the second and third terms in (6.5) do not exceed $\alpha K/2t$, we arrive at (6.4). □

Theorem 6.1. *There exists a trajectory under the penalized shifting feedback, and every such trajectory is solution approaching.*

Proof. Observing (6.1), we see that the penalized shifting feedback U^{ps} is closed and convex valued. By Lemma 2.2 U^{ps} is upper semicontinuous. Obviously, it is bounded. These properties imply the existence of a trajectory under U^{rs} (see [14, Theorem 4, p. 101]). Let $x(\cdot)$ be a trajectory under the regularized shifting feedback. By Lemma 6.2, for all $t > 0$ we have (4.4) and (6.4). The latter estimate implies that $|Fx(t)/t - b| \to 0$ as $t \to \infty$. Recall that by Lemma 2.1, $x(t)/t \in M$. Hence we conclude that the distance from $x(t)/t$ to the feasible set of problem (2.1) tends to zero as $t \to \infty$. Then in view of (4.4), $\lim_{t\to\infty} \operatorname{dist}(x(t)/t, X^0) = 0$, i.e., trajectory $x(\cdot)$ is solution approaching. □

Lemma 6.2 provides additional information on trajectories $x(\cdot)$ under the penalized shifting feedback. In particular, we see that, as $t \to \infty$, values $J(x(t)/t)$ converge to the optimal value J^0 from below.

It is easily seen that the penalized shifting feedback U^{ps} is single valued if J is strictly convex. For some typical problems, including problems of linear and quadratic programming, the feedback U^{ps} is specified explicitly. Consider, for instance, a problem of quadratic programming under linear and box constraints, i.e., let $J(x) = |x|^2$ and $M = \{x \in R^n : x_i^- \le x \le x_i^+,\ \ i = 1, \dots, n\}$. Set $Q(t,x) = M$. Then $u^{ps}(t,x)$, a single element in $U^{ps}(t,x)$, is represented as follows. Let $v(t,x)$ be a minimizer of $u \mapsto 2(Fx - tb)^T Fu + \alpha|u|^2$ in R^r, i.e.,

$$v(t,x) = -\frac{F^T(Fx - tb)}{\alpha}.$$

We have

$$u^{ps}(t,x)_i = \begin{cases} v(t,x)_i, & x_i^- \le v(t,x)_i \le x_i^+, \\ x_i^-, & v(t,x)_i < x_i^-, \\ x_i^+, & v(t,x)_i > x_i^+ \end{cases}$$

$$(i = 1, \dots, n).$$

A trajectory under feedback U^{ps} is described by the ODE

$$\dot{x}(t) = u^{ps}(t, x(t)), \quad x(0) = 0.$$

Its right-hand side is continuous and piecewise linear, with a finite number of linearity domains. Each linearity domain is characterized by a finite number of linear inequalities. A trajectory is unique and represented explicitly in each linearity domain. In order to build the trajectory, we must identify the order of visiting the linearity domains. In the next section we give an example of an analysis of this kind.

7. Solution-approaching dynamics: Example. Here we consider a particular problem of quadratic programming with linear and box constraints. Our goal is to find an explicit solution through the analytic design of a trajectory under the penalized shifting feedback. The trajectories are described by a piecewise-linear ODE. First, we show a trajectory locked in a single linearity domain. Then we change the parameters and build a trajectory visiting two linearity domains.

The problem under consideration is a discrete counterpart of a one-dimensional linear quadratic optimal control problem with state constraints:

$$\text{minimize } \sum_{i=1}^{N+1} y_i^2 + \sum_{i=1}^{N} s_i^2,$$

$$\begin{gathered} y_{i+1} = y_i + s_i \quad (i = 1, \dots, N), \\ y_i \in [y_i^-, y_i^+] \quad (i = 1, \dots, N+1), \\ s_i \in [s_i^-, s_i^+] \quad (i = 1, \dots, N). \end{gathered}$$

We set

$$x = (y_1, \dots, y_{N+1}, s_1, \dots, s_N)^T \tag{7.1}$$

and represent the problem in the form (2.1), where

$$J(x) = |x|^2, \quad M = \prod_{i=1}^{N+1} [y_i^-, y_i^+] \times \prod_{i=1}^{N} [s_i^-, s_i^+],$$

$$F = (F_1 \ F_2), \quad b = 0.$$

The $N \times (N+1)$ matrix F_1 is given by

$$F_1 = \begin{pmatrix} -1 & 1 & 0 & \dots & 0 & 0 & 0 \\ 0 & -1 & 1 & \dots & 0 & 0 & 0 \\ & & & \dots & & & \\ 0 & 0 & 0 & \dots & -1 & 1 & 0 \\ 0 & 0 & 0 & \dots & 0 & -1 & 1 \end{pmatrix},$$

and $F_2 = -I$, where I is an $N \times N$ identity matrix. We assume that the feasible set of problem (2.1) is nonempty. In our argument we use the matrix $F^T F$. We have

$$F^T F = \begin{pmatrix} G_{11} & G_{12} \\ G_{21} & G_{22} \end{pmatrix},$$

where the $(N+1) \times (N+1)$ matrix G_{11} is given by

$$G_{11} = \begin{pmatrix} 2 & -1 & 0 & \dots & 0 & 0 & 0 \\ -1 & 2 & -1 & \dots & 0 & 0 & 0 \\ 0 & -1 & 2 & \dots & 0 & 0 & 0 \\ & & & \dots & & & \\ 0 & 0 & 0 & \dots & 2 & -1 & 0 \\ 0 & 0 & 0 & \dots & -1 & 2 & -1 \\ 0 & 0 & 0 & \dots & 0 & -1 & 2 \end{pmatrix},$$

the $(N+1) \times N$ matrix G_{12} is given by

$$G_{12} = \begin{pmatrix} 1 & 0 & \dots & 0 & 0 \\ -1 & 1 & \dots & 0 & 0 \\ 0 & -1 & \dots & 0 & 0 \\ & & \dots & & \\ 0 & 0 & \dots & 1 & 0 \\ 0 & 0 & \dots & -1 & 1 \\ 0 & 0 & \dots & 0 & -1 \end{pmatrix},$$

and

$$G_{21} = G_{12}^T, \quad G_{22} = I.$$

We set $Q(t,x) = M$ and fix a penalty parameter $\alpha > 0$. The penalized shifting feedback U^{ps} is single valued. Let $u^{ps}(t,x)$ denote a single element in $U^{ps}(t,x)$. By (6.1), $u^{ps}(t,x)$ is a minimizer of $2(Fx)^T Fu + \alpha|u|^2$ in M. Note that $u^{ps}(t,x)$ does not depend on t; therefore we use the simpler notation $u^{ps}(x)$. Setting

$$u = (v_1, \dots, v_{N+1}, w_1, \dots, w_N)^T,$$

we get

$$2(Fx)^T Fu + \alpha|u|^2 = 2(F^T Fx)u + \alpha|u|^2$$

$$= 2\left(\sum_{i=1}^{N+1} f_i(x)v_i + \sum_{i=1}^{N} g_i(x)w_i\right) + \alpha \sum_{i=1}^{N+1} v_i^2 + \alpha \sum_{i=1}^{N} w_i^2, \tag{7.2}$$

where

$$(f_1(x), \dots, f_{N+1}(x), g_1(x), \dots, g_N(x)) = (F^T Fx)^T.$$

Using the form of $F^T F$ and (7.1), we obtain

$$\begin{gathered} f_1(x) = 2y_1 - y_2 + s_1, \\ f_i(x) = -y_{i-1} + 2y_i - y_{i+1} - s_{i-1} + s_i \ (i = 2, \dots, N), \\ f_{N+1}(x) = -y_N + 2y_{N+1} - s_N, \\ g_i(x) = y_i - y_{i+1} + s_i \ (i = 1, \dots, N). \end{gathered} \tag{7.3}$$

For

$$u^{ps}(x) = (v_1^{ps}(x), \dots, v_{N+1}^{ps}(x), w_1^{ps}(x), \dots, w_N^{ps}(x))^T,$$

a minimizer of (7.2) in M, we have

$$v_i^{ps}(x) = \begin{cases} -\frac{f_i(x)}{\alpha}, & y_i^- \le -\frac{f_i(x)}{\alpha} \le y_i^+, \\ y_i^-, & -\frac{f_i(x)}{\alpha} \le y_i^-, \\ y_i^+, & -\frac{f_i(x)}{\alpha} \ge y_i^+, \end{cases} \tag{7.4}$$

$$w_i^{ps}(x) = \begin{cases} -\frac{g_i(x)}{\alpha}, & s_i^- \le -\frac{g_i(x)}{\alpha}, \le s_i^+, \\ s_i^-, & -\frac{g_i(x)}{\alpha} \le s_i^-, \\ s_i^+, & -\frac{g_i(x)}{\alpha} \ge s_i^+. \end{cases} \tag{7.5}$$

A trajectory under the penalized shifting feedback U^{ps} is described by the ODE

$$\dot{x}(t) = u^{ps}(x(t)) \tag{7.6}$$

and the initial condition $x(0) = 0$. The right-hand side in (7.6) is linear in closed polyhedral domains. Each polyhedral linearity domain is defined by a combination of the linear inequalities given in (7.4) and (7.5). Within each of the linearity domains (7.6) is solved explicitly. We only need to identify the linearity domains visited by the trajectory. Here we restrict ourselves to the cases where the trajectory stays within a single linearity domain and crosses two linearity domains.

In what follows,

$$y_i^- > 0 \quad (i = 1, \dots, N+1), \quad s_i^- < 0 < s_i^+ \quad (i = 1, \dots, N). \tag{7.7}$$

Let $x(\cdot)$ be a trajectory under U^{ps}:

$$x(t) = (y_1(t), \dots, y_{N+1}(t), s_1(t), \dots, s_N(t))^T.$$

The initial conditions $y_i(0) = 0$, $s_i(0) = 0$, and assumptions (7.7) imply that for t close to the origin

$$-\frac{f_i(x(t))}{\alpha} < y_i^- \quad (i = 1, \dots, N+1), \tag{7.8}$$

$$s_i^- < -\frac{g_i(x(t))}{\alpha} < s_i^+ \quad (i = 1, \dots, N) \tag{7.9}$$

(see also (7.3)). These inequalities correspond to the linearity domain L_1, where

$$v_i^{ps}(x) = y_i^- \quad (i = 1, \dots, N+1),$$
$$w_i^{ps}(x) = -\frac{g_i(x)}{\alpha} \quad (i = 1, \dots, N)$$

(see (7.4) and (7.5)). Referring to the formula for $g_i(x)$ in (7.3), we find that

$$\dot{y}_i(t) = y_i^- \quad (i = 1, \dots, N+1), \tag{7.10}$$

$$\dot{s}_i(t) = -\frac{s_i(t)}{\alpha} + \frac{y_{i+1}(t) - y_i(t)}{\alpha} \quad (i = 1, \dots, N) \tag{7.11}$$

in a neighborhood of the origin. Explicitly,

$$y_i(t) = y_i^- t \quad (i = 1, \dots, N+1), \tag{7.12}$$

$$s_i(t) = (y_{i+1}^- - y_i^-)t - \alpha(y_{i+1}^- - y_i^-)(1 - e^{t/\alpha}) \quad (i = 1, \dots, N). \tag{7.13}$$

Case 1. Assume that

$$s_i^- \le y_{i+1}^- - y_i^- \le s_i^+ \quad (i = 1, \dots, N), \tag{7.14}$$

$$y_2^- - y_1^- \le y_1^-, \tag{7.15}$$

$$y_N^- - y_{N+1}^- \le 0, \tag{7.16}$$

$$y_{i-1}^- - 2y_i^- + y_{i+1}^- \le y_i^- \quad (i = 2, \dots, N). \tag{7.17}$$

Let us show that in this case $x(t)$ never escapes the linearity domain L_1, i.e., inequalities (7.8), (7.9) hold for all $t \ge 0$. Assume the contrary. Then $x(t)$ hits the boundary of L_1. Let ξ be the first hitting time, or, more accurately, the supremum of all $\tau \ge 0$ such that (7.8), (7.9) hold for all $t \in [0, \tau]$. We have either

$$-\frac{f_i(x(\xi))}{\alpha} = y_i^- \tag{7.18}$$

for some $i \in \{1, \dots, N+1\}$, or

$$-\frac{g_i(x(\xi))}{\alpha} \in \{s_i^-, s_i^+\} \tag{7.19}$$

for some $i \in \{1, \dots, N+1\}$. For all $t \in [0, \xi]$ the trajectory representation (7.12), (7.13) is valid. Substitute (7.12), (7.13) into the formulas for $f_i(x(t))$, $g_i(x(t))$ (see (7.3)). We get

$$-\frac{f_1(x(t))}{\alpha} = -\frac{y_1^- t}{\alpha} + (y_2^- - y_1^-)(1 - e^{-t/\alpha}), \tag{7.20}$$

$$-\frac{f_i(x(t))}{\alpha} = (y_{i-1}^- - 2y_i^- + y_{i+1}^-)(1 - e^{-t/\alpha}) \quad (i = 2, \dots, N), \tag{7.21}$$

$$-\frac{f_{N+1}(x(t))}{\alpha} = -\frac{y_{N+1}^- t}{\alpha} - (y_{N+1}^- - y_N^-)(1 - e^{-t/\alpha}), \tag{7.22}$$

$$-\frac{g_i(x(t))}{\alpha} = (y_{i+1}^- - y_i^-)(1 - e^{-t/\alpha}) \quad (i = 1, \dots, N) \tag{7.23}$$

for all $t \in [0, \xi]$. Estimate the right-hand sides using (7.15), (7.17), (7.7), (7.16), and (7.14). We obtain

$$-\frac{f_i(x(t))}{\alpha} < y_1^- \quad (i = 1, \dots, N+1),$$

$$-\frac{g_i(x(t))}{\alpha} \in (s_i^-, s_i^-) \quad (i = 1, \dots, N)$$

for all $t \in [0, \xi]$. Therefore (7.18) and (7.19) are violated. A contradiction proves that (7.8) and (7.9) hold true for all $t \ge 0$ and the trajectory representation (7.12), (7.13) is valid for all $t \ge 0$. Hence

$$\frac{y_i(t)}{t} = y_i^- \quad (i = 1, \dots, N+1),$$

$$\lim_{t \to \infty} \frac{s_i(t)}{t} = y_{i+1}^- - y_i^- \quad (i = 1, \dots, N).$$

Consequently

$$\lim_{t \to \infty} \frac{x(t)}{t} = x^0,$$

where

$$\begin{gathered} x^0 = (y_1^0, \dots , y_{N+1}^0, s_1^0, \dots , s_N^0)^T, \\ y_i^0 = y_i^- \quad (i = 1, \dots , N + 1), \\ s_i^0 = y_{i+1}^- - y_i^- \quad (i = 1, \dots , N). \end{gathered}$$

By Theorem 6.1 x^0 is a (unique) solution of problem (2.1).

Using the trajectory representation (7.12), (7.13), we can easily compute the discrepancies in constraints and objective values for the approximate solution $x(t)/t$. We have

$$\left| F\frac{x(t)}{t} \right| = \frac{\alpha}{t}(1 - e^{-t/\alpha}) \left(\sum_{i=1}^{N+1} (y_{i+1}^- - y_i^-)^2 \right)^{1/2},$$

$$J^0 - J\left(\frac{x(t)}{t}\right) = \frac{\alpha}{t}(1 - e^{-t/\alpha})[2 - (1 - e^{-t/\alpha})] \sum_{i=1}^{N+1} (y_{i+1}^- - y_i^-)^2.$$

The discrepancies vanish as $t \to \infty$. A simple analysis shows that discrepancy $J^0 - J(x(t)/t)$ is positive. This provides an explicit justification for estimate (4.4) given in Lemma 6.2.

Case 2. Let conditions (7.7), (7.14), (7.15), and (7.16) be again satisfied, and one of the inequalities (7.17) be violated. More accurately, instead of (7.17) we have

$$y_{i-1}^- - 2y_i^- + y_{i+1}^- \le y_i^- \quad (i = 2, \dots , N, \ i \ne k), \tag{7.24}$$

$$y_{k-1}^- - 2y_k^- + y_{k+1}^- > y_k^-, \tag{7.25}$$

where $2 \le k \le N$. Rough conditions sufficient for the fact that trajectory $x(\cdot)$ visits precisely two linearity domains also involve inequalities (7.49), (7.50), and (7.51) introduced later. (These inequalities require that y_k^+, the upper bound for variable y_k, is sufficiently large, and intervals $[s_{k-1}^-, s_{k-1}^+]$ and $[s_k^-, s_k^+]$ admissible for variables s_{k-1} and s_k are wide enough.)

As in Case 1, for t in a neighborhood of the origin we have inequalities (7.8) and (7.9) implying the explicit trajectory representation (7.12), (7.13) and formulas (7.20) through (7.23). Due to (7.25) the right-hand side in (7.21), where $i = k$, exceeds $y_k^-(1 - e^{-t/\alpha})$. Hence $-f_k(x(t))\alpha$ reaches y_k^-, i.e., $x(t)$ hits the boundary of the linearity domain L_1 at a finite time. Let ξ be the first hitting time defined as in Case 1. Arguing as in Case 1, we find that neither of the hitting conditions (7.18) with $i \ne k$ and (7.19) can hold. Therefore

$$-\frac{f_k(x(\xi))}{\alpha} = y_k^-, \tag{7.26}$$

$$-\frac{f_i(x(t))}{\alpha} < y_k^- \quad (t \in [0, \xi), \ i = 1, \dots , N + 1), \tag{7.27}$$

$$s_i^- < -\frac{g_i(x(t))}{\alpha} < s_i^+ \quad (t \in [0, \xi), \ i = 1, \dots , N). \tag{7.28}$$

Let us identify a linearity domain containing $x(t)$ after the hitting time ξ. According to (7.21), the left derivative of $f_k^*(\cdot) : t \mapsto f_k(x(t))$ at point ξ is given by $(y_{k-1}^- - 2y_k^- + y_{k-1}^-)e^{-\xi/\alpha}$. Assumption (7.25) shows that it is positive. Since $f_k(\cdot)$ (see (7.3)) and $x(\cdot)$ are continuously differentiable, $f_k^*(\cdot)$ is continuously differentiable as well, hence $\dot{f}_k^*(t)$ is positive for t in a right neighborhood of ξ. Due to (7.26), for these t we have

$$\frac{f_k(x(t))}{\alpha} > y_k^- . \tag{7.29}$$

On the other hand, (7.27) and (7.28) imply that for t in a right neighborhood of ξ,

$$-\frac{f_k(x(t))}{\alpha} < y_k^- \quad (i = 1, \dots , N + 1,\ i \neq k), \tag{7.30}$$

$$s_i^- < -\frac{g_i(x(t))}{\alpha} < s_i^+ \quad (i = 1, \dots , N). \tag{7.31}$$

Now (7.4) and (7.5) show that for t varying in a right neighborhood of ξ, point $x(t)$ moves within the linearity domain L_2, where the right-hand side of the ODE (7.6) is given by

$$v_i^{ps}(x) = y_i^- \quad (i = 1, \dots , N + 1,\ i \neq k), \tag{7.32}$$

$$v_k^{ps}(x) = \frac{f_k(x)}{\alpha}, \tag{7.33}$$

$$w_i^{ps}(x) = \frac{g_i(x)}{\alpha} \quad (i = 1, \dots , N). \tag{7.34}$$

Using formulas (7.3), we specify (7.6) as

$$\dot{y}_i(t) = y_i^- \quad (i = 1, \dots , N + 1,\ i \neq k), \tag{7.35}$$

$$\dot{y}_k(t) = \frac{y_{k-1}(t) - 2y_k(t) + y_{k+1}(t)}{\alpha} + \frac{s_{k-1}(t) + s_k(t)}{\alpha}, \tag{7.36}$$

$$\dot{s}_i(t) = -\frac{s_i(t)}{\alpha} + \frac{y_{i+1}(t) - y_i(t)}{\alpha} \quad (i = 1, \dots , N). \tag{7.37}$$

We see that the ODEs for $y_i(\cdot)$, where $i \neq k$, and $s_i(\cdot)$, where $i \neq k - 1, k$, do not differ from those in the linearity domain L_1 (see (7.10), (7.11)). Therefore for t close to ξ we have as in Case 1

$$y_i(t) = y_i^- t \quad (i = 1, \dots , N + 1,\ i \neq k), \tag{7.38}$$

$$\dot{s}_i(t) = -\frac{s_i(t)}{\alpha} + \frac{y_{i+1}(t) - y_i(t)}{\alpha} \quad (i = 1, \dots , N + 1,\ i \neq k - 1, k) \tag{7.39}$$

(see (7.12), (7.13)). Substitute (7.38) into (7.36), (7.37) for $i = k - 1, k$. We obtain a three-dimensional ODE for $y_k(\cdot)$, $s_{k-1}(\cdot)$, $s_k(\cdot)$. We can solve this ODE explicitly and find that the next representations hold in a right neighborhood of ξ:

$$\begin{aligned} y_k(t) = y_k^- &+ \frac{y_{k-1}^- + y_{k+1}^-}{3}(t - \xi) \\ &+ \frac{\alpha}{3}\left(y_k^- - \frac{y_{k-1}^- + y_{k+1}^-}{3}\right)(1 - e^{-3(t-\xi)/\alpha}), \end{aligned} \tag{7.40}$$

$$\begin{aligned} s_{k-1}(t) = {} & \left(\frac{y_{k-1}^- + y_{k+1}^-}{3} - y_{k-1}^-\right) t \\ & - \frac{\alpha}{6}\left(\frac{y_{k-1}^- + y_{k+1}^-}{3} - y_k^-\right)(1 - e^{-3(t-\xi)/\alpha}) \\ & + \alpha c_{k-1}\left(1 - e^{-(t-\xi)/\alpha}\right), \end{aligned} \tag{7.41}$$

$$\begin{aligned} s_k(t) = {} & \left(y_{k+1}^- - \frac{y_{k-1}^- + y_{k+1}^-}{3}\right) t \\ & + \frac{\alpha}{6}\left(\frac{y_{k-1}^- + y_{k+1}^-}{3} - y_k^-\right)(1 - e^{-3(t-\xi)/\alpha}) \\ & + \alpha c_k(1 - e^{-(t-\xi)/\alpha}). \end{aligned} \tag{7.42}$$

Here

$$c_{k-1} = (y_k^- - y_{k-1}^-)(1 - e^{-\xi/\alpha}) + \frac{y_k^- + y_{k-1}^- - y_{k+1}^-}{2},$$

$$c_k = (y_{k+1}^- - y_k^-)(1 - e^{-\xi/\alpha}) - \frac{y_k^- + y_{k-1}^- - y_{k+1}^-}{2}.$$

The differentiation yields that in a right neighborhood of ξ,

$$\dot y_k(t) = \phi_k(t), \quad \dot s_{k-1}(t) = \psi_{k-1}(t), \quad \dot s_k(t) = \psi_k(t),$$

where

$$\begin{aligned} \phi_k(t) = {} & \frac{y_{k-1}^- + y_{k+1}^-}{3} \\ & + \left(y_k^- - \frac{y_{k-1}^- + y_{k+1}^-}{3}\right) e^{-3(t-\xi)/\alpha}, \end{aligned} \tag{7.43}$$

$$\begin{aligned} \psi_{k-1}(t) = {} & \frac{y_{k-1}^- + y_{k+1}^-}{3} - y_{k-1}^- \\ & - \frac{1}{2}\left(y_k^- - \frac{y_{k-1}^- + y_{k+1}^-}{3}\right) e^{-3(t-\xi)/\alpha} \\ & + c_{k-1}e^{-(t-\xi)/\alpha}, \end{aligned} \tag{7.44}$$

$$\begin{aligned} \psi_k(t) = {} & y_{k+1}^- - \frac{y_{k-1}^- + y_{k+1}^-}{3} \\ & + \frac{1}{2}\left(y_k^- - \frac{y_{k-1}^- + y_{k+1}^-}{3}\right) e^{-3(t-\xi)/\alpha} \\ & + c_k e^{-(t-\xi)/\alpha}. \end{aligned} \tag{7.45}$$

If

$$y_k^- < \phi_k(t) < y_k^+, \tag{7.46}$$

$$s_{k-1}^- < \psi_{k-1}(t) < s_{k-1}^+, \tag{7.47}$$

$$s_k^- < \psi_k(t) < s_k^+ \tag{7.48}$$

for all $t > \xi$, then $x(t)$ lies in the linearity domain L_2 for all $t > \xi$, and consequently (7.40), (7.41), and (7.42) hold for all $t > \xi$. We can prove this by contradiction arguing as in Case 1. Let us specify the problem's parameters so as to guarantee (7.46), (7.47), (7.48) for all $t > \xi$. We start with (7.46). The second term in the right-hand side of (7.43) is negative for $t > \xi$ due to assumption (7.25). Hence the infimum and supremum of $\phi_k(t)$ in $[\xi, \infty)$ are achieved at ξ and infinity and are equal to y_k^- and $(y_{k-1}^- + y_{k+1}^-)/3$, respectively. Therefore

$$y_k^- < \phi_k(t) < \frac{y_{k-1}^- + y_{k+1}^-}{3}$$

for all $t > \xi$. We require

$$\frac{y_{k-1}^- + y_{k+1}^-}{3} \leq y_k^+ \tag{7.49}$$

and thus ensure (7.46) for all $t > \xi$.

The sum of the second and third terms on the right-hand side in (7.44) is estimated in absolute value by

$$\psi_{k-1}^* = \frac{1}{2}\left| y_k^- - \frac{y_{k-1}^- + y_{k+1}^-}{3} \right| + |y_k^- - y_{k-1}^-| + \frac{1}{2}|y_k^- + y_{k-1}^- - y_{k+1}^-|.$$

We guarantee (7.47) by assuming

$$s_{k-1}^- + \psi_{k-1}^* < \frac{y_{k-1}^- + y_{k+1}^-}{3} - y_{k-1}^- < s_{k-1}^+ - \psi_{k-1}^*. \tag{7.50}$$

Using (7.45), we similarly guarantee (7.48) by

$$s_k^- + \psi_k^* < y_{k+1}^- - \frac{y_{k-1}^- + y_{k+1}^-}{3} < s_k^+ - \psi_k^*; \tag{7.51}$$

here

$$\psi_k^* = \frac{1}{2}\left| y_k^- - \frac{y_{k-1}^- + y_{k+1}^-}{3} \right| + |y_{k+1}^- - y_k^-| + \frac{1}{2}|y_k^- + y_{k-1}^- - y_{k+1}^-|.$$

Thus assuming (7.49), (7.50), and (7.51), we have (7.40), (7.41), and (7.42) for all $t > \xi$. Hence

$$\lim_{t\to\infty} \frac{y_k(t)}{t} = \frac{y_{k-1}^- + y_{k+1}^-}{3},$$

$$\lim_{t\to\infty} \frac{s_{k-1}(t)}{t} = \frac{y_{k-1}^- + y_{k+1}^-}{3} - y_k^-,$$

$$\lim_{t\to\infty} \frac{s_k(t)}{t} = y_{k+1}^- - \frac{y_{k-1}^- + y_{k+1}^-}{3}.$$

The relations (7.35) and (7.37) show that $y_i(t)$ for $i \neq k$ and $s_i(t)$ for $i \neq k-1, k$ behave as in Case 1, i.e.,

$$\frac{y_i(t)}{t} = y_i^- \quad (i = 1, \ldots, N+1,\ i \neq k),$$

$$\lim_{t\to\infty} \frac{s_i(t)}{t} = y_{i+1}^- - y_i^- \quad (i = 1, \ldots, N,\ i \neq k-1, k).$$

Therefore

$$\lim_{t\to\infty} \frac{x(t)}{t} = x^0,$$

where

$$\begin{aligned} x^0 &= (y_1^0, \ldots, y_{N+1}^0, s_1^0, \ldots, s_N^0)^T, \\ y_i^0 &= y_i^- \quad (i = 1, \ldots, N+1,\ i \neq k), \\ y_k^0 &= \frac{y_{k-1}^- + y_{k+1}^-}{3}, \\ s_i^0 &= y_{i+1}^- - y_i^- \quad (i = 1, \ldots, N+1,\ i \neq k-1, k), \\ s_{k-1}^0 &= \frac{y_{k-1}^- + y_{k+1}^-}{3} - y_{k-1}^-, \\ s_k^0 &= y_{k+1}^- - \frac{y_{k-1}^- + y_{k+1}^-}{3}. \end{aligned}$$

By Theorem 6.1 x^0 is a (unique) solution of problem (2.1).

8. Discrete dynamics. In this section we consider discrete-time analogues of the shifting and penalized shifting trajectories. Here the feedback Q (see section 2) is not necessarily continuous.

Let (t_k) $(k = 1, 2, \ldots)$ be a sequence of positive instants increasing and convergent to infinity. We set

$$t_0 = 0, \quad \delta_k = t_{k+1} - t_k, \quad \tau_k = \sum_{i=0}^{k-1} \delta_i^2.$$

A *discrete-time trajectory under a feedback* U is defined to be a sequence $(x(t_k))$ in R^n satisfying $x(t_0) = 0$ and $x(x_{k+1}) \in x(t_k) + U(t_k, x(t_k))\delta_k$. Obviously, a discrete-time trajectory exists for every feedback. We can hardly expect a discrete-time trajectory to be solution tracking (see section 3) or solution abandoning (see section 4); each of these properties would require $x(t_1)/t_1$ to lie in the solution set or close to it, which is hardly possible.

We call a sequence $(x(t_k))$ in R^n *solution approaching* if $\mathrm{dist}(x(t_k), X^0) \to 0$ as $k \to \infty$. In what follows we assume that either

$$\lim_{k\to\infty} \frac{\tau_k}{t_k^2} = 0, \tag{8.1}$$

or

$$\lim_{k\to\infty} \frac{\tau_k}{t_k} = 0. \tag{8.2}$$

Since $t_k \to \infty$, (8.2) implies (8.1). Obviously (8.2) holds if the sequence (τ_k) is bounded, or, equivalently, the sum of the series $\delta_0^2 + \delta_1^2 + \cdots$ is finite, for instance, $\delta_k = 1/k$. If δ_k does not depend on k, $\delta_k = \delta$, then $\tau_k = \delta t_k$, and we have (8.1), while (8.2) is not valid.

THEOREM 8.1. *Let* (8.1) *be satisfied. Then every discrete-time trajectory under the shifting feedback is solution approaching.*

Proof. Let $(x(t_k))$ be a discrete-time trajectory under the shifting feedback U^s. We have $x(x_{k+1}) = x(t_k) + u(t_k)\delta$, where $u(t_k) \in U^s(t_k, x(t_k))$. By (2.4) $u(t_k) \in L^-(t, y_i)$, i.e., $(Fx(t_k) - t_k b)^T(Fu(t_k) - b) \le 0$. Hence

$$\begin{aligned}|Fx(t_{k+1}) - t_{k+1}b|^2 = {}&|Fx(t_k) - t_k b|^2\\ &+ 2(Fx(t_k) - t_k b)^T(Fu(t_k) - b)\delta_k + |Fu(t_k) - b|^2\delta_k^2\\ \le{}& |Fx(t_k) - t_k b|^2 + K\delta_k^2,\end{aligned}$$

where $K = \sup\{|Fu - b|^2 : u \in M\}$. So far as $Fx(t_0) - t_0 b = 0$, we obtain $|Fx(t_k) - t_k b|^2 \le K\tau_k$. Hence $|Fx(t_k/t_k) - b|^2 \le K\tau_k/t_k^2$. In view of (8.1), $\lim_{k\to\infty} |Fx(t_k/t_k) - b|^2 = 0$. Note that $x(t_k)/t_k \in M$. Therefore the sequence $(x(t_k)/t_k)$ converges to the feasible set of problem (2.1) (more accurately, the distance from $x(t_k)/t_k$ to the feasible set of problem (2.1) goes to zero as $k \to \infty$). By assumption $Q(t, x(t_k)) \cap X^0$ is nonempty. For $x_k^0 \in Q(t, x(t_k)) \cap X^0$ we have $(Fy_i - tb)^T(Fx_k^0 - b) = 0$. Hence $x_k^0 \in X^0 \cap L^-(t, x(t_k))$. Since $u(t_k) \in U^s(t_k, x(t_k))$, it holds that $J(u(t_k)) \le J(x_k^0) = J^0$. Using the convexity of J, we get

$$J\left(\frac{x(t_k)}{t_k}\right) \le \frac{1}{t_k}\sum_{i=0}^{k-1} J(u(t_k))\delta_k \le \frac{1}{t_k}\left(\sum_{i=0}^{k-1}\delta_k\right) J^0 = J^0.$$

Hence the sequence $(x(t_k)/t_k)$ (convergent to the feasible set of problem (2.1)) converges to the solution set X^0, and $\mathrm{dist}(x(t_k), X^0) \to 0$ as $k \to \infty$. □

THEOREM 8.2. *Let* (8.2) *be satisfied. Then every discrete-time trajectory under the penalized shifting feedback is solution approaching.*

Proof. Let $(x(t_k))$ be a discrete-time trajectory under the penalized shifting feedback U^{ps}, i.e., $x(x_{k+1}) = x(t_k) + u(t_k)\delta$, where $u(t_k) \in U^{ps}(t_k, x(t_k))$. Let

$$\lambda_k = |Fx(t_k) - t_k b|^2 + \alpha\sum_{i=0}^{k-1} J(u(t_k))\delta_k - \alpha t_k J^0.$$

Obviously,

$$\lambda_{k+1} - \lambda_k \le 2(Fx(t_k) - t_k b)^T(Fu(t_k) - b)\delta_k + K\delta_k^2 + \alpha J(u(t_k))\delta_k - \alpha J^0\delta_k,$$

where $K = \sup\{|Fu - b|^2 : u \in M\}$. For $x_k^0 \in Q(t, x(t_k)) \cap X^0$ we have $Fx_k^0 - b = 0$ and $J^0 = J(x^0(t))$. Therefore

$$\begin{aligned}\lambda_{k+1} - \lambda_k \le{} & [2(Fx(t_k) - t_k b)^T (Fu(t_k) - b) + \alpha J(u(t_k))]\delta_k \\ & - [2(Fx(t_k) - t_k b)^T (Fx_k^0 - b) + \alpha J^0]\delta_k + K\delta_k^2.\end{aligned}$$

The inclusion $u(t_k) \in U^{ps}(t_k, x(t_k))$ implies that the sum of the first two terms on the right is nonpositive. Thus $\lambda_{k+1} - \lambda_k \le K\delta_k^2$. Since $\lambda_0 = 0$, we have $\lambda_k \le K\tau_k$. Dividing by t_k^2, we get

$$\left| F\frac{x(t_k)}{t_k} - b \right|^2 \le -\alpha \frac{1}{t_k^2} \left(\sum_{i=0}^{k-1} J(u(t_k))\delta_k - t_k J^0 \right) + K\frac{\tau_k}{t_k^2}.$$

The right-hand side goes to zero as $k \to \infty$. That follows from (8.2) and the fact that J is bounded on M. Therefore the sequence $(x(t_k)/t_k)$ converges to the feasible set of problem (2.1). Now divide the inequality $\lambda_k \le K\tau_k$ by t_k. We obtain

$$\alpha \left(\frac{1}{t_k} \sum_{i=0}^{k-1} J(u(t_k))\delta_k - J^0 \right) \le K\frac{\tau_k}{t_k} - \frac{1}{t_k}|Fx(t_k) - b|^2 \le K\frac{\tau_k}{t_k}.$$

By (8.2) the right-hand side goes to zero as $k \to \infty$, and we have

$$\limsup_{k\to\infty} \frac{1}{t_k} \sum_{i=0}^{k-1} J(u(t_k))\delta_k \le J^0.$$

By the convexity of J

$$J\left(\frac{x(t_k)}{t_k} \right) \le \frac{1}{t_k} \sum_{i=0}^{k-1} J(u(t_k))\delta_k.$$

Therefore $\limsup_{k\to\infty} J(x(t_k)/t_k) \le J^0$. Since $(x(t_k)/t_k)$ converges to the feasible set of problem (2.1), it converges to the solution set X^0, and $\operatorname{dist}(x(t_k), X^0) \to 0$ as $k \to \infty$. □

SECOND-ORDER CONDITIONS FOR OPTIMIZATION PROBLEMS WITH CONSTRAINTS[*]

JEAN-PAUL PENOT[†]

Abstract. Using a projective approach, new necessary conditions and new sufficient conditions for optimization problems with explicit or implicit constraints are examined. They are compared to previous ones. A particular emphasis is given to mathematical programming problems with nonpolyhedral constraints. This case occurs in particular when the constraints are defined in functional spaces.

Key words. Lagrangian, mathematical programming, multiplier, optimality conditions, projective tangent set, second-order conditions

1. Introduction.

Devising efficient optimality conditions is an important objective when dealing with optimization problems. Therefore the literature on the subject is rich. (See [11], [15], [25], [29], [30], [41] for recent contributions.) Structured problems, such as mathematical programming problems, optimal control problems, continuous time problems, and semi-infinite programming problems, require a particular attention because the constraints are not necessarily defined by a finite number of scalar functions. This lack of polyhedrality causes a gap between necessary conditions and sufficient conditions, (see, for instance, [24], [28]). Moreover, the conditions cannot be given the simple and aesthetic form of the cases in which the constraints are polyhedral, as in [3], [4], [7], [17]–[19], and [23], for instance.

In [37] we reduced this gap to an acceptable extent: when the decision space is finite dimensional, the sufficient condition differs from the necessary condition by the replacement of an inequality by a strict inequality. As the unconstrained case shows, this difference is unavoidable. However, the second-order conditions of [37] are complex, and so are the conditions of [20], [27], and [31]. It is the purpose of the present work to present more handy conditions inspired by [11] and to compare them with recent proposals. It appears that the new conditions are not as selective as the previous ones: the sufficient (resp., the necessary) condition is a consequence of the sufficient (resp., necessary) condition of [37]. However, the new necessary condition is close to the sufficient condition, and such a fact is rather satisfactory.

For simplicity, we limit our study to the second-order case and we do not insist on the projective aspect of the tangent sets we deal with, which is just pointed out in section 2, although it is probably the main novelty here.

The optimality conditions are presented in section 3 along with a comparison with the results of [37]. Mathematical programming problems are considered in section 4. We devote section 5 to comparisons with recent works which came to our attention after the original version of the present paper was submitted. We are especially indebted to the referees for references [12] and [26]. We hope the clarifications we give

will provide hints for obtaining concrete and convenient conditions in the specially structured cases mentioned above.

2. Projective tangent sets. In what follows, we denote by $\mathbb{P}$ (resp., $\mathbb{R}_+$) the set of positive (resp., nonnegative) real numbers. The closed ball with center x and radius r in a normed vector space (n.v.s.) X is denoted by $B(x,r)$. The closure of a subset F of X is denoted by cl$F$. Recall that the projective space $P\left(X\right)$ associated with a vector space X is the set of equivalence classes of pairs $(v,r)\in X\times\mathbb{R}_+$ for the relation

$$(v,r)\sim(v',r')\ \text{ if }\ (v',r')=(tv,tr)\ \text{ for some } t>0.$$

Obviously, $P\left(X\right)$ can be identified with the union

$$P\left(X\right)=X_1\cup X_0,$$

where X_1 (resp., X_0) is the image of $X\times\{1\}$ (resp., $X\times\{0\}$) under the canonical mapping $p:X\times\mathbb{R}_+\to P(X)$. We write $[v,r]$ to denote $p\left(v,r\right)$ and we call p the projective projection. If Y is another vector space and if $h:X\to Y$ is a positively homogeneous mapping, then h induces a mapping $h^P:P\left(X\right)\to P\left(Y\right)$ satisfying $h^P\left(p\left(x,r\right)\right)=p\left(h\left(x\right),r\right)$ for each $(x,r)\in X\times\mathbb{R}_+$, hence $h^P\left(X_1\right)\subset Y_1$, $h^P\left(X_0\right)\subset Y_0$, and if $h^P([x,1])=[y,1]$, then $h^P([x,0])=[y,0]$. Conversely, any mapping $\widehat{h}:P\left(X\right)\to P\left(Y\right)$ satisfying these conditions is the mapping h^P associated with some positively homogeneous map $h:X\to Y$.

Definition 1. *Given an integer $k\geq 2$, a subset F of an n.v.s. X, $x\in$ cl F, $v_1,\ldots,v_{k-1}\in X$, the projective tangent set of order k to F at $(x,v_1,\ldots v_{k-1})$ is the image $PT^k\left(F,x,v_1,\ldots,v_{k-1}\right)$ by the projective projection p of the set $\widehat{T}^k\left(F,x,v_1,\ldots,v_{k-1}\right)$ of pairs $(w,r)\in X\times\mathbb{R}_+$ such that there exist sequences $\left(t_n\right)$, $\left(r_n\right)$ in $\mathbb{P}$ with limits 0 and r, resp., $\left(w_n\right)\overset{\sigma}{\to}w$ (weak convergence) such that $\left(r_n^{-1}t_n\right)\to 0$ and*

$$x_n:=x+t_nv_1+\frac{t_n^2}{2}v_2+\cdots+\frac{t_n^{k-1}}{(k-1)!}v_{k-1}+\frac{t_n^k}{k!}\frac{w_n}{r_n}\in F$$

for each n.

The preceding definition has been inspired by a notion presented in [11]; it is closely related to two notions given in [26]. A precise comparison will be given in the last section of the paper. Several variants are possible. For instance, one can take strong convergence instead of weak convergence in what precedes, or weak* convergence if X is a dual space. One could also use nets (or, rather, bounded nets). Also for some purposes, it would be possible to replace the condition $\left(r_n^{-1}t_n\right)\to 0$ by the weaker condition $\left(r_n^{-1}t_nw_n\right)\to 0$. Clearly, by its very definition, the weak tangent set of order k to F at $(x,v_1,\ldots,v_{k-1})$ (also denoted by $F^k\left(x,v_1,\ldots,v_{k-1}\right)$),

$$T^k\left(F,x,v_1,\ldots,v_{k-1}\right)=\limsup_{t\downarrow 0}k!t^{-k}\left(F-x-tv_1\cdots-\frac{t^{k-1}}{(k-1)!}v_{k-1}\right)$$

coincides with the set $F_1^k\left(x,v_1,\ldots,v_{k-1}\right)$, where

$$F_r^k\left(x,v_1,\ldots,v_{k-1}\right):=\left\{w\in X:(w,r)\in\widehat{T}^k\left(F,x,v_1,\ldots,v_{k-1}\right)\right\}.$$

Here the limit sup is the sequential limit sup with respect to the weak topology.

It may be useful to split the set $PT^2(F,x,v)$ into two parts.. We observe that this set is the union of $p\left(F^2(x,v)\times\{1\}\right)$ and $p\left(F_0^2(x,v)\times\{0\}\right)$, where

$$F^2(x,v)=\left\{w\in X:\exists(t_n)\searrow 0,\exists(w_n)\xrightarrow{\sigma}w,\ x+t_nv+\frac{1}{2}t_n^2w_n\in F\ \ \forall n\in\mathbb{N}\right\}$$

is the familiar (weak upper) *second-order tangent set* to F at (x,v) and

$$F_0^2(x,v)=\Big\{w\in X:\exists(t_n)\downarrow 0,\exists(r_n)\downarrow 0,\exists(w_n)\xrightarrow{\sigma}w,\left(r_n^{-1}t_n\right)\to 0,$$
$$x+t_nv+\frac{1}{2}r_n^{-1}t_n^2w_n\in F\ \ \forall n\Big\}$$

is what will be called the *asymptotic second-order tangent cone* to F at (x,v).

Similar decompositions hold for higher-order projective tangent sets. For the sake of simplicity, in what follows we focus our attention on the second-order case only.

Although the second-order tangent set to a smooth subset may be empty, as the example of

$$F:=\left\{(r,s)\in\mathbb{R}^2:r^2=s^3\right\},\ x=(0,0),\ v:=(1,0)$$

shows, the following result asserts that the projective tangent set of order two in the reflexive case is always nonempty.

PROPOSITION 2.1. *Let $v\in F'(x):=T(F,x)$, where F is an arbitrary subset of the reflexive Banach space X and $x\in\operatorname{cl}F$. Then either $F^2(x,v)$ or $F_0^2(x,v)$ is nonempty.*

Proof. By assumption, there exists a sequence $(t_n)\searrow 0$ such that the sequence (s_n) given by $s_n:=t_n^{-1}d(x+t_nv,F)$ converges to 0. Since $0\in F^2(x,v)$ if $s_n=0$ for infinitely many n, we may assume $s_n>0$ and set $r_n=\frac{1}{2}s_n^{-1}t_n$, $w_n=s_n^{-1}t_n^{-1}(z_n-x-t_nv)$, where $z_n\in F$ is such that $\|x+t_nv-z_n\|\leq 2s_nt_n$. Then $(r_n^{-1}t_n)=(2s_n)\to 0$ and

$$x+t_nv+\frac{1}{2}t_n^2r_n^{-1}w_n=z_n\in F.$$

Taking a subsequence if necessary, we may suppose $(r_n)\to r$ for some $r\in[0,\infty]$ and (w_n) has a weak limit w in $2B_X$. If $r=\infty$, setting $w_n'=r_n^{-1}w_n$, we get $(w_n')\to 0$ and $0\in F^2(x,v)$ (strong). If $r\in\mathbb{P}$ the same choice of (w_n') shows that $r^{-1}w\in F^2(x,v)$ (weak). Finally, if $r=0$ we have $w\in F_0^2(x,v)$. □

EXAMPLE 2.1. *Suppose F is the graph of a twice differentiable mapping $g:U\to V$ in $X=U\times V$, where U and V are n.v.s. Then, for $(u_0,v_0)\in F$, $(u,v)\in F'(u_0,v_0)$, $(w,z)\in X$, $r>0$, one has*

$$((w,z),r)\in\widehat{T}^2F((u_0,v_0),(u,v))$$

iff $z=g'(u_0)w+rg''(u_0)uu$, as an easy calculation shows. Since any submanifold of a normed vector space can be represented locally as a graph, this example applies in a variety of situations.

The following proposition shows the concept of projective tangent set is invariant under C^k-diffeomorphisms and thus can be extended to subsets of C^k-manifolds. We take $k=2$ for simplicity.

PROPOSITION 2.2. *Let $g:X\to Y$ be a mapping of class C^2 on an open subset X_0 of X, let B be a subset of X, $x\in X_0\cap\operatorname{cl}B$, and let C be a subset of Y with $g(B)\subset C$. Then for each $v\in X,(w,r)\in\widehat{T}^2(B,x,v)$ one has*

$$(g'(x)w+rg''(x)vv,r)\in\widehat{T}^2(C,g(x),g'(x)v).$$

Proof. By definition there exist sequences $(t_n) \searrow 0$, $(w_n, r_n) \to (w, r)$ such that $\{r_n\} \subset \mathbb{P}$, $\left(r_n^{-1} t_n\right) \to 0$, and $x_n := x + t_n v + 2^{-1} r_n^{-1} t_n^2 w_n \in B$ for each n. Then $g\left(x_n\right) \in C$, and since $(t_n v_n) \to 0$ strongly if $v_n := v + 2^{-1} r_n^{-1} t_n w_n$, for some $(y_n) \to 0$, one has

$$g\left(x_n\right) = g\left(x\right) + t_n g'\left(x\right) v + \frac{1}{2} r_n^{-1} t_n^2 \left(g'\left(x\right) w_n + r_n g''\left(x\right) vv\right) + t_n^2 y_n$$

in view of Taylor's expansion. Setting $z_n := g'\left(x\right) w_n + r_n g''\left(x\right) vv + 2 r_n y_n$ and observing that $(z_n) \xrightarrow{\sigma} z := g'\left(x\right) w + r g''\left(x\right) vv$ and that $\left(r_n^{-1} t_n\right) \to 0$, the result follows. □

The following property will be useful. For $r = 1$ it corresponds to a property similar to the one observed in [34], [13, Proposition 3.1].

Proposition 2.3. *Let C be a convex subset of X, and let $x \in C$, $v \in T\left(C, x\right)$. Then, for any $z \in T(T(C, x), v)$, $(w, r) \in \widehat{T}^2\left(C, x, v\right)$, one has*

$$(w + z, r) \in \widehat{T}^2\left(C, x, v\right).$$

Proof. By definition, $w \in F_r^2(x, v) := \left\{w \in X : (w, r) \in \widehat{T}^2\left(C, x, v\right)\right\}$, so that there exist sequences $(r_n) \to r$, $(t_n) \to 0_+$, $(w_n) \to w$ such that $\left(r_n^{-1} t_n\right) \to 0$, $r_n > 0$, and

$$x_n = x + t_n v + \frac{1}{2} r_n^{-1} t_n^2 w_n \in C$$

for each n. For any $y \in C$ and any $p, q \geq 0$ we have

$$\left(1 - \frac{1}{2} p r_n^{-1} t_n\right) x_n + \frac{1}{2} p r_n^{-1} t_n (x + q t_n (y - x)) \in C;$$

as $\left(r_n^{-1} t_n\right) \to 0$ we obtain $w + p(q(y - x) - v) \in F_r(x, v)$. As this set is closed, and as $\mathbb{R}_+(C - x)$ is dense in $T(C, x)$, we also have $w + p(T(C, x) - v) \subset F_r(x, v)$. Since $T(C, x)$ is convex, $\mathbb{R}_+(T(C, x) - v)$ is dense in $T(T(C, x), v)$ and we get $w + T(T(C, x), v) \subset F_r(x, v)$. □

Among the variants of Definition 1, the following one seems to be noticeable. We will see in section 5 that this variant is closely related to Definition 2.2 of [26].

Definition 2. *The second-order projective incident set to a subset F of X at (x, v) with $x \in F, v \in T(F, x)$ is the image by the projective projection of the set $\widehat{T}^{ii}(F, x, v)$ of $(w, r) \in X \times \mathbb{R}_+$ such that for any sequences $(t_n) \to 0_+$, $(r_n) \to r$ with $r_n > 0$, $(r_n^{-1} t_n) \to 0$, there exists a sequence $(w_n) \to w$ such that $x + t_n v + 2^{-1} r_n^{-1} t_n^2 w_n \in F$ for each n.*

Given $r \in \mathbb{R}_+$ we denote by $\widehat{T}^{ii}(F, x, v, r)$ the set of $w \in X$ such that $(w, r) \in \widehat{T}^{ii}(F, x, v)$, and we use the similar notation $\widehat{T}^2(F, x, v, r)$ when $\widehat{T}^{ii}(F, x, v)$ is replaced with $\widehat{T}^2(F, x, v)$.

Part of the interest of this notion stems from the following property, the proof of which follows easily from the definition.

Proposition 2.4. (a) *If F is convex, then $\widehat{T}^{ii}(F, x, v, r)$ is convex for each (x, v, r);*

(b) *if F is convex, then $(1 - \lambda)\widehat{T}^{ii}(F, x, v, r) + \lambda \widehat{T}^2(F, x, v, r) \subset \widehat{T}^2(F, x, v, r)$ for any $\lambda \in [0, 1]$;*

(c) $\widehat{T}^{ii}(F \times G, (x, y), (u, v), r) = \widehat{T}^{ii}(F, x, u, r) \times \widehat{T}^{ii}(G, y, v, r)$;

(d) $\widehat{T}^{ii}(F, x, u, r) \times \widehat{T}^2(G, y, v, r) \subset \widehat{T}^2(F \times G, (x, y), (u, v), r) \subset \widehat{T}^2(F, x, u, r) \times \widehat{T}^2(G, y, v, r)$.

Sequential concepts as in [21], [22], [37], and [38] can be devised for similar aims.

3. Optimality conditions. The following necessary optimality condition justifies the introduction of the projective tangent set of order two. The proof we present has been devised independently of the one in [12, Theorem 2]; however, results of this kind had been announced earlier by A. Cambini at a lecture in Marseille (see [11] for a partial account and section 5 for a comparison).

PROPOSITION 3.1. *Suppose $f : X \to \mathbb{R}$ is twice differentiable at $x \in F$ and attains a (local) minimum on $F \subset X$ at x. Then*

$$f'(x)\, v \geq 0 \text{ for each } v \in F'(x) = T(F,x),$$

and whenever $v \in F'(x) \cap \ker f'(x)$, one has

$$f'(x)\, w + r f''(x)\, vv \geq 0 \text{ for each } (w,r) \in \widehat{T}^2(F,x,v).$$

Clearly this last condition can be formulated on the second projective tangent space $PT^2(F,x,v)$.

Proof. Since for $g(\cdot) := f(\cdot) - f(x)$ we have $g(F) \subset \mathbb{R}_+$, the result follows from Proposition 2.2 and from the fact that for $y = 0$, $v = 0$ one has

$$\widehat{T}^2(\mathbb{R}_+, y, v) = \{(z,r) \in \mathbb{R} \times \mathbb{R}_+ : z \geq 0\}. \qquad \square$$

EXAMPLE 3.1. *Let $F = \mathbb{R} \times \{0\} \cup \{0\} \times \mathbb{R}$ in $X = \mathbb{R}^2$. Then $F'(0) = F$, and, as for $x = 0, v \in F$, the set $\widehat{T}^2(F,x,v)$ contains $(w,1)$, with $w = 0$, a necessary optimality condition for f on F at 0 is $f'(0) = 0$, $f''(0)\, vv \geq 0$ for each $v \in F$.* $\square$

It may be useful to split the condition of Proposition 3.1 into two parts, using the decomposition of $PT^2(F,x,v)$ we described above.

COROLLARY 3.2. *If $f : X \to \mathbb{R}$ is twice differentiable at $x \in F$ and attains a local minimum on F at x, then $f'(x)\, v \geq 0$ for each $v \in F'(x)$, and when $v \in F'(x) \cap \ker f'(x)$, one has*

$$f'(x)\, w + f''(x)\, vv \geq 0 \text{ for each } w \in F^2(x,v),$$
$$f'(x)\, w \geq 0 \text{ for each } w \in F_0^2(x,v).$$

The first condition is well known but the second one is new.

EXAMPLE 3.2. *Let $F = \left\{(r,s) \in \mathbb{R}^2 : s = \mid r \mid^{\alpha}\right\}$, where $\alpha \in]1,2[$. Then for $x = (0,0)$, $v = (1,0)$, the set $F^2(x,v)$ is empty but $F_0^2(x,v)$ contains $w = (0,1)$. Thus a necessary condition for $(0,0)$ to be a minimizer of f on F is $f'(0,0) = 0$. Such a condition can also be obtained from* [37, Theorem 1.2] *via a computation similar to the one in* [37, Example 1.4].

EXAMPLE 3.3. *Given a subset F of the space X, $x \in F$, $v \in X \backslash \{0\}$, given $0 < p < q$, let us denote by $T^{q/p}(F,x,v)$ the set of vectors w, such that for some sequences $(s_n) \to 0_+$, $(w_n) \to w$ one has $x + s_n^p v + s_n^q w_n \in F$ for each n. Then if $q > 2p$, one has $0 \in F^2(x,v)$ whenever $T^{q/p}(F,x,v)$ is nonempty, while for $q = 2p$ one has $F^2(x,v) = T^{q/p}(F,x,v)$; for $q < 2p$ and for $w \in T^{q/p}(F,x,v)$ one has $(w,0) \in \widehat{T}^2(F,x,v)$, as one can see by taking $(t_n) := (s_n^p)$, $(r_n) := (s_n^{2p-q})$. In the last case, a necessary condition for f to attain a local minimum on F at x is $f'(x)w \geq 0$ whenever $f'(x)v = 0$ and $w \in T^{q/p}(F,x,v)$. The relationships with the higher-order optimality conditions of* [14] *and* [15] *will be considered elsewhere.* $\square$

The preceding examples prompt us to clarify the relationships between Corollary 3.2 (which is equivalent to Proposition 3.1) and [37, Theorem 1.2].

PROPOSITION 3.3. *The necessary optimality condition of* [37]*:*

$$\frac{1}{2} f''(x)\, vv + \liminf_{(t,u) \to (0,v),\ t>0,\ x+tu \in F} f'(x) t^{-1}(u - v) \geq 0 \quad \forall v \in F'(x) \cap \ker f'(x)$$

implies the necessary condition of Corollary 3.2.

Proof. Let $v \in F'(x) \cap \ker f'(x)$. The condition $f''(x)vv + f'(x)w \geq 0$ for each $w \in F^2(x,v)$ is a consequence of [37, Theorem 1.2] by [37, Corollary 1.3]. Let us derive the condition $f'(x)w \geq 0$ for $w \in F_0^2(x,v)$. Suppose on the contrary that $f'(x)w < 0$ for some $w \in F_0^2(x,u)$. Then there exist sequences $(t_n) \downarrow 0$, $(r_n) \downarrow 0$, $(w_n) \xrightarrow{\sigma} w$ such that $\left(r_n^{-1}t_n\right) \downarrow 0$, $x_n := x + t_n v + (2r_n)^{-1} t_n^2 w_n \in F$ for each n. Setting $v_n := v + (2r_n)^{-1} t_n w_n$ we see that $(v_n) \to v$, $x + t_n v_n = x_n \in F$ and $f'(x)t_n^{-1}(v_n - v) = (2r_n)^{-1} f'(x)(w_n) \to -\infty$, which is a contradiction with our assumption. □

Although the necessary condition of Proposition 3.1 is not as strong as [37, Theorem 1.2], one can still associate to it a sufficient condition of the same type (see also [11] and [12, Theorem 2] for a closely related result).

Proposition 3.4. *If X is finite dimensional, if f is twice differentiable at $x \in F$, and if the following conditions hold, then x is a local strict minimizer of f on F:*

(a) $f'(x)v \geq 0$ *for each* $v \in F'(x)$;

(b) *if* $v \in F'(x) \cap \ker f'(x)$, $v \neq 0$, *then* $f'(x)w + rf''(x)vv > 0$ *for each* $(w,r) \in \widehat{T}^2(F,x,v) \setminus \{(0,0)\}$.

Proof. Suppose on the contrary there exists a sequence (x_n) of $F \setminus \{x\}$ with limit x such that $f(x_n) \leq f(x)$ for each $n \in \mathbb{N}$. Let $t_n := \|x_n - x\|$, $v_n := t_n^{-1}(x_n - x)$. Taking a subsequence if necessary, we may suppose (v_n) has a limit v with norm 1. Let $s_n := \|v_n - v\|$. When $s_n = 0$ for infinitely many n we get $0 \in F^2(x,v)$ and $f'(x)v = 0$ (by (a) and the inequality $t_n^{-1}(f(x+t_nv_n) - f(x)) \leq 0$), and $f''(x)vv \leq 0$, a contradiction, as we can take $(w,r) = (0,1)$ in (b). Thus we may suppose $s_n > 0$ for each n and assume that the sequence (r_n) given by $r_n := (2s_n)^{-1} t_n$ has a limit r in $\mathbb{R}_+ \cup \{\infty\}$, and the sequence $(w_n) := \left(s_n^{-1}(v_n - v)\right)$ has a limit w with norm 1. Then $\left(r_n^{-1}t_n\right) = (2s_n) \to 0$ and

$$x + t_n v + \frac{1}{2} r_n^{-1} t_n^2 w_n = x_n \in F \qquad \forall n.$$

Thus, when r is finite, we have $(w,r) \in \widehat{T}^2(F,x,v)$, and, since $f(A) \subset f(x) - \mathbb{R}_+$ for $A = \{x_n : n \in \mathbb{N}\}$, we obtain $f'(x)v \leq 0$, hence $f'(x)v = 0$, and

$$f'(x)w + rf''(x)vv \leq 0$$

by a computation similar to the one in Proposition 2.2. This is a contradiction, as $w \neq 0$.

When $r = \infty$, setting $r' = 1$, $r'_n = 1$, $w'_n = r_n^{-1} w_n$, we observe that $(w'_n) \to 0$ and $x + t_n v + \frac{1}{2} t_n^2 w'_n = x_n \in F$ for each n, so that $0 \in F^2(x,v)$ or $(w',r') \in \widehat{T}^2(F,x,v)$, and we get, as above, $f''(x)vv \leq 0$, which is a contradiction, since $(0,r') \in \widehat{T}^2(F,x,v)$, $v \neq 0$. □

The preceding sufficient condition is in fact a consequence of the sufficient condition of [37, Theorem 1.7], as the following result shows.

Proposition 3.5. *Suppose X is finite dimensional. If f is twice differentiable at $x \in F$ and $v \in F'(x) \cap \ker f'(x)$, $v \neq 0$, the condition*

(1) $$f'(x)w + rf''(x)vv > 0 \textit{ for each } (w,r) \in \widehat{T}^2(F,x,v) \setminus \{(0,0)\}$$

implies the condition

(2) $$\frac{1}{2} f''(x)vv + \liminf_{(t,u) \to (0,v),\ t>0,\ x+tu \in F} f'(x)t^{-1}(u-v) > 0 \ \ \forall v \in F'(0) \cap \ker f'(x).$$

Proof. Suppose on the contrary that the first condition holds and there exist sequences $(t_n) \to 0_+$, $(v_n) \to v$ such that $x + t_n v_n \in F$ for each n and

$$\frac{1}{2} f''(x)\, vv + f'(x)\, t_n^{-1}(v_n - v) \to c \leq 0.$$

Let $s_n = \|v_n - v\|$. If $s_n = 0$ for infinitely many n, we have $w := 0 \in F^2(x,v)$ and $\frac{1}{2} f''(x)\, vv = c \leq 0$, so that for $r = \frac{1}{2}$, $w = 0$, we get a contradiction with (1).

Thus, we may assume $s_n > 0$ for each n and that $(r_n) := \left(2^{-1} s_n^{-1} t_n\right)$ has a limit r in $\mathbb{R}_+ \cup \{\infty\}$ and $(w_n) := \left(s_n^{-1}(v_n - v)\right)$ has a limit $w \neq 0$. If $r = \infty$, setting $w'_n = 2 s_n t_n^{-1} w_n$, we see that $(w'_n) \to 0$, $x_n := x + t_n v + \frac{1}{2} t_n^2 w'_n = x + t_n v_n \in F$ for each n, hence $w' := 0 \in F^2(x,v)$, and, as $t_n^{-1}(v_n - v) = \frac{1}{2} w'_n$, we get $f'(x)\, 0 + \frac{1}{2} f''(x)\, vv = c \leq 0$, a contradiction with $(0,1) \in \widehat{T}^2(F,x,v)$. If $r < \infty$ we have

$$x_n := x + t_n v_n = x + t_n v + \frac{1}{2} r_n^{-1} t_n^2 w_n \in F$$

and $\left(r_n^{-1} t_n\right) = (2 s_n) \to 0$, so that $(w,r) \in \widehat{T}^2(F,x,v)$. Since

$$f'(x)\, w = \lim s_n^{-1} t_n f'(x)\, t_n^{-1}(v_n - v) = 2r\left(c - \frac{1}{2} f''(x)\, vv\right)$$

we get

$$f'(x)\, w + r f''(x)\, vv = 2rc \leq 0,$$

a contradiction. □

However, the implication shown in the preceding condition can be partly reversed.

PROPOSITION 3.6. *Suppose that f is twice differentiable at $x \in F$. Then, for each $v \in (F'(x) \setminus \{0\}) \cap \ker f'(x)$, the condition*

$$\liminf_{(t,u) \to (0,v),\ t>0,\ x+tu \in F} f'(x) t^{-1}(u - v) + \frac{1}{2} f''(x)\, vv > 0 \tag{3}$$

implies the condition

(4) $f'(x)\, w + r f''(x)\, vv > 0$ *for each* $(w,r) \in \widehat{T}^2(F,x,v)$ *with* $r \neq 0$.

Proof. Let $(w,r) \in \widehat{T}^2(F,x,v)$ with $r > 0$: there exist positive sequences $(t_n) \to 0$, $(r_n) \to r$, and a sequence $(w_n) \xrightarrow{\sigma} w$ such that $\left(r_n^{-1} t_n\right) \to 0$ and

$$x_n := x + t_n v + \frac{1}{2} r_n^{-1} t_n^2 w_n \in F$$

for each n. Let $v_n := t_n^{-1}(x_n - x) = v + \frac{1}{2} r_n^{-1} t_n w_n$, so that $(v_n) \to v$, $x + t_n v_n = x_n \in F$. By assumption, there exists some $c > 0$ such that, for n large enough, one has

$$\frac{1}{2} f''(x)\, vv + f'(x)\, t_n^{-1}(v_n - v) \geq c,$$

hence

$$\frac{1}{2} r_n f''(x)\, vv + \frac{1}{2} f'(x)\, w_n > c r_n > \frac{1}{2} c r > 0$$

as $r > 0$, and the result follows by taking limits. □

4. Application to mathematical programming. Let us consider in this section the mathematical programming problem

$$(\mathcal{M}) \quad \text{minimize } f\left(x\right) : x \in F := g^{-1}\left(C\right),$$

where $f : X \to \mathbb{R}$, $g : X \to Z$ are twice differentiable mappings, C is a closed convex subset of Z, and X and Z are Banach spaces. Such a formulation encompasses problems in which equality and inequality constraints are present.

We will need a series of preliminary results of some independent interest. The first one gives a characterization of the projective tangent set of order two to the feasible set F. It uses a condition of metric regularity introduced in [36]. Here, for $z \in Z$ we set $d(z, C) = \inf_{c \in C} \|z - c\|$ to denote the distance function to C, and we adopt a similar notation for subsets of X.

Proposition 4.1. *Suppose the following directional metric regularity condition is satisfied for $x \in X$, $v \in X$:*

(DMR) *there exists $\mu > 0$, $\rho > 0$ such that for $t \in (0, \rho)$, $u \in B\left(v, \rho\right)$ one has*

$$d\left(x + tu,\, g^{-1}\left(C\right)\right) \leq \mu\, d\left(g\left(x + tu\right), C\right).$$

Then, for $F = g^{-1}\left(C\right)$, one has

$$(w, r) \in \widehat{T}^2\left(F, x, v\right) \Leftrightarrow \left(g'\left(x\right)w + rg''\left(x\right)vv, r\right) \in \widehat{T}^2\left(C, g\left(x\right), g'\left(x\right)v\right).$$

Proof. In view of Proposition 2.2 it suffices to prove that $(w, r) \in \widehat{T}^2\left(F, x, v\right)$ whenever $\left(g'\left(x\right)w + rg''\left(x\right)vv, r\right) \in \widehat{T}^2\left(C, g\left(x\right), g'\left(x\right)v\right)$. Let $(r_n) \to r$, $(t_n) \to 0_+$, $(z_n) \to z := g'\left(x\right)w + rg''\left(x\right)vv$ be such that $\left(r_n^{-1}t_n\right) \to 0$, $r_n > 0$ and

$$g\left(x\right) + t_n g'\left(x\right)v + \frac{1}{2}r_n^{-1}t_n^2 z_n \in C$$

for each n. For n large enough we have $t_n \in (0, \rho)$, $u_n := v + 2^{-1}r_n^{-1}t_n w \in B\left(v, \rho\right)$, so that

$$\begin{aligned} d\left(x + t_n u_n, F\right) &\leq \mu\ d\left(g\left(x + t_n u_n\right), C\right) \\ &\leq \mu\ \left\|g\left(x + t_n u_n\right) - g\left(x\right) - t_n g'\left(x\right)v - 2^{-1}r_n^{-1}t_n^2 z_n\right\| \\ &\leq \frac{1}{2}r_n^{-1}t_n^2 \mu \left\|g'\left(x\right)w + r_n g''\left(x\right)vv - z_n\right\| + o\left(t_n^2\right). \end{aligned}$$

Since $(z_n) \to z$ we can find $x_n \in F$ such that $\left(r_n t_n^{-2}\left\|x + t_n u_n - x_n\right\|\right) \to 0$. Defining w_n by $x_n := x + t_n v + 2^{-1}r_n^{-1}t_n^2 w_n$ we get $(w_n) \to w$, so that $w \in \widehat{T}^2\left(F, x, v\right)$. □

Let us observe that condition (DMR) is a consequence of the following metric regularity condition:

(MR) there exist $\mu > 0$, $\delta > 0$ such that for each $x' \in B\left(x, \delta\right)$ one has

$$d\left(x', g^{-1}\left(C\right)\right) \leq \mu\, d\left(g\left(x'\right), C\right).$$

This condition is of more common use than the directional metric regularity condition (DMR). In turn, condition (MR) has been shown to be a consequence of the classical Mangasarian–Fromovitz qualification [28], [18] and of its extension to the infinite dimensional case in [40], [32], [6], [16], and [42], which can be written

$$(\mathrm{R^r}) \qquad g'\left(x\right)\left(X\right) - \mathbb{R}_+\left(C - g\left(x\right)\right) = Z.$$

When the interior int C of C is nonempty, it has been shown in [32] that the radial tangent cone $T^r(C,x) := \mathbb{R}_+(C - g(x))$ in the preceding condition can be replaced by the usual tangent cone $T(C, g(x)) = \mathrm{cl}(T^r(C, g(x)))$:

$$\text{(R)} \qquad g'(x)(X) - T(C, g(x)) = Z.$$

However, in general, condition (R) is weaker than condition (R^r) and does not imply (MR). We will use a second-order qualification condition which generalizes the Ben-Tal qualification condition [2]:

$$\text{(TR)} \qquad g'(x)(X) - T(T(C, g(x)), g'(x)v) = Z,$$

in which v is a given vector of X; it is still weaker than (R).

We will also need the following duality result.

LEMMA 4.2. *Let P and Q be closed convex cones of the Banach spaces X and Z, resp., and let $A : X \to Z$, $c : X \to \mathbb{R}$ be linear and continuous and such that for some $m \in \mathbb{R}, b \in Z$*

$$c(x) \geq m \text{ for each } x \in P \cap A^{-1}(b + Q).$$

Then, if $A(P) - Q = Z$, there exists $y \in Q^0$ such that for each $x \in P$

$$c(x) + \langle y, Ax - b\rangle \geq m.$$

Since P is a cone, the conclusion can be written $0 \in c+y\circ A+P^0$ and $\langle y, -b\rangle \geq m$. When $P = X$, we have $c + y \circ A = 0$. Taking $m = 0$, $b = 0$ we get a Farkas lemma:

$$-c \in (A^{-1}(Q) \cap P)^0 \Rightarrow \exists y \in Q^0 : -(c + y \circ A) \in P^0.$$

In what follows we say that $v \in X$ is a *critical vector* at x if $f'(x)v = 0$, $g'(x)v \in T(C, g(x))$, and we write $v \in K(x)$.

THEOREM 4.3. *Let x be a (local) solution to problem $(\mathcal{P})$. Suppose conditions* (DMR) *and* (TR) *are satisfied at x. Then, for each critical vector $v \in K(x)$, $v \neq 0$ and each $(z, r) \in \widehat{T}^2(C, g(x), g'(x)v)$ there exists some $y \in N(T(C, g(x)), g'(x)v)$ such that*

$$f'(x) + y \circ g'(x) = 0,$$
$$r(f''(x)vv + \langle y, g''(x)vv\rangle) \geq \langle y, z\rangle.$$

Proof. Given $v \in K(x)\backslash\{0\}$, $(z, r) \in \widehat{T}^2(C, g(x), g'(x)v)$, for each $w \in X$ such that

$$g'(x)w + rg''(x)vv - z \in T(T(C, g(x)), g'(x)v),$$

Proposition 2.3 ensures that

$$(g'(x)w + rg''(x)vv, r) \in \widehat{T}^2(C, g(x), g'(x)v).$$

It follows from Proposition 4.1 that

$$(w, r) \in \widehat{T}^2(F, x, v).$$

Then, by Proposition 3.1, we have

$$f'(x)w \geq -rf''(x)vv.$$

Taking in Lemma 4.2, $A = g'(x)$, $b = z - rg''(x)vv$, $c = f'(x)$, $P = X$, $Q = T(T(C, g(x)), g'(x)v)$, $m = -rf''(x)vv$, and observing that $A(P) - Q = Z$ by condition (TR), we get some $y \in Q^0 = N(T(C, g(x)), g'(x)v)$ such that

$$f'(x) + y \circ g'(x) = 0,$$

$$\langle y, -z + rg''(x)vv\rangle \geq -rf''(x)vv.$$

Thus the result is established. □

Let us present a variant of the preceding necessary condition.

THEOREM 4.4. *Let x be a (local) solution to problem $(\mathcal{P})$. Suppose conditions* (DMR) *and* (TR) *are satisfied at x. Then for each non-null critical vector $v \in K(x)$ and each nonempty closed convex subcone $\widehat{Q}$ of $\widehat{T}^2(C, g(x), g'(x)v)$ not contained in $Z \times \{0\}$, there exists some $y \in N(T(C, g(x)), g'(x)v)$ such that*

$$f'(x) + y \circ g'(x) = 0,$$
$$\inf_{(z,r)\in\widehat{Q}} [r(f''(x)vv + \langle y, g''(x)vv\rangle) - \langle y, z\rangle] \geq 0.$$

Proof. Given $v \in K(x)\setminus\{0\}$, and a cone $\widehat{Q}$ as above, in view of Proposition 2.3, for each $(w, r) \in X \times \mathbb{R}_+$ such that

$$(g'(x)(w) + rg''(x)vv, r) \in \mathrm{cl}(\widehat{Q} + T \times \{0\})$$

with $T := T(T(C, g(x)), g'(x)v)$, we have

$$(g'(x)(w) + rg''(x)vv, r) \in \widehat{T}^2(C, g(x), g'(x)v)$$

since $\widehat{T}^2(C, g(x), g'(x)v)$ is closed. It follows from Proposition 4.1 that

$$(w, r) \in \widehat{T}^2(F, x, v).$$

And then, by Proposition 3.1,

$$f'(x)w + rf''(x)vv \geq 0.$$

Setting $P = X \times \mathbb{R}_{+,}$ $Q = \mathrm{cl}(\widehat{Q} + T \times \{0\})$, and defining A by

$$A(w, r) := (g'(x)w + rg''(x)vv, r)$$

so that $A(P) - Q = Z \times \mathbb{R}$, as is easily seen, it follows from the Farkas lemma recalled above that there exists $(y, -s) \in Q^0 = (\widehat{Q} + T \times \{0\})^0$ such that

$$f'(x)w + rf''(x)vv - rs + \langle y, g'(x)w + rg''(x)vv\rangle \geq 0$$

for each $(w, r) \in X \times \mathbb{R}_+$. It follows that $y \in T^0 := N(T(C, g(x)), g'(x)v)$ and that

$$f'(x) + y \circ g'(x) = 0,$$
$$r(f''(x)vv + \langle y, g''(x)vv\rangle) \geq rs.$$

Since $rs \geq \langle y, z\rangle$ for each $(z, r) \in Q$, the result follows. □

Since the preceding optimality condition has been derived from Proposition 3.1, and since that criterion is a consequence of the results of [37], one may guess that it is a consequence of the necessary condition of [37] for mathematical programming problems. This is the case. Given $v \in K(x)$ and a nonempty closed convex subcone $\widehat{Q}$

of $\widehat{T}^2\left(C, g\left(x\right), g'\left(x\right)v\right)$, let us consider two cases. When $\widehat{Q}$ is contained in $Z \times \{0\}$ the condition $-\langle y, z\rangle \geq 0$ for each $z \in \widehat{Q}$ is satisfied by any y in the set $M(x)$ of multipliers, as is easily seen. When $\widehat{Q} \cap Z \times \mathbb{P}$ is nonempty, taking $T = X \times (\widehat{Q} \cap Z \times \{1\})$ in [37, Corollary 3.6] we get some $y \in M(x)$ such that

$$f''\left(x\right)vv + \langle y, g''\left(x\right)vv\rangle \geq \langle y, z\rangle$$

for each z such that $(z, 1) \in \widehat{Q}$. Taking into account the remarks above and a homogeneity argument, the conclusion follows.

Now, let us turn to sufficient conditions.

THEOREM 4.5. *The following conditions ensure that an element x of F is a strict local minimizer:*

(a) *X is finite dimensional;*

(b) *the set $M\left(x\right) = \{y \in N\left(C, g\left(x\right)\right) : f'\left(x\right) + y \circ g'\left(x\right) = 0\}$ of multipliers at x is nonempty;*

(c) *for each $v \in F'\left(x\right) \setminus \{0\}$ with $f'\left(x\right)v = 0$ and each $(w, r) \in X \times \mathbb{R}_+ \setminus \{(0,0)\}$ such that $(z, r) := (g'\left(x\right)w + rg''\left(x\right)vv, r) \in \widehat{T}^2\left(C, g\left(x\right), g'\left(x\right)v\right)$ there exists $y \in M\left(x\right)$ such that*

$$r\left(f''\left(x\right)vv + \langle y, g''\left(x\right)vv\rangle\right) > \langle y, z\rangle.$$

Proof. The existence of a multiplier y ensures condition (a) of Proposition 3.4 since for any $v \in F'\left(x\right)$ we have $g'\left(x\right)v \in T\left(C, g\left(x\right)\right)$ and $y \in N\left(C, g\left(x\right)\right)$, hence $\langle y, g'\left(x\right)v\rangle \leq 0$ and $f'\left(x\right)v \geq 0$.

In order to check condition (b) of Proposition 3.4, let us consider $v \in F'\left(x\right) \cap \ker f'\left(x\right)$ with $v \neq 0$ and $(w, r) \in \widehat{T}^2\left(F, x, v\right)$ with $(w, r) \neq (0, 0)$. Then Proposition 2.2 ensures that $(z, r) \in \widehat{T}^2\left(C, g\left(x\right), g'\left(x\right)v\right)$ for $z = g'\left(x\right)w + rg''\left(x\right)vv$. Then, taking $y \in M(x)$ as in assumption (c) we get

$$f'\left(x\right)w + rf''\left(x\right)vv > -\langle y, g'\left(x\right)w\rangle + \langle y, z\rangle - r\langle y, g''\left(x\right)vv\rangle = 0,$$

and condition (b) is satisfied. □

5. Comparisons with other works. As mentioned above, the definition we gave for the second-order projective incident cone $\widehat{T}^{ii}(F, x, v)$ to a subset F of X at (x, v) seems to be closely related to Definition 2.2 of [26]: $(w, r) \in TC^{(2)}(F, x, v)$ iff there exist $\varepsilon > 0$ and $\alpha : [0, \varepsilon] \to X$ such that $\alpha(s) \to 0$ as $s \to 0$,

$$x + s\sqrt{r}v + s^2 w + s^2\alpha(s) \in F \qquad \forall s \in [0, \varepsilon].$$

In fact, supposing X is finite dimensional, so that the weak topology coincides with the strong topology, setting $t = s\sqrt{r}$ we see that for $r > 0$ $(w, r) \in TC^{(2)}(F, x, v)$ iff $(w, r) \in \widehat{T}^{ii}(F, x, v)$ iff $r^{-1}w \in T^{ii}(F, x, v) := \liminf_{t \to 0_+} 2t^{-2}(F - x - tv)$. However, $(w, 0) \in TC^{(2)}(F, x, v)$ iff $w \in T^i(F, x) := \liminf_{t \to 0_+} t^{-1}(F - x)$, the first-order incident tangent cone, and there is no relationship with the case $(w, 0) \in \widehat{T}^{ii}(F, x, v)$. Another definition is given in [26], in the style of the Dubovitskii–Milyutin work: $(w, r) \in FC^{(2)}(F, x, v)$ iff there exists $\varepsilon > 0$ such that

$$x + s\sqrt{r}v + s^2 B(w, \varepsilon) \subset F \qquad \forall s \in [0, \varepsilon].$$

Setting $G := X \backslash F$, we see that for $r > 0$ we have $(w, r) \in FC^{(2)}(G, x, v)$ iff $(w, r) \notin \widehat{T}^2(F, x, v)$. However, for $r = 0$ we have $(w, r) \in FC^{(2)}(G, x, v)$ iff $w \notin T(F, x)$ and there is no connection with $\widehat{T}^2(F, x, v)$.

As mentioned in the introduction, the definition of the projective tangent set we introduced above has been inspired by a notion given in a work of Cambini, Martein, and Komlosi [11] (or, rather, a talk around that paper). With a slight change of notation, their definition is as follows:

$$w \in TC''(F,x,v) \Leftrightarrow (\exists k \in \mathbb{R}_+ \cup \{\infty\}\ \exists (x_n) \in F^{\mathbb{N}}\ (x_n) \to x,$$
$$\exists (\alpha_n), (\beta_n) \to \infty :\ (\alpha_n \beta_n^{-1}) \to k,\ (\beta_n [\alpha_n(x_n - x) - v]) \to w).$$

Clearly, this set is a cone, as is $\widehat{T}^2(F,x,v)$. Given $(w,r) \in \widehat{T}^2(F,x,v)$ and setting $\alpha_n = t_n^{-1}$, $\beta_n = 2r_n t_n^{-1}$ one sees that $w \in TC''(F,x,v)$ so that, denoting by p_X the canonical projection of $X \times \mathbb{R}$ onto X, one has

$$p_X(\widehat{T}^2(F,x,v)) \subset TC''(F,x,v).$$

This inclusion is strict in general as a vector w such that for some sequences $(x_n) \in F^{\mathbb{N}}$, $(x_n) \to x$, $(\alpha_n), (\beta_n) \to \infty :\ (\alpha_n \beta_n^{-1}) \to 0$, $(\beta_n [\alpha_n(x_n - x) - v]) \to w$ does not belong to the left-hand side of the preceding relation. The necessary condition of [11] is thus potentially richer than the one of our Proposition 3.1. However, for a vector w as just described, the necessary condition of [11] reads as

$$f'(x)(2kw) + f''(x)(v,v) \geq 0$$

with $k = 0$ or $f''(x)(v,v) \geq 0$. Then, since $x_n = x + \alpha_n^{-1} v + \alpha_n^{-2}(\alpha_n \beta_n^{-1}) w_n$, we have $(\alpha_n \beta_n^{-1} w_n) \to 0$, so that $0 \in T^2(F,x,v)$ (see [12, Observation 7], in this connection) and the conclusion $f''(x)(v,v) \geq 0$ is contained in Proposition 3.1. For a similar reason, the assumptions of their sufficient condition are not more restrictive than the ones of our Proposition 3.4. We refer to [12] for a precise formulation of the optimality conditions of [11] and a number of observations about the second-order tangent sets described above. Among them is the following property [12, Observations 4 and 5]:

$$\widehat{T}^2(F,x,v) + \mathbb{R}T(F,x) \times \{0\} \subset \widehat{T}^2(F,x,v),$$

which is related to the inclusion

$$T^2(F,x,v) + \mathbb{R}T(F,x) \subset T^2(F,x,v)$$

contained in [13, Proposition 3.1].

Moreover, pursuing the line of thought of several papers [8], [9], [10], Cambini, Martein, and Komlosi introduce in [11] a new notion of second-order tangent set and use it for optimality conditions. When applied to mathematical programming problems, another main feature of the approach of [11] is the fact that it takes place in the image of the decision space X by the joint mapping $h := (f,g) : X \to V := \mathbb{R} \times Z$. In such a setting, X can be an arbitrary topological space, V can be an arbitrary normed vector space, and the following tools address local minimizers rather than global minimizers. Given $x \in X$, let us denote by $T(X,h,x)$ the set of $v \in V$ such that there exist sequences $(x_n) \to x$, $(t_n) \to 0_+$, $(v_n) \to v$ in X, $\mathbb{P}$, and V, resp., such that $v_n = t_n^{-1}(h(x_n) - h(x_0))$ for each n. Now, given $v \in T(X,h,x)$, let $T^2(X,h,x,v)$ be the set of limits w of sequences $(w_n) = 2t_n^{-2}(h(x_n) - h(x) - t_n v)$, where $(x_n) \to x$, $(t_n) \to 0_+$. Clearly,

$$T(X,h,x) \subset T(h(X),h(x)),\ T^2(X,h,x,v) \subset T^2(h(X),h(x),v),$$

and if X is a normed space,

$$h'(x)(X) \subset T(X,h,x),\ h'(x)(X) + h''(x)(v,v) \subset T^2(h(X),h(x),v).$$

However, these sets do not seem to be directly related to the projective tangent sets we defined, although they also give rise to optimality conditions in the form

$$T(X,h,x)\cap((-\mathbb{P})\times \mathrm{int}C)=\emptyset,$$
$$T^2(X,h,x,v)\cap((-\mathbb{P})\times \mathrm{int}C)=\emptyset \quad \forall v\in T(X,h,x)\cap Fr((-\mathbb{P})\times \mathrm{int}C).$$

On the other hand, conditions in terms of multipliers can be deduced from such relations and from the use of the set A_2 of $v\in T(X,h,x)\backslash\{0\}$ such that there exist $t>0$ and sequences $(x_n)\to x$, $(t_n)\to 0_+$, $(v_n)\to v$ in X, $\mathbb{P}$, and V, resp., such that $v_n=t_n^{-1}(h(x_n)-h(x_0))$, $t_n=t\|h(x_n)-h(x)\|$, $\|x_n-x\|^{-2}(h(x_n)-h(x))\to 0$. Such a set seems to be more closely related to our projective tangent sets.

Now let us turn to a recent contribution of Bonnans, Cominetti, and Shapiro [5] using a notion of approximation to devise a sufficient optimality condition which we intend to compare with the one in [37]. We recall them briefly. The condition in [37] relies on the notion of *compound tangent set* to $E:=(-\mathbb{R}_+)\times C$ (we suppose $f(x)=0$ for simplicity). Given $u\in X$ one denotes by

$$S_u:=\limsup_{(t,u')\to(0_+,u)} 2t^{-2}(E-h(x)-th'(x)u')$$

the set formed with limits of sequences (w_n) such that there exist sequences $(t_n)\to 0_+$, $(u_n)\to u$ in $\mathbb{P}$ and X, resp., with $h(x)+t_nh'(x)u_n+\frac{1}{2}t_n^2w_n\in E$ for each n. Then one can give a sufficient condition in order that x be an *essential local minimizer of second order* for problem $(\mathcal{M})$ in the following sense, which differs slightly from the one in [1], [5], [35], [39], and [38]: there exists $\alpha>0,\beta>0,\gamma>0$ such that

$$f(u)\geq f(x)+\alpha\|u-x\|^2 \text{ for any } u\in B(x,\beta) \text{ such that } d(g(u),C)\leq\gamma\|u-x\|^2.$$

We make use of the set $J(x)$ of F. John's multipliers at x for problem $(\mathcal{M})$, i.e., the set of $(t,y)\in\mathbb{R}_+\times N(C,g(x))$ such that

$$tf'(x)+y\circ g'(x)=0$$

and of the set of *subcritical directions*

$$K^{\leq}(x):=\{u\in X: f'(x)u\leq 0,\ g'(x)u\in T(C,g(x))\}.$$

This set obviously coincides with the set of critical directions $K(x)$ whenever the set of multipliers $M(x)=\{y:(1,y)\in J(x)\}$ is nonempty.

PROPOSITION 5.1. *The following conditions ensure that an element x of F is an essential local minimizer of second order:*

(a) *X is finite dimensional;*

(b) *the set $J(x)$ of John's multipliers at x is nonempty;*

(c) *for each $u\in K^{\leq}(x)\setminus\{0\}$ and each $(r,z)\in S_u$ there exists a multiplier $(t,y)\in J(x)$ such that*

$$tf''(x)uu+\langle y,g''(x)uu\rangle > rt+\langle y,z\rangle. \tag{5}$$

Proof. Suppose on the contrary that there exist a sequence (x_n) of X and a sequence $(\varepsilon_n)\to 0_+$ such that $0<t_n:=\|x_n-x\|<\varepsilon_n, d(g(x_n),C)\leq\varepsilon_nt_n^2$, $f(x_n)<f(x)+t_n^2\varepsilon_n$ for each n. Without loss of generality we may assume that $(t_n^{-1}(x_n-x))$ converges to some u in X. It is easy to see that $u\in K^{\leq}(x)\setminus\{0\}$ and that $(r,z):=(f''(x)uu,g''(x)uu)\in S_u$. Thus we get a contradiction with (c). □

Now, in order to present the result of [5] let us introduce the following concepts in which the Pompeiu–Hausdorff *excess* of a subset C over another subset D of a metric space is given by

$$e(C,D) := \sup_{c\in C} d(c,D).$$

DEFINITION 3. *A subset A of a metric space is an outer (or upper) hemi-limit of a family $(A_w)_{w\in W}$ of subsets of X parametrized by a subset $W$of a topological space P as $w \to w_0 \in \mathrm{cl}W$, $w \in W$ if $e(A_w, A) \to 0$ as $w \to w_0$ in W.*

Such a limit is not unique: if A' contains A, then A' is again an outer hemi-limit of (A_w). Moreover, any closed outer hemi-limit of (A_w) contains $\limsup_{w\to w_0} A_w$, as is easily seen. The concept introduced in [5] can be reformulated as follows (in the case $d = Mu$, which is of interest to us).

DEFINITION 4. *Given n.v.s. X and Z, a subset C of Z, a continuous linear mapping $M : X \to Z$, $u \in X$, $z \in C$, a subset A of Z is said to be an upper (second-order) approximation to C at z with respect to M, z, u if it is an outer hemi-limit of the family $A_{t,u'} := 2t^{-2}(C - z - tMu')$ as $(t, u') \to (0, u)$ in $\mathbb{P} \times X$.*

A simpler notion can be introduced.

DEFINITION 5. *Given a subset C of an n.v.s. Z, $z \in C$, $v \in T(C, z)$, a subset A of Z is said to be an outer (second-order) approximation to C at z in the direction v if it is an outer hemi-limit of the family $A_t := 2t^{-2}(C - z - tv)$ as $t \to 0_+$.*

This definition is less demanding than the preceding one: if A is an upper approximation to C at z with respect to M, z, u, and if $v := Au$, then A is an outer approximation to C at z in the direction v.

EXAMPLE. *For any convex subset C of Z and any $z \in C$, $v \in T(C, z)$ the cone $T(T(C, z), v)$ is an outer approximation to C at z in the direction v. In fact, for any $t > 0$, $c \in C$, setting $w := 2t^{-2}(c - z - tv)$, $v' := v + (t/2)w = t^{-1}(c - z) \in T(C, z)$, one has $w = 2t^{-1}(v' - v) \in T(T(C, z), v)$.* □

The main result of [5] states that if x is feasible for problem $(\mathcal{M})$, if for each $u \in K^{\leq}(x)$ there exists an upper approximation A to C with respect to $M := g'(x)$, $z := g(x)$, u, and if there exists $(t, y) \in J(x)$ such that

$$tf''(x)\,uu + \langle y, g''(x)\,uu\rangle > \sigma(y, A) := \sup_{a\in A}\langle y, a\rangle, \tag{6}$$

then x is a strict locally optimal solution of $(\mathcal{M})$. In fact this result can be extended to the case when A is just an outer approximation to C at z in the direction $v := g'(x)u$, and, moreover, it is a simple consequence of the preceding proposition in view of the following lemma.

LEMMA 5.2. *If condition* (6) *holds for some outer approximation to C at $g(x)$ in the direction $v := g'(x)u$, then condition* (5) *holds.*

Proof. It suffices to prove that for any $u \in K^{\leq}(x)$, any $(r, z) \in S_u$, any $(t, y) \in J(x)$, and any outer approximation A to C at $g(x)$ in the direction $v := g'(x)u$, one has

$$\sigma(y, A) \geq \langle y, z\rangle + rt.$$

Now, since $(r, z) \in S_u$ there exist sequences $(t_n) \to 0_+$, $(u_n) \to u$, $(z_n) \to z$, $(r_n) \to r$ such that

$$c_n := g(x) + t_n g'(x)u_n + \frac{1}{2}t_n^2 z_n \in C,$$
$$f'(x)u_n + \frac{1}{2}t_n r_n \leq 0.$$

Let $w_n := 2t_n^{-1}(u_n - u)$, and let $q_n := g'(x)w_n + z_n$. Since A is an outer approximation to C at $g(x)$ in the direction $v := g'(x)u$, and since $q_n = 2t_n^{-2}(c_n - g(x) - t_n g'(x)u)$, there exists $a_n \in A$ such that $\varepsilon_n := \|q_n - a_n\| \to 0$. Then, using the definitions of $J(x)$ and $K^{\leq}(x)$, we get

$$\begin{aligned}\langle y, z_n\rangle + tr_n &= \langle y, q_n\rangle - \langle y, g'(x)w_n\rangle + tr_n\\ &= \langle y, q_n\rangle + tf'(x)w_n + tr_n\\ &= \langle y, q_n\rangle + 2tt_n^{-1}\left(f'(x)u_n + \frac{1}{2}t_n r_n\right)\\ &\leq \langle y, a_n\rangle + \varepsilon_n\|y\|.\end{aligned}$$

Therefore, taking limits, we get

$$\langle y, z\rangle + rt \leq \sigma(y, A).$$

COROLLARY 5.3. *Suppose that for an element x of F the conditions* (a) *and* (b) *of the preceding proposition hold while condition* (c) *is replaced with the following condition* (c′)*. Then x is an essential local minimizer of second order:*

(c′) *for each $u \in K^{\leq}(x) \setminus \{0\}$ there exist an outer approximation A of C at $g(x)$ in the direction $g'(x)u$ and a multiplier $(t, y) \in J(x)$ such that*

$$tf''(x)\,uu + \langle y, g''(x)\,uu\rangle > \sup_{a\in A}\langle y, a\rangle. \tag{7}$$

UNIFORM STABILIZATION OF THE DYNAMIC ELASTICA BY BOUNDARY FEEDBACK*

KAZUHO ITO†

Abstract. It is proved that the dynamic elastica, which is a nonlinear model describing the large deflecting motion of an inextensible beam, can be uniformly exponentially stabilized by boundary velocity feedback.

Key words. elastica, uniform stabilization, boundary control, exponential decay

AMS subject classifications. 93D15, 35B37, 73K05

1. Introduction.

We consider the large, planar motion of an inextensible elastic beam described by the following model, called the dynamic elastica:

$$\rho u_{tt} = \lambda_x, \tag{1.1}$$

$$\rho w_{tt} = \nu_x, \tag{1.2}$$

$$\lambda \sin\varphi - \nu\cos\varphi + I_\rho \varphi_{tt} - EI\varphi_{xx} = 0, \tag{1.3}$$

$$1 + u_x = \cos\varphi, \quad w_x = \sin\varphi. \tag{1.4}$$

The unknowns are u, w, φ, λ, and ν, which are functions of two variables x and t, $0 \le x \le L$, $t \ge 0$. In this model, the centerline (i.e., the locus of the centroid of the cross section) of the beam is assumed to lie in a fixed plane with the usual Cartesian coordinate system O-XY, and, in the reference state of the beam, to occupy the interval $0 \le X \le L$ of the X-axis. The unknowns $u(x,t)$ and $w(x,t)$ denote the displacements, at time t, in the X- and Y-direction, respectively, of the particle which occupies position $(x,0)$, $0 \le x \le L$, in the reference state; thus, the centerline at time t is described by the curve $x \mapsto (x + u(x,t), w(x,t))$. The unknown $\varphi(x,t)$ denotes the angle between the tangent $(1 + u_x(x,t), w_x(x,t))$ of the centerline and the X-axis. This, together with the inextensibility condition $\sqrt{(1+u_x)^2 + w_x^2} = 1$, implies (1.4). The unknowns $\lambda(x,t)$ and $\nu(x,t)$ denote the components in the X- and Y-direction, respectively, of the force acting on $\Gamma(x)$, where $\Gamma(x)$ is the cross section that is at $X = x$ when the beam is in the reference state. In the motion equations (1.1)–(1.3), the coefficients ρ, I_ρ, and EI are the mass per unit length, the mass moment of inertia of the cross section, and the bending stiffness of the beam. We assume that these coefficients are positive constants. For more detailed explanation of (1.1)–(1.3), see, e.g., [2], [1].

The boundary conditions we consider at $x = 0$ are

$$u(0,t) = w(0,t) = 0, \tag{1.5}$$

$$\varphi(0,t) = 0, \tag{1.6}$$

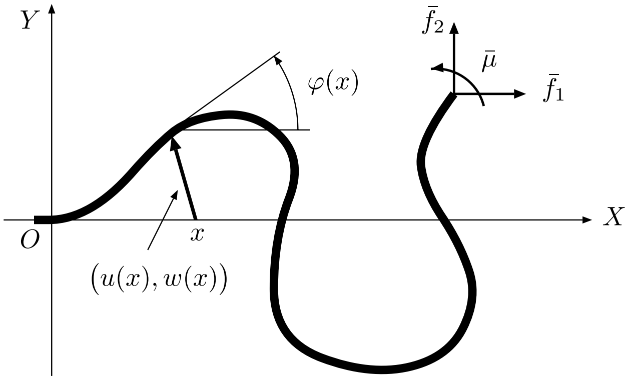

FIG. 1.1. *Elastica (the dependence of the functions upon t is suppressed).*

which represent that the beam is clamped at the end having the cross section $\Gamma(0)$, and the boundary conditions at $x = L$ are

$$\lambda(L,t) = \bar{f}_1(t), \quad \nu(L,t) = \bar{f}_2(t), \tag{1.7}$$

$$EI\varphi_x(L,t) = \bar{\mu}(t), \tag{1.8}$$

which represent that, at the cross section $\Gamma(L)$, the beam is subjected to external forces $\bar{f}_1$ and $\bar{f}_2$ in the X- and Y-direction, respectively, and to an external moment $\bar{\mu}$ (see Fig. 1.1).

For the model above, the strain energy of the beam is given by

$$U(t;\varphi) = \tfrac{1}{2}\int_0^L EI\varphi_x(x,t)^2\,dx, \tag{1.9}$$

and the kinetic energy is given by

$$K(t;\varphi) = \tfrac{1}{2}\int_0^L \left\{\rho u_t(x,t)^2 + \rho w_t(x,t)^2 + I_\rho \varphi_t(x,t)^2\right\} dx \tag{1.10}$$

(note that u and w, and thus K, are determined by φ through (1.4) and (1.5)). Indeed, the motion equations (1.1)–(1.3) and the natural boundary conditions (1.7)–(1.8) can be derived from Hamilton's principle with the Lagrangian

$$\mathcal{L}(\varphi) = \int_{t_0}^{t_1} \left\{U(t;\varphi) - K(t;\varphi) - (\bar{f}_1(t)u(L,t) + \bar{f}_2(t)w(L,t) + \bar{\mu}(t)\varphi(L,t))\right\} dt \tag{1.11}$$

and with the geometrical constraints (1.4), (1.5)–(1.6).

The purpose of this paper is to investigate uniform stabilization of the above model with the following boundary velocity feedback control (i.e., boundary damping):

$$\bar{f}_1(t) = -k_1 u_t(L,t), \tag{1.12}$$

$$\bar{f}_2(t) = -k_2 w_t(L,t), \tag{1.13}$$

$$\bar{\mu}(t) = -l\varphi_t(L,t), \tag{1.14}$$

where k_1, k_2, and l are positive constants representing feedback gains. For a linear wave equation with boundary damping, Chen [4], [5] adopted an approach using

Lyapunov-type functionals to establish exponential decay of solutions (this work was done as an extension of Quinn and Russell [20]). After that, this approach was used not only for extending Chen's result for linear wave equations (see, e.g., [14], [15], [17]), but also for obtaining exponential decay rates for some linear elastic systems with boundary damping (see, e.g., [12], [3], [7], [6]). One of the main advances in this approach was made by Komornik and Zuazua [9], [8] when they introduced a new type of Lyapunov functional. Their argument showed that the approach can be applied to nonlinear systems with boundary damping; results on uniform decay rates have been obtained for semilinear wave equations (see, e.g., [24]) and nonlinear elastic beams and plates (see, e.g., [13], [18], [10], [11], [16], [21], [19]) with linear or nonlinear boundary damping. On the other hand, there is another important approach to the problem of obtaining uniform decay rates for the similar systems. For this approach, see, for example, Tataru [22] and the bibliography therein.

We apply the Lyapunov functional approach: we construct a functional to establish that the total energy

$$E(t;\varphi) := K(t;\varphi) + U(t;\varphi) \tag{1.15}$$

of the controlled system (1.1)–(1.8), (1.12)–(1.14) has an exponential decay rate. As far as the author knows, all previous work, except [23], on uniform boundary stabilization for flexible systems (string, membrane, beam, plate) treats those models that are derived under the condition that the deflection of the body is small enough, even though the model equations are nonlinear. The present paper shows that the boundary velocity feedback control is effective for large deflecting flexible structures. Independently of the present work, Taylor has shown in an unpublished article [23] that the elastica model without the rotational inertia term (the third term of the left-hand side of (1.3)) is exponentially stabilized by the boundary feedback forces (1.12) and (1.13), assuming the existence of a solution of the model. However, for that model, the existence of a global classical solution has not been proven yet.

2. Preliminary results. In this section, we give some preliminary results, including the well-posedness of (1.1)–(1.8), (1.12)–(1.14).

First of all, we eliminate λ, ν, $\bar{f}_1$, $\bar{f}_2$, and $\bar{\mu}$ from (1.1)–(1.8), (1.12)–(1.14) to obtain

$$\begin{aligned}\int_L^x \rho u_{tt}(\xi,t)\,d\xi \sin\varphi - \int_L^x \rho w_{tt}(\xi,t)\,d\xi \cos\varphi + I_\rho \varphi_{tt} - EI\varphi_{xx} \\ = k_1 u_t(L,t)\sin\varphi - k_2 w_t(L,t)\cos\varphi,\end{aligned} \tag{2.1}$$

$$u(x,t) = \int_0^x \{\cos\varphi(\xi,t) - 1\}\,d\xi, \quad w(x,t) = \int_0^x \sin\varphi(\xi,t)\,d\xi, \tag{2.2}$$

$$\varphi(0,t) = 0, \tag{2.3}$$

$$EI\varphi_x(L,t) = -l\varphi_t(L,t). \tag{2.4}$$

In what follows, we are concerned with (2.1)–(2.4) exclusively.

Caflisch and Maddocks [2] proved the existence and uniqueness of global, classical solutions to the initial-boundary value problem corresponding to (1.1)–(1.8) with

$$\bar{f}_1(t) = \text{const}, \quad \bar{f}_2(t) = \bar{\mu}(t) = 0, \quad t \geq 0$$

(they dealt with the problem with variable coefficients). The existence result, Proposition 2.1 below, for our problem can be proved by similar argument to theirs. Thus we give only the outline of a proof.

Let C^n_{pw} ($n = 1, 2$) denote the class of those functions in C^{n-1} that have piecewise continuous derivatives of order n.

PROPOSITION 2.1. *Let $\varphi_0 \in C^2_{pw}[0, L]$, and let $\varphi_1 \in C^1_{pw}[0, L]$, where φ_0 and φ_1 satisfy*

$$\varphi_0(0) = \varphi_1(0) = 0, \quad EI\varphi_0'(L) = -l\varphi_1(L) \tag{2.5}$$

("$'$" stands for d/dx). Then there exists one and only one function $\varphi \in C^2_{pw}([0, L] \times [0, \infty))$ satisfying (2.1)–(2.4) *and*

$$\varphi(x, 0) = \varphi_0(x), \quad \varphi_t(x, 0) = \varphi_1(x). \tag{2.6}$$

Proof. Step 1: *semilinear form.* Throughout this step, the dependence of φ upon t is suppressed. Substituting (2.2) into (2.1) yields

$$\begin{aligned} (2.7)\quad & I_\rho\varphi_{tt}(x) - EI\varphi_{xx}(x) \\ &\quad + \int_0^L \hat{\rho}(x, \xi)\big\{\varphi_{tt}(\xi)\cos(\varphi(x) - \varphi(\xi)) + \varphi_t(\xi)^2\sin(\varphi(x) - \varphi(\xi))\big\}\, d\xi \\ &= -\int_0^L \varphi_t(\xi)\big\{k_1\sin\varphi(x)\sin\varphi(\xi) + k_2\cos\varphi(x)\cos\varphi(\xi)\big\}\, d\xi, \end{aligned}$$

where

$$\hat{\rho}(x, \xi) = \begin{cases} \rho(L - x) & : \xi < x, \\ \rho(L - \xi) & : x < \xi. \end{cases}$$

By integration by parts and (2.3), we have the equality

$$\begin{aligned} &\int_0^L \hat{\rho}(x, \xi)(EI/I_\rho)\varphi_{xx}(\xi)\cos(\varphi(x) - \varphi(\xi))\, d\xi \\ &= -\,\hat{\rho}(x, 0)(EI/I_\rho)\varphi_x(0)\cos\varphi(x) \\ &\quad - \int_0^L \hat{\rho}_\xi(x, \xi)(EI/I_\rho)\varphi_x(\xi)\cos(\varphi(x) - \varphi(\xi))\, d\xi \\ &\quad - \int_0^L \hat{\rho}(x, \xi)(EI/I_\rho)\varphi_x(\xi)^2\sin(\varphi(x) - \varphi(\xi))\, d\xi. \end{aligned}$$

Subtracting this equality from (2.7) yields

$$\begin{aligned} (2.8)\quad & I_\rho\varphi_{tt}(x) - EI\varphi_{xx}(x) \\ &\quad + \int_0^L \hat{\rho}(x, \xi)I_\rho^{-1}\big\{I_\rho\varphi_{tt}(\xi) - EI\varphi_{xx}(\xi)\big\}\cos(\varphi(x) - \varphi(\xi))\, d\xi = [A\varphi](x), \end{aligned}$$

where

$$\begin{aligned}[A\varphi](x) =&\hat{\rho}(x,0)(EI/I_\rho)\varphi_x(0)\cos\varphi(x)\\ &+\int_0^L \hat{\rho}(x,\xi)\big\{(EI/I_\rho)\varphi_x(\xi)^2-\varphi_t(\xi)^2\big\}\sin(\varphi(x)-\varphi(\xi))\,d\xi\\ &+\int_0^L \hat{\rho}_\xi(x,\xi)(EI/I_\rho)\varphi_x(\xi)\cos(\varphi(x)-\varphi(\xi))\,d\xi\\ &-\int_0^L \varphi_t(\xi)\big\{k_1\sin\varphi(x)\sin\varphi(\xi)+k_2\cos\varphi(x)\cos\varphi(\xi)\big\}\,d\xi.\end{aligned}$$

Define now the operator L_ψ for each $\psi\in C[0,L]$ by

$$[L_\psi f](x)=\int_0^L \hat{\rho}(x,\xi)I_\rho^{-1}\cos(\psi(x)-\psi(\xi))f(\xi)\,d\xi,\quad f\in L^2(0,L).$$

As stated in the next step, the operator $1+L_\psi$ has the inverse $(1+L_\psi)^{-1}=1+K_\psi$, with K_ψ a compact operator on $L^2(0,L)$. Thus (2.8) can be rewritten as

$$I_\rho\varphi_{tt}-EI\varphi_{xx}=(1+K_\varphi)A\varphi. \tag{2.9}$$

In the following, it is shown that this semilinear equation with the boundary conditions (2.3)–(2.4) and the initial conditions (2.6) has a unique C^2_{pw} solution.

Step 2: *properties of* L_φ, K_φ *and* $A\varphi$. Let $Q_T=[0,L]\times[0,T]$ for $T>0$, and let $Q_\infty=[0,L]\times[0,\infty)$. We denote by $||\cdot||_\infty$ and $||\cdot||_{L^2}$ the usual norms of $L^\infty(0,L)$, and $L^2(0,L)$, respectively, and define $||\cdot||_1$ by

$$||f(\cdot,t)||_1^2=||f(\cdot,t)||_{L^2}^2+||f_x(\cdot,t)||_{L^2}^2+||f_t(\cdot,t)||_{L^2}^2\quad\text{for } f\in C^1_{pw}(Q_\infty).$$

Let φ, $\psi\in C[0,L]$. The operator L_φ is a compact, positive operator on $L^2(0,L)$ into $C[0,L]$ and satisfies

$$\begin{gathered}||L_\varphi f||_\infty\le c_1||f||_{L^2},\\ ||(L_\varphi-L_\psi)f||_\infty\le c_1||\varphi-\psi||_\infty||f||_{L^2},\end{gathered}$$

where c_1 is a positive constant depending only on ρ, I_ρ, and L. If $\varphi\in C^1[0,L]$, then $L_\varphi f\in C^1[0,L]$.

Since L_φ is compact and positive definite, the operator $(1+L_\varphi)^{-1}$ on $L^2(0,L)$ is well defined, which is positive and satisfies

$$||(1+L_\varphi)^{-1}f||_{L^2}\le||f||_{L^2},\quad f\in L^2(0,L).$$

We define K_φ by

$$K_\varphi=-L_\varphi(1+L_\varphi)^{-1}=-(1+L_\varphi)^{-1}L_\varphi.$$

Thus, $(1+K_\varphi)=(1+L_\varphi)^{-1}$. By the definition, it follows that K_φ is a compact, self-adjoint operator on $L^2(0,L)$ into $C[0,L]$ and satisfies

$$\begin{gathered}||K_\varphi f||_\infty\le c_2||f||_{L^2},\\ ||(K_\varphi-K_\psi)f||_\infty\le c_2||\varphi-\psi||_\infty||f||_{L^2},\end{gathered}$$

where c_2 is a positive constant depending only on ρ, I_ρ, and L. Moreover, if $\varphi \in C^1[0,L]$, then $K_\varphi f \in C^1[0,L]$.

In the rest of this step, we suppose that $\varphi(x,t)$ and $\psi(x,t)$ belong to $C^1_{pw}(Q_\infty)$ (the dependence of φ and ψ upon t is suppressed) and $\varphi(0,t) = \psi(0,t) = 0$. By the definition of $A\varphi$ and by using the inequalities above, we obtain the following estimations, in which c_3 is a positive constant depending only on ρ, I_ρ, EI, L, k_1, and k_2:

$$||A\varphi||_\infty \leq c_3\big(||\varphi_x||_\infty + ||\varphi||_1 + ||\varphi||_1^2\big), \tag{2.10}$$

$$||(1+K_\varphi)A\varphi||_\infty \leq c_3\big(||\varphi_x||_\infty + ||\varphi||_1 + ||\varphi||_1^2\big), \tag{2.11}$$

$$\begin{aligned}||A\varphi - A\psi||_\infty &\\ \leq c_3\big(1 + ||\varphi_x||_\infty + ||\psi_x||_\infty &+ ||\varphi||_1 + ||\psi||_1 + ||\varphi||_1^2 + ||\psi||_1^2\big)\\ &\times \big(||\varphi_x - \psi_x||_\infty + ||\varphi - \psi||_1\big),\end{aligned} \tag{2.12}$$

$$\begin{aligned}||(1+K_\varphi)A\varphi - (1+K_\psi)A\psi||_\infty &\\ \leq c_3\big(1 + ||\varphi_x||_\infty + ||\psi_x||_\infty &+ ||\varphi||_1 + ||\psi||_1 + ||\varphi||_1^2 + ||\psi||_1^2\big)\\ &\times \big(||\varphi_x - \psi_x||_\infty + ||\varphi - \psi||_1\big).\end{aligned} \tag{2.13}$$

Step 3: *linear wave equation.* Consider the inhomogeneous initial-boundary value problem

$$\varphi_{tt} - \beta^2\varphi_{xx} = f, \quad 0 \leq x \leq L, \quad t \geq 0$$

with the boundary conditions (2.3)–(2.4) and the initial conditions (2.6), where $\beta = \sqrt{EI/I_\rho}$. Using d'Alembert's formula, we can express explicitly the solution of this problem:

$$\begin{aligned}\varphi(x,t) = \frac{1}{2}&\left(\int_0^{x+\beta t}\varphi^+(\xi)\,d\xi + \int_0^{x-\beta t}\varphi^-(\xi)\,d\xi\right)\\ &+ \frac{1}{2\beta}\int_0^t\int_{x-\beta(t-\tau)}^{x+\beta(t-\tau)}\tilde{f}(\xi,\tau)\,d\xi d\tau, \quad 0 \leq x \leq L, \quad t \geq 0.\end{aligned} \tag{2.14}$$

In this formula, $\varphi^+(x)$ $(x \geq 0)$, $\varphi^-(x)$ $(x \leq L)$, and $\tilde{f}(x,t)$ $(-\infty < x < \infty,\ t \geq 0)$ are defined by

$$\varphi^+(x+nL) = \begin{cases}\sigma^k\big(\varphi_0'(x) + \frac{1}{\beta}\varphi_1(x)\big) & : n = 2k,\\ \sigma^k\big(\varphi_0'(L-x) - \frac{1}{\beta}\varphi_1(L-x)\big) & : n = 2k+1\end{cases}$$
$$\text{for } 0 \leq x < L,\ k = 0,\ 1,\ 2,\ \dots,$$

$$\varphi^-(x+nL) = \begin{cases}\sigma^{|k|}\big(\varphi_0'(x) - \frac{1}{\beta}\varphi_1(x)\big) & : n = 2k,\\ \sigma^{|k|}\big(\varphi_0'(L-x) + \frac{1}{\beta}\varphi_1(L-x)\big) & : n = 2k-1\end{cases}$$
$$\text{for } 0 \leq x < L,\ k = 0,\ -1,\ -2,\ \dots,$$

$$\tilde{f}(x+nL,t) = \begin{cases}\sigma^{|k|}f(x,t) & : n = 2k,\\ -\sigma^{|k+1|}f(L-x,t) & : n = 2k+1\end{cases}$$
$$\text{for } 0 \leq x < L,\ t \geq 0,\ k = 0,\ \pm 1,\ \pm 2,\ \dots,$$

where

$$\sigma = -\frac{1-\alpha\beta}{1+\alpha\beta}\ \big(\in(-1,1)\big) \quad \text{with} \quad \alpha = \frac{l}{EI}\ (>0).$$

We can check that if $f(x,t) \in C(Q_\infty)$ and $\partial f/\partial x$ is a piecewise continuous function on Q_∞, then the right-hand side of (2.14) is in $C^2_{pw}(Q_\infty)$ (note that $\partial f/\partial t$ is not required to be piecewise continuous). Moreover, defining $N(\varphi(\cdot,t))$ to be

$$N(\varphi(\cdot,t)) = ||\varphi(\cdot,t)||_\infty + ||\varphi_x(\cdot,t)||_\infty + ||\varphi_t(\cdot,t)||_\infty,$$

it follows from (2.14) that the solution φ satisfies

$$N(\varphi(\cdot,t)) \le c_4\big(||\varphi_0||_\infty + ||\varphi_0'||_\infty + ||\varphi_1||_\infty\big) + c_4\int_0^t ||f(\cdot,\tau)||_\infty\, d\tau \tag{2.15}$$

for $t \ge 0$, where c_4 is a positive constant depending only on I_ρ, EI, L, and l.

Step 4: *existence.* Define $\varphi^{(n)}$ for $n = 0,\ 1,\ 2,\ \ldots$ by

$$\varphi^{(0)}(x,t) = \varphi_0(x) + t\varphi_1(x),$$
$$I_\rho\varphi_{tt}^{(n+1)} - EI\varphi_{xx}^{(n+1)} = (1+K_{\varphi^{(n)}})A\varphi^{(n)}$$

with the boundary conditions (2.3)–(2.4) and the initial conditions (2.6). Let

$$g^{(n)} = \frac{1}{I_\rho}(1+K_{\varphi^{(n)}})A\varphi^{(n)}.$$

Since $g^{(0)} \in C^1_{pw}(Q_\infty)$, $\varphi^{(n+1)}$ belongs to C^2_{pw} and satisfies (2.15) with $f = g^{(n)}$ for $n = 0,\ 1,\ \ldots$. From this estimate and (2.11), we can show that

$$N(\varphi^{(n)}(\cdot,t)) \le M_0, \quad 0 \le t \le t_0,\ n = 0,1,\ldots \tag{2.16}$$

for some positive constants M_0 and t_0 independent of n. Furthermore, letting $\psi^{(n)} = \varphi^{(n+1)} - \varphi^{(n)}$, $\psi^{(n+1)}$ then satisfies (2.15) with $\varphi_0 = \varphi_1 = 0$ and $f = g^{(n+1)} - g^{(n)}$. From this estimate, (2.13), and (2.16), we can see that

$$N(\psi^{(n+1)}(\cdot,t)) \le \tfrac{1}{2}\sup_{0\le\tau\le t_1} N(\psi^{(n)}(\cdot,\tau)), \quad 0 \le t \le t_1,\ n = 0,1,\ldots$$

for some positive constants $t_1 \le t_0$ independent of n. This implies that $\varphi^{(n)}$ is a Cauchy sequence in $C^1(Q_{t_1})$. The constants M_0, t_0, and t_1 depend only on ρ, I_ρ, EI, L, k_1, k_2, l, $||\varphi_0||_\infty$, $||\varphi_0'||_\infty$, $||\varphi_1||_\infty$, and $||\varphi_1'||_\infty$.

Let $\varphi \in C^1(Q_{t_1})$ be the limit of $\varphi^{(n)}$ and $g = I_\rho^{-1}(1+K_\varphi)A\varphi$. It follows from (2.13) that $g^{(n)}$ converges to g in $C(Q_{t_1})$. Hence, φ satisfies (2.14) with $f = g$. On the other hand, by the definitions of $A\varphi$ and K_φ, we see that $\partial g/\partial x \in C(Q_{t_1})$. Therefore, as stated in Step 3, φ is a C^2_{pw} solution of (2.9). The uniqueness of solutions follows easily from (2.15) and (2.13).

Global existence of the solution can be proved in exactly the same way as in the proof of Theorem 1 in [2] using the estimate $E(t;\varphi) \le E(0;\varphi)$, $t \ge 0$, of the energy E (see the proof of Lemma 3.2 below). □

The inequalities in the following lemma are used in the next section.

Lemma 2.2. *Let $\psi \in C^1_{pw}[0,L]$, and define*

$$p(x) = \int_0^x \{\cos\psi(\xi) - 1\}\, d\xi, \quad q(x) = \int_0^x \sin\psi(\xi)\, d\xi.$$

Then, for any $x \in [0,L]$, we have

$$|xp'(x) - p(x)| \le L^{3/2}\left(\int_0^L |\psi'(\xi)|^2\, d\xi\right)^{1/2},$$
$$|xq'(x) - q(x)| \le L^{3/2}\left(\int_0^L |\psi'(\xi)|^2\, d\xi\right)^{1/2}.$$

Proof. From the definition of p, it follows that for any $x \in [0,L]$,

$$\begin{aligned}|xp'(x) - p(x)| &= \left|\int_0^x \big(\cos\psi(x) - \cos\psi(\xi)\big)\, d\xi\right| \\ &\le \int_0^x |\psi(x) - \psi(\xi)|\, d\xi = \int_0^L \left|\int_\xi^x \psi'(\eta) d\eta\right| d\xi \\ &\le \int_0^L \int_0^L |\psi'(\eta)|\, d\eta d\xi \le L^{3/2}\left(\int_0^L |\psi'(\xi)|^2\, d\xi\right)^{1/2}.\end{aligned}$$

The inequality for $|xq'(x) - q(x)|$ can be verified in the same way as above. □

3. The main result and its proof.

The main result is as follows.

Theorem 3.1. *Let $\varphi(x,t)$ be the function stated in Proposition* 2.1. *Then there exist constants $M \ge 1$ and $\gamma > 0$ such that*

$$E(t;\varphi) \le Me^{-\gamma t}E(0;\varphi), \quad t \ge 0.$$

Proof. First of all, we introduce the functional

$$V(t;\varphi) = E(t;\varphi) + \epsilon F(t;\varphi) \quad (\epsilon > 0),$$

where $E(t;\varphi)$ is the energy functional defined in (1.15), and

$$F(t;\varphi) = \int_0^L \{\rho u_t(xu_x - u) + \rho w_t(xw_x - w) + I_\rho x\varphi_t\varphi_x\}\, dx.$$

Differentiating $V(t;\varphi)$ in t, we have (see Lemma 3.2 below)

$$\begin{aligned}\dot V(t;\varphi) = &- [k_1u_t^2 + k_2w_t^2 + l\varphi_t^2]_{x=L} \\ &- \epsilon E(t;\varphi) - \epsilon\int_0^L (\rho u_t^2 + \rho w_t^2)\, dx \\ &+ \tfrac{1}{2}L\epsilon[\rho u_t^2 + \rho w_t^2 + I_\rho\varphi_t^2 + (l^2/EI)\varphi_t^2]_{x=L} \\ &- \epsilon[k_1u_t(xu_x - u) + k_2w_t(xw_x - w)]_{x=L}\end{aligned} \tag{3.1}$$

("." stands for d/dt). Now using Lemma 2.2 and the inequality

$$\xi\eta \le \delta\xi^2 + \eta^2/(4\delta) \quad \text{for any real } \xi,\ \eta, \text{ and any } \delta > 0,$$

we obtain the following estimate on $\dot{V}(t;\varphi)$: for any $\epsilon > 0$ and $\delta > 0$,

$$\begin{aligned}\dot{V}(t;\varphi) \leq &-(\epsilon/2)\int_0^L (3\rho u_t^2 + 3\rho w_t^2 + I_\rho \varphi_t^2)\,dx \\ &- \epsilon \int_0^L (EI/2 - 2\delta)\varphi_x^2\,dx \\ &- \left\{k_1 - \left(\frac{L\rho}{2} + \frac{k_1 L^{3/2}}{4\delta}\right)\epsilon\right\} u_t(L,t)^2 \\ &- \left\{k_2 - \left(\frac{L\rho}{2} + \frac{k_2 L^{3/2}}{4\delta}\right)\epsilon\right\} w_t(L,t)^2 \\ &- \left\{l - \left(\frac{LI_\rho}{2} + \frac{Ll^2}{2EI}\right)\epsilon\right\} \varphi_t(L,t)^2.\end{aligned}$$

Therefore, if we choose δ, ϵ and the control gains such that

$$\begin{aligned}&k_1 > 0,\ k_2 > 0,\ l > 0, \\ &k_1 - \left(\frac{L\rho}{2} + \frac{k_1 L^{3/2}}{4\delta}\right)\epsilon > 0, \quad k_2 - \left(\frac{L\rho}{2} + \frac{k_2 L^{3/2}}{4\delta}\right)\epsilon > 0, \\ &l - \left(\frac{LI_\rho}{2} + \frac{Ll^2}{2EI}\right)\epsilon > 0, \quad EI/2 - 2\delta > 0,\end{aligned} \tag{3.2}$$

we have

$$\dot{V}(t;\varphi) \leq -\epsilon(1 - 4\delta/EI)E(t;\varphi), \quad t \geq 0. \tag{3.3}$$

On the other hand, it follows from Schwarz's inequality and Lemma 2.2 that

$$|F(t;\varphi)| \leq CE(t;\varphi), \quad t \geq 0,$$

where C is a constant depending only on ρ, I_ρ, EI, and L. This implies

$$(1 - C\epsilon)E(t;\varphi) \leq V(t;\varphi) \leq (1 + C\epsilon)E(t;\varphi). \tag{3.4}$$

Therefore, it follows from (3.3) that

$$\dot{V}(t;\varphi) \leq -\gamma V(t;\varphi), \quad t \geq 0, \tag{3.5}$$

where

$$\gamma = \epsilon\left(1 - \frac{4\delta}{EI}\right)\frac{1}{1 + C\epsilon} > 0.$$

If ϵ is chosen so as to satisfy, in addition to (3.2),

$$1 - C\epsilon > 0,$$

the inequalities (3.5) and (3.4) imply

$$E(t;\varphi) \leq \frac{1 + C\epsilon}{1 - C\epsilon} e^{-\gamma t} E(0;\varphi), \quad t \geq 0.$$

The proof is thus completed. □

Lemma 3.2. *For the function φ stated in Proposition* 2.1, *the equality* (3.1) *holds.*

Proof. In the proof, we often use the equality

$$\int_0^L f(x)\Big(\int_0^x g(\xi)\,d\xi\Big)\,dx = -\int_0^L \Big(\int_L^x f(\xi)\,d\xi\Big)g(x)\,dx, \tag{3.6}$$

where f and g are functions of $L^2(0,L)$.

Differentiating $V(t;\varphi)$ in t, we have

$$\dot V(t;\varphi) = \dot E(t;\varphi) + \epsilon \dot F(t;\varphi).$$

Let us calculate the right-hand side of the above. First of all, multiplying both sides of (2.1) by φ_t and integrating the result in x from 0 to L, we can see from (3.6), (2.2), integration by parts, and (2.4) that

$$\dot E(t;\varphi) = -[k_1u_t^2 + k_2w_t^2 + l\varphi_t^2]_{x=L}.$$

Next, we consider

$$\begin{aligned}\dot F(t;\varphi) = &\int_0^L \{\rho u_{tt}(xu_x - u) + \rho w_{tt}(xw_x - w) + I_\rho x\varphi_{tt}\varphi_x\}\,dx \\ &+ \int_0^L \{\rho u_t(xu_{xt} - u_t) + \rho w_t(xw_{xt} - w_t) + I_\rho x\varphi_t\varphi_{xt}\}\,dx.\end{aligned} \tag{3.7}$$

Substituting (2.1) into $I_\rho\varphi_{tt}$ of the above, and using (3.6), we see that the first term of the right-hand side of (3.7) is equal to

$$\begin{aligned}\int_0^L \Big\{&\rho u_{tt}(xu_x - u) + \rho w_{tt}(xw_x - w) \\ &- \rho u_{tt}\int_0^x \xi(\cos\varphi(\xi,t))_x\,d\xi - \rho w_{tt}\int_0^x \xi(\sin\varphi(\xi,t))_x\,d\xi \\ &+ \tfrac12 EIx(\varphi_x^2)_x - k_1u_t(L,t)x(\cos\varphi)_x - k_2w_t(L,t)x(\sin\varphi)_x\Big\}\,dx.\end{aligned} \tag{3.8}$$

Furthermore, from integration by parts and (2.2), we have that (3.8) is equal to

$$\frac12 EIL[\varphi_x^2]_{x=L} - \int_0^L \frac12 EI\varphi_x^2\,dx - [k_1u_t(xu_x - u) + k_2w_t(xw_x - w)]_{x=L}.$$

The second term of the right-hand side of (3.7) is calculated as

$$\begin{aligned}&\int_0^L \frac{x}{2}\{\rho(u_t^2)_x + \rho(w_t^2)_x + I_\rho(\varphi_t^2)_x\}\,dx - \int_0^L (\rho u_t^2 + \rho w_t^2)\,dx \\ &= \frac{L}{2}[\rho u_t^2 + \rho w_t^2 + I_\rho\varphi_t^2]_{x=L} - \frac12\int_0^L (3\rho u_t^2 + 3\rho w_t^2 + I_\rho\varphi_t^2)\,dx.\end{aligned}$$

Therefore, we arrive at

$$\begin{aligned}\dot F(t;\varphi) = &- E(t;\varphi) - \int_0^L (\rho u_t^2 + \rho w_t^2)\,dx \\ &+ (L/2)[\rho u_t^2 + \rho w_t^2 + I_\rho\varphi_t^2 + EI\varphi_x^2]_{x=L} \\ &- [k_1u_t(xu_x - u) + k_2w_t(xw_x - w)]_{x=L}.\end{aligned}$$

The proof is thus completed. □

ERRATUM: A UNIQUENESS RESULT FOR THE LINEAR SYSTEM OF ELASTICITY AND ITS CONTROL THEORETICAL CONSEQUENCES*

ENRIQUE ZUAZUA†

Abstract. In this note we explain why the three-dimensional counterexample of section 7.2 of the paper under consideration [E. Zuazua, *SIAM J. Control Optim.,* 34 (1996), pp. 1473–1495] is incorrect. It concerns the existence of eigenfunctions for the Dirichlet Laplacian of a special form. We claimed the existence of particular three-dimensional domains in which these eigenfunctions do exist. However, in a recent joint work with G. Sweers [G. Sweers and E. Zuazua, *J. Elasticity,* to appear], we have proved that they may not exist in any bounded Lipschitz domain in dimensions $n \geq 3$.

PII. S0363012998334122

There is a mistake in the counterexample given in section 7.2 for dimension $n = 3$. Indeed, the function ϕ that we propose on page 1490 of [1] does not satisfy the Dirichlet homogeneous boundary condition in the second surface of formula (7.2). This function ϕ does satisfy the differential equation

$$-\mu\Delta\Phi - (\lambda + 2\mu)\frac{\partial^2\Phi}{\partial x_3^2} = \kappa^2\Phi \tag{1}$$

but may not be considered as a counterexample for the Dirichlet problem. The domains indicated in the figures of that section correspond to the analytical expressions

$$-\frac{\sqrt{\lambda + 2\mu}}{k}\arcsin\left(p(x_1, x_2)\right) \leq x_3 \leq \frac{\sqrt{\lambda + 2\mu}}{k}\arcsin\left(p(x_1, x_2)\right). \tag{2}$$

The function ϕ given in that section can be slightly modified to fulfill the Dirichlet boundary condition on the boundary of that domain. It is sufficient to take

$$\phi\left(x_1, x_2, x_3\right) = p\left(x_1, x_2\right) - \sin\left(\frac{k}{\sqrt{\lambda + 2\mu}} \mid x_3 \mid\right) \tag{3}$$

(we just replace x_3 by $\mid x_3 \mid$). Note, however, that this ϕ satisfies

$$-\mu\Delta\phi - (\lambda + \mu)\partial_3^2\phi = k^2\phi + \xi, \tag{4}$$

ξ being a measure with support on $x_3 = 0$. Thus, it does not quite solve the eigenvalue problem under consideration. In fact, in a recent joint work with G. Sweers [2] we prove that, in dimension $n = 3$, there is no Lipschitz domain Ω in which there is a nontrivial solution of (1) satisfying the homogeneous Dirichlet boundary conditions and being of the form $\Phi(x_1, x_2, x_3) = p(x_1, x_2) + q(x_3)$. This unexpected result is sharp since, as indicated in section 7.1, in dimension $n = 2$, there are polygonal domains in which the corresponding two-dimensional problem admits nontrivial eigenfunctions of the form $\Phi(x_1, x_2) = p(x_1) + q(x_2)$. The rest of the results of this paper remain true. Note, however, that, according to the new developments indicated above, Theorem 1.3 is true for all Lipschitz bounded domains when $n = 3$ and not only under the additional assumptions of Theorem 1.1.

EXISTENCE AND APPROXIMATION OF ROBUST SOLUTIONS OF VARIATIONAL INEQUALITY PROBLEMS OVER POLYTOPES*

GERARD VAN DER LAAN[†], DOLF TALMAN[‡], AND ZAIFU YANG[§]

Abstract. We study nonlinear variational inequality problems over polytopes from a viewpoint of stability and propose a new solution concept. Extending an earlier concept proposed by Yang [Z. Yang, *SIAM J. Control Optim.*, 34 (1996), pp. 491–506] on the unit simplex, we will introduce the concept of the robust stationary point, which is a refinement of the concept of the stationary point. Though a stationary point need not be robust, it is shown that every continuous function on a polytope has a robust stationary point. We develop a simplicial algorithm to compute a robust stationary point of a continuous function on a polytope. The algorithm can be briefly stated as follows. Starting with any point in the relative interior of a polytope, the algorithm generates a piecewise linear path which leads to an approximate robust stationary point of any a priori chosen accuracy within a finite number of steps. Moreover, we also discuss several numerical examples and apply the new concept to noncooperative games and economic equilibrium problems.

1. Introduction.

We study nonlinear stationary point problems from a view point of stability. Given an arbitrary polytope P in $\mathbb{R}^n$ and an arbitrary function $f : \mathrm{P} \mapsto \mathbb{R}^n$, the problem of stationary point (or variational inequality) for f on P is to find a point $x^* \in \mathrm{P}$ such that

$$(x^* - x)^\top f(x^*) \geq 0$$

for any point $x \in \mathrm{P}$. Such a point x^* is called a stationary point of f on P. This problem has many important applications in various fields, such as noncooperative game theory, economic equilibrium theory, fixed point theory, nonlinear optimization theory, and engineering. The concept of a robust stationary point is a refinement of the concept of a stationary point of a continuous function on the unit simplex and was essentially motivated from problems of economic equilibrium, noncooperative games, biology, and engineering (see, e.g., Myerson [13], van Damme [3], and Yamamoto [20]). It is well known (see Hartman and Stampacchia [9] and Eaves [4]) that a continuous function on a compact convex nonempty subset of $\mathbb{R}^n$ has at least one stationary point. In general, a continuous function on a compact convex nonempty subset of $\mathbb{R}^n$ has multiple stationary points, and some of them are undesirable from a viewpoint of

stability. Hence it is very important to eliminate those undesirable stationary points in the context of game theory and general equilibrium theory.

Based on these ideas we will apply the concept of robust stationary point to nonlinear stationary point problems on polytopes. Though a stationary point need not be robust, it is shown that every continuous function on a polytope has a robust stationary point. When we apply this new concept to game theoretic problems and economic equilibrium problems, this concept is both game-theoretically and economically meaningful. Furthermore, we develop a simplicial algorithm to find a robust stationary point for any continuous function on a polytope. This algorithm can be briefly described as follows. Starting from an arbitrarily chosen interior point of the polytope, the algorithm generates a piecewise linear (PL) path which leads to an approximate robust stationary point of any a priori chosen accuracy within a finite number of steps. The path traced by the algorithm corresponds to a sequence of θ-robust stationary points of the PL approximation of the function with respect to a well-chosen triangulation of the polytope, where $0 < \theta \leq 1$. This triangulation has the novelty that when the path generated by the algorithm approaches the boundary of the polytope, the mesh size of the triangulation along the path automatically converges to zero. This property induces that θ goes to zero for the θ-robust stationary points induced by the path when the path approaches the boundary. Hence the algorithm shares the basic properties of a simplicial homotopy algorithm (see Eaves [5]) and a simplicial restart algorithm (see van der Laan and Talman [11]), but it dispenses with an extra dimension required by simplicial homotopy algorithms. It is also worthwhile to stress that another motivation of this paper comes from variational inequality problems in which the function is not monotone. We only require the function to be continuous. The results we obtain in this paper considerably generalize those of Yang [21] on the unit simplex and of Talman and Yang [17] on the simplotope. For extensive treatments of simplicial algorithms we refer to Allgower and Georg [1], Todd [18], and Yang [22].

This paper is organized as follows. In section 2 we introduce the concept of robust stationary point on polytopes and prove the existence of a robust stationary point for every continuous function. We also give an interpretation of a robust stationary point in term of the complementary slackness condition. Section 3 presents a triangulation of the polytope which underlies the algorithm. In section 4 we give the path of points followed by the algorithm, prove the convergence of the algorithm under the assumption that the function f to be considered is continuous, and also derive the accuracy of an approximate robust stationary point. Section 5 describes the steps of the algorithm. In section 6 we discuss two important and practical applications of the concept of robust stationary point in the context of game theory and economic equilibrium theory.

2. Robust stationary points on polytopes.

We first introduce some notation. The set N denotes the set of all natural numbers. The set N_0 is equal to the union of N and $\{0\}$. The notion $I \subset J$ means I is a proper subset of J and $I \subseteq J$ means $I \subset J$ or $I = J$. The set I_n denotes the set of positive integers $\{1, \ldots, n\}$. The vector $e(i)$ is the ith unit vector of $\mathbf{R}^n$ for each $i \in I_n$. The notion $\mathbf{0}$ is the n-vector of all zeros. Consider an arbitrary full-dimensional polytope

$$\mathrm{P} = \{x \in \mathbf{R}^n \mid a^{i\top} x \leq b_i, \text{ for all } i \in I_m\}.$$

We assume that P is simple and that no constraints are redundant.

For each subset I of I_m, define

$$F(I) = \{x \in \mathrm{P} \mid a^{i\top} x = b_i \ \text{ for all } i \in I\}.$$

Then $F(I)$ is a face of P unless it is empty. Note that $F(\emptyset) = \mathrm{P}$. Let

$$\mathcal{I} = \{\, I \subseteq I_m \mid F(I) \ \text{ is a nonempty face of } \ \mathrm{P}\}.$$

Under the above assumption that $\dim(P) = n$, P is a simple polytope, and the linear inequalities defining P are nonredundant, we have the following observations:

(i) for each face F of P the set $I \in \mathcal{I}$ with $F = F(I)$ is unique and identical with the set $\{i \in I_m \mid a^{i\top} x = b_i \ \text{ for all } x \in F\}$;

(ii) $\dim(F(I)) = n - |I|$;

(iii) G is a facet of $F(I)$ if and only if $G = F(I \cup \{h\})$ for some $h \notin I$ with $I \cup \{h\} \in \mathcal{I}$.

For each $I \in \mathcal{I}$, define

$$F^*(I) = \left\{ x \in \mathbb{R}^n \mid x = \sum_{h \in I} \nu_h a^h, \ \nu_h \geq 0, \ \text{ for all } \ h \in I \right\},$$

with $F^*(\emptyset) = \{\mathbf{0}\}$. Now we introduce the concept of a robust stationary point on polytopes. Let a function $f : \mathrm{P} \mapsto \mathbf{R}^n$ be given.

Definition 2.1. *For given $\theta > 0$ a point $x \in \mathrm{P}$ is a θ-robust stationary point of f if*

(1) *x is an interior point of* P*;*

(2) *for some $I \in \mathcal{I}$, $f(x) = \sum_{h \in I_m} \mu_h a^h$ with $\mu_h \geq 0$ for all $h \in I$ and $\mu_h = 0$ for all $h \in I_m \setminus I$, if $\mu_l > \mu_k$, then $b_l - a^{l\top} x \leq \theta(b_k - a^{k\top} x)$.*

A geometric interpretation of the above definition will be given later. We first give an easy observation.

Lemma 2.2. *For any $c \in \mathbb{R}^n$ there exists $I \in \mathcal{I}$ with $|I| = n$ such that $c = \sum_{h \in I} \mu_h a^h$ with $\mu_h \geq 0$ for all $h \in I$.*

It follows immediately that Definition 2.1 is valid.

Definition 2.3. *A point $x^* \in \mathrm{P}$ is a robust stationary point of f on* P *if there exist sequences $\{\, \theta_l \mid l \in \mathsf{N}\,\}$ of positive numbers and $\{\, x(\theta_l) \mid l \in \mathsf{N}\,\}$ of θ_l-robust stationary points $x(\theta_l)$ of f such that*

$$\lim_{l \to \infty} \theta_l = 0 \quad \textit{and} \quad \lim_{l \to \infty} x(\theta_l) = x^*.$$

Now we derive some properties of stationary points. The following lemma is explicitly given in Burke and More [2] and is implicitly used in Talman and Yamamoto [16].

Lemma 2.4. *Let $f : \mathrm{P} \mapsto \mathbb{R}^n$ be a continuous function. Then $x^* \in \mathrm{P}$ is a stationary point of f on* P *if and only if $x^* \in F(I)$ and $f(x^*) \in F^*(I)$ for some $I \in \mathcal{I}$.*

The following result states that the concept of robust stationary point is a refinement of that of the stationary point.

Lemma 2.5. *Let $f : \mathrm{P} \mapsto \mathbb{R}^n$ be a continuous function. If $x^* \in \mathrm{P}$ is a robust stationary point of f on* P*, then x^* is also a stationary point of f on* P.

Proof. We need to consider two cases. If x^* lies in the interior of P, then it follows from Definitions 2.1 and 2.3 that $f(x^*) = \mathbf{0}$. Hence x^* is a stationary point of f by

Lemma 2.4. If x^* lies on the boundary of P, it easily follows from Definitions 2.1 and 2.3 and Lemma 2.4 that x^* is a stationary point of f on P. □

Now we are going to give an interpretation of a robust stationary point. For a stationary point $x^* \in F(I)$ for some $I \in \mathcal{I}$, we have that $\mu_i > 0$ implies $b_i - a^{i\top} x^* = 0$ for any i. One might think of this relation as the complementary slackness condition, as in the linear programming (LP) theory. In order for x^* to be a robust stationary point, it is reasonable to require that the higher μ_i is, the stronger this equality should be. That is to say, in a neighborhood of x^* for any $\theta > 0$ there should be a point $x(\theta)$ such that if $\mu_i(\theta) > \mu_j(\theta)$, then $x(\theta)$ must be θ times closer to $F(\{i\})$ than to $F(\{j\})$, i.e., $b_i - a^{i\top} x(\theta) \leq \theta(b_j - a^{j\top} x(\theta))$. In section 6 we shall apply the concept of robust stationary point to noncooperative game theory and economic equilibrium theory.

The next two examples demonstrate that the concept of the robust stationary point is indeed a proper refinement of the concept of the stationary point.

Example 2.6. *Take $n = 2$ and $a^1 = -a^3 = (1,0)^\top$, $a^2 = -a^4 = (0,1)^\top$, $b_1 = b_2 = 1$, and $b_3 = b_4 = 0$. Then $\mathrm{P} = C^2 = \{x \in \mathbb{R}^2 \mid x_1 \leq 1,\, x_2 \leq 1,\, -x_1 \leq 0, \text{ and } -x_2 \leq 0\}$. Let a continuous function $f : \mathrm{P} \mapsto \mathbb{R}^2$ be given by*

$$f(x) = (x_1 - 1, x_2 - 1)^\top.$$

It is not difficult to show that for any continuous function $f : C^2 \mapsto \mathbb{R}^2$, x^* is a stationary point of f if and only if it holds that

$$\begin{array}{lll} f_i(x^*) \leq 0 & \text{if} & x_i^* = 0, \\ f_i(x^*) = 0 & \text{if} & 0 < x_i^* < 1, \\ f_i(x^*) \geq 0 & \text{if} & x_i^* = 1. \end{array}$$

The set of stationary points of the function is equal to

$$\{(0,0)^\top,\ (1,1)^\top,\ (1,0)^\top,\ (0,1)^\top\}.$$

However, only $(0,0)^\top$ is a robust stationary point of f. To show this, let for $\theta \in (0,1)$

$$x_1(\theta) = \theta,\ x_2(\theta) = \theta^2.$$

Clearly, $x(\theta)$ lies in the interior of P for each $\theta \in (0,1)$. Note that

$$f(x(\theta)) = \mu_3 a^3 + \mu_4 a^4 = \mu_3(-1,0)^\top + \mu_4(0,-1)^\top,$$

with $\mu_3 > 0$ and $\mu_4 > 0$. In fact we have $\mu_4 = 1 - \theta^2 > \mu_3 = 1 - \theta$. It also holds that

$$b_4 - a^{4\top} x(\theta) = \theta^2 \leq \theta(b_3 - a^{3\top} x(\theta)) = \theta^2.$$

Hence for each $\theta \in (0,1)$, $x(\theta)$ is a θ-robust stationary point. It is easy to see that

$$\lim_{\theta \to 0^+} x(\theta) = (0,0)^\top.$$

It is also easy to check why all other stationary points are not robust stationary points. We leave it to the reader.

Example 2.7. *Let $f : C^2 \mapsto \mathbb{R}^2$ be given by*

$$f(x) = (x_2(1 - x_1)^2(x_2 - 1), x_1(1 - x_2)^2(x_1 - 1))^\top,$$

where the set C^2 is as given in Example 2.6.

The set of stationary points of this function is equal to

$$\begin{gathered}\{(0,x)^\top \mid 0 \le x \le 1\} \cup \{(1,x)^\top \mid 0 \le x \le 1\} \\ \cup\{(x,1)^\top \mid 0 \le x \le 1\} \cup \{(x,0)^\top \mid 0 \le x \le 1\}.\end{gathered}$$

It is remarkable that this function has only one stationary point $(0,0)^\top$ which is a robust stationary point. We will prove it. For $\theta \in (0,1)$, let

$$x(\theta) = (\theta, \theta^2)^\top.$$

Clearly, $x(\theta)$ is an interior point of C^2. For each $\theta \in (0,1)$ we have

$$f(x(\theta)) = \mu_3 a^3 + \mu_4 a^4 = \mu_3(-1,0)^\top + \mu_4(0,-1)^\top,$$

with $\mu_3 = \theta^2(1-\theta)^2(1-\theta^2) > 0$ and $\mu_4 = \theta(1-\theta^2)^2(1-\theta) > 0$. Since $\frac{\mu_4}{\mu_3} = \frac{(1+\theta)}{\theta} > 1$, $\mu_4 > \mu_3$. It also holds that

$$b_4 - a^{4\top} x(\theta) = \theta^2 \le \theta(b_3 - a^{3\top} x(\theta)) = \theta^2.$$

Hence $x(\theta)$ is a θ-robust stationary point. Since

$$\lim_{\theta \to 0^+} x(\theta) = (0,0)^\top,$$

the point $(0,0)^\top$ is a robust stationary point by definition. It is left to the reader to check that any other stationary point is not a robust stationary point.

We now come to the question of under what conditions there exists a robust stationary point for a function on a polytope. In the remainder of this section we prove that every continuous function $f : \mathrm{P} \mapsto \mathbb{R}^n$ has a robust stationary point, and hence continuity is enough to ensure the existence of a robust stationary point.

Define the function $\eta : \mathbb{R}^n \mapsto \mathbb{R}$ by

$$\eta(x) = \min_{i \in I_m} (b_i - a^{i\top} x).$$

Let $\Upsilon = \max_{x \in \mathrm{P}} \eta(x)$. Since P is a bounded full-dimensional polyhedron, it is easy to see that $\Upsilon > 0$. Take any $\omega \in (0, \Upsilon]$. For $I \in \mathcal{I}$ and $\theta \in [0, \frac{1}{2}]$, we define a^I and $b_I(\theta)$ by

$$\begin{aligned} a^I &= \sum_{h \in I} a^h, \\ b_I(\theta) &= \sum_{h \in I} b_h - \omega \sum_{k=n+1-|I|}^{n} \theta^k. \end{aligned} \tag{2.1}$$

Definition 2.8. *For each $\theta \in [0, \frac{1}{2}]$, the set $A(\theta)$ in $\mathbb{R}^n$ is given by*

$$A(\theta) = \{\, x \in \mathbb{R}^n \mid a^{I\top} x \le b_I(\theta), \ \textit{for any} \ \ I \in \mathcal{I} \,\}.$$

We remark that for each $\theta \in [0, \frac{1}{2}]$, $A(\theta)$ is a polytope which is a nonempty subset of P and $A(0) = \mathrm{P}$. Note that we take the interval $[0, \frac{1}{2}]$ for the purpose of the triangulation to be introduced in the coming section.

Let the collection of ordered indexed sets, $\mathcal{J}$, be defined by

$$\mathcal{J} = \{L = (L_1, \ldots, L_k) \mid \emptyset \subset L_1 \subset \cdots \subset L_k \subseteq I \ \text{ for each } \ I \in \mathcal{I}, \ k \in I_n \,\} \cup \{\emptyset\}.$$

For $L = (L_1, \dots, L_k) \in \mathcal{J}$ and $\theta \in (0, \frac{1}{2}]$, let

$$F(\theta; L) = \{x \in A(\theta) \mid a^{L_h\top} x = b_{L_h}(\theta) \ \text{ for all } h \in I_k\}.$$

Then $F(\theta; L)$ is a face of $A(\theta)$ with dimension equal to $n - k$ in case $L_1 \neq \emptyset$. Note that $F(\theta; \emptyset) = A(\theta)$. For each $L = (L_1, \dots, L_k) \in \mathcal{J}$, define

$$F^*(L) = \{x \in \mathbb{R}^n \mid x = \sum_{h=1}^{k} \mu_h a^{L_h},\ \mu_h \geq 0 \ \text{ for all } \ h \in I_k\}$$

with $F^*(\emptyset) = \{\mathbf{0}\}$.

Let $f : \mathrm{P} \mapsto \mathbb{R}^n$ be a continuous function. Then for each $\theta \in [0, \frac{1}{2}]$ there is a stationary point of f on $A(\theta)$, since $A(\theta)$ is a nonempty convex compact set and f is a continuous function. For each $\theta \in [0, \frac{1}{2}]$, let $x(\theta)$ denote a stationary point of f on $A(\theta)$. Then by Lemma 2.4 there exists a minimal face $F(\theta; L(\theta))$ for some $L(\theta) = (L_1(\theta), \dots, L_k(\theta)) \in \mathcal{J}$ such that $x(\theta) \in F(\theta; L(\theta))$ and $f(x(\theta)) \in F^*(L(\theta))$. Note that $L_k(\theta) \in \mathcal{I}$ by definition. So there exist $\mu_l \geq 0$ for all $l \in L_k(\theta)$ and $\mu_l = 0$ for all $l \in I_m \setminus L_k(\theta)$ such that

$$f(x(\theta)) = \sum_{h \in I_m} \mu_h a^h.$$

We can choose $\omega \in (0, \Upsilon]$ so small that for every $\theta \in [0, \frac{1}{2}]$ it holds that

$$b_q - a^{q\top} x(\theta) \leq \theta(b_p - a^{p\top} x(\theta))$$

for all $q \in L_k(\theta)$ and all $p \in I_m \setminus L_k(\theta)$. Now we have the following lemma.

LEMMA 2.9. *Let $f : \mathrm{P} \mapsto \mathbb{R}^n$ be a continuous function. Then for each $\theta \in (0, \frac{1}{2}]$ a stationary point of f on $A(\theta)$ is a θ-robust stationary point of f.*

Proof. Since $A(\theta)$ is a nonempty convex compact set and f is a continuous function, f has a stationary point $z^* \in A(\theta)$, i.e.,

$$(z^* - x)^\top f(z^*) \geq 0$$

for all $x \in A(\theta)$. Then there exists a minimal face $F(\theta; L)$ with $L = (L_1, \dots, L_k) \in \mathcal{J}$ such that $z^* \in F(\theta; L)$ and $f(z^*) \in F^*(L)$. So there exist $\mu_1 \geq 0$, …, $\mu_k \geq 0$ such that

$$f(z^*) = \sum_{h=1}^{k} \mu_h a^{L_h}.$$

Without loss of generality we may assume that all $\mu_h > 0$. Let t_1, …, t_k be a sequence of increasing positive integers such that $L_h = \{i_{t_1}, \dots, i_{t_h}\}$ for each $h \in I_k$. Note that $t_k \leq n$. Let $L_0 = \emptyset$. For each $h \in I_k$ and $l \in L_h \setminus L_{h-1}$, let $\nu_l = \sum_{i=h}^{k} \mu_i$. Note that $|L_h| > 0$ for all $h \in I_k$ and $|L_p| < |L_q|$ with $1 \leq p < q \leq k$ by definition. Hence we have $\nu_p > \nu_q$ for all $p \in L_i$ and $q \in L_j$ with $1 \leq i < j \leq k$ and

$$f(z^*) = \sum_{h \in L_k} \nu_h a^h.$$

We will prove $b_p - a^{p\top} z^* \leq \theta(b_q - a^{q\top} z^*)$. It is sufficient to restrict to the case in which $p \in L_i$ and $q \in L_{i+1}$ with $1 \leq i \leq k - 1$. We have to consider the following cases.

Case 1. If $|L_i| + 1 = |L_{i+1}| = 2$, we have

$$\begin{array}{rcl} a^{p\top} z^* & = & b_p - \omega\theta^n, \\ (a^p + a^q)^\top z^* & = & b_p + b_q - \omega(\theta^n + \theta^{n-1}). \end{array}$$

It is easy to see that

$$b_p - a^{p\top} z^* \leq \theta(b^q - a^{q\top} z^*).$$

Case 2. If $1 = |L_i|$ and $|L_{i+1}| \geq 2$, then we have

$$\begin{array}{rcl} a^{p\top} z^* & = & b_p - \omega\theta^n, \\ (a^p + a^q)^\top z^* & \leq & b_p + b_q - \omega(\theta^n + \theta^{n-1}). \end{array}$$

It follows that

$$b_q - a^{q\top} z^* \geq \omega\theta^{n-1}.$$

Hence we have

$$b_p - a^{p\top} z^* \leq \theta(b^q - a^{q\top} z^*).$$

Case 3. If $1 < |L_i| + 1 = |L_{i+1}|$, then we have

$$\begin{array}{rcl} \sum_{h\in L_i\setminus\{p\}} a^{h\top} z^* & \leq & \sum_{h\in L_i\setminus\{p\}} b_h - \omega \sum_{h=n+2-|L_i|} \theta^h, \\ \sum_{h\in L_i} a^{h\top} z^* & = & \sum_{h\in L_i} b_h - \omega \sum_{h=n+1-|L_i|} \theta^h. \end{array}$$

It follows that

$$b_p - a^{p\top} z^* \leq \omega\theta^{n+1-|L_i|}.$$

On the other hand we have

$$b_q - a^{q\top} z^* = \omega\theta^{n-|L_i|}.$$

Hence

$$b_p - a^{p\top} z^* \leq \theta(b_q - a^{q\top} z^*).$$

Case 4. If $1 < |L_i| + 1 < |L_{i+1}|$, then we have

$$\begin{array}{rcl} \sum_{h\in L_i} a^{h\top} z^* & = & \sum_{h\in L_i} b_h - \omega \sum_{h=n+1-|L_i|}^{n} \theta^h, \\ \sum_{h\in L_i\setminus\{p\}} a^{h\top} z^* & \leq & \sum_{h\in L_i\setminus\{p\}} b_h - \omega \sum_{h=n+2-|L_i|}^{n} \theta^h. \end{array}$$

This implies

$$b_p - a^{p\top} z^* \leq \omega\theta^{n+1-|L_i|}. \tag{2.2}$$

On the other hand, we have

$$\begin{array}{rcl} \sum_{h\in L_i} a^{h\top} z^* & = & \sum_{h\in L_i} b_h - \omega \sum_{h=n+1-|L_i|}^{n} \theta^h, \\ \sum_{h\in L_i\cup\{q\}} a^{h\top} z^* & \leq & \sum_{h\in L_i\cup\{q\}} b_h - \omega \sum_{h=n+2-|L_i|}^{n} \theta^h. \end{array}$$

This implies

$$b_q - a^{q\top} z^* \geq \omega\theta^{n-|L_i|}. \tag{2.3}$$

Now it follows from (2.2) and (2.3) that

$$\frac{b_p - a^{p\top} z^*}{b_q - a^{q\top}} \leq \frac{\omega\theta^{n+1-|L_i|}}{\omega\theta^{n-|L_i|}} = \theta.$$

Hence

$$b_p - a^{p\top} z^* \leq \theta(b_q - a^{q\top} z^*).$$

Case 5. For any $q \in I_m \setminus L_k$, we have $\nu_q = 0$. Take any $p \in L_k$. It is clear that $\nu_p > \nu_q$. Now it follows from the choice of ω that

$$b_p - a^{p\top} z^* \leq \theta(b_q - a^{q\top} z^*).$$

We completed the proof. □

THEOREM 2.10. *Let $f : \mathrm{P} \mapsto \mathbb{R}^n$ be a continuous function. Then f has at least one robust stationary point.*

Proof. Let $\{\theta_k\}_1^\infty$ be a sequence of positive real numbers strictly between zero and $\frac{1}{2}$ converging to zero. According to Lemma 2.9 there exists a θ_k-robust stationary point $x(\theta_k)$ for each $k \in \mathsf{N}$. Since P is a compact set, there exists a subsequence out of $\{x(\theta_k)\}_1^\infty$ converging to a cluster point $x^* \in \mathrm{P}$. It is clear that x^* is a robust stationary point of f on P. □

In the subsequent sections we will develop an algorithm to find a robust stationary point of any continuous function. This also gives a constructive proof of Theorem 2.10.

