$$\begin{aligned} \theta_6(u) &= -ln(-u) \text{ (log barrier)}, \\ \theta_7(u) &= -(1/u) \text{ (inverse barrier method)}, \\ \theta_8(u) &= \begin{cases} -ln(-u) & \text{if } \delta \le u < 0, \\ a + b/u^2 - c/u & \text{if } u \le \delta, \end{cases} \end{aligned}$$

where $\delta < 0$, and the parameters $a, b > 0$, and $c > 0$ are chosen so that θ_8 is twice differentiable.

THEOREM 3.1. *Let $B = A + N_C$; suppose that the functions f_i are closed proper convex functions defined on $\mathbb{R}^N$, that A is maximal monotone with* int dom $A \supset C$, *and that* $0 \in$ ri $R(B)$. *Consider the case where θ and α satisfy* (H_0) *and* (H_2). *Suppose in addition that*

1) *when $\eta = 0, A$ is single valued on C and Slater's condition holds;*

2) *when $\eta > 0$,* dom $A = \mathbb{R}^N$ *and* int $R(B)$ *is nonempty.*

Then for each $r > 0$, the solution set S_r of $(\mathrm{VI})_r$ *defined by* (3.1) *is nonempty.*

Proof. Consider for r, n fixed the variational inequality

$(\mathrm{VI})_{r,n}$ find $x_n \in B_n := \{x : \|x\| \le n\}$ such that there exists $d_n \in (A + F_r)(x_n)$ with

$$\langle d_n, x - x_n\rangle \ge 0 \quad \forall x \in B_n.$$

Since $A + F_r$ is maximal monotone and since B_n is convex compact, then for n sufficiently large dom $(A + F_r) \cap$ int B_n is nonempty and such an x_n exists. This is a classical result (see, for example, [14, Cor. 4.(b)]). Then there exists $c(x_n) \in A(x_n), e(x_n) \in \partial g_r(x_n)$ such that

$$\langle c(x_n), x - x_n\rangle + r\langle e(x_n), x - x_n\rangle \ \ge 0 \quad \forall x \in B_n.$$

Furthermore, since g_r is convex we get

$$\langle c(x_n), x - x_n\rangle + rg_r(x) \ge rg_r(x_n) \quad \forall x \in B_n, \tag{3.3}$$

and from this inequality, since A is monotone it follows that

$$\langle c, x\rangle + rg_r(x) \ge \langle c, x_n\rangle + rg_r(x_n) \quad \forall x \in B_n \cap \text{ dom } A, \quad \forall c \in A(x). \tag{3.4}$$

a) Let $\overline{x}_n$ be the projection of x_n on $L_B^{\perp}$; then from (2.26) and (3.4) it follows that

$$\langle c, x\rangle + rg_r(x) \ge \langle c, \overline{x}_n\rangle + rg_r(\overline{x}_n) \quad \forall x \in B_n \cap \ C, c \in A(x). \tag{3.5}$$

Let us prove now that the sequence $\{\overline{x}_n\}$ is bounded. In the contrary case, we can suppose, without loss of generality, that

$$\lim_{n\to\infty} \|\overline{x}_n\| = +\infty, \ \lim \frac{\overline{x}_n}{\|\overline{x}_n\|} = d \text{ with } d \in L_B^{\perp}, d \ne 0.$$

Let $x \in C$ if $\eta > 0$ and $x \in$ ri C if $\eta = 0$. In both cases $g_r(x) < +\infty$, and then dividing both members of (3.5) by $\|\overline{x}_n\|$, it follows from formula (2.1), if we pass to the limit, that

$$\langle c, d\rangle + r(g_r)_\infty(d) \le 0 \quad \forall c \in A(x).$$

Set

$$h_i(x) = r\theta\left(\frac{f_i(x)}{r}\right) \text{ if } x \in \text{ dom } f_i, = +\infty \text{ otherwise.}$$

Then by [4, Prop. 2.1], h_i is a closed proper convex function and we have

$$(h_i)_\infty(d) = \theta_\infty((f_i)_\infty(d)) \text{ if } d \in \text{ dom } (f_i)_\infty, = +\infty \text{ otherwise}$$

and since $\theta_\infty(1) = +\infty, \theta_\infty(-1) = 0$, it follows from the definition of g_r that

$$(3.6) \qquad (f_i)_\infty(d) \leq 0 \quad \forall i = 1, 2, ..., m, \langle c, d\rangle \leq 0 \quad \forall c \in A(x).$$

Furthermore, if $\eta > 0$, since (3.6) holds for all $x \in C$, it follows that $f_\infty^{A,C}(d) \leq 0$, a contradiction to (2.23). If $\eta = 0$, for each $y \in C$ consider $x_\lambda = \lambda x_0 + (1-\lambda)y$ with $\lambda \in]0, 1]$ and $x_0 \in$ ri C. It follows that $x_\lambda \in$ ri C, and by (3.6) we have $\langle A(x_\lambda), d\rangle \leq 0$. Since A is single valued on C and int dom $A \supset C$, A is locally bounded and closed on C. As a consequence A is continuous on C and, passing to the limit when $\lambda \to 0^+$, we obtain

$$\langle A(y), d\rangle \leq 0 \quad \forall y \in C$$

and again $f_\infty^{A,C}(d) \leq 0$, a contradiction to (2.23).

b) Now let $\overline{x}$ be a limit point of the sequence $\{\overline{x}_n\}$. Such a point exists and, without loss of generality, we can suppose that $\overline{x} = \lim_{n\to+\infty}\overline{x}_n$.

b$_1$) Consider the case where $\eta = 0$. Then, A is single valued and continuous on C. Since in this case $\overline{x} \in C$, A is continuous at $\overline{x}$. Take in formula (3.5) $x \in$ ri C. Then passing to the limit in this formula, we obtain

$$\langle A(x), x - \overline{x}\rangle + rg_r(x) - rg_r(\overline{x}) \geq 0.$$

Let $x_t = \overline{x} + t(x - \overline{x})$ with $t \in]0, 1]$. Then from the above formula it follows that

$$\langle A(x_t), x - \overline{x}\rangle + \left[\frac{rg_r(x_t) - rg_r(\overline{x})}{t}\right] \geq 0.$$

Passing to the limit when $t \to 0^+$ in this inequality, we obtain

$$\langle A(\overline{x}), x - \overline{x}\rangle + rg_r'(\overline{x}; x - \overline{x}) \geq 0,$$

and since g_r is convex it follows that

$$(3.7) \qquad \langle A(\overline{x}), x\rangle + rg_r(x) \geq \langle A(\overline{x}), \overline{x}\rangle + rg_r(\overline{x}).$$

Let $y \in C$ and set $y_\lambda = (1-\lambda)y + \lambda x_0$ with $\lambda \in]0, 1]$ and $x_0 \in$ ri C. Then $y_\lambda \in$ ri C, and from (3.7) we have

$$\langle A(\overline{x}), y_\lambda\rangle + rg_r(y_\lambda) \geq \langle A(\overline{x}), \overline{x}\rangle + rg_r(\overline{x}).$$

Since $g_r(y) = \lim_{\lambda\to 0} g_r(y_\lambda)$, passing to the limit it follows that (3.7) holds for each $x \in C$ and which is, by the way, valid for all $x \in \mathbb{R}^N$. As a consequence $\overline{x}$ minimizes on $\mathbb{R}^N$ the function $x \to h(x) = \langle A(\overline{x}), x\rangle + rg_r(x)$. Then $0 \in \partial h(\overline{x}) = A(\overline{x}) + r\partial g_r(\overline{x})$ and S_r is nonempty.

b$_2$) Suppose now that $\eta > 0$. Then int $R(B)$ is nonempty, and $L_B^\perp = \mathbb{R}^N$ so that $x_n = \overline{x}_n$. Since A is locally bounded and closed at $\overline{x}$, passing to the limit in (3.3) we get

$$\langle \overline{c}, x - \overline{x} \rangle + r g_r(x) - r g_r(\overline{x}) \geq 0 \quad \forall x$$

for some $\overline{c} \in A(\overline{x})$. Then $\overline{x}$ minimizes the function $x \to \langle \overline{c}, x \rangle + r g_r(x)$ and, as above, it follows that S_r is nonempty. $\square$

Theorem 3.2. *Suppose the assumptions of Theorem* 3.1 *hold. For each solution* $x_r \in S_r$, *let* $x_r^1 = \sqcap_E(x_r)$ *be the projection of* x_r *on* $E = L_B^\perp$ *(the linear space generated by* $R(B)$*). Then the sequence* $\{x_r^1\}$ *stays bounded when* $r \to 0+$ *with all its limit points in* S *and*

$$\lim_{r \to 0+} d(x_r | S) = 0.$$

Furthermore, if $\eta > 0$, *the same result holds with* x_r *instead of* x_r^1.

Proof. Let $x_r \in S_r, x_r^1 = \Pi_E(x_r)$ with $E = L_B^\perp$. Since A is monotone and g_r convex, it follows from (3.1) that there exists $c(x_r) \in A(x_r)$ such that

$$\langle c(x_r), x - x_r \rangle + r g_r(x) \geq r g_r(x_r) \quad \forall x \tag{3.8}$$

and that

$$\langle c, x \rangle + r g_r(x) \geq \langle c, x_r \rangle + r g_r(x_r) \quad \forall c \in A(x), x \in \text{dom } A \tag{3.9}$$

a) From formulas (3.9) and (2.26) it follows that

$$\langle c, x \rangle + r g_r(x) \geq \langle c, x_r^1 \rangle + r g_r(x_r^1) \quad \forall x \in C, \quad \forall c \in A(x). \tag{3.10}$$

Let us prove that each selection $\{x_r^1\}$ with $r \to 0^+$ is bounded. In the contrary case, there would exist a sequence $r_k \to 0^+$ and an associated sequence $\{\overline{x}_k = \frac{x_{r_k}^1}{\|x_{r_k}^1\|}\}$ such that

$$\|x_{r_k}^1\| \to +\infty, \overline{x}_k \to d \text{ with } d \neq 0 \text{ and } d \in L_B^\perp.$$

Let $x \in C$ when $\eta > 0$ and $x \in$ ri C when $\eta = 0$. Let $a(x) = \max \ \{f_i(x) \mid i = 1, ..., m\}$.
Since θ is nondecreasing, it follows from (3.10) that

$$\langle c, x \rangle + m \ r_k \ \theta\left(\frac{a(x)}{r_k}\right) \geq \langle c, x_{r_k}^1 \rangle + r_k \sum_{i=1}^m \theta\left(\frac{f_i(x_{r_k}^1)}{r_k}\right). \tag{3.11}$$

Let $\varepsilon_i < (f_i)_\infty(d)$ for $i = 1, 2, ..., m$. Then from formula (2.1) there exists k_0 such that $f_i(x_{r_k}^1) \geq \varepsilon_i \ \|x_{r_k}^1\|$ for all $k \geq k_0$. Again since θ is nondecreasing, we deduce from (3.11)

$$\frac{\langle c, x \rangle}{\|x_{r_k}^1\|} + \frac{m \ r_k}{\|x_{r_k}^1\|} \ \theta\left(\frac{a(x)}{r_k}\right) \geq \langle c, \overline{x}_k \rangle + \sum_{i=1}^m \theta\left(\varepsilon_i \frac{\|x_{r_k}^1\|}{r_k}\right) \ \frac{r_k}{\|x_{r_k}^1\|}.$$

Since $a(x) \leq 0, \theta_\infty(a(x)) = 0$. Then passing to the limit in the above inequality, we obtain

$$\langle c, d \rangle + \sum_{i=1}^m \theta_\infty(\varepsilon_i) \leq 0. \tag{3.12}$$

Since $\theta_\infty(1) = +\infty$, it follows that $\varepsilon_i \leq 0$ so that $(f_i)_\infty(d) \leq 0$, for each i, and $d \in C_\infty$. Furthermore, $\theta_\infty(\varepsilon_i) = -\varepsilon_i \theta_\infty(-1) = 0$, and from (3.12) it follows that

$$\langle c, d\rangle \leq 0 \quad \forall c \in A(x) \text{ with } x \in C \text{ if } \eta > 0 \text{ and } x \in \text{ ri } C \text{ else.}$$

Then as in part a) of the proof of Theorem 3.1, it follows that in both cases $f_\infty^{A,C}(d) \leq 0$ which is a contradiction to (2.23).

b) Now let $\overline{x} = \lim\ x_{r_k}^1$ be a limit point of the sequence $\{x_r^1\}$ when $r \to 0^+$. Such a point exists. Take in formula (3.10) $x \in$ ri C if $\eta = 0$, and $x \in C$ if $\eta > 0$. Take also $\delta_i < f_i(\overline{x})$ for each i. Since f_i is closed, then $\delta_i < f_i(x_{r_k}^1)$ for k sufficiently large and from (3.10) we obtain

$$(3.13) \qquad \langle c, x\rangle + m\ r_k\ \theta\left(\frac{a(x)}{r_k}\right) \geq \langle c, x_{r_k}^1\rangle + r_k \sum_{i=1}^{m} \theta\left(\frac{\delta_i}{r_k}\right) \quad \forall c \in A(x)$$

with $a(x) = \max\ \{f_i(x) \mid i = 1, ..., m\}$.

b$_1$) Suppose that $\eta = 0$. Then obviously $\overline{x} \in C$. Furthermore in this case A is single valued, $\delta_i < 0, a(x) < 0$. Since $\theta_\infty(-1) = 0$, passing to the limit in 3.13 it follows that

$$\langle A(x), x - \overline{x}\rangle \geq 0 \quad \forall x \in riC.$$

Then taking the same arguments as in part b$_1$) of the proof of Theorem 3.1, it follows that

$$\langle A(\overline{x}), x - \overline{x}\rangle \geq 0\ \forall x \in C$$

and $\overline{x}$ is a solution of (VI). As a consequence, $d(x_r^1 \mid S) \to 0$ if $r \to 0$ and from (2.21) we have $\lim_{r\to 0} d(x_r \mid S) = 0$.

b$_2$) Suppose now that $\eta > 0$. Since $a(x) \leq 0, \theta_\infty(-1) = 0, \theta_\infty(1) = \infty$; if we pass to the limit in (3.13) it follows that $\delta_i \leq 0$ for each i so that $f_i(\overline{x}) \leq 0$ and $\overline{x} \in C$. Furthermore, in this case $x_r^1 = x_r$ and from (3.8) we get

$$(3.14) \qquad \langle c(x_{r_k}), x - x_{r_k}\rangle + m\ r_k\ \theta\ \left(\frac{a(x)}{r_k}\right) \geq r_k \sum_{i=1}^{m} \theta\left(\frac{\delta_i}{r_k}\right).$$

Since A is locally bounded and closed at $\overline{x}$, taking the same arguments as above, we obtain by passing to the limit in (3.14)

$$(\overline{c}, x - \overline{x}) \geq 0 \quad \forall x \in C$$

for some $\overline{c} \in A(\overline{x})$. As a consequence $\overline{x} \in S$ and $\lim_{r\to 0} d(x_r \mid S) = 0$. □

Remark 3.1. When θ and α satisfy (H_0) and (H_1), similar theorems such as Theorems 3.1 and 3.2 can be obtained using the same kinds of arguments. The only difference is that S_r is nonempty only for r sufficiently small. The proofs are left to the reader.

Remark 3.2. When $C = \mathbb{R}_+^N$ (complementarity problems), for $\theta = \theta_6$ the method coincides with the classical logarithm interior point method studied by Güler [12]. The existence theorem and the proof of primal convergence given in [12] suppose a stronger condition (condition 1.2 in [12]) than ours. Moreover, the use of formula (2.11) simplifies the proofs considerably, since we don't need the Brezis–Haraux's theorem as in [12], for which it is difficult to apply.

4. Dual convergence. The setting in this section is the same as in section 3.

4.1. The dual variational inequality. For each $\lambda \in \mathbb{R}^m_+$ we define $M(\lambda)$ as the set of vectors $x^* \in C$ for which there exist $c_0 \in A(x^*)$, $c_i \in \partial f_i(x^*)$, $i \in I(x^*)$ such that

$$c_0 + \sum_{i \in I(x^*)} \lambda_i c_i = 0, \quad \lambda_i = 0 \text{ for } i \notin I(x^*), \tag{4.1}$$

where $I(x^*) = \{i : f_i(x^*) = 0\}$.

We denote by M the set of all vectors $\lambda \in \mathbb{R}^m_+$ such that $M(\lambda)$ is nonempty and the dual problem to (VI) is defined as follows:

$$\text{Find a point } \lambda \in M. \tag{VID}$$

The next proposition in particular will help us to justify the denomination of "dual problem."

PROPOSITION 4.1. *Suppose that the functions f_i are closed proper convex functions defined on $\mathbb{R}^N$, that Slater's condition holds, and that $x^* \in C$. Then $x^* \in S$ if and only if there exists $\lambda \in \mathbb{R}^m_+$ such that $x^* \in M(\lambda)$. Furthermore, if S is a nonempty compact set, if each f_i is continuous on S and if A is maximal monotone with* int dom $A \supset S$, *then M is nonempty and compact.*

Proof. i) Let $x^* \in C$ with $\lambda \in \mathbb{R}^m_+$ such that $x^* \in M(\lambda)$. Take c_0 and c_i as in (4.1); then for each $x \in C$ it follows from (4.1) that

$$\langle c_0, x - x^* \rangle \geq \langle c_0, x - x^* \rangle + \sum_{i \in I(x^*)} \lambda_i \left[f_i(x) - f_i(x^*) \right] \geq \left\langle c_0 + \sum_{i \in I(x^*)} \lambda_i c_i, x - x^* \right\rangle = 0$$

and as a consequence $x^* \in S$.

ii) Conversely if $x^* \in S$, then there exists $c_0^* \in A(x^*)$ such that

$$\langle c_0^*, x - x^* \rangle \geq 0 \quad \forall x \in C.$$

Set $J(x) = \langle c_0^*, x - x^* \rangle$. From the above inequality it follows that x^* minimizes J on C, and since Slater's condition is satisfied, this implies the existence of multipliers $\lambda_i \geq 0$ for $i \in I(x^*)$ such that

$$c_0^* + \sum_{i \in I(x^*)} \lambda_i c_i^* = 0, \quad \lambda_i = 0 \text{ for } i \notin I(x^*),$$

where $c_i^* \in \partial f_i(x^*)$. In other words $x^* \in M(\lambda)$.

iii) Suppose now that the other assumptions are satisfied. As a consequence of part i) M is nonempty. Let us prove that M is bounded. In the contrary case there would exist a sequence $\{(\lambda^n, x_n, c_0^n, c_i^n)\}$ with $\lambda^n \in \mathbb{R}^m_+, x_n \in S, c_0^n \in A(x_n), c_i^n \in \partial f_i(x_n)$ for $i = 1, \ldots, m$ such that

$$\|\lambda^n\| \to +\infty, \frac{\lambda^n}{\|\lambda^n\|} \to \overline{\lambda} \neq 0, \quad x_n \to \overline{x}, \quad \lambda_i^n = 0 \text{ for } i \notin I(x_n)$$

and

$$c_0^n + \sum_{i \in I(x_n)} \lambda_i^n c_i^n = 0.$$

From the above equation it follows that

$$\frac{\langle c_0^n, x_0 - x_n \rangle}{\|\lambda^n\|} + \sum_{i \in I(x_n)} \frac{\lambda_i^n}{\|\lambda^n\|} f_i(x_0) \geq 0,$$

where x_0 satisfies Slater's condition.

Since A is locally bounded at $\overline{x} \in S$ and the functions f_i are continuous at $\overline{x}$, passing to the limit in the above inequality we obtain

$$\sum_{i \in I(\overline{x})} \overline{\lambda}_i f_i(x_0) \geq 0, \quad \overline{\lambda}_i = 0 \quad \text{for } i \notin I(\overline{x}), \overline{\lambda} \neq 0,$$

which is impossible since Slater's condition holds at x_0. □

If the variational inequality corresponds to a convex minimization problem ($A = \partial f_0$), then Proposition 4.1 tells us that M coincides with the set of Kuhn–Tucker vectors associated with each optimal solution. As a consequence, it follows from [18, Cor. 28.4.1] that M coincides with the optimal set of the usual dual problem. This justifies the denomination of dual problem for (VID).

4.2. The dual trajectory and its accumulation points.

THEOREM 4.2. *Consider the case where θ and α satisfy (H_0) and (H_2), and suppose that*

i) *θ is C^1 on $]-\infty, \eta[$.*

ii) *the functions f_i are closed proper convex functions defined on $\mathbb{R}^N$, and Slater's condition holds.*

iii) *A is maximal monotone, $C \subset$ int dom A.*

iv) *when $\eta = 0$, we assume that A is single valued on C, and when $\eta > 0$ we suppose that* dom $A = \mathbb{R}^n$.

Set $B = A + N_C$ and suppose in addition that $0 \in$ int $R(B)$. Then, all the assumptions of Theorems 3.1 and 3.2 are satisfied and to each solution $x_r \in S_r$ we can associate a "dual" vector λ^r with coordinates given by

$$\lambda_i^r = \theta' \left(\frac{f_i(x_r)}{r} \right) \quad \forall i = 1, 2, \ldots, m. \tag{4.2}$$

If we suppose also that all the functions f_i are continuous on a neighborhood V of the solution set S, then the sequence $\{x_r, \lambda^r\}$ stays bounded when $r \to 0^+$ and all its limit points $(\overline{x}, \overline{\lambda})$ are in $S \times M$ with $\overline{x} \in M(\overline{\lambda})$.

Proof. a) Obviously all the assumptions of Theorems 3.1 and 3.2 are satisfied and as a consequence, λ^r is well defined and the sequence $\{x_r\}$ is bounded with all its limit points in S. Furthermore, since θ is nondecreasing $\lambda^r \in \mathbb{R}_+^m$.

b) Set $\overline{\lambda}^r = \frac{\lambda^r}{\|\lambda^r\|}$ and suppose that the sequence $\{\lambda^r\}$ is not bounded when $r \to 0^+$. Then there exists a sequence $\{\lambda^{r_n}, x_{r_n}\}$ such that

$$r_n \to 0^+, \; x_{r_n} \to \overline{x}, \; \|\lambda^{r_n}\| \to \infty, \; \overline{\lambda}^{r_n} \to \overline{\lambda} \geq 0, \; \overline{\lambda} \neq 0.$$

From Theorem 3.2, $\overline{x} \in S$ and since the functions f_i are continuous at $\overline{x}$, it follows that $\frac{f_i(x_{r_n})}{r_n} \to -\infty$ for $i \notin I(\overline{x})$, and then from (4.2) we have

$$\overline{\lambda}_i = \lim_{n \to \infty} \overline{\lambda}_i^{r_n} = \lim_{n \to \infty} \lambda_i^{r_n} = 0 \quad \text{for } i \notin I(\overline{x}). \tag{4.3}$$

Now since the functions f_i are continuous on a neighborhood V of S, for r sufficiently small we have

$$r\partial g_r(x_r) = \sum_{i=1}^{m} \theta'\Big(\frac{f_i(x_r)}{r}\Big)\ \partial f_i(x_r)$$

and then from the definition of x_r and λ^r there exist $c_0^r \in A(x_r)$ and $c_i^r \in \partial f_i(x^r)$ such that

$$0 = c_0^r + \sum_{i=1}^{m} \lambda_i^r c_i^r. \tag{4.4}$$

As a consequence we get

$$0 = \frac{c_0^{r_n}}{\|\lambda^{r_n}\|} + \sum_{i=1}^{m} \overline{\lambda}_i^{r_n} c_i^{r_n}.$$

Then since the maps A and ∂f_i are locally bounded and closed at $\overline{x}$ (relative to C if $\eta = 0$), passing to the limit in the above equation, we obtain

$$0 = \sum_{i=1}^{m} \overline{\lambda}_i c_i$$

for some $\overline{c}_i \in \partial f_i(\overline{x}), i = 1, ..., m.$

Since $\overline{\lambda}_i = 0$ for $i \notin I(\overline{x}), \overline{\lambda} \neq 0$, and $\overline{\lambda}_i \geq 0$ for each i, obviously this yields a contradiction to Slater's condition.

c) Now let $(\overline{x}, \lambda)$ be a limit point of the sequence $\{x^r, \lambda^r\}$ when $r \to 0^+$. Since this sequence is bounded, such a point exists. By Theorem 3.2 $\overline{x} \in S$, and as in formula (4.3) we have $\lambda_i = 0$ for each $i \notin I(\overline{x})$. Since (4.4) is always valid, passing to the limit in this equation, we get

$$0 = c_0 + \sum_{i=1}^{m} c_i \lambda_i,$$

where $c_0 \in A(\overline{x})$, $c_i \in \partial f_i(\overline{x})$ (for the same reasons as in part b).

Since $\lambda \geq 0$ and $\lambda_i = 0$ for $i \notin I(\overline{x})$, this is equivalent to saying that $\lambda \in M$ and $\overline{x} \in M(\lambda)$. □

4.3. Convergence to a single point. In this section we suppose that A is maximal monotone with dom $A = \mathbb{R}^N$ and that A is strongly monotone; i.e., there exists $\alpha > 0$ such that

$$\langle c - d, x - y\rangle \geq \alpha\ \|x - y\|^2 \quad \forall c \in A(x) \quad d \in A(y) \quad \forall x, y \in \mathbb{R}^N. \tag{4.5}$$

As a consequence, $A + N_C$ is maximal monotone and S is reduced to a single point.

We suppose also that Slater's condition holds and that the functions f_i are finite on $\mathbb{R}^N$ and satisfy the following condition:

$$\limsup_{\|y\| \to \infty} \frac{|f_i(x + y) - f_i(x)|}{\|y\|^2} < +\infty. \tag{4.6}$$

This condition is not too restrictive since it is satisfied in particular by Lipschitz convex functions on $\mathbb{R}^N$, or more generally [16, Thm. 10.3] by uniformly continuous convex functions and also by quadratic functions and piecewise linear-quadratic functions. Since A is strongly monotone, for each $p \in \mathbb{R}^m_+$ the map $x \to A(x) + \sum_{i=1}^m p_i \partial f_i(x)$ is maximal monotone and strongly monotone, and it follows that the generalized equation

$$(VI)(p) \qquad 0 \in A(x) + \sum_{i=1}^{m} p_i \partial f_i(x)$$

admits one and only one solution $x(p)$.

We write

$$F(x) = (f_1(x), ..., f_m(x)), \ G(p) = -F(x(p)),$$
$$\widetilde{G}(p) = G(p) + N_{\mathbb{R}^m_+}(p) \text{ if } p \in \mathbb{R}^m_+, \ \widetilde{G}(p) = \phi \text{ else.}$$

Theorem 4.3. *Suppose that A is a maximal monotone map, strongly monotone with* dom $A = \mathbb{R}^N$. *Suppose also that Slater's condition holds and that the functions f_i are convex, finite on $\mathbb{R}^N$, and satisfy condition* (4.6). *Then $G(.)$ is monotone on $\mathbb{R}^m_+$. More precisely, we have*

$$(4.7) \qquad \langle G(p) - G(p'), \ p - p' \rangle \geq \alpha \ \|x(p) - x(p')\|^2 \quad \forall p, p' \in \mathbb{R}^m_+.$$

Furthermore, the function $p \to x(p)$ is continuous on $\mathbb{R}^m_+$ and $\widetilde{G}$ is maximal monotone and coercive. Finally, λ belongs to the dual set M of solutions (which is now a nonempty convex compact set) if and only if λ satisfies the variational inequality

$$(4.8) \qquad \lambda \in \mathbb{R}^m_+, \quad (G(\lambda), p - \lambda) \geq 0 \quad \forall p \in \mathbb{R}^m_+$$

which is equivalent to

$$(4.9) \qquad 0 \in \widetilde{G}(\lambda).$$

Proof. a) Let $p, q \in \mathbb{R}^m_+$; since the functions f_i are convex, from the definition of $x(p)$ and $x(q)$ we have

$$\big\langle c(p), x(q) - x(p) \big\rangle + \big\langle p, F\big(x(q)\big) - F\big(x(p)\big) \big\rangle \geq 0,$$
$$\big\langle c(q), x(p) - x(q) \big\rangle + \big\langle q, F\big(x(p)\big) - F\big(x(q)\big) \big\rangle \geq 0$$

with $c(p) \in A(x(p))$ and $c(q) \in A(x(q))$.

Then if we add both these inequalities we obtain

$$\langle c(p) - c(q), x(p) - x(q) \rangle + \langle p - q, F\big(x(p)\big) - F\big(x(q)\big) \rangle \leq 0$$

and (4.7) follows immediately by using (4.5) in the above inequality.

b) Let us prove now that the function $x(.)$ is continuous on $\mathbb{R}^m_+$. We first prove that it is locally bounded. In the contrary case there would exist $p \in \mathbb{R}^m_+$ and a sequence $p_n \in \mathbb{R}^m_+$ converging to p such that

$$\|x(p_n)\| \to +\infty, \quad \frac{x(p_n)}{\|x(p_n)\|} \to d \neq 0.$$

From (4.7) we obtain

$$\|p - p_n\| \quad \frac{\|F(x(p_n)) - F(x(p))\|}{\|x(p) - x(p_n)\|^2} \quad \geq \alpha > 0$$

and then since (4.6) holds, letting $n \to \infty$ we get $\alpha = 0$ which is impossible.

Now let $p_n \in \mathbb{R}^m_+$ converging to p, and let x^* be a limit point of the sequence $\{x(p_n)\}$. Since this sequence is bounded, such a point exists and, without loss of generality, we can suppose that $x^* = \lim_{n\to\infty} x(p_n)$. From the definition of $x(p_n)$ there exists $c_n \in A(x(p_n))$ such that

$$\langle c_n, x - x(p_n)\rangle + \langle p_n, F(x) - F(x(p_n))\rangle \geq 0 \quad \forall x.$$

Then, since A is locally bounded and closed and F is continuous, passing to the limit, we get for some $c \in A(x^*)$

$$\langle c, x - x^*\rangle + \langle p, F(x) - F(x^*)\rangle \geq 0 \quad \forall x \in \mathbb{R}^N$$

from which it follows that $x^* = x(p)$. As a consequence $x(.)$ is continuous on $\mathbb{R}^m_+$, and by the way, $G(.)$ is also.

Then from [19, Example 12.43] it follows that $\widetilde{G}$ is maximal monotone. Obviously (4.8) and (4.9) are equivalent, and λ satisfies (4.8) if and only if $\lambda \in M$. Then, from Proposition 4.1 and since $\widetilde{G}^{-1}(0)$ is closed and convex, it follows that M is a nonempty convex compact set. □

Let us now return to our algorithm and remark first that from the definitions of $x_r, \lambda^r, x(\lambda^r)$, we have

$$x_r = x(\lambda^r). \tag{4.10}$$

Let θ^* be the Fenchel conjugate of θ and write $t(\lambda) = \sum_{i=1}^m \theta^*(\lambda_i)$. Since $\partial\theta^* = (\theta')^{-1}$, it follows from (4.2) that $f_i(x_r) = r\partial\theta^*(\lambda^r_i)$. In other words we have

$$0 \in G(\lambda^r) + r\partial t(\lambda^r). \tag{4.11}$$

Since $0 \in N_{\mathbb{R}^m_+}(\lambda)$ for each $\lambda \in \mathbb{R}^m_+$, it follows that λ^r satisfies the generalized equation

$$0 \in \widetilde{G}(\lambda^r) + r\partial t(\lambda^r).$$

Hence λ^r can be interpreted as a result of a "viscosity" or "Tikhonov" regularization method, and the next proposition proves that the whole sequence $\{\lambda^r\}$ converges to a single point under additional assumptions on θ.

PROPOSITION 4.4. *Consider the case where θ and α satisfy (H_0) and (H_2). Suppose that the conditions of Theorem 4.3 are satisfied, and suppose that θ is C^1 on $]-\infty, \eta[$ and that either θ is bounded from below or there exists $\lambda \in M$ with $\lambda_i > 0$ for each i. Then there exists exactly one and only one $\overline{\lambda}$ which minimizes t on M and the whole sequence $\{\lambda_r\}$ converges to $\overline{\lambda}$ when $r \to 0^+$.*

Proof. With the above assumptions we remark that Theorem 4.2 is valid. Observing that dom $\theta^* = [0, +\infty[$ if θ is bounded below and dom $\theta^* =]0, +\infty[$ otherwise, it follows that dom $t \cap M$ is nonempty. Furthermore, since θ is differentiable on $]-\infty, \eta[$, it follows from [16, Thm. 26.3] that t is strictly convex on its domain. Now from (4.11) we have

$$\langle G(\lambda), \lambda - \lambda^r\rangle + r\ [t(\lambda) - t(\lambda^r)] \geq 0 \quad \forall \lambda \in M \cap \text{ dom } t.$$

Since $\langle G(\lambda), \lambda - \lambda^r\rangle \leq 0$ for each $\lambda \in M$ it follows that

$$t(\lambda) \geq t(\lambda^r) \quad \forall \lambda \in M.$$

Let $\tilde{\lambda}$ be a limit point of the sequence $\{\lambda^r\}$. From Theorem 4.2 such a point exists, and $\tilde{\lambda} \in M$. Since t is lower semicontinuous, passing to the limit it follows that $\tilde{\lambda}$ minimizes t on M. But since M is convex compact and t is strictly convex on its domain with $M \cap$ dom $t \neq \phi$, there exists only one point $\overline{\lambda}$ which minimizes t on M and $\tilde{\lambda} = \overline{\lambda}$. □

Remark. The assumption "θ is bounded from below" holds, for instance, in the case of $\theta_1, \theta_4, \theta_5, \theta_7, \theta_8$.

BOUNDARY STABILIZATION OF THE WAVE EQUATION IN ALMOST STAR-SHAPED DOMAINS[*]

PATRICK MARTINEZ[†]

Abstract. We improve several earlier results on the boundary stabilization of the wave equation in a bounded domain. First we weaken the usual geometrical conditions. Second, we improve the estimate of the decay rate in the case of polygonal domains. Then we show how to modify this method to study Maxwell's equations. The proofs are based on the construction of new multipliers, better adapted to the domain.

Key words. boundary stabilization, multipliers

1. Introduction.

The problem of exponential decay of the energy of the solutions of the wave equation in a bounded domain by the use of a boundary feedback has been studied by several authors. Bardos, Lebeau, and Rauch proved that the energy decays exponentially:

$$\forall t \geq 0, \quad E(t) \leq CE(0)e^{-\omega t} \tag{1.1}$$

if and only if a "geometric control condition" is satisfied [2]. However, their method closely relies on the hyperbolic structure of the problem, requires smooth geometric conditions, and does not give any information on the constants C and ω. On the other hand, the elementary multiplier methods developed, for example, by Lagnese [11], Lions [13], or Komornik [8] prove (1.1) with explicit constants, so as to measure the observability cost, but only under special geometrical conditions. Lasiecka and Triggiani [12] combined these two methods to obtain intermediate results.

The aim of this paper is to weaken the usual assumption of star-shapedness of the domain using adapted multipliers. In section 2, we introduce the notion of "almost star-shaped domains," and we give some examples. In section 3, we give a result of fast decay of the energy in such domains. In section 4, we use these results to improve the decay rate estimate of the energy in special plane star-shaped domains. At last, we show how to adapt this method to study Maxwell's equations in some non-star-shaped domains. This method is presented in a very well known situation but can also be applied to problems that microlocal analysis techniques are not yet able to solve, for example, to study the nonlinear stabilization of Kirchhoff plate models on some non-star-shaped domains. We can apply this method in another situation: Zuazua [18] studied the stabilization of a semilinear wave equation, with Dirichlet boundary conditions, damped by a linear velocity dissipation that is localized on a neighborhood of a part of the boundary; the notion of an "almost star-shaped domain" allows us to find analogous results for the similar problem with Neumann boundary condition (see [14]). This also allows us to improve the results found on a ball by Alabau and Komornik [1] in the study of the uniform decay of the solutions of general

elastodynamic systems (see also Horn [6] for the study of isotropic elastodynamic systems).

2. Almost star-shaped domains: Definition and examples. In the following, Ω will be a bounded open set of $\mathbb{R}^N$. Let $\{\Gamma_0, \Gamma_1\}$ be a partition of the boundary Γ of Ω. Let us denote by ν the outward unit normal vector to Γ and by $(\mid)$ the canonical Euclidean structure of $\mathbb{R}^N$.

DEFINITION. *$(\Omega, \Gamma_0, \Gamma_1)$ is an almost star-shaped domain if there exists $\phi \in \mathcal{C}^2(\overline{\Omega})$ such that*

$$\text{Sup}\,\{\Delta\phi(x) - 2\lambda_1(x), x \in \Omega\} < \text{Inf}\,\{\Delta\phi(x), x \in \Omega\}, \tag{2.1}$$

$$\partial_\nu \phi \leq \text{ on } \Gamma_0, \tag{2.2}$$

$$\partial_\nu \phi \geq \text{ on } \Gamma_1, \tag{2.3}$$

where $\lambda_1(x)$ is the smallest eigenvalue of the real symmetric squared matrix $D^2\phi(x)$.

In particular, $(\Omega, \Gamma_0, \Gamma_1)$ is almost star-shaped if there exists $\phi \in \mathcal{C}^2(\overline{\Omega})$ such that

$$\Delta\phi = 1 \text{ in } \Omega, \tag{2.4}$$

$$\lambda_1(\phi) := \text{Inf}\,\{\lambda_1(x), x \in \Omega\} > 0, \tag{2.5}$$

$$\partial_\nu \phi \leq 0 \text{ on } \Gamma_0, \tag{2.6}$$

$$\partial_\nu \phi \geq 0 \text{ on } \Gamma_1. \tag{2.7}$$

Remark. Lagnese [11] and Kapitonov [7] introduced similar notions.

The simplest example is the case where Ω is a star-shaped domain with respect to x^0; i.e., there exists a point x^0 such that $(x - x^0 | \nu(x)) \geq 0$ for all $x \in \Gamma$. Then the function

$$\phi_0(x) = \frac{1}{2N}|x - x^0|^2 \tag{2.8}$$

verifies (2.4)–(2.7) with $\Gamma_0 = \emptyset$ and $\Gamma_1 = \Gamma$, so $(\Omega, \emptyset, \Gamma)$ is almost star-shaped.

2.1. Perturbation of a star-shaped domain. In this section, we show that any sufficiently small perturbation of class $\mathcal{C}^2$ of a star-shaped domain Ω of class $\mathcal{C}^2$ gives an almost star-shaped domain. Let Ω be a bounded domain of class $\mathcal{C}^2$, star-shaped with respect to x^1. We can construct $f \in \mathcal{C}^2(\mathbb{R}^N)$ such that

$$\Gamma = \{x \in \mathbb{R}^N, f(x) = 0\} \quad \text{and} \quad |f(x)| \longrightarrow +\infty \text{ as } |x| \longrightarrow +\infty,$$
$$\forall x \in \Gamma,\ \nabla f(x) \neq 0,$$
$$\forall x \in \Gamma,\ \Big(x - x^1 | \nabla f(x)\Big) \geq 0,$$

using the signed distance to Γ, for example.

Set $\varepsilon > 0$ and $g \in \mathcal{C}^2(\mathbb{R}^N)$. Let Ω_ε be the bounded domain whose boundary Γ_ε is the set of points x_ε verifying

$$f(x_\varepsilon) + \varepsilon g(x_\varepsilon) = 0.$$

We apply the implicit functions theorem to deduce that if ε is small enough, x_ε is well defined and the function $\varepsilon \mapsto x_\varepsilon =: x(\varepsilon)$ is of class $\mathcal{C}^2$ on the neighborhood of each point of the boundary Γ.

Let us show that if ε is small enough, $(\Omega_\varepsilon, \emptyset, \Gamma_\varepsilon)$ is almost star-shaped: set $c > 0$ and define

$$\phi(x) = \frac{1}{2N}|x - x^1|^2 + \varepsilon c f(x).$$

Then

$$\begin{aligned}\Delta\phi(x) &= 1 + \varepsilon c \Delta f(x),\\ \Delta\phi(x) - 2\lambda_1(x) &= 1 - \frac{2}{N} + \varepsilon c(\Delta f(x) - 2\lambda_1(f)(x)),\end{aligned}$$

where $\lambda_1(f)(x)$ is the smallest eigenvalue of $D^2 f(x)$. So (2.1) is satisfied if εc is small enough. Now look at the normal derivative of ϕ: if $x_\varepsilon \in \Gamma_\varepsilon$,

$$\Big(\nabla\phi(x_\varepsilon)|\nabla f(x_\varepsilon) + \varepsilon\nabla g(x_\varepsilon)\Big) = \Big(\frac{1}{N}(x_\varepsilon - x^1) + \varepsilon c\nabla f(x_\varepsilon)|\nabla f(x_\varepsilon) + \varepsilon\nabla g(x_\varepsilon)\Big)$$
$$= \frac{1}{N}\Big(x_\varepsilon - x^1|\nabla f(x_\varepsilon)\Big) + \varepsilon c\|\nabla f(x_\varepsilon)\|^2 + \frac{\varepsilon}{N}\Big(x_\varepsilon - x^1|\nabla g(x_\varepsilon)\Big) + \varepsilon^2 c\Big(\nabla f(x_\varepsilon)|\nabla g(x_\varepsilon)\Big).$$

Let us recover Γ by a finite number of neighborhoods V_{x_i} of points $x_i \in \Gamma$ such that $\varepsilon \mapsto x_\varepsilon = x(\varepsilon)$ is of class $\mathcal{C}^2$ on V_{x_i}. Then it is easy to see that there exists $M > 0$ such that

$$\Big|\frac{1}{N}\Big(x_\varepsilon - x^1|\nabla f(x_\varepsilon)\Big) + \frac{\varepsilon}{N}\Big(x_\varepsilon - x^1|\nabla g(x_\varepsilon)\Big) - \frac{1}{N}\Big(x(0) - x^1|\nabla f(x(0))\Big)\Big| \le M\varepsilon.$$

Since $x(0) \in \Gamma$, $(x(0) - x^1|\nabla f(x(0))) \ge 0$. Thus it is sufficient to take c large enough so that

$$M \le \frac{c}{4}\|\nabla f(x(0))|^2 \le \frac{c}{2}\|\nabla f(x_\varepsilon)|^2$$

if ε is small enough. Then (2.3) follows if ε is small enough.

Now assume that $(\Omega, \Gamma_0, \Gamma_1)$ is almost star-shaped with some ϕ verifying (2.4)–(2.7). Set $x^0 \in \mathbb{R}^N$ and ϕ_0 defined by (2.8). Define P by

$$P := \phi - \phi_0. \tag{2.9}$$

Then P verifies

$$\Delta P = 0 \text{ in } \Omega, \tag{2.10}$$

$$\lambda_1(P) + \frac{1}{N} > 0, \tag{2.11}$$

$$\partial_\nu P + \frac{1}{N}\Big(x - x^0|\nu(x)\Big) \ge 0 \text{ on } \Gamma_1, \tag{2.12}$$

$$\partial_\nu P + \frac{1}{N}\Big(x - x^0|\nu(x)\Big) \le 0 \text{ on } \Gamma_0. \tag{2.13}$$

Reciprocally, if there exists $P \in \mathcal{C}^2\ (\overline{\Omega})$ and $x^0 \in \mathbb{R}^N$ such that (2.10)–(2.13) are verified, then ϕ defined by (2.9) verifies (2.4)–(2.7). So the problems (2.4)–(2.7) and (2.10)–(2.13) are equivalent through (2.9). The second problem will be easier to look at, particularly in the case of plane domains, using complex analysis.

2.2. Study of the plane domains using complex analysis. Let Ω be an open bounded connected set of $\mathbb{R}^2$. Let f be a holomorphic function of the complex variable $z = x + iy$ on Ω. We will identify the real vector (x, y) and the complex number $z = x + iy$. Assume that f belongs to $\mathcal{C}^2(\overline{\Omega})$. Let us denote by P its real part and by Q its imaginary part. Differentiating with respect to x and using the Cauchy–Riemann equations, we obtain that

$$f'(z) = \frac{\partial P}{\partial x}(x,y) + i\frac{\partial Q}{\partial x}(x,y) = \frac{\partial P}{\partial x}(x,y) - i\frac{\partial P}{\partial y}(x,y),$$
$$f''(z) = \frac{\partial^2 P}{\partial x^2}(x,y) - i\frac{\partial^2 P}{\partial x \partial y}(x,y).$$

Hence the vector $\nabla P(x, y)$ corresponds to the complex number $\overline{f'(z)}$.

Next we look at the Hessian matrix of the function ϕ defined by (2.9):

$$D^2\phi = \frac{1}{2}Id + D^2 P.$$

Thus

$$\lambda_1(\phi) = \frac{1}{2} + \lambda_1(P). \tag{2.14}$$

We have to compute $\lambda_1(P)$. Since P is a harmonic function, the two eigenvalues of the real symmetric matrix $D^2P(x, y)$, for all $(x, y) \in \Omega$, are real and opposite numbers. Denote them by μ and $-\mu$. We have

$$-\mu^2 = \det\, D^2P(x,y) = \frac{\partial^2 P}{\partial x^2}\frac{\partial^2 P}{\partial y^2} - \Big(\frac{\partial^2 P}{\partial x \partial y}\Big)^2$$
$$= -\Big(\frac{\partial^2 P}{\partial x^2}\Big)^2 - \Big(\frac{\partial^2 P}{\partial x \partial y}\Big)^2 = -|f''(z)|^2.$$

Hence

$$\lambda_1(\phi) = \frac{1}{2} - \|f''\|_\infty, \tag{2.15}$$

where $\|f''\|_\infty = \sup\{|f''(z)|, z \in \Omega\}$.

Now assume $(\Omega, \Gamma_0, \Gamma_1)$ is almost star-shaped and that there exists a harmonic function P that satisfies (2.10)–(2.13). If Ω is simply connected, then there exists a holomorphic function called f whose real part is P. Then f satisfies

$$\|f''\|_\infty < \frac{1}{2}, \tag{2.16}$$

$$\Big(\overline{f'(z)}|\nu(z)\Big) + \frac{1}{2}\Big(z - z_0|\nu(z)\Big) \le 0 \text{ on } \Gamma_0, \tag{2.17}$$

$$\Big(\overline{f'(z)}|\nu(z)\Big) + \frac{1}{2}\Big(z - z_0|\nu(z)\Big) \ge 0 \text{ on } \Gamma_1. \tag{2.18}$$

f'' must be small enough (condition (2.16)), but f' must be important enough, to correct the lack of star-shapedness of Ω if it is necessary (condition (2.18)). These two conditions are not always compatible; in the following section we show how to use them to obtain an explicit example of a domain that is almost star-shaped, although not star-shaped.

2.3. Application: Example of a truly almost star-shaped domain. Let Ω be the following polygonal domain $ABCDEFGH$ (see Fig. 2.1).

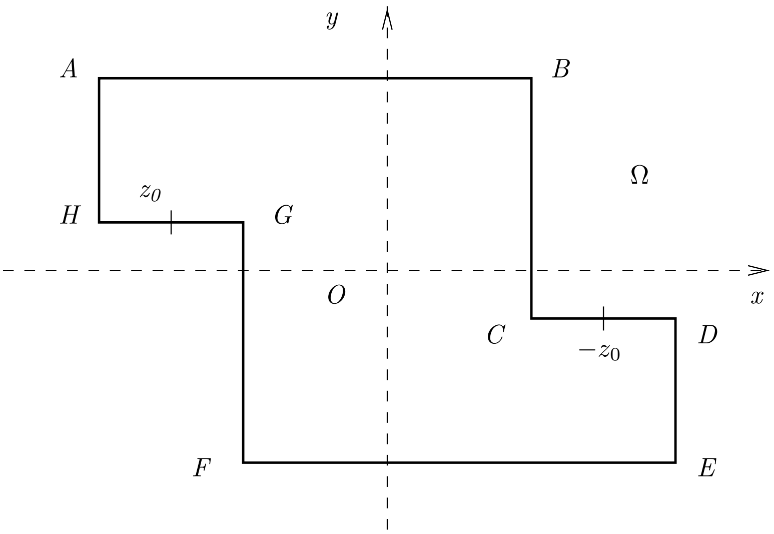

FIG. 2.1. *Example of an almost star-shaped domain.*

Denote

- $\rho :=$ min $\{|z|, z \in \Gamma\}$,
- $R :=$ max $\{|z|, z \in \Gamma\}$,
- z_0 the medium of the segment $[GH]$,
- L the length of the segment $[GH]$.

In order to simplify the calculations, assume that $[CD]$ and $[GH]$ are symmetric with respect to O.

PROPOSITION 2.1. *Let Ω be the polygonal domain ABCDEFGH. If z_0, L, ρ, R verify*

$$0 < \text{Im } z_0 \leq \frac{\rho}{R}\Big(|z_0| - \frac{L}{2}\Big), \tag{2.19}$$

then $(\Omega, \emptyset, \Gamma)$ is almost star-shaped without being star-shaped.

Remark. This provides an explicit example of an almost star-shaped domain that is not star-shaped. Then it is sufficient to smooth the corners to obtain an explicit example of an almost star-shaped domain of class $\mathcal{C}^2$.

Proof of Proposition 2.1. The hypothesis Im $z_0 > 0$ ensures that Ω is not star-shaped. In order to correct that lack of star-shapedness, we perturb $\phi_0(z) = \frac{1}{4}|z|^2$ by a harmonic function, chosen to be small enough so that (2.16) can be true, but whose normal derivative will correct $\partial_\nu \phi_0$ where it is necessary.

Set $\eta > 0$; we construct a holomorphic function f such that

$$\overline{f'(z_0)} = -\eta i \text{ and } \overline{f'(-z_0)} = \eta i.$$

We can choose

$$f(z) = \frac{1}{2}\eta i \frac{z^2}{z_0}. \tag{2.20}$$

Let us define ϕ by

$$\phi(x,y) = \frac{1}{4}|z|^2 + \operatorname{Re} f(z).$$

We have already shown that

$$\begin{aligned} \nabla\phi(x,y) &= \frac{1}{2}z + \overline{f'(z)}, \\ \lambda_1(\phi) &= \frac{1}{2} - \|f''\|_\infty. \end{aligned}$$

First we study $\partial_\nu\phi$ on $[CD]$ and on $[GH]$; using the symmetries of the domain and of the function, it is sufficient to study on $[GH]$, using the following parametrization:

$$z = t\Big(z_0 + \frac{L}{2}\Big) + (1-t)\Big(z_0 - \frac{L}{2}\Big) = z_0 + \Big(t - \frac{1}{2}\Big)L,\ t \in [0,1].$$

So

$$\begin{aligned} \partial_\nu\phi(z) &= -\frac{1}{2}\operatorname{Im} z_0 + \Big(\overline{\frac{\eta i}{z_0}\Big(z_0 + \Big(t-\frac{1}{2}\Big)L\Big)} | -i\Big) \\ &= -\frac{1}{2}\operatorname{Im} z_0 - \operatorname{Im}\Big(\overline{\frac{\eta i}{z_0}\Big(z_0 + \Big(t-\frac{1}{2}\Big)L\Big)}\Big) \\ &\geq \eta - \frac{1}{2}\operatorname{Im} z_0 - \frac{\eta L}{2|z_0|}. \end{aligned}$$

Next we study $\partial_\nu\phi$ on the other sides:

$$\partial_\nu\phi(z) = \frac{1}{2}\Big(z|\nu(z)\Big) + \Big(\overline{f'(z)}|\nu(z)\Big) \geq \frac{1}{2}\rho - \eta\frac{R}{|z_0|}.$$

That gives us the following conditions:

$$\|f''\|_\infty = \frac{\eta}{|z_0|} < \frac{1}{2}, \tag{2.21}$$

$$\eta - \frac{1}{2}\operatorname{Im} z_0 - \frac{\eta L}{2|z_0|} \geq 0, \tag{2.22}$$

$$\rho - 2\eta\frac{R}{|z_0|} \geq 0. \tag{2.23}$$

Equation (2.21) is satisfied when (2.23) is true, and the hypothesis (2.19) allows us to find η verifying (2.22)–(2.23). Thus $(\Omega, \emptyset, \Gamma)$ is almost star-shaped without being star-shaped. □

3. Uniform boundary stabilization of the wave equation in a smooth almost star-shaped domain. Let Ω be a bounded open set of $\mathbb{R}^N$ of class $\mathcal{C}^2$. Let us denote by ν the outward unit normal vector to Γ. Assume that the partition $\{\Gamma_0, \Gamma_1\}$ of the boundary satisfies

$$\overline{\Gamma_0} \cap \overline{\Gamma_1} = \emptyset. \tag{3.1}$$

Let q be a bounded nonnegative function on Ω, and a, ℓ be two nonnegative functions of class $\mathcal{C}^1$ on Γ_1 such that

$$q \not\equiv 0 \ \text{ or } \ \Gamma_0 \not\equiv 0 \ \text{ or } \ a \not\equiv 0. \tag{3.2}$$

As usual, let us denote $H^1_{\Gamma_0}(\Omega) := \{u \in H^1(\Omega), u = 0 \text{ on } \Gamma_0\}$. We consider the following evolutionary problem that has been studied by several authors, such as Komornik and Zuazua [10], Komornik [8], and Tcheugoué Tébou [17], on star-shaped domains:

$$u'' - \Delta u + qu = 0 \text{ in } \Omega, \tag{3.3}$$

$$u = 0 \text{ on } \Gamma_0, \tag{3.4}$$

$$\partial_\nu u + au + \ell u' = 0 \text{ on } \Gamma_1, \tag{3.5}$$

$$u(0) = u^0, u'(0) = u^1. \tag{3.6}$$

Applying a carefully chosen feedback and using a method introduced in Komornik and Zuazua [10], we shall obtain uniform stabilization with rather precise decay rate estimates. Then we will show how to use this result to improve the decay rate on some domains, carefully choosing the function ϕ that satisfies (2.4)–(2.7).

3.1. Existence and regularity theorem.

THEOREM 3.1. *Assume* (3.1)–(3.2).

1. *Given* $(u^0, u^1) \in H^1_{\Gamma_0}(\Omega) \times L^2(\Omega)$*, the problem* (3.3)–(3.6) *has a unique (so-called weak) solution*

$$u \in \mathcal{C}\Big(\mathbb{R}_+, H^1_{\Gamma_0}(\Omega)\Big) \cap \mathcal{C}^1\Big(\mathbb{R}_+, L^2(\Omega)\Big). \tag{3.7}$$

The energy $E : \mathbb{R}_+ \longrightarrow \mathbb{R}_+$ *of the solution* u *defined by*

$$E(t) = \frac{1}{2}\int_\Omega \Big(u'^2 + |\nabla u|^2 + qu^2\Big)\, dx + \frac{1}{2}\int_{\Gamma_1} au^2\, d\sigma \tag{3.8}$$

is a nonincreasing function.

2. *If* u^0 *and* u^1 *satisfy the stronger conditions*

$$\begin{cases} (u^0, u^1) \in H^2(\Omega) \cap H^1_{\Gamma_0}(\Omega) \times H^1_{\Gamma_0}(\Omega), \\ \partial_\nu u^0 + au^0 + \ell u^1 = 0 \ \text{ on } \Gamma_1, \end{cases} \tag{3.9}$$

then the solution u *has the stronger regularity property:*

$$u \in L^\infty\Big(\mathbb{R}_+, H^2(\Omega)\Big), u' \in L^\infty\Big(\mathbb{R}_+, H^1_{\Gamma_0}(\Omega)\Big), u'' \in L^\infty\Big(\mathbb{R}_+, L^2(\Omega)\Big). \tag{3.10}$$

In this case, u *will be called strong solution of the problem* (3.3)–(3.6).

This theorem is well known (see, for example, Komornik [9]).

3.2. Uniform stabilization under a carefully chosen feedback.

THEOREM 3.2. *Let* Ω *be a bounded open set of* $\mathbb{R}^N$ *of class* $\mathcal{C}^2$*; assume* $(\Omega, \Gamma_0, \Gamma_1)$ *is almost star-shaped. Assume that there exists* $\phi \in \mathcal{C}^2(\overline{\Omega})$ *satisfying* (2.4)–(2.7). *Define*

$$C := \max\left(\frac{2}{3}, 1 - \lambda_1(\phi)\right) \text{ and } Q_1 := \|\sqrt{q}\nabla\phi\|_\infty, \tag{3.11}$$

and assume that

$$C + Q_1 < 1. \tag{3.12}$$

Define the functions a and ℓ by

$$a = \frac{C}{2\|\nabla\phi\|_\infty^2}\partial_\nu\phi \text{ and } \ell = \frac{1}{\|\nabla\phi\|_\infty}\partial_\nu\phi. \tag{3.13}$$

Given $(u^0, u^1) \in H^1_{\Gamma_0}(\Omega) \times L^2(\Omega)$, the energy of the weak solution u satisfies the following estimate:

$$\forall t \geq 0, \quad E(t) \leq E(0)e^{1-\omega t} \text{ with } \omega := \frac{1 - C - Q_1}{2\|\nabla\phi\|_\infty}. \tag{3.14}$$

Remarks. 1. If ϕ satisfies only (2.1)–(2.3), the estimate (3.14) holds true. The only difference comes from the value of C.

2. One can easily generalize Theorem 3.2 to more general functions a, ℓ, and q, for example, assuming that a, ℓ, and $\partial_\nu\phi$ are positive on Γ_1 or using a nonlinear feedback as in Komornik [9].

3. Assume now that Ω is a bounded polygonal domain without crack such that each side belongs to Γ_0 or to Γ_1. Moreover, assume that the angles of the corners where there is a change of boundary condition have a measure strictly less than π. Then it is easy to adapt the method that Grisvard [4] or Moussaoui [15] used to study the regularity of the solutions of the problem of the wave equation with mixed boundary conditions (Dirichlet condition on Γ_0 and Neumann condition on Γ_1) in such domains. We find that the strong solutions of (3.3)–(3.6) have the following regularity:

$$u \in L^\infty(\mathbb{R}_+, H^s(\Omega))$$

for some $s > \frac{3}{2}$. This regularity allows us to justify the computations that lead to the key identity given in Lemma 3.4. Thus the estimate (3.14) holds true in such domains.

Proof of Theorem 3.2. The proof of this theorem is based on the multiplier method. We will prove only the estimate (3.14) for smooth initial data, i.e., (u^0, u^1) satisfying (3.9). The general case then follows by an easy density argument. The validity of all the computations is guaranteed by the regularity of u given by (3.10). We use the following convention:

$$\int_S^T \int_\Omega \quad \text{means} \quad \int_S^T \int_\Omega dx\ dt \quad \text{and} \quad \int_S^T \int_\Gamma \quad \text{means} \quad \int_S^T \int_\Gamma d\sigma\ dt.$$

Lemma 3.3. *Given (u^0, u^1) verifying* (3.9), *the strong solution of* (3.3)–(3.6) *satisfies*

$$\forall 0 \leq S < T < +\infty, \quad E(S) - E(T) = \int_S^T \int_{\Gamma_1} \ell u'^2. \tag{3.15}$$

Proof of Lemma 3.3. We multiply (2.5) by u' and we integrate by parts on

$\Omega \times [S,T]$:

$$\begin{aligned} 0 &= \int_S^T \int_\Omega u'(u'' - \Delta u + qu) \\ &= \frac{1}{2}\left[\int_\Omega u'^2 + |\nabla u|^2 + qu^2\right]_S^T - \int_S^T \int_\Gamma u'\partial_\nu u \\ &= \frac{1}{2}\left[\int_\Omega u'^2 + |\nabla u|^2 + qu^2 + \int_{\Gamma_1} au^2\right]_S^T + \int_S^T \int_{\Gamma_1} \ell u'^2. \qquad \square \end{aligned}$$

Set $c \in \mathbb{R}$ and

$$M(u) = 2\nabla\phi \cdot \nabla u + cu.$$

The key to the proof of Theorem 3.2 is the following basic identity.

LEMMA 3.4. *Given* (u^0, u^1) *verifying* (2.11) *and* $0 \le S < T < +\infty$, *we have*

$$\begin{aligned} &\int_S^T \int_{\Gamma_0} (\partial_\nu u)^2 \partial_\nu \phi + \int_S^T \int_{\Gamma_1} -(au + \ell u')M(u) + \partial_\nu \phi\ (u'^2 - |\nabla u|^2) \qquad (3.16) \\ &= \left[\int_\Omega u'M(u)\right]_S^T + \int_S^T \int_\Omega (1-c)(u'^2 - |\nabla u|^2) + quM(u) + 2\Big(D^2\phi \cdot \nabla u|\nabla u\Big). \end{aligned}$$

Proof of Lemma 3.4. We multiply (3.3) by $M(u)$ and we integrate by parts on $\Omega \times [S,T]$.

$$0 = \int_S^T \int_\Omega (u'' - \Delta u + qu)M(u)$$

$$\begin{aligned} = \left[\int_\Omega u'M(u)\right]_S^T - \int_S^T \int_\Omega u'(2\nabla\phi \cdot \nabla u' + cu') - \int_S^T \int_\Gamma \partial_\nu u\ M(u) \\ + \int_S^T \int_\Omega \nabla u \cdot \nabla(2\nabla\phi \cdot \nabla u + cu) + \int_S^T \int_\Omega quM(u) \end{aligned}$$

$$\begin{aligned} = \left[\int_\Omega u'M(u)\right]_S^T - \int_S^T \int_{\Gamma_1} \partial_\nu u\ M(u) - \int_S^T \int_{\Gamma_0} 2(\partial_\nu u)^2 \partial_\nu \phi + \int_S^T \int_\Omega quM(u) \\ - \int_S^T \int_\Omega \nabla\phi \cdot \nabla(u'^2) + cu'^2 + \int_S^T \int_\Omega c|\nabla u|^2 + 2\partial_i u\ \partial_i(\partial_j \phi\ \partial_j u) \end{aligned}$$

$$\begin{aligned} = \left[\int_\Omega u'M(u)\right]_S^T - \int_S^T \int_{\Gamma_1} \partial_\nu u M(u) - \int_S^T \int_{\Gamma_0} 2(\partial_\nu u)^2 \partial_\nu \phi + \int_S^T \int_\Omega quM(u) \\ - \int_S^T \int_\Gamma u'^2 \partial_\nu \phi + \int_S^T \int_\Omega u'^2 - c(u'^2 - |\nabla u|^2) + 2\Big(D^2\phi \cdot \nabla u|\nabla u\Big) + \nabla\phi \cdot \nabla\Big(|\nabla u|^2\Big). \end{aligned}$$

Thus, putting the boundary integrals in the left-hand side,

$$\int_S^T \int_{\Gamma_0} (\partial_\nu u)^2 \partial_\nu \phi + \int_S^T \int_{\Gamma_1} \partial_\nu u \ M(u) + \partial_\nu \phi \ (u'^2 - |\nabla u|^2)$$
$$= \left[\int_\Omega u' M(u) \right]_S^T + \int_S^T (1-c)(u'^2 - |\nabla u|^2) + 2(D^2\phi \cdot \nabla u | \nabla u) + quM(u). \qquad \square$$

Remark. As $u = 0$ on Γ_0, we used the fact that

$$\nabla u = (\partial_\nu u)\nu \text{ on } \Gamma_0.$$

First we estimate the terms of the left-hand side of (3.16). In the following, we will take $c > 0$, and we define a and ℓ by

$$a = \frac{c}{2\|\nabla\phi\|_\infty^2} \partial_\nu \phi \text{ and } \ell = \frac{1}{\|\nabla\phi\|_\infty} \partial_\nu \phi. \tag{3.17}$$

Lemma 3.5. *Assume a and ℓ are defined by* (3.17)*. Given (u^0, u^1) satisfying* (3.9)*, we have*

$$\int_S^T \int_{\Gamma_0} (\partial_\nu u)^2 \partial_\nu \phi + \int_S^T \int_{\Gamma_1} -(au + \ell u')M(u) + \partial_\nu \phi \ (u'^2 - |\nabla u|^2)$$
$$\leq 2\|\nabla\phi\|_\infty \Big(E(S) - E(T)\Big) - \frac{c}{2} \int_S^T \int_{\Gamma_1} au^2. \tag{3.18}$$

Proof of Lemma 3.5. According to (3.17), denote $a = \alpha \partial_\nu \phi$ and $\ell = \lambda \partial_\nu \phi$. Then

$$-(au + \ell u')(2\nabla\phi \cdot \nabla u + cu) + \partial_\nu \phi (u'^2 - |\nabla u|^2)$$
$$\leq \partial_\nu \phi \Big(\|\nabla\phi\|_\infty^2 (\alpha u + \lambda u')^2 + |\nabla u|^2 - c\alpha u^2 - c\lambda u u' + u'^2 - |\nabla u|^2 \Big)$$
$$\leq \partial_\nu \phi \Big((1 + \lambda^2 \|\nabla\phi\|_\infty^2) u'^2 + (\alpha^2 \|\nabla\phi\|_\infty^2 - c\alpha) u^2 + (2\alpha\lambda \|\nabla\phi\|_\infty^2 - c\lambda) uu' \Big).$$

Equation (3.18) follows from the carefully chosen values of α and λ given by (3.17), from the identity (3.15), and from (2.6). □

Lemma 3.6.

$$\left| \int_\Omega u' M(u) \right| \leq 2\|\nabla\phi\|_\infty E(t) \quad \textit{if } c \in [0,2]. \tag{3.19}$$

Proof of Lemma 3.6.

$$\int_\Omega (M(u))^2 = \int_\Omega (2\nabla\phi \cdot \nabla u + cu)^2 = \int_\Omega (2\nabla\phi \cdot \nabla u)^2 + c^2u^2 + 2c\nabla\phi \cdot \nabla(u^2)$$
$$= \int_\Omega (2\nabla\phi \cdot \nabla u)^2 + c^2u^2 + 2c\int_\Gamma \partial_\nu \phi \ u^2 - \int_\Omega 2cu^2$$
$$= \int_\Omega (2\nabla\phi \cdot \nabla u)^2 + c(c-2)u^2 + 2c\int_{\Gamma_1} \partial_\nu \phi \ u^2.$$

Assume $c \in [0,2]$. Then

$$\int_\Omega M(u)^2 \leq \int_\Omega (2\nabla\phi \cdot \nabla u)^2 + 2c \int_{\Gamma_1} \partial_\nu \phi \; u^2.$$

Set $d^2 = 2\|\nabla\phi\|_\infty$. Applying the Cauchy–Schwarz inequality, we obtain

$$\begin{aligned}\left|\int_\Omega u' M(u)\right| &\leq \left(\int_\Omega u'^2\right)^{1/2} \left(\int_\Omega M(u)^2\right)^{1/2}\\ &\leq \frac{d^2}{2}\int_\Omega u'^2 + \frac{1}{2d^2}\int_\Omega (2\nabla\phi\cdot\nabla u)^2 + \frac{c}{d^2}\int_{\Gamma_1} \partial_\nu\phi \; u^2\\ &\leq 2\|\nabla\phi\|_\infty E(t). \qquad \square\end{aligned}$$

Using the estimates (3.18) and (3.19), (3.16) becomes

$$\int_S^T \int_\Omega (1-c)(u'^2 - |\nabla u|^2) + 2(D^2\phi \cdot \nabla u|\nabla u) + quM(u) \\ + \frac{c}{2}\int_S^T \int_{\Gamma_1} au^2 \leq 4\|\nabla\phi\|_\infty E(S). \tag{3.20}$$

Thanks to (2.5), we can say that

$$\int_S^T \int_\Omega (1-c)u'^2 + \Big(2\lambda_1(\phi) - (1-c)\Big)|\nabla u|^2 + cqu^2 + 2qu\nabla\phi\cdot\nabla u \\ + \frac{c}{2}\int_S^T \int_{\Gamma_1} au^2 \leq 4\|\nabla\phi\|_\infty E(S). \tag{3.21}$$

Last, using the Cauchy–Schwarz inequality in the same way, we have

$$\left|\int_\Omega 2qu\nabla\phi\cdot\nabla u\right| \leq 2\|\sqrt{q}\nabla\phi\|_\infty E(t) = 2Q_1 E(t). \tag{3.22}$$

Thus

$$2\Big(\inf\Big\{\frac{c}{2}, (1-c), 2\lambda_1(\phi) - (1-c)\Big\} - Q_1\Big)\int_S^T E \leq 4\|\nabla\phi\|_\infty E(S). \tag{3.23}$$

It is easy to see that the constant c gives the better result, obtained when the coefficient of $\int_S^T E$ in (3.23) is the biggest, i.e., when c has the value C given by (3.11). Then (3.23) becomes

$$2(1 - C - Q_1)\int_S^T E \leq 4\|\nabla\phi\|_\infty E(S). \tag{3.24}$$

If $1-C-Q_1 > 0$, letting T go to $+\infty$, we see that E is a nonnegative and nonincreasing function that satisfies

$$\forall S \geq 0, \quad \int_S^{+\infty} E \leq \frac{1}{\omega} E(S).$$

Using a Gronwall-type inequality as in Haraux [5], we conclude that

$$\forall t \geq 0, \quad E(t) \leq E(0)e^{1-\omega t}.$$

We recall the proof of this inequality briefly: set $g(t) = \int_t^{+\infty} E(\tau)\, d\tau$. g satisfies the differential inequality

$$\forall t \geq 0,\ g'(t) + \omega g(t) \leq 0.$$

Thus

$$\forall t \geq 0,\ g(t) \leq g(0)e^{-\omega t} \leq \frac{1}{\omega} E(0)e^{-\omega t}.$$

Then since E is nonnegative and nonincreasing, for all $\varepsilon > 0$ we have

$$E(t) \leq \frac{1}{\varepsilon} \int_{t-\varepsilon}^{t} E(\tau)\, d\tau \leq \frac{1}{\varepsilon} g(t-\varepsilon) \leq \frac{1}{\omega\varepsilon} E(0)e^{\omega\varepsilon}e^{-\omega t},$$

and the best estimate is obtained for $\omega\varepsilon = 1$. □

Remark. When ϕ satisfies only the weaker conditions (2.1)–(2.3), one has to replace the coefficient $(1-c)$ by $(\Delta\phi - c)$ in (3.20). The assumption (2.1) allows us to choose a constant c such that (3.24) holds true.

4. Application: Fast decay of the energy in regular polygons. Let Ω be a convex polygon and $x^0 \in \Omega$. The function $\phi(x) = \phi_0(x) := \frac{1}{4}|x - x^0|^2$ satisfies

$$\Delta\phi = \frac{1}{2} + \frac{1}{2} = 1 \text{ in } \Omega, \tag{4.1}$$

$$\lambda_1(\phi) \left(= \frac{1}{2} \right) > 0, \tag{4.2}$$

$$\partial_\nu \phi = \Big(x - x^0 | \nu(x) \Big) \geq 0 \text{ on } \Gamma. \tag{4.3}$$

Define a and ℓ by (2.15). Given $(u^0, u^1) \in H^1(\Omega) \times L^2(\Omega)$, the solution of the evolutionary system

$$u'' - \Delta u = 0 \text{ in } \Omega, \tag{4.4}$$

$$\partial_\nu u + au + \ell u' = 0 \text{ on } \Gamma, \tag{4.5}$$

$$u(0) = u^0,\ u'(0) = u^1, \tag{4.6}$$

satisfies the energy estimate:

$$E(t) \leq E(0)e^{1-\omega t}, \text{ with } \omega = \frac{\inf\{\frac{1}{3}, \lambda_1(\phi)\}}{2\|\nabla\phi\|_\infty} = \frac{1}{3R(x^0)}, \tag{4.7}$$

where $R(x^0) := \sup_{x \in \Omega} |x - x^0|$. Our purpose is to improve this decay rate, first found by Tcheugoué Tébou [17], perturbing ϕ_0 by harmonic functions adapted to the domain.

4.1. Main result and first properties. Let Ω be the n-sided regular polygon centered in O whose vertices are the points $\mathrm{Re}^{2ik\pi/n}, 0 \leq k \leq n-1$.

THEOREM 4.1. *Let Ω be the n-sided regular polygon centered in O. Thanks to a careful choice of the function ϕ (and consequently the choice of a and ℓ), the solutions of the problem* (4.4)–(4.6) *satisfy the estimate*

$$\forall t \geq 0, \quad E(t) \leq E(0)e^{1-t/\rho_n}, \tag{4.8}$$

with

$$\rho_n = \left(3 - \frac{1}{n-1}\right) R \textit{ if } 3 \leq n \leq 8, \tag{4.9}$$

$$\rho_n = (3 - 6\varepsilon_n)R \textit{ with } \varepsilon_n = \frac{\sin^2 \frac{\pi}{2n}}{1 + (\cos \frac{\pi}{n})^{n-1}} \simeq \frac{\pi^2}{8n^2} \textit{ if } n \geq 9. \tag{4.10}$$

Moreover, in the case of the equilateral triangle ($n = 3$), *improved computations give the better estimate*

$$\rho_3 \leq 2,36R. \tag{4.11}$$

The function ϕ will be explicitly given in the proof.

Remarks. 1. A general principle of Russell [16] shows that uniform stabilization implies the exact controllability of the associated system in time $T > T_0 = \rho_n$. Applying this principle for the equilateral triangle, we obtain $T_0 \geq \rho_3 \geq 2R > R\sqrt{3}$. Thus the method is not powerful enough to find results that are already known (exact controllability in time $T > 2R$). So we cannot expect to find optimal results like Bardos, Lebeau, and Rauch [2] obtained when the domain is analytical.

2. It is an interesting question whether there exists an "optimal" function ϕ providing an optimal decay rate.

3. A technical difficulty (that Lemma 4.3 can help to imagine) prevents us from applying this method in dimension 3 to improve the decay rate for the tetrahedron, for example.

Proof of Theorem 4.1. Equation (4.8) is a consequence of Theorem 3.2 with a good choice of ϕ. We have to find ϕ such that $\omega(\phi)$ is the biggest possible. Because of (4.1), ϕ can be written as the perturbation of ϕ_0 by a harmonic function. It is clear that ∇P has to be entering at the vertices of Ω in order to reduce $\|\nabla\phi\|_\infty$. For example, if Ω is the equilateral triangle, ∇P has to be as indicated in Fig. 4.1.

First we study some properties we need to optimize the decay rate.

LEMMA 4.2. *Set $\phi \in \mathcal{C}^2(\overline{\Omega})$ such that $\lambda_1(\phi) > 0$. Then $\|\nabla\phi\|$ attains its upper bound only on the boundary of Ω.*

Proof of Lemma 4.2. An easy continuity argument shows that $\|\nabla\phi\|$ is bounded and attains its upper bound on $\overline{\Omega}$. Assume this happens in $z_1 = (x_1, y_1) \in \Omega$. As ϕ is $\mathcal{C}^2$,

$$\frac{\partial}{\partial x}\Big(\Big(\frac{\partial\phi}{\partial x}\Big)^2(x_1, y_1) + \Big(\frac{\partial\phi}{\partial y}\Big)^2(x_1, y_1)\Big) = 0,$$
$$\frac{\partial}{\partial y}\Big(\Big(\frac{\partial\phi}{\partial x}\Big)^2(x_1, y_1) + \Big(\frac{\partial\phi}{\partial y}\Big)^2(x_1, y_1)\Big) = 0.$$

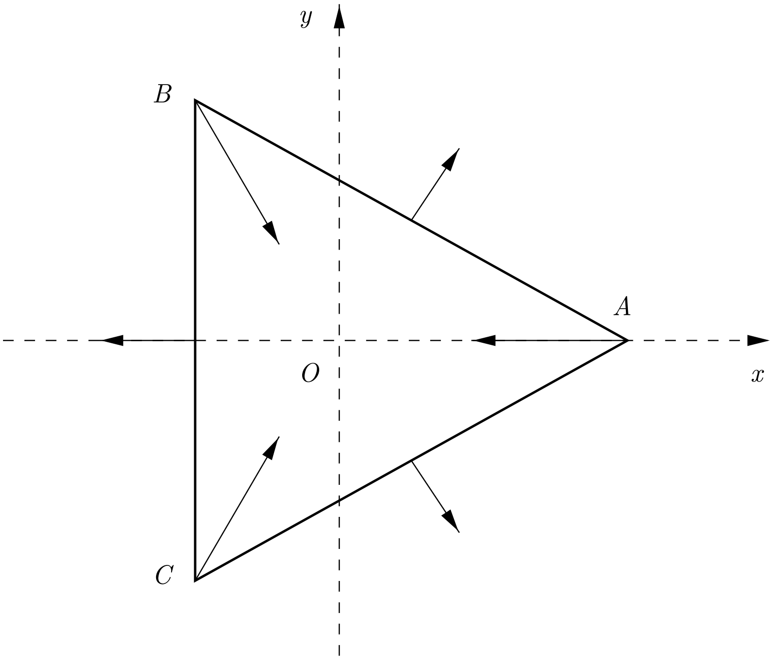

FIG. 4.1. *Behavior of* ∇P *on* Γ.

Thus we deduce that

$$D^2\phi \cdot \nabla\phi(x_1, y_1) = 0,$$

and this is impossible because $D^2\phi$ is invertible everywhere, and so $\nabla\phi(x_1, y_1)$ cannot be equal to $\overrightarrow{0}$ because of its definition. □

LEMMA 4.3. *Given* ϕ *verifying* (4.1)–(4.3) *and*

$$\nabla\phi(O) = 0, \tag{4.12}$$

the decay rate given by ϕ *can be optimal only if*

$$\lambda_1(\phi) \geq \frac{1}{3}. \tag{4.13}$$

Remark. We will see next that the additional hypothesis (4.12) is only a consequence of the symmetries of the polygon.

Proof of Lemma 4.3. Assume ϕ verifies (4.1)–(4.3), (4.12), and $\lambda_1(\phi) < \frac{1}{3}$. As usual, denote $\phi(z) - \frac{1}{4}|z|^2 = P(z) =$ Re $f(z)$. Define

$$\phi_\varepsilon = \phi_0 + \varepsilon P, \tag{4.14}$$

and choose $\varepsilon > 0$ such as

$$\lambda_1(\phi_\varepsilon) = \frac{1}{2} - \|\varepsilon f''\|_\infty = \frac{1}{3}.$$

Then ϕ_ε verifies (4.1), (4.2), (4.12), and (4.13). Assume ϕ_ε verifies (4.3). Then we shall prove that

$$\omega(\phi_\varepsilon) = \frac{1}{6\|\nabla\phi_\varepsilon\|_\infty} \geq \omega(\phi) = \frac{\lambda_1(\phi)}{2\|\nabla\phi\|_\infty}. \tag{4.15}$$

Effectively,

$$\begin{aligned}&\phi = \phi_0 + P = \phi_0 + \varepsilon P + (1-\varepsilon)P = \phi_\varepsilon + (1-\varepsilon)P,\\ &\nabla\phi(z) = \nabla\phi_\varepsilon(z) + (1-\varepsilon)\overline{f'(z)}.\end{aligned}$$

As $\overline{f'(0)} = \nabla P(O) = 0$, $|f'(z)| \leq R\|f''\|_\infty$. So

$$\|\nabla\phi\|_\infty \geq \|\nabla\phi_\varepsilon\|_\infty - (1-\varepsilon)\|f'\|_\infty,$$
$$\lambda_1(\phi) = \frac{1}{2} - \|f''\|_\infty = \frac{1}{2} - \varepsilon\|f''\|_\infty - (1-\varepsilon)\|f''\|_\infty = \frac{1}{3} - (1-\varepsilon)\|f''\|_\infty.$$

We deduce from this study that

$$\frac{2\|\nabla\phi\|_\infty}{\lambda_1(\phi)} \geq 2\frac{\|\nabla\phi_\varepsilon\|_\infty - (1-\varepsilon)R\|f''\|_\infty}{\frac{1}{3} - (1-\varepsilon)\|f''\|_\infty}, \tag{4.16}$$

but on the other hand

$$M := \frac{\|\nabla\phi_\varepsilon\|_\infty}{R} \geq \frac{1}{2} - \frac{\varepsilon}{R}\|\nabla P\|_\infty \geq \frac{1}{2} - \varepsilon\|f''\|_\infty = \frac{1}{3},$$

so (4.16) gives

$$\frac{2\|\nabla\phi\|_\infty}{\lambda_1(\phi)} \geq 2R\frac{M - (1-\varepsilon)\|f''\|_\infty}{\frac{1}{3} - (1-\varepsilon)\|f''\|_\infty} \geq 2R\frac{M}{\frac{1}{3}} = 6\|\nabla\phi_\varepsilon\|_\infty. \qquad \square$$

Next we study the problem of the normal derivative of ϕ_ε.

LEMMA 4.4. *Set $\phi \in \mathcal{C}^2(\overline{\Omega})$ verifying* (4.1), (4.12), *and* (4.13)*; then the condition* (4.3) *is automatically satisfied: $\partial_\nu\phi \geq 0$ on the boundary.*

Proof of Lemma 4.4. Set $z_k = \mathrm{Re}^{2ik\pi/n}, 0 \leq k \leq n-1$, and denote ν_k the outward unit normal vector to $]z_k, z_{k+1}[$.

$$\nu_k = \frac{z_{k+1} - z_k}{|z_{k+1} - z_k|}e^{-i\pi/2}. \tag{4.17}$$

All along the segment $]z_k, z_{k+1}[$, the normal derivative of ϕ is

$$\begin{aligned}\partial_\nu\phi(z) = \left(\frac{z}{2} + \overline{f'(z)}|\nu_k\right) &= \left(\frac{z}{2}|\nu_k\right) + \left(\overline{f'(z)}|\nu_k\right)\\ &= \left(\frac{z_k}{2}|\nu_k\right) + \left(\overline{f'(z)}|\nu_k\right) \geq \frac{R}{2}\cos\frac{\pi}{n} - R\|f''\|_\infty.\end{aligned}$$

However, $\cos\frac{\pi}{n} \geq \cos\frac{\pi}{3} \geq \frac{1}{2}$ and $\|f''\|_\infty = \frac{1}{2} - \lambda_1(\phi) \leq \frac{1}{6}$, so (4.3) follows. $\square$

This drives us to study the following optimization problem:

$$\begin{cases}\|f''\|_\infty \leq \frac{1}{6},\\ 6\|\nabla\phi\|_\infty \text{ the smallest possible.}\end{cases} \tag{4.18}$$

First assume that Ω is the equilateral triangle.

LEMMA 4.5. *If $n = 3$, we will seek only the functions f that have a development of the form*

$$f(z) = \sum_{k=1}^{+\infty} a_{3k} z^{3k}. \tag{4.19}$$

This lemma has a simple geometrical application: it is sufficient to study the harmonic functions P such that the gradient in each vertex S of the polygon is colinear to the vector $\overrightarrow{\mathrm{OS}}$.

Proof of Lemma 4.5. Set f a holomorphic function on Ω defined by a power series whose convergence radius is bigger than R:

$$f(z) = \sum_{k=0}^{+\infty} a_k z^k.$$

Then define for $i = 0$ to 2

$$g_i(z) = \sum_{k=1}^{+\infty} a_{3k+i} z^{3k+i}. \tag{4.20}$$

We show in the following that g_0 is better than f for our optimization problem: if ϕ (respectively, ψ_0) represents the function associated with f (respectively, with g_0), then

$$\begin{cases} \|g_0''\|_\infty \leq \|f''\|_\infty, \\ \|\nabla \psi_0\|_\infty \leq \|\nabla \phi\|_\infty. \end{cases} \tag{4.21}$$

Let z_0 be a maximum point of g_0'': $\|g_0''\|_\infty = |g_0''(z_0)|$. Let us show that the following system cannot be possible:

$$\begin{cases} |f''(z_0)| < |g_0''(z_0)|, \\ |f''(z_0 e^{2i\pi/3})| < |g_0''(z_0 e^{2i\pi/3})|, \\ |f''(z_0 e^{-2i\pi/3})| < |g_0''(z_0 e^{-2i\pi/3})|. \end{cases} \tag{4.22}$$

Denote $\beta_i := g_i''(z_0)$. Since $f = g_0 + g_1 + g_2$, the system (4.22) can be written

$$\begin{cases} |\beta_0 + \beta_1 + \beta_2| < |\beta_0|, \\ |\beta_0 e^{-4i\pi/3} + \beta_1 e^{-2i\pi/3} + \beta_2| < |\beta_0 e^{-4i\pi/3}|, \\ |\beta_0 e^{4i\pi/3} + \beta_1 e^{2i\pi/3} + \beta_2| < |\beta_0 e^{4i\pi/3}|. \end{cases} \tag{4.23}$$

If $\beta_0 = 0$, the result is clear. Otherwise, define

$$\gamma_1 := \frac{\beta_1}{\beta_0} \quad \text{and} \quad \gamma_2 := \frac{\beta_2}{\beta_0}.$$

Dividing each equation by $|\beta_0|$, we get from (4.23)

$$\begin{cases} |1 + \gamma_1 + \gamma_2| < 1, \\ |1 + \gamma_1 e^{2i\pi/3} + \gamma_2 e^{-2i\pi/3}| < 1, \\ |1 + \gamma_1 e^{-2i\pi/3} + \gamma_2 e^{2i\pi/3}| < 1. \end{cases} \tag{4.24}$$

But this is impossible:

$$|1+\gamma_1+\gamma_2|^2+|1+\gamma_1 e^{2i\pi/3}+\gamma_2 e^{-2i\pi/3}|^2+|1+\gamma_1 e^{-2i\pi/3}+\gamma_2 e^{2i\pi/3}|^2 \\ =3(1+|\gamma_1|^2+|\gamma_2|^2)\geq 3.$$

Thus

$$\|g_0''\|_\infty \leq \|f''\|_\infty.$$

We can proceed in the same way to prove that

$$\|\nabla\psi_0\|_\infty \leq \|\nabla\phi\|_\infty. \qquad \square$$

In the same way, when Ω is the n-sided regular polygon centered in O, we will seek f in the form

$$f(z)=\sum_{k=0}^{+\infty} a_{kn} z^{kn}. \tag{4.25}$$

4.2. Explicit computations: First study. Let Ω be the n-sided regular polygon. Thanks to the preliminary results, we study the results given by the function

$$f(z)=-\varepsilon\frac{1}{nR^{n-2}}z^n \text{ with } \varepsilon>0. \tag{4.26}$$

That gives the relations

$$\nabla\phi(z)=\frac{z}{2}-\varepsilon\frac{\overline{z}^{n-1}}{R^{n-2}}, \tag{4.27}$$

$$\lambda_1(\phi)=\frac{1}{2}-\varepsilon(n-1). \tag{4.28}$$

Because of Lemma 4.3, we will take $\varepsilon\in[0,\frac{1}{6(n-1)}]$. Moreover, the relation

$$|\nabla\phi(z)|=|\nabla\phi(ze^{2i\pi/n})|$$

allows us to study $\|\nabla\phi\|_\infty$ on only one side side of Ω. We shall treat the case "n odd," $n=2n'+1$; in order to simplify the computations, we will study the problem on the vertical side $I_{n'}:=[\mathrm{Re}^{2in'\pi/n},\mathrm{Re}^{2i(n'+1)\pi/n}]$. When n is even, it is convenient to do a rotation on Ω so that it has a vertical side. Set $z\in I_{n'}$:

$$z=R\cos\frac{2\pi n'}{n}+iy,\ y\in\left[-R\sin\frac{2\pi n'}{n},R\sin\frac{2\pi n'}{n}\right].$$

Denote

$$\rho:=R\cos\frac{2\pi n'}{n}=-R\cos\frac{\pi}{n}, \tag{4.29}$$

$$Y:=y^2 \text{ and } Y_{\max}:=\left(R\sin\frac{2\pi n'}{n}\right)^2=R^2\sin^2\frac{\pi}{n}. \tag{4.30}$$

So we have on $I_{n'}$

$$\|\nabla\phi(z)\|^2=\frac{1}{4}(\rho^2+Y)-\frac{\varepsilon\rho}{R^{n-2}}\sum_{q=0}^{n'}C_n^{2q}(-1)^q\rho^{n-2q-1}Y^q+\left(\frac{\varepsilon}{R^{n-2}}\right)^2(\rho^2+Y)^{n-1}.$$

Denote by $F_\varepsilon(Y)$ this function. In order to calculate $\|\nabla\phi\|_\infty$, we study the variations of F_ε. Let us show F_ε is a convex function on $[0, Y_{\max}]$:

$$F''_\varepsilon(Y) = -\frac{\varepsilon\rho}{R^{n-2}}\sum_{q=0}^{n'} q(q-1)C_n^{2q}(-1)^q\rho^{n-2q-1}Y^{q-2} \\ + (n-1)(n-2)\Big(\frac{\varepsilon}{R^{n-2}}\Big)^2(\rho^2+Y)^{n-3}.$$

- If $n' \leq 2$, F''_ε is clearly nonnegative.
- If $n' \geq 3$, putting the terms two by two, we see that F''_ε is the sum of the terms

$$\begin{aligned} J_{2k}(Y) &= 2k\rho^{n-4k-3}Y^{2k-2}\Big((2k-1)C_n^{4k}\rho^2 - (2k+1)C_n^{4k+2}Y\Big) \\ &= \frac{n!2k\rho^{n-1-4k-2}Y^{2k-2}}{(4k)!(n-4k-2)!}\left(\frac{2k-1}{(n-4k)(n-4k-1)}\rho^2 - \frac{2k+1}{(4k+2)(4k+1)}Y\right). \end{aligned}$$

So it is sufficient to show that each term $J_{2k}(Y)$ is nonnegative. $J_{2k}(Y)$ has the same sign than $V_{2k}(Y) := \Big(\frac{2k-1}{(n-4k)(n-4k-1)}\rho^2 - \frac{2k+1}{(4k+2)(4k+1)}Y\Big)$. By monotonicity,

$$\begin{aligned} V_{2k}(Y) \geq V_2(Y_{\max}) &= \frac{1}{(n-4)(n-5)}\rho^2 - \frac{1}{10}Y_{\max} \\ &\geq \left(\frac{10}{(n-4)(n-5)} - \tan^2\frac{\pi}{n}\right)\frac{\rho^2}{10}, \end{aligned}$$

but for all $n \geq 7$,

$$\tan^2\frac{\pi}{n} \leq \frac{10}{(n-4)(n-5)}.$$

Thus F_ε is convex, and then

$$\|F_\varepsilon\|_\infty = \sup\{F_\varepsilon(0), F_\varepsilon(Y_{\max})\}.$$

That ends the study of F_ε for ε fixed. Next we study the behavior of $\|F_\varepsilon\|_\infty$ with respect to ε:

$$F_\varepsilon(0) = \left(\frac{1}{2}\rho - \varepsilon\frac{\rho^{n-1}}{R^{n-2}}\right)^2 \text{ increases when } \varepsilon \text{ increases, because } \rho < 0;$$

$$F_\varepsilon(Y_{\max}) = |\nabla\phi(Re^{\frac{2i\pi n'}{n}})|^2 = |\nabla\phi(R)|^2 = \left(\frac{1}{2} - \varepsilon\right)^2 R^2 \text{ decreases when } \varepsilon \text{ increases.}$$

In order to minimize $\|\nabla\phi\|_\infty$, we will take, if it is possible, ε such that $F_\varepsilon(0) = F_\varepsilon(Y_{\max})$. That gives the value given in Theorem 4.1: $\varepsilon = \varepsilon_n$. However, we have still to verify that this value belongs to the interval $[0, \frac{1}{6(n-1)}]$ in which we search for ε. Computing the numerical values, we see that

- if $n \leq 8$, $\varepsilon_n > \frac{1}{6(n-1)}$; hence the best value of ε is $\frac{1}{6(n-1)}$, and

$$\omega(\phi) = 6\|\nabla\phi\|_\infty = 6|\nabla\phi(R)| = \left(3 - \frac{1}{n-1}\right)R;$$

- if $n \geq 9$, $\varepsilon_n \leq \frac{1}{6(n-1)}$; hence the best value of ε is ε_n, and

$$\omega(\phi) = (3 - 6\varepsilon_n)R. \qquad \square$$

4.3. Explicit computations: Second study. When Ω is the equilateral triangle, we can go further and study the results given by

$$f(z) = az^3 + bz^6 \quad \text{and} \quad \phi(z) = \frac{1}{4}|z|^2 + \varepsilon \text{ Re } f(z). \tag{4.31}$$

Assume $\nabla P(R) = (-R, 0)$. A careful study of the variations of $G(Y) := |f''(z)|^2$ on the vertical side of Ω shows that

- if $-5\frac{b}{a}R^3 \in [0, \frac{1}{4}]$, G is increasing on $[0, Y_{\max}]$; so the smallest value of f'' is obtained when

$$aR = -\frac{10}{27} \text{ and } bR^4 = \frac{1}{54}; \text{ then } \|f''\|_\infty = f''(R) = \frac{5}{3};$$

- if $-5\frac{b}{a}R^3 \in [\frac{1}{4}, \frac{1}{2}]$, G attains its upper bound only once and in $]0, Y_{\max}[$; we see with numerical values that

$$\text{if } aR \simeq -0,4 \text{ and } bR^3 \simeq 0,033, \text{ then } \|f''\|_\infty \simeq 1,56.$$

Then it is easy to see that $\|\nabla\phi\|$ is an increasing function of Y on $[0, Y_{\max}]$ if $\varepsilon\|f''\|_\infty \leq \frac{1}{6}$. So

$$6\|\nabla\phi\|_\infty = 6|\nabla\phi(R)| = 6\left(\frac{1}{2} - \varepsilon\right) R \leq 2,36R,$$

which proves the estimate (4.11). □

5. Uniform stabilization of Maxwell's equations in almost star-shaped domains.

The notion of "almost star-shaped domains" allows us to extend results of Komornik [9] on the uniform stabilization of Maxwell's equations. Kapitonov [7] also treated this problem in another class of "substarlike domains."

5.1. Statement of the problem and main results. We consider the following evolutionary system:

$$E' - \text{rot } H = 0 = H' + \text{rot } E \text{ in } \Omega \times \mathbb{R}_+, \tag{5.1}$$

$$\text{div } E = 0 = \text{div } H \text{ in } \Omega \times \mathbb{R}_+, \tag{5.2}$$

$$\nu \times (E \times \nu + H) = 0 \text{ on } \Gamma \times \mathbb{R}_+, \tag{5.3}$$

$$E(0) = E^0, H(0) = H^0 \text{ in } \Omega. \tag{5.4}$$

As usual denote the energy space

$$\mathcal{H} = \{(E, H) \in L^2(\Omega)^6, \text{div } E = \text{div } H = 0 \text{ dans } \Omega\}.$$

According to Barucq and Hanouzet [3], we have the following existence theorem.

THEOREM 5.1. *Let Ω be a bounded open domain of $\mathbb{R}^3$ of class $\mathcal{C}^2$.*

1. *Given $(E^0, H^0) \in \mathcal{H}$, there exists a unique weak solution*

$$(E, H) \in \mathcal{C}(\mathbb{R}_+, \mathcal{H}). \tag{5.5}$$

2. *Given $(E^0, H^0) \in \{(E, H) \in H^1(\Omega)^6, \nu \times (E \times \nu + H) = 0$ on $\Gamma\}$, which is a dense subspace of $\mathcal{H}$, there exists a unique strong solution*

$$(E, H) \in \mathcal{C}^1(\mathbb{R}_+, \mathcal{H}) \cap \mathcal{C}(\mathbb{R}_+, H^1(\Omega)^6). \tag{5.6}$$

Define the energy of solutions by

$$\mathcal{E}(t) = \frac{1}{2}\int_\Omega |E(t)|^2 + |H(t)|^2 \; dx = \|(E,H)\|^2_{\mathcal{H}}(t). \tag{5.7}$$

Assume there exists $\phi \in \mathcal{C}^2(\overline{\Omega})$ such that

$$\begin{cases} \Delta\phi = 1 \text{ in } \Omega, \\ \lambda_1(\phi) > \frac{1}{4}, \\ \partial_\nu \phi > 0 \text{ on } \Gamma. \end{cases} \tag{5.8}$$

The method exposed before allows us to construct almost star-shaped domains that are not star-shaped (and are not strictly starlike) that verify (5.8). On such domains we have the following stabilization result.

Theorem 5.2. *Given $(E^0, H^0) \in \mathcal{H}$, the energy of the associated weak solution satisfies the estimate*

$$\forall t \geq 0, \quad \mathcal{E}(t) \leq \mathcal{E}(0)e^{1-\frac{4\lambda_1(\phi)-1}{R(\phi)+\|\nabla\phi\|_\infty}t} \quad \textit{with } R(\phi) = \sup_\Gamma \frac{\|\nabla\phi\|^2_\infty}{\partial_\nu\phi}. \tag{5.9}$$

5.2. Key elements of the proof of Theorem 5.2. We prove (5.9) only for smooth initial data. Thanks to the boundary condition, the energy is nonincreasing and we have the following.

Lemma 5.3.

$$\forall\ 0 < S < T < +\infty: \quad \mathcal{E}(S) - \mathcal{E}(T) = \int_S^T \int_\Gamma |E_\tau|^2 = \int_S^T \int_\Gamma |H_\tau|^2, \tag{5.10}$$

where E_τ and H_τ designate the tangential components of E and H.

The key to the proof of Theorem 5.2 is the following identity.

Lemma 5.4.

$$\int_S^T \int_\Gamma (|E|^2 + |H|^2)\partial_\nu\phi - 2\int_S^T \int_\Gamma (H\cdot\nabla\phi)(H\cdot\nu) + (E\cdot\nabla\phi)(E\cdot\nu) \tag{5.11}$$
$$= -2\left[\int_\Omega (E\times H).\nabla\phi\right]_S^T + \int_S^T \int_\Omega |E|^2 + |H|^2 - 2\Big(D^2\phi\cdot E|E\Big) - 2\Big(D^2\phi\cdot H|H\Big).$$

Proof. Using (5.1) and (5.2), it is easy to verify that

$$\begin{aligned} 2&\left[\int_\Omega (E_1H_2 - E_2H_1)\phi_{,3}\right]_S^T \\ &= -\int_S^T \int_\Gamma (H_1^2 + H_2^2 + H_3^2 + E_1^2 + E_2^2 + E_3^2)\phi_{,3}\nu_3 \\ &\quad + 2\int_S^T \int_\Gamma \phi_{,3}H_3(H_1\nu_1 + H_2\nu_2) + \phi_{,3}E_3(E_1\nu_1 + E_2\nu_2) \\ &\quad + 2\int_S^T \int_\Gamma (H_3^2 + E_3^2)\phi_{,3}\nu_3 + \int_S^T \int_\Omega (H_1^2 + H_2^2 + H_3^2 + E_1^2 + E_2^2 + E_3^2)\phi_{,3,3} \\ &\quad - 2\int_S^T \int_\Omega H_3H_2\phi_{,3,2} + H_3H_1\phi_{,3,1} + E_3E_1\phi_{,3,1} + E_3E_2\phi_{,3,2} + H_3^2\phi_{,3,3} + E_3^2\phi_{,3,3}. \end{aligned}$$

Two similar identities are obtained by cyclical permutation of the indexes 1, 2, and 3. Adding the three identities, we obtain (5.11). Then it is easy to conclude, thanks to (5.8) and to the boundary condition (5.3), that we have

$$\int_\Omega |E|^2+|H|^2-2\Big(D^2\phi\cdot E|E\Big)-2\Big(D^2\phi\cdot H|H\Big) \\ \geq (4\lambda_1(\phi)-1)\int_\Omega |E|^2+|H|^2, \tag{5.12}$$

$$(|E|^2+|H|^2)\partial_\nu\phi-2(E.\nabla\phi)(E.\nu)-2(H.\nabla\phi)(H.\nu) \\ \leq \frac{\|\nabla\phi\|^2}{\partial_\nu\phi}(|E_\tau|^2+|H_\tau|^2). \tag{5.13}$$

Then using the estimates (5.10), (5.12), and (5.13), the identity (5.11) gives

$$\begin{aligned} 2(4\lambda_1(\phi)-1)\int_S^T\mathcal{E} &\leq \int_S^T\int_\Gamma \frac{\|\nabla\phi\|^2}{\partial_\nu\phi}(|E_\tau|^2+|H_\tau|^2)+2\|\nabla\phi\|_\infty(\mathcal{E}(S)+\mathcal{E}(T)) \\ &\leq 2R(\phi)(\mathcal{E}(S)-\mathcal{E}(T))+2\|\nabla\phi\|_\infty(\mathcal{E}(S)+\mathcal{E}(T)). \end{aligned}$$

Since by definition $R(\phi)\geq\|\nabla\phi\|_\infty$, we obtain that

$$(4\lambda_1(\phi)-1)\int_S^T\mathcal{E}\leq\Big(R(\phi)+\|\nabla\phi\|_\infty\Big)\mathcal{E}(S). \tag{5.14}$$

We conclude using the Gronwall-type inequality we used in section 3. □

Acknowledgments. I wish to thank B. Rao for fruitful discussions that led to the construction of Figure 2.1 and V. Komornik for his remarks.

SUPREMUM OPERATORS AND COMPUTATION OF SUPREMAL ELEMENTS IN SYSTEM THEORY*

S. HASHTRUDI ZAD[†], R. H. KWONG[†], AND W. M. WONHAM[†]

Abstract. Constrained supremum and supremum operators are introduced to obtain a general procedure for computing supremal elements of upper semilattices. Examples of such elements include supremal (A, B)-invariant subspaces in linear system theory and supremal controllable sublanguages in discrete-event system theory. For some examples, we show that the algorithms available in the literature are special cases of our procedure. Our iterative algorithms may also provide more insight into applications; in the case of supremal controllable subpredicate, the algorithm enables us to derive a lookahead policy for supervisory control of discrete-event systems.

Key words. discrete-event systems, linear systems, lattice theory, supervisory control, partition, supremal elements, supremum operators

1. Introduction.

In system theory, we sometimes encounter lattice structures [2], [5]. Examples are the lattice of equivalence relations in the theory of sequential machines [9], the lattice of subspaces in geometric control [29], and the lattice of sublanguages in algebraic discrete-event system theory [24]. In these cases, we are usually interested in computing the supremal (or dually, infimal) element of an upper (resp., lower) semilattice: for instance, supremal (A, B)-invariant subspaces [29] or supremal controllable sublanguages [28]. For some of these supremal elements, algorithms are available in the literature. For example, in [14] certain supremal and infimal elements are obtained as extremal solutions to systems of inequalities over the corresponding lattices. In this paper we present a general framework based on *constrained supremum* and *supremum operators* for computing supremal elements, which unifies many of the above-mentioned algorithms, including those of [14]. We will see that previous results are special cases of our general procedure, which we call the Δ-*method.* In some cases, these procedures provide us with more insight into the applications of system theory. For example, in the computation of supremal controllable subpredicate, we are led to a lookahead policy for supervisory control.

The supremum operator (referred to as the maximum operator in [9]) is used in [9] in the computation of the supremal elements of finite lattices. There, the underlying binary relation is assumed to be a pair algebra, and therefore is closed with respect to component-wise join and meet operations. In system theory, however, we are usually interested in the supremal elements of infinite upper semilattices. In these cases, the underlying relation of the supremum operator is not a pair algebra. In this paper, we will generalize the approach of [9] and obtain a procedure suitable for computing supremal elements in system theory. We will also introduce a constrained supremum operator, based on which we will present a second iterative algorithm for computing

supremal elements. Although our focus will be on computing supremal elements, dual results for infimal elements will be presented without proof to complete the discussion.

In section 2, we define constrained supremum and supremum operators and derive procedures for computing supremal elements. Next, in section 3, we apply our results to a number of examples in system theory. Dual results for computing infimal elements are given in section 4. Finally, we summarize our work in section 5.

In this paper, the bottom and top elements of lattices are denoted by $\perp$ and $\top$. In a poset L, $x \in L$ is a fixpoint of an operator $\varphi : L \to L$ iff $\varphi(x) = x$, and $\varphi(\cdot)$ is monotone iff $x \leq x'$ implies $\varphi(x) \leq \varphi(x')$ for all x, $x' \in L$. Also $|Q|$ denotes the cardinality of the set Q.

2. Supremum operators.

Throughout this section, $\leq$ denotes a partial order on the corresponding lattice (or poset). For any two elements x and y of a lattice (poset), $x \geq y$ means $y \leq x$. We shall also denote the meet and join operations by $\wedge$ and $\vee$ and use $\vee$ (resp., $\wedge$) and sup (resp., inf) interchangeably.

Consider a complete lattice L. Let $S \subseteq L$ be a complete upper semilattice under the join operation $\vee$ of L. For every $z \in L$, define

$$z^{\uparrow} := \sup\{x \mid x \in S, \quad x \leq z\}.$$

Of course $z^{\uparrow} \in S$. In this section, we will present algorithms for computing $z^{\uparrow}$. Toward this end, the *supremum operators* will be introduced.

We begin by defining *contractive operators.*

DEFINITION 1. *Let L be a poset. An operator $\varphi : L \to L$ is contractive iff $\varphi(x) \leq x$ for all $x \in L$.*

Theorem 1 presents the main algorithm for computing $z^{\uparrow}$.

THEOREM 1. *Let L be a complete lattice, $S \subseteq L$ be an upper semilattice under the join operation $\vee$ of L, and $\varphi : L \to L$ be an operator with the following properties:*

(i) $S = \{x \in L \mid \varphi(x) = x\}$,

(ii) $\varphi(\cdot)$ *is monotone,*

(iii) $\varphi(\cdot)$ *is contractive.*

Let $z \in L$, and suppose there exists an integer $k^* \geq 0$ such that the recursion

$$z_0 = z,$$
$$z_{k+1} = \varphi(z_k)$$

terminates in k^* steps. Then

$$z^{\uparrow} = \sup\{x \mid x \in S, \quad x \leq z\} = z_k \qquad \textit{for all } k \geq k^*.$$

Proof. Since $\varphi(\cdot)$ is contractive, $z_{k+1} = \varphi(z_k) \leq z_k$ for all $k \geq 0$. Therefore $\{z_k\}$ is a nonincreasing sequence. Since $z_{k+1} = z_k$ for all $k \geq k^*$ by assumption, $\varphi(z_{k^*}) = z_{k^*}$; hence $z_{k^*} \in S$. Moreover $z_{k^*} \leq z_0 = z$; therefore $z_{k^*} \in \{x \mid x \in S, \ x \leq z\}$. For any $x \in S$ such that $x \leq z$, if $x \leq z_k$ then $x = \varphi(x) \leq \varphi(z_k) = z_{k+1}$. Therefore, by induction, $x \leq z_k$ for all $k \geq 0$. As a result, z_{k^*} is the supremal element sought: $z^{\uparrow} = z_{k^*}$. □

Remark 1. In the theorem, the sequence $\{z_k\}$ is required to be finite. A poset in which, for any chain $z_0 \geq z_1 \geq \cdots \geq z_k \geq \cdots$ of elements there exists an integer $n \geq 0$ such that $z_k = z_n$ for all $k \geq n$ is said to satisfy the descending chain condition (DCC) [5]. A lattice of finite length, i.e., one in which the length of the longest chain is finite, satisfies the DCC. Graded lattices and finite lattices are of finite length and therefore satisfy the DCC [2]. Clearly, in Theorem 1, satisfaction of the DCC (by L) guarantees finite termination of the recursion. However, if L does not satisfy the DCC, then finite termination has to be established before the theorem can be used. One way to do this is to show that the chain $\{z_k\}$ is contained in a subset of L which satisfies the DCC. Formally we express this simple result as the following lemma.

LEMMA 1. *Suppose the chain* $z_0 \geq z_1 \geq \cdots \geq z_k \geq \cdots$ *of elements of a given poset is contained in a subset of the poset which satisfies the descending chain condition. Then there exists an integer* $n \geq 0$ *such that* $z_k = z_n$ *for all* $k \geq n$. □

In the next section, we shall see an application of this lemma in the computation of supremal controllable sublanguages.

Remark 2. Theorem 1 still holds if L is a complete upper semilattice.

In Theorem 1, $z^{\uparrow}$ is computed as the greatest fixpoint of the contractive monotone operator $\varphi(\cdot)$. By assumption, the set of fixpoints of φ coincides with the upper semisublattice S. We note that the fixpoints of a contractive monotone operator always form a complete upper semilattice (under the join operation of the underlying lattice). To see this, recall that by the Knaster–Tarski fixpoint theorem [26], the set of fixpoints of a monotone operator is nonempty. Now let $\{x_\alpha \mid \alpha \in A\}$ be a subset of the set of fixpoints of a contractive monotone operator φ. Then $\vee_\alpha x_\alpha = \vee_\alpha \varphi(x_\alpha) \leq \varphi(\vee_\alpha x_\alpha)$ because φ is monotone. Also since φ is contractive, $\varphi(\vee_\alpha x_\alpha) \leq \vee_\alpha x_\alpha$. Therefore $\vee_\alpha x_\alpha = \varphi(\vee_\alpha x_\alpha)$; i.e., $\vee_\alpha x_\alpha$ is a fixpoint of φ.

Theorem 1 presents a list of properties for the operator $\varphi(\cdot)$ sufficient to guarantee the convergence of the algorithm, but it does not suggest any particular structure for the operator explicitly. The *constrained supremum operator*, to be introduced shortly, is contractive and, as will be illustrated in the next section, with a suitable choice of its underlying binary relation can be made to satisfy the assumptions of Theorem 1.

DEFINITION 2. *Let* L *be a complete lattice and* $\Delta \subseteq L \times L$. *The constrained supremum operator* $\hat{\Psi} : L \to L$ *is defined as*

$$\hat{\Psi}(y) := \sup\{x \mid (x, y) \in \Delta, \quad x \leq y\}.$$

The symbol $\hat{\Psi}(\cdot)$ does not show the dependency of the constrained supremum operator on its underlying relation Δ. In this paper, no ambiguity will result because we will not work with more than one binary relation at a time. We will denote the supremum operator (Definition 4) and the infimum operators (section 4) following the same convention.

If for some $y \in L$ the set of x's in Definition 2 is empty, then by "empty set logic" $\hat{\Psi}(y) = \bot$.

LEMMA 2. *The constrained supremum operator is contractive.*

Proof. The proof follows immediately from Definition 2. □

We will need the definition of S-reflexive relations.

DEFINITION 3. *Let* L *be a poset and* $S \subseteq L$. *A relation* $\Delta \subseteq L \times L$ *is reflexive with respect to* S *or simply* S*-reflexive iff*

$$L_\Delta := \{x \in L \mid (x, x) \in \Delta\} = S.$$

A reflexive relation on L is obviously L-reflexive too.

Theorem 2 follows from Theorem 1 and presents an iterative procedure for computing $z^{\uparrow}$ in terms of the constrained supremum operator.

THEOREM 2. *Assume that* L *is a complete lattice and* $S \subseteq L$ *is an upper semilattice under the join operation* $\vee$ *of* L. *Let* $\Delta \subseteq L \times L$ *be* S*-reflexive, and assume that*

(i) $L_\Delta = \{x \in L \mid \hat{\Psi}(x) = x\}$,
(ii) $\hat{\Psi}(\cdot)$ *is monotone.*

Let $z \in L$, and suppose there exists an integer $k^* \geq 0$ such that the iteration

$$\begin{aligned} z_0 &= z, \\ z_{k+1} &= \hat{\Psi}(z_k) \end{aligned}$$

terminates in k^* steps. Then

$$z^\uparrow = \sup\{x \mid x \in S, \quad x \leq z\} = z_k \quad \textit{for all } k \geq k^*.$$

Proof. The proof follows from Theorem 1 and Lemma 2. □

Remarks 1 and 2 apply to Theorem 2 as well. Regarding assumption (i) in Theorem 2, we note that $L_\Delta \subseteq \{x \in L \mid \hat{\Psi}(x) = x\}$ is always true but the reverse inclusion $\supseteq$ depends on Δ. Assumptions (i) and (ii) are expressed in terms of $\hat{\Psi}(\cdot)$. As we shall see in the next section, in order to use Theorem 2, we start by defining a suitable Δ, and then we compute $\hat{\Psi}$. Sometimes verifying (i) and (ii) directly in terms of $\hat{\Psi}$ is difficult. The following propositions provide sufficient conditions for the satisfaction of (i) and (ii) in terms of Δ. These conditions are usually easier to check.

Proposition 1. *Let L be a complete lattice, $\Delta \subseteq L \times L$ and $\hat{\Psi}(\cdot)$ the corresponding constrained supremum operator. If, for every set of pairs $\{(x_\alpha, y) \in \Delta \mid \alpha \in A\}$, with A being some index set, we have $(\vee_\alpha x_\alpha, y) \in \Delta$, then*

$$L_\Delta = \{x \in L \mid \hat{\Psi}(x) = x\}.$$

Proof. If $x \in L_\Delta$, then $(x, x) \in \Delta$, therefore $\hat{\Psi}(x) = x$. Conversely, if $x = \hat{\Psi}(x)$, then $(x, x) \in \Delta$ (i.e., $x \in L_\Delta$) because $(\hat{\Psi}(x), x) \in \Delta$ by assumption. □

Proposition 2. *Let L be a complete lattice and $\Delta \subseteq L \times L$. If $(x, y) \in \Delta$ and $y \leq y'$ imply $(x, y') \in \Delta$, then the constrained supremum operator $\hat{\Psi}$ must be monotone.*

Proof. If $y \leq y'$, then it follows from the assumption that

$$\begin{aligned} \{x \mid (x, y) \in \Delta,\ x \leq y\} &\subseteq \{x \mid (x, y') \in \Delta,\ x \leq y\} \\ &\subseteq \{x \mid (x, y') \in \Delta,\ x \leq y'\}; \end{aligned}$$

therefore $\hat{\Psi}(y) \leq \hat{\Psi}(y')$. □

Now we discuss another iterative algorithm which is probably more familiar.

Definition 4. *Let L be a complete lattice and $\Delta \subseteq L \times L$. The supremum operator $\Psi : L \to L$ is defined according to*

$$\Psi(y) := \sup\{x \mid (x, y) \in \Delta\}.$$

If, for some $y \in L$, there exists no $x \in L$ such that $(x, y) \in \Delta$, then $\Psi(y) = \bot$ by "empty set logic."

Theorem 3. *Assume that L is a complete lattice and $S \subseteq L$ is an upper semilattice under the join operation $\vee$ of L. Let $\Delta \subseteq L \times L$ be S-reflexive, and assume that*

(i) $L_\Delta = \{x \in L \mid x \leq \Psi(x)\}$,
(ii) $\Psi(\cdot)$ *is monotone.*

Let $z \in L$ and suppose there exists an integer $k^* \geq 0$ such that the iteration

$$z_0 = z,$$
$$z_{k+1} = \Psi(z_k) \wedge z$$

terminates in k^* steps. Then

$$z^{\uparrow} = \sup\{x \mid x \in S,\ x \leq z\} = z_k \quad \textit{for all } k \geq k^*.$$

Proof. Let $\varphi(x) := \Psi(x) \wedge x$ for $x \in L$. Obviously $\varphi(\cdot)$ is contractive. It follows from the assumptions of the theorem that $\varphi(\cdot)$ is also monotone and L_Δ is its set of fixpoints. Using induction, we can show that with $\varphi(x) = \Psi(x) \wedge x$, the sequence in Theorem 1 is identical to the sequence generated in Theorem 3 and hence terminates in k^* steps. By Theorem 1, $z^{\uparrow} = z_k$ for all $k \geq k^*$. □

Remark 1 applies to Theorem 3 as well.

$L_\Delta \subseteq \{x \in L \mid x \leq \Psi(x)\}$ always holds, but the reverse inclusion $\supseteq$ depends on Δ. The following propositions will help in verifying assumptions (i) and (ii) of Theorem 3.

PROPOSITION 3. *Let L be a complete lattice, $\Delta \subseteq L \times L$, and $\Psi(\cdot)$ be the corresponding supremum operator. Suppose that*

(i) *for every set of pairs $\{(x_\alpha, y) \in \Delta \mid \alpha \in A\}$ with A being some index set, $(\vee_\alpha x_\alpha, y) \in \Delta$; and*

(ii) *$(x, y) \in \Delta$ and $x' \leq x$ imply $(x', y) \in \Delta$.*

Then

$$L_\Delta = \{x \in L \mid x \leq \Psi(x)\}.$$

Proof. If $x \in L_\Delta$, then $(x, x) \in \Delta$; therefore $x \leq \Psi(x)$. Conversely, let $x \leq \Psi(x)$. It follows from (i) that $(\Psi(x), x) \in \Delta$. Hence by (ii), $(x, x) \in \Delta$; i.e., $x \in L_\Delta$. □

PROPOSITION 4. *Let L be a complete lattice and $\Delta \subseteq L \times L$. If $(x, y) \in \Delta$ and $y \leq y'$ imply $(x, y') \in \Delta$, then the supremum operator $\Psi(\cdot)$ must be monotone.*

Proof. If $y \leq y'$, then $\{x \mid (x, y) \in \Delta\} \subseteq \{x \mid (x, y') \in \Delta\}$. Therefore $\Psi(y) \leq \Psi(y')$. □

Remark 3. In Theorems 2 and 3, one "sup" operation (over L_Δ) is replaced with another one (over x's satisfying $(x, z_k) \in \Delta$). As we shall see in the following section, the latter operation is usually easier to do. The usefulness of Theorems 2 and 3 is due to this fact.

Remark 4. Theorems 1, 2, and 3 compute the supremal element as the greatest fixpoint of monotone operators. This is a standard technique (see, e.g., [22], [27]) which relies on the Knaster–Tarski fixpoint theorem [26], [15]. In this paper we are presenting *a method for obtaining* these monotone operators, i.e., defining a suitable S-reflexive relation Δ and computing $\hat{\Psi}(\cdot)$ or $\Psi(\cdot)$. We shall refer to this method as the Δ-method. Examples given in the following section will show that the method is fairly general. Note that in this paper no systematic way for defining a suitable relation Δ is provided; however, the next section will demonstrate how such a relation can be chosen in a number of cases.

3. Applications.

In this section, we will apply the Δ-method to some examples in system theory. In each example, the first step is to identify the lattice L, then define an appropriate S-reflexive relation Δ. Next we have to compute the (constrained) supremum operator. If L does not satisfy the DCC, we also have to see if the iteration terminates in a finite number of steps.

Example 1. *Extremal solutions of inequalities.* In [14], the existence and computation of extremal solutions of inequalities over lattices are studied. Based on this, algorithms for the computation of some of the supremal and infimal elements in supervisory control of discrete-event systems are obtained. Specifically the following result is established.

THEOREM 4 (see [14]). *Consider the system of inequalities* $\{f_i(x) \leq g_i(x)\}_{1\leq i\leq n}$ *over a complete lattice* L, *with* f_i*'s being disjunctive and* g_i*'s monotone. Let* $f_i^{\perp}$ *denote the dual of* f_i, *and define* $h_1 : L \rightarrow L$ *as*

$$h_1(x) := \bigwedge_{i=1}^{n} f_i^{\perp}(g_i(x)).$$

If the iteration

$$z_0 = \top,$$
$$z_{k+1} = h_1(z_k)$$

terminates in a finite number of steps—say k^**—then*

$$z_{k^*} = \sup\{x \mid \textit{for all } i \leq n : f_i(x) \leq g_i(x)\}. \qquad \square$$

In a complete lattice L, the dual of a function $f : L \rightarrow L$ has been defined to be a function $f^{\perp} : L \rightarrow L$, with $f^{\perp}(y) = \sup\{x \in L \mid f(x) \leq y\}$ for every $y \in L$ [14]. Moreover $f : L \rightarrow L$ is called disjunctive iff for every subset $\{x_\alpha \in L \mid \alpha \in A\}$, with A being an index set, $f(\vee_\alpha x_\alpha) = \vee_\alpha f(x_\alpha)$ [7], [14]. Note that f disjunctive implies f monotone.

The remaining results in [14] are derived from the above theorem. We shall show that Theorem 4 and hence the resulting algorithms of [14] are special cases of Theorem 3.

Let $S = \{x \mid \text{for all } i \leq n : f_i(x) \leq g_i(x)\}$. Define $\Delta \subseteq L \times L$ to be

$$\Delta = \{(x, y) \mid x, y \in L \text{ and for all } i \leq n : f_i(x) \leq g_i(y)\}.$$

For every $x \in L$, $(x, x) \in \Delta$ iff x is a solution of $\{f_i(x) \leq g_i(x)\}_{1\leq i\leq n}$; therefore Δ is S-reflexive and

$$\sup\{x \mid \text{for all } i \leq n : f_i(x) \leq g_i(x)\} = \sup\{x \mid x \in L_\Delta\}.$$

For a set $\{(x_\alpha, y) \in \Delta \mid \alpha \in A\}$

$$\begin{aligned} f_i\left(\bigvee_\alpha x_\alpha\right) &= \bigvee_\alpha f_i(x_\alpha) \quad (f_i \text{ is disjunctive}) \\ &\leq g_i(y). \end{aligned}$$

Therefore $(\vee_\alpha x_\alpha, y) \in \Delta$. If $(x, y) \in \Delta$ and $x' \leq x$, then $f_i(x') \leq f_i(x) \leq g_i(y)$ for all $i \leq n$; hence $(x', y) \in \Delta$. Also $(x, y) \in \Delta$ and $y \leq y'$ imply $f_i(x) \leq g_i(y) \leq g_i(y')$ for all $i \leq n$, which in turn implies $(x, y') \in \Delta$.

By Definition 4

$$\begin{aligned} \Psi(y) &= \sup\{x \mid \text{for all } i \leq n : f_i(x) \leq g_i(y)\} \\ &= \sup\{x \mid x \leq h_1(y)\} \quad \text{(by Lemma 5 of [14])} \\ &= h_1(y). \end{aligned}$$

Now it is easy to see that Theorem 4 follows from Theorem 3 and Propositions 3 and 4.

The framework presented in this paper is more general than the one given in [14]. To see this, consider the lattice $L = \{\bot, x_1, x_2, \top\}$ with $\bot < x_1 < x_2 < \top$. Define functions f and g according to $f(\bot) = \bot$, $f(x_1) = \top$, $f(x_2) = \top$, $f(\top) = x_2$, $g(\bot) = \bot$, $g(x_1) = x_1$, $g(x_2) = x_2$, $g(\top) = x_2$. Consider the problem of finding $\sup\{x \in L \mid f(x) \leq g(x)\}$. Theorem 4 does not apply to this case, because f is not disjunctive. However, it is easy to see that the iteration in Theorem 2 with $\Delta = \{(x, y) \in L \times L \mid f(x) \leq g(y)\}$ will give us the supremal solution of the inequality. Note that there are problems that can be solved using our approach but cannot be (easily) cast into a problem of solving a system of inequalities. The "relational coarsest partition" problem [11], [23] is one example, to be discussed later in this paper.

Example 2. *Supremal* (A, B)*-invariant subspace.* Consider the finite-dimensional linear time-invariant system

$$\dot{x}(t) = Ax(t) + Bu(t),$$

where $x(t) \in \mathcal{X}$. A subspace $\mathcal{V} \subseteq \mathcal{X}$ is called (A, B)-invariant iff $A\mathcal{V} \subseteq \mathcal{V} + \mathrm{Im}B$ [29], where $\mathrm{Im}B$ is the subspace spanned by the columns of B. For every $\mathcal{K} \subseteq \mathcal{X}$, there exists a supremal (A, B)-invariant subspace $\mathcal{K}^{\uparrow}$ contained in $\mathcal{K}(\mathcal{K}^{\uparrow} \subseteq \mathcal{K})$ [29]. A recursion for computing $\mathcal{K}^{\uparrow}$ can be derived as follows.

The set of subspaces $\mathcal{V} \subseteq \mathcal{X}$ partially ordered by subspace inclusion $\subseteq$ and under operations sum $+$ and intersection $\cap$ of subspaces forms a complete lattice; call it L. In this case $\bot = 0$ and $\top = \mathcal{X}$. Let S be the set of (A, B)-invariant subspaces. Define $\Delta \subseteq L \times L$ as follows:

$$\Delta = \{(\mathcal{V}_1, \mathcal{V}_2) \mid \mathcal{V}_1, \mathcal{V}_2 \subseteq \mathcal{X} \text{ and } A\mathcal{V}_1 \subseteq \mathcal{V}_2 + \mathrm{Im}B\}.$$

For every $\mathcal{V} \subseteq \mathcal{X}$, $(\mathcal{V}, \mathcal{V}) \in \Delta$ iff $\mathcal{V}$ is (A, B)-invariant; hence Δ is S-reflexive and

$$\mathcal{K}^{\uparrow} = \sup\{\mathcal{V} \mid \mathcal{V} \in L_{\Delta}, \quad \mathcal{V} \subseteq \mathcal{K}\}.$$

Moreover Δ satisfies the assumptions of Propositions 3 and 4. Define $A^{-1}\mathcal{V} := \{x \in \mathcal{X} \mid Ax \in \mathcal{V}\}$ and observe that $(A^{-1}(\mathcal{V}+\mathrm{Im}B), \mathcal{V}) \in \Delta$ for any $\mathcal{V} \subseteq \mathcal{X}$ since $A(A^{-1}(\mathcal{V}+\mathrm{Im}B)) \subseteq \mathcal{V}+\mathrm{Im}B$. Also if for some $\mathcal{V}_1 \subseteq \mathcal{X}$ we have $(\mathcal{V}_1, \mathcal{V}) \in \Delta$, then $A\mathcal{V}_1 \subseteq \mathcal{V}+\mathrm{Im}B$ and hence $\mathcal{V}_1 \subseteq A^{-1}(\mathcal{V} + \mathrm{Im}B)$. Therefore $\Psi(\mathcal{V}) = A^{-1}(\mathcal{V} + \mathrm{Im}B)$. The lattice L is not finite, but it is of finite length (in fact, graded) with $d(\mathcal{V})$, denoting dimension of $\mathcal{V} \subseteq \mathcal{X}$, as the height function (in a poset of finite length, the height of an element is the least upper bound of the lengths of the chains that start at $\bot$ and end at the element) [2]. Therefore by Theorem 3 and Propositions 3 and 4

$$\begin{aligned}\mathcal{K}_0 &= \mathcal{K},\\ \mathcal{K}_{k+1} &= \mathcal{K} \cap A^{-1}(\mathcal{K}_k + \mathrm{Im}B),\\ \mathcal{K}^{\uparrow} &= \mathcal{K}_k, \qquad k \geq d(\mathcal{K}).\end{aligned}$$

This is a well-known result [29].

Similarly, Theorem 2 gives the following iteration:

$$\begin{aligned}\mathcal{K}_0 &= \mathcal{K},\\ \mathcal{K}_{k+1} &= \hat{\Psi}(\mathcal{K}_k) = \mathcal{K}_k \cap A^{-1}(\mathcal{K}_k + \mathrm{Im}B),\\ \mathcal{K}^{\uparrow} &= \mathcal{K}_k, \qquad k \geq d(\mathcal{K}).\end{aligned}$$

Example 3. *Supremal controllable sublanguage.* Let Σ be a nonempty finite alphabet of elements and Σ^* be the set of all finite strings of elements of Σ, including the empty string. A subset $K \subseteq \Sigma^*$ is called a language. Let N be a fixed language and Σ_u be a fixed subset of Σ. A language $K \subseteq \Sigma^*$ is controllable (with respect to N and Σ_u) iff $\overline{K}\Sigma_u \cap N \subseteq \overline{K}$, where $\overline{K}$ is the prefix closure of K [24]. Every language E has a supremal controllable sublanguage, denoted here by $E^{\uparrow}$ [24].

Let $L = \text{Pwr}(\Sigma^*)$ be the power set of Σ^*. Then L, partially ordered by set inclusion $\subseteq$ and under the operations union $\cup$ and intersection $\cap$ of sets, forms a complete lattice, with $\bot = \emptyset$ and $\top = \Sigma^*$. Let S be the set of controllable sublanguages. Define $\Delta \subseteq L \times L$ to be

$$\Delta = \{(K_1, K_2) \mid K_1, K_2 \in L \text{ and } \overline{K}_1\Sigma_u \cap N \subseteq \overline{K}_2\}.$$

For every $K \in L$, $(K, K) \in \Delta$ iff K is controllable; as a result Δ is S-reflexive and

$$E^{\uparrow} = \sup\{K \mid K \in L_\Delta, \quad K \subseteq E\}.$$

We see that for the set $\{(K_1^\alpha, K_2) \in \Delta \mid \alpha \in A\}$

$$\overline{\bigcup_\alpha K_1^\alpha}\Sigma_u \cap N = \bigcup_\alpha (\overline{K_1^\alpha}\Sigma_u \cap N) \subseteq \overline{K}_2;$$

hence $(\cup_\alpha K_1^\alpha, K_2) \in \Delta$. Also if $(K_1, K_2) \in \Delta$ and $K_1' \subseteq K_1$, then

$$\overline{K_1'}\Sigma_u \cap N \subseteq \overline{K}_1\Sigma_u \cap N \subseteq \overline{K}_2;$$

i.e., $(K_1', K_2) \in \Delta$. Therefore by Proposition 3, $L_\Delta = \{x \in L \mid x \leq \Psi(x)\}$. Similarly, using Proposition 4, we can show that $\Psi(\cdot)$ is monotone. According to Definition 4, for $K \in L$,

$$\Psi(K) = \sup\{D \mid \overline{D}\Sigma_u \cap N \subseteq \overline{K}\}.$$

The iteration in Theorem 3 becomes

$$\begin{aligned} E_0 &= E, \\ E_{k+1} &= E \cap \sup\{D \mid \overline{D}\Sigma_u \cap N \subseteq \overline{E}_k\}, \end{aligned}$$

which, when E and N are regular languages, is known to converge in a finite number of steps [28]—say, k^*. Hence by Theorem 3: $E^{\uparrow} = E_k$ for all $k \geq k^*$. Here the lattice L does not satisfy the DCC. However, when E and N are regular over the fixed, finite alphabet Σ, the languages E_k belong to the finite set $\{K \mid \|K\| \leq \|E\| \cdot \|N\| + 1\}$ [28]. Here $\|K\|$ denotes the minimal cardinality of the state set of an automaton that "recognizes" K [10]. Therefore, finite termination of the recursion follows from Lemma 1.

Example 4. *Supremal normal sublanguage.* With Σ and Σ^* as in Example 3, let K be a fixed language. Suppose that Σ_o is a fixed subset of Σ, and let $P : \Sigma^* \to \Sigma_o^*$ denote the natural projection. A language $N \subseteq K$ is (K, P)-normal iff $K \cap P^{-1}(PN) = N$ [20], [21]. Note that $N \subseteq K \cap P^{-1}(PN)$ always holds. Every language $E \subseteq K$ has a unique supremal normal sublanguage, denoted here by E^* [21].

Let L be the set of sublanguages of K; i.e., $L := \{N \mid N \subseteq K \subseteq \Sigma^*\}$. Then L is partially ordered by set inclusion $\subseteq$ and, under the operations union $\cup$ and intersection $\cap$ of sets, forms a complete lattice, with $\bot = \emptyset$ and $\top = K$. Let S be the set of (K, P)-normal languages. Now define

$$\Delta = \{(N_1, N_2) \mid N_1, N_2 \in L \text{ and } K \cap P^{-1}(PN_1) \subseteq N_2\}.$$

For every $N \in L$, $(N, N) \in \Delta$ iff N is (K, P)-normal; hence Δ is S-reflexive and

$$E^* = \sup\{N \mid N \in L_\Delta, \quad N \subseteq E\}.$$

Using Propositions 1 and 2 it is straightforward to verify that $\hat{\Psi}(\cdot)$ satisfies assumptions (i) and (ii) of Theorem 2. In this case the constrained supremum operator is

$$\begin{aligned}\hat{\Psi}(N) &= \sup\{N' \subseteq K \mid K \cap P^{-1}(PN') \subseteq N, \quad N' \subseteq N \subseteq K\}\\ &= \{x \in N \mid K \cap P^{-1}(Px) \in N \subseteq K\}.\end{aligned}$$

Using Figure 1 with

$$X = (K \cap P^{-1}(PN)) - N$$

we can see that $N \cap P^{-1}(PX)$ contains those strings $x \in N$ that violate $K \cap P^{-1}(Px) \in N$. Therefore

$$\begin{aligned}\hat{\Psi}(N) &= N - P^{-1}(PX)\\ &= N - P^{-1}P(K - N).\end{aligned}$$

The last equality holds because $P(K - (X \cup N)) \cap P(N) = \emptyset$. The recursion in Theorem 2 will be

$$\begin{aligned}E_0 &= E,\\ E_{k+1} &= E_k - P^{-1}P(K - E_k).\end{aligned}$$

The above iteration converges in one step since $E^* = E - P^{-1}P(K - E)$ [12]. We note that in this example the lattice L does not satisfy the DCC. If K and E are closed and L contains only the closed sublanguages of K, then the iteration becomes

$$\begin{aligned}E_0 &= E,\\ E_{k+1} &= E_k - P^{-1}P(K - E_k)\Sigma^*\end{aligned}$$

to keep E_k's closed. The above recursion also converges in only one step because $E^* = E - P^{-1}P(K - E)\Sigma^*$ [3].

Example 5. *Supremal controllable subpredicate.* Predicates and predicate transformers [6] are used in state-based control of discrete-event systems [25]. For other examples refer to [18] and [13] and their references. Using the notation in [18], let Q be the set of states of a discrete-event system G. A predicate P is controllable (with respect to G) iff $P \preceq M_\sigma(P)$ for all $\sigma \in \Sigma_u$ and $P \preceq R(G, P)$ [17], where $\preceq$ means "implies," Σ_u is the set of uncontrollable events, $M_\sigma(P)$ the "weakest liberal precondition" of P, and $R(G, P)$ the "reachability predicate." For every predicate P, there exists a supremal controllable subpredicate $P^\uparrow(\preceq P)$ [18].

Let L be the family of predicates on Q. Then L is partially ordered by $\preceq$ and under operations disjunction $\vee$ and conjunction $\wedge$ of predicates forms a complete

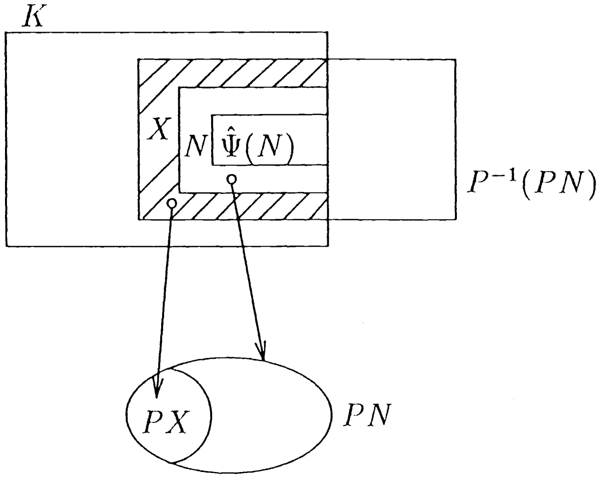

FIG. 1. *Computing* $\hat{\Psi}(N)$.

lattice. Here $\perp =$FALSE and $\top =$TRUE. Let S be the set of controllable predicates. If $\Delta \subseteq L \times L$ is defined as

$$\Delta = \{(P_1, P_2) \mid P_1, P_2 \in L \text{ and } (P_1 \preceq M_\sigma(P_2) \text{ for all } \sigma \in \Sigma_u) \text{ and } P_1 \preceq R(G, P_2)\},$$

then for every predicate P, $(P, P) \in \Delta$ iff P is controllable; therefore Δ is S-reflexive and

$$P^\uparrow = \sup\{P' \mid P' \in L_\Delta, \quad P' \preceq P\}.$$

Moreover, using the fact that $M_\sigma(\cdot)$ and $R(G, \cdot)$ are monotone, along with Propositions 1 and 2, it can be shown that Δ satisfies assumptions (i) and (ii) of Theorem 2. Theorem 2 provides the following recursion, which converges in a finite number of steps when the number of states is finite, $|Q| < \infty$:

$$\begin{aligned} P_0 &= P, \\ P_{k+1} &= \sup\{P' \mid P' \preceq M_\sigma(P_k) \text{ for all } \sigma \in \Sigma_u, \quad P' \preceq R(G, P_k)\} \\ &= R(G, P_k) \bigwedge \left(\bigwedge_{\sigma \in \Sigma_u} M_\sigma(P_k) \right), \\ P^\uparrow &= P_k, \qquad k \geq |P|. \end{aligned}$$

In the above recursion, $|P| := |\{q \in Q \mid q \in P\}|$. Computing $R(G, P_k)$ is computationally complex. The above iteration can be replaced with the simpler recursion:

$$\begin{aligned} P_0 &= P, \\ P_{k+1} &= \sup\{P' \mid P' \preceq M_\sigma(P_k) \text{ for all } \sigma \in \Sigma_u, \quad P' \preceq P_k\} \\ &= P_k \bigwedge \left(\bigwedge_{\sigma \in \Sigma_u} M_\sigma(P_k) \right), \\ P^* &= P_k \quad \text{for all } k \geq k^*, \\ P^\uparrow &= R(G, P^*). \end{aligned}$$

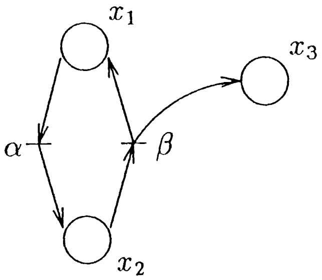

FIG. 2. *Petri net of the small factory.*

Here $k^* \leq |P|$. To verify the above iteration, we have to note only that [25] $P^* = [P]$ (the weakest subpredicate of P that is invariant under the flow induced by uncontrollable events) and use Proposition 8 of [18].

For the purpose of supervisory control, only [P] has to be computed and $P^{\uparrow}$ is not required [19]. We claim that knowing $[P]$ is not always necessary; knowing k^* is enough. To see this, recall that the above recursion for computing $[P]$ ends after k^* steps. This means that if a state $q \in P$, then either $q \in [P]$ or $q \notin [P]$ and there exists a string s of uncontrollable events of length less than or equal to k^* such that $\delta(q, s) \notin P$ (δ is the transition function of the discrete-event system). Therefore, to check whether $q \in [P]$ at any state q, we need only examine strings of uncontrollable events of length less than or equal to k^*. This is a lookahead policy. (See [4] and its references for other approaches to and applications of lookahead policies.) If k^* is not large, this forward search can be done on-line. Note that computation of k^* is done *off-line*. When the number of states, $|Q|$, is not finite, e.g., in vector discrete-event systems (VDES), k^* may still be finite. For VDES, k^* (if finite) may be calculated *off-line* using integer linear programming *without* the burden of computing $[P]$. The details are left for future research.

To illustrate the above point, consider a small factory consisting of 2 machines and a buffer with capacity 3. The Petri net of the factory is shown in Figure 2. Here x_1 is the number of idle machines, x_2 is the number of working machines, and x_3 is the number of workpieces produced. Event α ("take a workpiece") is controllable, while β ("one workpiece done") is uncontrollable. Since $x_1 + x_2 = 2$, the state of the system is described by two variables; we take $x := [x_2, x_3]$. The state graph of the system is shown in Figure 3. Horizontal transitions are α and diagonal ones β. The objective of supervision is to prevent buffer overflow; i.e., $x \in P$ iff $0 \leq x_3 \leq 3$ and $0 \leq x_2 \leq 2$. We assume initially $x_2 = x_3 = 0$. The sequence P_k can be obtained by inspection and is shown in Figure 3. In this figure, predicate P_k holds on those states that are below its corresponding dashed line. We see that $k^* = 2$, so to check whether $x \in [P]$, one has to examine strings β and $\beta\beta$. In general with n machines and a buffer capacity b, $k^* = \min(n, b)$.

Example 6. *The relational coarsest partition problem (RCP).* Consider a finite-state labeled transition system [1] $\mathcal{S} = (Q, \Sigma, R, q_0)$, where Q is the set of states and Σ the set of elementary actions (events). For simplicity we assume $\Sigma = \{\alpha\}$, $|\Sigma| = 1$. R is a binary relation on Q such that $(q, q') \in R$ iff $q' \in \alpha(q)$ with $\alpha(q)$ denoting the set of states reachable from q via a single α transition. Let $\pi = \{B_1, \ldots, B_p\}$ be a partition of Q, with B_i denoting the blocks of π. Then π is compatible with R [8] iff

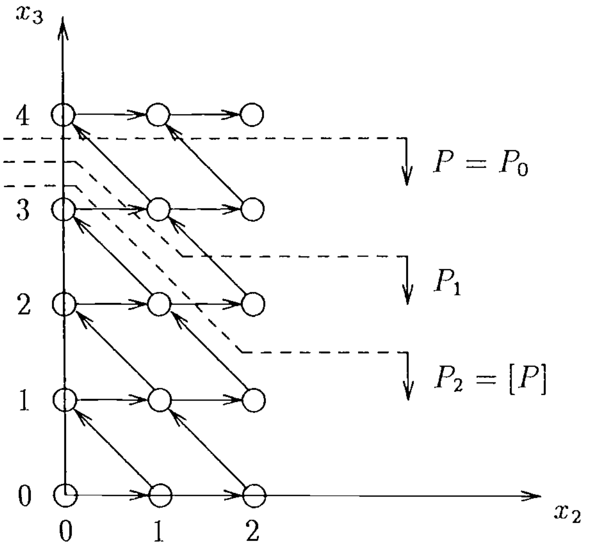

FIG. 3. *State graph.*

whenever q, q' are in the same block B_i, for any block B_j,

$$\alpha(q) \cap B_j \neq \emptyset \Leftrightarrow \alpha(q') \cap B_j \neq \emptyset.$$

Equivalently π is compatible with R iff for each pair of blocks B_i and B_j, either $B_i \subseteq R^{-1}(B_j)$ or $B_i \cap R^{-1}(B_j) = \emptyset$ [8]. Given a partition ρ, the RCP is to find the coarsest partition $\rho^\uparrow$ which is finer than ρ and compatible with R [11], [23]. For applications of the RCP in observer theory and the study of equivalence of labeled transition systems, the reader may refer to [1] and [16] and their references.

Let L be the set of partitions of (or equivalence relations on) Q. For two partitions π_1 and π_2, let $\pi_1 \leq \pi_2$ iff for every pair of blocks $B_1 \in \pi_1$ and $B_2 \in \pi_2$, either $B_1 \subseteq B_2$ or $B_1 \cap B_2 = \emptyset$. Then L partially ordered by $\leq$ forms a complete lattice [2]. In this lattice $\perp = \{\{q\} \mid q \in Q\}$ and $\top = \{Q\}$. Let S be the set of partitions compatible with R. Now we define $\Delta \subseteq L \times L$ to be

$$\begin{aligned}\Delta = \{(\pi_1, \pi_2) \mid \pi_1, \pi_2 \in L \text{ and}\\ ((\text{for all } B_1 \in \pi_1, \text{ for all } B_2 \in \pi_2)\ B_1 \subseteq R^{-1}(B_2) \quad \text{or} \quad B_1 \cap R^{-1}(B_2) = \emptyset)\}.\end{aligned}$$

Note that $(\pi_1, \pi_2) \in \Delta$ iff whenever q and q' are in the same block $B_1 \in \pi_1$, then for any block $B_2 \in \pi_2$,

$$\alpha(q) \cap B_2 \neq \emptyset \quad \Leftrightarrow \quad \alpha(q') \cap B_2 \neq \emptyset.$$

Δ is the generalization of the set of *partition pairs* of [9] to nondeterministic systems. When $\mathcal{S}$ is deterministic, Δ is a pair algebra [9]. In our case, $\mathcal{S}$ can be nondeterministic; therefore Δ is not a pair algebra in general. For example, consider $Q = \{a, b, c, d\}$ and $\alpha(a) = \{a, c\}$, $\alpha(b) = \{b, d\}$, $\alpha(c) = \alpha(d) = \emptyset$. Let $\pi_1 = \pi_1' = \{\{a, b\}, \{c, d\}\}$, $\pi_2 = \{\{a, b\}, \{c, d\}\}$, $\pi_2' = \{\{a, d\}, \{b, c\}\}$. Then $(\pi_1, \pi_2) \in \Delta$, $(\pi_1', \pi_2') \in \Delta$, but $(\pi_1 \wedge \pi_1', \pi_2 \wedge \pi_2') \notin \Delta$. Obviously π is compatible with R iff $(\pi, \pi) \in \Delta$; therefore Δ is S-reflexive and

$$\rho^\uparrow = \sup\{\pi \mid \pi \in L_\Delta, \quad \pi \leq \rho\}.$$

Using Propositions 1 and 2, the reader can show that Δ satisfies the assumptions (i) and (ii) of Theorem 2.

By Definition 2, for every $\rho \in L$,

$$\hat{\Psi}(\rho) = \sup\{\pi \mid (\pi, \rho) \in \Delta, \;\; \pi \leq \rho\}.$$

Let $\rho = \{B_1, \ldots, B_m\}$. Following [23], for a partition $\pi \in L$ and a subset $X \subseteq Q$, let $\mathit{split}(X, \pi)$ be the refinement of π obtained by replacing each block $B \in \pi$ such that $B \cap R^{-1}(X) \neq \emptyset$ and $B - R^{-1}(X) \neq \emptyset$, with the two blocks $B' = B \cap R^{-1}(X)$ and $B'' = B - R^{-1}(X)$. The reader can now verify that the following iteration computes $\hat{\Psi}(\rho)$:

$$\begin{aligned} \pi_0 &= \rho, \\ \pi_k &= \mathit{split}(B_k, \pi_{k-1}), \qquad 1 \leq k \leq m, \\ \hat{\Psi}(\rho) &= \pi_m. \end{aligned}$$

Therefore, using Theorem 2, the relational coarsest partition problem can be solved with the following recursion:

$$\begin{aligned} \rho_0 &= \rho, \\ \rho_{k+1} &= \hat{\Psi}(\rho_k), \\ \rho^{\uparrow} &= \rho_k \quad \text{for all } k \geq |Q| - 1. \end{aligned}$$

This procedure can be generalized to the case $|\Sigma| > 1$. The resulting algorithm turns out to be the one given in Proposition 3.10 of [8].

4. Dual results. Dual results for computing infimal elements are presented here. The proofs are similar to those in section 2 and are omitted.

Given a poset L, an operator $\varphi : L \to L$ is called *expansive* iff $x \leq \varphi(x)$ for all $x \in L$.

THEOREM 5. *Let L be a complete lattice, $S \subseteq L$ be a lower semilattice under the meet operation $\wedge$ of L, and $\varphi : L \to L$ be an operator with the following properties:*

(i) $S = \{x \in L \mid \varphi(x) = x\}$,

(ii) *$\varphi(\cdot)$ is monotone,*

(iii) *$\varphi(\cdot)$ is expansive.*

Let $z \in L$, and suppose that there exists an integer $k^* \geq 0$ such that $\varphi^{k^*}(z) = \varphi^{k^*+1}(z)$. Then

$$z^{\downarrow} := \inf\{x \mid x \in S, \; z \leq x\} = \varphi^k(z) \quad \text{for all } k \geq k^*. \qquad \square$$

For a binary relation $\Delta \subseteq L \times L$, the *constrained infimum operator* is defined as

$$\hat{\psi}(x) := \inf\{y \mid (x, y) \in \Delta, \quad x \leq y\}.$$

This operator is expansive. If Δ is S-reflexive and $\hat{\psi}(\cdot)$ satisfies properties (i) and (ii) of Theorem 5, then the iteration of the theorem can be used for computing $z^{\downarrow}$. If for every set of pairs $\{(x, y_\alpha) \in \Delta \mid \alpha \in A\}$, with A being some index set, we have $(x, \wedge_\alpha y_\alpha) \in \Delta$, then $L_\Delta = \{x \mid \hat{\psi}(x) = x\}$. Also, if $(x, y) \in \Delta$ and $x' \leq x$ imply $(x', y) \in \Delta$, then $\hat{\psi}(\cdot)$ is monotone.

Let the *infimum operator* corresponding to a relation $\Delta \subseteq L \times L$ be

$$\psi(x) := \inf\{y \mid (x, y) \in \Delta\}.$$

Assume that Δ is S-reflexive, $L_\Delta = \{x \in L \mid \psi(x) \leq x\}$, and $\psi(\cdot)$ is monotone. If the iteration

$$z_0 = z,$$
$$z_{k+1} = \psi(z_k) \vee z$$

terminates in a finite number of steps—say, k^*—then

$$z^{\downarrow} = \inf\{x \mid x \in S, \quad z \leq x\} = z_k \quad \text{for all } k \geq k^*.$$

If (i) for every set of pairs $\{(x, y_\alpha) \in \Delta \mid \alpha \in A\}$, with A being some index set, $(x, \wedge_\alpha y_\alpha) \in \Delta$, and (ii) $(x, y) \in \Delta$ and $y \leq y'$ imply $(x, y') \in \Delta$, then $L_\Delta = \{x \in L \mid \psi(x) \leq x\}$. If $(x, y) \in \Delta$ and $x' \leq x$ imply $(x', y) \in \Delta$, then $\psi(\cdot)$ is monotone.

5. Conclusion. In this paper, we introduced constrained supremum and supremum operators to obtain a general procedure, the Δ-method, for computing supremal elements of upper semilattices. These elements are used in system theory, and for some of them, specific algorithms are given in the literature. We applied our procedure to some well-known examples, and in all cases the algorithms available in the literature turned out to be instances of our procedure. These iterations are also informative from a practical point of view. For instance, in the case of supremal controllable subpredicate, the recursion resulted in a lookahead policy for supervisory control in which the required length of the lookahead window was equal to the number of the recursion steps.

Dual results for infimal elements of lower semilattices were presented for completeness.

Defining a suitable binary relation on the lattice is an important step in the procedure. This is not always easy. Also for lattices that do not satisfy the descending chain condition, establishing finite termination of the iteration is not necessarily trivial; see, e.g., [28]. Nevertheless, the procedure covers a variety of cases in control theory, especially in discrete-event system theory.

SMOOTH NORMAL APPROXIMATIONS OF EPI-LIPSCHITZIAN SUBSETS OF $\mathbb{R}^n$*

BERNARD CORNET[†] AND MARC-OLIVIER CZARNECKI[‡]

Abstract. A sequence (M_k) of closed subsets of $\mathbb{R}^n$ converges normally to $M \subset \mathbb{R}^n$ if (sc) $M = \limsup M_k = \liminf M_k$ in the sense of Painlevé–Kuratowski and (nc) $\limsup \mathrm{G}(N_{M_k}) \subset \mathrm{G}(N_M)$, where $\mathrm{G}(N_M)$ (resp., $\mathrm{G}(N_{M_k})$) denotes the graph of N_M (resp., N_{M_k}), Clarke's normal cone to M (resp., M_k).

This paper studies the normal convergence of subsets of $\mathbb{R}^n$ and mainly shows two results. The first result states that every closed epi-Lipschitzian subset M of $\mathbb{R}^n$, with a compact boundary, can be approximated by a sequence of smooth sets (M_k), which converges normally to M and such that the sets M_k and M are lipeomorphic for every k (i.e., the homeomorphism between M and M_k and its inverse are both Lipschitzian). The second result shows that, if a sequence (M_k) of closed subsets of $\mathbb{R}^n$ converges normally to an epi-Lipschitzian set M, and if we additionally assume that the boundary of M_k remains in a fixed compact set, then, for k large enough, the sets M_k and M are lipeomorphic.

In Cornet and Czarnecki [*Cahier Eco-Maths 95-55,* 1995], direct applications of these results are given to the study (existence, stability, etc.) of the generalized equation $0 \in f(x^*) + N_M(x^*)$ when M is a compact epi-Lipschitzian subset of $\mathbb{R}^n$ and $f : M \to \mathbb{R}^n$ is a continuous map (or more generally a correspondence).

Key words. epi-Lipschitzian, normal convergence, smooth approximation, lipeomorphism, homeomorphism, Clarke's normal cone

1. Introduction.

A closed subset M of $\mathbb{R}^n$ is said to be epi-Lipschitzian if its Clarke's normal cone $N_M(x)$ is pointed (i.e., if $N_M(x) \cap -N_M(x) = \{0\}$) at every $x \in M$. This class of sets, introduced in optimization by Rockafellar [16], is of particular importance since it includes both (i) closed convex sets with a nonempty interior and (ii) sets defined by finite smooth inequality constraints satisfying a nondegeneracy assumption (independence of the binding constraints). Closed epi-Lipschitzian subsets M of $\mathbb{R}^n$ are equivalently defined as sets that can be locally written as the epigraph of a Lipschitzian function (see [16]).

A sequence (M_k) of closed subsets of $\mathbb{R}^n$ converges normally to $M \subset \mathbb{R}^n$ if (sc) $M = \limsup M_k = \liminf M_k$ in the sense of Painlevé–Kuratowski and (nc) $\limsup \mathrm{G}(N_{M_k}) \subset \mathrm{G}(N_M)$, where $\mathrm{G}(N_M) = \{(x,y) \in \mathbb{R}^n \times \mathbb{R}^n | x \in M, y \in N_M(x)\}$ (resp., $\mathrm{G}(N_{M_k})$) denotes the graph of N_M (resp., N_{M_k}), Clarke's normal cone to M (resp., M_k).

This paper studies the normal convergence of subsets of $\mathbb{R}^n$ and mainly shows two results. The first result (Theorem 2.1) states that every closed epi-Lipschitzian subset M of $\mathbb{R}^n$, with a compact boundary, can be approximated by a sequence of smooth sets (M_k), which converges normally to M and such that, for every k, the sets M_k and M are lipeomorphic (i.e., the homeomorphism between M and M_k and its

inverse are both Lipschitzian). Moreover, we prove that one can additionally assume that the approximating sequence (M_k) is internal (resp., external) in the following sense: $M_k \subset \mathrm{int} M_{k+1}$ (resp., $M_{k+1} \subset \mathrm{int} M_k$) for all $k \in \mathbb{N}$. This result extends previous ones in the literature (which do not consider the lipeomorphism properties); see Benoist [1] and (with a different formalism, without the geometrical concept of Clarke's cones) Nečas [15] (in Russian), Massari and Pepe [13], and Doktor [8].

In the above result, the lipeomorphism property is in fact a consequence of the normal convergence of the sequence (M_k). This is a consequence of our second result (Theorem 2.2), which states that if (M_k) is a sequence of closed subsets of $\mathbb{R}^n$ which converges normally to an epi-Lipschitzian set M, then the sets M_k and M are lipeomorphic for k large enough if we additionally assume that, for all k, $\mathrm{bd} M_k$ remains in some given compact set $K \subset \mathbb{R}^n$. In fact, we shall show (Theorem 2.3) that one can weaken assertion (nc) by only assuming that the convex hull of the set $\{p \in \mathbb{R}^n | (x,p) \in \limsup \mathrm{G}(N_{M_k})\}$ is pointed for every $x \in M$.

In [7], direct applications of these results are given to the study (existence, stability, etc.) of the generalized equation $0 \in f(x^*) + N_M(x^*)$ when M is a compact epi-Lipschitzian subset of $\mathbb{R}^n$ and $f : M \to \mathbb{R}^n$ is a continuous map (or more generally a correspondence).

The paper is organized as follows. The definitions and the main results are given in section 2. The proof of the approximation result (Theorem 2.1) is given in section 3, and the proof of the lipeomorphism result (Theorem 2.3) is given in section 4.

2. Definitions and statement of the results.

2.1. Preliminaries[1]**.** Let M be a closed subset of $\mathbb{R}^n$ and let $x \in M$. We define Clarke's normal cone to M at x, denoted $N_M(x)$, in two steps as follows. We first call perpendicular vector to M at x every vector in the set

$$\perp_M(x) = \{v \in \mathbb{R}^n | \exists \alpha > 0, B(x + \alpha v, \alpha \|v\|) \cap M = \emptyset\}.$$

Then Clarke's normal cone to M at x is the closure of the convex hull of the following limiting cone:

$$\hat{N}_M(x) = \{v \in \mathbb{R}^n | \exists (x_k)_{k \in \mathbb{N}} \subset M,\ \forall k \in \mathbb{N},\ \exists v_k \in \perp_M(x_k),\ (x_k) \to x, (v_k) \to v\}.$$

We now define Clarke's tangent cone to M at x, denoted $T_M(x)$, as the negative polar cone of $N_M(x)$, i.e.,

$$T_M(x) = \{u \in \mathbb{R}^n \mid \forall v \in N_M(x), (u|v) \leq 0\}.$$

We recall that a closed subset M of $\mathbb{R}^n$ is said to be epi-Lipschitzian if $N_M(x)$ is pointed (i.e., $N_M(x) \cap -N_M(x) = \{0\}$) for all $x \in M$. We say that M is C^k-smooth if it is a C^k (with $k \in \{1, \dots, \infty\}$) submanifold with a boundary of $\mathbb{R}^n$ of full dimension,

[1] We let $\mathbb{R}_+ = \{x \in \mathbb{R} | x \geq 0\}$. If $x = (x_1, \dots, x_n)$ and $y = (y_1, \dots, y_n)$ belong to $\mathbb{R}^n$, we denote the scalar product of $\mathbb{R}^n$ by $(x|y) = \sum_{i=1}^n x_i y_i$, the Euclidean norm by $\|x\| = \sqrt{(x|x)}$; we denote $B(x,r) = \{y \in \mathbb{R}^n | \ \|x - y\| < r\}$, $\overline{B}(x,r) = \{y \in \mathbb{R}^n | \ \|x - y\| \leq r\}$, $S(x,r) = \{y \in \mathbb{R}^n | \ \|x - y\| = r\}$, $\overline{B} = \overline{B}(0,1)$, and $S = S(0,1)$. If $X \subset \mathbb{R}^n$, $Y \subset \mathbb{R}^n$, and $x \in \mathbb{R}^n$, we let $d(x,X) = \inf_{y \in X} \|x - y\|$ (also denoted $d_X(x)$), and we denote by $X + Y = \{x + y | x \in X, y \in Y\}$ the sum of X and Y, $B(X,r) = X + B(0,r)$, $\mathrm{cl} X$ or $\overline{X}$ the closure of X, $\mathrm{int} X$ the interior of X, $\mathrm{bd} X$ the boundary of X, and $\mathrm{co} X$ the convex hull of X. If X and Y are two nonempty compact subsets of $\mathbb{R}^n$, $\delta(X,Y) = \max\{\sup_{x \in X} d(x,Y), \sup_{y \in Y} d(y,X)\}$ is the Hausdorff distance between X and Y. A correspondence Φ from $X \subset \mathbb{R}^n$ to $\mathbb{R}^m$ is a map from X to the set of all the subsets of $\mathbb{R}^m$ and the graph of Φ, denoted $\mathrm{G}(\Phi)$, is defined by $\mathrm{G}(\Phi) = \{(x,y) \in X \times \mathbb{R}^m | y \in \Phi(x)\}$.

i.e., if for all $\overline{x} \in M$, there is an open neighborhood U of $\overline{x}$ and a C^k function $f : U \to \mathbb{R}$ such that $M \cap U = \{x \in U | f(x) \leq 0\}$, and such that $\nabla f(x) \neq 0$ if $f(x) = 0$. M is said to be smooth if it is C^∞-smooth.

We recall the following definitions and properties associated with a sequence (M_k) of subsets of $\mathbb{R}^n$ (see, for example, Kuratowski [12]):

$$\begin{aligned} \liminf M_k &= \{x \in \mathbb{R}^n | \exists (x_k) \subset \mathbb{R}^n, x_k \to x, x_k \in M_k \text{ for all } k\}; \\ \limsup M_k &= \{x \in \mathbb{R}^n | \exists (x_k) \subset \mathbb{R}^n, \exists \varphi \in \mathcal{I}, x_k \to x, x_k \in M_{\varphi(k)} \text{ for all } k\},^2 \end{aligned}$$

where $\mathcal{I}$ is the set of all increasing maps $\varphi : \mathbb{N} \to \mathbb{N}$.

We recall that the inclusion $\liminf M_k \subset \limsup M_k$ always holds true; the sequence (M_k) is said to be set-convergent if $\liminf M_k = \limsup M_k$. We say that the sequence (M_k) is smooth if the set M_k is smooth for k large enough. We say that it is increasing (resp., decreasing) if $M_k \subset \text{int} M_{k+1}$ (resp., $M_{k+1} \subset \text{int} M_k$) for all $k \in \mathbb{N}$. If (M_k) is an increasing (resp., decreasing) sequence, then one notices that it set-converges to some $M \subset \mathbb{R}^n$ if and only if $M = \text{cl}(\cup_{k \in \mathbb{N}} M_k)$ (resp., $M = \cap_{k \in \mathbb{N}} M_k$). An increasing (resp., decreasing) converging sequence is also called an internal (resp., external) approximation of its set-limit.

2.2. Statement of the results. We give a stronger notion of set-convergence which involves both the set-convergence and the convergence of the graph of the normal cones in the following sense.

Definition 2.1. *We say that a sequence (M_k) of closed subsets of $\mathbb{R}^n$ is a normal approximation of a closed subset $M \subset \mathbb{R}^n$ (or converges normally to M) if the two following assertions hold:*

(sc) *(set convergence)* $M = \limsup M_k = \liminf M_k$;
(nc) *(normal convergence)* $\limsup \mathrm{G}(N_{M_k}) \subset \mathrm{G}(N_M)$.

Remark 2.1 (the convex case). Let (M_k) be a sequence of closed convex subsets of $\mathbb{R}^n$. Assume that (M_k) set-converges to some subset $M \subset \mathbb{R}^n$. Then one easily notices that the set M is convex and that (M_k) is a normal approximation of M.

The next theorem shows the existence of internal and external smooth normal approximations of a compact epi-Lipschitzian subset of $\mathbb{R}^n$, which satisfy additional properties also of interest for themselves (in fact we weaken the compactness assumption by assuming only that M is closed and that $\text{bd}M$ is compact). We recall that subsets M and N of $\mathbb{R}^n$ are lipeomorphic if there exists a map $\Phi : M \to N$ which is a lipeomorphism, i.e., is a Lipschitzian invertible map with a Lipschitzian inverse.

Theorem 2.1. *Let M be a closed epi-Lipschitzian subset of $\mathbb{R}^n$, such that* $\text{bd}M$ *is nonempty and compact. Then there exists a smooth internal normal approximation and a smooth external normal approximation of M which both additionally satisfy the following properties:*

(lip) *the sets M_k and M are lipeomorphic for all k;*
(lip^c) *the sets $\mathbb{R}^n \setminus \text{int} M_k$ and $\mathbb{R}^n \setminus \text{int} M$ are lipeomorphic for all k;*
(L) *there is $\ell > 0$ and a compact subset $K \subset \mathbb{R}^n$ such that, for all k,* $\text{bd}M_k \subset K$ *and*

$$\delta(\text{bd}M_k, \text{bd}M_{k+1}) \leq \ell \min\{\|x - y\| \, | x \in \text{bd}M_k, y \in \text{bd}M_{k+1}\}.$$

Theorem 2.1 is proved in section 3. A general discussion about assertion (L) is given in the next section.

[2] Equivalently, $\limsup M_k = \cap_{p \in \mathbb{N}} \text{cl}(\cup_{k \geq p} M_k)$. Note also that for every subsequence $(M_{\varphi(k)})$ of (M_k), one has that $\liminf M_k \subset \liminf M_{\varphi(k)} \subset \limsup M_{\varphi(k)} \subset \limsup M_k$.

At this stage, it is worth pointing out that in Theorem 2.1 the two lipeomorphism assertions (lip) and (lip$^{\mathrm{c}}$) are a consequence of the normal convergence of the sequence (M_k) as is shown in the next result.

THEOREM 2.2. *Let (M_k) be a sequence of closed subsets of $\mathbb{R}^n$ such that the boundaries* $\mathrm{bd}M_k$ *remain in a given compact subset $K \subset \mathbb{R}^n$. Assume that (M_k) set-converges to some subset $M \subset \mathbb{R}^n$ and that*

($*$) *(M_k) converges normally to M, and M is epi-Lipschitzian.*

Then, for k large enough,

(i) *the sets M, $\mathbb{R}^n \setminus \mathrm{int}M$, M_k and $\mathbb{R}^n \setminus \mathrm{int}M_k$ are epi-Lipschitzian;*

(ii) *M_k is lipeomorphic to M and $\mathbb{R}^n \setminus \mathrm{int}M_k$ is lipeomorphic to $\mathbb{R}^n \setminus \mathrm{int}M$.*

Theorem 2.2 is a consequence of the following result, which slightly weakens assertion ($*$) by noticing that the condition (nc) of normal convergence implies that

$$\{p \in \mathbb{R}^n | (x,p) \in \limsup \mathrm{G}(N_{M_k})\} = \limsup_{x' \to x, k \to \infty} N_{M_k}(x') \subset N_M(x).$$

THEOREM 2.3. *Theorem* 2.2 *remains true if one replaces assertion* ($*$) *with the following assertion:*

($**$) $\mathrm{co}\limsup_{x' \to x, k\to\infty} N_{M_k}(x')$ *is pointed for all $x \in M$.*

The proof of Theorem 2.3 is given in section 4.

Remark 2.2. Theorem 2.2 and Theorem 2.3 may not be true if $\mathrm{bd}M_k$ does not remain in a fixed compact set K. Consider $M = \mathbb{R} \times \mathbb{R}_+$ and the smooth internal normal approximation of M defined by $M_k = \mathbb{R} \times [1/k, \infty) \setminus B((k, 3/k), 1/k)$ for $k \geq 1$. Then, for every k, M_k is clearly not homeomorphic to M.

Remark 2.3. Theorem 2.2 may not be true if the set-limit M is not epi-Lipschitzian. Consider $M = \{0\}$ in $\mathbb{R}$ and the smooth external normal approximation of M defined by $M_k = [-1/k, 1/k]$. Then for every k, M_k is not homeomorphic to M. Similarly, Theorem 2.3 may not be true without the assumption that $\mathrm{co}\limsup_{x' \to x, k\to\infty} N_{M_k}(x')$ is pointed for all $x \in M$, even if one assume that M is epi-Lipschitzian. Consider $M = [1, 1]$ in $\mathbb{R}$ and the smooth internal normal approximation of M defined by $M_k = [-1, -1/k] \cup [1/k, 1]$, and notice that $\mathrm{co}\limsup_{x' \to 0, k\to\infty} N_{M_k}(x') = \mathbb{R}$.

Remark 2.4. Theorem 2.3 may not be true if we do not assume that $\limsup M_k = \liminf M_k$. Consider $M_{2k} = \overline{B}(0,1)$, $M_{2k+1} = \overline{B}(0,1) \setminus B(0, 1/2)$ (or $M_{2k+1} = \emptyset$), and notice that $\overline{B}(0,1) = \limsup M_k$.

2.3. General remarks about assertion (L).

Remark 2.5. There may exist a normal (external or internal) approximation satisfying all the conclusions of Theorem 2.1 except for assertion (L). Consider the subset $M = [0,1]$ of $\mathbb{R}$ and the sets $M_k = [-1/k, 1 + 1/2^k]$.

Remark 2.6. If $\mathrm{bd}M$ is not compact, there may not exist an internal (or an external) normal approximation of M which satisfies assertion (L). Consider the following closed epi-Lipschitzian subset of $\mathbb{R}$:

$$M = \left(\mathbb{R}_- \setminus \cup_{k=1}^{\infty}\left(-k - \frac{1}{k+1}, -k + \frac{1}{k+1}\right)\right) \cup \left(\cup_{k=1}^{\infty}\left[k - \frac{1}{k+1}, k + \frac{1}{k+1}\right]\right).$$

Then, if (M_k) is any smooth internal (or external) normal approximation of M, we let the reader check that it does not satisfy assertion (L).

Remark 2.7. Note that the inequality

$$\delta(X,Y) \geq \min\{\|x - y\| \, | x \in X, y \in Y\}$$

is always true if X and Y are two nonempty compact subsets of $\mathbb{R}^n$. Hence, one necessarily has $\ell \geq 1$ in assertion (L) of Theorem 2.1.

Remark 2.8. If we additionally assume that (M_k) is increasing or decreasing, then

$$\text{(L}'\text{)} \qquad \forall k,\ \delta(\text{bd}M_k, \text{bd}M) \leq \ell \min\{\|x-y\| \,|x \in \text{bd}M, y \in \text{bd}M_k\}.$$

Indeed, one just needs to notice that $\delta(\text{bd}M_k, \text{bd}M) \leq \sum_{i=k}^{\infty} \delta(\text{bd}M_i, \text{bd}M_{i+1})$ and that

$$\min\{\|x-y\| \,|x \in \text{bd}M, y \in \text{bd}M_k\} \geq \sum_{i=k}^{\infty} \min\{\|x-y\| \,|x \in \text{bd}M_i, y \in \text{bd}M_{i+1}\}.$$

Assertion (L$'$) is no longer true if we do not assume that the sequence (M_k) is increasing or decreasing. Consider the set $M = [0,1]$, the sets $M_{2k} = [-1/k, 1]$ and $M_{2k+1} = [0, 1 + 1/(k+1)]$ for all $k \geq 1$. Then (M_k) is a smooth approximation of M which satisfies assertion (L), but the above property (L$'$) is not true.

2.4. Other concepts of normal convergence.

2.4.1. Involving the subdifferential of the distance function. We first recall the definition of Clarke's subdifferential of a locally Lipschitzian function.[3] Let U be an open subset of $\mathbb{R}^n$ and consider $f : U \to \mathbb{R}$; if f is differentiable at $x \in U$, we denote $\nabla f(x)$ the gradient of f at x. If f is locally Lipschitzian, its subdifferential $\partial f(x)$ at $x \in U$ is defined by

$$\partial f(x) = \text{co}\{\lim_{k\to\infty} \nabla f(x_k) | x_k \to x,\ x_k \in \text{Dom}(\nabla f)\},$$

where $\text{Dom}(\nabla f)$ is the set on which f is differentiable. In the case of the distance function d_M to a closed set $M \subset \mathbb{R}^n$, one can be more precise. Indeed, from Clarke [4, Thm. 2.5.6],

$$\partial d_M(x) = \text{co}\Big((\hat{N}_M(x) \cap S) \cup \{0\}\Big), \tag{1}$$

where $\hat{N}_M(x)$ is the limiting normal cone defined previously and S is the unit sphere in $\mathbb{R}^n$.

It seems natural to compare the normal convergence with the following concept of ∂-convergence, in which one replaces the normal cone by the subdifferential of the distance function. More precisely, we say that a sequence (M_k) of closed subsets of $\mathbb{R}^n$ ∂-converges to a closed subset $M \subset \mathbb{R}^n$ if it satisfies assertion (sc) together with

(∂c) $\quad \limsup \text{G}(\partial d_{M_k}) \subset \text{G}(\partial d_M)$.

It is worth noticing that the ∂-convergence can be formulated only in terms of the distance function, by noticing that assertion (sc) can be equivalently reformulated as follows:

(sc$'$) $\quad \forall x \in \mathbb{R}^n$, $\lim_{k\to\infty} d_{M_k}(x) = d_M(x)$.

The link between normal convergence and ∂-convergence can be summarized as follows. It will appear that the concept of ∂-convergence is too strong (for a matter of normalization), even in the epi-Lipschitzian case. Indeed, in this paper we

[3] If $X \subset \mathbb{R}^n$, a map $f : X \to \mathbb{R}^m$ is locally Lipschitzian if, for all $x \in X$, there is a neighborhood U of x and a real number $K \geq 0$ such that $\|f(y) - f(z)\| \leq K\|y - z\|$ for all y and z in U.

show that every compact epi-Lipschitzian set can be approximated in the sense of normal convergence by a sequence of smooth sets. This result is no longer true with the ∂-convergence as shown below (Proposition 2.2) by taking $M = \mathbb{R}^2 \setminus \mathrm{int}\mathbb{R}^2_+$. Furthermore, in the epi-Lipschitzian case, the following proposition shows that the ∂-convergence implies the normal convergence, a result which is no longer true in general (see Remark 2.9).

Proposition 2.1. *Let (M_k) be a sequence of closed subsets of $\mathbb{R}^n$ which ∂-converges to some epi-Lipschitzian set $M \subset \mathbb{R}^n$. Then (M_k) converges normally to the set M.*

Proof of Proposition 2.1. Let $(x,p) \in \limsup \mathrm{G}(N_{M_k})$. Then there is a sequence (x_k) converging to x, a sequence (p_k) converging to p, and an increasing map $\varphi : \mathbb{N} \to \mathbb{N}$, such that $x_k \in M_{\varphi(k)}$ and $p_k \in N_{M_{\varphi(k)}}(x_k)$ for all k. Since $N_{M_{\varphi(k)}}(x_k) = \mathrm{cl}[\cup_{\lambda \geq 0} \lambda \partial d_{M_{\varphi(k)}}(x_k)]$ (see Clarke [4]) for all k, there is a sequence $(\lambda_r^k)_{r\in\mathbb{N}}$ in $\mathbb{R}_+$ and a sequence $(v_r^k)_{r\in\mathbb{N}}$ in $\partial d_{M_{\varphi(k)}}(x_k)$ such that $\lambda_r^k v_r^k$ converges to p_k when $r \to \infty$. Hence, without any loss of generality (using a diagonal argument), we may assume that $p = \lim_{k\to\infty} \lambda_k v_k$, with $\lambda_k \geq 0$ and $v_k \in \partial d_{M_{\varphi(k)}}(x_k) \subset \overline{B}(0,1)$, and that the bounded sequence (v_k) converges to some $v \in \mathbb{R}^n$. Then, from above and (1), for every integer k,

$$v_k \in \partial d_{M_{\varphi(k)}}(x_k) = \mathrm{co}\Big((\hat{N}_{M_{\varphi(k)}}(x_k) \cap S) \cup \{0\}\Big).$$

Hence, from Carathéodory's theorem, there are $n+1$ elements (v_k^i, λ_k^i) ($i \in \{1,\dots,n+1\}$) in $\mathbb{R}^n \times \mathbb{R}_+$ such that $v_k^i \in \hat{N}_{M_{\varphi(k)}}(x_k) \cap S \subset \partial d_{M_{\varphi(k)}}(x_k)$, $\sum_{i=1}^{n+1} \lambda_k^i = 1$, and $\mu_k \in [0,1]$ such that

$$v_k = \mu_k \sum_{i=1}^{n+1} \lambda_k^i v_k^i.$$

Again, without any loss of generality, we may assume that $(v_k^1,\dots,v_k^{n+1},(\lambda_k^1,\dots,\lambda_k^{n+1}),\mu_k)$ converges to some element $(v^1,\dots,v^{n+1},(\lambda^1,\dots,\lambda^{n+1}),\mu) \in S^{n+1} \times \Sigma \times [0,1]$, where Σ is the unit simplex of $\mathbb{R}^{n+1}$. From assertion (∂c), we get that $v \in \partial d_M(x)$ and that $v^i \in \partial d_M(x)$ for all $i \in \{1,\dots,n+1\}$. But for all i, from above $v^i \in S$ and $v^i \in \mathrm{co}\Big((\hat{N}_M(x) \cap S) \cup \{0\}\Big)$, noticing that

$$\mathrm{co}\Big((\hat{N}_M(x) \cap S) \cup \{0\}\Big) \cap S = \hat{N}_M(x) \cap S,$$

we deduce that $v^i \in \hat{N}_M(x) \cap S$. Then $w = \sum_{i=1}^{n+1} \lambda^i v^i \in \mathrm{co}(\hat{N}_M(x) \cap S)$, which does not contain 0 since M is epi-Lipschitzian; hence $w \neq 0$. Recalling that $p = \lim_{k\to\infty} \lambda_k v_k = \lim_{k\to\infty} \lambda_k \mu_k \sum_{i=1}^{n+1} \lambda_k^i v_k^i$, the sequence $(\lambda_k \mu_k)$ converges to $\rho = \|p\|/\|w\|$, and $p = \rho w$ with $w \in \mathrm{co}(\hat{N}_M(x) \cap S) \subset \partial d_M(x)$; hence $p \in N_M(x)$. This shows that (M_k) converges normally to M. □

Remark 2.9. Proposition 2.1 may no longer be true if M is not epi-Lipschitzian. Consider the set

$$M = \{(x,y) \in \mathbb{R}^2 | y \leq \sqrt{|x|}\}$$

and, for every integer $k \geq 1$, the set

$$M_k = \{(x,y) \in \mathbb{R}^2 | [y \geq 0 \text{ and } y \leq \sqrt{|x|} - 1/k] \text{ or } [y < 0 \text{ and } y \leq |kx| - 1/k]\}.$$

Then the sequence (M_k) ∂-converges to M (note that $\partial d_M(0) = [-1,1] \times \{0\} = \limsup_{x' \to 0, k \to \infty} \partial d_{M_k}(x')$). But $\limsup_{x' \to 0, k \to \infty} N_{M_k}(x') = \mathbb{R} \times \mathbb{R}_+$ and $N_M(0) = \mathbb{R} \times \{0\}$; hence assertion (nc) is not satisfied. □

The next proposition shows that the concept of ∂-convergence is too strong (for a matter of normalization).

Proposition 2.2. *The set* $\mathbb{R}^2 \setminus \mathrm{int}\mathbb{R}^2_+$, *i.e., the complementary of the interior of* $\mathbb{R}^2_+$ *in* $\mathbb{R}^2$, *cannot be approximated, in the sense of the* ∂*-convergence, by a sequence of smooth sets.*

Proof of Proposition 2.2. Assume that it is not true, and let (M_k) be a sequence of smooth subsets of $\mathbb{R}^2$ which ∂-converges to $M = \mathbb{R}^2 \setminus \mathrm{int}\mathbb{R}^2_+$. From Proposition 2.1, since M is clearly epi-Lipschitzian, (M_k) converges normally to M; this implies that $(\mathbb{R}^2 \setminus \mathrm{int} M_k)$ converges normally to $\mathbb{R}^2 \setminus \mathrm{int} M = \mathbb{R}^2_+$ (see Proposition 3.1) and we shall prove later (Lemma 4.1) that this implies

$$\perp_{\mathbb{R}^2_+}(0) \subset \limsup_{x \to 0, k \to \infty} N_{\mathbb{R}^2 \setminus \mathrm{int} M_k}(x).$$

Since $v = -(1/\sqrt{2}, 1/\sqrt{2}) \in \perp_{\mathbb{R}^2_+}(0) (= -\mathbb{R}^2_+)$, the above inclusion implies that there is a sequence (x_k) converging to 0, a sequence (v_k) converging to v, and an increasing map $\varphi : \mathbb{N} \to \mathbb{N}$, such that, for all k, $x_k \in \mathrm{bd}(\mathbb{R}^2 \setminus \mathrm{int} M_{\varphi(k)}) = \mathrm{bd} M_{\varphi(k)}$ and $v_k \in N_{\mathbb{R}^2 \setminus \mathrm{int} M_{\varphi(k)}}(x_k) = -N_{M_{\varphi(k)}}(x_k)$ (since the set $M_{\varphi(k)}$ is smooth). For k large enough, $v_k \neq 0$; since the set $M_{\varphi(k)}$ is smooth, $-v_k/\|v_k\|$ is the unique element in $N_{M_{\varphi(k)}}(x_k) \cap S$ and hence belongs to $\partial d_{M_{\varphi(k)}}(x_k)$. Then the sequence $(-v_k/\|v_k\|)$ converges to $-v$, which, from assertion (∂c), belongs to $\partial d_M(0)$. Hence,

$$-v = (1/\sqrt{2}, 1/\sqrt{2}) \in \partial d_M(0) = \mathrm{co}\{(1,0),(0,1),(0,0)\},$$

which is a contradiction. □

2.4.2. Involving the limiting normal cone. We now compare the normal convergence with the following concept of $\hat{N}$-convergence, in which one replaces Clarke's normal cone N_M with the limiting normal cone $\hat{N}_M$ (see Mordukhovich [14]) defined previously. More precisely, we say that a sequence (M_k) of closed subsets of $\mathbb{R}^n$ $\hat{N}$-converges to a closed subset $M \subset \mathbb{R}^n$ if it satisfies assertion (sc) together with

($\hat{\mathrm{n}}$c) $\quad \limsup \mathrm{G}(\hat{N}_{M_k}) \subset \mathrm{G}(\hat{N}_M)$.

The next proposition shows that the $\hat{N}$-convergence and the ∂-convergence are in fact equivalent.

Proposition 2.3. *Let* (M_k) *be a sequence of closed subsets of* $\mathbb{R}^n$ *and let* M *be a closed subset of* $\mathbb{R}^n$. *Then* (M_k) $\hat{N}$*-converges to* M *if and only if* (M_k) ∂*-converges to the set* M.

Proof of Proposition 2.3 ($\hat{N}$-convergence $\Rightarrow$ ∂-convergence). Let

$$(x, v) \in \limsup \mathrm{G}(\partial d_{M_k}).$$

Then there is a sequence (x_k) converging to x, a sequence (v_k) converging to v, and an increasing map $\varphi : \mathbb{N} \to \mathbb{N}$, such that $x_k \in M_{\varphi(k)}$ and $v_k \in \partial d_{M_{\varphi(k)}}(x_k)$ for all k. Since from (1)

$$\partial d_{M_{\varphi(k)}}(x_k) = \mathrm{co}\Big((\hat{N}_{M_{\varphi(k)}}(x_k) \cap S) \cup \{0\}\Big),$$

from Carathéodory's theorem, there are $n+1$ elements (v_k^i, λ_k^i) ($i \in \{1, \ldots, n+1\}$) in

$\mathbb{R}^n \times \mathbb{R}_+$ and an element $\mu_k \in [0,1]$ such that $v_k^i \in \hat{N}_{M_{\varphi(k)}}(x_k) \cap S$, $\sum_{i=1}^{n+1} \lambda_k^i = 1$, and

$$v_k = \mu_k \sum_{i=1}^{m+1} \lambda_k^i v_k^i.$$

Without any loss of generality, we may assume that $(v_k^1, \ldots, v_k^{n+1}, (\lambda_k^1, \ldots, \lambda_k^{n+1}), \mu_k)$ converges to some element $(v^1, \ldots, v^{n+1}, (\lambda^1, \ldots, \lambda^{n+1}), \mu) \in S^{n+1} \times \Sigma \times [0,1]$, where Σ is the unit simplex of $\mathbb{R}^{n+1}$. From assertion ($\hat{\text{n}}$c), we deduce that $v^i \in \hat{N}_M(x) \cap S$ for all $i \in \{1, \ldots, n+1\}$. Then $v \in \text{co}((\hat{N}_M(x) \cap S) \cup \{0\}) = \partial d_M(x)$ from (1). This shows that (M_k) ∂-converges to M.

Proof of Proposition 2.3 (∂-convergence $\Rightarrow$ $\hat{N}$-convergence). Let $(x,p) \in \limsup \mathrm{G}(\hat{N}_{M_k})$. Then there is a sequence (x_k) converging to x, a sequence (p_k) converging to p, and an increasing map $\varphi : \mathbb{N} \to \mathbb{N}$, such that $x_k \in M_{\varphi(k)}$ and $p_k \in \hat{N}_{M_{\varphi(k)}}(x_k)$ for all k. If $p = 0$, then clearly $p \in \hat{N}_M(x)$. Assume now that $p \neq 0$. Then for k large enough, $p_k \neq 0$, and $p_k/\|p_k\|$ converges to $p/\|p\|$. Since $p_k/\|p_k\| \in \hat{N}_{M_{\varphi(k)}}(x_k) \cap S \subset \partial d_{M_{\varphi(k)}}(x_k)$ (from (1)), and since (M_k) ∂-converges to M, we deduce that $p/\|p\| \in \partial d_M(x)$. Since

$$\partial d_M(x) \cap S = \text{co}\Big((\hat{N}_M(x) \cap S) \cup \{0\}\Big) \cap S = \hat{N}_M(x) \cap S,$$

we deduce that $p/\|p\| \in \hat{N}_M(x) \cap S$, hence that $p \in \hat{N}_M(x)$. This shows that the sequence (M_k) $\hat{N}$-converges to M. □

Remark 2.10. The proof of the equivalence between the ∂-convergence and the $\hat{N}$-convergence relies heavily on the following equality:

$$\partial d_M(x) = \text{co}\Big((\hat{N}_M(x) \cap S) \cup \{0\}\Big).$$

The difference between the ∂-convergence and the normal convergence might be explained by the fact that the inclusion

$$\partial d_M(x) \subset \text{co}\Big((N_M(x) \cap S) \cup \{0\}\Big)$$

may be strict, even in the epi-Lipschitzian case. Consider $M = \mathbb{R}^2 \setminus \text{int}\mathbb{R}^2_+$.

3. Proof of the approximation result. The first idea to prove Theorem 2.1 is to smooth the distance function d_M by using a classical convolution argument. Indeed, by doing so one directly gets the existence of a normal smooth approximation of M. However, the lipeomorphism properties are more difficult to obtain and our proof will consist of using a more refined argument of convolution (in fact, by using the representation theorem in [6]).

The proof of Theorem 2.1 has three steps. In the first step, we show that (M_k) is an internal (resp., external) smooth approximation of M which satisfies (lip), (lip$^{\text{c}}$), and (L) if and only if $(\mathbb{R}^n \setminus \text{int}M_k)$ is an external (resp., internal) smooth approximation of $\mathbb{R}^n \setminus \text{int}M$ which satisfies (lip), (lip$^{\text{c}}$), and (L). In view of this equivalence property, it is sufficient to only show in the following the existence of smooth internal approximations of epi-Lipschitzian sets. In the second step, we improve the representation theorem of Cornet and Czarnecki [6] when the epi-Lipschitzian set is additionally assumed to have a compact boundary. In the third step, the previous representation result allows us to get the approximating sequence. These three steps are proved successively in the following three sections.

3.1. Complementarity property of internal and external approximations.

PROPOSITION 3.1. *Let M and M_k $(k \in \mathbb{N})$ be closed epi-Lipschitzian subsets of $\mathbb{R}^n$. Then the two following assertions are equivalent:*

(i) (M_k) *is a (resp., internal, resp., external, resp., smooth, resp., satisfying* (lip), *resp.,* (lip^c), *resp.,* (L)) *normal approximation of M;*

(ii) $(\mathbb{R}^n \setminus \mathrm{int}M_k)$ *is a (resp., external, resp., internal, resp., smooth, resp., satisfying* (lip^c), *resp.,* (lip), *resp.,* (L)) *normal approximation of* $\mathbb{R}^n \setminus \mathrm{int}M$.

Remark 3.1. Proposition 3.1 is no longer true if we do not assume that M is epi-Lipschitzian. Consider $M = \{0\}$ in $\mathbb{R}$ and $M_k = [-1/k, 1/k]$ for $k \geq 1$. Then (M_k) is a smooth external normal approximation of M and $(\mathbb{R} \setminus \mathrm{int}M_k)$ is not a normal approximation of $\mathbb{R} \setminus \mathrm{int}M$. Consider also the set $M = \{(x,y) \in \mathbb{R}^2 | y \geq \sqrt{|x|}\}$ and the set $M_k = \{(x,y) \in \mathbb{R}^2 | [y \geq 0 \text{ and } y \geq \sqrt{|x|} - 1/k] \text{ or } [y < 0 \text{ and } y \geq (k^3/4)x^2 - (1/4k)]\}$ for $k \geq 1$. Then (M_k) is a smooth internal approximation of M but $(\mathbb{R}^n \setminus \mathrm{int}M_k)$ is not a normal approximation of $\mathbb{R}^n \setminus \mathrm{int}M$. Indeed, $N_{\mathbb{R}^n \setminus \mathrm{int}M}(0) = \mathbb{R} \times \{0\}$; hence the set $\{0\} \times \mathbb{R}_+$, which is contained in $\limsup G(N_{\mathbb{R}^n \setminus \mathrm{int}M_k})$, is not contained in $G(N_{\mathbb{R}^n \setminus \mathrm{int}M})$.

Before proving Proposition 3.1, we prove a claim.

CLAIM 3.1. *Let (M_k) be a sequence of closed subsets of $\mathbb{R}^n$ converging normally to a closed subset $M \subset \mathbb{R}^n$. Then*

$$\begin{array}{lll} (\mathrm{int}) & \mathrm{int}M & = \cup_{p\in\mathbb{N}} \mathrm{int}(\cap_{k\geq p} \mathrm{int}M_k); \\ (\mathrm{scc}) & \mathbb{R}^n \setminus \mathrm{int}M & = \limsup(\mathbb{R}^n \setminus \mathrm{int}M_k) = \liminf(\mathbb{R}^n \setminus \mathrm{int}M_k). \end{array}$$

Proof of Claim 3.1. We first prove assertion (int).[4] Since

$$\cup_{p\in\mathbb{N}} \cap_{k\geq p} M_k \subset \liminf M_k = M,$$

the inclusion $\cup_{p\in\mathbb{N}} \mathrm{int}(\cap_{k\geq p} \mathrm{int}M_k) \subset \mathrm{int}M$ is immediate. Let us consider

$$x \in \mathrm{int}M \setminus \cup_{p\in\mathbb{N}} \mathrm{int}(\cap_{k\geq p} \mathrm{int}M_k) = \mathrm{int}M \cap [\cap_{p\in\mathbb{N}} \mathrm{cl}(\mathbb{R}^n \setminus \cap_{k\geq p} \mathrm{int}M_k)].$$

Then there is a sequence (x_k) in $\mathbb{R}^n$ converging to x such that, for all $k \in \mathbb{N}$, $x_k \notin \cap_{l\geq k} \mathrm{int}M_l$. Without any loss of generality, we may assume that there is an increasing map $\varphi : \mathbb{N} \to \mathbb{N}$ such that, for all k, $x_k \notin \mathrm{int}M_{\varphi(k)}$. Since $x \in \mathrm{int}M \subset \liminf M_k$, there is a sequence (y_k) in $\mathbb{R}^n$ converging to x such that for all $k \in \mathbb{N}$, $y_k \in M_k$. Since $y_{\varphi(k)} \in M_{\varphi(k)}$, there is $z_k \in \mathrm{bd}M_{\varphi(k)} \cap [x_k, y_{\varphi(k)}]$ and there is $v_k \in N_{M_{\varphi(k)}}(z_k) \cap S$ (see Clarke [4]). The sequence (z_k) converges to x, and we may assume without any loss of generality that v_k converges to some $v \in S$. Hence $(x, v) \in \limsup G(N_{M_k}) \subset G(N_M)$, which implies that $v \in N_M(x)$. The fact that $N_M(x) \neq \{0\}$ contradicts that $x \in \mathrm{int}M$.

Let us now prove assertion (scc). Since $M = \limsup M_k = \cap_{p\in\mathbb{N}} \mathrm{cl}(\cup_{k\geq p} M_k)$, we get that

$$\mathbb{R}^n \setminus M = \cup_{p\in\mathbb{N}} \mathrm{int}(\cap_{k\geq p} \mathbb{R}^n \setminus M_k) \subset \cup_{p\in\mathbb{N}} \cap_{k\geq p} \mathbb{R}^n \setminus \mathrm{int}M_k \subset \liminf(\mathbb{R}^n \setminus \mathrm{int}M_k),$$

hence that $\mathbb{R}^n \setminus \mathrm{int}M \subset \liminf(\mathbb{R}^n \setminus \mathrm{int}M_k) \subset \limsup(\mathbb{R}^n \setminus \mathrm{int}M_k)$. From assertion (int), we get that $\mathbb{R}^n \setminus \mathrm{int}M = \cap_{p\in\mathbb{N}} \mathrm{cl}(\cup_{k\geq p} \mathbb{R}^n \setminus \mathrm{int}M_k) = \limsup(\mathbb{R}^n \setminus \mathrm{int}M_k)$. □

Proof of Proposition 3.1. Note that, without any loss of generality, we only need to prove the implication [(i) ⇒ (ii)]. The implication [(ii) ⇒ (i)] can then be deduced

[4] In fact, we prove it in a more general setting later in this paper with a longer proof (Lemma 4.3).

from [(i) ⇒ (ii)], applying the result to the set $\mathbb{R}^n \setminus \operatorname{int} M$, since $\mathbb{R}^n \setminus \operatorname{int} M$ is epi-Lipschitzian, since $\mathbb{R}^n \setminus \operatorname{int}(\mathbb{R}^n \setminus \operatorname{int} M) = \overline{\operatorname{int} M} = M$[5] and $\mathbb{R}^n \setminus \operatorname{int}(\mathbb{R}^n \setminus \operatorname{int} M_k) = \overline{\operatorname{int} M_k} = M_k$ for all k.

In view of Claim 3.1, the sequence $(\mathbb{R}^n \setminus \operatorname{int} M_k)$ and the set $\mathbb{R}^n \setminus \operatorname{int} M$ clearly satisfy assertion (sc) of Definition 2.1. Let us prove that they satisfy assertion (nc). Let $(x,p) \in \limsup G(N_{\mathbb{R}^n \setminus \operatorname{int} M_k})$. Without any loss of generality, we may assume that $p \neq 0$, hence that $x \in \limsup \operatorname{bd}(\mathbb{R}^n \setminus \operatorname{int} M_k) = \limsup \operatorname{bd} M_k$, since $\operatorname{bd}(\mathbb{R}^n \setminus \operatorname{int} M_k) = (\mathbb{R}^n \setminus \operatorname{int} M_k) \setminus \operatorname{int}(\mathbb{R}^n \setminus \operatorname{int} M_k) = \overline{\operatorname{int} M_k} \setminus \operatorname{int} M_k = \operatorname{bd} M_k$ for all k (since M_k is epi-Lipschitzian). This implies that $x \in M \cap (\mathbb{R}^n \setminus \operatorname{int} M) = \operatorname{bd} M = \operatorname{bd}(\mathbb{R}^n \setminus \operatorname{int} M)$. Then, since M_k is epi-Lipschitzian, $N_{\mathbb{R}^n \setminus \operatorname{int} M_k}(x') = -N_{M_k}(x')$ for all $x' \in \operatorname{bd} M_k$, hence $(x,-p) \in \limsup G(N_{M_k})$, hence $(x,-p) \in G(N_M)$, which implies that $(x,p) \in G(N_{\mathbb{R}^n \setminus \operatorname{int} M})$, since $N_{\mathbb{R}^n \setminus \operatorname{int} M}(x) = -N_M(x)$. We proved that $(\mathbb{R}^n \setminus \operatorname{int} M_k)$ is an approximation of $\mathbb{R}^n \setminus \operatorname{int} M$. If (M_k) is a smooth (resp., internal, resp., external, resp., satisfying (lip), resp., (lip^c), resp., (L)) approximation of M, then $(\mathbb{R}^n \setminus \operatorname{int} M_k)$ is clearly a smooth (resp., external, resp., internal, resp., satisfying (lip), resp., (lip^c), resp., (L)) approximation of $\mathbb{R}^n \setminus \operatorname{int} M$. □

3.2. A representation theorem.

We first state a representation theorem of M when $\operatorname{bd} M$ is compact.

THEOREM 3.1. *Let M be a closed epi-Lipschitzian subset of $\mathbb{R}^n$ with compact boundary $\operatorname{bd} M$. Then there is a function $f_M : \mathbb{R}^n \to \mathbb{R}$ which is a quasi-smooth inequality representation of M in the following sense:*

(i) *f_M is locally Lipschitzian on $\mathbb{R}^n$ and C^∞ on $\mathbb{R}^n \setminus \operatorname{bd} M$;*

(ii) *$M = \{x \in \mathbb{R}^n | f_M(x) \le 0\}$;*

(iii) *$\operatorname{bd} M = \{x \in \mathbb{R}^n | f_M(x) = 0\}$;*[6]

(iv) *$0 \notin \partial f_M(x)$ if $f_M(x) = 0$;*

(v) *$N_M(x) \cap -N_{\mathbb{R}^n \setminus \operatorname{int} M}(x) = \cup_{\lambda \ge 0} \lambda \partial f_M(x)$ for all $x \in \operatorname{bd} M$.*

Furthermore, one can assume that for some $\varepsilon > 0$:

(vi) *$f_M^{-1}([-\varepsilon,\varepsilon])$ is compact;*

(vii) *$\forall x \in f_M^{-1}([-\varepsilon,\varepsilon])$, $\operatorname{co}\partial f_M(\overline{B}(x,\varepsilon)) \cap \overline{B}(0,\varepsilon) = \emptyset$.*

Proof of Theorem 3.1. The existence of a function f satisfying assertions (i)–(v) is exactly Theorem 2.1 of Cornet and Czarnecki [6] (in which the closed set M is not assumed to have a compact boundary).

Let f be a quasi-smooth representation of M on $\mathbb{R}^n$ (i.e., satisfying assertions (i)–(v)). Let $\alpha : \mathbb{R}^n \to [0,1]$ be a C^∞ function such that $\alpha(x) = 0$ if $x \in \overline{B}(\operatorname{bd} M, 1/2)$ and $\alpha(x) = 1$ if $x \notin B(\operatorname{bd} M, 1)$. We define the function $f_M : \mathbb{R}^n \to \mathbb{R}$ for all $x \in \mathbb{R}^n$ by

$$\begin{array}{lll} f_M(x) = (1-\alpha(x))f(x) + \alpha(x)\operatorname{sgn} f(x) & \text{if} & f(x) \neq 0, \\ f_M(x) = 0 & \text{if} & f(x) = 0, \end{array}$$

denoting $\operatorname{sgn} t = t/|t|$ if $t \in \mathbb{R} \setminus \{0\}$.

Proof of (i)–(iii). The function f_M clearly satisfies assertions (i), (ii), and (iii) of Theorem 3.1.

Proof of (iv) *and* (v). Let $x \in \operatorname{bd} M$. Since $\alpha = 0$ on a neighborhood of x, one gets that $\partial f_M(x) = \partial f(x)$; hence assertions (iv) and (v) of Theorem 3.1 are satisfied.

[5] This is a classical result on epi-Lipschitzian sets (see, for example, Cornet and Czarnecki [6]).

[6] This assertion is a consequence of assertions (ii) and (iv).

Proof of (vi). Since $f_M^{-1}((-1,1)) \subset B(\mathrm{bd}M, 1)$, then $\mathrm{cl}(f_M^{-1}((-1,1)))$ is compact.

Proof of (vii). It is a consequence of the following lemma (taking $m = n$, $K = \mathrm{bd}M = f_M^{-1}(\{0\})$, and $\Phi = \partial f_M$) and of the fact that $f_M^{-1}([-\varepsilon,\varepsilon]) \subset B(\mathrm{bd}M, r)$ for some $\varepsilon \in (0,1]$ (since $B(\mathrm{bd}M,r)$ is an open set containing the intersection of compact sets $\cap_{\varepsilon\in(0,1]} f_M^{-1}([-\varepsilon,\varepsilon])$).

LEMMA 3.1. *Let* K *be a compact subset of* $\mathbb{R}^n$ *and let* Φ *be a u.s.c. correspondence from* $\mathbb{R}^n$ *to* $\mathbb{R}^m$*, with nonempty compact convex values, such that* $0 \notin \Phi(x)$ *for every* $x \in K$*. Then there exists* $r > 0$ *such that*

$$\mathrm{co}\Phi(\overline{B}(x,r)) \cap \overline{B}(0,r) = \emptyset, \textit{ for all } x \in B(K,r).$$

Proof of Lemma 3.1 *(by contraposition).* Suppose that there exists a sequence (x^k) in $\mathbb{R}^n$ such that, for all k, $x^k \in B(K,1/k)$ and

$$\mathrm{co}\Phi(\overline{B}(x^k,1/k)) \cap \overline{B}(0,1/k) = \emptyset.$$

From Carathéodory's theorem, there exist $n+1$ elements $(x_i^k, y_i^k, \lambda_i^k)$ $(i = 1,\ldots,n+1)$ in $\mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}_+$ such that $x_i^k \in \overline{B}(x^k,1/k)$, $y_i^k \in \Phi(x_i^k)$, $\sum_{i=1}^{m+1} \lambda_i^k = 1$, and

$$\left\| \sum_{i=1}^{m+1} \lambda_i^k y_i^k \right\| \leq 1/k.$$

Without loss of generality, we assume that the sequence $(x^k, \lambda_1^k, \ldots, \lambda_{m+1}^k, y_1^k, \ldots, y_{m+1}^k)$ converges to some element $(x^*, \lambda_1^*, \ldots, \lambda_{m+1}^{k*}, y_1^*, \ldots, y_{m+1}^*) \in K \times \Sigma \times \mathbb{R}^{m(m+1)}$, since the sequence belongs to the compact set $\overline{B}(K,1) \times \Sigma \times \Phi(\overline{B}(K,1))^{m+1}$, where Σ is the unit simplex of $\mathbb{R}^{m+1}$ and the set $\Phi(\overline{B}(K,1))$ is clearly bounded (since $\Phi(\overline{B}(K,1))$ is the image of the compact set $\overline{B}(K,1)$ by the u.s.c. correspondence Φ). However, for all $i \in \{1,\ldots,m+1\}$, the sequence (x_i^k) also converges to x^* (since from above $\|x_i^k - x^k\| \leq 1/k$).

Taking the limit when $k \to \infty$, we get $0 = \sum_{i=1}^{m+1} \lambda_i^* y_i^*$ and $y_i^* \in \Phi(x^*)$ for all $i \in \{1,\ldots,m+1\}$, since the correspondence Φ is u.s.c. Consequently, $0 \in \Phi(x^*)$ since $\Phi(x^*)$ is convex. Since $x^* \in K$, this contradicts the assumption $0 \notin \Phi(x^*)$. □

Remark 3.2. When $\mathrm{bd}M$ is not compact, assertion (vi) is clearly false for any quasi-smooth inequality representation of M. The following example shows that assertion (vii) may not be true if $\mathrm{bd}M$ is not assumed to be compact. Consider the set $M = \{(x,y) \in \mathbb{R}^2 | (x \leq 0) \text{ or } (x > 0 \text{ and } y \in [-1/x, 1/x])\}$.

3.3. Proof of Theorem 2.1. In view of Proposition 3.1, we only need to show the existence of smooth internal approximations of epi-Lipschitzian sets. Let f_M be a quasi-smooth representation of M satisfying the conclusions of Theorem 3.1 for some $\varepsilon > 0$; we let

$$M_k = \{x \in \mathbb{R}^n | f_M(x) \leq -\varepsilon/k\}$$

for every integer $k \geq 1$. We shall prove that (M_k) is a smooth internal approximation of M satisfying the conclusions of Theorem 2.1.

It is clearly an increasing sequence, and the set-convergence assertion (sc) is immediate. The sets M_k are clearly smooth, since f_M is C^∞ on $\{x \in \mathbb{R}^n | f_M(x) \neq 0\}$ and since $\nabla f_M(x) \neq 0$ when $x \in \mathrm{bd}M_k$ (in that case, $f_M(x) = -\varepsilon/k$, $f_M(x) \in [-\varepsilon,\varepsilon]$ and $0 \notin \partial f_M(x) = \{\nabla f_M(x)\}$ from Theorem 3.1, assertion (vii)).

Proof of the normal convergence assertion (nc). Let $(x, v) \in \limsup G(N_{M_k})$. Then there exist two sequences (x_k) and (v_k) in $\mathbb{R}^n$ and an increasing function $\varphi : \mathbb{N} \to \mathbb{N}$, such that (x_k) converges to x, (v_k) converges to v, and, for all k, $x_k \in M_{\varphi(k)}$ and $v_k \in N_{M_{\varphi(k)}}(x_k)$. Then, for all k, there is $\lambda_k \geq 0$ such that $v_k = \lambda_k \nabla f_M(x_k)$. Since f_M is Lipschitzian on a neighborhood of x, the sequence $(\nabla f_M(x_k))$ is bounded. Without any loss of generality, we may assume that it converges to some $u \in \mathbb{R}^n$. Since the correspondence ∂f_M is u.s.c., $u \in \partial f_M(x)$, hence $u \neq 0$ since $0 \notin \partial f_M(x)$. This implies that the sequence (λ_k) converges to $\lambda = \|v\|/\|u\|$ and $v = \lambda u$ with $\lambda \geq 0$ and $u \in \partial f_M(x)$. Hence $v \in N_M(x)$.

Proof of the lipeomorphism assertions (lip) *and* (lip$^{\rm c}$). Let us now prove that the sets M and M_k are lipeomorphic for all k. In view of Bonnisseau–Cornet [2, Theorem 2.5],[7] assertion (lip) is a clear consequence of the following facts:

$$\begin{aligned}
&M_k = \{x \in \mathbb{R}^n | f_M(x) \leq -\varepsilon/k\} \text{ for every } k,\\
&M = \{x \in \mathbb{R}^n | f_M(x) \leq 0\},\\
&f_M^{-1}([-\varepsilon/k, 0]) \text{ is compact,}\\
&0 \notin \partial f_M(x) \text{ when } f_M(x) \in [-\varepsilon/k, 0].
\end{aligned}$$

The proof that the sets $\mathbb{R}^n \setminus \mathrm{int} M_k$ and $\mathbb{R}^n \setminus \mathrm{int} M$ are lipeomorphic is a consequence of the same result, since $\mathbb{R}^n \setminus \mathrm{int} M_k = \{x \in \mathbb{R}^n | f_M(x) \geq -\varepsilon/k\}$ and $\mathbb{R}^n \setminus \mathrm{int} M = \{x \in \mathbb{R}^n | f_M(x) \leq 0\}$.

Proof of (L). In view of assertion (sc) of Definition 2.1, since the sequence (M_k) is increasing, and since $\mathrm{bd} M$ is compact, there clearly is an integer k_0 such that $\mathrm{bd} M_k \subset B(\mathrm{bd} M, \varepsilon)$ for all $k \geq k_0$. Let us consider $k \geq k_0$, and let L be the Lipschitz constant of f_M on $B(\mathrm{bd} M, \varepsilon)$. We first prove that

$$\varepsilon[(1/k) - 1/(k+1)] \leq L \min\{\|x - y\|, x \in \mathrm{bd} M_k, y \in \mathrm{bd} M_{k+1}\}.$$

Indeed, if $x \in \mathrm{bd} M_k$ and $y \in \mathrm{bd} M_{k+1}$, then $f_M(x) = -\varepsilon/k$ and $f_M(y) = -\varepsilon/(k+1)$. Then $\varepsilon[(1/k) - 1/(k+1)] = |f_M(x) - f_M(y)| \leq L\|x - y\|$. We now end the proof of Theorem 2.1 by proving that

$$\delta(\mathrm{bd} M_k, \mathrm{bd} M_{k+1}) \leq [(1/k) - 1/(k+1)].$$

We first consider $x \in \mathrm{bd} M_k$. Since f_M satisfies Theorem 3.1, assertion (vii), we can separate the compact convex sets $\mathrm{co}\partial f_M(\overline{B}(x, \varepsilon))$ and $\overline{B}(0, \varepsilon)$. Hence there is $p \in S(0, 1)$ such that $(p|y) > \varepsilon$ for all $y \in \mathrm{co}\partial f_M(\overline{B}(x, \varepsilon))$. Then, considering the map $t \mapsto f_M(x + tp)$, from the mean-value theorem (see Clarke [4]) one easily proves that $f_M(x + tp) - f_M(x) \geq \varepsilon t$ for all $t \in [0, \varepsilon]$. Then $f_M(x + \varepsilon p) \geq -\varepsilon/k + \varepsilon^2 > 0$ (if k is large enough), hence there is $t \in [0, \varepsilon]$ such that $f_M(x + tp) = -\varepsilon/(k + 1)$. Hence $\varepsilon t \leq f_M(x + tp) - f_M(x) = \varepsilon[(1/k) - 1/(k + 1)]$. This implies that $d(x, \mathrm{bd} M_{k+1}) \leq \|tp\| \leq [(1/k) - 1/(k + 1)]$. One proves that $d(x, \mathrm{bd} M_k) \leq [(1/k) - 1/(k + 1)]$ for all $x \in \mathrm{bd} M_{k+1}$ in the same way. Hence $\delta(\mathrm{bd} M_k, \mathrm{bd} M_{k+1}) \leq [(1/k) - 1/(k + 1)]$. □

Remark 3.3. From the above proof, we note that assertion (L) is satisfied by the sequence $M_k = \{x \in \mathbb{R}^n | f_M(x) \leq \varepsilon_k\}$, where $f_M : \mathbb{R}^n \to \mathbb{R}$ is a quasi-smooth representation of M and (ε_k) is a strictly decreasing sequence of positive real numbers converging to zero. However, there may exist normal converging sequences which cannot be represented as above. Consider the example in Remark 2.5.

[7] Bonnisseau and Cornet [2] prove a homeomorphism result, but only a slight change in their proof gives a lipeomorphism result.

4. Proof of the lipeomorphism result. In view of Proposition 3.1, the proof of Theorem 2.3 has three steps. We first show that the sets M and M_k are epi-Lipschitzian for k large enough. In the second step, we show the existence of a Lipschitzian transverse field between M and M_k, in a sense that will be explained later. In the third step of the proof we show that, if there is a such transverse field between two sets M and N, then M and N are (epi-Lipschitzian and) lipeomorphic. These three steps are proved successively in the following three sections.

4.1. The sets M and M_k are epi-Lipschitzian.

PROPOSITION 4.1. *Let (M_k) be a sequence of closed subsets of $\mathbb{R}^n$ such that $\mathrm{bd} M_k \subset K$ for all k, for some fixed compact subset $K \subset \mathbb{R}^n$, and such that*

$(**)$ $\quad \mathrm{co}\limsup_{x'\to x,k\to\infty} N_{M_k}(x')$ *is pointed for all $x \in \limsup M_k$.*

Then the set $M = \limsup M_k$ and the set M_k, for k large enough, are epi-Lipschitzian.

Proof of Proposition 4.1. We first prove that M_k is epi-Lipschitzian for k large enough. Assume that it is not true. Then there is a sequence (x_k) in $\mathbb{R}^n$, a sequence (p_k) in S, and an increasing map $\varphi : \mathbb{N} \to \mathbb{N}$, such that, for all $k \in \mathbb{N}$, $x_k \in M_{\varphi(k)}$, $p_k \in N_{M_{\varphi(k)}}(x_k)$, and $-p_k \in N_{M_{\varphi(k)}}(x_k)$. Then $x_k \in \mathrm{bd} M_{\varphi(k)} \subset K$; hence we may assume without any loss of generality that the sequence x_k converges to some $x \in K$ and that the sequence p_k converges to some $p \in S$. Then $x \in M$ (since $M = \limsup M_k$) and p and $-p$ belong to $\limsup_{x'\to x,k\to\infty} N_{M_k}(x')$, which contradicts the fact that $\mathrm{co}\limsup_{x'\to x,k\to\infty} N_{M_k}(x')$ is pointed for every $x \in M$.

We now prove that M is epi-Lipschitzian. Let $x \in M$. Then, since the set $\mathrm{co}\limsup_{x'\to x,k\to\infty} N_{M_k}(x')$ is pointed, it is sufficient to prove that $N_M(x) \subset \mathrm{co}\limsup_{x'\to x,k\to\infty} N_{M_k}(x')$ for all $x \in M$, which we do in the next lemma, which generalizes Lemma 6.2 from Benoist [1] (see also Kruger and Mordukhovich [11, Theorem P.3] and Ioffe [10, Theorem 3]).

LEMMA 4.1. *Let (M_k) be a sequence of closed subsets of $\mathbb{R}^n$, and let $M = \limsup M_k$. Then, for all $x \in M$*

(i) $\quad \perp_M(x) \subset \limsup_{x'\to x,k\to\infty} N_{M_k}(x')$;[8]

(ii) $\quad N_M(x) \subset \mathrm{cl}\ (\mathrm{co}\limsup_{x'\to x,k\to\infty} N_{M_k}(x'))$;

(iii) $\quad$ *if we additionally assume that the set $\mathrm{co}\limsup_{x'\to x,k\to\infty} N_{M_k}(x')$ is pointed, then we can suppress* cl *in the above assertion, i.e., formally*

$$N_M(x) \subset \mathrm{co} \limsup_{x'\to x,k\to\infty} N_{M_k}(x').$$

Proof of Lemma 4.1. Proof of (i). Let $\overline{x} \in M$ and $\overline{p} \in \perp_M(\overline{x}) \setminus \{0\}$. One easily notices from the definition of $\perp_M(\overline{x})$ that, for $\mu > 0$ small enough,

$$\overline{B}(\overline{x} + \mu\overline{p}, \mu\|\overline{p}\|) \cap M = \{\overline{x}\}. \tag{2}$$

We define the function $\psi : \mathbb{R}^n \to \mathbb{R}$ by $\psi(x) = (1/2)\|x - (\overline{x} + \mu\overline{p})\|^2$. Then, for all integer k there is a solution $x_k \in \mathbb{R}^n$ of the following minimization problem:

$$(P_k)\left\{\begin{array}{ll} \text{minimize} & \psi(x), \\ x \in M_k. & \end{array}\right.$$

Then, from (2), $\overline{x} + \mu\overline{p} \notin M$. Hence, since $M = \limsup M_k$, $\overline{x} + \mu\overline{p} \notin M_k$ for k

[8] One can easily replace assertion (i) with $\perp_M(x) \subset \limsup_{x'\to x,k\to\infty} \perp_{M_k}(x')$ or, equivalently, $G(\perp_M) \subset \limsup G(\perp_{M_k})$. However, without the convexification of the right-hand side, assertion (iii) does not hold in general.

large enough; hence $x_k \in \mathrm{bd}M_k$. Then x_k satisfies the following first-order necessary condition associated with (P_k) (see Clarke [4]):

$$-x_k + \overline{x} + \mu\overline{p} = -\nabla\psi(x_k) \in N_{M_k}(x_k). \tag{3}$$

Let us show that the sequence (x_k) admits a bounded subsequence. Since $\overline{x} \in M = \limsup M_k$, there is a sequence $(\overline{x}_k)$ converging to $\overline{x}$ and an increasing map $\varphi : \mathbb{N} \to \mathbb{N}$, such that $\overline{x}_k \in M_{\varphi(k)}$ for all k. Then, for every k, $\overline{x}_k$ satisfies the constraint of $(P_{\varphi(k)})$; hence

$$\psi(x_{\varphi(k)}) = (1/2)\|x_{\varphi(k)} - \overline{x} - \mu\overline{p}\|^2 \leq \psi(\overline{x}_k) = (1/2)\|\overline{x}_k - \overline{x} - \mu\overline{p}\|^2. \tag{4}$$

Because the sequence $(\overline{x}_k)$ is convergent, hence bounded, this implies that $(x_{\varphi(k)})$ is bounded. Without any loss of generality, we may assume that the sequence $(x_{\varphi(k)})$ converges to some $x \in \mathbb{R}^n$. Since $x_{\varphi(k)} \in M_{\varphi(k)}$ for all $k \in \mathbb{N}$, we get that $x \in M$. Since the sequence $(\overline{x}_k)$ converges to $\overline{x}$, $\psi(\overline{x}_k)$ converges to $(1/2)\mu^2\|\overline{p}\|^2$, hence (4) implies that $\psi(x) \leq (1/2)\mu^2\|\overline{p}\|^2$ and hence that $x \in \overline{B}(\overline{x} + \mu\overline{p}, \mu\|\overline{p}\|)$. In view of (2), since additionally $x \in M$, we get that $x = \overline{x}$. Letting $p_{\varphi(k)} = (1/\mu)(-x_{\varphi(k)} + \overline{x} + \mu\overline{p})$, we proved that $\overline{p} = \lim_{k\to\infty} p_{\varphi(k)}$ with $p_{\varphi(k)} \in N_{M_{\varphi(k)}}(x_{\varphi(k)})$.

Proof of (ii) *and* (iii). Since $A = \limsup_{x'\to\overline{x},k\to\infty} N_{M_k}(x')$ is a cone, since the correspondence $x \mapsto \limsup_{x'\to x,k\to\infty} N_{M_k}(x')$ is closed at $\overline{x}$, we get that $N_M(\overline{x}) \subset \mathrm{cl}(\mathrm{co}A)$, which proves (ii). If we additionally assume that $\mathrm{co}A$ is pointed, then $\mathrm{cl}(\mathrm{co}A) = \mathrm{co}A$, since A is closed (recalling that $\mathrm{co}A$ is closed, when A is a closed cone such that $\mathrm{co}A$ is pointed). □

4.2. A transverse field between M and M_k.

PROPOSITION 4.2. *Let M and (M_k) satisfy the hypothesis of Theorem* 2.3*. Then, for k large enough, there exists a Lipschitzian transverse field between the two sets M and $N = M_k$ in the following sense:*

$$(\mathrm{T}) \left\{ \begin{array}{ll} \multicolumn{2}{l}{\textit{There is bounded Lipschitzian map } F : \mathbb{R}^n \to \mathbb{R}^n\textit{, such that}} \\ \text{(a)} & M \setminus \mathrm{int}N \textit{ and } N \setminus \mathrm{int}M \textit{ are compact;} \\ \text{(b)} & \forall x \in \mathrm{bd}M \ (\textit{resp.}, \mathrm{bd}N),\ F(x) \in \mathrm{int}T_M(x),\ (\textit{resp.}, F(x) \in \mathrm{int}T_N(x)); \\ \text{(c)} & \textit{for all } x \textit{ in an open neighborhood } U \textit{ of } M \setminus \mathrm{int}N \cup N \setminus \mathrm{int}M, \\ & \exists (t,t') \in \mathbb{R}^2, \varphi(t,x) \in \mathrm{bd}M, \varphi(t',x) \in \mathrm{bd}N.^{9} \end{array} \right.$$

Remark 4.1. From [5], the assertion $\forall x \in \mathrm{bd}M$, $F(x) \in \mathrm{int}T_M(x)$ is equivalent to the weaker one, $\forall x \in \mathrm{bd}M$, $F(x) \in \mathrm{int}\mathcal{T}_M(x)$, where $\mathcal{T}_M(x)$ is Bouligand's tangent cone to M at x.

Note that from Proposition 4.1 the sets M and M_k are epi-Lipschitzian for k large enough. Before proving Proposition 4.2, we prove some preliminary lemmas.

4.2.1. Preliminary lemmas.

The first lemma gives an extended Gauss correspondence, an essential step to the construction of the transverse field.

LEMMA 4.2. *There is $r > 0$ and a correspondence G from $\mathbb{R}^n$ to $\mathbb{R}^n$ which is u.s.c., with nonempty compact convex values and such that*

(i) *$G_M(x) = N_M(x) \cap S \subset G(x)$ for all $x \in \mathrm{bd}M$;*

(ii) *$G_{M_k}(x) = N_{M_k}(x) \cap S \subset G(x)$ for all $x \in \mathrm{bd}M_k$, for k large enough;*

[9] Where φ is the flow of the following differential equation:

$$(E)\ \dot{x}(t) = F(x(t)),\ x(0) = x,$$

i.e., $\varphi : \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}^n$ is the unique C^1 map such that $t \mapsto \varphi(t,x)$ is the (unique) maximal solution of (E) (and is defined on $\mathbb{R}$ since F is bounded).

(iii) $0 \notin G(x)$ *for all* $x \in B(\limsup \mathrm{bd} M_k, r)$,
recalling that S *is the unit sphere of* $\mathbb{R}^n$.

Proof of Lemma 4.2. We let

$$G_\infty(x) = \mathrm{co}\Big(\mathrm{co}\Big(\limsup_{x' \to x, k \to \infty} N_{M_k}(x')\Big) \cap S\Big) \text{ for all } x \in \limsup \mathrm{bd} M_k.$$

Claim 4.1. *The correspondence* G_∞, *from* $\limsup \mathrm{bd} M_k$ *to* $\mathbb{R}^n$, *is u.s.c. with nonempty compact convex values and* $0 \notin G_\infty(x)$ *for every* $x \in \limsup \mathrm{bd} M_k$.

Proof of Claim 4.1. The correspondence $x \mapsto \limsup_{x' \to x, k \to \infty} N_{M_k}(x')$ has a closed graph, hence the correspondence $x \mapsto \limsup_{x' \to x, k \to \infty} N_{M_k}(x') \cap S$ is u.s.c., with compact values. We now show that it has nonempty values. Let $x \in \limsup \mathrm{bd} M_k$. Then there is a sequence (x_k) in $\mathbb{R}^n$ converging to x and an increasing map $\varphi : \mathbb{N} \to \mathbb{N}$ such that $x_k \in \mathrm{bd} M_{\varphi(k)}$ for all k. Then there is a sequence (p_k) in S such that $p_k \in N_{M_{\varphi(k)}}(x_k)$ for all k (see Clarke [4]). Let p be a cluster point of the sequence (p_k). Then $p \in \limsup_{x' \to x, k \to \infty} N_{M_k}(x') \cap S \subset G_\infty(x)$. We proved that the correspondence G_∞ is u.s.c., with nonempty compact convex values. Finally $0 \notin G_\infty(x)$, for all $x \in \limsup \mathrm{bd} M_k \subset M$, since $\mathrm{co} \limsup_{x' \to x, k \to \infty} N_{M_k}(x')$ is pointed. □

In view of the extension theorem of Cellina [3],[10] we let $\widehat{G_\infty}$ be an extension of G_∞ on $\mathbb{R}^n$, which is u.s.c., with nonempty compact convex values. For $r > 0$ we define the correspondence G_r from $\mathbb{R}^n$ to $\mathbb{R}^n$ by

$$G_r(x) = \mathrm{co}\, \overline{B}\Big(\widehat{G_\infty}(\overline{B}(x, r)), r\Big).$$

It has clearly nonempty convex values. Also, the correspondence G_r has compact values (since it is the sum of a compact set and of the convex hull of the image of a compact set by a u.s.c. correspondence). The correspondence G_r is clearly u.s.c. (recalling that, if Φ is a u.s.c. correspondence with convex values from $\mathbb{R}^n$ to $\mathbb{R}^n$ and if $r > 0$, then the correspondence $\mathrm{co}\Phi$, and the correspondences Φ_1 and Φ_2, defined by $\Phi_1(x) = \Phi(\overline{B}(x, r))$ and $\Phi_2(x) = \overline{B}(\Phi(x), r)$, respectively, are also u.s.c.).

Proof of (i). Since $M = \limsup M_k$ and since $\mathrm{co} \limsup_{x' \to x, k \to \infty} N_{M_k}(x')$ is pointed, then $N_M(x) \subset \mathrm{co} \limsup_{x' \to x, k \to \infty} N_{M_k}(x')$ for all $x \in \mathrm{bd} M$ (Lemma 4.1). Since $M = \limsup M_k$, then, from Lemma 4.1, $\mathrm{bd} M \subset \limsup \mathrm{bd} M_k$ (this can also be proved more directly). Then assertion (i) is a direct consequence of the definition of G_r.

Proof of (ii). We now prove that, for k large enough, $N_{M_k}(x) \cap S \subset G_r(x)$ for all $x \in \mathrm{bd} M_k$. Suppose that it is not true, then we may assume without any loss of generality that there are two sequences (x_k) and (p_k) in $\mathbb{R}^n$ such that, for all k, $x_k \in \mathrm{bd} M_k$, $p_k \in N_{M_k}(x) \cap S$, and $p_k \notin G_r(x_k)$. Since the sequence (x_k, p_k) belongs to the compact set $K \times S$, without any loss of generality, we may assume that it converges to an element $(x, p) \in K \times S$. Then $x \in M$ (since $M = \limsup M_k$) and $p \in \limsup_{x' \to x, k \to \infty} N_{M_k}(x')$. For k large enough, $x_k \in \overline{B}(x, r)$ and $p_k \in \overline{B}(p, r)$, hence $p_k \in \widehat{G_\infty}(\overline{B}(x_k, r)) + \overline{B}(0, r) \subset G_r(x_k)$, which is a contradiction. □

Proof of (iii). Since $\limsup \mathrm{bd} M_k \subset K$, it is compact. The end of the proof consists of choosing $r > 0$ as in Lemma 3.1 (taking $m = n$, considering the compact

[10] Let Φ be a u.s.c. correspondence, with nonempty compact convex values defined on a closed set $X \subset \mathbb{R}^n$, with values in $\mathbb{R}^m$. Then there is a u.s.c. correspondence $\hat{\Phi}$, with nonempty compact convex values, defined on $\mathbb{R}^n$ with values in $\mathbb{R}^m$, such that $\hat{\Phi}|_X = \Phi$ and such that $\hat{\Phi}(\mathbb{R}^n) \subset \mathrm{co}\Phi(X)$.

set $\limsup \mathrm{bd} M_k$ and the correspondence G_∞), recalling that $0 \notin G_\infty(x)$ if $x \in \limsup \mathrm{bd} M_k$ (Claim 4.1). □

The second lemma is a consequence of Lemma 4.2 and eliminates the situation where $M = \overline{B}(0,1)$ and $M_k = M \setminus B(0, 1/k)$ for $k \geq 1$ (see Remark 2.3).

LEMMA 4.3.

$$\text{(int)} \qquad \mathrm{int} M = \cup_{p \in \mathbb{N}} \mathrm{int}(\cap_{k \geq p} \mathrm{int} M_k).$$

Proof of Lemma 4.3. We recall that the inclusion $\cup_{p\in\mathbb{N}} \mathrm{int}(\cap_{k\geq p} \mathrm{int} M_k) \subset \mathrm{int} M$ is an immediate consequence of the equality $\liminf M_k = M$. We now prove the converse inclusion. Let $x \in \mathrm{int} M$. There is $\varepsilon > 0$ such that $B(x, \varepsilon) \subset M$, and from Lemma 3.1, such that $0 \notin \mathrm{co} G(B(x, \varepsilon))$. Assume that $x \notin \cup_{p\in\mathbb{N}} \mathrm{int}(\cap_{k\geq p} \mathrm{int} M_k)$. Then there is a sequence (x_k) converging to x and a subsequence $(M_{\varphi(k)})$ such that, for all k, $x_k \in \mathrm{bd} M_{\varphi(k)}$ (see the proof of Claim 3.1). Hence $x \in \limsup \mathrm{bd} M_{\varphi(k)} \subset \limsup \mathrm{bd} M_k$. From a classical separation argument, there is $p \in S$ and a real number $a > 0$ such that $(p|y) > a$ for all $y \in \mathrm{co} G(\overline{B}(x, \varepsilon))$. We may assume without any loss of generality that $a = \varepsilon$. Then, since $\mathrm{co} G(\overline{B}(x, \varepsilon))$ is bounded (it is the convex hull of the image of a compact set by a u.s.c. correspondence), there is $\varepsilon' > 0$ such that $(p'|y) > 0$ for all $p' \in B(p, \varepsilon')$ and for all $y \in \mathrm{co} G(B(x, \varepsilon))$. Without any loss of generality, we may assume that $\varepsilon' = \varepsilon$. Then $-p' \in \mathrm{int} T_{M_k}(x')$ for all $x' \in B(x, \varepsilon) \cap \mathrm{bd} M_k$ and for all $p' \in B(p, \varepsilon')$, if k is large enough since, from Lemma 4.2, $N_{M_k}(x') \cap S \subset G(x')$.

Then the following claim implies that, for k large enough, $x_k + tp' \notin M_{\varphi(k)}$ for all $p' \in B(p, \varepsilon/2)$ and all $t \in (0, \varepsilon/2)$, hence that $B(x + (\varepsilon/3)p, (\varepsilon^2/6)) \cap M_{\varphi(k)} = \emptyset$, hence that $x + (\varepsilon/3)p \notin \limsup M_{\varphi(k)}$, contradicting the fact that $M = \limsup M_{\varphi(k)}$.[11] □

CLAIM 4.2. *Let M be a closed epi-Lipschitzian subset of $\mathbb{R}^n$, let $x \notin \mathrm{int} M$, $\varepsilon > 0$, and $p \in S$ such that $-p \in \mathrm{int} T_M(x')$ for all $x' \in B(x, \varepsilon) \cap M$. Then $x + tp \notin M$ for $t \in (0, \varepsilon)$.*

Proof of Claim 4.2. Assume that $x + tp \in M$ for some $t \in [0, \varepsilon)$. Since $x \notin \mathrm{int} M$, we may assume without any loss of generality that $x + tp \in \mathrm{bd} M$. Then $x + tp \in B(x, \varepsilon)$, hence $-p \in \mathrm{int} T_M(x + tp)$. We recall that from Rockafellar [16]

$$\begin{aligned} \mathrm{int} T_M(x + tp) = \{\, v \in \mathbb{R}^n | \exists \alpha > 0, y + \lambda w \in M \\ \text{for all } (y, w, \lambda) \in (B(x + tp, \alpha) \cap M) \times B(w, \alpha) \times [0, \alpha)\}. \end{aligned}$$

Let $\alpha > 0$ be chosen as above. Then $(x + tp) - (\alpha/2)p \in M$. Hence $(x + tp) - (\alpha/2)p + (\alpha/2)p' \in M$ for all $p' \in B(p, \alpha)$; hence $x + tp \in \mathrm{int} M$, which is a contradiction. □

4.2.2. Proof of Proposition 4.2. We now prove that, for k large enough, there is a Lipschitzian transverse field between the sets M and M_k. We recall that $\mathrm{bd} M \subset \limsup \mathrm{bd} M_k \subset K$, hence that it is compact. We let $U = B(\mathrm{bd} M, \varepsilon)$ for a given real number $\varepsilon > 0$.

Proof of (a). Since $B(M, \varepsilon) = M \cup B(\mathrm{bd} M, \varepsilon)$ and since $B(\mathbb{R}^n \setminus \mathrm{int} M, \varepsilon) = (\mathbb{R}^n \setminus \mathrm{int} M) \cup B(\mathrm{bd} M, \varepsilon)$, the following claim clearly implies that $M_k \setminus \mathrm{int} M \subset B(\mathrm{bd} M, \varepsilon) = U$ and that $M \setminus \mathrm{int} M_k \subset U$, hence that $M_k \setminus \mathrm{int} M$ and $M \setminus \mathrm{int} M_k$ are compact, since $\overline{B}(\mathrm{bd} M, \varepsilon)$ is clearly compact.

[11] Recalling that the equality $M = \limsup M_k = \liminf M_k$ implies that $M = \limsup M_{\varphi(k)} = \liminf M_{\varphi(k)}$.

Claim 4.3. *Let ε be a positive real number. Then, for k large enough,*[12]

$$\begin{array}{lcl} M_k & \subset & B(M,\varepsilon); \\ \mathbb{R}^n \setminus \mathrm{int} M_k & \subset & B(\mathbb{R}^n \setminus \mathrm{int} M,\varepsilon). \end{array}$$

Proof of Claim 4.3. Assume that the inclusion $M_k \subset B(M,\varepsilon)$ does not hold for k large enough. Then, without loss of generality, we assume that there is a sequence (x_k) in $\mathbb{R}^n$ such that, for all k, $x_k \in M_k$ and $d(x_k,M) \geq \varepsilon$. If $\{x|d(x,M)=\varepsilon\} \in M_k$: $S(M,\varepsilon) \cap M_k \neq \emptyset$, we let $y_k \in S(M,\varepsilon)\cap M_k$. If $S(M,\varepsilon)\cap M_k = \emptyset$, there is $y_k \in \mathrm{bd}M_k$ such that $d(y_k,M) > \varepsilon$. Indeed, let $x \in S(M,\varepsilon)$ such that $\|x_k - x\| = d(x_k, B(M,\varepsilon))$. Then $x \notin M_k$, $x_k \in M_k$ and hence there is $y_k \in (x,x_k] \cap \mathrm{bd}M_k$, and $d(y_k, B(M,\varepsilon)) > 0$; hence $d(y_k,M) > \varepsilon$. Then the sequence (y_k) is in the compact set $S(M,\varepsilon)\cup K$ (since $S(M,\varepsilon) \subset S(\mathrm{bd}M,\varepsilon)$, which is compact, and since $\mathrm{bd}M_k \subset K$). We may assume without any loss of generality that it converges to some $x \in S(M,\varepsilon)\cup K$. Then $d(x,M) \geq \varepsilon$, but, since $y_k \in M_k$ for all k, and since $M = \limsup M_k$, we get that $x \in M$, which is a contradiction. To get the second inclusion, apply the first result to the sets $\mathbb{R}^n \setminus \mathrm{int}M$ and $\mathbb{R}^n \setminus \mathrm{int}M_k$, noticing that assertion (int) (see Lemma 4.3) implies that $\mathbb{R}^n \setminus \mathrm{int}M = \limsup(\mathbb{R}^n \setminus \mathrm{int}M_k)$, that $\mathrm{bd}(\mathbb{R}^n \setminus \mathrm{int}M) = \overline{\mathrm{int}M} \setminus \mathrm{int}M \subset \mathrm{bd}M$, and that $\mathrm{bd}(\mathbb{R}^n \setminus \mathrm{int}M_k) = \overline{\mathrm{int}M_k} \setminus \mathrm{int}M_k \subset \mathrm{bd}M_k \subset K$. □

Proof of (b). We let $F : \mathbb{R}^n \to \mathbb{R}^n$ be a map satisfying the conclusions of the following lemma, which is a slightly different version of Lemma 3.1 of Bonnisseau–Cornet [2] (its proof is left to the reader). Then, in view of Lemma 4.2, if we choose $\varepsilon < r'$, assertion (b) follows.

Lemma 4.4. *There is $r' > 0$ and a bounded locally Lipschitzian map $F : \mathbb{R}^n \to \mathbb{R}^n$, such that*

$$\forall\ x \in B(\mathrm{bd}M, r'),\ \forall\ y \in G(x),\ (F(x)|y) > r'.$$

Proof of (c). We let $f : \mathbb{R}^n \to \mathbb{R}$ be a quasi-smooth representation of M satisfying the conclusions of Theorem 3.1, i.e., such that $f^{-1}([-\varepsilon_0,\varepsilon_0])$ is compact for some $\varepsilon_0 > 0$. Then from Lemma 4.4, since $\partial f(x) \subset N_M(x)$ for all $x \in \mathrm{bd}M$, since the correspondence ∂f is u.s.c., with nonempty convex compact values, and since $\mathrm{bd}M$ is compact, there is $r'' > 0$ such that

$$(F(x)|y) > r'' \quad \forall\ x \in \mathrm{bd}M \text{ and } \forall\ y \in \partial f(x).$$

Then assertion (c) holds, if we choose $\varepsilon > 0$ given by the following claim. □

Claim 4.4. *Let f be a quasi-smooth representation of an epi-Lipschitzian subset $M \subset \mathbb{R}^n$ such that $f^{-1}([-r,r])$ is compact for some $r > 0$, and such that $(F(x)|y) > r$ for all $x \in \mathrm{bd}M$ and for all $y \in \partial f(x)$. Then there are two real numbers $\varepsilon > 0$ and $\alpha > 0$ such that*

(i) $B(\mathrm{bd}M,\varepsilon) \subset f^{-1}([-\alpha,\alpha]) \subset B(\mathrm{bd}M,r)$;

(ii) $\big(\partial f(\varphi(t,x))|(\partial\varphi/\partial t)(t,x)\big) \subset [r,+\infty)\ \forall\ x \in B(\mathrm{bd}M,r)$ *and* $\forall\ t \in \mathbb{R}$ *such that* $|f(\varphi(t,x))| \leq \alpha$;

(iii) *the function* $f \circ \varphi(.,x)$ *is strictly increasing on* $\{t \in \mathbb{R}|\ |f(\varphi(t,x))| < \alpha\}\ \forall\ x\ \in B(\mathrm{bd}M,r)$;

(iv) *there are* t *and* t' *in* $\mathbb{R}$ *such that* $f(\varphi(t,x)) \leq -\alpha$ *and* $f(\varphi(t',x)) \geq \alpha\ \ \forall\ x \in f^{-1}([-\alpha,\alpha])$,

[12] Note that these inclusions imply that $\delta(M,M_k) \leq \varepsilon$ and that $\delta(\mathrm{bd}M,\mathrm{bd}M_k) \leq \varepsilon$, defining $\delta(X,Y) = \max\{\sup_{x\in X} d(x,Y), \sup_{y \in Y} d(y,X)\}$ if X and Y are two subsets of $\mathbb{R}^n$ (not necessarily nonempty compact), hence that $\delta(M,M_k) \to 0$ and that $\delta(\mathrm{bd}M,\mathrm{bd}M_k) \to 0$. Conversely, the assumption that $\delta(M,M_k) \in \mathbb{R}$ and converges to 0 implies that $M = \liminf M_k = \limsup M_k$.

recalling that $\varphi : \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}^n$ *is the flow of the differential equation* (E) $\dot{x}(t) = F(x(t))$, $x(0) = x$, *where* $\varphi(., x)$ *is defined on* $\mathbb{R}$.

Proof of Claim 4.4. Since the correspondence ∂f is u.s.c. with compact convex values and since the map F is continuous, the correspondence H defined by $H(x) = (F(x)|\partial f(x))$ is u.s.c., with compact convex values. Then, from Lemma 3.1, there is $\beta > 0$ such that $B(\mathrm{bd}M, \beta) \subset U$ and such that

$$(F(x)|y) \quad > \quad r \qquad \text{for all } x \in B(\mathrm{bd}M, \beta) \text{ and for all } y \in \partial f(x).$$

Then there is $\alpha > 0$ such that $f^{-1}([-\alpha, \alpha]) \subset B(\mathrm{bd}M, \beta)$ (since $B(\mathrm{bd}M, \beta)$ is an open set containing the intersection of compact sets $\cap_{\alpha \in (0, \varepsilon_0]} f^{-1}([-\alpha, \alpha))$. Without any loss of generality, we may assume that $f^{-1}([-\alpha, \alpha]) \subset B(\mathrm{bd}M, r)$. Since $f^{-1}((-\alpha, \alpha))$ is an open set containing the intersection of compact sets $\cap_{\epsilon > 0} \overline{B}(\mathrm{bd}M, \epsilon)$, there is $\varepsilon > 0$ such that $B(\mathrm{bd}M, \varepsilon) \subset f^{-1}([-\alpha, \alpha])$, which proves (i). Let $x \in B(\mathrm{bd}M, r)$. We define the function $h_x : \mathbb{R} \to \mathbb{R}$ by $h_x(t) = f(\varphi(t, x))$. Then, from Clarke [4],

$$\partial h_x(t) \subset \Big(\partial f(\varphi(t, x)) | (\partial \varphi / \partial t)(t, x)\Big),$$

i.e., $\partial h_x(t) \subset \Big(\partial f(\varphi(t, x)) | F(\varphi(t, x))\Big)$, which is minorized by r if $|f(\varphi(t, x))| < \alpha$; this proves (ii). Hence from the mean-value theorem, the function $f \circ \varphi(., x) = h_x$ is strictly increasing on $\{t \in \mathbb{R} |\, |f(\varphi(t, x))| < \alpha\}$, which proves (iii). If we additionally assume that $x \in f^{-1}([-\alpha, \alpha])$, then (see, for example, Hirsch and Smale [9]; the fact can also be proved directly) $\varphi(t, x) \notin f^{-1}([-\alpha, \alpha])$ when t is large enough; hence, from (ii), $f(\varphi(t, x)) \geq \alpha$ when $t \to +\infty$. In the same way, $f(\varphi(t, x)) \leq -\alpha$ when $t \to -\infty$. □

4.3. The sets M and M_k are lipeomorphic. In view of Propositions 4.1 and 4.2, the proof of Theorem 2.3 is finished if we prove the next proposition.

PROPOSITION 4.3. *Let M and N be two closed subsets of* $\mathbb{R}^n$ *admitting a Lipschitzian transverse field in the sense of* (T). *Then M and N are epi-Lipschitzian and lipeomorphic.*

Remark 4.2. One could reduce Proposition 4.3 to the smooth case. Indeed, since $\mathrm{bd}M$ and $\mathrm{bd}N$ are compact, there are two smooth normal approximations (M_k) and (N_k) of M and N, respectively. Then, for k large enough, there is a Lipschitzian transverse field between the two sets M_k and N_k in the sense of (T). But the proof would be identical. Proposition 4.3 can be proved directly, without using the notion of normal approximation, as we do in the following.

Proof of Proposition 4.3. The set M is clearly epi-Lipschitzian, since the transversality condition (T) implies that, for every $x \in \mathrm{bd}M$, $\mathrm{int}T_M(x) \neq \emptyset$, hence that $N_M(x)$ is pointed. Similarly, the set N is also epi-Lipschitzian. Let f_M (resp., f_N) be an inequality representation of M (resp., N) satisfying the conclusions of Theorem 3.1, i.e., such that $f_M^{-1}([-\varepsilon_0, \varepsilon_0])$ (resp., $f_N^{-1}([-\varepsilon_0, \varepsilon_0])$) is compact for some $\varepsilon_0 > 0$. The following lemma is a different version of Lemma 3.2 of Bonnisseau–Cornet [2] that we prove for the sake of completeness.

LEMMA 4.5. *There is a real number $\beta > 0$ and two Lipschitzian functions τ and θ, defined from $U \times [-\beta, \beta]$ to* $\mathbb{R}^n$, *such that*

$$\text{(i)} \quad \Big\{x \in \mathbb{R}^n |\min\{f_M(x), f_N(x)\} \leq \beta, \max\{f_M(x), f_N(x)\} \geq -\beta\Big\} \subset U$$

and such that, for all $(x, \delta, t) \in U \times [-\beta, \beta] \times \mathbb{R}$, then

(ii) $f_M(\varphi(x,t)) = \delta \Leftrightarrow t = \tau(x,\delta)$;
(iii) $f_N(\varphi(x,t)) = \delta \Leftrightarrow t = \theta(x,\delta)$.