3. A continuous refining triangulation of polytopes. In this section we introduce a triangulation of the polytope which underlies the algorithm. Let $v = (v_1, \ldots, v_n)^\top$ be any point in the interior of the polytope P. The point v will be the starting point of the algorithm. Take a sufficiently small $\omega \in (0, \Upsilon]$ such that v is contained in the interior of $A(\frac{1}{2})$.

We say that $I \in \mathcal{J}$ conforms to $J \in \mathcal{J}$ if it holds that every component of I is also a component of J. Let $\{\, \theta_k \mid k \in \mathsf{N}\}$ be a strictly decreasing sequence of real numbers in $(0, \frac{1}{2}]$ converging to zero. Let θ_0 be a constant bigger than θ_1. For $L = (L_1, \ldots, L_k) \in \mathcal{J}$, let

$$F(\theta_0, \theta_1; L) = \{\, x | x = av + (1-a)z \ \text{ for some } \ z \in F(\theta_1; L) \ \text{ and } \ a \in [0,1] \,\}$$

and for $k \in \mathsf{N}$

$$F(\theta_k, \theta_{k+1}; L) = \{\, x | x = ay + (1-a)z \ \text{ for some } y \in F(\theta_k; L), \\ z \in F(\theta_{k+1}; L), \text{ and } \ a \in [0,1] \,\}.$$

For $L \in \mathcal{J}$ and $l \in \mathsf{N}$, we denote the union of $F(\theta_{i-1}, \theta_i; L)$ over $i = 1, \ldots, l$ by $\mathcal{F}(\theta_l; L)$. For $l \in \mathsf{N}_0$, the union of $F(\theta_l, \theta_{l+1}; L)$ over all $L \in \mathcal{J}$ is denoted by $\mathcal{F}(\theta_l, \theta_{l+1})$. For $L \in \mathcal{J}$, we denote the union of $F(\theta_k, \theta_{k+1}; L)$ over all $k \in \mathsf{N}_0$ by $\mathcal{F}(L)$. Notice that the dimension of $\mathcal{F}(L)$ is equal to $t = n - k + 1$ for $L = (L_1, \ldots, L_k) \in \mathcal{J}$. The union of $F(\theta_l, \theta_{l+1}; L)$ over all $L \in \mathcal{J}$ and all $l \in \mathsf{N}_0$ is equal to the interior of the polytope P. The subdivision of $\mathrm{P} = C^2$ of Example 2.6 with $\theta_k = 2^{-k}$ for $k \in \mathsf{N}$, $\omega = \frac{1}{2}$, and $v = (1/2, 1/2)^\top$ is depicted in Figure 1. Note that in the figure we only draw the subdivision for $\theta_1 = \frac{1}{2}$ and $\theta_2 = \frac{1}{4}$.

A simplicial subdivision underlying the algorithm must be such that every set $F(\theta_k, \theta_{k+1}; L)$ is subdivided into t-dimensional simplices. Such a triangulation can be

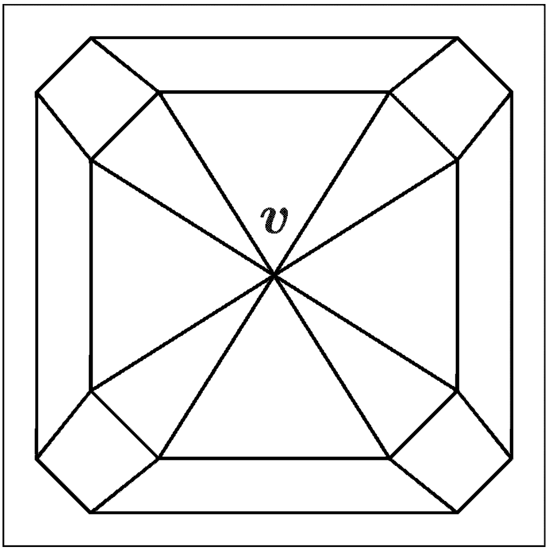

FIG. 1. *Subdivision of the interior of C^2.*

described as follows. For $L \in \mathcal{J}$, we denote $v(0,L) = v$, and for $l \in \mathsf{N}$, let $v(l,L)$ be a relative interior point (e.g., the barycenter) of $F(\theta_l; L)$. For $L \in \mathcal{J}$, if L consists of n components, then $F(\theta_l; L)$ is a vertex of $A(\theta_l)$. For general $L \in \mathcal{J}$, let $F(\theta_l; L(n))$ be a vertex of $F(\theta_l; L)$, i.e., $L(n)$ has n components and L conforms to $L(n)$. Moreover let $(L^1, L^2, \ldots, L^t) = \gamma(L, L(n))$ be a conformation between L and $L(n)$, i.e., $L^1 = L(n)$, $L^k \in \mathcal{J}$ for $k = 2, \ldots, t-1$, $L^t = L$, L^k conforms to L^{k-1} and has one component less than L^{k-1} for $k = 2, \ldots, t$. For given $k \in \mathsf{N}_0$, $L \in \mathcal{J}$, and $\gamma(L, L(n))$, the subset $F(\theta_k, \theta_{k+1}; L, \gamma(L, L(n)))$ of $F(\theta_k, \theta_{k+1}; L, \gamma(L, L(n)))$ of $F(\theta_k, \theta_{k+1}; L)$ is defined to be the convex hull of $v(k, L^1)$, $v(k, L^2)$, $\ldots$, $v(k, L^t)$, $v(k+1, L^1)$, $v(k+1, L^2)$, $\ldots$, and $v(k+1, L^t)$, so

$$F(\theta_k, \theta_{k+1}; L, \gamma(L, L(n))) = \left\{ x \in \mathrm{P} | x = v(k, L(n)) + \alpha q^0 + \sum_{j=1}^{t-1} \alpha_j q^j(\alpha), \right.$$

$$\left. 0 \leq \alpha \leq 1, \text{ and } 0 \leq \alpha_{t-1} \leq \cdots \leq \alpha_1 \leq 1 \right\},$$

where $q^0 = v(k+1, L(n)) - v(k, L(n))$, and for $j = 1, \ldots, t-1$, $0 \leq \alpha \leq 1$,

$$q^j(\alpha) = \alpha(v(k+1, J_{j+1}) - v(k+1, J_j)) + (1-\alpha)(v(k, J_{j+1}) - v(k, J_j)).$$

The dimension of $F(\theta_k, \theta_{k+1}; L, \gamma(L, L(n)))$ is equal to t, and $F(\theta_k, \theta_{k+1}; L)$ is the union of $F(\theta_k, \theta_{k+1}; L, \gamma(L, L(n)))$ over all conformations $\gamma(L, L(n))$ and over all index sets $L(n)$ conformed by L.

DEFINITION 3.1. *Let d be an arbitrary positive integer. For $k \in \mathsf{N}_0$, the set $G^d(k, k+1; L, \gamma(L, L(n)))$ is the collection of t-simplices $\sigma(a, \pi)$ with vertices y^1, $\ldots$, y^{t+1} in $F(\theta_k, \theta_{k+1}; L, \gamma(L, L(n)))$ such that*

(1) *$y^1 = v(k, L(n)) + a(0)d^{-1}q^0 + (a(0)+dk)^{-1} \sum_{j=1}^{t-1} a(j) q^j(d^{-1}a(0))$, where $a = (a(0), a(1), \ldots, a(n-1))^\top$ is a vector of integers such that $0 \leq a(0) \leq d-1$, and $a(n-1) = \cdots = a(t) = 0 \leq a(t-1) \leq \cdots \leq a(2) \leq a(1) \leq a(0) + dk$;*

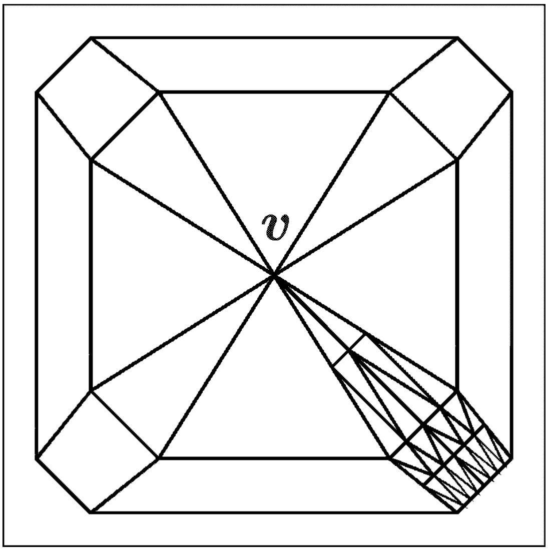

FIG. 2. *The P-triangulation of C^2 for $n = 2$.*

(2) *$\pi = (\pi_1, \ldots, \pi_t)$ is a permutation of $(0, 1, \ldots, t-1)$ such that $s < s'$ if for some $q \in \{1, \ldots, t-2\}$ it holds that $\pi_s = q$, $\pi_{s'} = q+1$, $a(q) = a(q+1)$ in case $q \geq 1$, and $a(0) + kd = a(1)$ in case $q = 0$;*

(3) *Let i be such that $\pi_i = 0$. Then*

$$\begin{aligned} y^{j+1} &= y^j + (a(0)+kd)^{-1} q^{\pi_j}(d^{-1}a(0)), \quad j = 1, \ldots, i-1, \\ y^{i+1} &= v(k, L(n)) + (a(0)+1)d^{-1}q^0 \\ &\quad + (a(0)+1+kd)^{-1} \sum_{j=1}^{t-1} a(j) q^j (d^{-1}(a(0)+1)) \\ &\quad + (a(0)+1+kd)^{-1} \sum_{j=1}^{i-1} q^{\pi_j}(d^{-1}(a(0)+1)), \\ y^{j+1} &= y^j + (a(0)+1+kd)^{-1} q^{\pi_j}(d^{-1}(a(0)+1)), \quad i < j \leq t. \end{aligned}$$

The set $G^d(k, k+1; L, \gamma(L, L(n)))$ is a simplicial subdivision of $F(\theta_k, \theta_{k+1}; L, \gamma(L, L(n)))$ with grid size d^{-1}. Moreover, the union $G^d(k, k+1; L)$ of $G^d(k, k+1; L, \gamma(L, L(n)))$ over all conformations $\gamma(L, L(n))$ and $L(n)$ conformed by L is a simplicial subdivision of $F(\theta_k, \theta_{k+1}; L)$. The union $G^d(k, k+1)$ of $G^d(k, k+1; L)$ over all sets $L \in \mathcal{J}$ induces a triangulation of $\mathcal{F}(\theta_k, \theta_{k+1})$. Taking the union $G^d(k)$ of $G^d(j, j+1)$ over $j = 0, 1, \ldots, k-1$, we obtain a simplicial subdivision of $A(\theta_k)$ with grid size d^{-1}. The union of $G^d(k)$ over all $k \in \mathsf{N}_0$ is a continuous refining simplicial subdivision of the interior of P and is called the P-triangulation of P. We remark that for $L \in \mathcal{J}$ the union $G^d(L)$ of $G^d(k, k+1; L)$ over $k = 0, 1, \ldots,$ is a simplicial subdivision of the set $\mathcal{F}(L)$. The P-triangulation of $\text{P} = C^2$ with $\theta_k = 2^{-k}$ for $k \in \mathsf{N}$, and $v = (1/2, 1/2)^\top$ with $\theta_k = 2^{-k}$ for $k \in \mathsf{N}$, and $v = (1/2, 1/2)^\top$ is illustrated in Figure 2. Note that in the figure we only draw a part of the P-triangulation.

As a norm we use the Euclidean norm $||\cdot||$ in $\mathbb{R}^n$. For a set B in $\mathbb{R}^n$, we define the diameter of B by

$$\mathrm{diam}(B) = \sup\{\, ||y^1 - y^2|| \mid y^1, y^2 \in B\,\}.$$

Then for given $k \in \mathsf{N}_0$ the mesh size of $G^d(k, k+1)$ is equal to

$$\delta_{k,d} = \sup\{\, \mathrm{diam}(\sigma) \mid \sigma \in G^d(k, k+1)\,\}.$$

Now we have the following observation.

LEMMA 3.2. *For the P-triangulation of* P *with grid size d^{-1}, it holds that*

$$\lim_{k\to\infty} \delta_{k,d} = 0.$$

The P-triangulation has the following property that the diameter of the simplices converges to zero when the boundary of P is approached.

4. The path of the algorithm. Now we discuss operation of the algorithm in the P-triangulation of the polytope P to approximate a robust stationary point of a continuous function f on P. Starting at the point v, the algorithm will generate a sequence of adjacent simplices of the P-triangulation in the set $\mathcal{F}(L)$ having L-complete common facets for varying $L \in \mathcal{J}$.

DEFINITION 4.1. *Let $f : \mathrm{P} \mapsto \mathbb{R}^n$ be a continuous function. For given $L = (L_1, \ldots, L_k) \in \mathcal{J}$ and $s = t$ or $t-1$, where $t = n-k+1$, an s-simplex σ with vertices $y^1, \ldots, y^{s+1}$ is L-complete if the system of linear equations*

$$\sum_{i=1}^{s+1} \lambda_i \begin{pmatrix} f(y^i) \\ 1 \end{pmatrix} - \sum_{j=1}^{k} \mu_j \begin{pmatrix} a^{L_j} \\ 0 \end{pmatrix} = \begin{pmatrix} \mathbf{0} \\ 1 \end{pmatrix} \tag{4.1}$$

has a solution λ_i^*, $i \in I_{s+1}$, μ_j^*, $j \in I_k$, satisfying $\lambda_i^* \geq 0$, $i \in I_{s+1}$, $\mu_j^* \geq 0$, $j \in I_k$.

Notice that the system (4.1) has $s+1+k$ columns, so when $s = t-1$, the system has $n+1$ columns, and for $s = t$ one column more. A solution λ_i^*, $i \in I_{s+1}$, μ_j^*, $j \in I_k$, will be denoted by (λ^*, μ^*).

Nondegeneracy assumption For $s = t-1$ the system (4.1) has a unique solution (λ^*, μ^*) with $\lambda_i^* > 0$, $i \in I_t$, and $\mu_j^* > 0$, $j \in I_k$, and for $s = t$ at most one component of (λ^*, μ^*) is equal to zero. We remark that this assumption can easily be dropped if we use the lexicographic pivoting method to solve system (4.1); see e.g., Todd [18] or Yang [22].

Under this nondegeneracy assumption $\sigma^0 = \{\, v\,\}$ is L^0-complete with $L^0 = (L_1^0, \ldots, L_n^0) \in \mathcal{J}$, where $L_h^0 = \{i_1, \ldots, i_h\}$ for $h \in I_n$ such that the system of linear equations

$$f(v) = \sum_{h=1}^{n} \mu_h a^{L_h^0}$$

has solutions $\mu_h > 0$ for all $h \in I_n$.

The algorithm now starts with σ^0 for $L = L^0$ and follows a sequence of adjacent t-simplices in $\mathcal{F}(L)$ for varying L, $L \in \mathcal{J}$, such that their common facets are L-complete. In this way within a finite number of steps either the algorithm reaches a point $\bar{x}$ in an n-dimensional simplex for which $\bar{f}_j(\bar{x}) = 0$ for every $j \in I_n$, where $\bar{f}$ is the PL approximation of f with respect to the P-triangulation, or for $k = 1, 2, \ldots,$ the algorithm finds a $J(k)$-complete simplex in $F(\theta_k; J(k))$ for some $J(k) \in \mathcal{J}$. Let $\{ \theta_t \mid t \in \mathsf{N} \}$ be given as in section 3. Now we have the following result.

Lemma 4.2. *For some $l \in \mathsf{N}$ and $L = (L_1, \ldots, L_k) \in \mathcal{J}$, let σ with vertices $y^1, \ldots, y^t$ be an L-complete $(t-1)$-simplex lying in $F(\theta_l; L)$. Let (λ^*, μ^*) be the corresponding unique solution of system (4.1). Then $x = \sum_{i=1}^t \lambda_i^* y^i$ is a θ_l-robust stationary point of the PL approximation $\bar{f}$ of f with respect to the P-triangulation. Moreover, x is a stationary point of $\bar{f}$ on $A(\theta_l)$.*

Proof. It follows from (4.1) that at $x = \sum_{i=1}^t \lambda_i^* y^i$

$$\bar{f}(x) = \sum_{h=1}^{k} \mu_h^* a^{L_h},$$

where $\mu_h^* > 0$ for $h = 1, \ldots, k$. So $x \in F(\theta_l; L)$ and $\bar{f}(x) \in F^*(L)$. According to Lemma 2.4 this implies that x is a stationary point of $\bar{f}$ on $A(\theta_l)$. By applying Lemma 2.9 we know that x is a θ_l-robust stationary point of $\bar{f}$. □

The next lemma shows that a θ_l-robust stationary point of $\bar{f}$ is an approximate θ_l-robust stationary point of f.

Lemma 4.3. *Let $\eta_{l,d} = \sup\{ \operatorname{diam}(f(\sigma)) \mid \sigma \in G^d(l-1, l) \}$. Let x be a θ_l-robust stationary point of the PL approximation $\bar{f}$ of f with respect to the P-triangulation with grid size d^{-1} obtained by the algorithm, so that $x \in F(\theta_l; L)$ for some $L \in \mathcal{J}$. Then $f(x)$ lies in the $\eta_{l,d}$-neighborhood of $F^*(L)$, i.e., there is a $y \in F^*(L)$ such that $||y - f(x)|| \leq \eta_{l,d}$.*

Proof. Let $y^1, \ldots, y^t$ be the vertices of a $(t-1)$-simplex of $G^d(l-1, l)$ in $F(\theta_l; L)$ containing x. Then $\bar{f} = \sum_{j=1}^t \lambda_j^* f(y^j)$ lies in $F^*(L)$, where $\lambda_1^*, \ldots, \lambda_t^*$ are convex combination coefficients such that $x = \sum_{j=1}^t \lambda_j^* y^j$. Hence we have

$$\begin{aligned} ||\bar{f}(x) - f(x)|| &= ||\textstyle\sum_{j=1}^t \lambda_j^* f(y^j) - f(x)|| \\ &= ||\textstyle\sum_{j=1}^t \lambda_j^* (f(y^j) - f(x))|| \\ &\leq \textstyle\sum_{j=1}^t \lambda_j^* ||f(y^j) - f(x)|| \\ &\leq \eta_{l,d}. \quad \square \end{aligned}$$

Given a function $f : \mathrm{P} \mapsto \mathbb{R}^n$, let us define a function $g : \mathrm{P} \mapsto \mathrm{P}$ by

$$g(x) = argmin\{(x + f(x) - y)^\top (x + f(x) - y) \mid y \in \mathrm{P}\}.$$

Now we have the following well-known result (see Hartman and Stampacchia [9] and Eaves [4]).

Theorem 4.4. *Let $f : \mathrm{P} \mapsto \mathbb{R}^n$ be a continuous function. Then x^* is a stationary point of f on* P *if and only if x^* is a fixed point of g on* P.

There are several ways of proving the existence of a stationary point in the above theorem. For example, one way is to use Brouwer's fixed point theorem. Of course, we could also use degree theory, as we could use degree theory to prove Brouwer's theorem.

We are now going to discuss the convergence properties of the algorithm. First we consider the case in which the algorithm converges to a boundary point of P. Since P is compact and f is continuous on P, the error $\eta_{l,d}$ tends to zero as the mesh size $\delta_{l,d}$ goes to zero when l goes to infinity. Let x^l be a θ_l-robust stationary point of $\bar{f}$

and $\eta_{l,d}$ the error in Lemma 4.3. Suppose that the algorithm generates the sequence $\{\, x^h \mid h \in \mathsf{N} \,\}$ of approximate θ_l-robust stationary points of f which therefore has a cluster point x^*. For simplicity of notation we can assume that this sequence itself converges to x^*. We are now ready to state the following theorem.

THEOREM 4.5. *Let* $\{\, x^l \mid l \in \mathsf{N} \,\}$ *be a sequence generated by the algorithm with* $x^l \in F(\theta_l; J(l))$ *for each* $l \in \mathsf{N}$. *Then the sequence* $\{\, x^l \mid l \in \mathsf{N} \,\}$ *has a cluster point* x^* *which is a robust stationary point of* f *on* P.

Proof. To prove the theorem, we first extend the domain of the PL approximation $\bar{f}$ of f. Recall from Lemma 3.2 that for a given positive integer d, the mesh size $\delta_{l,d}$ converges to zero as l goes to infinity. We can take $\bar{f}(x)$ to be $f(x)$ if x lies on the boundary of P, since f is a continuous function. Hence $\bar{f}$ is also a continuous function on P. From Lemma 4.2 we know that for each $l \in \mathsf{N}$, x^l is a θ_l-robust stationary point of $\bar{f}$. By definition x^* is a robust stationary point of $\bar{f}$ on P. Now we are going to show that for any given $\epsilon > 0$, there exists a positive integer M such that for $l \in \mathsf{N}$ with $l > M$ there is a θ_l-robust stationary point $y^l \in A(\theta_l)$ of f on P which is in the ϵ-neighborhood of x^l.

Let

$$U(\theta) = \begin{cases} A(\theta) & \text{for } \theta \in [0, \theta_1], \\ A(\theta_1)(\theta - 1)/(\theta_1 - 1) + \{\, v \,\}(\theta - \theta_1)/(1 - \theta_1) & \text{for } \theta \in [\theta_1, 1]. \end{cases}$$

Observe that $U(\theta)$ is a convex and compact set contained in $A(\theta_1)$ for any $\theta \in [\theta_1, 1]$. As θ decreases from 1 to 0, the set $U(\theta)$ first expands from the starting point v to the set $A(\theta_1)$ and then to the whole set P. Let $Y(\theta)$ denote the set of stationary points of f on $U(\theta)$ for $\theta \in [0, 1]$. Notice that for each $\theta \in (0, \theta_1]$, x is a θ-robust stationary point if x belongs to the set $Y(\theta)$.

For each $\theta \in [0, 1]$, define a function $g_\theta : \mathrm{P} \mapsto U(\theta)$ by

$$g_\theta(x) = argmin\{\, (x + f(x) - y)^\top (x + f(x) - y) \mid y \in U(\theta) \,\}.$$

Since $U(\theta)$ is a convex and compact set and f is continuous, the function g_θ is a continuous function. By Theorem 4.4, $x \in Y(\theta)$ if and only if $x = g_\theta(x)$. Define a homotopy function $H : \mathrm{P} \times [0, 1] \mapsto \mathbb{R}^n$ by

$$H(x, \theta) = x - g_\theta(x).$$

The function H is also a continuous function. Now let

$$H^{-1}(\mathbf{0}) = \{\, (x, \theta) \in \mathrm{P} \times [0, 1] \mid H(x, \theta) = \mathbf{0} \,\}.$$

Let $Z(\theta)$ denote the set of stationary points of $\bar{f}$ on $U(\theta)$ for each $\theta \in [0, 1]$. Similarly, a continuous function G with respect to $\bar{f}$ can be defined as

$$G : \mathrm{P} \times [0, 1] \mapsto \mathbb{R}^n$$

such that

$$Z(\theta) = \{\, x \in \mathrm{P} \mid G(x, \theta) = \mathbf{0} \,\},\ \theta \in [0, 1].$$

Let

$$G^{-1}(\mathbf{0}) = \{\, (x, \theta) \in \mathrm{P} \times [0, 1] \mid G(x, \theta) = \mathbf{0} \,\}.$$

For each $l \in \mathsf{N}$, let

$$\xi^l = (x^l, \theta_l).$$

It is clear that $\lim_{l\to\infty} \xi^l = \xi^* = (x^*, 0)$. Define

$$N(\epsilon) = \{\, (x, \theta) \in \mathrm{P} \times [0,1] \ \mid\ ||(x,\theta) - (z,\alpha)|| < \epsilon \ \text{ for some } \ (z,\alpha) \in H^{-1}(\mathbf{0})\}.$$

This implies that

$$||H(\psi)|| > 0 \ \text{ for any } \ \psi \in \mathrm{P} \times [0,1] \setminus N(\epsilon).$$

Notice that $N(\epsilon)$ is open, so the set $\mathrm{P} \times [0,1] \setminus N(\epsilon)$ is compact. It follows from the compactness that the minimum can be attained. There exists $\nu > 0$ such that

$$\min\{\, ||H(\psi)|| \ \mid\ \psi \in \mathrm{P} \times [0,1] \setminus N(\epsilon) \,\} > \nu.$$

This implies that if a point $\psi \in \mathrm{P} \times [0,1]$ satisfies

$$||H(\psi)|| \leq \nu, \tag{4.2}$$

then ψ must be in $N(\epsilon)$. Because H and G are uniformly continuous on $\mathrm{P} \times [0,1]$ and $\bar{f}$ is the LP approximation of f with respect to the P-triangulation, we can prove that

$$||H(\psi) - G(\psi)|| < \epsilon \tag{4.3}$$

for any $\psi = (x, \theta) \in \mathrm{P} \times [0,1]$ under the condition that the diameter of the simplices in which x lies is small enough, say, smaller than $\Delta > 0$. Given any $\epsilon > 0$, because of $\bar{f}$ being a PL approximation of f, it holds that

$$||f(x) - \bar{f}(x)|| < \epsilon,$$

for any $x \in \mathrm{P}$ when the diameter of the simplices in which x lies, is small enough. For any given $x \in \mathrm{P}$ and any $\theta \in [0,1]$, define a function $h_\theta : \mathbb{R}^n \mapsto U(\theta)$ by

$$h_\theta(x + z) = argmin\{(x + z - y)^\top (x + z - y) \mid y \in U(\theta)\}.$$

It is clear that h_θ is a Lipschitz continuous function. Furthermore, it is easy to see that for all $p, q \in \mathbb{R}^n$

$$||h_\theta(x + p) - h_\theta(x + q)|| \leq ||p - q||.$$

Then it follows immediately that

$$\begin{array}{rcl} ||H(\psi) - G(\psi)|| & = & ||h_\theta(x + f(x)) - h_\theta(x + \bar{f}(x))|| \\ & \leq & ||f(x) - \bar{f}(x)|| \\ & < & \epsilon. \end{array}$$

Lemma 3.2 states that given a positive integer d as l goes to infinity, the mesh size $\delta_{l,d}$ converges to zero. This implies that there exists a positive integer M such that for every $l \in \mathsf{N}$ with $l > M$, it holds that

$$\delta_{l,d} < \Delta.$$

Since for any $l \in \mathsf{N}$ with $l > M$, $\psi^l \in G^{-1}(\mathbf{0})$, i.e., $G(\psi^l) = \mathbf{0}$, it follows from (4.3) that

$$||H(\psi^l)|| < \epsilon.$$

By (4.2) ψ^l must be in $N(\epsilon)$. This implies that for any $l \in \mathsf{N}$ with $l > M$ there is $\psi^l \in H^{-1}(\mathbf{0})$ which is in the ϵ-neighborhood of ξ^l. Without loss of generality we may assume that $\psi^l = (y^l, \theta_l)$. This is what we claimed.

Now let us take a sequence of positive real numbers $\{\, \epsilon_l \mid l \in \mathsf{N} \,\}$ with limit zero. Then for any l there exists a y^{i_l} being a θ_{i_l}-robust stationary point of f with $||x^{i_l} - y^{i_l}|| \le \epsilon_l$. Since $\lim_{l\to\infty} x^{i_l} = x^*$ and $\lim_{l\to\infty} \epsilon_l = 0$, we have

$$\lim_{l\to\infty} y^{i_l} = x^*.$$

Hence x^* is a robust stationary point of f on P. □

Now we consider the case in which the algorithm converges to a simplex in the interior of the polytope. This means that the algorithm terminates with an n-dimensional simplex σ with vertices $y^1, \ldots, y^{n+1}$ within a finite number of steps. Let $\bar{x} = \sum_{i=1}^{n+1} \lambda_i^* y^i$. Then for each $k \in I_n$ it holds that $\bar{f}_k(\bar{x}) = 0$. It is clear that $\bar{x}$ is a robust stationary point of $\bar{f}$ on P. If the accuracy of approximation is not satisfactory, the algorithm can be restarted at the point $\bar{x}$ with a smaller grid size d^{-1} to find a better approximate robust stationary point, hopefully within a small number of steps. In this case we may assume that the algorithm generates a sequence $\{\, \bar{x}^h \mid h \in \mathsf{N} \,\}$, where $\bar{x}^h$ is the robust stationary point of $\bar{f}$ on P corresponding to the grid size d_h^{-1} for a strictly increasing sequence of positive integers $\{\, d_h \mid h \in \mathsf{N} \,\}$. It is readily seen that for every $k \in \mathsf{N}_0$, the mesh size δ_{k,d_h} tends to zero when h goes to infinity. Therefore the sequence $\{\, \bar{x}^h \mid h \in \mathsf{N} \,\}$ has a subsequence converging to a point being a robust stationary point of f on P. For a subset B of R^n, int(B) denotes the relative interior of B. We now have the following corollary.

COROLLARY 4.6. *Let $\bar{x}^h \in int(\mathrm{P})$ be the robust stationary point of $\bar{f}$ generated by the algorithm for the P-triangulation with grid size d_h^{-1} for $h \in \mathsf{N}$. Suppose that $\{d^h \mid h \in \mathsf{N}\}$ is a strictly increasing sequence of positive integers. Then the sequence $\{\bar{x}^h \mid h \in \mathsf{N}\}$ has a cluster point which is a robust stationary point of f on* P.

5. The steps of the algorithm. As described in the last section, starting at the point v, the algorithm will generate a unique PL path leading to an approximate solution by making alternating LP pivot steps in system (4.1) and replacement steps in the underlying triangulation. When, with respect to some simplex $\sigma(a, \pi)$ with vertices $y^1, \ldots, y^{t+1}$ in some $G^d(l, l+1; L, \gamma(L, L(n)))$ for some $l \in \mathsf{N}_0$ and $\gamma(L, L(n))$, the variable λ_q, for some q, $1 \le q \le t+1$, becomes zero through an LP pivot step in (4.1), then the replacement step determines the unique t-simplex $\bar{\sigma}(\bar{a}, \bar{\pi})$ in $F(\theta_l, \theta_{l+1}; L, \gamma(L, L(n)))$ sharing with σ a common facet τ opposite the vertex y^q, unless this facet lies on the boundary of the set $F(\theta_l, \theta_{l+1}; L, \gamma(L, L(n)))$. If τ does not lie on the boundary of $F(\theta_l, \theta_{l+1}; L, \gamma(L, L(n)))$, then $\bar{\sigma}(\bar{a}, \bar{\pi})$ can be obtained from a and π as given in Table 1, where $E(i-1)$ is the ith unit vector in $\mathbb{R}^n$ for $i \in I_n$.

The algorithm continues with $\bar{\sigma}$ by making an LP pivot step in (4.1) with $(f^\top(\bar{y}), 1)^\top$, where $\bar{y}$ is the vertex of $\bar{\sigma}$ opposite the facet τ. When the L-complete facet τ of the simplex $\sigma(a, \pi)$ in $G^d(l, l+1; L, \gamma(L, L(n)))$ is not a facet of another t-simplex in $G^d(l, l+1; L, \gamma(L, L(n)))$, then τ lies on the boundary of $F(\theta_l, \theta_{l+1}; L, \gamma(L, L(n)))$. According to Definition 3.1 we have the following lemma.

Table 1

Parameters of $\bar\sigma$ if the vertex y^q of $\sigma(a,\pi)$ is replaced.

	$\bar\pi$	$\bar a$
$q = 1$	$(\pi_2, ..., \pi_t, \pi_1)$	$a + E(\pi_1)$
$1 < q < t+1$	$(\pi_1, ..., \pi_{q-2}, \pi_q, \pi_{q-1}, \pi_{q+1} ..., \pi_t)$	a
$q = t+1$	$(\pi_t, \pi_1, ..., \pi_{t-1})$	$a - E(\pi_t)$

Lemma 5.1. *Let $\sigma(a,\pi)$ be a t-simplex in $F(\theta_l, \theta_{l+1}; L, \gamma(L, L(n)))$. The facet τ of σ opposite the vertex y^q, $1 \leq q \leq t+1$, lies on the boundary of this set if and only if one of the following cases occurs:*

(i) *$q = 1$, $\pi_1 = 0$, and $a(0) = d - 1$;*

(ii) *$1 < q < t+1$, $\pi_q = h+1$, $\pi_{q-1} = h$ for some $h \in \{0\} \cup I_{t-2}$, and $a(h) = a(h+1)$ in case $h \geq 1$, and $a(0) + kd = a(1)$ in case $h = 0$;*

(iii) *$q = t+1$, $\pi_t = 0$, and $a(0) = 0$;*

(iv) *$q = t+1$, $\pi_t = t-1$, and $a(t-1) = 0$.*

Suppose that the algorithm generates the simplex $\sigma(a,\pi)$ as given in Lemma 5.1 and λ_q becomes zero after making an LP pivot step in (4.1). Then the facet τ of σ opposite the vertex y^q is L-complete. In case (i) the facet τ lies in the face $F(\theta_{l+1}; L)$ of $A(\theta_{l+1})$ and the algorithm reaches a θ_{l+1}-robust stationary point $\bar x = \sum_{i=1}^{t+1} \lambda_i y^i$ of $\bar f$ lying in $F(\theta_{l+1}; L)$. If l is large enough, then $\bar x$ is an approximate robust stationary point of f. Otherwise, the algorithm continues with $\bar\sigma$ by making an LP pivot step in (4.1) with $(f^\top(\bar y), 1)^\top$, where $\bar y$ is the vertex of $\bar\sigma$ opposite the facet τ and $\bar\sigma$ in $F(\theta_{l+1}, \theta_{l+2}; L, \gamma(L, L(n)))$ is obtained according to Table 1.

In case (ii), and if $h = 0$, τ is a facet of the t-simplex $\bar\sigma = \sigma(a,\pi)$ in $F(\theta_l, \theta_{l+1}; L, \bar\gamma(L, \bar L(n)))$ with $\bar L(n)$ and $\bar\gamma$ defined as follows. Let $L^1 = L(n) = (L_1, \ldots, L_n)$. When $L^2 = (L_1, \ldots, L_{n-1})$, we have $\bar L(n) = (L_1, \ldots, L_{n-1}, \bar L_n)$ with $\bar L_n = L_{n-2} \cup (L(n) \setminus L_{n-1})$. When $L^2 = (L_2, \ldots, L_n)$, let $\bar L(n) = (\bar L_1, L_2, \ldots, L_n)$ with $\bar L_1 = L_2 \setminus L_1$. Finally, if $L^2 = (L_1, \ldots, L_i, L_{i+2}, \ldots, L_n)$ for some $i \in I_{n-3}$, we have $\bar L(n) = (L_1, \ldots, L_i, \bar L_{i+1}, L_{i+2}, \ldots, L_n)$ with $\bar L_{i+1} = L_i \cup (L_{i+2} \setminus L_{i+1})$. Then $\bar\gamma(L, \bar L(n)) = (\bar L(n), L^2, \ldots, L^t)$. In case (i), and if $h \geq 1$, the facet τ is a facet of the t-simplex $\bar\sigma = \sigma(a,\pi)$ in $F(\theta_l, \theta_{l+1}; L)$ lying in the subset $F(\theta_l, \theta_{l+1}; L, \bar\gamma(L, L(n)))$ with

$$\bar\gamma(L, L(n)) = (L^1, \ldots, L^h, \bar L^{h+1}, L^{h+2}, \ldots, L^t),$$

where $\bar L^{h+1} \in \mathcal{J}$, $\bar L^{h+1} \neq L^{h+1}$, is uniquely determined by the properties that $\bar L^{h+1}$ conforms to L^h, has one component less than L^h, and is conformed by L^{h+2}. In both subcases of case (ii) the algorithm proceeds by making an LP pivot step in (4.1) with $(f^\top(\bar y), 1)^\top$, where $\bar y$ is the vertex of the new t-simplex $\bar\sigma$ opposite the facet τ.

In case (iii) the facet τ lies in the face $F(\theta_l; L)$ of $A(\theta_l)$ and the algorithm continues with $\bar\sigma$ by making an LP pivot step in (4.1) with $(f^\top(\bar y), 1)^\top$, where $\bar y$ is the vertex $\bar\sigma$ opposite the vertex τ and σ in $F(\theta_{l-1}, \theta_l; L, \gamma(L, L(n)))$ is obtained from Table 1.

In case (iv) the facet lies in the set $F(\theta_l, \theta_{l+1}; L^{t-1})$ of $\mathcal{F}(L)$. More precisely, τ is the $(t-1)$-simplex $\sigma(a, \bar\pi)$ in $F(\theta_l, \theta_{l+1}; \bar L, \bar\gamma(\bar L, L(n)))$, where $\bar L = L^{t-1}$, $\bar\gamma(\bar L, L(n)) = (L^1, \ldots, L^{t-1})$. The algorithm now continues by making an LP pivot step in (4.1) with $(-(a^{L_h})^\top, 0)^\top$, where L_h is the unique component of L^{t-1} but not in L^t.

Finally, if, through an LP pivot step in (4.1), μ_i becomes zero for some $i \in I_k$ and $k = 1$, then the algorithm terminates with the approximate robust stationary point $\bar x = \sum_{j=1}^{n+1} \lambda_j y^i$. In case the accuracy is not satisfactory, the algorithm can restart at the point $\bar x$. When $k > 1$, then the simplex $\sigma(a,\pi)$ is a facet of a unique $(t+1)$-simplex

$\bar{\sigma}$ in $\mathcal{F}(\bar{L})$ with $\bar{L} = (L_1, \ldots, L_{i-1}, L_{i+1}, \ldots, L_k)$. To be precise, $\bar{\sigma} = \sigma(a, \bar{\pi})$ lies in $F(\theta_l, \theta_{l+1}; \bar{L}, \bar{\gamma}(\bar{L}, L(n)))$, where $\bar{\pi} = (\pi_1, \ldots, \pi_t, t)$ and $\bar{\gamma}(\bar{L}, L(n)) = (L^1, \ldots, L^t, \bar{L})$. The algorithm now proceeds by making an LP pivot step in (4.1) with $(f^\top(\bar{y}), 1)^\top$, where $\bar{y}$ is the vertex of σ opposite the facet σ.

This completes the description of how to follow a sequence of adjacent simplices of varying dimension in the P-triangulation of the polytope P.

6. Special cases and applications to games and economics. We now turn to discussing the cases when the polytope P is not full-dimensional. Moreover we also show the applications of the concept of robust stationary point in game theory and economic equilibrium theory. First we discuss the cases when the polytope P is not full-dimensional. If P is a lower-dimensional polytope we may assume that P can be described as

$$\mathrm{P} = \{x \in \mathbb{R}^n \mid {a^i}^\top x \le b_i,\ i \in I_m, \quad \text{and} \quad {c^j}^\top x = d_j,\ j \in I_{m^1}\}$$

and P is simple and no constraints are redundant, while $\dim(P) = n - m^1$, for some m^1, $0 \le m^1 \le n$. In this case for each $I \in \mathcal{I}$, the cone $F^*(I)$ is defined by

$$F^*(I) = \left\{ x \in \mathbb{R}^n \mid x = \sum_{i \in I} \nu_h a^i + \sum_{j \in I_{m^1}} \mu_j c^j,\ \nu_i \ge 0 \ \text{ for } \ i \in I,\ \mu_j \in \mathbb{R} \ \text{ for } j \in I_{m^1} \right\},$$

where $F(I)$ is a nonempty face of P and defined as

$$F(I) = \{x \in \mathrm{P} \mid {a^i}^\top x = b_i \quad \text{for} \quad i \in I\}.$$

The dimension of such a face $F(I)$ is equal to $n - m^1 - |I|$. Now the definition of robust stationary points is the same as in Definition 2.3 except that the definition of θ-robust stationary points is adapted as follows.

DEFINITION 6.1. *For given $\theta > 0$ a point $x \in \mathrm{P}$ is a θ-robust stationary point of f if*

(1) *x is a relative interior point of* P*;*

(2) *for some $I \in \mathcal{I}$, $f(x) = \sum_{h \in I_m} \mu_h a^h + \sum_{j \in I_{m^1}} \nu_j c^j$ with $\mu_h \ge 0$ for all $h \in I$ and $\mu_h = 0$ for all $h \in I_m \setminus I$, and $\nu_j \in \mathbb{R}$ for all $j \in I_{m^1}$, if $\mu_l > \mu_k$, then $b_l - {a^l}^\top x \le \theta(b_k - {a^k}^\top x)$.*

We leave it to the reader to prove the existence of a robust stationary point for any continuous function on a lower-dimensional polytope P in $\mathbb{R}^n$. Now the algorithm is the same as described in sections 4 and 5 except that the LP pivot steps are made in the following system for given $L = (L_1, \ldots, L_k) \in \mathcal{J}$:

$$\sum_{i=1}^{s+1} \lambda_i f(y^i) - \sum_{j=1}^{k} \mu_j a^{L_j} + \sum_{h=1}^{m^1} \nu_h c^h = \mathbf{0},$$

$$\sum_{i=1}^{s+1} \lambda_i = 1,$$

$$\lambda_i \ge 0,\ i \in I_{s+1};\ \mu_j \ge 0,\ j \in I_k;\ \nu_h \in \mathbb{R},\ h \in I_{m^1},$$

where $s = t$ or $t - 1$ with $t = n - m^1 - k + 1$.

It should be noted that when we study the stability and refinements of Nash equilibria or Walrasian equilibria, we often have to deal with problems over lower-dimensional polytopes.

Very special cases of the polytope P are the $(n-1)$-dimensional unit simplex $S^n = \{x \in \mathbb{R}^n_+ \mid \sum_{i=1}^n x_i = 1\}$ or the simplotope. We rewrite $S^n = \{x \in \mathbb{R}^n \mid {a^i}^\top x \le$

TABLE 2
Payoffs of the game.

Player 2

Player 1

	ϕ_1	ϕ_2	ϕ_3
ψ_1	$(1,1)$	$(0,0)$	$(-9,-9)$
ψ_2	$(0,0)$	$(0,0)$	$(-7,-7)$
ψ_3	$(-9,-9)$	$(-7,-7)$	$(-7,-7)$

$0, i \in I_n,$ and $\sum_{i=1}^{n} x_i = 1\}$, where $a^i = -e(i)$ for all $i \in I_n$. In case the polytope is the unit simplex S^n, Definition 6.1 coincides with Definition 2.1 in Yang [21]. The simplotope is the Cartesian product of, say, n, $n \in \mathsf{N}$, unit simplices S^{n_j}, $n_j \in \mathsf{N}$ and $j \in I_n$. In case the polytope is the simplotope, then the concept of robust stationary point is reduced to that in Talman and Yang [17]. We recall that concept here. The definition of robust stationary points is the same as in Definition 2.3, but the form of θ-robust stationary points becomes much simpler. Let $\mathcal{S} = \prod_{h=1}^{n} S^{n_h}$, where S^{n_h} is the $(n_h - 1)$-dimensional unit simplex for each $h \in I_n$.

DEFINITION 6.2. *Let $f : \mathcal{S} \mapsto \prod_{h=1}^{n} \mathbb{R}^{n_h}$ be a function. For given $\theta > 0$ a point $x \in \mathcal{S}$ is a θ-robust stationary point of f if*

(1) *x is a relative interior point of $\mathcal{S}$;*

(2) *$f_{h,i}(x) < f_{h,j}(x)$ implies $x_{h,i} \leq \theta x_{h,j}$ for $i, j \in I_{n_h}$ and $h \in I_n$.*

Furthermore, when the simplotope is the strategy space of a noncooperative finite n-person game, the concept of robust stationary point coincides with the well-known concept of proper Nash equilibrium in Myerson [13] provided that the function on the simplotope is defined as the marginal expected payoff of the game. We suggest the interested reader see Myerson [13] and van Damme [3] for the game-theoretic interpretation of the above concept. Let us illustrate this by a well-known example of Myerson [13].

EXAMPLE 6.3. *We consider a bimatrix game with two players. Each player has three pure strategies. The payoffs are given in Table* 2.

This game has three Nash equilibria: (ψ_1, ϕ_1), (ψ_2, ϕ_2), and (ψ_3, ϕ_3). Among these equilibria, (ψ_1, ϕ_1) is the only proper Nash equilibrium. The marginal expected payoff function is given by $f : S^3 \times S^3 \mapsto \mathbb{R}^3 \times \mathbb{R}^3$ with

$$f(x) = (f_{1,1}(x), f_{1,2}(x), f_{1,3}(x); f_{2,1}(x), f_{2,2}(x), f_{2,3}(x))^\top,$$

where

$$\begin{array}{rcl} f_{1,1}(x) & = & x_{2,1} - 9x_{2,3}, \\ f_{1,2}(x) & = & -7x_{2,3}, \\ f_{1,3}(x) & = & -9x_{2,1} - 7x_{2,2} - 7x_{2,3}, \\ f_{2,1}(x) & = & x_{1,1} - 9x_{1,3}, \\ f_{2,2}(x) & = & -7x_{1,3}, \\ f_{2,3}(x) & = & -9x_{1,1} - 7x_{1,2} - 7x_{1,3}. \end{array}$$

This function has three stationary points: $(1,0,0;1,0,0)^\top$, $(0,1,0;0,1,0)^\top$, and $(0,0,1;0,0,1)^\top$, corresponding to the three Nash equilibria given above, respectively. The point $(1,0,0;1,0,0)^\top$ is the only robust stationary point which corresponds to the only proper Nash equilibrium.

Finally let us apply the concept of robust stationary point to the standard exchange economy model with linear production. For detailed discussions, we refer to

Scarf [15] and Koopmans [10]. In such an economy, there are, say, n commodities, a finite number of production activities or firms, and a finite number of consumers, each of whom initially has a certain amount of commodities. Exchange of commodities is based on relative prices. All agents exchange their commodities to maximize their utility under their budget constraints, and all firms run their activities to achieve their maximal profits. This economy can be captured by an excess demand function $z : S^n \mapsto \mathbb{R}^n$ and an $n \times (n+k)$ matrix $A = [a^1, \ldots, a^{k+n}] = [a^1, \ldots, a^k, -e(1), \ldots, -e(n)]$, which satisfies the following standard conditions:

(i) z is continuous;

(ii) $p^\top z(p) = 0$ (Walras' law);

(iii) $Ay \geq \mathbf{0}$ and $y \in \mathbb{R}^{n+k}_+$ imply $y_i = 0$ for all $i \in I_{n+k}$. (No production without input.)

Now we explain the matrix A in some detail. For each $j \in I_k$, the jth column a^j of A represents an activity. It says that if activity j is operated at level one, $|a^j_i|$ units of commodity i are supplied as output for $a^j_i \geq 0$ or required as input for $a^j_i < 0$. The last n columns of A imply an assumption of free disposal. The Walrasian equilibrium is defined as follows. A pair $(p^*, y^*) \in S^n \times \mathbb{R}^{n+k}_+$ is an equilibrium if it satisfies $z(p^*) \leq Ay^*$ and $p^{*\top} A \leq \mathbf{0}$. The interpretation is that at equilibrium the demand is met by supply for all commodities and no activity makes positive profit. Note that at equilibrium we have $p^{*\top} A y^* = 0$. This means that an activity having a deficit ($p^{*\top} a^j < 0$) is not producing ($y^*_j = 0$) while an activity in operation ($y^*_j > 0$) runs at balance ($p^{*\top} a^j = 0$). It is shown in Scarf [15] that the economy has at least one equilibrium.

Define $S_A = \{p \in S^n \mid p^\top A \leq \mathbf{0}\}$. It is shown by Eaves [7] (see also van den Elzen [8]) that S_A is an $(n-1)$-dimensional polytope and (p^*, y^*) is an equilibrium if and only if p^* is a stationary point of the function z on S_A. It is easy to see that the set S_A can be expressed as $S_A = \{x \in \mathbb{R}^n \mid p^\top A \leq \mathbf{0}, \sum_{i=1} x_i = 1\}$. If there is a redundant constraint, we just delete it. So we may assume that all constraints describing S_A are nonredundant. Applying the concept of robust stationary point, we have the following economically meaningful concept which refines the Walrasian equilibrium concept. Let $m = k + n$ and 1^n be the n-vector of ones.

Definition 6.4. *For given $\theta \in (0,1)$ a point $p \in S_A$ is a θ-robust Walrasian equilibrium of z if*

(1) *p is a relative interior point of S_A;*

(2) *for some $I \in \mathcal{I}$, $z(p) = \sum_{h \in I_m} y_h a^h + \beta 1^n$ with $y_h \geq 0$ for all $h \in I$ and $y_h = 0$ for all $h \in I_m \setminus I$, and $\beta \in \mathbb{R}$, if $y_l > y_k$, then $a^{l\top} p \geq \theta a^{k\top} p$.*

A robust Walrasian equilibrium p^* is the limit of a sequence of θ_t-robust Walrasian equilibria (p^t) as θ_t converges to zero. We are now going to explain the above concept in terms of economics. First note that for each $h \in I_m$ the parameter $y_h \geq 0$ represents the level of activity h. At θ-robust equilibrium, all production activities are making deficits ($p^\top a^h < 0$ for all h). A θ-robust equilibrium requires that if $y_l > y_k$, then $(0 >) \, a^{l\top} p \geq \theta a^{k\top} p \, (> a^{k\top} p)$. It says that when all firms are making deficits, the higher an activity level of a firm is, the lower the per unit deficit of that firm must be. In other words, the higher deficit a firm makes, the less that firm should produce. Hence as θ converges to zero, this adjustment mechanism will eventually bring the negative profit $y_h a^{h\top} p$ of each firm h close to zero and a robust Walrasian equilibrium state will be reached. This reveals a thought similar to the classical Walrasian tâtonnement adjustment process. We should point out the difference between the classical Walrasian tâtonnement adjustment process and the algorithm proposed in this paper. The former process is known to be nonconvergent, but the latter algorithm is globally convergent and also admits a nice economic interpretation as described above.

A VARIABLE METRIC PROXIMAL POINT ALGORITHM FOR MONOTONE OPERATORS*

J. V. BURKE† AND MAIJIAN QIAN‡

Abstract. The proximal point algorithm (PPA) is a method for solving inclusions of the form $0 \in T(z)$, where T is a monotone operator on a Hilbert space. The algorithm is one of the most powerful and versatile solution techniques for solving variational inequalities, convex programs, and convex-concave mini-max problems. It possesses a robust convergence theory for very general problem classes and is the basis for a wide variety of decomposition methods called *splitting methods.* Yet the classical PPA typically exhibits slow convergence in many applications. For this reason, acceleration methods for the PPA algorithm are of great practical importance. In this paper we propose a variable metric implementation of the proximal point algorithm. In essence, the method is a Newton-like scheme applied to the Moreau–Yosida resolvent of the operator T. In this article, we establish the global and linear convergence of the proposed method. In addition, we characterize the superlinear convergence of the method. In a companion work, we establish the superlinear convergence of the method when implemented with Broyden updating (the nonsymmetric case) and BFGS updating (the symmetric case).

Key words. maximal monotone operator, proximal point methods, variable metric, global convergence, convergence rates

1. Introduction.

The proximal point algorithm (PPA) is one of the most powerful and versatile solution techniques for problems of convex programming and minimax convex-concave programming. It possesses a robust convergence theory for very general problem classes in finite- and infinite-dimensions (e.g., see [11, 16, 21, 22, 23, 28, 32, 41, 40]) and is the basis for a wide variety of decomposition methods called *splitting methods* (e.g., see [4, 9, 12, 43, 44]). Yet, the classical PPA typically exhibits slow convergence in many applications. For this reason, acceleration methods for the PPA are of great practical importance. In this paper we propose a variable metric implementation of the proximal point algorithm. Our approach extends and refines results that originally appeared in [38] and is in the spirit of several recent articles [3, 7, 10, 18, 20, 24, 25, 36]. However, there is a fundamental difference between the method presented here and those studied in [3, 7, 10, 18, 20, 24, 25, 36]. This difference has a profound impact on the methodology applied in this article. All previous work on this topic (except [38]) applies exclusively to monotone operators that arise as the subdifferential of a finite-valued, finite dimensional convex function. The results of this article apply to general monotone operators on a Hilbert space. The resulting difference in methodology roughly corresponds to the difference between methods for function minimization and methods for solving systems of equations.

There are both advantages and disadvantages to the more general approach. The advantages are that the method applies to a much broader class of problems. This is

so not only because the theory is developed in the Hilbert space setting, but, more important, because many monotone operators cannot be represented as the subdifferential of a finite-valued, finite dimensional convex function. General monotone operators do not possess many of the rich structural properties associated with the subdifferential of a convex function (e.g., subdifferentials of convex functions are the only maximal cyclically monotone operators [33]). In addition, in the case where the operator is the subdifferential of a convex function, we do not require the usual assumption that the underlying function be finite-valued.

The disadvantages of our general approach arise from the fact that the method cannot make use of the additional structure present when the operator is the subdifferential of a convex function. This complicates both the structure of the method and its analysis. Of particular note in this regard is the complexity of our global convergence result. If the operator is the subdifferential of a convex function, then solving the inclusion $0 \in T(x)$ is equivalent to minimizing the underlying convex function. The global convergence of a method is then typically driven by a line-search routine (e.g., see [3, 7, 10, 18, 20, 24, 25, 36]). In the general setting we do not have direct recourse to this strategy. This complicates both the structure of the algorithm and its convergence theory. Nonetheless, the proof technique developed in this paper can be refined in the convex programming setting, thereby significantly simplifying both the global and the local convergence results [5, 6].

Notwithstanding these differences in methodology, our approach is still nicely motivated by recalling the behavior of the PPA in the context of convex programming:

$$\min_{z\in\mathcal{H}} f(z)\ , \tag{1}$$

where $\mathcal{H}$ is a Hilbert space and $f\colon\mathcal{H}\mapsto\mathbb{R}\cup\{+\infty\}$ is a lower semicontinuous convex function that is not identically $+\infty$. Define the Moreau–Yosida regularization of f to be the function $f_\lambda\colon\mathcal{H}\mapsto\mathbb{R}$ given by

$$f_\lambda(\bar{z}) := \min_{z\in\mathcal{H}}\left\{\lambda f(z) + \frac{1}{2}\|z-\bar{z}\|^2\right\}.$$

The set of solutions to (1) corresponds precisely to the set of points at which f_λ attains its minimum value. The function f_λ is continuously Fréchet differentiable [28, Proposition 7.d]. The PPA applied to (1) is *approximately* the steepest descent algorithm applied to f_λ [11]. This analogy immediately suggests that a variable metric approach could be applied to the function f_λ to accelerate the method. This idea was first studied in [38] and is the basis of the acceleration techniques described in [3, 7, 10, 18, 20, 24, 25, 36].

In [3], Bonnans et al. develop methods along an algorithmic pattern originally suggested by Qian in [38]. This pattern circumvents many of the difficulties associated with a variable metric approach applied directly to the function f_λ. The key is to employ a matrix secant update based on the function f instead of f_λ. The local convergence results in [3, Section 3] require some smoothness assumptions. In particular, linear convergence is established when the function f is differentiable with Lipschitz continuous derivative, and superlinear convergence is established when f is twice strictly Fréchet differentiable at a unique solution $\bar{z}$, where the second derivative is positive definite (we speak only of quotient or q-rate of convergence).

In [18, 20, 24, 25], the authors apply the bundle concept for nonsmooth convex minimization [17] to approximate the Moreau–Yosida regularization f_λ and its derivative. Variable metric updates, in particular, quasi-Newton updates, are then applied using these approximate values. The superlinear convergence results in the papers [18, 20, 24] require either strong smoothness assumptions on the function f (such as the Lipschitz continuity of ∇f) or that the regularization parameter λ diverges to $+\infty$. In [20], Lemaréchal and Sagastizábal propose a clever *reversal* quasi-Newton formula which uses the value of the gradient of f_λ at a variety of points other than those strictly obtained by the iterates. This promising idea deserves further theoretical and numerical study.

In [10] and [36], the authors develop an approach based on Newton's method for semismooth functions as developed in [30, 31, 37, 34]. Properly speaking, these methods are neither an adaptation of the PPA algorithm nor a variable metric method. Nonetheless, the flavor of both of these methodologies is present. In order to obtain superlinear convergence, smoothness hypotheses are again required; however, these hypotheses are of a somewhat more technical nature. Specifically, it is required that

(a) the function f be *semismooth* at a unique solution to (1) [37],

(b) every element of the set-valued mapping

$$\partial_B^2 f(z) := \{\lim_{y_k \to z} \nabla^2 f_\lambda(y_k) \,:\, y_k \to x, \nabla f(y_k) \text{ exists for all } k = 1, 2, \ldots\}$$

be nonsingular at the unique solution $\bar{z}$, and

(c) the sequence of Hessian approximates $\{V_k\}$ used to generate the iterates $\{z_k\}$ satisfy

$$\lim_{k \to \infty} \operatorname{dist}(V_k, \partial_B^2 f(z_k)) = 0 \ . \tag{2}$$

One can show that the semismoothness hypotheses are satisfied in many cases of interest when f is finite-valued. Moreover, by Rademacher's theorem on the differentiability of Lipschitz continuous functions, it follows that the set-valued mapping $\partial_B^2 f(z)$ is always well-defined and compact-valued in the finite dimensional, finite-valued case, with the nonsingularity property being closely tied to the usual hypothesis of strong convexity. Although the limiting hypotheses on the V_k's is a bit strong, it is not entirely unreasonable in the absence of differentiability. In [36], Qi and Chen propose a very nice preconditioning technique wherein an exact value for the gradient of a *shifted* Moreau–Yosida regularization can be computed from inexact values for the gradient of f_λ. This technique is similar in spirit to the *reversal* quasi-Newton formula found in [20]. Both of these techniques should prove useful in numerical implementations.

The algorithm presented in this paper is most closely related to the methods proposed by Chen and Fukushima [7] and Mifflin, Sun, and Qi [25]. However, there are several fundamental distinctions, the foremost of which is that the methods in [7, 25] are restricted to finite dimensional finite-valued convex programming problems. Within this framework, these authors use bundle strategies to approximate f_λ and its gradient and establish the global convergence of their methods with the aid of a line search routine. Chen and Fukushima establish global and linear convergence results along with a generalization of the Dennis–Moré characterization theorem for superlinear convergence [14]. One of the most important features of the Chen–Fukushima algorithm is that the line search is based on the function f rather than approximations to the function f_λ. This is very important in practice since obtaining sufficiently accurate approximations to the function f_λ is usually quite time consuming. Their linear and superlinear convergence results blend bundle techniques with the theory of nonsmooth equations. Consequently, the convergence hypotheses are reminiscent of those employed in [10] and [36]; in particular, they require semismoothness, CD-regularity, and the strong approximation property (2). In [6], the methods of this paper are applied to the Chen–Fukushima algorithm to obtain the superlinear convergence of the method when BFGS matrix secant updating is employed.

In [25], Mifflin, Sun, and Qi obtain the first superlinear convergence result for a variable metric proximal point algorithm using the BFGS matrix secant update in the setting of finite dimensional finite-valued convex programming. Their proposed algorithm uses a line search based on approximations to the function f_λ and requires that the function f_λ is strongly convex with ∇f_λ Fréchet differentiable at the unique global solution to the convex program. In addition it is assumed that the iterates satisfy a certain approximation property involving the gradient ∇f_λ. In section 4 of this paper, we discuss how these hypotheses are related to those that are also required in our convergence analysis.

In this paper, we provide a general theory for a variable metric proximal point algorithm (VMPPA) applied to maximal monotone operators from a Hilbert space to itself. In the important special case of convex programming, where T is taken to be the subdifferential of the function f, we do not assume that f is finite-valued or differentiable on the whole space. However, to obtain superlinear convergence, we do require certain smoothness hypotheses at a unique global solution $\bar{z}$. These smoothness hypotheses differ from those assumed in [3, 18, 20, 24] since they are imposed on the operator T^{-1} rather than T. In this regard, they are reminiscent of the hypotheses employed in [25]. The choice of smoothness hypotheses has deep significance in the context of convex programming. Differentiability hypotheses on $T = \partial f$ imply the second-order differentiability of f, whereas differentiability hypotheses on $T^{-1} = (\partial f)^{-1}$ are related to the standard strong second-order sufficiency conditions of convex programming [40, Proposition 2] and thus reduce to the standard hypotheses used in local analysis of convergence. In particular, the differentiability of $(\partial f)^{-1}$ does not imply that ∂f is single-valued or differentiable, nor does it imply that f is finite-valued.

Our smoothness hypotheses also differ from those that appear in [7, 10, 36]. These methods rely on the theory of nonsmooth equations and require hypotheses such as semismoothness and nonsingularity of the elements of $\partial_B^2 f$. In addition, the proof theory for these methods specifically requires that the underlying convex function be finite-valued in a neighborhood of the unique solution to (1) (again, these methods assume that the function is finite-valued on all of $\mathbb{R}^n$). This limits direct application to constrained problems since in the constrained case solutions typically lie on the boundary of the constraint region (i.e., on the boundary of the domain of the essential objective function).

Throughout the paper we illustrate many of the ideas and results by applying them to the case of convex programming. Our purpose here is not only to show how the results can be applied, but also to ground them in the familiar surroundings of this concrete application. Further details on the application of these results to the case of convex programming can be found in [5].

The paper is structured as follows. We begin with a review of the classic proximal point algorithm in section 2. The VMPPA is introduced in section 3. This section contains the approximation criteria that must be satisfied at each iteration. Two criteria are presented. The first is required to obtain global convergence and the second is required to accelerate the local convergence of the method. This division into global and local criteria is one of the recurring themes of the paper. On the global level the method behaves like a steepest descent method, while at the local level it becomes more Newton-like. This feature is common to most general purpose methods in nonlinear programming, such as the nonmonotone descent methods, the dogleg method, and trust-region methods. In section 4 we discuss the smoothness hypotheses required for the local analysis. We also extend some of the differentiability results appearing in [19, 35] to maximal monotone operators. In section 5, we study the operators $\mathcal{N}_k$ associated with the Newton-like iteration proposed in section 3. The focus of this section is to provide conditions under which the operators $\mathcal{N}_k$ are nonexpansive at a solution to the inclusion $0 \in T(z)$. A global convergence result paralleling Rockafellar's 1976 result [41] is given in section 6. In section 7 we study local convergence rates. Linear convergence is established under a Lipschitz continuity assumption on T^{-1}, and a characterization of superlinear convergence for the VMPPA is also given. This characterization is modeled on the landmark characterization of superlinear convergence of variable metric methods in nonlinear programming due to Dennis and Moré [14]. In [6], we use this characterization result to establish the superlinear convergence of the method when the derivatives are approximated using the BFGS and Broyden updating strategies.

A word about our notation is in order. We denote the closed unit ball in the Hilbert space $\mathcal{H}$ by $\mathbb{B}$. Then the ball with center a and radius r is denoted by $a + r\mathbb{B}$. Given a set $Z \subset \mathcal{H}$ and an element $z \in \mathcal{H}$, the distance of z to Z is $\operatorname{dist}(z, Z) = \inf\{\|z - z'\| : z' \in Z\}$.

Let $\mathcal{H}_1$ and $\mathcal{H}_2$ be two Hilbert spaces. Given a *multifunction* (also referred to as a *mapping* or an *operator* depending on the context) $T : \mathcal{H}_1 \rightrightarrows \mathcal{H}_2$, the *graph* of T, $\operatorname{gph} T$, is the subset of the product space $\mathcal{H}_1 \times \mathcal{H}_2$ defined by $\operatorname{gph} T = \{(z, w) \in \mathcal{H}_1 \times \mathcal{H}_2 | w \in T(z)\}$. The *domain* of T is the set $\operatorname{dom} T := \{z \in \mathcal{H}_1 | T(z) \neq \emptyset\}$. The identity mapping will be denoted by I. The *inverse* of an operator T is defined by $T^{-1}(w) := \{z \in \mathcal{H}_1 | (z, w) \in \operatorname{gph} T\}$.

Given a lower semicontinuous convex function $f : \mathcal{H} \to \mathbb{R} \bigcup \{+\infty\}$, the *conjugate* of f is defined by $f^*(z^*) = \sup_{z \in \mathcal{H}}\{\langle z^*, z\rangle - f(z)\}$.

2. Monotone operators and the classic algorithm.

Given a real Hilbert space $\mathcal{H}$ with inner product $\langle \cdot, \cdot \rangle$, we say that the multifunction $T : \mathcal{H} \rightrightarrows \mathcal{H}$ is *monotone* if for every z and z' in $\operatorname{dom} T$, and $w \in T(z)$ and $w' \in T(z')$, we have $\langle z - z', w - w'\rangle \geq \kappa\|z - z'\|^2$ for some $\kappa \geq 0$. If $\kappa > 0$, then T is said to be *strongly monotone with modulus κ*. The monotone operator T is said to be *maximal* if its graph is not properly contained in the graph of any other monotone operator. An important example of a monotone operator is the *subgradient* of a convex function (see Minty [27] and Moreau [28]).

We are concerned with solving inclusions of the form

$$0 \in T(z), \tag{3}$$

where T is a maximal monotone operator. In the case of the convex programming problem (1), the operator T is the subdifferential of the convex function f, and the inclusion (3) characterizes the points z at which f attains its minimum value. A wide variety of other problems can be cast in this framework, e.g., variational inequalities, complementary problems, and mini-max problems. Existence results for inclusion (3) can be found in [41].

In 1962, Minty [27] showed that, when the operator T is maximal monotone, the *Moreau–Yosida resolvent* of T,

$$P_\lambda = (I + \lambda T)^{-1} \text{ with } \lambda > 0,$$

is single-valued and nonexpansive on $\mathcal{H}$. This result suggests that a solution to the inclusion $0 \in T(z)$ can be iteratively approximated by the recursion $z^{k+1} = P_\lambda(z^k)$. One can modify this scheme by varying the scalar λ and by choosing the iterates z^{k+1} to be an approximate solution to the equation $(I + \lambda_k T)(z) = z^k$. The PPA applies precisely these ideas. The algorithm, starting from any point z^0, generates a sequence $\{z^k\}$ in $\mathcal{H}$ by the approximation rule

$$z^{k+1} \approx (I + c_k T)^{-1}(z^k) \ . \tag{4}$$

The principal difficulty in applying the PPA lies in executing the operators $P_k = (I + c_k T)^{-1}$. In the case of convex programming, the iteration (4) reduces to the iteration

$$z^{k+1} \approx \arg\min_{z\in\mathcal{H}} \left\{ c_k f(z) + \frac{1}{2}\|z - z^k\|^2 \right\} \ .$$

Notice that executing the algorithm exactly (i.e., with "=" instead of "≈" in the above algorithm) can be as difficult as solving the original problem directly. Hence it is critical that the convergence results are obtained under the assumption of approximation.

In [22] and [23], Martinet proved the convergence of the *exact* PPA for certain cases of the operator T with fixed $c_k \equiv c$. The first theorem on the convergence of the general PPA was proved by Rockafellar [41] in 1976. His theorem not only insures the global convergence under an approximating rule, but also describes the global behavior when the inclusion $0 \in T(z)$ has no solution.

The convergence rate of the PPA depends on properties of the operator T, the choice of the sequence $\{c_k\}$, and the accuracy of the approximation in (4). The first rate of convergence results were also obtained by Rockafellar [41] in 1976, under the assumption that the solution set is a singleton $\{\bar{z}\}$. He proved that if the sequence $\{c_k\}$ is bounded away from 0, and $T^{-1}(w)$ is bounded by a linear function of $\|w\|$ when w is near 0, then the rate of convergence is at least linear. Luque [21] extended Rockafellar's theorem to the case where $T^{-1}(0)$ is not required to be a singleton, and showed that such an estimate of the convergence rate is tight.

3. The algorithm and approximation criteria. The algorithm proposed in this section is a Newton-like iteration for solving the resolvent equation $z = P_\lambda(z)$. In the context of the convex programming problem, the iteration takes the form

$$z^{k+1} = z^k - H_k \nabla f_\lambda(z^k) \ ,$$

where the operator H_k is used to approximate second-order properties of the function f_λ. If f_λ is twice differentiable with $[\nabla^2 f_\lambda(z^k)]^{-1}$ bounded, then for Newton's method one sets $H_k = [\nabla^2 f_\lambda(z^k)]^{-1}$. However, in general, f_λ is only known to be differentiable with Lipschitz continuous gradient [28]. Thus, in the finite dimensional case, the Hessian $\nabla^2 f_\lambda(x)$ is guaranteed to exist only on a dense subset by Rademacher's theorem. Further results on the second-order properties of f_λ can be found in [19, 35, 42].

It is well known that the negative gradient $-\nabla f_\lambda(z^k)$ is the unique element w^k solving the problem

$$\min_{w\in\mathcal{H}} \left\{ \lambda f(z^k + w) + \frac{1}{2}\|w\|^2 \right\}$$

or, equivalently, satisfying the inclusion

$$0 \in \lambda \partial f(z^k + w^k) + w^k \ . \tag{5}$$

The PPA for a general maximal monotone operator T can be formally derived from (5) by replacing λ, z^k, and ∂f by c_k, z^k, and T, respectively, to obtain

$$0 \in c_k T(z^k + w^k) + w^k \ ,$$

or equivalently,

$$w^k = [(I + c_k T)^{-1} - I](z^k) \ ,$$

where equality follows from the fact that w^k is unique. This motivates us to define the operator

$$D_k := (I + c_k T)^{-1} - I \ . \tag{6}$$

This operator provides the analogue of the direction of steepest descent in the operator setting.

The algorithm we propose for solving the inclusion $0 \in T(z)$ can be succinctly stated as follows.

The Variable Metric Proximal Point Algorithm.

Let $z^0 \in \mathcal{H}$ and $c_0 \geq 1$ be given. Having z^k, set

$$z^{k+1} := z^k + H_k w^k, \quad \text{where} \ \ w^k \approx D_k(z^k),$$

and choose $c_{k+1} \geq 1$.

As mentioned in the previous section, it is critical that the convergence results are obtained under the assumption that $D_k(z^k)$ can only be approximated. We use the following approximation criteria:

$$(\mathcal{G}) \qquad \|w^k - D_k(z^k)\| \leq \min\left\{1, \frac{1}{\|H_k\|}\right\} \epsilon_k \ \ \text{with} \ \ \sum_{k=0}^{\infty} \epsilon_k < \infty$$

and

$$(\mathcal{L}) \qquad \|w^k - D_k(z^k)\| \leq \delta_k \|w^k\| \ \ \text{with} \ \ \lim_{k \to \infty} \delta_k = 0 \ .$$

The approximation criterion $(\mathcal{G})$ is used to establish global convergence properties, while criterion $(\mathcal{L})$ is used to obtain local rates of convergence.

Although these criteria are used in the proof of convergence, they are impractical from the perspective of implementation. In their stead, we provide criteria that are implementable. To obtain these criteria we recall the following result from Rockafellar [41].

Proposition 1 (see [41, Proposition 3]). *Let $S_k(w) := T(z^k + w) + \frac{1}{c_k} w$. Then $0 \in S_k(w^k) \Leftrightarrow w^k = D_k(z^k)$. Moreover, for all $w \in \mathcal{H}$ we have the bound*

$$\|w - D_k(z^k)\| \leq c_k \text{dist}\,(0, S_k(w)) \ . \tag{7}$$

Proposition 1 yields the following alternative approximation criteria for the w^k's. Since this result is an immediate consequence of Proposition 1, its proof is omitted.

Proposition 2. *Consider the following acceptance criteria for the w^k's:*

$$(\mathcal{G}') \qquad \operatorname{dist}(0, S_k(w^k)) \le \min\left\{1, \frac{1}{\|H_k\|}\right\}\frac{\epsilon_k}{c_k} \quad \textit{with} \quad \sum_{k=0}^{\infty}\epsilon_k < \infty$$

and

$$(\mathcal{L}') \qquad \operatorname{dist}(0, S_k(w^k)) \le \frac{\delta_k}{c_k}\|w^k\| \quad \textit{with} \quad \lim_{k\to\infty}\delta_k = 0\ .$$

We have $(\mathcal{G}')$ implies $(\mathcal{G})$ and $(\mathcal{L}')$ implies $(\mathcal{L})$.

Remark. Note that to satisfy either $(\mathcal{G}')$ or $(\mathcal{L}')$ it is not necessary to find an element of $S_k(w^k)$ of least norm.

Before leaving this section we recall from [41] a few properties of the operators D_k and $P_k := D_k + I$ that are essential in the analysis to follow.

Proposition 3 (see [41, Proposition 1]).

a) *The operator D_k can be expressed as*

$$D_k = -\left(I + T^{-1}\frac{1}{c_k}\right)^{-1}, \tag{8}$$

and for any $z \in \mathcal{H}$, $-\frac{1}{c_k}D_k(z) \in T(P_k(z))$.

b) *For any $z, z' \in \mathcal{H}$, $\langle P_k(z) - P_k(z'), D_k(z) - D_k(z')\rangle \le 0$.*

c) *For any $z, z' \in \mathcal{H}$, $\|P_k(z) - P_k(z')\|^2 + \|D_k(z) - D_k(z')\|^2 \le \|z - z'\|^2$.*

Remark. An important consequence of part c) above is that the operators P_k and D_k are Lipschitz continuous with Lipschitz constant 1; that is, they are nonexpansive. Henceforth, we make free use of this fact.

4. On the differentiability of T^{-1} and D_k.

Just as Newton's method for minimization locates roots of the gradient, one can view the VMPPA as a Newton-like method for locating roots of the operator D_k. This perspective motivates our approach to the local convergence analysis. For this analysis, we require that the operator T^{-1} possesses certain smoothness properties. These properties in turn imply the smoothness of the operators D_k. Smoothness hypotheses are used in the convergence analysis in much the same way as they are used in the convergence analysis for Newton's method. For example, recall that to ensure the quadratic convergence of Newton's method one requires the derivative at a solution to be both locally Lipschitz and nonsingular. Nonsingularity ensures that the iterates are well-defined and can be bounded, while the Lipschitzian hypothesis guarantees that the error in the linearization is quadratically bounded (see [29, sections 3.2.12 and 10.2.2]). We make use of similar properties in our analysis.

In order to discuss the smoothness of T^{-1} and D_k, we recall various notions of differentiability for multivalued functions from the literature. For a more thorough treatment of these ideas in the context of monotone operators, we refer the reader to [1, 19, 26, 35, 42].

Definition 4. *We say that an operator $\Psi : \mathcal{H} \rightrightarrows \mathcal{H}$ is Lipschitz continuous at a point $\bar{w}$ (with modulus $\alpha \ge 0$) if the set $\Psi(\bar{w})$ is nonempty and there is a $\tau > 0$ such that*

$$\Psi(w) \subset \Psi(\bar{w}) + \alpha\|w - \bar{w}\|\mathbb{B} \qquad \textit{whenever } \|w - \bar{w}\| \le \tau\ .$$

We say that Ψ is differentiable at a point $\bar{w}$ if $\Psi(\bar{w})$ consists of a single element $\bar{z}$ and there is a continuous linear transformation $J : \mathcal{H} \to \mathcal{H}$ such that for some $\delta > 0$,

$$\emptyset \ne \Psi(w) - \bar{z} - J(w - \bar{w}) \subset o(\|w - \bar{w}\|)\mathbb{B} \qquad \textit{whenever } \|w - \bar{w}\| \le \delta\ .$$

We then write $J = \nabla\Psi(\bar{w})$.

Remarks. 1) These definitions of Lipschitz continuity and differentiability for multifunction are taken from [41, pp. 885 and 887] (also see [2, p. 41]). Note that these notions of Lipschitz continuity and differentiability correspond to the usual notions when Ψ is single-valued.

2) Rockafellar [41, Theorem 2] was the first to use Lipschitz continuity to establish rates of convergence for the PPA.

3) When the set $\Psi(\bar{w})$ is restricted to be a singleton $\{\bar{z}\}$, the differentiability of Ψ at $\bar{w}$ implies the Lipschitz continuity of Ψ at $\bar{w}$. Moreover, one can take $\alpha(\tau) \to \|J\|$ as $\tau \to 0$. This observation is verified in [41, Proposition 4].

4) It follows from the definition of monotonicity that if T is a maximal monotone operator, then the operator $\nabla T(z)$ is positive semidefinite whenever it exists.

We now give a result that relates the differentiability of a multivalued function to the differentiability of its inverse. The proof is omitted since it parallels the proof of a similar result for single-valued functions.

LEMMA 5. *Assume that* $\Psi : \mathcal{H} \rightrightarrows \mathcal{H}$ *is differentiable at* $\bar{z}$ *with* $\Psi(\bar{z}) = \{\bar{w}\}$ *and* $\nabla\Psi(\bar{z}) = J$ *with* J^{-1} *bounded. Also assume that* Ψ^{-1} *is Lipschitz continuous at* $\bar{w}$ *with* $\Psi^{-1}(\bar{w}) = \{\bar{z}\}$. *Then* Ψ^{-1} *is differentiable at* $\bar{w}$ *with* $\nabla\Psi^{-1}(\bar{w}) = J^{-1}$.

In the two examples that follow, we examine the concepts introduced in Definition 4 when the operator in question is the subdifferential of a convex function. The first example illustrates that ∂f^{-1} can be Lipschitz continuous but not differentiable at the origin, while in the second example ∂f^{-1} is differentiable at the origin, but ∂f is not differentiable on $(\partial f)^{-1}(0)$.

EXAMPLE 6. *Let*

$$f(z) := \begin{cases} 0 & \text{if } z < 0, \\ z & \text{if } z \geq 0, \end{cases} \qquad \text{and} \qquad T(z) := \partial f(z) = \begin{cases} 0 & \text{if } z < 0, \\ [0,1] & \text{if } z = 0, \\ 1 & \text{if } z > 0\ . \end{cases}$$

$$\text{Then} \qquad T^{-1}(y) = \begin{cases} \emptyset & \text{if } y < 0 \text{ or } y > 1, \\ (-\infty, 0] & \text{if } y = 0, \\ \{0\} & \text{if } y \in (0,1), \\ [0,\infty) & \text{if } y = 1\ . \end{cases}$$

T^{-1} *is Lipschitz continuous at* 0 *but is not differentiable at* 0.

EXAMPLE 7. *Let*

$$f(z) := \begin{cases} -z & \text{if } z < 0, \\ z^{5/3} & \text{if } z \geq 0, \end{cases} \qquad \text{and} \qquad T(z) := \partial f(z) = \begin{cases} -1 & \text{if } z < 0, \\ [-1,0] & \text{if } z = 0, \\ \frac{5}{3}z^{2/3} & \text{if } z > 0. \end{cases}$$

$$\text{Then} \qquad T^{-1}(y) = \begin{cases} \emptyset & \text{if } y < -1, \\ (-\infty, 0] & \text{if } y = -1, \\ \{0\} & \text{if } y \in (-1,0), \\ \frac{3}{5}y^{3/2} & \text{if } y \geq 0\ . \end{cases}$$

T^{-1} *is differentiable at* 0 *with* $J = 0$, *but* T *is not differentiable on* $T^{-1}(0)$.

The superlinear convergence result of section 7 requires the assumption that the operator T^{-1} be differentiable at the origin. Although this is a severe restriction on the applicability of these results, it turns out that in the case of convex programming it is a consequence of the standard second-order sufficiency conditions for constrained mathematical programs. This and related results were established by Rockafellar in [40, Proposition 2]. In this context, it is important to note that the second-order sufficiency condition is the standard hypothesis used in the mathematical programming literature to ensure the rapid local convergence of numerical methods. So, at least in the context of constrained convex programming, such a differentiability hypothesis is not as severe an assumption as one might at first suspect. To the contrary, it is a bit weaker than the standard hypothesis employed for such results. For the sake of completeness, we recall a portion of Rockafellar's result below.

Theorem 8. *Consider the convex programming problem* (1)*, where* $f : \mathbb{R}^n \to \mathbb{R} \cup \{\infty\}$ *is given by*

$$f(z) = \begin{cases} f_0(z) & \text{if } f_i(z) \leq 0 \text{ for } i = 1, 2, \ldots, m, \\ +\infty & \text{otherwise,} \end{cases}$$

with $f_i : \mathbb{R}^n \to \mathbb{R}$ *convex for* $i = 0, 1, \ldots, m$. *Suppose that the following conditions are satisfied:*

(i) *The functions* f_i *for* $i = 0, 1, \ldots, m$ *are* $k \geq 2$ *times continuously differentiable in a neighborhood of a point* $\bar{z} \in \mathbb{R}^n$.

(ii) *There is a Kuhn–Tucker vector* $\bar{y} \in \mathbb{R}^m$ *for* $\bar{z}$ *such that* $\bar{y}_i > 0$ *for* $i \in I(\bar{z}) = \{i : f_i(\bar{z}) = 0,\ i = 1, 2, \ldots, m\}$.

(iii) *The gradients* $\{\nabla f_i(\bar{z}) : i \in I(\bar{z})\}$ *are linearly independent.*

(iv) *The matrix* $H = \nabla^2 f_0(\bar{z}) + \sum_{i=1}^m \bar{y}_i \nabla^2 f_i(\bar{z})$ *satisfies* $u^T H u > 0$ *for every nonzero* $u \in \mathbb{R}^n$ *such that* $\nabla f_0(\bar{z})^T u = 0$, *and* $\nabla f_i(\bar{z})^T u = 0$ *for* $i \in I(\bar{z})$.

Then the operator ∂f^{-1} *is* $(k-1)$ *times continuously differentiable in a neighborhood of the origin.*

Remark. Theorem 8 follows by applying the implicit function theorem to the Kuhn–Tucker conditions for the parameterized problems $\min\{f(z) - \langle w, z\rangle\}$ in a neighborhood of $w = 0$. The relationship to ∂f^{-1} comes from the fact that $\partial f^{-1}(w) = \operatorname{argmin}\{f(z) - \langle w, z\rangle\}$. Rockafellar establishes the result only for $k = 2$. The extension to $k > 2$ follows trivially from the implicit function theorem.

We now examine the differentiability properties of the mapping D_k. Two results in this direction are given. The first uses (8) to relate the differentiability of the operators T^{-1} and D_k, while the second uses the definition of D_k given in (6) to relate the differentiability of the operators T and D_k.

Proposition 9. *Let* $T : \mathcal{H} \rightrightarrows \mathcal{H}$ *be maximal monotone and* $\lambda > 0$. *Define*

$$D(z) = -\left(I + T^{-1}\frac{1}{\lambda}\right)^{-1}(z) \ . \tag{9}$$

Let $\bar{z} \in \mathcal{H}$ *and set* $\bar{w} = D(\bar{z})$ *and* $\bar{y} = -\frac{1}{\lambda}\bar{w}$. *The operator* T^{-1} *is differentiable at* $\bar{y}$ *with* $[I + \frac{1}{\lambda}\nabla(T^{-1})(\bar{y})]^{-1}$ *bounded if and only if the operator* D *is differentiable at* $\bar{z}$ *with* $(\nabla D(\bar{z}))^{-1}$ *bounded. In either case, we have*

$$\nabla D(\bar{z}) = -\left[I + \frac{1}{\lambda}\nabla(T^{-1})(\bar{y})\right]^{-1} \ . \tag{10}$$

Proof. First assume that T^{-1} is differentiable at $\bar{y}$ with $\nabla(T^{-1})(\bar{y})$ bounded. The differentiability of T^{-1} at $\bar{y}$ clearly implies that of D^{-1} at $\bar{w}$ with

$$\nabla[D^{-1}](\bar{w}) = -\left(I + \frac{1}{\lambda}\nabla[T^{-1}](\bar{y})\right) .$$

Since D is Lipschitzian with $D(\bar{z}) = \bar{w}$, Lemma 5 implies that D is differentiable at $\bar{z}$ with derivative given by (10). Since $\nabla[D^{-1}](\bar{w}) = (\nabla D(\bar{z}))^{-1}$, we conclude that the latter is bounded.

Conversely, assume that D is differentiable at $\bar{z}$ with $(\nabla D(\bar{z}))^{-1}$ bounded. We show that D^{-1} is single-valued and Lipschitzian at $\bar{w}$. The result will then follow from Lemma 5.

Let $\delta > 0$ be as in Definition 4 for $\nabla D(\bar{z})$. Since D is single-valued and $\nabla D(\bar{z})$ is surjective (it is invertible), we may apply a standard open mapping result from functional analysis (e.g., [8, Theorem 15.5]) to obtain the existence of a $\rho > 0$ and a $0 < \hat{\delta} < \delta$ such that

$$\bar{w} + \rho\mathbb{B} \subset D(\bar{z} + \hat{\delta}\mathbb{B}) . \tag{11}$$

Hence for each $w \in \bar{w} + \rho\mathbb{B}$ and $z \in D^{-1}(w) \cap (\bar{z} + \hat{\delta}\mathbb{B}) \neq \emptyset$ we have

$$w = \bar{w} + \nabla D(\bar{z})(z - \bar{z}) + o(\|z - \bar{z}\|) . \tag{12}$$

Since $(\nabla D(\bar{z}))^{-1}$ is bounded, there is a $\kappa > 0$ such that

$$\|w - \bar{w}\| + o(\|z - \bar{z}\|) = \|\nabla D(\bar{z})(z - \bar{z})\| \geq \kappa\|z - \bar{z}\| .$$

Hence, by reducing ρ and $\hat{\delta}$ if necessary, we may assume that

$$\|w - \bar{w}\| \geq \frac{\kappa}{2}\|z - \bar{z}\| \geq \frac{\kappa}{2}\|w - \bar{w}\|$$

for $w \in \bar{w} + \rho\mathbb{B}$, where the second inequality follows since D is nonexpansive. Therefore, we can assume that $o(\|z - \bar{z}\|) = o(\|w - \bar{w}\|)$ for all $w \in \bar{w} + \rho\mathbb{B}$ and $z \in D^{-1}(w) \cap (\bar{z} + \hat{\delta}\mathbb{B})$. By substituting this into (12) and rearranging, we obtain

$$\begin{aligned} & z = \bar{z} + (\nabla D(\bar{z}))^{-1}(w - \bar{w}) + o(\|w - \bar{w}\|) \\ & \text{for all } w \in \bar{w} + \rho\mathbb{B} \text{ and } z \in D^{-1}(w) \cap (\bar{z} + \hat{\delta}\mathbb{B}). \end{aligned} \tag{13}$$

We now show that (13) implies the existence of an $\epsilon > 0$ such that $D^{-1}(\bar{w} + \epsilon\mathbb{B}) \subset \bar{z} + \hat{\delta}\mathbb{B}$. Indeed, if this were not the case, then there would exist sequences $\{w_i\}$ and $\{z_i\}$ such that $z_i \in D^{-1}(w_i)$, $\|z_i - \bar{z}\| > \hat{\delta}$, and $w_i \to \bar{w}$. Since D^{-1} is itself maximal monotone, its images are convex; hence, by (11), there exists a sequence $\{\hat{z}_i\}$ with $\hat{z}_i \in D^{-1}(w_i)$ and $\|\hat{z}_i - \bar{z}\| = \hat{\delta}$ for all $i = 1, 2, \ldots$. But then (13) implies that

$$\hat{z}_i = \bar{z} + (\nabla D(\bar{z}))^{-1}(w_i - \bar{w}) + o(\|w_i - \bar{w}\|)$$

for all $i = 1, 2, \ldots$. This contradicts the fact that $w_i \to \bar{w}$ and $\|\hat{z}_i - \bar{z}\| = \hat{\delta}$ for all $i = 1, 2, \ldots$, and so such an $\epsilon > 0$ must exist. This fact combined with (13) implies that D^{-1} is Lipschitzian at $\bar{w}$ with $D^{-1}(\bar{w}) = \{\bar{z}\}$. Lemma 5 now applies to yield the result. □

Proposition 10. *Let D be defined as in* (9). *Let $\bar{z} \in \mathcal{H}$ and set $\bar{y} = (I + D)(\bar{z})$. The operator T is differentiable at $\bar{y}$ with $[I + \lambda \nabla T(\bar{y})]^{-1}$ bounded if and only if the operator D is differentiable at $\bar{z}$ with $[I + \nabla D(\bar{z})]^{-1}$ bounded. In either case we have the formula*

$$\nabla D(\bar{z}) = [I + \lambda \nabla T(\bar{y})]^{-1} - I \ .$$

Proof. Replace D by $P := I + D = (I + \lambda T)^{-1}$ and observe that D is differentiable at $\bar{z}$ with $[I + \nabla D(\bar{z})]^{-1}$ bounded if and only if P is differentiable at $\bar{z}$ with $[\nabla P(\bar{z})]^{-1}$ bounded. The proof now follows the same argument as in the proof of Proposition 9 with D replaced by P, T^{-1} replaced by T, and $\bar{w}$ replaced by $\bar{y}$. □

Propositions 9 and 10 say quite different things about the differentiability of D_k. To illustrate this difference, observe that in Example 7 the operator T is not differentiable at 0, while T^{-1} and D are differentiable at 0. On the other hand, if we take $T = \partial f$ with $f(x) = |x|^3$, then T^{-1} is not differentiable at 0, while T and D are differentiable at 0. It is also important to note that even if neither T nor T^{-1} is differentiable, D may be differentiable. But, in this case, we know from Propositions 9 and 10 that if D is differentiable and neither T nor T^{-1} is differentiable, then both $\nabla D(\bar{z})$ and $\nabla P(\bar{z})$ have to be singular or have unbounded inverses. For a further discussion of these issues in the context of finite dimensional convex programming, see [35].

When T is assumed to be the subdifferential of a convex function f, Propositions 9 and 10 can be refined by making use of the relation $\partial f^{-1} = \partial f^*$, where f^* is the convex conjugate of f [39, Corollary 12A]. This allows us to extend [35, Theorem 1] and [35, Theorem 2] to the Hilbert space setting (also see [19, Theorem 3.1]). However, some caution in terminology is required since f^* is not necessarily twice differentiable in the classical sense at points where ∂f^* is differentiable in the sense of Definition 4. Indeed, ∂f^* may be multivalued arbitrarily close to a point of differentiability. The best way to interpret this result is through Alexandrov's theorem [1], which states that at almost every point $\bar{z}$ in the interior of the domain of a convex function $f : \mathbb{R}^n \mapsto \mathbb{R} \cup \{\infty\}$ there is a quadratic function $q_{\bar{z}}$ such that $f(x) = q_{\bar{z}}(x) + o(\|x - \bar{z}\|^2)$. In [19] and [35], the matrix $\nabla^2 q_{\bar{z}}$ is called a *generalized Hessian* and is denoted $Hf(x)$. Note that the existence of a generalized Hessian at the point $\bar{z}$ guarantees that f is strictly differentiable at $\bar{z}$. Moreover, if $\partial f(x)$ is single-valued in a neighborhood of a point $\bar{z}$ at which $Hf(\bar{z})$ exists, then $\nabla^2 f(\bar{z})$ exists and equals $Hf(\bar{z})$. We extend this terminology to the Hilbert space setting with the following definition.

Definition 11. *Let $\phi : \mathcal{H} \mapsto \mathbb{R} \cup \{\infty\}$ be a function on the Hilbert space $\mathcal{H}$. We say that ϕ is twice differentiable in the generalized sense at a point $\bar{z} \in \mathcal{H}$ if there is a continuous quadratic functional $q_{\bar{z}}$ such that $\phi(x) = q_{\bar{z}}(x) + o(\|x - \bar{z}\|^2)$. The operator $\nabla^2 q_{\bar{z}}$ is called a generalized Hessian of ϕ at $\bar{z}$ and is denoted by $H\phi(\bar{z})$.*

With this terminology in hand, we apply Propositions 9 and 10 to the case of convex programming. The proofs of these results are not required since they are a direct translation of Propositions 9 and 10 into the terminology of convex programming.

Corollary 12. *Let $f : \mathcal{H} \to \mathbb{R} \bigcup \{+\infty\}$ be lower semicontinuous and convex. Let $\bar{z} \in \mathcal{H}$ and set $\bar{w} = \nabla f_\lambda(\bar{z})$ and $\bar{y} = \frac{1}{\lambda}\bar{w}$. Then f_λ is twice (Fréchet) differentiable at $\bar{z}$ with $[\nabla^2 f_\lambda(\bar{z})]^{-1}$ bounded if and only if f^* has a generalized Hessian at $\bar{y}$ with $[I + \frac{1}{\lambda} Hf^*(\bar{y})]^{-1}$ bounded. In either case we have*

$$\nabla^2 f_\lambda(\bar{z}) = \left[I + \frac{1}{\lambda} Hf^*(\bar{y}) \right]^{-1} \ .$$

Corollary 13. *Let $f : \mathcal{H} \to \mathbb{R}\bigcup\{+\infty\}$ be lower semicontinuous and convex. Let $\bar{z} \in \mathcal{H}$ and set $\bar{y} = \bar{z} - \nabla f_\lambda(\bar{z})$. Then f_λ is twice (Fréchet) differentiable at $\bar{z}$ with $[I + \nabla^2 f_\lambda(\bar{z})]^{-1}$ bounded if and only if f is twice differentiable in the generalized sense at $\bar{y}$ with $[I + \lambda H f(\bar{y})]^{-1}$ bounded. In either case we have*

$$\nabla^2 f_\lambda(\bar{z}) = I - [I + \lambda H f(\bar{y})]^{-1} \ .$$

Remark. As observed earlier, the generalized Hessian is necessarily positive semidefinite. This observation can be used to further refine the statement of Corollaries 12 and 13.

5. Newton operators. In this section we study the operators associated with the variable metric proximal point iteration:

$$\mathcal{N}_k := I + H_k D_k = P_k + (H_k - I)D_k \ . \tag{14}$$

This notation emphasizes the fact that these operators produce Newton-like iterates. Just as in the case of the classical Newton's method for equation solving [29, section 12.6], one of the keys to the convergence analysis is to show that these operators are contractive with respect to the solution set $T^{-1}(0)$. Clearly the operators $\mathcal{N}_k$ are single-valued. Moreover, fixed points of the operators $\mathcal{N}_k$ are solutions to the inclusion $0 \in T(z)$ since

$$0 \in T(z) \ \Leftrightarrow \ P_k(z) = z \ \Leftrightarrow \ D_k(z) = 0 \ \Leftrightarrow \ \mathcal{N}_k(z) = z.$$

Thus, conditions that ensure that the operators $\mathcal{N}_k$ are nonexpansive with respect to $T^{-1}(0)$ are important for the global analysis of the variable metric proximal point iteration. To obtain this property, we impose the following conditions on the linear transformations $\{H_k\}$:

(H1) Each H_k is a continuous linear transformation with continuous inverse.

(H2) There is a nonempty closed bounded subset Γ of $T^{-1}(0)$ such that

$$\|(H_k - I)D_k(z^k)\| \le \gamma_k \|D_k(z^k)\| \quad \text{for all } k,$$

where

$$\gamma_k := \frac{\|D_k(z^k)\|}{2\sigma_k + 3\|D_k(z^k)\|} \quad \text{with } \sigma_k = \sup\{\|z^k - z\| \ : \ z \in \Gamma\}.$$

Remark. The set Γ in (H2) is used to guarantee the boundedness of the sequence $\{z^k\}$. By taking $\Gamma = \{\bar{z}\}$, one can show that every weak cluster point of the sequence $\{z^k\}$ is an element of $T^{-1}(0)$. It was observed by Iusem [13] that if $T^{-1}(0)$ is bounded and one takes $\Gamma = T^{-1}(0)$, then the sequence $\{z^k\}$ has a weak limit $z^\infty \in T^{-1}(0)$ (see Theorem 17 and [41, Theorem 1]).

Hypothesis (H1) is standard and is automatically satisfied in the finite dimensional case. On the other hand, hypothesis (H2) is quite technical and requires careful examination. This hypothesis is problematic since it specifies that the matrices H_k satisfy a condition that depends on the unknown values σ_k and $\|D_k(z^k)\|$. We will show that in certain cases it is possible to satisfy (H2) without direct knowledge of these unknown values. This is done in two steps. First it is shown in Lemma 14 that if T^{-1} is Lipschitz continuous or differentiable at the origin, then γ_k is bounded below by a positive constant (which can be taken to be 1/6 as $\|D_k(z^k)\|$ approaches zero).

Then, in Lemma 15, it is shown that (H2) is satisfied if a related condition in terms of H_k and w^k is satisfied. Taken together, these results imply that at least locally (H2) can be satisfied by checking a condition based on known quantities.

Further insight into hypothesis (H2) can be gained by considering the case in which T^{-1} is differentiable at the origin. In this case H_k is intended to approximate $-(\nabla D_k(0))^{-1} = (I + c_k^{-1} J)$, where $J = \nabla(T^{-1})(0)$ (by Proposition 9). Hence, if $H_k \approx -(\nabla D_k(0))^{-1}$, then $(H_k - I) \approx c_k^{-1} J$. Therefore, one can guarantee that (H2) is satisfied by choosing c_k sufficiently large and $H_k \approx I$. This fact is used in [6] to establish the superlinear convergence of the method when the H_k's are obtained via matrix secant updating techniques.

The purpose of hypothesis (H2) is to globalize what is essentially a local algorithm (Newton's method). In the context of convex programming, one commonly obtains global convergence properties with the aid of a line search routine applied to the objective function f or its regularization f_λ. However, in the operator setting there is no natural underlying objective function to which a line search can be applied. This is a key difference between the approach taken in this paper and those in [3, 7, 10, 18, 20, 24, 36]. In the convex programming setting, the global convergence of the VMPPA is driven by a line search routine applied to the objective function f (or its regularization f_λ). In the operator setting, hypothesis (H2) replaces the line search and the associated hypotheses needed to make the line search strategy effective (such as the finite-valuedness of the objective function f and the boundedness of the sequence $\{H_k\}$). On the other hand, when it is known that the operator T is the subdifferential of a finite-valued finite dimensional convex function, then the algorithm of this paper can be modified to include the line search routine of Chen and Fukushima [7], thereby avoiding the need for hypothesis (H2) [6].

We now show three cases where the γ_k's are bounded away from zero.

LEMMA 14. *Suppose $T^{-1}(0)$ is nonempty.*

(i) *If the operator T is strongly monotone with modulus κ, then $T^{-1}(0) = \{\bar{z}\}$,*

$$\|z^k - \bar{z}\| \le \left(1 + \frac{1}{\kappa c_k}\right) \|D_k(z^k)\| \ ,$$

and $\gamma_k \ge \frac{1}{5+\frac{2}{\kappa c_k}} \ge \frac{1}{5+2/\kappa}$ for all k.

(ii) *If the operator T^{-1} is Lipschitz continuous at the origin with modulus α, then*

$$\operatorname{dist}(z^k, T^{-1}(0)) \le \left(1 + \frac{\alpha}{c_k}\right) \|D_k(z^k)\| \ , \tag{15}$$

for all k such that $\|D_k(z^k)\| \le \tau$, where τ is given in Definition 4. Moreover, if $T^{-1}(0) = \{\bar{z}\}$, then $\gamma_k \ge \frac{1}{5+2\alpha/c_k} \ge \frac{1}{5+2\alpha}$ for all k such that $\|D_k(z^k)\| \le \tau$.

(iii) *If T^{-1} is differentiable at the origin with derivative J, then $T^{-1}(0) = \{\bar{z}\}$, there is a $\delta > 0$ such that for all k with $\|D_k(z^k)\| \le \tau$ we have*

$$\|z^k - \bar{z}\| \le \left(1 + \frac{\|J\|}{c_k} + \sigma(\|D_k(z^k)\|)\right) \|D_k(z^k)\| \ ,$$

and $\gamma_k \ge \frac{1}{5+2\frac{\|J\|}{c_k}+\sigma(\|D_k(z^k)\|)}$ for all k, where $\sigma(\tau) \to 0$ as $\tau \to 0$.

Proof.

(i) If T is strongly monotone with modulus κ, then $\|z - z'\| \le \frac{1}{\kappa}\|w - w'\|$ for any z, z', w, w' such that $w \in T(z)$ and $w' \in T(z')$. That is, T^{-1} is single-valued and Lipschitz continuous. Let $z = P_k(z^k)$ and $z' = \bar{z}$, where $\{\bar{z}\} = T^{-1}(0)$. By Proposition 3 a) we have $-\frac{1}{c_k}D_k(z^k) \in T(P_k(z^k))$. Hence

$$\|z^k - \bar{z}\| \leq \|z^k - P_k(z^k)\| + \|P_k(z^k) - \bar{z}\| \leq \left(1 + \frac{1}{\kappa c_k}\right)\|D_k(z^k)\| \ ,$$

since $D_k = P_k - I$. By the definition of γ_k,

$$\begin{aligned}\gamma_k &= \frac{\|D_k(z^k)\|}{2\|z^k - \bar{z}\| + 3\|D_k(z^k)\|} \\ &\geq \frac{\|D_k(z^k)\|}{2(1 + \frac{1}{\kappa c_k})\|D_k(z^k)\| + 3\|D_k(z^k)\|} \geq \frac{\kappa c_k}{5\kappa c_k + 2} \ .\end{aligned}$$

This establishes the result since $c_k \geq 1$ for all k.

(ii) If $\|D_k(z^k)\| \leq \tau$, Definition 4 implies that

$$T^{-1}\left(-\frac{1}{c_k}D_k(z^k)\right) \subset T^{-1}(0) + \alpha\left\|\frac{1}{c_k}D_k(z^k)\right\|\mathbb{B} = T^{-1}(0) + \frac{\alpha}{c_k}\|D_k(z^k)\|\mathbb{B} \ ,$$

or

$$\left(I + T^{-1}\frac{1}{c_k}\right)(-D_k(z^k)) + D_k(z^k) \subset T^{-1}(0) + \frac{\alpha}{c_k}\|D_k(z^k)\|\mathbb{B} \ .$$

Since $D_k(z^k) = -(I + T^{-1}\frac{1}{c_k})^{-1}(z^k)$, we have $z^k \in (I + T^{-1}\frac{1}{c_k})(-D_k(z^k))$, and so

$$z^k \in T^{-1}(0) - D_k(z^k) + \frac{\alpha}{c_k}\|D_k(z^k)\|\mathbb{B}.$$

Hence (15) holds. If $T^{-1}(0) = \{\bar{z}\}$, then the lower bound on γ_k follows as in part (i).

(iii) This result follows as in part (ii) using the second remark after Definition 4. □

When $w^k \approx D_k(z^k)$, one can establish the inequality in hypothesis (H2) from a related condition on the vectors w^k. A specific technique for accomplishing this is given in the following lemma.

LEMMA 15. *Let $\xi, \hat{\gamma}_k, \delta_k \in \mathbb{R}_+$ be such that*

$$0 \leq \xi < 1,\ \delta_k \leq \min\left\{1, \|H_k\|^{-1}\right\}\frac{3}{7}(1-\xi)\hat{\gamma}_k,\ \text{and } \hat{\gamma}_k \leq \frac{1}{3}, \tag{16}$$

and let H_k be a continuous linear transformation from $\mathcal{H}$ to itself. If $z^k, w^k \in \mathcal{H}$ satisfy

$$\|(I - H_k)w^k\| \leq \xi\hat{\gamma}_k\|w^k\| \text{ and } \|w^k - D_k(z^k)\| \leq \delta_k\|w^k\|, \tag{17}$$

then $\|(I - H_k)D_k(z^k)\| \leq \hat{\gamma}_k\|D_k(z^k)\|$. Therefore, if (H1) *and criterion* ($\mathcal{L}$) *are satisfied, and if ξ and the sequence $\{(\hat{\gamma}_k, \delta_k)\} \subset \mathbb{R}^2$ satisfy* (16)*, with $\hat{\gamma}_k \leq \gamma_k$ for all k* (*where γ_k is defined in* (H2))*, then hypothesis* (H2) *is satisfied.*

Proof. From (16) and (17), we have

$$\|w^k\| \leq \|D_k(z^k)\| + \|w^k - D_k(z^k)\| \leq \|D_k(z^k)\| + \frac{3}{7}(1-\xi)\hat{\gamma}_k\|w^k\|;$$

hence

$$\|w^k\| \le \frac{1}{1-\frac{3}{7}(1-\xi)\hat{\gamma}_k}\|D_k(z^k)\| \ .$$

Again by (17),

$$\begin{aligned}\|(I-H_k)D_k(z^k)\| &\le \|(I-H_k)w^k\| + \|H_k\|\|w^k - D_k(z^k)\| + \|w^k - D_k(z^k)\| \\ &\le \xi\hat{\gamma}_k\|w^k\| + (\|H_k\|+1)\delta_k\|w^k\| \le \left(\xi + \frac{6}{7}(1-\xi)\right)\hat{\gamma}_k\|w^k\| \\ &\le \frac{\xi+\frac{6}{7}(1-\xi)}{1-\frac{3}{7}(1-\xi)\hat{\gamma}_k}\hat{\gamma}_k\|D_k(z^k)\| \le \hat{\gamma}_k\|D_k(z^k)\|\end{aligned}$$

since the inequality $\hat{\gamma}_k \le \frac{1}{3}$ implies that $\frac{\xi+\frac{6}{7}(1-\xi)}{1-\frac{3}{7}(1-\xi)\hat{\gamma}_k} = \frac{6+\xi}{7-3(1-\xi)\hat{\gamma}_k} \le 1$. □

We conclude this section by showing that the operators $\mathcal{N}_k$ are nonexpansive with respect to the set $T^{-1}(0)$.

PROPOSITION 16. *Assume* $T^{-1}(0)$ *is nonempty. If the sequence of linear transformations* $\{H_k\}$ *satisfies hypotheses* (H1) *and* (H2)*, then for all k we have* $\|H_kD_k(z^k)\| \le \frac{3}{2}\|D_k(z^k)\|$ *and*

$$\|\mathcal{N}_k(z^k)-\bar{z}\|^2 + \frac{\gamma_k^2}{4}\|D_k(z^k)\|^2 \le \|z^k-\bar{z}\|^2 \quad \textit{for all } \bar{z}\in\Gamma. \tag{18}$$

Proof. Let $\bar{z}\in\Gamma$. From the definitions of P_k and $\mathcal{N}_k$, we have

$$\|P_k(z^k)-\bar{z}\| = \|\mathcal{N}_k(z^k)-(H_k-I)D_k(z^k)-\bar{z}\| \ge |\|\mathcal{N}_k(z^k)-\bar{z}\|-\|(H_k-I)D_k(z^k)\||; \tag{19}$$

hence

$$\|P_k(z^k)-\bar{z}\|^2 \ge \|\mathcal{N}_k(z^k)-\bar{z}\|^2+\|(H_k-I)D_k(z^k)\|^2-2\|(H_k-I)D_k(z^k)\|\|\mathcal{N}_k(z^k)-\bar{z}\| \ . \tag{20}$$

From hypothesis (H2), we have

$$\|H_kD_k(z^k)\| \le \|D_k(z^k)\| + \|(H_k-I)D_k(z^k)\| \le (1+\gamma_k)\|D_k(z^k)\| \le \frac{3}{2}\|D_k(z^k)\| \ .$$

Hence

$$\|\mathcal{N}_k(z^k)-\bar{z}\| \le \|z^k-\bar{z}\| + \|H_kD_k(z^k)\| \le \sigma_k + \frac{3}{2}\|D_k(z^k)\| \ .$$

Then, again by hypothesis (H2),

$$\|(H_k-I)D_k(z^k)\| \le \gamma_k\|D_k(z^k)\| = \frac{\|D_k(z^k)\|^2}{2\sigma_k+3\|D_k(z^k)\|} \le \frac{\|D_k(z^k)\|^2}{2\|\mathcal{N}_k(z^k)-\bar{z}\|} \ . \tag{21}$$

Thus, from (20) and (21),

$$\|P_k(z^k)-\bar{z}\|^2 \ge \|\mathcal{N}_k(z^k)-\bar{z}\|^2 + \|(H_k-I)D_k(z^k)\|^2 - \|D_k(z^k)\|^2 \ . \tag{22}$$

Letting $z=z^k$ and $z'=\bar{z}$ in Proposition 3 c) yields

$$\|P_k(z^k)-\bar{z}\|^2 + \|D_k(z^k)\|^2 \le \|z^k-\bar{z}\|^2 \ . \tag{23}$$

From (22) and (23) we have

$$\|\mathcal{N}_k(z^k) - \bar{z}\|^2 + \|(H_k - I)D_k(z^k)\|^2 \le \|z^k - \bar{z}\|^2 \ . \tag{24}$$

We now consider $\alpha_k = \frac{\|(H_k - I)D_k(z^k)\|}{\|D_k(z^k)\|}$. If $\alpha_k \ge \frac{\gamma_k}{2}$, then (18) holds by (24). Suppose that $\alpha_k < \frac{\gamma_k}{2}$. From (19), we have

$$\|P_k(z^k) - \bar{z}\| \ge \|\mathcal{N}_k(z^k) - \bar{z}\| - \frac{\gamma_k}{2}\|D_k(z^k)\| \ .$$

Therefore, by (23),

$$\|\mathcal{N}_k(z^k) - \bar{z}\| \le \sqrt{\|z^k - \bar{z}\|^2 - \|D_k(z^k)\|^2} + \frac{\gamma_k}{2}\|D_k(z^k)\| \ .$$

Using the inequality $\sqrt{a^2 - b^2} \le a - \frac{b^2}{2a}$ for $a > b > 0$,

$$\|\mathcal{N}_k(z^k) - \bar{z}\| \le \|z^k - \bar{z}_k\| - \frac{\|D_k(z^k)\|^2}{2\|z^k - \bar{z}\|} + \frac{\gamma_k}{2}\|D_k(z^k)\| \ .$$

But $\frac{\|D_k(z^k)\|}{2\|z^k - \bar{z}\|} \ge \gamma_k$; thus

$$\|\mathcal{N}_k(z^k) - \bar{z}\| \le \|z^k - \bar{z}\| - \frac{\gamma_k}{2}\|D_k(z^k)\|$$

or

$$\|\mathcal{N}_k(z^k) - \bar{z}\| + \frac{\gamma_k}{2}\|D_k(z^k)\| \le \|z^k - \bar{z}\| \ . \tag{25}$$

From (25) we again obtain (18). □

6. Global convergence. The statement and proof of the global convergence result given below parallels the development given by Rockafellar in [41, Theorem 1] for the classical PPA.

THEOREM 17. *Let $\{z^k\}$ be any sequence generated by the VMPPA under criterion $(\mathcal{G})$ (or $(\mathcal{G}')$). Suppose that the solution set $T^{-1}(0)$ is nonempty and the sequence of linear transformations $\{H_k\}$ satisfies the hypotheses* (H1) *and* (H2). *Then the sequence $\{z^k\}$ is bounded, each weak cluster point of this sequence is an element of $T^{-1}(0)$, and $\lim_k D_k(z^k) = 0$. If it is also assumed that $T^{-1}(0)$ is bounded and $\Gamma = T^{-1}(0)$ in* (H2), *then there is a $\bar{z} \in T^{-1}(0)$ such that $\{z^k\}$ converges weakly to $\bar{z}$.*

In order to establish this result we require the following technical lemma, whose proof is straightforward and so is omitted.

LEMMA 18. *Suppose the nonnegative sequences $\{\epsilon_k\}$ satisfy $\sum_{k=0}^{\infty} \epsilon_k < +\infty$. If $\{u_k\}$ is a nonnegative sequence satisfying $u_{k+1} \le \epsilon_k + u_k$, then $\{u_k\}$ is a Cauchy sequence.*

Proof of Theorem 17. We begin by showing that the limit $\lim_k \|z^k - \bar{z}\| = \mu(\bar{z})$ exists for every $\bar{z} \in \Gamma$. To this end let $\bar{z} \in \Gamma$ and observe that the definition of $\mathcal{N}_k$ and Proposition 16 imply that

$$\begin{aligned}\|z^{k+1} - \bar{z}\| &= \|z^{k+1} - \mathcal{N}_k(z^k) + \mathcal{N}_k(z^k) - \bar{z}\| \le \|z^{k+1} - \mathcal{N}_k(z^k)\| + \|\mathcal{N}_k(z^k) - \bar{z}\| \\ &\le \|H_k\|\|w^k - D_k(z^k)\| + \|z^k - \bar{z}\| \le \epsilon_k + \|z^k - \bar{z}\| \ .\end{aligned}$$

Therefore, Lemma 18 implies that the sequence $\{\|z^k - \bar{z}\|\}$ is Cauchy, and so $\mu(\bar{z})$ exists for every $\bar{z} \in \Gamma$. An immediate consequence of the existence of these limits is the boundedness of the sequences $\{z^k\}$ and σ_k.

We now show that the sequence $\{D_k(z^k)\}$ converges strongly to the origin. Indeed, if this is not the case, then there is a subsequence $J \subset \{1, 2, \ldots\}$ such that $\inf_J \|D_k(z^k)\| = \beta_1 > 0$. This in turn implies that $\inf_J \gamma_k = \beta_2 > 0$ since otherwise $\lim_J \|D_k(z^k)\| = 0$ due to the boundedness of the sequence $\{\sigma_k\}$. Let $\bar{z} \in \Gamma$. By Proposition 16,

$$\begin{aligned}
&\frac{\gamma_k^2}{4}\|D_k(z^k)\|^2 - \|z^k - \bar{z}\|^2 + \|z^{k+1} - \bar{z}\|^2 \le \|z^{k+1} - \bar{z}\|^2 - \|\mathcal{N}_k(z^k) - \bar{z}\|^2 \\
&= \langle z^{k+1} - \mathcal{N}_k(z^k), z^{k+1} - \bar{z} + \mathcal{N}_k(z^k) - \bar{z}\rangle \\
&\le \|z^{k+1} - \mathcal{N}_k(z^k)\|(\|z^{k+1} - \bar{z}\| + \|\mathcal{N}_k(z^k) - \bar{z}\|) \\
&\le \|H_k\|\|w^k - D_k(z^k)\|(\|z^{k+1} - \bar{z}\| + \|z^k - \bar{z}\|) \le \epsilon_k(\|z^{k+1}\| + 2\|\bar{z}\| + \|z^k\|) = \epsilon_k C_k \ ,
\end{aligned}$$

with $\{C_k\}$ bounded, where the final inequality follows from criterion $(\mathcal{G})$. Hence

$$\frac{\gamma_k^2}{4}\|D_k(z^k)\|^2 \le \|z^k - \bar{z}\|^2 - \|z^{k+1} - \bar{z}\|^2 + \epsilon_k C_k,$$

whereby we obtain the contradiction

$$\begin{aligned}
0 < \frac{\beta_1^2\beta_2^2}{4} &\le \limsup_J \frac{\gamma_k^2}{4}\|D_k(z^k)\|^2 \\
&\le \lim_J(\|z^k - \bar{z}\|^2 - \|z^{k+1} - \bar{z}\|^2 + \epsilon_k C_k) = \mu(\bar{z}) - \mu(\bar{z}) + 0 = 0 \ .
\end{aligned}$$

Therefore, $\lim_k \|D_k(z^k)\| = 0$.

Next let $J \subset \{1, 2, \ldots\}$ be such that the subsequence $\{z^k\}_J$ converges weakly to z^∞, i.e., z^∞ is a weak cluster point of the sequence $\{z^k\}$. We show that z^∞ must be an element of $T^{-1}(0)$. From Proposition 3 a), we have that $-\frac{1}{c_k}D_k(z^k) \in T(P_k(z^k))$ for all k; hence $0 \le \langle z - P_k(z^k), w + \frac{1}{c_k}D_k(z^k)\rangle$, or equivalently, $\langle z - z^k - D_k(z^k), w + \frac{1}{c_k}D_k(z^k)\rangle \ge 0$ for all k and z, w with $w \in T(z)$. Taking the limit over J yields the inequality $\langle z - z^\infty, w\rangle \ge 0$ for all z, w with $w \in T(z)$. Since T is maximal monotone, we get $0 \in T(z^\infty)$.

Under the assumption that $\Gamma = T^{-1}(0)$, the argument showing that there is no more than one weak cluster point of $\{z^k\}$ is identical to the one given by Rockafellar in [41, Theorem 1]. □

Remark. To ensure the strong convergence of the sequence $\{z^k\}$, one again requires a growth condition on the inverse mapping T^{-1} in a neighborhood of the origin. Rockafellar has shown that Lipschitz continuity of T^{-1} at the origin suffices for this purpose [41, Theorem 2]. Other conditions can be found in the work of Luque [21, Proposition 1.2]. The results of Rockafellar and Luque are easily extended to the VMPPA.

7. Convergence rates.

7.1. Linear convergence. Just as in Rockafellar [41, Theorem 2], we require that the operator T^{-1} is Lipschitz continuous at the origin in order to establish that the convergence rate is at least linear.

THEOREM 19. *Let $\{z^k\}$ be any sequence generated by the VMPPA satisfying both criteria $(\mathcal{G})$ and $(\mathcal{L})$ for all k. Assume that T^{-1} is Lipschitz continuous at the* *origin with modulus α and the solution set $T^{-1}(0)$ is a singleton $\{\bar{z}\}$. If the sequence $\{H_k\}$ satisfies the hypotheses* (H1) *and* (H2) *with $\delta_k\|H_k\| \to 0$, then the sequence $\{z^k\}$ strongly converges to the solution and there is an index $\bar{k}$ such that*

$$\|z^{k+1} - \bar{z}\| \leq \sigma_k \|z^k - \bar{z}\| \quad \textit{for all } k \geq \bar{k} \ ,$$

where σ_k satisfies $\limsup_{k\to\infty} \sigma_k < 1$. That is, the convergence rate is linear.

Proof. By Theorem 17, we have $\|D_k(z^k)\| \to 0$. Hence, Part (ii) of Lemma 14 implies that $\{z^k\}$ converges strongly to $\bar{z}$. We now establish the linear rate.

Let $\tau > 0$ be as in Definition 4, and let $\tilde{k}$ be such that $\|\frac{1}{c_k} D_k(z^k)\| \leq \tau$ for all $k \geq \tilde{k}$. By Proposition 3 a) and the Lipschitz continuity of T^{-1} at 0, we have

$$\|P_k(z^k) - \bar{z}\| \leq \frac{\alpha}{c_k} \|D_k(z^k)\| \ . \tag{26}$$

Hence relation (14) and hypothesis (H2) yield

$$\begin{aligned} \|\mathcal{N}_k(z^k) - \bar{z}\| &= \|P_k(z^k) + (H_k - I)D_k(z^k) - \bar{z}\| \\ &\leq \|P_k(z^k) - \bar{z}\| + \gamma_k \|D_k(z^k)\| \ . \end{aligned} \tag{27}$$

Let $a_k := \frac{\alpha}{c_k} + \gamma_k$. Using (26) and (27),

$$\|\mathcal{N}_k(z^k) - \bar{z}\| \leq \left(\frac{\alpha}{c_k} + \gamma_k\right) \|D_k(z^k)\| = a_k \|D_k(z^k)\| \ . \tag{28}$$

Let $\gamma := \frac{1}{2(5+2\alpha)}$. By Proposition 16 and Lemma 14 we have, for $k \geq \tilde{k}$, that

$$\|\mathcal{N}_k(z^k) - \bar{z}\|^2 + \gamma^2 \|D_k(z^k)\|^2 \leq \|z^k - \bar{z}\|^2 \ . \tag{29}$$

By (28) and (29), when $k \geq \tilde{k}$,

$$\|\mathcal{N}_k(z^k) - \bar{z}\|^2 \leq {a_k}^2 \|D_k(z^k)\|^2 \leq \frac{{a_k}^2}{\gamma^2} \|z^k - \bar{z}\|^2 - \frac{{a_k}^2}{\gamma^2} \|\mathcal{N}_k(z^k) - \bar{z}\|^2 \ . \tag{30}$$

Let $\mu_k := \frac{a_k}{\sqrt{a_k^2 + \gamma^2}}$. From (30) we have

$$\|\mathcal{N}_k(z^k) - \bar{z}\| \leq \mu_k \|z^k - \bar{z}\| \ . \tag{31}$$

By (31), criterion ($\mathcal{L}$) (or ($\mathcal{L}'$)), and Proposition 3 c),

$$\begin{aligned} &\|z^{k+1} - \bar{z}\| \leq \|z^{k+1} - \mathcal{N}_k(z^k)\| + \|\mathcal{N}_k(z^k) - \bar{z}\| \\ &\leq \delta_k \|H_k\| \|w^k\| + \mu_k \|z^k - \bar{z}\| \leq \frac{\delta_k \|H_k\|}{1 - \delta_k} \|D_k(z^k)\| + \mu_k \|z^k - \bar{z}\| \\ &\leq \left(\frac{\delta_k \|H_k\|}{1 - \delta_k} + \mu_k\right) \|z^k - \bar{z}\| = \sigma_k \|z^k - \bar{z}\| \ , \end{aligned}$$

where $\sigma_k := \frac{\delta_k \|H_k\|}{1-\delta_k} + \mu_k$. Since there is a $\tilde{\delta} > 0$ such that $\mu_k < 1 - \tilde{\delta}$ for any k, and $\delta_k \|H_k\| \to 0$, we have $\sigma_k < 1$ for k sufficiently large. Moreover, we have $\limsup_{k\to\infty} \sigma_k = \limsup_{k\to\infty} \mu_k \leq 1 - \tilde{\delta}$. □

7.2. Superlinear convergence. We now give an analogue of Dennis and Moré's [14] characterization theorem for the superlinear convergence of variable metric methods in nonlinear programming that applies to the VMPPA. This result is used in [6] to establish the superlinear convergence of the VMPPA when the Broyden (nonsymmetric case) or the BFGS (symmetric case) updating formula is used to generate the matrices H_k.

THEOREM 20. *Let $\{z^k\}$ be any sequence generated by the VMPPA satisfying criterion $(\mathcal{L})$ for all k. Suppose that the operator T^{-1} is differentiable at the origin with $T^{-1}(0) = \{\bar{z}\}$ and $\nabla T^{-1}(0) = J$. If* $\lim_k \|D_k(z^k)\| = 0$, *then $\{z^k\}$ converges to the solution $\bar{z}$ superlinearly if and only if*

$$\frac{[I - (I + \frac{1}{c_k}J)H_k^{-1}](z^{k+1} - z^k)}{\|z^{k+1} - z^k\|} \to 0 \quad as\ k \to \infty\ . \tag{32}$$

Remark. By Proposition 9 we have $\nabla D(\bar{z}) = -(I + \frac{1}{c}J)^{-1}$. Consequently, condition (32) can be recast in the more familiar form given in [15, Theorem 8.2.4]. Note that the assumption in (32) on the sequence $\{H_k\}$ is much weaker than assuming that this sequence converges. Specific choices of the linear transformations H_k satisfying (32) are discussed in [6].

The proof of Theorem 20 requires the following lemma.

LEMMA 21. *Under the conditions in Theorem* 20 *we have*

(a) $T^{-1}(\frac{-1}{c_k}D_k(z^k)) - \bar{z} - J(\frac{-1}{c_k}D_k(z^k)) \subset o(\|z^k - \bar{z}\|)\mathbb{B}$, *and*

(b) $(I + \frac{1}{c_k}J)H_k^{-1}(z^{k+1} - \mathcal{N}_k(z^k)) \in o(\|z^k - \bar{z}\|)\mathbb{B}$,

for all k sufficiently large.

Proof. For part (a), let $\delta > 0$ be such that

$$T^{-1}(w) - Jw - \bar{z} \subset o(\|w\|)\mathbb{B} \tag{33}$$

whenever $\|w\| < \delta$. Let $\bar{k}_1$ be such that whenever $k > \bar{k}_1$, $\|D_k(z^k)\| \leq \delta$. Then, by (33) and Proposition 3 c), when $k > \bar{k}_1$,

$$T^{-1}\left(\frac{-1}{c_k}D_k(z^k)\right) - \bar{z} - J\left(\frac{-1}{c_k}D_k(z^k)\right) \subset o(\|D_k(z^k)\|)\mathbb{B} \subset o(\|z^k - \bar{z}\|)\mathbb{B}\ .$$

We now prove (b). Note that $\mathcal{N}_k(z^k) = (I + H_kD_k)(z^k)$; hence by criterion $(\mathcal{L})$

$$\begin{aligned}\left\|\left(I + \frac{1}{c_k}J\right)H_k^{-1}(z^{k+1} - \mathcal{N}_k(z^k))\right\| &= \left\|\left(I + \frac{1}{c_k}J(w^k - D_k(z^k)\right)\right\| \\ &\leq (1 + \|J\|)\|w^k - D_k(z^k)\| \leq \delta_k(1 + \|J\|)\|w^k\| \\ &\leq \frac{\delta_k(1 + \|J\|)}{1 - \delta_k}\|D_k(z^k)\|\ . \end{aligned} \tag{34}$$

Therefore by (34) and Proposition 3 c),

$$\left(I + \frac{1}{c_k}J\right)H_k^{-1}(z^{k+1} - \mathcal{N}_k(z^k)) \in o(\|D_k(z^k)\|)\mathbb{B} \subset o(\|z^k - \bar{z}\|)\mathbb{B}. \qquad \square$$

Proof of Theorem 20. Let $\tilde{z}^{k+1} := \mathcal{N}_k(z^k) = (I + H_kD_k)(z^k)$. By Proposition 3 a) we have $\tilde{z}^{k+1} = z^k - H_k(I + T^{-1}\frac{1}{c_k})^{-1}(z^k)$. Hence

$$\begin{aligned} z^k &\in \left(I + T^{-1}\frac{1}{c_k}\right)[H_k^{-1}(z^k - \tilde{z}^{k+1})] \\ &= H_k^{-1}(z^k - \tilde{z}^{k+1}) + T^{-1}\left[\frac{1}{c_k}H_k^{-1}(z^k - \tilde{z}^{k+1})\right]\ , \end{aligned}$$

or equivalently,

$$\begin{aligned}
z^{k+1} - \bar{z} &= z^k - \bar{z} + (z^{k+1} - z^k) \\
&\in \left[T^{-1}\left(\frac{1}{c_k} H_k^{-1}(z^k - \tilde{z}^{k+1})\right) - \bar{z} + (z^{k+1} - z^k) + H_k^{-1}(z^k - \tilde{z}^{k+1})\right] \\
&= \left[T^{-1}\left(\frac{1}{c_k} H_k^{-1}(z^k - \tilde{z}^{k+1})\right) - \bar{z} - J\left(\frac{1}{c_k} H_k^{-1}(z^k - \tilde{z}^{k+1})\right)\right] \\
&\quad + \left[I - \left(I + \frac{1}{c_k} J\right) H_k^{-1}\right](z^{k+1} - z^k) \\
&\quad + \left(I + \frac{1}{c_k} J\right) H_k^{-1}(z^{k+1} - \tilde{z}^{k+1}) \\
&= \left[T^{-1}\left(\frac{-1}{c_k} D_k(z^k)\right) - \bar{z} - J\left(\frac{-1}{c_k} D_k(z^k)\right)\right] \\
&\quad + \left[I - \left(I + \frac{1}{c_k} J\right) H_k^{-1}\right](z^{k+1} - z^k) \\
&\quad + \left(I + \frac{1}{c_k} J\right) H_k^{-1}(z^{k+1} - \tilde{z}^{k+1}) \ .
\end{aligned} \tag{35}$$

By Lemma 21 the first and third of the three terms appearing on the right-hand side of this inclusion can be bounded by an expression of the form $o(\|z^k - \bar{z}\|)\mathbb{B}$. If (32) holds, then $[I - (I + \frac{1}{c_k} J)H_k^{-1}](z^{k+1} - z^k) \in o(\|z^{k+1} - z^k\|)\mathbb{B}$. Therefore there are positive sequences $\{\alpha_{1k}\}$ and $\{\alpha_{2k}\}$, each converging to zero such that, for $k > \bar{k}_1$,

$$\begin{aligned}
\|z^{k+1} - \bar{z}\| &\le \alpha_{1k}\|z^{k+1} - z^k\| + \alpha_{2k}\|z^k - \bar{z}\| \\
&\le \alpha_{1k}(\|z^k - \bar{z}\| + \|z^{k+1} - \bar{z}\|) + \alpha_{2k}\|z^k - \bar{z}\| \\
&= \alpha_{1k}\|z^{k+1} - \bar{z}\| + (\alpha_{1k} + \alpha_{2k})\|z^k - \bar{z}\|.
\end{aligned}$$

Let $\bar{k}_2 > \bar{k}_1$ be such that $\alpha_{1k} < \frac{1}{2}$ for all $k > \bar{k}_2$. Then, denoting $\frac{\alpha_{1k} + \alpha_{2k}}{1 - \alpha_{1k}}$ by τ_k,

$$\|z^{k+1} - \bar{z}\| \le \frac{\alpha_{1k} + \alpha_{2k}}{1 - \alpha_{1k}}\|z^k - \bar{z}\| = \tau_k\|z^k - \bar{z}\|$$

whenever $k > \bar{k}_2$, and $\tau_k \to 0$ as $k \to \infty$. Therefore $\{z^k\}$ converges to $\bar{z}$ superlinearly.

Conversely, suppose that

$$\lim_{k \to \infty} \frac{\|z^{k+1} - \bar{z}\|}{\|z^k - \bar{z}\|} = 0 \ . \tag{36}$$

Divide (35) by $\|z^k - \bar{z}\|$ and let $k \to \infty$. From (36) and Lemma 21 we obtain

$$\frac{[I - (I + \frac{1}{c_k} J)H_k^{-1}](z^{k+1} - z^k)}{\|z^k - \bar{z}\|} \to 0 \quad \text{as } k \to \infty \ .$$

However, from (36) we have

$$\frac{\|z^k - \bar{z}\|}{\|z^{k+1} - z^k\|} \le \frac{\|z^k - \bar{z}\|}{\|z^k - \bar{z}\| - \|z^{k+1} - \bar{z}\|} = \frac{1}{1 - \frac{\|z^{k+1} - \bar{z}\|}{\|z^k - \bar{z}\|}} \to 1$$

as $k \to \infty$. Hence (32) holds. □

8. Concluding remarks. In this paper, we introduced a new PPA for solving the inclusion $0 \in T(x)$, where T is an arbitrary maximal monotone operator. The global convergence of the algorithm is demonstrated with an inexact solution at each step. This is important in practice, since solving for the exact solution at each step is impractical and may in fact be almost as difficult as solving the original problem. If it is assumed that T^{-1} is Lipschitz continuous at the origin, then the method is shown to be linearly convergent. If it is further assumed that T^{-1} is differentiable at the origin, then the classical characterization of superlinear convergence due to Dennis and Moré also holds for the VMPPA. In [6], this characterization of superlinear convergence is applied to establish the super-linear convergence of the method when certain matrix secant updating strategies are employed to generate the matrices H_k. In [5], we give some of the implementation details in the case of convex programming. We show how to apply the method to solve the associated primal, dual, and Lagrangian saddle point problems. In particular, it is shown how the bundle technique [17] can be applied to satisfy the approximation criteria ($\mathcal{L}$) and ($\mathcal{G}$) in both the primal and saddle point solution techniques. Preliminary numerical results comparing these three approaches are also presented.

Acknowledgments. The authors would like to thank the reviewers for their thorough work. Their comments and suggestions have greatly contributed to our exposition. In particular, we would like to thank Professor Alfredo Iusem for observing an error in an earlier version of Theorem 17 and for his suggested revision of this result when the set $T^{-1}(0)$ is assumed to be bounded.

OPTIMIZING THE RATE OF DECAY OF SOLUTIONS OF THE WAVE EQUATION USING GENETIC ALGORITHMS: A COUNTEREXAMPLE TO THE CONSTANT DAMPING CONJECTURE*

PEDRO FREITAS†

Abstract. We consider the problem of optimizing the rate of decay of solutions of the linear damped wave equation on a bounded interval. This corresponds to optimizing the spectral abscissa of the associated linear operator. By writing the damping term as a Fourier cosine series and obtaining some inequalities that the coefficients in this series have to satisfy in order that the spectral abscissa be larger than a real number α, we are then able to use a genetic algorithm to obtain values of the spectral abscissa which are better than those given by the constant damping case. This provides a counterexample to the conjecture that the best possible decay was obtained for constant damping.

Key words. damped wave equation, spectral abscissa, genetic algorithms

1. Introduction.

Let $\mathcal{H}$ be a Hilbert space and consider the system of differential equations

$$Au_{tt} + Bu_t + Cu = 0, \tag{1.1}$$

supplemented by initial conditions, and where A, B, and C are self-adjoint linear operators whose domain is dense in $\mathcal{H}$, with A and C uniformly positive. When B is the zero operator, and under suitable conditions on A and C, solutions of (1.1) oscillate in time. Otherwise, the system is said to be damped, and depending on the choice of B, solutions will converge to zero, become unbounded, or may still display an oscillatory behavior [4, 5].

When B is a positive operator, the system is dissipative and solutions will, in general, converge to zero. From the point of view of applications, the rate at which this happens is quite important, and one normally distinguishes between two cases, depending on the existence or not of real eigenvalues of the associated eigenvalue problem. When such eigenvalues are not present, solutions will oscillate to zero. If the operator B is large enough in some sense, then there will exist modes which are associated with real eigenvalues and whose corresponding solutions are of the form $e^{-\alpha t}v$, where α is some positive real number and v is an element of $\mathcal{H}$.

The effect caused by increasing the damping can be illustrated by considering the very simple case of the second-order ordinary differential equation

$$u'' + 2bu' + cu = 0, \tag{1.2}$$

where b is now a real parameter and c is a fixed positive number. In this case it is well known that while for both very small and very large values of b the decay of solutions

is quite slow, there exists a critical value for which this rate of decay is optimal. This value is given by $b_o = c^{1/2}$ and corresponds exactly to a double real eigenvalue at the point of transition between complex and real eigenvalues. For values of b larger than b_o, the system is said to be overdamped.

This very simple situation suggests the following problem for the general case of (1.1):

> Consider (1.1) and assume that both A and C are given, together with a set $\mathcal{B}$ of operators. Maximize over $\mathcal{B}$ the values of ω for which all solutions of (1.1) satisfy
>
> $$\|u\|_{\mathcal{H}} \leq ke^{(\delta-\omega)t}$$
>
> for all positive values of t and all positive δ, where k is a positive constant. Describe the subset of $\mathcal{B}$ corresponding to the optimum.

The reason for including the positive number δ in this description of the problem is that, as can be seen in the simple example above, the optimal may correspond to a multiple eigenvalue for which the corresponding solutions are of the form $(c_0 + c_1 t + \cdots + c_m t^m)e^{-\omega_o t}v$, for some v in $\mathcal{H}$. If this is the case, then the inequality above might not hold when δ is zero.

The previous simple one-dimensional example also highlights the fact that although (1.1) is linear in u, the problem just described is nonlinear. Even in the general case of a finite-dimensional space $\mathcal{H}$, where A and C are real positive $n \times n$ matrices, the problem is already much more complex than is the case for (1.2). This situation has been addressed in [7], where it was shown that the optimal value ω is given by

$$\omega_o = \left[\frac{\det(C)}{\det(A)}\right]^{1/(2n)}$$

and that this optimum is attained. A full description of the class of symmetric matrices which are optimum is, however, unknown, except in the case where n is two.

As we have seen from the previous examples, this type of problem is related to the maximization of the minimum of the negative of the real parts of the eigenvalues of the quadratic pencil defined on $\mathcal{H}$ by

$$T(\lambda) = \lambda^2 A + \lambda B + C.$$

This value is usually referred to as the spectral abscissa of the pencil $T(\lambda)$ and, in general, it can only be guaranteed that it is greater than or equal to ω_o (see [2] and the references therein). Thus, in this version of the optimization problem the objective is, given the operators A and C, to maximize the spectral abscissa and describe the subset of operators B which are optimal.

When $\mathcal{H}$ is an infinite-dimensional Hilbert space, one of such optimization problems is related to the wave equation of the form

$$u_{tt} + 2b(x)u_t = u_{xx} \tag{1.3}$$

on the interval $J = (0, \pi)$, together with initial conditions and homogeneous Dirichlet boundary conditions, and with $b \in L^\infty(0, \pi)$. This problem and the related question of studying the distribution of the eigenvalues of the corresponding quadratic pencil have received much attention in the literature recently [1, 2, 3, 6, 8]. In [3], for instance, it has been proven that within the class of all damping terms which satisfy

$0 \leq b \leq 1$, the constant damping term $b(x) \equiv 1$ is optimal. Later, it was shown in [2] for the case of a general open bounded connected set D of $\mathbb{R}^n$ that the constant damping term is a critical point of the function

$$\Omega(b) = \inf_{\lambda \in \Sigma_T} \left[-\mathrm{Re}(\lambda)\right],$$

where Σ_T denotes the spectrum of the pencil T. More precisely, letting b_o denote the square root of the first eigenvalue of $-\Delta$ on D, and given b_1 in $L^\infty(D)$, they showed that the function $\epsilon \to \mu(\epsilon) = \Omega(b_o + \epsilon b_1)$ is strictly decreasing in $[0, \delta]$ for some positive δ. However, due to a lack of a uniform lower bound for $\delta = \delta(b_1)$, this does not necessarily imply that it is a local optimum. The authors then conjectured that this was in fact the optimal value of the spectral abscissa and that the optimal damping was constant. More recently, some numerical evidence was presented in [1] to support this conjecture.

The main purpose of this paper is to give numerical evidence, supported by some rigorous results, that this conjecture is in fact false and that there exist functions b which give a better decay than the constant damping.

In order to do this, we shall perform a spectral approximation of (1.3) based on a Fourier sine series of the unknown and then study the corresponding optimization problem in finite dimension. It should be remarked that this last step is not equivalent to solving the finite-dimensional problem mentioned above, as now the entries of the matrix obtained in the discretization process are not independent. The reason for opting for a spectral method lies in the fact that we are interested in a *global* property of the spectrum and not just in a small number of eigenvalues.

A crucial step in the whole process is the use of a Fourier cosine series for the damping coefficient b. This makes the equation resemble the well-known (complex) Hill equation, except that here we are dealing with different boundary conditions. The fundamental role of the first of the coefficients in the series—the average—in the asymptotic distribution of the high frequencies is well known (see, for instance, [3, 8]). Here we show that the other coefficients also play an important part and that an adequate way of looking at this problem in one dimension is to consider the effect of each of these coefficients on the spectrum. In particular, one of the main results in the paper shows that in order to increase the value of the spectral abscissa more and more terms in the series have to be considered.

One aspect of the optimization process that also has to be taken into consideration at this point is that the optimal value in such problems quite often corresponds to eigenvalues of high multiplicity. In the finite-dimensional problem, for instance, the optimum is achieved precisely when the spectrum consists of a single eigenvalue of maximum multiplicity. This implies that the function Ω described above will not be differentiable at such points. Furthermore, it may even happen that there will exist only one Jordan block associated with this eigenvalue, as can again be the case in the finite-dimensional problem considered in [7].

All this means that the choice of algorithms used for the optimization might be critical. Taking into account that the structure of this type of problem is not very well understood, and that in the case of (1.3) it is not even known if a finite optimum exists, the choice to use a genetic algorithm in the numerical optimization procedure arises naturally. These algorithms tend not to give the actual optimum, but, on the other hand, they quickly improve the starting value. Since the main purpose here is to provide a counterexample, this seems to be the right choice. Also for the same reason, we shall not go into much detail about the algorithm, although the main steps will be indicated. For a comprehensive treatment of this type of algorithms see, for instance, the books by Holland [10], Goldberg [9], or Michalewicz [12].

The paper is divided into three parts. In the first part (sections 2, 3, and 4), we state the problem and establish some rigorous results which in some sense show the direction that should be pursued in the numerical study. In the second part (sections 5 and 6), we briefly describe the algorithm and present the numerical results obtained. Finally, in section 7 we discuss the results obtained.

2. Statement of the problem and main results. Consider the self-adjoint quadratic pencil in $L^2(0,\pi)$

$$T(\lambda) = \lambda^2 I + 2\lambda b(x) - \frac{\partial^2}{\partial x^2}$$

with domain $\mathcal{H} = H^2(0,\pi) \cap H_0^1(0,\pi)$, and denote by Σ_T its spectrum, that is, the set of complex values of λ for which T does not have a bounded inverse with dense domain. In this instance, the spectrum is formed only by eigenvalues:

$$\Sigma_T = \{\lambda \in \mathbb{C} : T(\lambda)u = 0,\ u \neq 0\}.$$

We now define the function $\Omega : L^\infty \to \mathbb{R}$ by

$$\Omega(b) = \inf_{\lambda \in \Sigma_T} \left[-\mathrm{Re}(\lambda)\right].$$

For each function b in L^∞, the function above gives the corresponding spectral abscissa. In the one-dimensional case, this coincides with the uniform rate of decay of the solutions of (1.3) (see, for instance, [3]), and so by maximizing Ω we are optimizing the asymptotic rate of decay of solutions. The optimization problem then reduces to finding

$$\omega_o = \sup_{b \in L^\infty} \left[\Omega(b)\right]. \tag{2.1}$$

Although there are some results when further restrictions are imposed on the set where b is allowed to vary (see [3, 1]), for the full general problem described here, it is not even known whether ω_o is finite or not.

The procedure used here highlights the fact that the coefficients in the Fourier cosine series of the damping term are fundamental in the values that the spectral abscissa might take, and the main results of the paper along these lines are given in Theorem 4.2 and Corollaries 4.3 and 4.4. In particular, Corollary 4.3 gives intervals where each of the terms up to a certain order in the Fourier cosine series have to lie for the spectral abscissa to be larger than a certain value. This also establishes a *hierarchy* within these coefficients, showing their relative importance; note that this is not the case for, say, the Fourier sine coefficients of b.

Taking these results into account, we then obtain numerical evidence that the constant damping is in fact not optimal, by producing several examples with different sets of nonzero Fourier coefficients for which the corresponding spectral abscissa improves the value obtained for $b(x) \equiv 1$. These numerical results can be complemented with the asymptotics for the spectrum from [3, 8] to provide reliable evidence of this fact.

3. The discretized problem. We discretize (1.3) by means of a Fourier sine series on the interval $(0,\pi)$, in order to obtain a finite-dimensional approximation to the optimization problem (2.1). Writing

$$u(x,t) = \sum_{k=1}^{\infty} u_k(t)\sin(kx)$$

with

$$u_k(t) = \frac{2}{\pi}\int_0^{\pi} u(x,t)\sin(kx)dx,$$

we are thus led to the following infinite system of ordinary differential equations for the Fourier coefficients of u:

$$u_k''(t) + 2\sum_{j=1}^{\infty} b_{jk}u_k'(t) + k^2 u_k(t) = 0,$$

where

$$b_{jk} = b_{kj} = \frac{2}{\pi}\int_0^{\pi} b(x)\sin(jx)\sin(kx)dx.$$

So that we can obtain a manageable expression for these coefficients, we now expand the function b into a Fourier cosine series, that is,

$$b(x) = \frac{b_0}{2} + \sum_{k=1}^{\infty} b_k\cos(kx),$$

with

$$b_k = \frac{2}{\pi}\int_0^{\pi} b(x)\cos(kx)dx,\ k = 0, 1, \ldots.$$

Then

$$\begin{aligned} b_{jk} &= \frac{b_0}{2}\delta_{jk} + \frac{2}{\pi}\sum_{m=1}^{\infty} b_m \int_0^{\pi}\cos(mx)\sin(jx)\sin(kx)dx \\ &= \frac{b_0}{2}\delta_{jk} + \frac{1}{\pi}\sum_{m=1}^{\infty} b_m\left[\int_0^{\pi}\cos(mx)\left[\cos((k-j)x) - \cos((k+j)x)\right]\right]dx \\ &= \frac{b_{|k-j|} - b_{k+j}}{2}, \end{aligned}$$

where δ_{jk} denotes the Kronecker symbol. This can be summarized in the following proposition.

Proposition 3.1. *Let b_k, $k = 0, 1, \ldots,$ denote the Fourier cosine coefficients of the function b on the interval $(0,\pi)$. Then the nth-dimensional truncation of the discretized wave equation can be written as*

$$U_n''(t) + B_n U_n'(t) + C_n U_n(t) = 0,$$

where

$$B_n = \begin{bmatrix} b_0 - b_2 & b_1 - b_3 & b_2 - b_4 & \cdots & b_{n-1} - b_{n+1} \\ b_1 - b_3 & b_0 - b_4 & b_1 - b_5 & \cdots & b_{n-2} - b_{n+2} \\ b_2 - b_4 & b_1 - b_5 & b_0 - b_6 & \cdots & b_{n-3} - b_{n+3} \\ & & \vdots & & \\ b_{n-1} - b_{n+1} & b_{n-2} - b_{n+2} & b_{n-3} - b_{n+3} & \cdots & b_0 - b_{2n} \end{bmatrix} \tag{3.1}$$

and $C_n = \operatorname{diag}\{1, 4, \ldots, n^2\}$.

This is a known result, but no specific reference to it could be found in the literature.

The finite-dimensional problem obtained can now be written in the same manner as before, in terms of the optimization of the spectral abscissa of a quadratic pencil of matrices. To this end, define

$$L_n(\lambda) = \lambda^2 I + \lambda B + C$$

with B and C as in the previous proposition (in what follows we shall drop the indexes on the matrices) and let Σ_L^n denote its spectrum. The matrix B now belongs to a linear subspace of the space of symmetric $n \times n$ matrices. We shall denote this space by $\mathcal{B}_n$ and consider the function $\Omega_n : \mathcal{B}_n \to \mathbb{R}$ by

$$\Omega_n(B) = \min_{\lambda \in \Sigma_L^n} [-\operatorname{Re}(\lambda)] .$$

For each matrix B in $\mathcal{B}_n$, this function gives the corresponding spectral abscissa—note that C is fixed—and minimizing the rate at which solutions decay to zero then becomes equivalent to determining

$$\omega_o^n = \sup_{B \in \mathcal{B}_n} [\Omega_n(B)] .$$

4. Conditions on the coefficients b_j. We now present some results that emphasize the importance of the coefficients in the Fourier cosine series for b. The idea is that just like the average of b controls the real part of the high frequencies, the remaining coefficients in the Fourier cosine series play an important role in how large the spectral abscissa can be.

LEMMA 4.1. *If* $\Omega(b) > \alpha_0$ *for some* α_0, *then* $\langle T(-\alpha)u, u\rangle > 0$ *for all* $u \in D(T)$ *and all* $\alpha \leq \alpha_0$.

Proof. If $T(-\alpha)$ were not a positive operator, its smallest eigenvalue would clearly be nonpositive. This implies that the first eigencurve of $T(\lambda)$, that is, the curve described by the first eigenvalue of $T(\lambda)$ as λ varies over $\mathbb{R}$, would take a nonpositive value for λ equal to $-\alpha$. As this eigencurve is continuous and will be above the horizontal axis for large enough (real) λ, there would have to exist a number λ_0 larger than or equal to $-\alpha$ such that $T(\lambda_0)$ would have a zero eigenvalue. In other words, Σ_T would contain a point λ_0 satisfying $\lambda_0 \geq -\alpha \geq -\alpha_0$ and then $\Omega(b) \leq \alpha_0$. □

Using this result, we can now prove a relation between the first coefficients in the series for b and the maximum possible value for the spectral abscissa.

THEOREM 4.2. *If* $\Omega(b)$ *is larger than an integer* k, *then* $|b_0 - b_{2j}| < 2j$ *for* $j = 1, \ldots, k$.

Proof. If $\Omega(b) > k$, then the previous lemma gives that $\langle T(-\alpha)u, u\rangle > 0$ for all α smaller than or equal to k and all u in $\mathcal{H}$. In particular, for $u = \sin(jx)$ this yields that

$$\alpha^2 - (b_0 - b_{2j})\alpha + j^2 > 0,\ \alpha \leq k.$$

If $|b_0 - b_{2j}| \geq 2j$ for some j, then the polynomial above has a real root at

$$\alpha^- = \frac{b_0 - b_{2j} - \sqrt{(b_0 - b_{2j})^2 - 4j^2}}{2}.$$

If $b_0 - b_{2j} > 2j$, then the maximum possible value for α^- is j, and is attained when $b_0 - b_{2j} = 2j$. By the previous lemma this polynomial has to be positive for $\alpha \leq k$, and thus it follows that $b_0 - b_{2j}$ must be smaller than $2j$ for $j = 1, \ldots, k$. If $b_0 - b_{2j} < -2j$, then α^- will be negative and a similar argument applies. □

This result also highlights the importance of the coefficients corresponding to the even (around $\pi/2$) functions in the series. However, by itself it is not enough to show that the coefficients must be increased in order to increase the value of the spectral abscissa. In order to show that, we need the fact that the real part of the high frequencies clusters around minus the average of the function b, which, in this case, corresponds to $b_0/2$.

COROLLARY 4.3. *If b is in $BV(0, \pi)$ and $\Omega(b)$ is larger than a real number α, then b_0 is larger than 2α and the coefficients b_{2j} satisfy*

$$b_0 - 2j < b_{2j} < b_0 + 2j$$

for $j = 1, \ldots, k$, where k is the largest integer not exceeding α.

Proof. From [3, 8] we know that the real parts of the eigenvalues converge to $-b_0/2$ as the imaginary part of the eigenvalues grows to infinity. Thus if $\Omega(b)$ is larger than α, we must have b_0 larger than 2α. Since, by the previous theorem, $|b_0 - b_{2j}|$ is smaller than $2j$ for $j = 1, \ldots, k$, it follows that b_{2j} must satisfy the inequalities. □

We shall now consider the simple but important implications of this result. The eigenvalues of the operator $C = -\partial^2/\partial x^2$ on the interval $(0, \pi)$ and with homogeneous Dirichlet boundary conditions are $\gamma_j = j^2$, $j = 1, 2, \ldots$. When $b = \gamma_1^{1/2} = 1$, all eigenvalues have the same real parts which are equal to -1. If a damping term b exists for which $\Omega(b)$ is larger than $\gamma_1^{1/2}$, then b_0 must be larger than $2\gamma_1^{1/2}$ and it follows that b_2 must satisfy

$$0 < b_0 - 2 < b_2 < b_0 + 2.$$

In other words, if a damping term has a coefficient in $\cos(2x)$ which is smaller than or equal to zero, then the corresponding spectral abscissa has to be smaller than or equal to $\gamma_1^{1/2}$. This can be stated as follows.

COROLLARY 4.4. *If b is such that*

$$b_2 = \frac{2}{\pi} \int_0^\pi b(x) \cos(2x) dx \le 0,$$

then $\Omega(b)$ is smaller than or equal to 1.

In particular, if a function has a zero component in $\cos(2x)$, then Ω can be at most 1. Clearly similar results can be stated for the other Fourier coefficients. However, it should be kept in mind that the interest of this type of result for j larger than one will depend on whether Ω is unbounded or not.

5. Brief description of the algorithm. Genetic algorithms are a relatively new tool in optimization problems, with their first systematic presentation probably dating only as far back as 1975 with Holland's book [10]. Because of this, and also because of their nature, there are several possible choices to be made when using an algorithm of this type. Apart from the standard options, such as whether to use floating-point or binary representations, fixed of varying population sizes, etc., there are many others which normally depend on the problem in question. In this section we describe some of the choices which were made in this case, and also some of the main points related to the tuning of the algorithm.