Proof of Lemma 4.5. Note that, without any loss of generality, we only need to prove assertions (i) and (ii). Since the set

$$\Big\{x \in \mathbb{R}^n | \min\{f_M(x), f_N(x)\} \leq 0, \max\{f_M(x), f_N(x)\} \geq 0\Big\}$$

is equal to the set $[M \setminus \mathrm{int}N] \cup [N \setminus \mathrm{int}M]$, which is included in the set U, we get the inclusion

$$\cap_{\beta\in(0,\varepsilon_0]}\Big\{x \in \mathbb{R}^n | \min\{f_M(x), f_N(x)\} \leq \beta, \max\{f_M(x), f_N(x)\} \geq -\beta\Big\} \subset U.$$

This implies assertion (i) for some $\beta > 0$ (since we have an intersection of compact sets included in U). Then from the assumption (T), (b), there is $r > 0$ such that $(F(x)|y) > r$ for all $x \in \mathrm{bd}M$ and for all $y \in \partial f_M(x)$. We may assume that β is small enough and we thus satisfy the conclusions of Claim 4.4, given the function f_M. Then $f_M^{-1}([-\beta,\beta]) \subset U$, and the function $f_M \circ \varphi(.,x)$ is strictly increasing on $\{t \in \mathbb{R}| \, |f_M(\varphi(t,x))| < \beta\}$ for every $x \in \mathbb{R}^n$. Let us now consider $x \in U$. From the assumption (T), (c), there is $t \in \mathbb{R}$ such that $\varphi(x,t) \in \mathrm{bd}M$, i.e., $f_M(\varphi(x,t)) = 0$. Let $(\delta,t) \in [-\beta,\beta]\times\mathbb{R}$. Then there is one and only one $t' \in \mathbb{R}$ such that $f_M(\varphi(t',x)) = \delta$. We let $t' = \tau(x,\delta)$. Let us now prove that the function τ is Lipschitzian. We let

$$\Omega = \{(x,t,\delta) \in \Omega\times\mathbb{R}| \, |f_M(\varphi(t,x))| < \beta\},$$

and we define $H : \Omega \to \mathbb{R}$ by $H(x,t,\delta) = f_M(\varphi(t,x)) - \delta$. The function H is clearly Lipschitzian. The fact that τ is Lipschitzian around some (x,δ) is a direct consequence of the implicit function theorem [4, p. 255], if we prove that $t^* \neq 0$, for every element $(x^*,t^*,\delta^*) \in \partial H(x,t,\delta)$, where $t \in \mathbb{R}$ satisfies $H(x,t,\delta) = 0$. In other words, if $\pi_t : \mathbb{R}^n\times\mathbb{R}\times\mathbb{R} \to \mathbb{R}$ is the projection defined by $\pi_t(x,t,\delta) = t$, if $0 \notin \pi_t[\partial H(x,t,\delta)]$. From Clarke [4, Proposition 2.6.2], we get that

$$\pi_t[\partial H(x,t,\delta)] \subset \Big(\partial f_M(\varphi(t,x))|F(\varphi(t,x))\Big),$$

which is minorized by β if we chose β small enough (Claim 4.4). □

We then get the following property on the functions τ and θ.

Claim 4.5. *For all* $(x,\delta,t) \in U\times[-\beta,\beta]\times\mathbb{R}$

(i) $f_M(\varphi(x,t)) \geq \delta \Leftrightarrow t \geq \tau(x,\delta)$;
(ii) $f_N(\varphi(x,t)) \geq \delta \Leftrightarrow t \geq \theta(x,\delta)$;

If $y \in U$ *is such that* $\varphi(x,t) = y$ *for some* t, *then* $\tau(x,\delta) = \tau(y,\delta) + t$ *and* $\theta(x,\delta) = \theta(y,\delta) + t$ *for all* δ.

Proof of Claim 4.5. The proof comes from Lemma 4.5 and from the Cauchy–Lipschitz theorem for φ, since $f_M\circ\varphi(x,.)$ is strictly increasing on $\{t \in \mathbb{R}||f_M(\varphi(t,x))| < \beta\}$. □

We are now able to build the lipeomorphism between M and N. Let us define the map $h : M \to N$ by

$$\begin{array}{lcll} h(x) & = & x & \text{if } x \in \mathrm{int}(M_{-\beta}\cap N_{-\beta}),\\ h(x) & = & \varphi\Big(x, i_x(\tau_x - \theta_x)/(\tau_x - i_x)\Big) & \text{if } x \in M \setminus \mathrm{int}(M_{-\beta}\cap N_{-\beta}), \end{array}$$

where we let $M_{-\beta} = \{x \in \mathbb{R}^n | f_M(x) \leq -\beta\}$, $N_{-\beta} = \{x \in \mathbb{R}^n | f_N(x) \leq -\beta\}$, $\tau_x = \tau(x,0)$, $\theta_x = \theta(x,0)$, and $i_x = \inf\{\tau(x,-\beta), \theta(x,-\beta)\}$. Let $x \in M \setminus \mathrm{int}(M_{-\beta} \cap N_{-\beta})$; then $f_M(x) \leq 0$ and $\max\{f_M(x), f_N(x)\} \geq -\beta$; hence $x \in U$ from Lemma 4.5. Hence the map h is well defined. The map h has its values in N. Indeed, let $x \in M \setminus \mathrm{int}(M_{-\beta} \cap N_{-\beta})$. Then, recalling that $x = \varphi(x,0)$,

$$\begin{array}{rl} & f_M[\varphi(x,0)] = f_M(x) \geq -\beta = f_M[\varphi(x,\tau(x,-\beta))], \\ \text{or} & f_N[\varphi(x,0)] = f_N(x) \geq -\beta = f_N[\varphi(x,\theta(x,-\beta))]; \end{array}$$

hence, from Claim 4.5, and $0 \geq \tau(x,-\beta)$ or $0 \geq \theta(x,-\beta)$, which implies that $i_x \leq 0$. The same claim implies that $i_x < \tau_x$ (since $f_M[\varphi(x,\tau(x,-\beta))] < f_M[\varphi(x,\tau_x)]$), $i_x < \theta_x$ (since $f_N[\varphi(x,\theta(x,-\beta))] < f_N[\varphi(x,\theta_x)]$), and $\tau_x \geq 0$ (since $f_M[\varphi(x,0)] = f_M(x) \leq 0 = f_M[\varphi(x,\tau_x)]$). Then we get that $i_x(\tau_x - \theta_x)/(\tau_x - i_x) \leq \theta_x$, which proves that $f_N(h(x)) \leq 0$, i.e., $h(x) \in N$.

Claim 4.6. *The map h is locally Lipschitzian.*

Proof of Claim 4.6. The map h is clearly Lipschitzian on $\mathrm{int}(M_{-\beta} \cap N_{-\beta})$. From Lemma 4.5, the map $x \mapsto \inf\{\tau(x,-\beta), \theta(x,-\beta)\}$ is Lipschitzian and $\tau(x,0) - \inf\{\tau(x,-\beta), \theta(x,-\beta)\} \neq 0$ for all $x \in M \setminus (M_{-\beta} \cap N_{-\beta})$. Then clearly h is Lipschitzian on $M \setminus \mathrm{int}(M_{-\beta} \cap N_{-\beta})$. If $x \in \mathrm{bd}(M_{-\beta} \cap N_{-\beta})$, then $f_M(x) = -\beta$ or $f_N(x) = -\beta$; besides, $f_M(x) \leq -\beta$ and $f_N(x) \leq -\beta$. This implies that $\tau(x,-\beta) = 0$ or $\theta(x,-\beta) = 0$, and that $\tau(x,-\beta) \geq 0$ and $\theta(x,-\beta) \geq 0$. Hence $\inf\{\tau(x,-\beta), \theta(x,-\beta)\} = 0$ and $h(x) = x$. This proves that h is Lipschitzian on $M_{-\beta} \cap N_{-\beta}$. Hence h is Lipschitzian on M. □

Claim 4.7. *The map h is one to one, and h^{-1} is Lipschitzian.*

Proof of Claim 4.7. Let us define the map $k : N \to M$ by

$$\begin{array}{rcll} k(x) & = & x & \text{if } x \in \mathrm{int}(M_{-\beta} \cap N_{-\beta}); \\ k(x) & = & \varphi\Big(x, i_x(\theta_x - \tau_x)/(\theta_x - i_x)\Big) & \text{if } x \in N \setminus \mathrm{int}(M_{-\beta} \cap N_{-\beta}). \end{array}$$

We let the reader check that k has its values in M and that it is Lipschitzian. Let us now prove that $h \circ k = id_N$. Let us consider $x \in M$. We let $y = k(x)$; then $i_y = i_x - t$, $\tau_y = \tau_x - t$, and $\theta_y = \theta_x - t$, where $t = i_x(\theta_x - \tau_x)/(\theta_x - i_x)$. Hence $i_y(\tau_y - \theta_y)/(\tau_y - i_y) = i_x(\tau_x - \theta_x)/(\theta_x - i_x)$, and hence $h(y) = \varphi(y, i_y(\tau_y - \theta_y)/(\tau_y - i_y)) = x$. The fact that $k \circ h = id_M$ goes in the same way. □

Acknowledgment. We wish to thank an anonymous referee for suggesting that we consider the link between normal convergence and the one considered in section 2.4.2.

GLOBAL CONVERGENCE OF TRUST-REGION INTERIOR-POINT ALGORITHMS FOR INFINITE-DIMENSIONAL NONCONVEX MINIMIZATION SUBJECT TO POINTWISE BOUNDS*

MICHAEL ULBRICH†, STEFAN ULBRICH‡, AND MATTHIAS HEINKENSCHLOSS§

Abstract. A class of interior-point trust-region algorithms for infinite-dimensional nonlinear optimization subject to pointwise bounds in L^p-Banach spaces, $2 \le p \le \infty$, is formulated and analyzed. The problem formulation is motivated by optimal control problems with L^p-controls and pointwise control constraints. The interior-point trust-region algorithms are generalizations of those recently introduced by Coleman and Li [*SIAM J. Optim.*, 6 (1996), pp. 418–445] for finite-dimensional problems. Many of the generalizations derived in this paper are also important in the finite-dimensional context. All first- and second-order global convergence results known for trust-region methods in the finite-dimensional setting are extended to the infinite-dimensional framework of this paper.

Key words. infinite-dimensional optimization, bound constraints, affine scaling, interior-point algorithms, trust-region methods, global convergence, optimal control, nonlinear programming

1. Introduction.

This paper is concerned with the development and analysis of a class of interior-point trust-region algorithms for the solution of the following infinite-dimensional nonlinear programming problem:

$$\text{(P)} \qquad \begin{array}{ll} \text{minimize} & f(u) \\ \text{subject to} & u \in \mathcal{B} \overset{\text{def}}{=} \{u \in L^p(\Omega) \,:\, a(x) \le u(x) \le b(x),\ x \in \Omega\}. \end{array}$$

Here $\Omega \subset \mathbb{R}^n$ is a domain with positive and finite Lebesgue measure $0 < \mu(\Omega) < \infty$, and the objective function $f : \mathcal{D} \longrightarrow \mathbb{R}$ is continuous on an open neighborhood $\mathcal{D} \subset L^p(\Omega)$ of $\mathcal{B}$. All pointwise statements on measurable functions are meant to hold μ-almost everywhere. The lower and upper bound functions $a, b \in L^\infty(\Omega)$, are assumed to have a distance of at least $\nu > 0$ from each other. More precisely, $b(x) - a(x) \ge \nu$ on Ω.

Problems of type (P) arise, for instance, when the black-box approach is applied to optimal control problems with bound-constrained L^p-control. A typical example is the boundary control of a heat equation with a Stefan–Boltzmann boundary condition

given by

$$\begin{array}{ll} \text{minimize} & f(u) \stackrel{\text{def}}{=} \frac{1}{2}\|y(u)(T,.) - y_d\|_2^2 + \frac{\alpha}{2}\|u\|_2^2 \\ \text{subject to} & 0 \le u(t) \le 1,\ t \in [0,T], \end{array}$$

where $\alpha \ge 0$ is a given parameter and $y = y(u)$ is the solution of

$$\begin{aligned} y_t(t,x) &= y_{xx}(t,x), \quad (t,x) \in (0,T) \times (0,1) \\ y(0,x) &= 0, \quad x \in (0,1) \\ y_x(t,0) &= 0, \quad y_x(t,1) = -y(t,1)^4 + u(t), \quad t \in (0,T). \end{aligned} \tag{1.1}$$

Another example is an optimal control problem of Bolza type given by

$$\begin{array}{ll} \text{minimize} & f(u) \stackrel{\text{def}}{=} P(y(u)(1)) + \int_0^1 h_0(x, y(u)(x), u(x))\, dx \\ \text{subject to} & u \in \mathcal{B}, \end{array}$$

where $y = y(u)$ is the solution of

$$\frac{dy}{dx}(x) = h(x, y(x), u(x)), \quad y(0) = y^0. \tag{1.2}$$

These control problems and similar ones are studied, e.g., by Burger and Pogu [3], Kelley and Sachs [14], Sachs [18], and Tian and Dunn [21]. We will return to these two specific examples in section 8.

The algorithms in this paper are extensions of the interior-point trust-region algorithms for bound constrained problems in $\mathbb{R}^N$ introduced by Coleman and Li [6]. Algorithmic enhancements of these methods have been proposed and analyzed in the finite-dimensional context in Branch, Coleman, and Li [2], Coleman and Li [5], and Dennis and Vicente [11]. Dennis, Heinkenschloss, and Vicente [10] and Heinkenschloss and Vicente [13] extend these methods to solve a class of finite-dimensional constrained optimization problems with bound constraints on parts of the variables. See also Vicente [24]. The interior-point trust-region methods in [6] are based on the reformulation of the Karush–Kuhn–Tucker (KKT) necessary optimality conditions as a system of nonlinear equations using a diagonal matrix D. This affine-scaling matrix is computed using the sign of the gradient components and the distance of the variables to the bounds (see section 2). The nonlinear system is then solved by an affine-scaling interior-point method in which the trust region is scaled by $D^{-\frac{1}{2}}$. These methods enjoy strong theoretical convergence properties as well as a good numerical behavior. The latter is documented in [2], [6], [10], [11], where these algorithms have been applied to various standard finite-dimensional test problems and to some discretized optimal control problems.

The present work is motivated by the application of interior-point trust-region algorithms to optimal control problems with bounds on the controls. Even though the numerical solution of these problems requires a discretization and allows the application of the previously mentioned algorithms to the resulting finite-dimensional problems, it is known that the infinite-dimensional setting dominates the convergence behavior if the discretization becomes sufficiently small. If the algorithm can be applied to the infinite-dimensional problem and convergence can be proven in the infinite-dimensional setting, asymptotically the same convergence behavior can be expected if the algorithm is applied to the finite-dimensional discretized problems. Otherwise, the convergence behavior might—and usually does—deteriorate fast as the discretization is refined.

In the present context, the formulation of the interior-point trust-region algorithms for the solution of the infinite-dimensional problem (P) requires a careful statement of the problem and of the requirements on the function f. This will be done in section 4. The infinite-dimensional problem setting in this paper is similar to the ones in [12], [14], [15], [21]. The general structure of the interior-point trust-region algorithms presented here is closely related to the finite-dimensional algorithms in [6]. However, the statement and analysis of the algorithm in the infinite-dimensional context is more delicate and has motivated generalizations and extensions which are also relevant in the finite-dimensional context. The analysis performed in this paper allows for a greater variety of choices for the affine-scaling matrix and the scaling of the trust region than those presented previously in [6], [11]. Our convergence analysis is more comprehensive than the ones in [5], [6], [11], [24]. In particular, we adapt techniques proposed in Shultz, Schnabel, and Byrd [19] to prove that under mild assumptions every accumulation point satisfies the second-order necessary optimality conditions. Moreover, the convergence results proven in this paper extend all the finite-dimensional ones stated in [17], [19], [20] to our infinite-dimensional context with bound constraints. In the follow-up paper [23] we present a local convergence analysis of a superlinearly convergent affine-scaling interior-point Newton method which is based on (5.3), and we prove under appropriate assumptions that in a neighborhood of the solution the generated trial steps are accepted by our trust-region algorithms. There a projection onto the set $\mathcal{B}$ is used in the computation of trial steps.

Trust-region methods for infinite-dimensional problems like (P) have also been investigated by Kelley and Sachs [15] and Toint [22]. In both papers the constraints are handled by projections. The paper [22] considers trust-region algorithms for minimization on closed convex bounded sets in Hilbert space. They are extensions of the finite-dimensional algorithms by Conn, Gould, and Toint [7]. It is proven that the projected gradient converges to zero. A comprehensive finite-dimensional analysis of trust-region methods closely related to those introduced by Toint can be found in Burke, Moré, and Toraldo [4]. In contrast to the results in [22], our convergence analysis is also applicable to objective functions that are merely differentiable on a Banach space $L^p(\Omega)$, $p \in (2, \infty]$, which reduces the differentiability requirements substantially compared to the L^2-Hilbert space framework. Furthermore, for the problem class under consideration our convergence results are more comprehensive than the ones in [22]. The infinite-dimensional setting used in [15] fits into the framework of this paper but is more restrictive. The formulation of their algorithm depends on the presence of a penalty term $\alpha \int_\Omega u^2(x)dx$ in the objective function f, and they assume that $\Omega \subset \mathbb{R}$ is an interval. Their algorithm also includes a postsmoothing step, which is performed after the trust-region step is computed. The presence of the postsmoothing step ensures that existing local convergence results can be applied. Such postsmoothing is not needed in the global analysis of this paper.

This paper is organized as follows. In the next section we review the basics of the finite-dimensional interior-point trust-region algorithms in [6]. This is used in section 3 to motivate the infinite-dimensional setting applied in this paper. This section also contains some basic technical results. In section 4 we formulate the necessary optimality conditions in the framework needed for the interior-point trust-region algorithms, which are introduced in section 5. The main convergence results are given in section 6, which concerns the global convergence to points satisfying the first-order necessary optimality conditions, and in section 7, which concerns the global convergence to points satisfying the second-order necessary optimality conditions. These convergence results extend all the known convergence results for trust-region methods in finite dimensions to the infinite-dimensional setting of this paper. Some optimal control examples from the literature to which our analysis applies are discussed in section 8. The local convergence analysis of these algorithms is given in the follow-up paper [23], which also contains numerical examples illustrating the theoretical findings of this paper.

2. Review of the finite-dimensional algorithm.

We briefly review the main ingredients of the affine-scaling interior-point trust-region method introduced in [6]. We refer to that paper for more details. The algorithm solves finite-dimensional problems of the form

$$(\mathrm{P_N}) \qquad \begin{aligned} &\text{minimize} \quad f(u) \\ &\text{subject to} \quad u \in \mathcal{B}_N \overset{\text{def}}{=} \left\{ u \in \mathbb{R}^N \, : \, a \le u \le b \right\}, \end{aligned}$$

where $f : \mathbb{R}^N \longrightarrow \mathbb{R}$ is a twice continuously differentiable function and $a < b$ are given vectors in $\mathbb{R}^N$. (One can allow components of a and b to be $-\infty$ or ∞, respectively. This is excluded here to simplify the presentation.) Inequalities are understood componentwise.

The necessary optimality conditions for $(\mathrm{P_N})$ are given by

$$\begin{aligned} &\nabla f(\bar{u}) - \bar{\mu}^a + \bar{\mu}^b = 0, \\ &a \le \bar{u} \le b, \\ &(\bar{u} - a)^T \bar{\mu}^a + (b - \bar{u})^T \bar{\mu}^b = 0, \\ &\bar{\mu}^a \ge 0, \ \bar{\mu}^b \ge 0. \end{aligned}$$

With the diagonal matrix defined by

$$(2.1) \qquad \big(D(u)\big)_{ii} \overset{\text{def}}{=} \begin{cases} (b-u)_i & \text{if} \quad \big(\nabla f(u)\big)_i < 0, \\ (u-a)_i & \text{if} \quad \big(\nabla f(u)\big)_i \ge 0 \end{cases}$$

for $i = 1, \ldots, N$, the necessary optimality conditions can be rewritten as

$$(2.2) \qquad \begin{gathered} D(\bar{u})^r \nabla f(\bar{u}) = 0, \\ a \le \bar{u} \le b, \end{gathered}$$

where the power $r > 0$ is applied to the diagonal elements. This form of the necessary optimality conditions—we choose $r = 1$—can now be solved using Newton's method. The ith component of the function $D(u)$ is differentiable except at points where $(\nabla f(u))_i = 0$. However, this lack of smoothness is benign since $D(u)$ is multiplied by $\nabla f(u)$. One can use

$$(2.3) \qquad D(u)\nabla^2 f(u) + E(u)$$

as the approximate derivative of $D(u)\nabla f(u)$, where $E(u) = D'(u)\mathrm{diag}(\nabla f(u))$ and $D'(u)$ is the diagonal matrix

$$\big(D'(u)\big)_{ii} \overset{\text{def}}{=} \begin{cases} -1 & \text{if} \quad \big(\nabla f(u)\big)_i < 0, \\ 1 & \text{if} \quad \big(\nabla f(u)\big)_i > 0, \\ 0 & \text{otherwise.} \end{cases}$$

Here $D'(u)\text{diag}(v)$, $v \in \mathbb{R}^N$, plays the role of the generally nonexistent derivative of $D(u)v$ with respect to u, but the prime is not meant to indicate differentiation.

After symmetrization, one obtains

$$\hat{M}(u) = D(u)^{1/2}\nabla^2 f(u) D(u)^{1/2} + E(u). \tag{2.4}$$

One can show that the standard second-order necessary optimality conditions are equivalent to (2.2) and the positive semidefiniteness of $\hat{M}(\bar{u})$. The standard second-order sufficient optimality conditions are equivalent to (2.2) and the positive definiteness of $\hat{M}(\bar{u})$.

A point satisfying the necessary optimality conditions (2.2) is now computed using the iteration $u_{k+1} = u_k + s_k$, where for a given u_k with $a < u_k < b$, the trial step $s_k = D_k^{1/2}\hat{s}_k$ satisfies $a < u_k + s_k < b$, and $\hat{s}_k$ is an approximate solution of

$$\min \hat{\psi}_k(\hat{s}) \quad \text{subject to} \quad \|\hat{s}\|_2 \le \Delta_k \ , \quad u_k + D_k^{1/2}\hat{s} \in \mathcal{B}_N, \tag{2.5}$$

with $\hat{\psi}_k(\hat{s}) \overset{\text{def}}{=} \hat{g}_k^T \hat{s} + \frac{1}{2}\hat{s}^T \hat{M}_k \hat{s}$, $\hat{g}_k \overset{\text{def}}{=} D_k^{1/2}\nabla f_k$. The trust-region radius Δ_k is updated from iteration to iteration in the usual fashion. In (2.5) the Hessian $\nabla^2 f(u_k)$ might be replaced by a symmetric approximation B_k. If the approximate solution $\hat{s}_k$ of (2.5) satisfies a fraction of Cauchy decrease condition

$$\begin{aligned} &\hat{\psi}_k(\hat{s}_k) < \beta \min\left\{\hat{\psi}_k(\hat{s}) \ : \ \hat{s} = -t\hat{g}_k,\ t \ge 0,\ \|\hat{s}\|_2 \le \Delta_k,\ u_k + D_k^{1/2}\hat{s} \in \mathcal{B}_N\right\}, \\ &\|\hat{s}_k\|_2 \le \beta_0 \Delta_k, \end{aligned} \tag{2.6}$$

then under appropriate, standard conditions one can show the basic trust-region convergence result

$$\liminf_{k\to\infty} \|D(u_k)^{1/2}\nabla f(u_k)\| = 0. \tag{2.7}$$

Stronger convergence results can be proven if the assumptions on the function f and on the step computation $\hat{s}_k$ are strengthened appropriately. See [6], [5], [11].

Coleman and Li [6] show that close to nondegenerate KKT points one obtains trial steps $\hat{s}_k$ which meet these requirements if one first computes an approximate solution of (2.5) ignoring the bound constraints and then satisfies the interior-point condition $a < u_k + s_k < b$ by a step-size rule. A careful analysis of the proofs in [6] reveals that the same holds true for nearly arbitrary trust-region scalings. It becomes apparent that the crucial role of the affine scaling does *not* consist of the scaling of the trust-region but rather in leading to the additional term E_k in the Hessian $\hat{M}_k$ of $\hat{\psi}_k$. Near nondegenerate KKT points this positive semidefinite diagonal matrix shapes the level sets of $\hat{\psi}_k$ in such a way that all bad directions $\hat{s}$ which allow only for small step-sizes to the boundary of the box cannot minimize $\hat{\psi}_k$ on any reasonable trust region. The trust-region scaling in (2.5) and (2.6) tends to equilibrate the distance of the origin to the bounding box constraints $\{\hat{s} : u_k + D_k^{1/2}\hat{s} \in \mathcal{B}_N\}$. However, for this feature the equivalence of 2- and ∞-norm is indispensable and thus it does not carry over to our infinite-dimensional framework. In fact, in the infinite-dimensional setting the affine-scaled trust-region $\{\|\hat{s}\|_p \le \Delta_k\}$ no longer enjoys the property of reflecting the distance to the bounding box constraints. Therefore, we will allow for a very general class of trust-region scalings in our analysis. See also [11]. Since, as mentioned above, the term E_k in the Hessian $\hat{M}_k$ plays the crucial role in this affine-scaling interior-point method, all convergence results in [6] remain valid.

In the following section we state the assumptions that allow us to generalize the affine-scaling interior-point algorithm to the infinite-dimensional problems (P).

3. Infinite-dimensional problem setting.

3.1. Notation. We set

$$U \overset{\text{def}}{=} L^p(\Omega), \quad 2 \le p \le \infty, \quad V \overset{\text{def}}{=} L^\infty(\Omega).$$

In this notation, our optimization problem (P) is written as

$$\text{(P)} \qquad \begin{aligned} &\text{minimize} \quad f(u) \\ &\text{subject to} \ \ u \in \mathcal{B} \overset{\text{def}}{=} \{u \in U \ : \ a(x) \le u(x) \le b(x), \ x \in \Omega\}. \end{aligned}$$

We use the following notations. $\mathcal{L}(X, Y)$ is the space of linear bounded operators from a Banach space X into a Banach space Y. By $\|\cdot\|_q$ we denote the norm of the Lebesgue space $L^q(\Omega)$, $1 \le q \le \infty$, and we write $(\cdot,\cdot)_2$ for the inner product of the Hilbert space $H \overset{\text{def}}{=} L^2(\Omega)$. For $(v, w) \in (L^q(\Omega), L^q(\Omega)^*)$, with $L^q(\Omega)^*$ denoting the dual space of $L^q(\Omega)$, we use the canonical dual pairing $\langle v, w\rangle \overset{\text{def}}{=} \int_\Omega v(x)w(x)\,dx$, for which, if $q < \infty$, the dual space $L^q(\Omega)^*$ is given by $L^{q'}(\Omega)$, $1/q + 1/q' = 1$. (In the case $q = 1$ this means $q' = \infty$.) Especially, if $q = 2$, we have $L^2(\Omega)^* = L^2(\Omega)$ and $\langle\cdot,\cdot\rangle$ coincides with $(\cdot,\cdot)_2$.

Finally, we set $U' \overset{\text{def}}{=} L^{p'}(\Omega)$, $1/p + 1/p' = 1$, which is the same as U^*, if $p < \infty$. Moreover, it is easily seen that $w \longmapsto \langle\cdot, w\rangle$ defines a linear norm-preserving injection from $L^1(\Omega)$ into $L^\infty(\Omega)^*$. Therefore, we may always interpret U' as subspace of U^*. Lemma 3.2 guarantees that $L^{q_2}(\Omega) \subset L^{q_1}(\Omega)$ for $1 \le q_1 \le q_2 \le \infty$. As a consequence we get the following chain of continuous imbeddings:

$$V \hookrightarrow U \hookrightarrow H = H^* \hookrightarrow U' \hookrightarrow U^* \hookrightarrow V^*.$$

Throughout this paper we will work with differentiability in the Fréchet sense. We write $g(u) \overset{\text{def}}{=} \nabla f(u) \in U^*$ for the gradient and $\nabla^2 f(u) \in \mathcal{L}(U, U^*)$ for the second derivative of f at $u \in \mathcal{B}$ if they exist. The $\|\cdot\|_\infty$-interior of $\mathcal{B}$ is denoted by $\mathcal{B}^\circ$:

$$\mathcal{B}^\circ \overset{\text{def}}{=} \bigcup_{\delta > 0} \mathcal{B}_\delta\ , \quad \mathcal{B}_\delta \overset{\text{def}}{=} \{u \in U \ : \ a(x) + \delta \le u(x) \le b(x) - \delta, \ x \in \Omega\}.$$

We often write $f_k, g_k, \ldots$ for $f(u_k), g(u_k), \ldots$.

Finally, we recall that all pointwise statements on measurable functions are meant to hold μ-almost everywhere. Similarly, we call two sets equal if they differ at most by a set of measure zero.

3.2. Basic problem setting. The finite-dimensional convergence analysis heavily relies on the equivalency of norms in $\mathbb{R}^N$. This analysis is used, for example, to obtain pointwise ($\|\cdot\|_\infty$) estimates from $\|\cdot\|_2$ estimates. In the infinite-dimensional context the formulation of the algorithm and the proof of its convergence is more delicate. The following assumptions on the function f are needed to state the algorithm and to prove its basic global convergence property, which corresponds to (2.7). Additional assumptions are needed to derive refined convergence results and will be stated later.

The basic assumptions are as follows:

(A1) $f : \mathcal{D} \longrightarrow \mathbb{R}$ is differentiable on $\mathcal{D}$ with g mapping $\mathcal{B} \subset U$ continuously into U'.

(A2) The gradient g satisfies $g(\mathcal{B}) \subset V$.

(A3) There exists $c_1 > 0$ such that $\|g(u)\|_\infty \le c_1$ for all $u \in \mathcal{B}$.

The formulation of second-order necessary optimality conditions requires the following assumption, which is also the basis for our second-order convergence results.

(A4) f is twice continuously differentiable on $\mathcal{D}$. If $p = \infty$, then $\nabla^2 f(u) \in \mathcal{L}(U, U')$ for all $u \in \mathcal{B}$, and if $(h_k) \subset V$ converges to zero in all spaces $L^q(\Omega)$, $1 \le q < \infty$, then $\nabla^2 f(u) h_k$ tends to zero in U'.

For $p \in [2, \infty)$ the assumptions (A1) and (A4) simply say that f is continuously Fréchet differentiable or that f is twice continuously Fréchet differentiable, respectively. If $p = \infty$, then the requirements that $g(u), \nabla^2 f(u) h \in U' = L^1(\Omega) \ne U^*$ for $u \in \mathcal{B}$, $h \in V$ is a further condition. It allows us to use estimates like $\langle v, g(u) \rangle \le \|g(u)\|_{p'} \|v\|_p$ for $p \in [2, \infty)$ and $p = \infty$. Moreover, since on $L^1(\Omega)$ the L^1- and $(L^\infty)^*$-norms coincide, assumption (A4) implies that $\nabla^2 f : \mathcal{B} \subset U \longrightarrow \mathcal{L}(U, U')$ is continuous also for $p = \infty$. Finally, (A1) ensures that the gradient $g(u)$ is always at least an L^1-function which will be essential for many reasons, e.g., to allow the definition of a function space analogue for the scaling matrix D.

Remark 3.1. From (A1), (A3), the boundedness of $\mathcal{B}$, and the mean value theorem it follows that f is bounded on $\mathcal{B}$.

The above conditions limit the optimal control problems that fit into this framework. However, a large and important class of optimal control problems with L^p-controls satisfies these conditions. In section 8 we will discuss the validity of these assumptions for the control problems stated in the introduction.

3.3. Norm estimates. In this section we collect several useful norm estimates for L^q-spaces. The first lemma states that $\|\cdot\|_{q_1}$ is majorizable by a multiple of $\|\cdot\|_{q_2}$ if $q_2 \ge q_1$.

LEMMA 3.2. *For all* $1 \le q_1 \le q_2 \le \infty$ *and* $v \in L^{q_2}(\Omega)$ *we have*

$$\|v\|_{q_1} \le m_{q_1,q_2} \|v\|_{q_2}$$

with $m_{q_1,q_2} = \mu(\Omega)^{\frac{1}{q_1} - \frac{1}{q_2}}$. *Here* $1/\infty$ *is to be interpreted as zero.*

Proof. See, e.g., [1, Thm. 2.8]. □

As a consequence of Hölder's inequality we obtain the following result, which allows us to apply the principle of boundedness in the high norm and convergence in the low norm.

LEMMA 3.3 (interpolation inequality). *Given* $1 \le q_1 \le q_2 \le \infty$ *and* $0 \le \theta \le 1$, *let* $1 \le q \le \infty$ *satisfy* $1/q = \theta/q_1 + (1-\theta)/q_2$. *Then for all* $v \in L^{q_2}(\Omega)$ *the following is true:*

$$\|v\|_q \le \|v\|_{q_1}^{\theta} \|v\|_{q_2}^{1-\theta}. \tag{3.1}$$

Proof. In the nontrivial cases $0 < \theta < 1$ and $q < \infty$ observe that $[q_1/(\theta q)]^{-1} + [q_2/((1-\theta)q)]^{-1} = 1$ and apply Hölder's inequality:

$$\|v\|_q^q = \big\||v|^{\theta q} |v|^{(1-\theta)q}\big\|_1 \le \big\||v|^{\theta q}\big\|_{\frac{q_1}{\theta q}} \big\||v|^{(1-\theta)q}\big\|_{\frac{q_2}{(1-\theta)q}} = \|v\|_{q_1}^{(\theta q)} \|v\|_{q_2}^{(1-\theta)q}. \qquad \square$$

The next lemma will be used in the proof of Lemma 7.1.

LEMMA 3.4. *For* $v \in L^q(\Omega)$, $1 \le q < \infty$ *and all* $\delta > 0$ *holds*

$$\mu(\{x \in \Omega \,:\, |v(x)| \ge \delta\}) \le \delta^{-q} \|v\|_q^q.$$

Proof.

$$\|v\|_q^q = \||v|^q\|_1 \ge \|\chi_{\{|v| \ge \delta\}} |v|^q\|_1 \ge \mu(\{|v| \ge \delta\}) \delta^q. \qquad \square$$

4. Necessary optimality conditions and affine scaling.

The problem under consideration belongs to the class of cone constrained optimization problems in Banach space for which optimality conditions are available [16]. However, we believe that for our particular problem an elementary derivation of the necessary optimality conditions for problem (P) not only is simpler but also is more transparent than the application of the general theory. This derivation also helps us to motivate the choice of the affine scaling which is used to reformulate the optimality condition and which is the basis for the interior-point method.

4.1. First-order necessary conditions.

The first-order necessary optimality conditions in Theorem 4.1 are completely analogous to those for finite-dimensional problems with simple bounds ([6], Sect. 2). We have only to replace coordinatewise statements with pointwise statements and to ensure that the gradient $g(\bar{u})$ is a measurable function.

THEOREM 4.1 (first-order necessary optimality conditions). *Let $\bar{u}$ be a local minimizer of problem* (P) *and assume that f is differentiable at $\bar{u}$ with $g(\bar{u}) \in U'$. Then*

$$\bar{u} \in \mathcal{B}, \tag{O1}$$

$$g(\bar{u})(x) \begin{cases} = 0 & \text{for } x \in \Omega \text{ with } a(x) < \bar{u}(x) < b(x), \\ \geq 0 & \text{for } x \in \Omega \text{ with } \bar{u}(x) = a(x), \\ \leq 0 & \text{for } x \in \Omega \text{ with } \bar{u}(x) = b(x) \end{cases} \tag{O2}$$

are satisfied.

The first-order optimality conditions for infinite-dimensional problems are typically not stated in this form. The conditions (O1), (O2) can be deduced from other first order conditions such as those in [16]. For completeness, we provide an elementary proof of Theorem 4.1.

Proof. Condition (O1) is trivially satisfied. To verify (O2), define

$$A_- = \{x \in \Omega \;:\; \bar{u}(x) = a(x),\ g(\bar{u})(x) < 0\}\,, \quad A_-^k = \{x \in A_- \;:\; g(\bar{u})(x) \leq -1/k\}\,,$$

and assume that A_- has positive measure $\mu(A_-) > \varepsilon > 0$. Since μ is continuous from below and $A_-^k \uparrow A_-$, there exists $l > 0$ with $\mu(A_-^l) \geq \varepsilon$. This yields a contradiction because $\bar{u} + \tau s \in \mathcal{B}$, $s = \chi_{A_-}(b - a)$, for $0 \leq \tau \leq 1$, and

$$\frac{d}{d\tau} f(\bar{u} + \tau s)|_{\tau=0} = \langle s, g(\bar{u}) \rangle \leq -\frac{\varepsilon \nu}{l} < 0.$$

Hence, we must have $\mu(A_-) = 0$. In the same way we can show that $\mu(A_+) = 0$ for $A_+ = \{x \in \Omega \;:\; \bar{u}(x) = b(x),\ g(\bar{u})(x) > 0\}$. Finally, we look at

$$I = \{x \in \Omega \;:\; a(x) < \bar{u}(x) < b(x),\ g(\bar{u})(x) \neq 0\}\,.$$

Assume that $\mu(I) > \varepsilon > 0$. Since $I^k \uparrow I$ with

$$I^k = \{x \in \Omega \;:\; a(x) + 1/k \leq \bar{u}(x) \leq b(x) - 1/k,\ |g(\bar{u})(x)| \geq 1/k\}\,,$$

we can find $l > 0$ with $\mu(I^l) \geq \varepsilon$ and obtain for

$$s = -\chi_{I^l} \frac{g(\bar{u})}{|g(\bar{u})|}$$

that $\bar{u} + \tau s \in \mathcal{B}$, $0 \le \tau \le 1/l$, and

$$\frac{d}{d\tau} f(\bar{u} + \tau s)|_{\tau=0} = \langle s, g(\bar{u}) \rangle \le -\frac{\varepsilon}{l} < 0,$$

a contradiction to the local optimality of $\bar{u}$. Hence $\mu(I) = \mu(A_-) = \mu(A_+) = 0$, which means that (O2) holds. □

4.2. Affine scaling. Let assumption (A1) hold. Our algorithm will be based on the following equivalent affine-scaling formulation of (O2):

$$d^r(\bar{u}) g(\bar{u}) = 0, \tag{4.1}$$

where $r > 0$ is arbitrary and $d(u) \in V$, $u \in \mathcal{B}$, is a scaling function which is assumed to satisfy

$$d(u)(x) \begin{cases} = 0 & \text{if } u(x) = a(x) \text{ and } g(u)(x) \ge 0, \\ = 0 & \text{if } u(x) = b(x) \text{ and } g(u)(x) \le 0, \\ > 0 & \text{else}, \end{cases} \tag{4.2}$$

for all $x \in \Omega$. The equivalence of (O2) and (4.1) will be stated and proved in Lemma 4.2. Before we do this, we give two examples of proper choices for d. The first choice $d = d_{\mathrm{I}}$ is motivated by the scaling matrices used in [6] (see (2.1)). Except for points x with $g(u)(x) = 0$ it equals those used in [6] and [11]:

$$d_{\mathrm{I}}(u)(x) \overset{\text{def}}{=} \begin{cases} u(x) - a(x) & \text{if } g(u)(x) > 0 \text{ or} \\ & g(u)(x) = 0 \text{ and } u(x) - a(x) \le b(x) - u(x), \\ b(x) - u(x) & \text{if } g(u)(x) < 0 \text{ or} \\ & g(u)(x) = 0 \text{ and } b(x) - u(x) < u(x) - a(x). \end{cases} \tag{4.3}$$

This slight modification in comparison to (2.1) lets d_{I} satisfy (4.2). This will enable us to prove second-order global convergence without a nondegeneracy assumption, which is needed by Coleman and Li [6].

While the global analysis could be carried out entirely with this choice, the discontinuous response of $d(u)(x)$ to sign changes of $g(u)(x)$ raises difficulties for the design of superlinearly convergent algorithms in infinite dimensions. These can be circumvented by the choice $d = d_{\mathrm{II}}$, where

$$d_{\mathrm{II}}(u)(x) \overset{\text{def}}{=} \begin{cases} \min\{|g(u)(x)|, c(x)\} & \text{if } -g(u)(x) > u(x) - a(x) \\ & \text{and } u(x) - a(x) \le b(x) - u(x), \\ \min\{|g(u)(x)|, c(x)\} & \text{if } g(u)(x) > b(x) - u(x) \\ & \text{and } b(x) - u(x) \le u(x) - a(x), \\ \min\{u(x) - a(x), & \\ \qquad b(x) - u(x), c(x)\} & \text{else}. \end{cases} \tag{4.4}$$

Here $c : x \in \Omega \longmapsto \min\{\zeta(b(x) - a(x)), \kappa\}$ with $\zeta \in (0, 1/2]$ and $\kappa \ge 1$.

It is easily seen that $d = d_{\mathrm{I}}$ and $d = d_{\mathrm{II}}$ both satisfy (4.2).

LEMMA 4.2. *Let* (A1) *hold and* $\bar{u} \in \mathcal{B}$. *Then* (O2) *is equivalent to* (4.1) *for all* $r > 0$ *and all* d *satisfying* (4.2).

Proof. Since d^r, $r > 0$, also satisfies (4.2), we may restrict ourselves to the case $r = 1$. First assume that (O2) holds. For all $x \in \Omega$ with $g(\bar{u})(x) = 0$ we also have $d(\bar{u})(x) g(\bar{u})(x) = 0$. If $g(\bar{u})(x) > 0$, then by (O2) $\bar{u}(x) = a(x)$ and if $g(\bar{u})(x) < 0$ then $\bar{u}(x) = b(x)$. In both cases $d(\bar{u})(x) = 0$ and hence $d(\bar{u})(x) g(\bar{u})(x) = 0$. On the other hand, let $d(\bar{u})g(\bar{u}) = 0$ hold. For all $x \in \Omega$ with $a(x) < \bar{u}(x) < b(x)$ we have $d(\bar{u})(x) > 0$ which implies $g(\bar{u})(x) = 0$. For all $x \in \Omega$ with $\bar{u}(x) = a(x)$ we obtain $g(\bar{u})(x) \geq 0$ since $g(\bar{u})(x) < 0$ would yield the contradiction $d(\bar{u})(x) > 0$. Analogously, we see that $g(\bar{u})(x) \leq 0$ for all $x \in \Omega$ with $\bar{u}(x) = b(x)$. Therefore, (O2) holds. □

4.3. Second-order conditions. If assumption (A4) holds, we can derive second-order conditions which are satisfied at all local solutions of (P). These are also analogous to the well-known conditions for finite-dimensional problems.

THEOREM 4.3 (second-order necessary optimality conditions). *Let* (A4) *be satisfied and let $g(\bar{u}) \in U'$ hold at the local minimizer $\bar{u}$ of problem* (P). *Then* (O1), (O2), *and*

$$\text{(O3)} \qquad \langle s, \nabla^2 f(\bar{u})s \rangle \geq 0 \textit{ for all } s \in T(\mathcal{B}, \bar{u})$$

are satisfied, where

$$T(\mathcal{B}, \bar{u}) \overset{\text{def}}{=} \{s \in V \;:\; s(x) = 0 \textit{ for all } x \in \Omega \textit{ with } \bar{u}(x) \in \{a(x), b(x)\}\}$$

denotes the tangent space of the active constraints.

As in the case of Theorem 4.1, these second-order necessary optimality conditions are related to the general conditions in, e.g., [16]. However, they are tailored to our problem and are slightly different. For completeness, we provide an elementary proof.

Proof. Let the assumptions hold. As shown in Theorem 4.1, (O1) and (O2) are satisfied. In particular, we have that $sg(\bar{u}) = 0$ for all $s \in T(\mathcal{B}, \bar{u})$. Now assume the existence of $s \in T(\mathcal{B}, \bar{u})$ and $\varepsilon > 0$ with $\langle s, \nabla^2 f(\bar{u})s \rangle < -\varepsilon$. Let $I = \{x \in \Omega \;:\; a(x) < \bar{u}(x) < b(x)\}$,

$$I_k = \{x \in \Omega \;:\; a(x) + 1/k \leq \bar{u}(x) \leq b(x) - 1/k\}, \tag{4.5}$$

and define restrictions $s^k = \chi_{I_k} s \in V$. Since $I_k \uparrow I$ and $s = \chi_I s$, we get $\|s^k - s\|_q^q \leq \mu(I \backslash I_k)\|s\|_\infty^q$. Hence, the restrictions s^k converge to s in all spaces $L^q(\Omega)$, $1 \leq q < \infty$. Therefore, $\nabla^2 f(\bar{u})(s - s^k)$ tends to zero in U' by (A4) and, using the symmetry of $\nabla^2 f(\bar{u})$,

$$\begin{aligned}
\langle s^k, \nabla^2 f(\bar{u})s^k \rangle &= \langle s, \nabla^2 f(\bar{u})s \rangle - \langle s + s^k, \nabla^2 f(\bar{u})(s - s^k) \rangle \\
&< 2\,\|\nabla^2 f(\bar{u})(s - s^k)\|_{p'} \|s\|_p - \varepsilon \\
&\leq -\varepsilon/2
\end{aligned}$$

for all sufficiently large k. Let $l > 0$ be such that $\langle s^l, \nabla^2 f(\bar{u})s^l \rangle \leq -\varepsilon/2$. The observations that $s^l \in T(\mathcal{B}, \bar{u})$ and $\bar{u} + \tau s^l \in \mathcal{B}$ for $0 \leq \tau \leq 1/(l\|s\|_\infty)$ now yield the desired contradiction:

$$\frac{d}{d\tau} f(\bar{u} + \tau s^l)|_{\tau=0} = \langle s, g(\bar{u}) \rangle = 0,$$

$$\frac{d^2}{d\tau^2} f(\bar{u} + \tau s^l)|_{\tau=0} = \langle s^l, \nabla^2 f(\bar{u})s^l \rangle \leq -\varepsilon/2 < 0.$$

This readily shows that (O3) holds. □

5. The algorithm.

5.1. A Newton-like iteration. The key idea of the method to be developed consists in solving the equation $d(u)g(u) = 0$ by means of a Newton-like method augmented by a trust-region globalization. The bound constraints on u are enforced by, e.g., a scaling of the Newton-like step. In particular, all iterates will be strictly feasible with respect to the bounds $u_k \in \mathcal{B}^\circ$.

In general it is not possible to find a function d satisfying (4.2) that depends smoothly on u. For an efficient method, however, we need a suitable substitute for the derivative of dg. Formal application of the product rule suggests choosing an approximate derivative of the form

$$D(u)\nabla^2 f(u) + D_u(u)g(u), \ u \in \mathcal{B}^\circ,$$

with $D_u(u)w \in \mathcal{L}(U, U')$, $w \in U'$, replacing the generally nonexistent derivative of $u \in \mathcal{B} \longmapsto d(u)w \in U'$ at u. Here and in the sequel the linear operator $D^r(u)$, $r \geq 0$, denotes the pointwise multiplication operator associated with $d^r(u)$, i.e.,

$$D^r(u) : v \longmapsto d(u)^r v.$$

Since $d^r(u) \in V$, $D^r(u)$ maps $L^q(\Omega)$, $1 \leq q \leq \infty$, continuously into itself. Moreover, if the assumption (D2) below is satisfied and $u \in \mathcal{B}^\circ$, then $D^r(u)$ defines an automorphism of $L^q(\Omega)$, $1 \leq q \leq \infty$, with inverse $D^{-r}(u)$. In fact, for all $u \in \mathcal{B}^\circ$ there exists $0 < \delta \leq \delta_d$ such that $u \in \mathcal{B}_\delta$, and thus $d(u)(x) \geq \varepsilon_d(\delta)$ on Ω by (D2). If we look at the special case $d = d_{\mathrm{I}}$, the choice $D_u(u)w = d'_{\mathrm{I}}(u)w$ with

$$d'_{\mathrm{I}}(u)(x) \overset{\mathrm{def}}{=} \begin{cases} 1 & \text{if } g(u)(x) > 0 \text{ or} \\ & g(u)(x) = 0 \text{ and } u(x) - a(x) \leq b(x) - u(x) \\ -1 & \text{if } g(u)(x) < 0 \text{ or} \\ & g(u)(x) = 0 \text{ and } b(x) - u(x) < u(x) - a(x) \end{cases} \tag{5.1}$$

for $u \in \mathcal{B}, \ x \in \Omega$ seems to be the most natural. A suitable choice for d'_{II} is

$$d'_{\mathrm{II}}(u)(x) = \chi_{\{d'_{\mathrm{II}}(u)<c\}}(x) d'_{\mathrm{I}}(u)(x). \tag{5.2}$$

For the general case this suggests the choice

$$D(u)\nabla^2 f(u) + E(u),$$

where

$$E(u) : v \longmapsto e(u)v$$

is a multiplication operator characterized by $e(u) \in V$, which approximates $D_u(u)g(u)$. Properties of E will be specified below.

We are now able to formulate the following Newton-like iteration for the solution of $d(u)g(u) = 0$.

Given $u_k \in \mathcal{B}^\circ$, compute the new iterate $u_{k+1} := u_k + s_k \in \mathcal{B}^\circ$, where $s_k \in U$ solves

$$(D_k B_k + E_k)s_k = -d_k g_k \tag{5.3}$$

and B_k denotes a symmetric approximation of (or replacement for) $\nabla^2 f(u_k)$, i.e., $\langle v, B_k w\rangle = \langle w, B_k v\rangle$ for all $v, w \in U$.

We assume that B_k satisfies the following condition:

(A5) The norms $\|B_k\|_{U,U'}$ are uniformly bounded by a constant $c_2 > 0$.

In the following, we will not restrict our investigations to special choices of d and e. Rather, we will develop an algorithm that is globally convergent for all affine scalings d and corresponding e satisfying the assumptions (D1)–(D5):

(D1) The scaling d satisfies (4.2) for all $u \in \mathcal{B}$.

(D2) There exists $\delta_d > 0$ such that for all $\delta \in (0, \delta_d]$ there is $\varepsilon_d = \varepsilon_d(\delta) > 0$ such that $d(u)(x) \geq \varepsilon_d$ for all $u \in \mathcal{B}$ and all $x \in \Omega$ with $a(x) + \delta \leq u(x) \leq b(x) - \delta$.

(D3) The scaling satisfies $d(u)(x) \leq d_{\mathrm{I}}(u)(x)$ for all $u \in \mathcal{B}$, $x \in \Omega$ and d_{I} given by (4.3). In particular, $d(u)(x) \leq c_d$ for some $c_d > 0$.

(D4) For all $u \in \mathcal{B}$ the function $e(u)$ satisfies $0 \leq e(u)(x) \leq c_e$ for all $x \in \Omega$ and $g(u)(x) = 0$ implies $e(u)(x) = 0$.

(D5) The function $e(u)$ is given by $e(u) = d'(u)g(u)$, where $d'(u)$ satisfies $|d'(u)(x)| \leq c_{d'}$ for all $u \in \mathcal{B}$ and $x \in \Omega$.

We have seen that assumption (D1) is essential for the reformulation of the first-order necessary optimality conditions and that (D2) ensures the continuous invertibility of the scaling operator $D(u)$ for $u \in \mathcal{B}^\circ$. Furthermore, assumption (D2) will be used in the second-order convergence analysis. The assumption (D4), together with (A5), is needed to ensure uniform boundedness of the Hessian approximations $\hat{M}_k$ to be defined in the next section. The assumption (D5) is needed to prove second-order convergence results.

Obviously, (D1)–(D3) hold for either $d = d_{\mathrm{I}}$ and $d = d_{\mathrm{II}}$. The assumption (D4) is satisfied for $e(u) = d'_{\mathrm{I}}(u)g(u)$, where $d'_{\mathrm{I}}(u)$ is given by (5.1), provided that $\|g(u)\|_\infty$ is uniformly bounded on $\mathcal{B}$, i.e., provided that (A3) holds.

5.2. New coordinates and symmetrization. Since neither the global well-definedness nor the global convergence of the Newton-like iteration (5.3) can be ensured, we intend to safeguard and globalize it by means of a closely related trust-region method. To this end we have to transform (5.3) into an equivalent quadratic programming problem. While the iterates are required to stay strictly feasible with respect to the bound constraints, we want to use an affine-scaling interior-point approach to reduce the effect of the interfering bound constraints in the quadratic subproblem as far as possible. The affine scaling can be expressed by a change of coordinates $s \rightsquigarrow \hat{s}$ and has to be performed in such a way that we get enough distance from the boundary of the box $\mathcal{B}$ to be able to impose a useful fraction of Cauchy decrease condition on the trial step. An appropriate change of coordinates $s \rightsquigarrow \hat{s}$ is given by $\hat{s} \overset{\text{def}}{=} d_k^{-r} s$. Here

$$r \geq \frac{1}{2}$$

is arbitrary but fixed throughout the iteration. Performing this transformation and applying D_k^{r-1}, the multiplication operator associated with d_k^{r-1}, from the left to (5.3) leads to the equivalent equation

$$\hat{M}_k \hat{s}_k = -\hat{g}_k, \tag{5.4}$$

with $\hat{g}(u) \overset{\text{def}}{=} d^r(u)g(u)$, $\hat{M}_k \overset{\text{def}}{=} \hat{B}_k + \hat{C}_k$, where $\hat{B}_k \overset{\text{def}}{=} D_k^r B_k D_k^r$ and $\hat{C}_k \overset{\text{def}}{=} E_k D_k^{2r-1}$.

Remark 5.1. Assumptions (D3), (D4), and (A5) imply that $\|\hat{M}_k\|_{U,U'}$ are uniformly bounded by a constant $c_3 > 0$.

Since $\hat{M}_k$ is symmetric, $\hat{s}_k$ is a solution of (5.4) if and only if it is a stationary point of the quadratic function

$$\hat{\psi}_k(\hat{s}) \overset{\text{def}}{=} \langle \hat{s}, \hat{g}_k \rangle + \frac{1}{2} \langle \hat{s}, \hat{M}_k \hat{s} \rangle.$$

We will return to this issue later.

5.3. Second-order necessary conditions revisited. If $B_k = \nabla^2 f(u_k)$, then the operator

$$\hat{M}(u) \overset{\text{def}}{=} D(u)^r \nabla^2 f(u) D(u)^r + E(u) D(u)^{2r-1} \tag{5.5}$$

also plays an important role in the second-order necessary optimality conditions. In fact, we will show that if conditions (O1), (O2) hold at $\bar{u}$, then (O3) can be equivalently replaced by

$$\langle s, \hat{M}(\bar{u}) s\rangle \geq 0 \text{ for all } s \in T(\mathcal{B}, \bar{u}) \tag{O3$'$}$$

or even

$$\langle s, \hat{M}(\bar{u}) s\rangle \geq 0 \text{ for all } s \in V. \tag{O3$''$}$$

The proof requires the following two lemmas.

Lemma 5.2. *Let f be differentiable at $\bar{u}$ with $g(\bar{u}) \in U'$,* (D1) *be satisfied, and suppose that* (O1), (O2) *hold at $\bar{u}$. Then*

$$I^* \overset{\text{def}}{=} \{x \in \Omega \,:\, d(\bar{u})(x) > 0\} = \{x \in \Omega \,:\, a(x) < \bar{u}(x) < b(x)\} \overset{\text{def}}{=} I. \tag{5.6}$$

Proof. The inclusion $I \subset I^*$ is obvious from (4.2) and (O2). Now let $x \in I^*$ be given. Then $g(\bar{u})(x) = 0$ by (O2) and Lemma 4.2. From (4.2) we conclude $\bar{u}(x) \notin \{a(x), b(x)\}$, i.e., $x \in I$. □

Lemma 5.3. *Let f be twice continuously differentiable at $\bar{u}$ with $g(\bar{u}) \in U'$ and $\nabla^2 f(\bar{u}) \in \mathcal{L}(U, U')$. Assume that* (D1) *and* (D4) *are satisfied and* (O1), (O2) *hold at $\bar{u}$. Then the statements* (O3$'$) *and* (O3$''$) *are equivalent.*

Proof. Obviously (O3$''$) implies (O3$'$). To show the opposite direction, assume that (O3$'$) holds. Set $A = \Omega \backslash I$, where I is the set defined in (5.6). For arbitrary $s \in V$ we perform the splitting $s = s_I + s_A$, $s_I = \chi_I s \in T(\mathcal{B}, \bar{u})$, $s_A = \chi_A s$. Lemma 5.2 implies that $d^r(\bar{u}) s_A = 0$. Moreover, since s_I and s_A have disjoint support, integrals $\langle \cdot, \cdot \rangle$ involving both s_I and s_A are zero. With these observations we obtain

$$\begin{aligned}
\langle s, \hat{M}(\bar{u}) s\rangle &= \langle s_I, \hat{M}(\bar{u}) s_I\rangle + 2\langle s_A, e(\bar{u}) d^{2r-1}(\bar{u}) s_I\rangle \\
&\quad + 2\langle d^r(\bar{u}) s_A, \nabla^2 f(\bar{u}) d^r(\bar{u}) s_I\rangle + \langle d^r(\bar{u}) s_A, \nabla^2 f(\bar{u}) d^r(\bar{u}) s_A\rangle \\
&\quad + \langle s_A, e(\bar{u}) d^{2r-1}(\bar{u}) s_A\rangle \\
&= \langle s_I, \hat{M}(\bar{u}) s_I\rangle + \langle s_A, e(\bar{u}) d^{2r-1}(\bar{u}) s_A\rangle \geq \langle s_I, \hat{M}(\bar{u}) s_I\rangle \geq 0.
\end{aligned} \tag{5.7}$$

This completes the proof. □

Theorem 5.4. *Let* (D1), (D2), *and* (D4) *be satisfied. Then in Theorem* 4.3 *condition* (O3) *can be equivalently replaced by* (O3$'$) *or* (O3$''$).

Proof. Since the conditions of Theorem 4.3 and Lemma 5.3 guarantee that (O3$'$) and (O3$''$) are equivalent, we only need to show that (O3) can be replaced by (O3$'$).

Let (O1), (O2) be satisfied and let $s \in T(\mathcal{B}, \bar{u})$ be arbitrary. Condition (O2) implies $sg(\bar{u}) = 0$. Hence $\{s \neq 0\} \subset \{g(\bar{u}) = 0\}$ and, by (D4), $\{s \neq 0\} \subset \{e(\bar{u}) = 0\}$. This shows that

$$E(\bar{u}) s = 0 \quad \text{for all } s \in T(\mathcal{B}, \bar{u}). \tag{5.8}$$

To show that (O3) implies (O3′), let $s \in T(\mathcal{B}, \bar{u})$ be arbitrary. Since $d(\bar{u}) \geq 0$, $h = d^r(\bar{u})s \in T(\mathcal{B}, \bar{u})$. With (5.8) this yields

$$\begin{aligned}\langle s, \hat{M}(\bar{u})s\rangle &= \langle h, \nabla^2 f(\bar{u})h\rangle + \langle s, E(\bar{u})D^{2r-1}(\bar{u})s\rangle \\ &= \langle h, \nabla^2 f(\bar{u})h\rangle + \langle E(\bar{u})s, D^{2r-1}(\bar{u})s\rangle = \langle h, \nabla^2 f(\bar{u})h\rangle \geq 0.\end{aligned}$$

To prove the opposite direction, assume that there exist $s \in T(\mathcal{B}, \bar{u})$ and $\varepsilon > 0$ with $\langle s, \nabla^2 f(\bar{u})s\rangle < -\varepsilon$. As carried out in the proof of Theorem 4.3, we can find $l > 0$ such that $s^l = \chi_{I_l} s \in T(\mathcal{B}, \bar{u})$, I_l, as defined in (4.5), satisfies $\langle s^l, \nabla^2 f(\bar{u})s^l\rangle \leq -\varepsilon/2$. Since $d(\bar{u})$ is bounded away from zero on I_l by assumption (D2), we obtain that $h = \chi_{I_l} d^{-r}(\bar{u})s$ is an element of $T(\mathcal{B}, \bar{u})$. With (5.8) applied to h this yields

$$\begin{aligned}\langle h, \hat{M}(\bar{u})h\rangle &= \langle h, D(\bar{u})^r \nabla^2 f(\bar{u}) D(\bar{u})^r h\rangle + \langle h, E(\bar{u})D(\bar{u})^{2r-1}h\rangle \\ &= \langle s^l, \nabla^2 f(\bar{u})s^l\rangle \leq -\varepsilon/2,\end{aligned}$$

a contradiction to (O3′). □

The previous results show that $\hat{\psi}_k(\hat{s})$ is convex and admits a global minimum at $\hat{s} = 0$ if $B_k = \nabla^2 f(u_k)$ and $u_k = \bar{u}$ is a local solution of (P).

5.4. Trust-region globalization. The results on the second-order conditions in the previous section indicate that the Newton-like iteration (5.4) can be used locally under appropriate conditions on B_k. To globalize the iteration, we minimize $\hat{\psi}_k(\hat{s})$ over the intersection of the ball $\|\hat{w}_k\hat{s}\|_p \leq \Delta_k$ and the box $\mathcal{B}$ which leads to the following trust-region subproblem: Compute an approximate solution $\hat{s}_k$ with $u_k + d_k^r\hat{s}_k \in \mathcal{B}^\circ$ of

$$\min \hat{\psi}_k(\hat{s}) \quad \text{subject to} \quad \|\hat{w}_k\hat{s}\|_p \leq \Delta_k\,,\ u_k + d_k^r\hat{s} \in \mathcal{B}. \tag{5.9}$$

Here $\hat{w}_k \in V$ is a positive scaling function for the trust-region. We make the following assumption on $w_k = d_k^{-r}\hat{w}_k$:

(W) There exist $c_w > 0$ and $c_{w'} > 0$ such that $\|d_k^r w_k\|_\infty \leq c_w$ and $\|w_k^{-1}\|_\infty \leq c_{w'}$ for all k.

Examples for w_k are $w_k = d_k^{-r}$, which yields a ball in the $\hat{s}$-variables, and $w_k = 1$, which leads to a ball in the s-variables. Both choices satisfy (W) if (D3) holds. See also [11].

As noted in section 2, the crucial contributions of the affine scaling are the term $E(u)D(u)^{2r-1}$ in the Hessian $\hat{M}(u)$ and the scaling $\hat{g}$ of the gradient. The trust region serves as a tool for globalization. Therefore, general trust-region scalings can be admitted as long as they satisfy (W).

We will work with the original variables in terms of which the above problem reads as follows: Compute s_k with $u_k + s_k \in \mathcal{B}^\circ$ as an approximate solution of

$$\min \psi_k(s) \quad \text{subject to} \quad \|w_k s\|_p \leq \Delta_k\,,\ u_k + s \in \mathcal{B}, \tag{5.10}$$

with $\psi_k(s) = \langle s, g_k\rangle + \frac{1}{2}\langle s, M_k s\rangle$, $M_k = B_k + C_k$, $C_k = E_k D_k^{-1}$, and $w_k = d_k^{-r}\hat{w}_k$. The functions d_k^{-r} and d_k^{-1} are well defined only if $u_k \in \mathcal{B}^\circ$. Therefore, the condition $u_k + d_k^r\hat{s}_k \in \mathcal{B}^\circ$ on the trial iterate is essential. However, it is important to remark that the bound constraints do not need to be strictly enforced when computing $\hat{s}_k$. For example, in the finite-dimensional algorithms in [6], [11], an approximate solution of

$$\min \hat{\psi}_k(\hat{s}) \quad \text{subject to} \quad \|\hat{w}_k\hat{s}\|_p \leq \Delta_k$$

is computed and then scaled by $\tau_k > 0$ so that $u_k + \tau_k d_k^r \hat{s}_k \in \mathcal{B}^\circ$. Similar techniques also apply in the infinite-dimensional framework. Practical choices for the infinite-dimensional algorithm will be discussed in [23].

5.5. Cauchy decrease for the trial steps. An algorithm which is based on the iterative approximate solution of subproblem (5.10) can be expected to converge to a local solution of (P) only if the trial steps s_k produce a sufficiently large decrease of ψ_k. A well-established way to impose such a condition is the requirement that the decrease provided by s_k should be at least a fraction of the Cauchy decrease. Here the Cauchy decrease denotes the maximum possible decrease along the steepest descent direction of ψ_k at $s = 0$ with respect to an appropriate norm (or, equivalently, appropriate coordinates) inside the feasible region of the subproblem. We will see in Lemma 6.1 that the new coordinates $\hat{s} = d_k^{-r} s$ indeed provide enough distance to the boundary of $\mathcal{B}$ to allow the implementation of a useful Cauchy decrease strategy.

Unless as in the Hilbert space case, $p = 2$, the steepest descent direction of $\hat{\psi}_k$ at $\hat{s} = 0$ is *not* given by the negative gradient $-\hat{g}_k$ but rather by any $\hat{s}^d \neq 0$ satisfying $\langle \hat{s}^d, \hat{g}_k \rangle = \|\hat{s}^d\|_p \|\hat{g}_k\|_{p'}$. On the other hand, if $\hat{g}_k \in H$, then $-\nabla\hat{\psi}_k(0) = -\hat{g}_k$ is the $\|\cdot\|_2$-steepest descent direction of $\hat{\psi}_k$ at $\hat{s} = 0$. This is a strong argument for choosing this direction as basis for the Cauchy decrease condition. Of course, this approach is useful only if we ensure that $u_k - \tau d_k^r \hat{g}_k \in \mathcal{B}^\circ$ for all $\tau > 0$ sufficiently small which can be done by imposing condition (A2) on g, which is not very restrictive. Assuming this, we may take $-d_k^r \hat{g}_k = -d_k^{2r} g_k$ as the Cauchy decrease direction of ψ_k and therefore define the following fraction of Cauchy decrease condition: There exist $\beta, \beta_0 > 0$ (fixed for all k) such that s_k is an approximate solution of (5.10) in the sense

$$\|w_k s_k\|_p \le \beta_0 \Delta_k\,,\ u_k + s_k \in \mathcal{B}^\circ\,,\ \text{and } \psi_k(s_k) < \beta \psi_k(s_k^c), \tag{5.11a}$$

where s_k^c is a solution of the one-dimensional problem

$$\min \psi_k(s) \quad \text{subject to} \quad s = -t d_k^{2r} g_k\,,\ t \ge 0\,,\ u_k + s \in \mathcal{B}\,,\ \|w_k s\|_p \le \Delta_k. \tag{5.11b}$$

It is worth mentioning that, as in the finite-dimensional case, an approximate solution $\hat{s}_k$ of (5.10) satisfying (5.11a) can be easily obtained by applying any descent method which starts minimization at $s = 0$ along the Cauchy decrease direction $-d_k^{2r} g_k$.

5.6. Formulation of the algorithm. For the update of the trust-region radius Δ_k and the acceptance of the step we use a very common strategy. It is based on the demand that the actual decrease

$$ared_k(s_k) \overset{\text{def}}{=} f_k - f(u_k + s_k) \tag{5.12}$$

should be a sufficiently large fraction of the predicted decrease

$$pred_k(s_k) \overset{\text{def}}{=} -\langle s_k, g_k \rangle - \frac{1}{2}\langle s_k, B_k s_k \rangle = -\psi_k(s_k) + \frac{1}{2}\langle s_k, C_k s_k \rangle \tag{5.13}$$

promised by the quadratic model. Since the model error is at most $O(\|s_k\|_p^2)$, the decrease ratio

$$\rho_k \overset{\text{def}}{=} \frac{ared_k(s_k)}{pred_k(s_k)} \tag{5.14}$$

will tend to 1 for $s_k \to 0$. This suggests the following strategy for the update of the trust-region radius.

Algorithm 5.5 (update of the trust-region radius Δ_k).

Let $0 < \eta_1 < \eta_2 < \eta_3 < 1$, and $0 < \gamma_1 < 1 < \gamma_2 < \gamma_3$.

1. If $\rho_k \le \eta_1$, then choose $\Delta_{k+1} \in (0, \gamma_1\Delta_k]$.
2. If $\rho_k \in (\eta_1, \eta_2)$, then choose $\Delta_{k+1} \in [\gamma_1\Delta_k, \Delta_k]$.
3. If $\rho_k \in [\eta_2, \eta_3)$, then choose $\Delta_{k+1} \in [\Delta_k, \gamma_2\Delta_k]$.
4. If $\rho_k \ge \eta_3$, then choose $\Delta_{k+1} \in [\gamma_2\Delta_k, \gamma_3\Delta_k]$.

Remark 5.6. The forms of predicted and actual decrease follow the choices used in [11], [24] (and [10] for the constrained case). In [6] the decreases and the ratio are computed as follows:

$$\begin{aligned} pred_k^1(s_k) &\overset{\text{def}}{=} -\psi_k(s_k), \\ ared_k^1(s_k) &\overset{\text{def}}{=} ared_k(s_k) - \tfrac{1}{2}\langle s_k, C_k s_k\rangle, \\ \rho_k^1 &\overset{\text{def}}{=} \frac{ared_k^1(s_k)}{pred_k^1(s_k)}. \end{aligned} \tag{5.15}$$

We restrict the presentation to the choice (5.12), (5.13). However, we already note that all convergence results presented in this paper remain valid if ρ_k is replaced by ρ_k^1 . This will be discussed in more detail in Remarks 6.7 and 7.4 following the convergence results.

The algorithm iteratively computes a trial step s_k satisfying the fraction of Cauchy decrease condition. Depending on the decrease ratio ρ_k the trial step is accepted or rejected, and the trust-region radius is adjusted.

Algorithm 5.7 (trust-region interior-point algorithm).

```
Let $\eta_1 > 0$ as in Algorithm 5.5.
 1. Choose $u_0 \in \mathcal{B}^\circ$ and $\Delta_0 > 0$.
 2. For $k = 0, 1, \dots$
    2.1. Compute the gradient $g_k = g(u_k)$.
    2.2. Compute the scaling $d_k = d(u_k)$.
    2.3. Compute the trust-region scaling $w_k = w(u_k)$.
    2.4. Compute the Hessian approximation $B_k$.
    2.5. Compute $s_k$ satisfying (5.11).
    2.6. If $\|s_k\| = 0$ then stop with result $u_k$.
    2.7. Compute $\rho_k$ as defined in (5.14).
    2.8. If $\rho_k > \eta_1$ then set $u_{k+1} = u_k + s_k$, else set $u_{k+1} = u_k$.
    2.9. Compute $\Delta_{k+1}$ using Algorithm 5.5.
```

In the first-order version of Algorithm 5.7 one can stop after step 2.2 if $\|\hat{g}_k\| = 0$. The stopping criteria as applied above will be important in the second-order version of the algorithm, which will be introduced in section 7.

6. Convergence to first-order optimal points. The convergence of the algorithm is mainly achieved by two ingredients: a lower bound for the predicted decrease for trial steps satisfying the fraction of Cauchy decrease condition, and the relation $ared_k(s_k) > \eta_1 pred_k(s_k)$, which is always satisfied for successful steps s_k. The lower bound on the predicted decrease is established in the following lemma.

Lemma 6.1. *Let the assumptions* (A1), (A2), (D1)–(D4), *and* (W) *hold. Then there exists $c_4 > 0$ such that for all $u_k \in \mathcal{B}^\circ$ with $\hat{g}_k \ne 0$ and all s_k satisfying* (5.11) *the following holds:*

$$pred_k(s_k) \ge -\psi_k(s_k) \ge \frac{1}{2}\beta\|\hat{g}_k\|_2^2 \min\left\{ \frac{\Delta_k}{c_w\|\hat{g}_k\|_p}, \frac{\|\hat{g}_k\|_2^2}{\|\hat{M}_k\|_{U,U'}\|\hat{g}_k\|_p^2}, \frac{c_d^{1-2r}}{\|g_k\|_\infty} \right\}, \tag{6.1}$$

$$\geq c_4 \|\hat{g}_k\|_{p'}^2 \min\left\{ \frac{\Delta_k}{c_w \|\hat{g}_k\|_p}, \frac{\|\hat{g}_k\|_{p'}^2}{\|\hat{M}_k\|_{U,U'} \|\hat{g}_k\|_p^2}, \frac{c_d^{1-2r}}{\|g_k\|_\infty} \right\}. \tag{6.2}$$

If in addition the assumptions (A3) *and* (A5) *hold, then there exists* $c_4' > 0$ *such that for all* $u_k \in \mathcal{B}^\circ$ *with* $\hat{g}_k \neq 0$ *and all* s_k *satisfying* (5.11) *the following holds:*

$$pred_k(s_k) \geq -\psi_k(s_k) \geq c_4' \|\hat{g}_k\|_{p'}^2 \min\left\{ \Delta_k, \|\hat{g}_k\|_{p'}^2, c_d^{1-2r} \right\}. \tag{6.3}$$

Proof. Since C_k is obviously positive by (D4), we have

$$pred_k(s_k) = -\psi_k(s_k) + \frac{1}{2}\langle s_k, C_k s_k \rangle \geq -\psi_k(s_k).$$

From (5.11) we obtain that

$$\psi_k(s_k) \leq \beta \min_{[0,\tau^+]} \phi(\tau), \tag{6.4}$$

where $\phi(\tau) = \psi_k(-\tau d_k^{2r} g_k)$ and $\tau^+ = \min\{\tau_{\mathcal{B}}, \tau_\Delta\}$, with

$$\tau_{\mathcal{B}} = \max\big\{\tau \;:\; b(x) - u_k(x) + \tau d_k^{2r}(x) g_k(x) \geq 0 \text{ and } u_k(x) - a(x) - \tau d_k^{2r}(x) g_k(x) \geq 0 \text{ for all } x \in \Omega\big\}$$

and

$$\tau_\Delta = \frac{\Delta_k}{\|w_k d_k^{2r} g_k\|_p}.$$

We will derive an upper bound for $\min_{[0,\tau^+]} \phi(\tau)$.

First, we bound τ_Δ and $\tau_{\mathcal{B}}$ from below. Using (W), we obtain the bound

$$\tau_\Delta = \frac{\Delta_k}{\|w_k d_k^{2r} g_k\|_p} = \frac{\Delta_k}{\|\hat{w}_k \hat{g}_k\|_p} \geq \frac{\Delta_k}{c_w \|\hat{g}_k\|_p},$$

and using the positivity of d_k, the definition (4.3) of d_{I}, (D3), and $r \geq 1/2$, we obtain the following bound for $\tau_{\mathcal{B}}$:

$$\tau_{\mathcal{B}} = \min\left\{ \inf_{\{g_k(x)<0\}} \frac{b(x) - u_k(x)}{-d_k^{2r}(x) g_k(x)}, \inf_{\{g_k(x)>0\}} \frac{u_k(x) - a(x)}{d_k^{2r}(x) g_k(x)} \right\} = \inf_{\{g_k(x)\neq 0\}} \frac{d_{\mathrm{I}}(u_k)(x)}{d_k^{2r}(x)|g_k(x)|}$$
$$\geq \inf_{\{g_k(x)\neq 0\}} \frac{d_k^{1-2r}(x)}{|g_k(x)|} \geq \inf_{\{g_k(x)\neq 0\}} \frac{c_d^{1-2r}}{|g_k(x)|} \geq \frac{c_d^{1-2r}}{\|g_k\|_\infty}.$$

We have $\phi(\tau) = -\kappa_1 \tau + \frac{1}{2}\kappa_2 \tau^2$ with

$$\kappa_1 = \langle d_k^{2r} g_k, g_k \rangle = \|\hat{g}_k\|_2^2, \quad \kappa_2 = \langle d_k^{2r} g_k, M_k d_k^{2r} g_k \rangle = \langle \hat{g}_k, \hat{M}_k \hat{g}_k \rangle$$

and observe that $|\kappa_2| \leq \|\hat{M}_k\|_{U,U'} \|\hat{g}_k\|_p^2$. Let τ^* be a minimizer for ϕ on $[0, \tau^+]$.

If $\tau^* < \tau^+$, then $\kappa_2 > 0$, $\tau^* = \kappa_1/\kappa_2$, and

$$\phi(\tau^*) = -\frac{1}{2}\frac{\kappa_1^2}{\kappa_2} \leq -\frac{1}{2}\frac{\|\hat{g}_k\|_2^4}{\|\hat{M}_k\|_{U,U'} \|\hat{g}_k\|_p^2}. \tag{6.5}$$

If $\tau^* = \tau_\Delta$ and $\kappa_2 > 0$, then $\kappa_1/\kappa_2 \ge \tau_\Delta$ and

$$\phi(\tau^*) = -\kappa_1\tau_\Delta + \frac{\kappa_2}{2}\tau_\Delta^2 \le -\frac{\kappa_1}{2}\tau_\Delta \le -\frac{1}{2}\frac{\|\hat{g}_k\|_2^2}{c_w\|\hat{g}_k\|_p}\Delta_k. \tag{6.6}$$

If $\tau^* = \tau_\Delta$ and $\kappa_2 \le 0$, then even

$$\phi(\tau^*) \le -\kappa_1\tau_\Delta < -\frac{1}{2}\frac{\|\hat{g}_k\|_2^2}{c_w\|\hat{g}_k\|_p}\Delta_k. \tag{6.7}$$

For $\tau^* = \tau_\mathcal{B}$ analogous arguments show that

$$\phi(\tau^*) \le -\frac{\kappa_1}{2}\tau_\mathcal{B} \le -\frac{1}{2}c_d^{1-2r}\frac{\|\hat{g}_k\|_2^2}{\|g_k\|_\infty}. \tag{6.8}$$

The first inequality (6.1) now follows from the estimates (6.5)–(6.8) and (6.4). The second inequality (6.2) follows from (6.1) and the application

$$\|\hat{g}_k\|_{p'} \le m_{p',2}\|\hat{g}_k\|_2$$

of Lemma 3.2. Note that $p \ge 2$ and $1/p + 1/p' = 1$ yield $p' \le 2$.

The inequality (6.3) follows from (6.2) by applying the following observations. Assumptions (A3) and (D3) yield $\|\hat{g}_k\|_p = \|d_k^r g_k\|_p \le c_d^r \mu(\Omega)^{1/p}\|g_k\|_\infty \le c_d^r c_1 \mu(\Omega)^{1/p}$. Assumptions (D3), (D4), and (A5) imply that $\|\hat{M}_k\|_{U,U'}$ are uniformly bounded by a constant $c_3 > 0$ (see Remark 5.1). □

Let the assumptions of Lemma 6.1 hold. If the kth iteration of Algorithm 5.7 is successful, i.e., $\rho_k > \eta_1$ (or equivalently $u_{k+1} \ne u_k$), then (6.3) guarantees that with $c_5 = \eta_1 c_4' > 0$ the following estimate for the actual decrease holds:

$$f_k - f_{k+1} > c_5\|\hat{g}_k\|_{p'}^2 \min\left\{\Delta_k, \|\hat{g}_k\|_{p'}^2, c_d^{1-2r}\right\}. \tag{6.9}$$

The next statement is trivial.

Lemma 6.2. *Let* (Δ_k) *and* (ρ_k) *be generated by Algorithm* 5.7. *If* $\rho_k \ge \eta_2$ *for sufficiently large* k *then* (Δ_k) *is bounded away from zero.*

Now we can prove a first global convergence result.

Theorem 6.3. *Let assumptions* (A1)–(A3), (A5), (D1)–(D4), *and* (W) *hold. Let the sequence* (u_k) *be generated by Algorithm* 5.7. *Then*

$$\liminf_{k\to\infty}\|d_k^r g_k\|_{p'} = 0.$$

Even more,

$$\liminf_{k\to\infty}\|d_k^r g_k\|_q = 0 \quad \textit{for all } 1 \le q < \infty.$$

Proof. Assume that there are $K > 0$ and $\varepsilon > 0$ with $\|\hat{g}_k\|_{p'} \ge \varepsilon$ for all $k \ge K$. First we will show that this implies $\sum_{k=0}^\infty \Delta_k < \infty$. If there is only a finite number of successful steps then $\Delta_{k+1} \le \gamma_1\Delta_k$ for large k and we are done. Otherwise, if the sequence (k_i) of successful steps does not terminate, we conclude from $f_k \downarrow$ and the boundedness of f (see Remark 3.1) that $\sum_{k=0}^\infty (f_k - f_{k+1}) < \infty$.

For all $k = k_i$ we may use (6.9) and obtain, since $\|\hat{g}_{k_i}\|_{p'} \geq \varepsilon$ for $k_i \geq K$, that Δ_{k_i} tends to zero and, moreover, obeys the inequality

$$\Delta_{k_i} < \frac{1}{c_5 \varepsilon^2}(f_{k_i} - f_{k_i+1})$$

for all k_i sufficiently large. This shows $\sum_{i=0}^{\infty} \Delta_{k_i} < \infty$. Since for all successful steps $k \in \{k_i\}$ we have $\Delta_{k+1} \leq \gamma_2 \Delta_k$ and for all others $\Delta_{k+1} \leq \gamma_1 \Delta_k$, we conclude

$$\sum_{k=0}^{\infty} \Delta_k \leq \sum_{i=0}^{\infty} \Delta_{k_i} \left(1 + \frac{\gamma_2}{1-\gamma_1}\right) < \infty. \tag{6.10}$$

In a second step we will show that $|\rho_k - 1| \to 0$. Due to

$$\|u_{k+1} - u_k\|_p \leq \|s_k\|_p \leq \beta_0 \|w_k^{-1}\|_\infty \Delta_k \leq \beta_0 c_{w'} \Delta_k \tag{6.11}$$

and (6.10), (u_k) is a Cauchy sequence in U. Furthermore,

$$\begin{aligned} 2\left|\psi_k(s_k) - \langle s_k, g_k\rangle - \frac{1}{2}\langle s_k, C_k s_k\rangle\right| &= |\langle s_k, B_k s_k\rangle| \leq \|B_k\|_{U,U'} \|s_k\|_p^2 \\ &\leq c_2 \beta_0^2 c_{w'}^2 \Delta_k^2. \end{aligned}$$

The mean value theorem yields $f(u_k + s_k) - f_k = \langle s_k, \bar{g}_k\rangle$ for some $\tau_k \in [0,1]$ and $\bar{g}_k = g(u_k + \tau_k s_k)$, and hence

$$\begin{aligned} |pred_k(s_k)||\rho_k - 1| &= \left|f(u_k + s_k) - f_k + \frac{1}{2}\langle s_k, C_k s_k\rangle - \psi_k(s_k)\right| \\ &\leq \left|\langle s_k, g_k\rangle + \frac{1}{2}\langle s_k, C_k s_k\rangle - \psi_k(s_k)\right| + |\langle s_k, \bar{g}_k - g_k\rangle| \\ &\leq \left(\frac{c_2}{2}\beta_0^2 c_{w'}^2 \Delta_k + \beta_0 c_{w'} \|\bar{g}_k - g_k\|_{p'}\right) \Delta_k. \end{aligned}$$

Since (u_k) converges in the closed set $\mathcal{B}$, g is continuous, and (Δ_k) as well as $(\|s_k\|_p)$ (see (6.11)) tend to zero, the first factor in the last expression converges to zero, too. Equation (6.3) guarantees that $|pred_k(s_k)|/\Delta_k$ is uniformly bounded away from zero for $k \geq K$, since by assumption $\|\hat{g}_k\|_{p'} \geq \varepsilon$. This shows $|\rho_k - 1| \to 0$. But now Lemma 6.2 yields a contradiction to $\Delta_k \to 0$. Therefore, the assumption is wrong and the first part of the assertion holds.

The second part follows from Lemma 3.2 for $1 \leq q \leq p'$ and from (A3) and the interpolation inequality (3.1) for $p' < q < \infty$. □

Now we will show that if $\hat{g}$ is uniformly continuous, the limits inferior in Theorem 6.3 can be replaced by limits.

We introduce the following assumption:

(A6) The scaled gradient $\hat{g} = d^r g : \mathcal{B} \subset U \longrightarrow U'$ is uniformly continuous.

Condition (A6) is not as easy to verify for most choices of d. With Lemma 6.4, however, we provide a very helpful tool to check the validity of (A6). Moreover, we show in Lemma 6.5 that the following, more convenient, condition implies (A6).

(A6′) The gradient $g : \mathcal{B} \subset U \longrightarrow U'$ is uniformly continuous and $d = d_{\mathrm{I}}$ or $d = d_{\mathrm{II}}$.

The proofs of both lemmas can be found in the appendix. As a by-product of our investigations we get the valuable result that $\hat{g}$ inherits the continuity of g if we choose $d = d_{\mathrm{I}}$ or $d = d_{\mathrm{II}}$. We will derive the results concerning continuity and uniform continuity of $\hat{g}$ simultaneously. Additional requirements for the uniform continuity are written in parentheses.

LEMMA 6.4. *Let* (A1)–(A3), (D3) *hold and* $g : \mathcal{B} \subset U \longrightarrow U'$ *be* (*uniformly*) *continuous. Assume that* $\|\chi_{\{g(u)g(\tilde{u})>0\}}(d(u) - d(\tilde{u}))\|_{p'}$ *tends to zero* (*uniformly in* $u \in \mathcal{B} \subset U$) *for* $\tilde{u} \to u$ *in* $\mathcal{B} \subset U$. *Then* $\hat{g} = d^r g : \mathcal{B} \subset U \longrightarrow U'$ *is* (*uniformly*) *continuous.*

Proof. See appendix. □

The previous lemma is now applicable to the choices $d = d_{\mathrm{I}}$ and $d = d_{\mathrm{II}}$, as follows.

LEMMA 6.5. *Let* (A1)–(A3) *hold and* $d = d_{\mathrm{I}}$ *or* $d = d_{\mathrm{II}}$. *Then* $\hat{g} = d^r g : \mathcal{B} \subset U \longrightarrow U'$ *is continuous. If, in addition, g is uniformly continuous, then the same is true for* $\hat{g}$.

Proof. See appendix. □

Now we state the promised variant of Theorem 6.3.

THEOREM 6.6. *Let assumptions* (A1)–(A3), (A5), (D1)–(D4), (W), *and* (A6) *or* (A6′) *hold. Then the sequence* (u_k) *generated by Algorithm* 5.7 *satisfies*

$$\lim_{k\to\infty} \|d_k^r g_k\|_{p'} = 0. \tag{6.12}$$

Even more,

$$\lim_{k\to\infty} \|d_k^r g_k\|_q = 0 \quad \text{for all } 1 \le q < \infty. \tag{6.13}$$

Proof. Since, due to Lemma 6.5, $\hat{g} = d^r g$ is uniformly continuous, it suffices to show that under the assumption $\|\hat{g}_k\|_{p'} \ge \varepsilon_1 > 0$ for an infinite number of iterations k there exists a sequence of index pairs (m_i, l_i) with $\|\hat{g}_{m_i} - \hat{g}_{l_i}\|_{p'} \ge \delta > 0$ but $\|u_{m_i} - u_{l_i}\|_p \to 0$, which is a contradiction to the uniform continuity of $\hat{g}$.

Let us assume that (6.12) does not hold. Then there is $\varepsilon_1 > 0$ and a sequence (m_i) with $\|\hat{g}_{m_i}\|_{p'} \ge \varepsilon_1$. Theorem 6.3 yields a sequence (k_i) with $\|\hat{g}_{k_i}\|_{p'} \to 0$. For arbitrary $0 < \varepsilon_2 < \varepsilon_1$ we can thus find a sequence (l_i) such that

$$\|\hat{g}_k\|_{p'} \ge \varepsilon_2, \quad m_i \le k < l_i, \quad \|\hat{g}_{l_i}\|_{p'} < \varepsilon_2.$$

Since $\hat{g}_{l_i} \ne \hat{g}_{l_i - 1}$, iteration $l_i - 1$ is successful and one has for all successful iterations k, $m_i \le k < l_i$, by Lemma 6.1 and (6.9)

$$f_k - f_{k+1} > c_5 \varepsilon_2^2 \min\left\{\Delta_k, \varepsilon_2^2, c_d^{1-2r}\right\}. \tag{6.14}$$

The left-hand side converges to zero, because (f_k) is nonincreasing and bounded from below, i.e., it is a Cauchy sequence. We conclude that Δ_k tends to zero for successful steps $m_i \le k < l_i$ and with (6.11) we get that

$$f_k - f_{k+1} \ge c_5 \varepsilon_2^2 \Delta_k \ge \frac{c_5 \varepsilon_2^2}{\beta_0 c_{w'}} \|u_{k+1} - u_k\|_p \overset{\text{def}}{=} c_6 \|u_{k+1} - u_k\|_p,$$

which is clearly true also for unsuccessful iterations. Summing and using the triangle inequality yields

$$f_{m_i} - f_{l_i} \ge c_6 \|u_{m_i} - u_{l_i}\|_p.$$

Since (f_k) is a Cauchy sequence, the left-hand side converges to zero for $i \to \infty$. Hence, $\|u_{m_i} - u_{l_i}\|_p \longrightarrow 0$ but

$$\|\hat{g}_{m_i} - \hat{g}_{l_i}\|_{p'} \geq \|\hat{g}_{m_i}\|_{p'} - \|\hat{g}_{l_i}\|_{p'} \geq \varepsilon_1 - \varepsilon_2 > 0.$$

This is a contradiction to the uniform continuity of $\hat{g}$. The second assertion follows as in the proof of Theorem 6.3. □

Remark 6.7. The convergence results in Theorems 6.3 and 6.6 remain valid if the definitions (5.12), (5.13) of predicted reduction $pred_k$ and actual reduction $ared_k$ are replaced by (5.15), the choices in [6].

To see that this is true, note that the crucial estimate (6.2) remains valid for $pred_k^1(s_k)$. Under (D4), $\langle s_k, C_k s_k\rangle \geq 0$ and, consequently,

$$ared_k^1(s_k) \leq ared_k(s_k).$$

Hence, (6.9) remains valid for successful iterations if ρ_k is replaced by ρ_k^1. Finally, since

$$pred_k^1(s_k)(\rho_k^1 - 1) = pred_k(s_k)(\rho_k - 1),$$

the proof of Theorem 6.3 remains valid if $pred_k$ and ρ_k are replaced by $pred_k^1$ and ρ_k^1, respectively. Since the proof of Theorem 6.6 only depends on Theorem 6.3 and on (6.9) but not explicitly on $pred_k$ and $ared_k$, its proof remains valid without any changes.

7. Convergence to second-order optimal points. The first-order convergence results in the previous section could be shown under rather weak conditions on the trust-region step s_k and for arbitrary symmetric and bounded Hessian approximations. If stronger assumptions are imposed on B_k and on s_k, then it can be shown that every accumulation point of (u_k) satisfies the second-order necessary optimality conditions. This will be done in this section. We need the following assumption on the Hessian approximation:

(A7) For all accumulation points $\bar{u} \in U$ of (u_k) and all $\varepsilon > 0$ there is $\delta = \delta(\bar{u}, \varepsilon) > 0$ such that $\|u_k - \bar{u}\|_p \leq \delta$ implies $\|B_k - \nabla^2 f(\bar{u})\|_{U,U'} \leq \varepsilon$.

Obviously (A7) is satisfied if $B_k = \nabla^2 f(u_k)$ and if (A4) holds. However, (A7) also applies in other important situations. For example, (A7) applies if f is a least squares functional, $f(\bar{u}) = 0$, and B_k is the Gauss–Newton approximation of the Hessian.

The fraction of Cauchy decrease condition does not take into account any properties of the quadratic part of ψ_k. Apparently, this condition is too weak to guarantee the positivity of $\hat{M}(\bar{u})$ at accumulation points of (u_k). The decrease condition has to be strengthened in such a way that for $\bar{u}$ satisfying (O1) and (O2) but not (O3$''$) there are $\alpha, \varepsilon, c > 0$ such that $\psi_k(s_k) \leq -c \min\{\Delta_k^2, \alpha^2\}$ for all iterates u_k with $\|u_k - \bar{u}\|_p \leq \varepsilon$. For the finite-dimensional problem one can establish such an inequality near nondegenerate points $\bar{u}$ by using techniques similar to those of Coleman and Li [6] if the s_k satisfy a finite-dimensional fraction of optimal decrease condition of the form

$$\|w_k s_k\|_2 \leq \beta_0 \Delta_k\,,\ u_k + s_k \in \mathcal{B}^\circ\,,\ \text{and } \psi_k(s_k) < \beta \psi_k^o, \tag{7.1a}$$

where $\psi_k^o = \psi_k(\tau_k s_k^o)$, $\tau_k = \max\{\tau \geq 0 \,:\, u_k + \tau s_k^o \in \mathcal{B}\}$, and s_k^o solves

$$\min \psi_k(s) \quad \text{subject to} \quad \|w_k s\|_2 \leq \Delta_k. \tag{7.1b}$$

This approach is not directly transferable to our setting because the example

$$\min \quad -\int_0^1 ts^2(t)\,dt \quad \text{subject to} \quad \|s\|_2 \le \Delta \tag{7.2}$$

shows that even in a Hilbert space s_k^o may not exist. Moreover, the proofs in [6] use extensively a convenient characterization of s_k^o derived from the KKT conditions [20] and the equivalence of 2-norm and ∞-norm in $\mathbb{R}^N$. Since, as shown by (7.2), in Banach space the quadratic subproblem may not have a solution, this is not applicable in our framework. Our convergence proof requires that the trial steps yield a fraction of the Cauchy decrease and, moreover, a fraction of the decrease achievable along directions of negative curvature of ψ_k at $s = 0$. For convenience and simplicity of notation, however, we favor a more intuitive but stronger condition which is formulated in the flavor of (7.1). Our fraction of optimal decrease condition is given by the following. There exist $\beta, \beta_0 > 0$ (fixed for all k) such that

$$\|w_k s_k\|_p \le \beta_0 \Delta_k\,, \; u_k + s_k \in \mathcal{B}^\circ\,, \text{ and } \psi_k(s_k) < \beta\psi_k^o, \tag{7.3a}$$

where

$$\psi_k^o \overset{\text{def}}{=} \inf \psi_k(s) \quad \text{subject to} \; u_k + s \in \mathcal{B}\,, \; \|w_k s\|_p \le \Delta_k. \tag{7.3b}$$

There are two important differences between (7.1) and (7.3). Both arise in the definition of ψ_k^o. First, the min in (7.1b) is replaced by an inf in (7.3b) for the reasons explained above. Second, in the computation of ψ_k^o in (7.3b), the bound constraints are explicitly enforced. In the finite-dimensional context (7.1b) this is not necessary, since E_k tends to equilibrate the distance to the bounds along the optimal decrease direction s_k^o. As a consequence, the bound constraints can be enforced by simple scaling of the solution s_k^o of (7.1b) by τ_k. This equilibration property, however, makes use of the equivalence of the 2-norm and the ∞-norm in finite dimensions. Recall the discussion at the end of section 2.

To obtain global convergence results toward points satisfying second-order necessary optimality conditions, the fraction of optimal decrease condition has to be incorporated into Algorithm 5.7. Step 2.5 of Algorithm 5.7 has to be replaced by

2.5.′ Compute s_k satisfying (7.3).

When we refer to Algorithm 5.7 in this section we assume that step 2.5 is replaced by step 2.5′.

In the next lemma we show that in a neighborhood of an accumulation point $\bar{u}$ of (u_k) at which (O1), (O2) but not (O3″) hold, one can find a direction of negative curvature h^n of ψ_k such that $u_k \pm h^n \in \mathcal{B}$.

Lemma 7.1. *Let assumptions* (A1), (A2), (A4), (A5), (A7), (D1)–(D5) *hold and let the sequence* (u_k) *be generated by Algorithm* 5.7. *Assume that* $\bar{u} \in \mathcal{B}$ *is an accumulation point of* (u_k) *with* $\hat{g}(\bar{u}) = 0$ *and that there are* $\bar{h} \in V$, $\bar{h} \ne 0$, *and* $\lambda > 0$ *with*

$$\langle \bar{h}, \hat{M}(\bar{u})\bar{h} \rangle \le -\lambda \|\bar{h}\|_p^2. \tag{7.4}$$

Then there exist $\varepsilon, \alpha, \hat{\lambda} > 0$ *such that for all* u_k *with* $\|u_k - \bar{u}\|_p \le \varepsilon$ *one can find* $h \in V$, $\|h\|_p = 1$, *with* $u_k + \tau\alpha d_k^r h \in \mathcal{B}$ *for all* $\tau \in [-1, 1]$ *and*

$$\langle h, \hat{M}_k h \rangle \le -\hat{\lambda} \|h\|_p^2. \tag{7.5}$$

Proof. Since $\bar{u} \in \mathcal{B}$ and $\hat{g}(\bar{u}) = 0$, (O1) and (O2) are satisfied due to Lemma 4.2. Lemma 5.2 yields $I \overset{\text{def}}{=} \{x \in \Omega : \ a(x) < \bar{u}(x) < b(x)\} = \{x \in \Omega : \ d(\bar{u})(x) > 0\} \overset{\text{def}}{=} I^*$. Define $I_\delta = \{x \in \Omega : \ a(x) + \delta \le \bar{u}(x) \le b(x) - \delta\}$ for arbitrary $0 < \delta < 4\delta_d$ with δ_d as in (D2). We write $v_A = \chi_A v$ for measurable functions v and measurable sets $A \subset \Omega$.

We first show that (7.4) implies the existence of $\tilde{h} \in V$ with $\|\tilde{h}\|_p = 1$, $\{\tilde{h} \neq 0\} \subset I_\delta$, and

$$\langle \tilde{h}, \hat{M}(\bar{u})\tilde{h} \rangle \le -\frac{\lambda}{2}. \tag{7.6}$$

In the first step toward (7.6) we use the techniques of the proof of Lemma 5.3. More precisely, applying the inequalities (5.7) with s replaced by $\bar{h}$ we obtain that

$$0 > -\lambda \|\bar{h}\|_p^2 \ge \langle \bar{h}, \hat{M}(\bar{u})\bar{h} \rangle \ge \langle \bar{h}_I, \hat{M}(\bar{u})\bar{h}_I \rangle.$$

Hence, $\bar{h}_I \in V \setminus \{0\}$ and

$$\langle \bar{h}_I, \hat{M}(\bar{u})\bar{h}_I \rangle \le -\lambda \|\bar{h}\|_p^2 \le -\lambda \|\bar{h}_I\|_p^2 < 0, \tag{7.7}$$

i.e., (7.4) holds for $\bar{h}_I$ instead of $\bar{h}$. Furthermore, the symmetry of $\hat{M}(\bar{u})$ and the identity $\bar{h}_I = \bar{h}_{I_\delta} + \bar{h}_{I \setminus I_\delta}$ imply

$$\begin{aligned}
\langle \bar{h}_{I_\delta}, \hat{M}(\bar{u})\bar{h}_{I_\delta} \rangle &= \langle \bar{h}_I, \hat{M}(\bar{u})\bar{h}_I \rangle - \langle \bar{h}_{I_\delta} + \bar{h}_I, \hat{M}(\bar{u})\bar{h}_{I\setminus I_\delta} \rangle \\
&\le -\lambda \|\bar{h}_I\|_p^2 + \|\hat{M}(\bar{u})\bar{h}_{I\setminus I_\delta}\|_{p'} (\|\bar{h}_I\|_p + \|\bar{h}_{I_\delta}\|_p) \\
&\le -\lambda \|\bar{h}_I\|_p^2 + 2\|\hat{M}(\bar{u})\bar{h}_{I\setminus I_\delta}\|_{p'} \|\bar{h}_I\|_p.
\end{aligned}$$

By the definition of $\hat{M}(\bar{u})$ and the fact that $g(\bar{u})$ and thus, by (D4), $e(\bar{u})$ vanishes on I, with (D3) we get

$$\begin{aligned}
\|\hat{M}(\bar{u})\bar{h}_{I\setminus I_\delta}\|_{p'} &= \|(D^r(\bar{u})\nabla^2 f(\bar{u}) D^r(\bar{u}) + E(\bar{u}) D^{2r-1}(\bar{u}))\bar{h}_{I\setminus I_\delta}\|_{p'} \\
&= \|D^r(\bar{u})\nabla^2 f(\bar{u}) D^r(\bar{u})\bar{h}_{I\setminus I_\delta}\|_{p'} \le c_d^r \|\nabla^2 f(\bar{u}) D^r(\bar{u})\bar{h}_{I\setminus I_\delta}\|_{p'}.
\end{aligned}$$

Since the measure of $I \setminus I_\delta$ can be made arbitrarily small by reducing $\delta > 0$ we conclude that $\bar{h}_{I\setminus I_\delta}$ and $D^r(\bar{u})\bar{h}_{I\setminus I_\delta}$ tend to zero for $\delta \to 0$ in all spaces $L^q(\Omega)$, $1 \le q < \infty$. Hence, using (A4), we find $\delta > 0$ with

$$2\|\hat{M}(\bar{u})\bar{h}_{I\setminus I_\delta}\|_{p'} \le \frac{\lambda}{2}\|\bar{h}_I\|_p.$$

Obviously, $\{\tilde{h} \neq 0\} \subset I_\delta$. Thus, (7.6) holds with $\tilde{h} = \bar{h}_{I_\delta} / \|\bar{h}_{I_\delta}\|_p$.

Next, we use $\tilde{h}$ to construct h such that the assertions of the lemma are valid.

For $\varepsilon > 0$ and u_k with $\|u_k - \bar{u}\|_p \le \varepsilon$, define $h \in V$ by

$$h(x) = \begin{cases} \tilde{h}(x)\dfrac{d^r(\bar{u})(x)}{d_k^r(x)} & \text{if} \quad \min\{u_k(x) - a(x), b(x) - u_k(x)\} > \dfrac{\delta}{4}, \\ 0 & \text{otherwise.} \end{cases}$$

We have $I_h \overset{\text{def}}{=} \{h \neq 0\} \subset I_\delta$ and conclude from assumptions (D2) and (D3) that $\varepsilon_d(\delta/4) \le d_k(x) \le c_d$ on I_h and $\varepsilon_d(\delta/4) \le d(\bar{u})(x) \le c_d$ on I_δ, which implies that

$$\|h\|_p \le \gamma \ , \ \|h\|_\infty \le \gamma \|\tilde{h}\|_\infty \ , \ \|h\|_p \ge \frac{1}{\gamma}\|\tilde{h}_{I_h}\|_p \quad \text{with} \quad \gamma = \frac{c_d^r}{\varepsilon_d^r(\delta/4)}. \tag{7.8}$$

From $\bar{u}(x) - a(x), b(x) - \bar{u}(x) \geq \delta$ on I_δ follows

$$I_\delta \setminus I_h \subset \{x \in \Omega \, : \, |u_k(x) - \bar{u}(x)| \geq 3\delta/4\} \, .$$

If $p = \infty$, we achieve $\tilde{h}_{I_\delta \setminus I_h} = 0$ for $\varepsilon < 3\delta/4$. Otherwise, due to Lemma 3.4, we can make $\|\tilde{h}_{I_\delta \setminus I_h}\|_p \leq \mu(I_\delta \setminus I_h)^{1/p} \|\tilde{h}\|_\infty$ arbitrarily small by making $\varepsilon > 0$ small. Hence, in all cases we can reduce ε such that

$$\|h\|_p \geq \frac{1}{\gamma} \|\tilde{h}_{I_h}\|_p \geq \frac{1}{\gamma} \left(\|\tilde{h}\|_p - \|\tilde{h}_{I_\delta \setminus I_h}\|_p \right) \geq \frac{1}{2\gamma}. \tag{7.9}$$

By first using the definition of h, $I_h = \{h \neq 0\}$, then the fact that $g(\bar{u})(x) = 0$ on $I_\delta \supset I_h$, the definitions of B_k, $\hat{M}(\bar{u})$, and Hölder's inequality, and finally (D3), (D5), we get

$$\begin{aligned}
\langle h, \hat{M}_k h \rangle &= \langle h, d_k' g_k d_k^{2r-1} h \rangle + \langle d_k^r h, B_k d_k^r h \rangle \\
&= \langle d_k' d_k^{2r-1}, \chi_{I_h}(g_k h^2) \rangle + \langle d^r(\bar{u}) \tilde{h}_{I_h}, B_k d^r(\bar{u}) \tilde{h}_{I_h} \rangle \\
&= \langle d_k' d_k^{2r-1}, \chi_{I_h}(g_k h^2) \rangle + \langle d^r(\bar{u}) \tilde{h}_{I_h}, B_k d^r(\bar{u}) \tilde{h}_{I_h} \rangle + \langle \tilde{h}_{I_h}, d'(\bar{u}) g(\bar{u}) d^{2r-1}(\bar{u}) \tilde{h}_{I_h} \rangle \\
&\leq \|d_k'\|_\infty \|d_k\|_\infty^{2r-1} \|\chi_{I_h} g_k\|_{p'} \|h\|_p \|h\|_\infty + \langle \tilde{h}_{I_h}, \hat{M}(\bar{u}) \tilde{h}_{I_h} \rangle \\
&\quad + \|d(\bar{u})\|_\infty^{2r} \|B_k - \nabla^2 f(\bar{u})\|_{U,U'} \|\tilde{h}_{I_h}\|_p^2 \\
&\leq c_{d'} c_d^{2r-1} \|\chi_{I_h} g_k\|_{p'} \|h\|_\infty \|h\|_p + \langle \tilde{h}_{I_h}, \hat{M}(\bar{u}) \tilde{h}_{I_h} \rangle + c_d^{2r} \|B_k - \nabla^2 f(\bar{u})\|_{U,U'} \|\tilde{h}_{I_h}\|_p^2.
\end{aligned}$$

From $\tilde{h} = \tilde{h}_{I_\delta} = \tilde{h}_{I_h} + \tilde{h}_{I_\delta \setminus I_h}$ we obtain

$$\langle \tilde{h}_{I_h}, \hat{M}(\bar{u}) \tilde{h}_{I_h} \rangle = \langle \tilde{h}, \hat{M}(\bar{u}) \tilde{h} \rangle - \langle \tilde{h} + \tilde{h}_{I_h}, \hat{M}(\bar{u}) \tilde{h}_{I_\delta \setminus I_h} \rangle.$$

Using this equality, the fact that $g(\bar{u})(x) = 0$ on $I_\delta \supset I_h$, and $\|\tilde{h}_{I_h}\|_p \leq \|\tilde{h}\|_p$ in the previous estimate for $\langle h, \hat{M}_k h \rangle$ gives

$$\begin{aligned}
\langle h, \hat{M}_k h \rangle \leq \; & c_{d'} c_d^{2r-1} \|g_k - g(\bar{u})\|_{p'} \|h\|_\infty \|h\|_p + \langle \tilde{h}, \hat{M}(\bar{u}) \tilde{h} \rangle \\
& - \langle \tilde{h} + \tilde{h}_{I_h}, \hat{M}(\bar{u}) \tilde{h}_{I_\delta \setminus I_h} \rangle + c_d^{2r} \|B_k - \nabla^2 f(\bar{u})\|_{U,U'} \|\tilde{h}_{I_h}\|_p^2 \\
\leq \; & c_{d'} c_d^{2r-1} \|g_k - g(\bar{u})\|_{p'} \|h\|_\infty \|h\|_p + \langle \tilde{h}, \hat{M}(\bar{u}) \tilde{h} \rangle \\
& + 2 \|\tilde{h}\|_p \|\hat{M}(\bar{u})\|_{U,U'} \|\tilde{h}_{I_\delta \setminus I_h}\|_p + c_d^{2r} \|B_k - \nabla^2 f(\bar{u})\|_{U,U'} \|\tilde{h}_{I_h}\|_p^2.
\end{aligned}$$

Using (7.6), (7.8), (7.9), and $\|\tilde{h}\|_p = 1$ we arrive at the estimate

$$\begin{aligned}
\langle h, \hat{M}_k h \rangle \leq \; & \big(2 c_{d'} c_d^{2r-1} \gamma^2 \|\tilde{h}\|_\infty \|g_k - g(\bar{u})\|_{p'} - \frac{\lambda}{2\gamma^2} + 8\gamma^2 \|\hat{M}(\bar{u})\|_{U,U'} \|\tilde{h}_{I_\delta \setminus I_h}\|_p \\
& + c_d^{2r} \gamma^2 \|B_k - \nabla^2 f(\bar{u})\|_{U,U'} \big) \|h\|_p^2.
\end{aligned}$$

We have already shown that $\|\tilde{h}_{I_\delta \setminus I_h}\|_p$ can be made arbitrarily small by making $\varepsilon > 0$ small. By continuity the same is true for $\|g_k - g(\bar{u})\|_{p'}$ and by (A7) for $\|B_k - \nabla^2 f(\bar{u})\|_{U,U'}$ (since $\|u_k - \bar{u}\|_p \leq \varepsilon$). Hence, there exist $\varepsilon > 0$ and $\hat{\lambda} > 0$ such that for all u_k with $\|u_k - \bar{u}\|_p \leq \varepsilon$ we can carry out the above construction to obtain $h \in V \setminus \{0\}$ with

$$\langle h, \hat{M}_k h \rangle \leq -\hat{\lambda} \|h\|_p^2.$$

Since $h \neq 0$, $\|h\|_\infty \leq \gamma \|\tilde{h}\|_\infty$, and $\|h\|_p \geq \frac{1}{2\gamma}$, where γ depends only on δ, we get

$$\frac{\|h\|_\infty}{\|h\|_p} \leq 2\gamma^2 \|\tilde{h}\|_\infty \overset{\text{def}}{=} C.$$

In addition, we have by construction $I_h \subset \{x \in \Omega \,:\, a(x) + \delta/4 \leq u_k(x) \leq b(x) - \delta/4\}$ and consequently

$$u_k + \tau \frac{\delta}{4Cc_d^r} d_k^r \frac{h}{\|h\|_p} \in \mathcal{B} \text{ for all } \tau \in [-1, 1].$$

Setting $\alpha = \delta/4Cc_d^r$ and renorming h to unity completes the proof. □

Now we establish the required decrease estimate.

Lemma 7.2. *Let assumptions* (A1), (D3), (D4), (W) *hold and s_k satisfy* (7.3). *If for u_k there exist $\hat{\lambda}, \alpha > 0$, $h_k \in V$, $\|h_k\|_p = 1$, with $u_k + \tau\alpha d_k^r h_k \in \mathcal{B}$ for all $\tau \in [-1, 1]$ and*

$$\langle h_k, \hat{M}_k h_k \rangle \leq -\hat{\lambda} \|h_k\|_p^2,$$

then

$$pred_k(s_k) \geq -\psi_k(s_k) \geq \frac{\beta\hat{\lambda}}{2} \min\left\{ \frac{\Delta_k^2}{c_w^2}, \alpha^2 \right\}. \tag{7.10}$$

Proof. The first inequality is obvious. Now let $\hat{\lambda}, \alpha > 0$ be given. For all u_k which admit $h_k \in V$, $\|h_k\|_p = 1$, with $u_k \pm \alpha d_k^r h_k \in \mathcal{B}$ and $\langle h_k, \hat{M}_k h_k \rangle \leq -\hat{\lambda} \|h_k\|_p^2$, set

$$\hat{s}_k^n = \pm \min\{\Delta_k / c_w, \alpha\} h_k \text{ and } s_k^n = d_k^r \hat{s}_k^n,$$

and choose the sign such that $\langle \hat{s}_k^n, \hat{g}_k \rangle \leq 0$. Then $\|w_k s_k^n\|_p \leq \Delta_k$ by assumption (W) and $u_k + s_k^n \in \mathcal{B}$. Hence s_k^n is admissible for (7.3b) and can be used to get an upper bound for $\psi_k(s_k)$. The fraction of optimal decrease condition (7.3) gives

$$\begin{aligned} \psi_k(s_k) &\leq \beta\psi_k(s_k^n) = \beta\hat{\psi}_k(\hat{s}_k^n) = \beta\langle \hat{s}_k^n, \hat{g}_k \rangle + \frac{\beta}{2} \langle \hat{s}_k^n, \hat{M}_k \hat{s}_k^n \rangle \leq \frac{\beta}{2} \langle \hat{s}_k^n, \hat{M}_k \hat{s}_k^n \rangle \\ &\leq -\frac{\beta\hat{\lambda}}{2} \|\hat{s}_k^n\|_p^2 = -\frac{\beta\hat{\lambda}}{2} \min\left\{ \frac{\Delta_k^2}{c_w^2}, \alpha^2 \right\}. \qquad \square \end{aligned}$$

For a large class of trust-region algorithms for unconstrained finite-dimensional problems Shultz, Schnabel, and Byrd [19] proposed a very elegant way to prove that all accumulation points of the iterates satisfy the second-order necessary optimality conditions. The key idea is to increase the trust-region radius after exceedingly successful steps (case 4 in Algorithm 5.5). The following convergence theorem is an analogue to [19, Thm. 3.2].

Theorem 7.3. *Let assumptions* (A1)–(A7), (D1)–(D5), *and* (W) *hold. Moreover, let the sequence (u_k) be generated by the Algorithm* 5.7 *and let all s_k satisfy* (7.3). *Then every accumulation point $\bar{u} \in U$ of (u_k) satisfies the second-order necessary conditions* (O1)–(O3).

Proof. Let $\bar{u} \in U$ be an accumulation point of u_k. Then $\bar{u} \in \mathcal{B}$ and, since $\hat{g} : \mathcal{B} \subset U \longrightarrow U$ is continuous, $\hat{g}(\bar{u}) = 0$ by Theorem 6.6. Using Lemma 4.2, this implies (O1) and (O2).

Now assume that (O3) does not hold at $\bar{u}$. Then due to Theorem 5.4 there are $\bar{h} \in V$, $\bar{h} \neq 0$, and $\lambda > 0$ with $\langle \bar{h}, \hat{M}(\bar{u})\bar{h}\rangle \leq -\lambda \|\bar{h}\|_p^2$. Lemmas 7.1 and 7.2 yield $\alpha, c_7, \varepsilon > 0$ with $\mathit{pred}_k(s_k) \geq c_7 \min\{\Delta_k^2, \alpha^2\}$ for all u_k satisfying $\|u_k - \bar{u}\|_p \leq \varepsilon$. By choosing $0 < \Delta \leq \alpha$ we achieve that for all k with $\Delta_k \leq \Delta$ and $\|u_k - \bar{u}\|_p \leq \varepsilon$

$$\mathit{pred}_k(s_k) \geq c_7 \Delta_k^2.$$

Using this estimate, (A4), (A7), and $\|s_k\|_p \leq \beta_0 c_{w'} \Delta_k$ (see (6.11)) we find—possibly after reducing ε and Δ—with appropriate $\tau_k \in [0,1]$

$$\begin{aligned}
\mathit{pred}_k(s_k)\,|\rho_k - 1| &= \left| f(u_k + s_k) - f_k + \frac{1}{2}\langle s_k, C_k s_k\rangle - \psi_k(s_k)\right| \\
&= \frac{1}{2}\left|\langle s_k, (\nabla^2 f(u_k + \tau_k s_k) - B_k)s_k\rangle\right| \\
&\leq \frac{1}{2}\left(\|\nabla^2 f(u_k + \tau_k s_k) - \nabla^2 f(\bar{u})\|_{U,U'} + \|\nabla^2 f(\bar{u}) - B_k\|_{U,U'}\right)\|s_k\|_p^2 \\
&\leq (1-\eta_3)c_7\Delta_k^2 \leq (1-\eta_3)\mathit{pred}_k(s_k).
\end{aligned}$$

This shows $\rho_k \geq \eta_3$ for all k with $\Delta_k \leq \Delta$ and $\|u_k - \bar{u}\|_p \leq \varepsilon$ and hence $\Delta_{k+1} \in [\gamma_2\Delta_k, \gamma_3\Delta_k]$.

For all $K > 0$ there is $l > K$ with $\|u_l - \bar{u}\|_p \leq \varepsilon/2$ and $\rho_l > \eta_1$. In fact, since $\bar{u}$ is an accumulation point of (u_k), we can find $l' > K$ with $\|u_{l'} - \bar{u}\|_p \leq \varepsilon/2$. Now $\rho_k \leq \eta_1$ for all $k \geq l'$ cannot occur, because then $\Delta_k \leq \gamma_1^{k-l'}\Delta_{l'}$ eventually satisfies $\Delta_k \leq \Delta$ and consequently $\rho_k \geq \eta_3 > \eta_1$. Hence, there is $l \geq l' > K$ with $u_l = u_{l'}$ and $\rho_l > \eta_1$.

Since $\Delta_{k+1} \geq \gamma_2\Delta_k$ for all k with $\|u_k - \bar{u}\|_p \leq \varepsilon$ and $\Delta_k \leq \Delta$, it is easily seen that

1. $\Delta_l > \Delta$, or
2. $\Delta_l \leq \Delta$ and there is $m > l$ such that $\|u_k - \bar{u}\|_p \leq \varepsilon$ and $\Delta_k \leq \Delta$ for $l \leq k < m$, and
   2.1. $\Delta_m > \Delta$, or
   2.2. $\Delta_m \leq \Delta$ and $\|u_m - \bar{u}\|_p > \varepsilon$.

In case 1 we get

$$f_l - f_{l+1} > \eta_1 c_7 \min\{\Delta_l^2, \alpha^2\} \geq \eta_1 c_7 \Delta^2.$$

For case 2.1 we have $\Delta \geq \Delta_{m-1} \geq \Delta_m/\gamma_3 > \Delta/\gamma_3$, and $\rho_{m-1} \geq \eta_3$; hence

$$f_{m-1} - f_m \geq \eta_3 c_7 \Delta_{m-1}^2 \geq \eta_3 c_7 \frac{\Delta^2}{\gamma_3^2}.$$

In case 2.2 we get $\Delta_{k+1} \geq \gamma_2\Delta_k$, $k = l, \ldots, m-1$. This implies $\Delta_k \leq \gamma_2^{k-m+1}\Delta_{m-1}$ and

$$\begin{aligned}
\frac{\varepsilon}{2} &\leq \|u_m - \bar{u}\|_p - \|u_l - \bar{u}\|_p \leq \|u_m - u_l\|_p = \left\|\sum_{k=l}^{m-1} s_k\right\|_p \\
&\leq \sum_{k=l}^{m-1}\|s_k\|_p \leq \beta_0 c_{w'}\sum_{k=l}^{m-1}\Delta_k \leq \beta_0 c_{w'}\Delta_{m-1}\sum_{k=l}^{m-1}\gamma_2^{k-m+1} \leq \beta_0 c_{w'}\Delta_{m-1}\frac{\gamma_2}{\gamma_2 - 1}.
\end{aligned}$$

This yields

$$f_{m-1} - f_m \geq \eta_3 c_7 \Delta_{m-1}^2 \geq \eta_3 c_7 \left(\frac{\varepsilon(\gamma_2 - 1)}{2\beta_0 c_{w'} \gamma_2} \right)^2 .$$

Therefore, for infinitely many steps k we get a decrease $f_k - f_{k+1}$ of at least a constant value which yields $f_k \to -\infty$. This contradicts the boundedness of f on $\mathcal{B}$, which follows from (A1)–(A3) (see Remark 3.1). Thus, (O3) must hold at $\bar{u}$. □

Remark 7.4. As for the first-order convergence results, the second-order convergence result in Theorem 7.3 remains valid if the definitions (5.12), (5.13) of predicted reduction $pred_k$ and actual reduction $ared_k$ are replaced by (5.15), the choices in [6]. Since (7.10) remains valid for $pred_k^1$, in the proof of Theorem 7.3 $pred_k$ can be replaced by $pred_k^1$.

8. Examples. In this section we examine the examples presented in the introduction and show how the general class of algorithms presented in this paper can be applied in those cases. We give justifications for the assumptions (A1)–(A3) which are needed to guarantee the first-order convergence result Theorem 6.3. The other assumptions, which mostly address the second derivatives, can be justified in similar ways with proper adjustment of the assumptions on the problem data in the two problems. Since the mere statement of the second-order derivatives is rather lengthy, this has been omitted.

8.1. A parabolic boundary control problem of Stefan–Boltzmann type. If a metal rod is heated by radiation on its right side $x = 1$ with temperature $u(t)$, $t \in [0,T]$, the temperature distribution $y(t,x)$, $(t,x) \in [0,T] \times [0,1]$, satisfies in good approximation the heat equation with the Stefan–Boltzmann boundary condition (1.1). The control $u \in \mathcal{B} \overset{\text{def}}{=} \{u \in L^\infty(0,T) \ : \ 0 \leq u \leq 1\}$ shall be determined in such a way that the temperature $y(T,x)$ at time T follows a given temperature profile $y_d \in C([0,T])$. To this end we want to solve the problem

$$\begin{aligned} &\text{minimize} \quad f(u) \overset{\text{def}}{=} \frac{1}{2}\|y(u)(T,.) - y_d\|_2^2 + \frac{\alpha}{2}\|u\|_2^2 \\ &\text{subject to} \quad u \in \mathcal{B}, \end{aligned} \tag{8.1}$$

where $y = y(u)$ is the solution of (1.1) and $\alpha \geq 0$ is a regularization parameter. For the case $\alpha = 0$ this problem was considered in [18]. This optimization problem with $\alpha > 0$ is also considered in [14] and [15]. By defining mild solutions to (1.1) via a weakly singular integral equation of Volterra type it can be shown with the same techniques as in [18] that for $p > 2$ the mapping $u \in \mathcal{D} \subset L^p([0,T]) \longmapsto y(u) \in C([0,T] \times [0,1])$ is completely continuous and continuously Fréchet differentiable on an open neighborhood $\mathcal{D}$ of $\mathcal{B}$. Consequently, the objective function $f(u)$ of (8.1) is continuously Fréchet differentiable on $\mathcal{D} \subset L^p([0,T])$. Hence, assumption (A1) is shown for $U = L^p([0,T])$, $p > 2$. Since the 2-norm is weakly lower semicontinuous on $L^p([0,T])$, existence of an optimal solution to (8.1) can be proven as in [18], where only the case $\alpha = 0$ is considered. It remains to check (A2) and (A3). As shown in [18] the gradient representation $g(u)$ of $f(u)$ with respect to the L^2 dual pairing, $\langle h, \nabla f(u) \rangle = (h, g(u))_2$, is given by

$$g(u) = z(u,.,1) + \alpha u, \tag{8.2}$$

where $z = z(u) \in C([0,T] \times [0,1])$ is the mild solution of the adjoint equation

$$\begin{aligned} z_t(t,x) &= -z_{xx}(t,x), \quad (t,x) \in (0,T) \times (0,1) \\ z(T,x) &= y(T,x) - y_d(x), \quad x \in (0,1) \\ z_x(t,0) = 0, \quad z_x(t,1) &= -4y(t,1)^3 z(t,1), \quad t \in (0,T). \end{aligned} \tag{8.3}$$

In (8.3) $y = y(u)$ is the solution of (1.1). Using again the Volterra integral formulation of (8.3), it can be shown that $z(u)$ is uniformly bounded in $C([0,T] \times [0,1])$ for $u \in \mathcal{B}$, since this holds for $y(u)$. Hence, $\|g(u)\|_\infty \le \|z(u)\|_\infty + \alpha\|u\|_\infty \le c_1$ for all $u \in \mathcal{B}$. This shows that (A2) and (A3) also are satisfied.