The algorithm acts on a population with a fixed number p of vectors with m components, $\beta_j = (\beta_{j1}, \ldots, \beta_{jm})$, $j = 1, \ldots, p$, representing the Fourier cosine coefficients of the function b up to order m. In this respect, we have opted for a floating-point version of the algorithm instead of using a binary representation. These vectors are generated randomly at the beginning of each run, being weighted in order to impose a decay as k increases. In the cases presented in section 6, some of the components of each randomly generated vector were forced to be zero, while the nonzero components β_{jk} were uniformly distributed on intervals of the form $[-rs/(k+1), r(1-s)/(k+1)]$, where typically r and s where chosen to be, respectively, 10 and .3. This corresponds to considering functions whose Fourier coefficients roughly decay with $1/k$.

At each iteration the population is evaluated and a number n_r of vectors—those whose corresponding value of Ω_n is the smallest—are replaced by linear combinations of pairs of the members of the population—called arithmetical crossover. Once a vector has been in existence for a certain number of iterations, it will also be replaced, either by another linear combination or by a new randomly generated vector.

The main steps in each iteration can thus be described roughly as follows:

1. evaluation of the fitness of each vector over the total population,

2. generation of new vectors by means of arithmetical crossover to replace those with poorest performance in step 1,

3. replacement of the *older* vectors either by arithmetical crossover or by the introduction of new randomly generated vectors.

In the actual simulations, the size of the population p was taken to be 20 and that of n_r to be nine. The relation between these parameters turned out to be critical for the performance of the algorithm, in the sense that both smaller and larger values of n_r made the number of iterations necessary to attain a certain value much larger.

6. Numerical results. In this section we present a series of results obtained by running the algorithm for different choices of the set of nonzero Fourier cosine coefficients. The results obtained for eight trials are shown in Table 1. The best values for Ω obtained during each trial are given, together with the nonzero coefficients of the corresponding damping term. In general, the larger the number of nonzero coefficients used, the larger the corresponding value of Ω obtained. To keep numerical accuracy, the order of the coefficient corresponding to the highest frequency used was always kept much smaller than the order of the truncation. Typically, the value of n used varied between 15 and 30 during the runs, while the value of the best spectral abscissa obtained was then checked for n equal to 100. One of the features of the spectral method employed is that, with the exception of a few (one to four pairs in the cases tried) spurious eigenvalues in the highest frequencies, which, in any case, never deviated much from their real value, all the other eigenvalues are practically coincident for different values of n. This, together with the asymptotic behavior of the eigenvalues, ensured that the value obtained for the spectral abscissa remained constant when n was increased which makes it possible to compare different damping terms for relatively low values of n.

The first example shows that a damping term of the form $b_0/2 + b_2\cos(2x)$ is already sufficient to obtain a spectral abscissa greater than the best value obtained for the case of constant damping ($\Omega(1) = 1$). This case corresponds to a Mathieu equation with homogeneous Dirichlet boundary conditions and with complex coefficients which are not independent:

$$\begin{aligned}&u_{xx} + [w - z\cos(2x)]\,u = 0,\\ &w = -\lambda(b_0 + \lambda),\\ &z = 2b_2\lambda.\end{aligned}$$

Ω	1.2869	1.3146	1.3984	1.5055	1.5353	1.5358	1.5675	1.5712

In the second example, we introduced an odd term, $b_1 \cos(x)$, which allowed for an improvement. However, in general, the introduction of the odd terms, although improving the value of Ω, did not do so in a significant manner when compared to the introduction of higher-order even terms. The other examples in Table 1 are those obtained by considering even higher-order coefficients in the series.

In Figures 6.1 and 6.2, we have plotted the different spectra corresponding to these damping terms. We considered n to be 100 in order to evaluate the spectral abscissa in each case, but plotted only 120 eigenvalues. Of the remaining 80, with the exception of about 8 (spurious) eigenvalues, they are all situated near the asymptotic line for the real part. In any case, the spurious eigenvalues are also quite close and do not affect the value of Ω.

The effect of introducing more terms in the series is quite visible in that this will increase the number of low-frequency eigenvalues which get further and further away from the vertical line $\mathrm{Re}(\lambda) = -b_0/2$.

In Figure 6.3 we show the plots of some of the graphs corresponding to these damping terms.

7. Discussion. By writing the damping term in the wave equation as a Fourier cosine series, we have been able to relate these coefficients to the value of the corresponding spectral abscissa. Based on this, and by successively adding more terms to the series, it has been possible to construct damping terms which give a better value of the spectral abscissa than the constant damping. Due to the fact that the real parts of the high frequencies are asymptotically close to $-b_0/2$, and that the numerical results give only a very small number of eigenvalues which are away from this vertical line and which converge very fast, we believe these results to be quite reliable.

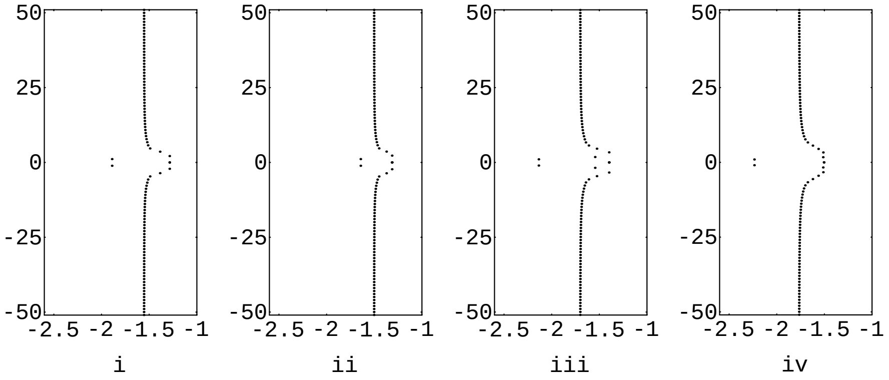

FIG. 6.1. *Spectra for cases* i–iv.

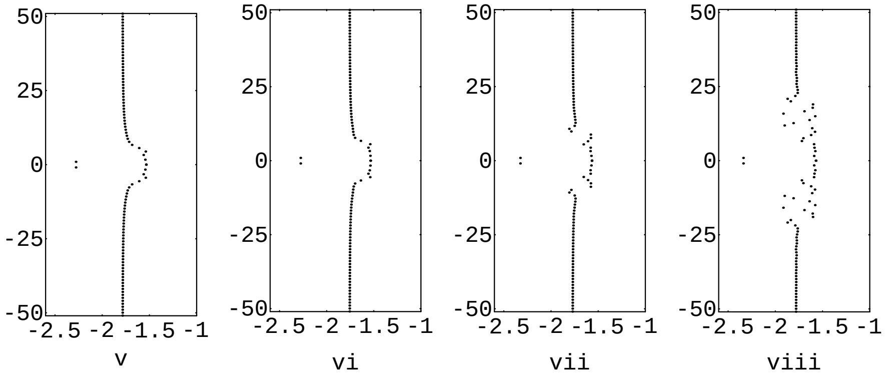

FIG. 6.2. *Spectra for cases* v–viii.

To prove in a rigorous way that this is in fact the case, one would have to proceed in two steps. First consider a ball B containing a number $2p$ of eigenvalues in such a way that the estimates for the eigenvalues outside B imply that their real parts are sufficiently close to $-b_0/2$. Then show that the eigenvalues given by the spectral approximation method considered converge to the eigenvalues of the original problem and obtain estimates for this convergence. After determining an order of the approximation which is sufficient to ensure that the approximate eigenvalues are close enough to the eigenvalues inside B, the desired result could be obtained. The second step indicated is fairly standard and methods for this type of problem can be found, for instance, in [11] (see also [13]). In particular, it is possible to obtain that $\Omega_n(B)$ converges to $\Omega(b)$. However, the estimates given in [8] for a general damping term and which are needed in order to determine the order p above which the eigenvalues outside B are close enough to the vertical line $\mathrm{Re}(\lambda) = -b_0/2$ are, from this point of view, quite poor. This makes the dimensions of the matrices that would have to be considered too high, and so either better estimates can be obtained for these particular cases or another line of approach has to be considered.

From a certain point onward it can be seen that the introduction of more terms in the Fourier series produces only a negligible increase in the best value of Ω obtained. There are several distinct reasons why this might be so. In the first place, it could

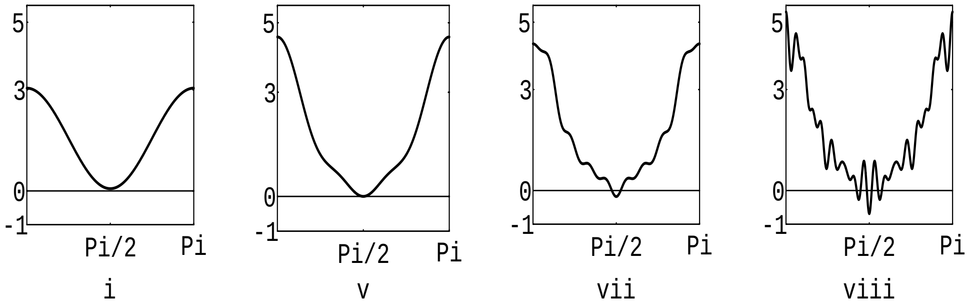

FIG. 6.3. *Graphs of* b *for cases* i, v, vii, *and* viii.

happen that the function Ω is in fact bounded from above, and that the values obtained are actually quite close to the optimum. Second, it might be possible that this algorithm ceases to be adequate at some stage due to a lack of capacity to negotiate its way past critical points other than the optimum; note that in all the runs the vector found always gave rise to a pair of eigenvalues which were very close to a double real eigenvalue with geometric multiplicity one. Finally, and related to this, it may also happen that the algorithm will have problems in getting the coefficients to lie in the desired intervals given by the results in section 4.

Regarding the shape of the damping terms given in section 6, there are several points worth noticing. To begin with, in all examples the way used to improve the spectral abscissa is by increasing the damping near the boundary and decreasing it in the middle of the interval. This becomes more noticeable as the number of nonzero terms grows. It also has the effect of making the minimum smaller and smaller, until it actually becomes negative. In the case of examples vii and viii, where, respectively, even terms up to b_{18} and b_{38} were included, and which gave a better value than those of the trials with less nonzero terms ($\Omega(b) = 1.5675$ and $\Omega(b) = 1.5712$), the corresponding damping terms obtained take negative values (see Figure 6.3). A similar phenomenon is already present in the finite-dimensional case treated in [7], where for some given matrices C the solution to the optimization problem is obtained for damping matrices which are indefinite (and in some cases only for these). From the results in [6], we know that if b is a damping term which changes sign, then the trivial solution of the equation

$$u_{tt} + 2pb(x)u_t = \Delta u,$$

where p is a real parameter, will become unstable if p is made large enough. This means that for this specific damping term, increasing the parameter p will first have the effect of moving all of the spectrum to the left side past the vertical line $\mathrm{Re}(\lambda) = -1.5$ for p close to one and then bringing some of the eigenvalues to the right-hand side of the complex plane for p large enough.

As is mentioned in the introduction, the main idea behind the numerical results presented here is to give a counterexample to the constant damping conjecture. In this sense, these should only be seen as a beginning to a more thorough study of the problem, both from the analytical and numerical points of view, but now from the perspective that the optimum is in fact not attained at the constant damping. In some sense, this is a characteristic use of genetic algorithms. As has been pointed out in [10], for instance, such algorithms can be quite useful in performing an initial search, selecting a subset of the whole possible space which is likely to contain the optimum. After that, the optimization process should be handed over to a procedure that takes advantage of the specific structure of the problem.

A BEHAVIORAL APPROACH TO CONTROL OF DISTRIBUTED SYSTEMS*

HARISH K. PILLAI† AND SHIVA SHANKAR†

Abstract. This paper develops a theory of control for distributed systems (i.e., those defined by systems of constant coefficient partial differential operators) via the behavioral approach of Willems. The study here is algebraic in the sense that it relates behaviors of distributed systems to submodules of free modules over the polynomial ring in several indeterminates. As in the lumped case, behaviors of distributed ARMA systems can be reduced to AR behaviors. This paper first studies the notion of AR controllable distributed systems following the corresponding definition for lumped systems due to Willems. It shows that, as in the lumped case, the class of controllable AR systems is precisely the class of MA systems. It then shows that controllable 2-D distributed systems are necessarily given by free submodules, whereas this is not the case for n-D distributed systems, $n \geq 3$. This therefore points out an important difference between these two cases. This paper then defines two notions of autonomous distributed systems which mimic different properties of lumped autonomous systems.

Control is the process of restricting a behavior to a specific desirable autonomous subbehavior. A notion of stability generalizing bounded input–bounded output stability of lumped systems is proposed and the pole placement problem is defined for distributed systems. This paper then solves this problem for a class of distributed behaviors.

Key words. distributed systems, systems of partial differential equations, controllability, stability, pole placement

1. Introduction.

In this paper we develop a theory of control of distributed systems patterned after the behavioral approach for lumped systems in Willems [10, 11]. Thus we study the control of behaviors of systems of linear, constant coefficient partial differential operators. In this paper, we demonstrate that, while behaviors of distributed systems are similar to the behaviors of lumped systems in some respects, there are nonetheless many points of departure between the two cases, especially in the techniques employed to arrive at the results. This is essentially due to the fact that lumped systems are defined over a principal ideal domain (PID), whereas distributed systems are not.

In [10], Willems initiates his approach to the study of systems by first considering ARMA systems. (We adopt the terminology there to define various systems like ARMA, AR, and MA systems, which are again formally defined in section 2 below.) He establishes an "elimination theorem" for ARMA systems; i.e., he proves that every ARMA system is equivalent to an AR system. This follows from the fact that every submodule of a free module over the principal ideal domain $\mathbb{R}[\frac{d}{dx}]$ is free. On the other hand, the elimination theorem for distributed systems requires the celebrated Ehrenpreis–Palamodov theorem (see Oberst [5, Corollary 38] for a constructive proof).

Our study of distributed systems is algebraic in the sense that we set up a correspondence between smooth behaviors and submodules of free modules over polynomial rings (in several indeterminates). That this correspondence is one to one is the content of a hard theorem of Oberst [5] and is in fact a central result of his seminal paper.

†Department of Electrical Engineering, Indian Institute of Technology, Powai, Bombay 400076, India (sshankar@ee.iitb.ernet.in).

The main body of this paper starts with a study of controllable systems. Our definition of controllability is patterned after Willems's definition for 1-D systems in [10, 9, 11] and that for discrete 2-D systems in [6]. (Following the spirit of Willems's work, our notion of controllability does not rely on any input-output structure.) We show that every MA system is controllable. We obtain a necessary and sufficient condition for an AR system to admit an MA representation. This condition allows us to conclude that every controllable AR system is MA. *Thus the class of distributed controllable AR systems is precisely the class of MA systems.* We also show that a submodule corresponding to such a system is maximal amongst the class of submodules with the same compactly supported behavior.

While every lumped behavior is of course given by a free submodule (as observed above), Rocha and Willems [6] show that every *controllable* 2-D discrete system is also given by a free submodule, which here corresponds to a system given by a left prime matrix. This is an important result, for free submodules over polynomial rings occupy a central position and geometrically correspond, by Serre, Quillen, and Suslin, to the class of vector bundles over affine space. In what we consider an important counterexample, we show that controllable AR distributed n-D systems for $n \geq 3$ are *not necessarily given by free submodules.* The same example also shows that systems described by left prime matrices need not be controllable. That such an example exists, we explain, is due to the fact that the global dimension of the ring $\mathbb{R}[\partial_1, \partial_2, \partial_3]$ over which 3-D systems are defined is 3. We show that such examples cannot occur if the global dimension of the ring over which the system is defined is less than or equal to 2. This therefore extends the result of Rocha and Willems on 2-D discrete systems alluded to earlier to 2-D distributed systems as well. These results follow from a necessary and sufficient condition which describes when a controllable system is given by a free submodule.

Given a behavior $\mathbf{B}$, corresponding to a submodule, say $\mathbf{R}$ of $(\mathbb{R}[\partial_1, \ldots, \partial_n])^k$, we wish to study subbehaviors of $\mathbf{B}$. These subbehaviors come from submodules of $(\mathbb{R}[\partial_1, \partial_2, \ldots, \partial_n])^k$ containing $\mathbf{R}$. By extending some set of generators of $\mathbf{R}$ to a set of generators of a submodule of $(\mathbb{R}[\partial_1, \partial_2, \ldots, \partial_n])^k$ containing $\mathbf{R}$, it is possible to restrict $\mathbf{B}$ to any subbehavior contained in it. Of all the subbehaviors contained in $\mathbf{B}$, we are interested primarily in a special class of behaviors which are analogous to autonomous behaviors of lumped systems. Restriction to such behaviors is the process of control. The above description explains the process of control for AR systems. We also translate this procedure to the case of MA systems.

Recollect from Willems [10, 9, 11] that an autonomous lumped behavior is one given by a submodule of $(\mathbb{R}[\frac{d}{dx}])^k$ of rank k. Such a behavior is a finite-dimensional $\mathbb{R}$-vector space. In the case of distributed systems, as shown in this paper, these two properties of a behavior need not coincide. This is essentially due to the fact that a subvariety of $\mathbb{C}$ (if not all of $\mathbb{C}$) is a finite set of points, whereas this is certainly not the case in $\mathbb{C}^n$, $n \geq 2$. As a result we introduce two kinds of autonomous behaviors to capture the above properties of a lumped autonomous behavior. By the first notion, the behavior of a single partial differential operator is autonomous, whereas the second notion of autonomy (namely, what we call a strongly autonomous system) implies a finite-dimensional behavior. Thus a strongly autonomous behavior resembles the behavior of a lumped autonomous system.

We generalize the notion of bounded input–bounded output stability of lumped behaviors by replacing the positive time axis by a (proper) cone S in $\mathbb{R}^n$ whose apex is the origin. A behavior is considered stable if the elements in it tend to zero along all directions in S. We show that a stable behavior must necessarily be autonomous. A stabilizing controller is one which restricts the behavior to a (nonzero) subbehavior stable with respect to S. We show that a controllable behavior can be stabilized with respect to any cone S. We also define the more general pole placement problem for AR systems. We solve this problem for a subclass of AR systems.

Our paper also contains what we feel are illuminating examples which point to the complexities of the behaviors of distributed systems. Moreover, since our approach to the study of distributed systems is algebraic, it makes available computational techniques from commutative algebra (Gröbner basis, etc.), although we do not directly address such issues here.

2. Preliminaries. In the notation of [10, 11], we consider systems of the form $(\mathbb{R}^n, \mathbb{R}^k, \mathbf{B})$, where $\mathbf{B}$ is a subspace of $(\mathcal{D}')^k$, the space of $\mathbb{R}^k$-valued distributions on $\mathbb{R}^n$. (In its stead we sometimes consider subspaces of $(\mathcal{C}^\infty)^k$, $\mathcal{D}^k$, etc.) These subspaces $\mathbf{B}$ are the behaviors of distributed ARMA systems which we now define.

Let

$$R : (\mathcal{D}')^k \rightarrow (\mathcal{D}')^l \tag{1}$$

and

$$M : (\mathcal{D}')^m \rightarrow (\mathcal{D}')^l \tag{2}$$

be *continuous local* $\mathcal{E}'$-module morphisms, where $\mathcal{E}'$ is the space of compactly supported distributions on $\mathbb{R}^n$. Note that $(\mathcal{D}')^p$ is an $\mathcal{E}'$-module for all p, where the action of $\mathcal{E}'$ on $(\mathcal{D}')^p$ is given by componentwise convolution, i.e.,

$$f * (v_1, \ldots, v_p) = (f * v_1, \ldots, f * v_p)$$

for f in $\mathcal{E}'$ and $(v_1, \ldots, v_p)$ in $(\mathcal{D}')^p$. We therefore require that $R(f * (u_1, \ldots, u_k)) = f * R(u_1, \ldots, u_k)$, and similarly for M. (In this paper we follow the notation in Hörmander [2], except that we use $\mathcal{D}$ to denote the space of compactly supported (complex valued) smooth functions instead of $\mathcal{C}_0^\infty$.)

It follows then that the kernel of R as well as the image of M are $\mathcal{E}'$-submodules of $(\mathcal{D}')^k$ and $(\mathcal{D}')^l$, respectively. Hence both the kernel of R as well as the image of M are subspaces that are shift invariant, i.e., closed under translations (take f above to be δ_x, the Dirac measure supported at x in $\mathbb{R}^n$). By local we mean that the support of $R(v)$ is contained in the support of v (and similarly for M), where for $v = (v_1, \ldots, v_p)$ in $(\mathcal{D}')^p$, the support of v is the union of the supports of v_i, $i = 1, \ldots, p$.

The behavior $\mathbf{B}$ of the ARMA system (R, M) defined by the maps (1) and (2) is the subspace of $(\mathcal{D}')^k$ consisting of those distributions that are mapped by R into the image of M, that is,

$$\mathbf{B} = \{u \in (\mathcal{D}')^k \mid Ru \in Im(M)\}.$$

As R is local, we have the restriction map

$$R_1 : (\mathcal{E}')^k \rightarrow (\mathcal{E}')^l$$

which is also continuous. We write a matrix for R_1, say (r_{ij}), with respect to the standard bases $e_1, \ldots, e_k$ and $f_1, \ldots, f_l$ on $(\mathcal{E}')^k$ and $(\mathcal{E}')^l$, respectively, where $e_i = (0, \ldots, \delta, 0, \ldots, 0)$ (δ in the ith slot) and similarly for the f_j's. As R_1 is local, the $R_1 e_i$'s are all supported at the origin, and hence each r_{ij} is also supported at the origin. Thus each r_{ij} is an $\mathbb{R}$-linear combination of δ and its derivatives (see Hörmander [2, Theorem 2.3.4]). We can therefore consider each r_{ij} as the corresponding constant coefficient partial differential operator. Then the action of R_1 on $(\mathcal{E}')^k$ is given by

$$R_1(u_1, \ldots, u_k) \;=\; \left(\sum_{i=1}^{k} r_{1i}(u_i), \ldots, \sum_{i=1}^{k} r_{li}(u_i) \right).$$

By density of $(\mathcal{E}')^k$ in $(\mathcal{D}')^k$, R is the unique extension of R_1 and thus admits the same matrix representation (r_{ij}). This same matrix also represents the restriction of R to the submodules $(\mathcal{C}^\infty)^k$, $\mathcal{D}^k$, etc. These considerations also hold for the map M yielding a matrix representation (m_{ij}) for it. We therefore, in this paper, study behaviors of distributed ARMA systems, that is, behaviors defined by *systems of constant coefficient partial differential operators.*

It is also of interest to consider, as in [10, 11], special cases of ARMA systems, namely MA and AR systems. MA systems are those systems for which $k = l$ and R is the identity morphism in (1). Thus an MA behavior is the image of an $\mathcal{E}'$-module morphism M. On the other hand, those behaviors that are kernels of $\mathcal{E}'$-module morphisms are called AR behaviors and correspond to the case when M in (2) is the zero map. In [10], Willems proves an elimination theorem for lumped systems that states that the $\mathcal{C}^\infty$ behavior of an ARMA system is equivalent to the $\mathcal{C}^\infty$ behavior of some AR system. An elimination theorem for distributed systems follows from the Ehrenpreis–Palamodov theorem, which we also use elsewhere in this paper. We now state this theorem in the notation that we employ.

Let (R, M) be an ARMA system and let (r_{ij}) and (m_{ij}) be the matrix representations for R and M, respectively, described above. Let $\mathcal{A}$ denote the commutative ring $\mathbb{R}[\partial_1, \ldots, \partial_n]$, that is, the polynomial ring in the variables $\partial_1, \ldots, \partial_n$, where ∂_i is the partial derivative in the ith direction x_i. Thus the entries of the above matrices are from the ring $\mathcal{A}$. Consider the set $\mathbf{Q}$ of all relations of the rows of (m_{ij}), that is, the set of all l-tuples $(q_1, \ldots, q_l)$ in $\mathcal{A}^l$ such that

$$\sum_{i=1}^{l} q_i m_{ij} \;=\; 0, \qquad j = 1, \ldots, m. \tag{3}$$

This set $\mathbf{Q}$ is clearly a submodule of $\mathcal{A}^l$. We now quote the theorem of Ehrenpreis–Palamodov from Hörmander [3, Theorem 7.6.13].

THEOREM (Ehrenpreis–Palamodov). *Let f be in $(\mathcal{C}^\infty)^l$. Then there exists a u in $(\mathcal{C}^\infty)^m$ such that $M(u) = f$ iff $q(f) = 0$ for all q in $\mathbf{Q}$, the module of relations of the rows of M, i.e., the rows of (m_{ij}).*

Remark. The Ehrenpreis–Palamodov theorem is valid in many other distribution spaces; see chapter 15 of Hörmander [2]. That it is also valid for $\mathcal{D}'$ is a consequence of a result of Oberst [5] which states that $\mathcal{D}'$ is an injective cogenerator.

COROLLARY 1 (the elimination theorem). *The $\mathcal{C}^\infty$ (or $\mathcal{D}'$) behavior of an ARMA system is the same as the $\mathcal{C}^\infty$ (or $\mathcal{D}'$) behavior of some AR system.*

This elimination theorem appears in Oberst [5], where there is in fact a constructive proof for it. Thus it suffices to study behaviors of AR systems.

Consider now the AR system defined by the map R in (1) represented by the matrix (r_{ij}). Consider each row of R as an element of the free $\mathcal{A}$-module $\mathcal{A}^k$. In what follows we consider each element $p = (p_1, \ldots, p_k)$ in $\mathcal{A}^k$ as an $\mathcal{E}'$-module morphism

$$p \;:\; (\mathcal{D}')^k \to \mathcal{D}',$$

$$(u_1, \dots, u_k) \to \sum_i p_i(u_i).$$

We also consider restrictions of the above morphism

$$p \ : \ (W)^k \to W,$$

where W is any $\mathcal{E}'$-submodule of $\mathcal{D}'$, for instance $\mathcal{C}^\infty$, $\mathcal{D}$, or $\mathcal{E}'$ itself. Correspondingly, we obtain the restrictions of R to the submodules $(W)^k$. Let $u = (u_1, \dots, u_k)$ be in the behavior $\mathbf{B}$ which is the kernel of R or, more generally, the kernel of its restriction to $(W)^k$. It then follows that this u is in the kernel of every p in the submodule $\mathbf{R}$ of $\mathcal{A}^k$ generated by the rows of R. Thus associated with a behavior in $(W)^k$ is a submodule of $\mathcal{A}^k$. Conversely, given a submodule $\mathbf{R}$ of $\mathcal{A}^k$, we obtain a behavior consisting of those u in $(W)^k$ that lie in the kernel of every p in $\mathbf{R}$. As $\mathcal{A}^k$ is Noetherian, $\mathbf{R}$ is finitely generated, say by $p_1, \dots, p_l$. The behavior corresponding to $\mathbf{R}$ can then be thought of as the kernel of a map $R : (W)^k \to (W)^l$ given by a matrix whose rows are $p_1, \dots, p_l$. Thus given an $\mathcal{E}'$-submodule W of $\mathcal{D}'$, this establishes a correspondence between behaviors in W^k and submodules of $\mathcal{A}^k$.

The principal idea in this paper is to exploit this correspondence to deduce properties of behaviors in terms of submodules of $\mathcal{A}^k$. This makes our study of behaviors of distributed systems tractable; note that $\mathcal{A}^k$ is a Noetherian $\mathcal{A}$-module whereas $(W)^k$ is not finitely generated as an $\mathcal{E}'$-module when W is $\mathcal{D}$, $\mathcal{D}'$, or $\mathcal{C}^\infty$.

We now elaborate on this correspondence between behaviors and submodules of $\mathcal{A}^k$. Thus given a behavior $\mathbf{B} \subset (W)^k$, denote by $\mathcal{M}(\mathbf{B})$ the submodule of $\mathcal{A}^k$ consisting of all the elements p which map to zero every element in $\mathbf{B}$, i.e., those p for which $p(u) = 0$ for all u in $\mathbf{B}$. Similarly, given a submodule $\mathbf{R}$ of $\mathcal{A}^k$, denote by $\mathcal{B}_W(\mathbf{R})$ the behavior in W corresponding to $\mathbf{R}$, i.e., those u in $(W)^k$ with $p(u) = 0$ for all p in $\mathbf{R}$. Clearly $\mathcal{B}_W(\mathbf{R})$ is an $\mathcal{E}'$-submodule of $(W)^k$ (note that $p(f * u) = f * p(u)$). Observe that a behavior $\mathbf{B}$ in W is the kernel of an $\mathcal{E}'$-module morphism R restricted to $(W)^k$ (equation (1)), and so in this notation, $\mathbf{B}$ is actually $\mathcal{B}_W(\mathbf{R})$, where $\mathbf{R}$ is the submodule generated by the rows of R.

LEMMA 1. *$\mathcal{B}_W \circ \mathcal{M}$ is the identity map on AR behaviors for any $\mathcal{E}'$-submodule W, i.e., $\mathcal{B}_W \circ \mathcal{M}(\mathbf{B}) = \mathbf{B}$.*

Proof. Clearly $\mathbf{B} \subset \mathcal{B}_W(\mathcal{M}(\mathbf{B}))$. As mentioned above, since $\mathbf{B}$ is an AR behavior, it is equal to $\mathcal{B}_W(\mathbf{R})$ for some submodule $\mathbf{R}$ of $\mathcal{A}^k$. Clearly, $\mathbf{R}$ is then contained in $\mathcal{M}(\mathbf{B}) = \mathcal{M}(\mathcal{B}_W(\mathbf{R}))$. Thus $\mathcal{B}_W(\mathcal{M}(\mathbf{B})) \subset \mathcal{B}_W(\mathbf{R}) = \mathbf{B}$. □

COROLLARY 2. *The correspondence $\mathbf{B} \to \mathcal{M}(\mathbf{B})$ is injective.*

Proof. Suppose $\mathcal{M}(\mathbf{B_1}) = \mathcal{M}(\mathbf{B_2})$. Then $\mathbf{B_1} = \mathcal{B}_W(\mathcal{M}(\mathbf{B_1})) = \mathcal{B}_W(\mathcal{M}(\mathbf{B_2})) = \mathbf{B_2}$. □

This raises the question of whether the correspondence $\mathbf{R} \to \mathcal{B}_W(\mathbf{R})$ is bijective, i.e., whether $\mathcal{B}_W$ and $\mathcal{M}$ are inverses of one another. The answer to this question of course depends upon W. Prompted by this question, we make the following definition.

DEFINITION 1. *A submodule $\mathbf{R}$ of $\mathcal{A}^k$ is called a Willems submodule with respect to W if $\mathcal{M}(\mathcal{B}_W(\mathbf{R})) = \mathbf{R}$.*

Thus the correspondence $\mathbf{R} \to \mathcal{B}_W(\mathbf{R})$ is bijective when restricted to the class of Willems submodules with respect to W. Given a submodule $\mathbf{R}$ of $\mathcal{A}^k$, $\mathcal{M}(\mathcal{B}_W(\mathbf{R}))$ is clearly the smallest Willems submodule that contains $\mathbf{R}$. We will call $\mathcal{M}(\mathcal{B}_W(\mathbf{R}))$ the Willems submodule with respect to W generated by $\mathbf{R}$. Clearly, $\mathcal{M}(\mathcal{B}_W(\mathbf{R}))$ is the largest submodule in $\mathcal{A}^k$ determining the same behavior in W^k as that of $\mathbf{R}$.

In terms of this definition, we now state the theorem of Oberst referred to in the introduction.

THEOREM (Oberst). *Every submodule of $\mathcal{A}^k$ is Willems with respect to $\mathcal{C}^\infty$ (or $\mathcal{D}'$).*

Later in this paper we determine *the class of submodules which are Willems with respect to $\mathcal{D}$ or $\mathcal{E}'$ to be precisely the class of MA systems.*

In this paper we often look at the subclass of AR systems given by MA systems which display several "nice" properties such as controllability and stabilizability. We therefore now discuss a parametrization of such systems.

PROPOSITION 1. *Every MA system is the image of a right prime morphism.*

Remark. By a right prime morphism, we mean a morphism given by a factor right prime matrix. For various notions of right and left primeness, see Bose [1].

Proof. Let an MA behavior be given as the image of a morphism whose matrix representation is given by M as in (2). We first show that this same MA behavior is also given by a submatrix M_0 of M which has full column rank.

Let the columns of M be given by elements $c_1, \dots, c_m$. Let the rank of M be m_0 and assume, without loss of generality, that $c_1, \dots, c_{m_0}$ are $\mathcal{A}$-independent. Let c_i, $i \neq 1, \dots, m_0$, be any other column of the matrix M. By assumption, there is a relation between the columns $c_1, \dots, c_{m_0}$ and c_i, say $ac_i = \sum_{j=1}^{m_0} \alpha_j c_j$, where a and the α_j's belong to $\mathcal{A}$. We will show that the image of c_i in $(\mathcal{C}^\infty)^l$ (or $(\mathcal{D}')^l$ as the case may be) is contained in the span of the images of $c_1, \dots, c_{m_0}$. For this consider any f in $\mathcal{C}^\infty$ (or $\mathcal{D}'$). By a standard result (see for instance Hörmander [2, Corollary 10.6.8]), there is a g in $\mathcal{C}^\infty$ (or $\mathcal{D}'$) such that $a(g) = f$. Then $c_i(f) = c_i(ag) = ac_i(g) = (\sum_{j=1}^{m_0} \alpha_j c_j)(g)$. This element is in the image of the submatrix M_0 given by the columns $c_1, \dots, c_{m_0}$.

Suppose now that M_0 is not right prime. Then $M_0 = M_1 T$, where M_1 is right prime and where T is a square $m_0 \times m_0$ matrix whose determinant is a nonconstant polynomial. Note that the module of relations of the rows of T is the 0 submodule of $\mathcal{A}^{m_0}$. Using the Ehrenpreis–Palamodov theorem or the injectivity result of Oberst in the remark following it, we conclude that T is surjective on $(\mathcal{C}^\infty)^{m_0}$ or $(\mathcal{D}')^{m_0}$, respectively.

Thus the image of M_0 equals the image of M_1, which is to say that the given MA behavior is also the image of a right prime morphism, namely M_1 above. □

In view of this proposition, we will henceforth describe MA behaviors using only right prime morphisms.

We conclude this section with the following definition and approximation theorem of Malgrange which we quote from Hörmander [2].

DEFINITION. *A solution f of the constant coefficient partial differential equation $p(f) = 0$ is called an exponential solution if it is of the form*

$$f(x) = q(x)e^{\langle x, \xi \rangle},$$

where $q(x)$ is a polynomial and ξ is in $\mathbb{C}^n$.

Remark. If $x = (x_1, \dots, x_n)$ and $\xi = (\xi_1, \dots, \xi_n)$, then by $\langle x, \xi \rangle$ we mean $\sum x_i \xi_i$. This is not the standard Hermitian inner product on $\mathbb{C}^n$. However, as in this paper x is always in $\mathbb{R}^n$, the above choice of the bilinear form $\langle , \rangle$ suffices.

It is easy to check that if $f = q(x)e^{\langle x, \xi \rangle}$ is a solution of $p(f) = 0$, then $p(\xi) = 0$, i.e., ξ lies in the variety of p (in $\mathbb{C}^n$).

THEOREM (see Theorem 7.3.6 in [2]). *The closed linear hull in $\mathcal{C}^\infty(\mathbb{R}^n)$ of the exponential solutions of the equation $p(f) = 0$ consists of all its solutions in $\mathcal{C}^\infty(\mathbb{R}^n)$.*

Remark (see remark following Theorem 10.5.1 in [2]). In fact Malgrange has proved that it is sufficient to use polynomial solutions in the above theorem iff every nonconstant factor of p vanishes at the origin. Also, it suffices to use solutions of the form $e^{\langle x,\xi \rangle}$ iff p has no multiple factors.

3. Controllable systems. We now discuss controllability properties of AR systems. Motivated by the definition of controllability of lumped systems in [10, 11] and of 2-D discrete systems in [6], we adopt a similar definition for distributed systems below.

DEFINITION 2. *Let* $(\mathbb{R}^n, \mathbb{R}^k, \mathbf{B})$ *be an AR system. Then* $\mathbf{B}$ *is said to be controllable if for* w_1 *and* w_2*, any two elements in* $\mathbf{B}$*, and for* U_1 *and* U_2 *any two open subsets of* $\mathbb{R}^n$ *such that their closures are disjoint (i.e.,* $\overline{U}_1 \cap \overline{U}_2 = \emptyset$*), there exists an element* w *in* $\mathbf{B}$ *which coincides with* w_1 *on* U_1 *and with* w_2 *on* U_2*.*

The above definition means that the action of w coincides with that of w_1 on test functions whose supports lie in U_1 and with the action of w_2 on test functions whose supports lie in U_2. If w_1 and w_2 are smooth functions, then the above implies that w coincides pointwise with w_1 on U_1 and with w_2 on U_2. Intuitively, w has patched up w_1 and w_2.

Note that our definition is symmetric with respect to all the variables $x_1, \dots, x_n$. This is motivated by the theory of 2-D systems applied to image processing where neither variable plays a special role. It is possible however that in some systems a variable plays a special role, for instance, that of time. In such systems it might be that it is necessary only to patch up elements in the behavior along this special variable. Then U_1 and U_2 in the above defintion need only be "strips," that is, open sets of the form $I \times \mathbb{R}^{n-1}$, where I is an open interval in $\mathbb{R}$. Note that such open sets are of course included in the definition above.

DEFINITION 3. *Let* U *be an open subset of* $\mathbb{R}^n$*, and let* V *be any closed subset whose interior contains the closure of* U*. Let* w *be an element in* $(\mathcal{D}')^k$*. An element* w' *in* $(\mathcal{D}')^k$ *is a cutoff of* w *with respect to* U *and* V *if* w' *coincides with* w *on* U *and with* 0 *on* V^C*, the complement of* V*.*

Recollect that given any U and V as above, there is a smooth function f which is identically 1 on U and 0 on V^C (i.e., a "bump" function). Thus in the above definition fw is such a w'. Note that if w is smooth, then such a cutoff is also smooth.

LEMMA 2. *Let* $\mathbf{B}$ *be an AR behavior in* $(W)^k$*, where* W *is any* $\mathcal{E}'$*-submodule of* $\mathcal{D}'$*. Then* $\mathbf{B}$ *is controllable iff for every* w *in* $\mathbf{B}$ *and for every* U *and* V *as in the definition above, some cutoff of* w *with respect to* U *and* V *is also in* $\mathbf{B}$*.*

Proof. Let $\mathbf{B}$ be controllable and let U and V be as in the definition above. Then U and V^C, the complement of V, are open sets whose closures are disjoint. Let w be in $\mathbf{B}$. As $\mathbf{B}$ is a linear subspace, the 0 distribution is in $\mathbf{B}$. By the definition of controllability, there is a w' in $\mathbf{B}$ which coincides with w on U and with 0 on V^C. This w' is a cutoff of w with respect to U and V.

Conversely, let w_1 and w_2 be any two elements in $\mathbf{B}$, and let U_1 and U_2 be open subsets whose closures are disjoint. As $\mathbb{R}^n$ is normal, we can find closed disjoint subsets V_1 and V_2 containing U_1 and U_2 in their interiors. There is a cutoff w_1' of w_1 with respect to U_1 and V_1 in $\mathbf{B}$ and, similarly, a cutoff w_2' of w_2 with respect to U_2 and V_2 in $\mathbf{B}$. By linearity of $\mathbf{B}$, $w = w_1' + w_2'$ is also in $\mathbf{B}$. This w obviously coincides with w_1 on U_1 and with w_2 on U_2. □

In [10, 11], Willems shows that all lumped controllable AR systems are MA systems and conversely. Rocha and Willems prove this same fact for 2-D discrete systems. They also show that controllable 2-D discrete systems are always given by free submodules or equivalently given by kernels of left prime matrices. The situation in the distributed case in three or more variables is more involved. We explain all this in terms of the global dimension of the ring $\mathcal{A}$.

In what follows we rely on the Ehrenpreis–Palamodov theorem (or its variant in the case of $\mathcal{D}'$ due to Oberst) in the proofs of many statements. As such a theorem is not valid for an arbitrary $\mathcal{E}'$-submodule W of $\mathcal{D}'$, *we henceforth restrict ourselves to behaviors with respect to* $\mathcal{C}^\infty$ *or* $\mathcal{D}'$.

We start this development with the following proposition.

PROPOSITION 2. *Every MA system is controllable.*

Proof. Let the MA system be given by the $\mathcal{E}'$-module morphism $M : (\mathcal{D}')^m \to (\mathcal{D}')^l$; i.e., let the behavior $\mathbf{B}$ be the image of M. Let w be any element in $\mathbf{B}$. Then $w = M(v)$ for some v in $(\mathcal{D}')^m$. Let U and V be as in Definition 3. Let v' be any cutoff of v with respect to U and V. Consider $w' = M(v')$. We claim that w' is a cutoff of w also with respect to U and V.

Let f be any test function in $(\mathcal{D})^l$ whose support is contained in U. Then $w'(f) = M(v')(f) = v'(M'(f))$, where $M' : (\mathcal{D})^l \to (\mathcal{D})^m$, the adjoint of M, is also a local continuous $\mathcal{E}'$-module morphism. Thus the support of $M'(f)$ is also contained in U. Then as v' is a cutoff of v with respect to U and V, $v'(M'(f)) = v(M'(f)) = M(v)(f) = w(f)$. Hence $w'(f) = w(f)$ for all f in $(\mathcal{D})^l$ with support in U. Similarly, w' coincides with 0 in V^C. Thus w' is indeed a cutoff of w with respect to U and V.

If we restrict the morphism M to the subspace $(\mathcal{C}^\infty)^m$, then there is a cutoff w' of w in $(\mathcal{C}^\infty)^l$ which is also smooth and is obtained by choosing a smooth cutoff v' of v. Thus MA systems are also controllable in the $\mathcal{C}^\infty$ sense. □

The question now arises as to which AR systems are controllable. We show below that the class of distributed controllable AR systems coincides with the class of MA systems. Toward this we first characterize those AR systems which are MA systems and hence controllable by the above proposition. For the sake of convenience, *we restrict ourselves further to the* $\mathcal{C}^\infty$ *category.* Note, however, that all the results that follow are equally valid for behaviors with respect to $\mathcal{D}'$.

Given the behavior $\mathbf{B}$ of an AR system $R : (\mathcal{C}^\infty)^k \to (\mathcal{C}^\infty)^l$, consider the subbehaviors of $\mathbf{B}$ which are MA systems, i.e., images of morphisms $M : (\mathcal{C}^\infty)^m \to (\mathcal{C}^\infty)^k$ that lie in the kernel of R. (Recollect from the discussion in section 2 that MA behaviors are in one-to-one correspondence with right prime morphisms M.) Representing R and such an M by matrices (r_{ij}) and (m_{ij}) as in section 2, it follows that

$$\sum_{j=1}^{k} r_{ij} m_{jh} = 0 \quad \text{for all } i = 1, \dots, l, \quad h = 1, \dots, m. \tag{4}$$

We can therefore consider the columns of M as relations between the columns of R. Conversely, relations between the columns of R determine a morphism whose image lies in the kernel of R. Consider now the module of all relations between the columns of R. Generators of this module, say g in number, determine a morphism $M_0 : (\mathcal{C}^\infty)^g \to (\mathcal{C}^\infty)^k$, whose image is clearly the largest subbehavior of $\mathbf{B}$ which admits an MA representation. Denote by $\mathbf{M_0}$ the submodule of $\mathcal{A}^g$ generated by the rows of the matrix representation of M_0. Consider next the submodule $\mathbf{R_0}$ of relations between the rows of the matrix representation of M_0. By (4) it follows that the rows of R lie in this module of relations. By Ehrenpreis–Palamodov, the image of M_0 is precisely the kernel of R_0, the morphism determined by $\mathbf{R_0}$. Thus we have the following.

THEOREM 1. *Let* $R : (\mathcal{C}^\infty)^k \to (\mathcal{C}^\infty)^l$ *be an AR system and let* $\mathbf{R}$ *be the submodule of* $\mathcal{A}^k$ *generated by the rows of* R*. Then the system admits an MA representation iff the module* $\mathbf{R_0}$ *defined above equals* $\mathbf{R}$.

Proof. By the theorem of Oberst, $\mathbf{R}$ and $\mathbf{R_0}$ define the same behavior iff they are equal. By construction the behavior of $\mathbf{R_0}$ is an MA behavior. □

Remark. We supplement the discussion preceding the above theorem with a few elementary remarks that we use elsewhere. Given a submodule of $\mathcal{A}^k$, define its rank to be the rank of the largest free submodule contained in it. It is easy to see that this rank is equal to the rank of any matrix whose rows generate the submodule and whose entries are now considered as belonging to the quotient field of the domain $\mathcal{A}$. It is equally elementary that this rank is also the dimension of the vector space obtained by tensoring the submodule with this quotient field. From this it follows that if the rank of a submodule $\mathbf{R}$ of $\mathcal{A}^k$ is i, then the rank of the submodule generated by all the relations between the columns of any matrix representation R of $\mathbf{R}$, namely the submodule $\mathbf{M_0}$ defined above, is $(k - i)$. We therefore conclude, similarly, that the rank of the submodule $\mathbf{R_0}$ in Theorem 1 equals the rank of $\mathbf{R}$. As $\mathbf{R}$ is contained in $\mathbf{R_0}$, it follows that for any p in $\mathbf{R_0}$, there is a nonzero a in $\mathcal{A}$ such that ap is in $\mathbf{R}$. In other words the quotient $\mathbf{R_0}/\mathbf{R}$ is a torsion module. We finally remark that from the construction of $\mathbf{M_0}$ and $\mathbf{R_0}$ above, it follows that if a p in $\mathcal{A}^k$ has the property that some ap is in $\mathbf{R}$ for a nonzero a in $\mathcal{A}$, then this p must be in $\mathbf{R_0}$. This is because if ap is in $\mathbf{R}$, then it lies in the module of relations of the rows of the matrix M_0, which by definition is $\mathbf{R_0}$. Thus the set of torsion elements of the module $\mathcal{A}^k/\mathbf{R}$ is precisely the submodule $\mathbf{R_0}/\mathbf{R}$. We can therefore reformulate the above theorem as follows.

THEOREM 2. *The AR system defined by a submodule* $\mathbf{R}$ *is MA iff* $\mathcal{A}^k/\mathbf{R}$ *is torsion free.*

An important case where the above theorem is applicable is when $\mathbf{R}$ can be "decoupled," namely, the proposition below.

PROPOSITION 3. *Let* $\mathbf{R}$ *be a submodule of* $\mathcal{A}^k$ *which is a direct summand. Then the AR behavior determined by it admits an MA representation.*

Proof. As $\mathbf{R}$ is a direct summand, it follows that $\mathcal{A}^k = \mathbf{R} \oplus \mathcal{A}^k/\mathbf{R}$. Thus $\mathcal{A}^k/\mathbf{R}$ is a projective module and hence free by Serre, Quillen, and Suslin. The result then follows from Theorem 2. □

The importance of this special case follows from the fact that this is *the* case for lumped systems.

COROLLARY 3 (1-D systems). *Let* $\mathcal{A} = \mathbb{R}[\frac{d}{dx}]$. *Then the behavior given by a submodule* $\mathbf{R}$ *of* $\mathcal{A}^k$ *is MA iff* $\mathbf{R}$ *is a direct summand.*

Proof. Suppose that the behavior of the submodule $\mathbf{R}$ is MA. Then $\mathbf{R}$ equals $\mathbf{R_0}$. By the above theorem $\mathcal{A}^k/\mathbf{R}$ is torsion-free. As $\mathcal{A}$ here is a PID; this implies that $\mathcal{A}^k/\mathbf{R}$ is free. It then follows that $0 \to \mathbf{R} \to \mathcal{A}^k \to \mathcal{A}^k/\mathbf{R} \to 0$ splits, i.e., that $\mathbf{R}$ is a direct summand. □

Remark. It is a result of Willems that every controllable lumped system is MA. Thus the above proposition actually provides a necessary and sufficient condition for the controllability of lumped systems.

We conclude this development with the following classical example.

Example 1 (the deRham complex on $\mathbb{R}^3$). Consider the behavior given by the kernel of the map $R : (\mathcal{C}^\infty)^3 \to (\mathcal{C}^\infty)^3$ whose matrix representation is given by

$$\begin{pmatrix} 0 & \frac{-\partial}{\partial z} & \frac{\partial}{\partial y} \\ \frac{\partial}{\partial z} & 0 & \frac{-\partial}{\partial x} \\ \frac{-\partial}{\partial y} & \frac{\partial}{\partial x} & 0 \end{pmatrix}.$$

Then the relations between the columns of R determine a map $M_0 : \mathcal{C}^\infty \to (\mathcal{C}^\infty)^3$ which is given by the matrix $(\frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z})^T$. As explained above, M_0 determines the largest MA subbehavior contained in the kernel of R. The module of relations $\mathbf{R_0}$ of the rows of M_0 is a submodule of $\mathcal{A}^3$ generated by $(0, \frac{-\partial}{\partial z}, \frac{\partial}{\partial y})$, $(\frac{\partial}{\partial z}, 0, \frac{-\partial}{\partial x})$, $(\frac{-\partial}{\partial y}, \frac{\partial}{\partial x}, 0)$, which coincides with $\mathbf{R}$, the module generated by the rows of R above. Thus by the above theorem, the kernel of R is an MA behavior, given by the image of M_0. Similarly, if one considers the map $R_1 : (\mathcal{C}^\infty)^3 \to \mathcal{C}^\infty$, given by $(\frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z})$, then the module of relations of its columns is generated by the columns of R. Moreover, the module of relations between the rows of R is a cyclic module, again generated by $(\frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z})$. Thus the kernel of R_1 is equal to the image of R. Note that this is just the familiar fact that the image of the gradient equals the kernel of curl and that the image of curl equals the kernel of divergence. □

Willems, and Rocha and Willems, prove that controllable AR systems are MA for 1-D and discrete 2-D systems by showing that MA behaviors are the kernels of left prime morphisms. We show below that while this is also true for distributed 2-D systems, n-D behaviors given by left prime morphisms are not necessarily controllable for $n \geq 3$ (Example 2). We also show that controllable systems, although MA, are not necessarily given by free submodules.

We first characterize the class of controllable AR systems.

Theorem 3. *Every distributed controllable AR system is an MA system.*

Proof. We show that if an AR system, say defined by the morphism $R : (\mathcal{C}^\infty)^k \to (\mathcal{C}^\infty)^l$, is not MA, then it is not controllable.

So assume that the behavior given by $\ker(R)$, the kernel of R, is not MA. By Theorem 1 above, the submodule $\mathbf{R}$ corresponding to R is strictly contained in the submodule $\mathbf{R_0}$. Let $p = (p_1, \ldots, p_k)$ be any element in $\mathbf{R_0}$ which is not in $\mathbf{R}$. It follows from the remark following Theorem 1 that ap is in $\mathbf{R}$ for some nonzero a in $\mathcal{A}$. Consider the maps

$$\begin{aligned} P : \ker(R) &\to \mathcal{C}^\infty, \\ (f_1, \ldots, f_k) &\mapsto \sum p_i(f_i), \end{aligned}$$

and

$$\begin{aligned} A : \mathcal{C}^\infty &\to \mathcal{C}^\infty, \\ f &\mapsto a(f), \end{aligned}$$

where p and a are as above.

By the theorem of Oberst quoted in the introduction, as p is not in $\mathbf{R}$, it does not kill every element in $\ker(R)$, i.e., the map P defined above is not the zero map. However, the composition $A \circ P : \ker(R) \to \mathcal{C}^\infty$, which maps $(f_1, \ldots, f_k)$ in $\ker(R)$ to $\sum ap_i(f_i)$, is the zero map as ap is in $\mathbf{R}$.

Now let u be any element in $\ker(R)$ which is not in the kernel of P. Let U be any bounded open subset of $\mathbb{R}^n$, where $P(u)$ is nonzero, and let V be any compact set whose interior contains the closure of U. Let u_c be any cutoff with respect to U and V. Then u_c has compact support and is clearly not in the kernel of P. If $\ker(R)$ were controllable, then some cutoff of u with respect to this U and V must also be in the kernel of R. This implies that the image under P of this cutoff must be in the kernel of A. It follows then that the PDE a admits a nonzero compactly supported solution. This is a contradiction to the Paley–Wiener theorem. □

If we were to consider the behavior of R in $(\mathcal{D}')^k$, then the same proof as above shows that every distributed controllable AR system is an MA system. A variant of the above proof yields another characterization of controllable systems.

THEOREM 4. *A submodule* $\mathbf{R}$ *of* $\mathcal{A}^k$ *defines a controllable AR system iff* $\mathbf{R}$ *is Willems with respect to* $\mathcal{D}$ *(or* $\mathcal{E}'$*).*

Proof. We prove the theorem for the case of $\mathcal{D}$, the proof for $\mathcal{E}'$ being similar. Thus we have to show that $\mathbf{R}$ is controllable iff $\mathcal{M}(\mathcal{B}_{\mathcal{D}}(\mathbf{R})) = \mathbf{R}$, i.e., $\mathbf{R}$ is Willems with respect to $\mathcal{D}$.

Suppose first that $\mathcal{M}(\mathcal{B}_{\mathcal{D}}(\mathbf{R})) = \mathbf{R_1}$ strictly contains $\mathbf{R}$. Then by the theorem of Oberst, $\mathcal{B}_{\mathcal{C}^\infty}(\mathbf{R_1})$ is strictly contained in $\mathcal{B}_{\mathcal{C}^\infty}(\mathbf{R})$. As $\mathcal{B}_{\mathcal{D}} \circ \mathcal{M}$ is the identity (Lemma 1), it follows that $\mathcal{B}_{\mathcal{D}}(\mathbf{R}) = \mathcal{B}_{\mathcal{D}}(\mathbf{R_1})$ which is in turn contained in $\mathcal{B}_{\mathcal{C}^\infty}(\mathbf{R_1})$. Thus the closure of $\mathcal{B}_{\mathcal{D}}(\mathbf{R})$ in $\mathcal{C}^\infty(\mathbb{R}^n)$ is contained in $\mathcal{B}_{\mathcal{C}^\infty}(\mathbf{R_1})$. This implies that the closure of $\mathcal{B}_{\mathcal{D}}(\mathbf{R})$ is strictly contained in $\mathcal{B}_{\mathcal{C}^\infty}(\mathbf{R})$. Thus $\mathbf{R}$ cannot be controllable, since the compactly supported behavior of any controllable system is dense in its $\mathcal{C}^\infty$-behavior.

Conversely, suppose the $\mathcal{C}^\infty$-behavior given by $\mathbf{R}$ is not controllable. We have to show that $\mathbf{R}$ is not Willems with respect to $\mathcal{D}$; i.e., $\mathbf{R}$ is strictly contained in $\mathcal{M}(\mathcal{B}_{\mathcal{D}}(\mathbf{R}))$. Since $\mathbf{R}$ is not controllable, $\mathbf{R}$ is not MA by the above theorem. Hence by Theorem 1, $\mathbf{R}$ is strictly contained in $\mathbf{R_0}$. This implies that $\mathcal{B}_{\mathcal{D}}(\mathbf{R_0}) \subset \mathcal{B}_{\mathcal{D}}(\mathbf{R})$. In fact we claim that these two compactly supported behaviors are identical, i.e., every p in $\mathbf{R_0}$ kills every element in $\mathcal{B}_{\mathcal{D}}(\mathbf{R})$. For suppose that this was not true for some p in $\mathbf{R_0}$. By the remark following Theorem 1, there exists some a in $\mathcal{A}$ such that ap is in $\mathbf{R}$. Thus ap kills every element in $\mathcal{B}_{\mathcal{D}}(\mathbf{R})$. So if p does not kill some element in $\mathcal{B}_{\mathcal{D}}(\mathbf{R})$, it follows as in the proof of the above theorem that the Paley–Wiener theorem is contradicted. Hence $\mathbf{R}$ is strictly contained in $\mathbf{R_0} \subset \mathcal{M}(\mathcal{B}_{\mathcal{D}}(\mathbf{R_0})) = \mathcal{M}(\mathcal{B}_{\mathcal{D}}(\mathbf{R}))$. Thus $\mathbf{R}$ is not Willems with respect to $\mathcal{D}$. □

We have thus established the following equivalences: $\mathbf{R}$ is controllable $\Leftrightarrow$ $\mathbf{R}$ is MA $\Leftrightarrow$ $\mathbf{R}$ is Willems with respect to $\mathcal{D}$ (or $\mathcal{E}'$) $\Leftrightarrow$ $\mathcal{A}^k/\mathbf{R}$ is torsion-free.

Rocha and Willems in [6] show that every controllable 2-D discrete system is given by a factor left prime matrix (whose rows necessarily generate a free submodule). We have already pointed out the importance of this result in the introduction. The question then arises as to whether this is so for distributed systems as well. This is not in general true as the following counterexample demonstrates.

Example 2. Let $R : (\mathcal{C}^\infty)^3 \to (\mathcal{C}^\infty)^2$ be the AR system determined by the following matrix:

$$R = \begin{pmatrix} 0 & -\frac{\partial}{\partial z} & \frac{\partial}{\partial y} \\ \frac{\partial}{\partial z} & 0 & -\frac{\partial}{\partial x} \end{pmatrix}.$$

Clearly R is factor left prime. Nonetheless the AR behavior determined by R is *not* controllable, as an easy calculation shows that R_0 is the matrix that appears in Example 1, namely curl. The system defined by curl is of course controllable, since it is the image of the gradient map. Note, however, that the matrix representation of curl is not factor left prime; in fact the submodule generated by the rows of this matrix is not even free. □

Thus the question now arises as to which controllable systems are given by free submodules. As pointed out in the introduction, this is an important question. We provide a necessary and sufficient condition below in the notation preceding Theorem 1.

THEOREM 5. *Let* $\mathbf{R}$ *be a submodule of* $\mathcal{A}^k$ *which determines a controllable behavior. Let* $\mathbf{R}$ *determine the submodule* $\mathbf{M_0}$ *of* $\mathcal{A}^g$ *as above. Then* $\mathbf{R}$ *is a free submodule iff the projective dimension of* $\mathcal{A}^g/\mathbf{M_0}$ *is less than or equal to* 2.

Proof. Consider the following resolution of $\mathcal{A}^g/\mathbf{M_0}$:

$$0 \to \mathbf{R_0} \xrightarrow{\phi_3} \mathcal{A}^k \xrightarrow{\phi_2} \mathcal{A}^g \xrightarrow{\phi_1} \mathcal{A}^g/\mathbf{M_0} \to 0,$$

where ϕ_1 and ϕ_3 are canonically defined and ϕ_2 takes a basis of $\mathcal{A}^k$ to the rows of the matrix M_0. By the discussion preceding Theorem 1, the kernel of ϕ_2 is the module $\mathbf{R_0}$, and hence the sequence above is indeed exact. As the behavior of $\mathbf{R}$ is controllable, $\mathbf{R_0}$ equals $\mathbf{R}$ by Theorem 3. A standard argument shows that $\mathrm{Ext}^1(\mathbf{R}, -) \approx \mathrm{Ext}^3(\mathcal{A}^g/\mathbf{M_0}, -)$, which equals 0 iff the projective dimension of $\mathcal{A}^g/\mathbf{M_0}$ is at most 2. This implies that $\mathbf{R}$ is projective. Now by Serre, Quillen, and Suslin, $\mathbf{R}$ must be free. $\square$

COROLLARY 4 (2-D distributed systems). *Every distributed 2-D controllable behavior is given by a free submodule.*

Proof. Observe that here $\mathcal{A} = \mathbb{R}[\partial_1, \partial_2]$. Thus the global dimension of $\mathcal{A}$ is 2 and hence the projective dimension of any $\mathcal{A}$-module is less than or equal to 2. This then satisfies the conditions of the above proposition. $\square$

Remark. From the proof of Theorem 3, it can be easily seen that if a controllable AR system is given by a free submodule $\mathbf{R}$, then $\mathbf{R}$ is maximal among all submodules with the same number of generators as $\mathbf{R}$. This would imply that the matrix representation of $\mathbf{R}$ is factor left prime. From the above corollary we can therefore further conclude that every distributed 2-D controllable behavior is given by a factor left prime matrix.

Thus the phenomenon exhibited in Example 2 above occurs only in dimension 3 or more.

Remark. It is now well known that there is an important difference between 1-D and n-D, $n \geq 2$, discrete systems, namely that while every 1-D system is feedback stabilizable, this is not, however, the case for 2-D systems (see Shankar and Sule [8]). The counterexample and corollary above point out, likewise, a difference between 2-D systems and n-D, $n \geq 3$, systems.

4. Autonomous systems. In [10, 11] Willems defines a lumped autonomous AR behavior to be one given by the kernel of a map R in $\mathbb{R}^{k\times k}[\frac{d}{dt}]$ whose characteristic polynomial, i.e., its determinant, is a nonzero polynomial. Intuitively, this definition singles out those AR behaviors that are far from being controllable in the sense that every element in the behavior of an autonomous system is determined by its values on any open interval of $\mathbb{R}$, i.e., by its germ at any point in $\mathbb{R}$. Thus if we specify the germ of an element in such a behavior, that element is specified in its entirety. We therefore have no "control" over it; i.e., it is "autonomous." In fact the elements in the behavior of a lumped autonomous system are entire functions which are linear combinations of exponential functions that arise from the zeros of the characteristic polynomial. As these zeros are finite in number, the exponential solutions span a finite-dimensional $\mathbb{R}$-vector subspace in the space of entire as well as $\mathcal{C}^\infty$ functions. Being finite dimensional, this subspace is closed, and hence by the Malgrange approximation theorem, the $\mathcal{C}^\infty$-behavior of an autonomous lumped system R also consists only of these entire functions. (In fact this finite dimensionality of the behavior is equivalent to R having full rank.) This finite dimensionality of the $\mathcal{C}^\infty$-behavior implies that if the derivatives up to some finite order of an element all vanish at a point, then this element must be the zero element. Hence an element in such a behavior can be specified by a "finite amount of data." This is considerably stronger than saying that the $\mathcal{C}^\infty$-behavior of a system consists only of entire functions. Note finally that the behavior of a single ordinary differential equation is autonomous.

We now wish to extend this definition of an autonomous behavior to distributed systems. So consider a distributed AR behavior given by the kernel of a morphism R. This behavior corresponds to a submodule of $\mathcal{A}^k$ generated by the rows of R. Observe that submodules of $\mathcal{A}^k$ can have larger than k number of generators when $\mathcal{A} = \mathbb{R}[\partial_1, \ldots, \partial_n]$, $n > 1$. (This does not happen in the lumped case, i.e., when $n = 1$, as then every submodule is free and thus requires fewer than or equal to k generators.) Thus in the distributed case, the matrix representation of R might necessarily need more than k rows. Like the behavior of an autonomous lumped system, we would expect the behavior of a distributed autonomous system R to be dependent on the various $k \times k$ submatrices of R. To describe this we use the following notation from Lang [4]. Let M be an $l \times m$ matrix with coefficients in $\mathcal{A}$. For $r \leq \min(l, m)$, the rth determinant ideal of M, denoted $I_r(M)$, is the ideal of $\mathcal{A}$ generated by the determinants of all the $r \times r$ minors of M. If $r > \min(l, m)$, $I_r(M)$ is defined to be the zero ideal. Define also the rth determinant variety of M to be the variety in $\mathbb{C}^n$ of $I_r(M)$.

In terms of this, a lumped autonomous behavior is one given by an $R \in \mathbb{R}^{k \times k}[\frac{d}{dt}]$ whose kth determinant ideal is not the zero ideal. It is this property that we generalize to define a distributed autonomous behavior. As behaviors correspond to submodules of $\mathcal{A}^k$, we first state the following lemma whose proof easily follows from the Cauchy–Binet formula.

Lemma 3. *Let* $\mathbf{R}$ *be a submodule of* $\mathcal{A}^k$. *Let* R_1 *and* R_2 *be two matrices whose rows generate* $\mathbf{R}$. *Then for every* i, *the* i*th determinant ideals of* R_1 *and* R_2 *are identical, and therefore their* i*th determinant varieties coincide.*

We can now make the following definition.

Definition 4. *Let* $\mathbf{R}$ *be any submodule of* $\mathcal{A}^k$. *Define the characteristic ideal of* $\mathbf{R}$ *to be the* k*th determinant ideal of any matrix representation of* $\mathbf{R}$. *The variety of this ideal* (*in* $\mathbb{C}^n$) *is called the characteristic variety of* $\mathbf{R}$. *We denote the characteristic ideal (characteristic variety) of* $\mathbf{R}$ *by* $I(\mathbf{R})(V(\mathbf{R}))$.

As pointed out above, a lumped autonomous behavior corresponds to an $\mathbf{R}$ whose characteristic variety is not all of $\mathbb{C}$. Hence we make the following definition.

Definition 5. *The behavior given by a submodule* $\mathbf{R}$ *of* $\mathcal{A}^k$ *is said to be* autonomous *if the characteristic variety of* $\mathbf{R}$ *is not all of* $\mathbb{C}^n$ *(i.e., its* k*th determinant ideal is not the zero ideal).*

We show below that if a behavior is not autonomous, then it contains nontrivial controllable subbehaviors. We wish to remark first that behaviors of autonomous systems whose characteristic varieties are nonempty contain exponentials corresponding to points on this variety. This is because if R is any matrix representation of $\mathbf{R}$, then substituting any point ξ of $V(\mathbf{R})$ into the entries of R will result in a matrix $R(\xi)$ with entries in $\mathbb{C}$ whose column rank is less than k. This implies that there is a nonzero element in the kernel of $R(\xi)$, say $(c_1, \ldots, c_k)$. Then an easy check shows that $(c_1 e^{\langle x, \xi \rangle}, \ldots, c_k e^{\langle x, \xi \rangle})$ is in the behavior of $\mathbf{R}$. Thus there are exponential solutions in the behavior corresponding to every point in $V(\mathbf{R})$.

Clearly any matrix representation of a distributed autonomous system has full column rank, i.e., there are no polynomial relations between the columns of R. As pointed out above, a submodule of $\mathcal{A}^k$ might have more than k generators, and thus every matrix representation of it will have more than k rows. Therefore a distributed autonomous system need not have a square matrix representation, for which reason we specify its column rank. This therefore is the right generalization of Willems's definition of lumped autonomous systems as those whose matrix representations have full rank.

Note also that as in the lumped case, the behavior of a single (nonzero) partial differential equation is autonomous. We further substantiate this definition below.

Proposition 4. *A behavior is autonomous iff it does not contain any (nontrivial) controllable subbehaviors.*

Proof. Suppose that the behavior of a submodule $\mathbf{R}$ of $\mathcal{A}^k$ is autonomous. Let R be any matrix representation of $\mathbf{R}$. Let R_1 be a $k \times k$ submatrix of R whose determinant Δ is nonzero. Clearly the behavior of R is contained in that of R_1. In turn the behavior of R_1 is contained in the behavior of $R_1^* R_1 = R_1 R_1^* = \operatorname{diag}(\Delta)$, where R_1^* is the adjoint matrix of R_1. Thus each entry in an element of the behavior of R lies in the kernel of Δ. As Δ is nonzero, none of these can have compact support (by Paley–Wiener). By Lemma 2, a controllable behavior necessarily has elements with compact support. Hence an autonomous behavior does not contain any nontrivial controllable subbehaviors.

Conversely, suppose that the behavior of R is not autonomous. This means that R does not have full column rank, and thus that there are nontrivial relations between the columns of R. Let $p = (p_1, \ldots, p_k)$ be such a relation. Then Rp^T is equal to zero. This implies that the image of the map $p^T : \mathcal{C}^\infty \to (\mathcal{C}^\infty)^k$ is contained in the behavior of R. Thus the behavior of R contains MA subbehaviors, which are controllable by Proposition 2. □

Corollary 5. *No nonzero element in an autonomous behavior can vanish outside a compact subset of* $\mathbb{R}^n$.

Proof. The proof is clear from the proof of Proposition 4. □

For lumped systems, the characteristic variety of an autonomous system is discrete, as it is not all of $\mathbb{C}$. However for distributed autonomous systems, this need not be the case. As a result, many of the properties of an autonomous lumped system that are consequences of the discreteness of the characteristic variety, do not carry over to distributed systems. To capture these properties, we present another definition.

Definition 6. *The behavior given by a submodule* $\mathbf{R}$ *of* $\mathcal{A}^k$ *is said to be* strongly autonomous *if the characteristic variety* $V(\mathbf{R})$ *of* $\mathbf{R}$ *is discrete* (*i.e., if* $\mathcal{A}/I(\mathbf{R})$ *has* (*Krull*) *dimension* 0).

Note that as $\mathcal{A}$ is Noetherian, discreteness of $V(\mathbf{R})$ implies that it is finite.

We show in the following theorem that a strongly autonomous distributed system satisfies the property of finite dimensionality of lumped autonomous behaviors. We first prove the following preliminary results.

Lemma 4. *Let I be a maximal ideal in $\mathcal{A} = \mathbb{R}[\partial_1, \ldots, \partial_n]$. Then $\mathcal{B}(I)$, the $\mathcal{C}^\infty$-behavior given by I, is finite dimensional.*

Proof. Observe first that as I is maximal, its variety in $\mathbb{C}^n$ consists of a finite number of points (in fact at most 2^n in number). Assume first that this variety intersects $\mathbb{R}^n$, say at $\xi = (\xi_1, \ldots, \xi_n)$. Then the ideal I must equal $(\partial_1 - \xi_1, \ldots, \partial_n - \xi_n)$ and the variety of this ideal must consist of this point alone. To say that an exponential solution is in $\mathcal{B}(I)$ is to say that $(\partial_i - \xi_i)(q(x)e^{\langle x, \xi \rangle}) = 0$ for all i. This forces $q(x)$ to be a constant. As the $\mathcal{C}^\infty$-behavior is the closed linear hull of the exponential solutions (by Malgrange), $\mathcal{B}(I)$ is 1-dimensional (and is in fact spanned by $e^{\langle x, \xi \rangle}$).

Suppose now that the variety does not intersect $\mathbb{R}^n$. Then it is a finite set, say $\{\xi^1, \ldots, \xi^k\} \subset \mathbb{C}^n$. The point $\xi^j = (\xi_1^j, \ldots, \xi_n^j)$ corresponds to the maximal ideal $(\partial_1 - \xi_1^j, \ldots, \partial_n - \xi_n^j)$ in $\mathbb{C}[\partial_1, \ldots, \partial_n]$. As above, the space of exponential solutions corresponding to this point is 1-dimensional. Thus the space of the exponential solutions in $\mathcal{B}(I)$ is the k-dimensional space spanned by the exponential solutions corresponding to each of the k points in the variety of I. Being finite dimensional, the closure of this space in $\mathcal{C}^\infty$ is itself. □

LEMMA 5. *Let $I = (p_1, \ldots, p_i, \ldots, p_N)$ be an ideal in $\mathbb{R}[\partial_1, \ldots, \partial_n]$ whose $\mathcal{C}^\infty$ behavior is finite dimensional. Then the $\mathcal{C}^\infty$-behavior of the ideal $J = (p_1, \ldots, p_i^2, \ldots, p_N)$ is also finite dimensional.*

Proof. Let I' be the ideal $(p_1, \ldots, \hat{p_i}, \ldots, p_N)$, where $\hat{p_i}$ means that p_i has been omitted. Consider the following $\mathbb{R}$-linear map:

$$P_i : \mathcal{B}(I') \to \mathcal{C}^\infty(\mathbb{R}^n),$$
$$f \mapsto p_i(f).$$

Then the behavior $\mathcal{B}(I)$ of I is the kernel of P_i, which by assumption is finite dimensional. Hence $P_i^{-1}(\mathcal{B}(I))$ is also finite dimensional. But $P_i^{-1}(\mathcal{B}(I))$ is precisely the behavior of J. □

COROLLARY 6. *Let I be an ideal in $\mathbb{R}[\partial_1, \ldots, \partial_n]$ such that the behavior of its radical, $\sqrt{I}$, is finite dimensional. Then the behavior of I is also finite dimensional.*

Proof. Some power of $\sqrt{I}$, say the rth power, is contained in I (as $\mathbb{R}[\partial_1, \ldots, \partial_n]$ is Noetherian!). Let J be the ideal generated by the rth powers of the generators of $\sqrt{I}$. An easy induction using Lemma 5 shows that $\mathcal{B}(J)$ is finite dimensional. However, now J is contained in I. So $\mathcal{B}(I)$ is contained in $\mathcal{B}(J)$, and hence $\mathcal{B}(I)$ is also finite dimensional. □

THEOREM 6. *A behavior is strongly autonomous iff it is a finite-dimensional subspace of the $\mathbb{R}$-vector space of $\mathcal{C}^\infty$ functions.*

Proof. Let a behavior $\mathbf{B}$ corresponding to a submodule $\mathbf{R}$ be strongly autonomous. Let $I(\mathbf{R})$ be generated by $\Delta_1, \ldots, \Delta_l$ in $\mathcal{A}$. Then every component of $f = (f_1, \ldots, f_k)$ in $\mathbf{B}$ is also a solution of Δ_i, $i = 1, \ldots, l$.

Now consider the variety V of $I(\mathbf{R})$. By assumption it is discrete. Hence the ideal of this variety, which is the radical of $I(\mathbf{R})$, is a finite intersection of maximal ideals. Now the exponential solutions of $\sqrt{I(\mathbf{R})}$ is the union of the exponential solutions corresponding to each of these maximal ideals. By Lemma 4, this spans a finite-dimensional $\mathbb{R}$-vector space. Thus by Malgrange, this space is also the $\mathcal{C}^\infty$-behavior of $\sqrt{I(\mathbf{R})}$. By Corollary 6, the $\mathcal{C}^\infty$-behavior of I is finite dimensional as well.

Conversely, suppose that $\mathbf{B}$ is not strongly autonomous. Then as $V(\mathbf{R})$ is not finite, it must contain an infinite number of points in $\mathbb{C}^n$. By the discussion following Definition 5, each of these points contribute nonzero exponential elements in $\mathbf{B}$. Clearly these exponential elements corresponding to different points in $V(\mathbf{R})$ are linearly independent. So $\mathbf{B}$ is not finite dimensional. □

COROLLARY 7. *Every $\mathcal{C}^\infty$ solution of a strongly autonomous system is entire. Thus no nonzero element in a strongly autonomous behavior can vanish on any open subset of $\mathbb{R}^n$.*

Proof. The proof is clear from the first part of the proof of Theorem 6. □

As a strongly autonomous system is clearly autonomous as well, Corollary 5 is valid for such systems. In fact even more is true, namely, the following.

COROLLARY 8. *No cutoff of an element in a strongly autonomous behavior $\mathbf{B}$ is in $\mathbf{B}$.*

COROLLARY 9. *An element in a strongly autonomous behavior $\mathbf{B}$ is determined by its values on any open subset of $\mathbb{R}^n$.*

Proof. If w_1 and w_2 are two elements in $\mathbf{B}$ that agree on some open subset of U of $\mathbb{R}^n$, then $w_1 - w_2$ is an element of $\mathbf{B}$ that vanishes on U. Then by Corollary 7, $w_1 - w_2$ equals zero. □

Remark. In fact much more is true. By the finite dimensionality of a strongly autonomous behavior $\mathbf{B}$, every element in it can be determined by its derivatives up to some finite order. It is in order to mimic this property of a lumped autonomous behavior that we made the above definition. In the case of a lumped system, the $\mathcal{C}^\infty$-behavior either contains elements that are not entire or is finite dimensional. For a distributed system, the behavior could consist of only entire functions but may not be finite dimensional. This will happen, for instance, if the behavior is specified by a single partial differential operator which is elliptic. As a result, such behaviors will also satisfy the above corollary but will not be strongly autonomous.

5. Control. Let $\mathbf{B}$ be a $\mathcal{C}^\infty$ AR behavior and let $\mathbf{R}$ be the submodule of $\mathcal{A}^k$ corresponding to it. Let $\{\mathbf{R}_\alpha\}$ be the class of submodules of $\mathcal{A}^k$ containing $\mathbf{R}$. The $\mathcal{C}^\infty$ AR behaviors given by any of these $\mathbf{R}_\alpha$'s is clearly contained in $\mathbf{B}$. This, by definition, is the class of AR subbehaviors of $\mathbf{B}$. (In fact, by Oberst, there is a one-to-one correspondence between the subbehaviors of $\mathbf{B}$ and the collection $\{\mathbf{R}_\alpha\}$.)

Let R be a matrix whose rows generate $\mathbf{R}$ so that $\mathbf{B}$ is the kernel of R. Let $\mathbf{B}_\alpha$ be a subbehavior of $\mathbf{B}$, and let $\mathbf{R}_\alpha$ be a submodule of $\mathcal{A}^k$ that generates $\mathbf{B}_\alpha$. As $\mathbf{R}_\alpha$ contains $\mathbf{R}$, we can obtain a matrix representation R_α by appending rows to R.

Suppose now that the behavior $\mathbf{B}$ is controllable. Then by Theorem 3, $\mathbf{B}$ is an MA behavior, i.e., suppose that $\mathbf{B}$ is the image of a morphism $M : (\mathcal{C}^\infty)^m \to (\mathcal{C}^\infty)^k$. We wish to explain how to obtain the subbehaviors $\{\mathbf{B}_\alpha\}$ of $\mathbf{B}$ in this setting.

Observe that the behavior $\mathbf{B}$ is the image under M of $(\mathcal{C}^\infty)^m$, which in turn can be thought of as the AR behavior given by the 0 submodule of $\mathcal{A}^m$. We claim that the subbehaviors of $\mathbf{B}$ can all be obtained as the images under M of the various AR subbehaviors of $(\mathcal{C}^\infty)^m$. Clearly, without loss of generality, it suffices to consider only those AR subbehaviors of $(\mathcal{C}^\infty)^m$ that contain the kernel of M.

Let $\mathbf{M}$ be the submodule of $\mathcal{A}^m$ generated by the rows of the matrix representation of the morphism M. Clearly any AR subbehavior of $(\mathcal{C}^\infty)^m$ that contains the kernel of M corresponds to a submodule $\mathbf{K}$ of $\mathbf{M}$. Let K be the morphism $(\mathcal{C}^\infty)^m \to (\mathcal{C}^\infty)^r$ corresponding to the submodule $\mathbf{K}$ (where r is the number of generators for $\mathbf{K}$). Clearly $K = TM$ for some morphism $T : (\mathcal{C}^\infty)^k \to (\mathcal{C}^\infty)^r$ (see the diagram below).

$$\begin{tikzcd}
(\mathcal{C}^\infty)^m \arrow[r, "M"] \arrow[d, "K"'] & (\mathcal{C}^\infty)^k \arrow[r, "R"] \arrow[dl, "T"] & (\mathcal{C}^\infty)^l \\
(\mathcal{C}^\infty)^r. & &
\end{tikzcd}$$

Equally clearly, the image under M of the kernel of K equals the intersection of the image of M with the kernel of T. By assumption the image of M is the AR behavior given by the morphism R. Thus the image under M of the kernel of K equals the intersection of the kernels of R and T. Hence we obtain a subbehavior $\mathbf{B}_\alpha$ (namely, by appending the rows of the matrix representation of the morphism T to the rows of R) as the image under M of a subbehavior of $(\mathcal{C}^\infty)^m$.

Control problems are always accompanied by criteria which single out certain subbehaviors as desirable. Such criteria are usually in the nature of stability or optimality requirements. In this paper we are concerned with stability requirements, which we model after the lumped situation. There, a very fruitful notion of stability has been the notion of bounded input–bounded output stability, where the growth of the signals in the system (i.e., inputs and outputs) is specified along the half-line $\mathbb{R}_+$, i.e., as the independent variable (time) tends to $+\infty$. We wish to generalize this notion of stability to distributed systems.

Definition 7. *The directions of stability is a closed convex cone S in $\mathbb{R}^n$ (with vertex at the origin). A $\mathcal{C}^\infty$-behavior* $\mathbf{B}$ *is stable with respect to S if every element in* $\mathbf{B}$ *tends to zero along every half-line in S.*

Remark. By a cone in $\mathbb{R}^n$ we mean a subset S, such that if x is in S, then tx is also in S, for every $t > 0$. Given a closed cone S, we also define the subset $S_<$ of $\mathbb{R}^n$ consisting of those points y in $\mathbb{R}^n$ such that $\langle y, x \rangle < 0$ for every nonzero x in S. Clearly $S_<$ is also a cone in $\mathbb{R}^n$. It is easy to check that $S_<$ is nonempty if S is a proper closed cone, i.e., S does not contain a full line. In fact $S_<$, in this case, has nonempty interior.

Proposition 5. *Let* $\mathbf{R}$ *be a submodule of $\mathcal{A}^k$ and* $\mathbf{B}$ *its behavior. If the projection of the characteristic variety of* $\mathbf{R}$*, $V(\mathbf{R})$, to $\mathbb{R}^n$ does not lie in $S_<$, then* $\mathbf{B}$ *is not stable with respect to S.*

Proof. If there is a point in the projection of $V(\mathbf{R})$ which does not lie in $S_<$, then the exponential solution corresponding to this point will not tend to zero along at least one half-line in S. □

It is not clear whether the assumption in the above proposition is also necessary. However, an additional hypothesis, which is generically satisfied, does guarantee stability.

Proposition 6. *Suppose that the characteristic ideal $I(\mathbf{R})$ of* $\mathbf{R}$ *contains a polynomial without repeated factors. Then if the projection of the characteristic variety is contained in $S_<$, and if its distance from the boundary of $S_<$ is strictly positive, then the behavior of* $\mathbf{R}$ *is stable with respect to S.*

Proof. As observed before, every component of every element in the behavior of $\mathbf{R}$ is also a homogeneous solution of every polynomial in the characteristic ideal $I(\mathbf{R})$ of $\mathbf{R}$. By assumption there is a polynomial p in $I(\mathbf{R})$ without repeated factors. Then by a remark in [2] quoted earlier at the end of section 2, it follows that the linear hull of exponential solutions of the form $e^{\langle x, \xi \rangle}$ is dense in the behavior of p. As the behavior of $I(\mathbf{R})$ is a closed subspace of the behavior of p, it follows that the linear hull of such exponentials (i.e., those without polynomial factors) is also dense in the behavior of $I(\mathbf{R})$.

We now claim that given any $\epsilon > 0$, there exists a ball, say B_ϵ, such that all the above exponential solutions (i.e., those of the form $e^{\langle x, \xi \rangle}$) are less in absolute value than ϵ at every point in $B_\epsilon^C \cap S$. This is because, by assumption, the projection of the characteristic variety to $\mathbb{R}^n$ is at a strictly positive distance from the boundary of $S_<$. Therefore every element in the behavior of $I(\mathbf{R})$ tends to zero along every half-line in S. This is therefore also true of every element in the behavior of $\mathbf{R}$. □

Observe that as the characteristic variety of a nonautonomous behavior $\mathbf{B}$ is all of $\mathbb{C}^n$, it contains exponentials corresponding to every $p \in \mathbb{C}^n$. Thus $\mathbf{B}$ cannot be stable with respect to any cone S in $\mathbb{R}^n$. Stability with respect to a cone S is therefore a property of autonomous behaviors. Hence by Proposition 4, a behavior that contains a controllable subbehavior is not stable with respect to any cone S. Restricting to an autonomous subbehavior stable with respect to a cone S is the process of *control* in stability problems. More generally we define control as the process of restricting $\mathbf{B}$ to some autonomous subbehavior.

Assume therefore that we are given an AR behavior $\mathbf{B}$ defined by a morphism $\mathbf{R}$. Let R be an $l \times k$ matrix representation of $\mathbf{R}$. Let K be a $j \times k$ matrix whose rows, when appended to the rows of R, define an autonomous *nontrivial* subbehavior $\mathbf{B}'$ of $\mathbf{B}$. The system defined by the matrix K we call the *controller.* If this subbehavior $\mathbf{B}'$, defined by $\left[\begin{smallmatrix} R \\ K \end{smallmatrix} \right]$, is stable with respect to a cone S, then we call K a stabilizing controller for R with respect to the cone S. We have already explained above how to obtain a controller if $\mathbf{B}$ is also a controllable behavior.

THEOREM 7. *A controllable behavior can be stabilized with respect to any proper cone S. In fact there is a controller that restricts this behavior to a strongly autonomous behavior stable with respect to S.*

Proof. As S is proper, $S_<$ is nonempty. Given any ξ in $\mathbb{C}^n$ which projects into $S_<$, the function $e^{\langle x,\xi\rangle}$, $x \in \mathbb{R}^n$, is stable with respect to S. The set of all such ξ has nonempty interior.

Observe now that if $(e^{\langle x,\xi\rangle}, \dots, e^{\langle x,\xi\rangle})$ lies in the kernel of a morphism $M : (\mathcal{C}^\infty)^m \to (\mathcal{C}^\infty)^k$ (the image of which defines the given behavior; for being controllable it is MA), then ξ must lie in the characteristic variety of M. We can assume that this characteristic variety is not all of $\mathbb{C}^n$ by Proposition 1 in section 2. Thus this variety has empty interior. Therefore for almost all ξ which project into $S_<$, the function $(e^{\langle x,\xi\rangle}, \dots, e^{\langle x,\xi\rangle})$ does not lie in the kernel of M.

Let $\xi_1, \dots, \xi_r$ be any finite set of points that project into $S_<$ and such that the corresponding exponentials do not lie in the kernel of M. Assume further that $\xi_1, \dots, \xi_r$ is closed under conjugation. Then $\xi_1, \dots, \xi_r$ is an affine variety in $\mathbb{C}^n$ given by an ideal say, $(p_1, \dots, p_t)$ in $\mathcal{A}$; i.e., each p_i has real coefficients. Now consider the matrix

$$\begin{pmatrix} 1 & & & & \\ & 1 & & 0 & \\ & & \ddots & & \\ & & & 1 & \\ & & & & p_1 \\ & 0 & & & \vdots \\ & & & & p_t \end{pmatrix}$$

in $\mathcal{A}^{(m+t-1)\times m}$. Clearly its determinantal ideal is $(p_1, \dots, p_t)$. The AR subbehavior of $(\mathcal{C}^\infty)^m$ defined by the kernel of this matrix is strongly autonomous and hence spanned by a finite number of exponential solutions that are all stable with respect to S. Thus the subbehavior itself is stable with respect to S. Clearly the image under M of such a subbehavior is also strongly autonomous and stable with respect to S. □

We now define the more general pole-placement problem for distributed systems which we pattern after the corresponding problem for lumped systems.

The pole-placement problem. Given a behavior $\mathbf{B}$ defined by R, and any ideal I in $\mathcal{A}$, is there a controller K such that the characteristic ideal of the augmented system $[\begin{smallmatrix} R \\ K \end{smallmatrix}]$ is I?

Observe that if the pole-placement problem can be solved for a behavior $\mathbf{B}$, then it contains nontrivial autonomous subbehaviors stable with respect to any proper cone S in $\mathbb{R}^n$.

A necessary condition for the solution of the above problem is the following.

LEMMA 6. *If the pole-placement problem can be solved for a behavior $\mathbf{B}$, then $\mathbf{B}$ is nonautonomous.*

Proof. Suppose $\mathbf{B}$ defined by R is autonomous. Then its characteristic ideal I is nonzero, and hence the characteristic ideal of any augmented system $[\begin{smallmatrix} R \\ K \end{smallmatrix}]$ contains I. □

The question therefore arises of whether the above is also sufficient. While we have not been able to solve this problem in all generality, we provide partial answers in what follows.

In this paper we treat the pole-placement problem only for free submodules $\mathbf{R}$ of $\mathcal{A}^k$. While this is not the most general situation for distributed systems, it is nonetheless the first generalization of Willems's results on pole placement for lumped systems [9], where everything is free. (Recall also our remarks on free submodules in the introduction.)

We begin by first considering a special class of AR systems introduced in Proposition 3, defined by submodules $\mathbf{R}$ which are direct summands of $\mathcal{A}^k$. By Proposition 3, a behavior defined by such an $\mathbf{R}$ is an MA behavior and hence is controllable. We have already shown that controllable behaviors can be stabilized with respect to any cone S. We now solve the pole-placement problem for such AR systems.

THEOREM 8. *The pole-placement problem can be solved for a behavior* $\mathbf{B}$ *defined by a submodule* $\mathbf{R}$ *which is a direct summand of* $\mathcal{A}^k$.

Proof. Since $\mathbf{R}$ is a direct summand, a basis for it consisting of l elements, say, can be extended to a basis for $\mathcal{A}^k$. Let K be the matrix whose rows are given by the $(k-l)$ elements that extend the basis for $\mathbf{R}$ above. Then the controller defined by the matrix K is such that the characteristic ideal of $\left[\begin{smallmatrix} R \\ K \end{smallmatrix}\right]$ is (u), where u is some unit in $\mathcal{A}$. Hence by replacing the last row of K by $u^{-1}r$ times that row (for some $r \in \mathcal{A}$), we can obtain a controller yielding the characteristic ideal (r).

Now let I be any ideal of $\mathcal{A}$, generated by $p_1, \dots, p_t$, say. Then we construct a controller K' from K as follows : K' has $k-l+t-1$ rows, where the first $k-l-1$ rows are the same as the first $k-l-1$ rows of K. The remaining t rows of K' are obtained by multiplying the last row of K by $u^{-1}p_1, \dots, u^{-1}p_t$, respectively.

The characteristic ideal of the augmented system $\left[\begin{smallmatrix} R \\ K' \end{smallmatrix}\right]$ is generated by the determinants of its $k \times k$ submatrices. If, in any $k \times k$ submatrix, more than $k-l$ rows of K' appear, then by construction the determinant is zero. Thus every nonzero determinant is obtained by choosing all the l rows of R and some $k-l$ rows of K'. Thus the characteristic ideal of the augmented system $\left[\begin{smallmatrix} R \\ K' \end{smallmatrix}\right]$ is precisely I. □

Observe from the proof of the above theorem that every principal ideal in $\mathcal{A}$ can be obtained as a characteristic ideal of a system augmented by a *free* controller. In [9], Willems shows that given a controllable system R in $\mathbb{R}^{l\times k}[\frac{d}{dx}]$ and any polynomial r in $\mathbb{R}[\frac{d}{dx}]$, there is a controller K in $\mathbb{R}^{(k-l)\times k}[\frac{d}{dx}]$ such that the characteristic polynomial of the augmented system $\left[\begin{smallmatrix} R \\ K \end{smallmatrix}\right]$ is (r). The theorem above is therefore the generalization of this result to distributed systems. For we have already shown that a lumped controllable system is given by a left prime matrix, i.e., by a submodule of $(\mathbb{R}[\frac{d}{dx}])^k$ which is a direct summand. See Proposition 3 and Corollary 3.

We therefore have solved the pole-placement problem for this special class of AR systems. We wish to extend these results to more general systems given by free submodules of $\mathcal{A}^k$.

We now address the question as to which principal ideals can be obtained using a free controller for systems defined by free submodules.

Let $\mathbf{R}$ be a free submodule of $\mathcal{A}^k$ of rank l and let R be any matrix representation for $\mathbf{R}$. Let $I_l(\mathbf{R})$ be its lth determinant ideal. Let $e_1, \dots, e_k$ be the (standard) basis of $\mathcal{A}^k$. Let $f_1, \dots, f_l$ in $\mathcal{A}^k$ freely generate the submodule $\mathbf{R}$. Consider the following map:

$$\phi : \Lambda^{k-l}\mathcal{A}^k \to \Lambda^k\mathcal{A}^k,$$

$$\sum g_1 \wedge \cdots \wedge g_{k-l} \mapsto \sum f_1 \wedge \cdots \wedge f_l \wedge g_1 \wedge \cdots \wedge g_{k-l}.$$

This is clearly an $\mathcal{A}$-module morphism. As $\Lambda^k \mathcal{A}^k$ is isomorphic to $\mathcal{A}$, the image of ϕ is therefore an ideal in $\mathcal{A}$. This image is of course spanned by the images of any basis for $\Lambda^{k-l}\mathcal{A}^k$.

Consider the following basis for $\Lambda^{k-l}\mathcal{A}^k$ obtained from the basis $e_1, \ldots, e_k$ for $\mathcal{A}^k$ by choosing a $(k-l)$-tuple from it, namely, elements of the form $e_{i_1} \wedge e_{i_2} \wedge \cdots \wedge e_{i_{k-l}}$ for $1 \leq i_1 < i_2 < \cdots < i_{k-l} \leq k$. The image of $e_{i_1} \wedge e_{i_2} \wedge \cdots \wedge e_{i_{k-l}}$ under ϕ is, up to sign, the determinant of the $l \times l$ submatrix of R obtained by choosing l columns of R which are *not* $i_1, i_2, \ldots, i_{k-l}$. However, this determinant is one of the generators of $I_l(\mathbf{R})$. Thus the image of the morphism ϕ is precisely $I_l(\mathbf{R})$. Hence if the controller is to be defined by a free submodule of rank $(k-l)$, then the characteristic ideal of the augmented system is a principal ideal that must lie in $I_l(\mathbf{R})$.

The question now is whether every principal ideal contained in $I_l(\mathbf{R})$ can be so obtained. To answer this observe that if K is a free controller of rank $(k-l)$, then the characteristic ideal of the augmented system $[\begin{smallmatrix} R \\ K \end{smallmatrix}]$ is a principal ideal generated by $f_1 \wedge \cdots \wedge f_l \wedge g_1 \wedge \cdots \wedge g_{k-l}$, where $g_1, \ldots, g_{k-l}$ are the rows of K. Thus these ideals come from the image under ϕ of homogeneous elements, denoted by $\mathcal{H}^{k-l}$, in $\Lambda^{k-l}\mathcal{A}^k$. Thus $\phi(\mathcal{H}^{k-l})$ correspond to the principal ideals in $I_l(\mathbf{R})$ which can be obtained by a free controller of rank $(k-l)$. It is also easy to see that $\phi(\mathcal{H}^{k-l})$ is in correspondence with free submodules of $\mathcal{A}^k$ of rank k, which contain $\mathbf{R}$ as a direct summand.

COROLLARY 10. *Let* $\mathbf{R}$ *be a free submodule of* $\mathcal{A}^k$ *of rank* $k-1$. *Then every principal ideal in* $I_{k-1}(\mathbf{R})$ *can be obtained by a free controller of rank* 1.

Proof. From the above discussion, observe that if l equals $k-1$, then $\mathcal{H}^{k-l} = \mathcal{H}^1$ is equal to all of $\Lambda^1\mathcal{A}^k$. Thus every element in $\Lambda^1\mathcal{A}^k$ is in $\mathcal{H}^1$ and so $\phi(\mathcal{H}^1)$ is all of $I_{k-1}(\mathbf{R})$. □

A constructive proof for the above corollary can also be given. Let R be a matrix representation of $\mathbf{R}$. Let (r) be any principal ideal contained in $I_{k-1}(\mathbf{R})$. Then $r = \sum a_i p_i$, where p_i is the determinant of the $(k-1) \times (k-1)$ submatrix of R obtained by dropping the ith column of R and $a_i \in \mathcal{A}$ for $i = 1, \ldots, k$. Then the controller given by $K = (a_1, -a_2, \ldots, (-1)^{i-1}a_i, \ldots, (-1)^{k-1}a_k)$ would give an augmented system that has (r) as its characteristic ideal.

COROLLARY 11. *Let* $\mathbf{R}$ *be a submodule of* $\mathcal{A}^k$ *and let* R *in* $\mathcal{A}^{l \times k}$ *be a matrix representation for it. Let* K *be a controller given by a submodule generated by* $g_1, \ldots, g_N$. *Suppose that every subset of* $\{g_1, \ldots, g_N\}$ *containing* $k-l+1$ *elements is* $\mathcal{A}$*-dependent. Then the characteristic ideal of the augmented system* $[\begin{smallmatrix} R \\ K \end{smallmatrix}]$ *is contained in* $I_l(\mathbf{R})$.

Proof. The proof is clear from the proof of Theorem 8 and the discussion following it. □

Remark. More generally in the above corollary, if every subset of $\{g_1, \ldots, g_N\}$ containing $k-l+t$ elements were $\mathcal{A}$-dependent, then the characteristic ideal of the augmented system would be contained in $I_{l-t+1}(\mathbf{R})$.

We have shown that a principal reason for the complexities of distributed behaviors as compared to lumped behaviors is due to the existence of submodules that are not free. We have, however, shown that in low projective dimensions (i.e., less than or equal to 2), the imposition of the property of controllability on a behavior forces the corresponding submodule to be free. This explains why controllable 2-D systems, even though not defined over a principal ideal domain, exhibit properties similar to controllable lumped systems. Our treatment therefore not only extends the results of Willems, and Rocha and Willems, on 1-D and discrete 2-D systems, but also provides a better understanding of this phenomena. Our treatment also shows why n-D systems for $n \geq 3$ are essentially different from 2-D systems. Our treatment of the pole-placement problem was essentially confined to behaviors given by free submodules. The pole-placement problem for general submodules will be considered elsewhere. Applications of this theory to specific distributed systems will also appear elsewhere [7].

Acknowledgments. We would like to thank the referees of an earlier version of this paper for their comments which led to significant improvements.

$\mathcal{H}_\infty$ CONTROL OF DIFFUSION SYSTEMS BY USING A FINITE-DIMENSIONAL CONTROLLER[*]

HIDEKI SANO[†] AND YOSHIYUKI SAKAWA[‡]

Abstract. In this paper, we consider $\mathcal{H}_\infty$ control of linear and semilinear diffusion systems by using a finite-dimensional controller. The main aim is to construct a finite-dimensional stabilizing controller for the linear diffusion system that makes the $\mathcal{H}_\infty$ norm of the closed-loop transfer function less than a given positive number δ. For that purpose, we first derive a finite-dimensional reduced-order system for the linear diffusion system. Then, a stabilizing controller that makes the $\mathcal{H}_\infty$ norm of the closed-loop transfer function less than another positive number is constructed for the reduced-order model. It is proved that the finite-dimensional controller, together with a residual mode filter, plays a role of a finite-dimensional stabilizing controller that makes the $\mathcal{H}_\infty$ norm of the closed-loop transfer function less than δ for the original linear diffusion system if the order of residual mode filter is chosen sufficiently large. Moreover, it is shown that the finite-dimensional $\mathcal{H}_\infty$ controller constructed for the linear diffusion system also works as a finite-dimensional $\mathcal{H}_\infty$ controller for a semilinear diffusion system with sufficiently small nonlinear term.

1. Introduction.

In recent years, $\mathcal{H}_\infty$ control theory for distributed parameter systems has been developed by extending the existing results for lumped parameter systems. In particular, $\mathcal{H}_\infty$ control with measurement feedback, which is of special importance from the practical point of view, has been investigated by Van Keulen [4]. In [4] the results given by Doyle et al. [3] are extended to the infinite-dimensional case by using the infinite-dimensional version of Redheffer's lemma developed by Van Keulen, and $\mathcal{H}_\infty$ controllers are constructed by using the solutions to two kinds of Riccati equations in an infinite-dimensional space. However, it seems difficult to apply Van Keulen's algorithm directly to actual infinite-dimensional systems, because the controllers obtained there are of infinite-dimension. In this paper, we study a design method of finite-dimensional $\mathcal{H}_\infty$ controllers for linear and semilinear diffusion systems. In our design method, we need not solve Riccati equations numerically in an infinite-dimensional space nor to reduce infinite-dimensional controllers to finite-dimensional ones by using approximation techniques. Instead, we use residual mode filters, which were originally adopted for the problem of stabilizing distributed parameter systems of modal type by using finite-dimensional dynamic compensators (see [6], [1], [7]).

In this paper, in order to construct a finite-dimensional controller that internally stabilizes the linear diffusion system and makes the $\mathcal{H}_\infty$ norm of the closed-loop transfer function from the disturbance input w to the controlled output z less than $\delta > 0$, we first derive a finite-dimensional model for the linear diffusion system. Next, we construct a stabilizing controller for the finite-dimensional model such that the $\mathcal{H}_\infty$

norm of the closed-loop transfer function from w to z is less than γ $(0 < \gamma < \delta)$, by using the algorithm given by Doyle et al. [3]. However, the finite-dimensional controller constructed in this way is not necessarily a stabilizing controller for the original infinite-dimensional system that makes the $\mathcal{H}_\infty$ norm of the closed-loop transfer function from w to z less than δ. Therefore, we consider a controller consisting of the above controller and a residual mode filter. One of our main results in this paper is to prove that a controller, which consists of a residual mode filter and the finite-dimensional controller constructed for the finite-dimensional model, yields a finite-dimensional stabilizing controller such that the closed-loop transfer function from w to z has $\mathcal{H}_\infty$ norm less than δ for the given original infinite-dimensional system if the order of the residual mode filter is chosen sufficiently large. Moreover, it is shown that the finite-dimensional $\mathcal{H}_\infty$ controller constructed for the linear diffusion system also works as a finite-dimensional $\mathcal{H}_\infty$ controller for a semilinear diffusion system with sufficiently small Lipschitz constant.

2. $\mathcal{H}_\infty$ control of linear diffusion systems.

2.1. System description. Let H be a real Hilbert space with inner product $\langle\,\cdot\,,\,\cdot\,\rangle$ and associated norm $\|\cdot\|$. We shall consider the linear system of the form

$$(2.1)\qquad \begin{cases} \dfrac{dx(t)}{dt} = Ax(t) + B_1 w(t) + B_2 u(t) \quad (t > 0), \quad x(0) = x_0, \\ z(t) = C_1 x(t) + D_{12} u(t), \\ y(t) = C_2 x(t) + D_{21} w(t), \end{cases}$$

where $x(t) \in H$ is the state, $w(t) \in \mathbf{R}^{m_1}$ is the disturbance input, $u(t) \in \mathbf{R}^{m_2}$ is the control input, $z(t) \in \mathbf{R}^{p_1}$ is the controlled output, and $y(t) \in \mathbf{R}^{p_2}$ is the measured output. A is the infinitesimal generator of a C_0-semigroup e^{tA} on H. Moreover, we assume that A is self-adjoint and that A has compact resolvent. From these assumptions for the operator A, by using the Hilbert–Schmidt theory for compact self-adjoint operators, it follows that there exists a set of eigenpairs $(\lambda_i,\, \phi_{ij})$ with finite multiplicity μ_i, such that

(1) $\sigma(A) = \{\, \lambda_1,\, \lambda_2,\, \dots \}$, with $\lambda_1 > \lambda_2 > \cdots > \lambda_i > \cdots$, $\lim_{i\to\infty} \lambda_i = -\infty$,

(2) $A\phi_{ij} = \lambda_i \phi_{ij} \quad (i \geq 1,\, 1 \leq j \leq \mu_i)$,

(3) $\{\, \phi_{ij}\,;\, i \geq 1,\, 1 \leq j \leq \mu_i \,\}$ forms a complete orthonormal system in H,

where $\sigma(A)$ denotes the spectrum of A. Therefore, $x \in H$ has a unique expression

$$x = \sum_{i=1}^{\infty} \sum_{j=1}^{\mu_i} \langle x, \phi_{ij} \rangle \phi_{ij},$$

and the operator A is expressed as

$$Ax = \sum_{i=1}^{\infty} \sum_{j=1}^{\mu_i} \lambda_i \langle x, \phi_{ij} \rangle \phi_{ij} \quad \text{for } x \in D(A),$$

where

$$D(A) = \left\{ x \in H\,;\, \sum_{i=1}^{\infty} \sum_{j=1}^{\mu_i} \lambda_i^2 \langle x, \phi_{ij} \rangle^2 < \infty \right\}.$$

The C_0-semigroup e^{tA} generated by A is analytic in $t > 0$, and it is given as

$$e^{tA}x = \sum_{i=1}^{\infty} \sum_{j=1}^{\mu_i} e^{\lambda_i t} \langle x, \phi_{ij} \rangle \phi_{ij} \quad (t \geq 0,\, x \in H).$$

In (2.1), $B_1 : \mathbf{R}^{m_1} \to H$, $B_2 : \mathbf{R}^{m_2} \to H$, $C_1 : H \to \mathbf{R}^{p_1}$, $C_2 : H \to \mathbf{R}^{p_2}$ are bounded linear operators, and D_{12} is a $p_1 \times m_2$ matrix and D_{21} is a $p_2 \times m_1$ matrix.

In this paper, we impose the following assumptions for the operators and the matrices appearing in (2.1):

(A1) The pair (A, B_1) is stabilizable and the pair (C_1, A) is detectable, where the former means that there exists a bounded linear operator $F_1 : H \to \mathbf{R}^{m_1}$ such that the analytic semigroup generated by $A + B_1F_1$ is exponentially stable, and the latter means that there exists a bounded linear operator $K_1 : \mathbf{R}^{p_1} \to H$ such that the analytic semigroup generated by $A + K_1C_1$ is exponentially stable.

(A2) The pair (A, B_2) is stabilizable and the pair (C_2, A) is detectable.

(A3) $D_{12}^T C_1 = 0$, $D_{12}^T D_{12} = I$, where D_{12}^T denotes the transpose of D_{12}.

(A4) $B_1 D_{21}^T = 0$, $D_{21} D_{21}^T = I$.

Moreover, it is assumed that $x_0 \in H$. As is well known, the system (2.1) represents a linear diffusion system subjected to both the disturbance input and the control input.

2.2. $\mathcal{H}_\infty$control problem. In the system (2.1), if a proper control law $u = K(s)y$ is given, the closed-loop transfer function from w to z can be calculated, which will be denoted by $G_{zw}(s)$.

Given a positive number $\delta > 0$, the problem is to find a finite-dimensional control law $u = K(s)y$ such that the controller is internally stabilizing the system (2.1), and that $\|G_{zw}(\cdot)\|_{\mathcal{H}_\infty(\mathcal{L}(\mathbf{C}^{m_1},\mathbf{C}^{p_1}))} < \delta$, where

$$\|G_{zw}(\cdot)\|_{\mathcal{H}_\infty(\mathcal{L}(\mathbf{C}^{m_1},\mathbf{C}^{p_1}))} := \sup_{s \in \mathbf{C}^+} \|G_{zw}(s)\|_{\mathcal{L}(\mathbf{C}^{m_1},\mathbf{C}^{p_1})},$$
$$\mathbf{C}^+ := \{\, s \in \mathbf{C}\,;\, \mathrm{Re}(s) > 0 \,\}.$$

Any finite-dimensional controller that satisfies the above two conditions will be called a finite-dimensional $\mathcal{H}_\infty$ controller.

Remarks. (i) In this paper, we do not discuss how to find a finite-dimensional stabilizing controller that minimizes $\|G_{zw}(\cdot)\|_{\mathcal{H}_\infty(\mathcal{L}(\mathbf{C}^{m_1},\mathbf{C}^{p_1}))}$ under the order constraint. This problem is very important from the practical point of view, but it is difficult to solve.

(ii) In [4] Van Keulen has given a design method of infinite-dimensional controllers satisfying the above two properties for a large class of infinite-dimensional systems.

3. Finite-dimensional $\mathcal{H}_\infty$controllers for linear diffusion systems.

3.1. Partitioned system. First of all, let us define the positive number β as

$$\begin{aligned}\beta := \max\Big\{ &1,\ \|C_1\|\,\|B_2\|\,\|D_{12}^T\|,\ \|C_1\|\,\|B_1\|,\ \|D_{21}^T\|\,\|C_2\|\,\|B_1\|,\\ &\|C_1\|\,\|B_2\|\,\|D_{12}^T\|\,\|D_{21}^T\|\,\|C_2\|\,\|B_1\| \Big\}.\end{aligned} \tag{3.1}$$

Let $\delta > 0$ and $\theta \in (0, 1)$ be given positive numbers. To derive a finite-dimensional model for the system (2.1), we define the orthogonal projection P_K by

$$P_K x = \sum_{i=1}^{K} \sum_{j=1}^{\mu_i} \langle x, \phi_{ij} \rangle \phi_{ij}.$$

Using the operator P_K, we decompose the system (2.1) according to the following steps.

Step 1. Given a positive number $\epsilon \in (0, \frac{\theta\delta}{\beta})$, we choose an integer l (≥ 1) such that

$$0 < \frac{1}{-\lambda_{l+1}} < \epsilon.$$

Step 2. We take another integer n such that $n > l$.

Step 3. Using the operators P_l and P_n corresponding to the integers l and n, we decompose the state variable $x(t)$ as follows:

$$x(t) = x_1(t) + x_2(t) + x_3(t),$$

where $x_1(t) := P_l x(t)$, $x_2(t) := (P_n - P_l)x(t)$, $x_3(t) := (I - P_n)x(t)$. The state space H can also be decomposed as

$$H = H_1 \oplus H_2 \oplus H_3,$$

where $H_1 := P_l H$, $H_2 := (P_n - P_l)H$, $H_3 := (I - P_n)H$, and their dimensions are given as $\dim H_1 = \bar{l}$, $\dim H_2 = \bar{n} - \bar{l}$, $\dim H_3 = \infty$. In the above $\bar{l} := \mu_1 + \mu_2 + \cdots + \mu_l$, $\bar{n} := \mu_1 + \mu_2 + \cdots + \mu_n$. Therefore, we see that the system (2.1) can be decomposed as follows:

$$\begin{cases} \dfrac{dx_1(t)}{dt} = A_1 x_1(t) + B_{11} w(t) + B_{21} u(t), \quad x_1(0) = x_{01}, \\ \dfrac{dx_2(t)}{dt} = A_2 x_2(t) + B_{12} w(t) + B_{22} u(t), \quad x_2(0) = x_{02}, \\ \dfrac{dx_3(t)}{dt} = A_3 x_3(t) + B_{13} w(t) + B_{23} u(t), \quad x_3(0) = x_{03}, \\ z(t) = C_{11} x_1(t) + C_{12} x_2(t) + C_{13} x_3(t) + D_{12} u(t), \\ y(t) = C_{21} x_1(t) + C_{22} x_2(t) + C_{23} x_3(t) + D_{21} w(t), \end{cases}$$

where

$$\begin{cases} A_1 := P_l A P_l, \\ B_{11} := P_l B_1, \\ B_{21} := P_l B_2, \\ C_{11} := C_1 P_l, \\ C_{21} := C_2 P_l, \\ x_{01} := P_l x_0, \end{cases} \quad \begin{cases} A_2 := (P_n - P_l) A (P_n - P_l), \\ B_{12} := (P_n - P_l) B_1, \\ B_{22} := (P_n - P_l) B_2, \\ C_{12} := C_1 (P_n - P_l), \\ C_{22} := C_2 (P_n - P_l), \\ x_{02} := (P_n - P_l) x_0, \end{cases} \quad \begin{cases} A_3 := (I - P_n) A (I - P_n), \\ B_{13} := (I - P_n) B_1, \\ B_{23} := (I - P_n) B_2, \\ C_{13} := C_1 (I - P_n), \\ C_{23} := C_2 (I - P_n), \\ x_{03} := (I - P_n) x_0. \end{cases}$$

In the above, only the operator A_3 is unbounded, whereas the other operators are bounded.

Hereafter, the Hilbert space H_1 will be identified with the Euclidean space $\mathbf{R}^{\bar{l}}$ with respect to the basis $(\phi_{11}, \ldots, \phi_{1\mu_1}, \ldots, \phi_{l,\mu_l})$. Thus, $x_1 \in H_1$ will be identified with the $\bar{l}$-dimensional vector, and the operators A_1, B_{11}, B_{21}, C_{11}, C_{21} are identified with the matrices, respectively. In the same way, $x_2 \in H_2$ will be identified with the $(\bar{n} - \bar{l})$-dimensional vector, and the operators A_2, B_{12}, B_{22}, C_{12}, C_{22} are identified with the matrices, respectively.

3.2. Design of finite-dimensional $\mathcal{H}_\infty$controllers using residual mode filters. In connection with (2.1), let us consider a finite-dimensional model given by

$$\begin{cases} \dfrac{dx_1(t)}{dt} = A_1x_1(t) + B_{11}w(t) + B_{21}u(t), \\ z(t) = C_{11}x_1(t) + D_{12}u(t), \\ y(t) = C_{21}x_1(t) + D_{21}w(t). \end{cases} \tag{3.2}$$

Then, by [9, Proposition 4.12 and Proposition 4.13], it is easy to see that the assumptions (A1) and (A2) for the original infinite-dimensional system (2.1) imply that

(A1$'$) the pair (A_1, B_{11}) is stabilizable and the pair (C_{11}, A_1) is detectable, and

(A2$'$) the pair (A_1, B_{21}) is stabilizable and the pair (C_{21}, A_1) is detectable.

Moreover, noting that $C_{11} = C_1P_l$ and $B_{11} = P_lB_1$, we see that the assumptions (A3) and (A4) imply

(A3$'$) $D_{12}^TC_{11} = 0$, $D_{12}^TD_{12} = I$, and

(A4$'$) $B_{11}D_{21}^T = 0$, $D_{21}D_{21}^T = I$.

Given a proper control law $u = \tilde{K}(s)y$, we denote by $T_{zw}(s)$ the closed-loop transfer function from w to z for the finite-dimensional model (3.2). Here, for the given positive numbers $\delta > 0$, $\theta \in (0, 1)$, and $\epsilon \in (0, \frac{\theta\delta}{\beta})$, let us define γ by

$$\gamma := \frac{1}{(1+\epsilon)^2}\left(\frac{\theta\delta}{\beta} - \epsilon\right) \in (0, \delta). \tag{3.3}$$

We seek a controller $u = \tilde{K}(s)y$ that satisfies the following two conditions.

Condition 1. The controller is internally stabilizing the finite-dimensional system (3.2).

Condition 2. $\|T_{zw}(\cdot)\|_{\mathcal{H}_\infty(\mathcal{L}(\mathbf{C}^{m_1},\mathbf{C}^{p_1}))} < \gamma$.

From the results given by Doyle et al. [3], under the conditions (A1$'$)–(A4$'$) for the finite-dimensional system (3.2), there exists a controller $u = \tilde{K}(s)y$ that satisfies the above two conditions 1 and 2 if and only if, for the matrices H_∞ and J_∞ defined by

$$H_\infty := \begin{bmatrix} A_1 & \gamma^{-2}B_{11}B_{11}^T - B_{21}B_{21}^T \\ -C_{11}^TC_{11} & -A_1^T \end{bmatrix},$$

$$J_\infty := \begin{bmatrix} A_1^T & \gamma^{-2}C_{11}^TC_{11} - C_{21}^TC_{21} \\ -B_{11}B_{11}^T & -A_1 \end{bmatrix},$$

the following conditions hold:

(B1) $H_\infty \in \mathrm{dom(Ric)}$, $X_\infty := \mathrm{Ric}(H_\infty) \geq 0$,

(B2) $J_\infty \in \mathrm{dom(Ric)}$, $Y_\infty := \mathrm{Ric}(J_\infty) \geq 0$,

(B3) $\rho(X_\infty Y_\infty) < \gamma^2$,

where the notations dom(Ric) and Ric(H_∞) are as defined in [3], and $\rho(X_\infty Y_\infty)$ denotes the spectral radius of the matrix $X_\infty Y_\infty$.

Hereafter, it is supposed that the conditions (B1)–(B3) are satisfied. Then, by [3], all the stabilizing controllers that satisfy $\|T_{zw}(\cdot)\|_{\mathcal{H}_\infty(\mathcal{L}(\mathbf{C}^{m_1},\mathbf{C}^{p_1}))} < \gamma$ for the finite-dimensional model (3.2) are given as follows:

$$\begin{cases} \dfrac{dq(t)}{dt} = \hat{A}_\infty q(t) - Z_\infty L_\infty y(t) + Z_\infty B_{21}v(t), \quad q(0) = q_0, \\ u(t) = F_\infty q(t) + v(t), \\ r(t) = -C_{21}q(t) + y(t), \end{cases} \tag{3.4}$$

$$\text{(3.5)}\qquad \begin{cases} \dfrac{d\lambda(t)}{dt} = A_\Lambda \lambda(t) + B_\Lambda r(t), \quad \lambda(0) = \lambda_0, \\ v(t) = C_\Lambda \lambda(t) + D_\Lambda r(t), \end{cases}$$

where

$$\hat{A}_\infty := A_1 + \gamma^{-2} B_{11} B_{11}^T X_\infty + B_{21} F_\infty + Z_\infty L_\infty C_{21},$$
$$F_\infty := -B_{21}^T X_\infty, \quad L_\infty := -Y_\infty C_{21}^T, \quad Z_\infty := (I - \gamma^{-2} Y_\infty X_\infty)^{-1},$$

and the linear system $(A_\Lambda, B_\Lambda, C_\Lambda, D_\Lambda)$ indicates a free parameter such that

$$\begin{cases} \operatorname{Re}\sigma(A_\Lambda) < 0, \\ \|C_\Lambda((\cdot)I - A_\Lambda)^{-1} B_\Lambda + D_\Lambda\|_{\mathcal{H}_\infty(\mathcal{L}(\mathbf{C}^{p_2}, \mathbf{C}^{m_2}))} < \gamma, \end{cases}$$

$\sigma(A_\Lambda)$ being the spectrum of A_Λ.

For simplicity, let us assume $D_\Lambda = 0$ in (3.5). Then, the closed-loop system consisting of the finite-dimensional model (3.2) and the controller (3.4), (3.5) is written as follows:

$$\begin{cases} \dfrac{d\eta(t)}{dt} = \mathcal{A}_1 \eta(t) + \mathcal{B}_1 w(t), \quad \eta(0) = \eta_0, \\ z(t) = \mathcal{C}_1 \eta(t), \end{cases}$$

where

$$\eta(t) := \begin{bmatrix} x_1(t) \\ p(t) \end{bmatrix} \quad \left(p(t) := \begin{bmatrix} q(t) \\ \lambda(t) \end{bmatrix} \right)$$

is in $\mathbf{R}^{\bar{l}} \times (\mathbf{R}^{\bar{l}} \times \mathbf{R}^S)$ ($\mathbf{R}^S$ denotes the state space of the free parameter (3.5)), and the matrices $\mathcal{A}_1$, $\mathcal{B}_1$, and $\mathcal{C}_1$ are defined by

$$\mathcal{A}_1 := \begin{bmatrix} A_1 & B_{21} L \\ N C_{21} & M \end{bmatrix}, \quad \mathcal{B}_1 := \begin{bmatrix} B_{11} \\ N D_{21} \end{bmatrix}, \quad \mathcal{C}_1 := \begin{bmatrix} C_{11} & D_{12} L \end{bmatrix},$$

$$M := \begin{bmatrix} \hat{A}_\infty & Z_\infty B_{21} C_\Lambda \\ -B_\Lambda C_{21} & A_\Lambda \end{bmatrix}, \quad N := \begin{bmatrix} -Z_\infty L_\infty \\ B_\Lambda \end{bmatrix}, \quad L := \begin{bmatrix} F_\infty & C_\Lambda \end{bmatrix}.$$

The condition 1 that the controller $\tilde{K}(s)$ is internally stabilizing the system means that the matrix $e^{t\mathcal{A}_1}$ is exponentially stable, i.e., there exist positive constants $m\,(\geq 1)$ and α such that

$$\text{(3.6)}\qquad \|e^{t\mathcal{A}_1}\| \leq m e^{-\alpha t} \quad (t \geq 0).$$

It should be noted that both m and α do not depend on the integer n. Also, noting that $T_{zw}(s) = \mathcal{C}_1 (sI - \mathcal{A}_1)^{-1} \mathcal{B}_1$, we see that Condition 2 is equivalent to the inequality

$$\text{(3.7)}\qquad \|\mathcal{C}_1((\cdot)I - \mathcal{A}_1)^{-1} \mathcal{B}_1\|_{\mathcal{H}_\infty(\mathcal{L}(\mathbf{C}^{m_1}, \mathbf{C}^{p_1}))} < \gamma.$$

However, it cannot be ensured that the controller (3.4), (3.5) works as a finite-dimensional stabilizing controller that satisfies $\|G_{zw}(\cdot)\|_{\mathcal{H}_\infty(\mathcal{L}(\mathbf{C}^{m_1}, \mathbf{C}^{p_1}))} < \delta$ for the given original infinite-dimensional system (2.1).

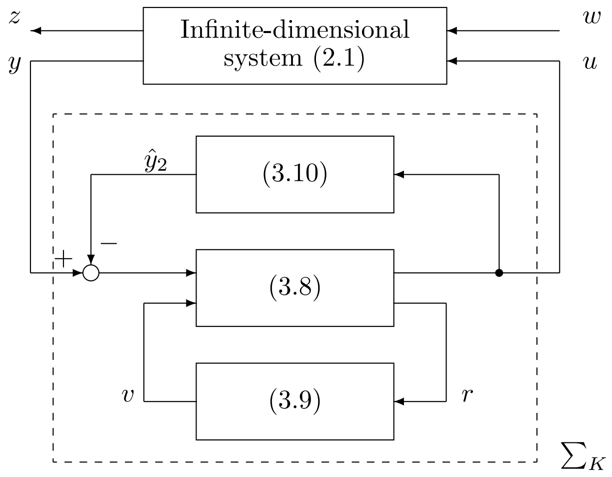

FIG. 1. *Finite-dimensional $\mathcal{H}_\infty$ controller Σ_K.*

Let us consider a controller, which consists of the controller (3.4), (3.5) with $D_\Lambda = 0$ constructed for (3.2) as well as a residual mode filter

$$\begin{cases} \dfrac{d\hat{x}_2(t)}{dt} = A_2\hat{x}_2(t) + B_{22}u(t), \quad \hat{x}_2(0) = \hat{x}_{20}, \\ \hat{y}_2(t) = C_{22}\hat{x}_2(t). \end{cases}$$

Then, the whole controller Σ_K (see Fig. 1) is described by

$$\text{(3.8)} \quad \begin{cases} \dfrac{dq(t)}{dt} = \hat{A}_\infty q(t) - Z_\infty L_\infty(y(t) - \hat{y}_2(t)) + Z_\infty B_{21}v(t), \quad q(0) = q_0, \\ u(t) = F_\infty q(t) + v(t), \\ r(t) = -C_{21}q(t) + y(t) - \hat{y}_2(t), \end{cases}$$

$$\text{(3.9)} \quad \begin{cases} \dfrac{d\lambda(t)}{dt} = A_\Lambda \lambda(t) + B_\Lambda r(t), \quad \lambda(0) = \lambda_0, \\ v(t) = C_\Lambda \lambda(t), \end{cases}$$

$$\text{(3.10)} \quad \begin{cases} \dfrac{d\hat{x}_2(t)}{dt} = A_2\hat{x}_2(t) + B_{22}u(t), \quad \hat{x}_2(0) = \hat{x}_{20}, \\ \hat{y}_2(t) = C_{22}\hat{x}_2(t). \end{cases}$$

The following theorem is one of our main results.

THEOREM 3.1. *Suppose that the assumptions* (A1)–(A4) *are satisfied. Let $\delta > 0$, $\theta \in (0,1)$, and $\epsilon \in (0, \frac{\theta\delta}{\beta})$ be given constants, where the constant β is defined by* (3.1), *and let the integers l and n be chosen such that $0 < \frac{1}{-\lambda_{l+1}} < \epsilon$ and $n > l$ hold, where λ_{l+1} is the $(l+1)$th eigenvalue of the operator A. Moreover, let the conditions* (B1)–(B3) *be satisfied with $\gamma = \frac{1}{(1+\epsilon)^2}(\frac{\theta\delta}{\beta} - \epsilon) \in (0, \delta)$. Then, the controller Σ_K, which consists of* (3.8), (3.9), *and* (3.10), *gives a finite-dimensional stabilizing controller that satisfies $\|G_{zw}(\cdot)\|_{\mathcal{H}_\infty(\mathcal{L}(\mathbf{C}^{m_1},\mathbf{C}^{p_1}))} < \delta$ for the linear infinite-dimensional system* (2.1) *if the integer n is taken sufficiently large.*

4. Proof of Theorem 3.1. First of all, let us state the lemma which will be frequently used in this section.

LEMMA 4.1 (Lemma 4.1 in [8]). *Let A_{11} and A_{22} be the generators of C_0-semigroups $S_1(t)$, $S_2(t)$ with $\|S_1(t)\|_{\mathcal{L}(X_1)} \leq M_1 e^{\omega_1 t}$, $\|S_2(t)\|_{\mathcal{L}(X_2)} \leq M_2 e^{\omega_2 t}$ $(\omega_1 \neq \omega_2)$ for $t \geq 0$ on Hilbert spaces X_1, X_2, respectively, and let $A_{12} : X_2 \to X_1$ and $A_{21} : X_1 \to X_2$ be bounded linear operators. Then, the C_0-semigroup $\bar{S}_{21}(t)$ on $X_1 \times X_2$ generated by the operator $\left[\begin{smallmatrix} A_{11} & 0 \\ A_{21} & A_{22} \end{smallmatrix}\right]$ and the C_0-semigroup $\bar{S}_{12}(t)$ on $X_1 \times X_2$ generated by the operator $\left[\begin{smallmatrix} A_{11} & A_{12} \\ 0 & A_{22} \end{smallmatrix}\right]$ have the following operator norm bounds:*

$$\|\bar{S}_{21}(t)\|_{\mathcal{L}(X_1 \times X_2)} \leq \max(M_1, M_2)\left(1 + \frac{\max(M_1, M_2)\|A_{21}\|_{\mathcal{L}(X_1, X_2)}}{|\omega_1 - \omega_2|}\right) e^{\max(\omega_1, \omega_2)t} \quad \textit{for} \quad t \geq 0,$$

$$\|\bar{S}_{12}(t)\|_{\mathcal{L}(X_1 \times X_2)} \leq \max(M_1, M_2)\left(1 + \frac{\max(M_1, M_2)\|A_{12}\|_{\mathcal{L}(X_2, X_1)}}{|\omega_1 - \omega_2|}\right) e^{\max(\omega_1, \omega_2)t} \quad \textit{for} \quad t \geq 0.$$

Let us introduce the variable $e_2(t) := x_2(t) - \hat{x}_2(t)$. Then, the closed-loop system of state equations from w to z in Fig. 1 is written as follows:

$$\begin{cases} \dfrac{d\xi(t)}{dt} = (\mathcal{A} + \Delta\mathcal{A})\xi(t) + (\mathcal{B} + \Delta\mathcal{B})w(t), \quad \xi(0) = \xi_0, \\ z(t) = (\mathcal{C} + \Delta\mathcal{C})\xi(t), \end{cases}$$

where the state vector

$$\xi(t) := \begin{bmatrix} x_1(t) \\ p(t) \\ x_2(t) \\ x_3(t) \\ e_2(t) \end{bmatrix} \quad \left(p(t) := \begin{bmatrix} q(t) \\ \lambda(t) \end{bmatrix}\right)$$

is in a real Hilbert space $X := \mathbf{R}^{\bar{l}} \times (\mathbf{R}^{\bar{l}} \times \mathbf{R}^{S}) \times \mathbf{R}^{\bar{n}-\bar{l}} \times H_3 \times \mathbf{R}^{\bar{n}-\bar{l}}$ with the inner product $\langle \cdot, \cdot \rangle_X$ defined by

$$\langle \xi, \tilde{\xi} \rangle_X := x_1^T \tilde{x}_1 + p^T \tilde{p} + x_2^T \tilde{x}_2 + \langle x_3, \tilde{x}_3 \rangle + e_2^T \tilde{e}_2$$
$$\text{for} \quad \xi = \begin{bmatrix} x_1 \\ p \\ x_2 \\ x_3 \\ e_2 \end{bmatrix}, \ \tilde{\xi} = \begin{bmatrix} \tilde{x}_1 \\ \tilde{p} \\ \tilde{x}_2 \\ \tilde{x}_3 \\ \tilde{e}_2 \end{bmatrix} \in X,$$

and the operators $\mathcal{A}$, $\Delta\mathcal{A}$, $\mathcal{B}$, $\Delta\mathcal{B}$, $\mathcal{C}$, and $\Delta\mathcal{C}$ are defined by

$$\mathcal{A} := \begin{bmatrix} A_1 & B_{21}L & 0 & 0 & 0 \\ NC_{21} & M & 0 & 0 & NC_{22} \\ 0 & B_{22}L & A_2 & 0 & 0 \\ 0 & 0 & 0 & A_3 & 0 \\ 0 & 0 & 0 & 0 & A_2 \end{bmatrix}, \quad \Delta\mathcal{A} := \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & NC_{23} & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & B_{23}L & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix},$$

$$\mathcal{B} := \begin{bmatrix} B_{11} \\ ND_{21} \\ B_{12} \\ 0 \\ B_{12} \end{bmatrix}, \quad \Delta\mathcal{B} := \begin{bmatrix} 0 \\ 0 \\ 0 \\ B_{13} \\ 0 \end{bmatrix},$$

$$\mathcal{C} := \begin{bmatrix} C_{11} & D_{12}L & C_{12} & 0 & 0 \end{bmatrix}, \quad \Delta\mathcal{C} := \begin{bmatrix} 0 & 0 & 0 & C_{13} & 0 \end{bmatrix},$$

$$M := \begin{bmatrix} \hat{A}_\infty & Z_\infty B_{21} C_\Lambda \\ -B_\Lambda C_{21} & A_\Lambda \end{bmatrix}, \quad N := \begin{bmatrix} -Z_\infty L_\infty \\ B_\Lambda \end{bmatrix}, \quad L := \begin{bmatrix} F_\infty & C_\Lambda \end{bmatrix}.$$

In the above, we remark that the operator $\mathcal{A}$ is unbounded because A_3 is unbounded, whereas the operators $\Delta\mathcal{A}$, $\mathcal{B}$, $\Delta\mathcal{B}$, $\mathcal{C}$, and $\Delta\mathcal{C}$ are bounded.

4.1. Exponential stability. Define the matrix $\mathcal{A}_2$ by

$$\mathcal{A}_2 := \begin{bmatrix} \mathcal{A}_1 & 0 \\ \begin{bmatrix} 0 & B_{22}L \end{bmatrix} & A_2 \end{bmatrix}.$$

Then, the operator $\mathcal{A}$ can be written as

$$\mathcal{A} = \begin{bmatrix} \mathcal{A}_2 & \begin{bmatrix} 0 & 0 \\ 0 & NC_{22} \\ 0 & 0 \end{bmatrix} \\ 0 & \begin{bmatrix} A_3 & 0 \\ 0 & A_2 \end{bmatrix} \end{bmatrix}.$$

First, we shall estimate the norm of the matrix $e^{t\mathcal{A}_2}$. For the matrix $e^{t\mathcal{A}_1}$, we know that under the assumptions of the theorem, inequality (3.6) holds. For a matrix e^{tA_2}, the following estimate holds:

$$\|e^{tA_2}\| = e^{\lambda_{l+1}t} \leq e^{-\omega t} \quad (t \geq 0), \tag{4.1}$$

where $\omega > 0$ is independent of n and is chosen such that $\lambda_{l+1} \leq -\omega$, $\alpha \neq \omega$. Also, we can easily derive the inequality

$$\left\| \begin{bmatrix} 0 & B_{22}L \end{bmatrix} \right\| \leq N_1, \tag{4.2}$$

where $N_1 := \|B_2\|\|L\|$ is independent of n. Therefore, by using Lemma 4.1 for $\mathcal{A}_2$ and by using (3.6), (4.1), and (4.2), it follows that

$$\|e^{t\mathcal{A}_2}\| \leq m' e^{-\sigma t} \quad (t \geq 0), \tag{4.3}$$

where

$$m' := m\left(1 + \frac{mN_1}{|\alpha - \omega|}\right) \ (\geq 1), \quad \sigma := \min(\alpha, \omega) \ (> 0)$$

are independent of n by Lemma 4.1.

Next, based on the above estimate (4.3), we shall find the operator norm bound of an analytic semigroup $e^{t\mathcal{A}}$ generated by the operator $\mathcal{A}$. For an analytic semigroup $\begin{bmatrix} e^{tA_3} & 0 \\ 0 & e^{tA_2} \end{bmatrix}$ generated by the operator $\begin{bmatrix} A_3 & 0 \\ 0 & A_2 \end{bmatrix}$, it is clear that

$$\left\| \begin{bmatrix} e^{tA_3} & 0 \\ 0 & e^{tA_2} \end{bmatrix} \right\|_{\mathcal{L}(H_3 \times \mathbf{R}^{\bar{n}-\bar{l}})} \leq e^{\lambda_{l+1}t} \quad (t \geq 0). \tag{4.4}$$

Also, it is easy to see that

$$\left\| \begin{bmatrix} 0 & 0 \\ 0 & NC_{22} \\ 0 & 0 \end{bmatrix} \right\|_{\mathcal{L}(H_3 \times \mathbf{R}^{\bar{n}-\bar{l}}, \mathbf{R}^{\bar{l}} \times (\mathbf{R}^{\bar{l}} \times \mathbf{R}^{S}) \times \mathbf{R}^{\bar{n}-\bar{l}})} \leq N_2, \tag{4.5}$$

where $N_2 := \|N\| \|C_2\|$ is independent of n. Therefore, by using Lemma 4.1 and (4.3), (4.4), and (4.5), it follows that

$$\|e^{t\mathcal{A}}\|_{\mathcal{L}(X)} \leq m'' e^{-\sigma t} \quad (t \geq 0), \tag{4.6}$$

where

$$m'' := m' \left(1 + \frac{m' N_2}{|\sigma + \lambda_{l+1}|} \right) (\geq 1)$$

is independent of n.

By using the well-known result (e.g. [5, Theorem 3.1.1], [11, Theorem 3.4.1]), for an analytic semigroup $e^{t(\mathcal{A}+\Delta\mathcal{A})}$ generated by the perturbed operator $\mathcal{A} + \Delta\mathcal{A}$, where $\Delta\mathcal{A}$ is bounded, we get

$$\|e^{t(\mathcal{A}+\Delta\mathcal{A})}\|_{\mathcal{L}(X)} \leq m'' e^{-\mu t} \quad (t \geq 0), \tag{4.7}$$

where

$$\mu := \sigma - m'' \|\Delta\mathcal{A}\|_{\mathcal{L}(X)}.$$

Therefore, noting that $\|\Delta\mathcal{A}\|_{\mathcal{L}(X)} \leq \|B_{23}\| \|L\| + \|N\| \|C_{23}\| \to 0$ $(n \to \infty)$ holds since $\|B_{23}\| \to 0$ $(n \to \infty)$ and $\|C_{23}\| \to 0$ $(n \to \infty)$, it follows that there exists an integer n_1 such that

$$\mu = \sigma - m'' \|\Delta\mathcal{A}\|_{\mathcal{L}(X)} > 0 \quad (\forall\, n \geq n_1),$$

i.e., $e^{t(\mathcal{A}+\Delta\mathcal{A})}$ is exponentially stable when n is chosen such that $n \geq n_1$. □

4.2. Norm condition. First, let us estimate the $\mathcal{H}_\infty$ norm of $G(s) := \mathcal{C}(sI - \mathcal{A})^{-1}\mathcal{B}$. Using the assumptions (A3) and (A4) (i.e., (A3′) and (A4′)), $G(s)$ is calculated as follows (see appendix):

$$\begin{aligned} G(s) = {} & T_{zw}(s) + C_{12}(sI - A_2)^{-1} B_{22} D_{12}^T T_{zw}(s) + C_{12}(sI - A_2)^{-1} B_{12} \\ & + T_{zw}(s) D_{21}^T C_{22}(sI - A_2)^{-1} B_{12} \\ & + C_{12}(sI - A_2)^{-1} B_{22} D_{12}^T T_{zw}(s) D_{21}^T C_{22} (sI - A_2)^{-1} B_{12}, \end{aligned} \tag{4.8}$$

where

$$T_{zw}(s) = \mathcal{C}_1 (sI - \mathcal{A}_1)^{-1} \mathcal{B}_1 = \begin{bmatrix} C_{11} & D_{12}L \end{bmatrix} \begin{bmatrix} sI - A_1 & -B_{21}L \\ -NC_{21} & sI - M \end{bmatrix}^{-1} \begin{bmatrix} B_{11} \\ ND_{21} \end{bmatrix}.$$

Under the assumptions of the theorem, we see that

$$\|T_{zw}(\cdot)\|_{\mathcal{H}_\infty(\mathcal{L}(\mathbf{C}^{m_1}, \mathbf{C}^{p_1}))} < \gamma.$$

Moreover, noting the fact that

$$\|((\cdot)I - A_2)^{-1}\|_{\mathcal{H}_\infty(\mathcal{L}(\mathbf{C}^{\bar{n}-\bar{l}}))} = \frac{1}{-\lambda_{l+1}} < \epsilon,$$

we can give the $\mathcal{H}_\infty$ norm bound of $G(s)$ as

$$\|G(\cdot)\|_{\mathcal{H}_\infty(\mathcal{L}(\mathbf{C}^{m_1},\mathbf{C}^{p_1}))} \leq \beta \left[(1+\epsilon)^2 \|T_{zw}(\cdot)\|_{\mathcal{H}_\infty(\mathcal{L}(\mathbf{C}^{m_1},\mathbf{C}^{p_1}))} + \epsilon\right] < \theta\delta.$$

Based on this fact, we shall find the $\mathcal{H}_\infty$ norm bound of

$$G_{zw}(s) = (\mathcal{C} + \varDelta\mathcal{C})\big(sI - (\mathcal{A} + \varDelta\mathcal{A})\big)^{-1}(\mathcal{B} + \varDelta\mathcal{B}).$$

Let us denote by X^c the complexification of X. First, noting that

$$\|((\cdot)I - \mathcal{A})^{-1}\|_{\mathcal{H}_\infty(\mathcal{L}(X^c))} \leq m''/\sigma$$

(by [5, Theorem 1.5.3 and Remark 1.5.4], together with the definition of $\mathcal{H}_\infty$ norm) and that $\|\varDelta\mathcal{A}\|_{\mathcal{L}(X^c)} = \|\varDelta\mathcal{A}\|_{\mathcal{L}(X)} \to 0$ $(n \to \infty)$, it follows that

$$\|((\cdot)I - \mathcal{A})^{-1}\varDelta\mathcal{A}\|_{\mathcal{H}_\infty(\mathcal{L}(X^c))} \to 0 \quad (n \to \infty),$$

which implies that there exists an integer n_2 such that

$$\|((\cdot)I - \mathcal{A})^{-1}\varDelta\mathcal{A}\|_{\mathcal{H}_\infty(\mathcal{L}(X^c))} < 1 \quad (\forall\, n \geq n_2).$$

Therefore, when n is chosen such that $n \geq n_2$, $(I - ((\cdot)I - \mathcal{A})^{-1}\varDelta\mathcal{A})^{-1} \in \mathcal{H}_\infty(\mathcal{L}(X^c))$ exists and the $\mathcal{H}_\infty$ norm can be estimated as follows:

$$\|(I - ((\cdot)I - \mathcal{A})^{-1}\varDelta\mathcal{A})^{-1}\|_{\mathcal{H}_\infty(\mathcal{L}(X^c))} \leq \frac{1}{1 - \|((\cdot)I - \mathcal{A})^{-1}\varDelta\mathcal{A}\|_{\mathcal{H}_\infty(\mathcal{L}(X^c))}}.$$

Here, setting $n_3 := \max(n_1, n_2)$, we can calculate

$$G_{zw}(s) = (\mathcal{C}+\varDelta\mathcal{C}) \Big[(sI - \mathcal{A})^{-1} + (sI - \mathcal{A})^{-1}\varDelta\mathcal{A}\big(I - (sI - \mathcal{A})^{-1}\varDelta\mathcal{A}\big)^{-1}(sI - \mathcal{A})^{-1}\Big] \times(\mathcal{B} + \varDelta\mathcal{B}), \quad s \in \mathbf{C}^+,$$

if n is chosen such that $n \geq n_3$. Moreover, noting that $\|\varDelta\mathcal{B}\|_{\mathcal{L}(\mathbf{C}^{m_1},X^c)} = \|\varDelta\mathcal{B}\|_{\mathcal{L}(\mathbf{R}^{m_1},X)} = \|B_{13}\| \to 0$ $(n \to \infty)$ and $\|\varDelta\mathcal{C}\|_{\mathcal{L}(X^c,\mathbf{C}^{p_1})} = \|\varDelta\mathcal{C}\|_{\mathcal{L}(X,\mathbf{R}^{p_1})} = \|C_{13}\| \to 0$ $(n \to \infty)$, we have

$$\|G_{zw}(\cdot) - G(\cdot)\|_{\mathcal{H}_\infty(\mathcal{L}(\mathbf{C}^{m_1},\mathbf{C}^{p_1}))} \to 0 \quad (n \to \infty), \tag{4.9}$$

which implies that there exists an integer n_4 $(\geq n_3)$ such that

$$\|G_{zw}(\cdot) - G(\cdot)\|_{\mathcal{H}_\infty(\mathcal{L}(\mathbf{C}^{m_1},\mathbf{C}^{p_1}))} < (1-\theta)\delta \quad (\forall\, n \geq n_4).$$

Hence, we finally obtain

$$\begin{aligned} \|G_{zw}(\cdot)\|_{\mathcal{H}_\infty(\mathcal{L}(\mathbf{C}^{m_1},\mathbf{C}^{p_1}))} &\leq \|G_{zw}(\cdot) - G(\cdot)\|_{\mathcal{H}_\infty(\mathcal{L}(\mathbf{C}^{m_1},\mathbf{C}^{p_1}))} + \|G(\cdot)\|_{\mathcal{H}_\infty(\mathcal{L}(\mathbf{C}^{m_1},\mathbf{C}^{p_1}))} \\ &< (1-\theta)\delta + \theta\delta = \delta \quad (\forall\, n \geq n_4). \qquad \square \end{aligned} \tag{4.10}$$

The proof of Theorem 3.1 is thus complete.

Remarks. (i) We cannot a priori estimate the order of the resulting controller $\bar{n}+S$ in Theorem 3.1 as well as the order of finite-dimensional dynamic compensators (see [6], [1], [7]). This is an open problem.

(ii) In Theorem 3.1, we can replace the operator A by a modal operator [1]. An unbounded closed linear operator A with the domain $D(A)$ dense in H is called a modal operator if A has the form

$$Ax = \sum_{i=1}^{\infty} \lambda_i \langle x, \phi_i \rangle \phi_i, \quad x \in D(A),$$

where λ_i are eigenvalues of A satisfying

$$\mathrm{Re}(\lambda_1) \geq \mathrm{Re}(\lambda_2) \geq \cdots \geq \mathrm{Re}(\lambda_i) \geq \cdots, \lim_{i\to\infty} \mathrm{Re}(\lambda_i) = -\infty,$$

and ϕ_i denote eigenfunctions corresponding to λ_i, and $\{\phi_i\,;\, i \geq 1\}$ forms a complete orthonormal system in H.

5. Example. Let $\Omega = (0, \pi)$ be a domain in $\mathbf{R}^1$ with a boundary $\Gamma = \{0, \pi\}$. We consider the linear diffusion system described by

$$(5.1) \quad \begin{cases} \dfrac{\partial x}{\partial t}(t,\xi) = \triangle x(t,\xi) + b_1(\xi)w_1(t) + b_2(\xi)u(t), \quad (t,\xi) \in (0,\infty)\times\Omega, \\ \dfrac{\partial x}{\partial \nu}(t,\eta) = 0, \quad (t,\eta) \in (0,\infty)\times\Gamma, \\ x(0,\xi) = x_0(\xi), \quad \xi \in \Omega, \\ z_1(t) = \displaystyle\int_\Omega c_1(\xi)x(t,\xi)d\xi, \\ z_2(t) = u(t), \\ y(t) = \displaystyle\int_\Omega c_2(\xi)x(t,\xi)d\xi + w_2(t). \end{cases}$$

In the above, $\triangle$ denotes the Laplacian, and $\partial/\partial\nu$ means the outward normal differentiation at the points $\eta = 0, \pi$.

We will formulate the above system in a real Hilbert space $L^2(\Omega)$ with inner product $\langle\,\cdot\,,\,\cdot\,\rangle_{L^2(\Omega)}$ and corresponding norm $\|\cdot\|_{L^2(\Omega)}$. First, we define the operator A in $L^2(\Omega)$ as follows:

$$Ax = \triangle x, \quad x \in D(A) = \left\{ x \in H^2(\Omega)\,;\, \frac{\partial x}{\partial \nu} = 0 \text{ on } \Gamma \right\}.$$

Then, A is a self-adjoint operator with compact resolvent and the eigenpairs of A are completely specified by

$$\begin{cases} \lambda_i = -(i-1)^2 \quad (i = 1, 2, 3, \ldots), \\ \phi_1(\xi) = \dfrac{1}{\sqrt{\pi}}, \quad \phi_i(\xi) = \sqrt{\dfrac{2}{\pi}}\cos(i-1)\xi \quad (i = 2, 3, \ldots). \end{cases}$$

Here, assuming that $b_1, b_2, c_1, c_2 \in L^2(\Omega)$, and defining bounded linear operators $\tilde{B}_1 : \mathbf{R}^1 \to L^2(\Omega)$, $B_2 : \mathbf{R}^1 \to L^2(\Omega)$, $\tilde{C}_1 : L^2(\Omega) \to \mathbf{R}^1$, and $C_2 : L^2(\Omega) \to \mathbf{R}^1$ by

$$\tilde{B}_1 w_1(t) := b_1 w_1(t), \quad B_2 u(t) := b_2 u(t),$$

$$\tilde{C}_1 x(t) := \langle c_1, x(t) \rangle_{L^2(\Omega)}, \quad C_2 x(t) := \langle c_2, x(t) \rangle_{L^2(\Omega)},$$

we can express the above system (5.1) as

$$\text{(5.2)}\qquad \begin{cases} \dfrac{dx(t)}{dt} = Ax(t) + \tilde{B}_1 w_1(t) + B_2 u(t), \quad x(0) = x_0, \\ z_1(t) = \tilde{C}_1 x(t), \\ z_2(t) = u(t), \\ y(t) = C_2 x(t) + w_2(t). \end{cases}$$

Moreover, defining the operators $B_1 : \mathbf{R}^2 \to L^2(\Omega)$, $C_1 : L^2(\Omega) \to \mathbf{R}^2$, the 2×1 matrix D_{12}, the 1×2 matrix D_{21}, and the vectors $w(t) \in \mathbf{R}^2$, $z(t) \in \mathbf{R}^2$ by

$$B_1 := \begin{bmatrix} \tilde{B}_1 & 0 \end{bmatrix}, \quad C_1 := \begin{bmatrix} \tilde{C}_1 \\ 0 \end{bmatrix}, \quad D_{12} := \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \quad D_{21} := \begin{bmatrix} 0 & 1 \end{bmatrix},$$

$$w(t) := \begin{bmatrix} w_1(t) \\ w_2(t) \end{bmatrix}, \quad z(t) := \begin{bmatrix} z_1(t) \\ z_2(t) \end{bmatrix},$$

the above system (5.2) can be expressed as in (2.1).

Now, we especially consider the case where $b_j \in L^2(\Omega)$ $(j = 1,2)$ and $c_j \in L^2(\Omega)$ $(j = 1,2)$ are given by

$$b_j(\xi) = \begin{cases} \dfrac{1}{\sqrt{(\beta_j - \alpha_j)\pi}}, \ \xi \in [\alpha_j\pi, \beta_j\pi], \\ 0, \quad \xi \in (0, \alpha_j\pi) \cup (\beta_j\pi, \pi), \end{cases} \qquad c_j(\xi) = \begin{cases} \dfrac{1}{\sqrt{(\delta_j - \gamma_j)\pi}}, \ \xi \in [\gamma_j\pi, \delta_j\pi], \\ 0, \quad \xi \in (0, \gamma_j\pi) \cup (\delta_j\pi, \pi), \end{cases}$$

where $\alpha_1 = 0.05$, $\beta_1 = 0.25$, $\alpha_2 = 0.5$, $\beta_2 = 0.75$, $\gamma_1 = 0.3$, $\delta_1 = 0.45$, $\gamma_2 = 0.8$, $\delta_2 = 0.95$. Then, noting that

$$\begin{aligned} &\|B_1\| = \|b_1\|_{L^2(\Omega)} = 1, \quad \|B_2\| = \|b_2\|_{L^2(\Omega)} = 1, \\ &\|C_1\| = \|c_1\|_{L^2(\Omega)} = 1, \quad \|C_2\| = \|c_2\|_{L^2(\Omega)} = 1, \\ &\|D_{12}^T\| = \|D_{12}\| = 1, \quad \|D_{21}^T\| = \|D_{21}\| = 1, \end{aligned}$$

it follows from (3.1) that $\beta = 1$.

Here, let us set $\delta = 1.85$ and $\theta = 0.96479$ (< 1). Then, we can choose ϵ as $\epsilon = 0.063$ $(< \frac{\theta\delta}{\beta} = 1.78486)$. Moreover, we can choose $l = 4$, and calculate the matrices of A_1, B_{11}, B_{21}, C_{11}, C_{21} with respect to the basis $(\phi_1, \phi_2, \phi_3, \phi_4)$ as follows:

$$A_1 = \begin{bmatrix} \lambda_1 & 0 & 0 & 0 \\ 0 & \lambda_2 & 0 & 0 \\ 0 & 0 & \lambda_3 & 0 \\ 0 & 0 & 0 & \lambda_4 \end{bmatrix}, \quad B_{11} = \begin{bmatrix} g_{1,1} & 0 \\ g_{1,2} & 0 \\ g_{1,3} & 0 \\ g_{1,4} & 0 \end{bmatrix}, \quad B_{21} = \begin{bmatrix} g_{2,1} \\ g_{2,2} \\ g_{2,3} \\ g_{2,4} \end{bmatrix},$$

$$C_{11} = \begin{bmatrix} h_{1,1} & h_{1,2} & h_{1,3} & h_{1,4} \\ 0 & 0 & 0 & 0 \end{bmatrix}, \quad C_{21} = \begin{bmatrix} h_{2,1} & h_{2,2} & h_{2,3} & h_{2,4} \end{bmatrix},$$

where

$$\begin{aligned} g_{j,i} &:= \langle b_j, \phi_i \rangle_{L^2(\Omega)} \quad (j = 1,2\,;\, i = 1,2,3,4), \\ h_{j,i} &:= \langle c_j, \phi_i \rangle_{L^2(\Omega)} \quad (j = 1,2\,;\, i = 1,2,3,4). \end{aligned}$$

In the above, A_1, B_{11}, B_{21}, C_{11}, and C_{21} are identified with their corresponding matrices. It is easily verified that the conditions (A3′) and (A4′) are satisfied. From

(3.3), we can calculate $\gamma = 1.52381$. Then, by using Robust Control TOOLBOX of MATLAB [2], we can verify that the conditions (A1′), (A2′), and (B1)–(B3) are satisfied.

Remark. In this example, we treated the system with $\beta = 1$. If β is larger, we see from (3.3) that the $\mathcal{H}_\infty$ norm bound γ for the finite-dimensional model becomes smaller. Consequently, if β is larger, conditions (B1)–(B3) may not be satisfied.

6. $\mathcal{H}_\infty$control of semilinear diffusion systems. Let H be a real Hilbert space with inner product $\langle\,\cdot\,,\,\cdot\,\rangle$ and associated norm $\|\cdot\|$. Consider the semilinear system of the form

$$\text{(6.1)}\qquad \begin{cases} \dfrac{dx(t)}{dt} = Ax(t) + F(x(t)) + B_1 w(t) + B_2 u(t) \quad (t > 0), \quad x(0) = x_0, \\ z(t) = C_1 x(t) + D_{12} u(t), \\ y(t) = C_2 x(t) + D_{21} w(t), \end{cases}$$

where the nonlinear term $F(\cdot) : H \to H$ satisfies the following condition:

$$\text{(6.2)}\qquad \begin{cases} \|F(x) - F(\tilde{x})\| \le k\|x - \tilde{x}\|, \quad x, \tilde{x} \in H, \\ F(0) = 0. \end{cases}$$

The other operators and matrices are the same ones as in section 2.

A function $x(\cdot) : [0,\infty) \to H$ is called a solution of the first equation of (6.1) if $x(\cdot) \in C([0,\infty);H) \cap C^1((0,\infty);H)$, $x(t) \in D(A)$ for $t > 0$, and $x(\cdot)$ satisfies the first equation of (6.1). For the first equation of (6.1), the following existence and uniqueness result is obtained by using the theory of semilinear evolution equations (see [5], [10]).

LEMMA 6.1. *Let $x_0 \in H$, $w(\cdot) \in C_\nu([0,\infty);\mathbf{R}^{m_1})$, and $u(\cdot) \in C_\nu([0,\infty);\mathbf{R}^{m_2})$ $(0 < \nu \le 1)$, where $C_\nu([0,\infty);\mathbf{R}^{m_1})$ denotes the Hölder space with the exponent ν, on $[0,\infty)$ taking values in $\mathbf{R}^{m_1}$. Then, the first equation of* (6.1) *has a unique solution.*

To the above system (6.1), we shall apply the linear controller (3.8)–(3.10) constructed for the linear diffusion system (2.1). By using the same notation as in section 4, the closed-loop system from w to z can be written as follows:

$$\text{(6.3)}\qquad \begin{cases} \dfrac{d\xi(t)}{dt} = (\mathcal{A} + \varDelta\mathcal{A})\xi(t) + \mathcal{F}(\xi(t)) + (\mathcal{B} + \varDelta\mathcal{B})w(t), \quad \xi(0) = \xi_0, \\ z(t) = (\mathcal{C} + \varDelta\mathcal{C})\xi(t), \end{cases}$$

where $\mathcal{F}(\cdot) : X \to X$ is defined as

$$\mathcal{F}(\xi(t)) := \begin{bmatrix} F_1(x_1(t), x_2(t), x_3(t)) \\ 0 \\ F_2(x_1(t), x_2(t), x_3(t)) \\ F_3(x_1(t), x_2(t), x_3(t)) \\ F_2(x_1(t), x_2(t), x_3(t)) \end{bmatrix},$$

$$F_1(\cdot) := P_l F(\cdot), \quad F_2(\cdot) := (P_n - P_l)F(\cdot), \quad F_3(\cdot) := (I - P_n)F(\cdot).$$

Here, we remark that $F_1(\cdot)$ and $F_2(\cdot)$ are identified with their corresponding vectors with respect to the bases $(\phi_{11}, \dots, \phi_{1\mu_1}, \dots, \phi_{l,\mu_l})$ of H_1 and $(\phi_{l+1,1}, \dots, \phi_{l+1,\mu_{l+1}}, \dots, \phi_{n,\mu_n})$ of H_2, respectively.