For this example, the computation of the gradient $g_k = g(u_k)$ in step 2.1 of Algorithm 5.7 requires the solution $y = y(u_k)$ of the heat equation (1.1) and the solution $z = z(u_k)$ of the adjoint equation (8.3). In steps 2.2 and 2.3 we can use $d_k = d_{\text{II}}(u_k)$ defined by (4.4), with $\zeta = \kappa = 0.075$, $r = 1$, and $w_k = 1$, the parameter values corresponding to those in the numerical example of [23]. As we have noted, these choices satisfy (D1)–(D4) and (W). The function $d'(u)$ defining $e(u)$ can be chosen to be $d'(u) = d'_{\text{II}}(u)$ defined by (5.2). This choice satisfies (D5). For this example, $c(x) = 0.075 \min\{1-0,1\} = 0.075$ and thus

$$d_{\text{II}}(u)(t) = \begin{cases} \min\{|z(u,t,1) + \alpha u(t)|, 0.075\} & \text{if } -(z(u,t,1) + \alpha u(t)) > u(t) \\ & \text{and } u(t) \le 1 - u(t), \\ \min\{|z(u,t,1) + \alpha u(t)|, 0.075\} & \text{if } z(u,t,1) + \alpha u(t) > 1 - u(t) \\ & \text{and } 1 - u(t) \le u(t), \\ \min\{u(t), 1-u(t), 0.075\} & \text{else.} \end{cases}$$

In the simplest case one could find a step s_k in step 2.5 of the algorithm by one-dimensional minimization of $\psi_k(-t d_k^2 g_k)$. The second-order term $\langle d_k^2 g_k, B_k d_k^2 g_k \rangle$ could be obtained by using a finite difference approximation of $\nabla^2 f(u_k) d_k^2 g_k$.

8.2. A control problem of Bolza type. We consider the control problem of Bolza type

$$\begin{aligned} &\text{minimize} \quad f(u) \overset{\text{def}}{=} P(y(u)(1)) + \int_0^1 h_0(x, y(u)(x), u(x))\,dx \\ &\text{subject to} \quad u \in \mathcal{B}, \end{aligned} \tag{8.4}$$

where $y = y(u)$ is the solution of (1.2). Our presentation is based on Tian and Dunn [21]. We work in $L^2([0,1])$, i.e., $\Omega = [0,1]$, $p = p' = 2$, and $U = H = U' = L^2([0,1])$. Let the function $P : \mathbb{R}^m \longrightarrow \mathbb{R}$ be twice continuously differentiable. The function h_0 and the right-hand side $h = (h_1, \ldots, h_m)^T$ of the state equation (1.2) are given by

$$h_i : [0,1] \times \mathbb{R}^m \times \mathbb{R} \longrightarrow \mathbb{R}\ , \quad h_i(x,y,u) = h_i^0(x,y) + h_i^1(x,y)u + h_i^2(x,y)u^2.$$

Hereby, the functions $h_i^k : [0,1] \times \mathbb{R}^m \longrightarrow \mathbb{R}$ as well as their first and second partial y-derivatives are assumed to be continuous and the derivatives $\nabla_y h_i^k$, $1 \le i \le m$ are assumed to be bounded on $[0,1] \times \mathbb{R}^m$.

For this problem one can prove the following assertions ([21] and the references therein):

(a) For every $u \in L^2([0,1])$ there exists a unique absolutely continuous solution $y(u)$ to (1.2) on $[0,1]$. Moreover, the mapping $u \in \mathcal{B} \subset L^2([0,1])$

$\longmapsto y(u) \in C^0([0,1])^m$ is continuous. In addition, $y(\mathcal{B})$ is a bounded set in $C^0([0,1])^m$.

(b) The objective function f is continuously Fréchet differentiable. The gradient $g(u) \in L^2([0,1])$ of f is given by

$$g(u)(x) = \frac{\partial h_0}{\partial u}(x,y,u) + z(x)^T \frac{\partial h}{\partial u}(x,y,u), \tag{8.5}$$

where $y = y(u)$ is the solution of (1.2) and $z = z(u) : [0,1] \longrightarrow \mathbb{R}^m$ solves the adjoint equation

$$\begin{aligned}\frac{dz}{dx}(x) &= -\nabla_y h_0(x,y(x),u(x)) - \nabla_y h(x,y(x),u(x))z(x),\\ z(1) &= \nabla P(y(1)),\end{aligned}$$

with $y = y(u)$. Here we have used the notation $\nabla_y h = (\nabla_y h_1, \ldots, \nabla_y h_m)$. As for the state one can show that the adjoint state $z(u)$ is uniquely defined and absolutely continuous and that the mapping $u \in L^2([0,1]) \longmapsto z(u) \in C^0([0,1])^m$ is continuous. Furthermore, $z(\mathcal{B})$ is a bounded set in $C^0([0,1])^m$.

We can now verify our assumptions. The validity of (A1) with $\mathcal{D} = L^2([0,1])$ is stated in (b). From the form of the functions h_i, the properties of state and adjoint state, and the gradient representation (8.5) we see that the gradient is obtained by adding and multiplying L^∞-functions which are uniformly bounded for $u \in \mathcal{B} \subset L^\infty([0,1])$. This shows that assumptions (A2) and (A3) hold true. It is also possible to prove that the gradient g is uniformly continuous, i.e., (A6$'$) holds.

One can show that f is even twice continuously Fréchet differentiable with a Hessian representation of the form

$$\langle v, \nabla^2 f(u) w\rangle = \int_0^1 v(x)S(u)(x)w(x)\,dx + \int_0^1\int_0^1 v(x)K(u)(x,\xi)w(\xi)\,d\xi\,dx,$$

where $S(u) \in L^\infty([0,1])$ and $K(u) \in L^2([0,1]\times[0,1])$ are certain functions depending on the problem data. The lengthy expressions for S and K are omitted here. We refer to [21, pp. 535, 536].

A particular version of Algorithm 5.7 for this example can now be obtained as before. One uses a modification of the conjugate gradient algorithm similar to [10] to compute s_k in step 2.5. This will be discussed in detail in [23].

Similar results can be obtained for the more general case

$$h_i(x,y,u) = \sum_{0\le k\le p} h_i^k(x,y)u^k, \quad p \ge 2,$$

if $U = L^p([0,1])$ is used instead of $L^2([0,1])$, which underlines the practical importance of our L^p-framework.

9. Conclusions and future work.

We have introduced and analyzed a globally convergent class of interior-point trust-region algorithms for infinite-dimensional nonlinear optimization subject to pointwise bounds in function space. The methods are generalizations of those presented by Coleman and Li [6] for finite-dimensional problems. We have extended all first- and second-order global convergence results that are available for the finite-dimensional setting to our infinite-dimensional L^p-Banach space framework. The analysis was carried out in a unified way for $2 \le p \le \infty$. The lack of the equivalence of norms required the development of new proof techniques. This is also a valuable contribution to the finite-dimensional theory because our results are derived completely without using norm equivalences and hence are almost independent of the problem dimension. In this sense our convergence theory can be considered to be mesh independent. Moreover, we have carried out our analysis for a very general class of affine-scaling operators and almost arbitrary scaling of the trust-region. This is also new from the finite-dimensional viewpoint.

The work on the trust-region algorithm presented in this paper is continued in [23], where a local convergence analysis is developed. To establish local convergence the general choice of scalings w_k allowed in our global convergence analysis will be important. That paper also contains numerical results for optimal control problems governed by a nonlinear parabolic PDE which proves the efficiency of our algorithms. Another important development of [23] is the incorporation of a projection onto the box into the computation of approximate solutions of the trust-region subproblems.

The results of this paper and [23] represent a first important step toward a rigorous justification for why trust-region interior-point and trust-region interior-point SQP methods perform so well on discretized control problems. See [10], [13], [23] for applications. The extension of our theory to methods with additional equality constraints is in progress.

10. Appendix.

In this section we present proofs of Lemmas 6.4 and 6.5. These proofs require the following three technical results.

LEMMA 10.1. *For $0 < r \le 1$, $1 \le q \le \infty$, $v_1, v_2 \in L^q(\Omega)$, $v_1, v_2 \ge 0$, the following holds:*

$$\|v_1^r - v_2^r\|_q \le m_{q,q/r} \|v_1 - v_2\|_q^r. \tag{10.1}$$

Proof. For $r = 1$ the assertion is trivial. For $\alpha, \beta \ge 0$, $0 < r < 1$, we use the estimate

$$|\alpha^r - \beta^r| \le |\alpha - \beta|^r. \tag{10.2}$$

This estimate can be seen as follows. Due to symmetry we may assume that $\alpha \ge \beta \ge 0$. The function $h(\alpha) = |\alpha - \beta|^r - |\alpha^r - \beta^r|$ satisfies $h(\beta) = 0$,

$$h'(\alpha) = r\left((\alpha - \beta)^{r-1} - \alpha^{r-1}\right) \ge 0 \quad (\alpha > \beta)$$

and, thus, $h(\alpha) \ge 0$ for all $\alpha \ge \beta$.

In the case $q = \infty$ the assertion follows immediately from (10.2). For $1 \le q < \infty$ we use Lemma 3.2 to get

$$\begin{aligned} \|v_1^r - v_2^r\|_q \le m_{q,q/r} \|v_1^r - v_2^r\|_{q/r} &= m_{q,q/r} \left(\int_\Omega |v_1(x)^r - v_2(x)^r|^{q/r} \, dx \right)^{r/q} \\ &\le m_{q,q/r} \left(\int_\Omega |v_1(x) - v_2(x)|^q \, dx \right)^{r/q} = m_{q,q/r} \|v_1 - v_2\|_q^r. \end{aligned}$$

This completes the proof. □

LEMMA 10.2. *For $r \ge 1$, $1 \le q \le \infty$, $v_1, v_2 \in V$, $v_1, v_2 \ge 0$, the following inequality holds:*

$$\|v_1^r - v_2^r\|_q \le r \max\left\{\|v_1\|_\infty, \|v_2\|_\infty\right\}^{r-1} \|v_1 - v_2\|_q. \tag{10.3}$$

Proof. In the case $r = 1$ there is nothing to show. First we prove that for all $r > 1$, $\alpha, \beta \in [0, \gamma]$, $\gamma > 0$, we have $h(\alpha) \overset{\text{def}}{=} r\gamma^{r-1}|\alpha - \beta| - |\alpha^r - \beta^r| \geq 0$. In fact, we may assume $\alpha \geq \beta$ and compute $h(\beta) = 0$,

$$h'(\alpha) = r(\gamma^{r-1} - \alpha^{r-1}) \geq 0 \ \ (\beta \leq \alpha \leq \gamma).$$

Therefore,

$$|v_1^r(x) - v_2^r(x)| \leq r \max\left\{\|v_1\|_\infty, \|v_2\|_\infty\right\}^{r-1} |v_1(x) - v_2(x)| \ \text{ for all } x \in \Omega$$

which immediately implies (10.3). □

LEMMA 10.3. *Let $\alpha_1, \ldots, \alpha_n$, and $\beta_1, \ldots, \beta_n$ be arbitrary real numbers. Then*

$$|\min\{\alpha_1, \ldots, \alpha_n\} - \min\{\beta_1, \ldots, \beta_n\}| \leq \max\{|\alpha_1 - \beta_1|, \ldots, |\alpha_n - \beta_n|\}$$

Proof. Without restriction, let $\beta_k = \min\{\beta_1, \ldots, \beta_n\} \leq \min\{\alpha_1, \ldots, \alpha_n\}$. Then the assertion follows from

$$|\min\{\alpha_1, \ldots, \alpha_n\} - \min\{\beta_1, \ldots, \beta_n\}| = \min\{\alpha_1, \ldots, \alpha_n\} - \beta_k \leq \alpha_k - \beta_k. \qquad \square$$

10.1. Proof of Lemma 6.4. We write $\|\cdot\|_{q,A}$ for $\|\chi_A \cdot\|_q$, $A \subset \Omega$ measurable. For arbitrary $u, \tilde{u} \in \mathcal{B}$ set $N = \{x \in \Omega \ : \ g(u)(x)g(\tilde{u})(x) > 0\}$. The triangle inequality gives the estimate

$$\begin{aligned}
\|\hat{g}(u) - \hat{g}(\tilde{u})\|_{p'} &= \|d^r(u)g(u) - d^r(\tilde{u})g(\tilde{u})\|_{p'} \\
&\leq \|d(u)\|_\infty^r \|g(u) - g(\tilde{u})\|_{p'} + \|(d^r(u) - d^r(\tilde{u}))g(\tilde{u})\|_{p'} \\
&\leq \|d(u)\|_\infty^r \|g(u) - g(\tilde{u})\|_{p'} + \|d^r(u) - d^r(\tilde{u})\|_\infty \|g(\tilde{u})\|_{p',\Omega\setminus N} \\
&\quad + \|g(\tilde{u})\|_\infty \|d^r(u) - d^r(\tilde{u})\|_{p',N}.
\end{aligned}$$

We use the fact that $|g(u) - g(\tilde{u})| \geq |g(\tilde{u})|$ on $\Omega \setminus N$ and obtain

$$\begin{aligned}
\|\hat{g}(u) - \hat{g}(\tilde{u})\|_{p'} &\leq (\|d(u)\|_\infty^r + \|d^r(u) - d^r(\tilde{u})\|_\infty)\|g(u) - g(\tilde{u})\|_{p'} \\
&\quad + \|g(\tilde{u})\|_\infty \|d^r(u) - d^r(\tilde{u})\|_{p',N} \\
&\leq 3c_d^r \|g(u) - g(\tilde{u})\|_{p'} + c_1 \|d^r(u) - d^r(\tilde{u})\|_{p',N}.
\end{aligned}$$

Now the (uniform) continuity of $\hat{g}$ follows from Lemma 10.1, Lemma 10.2, the (uniform) continuity of g, and the assumption $\|\chi_N(d(u) - d(\tilde{u}))\|_{p'} \longrightarrow 0$ (uniformly in u) on the scaling. □

10.2. Proof of Lemma 6.5. We restrict ourselves to the more complicated case $d = d_{\text{II}}$. The result follows from Lemma 6.4 if we verify that

$$\|\chi_{\{g(u)g(\tilde{u})>0\}}(d(u) - d(\tilde{u}))\|_{p'} \longrightarrow 0 \qquad \text{as } \tilde{u} \longrightarrow u \text{ (uniformly in } u\text{)}.$$

Let $u, \tilde{u} \in \mathcal{B}$ be arbitrary. Using symmetries, it is easily seen that we are done if we are able to establish appropriate upper bounds for $|d(u)(x) - d(\tilde{u})(x)|$ for the three cases that $g(u)(x) > 0$, $g(\tilde{u})(x) > 0$, and

(a) $d_{\text{II}}(u)(x)$ and $d_{\text{II}}(\tilde{u})(x)$ are both determined by the second case in (4.4),

(b) $d_{\text{II}}(u)(x)$ and $d_{\text{II}}(\tilde{u})(x)$ are both determined by the else case in (4.4),

(c) $d_{\text{II}}(u)(x)$ is determined by the second and $d_{\text{II}}(\tilde{u})(x)$ by the else case in (4.4).

Set $\rho(x) = |d_{\mathrm{II}}(u)(x) - d_{\mathrm{II}}(\tilde{u})(x)|$. We will use Lemma 10.3 several times.

Case (a):

$$\rho(x) = |\min\{g(u)(x), c(x)\} - \min\{g(\tilde{u})(x), c(x)\}| \le |g(u)(x) - g(\tilde{u})(x)|.$$

Case (b):

$$\begin{aligned}\rho(x) &= |\min\{u(x) - a(x), b(x) - u(x), c(x)\} \\ &\quad - \min\{\tilde{u}(x) - a(x), b(x) - \tilde{u}(x), c(x)\}| \\ &\le |u(x) - \tilde{u}(x)|.\end{aligned}$$

Case (c): From $b(x) - u(x) \le u(x) - a(x)$ follows $u(x) - a(x) \ge c(x)$ and therefore

$$\begin{aligned}d_{\mathrm{II}}(u)(x) &= \min\{u(x) - a(x), g(u)(x), c(x)\} \\ &\ge \min\{u(x) - a(x), b(x) - u(x), c(x)\}.\end{aligned}$$

If $g(\tilde{u})(x) > b(x) - \tilde{u}(x)$ then $b(x) - \tilde{u}(x) > \tilde{u}(x) - a(x)$ and hence

$$d_{\mathrm{II}}(\tilde{u})(x) = \min\{\tilde{u}(x) - a(x), g(\tilde{u})(x), c(x)\}.$$

Therefore, we obtain

$$\rho(x) \le \max\{|u(x) - \tilde{u}(x)|, |g(u)(x) - g(\tilde{u})(x)|\}.$$

Otherwise, if $g(\tilde{u})(x) \le b(x) - \tilde{u}(x)$, we have in the case $d_{\mathrm{II}}(u)(x) \ge d_{\mathrm{II}}(\tilde{u})(x)$ that

$$\begin{aligned}\rho(x) &\le \min\{u(x) - a(x), g(u)(x), c(x)\} - \min\{\tilde{u}(x) - a(x), g(\tilde{u})(x), c(x)\} \\ &\le \max\{|u(x) - \tilde{u}(x)|, |g(u)(x) - g(\tilde{u})(x)|\},\end{aligned}$$

and for $d_{\mathrm{II}}(u)(x) < d_{\mathrm{II}}(\tilde{u})(x)$ we get

$$\begin{aligned}\rho(x) &\le \min\{\tilde{u}(x) - a(x), b(x) - \tilde{u}(x), c(x)\} \\ &\quad - \min\{u(x) - a(x), b(x) - u(x), c(x)\} \\ &\le |u(x) - \tilde{u}(x)|.\end{aligned}$$

Taking all cases together, this shows that

$$\begin{aligned}\|\chi_{\{g(u)g(\tilde{u})>0\}}\rho\|_{p'} &\le \|u - \tilde{u}\|_{p'} + \|g(u) - g(\tilde{u})\|_{p'} \\ &\le m_{p',p}\|u - \tilde{u}\|_{p} + \|g(u) - g(\tilde{u})\|_{p'}.\end{aligned}$$

Now, the application of Lemma 6.4 shows that $\hat{g}$ inherits the (uniform) continuity of g. □

A NEW PROJECTION METHOD FOR VARIATIONAL INEQUALITY PROBLEMS*

M. V. SOLODOV† AND B. F. SVAITER†

Abstract. We propose a new projection algorithm for solving the variational inequality problem, where the underlying function is continuous and satisfies a certain generalized monotonicity assumption (e.g., it can be pseudomonotone). The method is simple and admits a nice geometric interpretation. It consists of two steps. First, we construct an appropriate hyperplane which strictly separates the current iterate from the solutions of the problem. This procedure requires a single projection onto the feasible set and employs an Armijo-type linesearch along a feasible direction. Then the next iterate is obtained as the projection of the current iterate onto the intersection of the feasible set with the halfspace containing the solution set. Thus, in contrast with most other projection-type methods, only two projection operations per iteration are needed. The method is shown to be globally convergent to a solution of the variational inequality problem under minimal assumptions. Preliminary computational experience is also reported.

Key words. variational inequalities, projection methods, pseudomonotone maps

1. Introduction.

We consider the classical variational inequality problem [1, 3, 7] VI(F, C), which is to find a point x^* such that

$$x^* \in C, \quad \langle F(x^*), x - x^* \rangle \geq 0 \quad \text{for all} \quad x \in C, \tag{1.1}$$

where C is a closed convex subset of $\Re^n$, $\langle \cdot, \cdot \rangle$ denotes the usual inner product in $\Re^n$, and $F : \Re^n \to \Re^n$ is a continuous function. Let S be the solution set of VI(F, C), which we assume to be nonempty. Let x^* be any element of the solution set S. We further assume that

$$\langle F(x), x - x^* \rangle \geq 0 \quad \text{for all} \quad x \in C. \tag{1.2}$$

It is clear that (1.2) is satisfied if $F(\cdot)$ is monotone; i.e.,

$$\langle F(x) - F(y), x - y \rangle \geq 0 \quad \text{for all} \quad x, y \in \Re^n.$$

More generally, (1.2) also holds if $F(\cdot)$ is pseudomonotone (as defined in [11]); i.e., for all $x, y \in \Re^n$

$$\langle F(y), x - y \rangle \geq 0 \quad \Longrightarrow \quad \langle F(x), x - y \rangle \geq 0.$$

Moreover, it is not difficult to construct examples where (1.2) is satisfied but $F(\cdot)$ is not monotone or pseudomonotone everywhere. Typically, condition (1.2) holds under some kind of generalized monotonicity assumptions on $F(\cdot)$, some of which are not difficult to check (see [26, 25]).

In the case when $F(\cdot)$ is strongly monotone and/or the feasible set C has some special structure (e.g., C is the nonnegative orthant or, more generally, a box), there exist many efficient methods that can be used to solve those special cases of $\mathrm{VI}(F, C)$ (see [4, 5, 14, 18, 19, 20, 22, 23, 34, 36, 2, 16, 29, 15, 28, 27, 31]). In some of those methods, $F(\cdot)$ is further assumed to be differentiable, or Lipschitz continuous, or affine. Sometimes it is also assumed that the method starts close enough to the solution set (i.e., only local convergence is guaranteed). In the general case when $F(\cdot)$ and C do not possess any special structure, relatively few methods are applicable. In that case, projection-type algorithms are of particular relevance (we refer the reader to [32] for a more detailed discussion). The oldest algorithm of this class is the extragradient method proposed in [13] and later refined and extended in [10, 12, 17, 33, 9]. Some new projection-type algorithms that appear to be more efficient than the extragradient method were recently introduced in [32] (see also references therein).

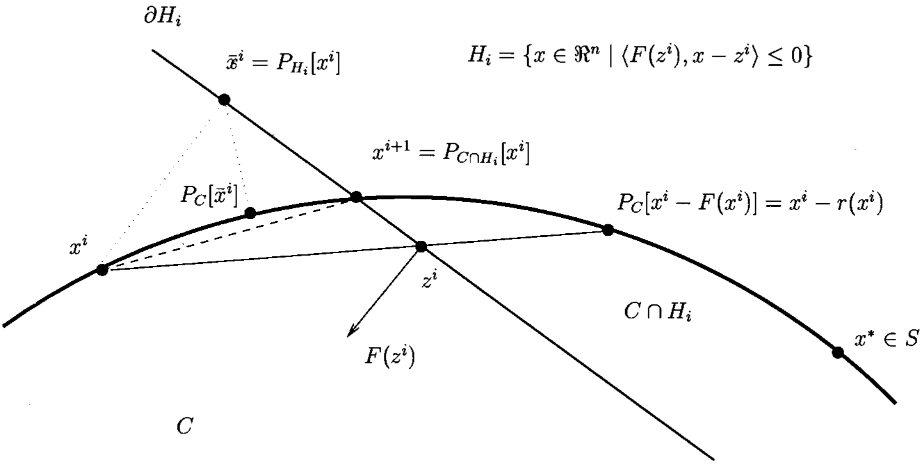
In this paper, we are mainly concerned with the general case when the projection operator

$$P_C[x] := \arg\min_{y \in C} \|y - x\|$$

is computationally expensive (i.e., one has to solve an optimization problem to find a projection). Furthermore, we make no assumptions on the problem other than continuity of $F(\cdot)$ and condition (1.2). In this setting, one of the important tasks in devising efficient algorithms is to minimize the number of projection operations performed at each iteration. We note that in the case when $F(\cdot)$ is not Lipschitz continuous or the Lipschitz constant is not known, the extragradient method, as described in [12, 17, 10, 33], requires a linesearch procedure to compute the stepsize, with a new projection needed for each trial point. The same holds for the modified projection-type method in [32]. Clearly, this can be very computationally expensive. A novel idea to get around this inefficiency was proposed in [9] for the extragradient method. Here we will use this idea to devise a new projection algorithm that has even better properties, both theoretically and in our computational experience.

The algorithm proposed here allows a nice geometric interpretation, which is given in Figure 1.1 for its simplest version. Suppose we have x^i, a current approximation to the solution of $\mathrm{VI}(F, C)$. First, we compute the point $P_C[x^i - F(x^i)]$. Next, we search the line segment between x^i and $P_C[x^i - F(x^i)]$ for a point z^i such that the hyperplane $\partial H_i := \{x \in \Re^n \mid \langle F(z^i), x - z^i \rangle = 0\}$ strictly separates x^i from any solution x^* of the problem. A computationally inexpensive Armijo-type procedure is used to find such z^i. Once the hyperplane is constructed, the next iterate x^{i+1} is computed by projecting x^i onto the intersection of the feasible set C with the halfspace $H_i := \{x \in \Re^n \mid \langle F(z^i), x - z^i \rangle \leq 0\}$, which contains the solution set S. It can be seen that x^{i+1} thus computed is closer to any solution $x^* \in S$ than x^i. At each iteration, our algorithm uses one projection onto the set C (to construct the separating hyperplane H_i), and one projection onto the intersection $C \cap H_i$, which gives the next iterate.

Before proceeding, we emphasize the differences between the method of [9] and our Algorithms 2.1 and 2.2. First, the second projection step in our method is onto the intersection $C \cap H_i$. In [9], x^i is projected first onto the separating hyperplane ∂H_i (this point is denoted by $\bar{x}^i$ in Figure 1.1) and then onto C (in Figure 1.1, the resulting point is denoted by $P_C[\bar{x}^i]$). It can be verified that our iterate x^{i+1} is closer to the solution set S than the iterate computed by the method of [9]. We also avoid the extra work of computing the point $\bar{x}^i$. (Even though it can be carried out



∂H_i
$\bar{x}^i = P_{H_i}[x^i]$
$H_i = \{x \in \Re^n \mid \langle F(z^i), x - z^i \rangle \leq 0\}$
$x^{i+1} = P_{C\cap H_i}[x^i]$
$P_C[\bar{x}^i]$
$P_C[x^i - F(x^i)] = x^i - r(x^i)$
x^i

$x^* \in S$
$F(z^i)$
C

FIG. 1.1. *The new projection method.*

explicitly, this is still some extra work.) Furthermore, the search direction in our method is not the same as in [9] for the following reasons. The search directions we use here are $P_C[x^i - \mu_i F(x^i)] - x^i$, where the stepsizes μ_i are chosen so that they are of the same order as the stepsizes η_i generating separating hyperplanes H_i (see Algorithm 2.2). The important point is that we allow *both* of them to go to zero if needed (but at the same rate). Coordination of the two stepsizes proves to be very significant in our computational experience (see section 3). We point out that [9] does not permit the stepsizes to go to zero in the first projection step even if the stepsizes generating the hyperplanes go to zero, and the proof there does not handle this case. The above-mentioned modifications seem to make a drastic difference in the numerical performance when our algorithm is compared to that of [9]. Our preliminary computational experience with the new algorithm is quite encouraging and is reported in section 3. However, we emphasize that comprehensive numerical study is not the primary focus of this paper.

Finally, our convergence results are stated under the assumption (1.2), which is considerably weaker than monotonicity of $F(\cdot)$ used in [9].

2. The algorithm and its convergence.

We first note that solutions of VI(F, C) coincide with zeros of the following projected residual function:

$$r(x) := x - P_C[x - F(x)];$$

i.e., $x \in S$ if and only if $r(x) = 0$.

We now formally state our algorithm described in section 1.

ALGORITHM 2.1. *Choose $x^0 \in C$ and two parameters $\gamma \in (0,1)$ and $\sigma \in (0,1)$.*

Having x^i, compute $r(x^i)$. If $r(x^i) = 0$, stop. Otherwise, compute

$$z^i = x^i - \eta_i r(x^i),$$

where $\eta_i = \gamma^{k_i}$, with k_i being the smallest nonnegative integer k satisfying

$$\langle F\left(x^i - \gamma^k r(x^i)\right), r(x^i)\rangle \geq \sigma \|r(x^i)\|^2. \tag{2.1}$$

Compute

$$x^{i+1} = P_{C \cap H_i}[x^i],$$

where

$$H_i = \{x \in \Re^n \mid \langle F(z^i), x - z^i \rangle \le 0\}.$$

The following well-known properties of the projection operator will be used below.

LEMMA 2.1. (see [35]). *Let B be any nonempty closed convex set in $\Re^n$. For any $x, y \in \Re^n$ and any $z \in B$ the following properties hold.*

1. $\langle x - P_B[x], z - P_B[x] \rangle \le 0$.
2. $\|P_B[x] - P_B[y]\|^2 \le \|x - y\|^2 - \|P_B[x] - x + y - P_B[y]\|^2$.

We start with a preliminary result. For now, we assume that the linesearch procedure in Algorithm 2.1 is well defined. This fact will be formally established in Theorem 2.1.

LEMMA 2.2. *Suppose that the linesearch procedure* (2.1) *of Algorithm* 2.1 *is well defined. Then it holds that*

$$x^{i+1} = P_{C \cap H_i}[\bar{x}^i],$$

where

$$\bar{x}^i = P_{H_i}[x^i].$$

Proof. Assuming that the point z^i is well defined, by (2.1) we have that

$$\langle F(z^i), x^i - z^i \rangle > 0.$$

It immediately follows that $x^i \notin H_i$. Also, by (1.2), $\langle F(z^i), x^* - z^i \rangle \le 0$ for any $x^* \in S$ because $z^i = (1 - \eta_i)x^i + \eta_i P_C[x^i - F(x^i)] \in C$ by the convexity of C. Therefore, $x^* \in H_i$. Since also $x^* \in C$, it follows that $C \cap H_i \ne \emptyset$. Because $C \cap H_i$ is a closed convex set that is nonempty, $x^{i+1} = P_{C \cap H_i}[x^i]$ is well defined.

It can be further verified that

$$\begin{aligned} \bar{x}^i = P_{H_i}[x^i] &= x^i - \frac{\langle F(z^i), x^i - z^i \rangle}{\|F(z^i)\|^2} F(z^i) \\ &= x^i - \frac{\eta_i \langle F(z^i), r(x^i) \rangle}{\|F(z^i)\|^2} F(z^i). \end{aligned}$$

Take any $y \in C \cap H_i$. Since $x^i \in C$ but $x^i \notin H_i$, there exist $\beta \in [0, 1]$ such that $\tilde{x} = \beta x^i + (1 - \beta) y \in C \cap \partial H_i$, where $\partial H_i := \{x \in \Re^n \mid \langle F(z^i), x - z^i \rangle = 0\}$. We have

$$\begin{aligned} \|y - \bar{x}^i\|^2 &\ge (1 - \beta)\|y - \bar{x}^i\|^2 \\ &= \|\tilde{x} - \beta x^i - (1 - \beta)\bar{x}^i\|^2 \\ &= \|\tilde{x} - \bar{x}^i\|^2 + \beta^2 \|x^i - \bar{x}^i\|^2 - 2\beta \langle \tilde{x} - \bar{x}^i, x^i - \bar{x}^i \rangle \\ &\ge \|\tilde{x} - \bar{x}^i\|^2, \end{aligned} \tag{2.2}$$

where the last inequality follows from Lemma 2.1 applied with $B = H_i$, $x = x^i$, and $z = \tilde{x} \in H_i$. Furthermore, we have

$$\begin{aligned} \|\tilde{x} - \bar{x}^i\|^2 &= \|\tilde{x} - x^i\|^2 - \|x^i - \bar{x}^i\|^2 \\ &\ge \|x^{i+1} - x^i\|^2 - \|x^i - \bar{x}^i\|^2 \\ &= \|x^{i+1} - \bar{x}^i\|^2, \end{aligned} \tag{2.3}$$

where the first equality is by $\bar{x}^i = P_{\partial H_i}[x^i]$, $\tilde{x} \in \partial H_i$, and Pythagoras's theorem; the inequality is by the fact that $\tilde{x} \in C \cap H_i$ and $x^{i+1} = P_{C\cap H_i}[x^i]$; and the last equality is again by Pythagoras's theorem. Combining (2.2) and (2.3), we obtain

$$\|y - \bar{x}^i\| \geq \|x^{i+1} - \bar{x}^i\| \quad \text{for all } y \in C \cap H_i.$$

Hence, $x^{i+1} = P_{C\cap H_i}[\bar{x}^i]$. □

We next prove our main convergence result.

THEOREM 2.1. *Let $F(\cdot)$ be continuous. Suppose the solution set S of VI(F, C) is nonempty and condition* (1.2) *is satisfied.*

Then any sequence $\{x^i\}$ generated by Algorithm 2.1 *converges to a solution of VI(F, C).*

Proof. We first show that the linesearch procedure in Algorithm 2.1 is well defined. If $r(x^i) = 0$, then the method terminates at a solution of the problem. Therefore, from now on, we assume that $\|r(x^i)\| > 0$. Also note that $x^i \in C$ for all i. Suppose that, for some i, (2.1) is not satisfied for any integer k, i.e., that

$$\langle F\left(x^i - \gamma^k r(x^i)\right), r(x^i)\rangle < \sigma\|r(x^i)\|^2 \quad \text{for all } k. \tag{2.4}$$

Applying Lemma 2.1 with $B = C,\ x = x^i - F(x^i),\ z = x^i \in C$, we obtain

$$\begin{aligned} 0 &\geq \langle x^i - F(x^i) - P_C[x^i - F(x^i)], x^i - P_C[x^i - F(x^i)]\rangle \\ &= \|r(x^i)\|^2 - \langle F(x^i), r(x^i)\rangle. \end{aligned}$$

Hence,

$$\langle F(x^i), r(x^i)\rangle \geq \|r(x^i)\|^2. \tag{2.5}$$

Since $x^i - \gamma^k r(x^i) \to x^i$ as $k \to \infty$, and $F(\cdot)$ is continuous, passing onto the limit as $k \to \infty$ in (2.4), we obtain

$$\langle F(x^i), r(x^i)\rangle \leq \sigma\|r(x^i)\|^2.$$

But the latter relation contradicts (2.5) because $\sigma < 1$ and $\|r(x^i)\| > 0$. Hence (2.1) is satisfied for some integer k_i.

Thus the linesearch step is well defined, and by Lemma 2.2 we know that the rest of the method is as well. In particular, $x^{i+1} = P_{C\cap H_i}[\bar{x}^i]$, where $\bar{x}^i = P_{H_i}[x^i]$. By Lemma 2.1 applied with $B = C \cap H_i,\ x = \bar{x}^i$, and $z = x^* \in S \subset C \cap H_i$, we obtain

$$\begin{aligned} 0 &\geq \langle \bar{x}^i - x^{i+1}, x^* - x^{i+1}\rangle \\ &= \|x^{i+1} - \bar{x}^i\|^2 + \langle \bar{x}^i - x^{i+1}, x^* - \bar{x}^i\rangle. \end{aligned}$$

Hence,

$$\langle x^* - \bar{x}^i, x^{i+1} - \bar{x}^i\rangle \geq \|x^{i+1} - \bar{x}^i\|^2.$$

Therefore,

$$\begin{aligned} \|x^{i+1} - x^*\|^2 &= \|\bar{x}^i - x^*\|^2 + \|x^{i+1} - \bar{x}^i\|^2 + 2\langle \bar{x}^i - x^*, x^{i+1} - \bar{x}^i\rangle \\ &\leq \|\bar{x}^i - x^*\|^2 - \|x^{i+1} - \bar{x}^i\|^2 \\ &= \|x^i - x^*\|^2 - \|x^{i+1} - \bar{x}^i\|^2 \end{aligned}$$

$$
\begin{aligned}
&+\left(\frac{\eta_i\langle F(z^i),r(x^i)\rangle}{\|F(z^i)\|}\right)^2-\frac{2\eta_i\langle F(z^i),r(x^i)\rangle}{\|F(z^i)\|^2}\langle F(z^i),x^i-x^*\rangle\\
&=\|x^i-x^*\|^2-\|x^{i+1}-\bar{x}^i\|^2-\left(\frac{\eta_i\langle F(z^i),r(x^i)\rangle}{\|F(z^i)\|}\right)^2\\
&\quad-\frac{2\eta_i\langle F(z^i),r(x^i)\rangle}{\|F(z^i)\|^2}\langle F(z^i),z^i-x^*\rangle\\
&\le\|x^i-x^*\|^2-\|x^{i+1}-\bar{x}^i\|^2-\left(\frac{\eta_i\sigma}{\|F(z^i)\|}\right)^2\|r(x^i)\|^4, \qquad (2.6)
\end{aligned}
$$

where the last inequality follows from (2.1) and (1.2).

Now (2.6) implies that the sequence $\{\|x^i-x^*\|\}$ is nonincreasing. Therefore, it converges. We further deduce that the sequence $\{x^i\}$ is bounded, and so is $\{z^i\}$. Thus there exists a constant $M>0$ such that $\|F(z^i)\|\le M$ for all i. Hence, from (2.6),

$$(2.7)\qquad \|x^{i+1}-x^*\|^2\le\|x^i-x^*\|^2-\|x^{i+1}-\bar{x}^i\|^2-(\sigma/M)^2\eta_i^2\|r(x^i)\|^4.$$

From convergence of $\{\|x^i-x^*\|\}$, it follows from (2.7) that

$$(2.8)\qquad \lim_{i\to\infty}\eta_i\|r(x^i)\|=0.$$

We consider the two possible cases. Suppose first that $\limsup_{i\to\infty}\eta_i>0$. For (2.8) to hold it must then be the case that $\liminf_{i\to\infty}\|r(x^i)\|=0$. Since $r(\cdot)$ is continuous and $\{x^i\}$ is bounded, there exists $\hat{x}$, an accumulation point of $\{x^i\}$, such that $r(\hat{x})=0$. It follows that $\hat{x}\in S$ and we can take $x^*=\hat{x}$ in the preceding arguments and, in particular, in (2.7). Thus the sequence $\{\|x^i-\hat{x}\|\}$ converges. Since $\hat{x}$ is an accumulation point of $\{x^i\}$, it easily follows that $\{\|x^i-\hat{x}\|\}$ converges to zero, i.e., that $\{x^i\}$ converges to $\hat{x}\in S$.

Suppose now that $\lim_{i\to\infty}\eta_i=0$. By the choice of η_i we know that (2.1) was not satisfied for k_i-1 (at least for i large enough, so that $\eta_i<1$); i.e.,

$$(2.9)\qquad \langle F\left(x^i-\gamma^{-1}\eta_i r(x^i)\right),r(x^i)\rangle<\sigma\|r(x^i)\|^2\quad\text{for all}\quad i\ge i_0.$$

Let $\hat{x}$ be any accumulation point of $\{x^i\}$ and $\{x^{i_j}\}$ be the corresponding subsequence converging to $\hat{x}$. Passing onto the limit in (2.9) along this subsequence, and using (2.5), we obtain

$$\sigma\|r(\hat{x})\|^2\ge\langle F(\hat{x}),r(\hat{x})\rangle\ge\|r(\hat{x})\|^2,$$

implying that $r(\hat{x})=0$, i.e., that $\hat{x}\in S$. Setting $x^*=\hat{x}$ in (2.7) and repeating the previous arguments, we conclude that the whole sequence $\{x^i\}$ converges to $\hat{x}\in S$. This completes the proof. □

We next propose a modification of Algorithm 2.1 that is motivated by our computational experience and appears to be more practical. For $\mu>0$, define

$$r(x,\mu):=x-P_C[x-\mu F(x)].$$

With this definition, we have $r(x,1)=r(x)$.

The idea is to use, for the first projection step at the current iteration, the stepsize that is not too different from the stepsize computed at the previous iteration (a similar technique was also used in [32, Algorithm 3.2]). Note that Algorithm 2.2 has a certain coordination between the stepsizes μ_i in the first projection step and η_i in the step computing the separating hyperplane. For example, both of them can go to zero if needed. This is in contrast with the method of [9], where the stepsize in the first projection step can never go to zero, even when η_i does. We found this coordination mechanism important in our computational results, reported in section 3. Note also that both stepsizes can increase from one iteration to the next.

ALGORITHM 2.2. *Choose* $x^0 \in C$, $\eta_{-1} > 0$, *and three parameters* $\gamma \in (0,1)$, $\sigma \in (0,1)$, *and* $\theta > 1$.

Having x^i, *compute* $r(x^i, \mu_i)$, *where* $\mu_i := \min\{\theta\eta_{i-1}, 1\}$. *If* $r(x^i, \mu_i) = 0$, *stop. Otherwise, compute*

$$z^i = x^i - \eta_i r(x^i, \mu_i),$$

where $\eta_i = \gamma^{k_i}\mu_i$ *with* k_i *being the smallest nonnegative integer* k *satisfying*

$$\langle F\left(x^i - \gamma^k \mu_i r(x^i, \mu_i)\right), r(x^i, \mu_i)\rangle \geq \frac{\sigma}{\mu_i}\|r(x^i, \mu_i)\|^2.$$

Compute

$$x^{i+1} = P_{C\cap H_i}[x^i],$$

where

$$H_i = \{x \in \Re^n \mid \langle F(z^i), x - z^i\rangle \leq 0\}.$$

THEOREM 2.2. *Let* $F(\cdot)$ *be continuous. Suppose that the solution set* S *of* VI(F, C) *is nonempty and* (1.2) *is satisfied.*

Then any sequence $\{x^i\}$ *generated by Algorithm* 2.2 *converges to a solution of* VI(F, C).

Proof. The proof of convergence uses the same ideas as the proof for Algorithm 2.1, so we supply only a sketch.

As with (2.5), it can be established that

$$\langle F(x^i), r(x^i, \mu_i)\rangle \geq \frac{1}{\mu_i}\|r(x^i, \mu_i)\|^2.$$

In particular, it follows that the linesearch procedure is well defined.

The proof then follows the pattern of the proof of Theorem 2.1, with (2.7) replaced by

$$\|x^{i+1} - x^*\|^2 \leq \|x^i - x^*\|^2 - \|x^{i+1} - \bar{x}^i\|^2 - (\sigma\eta_i/M)^2\mu_i^{-2}\|r(x^i, \mu_i)\|^4.$$

We next use the fact (see [6, Lemma 1]) that

$$\|r(x^i, \mu_i)\| \geq \min\{1, \mu_i\}\|r(x^i)\|.$$

It follows that

$$\|x^{i+1} - x^*\|^2 \leq \|x^i - x^*\|^2 - \|x^{i+1} - \bar{x}^i\|^2 - (\sigma\eta_i/M)^2\mu_i^2\|r(x^i)\|^4.$$

Taking into account that $\eta_i = \gamma^{k_i}\mu_i \leq \mu_i$, we further obtain

$$\|x^{i+1} - x^*\|^2 \leq \|x^i - x^*\|^2 - \|x^{i+1} - \bar{x}^i\|^2 - (\sigma/M)^2\eta_i^4\|r(x^i)\|^4,$$

and the rest of the convergence proof is identical to that of Theorem 2.1. □

3. Computational experience. To give some insight into the behavior of the new projection algorithm (Algorithm 2.2), we implemented it in MATLAB to solve linearly constrained variational inequality problems (using the quadratic-program solver qp.m from the MATLAB optimization toolbox to perform the projection). For a benchmark, we compared the performance of this implementation with analogous implementations of two versions of the extragradient method (as described in [17] and [33]) and with the modified projection algorithm as given in [32, Algorithm 3.2]. We also implemented the algorithm of [9] and tested it on the same problems as the other four methods. We do not report here the full results for the method of [9], mainly because they were rather poor. In particular, like the extragradient method, the method of [9] failed on the first two problems, and was *by far* the worst among all the methods on the remaining test problems. Thus we found it to be not useful for a benchmark comparison (unfortunately, no computational experience was reported in [9]). By contrast, our algorithm seems to perform better than the alternatives in most cases.

The choice of linearly constrained variational inequalities for our experiments is not incidental. It is clear that the new method should be especially effective when feasible sets are "no simpler" than general polyhedra (so that an optimization problem has to be solved to find a projection). In that case, adding one more linear constraint to perform a projection onto $C \cap H_i$ does not increase the cost compared to projecting onto the feasible set C. Actually, if the constraints are nonlinear, projecting onto $C \cap H_i$ can sometimes turn easier than onto C. On the other hand, when C has some special structure (for example, C is a box), adding a linear constraint would require solving an optimization problem, while projecting onto C can be carried out explicitly. In that case, the extragradient methods may be more attractive than our new method. However, in the case when C is a box (or the nonnegative orthant), there are many other efficient methods available (as discussed in section 1), so we will not focus on this case.

Though our experience is limited in scope, it suggests that the new projection method is a valuable alternative to the extragradient [17, 33] and modified projection [32] methods. We describe the test details below.

All MATLAB codes were run on the Sun UltraSPARCstation 1 under MATLAB version 5.0.0.4064. Our test problems are the same as those used in [32] to test the modified projection method in the nonlinear case. The first test problem, used first by Mathiesen [21], and later in [24, 36], has

$$F(x_1, x_2, x_3) = \begin{bmatrix} .9(5x_2 + 3x_3)/x_1 \\ .1(5x_2 + 3x_3)/x_2 - 5 \\ -3 \end{bmatrix},$$

$$C = \left\{(x_1, x_2, x_3) \in \Re^3_+ \mid x_1 + x_2 + x_3 = 1, x_1 - x_2 - x_3 \le 0\right\}.$$

For the other test problems, the feasible set is the simplex

$$C = \{x \in \Re^n_+ \mid x_1 + \cdots + x_n = n\},$$

and $F(\cdot)$ and n are specified as follows. For the third to fifth problems, $F(\cdot)$ is the function from, respectively, the Kojima–Shindo Nonlinear Complementarity Problem (NCP) (with $n = 4$) and the Nash–Cournot NCP (with $n = 5$ and $n = 10$) [24, pp. 321–322]. For the sixth problem, $n = 20$ and $F(\cdot)$ is affine, i.e.,

$$F(x) = Mx + q,$$

with the matrix M randomly generated as suggested in [8]:

$$M = AA^\top + B + D,$$

where every entry of the $n \times n$ matrix A and of the $n \times n$ skew-symmetric matrix B is uniformly generated from $(-5, 5)$, and every diagonal entry of the $n \times n$ diagonal B is uniformly generated from $(0, 0.3)$ (so M is positive definite), with every entry of q uniformly generated from $(-500, 0)$. For the last problem, we took the F from the sixth problem and added to its ith component the linear-quadratic term $\max\{0, x_i\}^2$ for $i = 1, \dots, \lfloor n/2 \rfloor$.

In the implementation of our Algorithm 2.2, we choose $\sigma = .3$, $\eta_{-1} = 1$, $\gamma = .5$, and $\theta = 4$. Implementations of the modified projection method and the extragradient method of [17] are the same as those reported in [32]. In particular, the parameters for both algorithms were tuned to optimize the performance. In the implementation of the other version of the extragradient method [33, Algorithm C], we set parameters as follows: $\eta = .1$, $\alpha = .3$, and $\gamma = 1.7$. On the Mathiesen problem, we used the same x^0 as in [36]; on the other problems, we used $x^0 = (1, \dots, 1)$. (The $F(\cdot)$ from the Mathiesen problem and from the Nash–Cournot NCP are defined on the positive orthant only.) The test results are summarized in Tables 3.1 and 3.2. In most cases, Algorithm 2.2 requires fewer iterations, function evaluations, and projections, and takes less CPU time than the other methods considered. Also note that our method solves problems, such as the Kojima–Shindo problem, even when $F(\cdot)$ is not monotone. We caution, however, that this study is very preliminary.

To investigate the effect of different starting points, we tested the methods on the problem Nash5, using as starting points the mesh points of the uniform triangulation of the simplex

$$\left\{ x \in \Re^5 \mid x \geq 0, \ \sum_{j=1}^{5} x_j = 5 \right\}.$$

The triangulation is obtained by cutting the simplex by equally spaced hyperplanes parallel to the faces of the simplex, with four cuts per face (the first cut is the face of the simplex, and the last is the opposing vertex). We have chosen the problem Nash5 because its function is defined on the positive orthant only, so that the *boundary effect* can also be studied. The modified projection method of [32] had trouble when starting at points with many zero components (such as, e.g., the point $(5, 0, 0, 0, 0)$). This is not very surprising, since the modified projection is actually an *infeasible* method; i.e., the iterates generated need not belong to the feasible set. Therefore, in principle, we may need to evaluate F at points outside of the nonnegative orthant, which gives trouble for problems like Nash5.However, the modified projection algorithm managed to solve the problem in most cases, with the average of 95 iterations (note that this is quite a bit more than the 74 iterations reported in Table 3.1 as needed for the starting point $x^0 = (1, 1, 1, 1, 1)$). In general, the more positive components x^0 has, the fewer iterations the modified projection method needs to solve the problem. The extragradient method of Marcotte [17] managed to solve the problem for all starting points, with the average of 62 iterations (which is again considerably higher than the 43 iterations needed when starting at the unit vector). Finally, Algorithm 2.2 managed to solve the problem from all the starting points, except from a few points for which the second and fourth components are *both* zero. On average, 32 iterations were required for convergence, which is fewer than for the modified projection or the

[4] The extragradient method as described in [17], with $\beta = .7$ and initial $\alpha = 1$. Dash—indicates that the method did not converge.

[5] The extragradient method as described in [33, Algorithm C], with $\eta = .1$, $\alpha = .3$, $\gamma = 1.7$. Dash—indicates that the method did not converge.

extragradient methods. However, the extragradient method appeared to be somewhat more robust for this problem.

4. Concluding remarks. A new projection algorithm for solving variational inequality problems was proposed. Under minimal assumptions of continuity of the underlying function and generalized monotonicity (for example, pseudomonotonicity), it was established that the iterates converge to a solution of the problem. The new method has some clear theoretical advantages over most of existing projection methods for general variational inequality problems with no special structure. Preliminary computational experience is also encouraging.

Some of the projection ideas presented here also proved to be useful in devising *truly* globally convergent (i.e., the *whole* sequence of iterates is globally convergent to a solution without any regularity assumptions) and locally superlinearly convergent inexact Newton methods for solving systems of monotone equations [30] and monotone NCPs [31].

Acknowledgments. We are grateful to the two anonymous referees and the editor for constructive suggestions that led to improvements in the paper. In particular, the observation that pseudomonotonicity is sufficient to establish convergence of the method is due to a referee.

CONTINUOUS DEPENDENCE WITH RESPECT TO THE INPUT OF TRAJECTORIES OF CONTROL-AFFINE SYSTEMS[*]

WENSHENG LIU[†] AND HÉCTOR J. SUSSMANN[†]

Abstract. We study the continuous dependence on the input of trajectories of control-affine systems belonging to the class $C^0(m)$ of all systems Σ of the form

$$\Sigma : \qquad \dot{x} = f_0(x) + \sum_{i=1}^{m} u_i(t) f_i(x),$$

where $f_0, \ldots, f_m$ are continuous vector fields on some open subset of $\mathbb{R}^n$ and the control functions belong to $L^1([0,T],\mathbb{R}^m)$. We give a simple necessary and sufficient condition for a control sequence $\{u^j\}_{j=1}^{\infty}$ to "$\mathcal{T}^0$-converge" to a control u^∞, i.e., to be such that, for every system Σ in $C^0(m)$, the trajectories generated by the u^j converge as $j \to \infty$ to the trajectories generated by u^∞. We also characterize $\mathcal{T}^k$-convergence (the concept of control convergence that arises when we use, instead of $C^0(m)$, the class $C^k(m)$ of systems Σ where the f_i are of class C^k) for $k \geq 1$ in the scalar input case, and we explain how the analogous characterization for the multi-input case fails to be true, unless one restricts oneself to the class $C^k_{comm}(m)$ of systems for which the vector fields $f_1, \ldots, f_m$ commute. As a preliminary, we define a "topology of trajectory convergence" (or "T-convergence") on the set of all time-varying vector fields $\Omega \times I \ni (x,t) \mapsto f(x,t) \in \mathbb{R}^n$, where Ω is an open subset of $\mathbb{R}^n$ and I is an interval, and we study some of its properties. This enables us to make the definition of $\mathcal{T}^k$-convergence precise for sequences and, more generally, for nets, by saying that a net $\{u^\alpha\}_{\alpha\in A}$ in $L^1([0,T],\mathbb{R}^m)$ $\mathcal{T}^k$-converges to a limit u^∞ if for every system Σ in $C^k(m)$ the time-varying vector fields $(x,t) \mapsto f_0(x) + \sum_{i=1}^m u_i^\alpha(t) f_i(x)$ $\mathcal{T}^k$-converge to $(x,t) \mapsto f_0(x) + \sum_{i=1}^m u_i^\infty(t) f_i(x)$.

Key words. control-affine systems, continuous dependence

1. Introduction.

In the control theory literature, the property of continuous dependence of the trajectories with respect to the control has received wide attention (cf. [1], [2], [3], [5], [7], [9], [12], [19], [20]) because of its fundamental role in proofs of closedness of reachable sets, existence of optimal controls, and continuity or lower semicontinuity of value functions. It is clear that continuous dependence always holds for trivial reasons if the space of input functions is given a sufficiently strong topology, but continuous dependence results are useful only when the topology involved is reasonably weak. (For example, many existence theorems for optimal controls depend on the fact that the space of inputs is compact, or has many compact subsets.) Thus it is of interest to determine concepts of convergence of inputs that lead to continuous dependence of trajectories and are as weak as possible.

In this paper we characterize the weakest possible concept of convergence of a sequence of input functions such that the trajectories depend continuously on the input for *all* control-affine systems of the form

$$\dot{x} = f_0(x) + \sum_{i=1}^{m} u_i f_i(x)\,, \quad x \in \Omega\,, \tag{1.1}$$

with a right-hand side continuous with respect to the state variable x, and we prove some results on the corresponding problem for more restricted classes of systems. These questions are in fact special cases of the following more general situation: we are given

(a) a set $\mathcal{U}$ of input functions $t \mapsto u(t)$ defined on an interval I,
(b) a class $\mathcal{C}$ of control systems Σ of the form $\dot{x} = g(x, u)$, all of which admit the members of $\mathcal{U}$ as inputs.

We then seek to characterize the *weakest* topology $\mathcal{T}$ on $\mathcal{U}$ with the property that, if $\mathcal{U}$ is equipped with $\mathcal{T}$, then

(CD) the trajectories of Σ depend continuously on the input $u \in \mathcal{U}$ for all systems Σ in $\mathcal{C}$.

Let us write $\mathcal{T}(\mathcal{U}, \mathcal{C})$ to denote this topology, and assume temporarily that the definition of $\mathcal{T}(\mathcal{U}, \mathcal{C})$ has been justified, by

(J1) assigning a mathematically precise meaning to (CD), and
(J2) proving the existence of a weakest topology on $\mathcal{U}$ for which (CD) holds.

Then the problems to be studied here are those of characterizing the topology $\mathcal{T}(\mathcal{U}, \mathcal{C})$ in two cases, namely, (i) when $\mathcal{C}$ is the class $C^0(m)$ of all systems of the form (1.1), with $f_0, \ldots, f_m$ continuous vector fields on some open subset Ω of some Euclidean space $\mathbb{R}^n$ and (ii) when $\mathcal{C}$ is an interesting subclass of $C^0(m)$, such as the set $C^1(m)$ of all systems (1.1) with C^1 vector fields. The input space $\mathcal{U}$ will be $L^1([0,T], \mathbb{R}^m)$, the set of all Lebesgue-integrable functions $t \mapsto u(t) = (u_1(t), \ldots, u_m(t))$ on some fixed interval $[0, T]$. Convergence with respect to $\mathcal{T}(L^1([0,T], \mathbb{R}^m), C^0(m))$ will be called "$\mathcal{T}^0$-convergence." For case (i), we will provide a complete and rather simple characterization of sequential $\mathcal{T}^0$-convergence by showing that a sequence $\{u^j\}$ $\mathcal{T}^0$-converges to a limit u^∞ iff the indefinite integrals $t \mapsto \int_0^t u^j(s)ds$ converge uniformly on $[0, T]$ to $t \mapsto \int_0^t u^\infty(s)ds$ and in addition $\sup_j \|u^j\|_{L^1} < \infty$. (Naturally, in order to provide a complete characterization of the topology $\mathcal{T}(L^1([0,T], \mathbb{R}^m), C^0(m))$, we should not limit our analysis to sequences and should seek instead to characterize $\mathcal{T}^0$-convergence of nets. This, however, appears to be a much more difficult question, as explained below, on which we will only be able to present some partial results.) For case (ii), we provide an even simpler characterization of $\mathcal{T}(L^1([0,T], \mathbb{R}^1), C^1(1))$-convergence of general nets $\{u^\alpha\}_{\alpha \in A}$ to a limit u^∞, by showing that it is equivalent to uniform convergence on $[0, T]$ of the indefinite integrals $t \mapsto \int_0^t u^\alpha(s)ds$ to the limit $t \mapsto \int_0^t u^\infty(s)ds$. This result is, however, valid only for the single-input case. To explain why, we analyze the m-input situation and prove, in sections 5 and 6, two results (Theorems 5.2 and 6.1), according to which (a) a characterization similar to that for $m = 1$ is true for general m on the class $C^1_{comm}(m)$ of systems (1.1) with C^1 vector fields such that all the Lie brackets $[f_j, f_k]$ for $j, k \in \{1, \ldots, m\}$ vanish, and (b) the result becomes false for any class $\mathcal{C}$ that contains at least one system in $C^1(m) \backslash C^1_{comm}(m)$. This shows that Lie brackets are intimately related to input convergence and ought to play a decisive role in any effort to achieve a better understanding of $\mathcal{T}(L^1([0,T], \mathbb{R}^m), C^1(m))$-convergence for $m > 1$.

So far, we have assumed that steps (J1) and (J2) have been carried out. We explain how this is done in section 2, where we define, on the set $TVVF(\Omega, I)$ of all time-varying vector fields $f : \Omega \times I \mapsto \mathbb{R}^n$ (where Ω is an open subset of $\mathbb{R}^n$ and I is a subinterval of $\mathbb{R}$), a topology $\mathcal{T}_T(\Omega, I)$—called the *topology of trajectory* *convergence*, or *T-convergence*—and argue that this topology captures the concept of "continuous dependence with respect to f of the solutions of the ordinary differential equation $\dot{x} = f(x,t)$." This topology takes into account the possibility of explosions and nonuniqueness of solutions—a fact of paramount importance for us, since, typically, the time-varying vector fields that arise from the systems (1.1) are continuous only with respect to x—and we will show in section 2 that it has all the right properties, at least when restricted to the set $TVVF_{Car,LIB}(\Omega, I)$ of those f's that satisfy the Carathéodory condition (i.e., are such that f is measurable in t for each x and continuous in x for each t) and are "locally integrably bounded," i.e., that satisfy, for every compact subset K of Ω, an integral bound

$$||f(x,t)|| \leq \varphi_K(t) \ \text{ for } \ (x,t) \in K \times I,$$

with a locally integrable function $\varphi_K : I \mapsto \mathbb{R}$. Moreover, the topology induced by $\mathcal{T}_T(\Omega, I)$ on the subset $TVVF_{Car,LIB}(\Omega, I)$ of $TVVF(\Omega, I)$ is the weakest topology on $TVVF_{Car,LIB}(\Omega, I)$ that gives rise to joint continuous dependence of the solutions on f and the initial condition.

Having defined $\mathcal{T}_T(\Omega, I)$, it is clear how to interpret (CD) and how to define $\mathcal{T}(\mathcal{U}, \mathcal{C})$: if $\Sigma \in \mathcal{C}$ is of the form $\dot{x} = g^\Sigma(x,u)$, $x \in \Omega^\Sigma$, then each input $t \mapsto u(t)$ belonging to $\mathcal{U}$ gives rise to a time-varying vector field $f^\Sigma(u) \in TVVF(\Omega^\Sigma, I)$, defined by

$$f^\Sigma(u) \overset{\text{def}}{=} \text{the map } (x,t) \mapsto g^\Sigma(x, u(t)) \,. \tag{1.2}$$

Then f^Σ is the *input-to-vector-field map* associated with Σ. If $\mathcal{T}$ is a topology on $\mathcal{U}$, then the statement that "the trajectories of Σ depend continuously on the input with respect to $\mathcal{T}$" can be translated as "f^Σ is continuous as a map from $\mathcal{U}$, equipped with $\mathcal{T}$, to $TVVF(\Omega^\Sigma, I)$, equipped with $\mathcal{T}_T(\Omega^\Sigma, I)$." Then the formal definition of $\mathcal{T}(\mathcal{U}, \mathcal{C})$ is simply the following:

> $\mathcal{T}(\mathcal{U}, \mathcal{C})$ *is the weakest topology on* $\mathcal{U}$ *that renders all the input-to-vector-field maps* $f^\Sigma : \mathcal{U} \mapsto TVVF(\Omega^\Sigma, I)$ *continuous for all* $\Sigma \in \mathcal{C}$, *when each* $TVVF(\Omega^\Sigma, I)$ *is given the topology* $\mathcal{T}_T(\Omega^\Sigma, I)$ *of trajectory convergence.*

To analyze in more detail the special case when $\mathcal{U} = L^1([0,T], \mathbb{R}^m)$ and $\mathcal{C}$ is the class $C^0(m)$, let us agree to use f_i^Σ to denote the vector fields f_i corresponding to a given system $\Sigma \in C^0(m)$ of the form (1.1), and let us go on using Ω^Σ to denote the state space of Σ. Write $\mathcal{U}_T^m \overset{\text{def}}{=} L^1([0,T], \mathbb{R}^m)$. As before, use "$\mathcal{T}^0$-convergence" for "convergence with respect to $\mathcal{T}(\mathcal{U}_T^m, C^0(m))$." Then our problem is to determine necessary and sufficient conditions for a sequence $\{u^j\}_{j=1}^\infty$ of functions belonging to the input space $\mathcal{U}_T^m$ to $\mathcal{T}^0$-converge to an input $u^\infty \in \mathcal{U}_T^m$, i.e., for the following property to hold:

(TC) For every possible choice of the system $\Sigma \in C^0(m)$, the time-varying vector fields $f^\Sigma(u^j)$ T-converge to $f^\Sigma(u^\infty)$.

As will be explained in section 2, one may substitute for (TC) either one of the following conditions, both of which turn out in fact to be equivalent to (TC):

(TC′) For every possible choice of the system $\Sigma \in C^0(m)$, if (i) ξ^j are maximal trajectories of (1.1) corresponding to the u^j and satisfying the initial conditions $\xi^j(0) = \bar{x}^j \in \Omega^\Sigma$, (ii) $\bar{x}^j \to \bar{x} \in \Omega^\Sigma$, and (iii) for the limiting initial value problem

$$\dot{x} = f^{\Sigma}(u^{\infty})(x,t) \overset{\mathrm{def}}{=} f_0^{\Sigma}(x) + \sum_{i=1}^{m} u_i^{\infty}(t) f_i^{\Sigma}(x)\,, \;\; x(0) = \bar{x}, \tag{1.3}$$

there is uniqueness of solutions as well as global existence on $[0,T]$, then the ξ^j are defined on $[0,T]$ for j large enough and converge uniformly on $[0,T]$ to the unique maximal solution ξ^{∞} of (1.3).

(TC$''$) For every possible choice of the system $\Sigma \in C^0(m)$, if (i) $\bar{x} \in \Omega^{\Sigma}$, (ii) ξ^j are maximal trajectories of (1.1) corresponding to the u^j and satisfying $\xi^j(0) = \bar{x}$, and (iii) the initial value problem (1.3) has uniqueness of solutions as well as global existence on $[0,T]$, then the ξ^j are defined on $[0,T]$ for j large enough and converge uniformly on $[0,T]$ to the unique maximal solution ξ^{∞} of (1.3).

Notice that (TC$'$) asserts "joint continuous dependence on the input and the initial condition," whereas (TC$''$) makes the weaker assertion of "continuous dependence on the input for each fixed initial condition," so the implication (TC$'$)$\Rightarrow$(TC$''$) is trivial, but the converse (TC$''$)$\Rightarrow$(TC$'$) is not at all obvious. (Example A.3 in the appendix shows that for a general sequence $\{f^j\}$ of time-varying vector fields it need not be true that convergence for each fixed initial condition of the trajectories of f^j to those of an $f \in TVVF(\Omega, I)$ implies convergence of trajectories for convergent initial conditions.)

Our characterization of sequential $\mathcal{T}^0$-convergence will be formulated in terms of a type of convergence somewhat weaker than other concepts of weak convergence previously considered in the literature. Precisely, let us say that a net $\{u^{\alpha}\}_{\alpha \in A} \subseteq \mathcal{U}_T^m$ based on a directed set $(A, \preceq_A)$ *converges in the integral sense* (or, for short, *I-converges*) to a $u^{\infty} \in \mathcal{U}_T^m$, if the following holds:

(IC) The indefinite integrals $U^{\alpha}(t) = \int_0^t u^{\alpha}(s)ds$ converge uniformly with respect to $t \in [0,T]$ to $U^{\infty}(t) = \int_0^t u^{\infty}(s)ds$.

Also, let us say that $\{u^{\alpha}\}_{\alpha \in A}$ satisfies the *uniform boundedness* condition if the following is true:

(UB) There exist a constant $C > 0$ and an $\alpha_0 \in A$ such that $\|u^{\alpha}\|_{L^1} \leq C$ whenever $\alpha_0 \preceq_A \alpha$.

Our main result (Theorem 4.1 below) then says that a sequence $\{u^j\}_{j=1}^{\infty}$ in $\mathcal{U}_T^m$ $\mathcal{T}^0$-converges to a function $u^{\infty} \in \mathcal{U}_T^m$ iff $\{u^j\}_{j=1}^{\infty}$ satisfies (UB) and I-converges to u^{∞}. An alternative formulation is in terms of *uniform weak convergence*. We say that a net $\{u^{\alpha}\}_{\alpha \in A}$ *UW-converges* to a limit u^{∞} if the following holds:

(UWC) For every continuous function $\varphi : [0,T] \mapsto \mathbb{R}$, if we define $\mathbb{R}^m$-valued functions U_{φ}^{α} by $U_{\varphi}^{\alpha}(t) = \int_0^t u^{\alpha}(s)\varphi(s)ds$ for $\alpha \in A \cup \{\infty\}$, then the U_{φ}^{α} converge to U_{φ}^{∞} uniformly on $[0,T]$.

For sequences, it is easily seen (cf. section 4) that the conjunction (IC) $\wedge$ (UB) is equivalent to (UWC), so Theorem 4.1 says in fact that a sequence $\{u^j\}_{j=1}^{\infty}$ $\mathcal{T}^0$-converges to a limit u^{∞} iff it UW-converges to u^{∞}.

For more general nets, the condition (IC) $\wedge$ (UB) still implies $\mathcal{T}^0$-convergence, which in turn implies UW-convergence, but the reverse implications no longer hold. (This is shown in the appendix by means of two examples.) Thus, although Theorem 4.1 provides a complete characterization of sequential $\mathcal{T}^0$-convergence in $\mathcal{U}_T^m$, it does not give a full characterization of the topology itself. To get such a characterization, one would have to understand $\mathcal{T}^0$-convergence of nets, and we have not yet been able to find a satisfactory characterization of $\mathcal{T}^0$-convergence of nets, comparable in simplicity to our results for sequences.

For sequences, the condition (IC) $\wedge$ (UB) or, equivalently, (UWC) is strictly weaker than weak convergence in $L^1([0,T],\mathbb{R}^m)$, as explained in section 7. In addition, the characterization of sequential $\mathcal{T}^0$-convergence in $\mathcal{U}_T^m$ depends crucially on the fact that we are working with the collection of *all* systems in $C^0(m)$. We could equally well have defined a concept of $\mathcal{T}^k$-convergence for any integer $k \geq 0$ by just taking $\mathcal{C}$ to be the class $C^k(m)$ of all systems of the form (1.1) with vector fields f_i of class C^k. But then it is no longer obvious that condition (UB) is still necessary for sequential $\mathcal{T}^k$-convergence for $k \geq 1$. (The proof that (UB) is necessary for sequential $\mathcal{T}^0$-convergence in $\mathcal{U}_T^m$ depends on using the uniform boundedness theorem and requires that we admit systems with an arbitrary continuous right-hand side. On the other hand, the necessity of (IC) depends only on the fact that the systems $\dot{x} = u_i$, $i = 1, \ldots, m$, are in our class, so (IC) is still necessary for trajectory convergence for practically any reasonable class of systems.) In fact, we show in section 5 that a sequence $\{u^j\}_{j=1}^{\infty} \subseteq \mathcal{U}_T^1$ may $\mathcal{T}^k$-converge to a $u^\infty \in \mathcal{U}_T^1$ even if (UB) fails.

To our knowledge, the problem of characterizing sequential $\mathcal{T}^k$-convergence in $\mathcal{U}_T^m$ for $k \geq 1$ is still open for $m > 1$ and appears to be quite difficult. The case $m = 1$ is special, as explained in section 5, where we give a complete characterization (in Theorem 5.1) of the topology $\mathcal{T}(\mathcal{U}_T^1, C^1(1))$ by showing that a net $\{u^\alpha\}_{\alpha\in A} \subseteq \mathcal{U}_T^1$ $\mathcal{T}(\mathcal{U}_T^1, C^1(1))$-converges to a limit u^∞ iff the u^α I-converge to u^∞. The profound reason why this characterization is possible for $m = 1$ but not for $m > 1$ is provided by Theorems 5.2 and 6.1: Theorem 5.2 shows that the condition of Theorem 5.1 is necessary and sufficient, for general m, for $\mathcal{T}(\mathcal{U}_T^m, \mathcal{C})$-convergence of the u^α to u^∞ if we take $\mathcal{C} = C^1_{comm}(m)$, the class of systems (1.1) where the f_i are of class C^1 and $f_1, \ldots, f_m$ *commute* (i.e., the Lie brackets $[f_i, f_j]$ vanish for $1 \leq i, j \leq m$), whereas Theorem 6.1 shows that for any class $\mathcal{C}$ such that $C^1_{comm}(m) \subseteq \mathcal{C} \subseteq C^1(m)$ and $\mathcal{C} \neq C^1_{comm}(m)$, the condition no longer suffices for $\mathcal{T}(\mathcal{U}_T^m, \mathcal{C})$-convergence, because there exists a sequence $\{u^j\}_{j=1}^{\infty}$ such that

(1) $\int_0^t u^j(s)ds \to 0$ uniformly;
(2) for every $\Sigma \in \mathcal{C}$ there is a time-varying vector field $h^\Sigma \in TVVF(\Omega^\Sigma, [0,T])$ such that the $\{f^\Sigma(u^j)\}$ T-converge to h^Σ;
(3) it is not true that $h^\Sigma = f^\Sigma(0)$ for all $\Sigma \in \mathcal{C}$.

(What really happens is that the sequence $\{u^j\}$ $\mathcal{T}(\mathcal{U}_T^m, \mathcal{C})$-converges to a “generalized input” that is no longer an ordinary input. A more detailed discussion of these issues is provided in section 6.)

The paper is organized as follows. In section 2 we present the definition and basic properties of the topology of T-convergence. We then give, in section 3, our precise definition of $\mathcal{T}^0$-convergence. The main theorem (Theorem 4.1) of the paper is stated and proved in section 4. In section 5 we discuss how the situation changes when $\mathcal{T}^k$-convergence for $k \geq 1$ is considered instead of $\mathcal{T}^0$-convergence. In section 6 we briefly discuss some of the phenomena that can cause a sequence $\{f^\Sigma(u^j)\}$ to T-converge to something other than its limit $f^\Sigma(u^\infty)$, in particular the occurrence of Lie bracket terms. Section 7 discusses how our continuous dependence conditions relate to those of Buttazzo–Conti, Kurzweil–Vorel, and Neustadt and shows that our $\mathcal{T}^0$-convergence conditions for sequences in $L^1([0,T],\mathbb{R}^m)$ are weaker than weak convergence in L^1. Finally, we include an appendix that presents three examples, showing (i) that UW-convergence of nets does not imply $\mathcal{T}^0$-convergence, (ii) that $\mathcal{T}^0$-convergence of nets does not imply the uniform boundedness condition (UB), and (iii) that, for general time-varying vector fields, "continuous dependence of trajectories for every fixed initial condition" does not imply "joint continuous dependence of trajectories on the vector field and the initial condition."

2. The topology of trajectory convergence. We begin by giving a precise meaning to the "T-convergence" condition that appears in (TC).

In what follows, the word "interval" means "connected, nonempty subset of $\mathbb{R}$." An interval is *nontrivial* if it is not reduced to a single point.

If Ω is a metric space, we use d_Ω to denote the corresponding distance function. A *curve* in Ω is a continuous map ξ from an interval $I \subseteq \mathbb{R}$ to Ω. If I is compact, then ξ will be called an *arc* in Ω. We use $ARC(\Omega)$ to denote the set of all arcs in Ω. For every $-\infty < a \leq b < \infty$, we let $C^0([a,b],\Omega)$ denote the set of all arcs in Ω whose domain is $[a,b]$. Then

$$ARC(\Omega) = \bigcup_{-\infty<a\leq b<\infty} C^0([a,b],\Omega)\,. \tag{2.1}$$

For each $\xi \in ARC(\Omega)$, we let $a(\xi)$, $b(\xi)$ be the unique a,b such that ξ belongs to $C^0([a,b],\Omega)$. If $\xi \in ARC(\Omega)$, let $\tilde{\xi}$ be the continuous curve $\tilde{\xi} : \mathbb{R} \mapsto \Omega$ obtained by extending ξ to the whole real line by just letting $\tilde{\xi}$ be constant on $]-\infty, a(\xi)]$ and on $[b(\xi),+\infty[$. We topologize $ARC(\Omega)$ by means of the metric $d_{ARC} : ARC(\Omega) \times ARC(\Omega) \mapsto \mathbb{R}$ given by

$$d_{ARC}(\xi,\eta) = |a(\xi)-a(\eta)| + |b(\xi)-b(\eta)| + \sup\{d_\Omega(\tilde{\xi}(t),\tilde{\eta}(t)) \,:\, t \in \mathbb{R}\}\,.$$

Then a sequence $\{\xi^j\}$ of arcs, possibly defined on different time intervals $[a^j,b^j]$, converges to an arc $\xi : [a,b] \mapsto \Omega$ if (i) $a^j \to a$, (ii) $b^j \to b$, and (iii) $\xi^j \to \xi$ uniformly, i.e., $\xi^j(t^j) \to \xi(t)$ whenever $t^j \in [a^j,b^j]$, $t^j \to t$.

If $\xi : J \mapsto \Omega$ is a curve, the *graph* of ξ is the set $G(\xi) = \{(\xi(t),t) : t \in J\}$.

If $\xi_i : [a_i,b_i] \mapsto \Omega$ for $i = 1,2$ are arcs in Ω, then the *concatenation* $\xi_1\#\xi_2$ is defined iff $b_1 = a_2$ and $\xi_1(b_1) = \xi_2(a_2)$, and is the arc whose graph is $G(\xi_1) \cup G(\xi_2)$. Concatenation is an associative partially defined binary operation on $ARC(\Omega)$.

A subset $\mathcal{A} \subseteq ARC(\Omega)$ is *bounded* if there is a compact subset K of $\Omega \times \mathbb{R}$ such that $G(\xi) \subseteq K$ for all $\xi \in \mathcal{A}$. We call $\mathcal{A}$ *equicontinuous* if for every $\varepsilon > 0$ there exists $\delta > 0$ such that $d_\Omega(\xi(t),\xi(s)) < \varepsilon$ whenever $\xi \in \mathcal{A}$, $t,s \in [a(\xi),b(\xi)]$, and $|t-s| \leq \delta$. It is then clear that a subset $\mathcal{A}$ of $ARC(\Omega)$ is relatively compact iff $\mathcal{A}$ is bounded and equicontinuous.

An *arc system in* Ω *with time domain* I is a subset $\mathcal{A}$ of $ARC(\Omega)$ such that

(AS.1) $G(\xi) \subseteq \Omega \times I$ for every $\xi \in \mathcal{A}$,

(AS.2) $\mathcal{A}$ contains every arc in Ω whose domain is of the form $\{t\}$ for $t \in I$,

(AS.3) $\mathcal{A}$ is closed under concatenations (that is, if ξ_1, ξ_2 are in $\mathcal{A}$ and $\xi_1\#\xi_2$ is defined, then $\xi_1\#\xi_2 \in \mathcal{A}$),

(AS.4) $\mathcal{A}$ is closed under restrictions (that is, if $\xi \in \mathcal{A}$ and $a(\xi) \leq \alpha \leq \beta \leq b(\xi)$, then the restriction $\xi\lceil[\alpha,\beta]$ of ξ to $[\alpha,\beta]$ is in $\mathcal{A}$).

We use $AS(\Omega,I)$ to denote the set of all arc systems in Ω with time domain I. If $\mathcal{A} \in AS(\Omega,I)$ and $K \subseteq \Omega \times I$, we write

$$\mathcal{A}(K) \overset{\text{def}}{=} \{\xi \in \mathcal{A} : G(\xi) \subseteq K\}\,. \tag{2.2}$$

If $\mathcal{A} \in AS(\Omega, I)$, then it follows easily that if (i) the arcs $\xi_1, \ldots, \xi_m$ belong to $\mathcal{A}$, (ii) $[a(\xi_1), b(\xi_1)] \cup \cdots \cup [a(\xi_m), b(\xi_m)]$ is an interval, (iii) $\xi_i \lceil I_i \cap I_j = \xi_j \lceil I_i \cap I_j$ for all $i, j \in \{1, \ldots, m\}$, where we write $I_\ell = [a(\xi_\ell), b(\xi_\ell)]$ for $\ell \in \{1, \ldots, m\}$, and (iv) we let $\xi_1 \vee \cdots \vee \xi_m$ be the arc whose graph is $G(\xi_1) \cup \cdots \cup G(\xi_m)$, then $\xi_1 \vee \cdots \vee \xi_m$ is also in $\mathcal{A}$.

If $\mathcal{A} \in AS(\Omega, I)$, we define $\mathcal{A}^\#$ to be the set of all curves $\xi : J \mapsto \Omega$ such that J is a subinterval of I and $\xi \lceil L \in \mathcal{A}$ for every compact subinterval L of J. The members of $\mathcal{A}^\#$ will be called *$\mathcal{A}$-curves*. An $\mathcal{A}$-curve $\xi \in \mathcal{A}^\#$ is *maximal* if there does not exist $\eta \in \mathcal{A}^\#$ such that $G(\xi)$ is a proper subset of $G(\eta)$. We use $\mathcal{A}^\#_{max}$ to denote the set of all maximal elements of $\mathcal{A}^\#$. A trivial application of Zorn's lemma shows that if $\mathcal{A} \in AS(\Omega, I)$, then every $\xi \in \mathcal{A}^\#$ can be extended to an $\eta \in \mathcal{A}^\#_{max}$. This implies, in particular, that through every point of $\Omega \times I$ there passes the graph of a $\xi \in \mathcal{A}^\#_{max}$.

If $\mathcal{A} \in AS(\Omega, I)$, we say that $\mathcal{A}$ has the *compactness property* if for every compact subset $K \subseteq \Omega \times I$ the set $\mathcal{A}(K)$ is compact in $ARC(\Omega)$. We say that $\mathcal{A}$ has the *local existence property* if for every $(x, t) \in \Omega \times I$ there exists $\xi \in \mathcal{A}$ such that t belongs to the interior of $[a(\xi), b(\xi)]$ relative to I and $\xi(t) = x$. We use $AS_{comp,le}(\Omega, I)$ to denote the set of all $\mathcal{A} \in AS(\Omega, I)$ that have the compactness property and the local existence property.

PROPOSITION 2.1. *Let Ω be a locally compact metric space, and let $I \subseteq \mathbb{R}$ be an interval. Assume that $\mathcal{A} \in AS_{comp,le}(\Omega, I)$. Let $\xi : J \mapsto \Omega$ be a curve in $\mathcal{A}^\#$. Then $\xi \in \mathcal{A}^\#_{max}$ iff* (i) *J is relatively open in I and* (ii) *for every compact subset K of $\Omega \times I$ the set $\{t \in J : (\xi(t), t) \in K\}$ is compact.*

Proof. Let $t_+ = \sup J$, $t_- = \inf J$.

Suppose first that (i) and (ii) hold, but ξ is not maximal. Let $\eta \in \mathcal{A}^\#$ be an extension of ξ to a strictly larger interval J'. Pick $s \in J' \backslash J$. Then either $s \geq t_+$ or $s \leq t_-$. Assume that $s \geq t_+$. (The other case is similar.) Then $t_+ \in I$, because $t_+ \leq s \in I$ and $t_+ \geq t$ for some $t \in J \subseteq I$. Therefore $t_+ \notin J$, because J is relatively open in I by (i). Pick $t \in J$. Let K_0 be the set $\{\eta(\tau) : t \leq \tau \leq t_+\}$. Let $K = K_0 \times [t, t_+]$. Then K is compact, so the set $L = \{\tau \in J : (\xi(\tau), \tau) \in K\}$ is compact by (ii). But this is a contradiction, because $[t, t_+[\subseteq L$ but $t_+ \notin L$.

Now assume that ξ is maximal. Suppose that J is not relatively open in I. Then either $t_+ \in J$ and $t_+ < \sup I$ or $t_- \in J$ and $t_- > \inf I$. Assume that $t_+ \in J$ and $t_+ < \sup I$, the other case being similar. By the local existence property, there is an $\eta \in \mathcal{A}$ for which $\eta(t_+) = \xi(t_+)$ and whose domain Q contains t in its interior relative to I. By the restriction property, we may assume that the domain of η is of the form $[t_+, t_+ + \varepsilon]$ for some $\varepsilon > 0$. But then $G(\xi) \cup G(\eta)$ is the graph of an arc in $\mathcal{A}^\#$, contradicting the maximality of ξ. So J is relatively open in I, as stated.

Let $K \subseteq \Omega \times I$ be compact, and assume that $L = \{t \in J : (\xi(t), t) \in K\}$ is not compact. Then in particular $L \neq \emptyset$. Let $\pi : \Omega \times I \mapsto I$ be the projection map $(x, t) \mapsto t$. Let $b = \sup L$, $a = \inf L$. Then $a \in I$ and $b \in I$, because $L \subseteq \pi(K) \subseteq I$, and $\pi(K)$ is compact. Also, $a < b$, since if $a = b$, then L would be equal to $\{a\}$, which is compact. Since $L \subseteq [a, b]$ and L is not compact, there exists a sequence $\{t_j\}$ in L that converges to a limit $\bar{t} \notin L$. On the other hand, the open interval $]a, b[$ is contained in J. If $a < \bar{t} < b$, it would follow that $\xi(t_j) \to \xi(\bar{t})$, so $(\xi(\bar{t}), \bar{t})$ would be in K, and $\bar{t}$ would belong to L. Therefore either $\bar{t} = a$ or $\bar{t} = b$. Assume $\bar{t} = b$, the case when $\bar{t} = a$ being similar. Since $(\xi(t_j), t_j) \in K$, which is compact, we may assume, after passing to a subsequence, that $\bar{x} = \lim_{j \to \infty} \xi(t_j)$ exists. Clearly, $(\bar{x}, \bar{t}) \in K$. Let K_0', be a compact neighborhood of $\bar{x}$ in Ω, and let J_0' be a compact subinterval of I such that $\bar{t}$ belongs to the interior of J_0' relative to I. Let $K' = K_0' \times J_0'$. Let

$\varepsilon > 0$ be such that $x \in \Omega$, $t \in I$, $||x - \bar{x}|| \leq \varepsilon$, $|\bar{t} - t| \leq \varepsilon$ implies $(x,t) \in K'$. Using the compactness property for $\mathcal{A}$, we can infer that $\mathcal{A}(K')$ is equicontinuous, so there exists a $\delta > 0$ such that $\eta \in \mathcal{A}$, $G(\eta) \subseteq K'$ implies $||\eta(t) - \eta(s)|| \leq \frac{\varepsilon}{3}$ whenever $|t-s| \leq \delta$. Pick j so large that $b - t_j < \delta$ and $||\xi(t_j) - \bar{x}|| < \frac{\varepsilon}{3}$. Then $\xi([t_j, b[) \subseteq K_0'$. (Otherwise, let $\tau = \inf\{t \in [t_j, b[: \xi(t) \notin K_0'\}$. Then $t_j < \tau < b$, $\xi(\tau) \in K_0'$, and $\xi\lceil[t_j,\tau] \in \mathcal{A}(K')$. Since $\tau - t_j < \delta$, we have $||\xi(\tau) - \xi(t_j)|| < \frac{\varepsilon}{3}$, so $||\xi(\tau) - \bar{x}|| < \frac{2\varepsilon}{3}$, and then $\xi(\tau)$ is an interior point of K_0'. But then $\xi(t) \in K_0'$ for $t > \tau$, $t - \tau$ small enough, contradicting the definition of τ.) Using equicontinuity again, for the set of arcs $\{\xi\lceil[t_j,t] : t_j \leq t < b\} \subseteq \mathcal{A}(K')$, we see that the limit of $\xi(t)$ as $t \uparrow b$ must exist. Therefore $\lim_{t\uparrow b} \xi(t) = \bar{x}$. Then the arcs $\xi\lceil[t_j,t]$ converge to η as $t \uparrow b$, where $\eta : [t_j, b] \mapsto \Omega$ is such that $\eta\lceil[t_j,b[= \xi\lceil[t_j,b[$ and $\eta(b) = \bar{x}$. By the compactness property, $\eta \in \mathcal{A}$. Therefore, if we extend ξ to $J \cup \{b\}$ by letting $\xi(b) = \bar{x}$, we see that the extension belongs to $\mathcal{A}^{\#}$. Since ξ is maximal, we conclude that $b \in J$ and $\xi(b) = \bar{x}$. Since $(\bar{x}, b) = \lim_{j\to\infty}(\xi(t_j), t_j)$, we see that $(\bar{x}, b) \in K$, so $b \in L$, contradicting the fact that $b = \bar{t} \notin L$. □

If X is a set, we use 2^X to denote the set of all subsets of X. If X is a topological space, we can topologize 2^X as follows. For each open subset U of X, let

$$V(U) = \{S \in 2^X \, : \, S \subseteq U\}\,. \tag{2.3}$$

We then let $\mathcal{T}_{USC}(X)$ denote the set of all subsets S of 2^X such that $S = \cup_\alpha V(U_\alpha)$ for some family $\{U_\alpha\}$ of open subsets of X. Then $\mathcal{T}_{USC}(X)$ is a topology on 2^X. We will call it the *USC topology* on 2^X, because of its relation to upper-semicontinuity of set-valued maps. (If Y is a topological space, a set-valued map $F : Y \mapsto 2^X$ is upper semicontinuous iff it is continuous as a map from Y to $(2^X, \mathcal{T}_{USC}(X))$.) The name *upper semifinite topology* has also been used in the literature; cf., e.g., [17].

If Ω is a metric space and I is an interval, then for every subset K of $\Omega \times I$ we have a set-valued map $T_{\Omega,I,K} : AS(\Omega, I) \mapsto 2^{ARC(\Omega)}$ given by $T_{\Omega,I,K}(\mathcal{A}) = \mathcal{A}(K)$. As K ranges over all the compact subsets of $\Omega \times I$, we have a collection of maps $T_{\Omega,I,K}$ from $AS(\Omega, I)$ to $2^{ARC(\Omega)}$. Therefore there exists a weakest topology on $AS(\Omega, I)$ that renders all the maps $T_{\Omega,I,K}$ continuous, where $2^{ARC(\Omega)}$ is equipped with the USC topology. This topology will be called the *topology of trajectory convergence* (or simply *T-convergence*) and will be denoted by $\mathcal{T}_T(\Omega, I)$. If $\{\mathcal{A}^\alpha\}_{\alpha\in A}$ is a net in $AS(\Omega, I)$ and $\mathcal{A} \in AS(\Omega, I)$, we say that $\{\mathcal{A}^\alpha\}_{\alpha\in A}$ *T-converges* to $\mathcal{A}$ (and write $\mathcal{A}^\alpha \xrightarrow{\text{T}} \mathcal{A}$) if the $\mathcal{A}^\alpha$ converge to $\mathcal{A}$ in $\mathcal{T}_T(\Omega, I)$.

Let Ω be a metric space, let $\xi : I \mapsto \Omega$ be a curve, and assume that $\{\xi^\alpha\}_{\alpha\in A}$ is a net of curves in Ω, with $\mathrm{Dom}(\xi^\alpha) = I^\alpha$. We say that the ξ^α *converge to* ξ *on compact sets* if for every compact subset $J \subseteq I$, there exists an $\alpha^*(J)$ such that (i) $J \subseteq I^\alpha$ for $\alpha \succeq_A \alpha^*(J)$ and (ii) the $\xi^\alpha\lceil J$ converge uniformly to $\xi\lceil J$.

We say that a net $\{\mathcal{A}^\alpha\}_{\alpha\in A}$ in $AS(\Omega, I)$ *converges to* $\mathcal{A} \in AS(\Omega, I)$ *in the maximal curve convergence sense* if, whenever $\{(x^\alpha, t^\alpha)\}_{\alpha\in A}$ is a net of points in $\Omega \times I$ that converges to a limit $(\bar{x}, \bar{t}) \in \Omega \times I$, and $\{\xi^\alpha\}_{\alpha\in A}$ is a net such that for each $\alpha \in A$ $\xi^\alpha \in (\mathcal{A}^\alpha)^{\#}_{max}$ and $\xi^\alpha(t^\alpha) = x^\alpha$, it follows that there exist a $\xi^\infty \in \mathcal{A}^{\#}_{max}$, with domain $I^\infty \subseteq I$, such that $\xi^\infty(\bar{t}) = \bar{x}$, and a subnet $\{\xi^{\mu(\beta)}\}_{\beta\in B}$ of $\{\xi^\alpha\}_{\alpha\in A}$ that converges to ξ^∞ on compact sets.

Proposition 2.2. *Let Ω be a locally compact metric space, and let $I \subseteq \mathbb{R}$ be an interval. Suppose that $\{\mathcal{A}^\alpha\}_{\alpha\in A}$ is a net in $AS_{comp,le}(\Omega, I)$, and $\mathcal{A} \in AS_{comp,le}(\Omega, I)$. Then the following conditions are equivalent:*

(I) *the $\mathcal{A}^\alpha$ T-converge to $\mathcal{A}$;*

(II) *every subnet of* $\{\mathcal{A}^\alpha\}_{\alpha\in A}$ *converges to* $\mathcal{A}$ *in the maximal curve convergence sense.*

Proof. The implication (II)⇒(I) is trivial. Indeed, suppose (II) holds, and let K be a compact subset of $\Omega\times I$. Since $\mathcal{A}(K)$ is compact, a fundamental system of neighborhoods of $\mathcal{A}(K)$ in $2^{ARC(\Omega)}$ is given by the sets

$$V_\varepsilon = \{\xi \in ARC(\Omega) : d_{ARC}(\xi, \mathcal{A}(K)) < \varepsilon\}$$

for $\varepsilon > 0$. So it suffices to fix ε and prove that $\mathcal{A}^\alpha(K)\subseteq V_\varepsilon$ for sufficiently large α. If this was not so, there would exist a subnet $\{\mathcal{A}^{\mu(\beta)}\}_{\beta\in B}$ of $\{\mathcal{A}^\alpha\}_{\alpha\in A}$ such that there are $\xi^\beta\in\mathcal{A}^{\mu(\beta)}(K)$ for which $d_{ARC}(\xi^\beta,\mathcal{A}(K))\geq\varepsilon$. Extend each ξ^β to a $\tilde\xi^\beta\in(\mathcal{A}^{\mu(\beta)})^\#_{max}$. Pick $t^\beta\in\mathrm{Dom}(\xi^\beta)$ in an arbitrary fashion, and let $x^\beta=\xi^\beta(t^\beta)$. Then $(x^\beta,t^\beta)\in K$, so by passing to a subnet if necessary we may assume that (x^β,t^β) converges to a limit $(\bar x,\bar t)$. Using (II) we may assume, after passing to a subnet, that there exists a $\tilde\xi\in\mathcal{A}^\#_{max}$ such that $\tilde\xi(\bar t)=\bar x$ and $\tilde\xi^\beta\to\tilde\xi$ on compact sets. After passing once again to a subnet, we may assume that $a(\xi^\beta)$ and $b(\xi^\beta)$ have limits a,b, both belonging to I. Let $J=\mathrm{Dom}(\tilde\xi)$. We will prove that $a\in J$ and $b\in J$. Since both proofs are similar, we will show only that $b\in J$. Suppose that $b\notin J$. Let $c=\sup J$, so $c\leq b$. Since $b\in I$, and J is relatively open in I, we have $c\notin J$. This implies in particular that $c>\bar t$, since $\bar t\in J$. Pick $c'\in[\bar t,c[$. Then $[\bar t,c']\subseteq J$, so $[\bar t,c']\subseteq\mathrm{Dom}(\tilde\xi^\beta)$ for large β, and $\tilde\xi^\beta\lceil[\bar t,c']\to\tilde\xi\lceil[\bar t,c']$ uniformly. Since $b(\xi^\beta)\to b>c'$, we have $b(\xi^\beta)>c'$ for large β. Since $a(\xi^\beta)\leq t^\beta\to\bar t<c'$, we have $a(\xi^\beta)<c'$ for large β. Therefore $c'\in\mathrm{Dom}(\xi^\beta)$ for large β, so $\tilde\xi(c')=\lim\xi^\beta(c')$. Therefore $(\tilde\xi(c'),c')\in K$. Since this is true for $c'<c$ but arbitrarily close to c, and the set $L=\{t\in J:(\tilde\xi(t),t)\in K\}$ is compact by Proposition 2.1, we conclude that $c\in L$, so in particular $c\in J$, which is a contradiction.

Thus a and b belong to J. Therefore $[a,b]\subseteq\mathrm{Dom}(\tilde\xi^\beta)$ for large β, and $\tilde\xi^\beta\lceil[a,b]$ converges to $\tilde\xi\lceil[a,b]$. Since $a(\xi^\beta)\to a$, and $b(\xi^\beta)\to b$, given any $s\in[a,b]$ we can find $s^\beta\in\mathrm{Dom}(\xi^\beta)$ such that $a^\beta\leq s^\beta\leq b^\beta$ and $s^\beta\to s$. Therefore $\xi^\beta(s^\beta)\to\tilde\xi(s)$. So $(\tilde\xi(s),s)\in K$. This shows that the restriction ξ of $\tilde\xi$ to $[a,b]$ is in $\mathcal{A}(K)$. Therefore $d_{ARC}(\xi^\beta,\xi)\geq\varepsilon$. On the other hand, $\xi^\beta\to\xi$ in $ARC(\Omega)$, so $d_{ARC}(\xi^\beta,\xi)\to0$. This contradiction proves that (II)⇒(I), as stated.

We now prove that (I)⇒(II). Assume that the net $\{\mathcal{A}^\alpha\}_{\alpha\in A}$ T-converges to $\mathcal{A}$. We want to show that every subnet of $\{\mathcal{A}^\alpha\}_{\alpha\in A}$ converges to $\mathcal{A}$ in the maximal curve convergence sense. Since every subnet of $\{\mathcal{A}^\alpha\}_{\alpha\in A}$ T-converges to $\mathcal{A}$, because the notion of T-convergence arises from a topology, it suffices to show that $\{\mathcal{A}^\alpha\}_{\alpha\in A}$ converges to $\mathcal{A}$ in the maximal curve convergence sense.

Let $\{\xi^\alpha\}_{\alpha\in A}$ be a net such that $\xi^\alpha\in(\mathcal{A}^\alpha)^\#_{max}$, and let I^α be the domain of ξ^α. Let $t^\alpha\in I^\alpha$ be such that $t^\alpha\to\bar t\in I$, and $x^\alpha\overset{\mathrm{def}}{=}\xi^\alpha(t^\alpha)\to\bar x\in\Omega$. Pick a compact neighborhood K_0 of $\bar x$ in Ω and a compact interval J_0 which is a relative neighborhood of $\bar t$ in I. By passing to a subnet of $\{\xi^\alpha\}$, we may assume that $x^\alpha\in K_0$ and $t^\alpha\in J_0$ for all α. Let $\mathbf{Q}$ be the set of all products $Q=K\times J$, where K is a compact subset of Ω such that $K_0\subseteq K$, and J is a compact subinterval of I such that $J_0\subseteq J$. For each $Q=K\times J\in\mathbf{Q}$, let $L^\alpha(Q)=\{t\in I^\alpha:(\xi^\alpha(t),t)\in Q\}$. Then $L^\alpha(Q)$ is compact. Let $S^\alpha(Q)$ be the connected component of $L^\alpha(Q)$ that contains t^α. Then $S^\alpha(Q)$ is a compact subinterval of I. Let $\xi^{\alpha,Q}$ be the restriction of ξ^α to $S^\alpha(Q)$. Then $\xi^{\alpha,Q}\in\mathcal{A}^\alpha(Q)$. Since $\mathcal{A}(Q)$ is compact, we can pick $\zeta^{\alpha,Q}\in\mathcal{A}(Q)$ such that $d_{ARC}(\xi^{\alpha,Q},\zeta^{\alpha,Q})=d_{ARC}(\xi^{\alpha,Q},\mathcal{A}(Q))$. Since $\mathcal{A}^\alpha\xrightarrow{\mathrm{T}}\mathcal{A}$, the distance

$d_{ARC}(\xi^{\alpha,Q},\mathcal{A}(Q))$ goes to 0. So $d_{ARC}(\xi^{\alpha,Q},\zeta^{\alpha,Q})\to 0$. Let

$$U=\prod_{Q\in\mathbf{Q}}\mathcal{A}(Q)\,. \tag{2.4}$$

Then U is a product of compact topological spaces. By Tikhonov's theorem, U is compact with respect to the product topology. Let $Z^\alpha=\{\zeta^{\alpha,Q}\}_{Q\in\mathbf{Q}}$. Then each Z^α is a member of U. Therefore there is a subnet $\{Z^{\mu(\beta)}\}_{\beta\in B}$ of $\{Z^\alpha\}_{\alpha\in A}$ that converges to a limit $Z=\{\zeta^Q\}_{Q\in\mathbf{Q}}\in U$. Then $\zeta^{\mu(\beta),Q}\to\zeta^Q$ for every $Q\in\mathbf{Q}$. Since $d_{ARC}(\xi^{\mu(\beta),Q},\zeta^{\mu(\beta),Q})\to 0$, we have shown that $\xi^{\mu(\beta),Q}\to\zeta^Q$ for each Q.

If $Q,Q'\in\mathbf{Q}$ and $Q\subseteq Q'$, then it is easy to see that $L^\alpha(Q)\subseteq L^\alpha(Q')$ for all $\alpha\in A$. Therefore $S^\alpha(Q)\subseteq S^\alpha(Q')$, and then $G(\xi^{\alpha,Q})\subseteq G(\xi^{\alpha,Q'})$. In particular, $G(\xi^{\mu(\beta),Q})\subseteq G(\xi^{\mu(\beta),Q'})$ for all β and then, taking limits, it follows that $G(\zeta^Q)\subseteq G(\zeta^{Q'})$. Since for any two members Q, Q' of $\mathbf{Q}$ there is a $Q''\in\mathbf{Q}$ such that $Q\cup Q'\subseteq Q''$, it follows that the arcs ζ^Q match, in the sense that the union of the graphs $G(\zeta^Q)$ is the graph of a map ζ. If $S(Q)=\mathrm{Dom}(\zeta^Q)$, then $\bar t\in S(Q)$, because $t^{\mu(\beta)}\in\mathrm{Dom}(\xi^{\mu(\beta),Q})$ for each β, and $t^{\mu(\beta)}\to\bar t$. Then $S=\cup_{Q\in\mathbf{Q}}S(Q)$ is an interval, and it is clear that $S=\mathrm{Dom}(\zeta)$. Obviously, $\zeta(\bar t)=\bar x$. We now have to show that $\zeta\in\mathcal{A}^{\#}_{max}$ and $\xi^{\mu(\beta)}\to\zeta$ on compact sets.

Write

$$S^\alpha(Q)=[a^\alpha(Q),b^\alpha(Q)]\,,\quad S(Q)=[a(Q),b(Q)]\,, \tag{2.5}$$

so $a(Q)=\lim_\beta a^{\mu(\beta)}(Q)$ and $b(Q)=\lim_\beta b^{\mu(\beta)}(Q)$.

Next, we make the following observation:

(*) Given any $\alpha\in A$ and any $Q=K\times J\in\mathbf{Q}$, the point $\xi^\alpha(b^\alpha(Q))$ belongs to $K\backslash\mathrm{Int}(K)$ unless $b^\alpha(Q)=\sup I$.

Indeed, if $b^\alpha(Q)<\sup I$ and $\xi^\alpha(b^\alpha(Q))\in\mathrm{Int}(K)$, then $\xi^\alpha(t)$ would be defined for $t=b^\alpha(Q)+h$ if $h>0$ is small enough, because the domain of ξ^α is relatively open in I. By continuity, $(\xi^\alpha(t),t)$ would be in Q for $t=b^\alpha(Q)+h$, $h>0$, h small, contradicting the definition of $b^\alpha(Q)$. Thus (*) holds, as stated.

Let $\sigma=\sup S$. We distinguish three cases, namely,

(i) $\sigma\notin I$,
(ii) $\sigma\in I\backslash S$,
(iii) $\sigma\in S$.

In cases (i) and (ii), if $b\in S$, then $b<\sigma$, so $b<b(Q)$ for some $Q\in\mathbf{Q}$, since $\sigma=\sup\{b(Q):Q\in\mathbf{Q}\}$. Therefore $b<b^{\mu(\beta)}(Q)$ for large enough β. In case (iii), we must have $\sigma=b(\bar Q)$ for a $\bar Q\in\mathbf{Q}$. Let $Q'=K'\times J'$ be such that $\zeta(\sigma)\in\mathrm{Int}_\Omega(K')$ and pick a $Q=K\times J\in\mathbf{Q}$ such that $\bar Q\cup Q'\subseteq Q$. Then $b(Q)=\sigma$, and $\zeta^Q(b(Q))=\zeta(b(Q))\in\mathrm{Int}(K)$. Thus $\xi^{\mu(\beta),Q}\in\mathrm{Int}(K)$ for large β. Therefore (*) implies that $b^{\mu(\beta)}(Q)=\sigma$ for large β.

Summarizing the above, we have shown the following:

(**) If $b\in S$, then there is a $Q\in\mathbf{Q}$ such that $b\le b^{\mu(\beta)}(Q)$ for all sufficiently large β.

Naturally, a similar reasoning shows that if $a\in S$, then there is a Q such that $a^{\mu(\beta)}(Q)\le a$ for all sufficiently large β. Therefore, if $S'=[a,b]$ is any compact subinterval of S, there exists a Q such that $[a,b]\subseteq S^{\mu(\beta)}(Q)$ for all large enough β. It follows that the restriction $\zeta\lceil[a,b]$ is the arc $\zeta^Q\lceil[a,b]$. Since $\zeta^Q\in\mathcal{A}$, we see that $\zeta\lceil[a,b]\in\mathcal{A}$.

This is true for every S'. So we have shown that $\zeta \in \mathcal{A}^{\#}$. Moreover, it also follows that, for any S', there is a Q such that the inclusion $S' \subseteq S^{\mu(\beta)}(Q) \subseteq \mathrm{Dom}(\xi^{\mu(\beta)})$ holds for large enough β. This shows that $\xi^{\mu(\beta)} \to \zeta$ on compact sets.

To conclude, we have to show that $\zeta \in \mathcal{A}^{\#}_{max}$. Assume that this is not true, and let $\tilde{\zeta} : \tilde{S} \mapsto \Omega$ be a curve, defined on a subinterval $\tilde{S}$ of I such that $S \subseteq \tilde{S}$ but $S \neq \tilde{S}$, for which $\tilde{\zeta}\lceil S = \zeta$. Pick $s \in \tilde{S} \backslash S$. Then either $s \geq \sup S$ or $s \leq \inf S$. We assume that $s \geq \sup S$, the other case being similar. As before, we write $\sigma = \sup S$. Then $\sigma \in I$, because $\sigma \leq s \in I$ and $\sigma \geq t$ for some $t \in S$. Pick a $Q_1 = K_1 \times J_1 \in \mathbf{Q}$ such that $\tilde{\zeta}(\sigma) \in \mathrm{Int}(K_1)$. Pick a $\sigma' \in S$ such that $\sigma' \leq \sigma$ and $\zeta(t) \in \mathrm{Int}(K_1)$ whenever $\sigma' \leq t$ and $t \in S$. Using (**), pick a $Q_2 = K_2 \times J_2$ such that $\sigma' \leq b^{\mu(\beta)}(Q_2)$ for all sufficiently large β. Pick $Q = K \times J \in \mathbf{Q}$ such that $Q_1 \cup Q_2 \subseteq Q$. Then $\xi^{\mu(\beta)}(b^{\mu(\beta)}(Q)) \to \zeta(b(Q)) \in \mathrm{Int}(K)$. Thus $\xi^{\mu(\beta)}(b^{\mu(\beta)}(Q))$ belongs to $\mathrm{Int}(K)$ for large β, and then it follows from (*) that $b^{\mu(\beta)}(Q) = \sup I$ for large β. But then $b(Q) = \sup I$, and this implies that $\sigma = b(Q) = \sup I$, and $\sigma \in S$. Since $s \in I$, and $s \geq \sigma$, we must have $s = \sigma$, contradicting the fact that $s \notin S$. □

Remark 2.1. If the space Ω is σ-compact (i.e., a countable union of compact subsets), then instead of considering the product U defined in (2.4), we can use the product $U' = \prod_{j=1}^{\infty} \mathcal{A}(Q_j)$, where $\{Q_j\}$ is a sequence of compact subsets of $\Omega \times I$ whose relative interiors cover $\Omega \times I$. Then U' is metrizable. Therefore the statement and proof of Proposition 2.2 can be repeated using sequences instead of nets, and subsequences instead of subnets. □

We now specialize to the arc systems defined by vector fields. Let Ω be an open subset of $\mathbb{R}^n$, and let I be a subinterval of $\mathbb{R}$. A *time-varying vector field* on Ω with time domain I is a map $f : \Omega \times I \mapsto \mathbb{R}^n$. We use $TVVF(\Omega, I)$ to denote the set of all such maps. An $f \in TVVF(\Omega, I)$ satisfies the *Carathéodory condition* if it is continuous in x for each fixed $t \in I$ and Lebesgue measurable in t for each fixed $x \in \Omega$. We call f *locally integrably bounded* (LIB) if f is bounded in norm by a locally integrable function of t, as long as x stays in a compact subset of Ω. We use $TVVF_{Car,LIB}(\Omega, I)$ to denote the set of all $f \in TVVF(\Omega, I)$ that satisfy the Carathéodory condition, and are LIB.

If $f \in TVVF(\Omega, I)$, a *trajectory* (or *integral curve*) of f is an absolutely continuous function $\xi : J \mapsto \Omega$ defined on some nonempty subinterval $J \subseteq I$ such that $\dot{\xi}(t) = f(\xi(t), t)$ for almost all $t \in J$. A *maximal trajectory* of f is a trajectory $\xi : J \mapsto \Omega$ that cannot be extended to a trajectory of f defined on a strictly larger interval. We write $\mathrm{Traj}(f)$ to denote the set of all trajectories of f, and $\mathrm{Traj}_c(f)$ to denote the set of all $\xi \in \mathrm{Traj}(f)$ that are arcs, i.e., such that $\mathrm{Dom}(\xi)$ is a compact interval. Also, we write $\mathrm{Traj}(f)_{max}$ to denote the set of all maximal trajectories of f. Then it is clear that $\mathrm{Traj}_c(f)$ is an arc system, and $\mathrm{Traj}_c(f)^{\#}$ is precisely $\mathrm{Traj}(f)$. Therefore $\mathrm{Traj}(f)_{max}$ is exactly the set $\mathrm{Traj}_c(f)^{\#}_{max}$.

Thus $f \mapsto \mathrm{Traj}_c(f)$ is a map from $TVVF(\Omega, I)$ to $AS(\Omega, I)$. Using this map, we can pull back the topology of trajectory convergence on $AS(\Omega, I)$ and define a *topology of trajectory convergence*, or *T-convergence*, on $TVVF(\Omega, I)$. We can also pull back properties of arc systems and apply them to vector fields. (For example, we will say that f has the local existence property if the arc system $\mathrm{Traj}_c(f)$ does.) We call f *trajectory compact* if $\mathrm{Traj}_c(f)$ has the compactness property. We use $TVVF_{comp,le}(\Omega, I)$ to denote the set of those $f \in TVVF(\Omega, I)$ that are trajectory compact and have the local existence property. We say that f has the *uniqueness property* if for every initial condition $(\bar{x}, \bar{t})$ in $\Omega \times I$ the maximal trajectory of f whose graph contains $(\bar{x}, \bar{t})$ is unique.

The Carathéodory existence theorem (cf. [6]) implies that every vector field $f \in TVVF_{Car,LIB}(\Omega, I)$ has the local existence property. Moreover, a simple application of the Ascoli–Arzelà theorem and the Lebesgue dominated convergence theorem shows that every time-varying vector field $f \in TVVF_{Car,LIB}(\Omega, I)$ is trajectory compact. Thus

$$TVVF_{Car,LIB}(\Omega, I) \subseteq TVVF_{comp,le}(\Omega, I)\,. \tag{2.6}$$

If S is a subset of $\Omega \times I$, we write $\mathrm{Traj}_c(f, S)$ to denote the set of all arcs $\xi \in \mathrm{Traj}_c(f)$ such that $G(\xi) \subseteq S$. We then have the following propositions.

PROPOSITION 2.3. *Let f be in $TVVF(\Omega, I)$ and $\{f^\alpha\}_{\alpha\in A}$ be a net in $TVVF(\Omega, I)$. Then $\{f^\alpha\}_{\alpha\in A}$ T-converges to f iff for every compact subset K of $\Omega \times I$ and every open subset V of $ARC(\Omega)$ containing $\mathrm{Traj}_c(f, K)$ there exists an $\alpha^*(V) \in A$ such that $\mathrm{Traj}_c(f^\alpha, K) \subseteq V$ whenever $\alpha^*(V) \preceq \alpha$.*

PROPOSITION 2.4. *If $f \in TVVF_{comp,le}(\Omega, I)$, then a net $\{f^\alpha\}_{\alpha\in A}$ in $TVVF(\Omega, I)$ T-converges to f iff*

$$\lim_{\alpha} \sup\{d_{ARC}(\xi, \mathrm{Traj}_c(f, K)) : \xi \in \mathrm{Traj}_c(f^\alpha, K)\} = 0 \tag{2.7}$$

for every compact subset K of $\Omega \times I$.

PROPOSITION 2.5. *Let $\mathbf{f} = \{f^\alpha\}_{\alpha\in A}$ be a net in $TVVF_{comp,le}(\Omega, I)$, and suppose that $f \in TVVF_{comp,le}(\Omega, I)$. Then $\mathbf{f}$ T-converges to f iff, whenever $\{f^{\mu(\beta)}\}_{\beta\in B}$ is a subnet of $\mathbf{f}$, $(x^\beta, t^\beta) \in \Omega \times I$ converge to $(\bar{x}, \bar{t}) \in \Omega \times I$, and $\boldsymbol{\xi} = \{\xi^\beta\}_{\beta\in B}$ is a family such that each ξ^β is a maximal trajectory of $f^{\mu(\beta)}$ for which $\xi^{\mu(\beta)}(t^\beta) = x^\beta$, it follows that there exist a maximal trajectory ξ of f such that $\xi(\bar{t}) = \bar{x}$ and a subnet $\{\xi^{\nu(\gamma)}\}_{\gamma\in C}$ of $\boldsymbol{\xi}$ that converges to ξ on compact sets.*

PROPOSITION 2.6. *If $f \in TVVF_{comp,le}(\Omega, I)$, then a sequence $\mathbf{f} = \{f^j\}_{j=1}^\infty$ of members of $TVVF_{comp,le}(\Omega, I)$ T-converges to f iff, whenever J is an infinite set of positive integers, $(x^j, t^j) \in \Omega \times I$ converge to $(\bar{x}, \bar{t}) \in \Omega \times I$ as $j \to \infty$ via values in J, and $\boldsymbol{\xi} = \{\xi^j\}_{j\in J}$ is a family such that each ξ^j is a maximal trajectory of f^j for which $\xi^j(t^j) = x^j$, it follows that there exist a maximal trajectory ξ of f such that $\xi(\bar{t}) = \bar{x}$ and an infinite subset J' of J such that $\{\xi^j\}_{j\in J'}$ converges to ξ on compact sets.*

PROPOSITION 2.7. *Suppose that $f \in TVVF_{comp,le}(\Omega, I)$ and that a net $\mathbf{f} = \{f^\alpha\}_{\alpha\in A}$ of members of $TVVF_{comp,le}(\Omega, I)$ T-converges to f; assume that $(x^\alpha, t^\alpha) \in \Omega \times I$ converge to $(\bar{x}, \bar{t}) \in \Omega \times I$, $\boldsymbol{\xi} = \{\xi^\alpha\}_{\alpha\in A}$ is a family such that each ξ^α is a maximal trajectory of f^α for which $\xi^\alpha(t^\alpha) = x^\alpha$, and the maximal trajectory ξ of f for which $\xi(\bar{t}) = \bar{x}$ is unique; then the net $\boldsymbol{\xi}$ converges to ξ on compact sets.*

PROPOSITION 2.8. *Suppose that $f \in TVVF_{comp,le}(\Omega, I)$ has the uniqueness property, and let $\mathbf{f} = \{f^\alpha\}_{\alpha\in A}$ be a net of members of $TVVF_{comp,le}(\Omega, I)$; then $\mathbf{f}$ T-converges to f iff, whenever $(x^\alpha, t^\alpha) \in \Omega \times I$ converge to $(\bar{x}, \bar{t}) \in \Omega \times I$, $\boldsymbol{\xi} = \{\xi^\alpha\}_{\alpha\in A}$ is a family such that each ξ^α is a maximal trajectory of f^α for which $\xi^\alpha(t^\alpha) = x^\alpha$, and ξ is the maximal trajectory of f for which $\xi(\bar{t}) = \bar{x}$, it follows that the net $\boldsymbol{\xi}$ converges to ξ on compact sets.*

All these properties are very easy to prove. Proposition 2.3 is just a restatement of the definition of T-convergence. Then Proposition 2.4 immediately follows from Proposition 2.3 by observing that if $\mathrm{Traj}_c(f, K)$ is compact, then the sets $\{\xi \in ARC(\Omega) : d_{ARC}(\xi, \mathrm{Traj}_c(f, K)) < \varepsilon\}$ form a fundamental system of neighborhoods of $\mathrm{Traj}_c(f)$. Proposition 2.5 follows from Proposition 2.2, and Proposition 2.6 follows from Remark 2.1. Finally, Propositions 2.7 and 2.8 follow trivially from Proposition 2.5. $\square$

3. $\mathcal{T}^0$-convergence for control-affine systems. We are now ready to give the precise definition of the topology of $\mathcal{T}^0$-convergence on $L^1([0,T],\mathbb{R}^m)$.

Let m be a positive integer. A $C^0(m)$ *system* is an $(m+2)$-tuple

$$\Sigma = (\Omega, f_0, \dots, f_m)\,, \tag{3.1}$$

where Ω is a nonempty open subset of $\mathbb{R}^n$ for some integer $n \geq 1$, and $f_0,\dots,f_m$ are continuous vector fields on Ω. The expressions f_i^Σ, Ω^Σ will be used to denote the vector fields f_i and the set Ω corresponding to a given system $\Sigma \in C^0(m)$.

If $T > 0$, and $u \in L^1([0,T],\mathbb{R}^m)$, then for each $\Sigma = (\Omega^\Sigma, f_0^\Sigma, \dots, f_m^\Sigma)$, we can consider the ordinary differential equation

$$\dot{x}(t) = f_0^\Sigma(x(t)) + \sum_{k=1}^m u_k(t) f_k^\Sigma(x(t))\,. \tag{3.2}$$

The right-hand side of (3.2) is a time-varying vector field on Ω^Σ with time domain $[0,T]$, which clearly belongs to $TVVF_{Car,LIB}(\Omega^\Sigma,[0,T])$. Thus we can associate with Σ the map

$$\Gamma_\Sigma\,:\, L^1([0,T],\mathbb{R}^m) \mapsto TVVF_{Car,LIB}(\Omega^\Sigma,[0,T]) \tag{3.3}$$

defined by

$$\Gamma_\Sigma(u)(x,t) = f^\Sigma(u)(x,t) \overset{\text{def}}{=} f_0^\Sigma(x) + u_1(t) f_1^\Sigma(x) + \cdots + u_m(t) f_m^\Sigma(x)\,. \tag{3.4}$$

For each $\Sigma \in C^0(m)$ and $T > 0$, the set $TVVF_{Car,LIB}(\Omega^\Sigma,[0,T])$ is a topological space with the topology of trajectory convergence. Therefore, for any subclass $\mathcal{C}$ of $C^0(m)$ we can consider the topology $T(\mathcal{C})$ on $L^1([0,T],\mathbb{R}^m)$ induced by the family of mappings $\{\Gamma_\Sigma : \Sigma \in \mathcal{C}\}$, i.e., the weakest topology on $L^1([0,T],\mathbb{R}^m)$ that makes all the maps Γ_Σ continuous, for all $\Sigma \in \mathcal{C}$. In particular, the *topology of* $\mathcal{T}^0$*-convergence* on $L^1([0,T],\mathbb{R}^m)$ is, by definition, the $T(C^0(m))$-topology. We say that a net $\{u^\alpha\}_{\alpha\in A}$ $\mathcal{T}^0$*-converges* to a u^∞ in $L^1([0,T],\mathbb{R}^m)$ if it converges to u^∞ in this topology. Equivalently, a net $\{u^\alpha\}_{\alpha\in A}$ $\mathcal{T}^0$-converges to a limit u^∞ iff

(TCN) for every possible choice of the system $\Sigma \in C^0(m)$, the time-varying vector $(x,t) \mapsto f^\Sigma(u^\alpha)(x,t)$ T-converge to $(x,t) \mapsto f^\Sigma(u^\infty)(x,t)$.

(This is exactly the version for nets of condition (TC) of the introduction.)

If (TCN) holds, then Proposition 2.7 implies that in particular the following conditions hold as well:

(TCN′) For every possible choice of $\Sigma \in C^0(m)$, if ξ^α are maximal trajectories of (1.1) determined by the u^α, $x^\alpha = \xi^\alpha(0)$, and $x^\alpha \to \bar{x} \in \Omega^\Sigma$, then the ξ^α are defined on $[0,T]$ for α large enough and converge uniformly on $[0,T]$ to the maximal trajectory ξ^∞ for u^∞, provided that for the limiting initial value problem $\dot{x} = f_0^\Sigma(x) + \sum_{i=1}^m u_i^\infty(t) f_i^\Sigma(x)$, $x(0) = \bar{x}$, there is uniqueness of solutions as well as global existence on $[0,T]$.

(TCN″) For every possible choice of the system $\Sigma \in C^0(m)$ and the initial condition $x(0) = \bar{x} \in \Omega^\Sigma$, if ξ^α are maximal trajectories of (1.1) determined by the u^α and $\bar{x}$, then the ξ^α are defined on $[0,T]$ for α large enough and converge uniformly on $[0,T]$ to the maximal trajectory ξ^∞ for u^∞, provided that for the limiting initial value problem $\dot{x} = f_0^\Sigma(x) + \sum_{i=1}^m u_i^\infty(t) f_i^\Sigma(x)$, $x(0) = \bar{x}$, there is uniqueness of solutions as well as global existence on $[0,T]$.

4. A characterization of sequential $\mathcal{T}^0$-convergence.

THEOREM 4.1. *Let* $\mathbf{u} = \{u^j\}_{j=1}^{\infty}$ *be a sequence of controls in* $L^1([0,T],\mathbb{R}^m)$*, and let* $u^\infty \in L^1([0,T],\mathbb{R}^m)$*. Then the following conditions are equivalent:*

(i) $\mathbf{u}$ *satisfies condition* (UB) *and I-converges to* u^∞*,*
(ii) $\mathbf{u}$ $\mathcal{T}^0$*-converges to* u^∞*,*
(iii) (TCN′) *holds,*
(iv) (TCN″) *holds,*
(v) $\mathbf{u}$ *UW-converges to* u^∞*.*

If $\mathbf{u} = \{u^\alpha\}_{\alpha\in A}$ *is a net in* $L^1([0,T],\mathbb{R}^m)$*, and* u^∞ *belongs to* $L^1([0,T],\mathbb{R}^m)$*, then* (i)$\Longrightarrow$(ii)$\Longrightarrow$(iii)$\Longrightarrow$(iv)$\Longrightarrow$(v)*, but in general* (v)$\not\Longrightarrow$(iv) *and* (ii)$\not\Longrightarrow$(i)*.*

Remark 4.1. At present, we do not know if the implications (iv)$\Longrightarrow$(iii)$\Longrightarrow$(ii) hold for general nets, i.e., whether (ii), (iii), and (iv) of Theorem 4.1 are equivalent for nets.