Then, we have the following theorem.

THEOREM 6.2. *Suppose that the assumptions of Theorem* 3.1 *are satisfied and that the integer n is chosen sufficiently large such that the inequality* (4.10) *holds. Moreover, assume that the Lipschitz constant k satisfies the inequality*

$$0 < k < \frac{\mu}{\sqrt{2}m''}, \tag{6.4}$$

where the constants m'' and μ are defined in (4.6) *and* (4.7)*, respectively. Then, the following results* (1) *and* (2) *hold:*

(1) *The solution of the equation*

$$\frac{d\xi(t)}{dt} = (\mathcal{A} + \varDelta\mathcal{A})\xi(t) + \mathcal{F}(\xi(t)), \quad \xi(0) = \xi_0 \tag{6.5}$$

is exponentially stable.

(2) *For the closed-loop system* (6.3) *with the initial condition $\xi(0) = 0$, the inequality*

$$\|z\|_{L^2(0,\infty;\mathbf{R}^{p_1})} \le (\delta + \delta_k)\|w\|_{L^2(0,\infty;\mathbf{R}^{m_1})}$$

holds for all $w \in L^2(0,\infty;\mathbf{R}^{m_1})$, where

$$\delta_k := \frac{\sqrt{2}km''^2\|\mathcal{B} + \varDelta\mathcal{B}\|_{\mathcal{L}(\mathbf{R}^{m_1},X)}\|\mathcal{C} + \varDelta\mathcal{C}\|_{\mathcal{L}(X,\mathbf{R}^{p_1})}}{\mu(\mu - \sqrt{2}km'')}. \tag{6.6}$$

Proof of (1). From (6.5), we have

$$\xi(t) = e^{t(\mathcal{A}+\varDelta\mathcal{A})}\xi_0 + \int_0^t e^{(t-s)(\mathcal{A}+\varDelta\mathcal{A})}\mathcal{F}(\xi(s))ds. \tag{6.7}$$

Since the condition (6.2) implies

$$\begin{cases} \|\mathcal{F}(\xi) - \mathcal{F}(\tilde{\xi})\|_X \le \sqrt{2}k\|\xi - \tilde{\xi}\|_X, & \xi, \tilde{\xi} \in X, \\ \mathcal{F}(0) = 0, \end{cases} \tag{6.8}$$

from (4.7) and (6.7), we obtain

$$e^{\mu t}\|\xi(t)\|_X \le m''\|\xi_0\|_X + \int_0^t \sqrt{2}km''e^{\mu s}\|\xi(s)\|_X ds.$$

Here, using Gronwall's inequality yields

$$\|\xi(t)\|_X \le m''\|\xi_0\|_X e^{-(\mu-\sqrt{2}km'')t}.$$

Hence, it follows under the assumption (6.4) that the solution of (6.5) is exponentially stable. □

Proof of (2). By setting $\xi(0) = 0$ in the closed-loop system (6.3), we have

$$\begin{cases} \xi(t) = \displaystyle\int_0^t e^{(t-s)(\mathcal{A}+\varDelta\mathcal{A})}\{\mathcal{F}(\xi(s)) + (\mathcal{B} + \varDelta\mathcal{B})w(s)\}ds, \\ z(t) = (\mathcal{C} + \varDelta\mathcal{C})\xi(t). \end{cases} \tag{6.9}$$

From (6.9), we get

$$z(t)=\int_0^t(\mathcal{C}+\varDelta\mathcal{C})e^{(t-s)(\mathcal{A}+\varDelta\mathcal{A})}(\mathcal{B}+\varDelta\mathcal{B})w(s)ds+\int_0^t(\mathcal{C}+\varDelta\mathcal{C})e^{(t-s)(\mathcal{A}+\varDelta\mathcal{A})}\mathcal{F}(\xi(s))ds.$$

Let us estimate the $L^2(0,\infty;\mathbf{R}^{p_1})$ norm of z. First, it follows from the above equation that

$$\begin{aligned}\|z\|_{L^2(0,\infty;\mathbf{R}^{p_1})}\le&\left\|\int_0^{\cdot}(\mathcal{C}+\varDelta\mathcal{C})e^{(\cdot-s)(\mathcal{A}+\varDelta\mathcal{A})}(\mathcal{B}+\varDelta\mathcal{B})w(s)ds\right\|_{L^2(0,\infty;\mathbf{R}^{p_1})}\\&+\left\|\int_0^{\cdot}(\mathcal{C}+\varDelta\mathcal{C})e^{(\cdot-s)(\mathcal{A}+\varDelta\mathcal{A})}\mathcal{F}(\xi(s))ds\right\|_{L^2(0,\infty;\mathbf{R}^{p_1})}.\end{aligned}\tag{6.10}$$

Here, noting that

$$\begin{aligned}&\sup_{\substack{\tilde{w}\in L^2(0,\infty;\mathbf{R}^{m_1})\\ \tilde{w}\neq0}}\frac{\left\|\int_0^{\cdot}(\mathcal{C}+\varDelta\mathcal{C})e^{(\cdot-s)(\mathcal{A}+\varDelta\mathcal{A})}(\mathcal{B}+\varDelta\mathcal{B})\tilde{w}(s)ds\right\|_{L^2(0,\infty;\mathbf{R}^{p_1})}}{\|\tilde{w}\|_{L^2(0,\infty;\mathbf{R}^{m_1})}}\\&\qquad=\|G_{zw}(\cdot)\|_{\mathcal{H}_\infty(\mathcal{L}(\mathbf{C}^{m_1},\mathbf{C}^{p_1}))}<\delta,\end{aligned}$$

it is easy to see that the first term of the right-hand side of (6.10) is estimated as

$$\left\|\int_0^{\cdot}(\mathcal{C}+\varDelta\mathcal{C})e^{(\cdot-s)(\mathcal{A}+\varDelta\mathcal{A})}(\mathcal{B}+\varDelta\mathcal{B})w(s)ds\right\|_{L^2(0,\infty;\mathbf{R}^{p_1})}\le\delta\|w\|_{L^2(0,\infty;\mathbf{R}^{m_1})}\tag{6.11}$$

for all $w\in L^2(0,\infty;\mathbf{R}^{m_1})$. Therefore, we have only to consider the second term of the right-hand side of (6.10). Using (4.7) and (6.8), and using Hölder's inequality, we get

$$\begin{aligned}&\left\|\int_0^t(\mathcal{C}+\varDelta\mathcal{C})e^{(t-s)(\mathcal{A}+\varDelta\mathcal{A})}\mathcal{F}(\xi(s))ds\right\|_{\mathbf{R}^{p_1}}\\&\le\sqrt{2}km''\|\mathcal{C}+\varDelta\mathcal{C}\|_{\mathcal{L}(X,\mathbf{R}^{p_1})}\int_0^te^{-\mu(t-s)}\|\xi(s)\|_Xds\\&\le\sqrt{2}km''\|\mathcal{C}+\varDelta\mathcal{C}\|_{\mathcal{L}(X,\mathbf{R}^{p_1})}\left(\int_0^te^{-\mu(t-s)}ds\right)^{\frac12}\left(\int_0^te^{-\mu(t-s)}\|\xi(s)\|_X^2ds\right)^{\frac12}\\&\le\sqrt{2}km''\|\mathcal{C}+\varDelta\mathcal{C}\|_{\mathcal{L}(X,\mathbf{R}^{p_1})}\left(\frac{1}{\mu}\right)^{\frac12}\left(\int_0^te^{-\mu(t-s)}\|\xi(s)\|_X^2ds\right)^{\frac12}.\end{aligned}\tag{6.12}$$

Here, squaring the both sides of (6.12), integrating from 0 to ∞ with respect to t, and interchanging the order of integration, we have

$$\begin{aligned}&\int_0^\infty\left\|\int_0^t(\mathcal{C}+\varDelta\mathcal{C})e^{(t-s)(\mathcal{A}+\varDelta\mathcal{A})}\mathcal{F}(\xi(s))ds\right\|_{\mathbf{R}^{p_1}}^2dt\\&\le2k^2m''^2\|\mathcal{C}+\varDelta\mathcal{C}\|^2_{\mathcal{L}(X,\mathbf{R}^{p_1})}\frac{1}{\mu}\int_0^\infty\left(\int_0^te^{-\mu(t-s)}\|\xi(s)\|_X^2ds\right)dt\\&=2k^2m''^2\|\mathcal{C}+\varDelta\mathcal{C}\|^2_{\mathcal{L}(X,\mathbf{R}^{p_1})}\frac{1}{\mu}\int_0^\infty\left(\int_s^\infty e^{-\mu(t-s)}\|\xi(s)\|_X^2dt\right)ds\\&=2k^2m''^2\|\mathcal{C}+\varDelta\mathcal{C}\|^2_{\mathcal{L}(X,\mathbf{R}^{p_1})}\frac{1}{\mu}\int_0^\infty\|\xi(s)\|_X^2\left(\int_s^\infty e^{-\mu(t-s)}dt\right)ds\\&=2k^2m''^2\|\mathcal{C}+\varDelta\mathcal{C}\|^2_{\mathcal{L}(X,\mathbf{R}^{p_1})}\frac{1}{\mu^2}\|\xi\|^2_{L^2(0,\infty;X)}.\end{aligned}\tag{6.13}$$

From (6.13), we obtain

$$\begin{aligned}
&\left\| \int_0^{\cdot} (\mathcal{C}+\Delta\mathcal{C}) e^{(\cdot - s)(\mathcal{A}+\Delta\mathcal{A})} \mathcal{F}(\xi(s)) ds \right\|_{L^2(0,\infty;\mathbf{R}^{p_1})} \\
&\leq \sqrt{2} k m'' \|\mathcal{C}+\Delta\mathcal{C}\|_{\mathcal{L}(X,\mathbf{R}^{p_1})} \frac{1}{\mu} \|\xi\|_{L^2(0,\infty;X)}.
\end{aligned} \tag{6.14}$$

Finally we estimate $\|\xi\|_{L^2(0,\infty;X)}$ in the right-hand side of (6.14) by $\|w\|_{L^2(0,\infty;\mathbf{R}^{m_1})}$. By using (4.7) and (6.8), and by using Hölder's inequality, it follows from the first equation of (6.9) that

$$\begin{aligned}
\|\xi(t)\|_X &\leq \sqrt{2} k m'' \int_0^t e^{-\mu(t-s)} \|\xi(s)\|_X ds \\
&\quad + m'' \|\mathcal{B}+\Delta\mathcal{B}\|_{\mathcal{L}(\mathbf{R}^{m_1},X)} \int_0^t e^{-\mu(t-s)} \|w(s)\|_{\mathbf{R}^{m_1}} ds \\
&\leq \sqrt{2} k m'' \left(\int_0^t e^{-\mu(t-s)} ds \right)^{\frac{1}{2}} \left(\int_0^t e^{-\mu(t-s)} \|\xi(s)\|_X^2 ds \right)^{\frac{1}{2}} \\
&\quad + m'' \|\mathcal{B}+\Delta\mathcal{B}\|_{\mathcal{L}(\mathbf{R}^{m_1},X)} \left(\int_0^t e^{-\mu(t-s)} ds \right)^{\frac{1}{2}} \left(\int_0^t e^{-\mu(t-s)} \|w(s)\|_{\mathbf{R}^{m_1}}^2 ds \right)^{\frac{1}{2}} \\
&\leq \sqrt{2} k m'' \left(\frac{1}{\mu} \right)^{\frac{1}{2}} \left(\int_0^t e^{-\mu(t-s)} \|\xi(s)\|_X^2 ds \right)^{\frac{1}{2}} \\
&\quad + m'' \|\mathcal{B}+\Delta\mathcal{B}\|_{\mathcal{L}(\mathbf{R}^{m_1},X)} \left(\frac{1}{\mu} \right)^{\frac{1}{2}} \left(\int_0^t e^{-\mu(t-s)} \|w(s)\|_{\mathbf{R}^{m_1}}^2 ds \right)^{\frac{1}{2}}.
\end{aligned} \tag{6.15}$$

Here, squaring both sides of (6.15) and integrating from 0 to ∞ with respect to t yield

$$\begin{aligned}
\int_0^\infty \|\xi(t)\|_X^2 dt \leq \Bigg[& \sqrt{2} k m'' \frac{1}{\mu} \left(\int_0^\infty \|\xi(s)\|_X^2 ds \right)^{\frac{1}{2}} \\
& + m'' \|\mathcal{B}+\Delta\mathcal{B}\|_{\mathcal{L}(\mathbf{R}^{m_1},X)} \frac{1}{\mu} \left(\int_0^\infty \|w(s)\|_{\mathbf{R}^{m_1}}^2 ds \right)^{\frac{1}{2}} \Bigg]^2.
\end{aligned}$$

In the above, we interchange the order of integration and use Hölder's inequality. Therefore, we have

$$\left(1 - \sqrt{2} k m'' \frac{1}{\mu} \right) \|\xi\|_{L^2(0,\infty;X)} \leq m'' \|\mathcal{B}+\Delta\mathcal{B}\|_{\mathcal{L}(\mathbf{R}^{m_1},X)} \frac{1}{\mu} \|w\|_{L^2(0,\infty;\mathbf{R}^{m_1})}.$$

Hence, it follows under the assumption (6.4) that

$$\|\xi\|_{L^2(0,\infty;X)} \leq \frac{m'' \|\mathcal{B}+\Delta\mathcal{B}\|_{\mathcal{L}(\mathbf{R}^{m_1},X)}}{\mu - \sqrt{2} k m''} \|w\|_{L^2(0,\infty;\mathbf{R}^{m_1})}. \tag{6.16}$$

Here, combining (6.14) and (6.16) gives

$$\left\| \int_0^{\cdot} (\mathcal{C}+\Delta\mathcal{C}) e^{(\cdot - s)(\mathcal{A}+\Delta\mathcal{A})} \mathcal{F}(\xi(s)) ds \right\|_{L^2(0,\infty;\mathbf{R}^{p_1})} \leq \delta_k \|w\|_{L^2(0,\infty;\mathbf{R}^{m_1})}, \tag{6.17}$$

where

$$\delta_k = \frac{\sqrt{2} k m''^2 \|\mathcal{B}+\Delta\mathcal{B}\|_{\mathcal{L}(\mathbf{R}^{m_1},X)} \|\mathcal{C}+\Delta\mathcal{C}\|_{\mathcal{L}(X,\mathbf{R}^{p_1})}}{\mu(\mu - \sqrt{2} k m'')}.$$

From (6.10), (6.11), and (6.17), we finally obtain

$$\|z\|_{L^2(0,\infty;\mathbf{R}^{p_1})} \le (\delta + \delta_k)\|w\|_{L^2(0,\infty;\mathbf{R}^{m_1})}$$

for all $w \in L^2(0,\infty;\mathbf{R}^{m_1})$. □

The proof of Theorem 6.2 is thus complete.

Remark. From (6.6), it is easy to see that $\delta_k \to 0$ as $k \downarrow 0$ and $\delta_k \to \infty$ as $k \uparrow \frac{\mu}{\sqrt{2m''}}$. This shows that the finite-dimensional $\mathcal{H}_\infty$ controller constructed for the linear infinite-dimensional system also works as a finite-dimensional $\mathcal{H}_\infty$ controller for a semilinear infinite-dimensional system with sufficiently small Lipschitz constant k.

Appendix: Derivation of (4.8). Noting that

$$\begin{aligned}
&(sI-\mathcal{A})^{-1}\\
&= \begin{bmatrix} sI-A_1 & -B_{21}L & 0 & 0 & 0 \\ -NC_{21} & sI-M & 0 & 0 & -NC_{22} \\ 0 & -B_{22}L & sI-A_2 & 0 & 0 \\ 0 & 0 & 0 & sI-A_3 & 0 \\ 0 & 0 & 0 & 0 & sI-A_2 \end{bmatrix}^{-1}\\
&= \begin{bmatrix} \begin{bmatrix} sI-A_1 & -B_{21}L & 0 \\ -NC_{21} & sI-M & 0 \\ 0 & -B_{22}L & sI-A_2 \end{bmatrix}^{-1} & -\begin{bmatrix} sI-A_1 & -B_{21}L & 0 \\ -NC_{21} & sI-M & 0 \\ 0 & -B_{22}L & sI-A_2 \end{bmatrix}^{-1} \begin{bmatrix} 0 & 0 \\ 0 & -NC_{22} \\ 0 & 0 \end{bmatrix} \begin{bmatrix} sI-A_3 & 0 \\ 0 & sI-A_2 \end{bmatrix}^{-1} \\ \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} & \begin{bmatrix} sI-A_3 & 0 \\ 0 & sI-A_2 \end{bmatrix}^{-1} \end{bmatrix}
\end{aligned}$$

and

$$\begin{aligned}
&\begin{bmatrix} sI-A_1 & -B_{21}L & 0 \\ -NC_{21} & sI-M & 0 \\ 0 & -B_{22}L & sI-A_2 \end{bmatrix}^{-1}\\
&= \begin{bmatrix} \begin{bmatrix} sI-A_1 & -B_{21}L \\ -NC_{21} & sI-M \end{bmatrix}^{-1} & \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\ -(sI-A_2)^{-1}\begin{bmatrix} 0 & -B_{22}L \end{bmatrix}\begin{bmatrix} sI-A_1 & -B_{21}L \\ -NC_{21} & sI-M \end{bmatrix}^{-1} & (sI-A_2)^{-1} \end{bmatrix},
\end{aligned}$$

$G(s) = \mathcal{C}(sI-\mathcal{A})^{-1}\mathcal{B}$ can be calculated as

$$G(s) = C_{12}(sI-A_2)^{-1}B_{12} + G_1(s) + G_2(s) + G_3(s) + G_4(s),$$

where

$$G_1(s) := \begin{bmatrix} C_{11} & D_{12}L \end{bmatrix} \begin{bmatrix} sI-A_1 & -B_{21}L \\ -NC_{21} & sI-M \end{bmatrix}^{-1} \begin{bmatrix} B_{11} \\ ND_{21} \end{bmatrix} = T_{zw}(s),$$

$$G_2(s) := C_{12}(sI-A_2)^{-1} \begin{bmatrix} 0 & B_{22}L \end{bmatrix} \begin{bmatrix} sI-A_1 & -B_{21}L \\ -NC_{21} & sI-M \end{bmatrix}^{-1} \begin{bmatrix} B_{11} \\ ND_{21} \end{bmatrix},$$

$$G_3(s) := \begin{bmatrix} C_{11} & D_{12}L \end{bmatrix} \begin{bmatrix} sI - A_1 & -B_{21}L \\ -NC_{21} & sI - M \end{bmatrix}^{-1} \begin{bmatrix} 0 \\ NC_{22}(sI - A_2)^{-1}B_{12} \end{bmatrix},$$

$$G_4(s) := C_{12}(sI - A_2)^{-1} \begin{bmatrix} 0 & B_{22}L \end{bmatrix} \begin{bmatrix} sI - A_1 & -B_{21}L \\ -NC_{21} & sI - M \end{bmatrix}^{-1} \times \begin{bmatrix} 0 \\ NC_{22}(sI - A_2)^{-1}B_{12} \end{bmatrix}.$$

Here, by using the assumptions (A3) and (A4) (i.e., (A3′) and (A4′)), $G_2(s)$, $G_3(s)$, and $G_4(s)$ can be rewritten as follows:

$$\begin{aligned}
&G_2(s) \\
&= C_{12}(sI - A_2)^{-1}B_{22} \begin{bmatrix} 0 & L \end{bmatrix} \begin{bmatrix} sI - A_1 & -B_{21}L \\ -NC_{21} & sI - M \end{bmatrix}^{-1} \begin{bmatrix} B_{11} \\ ND_{21} \end{bmatrix} \\
&= C_{12}(sI - A_2)^{-1}B_{22} \begin{bmatrix} D_{12}^TC_{11} & D_{12}^TD_{12}L \end{bmatrix} \begin{bmatrix} sI - A_1 & -B_{21}L \\ -NC_{21} & sI - M \end{bmatrix}^{-1} \begin{bmatrix} B_{11} \\ ND_{21} \end{bmatrix} \\
&= C_{12}(sI - A_2)^{-1}B_{22}D_{12}^T \begin{bmatrix} C_{11} & D_{12}L \end{bmatrix} \begin{bmatrix} sI - A_1 & -B_{21}L \\ -NC_{21} & sI - M \end{bmatrix}^{-1} \begin{bmatrix} B_{11} \\ ND_{21} \end{bmatrix} \\
&= C_{12}(sI - A_2)^{-1}B_{22}D_{12}^TT_{zw}(s),
\end{aligned}$$

$$\begin{aligned}
&G_3(s) \\
&= \begin{bmatrix} C_{11} & D_{12}L \end{bmatrix} \begin{bmatrix} sI - A_1 & -B_{21}L \\ -NC_{21} & sI - M \end{bmatrix}^{-1} \begin{bmatrix} 0 \\ N \end{bmatrix} C_{22}(sI - A_2)^{-1}B_{12} \\
&= \begin{bmatrix} C_{11} & D_{12}L \end{bmatrix} \begin{bmatrix} sI - A_1 & -B_{21}L \\ -NC_{21} & sI - M \end{bmatrix}^{-1} \begin{bmatrix} B_{11}D_{21}^T \\ ND_{21}D_{21}^T \end{bmatrix} C_{22}(sI - A_2)^{-1}B_{12} \\
&= \begin{bmatrix} C_{11} & D_{12}L \end{bmatrix} \begin{bmatrix} sI - A_1 & -B_{21}L \\ -NC_{21} & sI - M \end{bmatrix}^{-1} \begin{bmatrix} B_{11} \\ ND_{21} \end{bmatrix} D_{21}^TC_{22}(sI - A_2)^{-1}B_{12} \\
&= T_{zw}(s)D_{21}^TC_{22}(sI - A_2)^{-1}B_{12},
\end{aligned}$$

$$\begin{aligned}
&G_4(s) \\
&= C_{12}(sI - A_2)^{-1}B_{22} \begin{bmatrix} 0 & L \end{bmatrix} \begin{bmatrix} sI - A_1 & -B_{21}L \\ -NC_{21} & sI - M \end{bmatrix}^{-1} \\
&\qquad \times \begin{bmatrix} 0 \\ N \end{bmatrix} C_{22}(sI - A_2)^{-1}B_{12} \\
&= C_{12}(sI - A_2)^{-1}B_{22} \begin{bmatrix} D_{12}^TC_{11} & D_{12}^TD_{12}L \end{bmatrix} \begin{bmatrix} sI - A_1 & -B_{21}L \\ -NC_{21} & sI - M \end{bmatrix}^{-1} \\
&\qquad \times \begin{bmatrix} B_{11}D_{21}^T \\ ND_{21}D_{21}^T \end{bmatrix} C_{22}(sI - A_2)^{-1}B_{12} \\
&= C_{12}(sI - A_2)^{-1}B_{22}D_{12}^T \begin{bmatrix} C_{11} & D_{12}L \end{bmatrix} \begin{bmatrix} sI - A_1 & -B_{21}L \\ -NC_{21} & sI - M \end{bmatrix}^{-1} \\
&\qquad \times \begin{bmatrix} B_{11} \\ ND_{21} \end{bmatrix} D_{21}^TC_{22}(sI - A_2)^{-1}B_{12} \\
&= C_{12}(sI - A_2)^{-1}B_{22}D_{12}^TT_{zw}(s)D_{21}^TC_{22}(sI - A_2)^{-1}B_{12}.
\end{aligned}$$

Therefore, we finally obtain

$$\begin{aligned}G(s) = {} & C_{12}(sI - A_2)^{-1}B_{12} + T_{zw}(s) + C_{12}(sI - A_2)^{-1}B_{22}D_{12}^T T_{zw}(s) \\ & +T_{zw}(s)D_{21}^T C_{22}(sI - A_2)^{-1}B_{12} \\ & +C_{12}(sI - A_2)^{-1}B_{22}D_{12}^T T_{zw}(s)D_{21}^T C_{22}(sI - A_2)^{-1}B_{12}.\end{aligned}$$

GENERALIZED FOURIER AND TOEPLITZ RESULTS FOR RATIONAL ORTHONORMAL BASES*

BRETT NINNESS†, HÅKAN HJALMARSSON‡, AND FREDRIK GUSTAFSSON§

Abstract. This paper provides a generalization of certain classical Fourier convergence and asymptotic Toeplitz matrix properties to the case where the underlying orthonormal basis is not the conventional trigonometric one but rather a rational generalization which encompasses the trigonometric one as a special case. These generalized Fourier and Toeplitz results have particular application in dynamic system estimation theory. Specifically, the results allow a unified treatment of the accuracy of least-squares system estimation using a range of model structures, including those that allow the inclusion of prior knowledge of system dynamics via the specification of fixed pole or zero locations.

Key words. stochastic processes, prediction theory, system identification

1. Introduction.

In the area of applied mathematics, a fundamental idea is that of approximating or exactly expressing solutions by expanding them in terms of orthogonal basis functions. Well-known classical examples are Fourier analysis, solutions of the wave equation and Schrödinger's equation in terms of (respectively) Legendre and Laguerre orthogonal polynomials, and solutions of self-adjoint operator equations such as Sturm–Liouville systems in terms of the orthogonal eigenfunctions of the operator. More recently, particularly for the solution of signal processing and other system theoretic problems, there has been an explosion of interest in the development and use of a wide class of new orthogonal bases called "wavelets" [7, 5].

Indeed, tackling system theoretic problems using orthonormal descriptions has a particularly rich history, going back at least as far as the work of Kolmogorov [23] and Wiener [52], who exploited them in developing their now famous theory on the prediction of random processes. In that work, the orthonormal basis was the trigonometric one, but as was shown by Szegö there is great utility in reexpressing the problem with respect to another orthonormal basis that is adapted to the random process; namely, a basis of polynomials orthogonal to a given positive function f which is the spectral density of the process [45, 11]. Such polynomials are called "Szegö polynomials."

This latter approach derives its utility from the fact that the nth order Szegö polynomial is in fact the mean-square best, order n, one step ahead predictor of the random process [14, 45]. By exploiting the orthonormality of the basis to derive what is called a "Christoffel–Darboux" formula for the "reproducing kernel" associated with

the Szegö polynomial basis, theoretical analysis of this predictor is greatly facilitated. For example, it was by this means that Szegö was able to derive his famous formula

$$\sigma^2 = \exp\left\{\frac{1}{2\pi}\int_{-\pi}^{\pi} \log f(\omega)\,\mathrm{d}\omega\right\}$$

for the asymptotic in order n variance σ^2 of the prediction error associated with a spectral density f.

In addition, use of the Christoffel–Darboux formula provides a recursive in n formula for the Szegö polynomials [45, 11], and this in turn allows a computationally efficient means for calculating predictors. This recursive formula is of course the famous Levinson recursion, which was developed independently of Szegö's work by exploiting the properties of Toeplitz matrices [26, 38]. In practice, the so-called "reflection coefficients" required in the Levinson recursions are calculated by the Schur algorithm [41], originally proposed by Schur [43] as a means for testing whether or not a function is bounded positive real (or "Carathéodory" as it is known in some literature). Here again orthonormal bases and Toeplitz matrices arise since another test for positive realness involves testing for the positive definiteness of the Toeplitz matrix formed from the Fourier coefficients of the function [44].

These several links between Toeplitz matrices and orthonormal bases arise since (subject to some regularity conditions) the ℓ,mth element of any $n \times n$ symmetric Toeplitz matrix $T_n(f)$ may be expressed using the orthonormal trigonometric basis $\{e^{j\omega n}\}$ as

$$[T_n(f)]_{\ell,m} = \frac{1}{2\pi}\int_{-\pi}^{\pi} e^{j\omega\ell}e^{-j\omega m} f(\omega)\,\mathrm{d}\omega \tag{1.1}$$

for some positive function f. By recognizing this, certain quadratic forms of Toeplitz matrices that arise naturally in the frequency domain analysis of least-squares estimation problems may instead be conveniently rewritten as

$$\frac{1}{n}\Gamma_n^\star(\omega)T_n(f)\Gamma_n(\omega) = \sum_{k=-n}^{n}\left(1 - \frac{|k|}{n}\right) c_k\, e^{j\omega k} \tag{1.2}$$

where $\cdot^\star$ denotes "conjugate transpose" and

$$c_k \triangleq \frac{1}{2\pi}\int_{-\pi}^{\pi} f(\omega)e^{-j\omega k}\,\mathrm{d}\omega$$

is the kth Fourier coefficient of f with $\Gamma_n(\omega)$ an $n \times 1$ vector defined as

$$\Gamma_n^\star(\omega) \triangleq [1, e^{-j\omega}, e^{-j2\omega}, \ldots, e^{-j(n-1)\omega}].$$

The right-hand side of (1.2) may be recognized as the Cesàro mean reconstruction of a Fourier series which is known [10], provided f is continuous, to converge uniformly to $f(\omega)$ on $[-\pi, \pi]$.

This latter fact has been exploited by Ljung and coauthors [29, 31, 16, 30, 53, 27], who, reminiscent of Szegö's approach of examining the asymptotic in order n nature of predictors, have provided asymptotic-in-model-order results describing the variability of the frequency response of least-squares system estimates in such a way as to elucidate how they depend on excitation and measurement noise spectral densities, model order, and observed data length; see section 7 for more detail on this point.

Such results have found wide engineering application; see for example [2, 12, 28, 17]. However, to derive them, another key ingredient pertaining to the properties of Toeplitz matrices is required, namely, that asymptotically in size n, Toeplitz matrices possess the algebraic structure [14, 50]

$$T_n(f)T_n(g) \sim T_n(fg), \tag{1.3}$$

where f and g are any continuous positive functions, and for $n \times n$ matrices A_n and B_n, the notation $A_n \sim B_n$ means that $\lim_{n\to\infty} |A_n - B_n| = 0$, where $|\cdot|$ is the Hilbert–Schmidt matrix norm defined by

$$|A|^2 \triangleq \frac{1}{n}\text{Trace}\{A^\star A\}. \tag{1.4}$$

The main results of this paper extend the results of the convergence of the Cesàro mean (1.2) and the algebraic structure of Toeplitz matrices (1.3) to more general cases wherein the underlying orthonormal basis is not the trigonometric one but rather a generalization of it. More specifically, this paper studies the use of the basis functions $\mathcal{B}_n(z)$ given by

$$\mathcal{B}_n(z) \triangleq \frac{\sqrt{1-|\xi_n|^2}}{1-\xi_n z}\prod_{k=0}^{n-1}\left(\frac{z-\overline{\xi_k}}{1-\xi_k z}\right), \tag{1.5}$$

where the $\{\xi_k\}$ may be chosen (almost) arbitrarily inside and (in some cases) on the boundary of the open unit disc $\mathbf{D} \triangleq \{z \in \mathbf{C} : |z| < 1\}$ ($\mathbf{C}$ is the field of complex numbers). These functions $\{\mathcal{B}_n\}$ are orthonormal on the unit circle $\mathbf{T} = \{z \in \mathbf{C} : |z| = 1\}$, and the trigonometric basis is a special case of them if all the $\{\xi_k\}$ are chosen as zero. Using them, a generalization

$$[M_n(f)]_{\ell,m} \triangleq \frac{1}{2\pi}\int_{-\pi}^{\pi} \mathcal{B}_\ell(e^{j\omega})\overline{\mathcal{B}_m(e^{j\omega})}f(\omega)\,\mathrm{d}\omega \tag{1.6}$$

of Toeplitz matrices is considered, for which it is shown here that a generalization of (1.3) still holds, and with the redefinition

$$\Gamma_n^T(\omega) \triangleq [\mathcal{B}_0(e^{j\omega}),\ \mathcal{B}_1(e^{j\omega}),\ \dots, \mathcal{B}_{n-1}(e^{j\omega})] \tag{1.7}$$

it is also shown here that a generalization of the uniform convergence of the Cesàro mean (1.2) to $f(\omega)$ also holds.

In both cases, the generalization involves replacing the $1/n$ normalization appearing in (1.2) and in the definition of the matrix norm (1.4) with a frequency dependent term $K_n(\omega,\omega)$ which is the reproducing kernel associated with the linear space spanned by the basis functions $\{\mathcal{B}_0, \mathcal{B}_1, \dots, \mathcal{B}_{n-1}\}$.

Indeed, this reproducing kernel is the key to the results presented here. Classical derivations of Cesàro summability and Toeplitz matrix results rely heavily on the algebraic structure of the trigonometric basis, namely, that $e^{j\omega n}e^{j\omega m} = e^{j\omega(n+m)}$. In the cases considered here, since $\mathcal{B}_n\mathcal{B}_m \neq \mathcal{B}_{n+m}$ this algebraic structure is lost and pre-existing analysis techniques are not applicable. Instead, motivated by Szegö's approach to the study of orthogonal polynomials, this paper exploits a closed form expression for the appropriate reproducing kernel.

The utility of the new results presented here is that, just as the classical Fourier and Toeplitz results have been used by Ljung and coauthors to analyze estimation using finite impulse response (FIR) and certain other rational model structures, the results of this paper can be used to analyze estimation using generalizations of these model structures. As shown in [37] and as commented on in section 7, these generalized structures are actually quite common since they implicitly arise whenever the common practice of data prefiltering is performed.

There is much other work related to the results presented here. The study of the basis functions (1.5) dates back to Malmquist [34] and was taken up by Walsh [49] in the context of complex rational approximation theory and by other authors [52, 25, 21, 3, 9, 8, 32, 39] for system theoretic applications such as system approximation and network synthesis, including generalizations of Schur and Levinson recursions, lattice structures, and the concomitant solution of inverse scattering problems.

In the context of system identification, as well as pertaining to the aforementioned work [29, 31, 16, 30, 53, 27], the results of this paper also have close connections with much recent literature examining the use of model structures derived from orthonormal bases. In [22, 6, 20, 46, 48] the use of the so-called "Laguerre" basis is examined. This basis can be encompassed by the basis (1.5) by fixing all the poles at a common value $\xi_k = \xi \in \mathbf{R}$ ($\mathbf{R}$ denotes the field of real numbers) and with the substitution $z \mapsto 1/z$ so as to accommodate convention in the signal processing and control theory literature. In this case the name "Laguerre" derives from the ensuing functions being related to the classical Laguerre orthonormal polynomials via a Fourier and bilinear transform [35]. In [47] a generalization of this Laguerre case is analyzed wherein the common value ξ may be complex valued. In [18, 40], these analyses are again generalized to the case where a fixed set of poles $\{\xi_0, \ldots, \xi_r\}$ are cyclically repeated and orthonormal bases are generated with denominators given as $D_p(z) = \prod_{k=0}^{p-1}(z - \xi_k)$ and numerators as Szegö polynomials associated with the weight function $|D_p(e^{j\omega})|^{-2}$. The cyclic repetition of poles arises due to the latter numerator and denominator pair being multiplied by powers of the all-pass function $z^p D_p(1/z)/D_p(z)$ as the number of required basis functions increases beyond p.

In all these works, any analysis of estimation accuracy proceeds by exploiting the restriction on the choice of ξ_k to establish, via a bilinear transform [46, 47, 48] or a multilinear transform (dubbed a "Hambo" transform) [40] an algebra isomorphism to the trigonometric basis $\{e^{j\omega n}\}$. The utility of this is that the original results of Ljung [31] can then be employed, having been mapped through the isomorphism, to provide quantification of estimation accuracy.

In spite of the elegance of this approach, it suffers several drawbacks which are the motivation for the work at hand. First, the results pertain only to a restricted class of models in which all the poles $\{\xi_k\}$ either are chosen the same [46, 48, 47] or are cyclically repeated from a fixed set [40]. Second, and with particular reference to [40], the results are asymptotic not, as is the case here, to the number of poles $\{\xi_k\}$ chosen but to the number of times the whole set $\{\xi_0, \ldots, \xi_{p-1}\}$ is repeated. The results in this paper allow the avoidance of these limitations by eschewing a strategy of forcing an algebra isomorphism to the trigonometric case.

The presentation of these ideas is organized as follows. In section 2, the analysis begins by establishing that the general orthonormal bases (1.5) fundamental to this paper form a complete set in the Hilbert space $H_2(\mathbf{T})$. In order to study other approximating properties of the basis, a "reproducing kernel" approach is employed, and section 3 is devoted to explaining certain important principles relevant to this framework. Perhaps more importantly, section 3 also contains the derivation of a closed form "Christoffel–Darboux" type formula for the reproducing kernel. With these results in hand, section 4 then considers generalized Fourier analysis with respect to the basis (1.5), and using the reproducing kernel ideas establishes uniform convergence for generalized Cesàro mean reconstructions.

In fact, because of application demands, something more is derived: it is shown that for certain frequencies being different, uniform convergence to zero also ensues. The generalized Cesàro mean reconstruction is defined with respect to a generalized Toeplitz matrix, and section 5 is devoted to the study of the asymptotic algebraic properties of such matrices since, as already explained, these properties are of great utility in certain system theoretic applications.

Pertinent to this, section 5 defines a new notion of asymptotic equivalence between matrices and then uses this to establish that asymptotically, arbitrary products of generalized Toeplitz matrices and their inverses are equivalent to a single generalized Toeplitz matrix with a symbol equal to the product of the corresponding symbols and inverse symbols of the matrices in the product. This study of generalized Toeplitz matrix properties in terms of its symbol is continued in section 6, where the relationship between the spectrum of the matrices and the values of the symbol are explored and found to be intimately connected. Given these theoretical developments, section 7 provides a very brief overview of how the results here may be applied in the study of certain system identification problems that were, in fact, the original motivation for this work. More detail on this application is provided in the separate work [37]. Finally, section 8 provides a summary and concluding perspectives on the work presented here.

2. Completeness properties. The theme of this paper is examination of certain system theoretic issues pertaining to the use of the basis functions (1.5) for the purposes of describing discrete time dynamic systems. In what follows only bounded-input, bounded-output stable and causal systems will be of interest, so that it is natural to embed the analysis in the Hardy space $H_2(\mathbf{T})$ of functions $f(z)$ which are analytic on $\mathbf{D}$, square integrable on $\mathbf{T}$, and possess only a one-sided Fourier expansion. As is well known [19], $H_2(\mathbf{T})$ is a Hilbert space when endowed with the inner product

$$(2.1)\quad \langle f,g\rangle = \frac{1}{2\pi}\int_{-\pi}^{\pi} f(e^{j\omega})\overline{g(e^{j\omega})}\,\mathrm{d}\omega = \frac{1}{2\pi j}\oint_{\mathbf{T}} f(z)\overline{g(z)}\,\frac{\mathrm{d}z}{z}, \quad f,g\in H_2(\mathbf{T}).$$

That the functions (1.5) form an orthonormal set in that $\langle \mathcal{B}_n,\mathcal{B}_m\rangle = \delta(n-m) =$ Kronecker delta may easily be shown [36] using the contour integral formulation of the inner product in (2.1) and Cauchy's residue theorem.

What must be of central interest if the functions (1.5) are to be useful in such a system theoretic setting is whether or not linear combinations of them can describe an arbitrary system in $H_2(\mathbf{T})$ to any degree of accuracy. This may be answered in the affirmative by the following completeness result which has been developed elsewhere, but is presented here for the sake of a self-contained presentation.

Theorem 2.1 (Ninness and Gustafsson [36]).

$$\overline{\mathrm{Span}\,\{\mathcal{B}_k(z)\}_{k\ge 0}} = H_2(\mathbf{T})$$

if and only if

$$\sum_{k=0}^{\infty}(1-|\xi_k|)=\infty,$$

where here $\overline{X}$ denotes the norm closure of the space X.

3. Reproducing kernels. Given the completeness result in Theorem 2.1, to further examine the properties of approximants formed as linear combinations of the basis functions (1.5), this paper utilizes the ideas of reproducing kernel spaces [1, 45], of which a brief overview of the key ideas is as follows.

If an approximant $f_n(z)$ of a function $f(z)$ is formed as a certain linear combination of the n basis functions $\{\mathcal{B}_0, \mathcal{B}_1, \ldots, \mathcal{B}_{n-1}\}$, then for any $\mu \in \mathbf{D}$ it is also possible to form a linear functional F_μ defined as follows:

$$F_\mu : X_n \triangleq \operatorname{Span}\{\mathcal{B}_0, \mathcal{B}_1, \ldots, \mathcal{B}_{n-1}\} \to \mathbf{C}, \quad f_n \mapsto f_n(\mu).$$

Since the setting is a Hilbert space $H_2(\mathbf{T})$, by the Riesz representation theorem [42] there exists a unique μ dependent element in X_n, called $K_n(z,\mu)$, such that

$$g(\mu) \triangleq F_\mu(g) = \langle g(z), K_n(z,\mu)\rangle \quad \forall g \in X_n.$$

This element $K_n(z,\mu)$ is called the "reproducing kernel" on account of its property of reproducing values of elements of X_n at the point μ via an inner product.

Certain basic properties of $K_n(z,\mu)$ important for the purposes of this paper are that it is "Hermitian symmetric" as can be easily seen according to

$$K_n(\sigma,\mu) = \langle K_n(z,\mu), K_n(z,\sigma)\rangle = \overline{\langle K_n(z,\sigma), K_n(z,\mu)\rangle} = \overline{K_n(\mu,\sigma)}$$

so that $K_n(\mu,\mu) \in \mathbf{R}$ and also $K_n(\mu,\mu) > 0$, since if it were not, then since $K_n(\mu,\mu) = \langle K_n(z,\mu), K(z,\mu)\rangle = \|K_n(z,\mu)\|^2$, then $\|K_n(z,\mu)\| = 0$ would be implied, which would further imply that $g(\mu) = 0$ for every $g \in X_n$ which is impossible since, for example, $\mathcal{B}_0(\mu) \neq 0$ for any $\mu \in \mathbf{D}$.

As will be illustrated in what follows, the reproducing kernel is enormously useful in the study of the approximating properties of the linear span $\{\mathcal{B}_0, \ldots, \mathcal{B}_{n-1}\}$. As a preluding example, in the linear prediction context mentioned in the introduction, consider the problem of finding the nth order, mean square optimal, one step ahead predictor $\varphi_n(z) \in X_n$ of a wide-sense stationary process with spectral density $f(\omega)$. Here z is interpreted as the backward shift operator so that if $\{u_k\}$ is a sequence in ℓ_2, then $\{\varphi_n(z)u_k\}$ denotes a filtered version of that sequence. With this notation in hand φ_n is given by

$$\varphi_n = \arg\min_{\varphi \in X_n} \|1 - \varphi\| \quad \text{subject to } \varphi(0) = 0.$$

The constraint is added to ensure the one step ahead nature of the predictor, and the norm is induced by the inner product (2.1) modified so as to be weighted according to the spectral density $f(\omega)$. This constrained optimization problem is easily solved using the reproducing kernel $K_n(z,\mu)$ associated with $\operatorname{Span}\{1, \mathcal{B}_0, \ldots, \mathcal{B}_{n-1}\}$ and with respect to the modified inner product by first noting that via the Cauchy–Schwarz inequality

$$\begin{aligned} 1 = |1 - \varphi_n(0)|^2 &= |\langle 1 - \varphi_n, K_n(z,0)\rangle|^2 \\ &\leq \langle 1 - \varphi_n, 1 - \varphi_n\rangle \langle K_n(z,0), K_n(z,0)\rangle \\ &= \|1 - \varphi_n\|^2 K_n(0,0). \end{aligned}$$

However, equality occurs in the Cauchy–Schwarz inequality if and only if $1 - \varphi_n(z) = cK(z,0)$ for some constant c. The constraint $\varphi_n(0) = 0$ implies the choice $c = 1/K_n(0,0)$ which leads to the solution

$$\varphi_n(z) = 1 - \frac{K_n(z,0)}{K_n(0,0)}.$$

Given this utility of the reproducing kernel $K_n(z, \mu)$, the natural question of calculating it arises. This may be easily achieved as

$$K_n(z, \mu) = \sum_{k=0}^{n-1} \mathcal{B}_k(z)\overline{\mathcal{B}_k(\mu)}. \tag{3.1}$$

That this formulation is valid may be quickly checked by noting that for any $0 \le m < n$

$$\langle \mathcal{B}_m(z), K_n(z, \mu)\rangle = \sum_{k=0}^{n-1} \mathcal{B}_k(\mu)\langle \mathcal{B}_m(z), \mathcal{B}_k(z)\rangle = \mathcal{B}_m(\mu).$$

However, for the purposes of the analysis in this paper this representation is too cumbersome, and a more succinct description is required. This is in common with the study of orthogonal polynomials [45, 11] via the use of reproducing kernels, where simpler closed form formulae for $K_n(z, \mu)$ are called "Christoffel–Darboux formulae." Borrowing from this literature, the following theorem presents a Christoffel–Darboux formula for $K_n(z, \mu)$ which in what follows will be central to the derivation of the generalized Fourier and Toeplitz matrix results of this paper.

THEOREM 3.1 (Christoffel–Darboux formula). *Define the modified Blaschke product*

$$\varphi_n(z) \triangleq \prod_{k=0}^{n-1} \frac{z - \overline{\xi_k}}{1 - \xi_k z}.$$

Then the reproducing kernel of the space spanned by $\{\mathcal{B}_0, \mathcal{B}_1, \ldots, \mathcal{B}_{n-1}\}$ can be expressed as

$$K_n(z, \mu) = \frac{1 - \overline{\varphi_n(\mu)}\varphi_n(z)}{1 - z\overline{\mu}}. \tag{3.2}$$

Proof. Take $z, \mu \in \mathbf{D}$, consider the function $\Lambda_n(z, \mu) : \mathbf{C} \times \mathbf{C} \to \mathbf{C}$ defined by

$$\Lambda_n(z, \mu) \triangleq \frac{1 - \overline{\varphi_n(\mu)}\varphi_n(z)}{1 - z\overline{\mu}},$$

and define the space $X_n \triangleq \operatorname{Span}\{\mathcal{B}_0(z), \ldots, \mathcal{B}_{n-1}(z)\} \subset H_2(\mathbf{T})$. Clearly, since the product $\overline{\varphi_n(\mu)}\varphi_n(1/\overline{\mu}) = 1$, then $1 - \overline{\varphi_n(\mu)}\varphi_n(z)$ possesses a zero at $z = 1/\overline{\mu}$ so that $\Lambda_n(z, \mu) \in X_n$. Furthermore, by Cauchy's integral theorem

$$\left\langle \mathcal{B}_m(z), \frac{1}{1 - \overline{\mu}z} \right\rangle = \frac{1}{2\pi j} \oint_{\mathbf{T}} \frac{\mathcal{B}_m(z)}{z - \mu}\, \mathrm{d}z = \mathcal{B}_m(\mu),$$

and also, for any $m = 0, 1, \ldots, n-1$, by the change of integration variable $z \mapsto 1/z$ and Cauchy's integral theorem

$$\begin{aligned}\left\langle \mathcal{B}_m(z), \frac{\overline{\varphi_n(\mu)}\varphi_n(z)}{1 - \overline{\mu}z} \right\rangle &= \frac{\varphi_n(\mu)}{2\pi j} \oint_{\mathbf{T}} \frac{\mathcal{B}_m(z)\overline{\varphi_n(z)}}{z - \mu}\, \mathrm{d}z \\ &= \frac{\varphi_n(\mu)}{2\pi j} \oint_{\mathbf{T}} \frac{\mathcal{B}_m(1/z)\overline{\varphi_n(1/z)}}{1 - \mu z}\, \mathrm{d}z = 0.\end{aligned}$$

Therefore, $\Lambda_n(z,\mu)$ given by (3.2) has the property that $f(\mu) = \langle f(z), \Lambda_n(z,\mu)\rangle$ for any $f \in X_n$. However, the reproducing kernel $K_n(z,\mu)$ is the unique function in X_n with this property, so it must be that $K_n(z,\mu) = \Lambda_n(z,\mu)$. □

Often the expression (3.2) will be used by setting $\mu = re^{j\sigma}, z = re^{j\omega}$ and letting $r \to 1$ from below. In this case, with some abuse of notation in the interests of cleanliness of exposition, the theorem will be used in the form

$$K_n(\omega,\sigma) = \frac{1 - \overline{\varphi_n(e^{j\sigma})}\varphi_n(e^{j\omega})}{1 - e^{j(\sigma-\omega)}}. \tag{3.3}$$

4. Generalized Fourier series convergence. Given a function $f \in H_2(\mathbf{T})$, an obvious way of approximating it in terms of the basis functions $\{\mathcal{B}_0, \mathcal{B}_1, \ldots, \mathcal{B}_{n-1}\}$ is as f_n given by

$$f_n(z) = \operatorname*{arg\,min}_{g\in X_n} \|f - g\| = \sum_{k=0}^{n-1} \langle f, \mathcal{B}_k\rangle \mathcal{B}_k(z). \tag{4.1}$$

Provided $\sum(1 - |\xi_k|) = \infty$ holds, by the completeness theorem, Theorem 2.1, the approximation error $\|f_n - f\|$ can then be made arbitrarily small for arbitrarily large approximation order n.

A natural question to then ask is how the approximant f_n behaves with respect to other norms, for example, the supremum norm on $[-\pi,\pi]$. The purpose of this section is to show that a modified approximant, closely related to the above one and deriving from the Cesàro (or Fejér) mean of classical Fourier analysis, is also supremum norm convergent to f under the same condition of $\sum(1 - |\xi_k|) = \infty$. This result will encompass the classical result for the trigonometric basis by simply setting all the poles $\{\xi_k\}$ to zero.

To proceed, it is expedient to revisit the classical case by indeed setting $\xi_k = 0$ in (4.1) and also temporarily shifting to the $L_2(\mathbf{T})$ setting so that the sum in (4.1) becomes two-sided to obtain

$$f_n(\omega) = \frac{1}{2\pi}\sum_{k=-n}^{n} e^{jk\omega}\int_{-\pi}^{\pi} f(\sigma)e^{-j\sigma k}\,\mathrm{d}\sigma = \frac{1}{2\pi}\int_{-\pi}^{\pi} f(\sigma)D_n(\omega-\sigma)\,\mathrm{d}\sigma, \tag{4.2}$$

where

$$D_n(\theta) \triangleq \frac{\sin(2n+1)\theta/2}{\sin\theta/2}$$

is known [10] as the "Dirichlet kernel." Perhaps one of the more surprising facets of applied mathematics is that even if f is continuous on $[-\pi,\pi]$, then $\lim_{n\to\infty}|f_n - f| = 0$ uniformly on $[-\pi,\pi]$ is not guaranteed; this is a century-old observation due to Du Bois-Reymond [24]. This undesirable behavior stems from the fact that although from (4.2) one would wish $D_n(\theta)$ to behave more and more like a Dirac delta function as n increases, it does not in the sense that

$$\liminf_{n\to\infty}\int_{|\theta|>\rho} |D_n(\theta)|\,\mathrm{d}\theta \neq 0$$

for arbitrarily small ρ. In fact, the quantity $\|D_n\|_1$ (called the nth Lebesgue constant) is known to be bounded below by $(4/\pi^2)\log n$, so that since the norm of any linear projection $L_n : C[-\pi, \pi] \to \mathrm{Span}\{e^{-j\omega n}, \ldots, e^{-j\omega}, 1, e^{j\omega}, \ldots, e^{j\omega n}\}$ is known [4] to be underbounded by $\|D_n\|_1$, then by Du Bois-Reymond's result there always exists an $f \in C[-\pi, \pi]$ such that $\|L_n f\|$ becomes unbounded as $n \to \infty$. In fact, this difficulty has been the genesis of much work in the system identification literature, of which [33] offers a survey.

A remedy for this problem of nonconvergence is to replace the approximation (4.2) with the so-called Cesàro mean defined on the unit circle by

$$f_n(\omega) = \sum_{k=-n}^{n} \left(1 - \frac{|k|}{n}\right) \langle f, e^{jk\omega} \rangle e^{jk\omega} = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(\sigma) K_n(\omega - \sigma)\, \mathrm{d}\sigma, \tag{4.3}$$

where now

$$K_n(\theta) \triangleq \frac{\sin^2 n\theta/2}{n \sin^2 \theta/2}$$

is known [10] as the "Fejér kernel" and does possess the "delta-like" property

$$\lim_{n\to\infty} \int_{|\theta|>\rho} K_n(\theta)\, \mathrm{d}\theta = 0 \quad \forall \rho > 0 \tag{4.4}$$

so that since it is also true that

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} K_n(\theta)\, \mathrm{d}\theta = 1,$$

then

$$2\pi |f_n(\omega) - f(\omega)| \le \int_{|\omega-\sigma|\le\rho} |f_n(\sigma) - f(\omega)| K_n(\sigma)\, \mathrm{d}\sigma + \int_{|\omega-\sigma|>\rho} |f_n(\sigma) - f(\omega)| K_n(\sigma)\, \mathrm{d}\sigma$$

in which case if f is continuous, then use of (4.4) allows the conclusion that since ρ may be made arbitrarily small, then $\lim_{n\to\infty} |f_n(\omega) - f(\omega)| = 0$ uniformly on $[-\pi, \pi]$.

To develop the analogue of this result for the general case of approximants formed using the general orthonormal basis (1.5), it is necessary to first develop a generalization of the Cesàro mean (4.3). This may be accomplished by the definition

$$f_n(\omega) \triangleq \frac{\Gamma_n^\star(\omega) M_n(f) \Gamma_n(\omega)}{K_n(\omega, \omega)}, \tag{4.5}$$

where Γ_n defined in (1.7) is an $n \times 1$ vector of general rational orthonormal basis functions (1.5) and $M_n(f)$ is a generalized Toeplitz matrix as defined in (1.6). If all the poles $\{\xi_k\}$ are set to zero in (3.1), then it is straightforward to verify that the formulation (4.5) reduces (since in this case $M_n(f) = T_n(f)$) to the usual Cesàro mean (4.3). To analyze the convergence properties of (4.5), note that by the formulation (3.1)

$$\begin{aligned}
\Gamma_n^\star(\omega) M_n(f) \Gamma_n(\omega) &= \sum_{m=0}^{n-1} \sum_{n=0}^{n-1} \overline{\mathcal{B}_m(e^{j\omega})} \mathcal{B}_n(e^{j\omega}) [M_n(f)]_{m,n} \\
&= \frac{1}{2\pi} \int_{-\pi}^{\pi} f(\sigma) \sum_{m=0}^{n-1} \sum_{n=0}^{n-1} \overline{\mathcal{B}_m(e^{j\omega})} \mathcal{B}_n(e^{j\omega}) \mathcal{B}_m(e^{j\sigma}) \overline{\mathcal{B}_n(e^{j\sigma})}\, \mathrm{d}\sigma \\
&= \frac{1}{2\pi} \int_{-\pi}^{\pi} f(\sigma) \left| K_n(\omega, \sigma) \right|^2 \mathrm{d}\sigma.
\end{aligned}$$

Therefore, since by the defining property of the reproducing kernel

$$\frac{1}{2\pi}\int_{-\pi}^{\pi}|K_n(\omega,\sigma)|^2\,\mathrm{d}\sigma = \langle K_n(\omega,\sigma),K_n(\omega,\sigma)\rangle = K_n(\omega,\omega) = \sum_{m=0}^{n-1}|\mathcal{B}_m(e^{j\omega})|^2, \tag{4.6}$$

then

$$\begin{aligned}\frac{1}{2\pi}\left|\frac{\Gamma_n^\star(\omega)M_n(f)\Gamma_n(\omega)}{K_n(\omega,\omega)} - f(\omega)\right| &= \frac{1}{2\pi K_n(\omega,\omega)}\left|\Gamma_n^\star(\omega)M_n(f)\Gamma_n(\omega) - K_n(\omega,\omega)f(\omega)\right|\\ &= \frac{1}{2\pi K_n(\omega,\omega)}\left|\int_{-\pi}^{\pi}[f(\sigma)-f(\omega)]\,|K_n(\omega,\sigma)|^2\,\mathrm{d}\sigma\right| \qquad (4.7)\end{aligned}$$

and so, in analogy with classical Fourier analysis, convergence of the generalized Cesàro mean approximant (4.5) hinges on a kernel function (in this case depending on the reproducing kernel and being given by $|K_n(\omega,\sigma)|^2/K_n(\omega,\omega)$) behaving in some sense like the Dirac delta function $\delta(\omega-\sigma)$. Via use of the Christoffel–Darboux formula (3.3) for the reproducing kernel, it is possible to establish that this "delta-like" behavior does in fact occur in the following sense.

LEMMA 4.1. *For any $\rho > 0$ and provided*

$$\sum_{k=0}^{\infty}(1-|\xi_k|) = \infty,$$

then

$$\lim_{n\to\infty}\frac{1}{K_n(\omega,\omega)}\int_{\sigma\notin[\omega-\rho,\omega+\rho]}|K_n(\omega,\sigma)|^2\,\mathrm{d}\sigma = 0.$$

Proof. By Theorem 3.1 formulated as (3.3)

$$|K_n(\omega,\sigma)| \le \frac{2}{|e^{j(\sigma-\omega)}-1|} = \frac{1}{|\sin(\sigma-\omega)/2|}$$

so that

$$\int_{\sigma\notin[\omega-\rho,\omega+\rho]}|K_n(\omega,\sigma)|^2\,\mathrm{d}\sigma \le \frac{2\pi}{\sin^2\rho/2}.$$

Also, since $|1-\xi_k e^{j\omega}| \le 1+|\xi_k|$, then

$$K_n(\omega,\omega) = \sum_{k=0}^{n-1}\frac{1-|\xi_k|^2}{|1-\xi_k e^{j\omega}|^2} \ge \frac{1}{2}\sum_{k=0}^{n-1}(1-|\xi_k|) \tag{4.8}$$

so that

$$\frac{1}{K_n(\omega,\omega)}\int_{\sigma\notin[\omega-\rho,\omega+\rho]}|K_n(\omega,\sigma)|^2\,\mathrm{d}\sigma \le \frac{\pi}{\sin^2\rho/2}\left(\sum_{k=0}^{n-1}(1-|\xi_k|)\right)^{-1}$$

which tends to zero under the conditions of the lemma. □

Before using this result, some further notation is required since, motivated by the desire to provide results applicable to certain system theoretic problems, it is necessary to be more ambitious than to just prove convergence of f_n to f. Instead, it is also necessary to prove convergence to zero of the quadratic form

$$\frac{\Gamma_n^\star(\mu)M_n(f)\Gamma_n(\omega)}{K_n(\omega,\omega)}$$

when $\mu \neq \omega$, and this entails some delicacy in dealing with the distance between $e^{j\mu}$ and $e^{j\omega}$ on the unit circle, so that the distance between μ and ω must be considered modulo 2π. This is achieved by defining, for $-\pi \leq x, y \leq \pi$, the function $d(x,y) : [-\pi,\pi] \times [-\pi,\pi] \to [0,\pi]$ as

$$d(x,y) \triangleq \min(|x-y|, 2\pi - |x-y|). \tag{4.9}$$

Furthermore, letting Ω_1 and Ω_2 be subsets of $[-\pi,\pi]$, then

$$d(\Omega_1,\Omega_2) \triangleq \min_{x\in\Omega_1,\, y\in\Omega_2} d(x,y).$$

In what follows, it will also be useful to note that because

$$|\sin(x)| = |\sin(\pi - x)| = |\sin(-x)| = |\sin(-(\pi - x))|,$$

then

$$|\sin(x)| = \sin\frac{d(2x,0)}{2}, \quad -\pi \leq x \leq \pi$$

so that since $2x/\pi \leq \sin x \leq x$ for $0 \leq x \leq \pi/2$, then

$$\frac{2}{d(2x,0)} \leq \frac{1}{|\sin(x)|} \leq \frac{\pi}{d(2x,0)} \tag{4.10}$$

for any $x : |x| \leq \pi$, $x \neq 0$. The main use for these latter ideas is to develop further bounds such as the ones contained in the following lemma, which sharpen the interpretation (already begun in Lemma 4.1) of $K_n(\omega,\sigma)$ as behaving approximately like the Dirac delta $\delta(\omega,\sigma)$.

LEMMA 4.2. *Suppose that $|\xi_n| \leq 1 - \delta$ for some $\delta > 0$ and all n. Then for n large enough the following bounds apply:*

$$\frac{1}{2}\sum_{k=0}^{n-1}(1 - |\xi_k|) \leq |K_n(\omega,\sigma)| \leq \begin{cases} \dfrac{2n}{\delta} & \forall \sigma,\omega, \\[2ex] \dfrac{1}{|\sin(\omega-\sigma)/2|}, & \omega \neq \sigma. \end{cases} \tag{4.11}$$

Proof. Consider first the case of $\omega = \sigma$. Then by the expression (4.6) and the formulation (1.5)

$$K_n(\omega,\omega) = \sum_{k=0}^{n-1}\frac{1-|\xi_k|^2}{|1-\xi_k e^{j\omega}|^2} \leq \sum_{k=0}^{n-1}\frac{1+|\xi_k|}{1-|\xi_k|} \leq \frac{2}{\delta}n \tag{4.12}$$

so that using the Cauchy–Schwarz inequality the bound

$$|K_n(\omega,\sigma)| \leq \sqrt{|K_n(\omega,\omega)|}\ \sqrt{|K_n(\sigma,\sigma)|} \leq \frac{2}{\delta}n \tag{4.13}$$

applies for all ω, σ. For the case of $\omega \neq \sigma$, using (3.3) derived from Theorem 3.1 then leads to the bound

$$|K_n(\omega, \sigma)| = \frac{1}{\left|e^{j(\omega-\sigma)} - 1\right|} \leq \frac{1}{|\sin(\omega - \sigma)/2|}.$$

Finally, the underbound has already been established in (4.8). □

With these ideas in hand, the following result is available.

THEOREM 4.3. *Suppose $f(\omega)$ is a continuous, not necessarily real-valued function on $[-\pi, \pi]$. Then provided*

$$\sum_{k=0}^{\infty}(1 - |\xi_k|) = \infty$$

the following limit result holds:

$$\lim_{n\to\infty} \frac{\Gamma_n^\star(\omega) M_n(f) \Gamma_n(\omega)}{K_n(\omega, \omega)} = f(\omega)$$

uniformly in ω on $[-\pi, \pi]$. Under the strengthened condition that $|\xi_n| \leq 1 - \delta$ for some $\delta > 0$ and all n, then for $\mu \neq \omega$

$$\lim_{n\to\infty} \frac{\Gamma_n^\star(\mu) M_n(f) \Gamma_n(\omega)}{K_n(\omega, \omega)} = 0.$$

Proof. Consider first the case of $\mu = \omega$. Then from (4.7) and for arbitrary $\rho > 0$

$$\begin{aligned}\frac{1}{2\pi}\left|\frac{\Gamma_n^\star(\omega) M_n(f) \Gamma_n(\omega)}{K_n(\omega, \omega)} - f(\omega)\right| &= \frac{1}{2\pi K_n(\omega, \omega)}\left|\int_{-\pi}^{\pi} [f(\sigma) - f(\omega)]\, |K_n(\omega, \sigma)|^2 \,\mathrm{d}\sigma\right| \\ \leq \frac{1}{2\pi K_n(\omega, \omega)}&\left|\int_{\sigma\in[\omega-\rho,\omega+\rho]} [f(\sigma) - f(\omega)]\, |K_n(\omega, \sigma)|^2 \,\mathrm{d}\sigma\right| \\ + \frac{1}{2\pi K_n(\omega, \omega)}&\left|\int_{\sigma\notin[\omega-\rho,\omega+\rho]} [f(\sigma) - f(\omega)]\, |K_n(\omega, \sigma)|^2 \,\mathrm{d}\sigma\right|.\end{aligned}$$

Now, $f(\omega)$ is continuous, so for ρ sufficiently small

$$|f(\sigma) - f(\omega)| \leq \epsilon \text{ on } [\omega - \rho, \omega + \rho].$$

Using this and (4.6) gives that for sufficiently small ρ

$$\begin{aligned}\frac{1}{2\pi K_n(\omega, \omega)}\left|\int_{\sigma\in[\omega-\rho,\omega+\rho]} [f(\sigma) - f(\omega)]\, |K_n(\omega, \sigma)|^2 \,\mathrm{d}\sigma\right| &\leq \frac{\epsilon}{2\pi K_n(\omega, \omega)} \int_{-\pi}^{\pi} |K_n(\omega, \sigma)|^2 \,\mathrm{d}\sigma \\ &= \epsilon.\end{aligned}$$

Also, since f is continuous on compact $[-\pi, \pi]$, then $|f|$ is bounded by some $M/2 < \infty$. Therefore

$$\begin{aligned}&\frac{1}{2\pi K_n(\omega, \omega)}\left|\int_{\sigma\notin[\omega-\rho,\omega+\rho]} [f(\sigma) - f(\omega)]\, |K_n(\omega, \sigma)|^2 \,\mathrm{d}\sigma\right| \\ &\quad\leq \frac{M}{2\pi K_n(\omega, \omega)} \int_{\sigma\notin[\omega-\rho,\omega+\rho]} |K_n(\omega, \sigma)|^2 \,\mathrm{d}\sigma\end{aligned}$$

which provides

$$\frac{1}{2\pi}\left|\frac{\Gamma_n^\star(\omega)M_n(f)\Gamma_n(\omega)}{K_n(\omega,\omega)} - f(\omega)\right| \leq \epsilon + \frac{M}{2\pi K_n(\omega,\omega)}\int_{\sigma\notin[\omega-\rho,\omega+\rho]} |K_n(\omega,\sigma)|^2 \,\mathrm{d}\sigma.$$

Using Lemma 4.1 and the fact that ϵ is arbitrary then gives the result for $\mu = \omega$. Now consider the case $\mu \neq \omega$. Define the regions

$$\begin{aligned}
\Omega_1 &\triangleq \left\{\sigma \in [-\pi,\pi] : |\sigma-\mu| < K_n^{-\alpha}(\omega,\omega)\right\},\\
\Omega_2 &\triangleq \left\{\sigma \in [-\pi,\pi] : |\sigma-\omega| < K_n^{-\alpha}(\omega,\omega)\right\},\\
\Omega_3 &\triangleq \left\{\sigma \in [-\pi,\pi] : \sigma \notin \{\Omega_1\cup\Omega_2\}\right\},
\end{aligned}$$

where $\alpha \in (0,1/2)$ is arbitrary. In this case

$$\begin{aligned}
\left|\frac{\Gamma_n^\star(\mu)M_n(f)\Gamma_n(\omega)}{K_n(\omega,\omega)}\right| &= \left|\frac{1}{2\pi K_n(\omega,\omega)}\int_{-\pi}^{\pi} f(\sigma)K_n(\mu,\sigma)\overline{K_n(\omega,\sigma)}\,\mathrm{d}\sigma\right|\\
&\leq \frac{\|f\|_\infty}{2\pi K_n(\omega,\omega)}\int_{\Omega_1\cup\Omega_2\cup\Omega_3} |K_n(\mu,\sigma)\overline{K_n(\omega,\sigma)}|\,\mathrm{d}\sigma.
\end{aligned}$$

Consider the integrals over the various regions in turn. By Lemma 4.2 the bound $K_n(\omega,\omega) \geq 1/2\sum_{k=0}^{n-1}(1-|\xi_k|)$ holds, so that by the assumptions of the theorem, n can be taken large enough that Ω_1 and Ω_2 do not overlap. Assuming this to be the case, then $|\omega-\sigma| > K_n^{-\alpha}(\omega,\omega)$ on Ω_1 and hence using Lemma 4.2

$$|K_n(\omega,\sigma)| \leq \frac{1}{|\sin(\omega-\sigma)/2|} \leq \frac{\pi}{d^\alpha(\omega,\sigma)}, \quad \sigma \in \Omega_1.$$

Therefore, under the assumption that $|\xi_k| \leq 1-\delta, \delta > 0$, then by Lemma 4.2 $|K_n(\mu,\sigma)| \leq 2n/\delta$, so that assuming n is so large that $K_n^{-\alpha}(\omega,\omega) \leq d(\mu,\omega)/4$ gives, using Lemma B.1,

$$\int_{\Omega_1} |K_n(\mu,\sigma)\overline{K_n(\omega,\sigma)}|\,\mathrm{d}\sigma \leq \frac{2n}{\delta}\int_{\Omega_1}\frac{1}{|\sin(\omega-\sigma)/2|}\,\mathrm{d}\sigma \leq \frac{32\,n}{\delta K_n^\alpha(\omega,\omega)|\sin(\omega-\mu)/2|}.$$

Using an identical argument

$$\int_{\Omega_2} |K_n(\mu,\sigma)\overline{K_n(\omega,\sigma)}|\,\mathrm{d}\sigma \leq \frac{32\,n}{\delta K_n^\alpha(\omega,\omega)|\sin(\omega-\mu)/2|}.$$

Finally, by the definition of Ω_3 and Lemma 4.2

$$\int_{\Omega_3} |K_n(\mu,\sigma)\overline{K_n(\omega,\sigma)}|\,\mathrm{d}\sigma \leq \frac{2\pi}{\sin^2 K_n^{-\alpha}(\omega,\omega)/2} \leq 8\pi K_n^{2\alpha}(\omega,\omega).$$

Combining the bounds on the integrals over the various regions gives

$$\left|\frac{\Gamma_n^\star(\mu)M_n(f)\Gamma_n(\omega)}{K_n(\omega,\omega)}\right| \leq \frac{32n\|f\|_\infty}{\pi K_n^{1+\alpha}(\omega,\omega)|\sin(\omega-\mu)/2|} + \frac{4\|f\|_\infty}{K_n^{1-2\alpha}(\omega,\omega)}$$

which, according to the lower bound in Lemma 4.2 and since $\alpha \in (0,1/2)$, tends to zero as $n \to \infty$. □

5. Algebraic structure of generalized Toeplitz matrices. In applications [29, 31, 16, 30, 53, 27], the consideration of quadratic forms more complicated than (4.5) occur. In fact, what is of more interest are forms such as

$$\frac{\Gamma_n^\star(\omega) M_n(f) M_n(g) \Gamma_n(\omega)}{K_n(\omega,\omega)}.$$

In these aforementioned applications [29, 31, 16, 30, 53, 27], the underlying orthonormal basis is the trigonometric one $\{e^{j\omega n}\}$ in which case $M_n(f) = T_n(f)$ is a bonafide Toeplitz matrix for which classical results are at hand concerning their algebraic structure. Namely, following the notation defined in (1.3), the convenient property that $T_n(f)T_n(g) \sim T_n(fg)$ is assured [14, 50] (the meaning of the $\sim$ notation here is as described in conjunction with equation (1.3)).

The purpose of this section is to establish this same algebraic structure for the generalized Toeplitz matrices defined by (1.6), the classical results once again arising as the special case of $\xi_k = 0$ in (1.5). To begin, note that by the formulation (1.6)

$$\begin{aligned}[M_n(f)M_n(g)]_{m,\ell} &= \frac{1}{4\pi^2}\sum_{k=0}^{n-1}\int_{-\pi}^{\pi} \mathcal{B}_m(\omega)\overline{\mathcal{B}_k(\omega)} f(\omega)\,\mathrm{d}\omega \int_{-\pi}^{\pi} \overline{\mathcal{B}_\ell(\sigma)}\mathcal{B}_k(\sigma) g(\sigma)\,\mathrm{d}\sigma \\ &= \sum_{k=0}^{n-1} \langle \mathcal{B}_m f, \mathcal{B}_k\rangle \overline{\langle \mathcal{B}_\ell g, \mathcal{B}_k\rangle}\end{aligned}$$

and

$$[M_n(fg)]_{m,\ell} = \frac{1}{2\pi}\int_{-\pi}^{\pi} \mathcal{B}_m(\omega)\overline{\mathcal{B}_\ell(\omega)} f(\omega)\overline{g(\omega)}\,\mathrm{d}\omega = \langle \mathcal{B}_m f, \mathcal{B}_\ell g\rangle.$$

Therefore, by Parseval's theorem

$$\begin{aligned}\left|[M_n(f)M_n(g)]_{m,\ell} - [M_n(fg)]_{m,\ell}\right| &= \left|\sum_{k=0}^{n-1}\langle \mathcal{B}_m f, \mathcal{B}_k\rangle \overline{\langle \mathcal{B}_\ell g, \mathcal{B}_k\rangle} - \langle \mathcal{B}_m f, \mathcal{B}_\ell g\rangle\right| \\ &\le \|\mathcal{B}_m f - \widehat{f}_n\| \|\mathcal{B}_\ell g - \widehat{g}_n\|,\end{aligned}$$

where

$$\widehat{f}_n(z) = \sum_{k=0}^{n-1}\langle \mathcal{B}_m f, \mathcal{B}_k\rangle \mathcal{B}_k(z), \quad \widehat{g}_n(z) = \sum_{k=0}^{n-1}\langle \mathcal{B}_\ell g, \mathcal{B}_k\rangle \mathcal{B}_k(z)$$

so that if the Hilbert–Schmidt norm dependence of matrix equivalence (1.3), (1.4) is to be employed, then interest is centered on the behavior of the overbound

$$|M_n(f)M_n(g) - M_n(fg)| \le \frac{1}{n}\sum_{m=0}^{n-1}\sum_{\ell=0}^{n-1} \|\mathcal{B}_m f - \widehat{f}_n\| \|\mathcal{B}_\ell g - \widehat{g}_n\|. \tag{5.1}$$

Now, since $|\mathcal{B}_m|$ is bounded, then $\mathcal{B}_m f \in L_2(\mathbf{T})$; so since $\{\mathcal{B}_k\}$ is a basis for $H_2(\mathbf{T})$, since $\{z^{-k}\}, k > 0$, is a basis for the orthogonal complement $H_2(\mathbf{T})^\perp$ [19], and since $L_2 = H_2 \oplus H_2^\perp$, then $\mathcal{B}_m f$ can be expanded as

$$\mathcal{B}_m f = \sum_{k=0}^{\infty}\langle \mathcal{B}_m f, \mathcal{B}_k\rangle \mathcal{B}_k + \sum_{k=1}^{\infty}\langle \mathcal{B}_m f, z^{-k}\rangle z^{-k}$$

so that

$$\|\mathcal{B}_m f - \widehat{f}_n\|^2 = \sum_{k=n}^{\infty} |\langle \mathcal{B}_m f, \mathcal{B}_k\rangle|^2 + \sum_{k=1}^{\infty} \left|\langle \mathcal{B}_m f, z^{-k}\rangle\right|^2 \tag{5.2}$$

and the task then becomes to try to show that as n and m increase, the terms in these sums tend to zero sufficiently quickly. In the trigonometric case this is straightforward since, for example, $\langle \mathcal{B}_m f, \mathcal{B}_k\rangle$ becomes $\langle z^m f, z^k\rangle = \langle f, z^{k-m}\rangle$ which is the $k-m$th term in the Fourier expansion of f. Assuming f is sufficiently smooth that these Fourier components die at some exponential rate (say, $\eta^{|k-m|}$ with $|\eta| < 1$) then provides (with the same reasoning giving $|\langle z^m f, z^{-k}\rangle| = |\langle f, z^{-(m+k)}\rangle| \leq |\eta|^{m+k}$) $\|\mathcal{B}_m f - \widehat{f}_n\| \leq K(\eta^{n-m} + \eta^m)$ for some $K < \infty$ so that the sums in the overbound in (5.1) are convergent and hence (5.1) tends to zero with increasing n thereby establishing $T_n(f)T_n(g) \sim T_n(fg)$ as $n \to \infty$.

Generalizing this to the basis (1.5) is surprisingly more difficult. However, consider the simplifying assumption that both f and g have finite dimensional (say, nth order) spectral factors of the form $f(z) = H(z)H(1/z)$, where

$$H(z) = \sum_{r=0}^{\infty} h_r z^r, \quad h_r = \sum_{i=0}^{n-1} \gamma_i^r$$

with $|\gamma_i| < 1$ and where for expediency (but without loss of generality) it is assumed that the $\{\gamma_i\}$ are isolated. Then the $|\langle \mathcal{B}_m f, \mathcal{B}_k\rangle|$ term can be simply bounded by the calculation

$$\begin{aligned}
\langle \mathcal{B}_m f, \mathcal{B}_k\rangle &= \sum_{r=0}^{\infty}\sum_{\ell=0}^{\infty} h_r \overline{h_\ell} \langle \mathcal{B}_m \overline{\mathcal{B}_k} z^r, z^\ell\rangle \\
&= \sum_{i=0}^{n-1}\sum_{j=0}^{n-1}\sum_{r=0}^{\infty}\sum_{\ell=r+1}^{\infty} \gamma_i^r \overline{\gamma_j^\ell} \langle \mathcal{B}_m \overline{\mathcal{B}_k} z^r, z^\ell\rangle \\
&= \sum_{i=0}^{n-1}\sum_{j=0}^{n-1}\sum_{r=0}^{\infty} \gamma_i^r \overline{\gamma_j^r} \sum_{\ell=1}^{\infty} \overline{\gamma_j^\ell} \langle \mathcal{B}_m \overline{\mathcal{B}_k}, z^\ell\rangle \\
&= \sum_{i=0}^{n-1}\sum_{j=0}^{n-1}\sum_{r=0}^{\infty} \gamma_i^r \overline{\gamma_j^r} \frac{\overline{\gamma_j}\sqrt{(1-|\xi_m|^2)(1-|\xi_k|^2)}}{(\overline{\gamma_j} - \overline{\xi_k})(1-\overline{\gamma_j}\xi_m)} \prod_{t=m+1}^{k} \left(\frac{\overline{\gamma_j} - \overline{\xi_t}}{1-\xi_t\overline{\gamma_j}}\right),
\end{aligned}$$

where in progressing to the last line it has been recognized that the inner sum in the second-to-last line is the evaluation at $z = \overline{\gamma_j}$ of a function $\mathcal{B}_m(z)\overline{\mathcal{B}_k(z)}$ with impulse response terms $\langle \mathcal{B}_m \overline{\mathcal{B}}_k, z^\ell\rangle$ and without loss of generality it has also been assumed that $k > m$. Therefore, since $|\gamma_j| < 1$ there exists $|\eta| < 1$, $K < \infty$ both independent of n such that (K is different in different parts of the following expressions)

$$\begin{aligned}
|\langle \mathcal{B}_m f, \mathcal{B}_k\rangle| &\leq K \sum_{i=0}^{n-1}\sum_{j=0}^{n-1}\sum_{r=0}^{\infty} |\gamma_i|^r |\gamma_j|^r \eta^{k-m} \\
&= K\eta^{k-m} \sum_{i=0}^{n-1}\sum_{j=0}^{n-1} \frac{1}{1-|\gamma_i\gamma_j|} \\
&\leq K\eta^{|k-m|},
\end{aligned}$$

where in the last line the fact that the same argument works for $k < m$ has been taken into account. Using the same method, one can also bound $|\langle \mathcal{B}_m f, z^{-k}\rangle|$ to arrive at $\|\mathcal{B}_m f - \widehat{f}\| \le K(\eta^{p-m} + \eta^m)$, and arguing as before for the trigonometric case, the desired algebraic result $M_n(f)M_n(g) \sim M_n(fg)$ can be extended to the case of generalized Toeplitz matrix (1.6).

In passing, on an intuitive level this extended result may be understood by noting that since the basis functions $\{\mathcal{B}_m\}$ contain order m all-pass factors φ_m as defined in Theorem 3.1, then they approximate the order m shift z^m in that they may be written as $\varphi_m(e^{j\omega}) = e^{j\psi_m(\omega)}$, where $\psi_m(\omega)$ is a monotonically nondecreasing function taking values between 0 and $2m\pi$.

Note also in passing that this simplified development illustrates why convergence in the strong matrix norm is not possible. Specifically, the bounds just developed are of the form such that the difference $|[M_n(f)M_n(g) - M_n(fg)]_{m,\ell}| \le K(\eta^{p-m} + \eta^m)(\eta^{p-\ell} + \eta^\ell)$ is a matrix with "corners" not tending to zero with increasing n, so that vectors exist that decay exponentially at rate η^k, have bounded norm, and when used in quadratic forms of the matrix difference produce nonzero results no matter how large n is.

Leaving this intuitive development aside, it may be considered that the assumption that f and g have finite dimensional spectral factorization is too restrictive. In this case a more general result may be offered, applicable to any Lipschitz continuous f and g, but at the expense of somewhat weakening the definition of equivalence over that discussed in section 1 to one in which two $n \times n$ matrices A_n and B_n are said to be asymptotically equivalent as $n \to \infty$ with notation $A_n \sim B_n$ as $n \to \infty$ if

$$\lim_{n\to\infty} \frac{\Gamma_n^\star(\omega)[A_n - B_n][A_n - B_n]^\star \Gamma_n(\omega)}{K_n(\omega,\omega)} = 0 \quad \forall \omega \in [-\pi, \pi].$$

Note that this refinement of the definition of matrix equivalence makes no difference for the system theoretic applications motivating this paper (see (7.4) and the accompanying discussion in section 7 following, or the work [37] for more detail on this point). With this definition in hand, the following result on the algebraic structure of generalized Toeplitz matrices is available.

THEOREM 5.1. *Consider two not necessarily real-valued functions f and g of which at least one of them is Lipschitz continuous of order $\varepsilon > 0$ and the other one bounded. Suppose that the poles $\{\xi_k\}$ of the basis functions $\{\mathcal{B}_k\}$ in* (1.5) *satisfy $|\xi_k| \le 1 - \delta$ for some $\delta > 0$. Then*

$$M_n(f)M_n(g) \sim M_n(fg) \quad \textit{as } n \to \infty$$

with convergence rate faster than $O(\log^4 n / n^{\varepsilon/(\varepsilon+2)})$ *as* $n \to \infty$.

Proof. Without loss of generality assume that g is Lipschitz continuous and that f is bounded. From the definition (1.6) of $M_n(f)$ and the formulation (3.1) of $K_n(\omega,\sigma)$ it follows that with the definition

$$\Delta_n(\omega) \triangleq [M_n(f)M_n(g) - M_n(fg)]\, \Gamma_n(\omega),$$

then with the representation (1.6) and the formulation (3.1) in mind

$$\begin{aligned}\Delta_n(\omega) = &\left(\frac{1}{2\pi}\int_{-\pi}^{\pi} \Gamma_n(\mu)\Gamma_n^\star(\mu) f(\mu)\,\mathrm{d}\mu\right)\left(\frac{1}{2\pi}\int_{-\pi}^{\pi} \Gamma_n(\sigma)\Gamma_n^\star(\sigma) g(\sigma)\,\mathrm{d}\sigma\right)\Gamma_n(\omega)\\ &- \left(\frac{1}{2\pi}\int_{-\pi}^{\pi} \Gamma_n(\mu)\Gamma_n^\star(\mu) f(\mu) g(\mu)\,\mathrm{d}\mu\right)\left(\frac{1}{2\pi}\int_{-\pi}^{\pi} \Gamma_n(\sigma)\Gamma_n^\star(\sigma)\,\mathrm{d}\sigma\right)\Gamma_n(\omega)\end{aligned}$$

$$\begin{aligned}
&= \frac{1}{4\pi^2}\int_{-\pi}^{\pi}\Gamma_n(\mu)f(\mu)\int_{-\pi}^{\pi}\Gamma_n^\star(\mu)\Gamma_n(\sigma)\Gamma_n^\star(\sigma)\Gamma_n(\omega)g(\sigma)\,\mathrm{d}\sigma\,\mathrm{d}\mu\\
&\quad -\frac{1}{4\pi^2}\int_{-\pi}^{\pi}\Gamma_n(\mu)f(\mu)\int_{-\pi}^{\pi}\Gamma_n^\star(\mu)\Gamma_n(\sigma)\Gamma_n^\star(\sigma)\Gamma_n(\omega)g(\mu)\,\mathrm{d}\sigma\,\mathrm{d}\mu\\
&= \frac{1}{4\pi^2}\int_{-\pi}^{\pi}\Gamma_n(\mu)f(\mu)\int_{-\pi}^{\pi}K_n(\sigma,\mu)K_n(\omega,\sigma)[g(\sigma)-g(\mu)]\,\mathrm{d}\sigma\,\mathrm{d}\mu
\end{aligned}$$

or more compactly

$$\Delta_n(\omega) = \frac{1}{2\pi}\int_{-\pi}^{\pi}\Gamma_n(\mu)G_n(\omega,\mu)f(\mu)\,\mathrm{d}\mu, \tag{5.3}$$

where the following definition has been used:

$$G_n(\omega,\mu) \triangleq \frac{1}{2\pi}\int_{-\pi}^{\pi}K_n(\sigma,\mu)K_n(\omega,\sigma)[g(\sigma)-g(\mu)]\,\mathrm{d}\sigma. \tag{5.4}$$

Therefore, denoting when x is a vector the Euclidean norm of x as $\|x\|$, then

$$\|\Delta_n(\omega)\|^2 = \frac{1}{2\pi}\int_{-\pi}^{\pi}\overline{G_n(\omega,\lambda)}H_n(\omega,\lambda)\overline{f(\lambda)}\,\mathrm{d}\lambda, \tag{5.5}$$

where

$$H_n(\omega,\lambda) \triangleq \frac{1}{2\pi}\int_{-\pi}^{\pi}G_n(\omega,\mu)K_n(\mu,\lambda)f(\mu)\,\mathrm{d}\mu. \tag{5.6}$$

However, by using Lemma 4.2

$$|K_n(\omega,\sigma)| \le \begin{cases} \dfrac{2n}{\delta} & \forall \sigma,\omega,\\[2ex] \dfrac{1}{|\sin(\omega-\sigma)/2|}, & \omega\neq\sigma, \end{cases} \tag{5.7}$$

so that Lemma A.1 may be applied to (5.4) with $f_n(\omega,\sigma) = K_n(\omega,\sigma)$, $g_n(\sigma,\mu) = K_n(\sigma,\mu)[g(\sigma)-g(\mu)]$ and $\beta=\gamma=1$ to conclude that

$$|G_n(\omega,\mu)| \le \begin{cases} Cn^{2/(2+\varepsilon)} & \forall \omega,\mu,\\[2ex] \dfrac{C}{|\sin(\omega-\mu)/2|}\log n, & \omega\neq\mu, \end{cases} \tag{5.8}$$

for n sufficiently large. Applying Lemma A.1 again, this time to (5.6) with the choices $f_n(\omega,\sigma) = K_n(\omega,\sigma)f(\omega)$, $g_n(\sigma,\mu) = G_n(\sigma,\mu)/\log n$ and $\beta = 1, \gamma = 2/(2+\varepsilon)$ provides

$$|H_n(\omega,\lambda)| \le \begin{cases} Cn^{2/(2+\varepsilon)}\log^2 n & \forall \omega,\lambda,\\[2ex] \dfrac{C}{|\sin(\omega-\mu)/2|}\log^2 n, & \omega\neq\lambda. \end{cases}$$

Applying Lemma A.1 a final time, this time to (5.5) with the choices $f_n(\omega,\sigma) = H_n(\omega,\sigma)/\log^2 n$ and $g_n(\sigma,\mu) = G_n(\sigma,\mu)/\log n$, $\beta = 1, \gamma = 2/(2+\varepsilon)$ provides

$$\|\Delta_n(\omega)\|^2 \le Cn^{2/(2+\varepsilon)}\log^4 n$$

for some $C < \infty$ and for n sufficiently large. Therefore, under the assumption that $|\xi_k| < 1 - \delta$ for some $\delta > 0$, then by (4.8) $K_n(\omega, \omega) \geq \kappa n$ for some $\kappa > 0$ so that for some $C < \infty$

$$\lim_{n\to\infty} \frac{\|\Delta_n(\omega)\|^2}{K_n(\omega,\omega)} \leq \lim_{n\to\infty} \frac{C \log^4 n}{n^{\varepsilon/(\varepsilon+2)}} = 0$$

for any $\varepsilon > 0$ and the theorem is proved. □

Again, something more than this result is actually required in system theoretic applications where one is often concerned with multiple products that also contain matrix inverses. Such cases may be handled by the following corollary to the preceding result. In what follows, matrix products are to be interpreted in a left-to-right fashion as $\prod_{k=1}^{n} A_k = A_1 A_2 \cdots A_n$.

COROLLARY 5.2. *Suppose that the family of possibly complex valued functions $\{f_k\}_{k=1}^m$ are all Lipschitz continuous of order $\varepsilon > 0$. Suppose that the poles $\{\xi_k\}$ of the basis functions $\{\mathcal{B}_k\}$ in* (1.5) *satisfy $|\xi_k| \leq 1 - \delta$ for some $\delta > 0$. Then with $\sigma_k = \pm 1$*

$$\prod_{k=1}^{m} M_n^{\sigma_k}(f_k) \sim M_n\left(\prod_{k=1}^{m} f_k^{\sigma_k}\right) \quad \textit{as } n \to \infty$$

with convergence rate faster than $O(\log^4 n / n^{\varepsilon/(\varepsilon+2)})$ as $n \to \infty$ and provided the functions $\{f_k\}$ are invertible where required by the values of σ_k.

Proof. An inductive argument will be used to obtain the result. Define the matrix difference

$$\Delta_n(m) \triangleq M_n\left(\prod_{k=1}^{m} f_k^{\sigma_k}\right) - \prod_{k=1}^{m} M_n^{\sigma_k}(f_k)$$

which may be reexpressed as

$$\Delta_n(m) = \Delta_n'(m) + \widetilde{\Delta}_n(m), \tag{5.9}$$

where

$$\Delta_n'(m) \triangleq M_n\left(\prod_{k=1}^{m} f_k^{\sigma_k}\right) - \prod_{k=1}^{m} M_n(f_k^{\sigma_k}),$$
$$\widetilde{\Delta}_n(m) \triangleq \prod_{k=1}^{m} M_n(f_k^{\sigma_k}) - \prod_{k=1}^{m} M_n^{\sigma_k}(f_k).$$

The terms $\Delta_n'(m)$ and $\widetilde{\Delta}_n(m)$ will be considered separately. First, note that

$$\Delta_n'(m) = \Delta_n'(m-1) M_n(f_m^{\sigma_m}) + \left[M_n\left(\prod_{k=1}^{m} f_k^{\sigma_k}\right) - M_n\left(\prod_{k=1}^{m-1} f_k^{\sigma_k}\right) M_n(f_m^{\sigma_m}) \right] \tag{5.10}$$

and by Theorem 5.1 with the substitution $f = f_m^{\sigma_m}$, $g = \prod_{k=1}^{m-1} f_k^{\sigma_k}$ the second term in the above expression obeys

$$M_n\left(\prod_{k=1}^{m} f_k^{\sigma_k}\right) \sim M_n\left(\prod_{k=1}^{m-1} f_k^{\sigma_k}\right) M_n(f_m^{\sigma_m}) \quad \text{as } n \to \infty. \tag{5.11}$$

Furthermore, denoting when A is a matrix the spectral norm of A as $\|A\|$, then by Lemma 6.1 $\|M_n(f)\| \leq \|f\|_\infty$ so that by the Cauchy–Schwarz inequality

$$\left|\frac{\Gamma_n^\star(\omega)\Delta_n'(m-1)M_n(f_m^{\sigma_m})\Gamma_n(\omega)}{K_n(\omega,\omega)}\right|^2 \leq \|f_m^{\sigma_m}\|_\infty^2 \left|\frac{\Gamma_n^\star(\omega)\Delta_n'(m-1)[\Delta_n'(m-1)]^\star\Gamma_n(\omega)}{K_n(\omega,\omega)}\right|$$

so that $\Delta_n'(m) \sim 0$ as $n \to \infty$ if $\Delta_n'(m-1) \sim 0$ as $n \to \infty$. However, $\Delta_n'(1) = 0$, so that by induction $\Delta_n'(m) \sim 0$ as $n \to \infty$ for any $m \geq 1$.

Now consider the term $\widetilde{\Delta}_n(m)$ and note that by labeling $k_1, \ldots, k_r$ as being the indices k for which $\sigma_k = -1$, then $\widetilde{\Delta}_n(m)$ may be written as (given that if the lower index of a matrix product is greater than the upper index, then the product is understood to be equal to the identity matrix)

$$\widetilde{\Delta}_n(m) = \sum_{\ell=1}^{r}\prod_{k=1}^{k_\ell-1} M_n^{\sigma_k}(f_k)M_n^{-1}(f_{k_\ell})\left[M_n(f_{k_\ell})M_n(f_{k_\ell}^{-1}) - I\right]\prod_{k=k_\ell+1}^{m} M_n(f_k^{\sigma_k}).$$

This expression may be decomposed as $\widetilde{\Delta}_n(m) = \Sigma_n(m) + \Lambda_n(m)$ with the definitions

$$\Sigma_n(m) \triangleq \sum_{\ell=1}^{r}\prod_{k=1}^{k_\ell-1} M_n^{\sigma_k}(f_k)M_n^{-1}(f_{k_\ell})\left[M_n(f_{k_\ell})M_n(f_{k_\ell}^{-1}) - I\right] M_n\left(\prod_{k=k_\ell+1}^{m} f_k^{\sigma_k}\right),$$

$$\Lambda_n(m) \triangleq \sum_{\ell=1}^{r}\prod_{k=1}^{k_\ell-1} M_n^{\sigma_k}(f_k)M_n^{-1}(f_{k_\ell})\left[M_n(f_{k_\ell})M_n(f_{k_\ell}^{-1}) - I\right] \times\left[\prod_{k=k_\ell+1}^{m} M_n(f_k^{\sigma_k}) - M_n\left(\prod_{k=k_\ell+1}^{m} f_k^{\sigma_k}\right)\right].$$

Dealing with $\Sigma_n(m)$ and $\Lambda_n(m)$ in turn, note that

$$\Sigma_n(m) = \sum_{\ell=1}^{r}\prod_{k=1}^{k_\ell-1} M_n^{\sigma_k}(f_k)M_n^{-1}(f_{k_\ell}) \times\left[M_n(f_{k_\ell})M_n(f_{k_\ell}^{-1})M_n\left(\prod_{k=k_\ell+1}^{m} f_k^{\sigma_k}\right) - M_n\left(\prod_{k=k_\ell+1}^{m} f_k^{\sigma_k}\right)\right]$$

and by Lemma 6.1, the submultiplicativity of the matrix norm, and the continuity and positive definiteness assumptions on the f_k

$$\left\|M_n^{-1}(f_{k_\ell})\prod_{k=1}^{k_\ell-1} M_n^{\sigma_k}(f_k)\right\| \leq \prod_{k=1}^{k_\ell}\|f_k^{\sigma_k}\|_\infty < \infty$$

so that since it has been shown inductively that $\Delta'(m) \sim 0$ as $n \to \infty$ for any $m \geq 1$, then by the Cauchy–Schwarz inequality $\Sigma_n(m) \sim 0$ as $n \to \infty$ for any $n \geq 1$. Finally, again notice that $\Delta_n'(m) \sim 0$ as $n \to \infty$ implies that

$$\prod_{k=k_\ell+1}^{m} M_n(f_k^{\sigma_k}) \sim M_n\left(\prod_{k=k_\ell+1}^{m} f_k^{\sigma_k}\right) \quad \text{as } n \to \infty$$

so that once again using Lemma 6.1, the Cauchy–Schwarz inequality, and the submultiplicativity of the matrix norm $\Lambda_n(m) \sim 0$ as $n \to \infty$, which completes the proof. □

Combining this corollary with Theorem 4.3 then provides a further corollary representing an extension of the generalized Fourier convergence of Theorem 4.3.

COROLLARY 5.3. *Suppose that the family of possibly complex valued functions* $\{f_k\}_{k=1}^m$ *are all Lipschitz continuous of order* $\varepsilon > 0$. *Suppose that the poles* $\{\xi_k\}$ *of the basis functions* $\{\mathcal{B}_k\}$ *in* (1.5) *satisfy* $|\xi_k| \leq 1 - \delta$ *for some* $\delta > 0$. *Then the following limit result holds:*

$$\lim_{n\to\infty} \frac{1}{K_n(\omega,\omega)} \Gamma_n^\star(\mu) \left(\prod_{k=1}^m M_n^{\sigma_k}(f_k) \right) \Gamma_m(\omega) = \begin{cases} \prod_{k=1}^m f_k^{\sigma_k}(\omega), & \mu = \omega, \\ 0, & \mu \neq \omega, \end{cases}$$

for any $\omega \in [-\pi, \pi]$ *and where* $\sigma_k = \pm 1$ *with the functions* $\{f_k\}$ *assumed to be invertible when required by the values of* σ_k.

Proof.

$$\Gamma_n^\star(\mu) \left(\prod_{k=1}^m M_n^{\sigma_k}(f_k) \right) \Gamma_m(\omega) = \Gamma_n^\star(\mu) M_n \left(\prod_{k=1}^m f_k^{\sigma_k} \right) \Gamma_n(\omega) + \Gamma_n^\star(\mu) \Delta_n \Gamma_n(\omega),$$

where

$$\Delta_n \triangleq \prod_{k=1}^m M_n^{\sigma_k}(f_k) - M_n \left(\prod_{k=1}^m f_k^{\sigma_k} \right).$$

Now, by the Cauchy–Schwarz inequality

$$\left| \frac{\Gamma_n^\star(\mu)\Delta_n\Gamma_n(\omega)}{K_n(\omega,\omega)} \right|^2 \leq \left| \frac{\Gamma_n^\star(\omega)\Delta_n\Delta_n^\star\Gamma_n(\omega)}{K_n(\omega,\omega)} \right| \left| \frac{K_n(\mu,\mu)}{K_n(\omega,\omega)} \right|.$$

However, by Lemma 4.2, the lower bound $K_n(\omega,\omega) \geq \delta n/2$ applies and the upper bound $K_n(\mu,\mu) \leq 2n/\delta$ also applies so that $|K_n(\mu,\mu)/K_n(\omega,\omega)| \leq 1/\delta^2 < \infty$ independently of n. As well, by Corollary 5.2

$$\Delta_n \sim 0 \quad \text{as } n \to \infty$$

so that

$$\lim_{n\to\infty} \left| \frac{\Gamma_n^\star(\mu)\Delta_n\Delta_n^\star\Gamma_n(\omega)}{K_n(\omega,\omega)} \right| = 0.$$

Use of Theorem 4.3 with the substitution $f = \prod_{k=1}^m f_k^{\sigma_k}$ then completes the proof. □

As a simple but important example of the utility of this corollary, it allows the conclusion that when all the poles $\{\xi_k\}$ are chosen in a closed subset of $\mathbf{D}$, then

$$\lim_{n\to\infty} \frac{\Gamma_n^\star(\omega) M_n^{-1}(f) \Gamma_n(\omega)}{K_n(\omega,\omega)} = \frac{1}{f(\omega)} \tag{5.12}$$

which has particular relevance to the study of reproducing kernels with respect to weighted inner products.

More specifically, the emphasis so far has been on studying the reproducing kernel $K_n(z,\mu)$ associated with the space $X_n = \text{Span}\{\mathcal{B}_0, \ldots, \mathcal{B}_{n-1}\}$ and with respect to the inner product (2.1). However, as was illustrated in section 3 via a linear prediction example, there is utility in examining a related kernel $K_n'(z,\mu)$ which is still associated with X_n, but exists with respect to an inner product which is (2.1) with the integrand weighted by a positive function $f(\omega)$. In this case, since

$$\langle \Gamma_n^\star(\mu) M_n^{-1}(f)\Gamma_n(z), \Gamma_n^T(z)\rangle = \Gamma_n^\star(\mu) M_n^{-1}(f)\langle \Gamma_n(z), \Gamma_n^T(z)\rangle = \Gamma_n^\star(\mu),$$

then $\langle \mathcal{B}_k(z), \Gamma_n^\star(\mu) M_n^{-1}(f)\Gamma_n(z)\rangle = \mathcal{B}_k(\mu)$ for every $k = 0, 1, \ldots, n-1$, and hence since $K_n'(z,\mu)$ is the unique function in X_n with this property, then in fact $K_n'(z,\mu) = \Gamma_n^\star(\mu) M_n^{-1}(f)\Gamma_n(z)$ and so the asymptotic result (5.12) provides a means for providing the closed form approximation $K_n(\omega,\omega)/f(\omega)$ for $K_n'(\omega,\omega)$.

As a concluding remark for this section, it should be noted that the only other work known to the authors which addresses issues of generalizing Fourier convergence and asymptotic Toeplitz matrix properties in a similar context to this paper is that of Gunnarsson and Ljung [15, 16], wherein the generalization involves matrices not necessarily being Toeplitz but at least being approximately so in some sense. The details of this are such that the generalized matrices (and hence generalized Fourier convergence) considered in [15, 16] are quite different from those of the form $M_n(f)$ considered here, which are not approximately Toeplitz in any sense except that the spectral formulation (1.6) is reminiscent of the classical Toeplitz one (1.1).

6. Spectral properties of generalized Toeplitz matrices. A typical system identification application of the orthonormal bases (1.5) would be to seek a parameter vector $\theta \in \mathbf{R}^n$ in order to model the input-output relationship between N samples of an observed input sequence $\{u_k\}$ and output sequence $\{y_k\}$ as [46, 47, 40, 36]

$$y_k = \sum_{n=0}^{m-1} \theta_n \mathcal{B}_n(q) u_k = \phi_k^T \theta, \quad k = 0, 1, \ldots, N-1, \tag{6.1}$$

where q is the backward time shift operator and

$$\phi_k^T \triangleq [\mathcal{B}_0(q)u_k, \mathcal{B}_1(q)u_k, \ldots, \mathcal{B}_{n-1}(q)u_k]$$

is a vector of filtered versions of the signal $\{u_k\}$, the filtering depending on the orthonormal basis functions chosen. The least-squares solution $\widehat{\theta}$ for θ is then given as

$$\widehat{\theta} = R_N^{-1} \frac{1}{N} \sum_{k=0}^{N-1} \phi_k y_k, \quad R_N \triangleq \frac{1}{N} \sum_{k=0}^{N-1} \phi_k \phi_k^T$$

provided that R_N exists. It is well known [13] that the numerical robustness of solving for $\widehat{\theta}$ is intimately related to the condition number $\kappa(R_N)$ of R_N. By Parseval's theorem, for large N the matrix R_N converges as [27]

$$\lim_{N\to\infty} R_N = M_n(f),$$

where f is the spectral density of the observed input $\{u_k\}$ which, if containing deterministic components, is defined in the sense of Wiener's generalized harmonic analysis [51] or the quasi-stationarity sense of Ljung [27]. From a numerical point of view there is therefore significant practical relevance in examining the spectrum of generalized Toeplitz matrices.

For the classical trigonometric case wherein $\xi_k = 0$ and $M_n(f)$ is in fact a bonafide Toeplitz matrix, it is well known [14, 50] that the eigenvalues of $M_n(f)$ may be bounded above and below by the maximum and minimum values of f. This result can be easily extended to the general case, the classical case again emerging as a special case by setting $\xi_k = 0$.

LEMMA 6.1. *For continuous and real-valued $f(\omega) > 0$ let $M_n(f)$ be defined by* (1.6)*. Then*

$$\min_{\omega\in[-\pi,\pi]} f(\omega) \le \lambda(M_n(f)) \le \max_{\omega\in[-\pi,\pi]} f(\omega),$$

where $\lambda(A)$ is any eigenvalue of the matrix A. In the case that f is complex valued, then the upper bound

$$|\lambda(M_n(f))| \le \max_{\omega\in[-\pi,\pi]} |f(\omega)|$$

applies.

Proof. Consider the case of real-valued $f > 0$ first and take $x \in \mathbf{R}^n$ arbitrary but such that $x^\star x = 1$. Then

$$\begin{aligned} x^\star M_n(f)x &= \frac{1}{2\pi}\sum_{r=0}^{n-1}\sum_{k=0}^{n-1}\overline{x_r}x_k\int_{-\pi}^{\pi}\mathcal{B}_r(e^{j\omega})\overline{\mathcal{B}_k(e^{j\omega})}f(\omega)\,\mathrm{d}\omega,\\ &= \frac{1}{2\pi}\int_{-\pi}^{\pi} f(\omega)\left|\sum_{r=0}^{n-1}x_r\mathcal{B}_r(e^{j\omega})\right|^2\mathrm{d}\omega,\\ &\le \max_{\omega\in[-\pi,\pi]}\frac{f(\omega)}{2\pi}\sum_{r=0}^{n-1}\sum_{k=0}^{n-1}\overline{x_r}x_k\int_{-\pi}^{\pi}\mathcal{B}_r(e^{j\omega})\overline{\mathcal{B}_k(e^{j\omega})}\,\mathrm{d}\omega\\ &= \max_{\omega\in[-\pi,\pi]} f(\omega). \end{aligned}$$

However, since $M_n(f)$ is symmetric positive definite then

$$\max_{x^\star x=1} x^\star M_n(f)x = \lambda_{\max}(M_n(f)).$$

Using a similar argument to underbound the eigenvalues of $M_n(f)$ then completes the first part of the lemma. For the case of complex valued f note that the upper bound can be generated as a slight modification to the above reasoning as

$$|x^\star M_n(f)x| \le \frac{1}{2\pi}\int_{-\pi}^{\pi}|f(\omega)|\left|\sum_{r=0}^{n-1}x_r\mathcal{B}_r(e^{j\omega})\right|^2\mathrm{d}\omega \le \max_{\omega\in[-\pi,\pi]}|f(\omega)|. \qquad \square$$

This result provides a guaranteed overbound

$$\kappa(M_n(f)) \triangleq \frac{\lambda_{\max}(M_n(f))}{\lambda_{\min}(M_n(f))} \le \frac{\max_{\omega\in[-\pi,\pi]} f(\omega)}{\min_{\omega\in[-\pi,\pi]} f(\omega)} \tag{6.2}$$

on the condition number $\kappa(M_n(f))$ governing the numerical robustness of the least-squares estimation problem. The existence of this overbound has been one of the prime motivators for the recent interest in the use of orthonormal bases such as (1.5) for system identification applications [46, 47, 18, 40].

It is then natural to examine how conservative the bound (6.2) is. Considering that numerical robustness is of greatest concern when the dimension n is large, it is not unreasonable to simplify the examination of conservatism by letting $n \to \infty$. This allows the following result showing that for large n the bounds in Lemma 6.1 are tight so that the condition number of $M_n(f)$ actually achieves the bound (6.2).

THEOREM 6.2. *Define for continuous $f(\omega) > 0$ the operator $M(f) : \{x_k\} \in \ell_2^+ \mapsto \{y_k\} \in \ell_2^+$ as*

$$M(f) \triangleq \lim_{n\to\infty} M_n(f),$$

where this is understood to mean that the infinite sequence $\{y_k\}$ is generated from the infinite sequence $\{x_k\}$ as a natural limit of how finite length n $\{y_k\}$ are generated from finite length n $\{x_k\}$ via matrix multiplication by $M_n(f)$. Specifically

$$y_k = \frac{1}{2\pi}\int_{-\pi}^{\pi} \mathcal{B}_k(e^{j\omega})\overline{g(\omega)}\,\mathrm{d}\omega, \quad g(\omega) \triangleq f(\omega)\sum_{k=0}^{\infty} x_k \mathcal{B}_k(e^{j\omega}).$$

Then provided

$$\sum_{k=0}^{\infty}(1 - |\xi_k|) = \infty$$

it holds that

$$\lambda(M(f)) \triangleq \{\lambda \in \mathbf{C} : M(f) - \lambda I \text{ is not invertible}\} = \mathrm{Range}\{f(\omega)\}.$$

Proof. Take any $\mu \in [\min_\omega f(\omega), \max_\omega f(\omega)]$ and suppose $\mu \notin \lambda(M)$. Then since by orthogonality $M(1)$ is the identity operator, $M(f - \mu)$ is an invertible operator from $\ell_2^+ \to \ell_2^+$ so that in particular $\exists x \in \ell_2^+$ such that for $e_0 = (1, 0, 0, \ldots)$

$$x^T M(f - \mu) = e_0. \tag{6.3}$$

Therefore, defining $g(z) \in H_2(\mathbf{T})$ by $g(z) \triangleq (x_0 - 1)\mathcal{B}_0(z) + \sum_{k=1}^{\infty} x_k B_k(z)$ gives that from (6.3) $(f - \mu)g \perp \mathrm{Span}\{\mathcal{B}_k\}$. However, under the condition $\sum(1 - |\xi_k|) = \infty$ by Theorem 2.1, $\mathrm{Span}\{\mathcal{B}_k\} = H_2$ so that since $L_2 = H_2 \oplus H_2^\perp$ then $(f - \mu)\overline{g} \in H_2$. However, $g \in H_2$ by construction and the product of two H_2 functions is in H_1 [19]. Therefore $(f - \mu)|g|^2$ is a real-valued H_1 function, and the only such functions are constants [19]. However, since $\mu \in [\min_\omega f(\omega), \max_\omega f(\omega)]$, this function cannot be of constant sign; hence it cannot be a constant. This contradiction implies $[\min_\omega f(\omega), \max_\omega f(\omega)] \subset \lambda(M)$. Finally, Lemma 6.1 gives that $\lambda(M) \subset [\min_\omega f(\omega), \max_\omega f(\omega)]$. □

Again, this result represents an expansion to the case of generalized Toeplitz matrices (1.6) of results already known for conventional symmetric Toeplitz matrices [14, 50], the latter results being encompassed as a special case of Theorem 6.2. A practical conclusion arising from this theorem is that the numerical properties of the solution of (6.1) are governed solely by the spectral density f of $\{u_k\}$ and are independent of the particular orthonormal basis chosen in (6.1) via the selection of $\{\xi_k\}$.

Another conclusion arising from Theorem 6.2 is that in the previous results on the asymptotic algebraic structure of generalized Toeplitz matrices (a main conclusion of which was to conclude that $M_n^{-1}(f) \sim M_n(1/f)$ as $n \to \infty$) the assumptions imposed there of f being invertible cannot be weakened.

7. Applications. To put these results in context, this section presents a very brief outline of how they may be applied to certain system identification problems that have been previously alluded to. A much more detailed exposition of the issues raised here is contained in [37].

A result that has become of key importance to the intuitive understanding of various system identification methods [2, 12, 28, 17] is that the variability of the frequency response $G(e^{j\omega}, \widehat{\theta})$, of a model based on a least-squares estimate $\widehat{\theta}$ of an n dimensional parameter vector θ obtained from N observations of noise-corrupted input-output measurements, is approximately given by [31, 29]

$$\text{Var}\{G(e^{j\omega}, \widehat{\theta})\} \approx \frac{n}{N} \frac{\Phi_\nu(\omega)}{\Phi_u(\omega)}, \tag{7.1}$$

where $\Phi_u(\omega)$ is the spectral density of the observed input process and $\Phi_\nu(\omega)$ is the spectral density of the noise-corrupting process.

This is established in [29] for a wide range of model structures, unified by the requirement that a certain "shift" structure holds. In the interest of clarity, the discussion here will focus only on the case of measurement noise being white and the true system (including noise model) being encompassed by the model structure. In this case, it is established in [29] that with $\Phi_\nu(\omega) = \sigma^2$ being the constant white noise spectral density, then for large N

$$\frac{N}{n}\text{Var}\{G(e^{j\omega}, \widehat{\theta})\} \approx \frac{1}{n}\Gamma_n^\star(\omega) T_n^{-1}(\Phi_u) T_n(\sigma^2\Phi_u) T_n^{-1}(\Phi_u)\Gamma_n(\omega). \tag{7.2}$$

The reasoning of [29] then is that using the previously discussed classical results [14, 50] on the asymptotic algebraic structure of Toeplitz matrices, it can be argued that $T_n^{-1}(\Phi_u)T_n(\sigma^2\Phi_u)T_n^{-1}(\Phi_u) \approx T_n(\sigma^2/\Phi_u)$ so that the right-hand side of (7.2) is approximately an nth order Cesàro mean reconstruction of σ^2/Φ_u at frequency ω and hence should be approximately equal to $\sigma^2/\Phi_u(\omega)$.

However, it is very common, in the interest of concentrating estimation accuracy in certain frequency regions, to prefilter the measured data [27]. Identifying this filter with its transfer function $F(z)$ then allows the nature of the prefiltering to be characterized by the spectral density change of $\Phi_u(\omega) \mapsto |F(e^{j\omega})|^2\Phi_u(\omega)$. However, at the same time the use of data prefiltering implies a revision of the "noise model" as [29] $\Phi_\nu(\omega) \mapsto |F(e^{j\omega})|^2\Phi_\nu(\omega)$. In this case, the approximate estimation variability would be expected to be unchanged from (7.1) by reasoning that

$$\text{Var}\{G(e^{j\omega}, \widehat{\theta})\} \approx \frac{n}{N} \frac{|F(e^{j\omega})|^2\Phi_\nu(\omega)}{|F(e^{j\omega})|^2\Phi_u(\omega)} = \frac{n}{N}\frac{\Phi_\nu(\omega)}{\Phi_u(\omega)}. \tag{7.3}$$

However, as illustrated numerically in [37], the accuracy of this approximation depends very much on the relationship between the order of the filter F and the model order. The closer the two orders the more inaccurate the approximation.

In [37] this phenomenon is traced to the fact that as the filter order grows, the underlying Fourier reconstruction involved in (7.1) and hence (7.3) is with respect to a function with decreasing smoothness, and hence more terms (which grow with model order) are required in the Fourier expansion before convergence will approximately occur.

To circumvent this problem, a key observation of [37] is that the model can be reparameterized into one in which the prefilter poles are absorbed into the model structure. In this case (7.2) is replaced with

$$\frac{N}{K_n(\omega,\omega)}\mathrm{Var}\{G(e^{j\omega},\widehat{\theta})\} \approx \frac{\Gamma_n^\star(\omega)M_n^{-1}(\Phi_u)M_n(\sigma^2\Phi_u)M_n^{-1}(\Phi_u)\Gamma_n(\omega)}{K_n(\omega,\omega)}, \tag{7.4}$$

where the poles of the basis functions forming the generalized Toeplitz matrix $M_n(\Phi_u)$ are chosen the same as the prefilter. In this case, using Corollary 5.2 it can be argued that $M_n^{-1}(\Phi_u)M_n(\sigma^2\Phi_u)M_n^{-1}(\Phi_u) \sim M_n(\sigma^2/\Phi_u)$ as $n \to \infty$ so that

$$\frac{N}{K_n(\omega,\omega)}\mathrm{Var}\{G(e^{j\omega},\widehat{\theta})\} \approx \frac{1}{K_n(\omega,\omega)}\Gamma_n^\star(\omega)M_n(\sigma^2/\Phi_u)\Gamma_n(\omega) \tag{7.5}$$

which is a generalized Fourier reconstruction of a function σ^2/Φ_u that is *invariant* to the choice of prefilter. Therefore, using Theorem 4.3 to argue that (7.5) is approximately $\sigma^2/\Phi_u(\omega)$ the work [37] is able to suggest that

$$\mathrm{Var}\{G(e^{j\omega},\widehat{\theta})\} \approx \frac{K_n(\omega,\omega)}{N}\frac{\Phi_\nu(\omega)}{\Phi_u(\omega)} \tag{7.6}$$

is a more accurate approximation when all-pole prefiltering is employed and the ratio of model order to filter order is low. In other words, data prefiltering can affect the variability of the estimated model, and (7.6) quantifies how this occurs. The validity of these conclusions is illustrated numerically in [37]. As a final applications-oriented remark, note that when all poles $\{\xi_k\}$ are chosen at the origin (which corresponds to no prefiltering), then $K_n(\omega,\omega) = n$ so that the new approximation (7.6) becomes the "classical" one (7.1) as a special case.

8. Conclusion.

The purpose of this paper was to consider certain results in the study of Fourier series and Toeplitz matrices that have proved to be key to various system theoretic applications, and expand them to the case where the underlying orthonormal basis is not the classical trigonometric one but rather a rational formulation that encompasses the trigonometric basis as a special case. These results, and the ensuing generalizations developed in this paper, are summarized in Table 8.1.

One point worth clarifying is that in system theoretic settings for which these results will be applicable (control, signal processing, system identification) it is more common to associate the complex variable z with a forward time shift, rather than the backward shift association used here. This discrepancy is easily accommodated by simply transforming $z \mapsto 1/z$ in all the results presented here. A different basis function definition will result, which is in accordance with certain so-called Laguerre and Kautz bases studied in the control theory literature. However, the matrices $M_n(f)$ and the associated Fourier reconstruction formulas will be unchanged.

Appendix A. Bounds on integrals of kernel-like functions.

Throughout this appendix, C will denote a finite positive constant which may be different in different places of the same expression.

LEMMA A.1. *Let $f_n(\omega,\sigma) : [-\pi,\pi]\times[-\pi,\pi] \to \mathbf{C}$ be subject to*

$$|f_n(\omega,\sigma)| \le \begin{cases} Cn^\beta & \forall\omega,\sigma, \\ \dfrac{C}{|\sin(\omega-\sigma)/2|}, & \omega\neq\sigma, \end{cases} \tag{A.1}$$

TABLE 8.1
Summary of classical results and their relation to the generalizations derived here.

	Classical	Generalized
Basis	$e^{j\omega n}$	$\mathcal{B}_n(e^{j\omega}) \triangleq \frac{\sqrt{1-\lvert\xi_n\rvert^2}}{1-\xi_n e^{j\omega}} \prod_{k=0}^{n-1} \frac{e^{j\omega}-\overline{\xi_k}}{1-\xi_k e^{j\omega}}$
Completeness	$H_2(\mathbf{T})$	$H_2(\mathbf{T})$ provided $\sum(1-\lvert\xi_n\rvert)=\infty$

Extensions $\sigma_k = \pm 1$	$\prod_{k=1}^{m} T_n^{\sigma_k}(f_k) \sim T_n\left(\prod_{k=1}^{m} f_k^{\sigma_k}\right)$	$\prod_{k=1}^{m} M_n^{\sigma_k}(f_k) \sim M_n\left(\prod_{k=1}^{m} f_k^{\sigma_k}\right)$

for some $\beta \geq 0$ *and let* $g_n(\sigma,\mu) : [-\pi,\pi]\times[-\pi,\pi] \to \mathbf{C}$ *be subject to*

$$
|g_n(\sigma,\mu)| \leq \begin{cases} Cn^\gamma d^\varepsilon(\sigma,\mu) & \forall \mu,\sigma, \\ \dfrac{C}{|\sin(\mu-\sigma)/2|}, & \omega \neq \sigma, \end{cases} \tag{A.2}
$$

for some $\gamma,\varepsilon \geq 0$ *and where the meaning of* $d(\sigma,\mu)$ *is defined in* (4.9). *Then for* n *sufficiently large*

$$
\left|\int_{-\pi}^{\pi} f_n(\omega,\sigma) g_n(\sigma,\mu)\,d\sigma\right| \leq \begin{cases} C\min(n^\lambda, n^\delta \log n) & \forall \omega,\mu, \\ \dfrac{C}{|\sin(\omega-\mu)/2|}\log n, & \omega\neq\mu, \end{cases} \tag{A.3}
$$

where

$$
\lambda \triangleq \frac{\beta+\gamma}{2+\varepsilon}, \qquad \delta \triangleq \min(\beta,\gamma).
$$

Proof. Suppose, to begin with, that $\omega \neq \mu$. Then for any $\alpha > 0$, $d(\omega,\mu) \geq 6n^{-\alpha}$ for sufficiently large n. Assuming this is the case, define the following regions:

$$\begin{aligned}\Omega_1 &\triangleq \left\{\sigma \in [-\pi,\pi] : d(\omega,\sigma) < n^{-\alpha}\right\},\\ \Omega_2 &\triangleq \left\{\sigma \in [-\pi,\pi] : d(\mu,\sigma) \leq n^{-\alpha}\right\},\\ \Omega_3 &\triangleq \{\sigma \in [-\pi,\pi] : \sigma \notin \{\Omega_1 \cup \Omega_2\}\}.\end{aligned}$$

Therefore, using the assumed bounds on $f_n(\omega,\sigma), g_n(\sigma,\mu)$, noticing that by definition the regions Ω_1 and Ω_2 are disjoint, and using Lemma B.1 with $\varepsilon = 0$ lead to

$$\left|\int_{\Omega_1} f_n(\omega,\sigma)g_n(\sigma,\mu)\,\mathrm{d}\sigma\right| \leq \int_{\Omega_1} \frac{Cn^{\beta}}{|\sin(\mu-\sigma)/2|}\,\mathrm{d}\sigma \leq C\frac{n^{\beta-\alpha}}{|\sin(\mu-\omega)/2|}.$$

Similarly

$$\left|\int_{\Omega_2} f_n(\omega,\sigma)g_n(\sigma,\mu)\,\mathrm{d}\sigma\right| \leq \int_{\Omega_2} \frac{Cn^{\gamma}}{|\sin(\omega-\sigma)/2|}\,\mathrm{d}\sigma \leq C\frac{n^{\gamma-\alpha}}{|\sin(\mu-\omega)/2|}.$$

Finally, this time using Lemma B.2

$$\left|\int_{\Omega_3} f_n(\omega,\sigma)g_n(\sigma,\mu)\,\mathrm{d}\sigma\right| \leq \int_{\Omega_3} \frac{C}{|\sin(\sigma-\omega)/2\sin(\sigma-\mu)/2|}\,\mathrm{d}\sigma \leq \frac{C\alpha}{|\sin(\mu-\omega)|}\log n$$

so that for $\omega \neq \mu$, choosing $\alpha = \max(\beta,\gamma)$ provides the bound

$$\left|\int_{-\pi}^{\pi} f_n(\omega,\sigma)g_n(\sigma,\mu)\,\mathrm{d}\sigma\right| \leq \frac{C}{|\sin(\omega-\mu)/2|}\log n$$

for sufficiently large n. Now assume that $\omega = \mu$. In this case, again using the assumed bounds on $f_n(\omega,\sigma)$ and $g_n(\sigma,\mu)$,

$$\begin{aligned}\left|\int_{\Omega_1} f_n(\omega,\sigma)g_n(\sigma,\mu)\,\mathrm{d}\sigma\right| &\leq Cn^{\beta+\gamma}\int_{\Omega_1} d^{\varepsilon}(\sigma,\mu)\,\mathrm{d}\sigma \leq Cn^{\beta+\gamma}\int_0^{n^{-\alpha}} x^{\varepsilon}\,\mathrm{d}x\\ &= Cn^{\beta+\gamma-\alpha(\varepsilon+1)}.\end{aligned}$$

Also, using Lemma B.2

$$\left|\int_{\Omega_3} f_n(\omega,\sigma)g_n(\sigma,\mu)\,\mathrm{d}\sigma\right| \leq \int_{\Omega_3} \frac{C}{\sin^2(\sigma-\omega)/2}\,\mathrm{d}\sigma \leq \frac{C}{\sin n^{-\alpha}} \leq Cn^{\alpha},$$

so that when $\omega = \mu$ and hence $\Omega_1 = \Omega_2$, then for sufficiently large n

$$\left|\int_{-\pi}^{\pi} f_n(\omega,\sigma)g_n(\sigma,\mu)\,\mathrm{d}\sigma\right| \leq Cn^{\beta+\gamma-\alpha(\varepsilon+1)} + Cn^{\alpha}.$$

This bound is minimized (for large n) by the choice $\alpha = (\beta+\gamma)/(2+\varepsilon)$ as $Cn^{(\beta+\gamma)/(2+\varepsilon)}$. Alternatively, with the definition $\delta \triangleq \min(\beta,\gamma)$ the integral on Ω_3 can also be bounded using Lemma B.2 as

$$\left|\int_{\Omega_3} f_n(\omega,\sigma)g_n(\sigma,\mu)\,\mathrm{d}\sigma\right| \leq \int_{\Omega_3} \frac{Cn^{\delta}}{|\sin(\sigma-\omega)/2|}\,\mathrm{d}\sigma \leq C\alpha n^{\delta}\log n$$

to give the bound for $\omega = \mu$ and sufficiently large n of

$$\left|\int_{-\pi}^{\pi} f_n(\omega,\sigma)g_n(\sigma,\mu)\,\mathrm{d}\sigma\right| \leq Cn^{\beta+\gamma-\alpha(\varepsilon+1)} + C\alpha n^{\delta}\log n.$$

This bound is minimized (assuming without loss of generality that $\beta = \min(\beta,\gamma)$) by the choice (for large n) $\alpha = \gamma/(1+\varepsilon)$ as

$$\left|\int_{-\pi}^{\pi} f_n(\omega,\sigma)g_n(\sigma,\mu)\,\mathrm{d}\sigma\right| \leq Cn^{\delta}\log n.$$

Note that this latter bound will be smaller than the previous one whenever $\beta+\gamma > (2+\varepsilon)\min(\beta,\gamma)$ and for n sufficiently large. □

Appendix B. Integrals of reciprocals of sine functions.

LEMMA B.1. *Let* $0 < \alpha < \pi/8$ *and suppose that* $\omega,\mu \in [-\pi,\pi]$ *satisfies* $d(\mu,\omega) \geq 4\alpha$. *Then for any* $\Omega \subset [\mu-\alpha,\mu+\alpha]$, $\varepsilon \geq 0$ *and where the meaning of* $d(\mu,\omega)$ *is defined in* (4.9)

$$\int_{\Omega} \frac{d^{\varepsilon}(\sigma,\mu)}{|\sin(\sigma-\omega)/2|}\,\mathrm{d}\sigma \leq \frac{16\alpha^{\varepsilon+1}}{(\varepsilon+1)|\sin(\mu-\omega)/2|}.$$

Proof. It holds that

$$\begin{aligned}\sin\left(\frac{\mu-\omega}{2}+\frac{x}{2}\right) &= \cos\left(\frac{x}{2}\right)\sin\left(\frac{\mu-\omega}{2}\right) + \sin\left(\frac{x}{2}\right)\cos\left(\frac{\mu-\omega}{2}\right)\\ &= \cos\left(\frac{x}{2}\right)\sin\left(\frac{\mu-\omega}{2}\right)\left(1+\tan\left(\frac{x}{2}\right)\cot\left(\frac{\mu-\omega}{2}\right)\right),\end{aligned} \tag{B.1}$$

and for $x \in [-\alpha,\alpha]$

$$1+\tan\left(\frac{x}{2}\right)\cot\left(\frac{\mu-\omega}{2}\right) > 1 - \frac{\alpha/2}{\cos(\pi/8)}\,\frac{4}{d(\mu,\omega)} > 1/4. \tag{B.2}$$

Without loss of generality, assume Ω is such that $d(\sigma,\mu) = |\sigma-\mu|$ on Ω in which case the change of variables $x = \sigma-\mu$, together with (B.1)–(B.2), then gives

$$\begin{aligned}\int_{\Omega} \frac{d^{\varepsilon}(\sigma,\mu)}{|\sin(\sigma-\omega)/2|}\,\mathrm{d}\sigma &\leq \int_{-\alpha}^{\alpha} \frac{|x|^{\varepsilon}}{|\sin(\mu-\omega+x)/2|}\,\mathrm{d}x\\ &\leq \frac{1}{|\sin(\mu-\omega)/2|}\int_{-\alpha}^{\alpha} \frac{|x|^{\varepsilon}}{|\cos x/2|}\,\frac{1}{|1+\tan(x/2)\cot(\mu-\omega)/2|}\,\mathrm{d}x\\ &\leq \frac{1}{|\sin(\mu-\omega)/2|}\int_{-\alpha}^{\alpha} 2\,\times\,4|x|^{\varepsilon}\,\mathrm{d}x = \frac{16\alpha^{1+\varepsilon}}{(1+\varepsilon)|\sin(\mu-\omega)/2|}.\end{aligned}$$

□

LEMMA B.2. *Let* $-\pi \leq \alpha < \beta \leq \pi$ *and suppose that* $\omega \in [-\pi,\pi]$ *does not belong to* $[\alpha,\beta]$. *Then*

$$\int_{\alpha}^{\beta} \frac{1}{|\sin(\sigma-\omega)/2|}\,\mathrm{d}\sigma \leq 4\log\frac{8}{\gamma}, \tag{B.3}$$

where $\gamma \triangleq d(\omega, [\alpha, \beta])$*. Suppose also that* $\mu \in [-\pi, \pi]$ *does not belong to* $[\alpha, \beta]$*. Then*

$$\text{(B.4)}\quad \int_\alpha^\beta \frac{1}{|\sin(\sigma-\omega)/2\sin(\sigma-\mu)/2|}\,\mathrm{d}\sigma \leq \begin{cases} \dfrac{8}{|\sin(\mu-\omega)/2|}\log\dfrac{4}{\gamma}, & \omega \neq \mu, \\ \\ \dfrac{4}{\sin\gamma}, & \omega = \mu, \end{cases}$$

where in this latter case $\gamma \triangleq d(\{\omega, \mu\}, [\alpha, \beta])$*.*

Proof. To begin with assume that $\omega < \alpha$. The change of variables $x = (\sigma - \omega)/2$ then gives

$$\text{(B.5)}\qquad \int_\alpha^\beta \frac{1}{|\sin(\sigma-\omega)/2|}\,\mathrm{d}\sigma = 2\int_{\alpha'}^{\beta'} \frac{1}{\sin x}\,\mathrm{d}x,$$

where $0 < \alpha' \triangleq (\alpha-\omega)/2 < \beta' \triangleq (\beta-\omega)/2 < \pi$. Since $\sin(\beta'/2) > \sin(\alpha'/2)$ and $\cos(\alpha'/2) > \cos(\beta'/2)$ it follows from (B.5) that

$$\begin{aligned} \int_\alpha^\beta \frac{1}{|\sin(\sigma-\omega)/2|}\,\mathrm{d}\sigma &= 2\left[\log\left(\tan(x/2)\right)\right]_{\alpha'}^{\beta'}, \\ &= 2\log\left(\frac{\sin(\beta'/2)}{\sin(\alpha'/2)}\right) + 2\log\left(\frac{\cos(\alpha'/2)}{\cos(\beta'/2)}\right) \\ &\leq 2\log\left(\frac{1}{\sin(\alpha'/2)}\right) + 2\log\left(\frac{1}{\cos(\beta'/2)}\right) \\ &= 2\log\left(\frac{1}{\sin(\alpha'/2)}\right) + 2\log\left(\frac{1}{\sin(\pi/2-\beta'/2)}\right) \\ &\leq 2\log\left(\frac{4}{d(\alpha',0)}\right) + 2\log\left(\frac{4}{d(\pi-\beta',0)}\right) \\ &= 2\log\left(\frac{4}{d(\alpha',0)}\right) + 2\log\left(\frac{4}{d(\beta',0)}\right) \\ \text{(B.6)}\qquad &\leq 4\log\left(\frac{8}{\gamma}\right). \end{aligned}$$

The case where $\beta < \omega$ follows analogously, and the proof of the bound (B.3) is complete. Moving on to the proof of the bound (B.4), consider first the case $\omega \neq \mu$ and assume that

$$\text{(B.7)}\qquad -\pi \leq \omega < \mu < \alpha < \beta < \pi.$$

Let $0 < \alpha' \triangleq (\alpha-\mu)/2 < \beta' \triangleq (\beta-\mu)/2 < \pi$. The change of variables $x = (\sigma-\mu)/2$ then gives

$$\begin{aligned} &\int_\alpha^\beta \frac{1}{|\sin(\sigma-\omega)/2\sin(\sigma-\mu)/2|}\,\mathrm{d}\sigma \\ &= 2\int_{\alpha'}^{\beta'} \frac{1}{\sin\left((\mu-\omega)/2+x\right)\sin(x)}\,\mathrm{d}\sigma \\ &= 2\int_{\alpha'}^{\beta'} \frac{1}{\sin\left(\pi-(\mu-\omega)/2-x\right)\sin(x)}\,\mathrm{d}\sigma \end{aligned}$$

$$
\begin{aligned}
&= \frac{4}{\sin\left(\pi-(\mu-\omega)/2\right)}\left[\log\left(\frac{\sin(x)}{\sin\left(\pi-(\mu-\omega)/2-x\right)}\right)\right]_{\alpha'}^{\beta'}\\
&= \frac{4}{\sin(\mu-\omega)/2}\left(\log\left(\sin(\beta')\right) - \log\left(\sin\left(\pi-\frac{\mu-\omega}{2}-\beta'\right)\right)\right.\\
&\qquad\qquad \left. -\log\left(\sin(\alpha')\right) + \log\left(\sin\left(\pi-\frac{\mu-\omega}{2}-\alpha'\right)\right)\right)\\
&= \frac{4}{\sin(\mu-\omega)2}\left(\log\left(\sin\left(\frac{\beta-\mu}{2}\right)\right) - \log\left(\sin\left(\frac{\beta-\omega}{2}\right)\right)\right.\\
&\qquad\qquad \left. -\log\left(\sin\left(\frac{\alpha-\mu}{2}\right)\right) + \log\left(\sin\left(\frac{\alpha-\omega}{2}\right)\right)\right)\\
&\le \frac{4}{\sin(\mu-\omega)/2}\left(-\log\left(\sin\left(\frac{\beta-\omega}{2}\right)\right) - \log\left(\sin\left(\frac{\alpha-\mu}{2}\right)\right)\right)\\
&= \frac{4}{\sin(\mu-\omega)/2}\left(\log\left(\frac{1}{\sin(\beta-\omega)/2}\right) + \log\left(\frac{1}{\sin(\alpha-\mu)/2}\right)\right)\\
&\le \frac{4}{\sin(\mu-\omega)/2}\left(\log\left(\frac{4}{d(\beta,\omega)}\right) + \log\left(\frac{4}{d(\alpha,\mu)}\right)\right)
\end{aligned}
$$

$$
\le \frac{8}{\sin(\mu-\omega)/2}\log\left(\frac{4}{\gamma}\right), \tag{B.8}
$$

where use of (4.10) was made in the second-to-last inequality. This proves the lemma for the case (B.7). The other cases for $\omega \neq \mu$ follow analogously. Now suppose $\omega = \mu$. Let $0 < \alpha' \triangleq (\alpha-\omega)/2 < \beta' \triangleq (\beta-\omega)/2 < \pi$. Then the change of variables $x = (\sigma-\omega)/2$ gives

$$
\int_{\alpha}^{\beta} \frac{1}{\sin^2(\sigma-\omega)/2}\,\mathrm{d}\sigma = 2\int_{\alpha'}^{\beta'} \frac{1}{\sin^2 x}dx = \left[-2\,\frac{\cos x}{\sin x}\right]_{\alpha'}^{\beta'} \le \frac{4}{\sin\gamma} \tag{B.9}
$$

which proves the lemma when $\omega = \mu$. □

INGHAM-TYPE THEOREMS FOR VECTOR-VALUED FUNCTIONS AND OBSERVABILITY OF COUPLED LINEAR SYSTEMS[*]

VILMOS KOMORNIK[†] AND PAOLA LORETI[‡]

Abstract. We propose a new approach to study the observability of coupled linear distributed systems. It is based on a generalization of some classical theorems of nonharmonic analysis to vector-valued functions. Applying this method we answer some questions of J.-L. Lions [*Contrôlabilité exacte et stabilisation de systèms distribués*, Vol. 2, Masson, 1988] on the boundary observability of coupled linear distributed systems in particular cases.

Key words. observability, wave equation, Petrovsky system, nonharmonic analysis, Bessel functions

1. Introduction and formulation of the main results.

Let Ω be a bounded open domain in $\mathbb{R}^n$ having a boundary Γ of class C^4. Fix four real numbers A, B, C, D and consider the following coupled system:

$$
\begin{cases}
u_1'' - \Delta u_1 + Au_1 + Bu_2 = 0 \quad \text{in} \quad \mathbb{R}\times\Omega,\\
u_2'' + \Delta^2 u_2 + Cu_1 + Du_2 = 0 \quad \text{in} \quad \mathbb{R}\times\Omega,\\
u_1 = u_2 = \Delta u_2 = 0 \quad \text{on} \quad \mathbb{R}\times\Gamma,\\
u_i(0) = u_{i0} \quad \text{and} \quad u_i'(0) = u_{i1} \quad \text{in} \quad \Omega,\ i = 1, 2.
\end{cases}
\tag{1.1}
$$

One can readily verify by standard methods that (1.1) is well-posed in the following sense:

- Given

$$(u_{10}, u_{11}, u_{20}, u_{21}) \in H_0^1(\Omega) \times L^2(\Omega) \times H_0^1(\Omega) \times H^{-1}(\Omega)$$

arbitrarily, (1.1) has a unique *weak* solution $u = (u_1, u_2)$ satisfying

$$u_1 \in C(\mathbb{R}; H_0^1(\Omega)) \cap C^1(\mathbb{R}; L^2(\Omega))$$

and

$$u_2 \in C(\mathbb{R}; H_0^1(\Omega)) \cap C^1(\mathbb{R}; H^{-1}(\Omega)).$$

- If the initial data also satisfy the conditions

$$(u_{10}, u_{11}, u_{20}, u_{21}) \in H^2(\Omega) \times H^1(\Omega) \times H^2(\Omega) \times L^2(\Omega),$$

Most of this research was done during the visit of this author to the Istituto per le Applicazioni del Calcolo "Mauro Picone" del Consiglio Nazionale delle Ricerche in Rome in September 1996.

[‡] Istituto per le Applicazioni del Calcolo "Mauro Picone," Consiglio Nazionale delle Ricerche, Viale del Policlinico, 137, 00161 Roma, Italy. Current address: Dipartimento MeMoMat, Università degli Studi di Roma "La Sapienza," Via A. Scarpa, 16, 00161 Roma, Italy (loreti@dmmm.uniroma1.it).

then the following corresponding *strong* solutions are smoother:

$$u_1 \in C(\mathbb{R}; H^2(\Omega)) \cap C^1(\mathbb{R}; H^1(\Omega))$$

and

$$u_2 \in C(\mathbb{R}; H^2(\Omega)) \cap C^1(\mathbb{R}; L^2(\Omega)).$$

Let us denote by E_0 the *initial energy* of the solution, defined by the formula

$$E_0 = \tfrac{1}{2}\big(\|u_{10}\|^2_{H^1_0(\Omega)} + \|u_{11}\|^2_{L^2(\Omega)} + \|u_{20}\|^2_{H^1_0(\Omega)} + \|u_{21}\|^2_{H^{-1}(\Omega)}\big).$$

Here, as usual, $L^2(\Omega)$ and $H^1_0(\Omega)$ are endowed with the norms defined by

$$\|v\|^2_{L^2(\Omega)} = \int_\Omega |v|^2 \, dx, \quad \|v\|^2_{H^1_0(\Omega)} = \int_\Omega |\nabla v|^2 \, dx,$$

and $H^{-1}(\Omega)$ is endowed with the dual norm of that of $H^1_0(\Omega)$.

Let us denote by ν the outward unit normal vector to Γ. We have the following proposition.

PROPOSITION 1.1. *Fix a positive number T such that Ω belongs to a ball of diameter $< T$. Then there exists a positive number α such that if $|A| < \alpha$, $|B| < \alpha$, $|C| < \alpha$, and $|D| < \alpha$, then the strong solutions of* (1.1) *satisfy the estimates*

$$c_1 E_0 \le \int_0^T \int_\Gamma |\partial_\nu u|^2 \, d\Gamma \, dt \le c_2 E_0 \tag{1.2}$$

with two positive constants c_1, c_2 depending on T and α but not on the choice of the initial data.

In the uncoupled case $A = B = C = D = 0$, Proposition 1.1 follows from earlier results of Lasiecka and Triggiani [12], Lebeau [13], Lions [14], and Zuazua [21]. (See also [8] for simplified proofs.) In the general case the theorem will be proved by applying a perturbation method of Lions [15]. A general question raised in [15] is whether the smallness of the coupling parameters is necessary for the validity of the results or whether this restriction is merely related to the technique of the proof. Our next result suggests the second alternative.

THEOREM 1.2. *Let Ω be an open ball of radius R in $\mathbb{R}^n$. There exist countably many hypersurfaces in $\mathbb{R}^4$ such that if (A,B,C,D) does not belong to any of them, then the strong solutions of* (1.1) *satisfy the estimates* (1.2) *for every $T > 2R$. The constants $c_1, c_2 > 0$ depend on A, B, C, D, and T but not on the choice of the initial data.*

Note that the exceptional parameters form a set of measure zero in $\mathbb{R}^4$.

The second inequality in (1.2) allows us to define the boundary integrals in these estimates for weak solutions by a standard density argument. Then (1.2) remains valid for weak solutions in both results.

Proposition 1.1 and Theorem 1.2 imply some boundary observability results. Indeed, if a solution of (1.1) vanishes identically in a neighborhood of Γ in the time interval $(0, T)$, then by the first inequality of (1.2) the solution of (1.1) is in fact identically zero. Taking into account the linearity of the system it follows that two solutions of (1.1) corresponding to different initial data can be distinguished by observing them only in a small neighborhood of the boundary Γ for $0 < t < T$. Indeed, it suffices to apply the preceding argument for their differences.

Our proof of Theorem 1.2 will not show whether there are effectively exceptional parameters or whether they are excluded only because of the method of the proof. In fact there are exceptional parameters indeed; see the following proposition.

PROPOSITION 1.3. *Let Ω be an open ball in $\mathbb{R}^n$. There exist countably many two-dimensional surfaces in $\mathbb{R}^4$ such that if (A,B,C,D) belongs to one of them, then for some nonzero initial data the solution of* (1.1) *satisfies the equality*

$$\partial_\nu u = 0 \quad on \quad \mathbb{R}\times\Gamma. \tag{1.3}$$

Hence the first inequality in (1.2) *cannot hold.*

It remains an interesting open problem to determine the exact dimension (between 2 and 3) of the set of exceptional quadruples.

J. E. Lagnese asked one of the authors whether the exceptional cases can be eliminated if we require the estimates (1.2) only for initial data belonging to a suitably chosen finite codimensional subspace. The answer is positive; see the following proposition.

PROPOSITION 1.4. *Let Ω be an open ball of radius R in $\mathbb{R}^n$, and fix A, B, C, D arbitrarily. There exists a positive integer N such that the estimates* (1.2) *are satisfied for every $T > 2R$ for all strong solutions of* (1.1) *whose initial data are orthogonal to the first N eigenspaces of $-\Delta$ in $H_0^1(\Omega)$. The constants $c_1, c_2 > 0$ depend on A, B, C, D, and T but not on the particular choice of the initial data.*

Now consider the same system with Neumann-type boundary conditions:

$$\begin{cases} u_1'' - \Delta u_1 + Au_1 + Bu_2 = 0 \quad \text{in} \quad \mathbb{R}\times\Omega,\\ u_2'' + \Delta^2 u_2 + Cu_1 + Du_2 = 0 \quad \text{in} \quad \mathbb{R}\times\Omega,\\ \partial_\nu u_1 = \partial_\nu u_2 = \partial_\nu \Delta u_2 = 0 \quad \text{on} \quad \mathbb{R}\times\Gamma,\\ u_i(0) = u_{i0} \quad \text{and} \quad u_i'(0) = u_{i1} \quad \text{in} \quad \Omega,\ i = 1,2. \end{cases} \tag{1.4}$$

Let us denote by Z the vector space of all quadruples whose components are finite linear combinations of the eigenfunctions of $-\Delta$ in Ω with homogeneous Neumann boundary conditions. Clearly, for every $(u_{10}, u_{20}, u_{11}, u_{21}) \in Z$ the system (1.4) has a unique solution, given by a natural trigonometric sum. Given a bounded interval I, we define a seminorm in Z by setting

$$p_I(u_{10}, u_{20}, u_{11}, u_{21}) := \|u\|_{L^2(I\times\Gamma)}.$$

It follows easily from classical unique continuation theorems that p_I is a *norm* if I is sufficiently long. It turns out that all these norms are equivalent if Ω is a ball; see the following theorem.

THEOREM 1.5. *Let Ω be an open ball of radius R in $\mathbb{R}^n$. There exist countably many hypersurfaces in $\mathbb{R}^4$ such that if (A,B,C,D) does not belong to any of them, then for any two bounded intervals I and J of length $> 2R$, p_I and p_J are equivalent norms in Z.*

Again, there exist exceptional parameters; see the following proposition.

PROPOSITION 1.6. *Let Ω be an open ball in $\mathbb{R}^n$. There exist countably many two-dimensional surfaces in $\mathbb{R}^4$ such that if (A,B,C,D) belongs to one of them, then for some nonzero initial data the solution of* (1.4) *satisfies the equality*

$$u = 0 \quad on \quad \mathbb{R}\times\Gamma.$$

Hence p_I is not a norm in Z for any bounded interval I.

On the other hand, we have a result analogous to Proposition 1.4. Given a positive integer N, denote by Z_N the subspace of those elements of Z, all of whose components are orthogonal to the first N eigenspaces of $-\Delta$ in Ω with homogeneous Neumann boundary conditions.

PROPOSITION 1.7. *Let Ω be an open ball of radius R in $\mathbb{R}^n$, and fix A, B, C, D arbitrarily. There exists a positive integer N such that for any two bounded intervals I and J of length $> 2R$, p_I and p_J are equivalent norms in Z_N.*

Applying the Hilbert uniqueness method of Lions [14], [15], Proposition 1.1 and Theorems 1.2 and 1.5 yield several exact controllability results. Similarly, applying an analogous method developed in [9], they yield uniform stabilizability results. In order to not make the paper too long we do not study these questions here.

The norm equivalence in Theorem 1.5 implies that for a corresponding boundary exact controllability problem the space of controllable states remains the same for all sufficiently large time intervals (see [15, Vol. 1, pp. 156 and 218]). While this type of equivalence is obtained automatically for Dirichlet-type boundary conditions where the multiplier method is available, for Neumann-type boundary conditions it seems that the only known method is the one applied in the present paper.

The proofs of Theorems 1.2 and 1.5 are based on the generalization of some results of nonharmonic analysis to vector-valued functions and to complex exponents. Our method is thus a generalization of the approach of Graham and Russell [3]. The following two abstract theorems may represent some interest themselves. They can be applied to the study of various other coupled distributed systems in the same way as in this paper.

First we have the following generalization of a classical theorem of Ingham [5].

THEOREM 1.8. *Let $(\omega_n)_{n=-\infty}^{\infty}$ be a sequence of real numbers satisfying for some positive integer M and for some $\gamma > 0$ the condition*

$$\omega_{n+M} - \omega_n \geq \gamma \tag{1.5}$$

for all n. Let $(u_n)_{n=-\infty}^{\infty}$ be a sequence of vectors in a complex Hilbert space H, satisfying for some $0 \leq \eta < 1/(2M-2)$ the inequalities

$$|(u_n, u_k)_H| \leq \eta \|u_n\| \, \|u_k\| \tag{1.6}$$

whenever $n \not\equiv k \mod M$. Then

(a) *for every bounded interval I there exists a constant C_1 such that*

$$\int_I \Big\| \sum_{n=-\infty}^{\infty} \alpha_n e^{i\omega_n t} u_n \Big\|^2 \, dt \leq C_1 \sum_{n=-\infty}^{\infty} |\alpha_n|^2 \|u_n\|^2 \tag{1.7}$$

for all sequences (α_n) of complex numbers satisfying

$$\sum_{n=-\infty}^{\infty} |\alpha_n|^2 \|u_n\|^2 < +\infty; \tag{1.8}$$

(b) *for every bounded interval I of length $2T$ with*

$$T > \pi/\gamma \quad \text{and} \quad \frac{T^2\gamma^2 - \pi^2}{2T^2\gamma^2 + \pi^2} > (M-1)\eta \tag{1.9}$$

there exists a constant $C_2 > 0$ such that

$$\int_I \Big\| \sum_{n=-\infty}^{\infty} \alpha_n e^{i\omega_n t} u_n \Big\|^2 \, dt \ge C_2 \sum_{n=-\infty}^{\infty} |\alpha_n|^2 \|u_n\|^2 \tag{1.10}$$

for all sequences (α_n) of complex numbers satisfying (1.8).

Remarks. 1. Since $(M-1)\eta < 1/2$, the condition (1.9) is satisfied if T is sufficiently large.

2. For $M = 1$, $H = \mathbb{C}$, and $u_n \equiv 1$, Theorem 1.8 reduces to Ingham's original theorem.

3. Ingham's theorem was later improved and generalized very much in several works; see, e.g., [2], [17], [20], [18]. These works concern the scalar case and do not directly imply our result. Concerning the vector coefficient case, the monograph of Avdonin and Ivanov [1] contains several deep theorems and also includes many useful references. In particular, Corollary II.2.2 in [1] states that a vector family has the Riesz basis property if the associated scalar family does. However, in the case of our Theorem 1.8 the associated scalar family does not necessarily have the Riesz basis property because the assumption (1.5) for $M > 1$ does not imply that the exponents are separated, so one cannot apply this result here. As it will be seen later, in the typical applications to coupled systems there can even be repeated exponents, so that the weakened assumption (1.5) of Theorem 1.8 is essential. On the other hand, using the deep complex analytic tools of [1] one could probably obtain more general results than Theorem 1.8. However, we prefer the present result because it is sufficient for most applications to coupled linear systems and because its proof is much shorter and more elementary than that of a more general case. Furthermore, this can be adapted easily to prove some variants of Theorem 1.8 which are needed for the proof of typical *partial* observability results, such as Theorem 1.10 below, and which could be proved less easily by the general complex analytic approach.

4. In the proof we shall use some ideas of another earlier generalization of Ingham's theorem due to Loreti and Valente [16].

In our application the conditions of Theorem 1.8 will be satisfied only after the removal of a finite numbers of exponents ω_n. Then we shall complete our proof by applying the following generalization of a former theorem of Haraux [4].

PROPOSITION 1.9. *Let $(\omega_n)_{n=-\infty}^{\infty}$ be a sequence of pairwise distinct complex numbers such that*

$$|\omega_n| \to +\infty \quad \textit{as} \quad n \to \pm\infty \tag{1.11}$$

and

$$\textit{the sequence} \quad (\Im \omega_n) \quad \textit{is bounded}, \tag{1.12}$$

and let (u_n) be a sequence of nonzero vectors in a complex Hilbert space H.

Let T_0 be a nonnegative number. Assume that for every bounded interval I of length $> T_0$ there exists a finite set N of integers such that the estimates (1.7) *and* (1.10) *are satisfied for all complex sequences (α_n) satisfying* (1.8) *and*

$$\alpha_n = 0 \quad \textit{for all} \quad n \in N. \tag{1.13}$$

Then the same conclusion holds without the condition (1.13).

Remarks. 1. Proposition 1.9 improves Haraux's earlier results in two aspects: we allow nonreal exponents ω_n and vector coefficients α_n.

2. Proposition 1.9 also extends an earlier result in [6] and in [8, Chap. 5], where only real exponents were considered. Although intuitively the presence of complex exponents does not present extra difficulties, in fact we had to change part of the earlier proof where the reality of the exponents was used in a crucial way.

Let us note that Theorem 1.2 remains valid in fact for every bounded domain of class C^4: this more general result can be proved by an indirect compactness-uniqueness method; see [11]. Unlike that approach, the proof given here provides explicit constants in the estimates (1.2). On the other hand, we do not know another approach to prove Theorem 1.5, and we conjecture that this theorem holds true only if Ω is a ball.

The approach developed in this paper can also be applied to the study of *partial* observability problems. For example, we have the following.

THEOREM 1.10. *Let Ω be an open ball of radius R in $\mathbb{R}^n$. There exist countably many hypersurfaces in $\mathbb{R}^4$ such that if (A,B,C,D) does not belong to any of them, then the following estimates hold true:*

(a) *For every $T > 2R$ there exist two positive constants c_1, c_2 such that*

$$c_1E_0 \le \int_0^T \int_\Gamma |\partial_\nu u_1|^2 \ d\Gamma \ dt \le c_2E_0$$

for all strong solutions of (1.1) *whose initial data satisfy the condition*

$$u_{20} = u_{21} = 0 \quad in \quad \Omega.$$

(b) *For every $T > 0$ there exist two positive constants c_1, c_2 such that*

$$c_1E_0 \le \int_0^T \int_\Gamma |\partial_\nu u_2|^2 \ d\Gamma \ dt \le c_2E_0$$

for all strong solutions of (1.1) *whose initial data satisfy the condition*

$$u_{10} = u_{11} = 0 \quad in \quad \Omega.$$

Due to space limitations we shall not prove Theorem 1.10 here and we refer to [10] for similar results. Its proof is analogous to that of Theorems 1.2 and 1.5, but it requires modified versions of Theorem 1.8 and Proposition 1.9. Contrary to Theorems 1.2 and 1.5, we do not know whether there are effectively exceptional values in this problem.

2. Proof of Proposition 1.1. Let us consider, along with (1.1), the following two related systems:

$$\begin{cases} v_1'' - \Delta v_1 = 0 \quad \text{in} \quad \mathbb{R}\times\Omega, \\ v_2'' + \Delta^2 v_2 = 0 \quad \text{in} \quad \mathbb{R}\times\Omega, \\ v_1 = v_2 = \Delta v_2 = 0 \quad \text{on} \quad \mathbb{R}\times\Gamma, \\ v_i(0) = u_{i0} \quad \text{and} \quad v_i'(0) = u_{i1} \quad \text{in} \quad \Omega, \ i = 1,2, \end{cases} \tag{2.1}$$

and

$$\begin{cases} w_1'' - \Delta w_1 + Au_1 + Bu_2 = 0 \quad \text{in} \quad \mathbb{R}\times\Omega, \\ w_2'' + \Delta^2 w_2 + Cu_1 + Du_2 = 0 \quad \text{in} \quad \mathbb{R}\times\Omega, \\ w_1 = w_2 = \Delta w_2 = 0 \quad \text{on} \quad \mathbb{R}\times\Gamma, \\ w_i(0) = w_i'(0) = 0 \quad \text{in} \quad \Omega, \ i = 1,2. \end{cases} \tag{2.2}$$

Observe that $u = v + w$.

Since the system (2.1) is uncoupled, we may apply the earlier results of Lions [14] and Zuazua [21] mentioned in the introduction. Hence

$$c_3 E_0 \le \int_0^T \int_\Gamma |\partial_\nu v|^2 \, d\Gamma \, dt \le c_4 E_0 \tag{2.3}$$

for some positive constants c_3, c_4, independent of A, B, C, D (because these parameters do not appear in (2.1)). (All constants in this section are independent of the particular choice of the initial data.)

Fix $\alpha > 0$ (to be chosen later) and let $|A| < \alpha$, $|B| < \alpha$, $|C| < \alpha$, $|D| < \alpha$. It follows from the well-posedness of the system (1.1) that

$$\begin{aligned} \|Au_1\|^2_{L^1(0,T;H^1_0(\Omega))} + \|Bu_2\|^2_{L^1(0,T;H^1_0(\Omega))} + \|Cu_1\|^2_{L^1(0,T;H^1_0(\Omega))} \\ + \|Du_2\|^2_{L^1(0,T;H^1_0(\Omega))} \le c_5(\alpha) E_0 \end{aligned}$$

for some constants $c_5(\alpha)$ such that $c_5(\alpha) \to 0$ as $\alpha \to 0$. Therefore, applying the direct inequalities given in [14] for the wave equation and for the above Petrovsky system, we obtain that

$$\int_0^T \int_\Gamma |\partial_\nu w|^2 \, d\Gamma \, dt \le c_6(\alpha) E_0 \tag{2.4}$$

for some constant $c_6(\alpha)$ such that $c_6(\alpha) \to 0$ as $\alpha \to 0$.

Since $u = v + w$, we deduce from (2.3) and (2.4) the following inequalities:

$$\int_0^T \int_\Gamma |\partial_\nu u|^2 \, d\Gamma \, dt \le 2 \int_0^T \int_\Gamma |\partial_\nu v|^2 + |\partial_\nu w|^2 \, d\Gamma \, dt \le 2(c_4 + c_6(\alpha)) E_0,$$

$$2 \int_0^T \int_\Gamma |\partial_\nu u|^2 \, d\Gamma \, dt \ge \int_0^T \int_\Gamma |\partial_\nu v|^2 - 2|\partial_\nu w|^2 \, d\Gamma \, dt \ge (c_3 - 2c_6(\alpha)) E_0.$$

These inequalities imply (1.2) with

$$c_1 = (c_3 - 2c_6(\alpha))/2 \quad \text{and} \quad c_2 = 2(c_4 + c_6(\alpha)).$$

If we choose a sufficiently small α, then the constants c_1, c_2 are positive and the proposition follows. □

3. Proof of Theorem 1.8. If (1.7) and (1.10) are satisfied for an interval $I = (-T, T)$, then they are also satisfied for every translate $(-T+\tau, T+\tau)$ of this interval. Indeed, applying (1.7) and (1.10) to the function

$$z(t) := u(t+\tau) = \sum_n \big(a_n e^{i\omega_n \tau}\big) e^{i\omega_n t} u_n$$

and using the equalities $|e^{i\omega_n \tau}| = 1$ (because the ω_n's are real), we obtain that (1.7) and (1.10) are satisfied if we replace $\|u(t)\|^2$ by $\|z(t)\|^2$ in the integral. We conclude by observing that

$$\int_{-T+\tau}^{T+\tau} \|u(t)\|^2 \, dt = \int_{-T}^{T} \|z(t)\|^2 \, dt.$$

Hence it is sufficient to consider intervals of the form $I = (-T, T)$.

Let us introduce for any fixed $T > \pi/\gamma$ the continuous nonnegative function

$$k(t) = \begin{cases} \cos \frac{\pi t}{2T} & \text{if } |t| \le T, \\ 0 & \text{if } |t| \ge T. \end{cases}$$

We shall prove instead of (1.7) and (1.10) the estimates

$$\int_{-\infty}^{\infty} k(t) \Big\| \sum_{n=-\infty}^{\infty} \alpha_n e^{i\omega_n t} u_n \Big\|^2 \, dt \le C_1 \sum_{n=-\infty}^{\infty} |\alpha_n|^2 \|u_n\|^2 \tag{3.1}$$

and

$$\int_{-\infty}^{\infty} k(t) \Big\| \sum_{n=-\infty}^{\infty} \alpha_n e^{i\omega_n t} u_n \Big\|^2 \, dt \ge C_2 \sum_{n=-\infty}^{\infty} |\alpha_n|^2 \|u_n\|^2. \tag{3.2}$$

Since $k \le \chi_{[-T,T]}$, (1.10) follows at once from (3.2). For the proof of (1.7) we apply (3.1) with some $T' > T$ instead of T. Then the corresponding function k satisfies

$$k \ge \cos \frac{\pi T}{2T'} \; \chi_{[-T,T]}$$

and hence (1.7) follows with $C_1 / \cos(\pi T/(2T')) > 0$ instead of C_1.

Turning to the proofs of (3.1) and (3.2), let us denote by $K(x)$ the Fourier transform of $k(t)$

$$K(x) = \int_{-\infty}^{\infty} k(t) e^{ixt} \, dt.$$

An easy computation shows that

$$K(x) = \frac{4\pi T \cos(xT)}{\pi^2 - 4T^2 x^2}.$$

Hence $K(-x) \equiv K(x)$ and the maximum of $|K(x)|$ over $\mathbb{R}$ is attained by $K(0) = 4T/\pi$. Indeed, one can verify directly by looking at the graph of $K(x)$ that $|K(x)| \le K(0)$ for all $-1/T \le x \le 1/T$. Furthermore, for $x \ge 1/T$ we have

$$\begin{aligned} |K(x)| &= \Big| \frac{4\pi T \cos(xT)}{\pi^2 - 4T^2 x^2} \Big| = \Big| \frac{\pi T \sin(xT - (\pi/2))}{(xT - (\pi/2))(xT + (\pi/2))} \Big| \\ &= \Big| \frac{2\pi T}{2xT + \pi} \frac{\sin(xT - (\pi/2))}{xT - (\pi/2)} \Big| \le \frac{2\pi T}{2xT + \pi} \le \frac{4T}{\pi}. \end{aligned}$$

Finally, for $x \le -1/T$ we have $|K(x)| = |K(-x)| \le 4T/\pi$.

Developing the scalar product inside the integral in (3.1) and (3.2) we obtain

$$\int_{-\infty}^{\infty} k(t) \Big\| \sum_n \alpha_n e^{i\omega_n t} u_n \Big\|^2 \, dt = \sum_{n,k} \alpha_n \overline{\alpha_k} (u_n, u_k)_H K(\omega_n - \omega_k),$$

from which

$$\int_{-\infty}^{\infty} k(t) \Big\| \sum_n \alpha_n e^{i\omega_n t} u_n \Big\|^2 \, dt - K(0) \sum_n |\alpha_n|^2 \|u_n\|^2 = S_1 + S_2 \tag{3.3}$$

with

$$S_1 = \sum_{n\equiv k, n\neq k} \alpha_n \overline{\alpha_k} (u_n, u_k)_H K(\omega_n - \omega_k)$$

and

$$S_2 = \sum_{n\not\equiv k} \alpha_n \overline{\alpha_k} (u_n, u_k)_H K(\omega_n - \omega_k),$$

where $n \equiv k$ means $n \equiv k \bmod M$.

Using (1.5) and the inequality $T > \pi/\gamma$ we have for every fixed n the following estimate:

$$\begin{aligned}\sum_{k\equiv n, k\neq n} |K(\omega_n - \omega_k)| &\le \sum_{n\equiv k, n\neq k} \frac{4\pi T}{4T^2|\omega_n - \omega_k|^2 - \pi^2} \\ \le \sum_{n\equiv k, n\neq k} \frac{4\pi T}{4T^2(n-k)^2 M^{-2}\gamma^2 - T^2\gamma^2} &= \sum_{j=1}^{\infty} \frac{8\pi T}{T^2\gamma^2(4j^2-1)} \\ &= \frac{4\pi}{T\gamma^2} \sum_{j=1}^{\infty} \Big(\frac{1}{2j-1} - \frac{1}{2j+1} \Big) = \frac{4\pi}{T\gamma^2}.\end{aligned} \tag{3.4}$$

Therefore

$$\begin{aligned}|S_1| &\le \sum_{n\equiv k, n\neq k} |\alpha_n|\ |\alpha_k|\ \|u_n\|\ \|u_k\|\ |K(\omega_n - \omega_k)| \\ &\le \frac{1}{2} \sum_{n\equiv k, n\neq k} (|\alpha_n|^2 \|u_n\|^2 + |\alpha_k|^2 \|u_k\|^2) |K(\omega_n - \omega_k)| \\ &= \sum_{n\equiv k, n\neq k} |\alpha_n|^2 \|u_n\|^2 |K(\omega_n - \omega_k)| \\ &\le \frac{4\pi}{T\gamma^2} \sum_n |\alpha_n|^2 \|u_n\|^2.\end{aligned} \tag{3.5}$$

Next we remark that using (3.4) we have for any fixed n the estimate

$$\sum_{k\not\equiv n} |K(\omega_n - \omega_k)| \le \sum_{i=1}^{M-1} \sum_{k\equiv n+i} |K(\omega_n - \omega_k)| \le (M-1)\Big(\frac{4\pi}{T\gamma^2} + 2K(0) \Big),$$

because by (1.5) for each fixed $1 \le i \le M-1$ there are at most two integers $k \equiv n+i$ with $|\omega_n - \omega_k| < \gamma$. Therefore

$$\begin{aligned}|S_2| &\le \eta \sum_{k\not\equiv n} |\alpha_n|\ |\alpha_k|\ \|u_n\|\ \|u_k\|\ |K(\omega_n - \omega_k)| \\ &\le \frac{\eta}{2} \sum_{k\not\equiv n} (|\alpha_n|^2 \|u_n\|^2 + |\alpha_k|^2 \|u_k\|^2) |K(\omega_n - \omega_k)| \\ &= \eta \sum_{k\not\equiv n} |\alpha_n|^2 \|u_n\|^2 |K(\omega_n - \omega_k)| \\ &\le \eta(M-1)\Big(\frac{4\pi}{T\gamma^2} + 2K(0) \Big) \sum_n |\alpha_n|^2 \|u_n\|^2.\end{aligned} \tag{3.6}$$

Using (3.5), (3.6), and the equality $K(0) = 4T/\pi$ we deduce from (3.3) the inequality

$$\begin{aligned}&\Big|\int_{-\infty}^{\infty} k(t)\Big\|\sum_n \alpha_n e^{i\omega_n t}u_n\Big\|^2 \, dt - \frac{4T}{\pi}\sum_n |\alpha_n|^2\|u_n\|^2\Big|\\ &\le \Big[\frac{4\pi}{T\gamma^2} + \eta(M-1)\Big(\frac{8T}{\pi} + \frac{4\pi}{T\gamma^2}\Big)\Big]\sum_n |\alpha_n|^2\|u_n\|^2,\end{aligned}$$

and (1.7) and (1.10) follow by the choice (1.9) of T. □

4. Proof of Proposition 1.9. Given $\delta > 0$ and $\omega \in \mathbb{C}$ arbitrarily, for every continuous function $u : \mathbb{R} \to H$ we define another function $I_{\delta,\omega}u : \mathbb{R} \to H$ by the formula

$$I_{\delta,\omega}u(t) = u(t) - \frac{1}{2\delta}\int_{-\delta}^{\delta} e^{-i\omega s}u(t+s)\, ds.$$

We shall need two lemmas.

LEMMA 4.1. (a) *If $u(t) = e^{i\omega t}u_0$ with $u_0 \in H$, then $I_{\delta,\omega}u = 0$.*

(b) *If $u(t) = e^{i\mu t}u_0$ with $\mu \neq \omega$ and $u_0 \in H$, then*

$$I_{\delta,\omega}u(t) = \left(1 - \frac{\sin(\mu-\omega)\delta}{(\mu-\omega)\delta}\right)u(t).$$

(c) *The linear operators $I_{\delta,\omega}$ commute, i.e.,*

$$I_{\delta,\omega}I_{\delta',\omega'}u = I_{\delta',\omega'}I_{\delta,\omega}u$$

for all $\delta, \omega, \delta', \omega'$, and u.

Observe that since the analytic function $1 - (\sin z/z)$ does not vanish identically, the function in front of $u(t)$ in part (b) cannot vanish for more than a countable set of exceptional values of $\delta > 0$.

Proof. (a) We have

$$I_{\delta,\omega}u(t) = u(t) - \frac{1}{2\delta}\int_{-\delta}^{\delta} e^{-i\omega s}e^{i\omega(t+s)}u_0\, ds = u(t) - e^{i\omega t}u_0 = 0.$$

(b) We have

$$\begin{aligned}I_{\delta,\omega}u(t) &= u(t) - \frac{1}{2\delta}\int_{-\delta}^{\delta} e^{-i\omega s}e^{i\mu(t+s)}u_0\, ds = u(t) - \frac{1}{2\delta}\left[\frac{e^{i(\mu-\omega)s}}{i(\mu-\omega)}\right]_{-\delta}^{\delta} e^{i\mu t}u_0\\ &= u(t) - \frac{e^{i(\mu-\omega)\delta} - e^{-i(\mu-\omega)\delta}}{2i(\mu-\omega)\delta}e^{i\mu t}u_0 = \left(1 - \frac{\sin(\mu-\omega)\delta}{(\mu-\omega)\delta}\right)u(t).\end{aligned}$$

(c) This follows at once from the definition of the operators $I_{\delta,\omega}$. □

LEMMA 4.2. *For every continuous function $u : \mathbb{R} \to H$ we have*

$$\int_{-T}^{T} \|I_{\delta,\omega}u(t)\|^2 \, dt \le \left(2 + 2e^{2|\Im\omega|\delta}\right)\int_{-T-\delta}^{T+\delta} \|u(t)\|^2 \, dt. \tag{4.1}$$

Proof. For every fixed $t \in \mathbb{R}$ we have

$$\begin{aligned}\|I_{\delta,\omega}u(t)\|^2 &\le 2\|u(t)\|^2 + 2\Big\|\frac{1}{2\delta}\int_{-\delta}^{\delta} e^{-i\omega s}u(t+s)\ ds\Big\|^2\\ &\le 2\|u(t)\|^2 + \frac{1}{2\delta^2}\int_{-\delta}^{\delta}|e^{-i\omega s}|^2\ ds\int_{-\delta}^{\delta}\|u(t+s)\|^2\ ds\\ &\le 2\|u(t)\|^2 + \delta^{-1}e^{2|\Im\omega|\delta}\int_{t-\delta}^{t+\delta}\|u(x)\|^2\ dx.\end{aligned}$$

Therefore

$$\begin{aligned}&\int_{-T}^{T}\|I_{\delta,\omega}u(t)\|^2\ dt\\ &\le 2\int_{-T}^{T}\|u(t)\|^2\ dt + \delta^{-1}e^{2|\Im\omega|\delta}\int_{-T}^{T}\int_{t-\delta}^{t+\delta}\|u(x)\|^2\ dx\ dt\\ &= 2\int_{-T}^{T}\|u(t)\|^2\ dt + \delta^{-1}e^{2|\Im\omega|\delta}\int_{-T-\delta}^{T+\delta}\int_{\max\{-T,x-\delta\}}^{\min\{T,x+\delta\}}\|u(x)\|^2\ dt\ dx\\ &\le 2\int_{-T}^{T}\|u(t)\|^2\ dt + 2e^{2|\Im\omega|\delta}\int_{-T-\delta}^{T+\delta}\|u(t)\|^2\ dt\\ &\le \big(2+2e^{|\Im\omega|\delta}\big)\int_{T-\delta}^{T+\delta}\|u(x)\|^2\ dx. \qquad \square\end{aligned}$$

Now we turn to the proof of the theorem. Fix $\varepsilon > 0$ arbitrarily. We proceed in four steps.

Step 1. Fix $\varepsilon/(2|N|) < \delta < \varepsilon/|N|$ (to be chosen later), where $|N|$ denotes the number of elements in the set N, and let us denote by $I = I_\delta$ the composition of the linear operators I_{δ,ω_j}, where j runs over N. By Lemma 4.1 the definition does not depend on the order of the operators I_{δ,ω_j}. Therefore, using Lemma 4.1, if

$$u(t) = \sum_{n=1}^{\infty}\alpha_n e^{i\omega_n t}u_n,$$

then

$$(Iu)(t) = \sum_{n\notin N}\alpha_n\left(\prod_{j\in N}\left(1-\frac{\sin(\omega_n-\omega_j)\delta}{(\omega_n-\omega_j)\delta}\right)\right)e^{i\omega_n t}u_n =: \sum_{n=-\infty}^{\infty}\alpha_n' e^{i\omega_n t}u_n.$$

Next we choose $\varepsilon/(2|N|) < \delta < \varepsilon/|N|$ such that none of the products

$$\prod_{j\in N}\left(1-\frac{\sin(\omega_n-\omega_j)\delta}{(\omega_n-\omega_j)\delta}\right), \qquad n \notin N,$$

vanishes. This is possible by the analyticity remark preceding the proof of Lemma 4.1 because the numbers $\omega_n - \omega_j$ are all different from zero. (We have to exclude only a countable set of values of δ.)

Then there exists a constant $C' > 0$ such that

$$\Big|\prod_{j\in N}\left(1-\frac{\sin(\omega_n-\omega_j)\delta}{|(\omega_n-\omega_j)\delta|}\right)\Big|^2 \ge C'$$

for all $n \notin N$. Indeed, it is sufficient to observe that for any fixed $j \in N$ we have

$$\Big|\frac{\sin(\omega_n - \omega_j)\delta}{(\omega_n - \omega_j)\delta}\Big| \le \frac{\cosh(\Im(\omega_n - \omega_j)\delta)}{|(\omega_n - \omega_j)\delta|} \to 0$$

as $n \to \pm\infty$ because of our assumptions (1.11) and (1.12). Hence the above product tends to 1 as $n \to \pm\infty$, so that its absolute value is minorized, e.g., by $1/2$ for all sufficiently large $|n|$.

The above argument also implies that the above products are bounded with respect to n so that (α_n') also satisfies (1.8). Furthermore, $\alpha_n' = 0$ for all $n \in N$ so that we may apply our hypothesis to the function Iu on any interval $(-T, T)$ with $T > T_0/2$. It follows that

$$\int_{-T}^{T} \|Iu(t)\|^2 \, dt \ge C_2 \sum_{n \notin N} |\alpha_n'|^2 \|u_n\|^2 \ge C_2 C' \sum_{n \notin N} |\alpha_n|^2 \|u_n\|^2.$$

Applying (4.1) repeatedly with $\omega = \omega_j$, $j \in N$, and taking into account that $|N|\delta < \varepsilon$, it follows that

$$\sum_{n \notin N} |\alpha_n|^2 \|u_n\|^2 \le C'' \int_{-T-\varepsilon}^{T+\varepsilon} \|u(t)\|^2 \, dt \tag{4.2}$$

with

$$C'' = \frac{1}{C_2 C'} \prod_{j \in N} \big(2 + 2e^{2|\Im\omega_j|\varepsilon/|N|}\big).$$

Step 2. We are going to prove (1.7) for the interval $I = (-T - \varepsilon, T + \varepsilon)$. Let us first show that

$$\int_{-T-\varepsilon}^{T+\varepsilon} \Big\| \sum_{n \notin N} \alpha_n e^{i\omega_n t} u_n \Big\|^2 \, dt \le C_1(\varepsilon) \sum_{n \notin N} |\alpha_n|^2 \|u_n\|^2 \tag{4.3}$$

with a suitable constant $C_1(\varepsilon)$ defined later. Indeed, let us cover $(-T - \varepsilon, T + \varepsilon)$ by a finite number of translates

$$(-T + \tau_j, T + \tau_j), \qquad 1 \le j \le m$$

of the interval $(-T, T)$ and apply the hypothesis (1.7) m times as follows:

$$\begin{aligned} \int_{-T-\varepsilon}^{T+\varepsilon} \Big\| \sum_{n \notin N} \alpha_n e^{i\omega_n t} u_n \Big\|^2 \, dt &\le \sum_{j=1}^{m} \int_{-T+\tau_j}^{T+\tau_j} \Big\| \sum_{n \notin N} \alpha_n e^{i\omega_n t} u_n \Big\|^2 \, dt \\ &= \sum_{j=1}^{m} \int_{-T}^{T} \Big\| \sum_{n \notin N} \big(\alpha_n e^{i\omega_n \tau_j}\big) e^{i\omega_n t} u_n \Big\|^2 \, dt \end{aligned}$$

$$\le C_1 \sum_{j=1}^{m} \sum_{n \notin N} |\alpha_n e^{i\omega_n \tau_j}|^2 \cdot \|u_n\|^2 = C_1 \sum_{n \notin N} |\alpha_n|^2 \left(\sum_{j=1}^{m} e^{-2\Im\omega_n \tau_j} \right) \cdot \|u_n\|^2.$$

Thanks to hypothesis (1.12), the set of numbers

$$\sum_{j=1}^{m} e^{-2\Im\omega_n \tau_j}, \quad n \notin N$$

is bounded and therefore (4.3) follows with

$$C_1(\varepsilon) = C_1 \sup_{n \notin N} \sum_{j=1}^{m} e^{-2\Im \omega_n \tau_j}.$$

Next we show that

$$\int_{-T-\varepsilon}^{T+\varepsilon} \Big\| \sum_{n\in N} \alpha_n e^{i\omega_n t} u_n \Big\|^2 \, dt \le C_1'(\varepsilon) \sum_{n\in N} |\alpha_n|^2 \|u_n\|^2 \tag{4.4}$$

with some constant $C_1'(\varepsilon)$. Indeed, applying the Cauchy–Schwarz inequality we have

$$\Big\| \sum_{n\in N} \alpha_n e^{i\omega_n t} u_n \Big\|^2 \le \left(\sum_{n\in N} |\alpha_n| |e^{i\omega_n t}| \|u_n\| \right)^2 \le |N| \sum_{n\in N} |\alpha_n|^2 |e^{i\omega_n t}|^2 \|u_n\|^2,$$

and (4.4) follows with

$$C_1'(\varepsilon) = |N| \max \left\{ \int_{-T-\varepsilon}^{T+\varepsilon} |e^{i\omega_n t}|^2 \, dt \;\Big|\; n \in N \right\}.$$

Using the triangle inequality we deduce from (4.3) and (4.4) that

$$\begin{aligned} &\int_{-T-\varepsilon}^{T+\varepsilon} \Big\| \sum_{n=-\infty}^{\infty} \alpha_n e^{i\omega_n t} u_n \Big\|^2 \, dt \\ &\le \int_{-T-\varepsilon}^{T+\varepsilon} 2\Big\| \sum_{n\notin N} \alpha_n e^{i\omega_n t} u_n \Big\|^2 + 2\Big\| \sum_{n\in N} \alpha_n e^{i\omega_n t} u_n \Big\|^2 \, dt \\ &\le C_1(\varepsilon) \sum_{n\notin N} |\alpha_n|^2 \|u_n\|^2 + C_1'(\varepsilon) \sum_{n\in N} |\alpha_n|^2 \|u_n\|^2, \end{aligned}$$

and (1.7) follows with

$$\max\{C_1(\varepsilon), C_1'(\varepsilon)\}$$

in place of C_1.

Step 3. Now we prove (1.10). First, using the triangle inequality, our hypothesis (1.7), and the inequality (4.2) we obtain that

$$\begin{aligned} \int_{-T}^{T} \Big\| \sum_{n\in N} \alpha_n e^{i\omega_n t} u_n \Big\|^2 \, dt &\le \int_{-T}^{T} 2\|u(t)\|^2 + 2\Big\| \sum_{n\notin N} \alpha_n e^{i\omega_n t} u_n \Big\|^2 \, dt \\ &\le 2\int_{-T}^{T} \|u(t)\|^2 \, dt + 2C_1 \sum_{n\notin N} |\alpha_n|^2 \|u_n\|^2 \\ &\le 2\int_{-T}^{T} \|u(t)\|^2 \, dt + 2C_1 C'' \int_{-T-\varepsilon}^{T+\varepsilon} \|u(t)\|^2 \, dt \\ &\le (2 + 2C_1 C'') \int_{-T-\varepsilon}^{T+\varepsilon} \|u(t)\|^2 \, dt. \end{aligned}$$

Let us observe that the expression

$$\int_{-T}^{T} \Big\| \sum_{n\in N} \alpha_n e^{i\omega_n t} u_n \Big\|^2 \ dt$$

is a positive semidefinite quadratic form of the variable $\{\alpha_n \mid n \in N\} \in \mathbb{C}^{|N|}$. Moreover, it is positive *definite* because the functions $e^{i\omega_n t}u_n$, $n \in N$, are linearly independent. (Let us recall that N is a finite set, so that there is only one natural notion of linear independence and of positive definiteness here; cf. [1, pp. 23–26].) Hence it is minorized by a positive multiple of

$$\sum_{n\in N} |\alpha_n|^2 \|u_n\|^2,$$

and we deduce from the above inequality that

$$\sum_{n\in N} |\alpha_n|^2 \|u_n\|^2 \le C''' \int_{-T-\varepsilon}^{T+\varepsilon} \|u(t)\|^2 \ dt \tag{4.5}$$

for a suitable constant $C''' > 0$. Now (1.10) follows from (4.2) and (4.5) with $1/(C'' + C''')$ in place of C_2.

Step 4. Since $T > T_0/2$ and $\varepsilon > 0$ were chosen arbitrarily, we have proved (1.7) and (1.10) for all bounded intervals I of length $> T_0$ which are symmetrical with respect to 0. Finally, we prove that they remain valid for every interval I of length $2T > T_0$ even if it is not symmetrical with respect to 0.

Let us write $I = (-T + \tau, T + \tau)$ and consider the function $z(t) := u(t + \tau)$. We have clearly

$$\int_{-T+\tau}^{T+\tau} \|u(t)\|^2 \ dt = \int_{-T}^{T} \|z(t)\|^2 \ dt$$

and

$$z(t) = \sum_n \big(\alpha_n e^{i\omega_n \tau}\big) e^{i\omega_n t} u_n.$$

By hypothesis (1.12) there is a constant M such that $|\Im \omega_n| \le M$ for all n. Applying (1.7) and (1.10) to $z(t)$ on the interval $(-T, T)$ and using the inequalities

$$e^{-M\tau} \le |e^{i\omega_n \tau}| \le e^{M\tau}$$

we obtain that $u(t)$ satisfies (1.7) and (1.10) on the interval $I = (-T + \tau, T + \tau)$ with C_1, C_2 replaced by $C_1 e^{2M\tau}$ and $C_2 e^{-2M\tau}$, respectively.

5. Proof of Theorem 1.2. We may assume without loss of generality that Ω is the unit ball of $\mathbb{R}^n$: the general case then follows easily by a linear change of variables.

We shall only consider the case $n \ge 2$. The proof of the one-dimensional case is similar and simpler; we shall indicate briefly the modifications at the end of this section.

Let us denote by

$$\rho_{m1} < \rho_{m2} < \cdots$$

the sequence of the (strictly) positive roots of the Bessel function $J_{m-1+\frac{n}{2}}(x)$ for $m = 0, 1, \ldots$, and let us introduce the eigenvalues

$$\lambda_{mk} = \tfrac{1}{2}\Big(\rho_{mk}^4 + \rho_{mk}^2 + A + D + \sqrt{(\rho_{mk}^4 - \rho_{mk}^2 + D - A)^2 + 4BC}\Big) \tag{5.1}$$

and

$$\mu_{mk} = \tfrac{1}{2}\Big(\rho_{mk}^4 + \rho_{mk}^2 + A + D - \sqrt{(\rho_{mk}^4 - \rho_{mk}^2 + D - A)^2 + 4BC}\Big) \tag{5.2}$$

of the matrices

$$A_{mk} = \begin{pmatrix} \rho_{mk}^2 + A & B \\ C & \rho_{mk}^4 + D \end{pmatrix}$$

for $m = 0, 1, \ldots$ and $k = 1, 2, \ldots$. We recall from [19] that

$$\rho_{mk} \to \infty \quad \text{as} \quad m + k \to \infty. \tag{5.3}$$

These relations imply that

$$\rho_{mk}^4(\lambda_{mk} - \rho_{mk}^4 - D) = \rho_{mk}^4(\rho_{mk}^2 + A - \mu_{mk}) \to BC \tag{5.4}$$

as $m + k \to \infty$.

We shall assume that

$$B \neq 0, \quad C \neq 0 \tag{5.5}$$

and that the numbers

$$0, \lambda_{m1}, \mu_{m1}, \lambda_{m2}, \mu_{m2}, \ldots \tag{5.6}$$

are all different for each m.

Observe that these assumptions exclude only a set of measure zero of the quadruples (A, B, C, D) in $\mathbb{R}^4$. Indeed, more precisely, each of the countably many equations

$$\begin{aligned} B &= 0, \\ C &= 0, \\ \lambda_{mk} &= 0, \ k = 1, 2, \ldots, \\ \mu_{mk} &= 0, \ k = 1, 2, \ldots, \\ \lambda_{mk} &= \mu_{ml}, \ k, l = 1, 2, \ldots, \\ \lambda_{mk} &= \lambda_{ml}, \ k, l = 1, 2, \ldots, \ k \neq l, \\ \mu_{mk} &= \mu_{ml}, \ k, l = 1, 2, \ldots, \ k \neq l \end{aligned}$$

defines a hypersurface in $\mathbb{R}^4$, so that the union of these hypersurfaces has zero measure, and the conditions (5.5) and (5.6) are satisfied for all quadruples (A, B, C, D) outside this set.

Using (5.1)–(5.6) one can show easily that the vectors v_{mk} and w_{mk} defined by the formulas

$$\begin{cases} v_{mk} = (v_{mk1}, v_{mk2}) := (C^{-1}(\lambda_{mk} - \rho_{mk}^4 - D), 1), \\ w_{mk} = (w_{mk1}, w_{mk2}) := (1, B^{-1}(\mu_{mk} - \rho_{mk}^2 - A)) \end{cases} \tag{5.7}$$

satisfy the following conditions:

$$A_{mk}v_{mk} = \lambda_{mk}v_{mk} \quad \text{and} \quad A_{mk}w_{mk} = \mu_{mk}w_{mk}, \tag{5.8}$$

$$v_{mk} \text{ and } w_{mk} \quad \text{are linearly independent,} \tag{5.9}$$

$$v_{mk2} = w_{mk1} = 1, \tag{5.10}$$

$$v_{mk1}, w_{mk2} = O(\rho_{mk}^{-4}) \quad \text{as} \quad m+k \to \infty. \tag{5.11}$$

Applying the Fourier method we obtain that the solution of (1.1) is given by the series (we use hyperspherical coordinates)

$$\begin{aligned} u(t,r,\varphi) = \sum_{m=0}^{\infty}\sum_{k=1}^{\infty} & \quad r^{1-\frac{n}{2}} J_{m-1+\frac{n}{2}}(\rho_{mk}r) \\ & \times\big\{\big(a_{mk}(\varphi)e^{i\sqrt{\lambda_{mk}}t} + b_{mk}(\varphi)e^{-i\sqrt{\lambda_{mk}}t}\big)v_{mk} \\ & +\big(c_{mk}(\varphi)e^{i\sqrt{\mu_{mk}}t} + d_{mk}(\varphi)e^{-i\sqrt{\mu_{mk}}t}\big)w_{mk}\big\} \end{aligned} \tag{5.12}$$

with suitable spherical harmonics a_{mk}, b_{mk}, c_{mk}, d_{mk} of order m, depending on the initial data, and such that

$$\sum_{m=0}^{\infty}\sum_{k=1}^{\infty} |\rho_{mk}J'_{m-1+\frac{n}{2}}(\rho_{mk})|^2 \int_\Gamma |a_{mk}|^2 + |b_{mk}|^2 + |c_{mk}|^2 + |d_{mk}|^2 \ d\Gamma < \infty.$$

Expanding the initial data according to the eigenfunctions of $-\Delta$ with the homogeneous Dirichlet boundary condition, we obtain the orthogonal expansions

$$\begin{cases} u_{10}(r,\varphi) = \sum_{m=0}^{\infty}\sum_{k=1}^{\infty} r^{1-\frac{n}{2}} J_{m-1+\frac{n}{2}}(\rho_{mk}r)u_{10mk}(\varphi), \\ u_{20}(r,\varphi) = \sum_{m=0}^{\infty}\sum_{k=1}^{\infty} r^{1-\frac{n}{2}} J_{m-1+\frac{n}{2}}(\rho_{mk}r)u_{20mk}(\varphi), \\ u_{11}(r,\varphi) = \sum_{m=0}^{\infty}\sum_{k=1}^{\infty} r^{1-\frac{n}{2}} J_{m-1+\frac{n}{2}}(\rho_{mk}r)u_{11mk}(\varphi), \\ u_{21}(r,\varphi) = \sum_{m=0}^{\infty}\sum_{k=1}^{\infty} r^{1-\frac{n}{2}} J_{m-1+\frac{n}{2}}(\rho_{mk}r)u_{21mk}(\varphi), \end{cases} \tag{5.13}$$

where u_{10mk}, u_{20mk}, u_{11mk}, u_{21mk} are suitable spherical harmonics of order m. Comparing (5.12) and (5.13) we obtain the algebraic relations

$$\begin{cases} u_{10mk} = (a_{mk}+b_{mk})v_{mk1} + (c_{mk}+d_{mk})w_{mk1}, \\ u_{20mk} = (a_{mk}+b_{mk})v_{mk2} + (c_{mk}+d_{mk})w_{mk2}, \\ u_{11mk} = i\sqrt{\lambda_{mk}}(a_{mk}-b_{mk})v_{mk1} + i\sqrt{\mu_{mk}}(c_{mk}-d_{mk})w_{mk1}, \\ u_{21mk} = i\sqrt{\lambda_{mk}}(a_{mk}-b_{mk})v_{mk2} + i\sqrt{\mu_{mk}}(c_{mk}-d_{mk})w_{mk2}. \end{cases} \tag{5.14}$$

In order to simplify the notations we shall write $f \approx g$ if there exist two positive constants c' and c'' such that

$$c'f \le g \le c''f.$$

The constants c' and c'' will be assumed to be independent of $\varphi \in \Gamma$ and of the choice of the initial data in (1.1). Also, we shall write $f \approx g$ *uniformly for* $m+k \ge K$ if we can choose the same constants c' and c'' for all m and k satisfying $m+k \ge K$.

Let us first evaluate the initial energy.

LEMMA 5.1. *We have*

$$\begin{aligned} E_0 \approx \sum_{m=0}^{\infty}\sum_{k=1}^{\infty} \rho_{mk}^2 \int_0^1 r|J_{m-1+\frac{n}{2}}(\rho_{mk}r)|^2 \ dr \\ \times \int_\Gamma |a_{mk}|^2 + |b_{mk}|^2 + |c_{mk}|^2 + |d_{mk}|^2 \ d\Gamma \end{aligned}$$

for all solutions of (1.1).

Proof. Using (5.13) we obtain by an easy computation the identity

$$E_0 = n|\Omega| \sum_{m=0}^{\infty} \sum_{k=1}^{\infty} \rho_{mk}^2 \int_0^1 r|J_{m-1+\frac{n}{2}}(\rho_{mk}r)|^2 \, dr \tag{5.15}$$

$$\times \int_\Gamma |u_{10mk}(\varphi)|^2 + |u_{20mk}(\varphi)|^2 + \rho_{mk}^{-2}|u_{11mk}(\varphi)|^2 + \rho_{mk}^{-4}|u_{21mk}(\varphi)|^2 \, d\varphi,$$

where $|\Omega|$ denotes the volume of Ω. Hence it suffices to show that

$$\begin{aligned} |u_{10mk}|^2 + |u_{20mk}|^2 + \rho_{mk}^{-2}|u_{11mk}|^2 + \rho_{mk}^{-4}|u_{21mk}|^2 \\ \asymp |a_{mk}|^2 + |b_{mk}|^2 + |c_{mk}|^2 + |d_{mk}|^2 \end{aligned} \tag{5.16}$$

uniformly for all m and k.

Since $\lambda_{mk} \neq 0$, $\mu_{mk} \neq 0$ and since the vectors v_{mk} and w_{mk} are linearly independent, we deduce easily from (5.14) the implications

$$\begin{aligned} u_{10mk} = u_{20mk} = u_{11mk} = u_{21mk} = 0 \\ \iff a_{mk} = b_{mk} = c_{mk} = d_{mk} = 0 \end{aligned} \tag{5.17}$$

for each pair (m, k).

Furthermore, using (5.3), (5.4), (5.10), and (5.11) we deduce from (5.14) that

$$\begin{aligned} u_{10mk} &= (c_{mk} + d_{mk}) + (a_{mk} + b_{mk})o(1), \\ u_{20mk} &= (a_{mk} + b_{mk}) + (c_{mk} + d_{mk})o(1), \\ u_{11mk} &= \rho_{mk}(c_{mk} - d_{mk})(i + o(1)) + (a_{mk} - b_{mk})o(1), \\ u_{21mk} &= \rho_{mk}^2(a_{mk} - b_{mk})(i + o(1)) + (c_{mk} - d_{mk})o(1) \end{aligned}$$

as $m + k \to \infty$. Hence

$$\begin{aligned} |u_{10mk}|^2 + |u_{20mk}|^2 + \rho_{mk}^{-2}|u_{11mk}|^2 + \rho_{mk}^{-4}|u_{21mk}|^2 \\ = \big(2 + o(1)\big)\big(|a_{mk}|^2 + |b_{mk}|^2 + |c_{mk}|^2 + |d_{mk}|^2\big) \end{aligned} \tag{5.18}$$

as $m + k \to \infty$.

Now (5.17) and (5.18) imply (5.16). □

Next we evaluate the boundary integral in (1.2).

LEMMA 5.2. *Fix $T > 2$ arbitrarily. Then*

$$\int_{-T}^{T} \int_\Gamma |\partial_\nu u|^2 \, d\Gamma \, dt$$

$$\asymp \sum_{m=0}^{\infty} \sum_{k=1}^{\infty} \rho_{mk}^2 |J'_{m-1+\frac{n}{2}}(\rho_{mk})|^2 \int_\Gamma |a_{mk}|^2 + |b_{mk}|^2 + |c_{mk}|^2 + |d_{mk}|^2 \, d\Gamma$$

for all solutions of (1.1).

We prove this lemma in several steps.

Step 1. It follows from (5.12) that

$$\partial_\nu u(t, 1, \varphi) = \sum_{m=0}^{\infty} \sum_{k=1}^{\infty} \rho_{mk} J'_{m-1+\frac{n}{2}}(\rho_{mk})$$

$$\times\big\{\big(a_{mk}(\varphi)e^{i\sqrt{\lambda_{mk}}t}+b_{mk}(\varphi)e^{-i\sqrt{\lambda_{mk}}t}\big)v_{mk}$$
$$+\big(c_{mk}(\varphi)e^{i\sqrt{\mu_{mk}}t}+d_{mk}(\varphi)e^{-i\sqrt{\mu_{mk}}t}\big)w_{mk}\big\}$$
$$=:\sum_{m=0}^{\infty}\sum_{k=1}^{\infty}r_{mk}f_{mk}(t,\varphi).$$

Since the spherical harmonics of different order are orthogonal in $L^2(\Gamma)$, we have

$$\int_\Gamma |\partial_\nu u|^2\ d\Gamma=\sum_{m=0}^{\infty}\int_\Gamma\Big|\sum_{k=1}^{\infty}r_{mk}f_{mk}(t,\varphi)\Big|^2\ d\varphi.$$

Hence, applying the Fubini–Tonelli theorem,

$$\int_0^T\int_\Gamma |\partial_\nu u|^2\ d\Gamma\ dt=\sum_{m=0}^{\infty}\int_\Gamma\left(\int_0^T\Big|\sum_{k=1}^{\infty}r_{mk}f_{mk}(t,\varphi)\Big|^2\ dt\right)\ d\varphi.$$

Therefore it suffices to prove that the estimates

$$\int_0^T\Big|\sum_{k=1}^{\infty}r_{mk}f_{mk}(t,\varphi)\Big|^2\ dt \tag{5.19}$$
$$\asymp\sum_{k=1}^{\infty}r_{mk}^2(|a_{mk}(\varphi)|^2+|b_{mk}(\varphi)|^2+|c_{mk}(\varphi)|^2+|d_{mk}(\varphi)|^2)$$

hold uniformly in m.

Step 2. Let us prove that the estimates (5.19) hold uniformly for $m\ge m'$ for some sufficiently large m'. We recall from [19] that if $m-1+(n/2)\ge 1/2$, then the difference sequence $(\rho_{m,k+1}-\rho_{mk})$ is nonincreasing and tends to π as $k\to\infty$. Choosing $\pi>\gamma>2\pi/T$ arbitrarily and using (5.3) and (5.4), we conclude that

$$2\sqrt{\lambda_{m1}},\ 2\sqrt{\mu_{m1}},\ \inf_k\sqrt{\lambda_{m,k+1}}-\sqrt{\lambda_{mk}},\quad\text{and}\quad\inf_k\sqrt{\mu_{m,k+1}}-\sqrt{\mu_{mk}}$$

are all larger than γ if m is sufficiently large, say $m\ge m''$. Furthermore, it follows from (5.3), (5.10), and (5.11) that $(v_{mk},w_{ml})\to 0$ uniformly in k and l if $m\to\infty$. Hence for any fixed $0<\eta<1/2$ we may apply Theorem 1.8 for each sufficiently large m with $M=2$,

$$\{\omega_n\}=\{\pm\sqrt{\lambda_{mk}},\pm\sqrt{\mu_{mk}}\}$$

and with

$$u_n=\begin{cases}v_{mk} & \text{if } \omega_n=\pm\sqrt{\lambda_{mk}},\\ w_{mk} & \text{if } \omega_n=\pm\sqrt{\mu_{mk}}.\end{cases}$$

It follows that

$$\int_0^T\Big|\sum_{k=1}^{\infty}r_{mk}f_{mk}(t,\varphi)\Big|^2\ dt$$
$$\asymp\sum_{k=1}^{\infty}r_{mk}^2\big((|a_{mk}(\varphi)|^2+|b_{mk}(\varphi)|^2)\|v_{mk}\|^2+(|c_{mk}(\varphi)|^2+|d_{mk}(\varphi)|^2)\|w_{mk}\|^2\big)$$

uniformly for all sufficiently large m.

It follows from (5.3), (5.10), and (5.11) that none of the vectors v_{mk} and w_{mk} vanishes and that $\|v_{mk}\| \to 1$ and $\|w_{mk}\| \to 1$ if $m+k \to \infty$. Therefore we deduce from the above relation that for a suitably chosen integer $m' \ge m''$ the relations (5.19) hold uniformly for all $m \ge m'$.

Step 3. Now it suffices to prove the estimates (5.19) for each fixed $m < M$. We recall from [19] that $\rho_{m,k+1} - \rho_{mk} \to \pi$ as $k \to \infty$, for each m. Using (5.4) we may therefore choose K such that

$$2\sqrt{\lambda_{m,K+1}} > 2\pi/T, \quad \inf_{k>K} \sqrt{\lambda_{m,k+1}} - \sqrt{\lambda_{mk}} > 2\pi/T$$

and

$$2\sqrt{\mu_{m,K+1}} > 2\pi/T, \quad \inf_{k>K} \sqrt{\mu_{m,k+1}} - \sqrt{\mu_{mk}} > 2\pi/T.$$

Furthermore, by (5.3), (5.10), and (5.11) we have $(v_{mk}, w_{ml}) \to 0$ if $k, l \to \infty$. Therefore, choosing a larger K if necessary, we may apply Theorem 1.8 for the sequence (ω_n) containing the numbers $\pm\sqrt{\lambda_{mk}}$ and $\pm\sqrt{\mu_{mk}}$ for all $k > K$ and for the sequence (u_n) defined as in the preceding step.

We conclude that (5.19) holds true under the extra hypothesis

$$a_{mk} = b_{mk} = c_{mk} = d_{mk} = 0 \tag{5.20}$$

for all $k \le K$.

Step 4. It remains to remove the hypothesis (5.20). Thanks to hypothesis (5.6) we may apply Proposition 1.9 for (ω_n), (u_n) as in Step 2 and with N given by

$$\{\omega_n \mid n \in N\} = \{\pm\sqrt{\lambda_{mk}}, \pm\sqrt{\mu_{mk}} \mid k \le K\}$$

and the proposition follows.

Now Theorem 1.2 follows from Lemmas 5.1 and 5.2 and from the identity (see [19] or [7])

$$2\int_0^1 r|J_{m-1+\frac{n}{2}}(\rho_{mk}r)|^2\,dr = |J'_{m-1+\frac{n}{2}}(\rho_{mk})|^2.$$

In dimension $n = 1$ the proof is similar. Assuming for simplicity that $\Omega = (0,\pi)$, now the solutions of (1.1) are given by the formula

$$\begin{aligned} u(t,x) = \sum_{m=1}^{\infty} \Big\{ &\big(a_m e^{i\sqrt{\lambda_m}t} + b_m e^{-i\sqrt{\lambda_m}t}\big) v_m \\ &+ \big(c_m e^{i\sqrt{\mu_m}t} + d_m e^{-i\sqrt{\mu_m}t}\big) w_m \Big\} \sin mx \end{aligned} \tag{5.21}$$

instead of (5.12), where

$$\lambda_m = \tfrac{1}{2}\Big(m^4 + m^2 + A + D + \sqrt{(m^4 - m^2 + D - A)^2 + 4BC}\Big)$$

and

$$\mu_m = \tfrac{1}{2}\Big(m^4 + m^2 + A + D - \sqrt{(m^4 - m^2 + D - A)^2 + 4BC}\Big)$$

are the eigenvalues of the matrices

$$A_m = \begin{pmatrix} m^2 + A & B \\ C & m^4 + D \end{pmatrix};$$

$$v_m = (v_{m1}, v_{m2}) := (C^{-1}(\lambda_m - m^4 - D), 1),$$

and

$$w_m = (w_{m1}, w_{m2}) := (1, B^{-1}(\mu_m - m^2 - A))$$

are corresponding eigenvectors; and a_m, b_m, c_m, d_m are arbitrary numbers such that

$$\sum_{m=1}^{\infty} |a_m|^2 + |b_m|^2 + |c_m|^2 + |d_m|^2 < \infty.$$

Then the proof given above can be adapted easily.

6. Proof of Proposition 1.3. As in the preceding section, assume first that Ω is the unit ball of $\mathbb{R}^n$, $n \ge 2$. Fix a nonnegative integer m and fix three positive roots $\rho_{mk_1} < \rho_{mk_2} < \rho_{mk_3}$ of $J_{m-1+\frac{n}{2}}(x)$ arbitrarily. We will show later that for some suitable choices of the parameters A, B, C, D, the matrices A_{mk_1}, A_{mk_2}, and A_{mk_3} (defined at the beginning of the preceding section) have a common eigenvalue μ.

Then the theorem will follow easily. Indeed, denoting by β_1, β_2, β_3 corresponding nonzero eigenvectors in $\mathbb{R}^2$, the formula

$$u(t, r, \varphi) = \sum_{j=1}^{3} r^{1-\frac{n}{2}} J_{m-1+\frac{n}{2}}(\rho_{mk_j} r) \delta_j \beta_j h(\varphi) \cos \sqrt{\mu} t$$

defines a solution of (1.1) for every spherical harmonics $h(\varphi)$ of order m and for every choice of real numbers δ_1, δ_2, δ_3. Furthermore, we have

$$\partial_\nu u(t, r, \varphi) = \sum_{j=1}^{3} \rho_{mk_j} J'_{m-1+\frac{n}{2}}(\rho_{mk_j}) \delta_j \beta_j h(\varphi) \cos \sqrt{\mu} t$$

on the boundary of Ω. Since the three vectors β_j cannot be linearly independent in $\mathbb{R}^2$, we can choose δ_1, δ_2, and δ_3 such that not all of them are zero but

$$\sum_{j=1}^{3} \rho_{mk_j} J'_{m-1+\frac{n}{2}}(\rho_{mk_j}) \delta_j \beta_j = 0.$$

Now choose an arbitrary nonzero spherical harmonics $h(\varphi)$ of order m. Then the corresponding function u satisfies (1.1) and (1.3). Finally, u does not vanish identically because the positive roots of the Bessel functions are simple and hence

$$\rho_{mk_j} J'_{m-1+\frac{n}{2}}(\rho_{mk_j}) \ne 0$$

for $j = 1, 2, 3$.

It remains to show that we can choose A, B, C, D so that the matrices A_{mk_1}, A_{mk_2}, and A_{mk_3} have a common eigenvalue. Writing $c_j = \rho_{mk_j}$ for brevity, first we choose two real numbers a and d such that $c_j^6 + ac_j^4 + dc_j^2$ has the same value (say, P) for $j = 1, 2, 3$. This is possible because the linear system

$$\begin{aligned} c_1^6 + ac_1^4 + dc_1^2 &= c_2^6 + ac_2^4 + dc_2^2, \\ c_1^6 + ac_1^4 + dc_1^2 &= c_3^6 + ac_3^4 + dc_3^2 \end{aligned}$$

is equivalent to

$$\begin{aligned} (c_1^2 + c_2^2)a + d + c_1^4 + c_1^2c_2^2 + c_2^4 &= 0, \\ (c_1^2 + c_3^2)a + d + c_1^4 + c_1^2c_3^2 + c_3^4 &= 0, \end{aligned}$$

whose determinant $c_2^2 - c_3^2$ is different from zero.

Now fix a real number μ arbitrarily. Set $A = a + \mu$, $D = d + \mu$, and choose B, C such that $BC = P$. Then we have

$$c_j^6 + (A - \mu)c_j^4 + (D - \mu)c_j^2 + (A - \mu)(D - \mu) - BC = 0$$

for $j = 1, 2, 3$. In other words, μ is a common root of the characteristic polynomials of the matrices A_{mk_1}, A_{mk_2}, A_{mk_3}, and our assertion follows.

Since the set of such quadruples (A, B, C, D) forms a two-dimensional surface in $\mathbb{R}^4$ for every choice of m and of the roots $\rho_{mk_1} < \rho_{mk_2} < \rho_{mk_3}$, the proposition follows.

The proof can be modified easily for dimension $n = 1$. Assume for simplicity that $\Omega = (0, \pi)$. Fix three positive integers $m_1 < m_2 < m_3$ *having the same parity*, and then choose A, B, C, D so that the matrices A_{m_1}, A_{m_2}, and A_{m_3} have a common eigenvalue μ. Denoting by β_1, β_2, β_3 corresponding nonzero eigenvectors in $\mathbb{R}^2$, the formula

$$u(t, x) = \sum_{j=1}^{3} \delta_j \beta_j \sin m_j x \cos \sqrt{\mu} t$$

defines a solution of (1.1) for any choice of δ_1, δ_2, δ_3. It remains to choose them so that

$$\sum_{j=1}^{3} \delta_j \beta_j m_j = 0,$$

although at least one of the numbers δ_j is different from zero.

For example, for $(m_1, m_2, m_3) = (2, 4, 6)$ and for any fixed real number μ we can choose the parameters

$$A = -56 + \mu, \quad B = -52, \quad C = 800, \quad D = 784 + \mu.$$

Then the nonzero function

$$u(t, x) = \left\{ \begin{pmatrix} 65 \\ -65 \end{pmatrix} \sin 2x + \begin{pmatrix} -52 \\ 40 \end{pmatrix} \sin 4x + \begin{pmatrix} 13 \\ -5 \end{pmatrix} \sin 6x \right\} \cos \sqrt{\mu} t$$

satisfies (1.1) and (1.3).

7. Proof of Proposition 1.4. For brevity, henceforth we only consider the case where Ω is the unit ball of $\mathbb{R}^n$, $n \ge 2$. We modify the proof of Theorem 1.2 as follows. For any fixed A, B, C, D we define the eigenvalues of the matrices A_{mk} by the same formulas (5.1) and (5.2). Then the relations (5.4) remain valid.

Furthermore, we keep the definition (5.7) of the eigenvectors unchanged if $B \ne 0$ and $C \ne 0$ (otherwise they make no sense), but we define them differently in the remaining cases: we set

$$v_{mk} := (B(\lambda_{mk} - \mu_{mk})^{-1}, 1) \quad \text{and} \quad w_{mk} := (1, 0)$$

if $B \ne 0$ and $C = 0$,

$$v_{mk} := (0, 1) \quad \text{and} \quad w_{mk} := (1, C(\mu_{mk} - \lambda_{mk})^{-1})$$

if $B = 0$ and $C \ne 0$, and finally

$$v_{mk} := (0, 1) \quad \text{and} \quad w_{mk} := (1, 0)$$

if $B = C = 0$. Then (5.8), (5.9), (5.10), and (5.11) remain true.

Although we do not have (5.6) in the general case, for any fixed $\eta > 0$ there exists a positive integer M such that

$$\begin{aligned}
0 \ne \lambda_{mk} \ne \mu_{mk} \ne 0 &\quad \text{whenever} \quad m + k > M,\\
\lambda_{m1}, \lambda_{m2}, \dots &\text{ has no repeated elements if } m > M,\\
\mu_{m1}, \mu_{m2}, \dots &\text{ has no repeated elements if } m > M,\\
\lambda_{mM+1}, \lambda_{mM+2}, \dots &\text{ has no repeated elements if } m \le M,\\
\mu_{mM+1}, \mu_{mM+2}, \dots &\text{ has no repeated elements if } m \le M,\\
|(v_{mk}, w_{ml})_H| \le \eta \|v_{mk}\| \, \|w_{ml}\| &\quad \text{whenever} \quad m + k, m + l > M.
\end{aligned}$$

Using these properties we can repeat the proof of Theorem 1.2 except for Step 4 in the proof of Lemma 5.2. The proposition follows if we choose N so large that all functions of the form

$$r^{1-\frac{n}{2}} J_{m-1+\frac{n}{2}}(\rho_{mk_j} r) h(\varphi), \quad m + k \le M,$$

where h runs over the spherical harmonics of order m, belong to the first N eigenspaces of $-\Delta$ in Ω with homogeneous Dirichlet boundary conditions.

8. Proof of Theorem 1.5. We consider only initial data whose integral over Ω is equal to zero. This orthogonality condition can be eliminated by applying the method of Proposition 1.9, but we omit the details in order to keep the length of this paper reasonable.

Now let us denote by

$$\rho_{m1} < \rho_{m2} < \cdots$$

the sequence of the (strictly) positive roots of

$$\left(1 - \frac{n}{2}\right) J_{m-1+\frac{n}{2}}(x) + x J'_{m-1+\frac{n}{2}}(x)$$

for $m = 0, 1, \dots$. Introducing the eigenvalues λ_{mk} and μ_{mk} by the same formulas (5.1) and (5.2), we still have (5.3) and (5.4). Furthermore, assuming (5.5), (5.6), and defining v_{mk}, w_{mk} by (5.7), we still have (5.8)–(5.12). It follows that the restriction of the solution of (1.4) to the boundary is given by the formula

$$\begin{aligned} u(t,1,\varphi) = \sum_{m=0}^{\infty}\sum_{k=1}^{\infty} & J_{m-1+\frac{n}{2}}(\rho_{mk}) \\ \times\big\{ & \big(a_{mk}(\varphi)e^{i\sqrt{\lambda_{mk}}t} + b_{mk}(\varphi)e^{-i\sqrt{\lambda_{mk}}t}\big)v_{mk} \\ + & \big(c_{mk}(\varphi)e^{i\sqrt{\mu_{mk}}t} + d_{mk}(\varphi)e^{-i\sqrt{\mu_{mk}}t}\big)w_{mk}\big\} \\ =: \sum_{m=0}^{\infty}\sum_{k=1}^{\infty} & R_{mk}f_{mk}(t,\varphi). \end{aligned}$$

(We used the above-mentioned orthogonality assumption here.) As in section 5, it follows that

$$\int_\Gamma |u|^2 \, d\Gamma = \sum_{m=0}^{\infty} \int_\Gamma \Big|\sum_{k=1}^{\infty} R_{mk}f_{mk}(t,\varphi)\Big|^2 \, d\varphi$$

and then

$$\int_I\int_\Gamma |u|^2 \, d\Gamma \, dt = \sum_{m=0}^{\infty} \int_\Gamma \left(\int_I \Big|\sum_{k=1}^{\infty} R_{mk}f_{mk}(t,\varphi)\Big|^2 \, dt\right) \, d\varphi.$$

If the length of I is larger than 2, then by repeating the proof of Lemma 5.2 we obtain that

$$\begin{aligned} &\int_I \Big|\sum_{k=1}^{\infty} R_{mk}f_{mk}(t,\varphi)\Big|^2 \, dt \\ &\qquad \approx \sum_{k=1}^{\infty} R_{mk}^2(|a_{mk}(\varphi)|^2 + |b_{mk}(\varphi)|^2 + |c_{mk}(\varphi)|^2 + |d_{mk}(\varphi)|^2) \end{aligned}$$

uniformly in m, and hence

$$\int_I\int_\Gamma |u|^2 \, d\Gamma \, dt \approx \sum_{m=0}^{\infty}\sum_{k=1}^{\infty} R_{mk}^2(|a_{mk}(\varphi)|^2 + |b_{mk}(\varphi)|^2 + |c_{mk}(\varphi)|^2 + |d_{mk}(\varphi)|^2).$$

Since the length of I does not appear on the right-hand side of this estimate, the theorem follows.

9. Proof of Proposition 1.6. As in the proof of Proposition 1.3, we are going to construct a nontrivial solution of (1.4) which vanishes identically on the boundary of Ω. Fix a nonnegative integer m arbitrarily and fix arbitrarily three different positive roots c_1, c_2, c_3 of the function

$$\Big(1-\frac{n}{2}\Big) J_{m-1+\frac{n}{2}}(x) + xJ'_{m-1+\frac{n}{2}}(x).$$

Repeating the proof of Proposition 1.3 we obtain for some exceptional values of the coupling parameters a positive number λ and three nonzero vectors β_1, β_2, β_3 in $\mathbb{R}^2$ such that the function

$$u(t,r,\varphi) := \big[\delta_1 J(c_1 r)\beta_1 + \delta_2 J(c_2 r)\beta_2 + \delta_3 J(c_3 r)\beta_3\big] h(\varphi)\cos\sqrt{\lambda}t \tag{9.1}$$

is a solution of (1.4) (with suitable initial data) for any spherical harmonics h of order m and for every choice of real numbers δ_1, δ_2, and δ_3.

Fix a nonzero spherical harmonics h of order m arbitrarily and choose δ_1, δ_2, and δ_3 such that not all of them vanish but that the linear combination

$$\delta_1 J(c_1)\beta_1 + \delta_2 J(c_2)\beta_2 + \delta_3 J(c_3)\beta_3$$

is equal to zero. This is possible because β_1, β_2, β_3 cannot be linearly independent in $\mathbb{R}^2$. Then the function (9.1) has the required properties.

10. Proof of Proposition 1.7. The proof is similar to that of Proposition 1.4, and hence it is omitted.

Acknowledgments. The authors thank the referees for their suggestions and J. E. Lagnese for his question leading to Propositions 1.4 and 1.7. Vilmos Komornik is grateful to the Istituto per le Applicazioni del Calcolo “Mauro Picone” del Consiglio Nazionale delle Ricerche in Rome for its hospitality.

A DUALITY APPROACH IN THE OPTIMIZATION OF BEAMS AND PLATES*

J. SPREKELS† AND D. TIBA†‡

Abstract. We introduce a class of nonlinear transformations called "resizing rules" which associate with optimal shape design problems certain equivalent distributed control problems while preserving the state of the system. This puts into evidence the duality principle that the class of system states that can be achieved, under a prescribed force, via modifications of the structure (shape) of the system can be obtained as well via the modifications of the force action, under a prescribed structure.

We apply such transformations to the optimization of beams and plates, and in the simply supported or cantilevered cases, the obtained control problems are even convex. In all cases, we establish existence theorems for optimal pairs by assuming only boundedness conditions. Moreover, in the simply supported case, we also prove the uniqueness of the global minimizer. A general algorithm that iterates between the original transformed problems is introduced and studied. The applications also include the case of variational inequalities.

Key words. optimal design, nonconvex duality, resizing rules

1. Introduction.

It is our aim to study a class of *control into the coefficients* problems. The state equation has the form

$$\Delta(bu^3\Delta y) = f \quad \text{in } \Omega, \tag{1.1}$$

where Ω is a smooth bounded domain in $R^n, n \geq 1, f \in L^2(\Omega), u \in L^\infty(\Omega)$, and $b > 0$ is a constant. If $n \leq 2$, such models are used in the literature for the deflection y of plates or beams of thickness $u > 0$ almost everywhere (a.e.) in Ω and are subject to the transverse load f. The coefficient b is a material constant, and we shall fix $b = 1$ in what follows. For instance, (1.1) was recently proposed by Bendsoe [3] for modeling plates made of a material with special properties. We also quote Hlavacek, Bock, and Lovisek [12], [13], Haslinger and Neittaanmäki [11], Casas [4], Neto and Polak [21], and Langenbach [17] for more complex beams or plate equations. To derive (1.1), smoothness conditions are imposed on the thickness u. However, in the associated minimization problems, we show that this assumption is not necessary and that is why we take just $u \in L^\infty(\Omega)$.

To (1.1) we add various boundary conditions:

$$y = \Delta y = 0 \quad \text{on } \partial\,\Omega \tag{1.2}$$

(simply supported plates), and

$$y = \frac{\partial y}{\partial n} = 0 \quad \text{on } \partial\,\Omega \tag{1.3}$$

(clamped plates; $\frac{\partial}{\partial n}$ denotes the outward normal derivative to $\partial\Omega$).

In space dimension one, cantilevered beams or unilaterally supported beams (variational inequalities) will be discussed as well.

We associate with (1.1) various optimization problems:

$$\text{Min} \int_\Omega u(x)\,dx \tag{1.4}$$

(minimization of the weight or volume), and

$$\text{Min} \int_\Omega \big(y(x) - y_d(x)\big)^2\,dx \tag{1.5}$$

(identification-type problems: the function $y_d \in L^2(\Omega)$ is a "desired" or "observed" deflection).

Moreover, natural control and state constraints will be imposed on u, y:

$$0 \le m \le u(x) \le M \quad \text{a.e. in } \Omega, \tag{1.6}$$

$$y(x) \ge -\tau \quad \text{a.e. in } \Omega, \tag{1.7}$$

(m, M, τ are positive constants),

$$y \in A. \tag{1.8}$$

$A \subset L^2(\Omega)$ is a prescribed closed subset, not necessarily convex.

Problems of this type are well known in the literature and their difficulty, from both a theoretical and a numerical point of view, was put into evidence in the works of Neto and Polak [21] (with an example of approximating local minimizers converging to a nonstationary point of the original problem), Murat [20] (indicating counterexamples to the existence of minimizers for control into coefficients problems governed by second order equations) and Cheng and Olhoff [5] and Rozvany et al. [22], where comprehensive numerical experiments are discussed.

In general, in nonconvex minimization problems one may expect just approximation of stationary points. In the case of optimal design of beams, this is discussed by Polak and Neto [21] via the use of consistent approximations.

In this work, we introduce a class of nonlinear transformations which may be applied to any of the problems (1.1)–(1.8). We call them "resizing rules" with reference to a partial similarity that exists with the fully stressed design method (FSD) appearing in the engineering literature (see Haftka, Gürdal, and Kamat [10, Chap. 9].

Via the resizing rules, the control into coefficients problem is transformed into an equivalent distributed control problem. In this way, we see that the problems corresponding to simply supported or cantilevered boundary conditions are convex or even strictly convex (after transformation). This gives the uniqueness of the global minimum in the original problem. The optimization problem associated with clamped plates remains nonconvex after the transformation. Moreover, this approach allows us to relax the compactness assumptions on the set of admissible controls needed to show the existence of the minimizers. The boundedness condition (1.6) is sufficient for our method to work. In this respect, similar results were previously obtained by Cox and Overton [6] and Senatorov [23] in the case of ordinary differential equations and by a different approach.

In sections 2 and 3 such results are proved for simply supported, respectively, clamped, plates and beams. In section 4, an algorithmic approach is used for the optimization of a unilaterally supported beam, and a numerical example is discussed. This shows the multiple possibilities of the "resizing rule" method. Such algorithms were previously used by Sprekels and Tiba [25] for classical types of beams (simply supported, cantilevered, and clamped).

Finally, we point out that ours is a duality-type method: associated with the original minimization problem is another optimization problem which is simpler and gives relevant information on the first problem. From a theoretical point of view, the equivalence results are essential in proving convexity, uniqueness, or existence. From a numerical point of view, simple "dual" problems may be considered that provide efficient approximations in the examples. Let us also notice that this duality approach has a mechanical background and is not inspired by the convex duality theory or its nonconvex extensions. A detailed comparison (from this point of view) was performed by Sprekels and Tiba (see [25, sections 1 and 2].

2. Simply supported plates and beams. We start with a general equivalence result which, roughly speaking, says that the set of deflections obtained under a given load and for various thicknesses is the same as the set of deflections obtained for a fixed thickness, but with variable load. Namely, we consider the following two "state" systems:

$$\Delta(u^3\Delta y) = f \quad \text{in } \Omega, \tag{2.1}$$

$$y = \Delta y = 0 \quad \text{on } \partial\Omega, \tag{2.2}$$

$$0 < m \le u(x) \le M \quad \text{a.e. in } \Omega, \tag{2.3}$$

$$y \in A \tag{2.4}$$

and

$$\Delta\Delta y = h \quad \text{in } \Omega, \tag{2.5}$$

$$y = \Delta y = 0 \quad \text{on } \partial\Omega, \tag{2.6}$$

$$\min\{m^{-3}z(x), M^{-3}z(x)\} \le \Delta y(x) \le \max\{m^{-3}z(x),\, M^{-3}z(x)\} \text{ a.e. in } \Omega, \tag{2.7}$$

$$y \in A. \tag{2.8}$$

In (2.1)–(2.4), $f \in L^2(\Omega)$ is fixed, $u \in L^\infty(\Omega)$ is the optimization parameter, $A \subset L^2(\Omega)$ is closed, and m, M are positive real constants. No sign conditions are imposed on f, and the unique weak solution y satisfies $y \in V := H^2(\Omega) \cap H_0^1(\Omega), u^3\Delta y \in V$. One (convex) example for the set A is obtained via the constraint

$$y \ge -\tau \quad \text{in } \Omega \tag{2.9}$$

with $\tau > 0$ given.

In (2.5)–(2.8) we assume that $h \in V^*$, and we define $g \in L^2(\Omega)$ as the unique transposition solution (see Lions and Magenes [19]) to

$$\Delta g = h \quad \text{in } \Omega, \tag{2.10}$$

$$g = 0 \quad \text{on } \partial\Omega; \tag{2.11}$$

that is, by definition, we have

$$\int_\Omega g\,\Delta\rho\,dx \;=\; \int_\Omega h\,\rho\,dx \quad \forall\;\rho\;\in\;V. \tag{2.12}$$

Then, $y\;\in\;V$ is the strong solution to

$$\Delta y \;=\; g \quad \text{in } \Omega, \tag{2.13}$$

$$y \;=\; 0 \quad \text{on } \partial\,\Omega. \tag{2.14}$$

The second boundary condition, $\Delta y\;=\;0$ on $\partial\,\Omega$, is included in the choice of test mappings ρ in (2.12) and is not explicit. The mapping $z \in V$ from (2.7) is the strong solution to (2.10), (2.11), corresponding to $h = f$. We also mention that (2.10) is valid in the sense of distributions although $C_0^\infty(\Omega)$ is not dense in V. The constraint (2.7) shows that, for admissible y, the boundary condition $\Delta y = 0$ on $\partial\Omega$ has an explicit meaning.

THEOREM 2.1. *For any admissible pair* $[y, u]$ *for* (2.1)–(2.4), *there is some* $h \in V^*$ *such that the pair* $[y, h]$ *is admissible for* (2.5)–(2.8). *The converse is also true if meas* $\{x \in \Omega;\; z(x) = 0\} = 0$.

Proof. If $[y, u]$ is admissible for (2.1)–(2.4), then

$$\Delta y \;=\; \frac{1}{u^3}\,z\;\in\;L^2(\Omega). \tag{2.15}$$

We denote by $\tilde h \in V^*$ the linear bounded functional on V defined by

$$\langle \tilde h, \rho\rangle_{V^*\times V} \;=\; \int_\Omega \frac{1}{u^3}\,z\,\Delta\rho\,dx \quad \forall\;\rho\;\in\;V. \tag{2.16}$$

Then, (2.16), (2.12) show that $\tilde g\;=\;(1/u^3)z$ is the transposition solution to (2.10)–(2.11) associated with this $\tilde h$. By (2.15) and (2.2), it follows that y satisfies (2.5), (2.6) with $\tilde h$ given by (2.16). Then, (2.7) is a clear consequence of (2.15) and (2.3).

Conversely, taking $[\hat y, \hat h]$ admissible for (2.5)–(2.8), and $\hat g$ satisfying (2.10), (2.11) with $h = \hat h$, we see that

$$\Delta\hat y \;=\; \hat g \quad \text{a.e. in } \Omega. \tag{2.17}$$

We shall multiply (2.17) by $z(x) \cdot [\hat g(x)]^{-1}$ which we denote $v(x)$. By (2.7) and (2.17), we notice that $v \in L^\infty(\Omega)$, and $\hat u = v^{1/3}$ satisfies constraint (2.3). To see this, we analyze in (2.7) the situations $z(x) > 0, z(x) < 0$ to get

$$0\;<\;M^{-3}\;\le\;\frac{\hat g(x)}{z(x)}\;=\;[\hat u(x)]^{-3}\;\le\;m^{-3}. \tag{2.18}$$

Under our hypothesis, (2.18) is valid a.e. in Ω, and we obtain (2.3). Moreover,

$$\hat u^3(x)\Delta\hat y(x)\;=\;z(x) \quad \text{a.e. in } \Omega. \tag{2.19}$$

The definition of z and (2.19) show that $\hat y$ is a weak solution of (2.1) as well, and the proof is finished. □

Corollary 2.2. *For any admissible pair* $[y, u]$ *for* (2.1)–(2.4)*, there is some* $l \in L^2(\Omega)$ *such that the pair* $[y, l]$ *is admissible for the system*

$$\Delta y = zl \quad \textit{in } \Omega, \tag{2.20}$$

$$y = 0 \quad \textit{on } \partial\Omega, \tag{2.21}$$

$$M^{-3} \leq l(x) \leq m^{-3} \quad \textit{a.e. in } \Omega, \tag{2.22}$$

$$y \in A. \tag{2.23}$$

The converse is also true.

The proof is just a variant of the proof of Theorem 2.1.

Remark. While Theorem 2.1 has a physical interpretation which we have stressed from the very beginning, Corollary 2.2 represents a mathematical equivalence trick. Its advantages are to transform the fourth order equation into a second order one and to replace the "state" constraint (2.7) by the "control" constraints (2.22). Notice that no special assumption on z is necessary.

Remark. Theorem 2.1 and Corollary 2.2 are controllability-type results. They say that the reachable set of states is the same in the systems (2.1)–(2.4), (2.5)–(2.8), or (2.20)–(2.23).

Remark. One basic property for the above results is that the set of admissible pairs $[y, h]$ defined by (2.5)–(2.7), as well as the set of admissible $[y, l]$ given by (2.20)–(2.22), are convex. If A is convex (which is generally the case; see (2.9)), then the systems (2.5)–(2.8) or (2.20)–(2.23) define convex pair sets in the appropriate product spaces.

This fundamental property is not valid, in general, for the original set of admissible pairs $[y, u]$ since the transformation that we use is nonlinear. However, there is one example, due to Kawohl [15] and Kawohl and Lang [16], where the system (2.1)–(2.3) and (2.9) define a convex set of admissible "control" mappings u in $L^2(\Omega)$.

Example 2.3. We assume that $f \leq 0$ a.e. in Ω. Then the maximum principle gives that $z > 0$ in Ω, and we have the representation formula

$$y(x) = -\int_\Omega \sigma(x, y) \frac{z(y)}{u^3(y)} dy, \tag{2.24}$$

with σ being the Green function, again positive. Let u_1, u_2 be two admissible thicknesses for the system (2.1)–(2.3), (2.9), and $u_\lambda(x) = \lambda\, u_1(x) + (1 - \lambda)\, u_2(x)$ $\forall x \in [0, 1]$, $\forall\, \lambda \in [0, 1]$. We denote by y_1, y_2, y_λ the solutions of (2.1), (2.2) corresponding to u_1, u_2, u_λ, respectively.

Then, (2.24) and the positivity of σ, z give

$$y_\lambda(x) \geq \lambda\, y_1(x) + (1 - \lambda)\, y_2(x) \geq -\tau, \tag{2.25}$$

since the function $-u^{-3}$ is concave. We conclude that u_λ is admissible for any $\lambda \in [0, 1]$, that is, the admissible set of controls is convex. For the set of admissible states y this is also true since the function $\bar{y}_\lambda = \lambda\, y_1 + (1 - \lambda)\, y_2$ corresponds to the thickness $(\bar{u}_\lambda)^3 = (\lambda\, u_1^{-3} + (1 - \lambda) u_2^{-3})^{-1}$ which satisfies (2.3) and (2.9). However, since the operator $u \mapsto y$ is nonlinear, we cannot expect $\bar{y}_\lambda = y_\lambda$ in (2.25), and the set of admissible pairs $[y, u]$ is not convex. Moreover, such properties do not extend beyond the condition (2.9) to general convex state constraints expressed by (2.4) or to nonnegative f.

It is our aim now to apply this equivalence, especially in the form given by Corollary 2.2, which is the simplest one, to certain optimization problems. Let us associate with the system (2.1)–(2.4) one of the following cost functionals, to be minimized:

$$\text{Min} \int_\Omega u(x)\, dx, \tag{2.26}$$

$$\text{Min} \int_\Omega \left(-\, u^{-\,3}(x)\right)\, dx, \tag{2.27}$$

$$\text{Min} \int_\Omega \left(y(x) \,-\, y_d(x)\right)^2\, dx. \tag{2.28}$$

The minimization parameter is $u \in L^\infty(\Omega)$, and we denote by $(\mathbf{P}_i), i = \overline{1,3}$, the obtained minimization problems, in this order. Obviously, $(\mathbf{P}_1)$ is the minimization of weight (volume) problem, subject to the given constraints. $(\mathbf{P}_2)$ is related to this question, as will be explained later, and $(\mathbf{P}_3)$ is an identification-type problem ($y_d \in L^2(\Omega)$ is an "observed" or "desired" deflection of the plate).

With the system (2.20)–(2.23) we associate the following cost functionals:

$$\text{Min} \int_\Omega l^{-\,\frac{1}{3}}(x)\, dx, \tag{2.29}$$

$$\text{Min} \int_\Omega \left(-\, l(x)\right)\, dx, \tag{2.30}$$

$$\text{Min} \int_\Omega \left(y(x) \,-\, y_d(x)\right)^2 dx. \tag{2.31}$$

The minimization distributed control is the mapping $l \in L^2(\Omega)$, and we denote by $(\mathbf{D}_i)$, $i = \overline{1,3}$, the obtained optimization problems, in this order.

THEOREM 2.4. *The problems $(\mathbf{P}_i)$ are equivalent to the problems $(\mathbf{D}_i)$, $i = \overline{1,3}$, in the sense that if $[y,u]$ is admissible for $(\mathbf{P}_i)$, then $[y,l]$, $l = 1/u^3$, is admissible for $(\mathbf{D}_i)$ with the same cost, and conversely.*

This follows directly from Corollary 2.2 and the definitions (2.26)–(2.31).

COROLLARY 2.5. *Under admissibility assumptions, if A is convex, then problem $(\mathbf{P}_1)$ has a unique global minimum $u^* \in L^\infty(\Omega)$.*

Proof. The existence of u^* can be established from standard estimates in (2.1), (2.2) and the boundedness of minimizing sequences given by (2.3). The passage to the limit is a simplified variant of the one performed in Theorem 3.2. By Theorem 2.4, $l^* = (u^*)^{-3}$ is the (global) minimizer for $(\mathbf{D}_1)$. By Corollary 2.2 and its subsequent remarks, the set of admissible pairs $[y,l]$ is convex if A is convex. Since $l^{-\frac{1}{3}}$ is a strictly convex function for $l > 0$, then the integral cost (2.29) is strictly convex and the uniqueness of l^*, u^* follows. ☐

Remark. Instead of solving the nonconvex problems $(\mathbf{P}_i)$, $i = \overline{1,3}$, we suggest solving the equivalent convex problems $(\mathbf{D}_i)$, $i = \overline{1,3}$. In numerical experiments, this avoids the "trap" of local minimum points, and the uniqueness of the global optimum enhances the numerical stability.

Remark. It is known that, in discussing weight minimization problems, any increasing function $\mu(u)$ may be relevant as an integrand in the cost functional. The problem $(\mathbf{P}_2)$ uses the increasing mapping

$$\mu(u) = -\frac{1}{u^3}, \quad u > 0,$$

which has the advantage that the equivalent problem $(\mathbf{D}_2)$ is a linear optimization problem.

Remark. Similar results may be obtained in dimension one for the simply supported beam and the cantilevered beam, i.e., for the boundary conditions

$$y(0) = y'(0) = 0,$$

$$y''(1) = (u^3 y'')'(1) = 0.$$

One basic property which is important for the above analysis is that the state system can be decoupled into two independent second order differential equations. In the next sections, this property is no longer true; however, the results can be extended.

3. Clamped plates and beams. We investigate first the classical optimal shape design problem:

$$\text{Min} \int_\Omega u(x)\,dx \tag{3.1}$$

subject to

$$\Delta(u^3\,\Delta y) = f \quad \text{in } \Omega, \tag{3.2}$$

$$y = \frac{\partial y}{\partial n} = 0 \quad \text{on } \partial\Omega, \tag{3.3}$$

$$0 < m \le u(x) \le M \quad \text{a.e. in } \Omega, \tag{3.4}$$

$$y \in A\,. \tag{3.5}$$

As usual, $f \in L^2(\Omega)$, $A \subset L^2(\Omega)$ are given, and $u \in L^\infty(\Omega)$ is the thickness of the plate, the minimization parameter.

The existence of a unique weak solution $y \in H_0^2(\Omega)$ to (3.2), (3.3) is obvious since the bilinear form

$$a(u,\, y,\, v) = \int_\Omega u^3\,\Delta y\,\Delta v\,dx$$

is coercive on $H_0^2(\Omega) \times H_0^2(\Omega)$.

Fix the mapping $g \in H^2(\Omega) \cap H_0^1(\Omega)$ by

$$\Delta g = f \quad \text{in } \Omega, \tag{3.6}$$

$$g = 0 \quad \text{on } \partial\Omega. \tag{3.7}$$

Here, we use that $f \in L^2(\Omega)$ and use the regularity of linear elliptic equations.

THEOREM 3.1. (a) *The equation* (3.2)*,* (3.3) *is equivalent to*

$$\Delta y = g\,l + h\,l \quad \text{in } \Omega \tag{3.8}$$

and (3.3) *(both conditions), where* $h \in L^2(\Omega)$ *is a harmonic mapping in* Ω *and* $l = u^{-3} \in L^\infty(\Omega)$.

(b) *The optimization problem* (3.1)–(3.5) *is equivalent to*

$$\text{Min} \int_\Omega l^{-\frac{1}{3}}(x)\,dx \tag{3.9}$$

subject to (3.8)*,* (3.3)*,* (3.5)*, and*

$$M^{-3} \le l(x) \le m^{-3} \quad \text{a.e. in } \Omega. \tag{3.10}$$

Proof. (a) By (3.2), (3.3), and the definition of $a(u,\cdot,\cdot)$, we see that

$$\int_\Omega (u^3\,\Delta y - g)\,\Delta v\,dx = 0 \quad \forall\; v \in H_0^2(\Omega). \tag{3.11}$$

We denote $h = u^3\,\Delta y - g \in L^2(\Omega)$, and (3.11) gives $\Delta h = 0$ in the sense of distributions. The converse is obvious.

(b) This is a clear consequence of (a) and of $l^{-1/3} = u$. □

Remark. The above transformation shows that the obtained problem remains nonconvex. Conceptually, the harmonic mapping h may be determined from the "supplementary" boundary condition $\frac{\partial y}{\partial n} = 0$ on $\partial\,\Omega$. One such situation is explained in Corollary 3.4. In general, we interpret h as an extra control variable and $\frac{\partial y}{\partial n} = 0$ on $\partial\,\Omega$ as a new state constraint.

THEOREM 3.2. *Under admissibility assumptions, the problem* $(\mathbf{P}_4)$ *given by* (3.1)–(3.5) *has at least one solution* $\tilde{u} \in L^\infty(\Omega)$.

Proof. By admissibility, there exists a minimizing sequence $\{u_n\} \subset L^\infty(\Omega)$ such that

$$\int_\Omega u_n(x)\,dx \to \inf(\mathbf{P_4}) \tag{3.12}$$

for $n \to \infty$. We denote by $l_n = u_n^{-3}$ and $y_n \in H_0^2(\Omega)$ the corresponding weak solution of (3.2), (3.3). Conditions (3.4), (3.10) show that $\{u_n\}$, $\{l_n\}$ are bounded in $L^\infty(\Omega)$, and hence we may assume that $u_n \rightharpoonup \hat{u}$, $l_n \rightharpoonup \hat{l}$ weakly* in $L^\infty(\Omega)$. In general, $\hat{l} \neq \hat{u}^{-3}$!

We also notice that $\{y_n\}$ is bounded in $H_0^2(\Omega)$:

$$m \int_\Omega \left[\Delta y_n(x)\right]^2 dx \le \int_\Omega u_n^3 (\Delta y_n)^2\,dx = \int_\Omega f\,y_n\,dx \le |f|_{L^2(\Omega)}\,|y_n|_{L^2(\Omega)}.$$

We may, as well, assume that $y_n \rightharpoonup \tilde{y}$ weakly in $H_0^2(\Omega)$, where $\tilde{y} \in A$ since A is closed in $L^2(\Omega)$. Moreover, by (3.8), we see that $h_n = u_n^3\,\Delta y_n - g$ is bounded in $L^2(\Omega)$, and we may write $h_n \rightharpoonup \tilde{h}$ weakly in $L^2(\Omega)$. We now use a lemma that will be proved later.

LEMMA 3.3. *If a sequence of harmonic mappings is weakly convergent in $L^1(\Omega)$, then it is pointwisely convergent.*

We remark that the right-hand side in (3.8) is bounded in $L^2(\Omega)$, and hence we may assume that, with some $z \in L^2(\Omega)$,

$$g\, l_n + h_n\, l_n \rightharpoonup z \quad \text{weakly in } L^2(\Omega). \tag{3.13}$$

The difficulty is just to identify z, that is, the limit of the product $h_n\, l_n$. By Lemma 3.3 and the Egorov theorem, for any $\varepsilon > 0$, there is $\Omega_\varepsilon \subset \Omega$ measurable, such that meas $(\Omega \backslash \Omega_\varepsilon) < \varepsilon$ and $h_n \to \tilde{h}$ uniformly in Ω_ε. Then, we can pass to the limit in (3.13) on Ω_ε, and we get $z = g\,\hat{l} + \tilde{h}\,\hat{l}$ in Ω_ε. Since ε is arbitrarily small, we obtain that $z(x) = g(x)\,\hat{l}(x) + \tilde{h}(x)\,\hat{l}(x)$ a.e. in Ω. Hence we can pass to the limit in (3.8) to obtain

$$\Delta\tilde{y} = g\,\hat{l} + \tilde{h}\,\hat{l} \quad \text{in } \Omega. \tag{3.14}$$

Using Theorem 3.1 in (3.14), we see that $\tilde{u} = \hat{l}^{-1/3}$ is the thickness in (3.2) which generates the deflection $\tilde{y}$. Obviously, the pair $[\tilde{y}, \tilde{u}]$ is admissible for the problem $(\mathbf{P}_4)$, and (3.12) yields

$$\inf\,(\mathbf{P}_4) = \lim \int_\Omega u_n(x)dx = \lim \int_\Omega l_n^{-\frac{1}{3}}(x)dx \geq \liminf \int_\Omega l_n^{-\frac{1}{3}}(x)\,dx \,\geq\, \int_\Omega \hat{l}^{-\frac{1}{3}}(x)\,dx$$

$$= \int_\Omega \tilde{u}(x)\,dx \,\geq\, \inf\,(\mathbf{P}_4).$$

Here, we also use the weak lower semicontinuity of the integral functional (3.9). This ends the proof. □

Proof of Lemma 3.3. Since $h_n, \tilde{h}$ are harmonic in Ω, the Weyl lemma, (see Hörmander [14]) shows that they belong to $C^\infty(\Omega)$. For any $x \in \Omega$ and any ball centered in x and of radius ρ, $B_\rho(x) \subset \Omega$, we have the solid mean property

$$h_n(x) = \frac{m}{w_m\,\rho^m} \int_{B_\rho(x)} h_n(y)\,dy \to \frac{m}{w_m\,\rho^m} \int_{B_\rho(x)} \tilde{h}(y)\,dy = \tilde{h}(x).$$

Here, m is the dimension of Ω, and w_m denotes the area of the unit ball in R^m. □

Remark. The passage to the limit in Theorem 3.2 is based on the following general property: If $\{w_n\}$ is bounded in $L^p(\Omega)$, $p > 1$ and $w_n(x) \to w(x)$ a.e. in Ω, then $w_n \to w$ strongly in $L^s(\Omega)$ for any s such that $1 < s < p$.

Proof. Let $\varepsilon > 0$ be fixed and let $\Omega_\varepsilon \subset \Omega$ measurable, with meas $(\Omega \setminus \Omega_\varepsilon) < \varepsilon$ be such that $w_n \to w$ uniformly in Ω_ε (by Egorov's theorem). We have

$$\int_\Omega |w_n - w|^s\,dx = \int_{\Omega_\varepsilon} |w_n - w|^s\,dx + \int_{\Omega\backslash\Omega_\varepsilon} |w_n - w|^s\,dx \leq \int_{\Omega_\varepsilon} |w_n - w|^s\,dx$$

$$+ \left(\int_{\Omega \setminus \Omega_\varepsilon} |w_n - w|^p \right)^{\frac{s}{p}} \text{meas}\,(\Omega \setminus \Omega_\varepsilon)^{\frac{p-s}{p}} \leq \int_{\Omega_\varepsilon} |w_n - w|^s\,dx + C\,\varepsilon^{\frac{p-s}{p}}.$$

If $n \geq N(\varepsilon)$, we get $\int_\Omega |w_n - w|^s\,dx \leq c(\varepsilon)$, where $c(\varepsilon) \to 0$ for $\varepsilon \to 0$.
This is a slight extension of Lemma 1.3 of Lions [18]. □

Remark. By Theorem 3.2, we see that the "optimal" thickness $\tilde{u}$ is obtained by twice inverting the minimizing sequence $\{u_n\}$. If u_n is pointwisely convergent, then $\tilde{u} = \hat{u} = \lim u_n$. This is the case used in the existing literature; see Haslinger and Neittaanmäki [11], Casas [4], Hlavacek, Bock, and Lovisek [12], [13], Neto and Polak [21], and Bendsoe [2]. Our result just shows that the strong compactness assumption (the boundedness of $\{\nabla u_n\}$) is not necessary to get existence in the optimal shape design problem. The numerical experiments from [5], [22] put into evidence the so-called "stiffeners" into the process of optimization of beams and plates, which correspond to unbounded gradients.

Remark. Obviously, the same argument applies to the cost functionals (2.27) or (2.28).

COROLLARY 3.4. *In the case of beams, the equation*

$$(u^3 y'')'' = f \quad in\ ]0,1[,$$

$$y(0) = y(1) = y'(0) = y'(1) = 0$$

is equivalent to

$$y'' = g\,l + (a_l\,x + b_l)\,l \quad in\ ]0,1[$$

with the same boundary conditions and with a_l, $b_l \in R$, *g satisfying* (3.6), (3.7), *and* $l = u^{-3}$.

Remark. It is clear, by direct integration, that the harmonic mapping $h_l = a_l\,x + b_l$ can be uniquely determined from the "supplementary" boundary conditions $y'(0) = y'(1) = 0$. In general, by a finite element approximation, the discretization of h will introduce a finite number of new entries into the state system (3.8) that can, in principle, be determined from the discretization of $\frac{\partial y}{\partial n} = 0$, which will generate the same finite number of nonlinear algebraic equations.

In the recent work of Arnautu et al. [1], a finite element approach is examined which combines the decomposition (3.8) together with a penalization of the boundary condition $\frac{\partial y}{\partial n} = 0$ in the cost.

Remark. Sprekels and Tiba [25] proved that if $f \leq 0$ in $[0,1]$, y'' has exactly two distinct roots in $[0,1]$, and that $y \leq 0$ in $[0,1]$ (see also Theorem 4.5). For general $f \in L^2(0,1)$, it is easy to see that y'' has at least two distinct roots in $[0,1]$. Otherwise $u^3\,y''$ (which is continuous) has at most one change of sign in $[0,1]$, and the maximum principle together with the Hopf maximum principle will contradict the boundary conditions.

Then, denoting by $\xi < \zeta$ two such roots, one can find a_l, b_l, and h_l from the simple relations

$$g(\xi) + a_l \cdot \xi + b_l = 0,$$

$$g(\zeta) + a_l \cdot \zeta + b_l = 0.$$

In general, the determination of h is related to the zeros of Δy in Ω. This is an extension to the case of the clamped plate of the relation (2.7) which ensures (in the case of simply supported plates) that the zeros and the sign of Δy remain unmodified via the resizing transformation. The roots distribution is connected to the famous conjecture of Hadamard [9] on the positivity of the Green function for the biharmonic operator. While Duffin [7] provided a first counterexample, he also noticed that the sign of Δy in a neighborhood of $\partial\Omega$ is the same as that of y. Later, Garabedian [8] and Shapiro and Tegmark [24] obtained counterexamples in eccentric ellipses. By reworking this last one, which has an elementary character, we see that Δy may change sign on an interior subdomain but also in the neighborhood of $\partial\Omega$ (even with f of constant sign). Therefore, the properties of Δy in dimension two are essentially different from [25, Thm. 3.1] in the one-dimensional case.

4. Variational inequalities. We consider the elastic beam with a unilateral obstacle at the right end:

$$(4.1)\qquad \left(u^3 y'', y'' - z''\right)_{L^2(0,1)} \le (f, y - z)_{V^* \times V} \quad \forall\, z \in \mathcal{K},$$

$$(4.2)\qquad y \in \mathcal{K} = \{w \in V\,;\, y(1) \ge \alpha\} \quad (\alpha \in R \text{ given}),$$

$$(4.3)\qquad V = \{y \in H^2(0,1)\,;\, y(0) = y'(0) = 0\}.$$

The beam is clamped at the left end.

To any $u \in L^\infty(0,1)$ we associate the linear bounded operator $A(u) : V \to V^*$ via the bilinear form on V

$$(4.4)\qquad a\,(u, y, z) = \int_0^1 u^3\, y''\, z''\, dx \quad \forall\, y, z \in V.$$

Then the variational inequality (4.1), (4.2) may be rewritten in the abstract form

$$(4.5)\qquad \big(A\,(u)\, y, y - z\big) = a\,(u, y, y - z) \le (f, y - z)_{V^* \times V}$$

for any $z \in \mathcal{K}$ and with $y \in \mathcal{K}$.

If $u \in L^\infty(0,1)$ is positive, $A(u)$ is strictly maximal monotone, and if $u(x) \ge m > 0$ in $[0,1]$, then $A(u)$ is strongly monotone and coercive. This gives a unique weak solution $y \in V$ to the variational inequality (4.5), for any $f \in V^*$.

We now define two auxiliary problems. First, we consider a cantilevered beam (without unilateral conditions):

$$(4.6)\qquad \begin{aligned} \left(u^3 y_1''\right)'' &= f \quad \text{in }]0,1[,\\ y_1(0) = y_1'(0) &= 0,\\ y_1''(1) = 0, \quad \left(u^3 y_1''\right)'(1) &= 0. \end{aligned}$$

Second, we introduce a clamped–simply supported beam:

$$(4.7)\qquad \begin{aligned} \left(u^3 y_2''\right)'' &= f \quad \text{in }]0,1[,\\ y_2(0) = y_2'(0) &= 0,\\ y_2''(1) = 0, \quad y_2(1) &= \alpha. \end{aligned}$$

It is simple to check by direct integration that both y_1, y_2 are in $H^2(0,1)$ and $u^3\, y_1''$, $u^3\, y_2'' \in H^2(0,1)$ for $f \in L^2(0,1)$.

Theorem 4.1. *If $f \in L^2(0,1)$, then the solution y of the variational inequality* (4.1) *is either the solution of* (4.6) *or the solution of* (4.7). *It satisfies $u^3\, y'' \in H^2(0,1)$.*

Proof. Assume first that $y_1(1) \geq \alpha$ (that is, $y_1 \in \mathcal{K}$). We multiply (4.6) by $y_1 - z$ for any $z \in \mathcal{K}$, and we see (by partial integration) that y_1 is also a solution of (4.1), $y = y_1$, and the claimed regularity is clear.

Assume now that $y_1 \notin \mathcal{K}$. By (4.7), it is obvious that $y_2 \in \mathcal{K}$. We multiply (4.7) by $y_2 - z$, $z \in \mathcal{K}$, and integrate by parts:

$$(f, y_2 - z)_{L^2(0,1)} = \big(u^3 y_2''\big)'(1)\big(\alpha - z(1)\big) + \int_0^1 u^3 y_2'' (y_2'' - z)\, dx. \tag{4.8}$$

Assume that

$$\gamma = \big(u^3 y_2''\big)'(1) > 0, \tag{4.9}$$

and denote $w = y_2 - y_1$. By (4.6), (4.7), (4.9), we see that w satisfies

$$\big(u^3 w''\big)'' = 0 \quad \text{in }]0,1[,$$

$$w(0) = w'(0) = 0,$$

$$w''(1) = 0, \quad \big(u^3 w''\big)'(1) = \gamma > 0.$$

Then, $u^3(x)\, w''(x) = \gamma x - \gamma \leq 0$ in $[0,1]$. That is, w is a concave function, and $w(0) = w'(0) = 0$ gives $w \leq 0$ in $[0,1]$. Therefore, $y_2(1) \leq y_1(1) < \alpha$, according to the assumption $y_1 \notin \mathcal{K}$. However, this is a contradiction to $y_2(1) = \alpha$, and it follows that (4.9) is false. Then (4.8) gives that y_2 is now the solution of (4.1); i.e., $y = y_2$ again has the claimed regularity. □

Remark. The boundary conditions in $x = 1$, associated with (4.5), are

$$y''(1) = 0, \quad y(1) \geq \alpha, \quad \big(u^3 y''\big)'(1) \leq 0,$$

$$\big(y(1) - \alpha\big)\big(u^3 y''\big)'(1) = 0.$$

We formulate the optimization problem $(\mathbf{P}_5)$:

$$\text{Min} \int_0^1 u(x)\, dx, \tag{4.10}$$

subject to (4.1) and to

$$m \leq u(x) \leq M \quad \text{a.e. in } [0,1], \tag{4.11}$$

$$y(x) \geq -\tau \quad \text{in } [0,1]. \tag{4.12}$$

Without loss of generality, we may assume

$$\alpha > -\tau. \tag{4.13}$$

Otherwise, all the admissible pairs of $(\mathbf{P}_5)$ correspond to an inactive variational inequality (the case $y = y_1$), that is, to a cantilevered beam (by Theorem 4.1), and we can refer to section 2. We call *extremal* for $(\mathbf{P}_5)$ any admissible "thickness" $u \in L^\infty(0,1)$ such that the associated state is active with respect to the constraint (4.12).

PROPOSITION 4.2. *If* $\alpha \geq 0$ *and* $m = 0$*, any local minimum of* $(\mathbf{P}_5)$ *is an extremal of* $(\mathbf{P}_5)$.

Proof. If $[u,y]$ is local optimum for $(\mathbf{P}_5)$, but not extremal, there is some $\lambda > 1$ such that the pair $[\lambda^{-1/3}\, u,\ \lambda\, y]$ is admissible for $(\mathbf{P}_5)$—it clearly satisfies the constraints and the variational inequality since $\lambda\, y \in \mathcal{K}$ by $\alpha \geq 0$.

Obviously $\lambda^{-\frac{1}{3}}\, u$ gives a lower cost which contradicts the local optimality of u when $\lambda \to 1+$. □

Remark. The case $\alpha = 0$ was considered by Hlavacek, Bock, and Lovisek [12].

PROPOSITION 4.3. *Assume that* $f < 0$ *in* $[0,1]$*. Then any extremal pair has exactly one active point in* $]0,1[$.

Proof. The existence of at least one point $x_u \in [0,1]$ such that $y(x_u) = -\tau$ is obvious by the definition. Assume that there are at least two such points $x_u \neq \bar{x}_u$, i.e., $y(x_u) = y(\bar{x}_u) = -\tau$. Again by definition, x_u and $\bar{x}_u$ are minimum points for y, different from 0 and 1, that is, $y'(x_u) = y'(\bar{x}_u) = 0$. Then $y + \tau$ satisfies the clamped beam conditions on $[x_u,\, \bar{x}_u]$. By [25, Thm. 3.1], we see that $y \leq -\tau$ on $[x_u,\, \bar{x}_u]$; therefore $y \equiv -\tau$ on $[x_u,\, \bar{x}_u]$. This contradicts $f < 0$ a.e. in $[0,1]$. □

Remark. Notice that by $y(0) = 0$ and $y(1) \geq \alpha > -\tau$ (by (4.13)) the end points cannot be active with respect to the state constraint.

COROLLARY 4.4. *If* $f \leq 0$*, any extremal of* $(\mathbf{P}_5)$ *satisfies* (4.7) *and* $(u^3 y'')'(1) \leq 0$.

Proof. If $f \leq u$, then the cantilevered beam y_1 has the global minimum in $x = 1$ and $y_1(1) \geq \alpha$ by (4.2). Condition (4.13) shows that y_1 cannot be extremal and Theorem 4.1 gives that y should satisfy (4.7) in order to be extremal for $(\mathbf{P}_5)$. Then, relation (4.9) is false, as in the proof of Theorem 4.1, and this completes the argument. □

Remark. By Corollary 4.4 and Proposition 4.2, the shape optimization problem $(\mathbf{P}_5)$, governed by variational inequalities, is reduced to the linear state system (4.7). Some cases of control problems governed by variational inequalities of obstacle type which can be equivalently reformulated as convex control problems with state constraints are discussed in Tiba [26, Chap. III.5], by different approaches.

We formulate the "dual" problem

$$(\mathbf{D}_5) \qquad \text{Min} \int_0^1 f(x)\, dx,$$

$$\begin{aligned}
(4.14) \qquad (\bar{u}^3\, y'')'' &= f \quad \text{in }]0,1[,\\
y(0) = y'(0) &= 0,\\
y(1) = \alpha, \quad y''(1) &= 0,\\
f &\leq 0 \quad \text{a.e. in } [0,1],\\
(4.15) \qquad y &\geq -\tau \quad \text{in } [0,1].
\end{aligned}$$

Notice that this is again a linear optimization problem ($\bar{u}$ is a prescribed thickness).

Remark. The control constraint $f \leq 0$ is a simplified stronger variant of (2.7), due to the maximum principle. Then, the equivalence results from Theorems 2.1 and 2.4 are not valid in this setting. However, we put into evidence that between the problems $(\mathbf{P}_5)$ and $(\mathbf{D}_5)$ there still exists a very useful relationship explained in Algorithm 4.6

and in Theorem 4.7. In the cases discussed in sections 2 and 3 (only for beams), this weaker relationship was studied in Sprekels and Tiba [25]. The problem $(\mathbf{D}_5)$ is, in fact, a slightly simplified variant of the problem $(\mathbf{D}_2)$ of section 2. Moreover, this approach allows us to consider $m = 0$ and gives another form for the resizing transformation.

THEOREM 4.5. *Assume that $\bar{u}$ is continuous and let $[y, f]$ be extremal for $(\mathbf{D}_5)$. Then y'' has exactly one root in $[0,1[$. Moreover, $y \leq \max\{0; \alpha\}$ in $[0,1]$.*

Proof. We have $\bar{u}^3\, y'' = g$ in $[0,1]$, where, moreover, $g'' = f$ in $[0,1]$ and $g(1) = 0$. Since $f \leq 0$, then g is concave in $[0,1]$ and it may have at most one root in $[0,1[$, unless it is identically 0 in some subinterval.

In the last subcase, by concavity and $g(1) = 0$, there is some $\xi \in]0,1[$ such that $g(x) \equiv 0$, $x \in [\xi, 1]$, and $g(x) < 0$ in $[0, \xi[$. Then $y'' < 0$ in $[0, \xi[$ and, since $y(0) = y'(0) = 0$, we see that $y(\xi) < 0$, $y'(\xi) < 0$, and $y(x) = y'(\xi)\,(x - \xi) + y(\xi)$ for $x \in [\xi, 1]$. We obtain that

$$\alpha \;=\; y(1) \;<\; y(x) \quad \forall\, x \,\in\, [0,1],$$

which contradicts the extremality of $[y, f]$ and (4.13).

Therefore g has at most one root in $[0,1[$. Since $[y, f]$ is extremal, there is some $\bar{\xi}$ in $]0,1[$ such that $y(\bar{\xi}) = -\tau$, and this is a minimum point for y on $]0,1[$. Then $y'(\bar{\xi}) = 0$, and there is some $\eta \in]0, \bar{\xi}[$ such that $y''(\eta) = 0$, since $y'(0) = 0$ and y'' is continuous by the assumption on $\bar{u}$.

We conclude that y'' has exactly one root in $]0, \bar{\xi}[$. Let η be this root. Then $y'' \leq 0$ in $[0, \eta]$ and $y'' \geq 0$ in $[\eta, 1]$. By $y(0) = y'(0) = 0$ and the concavity of y, we get $y \leq 0$ in $[0, \eta]$. By $y(\eta) \leq 0$, $y(1) = \alpha$, and the convexity of y, we get $y \leq \max\{0; \alpha\}$ in $[\eta, 1]$ as well. This ends the proof. □

Based on Theorem 4.5, we can formulate the following algorithm.

[4]ALGORITHM 4.6 ($m = 0$, $M = +\infty$).

```
1. $n = 0$,   $u_0$ admissible for $(\mathbf{P}_5)$, continuous.
2. Min$(\tilde{D}_n)$ gives $[y_n, f_n]$, where $(\tilde{D}_n)$ is given by (4.14) with $\bar{u}$ replaced by $u_n$.
3. If $f_n - f$ "small," then STOP! Otherwise
4. ("resizing step")
α) compute the unique root $\xi_n$ in $[0,1[$ of $y_n''$
β) denote $g_n = u_n^3\, y_n''$ and define $\tilde{g}_n$ by
      i)  $\begin{cases} \tilde{g}_n'' = f & \text{in } ]\xi_n, 1[, \\ \tilde{g}_n(\xi_n) = 0, & \tilde{g}_n(1) = 0, \end{cases}$
      ii) $\begin{cases} \tilde{g}_n'' = f & \text{in } ]0, \xi_n[, \\ \tilde{g}_n(\xi_n) = 0, & \tilde{g}_n'(\xi_n -) = \tilde{g}_n'(\xi_n +). \end{cases}$
γ) resize $u_n$ by $u_{n+1}^3 = u_n^3\, \frac{\tilde{g}_n}{g_n}$, and set $n := n + 1$, GO TO step 2.
```

Remark. The resizing rule (γ) is well defined even in ξ_n and in 1 by the Hopf maximum principle and l'Hospital's rule. The sequence $\{u_n\}$ remains continuous in all iterations and $1/u_n^3 \in L^2(0,1)$ if $1/u_0^3 \in L^2(0,1)$.

THEOREM 4.7. *Algorithm* 4.6 *generates extremals u_n for* $(\mathbf{P}_5)$ *in each step $n \geq 1$.*

Proof. If f_n is a minimum for $(\tilde{\mathbf{D}}_n)$, then it is extremal for $(\tilde{\mathbf{D}}_n)$. Otherwise, $y_n(x) \geq -\tau + \varepsilon$ in $[0,1]$ for some positive ε. Consider $f_\delta = f - \delta$, δ positive constant, and y_δ the corresponding solution of (4.11).

Clearly $y_\delta \to y_n$ uniformly in $[0,1]$ for $\delta \to 0$. Then, for some small δ, $[y_\delta,\, f_\delta]$ is an admissible pair for $(\tilde{\mathbf{D}}_n)$ with a lower cost. This is a contradiction to the optimality of f_n. Extremality is obviously preserved by the resizing rule, since (γ) and (β) give

$$\left(u_{n+1}^3\, y_n''\right)'' = (\tilde{g}_n)'' = f \quad \text{in }]0,1[;$$

i.e., y_n is the state associated with u_{n+1} in (4.7), or equivalently in (4.1). □

Remark. The algorithm has a global character since it iterates between extremals of $(\mathbf{P}_5)$. If the cost functional (4.10) is replaced by (2.28), then Algorithm 4.6 has the descent property as well (again by the resizing rule).

We close this section with a numerical example.

Example 4.8. We have made several experiments with Algorithm 4.6 applied to the minimum weight problem $(\mathbf{P}_5)$. The state equation was discretized by usual finite difference approximations for the derivatives, using the grid $x_i = i\,h$, $i = \overline{0,m}$, $h = 1/m$. By the discretization process, the problem $(\mathbf{D}_5)$ is approximated by a linear programming problem (LPP) (this is one of the advantages of an algorithm). The variables of the LPP are given by the discrete values of the pair $[y,f]$. The cost functional is evaluated using Simpson's approximation rule.

The numerical tests have been made with $m = 50$ which allows the LPP to be accurately solved via the simplex algorithm. The root ξ_n in step 4α) of Algorithm 4.6 was found using a cubic spline approximation of y_n. The differential equations corresponding to $\tilde{g}_n$ were solved by integrating first mathematically, using convolution formulae, and approximating next the definite integrals by a sharp numerical integration routine.

Generally, the algorithm stopped by failing to solve the problem $(\tilde{\mathbf{D}}_n)$ when it cannot further decrease the thickness u. The numerical tests have been made on a PC Pentium with floating point arithmetic accuracy of order 10^{-20}. We have fixed the load $\bar{f} \equiv -50$ in $]0,1[$ and $\bar{f} \equiv -1$ in $x = 0$, $x = 1$ or $\hat{f} \equiv -1$ in $[0, 0.5]$, and $\hat{f} \equiv -50$ in $]0.5, 1]$. The obstacle α had the values 0.1 or 0 or -0.1, the state constraint was $\tau = 0.6$ or $\tau = 0.5$, and the initial iteration (thickness) was $\bar{u}_0 = 2 + x\,(x-1)$ or $\hat{u}_0 = 2 - x$. In all these variants a sharp decrease in the thickness was obtained in a maximum of seven iterations, but usually only in three iterations. This information is collected in the following table (each column gives an experiment and $v(u_i)$ is the L^1 norm of u_i):

f	$\bar{f}$	$\bar{f}$	$\bar{f}$	$\hat{f}$	$\hat{f}$
α	0.0	- 0.1	0.1	- 0.1	0.1
τ	0.6	0.6	0.6	0.6	0.5
u_0	$\hat{u}_0$	$\hat{u}_0$	$\bar{u}_0$	$\bar{u}_0$	$\hat{u}_0$
$v\,(u_1)$	1.1369	1.2987	1.5064	1.6727	1.2513
$v\,(u_2)$	0.9194	1.1146	1.2586	1.5916	1.1598
$v\,(u_3)$	0.7583	0.9823	1.2682	1.5693	1.1100
$v\,(u_4)$			0.9280	1.4288	1.0740
$v\,(u_5)$			0.7596	1.3296	1.0468
$v\,(u_6)$			0.6540	1.3760	
$v\,(u_7)$			0.5781	1.2778	

Acknowledgments. The numerical tests were performed with the help of Dr. V. Arnautu and Dr. A. Ignat of the University of Iaşi, Romania.

APPROXIMATE SOLUTION OF MARKOV RENEWAL PROGRAMS WITH FINITE TIME HORIZON*

KARL HINDERER† AND KARL-HEINZ WALDMANN‡

Abstract. The present paper investigates the error committed by using an infinite time horizon Markov renewal program as an approximation of the (often more realistic) Markov renewal program with a finite time horizon t_0. Under weak assumptions the error is shown to converge to zero exponentially fast when $t_0 \to \infty$. The convergence is based on explicit error bounds. Improved error bounds hold when the (transformed) transition law has a nontrivial stochastic lower bound. Some bounds use the discounted renewal function. For the latter, monotone upper and lower bounds are obtained by an iterative method combined with an extrapolation. Several examples demonstrate the applicability of the results.

Key words. Markov renewal programs, finite time horizon, approximate solution, discounted renewal function

1. Introduction.

A Markov renewal program (also known as a semi-Markov decision process) with infinite time horizon and infinitely many stages, denoted by MRP$^\infty$, is an important and intensively studied extension of the classical infinite-stage Markovian decision process. The extension concerns the time (points) $0 \equiv T_0 \leq T_1 \leq T_2 \leq \cdots$ where decisions (also called actions) are made. They are no longer fixed and equidistant, but random. In particular, at each time T_ν an action $a_\nu = \pi_\nu(s)$ is taken, depending on the present state $\zeta_\nu = s$ by means of a decision rule π_ν. Associated with a sequence $\pi := (\pi_\nu)_0^\infty$ of decision rules, known as a policy, is a sequence of rewards earned during the decision epochs $[T_\nu, T_{\nu+1})$. These rewards are discounted to time zero with a discount rate $\alpha > 0$. The goal consists of maximizing the expected total discounted reward within the set of all policies. As usual, it is assumed that $(T_{\nu+1} - T_\nu, \zeta_\nu), \nu \geq 1$, form a Markov chain for each policy.

Many applications in Markov renewal programming require a finite time horizon t_0 for a realistic modelling; i.e., the decision process runs for at most t_0 time units. This concerns, e.g., the many models of control of queues in cases where the servers only work during an interval of finite length or during a sequence of disjoint finite time intervals (e.g., during daytime) with identical initial states (e.g., an empty queue).

Despite its importance there is only a small amount of literature on Markov renewal programs with a finite time horizon t_0 (MRP^{t_0} for short). The first paper in this area is Jewell [6]. A thorough investigation of the foundations was made by Schellhaas [11]. Bounds for the value function are derived in Waldmann [13]. An application to asset selling and a survey on papers with applications (including Gertsbakh [4]) is given in Mamer [10].

The scarcity of the literature is probably due to the following reasons:

(i) As already observed by Jewell [6], the solution of a Markov renewal program with a finite time horizon can be formally reduced to one with an infinite time horizon with augmented states (s, t), consisting of the "internal" state s and the remaining time horizon t. Thus the action taken at time T_ν usually depends not only on the present internal state s but also on the remaining time horizon t. This enlarges the set of relevant policies considerably, and, as a consequence, much more effort is required for both a qualitative analysis and a numerical computation of MRP^{t_0} compared with MRP^∞. Therefore it is customary (usually without mentioning it) to use the solution of MRP^∞ as approximation for the solution of MRP^{t_0}.

(ii) It seems to be a general belief that the error made in solving MRP^{t_0} approximately by the corresponding infinite time horizon MRP^∞ is "small," at least if t_0 is "large." The goal of the present paper is to confirm this belief by deriving explicit bounds for the errors made.

In particular, we are interested in the following questions:

(a) Denote by $V^{t_0}(s)$ (resp., $V(s)$) the maximal expected total reward in MRP^{t_0} (resp., in MRP^∞) for a given initial state s. Then, using $V(s)$ as approximation for $V^{t_0}(s)$, we want to know "good" upper and lower bounds for the *error* $V^{t_0}(s) - V(s)$ and conditions under which $V^{t_0}(s)$ converges "quickly" to $V(s)$ for $t_0 \to \infty$.

(b) Let π^* be an optimal policy for MRP^∞, and let $V^{t_0}_{\pi^*}(s)$ be the associated expected total reward in MRP^{t_0}. Then we want to know lower bounds for the performance of π^* when applied in MRP^{t_0} as a substitute for an optimal horizon-dependent policy, i.e., lower bounds for the *error* $V^{t_0}_{\pi^*}(s) - V^{t_0}(s)$.

To the best of our knowledge, no results about problems (a) and (b) are known in the literature. (In Jewell [6, p. 745], a proof for the convergence of $V^{t_0}(s)$ to $V(s)$ is indicated for a special model, but it seems that only the convergence of $V^{t_0}_\pi(s)$ toward $V_\pi(s)$ for a fixed stationary policy π is shown; cf. also De Cani [2, p. 730].)

The main purpose of the present paper is to answer the questions in (a) and (b) by deriving under weak assumptions and for general transition law and general reward structure upper and lower bounds for $V^{t_0}(s) - V(s)$ and lower bounds for $V^{t_0}_{\pi^*}(s) - V^{t_0}(s)$ of the form

$$e^{-\delta t_0}\, b(s)\, K(t_0). \tag{1.1}$$

Here $s \mapsto b(s)$ is a bounding function of MRP^∞, which, as usual, ensures the existence and finiteness of $V^{t_0}(s)$ and of $V(s)$. Moreover, K is an explicitly given function, and δ can be chosen in some subinterval of $[0, \alpha]$, determined by integrability conditions; cf. assumptions (A1) and (A2) below. In general K depends on δ and is bounded in t for fixed δ. Then δ is crucial for the quality of the bounds (1.1). Moreover, we obtain exponential convergence of $V^{t_0}(s)$ to $V(s)$ for $t_0 \to \infty$ if upper and lower bounds for $V^{t_0}(s) - V(s)$ of the form (1.1) hold for some $\delta > 0$.

Some of our functions K (e.g., (3.19)) contain the discounted renewal function $H_\infty := \sum_{i=0}^\infty \gamma^i H^{i*}$, determined by a constant γ, defined in (3.7), and a distribution function H on $\mathbb{R}_+$, which is a lower stochastic bound for the "transformed" transition law G, defined in (3.8). As H_∞ is explicitly known in a few cases only, we obtain easily computable upper bounds for it (and hence for K) in the following way: One selects a distribution function $\tilde{H} \geq H$, whose probability distribution is concentrated on $\{0, \varepsilon, 2\,\varepsilon, \ldots, m\,\varepsilon\}$ for some $m \in \mathbb{N}$ and some $\varepsilon > 0$. Then the upper bound $\tilde{H}_\infty(k\,\varepsilon)$ of $H_\infty(k\,\varepsilon)$, $k \in \mathbb{N}$, can be found by a recursion, combined with an extrapolation. The latter is of general interest for approximate solutions of linear difference equations with constant coefficients without solving the characteristic equation.

For technical reasons we mainly study models MRP$^{\infty}$ and MRP^{t_0}, which have a finite number n of decision epochs only, i.e., planning horizon T_n and $\min(t_0, T_n)$, resp. These problems are of independent interest and they allow to derive easily the corresponding results for the case $n = \infty$ by letting n tend to infinity (cf. Theorem 3.7, Proposition 4.2(c) and Theorem 4.3(b)).

Another paper where both stages and a continuous-time horizon play a role is van Dijk [12].

This paper is organized as follows. In section 2 we rigorously introduce the model MRP$^{\infty}$, *for simplicity denoted by MRP from now on,* and the model MRP$'$, which comprises all models MRP^{t_0}, $t_0 > 0$. The flexibility of MRP^{t_0} is increased by including an additional reward $\tilde{h}$ which is obtained when the process passes the horizon t_0. Special cases of the reward structure which are important for many applications are considered in (2.1) and (2.3). In Theorems 3.5 through 3.7 we present upper bounds, which always hold for $H :\equiv 1$, and which yield improved bounds if a nontrivial stochastic lower bound H for the transformed transition law exists. In section 4 lower and absolute bounds are derived, and the performance of optimal policies for MRP, when applied to MRP^{t_0}, is studied. Section 5 is devoted to an efficient (approximate) computation of the discounted renewal function. Section 6 contains four examples.

Notation. $\mathbb{N}_0 := \{0, 1, \ldots\}$; $\mathbb{N} := \{1, 2, \ldots\}$; $\mathbb{R}_+ := [0, \infty)$; $x^{\pm} := \max\{0, \pm x\}$, $x \in \mathbb{R}$; δ_x is the one-point measure in the point $x \in \mathbb{R}$; $0/0 := 0$; $\sigma_n(x) := \sum_{i=0}^{n-1} x^i$ for $n \in \mathbb{N}_0$ and $x \in \mathbb{R}_+$; "measurable" means "measurable with respect to the σ-algebras under consideration." On countable sets we use the power set as σ-algebra. Probability distribution is abbreviated by p.d.

2. The models MRP and MRP$'$. Our infinite time-horizon Markov renewal program MRP with a fixed number $n \in \mathbb{N}$ of decision epochs (stages) consists of a tuple $(S, A, D, \kappa, \tilde{r}, \alpha, V_0)$ of the following meaning. S and A are the (arbitrary) state space and action space, endowed with some σ-algebra $\mathcal{S}$ and $\mathcal{A}$, resp., $D(s) \subset A$ is the set of admissible actions in state s; the constraint set $D := \{(s, a) \in S \times A \mid a \in D(s)\}$ is assumed to be measurable and to contain the graph of a measurable mapping from S into the action space A. The transition p.d. $\kappa(s, a, d(z, u))$ from D into $\mathbb{R}_+ \times S$ defines the joint p.d. of the sojourn time z in s (i.e., the length of the decision epoch) and of the next state u. (It is common to ensure by appropriate assumptions that $T_\nu \to \infty$ almost surely (a.s.) for $\nu \to \infty$. However, our optimization problem makes sense and our results hold without such assumptions.) The one-stage reward $\tilde{r}(s, a, z, u)$ is earned at the beginning of the decision epoch. Further we allow a terminal reward $V_0(s)$, which is realized at the end of the last decision epoch. We suppose $\tilde{r} : D \times \mathbb{R}_+ \times S \to \mathbb{R}$ and $V_0 : S \to \mathbb{R}$ to be measurable. Finally, all rewards are discounted to time zero with rate $\alpha > 0$.

In applications, $\tilde{r}$ often has the form

$$\tilde{r}(s, a, z, u) = \tilde{r}_1(s, a) + \int_0^z e^{-\alpha y}\, \tilde{r}_2(s, a, y)\, dy + e^{-\alpha z}\, \tilde{r}_3(s, a, z, u). \tag{2.1}$$

Here $\tilde{r}_1(s, a)$ and $\tilde{r}_3(s, a, z, u)$ are earned at the beginning and the end, resp., of the decision epoch, while $\tilde{r}_2(s, a, y)$ is a reward rate for continuously earned rewards.

For establishing existence and finiteness of the value functions, we must strengthen the well-known concept of a bounding function. We impose the condition that there exists some parameter $\delta \in [0, \alpha]$, which is kept fixed, for which the subsequent assumptions (A1) and (A2) hold.

(A1) There exists a measurable function b from S into $(0,\infty)$ and a constant $\varrho \geq 0$ such that for all $(s,a) \in D$

(i) $\int \kappa(s,a,d(z,u))e^{\delta z}\,|\tilde{r}(s,a,z,u)| \leq \varrho\, b(s)$,

(ii) $|V_0(s)| \leq \varrho\, b(s)$,

(iii) $0 < \int \kappa(s,a,d(z,u))e^{-(\alpha-\delta)z}\, b(u) \leq \varrho\, b(s)$.

If (A1) holds for some $\delta \in [0,\alpha]$, then it also holds for $\delta = 0$, which means that b is a bounding function of MRP. Let B be the set of measurable functions v on S, which have finite weighted supremum norm

$$\|v\|_b := \sup_{s\in S} [|v(s)|/b(s)].$$

Because of (A1) there exists

$$r(s,a) := \int \kappa(s,a,d(z,u))\,\tilde{r}(s,a,z,u).$$

As usual, a measurable mapping $f : S \to A$ with $f(s) \in D(s), s \in S$, is called a decision rule. A finite sequence $\pi = (f_n, f_{n-1}, \dots, f_1)$ of decision rules, specifying action $f_k(s)$ to be taken in state s at the beginning of the $(n-k+1)$th decision epoch (i.e., having k stages left), is called an n-stage (Markovian) policy. Let Δ_n denote the set of all n-stage policies. For each policy $\pi = (f_n, f_{n-1}, \dots, f_1)$ and initial state s there exists, as b is a bounding function, the expected n-stage reward

$$V_{n\pi}(s) := E_{\pi s}\left[\sum_{\nu=0}^{n-1} e^{-\alpha T_\nu}\cdot \tilde{r}(\zeta_\nu, f_{n-\nu}(\zeta_\nu), Z_{\nu+1}, \zeta_{\nu+1}) + e^{-\alpha T_n}\cdot V_0(\zeta_n)\right].$$

Here $\zeta_0 := s$, ζ_ν for $1 \leq \nu \leq n$ denotes the random state at time T_ν, and $Z_{\nu+1} := T_{\nu+1} - T_\nu$ is the sojourn time in state ζ_ν. $E_{\pi s}$ denotes the expectation determined by the initial state s, the policy π, and the transition law κ in the usual way.

A policy $\pi^* \in \Delta_n$ is called optimal if $V_{n,\pi^*}(s) = V_n(s) := \sup_{\pi\in\Delta_n} V_{n,\pi}(s)$ holds for all $s \in S$. We call V_n, which belongs to B as b is a bounding function, the n-stage value function.

Next we introduce the finite time-horizon version MRP^{t_0} of MRP, which consists of the MRP $(S, A, D, \kappa, \tilde{r}, V_0, \alpha)$, a finite time-horizon (called also initial residual time) $t_0 > 0$, and an additional measurable function $\tilde{h}$ on $\mathbb{R}_+ \times D \times \mathbb{R}_+ \times S$.

To explain the meaning of $\tilde{h}$, let us have $k > 0$ stages left and a residual time $t \geq 0$. Interpret s, a, z, and u as above. Then, if $t - z < 0$, the process stops with a terminal payoff $e^{\alpha t}\,\tilde{h}(t,s,a,z,u)$, which is realized at time t_0. Otherwise, i.e., if $t - z \geq 0$, the process earns immediately $\tilde{r}(s,a,z,u)$ and continues with $k-1$ stages left and residual time $t - z$. Finally, in case of $k = 0$ stages left and a residual time $t \geq 0$, there is a terminal reward $V_0(s)$ again.

All finite time-horizon problems $\mathrm{MRP}^{t_0}, t_0 > 0$, can be modelled by an infinite time-horizon model MRP′, say, with extended state space $X = \mathbb{R} \times S$, where the extended state $x = (t,s)$ consists of two parts, the momentary residual time t, and the momentary internal state s. (The states with $t < 0$ are only needed for a convenient modelling.) The other data are as follows:

- A is the action space.
- $D(s)$ is the set of admissible actions in state $x = (t,s)$.
- A transition occurs from $x = (t,s)$ to $\hat{x} = (t-z,u)$ according to $\kappa(s,a,d(z,u))$.

- The one-stage reward is

$$\tilde{r}'(t,s,a,z,u) := 1_{\mathbb{R}_+}(t)\left[\tilde{r}(s,a,z,u)1_{[0,t]}(z) + \tilde{h}(t,s,a,z,u)1_{(t,\infty)}(z)\right]. \tag{2.2}$$

- $V_0(s)1_{\mathbb{R}_+}(t)$ is the terminal reward.
- α is the discount rate.

If $\tilde{r}$ has the special form (2.1), we use as special form of $\tilde{r}'$ for $t \geq 0$

$$\begin{aligned} \tilde{r}'(t,s,a,z,u) &:= \tilde{r}_1(s,a) + \int_0^{z\wedge t} e^{-\alpha y}\,\tilde{r}_2(s,a,y)\,dy \\ &+ e^{-\alpha z}\,\tilde{r}_3(s,a,z,u)\,1_{[0,t]}(z) + e^{-\alpha t}\,R(t,s,a,z,u)1_{(t,\infty)}(z). \end{aligned} \tag{2.3}$$

Here $R(t,s,a,z,u)$ is an appropriately chosen reward, earned at time t_0. This case is covered by (2.2) by putting for $t \geq 0$

$$\tilde{h}(t,s,a,z,u) := \tilde{r}_1(s,a) + \int_0^t e^{-\alpha y}\,\tilde{r}_2(s,a,y)\,dy + e^{-\alpha t}R(t,s,a,z,u). \tag{2.4}$$

We additionally suppose the following:

(A2) There exists a measurable function $h : D \times \mathbb{R}_+ \times S \to \mathbb{R}_+$ such that there holds for all t,s,a,z,u

$$|\tilde{h}(t,s,a,z,u)| \leq h(s,a,z,u)$$

and

$$\int \kappa\,(s,a,d(z,u))\,e^{\delta z}\,h(s,a,z,u) \leq \varrho\,b(s).$$

(A1) and (A2) hold with $b \equiv 1$ if either V_0, $e^{\delta z}\tilde{r}(s,a,z,u)$ and $e^{\delta z}h(s,a,z,u)$ are bounded or if $V_0, \tilde{r}$, h and $\int \kappa(s,a,d(z,u))e^{\delta z}$ are bounded.

Define r^t by $r^t(s,a) := 0$ for $t < 0$ and for $t \geq 0$ by

$$\begin{aligned} r^t(s,a) :&= \int \kappa(s,a,d(z,u))\tilde{r}'(t,s,a,z,u) \\ &= r(s,a) + \int \kappa(s,a,d(z,u))1_{(t,\infty)}(z)\left[\tilde{h}(t,s,a,z,u) - \tilde{r}(s,a,z,u)\right]. \end{aligned} \tag{2.5}$$

In MRP′ the set Δ_n' of policies $\pi' = (f_n', f_{n-1}', \dots, f_1')$ is defined as in MRP, except that the decision rules f_k' depend on both the internal state s and the residual time t. For $\pi' \in \Delta_n'$ and initial state s there exists, as $(t,s) \mapsto b(s)\,1_{\mathbb{R}_+}(t)$ is a bounding function of MRP′ by (A1) and (A2), the expected n-stage reward

$$\begin{aligned} V_{n\pi'}^t(s) := E_{\pi'(t,s)}\Bigg[\sum_{\nu=0}^{n-1} e^{-\alpha T_\nu} \cdot \tilde{r}'(\tau_\nu, \zeta_\nu, f_{n-\nu}'(\tau_\nu,\zeta_\nu), Z_{\nu+1}, \zeta_{\nu+1}) \\ + e^{-\alpha T_n} \cdot V_0(\zeta_n) \cdot 1_{\mathbb{R}_+}(\tau_n)\Bigg]. \end{aligned}$$

Here τ_ν denotes the random residual time at time T_ν, and $E_{\pi'(t,s)}$ is the expectation determined by the residual time t, the initial state s, the policy π', and the transition law in MRP′ in the usual way.

A policy $\pi'^* \in \Delta'_n$ is called optimal if $V^t_{n,\pi'^*}(s) = V^t_n(s) := \sup_{\pi' \in \Delta'_n} V^t_{n,\pi'}(s)$ holds for all $(t,s) \in X$. The function $(t,s) \mapsto V^t_n(s)$, which is the n-stage value function in MRP$'$, belongs to the set B' of measurable functions v' on X with $v'(t,s) = 0$ for $t < 0$ and which have finite weighted supremum norm

$$\|v'\|_b := \sup_{(t,s)\in X} [|v'(t,s)|/b(s)].$$

Our bounds for $V^t_n - V_n$ are based on the value iteration in MRP and in MRP$'$, i.e., on the recursions

$$V_n(s) = \sup_{a\in D(s)} \left[r(s,a) + \int \kappa\,(s,a,d(z,u))\; e^{-\alpha z}\, V_{n-1}(u) \right] \tag{2.6}$$

and for $t \in \mathbb{R}$

$$V^t_n(s) = \sup_{a\in D(s)} \left[r^t(s,a) + \int \kappa\,(s,a,d(z,u))\; e^{-\alpha z}\, V^{t-z}_{n-1}(u) \right]. \tag{2.7}$$

As there exist a variety of approaches to ensure the validity of the value iterations, some of which are quite elementary, we do not make any topological assumptions on S and/or A (such as being Borel spaces), but instead make the following assumption:

(A3) The functions $s \to V_n(s)$ and $(t,s) \to V^t_n(s)$ are measurable and satisfy (2.6) and (2.7), resp.

Clearly, if S and A are finite, (A3) holds trivially. Note that (2.7) implies that $V^t_n(s) = 0$ for $t < 0$.

3. Upper bounds for $V^t_n - V_n$. We first make some preparations. For $v \in B$ and $(s,a) \in D$ put

$$\psi v(s,a) := \int \kappa\,(s,a,d(z,u))\, e^{-\alpha z} v(u),$$
$$\psi_t\, v(s,a) := \int \kappa(s,a,d(z,u)) 1_{(t,\infty)}(z) e^{-\alpha z} v(u),\ t \geq 0.$$

Application to b yields the constants

$$\underline{\beta} := \inf_{(s,a)\in D} \psi b(s,a)/b(s),$$
$$\beta := \sup_{(s,a)\in D} \psi b(s,a)/b(s),$$

and a transition measure μ from D into $\mathbb{R}_+$, defined by

$$\mu(s,a,(t,\infty)) := \psi_t\, b(s,a)/b(s), \quad t \geq 0.$$

Finally, let

$$d := \sup_{s\in S} (V_0(s) - V_1(s))/b(s),$$

and for $n \in \mathbb{N}_0$,

$$e_n := d\,\sigma_n(\beta) \text{ if } d \geq 0, \text{ and } e_n := d\,\sigma_n(\underline{\beta}) \text{ otherwise.}$$

Note that d is finite as V_0, $V_1 \in B$.

LEMMA 3.1. *Assume* (A1)–(A3). *Then*

$$V_0(s) - V_n(s) \le e_n b(s) \text{ for all } s \in S, n \in \mathbb{N}.$$

Proof. The assertion follows by an inductive argument based on

$$\begin{aligned} V_0(s) - V_n(s) &= \Big(V_0(s) - V_1(s)\Big) + \Big(V_1(s) - V_n(s)\Big) \\ &\le d\, b(s) + \sup_a \psi\,(V_0 - V_{n-1})\,(s,a),\ n \ge 1. \qquad \square \end{aligned}$$

For

$$\Delta^t(s,a) := e^{\delta t}\Big[r^t(s,a) - r(s,a) - \psi_t V_0(s,a)\Big], \quad t \ge 0, \tag{3.1}$$

we obtain the next result.

LEMMA 3.2. *Assume* (A1) *and* (A2). *Then*

$$0 \le w := \sup\{\Delta^t(s,a)/b(s) : (s,a) \in D,\ t \ge 0\} < \infty.$$

Proof. From (2.5) we see that $\Delta^t(s,a) = \int \kappa(s,a,d(z,u))\, g_t(s,a,z,u)$, where

$$g_t(s,a,z,u) := e^{\delta t}\, 1_{(t,\infty)}(z)\Big[\tilde{h}(t,s,a,z,u) - \tilde{r}(s,a,z,u) - e^{-\alpha z} \cdot V_0(u)\Big].$$

Because of $g_t(s,a,z,u) = 0$ for $t \ge z$, $g_t(s,a,z,u)$ trivially converges for $t \to \infty$ to zero. Moreover,

$$\begin{aligned} |g_t(s,a,z,u)| &\le \Lambda(s,a,z,u) \\ := e^{\delta z}\Big(h(s,a,z,u) + |\tilde{r}(s,a,z,u)|\Big) &+ e^{-(\alpha-\delta)z} \cdot |V_0(u)|. \end{aligned}$$

Utilizing (A1) and (A2) we obtain

$$\begin{aligned} \int \kappa(s,a,d(z,u))\,\Lambda(s,a,z,u) &\le \int \kappa(s,a,d(z,u))\Big[e^{\delta z}\, h(s,a,z,u) \\ &\qquad + e^{\delta z} \cdot |\tilde{r}(s,a,z,u)| + e^{-(\alpha-\delta)z} \cdot |V_0(u)|\Big] \\ &\le \varrho\,(2+\varrho)\, b(s). \end{aligned}$$

By the dominated convergence theorem $\Delta^t(s,a)$ converges for $t \to \infty$ to zero, from which the assertion follows. $\square$

We define operators L on B and L' on B', resp., by

$$\begin{aligned} Lv(s,a) &:= r(s,a) + \int \kappa(s,a,d(z,u)) e^{-\alpha z} v(u),\ (s,a) \in D, \\ L'v'(t,s,a) &:= r^t(s,a) + \int \kappa(s,a,d(z,u)) e^{-\alpha z} v'(t-z,u),\ (t,s,a) \in \mathbb{R} \times D. \end{aligned}$$

The next two results are our main tools for deriving bounds.

LEMMA 3.3. *Assume* (A1) *and* (A2). *Let* $v \in B, v' \in B'$, *and*

$$v'(t,s) - v(s) \le e^{-\delta t}\, b(s)\, K(t),\ t \ge 0,\ s \in S, \tag{3.2}$$

for some lower bounded measurable function K *on* $\mathbb{R}_+$. *Then*

$$L'v'(t,s,a) - Lv(s,a) \le e^{-\delta t} b(s) \hat{K}_v(t),\ t \ge 0,\ (s,a) \in D, \tag{3.3}$$

where

$$\hat{K}_v(t) := w + \sup_{(s,a)\in D}\left[\hat{d}_v\, e^{\delta t}\mu(s,a,(t,\infty)) + \int_{[0,t]} \mu(s,a,dz)e^{\delta z}K(t-z)\right]$$

and $\hat{d}_v := \sup_{s\in S}(V_0(s) - v(s))/b(s)$ *(which is finite as* $v, V_0 \in B$*).*

Proof. Fix $t \geq 0$, $(s,a) \in D$. Then

$$\begin{aligned} &L'v'(t,s,a) - Lv(s,a)\\ &= r^t(s,a) + \int \kappa(s,a,d(z,u))1_{[0,t]}(z)\, e^{-\alpha z}\, v'(t-z,u) - r(s,a) - \psi v(s,a)\\ &= e^{-\delta t}\Bigg[\ \Delta^t(s,a) + e^{\delta t}\psi_t(V_0 - v)(s,a)\\ &\qquad + \int \kappa(s,a,d(z,u))1_{[0,t]}(z)e^{\delta t-\alpha z}(v'(t-z,u) - v(u))\Bigg]. \end{aligned} \tag{3.4}$$

As $V_0(s) - v(s) \leq \hat{d}_v\, b(s)$, we have

$$\psi_t(V_0 - v)(s,a)/b(s) \leq \hat{d}_v\, \psi_t b(s,a)/b(s) = \hat{d}_v\, \mu(s,a,(t,\infty)).$$

Now the assertion follows, using equation (3.2), by taking the supremum over (s,a) in equation (3.4). □

LEMMA 3.4. *Assume* (A1)–(A3). *Then there holds for all* $n \in \mathbb{N}$ *and* $t \geq 0$

$$V_n^t(s) - V_n(s) \leq e^{-\delta t} b(s) K_n(t), \quad s \in S, \tag{3.5}$$

for each sequence $(K_n)_0^\infty$ *of lower bounded measurable functions on* $\mathbb{R}_+$*, fulfilling* $K_0 \equiv 0$ *and for* $n \in \mathbb{N}_0$, $t \geq 0$ *and* $(s,a) \in D$ *the condition*

$$K_{n+1}(t) \geq w + e_n\, e^{\delta t}\mu(s,a,(t,\infty)) + \int_{[0,t]} \mu(s,a,dz)e^{\delta z}K_n(t-z). \tag{3.6}$$

Proof. For $n = 1$, (3.5) follows from Lemma 3.3 with $v'(t,s) := V_0(s)\, 1_{\mathbb{R}_+}(t)$ and $v(s) := V_0(s)$. Thus assume (3.5) to hold for some $n \geq 0$. From (2.6) and (2.7) we know that

$$\begin{aligned} V'_{n+1}(t,s) - V_{n+1}(s) &= \sup_{a\in D(s)} L'V'_n(t,s,a) - \sup_{a\in D(s)} LV_n(s,a)\\ &\leq \sup_{a\in D(s)} (L'V'_n(t,s,a) - LV_n(s,a)), \end{aligned}$$

where $V'_n(t,s) = V_n^t(s)$. Now (3.5) follows for $n+1$ from Lemma 3.3 with $v' := V'_n$ and $v := V_n$, as $\hat{d}_v \leq e_n$ by Lemma 3.1. □

Now we construct explicitly given sequences $(K_n)_1^\infty$ of bounded functions satisfying (3.5). They lead to our main results, Theorems 3.5–3.7 and the supplementary Remark 3.3. Define

$$\gamma := \sup_{(s,a)\in D}\left\{b(s)^{-1} \cdot \int \kappa(s,a,d(z,u))e^{-(\alpha-\delta)z}b(u)\right\}, \tag{3.7}$$

and for fixed $(s,a) \in D$ a distribution function $G(s,a,\cdot)$ with $G(s,a,t) := 0$ for $t < 0$ by

$$\begin{aligned}(3.8)\quad & G(s,a,t) \\ & := \int \kappa(s,a,d(z,u)) 1_{[0,t]}(z) e^{-(\alpha-\delta)z} b(u) \Big/ \int \kappa(s,a,d(z,u)) e^{-(\alpha-\delta)z} b(u), \quad t \geq 0.\end{aligned}$$

We call $G(s,a,\cdot)$ the transformed transition law. Because of (A1) we have $0 < \beta \leq \gamma \leq \rho$, and $\gamma = \beta$ if and only if $\delta = 0$.

We additionally suppose the following:

(A4) There is some distribution function H with $H(t) = 0$ for $t < 0$ such that

$$H(t) \geq G(s,a,t), \quad (s,a) \in D, \quad t \geq 0.$$

Assumption (A4) is equivalent to saying that H is stochastically smaller than $G(s,a,\cdot)$ for all $(s,a) \in D$, or equivalently, that H is a stochastic lower bound of the transformed transition law. Clearly (A4) is always fulfilled for $H \equiv 1$. Therefore the subsequent bounds hold already under (A1)–(A3) when H^{i*}, the i-fold convolution of H with itself, is replaced everywhere by 1. If both S and A are finite, (A4) holds with $H(t) := \max_{(s,a)} G(s,a,t)$. In applications, often κ has the form $\kappa(s,a,d(z,u)) = Q(dz) \times P(s,a,z,du)$. Then, if either $P(s,a,z,du)$ does not depend on z or if (A1) and (A2) hold for $b \equiv 1$, $G(s,a,\cdot) = G(\cdot)$ is independent of $(s,a) \in D$, and then (A4) holds with $H := G$. Some of our bounds use

$$H_n := \sum_{i=0}^{n-1} \gamma^i H^{i*}.$$

As $H^{i*} \leq H^i$, we have the simple bound $H_n \leq \sigma_n(\gamma H)$, with equality when $H \equiv 1$. Observe that the subsequent bounds depend on the constants d, w, γ, and β or $\underline{\beta}$.

THEOREM 3.5. *Assume* (A1)–(A4). *Then* (3.5) *holds for the bounded functions*

$$K_n = \max\{w,d\} \cdot \left[\sigma_n(\beta) + (\gamma - \beta) \cdot \sum_{i=0}^{n-2} \gamma^i H^{i*} \sigma_{n-i-1}(\beta)\right] \tag{3.9}$$

$$\leq \max\{w,d\} \cdot \{1 + \sigma_{n-1}(\beta)\,[\beta + (\gamma - \beta) H_{n-1}]\} \tag{3.10}$$

Remark 3.1. Let $\hat{e}_n := \max\{w,d\}\,\sigma_n(\beta)$. Then $(K_n)_1^\infty$ as defined in (3.9) can be computed recursively via

$$K_{n+1} - \hat{e}_{n+1} = (\gamma - \beta)\hat{e}_n + \gamma H * (K_n - \hat{e}_n), \quad n \geq 0. \tag{3.11}$$

Proof of Theorem 3.5. For use later in the proof of Proposition 4.2, we prove a bit more than needed for the moment. (a) Consider K_n as defined in (3.9), but with arbitrary numbers $w \in \mathbb{R}_+$, $d \in \mathbb{R}$. Then $(K_n)_0^\infty$ still satisfies (3.11). We show that $(K_n)_0^\infty$ satisfies (3.6). First, (3.6) holds for $n = 0$. Thus assume (3.6) to hold for some $n \geq 0$. Since $\hat{e}_n \geq 0$ ensures $e^{\delta z}\hat{e}_n \geq e^{\delta t}\hat{e}_n$ for $z \geq t$, since $\hat{e}_1 \geq w$ and since $\gamma \geq \int \mu(s,a,dz) e^{\delta z}$ we get

$$\hat{e}_{n+1} + (\gamma - \beta)\hat{e}_n = \hat{e}_1 + \gamma \hat{e}_n \geq w + \hat{e}_n \int \mu(s,a,dz) \left(1_{[0,t]}(z) e^{\delta z} + 1_{(t,\infty)}(z) e^{\delta t}\right).$$

Further, since $H \leq_{st} G(s,a,\cdot), (s,a) \in D$, and since $K_n(t-z) - \hat{e}_n$ is nonnegative and decreasing in z by (3.9),

$$\begin{aligned}\gamma H * (K_n - \hat{e}_n)(t) &\geq \gamma \int_{[0,t]} G(s,a,dz)\left[K_n(t-z) - \hat{e}_n\right] \\ &\geq \int_{[0,t]} \mu(s,a,dz)e^{\delta z}\left[K_n(t-z) - \hat{e}_n\right].\end{aligned}$$

By combining (3.11) with both inequalities, (3.6) is obtained for $n+1$.

(b) Using (a) for the original w and d, the assertion follows immediately from Lemma 3.4. □

Our second type of bounds uses e_n instead of $\hat{e}_n$.

THEOREM 3.6. *Assume* (A1)–(A4). *Then* (3.5) *holds for the bounded function*

$$\begin{aligned}&(3.12) \qquad K_n = e_n + \sum_{i=0}^{n-1} \gamma^i H^{i*}\left[w - d + (\gamma-\beta)e_{n-i-1}^+\right]^+ \\ &(3.13) \qquad \leq e_n + \left[w - d + (\gamma-\beta)e_{n-1}^+\right]^+ \cdot H_n.\end{aligned}$$

Remark 3.2. $(K_n)_1^\infty$ as defined in (3.12) can be computed recursively via

$$(3.14) \qquad K_{n+1} - e_{n+1} = \left[w - d + (\gamma-\beta)e_n^+\right]^+ + \gamma H * (K_n - e_n), \quad n \in \mathbb{N}_0.$$

Proof of Theorem 3.6. (a) Consider K_n as defined in (3.12), but with arbitrary numbers $w \in \mathbb{R}_+$, $d \in \mathbb{R}$. Then $(K_n)_1^\infty$ still satisfies (3.14). We show that $(K_n)_0^\infty$ satisfies (3.6). First, it follows from (3.14) by induction that $K_n - e_n \geq 0$. Then, using

$$\beta(x) := \beta \text{ if } x \geq 0, \text{ and } \beta(x) := \underline{\beta} \text{ else,}$$

we obtain from (3.14)

$$\begin{aligned}K_{n+1} &= d + \beta(d)e_n + \left[w - d + (\gamma-\beta)e_n^+\right]^+ + \gamma H * (K_n - e_n) \\ &= \max\{d + \beta(d)e_n, w + \beta(d)e_n + (\gamma-\beta)e_n^+\} + \gamma H * (K_n - e_n).\end{aligned}$$

As $\beta(d)\, e_n - \beta\, e_n^+ = -\underline{\beta}e_n^-$ we get

$$(3.15) \qquad K_{n+1} \geq w + \gamma e_n^+ - \underline{\beta}e_n^- + \gamma H * (K_n - e_n).$$

Obviously (3.6) holds for $n = 0$. Assume it to hold for $n \geq 0$. Then from (3.15), as $K_n(t-z) - e_n$ is nonnegative and decreasing in z by (3.12),

$$\begin{aligned}K_{n+1} - w \geq\ & e_n^+ \int_{[0,t]} \mu(s,a,dz)e^{\delta z} + e_n^+ e^{\delta t}\mu(s,a,(t,\infty)) \\ & - e_n^- \int_{[0,t]} \mu(s,a,dz)e^{\delta z} - e_n^- e^{\delta t}\mu(s,a,(t,\infty)) \\ & + \int_{[0,t]} \mu(s,a,dz)e^{\delta z}\left(K_n(t-z) - e_n\right) \\ =\ & e_n e^{\delta t}\mu(s,a,(t,\infty)) + \int_{[0,t]} \mu(s,a,dz)e^{\delta z} K_n(t-z).\end{aligned}$$

Thus (3.6) holds for $n+1$.

(b) Now the assertion follows from Lemma 3.4, using (a) for the original w and d. $\square$

In general neither of the two bounds in (3.9) and (3.12) are better than the other. For example, if $w = 0$ and $d < 0$, then K_n from (3.9) equals zero while K_n from (3.12) equals $d\sum_{i=0}^{n-1}(\beta^i - \gamma^i\, H^{i*})$, which may be positive or negative.

Simpler, yet weaker bounds than those in Theorems 3.5 and 3.6 can easily be obtained in case $\gamma \leq 1$ from (3.9) and (3.13) by incorporating the discounted renewal function

$$H_\infty := \sum_{i=0}^{\infty} \gamma^i H^{i*}.$$

Note that H_∞ is bounded for $\gamma < 1$ by $1/(1-\gamma\, H) \leq 1/(1-\gamma)$ and (by a well-known result in renewal theory) affinely upper bounded for $\gamma = 1$. The condition $\gamma \leq 1$ in Remark 3.3 and Theorem 3.7 below is fulfilled if (A1) holds with $b \equiv 1$. If in addition S and A are finite, then $\beta < 1$.

Remark 3.3. Assume (A1)–(A4) and $\gamma \leq 1$. The upper bound (3.5) holds for

$$K_n := e_n + \left[w - d + (\gamma - \beta)e^+_{n-1}\right]^+ \cdot H_\infty \tag{3.16}$$

and also for

$$K_n := e_n + (w + d^-)H_n \tag{3.17}$$

$$\leq e_n + (w + d^-)H_\infty. \tag{3.18}$$

Note that (3.17) follows from (3.16) as $(\gamma - \beta)e^+_{n-1} \leq (1 - \beta^n)d^+ \leq d^+$.

It is well known that under $\beta < 1$ the value functions V_n and V^t_n converge toward the value functions V and V^t of the infinite-stage Markov renewal programs MRP and MRP$'$, resp. (This holds also if T_∞, the limit of the sequence of decision epochs T_n for $n \to \infty$, is finite with positive probability. Therefore we did not include the usual condition which ensures that $T_\infty = \infty$ a.s.)

From (3.10), (3.16), and (3.18) we immediately get the following theorem.

THEOREM 3.7. *Assume* (A1)–(A4), $\gamma \leq 1$, *and* $\beta < 1$. *Then there hold the upper bounds*

$$V^t(s) - V(s) \leq e^{-\delta t}\, b(s)\, K(t),$$

where

$$K := \frac{\max\{w, d\}}{1 - \beta}\Big(1 + (\gamma - \beta)H_\infty\Big) \tag{3.19}$$

or

$$K := \frac{d}{1 - \beta(d)} + \left[w - d + \frac{(\gamma - \beta)d^+}{1 - \beta}\right]^+ H_\infty \tag{3.20}$$

$$\leq \frac{d}{1 - \beta(d)} + (w + d^-)H_\infty. \tag{3.21}$$

Note that d and w depend on V_0, and each V_0 with bounded V_0/b is admissible.

4. Further bounds and the performance of optimal policies for MRP when applied to MRP′. Assume (A1)–(A3). Define $\underline{d}$ and $\underline{w}$ like d and w, resp., with "sup" replaced by "inf." Set

$$\underline{e}_n := \underline{d} \cdot \sigma_n(\underline{\beta}) \text{ if } \underline{d} \geq 0, \text{ and } \underline{e}_n := \underline{d} \cdot \sigma_n(\beta) \text{ otherwise.}$$

We now investigate the performance of an optimal policy $\pi \in \Delta_n$ for MRP, when applied to MRP′. Note that policies for MRP are also policies for MRP′, but not vice versa. We need as preparation a counterpart to Lemma 3.4 which as by-product yields lower bounds for $V_n^t - V_n$.

Lemma 4.1. *Assume* (A1)–(A2).

(a) *Let* $\pi \in \Delta_n$ *be any policy for MRP. Let* $(\underline{K}_n)_0^\infty$ *be any sequence of upper bounded measurable functions on* $\mathbb{R}_+$*, fulfilling* $K_0 \equiv 0$ *and for* $n \in \mathbb{N}_0$*,* $t \geq 0$*, and* $(s,a) \in D$ *the condition*

$$\underline{K}_{n+1}(t) \leq \underline{w} + \underline{e}_n\, e^{\delta t} \mu(s,a,(t,\infty)) + \int_{[0,t]} \mu(s,a,dz) e^{\delta z} \underline{K}_n(t-z). \tag{4.1}$$

Then

$$V_{n\pi}^t(s) - V_{n\pi}(s) \geq e^{-\delta t} b(s) \underline{K}_n(t), \quad t \geq 0. \tag{4.2}$$

(b) *Any sequence* $(\underline{K}_n)_0^\infty$ *which satisfies* (4.1) *and is independent of* π *yields the lower bound*

$$V_n^t(s) - V_n(s) \geq e^{-\delta t} b(s) \underline{K}_n(t), \quad t \geq 0. \tag{4.3}$$

Proof. (a1) For $v \in B$ put $\hat{\underline{d}}_v := \inf_{s \in S}(V_0(s) - v(s))/b(s)$. Let F be the set of decision rules in MRP. Exactly as in the proof of Lemma 3.3 one shows the following: If

$$v'(t,s) - v(s) \geq e^{-\delta t}\, b(s)\, \underline{K}(t),\ t \geq 0,\ s \in S, \tag{4.4}$$

for some upper bounded measurable function $\underline{K}$ on $\mathbb{R}_+$, then for $f \in F$, $t \geq 0$, $s \in S$

$$U_f' v'(t,s) - U_f v(s) := L'v'(t,s,f(s)) - Lv(s,f(s)) \geq e^{-\delta t} b(s) \hat{\underline{K}}_v(t),$$

where

$$\hat{\underline{K}}_v(t) :=\underline{w} + \inf_{(s,a) \in D} \Big[\hat{\underline{d}}_v\, e^{\delta t} \mu(s,a,(t,\infty)) \\ + \int_{[0,t]} \mu(s,a,dz) e^{\delta z} \underline{K}(t-z) \Big].$$

(a2) Assertion (a) for $n = 1$ follows from (a1) with $v'(t,s) := V_0(s)\, 1_{\mathbb{R}_+}(t)$, $v(s) := V_0(s)$. Assume it to hold for some $n \geq 1$. It is well known that for any $(n+1)$-stage policy $\pi := (f_{n+1}, f_n, \ldots, f_1) =: (f, \sigma)$ there holds $V_{n+1,\pi}' = U_{f_{n+1}}' V_{n\sigma}'$ with $V_{n\sigma}'(t,s) := V_{n\sigma}^t(s)$ and $V_{n+1,\pi} = U_{f_{n+1}} V_{n\sigma}$. Now (a) follows for $n+1$ from (a1) with $v' := V_{n\sigma}'$ and $v := V_{n\sigma}$, as

$$\hat{\underline{d}}_v = \inf_s (V_0(s) - V_{n\sigma}(s))/b(s) \geq \inf_s (V_0(s) - V_n(s))/b(s) = \underline{e}_n.$$

(b) The assertion follows from (a) as

$$V_n^t(s) \geq \sup_{\pi \in \Delta_n} V_{n\pi}^t(s) \geq \sup_{\pi \in \Delta_n} V_{n\pi}(s) + e^{-\delta t} b(s) \underline{K}_n(t). \qquad \square$$

We now list a few consequences of Lemma 4.1.