THEOREM 4.2. *Let* $\mathbf{u} = \{u^\alpha\}_{\alpha\in A}$ *be a net of inputs belonging to* $L^1([0,T],\mathbb{R}^m)$*, and let* $u^\infty \in L^1([0,T],\mathbb{R}^m)$ *be such that* (i) *of Theorem* 4.1 *holds. Let* Ω *be open in* $\mathbb{R}^n$*, and let* $h^\alpha : \Omega\times[0,T] \mapsto \mathbb{R}^n$ *be time-varying vector fields given by*

$$h^\alpha(x,t) = \dot\theta^\alpha(t) + f_0(x) + \sum_{i=1}^m u_i^\alpha(t) f_i(x)\,,$$

where the $f_i : \Omega \mapsto \mathbb{R}^n$ *are continuous, the* $\theta^\alpha : [0,T] \mapsto \mathbb{R}^n$ *are absolutely continuous, and* $\theta^\alpha \to 0$ *uniformly. Then the net* $\{h^\alpha\}_{\alpha\in A}$ *T-converges to the vector field* h^∞ *given by* $h^\infty(x,t) = f_0(x) + \sum_{i=1}^m u_i^\infty(t) f_i(x)$*.*

Proof of Theorems 4.1 *and* 4.2. We first prove that (i) implies (v). We have to show that (UB) $\wedge$ (IC) implies (UWC). Pick a function $\varphi\in C^0([0,T],\mathbb{R})$ and a $\delta>0$, and find a piecewise constant function $\psi=\sum_{k=1}^N \psi_k\chi_{J_k}$ (where the J_k are subintervals of $[0,T]$ and χ_J denotes the indicator function of J) such that $|\varphi(t)-\psi(t)|<\delta$ for all $t \in [0,T]$. If (UB) holds, then there exists α^* and a $C > 0$ such that $\|u_i^\alpha\|_{L^1} \le C$ for all $i = 1,\ldots,m$, and $\alpha \succeq_A \alpha^*$ including $\alpha = \infty$. But then $|\int_0^t u_i^\alpha(s)\varphi(s)ds - \int_0^t u_i^\alpha(s)\psi(s)ds| \le C\delta$ for all i, t, and $\alpha \succeq_A \alpha^*$. In view of (IC), $\int_0^t u_i^\alpha(s)\psi(s)ds \to \int_0^t u_i^\infty(s)\psi(s)ds$ uniformly with respect to t. So $|\int_0^t u_i^\alpha(s)\psi(s)ds - \int_0^t u_i^\infty(s)\psi(s)ds| \le \delta$ for all t, if α is large enough. But then $|\int_0^t u_i^\alpha(s)\varphi(s)ds - \int_0^t u_i^\infty(s)\varphi(s)ds| \le (2C+1)\delta$ for all t if α is sufficiently large. Since δ is arbitrary, (UWC) follows.

Next, we prove Theorem 4.2, which contains as a particular case the implication (i)$\Longrightarrow$(ii) of Theorem 4.1. Let $\mathbf{u} = \{u^\alpha\}_{\alpha\in A}$, and let $\Omega, f_0, \ldots, f_m$, and the θ^α be as in the statement of Theorem 4.2. Let $\Sigma = (\Omega, f_0, \ldots, f_m)$ be a $C^0(m)$ system. We have to show that the h^α T-converge to h^∞. Let K be a compact subset of $\Omega\times[0,T]$. We will show that the sets $\mathrm{Traj}_c(h^\alpha,K)$ converge to $\mathrm{Traj}_c(h^\infty,K)$. For this we first prove the following:

(CTR) If $\{\xi^\alpha\}_{\alpha\in A}$ is a net in $ARC(\Omega)$ such that $\xi^\alpha \in \mathrm{Traj}_c(h^\alpha,K)$, then $\{\xi^\alpha\}_{\alpha\in A}$ has a subnet $\{\xi^{\nu(\beta)}\}_{\beta\in B}$ that converges to an $\eta \in \mathrm{Traj}_c(h^\infty,K)$.

Clearly, if we show that $\{\xi^\alpha\}_{\alpha\in A}$ has a subnet that converges in $ARC(\Omega)$, then (CTR) would follow. Indeed, let $\{\xi^{\nu(\beta)}\}_{\beta\in B}$ be a subnet of $\{\xi^\alpha\}_{\alpha\in A}$ that converges in $ARC(\Omega)$. Let η be the limit. Let $I^\alpha = \mathrm{Dom}(\xi^\alpha)$ and $I = \mathrm{Dom}(\eta)$. If I just contains one point, then η is in $\mathrm{Traj}_c(h^\infty,K)$ by definition. Otherwise, for β large enough, $I^{\nu(\beta)} \cap I \neq \emptyset$. Write $I^\alpha = [a^\alpha,b^\alpha]$, and let $I = [a,b]$. Then $a^{\nu(\beta)} \to a$ and $\xi^{\nu(\beta)}(a^{\nu(\beta)}) \to \eta(a)$.

Let

$$\sigma^\alpha(t) = \xi^\alpha(a^\alpha) + \theta^\alpha(t) - \theta^\alpha(a^\alpha)\,. \tag{4.1}$$

We then have, for all $t \in I^{\nu(\beta)} \cap I$,

$$\begin{aligned} \xi^{\nu(\beta)}(t) = \sigma^{\nu(\beta)}(t) &+ \int_{a^{\nu(\beta)}}^t f_0\Big(\xi^{\nu(\beta)}(s)\Big)\,ds + \sum_{k=1}^m \int_{a^{\nu(\beta)}}^t u_k^{\nu(\beta)}(s) f_k\left(\eta(s)\right)\,ds \\ &+ \sum_{k=1}^m \int_{a^{\nu(\beta)}}^t u_k^{\nu(\beta)}(s) \Big\{ f_k\Big(\xi^{\nu(\beta)}(s)\Big) - f_k\left(\eta(s)\right)\Big\}\,ds\,. \end{aligned} \tag{4.2}$$

Then (4.2) implies (since $f_k\left(\xi^{\nu(\beta)}(s)\right) - f_k\left(\eta(s)\right) \to 0$ uniformly, the L^1 norms of the u^α are bounded by a fixed constant for large α, (UWC) holds, and $\theta^{\nu(\beta)}(t) - \theta^{\nu(\beta)}(a^\beta) \to 0$ uniformly) that, for $t \in I$,

$$\eta(t) = \eta(a) + \int_a^t f_0\left(\eta(s)\right)\,ds + \sum_{k=1}^m \int_a^t u_k^\infty(s) f_k\left(\eta(s)\right)\,ds\,.$$

Thus η is a trajectory of h^∞. Clearly the graph $G(\eta)$ of η is contained in K. Therefore $\eta \in \mathrm{Traj}_c(h^\infty, K)$ and then (CTR) follows.

We now show that the net $\{\xi^\alpha\}_{\alpha\in A}$ has a subnet that converges in $ARC(\Omega)$. Again let $I^\alpha = [a^\alpha, b^\alpha] = \mathrm{Dom}(\xi^\alpha)$. Then for $t \in I^\alpha$, we have

$$\begin{aligned} \xi^\alpha(t) &= \theta^\alpha(t) - \theta^\alpha(a^\alpha) + \xi^\alpha(a^\alpha) + \int_{a^\alpha}^t f_0\Big(\xi^\alpha(s)\Big)ds + \sum_{k=1}^m \int_{a^\alpha}^t u_k^\alpha(s) f_k\Big(\xi^\alpha(s)\Big)ds \\ &= \theta^\alpha(t) - \theta^\alpha(a^\alpha) + \xi^\alpha(a^\alpha) + \int_{a^\alpha}^t f_0\Big(\xi^\alpha(s)\Big)ds + \sum_{k=1}^m \int_{a^\alpha}^t u_k^\infty(s) f_k\Big(\xi^\alpha(s)\Big)ds \\ &\quad + \sum_{k=1}^m \int_{a^\alpha}^t \Big(u_k^\alpha(s) - u_k^\infty(s)\Big) f_k\Big(\xi^\alpha(s)\Big)ds\,. \end{aligned}$$

Let

$$\zeta^\alpha(t) = \xi^\alpha(a^\alpha) + \int_{a^\alpha}^t f_0\Big(\xi^\alpha(s)\Big)ds + \sum_{k=1}^m \int_{a^\alpha}^t u_k^\infty(s) f_k\Big(\xi^\alpha(s)\Big)ds\,.$$

It is obvious that the set $\{\zeta^\alpha : \alpha \in A\}$ is equicontinuous and uniformly bounded. The $\theta^\alpha(t) - \theta^\alpha(a^\alpha)$ converge to 0 uniformly by our assumption. Thus in order to show that $\{\xi^\alpha\}_{\alpha\in A}$ has a convergent subnet, we need only show that for each $k \in \{1, \ldots, m\}$, the integrals $\int_{a^\alpha}^t \left(u_k^\alpha(s) - u_k^\infty(s)\right) f_k\left(\xi^\alpha(s)\right) ds$ converge to 0 uniformly with respect to t.

Fix an integer $k \in \{1, \ldots, m\}$. Write $\hat{u}_k^\alpha = u_k^\alpha - u_k^\infty$. Then (UB) implies that there exist an $\alpha^* \in A$ and a constant $C > 0$ such that $\|\hat{u}^\alpha\|_{L^1} \le C$ for $\alpha \succeq_A \alpha^*$. Let

$$\hat{\xi}^\alpha(t) = \xi^\alpha(t) - \theta^\alpha(t)\,. \tag{4.3}$$

Then $\hat{\xi}^\alpha(t) - \xi^\alpha(t)$ goes to 0 uniformly, so $f_k\big(\hat{\xi}^\alpha(t)\big) - f_k\left(\xi^\alpha(t)\right)$ goes to 0 uniformly for each k. Since the L^1 norms of the functions $\hat{u}_k^\alpha$ are bounded, we can conclude that the integrals

$$\int_{a^\alpha}^t \Big(u_k^\alpha(s) - u_k^\infty(s)\Big)\Big(f_k\Big(\hat{\xi}^\alpha(s)\Big) - f_k\Big(\xi^\alpha(s)\Big)\Big)ds$$

converge to 0 uniformly with respect to t. So it suffices to show that

$$\int_{a^\alpha}^{t}\Big(u_k^\alpha(s)-u_k^\infty(s)\Big)f_k\Big(\hat{\xi}^\alpha(s)\Big)ds\to 0\ \text{uniformly}\,. \tag{4.4}$$

Let $\mathcal{K}$ be a compact subset of Ω such that $K\subseteq\mathcal{K}\times[0,T]$. For any given $\varepsilon>0$, let $g_k:\Omega\mapsto\mathbb{R}^n$ be vector fields of class C^∞ with compact support such that

$$\sup_{x\in\mathcal{K}}\|f_k(x)-g_k(x)\|<\frac{\varepsilon}{C}\,. \tag{4.5}$$

Then

$$\begin{aligned}\int_{a^\alpha}^{t}\hat{u}_k^\alpha(s)f_k\Big(\hat{\xi}^\alpha(s)\Big)ds&=\int_{a^\alpha}^{t}\hat{u}_k^\alpha(s)g_k\Big(\hat{\xi}^\alpha(s)\Big)\,ds\\&\quad+\int_{a^\alpha}^{t}\hat{u}_k^\alpha(s)\Big(f_k\Big(\hat{\xi}^\alpha(s)\Big)-g_k\Big(\hat{\xi}^\alpha(s)\Big)\Big)\,ds\,.\end{aligned} \tag{4.6}$$

The sup norm of the second term on the right-hand side of (4.6) is less than ε. Via integration by parts, we can rewrite the first term as

$$\hat{U}_k^\alpha(t)\cdot g_k\Big(\hat{\xi}^\alpha(t)\Big)-\int_{a^\alpha}^{t}\hat{U}_k^\alpha(s)\frac{d}{ds}\Big(g_k(\hat{\xi}^\alpha(s))\Big)\,ds\,, \tag{4.7}$$

where

$$\hat{U}_k^\alpha(t)=\int_{a^\alpha}^{t}\hat{u}_k^\alpha(s)\,ds\,. \tag{4.8}$$

Since $\hat{U}_k^\alpha(t)\to 0$ uniformly, the g_k are uniformly bounded, and the functions $t\mapsto\frac{d}{dt}\big(g_k(\hat{\xi}^\alpha(t))\big)$ are uniformly bounded in L^1 for large α, because

$$\frac{d}{dt}\Big(g_k(\hat{\xi}^\alpha(t))\Big)=\frac{\partial g_k}{\partial x}(\hat{\xi}^\alpha(t))\left(f_0(\xi^\alpha(t))+\sum_{\ell=1}^{m}u_\ell^\alpha(t)f_\ell(\xi^\alpha(t))\right)\,, \tag{4.9}$$

we can conclude that the integrals $\int_{a^\alpha}^{t}\hat{u}_k^\alpha(s)g_k\big(\hat{\xi}^\alpha(s)\big)\,ds$ go to zero uniformly. This implies that

$$\limsup_{\alpha}\left\|\int_{a^\alpha}^{t}\hat{u}_k^\alpha(s)f_k\Big(\hat{\xi}^\alpha(s)\Big)ds\right\|\le\varepsilon\,. \tag{4.10}$$

Since ε is arbitrary, we have shown that $\int_{a^\alpha}^{t}\hat{u}_k^\alpha(s)f_k\big(\hat{\xi}^\alpha(s)\big)\,ds\to 0$ uniformly. As explained before, this shows that $\{\xi^\alpha\}_{\alpha\in A}$ has a convergent subnet in $ARC(\Omega)$.

The above argument clearly applies to any subnet of $\{h^\alpha\}$. Thus we have actually proved the following:

(CTR1) For every compact subset K of $\Omega\times I$, if we are given a subnet $\{h^{\nu(\beta)}\}_{\beta\in B}$ of $\{h^\alpha\}_{\alpha\in A}$ and a family $\{\xi^\beta\}_{\beta\in B}\subseteq ARC(\Omega)$ with the property that $\xi^\beta\in\mathrm{Traj}_c(h^{\nu(\beta)},K)$, then the net $\{\xi^\beta\}_{\beta\in B}$ has a subnet $\{\xi^{\mu(\gamma)}\}_{\gamma\in C}$ that converges to an $\eta\in\mathrm{Traj}_c(h^\infty,K)$.

It follows easily from (CTR1) that the h^α T-converge to h^∞. Indeed, (CTR1) clearly implies that

$$\sup\{d_{ARC}(\xi, \mathrm{Traj}_c(h^\infty, K)) : \xi \in \mathrm{Traj}_c(h^\alpha, K)\} \to 0$$

for every K, and then the T-convergence of h^α to h^∞ follows from Proposition 2.4. This completes the proof of Theorem 4.2. In particular, we have established that (i) of Theorem 4.1 implies (ii).

We now continue with the proof of Theorem 4.1. The implication (ii)$\Longrightarrow$(iii) follows from Proposition 2.7, and (iii) implies (iv) trivially. We now prove that (iv) implies (v). To see this, let $\varphi : [0,T] \mapsto \mathbb{R}$ be continuous. Consider the $C^0(m)$ system $\Sigma = (\mathbb{R}^{m+1}, f_0, \ldots, f_m)$ where—using $(x_0, x_1, \ldots, x_m)$ to denote the standard coordinates in $\mathbb{R}^{m+1}$ and $(e_0, e_1, \ldots, e_m)$ to denote the canonical basis—$f_0(x) \equiv e_0$, $f_i(x) \equiv \varphi(x_0)e_i$ for $i = 1, \ldots, m$. Then the differential equation associated with Σ and u^α is $\dot{x}_0 = 1$, $\dot{x}_i = \varphi(x_0)u_i^\alpha$ for $i = 1, \ldots, m$. Take the initial condition $\bar{x} = (0, \ldots, 0)$. Then the components ξ_i^α of the solution, for $i = 1, \ldots, m$, are precisely the components of the vector U_φ^α. Thus (UWC) holds.

Next we prove that (v) implies (i) for sequences. Let $\{u^j\}_{j=1}^\infty$ be a sequence in $L^1([0,T], \mathbb{R}^m)$, and let $u^\infty \in L^1([0,T], \mathbb{R}^m)$. Assume that (UWC) holds for $\{u^j\}$ and u^∞. Then, in particular, the integrals $\langle u_i^j, \varphi\rangle = \int_0^T u_i^j(t)\varphi(t)dt$ converge to $\langle u_i^\infty, \varphi\rangle = \int_0^T u_i^\infty(t)\varphi(t)dt$ for each i and for each continuous function $\varphi : [0,T] \mapsto \mathbb{R}$. So the u_i^j weak*-converge to u_i^∞ as linear functionals on the Banach space $C^0([0,T], \mathbb{R})$ of continuous real-valued functions on $[0,T]$. It is well known that, if ψ belongs to $L^1([0,T], \mathbb{R})$, then the norm of the linear functional $C^0([0,T], \mathbb{R}) \ni \rho \mapsto \int_0^T \rho(t)\psi(t)dt$ is precisely the L^1 norm of ψ. Therefore the L^1 norms of the u_i^j are bounded by a fixed constant, by the uniform boundedness theorem. Thus (UB) holds. Moreover, taking $\varphi \equiv 1$ we conclude that the u^j I-converge to u^∞.

The proof that in general (v) $\not\Longrightarrow$ (iv) and (ii)$\not\Longrightarrow$ (i) is given in the appendix, where we exhibit an example of a net that satisfies (v) but not (iv) and one of a net that satisfies (ii) but not (i). □

5. Other classes of systems. The equivalence for sequences of the five conditions of Theorem 4.1 depends very strongly on the fact that the class of systems under consideration is $C^0(m)$. One could equally well have considered T($\mathcal{C}$)-convergence in $L^1([0,T], \mathbb{R}^m)$ with respect to other classes $\mathcal{C}$ of systems. For example, we could have taken $\mathcal{C}$ to be the class $C^k(m)$ of all the $\Sigma \in C^0(m)$ such that $f_0^\Sigma, \ldots, f_m^\Sigma$ are of class C^k on Ω^Σ, for an arbitrary integer $k > 0$. Let us call the T($C^k(m)$)-convergence in $L^1([0,T], \mathbb{R}^m)$ simply *$\mathcal{T}^k$-convergence.*

It is then natural to ask whether explicit characterizations of $\mathcal{T}^k$-convergence of sequences exist. The necessary and sufficient conditions for $\mathcal{T}^0$-convergence are of course sufficient to ensure $\mathcal{T}^k$-convergence, but they are no longer necessary. For example, if a sequence $\{u^j\}$ $\mathcal{T}^k$-converges to u^∞ in $L^1([0,T], \mathbb{R}^m)$ for some $k \geq 1$, then we can no longer apply the uniform boundedness theorem to conclude that the L^1 norms of the u^j are bounded. The following theorem, which characterizes $\mathcal{T}^k$-convergence of nets in $L^1([0,T], \mathbb{R})$ for $k \geq 1$, implies in particular that it is indeed possible for a sequence $\{u^j\}_{j=1}^\infty \subseteq L^1([0,T], \mathbb{R})$ to $\mathcal{T}^1$-converge to a $u^\infty \in L^1([0,T], \mathbb{R})$ even if the $\|u^j\|_{L^1}$ are not bounded.

THEOREM 5.1. *Let $T > 0$, and let $k > 0$ be an integer. A net $\{u^\alpha\}_{\alpha \in A}$ in $L^1([0,T], \mathbb{R})$ $\mathcal{T}^k$-converges to a $u^\infty \in L^1([0,T], \mathbb{R})$ if and only if $\{u^\alpha\}$ I-converges to u^∞, i.e., iff the integrals $\int_0^t u^\alpha(s)ds$ converge to $\int_0^t u^\infty(s)ds$ uniformly on $[0,T]$.*

Before proving Theorem 5.1, it is natural to ask whether a similar characterization might be valid for $m > 1$. The answer is negative, as will be shown by an example in the next section. The reason for this is by now well understood. The obstructions for the validity of Theorem 5.1 when $m > 1$ are the Lie brackets of the vector fields f_i for $i > 0$. Precisely, call a system $\Sigma \in C^1(m)$ *commutative* if the Lie brackets $[f_i^\Sigma, f_j^\Sigma]$ vanish identically for all $i, j \in \{1, \dots, m\}$. (We do *not* require that the brackets involving f_0 vanish. Therefore for $m = 1$ *every* system is commutative.) For $k \geq 1$, let $C^k_{comm}(m)$ be the class of all commutative systems in $C^k(m)$. A net $\mathbf{u}$ in $L^1([0,T], \mathbb{R}^m)$ *$\mathcal{T}^k_{comm}$-converges* to $u \in L^1([0,T], \mathbb{R}^m)$ if it converges to u in the topology $\mathcal{T}(C^k_{comm}(m))$, i.e., if the time-varying vector fields $f^\Sigma(u^\alpha)$ T-converge to $f^\Sigma(u)$ for all $\Sigma \in C^k_{comm}(m)$.

THEOREM 5.2. *Let $T > 0$, and let m be a positive integer. For any integer $k \geq 1$, a net $\{u^\alpha\}_{\alpha \in A}$ in $L^1([0,T], \mathbb{R}^m)$ $\mathcal{T}^k_{comm}$-converges to a $u^\infty \in L^1([0,T], \mathbb{R}^m)$ iff $\{u^\alpha\}$ I-converges to u^∞, i.e., iff the integrals $\int_0^t u^\alpha(s)ds$ converge to $\int_0^t u^\infty(s)ds$ uniformly on $[0,T]$.*

Since for $m = 1$ every C^k system is commutative, Theorem 5.1 is a particular case of Theorem 5.2.

Proof of Theorem 5.2. First of all, we observe that $\mathcal{T}^k_{comm}$-convergence obviously implies I-convergence. To show the converse, we assume that $\mathbf{u} = \{u^\alpha\}_{\alpha \in A}$ I-converges to u^∞ and seek to prove that the net $\{f^\Sigma(u^\alpha)\}_{\alpha \in A}$ T-converges to $f^\Sigma(u^\infty)$ for every $C^1_{comm}(m)$ system Σ. We consider first the special case of systems

$$\Sigma : \quad \dot{x} = f_0(x) + \sum_{i=1}^m u_i b_i = f_0(x) + u \cdot B \,, \; x \in \Omega \,, \tag{5.1}$$

where f_0 is continuous (but not necessarily of class C^1) and the vector fields $f_1, \dots, f_m$ are constant. Let $U_i^\alpha(t) = \int_a^t u_i^\alpha(s)\, ds$ for $\alpha \in A \cup \{\infty\}$, so $U^\alpha \to U^\infty$ uniformly on $[0,T]$. Let $\xi^\alpha : [a^\alpha, b^\alpha] \mapsto \Omega$ be trajectories of Σ for the u^α, such that $G(\xi^\alpha) \subseteq K$ for some compact subset K of $\Omega \times [0,T]$. We want to find a subnet of $\{\xi^\alpha\}_{\alpha \in A}$ that converges to a $\xi^\infty \in \mathrm{Traj}_c(f^\Sigma(u^\infty), K)$. By passing to a subnet, we may assume that a^α, b^α have limits a, b, and $x^\alpha = \xi^\alpha(a^\alpha)$ converges to a limit $\bar{x}$. Then $(\bar{x}, a) \in K$. Since

$$\xi^\alpha(t) = x^\alpha + \int_{a^\alpha}^t f_0(\xi^\alpha(s))\, ds + (U^\alpha(t) - U^\alpha(a^\alpha)) \cdot B \,, \tag{5.2}$$

and the U^α converge uniformly to U^∞, it is clear that $\{\xi^\alpha\}$ is equicontinuous. Thus by passing to a subnet we may assume that ξ^α converges uniformly to a limit ξ^∞. Then a trivial argument allows us to pass to the limit in (5.2) and conclude that ξ^∞ is a trajectory for U^∞. The above argument clearly applies to any subnet of $\{\xi^\alpha\}_{\alpha \in A}$. Then Proposition 2.4 implies that the $f^\Sigma(u^\alpha)$ T-converge to $f^\Sigma(u^\infty)$ in this special case.

We now consider the case when Σ is such that the vector fields $f_1^\Sigma, \dots, f_m^\Sigma$ are linearly independent at each point. In this case, each point $x \in \Omega^\Sigma$ has an open neighborhood U_x such that there is a C^1 diffeomorphism Φ_x from U_x to some other open subset V_x of $\mathbb{R}^n$ that transforms the f_i^Σ, for $i = 1, \dots, m$, to constant vector fields $g_{i,x}$. Let $g_{0,x}$ be the vector field on V_x that corresponds to $f_0^\Sigma \lceil U_x$ under Φ_x, that is, $g_{0,x}(y) = D\Phi_x(z).f_0^\Sigma(z)$, where $z = \Phi_x^{-1}(y)$. (Notice that $g_{0,x}$ is continuous but not necessarily of class C^1.) Let Σ_x be the restriction of Σ to U_x and $\tilde{\Sigma}_x$ be the system $(V_x, g_{0,x}, g_{1,x}, \dots, g_{m,x})$. Then $\tilde{\Sigma}_x$ is a $C^0(m)$ system. Since the vector fields $g_{1,x}, \ldots, g_{m,x}$ are constant, we know that $f^{\tilde{\Sigma}_x}(u^\alpha) \xrightarrow{\mathrm{T}} f^{\tilde{\Sigma}_x}(u^\infty)$. Since T-convergence is preserved by C^1 diffeomorphisms, we conclude that $f^{\Sigma_x}(u^\alpha) \xrightarrow{\mathrm{T}} f^{\Sigma_x}$ (u^∞). This says that our desired conclusion holds locally, in the sense that every $x \in \Omega$ has a neighborhood U_x such that the conclusion holds for the restriction of Σ to U_x. From this, we have to infer that the conclusion also holds globally. It suffices to show that, if (a) $\{\xi^\alpha\}_{\alpha \in A}$ is a net of maximal trajectories of the $f^\Sigma(u^\alpha)$, (b) $\{(x^\alpha, t^\alpha)\}_{\alpha \in A}$ is a net of points in $\Omega \times [0,T]$ such that $\xi^\alpha(t^\alpha) = x^\alpha$ for each α, and (c) $(x^\alpha, t^\alpha) \to (x^\infty, t^\infty) \in \Omega \times [0,T]$, then $\{\xi^\alpha\}_{\alpha \in A}$ converges on compact sets to the maximal trajectory ξ^∞ of $f^\Sigma(u^\infty)$ such that $\xi(t^\infty) = x^\infty$ (using the fact that Σ is a C^1 system and therefore has uniqueness of trajectories). For $\alpha \in A \cup \{\infty\}$, let $I^\alpha = \mathrm{Dom}(\xi^\alpha)$, so I^α is relatively open in $[0,T]$ and $t^\alpha \in I^\alpha$. Call a compact subinterval J of I^∞ "good" if there exists an $\alpha^*(J) \in A$ such that $J \subseteq I^\alpha$ whenever $\alpha \succeq_A \alpha^*(J)$, and the net $\{\xi^\alpha\}_{\alpha \in A; \alpha \succeq_A \alpha^*(J)}$ converges to ξ^∞ uniformly on J. We have to prove that every compact subinterval of I^∞ is good. It clearly suffices to consider intervals J of the form $[a, t^\infty]$ or $[t^\infty, b]$. The proof is similar in both cases, so we will only consider the second case and assume that $J = [t^\infty, b]$ for some $b \in [0,T]$. Pick an integer $N > 0$ such that $\frac{1}{N}$ is a Lebesgue number of the covering $\{(\xi^\infty)^{-1}(U_x) : x \in \Omega\}$ of J. Let $b_k = t^\infty + \frac{k}{N}(b - t^\infty)$ for $k = 0, 1, \ldots, N$, so $b_0 = t^\infty$ and $b_N = b$. Let $J_k = [b_0, b_k]$, so $J = J_N$. Let $L_k = [b_{k-1}, b_k]$ for $k = 1, \ldots, N$. Pick $x_k \in \Omega$ such that $\xi^\infty(L^k) \subseteq U_{x_k}$. Write $\Omega_k = U_{x_k}$, $\Sigma_k = \Sigma_{x_k}$. We prove by induction on k that J_k is good. First, we show that J_1 is good. Fix an $\varepsilon > 0$. For $\alpha \in A \cup \{\infty\}$, let η^α be the maximal trajectory of $f^{\Sigma_1}(u^\alpha)$ that goes through x^α at time t^α. Since $f^{\Sigma_1}(u^\alpha) \xrightarrow{\mathrm{T}} f^{\Sigma_1}(u^\infty)$, Σ_1 has uniqueness of trajectories, and $J_1 \subseteq \mathrm{Dom}(\eta^\infty)$, there exists an α^* such that $J_1 \subseteq \mathrm{Dom}(\eta^\alpha)$ and $\|\eta^\alpha(t) - \eta^\infty(t)\| < \varepsilon$ on J_1 whenever $\alpha \succeq_A \alpha^*$. On the other hand, η^α is a trajectory of $f^\Sigma(u^\alpha)$, so $\eta^\alpha = \xi^\alpha \lceil \mathrm{Dom}(\eta^\alpha)$. Therefore $J_1 \subseteq \mathrm{Dom}(\xi^\alpha)$ and $\|\xi^\alpha(t) - \xi^\infty(t)\| < \varepsilon$ for all $t \in J_1$ whenever $\alpha \succeq_A \alpha^*$. This establishes that J_1 is good. Now suppose that $0 < k \leq N$ and J_{k-1} is good. Pick α_1^* such that $J_{k-1} \subseteq I^\alpha$ whenever $\alpha \succeq_A \alpha_1^*$ and $\{\xi^\alpha\}_{\alpha \in A; \alpha \succeq_A \alpha_1^*}$ converges to ξ^∞ uniformly on J_{k-1}. Then $\{\xi^\alpha(b_{k-1})\}_{\alpha \in A; \alpha \succeq_A \alpha_1^*}$ converges to $\xi^\infty(b_{k-1})$. Thus there exists $\alpha_2^* \in A$ such that $\alpha_2^* \succeq_A \alpha_1^*$ and $\xi^\alpha(b_{k-1}) \in \Omega_k$ for $\alpha \succeq_A \alpha_2^*$. For $\alpha \succeq_A \alpha_2^*$, or $\alpha = \infty$, let η^α be the maximal trajectory of $f^{\Sigma_k}(u^\alpha)$ that goes through $\xi^\alpha(b_{k-1})$ at time b_{k-1}. Since $\xi^\infty \lceil L_k$ is a trajectory of $f^{\Sigma_k}(u^\infty)$, we have $L_k \subseteq \mathrm{Dom}(\eta^\infty)$. Since $f^{\Sigma_k}(u^\alpha) \xrightarrow{\mathrm{T}} f^{\Sigma_k}(u)$, Σ_k has uniqueness of trajectories, and $L_k \subseteq \mathrm{Dom}(\eta^\infty)$, there exists an α^* such that $\alpha^* \succeq_A \alpha_2^*$, $L_k \subseteq \mathrm{Dom}(\eta^\alpha)$ whenever $\alpha \succeq_A \alpha^*$, and $\eta^\alpha \to \eta^\infty$ uniformly on L_k. On the other hand, η^α is a trajectory of $f^\Sigma(u^\alpha)$ and $\eta^\alpha(b_{k-1}) = \xi^\alpha(b_{k-1})$, so $\eta^\alpha = \xi^\alpha \lceil \mathrm{Dom}(\eta^\alpha)$. Therefore $L_k \subseteq \mathrm{Dom}(\xi^\alpha)$ whenever $\alpha \succeq_A \alpha^*$, and $\xi^\alpha \to \xi^\infty$ uniformly on L_k. Since $\alpha^* \succeq_A \alpha_1^*$, we have in fact shown that $J_k \subseteq \mathrm{Dom}(\xi^\alpha)$ whenever $\alpha \succeq_A \alpha^*$, and $\xi^\alpha \to \xi^\infty$ uniformly on J_k. So J_k is good. This completes the inductive proof that all the J_k are good, and in particular $J = J_N$ is good. So $\xi^\alpha \to \xi^\infty$ on compact sets. Therefore $f^\Sigma(u^\alpha) \xrightarrow{\mathrm{T}} f^\Sigma(u^\infty)$.

We now remove the restriction that $f_1^\Sigma, \ldots, f_m^\Sigma$ be linearly independent at each point. Let $\Sigma = (\Omega, f_0, f_1, \ldots, f_m)$ be an arbitrary system in $C^1_{comm}(m)$. Let $\hat{\Omega} = \Omega \times \mathbb{R}^m$, and let $\hat{\Sigma}$ be the system on $\hat{\Omega}$ given by

$$\dot{x} = f_0(x) + u_1 f_1(x) + \cdots + u_m f_m(x)\,, \quad \dot{y}_1 = u_1, \ldots, \dot{y}_m = u_m\,. \tag{5.3}$$

Then $\hat{\Sigma} \in C^1_{comm}(m)$, and it is clear that

$$\Big(f^{\hat{\Sigma}}(u^\alpha) \xrightarrow{\mathrm{T}} f^{\hat{\Sigma}}(u^\infty)\Big) \Rightarrow \Big(f^\Sigma(u^\alpha) \xrightarrow{\mathrm{T}} f^\Sigma(u^\infty)\Big)\,. \tag{5.4}$$

Moreover, the vector fields $f_1^{\hat\Sigma}, \dots, f_m^{\hat\Sigma}$ are linearly dependent at each point. Thus we conclude that $f^{\hat\Sigma}(u^\alpha) \xrightarrow{\mathrm{T}} f^{\hat\Sigma}(u^\infty)$, and therefore $f^{\Sigma}(u^\alpha) \xrightarrow{\mathrm{T}} f^{\Sigma}(u^\infty)$. □

6. Beyond I-convergence: The role of Lie brackets. Theorem 5.2 characterizes the topology of $\mathcal{T}^1_{comm}$-convergence on the input space $L^1([0,T],\mathbb{R}^m)$ by showing that $\mathcal{T}^1_{comm}$-convergence is exactly equivalent to I-convergence. It is natural to ask whether I-convergence actually implies T-convergence for at least some noncommutative systems. The answer to this question turns out to be negative.

THEOREM 6.1. *Let $\mathcal{C}$ be any subclass of $C^1(m)$ that contains at least one noncommutative system. Then there exists a sequence $\{u^j\}_{j=1}^\infty$ in $L^1([0,T],\mathbb{R}^m)$ such that* (i) *$\{u^j\}$ I-converges to a limit $u^\infty \in L^1([0,T],\mathbb{R}^m)$,* (ii) *for every $\Sigma \in \mathcal{C}$ the time-varying vector fields $f^\Sigma(u^j)$ T-converge to a limit h^Σ, but* (iii) *it is not true that $h^\Sigma = f^\Sigma(u^\infty)$ for all $\Sigma \in \mathcal{C}$.*

This result—which will follow from Proposition 6.2—says that noncommutativity is the fundamental obstruction for I-convergence of the inputs to imply convergence of trajectories. The best way to understand why this is so is to think of the space $L^1([0,T],\mathbb{R}^m)$ of ordinary inputs as embedded in a larger space $\mathcal{GI}(m)$ of *generalized m*-dimensional inputs, whose elements have components not only for the m input channels corresponding to the vector fields $f_1, \dots, f_m$ but also in "Lie bracket channels" such as $[f_1, f_2]$. An "ordinary input" $u \in L^1([0,T],\mathbb{R}^m)$ gives rise, for each system Σ, to a time-varying vector field $f^\Sigma(u)$. Thus an ordinary input can be thought of as a "functional" that to every system Σ in a given class $\mathcal{C}$ assigns a time-varying vector field. It is then natural to extend the class of ordinary inputs by allowing more general functionals. By analogy with other constructions of spaces of "generalized functions" (e.g., Schwartz distributions), we should also require that such a functional be approximable by ordinary inputs. So we first define, for a class $\mathcal{C} \subseteq C^0(m)$ and an interval $[a,b]$, the space $\mathcal{PGI}(\mathcal{C},a,b)$ of all maps v that assign to every $\Sigma = (\Omega, f_0, \dots, f_m) \in \mathcal{C}$ a time-varying vector field $v_\Sigma \in TVVF(\Omega,[a,b])$, and call the elements of $\mathcal{PGI}(\mathcal{C},a,b)$ "pseudogeneralized inputs." Then $\mathcal{PGI}(\mathcal{C},a,b)$ is just the product $\Pi_{(\Omega,f_0,\dots,f_m)\in\mathcal{C}} TVVF(\Omega,[a,b])$, and we can topologize it by means of the product topology. An ordinary input $u \in L^1([a,b],\mathbb{R}^m)$ can then be regarded as a member of $\mathcal{PGI}(\mathcal{C},a,b)$ by associating to it the map—also labeled u—$\Sigma \mapsto f^\Sigma(u)$. A "generalized input" on $[a,b]$ for the class $\mathcal{C}$ is then a member of $\mathcal{PGI}(\mathcal{C},a,b)$ which is a limit of ordinary inputs. We use $\mathcal{GI}(\mathcal{C},a,b)$ to denote the set of all generalized inputs, so by construction $\mathcal{GI}(\mathcal{C},a,b)$ is a topological space in which the space $L^1([a,b],\mathbb{R}^m)$ is densely embedded.

Particular examples of members of $\mathcal{PGI}(\mathcal{C},a,b)$ can be constructed by means of *formal Lie bracket expressions* such as

$$X_0 + v_1(t)X_1 + v_2(t)X_2 + v_3(t)[X_1,X_2] + v_4(t)[X_2,[X_1,X_2]]\,.$$

Here the indeterminates X_i should be thought of as "slots" where, for each particular system Σ with vector fields $f_0, \dots, f_m$, the f_i are to be plugged in, thus giving rise to a time-varying vector field. Precisely, we can define a *formal pseudogeneralized input on* $[a,b]$ to be an integrable function with values in the free Lie algebra $L(m+1)$ in $m+1$ indeterminates $X_0, \dots, X_m$. (The field of scalars is of course $\mathbb{R}$.) Use $\mathcal{FPGI}(m,a,b)$ to denote the set of all such objects. Then a $v \in \mathcal{FPGI}(m,a,b)$ gives rise to a true pseudogeneralized input—also labeled v—for any class $\mathcal{C} \subseteq C^0(m)$ of control-affine systems that has enough differentiability for all the Lie brackets occurring in the formal expression to make sense. For example, to an ordinary input $u = (u_1, \dots, u_m)$ we associate the $L(m+1)$-valued function $t \mapsto X_0+u_1(t)X_1+\cdots+u_m(t)X_m$, and in this case it is possible to plug in $f_0,\ldots,f_m$ for $X_0,\ldots,X_m$ for every system $\mathcal{C} \in C^0(m)$. On the other hand, if $m \geq 2$, then an expression v such as $X_0+v_1(t)X_1+v_2(t)X_2+v_3(t)[X_1,X_2]$ will give rise to a member of $\mathcal{PGI}(\mathcal{C},a,b)$ only if $\mathcal{C}$ consists of systems $(\Omega,f_0,\ldots,f_m)$ for which the Lie bracket $[f_1,f_2]$ is well defined. This will be the case, in particular, if $\mathcal{C} \subseteq C^1(m)$.

Thus, for example, the formal pseudogeneralized input $w = X_0+\frac{1}{2}[X_1,X_2]$ gives rise to a pseudogeneralized input $w \in \mathcal{PGI}(C^1(2),a,b)$. With this terminology, the following result exhibits an example of a sequence $\{u^j\} \subseteq L^1([0,T],\mathbb{R}^2)$ that I-converges to zero but converges in $\mathcal{PGI}(C^1(2),0,T)$ to w. This shows that $w \in \mathcal{GI}(C^1(2),a,b)$, i.e., that w is a true generalized input. It is now clear why, when we look only at classes $\mathcal{C}$ of systems for which $[f_1,f_2]=0$, as we did in Theorem 5.2, the sequence $\{u^j\}$ $\mathcal{T}(\mathcal{C})$-converges to 0, whereas, as soon as $\mathcal{C}$ contains one system for which $[f_1,f_2] \neq 0$, the $\mathcal{T}(\mathcal{C})$-limit of $\{u^j\}$ is no longer 0. The reason is that the "true" limit is w, and w contains "Lie bracket components" that are seen only when w is tested against a noncommutative system.

PROPOSITION 6.2. *Let $T>0$. For $j=1,2,\ldots$, let $u^j \in L^1([0,T],\mathbb{R}^2)$ be the input given by*

$$u^j(t) = (j^{\frac{1}{2}}\cos jt, j^{\frac{1}{2}}\sin jt)\,. \tag{6.1}$$

Let $\Sigma = (\Omega,f_0,f_1,f_2)$ be a system of class C^1. Let

$$f^j(x,t) = f^{\Sigma}(u^j)(x,t) = f_0(x)+j^{\frac{1}{2}}\cos jt\, f_1(x)+j^{\frac{1}{2}}\sin jt\, f_2(x) \tag{6.2}$$

and

$$f^{\infty}(x,t) = f_0(x)+\frac{1}{2}[f_1,f_2](x) \tag{6.3}$$

for $(x,t) \in \Omega \times [0,T]$. Then the f^j T-converge to f^{∞} in $TVVF_{LIB}(\Omega,[0,T])$.

Proof. Suppose K is a compact subset of the product $\Omega \times [0,T]$. We have to show that $\mathrm{Traj}_c(f^j,K)$ converges to $\mathrm{Traj}_c(f^{\infty},K)$. Let $\{\xi^j\} \subseteq ARC(\Omega)$ be a sequence of functions such that $\xi^j \in \mathrm{Traj}_c(f^j,K)$ for each j. We will first show that there exists a subsequence of $\{\xi^j\}$ that converges to a $\xi \in \mathrm{Traj}_c(f^{\infty},K)$ in $ARC(\Omega)$. Let $I^j=[a^j,b^j]=\mathrm{Dom}(\xi^j)$. On I^j we have

$$\dot{\xi}^j(t) = f_0(\xi^j(t))+j^{\frac{1}{2}}\cos jt\, f_1(\xi^j(t))+j^{\frac{1}{2}}\sin jt\, f_2(\xi^j(t))\,. \tag{6.4}$$

But $j^{\frac{1}{2}}\cos jt\, f_1(\xi^j(t))$ is equal to

$$\dot{\theta}^j_1(t) - j^{-\frac{1}{2}}\sin jt\, g_1(\xi^j(t)) - \frac{1}{2}\sin 2jt\, g_2(\xi^j(t)) - \sin^2 jt\, g_3(\xi^j(t))\,,$$

where $g_1 = Df_1 \cdot f_0$, $g_2 = Df_1 \cdot f_1$, $g_3 = Df_1 \cdot f_2$, Df_1 denotes the Jacobian matrix of f_1, and $\theta^j_1 = j^{-\frac{1}{2}}\sin jt\, f_1(\xi^j(t))$. Similarly, $j^{\frac{1}{2}}\sin jt\, f_2(\xi^j(t))$ is equal to

$$\dot{\theta}^j_2(t) + j^{-\frac{1}{2}}\cos jt\, g_4(\xi^j(t)) + \cos^2 jt\, g_5(\xi^j(t)) + \frac{1}{2}\sin 2jt\, g_6(\xi^j(t))\,,$$

where $g_4 = Df_2 \cdot f_0$, $g_5 = Df_2 \cdot f_1$, $g_6 = Df_2 \cdot f_2$, and $\theta^j_2 = -j^{-\frac{1}{2}}\cos jt\, f_2(\xi^j(t))$. Thus, if we let

$$\begin{aligned} h^j(x,t) = {} & f_0(x)+\dot{\theta}^j_1(t)+\dot{\theta}^j_2(t) \\ & -j^{-\frac{1}{2}}\sin jt\, g_1(x) - \frac{1}{2}\sin 2jt\, g_2(x) - \sin^2 jt\, g_3(x) \\ & +j^{-\frac{1}{2}}\cos jt\, g_4(x) + \cos^2 jt\, g_5(x) + \frac{1}{2}\sin 2jt\, g_6(x)\,, \end{aligned}$$

then $\xi^j \in \mathrm{Traj}_c(h^j, K)$.

Theorem 4.2 then implies that the sequence of time-varying vector fields h^j T-converges to the vector field h^∞ given by

$$h^\infty(x,t) = f_0(x) + \frac{1}{2}(g_5(x) - g_3(x)) = f_0(x) + \frac{1}{2}[f_1, f_2](x)\,.$$

(We apply the theorem to the control system $\dot{x} = f_0(x) + \sum_{i=1}^{6} v_i g_i(x)$, and the controls v^j given by

$$v^j(t) = \Big(- j^{-\frac{1}{2}} \sin jt, -\frac{1}{2}\sin 2jt, -\sin^2 jt, j^{-\frac{1}{2}}\cos jt, \cos^2 jt, \frac{1}{2}\sin 2jt\Big)\,.$$

It is clear that the controls v^j $\mathcal{T}^0$-converge to $(0, 0, -\frac{1}{2}, 0, \frac{1}{2})$. Since $\theta^j \to 0$ uniformly, Theorem 4.2 applies.)

It is clear that $h^\infty = f^\infty$. So $\{\xi^j\}$ has a subsequence that converges to a $\xi^\infty \in \mathrm{Traj}_c(f^\infty, K)$.

The above arguments clearly apply to any subsequence of $\{u^j\}$. Then from Proposition 2.4 we conclude that the f^j T-converge to f^∞. □

Proof of Theorem 6.1. Let $\Sigma \in \mathcal{C}$ have vector fields $f_0, f_1, \ldots, f_m$ such that $[f_i, f_\ell] \neq 0$ for some $i, \ell \in \{1, \ldots, m\}$. Define inputs u^j by letting $u_k^j(t) = 0$ if $k \notin \{i, \ell\}$, $u_i^j(t) = j^{\frac{1}{2}}\cos jt$, $u_\ell^j(t) = j^{\frac{1}{2}}\sin jt$. By Proposition 6.2, the time-varying vector fields $f^\Sigma(u^j)$ T-converge to $f_0 + \frac{1}{2}[f_i, f_\ell]$. □

To understand the relationship between ordinary and generalized inputs, it is useful to keep in mind the following simple analogy. Integrable functions on, say, the interval $[0,1]$, are members of the more general class of Borel measures on $[0,1]$, modulo an obvious identification. A measure μ has a decomposition $\mu = \mu_{ac} + \mu_{sing}$ into an absolutely continuous part and a singular part. (We include in μ_{sing} all the atoms of μ.) If μ is absolutely continuous, i.e., if $d\mu = f\,dx$, where $f \in L^1$, then of course μ has no singular part. A sequence $\{\mu^j\}$ of absolutely continuous measures will converge to an absolutely continuous measure μ provided that the μ^j weak*-converge to μ and the functions $f^j = \frac{d\mu^j}{dx}$ are "kept under control," e.g., if the sequence $\{f^j\}$ is equi-integrable. If, on the other hand, the μ^j weak*-converge to μ but $\{f^j\}$ is not equi-integrable, then the limit μ can have a singular part even though the μ^j do not. Similarly, the general picture for ordinary differential equations $\dot{x} = f_0(x) + \sum_i u_i(t) f_i(x)$ is that each right-hand side is in fact a member of a larger class of "generalized" objects, which contain Lie bracket terms as well as "ordinary" terms. An "ordinary" right-hand side has no Lie bracket terms, but a sequence $\{f^j\}$ of ordinary right-hand sides can converge to a "generalized" one, which contains Lie bracket terms in addition to the averaged limit, unless $\{f^j\}$ is "kept under control," e.g., by means of the boundedness conditions of our Theorem 4.1.

There is a more general theory that shows in a systematic way how iterated Lie brackets can occur as limits of the right-hand sides of *highly oscillatory* differential equations, such as the ones considered in Proposition 6.2. The results described in Theorem 4.1 can be thought of as the zeroth level of this more general theory, in which Lie bracket terms do not occur in the limit. High-level results, in which the structure of general limits involving Lie bracket terms is analyzed in detail, are described in [13], [14], [15], [16], [22], [23], and [24]. (Some special cases of these limiting processes have also been studied by Kurzweil and Jarnik in [10] and [11].)

7. Comparison with other conditions.

We recall that a sequence $\{u^j\}_{j=1}^\infty$ of functions in $L^1([0,T], \mathbb{R}^m)$ *converges weakly* to a limit $u^\infty \in L^1([0,T], \mathbb{R}^m)$ if

$\lim_{j\to\infty}\int_0^T \varphi(t)u^j(t)dt = \int_0^T \varphi(t)u^\infty(t)dt$ for all functions $\varphi \in L^\infty([0,T],\mathbb{R})$. It is well known (cf. Theorem 3.1 on page 53 of [5]) that $\{u^j\}_{j=1}^\infty$ converges weakly to u^∞ iff (i) the integrals $U^j(t) = \int_0^t u^j(s)ds$ converge to $U^\infty(t) = \int_0^t u^\infty(s)ds$ for each t, and (ii) the sequence $\{u^j\}$ is *equi-integrable* in the sense that for every $\varepsilon > 0$ there is a $\delta > 0$ such that $\int_E \|u^j(t)\|dt \leq \varepsilon$ for every j and every measurable subset E of $[0,T]$ whose measure is $\leq \delta$.

It is clear that equi-integrability implies that the sequence $\{U^j\}$ is equicontinuous. So (i) and (ii) actually imply (IC). Moreover, the equi-integrability condition also implies (UB). Thus one particular consequence of our main result is that *weak convergence implies $\mathcal{T}^0$-convergence.* On the other hand, the following example shows that a sequence can satisfy the conditions of Theorem 4.1 without being weakly convergent, so our necessary and sufficient condition for sequences is strictly weaker than weak convergence.

Example 7.1. Let $m = 1$, $u^j(t) = j^{\frac{1}{2}}\cos jt$ for $0 \leq t \leq j^{-\frac{1}{2}}$, and $u^j(t) = 0$ for $j^{-\frac{1}{2}} < t \leq T$. Then $\{u^j\}_{j=1}^\infty$ satisfies (IC) and (UB), with $u^\infty \equiv 0$. It follows from Theorem 4.1 that $\{u^j\}_{j=1}^\infty$ $\mathcal{T}^0$-converges to u^∞.

On the other hand, it is not hard to see that *the sequence $\{u^j\}_{j=1}^\infty$ is not weakly convergent in $L^1[0,T]$*. Indeed, the integrals $\int_0^{j^{-1/2}} |u^j(t)|dt$ converge to $\frac{2}{\pi}$ as $j \to \infty$, and then $\{u^j\}$ is not equi-integrable. □

The preceding example also makes it possible to show that our convergence condition is weaker than those of Buttazzo–Conti, Kurzweil–Vorel, and Neustadt; cf. [4], [9], [19]. Indeed, the Kurzweil–Vorel conditions amount to saying that

$$\int_0^t u^j(s)ds \to \int_0^t u^\infty(s)ds \quad \text{and} \quad \sup_j |u^j| \in L^1[0,T]\,.$$

(Our example violates the latter condition because if we let $v(t) = \sup_j |u^j(t)|$, then $v(t) \geq j^{1/2}|\cos jt|$ on the interval $[0, j^{-1/2}]$. Thus

$$\int_0^{j^{-\frac{1}{2}}} v(t)dt \geq j^{1/2}\int_0^{j^{-1/2}} |\cos jt|dt.$$

Since the latter integral goes to $\frac{2}{\pi}$ as $j \to \infty$, we see that $\int_0^{j^{-1/2}} v(t)dt$ is bounded away from zero as $j \to \infty$. Therefore v is not integrable.) The Neustadt theorem requires that $\int_0^t u^j(s)ds \to \int_0^t u^\infty(s)ds$ and $\sup_j \int_t^\tau |u^j(s)|ds \overset{\tau\to t+}{\longrightarrow} 0$ uniformly in t. Our example violates this if $t = 0$. The Buttazzo–Conti theorem, when specialized to control-affine systems (1.1), requires that the vector fields $f_0, \ldots, f_m$ be Lipschitz, although they assume only that the u^j and u^∞ satisfy (IC) and (UB).

Appendix A. We give three examples. The first two pertain, respectively, to the assertions made in Theorem 4.1 that in general (v) $\not\Longrightarrow$(iv) and (ii)$\not\Longrightarrow$ (i). The third one illustrates the difference, for general vector fields, between "continuous dependence of the trajectories for every fixed initial condition," and "joint continuous dependence of the trajectories on the right-hand side and the initial condition."

As shown in Theorem 4.1, uniform weak convergence is necessary for a net $\{u^\alpha\}_{\alpha\in A}$ to $\mathcal{T}^0$-converge to u^∞ in $L^1([0,T],\mathbb{R}^m)$ and is also sufficient if $\{u^\alpha\}_{\alpha\in A}$ is a sequence. The following example shows that (UWC) is no longer sufficient in general for a net $\{u^\alpha\}$ to $\mathcal{T}^0$-converge to u^∞, and therefore proves that condition (v) of Theorem 4.1 does not in general imply (iv).

Example A.1. Let $T = 2\pi$. For every integer $n \geq 1$, every choice $\varphi_1, \ldots, \varphi_n$ of n real-valued continuous functions on $[0, T]$, and every $\varepsilon > 0$, set

$$V(\varphi_1, \ldots, \varphi_n, \varepsilon) = \left\{ \psi \in L^1([0,T], \mathbb{R}) \colon \sup_{0 \leq t \leq T} \left| \int_0^t \varphi_i(s)\psi(s)ds \right| < \varepsilon, i = 1, \ldots, n \right\}.$$

Let $\mathcal{V}$ be the set of all sets $V(\varphi_1, \ldots, \varphi_n, \varepsilon)$, for all possible integers $n \geq 1$, all n-tuples $(\varphi_1, \ldots, \varphi_n)$ of continuous functions on $[0, T]$, and all positive numbers ε. We define a directed set $(I, \preceq_I)$ by letting

$$I = \{(V, N) \ : \ V \in \mathcal{V}, N \text{ is an integer} > 0\},$$

with the partial ordering $\preceq_I$ such that

$$(V_1, N_1) \preceq_I (V_2, N_2) \Longleftrightarrow (V_2 \subseteq V_1 \text{ and } N_2 \geq N_1).$$

Let $m = 2$. We define a net $\{u^\alpha\}_{\alpha \in I}$ in $L^1([0, T], \mathbb{R}^2)$ as follows. For each index $\alpha = (V, N) \in I$, we let $u_1^\alpha(t) = N\cos(j_\alpha t)$, $u_2^\alpha(t) = N \sin(j_\alpha t)$, where j_α is the smallest integer $j > 0$ such that the functions $N\cos(jt), N\sin(jt)$ belong to V. (It follows from the Riemann-Lebesgue lemma that, for each fixed V and N, the functions $N\cos(jt)$ and $N\sin(jt)$ belong to V when j is large enough. Thus j_α exists.) Now it is easy to see that the net $\{u^\alpha\}_{\alpha \in I}$ thus defined satisfies (UWC) with $u^\infty = (0, 0)$. (To see this, let $\varepsilon > 0$, and let φ be a continuous function on $[0, T]$. Let $\alpha_0 = (V(\varphi, \varepsilon), 1)$. Then, if $\alpha = (V, N) \succeq_I \alpha_0$, it follows that $V \subset V_0(\varphi, \varepsilon)$. By definition, $(u_1^\alpha, u_2^\alpha) \in V \subset V_0(\varphi, \varepsilon)$, which implies $\sup_{0 \leq t \leq T} | \int_0^t \varphi(s)u_k^\alpha(s)ds| < \varepsilon, k = 1, 2.$)

We will now show that the above net does not $\mathcal{T}^0$-converge to the limit $u^\infty{=}(0, 0)$ in $L^1([0, T], \mathbb{R}^2)$. Let $\Sigma{=}(\mathbb{R}^2, f_0, f_1, f_2)$ with $f_0 = (0, 0)$, $f_1 = (1, 0)$, $f_3 = (0, x^{\frac{1}{5}})$. It is clear that this system is in $C^0(2)$. Consider, for each input $u \in L^1([0, T], \mathbb{R}^2)$, the system of differential equations $\dot{x}_1 = u_1$, $\dot{x}_2 = x_1^{1/5} u_2$. This system has the global existence and uniqueness property for every initial condition and every $u \in L^1([0, T], \mathbb{R}^2)$. Fix the initial condition $x(0) = (0, 0)$. We prove that $\{u^\alpha\}$ does not $\mathcal{T}^0$-converge to u^∞ by showing that the trajectories x^α of the above differential equations that correspond to the u^α do not converge to $x^\infty \equiv (0, 0)^T$. First, we prove a lemma.

Lemma A.1. *Fix a $V = (\varphi_1, \ldots, \varphi_n, \varepsilon) \in \mathcal{V}$. Then there exists an $N_V > 0$ such that if $N > N_V$ and $\alpha = (V, N)$, then $j_\alpha \leq N^5$.*

Proof. Let $A = \max_{k=1,\ldots,n}\{\|\varphi_k\|\}$, where $\|\cdot\|$ denotes the sup norm on $[0, T]$. Let $N_V = \frac{4A\pi}{\varepsilon}(\frac{nAT}{\varepsilon} + n)^{\frac{1}{2}}$. We show that $j_\alpha \leq N^5$ if $\alpha = (V, N)$, $N > N_V$. Suppose there is an $N > N_V$ such that $j_\alpha > N^5$. Then by the definition of the j_α, for every $1 \leq j \leq N^5$, we have

$$\text{(A.1)} \qquad \sup_{0 \leq t \leq T, k=1,\ldots,n} \max\left(\left| \int_0^t \cos(js)\varphi_k(s)ds \right|, \left| \int_0^t \sin(js)\varphi_k(s)ds \right| \right) \geq \frac{\varepsilon}{N}.$$

Let $K = [\frac{2ANT}{\varepsilon}] + 1$, where $[\cdot]$ denotes the integer part function (i.e., $[r]$ is the largest integer ν such that $\nu \leq r$). Divide the interval $[0, T]$ into K equal parts. Let $t_\ell = \frac{T\ell}{K}, \ell = 0, \ldots, K$, be the partition points, and define $\varphi_{k,\ell}(t) = \varphi_k(t)\chi_{[0,t_\ell]}$, where $\chi_{[0,t_\ell]}$ is the indicator function of $[0, t_\ell]$. For any two functions φ, ψ in $L^2[0, T]$, let us use $\langle \varphi, \psi \rangle = \int_0^T \varphi(s)\psi(s)ds$ to denote the inner product of φ, ψ. Then $\{\frac{\cos jt}{\sqrt{\pi}} :$

$j = 1, 2, \ldots\} \cup \{\frac{\sin jt}{\sqrt{\pi}} : j = 1, 2, \ldots\}$ is an orthonormal set in $L^2[0, T]$. From Bessel's inequality we know that

$$\begin{aligned}&\sum_{\ell=1}^{K}\sum_{k=1}^{n}\sum_{j=1}^{N^5}\left\{\left|\left\langle\frac{\cos(jt)}{\sqrt{\pi}}, \varphi_{k,\ell}\right\rangle\right|^2 + \left|\left\langle\frac{\sin(jt)}{\sqrt{\pi}}, \varphi_{k,\ell}\right\rangle\right|^2\right\} \\ \text{(A.2)}\qquad &\leq \sum_{\ell=1}^{K}\sum_{k=1}^{n} \|\varphi_{k,\ell}\|^2_{L^2[0,T]} \leq \sum_{\ell=1}^{K}\sum_{k=1}^{n} \|\varphi_k\|^2_{L^2[0,T]} \leq 2\pi nKA^2\,.\end{aligned}$$

On the other hand, it follows from (A.1) that for each $j \in \{1, \ldots, N^5\}$ there exist a number $k(j) \in \{1, \ldots, n\}$ and a $t(j) \in [0, T]$ such that at least one of the numbers

$$\Big|\int_0^{t(j)} \cos(js)\varphi_{k(j)}(s)ds\Big|\,, \qquad \Big|\int_0^{t(j)} \sin(js)\varphi_{k(j)}(s)ds\Big|$$

is $\geq \frac{\varepsilon}{N}$. Then $t(j) \in [t_{\ell-1}, t_\ell]$ for some $\ell = \ell(j)$. It is clear that the integrals of $\cos(js)\varphi_{k(j)}(s)ds$ and $\sin(js)\varphi_{k(j)}(s)ds$ from $t(j)$ to $t_{\ell(j)}$ are bounded by $\frac{AT}{K}$. Since $K > \frac{2ANT}{\varepsilon}$, we have $\frac{AT}{K} < \frac{\varepsilon}{2N}$. Thus at least one of the numbers

$$\Big|\int_0^{t_{\ell(j)}} \cos(js)\varphi_{k(j)}(s)ds\Big|\,, \qquad \Big|\int_0^{t_{\ell(j)}} \sin(js)\varphi_{k(j)}(s)ds\Big|$$

is $\geq \frac{\varepsilon}{2N}$. Therefore

$$\left|\left\langle\frac{\cos(jt)}{\sqrt{\pi}}, \varphi_{k(j),\ell(j)}\right\rangle\right|^2 + \left|\left\langle\frac{\sin(jt)}{\sqrt{\pi}}, \varphi_{k(j),\ell(j)}\right\rangle\right|^2 \geq \frac{\varepsilon^2}{4\pi N^2}\,.$$

Thus we have

$$\text{(A.3)}\quad \sum_{\ell=1}^{K}\sum_{k=1}^{n}\sum_{j=1}^{N^5}\left\{\left|\left\langle\frac{\cos(jt)}{\sqrt{\pi}}, \varphi_{k,\ell}\right\rangle\right|^2 + \left|\left\langle\frac{\sin(jt)}{\sqrt{\pi}}, \varphi_{k,\ell}\right\rangle\right|^2\right\} \geq N^5\frac{\varepsilon^2}{4\pi N^2} = \frac{\varepsilon^2 N^3}{4\pi}\,.$$

If we compare this with (A.2), we see that

$$N^3 \leq \frac{8\pi^2 nKA^2}{\varepsilon^2}\,.$$

Since $K < \frac{2ANT}{\varepsilon} + 2$, and $N \geq 1$, we easily get the inequality

$$N^2 \leq \frac{16\pi^2 A^2}{\varepsilon^2}\left(\frac{nAT}{\varepsilon} + n\right),$$

so that $N \leq N_V$. This contradiction completes our proof. □

Using the lemma, it is easy to see that the x^α do not converge to x^∞. Indeed, for any $\alpha = (V, N) \in I$, the solution x^α is given by

$$\text{(A.4)}\qquad x_1^\alpha(t) = \frac{N}{j_\alpha}\sin(j_\alpha t)\,, \qquad x_2^\alpha(t) = \frac{N^{\frac{6}{5}}}{j_\alpha^{\frac{1}{5}}}\int_0^t (\sin j_\alpha s)^{\frac{6}{5}}ds\,.$$

Take $\varepsilon_0 = 1$. If the net $\{x^\alpha\}$ converged to x^∞, then there would exist an $\alpha_0 = (V, N_0) \in I$ such that $\|x^\alpha(t)\| \leq 1$ for all $\alpha \succeq_I \alpha_0$ and all $t \in [0, T]$. Let $\alpha = (V, N)$ with $N > \max\{N_0, N_V\}$. Then $\alpha \succeq_I \alpha_0$ and

$$x_2^\alpha(T) = \frac{N^{\frac{6}{5}}}{j_\alpha^{\frac{1}{5}}}\int_0^T \sin^{\frac{6}{5}} j_\alpha s\, ds\,.$$

Clearly, $\int_0^T \sin^{\frac{6}{5}} j_\alpha s\, ds$ is bounded away from 0. Since $j_\alpha \leq N^5$, we conclude that $x_2^\alpha(T) \to \infty$ as $N \to \infty$. This contradiction proves that $\{x^\alpha\}$ does not converge. □

Our second example shows that a net $\{u^\alpha\}_{\alpha\in A}$ in $L^1([0,T],\mathbb{R}^m)$ may $\mathcal{T}^0$-converge to a $u \in L^1([0,T],\mathbb{R}^m)$ while failing to satisfy (UB). This will prove the assertion that in general (ii)$\not\Longrightarrow$(i) in Theorem 4.1.

Example A.2. Take $m = 1, T = 1$. Let $\mathcal{F}_1$ be the collection of all pairs (Σ, K), where Σ is an element of $C^0(1)$ and K is a compact subset of $\Omega^\Sigma \times [0,1]$. Let $\mathcal{F}_2$ be the set of all finite subsets of $\mathcal{F}_1$. Let $\mathcal{F} = \mathcal{F}_2 \times \mathbb{N}$, where $\mathbb{N}$ is the set of positive integers. Define a partial ordering $\preceq_{\mathcal{F}}$ on $\mathcal{F}$ by letting $(F_1, n_1) \preceq_{\mathcal{F}} (F_2, n_2)$ if $F_1 \subseteq F_2$ and $n_1 \leq n_2$. Then $(\mathcal{F}, \preceq_{\mathcal{F}})$ is a directed set. We define a net $\{u^{(F,n)}\}_{(F,n)\in\mathcal{F}}$ in $L^1([0,1],\mathbb{R})$ as follows. For each $n, k \in \mathbb{N}$, let $u_n^k(t) = n \sin kt$. Then from Theorem 4.1 we know that, for each fixed n, the sequence $\{u_n^k\}_{k=1}^\infty$ $\mathcal{T}^0$-converges to $u = 0$ in $L^1([0,1],\mathbb{R})$. Therefore, for each $(\Sigma, K) \in \mathcal{F}_1$, the set $\mathrm{Traj}_c(f^\Sigma(u_n^k), K)$ converges, as $k \to \infty$, to $\mathrm{Traj}_c(f^\Sigma(u), K)$ in $2^{ARC(\Omega^\Sigma)}$ under the topology $\mathcal{T}_{USC}(ARC(\Omega^\Sigma))$. Let $k_{\Sigma,K,n}$ be an integer such that $\mathrm{Traj}_c(f^\Sigma(u_n^k), K) \subseteq U_{\frac{1}{n}}(f^\Sigma(u), K)$ if $k \geq k_{\Sigma,K,n}$, where $U_\varepsilon(f, K)$ is the ε-neighborhood of $\mathrm{Traj}_c(f, K)$, i.e.,

$$U_\varepsilon(f,K) = \{\xi \in ARC(\Omega) : d_{ARC}(\xi,\zeta) < \varepsilon \text{ for some } \zeta \in \mathrm{Traj}_c(f,K)\}\,.$$

For any $F \in \mathcal{F}$, we let $k_{F,n} = \max\{k_{\Sigma,K,n} : (\Sigma, K) \in F\}$, and then define $u^{(F,n)}(t) = u_n^{k_{F,n}}(t)$. Clearly $\{u^{(F,n)}\}_{(F,n)\in\mathcal{F}}$ does not satisfy (UB). However, it is easy to show that $\{u^{(F,n)}\}_{(F,n)\in\mathcal{F}}$ $\mathcal{T}^0$-converges to u in $L^1([0,1],\mathbb{R})$. To see this, let $\Sigma \in C^0(1)$ be a system and K be a compact subset of $\Omega^\Sigma \times [0,1]$. We need to show that $\mathrm{Traj}_c(f^\Sigma(u^{(F,n)}), K)$ converges to $\mathrm{Traj}_c(f^\Sigma(u), K)$. For any given $\varepsilon > 0$, let $n(\varepsilon)$ be an integer such that $\frac{1}{n(\varepsilon)} < \varepsilon$. Let $F_0 = \{(\Sigma, K)\}$. Then if $(F_0, n(\varepsilon)) \preceq_{\mathcal{F}} (F, n)$, by definition, $n \geq n(\varepsilon)$ and $(\Sigma, K) \in F$. Therefore,

$$\mathrm{Traj}_c(f^\Sigma(u^{(F,n)}), K) \subseteq U_{\frac{1}{n}}(f^\Sigma(u), K) \subseteq U_\varepsilon(f^\Sigma(u), K)\,. \qquad \square$$

Our third example shows that, for general vector fields, the fact that for every fixed initial condition $x(\bar{t}) = \bar{x}$ the trajectory of f^j converges to the trajectory of f does not imply that f^j T-converges to f.

Example A.3. Let $\varphi : \mathbb{R} \to \mathbb{R}$ be a smooth function such that $\varphi(s) = 0$ if $s \leq 0$ or $s \geq 2$, and $\varphi(s) > 0$ if $0 < s < 2$. Define $f^j : \mathbb{R}^2 \times \mathbb{R} \to \mathbb{R}^2$ by letting $f^j(x,y,t) = (0, j\varphi(jx))$, and let $f(x,y,t) \equiv 0$. Then f and the f^j are time-varying vector fields on $\mathbb{R}^2$. Given any initial condition $(\bar{x},\bar{y},\bar{t})$, the solution $\xi_{j,\bar{x},\bar{y},\bar{t}} : \mathbb{R} \to \mathbb{R}^2$ of the initial value problem $\dot{\xi}(t) = f^j(\xi(t), t)$, $\xi(\bar{t}) = (\bar{x},\bar{y})$, is given by $\xi_{j,\bar{x},\bar{y},\bar{t}}(t) = (\bar{x}, \bar{y} + j(t-\bar{t})\varphi(j\bar{x}))$. For each $\bar{x}$, the number $\varphi(j\bar{x})$ is equal to zero for sufficiently large j. So for each initial condition $(\bar{x},\bar{y},\bar{t})$ the curve $t \to \xi_{j,\bar{x},\bar{y},\bar{t}}(t)$ converges uniformly, as $j \to \infty$, to the constant curve $\xi_{\infty,\bar{x},\bar{y},\bar{t}} \equiv (\bar{x},\bar{y})$, and $\xi_{\infty,\bar{x},\bar{y},\bar{t}}$ is precisely the solution of the limiting initial value problem $\dot{\xi} = f(\xi, t)$, $\xi(\bar{t}) = (\bar{x},\bar{y})$. On the other hand, if we consider a j-dependent initial condition $(\bar{x}^j, \bar{y}^j, \bar{t}^j)$ given by $\bar{x}^j = \frac{1}{j}$, $\bar{y}^j = 0$, $\bar{t}^j = 0$, and let $t^j = \frac{1}{j}$, then $\xi_{j,\bar{x}^j,\bar{y}^j,\bar{t}^j}(t^j) = (\frac{1}{j}, \varphi(1))$, which does not converge to $\xi_{\infty,0,0,0}(0)$, even though $(\bar{x}^j,\bar{y}^j,\bar{t}^j) \to (0,0,0)$ and $t^j \to 0$. Thus the curves $\xi_{j,\bar{x}^j,\bar{y}^j,\bar{t}^j}$ do not converge uniformly to $\xi_{\infty,0,0,0}(0)$ on the compact interval $[0,1]$. (Alternatively, we could have taken $\bar{t}^j = -\frac{1}{j}$, and then $\xi_{j,\bar{x}^j,\bar{y}^j,\bar{t}^j}(0) = (\frac{1}{j}, \varphi(1))$, so $\xi_{j,\bar{x}^j,\bar{y}^j,\bar{t}^j}$ does not even converge pointwise to $\xi_{\infty,0,0,0}$.) □

STOCHASTIC SHORTEST PATH GAMES*

STEPHEN D. PATEK[†] AND DIMITRI P. BERTSEKAS[‡]

Abstract. We consider dynamic, two-player, zero-sum games where the "minimizing" player seeks to drive an underlying finite-state dynamic system to a special terminal state along a least expected cost path. The "maximizer" seeks to interfere with the minimizer's progress so as to maximize the expected total cost. We consider, for the first time, undiscounted finite-state problems, with compact action spaces, and transition costs that are not strictly positive. We admit that there are policies for the minimizer which permit the maximizer to prolong the game indefinitely. Under assumptions which generalize deterministic shortest path problems, we establish (i) the existence of a real-valued equilibrium cost vector achievable with stationary policies for the opposing players and (ii) the convergence of value iteration and policy iteration to the unique solution of Bellman's equation.

Key words. game theory, stochastic games, optimization, dynamic programming, stochastic shortest paths

1. Introduction.

This paper develops basic theory relating to stochastic shortest path games. These are two-player, zero-sum games where the minimizing player seeks to drive an underlying finite-state dynamic system to a special terminal state along a least expected cost path. The maximizer seeks to interfere with the minimizer's progress so as to maximize the expected total cost. In actual play, the players implement actions simultaneously at each stage with full knowledge of the state of the system but *without* knowledge of each other's current decision.

Games of this type have been studied for some time. The field was initiated by Shapley in his classical paper [7]. In Shapley's games, two players are successively faced with matrix games (in mixed strategies) where both the immediate cost and the transition probabilities to new matrix games are influenced by the stagewise decisions of the players. In this formulation, the state of the system is the matrix game currently being played. It is assumed that this set of states is finite and that there is a nonzero minimal probability that, at any stage, the game will transition to a terminal state, ending the sequence of rewards and payoffs. This formulation is closely related to infinite-horizon games with *discounted* additive cost. The analysis of such games is straightforward, the main results being (i) the existence and characterization of a unique real-valued equilibrium cost vector achievable in stationary randomized policies and (ii) the convergence of value iteration and policy iteration to the equilibrium cost.

Since Shapley's work, game theorists have actively studied extensions to the discounted-cost model. In [4], Kushner and Chamberlain consider undiscounted, pursuit/evasion, stochastic games where there is a terminal state corresponding to the evader being "caught." The state space is assumed to be finite (with $n + 1$ elements,

one of which is the terminal state). Making some regularity assumptions on the transition probabilities and cost functions, they consider pure strategies over compact action spaces. In addition, they assume either of the following.

1. The n-stage probability transition matrix $[P(\mu,\nu)]^n$ (from nonterminal states to nonterminal states) is a "uniform contraction" in the stationary policy pairs (μ,ν) of the two players. (That is, for some $\epsilon > 0$, $[P(\mu,\nu)]^n$ has row-sums less than $1-\epsilon$ for all stationary policy pairs (μ,ν).)
2. The transition costs (to the pursuer) are uniformly bounded below by $\delta > 0$, and there exists a stationary policy $\tilde{\mu}$ for the pursuer that makes $[P(\tilde{\mu},\nu)]^n$ a uniform contraction under all stationary policies for the evader.

They show that there exists an equilibrium cost vector for the game which can be found through value iteration. In [10], van der Wal considers a special case of Kushner and Chamberlain's games. Under more restrictive assumptions about the pursuer's ability to catch the evader, he gives error bounds for the updates in value iteration.

In [3], Kumar and Shiau give a detailed analysis of stochastic games with very mild assumptions about the state space and control constraint sets. For the case of nonnegative additive cost (with no discounting), they establish the existence of an extended real equilibrium cost vector in non-Markov randomized policies (where for both players the best mixed action can depend on all of the past states and controls, as well as the current state). They show that the minimizing player can achieve the equilibrium using a stationary Markov randomized policy and that, in case the state space is finite, the maximizing player can play ϵ-optimally using stationary randomized policies.

Other researchers have studied so-called nonterminating stochastic games (also sometimes called "undiscounted" stochastic games), where the costs are not discounted but are averaged instead. Such *average-cost* games have a rich mathematical structure which has been extensively covered in the literature [13, 5].

In this paper, we consider undiscounted additive cost games without averaging. We admit that there are policies for the minimizer which allow the maximizer to prolong the game indefinitely at infinite cost to the minimizer. We do not assume nonnegativity of cost, as in [4] and [3]. We make alternative assumptions which guarantee that, at least under optimal policies, the terminal state is reached with probability one. Our results imply the results of Shapley [7], as well as those of Kushner and Chamberlain [4]. Because of our assumptions relating to termination, we are able to derive stronger conclusions than those made by Kumar and Shiau [3] for the case of a finite state space. Note that because we do not assume nonnegativity of the costs, the analysis is much more complicated than the corresponding analysis of Kushner and Chamberlain [4]. Our formal assumptions generalize (to the case of two players) those for stochastic shortest path problems [2]. Because of this, we refer to our class of games as "stochastic shortest path games." Our games are characterized by either (i) inevitable termination (under all policies) or (ii) an incentive for the minimizer to drive the system to termination in a finite expected number of stages. We shall see that the results of [2] are essential in developing our present theory.

In section 2 we give a precise mathematical formulation for stochastic shortest path games. In section 3, we relate our general formulation to Shapley's original games [7]. We develop our main results in section 4. This is where we show that stochastic shortest path games have an equilibrium solution which can be characterized by the unique solution to Bellman's equation. We also prove the convergence of value iteration and policy iteration to the equilibrium cost. In section 5, we give an example of pursuit and evasion, illustrating our main results. Finally, in the appendix we collect some well-known results about dynamic games which are crucial to our development.

2. Mathematical formulation. Let S denote a finite state space with elements labeled $i = 1, \dots, n$. For each $i \in S$, define $U(i)$ and $V(i)$ to be the sets of actions available to the minimizer and maximizer at state i, respectively. These are collectively referred to as *control constraint sets.* The probability of transitioning from $i \in S$ to $j \in S$ under $u \in U(i)$ and $v \in V(i)$ is denoted $p_{ij}(u, v)$. The expected cost (to the minimizer) of transitioning from $i \in S$ under $u \in U(i)$ and $v \in V(i)$ is denoted $c_i(u, v)$.

We denote the sets of one-stage policies for the minimizing and maximizing players as M and N, respectively, where

$$M = \left\{ \mu : S \mapsto \bigcup_{i \in S} U(i) \quad | \quad \mu(i) \in U(i) \quad \forall\, i \in S \right\},$$

$$N = \left\{ \nu : S \mapsto \bigcup_{i \in S} V(i) \quad | \quad \nu(i) \in V(i) \quad \forall\, i \in S \right\}.$$

The sets of policies for the minimizing and maximizing players are denoted by $\bar{M}$ and $\bar{N}$, where

$$\begin{aligned} \pi_M = \{\mu^0, \mu^1, \dots\} \in \bar{M} \quad &\Longleftrightarrow \quad \mu^k \in M \quad \forall\, k, \\ \pi_N = \{\nu^0, \nu^1, \dots\} \in \bar{N} \quad &\Longleftrightarrow \quad \nu^k \in N \quad \forall\, k. \end{aligned}$$

Given $\mu \in M$ and $\nu \in N$, let $P(\mu, \nu)$ denote the transition probability matrix that results when μ and ν are in effect. That is,

$$[P(\mu, \nu)]_{ij} = p_{ij}(\mu(i), \nu(i)).$$

Let $c(\mu, \nu)$ denote the vector whose components are $c_i(\mu(i), \nu(i))$. That is,

$$[c(\mu, \nu)]_i = c_i(\mu(i), \nu(i)).$$

Given two allowable opposing policies, $\pi_M = \{\mu^0, \mu^1, \dots\} \in \bar{M}$ and $\pi_N = \{\nu^0, \nu^1, \dots\} \in \bar{N}$, we formally define the resulting cost (to the minimizer) to be

$$x(\pi_M, \pi_N) = \liminf_{t \to \infty} h^t_{\pi_M, \pi_N}, \tag{2.1}$$

where

$$h^t_{\pi_M, \pi_N} \triangleq \left\{ c(\mu^0, \nu^0) + \sum_{k=1}^{t} [P(\mu^0, \nu^0) \cdots P(\mu^{k-1}, \nu^{k-1})] c(\mu^k, \nu^k) \right\}. \tag{2.2}$$

Note that $h^t_{\pi_M, \pi_N}$ can be interpreted loosely as the expected t-stage cost vector under the policies π_M and π_N.

In establishing our main results, the definitions and assumptions in the following paragraphs will be helpful. We say that a policy $\pi_M = \{\mu^0, \mu^1, \dots\}$ for the minimizer is *stationary* if $\mu^k = \mu$ for all k. When this is the case and no confusion can arise, we use μ to denote the corresponding policy π_M, and we refer to π_M as *the stationary policy* μ. Similar definitions hold for stationary policies of the maximizer.

The state $1 \in S$ has special importance. We shall refer to it as the *terminal state.* This state is assumed to be absorbing and cost free, that is, $p_{11}(u,v) = 1$ and $c_1(u,v) = 0$ for all $u \in U(1)$ and $v \in V(1)$. Let $\pi_M = \{\mu^0, \mu^1, \dots\} \in \bar{M}$ and $\pi_N = \{\nu^0, \nu^1, \dots\} \in \bar{N}$ be an arbitrary pair of policies. We say that the corresponding Markov chain *terminates with probability one* if the following limit satisfies:

$$\lim_{t\to\infty} [P(\mu^0,\nu^0)P(\mu^1,\nu^1)\cdots P(\mu^t,\nu^t)]_{i1} = 1 \quad \forall\, i \in S. \tag{2.3}$$

(The limit above exists because the sequence (for each $i \in S$) is monotonically nondecreasing and bounded above.) We shall refer to a pair of policies (π_M, π_N) as *terminating with probability one* if the corresponding Markov chain terminates with probability one; otherwise, we refer to the pair as *prolonging.*

A stationary policy $\mu \in M$ for the minimizer is said to be *proper* if the pair (μ, π_N) is terminating with probability one for all $\pi_N \in \bar{N}$. A stationary policy μ is *improper* if it is not proper. If μ is improper, then there is a policy for the maximizer $\pi_\mu \in \bar{N}$ under which there is a positive probability that the game will never end from some initial state. The designation of proper (or improper) applies only to stationary policies for the minimizer.

It is convenient to define the set $X = \{x \in R^n \mid x_1 = 0\}$. This is the space (of cost vectors) over which our main results hold. We denote by $\mathbf{0}$ the zero vector in X. Let $\mathbf{1}_X$ denote the vector $(0,1,1,\dots 1)' \in X$. It is useful to define the following operators on X.

$$T_{\mu\nu}(x) = c(\mu,\nu) + P(\mu,\nu)x; \qquad \mu \in M, \nu \in N. \tag{2.4}$$

$$T_\mu(x) = \sup_{\nu \in N} \left[c(\mu,\nu) + P(\mu,\nu)x\right]; \qquad \mu \in M, \tag{2.5}$$

$$T(x) = \inf_{\mu \in M} \sup_{\nu \in N} \left[c(\mu,\nu) + P(\mu,\nu)x\right]. \tag{2.6}$$

$$\tilde{T}_\nu(x) = \inf_{\mu \in M} \left[c(\mu,\nu) + P(\mu,\nu)x\right]; \qquad \nu \in N, \tag{2.7}$$

$$\tilde{T}(x) = \sup_{\nu \in N} \inf_{\mu \in M} \left[c(\mu,\nu) + P(\mu,\nu)x\right]. \tag{2.8}$$

The suprema and infima in the above are taken componentwise. We use the notation $T^t_{\mu\nu}(x)$ to denote the t-fold composition of $T_{\mu\nu}$ applied to $x \in X$. Similar definitions hold for $T^t_\mu(x)$, $T^t(x)$, $\tilde{T}^t_\nu(x)$, and $\tilde{T}^t(x)$. In the appendix, we collect (and prove for completeness) some well-known results about these "T"-operators: monotonicity (Lemma A.1) and continuity (Lemma A.3).

The following are our standing assumptions.

Assumption SSP. The following are true:

1. There exists at least one proper policy for the minimizer.
2. If a pair of policies (π_M, π_N) is prolonging, then the expected cost to the minimizer is infinite for at least one initial state. That is, there is a state i for which $\lim_{t\to\infty}[h^t_{\pi_M,\pi_N}]_i = \infty$.

Assumption R (regularity). The following are true:

1. The control constraint sets are compact. That is, for each $i \in S$, $U(i)$ and $V(i)$ are compact subsets of metric spaces. (This implies that M and N are compact.)
2. The functions $p_{ij}(u,v)$ are continuous with respect to $(u,v) \in U(i) \times V(i)$, and the functions $c_i(u,v)$ are

   (a) lower semicontinuous with respect to $u \in U(i)$ (with $v \in V(i)$ fixed) and
   (b) upper semicontinuous with respect to $v \in V(i)$ (with $u \in U(i)$ fixed).

   (The Weierstrass theorem implies that the supremum and infimum in the definitions of the operators T_μ and $\tilde{T}_\nu$ are always achieved by elements of N and M, respectively. That is, for every $x \in X$, there exists $\nu \in N$ such that $T_\mu(x) = T_{\mu\nu}(x) \in X$. Similarly, for every $x \in X$, there exists $\mu \in M$ such that $\tilde{T}_\nu(x) = T_{\mu\nu}(x) \in X$.)

3. For all $x \in X$, the infimum and supremum in the definitions of the operators T and $\tilde{T}$ are achieved by elements of M and N. That is, for every $x \in X$, there exists $\mu \in M$ and $\nu \in N$ such that $T(x) = T_\mu(x) \in X$ and $\tilde{T}(x) = \tilde{T}_\nu(x) \in X$.
4. For each $x \in X$, we have $T(x) = \tilde{T}(x)$.

Note that part 4 of Assumption R is satisfied under conditions for which a minimax theorem can be used to interchange "inf" and "sup." In particular, this part, as well as the entire Assumption R, is satisfied if

1. the sets $U(i)$ and $V(i)$ are nonempty, convex, and compact subsets of Euclidean spaces,
2. the functions $p_{ij}(u,v)$ are bilinear of the form $u'Q_{ij}v$, where Q_{ij} is a real matrix of dimension commensurate with $U(i)$ and $V(i)$,
3. the functions $c_i(u,v)$ are
   (a) convex and lower semicontinuous as functions of $u \in U(i)$ with v fixed in $V(i)$, and
   (b) concave and upper semicontinuous as functions of $v \in V(i)$ with u fixed in $U(i)$.

This follows from the Sion–Kakutani theorem (see [8, p. 232] or [6, p. 397]). We will show in section 3 that dynamic games with "mixed" strategies over finite underlying action spaces satisfy this assumption.

To verify that a stationary policy $\mu \in M$ is proper, we need only check whether (μ, ν) is terminating with probability one for all *stationary* policies $\nu \in N$ for the maximizer. Furthermore, if $\mu \in M$ is improper, then we can always find a *stationary* policy $\nu \in N$ for the maximizer which is prolonging when paired with μ. This is shown in the following lemma.

LEMMA 2.1. *If $\mu \in M$ is such that (μ, ν) terminates with probability one for all $\nu \in N$, then μ is proper.*

Proof. The proof uses the analysis of [2]. Let $\mu \in M$ be a fixed policy for the minimizer, and suppose that the pair (μ, ν) is terminating with probability one for all stationary policies of the maximizer $\nu \in N$. With μ fixed, the maximizer is faced with a stochastic shortest path problem of the type considered in [2]. (The maximizer has no improper policies (against μ).) Now modify the problem such that the costs of transitioning from nonterminal states are all set to one but all of the transition probabilities are left unchanged. The assumptions of [2] remain satisfied, so the optimal expected cost for the maximizer in the new problem is bounded, even over nonstationary policies. Thus, the maximum expected number of stages to termination under μ is finite. This is true for both the modified problem and the original version of the game. This implies that μ is proper. □

One of the objectives of this paper is to show that under Assumptions SSP and R there exist policies $\pi_M^* \in \bar{M}$ and $\pi_N^* \in \bar{N}$ such that

$$x(\pi_M, \pi_N^*) \geq x(\pi_M^*, \pi_N^*) \qquad \forall\ \pi_M \in \bar{M},$$
$$x(\pi_M^*, \pi_N) \leq x(\pi_M^*, \pi_N^*) \qquad \forall\ \pi_N \in \bar{N}.$$

Such a cost vector $x^* \overset{\triangle}{=} x(\pi_M^*, \pi_N^*)$ is called the *equilibrium cost vector* (or *value*) of the stochastic shortest path game. The policies π_M^* and π_N^* form an *equilibrium solution.* Since this is a zero-sum game, we know that the equilibrium cost (if it exists) is unique. Another objective of this paper is to show that the equilibrium cost vector is characterized as the unique solution to Bellman's equation, with *stationary* equilibrium policies for the opposing players. After these results are established, we proceed to show that value iteration and policy iteration converge to the unique solution of Bellman's equation.

3. Connection to Shapley's stochastic games.

The mathematical formulation of the preceding section includes as a special case the stochastic games of Shapley. To see this, assume that the number of actions available to either player at any state is finite. As before, the players implement underlying actions simultaneously at each stage with full knowledge of the state of the system but *without* knowledge of each other's current decision. However, the players are now allowed to randomize their decisions in formulating a policy so as to keep their opponents from adapting to a deterministic policy. That is, in considering what to do at each state, the players choose *probability distributions* over underlying control sets rather than specific underlying control actions. In other words, the players use randomized or "mixed" policies.

For each $i \in S$, define $A(i)$ and $B(i)$ to be the *finite* sets of underlying actions to the minimizer and maximizer, respectively. These are the physical controls the players may ultimately implement at state i. Let $|A(i)|$ and $|B(i)|$ denote the numbers of elements in each set of actions. We define the players' "control constraint sets" for the game as

$$U(i) = \left\{ u \in R^{|A(i)|} \;\middle|\; \sum_{j \in A(i)} u_j = 1; \quad u_j \; \geq \; 0 \right\}, \tag{3.1}$$

$$V(i) = \left\{ v \in R^{|B(i)|} \;\middle|\; \sum_{j \in B(i)} v_j = 1; \quad v_j \; \geq \; 0 \right\}. \tag{3.2}$$

Thus, $U(i)$ is the set of probability distributions over control actions $A(i)$ available to the minimizer from state $i \in S$. Similarly, $V(i)$ is the set of probability distributions over underlying control actions $B(i)$ available to the maximizer from state $i \in S$. Here the functions $p_{ij}(u,v)$ and $c_i(u,v)$ are, respectively, of the form

$$p_{ij}(u,v) = \sum_{k \in A(i)} \sum_{l \in B(i)} \underline{p}_{ij}(k,l) u_k v_l, \tag{3.3}$$

$$c_i(u,v) = \sum_{j \in S} \sum_{k \in A(i)} \sum_{l \in B(i)} \underline{g}_{ij}(k,l) \underline{p}_{ij}(k,l) u_k v_l, \tag{3.4}$$

where the functions $\underline{p}_{ij}$ and $\underline{g}_{ij}$ denote the transition probabilities and costs of the underlying two-player Markov decision process. Since the sets $U(i)$ and $V(i)$ are polyhedral and the functions $c_i(u,v)$ and $p_{ij}(u,v)$ are bilinear for all i and j (and continuous) as functions of $(u,v) \in U(i) \times V(i)$, it is clear that Assumption R is satisfied. (Parts 3 and 4 are satisfied thanks to the minimax theorem of von Neumann [11].)

4. Main results.

We now develop our main results; namely, the existence and characterization of a unique equilibrium cost vector, the convergence of value iteration, and the convergence of policy iteration. In sections 4.1 and 4.2, we characterize optimal solutions for the maximizer and minimizer, respectively, for the case where the opposing player fixes a policy. After we lay this groundwork, we consider the game proper in section 4.3.

4.1. The case where the minimizer's policy is fixed. Consider the policy $\pi_M = \{\mu^0, \mu^1, \dots\} \in \bar{M}$. The *cost of* π_M is defined by

$$x(\pi_M) = \liminf_{t\to\infty} \max_{\pi_N \in \bar{N}} h^t_{\pi_M,\pi_N}. \tag{4.1}$$

The appendix shows that, with our assumptions on c and P, the maximum in (4.1) is attained for every t (see Lemma A.5). The cost of a stationary policy μ for the minimizer is denoted $x(\mu)$ and is computed according to equation (4.1) where $\pi_M = \{\mu, \mu, \dots\}$.

Given a vector $w \in R^n$ whose elements are positive, the corresponding weighted sup-norm, denoted $\|\cdot\|^w_\infty$, is defined by

$$\|x\|^w_\infty = \max_{i=1,\dots,n} x_i/w_i \qquad \forall\, x \in R^n.$$

The next lemma, similar to results derived in [1, 9], follows from the theory of one-player stochastic shortest paths.

LEMMA 4.1. *Assume that all stationary policies for the minimizer are proper. The operator T is a contraction mapping on the set $X = \{x \in R^n \mid x_1 = 0\}$ with respect to a weighted sup-norm. Moreover, if $\mu \in M$ is proper, then T_μ is a contraction mapping with respect to a weighted sup-norm.*

Proof. We will first show the result about T for the case that all stationary policies are proper. Our strategy is to identify a vector of weights w and to show that this set of weights is one for which T is a contraction with respect to $\|\cdot\|^w_\infty$.

Let us define a new one-player stochastic shortest path problem of the type considered in [2]. This problem is defined such that the transition probabilities remain unchanged and the transition costs are all set equal to -1 for all states other than the terminal state. The important difference is that the maximizer and minimizer "work together" in the sense that the decision space (for the single player of the new problem) is over $\bar{M} \times \bar{N}$. This is a stochastic shortest path problem where all stationary policies are proper. Using the results of [2], there is an optimal cost vector $\tilde{x} \in X$ which can be achieved using a stationary policy $(\tilde{\mu}, \tilde{\nu}) \in \bar{M} \times \bar{N}$. Note that, since the transition costs from all nonterminal states are set to -1 in the new stochastic shortest path problem, we have $\tilde{x}_i \le -1$ for all $i \ne 1$. Moreover, from Bellman's equation we have

$$\tilde{x} = -\mathbf{1}_X + P(\tilde{\mu}, \tilde{\nu})\tilde{x},$$

where $\mathbf{1}_X = (0, 1, 1, \dots, 1)' \in X$. Also, for all $\mu \in M$ and $\nu \in N$,

$$\tilde{x} \le -\mathbf{1}_X + P(\mu, \nu)\tilde{x}.$$

Thus, for all $\mu \in M$, $\nu \in N$, and $i \ne 1$,

$$\begin{aligned} \sum_{j=2}^{n} p_{ij}(\mu(i), \nu(i)) \cdot (-\tilde{x}_j) &\le -\tilde{x}_i - 1 \\ &\le -\tilde{x}_i \gamma, \end{aligned} \tag{4.2}$$

where $\gamma = \max_{i \neq 1}(\tilde{x}_i + 1)/\tilde{x}_i$. Since the $\tilde{x}_i \leq -1$ for all $i \neq 1$, we have that $\gamma \in [0, 1)$. Now define $w = -\tilde{x} + (1, 0, 0, \ldots, 0)'$. Note that w is a vector in R^n whose elements are all strictly positive.

Let us now resume consideration of the original stochastic shortest path game. Let x and $\bar{x}$ be any two elements of X such that $\|x - \bar{x}\|_\infty^w = c$. Let $\mu \in M$ be such that $T_\mu(x) = T(x)$, and let $\nu \in N$ be such that $T_\mu(\bar{x}) = T_{\mu\nu}(\bar{x})$. Then,

$$\begin{aligned} T(\bar{x}) - T(x) &= T(\bar{x}) - T_\mu(x) \\ &\leq T_\mu(\bar{x}) - T_\mu(x) \\ &= T_{\mu\nu}(\bar{x}) - T_\mu(x) \\ &\leq T_{\mu\nu}(\bar{x}) - T_{\mu\nu}(x). \end{aligned}$$

Thus,

$$[T(\bar{x})]_i - [T(x)]_i \leq \sum_{j=2}^{n} [P(\mu, \nu)]_{ij} (\bar{x}_j - x_j).$$

Using this, we see that for all $i \neq 1$

$$\begin{aligned} \frac{[T(\bar{x}) - T(x)]_i}{c w_i} &\leq \frac{1}{c w_i} \sum_{j=2}^{n} p_{ij}(\mu(i), \nu(i))(\bar{x}_j - x_j) \\ &\leq \frac{1}{w_i} \sum_{j=2}^{n} p_{ij}(\mu(i), \nu(i)) w_j \\ &= \frac{1}{-\tilde{x}_i} \sum_{j=2}^{n} p_{ij}(\mu(i), \nu(i))(-\tilde{x}_j) \\ &\leq \frac{1}{-\tilde{x}_i}(-\tilde{x}_i)\gamma = \gamma, \end{aligned}$$

where the last inequality follows from (4.2). Thus, we get

$$\frac{[T(\bar{x})]_i - [T(x)]_i}{w_i} \leq c\gamma \quad \forall\, i \neq 1.$$

Since $[T(\bar{x})]_1 - [T(x)]_1 = 0$,

$$\frac{[T(\bar{x})]_i - [T(x)]_i}{w_i} \leq c\gamma \quad \forall\, i.$$

Using similar arguments, we may show that

$$\frac{[T(x)]_i - [T(\bar{x})]_i}{w_i} \leq c\gamma \quad \forall\, i.$$

Combining the preceding inequalities, we see that $\|T(x) - T(\bar{x})\|_\infty^w \leq c\gamma$. Since $0 \leq \gamma < 1$, we have that T is a contraction over X with respect to $\|\cdot\|_\infty^w$.

Now suppose $\mu \in M$ is proper. By viewing T_μ as the "T"-operator in a new game where $U(i) \equiv \{\mu(i)\}$, we have the desired result. □

LEMMA 4.2. *Given a proper policy μ, the following are true.*

1. *The cost $x(\mu)$ of μ is the unique fixed point of T_μ in $X = \{x \in R^n \mid x_1 = 0\}$.*
2. $x(\mu) = \sup_{\pi_N \in \bar{N}} x(\mu, \pi_N)$.
3. *We have $T_\mu^t(x) \to x(\mu)$ for all $x \in X$ with linear convergence.*

Proof. An induction argument (cf. Lemma A.5) easily shows that

$$T_\mu^{t+1}(\mathbf{0}) = \max_{\{\nu^0,\dots,\nu^t\}} \left\{ c(\mu,\nu^0) + \sum_{k=1}^{t} [P(\mu,\nu^0)P(\mu,\nu^1)\cdots P(\mu,\nu^{k-1})]c(\mu,\nu^k) \right\},$$

where $\mathbf{0}$ is the zero vector in X. Thus, using the preceding lemma and the definition of $x(\mu)$, we have

$$x(\mu) = \lim_{t\to\infty} T_\mu^{t+1}(\mathbf{0}) = \tilde{x}_\mu,$$

where $\tilde{x}_\mu$ is the unique fixed point of the contraction mapping T_μ within X, proving statement 1.

Consider the following infinite-horizon stochastic shortest path problem for the maximizer:

$$\sup_{\pi_N \in \bar{N}} \liminf_{t\to\infty} \left\{ c(\mu,\nu^0) + \sum_{k=1}^{t} [P(\mu,\nu^0)\cdots P(\mu,\nu^{k-1})]c(\mu,\nu^k) \right\}.$$

This problem is covered by the theory developed in [2] since the fact that μ is proper implies that termination is inevitable under all policies in the maximizer's problem. The optimal cost of this problem is $\sup_{\pi_N \in \bar{N}} x(\mu, \pi_N)$, and according to the theory of [2], it is equal to the limit of the successive approximation method applied to this problem, which is $\lim_{t\to\infty} T_\mu^{t+1}(\mathbf{0})$ and is also the unique fixed point of T_μ within X. This proves statement 2.

Finally, the linear convergence of $T_\mu^{t+1}(\mathbf{0})$ follows from the contraction property of T_μ. □

LEMMA 4.3. *If $x \geq T_\mu(x)$ for some $x \in X$, then μ is proper.*

Proof. To reach a contradiction, suppose μ is improper. According to Assumption SSP and Lemma 2.1, there exists a stationary maximizer's policy $\bar{\nu} \in N$ such that $(\mu, \bar{\nu})$ is prolonging and results in unbounded expected cost from some initial state when played against μ.

Let x be an element in X such that $x \geq T_\mu(x)$. Then, applying T_μ to x, we have that

$$x \geq T_\mu(x) \geq c(\mu,\bar{\nu}) + P(\mu,\bar{\nu})x,$$

where the second inequality follows from the definition of T_μ. From the monotonicity of T_μ, we get

$$\begin{aligned} x \geq T_\mu(x) \geq T_\mu^2(x) &\geq T_\mu(c(\mu,\bar{\nu}) + P(\mu,\bar{\nu})x) \\ &\geq P(\mu,\bar{\nu})P(\mu,\bar{\nu})x + [c(\mu,\bar{\nu}) + P(\mu,\bar{\nu})c(\mu,\bar{\nu})], \end{aligned}$$

where the last inequality follows again from the definition of T_μ. Proceeding inductively and using the same steps, we have that for all t

$$x \geq T_\mu^t(x) \geq P(\mu,\bar{\nu})^{t+1}x + \sum_{k=0}^{t} P(\mu,\bar{\nu})^k c(\mu,\bar{\nu}).$$

On the other hand, because the policy $\bar{\nu}$ results in infinite expected cost (from some initial state) when played against μ, some subsequence of $\sum_{k=0}^{t} [P(\mu, \bar{\nu})]^k c(\mu, \bar{\nu})$ must have a coordinate that tends to infinity. (The term involving x remains bounded because it is just x multiplied by the product of stochastic matrices.) This contradicts the above inequality. Thus, μ must be proper. □

4.2. The case where the maximizer's policy is fixed. By Assumption SSP there exists a proper policy for the minimizer. Thus, it is impossible that a single policy for the maximizer prolongs the game for *all* policies of the minimizer. Let us define $\tilde{x}(\pi_N)$ to be *the cost of the policy* $\pi_N \in \bar{N}$, as follows:

$$\tilde{x}(\pi_N) = \liminf_{t\to\infty} \min_{\pi_M \in \bar{M}} h^t_{\pi_M, \pi_N}, \tag{4.3}$$

where $\pi_N = \{\nu^0, \nu^1, \dots\}$. The cost of a stationary policy ν for the minimizer is denoted $\tilde{x}(\nu)$ and is computed according to equation (4.3), where $\pi_N = \{\nu, \nu, \dots\}$.

LEMMA 4.4. *For any $\nu \in N$, the following are true.*

1. *The cost $\tilde{x}(\nu)$ of ν is the unique fixed point of $\tilde{T}_\nu$ in $X = \{x \in R^n \mid x_1 = 0\}$.*
2. *$\tilde{x}(\nu) = \inf_{\pi_M \in \bar{M}} x(\pi_M, \nu)$.*
3. *We have $\tilde{T}^t_\nu(x) \to \tilde{x}(\nu)$ for all $x \in X$. If for all $\mu \in M$ the pair (μ, ν) terminates with probability one, then the convergence is linear.*

Proof. This follows directly from the theory of (one-player) stochastic shortest path problems. □

4.3. Main results for the game. We now establish the main results of the paper: the existence and characterization of a unique equilibrium solution, the convergence of value iteration, and the convergence of policy iteration.

PROPOSITION 4.5. *The operator T has a unique fixed point x^* on X.*

Proof. We begin by showing that T has at most one fixed point in X. Suppose x and x' are both fixed points of T in X. We can select $\mu \in M$ and $\mu' \in M$ such that $x = T(x) = T_\mu(x)$ and $x' = T(x') = T_{\mu'}(x')$. By Lemma 4.3, we have that μ and μ' are proper. Lemma 4.2 implies that $x = x(\mu)$ and $x' = x(\mu')$. Since μ' isn't necessarily optimal with respect to x in applying the T operator, we have from the monotonicity of T that $x = T^t(x) \le T^t_{\mu'}(x)$ for all $t > 0$. Thus, by Lemma 4.2, we have that $x \le \lim_{t\to\infty} T^t_{\mu'}(x) = x(\mu') = x'$. Similarly, $x' \le x$, which implies that $x = x'$ and that T has at most one fixed point in X.

To establish the existence of a fixed point, fix a proper policy $\mu \in M$ for the minimizer. (One exists thanks to Assumption SSP.) By Lemma 4.2, we have that $x(\mu) = T_\mu(x(\mu))$. Thus, $x(\mu) \ge T(x(\mu))$. Similarly, by fixing a stationary policy $\nu \in N$ for the maximizer, we obtain from Lemma 4.4 that $\tilde{x}(\nu) = \tilde{T}_\nu(\tilde{x}(\nu))$. Thus, $\tilde{x}(\nu) \le \tilde{T}(\tilde{x}(\nu)) = T(\tilde{x}(\nu))$. We now claim that $\tilde{x}(\nu) \le x(\mu)$. To see this, note that, for every $\pi_M \in \bar{M}$, $\pi_N \in \bar{N}$, and $t > 0$,

$$h^t_{\pi_M, \pi_N} \le \max_{\tilde{\pi}_N \in \bar{N}} h^t_{\pi_M, \tilde{\pi}_N}$$

and

$$h^t_{\pi_M, \pi_N} \ge \min_{\tilde{\pi}_M \in \bar{M}} h^t_{\tilde{\pi}_M, \pi_N},$$

where we have used the notation defined in (2.2). Thus, for any $\pi_N \in \bar{N}$ and for any $\pi_M \in \bar{M}$,

$$\min_{\tilde{\pi}_M \in \bar{M}} h^t_{\tilde{\pi}_M, \pi_N} \le \max_{\tilde{\pi}_N \in \bar{N}} h^t_{\pi_M, \tilde{\pi}_N}.$$

By taking the limit inferior of both sides with respect to t, we see that $\tilde{x}(\pi_N) \leq x(\pi_M)$ for all $\pi_N \in \bar{N}$ and $\pi_M \in \bar{M}$. In particular, $\tilde{x}(\nu) \leq x(\mu)$.

Using the monotonicity of T we have that

$$\tilde{x}(\nu) \leq T(\tilde{x}(\nu)) \leq T(x(\mu)) \leq x(\mu).$$

Again from the monotonicity of T, we obtain for all $t > 1$ that

$$\tilde{x}(\nu) \leq T^{t-1}(\tilde{x}(\nu)) \leq T^t(\tilde{x}(\nu)) \leq x(\mu).$$

Thus, the sequence $\{T^t(\tilde{x}(\nu))\}$ converges to a vector $x^\infty \in X$. From the continuity of T, we have that $x^\infty = T(x^\infty)$. Thus, T has a fixed point in X. □

PROPOSITION 4.6. *The unique fixed point $x^* = T(x^*)$ is the equilibrium cost of the stochastic shortest path game. There exist stationary policies $\mu^* \in M$ and $\nu^* \in N$ which achieve the equilibrium. Moreover, if $x \in X$, $\mu \in M$, and $\nu \in N$ are such that $x = T(x) = T_\mu(x) = \tilde{T}_\nu(x)$, then*

1. $x = x(\mu, \nu)$,
2. $x(\pi_M, \nu) \geq x(\mu, \nu) \quad \forall\, \pi_M \in \bar{M}$,
3. $x(\mu, \pi_N) \leq x(\mu, \nu) \quad \forall\, \pi_N \in \bar{N}$.

Proof. That there exists a unique fixed point $x^* = T(x^*)$ follows from the preceding proposition. Let $\mu^* \in M$ be such that $x^* = T(x^*) = T_{\mu^*}(x^*)$, and let $\nu^* \in N$ be such that $x^* = T(x^*) = \tilde{T}(x^*) = \tilde{T}_{\nu^*}(x^*)$. (Such policies exist thanks to Assumption R.) By Lemma 4.3, we have that μ^* is proper. Thus, by Lemma 4.2, we have that $x^* = x(\mu^*) = \sup_{\pi_N \in \bar{N}} x(\mu^*, \pi_N)$. Similarly, by Lemma 4.4, we have that $x^* = \tilde{x}(\nu^*) = \inf_{\pi_M \in \bar{M}} x(\pi_M, \nu^*)$. Combining these results we obtain

$$\inf_{\pi_M \in \bar{M}} \sup_{\pi_N \in \bar{N}} x(\pi_M, \pi_N) \leq x^* \leq \sup_{\pi_N \in \bar{N}} \inf_{\pi_M \in \bar{M}} x(\pi_M, \pi_N).$$

Since in general we have

$$\inf_{\pi_M \in \bar{M}} \sup_{\pi_N \in \bar{N}} x(\pi_M, \pi_N) \geq \sup_{\pi_N \in \bar{N}} \inf_{\pi_M \in \bar{M}} x(\pi_M, \pi_N)$$

(a statement of the minimax inequality), we obtain the following desired result:

$$\inf_{\pi_M \in \bar{M}} \sup_{\pi_N \in \bar{N}} x(\pi_M, \pi_N) = x^* = \sup_{\pi_N \in \bar{N}} \inf_{\pi_M \in \bar{M}} x(\pi_M, \pi_N). \qquad □$$

Lemma 4.1 implies that, when all stationary policies for the minimizer are proper, the iteration $x^{t+1} = T(x^t)$ converges linearly to the equilibrium cost x^* for all $\mathbf{0} \in X$. This follows from the contraction mapping principle. In the following proposition, we extend this result to the case where not all stationary policies for the minimizer are proper.

PROPOSITION 4.7. *For every $x \in X$, there holds*

$$\lim_{t \to \infty} T^t(x) = x^*, \tag{4.4}$$

where x^* is the unique equilibrium cost vector.

Proof. The uniqueness and existence of a fixed point for T was established in Proposition 4.5. Let x^* be the unique fixed point, and let $\mu^* \in M$ (proper) be such that $T(x^*) = T_{\mu^*}(x^*)$. Our objective is to show that $T^t(x) \to x^*$ for all $x \in X$. Let Δ be the vector with coordinates

$$\Delta_i = \begin{cases} 0 & \text{if } i = 1, \\ \delta & \text{if } i \neq 1, \end{cases} \tag{4.5}$$

where δ is some scalar. Let x^Δ be the unique vector in X satisfying $T_{\mu^*}(x^\Delta) = x^\Delta - \Delta$. (Such a vector exists because μ^* is proper, making the operator $T_{\mu^*}(\cdot) + \Delta$ a contraction.) Note that

$$\begin{aligned} x^\Delta &= T_{\mu^*}(x^\Delta) + \Delta \\ &= \max_{\nu \in N} [c(\mu^*, \nu) + P(\mu^*, \nu) x^\Delta] + \Delta \\ &= \max_{\nu \in N} [c(\mu^*, \nu) + \Delta + P(\mu^*, \nu) x^\Delta]. \end{aligned}$$

Thus, x^Δ is the cost of the fixed policy μ^* with the immediate transition cost $c(\mu^*, \cdot)$ replaced with $c(\mu^*, \cdot) + \Delta$. We have that

$$x^\Delta = T_{\mu^*}(x^\Delta) + \Delta \geq T_{\mu^*}(x^\Delta).$$

Thus, from the monotonicity of T_{μ^*} we have that for all $t > 0$

$$T^t_{\mu^*}(x^\Delta) \leq x^\Delta.$$

By taking the limit as $t \to \infty$, we see that $x(\mu^*) \leq x^\Delta$.

Now using the monotonicity of T and the fact that $x^* = x(\mu^*)$, we get

$$x^* = T(x^*) \leq T(x^\Delta) \leq T_{\mu^*}(x^\Delta) = x^\Delta - \Delta \leq x^\Delta.$$

Proceeding inductively, we get

$$x^* \leq T^t(x^\Delta) \leq T^{t-1}(x^\Delta) \leq x^\Delta.$$

Hence, $\{T^t(x^\Delta)\}$ is a monotonically decreasing sequence bounded below which converges to some $\tilde{x} \in X$. By continuity of the operator T, we must have that $\tilde{x} = T(\tilde{x})$. By the uniqueness of the fixed point of T, we have that $\tilde{x} = x^*$.

We now examine the convergence of the operator T^t applied to $x^* - \Delta$. Note that

$$x^* - \Delta = T(x^*) - \Delta \leq T(x^* - \Delta) \leq T(x^*) = x^*,$$

where the first inequality follows from the fact that $P(\mu, \nu)\Delta \leq \Delta$ for all $\mu \in M$ and $\nu \in N$. Once again monotonicity of T prevails, implying that $T^t(x^* - \Delta)$ is monotonically increasing and bounded above. From the continuity of T we have that $\lim_{t \to \infty} T^t(x^* - \Delta) = x^*$.

We saw earlier that $x^\Delta = T_{\mu^*}(x^\Delta) + \Delta$ and that $x^\Delta \geq x^*$. Then, from the monotonicity of T_{μ^*},

$$x^\Delta \geq T_{\mu^*}(x^*) + \Delta = x^* + \Delta.$$

Thus, for any $x \in X$, we can find $\delta > 0$ such that $x^* - \Delta \leq x \leq x^\Delta$. By the monotonicity of T, we then have

$$T^t(x^* - \Delta) \leq T^t(x) \leq T^t(x^\Delta) \quad \forall\, t \geq 1.$$

Taking limits, we see that $\lim_{t\to\infty} T^t(x) = x^*$. □

PROPOSITION 4.8. *Given a proper stationary policy $\mu^0 \in M$, we have that*

$$x(\mu^k) \to x^*,$$

where x^* is the unique equilibrium cost vector and $\{\mu^k\}$ is a sequence of policies (generated by policy iteration) such that $T(x(\mu^k)) = T_{\mu^{k+1}}(x(\mu^k))$ for all k.

Proof. Choose $\mu^1 \in M$ such that $T_{\mu^1}(x(\mu^0)) = T(x(\mu^0))$. (Assumption SSP implies that such an initial proper policy μ^0 exists.) We have $T_{\mu^1}(x(\mu^0)) = T(x(\mu^0)) \leq T_{\mu^0}(x(\mu^0)) = x(\mu^0)$. By Lemma 4.3, μ^1 is proper. By the monotonicity of T_{μ^1} and Lemma 4.2, we have that for all t

$$x(\mu^0) \geq T(x(\mu^0)) \geq T_{\mu^1}^{t-1}(x(\mu^0)) \geq T_{\mu^1}^{t}(x(\mu^0)).$$

Thus,

$$x(\mu^0) \geq T(x(\mu^0)) \geq \lim_{t\to\infty} T_{\mu^1}^{t}(x(\mu^0)) = x(\mu^1).$$

Applying this argument iteratively, we construct a sequence $\{\mu^k\}$ of proper policies such that

$$x(\mu^k) \geq T(x(\mu^k)) \geq x(\mu^{k+1}) \geq x^* \quad \forall\, k = 0, 1, \ldots\ . \tag{4.6}$$

Since $\{x(\mu^k)\}$ is monotonically decreasing and bounded below by x^*, we have that the entire sequence converges to some vector x^∞. From (4.6) and the continuity of T, we have that $x^\infty = T(x^\infty)$. Since x^* is the unique fixed point of T on X, we have that $x(\mu^k) \to x^*$. □

5. An example of pursuit and evasion.

Consider the following two-player game, played around a table with four corners. One player, the pursuer (who is actually the minimizer), is attempting to "catch" in minimum time the other player, the evader (who is the maximizer). The game evolves in stages where, in each stage, both players implement actions simultaneously. When the players are across from one another, they each decide (independently) whether to stay where they are, move one corner clockwise, or move one corner counter-clockwise. When the two players are adjacent to one another, they each decide (independently) whether to stay where they are, move toward the other's current location, or move away from the other's current location. The pursuer catches the evader only by arranging to land on the same corner of the table as the evader. (The possibility exists that, when they are adjacent, they can both move toward each other's current location. This does not result in the evader being caught "in midair.") The evader is slower than the pursuer in the sense that when the evader decides to change location, he succeeds in doing so only with probability $p \in (0, 1)$. (With probability $1 - p$, the evader will wind up not moving at all.) Thus, the pursuer can ultimately catch the evader, provided he implements an appropriate policy (such as "always move toward the present location of the evader"). On the other hand, there exist policies for the pursuer (such as "always stay put") which allow the maximizer to prolong the game indefinitely. This results in infinite cost (i.e., infinite capture time) to the pursuer.

This game fits into our framework for stochastic shortest path games. As described above there are three states: evader caught (state 1), players adjacent to one another (state 2), and players across from one another (state 3). Thus, $S = \{1, 2, 3\}$. Once the evader is caught the game is over, so state 1 serves as the terminal state, which is zero cost and absorbing.

In state two, when the players are adjacent, the players may move toward the other's location (action 1), stay where they are (action 2), or move away from the other's location (action 3). Thus, $A(2) = B(2) = \{1, 2, 3\}$. From the description of the problem given above, it is not hard to see that

$$\begin{aligned} p_{21}(u, v) &= u_1[(v_1 + v_3)(1 - p) + v_2] + u_2 v_1 p, \\ p_{22}(u, v) &= (u_1 + u_3)(v_1 + v_3)p + u_2[(v_1 + v_3)(1 - p) + v_2], \\ p_{23}(u, v) &= u_2 v_3 p + u_3[(v_1 + v_3)(1 - p) + v_2]. \end{aligned}$$

The expected transition cost functions $c_2(u, v)$ take on the value of one for all $u \in U(2)$ and $v \in V(2)$.

In state three (when the players are on opposite corners of the table), the players may move clockwise toward the other's current location (action 1), stay where they are (action 2), or move counter-clockwise toward the other's location (action 3). Thus, $A(3) = B(3) = \{1, 2, 3\}$. It is not hard to see that

$$\begin{aligned} p_{31}(u, v) &= u_1 v_3 p + u_3 v_1 p, \\ p_{32}(u, v) &= (u_1 + u_3)[(v_1 + v_3)(1 - p) + v_2] + u_2(v_1 + v_3)p, \\ p_{33}(u, v) &= u_1 v_1 p + u_2[(v_1 + v_3)(1 - p) + v_2] + u_3 v_3 p. \end{aligned}$$

The expected transition cost functions $c_3(u, v)$ take on the value of one for all $u \in U(3)$ and $v \in V(3)$.

We will show that the equilibrium value of this stochastic shortest path game is given by

$$x^* = \left(0, \frac{1}{1 - p}, \frac{2 - p}{1 - p}\right)'$$

and that equilibrium randomized strategies for the two players are given by $\mu^* \in M$ and $\nu^* \in N$ such that

$$\begin{aligned} \mu^*(2) &= (1, 0, 0)', \\ \nu^*(2) &= (v_1, 0, v_3)', \\ \mu^*(3) &= (u_1, 0, u_3)', \\ \nu^*(3) &= (0, 1, 0)', \end{aligned}$$

where v_1, v_3, u_1, and u_3 are nonnegative and $v_1 + v_3 = 1$ and $u_1 + u_3 = 1$. Thus, any probability vector $v \in V(2)$ such that $v_2 = 0$ forms an equilibrium strategy for the evader. In other words, as long as the evader chooses not to remain at his current location (when the two players are adjacent), any mixed decision (at state 2) for the evader is optimal. The pursuer does not have the same flexibility; his optimal mixed decision is deterministic: always move toward the evader. On the other hand, any probability vector $u \in U(3)$ such that $u_2 = 0$ forms an equilibrium strategy for the pursuer. In other words, as long as the pursuer decides to not stay at his current location (when the two players are across from one another), any mixed decision for the pursuer (at state 3) is optimal. This time, it is the evader's strategy which is inflexible. His optimal action is to stay at his current location. Thus, when both players play optimally, the game will always transition from state $i = 3$ to $i = 2$ in one stage. Happily, the equilibrium cost reflects this: $x_3^* = \frac{2-p}{1-p} = 1 + x_2^*$.

To verify that these are indeed equilibrium policies, we will show that $x^* = T(x^*) = T_{\mu^*}(x^*) = \tilde{T}_{\nu^*}(x^*)$. (Notice that the policy μ^* corresponds to one where the pursuer always decides to move in the direction of the current location of the evader. This policy is clearly proper. The desired result follows from Proposition 4.6.)

Let us first consider the case where the two players are adjacent (i.e., state 2). Let a general cost-to-go vector be given as $x = (0, x_2, x_3)' \in X$. (Shortly, we shall consider the case where $x = x^*$, as suggested above.) To evaluate the second element of $T(x)$, we must compute

$$\min_{u \in U(2)} \max_{v \in V(2)} u' G_2(x) v,$$

where the matrix $G_2(x)$ is computed as

$$G_2(x) = \begin{bmatrix} 1 + px_2 & 1 & 1 + px_2 \\ 1 + (1-p)x_2 & 1 + x_2 & 1 + (1-p)x_2 + px_3 \\ 1 + px_2 + (1-p)x_3 & 1 + x_3 & 1 + px_2 + (1-p)x_3 \end{bmatrix}.$$

In other words, the second element of $T(x)$ is evaluated as the value of the matrix game (in mixed strategies) defined by $G_2(x)$. It is well known that the equilibrium cost and equilibrium strategies for a matrix game are characterized as the optimal value and solutions to a particular linear program and its dual [12]. In particular,

$$\frac{1}{[T(x)]_2} = \begin{array}{l} \min e'\breve{v} \\ \text{subject to } \; G_2(x)\breve{v} \geq e, \; \breve{v} \geq 0, \end{array}$$

$$\frac{v^*}{[T(x)]_2} \in \begin{array}{l} \arg\min e'\breve{v} \\ \text{subject to } \; G_2(x)\breve{v} \geq e, \; \breve{v} \geq 0, \end{array}$$

where e is the vector of all ones in R^3 and v^* is an equilibrium strategy for the maximizer in the matrix game. We shall refer to the linear program above as the "primal" problem. The dual of the primal problem characterizes equilibrium strategies u^* for the minimizer of the matrix game, as follows:

$$\frac{u^*}{[T(x)]_2} \in \begin{array}{l} \arg\max e'\breve{u} \\ \text{subject to } \; G_2(x)'\breve{u} \leq e, \; \breve{u} \geq 0. \end{array}$$

Now consider $G_2(x^*)$ and define

$$\begin{aligned} \breve{u}^* = \mu^*(2)/x_2^* \; &= \; (1-p)\,(1,0,0)', \\ \breve{v}^* = \nu^*(2)/x_2^* \; &= \; (1-p)\,(v_1,0,v_3)'. \end{aligned}$$

It is straightforward to verify that $\breve{v}^*$ is feasible for the primal linear program and that $\breve{u}^*$ is feasible for the dual problem. Moreover, the primal cost corresponding to $\breve{v}^*$ is exactly $1-p$, just as the dual value of $\breve{u}^*$ is also exactly $1-p$. Thus, we have found a primal/dual feasible pair for which the primal cost equals the dual value. Then, according to the duality theorem of linear programming, $\breve{v}^*$ and $\breve{u}^*$ are primal/dual optimal and the optimal values of the primal and dual problems equal $1-p$, which is exactly $\frac{1}{x_2^*}$. This verifies that $x_2^* = [T(x^*)]_2$ and that $\mu^*(2)$ and $\nu^*(2)$ form an equilibrium pair of mixed decisions at state $2 \in S$.