Proposition 4.2. *Assume* (A1)–(A4).

(a) *The inequalities* (4.2) *and* (4.3) *hold for both*

$$\underline{K}_n := \min\{\underline{w}, \underline{d}\} \cdot [1 + \sigma_{n-1}(\beta)(\beta + (\gamma - \beta)\, H_{n-1})] \tag{4.5}$$

and

$$\underline{K}_n := \underline{e}_n - [\underline{w} - \underline{d} - (\gamma - \beta)\underline{e}_{n-1}^{-}]^{-} \cdot H_n. \tag{4.6}$$

(b) *Put*

$$d_0 := \sup_{s \in S} (|V_0(s) - V_1(s)|/b(s)) = \max(d, -\underline{d})$$

and

$$w_0 := \sup\{|\Delta^t(s,a)|/b(s) : (s,a) \in D,\, t \geq 0\} = \max(w, -\underline{w}).$$

There holds

$$|V_n^t(s) - V_n(s)| \leq e^{-\delta t} b(s) K_n(t), \quad t \geq 0, \tag{4.7}$$

for

$$K_n := \max\{w_0, d_0\} \cdot [1 + \sigma_{n-1}(\beta)(\beta + (\gamma - \beta)\, H_{n-1})]\,. \tag{4.8}$$

(c) *If* $\gamma \leq 1$, *then* (4.7) *holds for*

$$K_n := d_0\, \sigma_n(\beta) + (w_0 + d_0) H_n.$$

If in addition $\beta < 1$, *there holds*

$$|V^t(s) - V(s)| \leq e^{-\delta t}\, b(s)\, K(t),$$

both for

$$K := \frac{\max\{w_0, d_0\}}{1 - \beta}(1 + (\gamma - \beta) H_\infty) \tag{4.9}$$

and for

$$K := \frac{d_0}{1 - \beta} + (w_0 + d_0)\, H_\infty. \tag{4.10}$$

Proof. (a) Instead of (4.5) we verify the stronger assertion that (4.1) holds for

$$\begin{aligned}\underline{K}_n &:= -\max\{-\underline{w}, -\underline{d}\} \cdot \left[\sigma_n(\beta) + (\gamma - \beta) \cdot \sum_{i=0}^{n-2} \gamma^i H^{i*} \sigma_{n-i-1}(\beta)\right] \\ &\geq \min\{\underline{w}, \underline{d}\} \cdot \{1 + \sigma_{n-1}(\beta)\,[\beta + (\gamma - \beta) H_{n-1}]\}\,.\end{aligned}$$

In fact, part (a1) of the proof of Theorem 3.5 with w and d replaced by $-\underline{w}$ and by $-\underline{d}$, resp., shows that $(\underline{K}_n)_0^\infty$ satisfies (4.1).

(b) The proof of (4.6) is similar, and the other bounds follow easily. □

Combining (4.2) with $\underline{K}_n$ from (4.5) and (3.5) with K_n from (3.10), we obtain part (a) of our subsequent main result of this section. Part (b) follows by letting n tend to ∞. Several similar bounds may be derived from the preceding results.

THEOREM 4.3. *Assume* (A1)–(A4). *Put* $\Theta := \max(w, d) - \min(\underline{w}, \underline{d})$.

(a) *If* $\pi \in \Delta_n$ *is optimal for MRP, then*

$$V^t_{n\pi}(s) \geq V^t_n(s) - e^{-\delta t} b(s) K_n(t), \tag{4.11}$$

where

$$K_n := \Theta \cdot [1 + \sigma_{n-1}(\beta)(\beta + (\gamma - \beta) H_{n-1})] . \tag{4.12}$$

(b) *If* $\beta < 1, \gamma \leq 1$ *and if* $(f, f, \ldots)$ *is a stationary optimal policy for the infinite-stage MRP, then*

$$V^t_f(s) \geq V^t(s) - e^{-\delta t} b(s) K(t), \tag{4.13}$$

where

$$K := \Theta \cdot [1 + (\gamma - \beta) H_\infty] / (1 - \beta). \tag{4.14}$$

5. Bounds for the discounted renewal function H_∞.

Throughout this section we assume $\gamma < 1$. In what follows we are interested in deriving easy-to-calculate bounds for $H_\infty = \sum_{i=0}^\infty \gamma^i H^{i*}$. First, $H_n \leq \sigma_n(\gamma H)$ implies $H_\infty \leq 1/(1 - \gamma H)$. Our further bounds for H_∞ are obtained by means of bounds for

$$W(t) := (1-\gamma) H_\infty(t) = 1 - \gamma + \gamma H * W(t), \quad t \in \mathbb{R}_+,$$

(and $W(t) := 0$ for $t < 0$). W can be thought of as the distribution function of a random sum $Z = Y_1 + \cdots + Y_\tau$ of independently and identically distributed (i.i.d.) nonnegative random variables $Y_1, Y_2, \ldots$ with distribution function H such that $\tau + 1 \sim$ Geo$(1-\gamma)$. In general, W has to be determined numerically, as explicit representations of W are only known for some special cases. Denote by *Geo*(p), $0 < p \leq 1$, the p.d. with discrete density $p(1-p)^{k-1}$, $k \in \mathbb{N}$. Using, e.g., Laplace transforms one obtains

(a) If $Y_1 \sim$ Bi$(1, p)$, $0 \leq p \leq 1$, then $Z + 1 \sim$ Geo(p'), where $p' := (1-\gamma)/(1 - \gamma(1-p))$. Hence

$$W(k) = 1 - (1 - p')^{k+1}, \quad k \in \mathbb{N}_0. \tag{5.1}$$

(b) If $Y_1 + 1 \sim$ Geo(p), then $Z \sim (1-\gamma)\delta_0 + \gamma\,Geo(p')$, where $1 - p' = (1-p)/(1-\gamma p)$, i.e.,

$$W(k) = 1 - \gamma(1 - p')^{k+1}, \quad k \in \mathbb{N}_0.$$

(c) If $Y_1 \sim$ Exp(λ), then $Z \sim (1-\gamma)\delta_0 + \gamma\,Exp((1-\gamma)\lambda)$, i.e.,

$$W(t) = 1 - \gamma e^{-(1-\gamma)\lambda t}, \quad t \geq 0. \tag{5.2}$$

Our numerical approach for calculating W is based on the following:

(A5) The p.d. corresponding to H is concentrated on $\{0, 1, \ldots, m\}$ for some $m \in \mathbb{N}$, and the discrete density g of H satisfies $g(m) > 0$.

Then the relation $W = 1 - \gamma + \gamma H * W$ yields the following recursive method for computing W, starting with $W(0) = (1-\gamma)\,/\,(1 - \gamma g(0))$:

$$W(k) = \frac{1}{1 - \gamma g(0)} \cdot \left\{ 1 - \gamma + \gamma \cdot \sum_{i=1}^{k \wedge m} g(i)\, W(k-i) \right\}, \quad k \in \mathbb{N}, \tag{5.3}$$

(It is obvious how (5.3) must be modified for the more general case where the probability distribution corresponding to H is concentrated on $\{0, \varepsilon, \ldots, m\varepsilon\}$ for some $m \in \mathbb{N}$ and some $\varepsilon > 0$.)

Having computed $W(k)$ by means of (5.3) up to some $k_0 \geq m$, we can find bounds for $W(k), k > k_0$, by extrapolation. As the method may be of independent interest, we state it for more general difference equations than (5.3), as follows.

PROPOSITION 5.1. *Let $(b_k)_0^\infty$ be the solution of the homogeneous linear difference equation of order $m \in \mathbb{N}$*

$$b_k = \sum_{i=1}^{m} d_i \, b_{k-i}, \quad k \geq m,$$

with nonnegative coefficients $d_i, 1 \leq i \leq m$, with $d_m > 0$ and positive initial values $b_j, 0 \leq j \leq m-1$. Put

$$c_k := \min_{1 \leq i \leq m} \frac{b_{k-i+1}}{b_{k-i}}, \quad k \geq m.$$

Then $(c_k)_m^\infty$ is increasing, and for $k \geq m$ and $j \in \mathbb{N}$ we have

$$b_{k+j} \geq c_{k+1}^{j-1} \cdot b_{k+1} \geq c_k^j \cdot b_k.$$

Analogously, for the decreasing sequence of numbers

$$\underline{c}_k := \max_{1 \leq i \leq m} \frac{b_{k-i+1}}{b_{k-i}}, \quad k \geq m,$$

we obtain

$$b_{k+j} \leq \underline{c}_{k+1}^{j-1} \cdot b_{k+1} \leq \underline{c}_k^j \cdot b_k.$$

Proof. First, $d_m > 0$ and $b_j > 0$ for $0 \leq j \leq m-1$ implies $b_i > 0$ for $i \geq m$ and hence $c_k > 0$ for $k \geq m$. Fix $k \geq m$. The definition of c_k implies $b_{k-i+1} \geq c_k b_{k-i}$ for $1 \leq i \leq m$. Therefore

$$b_{k+1} \geq c_k \sum_{i=1}^{m} d_i b_{k-i} = c_k b_k, \quad k \geq m. \tag{5.4}$$

Thus $\frac{b_{k+1}}{b_k} \geq c_k$, which implies

$$c_{k+1} = \min \left\{ \frac{b_{k+1}}{b_k}, \ldots, \frac{b_{k-m+2}}{b_{k-m+1}} \right\} \geq \min \left\{ \frac{b_{k+1}}{b_k}, c_k \right\} \geq c_k. \tag{5.5}$$

Finally the first assertion follows from (5.4) and (5.5) by induction on j, while the second one can be obtained analogously. □

For $k \geq m$ the recursion (5.3) may be written in terms of $\overline{W} = 1 - W$, yielding

$$\overline{W}(k) = \frac{\gamma}{1 - \gamma g(0)} \sum_{i=1}^{m} g(i) \overline{W}(k-i), \quad k \geq m. \tag{5.6}$$

Equation (5.3) implies $W(k) \leq W(0) + \overline{W}(0) \, W(k-1)$, from which we infer both

$$\overline{W}(k)/\overline{W}(k-1) \geq \overline{W}(0) = \gamma(1 - g(0))/(1 - \gamma g(0)) > 0$$

and $\overline{W}(k) \geq \overline{W}(0)^k > 0$, $k \in \mathbb{N}$.

Applying Proposition 5.1 to the difference equation (5.3) yields the announced upper bounds for W, as follows.

THEOREM 5.2. *Assume* (A5). *For all* $k \geq m, j \in \mathbb{N}$

$$W(k+j) \leq 1 - c_{k+1}^{j-1} \cdot \overline{W}(k+1) \leq 1 - c_k^j \cdot \overline{W}(k), \tag{5.7}$$

where

$$c_k := \min_{1 \leq i \leq m} \frac{\overline{W}(k-i+1)}{\overline{W}(k-i)} \in [\overline{W}(0), 1]$$

is increasing in k.

Note that in the special case $m = 1$, which corresponds to $Y_1 \sim \mathrm{Bi}(1, 1-g(0))$, the bounds for W coincide with the exact values given in (5.1). Concerning the asymptotic behavior of the numbers c_k, the following can be said. Assume that the different roots of the characteristic equation of the difference equation (5.6), i.e., of the equation

$$B(\lambda) := (1 - \gamma g(0))\lambda^m - \gamma g(1)\lambda^{m-1} - \cdots - \gamma g(m) = 0, \tag{5.8}$$

have distinct moduli. By Descartes's rule of signs, (5.8) has a unique positive root λ^*, and $\lambda^* < 1$, as $B(0) = -\gamma g(m) < 0 < B(1) = 1 - \gamma$. Now a well-known result (cf., e.g., Elaydi [3, p. 310]) implies that $\lim_{k\to\infty} \overline{W}(k+1)/\overline{W}(k) = \lambda^*$, and hence $\lim_{k\to\infty} c_k = \lambda^*$. Similar monotone lower bounds for W can be obtained, using the numbers $\underline{c}_k$, defined like c_k with "min" replaced by "max." Also the asymptotic behavior of $\underline{c}_k$ is the same.

We finally remark that our monotone upper (and lower) bounds for W are of independent interest, e.g., they may be exploited for evaluating the equilibrium waiting time distribution for an M/G/1 queue. Further, there is an application in the collective risk theory, where one refers to W as the distribution function of the total claim amounts. These fields of active research have led to various (nonadaptive) exponential bounds on the tails of W. We only refer to Lin [8] and the references given there.

A second type of upper bounds for W is due to Kalashnikov [7], who utilizes Jensen's inequality to prove

$$W(t) \leq 1 - \gamma^{R(t)}, \quad t \geq 0, \tag{5.9}$$

where $R(t) := \sum_{i=0}^{\infty} H^{i*}$ denotes the standard renewal function. Some elementary upper bounds for $R(t)$ (e.g., the well-known ones of an affine type $\nu_1 t + \nu_2$ proved by Lorden [9] and Brown [1]) may be used to obtain from (5.9) simple upper bounds for W, too.

6. Examples. As a test for the quality of our bounds we first derive from our bounds the classical ones for the standard Markovian decision model. Then we look at three special examples: a stopping problem, a renewal problem, and an allocation problem. In all examples $\tilde{r}$ and $\tilde{r}'$ have the special form (2.1) and (2.3) with $\tilde{r}_3 \equiv 0$, resp. The computation of w is facilitated by the formula

$$\begin{aligned} r^t(s,a) - r(s,a) = \int \kappa(s,a,d(z,u))\, 1_{(t,\infty)}(z) \Bigg[& e^{-\alpha t} R(t,s,a,z,u) \\ & - \int_t^z e^{-\alpha y} \tilde{r}_2(s,a,y) dy \Bigg]. \end{aligned} \tag{6.1}$$

Example 6.1 (the standard Markovian decision model). *Consider the familiar infinite-stage Markovian decision model with transition law $P(s,a,du)$, bounded one-stage rewards $r(s,a)$, and discount factor $\beta < 1$. Being interested in the approximation of the infinite-stage model by a finite-stage one without terminal reward (or the other way around), the results of sections* 3–5 *can be applied to the MRP and MRP′ with $\kappa(s,a,d(z,u)) = \delta_1(dz) \times P(s,a,du)$, $\tilde{r}_1 = r$, $\tilde{r}_2 = R \equiv 0$. Then V^t and V are the value function of the t-stage ($t \in \mathbb{N}$) and the infinite-stage model, resp.*

(A1) and (A2) hold for $0 \leq \delta \leq \alpha$ with $b \equiv 1$, and (A3) is assumed to be true. (A4) holds with $H = 1_{[1,\infty]}$, hence $H_\infty(t) = \sigma_{t+1}(\gamma)$. For $\delta \in [0,\alpha]$ we have $r^t - r \equiv 0$, hence $w = 0$; $\beta = \underline{\beta} = e^{-\alpha} < 1$; $\gamma = e^{-(\alpha-\delta)} \leq 1$. From (3.21) we obtain in case $d \geq 0$

$$V^t(s) - V(s) \leq d\frac{(\beta/\gamma)^t}{1-\beta}, \tag{6.2}$$

and in case $d < 0$

$$V^t(s) - V(s) \leq d\,(\beta/\gamma)^t \left(\frac{1}{1-\beta} - \sigma_{t+1}(\gamma)\right). \tag{6.3}$$

The bounds in (6.2) and (6.3) are minimal for $\delta = \alpha$ (hence $\gamma = 1$) and $\delta = 0$, resp. Then (6.2) becomes a classical bound while (6.3) yields the slightly weaker bound $V^t(s) - V(s) \leq d\beta^{t+1}/(1-\beta)$. Similar arguments also work for lower bounds for $V^t - V$.

Example 6.2 (an optimal stopping problem). *Consider a homogenous Markov chain in continuous time with finite state space $S' \subset \mathbb{R}$. Interpret the states of the Markov chain as offers, which, at the time points the jumps occur, can be accepted (action $a = 1$) or not (action $a = 0$). If an offer is accepted, there is a utility $g(s)$ with $\min_s g(s) = 0$ and the process stops. As long as the process is not stopped there is a cost $c > 0$ per unit time. If the process is not stopped during the time interval $[0,t_0]$ under consideration, there is an additional terminal reward $R_0 \in \mathbb{R}$. Future payoffs are discounted with rate $\alpha > 0$.*

Denote by $\lambda > 0$ the parameter of the exponentially distributed sojourn time. We say that the process goes to ∞ when the stop action is chosen. Then the above is a two action MRP with $S = S' \cup \{\infty\}$, $\kappa(s,a,[0,z] \times \{u\}) = (1-e^{-\lambda z})\,P_{s,u}(a)$, where $P_{s,\infty}(a) = a$ for $s < \infty$ and $P_{\infty,\infty}(a) = 1$. For $s < \infty$ we have $\tilde{r}_1(s,a) = a\,g(s)$; $\tilde{r}_2(s,a,y) = -(1-a)c$; $R(t,s,a,z,u) = (1-a)R_0$, while for $s = \infty$ these quantities vanish.

(A1) and (A2) hold for $b \equiv 1$ if $\delta < \lambda$, (A3) holds as A is finite, and (A4) holds with $H \sim \mathrm{Exp}(\alpha + \lambda - \delta)$. Now we get—using $V_0 :\equiv 0$, $d = 0$, $\beta = \lambda/(\alpha+\lambda) < 1$—$\gamma = \lambda/(\alpha + \lambda - \delta) \leq 1$ and

$$w = \left[R_0 + \frac{c}{\lambda+\alpha}\right]^+.$$

From (3.21) we obtain for $\delta < \alpha$, hence $\gamma < 1$, using (5.2)

$$V^t(s) - V(s) \leq e^{-\delta t} w \frac{1 - \gamma e^{-(\alpha+\lambda-\delta)(1-\gamma)t}}{1-\gamma},$$

and for $\delta = \alpha$

$$V^t(s) - V(s) \leq e^{-\alpha t} w(\lambda t + 1).$$

Example 6.3 (an optimal renewal problem). *Consider a system (or unit) which is subject to failure. Upon failure the system is renewed instantaneously at a cost* $c(a) \geq 0$, *depending on the type* a *of renewal. Associated with a renewal of type* a *(action* $a \in \{1, \dots, m\}$ *with* $m \in \mathbb{N}$*) is an exponentially distributed lifetime with parameter* $\lambda_a > 0$ *fulfilling* $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_m > 0$. *Further we assume* $0 \leq c(1) \leq c(2) \leq \cdots \leq c(m)$.

We want to find the successive renewals for which the expected total cost guaranteeing a total lifetime of at least t_0 time units becomes minimal.

Note that S consists of one element only. Letting $\tilde{r}_1(s,a) = -c(a)$ and $\tilde{r}_2 = R \equiv 0$, we see, that (A1) and (A2) hold for $b \equiv 1$ if $\delta < \lambda_m$. (A3) holds as A is finite and (A4) holds with $H \sim \operatorname{Exp}(\alpha + \lambda - \delta)$. Now we get from (3.21), using $\beta = \lambda_1/(\lambda_1 + \alpha)$ and $V_0 :\equiv 0$, $w = 0$ and $d = c(1) \geq 0$ for all $\delta \leq \alpha, \delta < \lambda_m$,

$$V^t(s) - V(s) \leq e^{-\delta t} c(1) \left(\lambda_1 + \alpha\right) / \alpha.$$

Example 6.4 (optimal N-stage allocation with decision times according to a Poisson process). *Initially a capital of amount* $\overline{s} > 0$ *is available. The times between successive investment decisions are i.i.d. random variables distributed as* $\operatorname{Exp}(\lambda)$. *Let* s *be the momentarily available capital. Then each investment of amount* $a \in [0, s]$ *has utility* $\sqrt{a}$. *The terminal utilities are* $R(t,s,a,z,u) = \sqrt{s-a}$ *and* $V_0(s) = \sqrt{s}$*, resp. The discount rate is* $\alpha > 0$. *It follows that* $\kappa(s,a,d(z,u)) = \operatorname{Exp}(\lambda) \times \delta_{s-a}$, $\tilde{r}_1(s,a) = \sqrt{a}$*, and* $\tilde{r}_2 \equiv 0$. *From* (2.4) *we get*

$$\tilde{h}(t,s,a,z,u) = \sqrt{a} + \sqrt{s-a}\, e^{-\alpha t} \leq 2\sqrt{s} =: h(s,a,z,u).$$

We assume $0 \leq \delta \leq \alpha$ and $\delta < \lambda$. Then (A1) and (A2) hold with $b(s) = \varepsilon + \sqrt{s}$ for any $\varepsilon > 0$, while (A3) can be verified sequentially using Lemma 4.2 in Hinderer and Stieglitz [5]. Furthermore, $\beta = \lambda/(\alpha + \lambda)$. Using

$$\sup_{0 \leq a \leq s} \left(\sqrt{a} + c\sqrt{s-a}\right) = \sqrt{1+c^2}\,\sqrt{s},\ c \geq 0,$$

we get from (2.6) by induction the well-known result that

$$V_n(s) = \sqrt{\sigma_{n+1}(\beta^2)}\,\sqrt{s},$$

and in the same way from (2.7)

$$V_n^t(s) = d_n(t)\sqrt{s} \text{ for } t \geq 0,$$

where $d_0(\cdot) :\equiv 1$, and

$$d_{n+1}^2(t) = 1 + \left[e^{-(\alpha+\lambda)t} + \frac{\lambda}{\alpha+\lambda} \cdot \operatorname{Exp}(\alpha+\lambda) * d_n(t)\right]^2, \quad n \geq 0.$$

With $\eta := \lambda + \alpha - \delta$ we have $\gamma = \lambda/\eta \leq 1$, $d = 0$, $w \leq \alpha/(\alpha+\lambda)$. By applying (3.17) with $H(t) = 1 - e^{-\eta t}$ and letting ϵ tend to zero, we obtain the following upper bound for the complicated function $d_n(\cdot)$:

$$d_n(t) \leq \sqrt{\sigma_{n+1}(\beta^2)} + \alpha\, e^{-\delta t} \sigma_n(\gamma\, H(t))/(\alpha+\lambda). \tag{6.4}$$

If $\delta < \alpha$ it follows, using (5.2), that $\sigma_n(\gamma\, H(t))$ in (6.4) can be replaced by

$$H_\infty(t) = \left(\eta - \lambda e^{-(\alpha-\delta)t}\right) / \left(\alpha - \delta\right).$$

Note added in proof. Recursion formula (5.6) has already been used by F. Dufresne and H. Gerber, *Three methods to calculate the probability of ruin*, Astin Bulletin, 19 (1989), pp. 71–90.

BOUNDARY OBSERVABILITY, CONTROLLABILITY, AND STABILIZATION OF LINEAR ELASTODYNAMIC SYSTEMS*

FATIHA ALABAU† AND VILMOS KOMORNIK‡

Abstract. In 1988 Lions obtained observability and exact controllability results for linear homogeneous isotropic elastodynamic systems [*SIAM Rev.*, 30 (1988), pp. 1–68]. Applying some new identities we extend his theorems to nonisotropic systems. In 1991 Lagnese obtained uniform stabilizability results for two-dimensional linear homogeneous isotropic systems by applying a somewhat artificial feedback [*Nonlinear Anal.*, 16 (1991), pp. 35–54]. Then he asked whether analogous results hold for a natural and physically implementable boundary feedback. Using some new identities and applying a method introduced in 1987 by Zuazua and the second author [*J. Math. Pures. Appl.*, 69 (1990), pp. 33–54], we give an affirmative answer to this question in all dimensions and also for nonisotropic systems. Moreover, we obtain good decay estimates. Finally, applying a recent general method of uniform stabilization, we construct boundary feedbacks leading to arbitrarily large energy decay rates.

Key words. observability, controllability, stabilizability by feedback, partial differential equation, elasticity

1. Introduction and formulation of the main results.

Let n be a positive integer, and let (a_{ijkl}) be a tensor such that

$$a_{ijkl} = a_{jikl} = a_{klij}$$

(all indices run over the integers $1, \dots, n$), satisfying for some $\alpha > 0$ the ellipticity condition

$$a_{ijkl}\varepsilon_{ij}\varepsilon_{kl} \geq \alpha\varepsilon_{ij}\varepsilon_{ij} \tag{1.1}$$

for every *symmetric* tensor ε_{ij}. (Here and in what follows we shall use the summation convention for repeated indices.)

Let Ω be a nonempty bounded open set in $\mathbb{R}^n$ having a boundary Γ of class C^2. Given a function $\xi = (\xi_1, \dots, \xi_n) : \Omega \to \mathbb{R}^n$, we shall use the notations

$$\varepsilon_{ij} = \tfrac{1}{2}(\xi_{i,j} + \xi_{j,i}), \qquad \sigma_{ij} = a_{ijkl}\varepsilon_{kl},$$

where $\xi_{i,j} = \partial\xi_i/\partial x_j$ and $\xi_{j,i} = \partial\xi_j/\partial x_i$. If it is necessary to be more precise, we shall write $\varepsilon_{ij}(\xi)$ and $\sigma_{ij}(\xi)$ instead of ε_{ij}, σ_{ij}.

‡Institut de Recherche Mathématique Avancée, Université Louis Pasteur et CNRS, 7, rue René Descartes, 67084 Strasbourg Cédex, France (komornik@math.u-strasbg.fr).

Consider the problem

$$\begin{cases} \xi_i'' - \sigma_{ij,j} = 0 \quad \text{in} \quad \Omega \times \mathbb{R}, \\ \xi_i = 0 \quad \text{on} \quad \Gamma \times \mathbb{R}, \\ \xi_i(0) = \xi_i^0 \quad \text{and} \quad \xi_i'(0) = \xi_i^1 \quad \text{in} \quad \Omega, \\ i = 1, \dots, n, \end{cases} \tag{1.2}$$

where $\xi_i' = \partial \xi_i / \partial t$ and $\xi_i'' = \partial^2 \xi_i / \partial t^2$. For $n = 1, 2, 3$ this is the linear model of homogeneous elastodynamic systems.

We recall (see, e.g., [7]) that this problem is well-posed in the following sense:

- Given $(\xi_0, \xi_1) \in H_0^1(\Omega)^n \times L^2(\Omega)^n$ arbitrarily, the problem (1.2) has a unique (so-called *weak*) solution

$$\xi \in C(\mathbb{R}; H_0^1(\Omega)^n) \cap C^1(\mathbb{R}; L^2(\Omega)^n).$$

- If $(\xi_0, \xi_1) \in (H^2(\Omega) \cap H_0^1(\Omega))^n \times H_0^1(\Omega)^n$, then the solution is more regular:

$$\xi \in C(\mathbb{R}; (H^2(\Omega) \cap H_0^1(\Omega))^n) \cap C^1(\mathbb{R}; H_0^1(\Omega)^n) \cap C^2(\mathbb{R}; L^2(\Omega)^n);$$

it is called a *strong* solution.

- The energy of the (weak) solutions, defined by the formula

$$E = \tfrac{1}{2} \textstyle\int_\Omega \xi_i' \xi_i' + \sigma_{ij} \varepsilon_{ij} \; dx, \tag{1.3}$$

is independent of the time $t \in \mathbb{R}$.

In order to simplify we shall only consider in this paper time-independent homogeneous systems: the coefficients a_{ijkl} do not depend on $x \in \Omega$ or on $t \in \mathbb{R}$.

Fix a point $x_0 \in \mathbb{R}^n$ arbitrarily and fix a measurable partition Γ_0, Γ_1 of Γ such that

$$(x - x_0) \cdot \nu(x) \leq 0 \quad \text{for all} \quad x \in \Gamma_0, \tag{1.4}$$

where $\nu = (\nu_1, \dots, \nu_n)$ denotes the outward unit normal vector to Γ. In other words, Γ_1 contains all points $x \in \Gamma$ for which $(x - x_0) \cdot \nu(x) > 0$. (The simplest way to satisfy (1.4) is to choose $\Gamma_0 = \emptyset$ and $\Gamma_1 = \Gamma$.) Set

$$R = \sup\{|x - x_0| \ : \ x \in \Omega\}. \tag{1.5}$$

Then we have the following theorem.

THEOREM 1.1. *Assume* (1.1), (1.4), *and let* $T > 2\sqrt{2/\alpha}R$. *Then there exist two positive constants* c_1 *and* c_2 *such that every strong solution of* (1.2) *satisfies the inequalities*

$$c_1 E \leq \int_0^T \int_{\Gamma_1} \sigma_{ij} \varepsilon_{ij} \; d\Gamma \; dt \leq c_2 E. \tag{1.6}$$

Remarks.

- In the isotropic case Theorem 1.1 reduces to a former result of Lions [21].

- Theorem 1.1 means that in some sense the observation of the solution in a neighborhood of the boundary during a sufficiently large time allows one to determine the initial data. Indeed, if two solutions coincide in this set, then the boundary integral in (1.6) for their difference vanishes, and therefore the energy of their difference is equal to zero by the first inequality in (1.6). This implies that the two solutions correspond in fact to the same initial data, and hence they are identical.
- By a simple density argument, the second estimate in (1.6) allows us to *define* the trace of $\sigma_{ij}\varepsilon_{ij}$ on $\Gamma_1 \times \mathbb{R}$ as an element of $L^2_{loc}(\mathbb{R}; L^2(\Gamma_1))$ for every *weak solution* of (1.2). Then the estimates (1.6) remain valid for all weak solutions, too.
- Due to the finite propagation property of the system of elasticity, the first inequality in (1.6) cannot hold for arbitrarily small T. The proof of Theorem 2 in [13] shows that the condition $T > 2\sqrt{2/\alpha}R$ is the best possible if the system is isotropic, i.e., when

$$a_{ijkl} = \lambda\delta_{ij}\delta_{kl} + \mu(\delta_{ik}\delta_{jl} + \delta_{il}\delta_{jk}),$$

where λ and μ are the (positive) Lamé constants.

Applying the Hilbert uniqueness method (HUM) we shall deduce from Theorem 1.1 an exact controllability result for the nonhomogeneous problem

$$\begin{cases} y_i'' - \sigma_{ij,j}(y) = 0 \quad \text{in} \quad \Omega \times \mathbb{R}, \\ y_i = v_i \quad \text{on} \quad \Gamma \times \mathbb{R}, \\ y_i(0) = y_i^0 \quad \text{and} \quad y_i'(0) = y_i^1 \quad \text{in} \quad \Omega, \\ i = 1, \dots, n. \end{cases} \tag{1.7}$$

Theorem 1.2. *Assume* (1.1), (1.4) *and fix* $T > 2\sqrt{2/\alpha}R$ *arbitrarily. Then for any given* $y^0, \tilde{y}^0 \in L^2(\Omega)^n$ *and* $y^1, \tilde{y}^1 \in H^{-1}(\Omega)^n$ *there exists* $v \in L^2_{loc}(\mathbb{R}; L^2(\Gamma)^n)$ *such that the solution of* (1.7) *satisfies*

$$y(T) = \tilde{y}^0 \quad \textit{and} \quad y'(T) = \tilde{y}^1 \quad \textit{in} \quad \Omega.$$

Moreover, we may assume that v *vanishes outside of* $\Gamma_1 \times (0, T)$.

This extends an earlier theorem of Lions [21] to nonisotropic systems.

In the second half of the paper we shall study the uniform stabilizability of elasticity systems by applying suitable dissipative boundary feedbacks. A natural and physically implementable system of this type was proposed by Lagnese [17], [18]:

$$\begin{cases} \xi_i'' - \sigma_{ij,j} = 0 \quad \text{in} \quad \Omega \times (0, \infty), \\ \xi_i = 0 \quad \text{on} \quad \Gamma_0 \times (0, \infty), \\ \sigma_{ij}\nu_j + A\xi_i + B\xi_i' = 0 \quad \text{on} \quad \Gamma_1 \times (0, \infty), \\ \xi_i(0) = \xi_i^0 \quad \text{and} \quad \xi_i'(0) = \xi_i^1 \quad \text{in} \quad \Omega, \\ i = 1, \dots, n. \end{cases} \tag{1.8}$$

Here A, B are given nonnegative numbers for simplicity. It is easy to generalize our results to the case where A and B are nonnegative functions of class C^1 on Γ_1. Indeed, defining the energy of the solutions of (1.8) by

$$E = \frac{1}{2}\int_\Omega \xi_i'\xi_i' + \sigma_{ij}\varepsilon_{ij}\ dx + \frac{1}{2}\int_{\Gamma_1} A\xi_i\xi_i\ d\Gamma, \tag{1.9}$$

an easy computation shows that the energy is a nonincreasing function of $t \in [0, +\infty)$.

We shall consider this problem under a rather strict geometric assumption on Ω and Γ_0, Γ_1: we assume that

$$\Omega = \Omega_1 \backslash \overline{\Omega_0}, \tag{1.10}$$

where Ω_1 is an open ball, say $\Omega_1 = B(x_0; R)$, Ω_0 is a star-shaped domain with respect to x_0 whose closure belongs to Ω_1, and

$$\Gamma_0 = \partial\Omega_0, \quad \Gamma_1 = \partial\Omega_1.$$

We do not exclude the case $\Omega_0 = \emptyset$; then $\Omega = B(x_0; R)$, $\Gamma_0 = \emptyset$, and $\Gamma_1 = \Gamma$. Another typical case is

$$\Omega = \{x \in \mathbb{R}^n \ : \ r < |x - x_0| < R\}$$

for some $0 < r < R$, and

$$\Gamma_0 = \{x \in \mathbb{R}^n \ : \ |x - x_0| = r\},$$
$$\Gamma_1 = \{x \in \mathbb{R}^n \ : \ |x - x_0| = R\}.$$

We shall prove the following theorem.

Theorem 1.3. *Assume* (1.1)*, and let* Ω*,* Γ_0*, and* Γ_1 *be as described above. Given two positive constants* A *and* B *with* $A < \alpha/(4R)$*, there exists a positive number* ω *such that all (weak) solutions of* (1.8) *satisfy the energy estimate*

$$E(t) \le E(0)e^{1-\omega t} \tag{1.11}$$

for all $t \ge 0$.

If $\Gamma_0 \ne \emptyset$*, then the result holds also for* $A = 0$.

Remarks.

- This result seems to be new even in the isotropic case.
- Our proof will be based on a Liapunov-type method introduced in [15] and then modified in [10]. We shall also need a crucial new identity (see (4.4)) which will allow us to estimate some boundary integrals.
- The interest of this result can be questioned because of the very restrictive geometric assumptions. We recall, however, that the validity of this result was not at all obvious, and some researchers even conjectured that this result does not hold for any domain. See also a remark in [18, p. 37] in this respect.
- In fact, our proof given below can be easily adapted for slightly more general domains such that Ω_1 is *close* to a ball. We shall outline the suitable modifications of the proof at the end of section 4 for a special case (see Theorem 4.4), and we refer to [22] for more general results. It is plausible that the theorem remains valid if we allow Ω_1 to be a general star-shaped domain with respect to x_0. However, our "elementary" method may not be sufficiently powerful for this. A similar problem for the wave equation was solved earlier by Lasiecka and Triggiani [19] by using microlocal estimates: they relaxed a geometric condition of an earlier result of Lagnese [16]. Adapting their approach, recently Horn [8] obtained very interesting stabilization results for the system of elasticity: she established similar results to our Theorem 1.3, without geometric conditions on Ω, in the particular case of *isotropic* elasticity systems. Unlike our result, due to an indirect compactness-uniqueness argument, she did not obtain explicit constants in the estimates.

- Theorem 1.3 probably remains valid without the condition $A < \alpha/(4R)$, but we could not prove it.

The proof of Theorem 1.3 will provide an explicit constant ω. If ω is bigger, then the energy decay is faster. However, some results of Koch and Tataru [9] indicate that we cannot achieve arbitrarily large decay rates ω by using feedbacks of the type as in (1.8). On the other hand, in [14] a general method was developed for this purpose. This method, similar in its spirit to HUM, allows us to construct boundary feedbacks for observable systems which lead to arbitrarily large decay rates. Applying this approach we shall deduce from Theorem 1.1 the following theorem.

THEOREM 1.4. *Assume* (1.1), (1.4), *and assume that* Γ_0 *is closed. Fix* $\omega > 0$ *arbitrarily. Then there exist two bounded linear maps*

$$P : H^{-1}(\Omega)^n \to H_0^1(\Omega)^n \quad \textit{and} \quad Q : L^2(\Omega)^n \to H_0^1(\Omega)^n$$

and a constant $M > 0$ *such that the problem*

$$\begin{cases} \xi_i'' - \sigma_{ij,j} = 0 \quad \textit{in} \quad \Omega \times \mathbb{R}, \\ \xi_i = 0 \quad \textit{on} \quad \Gamma_0 \times \mathbb{R}, \\ \xi_i = \sigma_{ij}(P\xi' + Q\xi)\nu_j \quad \textit{on} \quad \Gamma_1 \times \mathbb{R}, \\ \xi_i(0) = \xi_i^0 \quad \textit{and} \quad \xi_i'(0) = \xi_i^1 \quad \textit{in} \quad \Omega, \\ i = 1, \dots, n \end{cases} \tag{1.12}$$

is well-posed in $\mathcal{H} = L^2(\Omega)^n \times H^{-1}(\Omega)^n$ *and its solutions satisfy the estimate*

$$\|(\xi, \xi')(t)\|_{\mathcal{H}} \le M \|(\xi, \xi')(0)\|_{\mathcal{H}} e^{-\omega t} \tag{1.13}$$

for all $t \ge 0$.

Remarks.

- Note that (unlike in the preceding theorem) we do not have any geometric assumption on Ω. Thus Theorem 1.4 applies to all bounded domains of class C^2, choosing, for example, $\Gamma_0 = \emptyset$ and $\Gamma_1 = \Gamma$.
- Although the feedback has a more complicated structure than in Theorem 1.3, it can be constructed explicitly. Let us note that Bourquin and Briffaut [3] tested numerically the method of [14]; this required the use of the explicit form of the operators P and Q.
- Our proof allows us to estimate the constant M in (1.13).

Some results of this paper were announced without proof in [1].

2. Observability: Proof of Theorem 1.1. We proceed in three steps.

Step 1. Fix an arbitrary function $h \in W^{1,\infty}(\Omega)^n$ and a number $T > 0$. Integrating by parts it follows from the equation in (1.2) that

$$\begin{aligned} 0 = \int_0^T \int_\Omega (h_m \xi_{i,m})(\xi_i'' - \sigma_{ij,j}) \, dx \, dt \\ = \left[\int_\Omega h_m \xi_{i,m} \xi_i' \, dx \right]_0^T - \int_0^T \int_\Gamma h_m \xi_{i,m} \sigma_{ij} \nu_j \, d\Gamma \, dt \\ + \int_0^T \int_\Omega h_{m,j} \sigma_{ij} \xi_{i,m} + h_m \sigma_{ij} \xi_{i,jm} - \frac{1}{2} h_m (\xi_i' \xi_i')_{,m} \, dx \, dt. \end{aligned}$$

Since

$$\sigma_{ij}\xi_{i,jm} = \sigma_{ij}\varepsilon_{ij,m} = \frac{1}{2}(\sigma_{ij}\varepsilon_{ij})_{,m},$$

integrating by parts the last two terms in the last integral and then multiplying by two the whole expression we obtain the following identity:

$$\begin{aligned}\text{(2.1)}\quad \int_0^T \int_\Gamma 2h_m\xi_{i,m}\sigma_{ij}\nu_j + (h\cdot\nu)(\xi_i'\xi_i' - \sigma_{ij}\varepsilon_{ij})\ d\Gamma\ dt &\\ = \left[\int_\Omega 2h_m\xi_{i,m}\xi_i'\ dx\right]_0^T &\\ + \int_0^T \int_\Omega 2h_{m,j}\sigma_{ij}\xi_{i,m} + (\operatorname{div}\ h)(\xi_i'\xi_i' - \sigma_{ij}\varepsilon_{ij})\ dx\ dt.&\end{aligned}$$

Note that in the proof of identity (2.1) we did not use the boundary conditions in (1.2).

Step 2. Using the Korn inequality and the assumption $h \in W^{1,\infty}(\Omega)^n$, the right-hand side of (2.1) can be easily majorized by a constant multiple cE of the energy E. (Let us recall that in this case the Korn equality is easy to establish; see the identity (2.4) below.)

Furthermore, we deduce from the homogeneous Dirichlet boundary conditions (1.2) that $\xi_i' = 0$ and

$$\xi_{i,m}\nu_j = \xi_{i,\nu}\nu_m\nu_j = \xi_{i,j}\nu_m$$

on Γ, and hence

$$h_m\xi_{i,m}\sigma_{ij}\nu_j = (h\cdot\nu)\sigma_{ij}\xi_{i,j} = (h\cdot\nu)\sigma_{ij}\varepsilon_{ij}.$$

Therefore the left-hand side of (2.1) reduces to

$$\int_0^T \int_\Gamma (h\cdot\nu)\sigma_{ij}\varepsilon_{ij}\ d\Gamma\ dt.$$

Choosing h such that $h = \nu$ on Γ, the second inequality in (1.6) follows with $c_2 = c$.

Step 3. Choosing now $h(x) = x - x_0$, the identity (2.1) reduces to

$$\begin{aligned}\int_0^T \int_\Gamma (h\cdot\nu)\sigma_{ij}\varepsilon_{ij}\ d\Gamma\ dt &\\ = \left[\int_\Omega 2h_m\xi_{i,m}\xi_i'\ dx\right]_0^T + \int_0^T \int_\Omega (2-n)\sigma_{ij}\varepsilon_{ij} + n\xi_i'\xi_i'\ dx\ dt.&\end{aligned}$$

Furthermore, we also deduce from (1.2) that

$$\begin{aligned}0 &= \int_0^T \int_\Omega \xi_i(\xi_i'' - \sigma_{ij,j})\ dx\ dt\\ &= \left[\int_\Omega \xi_i\xi_i'\ dx\right]_0^T - \int_0^T \int_\Gamma \xi_i\sigma_{ij}\nu_j\ d\Gamma\ dt + \int_0^T \int_\Omega \sigma_{ij}\varepsilon_{ij} - \xi_i'\xi_i'\ dx\ dt\\ &= \left[\int_\Omega \xi_i\xi_i'\ dx\right]_0^T + \int_0^T \int_\Omega \sigma_{ij}\varepsilon_{ij} - \xi_i'\xi_i'\ dx\ dt.\end{aligned}$$

Combining with the preceding identity we obtain that

$$\int_0^T \int_\Gamma (h\cdot\nu)\sigma_{ij}\varepsilon_{ij}\ d\Gamma\ dt = \left[\int_\Omega (2h_m\xi_{i,m} + (n-1)\xi_i)\xi_i'\ dx\right]_0^T + \int_0^T \int_\Omega \sigma_{ij}\varepsilon_{ij} + \xi_i'\xi_i'\ dx\ dt$$

whence

$$R\int_0^T \int_{\Gamma_1} \sigma_{ij}\varepsilon_{ij}\ d\Gamma\ dt \geq 2TE - \left|\left[\int_\Omega (2h_m\xi_{i,m} + (n-1)\xi_i)\xi_i'\ dx\right]_0^T\right|. \tag{2.2}$$

Let us majorize the last integral. Thanks to the boundary condition in (1.2) we have

$$\|2h_m\xi_{i,m} + (n-1)\xi_i\|_{L^2(\Omega)} \leq \|2h_m\xi_{i,m}\|_{L^2(\Omega)}$$

for each fixed i. Indeed, as it was shown in [10], we have

$$\begin{aligned}\|2h_m\xi_{i,m} + (n-1)\xi_i\|^2_{L^2(\Omega)} - \|2h_m\xi_{i,m}\|^2_{L^2(\Omega)} &= \int_\Omega (n-1)^2\xi_i^2 + 4(n-1)h_m\xi_i\xi_{i,m}\ dx \\ &= \int_\Omega (n-1)^2\xi_i^2 - 2n(n-1)\xi_i^2\ dx + \int_\Gamma (2n-2)h_m\nu_m\xi_i^2\ d\Gamma \\ &= (1-n^2)\int_\Omega \xi_i^2\ dx \leq 0.\end{aligned}$$

Therefore for any fixed $\delta > 0$ we have

$$\begin{aligned}\left|\int_\Omega (2h_m\xi_{i,m} + (n-1)\xi_i)\xi_i'\ dx\right| &\leq 2R\sum_{i=1}^n \left(\int_\Omega |\nabla\xi_i|^2\ dx\right)^{1/2} \left(\int_\Omega (\xi_i')^2\ dx\right)^{1/2} \\ &\leq R\delta\int_\Omega \xi_{i,m}\xi_{i,m}\ dx + R\delta^{-1}\int_\Omega \xi_i'\xi_i'\ dx.\end{aligned} \tag{2.3}$$

Furthermore, applying the Green formula and using the boundary condition in (1.2), we have

$$\int_\Omega \xi_{i,m}\xi_{i,m}\ dx = \int_\Omega 2\varepsilon_{im}\xi_{i,m}\ dx - \int_\Omega \xi_{m,i}\xi_{i,m}\ dx = \int_\Omega 2\varepsilon_{im}\varepsilon_{im} - \xi_{m,m}\xi_{i,i}\ dx,$$

i.e.,

$$\int_\Omega 2\varepsilon_{im}\varepsilon_{im}\ dx = \int_\Omega \xi_{i,m}\xi_{i,m}\ dx + \int_\Omega |\mathrm{div}\ \xi|^2\ dx. \tag{2.4}$$

It follows from (1.1) and (2.4) that

$$\int_\Omega \xi_{i,m}\xi_{i,m}\ dx \leq (2/\alpha)\int_\Omega \sigma_{im}\varepsilon_{im}\ dx.$$

Substituting into (2.3), choosing $\delta = \sqrt{\alpha/2}$, and using the definition (1.3) of the energy we obtain that

$$\left|\int_\Omega (2h_m \xi_{i,m} + (n-1)\xi_i)\xi_i' \, dx\right| \le 2\sqrt{2/\alpha} RE.$$

Therefore we deduce from (2.2) the inequality

$$R\int_0^T \int_{\Gamma_1} \sigma_{ij}\varepsilon_{ij} \, d\Gamma \, dt \ge (2T - 4\sqrt{2/\alpha_1}R)E,$$

and the first estimate of (1.6) follows with $c_1 = (2T - 4\sqrt{2/\alpha}R)/R$. The proof of Theorem 1.1 is completed.

In the next section we shall also need the following result, which gives an equivalent form of the integral in (1.6).

Lemma 2.1. *Assume* (1.1) *and put*

$$\beta = \sum_{i,j,k,l} |a_{ijkl}|^2.$$

Then every strong solution of (1.2) *satisfies on* $\Gamma \times \mathbb{R}$ *the inequalities*

$$(\alpha/2)\sigma_{ij}\varepsilon_{ij} \le \sum_{i=1}^n |\sigma_{ij}\nu_j|^2 \le (\beta/\alpha)\sigma_{ij}\varepsilon_{ij}. \tag{2.5}$$

Proof. The proof of the second inequality does not use the boundary conditions

$$\sum_i |\sigma_{ij}\nu_j|^2 \le \sum_{i,j} |\sigma_{ij}|^2 = \sum_{i,j} |a_{ijkl}\varepsilon_{kl}|^2$$
$$\le \sum_{i,j}\left(\sum_{k,l}|a_{ijkl}|^2 \sum_{k,l}|\varepsilon_{kl}|^2\right) = \beta\varepsilon_{kl}\varepsilon_{kl} \le (\beta/\alpha)\sigma_{ij}\varepsilon_{ij}.$$

For the proof of the reverse inequality first we note that, thanks to the boundary conditions in (1.2), we have

$$\xi_{i,j}\xi_{i,j} = \frac{1}{2}\sum_{i,j}(\xi_{i,j} + \xi_{j,i})^2 - \xi_{i,j}\xi_{j,i} = 2\varepsilon_{ij}\varepsilon_{ij} - \xi_{i,\nu}\nu_j\xi_{j,\nu}\nu_i = 2\varepsilon_{ij}\varepsilon_{ij} - |\text{div}\ \xi|^2,$$

i.e.,

$$2\varepsilon_{ij}\varepsilon_{ij} = \xi_{i,j}\xi_{i,j} + |\text{div}\ \xi|^2 \qquad \text{on} \qquad \Gamma. \tag{2.6}$$

(Compare with (2.4).) Therefore

$$\sigma_{ij}\varepsilon_{ij} = \sigma_{ij}\xi_{i,j} = \sigma_{ij}\nu_j\xi_{i,\nu} \le \left(\sum_i |\sigma_{ij}\nu_j|^2\right)^{1/2} (\xi_{i,\nu}\xi_{i,\nu})^{1/2}$$
$$\le \left(\sum_i |\sigma_{ij}\nu_j|^2\right)^{1/2} (2\varepsilon_{ij}\varepsilon_{ij})^{1/2} \le \left(\sum_i |\sigma_{ij}\nu_j|^2\right)^{1/2} (2\alpha^{-1}\sigma_{ij}\varepsilon_{ij})^{1/2},$$

and the first inequality in (2.5) follows. □

3. Controllability: Proof of Theorem 1.2. Let us first study the well-posedness of the nonhomogeneous problem (1.7). In order to find a reasonable *definition* of the solution, let us multiply the equation in (1.7) by an arbitrary solution of the problem (1.2) and integrate by parts formally. We obtain that

$$\begin{aligned}\int_0^T \int_\Omega \xi_i(y_i'' - \sigma_{ij,j}(y))\ dx\ dt \\ = \int_0^T \int_\Omega (\xi_i'' - \sigma_{ij,j}(\xi))y_i\ dx\ dt + \left[\int_\Omega \xi_i y_i' - \xi_i' y_i\ dx\right]_0^T \\ + \int_0^T \int_\Gamma -\xi_i\sigma_{ij}(y)\nu_j + \sigma_{ij}(\xi)\nu_j y_i\ d\Gamma\ dt \\ = \left[\int_\Omega \xi_i y_i' - \xi_i' y_i\ dx\right]_0^T + \int_0^T \int_\Gamma \sigma_{ij}(\xi)\nu_j v_i\ d\Gamma\ dt.\end{aligned}$$

Hence, putting

$$H = H^{-1}(\Omega)^n \times L^2(\Omega)^n, \quad \text{and} \quad H' = H_0^1(\Omega)^n \times L^2(\Omega)^n$$

for brevity, we have

$$\begin{aligned}(3.1) \quad \langle (y'(T), -y(T)), (\xi(T), \xi'(T)\rangle_{H,H'} \\ = \langle (y_i^1, -y_i^0), (\xi_i^0, \xi_i^1)\rangle_{H,H'} - \int_0^T \int_\Gamma \sigma_{ij}(\xi)\nu_j v_i\ d\Gamma\ dt.\end{aligned}$$

This leads to the following definition.

Definition. *A solution of* (1.7) *is a* continuous *function* $(y', -y) : \mathbb{R} \to H$ *satisfying the identity* (3.1) *for all* $T \in \mathbb{R}$ *and for all (weak) solutions of the problem* (1.2).

This definition is justified by the following theorem.

Theorem 3.1. *Assume* (1.1). *Then for any given*

$$y^0 \in L^2(\Omega)^n, \quad y^1 \in H^{-1}(\Omega)^n, \quad \textit{and} \quad v \in L^2_{loc}(\mathbb{R}; L^2(\Gamma)^n)$$

the problem (1.7) *has a unique solution satisfying*

$$y \in C(\mathbb{R}; L^2(\Omega)^n) \cap C^1(\mathbb{R}; H^{-1}(\Omega)^n).$$

Furthermore, the linear map $(y^0, y^1, v) \mapsto y$ *is continuous with respect to these topologies.*

Proof. We apply Theorem 1.1. Thanks to the second estimate in (1.6), the right-hand side of the equality (3.1) defines a bounded linear form of $(\xi^0, \xi^1) \in H'$. Since the linear map $(\xi^0, \xi^1) \mapsto (\xi(T), \xi'(T))$ is an automorphism of H' (because the problem (1.2) is reversible), the right-hand side of the equality (3.1) can also be considered as a bounded linear form of $(\xi(T), \xi'(T)) \in H'$. Since $H'' = H$, we conclude the existence of a unique $(y'(T), -y(T)) \in H$ satisfying (3.1).

Since the bounded linear form used in this proof depends continuously on $t \in \mathbb{R}$, the solution y has the regularity required in the theorem. Finally, the bounded linear form clearly depends continuously on the initial data and on the boundary value, hence y also has this property. □

Turning to the proof of Theorem 1.2, let us first note that it is sufficient to consider the case where $\tilde{y}^0 = \tilde{y}^1 = 0$ in Ω. The general case then follows by a standard argument, valid for every linear reversible problem; see, e.g., [12], [14].

The main idea is to seek a control in the form $v_i = \sigma_{ij}(\xi)\nu_j$, where ξ is the solution of (1.2) for some suitable initial data. (Thanks to Theorem 1.1 and to Lemma 2.1, these controls have the required regularity for the well-posedness of (1.7).)

Given $(\xi^0, \xi^1) \in H'$ arbitrarily, first solve the problem (1.2), then solve the problem

$$\begin{cases} y_i'' - \sigma_{ij,j}(y) = 0 \quad \text{in} \quad \Omega \times \mathbb{R}, \quad 1 \le i \le n, \\ y_i = 0 \quad \text{on} \quad \Gamma_0 \times \mathbb{R}, \quad 1 \le i \le n, \\ y_i = \sigma_{ij}(\xi)\nu_j \quad \text{on} \quad \Gamma_1 \times \mathbb{R}, \quad 1 \le i \le n, \\ y_i(T) = y_i'(T) = 0 \quad \text{in} \quad \Omega, \quad 1 \le i \le n, \end{cases} \tag{3.2}$$

and set

$$\Lambda(\xi^0, \xi^1) = (y'(0), -y(0)).$$

(The problem (3.2) is well-posed in an analogous sense as (1.7) because the different choice of the initial time does not change the character of a time-reversible problem.) Obviously, $\Lambda : H' \to H$ is a bounded linear map. Applying HUM, it is sufficient to show that Λ is onto. Indeed, then for any given $(y^0, y^1) \in L^2(\Omega)^n \times H^{-1}(\Omega)^n$ it will suffice to choose the control v defined by $v_i = 0$ on $\Gamma_0 \times (0, \infty)$ and $v_i = \sigma_{ij}(\xi)\nu_j$ on $\Gamma_1 \times (0, \infty)$, where ξ is the solution of (1.2) corresponding to $(\xi^0, \xi^1) = \Lambda^{-1}(y^1, -y^0)$.

We shall prove that Λ is in fact an isomorphism. For this first we prove the identity

$$\langle \Lambda(\xi^0, \xi^1), (\xi^0, \xi^1) \rangle_{H,H'} = \int_0^T \int_{\Gamma_1} \sum_i |\sigma_{ij}(\xi)\nu_j|^2 \, d\Gamma \, dt. \tag{3.3}$$

This follows from the equality

$$\begin{aligned} &\int_0^T \int_\Omega \xi_i (y_i'' - \sigma_{ij,j}(y)) \, dx \, dt \\ &\qquad = \left[\int_\Omega \xi_i y_i' - \xi_i' y_i \, dx \right]_0^T + \int_0^T \int_\Omega (\xi_i'' - \sigma_{ij,j}(\xi)) y_i \, dx \, dt \\ &\qquad\qquad + \int_0^T \int_\Gamma -\xi_i \sigma_{ij}(y)\nu_j + \sigma_{ij}(\xi)\nu_j y_i \, d\Gamma \, dt, \end{aligned}$$

using the definition of Λ and the equations of (1.2) and (3.2).

Applying the first estimate of (1.6) in Theorem 1.1 and Lemma 2.1, we conclude from the identity (3.3) that Λ is coercive. Applying the Lax–Milgram theorem we conclude that Λ is an isomorphism.

4. Stabilizability: Proof of Theorem 1.3. We assume throughout this section that Ω, Γ_0, and Γ_1 satisfy the conditions of Theorem 1.3. The well-posedness of the problem (1.8) can be established by standard methods as, e.g., in [17], [18]; we omit the details. Setting

$$V = \{ v \in H_0^1(\Omega) \ : \ v = 0 \ \text{ on } \ \Gamma_0 \}$$

we have the following proposition.

PROPOSITION 4.1. *Assume* (1.1). *Then for every given* $\xi^0 \in V^n$ *and* $\xi^1 \in L^2(\Omega)^n$ *the problem* (1.8) *has a unique (weak) solution satisfying*

$$\xi \in C([0,+\infty); V^n) \cap C^1([0,+\infty); L^2(\Omega)^n).$$

Now assume also that $\xi^0 \in (H^2(\Omega) \cap V)^n$, $\xi^1 \in V^n$ *and* $\sigma_{ij}(\xi^0)\nu_j + A\xi_i^0 + B\xi_i^1 = 0$ *on* Γ_1, $i = 1, \ldots, n$. *Then the corresponding (strong) solution is more regular:*

$$\xi \in C([0,+\infty); (H^2(\Omega) \cap V)^n) \cap C^1([0,+\infty); V^n) \cap C^2([0,+\infty); L^2(\Omega)^n).$$

Let us turn to the proof of Theorem 1.3. All computations which follow will be justified for strong solutions. Since the constant ω in (1.11) will not depend on the choice of the initial data, once the estimates (1.11) will be established for regular solutions, they will also be satisfied for all weak solutions by an easy density argument. So in the rest of this section we shall only consider strong solutions.

Furthermore, we shall assume that $n \geq 2$. The case $n = 1$ is similar and even simpler, but we have to choose some constants differently. In any case, for $n = 1$, our problem reduces to the usual wave equation which has been studied extensively before; see, e.g., [15], [23], [11].

First we show the dissipativity of the problem (1.8).

LEMMA 4.2. *The energy of the strong solutions of* (1.8) *is a nonincreasing function of the time* $t \geq 0$. *More precisely, we have*

$$E(S) - E(T) = \int_S^T \int_{\Gamma_1} B\xi_i'\xi_i' \, d\Gamma \, dt, \quad 0 \leq S < T < +\infty. \tag{4.1}$$

Proof. We have

$$\begin{aligned} E' &= \int_\Omega \xi_i'\xi_i'' + \sigma_{ij}\varepsilon_{ij}' \, dx + \int_{\Gamma_1} A\xi_i\xi_i' \, d\Gamma \\ &= \int_\Omega \xi_i'\sigma_{ij,j} + \sigma_{ij}\xi_{i,j}' \, dx + \int_{\Gamma_1} A\xi_i\xi_i' \, d\Gamma \\ &= \int_\Gamma \xi_i'\sigma_{ij}\nu_j \, d\Gamma + \int_{\Gamma_1} A\xi_i\xi_i' \, d\Gamma = -\int_{\Gamma_1} B\xi_i'\xi_i' \, d\Gamma \leq 0; \end{aligned}$$

integrating between S and T the lemma follows. □

Now we are going to establish a basic identity for the solutions of (1.8). Given $0 \leq S < T < +\infty$ arbitrarily, we have

$$\begin{aligned} 0 &= \int_S^T \int_\Omega \xi_i(\xi_i'' - \sigma_{ij,j}) \, dx \, dt \\ &= \left[\int_\Omega \xi_i\xi_i' \, dx\right]_S^T - \int_S^T \int_\Gamma \xi_i\sigma_{ij}\nu_j \, d\Gamma \, dt + \int_S^T \int_\Omega \sigma_{ij}\varepsilon_{ij} - \xi_i'\xi_i' \, dx \, dt \end{aligned}$$

whence

$$\int_S^T \int_\Gamma \xi_i\sigma_{ij}\nu_j \, d\Gamma \, dt = \left[\int_\Omega \xi_i\xi_i' \, dx\right]_S^T + \int_S^T \int_\Omega \sigma_{ij}\varepsilon_{ij} - \xi_i'\xi_i' \, dx \, dt. \tag{4.2}$$

Note that the identity (2.1) of section 2 remains valid if we replace the lower integral limit 0 by S; just take the difference of this identity taken for T and for S instead of T. Apply this identity with $h(x) \equiv x - x_0$ and combine it with (4.2). Writing

$$M\xi_i = 2h_m\xi_{i,m} + (n-1)\xi_i$$

for brevity, we have

$$\int_S^T \int_\Gamma (M\xi_i)\sigma_{ij}\nu_j + (h\cdot\nu)(\xi_i'\xi_i' - \sigma_{ij}\varepsilon_{ij})\ d\Gamma\ dt \\ = \left[\int_\Omega (M\xi_i)\xi_i'\ dx\right]_S^T + \int_S^T \int_\Omega \sigma_{ij}\varepsilon_{ij} + \xi_i'\xi_i'\ dx\ dt.$$

Taking into account the definition (1.9) of the energy, we can rewrite it in the following form:

$$2\int_S^T E\ dt + \left[\int_\Omega (M\xi_i)\xi_i'\ dx\right]_S^T \\ = \int_S^T \int_\Gamma (M\xi_i)\sigma_{ij}\nu_j + (h\cdot\nu)(\xi_i'\xi_i' - \sigma_{ij}\varepsilon_{ij})\ d\Gamma\ dt \\ + \int_S^T \int_{\Gamma_1} A\xi_i\xi_i\ d\Gamma\ dt.$$

Now using the boundary conditions in (1.8) we obtain that

$$(4.3)\quad 2\int_S^T E\ dt + \left[\int_\Omega (M\xi_i)\xi_i'\ dx\right]_S^T \\ = \int_S^T \int_{\Gamma_0} (h\cdot\nu)\sigma_{ij}\varepsilon_{ij}\ d\Gamma\ dt \\ + \int_S^T \int_{\Gamma_1} A\xi_i\xi_i - (M\xi_i)(A\xi_i + B\xi_i') + (h\cdot\nu)(\xi_i'\xi_i' - \sigma_{ij}\varepsilon_{ij})\ d\Gamma\ dt.$$

(The term on Γ_0 is obtained in the same way as in Step 2 of the proof of Theorem 1.1.)

Next we transform the integral over Γ_1. Applying the Green formula twice and using the boundary condition on Γ_0 we have

$$\int_\Omega \xi_{m,i}\xi_{i,m}\ dx = \int_\Gamma \xi_{m,i}\xi_i\nu_m\ d\Gamma - \int_\Omega \xi_{m,im}\xi_i\ dx \\ = \int_\Gamma \xi_{m,i}\xi_i\nu_m - \xi_{m,m}\nu_i\xi_i\ d\Gamma + \int_\Omega \xi_{m,m}\xi_{i,i}\ dx \\ = \int_{\Gamma_1} 2\varepsilon_{mi}\xi_i\nu_m - \xi_{i,m}\xi_i\nu_m - \varepsilon_{mm}\nu_i\xi_i\ d\Gamma + \int_\Omega \varepsilon_{mm}\varepsilon_{ii}\ dx.$$

On the other hand,

$$\int_\Omega \xi_{m,i}\xi_{i,m}\ dx = \int_\Omega 2\varepsilon_{mi}\xi_{i,m} - \xi_{i,m}\xi_{i,m}\ dx = \int_\Omega 2\varepsilon_{mi}\varepsilon_{mi} - \xi_{i,m}\xi_{i,m}\ dx,$$

and therefore

$$\int_\Omega 2\varepsilon_{mi}\varepsilon_{mi} - \xi_{i,m}\xi_{i,m} - \varepsilon_{mm}\varepsilon_{ii}\ dx = \int_{\Gamma_1} 2\varepsilon_{mi}\xi_i\nu_m - \xi_{i,m}\xi_i\nu_m - \varepsilon_{mm}\nu_i\xi_i\ d\Gamma. \tag{4.4}$$

This is a crucial new identity. Since $h = R\nu$ on Γ_1, we deduce the following equality:

$$\begin{aligned}\int_S^T\int_{\Gamma_1} -2Ah_m\xi_{i,m}\xi_i\ d\Gamma\ dt &= \int_S^T\int_\Omega 4AR\varepsilon_{mi}\varepsilon_{mi} - 2AR\xi_{i,m}\xi_{i,m} - 2AR|\text{div }\xi|^2\ dx\ dt\\ &\quad + \int_S^T\int_{\Gamma_1} 2AR(\text{div }\xi)(\nu\cdot\xi) - 4AR\varepsilon_{mi}\xi_i\nu_m\ d\Gamma\ dt.\end{aligned} \tag{4.5}$$

Next we obtain by a similar computation that

$$\begin{aligned}\int_S^T\int_\Omega \xi_{m,i}\xi'_{i,m}\ dx\ dt &= \int_S^T\int_\Gamma \xi_{m,i}\xi'_i\nu_m\ d\Gamma\ dt - \int_S^T\int_\Omega \xi_{m,im}\xi'_i\ dx\ dt\\ &= \int_S^T\int_\Gamma \xi_{m,i}\xi'_i\nu_m - \xi_{m,m}\nu_i\xi'_i\ d\Gamma\ dt + \int_S^T\int_\Omega \xi_{m,m}\xi'_{i,i}\ dx\ dt\\ &= \int_S^T\int_{\Gamma_1} 2\varepsilon_{mi}\xi'_i\nu_m - \xi_{i,m}\xi'_i\nu_m - \varepsilon_{mm}\nu_i\xi'_i\ d\Gamma\ dt + \left[\frac{1}{2}\int_\Omega |\text{div }\xi|^2\ dx\right]_S^T.\end{aligned}$$

Furthermore,

$$\begin{aligned}\int_S^T\int_\Omega \xi_{m,i}\xi'_{i,m}\ dx\ dt = \int_S^T\int_\Omega 2\varepsilon_{mi}\varepsilon'_{mi} - \xi_{i,m}\xi'_{i,m}\ dx\ dt\\ = \left[\int_\Omega \varepsilon_{mi}\varepsilon_{mi} - \frac{1}{2}\xi_{i,m}\xi_{i,m}\ dx\right]_S^T.\end{aligned}$$

Using again the relation $h = R\nu$ on Γ_1, it follows that

$$\begin{aligned}\int_S^T\int_{\Gamma_1} -2Bh_m\xi_{i,m}\xi'_i\ d\Gamma\ dt &= \int_S^T\int_\Omega 2BR\xi_{m,i}\xi'_{i,m}\ dx\ dt - \left[\int_\Omega BR|\text{div }\xi|^2\ dx\right]_S^T\\ &\quad + \int_S^T\int_{\Gamma_1} 2BR\varepsilon_{mm}\nu_i\xi'_i - 4BR\varepsilon_{mi}\xi'_i\nu_m\ d\Gamma\ dt\\ &= \left[\int_\Omega 2BR\varepsilon_{mi}\varepsilon_{mi} - BR\xi_{i,m}\xi_{i,m} - BR|\text{div }\xi|^2\ dx\right]_S^T\\ &\quad + \int_S^T\int_{\Gamma_1} 2BR(\text{div }\xi)(\nu\cdot\xi') - 4BR\varepsilon_{mi}\xi'_i\nu_m\ d\Gamma\ dt.\end{aligned}$$

Substituting the equalities (4.5) and (4.6) into the identity (4.3) and using the equality $h \cdot \nu = R$ on Γ_1 we obtain that

$$
\begin{aligned}
(4.6)\quad & 2\int_S^T E\,dt \\
&= \left[\int_\Omega -(M\xi_i)\xi_i' + 2BR\varepsilon_{mi}\varepsilon_{mi} - BR\xi_{i,m}\xi_{i,m} - BR|\mathrm{div}\ \xi|^2\,dx\right]_S^T \\
&\quad + \int_S^T\int_\Omega 4AR\varepsilon_{mi}\varepsilon_{mi} - 2AR\xi_{i,m}\xi_{i,m} - 2AR|\mathrm{div}\ \xi|^2\,dx\,dt \\
&\quad + \int_S^T\int_{\Gamma_0}(h\cdot\nu)\sigma_{ij}\varepsilon_{ij}\,d\Gamma\,dt \\
&\quad + \int_S^T\int_{\Gamma_1} A\xi_i\xi_i - (n-1)\xi_i(A\xi_i + B\xi_i') + R(\xi_i'\xi_i' - \sigma_{ij}\varepsilon_{ij}) + 2AR(\mathrm{div}\ \xi)(\nu\cdot\xi) \\
&\qquad - 4AR\varepsilon_{mi}\xi_i\nu_m + 2BR(\mathrm{div}\ \xi)(\nu\cdot\xi') - 4BR\varepsilon_{mi}\xi_i'\nu_m\,d\Gamma\,dt.
\end{aligned}
$$

Let us rewrite it in the following form:

$$
\begin{aligned}
(4.7)\quad & 2\int_S^T E\,dt \\
&= \left[\int_\Omega -(M\xi_i)\xi_i' + 2BR\varepsilon_{mi}\varepsilon_{mi} - BR\xi_{i,m}\xi_{i,m} - BR|\mathrm{div}\ \xi|^2\,dx\right]_S^T \\
&\quad + \left[\frac{1}{2}\int_{\Gamma_1}(1-n)B\xi_i\xi_i\,d\Gamma\right]_S^T \\
&\quad + \int_S^T\int_\Omega 4AR\varepsilon_{mi}\varepsilon_{mi} - 2AR\xi_{i,m}\xi_{i,m} - 2AR|\mathrm{div}\ \xi|^2\,dx\,dt \\
&\quad + \int_S^T\int_{\Gamma_0}(h\cdot\nu)\sigma_{ij}\varepsilon_{ij}\,d\Gamma\,dt \\
&\quad + \int_S^T\int_{\Gamma_1}(2-n)A\xi_i\xi_i + R(\xi_i'\xi_i' - \sigma_{ij}\varepsilon_{ij}) + 2AR(\mathrm{div}\ \xi)(\nu\cdot\xi) \\
&\qquad - 4AR\varepsilon_{mi}\xi_i\nu_m + 2BR(\mathrm{div}\ \xi)(\nu\cdot\xi') - 4BR\varepsilon_{mi}\xi_i'\nu_m\,d\Gamma\,dt.
\end{aligned}
$$

This is our main identity.

Let us majorize the right-hand side of this identity. First of all, using the definition of the energy and the Korn inequality,

$$\left|\int_\Omega -(M\xi_i)\xi_i' + 2BR\varepsilon_{mi}\varepsilon_{mi} - BR\xi_{i,m}\xi_{i,m} - BR|\mathrm{div}\ \xi|^2\,dx\right| \le c_1E$$

with some constant c_1, depending on A, B but independent of S, T and of the particular choice of the initial data in (1.8). We have similarly

$$\left|\frac{1}{2}\int_{\Gamma_1}(1-n)B\xi_i\xi_i\,d\Gamma\right| \le c_2E.$$

For the estimate of the third term on the right-hand side note that

$$\int_\Omega 4AR\varepsilon_{mi}\varepsilon_{mi} - 2AR\xi_{i,m}\xi_{i,m} - 2AR|\text{div }\xi|^2\ dx \le 8AR\alpha^{-1}E$$

with α defined by the ellipticity condition (1.1):

$$\sigma_{ij}\varepsilon_{ij} \ge \alpha\varepsilon_{ij}\varepsilon_{ij}.$$

Since $h\cdot\nu = -r \le 0$ on Γ_0, the integral on Γ_0 is ≤ 0. In the integral over Γ_1 we have $(2-n)A\xi_i\xi_i \le 0$ because $n \ge 2$, and we have

$$-R\sigma_{ij}\varepsilon_{ij} \le -R\alpha\varepsilon_{ij}\varepsilon_{ij}$$

by using (1.1) again. Finally, applying Lemma 4.2 we deduce from the identity (4.7) the following inequality:

$$\begin{aligned}(4.8)\quad 2\int_S^T E\ dt \le c_3E(S) + 8AR\alpha^{-1}\int_S^T E\ dt\\ + \int_S^T\int_{\Gamma_1} R\xi_i'\xi_i' - R\alpha\varepsilon_{ij}\varepsilon_{ij} + 2AR(\text{div }\xi)(\nu\cdot\xi)\\ - 4AR\varepsilon_{mi}\xi_i\nu_m + 2BR(\text{div }\xi)(\nu\cdot\xi') - 4BR\varepsilon_{mi}\xi_i'\nu_m\ d\Gamma\ dt.\end{aligned}$$

Here $c_3 = 2c_1 + 2c_2$ is a constant depending on A and B but not on the choice of the initial data.

From now on we shall distinguish three cases. Consider first the case $A = 0$; then $\Gamma_0 \ne \emptyset$ by assumption. For any fixed $\delta > 0$ we have

$$2BR(\text{div }\xi)(\nu\cdot\xi') \le \delta|\text{div }\xi|^2 + B^2R^2\delta^{-1}|\xi'|^2,$$

$$-4BR\varepsilon_{mi}\xi_i'\nu_m \le \delta\varepsilon_{mi}\varepsilon_{mi} + 4B^2R^2\delta^{-1}|\xi'|^2.$$

Using these inequalities and the obvious inequality $|\text{div }\xi|^2 \le \varepsilon_{mi}\varepsilon_{mi}$, we deduce from (4.8) that

$$2\int_S^T E\ dt \le c_3E(S) + \int_S^T\int_{\Gamma_1}(R + 5B^2R^2\delta^{-1})|\xi'|^2 + (2\delta - R\alpha)\varepsilon_{ij}\varepsilon_{ij}\ d\Gamma\ dt.$$

Choosing $\delta = R\alpha/2$ and using (4.1), it follows that

$$2\int_S^T E\ dt \le c_4E(S)$$

with

$$c_4 = c_3 + RB^{-1} + 10BR\alpha^{-1}.$$

Hence there exists a constant $\omega > 0$, independent of the choice of the initial data, such that

$$(4.9)\qquad \omega\int_S^T E\ dt \le E(S)$$

for all $0 \leq S < T < +\infty$. Since the function $E(t)$ is nonnegative and nonincreasing and applying a well-known Gronwall-type inequality (see, e.g., [12, Theorem 8.1]), hence we conclude that the inequality (1.11) is satisfied.

Now let us consider the case where $0 < A < \alpha/(24R)$. Applying the Young inequality, for any fixed $\delta > 0$ we have

$$2AR(\text{div }\xi)(\nu \cdot \xi) \leq A\delta|\xi|^2 + AR^2\delta^{-1}|\text{div }\xi|^2,$$

$$2BR(\text{div }\xi)(\nu \cdot \xi') \leq B^2A^{-1}\delta|\xi'|^2 + AR^2\delta^{-1}|\text{div }\xi|^2,$$

$$-4AR\varepsilon_{mi}\xi_i\nu_m \leq A\delta|\xi|^2 + 4AR^2\delta^{-1}\varepsilon_{mi}\varepsilon_{mi},$$

$$-4BR\varepsilon_{mi}\xi_i'\nu_m \leq B^2A^{-1}\delta|\xi'|^2 + 4AR^2\delta^{-1}\varepsilon_{mi}\varepsilon_{mi}.$$

Substituting them into (4.8) and using the inequality $|\text{div }\xi|^2 \leq \varepsilon_{mi}\varepsilon_{mi}$ again, we obtain that

$$\begin{aligned}2\int_S^T E\ dt &\leq c_3E(S) + 8AR\alpha_1^{-1}\int_S^T E\ dt \\ &+ \int_S^T\int_{\Gamma_1}(R + 2B^2A^{-1}\delta)|\xi'|^2 + 2A\delta|\xi|^2 + (10AR^2\delta^{-1} - R\alpha_1)\varepsilon_{ij}\varepsilon_{ij}\ d\Gamma\ dt.\end{aligned}$$

Using (4.1) we have

$$\begin{aligned}&\int_S^T\int_{\Gamma_1}(R + 2B^2A^{-1}\delta)|\xi'|^2\ d\Gamma\ dt \\ &\qquad = (RB^{-1} + 2BA^{-1}\delta)(E(S) - E(T)) \leq (RB^{-1} + 2BA^{-1}\delta)E(S).\end{aligned}$$

Substituting into the preceding inequality and choosing $\delta = 10AR/\alpha$, we conclude that

$$2\int_S^T E\ dt \leq c_4E(S) + 8AR\alpha^{-1}\int_S^T E\ dt + \int_S^T\int_{\Gamma_1}20A^2R\alpha^{-1}|\xi|^2\ d\Gamma\ dt \tag{4.10}$$

with

$$c_4 = c_3 + RB^{-1} + 20BR\alpha^{-1}.$$

Now observe that

$$\int_S^T\int_{\Gamma_1}20A^2R\alpha^{-1}|\xi|^2\ d\Gamma\ dt \leq 40AR\alpha^{-1}\int_S^T E\ dt$$

by the definition of the energy; therefore we conclude from (4.10) the estimate (4.9) with

$$\omega = (2 - 48AR\alpha^{-1})/c_4.$$

If $0 < A < \alpha/(24R)$, then $\omega > 0$ and the estimate (1.11) follows as in the first case.

Now let us turn to the case $\alpha/(24R) \leq A < \alpha/(4R)$. In this case we have to estimate the last integral of (4.10) in a different way. Applying a method of [5] we shall prove the following lemma.

LEMMA 4.3. *There exists a constant* $c_5 > 0$ *such that*

$$\int_S^T \int_{\Gamma_1} |\xi|^2 \, d\Gamma \, dt \leq c_5 \varepsilon^{-1} E(S) + \varepsilon \int_S^T E \, dt$$

for all $0 < \varepsilon < 1$ *and for all* $0 \leq S < T < +\infty$.

Assuming this lemma for the moment, we deduce from (4.10) the inequality

$$(2 - 8AR\alpha^{-1} - \varepsilon) \int_S^T E \, dt \leq (c_4 + 20A^2 R\alpha^{-1} c_5 \varepsilon^{-1}) E(S).$$

Choosing $\varepsilon < 2 - 8AR\alpha^{-1}$, the integral inequality (4.9) follows again and the proof can be completed as before.

It remains to prove the lemma. For every $t \geq 0$ let us denote by $\eta(t)$ the solution of the problem

$$\begin{cases} -\sigma_{ij,j} = 0 & \text{in} \quad \Omega, \\ \eta = \xi & \text{on} \quad \Gamma. \end{cases}$$

Then we have

$$\|\eta\|_{L^2(\Omega)^n} \leq c\|\xi\|_{L^2(\Gamma)^n} \leq c\sqrt{E} \tag{4.11}$$

by the elliptic regularity theory. (See, e.g., [4] or [6] for the proof of the ellipticity of the above system.) Applying this result with ξ' instead of ξ we also obtain that

$$\|\eta'\|_{L^2(\Omega)^n} \leq c\|\xi'\|_{L^2(\Gamma)^n} \leq c\sqrt{|E'|}. \tag{4.12}$$

Let us also observe that

$$\begin{aligned} &\int_\Omega \sigma_{ij}(\eta)\varepsilon_{ij}(\xi - \eta) \, dx \\ &\qquad = -\int_\Omega \sigma_{ij,j}(\eta)(\xi_i - \eta_i) \, dx + \int_\Gamma \sigma_{ij}(\eta)\nu_j(\xi_i - \eta_i) \, d\Gamma = 0; \end{aligned} \tag{4.13}$$

hence

$$\int_\Omega \sigma_{ij}(\eta)\varepsilon_{ij}(\xi) \, dx = \int_\Omega \sigma_{ij}(\eta)\varepsilon_{ij}(\eta) \, dx \geq 0. \tag{4.14}$$

Now consider the following equality:

$$\begin{aligned} 0 &= \int_S^T \int_\Omega \eta_i(\xi_i'' - \sigma_{ij,j}(\xi)) \, dx \, dt \\ &= \left[\int_\Omega \eta_i \xi_i' \, dx\right]_S^T + \int_S^T \int_\Omega -\eta_i'\xi_i' + \sigma_{ij}(\xi)\varepsilon_{ij}(\eta) \, dx \, dt - \int_S^T \int_\Gamma \eta_i \sigma_{ij}(\xi)\nu_j \, d\Gamma \, dt \\ &= \left[\int_\Omega \eta_i \xi_i' \, dx\right]_S^T + \int_S^T \int_\Omega -\eta_i'\xi_i' + \sigma_{ij}(\xi)\varepsilon_{ij}(\eta) \, dx \, dt + \int_S^T \int_\Gamma \xi_i(A\xi_i + B\xi_i') \, d\Gamma \, dt. \end{aligned}$$

(In the last step we used the boundary conditions on ξ and on η.) Using (4.13) we deduce the following inequality:

$$\begin{aligned}(4.15)\quad A\int_S^T\int_\Gamma|\xi|^2 d\Gamma\ dt \\ \le \left|\left[\int_\Omega \eta_i\xi_i'\ dx\right]\right|_S^T + \int_S^T\int_\Omega \eta_i'\xi_i'\ dx\ dt - B\int_S^T\int_\Gamma \xi_i\xi_i'\ d\Gamma\ dt.\end{aligned}$$

Using (4.11), (4.12) and applying the Poincaré inequality we can estimate the right-hand side of this inequality as follows:

$$\left|\left[\int_\Omega \eta_i\xi_i'\ dx\right]\right| \le \|\eta\|_{L^2(\Omega)^n}\|\xi'\|_{L^2(\Omega)^n} \le cE;$$

$$\begin{aligned}\int_S^T\int_\Omega \eta_i'\xi_i'\ dx\ dt &\le \int_S^T \|\eta'\|_{L^2(\Omega)^n}\|\xi'\|_{L^2(\Omega)^n}\ dt \\ &\le c\int_S^T \sqrt{|E'|}\sqrt{E}\ dt \le \int_S^T (A\varepsilon/2)E + (c/\varepsilon)|E'|\ dt \\ &= \int_S^T (A\varepsilon/2)E\ dt + (c/\varepsilon)E(S) - (c/\varepsilon)E(T) \\ &\le \int_S^T (A\varepsilon/2)E\ dt + (c/\varepsilon)E(S),\end{aligned}$$

and finally

$$\begin{aligned}-B\int_S^T\int_\Gamma \xi_i\xi_i'\ d\Gamma\ dt &\le \int_S^T \|\xi\|_{L^2(\Gamma)^n}\|\xi'\|_{L^2(\Gamma)^n}\ dt \\ &\le c\int_S^T \sqrt{E}\sqrt{|E'|}\ dt \le \int_S^T (A\varepsilon/2)E + (c/\varepsilon)|E'|\ dt \\ &\le \int_S^T (A\varepsilon/2)E\ dt + (c/\varepsilon)E(S).\end{aligned}$$

Substituting these inequalities into (4.15) the lemma follows.

We end this section by showing that Theorem 1.3 can be extended to cases where the outer boundary of Ω is not exactly (but is close to) a sphere. Fix n numbers $\beta_1, \beta_2, \dots, \beta_n \in (0,1)$, and set

$$\Omega = \left\{x \in \mathbb{R}^n\ :\ 1 < \sum_{i=1}^n \beta_i x_i^2 < 4\right\},$$

$$\Gamma_0 = \left\{x \in \mathbb{R}^n\ :\ \sum_{i=1}^n \beta_i x_i^2 = 1\right\},$$

$$\Gamma_1 = \left\{x \in \mathbb{R}^n\ :\ \sum_{i=1}^n \beta_i x_i^2 = 4\right\}.$$

Theorem 4.4. *Assume* (1.1) *and fix two positive constants A and B with $A < \alpha/48$. If $\beta_1, \beta_2, \dots, \beta_n$ are sufficiently close to* 1*, then there exists a positive number ω such that all (weak) solutions of* (1.8) *satisfy the energy estimate*

$$E(t) \le E(0)e^{1-\omega t}$$

for all $t \ge 0$.

The idea of the proof is to modify the *multiplier* so as to preserve the property $h = R\nu$ on Γ_1. The price to pay will be to have some extra terms in the modified identity (4.7). Fortunately these extra terms can be easily estimated by applying the Korn inequality.

More precisely, let us define a function $h : \overline{\Omega} \to \mathbb{R}^n$ by the formula

$$h(x) = \left(\frac{\beta_1 x_1^2 + \cdots + \beta_n x_n^2}{\beta_1^2 x_1^2 + \cdots + \beta_n^2 x_n^2} \right)^{1/2} (\beta_1 x_1, \dots, \beta_n x_n).$$

Then h is of class C^∞ and $h = -\nu$ on Γ_0, $h = 2\nu$ on Γ_1.

Applying the identity (2.1) with this h and repeating the proof of Theorem 1.3 we obtain instead of (4.3) the identity

$$\begin{aligned} 2\int_S^T E\,dt + \left[\int_\Omega (M\xi_i)\xi_i'\,dx \right]_S^T &= \int_S^T \int_{\Gamma_0} (h\cdot\nu)\sigma_{ij}\varepsilon_{ij}\,d\Gamma\,dt \\ &+ \int_S^T \int_{\Gamma_1} A\xi_i\xi_i - (M\xi_i)(A\xi_i + B\xi_i') + (h\cdot\nu)(\xi_i'\xi_i' - \sigma_{ij}\varepsilon_{ij})\,d\Gamma\,dt \\ &- \int_S^T \int_\Omega 2f_{m,j}\sigma_{ij}\xi_{i,m} + (\mathrm{d}iv\ f)(\xi_i'\xi_i' - \sigma_{ij}\varepsilon_{ij})\,dx\,dt, \end{aligned}$$

where f is defined by the formula $f(x) = h(x) - x$.

Leaving the last two new terms unchanged and transforming the boundary integrals as before (now $R = 2$), we obtain instead of (4.10) the identity

$$\begin{aligned} 2\int_S^T E\,dt \le c_4E(S) + 16A\alpha^{-1}\int_S^T E\,dt + \int_S^T \int_{\Gamma_1} 40A^2\alpha^{-1}|\xi|^2\,d\Gamma\,dt \\ - \int_S^T \int_\Omega 2f_{m,j}\sigma_{ij}\xi_{i,m} + (\mathrm{d}iv\ f)(\xi_i'\xi_i' - \sigma_{ij}\varepsilon_{ij})\,dx\,dt. \end{aligned}$$

Majorizing the boundary integral by using the definition of the energy as before, we deduce the inequality

$$\begin{aligned} 2\int_S^T E\,dt \le c_4E(S) + 96A\alpha^{-1}\int_S^T E\,dt \\ - \int_S^T \int_\Omega 2f_{m,j}\sigma_{ij}\xi_{i,m} + (\mathrm{d}iv\ f)(\xi_i'\xi_i' - \sigma_{ij}\varepsilon_{ij})\,dx\,dt. \end{aligned}$$

It remains to show that for any given $\varepsilon > 0$ the last integral can be majorized by

$$\varepsilon \int_S^T E\,dt$$

if $\beta_1, \beta_2, \dots, \beta_n$ are sufficiently close to 1.

First we note that

$$\left| \int_S^T \int_\Omega 2f_{m,j}\sigma_{ij}\xi_{i,m} + (\mathrm{d}iv\ f)(\xi_i'\xi_i' - \sigma_{ij}\varepsilon_{ij})\ dx\ dt \right| \\ \leq c \sum_{i,j=1}^n \|f_{i,j}\|_{L^\infty(\Omega)} \int_S^T E\ dt$$

with a constant $c = c(\beta_1, \beta_2, \dots, \beta_n)$ coming from the Korn inequality. Looking at the proof of this inequality in [7] we see that c remains uniformly bounded as β_1, β_2, … , β_n all tend to 1. (The constants appear at the moment of using a partition of unity and the approximated domain, a ball, is very smooth.) It remains to show that the functions $f_{i,j}$ converge to 0 uniformly on $\overline{\Omega}$ as β_1, β_2, … , β_n all tend to 1. Now a direct easy computation shows that $h_{i,j}$ converges to $\delta_{i,j}$ uniformly on $\overline{\Omega}$, and hence the claim follows. (At this point we use the fact that Ω has a hole inside, in order to remove a possible singularity of h at the origin.)

5. Stabilizability: Proof of Theorem 1.4. Let us first consider the homogeneous problem (1.2) of Theorem 1.1 with the boundary observation $\psi_i = \sigma_{ij,j}(\xi)\nu_j|_{\Gamma_1}$:

$$\begin{cases} \xi_i'' - \sigma_{ij,j} = 0 \quad \text{in} \quad \Omega \times \mathbb{R}, \\ \xi_i = 0 \quad \text{on} \quad \Gamma \times \mathbb{R}, \\ \xi_i(0) = \xi_i^0 \quad \text{and} \quad \xi_i'(0) = \xi_i^1 \quad \text{in} \quad \Omega, \\ \psi_i = \sigma_{ij,j}(\xi)\nu_j|_{\Gamma_1} \quad \text{in} \quad \mathbb{R}, \\ i = 1, \dots, n. \end{cases} \tag{5.1}$$

Putting $\varphi = (\xi, \xi')$, $\varphi_0 = (\xi^0, \xi^1)$ and introducing two linear operators A^* and B^* by the formulas

$$D(A^*) = D(B^*) = (H^2(\Omega) \cap H_0^1(\Omega))^n \times H_0^1(\Omega)^n, \\ A^*(\eta^0, \eta^1) = -(\eta^1, \sigma_{ij,j}(\eta^0)), \\ B^*(\eta^0, \eta^1) = \sigma_{ij,j}(\xi)\nu_j|_{\Gamma_1},$$

we may rewrite (5.1) in the following operational form:

$$\varphi' = -A^*\varphi, \quad \varphi(0) = \varphi_0, \quad \psi = B^*\varphi. \tag{5.2}$$

Let us introduce the Hilbert spaces $H = H^{-1}(\Omega)^n \times (L^2(\Omega)^n)$ and $G = L^2(\Gamma_1)^n$. Identifying $L^2(\Omega)$ and $L^2(\Gamma_1)$ with their duals, we have $H' = H_0^1(\Omega)^n \times L^2(\Omega)^n$ and $G' = L^2(\Gamma_1)^n$.

We claim that the following four conditions are satisfied:

(H1) The operator A^* generates a *group* e^{sA^*} in H'.

(H2) We have $D(A^*) = D(B^*)$ and there exist two numbers $\lambda \in \mathbb{C}$ and $c \in \mathbb{R}$ such that

$$\|B^*\phi\| \leq c\|(A + \lambda I)^*\phi\|$$

for all $\phi \in D(A^*)$.

(H3) There exist two positive numbers T' and c' such that

$$\|\psi\|_{L^2(0,T';G')} \leq c'\|\varphi_0\|_{H'}$$

for all $\varphi_0 \in D(A^*)$.

(H4) There exist two positive numbers T and c such that

$$\|\psi\|_{L^2(0,T;G')} \geq c\|\varphi_0\|_{H'}$$

for all $\varphi_0 \in D(A^*)$.

Indeed, property (H1) is satisfied by the well-posedness and time-reversibility of the problem (1.2) studied in section 1. Property (H2) (with $\lambda = 0$) follows from the elliptic regularity of the system of elasticity; see, e.g., [4] or [6]. The properties (H3) and (H4) are equivalent to the two inequalities (1.6) in Theorem 1.1; we can choose any $T', T > 2\sqrt{2/\alpha}R$.

We may now apply the following theorem proved in [14].

THEOREM 5.1. *Assume* (H1) *to* (H4) *for some* $T > 0$. *Then for every fixed* $\omega > 0$ *there exists an isomorphism* Λ_ω *of* H' *onto* H *such that putting* $F = -B^*\Lambda_\omega^{-1}$ *the operator* $A + BF$ *generates (in some sense) a strongly continuous* group *in* H, *and there exists a constant* M *such that the solutions of the closed-loop problem*

$$x' = Ax + BFx, \qquad x(0) = x_0 \tag{5.3}$$

satisfy the estimate

$$\|x(t)\|_H \leq M\|x_0\|_H e^{-\omega t}, \qquad \textit{for all } t > 0,$$

for all $x_0 \in H$, *and for all* $t \geq 0$.

Let us remark that the operator Λ_ω is constructed explicitly and that the constant M can also be estimated explicitly. See [14] for details.

Let us write the problem (5.3) in a more explicit form. First of all, it follows from the proof of Theorem 3.1 in section 3 that the open-loop problem

$$x' = Ax + Bu, \qquad x(0) = x_0,$$

where $x = (-y', y)$ and $x_0 = (-y^1, y^0)$, can be written in the following form:

$$\begin{cases} y_i'' - \sigma_{ij,j}(y) = 0 \quad \text{in} \quad \Omega \times \mathbb{R}, \\ y_i = 0 \quad \text{on} \quad \Gamma_0 \times \mathbb{R}, \\ y_i = u_i \quad \text{on} \quad \Gamma_1 \times \mathbb{R}, \\ y_i(0) = y_i^0 \quad \text{and} \quad y_i'(0) = y_i^1 \quad \text{in} \quad \Omega, \\ i = 1, \ldots, n. \end{cases}$$

Therefore it only remains to show that $u = Fx$ can be written as

$$u_i = \sigma_{ij}(Py' + Qy)\nu_j \quad \text{on} \quad \Gamma_1 \times \mathbb{R}$$

with suitable bounded linear maps P, Q as given in Theorem 1.4. This follows easily from the properties of Λ_ω and from the definition of B^*. Indeed, writing the operator

$$\Lambda_\omega^{-1} : H^{-1}(\Omega)^n \times L^2(\Omega)^n \to H_0^1(\Omega)^n \times L^2(\Omega)^n$$

in the matrix form

$$\Lambda_\omega^{-1} = \begin{pmatrix} P & -Q \\ -R & S \end{pmatrix},$$

we have

$$u = -B^* \Lambda_\omega^{-1} x = \sigma_{ij}(Py' + Qy)$$

on Γ_1, and the proof of Theorem 1.4 is completed.

EXACT BOUNDARY CONTROLLABILITY OF THE KORTEWEG–DE VRIES EQUATION*

BING-YU ZHANG†

Abstract. We consider boundary control of the distributed parameter system described by the Korteweg–de Vries (KdV) equation posed on a finite interval $\alpha \leq x \leq \beta$:

$$\begin{cases} u_t + u_x + uu_x + u_{xxx} = 0 \\ u(\alpha,t) = h_1(t), \qquad u(\beta,t) = h_2(t), \qquad u_x(\beta,t) = h_3(t)u \end{cases} \tag{$*$}$$

for $t \geq 0$. It is shown that by choosing appropriate control inputs $(h_j(t),\ j = 1,2,3)$, one can always guide the system $(*)$ from a given initial state $\phi \in H^s(\alpha,\beta)$ to a given terminal state $\psi \in H^s(\alpha,\beta)$ in the time period $[0,T]$ so long as ϕ and ψ satisfy

$$\|\phi(\cdot) - w(\cdot,0)\|_{H^s(\alpha,\beta)} \leq \delta \quad \text{and} \quad \|\psi(\cdot) - w(\cdot,T)\|_{H^s(\alpha,\beta)} \leq \delta$$

for some $\delta > 0$ independent of ϕ and ψ, where $s \geq 0$ and $w \equiv w(x,t)$ is a given smooth solution of the KdV equation. This exact boundary controllability is established by considering a related initial value control problem of the KdV equation posed on the whole line R. Various recently discovered smoothing properties of the KdV equation have played important roles in our approach.

Key words. boundary control, exact controllability, the KdV equation, smoothing properties

1. Introduction.

In this paper we continue our earlier work [27] to study control of the system described by the Korteweg–de Vries (KdV) equation

$$u_t + uu_x + u_{xxx} = 0, \tag{1.1}$$

where $u \equiv u(x,t)$ is a real-valued function of the two real variables x and t and the subscripts denote the corresponding partial derivatives. The equation was first derived by Korteweg and de Vries in 1895 as a model for propagation of some surface water waves along a channel [16]. Its original form is

$$\eta_t = \frac{3}{2}\sqrt{\frac{g}{l}}\left(\frac{1}{2}\eta^2 + \frac{2}{3}\alpha\eta + \frac{1}{3}\sigma\eta_{xx}\right)_x, \tag{1.2}$$

where η is the surface elevation above the equilibrium level l, α is a small constant related to the uniform motion of the liquid, g is the gravitational constant, and $\sigma = l^3/3 - Tl/\rho g$ with surface capillary tension T and density ρ. When posed on the whole line R or on a periodic domain, (1.2) can always be reduced by certain variable transformations to its standard form (1.1). The KdV equation has been intensively studied from various aspects of both mathematics and physics since the 1960s, [2], [7], [8], [28], [29] when *solitons* were discovered through solving the KdV equation and the *inverse scattering method*, a so-called nonlinear Fourier transform, was invented to seek solitons [1], [9], [6]. It turns out that the equation is not only a good model

*Received by the editors September 19, 1997; accepted for publication (in revised form) April 1, 1998; published electronically January 28, 1998.

†Department of Mathematical Sciences, University of Cincinnati, Cincinnati, OH 45221-0025 (bzhang@math.uc.edu).

for some water waves but also a very useful approximation model in nonlinear studies whenever one wishes to include and balance a weak nonlinearity and weak dispersive effects [19]. In particular, the equation is now commonly accepted as a mathematical model for the unidirectional propagation of small-amplitude long waves in nonlinear dispersive systems. In such applications, u is typically an amplitude or velocity, x is often proportional to distance in the direction of propagation, and t is proportional to elapsed time. In [27], we considered distributed control of the KdV equation

$$u_t + uu_x + u_{xxx} = f \tag{1.3}$$

on the domain $0 \leq x \leq 2\pi$, $t \geq 0$ with periodic conditions

$$u(0,t) = u(2\pi,t), \quad u_x(0,t) = u_x(2\pi,t), \quad u_{xx}(0,t) = u_{xx}(2\pi,t). \tag{1.4}$$

The distributed control $f \equiv f(x,t)$ is restricted so that the "volume" $\int_0^{2\pi} u(x,t)dx$ of the solution is conserved. If f is allowed to act on the whole spatial domain $(0,2\pi)$, the system is shown to be *globally* exactly controllable, i.e., for given $T > 0$ and functions $\phi(x)$, $\psi(x)$ with the same "volume," one can always find a control f so that the system (1.3)–(1.4) has a solution $u(x,t)$ satisfying

$$u(x,0) = \phi(x) \quad \text{and} \quad u(x,T) = \psi(x).$$

If the control f is allowed to act on only a small subset of the domain $(0,2\pi)$, then the system is *locally* exactly controllable in the sense that the initial and terminal states, ϕ and ψ, are required to have small "amplitude" in a certain sense (cf. [27] for the details).

In this paper we consider boundary control of the KdV equation

$$u_t + u_x + uu_x + u_{xxx} = 0 \tag{1.5}$$

on the domain (α,β), $t \geq 0$ with the boundary conditions

$$u(\alpha,t) = h_1(t), \qquad u(\beta,t) = h_2(t), \qquad u_x(\beta,t) = h_3(t). \tag{1.6}$$

The boundary value functions $h_j(t)$, $j = 1,2,3$, are considered as control inputs. Note that there is an extra term u_x in (1.5) as compared with the standard KdV equation (1.1). This occurs because, when posed on a finite interval, one cannot reduce the original KdV equation (1.2) to its standard form; the term u_x does not go away. On the other hand, the existence of the term u_x does make some differences for the equation when posed on a finite interval.[1]

Our main concern for the system (1.5)–(1.6) is the following exact control problem.

[1] For instance, while the boundary value problem

$$\begin{cases} u_t + u_{xxx} = 0, \quad x \in (0,2\pi),\ t > 0, \\ u(0,t) = u(2\pi,t) = u_x(2\pi,t) = 0 \end{cases}$$

has no nontrivial steady solutions, the problem

$$\begin{cases} u_t + u_x + u_{xxx} = 0, \quad x \in (0,2\pi),\ t > 0, \\ u(0,t) = u(2\pi,t) = u_x(2\pi,t) = 0 \end{cases}$$

does have some nontrivial steady solutions.

Let $T > 0$ and $s \geq 0$ be given. For any $\phi \in H^s(\alpha,\beta)$ and $\psi \in H^s(\alpha,\beta)$, can one find appropriate boundary control inputs h_j, $j = 1,2,3$, such that the system (1.5)–(1.6) *has a solution $u \in C([0,T]; H^s(\alpha,\beta))$ satisfying*

$$u(x,0) = \phi(x) \quad \textit{and} \quad u(x,T) = \psi(x)$$

on the interval (α,β)?

Here, by saying that $f(x) = g(x)$ on the interval (α,β), we mean that

$$\int_\alpha^\beta f(x)\xi(x)dx = \int_\alpha^\beta g(x)\xi(x)dx \qquad \text{for any } \xi \in C_0^\infty(\alpha,\beta).$$

In other words, f and g are equal in the interval (α,β) in the sense of distributions. In the case of $s > 1/2$, this is equivalent to saying that $\phi(x) = \psi(x)$ in the pointwise sense for any $x \in (\alpha,\beta)$.

Recently this exact boundary control problem was considered by Rosier [21] and the following result was obtained.

Let $T > 0$ be given. Let

$$\mathcal{N} = \left\{ 2\pi\sqrt{\frac{k^2+kl+l^2}{3}}; \quad \textit{k and l are any positive integers} \right\}.$$

If $\alpha < \beta$ satisfying $\beta - \alpha \notin \mathcal{N}$, then there exists a $\delta > 0$ such that for ϕ, $\psi \in L^2(\alpha,\beta)$ satisfying

$$\|\phi\|_{|L^2(\alpha,\beta)} \leq \delta \quad \textit{and} \quad \|\psi\|_{L^2(\alpha,\beta)} \leq \delta,$$

one can choose $h_1 = h_2 \equiv 0$ and $h_3 \in L^2(0,T)$ so that (1.5)–(1.6) *has a solution $u \in C([0,T]; L^2(\alpha,\beta)) \cap L^2(0,T; H^1(\alpha,\beta))$ satisfying*

$$u(x,0) = \phi(x) \quad \textit{and} \quad u(x,T) = \psi(x)$$

on the interval (α,β).

In this paper we present the following theorem.

THEOREM 1.1. *Let $T > 0$ and $s \geq 0$ be given and $[\alpha,\beta] \subset (\alpha_1,\beta_1)$. Suppose that*

$$w \equiv w(x,t) \in C^\infty(\alpha_1,\beta_1) \times (-\epsilon, T+\epsilon)$$

for some $\epsilon > 0$ satisfies

$$w_t + w_x + ww_x + w_{xxx} = 0, \qquad (x,t) \in (\alpha_1,\beta_1) \times (-\epsilon, T+\epsilon).$$

Then there exists a $\delta > 0$ such that for any ϕ, $\psi \in H^s(\alpha,\beta)$ satisfying

$$\|\phi(\cdot) - w(\cdot,0)\|_{H^s(\alpha,\beta)} \leq \delta \quad \textit{and} \quad \|\psi(\cdot) - w(\cdot,T)\|_{H^s(\alpha,\beta)} \leq \delta,$$

one can find control inputs h_1, h_2, and $h_3 \in L^2(0,T)$ ($h_j \in C[0,T]$, $j = 1,2,3$, if $s > 3/2$) such that the system (1.5)–(1.6) *has a solution*

$$u \in C([0,T]; H^s(\alpha,\beta)) \cap L^2(0,T; H^{s+1}(\alpha,\beta))$$

satisfying

$$u(x,0) = \phi(x) \quad \textit{and} \quad u(x,T) = \psi(x)$$

on the interval (α,β).

Several remarks are now in order.

(i) The local controllability result presented in Theorem 1.1 is stronger than the usual sense of local controllability. In general, we say a nonlinear system has exact local controllability if one can find control inputs to guide the system from a given initial state to a given terminal state so long as the "amplitude" of the initial and terminal states are small in a certain sense. The exact controllability we established for the system (1.3)–(1.4) is of this type and so is the result of Rosier cited earlier. In Theorem 1.1, the "amplitude" of the given initial and terminal states does not have to be small. In fact their "amplitudes" can be as large as one wishes so long as they locate in a δ-neighborhood of the initial state and terminal state, respectively, of a smooth solution of the KdV equation.

(ii) The solution u in the theorem is usually called the "path" to connect the given initial state ϕ and the terminal state ψ. Theorem 1.1 shows that the "smoother" ϕ and ψ are, the "smoother" the path—as are the control inputs one needs. In particular, if $s > 7/2$, then the solution

$$u \in C^1([0,T]; C[\alpha,\beta]) \cap C([0,T]; C^3[\alpha,\beta])$$

and the KdV equation is satisfied in the classical sense.

(iii) In the linear case (dropping the nonlinear term uu_x from the equation), Theorem 1.1 holds without any size restriction on the initial and terminal states. Moreover, the control inputs h_j, $j = 1, 2, 3$, are C^∞-smooth functions in the interval $(0,T)$ and the corresponding solution $u \equiv u(x,t)$ is also a C^∞-smooth function in the domain $(\alpha,\beta) \times (0,T)$, although its initial state ϕ and the terminal state ψ may belong only to the space $L^2(\alpha,\beta)$. In other words, the interior regularity of the control inputs and the corresponding solution are all C^∞ no matter what the regularity of the initial state and the terminal state is. Consequently, both (1.5) (dropping uu_x) and the boundary conditions (1.6) are satisfied in the pointwise sense for any $x \in (\alpha,\beta)$ and $t \in (0,T)$, rather than in the sense of distributions. We believe that this should also be the case for the nonlinear system.

(iv) The function $w(x,t)$ in Theorem 1.1 is assumed to be C^∞-smooth only for simplicity. In fact it will be sufficient to require $w \in C(-\epsilon, T+\epsilon, H^{s+1}(\alpha_1, \beta_1))$.

Consider a control system in a Hilbert space X described by the following abstract semilinear evolution equation:

$$\frac{dy}{dt} = Ay + F(y) + Bh, \tag{1.7}$$

where A is the infinitesimal generator of a C^0-semigroup $W(t)$ in the space X, F is a nonlinear mapping from X to X, B is a linear operator from another Hilbert space Y to the space X, and $h \in L^2(0,T;Y)$ is considered as a control input. A standard approach to establish exact controllability of the system (1.7) can be summarized as the following three steps.

Step 1. Establish exact controllability of the corresponding linear control system

$$\frac{dy}{dt} = Ay + Bh$$

by showing that there exists a bounded linear operator G from $X \times X$ to the space $L^2(0,T;Y)$ such that for any ϕ, $\psi \in X$, the unique solution $y(t)$ of the initial value problem

$$\frac{dy}{dt} = Ay + BG(\phi, \psi), \qquad y(0) = \phi$$

satisfies $y(T) = \psi$.

Step 2. Rewrite the nonlinear system (1.7) in its integral form:

$$y(t) = W(t)y(0) + \int_0^t W(t-\tau)F(y(\tau))d\tau + \int_0^t W(t-\tau)Bh(\tau)d\tau.$$

For given ϕ, $\psi \in X$, let

$$\omega(T, u) \equiv \int_0^T W(t-\tau)F(u(\tau))d\tau$$

and define

$$\Gamma(u) = W(t)\phi + \int_0^t W(t-\tau)F(u(\tau))d\tau + \int_0^t W(t-\tau)BG(\phi, \psi - \omega(T, u))(\tau)d\tau.$$

Note that

$$\Gamma(u)(0) = \phi \quad \text{and} \quad \Gamma(u)(T) = \omega(T, u) + \psi - \omega(T, u) = \psi$$

by virtue of the operator G.

Step 3. Show that the map Γ has a fixed point in a complete metric space $\mathcal{X}$ which is contained in the space $C([0, T], X)$.

However, there are some difficulties when applying this approach for the distributed control system (1.3)–(1.4). In particular, Step 3 is hard to carry out. Partially this is caused by the nonlinear term uu_x in the equation whose regularity is less than that of u because of differentiation. In order to show that the map Γ has a fixed point, it is necessary that the corresponding linear equation

$$(1.8) \qquad \begin{cases} u_t + u_{xxx} = f, \\ u(x, 0) = 0, \qquad 0 < x < 2\pi, \ t > 0, \\ u(0, t) = u(2\pi, t), \quad u_x(0, t) = u_x(2\pi, t), \quad u_{xx}(0, t) = u_{xx}(2\pi, t) \end{cases}$$

has certain smoothing properties to recover the lost regularity. But it is well known that, in contrast to the heat equation and the wave equation, $f \in L^1(0, T; H^s_p)$ can only lead to a solution u of (1.8) in the space $C([0, T]; H^s_p)$. Here H^s_p denotes the set of all periodic functions in the space $H^s(0, 2\pi)$. Thus the spatial regularity of the solution u of (1.8) is the same as that of the forcing term f. For many years people thought that it might be impossible for the solution u of (1.8) to possess higher spatial regularity than that of f. It came as a surprise when Bourgain [4], [5] discovered a rather subtle smoothing property for periodic solutions of the KdV equation in 1993. This type of smoothing property of Bourgain played a key role in establishing exact controllability of the system (1.3)–(1.4) in [27].

As for the boundary control system (1.5)–(1.6), there are even more difficulties using this approach. The spatial regularity is not only lost through the term uu_x but also through the boundary value functions h_1, h_2, and h_3 when they are considered as the trace of the solution u.

To obtain his result for the exact boundary control problem of the KdV equation, Rosier used the following type of smoothing property to carry out Step 3. For the initial-boundary value problem

$$\begin{cases} u_t + u_x + u_{xxx} = f, & x \in (\alpha, \beta),\ t > 0, \\ u(x,0) = \phi(x), & \\ u(\alpha, t) = u(\beta, t) = u_x(\beta, t) = 0, & \end{cases} \tag{1.9}$$

$\phi \in L^2(\alpha, \beta)$ and $f \in L^2(0,T; L^2(\alpha,\beta))$ implies that the solution u of (1.9) belongs to the space $C([0,T]; L^2(\alpha,\beta)) \cap L^2(0,T; H^1(\alpha,\beta))$ and $u_x(\alpha,t) \in L^2(0,T)$ with

$$\sup_{t\in(0,T)} \|u(\cdot,t)\|_{L^2(0,T)} + \|u\|_{L^2(0,T;H^1(\alpha,\beta))} + \|u_x(\alpha,t)\|_{L^2(0,T)}$$
$$\leq c\left(\|\phi\|_{L^2(0,T)} + \|f\|_{L^2(0,T;L^2(\alpha,\beta))}\right),$$

where $c > 0$ is independent of f and ϕ. To establish the needed exact controllability of the associated linear system, he used the Hilbert uniqueness method together with a compactness argument.

Our approach is different from Rosier's. Our strategy to overcome these difficulties caused by losing regularity is to bypass them rather than look for some stronger smoothing properties. More precisely, instead of considering boundary control of the KdV equation posed on the finite interval (α, β), we consider initial value control of the KdV equation posed on the whole real line R:

$$\begin{cases} u_t + u_x + uu_x + u_{xxx} = 0, & x,\ t \in R, \\ u(x,0) = h(x). & \end{cases} \tag{1.10}$$

Initial value control problem. *Let $T > 0$ and $s \geq 0$ be given. For any ϕ, $\psi \in H^s(R)$, can we find an external modification of $\phi(x)$, $h \in H^s(R)$, such that the corresponding solution u of the initial value problem (IVP)* (1.10) *satisfies*

$$u(x,0) = \phi(x) \quad \textit{and} \quad u(x,T) = \psi(x)$$

on the interval (α, β)?

An affirmative answer to this initial value control problem leads to a positive answer to the boundary control problem asked earlier, but not vice versa. Indeed, for any given ϕ, $\psi \in H^s(\alpha,\beta)$, we can extend ϕ and ψ to be functions in $H^s(R)$ (let us still write their extensions as ϕ and ψ). If we could find an $h \in H^s(R)$ such that the corresponding unique solution u of the IVP (1.10) satisfies

$$u(x,0) = \phi(x) \quad \text{and} \quad u(x,T) = \psi(x)$$

on the interval (α,β), then we could simply choose $h_1(t) = u(\alpha,t)$, $h_2(T) = u(\beta,t)$, and $h_3(t) = u_x(\beta,t)$. The restriction of u to the domain $[\alpha,\beta] \times [0,T]$ would be the desired solution of the boundary control system (1.5)–(1.6).

We point out that this kind of problem is of interest in its own right. Let us take the linearized KdV equation

$$u_t + u_x + (a(x,t)u)_x + u_{xxx} = 0, \quad x, t \in R, \tag{1.11}$$

as an example. For given ϕ, $\psi \in H^s(R)$, to find a solution u of (1.11) satisfying

$$u(x,0) = \phi(x) \quad \text{and} \quad u(x,T) = \psi(x) \tag{1.12}$$

on the interval $(-\infty, \infty)$ is an overdetermined problem; there is no solution in general. A further question then is the following.

Is there a solution of (1.11) *satisfying* (1.12) *on a given finite interval*?

As we will see later, there are infinitely many such solutions! We will prove the following result for the initial value control problem.

THEOREM 1.2. *Let $T > 0$ and $s \geq 0$ be given. Suppose that $w \in C(R; H^\infty(R))$ is a given solution of*

$$w_t + w_x + ww_x + w_{xxx} = 0, \quad x, t \in R.$$

Then there exists a $\delta > 0$ such that for any ϕ, $\psi \in H^s(\alpha, \beta)$ satisfying

$$\|\phi(\cdot) - w(\cdot, 0)\|_{H^s(\alpha,\beta)} \leq \delta, \quad \|\psi(\cdot) - w(\cdot, T)\|_{H^s(\alpha,\beta)} \leq \delta,$$

one can find $h \in H^s(R)$ such that the corresponding solution u of the IVP (1.10) *satisfies*

$$u(x,0) = \phi(x) \quad \textit{and} \quad u(x,T) = \psi(x)$$

on the interval (α, β).

This theorem is proved using the approach outlined earlier for the abstract system. In contrast with the boundary control problem of the KdV equation, the initial value control problem is easier to handle although it is more general. First of all the needed smoothing properties of the KdV equation have been well established in the literature. Second, we do not need to handle some difficult regularity problems associated with the boundary value problem.

The idea of dealing with a problem posed on a finite interval by extending it to a related problem on the whole line R is not new in the literature. To our knowledge, it is Russell [22], [23] who first used this idea in the field of control theory to establish exact boundary controllability of a class of linear hyperbolic equations. Later this idea was explored by Littman [17] and Littman and Taylor [18]. A systematic method has been developed to handle exact boundary control problems of partial differential equations; the method is summarized by Littman and Taylor [18] as follows:

reversibility + smoothing property + uniqueness → controllability.

We will use this method to establish exact controllability of the associated linear KdV equation which is one of the key steps leading to the exact controllability of the nonlinear KdV equation.

The remainder of the paper is organized as follows.

In section 2, we recall various smoothing properties of the linear KdV equation posed on the whole line R. As we have explained earlier, those smoothing properties will play a major role in the proof of our main theorems.

In section 3, the exact controllability of the associated linear system is established using a method due to Littman [17] with some modification.

The proofs of our main results, Theorems 1.1 and 1.2, are provided in section 4.

2. Smoothing properties. In this section we recall several smoothing properties of the KdV equation. Those smoothing properties not only play important roles in establishing exact controllability of the KdV equation but also are very useful in studying other aspects of the KdV equation. We refer to [3], [4], [5], [11], [12], [13], [14], [31], [32], [33] for other applications of those smoothing properties.

To begin, let $\{W(t)\}_{-\infty}^{+\infty}$ denote the unitary group generated by the linear third order operator A from $L^2(R)$ to $L^2(R)$:

$$Af = -f' - f'''$$

with $\mathcal{D}(A) = H^3(R)$. Then the solution of the IVP associated with the linear KdV equation

$$\begin{cases} u_t + u_x + u_{xxx} = 0, \quad x, t \in R, \\ u(x,0) = \phi(x) \end{cases} \tag{2.1}$$

is given by

$$u(t) = W(t)\phi,$$

and the solution of the inhomogeneous equation

$$\begin{cases} u_t + u_x + u_{xxx} = f, \quad x, t \in R\ , \\ u(x,0) = 0 \end{cases} \tag{2.2}$$

is represented by

$$u(t) = \int_0^t W(t-\tau)f(\cdot,\tau)d\tau.$$

For given $b > 0$ let L_b^2 denote the weighted Sobolev space $L^2(e^{2bx}dx)$. The operator A also generates a semigroup $W_b(t)$ in the space L_b^2 which is formally equivalent to the semigroup

$$W_b(t) = \exp[-t(D-b)^3 - t(D-b)] \tag{2.3}$$

in the space $L^2(R)$ (cf. [10]).

The following two smoothing properties of the linear KdV equation are due to Kato [10]. Lemma 2.1 asserts that the solution u of the IVP (2.1) is smoother than its initial data ϕ if ϕ belongs to a certain weighted Sobolev space. Lemma 2.2 shows that the solutions of the inhomogeneous problem (2.2) possess a similar smoothing property.

LEMMA 2.1. *$\{W_b(t),\ t > 0\}$ is an infinitely differentiable semigroup on $H^s(R)$ for each real s. Moreover, for any $s \le s'$, $W_b(t)$ is bounded as an operator from $H^s(R)$ to $H^{s'}(R)$,*

$$\|W_b(t)\|_{\mathcal{L}(H^s,\,H^{s'})} \le ct^{-(s'-s)/2}\exp(b^3t), \tag{2.4}$$

where $\|\cdot\|_{\mathcal{L}(H^s,\,H^{s'})}$ denotes the operator norm for bounded linear operators from $H^s(R)$ to $H^{s'}(R)$.

As a result, if $\phi \in H^s(R)$ has compact support, then $W(t)\phi$ is infinitely smooth everywhere except at $t = 0$.

LEMMA 2.2. *For any real s, let*

$$e^{bx}u \in L^\infty([0,T]; H^s(R)), \qquad e^{bx}f \in L^\infty([0,T]; H^{s-1}(R)),$$

and

$$u_t + u_{xxx} + u_x = f, \quad 0 < t < T.$$

Then

$$e^{bx}u \in C([0,T]; H^0) \cap C([0,T]; H^s) \quad \textit{for every } s' < s+1,$$

and

$$e^{bx}u(t) = W_b(t)u(0) + \int_0^t W_b(t-\tau)e^{bx}f(\tau)d\tau.$$

Next we recall several more subtle smoothing properties of the linear KdV equation due to Bourgain [4], [5] and Kenig, Ponce, and Vega [13]. First we introduce a special Sobolev-type space used by Kenig, Ponce, and Vega in [13].

For any $s, b \in R$, let $Y_{s,b}$ be the completion of the space $S(R^2)$ of tempered test functions with respect to the norm

$$\|f\|^2_{Y_{s,b}} = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} (1 + |\tau - \xi - \xi^3|)^{2b}(1+|\xi|)^{2s}|\hat{f}(\xi,\tau)|^2 d\xi d\tau,$$

where $\hat{f}(\xi, \tau)$ denotes the Fourier transform of $f(x,t)$. As shown in [13], if $u \in Y_{s,b}$ with $s > -1$ and $b > 1/2$, one has

$$u \in C^{[1+s],\alpha}_{loc}(R; L^2_t(R))$$

for any $0 \le \alpha \le 1 + s - [1+s]$, and consequently

$$u \in L^p_{x,loc}(R; L^2_t(R)),$$

for $1 \le p \le \infty$. Here $[1+s]$ denotes the integer part of $1+s$. In particular, if $s \ge 0$, then $u \in C^1(R; L^2_t(R))$.

The following lemmas can be found in [13] or followed directly from the results there (cf. also [3], [33]).

LEMMA 2.3. *Let there be given $s > -3/4$ and $\sigma \in C_0^\infty(R)$. Then there exists a $\beta_0 \in (1/2, 1)$ such that for any $b \in (1/2, \beta_0)$, there is a constant $c > 0$ for which*

$$\|\sigma(t)\partial_x(uv)\|_{Y_{s,b-1}} \le c\|u\|_{Y_{s,b}}\|v\|_{Y_{s,b}} \tag{2.5}$$

for any u, $v \in Y_{s,b}$.

Equation (2.5) is a key estimate, which reveals a subtle smoothing property of the linear KdV equation. When $s = 0$ and $b = 1/2$, the estimate was established by Bourgain in [5]. Then it was proved by Kenig, Ponce, and Vega in [13] for $s > -5/8$, and for $s > -3/4$ in [14]. Estimate (2.5) is not true for $s < -3/4$ (see [14]).

LEMMA 2.4. *Let $b > 1/2$ and $s \in R$ be given. Then $Y_{s,b} \subset C(R; H^s(R))$ and there is a constant $c > 0$ such that for any $f \in Y_{s,b}$,*

$$\sup_{t \in R} \|f(\cdot, t)\|_{H^s(R)} \leq c \|f\|_{Y_{s,b}}.$$

LEMMA 2.5. *Suppose $\sigma \in C_0^\infty(R)$. For given $s \in R$ and $b \in (1/2, 1]$, there is a constant $c > 0$ such that*

$$\|\sigma(t) W(t) u_0\|_{Y_{s,b}} \leq c \|u_0\|_{H^s(R)} \tag{2.6}$$

and

$$\left\| \sigma(t) \int_0^t W(t-\tau) f(\tau) d\tau \right\|_{Y_{s,b}} \leq c \|f\|_{Y_{s,b-1}} \tag{2.7}$$

for any $u_0 \in H^s(R)$ and $f \in Y_{s,b-1}$.

Remark 2.1. Combining (2.5) and (2.7), one has

$$\left\| \sigma_1(t) \int_0^t W(t-\tau) \sigma^2(\tau) (\partial_x(uv))(\cdot, \tau) d\tau \right\|_{Y_{s,b}} \leq c \|u\|_{Y_{s,b}} \|v\|_{Y_{s,b}}. \tag{2.8}$$

This constitutes a global smoothing property of the linear KdV equation.

In order to prove the main exact control results in the paper we need to extend the above smoothing properties to solutions of the linearized KdV equation with variable coefficient:

$$u_t + u_x + (a(x,t)u)_x + u_{xxx} = 0, \qquad u(x,0) = \phi(x) \tag{2.9}$$

for $x, t \in R$. We assume $a \in C(R; H^\infty(R))$ for the sake of simplicity. By the standard semigroup theory, for each given real s and $\phi \in H^s(R)$, (2.9) possesses a unique solution $u \in C(R; H^s(R))$ satisfying

$$\sup_{t \in [-T,T]} \|u(\cdot, t)\|_{H^s(R)} \leq c \|\phi\|_{H^s(R)}, \tag{2.10}$$

where the constant c depends only on s, T, and a. In addition, if $e^{bx}\phi \in H^s(R)$ for some $b > 0$, then $e^{bx}u \in C(R; H^s(R))$. The following lemma is an extension of Lemma 2.1.

LEMMA 2.6. *For given $T > 0$, $s \in R$, and $b > 0$, suppose $e^{bx}\phi(x) \in H^s(R)$ and u is the solution of (2.9). Then $e^{bx}u(x,t)$ belongs to the space $C((0,T]; H^{s'}(R))$ for any $s \leq s' < s+1$. Moreover,*

$$\|e^{b\cdot} u(\cdot, t)\|_{H^{s'}(R)} \leq c t^{-(s'-s)/2} \|\phi(\cdot)\|_{H^s(R)} \tag{2.11}$$

for any $0 < t < T$, where $c > 0$ depends only on s, s', a, and T.

Proof. Since $e^{bx}u \in C([0,T]; H^s(R))$ and

$$u_t + u_x + u_{xxx} = -(a(x,t)u)_x$$

with $e^{bx}(a(x,t)u)_x \in C([0,T]; H^{s-1}(R))$, it follows from Lemma 2.2 that $e^{bx}u \in C((0,T]; H^{s'}(R))$ for any $s' < s+1$ and

$$e^{bx}u(t) = W_b(t)\phi(x) - \int_0^t W_b(t-\tau) e^{bx} (a(x,\tau)u(x,\tau))_x d\tau.$$

Applying Lemma 2.1 yields

$$\|e^{b\cdot}u(\cdot,t)\|_{H^{s'}(R)} \le \|W_b(t)\phi\|_{H^{s'}(R)} + \int_0^t \|W_b(t-\tau)e^{b\cdot}(a(\cdot,t)u(\cdot,t))_x\|_{H^{s'}(R)}d\tau$$

$$\le ct^{-(s'-s)/2}e^{b^3t}\|\phi\|_{H^s(R)} + c\int_0^t (t-\tau)^{-(s'-s+1)/2}e^{b^3(t-\tau)}\|e^{b\cdot}(a(\cdot,\tau)u(\cdot,\tau))_x\|_{H^{s-1}(R)}d\tau$$

$$\le ct^{-(s'-s)/2}e^{b^3t}\|\phi\|_{H^s(R)} + c\int_0^t (t-\tau)^{-(s'-s+1)/2}e^{b^3(t-\tau)}\|e^{b\cdot}u(\cdot,\tau)\|_{H^s(R)}d\tau$$

for any $t > 0$. Let

$$w(t) = t^{(s'-s)/2}e^{-b^3t}\|e^{b\cdot}u(\cdot,\tau)\|_{H^{s'}(R)}.$$

Then

$$w(t) \le c\|\phi\|_{H^s(R)} + c\int_0^t t^{(s'-s)/2}\tau^{-(s'-s)/2}(t-\tau)^{-(s'-s+1)/2}w(\tau)d\tau.$$

One can choose T^* small enough so that

$$c\int_0^t t^{(s'-s)/2}\tau^{-(s'-s)/2}(t-\tau)^{-(s'-s+1)/2}d\tau < 1/2$$

for $0 < t \le T^*$. Then

$$w(t) \le c\|\phi\|_{H^s(R)} + \frac{1}{2}\sup_{0\le\tau\le t} w(\tau)$$

for any $0 < t \le T^*$. This implies that

$$w(t) \le c\|\phi\|_{H^s(R)}$$

for any $0 < t \le T^*$, i.e.,

$$\|e^{b\cdot}u(\cdot,t)\|_{H^{s'}(R)} \le ct^{-(s'-s)/2}e^{b^3t}\|\phi\|_{H^s(R)}$$

for any $t \in (0, T^*]$. As the chosen T^* does not depend on ϕ, a standard argument enables us to extend T^* to $T^* = T$ so that for any $t \in (0, T)$,

$$\|e^{b\cdot}u(\cdot,t)\|_{H^{s'}(R)} \le ct^{-(s'-s)/2}e^{3t}\|\phi\|_{H^s(R)}.$$

Here $c > 0$ depends only on T, s, and s' as well as a. The proof is complete. □

The next lemma is an extension of Lemma 2.5 for the linearized KdV equation (2.9). Its proof can be found in [3].

LEMMA 2.7. *Suppose $s > -3/4$ is given, $T > 0$, b is as in Lemma 2.3 with $1/2 < b \le 1$, and $a \in Y_{s,b}$. Then for any $u_0 \in H^s(R)$ and $f \in Y_{s,b-1}$, the IVP (2.9) has a unique solution $u \in C(-T, T; H^s(R))$ which is the restriction to $(-T, T)$ of a function $\bar{u} \in Y_{s,b}$ that satisfies the estimate*

$$\|\bar{u}\|_{Y_{s,b}} \le c_1\left(\|u_0\|_{H^s(R)} + \|f\|_{Y_{s,b-1}}\right), \tag{2.12}$$

where $c_1 = c_1(T, \|a\|_{Y_{s,b}})$.

3. The linear system. In this section we consider the initial value control problem for the linearized KdV equation posed on the whole line R:

$$(3.1)\qquad \begin{cases} z_t + z_x + (a(x,t)z)_x + z_{xxx} = 0, & x,\ t \in R, \\ \\ z(x,0) = h(x). \end{cases}$$

Again we assume $a \equiv a(x,t)$ is H^∞ smooth for simplicity. The theorem below is a linear version of Theorem 1.2 but without the restriction on the amplitude of the initial and terminal states.

THEOREM 3.1. *Let $s \geq 0$ and $T > 0$ be given. There exists a bounded linear operator G: $H^s(\alpha,\beta) \times H^s(\alpha,\beta) \to H^s(R)$ such that for any ϕ and ψ in $H^s(\alpha,\beta)$ if one chooses $h = G(\phi,\psi) \in H^s(R)$, then the corresponding solution z of* (3.1) *satisfies*

$$z(x,0) = \phi(x), \qquad z(x,T) = \psi(x)$$

on the interval $\in (\alpha,\beta)$ and

$$\|h\|_{H^s(R)} = \|G(\phi,\psi)\|_{H^s(R)} \leq c(\|\phi\|_{H^s(\alpha,\beta)} + \|\psi\|_{H^s(\alpha,\beta)}),$$

where $c > 0$ is independent of ϕ and ψ.

Remark 3.1. By the standard semigroup theory, the solution

$$u \in C([0,T]; H^s(R)) \cap L^2(0,T; H^{(s+1)}_{loc}(R)).$$

However, from the proof of the theorem one can see that, in fact, $u \in C^\infty(R \times (0,T))$ even though its initial state and the terminal state belong only to $L^2(R)$.

Proof. Without loss of generality, we may assume that $\psi \equiv 0$ since the system is time reversible. We split the proof into several steps.

Step 1. Let $\epsilon > 0$ be small and let $p(x)$ be a smooth function satisfying

$$p(x) = \begin{cases} 1 & \text{for } x \in (\alpha,\beta), \\ \\ 0 & \text{for } x \in (\alpha-\epsilon, \beta+\epsilon). \end{cases}$$

We define an operator $\mathcal{P}$ from $H^s(R)$ to $H^s(R)$ by

$$\mathcal{P}(f)(x) = p(x)f(x)$$

for any $f \in H^s(R)$. Obviously $\mathcal{P}$ is a bounded linear operator and the support of $\mathcal{P}(f)$ is in the interval $(\alpha-\epsilon, \beta+\epsilon)$ for any $f \in H^s(R)$. In addition, let $\mathcal{E}$ denote the usual extension operator from $H^s(\alpha,\beta)$ to $H^s(R)$: for any $f \in H^s(\alpha,\beta)$,

- $\mathcal{E}(f) \in H^s(R)$ and $\mathcal{E}(f)(x) = f(x)$ on (α,β);
- $\mathcal{E}(f)$ has a compact support;
- $\|\mathcal{E}(f)\|_{H^s(R)} \leq c\|f\|_{H^s(\alpha,\beta)}$, where $c > 0$ does not depend on f.

Let $W_a(t)$ denote the continuous group associated to the IVP (3.1). Then for any given $h \in H^s(R)$, the unique solution of (3.1) is represented by

$$z(t) = W_a(t)h.$$

For given $T > 0$, let $K = W_a(-T)\mathcal{P}W_a(T)\mathcal{E}$. Consider the following function equation in the space $H^s(\alpha,\beta)$:

$$(3.2)\qquad (I - K)f = \phi.$$

Claim 3.1. *For any $\phi \in H^s(\alpha,\beta)$, if* (3.2) *has a solution $f \in H^s(\alpha,\beta)$, then there exists an $h \in H^s(R)$ such that the corresponding solution z of the IVP* (3.1) *satisfies*

$$z(x,0) = \phi(x), \qquad z(x,T) = 0$$

in the interval (α,β).

Indeed, if $f \in H^s(\alpha,\beta)$ is a solution of (3.2) for given ϕ, let

$$h = \mathcal{E}f - W_a(-T)\mathcal{P}W_a(T)\mathcal{E}f \tag{3.3}$$

be the initial value of (3.1); then the unique solution $z = W_a(t)h$ of (3.1) satisfies

$$z(x,0) = W_a(0)h = \phi(x), \quad \text{on } (\alpha,\beta)$$

and

$$\begin{aligned} z(x,T) &= W_a(T)h \\ &= W_a(T)\mathcal{E}f - \mathcal{P}W_a(T)\mathcal{E}f \\ &= 0 \qquad \text{on } (\alpha,\beta). \end{aligned}$$

Remark 3.2. If h is given by (3.3), then $z = W_a(t)h \in C^\infty(R \times (0,T))$. This is because $h_1 \equiv \mathcal{E}f$ has compact support, and $h_2 \equiv W_a(-T)\mathcal{P}W_a(T)\mathcal{E}f \in H^\infty(R)$ for $\mathcal{P}W_a(T)\mathcal{E}f \in H^\infty(R)$.

Step 2. We seek a necessary and sufficient condition for (3.2) to have a solution.

By the definition of the operator $\mathcal{E}$, for any $f \in H^s(\alpha,\beta)$, the function $\mathcal{E}f$ belongs to the space $H^s(R)$ and has compact support in R. Therefore $e^{bx}\mathcal{E}f \in H^s(R)$. By Lemma 2.6,

$$\|e^{b\cdot}W_a(T)\mathcal{E}f\|_{H^{s'}(R)} \le cT^{-(s'-s)/2}\|\mathcal{E}f\|_{H^s(R)} \le cT^{-(s'-s)/2}\|f\|_{H^s(\alpha,\beta)}$$

for any $s \le s' < s+1$. It then follows that

$$\|W_a(T)\mathcal{E}f\|_{H^{s'}(R)} \le c\|e^{b\cdot}W_a(T)\mathcal{E}f\|_{H^{s'}(R)} \le cT^{-(s'-s)/2}\|f\|_{H^s(\alpha,\beta)}.$$

Consequently, as an operator from $H^s(\alpha,\beta)$ to $H^s(\alpha,\beta)$, $W_a(T)\mathcal{E}$ is a compact operator and so is the operator $K = W_a(-T)\mathcal{P}W_a(T)\mathcal{E}$. Equation (3.2) is then a Fredholm equation in the space $H^s(\alpha,\beta)$. According to the Fredholm theory, the following statements are true for the operator $(I-K)$:

(a) the range $\mathcal{R}(I-K)$ of the operator $I-K$ is a closed subspace of $H^s(\alpha,\beta)$;

(b) the null space $\mathcal{N}(I-K)$ of $I-K$ is a finite dimensional subspace of $H^s(\alpha,\beta)$, and its dimension equals the dimension of the null space $\mathcal{N}(I-K^*)$ of the operator $I-K^*$. Here K^* is the adjoint of K;

(c) $\phi \in \mathcal{R}(I-K)$ if and only if ϕ is orthogonal to the space $\mathcal{N}(I-K^*)$;

(d) considered as an operator from $(\mathcal{N}(I-K))^\perp$, the orthogonal complement of $\mathcal{N}(I-K)$ in the space $H^s(\alpha,\beta)$, to $\mathcal{R}(I-K)$, the operator $I-K$ has a bounded inverse $(I-K)^{-1}$ from$\mathcal{R}(I-K)$ to $(\mathcal{N}(I-K))^\perp$, i.e., for any $\phi \in \mathcal{R}(I-K)$ there exists a unique $f \in (\mathcal{N}(I-K))^\perp$ satisfying

$$\|f\|_{H^s(\alpha,\beta)} = \|(I-K)^{-1}\phi\|_{H^s(\alpha,\beta)} \le c\|\phi\|_{H^s(\alpha,\beta)}, \tag{3.4}$$

where $c > 0$ is independent of ϕ.

As a result, we may assume that $\mathcal{N}(I-K^*)$ is a space of dimension m with $\{\psi_1, \psi_2, \dots, \psi_m\}$ as its orthonormal basis; $(\psi_i, \psi_j)_{H^s(\alpha,\beta)} = \delta_{ij}$ for i, $j = 1, 2, \dots, m$. The following claim then holds.

CLAIM 3.2. *For a given function* $\phi \in H^s(\alpha, \beta)$, (3.2) *has a solution, i.e.,* $\phi \in \mathcal{R}(I-K)$, *if and only if*

$$(\phi, \psi_j)_{H^s(\alpha,\beta)} = 0, \qquad j = 1, 2, \dots, m.$$

Step 3. We show that the set of all $\phi \in H^s(\alpha, \beta)$ such that (3.2) has a solution is a dense subset of the space $H^s(\alpha, \beta)$.

CLAIM 3.3. *For any given* $\phi \in H^s(\alpha, \beta)$ *and* $\epsilon > 0$, *one can find* $h \in H^\infty(R)$ *and* $\phi_1 \in H^\infty(\alpha, \beta)$ *with*

$$\|\phi - \phi_1\|_{H^s(\alpha,\beta)} \leq \epsilon$$

such that the solution $z = W_a(t)h$ *of* (3.1) *satisfies*

$$z(x, 0) = \phi_1(x) \quad \textit{and} \quad z(x, T) = 0 \quad \textit{on } (\alpha, \beta).$$

The following technical lemma is needed for the proof of Claim 3.3.

LEMMA 3.2. *Let* $Q = (\alpha, \beta) \times (0, T)$,

$$L \equiv \partial_t + \partial_x + \partial_x(a(x,t)u) + \partial_x^3,$$

and $\mathcal{L}$ *be the set of the collection of all smooth functions* $f(x,t)$ *in the cylinder* $R \times [-2T, 2T]$ *vanishing near the top and the bottom of* $\bar{Q}$. *Then the set*

$$L(\mathcal{L}) = \{\textit{the restriction of } Lf \textit{ on } (\alpha, \beta) \times (0, T) : \quad f \in \mathcal{L}\}$$

is dense in the space $L^2(0, T; H^s(\alpha, \beta))$.

We prove Lemma 3.2 by contradiction. Suppose that the set $L(\mathcal{L})$ is not dense in $L^2(0, T : H^s(\alpha, \beta))$. Then there exists a nonzero $g \in L^2(0, T; H^s(\alpha, \beta))$ which is orthogonal to $\overline{L(\mathcal{L})}$. Thus

$$L^* g = 0 \qquad \text{in } Q$$

and g has Cauchy data zero on the lateral boundary of Q (as a matter of fact, g can be extended to be zero outside the lateral boundary of Q). In other words, g solves

$$g_t + g_x + a(x,t) g_x + g_{xxx} = 0, \qquad x \in R, \ t \in (0, T),$$

and vanishes outside $(\alpha, \beta) \times (0, T)$. By the smoothing properties of the equation, we know that $g(\cdot, t) \in C^\infty(R)$ for any $t \in (0, T)$, which leads to $g \equiv 0$ by the unique continuation property of the equation (cf. [30]). This is a contradiction.

Now we prove Claim 3.3. First we choose $\psi \in H^\infty(R)$ such that

$$\|\psi - \phi\|_{H^s(\alpha,\beta)} \leq \epsilon.$$

Let v be the solution of the IVP

$$v_t + v_x + (a(x,t)v)_x + v_{xxx} = 0, \quad v(x, 0) = \psi(x)$$

for $x \in R$ and $t \in (0, T)$. Suppose that $\theta(t)$ is a given cutoff function: $\theta(t) \equiv 1$ near $t = 0$ and $\theta(t) \equiv 0$ near T. Let $L(\theta(t)v) = F(x, t)$. Note that F is C^∞-smooth and $F \in C^k(R; H^m(R))$ for any $k \geq 1$, $m \geq 1$. Then there exists a smooth function $u \in C^\infty(R, H^\infty(R))$ vanishing near the top and the bottom of $\overline{Q}$ such that $F_1 := Lu \in C^\infty(R, H^\infty(R))$ satisfying

$$\|F - F_1\|_{L^2(0,T;H^s(\alpha,\beta))} \leq \epsilon$$

for $L(\mathcal{L})$ is dense in the space $L^2(0,T;H^s(\alpha,\beta))$ (Lemma 3.2). Let w be the unique solution of

$$w_t + w_x + (a(x,t)w)_x + w_{xxx} = F - F_1, \quad w(x,0) = 0$$

for $x \in R$ and $t \in (0,T)$ and set

$$z(x,t) = \theta(t)v - u - w - y,$$

where $y(x,t)$ solves the linear KdV equation on R posed backward in time:

$$y_t + y_x + (a(x,t)y)_x + y_{xxx} = 0, \qquad y(x,T) = w(x,T).$$

Then $Lz = 0$ and $z(x,T) = w(x,T) - y(x,T) = 0$ on (α,β) and

$$\begin{aligned} \|z(\cdot,0) - \phi(\cdot)\|_{H^s(\alpha,\beta)} &\leq \|z(\cdot,0) - \psi(\cdot)\| + \|\psi(\cdot) - \phi(\cdot)\| \\ &\leq \epsilon + \|y(\cdot,0)\|_{H^s(\alpha,\beta)} \\ &\leq \epsilon + c\|w(\cdot,T)\|_{H^s(\alpha,\beta)} \\ &\leq \epsilon + c\|F - F_1\|_{L^2(0,T;H^s(\alpha,\beta))} \\ &\leq c\epsilon. \end{aligned}$$

Consequently, we only need to choose $h(x) = \phi_1(x) = z(x,0)$ to complete the proof of Claim 3.3.

Step 4. We construct the needed control operator G to complete the proof of Theorem 3.1.

Recall from Step 2 that the set $\{\psi_1, \ldots, \psi_m\}$ is an orthonormal basis for the space $\mathcal{N}(I - K^*)$ and

$$(\psi_i, \psi_j)_{H^s(\alpha,\beta)} = \delta_{ij}$$

for i, $j = 1, 2, \ldots, m$. According to Claim 3.3, we can find $\phi_j \in H^\infty(\alpha,\beta)$ sufficiently close to ψ_j, and $h_j \in H^\infty(R)$ for $j = 1, 2, \cdot, m$ such that

$$\det((\phi_j, \psi_i)_{H^s(\alpha,\beta)}) \neq 0 \tag{3.5}$$

and $w_j(t) = W_a(t)h_j$ satisfies

$$w_j(x,0) = \phi_j(x), \qquad w_j(x,T) = 0 \tag{3.6}$$

on the interval (α,β) for $j = 1, 2, \ldots, m$.

For any given $\phi \in H^s(\alpha,\beta)$, consider the following system of linear equations for a_1, $a_2, \ldots, a_m$:

$$\sum_{i=1}^{n} (\psi_j, \phi_i)_{H^s(\alpha,\beta)} a_i = (\phi, \psi_j), \ j = 1, 2, \ldots, m. \tag{3.7}$$

By (3.5), it has a unique solution $\vec{a} = (a_1, a_2, \ldots, a_m)$. Moreover,

$$\sum_{j=1}^{m} |a_j| \leq c\|\phi\|_{H^s(\alpha,\beta)} \tag{3.8}$$

for some constant $c >$ independent of ϕ. If we let

$$\phi_N = \sum_{j=1}^{m} a_j\phi_j, \qquad h_N = \sum_{j=1}^{m} a_j h_j, \tag{3.9}$$

then $z_N(t) = W_a(t)h_N = \sum_{j=1}^{m} W_a(t)a_j h_j$ satisfies

$$z_N(x,0) = \sum_{j=1}^{m} a_j\phi_j(x) = \phi_N(x), \qquad z_N(x,T) = 0 \tag{3.10}$$

on the interval (α, β). In addition,

$$\begin{aligned}\|h_N\|_{H^s(R)} &\leq \sum_{j=1}^{m} |a_j|\|h_j\|_{H^s(R)} \\ &\leq \max_{j=1,2,\ldots,m} \|h_j\|_{H^s(R)} \sum_{j=1}^{m} |a_j|.\end{aligned}$$

By (3.8), there exists a constant $c > 0$ independent of ϕ such that

$$\|h_N\|_{H^s(R)} \leq c\|\phi\|_{H^s(\alpha,\beta)}. \tag{3.11}$$

Furthermore, if we let

$$\phi_R = \phi - \phi_N,$$

then it follows from (3.7) that

$$(\phi_R, \psi_i)_{H^s(\alpha,\beta)} = 0, \quad i = 1, 2, \ldots, m.$$

Hence $\phi_R \in \mathcal{R}(I - K)$ by Claim 3.2. According to what we have proved in Step 2 there exists a unique $f_R \in (\mathcal{N}(I-K))^{\perp}$ which solves (3.2) and satisfies

$$\|f_R\|_{H^s(\alpha,\beta)} \leq c\|\phi_R\|_{H^s(\alpha,\beta)} \leq c\|\phi\|_{H^s(\alpha,\beta)} \tag{3.12}$$

for some constant $c > 0$ independent of ϕ. Define

$$h_R = \mathcal{E}f_R - W_a(-T)\mathcal{P}W_a(T)\mathcal{E}f_R. \tag{3.13}$$

By Claim 3.1, the solution $w_R(t) \equiv W_a(t)h_R$ of (3.1) satisfies

$$w_R(x,0) = \phi_R(x), \quad w_R(\cdot,T) = 0$$

on the interval (α, β) and

$$\|h_R\|_{H^s(R)} \leq c\|\phi_R\|_{H^s(\alpha,\beta)} \leq c\|\phi\|_{H^s(\alpha,\beta)}, \tag{3.14}$$

where c is independent of ϕ. Consequently, if we define

$$G\phi = h_N + h_R \quad \text{for any } \phi \in H^s(\alpha,\beta),$$

where h_N and h_R are as given by (3.9) and (3.14), respectively, then G is a bounded linear operator from $H^s(\alpha,\beta)$ to $H^s(R)$ and $z(t) = W_a(t)G\phi$ is a solution of (3.1) with $h = G(\phi)$, which satisfies

$$z(x,0) = \phi(x), \qquad z(x,T) = 0$$

on the interval (α,β). Moreover, $W_a(t)G(\phi) \in C^\infty(R \times (0,T))$ since both $W_a(t)h_N$ and $W_a(t)h_R$ belong to $C^\infty(R \times (0,T))$. The proof is complete. □

As a corollary of Theorem 3.1, we have the following result for the two point (in time) boundary value problem for the linearized KdV equation:

$$\text{(3.15)} \qquad \begin{cases} u_t + u_x + (a(x,t)u)_x + u_{xxx} = 0, \quad x \in R,\ t \in (0,T), \\ u(x,0) = \phi(x) \quad \text{and} \quad u(x,T) = \psi(x) \quad \text{on the interval } (\alpha,\beta). \end{cases}$$

COROLLARY 3.3. *Let $s \geq 0$ and $T > 0$ be given. Then for any $\phi, \psi \in H^s(R)$, the problem* (3.15) *has a solution*

$$u \in C([0,T]; H^s(R)) \cap L^2(0,T; H^{s+1}_{loc}(R)) \cap C^\infty(R \times (0,T)).$$

Remark 3.3. In fact, there are infinitely many such solutions.

As another corollary to Theorem 3.1, we have the following result for boundary control of the linearized KdV equation posed on a bounded domain (α,β):

$$\text{(3.16)} \qquad \begin{cases} u_t + u_x + (a(x,t)u)_x + u_{xxx} = 0, \quad x \in (\alpha,\beta),\ t \in (0,\infty), \\ u(\alpha,t) = h_1(t), \qquad u(\beta,t) = h_2(t), \qquad u_x(\beta,t) = h_3(t), \end{cases}$$

where $h_j(t)$, $j = 1,2,3$, are considered as control inputs.

COROLLARY 3.4. *Let $s \geq 0$ and $T > 0$ be given. For any $\phi \in H^s(\alpha,\beta)$, $\psi \in H^s(\alpha,\beta)$, there exist h_1, h_2, and $h_3 \in L^2(0,T)$ ($h_j \in C[0,T]$, $j = 1,2,3$, if $s > 3/2$) such that* (3.16) *has a solution*

$$u \in C([0,T]; H^s(\alpha,\beta)) \cap L^2(0,T; H^{s+1}(\alpha,\beta))$$

satisfying

$$u(x,0) = \phi(x), \qquad u(x,T) = \psi(x)$$

in the interval (α,β).

Remark 3.4. In fact we have $h_j \in C^\infty(0,T)$, $j = 1,2,3$, and the corresponding solution

$$u \in C^\infty((\alpha,\beta) \times (0,T)).$$

Proof. For given ψ, $\phi \in H^s(\alpha,\beta)$, let $h = G(\phi,\psi)$ and $w(t) = W_a(t)h$. Then $w \in C([0,T]; H^s(R)) \cap L^2(0,T; H^{s+1}_{loc}(R))$ and by Theorem 3.1,

$$w(x,0) = \phi(x), \qquad w(x,T) = \psi(x)$$

in the interval (α,β). Thus if we let $u(x,t)$ be the restriction of $w(x,t)$ to the domain $[\alpha,\beta]\times[0,T]$, then $u\in C([0,T];H^s(\alpha,\beta))\cap L^2(0,T;H^{s+1}(\alpha,\beta))$ solves (3.16) with the boundary value functions there given by

$$h_1(t)=w(\alpha,t),\qquad h_2(t)=w(\beta,t),\qquad h_2(t)=w_x(\beta,t)$$

and satisfies

$$u(x,0)=\phi(x),\qquad u(x,T)=\psi(x).$$

The proof is complete. □

4. Nonlinear system. Before presenting the proofs for our main results, Theorems 1.1 and 1.2, we consider initial value control of the following nonlinear system described by the KdV equation with variable coefficient:

$$\begin{cases} v_t+v_x+vv_x+(a(x,t)v)_x+v_{xxx}=0, & x\in R,\ t\in R,\\ v(x,0)=h(x). \end{cases}\tag{4.1}$$

Here $a(x,t)$ is assumed to be smooth for simplicity. When the initial value h is considered as a control input, the system possesses the following type of exact controllability.

PROPOSITION 4.1. *Let $s\geq 0$, $T>0$, and $b>0$ as given in Lemma 2.3. In addition, suppose $a\in Y_{s,b}$. Then there exists $\delta>0$ such that if ϕ, $\psi\in H^s(\alpha,\beta)$ with*

$$\|\phi\|_{H^s(\alpha,\beta)}\leq\delta \quad \textit{and} \quad \|\psi\|_{H^s(\alpha,\beta)}\leq\delta,$$

one can find $h\in H^s(R)$ such that the corresponding solution v of (4.1) satisfies

$$v(x,0)=\phi(x),\quad v(x,T)=\psi(x)$$

on the interval (α,β).

Proof. Using the notation of the C^0-group $W_a(t)$ we write (4.1) in its equivalent integral equation form:

$$v(t)=W_a(t)h-\int_0^t W_a(t-\tau)(vv_x)(\tau)d\tau.\tag{4.2}$$

Let

$$\omega(T,v)\equiv\int_0^T W_a(T-\tau)(vv_x)(\tau)d\tau.$$

Then, according to Theorem 3.1, for given ϕ, $\psi\in H^s(\alpha,\beta)$, if one chooses

$$h=G(\phi,\psi+\omega(T,v))$$

in (4.2), then

$$v(t)=W_a(t)G(\phi,\psi+\omega(T,v))-\int_0^t W_a(t-\tau)(vv_x)(\tau)d\tau$$

satisfies

$$v(x,0)=\phi(x),\qquad v(x,T)=\psi(x)$$

on the interval (α, β) by virtue of the definition of the operator G. This suggests that we consider the map

$$\Gamma(v) = W_a(t)G(\phi, \psi + \omega(T, v)) - \int_0^t W_a(t-\tau)(vv_x)(\tau)d\tau.$$

If we can show that the map Γ is a contraction in an appropriate Banach space, then its fixed point v is a solution of (4.1) with $h = G(\phi, \psi + \omega(T, v))$ which satisfies $v(x, 0) = \phi(x)$ and $v(x, T) = \psi(x)$ on the interval (α, β). We show that this is the case in the space $Y_{s,b}$ given earlier in section 2.

To this end, we modify the map Γ as follows:

$$\Gamma(v) = \sigma_1(t)W_a(t)\Phi(\phi, \psi + \omega(T, v)) - \sigma_1(t)\int^t W_a(t-\tau)\sigma_2(\tau)(vv_x)(\tau)d\tau$$

for any $v \in Y_{s,b}$, where $\sigma_1(t)$ is a smooth nonnegative function satisfying $\sigma_1(t) = 1$ for any $t \in (-T, T)$ but with its support inside the interval $(-T - 1/2, T + 1/2)$, and σ_2 is also a nonnegative smooth function with its support contained in $(-T - 1/2, T + 1/2)$ but is identically equal to 1 on the support of σ_1. By Lemma 2.7,

$$\begin{aligned}\|\Gamma(v)\|_{Y_{s,b}} &\le c\|G(\phi, \psi + \omega(T, v))\|_{H^s(R)} + c\|v\|^2_{Y_{s,b}} \\ &\le c(\|\phi\|_{H^s(R)} + \|\psi\|_{H^s(R)} + \|\omega(T, v)\|_{H^s(R)} + c\|v\|^2_{Y_{s,b}}).\end{aligned}$$

As

$$\begin{aligned}\|\omega(T, v)\|_{H^s(R)} &= \left\| \int_0^T W_a(T-\tau)(vv_x)(\tau)d\tau \right\|_{H^s(R)} \\ &\le \sup_{t\in R} \|\sigma_1(t)\int_0^t W_a(t-\tau)\sigma_2(\tau)(vv_x)(\tau)d\tau\|_{H^s(R)} \\ &\le c\|\sigma_1(t)\int_0^t W_a(t-\tau)\sigma_2(\tau)(vv_x)(\tau)d\tau\|_{Y_{s,b}} \\ &\le c\|v\|^2_{Y_{s,b}},\end{aligned}$$

we have

$$\|\Gamma(v)\|_{Y_{s,b}} \le c\left(\|\phi\|_{H^s(\alpha,\beta)} + \|\psi\|_{H^s(\alpha,\beta)}\right) + c\|v\|^2_{Y_{s,b}}.$$

For $M > 0$, let

$$S_M = \{v \in Y_{s,b}; \quad \|v\|_{Y_{s,b}} \le M\}.$$

Then for any $v \in S_M$,

$$\|\Gamma(v)\|_{Y_{s,b}} \le c\left(\|\phi\|_{H^s(\alpha,\beta)} + \|\psi\|_{H^s(\alpha,\beta)}\right) + cM^2$$

for some appropriate constant $c > 0$ independent of v.