Let us now consider the case where the two players are across from one another (i.e., state 3). To evaluate the third element of $T(x)$ for general $x \in X$, we must compute

$$\min_{u \in U(3)} \max_{v \in V(3)} u' G_3(x) v,$$

where $G_3(x)$ is a matrix computed as

$$G_3(x) = \begin{bmatrix} 1+(1-p)x_2+px_3 & 1+x_2 & 1+(1-p)x_2 \\ 1+px_2+(1-p)x_3 & 1+x_3 & 1+px_2+(1-p)x_3 \\ 1+(1-p)x_2 & 1+x_2 & 1+(1-p)x_2+px_3 \end{bmatrix}.$$

Thus, the third element of $T(x)$ is evaluated as the value of the matrix game defined by $G_3(x)$. As before, the solution to this matrix game can be computed by solving a primal/dual pair of linear programs, as follows:

$$\begin{aligned} &\min e'\breve{v} \\ &\text{subject to } \; G_3(x)\breve{v} \geq e, \; \breve{v} \geq 0, \end{aligned}$$

$$\begin{aligned} &\max e'\breve{u} \\ &\text{subject to } \; G_3(x)'\breve{u} \leq e, \; \breve{u} \geq 0. \end{aligned}$$

Now consider the primal and dual problems given by $G_3(x^*)$. Define

$$\begin{aligned} \breve{u}^* = \mu^*(3)/x_3^* &= \frac{1-p}{2-p}\,(u_1, 0, u_3)', \\ \breve{v}^* = \nu^*(3)/x_3^* &= \frac{1-p}{2-p}\,(0, 1, 0)'. \end{aligned}$$

Again, it is straightforward to verify that $\breve{v}$ and $\breve{u}$ form a feasible primal/dual pair where the primal cost of $\breve{v}$ equals the dual value of $\breve{u}$. Thus, by the duality theorem, $\breve{v}$ and $\breve{u}$ are primal/dual optimal. This time the optimal cost works out to be $\frac{1-p}{2-p}$, which is exactly $\frac{1}{x_3^*}$. This verifies that $x_3^* = [T(x^*)]_3$ and that $\mu^*(3)$ and $\nu^*(3)$ form an equilibrium pair of mixed decisions at state $3 \in S$.

Appendix. Proofs of lemmas. We collect here some useful but well-known results. We give proofs for completeness. We require Assumption R throughout.

The following lemmas summarize some important properties of the operators $T_{\mu\nu}$, T_μ, T, $\tilde{T}_\nu$, and $\tilde{T}$.

Lemma A.1 (monotonicity). *Suppose $x \in R^n$ and $x' \in R^n$ (or $x \in X$ and $x' \in X$) are such that $x \leq x'$ is componentwise. Then*

$$T_{\mu\nu}(x) \leq T_{\mu\nu}(x'), \quad \mu \in M, \nu \in N, \tag{A.1}$$

$$T_\mu(x) \leq T_\mu(x'), \quad \mu \in M, \tag{A.2}$$

$$T(x) \leq T(x'), \tag{A.3}$$

$$\tilde{T}_\nu(x) \leq \tilde{T}_\nu(x'), \quad \nu \in N, \tag{A.4}$$

$$\tilde{T}(x) \leq \tilde{T}(x'). \tag{A.5}$$

Proof. This proof is straightforward using the definitions of various "T"-operators. □

LEMMA A.2 (cost shifting). *For all $x \in R^n$, scalars $r \in R$, integers $t > 0$, and functions $\mu^k \in M$ and $\nu^k \in N$ for $k = 1, \dots, t$ we have*

$$(T_{\mu^1\nu^1}T_{\mu^2\nu^2}\cdots T_{\mu^t\nu^t})(x + r\cdot\mathbf{1}) = (T_{\mu^1\nu^1}T_{\mu^2\nu^2}\cdots T_{\mu^t\nu^t})(x) + r\cdot\mathbf{1}, \tag{A.6}$$

$$(T_{\mu^1}T_{\mu^2}\cdots T_{\mu^t})(x + r\cdot\mathbf{1}) = (T_{\mu^1}T_{\mu^2}\cdots T_{\mu^t})(x) + r\cdot\mathbf{1}, \tag{A.7}$$

$$(TT\cdots T)(x + r\cdot\mathbf{1}) = (TT\cdots T)(x) + r\cdot\mathbf{1}, \tag{A.8}$$

where $\mathbf{1} = (1, \dots, 1)' \in R^n$. The same relationships hold for T_μ, $T_{\mu\nu}$, $\tilde{T}_{nu}$, and $\tilde{T}$.

Proof. This follows by induction and by the definition of $T_{\mu\nu}$, T_μ, and T. □

LEMMA A.3 (continuity). *The mappings T, T_μ, $T_{\mu\nu}$, $\tilde{T}_{nu}$, and $\tilde{T}$ are continuous over R^n.*

Proof. Let x and x' be any two elements of R^n, and let $r = \|x - x'\|_\infty$, where $\|\cdot\|_\infty$ denotes the usual sup-norm (l_∞-norm) on X. Then we have

$$x - r\cdot\mathbf{1} \le x' \le x + r\cdot\mathbf{1},$$

where $\mathbf{1} = (1, \dots, 1)' \in X$. Lemmas A.1 and A.2 imply that

$$\begin{aligned} T(x) - r\cdot\mathbf{1} \le T(x') &\le T(x) + r\cdot\mathbf{1}, \\ T_\mu(x) - r\cdot\mathbf{1} \le T_\mu(x') &\le T_\mu(x) + r\cdot\mathbf{1}, \\ T_{\mu\nu}(x) - r\cdot\mathbf{1} \le T_{\mu\nu}(x') &\le T_\mu(x) + r\cdot\mathbf{1}. \end{aligned}$$

Therefore,

$$\begin{aligned} \|T(x) - T(x')\|_\infty &\le \|x - x'\|_\infty, \\ \|T_\mu(x) - T_\mu(x')\|_\infty &\le \|x - x'\|_\infty, \\ \|T_{\mu\nu}(x) - T_{\mu\nu}(x')\|_\infty &\le \|x - x'\|_\infty. \end{aligned}$$

Thus, T is continuous on R^n. Similar arguments hold for T_μ, $T_{\mu\nu}$, $\tilde{T}_{nu}$, and $\tilde{T}$. □

The remainder of this appendix examines finite-horizon dynamic games where at each stage the maximizer has access to the minimizer's decision. We show that minimax and maximin versions of these games can be solved in a straightforward manner through dynamic programming. In doing so, we prove several results relevant to the main body of this paper.

LEMMA A.4. *Let M, N, T, T_μ, and $\tilde{T}_\nu$ all be defined as in previous sections. Then, for any square matrix of nonnegative elements $\bar{P}$ and any $x \in X$, we have*

$$\begin{aligned} \min_{\mu\in M}\max_{\nu\in N} \bar{P}\left[c(\mu,\nu) + P(\mu,\nu)x\right] &= \bar{P}\min_{\mu\in M}\max_{\nu\in N}\left[c(\mu,\nu) + P(\mu,\nu)x\right] = \bar{P}T(x), \\ \max_{\nu\in N} \bar{P}\left[c(\mu,\nu) + P(\mu,\nu)x\right] &= \bar{P}\max_{\nu\in N}\left[c(\mu,\nu) + P(\mu,\nu)x\right] = \bar{P}T_\mu(x), \\ \min_{\mu\in M} \bar{P}\left[c(\mu,\nu) + P(\mu,\nu)x\right] &= \bar{P}\min_{\mu\in M}\left[c(\mu,\nu) + P(\mu,\nu)x\right] = \bar{P}\tilde{T}_\nu(x). \end{aligned}$$

Proof. It is sufficient to show that the first equation holds. The remaining equations follow as corollaries by redefining the control constraint sets for the minimizing and maximizing players as $\tilde{U}(i) = \{\mu(i)\}$ and $\tilde{V}(i, u) = \{\nu(i)\}$, respectively.

The ith component of $\bar{P}\left[c(\mu,\nu) + P(\mu,\nu)x\right]$ can be expressed as

$$\sum_{s=1}^{n} \bar{p}_{is} g_s(\mu(s), \nu(s)),$$

where $\bar{p}_{is}$ is the $(i \times s)$th component of $\bar{P}$ and $g_s(u,v) \overset{\triangle}{=} c_s(u,v) + \sum_{j=1}^{n} p_{sj}(u,v)x_j$ for $u \in U(s)$ and $v \in V(s)$.

Since the min and max are taken componentwise and since the elements of P are nonnegative, we have that

$$\begin{aligned}\min_{\mu\in M}\max_{\nu\in N}\sum_{s=1}^{n}\bar{p}_{is}g_s(\mu(s),\nu(s)) &= \min_{\mu\in M}\max_{v^1\in V(1),\dots,v^n\in V(n)}\sum_{s=1}^{n}\bar{p}_{is}g_s(\mu(s),v^s)\\ &= \min_{\mu\in M}\sum_{s=1}^{n}\bar{p}_{is}\max_{v^s\in V(s)} g_s(\mu(s),v^s).\end{aligned}$$

Similarly, because the elements of $\bar{P}$ are nonnegative,

$$\begin{aligned}\min_{\mu\in M}\sum_{s=1}^{n}\bar{p}_{is}\max_{v^s\in V(s)} g_s(\mu(s),v^s) &= \min_{u^1\in U(1),\dots,u^n\in U(n)}\sum_{s=1}^{n}\bar{p}_{is}\max_{v^s\in V(s)} g_s(u^s,v^s)\\ &= \sum_{s=1}^{n}\bar{p}_{is}\min_{u^s\in U(s)}\max_{v^s\in V(s)} g_s(u^s,v^s)\\ &= \sum_{s=1}^{n}\bar{p}_{is}[T(x)]_s.\end{aligned}$$

Since this same expression applies for all $i = 1,\dots,n$, the desired result holds. □

LEMMA A.5. *Let M, N, T, T_μ, and $\tilde{T}_\nu$ all be defined as in previous sections. Then, for any $x \in X$, we have*

$$\begin{aligned}\min_{\pi_M=\{\mu^0,\dots,\mu^t\}}\max_{\pi_N=\{\nu^0,\dots,\nu^t\}}\left[h^t_{\pi_M,\pi_N} + P(\mu^0,\nu^0)\cdots P(\mu^t,\nu^t)x\right] &= T^{t+1}(x),\\ \max_{\pi_N=\{\nu^0,\dots,\nu^t\}}\left[h^t_{\mu,\pi_N} + P(\mu,\nu^0)\cdots P(\mu,\nu^t)x\right] &= T^{t+1}_\mu(x),\\ \min_{\pi_M=\{\mu^0,\dots,\mu^t\}}\left[h^t_{\pi_M,\nu} + P(\mu^0,\nu)\cdots P(\mu^t,\nu)x\right] &= \tilde{T}^{t+1}_\nu(x),\end{aligned}$$

where μ and the μ^k are elements of M and ν and the ν^k are elements of N.

Proof. It is sufficient to show that the first equation holds. The remaining equations follow as corollaries by redefining the control constraint sets for the minimizing and maximizing players as $\tilde{U}(i) = \{\mu(i)\}$ and $\tilde{V}(i) = \{\nu(i)\}$, respectively.

Notice that

$$\begin{aligned}&\min_{\pi_M=\{\mu^0,\dots,\mu^t\}}\max_{\pi_N=\{\nu^0,\dots,\nu^t\}}\left[h^t_{\pi_M,\pi_N} + P(\mu^0,\nu^0)\cdots P(\mu^t,\nu^t)x\right]\\ &\quad= \min_{\pi_M}\max_{\pi_N}\left\{h^{t-1}_{\bar{\pi}_M,\bar{\pi}_N} + \bar{P}(\bar{\pi}_M,\bar{\pi}_N)\left[c(\mu^t,\nu^t) + P(\mu^t,\nu^t)x\right]\right\}\\ &\quad= \min_{\pi_M}\max_{\bar{\pi}_N}\left\{h^{t-1}_{\bar{\pi}_M,\bar{\pi}_N} + \max_{\nu^t}\bar{P}(\bar{\pi}_M,\bar{\pi}_N)\left[c(\mu^t,\nu^t) + P(\mu^t,\nu^t)x\right]\right\}\\ &\quad= \min_{\bar{\pi}_M}\min_{\mu^t}\max_{\bar{\pi}_N}\left\{h^{t-1}_{\bar{\pi}_M,\bar{\pi}_N} + \max_{\nu^t}\bar{P}(\bar{\pi}_M,\bar{\pi}_N)\left[c(\mu^t,\nu^t) + P(\mu^t,\nu^t)x\right]\right\}\\ &\quad\geq \min_{\bar{\pi}_M}\max_{\bar{\pi}_N}\min_{\mu^t}\left\{h^{t-1}_{\bar{\pi}_M,\bar{\pi}_N} + \max_{\nu^t}\bar{P}(\bar{\pi}_M,\bar{\pi}_N)\left[c(\mu^t,\nu^t) + P(\mu^t,\nu^t)x\right]\right\}\\ &\quad= \min_{\bar{\pi}_M}\max_{\bar{\pi}_N}\left\{h^{t-1}_{\bar{\pi}_M,\bar{\pi}_N} + \min_{\mu^t}\max_{\nu^t}\bar{P}(\bar{\pi}_M,\bar{\pi}_N)\left[c(\mu^t,\nu^t) + P(\mu^t,\nu^t)x\right]\right\},\end{aligned}$$

where

$$\bar{\pi}_M \overset{\triangle}{=} \{\mu^0, \dots, \mu^{t-1}\}, \qquad \bar{\pi}_N \overset{\triangle}{=} \{\nu^0, \dots, \nu^{t-1}\},$$

and $\bar{P}(\bar{\pi}_M, \bar{\pi}_N) \overset{\triangle}{=} P(\mu^0, \nu^0) \cdots P(\mu^{t-1}, \nu^{t-1})$. (The inequality follows from the minimax inequality.)

We now prove the reverse relationship. First, we claim there exists a policy $\bar{\mu} \in M$ such that

$$\min_{\mu^t \in M} \max_{\nu^t \in N} \bar{P}(\bar{\pi}_M, \bar{\pi}_N)[c(\mu^t, \nu^t) + P(\mu^t, \nu^t)x] = \max_{\nu^t \in N} \bar{P}(\bar{\pi}_M, \bar{\pi}_N)[c(\bar{\mu}, \nu^t) + P(\bar{\mu}, \nu^t)x].$$

To see this, notice that

$$\begin{aligned} &\min_{\mu_t \in M} \max_{\nu_t \in N} \bar{P}(\bar{\pi}_M, \bar{\pi}_N) \left[c(\mu_t, \nu_t) + P(\mu_t, \nu_t)x\right] \\ &\qquad = \bar{P}(\bar{\pi}_M, \bar{\pi}_N) \min_{\mu_t \in M} \max_{\nu_t \in N} \left(c(\mu_t, \nu_t) + P(\mu_t, \nu_t)x\right) \\ &\qquad = \bar{P}(\bar{\pi}_M, \bar{\pi}_N) \max_{\nu_t \in N} \left(c(\bar{\mu}, \nu_t) + P(\bar{\mu}, \nu_t)x\right) \\ &\qquad = \max_{\nu_t \in N} \bar{P}(\bar{\pi}_M, \bar{\pi}_N) \left[c(\bar{\mu}, \nu_t) + P(\bar{\mu}, \nu_t)x\right], \end{aligned}$$

where the first and last equalities follow from the preceding lemma and $\bar{\mu}$ is the minimax solution to $\min_{\mu_t \in M} \max_{\nu_t \in N} \left(c(\mu_t, \nu_t) + P(\mu_t, \nu_t)x\right)$. This completes the proof of our claim. Thus,

$$\begin{aligned} &\min_{\bar{\pi}_M} \min_{\mu^t} \max_{\bar{\pi}_N} \left\{ h^{t-1}_{\bar{\pi}_M, \bar{\pi}_N} + \max_{\nu^t} \bar{P}(\bar{\pi}_M, \bar{\pi}_N) \left[c(\mu^t, \nu^t) + P(\mu^t, \nu^t)x\right] \right\} \\ &\quad = \min_{\bar{\pi}_M} \max_{\bar{\pi}_N} \left\{ h^{t-1}_{\bar{\pi}_M, \bar{\pi}_N} + \min_{\mu^t} \max_{\nu^t} \bar{P}(\bar{\pi}_M, \bar{\pi}_N) \left[c(\mu^t, \nu^t) + P(\mu^t, \nu^t)x\right] \right\} \\ &\quad \le \min_{\bar{\pi}_M} \max_{\bar{\pi}_N} \left\{ h^{t-1}_{\bar{\pi}_M, \bar{\pi}_N} + \max_{\nu^t} \bar{P}(\bar{\pi}_M, \bar{\pi}_N) \left[c(\bar{\mu}, \nu^t) + P(\bar{\mu}, \nu^t)x\right] \right\} \\ &\quad = \min_{\bar{\pi}_M} \max_{\bar{\pi}_N} \left\{ h^{t-1}_{\bar{\pi}_M, \bar{\pi}_N} + \min_{\mu^t} \max_{\nu^t} \bar{P}(\bar{\pi}_M, \bar{\pi}_N) \left[c(\mu^t, \nu^t) + P(\mu^t, \nu^t)x\right] \right\}. \end{aligned}$$

Combining the preceding inequalities, we see that

$$\begin{aligned} &\min_{\pi_M} \max_{\pi_N} \left[h^t_{\pi_M, \pi_N} + P(\mu^0, \nu^0) \cdots P(\mu^t, \nu^t)x\right] \\ &\quad = \min_{\bar{\pi}_M} \max_{\bar{\pi}_N} \left\{ h^{t-1}_{\bar{\pi}_M, \bar{\pi}_N} + \min_{\mu^t} \max_{\nu^t} \bar{P}(\bar{\pi}_M, \bar{\pi}_N) \left[c(\mu^t, \nu^t) + P(\mu^t, \nu^t)x\right] \right\} \\ &\quad = \min_{\bar{\pi}_M} \max_{\bar{\pi}_N} \left\{ h^{t-1}_{\bar{\pi}_M, \bar{\pi}_N} + \bar{P}(\bar{\pi}_M, \bar{\pi}_N) \min_{\mu^t} \max_{\nu^t} \left[c(\mu^t, \nu^t) + P(\mu^t, \nu^t)x\right] \right\} \\ &\quad = \min_{\bar{\pi}_M} \max_{\bar{\pi}_N} \left[h^{t-1}_{\bar{\pi}_M, \bar{\pi}_N} + P(\mu^0, \nu^0) \cdots P(\mu^{t-1}, \nu^{t-1}) T(x)\right], \end{aligned}$$

where the second inequality follows from Lemma A.4.

Mathematical induction, repeating the same argument above, gives the desired result. □

LEMMA A.6. *Let M, N, and $\tilde{T}$ all be defined as in previous sections. Then, for any square matrix with nonnegative elements $\bar{P}$ and any $x \in X$,*

$$\max_{\nu \in N} \min_{\mu \in M} \bar{P} \left[c(\mu,\nu) + P(\mu,\nu)x \right] = \bar{P} \max_{\nu \in N} \min_{\mu \in M} \left[c(\mu,\nu) + P(\mu,\nu)x \right] = \bar{P}\tilde{T}(x).$$

Proof. The proof of this lemma is exactly analogous to that given for Lemma A.4. The interchange of the max and min has no bearing on the logical flow of the argument. □

LEMMA A.7. *Let M, N, and $\tilde{T}$ all be defined as in previous sections. Then, for any $x \in X$,*

$$\max_{\pi_n=\{\nu^0,\dots,\nu^t\}} \min_{\pi_M=\{\mu^0,\dots,\mu^t\}} \left[h^t_{\pi_M,\pi_N} + P(\mu^0,\nu^0)\cdots P(\mu^t,\nu^t)x \right] \quad = \quad \tilde{T}^{t+1}(x),$$

where the μ^k are elements of M and the ν^k are elements of N.

Proof. The proof of this is symmetrical to that given for Lemma A.5. □

Using the fact that $T(x) = \tilde{T}(x)$ (under Assumption R), we obtain

$$\begin{aligned}
&\min_{\pi_M=\{\mu^0,\dots,\mu^t\}} \max_{\pi_N=\{\nu^0,\dots,\nu^t\}} \left[h^t_{\pi_M,\pi_N} + P(\mu^0,\nu^0)\cdots P(\mu^t,\nu^t)x+ \right] \\
&\qquad = T^{t+1}(x) \\
&\qquad = \tilde{T}^{t+1}(x) \\
&\qquad = \max_{\pi_N=\{\nu^0,\dots,\nu^t\}} \min_{\pi_M=\{\mu^0,\dots,\mu^t\}} \left[h^t_{\pi_M,\pi_N} + P(\mu^0,\nu^0)\cdots P(\mu^t,\nu^t)x \right].
\end{aligned}$$

Thus, for finite-horizon games (with or without a terminal state), an equilibrium cost exists and can be found via dynamic programming iterations.

Acknowledgments. Our proof of Lemma 4.1 was inspired by an argument by John Tsitsiklis for a similar result in one-player stochastic shortest path problems. We would like to thank our anonymous SIAM reviewers who, through their persistence, have helped us to find the shortest path to establishing our results.

FULLY COUPLED FORWARD-BACKWARD STOCHASTIC DIFFERENTIAL EQUATIONS AND APPLICATIONS TO OPTIMAL CONTROL[*]

SHIGE PENG[†] AND ZHEN WU[†]

Abstract. Existence and uniqueness results of fully coupled forward-backward stochastic differential equations with an arbitrarily large time duration are obtained. Some stochastic Hamilton systems arising in stochastic optimal control systems and mathematical finance can be treated within our framework.

Key words. stochastic differential equations, Hamilton system, stochastic optimal control, stochastic analysis

1. Introduction.

Let $(\Omega, \mathcal{F}, P)$ be a probability space, and let $\{B_t\}_{t\geq 0}$ be a d-dimensional Brownian motion in this space. We denote the natural filtration of this Brownian motion by $\mathcal{F}_t$. In this paper, we consider the following fully coupled forward-backward stochastic differential equation (FBSDE):

$$\begin{aligned} x_t &= a + \int_0^t b(s, x_s, y_s, z_s)ds + \int_0^t \sigma(s, x_s, y_s, z_s)dB_s, \\ y_t &= \Phi(x_T) + \int_t^T f(s, x_s, y_s, z_s)ds - \int_t^T z_s dB_s, \quad t \in [0, T], \end{aligned}$$

where (x, y, z) takes values in $\mathbf{R}^n \times \mathbf{R}^m \times \mathbf{R}^{m\times d}$, and b, and σ, and f are mappings with appropriate dimensions which are, for each fixed (x, y, z), $\mathcal{F}_t$-progressively measurable. We assume that they are Lipschitz with respect to (x, y, z); $T > 0$ is an arbitrarily prescribed number and the time interval is called the *time duration.* We look for a triple of $\mathcal{F}_t$-adapted processes (x_s, y_s, z_s) satisfying this equation.

A special situation of this problem is the well-known forward and backward ordinary differential equations (FBODEs):

$$\begin{aligned} \dot{x}(t) &= \overline{b}(x(t), y(t)), \\ -\dot{y}(t) &= \overline{f}(x(t), y(t)), \\ x(0) &= a, \quad y(T) = \overline{\Phi}(X(T)). \end{aligned}$$

The so-called two-point boundary problem for the second-order ODE is a special setting of this problem. There exist many examples in FBODE showing that, even if the uniform Lipschitz condition is imposed for all coefficients $\overline{b}$, $\overline{f}$, and $\overline{g}$, the existence and/or uniqueness of this ODE (with an arbitrarily large time duration) may fail.

One of the few types of such equations which is well understood is the Hamiltonian system motivated by the problems of classical variation method as well as the

maximum principle in optimal control problems (see Pontryagin et al. [Pon]). For the linear deterministic case, see Kalman [Ka] for the motivation of control problems in linear quadratic optimal regulators. Parallel to this deterministic situation, Bismut [Bis] obtained stochastic Hamiltonian systems, a kind of extension of the above Hamiltonian systems, as well as that of the Pontryagin's maximum principle (see also Kushner [Ku], Bensoussan [Ben], Haussmann [Hau], Peng [P1]). The corresponding linear case was also discussed.

Recently Antonelli gave a counterexample (see [A]) showing that the Lipschitz condition is not enough for the existence of FBSDE in an arbitrarily large time duration. It is clear that more assumptions are essentially needed.

An interesting problem is, What is the more suitable setting of the above stochastic Hamiltonian problems for which the solution exists and is unique? Is the background of optimization problem necessary? Is the constraint $m = n$ necessary?

In this paper we present a probabilistic method to treat a large kind of FBSDE with an arbitrarily prescribed time duration. Many problems like the above-mentioned FBODE and FBSDE are special situations of our setting. It is due to a new observation: for a large kind of FBSDE raised in stochastic control systems, mathematical finance, and other applied mathematics, the coefficients f, b, and σ are G-monotone, i.e., there exists a nondegenerate $m \times n$-matrix G such that, for each fixed (ω, t), the mapping

$$A(x,y,z) \overset{def}{=} \begin{pmatrix} -G^T f \\ Gb \\ G\sigma \end{pmatrix} (x,y,z): \quad R^{n+m+m\times d} \longrightarrow R^{n+m+m\times d}$$

is monotonous in (x, y, z) in the sense of (H2.2) in section 2. In this case, in order to obtain the a priori estimate for the difference of two solutions $(\hat{x}, \hat{y}, \hat{z})$, the right method is not to apply Itô's formula to $|\hat{x}_t|^2$ and $|\hat{y}_t|^2$, but to $\langle G\hat{x}_{t,}\hat{y}_t\rangle$. With this observation we succeed in obtaining the existence and uniqueness theorem under the G-monotone assumptions of A and Φ. Stochastic Hamiltonian systems introduced by Bismut [Bis] (see also Bensoussan [Ben]) can be treated as a special case.

It has been observed by the first author (see [P3]) that, coupled with a forward SDE, i.e., a classical SDE of Itô's type, the backward stochastic differential equation (BSDE) gives a probabilistic interpretation for a large kind of (systems of) second-order quasi-linear partial differential equations. This naturally generalizes the well-known Feynman–Kac formula to nonlinear case (see also [PP1], [P2], [PP2], [P4], [EPQ], [EQ], etc. for further developments in this direction).

Several major progressions have been made in the direction of fully coupled FBSDEs (see [P5], [A], [MPY]) and applications to mathematical finance (see [DE], [DMY]). It now becomes more clear that certain important problems in mathematical economics and mathematical finance, especially in the optimization problem, are formulated to be FBSDEs.

To our knowledge, actually there exist two methods in the study of FBSDEs. The first one is purely probabilistic (see Peng [P5], Antonelli [A]). Their main idea was to apply Itô's formula to $|\hat{x}|^2$ and $|\hat{y}|^2$ and then to construct a contraction mapping, where $(\hat{x}, \hat{y})$ stands for the difference of two solutions (x, y) and (x', y').

This method may be regarded as a sort of direct extension of Picard's iteration (see [A], [P3]). This was shown to be successful in treating stochastic differential equations (SDEs) of Itô's type as well as BSDEs, but the application of these techniques to FBSDEs is limited: one can only obtain the local existence and uniqueness results;

i.e., the time duration $[0, T]$ on which the solutions exist (without explosion) has to be sufficiently small.

The second method concerns a kind of "four-steps scheme" approach (see Ma, Protter, and Yong [MPY] and Duffie, Ma, and Yong [DMY]). This method may be regarded as a sort of combination of the methods of partial differential equation and probability or stochastic optimal control. With this method those authors have successfully obtained the results of existence and uniqueness of FBSDE in an arbitrarily prescribed time duration, but they need the equation to be nondegenerate in the sense that the matrix-valued coefficient σ is nondegenerate. On the other hand, as it is well known, the partial differential equation approach cannot be used to treat the case where the coefficients themselves are randomly disturbed, which is often the case in the practical situation, e.g., in financial markets.

The advantages of our method are as follows: (i) the assumptions are very easy to verify. (ii) Many existing problems of FBSDE in optimal control and Hamiltonian systems satisfy these assumptions. (iii) We do not need to impose the nondegenerate condition on the diffusion term σ; the coefficients are allowed to be randomly perturbed (e.g., $\Phi = \Phi(\omega, x)$, etc.).

This paper improves the recent result of [HP] in the following points: (i) One of typical case; i.e., the existence and uniqueness of a Hamiltonian system related to the cost function satisfying some convex conditions such as the linear quadratic optimal control problem under classical condition is a simple corollary of our result. In [HP], a similar result can also be obtained, but the assumption will become unreasonably strong. (ii) The result in [HP] is limited to the case where x and y in FBSDE take the same dimension; i.e., $m = n$ in our paper. This paper successfully removes this heavy restriction. (iii) Even in the case where $m = n$, our monotone assumptions are clearly weaker and the corresponding conclusions are stronger. An example is given in section 3 to show that some stochastic Hamiltonian systems arising from differential games are also G-monotone. (iv) In section 2, a counterexample is given showing that, without our monotone conditions, the existence result of FBSDE in an arbitrarily large time duration does not hold true.

This paper is organized as follows: In the next section we present our main result about the existence and uniqueness of FBSDE under the monotone conditions. Several examples of FBSDE related to stochastic optimal control and differential games problems are given in section 3. We also obtain the existence and uniqueness of an FBSDE corresponding linear quadratic optimal control problem in this section.

2. FBSDE: Existence and uniqueness. We consider the following FBSDEs:

$$\begin{aligned} dx_t &= b(t, x_t, y_t, z_t)dt + \sigma(t, x_t, y_t, z_t)dB_t, \\ -dy_t &= f(t, x_t, y_t, z_t)dt - z_t dB_t, \\ x_0 &= a, \quad y_T = \Phi(x_T), \end{aligned} \tag{2.1}$$

where

$$\begin{aligned} &b : \Omega \times [0, T] \times \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^{m\times d} \longrightarrow \mathbb{R}^n, \\ &\sigma : \Omega \times [0, T] \times \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^{m\times d} \longrightarrow \mathbb{R}^{n\times d}, \\ &f : \Omega \times [0, T] \times \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^{m\times d} \longrightarrow \mathbb{R}^m, \\ &\Phi : \Omega \times \mathbb{R}^n \longrightarrow \mathbb{R}^m. \end{aligned}$$

We are given an $m \times n$ full-rank matrix G. We use the notations

$$u = \begin{pmatrix} x \\ y \\ z \end{pmatrix}, \quad A(t,u) = \begin{pmatrix} -G^T f \\ Gb \\ G\sigma \end{pmatrix}(t,u),$$

where $G\sigma = (G\sigma_1 \cdots G\sigma_d)$. We use the usual inner product and Euclidean norm in $\mathbb{R}^n$, $\mathbb{R}^m$, and $\mathbb{R}^{m\times d}$.

Definition 2.1. *A triple of process (X,Y,Z): $\Omega \times [0,T] \longrightarrow \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^{m\times d}$ is called an adapted solution of FBSDE* (2.1) *if $(X,Y,Z) \in M^2(0,T;\mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^{m\times d})$ and it satisfies FBSDE* (2.1).

We assume that

$$\text{(H2.1)} \qquad \begin{cases} \text{(i) } A(t,u) \textit{ is uniformly Lipschitz with respect to } u; \\ \text{(ii) } \textit{for each } u,\ A(\cdot,u) \textit{ is in } M^2(0,T); \\ \text{(iii) } \Phi(x) \textit{ is uniformly Lipschitz with respect to } x \in \mathbb{R}^n; \\ \text{(iv) } \textit{for each } x,\ \Phi(x) \textit{ is in } L^2(\Omega,\mathcal{F}_T,\mathbf{P}). \end{cases}$$

The following monotone conditions are our main assumptions:

$$\text{(H2.2)} \qquad \begin{aligned} &\langle A(t,u) - A(t,\overline{u}), u - \overline{u}\rangle \le -\beta_1 |G\widehat{x}|^2 - \beta_2 |G^T\widehat{y}|^2, \\ &\langle \Phi(x) - \Phi(\overline{x}), G(x-\overline{x})\rangle \ge 0 \\ &\forall u = (x,y,z), \quad \overline{u} = (\overline{x},\overline{y},\overline{z}), \quad \widehat{x} = x - \overline{x}, \quad \widehat{y} = y - \overline{y}, \quad \widehat{z} = z - \overline{z}, \end{aligned}$$

where β_1 and β_2 are given nonnegative constants with $\beta_1 + \beta_2 > 0$. Moreover we have $\beta_1 > 0$ (resp., $\beta_2 > 0$) when $m > n$ (resp., $n > m$).

Our first result of this section is the following uniqueness theorem.

Theorem 2.2. *We assume* (H2.1) *and* (H2.2). *Then FBSDE* (2.1) *has at most one adapted solution.*

Proof. Let $u_s = (x_s, y_s, z_s)$ and $u'_s = (x'_s, y'_s, z'_s)$ be two solutions of (2.1). We set $\widehat{u} = (x - x', y - y', z - z') = (\widehat{x},\widehat{y},\widehat{z})$. We use Itô's formula applied to $\langle G\widehat{x}_s, \widehat{y}_s\rangle$:

$$\begin{aligned} \mathbb{E}\langle \Phi(x_T) - \Phi(x'_T), G\widehat{x}_T\rangle - \mathbb{E}\langle \widehat{y}_t, G\widehat{x}_t\rangle &= \mathbb{E}\int_t^T \langle A(s,u_s) - A(s,u'_s), \widehat{u}_s\rangle ds \\ &\le -\beta_1 \mathbb{E}\int_t^T \langle G\widehat{x}_s, G\widehat{x}_s\rangle ds - \beta_2 \mathbb{E}\int_t^T \langle G^T\widehat{y}_s, G^T\widehat{y}_s\rangle ds. \end{aligned}$$

This with the monotone of Φ and A implies

$$\beta_1 \mathbb{E}\int_0^T \langle G\widehat{x}_s, G\widehat{x}_s\rangle ds + \beta_2 \mathbb{E}\int_0^T \langle G^T\widehat{y}_s, G^T\widehat{y}_s\rangle ds \le 0.$$

We first treat the case where $m > n$. In this case $\beta_1 > 0$, then $\langle G\widehat{x}_s, G\widehat{x}_s\rangle \equiv 0$. We have $\widehat{x}_s \equiv 0$. Thus $x_s \equiv x'_s$. In particular, $\Phi(x_T) \equiv \Phi(x'_T)$. Thus, from the uniqueness of BSDE, it follows that $y_s \equiv y'_s$ and $z_s \equiv z'_s$.

We now discuss the second case where $m < n$. In this case $\beta_2 > 0$, then $\langle G^T\widehat{y}_s, G^T\widehat{y}_s\rangle \equiv 0$. We have $y_s \equiv y'_s$. We apply Itô's formula to $|\widehat{y}_s|^2 \equiv 0$. It follows that $\int_0^T |z_s - z'_s|^2 ds = 0$. Thus $z_s \equiv z'_s$. Finally, from the uniqueness of Itô's SDE it follows that $x_s \equiv x'_s$. Similarly to the above two cases, the result can be obtained easily in the case $m = n$. □

We now give an existence result of FBSDE (2.1) for a special case where Φ does not depend on x, i.e., $\Phi(x) \equiv \xi$.

THEOREM 2.3. *We assume* $y_T = \xi$, $\xi \in L^2(\Omega, \mathcal{F}_T, \mathbf{P})$ *and* (H2.1), (H2.2). *Then there exists a unique triple* $u_s = (x_s, y_s, z_s), s \in [0, T]$ *satisfying equations* (2.1).

The uniqueness is an immediate consequence of Theorem 2.2.

The proof of the existence is a combination of the above technique and an a priori estimate technique introduced in [P3]. We first need the following two lemmas. Consider the following family of FBSDEs parametrized by $\alpha \in [0, 1]$:

$$\begin{aligned} dx_t^\alpha &= \left[(1-\alpha)\beta_2(-G^T y_t^\alpha) + \alpha b(t, u_t^\alpha) + \phi_t\right] dt \\ &\quad + \left[(1-\alpha)\beta_2(-G^T z_t^\alpha) + \alpha\sigma(t, u_t^\alpha) + \psi_t\right] dB_t, \\ -dy_t^\alpha &= [(1-\alpha)\beta_1 G x_t^\alpha + \alpha f(t, u_t^\alpha) + \gamma_t]\, dt - z_t^\alpha dB_t, \\ x_0^\alpha &= a, \qquad y_T^\alpha = \xi, \end{aligned} \tag{2.2}$$

where ϕ, ψ, and γ are given processes in $M^2(0, T)$ with values in $\mathbb{R}^n$, $\mathbb{R}^{n\times d}$, and $\mathbb{R}^m$, resp. Clearly, when $\alpha = 1$ the existence of the solution of (2.2) implies that of (2.1) for $y_T \equiv \xi$. The following lemma gives an a priori estimate for the "existence interval" of (2.2) with respect to $\alpha \in [0, 1]$.

LEMMA 2.4. *We assume* (H2.1) *and* (H2.2). *Then there exists a positive constant* δ_0 *such that if, a priori, for an* $\alpha_0 \in [0, 1)$ *there exists a solution* $(x^{\alpha_0}, y^{\alpha_0}, z^{\alpha_0})$ *of* (2.2), *then for each* $\delta \in [0, \delta_0]$ *there exists a solution* $(x^{\alpha_0+\delta}, y^{\alpha_0+\delta}, z^{\alpha_0+\delta})$ *of* (2.2) *for* $\alpha = \alpha_0 + \delta$.

Proof. Since for each $\phi \in M^2(0, T; \mathbb{R}^n)$, $\gamma \in M^2(0, T; \mathbb{R}^m)$, $\psi \in M^2(0, T; \mathbb{R}^{n\times d})$, $\alpha \in [0, 1)$ there exists a (unique) solution of (2.2), thus, for each triple

$$u_s = (x_s, y_s, z_s) \in M^2(0, T; \mathbb{R}^{n+m+m\times d})$$

there exists a unique triple $U_s = (X_s, Y_s, Z_s) \in M^2(0, T; \mathbb{R}^{n+m+m\times d})$ satisfying the following FBSDE:

$$\begin{aligned} dX_t &= \left[(1-\alpha_0)\beta_2(-G^T Y_t) + \alpha_0 b(t, U_t) + \delta(\beta_2 G^T y_t + b(t, u_t)) + \phi_t\right] dt \\ &\quad + \left[(1-\alpha_0)\beta_2(-G^T Z_t) + \alpha_0\sigma(t, U_t) + \delta(\beta_2 G^T z_t + \sigma(t, u_t)) + \psi_t\right] dB_t, \\ -dY_t &= [(1-\alpha_0)\beta_1 G X_t + \alpha_0 f(t, U_t) + \delta(-\beta_1 G x_t + f(t, u_t)) + \gamma_t]\, dt - Z_t dB_t, \\ X_0 &= a, \qquad Y_T = \xi. \end{aligned}$$

We are going to prove that the mapping defined by

$$I_{\alpha_0+\delta}(u) = U : M^2(0, T; \mathbb{R}^{n+m+m\times d}) \to M^2(0, T; \mathbb{R}^{n+m+m\times d})$$

is a contraction.

Let $u' = (x', y', z') \in M^2(0, T; \mathbb{R}^{n+m+m\times d})$, and let $U' = (X', Y', Z') = I_{\alpha_0+\delta}(u')$. We set

$$\widehat{u} = (\widehat{x}, \widehat{y}, \widehat{z}) = (x - x', y - y', z - z'), \quad \widehat{U} = (\widehat{X}, \widehat{Y}, \widehat{Z}) = (X - X', Y - Y', Z - Z').$$

Using Itô's formula applied to $\langle G\widehat{X}_s, \widehat{Y}_s\rangle$ it yields

$$\begin{aligned}0 &= \mathbb{E}\int_0^T \langle \alpha_0(A(s,U_s)-A(s,U'_s)), \widehat{U}_s\rangle ds\\ &- (1-\alpha_0)\mathbb{E}\int_0^T (\beta_1\langle G\widehat{X}_s, G\widehat{X}_s\rangle + \beta_2\langle G^T\widehat{Y}_s, G^T\widehat{Y}_s\rangle + \beta_2\langle G^T\widehat{Z}_s, G^T\widehat{Z}_s\rangle)ds\\ &+ \delta\mathbb{E}\int_0^T (\beta_1\langle G\widehat{X}_s, G\widehat{x}_s\rangle + \beta_2\langle G^T\widehat{Y}_s, G^T\widehat{y}_s\rangle + \beta_2\langle G^T\widehat{Z}_s, G^T\widehat{z}_s\rangle\\ &+ \langle \widehat{X}_s, -G^T\bar{f}_s\rangle + \langle G^T\widehat{Y}_s, \bar{b}_s\rangle + \langle \widehat{Z}_s, G\bar{\sigma}_s\rangle)ds,\end{aligned}$$

where

$$\bar{f}_s = f(s,u_s) - f(s,u'_s), \quad \bar{b}_s = b(s,u_s) - b(s,u'_s), \quad \bar{\sigma}_s = \sigma(s,u_s) - \sigma(s,u'_s).$$

From (H2.1) and (H2.2), we can get

$$\mathbb{E}\int_0^T \left(\beta_1\langle G\widehat{X}_s, G\widehat{X}_s\rangle + \beta_2\langle G^T\widehat{Y}_s, G^T\widehat{Y}_s\rangle\right) ds \le \delta C_1\mathbb{E}\int_0^T \left(|\widehat{u}_s|^2 + |\widehat{U}_s|^2\right) ds.$$

On the other hand, since X and X' are solutions of SDE of Itô's type, applying the usual technique, the estimates for the difference $\widehat{X} = X - X'$ are obtained by

$$\sup_{0\le s\le T} \mathbb{E}|\widehat{X}_s|^2 \le C_1\delta\mathbb{E}\int_0^T |\widehat{u}_s|^2 ds + C_1\mathbb{E}\int_0^T \left(|\widehat{Y}_s|^2 + |\widehat{Z}_s|^2\right) ds,$$

$$\mathbb{E}\int_0^T |\widehat{X}_s|^2 ds \le C_1T\delta\mathbb{E}\int_0^T |\widehat{u}_s|^2 ds + C_1T\mathbb{E}\int_0^T \left(|\widehat{Y}_s|^2 + |\widehat{Z}_s|^2\right) ds.$$

Similarly, for the difference of the solutions $(\widehat{Y}, \widehat{Z}) = (Y - Y', Z - Z')$, we apply the usual technique to the BSDE:

$$\mathbb{E}\int_0^T \left(|\widehat{Y}_s|^2 + |\widehat{Z}_s|^2\right) ds \le C_1\delta\mathbb{E}\int_0^T |\widehat{u}_s|^2 ds + C_1\mathbb{E}\int_0^T |\widehat{X}_s|^2 ds.$$

Here the constant C_1 depends on the Lipschitz constants as well as G, β_1, β_2, and T. Using Itô's formula to $|\widehat{Y}_s|^2$ to the BSDE once more it yields

$$\begin{aligned}&|\widehat{Y}_0|^2 + \mathbb{E}\int_0^T |\widehat{Z}_s|^2 ds\\ &= \mathbb{E}\int_0^T 2\widehat{Y}_s[\alpha_0(f(s,U_s) - f(s,U'_s)) + (1-\alpha_0)\beta_1 G\widehat{X}_s + \delta\bar{f}_s - \delta\beta_1 G\widehat{x}_s]ds\\ &\le \frac{1}{4}\mathbb{E}\int_0^T |\widehat{Z}_s|^2 + \frac{1}{4L}\mathbb{E}\int_0^T |\widehat{X}_s|^2 ds + C_2\mathbb{E}\int_0^T |\widehat{Y}_s|^2 ds + C_2\delta\mathbb{E}\int_0^T |\widehat{u}_s|^2 ds.\end{aligned}$$

Here $L = \max(C_1T, 1)$, C_2 is a sufficiently large constant which depends on L, G, β_1, and the Lipschitz constants.

Combining the above five estimates, it is clear that, whenever $\beta_1 > 0$, $\beta_2 \ge 0$, and/or $\beta_1 \ge 0$, $\beta_2 > 0$ hold true, we always have

$$\mathbb{E}\int_0^T |\widehat{U}_s|^2 ds \le C\delta\mathbb{E}\int_0^T |\widehat{u}_s|^2 ds,$$

where the constant C depends only on C_1, C_2, L, and T. We now choose $\delta_0 = \frac{1}{2C}$. It is clear that, for each fixed $\delta \in [0, \delta_0]$, the mapping $I_{\alpha_0+\delta}$ is a contraction in the sense that

$$\mathbb{E}\int_0^T |\widehat{U}_s|^2 ds \leq \frac{1}{2}\mathbb{E}\int_0^T |\widehat{u}_s|^2 ds.$$

It follows immediately that this mapping has a unique fixed point $U^{\alpha_0+\delta} = (X^{\alpha_0+\delta}, Y^{\alpha_0+\delta}, Z^{\alpha_0+\delta})$ which is the solution of (2.2) for $\alpha = \alpha_0 + \delta$. The proof is complete. □

It remains to prove that, when $\alpha = 0$, (2.2), i.e.,

$$\begin{aligned} dx_t^0 &= \left[-\beta_2 G^T y_t^0 + \phi_t\right] dt + \left[-\beta_2 G^T z_t^0 + \psi_t\right] dB_t, \\ -dy_t^0 &= \left[\beta_1 G x_t^0 + \gamma_t\right] dt - z_t^0 dB_t, \\ x_0^0 &= a, \quad y_T^0 = \xi, \end{aligned}$$

has a unique solution.

We will treat a more general situation which can also be used in the proof of Theorem 2.6.

Lemma 2.5. *The following equation has a unique solution:*

$$\begin{aligned} dx_t &= \left[-\beta_2 G^T y_t + \phi_t\right] dt + \left[-\beta_2 G^T z_t + \psi_t\right] dB_t, \\ -dy_t &= \left[\beta_1 G x_t + \gamma_t\right] dt - z_t dB_t, \\ x_0 &= a, \quad y_T = \lambda G x_T + \xi, \end{aligned} \tag{2.3}$$

where λ is a nonnegative constant.

Proof. We observe that the matrix G is of full rank. The proof of the existence for (2.3) will be divided into two cases: $n \leq m$ and $n > m$.

For the first case, the matrix $G^T G$ is strictly positive. We set

$$\begin{pmatrix} x' \\ y' \\ z' \end{pmatrix} = \begin{pmatrix} x \\ G^T y \\ G^T z \end{pmatrix}, \qquad \begin{pmatrix} y'' \\ z'' \end{pmatrix} = \begin{pmatrix} (I_m - G(G^T G)^{-1} G^T) y \\ (I_m - G(G^T G)^{-1} G^T) z \end{pmatrix}.$$

Multiplying G^T on both sides of the BSDE for (y, z) yields

$$\begin{aligned} dx_t' &= \left[-\beta_2 y_t' + \phi_t\right] dt + \left[-\beta_2 z_t' + \psi_t\right] dB_t, \\ -dy_t' &= \left[\beta_1 G^T G x_t' + G^T \gamma_t\right] dt - z_t' dB_t, \\ x_0' &= a, \quad y_T' = \lambda G^T G x_T' + G^T \xi. \end{aligned} \tag{2.4}$$

Similarly, multiplying $(I_m - G(G^T G)^{-1} G^T)$ on both sides of the same equation yields

$$\begin{aligned} -dy_t'' &= (I_m - G(G^T G)^{-1} G^T)\gamma_t dt - z_t'' dB_t, \\ y_T'' &= (I_m - G(G^T G)^{-1} G^T)\xi. \end{aligned}$$

Obviously the pair (y'', z'') is uniquely determined. The uniqueness of (x', y', z') follows from Theorem 2.2. In order to solve (2.4), we introduce the following $n \times n$-symmetric matrix-valued ordinary differential equation, known as the matrix-Riccati equation:

$$\begin{aligned} -\dot{K}(t) &= -\beta_2 K^2 + \beta_1 G^T G, \quad t \in [0, T], \\ K(T) &= \lambda G^T G. \end{aligned}$$

It is well known that this equation has a unique nonnegative solution $K(\cdot) \in C^1([0,T]; S^n)$, where S^n stands for the space of all $n \times n$-symmetric matrices. We then consider the solution $(p,q) \in M^2(0,T;\mathbb{R}^{n+n\times d})$ of the following linear simple BSDE:

$$\begin{aligned} -dp_t &= [-\beta_2 K(t)p_t + K(t)\phi_t + G^T\gamma_t]dt \\ &\qquad + [K(t)\psi_t - (I_n + \beta_2 K(t))q_t]dB_t, \quad t \in [0,T], \\ p_T &= G^T\xi. \end{aligned}$$

We now let x'_t be the solution of the SDE

$$\begin{aligned} dx'_t &= [-\beta_2(K(t)x'_t + p_t) + \phi_t]\,dt + [\psi_t - \beta_2 q_t]\,dB_t, \quad t \in [0,T], \\ x'_0 &= a. \end{aligned}$$

Then it is easy to check that $(x'_{t,}y'_t, z'_t) = (x'_t, K(t)x'_t + p_t, q_t)$ is the solution of (2.4). Once (x', y', z') and (y'', z'') are resolved, then the triple (x,y,z) is uniquely obtained by

$$\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} x' \\ G(G^TG)^{-1}y' + y'' \\ G(G^TG)^{-1}z' + z'' \end{pmatrix}.$$

The proof for the case $n > m$ is analogous to the above opposite case. We observe that in this case the matrix GG^T is of full rank. We set

$$\begin{pmatrix} x' \\ x'' \\ y' \\ z' \end{pmatrix} = \begin{pmatrix} Gx \\ (I_n - G^T(GG^T)^{-1}G)x \\ y \\ z \end{pmatrix}.$$

x'' is the unique solution of the following linear forward SDE:

$$\begin{aligned} dx''_t &= (I_n - G^T(GG^T)^{-1}G)\phi_t dt + (I_n - G^T(GG^T)^{-1}G)\psi_t dB_t, \\ x''_0 &= (I_n - G^T(GG^T)^{-1}G)a. \end{aligned}$$

The triple (x', y', z') solves the FBSDE

$$\begin{aligned} dx'_t &= \left[-\beta_2 GG^T y'_t + G\phi_t\right]dt + \left[G\psi_t - \beta_2 GG^T z'_t\right]dB_t, \\ -dy'_t &= [\beta_1 x'_t + \gamma_t]\,dt - z'_t dB_t, \\ x'_0 &= Ga, \quad y'_T = \lambda x'_T + \xi. \end{aligned} \tag{2.5}$$

To solve this equation, we introduce the solution $K(\cdot) \in C([0,T]; S^m)$ of the $m \times m$ symmetric matrix-valued Riccati equation

$$\begin{aligned} -\dot{K}(t) &= \beta_1 I_m - \beta_2 KGG^TK, \quad t \in [0,T], \\ K(T) &= \lambda I_m. \end{aligned}$$

We then consider the unique solution $(p,q) \in M^2(0,T;\mathbb{R}^{m+m\times d})$ of the following linear BSDE:

$$\begin{aligned} -dp_t &= \left(-\beta_2 K(t)GG^Tp_t + K(t)G\phi_t + \gamma_t\right)dt \\ &\qquad + \left(K(t)G\psi_t - (I_m + \beta_2 K(t)GG^T)q_t\right)dB_t, \quad t \in [0,T], \\ p_T &= \xi. \end{aligned}$$

We now let x'_t be the solution of the SDE

$$\begin{aligned} dx'_t &= \left[-\beta_2 GG^T(K(t)x'_t + p_t) + G\phi_t\right] dt \\ &\quad + \left[G\psi_t - \beta_2 GG^T q_t\right] dB_t, \quad t \in [0,T], \\ x'_0 &= Ga. \end{aligned}$$

It is then easy to see that $(x'_t, y'_t, z'_t) = (x'_t, K(t)x'_t + p_t, q_t)$ is the solution of (2.5). Once (x', x'', y', z') are resolved, by the definition, the triple (x, y, z) is uniquely obtained by

$$\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} G^T(GG^T)^{-1}x' + x'' \\ y' \\ z' \end{pmatrix}.$$

The proof is complete. □

We now proceed to give the following.

Proof of the existence of Theorem 2.3. By Lemma 2.5, when $\lambda = 0$ in (2.3), (2.2) for $\alpha_0 = 0$ has a unique solution.

It then follows from Lemma 2.4 that there exists a positive constant $\delta_0 = \delta_0(C_1, C_2, L, T)$ such that for each $\delta \in [0, \delta_0]$, (2.2) for $\alpha = \alpha_0 + \delta$ has a unique solution. Since δ_0 depends only on (C_1, C_2, L, T), we can repeat this process for N-times with $1 \le N\delta_0 < 1 + \delta_0$. It then follows that, in particular, (2.2) for $\alpha = 1$ with $\phi_s \equiv 0$, $\gamma_s \equiv 0$, and $\psi_s \equiv 0$ has a unique solution. The proof is complete. □

Now we can consider the FBSDE (2.1) for $y_T = \Phi(x_T)$. In fact, the assumption (H2.1) has to be strengthened to the following (H2.3):

$$\text{(H2.3)} \qquad \begin{aligned} &\langle A(t,u) - A(t,\overline{u}), u - \overline{u}\rangle \le -\beta_1 |G\widehat{x}|^2 - \beta_2(|G^T\widehat{y}|^2 + |G^T\widehat{z}|^2), \\ &\langle \Phi(x) - \Phi(\overline{x}), G(x - \overline{x})\rangle \ge \mu_1 |G\widehat{x}|^2 \\ &\forall u = (x,y,z), \quad \overline{u} = (\overline{x}, \overline{y}, \overline{z}), \quad \widehat{x} = x - \overline{x}, \quad \widehat{y} = y - \overline{y}, \quad \widehat{z} = z - \overline{z}, \end{aligned}$$

where β_1, β_2, and μ_1 are given nonnegative constants with $\beta_1 + \beta_2 > 0$, $\mu_1 + \beta_2 > 0$. Moreover we have $\beta_1 > 0$, $\mu_1 > 0$ (resp., $\beta_2 > 0$) when $m > n$ (resp., $n > m$).

We have the following main result of this section.

Theorem 2.6. *Let* (H2.1) *and* (H2.3) *hold. Then there exists a unique adapted solution* (X, Y, Z) *of FBSDE* (2.1).

Actually the method to prove the existence is similar to Theorem 2.3. We now consider the following (2.6) for each $\alpha \in [0,1]$:

$$\text{(2.6)} \qquad \begin{aligned} dx^\alpha_t &= \left[(1-\alpha)\beta_2(-G^T y^\alpha_t) + \alpha b(t, u^\alpha_t) + \phi_t\right] dt \\ &\quad + \left[(1-\alpha)\beta_2(-G^T z^\alpha_t) + \alpha\sigma(t, u^\alpha_t) + \psi_t\right] dB_t, \\ -dy^\alpha_t &= \left[(1-\alpha)\beta_1 G x^\alpha_t + \alpha f(t, u^\alpha_t) + \gamma_t\right] dt - z^\alpha_t dB_t, \\ x^\alpha_0 &= a, \quad y^\alpha_T = \alpha\Phi(x^\alpha_T) + (1-\alpha)Gx^\alpha_T + \xi, \end{aligned}$$

where ϕ, ψ, and γ are given processes in $M^2(0,T)$ with values in $\mathbb{R}^n$, $\mathbb{R}^{n\times d}$, and $\mathbb{R}^m$, resp., $\xi \in L^2(\Omega, \mathcal{F}_T, P)$. Clearly the existence of (2.6) for $\alpha = 1$ implies the existence of (2.1).

In order to obtain this conclusion, we also need the following lemma.

Lemma 2.7. *We assume* (H2.1) *and* (H2.3). *Then there exists a positive constant* δ_0 *such that if, a prior, for a* $\alpha_0 \in [0,1)$ *there exists a triple of solution* $(X^{\alpha_0}, Y^{\alpha_0}, Z^{\alpha_0})$

of (2.6)*, then for each* $\delta \in [0,\delta_0]$ *there exists a solution* $(X^{\alpha_0+\delta}, Y^{\alpha_0+\delta}, Z^{\alpha_0+\delta})$ (2.6) *for* $\alpha = \alpha_0 + \delta$.

Proof. Since for each $\phi \in M^2(0,T;\mathbb{R}^n)$, $\gamma \in M^2(0,T;\mathbb{R}^m)$, $\psi \in M^2(0,T;\mathbb{R}^{n\times d})$, $\xi \in L^2(\Omega,\mathcal{F}_T,P)$, $\alpha_0 \in [0,1)$ there exists a (unique) solution of (2.6), thus, for each $x_T \in L^2(\Omega,\mathcal{F}_T,P)$ and a triple $u_s = (x_s,y_s,z_s) \in M^2(0,T;\mathbb{R}^{n+m+m\times d})$ there exists a unique triple $U_s = (X_s,Y_s,Z_s) \in M^2(0,T;\mathbb{R}^{n+m+m\times d})$ satisfying the following FBSDE:

$$\begin{aligned}
dX_t &= \left[(1-\alpha_0)\beta_2(-G^TY_t) + \alpha_0 b(t,U_t) + \delta(\beta_2 G^T y_t + b(t,u_t)) + \phi_t\right] dt\\
&\qquad + \left[(1-\alpha_0)\beta_2(-G^TZ_t) + \alpha_0\sigma(t,U_t) + \delta(\beta_2 G^T z_t + \sigma(t,u_t)) + \psi_t\right] dB_t,\\
-dY_t &= [(1-\alpha_0)\beta_1 GX_t + \alpha_0 f(t,U_t) + \delta(-\beta_1 Gx_t + f(t,u_t)) + \gamma_t]\, dt - Z_t dB_t,\\
X_0 &= a, \quad Y_T = \alpha_0\Phi(X_T) + (1-\alpha_0)GX_T + \delta(\Phi(x_T) - Gx_T) + \xi.
\end{aligned}$$

We now proceed to prove that, if δ is sufficiently small, the mapping defined by

$$\begin{aligned}
&I_{\alpha_0+\delta}(u \times x_T) = U \times X_T :\\
&M^2(0,T;\mathbb{R}^{n+m+m\times d}) \times L^2(\Omega,\mathcal{F}_T,P;\mathbb{R}^n) \to M^2(0,T;\mathbb{R}^{n+m+m\times d}) \times L^2(\Omega,\mathcal{F}_T,P;\mathbb{R}^n)
\end{aligned}$$

is a contraction.

Let $u' = (x',y',z') \in M^2(0,T;\mathbb{R}^{n+m+m\times d})$, and let $U' \times X'_T = I_{\alpha_0+\delta}(u' \times x'_T)$.

We set

$$\widehat{u} = (\widehat{x},\widehat{y},\widehat{z}) = (x-x', y-y', z-z'), \quad \widehat{U} = (\widehat{X},\widehat{Y},\widehat{Z}) = (X-X', Y-Y', Z-Z').$$

Using Itô's formula applied to $\langle G\widehat{X}_s, \widehat{Y}_s\rangle$ yields

$$\begin{aligned}
&\alpha_0\mathbb{E}\langle\Phi(X_T) - \Phi(X'_T), G\widehat{X}_T\rangle + (1-\alpha_0)\mathbb{E}\langle G\widehat{X}_T, G\widehat{X}_T\rangle\\
&\qquad\qquad + \delta\mathbb{E}\langle\Phi(x_T) - \Phi(x'_T) - G\widehat{x}_T, G\widehat{x}_T\rangle\\
&= \mathbb{E}\int_0^T \langle\alpha_0(A(s,U_s) - A(s,U'_s)), \widehat{U}_s\rangle ds\\
&- (1-\alpha_0)\mathbb{E}\int_0^T (\beta_1\langle G\widehat{X}_s, G\widehat{X}_s\rangle + \beta_2\langle G^T\widehat{Y}_s, G^T\widehat{Y}_s\rangle + \beta_2\langle G^T\widehat{Z}_s, G^T\widehat{Z}_s\rangle)ds\\
&+ \delta\mathbb{E}\int_0^T (\beta_1\langle G\widehat{X}_s, G\widehat{x}_s\rangle + \beta_2\langle G^T\widehat{Y}_s, G^T\widehat{y}_s\rangle + \beta_2\langle G^T\widehat{Z}_s, G^T\widehat{z}_s\rangle\\
&\qquad + \langle\widehat{X}_s, -G^T\bar{f}_s\rangle + \langle G^T\widehat{Y}_s, \bar{b}_s\rangle + \langle\widehat{Z}_s, G\bar{\sigma}_s\rangle)ds,
\end{aligned}$$

where

$$\bar{f}_s = f(s,u_s) - f(s,u'_s), \quad \bar{b}_s = b(s,u_s) - b(s,u'_s), \quad \bar{\sigma}_s = \sigma(s,u_s) - \sigma(s,u'_s).$$

From (H2.1) and (H2.3), we can get

$$\begin{aligned}
&(\alpha_0\mu_1 + (1-\alpha_0))\mathbb{E}|G\widehat{X}_T|^2 + \beta_1\mathbb{E}\int_0^T |G\widehat{X}_s|^2 ds + \beta_2\mathbb{E}\int_0^T (|G^T\widehat{Y}_s|^2 + |G^T\widehat{Z}_s|^2)ds\\
&\le \delta K_1\mathbb{E}\int_0^T \left(|\widehat{u}_s|^2 + |\widehat{U}_s|^2\right) ds + \delta K_1\mathbb{E}|\widehat{X}_T|^2 + \delta K_1\mathbb{E}|\widehat{x}_T|^2.
\end{aligned}$$

Applying the same technique as Lemma 2.4, we have the following estimates:

$$\begin{aligned}
&\sup_{0\le s\le T}\mathbb{E}|\widehat{X}_s|^2 \le K_1\delta\mathbb{E}\int_0^T|\widehat{u}_s|^2ds + K_1\mathbb{E}\int_0^T\left(|\widehat{Y}_s|^2+|\widehat{Z}_s|^2\right)ds,\\
&\mathbb{E}\int_0^T|\widehat{X}_s|^2ds \le K_1T\delta\mathbb{E}\int_0^T|\widehat{u}_s|^2ds + K_1T\mathbb{E}\int_0^T\left(|\widehat{Y}_s|^2+|\widehat{Z}_s|^2\right)ds,\\
&\mathbb{E}\int_0^T\left(|\widehat{Y}_s|^2+|\widehat{Z}_s|^2\right)ds \le K_1\delta\mathbb{E}\int_0^T|\widehat{u}_s|^2ds + K_1\delta\mathbb{E}|\widehat{x}_T|^2\\
&\qquad\qquad + K_1\mathbb{E}\int_0^T|\widehat{X}_s|^2ds + K_1\mathbb{E}|\widehat{X}_T|^2.
\end{aligned}$$

Here the constant K_1 depends on the Lipschitz constants G, β_1, β_2, and T. If $\mu_1>0$, then $\alpha_0\mu_1+(1-\alpha_0)\ge\mu$, $\mu=\min(1,\mu_1)>0$.

Combining the above four estimates, it is clear that, whatever $\beta_1>0$, $\mu_1>0$, $\beta_2\ge0$ or $\beta_1\ge0$, $\mu_1\ge0$, $\beta_2>0$, we always have

$$\mathbb{E}\int_0^T|\widehat{U}_s|^2ds+\mathbb{E}|\widehat{X}_T|^2\le K\delta\left(\mathbb{E}\int_0^T|\widehat{u}_s|^2ds+\mathbb{E}|\widehat{x}_T|^2\right).$$

Here the constant K depends only on β_1, β_2, μ, K_1, and T. We now choose $\delta_0=\frac{1}{2K}$. It is clear that, for each fixed $\delta\in[0,\delta_0]$, the mapping $I_{\alpha_0+\delta}$ is a contraction in the sense that

$$\mathbb{E}\int_0^T|\widehat{U}_s|^2ds+\mathbb{E}|\widehat{X}_T|^2\le\frac{1}{2}\left(\mathbb{E}\int_0^T|\widehat{u}_s|^2ds+\mathbb{E}|\widehat{x}_T|^2\right).$$

It follows that this mapping has a unique fixed point $U^{\alpha_0+\delta}=(X^{\alpha_0+\delta},Y^{\alpha_0+\delta},Z^{\alpha_0+\delta})$ which is the solution of (2.6) for $\alpha=\alpha_0+\delta$. The proof is complete. □

We now give the proof of Theorem 2.6.

Proof of Theorem 2.6. The uniqueness is obvious from Theorem 2.2.

By Lemma 2.5, when $\lambda=1$, $\xi=0$ in (2.3), (2.6) for $\alpha_0=0$ has a unique solution. It then follows from Lemma 2.7 that there exists a positive constant δ_0 depending on Lipschitz constants, β_1,β_2,μ_1, and T such that, for each $\delta\in[0,\delta_0]$, (2.6) for $\alpha=\alpha_0+\delta$ has a unique solution. We can repeat this process for N-times with $1\le N\delta_0<1+\delta_0$. It then follows that, in particular, FBSDE (2.6) for $\alpha=1$ with $\xi\equiv0$ has a unique solution. The proof is complete. □

REMARK 2.8. *If $m=n$, $G=I_n$, as a special case of Theorem* 2.6, *we improve the main result in* [HP]. *Actually, our monotonicity assumptions are clearly weaker than similar assumptions in* [HP]. *Moreover, if* (2.1) *satisfy the following monotone conditions and* (H2.1),

$$\begin{aligned}
\langle A(t,u)-A(t,\bar{u}),u-\bar{u}\rangle &\le -\beta_2|\widehat{y}|^2,\\
\langle\Phi(x)-\Phi(\bar{x}),\widehat{x}\rangle &\ge \mu_1|\widehat{x}|^2,
\end{aligned}$$

where $m=n$, $G=I_n$, $\beta_2>0$, $\mu_1>0$, we can also obtain the same result as Theorem 2.6. *The proof method is similar.*

At last, in this section, we consider a simple case where the monotone condition (H2.3) is not satisfied.

Example 2.1. In FBSDE (2.1), we set

$$b = z, \quad \sigma = y, \quad f = 0, \quad \Phi = x.$$

In a given time interval $s \in [t, T]$, FBSDE takes the form

$$\begin{aligned} dx_s =& z_s ds + y_s dB_s, \\ -dy_s =& - z_s dB_s, \\ x_t =& x, \quad y_T = x_T. \end{aligned}$$

It is clear that the monotone assumption of (H2.3) fails. Indeed, though the monotone for Φ still holds true,

$$\langle \Phi(x) - \Phi(\overline{x}), x - \overline{x} \rangle = |x - \overline{x}|^2 \geq 0,$$

but for A we have

$$\begin{aligned} \langle A(t,u) - A(t,\overline{u}), u - \overline{u} \rangle &= 2(y - \overline{y})(z - \overline{z}) \\ \forall u = (x,y,z), &\quad \overline{u} = (\overline{x}, \overline{y}, \overline{z}). \end{aligned}$$

According to the local existence and uniqueness theorem (see Peng [P5] and Antonelli [A]), if the length of the interval $[t, T]$ is sufficiently small, then the FBSDE has a unique solution. As a matter of fact, this solution can be written explicitly by

$$(x_s^t, y_s^t, z_s^t) = (x_s^t, p(s)x_s^t, p^2(s)x_s^t), \quad s \in [t, T],$$

with

$$p(s) = \frac{1}{\sqrt{1 - 2(T - s)}}$$

and

$$\begin{aligned} dx_s^t &= p^2(s)x_s^t ds + p(s)x_s^t dB_s, \quad s \in [t, T], \\ x_t^t &= x. \end{aligned}$$

In particular, $y_t^t = p(t)x$, $z_t^t = p^2(t)x$, but since $p(t) \uparrow \infty$ as $t \downarrow (T - \frac{1}{2})$, (y_s^t, z_s^t) will explode when $t \downarrow (T - \frac{1}{2})$.

3. Applications of FBSDE to stochastic optimal controls and differential games.

Example 3.1. *3.1 (stochastic Hamilton system).* (stochastic Hamilton system). Let $n = m$, and let $h(x) : \mathbb{R}^n \to \mathbb{R}$. For notational simplification, we assume that $d = 1$. We consider the following "generalized Hamiltonian":

$$H(x,y,z) : \mathbb{R}^{n+n+n} \longrightarrow \mathbb{R}.$$

We assume that H and h are twice continuously differentiable such that the second derivatives are bounded. We consider the following FBSDE:

$$\begin{aligned} dx_t &= H_y(x_t, y_t, z_t)dt + H_z(x_t, y_t, z_t)dB_t, \\ -dy_t &= H_x(x_t, y_t, z_t)dt - z_t dB_t, \\ x_0 &= a, \quad y_T = h_x(x_T), \end{aligned} \tag{3.1}$$

where $(H_x \quad H_y \quad H_z)$ (resp., h_x) stands for the gradient of H (resp., h). It is clear that the stochastic Hamiltonian equations are a special case of FBSDE (2.1) with

$$f = H_x, \quad b = H_y, \quad \sigma = H_z.$$

Thus the monotone conditions, i.e., (H2.3), correspond, for this special case, to the nonnegativity of the matrix h_{xx} and

$$\begin{pmatrix} -H_{xx} & -H_{xy} & -H_{xz} \\ H_{yx} & H_{yy} & H_{yz} \\ H_{zx} & H_{zy} & H_{zz} \end{pmatrix} (x, y, z) \leq - \begin{pmatrix} \beta_1 I_n & 0 & 0 \\ 0 & \beta_2 I_n & 0 \\ 0 & 0 & \beta_2 I_n \end{pmatrix},$$

where $\beta_1 \geq 0$, $\beta_2 > 0$.

A classical optimization problem of a stochastic control system is formulated as follows: the control system is

$$\begin{aligned} dx_t &= g(x_t, v_t)dt + \mu(x_t, v_t)dB_t, \\ x_0 &= a, \end{aligned}$$

where v_s, $s \in [0, T]$, is an admissible control process, i.e., an $\mathcal{F}_t$-adapted square-integrable process taking values in a given subset U of $\mathbb{R}^k$. Here g and μ are given functions defined on $\mathbb{R}^n \times \mathbb{R}^k$ with values in $\mathbb{R}^n$. The optimal control problem is to minimize the cost function

$$J(v(\cdot)) = \mathbb{E}\left\{ \int_0^T L(x_t, v_t)dt + h(x_T) \right\}$$

over the set of admissible controls. One of the two important methods of the resolution of this optimization problem is the so-called stochastic maximum principle which may be considered as a natural generalization of the well-known Pontryagin's maximum principle to situations with uncertainty. This principle tells us that, under certain reasonable assumptions imposed on the coefficients g, μ, L, h, if $u(\cdot)$ is an admissible optimal control, and if the trajectory corresponding to $u(\cdot)$ is $x(\cdot)$, then, necessarily, there exists a pair of square-integrable adapted processes (y, z) taking values in $\mathbb{R}^n \times \mathbb{R}^n$ such that the triple of processes $(x(\cdot), y(\cdot), z(\cdot))$ satisfies the stochastic Hamiltonian system (3.1), where the Hamiltonian H is defined by

$$H(x, y, z) = \inf_{v \in U} \left\{ \langle y, g(x, v) \rangle + \langle z, \mu(x, v) \rangle + L(x, v) \right\}.$$

A coproduct of this stochastic maximum principle is that it gives us an example of the existence of the solution to FBSDE, but one of the inconveniences of such methods is that checking the conditions of the existence of an optimal control is a very hard problem. Another inconvenience is that this approach does not provide us any information about the uniqueness of the solution of (3.1).

Example 3.2. We now consider a more typical situation. We assume that in the above example g and μ are linear functions

$$g(x, v) = Ax + Bv, \quad \mu(x, v) = Cx + Dv,$$

where A and C are $n \times n$ matrices, B and D are $n \times k$ matrices. We also assume that there is no constraint imposed on the control processes $U = \mathbb{R}^k$. $L(x, v)$, $h(x)$ are twice continuously differentiable with respect to (x, v) and x; $L_x(x, v)$ are bounded by $C(1 + |x| + |v|)$.

In this case, if we assume that

(H3.1)
$$\begin{cases} \text{(i) } k \times k \text{ matrix } L_{vv}(x, v) \geq \beta I_k,\ \beta > 0, \\ \text{(ii) } n \times n \text{ matrix } L_{xx}(x, v) - L_{xv}(x, v) L_{vv}^{-1} L_{vx}(x, v) \text{ is nonnegative,} \\ \text{(iii) } n \times n \text{ matrix } h_{xx}(x) \text{ is nonnegative,} \end{cases}$$

and, if $u(\cdot)$ is an admissible optimal control, the trajectory corresponding to $u(\cdot)$ is $x(\cdot)$, then the Hamiltonian H is defined by

$$H(x, y, z) = \inf_{v \in U} \left\{ \langle y, Ax + Bv \rangle + \langle z, Cx + Dv \rangle + L(x, v) \right\}.$$

We have, necessarily,

$$L_v(x_t, u_t) + B^T y_t + D^T z_t = 0 \tag{3.2}$$

and (x, y, z) satisfy the following FBSDE:

$$\begin{aligned} dx_t &= (Ax_t + Bu_t)dt + (Cx_t + Du_t)dB_t, \\ -dy_t &= (A^T y_t + C^T z_t + L_x(x_t, u_t))dt - z_t dB_t, \\ x_0 &= a, \quad y_T = h_x(x_T). \end{aligned} \tag{3.3}$$

If the optimal control process $u(\cdot)$ does not exist, the solution of (3.3) does not exist. In optimal control theory, we can prove the $u(\cdot)$ exists and is unique. Then there exist solutions to FBSDE (3.3). This is an indirect method and we cannot know whether it is unique. Now we study FBSDE (3.3) directly. It is clear that without Assumption (H2.3), Theorem 2.6 cannot be applied to obtain the existence and uniqueness of (3.3) . Fortunately, for the special case like the following form, we have a better result.

We consider the following kind of FBSDE:

$$\begin{aligned} dx_t &= b(t, x_t, By_t, Cz_t)dt + \sigma(t, x_t, By_t, Cz_t)dB_t, \\ -dy_t &= f(t, x_t, y_t, z_t)dt - z_t dB_t, \\ x_0 &= a, \quad y_T = \Phi(x_T). \end{aligned} \tag{3.4}$$

Here B is a $k \times n$ matrix, C a is $k \times n$ matrix, $(x, y, z) \in \mathbb{R}^{n+n+n}$, and b, f, σ have appropriate dimensions. We use the notations

$$u = \begin{pmatrix} x \\ y \\ z \end{pmatrix}, \quad A(t, u) = \begin{pmatrix} -f \\ b \\ \sigma \end{pmatrix} (t, u)$$

and impose the following monotone conditions:

$$\begin{aligned} &\langle A(t, u) - A(t, \overline{u}), u - \overline{u} \rangle \leq -\nu_1 |\widehat{x}|^2 - \nu_2 |B\widehat{y} + C\widehat{z}|^2, \\ &\langle \Phi(x) - \Phi(\overline{x}), (x - \overline{x}) \rangle \geq 0 \\ &\forall \widehat{u} = (u - \overline{u}) = (\widehat{x}, \widehat{y}, \widehat{z}) = (x - \overline{x}, y - \overline{y}, z - \overline{z}). \end{aligned} \tag{H3.2}$$

Here $\nu_1 \geq 0$, $\nu_2 > 0$. We also assume that

(H3.3)

$$\begin{cases} \text{(i) } A(t,u) \text{ is uniformly Lipschitz with respect to } u; \\ \text{(ii) for each } u,\ A(\cdot,u) \text{ is in } M^2(0,T); \\ \text{(iii) } \Phi(x) \text{ is uniformly Lipschitz with respect to } x \in \mathbb{R}^n; \\ \text{(iv) for each } x,\ \Phi(x) \text{ is in } L^2(\Omega,\mathcal{F}_T,\mathbf{P}); \\ \text{(v) } \forall x, |l(t,x,By,Cz) - l(t,x,B\overline{y},C\overline{z})| \leq K(|B\widehat{y} + C\widehat{z}|), K > 0, l = b, \sigma. \end{cases}$$

Then we have the following result.

Theorem 3.1. *Let* (H3.2) *and* (H3.3) *hold. Then there exists a unique solution* $u_s = (x_s, y_s, z_s)$ *satisfying FBSDE* (3.4).

Proof. We first prove the uniqueness for FBSDE (3.4). Let $u_s = (x_s, y_s, z_s)$ and $u'_s = (x'_s, y'_s, z'_s)$ be two solutions of (3.4). We set $\widehat{u} = (x - x', y - y', z - z') = (\widehat{x}, \widehat{y}, \widehat{z})$. We use Itô's formula applied to $\langle \widehat{x}_s, \widehat{y}_s \rangle$:

$$\mathbb{E}\langle \Phi(x_T) - \Phi(x'_T), \widehat{x}_T \rangle - \mathbb{E}\langle \widehat{y}_t, \widehat{x}_t \rangle = \mathbb{E} \int_t^T \langle A(s,u_s) - A(s,u'_s), \widehat{u}_s \rangle ds.$$

This with the monotonicity of Φ and A implies

$$\nu_2 \mathbb{E} \int_0^T |B\widehat{y}_s + C\widehat{z}_s|^2 ds \leq 0.$$

$B\widehat{y}_s + C\widehat{z}_s \equiv 0$. Following (H3.3)(v) and a classical result for the uniqueness of Itô's FSDE, we have $\widehat{x}_s \equiv 0$. Thus $x_s \equiv x'_s$. In particular, $\Phi(x_T) \equiv \Phi(x'_T)$. Thus from the uniqueness of BSDE it follows that $y_s \equiv y'_s$ and $z_s \equiv z'_s$.

The method to prove the existence is similar to Theorems 2.3 and 2.6. We consider the following FBSDE:

$$\begin{aligned} dx_t^\alpha &= \left[(1-\alpha)(-B^T B y_t^\alpha - B^T C z_t^\alpha) + \alpha b(t, x_t^\alpha, B y_t^\alpha, C z_t^\alpha) + \phi_t\right] dt \\ &\quad + \left[\alpha \sigma(t, x_t^\alpha, B y_t^\alpha, C z_t^\alpha) + (1-\alpha)(-C^T C z_t^\alpha - C^T B y_t^\alpha) + \psi_t\right] dB_t, \\ -dy_t^\alpha &= \left[(1-\alpha) x_t^\alpha + \alpha f(t, x_t^\alpha, y_t^\alpha, z_t^\alpha) + \gamma_t\right] dt - z_t^\alpha dB_t, \\ x_0^\alpha &= a, \quad y_T^\alpha = \alpha \Phi(x_T^\alpha) + \xi, \end{aligned} \tag{3.5}$$

where ϕ, ψ, and γ are given processes in $M^2(0,T)$ with values in $\mathbb{R}^n$, $\xi \in L^2(\Omega, \mathcal{F}_T, P; \mathbb{R}^n)$. Clearly the existence of (3.5) for $\alpha = 1$ implies our conclusion. If $\alpha = 0$, we can obtain the existence and uniqueness result using Theorem 2.3 directly. So we only need to consider

$$\begin{aligned} dX_t &= [(1-\alpha_0)(-B^T B Y_t - B^T C Z_t) + \alpha_0 b(t, X_t, B Y_t, C Z_t)] dt \\ &\quad + [\delta(B^T B y_t + B^T C z_t + b(t, x_t, B y_t, C z_t)) + \phi_t] dt \\ &\quad + \left[\alpha_0 \sigma(t, X_t, B Y_t, C Z_t) + (1-\alpha_0)(-C^T C Z_t - C^T B Y_t)\right] dB_t \\ &\quad + \left[\delta(\sigma(t, x_t, B y_t, C z_t) + C^T C z_t + C^T B y_t) + \psi_t\right] dB_t, \\ -dY_t &= \left[(1-\alpha_0) X_t + \alpha_0 f(t, U_t) - \delta(x_t - f(t, u_t)) + \gamma_t\right] dt - Z_t dB_t, \\ X_0 &= a, \quad Y_T = \alpha_0 \Phi(X_T) + \delta \Phi(x_T) + \xi \end{aligned}$$

and prove that the mapping defined by

$$I_{\alpha_0+\delta}(u \times x_T) = U \times X_T :$$
$$M^2(0,T;\mathbb{R}^{n+n+n\times d}) \times L^2(\Omega,\mathcal{F}_T,P;\mathbb{R}^n) \to M^2(0,T;\mathbb{R}^{n+n+n\times d}) \times L^2(\Omega,\mathcal{F}_T,P;\mathbb{R}^n)$$

is a contraction.

For the difference $(\widehat{X},\widehat{Y}) = (X - X', Y - Y')$, using a similar technique as in Lemmas 2.4 and 2.7 to $\langle \widehat{X},\widehat{Y}\rangle$, we have

$$\begin{aligned}&\nu_2\alpha_0\mathbb{E}\int_0^T \left(|B\widehat{Y}_s + C\widehat{Z}_s|^2\right) ds + (1-\alpha_0)\mathbb{E}\int_0^T \left(|B\widehat{Y}_s + C\widehat{Z}_s|^2\right) ds \\ &\leq \delta C_1\mathbb{E}\int_0^T |\widehat{u}_s|^2 ds + \delta C_1\mathbb{E}|\widehat{x}_T|^2 + \delta C_1\mathbb{E}\int_0^T |\widehat{U}_s|^2 ds + \delta C_1 \mathbb{E}|\widehat{X}_T|^2,\end{aligned}$$

where $\widehat{U}$ and $\widehat{u}$ are defined similarly as in Lemma 2.4.

Here C_1 depends on the Lipschitz constants of b, σ, f, and Φ, $\nu_2\alpha_0+(1-\alpha_0) \geq L_1$, $L_1 = \min(1,\nu_2) > 0$, so

$$\begin{aligned}&\mathbb{E}\int_0^T \left(|B\widehat{Y}_s + C\widehat{Z}_s|^2\right) ds \\ &\leq \delta C_2\mathbb{E}\int_0^T |\widehat{u}_s|^2 ds + \delta C_2\mathbb{E}|\widehat{x}_T|^2 + \delta C_2\mathbb{E}\int_0^T |\widehat{U}_s|^2 ds + \delta C_2\mathbb{E}|\widehat{X}_T|^2.\end{aligned}$$

Here $C_2 = \frac{C_1}{L_1}$. Applying the usual technique to the $\widehat{X}_t = X_t - X'_t$, we obtain

$$\sup_{0\leq s\leq T} \mathbb{E}|\widehat{X}_s|^2 \leq C_3\delta\mathbb{E}\int_0^T |\widehat{u}_s|^2 ds + C_3\mathbb{E}\int_0^T \left(|B\widehat{Y}_s + C\widehat{Z}_s|^2\right) ds,$$

$$\mathbb{E}\int_0^T |\widehat{X}_s|^2 ds \leq C_3T\delta\mathbb{E}\int_0^T |\widehat{u}_s|^2 ds + C_3T\mathbb{E}\int_0^T \left(|B\widehat{Y}_s + C\widehat{Z}_s|^2\right) ds.$$

Similarly, for the difference of the solutions $(\widehat{Y},\widehat{Z}) = (Y - Y', Z - Z')$, applying the usual technique to the BSDE, we have

$$\mathbb{E}\int_0^T \left(|\widehat{Y}_s|^2 + |\widehat{Z}_s|^2\right) ds \leq C_3\delta\mathbb{E}\int_0^T |\widehat{u}_s|^2 ds + C_3\mathbb{E}\int_0^T |\widehat{X}_s|^2 ds + C_3\mathbb{E}|\widehat{X}_T|^2.$$

Here the constant C_3 depends on the Lipschitz constants, K, B, C, and T. Combining the above four estimates, it is clear that we always have

$$\mathbb{E}\int_0^T |\widehat{U}_s|^2 ds + \mathbb{E}|\widehat{X}_T|^2 \leq L\delta\left(\mathbb{E}\int_0^T |\widehat{u}_s|^2 ds + \mathbb{E}|\widehat{x}_T|^2\right),$$

where the constant L depends on C_1, C_2, C_3, and T. So we can choose $\delta_0 = \frac{1}{2L}$. Then for each $\delta \in [0,\delta_0]$, the mapping $I_{\alpha_0+\delta}$ is a contraction.

The other part is the same as in Theorem 2.3 or 2.6; we omit it. □

Now we can consider the FBSDE (3.3) again. Noticing (3.2), we can get

$$L_{vv}(x_t,u_t)u_y = -B^T, L_{vv}(x_t,u_t)u_z = -D^T, L_{vx}(x_t,u_t) + L_{vv}(x_t,u_t)u_x = 0.$$

Combining (H3.1), we can easily verify (3.3), satisfying the assumptions (H3.2) and (H3.3). Then applying Theorem 3.1 there exists a unique solution.

Example 3.3. *We give a more special situation of Example* 3.2: *a linear Hamiltonian system related to a classical linear quadratic optimal control problem.*

We also assume that in Example 3.1 g and μ are linear functions:

$$g(x, v) = Ax + Bv, \quad \mu(x, v) = Cx + Dv,$$

and L is a quadratic function of (x, v); h is a nonnegative quadratic function of x:

$$L(x, v) = \frac{1}{2}\langle Rx, x\rangle + \frac{1}{2}\langle Nv, v\rangle, \quad h = \frac{1}{2}\langle Qx, x\rangle,$$

where Q and R are $n \times n$ nonnegative symmetric matrices, and N is a $k \times k$ positive matrix. The control domain is $U = R^k$; in this case the Hamiltonian H has an explicit form

$$H(x, y, z) = \frac{1}{2}\langle Rx, x\rangle + \langle y, Ax\rangle + \langle z, Cx\rangle - \frac{1}{2}(y^T, z^T)\begin{pmatrix} BN^{-1}B^T & BN^{-1}D^T \\ DN^{-1}B^T & DN^{-1}D^T \end{pmatrix}\begin{pmatrix} y \\ z \end{pmatrix}.$$

Thus the Hessian of H is

$$\begin{pmatrix} -H_{xx} & -H_{xy} & -H_{xz} \\ H_{yx} & H_{yy} & H_{yz} \\ H_{zx} & H_{zy} & H_{zz} \end{pmatrix} = \begin{pmatrix} -R & -A^T & -C^T \\ A & -BN^{-1}B^T & -BN^{-1}D^T \\ C & -DN^{-1}B^T & -DN^{-1}D^T \end{pmatrix}.$$

The corresponding Hamiltonian system is

$$\begin{aligned} dx_t &= (Ax_t - BN^{-1}B^T y_t - BN^{-1}D^T z_t)dt \\ &\qquad + (Cx_t - DN^{-1}B^T y_t - DN^{-1}D^T z_t)dB_t, \\ -dy_t &= (A^T y_t + C^T z_t + Rx_t)dt - z_t dB_t, \\ x_0 &= a, \qquad y_T = Qx_T. \end{aligned} \tag{3.6}$$

It is easy to verify (3.6), satisfying assumptions (H3.2) and (H3.3). Then according to Theorem 3.1 there exists a unique solution.

The above three examples are connected with stochastic optimal control problems. Now we give an example of FBSDE under stochastic differential games circumstances. We can see one of the advantages of introducing the adjustment matrix G is that some stochastic Hamiltonian systems arising from differential games, which are in general far more difficult than stochastic optimal control, can also be dealt with using this method.

Example 3.4. *We consider the following differential game:*

$$\begin{aligned} dx_t &= g(x_t, v_t^1, v_t^2)dt + \mu(x_t, v_t^1, v_t^2)dB_t, \\ x_0 &= a, \end{aligned}$$

with

$$\inf_{v^1}\sup_{v^2}\mathbb{E}\left\{\int_0^T L(x_t, v_t^1, v_t^2)dt + h(x_T)\right\},$$

$v = (v^1, v^2) \in \mathbb{R}^k$.

We only consider a very simple case:

$$\begin{aligned} &g(x,v)=Ax+Bv, &&\mu(x,v)=Cx+Dv,\\ &Bv=B_1v^1+B_2v^2, &&Dv=D_1v^1+D_2v^2,\\ &L=\frac{1}{2}(\langle Rx,x\rangle+\langle Nv,v\rangle), &&h=\frac{1}{2}\langle Qx,x\rangle. \end{aligned}$$

In this case,

$$\begin{aligned} H(x,y,z)&=\sup_{v^2}\inf_{v^1}\left\{\frac{1}{2}(\langle Rx,x\rangle+\langle Nv,v\rangle)+\langle y,Ax+Bv\rangle+\langle z,Cx+Dv\rangle\right\}\\ &=\inf_{v^1}\sup_{v^2}\left\{\frac{1}{2}(\langle Rx,x\rangle+\langle Nv,v\rangle)+\langle y,Ax+Bv\rangle+\langle z,Cx+Dv\rangle\right\}\\ &=\frac{1}{2}(\langle Rx,x\rangle-\langle N^{-1}(B^Ty+D^Tz),B^Ty+D^Tz\rangle)+\langle y,Ax\rangle+\langle z,Cx\rangle. \end{aligned}$$

The related stochastic Hamiltonian system is

$$\begin{aligned} dx_t&=H_ydt+H_zdB_t,\\ -dy_t&=H_xdt-z_tdB_t,\\ x_0&=a,\quad y_T=Qx_T, \end{aligned}$$

or

$$\begin{cases} dx_t=(Ax_t-BN^{-1}B^Ty_t-BN^{-1}D^Tz_t)dt\\ \qquad\quad+(Cx_t-DN^{-1}B^Ty_t-DN^{-1}D^Tz_t)dB_t\\ -dy_t=(A^Ty_t+C^Tz_t+Rx_t)dt-z_tdB_t\\ x_0=a,\qquad y_T=Qx_T. \end{cases}$$

If we set

$$N=\begin{bmatrix}1&0\\0&-1\end{bmatrix},\quad R=\begin{bmatrix}1&0\\0&-1\end{bmatrix},\quad B=I_2,\quad D=I_2,\quad Q=\begin{bmatrix}1&0\\0&-1\end{bmatrix},$$

then the above equation becomes

$$\begin{aligned} dx_t&=(Ax_t-N^{-1}y_t-N^{-1}z_t)dt+(Cx_t-N^{-1}y_t-N^{-1}z_t)dB_t,\\ -dy_t&=(A^Ty_t+C^Tz_t+Rx_t)dt-z_tdB_t,\\ x_0&=a,\qquad y_T=Qx_T. \end{aligned}$$

Here N and R are indefinite. We cannot deal with this system using a traditional method. This is the same dimensional FBSDE, but if we set $G=I_2$, we cannot get the desired result. Now we set

$$G=\begin{bmatrix}1&0\\0&-1\end{bmatrix}.$$

It is easy to check that

$$\begin{bmatrix}-G^T(Rx+A^Ty+C^Tz)\\ G(Ax-N^{-1}y-N^{-1}z)\\ G(Cx-N^{-1}y-N^{-1}z)\end{bmatrix}\cdot\begin{pmatrix}x\\y\\z\end{pmatrix}=-|x|^2-|y+z|^2.$$

From Theorem 3.1, this Hamiltonian system has a unique solution.

In the example, even A and C are randomly disturbed, and the Hamiltonian system cannot be dealt with using differential games or an optimal control method. We can also adjust matrix G to get the desired result.

ANALYTIC CONTROLLABILITY OF A LINEAR HYBRID SYSTEM*

BRICE ALLIBERT†

Abstract. In this paper, we consider a boundary control problem for a model of a fluid-structure hybrid system. This model has been introduced by Micu and Zuazua in connection with the works of Banks et al. They have given explicit values for the spectral data in [S. Micu and E. Zuazua, *SIAM J. Math. Anal.*, 29 (1998), pp. 967–1001] and results for the control problem in [S. Micu and E. Zuazua, *SIAM J. Control. Optim.,* 35 (1997), pp. 1614–1637]. In the latter paper, they use variable separation and Ingham inequalities to prove an observation estimate that implies, through the Hilbert uniqueness method, that initial data can be controlled within finite time. This paper improves these results by using a stronger form of Ingham inequality for low frequencies. Indeed, we prove that any analytic function is controlled in a finite time whose dependence on the analyticity can be sharply estimated.

Key words. wave equation, analyticity, boundary control, nongeometric control, reachable set

1. Introduction.

1.1. Setting of the problem.

Micu and Zuazua have recently introduced in [MZ1] a PDE system as a model of a fluid-structure elastic interaction. This model follows from a series of works by Banks et al. [BFSS].

Let us denote by Ω the square $[0,1]^2$, Γ_0 the subset $\{0\} \times [0,1]$ of its boundary, and $\Gamma_1 = \partial M \setminus \Gamma_0$ the rest of it. The equations of the model are the following:

$$(1) \qquad \begin{cases} \Delta\Phi - \Phi_{tt} = 0 & \text{over } \Omega \times (0,T), \\ \frac{\partial\Phi}{\partial n} = 0 & \text{over } \Gamma_1 \times (0,T), \\ \frac{\partial\Phi}{\partial n} = W_t & \text{over } \Gamma_0 \times (0,T), \\ W_{tt} - W_{yy} + \Phi_t = \beta & \text{over } \Gamma_0 \times (0,T), \\ W_y(0,t) = W_y(1,t) = 0 & \text{over } (0,T), \\ (\Phi, \partial_t\Phi, W, \partial_t W)|_{t=0} = (\Phi_0, \Phi_1, W_0, W_1), \\ \text{with } (\Phi_0, \Phi_1, W_0, W_1) \in L^2(\Omega) \oplus H^{-1}(\Omega) \oplus L^2(\Gamma_0) \oplus H^{-1}(\Gamma_0). \end{cases}$$

For this problem, two values remain constant in time:

$$c_1 = \int_{\Gamma_0} (W_t(y) + \Phi(0,y))\, dy$$

and

$$c_2 = \int_{\Gamma_0} W(y)\, dy + \int_\Omega \Phi_t(x,y)\, dx\, dy.$$

The control problem in time T is to find a function β such that the solution of (1) reaches an equilibrium at time T, e.g.,

$$(\Phi, \partial_t\Phi, W, \partial_t W)|_{t=T} = (c_1, 0, c_2, 0).$$

*Received by the editors April 30, 1997; accepted for publication (in revised form) April 1, 1998; published electronically March 17, 1999.

http://www.siam.org/journals/sicon/37-3/32062.html

†Centre de Mathématiques, UMR 7640 du CNRS, Ecole Polytechnique, F-91128 Palaiseau, France (allibert@math.polytechnique.fr).

As the problem is linear, we may consider only initial conditions such that $c_1 = c_2 = 0$ and look for a control function β that drives the solution of (1) to

$$(\Phi, \partial_t\Phi, W, \partial_t W)|_{t=T} = (0, 0, 0, 0).$$

Then, the control function β will drive any initial condition $(\Phi_0, \Phi_1, W_0, W_1)+(c_1, 0, c_2, 0)$ to the equilibrium $(c_1, 0, c_2, 0)$.

As the geometric control hypothesis of [BLR] does not hold, the space F_T of controlled functions should be different from the space $L^2(\Omega) \oplus H^{-1}(\Omega) \oplus L^2(\Gamma_0) \oplus H^{-1}(\Gamma_0)$. Nevertheless, as the geometry is simple, we can separate the variables in order to get some results about F_T.

In [MZ1] and [MZ2], Micu and Zuazua have used this method. They get an infinite number of one-dimensional systems, indexed by an integer n. Then they apply the Hilbert uniqueness method (HUM) in order to get the adjoint problem

$$(2) \qquad \begin{cases} \Delta\Psi - \Psi_{tt} = 0 & \text{over } \Omega \times (0, T), \\ \frac{\partial\Psi}{\partial n} = 0 & \text{over } \Gamma_1 \times (0, T), \\ \frac{\partial\Psi}{\partial n} = -V_t & \text{over } \Gamma_0 \times (0, T), \\ V_{tt} - V_{yy} + \Psi_t = 0 & \text{over } \Gamma_0 \times (0, T), \\ V_y(0, t) = V_y(1, t) & \text{over } (0, T), \end{cases}$$

with initial conditions $(\underline{\Psi}, \underline{V}) = ((\Psi, \Psi_t), (V, V_t))|_{t=0}$ in

$$\Big(H_0^1([0, 1]) \times L^2([0, 1]) \times \mathbb{C} \times \mathbb{C}\Big)e^{i\pi ny}.$$

For $n \neq 0$, the HUM method, described in [MZ2, sect. 2.4], shows that if there is a constant $C(n, T)$ such that for any solution of problem (2)

$$||(\underline{\Psi}, \underline{V})||_{\mathcal{X}}^2 \leq C(n, T) \int_{-T}^{T} |V_{tt}(0, t)|^2 \ dt,$$

then for any initial data

$$(\Phi_0, \Phi_1, W_0, W_1) \in (L^2([0, 1]) \times H^{-1}([0, 1]) \times \mathbb{C} \times \mathbb{C})e^{i\pi ny}$$

a control β can be built, such that the solution of the control problem (1) satisfies

$$(\Phi, \partial_t\Phi, W, \partial_t W)|_{t=T} = 0.$$

This method naturally leads to controls β defined as $\beta := \frac{d^2}{dt^2}\rho$, with

$$(3) \qquad |\rho|_{L^2(\Gamma_0 \times (0,T))} \leq C(n, T)|(\Phi_0, \Phi_1, W_0, W_1)|_{L^2([0,1]) \times H^{-1}([0,1]) \times \mathbb{C} \times \mathbb{C}}.$$

This is why we will consider controls β in H^{-2}.

For $n = 0$, the same result holds, providing $c_1 = c_2 = 0$ (see [MZ2, sect. 2.5]).

Now suppose we take an initial condition

$$(\Phi_0, \Phi_1, W_0, W_1) \in L^2(\Omega) \oplus H^{-1}(\Omega) \oplus L^2(\Gamma_0) \oplus H^{-1}(\Gamma_0),$$

with $c_1 = c_2 = 0$ and such that its Fourier series in y

$$(\Phi_0, \Phi_1, W_0, W_1) = \sum_n (\Phi_0, \Phi_1, W_0, W_1)_n e^{i\pi ny}$$

is such that

$$\left(C(n,T)||(\Phi_0,\Phi_1,W_0,W_1)_n||_{H_0^1([0,1])\times L^2([0,1])\times\mathbb{C}\times\mathbb{C}}\right)_n \in l^2(\mathbb{Z}). \tag{4}$$

Then for each value of n, we can build a control β_n that drives $(\Phi_0,\Phi_1,W_0,W_1)_n$ to 0 in time T. Therefore, if we put $\beta := \sum_n \beta_n$, the control β drives (Φ_0,Φ_1,W_0,W_1) to 0 in time T. Notice that the control β exists and is in $H^{-2}(\Gamma_0\times(0,T))$ because of (4) and (3). Hence the space H of such initial data is a subset of F_T. So any result about the constants $C(n,T)$ gives an estimate about the space F_T.

In [MZ2], Micu and Zuazua use explicit spectral results and Ingham techniques to prove that for any real number $\alpha > 1$, there is a positive constant K_α such that for any integer n, and any time $T > 2$,

$$C(n,T) \leq K_\alpha e^{K_\alpha n^\alpha}.$$

In this case, though, Ingham techniques fail to give sharp estimates because frequencies $\nu_{n,k}$ such that $k = o(n)$ have no finite gap between each other; $\nu_{n,k+1} - \nu_{n,k} \to 0$ when n goes to infinity.

1.2. Main result. In this paper, we will replace these techniques by biorthogonal sequences methods in the bad part of the spectrum. It will allow us to get the following theorem.

THEOREM 1. *For any positive δ and ϵ, there is a time $T(\epsilon,\delta)$ smaller than $\frac{C_\delta}{\epsilon^{1+\delta}}$ and a positive constant $C_{\epsilon,\delta}$ such that for any positive integer n and any time $T > T(\epsilon,\delta)$,*

$$C(n,T) \leq C_{\epsilon,\delta}\ e^{\epsilon|n|}.$$

In other terms, this theorem means that any initial data (Φ_0,Φ_1,W_0,W_1) such that

$$\left(e^{\alpha|n|}||(\Phi_0,\Phi_1,W_0,W_1)_n||_{H_0^1([0,1])\times L^2([0,1])\times\mathbb{C}\times\mathbb{C}}\right)_n \in l^2(\mathbb{Z})$$

belongs to F_T if

$$T > T(\alpha,\delta).$$

Thus, the following corollary holds.

COROLLARY 1.

$$C^\omega \times C^\omega \times C^\omega \times C^\omega \subset \bigcup_T F_T.$$

As Ω has a boundary, C^ω functions over Ω must be understood as functions that have an analytic continuation over a neighborhood of Ω. This corollary states that any such initial condition can be controlled within finite time. Of course, this time depends on the condition.

Indeed, it would be enough to take functions that are analytic with respect to y and whose values are Sobolev functions with respect to x. Such spaces may not be familiar to the reader. However, one may keep in mind that regularity with respect to y is the key.

Proof. Let $(\Phi_0, \Phi_1, W_0, W_1)(x, y)$ be an element of $L^2(\Omega) \times H^{-1}(\Omega) \times L^2(\Gamma) \times H^{-1}(\Gamma)$, with

$$(\Phi_0, \Phi_1, W_0, W_1)(x, y) = \sum_n (\Phi_0, \Phi_1, W_0, W_1)_n(x) e^{i\pi n y}.$$

First, notice that we can subtract $(c_1, 0, c_2, 0)$ from the initial condition in order to ensure that $c_1 = c_2 = 0$.

The Fourier coefficients can be computed by

$$(\Phi_0, \Phi_1, W_0, W_1)_n(x) = \int_0^1 (\Phi_0, \Phi_1, W_0, W_1)(x, y) e^{-i\pi n y}\, dy. \tag{5}$$

If $(\Phi_0, \Phi_1, W_0, W_1)$ is analytic (analytic with respect to y is enough), then there is a positive real number ϵ such that

$$y \mapsto (\Phi_0, \Phi_1, W_0, W_1)(., y + i\epsilon), \tag{6}$$

and

$$y \mapsto (\Phi_0, \Phi_1, W_0, W_1)(., y - i\epsilon). \tag{7}$$

are analytic and hence L^2.

Now we can shift the integration contour in (5) to the imaginary direction (because $(\Phi_0, \Phi_1, W_0, W_1)$ is periodic with respect to y). Thus,

$$(\Phi_0, \Phi_1, W_0, W_1)_n(x) = \int_0^1 (\Phi_0, \Phi_1, W_0, W_1)(x, y + i\epsilon) e^{-i\pi n y + n\pi\epsilon}\, dy.$$

Thus, $(\Phi_0, \Phi_1, W_0, W_1)_n e^{n\pi\epsilon}$ is the nth Fourier coefficient of function (6) that is in L^2. Therefore,

$$((\Phi_0, \Phi_1, W_0, W_1)_n e^{n\pi\epsilon})_n \in l^2(\mathbb{Z}).$$

For symmetric reasons

$$((\Phi_0, \Phi_1, W_0, W_1)_n e^{-n\pi\epsilon})_n \in l^2(\mathbb{Z}).$$

Thus,

$$((\Phi_0, \Phi_1, W_0, W_1)_n e^{|n|\pi\epsilon})_n \in l^2(\mathbb{Z}).$$

Therefore, by Theorem 1, if $T > T(\pi\epsilon, 1)$, $(\Phi_0, \Phi_1, W_0, W_1) \in F_T$. Therefore,

$$(\Phi_0, \Phi_1, W_0, W_1) \in \bigcup_T F_T. \qquad \square$$

This paper aims at proving Theorem 1. In section 2, we will recall Micu and Zuazua's spectral results and give more detail about the eigenvalues of the problem. Then in section 3 we will state two propositions, dealing with high and low frequencies, and show how we can prove the theorem out of them. Finally, we will prove those propositions in sections 4 and 5.

2. Notations and preliminaries. At first, let us recall a few notations and results from [MZ1]. $\mathcal{X}$ is the energy space $H^1(\Omega)\oplus L^2(\Omega)\oplus H^1(\Gamma_0)\oplus L^2(\Gamma_0)$. Reference [MZ1] introduces a skew-adjoint operator over $\mathcal{X}$, denoted $\mathcal{A}_C$, whose domain is a subset of $H^2(\Omega)\times H^1(\Omega)\times H^2(\Gamma_0)\times H^1(\Gamma_0)$. It is defined by

$$\mathcal{A}_C(\Psi_0,\Psi_1,V_0,V_1)=(-\Psi_1,-\Delta\Psi_0,-V_1,-V_{0yy}+V_1+\Psi_1).$$

It can be diagonalized over an orthogonal basis of eigenvectors

$$\xi_\nu\cos n\pi y=\begin{pmatrix}\xi_\nu^1\cos n\pi y\\ \xi_\nu^2\cos n\pi y\\ \xi_\nu^3\cos n\pi y\\ \xi_\nu^4\cos n\pi y\end{pmatrix}=\begin{pmatrix}\frac{1}{\nu}\cosh(\sqrt{n^2\pi^2+\nu^2}(x-1))\cos n\pi y\\ -\cosh(\sqrt{n^2\pi^2+\nu^2}(x-1))\cos n\pi y\\ \frac{-\sqrt{n^2\pi^2+\nu^2}}{\nu^2}\sinh(\sqrt{n^2\pi^2+\nu^2})\cos n\pi y\\ \frac{\sqrt{n^2\pi^2+\nu^2}}{\nu}\sinh(\sqrt{n^2\pi^2+\nu^2})\cos n\pi y\end{pmatrix},$$

and the solution of (2) with initial condition $\xi_\nu\cos n\pi y$ is such that

$$\begin{pmatrix}\Psi(x,y,t)\\ \Psi_t(x,y,t)\\ V(y,t)\\ V_t(y,t)\end{pmatrix}=\xi_\nu(x)\cos n\pi y\ e^{\nu t}.$$

As this basis is not normalized, we will denote $\Xi_\nu=||\xi_\nu||_{\mathcal{X}}$.

The values ν that belong to $i\mathbb{R}$ are the eigenvalues of $\mathcal{A}_C$. For any integer n they are the roots of

$$\nu^2+n^2\pi^2=-z^2,$$

with

$$\tan z=\frac{z^2+n^2\pi^2}{z^3}. \tag{8}$$

For $n=0$ only, $\nu=0$ belongs to the spectrum. Otherwise, (8) has two kinds of solutions:

• Either z is real, denoted $z_{n,k}$ with k in $\mathbb{N}^*$. This corresponds to eigenvalues $\nu_{n,k}$ of modulus greater than $n\pi$. We denote $\nu_{n,-k}=-\nu_{n,k}$.

• Or $z=it$ is imaginary, with $\tanh t=\frac{-t^2+n^2\pi^2}{t^3}$. We denote it $z_{n,*}$. It gives rise to two eigenvalues denoted $\nu_{n,*}$ and $\nu_{n,**}=-\nu_{n,*}$ whose moduli are smaller than $n\pi$.

For any $(\underline{\Psi},\underline{V})$ in $\mathcal{X}$,

$$\begin{pmatrix}\underline{\Psi}(x,y)\\ \underline{V}(y)\end{pmatrix}=\sum_{\substack{n\in\mathbb{Z}\\ k\in\mathbb{Z}^*\cup\{*,**\}}}\frac{a_{n,k}}{\Xi_{n,k}}\ \xi_{n,k}(x,y),$$

with $(a_{n,k})_{n,k}\in l^2$.

We will denote $\mathcal{X}_{-1}$ the space of functions defined by the above formula, with the condition $(\frac{a_{n,k}}{\nu_{n,k}})_{n,k}\in l^2$, and we will denote $\mathcal{W}$ the same type of space with the condition $(a_{n,k}(1+|n|))_{n,k}\in l^2$.

If we denote (Ψ,V) as the solution of problem (2) with the initial conditions $(\Psi,\Psi_t)|_{t=0}=\underline{\Psi}$, $(V,V_t)|_{t=0}=\underline{V}$, the well-posedness of the problem implies that

$$||\Psi||_{H^1(\Omega\times(0,T))}\leq C||(\underline{\Psi},\underline{V})||_{\mathcal{X}}$$

and

$$||\Psi||_{L^2(\Omega\times(0,T))} \leq C||(\underline{\Psi},\underline{V})||_{\mathcal{X}_{-1}}.$$

To end with, we will also write for any $(\underline{\Psi},\underline{V})$ in $\mathcal{X}$ that

$$(\underline{\Psi},\underline{V}) \in \mathcal{X}^{n_0} \text{ if } n \neq n_0 \Rightarrow a_{n,k} = 0,$$
$$(\underline{\Psi},\underline{V}) \in \mathcal{X}^{(1)} \text{ if } |k| > |n| \Rightarrow a_{n,k} = 0,$$
$$(\underline{\Psi},\underline{V}) \in \mathcal{X}^{(2)} \text{ if } \Big(|k| \leq |n| \text{ or } k \in \{*, **\}\Big) \Rightarrow a_{n,k} = 0.$$

For any $(\underline{\Psi},\underline{V}) \in \mathcal{X}$, we have the following decomposition:

$$(\underline{\Psi},\underline{V}) = (\underline{\Psi},\underline{V})^{(1)} + (\underline{\Psi},\underline{V})^{(2)},$$

with $(\underline{\Psi},\underline{V})^{(1)} \in \mathcal{X}^{(1)}$ and $(\underline{\Psi},\underline{V})^{(2)} \in \mathcal{X}^{(2)}$.

Moreover, I will be the set of (k,n) such that $k \in \{*, **\}$ or $|k| \leq |n|$, and we will agree that $** = -*$.

Notice that for any integer n, $\mathcal{X}^n \subset \mathcal{W}$.

The following lemma gives a few results about the numbers $\nu_{n,k}$.

Lemma 1. *For all integers n and k, the following inequalities hold:*

$$\text{(i)} \quad \sqrt{n^2\pi^2 + (k-1)^2\pi^2} \leq |\nu_{n,k}| \leq \sqrt{n^2\pi^2 + \left(k - \frac{1}{2}\right)^2 \pi^2},$$

$$\text{(ii)} \quad \left|\sqrt{|\nu_{n,k}|^2 - n^2\pi^2} - \left(k - \frac{1}{2}\right)\pi\right| \geq \frac{C}{1+n^2},$$

$$\text{(iii)} \quad \left|\sqrt{|\nu_{n,k}|^2 - n^2\pi^2} - (k-1)\pi\right| \geq \frac{C}{k}.$$

Furthermore, with n going to infinity, we also have

$$\text{(iv)} \quad \pi - \frac{|\nu_{n,*}|}{n} \sim \frac{1}{2}\pi^{\frac{1}{3}} n^{-\frac{2}{3}}.$$

Proof. We denote, as in [MZ2], $z_{n,k} = \sqrt{|\nu_{n,k}|^2 - n^2\pi^2}$. $z_{n,k}$ satisfies

$$\tan z_{n,k} = \frac{z_{n,k}^2 + n^2\pi^2}{z_{n,k}^3}.$$

(See Figure 2.1.)

Inequality (i) follows from $(k-1)\pi \leq z_{n,k} \leq (k - \frac{1}{2})\pi$ and $|\nu_{n,k}| = \sqrt{z_{n,k}^2 + n^2\pi^2}$.

As we have $|z_{n,k} - ((k-1)\pi + \frac{\pi}{2})| \geq |z_{n,1} - \frac{\pi}{2}|$, (ii) follows from $|z_{n,1} - \frac{\pi}{2}| \geq \frac{C}{1+n^2}$. To prove (iii), it is enough to bound $|y_{n,k} - (k-1)\pi|$ from below, where $y_{n,k}$ satisfies $\frac{y_{n,k}^2}{y_{n,k}^3} = C(y_{n,k} - (k-1)\pi)$. The latter equation has an explicit solution that ensures $|y_{n,k} - (k-1)\pi| \leq \frac{C}{k\pi}$.

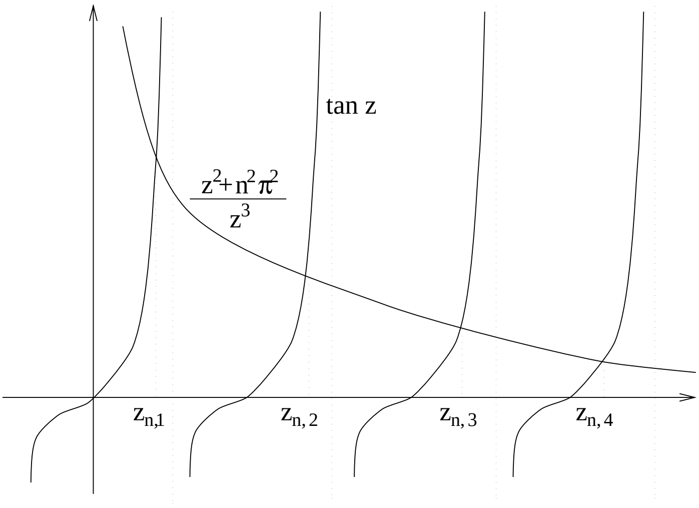

FIG. 2.1. *Determination of* $z_{n,k}$.

To end with, if we denote $z_{n,*} = \sqrt{n^2\pi^2 - |\nu_{n,*}|^2}$, we have

$$e^{2z_{n,*}} = \frac{z_{n,*}^3 - z_{n,*}^2 + \pi^2 n^2}{z_{n,*}^3 + z_{n,*}^2 - \pi^2 n^2}.$$

Thus,

$$z_{n,*} \sim (\pi^2 n^2)^{\frac{1}{3}} \Rightarrow \pi - \frac{|\nu_{n,*}|}{n} \sim \frac{1}{2}\pi^{\frac{1}{3}} n^{-\frac{2}{3}}(1 + o(1)). \qquad \square$$

From Lemma 1 and in view of the explicit value of $\xi_{n,k}$, we can see that there is a constant C such that for any (n,k) we have

$$\Xi_{n,k} \le Ce^{Cn^{\frac{2}{3}}}. \tag{9}$$

3. Proof of Theorem 1. In order to prove this theorem, we will need two estimates, for high and low frequencies.

PROPOSITION 1 (high frequencies). *There exists a constant C and a positive time T_1 such that for any initial condition $(\underline{\Psi}, \underline{V})$ in $\mathcal{W}$, we have*

$$||(\underline{\Psi}, \underline{V})^{(2)}||_{\mathcal{W}}^2 \le C\Big(||\Psi||^2_{L^2((-2T_1,2T_1)\times\Omega)} + ||V_{tt}||^2_{L^2((0,T_1)\times\Gamma_0)}\Big).$$

This proposition looks like the usual estimate given by microlocal analysis when the geometric control hypothesis of Bardos–Lebeau–Rauch holds (see [Le]). This is not surprising because the rays that correspond to those frequencies always hit the controlled boundary within a uniform finite time.

PROPOSITION 2 (low frequencies). *For any positive ϵ and δ, there exists a constant $C_{\epsilon,\delta}$, an integer $n_1(\epsilon)$, and a positive time $T_2(\epsilon,\delta) \le \frac{C_\delta}{\epsilon^{1+\delta}}$ such that for any integer n greater than $n_1(\epsilon)$ and any initial condition $(\underline{\Psi}, \underline{V})$ in $\mathcal{X}^n$*

$$||(\underline{\Psi}, \underline{V})^{(1)}||_{\mathcal{X}}^2 \le C_{\epsilon,\delta}\; e^{2\epsilon|n|} \int_{-T_2(\epsilon,\delta)}^{T_2(\epsilon,\delta)} |V_{tt}(0,t)|^2 \; dt.$$

The difficult part of the problem is concentrated in this part of the spectrum, where the gap between the frequencies is not bounded from below. This is why the relevant constants appear in that proposition. Not much is known about those constants. When ϵ goes to 0, $C_{\epsilon,\delta}$ certainly goes to infinity; if it were bounded, we could take the limit and prove that any initial data can be controlled, without any hypothesis. This certainly is not true because of Bardos–Lebeau–Rauch's theorem.

To the author's knowledge, no such thing can be said about the constant C_δ when δ goes to 0.

We also have the following lemma.

Lemma 2. *There is a constant C such that for any integer n and any initial condition $(\underline{\Psi}, \underline{V})$ in $\mathcal{X}^n$*

$$||(\underline{\Psi}, \underline{V})^{(2)}||^2_{\mathcal{X}_{-1}} \leq \frac{C}{1+n^2}\ ||(\underline{\Psi}, \underline{V})^{(2)}||^2_{\mathcal{X}}.$$

Proof of Lemma 2. All frequencies in $(\underline{\Psi}, \underline{V})^{(2)}$ of nonzero amplitude are such that $|k| > |n|$.

Now, it follows from Lemma 1 that $|k| > |n| \Rightarrow |\nu_{n,k}|^2 \geq C(1+n^2)$. Furthermore,

$$||(\underline{\Psi}, \underline{V})||^2_{\mathcal{X}_{-1}} = \sum_k \frac{1}{|\nu_{n,k}|^2}|a_{n,k}|^2, \qquad ||(\underline{\Psi}, \underline{V})||^2_{\mathcal{X}} = \sum_k |a_{n,k}|^2. \qquad \square$$

Let us first prove that Propositions 1 and 2 and Lemma 2 imply that Theorem 1 holds.

Proof. Let ϵ and δ be two positive real numbers. Out of Propositions 1 and 2, we get two positive times, denoted T_1 and $T_2(\epsilon, \delta)$. Let us define

$$T(\epsilon, \delta) = \sup(T_1, T_2(\epsilon, \delta)).$$

Let n be a positive integer and $(\underline{\Psi}, \underline{V})$ any initial condition in $\mathcal{X}^n$. Then we have

$$\begin{aligned} ||(\underline{\Psi}, \underline{V})||^2_{\mathcal{X}} &= ||(\underline{\Psi}, \underline{V})^{(1)}||^2_{\mathcal{X}} + ||(\underline{\Psi}, \underline{V})^{(2)}||^2_{\mathcal{X}}, \\ &\leq ||(\underline{\Psi}, \underline{V})^{(1)}||^2_{\mathcal{X}} + ||(\underline{\Psi}, \underline{V})^{(2)}||^2_{\mathcal{W}}. \end{aligned}$$

Hence, by Propositions 1 and 2, for $n \geq n_1(\epsilon)$,

$$||(\underline{\Psi}, \underline{V})||^2_{\mathcal{X}} \leq C_{\epsilon,\delta}\ e^{2\epsilon|n|} \int_{-T_2(\epsilon,\delta)}^{T_2(\epsilon,\delta)} |V_{tt}(0,t)|^2\ dt$$

$$+\ C\ \left[\int_0^{T_1} |V_{tt}(0,t)|^2\ dt\ +\ ||\Psi||^2_{L^2((-2T_1,2T_1)\times\Omega)}\right].$$

Thus,

$$||(\underline{\Psi}, \underline{V})||^2_{\mathcal{X}} \leq C'_{\epsilon,\delta}\ e^{2\epsilon|n|} \int_{-T(\epsilon,\delta)}^{T(\epsilon,\delta)} |V_{tt}(0,t)|^2\ dt + C\ ||\Psi||^2_{L^2((-2T_1,2T_1)\times\Omega)}.$$

As the problem is well posed,

$$\begin{aligned}||(\underline{\Psi},\underline{V})||^2_{\mathcal{X}} &\leq C'_{\epsilon,\delta}\ e^{2\epsilon|n|}\int_{-T(\epsilon,\delta)}^{T(\epsilon,\delta)}|V_{tt}(0,t)|^2\ dt + C'\ ||(\underline{\Psi},\underline{V})||^2_{\mathcal{X}_{-1}},\\ &\leq C'_{\epsilon,\delta}\ e^{2\epsilon|n|}\int_{-T(\epsilon,\delta)}^{T(\epsilon,\delta)}|V_{tt}(0,t)|^2\ dt + C'\ ||(\underline{\Psi},\underline{V})^{(1)}||^2_{\mathcal{X}_{-1}} + C'\ ||(\underline{\Psi},\underline{V})^{(2)}||^2_{\mathcal{X}_{-1}},\\ &\leq C'_{\epsilon,\delta}\ e^{2\epsilon|n|}\int_{-T(\epsilon,\delta)}^{T(\epsilon,\delta)}|V_{tt}(0,t)|^2\ dt + C'\ ||(\underline{\Psi},\underline{V})^{(1)}||^2_{\mathcal{X}} + C'\ ||(\underline{\Psi},\underline{V})^{(2)}||^2_{\mathcal{X}_{-1}}.\end{aligned}$$

Hence by Proposition 2,

$$||(\underline{\Psi},\underline{V})||^2_{\mathcal{X}} \leq C'_{\epsilon,\delta}\ e^{2\epsilon|n|}\int_{-T(\epsilon,\delta)}^{T(\epsilon,\delta)}|V_{tt}(0,t)|^2\ dt\ +\ C'C_{\epsilon,\delta}\ e^{2\epsilon|n|}\int_{-T_2(\epsilon,\delta)}^{T_2(\epsilon,\delta)}|V_{tt}(0,t)|^2\ dt$$

$$+C'\ ||(\underline{\Psi},\underline{V})^{(2)}||^2_{\mathcal{X}_{-1}}.$$

Therefore, by Lemma 2,

$$||(\underline{\Psi},\underline{V})||^2_{\mathcal{X}} \leq C''_{\epsilon,\delta}\ e^{2\epsilon|n|}\int_{-T(\epsilon,\delta)}^{T(\epsilon,\delta)}|V_{tt}(0,t)|^2\ dt + \frac{C}{1+n^2}\ ||(\underline{\Psi},\underline{V})^{(2)}||^2_{\mathcal{X}}.$$

Thus,

$$||(\underline{\Psi},\underline{V})||^2_{\mathcal{X}} \leq C''_{\epsilon,\delta}\ e^{2\epsilon|n|}\int_{-T(\epsilon,\delta)}^{T(\epsilon,\delta)}|V_{tt}(0,t)|^2\ dt + \frac{C}{1+n^2}\ ||(\underline{\Psi},\underline{V})||^2_{\mathcal{X}}.$$

For $|n| \geq \sqrt{2C-1}$, $\frac{C}{1+n^2} \leq \frac{1}{2}$.

Thus, if $n \geq n_2(\epsilon) = \sup\{n_1(\epsilon), \sqrt{2C-1}\}$,

$$||(\underline{\Psi},\underline{V})||^2_{\mathcal{X}} \leq 2\ C''_{\epsilon,\delta}\ e^{2\epsilon|n|}\int_{-T(\epsilon,\delta)}^{T(\epsilon,\delta)}|V_{tt}(0,t)|^2\ dt.$$

As we can increase the constant to take care of the first $n_2(\epsilon)$ values of n, we have proved Theorem 1. (Note that it is enough to prove estimates for each $\mathcal{X}^n$ because of the orthogonality of the solutions for different values of n.) □

We still have to prove the two propositions. This will be dealt with in the following two sections.

4. Proof of Proposition 1 (high frequencies). A simple application of Ingham techniques would allow us to prove a slightly weaker form of this proposition; specifically, it would prove that

$$||(\underline{\Psi},\underline{V})^{(2)}||_{\mathcal{W}} \leq C\Big(||\Psi||_{L^2((-2T_1,2T_1)\times\Omega)} + ||V^{(2)}{}_{tt}||_{L^2((0,T_1)\times\Gamma_0)}\Big).$$

In order to get V instead of $V^{(2)}$ in the right-hand side of the estimate, we will use microlocal techniques.

The proof is based upon the techniques that are used when the geometric control hypothesis holds, e.g., when every ray hits the boundary. In our case, we will have to get rid of uncontrolled rays by cutting off their frequencies. We cannot take a brutal cutoff because it would not be pseudodifferential. Thus, we will have to introduce smooth pseudodifferential cutoffs, which we will denote P_1 and P_2. These will be chosen to ensure $P_1 + P_2 = Id$, but their images will have a nonzero intersection. Dealing with this intersection will be the main source of dissemblance between the proof of this proposition and the classical one (see [Le], for instance).

Let T_1 be a positive time that will be fixed later. Let us introduce a few functional spaces.

Let $\mathcal{Z}$ be the set of all (Ψ, V) in $L^2((-2T_1, 2T_1) \times \Omega) \times L^2((0, T_1) \times \Gamma_0)$ such that

$$\begin{cases} \Box\Psi = 0 \text{ over } (-2T_1, 2T_1) \times \Omega, \\ \frac{\partial \Psi}{\partial n} = 0 \text{ over } \Gamma_1 \times (-2T_1, 2T_1), \\ \frac{\partial \Psi}{\partial n} = -V_t \text{ over } \Gamma_0 \times (-2T_1, 2T_1), \\ V_{tt} - V_{yy} + \Psi_t = 0 \text{ over } \Gamma_0 \times (-2T_1, 2T_1), \end{cases}$$

and

$$V_{tt} \text{ belongs to } L^2((0, T_1) \times \Gamma_0).$$

The norm over $\mathcal{Z}$ will be defined as

$$||(\Psi, V)||^2_{\mathcal{Z}} = ||\Psi||^2_{L^2((-2T_1,2T_1)\times\Omega)} + ||V_{tt}||^2_{L^2((0,T_1)\times\Gamma_0)}.$$

The functions of $\mathcal{Z}$ can always be written as

$$\Psi(x, y, t) = \sum_{\substack{n\in\mathbb{Z} \\ k\in\mathbb{Z}^*\cup\{*,**\}}} \frac{a_{n,k}}{\Xi_{n,k}} e^{\nu_{n,k}t} \cos \pi ny \; \xi^1_{n,k}(x),$$

$$V(y, t) = \sum_{\substack{n\in\mathbb{Z} \\ k\in\mathbb{Z}^*\cup\{*,**\}}} \frac{a_{n,k}}{\Xi_{n,k}} e^{\nu_{n,k}t} \cos \pi ny \; \xi^3_{n,k},$$

with $(\frac{a_{n,k}}{\nu_{n,k}})_{n,k} \in l^2$.

Therefore, we can separate the high frequencies from the low ones. Let us denote

$$(\Psi, V) \in \mathcal{Z}^{(1)} \text{ if } |k| > |n| \Rightarrow a_{n,k} = 0.$$

(Note for easier understanding: The functions of $\mathcal{Z}^{(1)}$ have the same frequencies as those of $\mathcal{X}^{(1)}$. Nevertheless, $\mathcal{X}^{(1)} \neq \mathcal{Z}^{(1)}$.)

To end with, for a $(\underline{\Psi}, \underline{V})$ in $\mathcal{W}$, we shall write $(\underline{\Psi}, \underline{V}) \in \mathcal{W}^{(3)}$ if

$$\left(|k| \leq \frac{n}{2} \text{ or } |k| = *\right) \Rightarrow a_{n,k} = 0.$$

If $(\underline{\Psi}, \underline{V})$ belongs to $\mathcal{W} \cap \mathcal{X}^{(2)}$, then $(\underline{\Psi}, \underline{V})$ belongs to $\mathcal{W}^{(3)}$.

Let S map any initial condition $(\underline{\Psi}, \underline{V})$ in $\mathcal{X}_{-1}$ to the solution of problem (2) over $(-2T_1, 2T_1) \times \Omega$ with $(\underline{\Psi}, \underline{V})$ as initial conditions.

In view of Proposition (2.1) of [MZ2], if we put $(\underline{\Psi}, \underline{V})(x, y) = \sum_n (\underline{\Psi}, \underline{V})_n(x) e^{iny}$, we have

$$\int_0^{T_1} |(V_n)_{tt}|^2 \; dt \leq C(n^4 + 1)||(\underline{\Psi}, \underline{V})_n||^2_{H^1(0,1)\times L^2(0,1)\times\mathbb{R}\times\mathbb{R}}.$$

Therefore,

$$S(\mathcal{W}) \subset \mathcal{Z}.$$

Let us define the mapping $\tilde{\imath}$ as follows:

$$\tilde{\imath}:\left|\begin{array}{l}\mathcal{W}^{(3)}\oplus\mathcal{Z}^{(1)}\to\mathcal{Z}\\ ((\underline{\Psi},\underline{V}),(\Phi,W))\mapsto S(\underline{\Psi},\underline{V})+(\Phi,W),\end{array}\right.$$

$$\tilde{\imath}((\underline{\Psi},\underline{V})\ \ (\Phi,W))=0\Leftrightarrow S(\underline{\Psi},\underline{V})+(\Phi,W)=0\Leftrightarrow S(\underline{\Psi},\underline{V})=-(\Phi,W).$$

Therefore, the only nonzero coefficients $a_{n,k}$ are such that $\frac{|n|}{2}<|k|\leq|n|$. $\tilde{\imath}$ induces an injective mapping i from $G=(\mathcal{W}^{(3)}\oplus\mathcal{Z}^{(1)})/\ker\tilde{\imath}$ to $\mathcal{Z}$.

LEMMA 3. *If T_1 is big enough, i is onto.*

We will prove Lemma 3 later on.

First, let us see how we can end the proof of the proposition out of this lemma for such a T_1.

As i is a one-to-one continuous morphism, its reciprocal mapping is also continuous. Thus, there exists a constant C such that for any couple $((\underline{\Psi},\underline{V}),\ (\Phi,W))$ in $\mathcal{W}^{(3)}\oplus\mathcal{Z}^{(1)}$, we have

$$||[(\underline{\Psi},\underline{V}),\ (\Phi,W)]||_G\leq C\ ||\tilde{\imath}((\underline{\Psi},\underline{V}),\ (\Phi,W))||_{\mathcal{Z}}. \tag{10}$$

Here, $[(\underline{\Psi},\underline{V}),\ (\Phi,W)]$ denotes the class of $((\underline{\Psi},\underline{V}),\ (\Phi,W))$ in G, and the norm on this quotient space has the usual definition:

$$||[(\underline{\Psi},\underline{V}),\ (\Phi,W)]||_G^2=\inf_{(w_1,w_2)\in\ker\tilde{\imath}}||((\underline{\Psi},\underline{V}),\ (\Phi,W))+(w_1,w_2)||^2_{\mathcal{W}^{(3)}\oplus\mathcal{Z}^{(1)}}.$$

Let $(\underline{\Psi},\underline{V})$ be any element of $\mathcal{W}$.

We can split it into $(\underline{\Psi},\underline{V})=(\underline{\Psi},\underline{V})_1+(\underline{\Psi},\underline{V})_3$ with $(\underline{\Psi},\underline{V})_3\in\mathcal{W}^{(3)}$ and $S(\underline{\Psi},\underline{V})_1=(\Psi_1,V_1)\in\mathcal{Z}^{(1)}$ (by deciding for each frequency whether $|k|\leq\frac{|n|}{2}$).

Indeed, $S(\underline{\Psi},\underline{V})_1$ has the same frequencies as $(\underline{\Psi},\underline{V})_1$ that belongs to $\mathcal{W}$. Thus,

$$\begin{aligned}||\tilde{\imath}((\underline{\Psi},\underline{V})_3,(\Psi_1,V_1))||^2_{\mathcal{Z}}&=||S(\underline{\Psi},\underline{V})_3+S(\underline{\Psi},\underline{V})_1||^2_{\mathcal{Z}}\\&=||\Psi||^2_{L^2((-2T_1,2T_1)\times\Omega)}+||V_{tt}||^2_{L^2((0,T_1)\times\Gamma_0)}.\end{aligned}\tag{11}$$

On the other hand,

$$||[(\underline{\Psi},\underline{V})_3\ ,\ (\Psi_1,V_1)]||_G^2=\inf_{Sw_2=-w_1}\Big(||(\underline{\Psi},\underline{V})_3+w_2||^2_{\mathcal{W}^{(3)}}+||(\Psi_1,V_1)+w_1||^2_{\mathcal{Z}^{(1)}}\Big).$$

The nonzero coefficients in w_2 are such that $\frac{|n|}{2}<|k|\leq|n|$. They correspond to elements of the basis that are orthogonal to $\mathcal{W}\cap\mathcal{X}^{(2)}$. So, as the basis is orthogonal, for any initial condition $(\underline{\Psi},\underline{V})$ in $\mathcal{W}$

$$\begin{aligned}||(\underline{\Psi},\underline{V})^{(2)}||^2_{\mathcal{W}}&=\inf_{Sw_2=-w_1}||(\underline{\Psi},\underline{V})_3+w_2||^2_{\mathcal{W}^{(3)}},\\&\leq\inf_{Sw_2=-w_1}\Big(||(\underline{\Psi},\underline{V})_3+w_2||^2_{\mathcal{W}^{(3)}}+||(\Psi_1,V_1)+w_1||^2_{\mathcal{Z}^{(1)}}\Big).\end{aligned}$$

Therefore, by definition of the norm over G,

$$||(\underline{\Psi},\underline{V})^{(2)}||^2_{\mathcal{W}}\leq||[(\underline{\Psi},\underline{V})_3,\ (\Psi_1,V_1)]||^2_G.$$

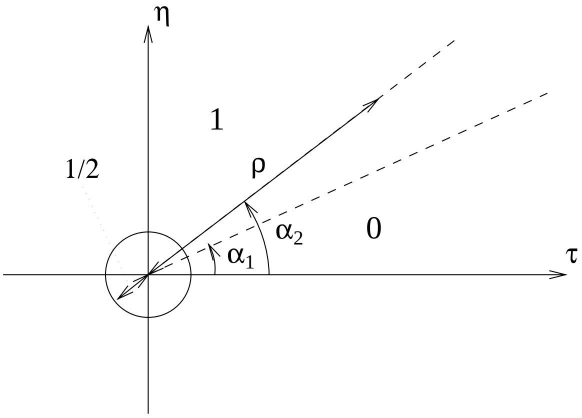

FIG. 4.1. *Angles α_1 and α_2.*

Thus, out of (10),

$$||(\underline{\Psi},\underline{V})^{(2)}||^2_{\mathcal{W}} \le C\ ||\tilde{\imath}((\underline{\Psi},\underline{V})_3,\ (\Psi_1,V_1))||^2_{\mathcal{Z}}.$$

Then, out of (11),

$$||(\underline{\Psi},\underline{V})^{(2)}||^2_{\mathcal{W}} \le C\ \Big(||\Psi||^2_{L^2((-2T_1,2T_1)\times\Omega)} + ||V_{tt}||^2_{L^2((0,T_1)\times\Gamma_0)}\Big). \qquad \square$$

Proof of Lemma 3. In order to prove that i is surjective, we have to prove that for any couple (Φ,W) in $\mathcal{Z}$, we can find an element $((\underline{\Psi},\underline{V})_3,\ (\Phi_1,W_1))$ of $\mathcal{W}^{(3)}\oplus\mathcal{Z}^{(1)}$ such that

$$\tilde{\imath}((\underline{\Psi},\underline{V})_3,\ (\Phi_1,W_1)) = (\Phi,W).$$

Let (Φ,W) be an element in $\mathcal{Z}$. It can be written as

$$\Phi(x,y,t) = \sum_{\substack{n\in\mathbb{Z}\\ k\in\mathbb{Z}^*\cup\{*,**\}}} \frac{a_{n,k}}{\Xi_{n,k}}\ e^{\nu_{n,k}t}\cos\pi ny\ \xi^1_{n,k}(x),$$

$$W(y,t) = \sum_{\substack{n\in\mathbb{Z}\\ k\in\mathbb{Z}^*\cup\{*,**\}}} \frac{a_{n,k}}{\Xi_{n,k}}\ e^{\nu_{n,k}t}\cos\pi ny\ \xi^3_{n,k}.$$

We shall consider Φ as defined over $\mathbb{R}_t\ \times\ \mathbb{R}_x\ \times\ \mathbb{R}_y$ by continuing the functions $\xi(x)$ by $\xi(x)=0$ if $x\notin[0,1]$.

Let us denote $\tilde\Omega=(0,1)\times\mathbb{R}$. Φ is a distribution that satisfies $\Box\Phi=0$ over $\tilde\Omega\times\mathbb{R}_t$ and whose restriction outside $\tilde\Omega\times\mathbb{R}_t$ is zero. Moreover, Φ belongs to $\mathcal{S}'(\mathbb{R}^3)$.

We shall introduce two symbols. Let γ_1 and γ_2 be two real numbers such that $\frac{1}{2}<\gamma_2<\gamma_1<1$ and denote $\alpha_k=\frac{1}{\sqrt{1+\gamma_k^2}}$, $k=1,2$. See Figure 4.1.

We define the symbol $\sigma_1(\eta,\tau)$ (the degree of which is zero) as follows.

If $\eta^2+\tau^2$ is greater than $\frac{1}{2}$, σ_1 is homogeneous of degree 0 and is an even, C^∞ function of $\alpha=\frac{\eta}{\tau}$. It is equal to 1 in the neighborhood of the set $|\frac{\eta}{\tau}|\ge\alpha_2$ and to 0 in the neighborhood of $|\frac{\eta}{\tau}|\le\alpha_1$. Furthermore, on the other regions, we demand that $\sigma_1(\eta,\tau)$ remain C^∞.

Let us denote $P_1 = Op(\sigma_1)$ as the pseudodifferential operator associated with the symbol σ_1. It is tangential with respect to x and of degree zero. It is operating over $\mathcal{S}'(\mathbb{R}^3)$.

If we put $\sigma_2 = 1 - \sigma_1$ and $P_2 = Op(\sigma_2)$, we get another operator with the same properties, such that $P_1 + P_2 = Id$.

Let us define $\Phi_1 = P_1\Phi$ and $\Phi_2 = P_2\Phi$. We have $\Phi_1 + \Phi_2 = \Phi$.

We may compute the explicit form of Φ_2:

$$\widehat{\Phi} = \sum_{n,k} \frac{a_{n,k}}{\Xi_{n,k}}\ \widehat{\xi^1_{n,k}}(\xi)\ \frac{\delta_{\pi n} + \delta_{-\pi n}}{2}(\eta)\ \delta_{-i\nu_{n,k}}(\tau),$$

so

$$\sigma_2(\eta,\tau)\widehat{\Phi} = \sum_{n,k} \frac{a_{n,k}}{\Xi_{n,k}}\ \sigma_2(\pi n, -i\nu_{n,k})\ \widehat{\xi^1_{n,k}}(\xi)\ \frac{\delta_{\pi n} + \delta_{-\pi n}}{2}(\eta)\ \delta_{-i\nu_{n,k}}(\tau),$$

then

$$\Phi_2 = P_2\Phi = \sum_{n,k} \frac{a_{n,k}}{\Xi_{n.k}}\ \sigma_2(\pi n, -i\nu_{n,k})\ \xi^1_{n,k}(x)\ \cos ny\pi\ e^{t\nu_{n,k}}.$$

Like Φ, Φ_2 satisfies $\Box\Phi_2 = 0$ in $\Omega \times \mathbb{R}_t$.

Furthermore, if we denote

$$W_2 = P_2 W = \sum_{n,k} \frac{a_{n,k}}{\Xi_{n,k}}\ \sigma_2(\pi n, -i\nu_{n,k})\ \xi^3_{n,k}\ \cos ny\pi\ e^{t\nu_{n,k}},$$

we can notice that (Φ_2, W_2) still is a solution to problem (2).

The same computation and remark can be done about Φ_1 and W_1.

Let us study the singularities of W_2.

As P_2 is of order 0 and W_{tt} belongs to $L^2((0,T_1)\times\Gamma_0)$, W_{2tt} also belongs to $L^2((0,T_1)\times\Gamma_0)$. Furthermore, as P_2 is tangential with respect to x and σ_2 is zero near $|\frac{\eta}{\tau}| \geq \alpha_2$, we have

$$WF(W_2) \subset \left\{|\frac{\eta}{\tau}| \leq \alpha_2\right\}. \tag{12}$$

Now, on the part $\{|\frac{\eta}{\tau}| \leq \alpha_2\}$ of the cotangent set, we have $\tau \neq 0$, so as W_{2tt} belongs to $L^2((0,T_1)\times\Gamma_0)$ we know that if $\sigma \in ((0,T_1)\times\Gamma_0)\times\{|\frac{\eta}{\tau}| \leq \alpha_2\}$, W_2 belongs to H^2_σ. Together with the inclusion (12), this means that W_2 belongs to $H^2((0,T_1)\times\Gamma_0)$; thus,

$$W_{2yy} \in L^2((0,T_1)\times\Gamma_0).$$

This means that

$$\int_0^{T_1}\int_0^1 \left|\sum_{n,k} \frac{n^2 a_{n,k}}{\Xi_{n,k}} \sigma_2(\pi n, -i\nu_{n,k})\xi^3_{n,k}\ \cos ny\pi\ e^{t\nu_{n,k}}\right|^2\ dy\ dt < +\infty.$$

Now, as $\sigma_2(\pi n, -i\nu_{n,k})$ is 0 if $|k| = *$ or $|k| \leq \gamma_2 n$, the sum ranges only on $|k| \geq \gamma_2|n|$; therefore, through Lemma 1, there is a positive ϵ such that for any n, k, $|\nu_{n,k+1}| -$

$|\nu_{n,k}| \geq \epsilon$. Thus, according to Ingham's inequality (see, for instance, [Z, p. 222]), if we put $T_1 > \frac{2\pi}{\epsilon}$,

$$\sum_{n,k} \left| \frac{n^2 a_{n,k} \sigma_2(\pi n, -i\nu_{n,k}) \xi^3_{n,k}}{\Xi_{n,k}} \right|^2 < +\infty.$$

Now Lemma 1 proves that for $|k| \geq \gamma_2 |n|$

$$c \leq \Xi_{n,k} \leq C$$

and

$$\frac{c}{n} \leq \xi^3_{n,k} \leq \frac{C}{n}.$$

Thus, we get

$$\sum_{n,k} |n a_{n,k} \sigma_2(\pi n, -i\nu_{n,k})|^2 < +\infty.$$

Together with the same computation based upon $W_2 \in L^2((0,T_1) \times \Gamma_0)$, we get

$$\Big((1+|n|) a_{n,k} \sigma_2(\pi n, -i\nu_{n,k})\Big)_{n,k} \in l^2.$$

Thus, we have proved that (Φ_2, W_2) corresponds to a couple $(\underline{\Psi}, \underline{V})_3$ of $\mathcal{W}$ such that $(\Phi_2, W_2) = S(\underline{\Psi}, \underline{V})_3$. Moreover, the set of frequencies allowed by σ_2 in $(\underline{\Psi}, \underline{V})_3$ shows that $(\underline{\Psi}, \underline{V})_3$ belongs to $\mathcal{W}^{(3)}$.

To conclude, as $(\Phi_1, W_1) = (\Phi, W) - (\Phi_2, W_2)$ and (Φ_2, W_2) belongs to $S(\mathcal{W}) \subset \mathcal{Z}$, (Φ_1, W_1) also belongs to $\mathcal{Z}$. As it has the same frequencies as Φ_1, we even know that it belongs to $\mathcal{Z}^{(1)}$.

Thus, we have found a couple $((\underline{\Psi}, \underline{V})_3,\ (\Phi_1, W_1))$ in $\mathcal{W}^{(3)} \oplus \mathcal{Z}^{(1)}$ such that

$$\tilde{\imath}((\underline{\Psi}, \underline{V})_3,\ (\Phi_1, W_1)) = S(\underline{\Psi}, \underline{V})_3 + (\Phi_1, W_1) = (\Phi, W).$$

Hence, we have proved Lemma 3 and Proposition 1. □

5. Proof of Proposition 2 (low frequencies). In low frequencies of the spectrum, Ingham techniques fail because the gap $\nu_{n,k+1} - \nu_{n,k}$ goes to 0. In order to get a sharp estimate, we will use biorthogonal sequences.

The idea is to build functions $h_{n,k}$ for which $\widehat{h}_{n,k}(\nu_{n,k_0}) = \delta_k^{k_0}$, supported by $[-T, T]$ and such that their L^2 norm is bounded from above.

The usual technique is based upon the functions

$$\prod_k \Big(1 - \frac{z^2}{\nu^2_{n,k}}\Big).$$

We will build that kind of function (which we will call functions f) by more explicit means in section 5.1.

These functions have a problem, though: Their L^2 norms behave like $e^{\pi|n|}$ and, therefore, are not bounded. Nevertheless, the zone where this L^2 norm is big is concentrated in the frequency interval $[-n, n]$ that includes only two eigenfrequencies: $\nu_{n,*}$ and $\nu_{n,**}$. Thus, in section 5.2 we will build a sequence of functions $g_{n,k}$ such that

$||\widehat{g}_{n,k}||_{L^2}$ is exponentially small in $[-n,n]$ and bounded from below outside. Then we will put $h=f*g$ in order to compensate the size of f without hindering its properties at frequencies $\nu_{n,k}$.

Indeed, we will prove the following lemma.

LEMMA 4. *For any odd integer q and any positive real number ϵ, there exists a time $T_2(q,\epsilon)$ smaller than $C_q\epsilon^{\frac{q+1}{1-q}}$ such that we can find a biorthogonal sequence $(h_{\epsilon,q}^{k_0,n})_{(n,k_0)\in\mathbb{N}^*\times(\mathbb{Z}^*\cup\{*,**\})}$ of L^2 functions for which the following properties hold:*

(i) *$h_{\epsilon,q}^{k_0,n}$ is supported by $[-T_2(q,\epsilon),T_2(q,\epsilon)]$;*

(ii) *$||h_{\epsilon,q}^{k_0,n}||_{L^2}^2\leq C\ e^{2\epsilon|n|}$;*

(iii) *if $k\neq\pm k_0$, $\int h_{\epsilon,q}^{k_0,n}(t)e^{t\nu_{n,k}}\ dt=0$;*

(iv) *if $n\geq n_1(\epsilon,q)$ and $(k_0,n)\in I=\{(k,n)\mid|k|=*\text{ or }|k|\leq n\}$,*
$|\int h_{\epsilon,q}^{k_0,n}(t)e^{t\nu_{n,\pm k_0}}\ dt\ |\geq\frac{c}{n^{N_q}}$.

The constants depend only on q and ϵ. Moreover, the functions h can be chosen as even or odd. We will denote them $h_{e_{\epsilon,q}}^{k_0,n}$ or $h_{o_{\epsilon,q}}^{k_0,n}$.

Let us first prove Proposition 2 from this lemma.

Let n be an integer greater than $n_1(\epsilon)$ and $(\underline{\Psi},\underline{V})$ an initial condition in $\mathcal{X}^n$. Let us denote (Ψ,V) the solution of (2) with these initial data. We will denote K as the operator that maps $(\underline{\Psi},\underline{V})$ in $\mathcal{X}^n$ to $V_{tt}(y=0,.)$.

If we denote $a_{n,k}=\langle(\underline{\Psi},\underline{V}),\frac{\xi_{n,k}}{\Xi_{n,k}}\rangle$, we notice that

$$V(y,t)=\sum_{k\in\mathbb{Z}^*\cup\{*,**\}}a_{n,k}\ \frac{\xi_{n,k}^3}{\Xi_{n,k}}\cos\pi ny\ e^{\nu_{n,k}t}.$$

Thus,

$$K(\underline{\Psi},\underline{V})(t)=\sum_{k\in\mathbb{Z}^*\cup\{*,**\}}a_{n,k}\ \frac{\xi_{n,k}^3}{\Xi_{n,k}}\nu_{n,k}^2e^{\nu_{n,k}t}.$$

Now for (k_0,n) in I and L in $\mathbb{N}^*$, as $\widehat{h_e}$ is even,

$$\int h_{e_{\epsilon,q}}^{k_0,n}(t)K\Big(\sum_{\substack{|k|=*\\|k|\leq L}}a_{n,k}\ \frac{\xi_{n,k}}{\Xi_{n,k}}\Big)(t)\ dt=\sum_{\substack{k=*\\1\leq k\leq L}}(a_{n,k}+a_{n,-k})\frac{\xi_{n,k}^3}{\Xi_{n,k}}\nu_{n,k}^2\int h_{e_{\epsilon,q}}^{k_0,n}(t)e^{\nu_{n,k}t}\ dt.$$

From (iii), if $L\geq k_0$,

$$\int h_{e_{\epsilon,q}}^{k_0,n}(t)K\Big(\sum_{\substack{|k|=*\\|k|\leq L}}a_{n,k}\ \frac{\xi_{n,k}}{\Xi_{n,k}}\Big)(t)\ dt=(a_{n,k_0}+a_{n,-k_0})\frac{\xi_{n,k_0}^3}{\Xi_{n,k_0}}\nu_{n,k_0}^2\int h_{e_{\epsilon,q}}^{k_0,n}(t)e^{\nu_{n,k_0}t}\ dt.$$

From (iv), we get that

$$\left|\int h_{e_{\epsilon,q}}^{k_0,n}(t)K\Big(\sum_{\substack{|k|=*\\|k|\leq L}}a_{n,k}\frac{\xi_{n,k}}{\Xi_{n,k}}\Big)(t)\ dt\right|\geq|a_{n,k_0}+a_{n,-k_0}|\ \left|\frac{\xi_{n,k_0}^3}{\Xi_{n,k_0}}\right|\ |\nu_{n,k_0}|^2\ \frac{c}{n^{N_q}}.$$

Now Lemma 1 implies that

$$|\xi_{n,k_0}^3|=\frac{|z_{n,k_0}|}{|\nu_{n,k_0}|}|\sin z_{n,k_0}|\geq\frac{C_\gamma}{n^N}.$$

Thus,

$$\left|\int h_{e\epsilon,q}^{k_0,n}(t)K\Big(\sum_{\substack{|k|=*\\|k|\leq L}} a_{n,k}\frac{\xi_{n,k}}{\Xi_{n,k}}\Big)(t)\ dt\right| \geq |a_{n,k_0}+a_{n,-k_0}|\ C\ e^{-Cn^{\frac{2}{3}}}.$$

If we take the limit with $L \to +\infty$,

$$\left|\int h_{e\epsilon,q}^{k_0,n}(t)K(\underline{\Psi},\underline{V})(t)\ dt\right| \geq |a_{n,k_0}+a_{n,-k_0}|\ C\ e^{-Cn^{\frac{2}{3}}}.$$

We can prove the same way that

$$\left|\int h_{o\epsilon,q}^{k_0,n}(t)K(\underline{\Psi},\underline{V})(t)\ dt\right| \geq |a_{n,k_0}-a_{n,-k_0}|\ C\ e^{-Cn^{\frac{2}{3}}}.$$

Thus, by summing conveniently,

$$(13)\quad |a_{n,k_0}| \leq C\ e^{Cn^{\frac{2}{3}}}\left[\left|\int h_{e\epsilon,q}^{k_0,n}(t)K(\underline{\Psi},\underline{V})(t)\ dt\right| + \left|\int h_{o\epsilon,q}^{k_0,n}(t)K(\underline{\Psi},\underline{V})(t)\ dt\right|\right].$$

For any n greater than $n_1(\epsilon)$

$$||(\underline{\Psi},\underline{V})^{(1)}||_{\mathcal{X}}^2 = \sum_{\substack{|k|=*\\|k|\leq|n|}} |a_{n,k}|^2.$$

From (13)

$$||(\underline{\Psi},\underline{V})^{(1)}||_{\mathcal{X}}^2 \leq C \sum_{\substack{|k|=*\\|k|\leq|n|}} e^{Cn^{\frac{2}{3}}}\ \left|\int h_{e\epsilon,q}^{k,n}(t)\ V_{tt}(0,t)\ dt\right|^2 + \text{same with } h_o.$$

Hence, from (i)

$$||(\underline{\Psi},\underline{V})^{(1)}||_{\mathcal{X}}^2 \leq Ce^{Cn^{\frac{2}{3}}} \sum_{\substack{|k|=*\\|k|\leq|n|}} \int \left|h_{\epsilon,q}^{k,n}(t)\right|^2 dt \int_{-T_2(q,\epsilon)}^{T_2(q,\epsilon)} |V_{tt}(0,t)|^2\,dt.$$

Thus, from (ii)

$$||(\underline{\Psi},\underline{V})^{(1)}||_{\mathcal{X}}^2 \leq C\ e^{Cn^{\frac{2}{3}}}\ e^{2\epsilon|n|} \int_{-T_2(q,\epsilon)}^{T_2(q,\epsilon)} |V_{tt}(0,t)|^2\,dt.$$

When q goes to infinity, if $\frac{q+1}{1-q} = -1-\delta$, δ goes to 0. Thus, we have proved Proposition 2. □

We still have to prove Lemma 4. We will proceed by two steps.

First, we will introduce a sequence of functions $f^{k_0,n}$ that will satisfy conditions (i), (iii), and (iv) but whose L^2 norms will behave like $e^{n\pi}$, which is too big for (ii). We will notice, however, that these norms will be mostly concentrated within $[-\pi n, \pi n]$ on the Fourier side.

Then we will build a sequence of functions g of which we will know, by stationary phases computations, that their norms on the Fourier side are exponentially small over $[-\pi n, \pi n]$ and reasonably bounded outside.

We will then put $h = f * g$ and prove that h satisfies (i) to (iv) for suitable parameters.

5.1. Construction of functions $\boldsymbol{f}$. Let $f_0^n(z) = (\sqrt{z^2-n^2\pi^2}^3 \tan\sqrt{z^2-n^2\pi^2} - z^2)\cos\sqrt{z^2-n^2\pi^2}$.

The following properties hold:

(f-i) $f_0^n \in \mathcal{O}(\mathbb{C})$.

(f-iii) From (8), for any k in $\mathbb{Z}^* \cup \{*,**\}$,

$$f_0^n(\pm|\nu_{n,k}|) = (z_{n,k}^3 \tan z_{n,k} - z_{n,k}^2 - n^2\pi^2)\cos z_{n,k} = 0.$$

Let us evaluate $f_0^{n\prime}(|\nu_{n,k}|)$. We shall write $F(z) = z^3\tan z - z^2 - n^2\pi^2$ and $G(z) = \sqrt{z^2-n^2\pi^2}$. We have

$$f_0^n(z) = F(G(z)) \cdot \cos G(z) \text{ and } G(|\nu_{n,k}|) = z_{n,k}.$$

So

$$f_0^{n\prime}(z) = G'(z)\cdot F'(G(z))\cdot\cos G(z) - F(G(z))\cdot G'(z)\cdot\sin G(z).$$

Thus,

$$|f_0^{n\prime}(|\nu_{n,k}|)| = |G'(|\nu_{n,k}|)\cdot\cos z_{n,k}|\ |F'(z_{n,k})|. \tag{14}$$

Now

$$F'(z) = 3z^2\tan z + z^3(1+\tan^2 z) - 2z$$

and

$$\tan z_{n,k} = \frac{z_{n,k}^2 + n^2\pi^2}{z_{n,k}^3}.$$

So for any (n,k) in $\mathbb{N}^* \times (\mathbb{N}^* \cup \{*\})$,

$$F'(z_{n,k}) = 2z_{n,k} + \frac{5\pi^2 n^2}{z_{n,k}} + z_{n,k}^3 + \frac{\pi^4 n^4}{z_{n,k}^3} \geq 2z_{n,k} + z_{n,k}^3 \geq 1.$$

Moreover,

$$|G'(|\nu_{n,k}|)| = \frac{|\nu_{n,k}|}{z_{n,k}} \geq \frac{1}{2}.$$

At last, from Lemma 1 (ii),

$$|\cos z_{n,k}| \geq \frac{1}{5}|z_{n,k} - \left(|k| - \frac{1}{2}\right)\pi| \geq \frac{C}{1+n^2}.$$

Thus, from (14), we get that for any couple (n,k) in $\mathbb{N}^* \times (\mathbb{Z}^* \cup \{*,**\})$,

$$|f_0^{n\prime}(|\nu_{n,k}|)| \geq \frac{C}{1+n^2}. \tag{15}$$

Let us put for any k in $\mathbb{Z}^* \cup \{*,**\}$

$$f_0^{k,n}(z) = f_0^n(z)\ \frac{1}{z^2 - |\nu_{n,k}|^2}\ \left(\frac{\sin\sqrt{z^2-\pi^2n^2}}{\sqrt{z^2-\pi^2n^2}}\right)^2.$$

(The last term ensures that f remains in L^2.)

We have kept properties (f-i) and (f-iii):

(f-i) $f_0^{k,n} \in \mathcal{O}(\mathbb{C})$. Moreover, $f_0^{k,n} \in L^2(\mathbb{R})$ and, for any complex number z, $|f_0^{k,n}(z)| \leq C\ e^{3|\Im m\ z|}$.

(f-iii) for any k in $(\mathbb{Z}^* \cup \{*, **\})\backslash\{\pm k_0\}$, $f_0^{k_0,n}(\pm|\nu_{n,k}|) = 0$.

We have one more property; from the upper bound we got for the derivative at the pole

$$f_0^{k,n}(\pm|\nu_{n,k}|) = f_0^{n\prime}(\pm|\nu_{n,k}|)\Big(\frac{\sin z_{n,k}}{z_{n,k}}\Big)^2 \frac{1}{\mp 2|\nu_{n,k}|}.$$

Thus,

$$|f_0^{k,n}(\pm|\nu_{n,k}|)| \geq \frac{C}{(1+n^2)|k|^3}|\sin z_{n,k}|^2.$$

Therefore, from Lemma 1 (i) and (iii),
(f-iv) $f_0^{k,n}(\pm|\nu_{n,k}|) \geq \frac{C}{(1+n^2)|k|^{N_2}}$.

Unfortunately, $||f^{k,n}||_{L^2} \geq C\ e^n$ so (ii) doesn't hold for functions f. However, the following estimate holds for any integers k, n and $z \in [-\pi n, \pi n]$:

$$|f^{k,n}(z)| \leq Ce^{3n\sqrt{\pi^2-(\frac{z}{n})^2}}. \tag{16}$$

5.2. Introduction of functions *g*. Let q be an odd integer and let us denote $h_q(x)$ the solution of $y' = 1 + y^{q-1}$ for which $y(0) = 0$. This function is defined over $(-x_q, x_q)$ for a positive x_q. It is odd, strictly increasing and analytic. Moreover, we have $h_q(x) = x + \alpha_q x^q + o(x^q)$ when x is close to 0, with a positive α_q, and when x goes to x_q, h_q goes to infinity.

We shall denote by H_q the reciprocal function to h_q. It is defined over $\mathbb{R}$, odd, strictly increasing, and bounded by x_q. We have $H_q(x) = x - \alpha_q x^q + o(x^q)$ if x is close to 0. Let δ be a real number, greater than 1 and close to 1, that will be fixed later.

Let us introduce functions g as follows:

$$g_{+T,q}^{\ n}(t) = \mathbf{1}_{(-T,T)} e^{in\frac{T}{\delta x_q}h_q(\frac{x_q}{T}t)}.$$

Then

$$\widehat{g_{+T,q}^{\ n}}(\tau) = \int_{-T}^{T} e^{in\frac{T}{\delta x_q}h_q(\frac{x_q}{T}t)-i\tau t}\ dt.$$

If we put

$$\Psi_q(s) = \frac{T}{x_q}H_q(\frac{\delta x_q}{T}s),$$

we can write

$$\widehat{g_{+T,q}^{\ n}}(\tau) = \int_{-\infty}^{+\infty} e^{ins-i\tau\Psi_q(s)}\ \Psi_q'(s)\ ds.$$

Let us also denote

$$\theta_q(s) = \frac{1}{x_q}H_q(\delta x_q s),$$

then

$$\begin{aligned}\widehat{g_{+}{}^{n}_{T,q}}(\tau) &= \int_{-\infty}^{+\infty} \theta_q'\Big(\frac{s}{T}\Big) e^{inT\left(\frac{s}{T}-\frac{\tau}{n}\theta_q(\frac{s}{T})\right)}\, ds,\\ &= T\int_{-\infty}^{+\infty} \theta_q'(v) e^{inT\left(v-\frac{\tau}{n}\theta_q(v)\right)}\, dv.\end{aligned}$$

We will eventually prove the following lemma about functions $g_{+}{}^{n}_{T,\delta}$.

LEMMA 5. *For T big enough, there exist three positive constants $C_q^1, C_{q,T}^2, c_{q,T,\delta}^3$ and two integers $r_q, n(q,\delta)$ such that*

(i) *for any positive integer n and any real number τ smaller than $\frac{n}{\delta}$,*

$$\left|\widehat{g_{+}{}^{n}_{T,q}}(\tau)\right| \le C_{q,T}^2\ e^{-Tn\ C_q^1 \min\{(\frac{1}{\delta}-\frac{\tau}{n})^{\frac{q}{q-1}},1\}};$$

(ii) *for any integer n greater than $n(q,\delta)$, if $k_0 = *$ or $1 \le k_0 \le n$, there is a time T_{n,k_0} in $[T, T+1]$ such that*

$$\left|\widehat{g_{+}{}^{n}_{T_{n,k_0},q}}\left(\frac{|\nu_{n,k_0}|}{\pi}\right)\right| \ge \frac{c_{q,T,\delta}^3}{\sqrt{n}}.$$

Let us see how this lemma allows us to construct a sequence of functions h for which the properties of Lemma 4 hold.

5.2.1. Construction of *h*. First, let us notice that we can prove a lemma that is similar to Lemma 5 for functions $g_{-}{}^{n}_{T,q}(t) = \mathbf{1}_{(-T,T)} e^{-in\frac{T}{\delta x_q}h_q(\frac{x_q}{T}t)}$ by changing t into $-t$.

As $g_{-}{}^{n}_{T,q} = \overline{g_{+}{}^{n}_{T,q}}$, we have $T_{n,k_0,+} = T_{n,k_0,-}$. Thus, if we put

$$g_{e}{}^{n}_{T,q}(t) = \mathbf{1}_{(-T,T)} \cos\left(n\frac{T}{\delta x_q} h_q\left(\frac{x_q}{T}t\right)\right) = \Re e\ (g_{+}{}^{n}_{T,q}) = \frac{1}{2}(g_{+}{}^{n}_{T,q}(t) + g_{-}{}^{n}_{T,q}(t)),$$

the following inequalities hold.

If $|\frac{\tau}{n}| \le \frac{1}{\delta}$,

$$\left|\widehat{g_{e}}{}^{n}_{T,q}(\tau)\right| \le C_{q,T}\ e^{-Tn\ C_q(\frac{1}{\delta}-|\frac{\tau}{n}|)^{\frac{q}{q-1}}}. \tag{17}$$

And if $n \ge n(q,\delta)$ and ($|k_0| \le n$ or $|k_0| = *$), as $C_{q,T}^2\ e^{-nT_uC_q^1} \le \frac{c_{q,T,\delta}^3}{2\sqrt{n}}$ if n is big enough,

$$\left|\widehat{g_{\pm}{}^{n}_{T_{n,k_0},q}}(\tau)\right| \le \frac{1}{2}\left|\widehat{g_{\mp}{}^{n}_{T_{n,k_0},q}}(\tau)\right| \text{ for } \tau = \mp\frac{|\nu_{n,k_0}|}{\pi}.$$

As we can increase C to cope with the finite number of (n,k) in I for which n is not big enough, we get for (n,k_0) in $I, \tau = \pm\frac{|\nu_{n,k_0}|}{\pi}$

$$\left|\widehat{g}_{e}{}_{T_{n,k_0},q}(\tau)\right| \ge \frac{c_{q,T,\delta}}{\sqrt{n}}. \tag{18}$$

Thus, we have the following lemma for g_e.

LEMMA 6. *For T big enough, there exist three positive constants $C_q^1, C_{q,T}^2, c_{q,T,\delta}^3$ and two integers $r_q, n(q,\delta)$ such that*

(i) *for any positive integer* n *and any real number* τ *in* $[-\frac{n}{\delta},\frac{n}{\delta}]$,

$$\left|\widehat{g_e}^{\,n}_{T,q}(\tau)\right| \le C^2_{q,T}\ e^{-Tn\ C^1_q\left(\frac{1}{\delta}-|\frac{\tau}{n}|\right)^{\frac{q}{q-1}}};$$

(ii) *for any integer* n *greater than* $n(q,\delta)$, *if* $|k_0| = *$ *or* $1 \le |k_0| \le n$, *there is a time* T_{n,k_0} *in* $[T, T+1]$ *such that*

$$\left|\widehat{g_e}^{\,n}_{T_{n,k_0},q}\left(\frac{|\nu_{n,k_0}|}{\pi}\right)\right| \ge \frac{c^3_{q,T,\delta}}{\sqrt{n}}.$$

Of course, we get the same kind of results for

$$g_o{}^{n}_{T,q}(t) = \mathbf{1}_{(-T,T)}\sin\left(n\frac{T}{\delta x_q}h_q\left(\frac{x_q}{T}t\right)\right).$$

Obviously, g_e is even and g_o is odd.

We shall now define the functions h. Let ϵ be a positive real number. Pick δ_ϵ such that

$$3\pi\sqrt{1-\left(\frac{1}{\delta_\epsilon}\right)^2} = \frac{\epsilon}{2}$$

and T^ϵ such that

$$\sup_{\beta\in[0,\frac{1}{\delta_\epsilon}]}\left(3\pi\sqrt{1-\beta^2} - C^1_q\ T^\epsilon\ \left(\frac{1}{\delta_\epsilon}-\beta\right)^{\frac{q}{q-1}}\right) \le \epsilon. \tag{19}$$

Indeed, the derivative of the function under the sup is

$$\frac{-3\pi\beta}{\sqrt{1-\beta^2}} + \frac{q}{q-1}T^\epsilon C^1_q\left(\frac{1}{\delta_\epsilon}-\beta\right)^{\frac{1}{q-1}},$$

so we get the right estimate if we choose T^ϵ such that this derivative is 0 for β_ϵ such that

$$3\pi\sqrt{1-\beta_\epsilon^2} = \epsilon.$$

We have $\delta_\epsilon = 1 + \frac{\epsilon^2}{72\pi^2} + o(\epsilon^2)$, $\beta_\epsilon = 1 - \frac{\epsilon^2}{18\pi^2} + o(\epsilon^2)$ so $\frac{1}{\delta_\epsilon} - \beta_\epsilon \sim \frac{\epsilon^2}{24\pi^2}$; hence,

$$T^\epsilon \sim C_q\epsilon^{\frac{q+1}{1-q}}.$$

Let us define positive times T^ϵ_{n,k_0} as follows.

For integers k_0 such that $|k_0| \le |n|$ or $|k_0| = *$, we take the time T^ϵ_{n,k_0} given by Lemma 6 with $T = T^\epsilon$, and for $|k_0| > |n|$, we put $T^\epsilon_{n,k_0} = T^\alpha$.

$$T^\epsilon_{n,k_0} \in [T^\epsilon, T^\epsilon + 1],\ \text{so}\ c^1_q\epsilon^{\frac{q+1}{1-q}} \le T^\epsilon_{n,k_0} \le c^2_q\epsilon^{\frac{q+1}{1-q}}.$$

Let us denote

$$\widehat{h_{e_{\epsilon,q}}}^{k_0,n}(\tau) = f^{k_0,n}(\tau)\cdot\ \widehat{g_e}^{\,n}_{T^\epsilon_{n,k_0},q}\left(\frac{\tau}{\pi}\right),$$

$$\widehat{h_{o\epsilon,q}}^{k_0,n}(\tau) = f^{k_0,n}(\tau) \cdot \ \widehat{g}_{oT^{\epsilon}_{n,k_0},q}^{\ n}\left(\frac{\tau}{\pi}\right).$$

The subscript means that h is even or odd. We will drop this subscript when it is not required.

We shall now prove step by step that $h_{\epsilon,q}^{k_0,n}$ satisfies all the properties of Lemma 4.

• Proof of (i): $h_{\epsilon,q}^{k_0,n}$ is a convolution product of $\widehat{f}^{k_0,n}$, whose support is located within $[-3\pi, 3\pi]$ and $g^n_{T^{\epsilon}_{n,k_0},q}$ that is supported by $[-T^{\epsilon}_{n,k_0}, T^{\epsilon}_{n,k_0}]$. So we can put $T_2(q,\epsilon) = 3\pi + c_q^2 \epsilon^{\frac{q+1}{1-q}}$ so that $h_{\epsilon,q}^{k_0,n}$ is supported by $[-T_2(q,\epsilon), T_2(q,\epsilon)]$. The estimate on T^{ϵ}_{n,k_0} ensures that $T_2(q,\epsilon) \leq C_q \epsilon^{\frac{q+1}{1-q}}$.

• Proof of (ii): We will use results about the small size of $||g||$ that will compensate $||f||$. Outside of $[-\pi n, \pi n]$, the L^2 norm of f is bounded by a polynomial in n and $|\widehat{g}|_{L^\infty}$ is bounded by $2T_2(q,\epsilon)$, so the problems are located within this interval.

We must estimate $\int_{-n}^{n} |\widehat{h}_{\epsilon,q}^{k_0,n}(\tau)|^2 \ d\tau$.

Now, by (16) we know that if $\frac{\tau}{n}$ belongs to $[-\pi, \pi]$, we have

$$|f^{k_0,n}(\tau)|^2 \leq C \ e^{6n\sqrt{\pi^2 - |\frac{\tau}{n}|^2}} = C \ e^{6\pi n\sqrt{1-|\frac{\tau}{\pi n}|^2}}.$$

Thus, if $|\frac{\tau}{\pi n}| \geq \frac{1}{\delta_\epsilon}$,

$$|\widehat{h}_{\epsilon,q}^{k_0,n}(\tau)|^2 \leq Ce^{\epsilon n}.$$

Moreover, by Lemma 6, if $|\frac{\tau}{\pi n}|$ is smaller than $\frac{1}{\delta_\epsilon}$, we have

$$|\widehat{g}^n_{T^{\epsilon}_{n,k_0},q}\left(\frac{\tau}{\pi}\right)|^2 \leq C \ e^{-2T^{\epsilon}_{n,k_0} n C_q^1 (\frac{1}{\delta_\epsilon} - |\frac{\tau}{\pi n}|)^{\frac{q}{q-1}}}.$$

Therefore, from (19), we get that if $|\frac{\tau}{\pi n}|$,

$$|\widehat{h}_{\epsilon,q}^{k_0,n}(\tau)|^2 \leq C \ e^{2\epsilon n}.$$

Thus,

$$||\widehat{h}_{\epsilon,q}^{k_0,n}||^2_{L^2} \leq Ce^{2\epsilon n}.$$

• Proof of (iii): This is a simple consequence of property (f-iii) for functions f. Indeed, for any integer k different from k_0, $f^{k_0,n}(|\nu_{n,k}|) = 0$. Thus, by definition of h we also have $\widehat{h}_{\epsilon,q}^{k_0,n}(|\nu_{n,k}|) = 0$, which is exactly the Fourier transcription of (iii).

• Proof of (iv): For any couple (n, k_0) in I, from (f-iv) and (18) we get

$$\left|\widehat{h}_{\epsilon,q}^{k_0,n}(\pm|\nu_{n,k_0}|)\right| \geq \frac{C}{n^N}\frac{c_{q,T_\epsilon,\delta_\epsilon}}{\sqrt{n}} \geq \frac{C_{q,\epsilon}}{n^{N'}}.$$

This again is the Fourier transcription of the needed result.

We shall now prove Lemma 5 to end our demonstration.

5.2.2. Proof of Lemma 5. Let us keep in mind that we have put

$$\widehat{g_{+T,q}^{n}}(\tau) = T\int_{-\infty}^{\infty} \theta_q'(v) e^{inT(v - \frac{\tau}{n}\theta_q(v))} \ dv.$$

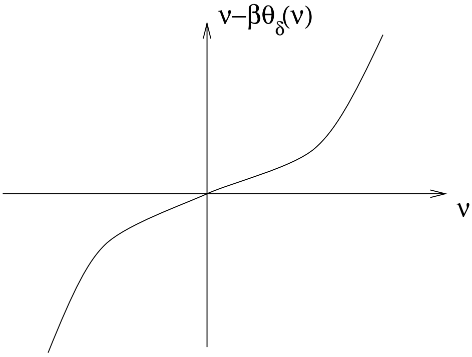
Let us put $\alpha = nT$ and $\beta = \frac{\tau}{n}$. We will estimate

$$\phi(\alpha, \beta) = \int \theta'_\delta(v) e^{i\alpha\left[v - \beta\theta_\delta(v)\right]}\, dv,$$

when α goes to infinity.

There will be two kinds of estimates depending upon the value of β as compared to $\frac{1}{\delta}$: $\beta < \frac{1}{\delta}$ and $\beta \geq 1 (> \frac{1}{\delta})$.

If $\beta < \frac{1}{\delta}$,



In this zone, the phase is nonstationary. Thus, we will get an exponential decrease.

Let us shift slightly in the imaginary direction. For any real number v, any β smaller than $\frac{1}{\delta}$, and any small ϵ we get

$$\begin{aligned}
\Im m\ \Big(v + i\epsilon - \beta\theta_q(v + i\epsilon)\Big) &= \epsilon - \beta\ \Im m\ \theta_q(v + i\epsilon),\\
&= \epsilon - \beta\ \Im m\ \Big(\theta_q(v + i\epsilon) - \theta_q(v)\Big),\\
&= \epsilon - \beta\ \Im m\ \int_v^{v+i\epsilon} \theta'_q(z)\, dz,\\
&= \epsilon - \beta\ \Im m\ \int_v^{v+i\epsilon} \frac{\delta dz}{1 + \delta^{q-1} x_q^{q-1} z^{q-1}},\\
&= \epsilon - \beta\epsilon\delta\ \Re e\ \int_0^1 \frac{du}{1 + \delta^{q-1} x_q^{q-1} (v + i\epsilon u)^{q-1}}.
\end{aligned}$$

Thus, if $\beta \leq 0$,

$$\Im m\ \Big(v + i\epsilon - \beta\theta_q(v + i\epsilon)\Big) \geq \epsilon \text{ if } \beta \leq 0.$$

If β is positive,

$$\Im m\ \Big(v + i\epsilon - \beta\theta_q(v + i\epsilon)\Big) \geq \epsilon - \beta\epsilon\delta \left| \int_0^1 \frac{du}{1 + \delta^{q-1} x_q^{q-1} (v + i\epsilon u)^{q-1}} \right|.$$

Now for any real number v,

$$\underbrace{\left| \int_0^1 \frac{du}{1 + \delta^{q-1} x_q^{q-1} (v + i\epsilon u)^{q-1}} \right|}_{I} \leq \frac{1}{1 - c_q \epsilon^{q-1}},$$

because either $v \gg \epsilon$ and then $I \leq \frac{c}{1+v^{q-1}} \leq 1$ or $v \leq M_q \epsilon$ and then

$$|v + i\epsilon u|^{q-1} \leq C_q \epsilon^{q-1} \Rightarrow |1 + \delta^{q-1} x_q^{q-1} (v + i\epsilon u)^{q-1}| \geq 1 - c_q \epsilon^{q-1} \Rightarrow I \leq \frac{1}{1 - c_q \epsilon^{q-1}}.$$

Thus,

$$\begin{aligned} \Im m \, \Big(v + i\epsilon - \beta \theta_q (v + i\epsilon) \Big) &\geq \epsilon - \frac{\beta \delta \epsilon}{1 - c_q \epsilon^{q-1}}, \\ &\geq \epsilon (1 - \delta \beta) - c_q' \beta \epsilon^q, \\ &\geq \epsilon (\frac{1}{\delta} - \beta) - c_q' \beta \epsilon^q. \end{aligned}$$

Now

$$\begin{aligned} \max_{\epsilon} \epsilon \left(\frac{1}{\delta} - \beta \right) - c_q \beta \epsilon^q &= c_q' \left(\frac{1}{\delta} - \beta \right)^{\frac{q}{q-1}} \beta^{\frac{1}{1-q}}, \\ &\geq c_q'' \left(\frac{1}{\delta} - \beta \right)^{\frac{q}{q-1}}. \end{aligned}$$

We can choose a real number ϵ and a very small c_q such that for any real number v

$$\begin{cases} \Im m \, \Big(v + i\epsilon - \beta \theta_q (v + i\epsilon) \Big) \geq c_q^{te} (\frac{1}{\delta} - \beta)^{\frac{q}{q-1}} \text{ if } \beta \in (0, \frac{1}{\delta}], \\ \Im m \, \Big(v + i\epsilon - \beta \theta_q (v + i\epsilon) \Big) \geq c_q^{te} \text{ if } \beta \leq 0. \end{cases}$$

Now we can shift the integration line over v from $\mathbb{R}$ to $\mathbb{R} + i\epsilon$. Then

$$\phi(\alpha, \beta) = \int \theta_q' (v + i\epsilon) e^{i\alpha \left[v + i\epsilon - \beta \theta_q (v + i\epsilon) \right]} \, dv.$$

To conclude, as

$$\theta_q' (v + i\epsilon) = \frac{\delta}{1 + (\delta x_q (v + i\epsilon))^q - 1},$$

we get

$$|\theta_q' (v + i\epsilon)| \leq \frac{C_q}{1 + v^{q-1}}.$$

Hence, for any real number α and any $\beta \leq \frac{1}{\delta}$,

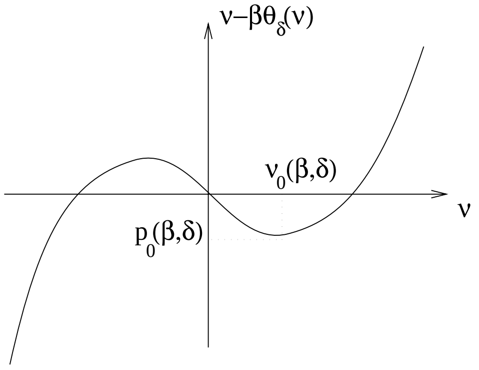
$$|\phi(\alpha, \beta)| \leq \int \frac{C_q}{1 + v^{q-1}} \, e^{-\alpha \ c_q \min \left\{ (\frac{1}{\delta} - \beta)^{\frac{q}{q-1}}, 1 \right\}} \, dv \leq C_q \ e^{-\alpha \ c_q \min \left\{ (\frac{1}{\delta} - \beta)^{\frac{q}{q-1}}, 1 \right\}}.$$

Thus, if $\frac{\tau}{n} \leq \frac{1}{\delta}$,

$$\left| \widehat{g_{+T,q}^{n}} (\tau) \right| \leq C_q \ T \ e^{-nTc_q \min \left\{ (\frac{1}{\delta} - \frac{\tau}{n})^{\frac{q}{q-1}}, 1 \right\}}. \tag{20}$$

That is the first part of Lemma 5.

If $\beta \geq 1 \ \ (> \frac{1}{\delta})$,



.

Through the stationary phase formula, we get

$$\phi(\alpha,\beta) = \Big(|H_{\beta,\delta}| \ \cos \alpha p_0(\beta,\delta)\Big) \left[\frac{\theta_q'(v_0(\beta,\delta))}{\sqrt{\alpha}} + \sum_{j=1}^{N} \frac{a_j(\beta,\delta)}{\alpha^j \sqrt{\alpha}} \right] + r_{\beta,\delta}(\alpha),$$

with $r_{\beta,\delta}(\alpha) \leq \frac{C_\beta}{\alpha^{N+1}}$ and $\alpha \geq A_{\beta,\delta}$. $H_{\beta,\delta}$ is the square root of the Hessian at the critical points.

Moreover, in this formula, C and A are continuous with respect to β and δ, and $a_j(\beta,\delta)$ depends on the first $2j+1$ derivatives of $v \mapsto \theta_q(v)$ at $v = v_0(\beta,\delta)$.

Let us compute $p_0(\beta,\delta)$:

$$\begin{aligned} \frac{\partial}{\partial v}\Big(v - \beta\theta_q(v)\Big) = 0 \Leftrightarrow 1 - \frac{\beta\delta}{1 + \delta^{q-1}x_q^{q-1}v^{q-1}} &= 0, \\ \Rightarrow 1 + \delta^{q-1}x_q^{q-1}v_0^{q-1}(\beta,\delta) &= \beta\delta, \\ \Rightarrow v_0(\beta,\delta) &= \frac{1}{\delta x_q}(\delta\beta - 1)^{\frac{1}{q-1}}. \end{aligned}$$

If β takes the values $\frac{|\nu_{n,k}|}{n\pi}$ for any couple (n,k) such that $|k| \leq n$, we have $1 \leq \beta \leq \pi\sqrt{2}$ through point (i) of Lemma 1.

Moreover, if $\beta = \frac{|\nu_{n,*}|}{n\pi}$, by point (iv) of Lemma 1 $\beta \geq 1 - \frac{C}{\sqrt{n}} \geq \frac{1}{2}(1 + \frac{1}{\delta})$ as soon as $n \geq n_0(\delta)$.

Therefore, for any n greater than $n_0(\delta)$, if (n,k) belongs to I and $\beta = \frac{|\nu_{n,k}|}{n\pi}$,

$$C \geq v_0(\beta,\delta), |p_0(\beta,\delta)|, |H_{\beta,\delta}| \geq c_\delta;$$

thus,

$$1 \geq \theta_q'(v_0(\beta,\delta)) \geq c_q.$$

Moreover,

$$a_j(\beta,\delta) \leq C_{j,\delta}.$$

Let T be a positive real time. As $|p_0(\beta,\delta)| \geq c_\delta$, for any n greater than $n_0(\delta)$ and k_0 such that (n,k_0) belongs to I, one can pick a time T_{n,k_0} in $[T, T+1]$ such that

$$\cos\left(nT_{n,k_0}p_0\left(\frac{|\nu_{n,k_0}|}{n\pi},\delta\right)\right) \geq c_\delta'.$$

Thus, for $T > T_u,\ n \geq n(q,\delta),\ \alpha = Tn,\ (k_0, n) \in I$, and $\beta = \frac{|\nu_{n,k_0}|}{n\pi}$,

$$\left| \frac{\theta_q'(v_0(\beta,\delta))}{\sqrt{\alpha}} + \sum_{j=1}^{N} \frac{a_j(\beta,\delta)}{\alpha^j \sqrt{\alpha}} \right| \geq \frac{|\theta_q'(v_0(\beta,\delta))|}{2\sqrt{\alpha}},$$

$$|r_{\beta,\delta}(\alpha)| \leq c_\delta' \frac{|H_{\beta,\delta}|\ \theta_q'(v_0(\beta,\delta))}{4\sqrt{\alpha}}.$$

In the same conditions, there is a time T_{n,k_0} in $[T, T+1]$ such that

$$\left| \phi\left(nT_{n,k_0}, \frac{|\nu_{n,k_0}|}{n\pi} \right) \right| \geq \frac{c_\delta' |H|\ \theta_q'(v_0(\frac{\nu_{n,k_0}}{n\pi},\delta))}{4\sqrt{n}\sqrt{T_{n,k_0}}} \geq \frac{C}{\sqrt{n}}.$$

We have proved that for any time T greater than T_u, for any n bigger than $n(q,\delta)$ and k_0 such that $|k_0| = *$ or $|k_0| \leq n$, there is a time T_{n,k_0} in $[T, T+1]$ such that

$$\left| \widehat{g^n_{+T_{n,k_0},q}}\left(\frac{|\nu_{n,k_0}|}{\pi} \right) \right| \geq \frac{C_{T,q,\delta}}{\sqrt{n}}. \tag{21}$$

This proves the second part of Lemma 5 and ends the proof of Proposition 2. □

CONVERGENCE RESULTS FOR THE FLUX IDENTIFICATION IN A SCALAR CONSERVATION LAW[*]

FRANÇOIS JAMES[†] AND MAURICIO SEPÚLVEDA [‡]

Abstract. Here we study an inverse problem for a quasilinear hyperbolic equation. We start by proving the existence of solutions to the problem which is posed as the minimization of a suitable cost function. Then we use a Lagrangian formulation in order to formally compute the gradient of the cost function introducing an adjoint equation. Despite the fact that the Lagrangian formulation is formal and that the cost function is not necessarily differentiable, a viscous perturbation and a numerical approximation of the problem allow us to justify this computation. When the adjoint problem for the quasi-linear equation admits a smooth solution, then the perturbed adjoint states can be proved to converge to that very solution. The sequences of gradients for both perturbed problems are also proved to converge to the same element of the subdifferential of the cost function. We evidence these results for a large class of numerical schemes and particular cost functions which can be applied to the identification of isotherms for conservation laws modeling distillation or chromatography. They are illustrated by numerical examples.

1. Introduction.

In this paper, we are interested in the following inverse problem: Consider the scalar hyperbolic conservation law

$$\partial_t w + \partial_x f(w) = 0, \qquad x \in \mathbb{R},\ t > 0, \tag{1.1}$$

together with the Cauchy data

$$w(x,0) = w^0(x) \in BV(\mathbb{R}) \cap L^\infty(\mathbb{R}). \tag{1.2}$$

It is well known that there exists one and only one entropy solution in $L^\infty(\mathbb{R}_+, BV(\mathbb{R})) \cap L^\infty(\mathbb{R} \times (-\infty, +\infty))$ of (1.1)–(1.2) (see [6], [18]), and we emphasize the fact that the unique entropy solution to (1.1) depends continuously (in a sense which we shall describe precisely) on the smooth function f by denoting it w_f. The question we address is whether, given an observation w^{obs} at time $T > 0$, one can identify the nonlinearity f such as w_f at time T is as close as possible to w^{obs}.

It is quite natural to formulate this problem more or less like an optimal control problem: For any function $v : \mathbb{R} \to \mathbb{R}$ we define a cost function $J(v)$, and we look for an f solving

$$\min_f J(w_f(.,T)), \tag{1.3}$$

thus giving a precise meaning to the phrase "as close as possible." Therefore we are led to the constrained optimization problem of minimizing $J(w(.,T))$ under the constraint

for w to satisfy the partial differential equation (1.1)–(1.2). This problem can be viewed as well as an unconstrained minimization problem: If we set $\tilde{J}(f) = J(w_f)$, then problem (1.3) boils down to minimizing $\tilde{J}$ on a suitable set of functions.

In theory, this inverse problem is in general ill-posed in uniqueness when there are discontinuities in the solution. For instance, a well-known undesirable case appears when we try to identify f over a shock wave with a propagation speed equal to σ: there are infinitely many functions f giving the same entropic solution w_f of (1.1)–(1.2) equal to the shock wave (see [4] for more details). Yet, as far as applications are concerned some interesting practical problems can be found: It is possible to resolve the identification of f (or "a part of f") via a gradient technique in order to compute numerically the minimum of $\tilde{J}$. This was achieved in a preceding paper [9] in which we considered the identification problem arising from a model of diphasic propagation in chromatography. Therefore we dealt with a system of conservation laws, and we obtained successful numerical results because the function f was given a precise analytic form, so the minimization occurred on $\mathbb{R}^n$, and we chose adequate criteria for the cost function linked to the physical parameter of the problem.

The classical gradient technique used in order to obtain the gradient of $\tilde{J}$ consists of writing a Lagrangian formulation for the constrained problem and introducing the adjoint state. This has to be done at two levels.

First we consider a formal level; that is, we take a solution of the continuous equation (1.1) and perform the computations. We obtain a backward linear hyperbolic equation for the adjoint state. The trouble is that this equation is ill-posed as soon as the solution of (1.1) is not smooth—which is of course the case in most of the applications. This is related to the fact that the inverse problem is ill-posed in uniqueness when there are discontinuities in the solution. Thus, in general, the computation of the gradient of $\tilde{J}$ remains formal. Furthermore, it is easy to find some counterexamples where the gradient does not exist.

On the other hand, we can perform the same computations at a discrete level, that is, when both (1.1) and the cost function J are discretized. This introduces a "discrete adjoint state" which we call the adjoint scheme, and we obtain the gradient for the discretization of $\tilde{J}$, which is well defined. Thus we are able to perform numerical computations, using standard conjugate gradient techniques, and the numerical evidence is that the method seems to converge (see [9, section 5] and [11] for application on real data).

The aim of this paper is to interpret and justify the convergence of the method in the scalar case and in a particular case, namely, when the solution of the adjoint state is Lipschitz continuous. We shall consider two modified problems: First we add a viscous term to (1.1), then we turn to the discretized problem. In both cases, we prove that the perturbed adjoint states converge to the solution of the original problem. That enables us to pass to the limit in the approximation of the gradient, and we prove that both approximations tend to the same limit. This limit is not necessarily the gradient of the cost function because the gradient does not exist a priori. In fact, we also prove by means of convexity hypotheses that it is an element of the subdifferential of $\tilde{J}$. This result gives an interpretation of the formal computation of the gradient for continuous cost functions including some cases when the gradient does not exist.

Therefore the paper is organized as follows. First we precisely state the problem, in particular concerning the cost function we consider, which is not the standard least square function. Then we consider the identification problem for a parabolic regularization of the conservation equation and, in particular, we prove the differentiability of the cost function. We also prove the convergence of the sequence of the perturbed gradients to an element of the subdifferential of $\tilde{J}$. Finally we prove that we can obtain the same element of the subdifferential via a discretized problem and for a large class of numerical schemes, and we illustrate these results by a numerical application on experimental data.

2. The identification problem.

2.1. The cost function. A classical example of cost function J arises in the well-known output least square method (see [4] for instance):

$$J_0(w) = \frac{1}{2}\int_{x\in\mathbb{R}} |w(x,T) - w^{\mathrm{obs}}(x)|^2 dx. \tag{2.1}$$

For practical reasons, in [9] the following modified cost function J_ρ was used:

$$J_\rho(w) = J_0(w) + \frac{\rho}{2}|\mu_1\big(w(\cdot,T)\big) - \mu_1(w^{\mathrm{obs}})|^2, \tag{2.2}$$

where ρ is a constant parameter to be adjusted, and where $\mu_1(\mathrm{X})$ is the first moment of the function $X : \mathbb{R} \to \mathbb{R}$:

$$\mu_1(\mathrm{X}) = \int_{\mathbb{R}} x\mathrm{X}(x)dx. \tag{2.3}$$

Roughly speaking, the advantage of J_ρ over J_0 is that it is more sensitive to the localization of the observed signal on the x-axis, whereas J_0 essentially takes care of the shape of the signal over its localization.

Notice that we shall always consider initial data with compact support so that, by the finite velocity of propagation, the solution at any time $t > 0$ will also have a compact support. Thus all the integrals in the definitions of J_0 and of J_ρ have a meaning as soon as w is in $L^\infty(\mathbb{R})$.

For practical reasons, what follows is essentially focused on the study of criteria (2.1) or (2.2)–(2.3).

2.2. Existence and Lipschitz continuous dependence. We can assure the existence of at least one solution f of our identification problem (1.3) when we search it in a compact of the Lipschitz continuous functions. In fact, this is a consequence of the following theorem, the proof of which is contained in a paper by Lucier (see [13]).

THEOREM 2.1. *The application $f \mapsto w_f$ is Lipschitz continuous from the space of Lipschitz functions to L^1, that is,*

$$\|w_f(.,t) - w_g(.,t)\|_{L^1} \leq t\|f-g\|_{\mathrm{Lip}}\|w^0\|_{BV}, \tag{2.4}$$

where $\|\cdot\|_{BV}$ is the usual norm of $BV(\mathbb{R})$.

COROLLARY 2.2. *The function $\tilde{J} : f \mapsto J_\rho(w_f)$ is Lipschitz continuous from* $\mathrm{Lip}(\mathbb{R})$ *to* $\mathbb{R}_+$.

Proof. Concerning the function J_0, the estimate follows immediately from the L^∞ estimate which holds uniformly in g:

$$\forall t > 0, \quad \|w_g(.,t)\|_{L^\infty} \leq \|w^0\|_{L^\infty}. \tag{2.5}$$

Indeed we have

$$\begin{aligned} |J_0(g) - J_0(f)| &\leq \frac{1}{2}\int_{\mathbb{R}} |(w_g - w_f)(x,T)|\,|(w_g + w_f)(x,T) - 2w^{\mathrm{obs}}(x)|\,dx \\ &\leq \max(\|w^0\|_{L^\infty}, \|w^{\mathrm{obs}}\|_{L^\infty})\,\|w_g(,.T) - w_f(.,T)\|_{L^1} \end{aligned}$$

by Hölder's inequality. The result follows by (2.4). Now for the momentum criterion, if we assume all the supports included in $[-L, L]$ for some L large enough, we get, again using (2.5):

$$\begin{aligned} |J_1(g) - J_1(f)| &\leq \frac{1}{2}|\mu_1(w_g(.,T)) - \mu_1(w_f(.,T))|\,|\mu_1(w_g + w_f(.,T)) - 2\mu_1(w^{\mathrm{obs}})| \\ &\leq L^3 \max(\|w^0\|_{L^\infty}, \|w^{\mathrm{obs}}\|_{L^\infty})\,\|w_g(.,T) - w_f(.,T)\|_{L^1}. \qquad \square \end{aligned}$$

By considering a minimizing sequence for J_ρ, we easily deduce form Corollary 2.2 the following existence result.

COROLLARY 2.3. *If $f \in \mathcal{F}$ is a compact set of the Lipschitz continuous functions, then there exists at least one solution of the identification problem* (1.3)*, with the cost function defined by* (2.1) *or* (2.2)–(2.3).

Remarks. The compactness of the set $\mathcal{F}$ is a necessary hypothesis, but it is not a restrictive condition for many practical identification problems: the function f can have a precise analytic form so that the minimization occurs on a bounded subset of $\mathbb{R}^n$ (for instance, see [9]). Another way to obtain Lipschitz compactness is to seek f, for instance, in $W^{2,\infty}(\mathbb{R})$.

We cannot ensure the uniqueness of the solution in Corollary 2.3 for the reasons given in the introduction. Obviously, we can try to modify the cost functions to obtain a strictly convex functional and, for instance, search the flux f with minimal $W^{2,\infty}(\mathbb{R})$ norm. Yet in general, this is an arbitrary mathematical condition. Thus we prefer to deal with the cost functions defined by (2.1), (2.2), and (2.3), which have a realistic physical sense and to leave the uniqueness problem as an open problem.

2.3. Remarks on differentiability.

Since we are concerned with the problem of minimizing $\tilde{J}(f) = J_\rho(w_f)$ with respect to f, differentiability is of course of crucial importance: optimality conditions, gradient algorithms rely on it. For the function $\tilde{J}$, the problem is open in general, and we are going to point out precisely the difficulties. These will come of course from the operator $f \mapsto w_f$, since the functions J_0 and J_1 are smooth convex functions. Let us first consider this operator in the nice case where all the involved functions are smooth. Indeed, if $w^0 \in C^1(\mathbb{R})$ and $f \in C^1(\mathbb{R})$, then there exists $T > 0$ such that $w_f \in C^1(\mathbb{R} \times [0, T])$. Let us use the notations of the calculus of variations, denoting by δw the variation of w_f corresponding to some variation δf of f. Then δw has to solve

$$(2.6) \qquad \left\{ \begin{aligned} \partial_t \delta w + \partial_x[f'(w_f)\delta w] + \partial_x[\delta f(w_f)] &= 0, \\ \delta w(.,0) &= 0. \end{aligned} \right.$$

Under the above assumptions, we are faced with a standard linear conservation equation with smooth coefficients. Actually, by applying the inverse functions theorem to

$$\begin{aligned} F \quad : \quad C^1(\mathbb{R}) \times \mathrm{Lip}(\mathbb{R}) &\rightarrow C^0(\mathbb{R}) \times C^0(\mathbb{R}), \\ (w, f) &\mapsto (\partial_t w + \partial_x f(w), w(.,0) - w^{\mathrm{obs}}), \end{aligned}$$

we can prove that $f \mapsto w_f$ is differentiable in a strong sense from $\mathrm{Lip}(\mathbb{R})$ to $C^1(\mathbb{R})$. Thus $\tilde{J}$ is also differentiable, with

$$(2.7) \qquad \begin{aligned} \tilde{J}'(f)\delta f \quad = \quad & \int_{\mathbb{R}} (w_f(x,T) - w^{\mathrm{obs}}(x))\delta w(x,T)\, dt \\ & + \rho\,(\mu_1(w_f(.,T)) - \mu_1(w^{\mathrm{obs}}))\,\mu_1(\delta w(.,T)). \end{aligned}$$

This, by the way, justifies in this case the integrations by parts we perform in the next section.

We would like to point out now that if w_f happens to be discontinuous, then the resolution of (2.6) is much more difficult. Indeed it becomes a conservation law with discontinuous coefficient $(f'(w_f))$ and a measure-valued source term $(\partial_x \delta f(w_f))$. The solution therefore has to be sought in the class of measures on $\mathbb{R}$, generalizing the results obtained by Bouchut and James [2], [3] in the absence of a source term. Until now, this has been possible only if f is convex. In this context, it is reasonable to hope for some very weak differentiability results, the involved topology being the usual weak convergence of measures. The general case of a nonconvex f is still completely open.

However, even the differentiability of $f \mapsto w_f$ does not settle the problem for $\tilde{J}(f)$. Indeed since δw is a measure, (2.7) is meaningful if $w_f(.,T) - w^{\text{obs}} \in L^1(\delta w(.,T))$, which is a priori not obvious. In the same way, $\mu_1(\delta w(.,T))$ has to be defined. We refer to the next section for an explicit example and further comments.

For all these reasons, we leave the problem of a rigorous differentiation of $\tilde{J}$ (and possibly the choice of theoretically more convenient cost functions) to a future work. In the following, we focus on the study of two approximated problems where all the involved quantities are well defined. We prove, when it is possible, the convergence of these problems to the original one. We begin by a formal computation of the gradient of $\tilde{J}$, as it was done in [9]. The basic tool for that is to consider the constrained minimization problem and its Lagrangian formulation.

2.4. Lagrangian formulation and the adjoint problem. In [9] and [17], we formally obtain the gradient through the following Lagrangian formulation for the constrained minimization problem:

$$\mathcal{L}\left(w,p;f\right) \overset{def}{=} J(w) - E\left(w,p;f\right), \tag{2.8}$$

where $E\left(w,p;f\right)$ is a weak form of (1.1), defined by

$$E\left(w,p;f\right) = -\int_0^T \int_0^L \left(w\partial_t p + f(w)\partial_z p\right) + \int_{t=T} wp - \int_{t=0} w^0 p. \tag{2.9}$$

We are interested in canceling $(\partial\mathcal{L})/(\partial w)$. For that purpose, we take p solution to the following backward adjoint problem:

$$\begin{cases} \partial_t p + f'(w_f)\partial_x p = 0, & x \in \mathbb{R},\ t \le T, \\ p(x,T) = p^T(x), \end{cases} \tag{2.10}$$

where $f'(w_f)$ represents the derivative of f with respect to w evaluated on the solution w_f of (1.1). The function p^T depends on J, w, and w^{obs}. More precisely, we have

$$\int_{\mathbb{R}} p^T \delta w = D_w J(w_f)\delta w \qquad \forall \delta w \in \mathcal{D}(\mathbb{R}), \tag{2.11}$$

where $D_w J\delta w$ represents the derivative of J in the direction δw. The problem (2.10) is called the *adjoint problem* associated with the direct problem (1.1).

Thus we can compute the gradient of $\tilde{J}$ by the formula

$$D\tilde{J}(f)\delta f = \int_0^T \int_{-\infty}^{+\infty} \partial_x p\, \delta f(w_f) dx dt, \tag{2.12}$$

where p is solution of (2.10), in a sense which has to be made precise (see Remark below).

Remark. Formula (2.12) is a formal result, since the derivative of function $\widetilde{J}$ does not necessarily exist, as a rule. For instance, consider the entropic solution of the Riemann problem

$$w_k(x,t) = \begin{cases} 1 & \text{if } x \geq kt, \\ 0 & \text{otherwise} \end{cases}$$

for the Burgers equation—$f(w) = kw^2$—and suppose $w^{\text{obs}}(x) = w_{k_0}(x,T)$ for some given k_0. Then we have that the cost function given by the criterion of the norm L^2 (2.1) is equal to

$$\tilde{J}_0(k) = J_0(w_k) = T|k - k_0|, \tag{2.13}$$

which is not differentiable in k_0. Moreover, the backward equation defining p is ill-posed as soon as discontinuities occur in the solution of the direct problem. Actually the solution is not uniquely defined by the characteristics.

If we assume that we are in the neighborhood of a minimum, the function $\tilde{J}$ is locally convex, so the subdifferential $\partial\tilde{J}$ is a nonempty set. We may hope that $D\tilde{J}(f)$ defined by (2.12) is an element of $\partial\tilde{J}$ when the adjoint equation is ill-posed. We are not going to answer this question here. We will restrict ourselves to the particular case where there exists a smooth solution to the adjoint equation. In this case we shall study whether (2.12) is well defined and whether it is an element of the subdifferential. First, we give an existence result for Lipschitz solutions to the adjoint problem (2.10), then, we give conditions for the uniqueness.

Definition 2.4. *The function $a(x,t)$ verifies the one-side-Lipschitz-continuous condition (OSLC) when there exists a function $m \in L^1(0,T)$ such as*

$$L^+\left(a(x,t)\right) \overset{def}{=} \text{ess} \sup_{x \neq y} \left(\frac{a(x,t) - a(y,t)}{x - y} \right)^+ \leq m(t). \tag{2.14}$$

In other words, (OSLC) means that the function $a(\cdot,t)$ must be Lipschitz continuous for all t, when $a(\cdot,t)$ is increasing, and it allows decreasing jumps $a(x-,t) > a(x+,t)$. This condition has been used by several authors, e.g., Oleinik [14], Conway [5], Hoff [8], and Tadmor [19], to prove the existence of at least one Lipschitz continuous solution to the adjoint problem (2.10), when $p^T \in W^{1,\infty}(\mathbb{R})$. A refined version of Oleinik's entropy condition (Hoff [8]) states that $f'(w)$ verifies (OSLC) when w accepts only entropic shocks as discontinuities and when f is convex. We need this result to make sense out of solving p by the characteristics method. So far, we do not know a general existence result for any f. The problem with this result is that its solution is ill-posed in uniqueness. For instance, if we assume that $f'(w_f)(x,t) = -\text{sign}(x)$, and $\|p^T\|_{W^{1,\infty}(\mathbb{R})} > 0$, then it is easy to verify that

$$p(x,t) = \begin{cases} p^T\left(x - \text{sign}(x)(T-t)\right) & \text{when } t + |x| \geq T, \\ \varphi(t + |x|) & \text{otherwise} \end{cases}$$

are Lipschitz continuous solutions of adjoint problem (2.10), for any $\varphi(t)$ Lipschitz continuous function such that $\varphi(T) = p^T(0)$.

We recall briefly here the definition of the so-called "reversible solutions" introduced in [2], [3], for which uniqueness holds. First, we define the set $\mathcal{E}$ of "exceptional solutions" as the space of all the Lipschitz continuous solutions of (2.10) with $p^T = 0$. Next, we introduce the open set called "support of exceptional solutions":

$$\mathcal{V} \overset{def}{=} \{(t,x) \in]0,T[\times\mathbb{R} \quad | \quad \exists p_e \in \mathcal{E},\ p_e(t,x) \neq 0\}. \tag{2.15}$$

The following result is obtained in [3].

THEOREM 2.5. *Let p be a Lipschitz continuous solution of* (2.10). *Then, the following properties are equivalent:*

(i) *p is locally constant in $\mathcal{V}$;*

(ii) *there exist p_1 and p_2 in $\mathrm{Lip}_{\mathrm{loc}}([0,T]\times\mathbb{R})$, verifying $\partial_t p_i + f'(w)\partial_x p_i = 0$ and $\partial_x p_i \geq 0$, such that $p = p_1 - p_2$.*

Furthermore, for all $p^T \in W^{1,\infty}(\mathbb{R})$ there exists one and only one Lipschitz continuous solution p of (2.10) *verifying one of these properties and the following estimate:*

$$\|p(\cdot,t)\|_{W^{1,\infty}(\mathbb{R})} \leq \|p^T\|_{W^{1,\infty}(\mathbb{R})} \cdot \exp\left\{\int_t^T m(\tau)d\tau\right\} \qquad \forall t \leq T. \tag{2.16}$$

This function p is called the reversible solution *of* (2.10).

Remarks. According to property (i) of Theorem 2.5, we can choose a constant for p in each *fan-wise set* defined by all the characteristic straight lines which converge to a discontinuity of w. This constant is equal to the value of $p^T(x)$, where (x,T) is a point in the discontinuity of w. Property (ii) is a monotonicity property of the reversible solution.

Choosing the reversible solution in counterexample (2.13) is equivalent to choosing the characteristic element of the subdifferential of $\tilde{J}_0(k_0)$ equal to zero. This is not an arbitrary choice. At the limit, we will see that we obtain an element of the subdifferential of $\tilde{J}$ characterized by the reversible solution, when we consider viscosity approximation and some classical numerical schemes.

When we consider the cost function (2.1) or (2.3), the hypothesis $p^T \in W^{1,\infty}(\mathbb{R})$ is equivalent to $(w(\cdot,T) - w^{\mathrm{obs}}) \in W^{1,\infty}(\mathbb{R})$. In practice, this is a very restrictive hypothesis in the sense that it means a regular solution w, or at least a solution in which the shocks at $t = T$ are canceled with the shocks of the observation w^{obs}. When w is regular (without shocks), it is clear that we do not need the notion of reversible solution: In this case we have seen that the cost function is differentiable. The resolution of (2.10) when $p^T \notin W^{1,\infty}(\mathbb{R})$ remains an open problem.

3. Artificial viscosity.

We introduce the classical viscous regularization of (1.1):

$$\begin{cases} \partial_t w^\varepsilon + \partial_x f(w^\varepsilon) = \varepsilon \partial_{xx}^2 w^\varepsilon, & x \in \mathbb{R},\ t > 0, \\ w^\varepsilon(x,0) = w^0(x). \end{cases} \tag{3.1}$$

It is well known that (3.1) admits a unique smooth solution which approaches the entropy solution of (1.1) in the following sense (see, e.g., Smoller [18]).

THEOREM 3.1. *We suppose that $w^0 \in BV(\mathbb{R})$. Then,*

(i) *Problem* (3.1) *has a solution $w^\varepsilon(\cdot,t) \in BV(\mathbb{R})$ for all $t > 0$. This solution is C^1 on $\mathbb{R}\times(0,\infty)$. Furthermore, for all $t > 0$,*

$$\|w^\varepsilon\|_{L^\infty(\mathbb{R})} \leq \textit{constant}, \qquad TV(w^\varepsilon(\cdot,t)) \leq TV(w^0).$$

(ii) *The only accumulation point in $L^\infty(\mathbb{R}\times(0,+\infty))$-weakly$*$, and $L^1_{\mathrm{loc}}(\mathbb{R}\times(0,+\infty))$-strong, of the sequence w^ε is the entropic solution w of* (1.1).

Now we shall limit ourselves to the (restrictive) case where the final data for the adjoint state are in $W^{1,\infty}(\mathbb{R})$ and consider the following minimization problem:

$$\min_f \widetilde{J}^\varepsilon(w_f^\varepsilon), \qquad \text{where } \widetilde{J}^\varepsilon(w_f^\varepsilon) = J_\rho(w_f^\varepsilon), \tag{3.2}$$

w^ε_f is the solution of the parabolic problem (3.1), and the cost function J_ρ is defined by (2.2).

We are going to proceed in three steps. First we compute the *exact* derivative of the function $\widetilde{J}^\varepsilon$. Then we shall prove that the adjoint equation is well-posed, which will give a characterization of the derivative. Finally, we are going to prove the convergence of the adjoint state and of the derivative of the viscous problem to the corresponding quantities for the hyperbolic problem, when ε tends to 0.

3.1. Derivative of the viscous cost function. We want to determine the Gateaux derivative of $\widetilde{J}^\varepsilon$. We shall prove that the directional derivative

$$D\widetilde{J}^\varepsilon(f)\delta f = \lim_{h\to 0} \delta_h \widetilde{J}^\varepsilon(f) = \lim_{h\to 0} \frac{\widetilde{J}^\varepsilon(f+h\delta f) - \widetilde{J}^\varepsilon(f)}{h} \tag{3.3}$$

exists for all Lipschitz continuous function δf (δf is called a Lipschitz direction). We then have the following propostion.

PROPOSITION 3.2. *Let w^ε_f be the solution of the viscous problem* (3.1). *We suppose that the flux $f = f(w^\varepsilon)$ is of class C^1 and Lipschitz continuous with respect to w^ε with a Lipschitz constant C_{Lip}. Then the limit* (3.3) *exists for all Lipschitz direction δf (which we can suppose with the same Lipschitz constant C_{Lip}). It is characterized by*

$$D\widetilde{J}^\varepsilon(f)\delta f = D_w J_\rho(w^\varepsilon_f) w^\varepsilon_1, \tag{3.4}$$

where w^ε_1 is the solution in $L^2(0,T,L^2(\mathbb{R})) \cap C^1(\mathbb{R}\times(0,+\infty))$ of the following linear parabolic problem:

$$\begin{cases} \partial_t(w^\varepsilon_1) + \partial_x\left(f'(w^\varepsilon_f)w^\varepsilon_1 + \delta f(w^\varepsilon_f)\right) = \varepsilon\partial^2_{xx}w^\varepsilon_1, \\ w^\varepsilon_1(x,0) = 0. \end{cases} \tag{3.5}$$

Proof. Recall that $J_\rho = J_0 + \rho J_1$. Then we can write

$$\begin{cases} D_w J_0(w^\varepsilon_f)w^\varepsilon_1 = \displaystyle\int_{\mathbb{R}} \left(w^\varepsilon_f(x,T) - w^{\text{obs}}(x)\right) w^\varepsilon_1(x,T)dx, \\ D_w J_1(w^\varepsilon_f)w^\varepsilon_1 = \left(\mu_1\big(w^\varepsilon_f(\cdot,T)\big) - \mu_1(w^{\text{obs}})\right)\mu_1\big(w^\varepsilon_1(\cdot,T)\big), \end{cases} \tag{3.6}$$

and we remark that

$$\begin{cases} \delta_h J_0(w^\varepsilon_f) = \displaystyle\int_{\mathbb{R}} \left(\frac{w^\varepsilon_f + w^\varepsilon_{f^h}}{2}(x,T) - w^{\text{obs}}(x)\right)\delta_h w^\varepsilon(x,T)dx, \\ \delta_h J_1(w^\varepsilon_f) = \left(\dfrac{\mu_1(w^\varepsilon_f(\cdot,T)) + \mu_1(w^\varepsilon_{f^h}(\cdot,T))}{2} - \mu_1(w^{\text{obs}})\right)\mu_1(\delta_h w^\varepsilon(\cdot,T)), \end{cases} \tag{3.7}$$

where $f^h = f + h\delta f$ and $\delta_h w^\varepsilon = w^\varepsilon_{f^h} - w^\varepsilon_f/h$.

We first prove the convergence of the derivative of the L^2-criterion:

$$\delta_h \widetilde{J}_0(w^\varepsilon_f) \to D_w J_0(w^\varepsilon_f)w^\varepsilon_1, \qquad \text{when } h \to 0. \tag{3.8}$$

We have that w^ε_f and $w^\varepsilon_{f^h}$ are solutions of the parabolic problem (3.1) with the respective nonlinear flux f and f^h. Thus, if we take the difference between the equation in w_f^ε and the equation in $w_{f^h}^\varepsilon$, we deduce that $\delta_h w^\varepsilon$ is the solution of

$$\partial_t \delta_h w^\varepsilon + \partial_x \left(\frac{f^h(w_{f^h}^\varepsilon) - f^h(w_f^\varepsilon)}{h} + \delta f(w_f^\varepsilon) \right) = \varepsilon \partial_{xx}^2 \delta_h w^\varepsilon. \tag{3.9}$$

We multiply this equation by $\delta_h w^\varepsilon$ and we integrate by parts. Using classical estimate arguments and the Gronwall lemma, we prove

$$\|\delta_h w^\varepsilon(\cdot,t)\|_{H^1} \leq C(\varepsilon) \quad \forall t \in (0,T), \tag{3.10}$$

where $C(\varepsilon)$ is a constant which does not depend on h. Thus, up to a subsequence, there exists $w_1^\varepsilon(\cdot,t)$, such that

$$\delta_h w^\varepsilon(\cdot,T) \rightharpoonup w_1^\varepsilon(\cdot,T) \text{ in } H^1(\mathbb{R})\text{-weak}, \qquad \text{when } h \to 0.$$

We can easily verify that $w_{f^h}^\varepsilon(\cdot,T) \to w_f^\varepsilon(\cdot,T)$ in $L^2(\mathbb{R})$-strong when $h \to 0$. Hence we deduce (3.8).

Next we prove the convergence of the derivative of the first moment criterion:

$$\delta_h \widetilde{J}_1(w_f^\varepsilon) \to D_w J_1(w_f^\varepsilon) w_1^\varepsilon, \qquad \text{when } h \to 0. \tag{3.11}$$

We deduce from the compact support of w^0, and from the maximum principle applied to (3.1), (3.5), and (3.9), that the functions $|w_f^\varepsilon(\cdot,T)|$, $|w_{f^h}^\varepsilon(\cdot,T)|$, $|\delta_h w^\varepsilon(\cdot,T)|$, and $|w_1^\varepsilon(\cdot,T)|$ are bounded by a function $g(x) = C\exp(-r|x|)$, where C, r are constants which depend only on T and $\|w^0\|_{L^\infty}$, and thus are independent of h. We obtain that

$$\begin{aligned}
&|\mu_1(\delta_h w^\varepsilon(\cdot,T)) - \mu_1(w_1^\varepsilon(\cdot,T))| \\
&\qquad \leq \int_{-R}^{R} |x\,(\delta_h w^\varepsilon - w_1^\varepsilon)\,(x,T)|dx \; + \int_{|x|>R} |xg(x)|dx.
\end{aligned}$$

Using the convergence L^2-weak of $\delta_h w^\varepsilon(\cdot,T)$ we have that the first term of the right-hand side converges to 0. The second term uniformly converges to 0 in h, when $R \to \infty$. This implies the convergence $\mu_1(\delta_h w^\varepsilon(\cdot,T)) \to \mu_1(w_1^\varepsilon(\cdot,T))$, when $h \to 0$. In the same way, and using the convergences L^2-strong of $w_{f^h}^\varepsilon(\cdot,T)$, we have that $\mu_1(w_{f^h}^\varepsilon(\cdot,T)) \to \mu_1(w_f^\varepsilon(\cdot,T))$, when $h \to 0$. From these convergences of the moments, we deduce the result (3.11).

Finally, we prove that w_1^ε is the solution of (3.5). Using (3.10) and the compact injection $H^1_{\mathrm{loc}}(\mathbb{R}) \hookrightarrow L^2_{\mathrm{loc}}(\mathbb{R})$, we have the following strong convergence:

$$\delta_h w^\varepsilon(\cdot,t) \to w_1^\varepsilon(\cdot,t) \text{ in } L^2_{\mathrm{loc}}(\mathbb{R})\text{-strong}, \qquad \text{when } h \to 0. \tag{3.12}$$

We multiply (3.9) by a test function $\varphi \in C_0^1([0,+\infty) \times \mathbb{R})$ and we integrate by parts. Hence, by passing to the limit in (3.9), we obtain that w_1^ε is a weak solution of (3.5). Therefore, by the existence and uniqueness of the solution of the linear parabolic problem (3.5), we have that function w_1^ε is the strong solution in $L^2(0,T,L^2(\mathbb{R})) \cap C^\infty(\mathbb{R} \times (0,+\infty))$ of this equation. □

3.2. Viscous adjoint problem. We showed that the Gateaux derivative of $\widetilde{J}^\varepsilon(f)$ is well defined for cost function J_ρ defined by (2.2). Now we shall use the Lagrangian formulation in order to give a characterization of this derivative. First we define the weak form associated with (3.1) by

$$\begin{aligned}
E^\varepsilon\left(w^\varepsilon, p^\varepsilon, f\right) \overset{def}{=} &- \int_0^T \int_{-\infty}^{+\infty} \left(w^\varepsilon \partial_t p^\varepsilon + f(w^\varepsilon)\partial_x p^\varepsilon - \varepsilon \partial_x w^\varepsilon \partial_x p^\varepsilon\right) \\
&+ \int\limits_{t=T} w^\varepsilon p^\varepsilon - \int\limits_{t=0} w^\varepsilon p^\varepsilon
\end{aligned}$$

and the Lagrangian by $L^\varepsilon(w^\varepsilon, p^\varepsilon, f) = J(w^\varepsilon) - E^\varepsilon(w^\varepsilon, p^\varepsilon, f)$, where p^ε is a regular function in (x,t). We take p^ε equal to the solution of the following backward parabolic equation (called *viscous adjoint problem*):

$$\left\{\begin{array}{ll} \partial_t p^\varepsilon + f'(w^\varepsilon)\partial_x p^\varepsilon = -\varepsilon\partial^2_{xx}p^\varepsilon, & x\in\mathbb{R},\ t<T, \\ p^\varepsilon(x,T) = p^T(x), & \end{array}\right. \tag{3.13}$$

where the final condition p^T is defined by (2.11). In this case, the derivative of the Lagrangian with respect to w^ε is equal to zero, and the Gateaux-derivative of the cost function is characterized by

$$D\widetilde{J}^\varepsilon(f)\delta f = \int_0^T \int_{-\infty}^{+\infty} \partial_x \mathrm{p}^\varepsilon \delta f(w^\varepsilon_f). \tag{3.14}$$

Equation (3.13) is a parabolic linear equation, and it is known that it admits only one solution in $L^2(0,T,\,L^2(\mathbb{R}))\cap C^1(\mathbb{R}\times(0,\infty))$ which depends on w^ε.

On the other hand, if $\beta \geq f'' \geq \alpha > 0$, we can prove the following (OSLC) estimate (see [19]) by a maximum principle argument applied to (3.1):

$$L^+\left(f'(w^\varepsilon(x,t))\right) \leq \frac{\beta L^+\left(w^0\right)}{1+\alpha t L^+\left(w^0\right)} = m(t) \in L^1(0,T). \tag{3.15}$$

From this result, we shall deduce BV and $W^{1,\infty}$ estimates on the adjoint state.

THEOREM 3.3. *We consider the solution $p^\varepsilon(x,t)$ of linear parabolic problem* (3.13)*, with $p^T \in W^{1,\infty}(\mathbb{R})\cap BV(\mathbb{R})$. We suppose $\beta \geq f'' \geq \alpha > 0$, with α, β constants independent of w. Then $(x,t)\mapsto f'(w_f(x,t))$ verifies the* (OSLC)*, and*

$$\|p^\varepsilon(\cdot,t)\|_{L^\infty(\mathbb{R})} \leq \|p^T\|_{L^\infty(\mathbb{R})}, \tag{3.16}$$

$$\|\partial_x p^\varepsilon(\cdot,t)\|_{L^1(\mathbb{R})} \leq \|p^T\|_{BV(\mathbb{R})}, \tag{3.17}$$

$$\|\partial_x p^\varepsilon(\cdot,t)\|_{L^\infty} \leq \|p^T\|_{W^{1,\infty}} \cdot \exp\left\{\int_t^T m(T-\tau)d\tau\right\} \tag{3.18}$$

for all $t \leq T$, where $m \in L^1(0,T)$ is the function defined in (3.15)*.*

Proof. Estimates (3.16) and (3.17) are classical results of the theory of nonlinear hyperbolic equations, and the proofs can be found in [12] and [6]. The proof of the estimate (3.18) is very similar to the arguments used by Tadmor [19]. Let us recall them briefly.

We consider p and p^ε solutions to the problems (2.10) and (3.13), respectively. Let $q^\varepsilon(x,t) = p^\varepsilon(-x, T-t)$ and $\psi_\varepsilon(x,t) = \partial_x q^\varepsilon(x,t)$. We differentiate (3.13), and we notice that the function ψ_ε verifies

$$\begin{aligned} &\partial_t\psi_\varepsilon + f'(w^\varepsilon(-x,T-t))\partial_x\psi_\varepsilon \\ &\qquad = -\left(\partial_x f'(w^\varepsilon(-x,T-t))\right)\psi_\varepsilon + \varepsilon\partial^2_{xx}\psi_\varepsilon. \end{aligned} \tag{3.19}$$

Let $\lambda \geq 2$ be an even integer. We multiply (3.19) by $\lambda\psi_\varepsilon^{\lambda-1}$ and we integrate by parts. We obtain

$$\begin{aligned} \frac{d}{dt}\|\psi_\varepsilon(\cdot,t)\|^\lambda_{L^\lambda} = &-(\lambda-1)\int_{x\in\mathbb{R}}\left\{\partial_x\frac{\partial f}{\partial w}(w^\varepsilon(-x,T-t))\right\}\psi_\varepsilon^\lambda dx \\ &-\varepsilon\lambda(\lambda-1)\int_{x\in\mathbb{R}}\left(\partial_x\psi_\varepsilon\right)^2\psi_\varepsilon^{\lambda-2}dx. \end{aligned} \tag{3.20}$$

Using the (OSLC) inequality (3.15) and the Gronwall lemma in (3.20), we deduce $\forall t \leq T$

$$\|\psi_\varepsilon(\cdot,t)\|_{L^\lambda} \leq \|\psi_\varepsilon(\cdot,0)\|_{L^\lambda} \cdot \exp\left\{-\frac{\lambda-1}{\lambda}\int_t^T m(T-\tau)d\tau,\right\}. \tag{3.21}$$

We pass to the limit when λ tends to $+\infty$ in (3.21). By the definition of ψ_ε, we deduce (3.18). □

3.3. Convergence of the method. Now we prove that the artificial viscosity method converges in the sense that the sequences w^ε and p^ε converge, respectively, to the entropy solution of (1.1)—which is logical—and to the reversible solution of the adjoint equation. Moreover, the sequence of the derivatives of $\widetilde{J}^\varepsilon$ also converges toward an element of the subdifferential of $\widetilde{J}$. Using these BV and $W^{1,\infty}$ estimates we have the following convergence result concerning the adjoint state.

THEOREM 3.4. *We consider the solution $p^\varepsilon(x,t)$ of the linear parabolic problem* (3.13). *We suppose that the flux f satisfies $\beta \geq f'' \geq \alpha > 0$ and p^T is a function of $W^{1,\infty}(\mathbb{R}) \cap BV(\mathbb{R})$. Then*

$$p^\varepsilon \;\to\; p \qquad \textit{uniformly in } \bar{\Omega}, \tag{3.22}$$

where $\Omega = \omega \times (0,T)$, ω is a compact of $\mathbb{R}$, and p is the reversible solution of (2.10) *given by Theorem* 2.5.

Proof. The functions p^ε and $\partial_x p^\varepsilon$ are bounded in L^∞ (by (3.16) and (3.18)). We can extract a subsequence, still denoted by p^ε, and we have

$$p^\varepsilon(\cdot,t) \;\rightharpoonup\; p(\cdot,t) \qquad \text{in } W^{1,\infty}(\mathbb{R})\text{-weak}* . \tag{3.23}$$

By the Rellich–Kondrachov theorem (see Adams [1]) we deduce the strong convergence in $C^{0,\alpha}(\bar{\omega})$ for all $0 < \alpha < 1$, and ω compact set of $\mathbb{R}$, and using a classical diagonalization argument (see, for instance, [6]), we obtain the uniform convergence in $\bar{\Omega}$.

Now, in order to prove that p is a Lipschitz continuous solution of (2.10), we multiply the backward parabolic equation (3.13) by a test function $\varphi \in C_0^\infty$ $(\mathbb{R} \times (0,+\infty))$, and we integrate by parts. We have

$$\begin{aligned} 0 = &-\int_0^\infty \int_{\mathbb{R}} \{p^\varepsilon \partial_t \varphi - f'(w^\varepsilon)\partial_x p^\varepsilon \varphi - \varepsilon \partial_x p^\varepsilon \partial_x \varphi\}\, dxdt \\ &- \int_{\mathbb{R}} p^T(x)\varphi(x,0)dx. \end{aligned} \tag{3.24}$$

On the other hand, multiplying (3.13) by $p(\cdot,t)$, integrating by parts, and using Gronwall's lemma, we deduce that

$$\varepsilon^{\frac{1}{2}} \|\partial_x p^\varepsilon\|_{L^2(\mathbb{R}\times(0,T))} \leq C, \tag{3.25}$$

where C is a constant independent of ε. That implies

$$\varepsilon \partial_{xx}^2 p^\varepsilon \to 0 \quad \text{in } L^2(0,T,H^{-1}(\mathbb{R}))\text{-strong}. \tag{3.26}$$

Now, we know by Theorem 3.1 that $w^\varepsilon \to w$ in $L^1_{\text{loc}}(\mathbb{R} \times (0,+\infty))$-strong, and by Lebesgue's dominated convergence theorem we have $f'(w^\varepsilon) \;\to\; f'(w)$, in $L^1_{\text{loc}}(\mathbb{R} \times (0,+\infty))$-strong. Using the convergence $W^{1,\infty}$-weak$*$ of p^ε (3.23), we deduce

$$f'(w^\varepsilon)\partial_x p^\varepsilon \rightharpoonup f'(w)\partial_x p \quad \text{in } \mathcal{D}'(\mathbb{R} \times (0,+\infty)). \tag{3.27}$$

Using convergence results (3.26), (3.27), and the uniform convergence of p^ε, we let $\varepsilon \to 0$ in (3.24). We obtain

$$0 = -\int_0^\infty \int_{\mathbb{R}} \{p\partial_t\varphi - f'(w)\partial_x p\varphi\}\, dxdt - \int_{\mathbb{R}} p^T(x)\varphi(x,0)dx.$$

Thus the limit of p^ε is a solution of the backward transport equation (2.10) in the sense of distributions. In keeping with the $W^{1,\infty}$-weak$*$ convergence (3.23), we obtain that the limit p verifies $p(\cdot,t) \in W^{1,\infty}(\mathbb{R})\ \forall t \leq T$. On the other hand, by letting $\varepsilon \to 0$ in (3.18), we obtain inequality (2.16).

In order to prove the convergence of the whole sequence p^ε, we will prove that the limit of any converging subsequence is the unique reversible solution, which we denote p_r. For that, we suppose that $p^\varepsilon \to p$, and using the definition (2.15) of the support of exceptional solutions, at first we have

$$p = p_r \quad \text{almost everywhere (a.e.) } (x,t) \in \mathbb{R} \times (0,T) \setminus \mathcal{V}. \tag{3.28}$$

We set $\psi_\varepsilon(x,t) = \partial_x p^\varepsilon(-x, T-t)$ and $\psi_r(x,t) = \partial_x p_r(-x,T-t)$. Then, we substract (2.10) from (3.13) and we differentiate with respect to x. We obtain

$$\partial_t(\psi_\varepsilon - \psi_r) = -\partial_x\left(a_\varepsilon(\psi_\varepsilon - \psi_r)\right) - \partial_x\left((a_\varepsilon - a)\psi_r\right) + \varepsilon\partial_{xx}\psi_\varepsilon,$$

where $a_\varepsilon = f'(w^\varepsilon(-x,T-t))$ and $a = f'(w(-x,T-t))$. We multiply this last equation by $2(\psi_\varepsilon - \psi_r)$, and we integrate by parts. Using the (OSLC) inequality (3.15), we deduce

$$\begin{aligned}\frac{d}{dt}\left\{\|\psi_\varepsilon(\cdot,t) - \psi_r(\cdot,t)\|^2_{L^2(\mathbb{R})}\right\} &+ \varepsilon\|\partial_x\psi_\varepsilon(\cdot,t)\|^2_{L^2(\mathbb{R})} \\ &\leq m(T-t)\|\psi_\varepsilon(\cdot,t) - \psi_r(\cdot,t)\|^2_{L^2(\mathbb{R})} \\ &\quad - \int_{-\infty}^{+\infty}(a_\varepsilon - a)(\psi_\varepsilon - \psi_r)\partial_x\psi_r dx \\ &\quad - \int_{-\infty}^{+\infty}(\partial_x a_\varepsilon - \partial_x a)(\psi_\varepsilon - \psi_r)\psi_r dx \\ &\quad -\varepsilon\int_{-\infty}^{+\infty}\partial^2_{xx}\psi^\varepsilon\psi_r dx.\end{aligned} \tag{3.29}$$

From (3.23), (3.22), (3.26), and (3.27), we have that the second and fourth terms on the right-hand side converge to 0 when $\varepsilon \to 0$. On the other hand, from property (i) of Theorem 2.5 we have that $\psi_r = 0$ in $\mathcal{V}_t = \{x \mid (-x, T-t) \in \mathcal{V}\}$, and using the equality (3.28), we deduce

$$\int_{-\infty}^{+\infty}(\partial_x a_\varepsilon - \partial_x a)(\psi_\varepsilon - \psi_r)\psi_r dx = \int_{x\in\mathbb{R}\setminus\mathcal{V}_t}(\partial_x a_\varepsilon - \partial_x a)(\psi_\varepsilon - \psi_r)\psi_r dx \ \to\ 0,$$

when $\varepsilon \to 0$. Then, the third term on the right-hand side converges to 0. We can pass to the limit in (3.29) and using Gronwall's lemma, we obtain $\lim_{\varepsilon\to 0}\psi_\varepsilon = \psi_r$ and consequently $p = p_r$. □

Remark. Another way to prove this last result is to make use of the characterization (ii) of Theorem 2.5. Indeed, standard arguments allow us to prove that if $\partial_x p^T \geq 0$, then $\partial_x p^\varepsilon \geq 0$. Now, for any final data p we rewrite $p^T = p_1^T - p_2^T$, with $\partial_x p_1^T = (\partial_x p^T)_+$ and $\partial_x p_2^T = (\partial_x p^T)_-$. We denote by p_i^ε the solution of (3.13) with final data p_i^T. Therefore we have $p^\varepsilon = p_1^\varepsilon - p_2^\varepsilon$, with $\partial_x p_i^\varepsilon \geq 0$. We know that $p^\varepsilon \to p$,

$p_i^\varepsilon \to p_i$ with $\partial_x p_i \geq 0$, and p_i is solution of (2.10). Thus p is reversible. A similar monotonicity argument will be used for numerical schemes.

Now we turn to the convergence of the derivative. A fundamental consequence of the convergence of the solution of the adjoint problem with artificial viscosity is the convergence of $D\widetilde{J}^\varepsilon$ when $\varepsilon \to 0$. More precisely, we have the following theorem.

THEOREM 3.5. *Let $\widetilde{J}^\varepsilon : f \mapsto J(w_f^\varepsilon)$ be the cost function* (3.2) *defined for all Lipschitz continuous functions f, with w_f^ε the solution of the parabolic problem* (3.13), *and assume that w^0 has compact support. We suppose that the flux f satisfies $\beta \geq f'' \geq \alpha > 0$ and p^T satisfies a function of $W^{1,\infty}(\mathbb{R}) \cap BV(\mathbb{R})$. Then we have, if w_f is the entropy solution of* (1.1) *and p_f the reversible solution of* (2.10),

$$D\widetilde{J}^\varepsilon(f)\delta f \to \int_0^T \int_{-\infty}^{+\infty} \partial_x p_f \delta f(w_f) dxdt, \qquad \textit{when } \varepsilon \to 0 \tag{3.30}$$

for all Lipschitz direction δf.

Proof. From Theorem 3.4 and the continuity of δf, we obtain the result

$$\left\{ \begin{array}{rcl} \delta f(w_f^\varepsilon) & \to & \delta f(w_f) \quad \text{in } L^1_{\text{loc}}(\mathbb{R} \times (0, +\infty))\text{-strong}, \\ \|\delta f(w_f^\varepsilon)\|_{L^\infty(\mathbb{R}\times(0,+\infty))} & \leq & C \end{array} \right. \tag{3.31}$$

for some constant C independent of ε. Let $\theta \in C_0^\infty(\mathbb{R} \times (0, +\infty))$. In keeping with the convergence $W^{1,\infty}$-weak of p^ε (3.23), and using (3.31), we obtain

$$\int_0^T \int_{-\infty}^{+\infty} \theta \partial_x p_f^\varepsilon \delta f(w_f^\varepsilon) dxdt \to \int_0^T \int_{-\infty}^{+\infty} \theta \partial_x p_f \delta f(w_f) dxdt. \tag{3.32}$$

By hypothesis, w^0 has a compact support. It is known that for finite propagation velocity, the function $[\partial_x p_f]\delta f(w_f)$ stays in a compact support, for $T < \infty$ (see Kružkov [12]). We have

$$\begin{aligned} &\left| D\widetilde{J}^\varepsilon(f)\delta f - \int_0^T \int_{-\infty}^{+\infty} \partial_x \text{p} \delta f(w_f) \right| \\ &\qquad \leq \int_0^T \int_{-R}^{R} |\partial_x p_f^\varepsilon \delta f(w_f^\varepsilon) - \partial_x p_f \delta f(w_f)| \\ &\qquad + \int_0^T \int_{|x|>R} |\partial_x p_f^\varepsilon \delta f(w_f^\varepsilon)| \end{aligned} \tag{3.33}$$

for R large enough. Hence, by (3.32), the first term of the right-hand side in (3.33) converges to 0 when $\varepsilon \longrightarrow 0$ for all R large enough.

Let us prove the convergence of the second term. We deduce from the compact support of w^0 and from the maximum principle applied to the linear parabolic equation (3.13) that $|p^\varepsilon(x,t)| \leq C \exp(-r|x|)$, where C, r are constants which depend only on T and $\|w^0\|_{L^\infty}$ and thus are independent of ε. We deduce that the second term of the right-hand side of (3.33) uniformly converges to 0 in ε, when $R \to \infty$. This concludes the proof of (3.30). □

If the derivative of $\widetilde{J}(f)$ exists, then $D\widetilde{J}(f)$ is characterized by (2.12), and we deduce from Theorem 3.5 that $D\widetilde{J}^\varepsilon(f)\delta f \to D\widetilde{J}(f)\delta f$, when $\varepsilon \to 0$. The trouble is that we have no result concerning the differentiability of $\widetilde{J}$. Nevertheless, since we are interested in the behavior of $\widetilde{J}$ near a minimum, we can assume that $\widetilde{J}$ is convex in a neighborhood of this point. Therefore, we can define its subdifferential $\partial\widetilde{J}(f)$.

COROLLARY 3.6. *Assume that $\widetilde{J}$ is a minimum at f and that $\widetilde{J}$ and $\widetilde{J}^\varepsilon$ are convex in a neighborhood of f for all ε. Then, under the hypotheses of Theorem* 3.5*, $D\widetilde{J}^\varepsilon(f)\delta f$ converges to an element of the subdifferential $\partial\widetilde{J}(f)$ of $\widetilde{J}(f)$, when $\varepsilon \to 0$, that is,*

$$\partial\widetilde{J}(f) \ni \int_0^T \int_{-\infty}^{+\infty} \partial_x p_f \delta f(w_f) dx dt.$$

Proof. From the definition of convexity we have

$$D\widetilde{J}^\varepsilon(f)f - \widetilde{J}^\varepsilon(f) \geq D\widetilde{J}^\varepsilon(f)\nu - \widetilde{J}^\varepsilon(\nu)$$

for all Lipschitz continuous function ν. We apply Theorem 3.5, and we pass to the limit when $\varepsilon \to 0$. We obtain

$$\int_0^T \int_{-\infty}^{+\infty} [\partial_x p_f] \left[(f-\nu)(w_f)\right] dx dt \geq \widetilde{J}(f) - \widetilde{J}(\nu).$$

That is a characterization of the subgradient for convex functions (see Rockafellar [15]). Thus, the limit of sequence $D\widetilde{J}^\varepsilon(f)\delta f$ is an element of the set $\partial J(f)$. □

4. Numerical approximation. Now we shall give similar convergence results for discretization of the identification problem, and we will remark that at the limit, both approximations (artificial viscosity and discretization) reach the same element of the subdifferential $\partial J(f)$ characterized by the reversible solution of the adjoint problem. We shall prove these results for a large class of numerical schemes which contains the schemes used to resolve the identification problem in [9].

First we discretize the cost function (denoted J_Δ) and the direct problem (1.1). Next we compute a discrete Lagrangian, which will lead to a discrete adjoint state, and finally to a discrete gradient of J_Δ. This method of computing the exact gradient of the discretized problem seems to have better properties (concerning stability, for instance) than discretizing the exact adjoint state. Moreover, notice that we have no natural way to discretize it since the adjoint equation is ill-posed.

4.1. Discretization and convergence for the direct problem. Let Δz (respectively, Δt) be a positive space (respectively, time) step. These parameters will tend to 0, the ratio $\lambda = \Delta t/\Delta z$ remaining constant. For $n = 0, \dots, N$, $j = 0, \dots, J$, the sequence w_j^n is an approximation of solution w at the point $(z_j = j\Delta z, t_n = n\Delta t)$. In the same way, we discretize $w^0(z)$, $w^{\text{obs}}(z)$, by w_j^0, w_j^{obs}, respectively. We consider a conservative $(2K+1)$-points scheme for the hyperbolic equation (1.1)

$$w_j^{n+1} = w_j^n - \lambda \left\{ g_{j+\frac{1}{2}}^n(f) - g_{j-\frac{1}{2}}^n(f) \right\}, \tag{4.1}$$

where $g_{j+\frac{1}{2}}^n(f) = g_f(w_{j-K+1}^n, \dots, w_{j+K}^n)$, g_f being the numerical flux of the scheme, consistent with f: $g_f(w, \dots, w) = f(w)$. Then the discretized identification problem becomes the following minimization problem:

$$\min_f J\left(w_f^\Delta\right), \tag{4.2}$$

where w_f^Δ is the piecewise constant function defined by the sequence $\left\{w_j^n(f)\ ;\ j = 0, \dots, J-1,\ n = 0, \dots, N-1\right\} \in \mathbb{R}^M$, which was built out of (4.1).

To obtain the exact gradient of the discretized cost function, we follow along exactly the same lines as in the formal computation and viscous regularization, that is, we build up a discrete Lagrangian $\mathcal{L}_\Delta$ using a "discrete weak form" of the direct scheme (4.1), then we differentiate with respect to w_j^n, and we choose the sequence p_j^n in order to cancel $\partial\mathcal{L}_\Delta/\partial w_j^n$ for all j and n. This defines the adjoint scheme. Finally, for the discrete gradient, the computations give

$$D\widetilde{J}_\Delta(f)\delta f = \, -\Delta t \sum_{n,j} \left(p_j^{n+1} - p_{j+1}^{n+1}\right) Dg_{j+\frac{1}{2}}^n(f)\delta f, \tag{4.3}$$

where p_Δ is the solution of the adjoint scheme

$$\begin{cases} p_j^n = p_j^{n+1} - \lambda \displaystyle\sum_{k=-K}^{K-1} \frac{\partial}{\partial w_j^n} g_{j+k+\frac{1}{2}}^n (p_{j+k}^{n+1} - p_{j+k+1}^{n+1}), \\ \\ p_j^N = \dfrac{\partial J\left(w^\Delta\right)}{\partial w_j^N}. \end{cases} \tag{4.4}$$

The complete computations are rather tedious, and we refer to [9] or [17] for greater detail and for some examples as well.

First we show a convergence result of our discretized cost function, which allows us to say that the continuous identification problem can be approximated by the discretized identification problem. We consider a suitable set of functions $\mathcal{F}$, which we suppose are bounded and closed for the Lipschitz continuous norm $\| \, \|_{\mathrm{Lip}}$. Next we suppose that the numerical flux g introduced in (4.1) is Lipschitz continuous with respect to $w_{-k}, \dots, w_k$ and independent of $f \in \mathcal{F}$, i.e., that there exists a constant C_{Lip} independent of f, such that

$$\sup_{w,v\geq 0} \left\{ \frac{|g_f(w) - g_f(v)|}{|w-v|} \right\} \leq \; C_{\mathrm{Lip}} \qquad \forall f \in \mathcal{F}. \tag{4.5}$$

We also suppose that the scheme (4.1) satisfies

$$|w_j^n(f)| \leq C_\infty \qquad \forall\, j, n, \qquad \text{and for any } f \in \mathcal{F}, \tag{4.6}$$

where C_∞ is a constant independent of f. Condition (4.6) is verified for the Lax–Friedrichs, Godunov [7], and Van Leer [20] schemes, when the following CFL-condition is satisfied:

$$\lambda \sup_{\substack{w \,\geq\, 0 \\ f \,\in\, \mathcal{F}}} |f'(w)| < 1. \tag{4.7}$$

This leads us to our convergence result.

Proposition 4.1. *Let $w_{f_\Delta}^\Delta$ be built out of the conservative scheme* (4.1) *which we suppose consistent with* (1.1)*, and verifying hypotheses* (4.5) *and* (4.6)*, f_Δ being the solution of* (4.2)*. If the initial condition w_Δ^0 is bounded in $L^\infty(\mathbb{R}) \cap BV(\mathbb{R})$, then $w_{f_\Delta}^\Delta$ is bounded in $L^\infty(\mathbb{R}\times(0,+\infty))$ and in $L^\infty(0,T,\, BV\ (\mathbb{R}))$ for all $T>0$. Furthermore, if $f_{\Delta_k} \to \bar{f} \in \mathcal{F}$, for the Lipschitz continuous norm $\| \, \|_{\mathrm{Lip}}$, then*

$$w_{f_{\Delta_k}}^{\Delta_k} \to w_{\bar{f}} \quad \textit{in } L^\infty(0,T,L^1(0,L))\textit{-strong}, \tag{4.8}$$

$$w_{f_{\Delta_k}}^{\Delta_k} \rightharpoonup w_{\bar{f}} \quad \textit{in } L^\infty(\Omega)\textit{-weak}\,*\,. \tag{4.9}$$

Remarks. We can prove this proposition thanks to the continuity result of Lucier [13] and by copying the proof of a convergence result for schemes approximating scalar conservation laws in [6]. We omit the detail of this proof.

For instance, we consider the identification problem arising from the chromatographic model (see [9]), and we take a bounded subset of parameters $\mathcal{K} \in \mathbb{R}^N$. Then we deduce the CFL-condition (4.7), and we have at least one accumulation point of the sequence $\{f_\Delta\}_{\Delta x, \Delta t}$.