Choose $\delta > 0$ and M such that

$$2c\delta + CM^2 \le M, \qquad cM < 1/2. \tag{4.3}$$

Then

$$\|\Gamma(v)\|_{Y_{s,b}} \leq M$$

for any $v \in S_M$ if $\|\phi\|_{H^s(\alpha,\beta)} \leq \delta$, $\|\psi\|_{H^s(\alpha,\beta)} \leq \delta$. In addition, for any $v_1,\ v_2 \in S_M$,

$$\Gamma(v_1) - \Gamma(v_2) = \sigma_1(t)W_a(t)(G(\phi, \psi + \omega(T, v_1)) - G(\phi, \psi + \omega(T, v_2)))$$

$$- \sigma_1(t)\int_0^t W_a(t-\tau)\sigma_2(\tau)\left(\frac{1}{2}\partial_x((v_1+v_2)(v_1-v_2))\right)(\tau)d\tau$$

$$= \quad \sigma_1(t)W_a(t)G(\phi, \omega(T, v_1) - \omega(T, v_2))$$

$$- \sigma_1(t)\int_0^t W_a(t-\tau)\sigma_2(\tau)\left(\frac{1}{2}\partial_x((v_1+v_2)(v_1-v_2))\right)(\tau)d\tau$$

and

$$\omega(T, v_1) - \omega(T, v_2) = \int_0^T W_a(T-\tau)\left(\frac{1}{2}\partial_x((v_1+v_2)(v_1-v_2))\right)(\tau)d\tau.$$

A similar argument shows that

$$\begin{aligned}\|\Gamma(v_1) - \Gamma(v_2)\|_{Y_{s,b}} &\leq \frac{1}{2}\|v_1+v_2\|_{Y_{s,b}}\|v_1-v_2\|_{Y_{s,b}} \\ &\leq cM\|v_1-v_2\|_{Y_{s,b}} \\ &\leq \frac{1}{2}\|v_1-v_2\|_{Y_{s,b}}.\end{aligned}$$

Thus the map Γ is a contraction on S_M provided that δ and M are chosen according to (4.3). As a result, its fixed point $v \in S_M$ is a solution of the integral equation

$$v(t) = \sigma_1(t)W_a(t)G(\phi, \psi + \omega(T, v)) - \sigma_1(t)\int^t \sigma_2(\tau)W_a(t-\tau)(vv_x)(\tau)d\tau$$

for any $t \in R$. In particular, for $t \in (0, T)$,

$$v(t) = W_a(t)G(\phi, \psi + \omega(T, v)) - \int_0^t W_a(t-\tau)(vv_x)(\tau)d\tau.$$

That is to say, $v \in C([0, T]; H^s(R))$ solves the IVP

$$\begin{cases} v_t + vv_x + v_x + (a(x,t)v)_x + v_{xxx} = 0, \\ v(x, 0) = G(\phi, \psi + \omega(T, v)) = h(x) \end{cases}$$

for any $t \in (0, T)$ and satisfies

$$v(x, 0) = \phi(x), \qquad v(x, T) = \psi(x), \qquad \text{on the interval } (\alpha, \beta).$$

The proof is complete. □

Now we turn to the proof of the main theorems described in the introduction of this paper.

Proof of Theorem 1.1. Let u be a solution of (1.5)–(1.6) satisfying

$$u(x,0) = \phi(x)$$

and let

$$z(x,t) = u(x,t) - w(x,t),$$

where w is as given in the assumption. Then $z(x,t)$ solves

$$\begin{cases} z_t + zz_x + z_x + (w(x,t)z)_x + z_{xxx} = 0, \\ z(x,0) = \phi(x) - w(x,0), \\ z(\alpha,t) = \tilde{h_1}(t),\ z(\beta,t) = \tilde{h_2}(t),\ z_x(\beta,t) = \tilde{h_3}(t) \end{cases} \tag{4.4}$$

with

$$\tilde{h_1}(t) = h_1(t) - w(\alpha,t), \quad \tilde{h_2}(t) = h_2(t) - w(\beta,t), \quad \tilde{h_3}(t) = h_3(t) - w_x(\beta,t).$$

Let $\xi(x,t)$ be a smooth function of x and t with compact support in $(\alpha_1,\beta_1)\times(-T,T+1)$ and $\xi(x,t) = 1$ for any $(x,t) \in (\alpha,\beta)\times[0,T]$. Setting $a(x,t) = \xi(x,t)w(x,t)$, we consider the following KdV equation posed on the whole line R:

$$v_t + v_x + vv_x + (a(x,t)v)_x + v_{xxx} = 0, \quad v(x,0) = h(x). \tag{4.5}$$

Note that $a \in Y_{s,b}$ by its definition. It follows from Proposition 4.1 that there exists a $\delta > 0$ such that if $\|(\phi(\cdot) - w(\cdot,0))\|_{H^s(\alpha,\beta)} \le \delta$ and $\|(\psi(\cdot) - w(\cdot,T))\|_{H^s(\alpha,\beta)} \le \delta$, then one can find an $h \in H^s(R)$ such that the corresponding solution v of (4.5) satisfies

$$v(x,0) = \phi(x) - w(x,0), \qquad v(x,T) = \psi(x) - w(x,T)$$

on the interval (α,β). When restricted to the interval (α,β), $a(x,t) \equiv w(x,t)$ and $v(x,t)$ solves (4.4) on the domain $(\alpha,\beta)\times(0,T)$ with

$$h_1(t) = v(\alpha,t) + w(\alpha,t), \quad h_2(t) = v(\beta,t) + w(\beta,t), \quad h_3(t) = v_x(\beta,t) + w_x(\beta,t).$$

Consequently, $u = z(x,t) + w(x,t)$ is the desired solution we are looking for. The proof is complete. □

Proof of Theorem 1.2. Let

$$\tilde{\phi}(x) = \phi(x) - w(x,0) \quad \text{and} \quad \tilde{\psi}(x) = \psi(x) - w(x,T).$$

Applying Proposition 4.1 to

$$v_t + v_x + vv_x + (a(x,t)v)_x + v_{xxx} = 0, \quad v(x,0) = \tilde{h}(x) \tag{4.6}$$

for $x,\ t \in R$, where $a(x,t) = \sigma(t)w(x,t)$ and $\sigma(t)$ is a smooth function with compact support and $\sigma(t) = 1$ for $t \in [0,T]$, yields that there exists an $\tilde{h} \in H^s(R)$ such that (4.6) has a solution v satisfying

$$v(x,0) = \tilde{\phi}(x) \quad \text{and} \quad v(x,T) = \tilde{\psi}(x)$$

on the interval (α, β). Consequently, if we let

$$h(x) = \tilde{h}(x) + w(x, 0)$$

in (1.9), then the corresponding solution u satisfies

$$u(x, 0) = \phi(x) \quad \text{and} \quad u(x, T) = \psi(x)$$

on the interval (α, β). The proof is complete. □

CENTRAL PATHS, GENERALIZED PROXIMAL POINT METHODS, AND CAUCHY TRAJECTORIES IN RIEMANNIAN MANIFOLDS*

ALFREDO N. IUSEM†, B. F. SVAITER†, AND JOÃO XAVIER DA CRUZ NETO‡

Abstract. We study the relationships between three concepts which arise in connection with variational inequality problems: central paths defined by arbitrary barriers, generalized proximal point methods (where a Bregman distance substitutes for the Euclidean one), and Cauchy trajectory in Riemannian manifolds. First we prove that under rather general hypotheses the central path defined by a general barrier for a monotone variational inequality problem is well defined, bounded, and continuous and converges to the analytic center of the solution set (with respect to the given barrier), thus generalizing results which deal only with complementarity problems and with the logarithmic barrier. Next we prove that a sequence generated by the proximal point method with the Bregman distance naturally induced by the barrier function converges precisely to the same point. Furthermore, for a certain class of problems (including linear programming), such a sequence is contained in the central path, making the concepts of central path and generalized proximal point sequence virtually equivalent. Finally we prove that for this class of problems the central path also coincides with the Cauchy trajectory in the Riemannian manifold defined on the positive orthant by a metric given by the Hessian of the barrier (i.e., a curve whose direction at each point is the negative gradient of the objective function at that point in the Riemannian metric).

Key words. convex programming, linear programming, variational inequalities, complementarity problems, interior point methods, central path, generalized distances, proximal point method, Riemannian manifolds

1. Introduction.

We study in this paper the connection among three concepts which arise in relation to convex optimization problems and, more generally, monotone variational inequality problems.

These three concepts are central paths derived from barrier functions, proximal point algorithms with generalized distances, and Cauchy trajectories in Riemannian manifolds. In recent years these notions have been the object of intense study, and many results have been obtained regarding each of them in an independent way.

We will prove that in some cases, including linear programming, these three concepts are in a certain way equivalent, opening the road to a process of cross-fertilization, exchanging the results obtained with each approach. For other problems this equivalence breaks down, but there are nevertheless striking connections, which will be brought forth in our discussion.

It happens to be the case that though many results obtained for these concepts are quite similar, the technical hypotheses made in their proofs are somewhat different. As a consequence, the comparison among results becomes difficult. To overcome this obstacle, we present in section 2 a development of the concept and convergence properties of central paths which generalizes previous expositions both with regard to the type of problems being considered and to the class of barrier functions.

‡Departamento de Matemática, CNN, Universidade Federal do Piauí, Teresina, PI, CEP 64000-00, Brazil (jxavier@ufpi.br).

We start with an informal presentation of these three concepts, beginning with central paths. Given a monotone operator $T : \mathbf{R}^n \to \mathcal{P}(\mathbf{R}^n)$ and a closed and convex set $C \subset \mathbf{R}^n$, the variational inequality problem VIP(T,C) consists of finding $z \in C$ such that, for some $u \in T(z)$, it holds that $\langle u, z - x\rangle \geq 0$ for all $x \in C$ (see [Kin]). Assuming that the interior C^o of C is nonempty, we consider a *barrier* h for C. The function $h : C^o \to \mathbf{R}$ is assumed to be strictly convex and differentiable, and its gradient ∇h must diverge at the boundary ∂C of C. For $\mu \in \mathbf{R}_{++}$ let $x(\mu) \in C$ be such that

$$-\frac{1}{\mu}\nabla h(x(\mu)) \in T(x(\mu)). \tag{1}$$

The set $\{x(\mu) : \mu > 0\}$ is called the *central path* for VIP(T,C) with barrier h. We analyze in section 2 conditions on T, C, and h guaranteeing existence and uniqueness of the central path, which is contained in C^o. (For this reason h is said to be a barrier for VIP(T,C).) If $T = \partial f$ for a convex $f : \mathbf{R}^n \to \mathbf{R} \cup \{\infty\}$, then (1) is equivalent to

$$x(\mu) = \operatorname*{argmin}_{x \in C}\{\mu f(x) + h(x)\}. \tag{2}$$

The problem of interest is the behavior of $x^* = \lim_{\mu\to\infty} x(\mu)$. One expects this limit to exist and to be a solution of VIP(T,C). We will prove in section 2 that this result holds under quite general hypotheses. Another issue to be considered is the characterization of such a limit in a more precise way, particularly when VIP(T,C) has multiple solutions. Here we have to consider two possibilities. Let $S(T, C)$ be the set of solutions of VIP(T,C). We will prove that if the effective domain ED(h) of h intersects $S(T, C)$, then x^* is the solution of

$$\min h(x) \tag{3}$$

$$\text{subject to } x \in S(T, C). \tag{4}$$

The solution of this problem (unique if it exists, by strict convexity of h) is called the *analytic center* of $S(T, C)$ with respect to the barrier h.

Most of the work concerned with central paths for linear programming use the logarithmic barrier $h(x) = -\sum_{j=1}^n \log x_j$, which in general diverges at all optimal solutions, since they belong to the boundary of $\mathbf{R}^n_+$. For cases such as this, we are still able to provide a characterization of x^* in some special cases. Theorem 2 of this paper says that x^* is the solution of

$$\min \tilde{h}(x) \tag{5}$$

$$\text{s.t. } x \in S(T, C) \tag{6}$$

for some appropriate $\tilde{h}$. This theorem covers the cases of linear programming, convex quadratic programming, some monotone linear complementarity problems, and also some cases of linearly constrained nonlinear convex optimization problems and nonlinear complementarity problems.

At this point, it is convenient to relate these results with the existing literature on central paths. The concept of central path has aroused a keen interest in connection with interior point methods for linear programming, because sequences which lie close enough to the central path with respect to the logarithmic barrier $h(x) = -\sum_{j=1}^{n} \log x_j$ enjoy very interesting convergence properties (see [Gon]). The concept can be traced back to [McL], where a very special case is considered. The central path with the logarithmic barrier for the linear programming problem has been considered in [Meg1], and its convergence to the analytic center of the solution set has been proved in [Meg2]. [Adl2] considers the weighted logarithmic barrier $h(x) = -\sum_{j=1}^{n} \sigma_j \log x_j$, with $\sigma_j > 0$, and proves furthermore that $\lim_{\mu \to \infty} \dot{x}(\mu)$ exists and can be well characterized, again in the case of linear programming. The central path with logarithmic barrier for linear complementarity problems is considered in [Koj] and [Mon]. The fact that the central path with logarithmic barrier coincides with the affine scaling path in the case of linear programming has been established in [Bay] and is a particular case of Theorem 4 (see section 4). The central path with the weighted logarithmic barrier for the nonlinear complementarity problem has been studied in [Gul], where it is proved that under adequate assumptions the path is continuous and bounded and that its cluster points are solutions of the problem.

Now we discuss generalized proximal point methods for variational inequality problems. We start with a strictly convex function $g : C \to \mathbf{R}$, continuously differentiable in C^o, and we define $D_g : C \times C^o \to \mathbf{R}$ as $D_g(x, y) = g(x) - g(y) - \langle \nabla g(y), x - y \rangle$. Several technical hypotheses are made on g. (One of them is akin to divergence of ∇g at ∂C; see section 3.) The generalized proximal point algorithm (GPPA) for VIP(T,C) using D_g generates a sequence $\{x^k\} \subset C^o$ in the following way. It starts with $x^0 \in C^o$, and given x^k it defines the operator T_k as

$$T_k(x) = T(x) + \lambda_k \partial_1 D_g(x, x^k), \tag{7}$$

where λ_k is an exogenously given positive number (called the regularization parameter) and ∂_1 indicates the subdifferential with respect to the first argument. Then x^{k+1} is chosen so that

$$0 \in T_k(x^{k+1}). \tag{8}$$

Existing results on this method, established in [Bur2] and [Ius3], are formally presented in section 3, where we study the connection between central paths and GPPA sequences. We prove that the GPPA sequence $\{x^k\}$ converges to the same point as the central path with barrier $h(x) = D_g(x, x^0)$. One could be tempted to conjecture that the sequence $\{x^k\}$ is contained in this central path. We prove that this is the case for linear programming and, more generally, for problems of the type min $c^t x$ s.t. $Ax = b, x \in C$, where C is any closed and convex set with nonempty interior. Moreover, any sequence $\{x(\mu_k)\}$ with increasing $\{\mu_k\}$ can be realized as a GPPA sequence $\{x^k\}$ for a specific choice of the regularization parameters λ_k, making the concepts of central path and GPPA sequence virtually identical in this case and, in particular, for linear programming problems.

On the other hand, for other problems for which convergence to the analytic center holds both for central paths and GPPA sequences (e.g., convex quadratic programming, monotone linear complementarity problems, etc.), the GPPA sequence is not contained in the central path, though both converge to the same point.

We summarize now the history of GPPA. It is an extension of the classical proximal point method (see [Lem]), with $D_g(x, y)$ substituting for $\|x - y\|^2$. It was considered first only for the case of linear programming with $g(x) = \sum_{j=1}^{n} x_j \log x_j$ in [Eri] and then for the same g and general convex optimization problems in [Egg]. The next four steps also dealt only with the convex optimization case ($T = \partial f$ with convex f). In [Cen1] a general g is allowed, but it is assumed that there exist solutions in C^o (so that the constraint set C is superfluous). This hypothesis was removed in [Che], which imposed an additional condition on g (see H4 in section 2) and then in [Ius1], which resulted in a weaker condition (see H2 in section 2). More recently, the method was further generalized in [Kiw2], the results of which are discussed in section 3.

Moving beyond the convex optimization case, the method was studied in [Eck] for the problem of finding zeros of monotone operators and later on in [Bur1], [Bur2] for the more general case of variational inequality problems.

Finally, we discuss in section 4 Cauchy trajectories in Riemannian manifolds. Given a function f defined on a Riemannian manifold M, it is possible to define its gradient grad f with respect to the metric of M, and a *Cauchy trajectory* $x(t)$ is a curve contained in M such that $\dot{x}(t) = -\text{grad } f(x(t))$ for all t. We prove that the central paths introduced in section 2 can be seen in certain cases as Cauchy trajectories in a Riemannian manifold, whose metric is given by the Hessian matrix of the barrier h. The ability of looking at central paths in this way has given, in the case of linear programming with the logarithmic barrier, new insights into the properties of the path. For instance, computational complexity of path following methods has been related to the total Riemannian curvature of the central path (see [Kar]). We hope that our results for general barriers will give rise to similar new insights.

The Cauchy trajectory, also called *gradient trajectory*, has been studied in connection with algorithms for optimization problems in Riemannian manifolds; see, e.g., [Hel].

2. Central paths with general barriers for variational inequalities.

The main goal of this section is to prove that, under quite general hypotheses, the central path $\{x(\mu)\}$ for VIP(T,C) with barrier h converges, as μ goes to ∞, to a solution of VIP(T,C) and that, under more restrictive assumptions, the limit of $\{x(\mu)\}$ is the analytic center of the solution set $S(T,C)$. The set C is assumed to be closed and convex, with nonempty interior C^o.

Next we enumerate the various assumptions on h, T, and C which will be used in this section. Some of them are required in all our results, while others are alternative hypotheses required for some specific results. The first group of assumptions does not involve the operator T. $h : \mathbf{R}^n \to \mathbf{R} \cup \{\infty\}$ is assumed to satisfy the following conditions:

H1. h is strictly convex, closed, and continuous on its effective domain and continuously differentiable in C^o.

H2. If $\{x^k\}$ is a sequence contained in C^o which converges to a point $\bar{x}$ in the boundary ∂C of C, and y is any point in C^o, then $\lim_{k\to\infty}\langle \nabla h(x^k), y - x^k\rangle = -\infty$.

These two assumptions are needed in practically all our results. H2, called *boundary coerciveness*, has been introduced in [Ius1]. It is closely connected to *essential smoothness*, as defined in [Roc1].

Some of our results will require the following additional assumptions:

H3. h is finite, continuous, and strictly convex on C.

We will say that a function satisfying H3 is *finite at the boundary.*

H4. For all $y \in \mathbf{R}^n$ there exists $x \in C^o$ such that $\nabla h(x) = y$.

H3, which entails finiteness of h at any solution of VIP(T,C), simplifies the proof of convergence of the central path to the analytic center. In its absence, the analytic center has to be defined in a more complicated way, with an auxiliary function $\tilde{h}$

instead of h. H4, called *zone coerciveness*, has been introduced in [Cen2], where the relations among H2, H4, and essential smoothness are treated in detail. It has been proved in [Cen2] that when h is twice continuously differentiable with nonsingular Hessian matrix at any point in C^o, H4 implies H2 and they are equivalent when C is bounded. With H4 it is possible to prove existence of the central path without any hypotheses on T beyond monotonicity.

For the case in which C is a *generalized box*, i.e., $C = [\alpha_1, \beta_2] \times \cdots \times [\alpha_n, \beta_n]$, with $\alpha_j \in [-\infty, \infty)$, $\beta_j \in (-\infty, \infty]$, $\alpha_j < \beta_j$, we also consider the following condition, called *separability*:

H5. $h(x) = \sum_{j=1}^n h_j(x_j)$ with $h_j : (\alpha_j, \beta_j) \to \mathbf{R}$.

H5 will be used to prove convergence of the central path to the analytic center, in the absence of H3.

For the case of $C = \mathbf{R}^n_+$, two examples of barrier functions are $h(x) = -\sum_{j=1}^n \log x_j$, which satisfies H1, H2, and H5 but neither H3 nor H4, and $h(x) = \sum_{j=1}^n x_j \log x_j$, which satisfies H1–H5 (with the convention that $0 \log 0 = 0$).

The second group of hypotheses refers to the operator $T : \mathbf{R}^n \to \mathcal{P}(\mathbf{R}^n)$. The first two of them, which are needed in most of our results, are the following:

H6. T is *maximal monotone*; i.e., it is monotone, meaning that $\langle u - v, x - y\rangle \geq 0$ for all $x, y \in \mathbf{R}^n$, $u \in T(x)$, $v \in T(y)$, and if $T(x) \subset T'(x)$ for some monotone operator T' and all $x \in \mathbf{R}^n$, then $T(x) = T'(x)$ for all $x \in \mathbf{R}^n$.

H7. T is *paramonotone*, meaning that it is maximal monotone and additionally $\langle u - v, x - y\rangle = 0$ with $u \in T(x)$, $v \in T(y)$ implies $u \in T(y)$, $v \in T(x)$.

Paramonotonicity has been introduced in [Cen2]. The main properties of paramonotone operators are summarized in the following proposition. For a matrix $B \in \mathbf{R}^{n \times n}$, B^s will denote its symmetric part, i.e., $B^s = 1/2(B + B^t)$ and $rk(B)$ its rank. The Jacobian matrix of a point-to-point and differentiable operator U at a point x will be denoted by $J_U(x)$.

Proposition 1.

i) *If $T = \partial f$ for some convex $f : \mathbf{R}^n \to \mathbf{R} \cup \{\infty\}$, then T is paramonotone.*

ii) *If T is paramonotone, $z \in S(T, C)$ and $\langle u, z - x\rangle \geq 0$ for some $x \in C$ and some $u \in T(x)$, then $x \in S(T, C)$.*

iii) *If T_1 and T_2 are paramonotone, then $T_1 + T_2$ is paramonotone.*

iv) *If T is point-to-point and differentiable, $J_T(x)$ is positive semidefinite (not necessarily symmetric) and* $\operatorname{Ker}(J_T(x)) = \operatorname{Ker}(J_T(x)^s)$ *for all $x \in \mathbf{R}^n$, then T is paramonotone.*

v) *If T is point-to-point and differentiable, $J_T(x)$ is positive semidefinite and $rk(J_T(x)) = rk(J_T(x)^s)$ for all $x \in \mathbf{R}^n$, then T is paramonotone.*

Proof. See [Ius2, Propositions 1, 2, and 6]. □

The following assumption is needed to prove existence of the central path in the absence of H4. Before presenting it, we recall certain known facts on normal cones. For a closed, convex, and nonempty set $V \subset \mathbf{R}^n$, let δ_V be the indicator function of V, i.e.,

$$\delta_V(x) = \begin{cases} 0 & \text{if } x \in V, \\ +\infty & \text{otherwise.} \end{cases}$$

We define the normality operator N_V of V as $N_V(x) = \partial\delta_V(x)$ (i.e., the set of subgradients of δ_V at x). It is easy to check that $N_V(x) = \emptyset$ if $x \notin V$; $N_V(x) = \{0\}$ if $x \in V^o$; $N_V(x)$ is a positive cone for all x; and, given $x \in V$, $v \in N_V(x)$ if and only if

$$\langle v, x' - x\rangle \leq 0. \tag{9}$$

The assumption is the following.

H8. $T = \hat{T} + N_V$ for some point-to-point, continuous, and paramonotone $\hat{T} : \mathbf{R}^n \to \mathbf{R}^n$ and some nonempty, closed, and convex $V \subset \mathbf{R}^n$.

The rationale behind H8 is the following. It is easy to check (e.g., [Roc2]) that the set of solutions of VIP(T,C) is the set of zeros of $T + N_C$ and more generally that

$$S(T, V \cap C) = S(T + N_V, C). \tag{10}$$

Now, in many cases the problem of interest is a variational inequality problem with a well-behaved operator T in a constraint set with empty interior, which makes the introduction of barrier functions difficult. The trick to avoid this obstacle is to write the constraint set as $C \cap V$ with $C^o \neq \emptyset$ and then to transfer the additional constraints, given by V, to the operator, as in (10). For instance, for linear programming we take $C = \mathbf{R}^n_+$, $V = \{x \in \mathbf{R}^n : Ax = b\}$. It is easy to check that for this V we have $N_V(x) = \mathrm{Im}(A^t)$ for all $x \in \mathbf{R}^n$. Our proofs would become much simpler assuming that T is point-to-point and continuous, or at least bounded over bounded sets, but then we lose the option of including affine constraints in the operator.

It follows from Proposition 1(i) and (iii) and the definition of N_V that H8 implies paramonotonicity of T (see H7). It can be easily checked that H8 also implies maximal monotonicity of T (see H6).

The following assumption is needed in order to prove convergence to the analytic center without finiteness of h at the boundary (see H3).

H9. Let $\hat{T}$ and V be as given in H8. V is an affine manifold, $\hat{T}$ is continuously differentiable, and there exists a subspace W such that $\mathrm{Ker}(J_{\widehat{T}}(x)) = W$ for all $x \in C \cap V$.

As examples for which H9 holds we have linear programming, in which case $\hat{T}(x) = c \in \mathbf{R}^n$ so that $J_{\widehat{T}}(x) = 0$ and $W = \mathbf{R}^n$; monotone linear complementarity problems (including convex quadratic programming problems), in which case $\hat{T}(x) = Qx$ with $Q \in \mathbf{R}^{n \times n}$ and $W = \mathrm{Ker}(Q)$; and also many cases of nonlinear operators. Among them we can mention the gradients of self-concordant functions, introduced in [Nes], which satisfy H9 by [Nes, Corollary 2.1.1]. Another case of interest is $\hat{T}(x) = A^t \nabla f(Ax)$, with f twice continuously differentiable and $\nabla^2 f(x)$ positive definite for all $x \in C \cap V$. Then $J_{\widehat{T}}(x) = A^t \nabla^2 f(Ax) A$ and it is easy to check that H9 holds with $W = \mathrm{Ker}(A)$. This case occurs in maximum likelihood estimation problems. A proof of convergence of the central path to the analytic center of the solution set with respect to a special smoothing barrier for this type of problem can be found in [Ius4], from which we took some of the main ideas for this paper.

Finally the third group of assumptions involve both T and C (i.e., VIP(T,C)) and in some cases also the barrier h. First we have two basic and elementary assumptions on VIP(T,C). Let $\mathrm{dom}(T) = \{x \in \mathbf{R}^n : T(x) \neq \emptyset\}$.

H10. $\mathrm{dom}(T) \cap C^o \neq \emptyset$.

A variational inqulity problem satisfying H10 will be said to be *regular*.

H11. $S(T, C) \neq \emptyset$.

We remark that in the presence of H8, H10 becomes equivalent to $V \cap C^o \neq \emptyset$, because $\mathrm{dom}(T) = \mathrm{dom}(\hat{T}) \cap \mathrm{dom}(N_V)$, $\mathrm{dom}(\hat{T}) = \mathbf{R}^n$, and $\mathrm{dom}(N_V) = V$.

Next we need two assumptions in order to guarantee existence of the central path in the absence of zone coerciveness (see H4).

H12. h attains its minimum on $\mathrm{dom}(T) \cap C^o$ at some point $\tilde{x}$.

H12 holds automatically when $h(x) = D_g(x, \tilde{x})$ for some $\tilde{x} \in C^o$ and D_g is a Bregman function (see section 3). The next assumption requires introduction of the gap function $q_{T,C} : \mathbf{R}^n \to \mathbf{R}$ for VIP(T,C), defined as

$$q_{T,C}(x) := \sup_{(v,y)\in G_C(T)} \langle v, x-y\rangle, \tag{11}$$

where $G_C(T) := \{(v,y) : v \in T(y), y \in C\}$. Note that, taking $y = x$ in (11), we get that $q_{T,C}(x) \geq 0$ for all $x \in \mathrm{dom}(T) \cap C$. The assumption on the gap function is the following:

H13. $q_{T,C}(x) < \infty$ for all $x \in \mathrm{dom}(T) \cap C$.

Similar gap functions for variational inequality problems have been considered, e.g., in [Mar] and [Ngu]. We take our $q_{T,C}$ from [Bur1], where it has been proved that H13 holds, e.g., when T is coercive, when T is the subdifferential of a convex function bounded below, when T is strongly monotone, or when $\mathrm{dom}(T) \;\cap\; C$ is bounded (see [Bur1, Proposition 3.1]). It follows easily from (17) that q is convex and that $q_{T,C}(x) \geq 0$ for all $x \in C$. Also, it is easy to check, and is proved in [Bur1] that in the presence of H10 and H11, $q_{T,C}(x) = 0$ if and only if $x \in S(T,C)$. Finiteness of $q_{T,C}$ is a regularity condition which ensures that $T + \partial h$ has zeros for any strictly convex h which attains its global minimizer, even when ∂h is not onto and T does not have zeros (see Proposition 2(ii)).

The last assumption is needed to ensure boundedness of the central path without H4.

H14. Either

i) $S(T,C)$ is bounded and $T = \partial f$ for some convex $f : \mathbf{R}^n \to \mathbf{R} \cup \{\infty\}$,

ii) there exists $y \in C^o \cap \mathrm{dom}(T)$ such that $\lim_{k\to\infty}\langle u^k, x^k - y\rangle = \infty$ for all $\{x^k\}$ such that $\lim_{k\to\infty}\left\|x^k\right\| = \infty$ and all $\{u^k\}$ such that $u^k \in T(x^k)$, or

iii) $\mathrm{dom}(T) \cap C$ is bounded.

H14(ii) holds, e.g., when T is coercive, though it is much weaker than coerciveness. We conjecture that H14 can be replaced, in the proof of boundedness of the central path, by the much simpler and weaker hypothesis of boundedness of $S(T,C)$, but we have not been able to prove the result under this weaker assumption.

We end this preliminary discussion with a few technical lemmas on monotone operators.

LEMMA 1. *If h satisfies* H1 *and is either zone or boundary coercive* (*see* H4 *and* H2, *respectively*), *then dom*$(\partial h) = C^o$.

Proof. See [Bur2, Lemma 1]. □

LEMMA 2. i) *If T_1 and T_2 are maximal monotone operators such that dom*$(T_1) \cap$ *dom*$(T_2)^o \neq \emptyset$, *then $T_1 + T_2$ is maximal monotone.*

ii) *If furthermore T_2 is the subdifferential of a closed and proper convex function, and T_2 is onto, then $T_1 + T_2$ is onto.*

Proof. See [Bur2, Corollary 1]. □

LEMMA 3. *If T is maximal monotone and dom*(T) *is bounded, then T is onto.*

Proof. See [Brez, Corollary 2.2]. □

Finally, after all these preliminaries, we start the study of the central path. For an operator $T : \mathbf{R}^n \to \mathcal{P}(\mathbf{R}^n)$, a convex function h, and a scalar $\mu > 0$, let $T_\mu = \mu T + \partial h$.

PROPOSITION 2. *Assume that h satisfies* H1, *T is maximal monotone* (*see* H6), *VIP(T,C) is regular* (*see* H10), *and either*

i) *h is zone coercive* (*see* H4), *or*

ii) *h is boundary coercive* (*see* H2) *and attains its minimum on dom*$(T) \cap C^o$ (*see* H12), *the gap function is finite everywhere* (*see* H13), *and T satisfies* H8.
Then the operator T_μ has a unique zero $x(\mu)$ which belongs to dom$(T) \cap C^o$.

Proof. i) Let $T_1 = \mu T$, $T_2 = \partial h$. By Lemma 1, $\mathrm{dom}(T_2) = C^o$. By regularity, $\mathrm{dom}(T_1) \cap \mathrm{dom}(T_2)^o \neq \emptyset$. By Lemma 2(i), using H1 and maximal monotonicity of T, $T_\mu = T_1 + T_2$ is maximal monotone. By zone coerciveness of h, T_2 is onto. By Lemma 2(ii) T_μ is onto; i.e., there exists $x \in \mathrm{dom}(T_\mu)$ such that $0 \in T_\mu(x)$. Since h is strictly convex, ∂h is strictly monotone, and therefore, by monotonicity of T, T_μ is strictly monotone, so that the zero is unique. Note that $x \in \mathrm{dom}(T_\mu) = \mathrm{dom}(T_1) \cap \mathrm{dom}(T_2) = \mathrm{dom}(T_1) \cap C^o$. The result holds.

ii) Now, in the absence of zone coerciveness, ∇h is not onto and the argument is more involved. Let $\tilde{x}$ be the minimizer of h in $\mathrm{dom}(T) \cap C^o$ (which exists by H12). By H13, $q_{T,C}(\tilde{x}) < \infty$. We consider two cases:

a) $q_{T,C}(\tilde{x}) = 0$. In this case, as mentioned above, $\tilde{x} \in S(T, C)$. Since $\tilde{x} \in C^o$, it follows that $0 \in T(\tilde{x})$; i.e., using H8,

$$0 = \hat{T}(\tilde{x}) + v \tag{12}$$

with $v \in N_V(\tilde{x})$. On the other hand, since $\tilde{x}$ minimizes h in $\mathrm{dom}(T)$ and $\tilde{x}$ belongs to C^o, $\tilde{x}$ solves VIP(∂h,dom(T)); i.e., $0 \in (\partial h + N_{\mathrm{dom}(T)})(\tilde{x})$ (note that $C^o \subset \mathrm{dom}(T) \subset C$ by Lemma 1). By H8, $\mathrm{dom}(T) = \mathrm{dom}(\hat{T}) \cap \mathrm{dom}(N_V) = \mathbf{R}^n \cap V = V$; i.e.,

$$0 = \nabla h(\tilde{x}) + v', \tag{13}$$

with $v' \in N_V(\tilde{x})$. Let $\bar{v} = \mu v + v'$. Since $N_V(\tilde{x})$ is a cone, $\bar{v} \in N_V(\tilde{x})$. From (12) and (13), $0 = \mu\hat{T}(\tilde{x}) + \bar{v} + \nabla h(\tilde{x})$; i.e., $0 \in (\mu T + \partial h)(\tilde{x}) = T_\mu(\tilde{x})$. Since $\tilde{x} \in \mathrm{dom}(T) \cap C^o$, the result follows.

b) $q_{T,C}(\tilde{x}) > 0$. Let $W = \{x \in C : h(x) \leq \mu q_{T,C}(\tilde{x}) + h(\tilde{x})\}$. W is closed and convex by H1. Observe that $W^o = \{x \in C^o : h(x) < \mu q_{T,C}(\tilde{x}) + h(\tilde{x})\}$. We claim that $V \cap W$ is bounded. By H8, $\mathrm{dom}(T) = V$, so that $V \cap W$ is the intersection of a level set of h with $\mathrm{dom}(T) \cap C$, i.e., a level set of $\hat{h}$ defined as

$$\hat{h}(x) = \begin{cases} h(x) & \text{if } x \in \mathrm{dom}(T) \cap C, \\ \infty & \text{otherwise.} \end{cases}$$

$\hat{h}$ attains its minimum by H12, and the minimizer $\tilde{x}$ is unique by strict convexity of h (see H1). So $\{x \in C : \hat{h}(x) \leq \hat{h}(\tilde{x})\} = \{\tilde{x}\}$. Since $\hat{h}$ has one bounded level set, all its level sets are bounded, in particular $V \cap W$, and the claim is established, noting that $\mu q_{T,C}(\tilde{x})$ is finite by H13.

Let $U = T_\mu + N_W$. As proved in item (i), T_μ is maximal monotone. By assumption, $\tilde{x} \in \mathrm{dom}(T_\mu)$. Since $q_{T,C}(\tilde{x}) > 0$, $\tilde{x} \in W^o = \mathrm{dom}(N_W)^o$. By Lemma 2(i), U is maximal monotone. Note that $\mathrm{dom}(U) = \mathrm{dom}(T_\mu) \cap \mathrm{dom}(N_W) = \mathrm{dom}(\hat{T}) \cap V \cap \mathrm{dom}(\partial h) \cap W = V \cap C^o \cap W \subset W$, using Lemma 1. Since W is bounded, $\mathrm{dom}(U)$ is bounded, and then U is onto by Lemma 3. Therefore there exists $x \in \mathrm{dom}(U) = V \cap C^o \cap W$ such that $0 \in U(x)$. By H8,

$$0 = \mu\hat{T}(x) + \mu v + w + \nabla h(x) \tag{14}$$

with $v \in N_V(x)$, $w \in N_W(x)$. We claim that $x \in W^o$. This is immediate if $x = \tilde{x}$, because $q_{T,C}(\tilde{x}) > 0$. Otherwise, multiplying (14) by $x - \tilde{x}$ and using strict convexity of h,

$$h(x) - h(\tilde{x}) < \langle \nabla h(x), x - \tilde{x}\rangle = \mu\langle \hat{T}(x), \tilde{x} - x\rangle + \mu\langle v, \tilde{x} - x\rangle + \langle w, \tilde{x} - x\rangle. \tag{15}$$

Note that both $\tilde{x}$ and x belong to $V \cap W$. It follows from (9) that the last two inner products in the rightmost expression of (15) are nonpositive, so that

$$h(x) < h(\tilde{x}) + \mu\langle \hat{T}(x), \tilde{x} - x\rangle \le h(\tilde{x}) + \mu q_{T,C}(\tilde{x}) \tag{16}$$

using the definition of $q_{T,C}$ in the last inequality of (16). It follows from (16) and the definition of W that $x \in W^o$, and the claim is established. Then $N_W(x) = \{0\}$, i.e., $w = 0$. Thus, we get from (14) that $0 = \mu\hat{T}(x) + v + \nabla h(x)$, with $v \in N_V(x)$. By H8, $0 \in (\mu T + \partial h)(x) = T_\mu(x)$. Uniqueness follows as in item (i). □

Proposition 2 states that the central path $\{x(\mu) : \mu > 0\}$ given by (1) is well defined and contained in C^o. As mentioned in section 1, if $T(x) = \partial f(x)$, then

$$x(\mu) = \operatorname*{argmin}_{x \in C}\{\mu f(x) + h(x)\}. \tag{17}$$

corresponding to the standard definition of the central path. We prove now that the central path has cluster points. A cluster point of $\{x(\mu)\}$ is a point $\bar{x}$ such that $\bar{x} = \lim_{k\to\infty} x(\mu_k)$ for some sequence $\{\mu_k\}$ such that $\lim_{k\to\infty}\mu_k = \infty$. We need a preparatory result, of some interest on its own.

PROPOSITION 3. *Under the assumptions of Proposition* 2*,*

i) $h(x(\mu))$ *is nondecreasing in* μ*,*

ii) $x(\mu)$ *is continuous at any* $\mu > 0$.

Proof. Take $\mu_1, \mu_2 > 0$ and let $x^i = x(\mu_i)$ $(i = 1, 2)$. By definition of $x(\mu)$, $0 \in T_\mu(x(\mu))$, which is equivalent to $-\mu^{-1}\nabla h(x(\mu)) \in T(x(\mu))$. Let $u^i = -\mu_i^{-1}\nabla h(x^i)$ $(i = 1, 2)$. Then, it holds that

$$u^i \in T(x^i) \qquad (i = 1, 2), \tag{18}$$

$$\frac{1}{\mu_1}(h(x^1) - h(x^2)) \le \frac{1}{\mu_1}\langle \nabla h(x^1), x^1 - x^2\rangle = \langle u^1, x^2 - x^1\rangle, \tag{19}$$

$$\frac{1}{\mu_2}(h(x^2) - h(x^1)) \le \frac{1}{\mu_2}\langle \nabla h(x^2), x^2 - x^1\rangle = \langle u^2, x^1 - x^2\rangle, \tag{20}$$

using convexity of h in the inequalities. Adding (19) and (20)

$$\left(\frac{1}{\mu_1} - \frac{1}{\mu_2}\right)(h(x^1) - h(x^2)) \le \frac{1}{\mu_1}\langle \nabla h(x^1), x^1 - x^2\rangle + \frac{1}{\mu_2}\langle \nabla h(x^2), x^2 - x^1\rangle$$

$$= \langle u^1 - u^2, x^2 - x^1\rangle \le 0, \tag{21}$$

using (18) and monotonicity of T in the second inequality. Assume now that $\mu_1 > \mu_2$. Looking at the extreme expressions in (21), we get

$$h(x^1) \ge h(x^2), \tag{22}$$

establishing (i). By (19), (21), and (22)

$$0 \le \frac{1}{\mu_1}[h(x^1) - h(x^2)] \le \frac{1}{\mu_1}\langle \nabla h(x^1), x^1 - x^2\rangle \le \frac{1}{\mu_2}\langle \nabla h(x^2), x^1 - x^2\rangle. \tag{23}$$

Fix now $\bar{\mu} > 0$, and take $\hat{\mu}$, $\tilde{\mu}$ such that $\tilde{\mu} > \bar{\mu} > \hat{\mu}$. For any $\mu \in (\hat{\mu}, \tilde{\mu})$ we get

$$h(x(\mu)) \leq h(x(\tilde{\mu})) \tag{24}$$

using (22) with $\mu_1 = \tilde{\mu}$, $\mu_2 = \mu$, and

$$0 \leq \langle \nabla h(x(\hat{\mu})), x(\mu) - x(\hat{\mu}) \rangle \tag{25}$$

using (23) with $\mu_1 = \mu$, $\mu_2 = \hat{\mu}$. Let $L_1 = \{x \in C : h(x) \leq h(x(\tilde{\mu}))\}$, $L_2 = \{x \in C : \langle \nabla h(x(\hat{\mu})), x - x(\hat{\mu}) \rangle \geq 0\}$, and $L = L_1 \cap L_2$. By Proposition 2, (24), and (25), $\{x(\mu) : \hat{\mu} \leq \mu \leq \tilde{\mu}\} \subset L$. We claim that L is bounded. Define $\bar{h}$ as

$$\bar{h}(x) = \begin{cases} h(x) & \text{if } x \in L_2, \\ \infty & \text{otherwise.} \end{cases}$$

It is easy to see that $\bar{h}$ is strictly convex and that $x(\hat{\mu})$ is its unique minimizer, so that $\bar{h}$ has one bounded level set, and therefore all its level sets are bounded, among them L, which can be written as $\{x \in \mathbf{R}^n : \bar{h}(x) \leq \bar{h}(x(\tilde{\mu}))\}$. The claim is established, and therefore $\{x(\mu) : \hat{\mu} \leq \mu \leq \tilde{\mu}\}$ is bounded. In order to prove that $x(\mu)$ is continuous at $\bar{\mu}$, it suffices to prove that $\lim_{k\to\infty} x(\mu_k) = x(\bar{\mu})$ for any sequence $\{\mu_k\}$ such that $\lim_{k\to\infty} \mu_k = \bar{\mu}$. Given such a sequence $\{\mu_k\}$, $\mu_k \in (\hat{\mu}, \tilde{\mu})$ for large enough k, so that $\{x(\mu_k)\}$ is bounded. Let y be any cluster point of $\{x(\mu_k)\}$, $\bar{x} = x(\bar{\mu})$, and $x^k = x(\mu_k)$. Without loss of generality (i.e., refining the sequence if necessary), we may assume that $y = \lim_{k\to\infty} x^k$.

Let $K_1 = \{k : \mu_k \leq \bar{\mu}\}$ and take $k \in K$. Using (23) with $\mu_1 = \bar{\mu}$, $\mu_2 = \mu_k$, we get, by convexity of h,

$$\frac{1}{\bar{\mu}}[h(\bar{x}) - h(x^k)] \leq \frac{1}{\bar{\mu}}\langle \nabla h(\bar{x}), \bar{x} - x^k \rangle \leq \frac{1}{\mu_k}\langle \nabla h(x^k), \bar{x} - x^k \rangle \leq \frac{1}{\mu_k}[h(\bar{x}) - h(x^k)]. \tag{26}$$

Note that $\{x^k\} \subset L_1 \subset \mathrm{ED}(h)$. By H1, h is continuous at $y = \lim_{k\to\infty} x^k$, and hence $y \in ED(h)$. Then, if K_1 is infinite, we take limits in (26) as k goes to ∞, with $k \in K_1$, obtaining

$$\frac{1}{\bar{\mu}}[h(\bar{x}) - h(y)] \leq \frac{1}{\bar{\mu}}\langle \nabla h(\bar{x}), \bar{x} - y \rangle \leq \frac{1}{\bar{\mu}}[h(\bar{x}) - h(y)]. \tag{27}$$

From (27), we get $h(\bar{x}) - h(y) = \langle \nabla h(\bar{x}), \bar{x} - y \rangle$. By strict convexity of h, $y = \bar{x}$. If K_1 is finite (or empty), then we consider the complement K_2 of K_1, which certainly is infinite, and apply (23) with $\mu_1 = \mu_k$, $\mu_2 = \bar{\mu}$, obtaining a chain of inequalities similar to (26). After passing to the limit as k goes to ∞, with $k \in K_2$, we get a chain of inequalities like (27) with the roles of $\bar{x}$ and y reversed and obtain again that $y = \bar{x}$. We have proved that in any case all cluster points of x^k are equal to $\bar{x}$. We conclude that $\lim_{k\to\infty} x^k = \bar{x}$, i.e., that $x(\mu)$ is continuous at $\bar{\mu}$. □

With the help of Proposition 3(i), we prove now, under several alternative hypotheses, that the set $\{x(\mu) : \mu \geq \bar{\mu}\}$ is bounded for any $\bar{\mu} > 0$.

PROPOSITION 4. *Assume that T satisfies* H8, *that VIP(T,C) has solutions* (*see* H11), *that h attains its minimum in dom(T) $\cap$ C^o* (*see* H12) *and that all the hypotheses of Proposition* 2 *hold. If either*

i) *h is finite at the boundary* (*see* H3), *or*

ii) H14 *holds,*

then $\{x(\mu)\}$ has cluster points.

Proof. We start with a basic chain of inequalities which will be used in this and other proofs. By definition of $x(\mu)$, $-\mu^{-1}\nabla h(x(\mu)) \in T(x(\mu))$. Then, for all $y \in V$,

$$\frac{1}{\mu}\langle \nabla h(x(\mu)), x(\mu) - y\rangle = \langle \hat{T}(x(\mu)), y - x(\mu)\rangle + \langle v, y - x(\mu)\rangle$$

$$\leq \langle \hat{T}(x(\mu)), y - x(\mu)\rangle \leq \langle \hat{T}(y), y - x(\mu)\rangle, \tag{28}$$

with $v \in N_V(x(\mu))$, using H8 in the equality, (9) in the first inequality, and monotonicity of T in the second one.

Consider the first case (i). By H11, $S(T,C) \neq \emptyset$. Take $z \in S(T,C)$. Since h is finite at the boundary (see H3), $z \in \mathrm{ED}(h)$. Take $y = z$ in (28), and get

$$\frac{1}{\mu}[h(x(\mu)) - h(z)] \leq \frac{1}{\mu}\langle \nabla h(x(\mu)), x(\mu) - z\rangle \leq \langle \hat{T}(x(\mu)), z - x(\mu)\rangle, \tag{29}$$

using H1 in the first inequality. Since $N_V(x(\mu))$ is a positive cone, $0 \in N_V(x(\mu))$, i.e., $\hat{T}(x(\mu)) \in T(x(\mu))$, and, since $z \in S(T,C)$, $\langle \hat{T}(x(\mu)), z - x(\mu)\rangle \leq 0$. It follows from (29) that $h(x(\mu)) \leq h(z)$ for all $\mu > 0$. As in the proof of Proposition 2, H12 implies that the intersections of V with the level sets of h are bounded, and $\{x(\mu)\}$ is contained in one of them. The result follows.

Now we consider hypothesis (ii). If h fails to be finite at the boundary, we may have $h(z) = \infty$ for all $z \in S(T,C)$ and the previous argument breaks down. Now, under H14(i), $T = \partial f$, so that $-\mu^{-1}\nabla h(x(\mu)) \in T(x(\mu)) = \partial f(x(\mu))$. Fix $\bar{\mu} > 0$ and take any $\mu \geq \bar{\mu}$. Therefore

$$\frac{1}{\mu}[h(x(\mu)) - h(x(\bar{\mu}))] \leq \frac{1}{\mu}\langle \nabla h(x(\mu)), x(\mu) - x(\bar{\mu})\rangle \leq f(x(\bar{\mu})) - f(x(\mu)) \tag{30}$$

using convexity of h in the first inequality and convexity of f in the second one. Use Proposition 3 and (30) to conclude that $f(x(\mu)) \leq f(x(\bar{\mu}))$. So, $\{x(\mu) : \mu \geq \bar{\mu}\}$ is contained in a level set of f. By C5, VIP(T,C) is equivalent to min $f(x)$ s.t. $x \in C$ and the set of solutions of this problem, which is a level set of the restriction of f to C, is bounded. Then all such level sets are bounded, and it follows that $\{x(\mu) : \mu \geq \bar{\mu}\}$ is bounded. Thus, $\{x(\mu)\}$ has cluster points.

Consider next assumption H14(ii). Fix $\bar{\mu} > 0$. Let $u = -\mu^{-1}\nabla h(x(\mu)) \in T(x(\mu))$. By H1, with $\mu \geq \bar{\mu}$ and y as in H14(ii),

$$\langle u, x(\mu) - y\rangle \leq \frac{1}{\mu}[h(y) - h(x(\mu))] \leq \frac{1}{\mu}[h(y) - h(x(\bar{\mu}))]$$

$$\leq \frac{1}{\mu}\left|h(y) - h(x(\bar{\mu}))\right| \leq \frac{1}{\bar{\mu}}\left|h(y) - h(x(\bar{\mu}))\right|, \tag{31}$$

using Proposition 3(i) in the second inequality. Let θ be the rightmost expression in (31). If $\{x(\mu) : \mu \geq \bar{\mu}\}$ is unbounded, there exists a sequence $\{\mu_k\}$ such that $\lim_{k\to\infty}\|x(\mu_k)\| = \infty$ and $\langle u^k, x(\mu_k) - y\rangle \leq \theta$ for all k, with $u^k = -\mu_k^{-1}\nabla h(x(\mu_k)) \in T(x(\mu_k))$, in contradiction with H14(ii). So $\{x(\mu) : \mu \geq \bar{\mu}\}$ is bounded and the result holds.

The result is immediate under assumption H14(iii), because $\{x(\mu)\} \subset \mathrm{dom}(T) \cap C$. □

Now we prove that the cluster points of $\{x(\mu)\}$ solve VIP(T,C). This is the point where the paramonotonicity assumption implicit in H8 is used for the first time.

PROPOSITION 5. *Under the assumptions of Proposition* 4*, all cluster points of* $\{x(\mu)\}$ *are solutions of VIP(T,C).*

Proof. Take $z \in S(T,C)$ and $y \in V \cap C^o$ (both sets are nonempty by H10, H11). Let $\bar{x}$ be a cluster point of $\{x(\mu)\}$ (which exists by Proposition 4) and $\{\mu_k\}$ a sequence such that $\lim_{k\to\infty} \mu_k = \infty$ and $\lim_{k\to\infty} x(\mu_k) = \bar{x}$. Let $x^k = x(\mu_k)$ and $y(\varepsilon) = (1-\varepsilon)z + \varepsilon y$ with $\varepsilon \in (0,1)$. Then $y(\varepsilon) \in V \cap C^o$ and using (28)

$$\frac{1}{\mu_k}\langle \nabla h(y(\varepsilon)), x^k - y(\varepsilon)\rangle \le \langle \hat{T}(x^k), y(\varepsilon) - x^k\rangle. \tag{32}$$

Since $\lim_{k\to\infty}\langle \nabla h(y(\varepsilon)), x^k - y(\varepsilon)\rangle$ has the finite value $\langle \nabla h(y(\varepsilon)), \bar{x} - y(\varepsilon)\rangle$, the leftmost expression in (32) converges to 0 as k goes to ∞. Thus, taking limits in (32) we get

$$0 \le \langle \hat{T}(\bar{x}), y(\varepsilon) - \bar{x}\rangle \tag{33}$$

using H8. Taking limits in (33) as ε goes to 0, we get $0 \le \langle \hat{T}(\bar{x}), z - \bar{x}\rangle$. Since $\bar{x} \in V$ because V is closed, $0 \in N_V(\bar{x})$, and therefore $\hat{T}(\bar{x}) \in T(\bar{x})$. By Proposition 1(i) and (iii) and paramonotonicity of $\hat{T}$, T is paramonotone. By Proposition 1(ii), $\bar{x}$ solves VIP(T,C). □

Now we establish convergence of $\{x(\mu)\}$ to the analytic center of $S(T,C)$ when h is finite at the boundary (see H3). In this case H9 is not needed.

PROPOSITION 6. *Under the assumptions of Proposition* 4 *if h is finite at the boundary* (*see* H3), *then* $\lim_{\mu\to\infty} x(\mu)$ *exists and is the solution of*

$$\min h(x) \tag{34}$$

$$s.t.\ x \in S(T,C). \tag{35}$$

Proof. Let $\bar{x}$ be a cluster point of $\{x(\mu)\}$. $\bar{x} \in S(T,C)$ by Proposition 5. Take a sequence $\{x^k\}$ as in the proof of Proposition 5, and $z \in S(T,C)$. Then, using (28),

$$\frac{1}{\mu_k}\langle \nabla h(x^k), x^k - z\rangle \le \langle \hat{T}(x^k), z - x^k\rangle. \tag{36}$$

Since $x^k \in V$, $0 \in N_V(x^k)$, and so $\hat{T}(x^k) \in T(x^k)$. Since $z \in S(T,C)$ and $x^k \in C$, it follows that the right-hand side of (36) is nonpositive, so that, using convexity of h in (36), we get

$$h(x^k) - h(z) \le \langle \nabla h(x^k), x^k - z\rangle \le 0. \tag{37}$$

Since h is finite at the boundary, taking limits in (37) as k goes to ∞, we get $h(\bar{x}) \le h(z)$. Since z is an arbitrary element in $S(T,C)$, it follows that $\bar{x}$ minimizes h in $S(T,C)$. Since $S(T,C)$ is convex for monotone T and h is strictly convex in C by H3, the minimizer is unique. Therefore all cluster points coincide and $\{x(\mu)\}$ converges, as μ goes to ∞, to the solution of (34)–(35). □

Before proving a result similar to Proposition 6 without finiteness of h at the boundary, we summarize the results of Propositions 2–6 in the following theorem.

Theorem 1. *Assume that h satisfies* H1, *is boundary coercive* (*see* H2), *and attains its minimum on dom(T) $\cap C^o$* (*see* H12); *that T satisfies* H8; *that VIP(T,C) is regular and has solutions* (*see* H10 *and* H11); *and additionally that either*

i) *h is zone coercive and finite at the boundary* (*see* H4 *and* H3), *or*

ii) *the gap function is finite* (*see* H13) *and any of the alternatives in* H14 *holds. Then for any $\bar{\mu} > 0$ the curve $\{x(\mu) : \mu \geq \bar{\mu}\}$ is well defined, continuous, bounded, and contained in C^o, and all its limit points are solutions of VIP(T,C). In the case in which h is finite at the boundary, the path converges to the analytic center of the solution set with respect to the barrier h, i.e., to the solution of* (34)–(35).

Proof. We get that $\{x(\mu)\}$ is well defined and contained in C^o from Proposition 2. We remark that the hypotheses of Proposition 2 hold in all the cases we are considering here, because H8 implies maximal monotonicity of T. The remaining results follow from Propositions 3(ii), 4, 5, and 6, all of whose hypotheses are included in the assumptions of this theorem. □

We mention here specifically the case of the optimization problem, i.e., min $f(x)$ s.t. $x \in C$, where f is the restriction of a convex and differentiable function $\hat{f} : \mathbf{R}^n \to \mathbf{R}$ to a closed and convex set V. In this case H8 holds with $\hat{T} = \nabla \hat{f}$, and we get boundedness of the central path and optimality of the cluster points under H1, H2, H10, H11, H12, and additionally either H3 and H4, or boundedness of the solution set and convergence of the whole path to the analytic center of the solution set under H3. The case of a nondifferentiable function is not precisely covered here, because, taking $\hat{T} = \partial f$, $\hat{T}$ is not point-to-point in general. This is part of the bit of generality lost when we decided to use H8 instead of pseudomonotonicity (see section 3). The result can be obtained for this case also, at the cost of quite a few technical complications in the proofs.

Finally we proceed to study the limit of $x(\mu)$ without finiteness of h at the boundary (see H3). We impose more restrictive assumptions. First we assume that C is a box and that h is separable (see H5). For the sake of simplicity we will take $C = \mathbf{R}^n_+$, but the result holds without any changes in an arbitrary box, either bounded or unbounded. We will assume also that T satisfies both H8 and H9. We need two preparatory results. The first one establishes that under these hypotheses $S(T,C)$ is a polyhedron.

Proposition 7. *Assume that T satisfies* H8–H9, *and that VIP(T,C) is regular and has solutions* (*see* H10 *and* H11). *Fix any $z \in S(T,C)$ and any $\tilde{x} \in C \cap V$. Then*

$$S(T,C) = \{x \in V \cap C : \hat{T}(\tilde{x})^t x = \hat{T}(\tilde{x})^t z, J_{\hat{T}}(\tilde{x})x = J_{\hat{T}}(\tilde{x})z\}. \tag{38}$$

Proof. See [Ius3, Proposition 2.4]. □

We remark that the proof of Proposition 7 does not require V to be an affine manifold, as in H9, but just a closed and convex set, as in H8. But it requires that the kernel of the Jacobian matrix of $\hat{T}$ be constant. When $C \cap V$ is a polyhedron, it follows that $S(T,C)$ is also a polyhedron, namely the intersection of $V \cap C$ with the affine manifold defined by the linear equations in (38).

We need also an intermediate optimality result, for which polyhedrality of $C \cap V$ is essential.

Proposition 8. *Let $C = \mathbf{R}^n_+$. Under the assumptions of Propositions* 2 *and* 7, *the point $x(\mu)$ belonging to the central path is the solution of*

$$\min h(x) \tag{39}$$

$$s.t.\ x \in S(\mu), \tag{40}$$

where

$$S(\mu)=\{x\in\mathbf{R}^n:\hat{T}(\tilde{x})^tx=\hat{T}(\tilde{x})^tx(\mu),J_{\widehat{T}}(\tilde{x})x=J_{\widehat{T}}(\tilde{x})x(\mu),Ax=b,x\geq 0\},\tag{41}$$

$V=\{x\in\mathbf{R}^n:Ax=b\}$, *and* $\tilde{x}$ *is any point in* $C\cap V$.

Proof. $x(\mu)$ is well defined and contained in C^o by Proposition 2. Since $x(\mu)\in C^o\cap V$, it follows that $x(\mu)\in S(\mu)$. By convexity of h, it suffices to check the Karush–Kuhn–Tucker conditions for (39)–(40), which are $x(\mu)\in S(\mu)$ (already checked), and existence of $u\in\mathbf{R}^m$, $w\in\mathbf{R}^n$, and $\xi\in\mathbf{R}$ such that

$$\nabla h(x(\mu))+A^tu+J_{\widehat{T}}(\tilde{x})^tw+\xi\hat{T}(\tilde{x})\geq 0,\tag{42}$$

$$x(\mu)^t[\nabla h(x(\mu))+A^tu+J_{\widehat{T}}(\tilde{x})^tw+\xi\hat{T}(\tilde{x})]=0.\tag{43}$$

We will exhibit u, w, and ξ such that (42) holds with equality and consequently (43) also holds. By definition of $x(\mu)$, $-1/\mu\nabla h(x(\mu))\in T(x(\mu))$; i.e., there exists $v\in N_V(x(\mu))$ such that

$$-\frac{1}{\mu}\nabla h(x(\mu))=\hat{T}(x(\mu))+v.\tag{44}$$

It is easy to check that $N_V(x)=\text{Im}(A^t)$ for all $x\in V$. Thus $\mu v\in\text{Im}(A^t)$; i.e., $\mu v=A^tu$ for some $u\in\mathbf{R}^m$ and (44) can be rewritten as

$$\nabla h(x(\mu))+\mu\hat{T}(x(\mu))+A^tu=0.\tag{45}$$

Now, we write $\hat{T}(x(\mu))$ as

$$\hat{T}(x(\mu))=\hat{T}(\tilde{x})+\int_0^1 J_{\widehat{T}}(y(\tau))(x(\mu)-\tilde{x})d\tau,\tag{46}$$

with $y(\tau)=\tilde{x}+\tau(x(\mu)-\tilde{x})$. It is well known and easy to prove (e.g., see [Ius3, Proposition 2.2]) that for a monotone and differentiable operator U it holds that $\text{Ker}(J_U(x))=\text{Ker}(J_U(x)^t)$. Then, using H9,

$$J_{\widehat{T}}(y(\tau))(x(\mu)-\tilde{x})\in\text{Im}[J_{\widehat{T}}(y(\tau))]=\text{Ker}[J_{\widehat{T}}(y(\tau))^t]^\perp=\text{Ker}[J_{\widehat{T}}(y(\tau))]^\perp=W^\perp.$$

It follows that $\int_0^1 J_{\widehat{T}}(y(\tau))(x(\mu)-\tilde{x})d\tau\in W^\perp$, and therefore, by (46) and H9, $\mu\hat{T}(x(\mu))=\mu\hat{T}(\tilde{x})+p$, with $p\in W^\perp=\text{Ker}[J_{\widehat{T}}(\tilde{x})]^\perp=\text{Im}[J_{\widehat{T}}(\tilde{x})^t]$, so that $p=J_{\widehat{T}}(\tilde{x})^tw$ for some $w\in\mathbf{R}^n$. We conclude that

$$\mu\hat{T}(x(\mu))=\mu\hat{T}(\tilde{x})+J_{\widehat{T}}(\tilde{x})^tw.\tag{47}$$

Replacing (47) in (45),

$$\nabla h(x(\mu))+\mu\hat{T}(\tilde{x})+J_{\widehat{T}}(\tilde{x})^tw+A^tu=0,\tag{48}$$

which gives equality in (42) with $\xi=\mu$. □

The idea now is to push the optimality property of $x(\mu)$ given in Proposition 8 to the limit as $\mu\to\infty$, so that $S(\mu)$ becomes $S(T,C)$ by Proposition 7. The problem is that $\lim_{\mu\to\infty}x(\mu)$ may belong to ∂C where h is possibly ∞. We must work now with the optimal face of the orthant and use the separability of h (H5), under which

$h(x) = \sum_{j=1}^{n} h_j(x_j)$. Let $J = \{j \in \{1, \dots, n\} : \exists z \in S(T,C) \text{ such that } z_j > 0\}$. By convexity of $S(T,C)$ the set $\{z \in S(T,C) : z_j > 0 \text{ for all } j \in J\}$ is nonempty, and it is in fact the relative interior of $S(T,C)$. We define $\tilde{h} : \mathbf{R}^n_{++} \to \mathbf{R}$ as

$$\tilde{h}(x) = \sum_{j \in J} h_j(x_j). \tag{49}$$

We prove now the optimality property of $\lim_{\mu\to\infty} x(\mu)$ without finiteness of h at the boundary (see H3).

THEOREM 2. *Let $C = \mathbf{R}^n_+$. Assume that h satisfies* H1, *is boundary coercive* (*see* H2) *and separable* (*see* H5) *and attains its minimum in dom* $(T) \cap C^o$ (*see* H12); *that T satisfies* H8–H9; *that VIP(T,C) is regular* (*see* H10) *and has solutions* (*see* H11), *and its gap function is finite* (*see* H13); *and that some of the alternatives in* H14 *hold. Then the central path $\{x(\mu)\}$ converges as $\mu \to \infty$ to the solution x^* of*

$$\min \tilde{h}(x) \tag{50}$$

$$s.t.\ x \in S(T,C), \tag{51}$$

with $\tilde{h}$ as in (49).

Proof. By Theorem 1, $\{x(\mu)\}$ has cluster points. Let $\bar{x}$ be a cluster point of $\{x(\mu)\}$ and $\{\mu_k\}$ a sequence such that $\lim_{k\to\infty} \mu_k = \infty$, $\lim_{k\to\infty} x(\mu_k) = \bar{x}$. Call $x^k = x(\mu_k)$. Fix some $\tilde{x} \in V \cap C$ as in Propositions 7 and 8. Take any $z \in S(T,C)$. We will prove that

$$\tilde{h}(\bar{x}) \le \tilde{h}(z). \tag{52}$$

We consider first the case in which z belongs to the relative interior of $S(T,C)$; i.e., $z_j > 0$ for all $j \in J$. Define $y^k = z - \bar{x} + x^k$. We claim that $y^k \in S(\mu_k)$ for large enough k, with $S(\mu_k)$ as in (41). Let $I = \{1, \dots, n\} \setminus J$. It follows from the definition of J that $x_j = 0$ for all $j \in I$ and all $x \in S(T,C)$. Since $\bar{x} \in S(T,C)$ by Theorem 1 and $z \in S(T,C)$ by assumption, we get

$$y^k_j = x^k_j \qquad (j \in I). \tag{53}$$

Since $x^k \in C^o$ by Proposition 2, we have $y^k_j > 0$ for $j \in I$. For $j \in J$, we have $y^k_j = z_j - \bar{x}_j + x^k_j$. Since $\lim_{k\to\infty} x^k_j = \bar{x}_j$ and $z_j > 0$ for $j \in J$, we have $y^k_j > 0$ for $j \in J$ and k large enough. We conclude that $y^k > 0$ for large enough k.

Let the set V of H8, H9 be equal to $\{x \in \mathbf{R}^n : Ax = b\}$. Since $\bar{x}$, $z \in S(T,C) \subset \text{dom}(T) = \mathbf{R}^n \cap V = V$, we have $Az = A\bar{x} = b$, and therefore $Ay^k = Ax^k = b$, because $x(\mu) \in \text{dom}(T) \subset V$. So, it suffices to check that $\hat{T}(\tilde{x})^t(x^k - y^k) = 0$ and that $J_{\widehat{T}}(\tilde{x})(y^k - x^k) = 0$. Since $x^k - y^k = \bar{x} - z$, this follows from Proposition 7, because $\bar{x} \in S(T,C)$ by Theorem 1. We have proved that $y^k \in S(\mu_k)$. By Proposition 8, $h(x^k) \le h(y^k)$; i.e.,

$$\tilde{h}(x^k) + \sum_{j \in I} h_j(x^k_j) \le \tilde{h}(y^k) + \sum_{j \in I} h_j(y^k_j). \tag{54}$$

From (53) and (54),

$$\tilde{h}(x^k) \le \tilde{h}(y^k). \tag{55}$$

Now, since we do not have finiteness of h at the boundary (see H3), we must be careful with the behavior of $\tilde{h}$ at the boundary of $\mathbf{R}^n_+$. It follows from H1 and the separability of h (see H5) that $h_j : \mathbf{R}_{++} \to \mathbf{R}$ is continuous and closed. Thus, $\lim_{t\to 0} h_j(t)$ is well defined (possibly infinity), and we can take limits in (55) as k goes to ∞. Since $\lim_{k\to\infty} y^k = z$, $\lim_{k\to\infty} x^k = \bar{x}$, and $z_j > 0$ for all $j \in J$, we conclude that

$$\tilde{h}(\bar{x}) \leq \tilde{h}(z) < \infty \tag{56}$$

for any z in the relative interior of $S(T, C)$. By the same argument as above, (56) holds in fact for all $z \in S(T, C)$ (note that $\tilde{h}(z)$ might be infinite for some z in the relative boundary of $S(T, C)$, i.e., such that $z_j = 0$ for some $j \in J$). So $\bar{x}$ solves (50)–(51). Observe that $\tilde{h}$ is not strictly convex in $\mathbf{R}^n_{++}$, but it is strictly convex in $S(T, C)$ because h_j is strictly convex by H1 and $x_j = 0$ for all $j \notin J$ and all $x \in S(T, C)$, by definition of J. Therefore problem (50)–(51) has a unique solution, and since all cluster points of $\{x(\mu)\}$ are equal to this solution, we conclude that $\lim_{\mu\to\infty} x(\mu)$ exists and that the result holds. □

3. Generalized proximal point methods for variational inequalities. Let C be a closed and convex subset of $\mathbf{R}^n$, with nonempty interior. Consider a function $g : C \to \mathbf{R}$ satisfying H1 and H3 of section 2, and define $D_g : C \times C^o \to \mathbf{R}$ as

$$D_g(x, y) = g(x) - g(y) - \langle \nabla g(y), x - y \rangle.$$

g is said to be a Bregman function if it satisfies H1 and H3 of section 2 and, additionally, the following hold.

B1. For all $\nu \in \mathbf{R}$ the partial level sets $\Gamma(x, \nu) = \{y \in C^o : D_g(x, y) \leq \nu\}$ are bounded for all $x \in C$.

B2. If $\{y^k\} \subset C^o$ converges to y^*, then $D_g(y^*, y^k)$ converges to 0.

B3. If $\{x^k\} \subset C$ and $\{y^k\} \subset C^o$ are sequences such that $\{x^k\}$ is bounded, $\lim_{k\to\infty} y^k = y^*$ and $\lim_{k\to\infty} D_g(x^k, y^k) = 0$, then $\lim_{k\to\infty} x^k = y^*$.

C^o is called the *zone* of g. This definition originates in the results of [Breg]. It is easy to check that $D_g(x, y) \geq 0$ for all $x \in C$, $y \in C^o$, and $D_g(x, y) = 0$ if and only if $x = y$. Also, $D_g(\cdot, y)$ is strictly convex and continuous in C for all $y \in C^o$.

As examples of Bregman functions for the case of $C = \mathbf{R}^n_+$ we have the following.

Example 1. $g(x) = \sum_{j=1}^n x_j \log x_j$, extended with continuity to $\partial\mathbf{R}^n_+$ with the convention that $0 \log 0 = 0$. In this case $D_g(x, y) = \sum_{j=1}^n (x_j \log \frac{x_j}{y_j} + y_j - x_j)$, which is the Kullback–Leibler divergence, widely used in statistics (see [Lie]).

Example 2. $g(x) = \sum_{j=1}^n (x_j^\alpha - x_j^\beta)$ with $\alpha \geq 1$, $0 < \beta < 1$. For $\alpha = 2$, $\beta = \frac{1}{2}$ we get $D_g(x, y) = \|x - y\|^2 + \sum_{j=1}^n \frac{1}{2\sqrt{y_j}}(\sqrt{x_j} - \sqrt{y_j})^2$, and for $\alpha = 1$, $\beta = \frac{1}{2}$, we get $D_g(x, y) = \sum_{j=1}^n \frac{1}{2\sqrt{y_j}}(\sqrt{x_j} - \sqrt{y_j})^2$.

The functions g of Examples 1 and 2 satisfy B1–B3 and H1–H5, except for the case of g as in Example 2 with $\alpha = 1$, which fails to satisfy only H4. Examples of Bregman functions for other convex sets, like balls, boxes, and polyhedra with nonempty interiors, can be found in [Cen2].

If we discard H3, we can consider also $g(x) = -\sum_{j=1}^n \log x_j$, which satisfies H1, H2, H5, and B1–B3. In this case $D_g : C^o \times C^o \to \mathbf{R}$ is given by

$$D_g(x, y) = \sum_{j=1}^n \left[\frac{x_j}{y_j} - \log\left(\frac{x_j}{y_j}\right) - 1 \right] \tag{57}$$

and is called the Itakura–Saitu distance (see [Csi]).

The GPPA algorithm for VIP(T,C) is defined as follows. Take a Bregman function g with zone C^o and a sequence $\{\lambda_k\}$ of positive numbers bounded above by some $\bar{\lambda} > 0$. Let $\{x^k\}$ be defined by the following.

INITIALIZATION:

$$x^0 \in C^o.$$

ITERATIVE STEP: Given x^k, consider the operator T_k defined by

$$T_k(\cdot) = T(\cdot) + \lambda_k[\nabla g(\cdot) - \nabla g(x^k)]. \tag{58}$$

Then, take x^{k+1} such that

$$0 \in T_k(x^{k+1}). \tag{59}$$

We summarize the convergence properties of this algorithm in the following proposition.

PROPOSITION 9. *Assume that g satisfies* H1, H3, *and* B1–B3, *T satisfies* H8–H9, *and VIP(T,C) satisfies* H10–H11. *If either* H2 *and* H13 *or* H4 *holds, then the sequence $\{x^k\}$ generated by GPPA* (*i.e., by* (58)–(59)) *converges to the solution of*

$$\min D_g(x, x^0) \tag{60}$$

$$s.t.\ x \in S(T, C). \tag{61}$$

Proof. See [Ius3, Theorem 5.1]. □

The proof of Proposition 9 addresses mainly the issue of characterizing the limit of the sequence as the solution of (60)–(61), using H9. The fact that the sequence does converge was previously proved in [Bur2, Corollary 3], and does not require H9. This proof uses H6, H7, and a hypothesis which is weaker than H8, namely *pseudomonotonicity*, which is rather technical.

We study next the connection between the central path and the GPPA. Our first result is just a corollary of Theorem 1 and Proposition 9 and shows that in many relevant cases the GPPA sequence and the central path (with the Bregman function as a barrier) converge precisely to the same point.

COROLLARY 1. *Assume that T satisfies* H8 *and* H9; *that g satisfies both* H1 *and the Bregman assumptions* B1–B3 *and is zone coercive* (H4) *and finite at the boundary* (H3); *and that VIP(T,C) is regular and has solutions* (H10–H11). *Let $\{x^k\}$ be the sequence generated by GPPA with Bregman function g starting at some $x^0 \in$ dom$(T) \cap C^o$ and $\{x(\mu)\}$ the central path with barrier $h(x) = D_g(x, x^0)$. Then both* $\lim_{k\to\infty} x^k$ *and* $\lim_{\mu\to\infty} x(\mu)$ *are equal to the solution of* (60)–(61), *i.e., the analytic center of $S(T, C)$ with respect to the barrier h.*

Proof. The result for $\{x^k\}$ follows from Proposition 9, and the result for $\{x(\mu)\}$ follows from Theorem 1(i), which holds because $g(\cdot)$ and $D_g(\cdot, x^0)$ differ by the affine term $\langle \nabla h(x^0), x - x^o \rangle$, and H1, H3, and H4 are invariant through additions of affine functions, so that h also satisfies H1, H3, and H4. Also, in this case H12 holds because the function $h(x) = D_g(x, x^0)$ attains its minimum at $x^0 \in \text{dom}(T) \cap C^o$. □

We remark that in the central path approach, convergence to the analytic center under finiteness of h at the boundary (see H3) does not require $S(T, C)$ to be a polyhedron, as is the case when H9 holds. In the case of GPPA assumption, H9 seems to be necessary. The validity of Proposition 9 without demanding H9 remains as an open problem.

Another interesting issue is the convergence of GPPA without finiteness of g at the boundary (see H3). An extension of the notion of Bregman function has been recently presented in [Kiw1], where H3 is omitted and H1 is weakened (g need not be differentiable in C^o). GPPA for the kind of g's considered by Kiwiel is studied in [Kiw2], where only the optimization case ($T = \partial f$) is considered. The GPPA of [Kiw2] works for g's which do not satisfy H3, like the Itakura–Saitu distance (57), which, when looked at as a barrier function, produces the logarithmic barrier considered in the references mentioned in section 1. However, the convergence results in [Kiw2] request $S(T, C) \cap \mathrm{ED}(g) \neq \emptyset$. If the effective domain of g is C^o, as in the case of (57), this implies existence of solutions in the interior of C, which leaves out most interesting problems (e.g., linear programming).

Corollary 1 raises the following question: Is it the case that the sequence $\{x^k\}$ generated by GPPA is contained in the central path with barrier $h(x) = D_g(x, x^o)$? The answer is affirmative when the operator $\hat{T}$ is constant and V is an affine manifold (e.g., in the linear programming case) and negative otherwise, as we show next.

THEOREM 3. *Consider VIP(T,C) with $T(x) = c + N_V$ and $V = \{x \in \mathbf{R}^n : Ax = b\}$. Assume that VIP(T,C) is regular and has solutions* (*see* H10–H11) *and that g satisfies* H1 *and is boundary coercive* (*see* H2). *Let $\{x^k\}$ be the sequence generated by GPPA with $x^0 \in V \cap C^o$ and $\{x(\mu)\}$ be the central path with barrier $h(x) = D_g(x, x^0)$. Then $\{x^k\} \subset \{x(\mu) : \mu > 0\}$, and for each increasing sequence $\{\mu_k\} \subset \mathbf{R}_{++}$ there exists a sequence $\{\lambda_k\} \subset \mathbf{R}_{++}$ such that $x(\mu_k) = x^k$, where $\{x^k\}$ is the sequence generated by GPPA with Bregman function g and regularization parameters λ_k.*

Proof. First we check that under these hypotheses both x^k and $x(\mu)$ are well defined. We start with $x(\mu)$. We are within hypothesis (ii) of Proposition 2 because it has been proved in [Bur1, Proposition 3.1] that H13 follows from H11 in the optimization case. For x^k, the result follows from [Bur2, Theorem 2].

Next, we observe that in this case (59) can be written as

$$\frac{1}{\lambda_\ell}(c + A^t w^\ell) + \nabla g(x^{\ell+1}) - \nabla g(x^\ell) = 0 \tag{62}$$

for some $w^\ell \in \mathbf{R}^m$, because $N_V(x) = \mathrm{Im}(A^t)$ for all $x \in V$. Summing (62) from $\ell = 0$ to $k-1$ and taking $\mu_k = \sum_{\ell=1}^{k-1} \lambda_\ell^{-1}$, $\bar{w}^k = \mu_k^{-1} \sum_{\ell=0}^{k-1} \lambda_\ell^{-1} w^\ell$, we get

$$0 = \mu_k(c + A^t \bar{w}^k) + \nabla g(x^k) - \nabla g(x^0) = \mu_k(c + A^t \bar{w}^k) + \nabla h(x^k). \tag{63}$$

By (63), $x^k{=}x(\mu_k)$. If an increasing sequence $\{\mu_k\}$ is given, then we get by the same argument $x^k = x(\mu_k)$, where $\{x^k\}$ is generated with $\lambda_k = (\mu_k - \mu_{k-1})^{-1} > 0$. □

Theorem 3 says that in the case of linear programming (i.e., when $C = \mathbf{R}^n_{++}$) the notions of central path and generalized proximal point sequence coincide. The result depends in an essential way on the fact that $\hat{T}$ is constant. It does not hold in more general cases, not even for quadratic programming, as we show next.

Let $n = 2$, and consider the problem $\min \frac{1}{2}\|x\|^2$ s.t. $x \geq 0$. Take $g(x) = -\sum_{j=1}^{2} \log x_j$ and $x^0 = (1/8, 1/2)$. Then $x(\mu) = \mathrm{argmin}\{\frac{\mu}{2}\|x\|^2 + D_g(x, x^0)\}$ with D_g as in (57), and a direct calculation gives $x(\mu) = \mu^{-1}(\sqrt{16+\mu}-4, \sqrt{1+\mu}-1)$. Now we look at the GPPA sequence, given by $x^{k+1} = \mathrm{argmin}\{\frac{1}{2}\|x\|^2 + \lambda_k D_g(x, x^k)\}$. Take $\lambda_0 = 1/48$, $\lambda_1 = 1/9$. Then $x^1 = (1/12, 1/8)$, which coincides with $x(\lambda_0^{-1}) = x(48)$, but $x^2 = ((\sqrt{5}-2)/6, 1/18)$, and it follows from the formula above for $x(\mu)$ that

$x^2 \neq x(\mu)$ for all $\mu > 0$. Therefore, the GPPA sequence is not contained in the central path.

It is interesting to discuss some consequences of Theorem 3. Consider, for instance, the case of $h(x) = -\sum_{j=1}^{n} \log x_j$. Since h is not continuous on the boundary of $\mathbf{R}^n_+$ (i.e., it does not satisfy H3) convergence of the GPPA sequence with the Itakura–Saitu distance given by (57) is not dealt with by most papers on GPPA (e.g., [Cen1], [Che], [Eck], [Ius1], [Bur2], or [Kiw2] for the case of solutions in ∂C). On the other hand, it follows from our Theorem 2 that, for a linear programming problem with a bounded set of solutions, the central path converges to the analytic center of the solution set; and then from our Theorem 3, that such central path contains the GPPA sequence $\{x^k\}$; and furthermore that $\lim_{k\to\infty} x^k = \lim_{k\to\infty} x(\mu_k)$ with $\mu_k = \sum_{\ell=0}^{k-1} \lambda_\ell^{-1}$. Since $\{\lambda_k\}$ is bounded above, $\lim_{k\to\infty} \mu_k = \infty$, and so $\{x^k\}$ converges to the analytic center of the solution set.

Of course, the central path trajectory for this h converges also in the more general cases included in the hypotheses of Theorem 2 (quadratic programming, paramonotone linear complementarity problems, etc.), but in these cases the GPPA sequence is not contained in the central path, and therefore its convergence for the case of the solution set contained in the boundary of C remains as an open problem.

Another interesting consequence of Theorem 3 is related to the limiting direction of the central path, i.e., $\lim_{\mu\to\infty} \dot{x}(\mu)$. For the case of linear programming with the logarithmic barrier, existence of this limit has been established in [Adl2], where a precise characterization of this limiting direction is given. Similar results with the same barrier for monotone linear complementarity problems have been proved in [Mon]. In view of Theorem 3, such results apply to the GPPA for linear programming with the Itakura–Saitu distance given by (57), since the limiting direction $\lim_{\mu\to\infty} \dot{x}(\mu)$ can be seen as the limiting direction of the GPPA sequence $\{x^k\}$. This limiting direction has not been considered in the GPPA literature. Extensions of the results in [Adl2] to more general barriers (e.g., $h(x) = \sum_{j=1}^{n} x_j \log x_j$) will, by virtue of Theorem 3, hold also for the GPPA sequence.

4. The relation between central paths and Cauchy trajectories in Riemannian manifolds. Let M be a Riemannian manifold of dimension s, with metric $\langle \cdot, \cdot \rangle$. Given a local coordinate system in a neighborhood U of a point $p \in M$, the metric in M is given by the symmetric and positive definite matrix $H(q)$, with $H(q)_{ij} = \langle \frac{\partial}{\partial x_i}|_q, \frac{\partial}{\partial x_j}|_q \rangle$ for all $q \in U$, where $\{\frac{\partial}{\partial x_i}\}$ is a basis of the tangent space to M. If $f : M \to \mathbf{R}$ is differentiable, the gradient of f is the vector field grad f defined by

$$\langle \text{grad } f, X \rangle = df(X) = \frac{\partial f}{\partial X},$$

where X is any vector field and $\frac{\partial f}{\partial X}$ is the derivative of f in the direction of X. It is well known that grad $f(q) = H(q)^{-1} \nabla f(q)$, where $\nabla f(q) = (\frac{\partial f}{\partial x_1}(q), \dots, \frac{\partial f}{\partial x_s}(q))$.

Let $N \subset M$ be a submanifold of M. For $x \in N$, let T_xM and T_xN be the tangent spaces to M and N at x, respectively, and let $\Pi_x : T_xM \to T_xN$ be the orthogonal projection onto T_xN with respect to the metric of the manifold. If $f_{/N}$ is the restriction of f to N, then the gradient of $f_{/N}$ with respect to the induced metric in N turns out to be given by grad $f_{/N}(x) = \Pi_x(\text{grad } f(x))$. A *Cauchy trajectory* for f in N is a curve $x : [0, \beta) \to N$ given by

$$x(0) = x^0, \tag{64}$$

$$\dot{x}(t) = -\text{grad } f_{/N}(x(t)) \tag{65}$$

for a given $x^0 \in N$ and some $\beta > 0$. It is well known that for each $x^0 \in N$ there exists $\beta > 0$ such that (64)–(65) has a unique solution.

We remark that if M is an open subset of $\mathbf{R}^s$, then the representation of the metric given by $H(x)$ is global, rather than local, $H : M \to \mathbf{R}^{s\times s}$ is differentiable, and ∇f coincides with the ordinary gradient in $\mathbf{R}^s$.

We prove now that, under the hypotheses of Theorem 3, the Cauchy trajectory and the central path for a certain barrier associated with the metric coincide.

THEOREM 4. *Let M be an open subset of $\mathbf{R}^n$, $N = M \cap \{x \in \mathbf{R}^n : Ax = b\}$, and $f(x) = c^t x$. Let H represent the metric in M and assume that there exists $h : M \to \mathbf{R}$ such that $\nabla^2 h(x) = H(x)$ for all $x \in M$ and $\nabla h(x^0) = 0$. If the Cauchy trajectory $\{x(t)\}$ and the central path $\{x(\mu)\}$ exist, then they coincide.*

Proof. The central path in this case, as in (63) with an arbitrary μ, satisfies

$$0 = \mu(c + A^t w(\mu)) + \nabla h(x(\mu)). \tag{66}$$

By (66), $\nabla h(x(0)) = 0$. Since $\nabla h(x^0) = 0$, by strict convexity of h we get $x(0) = x^0$; i.e., (64) holds. We must check that (65) holds. Let P_A be the orthogonal projection onto $\operatorname{Ker}(A)$. By (66), $\mu c + \nabla h(x(\mu)) \in \operatorname{Im}(A^t)$, so that, for all $\mu > 0$,

$$0 = P_A[\mu c + \nabla h(x(\mu))]. \tag{67}$$

Since P_A is linear, differentiating with respect to μ in (67) we get

$$0 = P_A[c + \nabla^2 h(x(\mu))\dot{x}(\mu)] = P_A[c + H(x(\mu))\dot{x}(\mu)] \tag{68}$$

or, equivalently,

$$H(x(\mu))\dot{x}(\mu) - c \in \operatorname{Im}(A^t). \tag{69}$$

Now we look at grad $f_{/N}(x(\mu))$. As observed above,

(70)
$$\operatorname{grad} f_{/N}(x(\mu)) = \Pi_{x(\mu)} \operatorname{grad} f(x(\mu)) = \Pi_{x(\mu)} H(x(\mu))^{-1} \nabla f(x(\mu)) = \Pi_{x(\mu)} H(x(\mu))^{-1} c,$$

where $\Pi_{x(\mu)}$ is the orthogonal projection of $T_{x(\mu)}M$ onto $T_{x(\mu)}N$ with respect to the inner product induced by the metric; i.e., $\langle u, v\rangle = u^t H(x(\mu))v$. Since M is open and N is an affine manifold, we have $T_{x(\mu)}M = \mathbf{R}^n$ and $T_{x(\mu)}N = \operatorname{Ker}(A)$, so that, for any $y \in \mathbf{R}^n$, $\Pi_{x(\mu)}(y)$ is the unique solution z of

$$\min (z - y)^t H(x(\mu))(z - y) \tag{71}$$

$$\text{s.t.} \qquad Az = 0, \tag{72}$$

whose sufficient Karush–Kuhn–Tucker conditions are (72), plus

$$H(x(\mu))(z - y) = A^t w \tag{73}$$

for some $w \in \mathbf{R}^m$. Note that $H(x(\mu))$ is the Hessian of h at $x(\mu)$, and so it is symmetric and positive semidefinite. For $y = H(x(\mu))^{-1}c$, (73) reduces to

$$-H(x(\mu))z + c \in \operatorname{Im}(A^t). \tag{74}$$

By (69), $z = -\dot{x}(\mu)$ satisfies (74). Since $x(\mu) \in \operatorname{dom}(T) \subset V = N$, we have $Ax(\mu) = b$ for all $\mu > 0$, which implies $0 = A\dot{x}(\mu) = A(-\dot{x}(\mu))$, so that $z = -\dot{x}(\mu)$ satisfies (72) and (74) and is therefore equal to $\Pi_{x(\mu)} y = \Pi_{x(\mu)} H(x(\mu))^{-1} c$. By (70), $\dot{x}(\mu) = -\text{grad } f_{/N}(x(\mu))$; i.e., (65) holds. We have proved that the path $\{x(\mu)\}$ coincides with the Cauchy trajectory. □

As mentioned above, the result of Theorem 4 covers the case of linear programming (with $M = \mathbf{R}^n_{++}$). It is worthwhile to remark that only one of the two conditions imposed on h in the hypotheses of Theorem 4 is indeed relevant, namely $\nabla^2 h(x) = H(x)$. If this relation is satisfied by some $\bar{h}$, then we define $h(x) = \bar{h}(x) - \nabla\bar{h}(x^0)^t x$, and we get $\nabla^2 h(x) = H(x)$ and $\nabla h(x^0) = 0$.

In view of (70) and (74), it is easy to prove that, when A has full rank, (65) can be rewritten as

$$\dot{x}(t) = -H(x(t))^{-1}[I - A^t(AH(x(t))^{-1}A^t)^{-1}AH(x(t))^{-1}]\nabla f(x(t)). \tag{75}$$

Theorem 4 says that, when $H(x) = \nabla^2 h(x)$ and $\nabla h(x^0) = 0$, the curve given by (64), (75) coincides with the curve

$$x(\mu) = \operatorname{argmin}\{\mu c + h(x)\} \tag{76}$$

$$\text{s.t. } Ax = b. \tag{77}$$

It is worthwhile to consider the form of (75) under different choices of H. For h as in Example 1, i.e., $h(x) = \sum_{j=1}^n x_j \log x_j$, we get

$$H(x)^{-1} = \operatorname{diag}(x_1, \dots, x_n). \tag{78}$$

The curve given by (64) and (75), (78) has been considered in [Fay], while, by Theorems 3 and 4, this curve contains any sequence generated by GPPA for the linear programming problem with the Kullback–Leibler divergence, a particular case of the methods for linear programming considered in [Ius5].

For h as in Example 2, with $\alpha = 1$, $\beta = 1/2$, we get

$$H(x)^{-1} = 4\operatorname{diag}(x_1^{3/2}, \dots, x_n^{3/2}). \tag{79}$$

This "scaling" has not been particularly studied, either from the perspective of interior point methods for linear programming or from the point of view of generalized proximal point methods. We feel that it deserves more attention.

Finally, for $h(x) = -\sum_{j=1}^n \log x_j$, we get

$$H(x)^{-1} = \operatorname{diag}(x_1^2, \dots, x_n^2). \tag{80}$$

In this case, (64), (75), with $H(x)^{-1}$ as in (80) gives the affine scaling trajectory, widely studied from the point of view of interior point methods for linear programming (see, e.g., [Adl1]).

ON HOMOTOPY-SMOOTHING METHODS FOR BOX-CONSTRAINED VARIATIONAL INEQUALITIES*

XIAOJUN CHEN† AND YINYU YE‡

Abstract. A variational inequality problem with a mapping $g : \Re^n \to \Re^n$ and lower and upper bounds on variables can be reformulated as a system of nonsmooth equations $F(x) = 0$ in $\Re^n$. Recently, several homotopy methods, such as interior point and smoothing methods, have been employed to solve the problem. All of these methods use parametric functions and construct perturbed equations to approximate the problem. The solution to the perturbed system constitutes a smooth trajectory leading to the solution of the original variational inequality problem. The methods generate iterates to follow the trajectory. Among these methods Chen–Mangasarian and Gabriel–Moré proposed a class of smooth functions to approximate F. In this paper, we study several properties of the trajectory defined by solutions of these smooth systems. We propose a homotopy-smoothing method for solving the variational inequality problem, and show that the method converges globally and superlinearly under mild conditions. Furthermore, if the involved function g is an affine function, the method finds a solution of the problem in finite steps. Preliminary numerical results indicate that the method is promising.

1. Introduction.

We consider the following variational inequality problem (VIP). Given a continuously differentiable mapping $g : \Re^n \to \Re^n$, $l \in \{\Re \cup -\infty\}^n$, and $u \in \{\Re \cup \infty\}^n$, where $l < u$, find $x \in [l, u]$ such that

$$(y - x)^T g(x) \geq 0 \qquad \text{for any } y \in [l, u].$$

Such problem is called a box-constrained VIP or mixed complementarity problem in [6, 9, 11, 15, 17, 18, 19, 24]. We denote this problem by VI(l, u, g).

Several algorithms have been developed for solving VIP [17, 20]. In the last few years, smoothing methods have been studied extensively. Smoothing methods for solving VI(l, u, g) are based on the reformulation of nonsmooth equations

$$F(x) := x - \text{mid}(l, u, x - g(x)) = 0, \tag{1.1}$$

where mid$(\cdot)$ denotes the componentwise median operator, i.e.,

$$\text{mid}(l_i, u_i, x_i - g_i(x)) = \begin{cases} l_i, & x_i - g_i(x) \leq l_i, \\ x_i - g_i(x), & l_i \leq x_i - g_i(x) \leq u_i, \\ u_i, & x_i - g_i(x) \geq u_i. \end{cases}$$

These methods use parametric smooth functions and construct perturbed equations to approximate nonsmooth equations (1.1). The solution to the perturbed system constitutes a smooth trajectory leading to the solution of the original VIP.

In contrast with Newton methods using generalized Jacobian [3, 15, 16, 35, 38], smoothing methods have a notable advantage in that they can be extended to solve nonsmooth problems in function spaces [7, 10, 26]. In fact, smoothing methods are closely related to splitting methods for solving nonsmooth equations in function spaces for which the nonlinear function can be split into smooth and nonsmooth parts. Such problems arise from differential equations with nondifferentiable terms, nonsmooth compact fixed point problems, etc. In particular, a class of problems arises in optimal control problems for parabolic partial differential equations with bound constraints on the control. In a survey paper [26], Kelley considered the splitting methods for solving the nonsmooth equations

$$x(t) - P(K(x))(t) = 0, \tag{1.2}$$

where K is a completely continuous map from $L^\infty(\Omega)$ to $C(\Omega)$ for some bounded $\Omega \subseteq \Re^m$, and P is the map on $C(\Omega)$ given by

$$P(K(x))(t) = \begin{cases} l(t), & K(x)(t) \le l(t), \\ K(x)(t), & l(t) \le K(x)(t) \le u(t), \\ u(t), & K(x)(t) \ge u(t), \end{cases}$$

for given l and u in $C(\Omega)$. A paradigm for problems of the form (1.2) is the Urysohn equation [27]. Nonsmooth equation (1.1) may be considered as a special case of the form (1.2) in $\Re^n$.

In this paper, we will use the Jacobian of smooth approximation functions and directional derivative consistency property [7, 19] in the smoothing algorithm and its convergence analysis. Thus, these results can be extended to function spaces without difficulties.

The box-constrained VIP includes the nonlinear complementarity problem (NCP) [29, 30, 34], where $l_i = 0$ and $u_i = \infty$ for $i = 1, \dots, n$. In the NCP case, (1.1) is reduced to

$$F(x) = x - \max(0, x - g(x)) = 0. \tag{1.3}$$

Chen and Mangasarian [6] introduced a class of parametric smooth approximation functions for the nonsmooth function F in (1.3). A family of homotopy continuation methods, including an interior point path-following method, can be constructed to solve the NCP based on Chen–Mangasarian smooth approximation equations. Using the proving techniques developed in Kojima, Megiddo, and Noma [28], Chen and Harker [5] established the existence, uniqueness, and limiting properties of the trajectory defined by these approximation equations under certain conditions. Recently, Xu and Burke [40] gave a polynomial complexity bound for an interior point smoothing method for the monotone linear complementarity problem (LCP) based on the Chen–Harker–Kanzow–Smale function [4, 23] and Tseng's convergence analysis for a class of infeasible interior point methods [39]. More recently, Burke and Xu [2] and Hotta and Yoshise [22] studied the global convergence of non–interior point algorithms using the Chen–Harker–Kanzow–Smale function.

A number of important problems in engineering and economics have lower and/or upper bounds on the variables, rather than just nonnegative constraints as in the NCP. The VI(l, u, g) model includes more general problems and attracts researchers' attention [6, 9, 11, 15, 17, 18, 19, 24]. Gabriel and Moré [19] defined a parametric function $f\colon \Re^n \times R_{++} \to \Re^n$ to approximate function F in (1.1), where $f(x, \varepsilon)$ is continuously differentiable with respect to variable vector x and $\|F(x)-f(x,\varepsilon)\| \leq \mu\varepsilon$. Here μ is a positive constant.

In section 2, we reformulate $\mathrm{VI}(l,u,g)$ as a generalized complementarity problem (GCP) in $\Re^n$:

$$q(x) \geq 0, \quad p(x) \geq 0, \quad p(x)^T q(x) = 0,$$

where the set $\{x : \; p(x) \geq 0, \; q(x) \geq 0\}$ is usually called the feasible set of the GCP. We show that for any $\varepsilon > 0$, if x is a solution of $f(x,\varepsilon) = 0$, then x is approximately feasible for the GCP—$q(x) \geq 0$ and $p(x) \geq -O(\varepsilon)e$, and for each i, $|p_i(x)q_i(x)| \leq O(\varepsilon^2)$ (which is stronger than the current result that $|p_i(x)q_i(x)|$ is bounded). Furthermore, if the VIP or GCP is merely an NCP, then any solution of $f(x,\varepsilon) = 0$ is an exactly feasible point of the NCP, i.e., $x \geq 0$ and $g(x) \geq 0$, and for each i, $x_i g_i(x) \leq O(\varepsilon^2)$.

Under the assumptions that g is a P_0 function and the level sets $\{x \; : \; \|F(x)\| \leq \Gamma\}$ with $\Gamma > 0$ are bounded, we investigate the trajectory formed by solutions of $f(x,\varepsilon) = r$ as $\varepsilon > 0$ and $r \in \Re^n$ vary. We show that the monotone complementarity problem with a feasible interior point satisfies the assumptions on certain level sets. Our trajectory analysis is related to the one established in Chen and Harker [5]. However, there are several fundamental distinctions. For example, the Gabriel–Moré approximation function is not convex. Consequently, assumptions A1, A2, and A4 in [5], which play an important role in their proof, do not hold for the Gabriel–Moré approximation function.

In section 3, we modify a smoothing Newton method for solving $\mathrm{VI}(l,u,g)$, which was originally proposed in [9]. The new method simplifies the ε update step in the Chen–Qi–Sun method without loss of its feature that it solves a system of linear equations at each step and generates iterates converging to a solution of (1.1) globally and superlinearly when g is a uniform P function. Moreover, motivated by the finite convergence result of other algorithms [16, 42], we use a Newton step in the new method. The resulting method finds a solution of $\mathrm{VI}(l,u,g)$ in finite steps if the involved function g is an affine function.

It is notable that the existence of smooth path and global convergence of the smoothing method requires the same condition that g be a P_0 function and the level sets $\{x \; : \; \|F(x)\| \leq \Gamma\}$ with $\Gamma > 0$ be bounded. Like the central path in interior point methods, the smooth path plays a key role in smoothing methods although it does not appear in algorithms.

We have tested the hybrid Newton-smoothing method with three approximation functions on seven types of samples which contain 27 linear VIPs and 4 nonlinear VIPs. Our preliminary numerical results reported in section 4 show that the new method is promising.

Some words about our notation are in order. Let $N = \{i \; : \; i = 1,2,\ldots,n\}$. The $n \times n$ identity matrix is denoted by I. The ith row of an $n \times n$ matrix M is denoted by M_i. We use $\|\cdot\|$ to denote the Euclidean norm. Let e denote the vector of ones, i.e.,

$$e = (1,1,\ldots,1)^T.$$

We denote

$$\Re_+ = \{\varepsilon \; : \; \varepsilon \in \Re, \varepsilon \geq 0\} \quad \text{and} \quad \Re_{++} = \{\varepsilon \; : \; \varepsilon \in \Re, \varepsilon > 0\}.$$

2. Smoothing approximations. Let $\rho : \Re \to \Re_+$ be a density function with a bounded absolute mean, that is,

$$\kappa := \int_{-\infty}^{\infty} |s|\rho(s)ds < \infty. \tag{2.1}$$

In addition, let ρ satisfy

$$\zeta^2 := \max\left\{\sup_{t\geq 0}\int_t^{\infty} ts\rho(s)ds, \quad \sup_{t\leq 0}\int_{-\infty}^{t} ts\rho(s)ds\right\} < \infty. \tag{2.2}$$

It is easy to verify that

$$\zeta^2 \leq \int_{-\infty}^{\infty} s^2\rho(s)ds.$$

The three density functions used in our computational experiment satisfy these two conditions (see section 4). Note that if the second moment of ρ is bounded, then ρ satisfies (2.1) and (2.2). The condition (2.2) is new. We introduce it to establish a strong complementarity error bound in Theorem 2.1.

The class of Gabriel–Moré approximation functions to function F in (1.1) is defined by

$$f_i(x,\varepsilon) = x_i - \int_{-\infty}^{\infty} \text{mid}(l_i, u_i, x_i - g_i(x) - \varepsilon s)\rho(s)ds, \quad i = 1,\ldots,n. \tag{2.3}$$

By using (2.3), a smooth approximation function can be generated by an appropriate density function. The following proposition is known.

PROPOSITION 2.1 (see [7, 9, 19]). *The function $f : \Re^n \times \Re_{++} \to \Re^n$ defined by (2.3) satisfies the following four conditions:*

(i) *For any $(x,\varepsilon) \in \Re^n \times \Re_{++}$,*

$$|F_i(x) - f_i(x,\varepsilon)| \leq \kappa\varepsilon, \quad i = 1,2,\ldots,n. \tag{2.4}$$

(ii) *f is continuously differentiable with respect to the variable x, and for any $(x,\varepsilon) \in \Re^n \times \Re_{++}$,*

$$f_x(x,\varepsilon) = I - D(x)(I - g'(x)), \tag{2.5}$$

where $D(x)$ is a diagonal matrix whose diagonal elements are

$$D_{ii}(x) = \int_{(x-g(x)-u)_i/\varepsilon}^{(x-g(x)-l)_i/\varepsilon} \rho(s)ds, \quad i = 1,2,\ldots,n.$$

(iii) *For any $x \in \Re^n$,*

$$\lim_{\varepsilon\downarrow 0} f_x(x,\varepsilon) = f^0(x), \tag{2.6}$$

where for $i \in N$,

$$f_i^0(x) = \begin{cases} g_i'(x) & \textit{if } x_i - g_i(x) \in (l_i, u_i), \\ I_i & \textit{if } x_i - g_i(x)_i \notin [l_i, u_i], \\ I_i - \left(\int_{-\infty}^{0}\rho(s)ds\right)(I_i - g_i'(x)) & \textit{if } x_i - g_i(x) = l_i, \\ I_i - \left(\int_{0}^{\infty}\rho(s)ds\right)(I_i - g_i'(x)) & \textit{if } x_i - g_i(x) = u_i. \end{cases}$$

(iv) *For any* $x \in \Re^n$, f *satisfies the* directional derivative consistency *property at* x [7], *i.e.,*

$$\lim_{h\to 0} \frac{F(x+h) - F(x) - f^0(x+h)h}{\|h\|} = 0. \tag{2.7}$$

It is shown in [9] that $f^0(x) \in \partial_C F(x)$ for any $x \in \Re^n$, where $\partial_C F(x)$ is the generalized Jacobian at x. This property is called Jacobian consistency property in [9]. However, the definition of the generalized Jacobian and the semismoothness for superlinear convergence [9, 35] are restricted in $\Re^n$. In order to make smoothing methods applicable in function spaces, we use the definition of $f^0(x)$ and the directional derivative consistency property in this paper.

We now develop the following proposition which will be used in our analysis.

PROPOSITION 2.2. *For a given* $\varepsilon \in \Re_{++}$ *and a pair* $a, b \in \Re \cup \{-\infty, \infty\}$ *such that* $a < b$, *let* $\rho(s) = \rho(-s)$ *and*

$$h(t) = \int_{-\infty}^{\infty} \text{mid}(a, b, t - \varepsilon s)\rho(s)ds.$$

Then

$$0 \le h'(t) \le 1 \tag{2.8}$$

and

$$h(t) \ge \text{mid}(a, b, t) \quad \Leftrightarrow \quad t \le \frac{a+b}{2}. \tag{2.9}$$

Furthermore, if supp$\{\rho\} = \Re$, *then*

$$0 < h'(t) < 1 \tag{2.10}$$

and

$$h(t) > \text{mid}(a, b, t) \quad \Leftrightarrow \quad t < \frac{a+b}{2}. \tag{2.11}$$

Proof. The result on $h'(t)$ was proved in Lemma 2.3 of Gabriel and Moré [19]. We focus on proving the rest of the proposition.

Using $\rho(s) = \rho(-s)$, we have

$$\int_{-\infty}^{\infty} s\rho(s)ds = 0,$$

which implies

$$\int_{-\infty}^{\infty} (t - \varepsilon s)\rho(s)ds = t.$$

By the definition of the median operator, we obtain

$$h(t) = \int_{-\infty}^{(t-b)/\varepsilon} b\rho(s)ds + \int_{(t-a)/\varepsilon}^{\infty} a\rho(s)ds + \int_{(t-b)/\varepsilon}^{(t-a)/\varepsilon} (t - \varepsilon s)\rho(s)ds$$

$$= \int_{-\infty}^{(t-b)/\varepsilon} b\rho(s)ds + \int_{(t-a)/\varepsilon}^{\infty} a\rho(s)ds + \int_{-\infty}^{\infty} (t-\varepsilon s)\rho(s)ds$$

$$- \int_{-\infty}^{(t-b)/\varepsilon} (t-\varepsilon s)\rho(s)ds - \int_{(t-a)/\varepsilon}^{\infty} (t-\varepsilon s)\rho(s)ds$$

$$= \int_{-\infty}^{(t-b)/\varepsilon} (b-t+\varepsilon s)\rho(s)ds + \int_{(t-a)/\varepsilon}^{\infty} (a-t+\varepsilon s)\rho(s)ds + t. \tag{2.12}$$

Suppose that $t \leq (a+b)/2$. Then there are only two cases: $\mathrm{mid}(a,b,t) = t$ or $\mathrm{mid}(a,b,t) = a$.

If $\mathrm{mid}(a,b,t) = t$, then from (2.12), $b-t \geq t-a \geq 0$, and $\rho(s) = \rho(-s)$ we have

$$h(t) - \mathrm{mid}(a,b,t)$$
$$= \int_{-\infty}^{(t-b)/\varepsilon} (a+b-2t)\rho(s)ds + \int_{(t-a)/\varepsilon}^{(b-t)/\varepsilon} (a-t+\varepsilon s)\rho(s)ds \geq 0. \tag{2.13}$$

If $\mathrm{mid}(a,b,t) = a$, then from (2.12) and $0 \geq t-a \geq t-b$ we have

$$h(t) - \mathrm{mid}(a,b,t)$$
$$= \int_{-\infty}^{(t-b)/\varepsilon} (b-a+\varepsilon s)\rho(s)ds + \int_{(t-b)/\varepsilon}^{\infty} (t-a)\rho(s)ds + \int_{(t-a)/\varepsilon}^{\infty} (a-t+\varepsilon s)\rho(s)ds$$
$$= \int_{-\infty}^{(t-b)/\varepsilon} (b-a)\rho(s)ds + \int_{(t-b)/\varepsilon}^{(t-a)/\varepsilon} (t-a-\varepsilon s)\rho(s)ds \geq 0. \tag{2.14}$$

Hence, we obtain the $\Leftarrow$ part of (2.9) from (2.13) and (2.14).

Assume that $t \geq (a+b)/2$. Then following the same argument above, we can show that $h(t) \leq \mathrm{mid}(a,b,t)$. This implies the $\Rightarrow$ part of (2.9). So the proof of (2.9) is completed.

Notice that $\mathrm{supp}\{\rho\} = \Re$ implies that for any α, β satisfying $\alpha < \beta$,

$$\int_{\beta}^{\alpha} \rho(s)ds > 0.$$

Using this fact and following the above argument, we can prove (2.11). □

To study the smooth path defined by the smooth equations $f(x,\varepsilon) = 0$ for $\varepsilon > 0$, we introduce a generalized complementarity problem. Let $z \in \Re^n$ and E be a diagonal matrix whose diagonal elements are

$$E_{ii}(z) = \begin{cases} 1, & z_i \geq 0, \\ -1, & z_i < 0, \quad i = 1, 2, \ldots, n. \end{cases}$$

It is easy to verify that a vector $x \in \Re^n$ solves (1.1) if and only if x solves the following complementarity problem:

$$q(x) := \min(x-l, u-x) \geq 0, \tag{2.15}$$

$$p(x) := E\left(\frac{l+u}{2} - x\right) g(x) \geq 0, \tag{2.16}$$

$$q(x)^T p(x) = 0. \tag{2.17}$$

In the complementarity formulation (2.15)–(2.17), for $i \in N$ we regard $l_i \cdot 0 = 0$ and $u_i \cdot 0 = 0$ even for $l_i = -\infty$ or $u_i = \infty$.

Based on the complementarity problem (2.15)–(2.17), we define a restricted feasible set of the variational inequality problem VI(l, u, g) by

$$X_0 = \{x \ : \ q(x) \geq 0, \ p(x) \geq 0\}.$$

$q(x) \geq 0$ implies that $x \in [l, u]$, which is desired, but $p(x) \geq 0$ implies that $g(x) \geq 0$ if $x \leq \frac{l+u}{2}$ and $g(x) \leq 0$ if $x > \frac{l+u}{2}$, which is strictly contained in the feasible set of the original VIP

$$\{x \ : \ q(x) \geq 0, \ g_i(x) \geq 0 \text{ if } x_i = l_i; \qquad g_i(x) \leq 0 \text{ if } x_i = u_i, \ i = 1, \ldots, n\}.$$

Thus, we define another set X associated with X_0 as

$$X = \left\{x \ : \ q(x) \geq 0, \ E\left(\frac{l+u}{2} + g(x) - x\right) g(x) \geq 0\right\}$$

and its interior by

$$\text{int}X = \left\{x \ : \ q(x) > 0, \ E\left(\frac{l+u}{2} + g(x) - x\right) g(x) > 0\right\}.$$

Obviously, we have

$$X_0 \subseteq X,$$

and both X_0 and X contain the solution set of the VIP if it exists. Furthermore, if $l_i = 0$ and $u_i = \infty$ for each $i \in N$, then VI(l, u, g) reduces to the NCP and

$$X_0 = X = \{x \ : \ x \geq 0, \ g(x) \geq 0\},$$

which is known as the feasible set for the NCP.

The following theorem shows that the homotopy equation $f(x, \varepsilon) = 0$ possesses several desired features and is closely related to the interior point homotopy equation for the GCP (2.15)–(2.17).

THEOREM 2.1. *Suppose that $\rho(s) = \rho(-s)$. Let x be a solution of*

$$f(x, \varepsilon) = 0.$$

Then

(i) *For any $\varepsilon \in \Re_{++}$,*

$$x \in X.$$

Furthermore, if $\text{supp}(\rho) = \{s : \rho(s) > 0\} = \Re$, *then*

$$x \in \text{int}X \cup \left\{x \ : \ x_i = \frac{l_i + u_i}{2}, \ \exists \ i \in N\right\}.$$

(ii) *For $\varepsilon \in \Re_{++}$ satisfying $\varepsilon < \frac{1}{2\kappa} \min_{1 \leq i \leq n}(u_i - l_i)$,*

$$x \in X_\varepsilon = \{x \ : \ q(x) \geq 0, \quad p(x) \geq -\kappa\varepsilon e\}.$$

(iii) *For any* $\varepsilon \in \Re_{++}$,

$$|q_i(x)p_i(x)| \le \varepsilon^2(\zeta^2 + \kappa^2/2), \qquad i = 1, 2, \ldots, n.$$

Proof. To simplify the proof, we denote $y = g(x)$.

(i) Since $l_i \le$ mid $(l_i, u_i, x_i - y_i - \varepsilon s) \le u_i$ and $\rho(s) \ge 0$, we have

$$l_i \le x_i - f_i(x, \varepsilon) = x_i \le u_i, \quad i = 1, 2, \ldots, n.$$

Now we show

$$E_{ii}\left(\frac{l+u}{2} + y - x\right) y_i \ge 0, \quad i = 1, 2, \ldots, n. \tag{2.18}$$

By Proposition 2.2, $f(x, \varepsilon) = 0$ implies that for any $i \in N$

$$x_i \ge \text{mid}(l_i, u_i, x_i - y_i) \quad \Leftrightarrow \quad x_i - y_i \le \frac{l_i + u_i}{2}. \tag{2.19}$$

Suppose that $x_i - y_i \le \frac{l_i + u_i}{2}$. Then from (2.19), we have either

$$x_i \ge x_i - y_i \ge l_i \quad \text{or} \quad x_i \ge l_i \ge x_i - y_i.$$

In either case, $y_i \ge 0$.

Suppose that $x_i - y_i \ge \frac{l_i + u_i}{2}$. Then from (2.19), we have either

$$x_i \le x_i - y_i \le u_i \quad \text{or} \quad x_i \le u_i \le x_i - y_i.$$

In either case, $y_i \le 0$.

Therefore (2.18) holds, and hence $x \in X$.

The assumption supp$(\rho) = \Re$ implies that ρ vanishes in any nontrivial interval. In such a case, from

$$\begin{aligned} x_i &= x_i - f_i(x, \varepsilon) \\ &= \int_{-\infty}^{\frac{x_i - y_i - u_i}{\varepsilon}} u_i \rho(s) ds + \int_{\frac{x_i - y_i - l_i}{\varepsilon}}^{\infty} l_i \rho(s) ds + \int_{\frac{x_i - y_i - u_i}{\varepsilon}}^{\frac{x_i - y_i - l_i}{\varepsilon}} (x_i - y_i - \varepsilon s)\rho(s) ds \end{aligned}$$

we have $l_i < x_i < u_i$. Furthermore, using (2.11) and following the same argument above, we can show

$$E_{ii}\left(\frac{l+u}{2} + y - x\right) y_i > 0 \quad \text{for} \quad x_i - y_i \ne \frac{l_i + u_i}{2} \quad i = 1, 2, \ldots, n.$$

If $x_i - y_i = (l_i + u_i)/2$, then by (2.11) $y_i = 0$. Hence, we obtain $x \in$ int $X \cup \{x : x_i = (l_i + u_i)/2, \exists\, i \in N\}$.

(ii) By (2.4) and $f(x, \varepsilon) = 0$, we have

$$|F_i(x)| = |x_i - \text{mid}(l_i, u_i, x_i - y_i)| \le \kappa\varepsilon.$$

This implies

$$x_i - \kappa\varepsilon \le \text{mid}(l_i, u_i, x_i - y_i) \le x_i + \kappa\varepsilon. \tag{2.20}$$

If $x_i \le (l_i + u_i)/2$, then from the second inequality in (2.20) and $\varepsilon < \frac{u_i - l_i}{2\kappa}$, we have either

$$\text{mid}(l_i, u_i, x_i - y_i) = l_i \tag{2.21}$$

or

$$\text{mid}(l_i, u_i, x_i - y_i) = x_i - y_i. \tag{2.22}$$

Moreover, (2.21) implies that $y_i \ge x_i - l_i \ge 0$, and (2.22) with (2.20) implies $y_i \ge -\kappa\varepsilon$.

If $x_i \ge (l_i + u_i)/2$, then from the first inequality in (2.20) and $\varepsilon < \frac{u_i - l_i}{2\kappa}$ we have either

$$\text{mid}(l_i, u_i, x_i - y_i) = u_i \tag{2.23}$$

or

$$\text{mid}(l_i, u_i, x_i - y_i) = x_i - y_i. \tag{2.24}$$

Moreover, (2.23) implies that $y_i \le x_i - u_i \le 0$, and (2.24) with (2.20) implies $y_i \le \kappa\varepsilon$.

Hence, $p_i(x) = E_{ii}(\frac{l+u}{2} - x)y_i \ge -\kappa\varepsilon$.

(iii) For a fixed i, we consider three cases.

Case 1. $\text{mid}(l_i, u_i, x_i - y_i) = l_i$. We have

$$x_i - y_i \le l_i < u_i, \quad x_i - l_i \ge 0, \quad y_i \ge 0,$$

and

$$x_i - l_i \le \kappa\varepsilon.$$

Moreover,

$$\begin{aligned}
&x_i - l_i \\
&= \int_{-\infty}^{\frac{x_i - y_i - u_i}{\varepsilon}} (u_i - x_i + y_i + \varepsilon s)\rho(s)ds - \int_{-\infty}^{\frac{x_i - y_i - l_i}{\varepsilon}} (l_i - x_i + y_i + \varepsilon s)\rho(s)ds \\
&= \varepsilon \left(\int_{-\infty}^{\frac{x_i - y_i - u_i}{\varepsilon}} \left(\frac{u_i - x_i + y_i}{\varepsilon} + s \right) \rho(s)ds - \int_{-\infty}^{\frac{x_i - y_i - l_i}{\varepsilon}} \left(\frac{l_i - x_i + y_i}{\varepsilon} + s \right) \rho(s)ds \right) \\
&\le -\varepsilon \int_{-\infty}^{\frac{x_i - y_i - l_i}{\varepsilon}} \left(\frac{l_i - x_i + y_i}{\varepsilon} + s \right) \rho(s)ds \\
&\le -\varepsilon \int_{-\infty}^{\frac{x_i - y_i - l_i}{\varepsilon}} s\rho(s)ds,
\end{aligned}$$

since the first integral in the parenthesis has a negative value and $l_i - x_i + y_i \ge 0$. Thus,

$$\begin{aligned}
y_i(x_i - l_i) &\le (l_i - x_i + y_i + x_i - l_i) \left(-\varepsilon \int_{-\infty}^{\frac{x_i - y_i - l_i}{\varepsilon}} s\rho(s)ds \right) \\
&\le (l_i - x_i + y_i + \kappa\varepsilon) \left(-\varepsilon \int_{-\infty}^{\frac{x_i - y_i - l_i}{\varepsilon}} s\rho(s)ds \right) \\
&= \varepsilon^2 \frac{x_i - y_i - l_i}{\varepsilon} \int_{-\infty}^{\frac{x_i - y_i - l_i}{\varepsilon}} s\rho(s)ds - \varepsilon^2\kappa \int_{-\infty}^{\frac{x_i - y_i - l_i}{\varepsilon}} s\rho(s)ds \\
&\le \varepsilon^2 \left(\frac{\zeta^2 + \kappa^2}{2} \right).
\end{aligned}$$

Case 2. $\mathrm{mid}(l_i, u_i, x_i - y_i) = u_i$. The proof of Case 2 is similar to Case 1, where we have

$$l_i < u_i \le x_i - y_i, \quad u_i - x_i \ge 0, \quad y_i \le 0,$$

and

$$u_i - x_i \le \kappa\varepsilon.$$

Case 3. $\mathrm{mid}(l_i, u_i, x_i - y_i) = x_i - y_i$ and $l_i < x_i - y_i < u_i$. We have

$$|y_i| \le \kappa\varepsilon.$$

Moreover,

$$y_i = \int_{-\infty}^{\frac{x_i - y_i - u_i}{\varepsilon}} (u_i - x_i + y_i + \varepsilon s)\rho(s)ds + \int_{\frac{x_i - y_i - l_i}{\varepsilon}}^{\infty} (l_i - x_i + y_i + \varepsilon s)\rho(s)ds.$$

Since the first integral has negative value and the second has positive value, we have

$$\int_{-\infty}^{\frac{x_i - y_i - u_i}{\varepsilon}} (u_i - x_i + y_i + \varepsilon s)\rho(s)ds \le y_i \le \int_{\frac{x_i - y_i - l_i}{\varepsilon}}^{\infty} (l_i - x_i + y_i + \varepsilon s)\rho(s)ds.$$

Furthermore, since $u_i - x_i + y_i \ge 0$ and $l_i - x_i + y_i \le 0$, we have

$$\int_{-\infty}^{\frac{x_i - y_i - u_i}{\varepsilon}} \varepsilon s\rho(s)ds \le y_i \le \int_{\frac{x_i - y_i - l_i}{\varepsilon}}^{\infty} \varepsilon s\rho(s)ds.$$

Thus,

$$\begin{aligned}
\min(x_i - l_i, u_i - x_i)y_i &\le (x_i - l_i)\int_{\frac{x_i - y_i - l_i}{\varepsilon}}^{\infty} \varepsilon s\rho(s)ds \\
&= (x_i - l_i - y_i + y_i)\int_{\frac{x_i - y_i - l_i}{\varepsilon}}^{\infty} \varepsilon s\rho(s)ds \\
&\le (x_i - l_i - y_i + \kappa\varepsilon)\int_{\frac{x_i - y_i - l_i}{\varepsilon}}^{\infty} \varepsilon s\rho(s)ds \\
&= \varepsilon^2 \frac{x_i - l_i - y_i}{\varepsilon}\int_{\frac{x_i - y_i - l_i}{\varepsilon}}^{\infty} s\rho(s)ds + \varepsilon^2\kappa\int_{\frac{x_i - y_i - l_i}{\varepsilon}}^{\infty} s\rho(s)ds \\
&\le \varepsilon^2\left(\frac{\zeta^2 + \kappa^2}{2}\right).
\end{aligned}$$

Similarly, we can prove

$$\min(x_i - l_i, u_i - x_i)y_i \ge -\varepsilon^2(\zeta^2 + \kappa^2/2).$$

Therefore,

$$|\min(x_i - l_i, u_i - x_i)y_i| \le \varepsilon^2(\zeta^2 + \kappa^2/2). \qquad \square$$

Theorem 2.1 presents some properties of the smooth path

$$\{x(\varepsilon)\ :\ f(x, \varepsilon) = 0, \varepsilon > 0\}.$$

Result 1 shows that the smooth path is in the box $[l, u]$, i.e., $l \leq x(\varepsilon) \leq u$ and $l < x(\varepsilon) < u$ if $\operatorname{supp}(\rho) = \{s : \rho(s) > 0\} = \Re$. Result 2, together with result 1, shows that $x(\varepsilon)$ is approximately feasible, and the distance from $x(\varepsilon)$ to the feasible set goes to zero as ε goes to zero. Result 3 shows that the complementarity gap goes to zero quadratically in ε. Hence, the solution trajectory $x(\varepsilon)$, if it exists, converges to the solution set of the VIP as $\varepsilon \to 0$.

The following corollary further illustrates the behavior of the trajectory for NCP.

COROLLARY 2.1. *Suppose that $\rho(s) = \rho(-s)$ and consider the NCP problem, i.e., $l_i = 0$ and $u_i = \infty$ for each $i \in N$. Let x be a solution of*

$$f(x, \varepsilon) = 0.$$

Then we have the following:

(i) *For any $\varepsilon \in \Re_{++}$,*

$$x \in X.$$

Furthermore, if $\operatorname{supp}(\rho) = \{s : \rho(s) > 0\} = \Re$, *then*

$$x \in \operatorname{int} X.$$

(ii) *If*

$$\xi^2 := \inf_{t \leq 0} \left(\int_{-\infty}^{t} (t - s)\rho(s)ds \right) \left(\int_{-\infty}^{t} (t - s)\rho(s)ds - t \right) > 0, \tag{2.25}$$

then for any $\varepsilon \in \Re_{++}$ and each $i \in N$,

$$x_i g_i(x) \geq \epsilon^2 \xi^2.$$

Proof. Result (i) follows from Theorem 2.1. We now prove (ii), which is similar to the proof of (iii) of Theorem 2.1. (Note that Case 2 no longer exists here.)

Case 1. $y_i := g_i(x) \geq x_i$. We have

$$x_i - y_i \leq 0, \quad x_i \geq 0, \quad y_i \geq 0.$$

Let $t = \frac{x_i - y_i}{\varepsilon}$. Then $t \leq 0$, $y_i = x_i - \varepsilon t$, and

$$\begin{aligned} x_i &= -\int_{-\infty}^{\frac{x_i - y_i}{\varepsilon}} (-x_i + y_i + \varepsilon s)\rho(s)ds \\ &= \varepsilon \int_{-\infty}^{\frac{x_i - y_i}{\varepsilon}} \left(\frac{x_i - y_i}{\varepsilon} - s \right) \rho(s)ds \\ &= \varepsilon \int_{-\infty}^{t} (t - s)\rho(s)ds. \end{aligned}$$

Thus,

$$\begin{aligned} y_i x_i &= (x_i - \varepsilon t)x_i \\ &= \varepsilon^2 \left(\int_{-\infty}^{t} (t - s)\rho(s)ds \right) \left(\int_{-\infty}^{t} (t - s)\rho(s)ds - t \right) \\ &\geq \varepsilon^2 \xi^2. \end{aligned}$$

Similarly, we can prove Case 3 where $y_i \leq x_i$. □

The density function generating the Chen–Harker–Kanzow–Smale smooth approximation function satisfies condition (2.25). Moreover, it provides

$$\left(\int_{-\infty}^{t}(t-s)\rho(s)ds\right)\left(\int_{-\infty}^{t}(t-s)\rho(s)ds-t\right)\equiv 1.$$

By the proof of Corollary 2.1, we have

$$x_i g_i(x) = \varepsilon^2, \quad i = 1, 2, \dots, n,$$

for this density function. However, the other two density functions used in section 4 do not satisfy condition (2.25).

If both (iii) of Theorem 2.1 and (ii) of Corollary 2.1 hold, then for each $i \in N$,

$$\frac{x_i g_i(x)}{x^T g(x)/n} \geq \frac{\xi^2}{\zeta^2 + \kappa^2/2} > 0.$$

This inequality implies that $x(\varepsilon)$ converges to a maximal complementary solution (the number of positive components in x and $g(x)$ is maximal) if $g(x)$ is a monotone function (see [41] and references therein). This also implies that $x(\varepsilon)$ converges to a strictly complementary solution if $g(x)$ is monotone and the NCP has a strictly complementary solution, which property is possessed by most interior point algorithms.

We now turn our attention to the existence of the trajectory defined by

$$\{x(\varepsilon, r) \ : \ f(x, \varepsilon) = r, \quad \varepsilon > 0, r \in \Re^n\}.$$

The following two assumptions will be used to establish a sufficient condition for the existence of a solution to $f(x, \varepsilon) = r$, where r is a given n-dimensional vector.

A1. The level sets

$$D(\Gamma) = \{x \in \Re^n \ : \ \|F(x)\| \leq \Gamma\}$$

are bounded for all positive numbers Γ.

A2. For any $\varepsilon > 0$ and $x \in \Re^n$, $f_x(x, \varepsilon)$ is nonsingular.

Assumptions related to A1 and A2 have been used in several papers on smoothing methods. We state some results here.

PROPOSITION 2.3. *Any of the following conditions implies assumption* A1*:*

(i) *g is a uniform P function* [24]*;*

(ii) $-\infty < l_i < u_i < \infty$ *for* $i = 1, 2, \dots, n$ [9]*;*

(iii) $l_i = 0$ *for* $i = 1, 2, \dots, n$*, and g is an R_0 function* [5].

Any of the following conditions implies assumption A2*:*

(i) *g is a uniform P function* [19]*;*

(ii) *g is a P_0 function and* $\text{supp}\{\rho\} = \Re$ [19].

Many interior point algorithms (e.g., [28, 41]) for solving the NCP use the following assumption:

AIP. g is monotone and the set of all the strictly positive feasible solutions

$$S_{++}(g) = \{x \in \Re^n : g(x) > 0,\ x > 0\}$$

is nonempty.

The existence of a feasible interior point is the standard assumption for any interior point algorithm, and the monotonicity of g is necessary to have a convex objective for the LCP [41]

$$\begin{array}{rl} \min & x^T g(x), \\ \text{subject to} & g(x) = Mx + q, (x, g(x)) \geq 0. \end{array}$$

The existence and uniqueness of trajectories defined by

$$\{x(\varepsilon, 0) \ : \ f(x, \varepsilon) = 0, \varepsilon > 0\}$$

were established in [5, 28] under assumption AIP. It is interesting to see the relation between interior point methods and smoothing methods from the difference of assumptions A1, A2, and AIP.

Since the monotonicity is stronger than the P_0 property, the assumption AIP implies A2 for smooth functions with $\text{supp}\{\rho\} = \Re$. However, neither of the two assumptions, A1 and AIP, implies the other. A1 does not imply AIP, because the uniform P property satisfies A1 but fails to satisfy the monotonicity. Kanzow, Yamashita, and Fukushima [25] gave a simple example to show that AIP does not imply A1. In their example, $g(x) \equiv 1$, for $x \in \Re$. Then g is monotone and $S_{++}(g)$ is nonempty. However, for $\Gamma \geq 1$, $[1, \infty) \subset D(\Gamma)$.

Nevertheless, the following proposition shows that AIP implies the boundedness of certain level sets for the NCP.

Proposition 2.4. *Under assumption* AIP*, the level sets* $D(\Gamma)$ *are bounded for all positive numbers* $\Gamma < \Gamma_0$, *where*

$$F(x) := \min(x, g(x))$$

and

$$\Gamma_0 := \sup\left\{\min_{i \in N} F_i(x), \ x \in S_{++}(g)\right\}.$$

Proof. Let $\Gamma < \Gamma_0$ and $\hat{x} \in S_{++}(g)$ satisfy

$$\Gamma < \min_{i \in N} F_i(\hat{x}).$$

This means that for each $i \in N$, $g_i(\hat{x}) > \Gamma$ and $\hat{x}_i > \Gamma$.

Suppose on the contrary that we have an unbounded sequence $\{x^k\} \subset D(\Gamma)$. Since $x^k \in D(\Gamma)$ implies that $|\min(x_i^k, g_i(x^k))| \leq \Gamma$ for each $i \in N$, there is no index j such that $x_j^k \to -\infty$ or $g_j(x^k) \to -\infty$. Define the index sets $J = \{i \ : \ x_i^k \to \infty, \ i \in N\}$ and $L = \{\ell \ : \ g_\ell(x^k) \to \infty, \ \ell \in N\}$. Since $\{x^k\}$ is unbounded by assumption, the set J is nonempty, while the set L can be either empty or nonempty.

Then there is a $k' \geq 0$ such that for all $k \geq k'$,

$$|\min(x_i^k, g_i(x^k))| = |g_i(x^k)| \leq \Gamma \quad \text{for} \quad i \in J$$

and

$$|\min(x_\ell^k, g_\ell(x^k))| = |x_\ell^k| \leq \Gamma \quad \text{for} \quad \ell \in L \text{ (if } L \neq \emptyset).$$

Hence we have

$$x_i^k - \hat{x}_i \to \infty, \quad |g_i(x^k)| \leq \Gamma < g_i(\hat{x}) \quad \text{for} \quad k \geq k', \ i \in J$$

and

$$g_\ell(x^k) - g_\ell(\hat{x}) \to \infty, \quad |x^k_\ell| \le \Gamma < \hat{x}_\ell \quad \text{for} \quad k \ge k',\ \ell \in L \text{ (if } L \ne \emptyset).$$

Note this results in a contradiction to the monotonicity of g, i.e,

$$(g(x^k) - g(\hat{x}))^T(x^k - \hat{x}) \ge 0.$$

Thus $D(\Gamma)$ must be bounded. □

Subsequent to the writing of this paper, several interesting results on the boundedness of the level set $D(\Gamma)$ and the existence of an interior feasible point for the P_0-function NCP were established [3, 14, 37]. We summarize these results by the following theorem.

Theorem 2.2. *Suppose that g is a P_0 function and the solution set of the NCP is nonempty and bounded. Then we have the following:*

(i) $D(\Gamma)$ *is bounded for all sufficiently small* $\Gamma > 0$ [14, 37]*;*

(ii) $S_{++}(g)$ *is nonempty* [3, 37].

The assumption of Theorem 2.2 is weaker than assumption AIP, because every monotone function is a P_0 function and that $S_{++}(g)$ is nonempty implies that the solution set of the monotone NCP is nonempty and bounded. On the other hand, under assumption AIP, by Proposition 2.4, we can have a bounded level set for smoothing methods after we find an interior point (see Corollary 3.1). Precisely, if $\tilde{x} \in S_{++}(g)$, then

$$\min_{i\in N} F_i(\tilde{x}) \le \Gamma_0 = \sup\left\{\min_{i\in N} F_i(x), x \in S_{++}(g)\right\}.$$

Hence for every point x^0 satisfying

$$\|F(x^0)\| < \min_{i\in N} F_i(\tilde{x}),$$

the level set $D(\|F(x^0)\|)$ is bounded. However, we cannot define a bounded level set by using an interior point based on Theorem 2.2.

Theorem 2.3. *Suppose that assumptions* A1 *and* A2 *hold; then for any $\varepsilon > 0$ and $r \in \Re^n$, there is a solution $x(\varepsilon, r)$ of $f(x,\varepsilon) = r$. Furthermore, if g is a P_0 function and* $\text{supp}\{\rho\} = \Re$, *then, $x(\varepsilon, r)$ is unique.*

Proof. Let $\mu = \kappa\sqrt{n}$. We choose $x^0 \in \Re^n$ and a positive number Γ satisfying $\Gamma > \mu\varepsilon + \|r\|$ and $\Gamma - \mu\varepsilon - \|r\| > \|F(x^0)\|$. We define

$$C_{\varepsilon,r}(\Gamma) = \{x \ :\ \|f(x,\varepsilon) - r\| \le \Gamma\}.$$

By (2.4), we have

$$\|f(x,\varepsilon) - r\| \le \|F(x)\| + \mu\varepsilon + \|r\| \tag{2.26}$$

and

$$\|F(x)\| \le \|f(x,\varepsilon) - r\| + \mu\varepsilon + \|r\|. \tag{2.27}$$

Since $x^0 \in D(\Gamma - \mu\varepsilon - \|r\|)$, (2.26) implies that $x^0 \in C_{\varepsilon,r}(\Gamma)$, and hence $C_{\varepsilon,r}(\Gamma)$ is nonempty. By (2.27), we have

$$C_{\varepsilon,r}(\Gamma) \subseteq D(\Gamma + \mu\varepsilon + \|r\|).$$

Hence, from assumption A1, the level set $C_{\varepsilon,r}(\Gamma)$ is bounded.

Let $\theta(x) := \frac{1}{2}\|f(x,\varepsilon)-r\|^2$. The boundedness of $C_{\varepsilon,r}(\Gamma)$ and the continuous differentiability of $f(\cdot,\varepsilon)$ imply that θ has a global minimum point x^* in $C_{\varepsilon,r}(\Gamma)$ [33, Thm. 4.2.2]. Since $\theta(x^*) \le \theta(x^0)$ and $\|f(x^0,\varepsilon)-r\| < \Gamma$, $x^* \in \operatorname{int} C_{\varepsilon,r}(\Gamma)$. Moreover, by assumption A2, $f'_{\mathbf{1}}(x^*,\varepsilon)$ is nonsingular. Therefore, by [33, Thm. 4.1.3], $\theta'(x^*) = f'_{\mathbf{1}}(x^*,\varepsilon)^T(f(x^*,\varepsilon)-r) = 0$, and so $f(x^*,\varepsilon)=r$.

Now we prove the uniqueness of $x(\varepsilon,r)$.

Let $y=g(x)$, $t=x-y$, and

$$h_i(t) = \int_{-\infty}^{\infty} \operatorname{mid}(l_i,u_i,t_i-\varepsilon s)\rho(s)ds, \quad i=1,\dots n.$$

By Proposition 2.2, $h_i(t)$ is an increasing function—therefore, an increasing function in x_i and a decreasing function in y_i. Furthermore, by Lemma 2.3 in [19], we can claim $h'_i(t) \in (0,1)$.

Suppose on the contrary that we have both x^1 and x^2 as solutions. Let $y^1=g(x^1)$ and $y^2=g(x^2)$. Since $g(x)$ is a P_0 function, we have an index i such that

$$x_i^1 \ne x_i^2 \quad \text{and} \quad (y_i^1-y_i^2)(x_i^1-x_i^2) \ge 0.$$

Assume that, without loss of generality, $x_i^1 > x_i^2$. Then we have $y_i^1 \ge y_i^2$. Moreover,

$$\begin{aligned} & x_i^1 - x_i^2 \\ & = h_i(x_i^1-y_i^1) - h_i(x_i^2-y_i^2) \\ & \le h_i(x_i^1-y_i^2) - h_i(x_i^2-y_i^2) \\ & = h'_i(\theta)(x_i^1-x_i^2) \\ & < x_i^1-x_i^2, \end{aligned}$$

where θ is between $x_i^1-y_i^2$ and $x_i^2-y_i^2$ according to the Taylor theorem. Note that this results in a contradiction. Thus, we must have $x^1=x^2$. □

3. Algorithm and convergence. In this section, we propose a hybrid Newton-smoothing algorithm for solving VI(l,u,g). We show that the algorithm converges globally and superlinearly under assumptions A1 and A2. Furthermore, the method is finitely convergent if

$$g(x) = Mx+q,$$

where M is an $n\times n$ matrix and q is an n-dimensional vector. In this case, we denote the linear variational inequality problem by VI(l,u,M,q).

We denote

$$\Theta(x) = \frac{1}{2}\|F(x)\|^2$$

and

$$\theta_k(x) = \frac{1}{2}\|f(x,\varepsilon_k)\|^2.$$

ALGORITHM 3.1. *Given $\rho,\alpha,\eta \in (0,1)$ and a starting point $x^0 \in \Re^n$, choose a scalar $\sigma \in (0,\frac{1}{2}(1-\alpha))$. Let $\nu = \frac{\alpha}{2\sqrt{n}\kappa}$. Let $\beta_0 = \|F(x^0)\|$ and $\varepsilon_0 = \nu\beta_0$.*

For $k\ge 0$:

1. *Find a solution* $\hat{d}^k$ *of the system of linear equations*

$$F(x^k) + f^0(x^k)d = 0. \tag{3.1}$$

If $\|F(x^k + \hat{d}^k)\| \le \eta\beta_k$, *let* $x^{k+1} = x^k + \hat{d}^k$. *Otherwise perform step* 2.

2. *Find a solution* d^k *of the system of linear equations*

$$F(x^k) + f_x(x^k, \varepsilon_k)d = 0. \tag{3.2}$$

Let m_k *be the smallest nonnegative integer* m *such that*

$$\theta_k(x^k + \rho^m d^k) - \theta_k(x^k) \le -2\sigma\rho^m\Theta(x^k). \tag{3.3}$$

Set $t_k = \rho^{m_k}$ *and* $x^{k+1} = x^k + t_k d^k$.

3. 3.1. *If* $\|F(x^{k+1})\| = 0$, *terminate.*

 3.2. *If*

$$0 < \|F(x^{k+1})\| \le \max\{\eta\beta_k, \alpha^{-1}\|F(x^{k+1}) - f(x^{k+1}, \varepsilon_k)\|\}, \tag{3.4}$$

let

$$\beta_{k+1} = \|F(x^{k+1})\| \quad \textit{and} \quad \varepsilon_{k+1} = \min\left\{\nu\beta_{k+1}, \frac{\varepsilon_k}{2}\right\}.$$

 3.3. *Otherwise, let* $\beta_{k+1} = \beta_k$ *and* $\varepsilon_{k+1} = \varepsilon_k$.

Algorithm 3.1 is a modification of the smoothing method proposed in [9]. This algorithm simplifies the ε update step in [9] and has finite convergence property for linear box constrained VIP.

THEOREM 3.1. *Suppose that assumptions* A1 *and* A2 *hold. Then for any starting point* $x^0 \in \Re^n$, *Algorithm* 3.1 *is well defined and the generated sequence* $\{x^k\}$ *remains in* $D_0 := D((1+\alpha)\|F(x^0)\|)$ *and satisfies*

$$\lim_{k\to\infty} \|F(x^k)\| = 0. \tag{3.5}$$

Proof. By Lemma 3.1 in [9], there exists a finite nonnegative integer m_k such that (3.3) holds. Hence, Algorithm 3.1 is well defined.

Let

$$K = \{k \ : \ \|F(x^k + \hat{d}^k)\| \le \eta\beta_k, \quad k \ge 0\}.$$

By the construction of Algorithm 3.1, for $k \in K$, $x^{k+1} = x^k + \hat{d}^k$ and $\beta_{k+1} = \|F(x^{k+1})\| \le \eta\beta_k \le (1+\alpha)\|F(x^0)\|$. Hence, $x^{k+1} \in D_0$ for $k \in K$. Moreover, following the proof of Theorem 3.1 in [9], we can show $x^{k+1} \in D_0$ for $k \notin K$. Hence, $\{x^k\}$ remains in D_0.

Now we prove (3.5).

If K is finite, then there exists $k_0 \ge 0$ such that step 2 is performed for all $k \ge k_0$. By Theorem 3.1 in [9],

$$\lim_{\substack{k\to\infty \\ k\ge k_0}} \|F(x^k)\| = 0.$$

Hence the whole sequence $\{x^k\}$ satisfies (3.5).

If K is infinite, then by the construction of Algorithm 3.1,

$$\lim_{\substack{k\to\infty \\ k\in K}} \|F(x^k)\| = 0.$$

Let

$$\bar{K} = \{k \ : \ \|F(x^{k+1})\| \le \max\{\eta\beta_k, \alpha^{-1}\|F(x^{k+1}) - f(x^{k+1}, \varepsilon_k)\|\}\}.$$

Then $K \subseteq \bar{K}$. Assume that $\bar{K}$ consists of $k_0 = 0 < k_1 < k_2 < \cdots$.

Let k be an arbitrary nonnegative integer. Let k_j be the largest number in $\bar{K}$ such that $k_j \le k$. Then $\varepsilon_k = \varepsilon_{k_j}$ and $\beta_k = \beta_{k_j}$. By the line search rule

$$\|f(x^k, \varepsilon_{k_j})\| \le \|f(x^{k_j}, \varepsilon_{k_j})\|.$$

Hence by (2.4), for $j \ge 0$,

$$\begin{aligned} \|F(x^k)\| &\le \|f(x^k, \varepsilon_k)\| + \|F(x^k) - f(x^k, \varepsilon_k)\| \\ &= \|f(x^k, \varepsilon_{k_j})\| + \|F(x^k) - f(x^k, \varepsilon_{k_j})\| \\ &\le \|f(x^{k_j}, \varepsilon_{k_j})\| + \mu\varepsilon_{k_j} \\ &\le \|F(x^{k_j})\| + 2\mu\varepsilon_{k_j} \\ &= \beta_{k_j} + 2\mu\varepsilon_{k_j}, \end{aligned}$$

where $\mu = \kappa\sqrt{n}$.

Since K is infinite, $\bar{K}$ is infinite and hence $\beta_{k_j} \to 0$ and $\varepsilon_{k_j} \to 0$ as $j \to \infty$. Therefore, the whole sequence $\{x^k\}$ satisfies (3.5). □

COROLLARY 3.1. *Suppose that assumption AIP holds and* $l_i = 0, u_i = \infty$ *for each* $i \in N$. *Then for any smooth function* f *with* $\operatorname{supp}\{\rho\} = \Re$ *and any starting point* $x^0 \in \Re^n$*, Algorithm* 3.1 *is well defined and the generated sequence* $\{x^k\}$ *remains in* $D_0 := D((1+\alpha)\|F(x^0)\|)$. *Furthermore, if* x^0 *satisfies*

$$(3.6) \qquad (1+\alpha)\|F(x^0)\| < \sup\left\{\min_{i\in N} F_i(x),\ x \in S_{++}(g)\right\},$$

then $\lim_{k\to\infty} \|F(x^k)\| = 0$.

Proof. By Theorem 4.2 in [19], the monotonicity of g implies assumption A2. By Lemma 3.1 in [9], there is a finite nonnegative integer m_k such that (3.3) holds. Hence Algorithm 3.1 is well defined. Following the proof of Theorem 3.1 in [9] and Theorem 3.1 here, we can show $\{x^k\} \subset D_0$ for any starting point $x^0 \in \Re^n$. By Proposition 2.4, if x^0 satisfies (3.6), then D_0 is bounded. Therefore, we can show that $\lim_{k\to\infty} \|F(x^k)\| = 0$ by following the proof of Theorem 3.1. □

The following lemma shows that if an iterate is sufficiently close to a solution of VI(l, u, M, q), Algorithm 3.1 finds the solution in one step. We define

$$\begin{aligned} \gamma(x) = \min_{1\le i,j\le n} \{&|x - Mx - q - l|_i, |x - Mx - q - u|_j : \\ &(x - Mx - q - l)_i \ne 0, (x - Mx - q - u)_j \ne 0\}. \end{aligned}$$

Since $l_i < u_i$ for all $i \in N$, $\gamma(x) > 0$ for any $x \in \Re^n$.

LEMMA 3.1. *Let* $x^* \in \Re^n$ *be a solution of VI*(l, u, M, q). *Let*

$$(3.7) \qquad B := \begin{cases} \{x \in \Re^n \ : \ \|x - x^*\|_\infty \le \gamma(x^*)/\|I - M\|_\infty\} & \textit{if } I \ne M, \\ \Re^n & \textit{otherwise.} \end{cases}$$

Then for any $x \in B$,

$$F(x) + f^0(x)(x^* - x) = 0. \tag{3.8}$$

Proof. If $M = I$, then $f^0(x) = I$ for any $x \in \Re^n$. Moreover, x^* =mid$(l, u, -q)$ is a solution of $F(x) = 0$. Hence, in this case for any $x \in \Re^n$,

$$F(x) + f^0(x)(x^* - x) = x - \mathrm{mid}(l, u, -q) + (x^* - x) = 0.$$

Suppose that $I \neq M$ and $x \in B$. Then

$$\begin{aligned} |x - Mx - q - x^* + Mx^* + q|_i &\leq \|I - M\|_\infty \|x - x^*\|_\infty \\ &\leq \gamma(x^*). \end{aligned} \tag{3.9}$$

For a fixed i, we consider two cases.

Case 1. $(x^* - Mx^* - q)_i \neq l_i$ and $(x^* - Mx^* - q)_i \neq u_i$.

By the definition $\gamma(x)$ and (3.9), we have

$$(x^* - Mx^* - q)_i < l_i \quad \Rightarrow (x - Mx - q)_i < l_i, \tag{3.10}$$

$$l_i < (x^* - Mx^* - q)_i < u_i \quad \Rightarrow l_i < (x - Mx - q)_i < u_i, \tag{3.11}$$

and

$$(x^* - Mx^* - q)_i > u_i \quad \Rightarrow (x - Mx - q)_i > u_i. \tag{3.12}$$

If $(x^* - Mx^* - q)_i \in (l_i, u_i)$, then $(Mx^* + q)_i = 0$. By (3.11) and (2.6), $f_i^0(x) = M_i$ and

$$F_i(x) + f_i^0(x)(x^* - x) = x_i - (x - Mx - q)_i + M_i(x^* - x) = (Mx^* + q)_i = 0. \tag{3.13}$$

If $(x^* - Mx^* - q)_i < l_i$, then $x_i^* = l_i$. By (3.10) and (2.6), $f_i^0(x) = I_i$ and

$$F_i(x) + f_i^0(x)(x^* - x) = x_i - l_i + I_i(x^* - x) = x_i^* - l_i = 0. \tag{3.14}$$

Similarly, we can show

$$F_i(x) + f_i^0(x)(x^* - x) = x_i^* - u_i = 0,$$

for $(x^* - Mx^* - q)_i > u_i$.

Case 2. $(x^* - Mx^* - q)_i = l_i$ or $(x^* - Mx^* - q)_i = u_i$.

If $(x^* - Mx^* - q)_i = l_i$, then $x_i^* = l_i$ and $(Mx^* + q)_i = 0$.

If $(x - Mx - q)_i > l_i$ or $(x - Mx - q)_i < l_i$, we can find $F_i(x) + f_i^0(x)(x^* - x) = 0$ by following the same argument in (3.13) and (3.14). If $(x - Mx - q)_i = l_i$, then $f_i^0(x) = I_i - \lambda(I_i - M_i)$, where $\lambda \in (0, 1)$. Furthermore, we have

$$\begin{aligned} &F_i(x) + f_i^0(x)(x^* - x) \\ &= x_i - l_i + (I_i - \lambda(I_i - M_i))(x^* - x) \\ &= \lambda(M_i - I_i)(x^* - x) \\ &= \lambda(x_i - l_i + (Mx^* + q - Mx - q)_i) \\ &= \lambda((x - l - Mx - q)_i + (Mx^* + q)_i) = 0. \end{aligned}$$

The proof of the case $(x^* - Mx^* - q)_i = u_i$ is similar. □

THEOREM 3.2. *Suppose that* A1 *and* A2 *hold. Assume that for an accumulation point x^* of $\{x^k\}$, there is an open ball $\hat{B} := \hat{B}(x^*, \bar{r}) = \{x \ : \ \|x - x^*\| < \bar{r}\}$ and a positive number Υ such that for any $x \in \hat{B}$, $f^0(x)$ is nonsingular and $\|f^0(x)^{-1}\| \le \Upsilon$. Then x^* is a solution of* (1.1) *and $\{x^k\}$ converges to x^* superlinearly. Moreover, if g has a locally Lipschitz continuous derivative around x^*, the convergence rate is quadratic. In addition, if g is an affine function, the convergence is finite.*

Proof. By Theorem 3.1, x^* is a solution of (1.1). By Lemma 2.4 in [7], x^* is the unique solution of (1.1) in $\hat{B}$. Let K_* be a subsequence of $\{0, 1, \ldots\}$ such that

$$\lim_{\substack{k \to \infty \\ k \in K_*}} x^k = x^*.$$

By the directional derivative consistency property of f at x^*, for $k \in K_*$,

$$\begin{aligned}
&\|x^k + \hat{d}^k - x^*\| \\
&= \|x^k - f^0(x^k)^{-1}F(x^k) - x^*\| \\
&= \|f^0(x^k)^{-1}(f^0(x^k)(x^k - x^*) - F(x^k) + F(x^*))\| \\
&\le \Upsilon \|F(x^k) - F(x^*) - f^0(x^k)(x^k - x^*)\| \\
&= o(\|x^k - x^*\|).
\end{aligned} \tag{3.15}$$

Following the proof of Theorem 3.1 in [35],

$$\|F(x^k + \hat{d}^k)\| = o(\|F(x^k)\|).$$

This implies that there is $k_* \in K_*$ such that for all $k \ge k_*$,

$$\|F(x^k + \hat{d}^k)\| \le \eta \|F(x^k)\|$$

and $x^{k+1} = x^k + \hat{d}^k$. Hence, $\{x^k\}$ converges to x^* superlinearly.

Moreover, if g has a locally Lipschitz continuous derivative, F is directionally differentiable of degree 2 at x^*. Thus

$$\|F(x^k) - F(x^*) - f^0(x^k)(x^k - x^*)\| = O(\|x^k - x^*\|^2).$$

Following the argument in (3.15), we obtain the quadratic convergence rate.

The finite convergence follows from Lemma 3.1 and the fact that $k \in K_*$ for all $k \ge k_*$. □

Remark 3.1. If g is a uniform P function, by Theorem 4.3 in [19], for any $x \in \Re^n$, $f^0(x)$ is nonsingular. Hence, by Proposition 2.3, Algorithm 3.1 converges globally and superlinearly for VI(l, u, g), and converges globally and finitely for VI(l, u, M, q), assuming only that g is a uniform P function. It is notable that global convergence of Algorithm 3.1 requires only that g be a P_0 function and the level sets $\{x \ : \ \|F(x)\| \le \Gamma\}$ with $\Gamma > 0$ be bounded. Furthermore, Algorithm 3.1 converges to the solution set of the NCP if g is monotone, $S_{++}(g)$ is nonempty, and the starting point is in a certain level set.

4. Numerical experiments.

We numerically tested Algorithm 3.1 with seven examples containing 27 linear box-constrained VIPs and 4 nonlinear VIPs. We use three smooth approximation functions which are generated by (2.3) and density functions ρ satisfying (2.1) and (2.2) (cf. [5, 6, 7, 8, 9, 15, 19, 23, 36]).

Let

$$z = x - Mx - q.$$

Neural networks smooth approximation function (S1):

Let the density function be

$$\rho(x) = \frac{e^{-s}}{(1+e^{-s})^2}.$$

The smooth approximation function is

$$f_i(x,\varepsilon) = x_i - u_i - \varepsilon \log(1 + e^{(l_i - z_i)/\varepsilon}) + \varepsilon \log(1 + e^{(u_i - z_i)/\varepsilon})$$

and $f_x(x,\varepsilon) = I - D(x)(I - M)$, where

$$d_{ii}(x) = \frac{-e^{(l_i - z_i)/\varepsilon}}{1 + e^{(l_i - z_i)/\varepsilon}} + \frac{e^{(u_i - z_i)/\varepsilon}}{1 + e^{(u_i - z_i)/\varepsilon}}.$$

Chen–Harker–Kanzow–Smale smooth approximation function (S2):

Let the density function be

$$\rho(s) = \frac{2}{(s^2+4)^{\frac{3}{2}}}.$$

The smooth approximation function is

$$f_i(x,\varepsilon) = x_i - \frac{1}{2}\left(\sqrt{(l_i - z_i)^2 + 4\varepsilon^2} - \sqrt{(u_i - z_i)_i^2 + 4\varepsilon^2} + u_i + l_i\right)$$

and $f_x(x,\varepsilon) = I - D(x)(I - M)$, where

$$d_{ii}(x) = \frac{1}{2}\left(\frac{z_i - l_i}{\sqrt{(z_i - l_i)^2 + 4\varepsilon^2}} - \frac{z_i - u_i}{\sqrt{(z_i - u_i)^2 + 4\varepsilon^2}}\right).$$

Uniform smooth approximation function (S3):

Let the density function be

$$\rho(s) = \begin{cases} 1, & |s| \le 0.5, \\ 0 & \text{otherwise.} \end{cases}$$

For $0 < \varepsilon \le \min_{1 \le i \le n}\{u_i - l_i\}$,

$$f_i(x,\varepsilon) = \begin{cases} 1/2(Mx + q + x)_i + 1/2\varepsilon(u_i - z_i)^2 + \varepsilon/8 - u_i/2 & \text{if } |u_i - z_i| \le \varepsilon/2, \\ 1/2(Mx + q + x)_i - 1/2\varepsilon(l_i - z_i)^2 - \varepsilon/8 - l_i/2 & \text{if } |l_i - z_i| \le \varepsilon/2, \\ F_i(x) & \text{otherwise,} \end{cases}$$

and

$$f_x(x,\varepsilon) = \begin{cases} 1/2(I_i + M_i) + 1/\varepsilon(u_i - z_i)(M_i - I_i) & \text{if } |u_i - z_i| \le \varepsilon/2, \\ 1/2(I_i + M_i) - 1/\varepsilon(l_i - z_i)(M_i - I_i) & \text{if } |l_i - z_i| \le \varepsilon/2, \\ F_i'(x) & \text{otherwise.} \end{cases}$$

S3	2, 0, 0.0	2, 0, 0.2	2, 0, 0.8	2, 0, 1.0
$l_i = -1.0$, $u_i = 0.5$ for i is even, $l_i = -0.5$, $u_i = 1.0$ for i is odd.				
n	50	100	150	180
S1	14, 32, 0.7	18, 58, 3.0	25, 108, 26.4	26, 104, 17
S2	14, 30, 0.3	17, 53, 1.7	24, 101, 21.4	7, 10, 3.4
S3	14, 32, 0.5	18, 58, 2.2	25, 108, 19.2	45, 307, 24.4

The three density functions have a common property: $\rho(-s) = \rho(s)$. By (2.6), this implies that for any $x \in \Re^n$, the derivatives $f_x(x, \varepsilon)$ of the three smooth approximation functions have the same limit $f^0(x)$ as $\varepsilon \downarrow 0$, where

$$f_i^0(x) = \begin{cases} M_i & \text{if } z_i \in (l_i, u_i), \\ I_i & \text{if } z_i \notin [l_i, u_i], \\ 1/2(I_i + M_i) & \text{otherwise.} \end{cases} \tag{4.1}$$

Furthermore, the three density functions satisfy (2.1) and (2.2).

We chose $x^0 = e$, $\rho = 0.75$, $\alpha = 0.56$, $\eta = 0.87$, and $\sigma = 0.2$ in Algorithm 3.1. The stopping criterion was $\|F(x^k)\| \le 10^{-8}$. Numerical results were obtained using MATLAB 4.2c on a Sun 2000 workstation. These testing problems are constructed from some testing problems for LCP and NCP. We added different lower and upper bounds on the variables. We report the iterations k, the total numbers of line search steps $\sum_{i=1}^{k} m_i$, and CPU time in Tables 1–5 for solving these problems with different dimensions in Examples 4.1–4.5. We report the iterations k, the numbers of iterations where the Newton step in step 1 was accepted, and the number of iterations where the smooth step and line search were taken in step 2 as well as the function values at the final step $\|F(x^k)\|$ in Tables 6 and 7 for solving these problems in Examples 4.6 and 4.7. The three smooth approximation functions perform similarly in our numerical test.

$$g(x) = \begin{pmatrix} 3x_1^2 + 2x_1x_2 + 2x_2^2 + x_3 + 3x_4 - 6 \\ 2x_1^2 + x_1 + x_2^2 + 10x_3 + 2x_4 - 2 \\ 3x_1^2 + x_1x_2 + 2x_2^2 + 2x_3 + 9x_4 - 9 \\ x_1^2 + 3x_2^2 + 2x_3 + 3x_4 - 3 \end{pmatrix}.$$

Remark 4.1. Both Lemke's complementarity pivot algorithm and the Cottle and Dantzig principal pivoting method are known to run in exponential time for Examples 4.1 and 4.2 with $l_i = 0, u_i = \infty$ (i.e., the LCP). Tables 1 and 2 show that the hybrid Newton-smoothing method takes only a few iterations for the LCP. It is notable that the LCP is relatively easier than the problem having different lower and upper bounds. To see the reason, we consider Example 4.1. The solution for the LCP is

$$x^* = (0, 0, \ldots, 0, 1)^T$$

S3	2	2	0	0	0	0.03

and

$$Mx^* + q = (1, 1, \dots, 1, 0)^T.$$

In this case $q_i(x) + p_i(x) > 0$, $i = 1, 2, \dots, n$, i.e., x^* is a strictly complementary solution. The function F is differentiable at x^*.

For $0 < l < u = 1$, the solution for $\text{VI}(l, u, M, q)$ is

$$x^* = (l_1, \dots, l_{n-1}, u)$$

and

$$(Mx^* + q)_i > 0, \quad i = 1, \dots, n-1, \quad (Mx^* + q)_n = 0.$$

In this case, $q_i(x) + p_i(x) > 0$, $i = 1, 2, \dots, n-1$, and $q_n(x) + p_n(x) = 0$.

This problem is relatively easy to solve, if $l \geq 0$ or $u \leq 0$. However, this problem becomes hard if $l < 0$ but $u > 0$. For example, if $l_i = -1$ and $u_i = 1$ for each $i \in N$, the solution is

$$x^* = (1, -1, 1, -1, \dots, 1) \quad \text{if } n \text{ is odd}$$

or

$$x^* = (-1, 1, -1, 1, \dots, 1) \quad \text{if } n \text{ is even},$$

and

$$Mx^* + q = 0.$$

This means $p_i(x) + q_i(x) = 0$ for $i = 1, \dots, n$.

Acknowledgments. The authors would like to thank J.S. Pang for his comment on limiting behavior of trajectories, D. Sun for his helpful comments, and the referees for their constructive suggestions.

EXACT PENALIZATION OF MATHEMATICAL PROGRAMS WITH EQUILIBRIUM CONSTRAINTS[*]

STEFAN SCHOLTES[†] AND MICHAEL STÖHR[‡]

Abstract. We study theoretical and computational aspects of an exact penalization approach to mathematical programs with equilibrium constraints (MPECs). In the first part, we prove that a Mangasarian–Fromovitz-type condition ensures the existence of a stable local error bound at the root of a real-valued nonnegative piecewise smooth function. A specification to nonsmooth formulations of equilibrium constraints, e.g., complementarity conditions or normal equations, provides conditions which guarantee the existence of a nonsmooth exact penalty function for MPECs. In the second part, we study a trust region minimization method for a class of composite nonsmooth functions which comprises exact penalty functions arising from MPECs. We prove a global convergence result for the general method and incorporate a penalty update rule. A further specification results in an SQP trust region method for MPECs based on an ℓ_1 penalty function.

Key words. bilevel program, error bound, exact penalization, ℓ_1 penalty function, Mangasarian–Fromovitz constraint qualification, mathematical program with equilibrium constraints (MPEC), piecewise smooth, sequential quadratic programming, trust region

1. Introduction.

Mathematical programs with equilibrium constraints (MPECs) are mathematical programs which involve, besides the usual differentiable equality and inequality constraints, a so-called equilibrium constraint. Such MPECs arise naturally in different areas, such as economics, computational mechanics, neural network training, and traffic control, and have been the subject of a number of recent studies (e.g., [1, 19, 20, 21, 22, 24, 25, 26, 34]). An equilibrium constraint requires that some of the variables, the state variables, satisfy an equilibrium condition which, however, changes with the remaining so-called design variables. The equilibrium condition is usually formulated in terms of a variational inequality induced by a parametric vector field $F(.,y)$ over a set $S(y)$, where y is the design variable. Recall that a vector x satisfies the variational inequality for a fixed design vector y if $x \in S(y)$ and $F(x,y)^\top(z-x) \geq 0$ for every $z \in S(y)$. If $S(y)$ has a functional representation

$$S(y) = \{x \in \mathbb{R}^n \mid h(x,y) = 0, g(x,y) \leq 0\},$$

where g, h are smooth vector valued functions, then the variational inequality is often replaced by the corresponding stationarity condition

$$\begin{aligned} F(x,y) + \nabla_x h(x,y)^\top \mu + \nabla_x g(x,y)^\top \lambda &= 0, \\ h(x,y) &= 0, \\ g(x,y) &\leq 0, \\ \lambda &\geq 0, \\ g(x,y)^\top \lambda &= 0. \end{aligned} \tag{1.1}$$

[‡] Universität Karlsruhe, Institut für Statistik und Mathematische Wirtschaftstheorie, 76128 Karlsruhe, Germany.

Two special cases are of particular interest. If, on the one hand, $F(.,y)$ is the gradient with respect to the state variable x of a function $f(.,y)$, then condition (1.1) corresponds to the Karush–Kuhn–Tucker (KKT) conditions of the parametric mathematical program $\min\{f(x,y) \mid x \in S(y)\}$. If, on the other hand, the function h is absent and $g(x,y) = -x$, then the multipliers λ and μ can be eliminated and (1.1) turns into the parametric nonlinear complementarity problem

$$\begin{aligned} F(x,y) &\geq 0, \\ x &\geq 0, \\ x^\top F(x,y) &= 0. \end{aligned} \tag{1.2}$$

We shall assume throughout that the functions F, g, and h are smooth so that (1.1) and (1.2) are systems of smooth equations and inequalities. If all further constraints of the MPEC are smooth equations or inequalities, then the problem turns into a smooth nonlinear program and one may want to apply the well-developed methods for such problems. Unfortunately, any set of constraints which involves a complementarity condition of the general form

$$\Phi(z) \geq 0, \quad \Psi(z) \geq 0, \quad \Phi(z)^\top \Psi(z) = 0 \tag{1.3}$$

is inherently unstable so that standard methods are likely to fail in the presence of round-off errors. The instability is due to the fact that the Mangasarian–Fromovitz constraint qualification, which is necessary for the stability of a nonlinear program [14, 35], is violated at any feasible point of the constraint set [4].

It is possible to circumvent these difficulties by reformulating system (1.1) as a system of nonsmooth equations

$$\begin{aligned} F(x,y) + \nabla_x h(x,y)^\top \mu + \nabla_x g(x,y)^\top \lambda &= 0, \\ h(x,y) &= 0, \\ \min\{-g(x,y), \lambda\} &= 0. \end{aligned} \tag{1.4}$$

From the viewpoint of nonsmooth optimization, there is no severe problem with this set of equations, i.e., constraint qualifications are satisfied under reasonable conditions [18].

If the constraint set S for the variational inequality is closed, convex, and independent of y, one may avoid the explicit use of the multipliers λ and μ in (1.1) and instead use an alternative nonsmooth formulation of the variational inequality either as a direct normal equation

$$\Pi_S(x - F(x,y)) - x = 0$$

or as Robinson's normal equation [38]

$$\Pi_S(z) - F(\Pi_S(z), y) - z = 0.$$

The solutions of the two equations are related via $x = \Pi_S(z)$ and $z = x - F(x,y)$.

Our aim in this paper is to study the classical nonsmooth exact penalization technique for optimization problems which involve nonsmooth formulations of equilibrium conditions. In the next section, we recall some results from the theory of piecewise smooth functions which we shall employ in the subsequent sections, and we give a short review of the principle of exact penalization. In section 3 we derive conditions for the existence of local error bounds for piecewise smooth constraints. By specifying these conditions to piecewise smooth formulations of equilibrium constraints we obtain exact penalization results for MPECs. In section 4 we present a globally convergent trust region method for the minimization of the type of composite piecewise smooth functions which arise, e.g., as exact penalty functions for MPECs. We include a penalty update rule and specify the method to MPECs with complementarity constraints in section 5. The study is complemented by some preliminary numerical results.

2. Preliminaries.

2.1. Piecewise smooth functions. In this first section we review some properties of piecewise differentiable functions which we shall use in subsequent sections. For a detailed account we refer to [41]. A continuous function $f\colon U \to \mathbb{R}^m$ defined on an open set $U \subseteq \mathbb{R}^n$ is said to be a PC^r-function at $x^0 \in U$ if there exists an open neighborhood $V \subseteq U$ of x^0 and a finite family of C^r-functions $f_1, \ldots, f_l\colon V \to \mathbb{R}^m$ such that

$$f(x) \in \{f_1(x), \ldots, f_l(x)\} \qquad \forall x \in V. \tag{2.1}$$

The function f is called piecewise affine (piecewise linear) if $U = V = \mathbb{R}^n$ and (2.1) holds for affine (linear) functions $f_1, \ldots, f_l$. A collection of functions $f_1, \ldots, f_l$ satisfying (2.1) is called a collection of *selection functions* of f at x^0 and f is said to be a continuous selection of the functions $f_1, \ldots, f_l$ on V. A selection function f_i is called *essentially active* at x^0 if $x^0 \in \mathrm{clint}\{x \in V \mid f(x) = f_i(x)\}$, where $\mathrm{cl}S$ and $\mathrm{int}S$ denote the closure and interior, respectively, of a set S. The subcollection of essentially active selection functions is still a collection of selection functions at x^0, i.e., f is a continuous selection of the essentially active selection functions on a possibly smaller open neighborhood $\tilde{V}$ of x^0 [41].

The function f is called a PC^r-function if it is a PC^r-function at every point of its domain. When we use the term PC^r-function, we tacitly assume that $r \geq 1$. The term *piecewise differentiable function* refers to a PC^1-function. Some properties of piecewise differentiable functions are summed up in the following proposition.

Proposition 2.1. *Let $U \subseteq \mathbb{R}^n$ be open and $f : U \to \mathbb{R}^m$ be a piecewise differentiable function with C^1-selection functions $f_1, \ldots, f_p\colon V \to \mathbb{R}^m$ in a neighborhood $V \subseteq U$ of $x^0 \in U$.*

1. *f is Lipschitzian and B-differentiable in the sense of* [37] *in a neighborhood of x^0 and its B-derivative $f'(x^0;.)$ is a continuous selection of the F-derivatives of the essentially active selection functions at x^0.*
2. *f is semismooth in the sense of* [23, 30].
3. *The set of all Jacobians of the essentially active selection functions of f at x coincides with the set*

$$\{M \in \mathbb{R}^{m\times n} \quad | \quad \exists x^k \to x \text{ such that } f \text{ is F-differentiable at } x^k \text{ and } \nabla f(x^k) \to M\},$$

the convex hull of which is Clarke's generalized Jacobian [5].

A proof of the first statement can be found in [41]. The second statement has been proved in [3] (cf. also [30, Cor. 2.4]). The final statement is an immediate consequence of the first statement and the definitions involved.

The notion of coherent orientation plays an important role in connection with inverse and implicit function theorems for piecewise differentiable functions. We slightly extend the standard definition and call a collection of $p \times q$ matrices $M_1, \ldots, M_k$ with $p \leq q$ *coherently oriented* if there exists a $(q-p) \times q$ matrix A such that all matrices

$$\begin{bmatrix} M_i \\ A \end{bmatrix}, \qquad i = 1, \ldots, k, \tag{2.2}$$

have the same nonvanishing determinantal sign. In the case $p = q$ the matrix A is superfluous. We shall employ the following implicit function theorem from [33] in the sequel.

Theorem 2.2. *Let $f : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$ be a PC^r function with C^r-selection functions $f_1, \ldots, f_p : U \times V \to \mathbb{R}^n$ in a neighborhood of $(x^0, y^0) \in U \times V$ and let $z^0 = f(x^0, y^0)$. Then the following two statements are equivalent:*

1. *There exist neighborhoods $\tilde{U}, \tilde{V}, \tilde{W}$ of x^0, y^0, and z^0, respectively, such that the equation*

$$f(x, y) = z$$

has a unique solution $x(y, z)$ in $\tilde{U}$ for every $(y, z) \in \tilde{V} \times \tilde{W}$.

2. *The partial Jacobians with respect to x of the essentially active selection functions of f at (x^0, y^0) are coherently oriented and the piecewise linear equation*

$$f'((x^0, y^0); (u, v)) = w$$

has a unique solution $u(v, w)$ for every $(v, w) \in \mathbb{R}^m \times \mathbb{R}^n$.

Moreover, if either of the statements is true, then the solution function $x(.,.)$ is a PC^r function and $x'((y^0, z^0); (v, w)) = u(v, w)$.

The following result is an immediate consequence of the foregoing theorem and Corollary 19 of [33].

Corollary 2.3. *Let $f : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$ be a PC^r function with C^r-selection functions $f_1, \ldots, f_p : U \times V \to \mathbb{R}^n$ in a neighborhood of $(x^0, y^0) \in U \times V$ and let $z^0 = f(x^0, y^0)$. Let $\mathcal{M}(x^0, y^0)$ be the collection of all matrices whose jth row coincides with the jth row of the partial Jacobian $\nabla_x f_i(x^0, y^0)$ of some essentially active selection function f_i of f at (x^0, y^0). If the matrices in $\mathcal{M}(x^0, y^0)$ have the same nonvanishing determinantal sign, then statement* 1 *of Theorem* 2.2 *holds.*

2.2. The principle of exact penalization.

The exact penalization approach toward constrained optimization problems

$$\min\{f(x) \mid x \in C\}$$

goes back to Eremin [8] and Zangwill [48]. It aims at replacing the constrained problem by an equivalent unconstrained problem by augmenting the objective function f through the addition of a term which penalizes infeasibility. From a geometric point of view, infeasibility is most naturally measured in terms of the distance

$$d_C(y) = \min\{\|x - y\| \mid x \in C\}$$

of the point y to the closed set C. The following seminal result of Clarke shows that the distance function d_C is indeed an appropriate tool for exact penalization. Recall that a function $f : S \to \mathbb{R}$ is said to be Lipschitz of rank K on S if

$$|f(y) - f(z)| \leq K\|y - z\|$$

for all $y, z \in S$.

THEOREM 2.4. [5] *Let $x \in S \subseteq \mathbb{R}^n$ and let $C \subseteq S$ be nonempty and closed. Suppose $f : S \to \mathbb{R}$ is Lipschitz of rank K on S and let $\hat{K} > K$. Then x is a global minimizer of f over C if and only if x is a global minimizer of the function $f + \hat{K} d_C$ over S.*

A result analogous to Theorem 2.4 for local minima is readily obtained using the following well-known properties of the distance function which are direct consequences of the triangle inequality.

LEMMA 2.5. *Let $C \subseteq \mathbb{R}^n$ be nonempty and closed.*

1. *If $d_C(y) = \|\bar{x} - y\|$ for some $\bar{x} \in C$, then $d_C(\alpha y + (1-\alpha)\bar{x}) = \alpha d_C(y)$ for every $\alpha \in [0, 1]$.*
2. *If $x \in C$, $B(x, \epsilon)$ is a closed ball around x with positive radius ϵ and $y \in B(x, \frac{\epsilon}{2})$, then $d_C(y) = d_{C \cap B(x,\epsilon)}(y)$.*

COROLLARY 2.6. *Let $x \in \mathbb{R}^n$, $f : \mathbb{R}^n \to \mathbb{R}$ be Lipschitz of rank K in a ball around x which intersects a closed and nonempty set $C \subseteq \mathbb{R}^n$. If $\hat{K} > K$, then x is a local minimizer of f over C if and only if x is an unconstrained local minimizer of $f + \hat{K} d_C$.*

Proof. First we show that every local minimizer of $f + \hat{K} d_C$ is contained in C. Suppose x is a local minimizer of $f + \hat{K} d_C$ and let $\bar{x} \in C$ be such that $\|x - \bar{x}\| = d_C(x)$. Then there exists a scalar $\alpha \in [0, 1)$ such that

$$\begin{aligned} f(x) + \hat{K} d_C(x) &\le f(\alpha x + (1-\alpha)\bar{x}) + \hat{K} d_C(\alpha x + (1-\alpha)\bar{x}) \\ &= f(\alpha x + (1-\alpha)\bar{x}) + \hat{K} \alpha d_C(x), \end{aligned}$$

where the last equation is a consequence of the first part of Lemma 2.5. Since f is Lipschitz of rank K in a ball around x which intersects C and thus contains $\bar{x}$, we further obtain

$$f(\alpha x + (1-\alpha)\bar{x}) - f(x) \le (1-\alpha) K \|x - \bar{x}\|.$$

Putting the foregoing two inequalities together, we arrive at

$$(1-\alpha) K \|x - \bar{x}\| \ge f(\alpha x + (1-\alpha)\bar{x}) - f(x) \ge (1-\alpha) \hat{K} \|x - \bar{x}\|.$$

Since $\hat{K} > K$ and $\alpha < 1$ we conclude that $x = \bar{x} \in C$. Hence if x is a local minimizer of $f + \hat{K} d_C$, then it is contained in C and, since f and $f + \hat{K} d_C$ coincide on C, it is a local minimizer of f over C.

To see the reverse implication, suppose that x is a local minimizer of f over C. Then there exists a closed ball $B(x, \epsilon)$ around x with positive radius ϵ such that x is a global minimizer of f over $C \cap B(x, \epsilon)$ and f is Lipschitz of rank K on $B(x, \epsilon)$. Hence Theorem 2.4 implies that x is a global minimizer of $\tilde{g} = f + \hat{K} d_{C \cap B(x,\epsilon)}$ on $B(x, \epsilon)$ and thus an application of the second part of Lemma 2.5 shows that x is a local minimizer of $f + \hat{K} d_C$. □

Although the foregoing results are theoretically very appealing, they are only of limited practical value since the mere evaluation of the penalty function involves the solution of a constrained optimization problem. Thus, nothing is won in passing from the constrained problem $\min\{f(x) \mid x \in C\}$ to the unconstrained problem $\min\{(f + \hat{K} d_C)(x) \mid x \in \mathbb{R}^n\}$. One is therefore interested in finding upper bounds for the distance function in terms of functions which are easier to evaluate. Such majorants can again be used as penalization terms as pointed out in the following corollary. In [20] this fact is called the *principle of exact penalization.*

COROLLARY 2.7. *If the assumptions of Theorem* 2.4 *hold and if* $\psi: S \to \mathbb{R}$ *is a function such that*

1. $\psi(y) \geq d_C(y)$ *for every* $y \in S$,
2. $\psi(y) = d_C(y)$ *for every* $y \in C$,

then x *is a global minimizer of* f *over* C *if and only if* x *is a global minimizer of* $f + \hat{K}\psi$ *over* S.

The foregoing statement is indeed an immediate corollary of Theorem 2.4 because the functions $f + \hat{K}d_C$ and $f + \hat{K}\psi$ coincide on C and the latter function majorizes the former over S, so that, by Theorem 2.4, the sets of global minimizers of both functions coincide. The foregoing principle is the basis for many exact penalty results. We refer to the surveys in [2, 20] and the references therein. Notice that a function ψ which satisfies the majorization assumptions

1. $\psi(y) \geq d_C(y)$ for every $y \in S$,
2. $\psi(y) = d_C(y)$ for every $y \in C$,

where C is a closed set contained in the interior of a set S, is necessarily nonsmooth at every $x \in C$ which is a distance minimizer of some point $y \neq x$. In fact, if $d_C(y) = \|y-x\|$ for some $y \neq x$, then Lemma 2.5 shows that $d_C(x+\lambda(y-x)) = \lambda d_C(y)$ for every $\lambda \in [0,1]$ and hence the function d_C has positive slope $d_C(y)$ at x in the direction $y-x$, while a smooth majorant ψ would have zero slope at x in all directions because x is a minimizer of ψ.

Unfortunately, a direct pendant of the local exact penalization result of Corollary 2.6 does not hold with d_C being replaced by a majorant ψ. In fact, the simple one-dimensional example $f(x) = 0$, $C = \{0\}$ and $\psi(x) = |x| + |2x^2 \sin 1/x|$ shows that the function $f + \hat{K}\psi$ may have strict local minima outside C that are arbitrarily close to a global minimum in C. However, the following result, which requires the local minimizer x to be contained in C, holds without additional assumptions on ψ (cf., e.g., [6, 20]).

COROLLARY 2.8. *If the assumptions of Corollary* 2.6 *hold and if* $\psi: \mathbb{R}^n \to \mathbb{R}$ *is a function such that for some neighborhood* U *of* x

1. $\psi(y) \geq d_C(y)$ *for every* $y \in U$,
2. $\psi(y) = d_C(y)$ *for every* $y \in C \cap U$,

then x *is a local minimizer of* f *over* C *if and only if* x *is an unconstrained local minimizer of* $f + \hat{K}\psi$ *and* $x \in C$.

Proof. Since f and $f + \hat{K}\psi$ coincide on $C \cap U$, x is a local minimizer of f over C, provided it is a local minimizer of $f + \hat{K}\psi$. Conversely, if x is a local minimizer of f over C, then it is a local minimizer of $f + \hat{K}d_C$, by Corollary 2.6, and thus it is a local minimizer of $f + \hat{K}\psi$ which coincides with $f + \hat{K}d_C$ at $x \in C$ and majorizes the latter function in a neighborhood of x. □

A pendant of the result of Corollary 2.6 with d_C replaced by a majorant ψ holds under the additional, rather strong assumption that

$$\liminf_{z \to y} \frac{\psi(z) - \psi(y)}{\|z - y\|} \leq -1 \tag{2.3}$$

for every y not contained in C. In fact, if under the assumptions of Corollary 2.6 the point x is a local minimizer of $f + \hat{K}\psi$, then $f(x) + \hat{K}\psi(x) \leq f(z) + \hat{K}\psi(z)$ for every z close to x. Hence if f is Lipschitz of rank $K < \hat{K}$, then

$$\frac{\psi(z) - \psi(x)}{\|z - x\|} \geq \frac{f(x) - f(z)}{\hat{K}\|x - z\|} \geq \frac{-K\|x - z\|}{\hat{K}\|x - z\|} > -1.$$

Since (2.3) holds if x is not contained in C we conclude that $x \in C$. Note that, in view of the first part of Lemma 2.5, $\psi = d_C$ satisfies (2.3) for every $y \notin C$.

3. Local error bounds. In this section we focus attention on sets of the form

$$C = \{z \in \mathbb{R}^n \mid \phi(z) = 0\},$$

where ϕ is a continuous nonnegative and real-valued function. Any closed set C can be represented in this way with $\phi = d_C$. However, the function ϕ in this representation may be much easier to evaluate than the distance function. If, e.g., C is of the form

$$C = \{z \in \mathbb{R}^n \quad | \quad \begin{array}{ll} h_i(z) = 0, & i = 1, \dots, m, \\ g_j(z) \leq, 0 & j = 1, \dots, k\} \end{array} \tag{3.1}$$

for continuous functions h_i and g_j, then C is the set of roots of the continuous nonnegative function

$$\phi(z) = \max\{|h_1(z)|, \dots, |h_m(z)|, g_1(z), \dots, g_k(z)\}. \tag{3.2}$$

If the function ϕ is easy to evaluate, then a positive multiple $\gamma\phi$ is a desirable candidate for the penalization of infeasibility. The principle of exact penalization implies that $\gamma\phi$ is an admissible penalty term in a neighborhood of a root z^0 if

$$d_{\phi^{-1}(0)}(z) \leq \gamma\phi(z)$$

for all z in a neighborhood of z^0. If that is the case for a scalar γ, then the function ϕ is said to admit a *local error bound* at the root z^0. A continuous parametric family of nonnegative functions $\phi_t = \phi(.,t)$ is said to admit a *stable local error bound* at the root (z^0, t^0) if there exists a scalar γ such that

$$d_{\phi_t^{-1}(0)}(z) \leq \gamma\phi(z,t)$$

for every (z,t) in a neighborhood of (z^0, t^0). For the sake of simplicity we shall focus on finite dimensional parameters t. Robinson [35] has shown that the function ϕ in (3.2) admits a local error bound at a root z^0 if the functions h_i, g_j are smooth and the constraint set (3.1) satisfies the Mangasarian–Fromovitz constraint qualification at z^0. Moreover, this local error bound is stable if the functions h_i and g_j are embedded in Lipschitzian families of functions.

Notice, however, that Robinson's result does not apply to MPECs with complementarity constraints since, as mentioned before, any set of constraints that includes a complementarity constraint necessarily violates the Mangasarian–Fromovitz constraint qualification at any feasible point. In [20, Chap. 2] Luo, Pang, and Ralph give conditions which ensure the existence of error bounds for complementarity constraints. In particular, they give conditions which ensure that the function

$$\phi(x,y) = \| \min\{F(x,y), x\} \|$$

admits an error bound. However, since they obtain bounds which are global with respect to x, their conditions have to be rather restrictive. In fact, their conditions imply that the solution of the complementarity problem is a single valued Lipschitz continuous function of the parameters y in a given compact set (cf. [20, Lem. 2.3.15]). The aim of this section is to develop conditions which ensure the existence of a local error bound without an implicit function assumption. The conditions to be developed will be related to the Mangasarian–Fromovitz-type condition of [18] and to the piecewise Mangasarian–Fromovitz constraint qualification studied in [20, 39]. To this end, we shall first extend Robinson's result for functions ϕ of the form (3.2) to arbitrary piecewise differentiable functions ϕ. This will then enable us to derive local error bound results for constraint sets involving piecewise smooth formulations of equilibrium conditions and, a fortiori, exact penalization results for MPECs.

3.1. Local error bounds for piecewise smooth functions. The starting point for our discussion is the following lemma, which is a direct consequence of more general results in [36].

LEMMA 3.1. *If $\phi : \mathbb{R}^n \to \mathbb{R}$ is a nonnegative piecewise affine function, then it admits a local error bound at every root.*

The trivial example $\phi(z) = |z|$ versus $\tilde{\phi}(z) = |z^3|$ with $z^0 = 0$ shows that the local error bound property is not a topological property, i.e., it depends on the chosen local coordinate system. However, the property is preserved under local Lipschitzian coordinate changes. This fact has been implicitly used in the proof of Theorem 1 of [11].

LEMMA 3.2. *Let $\phi : \mathbb{R}^n \to \mathbb{R}$ be a nonnegative continuous function, $W \subseteq \mathbb{R}^n$, and γ a positive scalar, and suppose that*

$$d_{\phi^{-1}(0)}(\zeta) \leq \gamma\phi(\zeta) \quad \forall\zeta \in W.$$

If $\Psi : W \to \mathbb{R}^n$ is Lipschitzian of rank L on W and maps W homeomorphically onto U, then

$$d_{(\phi\circ\Psi^{-1})^{-1}(0)}(z) \leq \gamma L(\phi \circ \Psi^{-1})(z) \quad \forall z \in U.$$

Proof. Let $z \in U$, $\zeta = \Psi^{-1}(z) \in W$, and $\xi \in \phi^{-1}(0)$ with $d_{\phi^{-1}(0)}(\zeta) = \|\zeta - \xi\|$. Then $x = \Psi(\xi)$ is a root of $\phi \circ \Psi^{-1}$ and hence

$$\begin{aligned} d_{(\phi\circ\Psi^{-1})^{-1}(0)}(z) &\leq \|z - \Psi(\xi)\| \\ &= \|\Psi(\zeta) - \Psi(\xi)\| \\ &\leq L\|\zeta - \xi\| \\ &= L d_{\phi^{-1}(0)}(\zeta) \\ &\leq \gamma L\phi(\zeta) \\ &= \gamma L(\phi \circ \Psi^{-1})(z). \qquad \square \end{aligned}$$

Clarke's inverse function theorem [5] can be used in connection with Lemmas 3.1 and 3.2 to prove the following stable local error bound result, which is the main result of this section. The main idea of the proof is borrowed from [13], where a similar argument is used in a different context.

THEOREM 3.3. *Let $\phi : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}$ be a nonnegative continuous function and let $(z^0, t^0) \in \mathbb{R}^n \times \mathbb{R}^m$ be a root of ϕ. Suppose that at every point (z, t) in a neighborhood of (z^0, t^0) the function ϕ coincides with at least one of the functions*

$$s_i(z, t) = \sum_{j=1}^{q} \alpha_{ij} h_j(z, t) + \beta_i g(z, t) + \rho_i, \qquad i = 1, \ldots, l,$$

where α_{ij}, β_i, and ρ_i are scalars, $h_1, \ldots, h_q$ are C^1 functions, and g is a locally Lipschitz continuous function. Suppose the following conditions hold:

1. *The gradients $\nabla_z h_1(z^0, t^0), \ldots, \nabla_z h_q(z^0, t^0)$ are linearly independent.*
2. *There exists a vector $v \in \mathbb{R}^n$ with $\nabla_z h_1(z^0, t^0)v = \cdots = \nabla_z h_q(z^0, t^0)v = 0$ and $w^\top v < 0$ for every $w \in \partial_z g(z^0, t^0)$, where ∂_z denotes Clarke's partial subgradient operator with respect to z [5].*

Then $\phi(., t)$ admits a stable local error bound at (z^0, t^0).

Proof. Let $h = (h_1, \ldots, h_q)$ and define

$$\Phi(z, t) = \big(h(z, t), g(z, t), Az, t\big)^\top,$$

where A is a matrix whose rows complement the gradients $\nabla_z h_i(z^0, t^0)$ to a basis of the orthogonal complement of v. Let $(\zeta^0, t^0) = \Phi(z^0, t^0)$. We shall use Clarke's inverse function theorem [5] to show that Φ is a Lipschitzian homeomorphism at (z^0, t^0). Let I_m denote the $m \times m$ identity matrix and consider the $(n + m) \times (n + m)$ matrix

$$M = \begin{bmatrix} \nabla_z h(z^0, t^0) & \nabla_t h(z^0, t^0) \\ -v & 0 \\ A & 0 \\ 0 & \mathrm{I}_m \end{bmatrix}.$$

By our choice of A the matrix M is nonsingular. Now suppose the row $(-v, 0)$ is replaced by an element (w, u) of $\partial g(z^0, t^0)$, where $w \in \partial_z g(z^0, t^0)$. If the new matrix is singular, then w is contained in the span of the vectors $\nabla_z h_i(z^0, t^0)$ and the rows of A and is thus orthogonal to v which, however, contradicts the assumption that $w^\top v < 0$. Hence the matrix M remains nonsingular if the row $(-v, 0)$ is replaced by a gradient $(w, u) \in \partial g(z^0, t^0)$. Thus the generalized Jacobian $\partial\Phi(z^0, t^0)$ is regular and Clarke's inverse function theorem [5] shows that Φ is a local Lipschitzian homeomorphism mapping an open neighborhood S of (z^0, t^0) onto an open neighborhood T of (ζ^0, t^0).

Let $B(x, \epsilon)$ denote the ball around x of radius ϵ and let $\epsilon \geq \delta > 0$ be such that

$$\begin{aligned} &B(\zeta^0, \epsilon) \times B(t^0, \epsilon) \subseteq T, \\ &B(z^0, \delta) \times B(t^0, \delta) \subseteq \Phi^{-1}(B(\zeta^0, \epsilon) \times B(t^0, \epsilon)). \end{aligned}$$

Let $\Psi(\zeta, t)$ be the vector of the first n components of $\Phi^{-1}(\zeta, t)$, i.e., $z = \Psi(\zeta, t)$ is the unique solution of the equation

$$(h(z, t), g(z, t), Az) = \zeta$$

for $(\zeta, t) \in T$. If L is a Lipschitz constant of Ψ on $B(\zeta^0, \epsilon) \times B(t^0, \epsilon)$, then

$$\|\Psi(\zeta, t) - \Psi(\tilde{\zeta}, t)\| \leq L\|\zeta - \tilde{\zeta}\|$$

for every $\zeta, \tilde{\zeta} \in B(\zeta^0, \epsilon)$ and every $t \in B(t^0, \epsilon)$, i.e., for every $t \in B(t^0, \epsilon)$ the mapping $\Psi_t = \Psi(., t)$ is Lipschitzian of rank L in $B(\zeta^0, \epsilon)$. Moreover, the mappings Ψ_t map the balls $B(\zeta^0, \epsilon)$ homeomorphically onto $\Psi_t(B(\zeta^0, \epsilon))$. Note that $B(z^0, \delta) \subseteq \Psi_t(B(\zeta^0, \epsilon))$ for every $t \in B(t^0, \delta)$.

Reducing ϵ if necessary, we may assume that ϕ is a continuous selection of the functions

$$s_i(z, t) = \sum_{j=1}^{q} \alpha_{ij} h_j(z, t) + \beta_i g(z, t) + \rho_i$$

on $\Phi^{-1}(B(\zeta^0,\epsilon)\times B(t^0,\epsilon))$. By the definition of Ψ_t we obtain

$$s_i(\Psi_t(\zeta),t)=\sum_{j=1}^{q}\alpha_{ij}\zeta_j+\beta_i\zeta_{q+1}+\rho_i$$

for every $t\in B(t^0,\epsilon)$ and $\zeta\in B(\zeta^0,\epsilon)$. Hence the function

$$\tilde{\phi}(\zeta,t)=\phi(\Psi_t(\zeta),t)$$

is a continuous selection of the latter affine functions in the ball $B(\zeta^0,\epsilon)$ and, moreover, is independent of t for $t\in B(t^0,\epsilon)$. Further reducing ϵ if necessary, we may thus assume, in view of Lemma 3.1, that there exists a positive constant γ such that

$$d_{\tilde{\phi}_t^{-1}(0)}(\zeta)\le\gamma\tilde{\phi}(\zeta,t)$$

for every $\zeta\in B(\zeta^0,\epsilon)$, where $\tilde{\phi}_t=\tilde{\phi}(.,t)$. Note that

$$\phi_t(z):=\phi(z,t)=\tilde{\phi}(\Psi_t^{-1}(z),t)=\tilde{\phi}_t(\Psi_t^{-1}(z)).$$

Recall that Ψ_t is Lipschitzian of rank L on $B(\zeta^0,\epsilon)\supseteq\Psi_t^{-1}(B(z^0,\delta))$ and that the latter set is mapped homeomorphically onto $B(z^0,\delta)$ by Ψ_t. Hence Lemma 3.2 shows that

$$d_{\phi_t^{-1}(0)}(z)\le\gamma L\phi(z,t)$$

for every $z\in B(z^0,\delta)$ and every $t\in B(t^0,\delta)$, which proves the assertion. □

The relation of the assumptions of Theorem 3.3 to the classical Mangasarian–Fromovitz constraint qualification is obvious in view of part 3 of Proposition 2.1.

COROLLARY 3.4. *If in the setting of Theorem* 3.3 *the function g is piecewise smooth in a neighborhood of (z^0,t^0) with selection functions $g_1,\dots,g_p$, then $\phi(.,t)$ admits a stable local error bound at a root (z^0,t^0), provided the following conditions hold:*

1. *The gradients $\nabla_z h_1(z^0,t^0),\dots,\nabla_z h_q(z^0,t^0)$ are linearly independent.*
2. *There exists a vector $v\in\mathbb{R}^n$ with $\nabla_z h_1(z^0,t^0)v=\cdots=\nabla_z h_q(z^0,t^0)v=0$ and $\nabla_z g_j(z^0,t^0)^\top v<0$ for every $j\in\{1,\dots,p\}$ with $g_j(z^0,t^0)=g(z^0,t^0)$.*

The foregoing result is a generalization of the aforementioned result of Robinson [35] which applies to sets of the form

$$C(t)=\{z\mid h_i(z,t)=0,\quad i=1,\dots,q,\quad g_j(z,t)\le 0,\quad j=1,\dots,p\}.$$

Indeed, for $g(z,t)=\max\{g_1(z,t),\dots,g_p(z,t)\}$ the set $C(t)$ is the set of roots of the nonnegative piecewise smooth function

$$\phi(z,t)=\max\{g(z,t),|h_1(z,t)|,\dots,|h_q(z,t)|\}$$

and the assumptions of Corollary 3.4 hold at (z^0,t^0) if and only if the Mangasarian–Fromovitz constraint qualification is satisfied at $z^0\in C(t^0)$. Note that g is not needed as a local selection function if $g(z^0,t^0)<0$. A linear independence–type result can be readily obtained from Corollary 3.4 in view of the following well-known fact.

LEMMA 3.5. *If the gradients $\nabla_z g_i(z^0,t^0)$, $i=1,\dots,p$, and $\nabla_z h_j(z^0,t^0)$, $j=1,\dots,q$, are linearly independent, then assumptions* 1 *and* 2 *of Corollary* 3.4 *hold.*

Nonsmooth formulations of equilibrium constraints often involve composite equations of the form

$$G \circ H(z) = 0, \tag{3.3}$$

where the function G is nonsmooth and is thought of as a structure function determining a problem class, while H is smooth and represents the data of a problem instance [33]. A typical example is the equation

$$\min\{x, F(x,y)\} = 0,$$

which reformulates a parametric nonlinear complementarity problem. If we apply Corollary 3.4 to constraints involving composite equations, we obtain the following corollary.

COROLLARY 3.6. *Consider the set*

$$\Omega(t) = \{z \in \mathbb{R}^n \ \mid \ G(H(z,t)) = 0, \quad g(z,t) \leq 0, \quad h(z,t) = 0\}$$

with $t \in \mathbb{R}^m$*,* $G(H(z,t)) \in \mathbb{R}^r$*,* $g(z,t) \in \mathbb{R}$*,* $h(z,t) \in \mathbb{R}^q$ *and suppose* H *and* h *are smooth,* g *is piecewise smooth, and* G *is piecewise affine. Let* $z^0 \in \Omega(t^0)$ *and let* $g_1, \ldots, g_l$ *be a collection of smooth selection functions for* g *at* (z^0, t^0)*. If*

1. *the matrix* $[\nabla_z H(z^0,t^0)^\top, \nabla_z h(z^0,t^0)^\top]$ *has full column rank,*
2. *there exists a vector* $v \in \mathbb{R}^n$ *such that*

$$\nabla_z H(z^0,t^0)v = 0, \quad \nabla_z h(z^0,t^0)v = 0, \quad \nabla_z g_i(z^0,t^0)v < 0 \quad \forall i : g_i(z^0,t^0) = 0,$$

then there exist neighborhoods U *of* z^0 *and* V *of* t^0 *and a constant* γ *such that*

$$d_{\Omega(t)}(z) \leq \gamma \phi(z,t) \quad \forall (z,t) \in U \times V,$$

where

$$\phi(z,t) = \max\{\|G(H(z,t))\|_\infty, \|h(z,t)\|_\infty, g(z,t)\}.$$

Proof. Locally around (z^0,t^0) the function ϕ has the selection functions g_i, $i : g_i(z^0,t^0) = 0$, $\pm h_i$, and

$$\pm \sum_{j=1}^{p} \alpha_{ij} H_j(z,t) + \rho_i,$$

where $\alpha_{ij} v_j + \rho_i$ is a selection function of the piecewise affine function G_i. Hence, replacing the function h in the statement of Corollary 3.4 by the function (H,h), we obtain the result. □

3.2. Local error bounds for MPECs.

3.2.1. Stationarity constraints. We shall next apply the foregoing results to constraint sets which involve equilibrium constraints in the form of stationarity conditions for variational inequalities. In order not to overload the exposition with too many technicalities, we confine ourselves to variational inequalities over inequality constrained sets and assume that all further constraints of the MPEC are expressed as a single piecewise smooth inequality. More precisely, we assume that the constraint set of the MPEC is of the form

$$\Omega(t) = \{(x,y,\lambda) \mid \begin{array}{l} F(x,y,t) + \nabla_x\Psi(x,y,t)^\top\lambda = 0, \\ \min\{-\Psi(x,y,t),\lambda\} = 0, \\ g(x,y,t) \le 0\} \end{array} \tag{3.4}$$

for some fixed perturbation parameter t, where F is a C^1-function, Ψ is a C^2-function, and g is a real-valued PC^1-function. The set $\Omega(t)$ is the set of roots of the function

$$\begin{aligned}\phi(x,y,\lambda,t) = \quad & \max\{\|F(x,y,t) + \nabla_x\Psi(x,y,t)^\top\lambda\|_\infty, \\ & \qquad \|\min\{-\Psi(x,y,t),\lambda\}\|_\infty, g(x,y,t)\}.\end{aligned} \tag{3.5}$$

Note that ϕ coincides in a neighborhood of a root (x^0,y^0,λ^0,t^0) with the function

$$\begin{aligned}\tilde\phi(x,y,\lambda,t) = \max\{&\|F(x,y,t) + \nabla_x\Psi(x,y,t)^\top\lambda\|_\infty, \\ &\|\Psi_I(x,y,t)\|_\infty, \|\lambda_K\|_\infty, \\ &\|\min\{-\Psi_J(x,y,t),\lambda_J\}\|_\infty, g(x,y,t)\},\end{aligned}$$

where

$$\begin{array}{rcl} I &=& \{i \mid \Psi_i(x^0,y^0,t^0) = 0 < \lambda_i^0\}, \\ J &=& \{j \mid \Psi_j(x^0,y^0,t^0) = 0 = \lambda_j^0\}, \\ K &=& \{k \mid \Psi_k(x^0,y^0,t^0) < 0 = \lambda_k^0\}. \end{array} \tag{3.6}$$

Given a vector z and an index set I we have used the notation z_I to denote the vector with components z_i, $i \in I$. In view of the above observation, Corollary 3.6 yields the following stable local error bound conditions.

Corollary 3.7. *Let (x^0,y^0,λ^0,t^0) be a root of the function ϕ defined by* (3.5)*, let the index sets I and J be defined by* (3.6)*, and let*

$$M_{x\lambda} = \begin{pmatrix} \nabla_x F(x^0,y^0,t^0) + \sum_{i\in I}\lambda_i^0\nabla_{xx}^2\Psi_i(x^0,y^0,t^0) & \nabla_x\Psi_I(x^0,y^0,t^0)^\top \\ -\nabla_x\Psi_{I\cup J}(x^0,y^0,t^0) & 0 \end{pmatrix},$$

$$M_y = \begin{pmatrix} \nabla_y F(x^0,y^0,t^0) + \sum_{i\in I}\lambda_i^0\nabla_{xy}^2\Psi_i(x^0,y^0,t^0) \\ -\nabla_y\Psi_{I\cup J}(x^0,y^0,t^0) \end{pmatrix}.$$

Then $\phi(.,t)$ admits a stable local error bound at (x^0,y^0,λ^0,t^0) if the following conditions hold:

1. *The matrix $M = (M_{x\lambda}, M_y)$ has full row rank.*
2. *If $g(x^0,y^0,t^0) = 0$, then there exists a collection of C^1 selection functions $g_1,\dots,g_p$ of g at (x^0,y^0,t^0) and vectors u,v,w such that $M_{x\lambda}(u,v)^\top + M_y w = 0$ and*

   $$\nabla_x g_k(x^0,y^0,t^0)u + \nabla_y g_k(x^0,y^0,t^0)w < 0$$

   for every $k = 1,\dots,p$.

Lemma 3.5 shows that the assumptions of the corollary are particularly satisfied if the gradients of the active constraint functions are linearly independent, i.e., if the matrix

$$\left(\begin{array}{cc} M_{x\lambda} & M_y \\ (\nabla_x g_1(x^0,y^0,t^0),0) & \nabla_y g_1 L(x^0,y^0,t^0) \\ \vdots & \vdots \\ (\nabla_x g_p(x^0,y^0,t^0),0) & \nabla_y g_p L(x^0,y^0,t^0) \end{array}\right)$$

has full row rank. The first condition of the corollary can be viewed as a regularity condition for the variational inequality at the solution point x^0 for the given parameter vector y^0. Recall that the global error bound conditions of [20], which are concerned with the problem for fixed parameter t^0, imply that the stationary solution x of the variational inequality is a Lipschitz continuous function of y. If t^0 is fixed and the linear independence constraint qualification and strict complementarity, i.e., $J = \emptyset$, hold for the lower level problem, then the Lipschitz continuity of x as a function of y is equivalent to the nonsingularity of the matrix

$$\begin{pmatrix} \nabla_x F(x^0,y^0,t^0) + \sum\limits_{i\in I} \lambda_i^0 \nabla_{xx}^2 \Psi_i(x^0,y^0,t^0) & \nabla \Psi_I(x^0,y^0,t^0)^\top \\ -\nabla \Psi_I(x^0,y^0,t^0) & 0 \end{pmatrix},$$

which implies that the first condition of the above corollary holds. However, the latter condition is considerably weaker. In particular it does not imply Lipschitzian behavior of the stationary point x as a function of y. In fact, if g is of the type

$$g(x,y) = \max\{g_1(x,y),\ldots,g_p(x,y)\}$$

with smooth functions g_i and strict complementarity holds at (x^0,y^0,λ^0,t^0), i.e., $J = \emptyset$, then the condition of the corollary is equivalent to the Mangasarian–Fromovitz condition for the set

$$\begin{array}{lcl} \{(x,y,\lambda) & | & F(x,y,t) + \nabla_x \Psi(x,y,t)^\top \lambda = 0, \\ & & \Psi_I(x,y,t) = 0, \\ & & \lambda_K = 0, \\ & & g(x,y,t) \leq 0\}, \end{array}$$

which coincides with $\Omega(t)$ in a neighborhood of (x^0,y^0,λ^0,t^0) and the assertion follows from Robinson's result [35] in this special case.

It follows from the results of [40] that the conditions of Corollary 3.7 serve as a constraint qualification for MPECs in the sense that they guarantee that a local minimizer is a stationary point. Alternative constraint qualifications based on piecewise smooth formulations of MPECs have been suggested [18, 20]. In the first reference condition 1 of Corollary 3.7 is relaxed to the requirement that either M has full row rank or every square submatrix of M of maximal dimension has full row rank. This relaxation allows for more active constraints than variables and is in the spirit of a constant rank assumption. In [20, 39], a so-called piecewise Mangasarian–Fromovitz constraint qualification was suggested. Here, we confine ourselves to the setting of [20] which assumes that

$$g(x,y) = \max\{g_1(x,y),\ldots,g_p(x,y)\}$$

for smooth functions g_i. The approach is based on the observation that the constraint set (3.4) is in a neighborhood of $(x^0, y^0, \lambda^0, t^0)$ locally representable as the finite union of the constraint sets

$$\begin{aligned}\Omega_\alpha(t) = \{(x, y, \lambda) \quad | \quad & F(x, y, t) + \nabla_x \Psi(x, y, t)^\top \lambda = 0,\\ & \Psi_{I\cup\alpha}(x, y, t) = 0,\\ & \lambda_{I\cup\alpha} \geq 0,\\ & \Psi_{K\cup\bar{\alpha}}(x, y, t) \leq 0,\\ & \lambda_{K\cup\bar{\alpha}}(x, y, t) = 0,\\ & g_1(x, y, t) \leq 0,\\ & \vdots\\ & g_p(x, y, t) \leq 0\},\end{aligned}$$

where I, J, K are as defined in (3.6), $\alpha \subseteq J$, and $\bar{\alpha}$ is the complement of α in J. The piecewise Mangasarian–Fromovitz constraint qualification requires that all sets $\Omega_\alpha(t^0)$ with $\alpha \subseteq J$ satisfy the smooth Mangasarian–Fromovitz constraint qualification at (x^0, y^0, λ^0). This condition is weaker than the condition of Corollary 3.7 which is equivalent to the requirement that the set

$$\begin{aligned}\Omega^*(t) = \{(x, y, \lambda) \quad | \quad & F(x, y, t) + \nabla_x \Psi(x, y, t)^\top \lambda = 0,\\ & \Psi_{I\cup J}(x, y, t) = 0,\\ & \lambda_{K\cup J} = 0,\\ & g_1(x, y, t) \leq 0,\\ & \vdots\\ & g_p(x, y, t) \leq 0\}\end{aligned}$$

satisfies the smooth Mangasarian–Fromovitz constraint qualification. The weaker piecewise Mangasarian–Fromovitz constraint qualification still gives rise to local error bounds by means of the maximum of the local error bounds for the pieces $\Omega_\alpha(t)$, since the distance to $\Omega(t)$ is locally the minimum of the distances to $\Omega_\alpha(t)$ and ϕ coincides locally with the minimum of the functions ϕ_α corresponding to the sets $\Omega_\alpha(t)$.

3.2.2. Complementarity constraints. If $\Psi(x, y, t) = -x$, then the multiplier λ of the stationarity condition for the variational inequality can be eliminated and the stationarity condition turns into a nonlinear complementarity problem. The constraint set of the MPEC is then of the form

$$\Omega(t) = \{(x, y) \quad | \quad \min\{x, F(x, y, t)\} = 0, g(x, y, t) \leq 0\} \tag{3.7}$$

for some parameter t. This feasible set is the set of roots of the nonnegative function

$$\phi(x, y, t) = \max\{\|\min\{x, F(x, y, t)\}\|_\infty, g(x, y, t)\} \tag{3.8}$$

and we obtain the following conditions for a stable local error bound of $\phi(., t)$ at a root (x^0, y^0, t^0).

COROLLARY 3.8. *Let (x^0, y^0, t^0) be a root of the function ϕ defined by* (3.8) *and let*

$$I = \{i \mid F_i(x^0, y^0, t^0) = 0\}, \quad J = \{i \mid x_i^0 > 0\}.$$

Then $\phi(., t)$ admits a stable local error bound at (x^0, y^0, t^0) if the following conditions hold:

1. *The matrix*

$$\big(\nabla_{x_J} F_I(x^0, y^0, t^0), \quad \nabla_y F_I(x^0, y^0, t^0)\big)$$

has full row rank.

2. *If* $g(x^0, y^0, t^0) = 0$*, then there exists a collection of* C^1 *selection functions* $g_1, \dots, g_p$ *of* g *at* (x^0, y^0, t^0) *and vectors* u, v *such that*

$$\nabla_{x_J} F_I(x^0, y^0, t^0)u + \nabla_y F_I(x^0, y^0, t^0)v = 0$$

and

$$\nabla_{x_J} g_k(x^0, y^0, t^0)u + \nabla_y g_k(x^0, y^0, t^0)v < 0$$

for every $k = 1, \dots, p$.

3.2.3. Normal equation constraints. Next we derive error bound conditions for constraints involving normal equations. We assume that P is a closed convex set and $F(.,.)$ is a parametric vector field. Recall that ξ satisfies the variational inequality induced by $F(., y)$ over P if and only if $\xi = \Pi_P(x)$ and x solves Robinson's normal equation [38]

$$H(x, y) := \Pi_P(x) - F(\Pi_P(x), y) - x = 0. \tag{3.9}$$

Recall that H is locally Lipschitzian, provided F is locally Lipschitzian. We can thus apply the following result, which is a direct consequence of Lemmas 3.1 and 3.2.

LEMMA 3.9. *Let*

$$\Omega(t) = \{z \in \mathbb{R}^n \mid g(z, t) \le 0, h(z, t) = 0\},$$

where $g: \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}$ *and* $h: \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^p$ *are locally Lipschitzian, let* $z^0 \in \Omega(t^0)$*, let* $f: O \to \mathbb{R}^{n-p-1}$ *be a locally Lipschitzian function defined in a neighborhood* O *of* (z^0, t^0)*, and let* $\Psi: \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$ *be defined by*

$$\Psi(z, t) = \big(g(z, t), h(z, t), f(z, t)\big).$$

If the equation $\Psi(z, t) = u$ *has a locally unique and Lipschitzian solution* $z(u, t)$ *in a neighborhood of* $(z^0, t^0, \Psi(z^0, t^0))$*, then there exists a constant* γ *and neighborhoods* U *of* z^0 *and* V *of* t^0 *such that*

$$d_{\Omega(t)}(z) \le \gamma \phi(z, t) \quad \forall (z, t) \in U \times V,$$

where

$$\phi(z, t) = \max\{\|h(z, t)\|_\infty, g(z, t)\}.$$

Proof. Let $\Psi_t^{-1}(u)$ be the locally unique solution z of $\Psi(z, t) = u$. If $u = (\alpha, v, w)$ with $\alpha \in \mathbb{R}$, $v \in \mathbb{R}^p$, and $w \in \mathbb{R}^{n-p-1}$, then $\phi \circ \Psi_t^{-1}(u) = \max\{\|v\|_\infty, \alpha\}$ which is piecewise linear. Hence the Lipschitz continuity of the solution function $z(.,.)$ implies the result in view of the Lemmas 3.1 and 3.2. □

The foregoing result can be used to derive stable local error bound conditions for normal maps if Π_P is piecewise differentiable and F is differentiable. Sufficient conditions for the piecewise smoothness of Π_P have been derived in [17, 28]. In fact, if $P = \{x \in \mathbb{R}^n \mid g_i(x) \leq 0\}$ with convex C^{r+1}-functions g_i and Janin's constant rank condition [12] holds at $\Pi_P(x) \in P$, then Π_P is a PC^r function in a neighborhood of x.

PROPOSITION 3.10. *Let*

$$\begin{aligned}\Omega(t) = \{(x,y) \in \mathbb{R}^p \times \mathbb{R}^q \quad | \quad & \Pi_P(x) - F(\Pi_P(x), y, t) - x = 0,\\ & h(\Pi_P(x), y, t) = 0,\\ & g(\Pi_P(x), y, t) \leq 0\},\end{aligned}$$

where $F: \mathbb{R}^p \times \mathbb{R}^q \times \mathbb{R}^m \to \mathbb{R}^p$, $h: \mathbb{R}^p \times \mathbb{R}^q \times \mathbb{R}^m \to \mathbb{R}^s$ *and* $g: \mathbb{R}^p \times \mathbb{R}^q \times \mathbb{R}^m \to \mathbb{R}^r$ *are* C^1 *functions, and* $P \subseteq \mathbb{R}^p$ *is a closed convex set. Let* $(x^0, y^0) \in \Omega(t^0)$ *and let* $J = \{j \mid g_j(\Pi_P(x^0), y^0, t^0) = 0\}$. *Suppose* Π_P *is* PC^1 *with selection functions* $P_1, \ldots, P_l$ *in a neighborhood of* x^0. *If the matrices*

$$M_i = \left[\begin{array}{cc} \nabla P_i(x^0) - \nabla_x F(\Pi_P(x^0), y^0, t^0)\nabla P_i(x^0) - \mathrm{I} & -\nabla_y F(\Pi_P(x^0), y^0, t^0) \\ \nabla_x h(\Pi_P(x^0), y^0, t^0)\nabla P_i(x^0) & \nabla_y h(\Pi_P(x^0), y^0, t^0) \\ \nabla_x g_J(\Pi_P(x^0), y^0, t^0)\nabla P_i(x^0) & \nabla_y g_J(\Pi_P(x^0), y^0, t^0) \end{array}\right]$$

with $i \in \{1, \ldots, l\}$ *are coherently oriented* (*cf.* (2.2)), *then there exist neighborhoods* U *of* (x^0, y^0) *and* V *of* t^0 *and a constant* γ *such that*

$$d_{\Omega(t)}(x,y) \leq \gamma\phi(x,y,t) \quad \forall (x,y,t) \in U \times V,$$

where

$$\begin{aligned}\phi(x,y,t) = \max\{&\|\Pi_P(x) - F(\Pi_P(x), y, t) - x\|_\infty, \|h(\Pi_P(x), y, t)\|_\infty,\\ & g_1(\Pi_P(x), y, t), \ldots, g_r(\Pi_P(x), y, t)\}.\end{aligned}$$

Proof. Since $\phi(x,y,t)$ locally coincides with the function

$$\tilde{\phi}(x,y,t) = \max_{j \in J}\{\|\Pi_P(x) - F(\Pi_P(x), y, t) - x\|_\infty, \|h(\Pi_P(x), y, t)\|_\infty, g_j(\Pi_P(x), y, t)\},$$

we may neglect nonactive inequalities and assume for simplicity that $J = \{1, \ldots, r\}$. Recall that coherent orientation requires the existence of a matrix $A = (A_x, A_y)$ such that all matrices

$$\begin{pmatrix} M_i \\ A \end{pmatrix}$$

have the same nonvanishing determinantal sign. The foregoing matrices are in fact the partial Jacobians with respect to (x,y) of the selection functions of the mapping

$$\Psi(x,y,t) = \left[\begin{array}{c} \Pi_P(x) - F(\Pi_P(x), y, t) - x \\ h(\Pi_P(x), y, t) \\ g(\Pi_P(x), y, t) \\ A_x x + A_y y \end{array}\right]$$

at (x^0, y^0, t^0). To apply Theorem 2.2, it thus remains to show that the first-order approximation of the equation $\Psi(x,y,t) = s$ defines a unique solution function. The B-derivative of Ψ is given by

$$\Psi'((x^0, y^0, t^0); (u,v,w)) = \left[\begin{array}{l} \Pi_P'(x^0; u) - \nabla_x F(\Pi_P(x^0), y^0, t^0)\Pi_P'(x^0; u) - \\ \qquad \nabla_y F(\Pi_P(x^0), y^0, t^0)v - \nabla_t F(\Pi_P(x^0), y^0, t^0)w - u \\ \nabla h(\Pi_P(x^0), y^0, t^0)(\Pi_P'(x^0; u), v, w)^\top \\ \nabla g(\Pi_P(x^0), y^0, t^0)(\Pi_P'(x^0; u), v, w)^\top \\ A_x u + A_y v \end{array}\right].$$

Recall that the B-derivative of a piecewise differentiable function is piecewise linear. In fact, the B-derivative $\Pi'_P(x^0;.)$ is the projection onto a polyhedral cone (cf., e.g., [28]). Hence the branching number of the underlying subdivision is 4 (cf. [32, 42]) and thus the fact that the block matrices with rows M_i and A have the same nonvanishing determinantal sign ensures that the equation $\Psi'((x^0, y^0, t^0); (u, v, w)) = r$ has a unique solution $u(w, r), v(w, r)$ [16]. Hence we can apply Theorem 2.2 to deduce that the equation $\Psi(x, y, t) = s$ has a locally unique solution $x(t, s), y(t, s)$. An application of Lemma 3.9 thus proves the assertion. □

To check the assumption of the foregoing proposition one has to calculate a collection of selection functions for Π_P at the point x^0. This has been done in [17, 28] for sets of the form $P = \{z \in \mathbb{R}^n \mid q_i(z) \leq 0, i = 1, \ldots, m\}$ with convex C^2-functions q_i under certain constraint qualifications. For the sake of completeness we repeat the arguments for the most important case that the linear independence constraint qualification holds at a point $p^0 = \Pi_P(x^0)$. The linear independence assumption implies that for every index set $I \subseteq I^0 = \{i \mid q_i(x^0) = 0\}$ there exists a unique solution $p_I(x), \lambda_I(x)$ of the stationary point equation

$$\begin{aligned} p + \nabla q_I(p)^\top \lambda_I &= x, \\ q_I(p) &= 0 \end{aligned}$$

in a neighborhood of $(p^0 + \nabla q_I(p^0)^\top \lambda_I^0, p^0, \lambda_I^0)$ and furthermore that the point $p_I(x^0)$ coincides with the point p^0 if and only if $I^+ \subseteq I \subseteq I^0$, where $I^+ = \{i \mid \lambda_i^0 > 0\}$. Hence, the functions $p_I(.)$, $I^+ \subseteq I \subseteq I^0$ constitute a collection of selection functions for Π_P in a neighborhood of x^0. The inverse function theorem yields the gradients of the functions p_I at x^0.

In [19, 20] it has been shown that a parametric normal equation $H(x, y) = t$ admits a local error bound at a solution, provided the solution x of the normal equation is locally a Lipschitz continuous function of the parameters y and t. This result is encompassed by the above proposition if one chooses the matrix $A = (A_x, A_y) = (0, \mathrm{I})$ to augment the matrices in the coherency condition. Our result, however, is in the spirit of a full rank assumption rather than an implicit function assumption. In fact, if specialized to the case $P = \mathbb{R}^n$, in which case Π_P is the identity mapping and the normal equation turns into the equation $-F(x, y) = 0$, then for smooth F the condition in [19] requires that $\nabla_x F(x^0, y^0, t^0)$ is nonsingular, while our condition requires that the matrix

$$\big(\nabla_x F(x^0, y^0, t^0), \nabla_y F(x^0, y^0, t^0)\big)$$

has full row rank.

The proof of Proposition 3.10 can mutatis mutandis be adopted to prove an analogous result for constraint sets involving the direct normal equation

$$\Pi_P(x - F(x, y)) - x = 0.$$

We leave the details to the reader.

The results of this section hold not only for the specified functions ϕ but in fact for any other nonnegative piecewise affine composition of the constraint functions of the MPEC; e.g., the function

$$\phi(x, y, t) = \sum |\min\{x_i, F_i(x, y, t)\}| + \sum \max\{g_j(x, y, t), 0\}$$

admits a local error bound at a point (x^0, y^0, t^0) if the conditions of Corollary 3.8 hold. We shall make use of a penalty function of the latter type in section 5.

The stable error bound results of this section can be refined and extended to infinite dimensional perturbation parameters by using Theorem 11 and Corollary 21 of [33] instead of Clarke's inverse function theorem [5], Theorem 2.2, or Corollary 2.3. The former results allow for general perturbations in the C^1 topology rather than merely for parametric perturbations.

In view of the principle of exact penalization, the foregoing local error bound results yield the following concluding exact penalty result for MPECs.

THEOREM 3.11. *Suppose the assumptions of Corollary* 3.7*, Corollary* 3.8*, or Proposition* 3.10 *hold and let* $f(x, y)$ *be a locally Lipschitz continuous function. Then there exists a neighborhood* U *of* (x^0, y^0, t^0) *and a positive scalar* γ^0 *such that for all* $(x, y, t) \in U$ *with* $(x, y) \in \Omega(t)$ *the following two statements are equivalent:*

1. (x, y) *is a local minimizer of the* MPEC $\min\{f(\xi, \eta) \mid (\xi, \eta) \in \Omega(t)\}$,
2. (x, y) *is a local minimizer of the function* $f(.,.) + \gamma\phi(.,.,t)$ *for every* $\gamma \geq \gamma^0$.

4. A trust region method.

The MPEC penalty functions that we encountered in the last section are of the type

$$f(x) = g(x) + p(h(x)),$$

where g is the C^1 objective function, p is piecewise affine, and h is a vector valued C^1-function. Such functions are locally Lipschitz and B-differentiable and one can thus associate two different stationarity concepts with them. We call a point x a *Bouligand stationary* (B-stationary) point of f if $f'(x; .) \geq 0$, and we call it *Clarke stationary* (C-stationary) if $0 \in \partial f(x)$, where ∂f denotes Clarke's subdifferential [5]. Since the B-derivative is always majorized by Clarke's derivative, a B-stationary point is C-stationary as well. The reverse statement holds generally only if f is regular at x, i.e., its B-derivative at x coincides with Clarke's derivative at this point.

A suitable tool for the minimization of the penalty functions f is the bundle-trust-region method of Schramm and Zowe [43]. However, their method is designed to find a C-stationary point and, in fact, their convergence theory states that under suitable assumptions at least one of the accumulation points of the computed sequence will be C-stationary. To apply the method it is necessary to be able to compute a Clarke subgradient of the penalty function at a given point x. Since the B-derivative is majorized by the Clarke derivative, the subdifferential of the first-order approximation of f is a subset of the subdifferential of f. It thus suffices to calculate a subgradient of the piecewise linear B-derivative

$$f'(x; y) = \nabla g(x)y + p'(h(x); \nabla h(x)y)$$

at $y = 0$. Recall that the Clarke subdifferential of a piecewise differentiable function is the convex hull of the collection of all gradients of its essentially active selection functions. So it suffices to determine an essentially active selection function of the piecewise linear function $f'(x; .)$. However, this can be a nontrivial combinatorial problem and the best way to do it depends heavily on the function p. We will not go into the details of the bundle-trust-region approach here, but instead propose a different trust region method which is applicable to the nonsmooth MPEC penalty functions and is designed to find a B-stationary point.

4.1. The trust region framework.

In this section, we present a general trust region framework for the minimization of locally Lipschitz continuous B-differentiable functions $f : \mathbb{R}^n \to \mathbb{R}$.

Given a point x^k, a trust region method employs a local model $m_k(.)$ of the function $f(x^k + .)$ which is assumed to be sufficiently accurate within the so-called trust radius δ_k about x^k. In order to determine a better point x^{k+1}, one determines an approximation s^k of the optimal solution of the problem

$$\min_{\|s\| \le \delta_k} m_k(s). \tag{4.1}$$

Having determined s^k, one checks whether the model $m_k(.)$ of the function $f(x^k + .)$ is indeed sufficiently accurate at the point s^k by comparing the actual reduction $f(x^k) - f(x^k + s^k)$ of the function value with the predicted reduction $m_k(0) - m_k(s^k)$ given by the model $m_k(.)$. If, on the one hand, the actual reduction does not exceed a fixed fraction of the predicted reduction, then the model is considered to be inadequate in the ball around x^k with radius δ_k; the method will reduce the trust radius and possibly improve the model, but it will not move to the point $x^k + s^k$. If, on the other hand, the actual reduction exceeds a certain fixed fraction of the predicted reduction, then x^k is updated to $x^{k+1} = x^k + s^k$ and a new model m_{k+1} along with a suitable update $\delta_{k+1} \ge \delta_k$ of the trust radius is determined. We shall use the following setup for the trust region method.

Trust Region Method. Let $f : \mathbb{R}^n \to \mathbb{R}$ be a function and let $0 < c_0 < c_1 < 1$ be fixed parameters.

```
kth iteration: Let $x^k \in \mathbb{R}^n$, $\delta_k > 0$ and $m_k : \mathbb{R}^n \to \mathbb{R}$ be given.

    Determine a vector $s^k$ with $\|s^k\| \le \delta_k$ and $m_k(s^k) < m_k(0)$. If no such
    vector exists, then stop.

    Set $r_k := \frac{f(x^k) - f(x^k + s^k)}{m_k(0) - m_k(s^k)}$.

    If $r_k \le c_0$, then set $x^{k+1} := x^k, \delta_{k+1} := Reduce(\delta_k)$,
    else if $c_0 < r^k \le c_1$, then set $x^{k+1} := x^k + s^k, \delta_{k+1} := \delta_k$,
        else set $x^{k+1} := x^k + s^k$, $\delta_{k+1} := Increase(\delta_k)$.

    Determine $m_{k+1}$.
```

A sequence $\{x^k\}_{k \in \mathbb{N}}$ is called a trust region sequence if it can be generated by the above procedure from some initial vector x^0. The above method is clearly a descent method, i.e., $f(x^{k+1}) \le f(x^k)$ for every $k \in \mathbb{N}$. This framework can thus be employed for the minimization of an arbitrary function f. However, to obtain convergence results, one has to impose a number of assumptions. Our first assumption concerns the function class for which we analyse the method.

(A1) *The function $f : \mathbb{R}^n \to \mathbb{R}$ is locally Lipschitz continuous and B-differentiable.*

In order to convert the trust region framework into an algorithm, one has to specify the model function m_k, a method for the determination of s_k, as well as the trust radius adjustments *Reduce*(.) and *Increase*(.). We will not give specific recipes for these selections but instead impose certain restrictions on such recipes. The assumptions that we use here are not the most general convergence assumptions, but they are general enough to cover the case of MPEC penalty functions and at the same time allow a fairly straightforward convergence proof. They are not implied by the assumptions made in [7, 31]. A convergence proof for the method under slightly more general assumptions as well as a comparison of the assumptions with the convergence conditions used in [7, 27, 31] is given in [44].

We first assume that s^k is chosen in such a way that a certain fixed fraction of the optimal model reduction can be guaranteed in each step.

(A2) *There is a number* $\tau \in (0,1]$ *(independent of* k*) such that*

$$m_k(0) - m_k(s^k) \geq \tau(m_k(0) - m_k^*), \tag{4.2}$$

where $m_k^* = \min_{\|s\| \leq \delta_k} m_k(s)$*.*

Our next assumption concerns the functions *Reduce*$(.)$ and *Increase*$(.)$.

(A3) *For each* $\delta_0 > 0$ *the assignment* $\delta_k := \mathit{Reduce}(\delta_{k-1})$ *generates a strictly decreasing positive nullsequence and there exists* $c_R \in (0,1)$ *such that*

$$\mathit{Reduce}(\delta) \geq c_R \delta.$$

For each $\delta_0 > 0$ *the assignment* $\delta_k := \mathit{Increase}(\delta_{k-1})$ *generates an increasing sequence and there exists* $c_I > 1$ *and* $\delta_{\max} > 0$ *such that*

$$\mathit{Increase}(\delta) \geq c_I \delta$$

for every $\delta \leq \delta_{\max}$*.*

The final set of assumptions concerns the choice of the model function and its approximation properties.

(A4) *The model function* m_k *is of the form*

$$m_k(s) = \Phi(x^k; s) + \frac{1}{2} s^T B_k s, \tag{4.3}$$

where B_k *is an* $n \times n$*-matrix and* $\Phi : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$ *is a function which does not depend on* k *and has the following properties:*

(A4.1) *For every* $x \in \mathbb{R}^n$ *the function* $\Phi_x = \Phi(x;.) : \mathbb{R}^n \to \mathbb{R}$ *is locally Lipschitz continuous and B-differentiable.*

(A4.2) $\Phi_x(0) = f(x)$ *and* $\Phi_x'(0;s) = f'(x;s)$*.*

(A4.3) *If* $\bar{x}$ *is an accumulation point of the trust region sequence, then*

1. $\displaystyle\lim_{(x,s)\to(\bar{x},0)} \frac{f(x+s) - \Phi(x;s)}{\|s\|} = 0,$
2. *there exists a positive number* ϵ *such that for every fixed* s *with* $\|s\| < \epsilon$ *the function* $x \to \Phi_s(x) := \Phi(x;s) : \mathbb{R}^n \to \mathbb{R}$ *is upper semicontinuous at* $\bar{x}$*.*

(A4.4) *There exists a number* M *such that* $\|B_k\| \leq M$ *for every* k*.*

assumption (A4.3) is rather restrictive. In general the first-order approximation $f(x) + f'(x;s)$ does not satisfy this assumption. We have seen, however, that a typical MPEC penalty function has the form

$$f(x) = g(x) + p(h(x)), \tag{4.4}$$

where $g : \mathbb{R}^n \to \mathbb{R}$ and $h : \mathbb{R}^n \to \mathbb{R}^m$ are differentiable and $p : \mathbb{R}^m \to \mathbb{R}$ is piecewise linear. A natural approximation of such functions f is of the form

$$\Phi(x;s) = g(x) + \nabla g(x)s + p(h(x) + \nabla h(x)s). \tag{4.5}$$

The following theorem shows that this approximation function satisfies assumption (A4).

THEOREM 4.1. *Let $g:\mathbb{R}^n \to \mathbb{R}$ and $h:\mathbb{R}^n \to \mathbb{R}^m$ be C^1-functions and $p:\mathbb{R}^m \to \mathbb{R}$ be locally Lipschitz continuous and B-differentiable. If f has the form* (4.4) *and Φ is defined by* (4.5)*, then Φ satisfies the conditions of assumption* (A4).

Proof. The function Φ_x is certainly locally Lipschitz continuous and B-differentiable. Moreover, $\Phi_x(0) = f(x)$ and

$$\begin{aligned}\Phi'_x(0; s) &= \nabla g(x)s + p'(h(x); \nabla h(x)s)\\ &= f'(x; s),\end{aligned}$$

in view of the chain rule for the B-derivative [35]. Since the function Φ_s is continuous for every $s \in \mathbb{R}^n$, it remains to be shown that

$$\lim_{(x,s)\to(\bar{x},0)} \frac{f(x+s) - \Phi(x;s)}{\|s\|} = 0. \tag{4.6}$$

Note first of all that

$$\lim_{(x,s)\to(\bar{x},0)} \frac{g(x+s) - g(x) - \nabla g(x)s}{\|s\|} = 0 \tag{4.7}$$

since g is a C^1-function. Moreover, if L is a Lipschitz constant of p, then

$$\frac{\|p(h(x+s)) - p(h(x) + \nabla h(x)s)\|}{\|s\|} \leq L \frac{\|h(x+s) - h(x) - \nabla h(x)s\|}{\|s\|}.$$

Since h is a C^1-function, the right-hand side of the inequality tends to zero, provided x tends to $\bar{x}$ and s tends to zero. This proves (4.6) in view of (4.7). □

Note that the iteration function $\Phi(x; s)$ does not satisfy the assumptions of the trust region methods found in [7, 31] since it is generally neither regular nor subhomogeneous in s.

4.2. Convergence analysis. Having set out the method along with some general assumptions, we shall next study properties of the accumulation points of the trust region sequence. The first rather trivial observation tells us that the trust region method will not stop unless a Bouligand stationary point of the function f is found.

PROPOSITION 4.2. *Suppose assumptions* (A1), (A4.1)*, and* (A4.2) *are satisfied. If the trust region method stops at iteration k and $\delta_k > 0$, then x^k is a Bouligand stationary point of f.*

Proof. If $\delta_k > 0$, then the trust region method stops at iteration k if and only if the origin is a local minimizer and a fortiori a Bouligand stationary point of $m_k(.)$, i.e., $\Phi'_{x^k}(0; .) \geq 0$. Assumption (A4) thus implies that $f'(x^k; .) \geq 0$, i.e., x^k is a Bouligand stationary point of f. □

Next, we show that if x^k is not B-stationary, then the trust region sequence will eventually move to a new point.

PROPOSITION 4.3. *Suppose assumptions* (A1)–(A4) *hold. If x^k is not a B-stationary point of f, then there exists a number $r \in \mathbb{N}$ such that $x^{k+r} \neq x^k$.*

Proof. Since x^k is not a B-stationary point of f, the method cannot terminate at the point x^k in view of Proposition 4.2. It thus either moves to a new point at some iteration or produces a stationary sequence. Let us assume the latter, i.e., $x^k = x^{k+r}$ for every $r \geq 1$. Then the trust radius is reduced at every iteration and thus assumption (A3) implies that δ_k is a nullsequence. Since x^k is not a B-stationary point of f, there exists a direction s with $\|s\| = 1$ and a real number $\alpha > 0$ such that $f'(x^k; s) = -\alpha$. Since we have assumed that the sequence is stationary, the point x^k is an accumulation point of the trust region sequence and hence assumption (A4) implies that

$$m_k'(0; s) = \Phi'_{x^k}(0; s) = f'(x^k; s) = -\alpha.$$

Thus, there exists a number $\bar{\delta} > 0$ such that

$$m_k(\delta s) - m_k(0) \le \frac{-\alpha\delta}{2}$$

for every $\delta \in [0, \bar{\delta}]$. Set $m_k^* = \min\{m_k(s) \mid \|s\| \le \delta_k\}$. If $0 < \delta_k \le \bar{\delta}$, which is eventually the case since δ_k is a positive nullsequence, then

$$m_k(0) - m_k^* \ge m_k(0) - m_k(\delta_k s) \ge \frac{\alpha\delta_k}{2} > 0. \tag{4.8}$$

Now we expand

$$\begin{aligned}\frac{f(x^k) - f(x^k + s^k)}{m_k(0) - m_k(s^k)} &= \frac{m_k(0) - m_k(s^k) - f(x^k + s^k) + m_k(s^k)}{m_k(0) - m_k(s^k)}\\ &= 1 - \frac{[f(x^k + s^k) - m_k(s^k)]}{m_k(0) - m_k(s^k)}\\ &= 1 - \frac{[m_k(0) - m_k^*]}{[m_k(0) - m_k(s^k)]}\,\frac{\|s^k\|}{[m_k(0) - m_k^*]}\,\frac{[f(x^k + s^k) - m_k(s^k)]}{\|s^k\|}.\end{aligned}$$

First, assumption (A2) ensures that the positive number $\frac{m_k(0) - m_k^*}{m_k(0) - m_k(s^k)}$ is bounded above by $\frac{1}{\tau}$. Second, since $\|s^k\| \le \delta_k$, inequality (4.8) implies

$$\frac{\|s^k\|}{m_k(0) - m_k^*} \le \frac{2\delta_k}{\alpha\delta_k} = \frac{2}{\alpha}.$$

Finally, since δ_k tends to zero and x^k is an accumulation point of the stationary sequence, assumption (A4) implies that

$$\lim_{k\to\infty} \frac{f(x^k + s^k) - m_k(s^k)}{\|s^k\|} = 0.$$

Hence $(f(x^k) - f(x^k + s^k))/(m_k(0) - m_k(s^k))$ tends to unity and thus $x^k + s^k$ will eventually be accepted by the method. This contradicts the stationarity of the sequence. □

The next proposition shows that an accumulation point of a trust region sequence is B-stationary, provided the corresponding sequence of trust radii does not tend to zero.

PROPOSITION 4.4. *Let $\{x^k\}_{k\in\mathbb{N}}$ be an infinite trust region sequence and let x^* be an accumulation point of this sequence. Suppose assumptions* (A1), (A2), *and* (A4) *hold. If x^* is not a B-stationary point of f, then there exists a subsequence $\{x^{k_i}\}_{i\in\mathbb{N}}$ tending to x^* such that the sequence of trust radii δ_{k_i} tends to zero.*

Proof. Since x^* is an accumulation point of the trust region sequence, there exists a subsequence $\{x^{k_i}\}_{i\in\mathbb{N}}$ converging to x^*. In view of Propositions 4.2 and 4.3, we may assume that $x^{k_i} \neq x^{k_i+1}$, i.e., the step $x^{k_i+1} := x^{k_i} + s^{k_i}$ was accepted at each iteration k_i, $i \in \mathbb{N}$. Hence

$$f(x^{k_i}) - f(x^{k_i+1}) > c_0[m_{k_i}(0) - m_{k_i}(s^{k_i})]. \tag{4.9}$$

By assumption (A4.4) we may pass to a subsequence with the property that the sequence of matrices B_{k_i} converges to a matrix B^*. Since x^* is not a B-stationary point of f, assumption (A4.2) shows that it is not a B-stationary point of the function $m^*(.)$ defined by $m^*(s) = \Phi(x^*, s) + \frac{1}{2}s^T B^* s$. Hence, for an arbitrarily chosen $\epsilon > 0$ we can find a point $s^* \in \mathbb{R}^n$ with $\|s^*\| \leq \epsilon$ such that

$$m^*(s^*) < m^*(0). \tag{4.10}$$

Now suppose the statement of the proposition is false, i.e., there exists a scalar $\mu > 0$ such that $\delta_{k_i} \geq \mu$ for every $i \in \mathbb{N}$. Choose $\epsilon \leq \mu$ in such a way that $\Phi(., s^*)$ is upper semicontinuous at x^*, which is possible in view of assumption (A4.3). Hence

$$\limsup_{i \to \infty} m_{k_i}(s^*) \leq m^*(s^*), \tag{4.11}$$

and since $\|s^*\| \leq \epsilon \leq \mu \leq \delta_{k_i}$ for every $i \in \mathbb{N}$, we further obtain

$$m_{k_i}(0) - \min_{\|s\| \leq \delta_{k_i}} m_{k_i}(s) \geq m_{k_i}(0) - m_{k_i}(s^*). \tag{4.12}$$

In view of assumptions (A2) and (A4.2), the inequalities (4.11) and (4.12) imply that

$$\begin{array}{rcl} m_{k_i}(0) - m_{k_i}(s^{k_i}) & \geq & \tau[m_{k_i}(0) - m_{k_i}(s^*)] \\ & \geq & \frac{\tau}{2}[m^*(0) - m^*(s^*)] \end{array} \tag{4.13}$$

for every sufficiently large $i \in \mathbb{N}$. Hence, in view of (4.9), the inequality

$$f(x^{k_i}) - f(x^{k_i+1}) > \frac{c_0 \tau}{2}[m^*(0) - m^*(s^*)]$$

holds for every sufficiently large $i \in \mathbb{N}$. On the one hand, by (4.10), the term on the right-hand side of the foregoing inequality is positive, and hence the series $\sum_{i=1}^{\infty}[f(x^{k_i}) - f(x^{k_i+1})]$ tends to infinity. On the other hand, $f(x^{k_i+1}) \geq f(x^{k_{i+1}})$ since the trust region method is a descent method, and hence

$$\sum_{i=1}^{\infty}[f(x^{k_i}) - f(x^{k_i+1})] \leq \sum_{i=1}^{\infty}[f(x^{k_i}) - f(x^{k_{i+1}})] = f(x^{k_1}) - f(x^*).$$

Thus the assumption that $\delta_{k_i} \geq \mu > 0$ for every $i \in \mathbb{N}$ leads to a contradiction. □

The final proposition shows that an accumulation point of the trust region method is a C-stationary point of the function if it is the limit point of a subsequence x^{k_i} whose corresponding sequence of trust radii δ_{k_i} tends to zero.

PROPOSITION 4.5. *Let $\{x^{k_i}\}_{i \in \mathbb{N}}$ be a convergent subsequence of an infinite trust region sequence $\{x^k\}_{k \in \mathbb{N}}$. Suppose assumptions* (A1)–(A4) *hold. If the sequence of trust radii δ_{k_i} tends to zero, then the limit point x^* of the sequence $\{x^{k_i}\}_{i \in \mathbb{N}}$ is a C-stationary point.*

Proof. Suppose x^* is not a C-stationary point. Then there exists a direction $\bar{y} \in \mathbb{R}^n$ with $\|\bar{y}\| = 1$ and $f^\circ(x^*; \bar{y}) < 0$, where $f^\circ(.;.)$ denotes Clarke's generalized derivative [5]. The definition of $f^\circ(x^*;.)$ yields the existence of positive numbers $\bar{\nu}, \bar{\epsilon}$, and $\bar{\delta}$ such that

$$f(x^k) - f(x^k + \delta_k \bar{y}) \geq \bar{\nu}\delta_k$$

for every $k \in \mathbb{N}$ satisfying

$$\begin{aligned} \|x^k - x^*\| &\leq \bar{\epsilon}, \\ \delta_k &\leq \bar{\delta}. \end{aligned} \tag{4.14}$$

If we set $m_k^* = \min\{m_k(s) \mid \|s\| \leq \delta_k\}$, then we obtain

$$\frac{f(x^k) - m_k^*}{\delta_k} \geq \frac{f(x^k) - m_k(\delta_k \bar{y})}{\delta_k} \geq \bar{\nu} + \frac{f(x^k + \delta_k \bar{y}) - m_k(\delta_k \bar{y})}{\delta_k}$$

for every k satisfying (4.14). Assumptions (A4.3) and (A4.4) imply that

$$\frac{f(x^k) - m_k^*}{\delta_k} \geq \frac{\bar{\nu}}{2} \tag{4.15}$$

for every k satisfying (4.14), provided we have chosen $\bar{\epsilon}$ and $\bar{\delta}$ small enough. Now we show that the ratio r_k is arbitrarily close to 1, provided $\bar{\epsilon}$ and $\bar{\delta}$ are chosen sufficiently small. Expand

$$\begin{aligned} r_k &= \frac{f(x^k) - f(x^k + s^k)}{f(x^k) - m_k(s^k)} \\ &= 1 - \frac{f(x^k + s^k) - m_k(s^k)}{f(x^k) - m_k(s^k)} \\ &= 1 - \frac{f(x^k + s^k) - m_k(s^k)}{\|s^k\|} \frac{\|s^k\|}{\delta_k} \frac{\delta_k}{f(x^k) - m_k^*} \frac{f(x^k) - m_k^*}{f(x^k) - m_k(s^k)}. \qquad (4.16) \end{aligned}$$

Note that

$$\begin{aligned} \frac{\|s^k\|}{\delta_k} &\leq 1, \\ \frac{\delta_k}{f(x^k) - m_k^*} &\leq \frac{2}{\bar{\nu}}, \\ \frac{f(x^k) - m_k^*}{f(x^k) - m_k(s^k)} &\leq \frac{1}{\tau}, \end{aligned}$$

where the second inequality follows from (4.15) and the last inequality follows from assumption (A2) since $m_k(0) = f(x^k)$. Assumptions (A4.3) and (A4.4) ensure that the term

$$\frac{f(x^k + s^k) - m_k(s^k)}{\|s^k\|}$$

will be arbitrarily small, provided k satisfies (4.14) and $\bar{\epsilon} > 0$ and $\bar{\delta} > 0$ are chosen small enough. Hence we conclude that for sufficiently small positive numbers $\bar{\epsilon}$ and $\bar{\delta}$ the inequality

$$r_k > c_1, \ c_1 \in [c_0, 1) \tag{4.17}$$

holds for every k satisfying (4.14). Now consider the subsequence $\{x^{k_i}\}_{i\in\mathbb{N}}$. Reducing $\bar{\delta}$ if necessary, we may assume that $\bar{\delta} \le \delta_{\max}$, where the latter constant is given in (A3). Thus the trust radius will always be increased for sufficiently large k_i, i.e., $\delta_{k_i+1} \ge c_I\delta_{k_i}$, where $c_I > 1$ is the constant given in assumption (A3). Now let k_i be such that $\delta_{k_i} < c_R\bar{\delta}$, where c_R is again given in assumption (A3) and $\|x^{k_i} - x^*\| \le \bar{\epsilon}/2$. Let $j_i \le k_i$ be the smallest index such that all ratios $r_{j_i+1}, \dots, r_{k_i}$ exceed c_1. Let us first show that

$$\|x^{j_i} - x^*\| > \bar{\epsilon}. \tag{4.18}$$

We may assume without loss of generality that $\bar{\epsilon}$ has been chosen small enough so that $\|x^0 - x^*\| > \bar{\epsilon}$ since we have assumed that x^* is not C-stationary and, a fortiori, not B-stationary and thus, in view of Proposition 4.3, $x^* \neq x^0$. Hence (4.18) holds if $j_i = 0$. To see that the inequality also holds for $j_i \ge 1$, note that $\delta_{j_i} \le \bar{\delta}$ since the trust region bound has been increased in the steps $j_i + 1, \dots, k_i$; hence $\delta_{j_i+1} \le \delta_{k_i} \le c_R\bar{\delta}$ and, in view of assumption (A3), $c_R\delta_{j_i} \le \mathit{Reduce}(\delta_{j_i}) \le \delta_{j_i+1}$. Since $r_{j_i} \le c_1$ and (4.17) holds for every k satisfying (4.14), we conclude that (4.18) holds. Since $\|x^{k_i} - x^*\| \le \bar{\epsilon}/2$, we obtain from (4.18) and assumption (A3) that

$$\frac{\bar{\epsilon}}{2} \le \|x^{k_i} - x^{j_i}\| \le \sum_{m=0}^{k_i-j_i-1} \|s^{j_i+m}\| \le \delta_{j_i} + \sum_{\mu=1}^{k_i-j_i-1} \delta_{k_i-\mu}.$$

Note that, in view of assumption (A3), $\delta_{k_i-\mu} \le \frac{\delta_{k_i}}{c_I^\mu}$ for $\mu = 1, \dots, k_i - j_i - 1$. Moreover, again due to (A3), $\delta_{j_i} \le \delta_{k_i}/c_R$. Hence

$$\frac{\bar{\epsilon}}{2} \le \frac{\delta_{k_i}}{c_R} + \sum_{\mu=1}^{\infty} \frac{\delta_{k_i}}{c_I^\mu} = [\frac{1}{c_R} + \frac{1}{c_I - 1}]\delta_{k_i}.$$

Since, by (A3), $c_R > 0$ and $c_I > 1$, we conclude that δ_{k_i} is bounded away from zero which, however, leads to a contradiction as we have assumed that δ_{k_i} tends to zero. Thus x^* is a C-stationary point. □

4.3. A penalty update rule. In order to apply the trust region method to nonsmooth penalty functions $g + \alpha p \circ h$ arising from constrained optimization problems

$$\min\{g(x) \mid p(h(x)) = 0\}$$

with nonnegative function $p \circ h$, one has to specify a penalty parameter α. Rather than determining this parameter in advance, one may update it in the course of the method. To allow for penalty parameter updates, we consider the model functions

$$m_k(s) = g(x^k) + \nabla g(x^k)s + \alpha_k p(h(x^k) + \nabla h(x^k)s) + \frac{1}{2}s^\top B_k s.$$

In this section we show how the penalty update rule suggested by Yuan [47] can be incorporated into our method. Yuan's method determines the sequence of penalty parameters α_k by means of a control sequence β_k which is also determined during the course of the method. In fact, starting from some initial positive parameters α_0 and β_0, the method generates the sequences α_k and β_k which are updated after each accepted step s^k using the following rule.

Penalty update rule for iteration k.

Let $\bar{\alpha}, \bar{\beta}$ be constants independent of k with $0 < \bar{\beta} < 1 < \bar{\alpha}$.

If

$$m_k(0) - m_k(s^k) < \beta_k \alpha_k \min\{\delta_k, p(h(x^k))\},$$

then

$$\alpha_{k+1} = \bar{\alpha}\alpha_k \text{ and } \beta_{k+1} = \bar{\beta}\beta_k,$$

else

$$\alpha_{k+1} = \alpha_k \text{ and } \beta_{k+1} = \beta_k.$$

Theorem 4.6. *Let* $\{x^k\}$ *be a bounded trust region sequence and suppose* (A1), (A2), *and* (A4) *hold.*

1. *If* $\alpha_k \overset{k\to\infty}{\longrightarrow} \infty$, *then there exists a subsequence which converges to a C-stationary point of* $p \circ h$.
2. *If* $\lim_{k\to\infty} \alpha_k < \infty$ *and* (A3) *holds, then every accumulation point of the trust region sequence is a feasible Clarke stationary point of the function* $g + \alpha(p \circ h)$ *for every* $\alpha \geq \lim_{k\to\infty} \alpha_k$.

Proof. Define $\rho_k = \min\{\delta_k, p(h(x^k))\}$.

1. Since $\alpha_k \overset{k\to\infty}{\longrightarrow} \infty$ and $\{x^k\}$ is bounded, there exists a subsequence x^{k_i} such that $\alpha_{k_i+1} > \alpha_{k_i}$ and $x^{k_i} \overset{i\to\infty}{\longrightarrow} x^*$. We first prove that

$$\lim_{i\to\infty} \frac{p(h(x^{k_i})) - \min\limits_{||d||\leq\rho_{k_i}} p(h(x^{k_i}) + \nabla h(x^{k_i})d)}{\rho_{k_i}} = 0. \tag{4.19}$$

Note that $p(h(x^{k_i})) > 0 \;\forall\; i$. Let d^{k_i} be a solution of

$$\min_{||d||\leq\rho_{k_i}} p(h(x^{k_i}) + \nabla h(x^{k_i})d).$$

Since $\alpha_{k_i+1} > \alpha_{k_i}$, we obtain

$$\begin{aligned} \alpha_{k_i}\beta_{k_i}\rho_{k_i} &> m_{k_i}(0) - m_{k_i}(s^{k_i}) \\ &\geq \tau[m_{k_i}(0) - m_{k_i}(s^*)] \\ &\geq \tau[m_{k_i}(0) - m_{k_i}(d^{k_i})] \\ &\geq \tau\Big[- \nabla g(x^{k_i})d^{k_i} - \frac{1}{2}(d^{k_i})^\top B_{k_i} d^{k_i} \\ &\qquad + \alpha_{k_i}\left(p(h(x^{k_i})) - p(h(x^{k_i}) + \nabla h(x^{k_i})d^{k_i})\right)\Big]. \end{aligned} \tag{4.20}$$

Dividing the inequalities by $\alpha_{k_i}\rho_{k_i}$ we obtain

$$\begin{aligned} \beta_{k_i} \quad \geq \quad \tau\Bigg[&\frac{-2\nabla g(x^{k_i})d^{k_i} - (d^{k_i})^\top B_{k_i} d^{k_i}}{2\alpha_{k_i}\rho_{k_i}} \\ &+ \frac{p(h(x^{k_i})) - p(h(x^{k_i}) + \nabla h(x^{k_i})d^{k_i})}{\rho_{k_i}}\Bigg]. \end{aligned} \tag{4.21}$$

Note that

$$\left|\frac{-2\nabla g(x^{k_i})d^{k_i} - (d^{k_i})^\top B_{k_i} d^{k_i}}{2\alpha_{k_i}\rho_{k_i}}\right| \leq \frac{2\|\nabla g(x^{k_i})\|_2 \|d^{k_i}\|_2 + \|d^{k_i}\|_2 \|B_{k_i}\|_2^* \|d^{k_i}\|_2}{\alpha_{k_i}\rho_{k_i}}$$
$$\leq \frac{2\|\nabla g(x^{k_i})\|_2 + \|d^{k_i}\|_2 \|B_{k_i}\|_2^*}{\alpha_{k_i}},$$

where $\|.\|_2$ and $\|.\|_2^*$ denote the ℓ_2 vector and operator norm, respectively. Since B_k is bounded, x^{k_i} converges to x^*, and $\alpha_{k_i} \overset{i\to\infty}{\longrightarrow} \infty$, we conclude that the first term in the right-hand bracket of (4.21) tends to zero. Note that $\beta_{k_i} \overset{i\to\infty}{\longrightarrow} 0$ since $\alpha_{k_i} \overset{i\to\infty}{\longrightarrow} \infty$; hence we conclude that the nonnegative term

$$\frac{p(h(x^{k_i})) - p(h(x^{k_i}) + \nabla h(x^{k_i})d^{k_i})}{\rho_{k_i}}$$

tends to 0 as i tends to ∞, thus proving (4.19).

Now suppose x^* is not a Clarke stationary point of $p(h(.))$, i.e., there exists a descent direction $d \in \mathbb{R}^n : ||d|| = 1$ in x^* of Clarke's generalized derivative [5]. In other words, there exist positive constants $\epsilon, \tilde{\delta}, \gamma$ such that

$$p(h(x)) - p(h(x + \delta d)) > \gamma\delta \quad \forall ||x - x^*|| \leq \epsilon, 0 < \delta \leq \tilde{\delta}$$

and hence, reducing ϵ and $\tilde{\delta}$ if necessary, that

$$p(h(x)) - p(h(x) + \nabla h(x)\delta d)) > \frac{1}{2}\gamma\delta \quad \forall ||x - x^*|| \leq \epsilon, 0 < \delta \leq \tilde{\delta}.$$

Now suppose, on the one hand, that $\rho_{k_i} \leq \tilde{\delta}$. Then

$$\frac{p(h(x^{k_i})) - p(h(x^{k_i}) + \nabla h(x^{k_i})d^{k_i})}{\rho_{k_i}} \geq \frac{p(h(x^{k_i})) - p(h(x^{k_i}) + \nabla h(x^{k_i})\rho_{k_i} d)}{\rho_{k_i}}$$
$$\geq \frac{1}{2}\gamma.$$

If, on the other hand, $\rho_{k_i} > \tilde{\delta}$, then

$$\frac{p(h(x^{k_i})) - p(h(x^{k_i}) + \nabla h(x^{k_i})d^{k_i})}{\rho_{k_i}} \geq \frac{p(h(x^{k_i})) - p(h(x^{k_i}) + \nabla h(x^{k_i})\tilde{\delta} d)}{\rho_{k_i}}$$
$$\geq \frac{1}{2}\gamma\frac{\tilde{\delta}}{\rho_{k_i}}.$$

Note that $\limsup \rho_{k_i}$ is bounded above by $p(h(x^*))$. Hence both inequalities taken together constitute a contradiction to (4.19).

2. Because of the assumption $\lim_{k\to\infty} \alpha_k < \infty$ we know that the penalty parameter sequence remains constant for sufficiently large k, i.e., $\alpha_k = \alpha$ and $\beta_k = \beta$ for every $k > k_0$. Therefore we can apply the convergence results of our trust region method. Hence every accumulation point of the trust region sequence is stationary in the sense of Clarke. We have only to show that these points are also feasible.

Let x^* be an arbitrary accumulation point and (x^{k_i}) a subsequence of successful steps which converges to x^*. Suppose x^* is not a feasible point. Then there exists a positive number $\hat{\delta}$ such that

$$p(h(x^{k_i})) \geq \hat{\delta} \ \forall \ k_i \in \mathbb{N} \text{ large enough.}$$

Hence the definition of the penalty update rule yields

$$m_{k_i}(0) - m_{k_i}(s^{k_i}) \geq \alpha\beta\rho_{k_i} \geq \alpha\beta \min\{\delta_{k_i}, \hat{\delta}\}$$

for every sufficiently large k_i and thus, since the left-hand side of this inequality tends to zero, there exists $\tilde{c} > 0$ such that

$$m_{k_i}(0) - m_{k_i}(s^{k_i}) \geq \tilde{c}\delta_{k_i}. \tag{4.22}$$

We have

$$\infty > f(x^{k_1}) - f(x^*) = \sum_{i=1}^{\infty}[f(x^{k_i}) - f(x^{k_{i+1}})] \geq \sum_{i=1}^{\infty}[f(x^{k_i}) - f(x^{k_i+1})] \geq \sum_{i=1}^{\infty} c_0\tilde{c}\delta_{k_i}$$

and conclude that (δ_{k_i}) is a nullsequence. Expanding r_{k_i} as in (4.16), we conclude from (4.22) that $\lim_{i\to\infty} r_{k_i} = 1$. Now we can apply similar arguments as in the proof of Proposition 4.5 to verify that the corresponding trust radius sequence (δ_{k_i}) is bounded away from zero and thus obtain a contradiction to our assumptions. □

5. An ℓ_1 penalty function for MPECs. In order to apply the proposed trust region method to MPECs, we have to specify the matrices B_k along with a method for the determination of an approximate solution s^k of the subproblem

$$\begin{array}{ll} \min & \nabla g(x^k)s + p(h(x^k) + \nabla h(x^k)s) + \frac{1}{2}s^\top B_k s \\ \text{s.t.} & \|s\| \leq \delta_k. \end{array} \tag{5.1}$$

We shall use a specification which turns into the $S\ell_1QP$ method of Fletcher [10, Chap. 12] if no complementarity constraints are present. We choose the ℓ_∞ norm for the trust region and consider ℓ_1 penalty terms of the form $\phi = p \circ h$, where

$$p(z) = \sum_{i=1}^{m} |\min\{z_i, z_{m+i}\}| + \sum_{v=2m+1}^{2m+p} \max\{z_v, 0\} + \sum_{w=2m+p+1}^{2m+p+q} |z_w|. \tag{5.2}$$

Such penalty terms arise from MPECs with complementarity constraints. The term $|\min\{z_i, z_{m+i}\}|$ is used to penalize the violation of the complementarity conditions $z_i \geq 0$, $z_{m+i} \geq 0$, $z_i z_{m+i} = 0$. Notice that, by our choice of p, the subproblem (5.1) is nonconvex, even if the matrix B_k is positive semidefinite. To overcome the inherent combinatorial difficulties, we suggest solving a related subproblem which is obtained by replacing the nonconvex function p by a suitable convex majorant

$$\begin{aligned} p_I(z) = & \sum_{\substack{i=1 \\ i\in I}}^{m} \max\{|z_i|, -z_{m+i}\} + \sum_{\substack{j=1 \\ m+j\in I}}^{m} \max\{|z_{m+j}|, -z_j\} \\ & + \sum_{v=2m+1}^{2m+p} \max\{z_v, 0\} + \sum_{w=2m+p+1}^{2m+p+q} |z_w|, \end{aligned} \tag{5.3}$$

where $I \subseteq \{1, \ldots, 2m\}$ and for every $i \in \{1, \ldots, m\}$ either $i \in I$ or $m + i \in I$, but not both. Notice that the function p is the pointwise minimum over all functions p_I and if

$$\begin{array}{rcl} \{i \mid h_i(x) < h_{m+i}(x)\} \cup \{m + i \mid h_{m+i}(x) < h_i(x)\} & \subseteq & I, \\ \{i \mid h_i(x) \leq h_{m+i}(x)\} \cup \{m + i \mid h_{m+i}(x) \leq h_i(x)\} & \supseteq & I, \end{array} \tag{5.4}$$

then $p_I(h(x)) = p(h(x))$. Thus, if x is a B-stationary point of $g + \alpha(p \circ h)$, then it is a B-stationary point of $g + \alpha(p_I \circ h)$ for every I satisfying (5.4). Initially we set $I_0 = \{i \mid h_i(x_0) \leq h_{m+i}(x_0)\} \cup \{m+j \mid h_{m+j}(x_0) < h_j(x_0)\}$, where x_0 is the starting point.

To incorporate second-order information in the model we make use of multiplier vectors $\lambda^k \in \mathbb{R}^{2m+p+q}$ which correspond to the Lagrangian

$$L(x, \lambda) = g(x) + h(x)^\top \lambda.$$

These multipliers will be obtained by employing the above majorant of the model function. Initially we set $\lambda^0 = 0$.

At iteration k we are given the current iterate x^k, a multiplier vector λ^k, a trust radius δ_k, a penalty parameter α_k, a matrix B_k, and an index set I_k. We determine s^k as a locally optimal solution of the program

$$(5.5) \qquad \begin{array}{ll} \min & \nabla g(x^k)s + \alpha_k p_{I_k}(h(x^k) + \nabla h(x^k)s) + \frac{1}{2}s^\top B_k s \\ \text{s.t.} & -\delta_k \leq s_t \leq \delta_k, \quad t = 1, \dots, n, \end{array}$$

where $B_k = \nabla^2_{xx} L(x^k, \lambda^k)$. If s^k is a local minimizer of (5.5), then it satisfies Clarke's stationarity condition [2, 5], i.e., there exist multipliers (μ^k, r_k, ξ^k) such that

$$(5.6) \qquad \begin{array}{rcl} \nabla g(x^k)^\top + B_k s^k + \nabla h(x^k)^\top \mu^k + r_k \xi^k & = & 0, \\ \mu^k & \in & \alpha_k \partial p_{I_k}(h(x^k) + \nabla h(x^k)s^k), \\ \xi^k & \in & \partial \|s^k\|_\infty, \\ r_k & \geq & 0, \\ r_k(\|s^k\| - \delta_k) & = & 0. \end{array}$$

We solve (5.5) by rewriting it as the quadratic program

$$\begin{array}{llll} \min & \multicolumn{3}{l}{\nabla g(x^k)s + \alpha_k[\sum_{i=1}^m \gamma_i + \sum_{v=1}^p \rho_v + \sum_{w=1}^q \sigma_w] + \frac{1}{2}s^\top B_k s} \\ \text{s.t.} & & & \\ -\gamma_i \leq & h_i(x^k) + \nabla h_i(x^k)s & \leq \gamma_i, & i \in I_k \cap \{1, \dots, m\}, \\ -\gamma_i \leq & h_{m+i}(x^k) + \nabla h_{m+i}(x^k)s, & & i \in I_k \cap \{1, \dots, m\}, \\ -\gamma_j \leq & h_{m+j}(x^k) + \nabla h_{m+j}(x^k)s & \leq \gamma_j, & m+j \in I_k \cap \{m+1, \dots, 2m\}, \\ -\gamma_j \leq & h_j(x^k) + \nabla h_j(x^k)s, & & m+j \in I_k \cap \{m+1, \dots, 2m\}, \\ & h_{2m+v}(x^k) + \nabla h_{2m+v}(x^k)s & \leq \rho_v, & v = 1, \dots, p, \\ & 0 & \leq \rho_v, & v = 1, \dots, p, \\ -\sigma_w \leq & h_{2m+p+w}(x^k) + \nabla h_{2m+p+w}(x^k)s & \leq \sigma_w, & w = 1, \dots, q, \\ -\delta_k \leq & s_t & \leq \delta_k, & t = 1, \dots, n. \end{array}$$

Given the Lagrange multipliers for this quadratic program at a local minimizer s^k, we define a vector $(\mu^k, \nu^k) \in \mathbb{R}^{2m+p+q} \times \mathbb{R}^n$ as follows. Let $1 \leq i \leq 2m+p+q$. If the term $h_i(x^k) + \nabla h_i(x^k)s$ is constrained from two sides, e.g., $-\gamma_i \leq h_i(x^k) + \nabla h_i(x^k)s \leq \gamma_i$, and $\mu^k_{i,+} \geq 0$ and $\mu^k_{i,-} \leq 0$ are the multipliers corresponding to the right-hand and left-hand sides, respectively, of the two-sided inequality, then we set $\mu^k_i = \mu^k_{i,+} + \mu^k_{i,-}$. Otherwise, we let μ^k_i be the multiplier corresponding to the one-sided inequality constraining the term $h_i(x^k) + \nabla h_i(x^k)s$. The multipliers corresponding to $0 \leq \rho_v$ are neglected and we finally set $\nu^k_t = \nu^k_{t,+} + \nu^k_{t,-}$, where $\nu^k_{t,+} \geq 0$ and $\nu^k_{t,-} \leq 0$ are the multipliers corresponding to the right-hand and left-hand sides, respectively, of the two-sided inequality $-\delta_k \leq s_t \leq \delta_k$. A straightforward but rather lengthy comparison of the KKT conditions of the above quadratic program with the stationarity conditions

(5.6) shows that (μ^k, ν^k) is of the form $(\mu^k, r_k\xi^k)$, where (μ^k, r_k, ξ^k) satisfies (5.6). Note that this implies in particular that

$$\|\mu^k\|_\infty \leq \alpha_k, \tag{5.7}$$

since the subdifferential of every function p_I at every point is contained in the ℓ_∞ unit-ball.

If step s^k is rejected by the trust region method, then we set $\lambda^{k+1} := \lambda^k$ and $I_{k+1} := I_k$. Otherwise, we set $\lambda^{k+1} := \mu^k$ and determine the index set I_{k+1} by the following rule, which makes use of two predetermined positive tolerances τ_1, τ_2. For every $i = 1, \dots, m$ we have to decide whether to include i or $m + i$ in I_{k+1}:

If $\max\{|h_i(x^{k+1})|, |h_{m+i}(x^{k+1})|\} < \tau_1$ and $\lambda_i^{k+1} > \tau_2$, then $m + i \in I_{k+1}$,
else if $\max\{|h_i(x^{k+1})|, |h_{m+i}(x^{k+1})|\} < \tau_1$ and $\lambda_{m+i}^{k+1} > \tau_2$, then $i \in I_{k+1}$,
    else if $h_i(x^{k+1}) \leq h_{m+i}(x^{k+1})$, then $i \in I_{k+1}$,
        else $m + i \in I_{k+1}$.

The first part of this rule needs some explanation. Let us focus attention on the first if statement. Note first that the multiplier λ_i^{k+1} can be positive only if i is already contained in I_k, i.e., we had forced h_i to be close to zero at the last iteration and allowed the complementary function h_{m+i} to become positive. The first if statement, however, indicates that the objective function seems to force the function h_{m+i} to be close to zero anyway. Therefore, instead of allowing h_{m+i} to become positive and forcing h_i to be zero, we swap, i.e., in the next step we force h_{m+i} to be close to zero and allow h_i to become positive. This is done by including $m+i$ in I_{k+1}. The positive multiplier λ_i^{k+1} indicates that this swap seems to be favorable.

5.1. Relation to SQP methods. If the gradients $\nabla h_i(x^*)$ of the active functions h_i are linearly independent and x^* is a local minimizer of the MPEC, then there exists a uniquely determined Lagrange multiplier vector $\lambda^* \in \mathbb{R}^{2m+p+q}$ such that

(5.8)

$$\begin{aligned}
\nabla g(x^*)^\top + \nabla h(x^*)^\top \lambda^* &= 0, \\
h_i(x^*)\lambda_i^* &= 0 \quad \forall i = 1, \dots, 2m + p, \\
\lambda_i^*, \lambda_{m+i}^* &\leq 0 \quad \forall i \in \{1, \dots, m\} \text{ s.t. } h_i(x^*) = h_{m+i}(x^*) = 0, \\
\lambda_l^* &\geq 0 \quad \forall l = 2m + 1, \dots, 2m + p,
\end{aligned}$$

and this is equivalent to B-stationarity of x^* for $g + \alpha p \circ h$ for every sufficiently large α, [20, 40]. The next proposition gives conditions under which the estimates λ^k of the method converge to the Lagrange multipliers λ^*.

Proposition 5.1. *Suppose the sequence of matrices B_k is bounded, the sequence of iterates x^k tends to a feasible C-stationary point x^*, and the gradients of the active functions h_i at x^* are linearly independent. Then there exists a unique multiplier λ^* such that*

$$\begin{aligned}
\nabla g(x^*)^\top + \nabla h(x^*)^\top \lambda^* &= 0, \\
h_i(x^*)\lambda_i^* &= 0 \quad \forall i = 1, \dots, 2m + p + q, \\
\lambda_l^* &\geq 0 \quad \forall l = 2m + 1, \dots, 2m + p.
\end{aligned} \tag{5.9}$$

If the trust radius sequence δ_k is bounded away from zero, then there exists a positive scalar $\bar{\tau}_1$, such that for every choice of the tolerance $\tau \in (0, \bar{\tau}_1)$ the sequence λ^k

converges to λ^*. *Moreover, there exists a second positive scalar* $\bar\tau_2$ *such that*

$$\lambda_i^*, \lambda_{m+i}^* \le 0 \quad \forall i \in \{1,\dots,m\} \ \text{ s.t. } \ h_i(x^*) = h_{m+i}(x^*) = 0,$$

provided $\tau_2 \in [0, \bar\tau_2)$.

Proof. The existence and uniqueness of λ^* satisfying (5.9) follows from the definition of C-stationarity and the linear independence assumption. Let

$$\bar\tau_1 = \min\{h_j(x^*) \mid h_j(x^*) > 0, \ \ j = 1,\dots,2m\}$$

and suppose $0 < \tau_1 < \bar\tau_1$. Note first that for sufficiently large k the index set $I = I_k$ satisfies (5.4) with $x = x^*$ and hence $p_{I_k}(h(x^*)) = p(h(x^*))$. Indeed, for every $i = 1,\dots,m$ the equation $\min\{h_i(x^*), h_{m+i}(x^*)\} = 0$ holds since x^* is feasible. Hence, if, on the one hand, $0 = h_i(x^*) < h_{m+i}(x^*)$ and k is sufficiently large, then $\max\{|h_i(x^k)|, |h_{m+i}(x^k)|\} > \tau_1$ and thus $i \in I_k$. On the other hand, if $i \in I_k$, then $h_i(x^*) \le h_{m+i}(x^*)$ because, if $0 = h_{m+i}(x^*) < h_i(x^*)$, then again $\max\{|h_i(x^k)|, |h_{m+i}(x^k)|\} > \tau_1$ for sufficiently large k and hence $m + i \in I_k$ and $i \notin I_k$. The same argument holds with i and $m + i$ swapped.

Recall that $\lambda^{k+1} = \lambda^k$ if s^k is not accepted by the method. Let s^{k_i} be the subsequence of accepted steps. Since the steps s^{k_i} tend to zero and hence the corresponding trust radius is thus eventually inactive, (5.6) implies that λ^{k_i+1} satisfies

$$\begin{array}{rcl} 0 & = & \nabla g(x^{k_i})^\top + B_{k_i} s^{k_i} + \nabla h(x^{k_i})^\top \lambda^{k_i+1}, \\ \lambda^{k_i+1} & \in & \alpha_{k_i} \partial p_{I_{k_i}}(h(x^{k_i}) + \nabla h(x^{k_i}) s^{k_i}), \end{array}$$

provided k_i is sufficiently large. If $h_j(x^*) \ne p(h(x^*)) = 0$, then $h_j(x^*) \ne p_{I_{k_i}}(h(x^*)) = p(h(x^*))$; hence $h_j(x^{k_i}) + \nabla h_j(x^{k_i}) s^{k_i} \ne 0$ for sufficiently large k_i and thus $\lambda_j^{k_i+1} = 0$. Now consider the chain of inequalities

$$\begin{aligned} 0 &= \|\nabla g(x^{k_i})^\top + \nabla h(x^{k_i})^\top \lambda^{k_i+1} + B_{k_i} s^{k_i}\| \\ &= \|\nabla g(x^{k_i})^\top + \nabla h(x^{k_i})^\top \lambda^{k_i+1} + B_{k_i} s^{k_i} \\ &\quad \underbrace{-\nabla g(x^*)^\top - \nabla h(x^*)^\top \lambda^*}_{=0} + (\nabla h(x^*) - \nabla h(x^*))^\top \lambda^{k_i+1}\| \\ &\ge \|\nabla h(x^*)^\top (\lambda^{k_i+1} - \lambda^*)\| - \\ &\quad \underbrace{\|\nabla g(x^{k_i})^\top - \nabla g(x^*)^\top - (\nabla h(x^*) - \nabla h(x^{k_i}))^\top \lambda^{k_i+1} + B_{k_i} s^{k_i}\|}_{\to 0 \quad \text{if} \quad k_i \to \infty}. \end{aligned}$$

We conclude that

$$\lim_{k_i \to \infty} \|\nabla h(x^*)^\top (\lambda^{k_i+1} - \lambda^*)\| = 0. \tag{5.10}$$

Since $\lambda_j^{k_i+1} = 0$ if $h_j(x^*) \ne p(h(x^*)) = 0$, we obtain

$$\nabla h(x^*)^\top (\lambda^{k_i+1} - \lambda^*) = \nabla h_{I_0}(x^*)^\top (\lambda_{I_0}^{k_i+1} - \lambda_{I_0}^*), \tag{5.11}$$

where I_0 is the set of indices of those functions h_j which vanish at x^*. The convergence thus follows from (5.10), (5.11), and the full column rank of $\nabla h_{I_0}(x^*)^\top$.

Finally, suppose $h_i(x^*) = h_{m+i}(x^*)$ and $\lambda_i^* > 0$. Then there exists $\bar k$ such that $\lambda_i^k > 0$ for every $k \ge \bar k$; hence

$$i \in I_k \quad \forall k \ge \bar k. \tag{5.12}$$

Now let

$$\tau_2 < \min\{\lambda_i^* \mid \lambda_i^* > 0, \quad i = 1, \ldots, 2m\}.$$

Enlarging $\bar{k}$ if necessary, we may assume that $\max\{|h_i(x^k)|, |h_{m+i}(x^k)|\} < \tau_1$ for every $k \geq \bar{k}$. Since λ^k converges to λ^*, we may further assume that $\lambda_i^k > \tau_2$ for every $k \geq \bar{k}$. Now let $k \geq \bar{k}$ be such that s_k is accepted and hence $\lambda^{k+1} = \mu^k$. Since $\lambda^{k+1} > \tau_2$, the rule for the determination of I_{k+1} yields $m + i \in I_{k+1}$, contradicting (5.12). $\square$

Note that we solve in iteration k the subproblem of Fletcher's trust region SNQP method [10] applied to the nonlinear program

$$\begin{array}{lll} \min & g(x), & \\ \text{s.t.} & h_i(x) = 0, & i \in I_k, \\ & h_j(x) \geq 0, & j = \{1, \ldots, 2m\} \backslash I_k, \\ & h_l(x) \leq 0, & l = 2m+1, \ldots, 2m+p, \\ & h_r(x) = 0, & r = 2m+p+1, \ldots, 2m+p+q. \end{array} \tag{5.13}$$

If the trust region bound is eventually inactive and the sequence of iterates converges, then the trust region SNQP method turns into a local SNQP method. Theorem 14.4.1 of [10] gives conditions under which the nonglobalized SNQP method turns asymptotically into an SQP method and thus inherits the favorable local convergence properties. If these conditions hold, then

$$p_{I_k}(h(x^k) + \nabla h(x^k) s^k) = 0. \tag{5.14}$$

If, in addition, upper-level strict complementarity holds, i.e., $\lambda_i^* \lambda_{m+i}^* \neq 0$ for every i with $h_i(x^*) = h_{m+i}(x^*)$, then the first branch in the rule for determination of I_k will not be used for sufficiently large k and thus $p_{I_k}(h(x^k)) = p(h(x^k))$. This equation together with (5.14) implies that the step s^k of the SNQP method is accepted by our method, provided it is accepted by the trust region SNQP method [10], since the ratio of actual reduction by predicted reduction in our method is at least as large as the same ratio with p replaced by p_{I_k}. Note that our method may change the index set I_k after each iteration. However, a direct extension of the proof of [20, Thm. 6.4.3] shows that the convergence results for the SNQP method carry over to the present case.

The most severe assumption in the above arguments is the boundedness of $1/\delta_k$, [46]. In order to ensure this, Fletcher [10] suggests the use of second-order correction steps and, indeed, Yuan [45] shows that under mild assumptions the trust region radius is bounded away from zero if second-order correction steps are used. The incorporation of second-order correction steps into our method, however, would require a modification of the outer trust region framework and is beyond the scope of the present study.

6. Numerical experiments. We have tested the method on various small-scale examples of MPECs. The performance of the method was found to be comparable with the reported performance of the $S\ell_1QP$ method in the literature [10]. Occasionally, slow convergence due to the Maratos effect has been observed. As mentioned above, this phenomenon could possibly be prevented if second-order correction steps were included. A very important feature of the method is its apparent insensitivity to violated strict complementarity in the lower-level problem at the optimal solution.

We give some numerical results for two particular instances, a simple three-dimensional example and a five-dimensional example from the literature. For the

experiments the method was implemented in MATLAB 5.0 and the built-in QP-Solver was used for the solution of the subproblems. In the examples below, we have used the following parameters: $\alpha_0 = 4, \beta_0 = 1, \bar{\alpha} = 2, \bar{\beta} = 0.25, c_0 = 0.25, c_1 = 0.75, \delta_0 = 1, \tau_1 = 10^{-6}, \tau_2 = 0$, *Reduce*$(\delta) = 0.25\delta$, *Increase*$(\delta) = 2\delta$. Stopping criterion for the method was that $\|\nabla g(x^k)^\top + \nabla h(x^k)^\top \lambda^k\| \leq 10^{-10}$ and that the multipliers corresponding to violated strict complementarity in the lower level are less than τ_1.

6.1. A three-dimensional example. We first tested the method on the problem

$$\begin{array}{ll} \min & f(x,y) \\ \text{s.t.} & \min\{x, -e^x + y_1 - e^{y_2}\} = 0, \\ & y_2 \geq 0 \end{array}$$

for various quadratic objective functions f. Tables 6.1 and 6.2 show two typical runs. The abbreviations FV and PFV refer to the values of $f((x,y)^k)$ and $f((x,y)^k) + \alpha_k p(h((x,y)^k))$, respectively. Note that the point $(0,2,0)$ is a Clarke stationary point and that this point is localized at iteration 3 of the first example. However, one of the corresponding Lagrange multipliers is positive and thus a change of the index set I_k occurs, which then allows the method to find the minimizer in iteration 4. Strict complementarity in the lower-level problem is violated at the optimal point in the second example, i.e., both functions in the min expression are active. This has no negative effect on the performance of the method.

6.2. Outrata's example. The following example is due to Outrata [25], who used it to illustrate an implicit function-based bundle trust region method for MPECs. The example also was applied in [9] to illustrate a homotopy method. The MPEC is

Table 6.3
Number of solved QPs in Outrata's example.

	f_1	f_2	f_3	f_4
$y^0 = 0$	20	27	14	11
$y^0 = 10$	9	9	10	10

of the form

$$\begin{array}{rl} \min & f(x,y), \\ \text{s.t.} & \min\{x_1, (1+0.2y)x_1 - (1+1.333y) - 0.333x_3 + 2x_1x_4\} = 0, \\ & \min\{x_2, (1+0.1y)x_2 - y + x_3 + 2x_2x_4\} = 0, \\ & \min\{x_3, 0.333x_1 - x_2 + 1 - 0.1y\} = 0, \\ & \min\{x_4, 9 + 0.1y - x^2 - x^2\} = 0, \\ & 0 \le y \le 10. \end{array}$$

The equilibrium constraints are stationary point conditions of a convex programming problem and are uniquely solvable for every feasible parameter value y. This fact has been exploited by Outrata [25] and is also important in the theoretical convergence analysis of [9]. Although our method does not make use of such information, it gives competitive results, as reported in Table 6.3. The method was started at the points $x^0 = (0,0,0,0)$ and $y^0 = 0$ as well as $y^0 = 10$ with the objective functions

$$\begin{aligned} f_1(x,y) &= \tfrac{1}{2}[(x_1-3)^2 + (x_2-4)^2], \\ f_2(x,y) &= \tfrac{1}{2}[(x_1-3)^2 + (x_2-4)^2 + (x_3-1)^2], \\ f_3(x,y) &= \tfrac{1}{2}[(x_1-3)^2 + (x_2-4)^2 + 10x_4^2], \\ f_4(x,y) &= \tfrac{1}{2}[(x_1-3)^2 + (x_2-4)^2 + (x_3-1)^2 + (x_4-1)^2 + y^2]. \end{aligned}$$

The method detected the optimal solutions reported in [25] and the numerical results indicate local quadratic convergence in all cases. Note that lower-level strict complementarity is violated at the optimal solution corresponding to the objective function f_1.

The method showed similar behavior on the small-scale test problems used in [9]. For all these problems, global convergence and local quadratic convergence to the local minimum reported in [9] was observed.

7. Conclusion. We have studied theoretical and computational aspects of the exact penalization approach to MPECs and more general composite piecewise smooth programs. In the first part, we have extended the local error bound result of Robinson [35] to piecewise smooth programs and then specified the result to MPECs. This yields a theoretical justification for the use of exact penalization methods. We then proposed a general trust region method for composite piecewise smooth functions which combines the approaches of Fletcher [10] and Dennis, Li, and Tapia [7] and includes the penalty update rule of Yuan [47]. We have proved a global convergence result. Finally, we have specified the method to make it applicable for MPECs with complementarity constraints. The resulting method extends Fletcher's $S\ell_1QP$ method to MPECs. Some preliminary numerical results are reported.

Acknowledgments. We thank Daniel Ralph for pointing out that the piecewise Mangasarian–Fromovitz constraint qualification discussed in section 3.2.1 gives rise to a local error bound. We also wish to thank two anonymous referees for their valuable remarks and suggestions.

ASYMPTOTIC ANALYSIS FOR PENALTY AND BARRIER METHODS IN VARIATIONAL INEQUALITIES[*]

A. AUSLENDER[†]

Abstract. We study the convergence of a class of penalty and barrier methods for solving monotone variational inequalities with constraints. This class of methods is an extension of penalty and barrier methods for convex optimization to the setting of variational inequalities. Primal convergence is established under weaker conditions than usual: the solution set is supposed either to be a compact set or, for the case of interior barrier methods, the sum of a compact set and a linear space. Dual convergence is also analyzed. The analysis strongly exploits a new formula related to recession calculus.

Key words. variational inequalities, maximal monotone operators, convex analysis, recession functions, penalty and barrier methods

1. Introduction.

Let C be a nonempty closed convex set in $\mathbb{R}^N$ and let A be a multivalued map from $\mathbb{R}^N$ into $\mathbb{R}^N$ such that dom $A := \{x \in \mathbb{R}^N : A(x) \neq \phi\}$ contains C. In this paper we consider the variational inequality

$$\text{(VI)} \qquad \begin{array}{l} \text{“find } x^* \in C \text{ and } c^* \in A(x^*) \text{ satisfying} \\ \langle c^*, x - x^* \rangle \geq 0 \quad \forall x \in C\text{”} \end{array}$$

and we denote by S the set of such x^*, solutions of (VI).

All the notations and definitions used in this paper are standard in convex analysis and can be found in Rockafellar's book [18].

When A is a monotone operator, most of the methods for solving (VI) are extensions of well-known methods in optimization theory. In optimization, A is the subdifferential ∂f_0 of a closed proper convex function f_0, and (VI) consists of minimizing f_0 on C. The usual assumption which ensures convergence is that the optimal set S is a nonempty compact set, which can be expressed equivalently in many ways, in particular, in terms of recession analysis (see for example [18, Thm. 27.1]). These characterizations are, in general, useful to prove convergence of numerical methods. In contrast, when (VI) does not reduce to an optimization problem, most convergence results are based on a coercivity assumption stronger than the compactness of the solution set S.

For instance, it is often supposed that the "feasible set is compact" (see, for example, Fukushima [11]; Marcotte and Dussault [15]) or that there exists $v_0 \in C$ such that

$$\lim_{\|x\| \to +\infty} \left\langle c(x), \frac{x - v_0}{\|x - v_0\|} \right\rangle = +\infty \quad \text{with } c(x) \in A(x),$$

a condition satisfied by strongly monotone operators (see for example Pang and Chan [17]).

If we consider the classical exterior penalty methods and interior barrier methods which were introduced more than twenty years ago, there have been no proofs of convergence under the weaker assumption that the solution set S is compact, as is the case for optimization problems. There is a real technical difficulty. So the first challenge of this paper is to find completely new techniques to overcome this difficulty. To do this, in section 2 we establish a simple but truly new formula (formula (2.11)) related to recession analysis for monotone operators.

This formula is of particular interest. It plays a fundamental role not only in proving convergence of algorithms but also in characterizing the compactness of the set of solutions S. Such a characterization has recently been established independently by Crouzeix [10] and by Rockafellar and Wets [19]. In [10], A is pseudomonotone, upper semicontinuous, and for each $x \in C$, $A(x)$ is compact (which is unnecessary in our case). In [19] the result is given for A assumed monotone, single valued, and continuous on C. But in fact it can be stated, without effort, for more general situations as an immediate consequence of formula (2.11). We shall do so in section 2.

When S is a nonempty compact set we say that (VI) is "coercive"; when S is a sum of a nonempty compact set and a linear space we say that (VI) is "weakly coercive." These properties are discussed in section 2, and then by exploiting the recession formula (2.11), the proof of convergence of the algorithms will be established, assuming only coercivity, and for interior methods weak coercivity.

Very recently Auslender, Cominetti, and Haddou [4] introduced a wide class of penalty and barrier methods for convex programming including most of the specific functions proposed in the literature as well as some new ones. They gave also a systematic way to generate penalty and barrier functions in this class. This clearly calls for an extension of the approach to variational inequalities. This is done in detail in section 3 and is the main purpose of this paper. The idea is the following: Suppose the feasible set C is defined by

$$C = \{x \in \mathbb{R}^N : f_i(x) \leq 0, \quad i = 1, 2 \dots m\}$$

where $f_i : \mathbb{R}^N \to \mathbb{R} \cup +\infty$ are closed proper convex functions.
In order to solve the variational inequality (VI) we approximate it by solving a family of unconstrained generalized equations of the form

$(\mathrm{VI})_r$ find x_r satisfying

$$0 \in A(x_r) + F_r(x_r) \tag{1.1}$$

with

$$F_r(x) = \alpha(r)\partial g_r(x), \quad g_r(x) = \sum_{i=1}^{m} \theta\left(\frac{f_i(x)}{r}\right), \text{ if } x \in \bigcap_{i=1}^{m} \mathrm{dom}\ f_i \text{ , } +\infty \text{ otherwise,} \tag{1.2}$$

where $\partial g_r(x)$ is the subdifferential of g_r at x and $r > 0$ is a penalty parameter which will ultimately go to 0. The functions $\theta : \mathbb{R} \to \mathbb{R} \cup \{+\infty\}$ and $\alpha : \mathbb{R}_+ \to \mathbb{R}_+$ are such that θ is closed, proper, convex, and nondecreasing with

$$\mathrm{dom}\theta := \{u : \theta(u) < +\infty\} =]-\infty, \eta[, \quad 0 \leq \eta \leq +\infty,$$

and

$$\lim_{r\to 0^+} \alpha(r) = 0, \qquad \liminf_{r\to 0^+} \frac{\alpha(r)}{r} > 0.$$

Additional assumptions concerning the recession function of θ (the same as in [4]) are needed for ensuring convergence when (VI) is coercive. Concrete examples concerning the functions θ (the same as in [4]) are given that will convince the reader of the breath of the framework. Primal convergence is proved for interior methods ($\eta = 0$) under a weaker assumption than in [4]: weak coercivity instead of coercivity.

Finally, section 4 concerns the convergence of dual paths corresponding to primal paths. In contrast to optimization problems, a complete and useful duality theory is not available for variational inequalities. Nevertheless, a dual variational inequality (VID) is associated with the primal variational inequality (VI). Roughly speaking, the dual variables correspond to Kuhn–Tucker multipliers. The properties relating (VI) and (VID) are outlined in [3], [5].

In this last section, these relations are improved and new results obtained. For example, we prove in Theorem 4.3 that under reasonable conditions (VID) is related to a maximal monotone operator which allows us to exploit the rich structure of this type of operator. In particular, it is possible to prove the convergence of the whole dual path to a single point for some methods.

2. Coercive and weakly coercive variational inequalities. For optimization problems, the fact that the optimal solution set S is a nonempty compact set can be written in terms of recession functions. Recall that for a set $\mathcal{Q} \subset \mathbb{R}^N$, its asymptotic or recession cone is denoted by $\mathcal{Q}_\infty$ or $0^+\mathcal{Q}$ and is defined by

$$\mathcal{Q}_\infty = \Big\{ y : \exists t_k \to +\infty, x_k \in \mathcal{Q}, \text{ with } y = \lim_{k\to\infty} \frac{x_k}{t_k} \Big\}.$$

Recall also that for a closed and proper function $f : \mathbb{R}^N \to \mathbb{R} \cup +\infty$, the recession function f_∞ of f is defined by

$$epi\ (f_\infty) = (epif)_\infty, \text{ where } epif = \big\{ (x,r) \in \mathbb{R}^N \times \mathbb{R} : f(x) \le r \big\}.$$

As a straightforward consequence of this definition we obtain

$$f_\infty(y) = \inf \Big\{ \liminf_{k\to\infty} \frac{f(t_k x_k)}{t_k} \Big| \ t_k \to +\infty, x_k \to y \Big\}, \tag{2.1}$$

where $\{t_k\}$ and $\{x_k\}$ are sequences in $\mathbb{R}$ and $\mathbb{R}^N$, respectively.

For closed proper convex functions, we also have

$$f_\infty(y) = \lim_{t\to+\infty} \frac{f(x+ty) - f(x)}{t} \quad \forall x \in \mathrm{dom} f,$$

and

$$f_\infty(y) = \sup\ \{ \langle y, d\rangle \mid d \in \partial f(x), x \in \ \mathrm{dom}\partial f \}. \tag{2.2}$$

Then, when $A = \partial f_0$, it is well known that the assumption "S is nonempty and compact" is equivalent to

$$(f_0)_\infty(d) > 0 \qquad \forall d \in C_\infty,\ d \ne 0. \tag{2.3}$$

Recall also that when C is defined by

$$C = \{x : f_i(x) \leq 0, \qquad i = 1, 2, ..., m\}, \tag{2.4}$$

where $f_i : \mathbb{R}^N \to \mathbb{R} \cup +\infty$ are closed, proper, and convex functions, then C_∞ is given by

$$C_\infty = \{d : \ (f_i)_\infty(d) \leq 0, \qquad i = 1, ..., m\}. \tag{2.5}$$

Such an equivalence is very advantageous and has been largely used for proving convergence of algorithms in [4]. Can we extend such a characterization to variational inequalities? To answer this, we have to refer to the recession analysis for general maximal monotone operators.

The first attempts to define a notion of recession function for monotone operators, well suited to characterize existence of solutions of (VI), can be found in the seminal work of Brezis and Nirenberg [7], Lions [13], and Browder [8]. More recently, Attouch, Chbani, and Moudafi [1] have compared the various definitions and, for different reasons, have concluded that the best choice is the support function of the range of the operator. For the rest of this paper we shall denote, as in [1],

$$f_\infty^B \ (d) = \sup \{\langle c, d\rangle \mid c \in R(B)\}, \tag{2.6}$$

where B is a multivalued map from $\mathbb{R}^N$ into $\mathbb{R}^N$ and $R(B)$ is the range of the map, and, as in [1], we shall call this function the recession function of B. When B is a maximal monotone map it is worthwhile to note that it was proven by Lions [13] that the subdifferential of this recession function is a maximal monotone operator B_∞ which is the graphical limit of $B(t.)$ when $t \to +\infty$. Furthermore, thanks to Theorem 13.3 in [18], this definition coincides with the usual notion in the case of a convex function.

In order to illustrate the use of the recession function of an operator, consider the generalized equation

$$0 \in B(x), \tag{2.7}$$

where B is a maximal monotone operator, and let $T = B^{-1}(0)$ denote its solution set. Recall that $R(B) = \operatorname{dom} B^{-1}$ and that T is a nonempty compact set if and only if $0 \in \operatorname{int} R(B)$. This has been proved in [19, Thm. 12.35] and [14] but appears as an immediate consequence of the formula

$$B^{-1} \ (0)_\infty = N_{R(B)} \ (0)$$

given in [2, formula (2.2)] ($N_{R(B)}(0)$ denotes the usual normal cone of $R(B)$ at 0).

Since by Minty's theorem [16] int $R(B)$ is convex, it follows from [18, Thm. 13.1] that T is a nonempty compact set if and only if

$$f_\infty^B \ (d) > 0 \qquad \forall d \neq 0. \tag{2.8}$$

In such a case we shall say that B is coercive.

Let us now return to our initial variational inequality and let $N_C(x)$ denote the usual normal cone of C at x. Recall that if $\delta(. \mid C)$ is the indicator function of C, i.e.,

$$\delta(x \mid C) = 0 \text{ if } x \in C, \quad +\infty \text{ else},$$

then

$$N_C(x) = \partial\delta(x \mid C),$$

where ∂ is the subdifferential operator.

From the above formula it follows that N_C is a maximal monotone operator. Furthermore, it is well known that the set of solutions S of (VI) is given by

$$S = (A + N_C)^{-1}\ (0). \tag{2.9}$$

So, if we want to use criteria such as (2.8) we are led to suppose that $A + N_C$ is maximal monotone.

If E and F are maximal monotone operators, defined on $\mathbb{R}^N$, there exist many criteria which ensure that $E + F$ is maximal monotone (see, in particular, [19] and the references therein).
Special cases of interest are the following:

i) int dom $E \cap$ dom $F \neq \phi$,

ii) ri dom $E \cap$ ri dom $F \neq \phi$ (ri dom E denotes the relative interior of dom E and is nonempty and convex thanks to Minty's theorem).

iii) F is a single valued map defined on C, monotone and continuous on C and $E = N_C$.

If we consider criteria (2.3) we see that it is equivalent to saying that

$$[f_0 + \delta(|C)]_\infty(d) > 0 \quad \forall d \neq 0,$$

since we have

$$[f_0 + \delta(|C)]_\infty(d) = (f_0)_\infty(d) + \delta(d \mid C_\infty).$$

Unfortunately, such a formula cannot be extended to maximal monotone operators, as can be seen in the following counterexample given by Brezis and Haraux [6]: A is the rotation with angle $\frac{\pi}{2}$ in $\mathbb{R}^2$ and $C = \mathbb{R} \times 0$. In this case if we set $B = A + N_C$, then

$$f^B_\infty\ (d_1, d_2) = 0 \quad \text{if } d_2 = 0,\ +\infty \text{ else and } f^A_\infty\ (d) + f^{N_C}_\infty\ (d) = +\infty.$$

Thus, even when A and $A + N_C$ are maximal monotone, we cannot expect, in general, the formula

$$f^B_\infty(d) = f^A_\infty(d) + f^{N_C}_\infty\ (d) = f^A_\infty\ (d) + \delta(d|C_\infty)$$

with $B = A + N_C$.

Such a formula is valid only under strict conditions such as those given in [6, Thm. 3]. By avoiding such restrictive assumptions, we give, in the next proposition, a formula that is useful for proving convergence of algorithms and that is extensively used in section 3.

PROPOSITION 2.1. *Let $B = A + N_C$ and define $f^{A,C}_\infty$ by*

$$f^{A,C}_\infty(d) = \sup\big\{\langle c, d\rangle | c \in A(x), x \in C\big\} \textit{ if } d \in C_\infty, +\infty \textit{ else.} \tag{2.10}$$

Suppose that dom $A \supset C$ *and that C is a nonempty closed convex set in $\mathbb{R}^N$. Then*

$$f^B_\infty = f^{A,C}_\infty. \tag{2.11}$$

Furthermore, if $A + N_C$ is maximal monotone, then S is a nonempty compact set if and only if

$$f^{A,C}_\infty(d) > 0 \quad \forall d \neq 0. \tag{2.12}$$

Proof. Thanks to the above discussion, we have only to prove formula (2.11). Recall that the Fenchel conjugate $\delta^*(|C)$ of $\delta(|C)$ is the support functional of C and let us denote by $ba(C)$ the barrier cone of C. By definition $ba(C) = \text{dom } \delta^*(|C)$.

1) Let $d \notin C_\infty$. Then, since $\overline{ba(C)}$ is the polar cone of the recession cone [18, Cor. 14.2.1], there exist $\tilde{u} \in \overline{ba(C)}$ such that $\langle \tilde{u}, d\rangle > 0$.

Let us prove that there exists (x, u) such that

$$x \in C, u \in N_C(x) \text{ and } \langle u, d\rangle > 0. \tag{2.13}$$

Since $\tilde{u} \in \overline{ba(C)}$ we have $\tilde{u} = \lim_{n\to\infty} u_n$ with $u_n \in \text{ri } ba(C)$. Then since $u_n \in \text{ri } ba(C)$, $\delta^*(|C)$ is subdifferentiable at u_n and $v_n \in \partial\delta^*(u_n|C)$ if and only if $v_n \in C$ with $u_n \in N_C(v_n)$. As a consequence (2.13) is satisfied for $(u, x) = (u_n, v_n)$ and n sufficiently large.

Now let u be such that (2.13) holds. Since $\lambda u \in N_C(x)$ for all $\lambda > 0$, it follows that $f_\infty^B(d) = +\infty$ and then (2.11) holds for each $d \notin C_\infty$.

2) Now let $d \in C_\infty$. Since $\overline{ba(C)}$ is the polar cone for C_∞ and since $R[N_C] \subset ba(C)$, we have

$$\langle u, d\rangle \le 0 \qquad \forall u \in R[N_C]$$

and then $f_\infty^B(d) \le f_\infty^{A,C}(d)$. Furthermore, let $x_n \in C, c_n \in A(x_n)$ such that $f_\infty^{A,C}(d) = \lim_{n\to\infty} \langle c_n, d\rangle$. Then since $u_n = 0 \in N_C(x_n)$, we have $\langle c_n + u_n, d\rangle = \langle c_n, d\rangle \le f_\infty^B(d)$ and then $f_\infty^{A,C}(d) \le f_\infty^B(d)$. □

Now we want to weaken conditions (2.8) and (2.12) in order to consider variational inequalities with noncompact solution sets. For optimization problems, condition (2.8) corresponds to the assumption "$0 \in \text{int dom } f_0^*$," where f_0^* is the usual Fenchel conjugate, and it is well known that the assumption $0 \in \text{ri dom } f^*$ weakens the above and plays a fundamental role in convex analysis. Since $\text{ri dom } f_0^* = \text{ri dom } \partial f_0^*$, the natural extension will be

$$0 \in \text{r}i\ R(B). \tag{2.14}$$

In this case we shall say that B is weakly coercive.

From [18, Thm. 13.1], this is equivalent to saying that

$$f_\infty^B(d) \ge 0 \quad \forall d \text{ and } L_B := \left\{d : f_\infty^B(d) = 0\right\} \quad \text{is } a \textit{ linear space} \tag{2.15}$$

or equivalently

$$f_\infty^B(d) > 0 \quad \forall d \in L_B^\perp,\ d \neq 0 \tag{2.16}$$

(with L_B supposedly a linear space and $L_B^\perp$ the orthogonal of L_B).

Example. Suppose that B is coercive and let F be a matrix (m, N) with $m > N$ such that rank $F^t = N$. Then, by [19, Thm. 12.38], the operator $D = F \circ B \circ F^t$ is maximal monotone. Since B is coercive and F is of full rank, it follows in a straightforward way that D is weakly coercive and that

$$L_D = \text{k}er\ F^t. \tag{2.17}$$

Let us now characterize weakly coercive maximal monotone operators B via the structure of the set of solutions T of the generalized equation (2.7).

For this, as in [2, p. 167] we denote by E_t the affine hull of dom B^{-1}, E the parallel subspace to E_t, and Π_E the projector operator on E. Since $E_t + E^\perp = \mathbb{R}^N$, every $x \in \mathbb{R}^N$ can be uniquely decomposed as follows:

$$x = \Pi_{E_t} x + x_{E^\perp} \text{ with } x_{E^\perp} \in E^\perp.$$

Following [2, p. 168], we define the extension operator B_E^{-1} of B^{-1} by

$$B_E^{-1}(x) = B^{-1}\ (\Pi_{E_t} x) \cap E \quad \forall x \in \mathbb{R}^N. \tag{2.18}$$

It has been proved in [2, Prop. 2.4 and Cor. 2.5] that B_E^{-1} is a maximal monotone operator and that

$$B^{-1}(x) = B_E^{-1}(x) + E^\perp \text{ i}f\ x \in E_t, = \phi \text{ e}lse, \tag{2.19}$$

$$\text{i}nt\ dom\ B_E^{-1} = \text{ r}i\ dom\ B^{-1} + E^\perp \neq \phi, \tag{2.20}$$

$$d(x^*|B^{-1}(0)) = d(\Pi_E x^*|B_E^{-1}(0)) \quad \forall x^*, \tag{2.21}$$

with $d(.|B^{-1}(0))$ denoting the distance to the set $B^{-1}(0)$.

Furthermore, we have the following.

PROPOSITION 2.2. *Let B be a multivalued maximal monotone map. Then* $0 \in$ ri $R(B)$ *if and only if the solution set T of* (2.7) *is given by the formula*

$$T = B_E^{-1}(0) + E^\perp, \tag{2.22}$$

where $B_E^{-1}(0)$ is a nonempty compact set.

In addition, in this case we have

$$E^\perp = L_B = \{d : \langle c, d\rangle = 0 \quad \forall c \in R(B)\}.$$

Proof. a) Suppose that $0 \in$ ri $R(B) =$ ri dom B^{-1}. Then by [2, Cor. 3.2] (2.22) holds and $B_E^{-1}(0)$ is a nonempty compact set. Conversely, suppose that (2.22) holds and that $B_E^{-1}(0)$ is a nonempty compact set. Then from [2, formula (2.2)] it follows that $0 \in$ int domB_E^{-1}, and by (2.20) we deduce that $0 \in$ ri dom B^{-1}.

b) When $0 \in$ ri dom B^{-1}, then from the definition of f_∞^B, and since L_B defined in (2.15) is a linear space, it follows that

$$L_B = R(B)^\perp = (\text{dom } B^{-1})^\perp = E^\perp. \qquad \square$$

COROLLARY 2.3. *Let S be the solution set of* (VI). *Set $B = A + N_C$. Suppose* dom $A \supset C$, *C is a nonempty closed convex set in $\mathbb{R}^N$, and B is maximal monotone. Then $S = B_E^{-1}(0) + E^\perp$, where $E = L_B^\perp$ and $B_E^{-1}(0)$ is a nonempty compact set if and only if* $0 \in$ ri $R(B)$, *or equivalently, if and only if*

$$f_\infty^{A,C}(d) > 0 \quad \forall d \in L_B^\perp \quad d \neq 0 \tag{2.23}$$

with

$$L_B = \{d \in C_\infty \cap -C_\infty : \langle c, d\rangle = 0 \quad \forall c \in A(x),\ \forall x \in C\}. \tag{2.24}$$

Proof. From the definition of L_B (see formula (2.15)) and the fact that L_B is a linear space, it follows from Proposition 2.1 that

$$L_B = \{d : f_\infty^{A,C}(d) = f_\infty^{A,C}(-d) = 0\}.$$

Using the definition of $f_\infty^{A,C}$ (see formula (2.10)) we then get formula (2.24). Then, as it was recalled above, $0 \in \text{ri }(B)$ if and only if (2.16) holds. Using formula (2.11) this is equivalent to saying that $0 \in \text{ri }(B)$ if and only if (2.23) is satisfied. □

Remark. When C is defined by (2.4), then formula (2.24) becomes

(2.25)
$$L_B = \{d : (f_i)_\infty(d) = (f_i)_\infty(-d) = 0\, \forall\, i = 1, 2 \dots m, \langle c, d\rangle = 0 \quad \forall c \in A(u), \quad \forall u \in C\}.$$

Furthermore, let us denote by $\overline{x}$ the projection of x onto $L_B^\perp$. Since $x = \overline{x} + \Pi_{L_B}(x)$, and since for each $d \in C_\infty \cap -C_\infty$ we have $f_i(\overline{x} + d) = f_i(\overline{x})$, it follows that

$$f_i(x) = f_i(\overline{x}) \quad \forall i = 1, 2, \dots, m, \quad \langle c, x\rangle = \langle c, \overline{x}\rangle \quad \forall c \in A(u) \quad \forall u \in C. \tag{2.26}$$

This formula will be used for proving the convergence of the forthcoming algorithms.

3. Penalty and barrier methods for variational inequalities.

In this section we suppose that A is a maximal monotone operator with int dom $A \supset C$. This implies that [int dom A] $\cap$ dom N_C is nonempty and then, as it was recalled in section 2, it follows that $A + N_C$ is maximal monotone. Furthermore, suppose that C is now defined by

$$C = \bigl\{x \in \mathbb{R}^N : f_i(x) \le 0, \quad i = 1, \dots, m\bigr\},$$

where $f_i : \mathbb{R}^N \to \mathbb{R} \cup +\infty$ are closed proper convex functions. Recall that in this case C_∞ is given by (2.5).

In this section we propose to extend the methods introduced in [4] for optimization problems to variational inequalities. Therefore, and in order to solve (VI), we introduce a new class of penalty and barrier methods which consists of solving a family of unconstrained generalized equations of the following form.

$(\text{VI})_r$ find x_r satisfying

$$0 \in A(x_r) + F_r(x_r) \tag{3.1}$$

with

(3.2)
$$F_r(x) = \alpha(r)\partial g_r(x), \quad g_r(x) = \sum_{i=1}^m \theta\left(\frac{f_i(x)}{r}\right), \text{ if } x \in \bigcap_{i=1}^m \text{dom } f_i \;, \; +\infty \text{ otherwise,}$$

where $r > 0$ is a penalty parameter which will ultimately go to 0. The functions $\theta : \mathbb{R} \to \mathbb{R} \cup \{+\infty\}$ and $\alpha : \mathbb{R}_+ \to \mathbb{R}_+$ are such that

$$(H_0) \qquad \begin{cases} \theta \text{ is closed proper, convex, and nondecreasing} \\ \text{with dom } \theta =]-\infty, \eta[\text{ and } 0 \le \eta \le +\infty, \\ \lim_{u\to\eta^-} \theta(u) = +\infty, \quad \theta_\infty(1) > 0, \\ \lim_{r\to 0^+} \alpha(r) = 0, \quad \liminf_{r\to 0^+} \alpha(r)/r > 0. \end{cases}$$

For the case $\eta = 0$, we assume Slater's condition

$$\text{“There exists } x_0 \in \bigcap_{i=1}^m \text{ri dom } f_i \text{ such that } f_i(x_0) < 0 \text{ for each } i\text{”}$$

and then it follows by [18, Thms. 6.5 and 7.6] that

$$\text{ri C} = \left\{ x \in \bigcap_{i=1}^{m} \text{ri dom } f_i : f_i(x) < 0, \quad \forall \text{i} = 1, \ldots, m \right\}$$

and every solution x_r of $(\text{VI})_r$ satisfies $f_i(x_r) < 0$ for each i.

For the case $\eta > 0$ we suppose that dom $A = \mathbb{R}^N$.

With these assumptions g_r is a closed convex proper function and dom $g_r \cap C$ is nonempty. Then dom $g_r \cap$ int dom A is nonempty and since ri dom $g_r =$ ri dom ∂g_r, it follows that ri dom $\partial g_r \cap$ int dom A is nonempty. As a consequence, as it was recalled in section 2, $A + F_r$ is maximal monotone.

We shall study two classes of methods. For the first class we suppose

$$(H_1) \qquad \begin{cases} \lim_{t \to -\infty} \theta(t) = 0, \\ \theta_\infty(1) < +\infty, \\ \lim_{r \to 0^+} \alpha(r)/r = +\infty, \end{cases}$$

while for the second class of methods we suppose

$$(H_2) \qquad \begin{cases} \theta_\infty(-1) = 0, \\ \theta_\infty(1) = +\infty, \\ \alpha(r) = r. \end{cases}$$

In [4] a systematic way to generate functions satisfying (H_1) and (H_2) is given. In fact, for functions θ satisfying (H_1) the method of generation was given by Chen and Mangasarian [9] and consists of integrating twice a function p which is a piecewise continuous probability density function with a finite number of pieces and with supp $(p) = \mathbb{R}$. In order to obtain functions satisfying (H_2), one can start from functions of class C^2 satisfying (H_1) and take a primitive of such functions as indicated in [4], but there are also many other ways to do it as described in [4].

Functions satisfying (H_2) can be divided into two subclasses: those for which $\eta > 0$ as penalty-barrier functions used in augmented Lagrangian methods, and those for which $\eta = 0$, which may be designated as *interior* methods.

Specific cases of interest for $\eta > 0$ are

$\theta_1(u) \quad = \exp\,(u)$ (exponential penalty),

$\theta_2(u) \quad = -ln(1-u)$ for $u < 1$ (modified barrier),

$$\theta_3(u) \quad = \begin{cases} u + \frac{1}{2}u^2 & \text{if } u \geq -\frac{1}{2} \\ -\frac{1}{4}\, ln(-2u) - \frac{3}{8} & \text{if } u \leq -\frac{1}{2} \end{cases} \quad \text{(quadratic logarithmic method).}$$

In this last method the second derivative θ_3'' is continuous and bounded, which is advantageous for algorithms based on Newton steps. Another example in the same class is given by

$$\theta_4(u) = u/(1-u) \quad \text{for } u < 1 \quad \text{(hyperbolic MBF (modified barrier formula)).}$$

The idea of combining barrier methods and quadratic penalty methods as in θ_6 can be extended to other types of barrier functions, for example:

$$\theta_5(u) \quad = \begin{cases} u/(1-u) & \text{if } u \leq -\eta, \\ au^2 + bu + c & \text{otherwise,} \end{cases}$$

with $a > 0, b, c$ and $\eta > -1$ conveniently chosen so that θ_5 is of class C^2.

For $\eta = 0$ specific cases of interest are