We suppose that w^{obs} and w^0 have a compact support, so that for $0 < t < T$, the support of the solution w_f to (1.1), with $f \in \mathcal{F}$, is in a compact set $\Omega = (0, L) \times (0, T)$. Proposition 4.1 and a convergence result of [9] imply the following.

COROLLARY 4.2. *Let $w^\Delta_{f_\Delta}$ be the solution of a conservative and TVD scheme* (4.1)*, consistent with* (1.1)*. Then any accumulation point $\bar{f} \in \mathcal{F}$ of the sequence $\{f_\Delta\}_{\Delta x, \Delta t}$, for the Lipschitz continuous norm is a solution of*

$$J(w_f) = \min_{g \in \mathcal{F}} J(w_g),$$

where w_f is the entropy solution of (1.1)*, with $f \in \mathcal{F}$.*

4.2. Monotone and TVD adjoint schemes. Here we study some properties of monotonicity and BV estimates for adjoint schemes associated with the schemes in conservative form (4.1). We notice that adjoint schemes cannot be put in conservative form, which is not surprising, since the adjoint equation is not conservative. However, we shall prove that a family of TVD difference schemes, including the Godunov and the Van Leer schemes, is associated with TVD adjoint schemes.

First we define the function $\delta_x p_\Delta$ by

$$\delta_x p_\Delta(x, t) = \frac{p_\Delta(x, t) - p_\Delta(x + \Delta x, t)}{\Delta x},$$

where $\delta_x p_\Delta$ is the piecewise constant function with value $\Delta p^n_{j+\frac{1}{2}} / \Delta x$ in the rectangle

$$\Pi^n_j = \left(\left(j - \frac{1}{2} \right) \Delta x, \left(j + \frac{1}{2} \right) \Delta x \right) \times (n\Delta t, (n+1)\Delta t).$$

On the other hand, we define the differences $\Delta p^n_{j+\frac{1}{2}} = p^n_j - p^n_{j+1}$ for all $j \in \mathbf{Z}$, $n \leq N$. Using the linearity of the scheme (4.4), we deduce the following scheme for $\Delta p^n_{j+\frac{1}{2}}$:

$$\Delta p^n_{j+\frac{1}{2}} = \sum_{k=-K}^{K} A^k_{j+k} \Delta p^{n+1}_{j+k+\frac{1}{2}}, \tag{4.10}$$

where the coefficients A^k_j are defined by

$$\begin{cases} A^k_j = -\lambda \left(\dfrac{\partial}{\partial w^n_{j-k}} - \dfrac{\partial}{\partial w^n_{j-k+1}} \right) g^n_{j+\frac{1}{2}} \quad \text{for } k \notin \{-K, 0, K\}, \\ A^{-K}_j = -\lambda \dfrac{\partial}{\partial w^n_{j+K}} g^n_{j+\frac{1}{2}}, \qquad A^K_j = \lambda \dfrac{\partial}{\partial w^n_{j-K+1}} g^n_{j+\frac{1}{2}}, \\ A^0_j = 1 - \lambda \left(\dfrac{\partial}{\partial w^n_j} - \dfrac{\partial}{\partial w^n_{j+1}} \right) g^n_{j+\frac{1}{2}}. \end{cases} \tag{4.11}$$

Notice that by construction the coefficients A^k_j satisfy

$$\sum_{k=-K}^{K} A^k_j = 1 \quad \forall j \in \mathbf{Z}. \tag{4.12}$$

Now we wish the adjoint scheme to have the same property of monotonicity preservation as the continuous equation. Thus, in view of (4.10), it is natural to impose

$$A_j^k \geq 0 \quad \text{for } -K \leq k \leq K,\ j \in \mathbf{Z}. \tag{4.13}$$

This is somehow the discrete version to the (OSLC) condition (3.15) used for the convergence of the viscous perturbation.

Example. In the model of chromatography, the Godunov scheme is very simple. (It is just an upwind scheme.) The adjoint scheme is given by (see [9])

$$p_j^n = p_j^{n+1} - \lambda f'(w_j^n)\left(p_j^{n+1} - p_{j+1}^{n+1}\right). \tag{4.14}$$

In this case, the coefficients A_j^k are

$$A_j^{-1} = \lambda f'(w_j^n), \qquad A_j^0 = 1 - \lambda f'(w_j^n), \qquad A_j^1 = 0.$$

The CFL-condition (4.7) implies that these coefficients are positive.

Similarly, the adjoint scheme associated with the Van Leer difference scheme verifies the hypothesis $A_j^k \geq 0$ when we have CFL-condition (4.7), and it is a monotone and TVD scheme, whereas we can see that the adjoint scheme associated with the Lax–Friedrichs difference scheme does not verify this hypothesis of positivity and that it is an unstable scheme in $BV(\mathbb{R})$.

We have the following a priori estimates.

PROPOSITION 4.3. *We consider a linear scheme in form* (4.4)*, with its coefficients defined by* (4.11) *and verifying the monotonicity property* (4.13)*. Then we have for all* $0 < s, t < T$ *the following estimates:*

$$TV(p_\Delta(.,t)) \leq TV(p_\Delta(.,T)), \tag{4.15}$$

$$\|p_\Delta(.,t)\|_{L^1(\mathbb{R})} \leq \|p_\Delta(.,T)\|_{L^1(\mathbb{R})} + CT\ TV(p_\Delta(.,T)), \tag{4.16}$$

$$\|\delta_x p_\Delta(\cdot,t)\|_{L^\infty(\mathbb{R})} \leq \|\delta_x p_\Delta(\cdot,T)\|_{L^\infty(\mathbb{R})}, \tag{4.17}$$

$$\|p_\Delta(.,t) - p_\Delta(.,s)\|_{L^p(\omega)} \leq C\frac{|t-s| + \Delta t}{|\Delta t|^{\frac{p-1}{p}}}\|\delta_x p_\Delta(\cdot,T)\|_{L^\infty(\mathbb{R})}, \tag{4.18}$$

where ω *is a compact set in* $\mathbb{R}$*,* $1 \leq p \leq +\infty$*, and* $C > 0$ *is a constant independent of the discretization.*

Remark. Estimates (4.15) and (4.16) are classical results of the theory of approximation of nonlinear conservation laws. They rely upon monotonicity properties of the schemes and are in particular independent of the conservative form. The estimate (4.18) is a technical result allowing us to use a diagonalization argument in order to pass to the limit, when $\Delta t, \Delta z \to 0$.

Notice that the result of estimate (4.17) bears some resemblance to that of the $W^{1,\infty}$ estimate proved in Theorem 3.3.

Proof of Proposition 4.3. Let $R \geq K$. Summing up (4.10) from $j = -R$ to $j = R$, and using the positivity of A_j^k and property (4.12), and passing to the limit $R \to +\infty$, we obtain the estimate (4.15). On the other hand, using this BV estimate, the L^1 estimate (4.16) is obtained by an analysis that is similar to the one made by Godlewski and Raviart [6, Chap. III] for the different schemes in conservative form. Now, using the condition $A_{j+k}^k \geq 0$, the estimate (4.17) results from the monotonicity of

$$(H_\Delta(\Delta p))_j = \sum_{k=-K}^{K} A_{j+k}^k \Delta p_{j+k+\frac{1}{2}}^{n+1}.$$

In order to obtain the next estimate (4.18), we write the scheme (4.4) in the form

$$p_j^n - p_j^{n+1} = -\lambda \sum_{k=-K}^{K-1} \frac{\partial}{\partial w_j^n} g_{j+k+\frac{1}{2}}^n \Delta p_{j+k+\frac{1}{2}}^{n+1},$$

and by the Lipschitz condition of g, we have

$$|p_j^n - p_j^{n+1}| \leq \lambda C \sup_{j\in\mathbf{Z}} |\Delta p_{j+\frac{1}{2}}^{n+1}|,$$

with a constant C independent of the discretization. That implies

$$\|p_\Delta(\cdot, n\Delta t) - p_\Delta(\cdot,(n+1)\Delta t)\|_{L^p(\omega)} \leq \lambda^{\frac{p-1}{p}} C|\omega|^{\frac{1}{p}}|\Delta t|^{\frac{1}{p}} \sup_{j\in\mathbf{Z}} |\Delta p_{j+\frac{1}{2}}^{n+1}|.$$

Let $m > n$. Applying successively this same result for $n, n+1, \ldots, m-1$, and using the triangular inequality of the norm $\|\cdot\|_{L^p}$, we obtain

$$\|p_\Delta(\cdot, n\Delta t) - p_\Delta(\cdot, m\Delta t)\|_{L^p(\omega)} \leq C|\Delta t|^{\frac{1}{p}}(n-m) \sup_{j\in\mathbf{Z}} |\Delta p_{j+\frac{1}{2}}^{N}|. \tag{4.19}$$

Let s, t such that $n\Delta t \leq s \leq (n+1)\Delta t$, $m\Delta t \leq t \leq (m+1)\Delta t$. We notice that $(m-n)\Delta t \leq |t-s| + \Delta t$. Inequality (4.19) gives the desired result (4.18). □

4.3. Convergence for adjoint schemes and derivatives. Now we shall provide evidence that the sequence of discrete gradients converges to the same element of the subdifferential of the cost function given by the limit of the viscous perturbation. First we have the following convergence result for the solution of the adjoint scheme.

THEOREM 4.4. *We consider the linear difference scheme in the form* (4.4)*, where the coefficients are defined in* (4.11) *and verify the monotonicity property* (4.13)*. We suppose* $p^T \in W^{1,\infty}(\mathbb{R}) \cap BV(\mathbb{R})$ *and the (OSLC)* (3.15)*. Then,*

$$p_\Delta \;\to\; p \quad \textit{in } L^\infty(0,T,L^q_{\mathrm{loc}}(\mathbb{R}))\textit{-strong}, \qquad 1 \leq q < +\infty,$$

where p *is the reversible solution of* (2.10)*.*

Proof. In accordance with the estimate (4.17) and in keeping with the hypothesis $p^T \in W^{1,\infty}(\mathbb{R})$, we have

$$\sup_x |\delta_x p_\Delta(x,t)| \leq C. \tag{4.20}$$

Applying the theorem of Riesz–Fréchet–Kolmogorov (see Adams [1]) in the last inequality, we deduce that we can take a subsequence $\Delta_k x, \Delta_k t \to 0$ which we still denote with $\Delta x, \Delta t$, such as

$$p_\Delta(\cdot,t) \;\to\; p(\cdot,t) \quad \text{in } L^q_{\mathrm{loc}}(\mathbb{R}))\text{-strong} \quad \forall t \in (0,T)$$

for all $1 \leq q < +\infty$. Using the estimate (4.18) and a classical diagonalization argument (see [6]), we deduce the convergence in $L^\infty(0,T,L^q_{\mathrm{loc}}(\mathbb{R}))$.

In order to prove that the limit p is a Lipschitz continuous solution of (2.10), we proceed by similar arguments to the proof of Theorem 3.4. Next we notice that the scheme in the form (4.4) preserves monotonicity as soon as $A_j^k \geq 0$ (which is satisfied, for instance, by the adjoints of Godunov and Van Leer schemes). Finally, we use the same arguments of the first remark following the proof of Theorem 3.4. That is,

$$\begin{cases} p_\Delta \to p \text{ in } L^\infty(0,T,L^q_{\mathrm{loc}}(\mathbb{R})), \\ p_\Delta = p_\Delta^1 - p_\Delta^2, \text{ with } (p_j^n)^i \leq (p_{j+1}^n)^i, \text{ and } p_\Delta^i \text{ solution of the scheme (4.4)} \end{cases}$$

implies that p is reversible. □

It is easy to verify that $\widetilde{J}_\Delta : f \mapsto J(w_f^\Delta)$ has a continuous derivative if the numerical flux g is of class C^1 with respect to $(w_{j-K+1}^n, \cdots, w_{j+K}^n)$. As a consequence of Theorem 4.4, we have the following.

COROLLARY 4.5. *Let $\widetilde{J}_\Delta : f \mapsto J(w_f^\Delta)$ be a discretized cost function defined for all Lipschitz continuous function f, with w_f^Δ solution of the scheme in the conservation form* (4.1). *We suppose that the coefficients A_j^k in* (4.11) *satisfy $A_j^k \geq 0$ for $-K \leq k \leq K$, $j \in \mathbf{Z}$, and that w^0 has a compact support. Furthermore, we suppose that $p^T \in W^{1,\infty}(\mathbb{R}) \cap BV(\mathbb{R})$. Let w_f be the entropy solution of* (1.1) *and p_f be the reversible solution of* (2.10). *Then we have*

$$D\widetilde{J}_\Delta(f)\delta f \to \int_0^T \int_{-\infty}^{+\infty} \partial_x p_f \delta f(w_f) dx dt, \qquad \text{when } \Delta x, \Delta t \to 0 \tag{4.21}$$

for all Lipschitz direction δf.

Remark. We note that Theorem 3.5 and Corollary 4.5 make it clear that a viscous perturbation or a numerical approximation of the gradient give the same result at the limit.

We clarify this result by another corollary, as follows.

COROLLARY 4.6. *Assume that $\widetilde{J}$ is a minimum at f and that $\widetilde{J}$ and $\widetilde{J}_\Delta$ are convex for all $(\Delta x, \Delta t)$ in a neighborhood of f. Then, under the hypotheses of Theorem* 4.5, *$D\widetilde{J}_\Delta(f)\delta f$ converges to the same element of the subdifferential $\partial J(f)$ of $J(f)$ which we have obtained by a viscous perturbation in Corollary* 3.6, *when $\Delta x, \Delta t \to 0$.*

5. Numerical results. In this section we illustrate our results by a numerical application on real experimental data. We consider the propagation of a single, pure compound in a column, which leads under several physical assumptions to a scalar conservation law of the form (1.1). More precisely, the experimental data are concentration profiles obtained from the adsorption of gaseous n-hexane on graphite carbon with helium vector gas. We refer to Rouchon et al. [16] for the complete description of the experiment, the discussion of the model, and the original results. A remarkable feature of this experiment is that we have an experimentally identified flux with which to compare.

The observation here is a profile of concentration versus time, at a fixed $L > 0$, where L is the length of the column. This is not quite the context of the previous analysis, but since in this kind of model the flux satisfies $f'(w) > 0$, only a slight modification is needed. The direct problem is discretized through a Godunov scheme, and we compute the exact gradient of the discrete functional as indicated in section 4.1 (see also [9] for details). At this discrete level, all the quantities are well defined, so we are able to apply a gradient-based minimization algorithm. Thus we are left with the problem of nonuniqueness for f which was mentioned before. To handle this, we specify an analytic form for f, based on physical arguments, which we do not detail here. We refer the interested reader to [10] and the references therein for more complete information. If c denotes the concentration of the compound, then a family of fluxes depending on a finite number of parameters is given by

$$f(c) = N \frac{KcP'(Kc)}{qP(Kc)}, \quad P(w) = \sum_{i=0}^{q} \alpha_i \exp(-\beta E_i) w^i, \tag{5.1}$$

where $q \geq 1$ is an integer and α_i and β are given constants involving temperature and other fixed parameters of the experiment. The relevant parameters to identify here are the so-called Langmuir coefficient K, N, and E_i, $2 \leq i \leq q$ ($E_0 = E_1 = 0$ by

TABLE 5.1
Initial and identified coefficients (1).

Parameters	Initial guess (Langmuir)	Identification result
K	1596.	1178.
E_2	0.	-806.
E_3	0.	-213.
E_4	0.	-16.

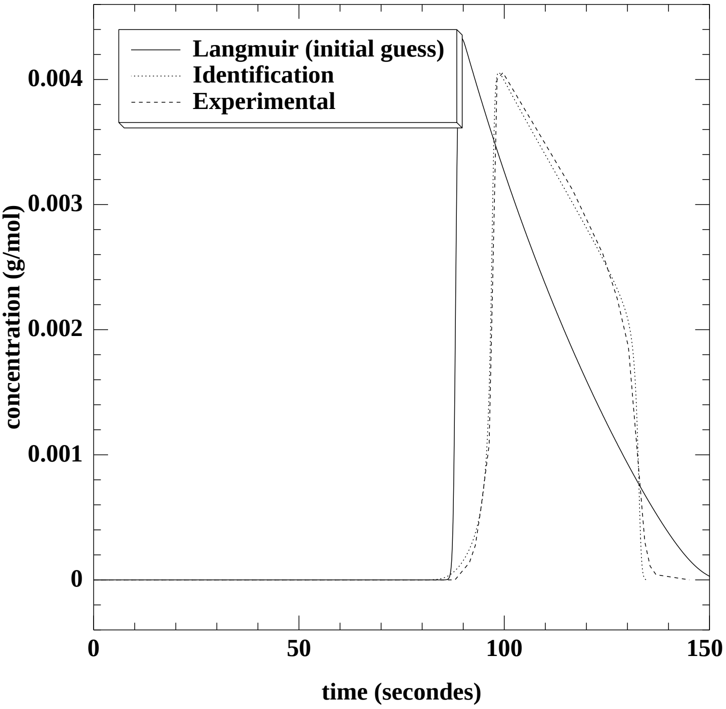

FIG. 5.1. *Comparison between experimental and identified profiles.*

construction). The model obtained with $q = 1$ or equivalently with $E_i = 0\ \forall i$ is the classical Langmuir model.

These parameters do not have the same influence on the concentration profiles. Roughly speaking, K and N act essentially on the position of the profile, while E_i modifies its shape. The minimization algorithm has therefore to be carefully modified to handle this problem (see [9]). In the first application, we chose as an initial guess the Langmuir model, with a given value of K, and we fixed the value of $N = 2.19\ 10^{-2}$.

The coefficients of the initial guess and the identification result are given in Table 5.1, and the comparison between the experimental flux, the initial guess, and the identified flux is shown in Figure 5.2. Finally, Figure 5.1 shows the experimental and identified concentration profiles.

These figures deserve a few remarks. The comparison between the profiles in Figure 5.1 proves that our identification is quite successful. Concerning the fluxes themselves, we notice in Figure 5.2 the good agreement with the experiment on the whole domain of measurement, even though the domain of identification is $0 \leq c \leq 0.004$ g./mol.

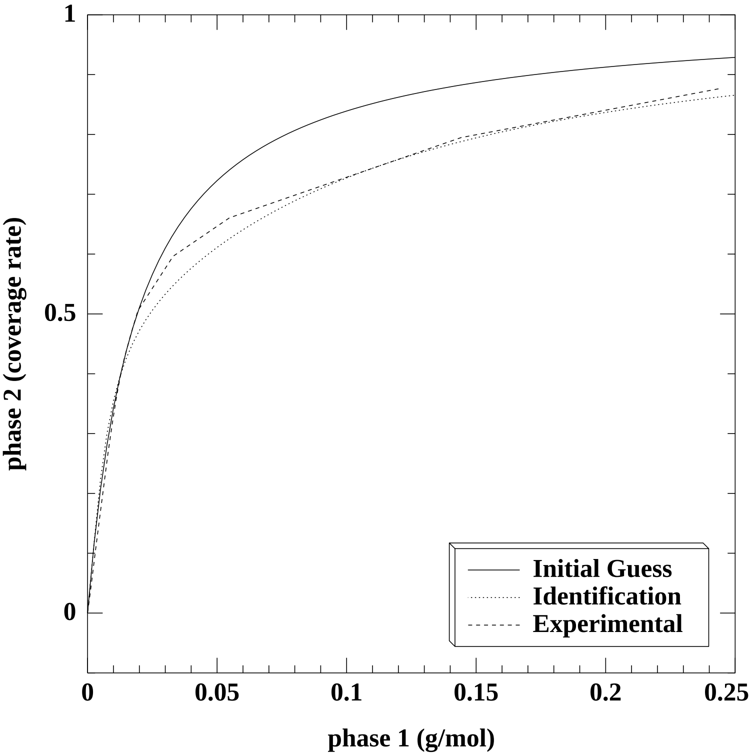

FIG. 5.2. *Comparison between experimental and identified isotherm.*

TABLE 5.2
Initial and identified coefficients (2).

Parameters	Initial guess	Identification result
N	$2.19\ 10^{-2}$	$1.42\ 10^{-2}$
K	1596.	2068.
E_2	214.	214.
E_3	-1252.	-1252.
E_4	1251.	1251.

In order to illustrate the nonuniqueness, we tried another identification. Starting from an initial guess which has a convenient shape, we tried to identify only the coefficients N and K, leaving the ratio K/N constant. The results are shown in Table 5.2. The resulting profile is identical to the one in Figure 5.1.

Figure 5.3 shows the preceding identification (labeled 1) and this one (labeled 2). We notice that, indeed, we obtain different functions but in the domain of identification, they are virtually indistinguishable.

We would like to emphasize that the choice of a physically relevant model for the flux is of great importance to obtain a good agreement with experiment. But even in this case the problem of uniqueness is not solved, and the correct choice of the flux therefore has to rely on physical arguments: The parameters here have a precise meaning, which has not been explored in these experiments. We refer to [11] for similar results on a binary mixture or, in terms of partial differential equations, on a system of two equations.

AN AUGMENTED LAGRANGIAN METHOD FOR IDENTIFYING DISCONTINUOUS PARAMETERS IN ELLIPTIC SYSTEMS[*]

ZHIMING CHEN[†] AND JUN ZOU[‡]

Abstract. The identification of discontinuous parameters in elliptic systems is formulated as a constrained minimization problem combining the output least squares and the equation error method. The minimization problem is then proved to be equivalent to the saddle-point problem of an augmented Lagrangian. The finite element method is used to discretize the saddle-point problem, and the convergence of the discretization is also proved. Finally, an Uzawa algorithm is suggested for solving the discrete saddle-point problem and is shown to be globally convergent.

Key words. parameter identification, elliptic system, augmented Lagrangian, finite element method

1. Introduction. The main purpose of this paper is to propose a numerical approach and conduct convergence analyses on each approximation process in the identification of the unknown coefficient q in the elliptic problem

$$-\nabla \cdot (q\nabla u) = f \quad \text{in} \quad \Omega; \quad u = 0 \quad \text{on} \quad \Gamma.$$

The identifying process is carried out so that the solution u matches its observation data z optimally in a certain sense. Here Ω can be any bounded domain in R^d, $d = 1, 2$, or 3, with piecewise smooth boundary Γ and $f \in H^{-1}(\Omega)$ as given. The problem may describe the flow of a fluid (e.g., groundwater) through some medium with permeability $q(x)$, or the heat transfer in a material with conductivity $q(x)$; we refer to the books by Bank and Kunisch [1] and Engl, Hanke, and Neubauer [7]. Practically, it is often easier to measure the solution u at various points in the medium than to measure the parameter $q(x)$ itself [11]. Then the measured data of u (often the interpolated function of the data) are utilized to estimate the parameter $q(x)$ through the above boundary value problem. We study a hybrid method proposed in [13, 14] that combines the output least squares and the equation error formulation within the mathematical framework given by the augmented Lagrangian technique. The augmented Lagrangian methods have been widely used earlier in nonlinear constrained optimization problems and nonlinear boundary value problems to relax some complicated constraints or difficult couplings among some nonlinear and nonsmooth terms or to enhance convexities of the objective functions (cf. [10, 2]). Ito and Kunisch [13, 14] applied the augmented Lagrangian method for parameter identifying problems, incorporated with a regularization term of the H^2 seminorm of the parameters to be estimated. Their methods appear to be very efficient and successful in recovering the smooth parameters. The major novelty of this paper is to generalize the

aforementioned method so that we can identify even nonsmooth parameters. To this aim, we propose to search for the coefficients in the space of functions with bounded variation (BV), namely, in the space

$$BV(\Omega) = \Big\{ q \in L^1(\Omega); \quad \|q\|_{BV(\Omega)} < \infty \Big\}.$$

Here $\|q\|_{BV(\Omega)} = \|q\|_{L^1(\Omega)} + \int_\Omega |Dq|$ with the notation $\int_\Omega |Dq|$ defined by

$$\int_\Omega |Dq| = \sup \Big\{ \int_\Omega q \operatorname{div} g \, dx; \quad g \in \big(C_0^1(\Omega)\big)^d \quad \text{and} \quad |g(x)| \le 1 \quad \text{in} \quad \Omega \Big\},$$

which allows us to identify the discontinuous parameters in elliptic systems.

Because of the involvement of the $BV(\Omega)$ norm in the cost function and because there is not as much regularity as in [13, 14], we cannot apply the techniques of Ito and Kunisch to show the existence of the saddle-points of the augmented Lagrangian and the convergence of the discrete saddle-points to the continuous ones. Instead, our crucial tool for the convergence analyses will be an appropriate application of the Hahn–Banach convex separating theorem. This enables us to have a clear and simple convergence theory without making any a priori assumptions on cost functional or constraint functionals. We note that quite a different approach was used in [12] for the identification of discontinuous parameters.

We now formulate the aforementioned parameter identifying problem as the following constrained minimization problem:

$$\text{(1.1)} \qquad \text{minimize} \quad J(q,v) = \frac{1}{2} \int_\Omega q |\nabla v - \nabla z|^2 dx + \beta \int_\Omega |Dq|$$

$$\text{(1.2)} \qquad \text{subject to} \quad (q,v) \in K \times V \quad \text{and}$$

$$\text{(1.3)} \qquad e(q,v) = (-\Delta)^{-1}(\nabla \cdot (q \nabla v) + f) = 0,$$

where $V = H_0^1(\Omega)$ and K is a subset of the function space $BV(\Omega)$ of BVs defined by

$$K = \{ q \in BV(\Omega); \quad \alpha_1 \le q(x) \le \alpha_2 \quad \text{almost everywhere (a.e.)} \quad \text{in } \Omega \}.$$

Here α_1 and α_2 are two positive constants and $\beta > 0$ is a regularization parameter. $-\Delta$ is the Laplace operator from $H_0^1(\Omega)$ to its dual space $H^{-1}(\Omega)$, so $e(q,v)$ is understood as an operator from $K \times V$ into V defined by

$$\text{(1.4)} \qquad (\nabla e(q,v), \nabla \phi) = (q \nabla v, \nabla \phi) - (f, \phi) \quad \forall\, (q,v) \in K \times V, \qquad \phi \in V,$$

where $(\cdot,\cdot)$ denotes the duality pairing between $H^{-1}(\Omega)$ and $H_0^1(\Omega)$, which is the extension of the inner product in $L^2(\Omega)$. It is useful to remark that $e(q,v)$ is convex with respect to each variable.

The problem (1.1)–(1.3) will be solved by the augmented Lagrangian method. Thus we introduce the augmented Lagrangian functional $\mathcal{L}_r : K \times V \times V \to R$ by

$$\text{(1.5)} \qquad \mathcal{L}_r(q,v;\mu) = J(q,v) + (\nabla \mu, \nabla e(q,v)) + \frac{r}{2} \|\nabla e(q,v)\|^2_{L^2(\Omega)},$$

where $r \ge 0$ is some given constant. The first main result of the paper states that the minimization problem (1.1)–(1.3) is equivalent to the saddle-point problem associated with the Lagrangian functional $\mathcal{L}_r$ in (1.5). To solve the saddle-point problem, we propose a finite element discretization of the problem and show that the saddle-points of the discrete problem converge to those of the continuous problem. Finally, we propose an Uzawa algorithm to solve the discrete saddle-point problem and prove the global convergence of the algorithm. We note that recently Chan and Tai have performed many numerical experiments on a local convergent Uzawa algorithm and its combination with domain decomposition and multigrid methods [4, 16].

Throughout the paper, the constant C is a generic constant that might be different at each occurrence but is independent of the mesh parameter h and of the various functions involved.

2. The continuous saddle-point problem. We start this section with the existence of the solutions to the minimization problem (1.1)–(1.3) and then prove that the minimization problem is equivalent to the saddle-point problem of the augmented Lagrangian $\mathcal{L}_r$ defined in (1.5).

LEMMA 2.1. *There exists at least one solution to the minimization problem* (1.1)–(1.3).

Proof. Let

$$A = \Big\{(q,v) \in K \times V; \quad e(q,v) = 0\Big\}$$

be the admissible set of the minimization problem (1.1)–(1.3). It is clear that $A \neq \emptyset$ and $J(q,v) \geq 0$ on A. Thus there exists a minimizing sequence $(q_n, v_n) \in A$ such that

$$\lim_{n\to\infty} J(q_n, v_n) = \inf_{(q,v)\in A} J(q,v). \tag{2.1}$$

Hence $J(q_n, v_n) \leq C$ for each $n > 0$, which implies by definition of J and K that

$$\|v_n\|_{H^1(\Omega)} + \|q_n\|_{BV(\Omega)} \leq C.$$

Therefore, by possibly extracting a subsequence, there exists a pair $(q^*, v^*) \in BV(\Omega) \times V$ satisfying

$$v_n \rightharpoonup v^* \quad \text{in} \quad H_0^1(\Omega), \qquad q_n \to q^* \quad \text{in} \quad L^1(\Omega). \tag{2.2}$$

Since $q_n \in K$, we also have $q^* \in K$. To show that $e(q^*, v^*) = 0$, we first note that $e(q_n, v_n) = 0$ as $(q_n, v_n) \in A$; therefore,

$$(q_n \nabla v_n, \nabla \phi) = (f, \phi) \quad \forall\, \phi \in V. \tag{2.3}$$

However,

$$\begin{aligned}
&\Big|(q_n \nabla v_n, \nabla\phi) - (q^* \nabla v^*, \nabla\phi)\Big| \\
&\leq \Big|((q_n - q^*)\nabla v_n, \nabla\phi)\Big| + \Big|(q^*\nabla(v_n - v^*), \nabla\phi)\Big| \\
&\leq \Big\{\int_\Omega |q_n - q^*|\,|\nabla\phi|^2 dx\Big\}^{1/2} \Big\{\int_\Omega |q_n - q^*|\,|\nabla v_n|^2 dx\Big\}^{1/2} + \Big|(q^*\nabla(v_n - v^*), \nabla\phi)\Big| \\
&\leq C\Big\{\int_\Omega |q_n - q^*|\,|\nabla\phi|^2 dx\Big\}^{1/2} + \Big|(q^*\nabla(v_n - v^*), \nabla\phi)\Big|,
\end{aligned} \tag{2.4}$$

where we have used the fact that $\alpha_1 \leq q_n, q \leq \alpha_2$ and $\|v_n\|_{H^1(\Omega)} \leq C$. Now letting $n \to \infty$ in (2.4), we obtain

$$(q_n \nabla v_n, \nabla\phi) \to (q^* \nabla v^*, \nabla\phi) \quad \forall\, \phi \in V$$

by means of the Lebesgue dominant convergence theorem and the weak convergence in (2.2). Thus we see that $e(q^*, v^*) = 0$ by (2.3) and the definition of $e(\cdot, \cdot)$. Now using (2.2), we have (cf. [9])

$$\int_\Omega |Dq^*| \le \liminf_{n\to\infty} \int_\Omega |Dq_n|.$$

On the other hand, by $e(q_n, v_n) = 0$, we have

$$(q_n \nabla(v_n - z),\ \nabla\phi) = (f, \phi) - (q_n \nabla z,\ \nabla\phi) \quad \forall\, \phi \in V.$$

Taking $\phi = v_n - z$ gives

$$\int_\Omega q_n |\nabla(v_n - z)|^2 dx = (f, v_n - z) - (q_n \nabla z,\ \nabla(v_n - z)).$$

Similarly, using $e(q^*, v^*) = 0$, we get

$$\int_\Omega q^* |\nabla(v^* - z)|^2 dx = (f, v^* - z) - (q^* \nabla z,\ \nabla(v^* - z)).$$

Then using the last two relations, (2.2), and the Lebesgue dominant convergence theorem, we can immediately derive

$$\int_\Omega q^* |\nabla(v^* - z)|^2 dx = \lim_{n\to\infty} \int_\Omega q_n |\nabla(v_n - z)|^2 dx, \tag{2.5}$$

which with (2.1) yields

$$\begin{aligned} J(q^*, v^*) &\le \liminf_{n\to\infty}\ \frac{1}{2}\int_\Omega q_n |\nabla v_n - \nabla z|^2 dx + \liminf_{n\to\infty} \int_\Omega |Dq_n| \\ &\le \liminf_{n\to\infty} J(q_n, v_n) = \inf_{(q,v)\in A} J(q, v). \end{aligned}$$

This completes the proof of Lemma 2.1 as $(q^*, v^*) \in A$. □

The following theorem is the main result of this section.

THEOREM 2.2. *$(q^*, v^*) \in K \times V$ is a solution of the minimization problem (1.1)–(1.3) if and only if there exists a $\lambda^* \in V$ such that $(q^*, v^*, \lambda^*) \in K \times V \times V$ is a saddle-point of the augmented Lagrangian $\mathcal{L}_r : K \times V \times V \to R$, namely,*

$$\mathcal{L}_r(q^*, v^*; \mu) \le \mathcal{L}_r(q^*, v^*; \lambda^*) \le \mathcal{L}_r(q, v; \lambda^*) \quad \forall\, (q, v, \mu) \in K \times V \times V. \tag{2.6}$$

The key step in proving Theorem 2.2 is an appropriate application of the Hahn–Banach convex set separating theorem. To do so, we introduce two subsets in $R \times V$:

$$S = \Big\{ (J(q, v) - J(q^*, v^*) + s,\ e(q, v)) \in R \times V; \quad (q, v) \in K \times V,\ s \ge 0 \Big\}, \tag{2.7}$$

$$T = \Big\{ (-t, 0) \in R \times V; \quad t > 0 \Big\}, \tag{2.8}$$

where $(q^*, v^*) \in K \times V$ is some minimal point of the problem (1.1)–(1.3). The following three lemmas provide the properties of two subsets required by the Hahn–Banach theorem.

LEMMA 2.3. *S and T are two convex subsets in $R \times V$.*

Proof. It is obvious that T is a convex subset in $R \times V$. To see that S is also a convex subset, we let

$$P_i = (J(q_i, v_i) - J(q^*, v^*) + s_i,\ e(q_i, v_i)), \qquad i = 1, 2,$$

be two points in S, where $(q_i, v_i) \in K \times V$ and $s_i \geq 0$. We let $0 < \alpha < 1$, and we have to show that

$$P_\alpha = \alpha P_1 + (1-\alpha)P_2 \equiv (p_\alpha, w_\alpha)$$

with

$$\begin{aligned} p_\alpha &= \alpha J(q_1, v_1) + (1-\alpha)J(q_2, v_2) - J(q^*, v^*) + \alpha s_1 + (1-\alpha)s_2, \\ w_\alpha &= \alpha e(q_1, v_1) + (1-\alpha)e(q_2, v_2) \end{aligned}$$

is also a point in S. Let us now define $q_\alpha \in K$ as

$$q_\alpha = \alpha q_1 + (1-\alpha)q_2$$

and $v_\alpha \in V$ as the solution of the variational problem

$$(q_\alpha \nabla v_\alpha, \nabla \phi) = (\alpha q_1 \nabla v_1 + (1-\alpha)q_2 \nabla v_2,\ \nabla \phi) \quad \forall\, \phi \in V. \tag{2.9}$$

Clearly, $(q_\alpha, v_\alpha) \in K \times V$ is well defined. By (2.9) and the definition of $e(\cdot, \cdot)$, we have

$$\begin{aligned} (\nabla e(q_\alpha, v_\alpha),\ \nabla\phi) &= (q_\alpha \nabla v_\alpha, \nabla\phi) - (f, \phi) \\ &= (\alpha q_1 \nabla v_1 + (1-\alpha)q_2\nabla v_2,\ \nabla\phi) - (f,\ \phi) \\ &= \alpha\{(q_1\nabla v_1,\ \nabla\phi) - (f,\ \phi)\} + (1-\alpha)\{(q_2\nabla v_2,\ \nabla\phi) - (f,\ \phi)\} \\ &= (\alpha\nabla e(q_1, v_1) + (1-\alpha)\nabla e(q_2, v_2),\ \nabla\phi) \quad \forall\, \phi \in V, \end{aligned}$$

which implies that

$$e(q_\alpha, v_\alpha) = \alpha e(q_1, v_1) + (1-\alpha)e(q_2, v_2). \tag{2.10}$$

On the other hand, by the convexity of the BV-seminorm we have

$$\int_\Omega |Dq_\alpha| \leq \alpha \int_\Omega |Dq_1| + (1-\alpha)\int_\Omega |Dq_2|, \tag{2.11}$$

and we know from (2.9) that

$$(q_\alpha \nabla(v_\alpha - z),\ \nabla z) = (\alpha q_1 \nabla(v_1 - z) + (1-\alpha)q_2\nabla(v_2 - z),\ \nabla\phi).$$

Then letting $\phi = v_\alpha - z$ and using Schwarz's inequality give

$$\begin{aligned} &\int_\Omega q_\alpha |\nabla(v_\alpha - z)|^2 dx \\ &\leq \int_\Omega q_\alpha^{-1} |\alpha q_1 \nabla(v_1 - z) + (1-\alpha)q_2\nabla(v_2 - z)|^2 dx \\ &\leq \int_\Omega q_\alpha \left| \frac{\alpha q_1}{q_\alpha}\nabla(v_1 - z) + \frac{(1-\alpha)q_2}{q_\alpha}\nabla(v_2 - z)\right|^2 dx \\ &\leq \int_\Omega q_\alpha \left\{ \frac{\alpha q_1}{q_\alpha}|\nabla(v_1 - z)|^2 + \frac{(1-\alpha)q_2}{q_\alpha}|\nabla(v_2 - z)|^2 \right\} dx \\ &= \alpha\int_\Omega q_1|\nabla(v_1 - z)|^2 dx + (1-\alpha)\int_\Omega q_2|\nabla(q_2 - z)|^2 dx, \end{aligned}$$

where we have used the fact that $(\alpha q_1 + (1-\alpha)q_2)/q_\alpha = 1$ and the convexity of the function $|\cdot|^2$. Now combining this bound with (2.11) we obtain

$$J(q_\alpha, v_\alpha) \le \alpha J(q_1, v_1) + (1-\alpha) J(q_2, v_2), \tag{2.12}$$

and so (2.10) and (2.12) imply that

$$P_\alpha = (J(q_\alpha, v_\alpha) - J(q^*, v^*) + s_\alpha,\ e(q_\alpha, v_\alpha)\ ) \in S$$

since $(q_\alpha, v_\alpha) \in K \times V$ and

$$s_\alpha = \alpha s_1 + (1-\alpha)s_2 + \alpha J(q_1, v_1) + (1-\alpha)J(q_2, v_2) - J(q_\alpha, v_\alpha) \ge 0.$$

This completes the proof of Lemma 2.3. □

LEMMA 2.4. *We have $S \cap T = \emptyset$.*

Proof. Assume that $(a, w) \in S \cap T$; then there exists $(q, v) \in K \times V$ and $s \ge 0$ such that

$$a = J(q, v) - J(q^*, v^*) + s, \qquad w = e(q, v).$$

But $(a, w) \in T$ implies that $a < 0$ and $w = e(q, v) = 0$. Thus

$$J(q, v) + s < J(q^*, v^*),$$

which contradicts the assumption that (q^*, v^*) is a minimal point of the problem (1.1)–(1.3). □

LEMMA 2.5. *The subset S has at least one interior point.*

Proof. It is easy to see that for any $s_0 > 0$, $(s_0, 0) = (J(q^*, v^*) - J(q^*, v^*) + s_0,\ e(q^*, v^*))$ is a point in S. We will show that $(s_0, 0) \in R \times V$ is also an interior point of S. For any $\varepsilon \in (0, 1)$, let (s, w) belong to the ε-neighborhood of $(s_0, 0)$ in $R \times V$, that is,

$$|s - s_0| + \|w\|_{H^1(\Omega)} \le \varepsilon. \tag{2.13}$$

Let $q = q^*$ and $v \in V$ be the solution to the equation

$$(q\nabla v,\ \nabla\phi) = (f, \phi) + (\nabla w,\ \nabla\phi) \quad \forall\, \phi \in V. \tag{2.14}$$

Then we have $e(q, v) = w$. Let

$$\begin{aligned} s' &= s + J(q^*, v^*) - J(q, v) \\ &= s + \frac{1}{2}\int_\Omega q^*|\nabla(v^* - z)|^2 dx - \frac{1}{2}\int_\Omega q^*|\nabla(v - z)|^2 dx \\ &= s - \frac{1}{2}\int_\Omega q^*\nabla(v - v^*)\cdot\nabla(v + v^* - 2z)dx. \end{aligned} \tag{2.15}$$

From (2.14) and $e(q^*, v^*) = 0$, we derive that $\|\nabla v^*\|_{L^2(\Omega)} \le \|f\|_{H^{-1}(\Omega)}/\alpha_1$ and

$$(q^*\nabla(v - v^*),\ \nabla\phi) = (\nabla w,\ \nabla\phi) \quad \forall\, \phi \in V,$$

which yields $\|\nabla(v - v^*)\|_{L^2(\Omega)} \le \varepsilon/\alpha_1$ by (2.13). Also, (2.14) implies that $\|\nabla v\|_{L^2(\Omega)} \le (\|f\|_{H^{-1}(\Omega)} + \varepsilon)/\alpha_1$, thus we deduce from (2.15) that

$$\begin{aligned} s' &\ge s_0 - \varepsilon - \frac{1}{2}\alpha_2\|\nabla(v - v^*)\|_{L^2(\Omega)}\,\|\nabla(v + v^* - 2z)\|_{L^2(\Omega)} \\ &\ge s_0 - \varepsilon - \frac{\alpha_2}{2\alpha_1^2}\varepsilon\ \{\varepsilon + 2\|f\|_{H^{-1}(\Omega)} + 2\alpha_1\|\nabla z\|_{L^2(\Omega)}\}. \end{aligned}$$

Now if ε is sufficiently small, then $s' \geq 0$. Therefore

$$(s, w) = (J(q, v) - J(q^*, v^*) + s',\ e(q, v)\ ) \in K \times V$$

for any (s, w) in the ε-neighborhood of $(s_0, 0)$. This completes the proof. □

Now we are ready to prove Theorem 2.2.

Proof of Theorem 2.2. First, assume that $(q^*, v^*, \lambda^*) \in K \times V \times V$ is a saddle-point of $\mathcal{L}_r$. Then the first inequality in (2.6) immediately gives $e(q^*, v^*) = 0$, and the fact that (q^*, v^*) is a minimal point of the problem (1.1)–(1.3) follows readily from the second inequality in (2.6).

Next we prove the remaining part of the theorem. Let (q^*, v^*) be a minimal point of the problem (1.1)–(1.3), so we have

$$J(q^*, v^*) \leq J(q, v) \quad \forall\, (q, v) \in K \times V \quad \text{satisfying} \quad e(q, v) = 0. \tag{2.16}$$

By Lemmas 2.3–2.5, we can apply the Hahn–Banach theorem (see, e.g., [3, 4, 5, 6]) to separate the two convex subsets S and T defined in (2.7) and (2.8). Thus there exists a pair $(\alpha_0, \lambda_0) \in R \times V$, but $(\alpha_0, \lambda_0) \neq (0, 0) \in R \times V$ such that

$$\alpha_0(J(q, v) - J(q^*, v^*) + s) + (\nabla\lambda_0,\ \nabla e(q, v)) \geq \alpha_0(-t)$$

for any $(q, v) \in K \times V$, $s \geq 0$, and $t > 0$. Taking $(q, v) = (q^*, v^*)$, $s = t = 1$, we get $\alpha_0 \geq 0$, while taking $s = 0$ and letting $t \to 0^+$, we obtain

$$\alpha_0(J(q, v) - J(q^*, v^*)) + (\nabla\lambda_0,\ \nabla e(q, v)) \geq 0 \quad \forall\, (q, v) \in K \times V. \tag{2.17}$$

We now claim that $\alpha_0 > 0$. Otherwise, if $\alpha_0 = 0$ we have from (2.17) that

$$(\nabla\lambda_0,\ \nabla e(q, v)) = (q\nabla v,\ \nabla\lambda_0) - (f, \lambda_0) \geq 0 \quad \forall\, (q, v) \in K \times V, \tag{2.18}$$

which implies that $\lambda_0 = 0$. In fact, taking $q = q^* \in K$ and $v \in V$ to be the solution of the equation

$$(q^*\nabla v,\ \nabla\phi) = (f - \lambda_0,\ \phi) \quad \forall\, \phi \in V, \tag{2.19}$$

we know from (2.18), (2.19) that $-\|\lambda_0\|^2_{L^2(\Omega)} \geq 0$. Thus we have $(\alpha_0, \lambda_0) = (0, 0)$, which is a contradiction. Therefore $\alpha_0 > 0$. Then taking $\lambda^* = \lambda_0/\alpha_0$ and dividing both sides of (2.17) by α_0, we get

$$J(q^*, v^*) \leq J(q, v) + (\nabla\lambda^*,\ \nabla e(q, v)) \quad \forall\, (q, v) \in K \times V,$$

which, combined with (2.16) indicates that $(q^*, v^*, \lambda^*) \in K \times V \times V$ is a saddle-point of the augmented Lagrangian $\mathcal{L}_r$. So we have proved Theorem 2.2. □

3. The discrete saddle-point problem.

Theorem 2.2 tells us that the minimization problem (1.1)–(1.3) is equivalent to finding the saddle-points of the functional $\mathcal{L}_r$ defined in (1.5). In this section, we will consider how to discretize the augmented Lagrangian $\mathcal{L}_r$ and derive a discrete saddle-point problem.

Let Ω be a polyhedral domain in R^d, $d = 1, 2$, or 3, and $\{\mathcal{T}^h\}_{h>0}$ be a family of regular triangulations (cf. Ciarlet [5]) of the domain Ω, with simplicial elements. Denote by V_h the standard piecewise linear finite element space over the triangulation $\mathcal{T}^h$ and

$$\overset{\circ}{V}_h = V_h \cap H^1_0(\Omega), \qquad K_h = K \cap V_h.$$

We now introduce a discrete version of the operator $e(q,v) : K \times V \to V$ defined in (1.4): for any $(q_h, v_h) \in K_h \times \overset{\circ}{V}_h$, $e_h(q_h, v_h) \in \overset{\circ}{V}_h$ is the solution of the system

$$(\nabla e_h(q_h, v_h),\ \nabla\phi) = (q_h \nabla v_h,\ \nabla\phi) - (f, \phi) \quad \forall\, \phi \in \overset{\circ}{V}_h\ . \tag{3.1}$$

It is clear that the operator $e_h : K_h \times \overset{\circ}{V}_h \to \overset{\circ}{V}_h$ is well defined. Moreover, the following estimate holds:

$$\|\nabla e_h(q_h, v_h)\|_{L^2(\Omega)} \le \{\alpha_2 \|\nabla v_h\|_{L^2(\Omega)} + C\|f\|_{H^{-1}(\Omega)}\} \quad \forall\, (q_h, v_h) \in K_h \times V_h, \tag{3.2}$$

where the constant C comes from the Poincaré inequality.

Now for any given $r \ge 0$, we define the discrete augmented Lagrangian L_r: $K_h \times \overset{\circ}{V}_h \times \overset{\circ}{V}_h \to R$ as follows:

$$L_r(q_h, v_h; \mu_h) = J_h(q_h, v_h) + (\nabla \mu_h,\ \nabla e_h(q_h, v_h)) + \frac{r}{2}\|\nabla e_h(q_h, v_h)\|^2_{L^2(\Omega)} \tag{3.3}$$

with

$$J_h(q_h, v_h) = \frac{1}{2}\int_\Omega q_h |\nabla(v_h - z)|^2 dx + \beta \int_\Omega \sqrt{|\nabla q_h|^2 + \delta(h)}\ dx,$$

where $\delta(h)$ above is any given positive function satisfying $\lim_{h\to 0} \delta(h) = \delta(0) = 0$.

With the above preparations, we can state the following theorem.

THEOREM 3.1. *For any $r \ge 0$, there exists at least one saddle-point for the discrete augmented Lagrangian $L_r : K_h \times \overset{\circ}{V}_h \times \overset{\circ}{V}_h \to R$. Moreover, each saddle-point $(q_h^*, v_h^*, \lambda_h^*)$ of L_0 is a saddle-point of L_r for any $r > 0$.*

Proof. It is obvious that each saddle-point of L_0 is a saddle-point of L_r for any $r > 0$. Then it suffices to show that $L_0 : K_h \times \overset{\circ}{V}_h \times \overset{\circ}{V}_h \to R$ has a saddle-point, which we can argue in exactly the same way as in the proof for the continuous saddle-point problem of the last section by showing first the existence of the solutions to the discrete minimization problem

$$\min_{(q_h, v_h) \in A_h} J_h(q_h, v_h) \tag{3.4}$$

with

$$A_h = \{(q_h, v_h) \in K_h \times \overset{\circ}{V}_h; \quad e_h(q_h, v_h) = 0\},$$

and then the existence of the Lagrangian multiplier $\lambda_h^* \in \overset{\circ}{V}_h$ satisfying

$$J_h(q_h^*, v_h^*) \le J_h(q_h, v_h) + (\nabla \lambda_h^*,\ \nabla e_h(q_h, v_h)) \quad \forall\, (q_h, v_h) \in K_h \times \overset{\circ}{V}_h$$

for some minimal point (q_h^*, v_h^*) of the problem (3.4). We omit the details. □

The following theorem is the main result of this section.

THEOREM 3.2. *Each subsequence of the saddle-points $\{(q_h^*, v_h^*; \lambda_h^*)\}_{h>0}$ of the discrete augmented Lagrangian $L_r : K_h \times \overset{\circ}{V}_h \times \overset{\circ}{V}_h \to R$ defined in* (3.3) *has a subsequence that converges to some saddle-point $(q^*, v^*; \lambda^*)$ of the augmented Lagrangian $\mathcal{L}_r : K \times V \times V \to R$ defined in* (1.5) *strongly in $L^1(\Omega) \times L^2(\Omega) \times L^2(\Omega)$.*

The proof of Theorem 3.2 depends on the following three lemmas.

LEMMA 3.3. *Let $g \in BV(\Omega)$. Then for any $\varepsilon > 0$, there exists a function $g_\varepsilon \in C^\infty(\bar{\Omega})$ such that*

$$\int_\Omega |g - g_\varepsilon| dx < \varepsilon, \qquad \Big| \int_\Omega |\nabla g_\varepsilon| dx - \int_\Omega |Dg| \Big| < \varepsilon.$$

Proof. By the approximation property of functions with BVs (cf. p. 172 of [8]), there exists $\tilde{g}_\varepsilon \in C^\infty(\Omega) \cap W^{1,1}(\Omega)$ satisfying

$$\int_\Omega |g - \tilde{g}_\varepsilon| dx < \varepsilon/2, \qquad \Big| \int_\Omega |\nabla \tilde{g}_\varepsilon| dx - \int_\Omega |Dg| \Big| < \varepsilon/2.$$

Then the lemma follows from the density of $C^\infty(\bar{\Omega})$ in $W^{1,1}(\Omega)$ as $\partial\Omega$ is Lipschitz continuous (cf. page 127 of [8]). □

In what follows we will make use of the standard nodal value interpolant $I_h : C(\bar{\Omega}) \to V_h$ and the projection operator $R_h : V \to \overset{\circ}{V}_h$ defined by

$$(\nabla R_h v,\ \nabla \phi) = (\nabla v,\ \nabla \phi) \quad \forall\, v \in V, \qquad \phi \in \overset{\circ}{V}_h\ . \tag{3.5}$$

It is well known (cf. [5]) that for any $p > d = \dim(\Omega)$,

$$\lim_{h \to 0} \|v - I_h v\|_{W^{1,p}(\Omega)} = 0 \quad \forall\, v \in W^{1,p}(\Omega), \tag{3.6}$$

$$\lim_{h \to 0} \|v - R_h v\|_{H_0^1(\Omega)} = 0 \quad \forall\, v \in V. \tag{3.7}$$

LEMMA 3.4. *Assume that $(q, v) \in K \times V$ and $(q_h, v_h) \in K_h \times \overset{\circ}{V}_h$. Then $\lim_{h\to 0} q_h = q$ in $L^1(\Omega)$ and $\lim_{h \to 0} v_h = v$ in $H_0^1(\Omega)$ imply $\lim_{h\to 0} e_h(q_h, v_h) = e(q, v)$ in $H_0^1(\Omega)$.*

Proof. By the definitions of $e(\cdot, \cdot)$ and $e_h(\cdot, \cdot)$ we have

$$(\nabla\{e_h(q_h, v_h) - e(q, v)\},\ \nabla\phi) = ((q_h - q)\nabla v,\ \nabla \phi) + (q_h \nabla(v_h - v), \nabla\phi) \quad \forall\, \phi \in \overset{\circ}{V}_h\ .$$

By taking $\phi = e_h(q_h, v_h) - R_h e(q, v) \in \overset{\circ}{V}_h$ above and using (3.5) we obtain

$$\begin{aligned} \|\nabla\{e_h(q_h, v_h) - R_h e(q, v)\}\|^2_{L^2(\Omega)} &\le 2 \int_\Omega |q_h - q|^2\, |\nabla v|^2 dx + 2 \int_\Omega q_h^2 |\nabla(v_h - v)|^2 dx \\ &\le 2 \int_\Omega |q_h - q|^2\, |\nabla v|^2 dx + 2(\alpha_2)^2 \int_\Omega |\nabla(v_h - v)|^2 dx. \end{aligned}$$

Then the Lebesgue dominant convergence theorem and the fact that $\lim_{h\to 0} v_h = v$ in $H_0^1(\Omega)$ show that

$$\lim_{h\to 0} \|\nabla\{e_h(q_h, v_h) - R_h e(q, v)\}\|_{L^2(\Omega)} = 0.$$

Lemma 3.4 now follows from (3.7). □

LEMMA 3.5. *Assume that $(q, v) \in K \times V$ and $(q_h, v_h) \in K_h \times \overset{\circ}{V}_h$. Then $\lim_{h \to 0} q_h = q$ in $L^1(\Omega)$ and $\lim_{h\to 0} v_h = v$ weakly in $H_0^1(\Omega)$ imply that $\lim_{h\to 0} e_h(q_h, v_h) = e(q, v)$ weakly in $H_0^1(\Omega)$.*

Proof. For any $\phi \in V$, let $\phi_h = R_h\phi$. By the definition of R_h and $e_h(\cdot,\cdot)$ we have

$$\begin{aligned}
&(\nabla e_h(q_h, v_h),\ \nabla\phi)\\
&= (\nabla e_h(q_h, v_h),\ \nabla\phi_h)\\
&= (q\nabla v_h,\ \nabla\phi_h) + ((q_h - q)\nabla v_h,\ \nabla\phi_h) - (f, \phi_h)\\
&= (q\nabla v_h,\ \nabla\phi_h) + ((q_h - q)\nabla v_h,\ \nabla\phi) - (f, \phi_h)\\
&\quad +((q_h - q)\nabla v_h,\ \nabla(\phi_h - \phi)).
\end{aligned} \tag{3.8}$$

Then using the assumed convergence on v_h, we know that $\{\|\nabla v_h\|_{L^2(\Omega)}\}$ is bounded; combining this with the Lebesgue dominant convergence theorem we derive

$$\Big|((q_h - q)\nabla v_h,\ \nabla\phi)\Big| \le \|\nabla v_h\|_{L^2(\Omega)}\Big\{\int_\Omega |q_h - q|^2|\nabla\phi|^2 dx\Big\}^{1/2} \to 0 \quad \text{as} \quad h \to 0.$$

Similarly, we can show that all other terms in (3.8) converge; we then take the limit in (3.8) and use the definition of $e(\cdot,\cdot)$ to yield

$$\lim_{h\to 0}(\nabla e_h(q_h, v_h),\ \nabla\phi) = (q\nabla v,\ \nabla\phi) - (f, \phi) = (\nabla e(q, v),\ \nabla\phi) \quad \forall\,\phi \in V.$$

Thus we have proved Lemma 3.5. □

Now we are ready to prove Theorem 3.2.

Proof of Theorem 3.2. Let $(q_h^*, v_h^*, \lambda_h^*) \in K_h\times \overset{\circ}{V}_h \times \overset{\circ}{V}_h$ be the saddle-point of L_r, that is,

$$L_r(q_h^*, v_h^*; \mu_h) \le L_r(q_h^*, v_h^*; \lambda_h^*) \le L_r(q_h, v_h; \lambda_h^*) \quad \forall\,(q_h, v_h, \mu_h) \in K_h\times \overset{\circ}{V}_h \times \overset{\circ}{V}_h\ .$$

The first inequality implies immediately that $e_h(q_h^*, v_h^*) = 0$, and the second inequality gives us

$$\begin{aligned}
J_h(q_h^*, v_h^*) \le J_h(q_h, v_h) + (\nabla\lambda_h^*,\ \nabla e_h(q_h, v_h)) + \frac{r}{2}\|\nabla e_h(q_h, v_h)\|^2_{L^2(\Omega)}\\
\forall\,(q_h, v_h) \in K_h\times \overset{\circ}{V}_h\ .
\end{aligned} \tag{3.9}$$

By letting $q_h = \alpha_1$, a constant, and $v_h \in\overset{\circ}{V}_h$ be the unique solution of the equation

$$(\nabla v_h,\ \nabla\phi) = \left(\frac{1}{\alpha_1}f,\ \phi\right) \quad \forall\,\phi \in\overset{\circ}{V}_h$$

and hence $e_h(q_h, v_h) = 0$, we deduce from (3.9) that $\|q_h^*\|_{BV(\Omega)} + \|v_h^*\|_{H^1(\Omega)} \le C$. But taking $q_h = q_h^*$ in (3.9) and using (3.2) and the definition of $e_h(\cdot,\cdot)$ we get for any $v_h \in\overset{\circ}{V}_h$ that

$$\begin{aligned}
&\frac{1}{2}\int_\Omega q_h^*|\nabla(v_h^* - z)|^2 dx\\
&\le \frac{1}{2}\int_\Omega q_h^*\,|\nabla(v_h - z)|^2 dx + (q_h^*\nabla v_h, \nabla\lambda_h^*) - (f, \lambda_h^*) + \frac{r}{2}\|\nabla e_h(q_h^*, v_h)\|^2_{L^2(\Omega)}\\
&\le (q_h^*\nabla v_h, \nabla\lambda_h^*) + \eta\|\nabla\lambda_h^*\|^2_{L^2(\Omega)} + \frac{C}{\eta}\|f\|^2_{H^{-1}(\Omega)} + C\{\|\nabla v_h\|^2_{L^2(\Omega)} + \|\nabla z\|^2_{L^2(\Omega)}\}
\end{aligned}$$

for any $\eta > 0$. Now we take $v_h = -\varepsilon\lambda_h^*$ for some constant $\varepsilon > 0$ and $\eta = \frac{1}{2}\alpha_1\varepsilon$ and we derive

$$\frac{1}{2}\alpha_1\varepsilon\|\nabla\lambda_h^*\|^2_{L^2(\Omega)} \le C\Big\{\varepsilon^2\|\nabla\lambda_h^*\|^2_{L^2(\Omega)} + \frac{1}{\varepsilon}\|f\|^2_{H^{-1}(\Omega)} + \|\nabla z\|^2_{L^2(\Omega)}\Big\}.$$

Then choosing $\varepsilon = \alpha_1/(4C)$ above gives $\|\nabla\lambda_h^*\|_{L^2(\Omega)} \le C$. Hence each subsequence of $\{(q_h^*, v_h^*, \lambda_h^*)\}_{h>0}$ has a subsequence, still denoted by $\{(q_h^*, v_h^*, \lambda_h^*)\}$, satisfying

$$q_h^* \to q^* \text{ in } L^1(\Omega), \qquad v_h^* \to v^* \text{ weakly in } H_0^1(\Omega), \qquad \lambda_h^* \to \lambda^* \text{ weakly in } H_0^1(\Omega) \tag{3.10}$$

or

$$q_h^* \to q^* \text{ in } L^1(\Omega), \qquad v_h^* \to v^* \text{ in } L^2(\Omega), \qquad \lambda_h^* \to \lambda^* \text{ in } L^2(\Omega)$$

for some $(q^*, v^*, \lambda^*) \in K \times V \times V$. By Lemma 3.5 we have $e_h(q_h^*, v_h^*) \to e(q^*, v^*)$ weakly in $H_0^1(\Omega)$. Thus $e_h(q_h^*, v_h^*) = 0$ also implies that $e(q^*, v^*) = 0$, and the following holds:

$$\mathcal{L}_r(q^*, v^*; \mu) \le \mathcal{L}_r(q^*, v^*; \lambda^*) \quad \forall\, \mu \in V. \tag{3.11}$$

On the other hand, for any $(q, v) \in K \times V$ and any $\varepsilon > 0$, by Lemma 3.3 we can find a function $q_\varepsilon \in C^\infty(\bar{\Omega})$ satisfying

$$\int_\Omega |q_\varepsilon - q| dx < \varepsilon, \qquad \Big| \int_\Omega |\nabla q_\varepsilon| dx - \int_\Omega |Dq| \Big| < \varepsilon. \tag{3.12}$$

Now we define

$$\tilde{q}_\varepsilon = \begin{cases} \alpha_1 & \text{if } \; q_\varepsilon < \alpha_1, \\ q_\varepsilon & \text{if } \; \alpha_1 \le q_\varepsilon \le \alpha_2, \\ \alpha_2 & \text{if } \; q_\varepsilon > \alpha_2. \end{cases} \tag{3.13}$$

Then $\tilde{q}_\varepsilon \in K \cap W^{1,\infty}(\Omega)$ since

$$\nabla\tilde{q}_\varepsilon = \begin{cases} \nabla q_\varepsilon & \text{on } \; A_\varepsilon = \{x \in \Omega : \alpha_1 \le q_\varepsilon \le \alpha_2\}, \\ 0 & \text{on } \; \Omega \setminus A_\varepsilon. \end{cases} \tag{3.14}$$

Now we take $(q_h, v_h) = (I_h\tilde{q}_\varepsilon, R_h v) \in K_h \times \overset{\circ}{V}_h$ in (3.9) and get

$$J_h(q_h^*, v_h^*) \le J_h(I_h\tilde{q}_\varepsilon, R_h v) + (\nabla\lambda_h^*, \nabla e_h(I_h\tilde{q}_\varepsilon, R_h v)) + \frac{r}{2}\|\nabla e_h(I_h\tilde{q}_\varepsilon, R_h v)\|_{L^2(\Omega)}^2. \tag{3.15}$$

Then by the lower semicontinuity of the BV-norm (cf. [9]) we derive

$$\begin{aligned} &\liminf_{h\to 0} J_h(q_h^*, v_h^*) \\ &\ge \liminf_{h\to 0} \Big\{ \frac{1}{2}\int_\Omega q_h^* |\nabla(v_h^* - z)|^2 dx + \beta \int_\Omega |Dq_h^*| \Big\} \\ &\ge \liminf_{h\to 0} \frac{1}{2}\int_\Omega q_h^* |\nabla(v_h^* - z)|^2 dx + \liminf_{h\to 0} \beta \int_\Omega |Dq_h^*| \\ &\ge \frac{1}{2}\int_\Omega q^* \, |\nabla(v^* - z)|^2 dx + \beta \int_\Omega |Dq^*| = J(q^*, v^*), \end{aligned} \tag{3.16}$$

where we have used the following result:

$$\lim_{h\to 0} \frac{1}{2}\int_\Omega q_h^* |\nabla(v_h^* - z)|^2 dx = \frac{1}{2}\int_\Omega q^* \, |\nabla(v^* - z)|^2 dx,$$

which can be proved in exactly the same way as for (2.5).

Now by (3.6) and (3.7) we know that

$$\lim_{h\to 0} I_h\tilde{q}_\varepsilon = \tilde{q}_\varepsilon \text{ in } W^{1,1}(\Omega), \qquad \lim_{h\to 0} R_h v = v \text{ in } H_0^1(\Omega);$$

combining this with Lemma 3.4 gives

$$\lim_{h\to 0} e_h(I_h\tilde{q}_\varepsilon, R_h v) = e(\tilde{q}_\varepsilon, v) \text{ in } H_0^1\Omega).$$

Then letting $h \to 0$ in (3.15) and using (3.16) we obtain

$$J(q^*, v^*) \le J(\tilde{q}_\varepsilon, v) + (\nabla\lambda^*, \nabla e(\tilde{q}_\varepsilon, v)) + \frac{r}{2}\|\nabla e(\tilde{q}_\varepsilon, v)\|^2_{L^2(\Omega)}. \tag{3.17}$$

Since $q \in K$, we have from (3.12) and (3.13) that

$$\|\tilde{q}_\varepsilon - q\|_{L^1(\Omega)} \le \|q_\varepsilon - q\|_{L^1(\Omega)} < \varepsilon.$$

Thus $\lim_{\varepsilon\to 0}\tilde{q}_\varepsilon = q$ in $L^1(\Omega)$, which implies that $\lim_{\varepsilon\to 0} e(\tilde{q}_\varepsilon, v) = e(q, v)$ in $H_0^1(\Omega)$. Hence as $\varepsilon \to 0$, we derive

(3.18)
$$(\nabla\lambda^*, \nabla e(\tilde{q}_\varepsilon, v)) + \frac{r}{2}\|\nabla e(\tilde{q}_\varepsilon, v)\|^2_{L^2(\Omega)} \to (\nabla\lambda^*, \nabla e(q, v)) + \frac{r}{2}\|\nabla e(q, v)\|^2_{L^2(\Omega)}.$$

But by (3.14) and (3.12) we obtain

$$\int_\Omega |\nabla\tilde{q}_\varepsilon| dx = \int_{A_\varepsilon} |\nabla q_\varepsilon| dx \le \int_\Omega |\nabla q_\varepsilon| dx \le \int_\Omega |Dq| + \varepsilon;$$

therefore

$$\liminf_{\varepsilon\to 0} J(\tilde{q}_\varepsilon, v) \le \frac{1}{2}\int_\Omega q|\nabla(v - z)|^2 dx + \beta\int_\Omega |Dq| = J(q, v). \tag{3.19}$$

By substituting (3.18), (3.19) into (3.17) and passing to the limit $\varepsilon \to 0$ we finally get

$$\mathcal{L}_r(q^*, v^*; \lambda^*) = J(q^*, v^*) \le \mathcal{L}_r(q, v; \lambda^*) \quad \forall\,(q, v) \in K \times V.$$

This, together with (3.11), indicates that $(q^*, v^*; \lambda^*)$ is a saddle-point of $\mathcal{L}_r$. □

4. An Uzawa algorithm.

In this section, we study an algorithm of the Uzawa type to find the saddle-points of the discrete augmented Lagrangian $L_r :\ K_h\times \overset{\circ}{V}_h \times \overset{\circ}{V}_h\to R$ defined in (3.3). We consider the following algorithm.

Uzawa Algorithm 1. We are given $\lambda^0 \in\overset{\circ}{V}_h$. Then for $n \ge 0$, with λ^n known, determine the pair $\{p^n, u^n\} \in K_h\times \overset{\circ}{V}_h$ such that

$$L_r(p^n, u^n; \lambda^n) \le L_r(q, v; \lambda^n) \quad \forall\,(q, v) \in K_h\times \overset{\circ}{V}_h; \tag{4.1}$$

then compute λ^{n+1} by

$$\lambda^{n+1} = \lambda^n + \rho_n e_h(p^n, u^n). \tag{4.2}$$

THEOREM 4.1. *Assume that* $0 < \beta_0 \le \rho_n \le \beta_1 < r$ *for any* $n = 1, 2, \ldots.$ *Then any subsequence of* $\{p^n, u^n; \lambda^n\}$ *computed in the Uzawa algorithm* (4.1), (4.2) *has a subsequence (still denoted by)* $\{p^n, u^n; \lambda^n\}$ *such that*

$$p^n \to p \quad in \quad L^1(\Omega), \qquad u^n \to u \quad in \quad L^2(\Omega), \qquad \lambda^n \to \lambda \quad in \quad L^2(\Omega),$$

and $J_h(p^n, u^n) \to J_h(p, u)$ *as* $n \to \infty$. *Furthermore,* $\{p, u; \lambda\} \in K_h \times \overset{\circ}{V}_h \times \overset{\circ}{V}_h$ *is a saddle-point of* $L_r : K_h \times \overset{\circ}{V}_h \times \overset{\circ}{V}_h \to R$.

Proof. First, by Theorem 3.1 there exists a saddle-point $(q_h^*, v_h^*; \lambda_h^*)$ of $L_0 : K_h \times \overset{\circ}{V}_h \times \overset{\circ}{V}_h$, namely,

$$L_0(q_h^*, v_h^*; \mu_h) \le L_0(q_h^*, v_h^*; \lambda^*) \le L_0(q_h, v_h; \lambda^*) \quad \forall\, (q_h, v_h, \mu_h) \in K_h \times \overset{\circ}{V}_h \times \overset{\circ}{V}_h \,.$$

The first inequality immediately gives $e_h(q_h^*, v_h^*) = 0$, and the second implies that

$$(4.3) \quad J_h(q_h^*, v_h^*) \le J_h(q_h, v_h) + (\nabla \lambda_h^*,\ \nabla e_h(q_h, v_h)), \qquad \forall\, (q_h, v_h) \in K_h \times \overset{\circ}{V}_h \,.$$

Then taking $(q, v) = (q_h^*, v_h^*)$ in (4.1) and using (4.3) we obtain

$$\begin{aligned} &J_h(p^n, u^n) + (\nabla \lambda^n,\ \nabla e_h(p^n, u^n)) + \frac{r}{2}\|\nabla e_h(p^n, u^n)\|^2_{L^2(\Omega)} \\ \le\ &L_r(q_h^*, v_h^*; \lambda^n) = J_h(q_h^*, v_h^*) \\ \le\ &J_h(p^n, u^n) + (\nabla \lambda_h^*,\ \nabla e_h(p^n, u^n)). \end{aligned}$$

Hence

$$(4.4) \qquad (\nabla(\lambda^n - \lambda_h^*),\ \nabla e_h(p^n, u^n)) + \frac{r}{2}\|\nabla e_h(p^n, u^n)\|^2_{L^2(\Omega)} \le 0.$$

Now let $\bar\lambda^n = \lambda^n - \lambda_h^*$; then we have

$$\bar\lambda^{n+1} = \bar\lambda^n + \rho_n e_h(p^n, u^n)$$

and thus

$$\begin{aligned} (\nabla \bar\lambda^n,\ \nabla e_h(p^n, u^n)) &= \frac{1}{\rho_n}(\nabla \bar\lambda_h,\ \nabla(\bar\lambda^{n+1} - \bar\lambda^n)) \\ &= \frac{1}{2\rho_n}\left\{\|\nabla \bar\lambda^{n+1}\|^2_{L^2(\Omega)} - \|\nabla \bar\lambda^n\|^2_{L^2(\Omega)} - \|\nabla(\bar\lambda^{n+1} - \bar\lambda^n)\|^2_{L^2(\Omega)}\right\} \\ &= \frac{1}{2\rho_n}\left\{\|\nabla \bar\lambda^{n+1}\|^2_{L^2(\Omega)} - \|\nabla \bar\lambda^n\|^2_{L^2(\Omega)} - \rho_n^2\|\nabla e_h(p^n, u^n)\|^2_{L^2(\Omega)}\right\}. \end{aligned}$$

Substituting this into (4.4), we get

$$\frac{1}{2\rho_n}\left\{\|\nabla \bar\lambda^{n+1}\|^2_{L^2(\Omega)} - \|\nabla \bar\lambda^n\|^2_{L^2(\Omega)}\right\} + \frac{1}{2}(r - \rho_n)\|\nabla e_h(p^n, u^n)\|^2_{L^2(\Omega)} \le 0.$$

Thus if $0 < \rho_n < r$, the sequence $\{\|\nabla \bar\lambda^n\|^2_{L^2(\Omega)}\}$ is monotonically decreasing and $\|\nabla e_h(p^n, u^n)\|_{L^2(\Omega)} \to 0$ as $n \to \infty$. Now letting $(q, v) = (q_h^*, v_h^*)$ in (4.1) we derive

$$J_h(p^n, u^n) \le J_h(q_h^*, v_h^*) - (\nabla \lambda^n,\ \nabla e_h(p^n, u^n)) \le C$$

with constant C independent of n. Therefore

$$\|p^n\|_{BV(\Omega)} + \|\nabla u^n\|_{L^2(\Omega)} \le C,$$

which implies that each subsequence of $\{p^n, u^n, \lambda^n\}$ has a subsequence (still denoted by) $\{p^n, u^n, \lambda^n\}$ such that

$$(p^n, u^n, \lambda^n) \to (p, u, \lambda) \text{ in } L^1(\Omega) \times L^2(\Omega) \times L^2(\Omega) \quad \text{as} \quad n \to \infty$$

for some $(p, u, \lambda) \in K_h\times \overset{\circ}{V}_h \times \overset{\circ}{V}_h$. Note that in a finite-dimensional space all the convergences are equivalent. Thus $e_h(p, u) = 0$ by means of

$$\|\nabla e_h(p^n, u^n)\|_{L^2(\Omega)} \to 0 \quad \text{and} \quad e_h(p^n, u^n) \to e_h(p, u) \quad \text{as} \quad n \to \infty.$$

Now letting $n \to \infty$ in (4.1) we easily obtain

$$L_r(p, u; \lambda) \le L_r(q, v; \lambda) \quad \forall\, (q, v) \in K_h\times \overset{\circ}{V}_h\ .$$

Therefore $(p, u, \lambda) \in K_h\times \overset{\circ}{V}_h \times \overset{\circ}{V}_h$ is a saddle-point of L_r. □

Remark. To reduce the size of the minimization problem in (4.1), one may further divide the problem into two minimization subproblems with each seeking only one of the first two variables of the discrete augmented Lagrangian $L_r(\cdot, \cdot; \cdot)$. See Uzawa Algorithm 2 in the next section and [10, 3] for more algorithms of the same kind.

5. Numerical experiments. We now show some numerical experiments on the proposed method for parameter identification. We first describe how to implement the optimization step in (4.1). In order to solve the system (4.1) for the pair $\{p^n, u^n\}$, we use the following alternative iteration.

Uzawa Algorithm 2. We are given $\lambda^0 \in\overset{\circ}{V}_h$ and $q^0 \in K_h$. Set $n = 1$.

1. Set $k = 1$ and $q^{n,0} = q^{n-1}$.

2. Compute $u^{n,k}$ by solving

$$L_r(q^{n,k-1}, u^{n,k}; \lambda^{n-1}) = \min_{v_h \in V_h^0} L_r(q^{n,k-1}, v_h; \lambda^{n-1}), \tag{5.1}$$

and then compute $q^{n,k}$ by solving

$$L_r(q^{n,k}, u^{n,k}; \lambda^{n-1}) = \min_{p_h \in V_h} L_r(p_h, u^{n,k}; \lambda^{n-1}). \tag{5.2}$$

Compute $q^{n,k} = \max\{\alpha_1, \min\{q^{n,k}, \alpha_2\}\}$.
If $\|q^{n,k} - q^{n,k-1}\| \le$ tolerance, set $u^n = u^{n,k}$ and $q^n = q^{n,k}$, GOTO **3**;
Otherwise set $k = k + 1$, GOTO **2.**

3. Compute λ^n by

$$\lambda^n = \lambda^{n-1} + \frac{3}{4}\, r\, e_{_h}(p^n, u^n). \tag{5.3}$$

Set $n = n + 1$, GOTO **1.**

We use the Armijo algorithm (cf. Keung and Zou [15]) to solve problem (5.2). As the problem corresponds to a nonlinear algebraic system of equations, one may also use some other more efficient iterative methods. Problem (5.1), combining with the equation for $e_{_h}(q^{n,k-1}, u^{n,k})$, corresponds to two linear algebraic systems of equations (both are positive definite), which are solved here by the conjugate gradient method.

We apply Uzawa Algorithm 2 to identify the discontinuous coefficients in the following test problem:

$$-\frac{d}{dx}\Big(q(x)\frac{d}{dx}u(x)\Big) = f(x), \qquad x \in (0, 1) \quad \text{with} \quad u(0) = u(1) = 0. \tag{5.4}$$

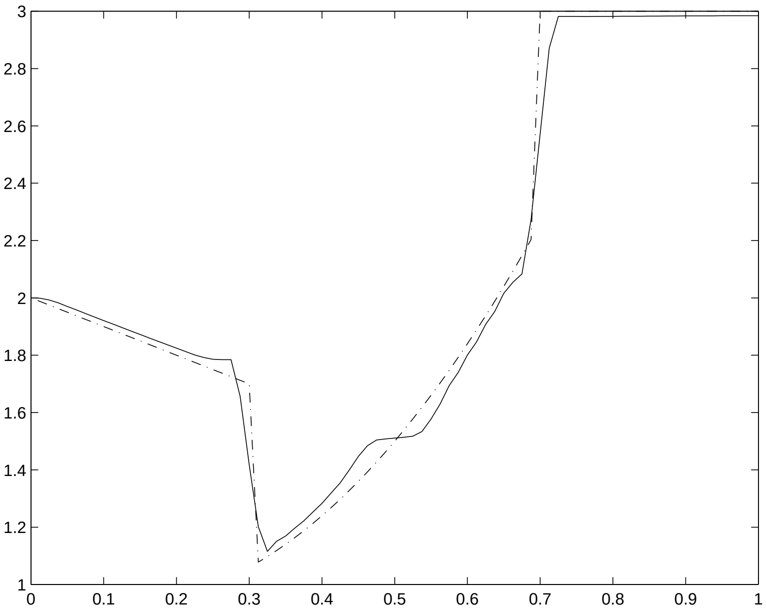

FIG. 5.1. $q_h^0 = 5.0$, $\beta = 10^{-3}$, *error* $= 0.032$, *iter* $= 5$.

Most parameters used in the algorithm are given below each figure. The error shown is the relative L^2-norm error between the exact parameter $q(x)$ to be identified and the computed parameter q_h. The regularization and smoothing parameters β and $\delta(h)$ (see (3.3)) are chosen to be 10^{-3} and 0.01. The augmented Lagrangian coefficient r is taken to be 1, and the finite element mesh size h to be 1/80. The lower and upper bounds α_1 and α_2 in the constrained set K are taken to be 0.5 and 20.0, respectively.

Example 1. We take the following discontinuous coefficient:

$$q(x) = \begin{cases} 2 - x, & x \in [0,\ 0.3], \\ 1 - x + 4x^2, & x \in (0.3,\ 0.7), \\ 3, & x \in [0.7,\ 1], \end{cases}$$

and compare it with the numerically identified solution q_h obtained by using Uzawa Algorithm 2. The exact observation data z is taken as $z(x) = u(q)(x) = \sin(\pi x)$, and the function $f(x)$ is then computed by (5.4) using $u(x)$ and $q(x)$. Figure 5.1 shows the exact solution $q(x)$ (the dotted line) and the numerically identified solution $q_h(x)$ (the solid line). The initial guesses λ^0 and q_h^0 are taken to be the constants 0 and 5.0, respectively. $q_h^0 = 5.0$ is not a good initial guess at all, but the numerical method converges very stably and fast; Figure 5.1 gives the result of the 5th iteration ($n = 5$).

We now add some random noise to the gradient of the true solution u. (Recall that we used the energy-norm in the output least squares formulation. If the L^2-norm is used, one should consider the noised observation data z of the true solution u directly, instead of the gradient.) Namely, we replace the gradient ∇z in the cost functional L_r with the noised data

$$\nabla z^\delta(x) = \nabla z(x) + \delta\, \mathrm{rand}\,(x),$$

where rand (x) is a uniformly distributed random function in $[-1, 1]$ and δ is the noise level parameter. The numerical result of the 5th iteration is shown in Figure 5.2 with

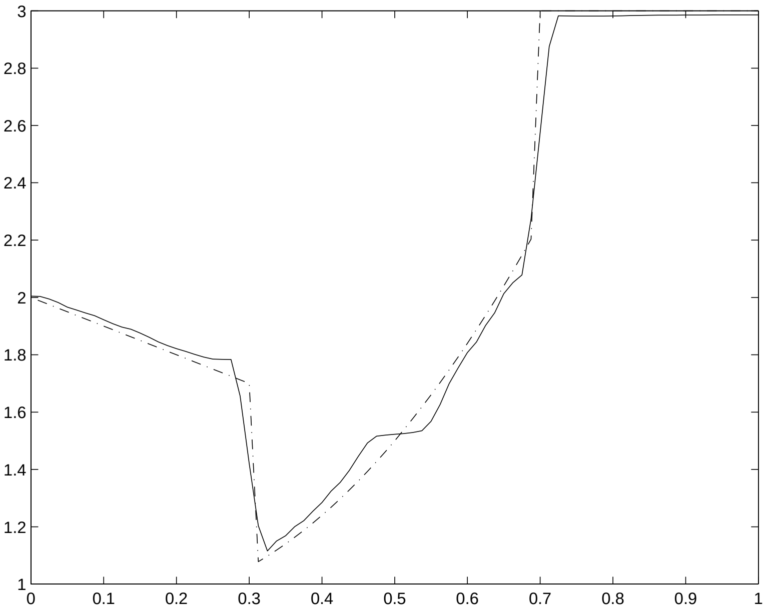

FIG. 5.2. $q_h^0 = 5.0$, $\beta = 10^{-3}$, *noise level* $\delta = 1\%$, *error* $= 0.033$, *iter* $= 5$.

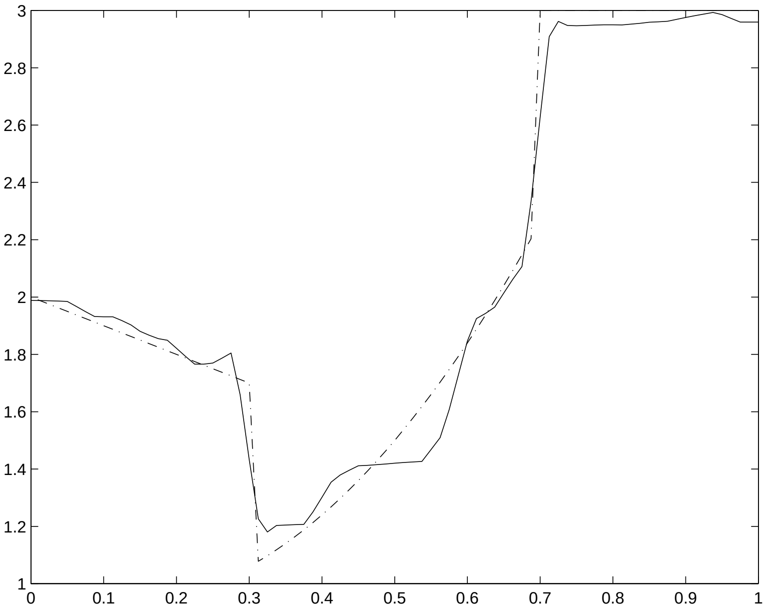

FIG. 5.3. $q_h^0 = 5.0$, $\beta = 10^{-3}$, *noise level* $\delta = 10\%$, *error* $= 0.038$, *iter* $= 5$.

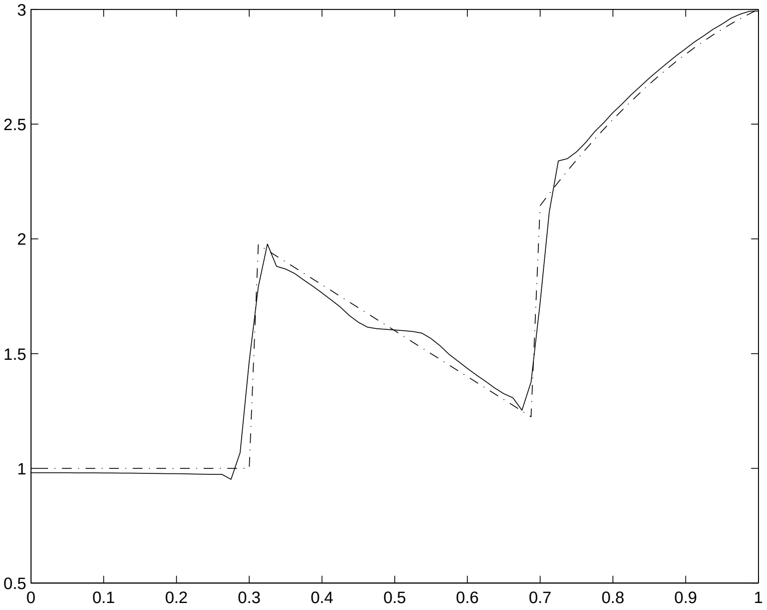

FIG. 5.4. $q_h^0 = 5.0$, $\beta = 10^{-3}$, *error* $= 0.043$, *iter* $= 5$.

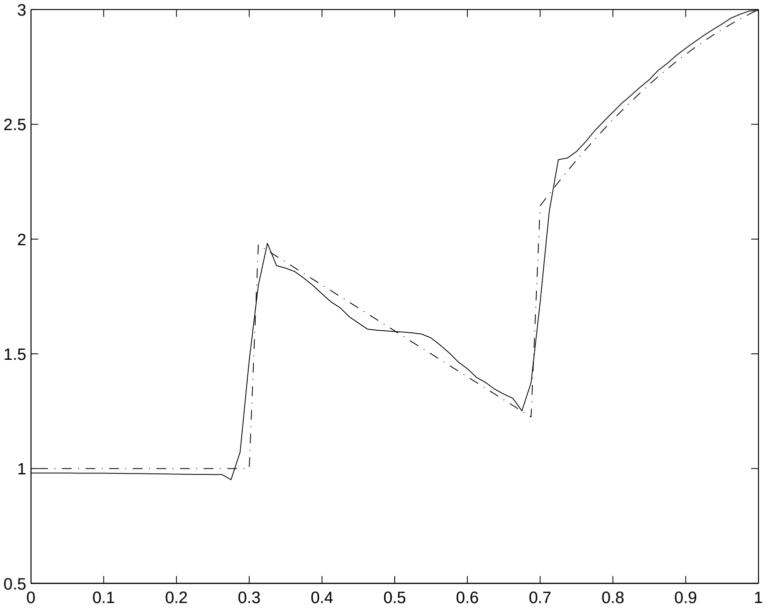

FIG. 5.5. $q_h^0 = 5.0$, $\beta = 10^{-3}$, *noise level* $\delta = 1\%$, *error* $= 0.045$, *iter* $= 5$.

the noise level parameter $\delta = 1\,\%$. We do not see much difference compared with the noise-free case (Figure 5.1). When the noise increases to 10%, the numerical identified solution is still very satisfactory; see Figure 5.3. This indicates that the numerical

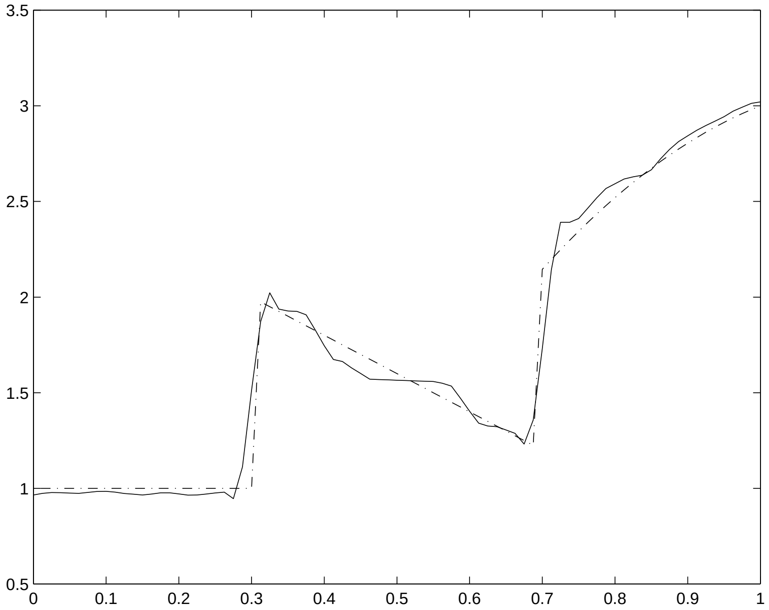

FIG. 5.6. $q_h^0 = 5.0$, $\beta = 10^{-3}$, *noise level* $\delta = 10\%$, *error* $= 0.051$, *iter* $= 5$.

method is not very sensitive to the noise.

Example 2. We take the discontinuous coefficient:

$$q(x) = \begin{cases} 1, & x \in [0,\ 0.3], \\ 2.6 - 2x, & x \in (0.3,\ 0.7), \\ -9\,x^2/2 + 21\,x/2 - 3, & x \in [0.7,\ 1], \end{cases}$$

and compare it again with the numerical solution q_h recovered by Uzawa Algorithm 2. Figure 5.4 shows the exact solution $q(x)$ (the dotted line) and the numerically identified solution $q_h(x)$ (the solid line), where we have taken the initial guesses $\lambda^0 = 0$ and $q_h^0 = 5.0$. We see again that the numerical method converges very stably and fast. Figure 5.4 is the result of the 5th iteration ($n = 5$).

Again, we add some random noise to the gradient of the true solution u; namely, we assume that the available data are the following noised data:

$$\nabla z^\delta(x) = \nabla z(x) + \delta\,\mathrm{rand}\,(x).$$

Figure 5.5 gives the numerical result of the 5th iteration with the noise level parameter $\delta = 1\,\%$. We can see that noise of this level has very little effect on the accuracy and stability of the numerical method. When the noise increases to 10%, the numerical identified solution is still very satisfactory; see Figure 5.6.

Our numerical experiences show that the numerical method proposed in the paper converges very fast (5 iterations for the considered examples) and globally, which is consistent with our theory. In fact one can take much worse initial guesses than the preceding ones ($q_h^0 = 5.0$). More importantly, the method seems to be not very sensitive to the noise.

PIECEWISE-CONSTANT STABILIZATION*

SERGEY NIKITIN†

Abstract. With the help of topological necessary conditions for continuous stabilization it is shown that, in general, in order to stabilize continuous- and discrete-time systems one has to use time-dependent or discontinuous feedback controls. On the other hand, the criterion of stabilization in the class of piecewise-constant feedbacks is established. In the context of this paper a piecewise-constant feedback is associated with a piecewise-constant function of the form $u = u(x)$, where $x \in \mathrm{R}^n_x$. The piecewise-constant feedback synthesis outlined here has several attractive features. First, it can be effectively applied to design feedback stabilizers subjected to control constraints. Second, the designed feedback laws do not cause sliding mode or chattering behavior in the closed loop system; i.e., on a finite interval of time the control in the closed loop system may have only a finite number of jump discontinuities.

Key words. nonlinear system, degree of functions, feedback stabilization, discrete-time system

1. Introduction.

Stabilization of dynamical systems is one of the basic problems in systems theory. In [9], [10], and [11] it is shown that many nonlinear systems are not stabilizable by any continuous feedback of the form $u = u(x)$. For the purpose of illustration we give a geometrical interpretation of the results presented in [9], [10], and [11]. In particular, one can see from these geometrical illustrations that on a compact, simply connected manifold a nonlinear system cannot be globally stabilized at any of its equilibria by a continuous feedback of the form $u = u(x)$. We use this fact as a motivation for our work on the main contribution of this paper, the criterion of stabilization by means of piecewise-constant feedbacks that do not cause sliding mode or chattering behavior. In other words, on a finite interval of time the control in the closed loop system may have only a finite number of jump discontinuities.

This paper deals with a dynamical nonlinear system having either the form

$$\dot{x} = f(x, u) \tag{1}$$

or

$$x_{k+1} = f(x_k, u_k), \tag{2}$$

where $x \in \mathrm{R}^n$ (R^n denotes n-dimensional Euclidean space) and $u \in \mathrm{U} \subset \mathrm{R}^m$.

Let pr_x denote the projection of $\mathrm{R}^n_x \times \mathrm{R}^n_u$ onto R^n_x, i.e., $pr_x(x, u) = x$. It will be shown that (1) (or (2)) is stabilizable at an equilibrium

$$(x^*, u^*) \in f^{-1}(0) = \{(x, u) \in \mathrm{R}^n \times \mathrm{U} : \quad f(x, u) = 0\} \text{ for system (1),}$$

or

$$(x^*, u^*) \in (pr_x - f)^{-1}(0) = \{(x, u) \in \mathrm{R}^n \times \mathrm{U} : \quad f(x, u) = x\} \text{ for system (2),}$$

over a compact set $\mathrm{K} \subset \mathrm{R}^n$ if and only if one can steer the system from any initial point $x \in \mathrm{K}$ into x^* with the help of piecewise-constant control inputs and system (1) (or (2)) satisfies the following condition (of some sort of stability) at $(x^*, u^*) \in f^{-1}(0)$: For any neighborhood W of x^* (open connected set containing x^*) there exists another neighborhood V of x^*, such that one can move the system (1) (or (2)) from any point in V into x^* without leaving the neighborhood W. Although we prove all our results for systems defined on R^n, their reformulation for systems on a smooth manifold is straightforward and seems not to bring anything new except some changes in phraseology.

The use of continuous stationary feedbacks of the form $u = u(x)$ does not allow solution of the problem of stabilization for many nonlinear systems. This fact was understood by many system researchers (see, e.g., [1], [2], [7]). Thus, to stabilize a nonlinear system in many practical and theoretical situations one needs to design time-dependent or discontinuous feedbacks instead of continuous feedbacks of the form $u = u(x)$. The use of time-dependent continuous feedback laws was considered, for instance, in [4], [12], [13], [14] and discontinuous feedback controls have been discussed in, e.g., [9], [10].

The idea of using discontinuous instead of continuous stabilizers is not new and was broadly discussed in the framework of variable structure systems (see, e.g., [5]). The mathematical foundation of variable structure systems was developed in [15].

Necessary conditions of smooth stabilization underline the fact that the use of nonstationary and discontinuous feedback stabilizers is unavoidable in many applications of control theory. The commonly accepted starting point for the discussion on necessary conditions of smooth stabilization is the classical result of [2].

Theorem 1 (see Brockett [2]). *If the system $\dot{x} = f(x, u)$ is continuously stabilizable at (x^*, u^*), then:*

(bi) *all the modes of its linearization $\dot{x} = Ax + Bu$ with positive real parts are controllable;*

(bii) *there exists some neighborhood Q of $x^* \in \mathrm{R}$ such that for each $y \in Q$ one can find a control*

$$u_y(t) : [0, \infty) \to \mathrm{R}^{\mathrm{m}},$$

which steers the system from y at $t = 0$ to x^* at $t = \infty$;

(biii) *the mapping $f(x, u) : \mathrm{R}^{\mathrm{n}}_{\mathrm{x}} \times \mathrm{R}^{\mathrm{m}}_{\mathrm{u}} \to \mathrm{R}^{\mathrm{n}}$ maps every neighborhood of (x^*, u^*) onto a neighborhood of zero.*

Theorem 1 was one of the first necessary conditions for smooth stabilizability of nonlinear systems. It played an outstanding role in the development of nonlinear control theory. For example, Theorem 1 was successfully used to establish that many drift-free nonholonomic nonlinear control systems cannot be continuously stabilized. Nevertheless, necessary condition (biii) suffers deficiency of being generic, i.e., (biii) is almost always satisfied. The result obtained in [3] strengthens (biii), but nevertheless (biii) remains generic and therefore fulfilled for almost every smooth nonlinear system (1).

In [10], [11] the first nongeneric topological necessary conditions have been obtained. Here we give geometrical illustration of these conditions and generalize them to the class of discrete-time systems having form (2). These necessary conditions imply that on a smooth compact manifold neither any continuous nor any discrete-time system is globally stabilized by a continuous feedback of the form $u = u(x)$. We also prove the criterion of stabilization in the class of piecewise-constant feedbacks and discuss synthesis procedures for this class of feedback control laws. The motivation for studying piecewise-constant feedbacks is threefold. First, a piecewise-constant feedback is meant to be implemented on digital processors and does not require quantification of input-output signals. Second, the control theory ideology and, in particular, piecewise-constant feedback stabilization may serve as a framework for software development projects in which a software package is treated as a feedback control. Third, as one can see from the results of this paper, any system that is stabilized by a continuous feedback $u = u(t, x)$ can be stabilized by a piecewise-constant feedback.

We hope that we have convinced our reader that, in some situations where stabilization of a nonlinear system is concerned, a piecewise-constant feedback could be preferable to a continuous one.

The structure of the paper is as follows. The first section is introductory. The second section presents geometrical interpretation of the necessary conditions obtained in [11] and generalizes them to the class of discrete-time systems of the form (2). The third section contains the criterion of stabilization in the class of piecewise-constant feedbacks. The fourth section presents conclusions.

2. Topological necessary conditions of continuous stabilization. This section presents topological necessary conditions for continuous stabilization. It also contains geometrical interpretations of the results obtained in [11], as well as new formulation and proof of these results for discrete-time systems.

2.1. Continuous-time systems. Consider the system

$$\dot{x} = f(x, u),$$

where $x \in \mathbf{R}^n,\ u \in \mathbf{R}^m$. $f(x, u)$ is a complete C^∞ vector field on $\mathbf{R}^{\mathrm{n}}$ for every $u \in \mathbf{R}^{\mathrm{m}}$ fixed.

The set

$$f^{-1}(0) = \{(x, u) \in \mathbf{R}^{\mathrm{n+m}};\ \ f(x, u) = 0\}$$

is called the *equilibrium set* of the control system.

A system is said to be *continuously stabilizable* at $(x^*, u^*) \in f^{-1}(0)$ over a set $K \subset \mathrm{R}^n$ if there exists a continuous function $u = u(x)$, such that $u(x^*) = u^*$ and x^* is an asymptotically stable equilibrium of the closed loop system

$$\dot{x} = f(x, u(x))$$

and the domain of x^*-attraction contains K, i.e.,

$$\lim_{t \to +\infty} e^{tf} x = x^* \quad \forall\, x \in K \subset \mathbf{R}^n,$$

where e^{tf} is the flow generated by the vector field $f(x, u(x))$. We say that x^* is stable if for any neighborhood W of x^* (open connected set containing x^*) there is a neighborhood V of x^*, such that

$$\forall\ \ t \geq 0 \quad e^{tf} V \subset W,$$

where $e^{tf} V = \{e^{tf} x;\ \ x \in V\}$.

A system which is continuously stabilizable at $(x^*, u^*) \in f^{-1}(0)$ over R^n is said to be *continuously stabilizable in the large.*

2.1.1. Basics of function degree. For the sake of completeness and reader convenience, we briefly recall some facts about the degree of continuous functions. Additional details can be found in [6], [8]. We use the following notation:

(i) M is a compact, n-dimensional, oriented C^∞ manifold. Its interior is denoted by $\mathrm{Int}(M)$, its boundary by ∂M.

(ii) $x = (x_1, \ldots, x_n) \in \mathrm{R}^\mathrm{n}$; $|x|^2 = \langle x, x\rangle$, where

$$\langle x, y\rangle = \sum_{i=1}^{n} x_i y_i \quad \forall\, x,\ y \in \mathrm{R}^\mathrm{n}.$$

x is also used for local coordinates on M with a fixed orientation. If local coordinates are given, then $\frac{\partial}{\partial x} f(x)$ is the Jacobian matrix and $\det(\frac{\partial}{\partial x} f(x))$ is the Jacobian determinant of f at x.

(iii) $f \in C^1(M)$ if $f : M \to \mathrm{R}^\mathrm{n}$ and f has continuous first-order partial derivatives in M. $f \in C(M)$ if f is a continuous function from M into R^n.

(iv) Given a real positive number r and $y \in \mathrm{R}^\mathrm{n}, B_r(y)$ is the closed ball center y, radius r:

$$B_r(y) = \{x \in \mathrm{R}^\mathrm{n};\ \mid x - y \mid \leq r\ \}.$$

(v) An immersion $i:\ M \ \to\ \mathrm{R}^\mathrm{n}_\mathrm{x} \times \mathrm{R}^\mathrm{m}_\mathrm{u}$ which maps M homeomorphically into its image $i(M) \subset \mathrm{R}^\mathrm{n}_\mathrm{x} \times \mathrm{R}^\mathrm{m}_\mathrm{u}$ with topology induced by $\mathrm{R}^\mathrm{n}_\mathrm{x} \times \mathrm{R}^\mathrm{m}_\mathrm{u}$ is called a natural embedding. $i_x:\ M\ \to\ \mathrm{R}^\mathrm{n}_\mathrm{x}, i_\mathrm{u}:\ \mathrm{M}\ \to\ \mathrm{R}^\mathrm{m}_\mathrm{u}$ are used for $P_x \circ i$ and $P_u \circ i$, respectively, where $P_x,\ P_u$ are the projections: $P_x(x, u) = x,\ \ P_u(x, u) = u$.

Definition 1. *Suppose $\phi \in C^1(M)$, $p \notin \phi(\partial M)$ and p is not a critical value of ϕ on M, i.e.,*

$$\det\left(\frac{\partial}{\partial x}\phi(x)\right) \neq 0 \quad \forall\, x \in \phi^{-1}(p) = \{x \in M;\quad \phi(x) = p\}.$$

Define the degree of ϕ at p relative to M to be $d(\phi, M, p)$, where

$$d(\phi, M, p) = \sum_{x\in\phi^{-1}(p)} sign\left[\det\left(\frac{\partial}{\partial x}\phi(x)\right)\right].$$

If $\phi \in C(M)$, then the degree of ϕ can be defined as the degree of a sufficiently good C^1 approximation of ϕ (for details, see [6], [8]).

Definition 2. *Suppose that $\phi \in C(M)$ and $p \notin \phi(\partial M)$. Define $d(\phi, M, p)$ to be $d(\psi, M, p)$, where ψ is any function in $C^1(M)$ satisfying*

$$\mid \phi(x) - \psi(x) \mid < \rho(p, \phi(\partial M)) \quad \forall\, x \in M,$$

where $\rho(x, \phi(\partial M)) = \inf_{y\in\phi(\partial M)} \mid x - y \mid$ and p is not a critical value of ψ on M.

Recall that if X and Y are topological spaces, two continuous functions f and g are said to be homotopic ($f \sim g$) if there is a continuous function (homotopy)

$$H:\ \ [0, 1] \times X\ \to\ Y$$

such that

$$H(0, x) = f(x), \quad H(1, x) = g(x) \quad (x \in X).$$

We will need the following properties of degree.

THEOREM 2.

(1) *If $H(t,x) \equiv h_t(x)$ is a homotopy and $p \notin h_t(\partial M)$ for $0 \leq t \leq 1$, then $d(h_t, M, p)$ is independent of $t \in [0,1]$.*

(2) *If a continuous feedback $u = u(x)$ stabilizes the system $\dot{x} = f(x,u)$ at $p \in \mathrm{Int}(B_r(0)) \subset \mathrm{R}^{\mathrm{n}}$, then*

$$d(f(\cdot, u(\cdot)), B_r(0), 0) = (-1)^n.$$

(3) *Suppose $\phi \in C(M)$. If $d(\phi, M, p)$ is defined and nonzero, then there is $q \in M$ such that $\phi(q) = p$.*

(4) *If a continuous feedback $u = u(x)$ stabilizes the system $x_{k+1} = f(x_k, u)$ at $p \in \mathrm{Int}(B_r(0)) \subset \mathrm{R}^{\mathrm{n}}$, then*

$$d(Id_n - f(\cdot, u(\cdot)), B_r(0), 0) = 1,$$

where Id_n is the identity $n \times n$ matrix.

For a proof, see [6], [8].

LEMMA 1. *Let $f : \mathrm{R}^{\mathrm{n}}_{\mathrm{x}} \times \mathrm{R}^{\mathrm{m}}_{\mathrm{u}} \rightarrow \mathrm{R}^{\mathrm{n}}$ be a smooth function, and let ω be a bounded connected component of $f^{-1}(0)$ such that*

$$\mathrm{rank}\left(\frac{\partial}{\partial x} f(x,u), \frac{\partial}{\partial u} f(x,u)\right) = n \quad \forall \ (x,u) \in \omega.$$

If $u = v(x) : \mathrm{R}^n_x \rightarrow \mathrm{R}^m_u$ is a continuous function such that

$$f^{-1}(0) \cap \{(x,u) \in \mathrm{R}^n_x \times \mathrm{R}^m_u \ ; \ u = v(x)\} = \omega \cap \{(x,u) \in \mathrm{R}^n_x \times \mathrm{R}^m_u ; u = v(x)\},$$

then

$$d((f, P_u - v \circ P_x), B_R(0), 0) = 0,$$

where $R > 0$ such that $\omega \subset \mathrm{Int}(B_R(0))$ and P_x, P_u are the projections: $P_x(x,u) = x, P_u(x,u) = u$.

This lemma is proved in [10], [11].

2.1.2. Geometrical illustrations of necessary conditions. We start with the following necessary condition of continuous stabilization.

THEOREM 3. *If $f : \mathrm{R}^{\mathrm{n}}_{\mathrm{x}} \times \mathrm{R}^{\mathrm{m}}_{\mathrm{u}} \rightarrow \mathrm{R}^{\mathrm{n}}$ is a smooth function and $f^{-1}(0)$ is bounded, then the system $\dot{x} = f(x,u)$ is not continuously stabilizable in the large at any point $(x^*, u^*) \in f^{-1}(0)$.*

For a proof of this theorem see [10], [11].

For geometrical illustrations consider a nonlinear single-input system of the form

$$\dot{x} = f(x,u),$$

where $(x,u) \in \mathrm{R}^2_x \times \mathrm{R}_u$.

If $f^{-1}(0)$ is bounded, then Theorem 3 asserts that the system cannot be continuously stabilizable. The reason is that the graph of any continuous feedback $u = u(x)$ stabilizing the system has at least two points of intersection with the equilibrium set $f^{-1}(0)$. Figure 1 depicts a geometrical illustration of this fact.

Example 1. Consider the system

$$\dot{x}_1 = \sin(x_1^2 + x_2^2),$$
$$\dot{x}_2 = u.$$

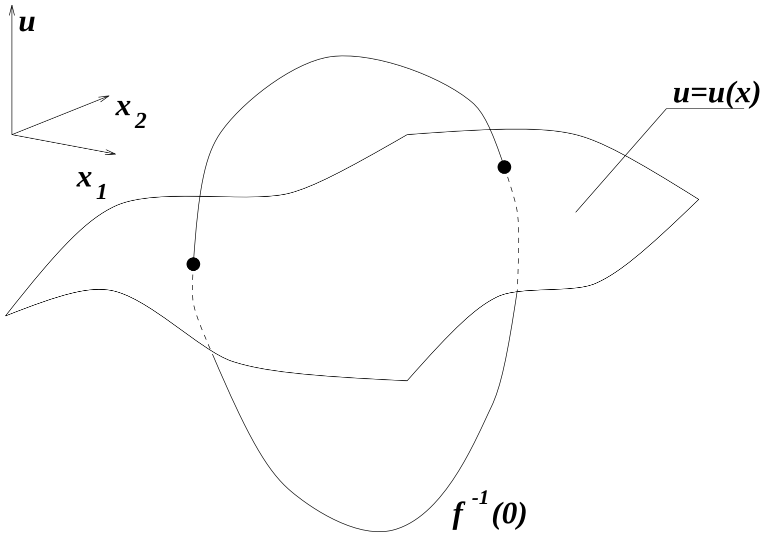

Fig. 1. *If $f^{-1}(0)$ is a closed curve, then the graph of a continuous feedback $u = u(x)$ intersects $f^{-1}(0)$ more than once.*

The equilibrium set for this system is defined by

$$\{(x_1, x_2, u) : \quad u = 0, \;\; x_1^2 + x_2^2 = \pi \cdot n, \quad \text{where} \;\; n = 0, 1, 2, \ldots\}.$$

The system is locally continuously stabilizable at any point of its equilibrium set with $x_2 \neq 0$ (see [10] for further details). But it is not continuously stabilizable at $(x_1^*, x_2^*, 0)$ (with $(x_1^*)^2 + (x_2^*)^2 = \pi \cdot n$) over any compact set containing the entire circle $(x_1^*)^2 + (x_2^*)^2 = \pi \cdot n$. It happens because on a compact set containing the circle the graph of any continuous feedback locally stabilizing the system at (x_1^*, x_2^*) has at least two points of intersection with this circle (Figure 2).

As illustrated by Example 1, system (1) is not continuously stabilizable at any point of a connected bounded component of its equilibrium set. This leads us to the following theorem.

Theorem 4. *Let $f : \mathrm{R}^{\mathrm{n}}_{\mathrm{x}} \times \mathrm{R}^{\mathrm{m}}_{\mathrm{u}} \rightarrow \mathrm{R}^{\mathrm{n}}$ be a smooth function, and let ω be a connected component of $f^{-1}(0)$ such that*

$$\operatorname{rank}\left(\frac{\partial}{\partial x} f(x, u), \frac{\partial}{\partial u} f(x, u)\right) = n \quad \forall \;\; (x, u) \in \omega.$$

If the system $\dot{x} = f(x, u)$ is smoothly stabilizable in the large at a point $(x^*, u^*) \in \omega$, then ω is unbounded.

The proof of this theorem is given in [10], [11].

Theorems 3 and 4 give us the topological necessary conditions that are stable under perturbations which are small in fine Whitney topology. Moreover, these conditions remain valid for a system on a compact smooth simply connected manifold, and since on the compact manifold the equilibrium set $f^{-1}(0)$ is evidently bounded, we conclude that the system cannot be continuously stabilizable over this manifold. Thus a smooth generic system is never globally continuously stabilizable on a compact simply connected manifold.

Theorems 3 and 4 may give an impression that the topological barrier for continuous stabilization is provided only by the fact that either the equilibrium set or

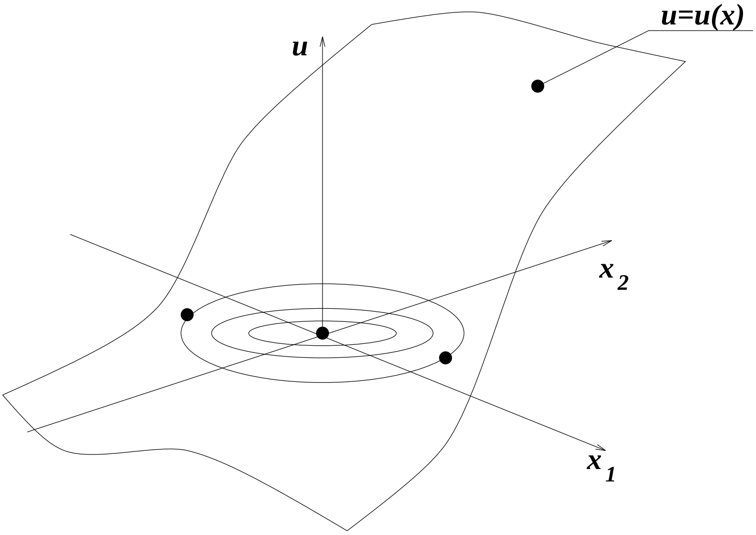

FIG. 2. *Over a compact set containing the circle* $(x_1^*)^2 + (x_2^*)^2 = \pi \cdot n$ *a graph of a continuous feedback stabilizing the system at* (x_1^*, x_2^*) *has at least two points of intersection with the circle.*

one of its connected components is bounded. However, stabilization also depends upon the way in which one connected component of the equilibrium set loops around another. Let us consider a single-input nonlinear system. We introduce the normal parameterization of $f^{-1}(0)$ as follows.

DEFINITION 3. *Let* $\zeta \subset \mathbf{R}_{\mathrm{x}}^{\mathrm{n}} \times \mathbf{R}_{\mathrm{u}}$ *be a segment of a connected component of* $f^{-1}(0)$, *and let*

$$\operatorname{rank}\left(\frac{\partial}{\partial x} f(x,u), \frac{\partial}{\partial u} f(x,u)\right) = n \quad \forall \ (x,u) \in \zeta.$$

Then a parameterization

$$\zeta = \{(x_\zeta(\tau), u_\zeta(\tau)) \in \mathbf{R}_{\mathrm{x}}^{\mathrm{n}} \times \mathbf{R}_{\mathrm{u}}; \ \ \tau \in \mathbf{R}\}$$

of the segment will be called normal if

$$\det\begin{pmatrix} \frac{dx_\zeta(\tau)}{d\tau} & \frac{du_\zeta(\tau)}{d\tau} \\ \frac{\partial}{\partial x} f(x_\zeta(\tau), u_\zeta(\tau)) & \frac{\partial}{\partial u} f(x_\zeta(\tau), u_\zeta(\tau)) \end{pmatrix} > 0 \qquad \forall \tau \in \mathbf{R}.$$

We can formulate the following necessary condition of smooth stabilization in the large.

THEOREM 5. *Let* $\dot{x} = f(x,u)$ *be a smooth single-input system such that*

$$\operatorname{rank}\left(\frac{\partial}{\partial x} f(x,u), \frac{\partial}{\partial u} f(x,u)\right) = n \quad \forall \ (x,u) \in \zeta,$$

where $\zeta \subset f^{-1}(0)$ *is a segment with the normal parameterization*

$$\zeta = \{(x_\zeta(\tau), u_\zeta(\tau)) \in \mathbf{R}_{\mathrm{x}}^{\mathrm{n}} \times \mathbf{R}_{\mathrm{u}}; \ \ \tau \in \mathbf{R}\}.$$

Then the system is not continuously stabilizable in the large at a point $(x^*, u^*) \in \zeta$ *whenever there is a connected component* $\tilde{\omega} \subset f^{-1}(0) \setminus \zeta$ *such that one can find points* $(\tilde{x}, \tilde{u}),\ \ (\hat{x}, \hat{u}) \in \tilde{\omega}$ *such that*

$$x_\zeta(\tau_1) = \hat{x}, \qquad \tau_1 < \tau^*,$$

$$x_\zeta(\tau_2) = \tilde{x}, \qquad \tau_2 > \tau^*,$$

and

$$\begin{aligned} u_\zeta(\tau_1) &\geq \hat{u}, \\ u_\zeta(\tau_2) &\leq \tilde{u}, \end{aligned} \tag{3}$$

where $\tau^* \in \mathrm{R}$ *and* $x_\zeta(\tau^*) = x^*, \quad u_\zeta(\tau^*) = u^*.$

The proof of this theorem is given in [10], [11].

If the system $\dot{x} = f(x,u)$ is continuously stabilizable at (x^*, u^*), then without loss of generality [8] we can assume that $f(x, u(x))$ is differentiable at x^* and

$$sign\left(\det\left(\frac{\partial}{\partial x} f(x, u(x))\right)|_{x=x^*}\right) = (-1)^n,$$

where $(x^*, u^*) \in f^{-1}(0)$ and $u^* = u(x^*)$.

Let $\zeta \subset f^{-1}(0)$ be a segment with the normal parameterization

$$\zeta = \{(x_\zeta(\tau), u_\zeta(\tau)) \in \mathrm{R}^{\mathrm{n}}_{\mathrm{x}} \times \mathrm{R}_{\mathrm{u}};\ \ \tau \in \mathrm{R}\}$$

and $\tau^* \in \mathrm{R},\ \ x_\zeta(\tau^*) = x^*,\ \ u_\zeta(\tau^*) = u^*.$

Then it follows from the definition of natural parameterization that there exists a positive real number α such that

$$\frac{d}{d\tau}(u_\zeta(\tau) - u(x_\zeta(\tau)))|_{\tau=\tau^*} = \left(\frac{du}{d\tau} - \frac{\partial u}{\partial x}\frac{dx}{d\tau}\right)|_{\tau=\tau^*}$$

$$= \alpha \cdot \det\begin{pmatrix} -\frac{\partial u}{\partial x} & 1 \\ \frac{\partial}{\partial x} f(x,u) & \frac{\partial}{\partial u} f(x,u) \end{pmatrix}|_{x=x^*,\ u=u^*}$$

$$= \alpha \cdot \det\begin{pmatrix} 0 & 1 \\ \frac{\partial}{\partial x}(f(x,u(x))) & \frac{\partial}{\partial u} f(x,u) \end{pmatrix}|_{x=x^*,\ u=u^*}$$

$$= \alpha \cdot (-1)^{n+2} \cdot \det\left(\frac{\partial}{\partial x}(f(x,u(x)))\right)|_{x=x^*} > 0,$$

since

$$sign\left(\det\left(\frac{\partial}{\partial x}(f(x,u(x)))\right)|_{x=x^*}\right) = (-1)^n.$$

Thus

$$u_\zeta(\tau) \leq u(x_\zeta(\tau)) \quad \text{for} \quad \tau \leq \tau^*$$

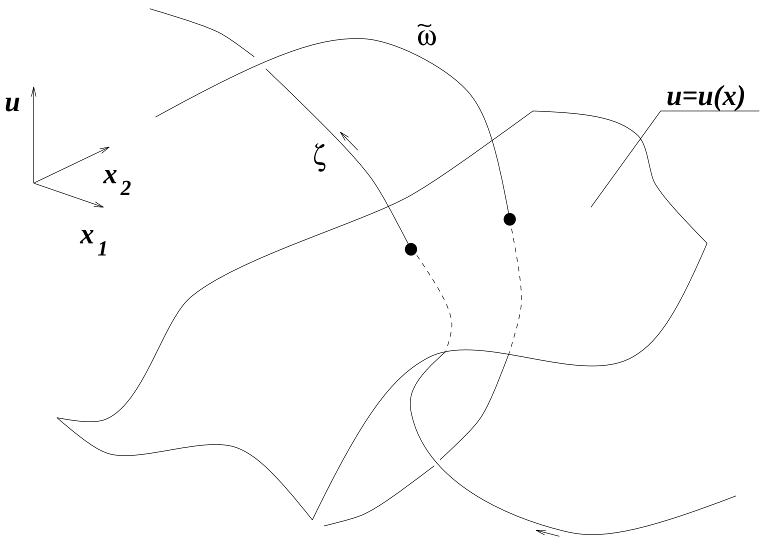

FIG. 3. *If $f^{-1}(0)$ has two connected components knotted as shown, then the graph of a continuous feedback $u = u(x)$ intersects $f^{-1}(0)$ more than once. Arrows show the normal parameterization of ζ.*

and

$$u_\zeta(\tau) \geq u(x_\zeta(\tau)) \quad \text{for } \tau \geq \tau^*.$$

Taking these inequalities into account and using the fact that $\tilde{\omega}$ is a connected component of the equilibrium set we conclude that under the conditions of Theorem 5 the graph of the feedback $u = u(x)$ has at least two points of intersection with the equilibrium set $f^{-1}(0)$. One of these points of intersection is (x^*, u^*) and another is on the connected component $\tilde{\omega}$ defined in Theorem 5. A geometrical illustration of this fact is Figure 3.

Example 2. Consider the system

$$\dot{x}_1 = (x_1 - \cos(u)) \cdot u,$$
$$\dot{x}_2 = (x_2 - \sin(u)).$$

The equilibrium set of this system is defined by

$$(x_1 - \cos(u)) \cdot u = 0,$$
$$x_2 - \sin(u) = 0.$$

It is easy to show that the system is locally stabilizable at the origin by a linear feedback law. On the other hand, our topological considerations, in particular Theorem 5, show that this system is not continuously stabilizable over any set containing the unit disk centered at the origin (Figure 4).

The discussion presented in this subsection shows that many systems are not continuously stabilizable. Hence it is reasonable and even sometimes necessary to design piecewise-constant stabilizers.

2.2. Discrete-time systems. This subsection shows that many discrete-time systems are not continuously stabilizable. Consider a discrete-time system of the form

$$x_{k+1} = f(x_k, u), \tag{4}$$

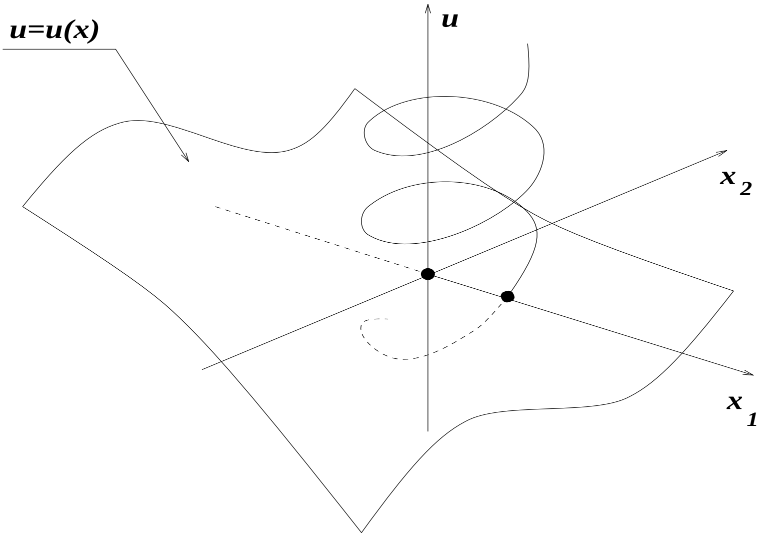

FIG. 4. *Due to the topological structure of the equilibrium set the continuous stabilization at the origin over a set containing the unit disk* $x_1^2 + x_2^2 \leq 1$ *is impossible.*

where $u \in \mathrm{R}^m$, $k \in \mathbf{N} = \{0, 1, 2, \ldots\}$, and for any $k \in \mathrm{N}$, $x_k \in \mathrm{R}^n$.

Let pr_x denote the projection of $\mathbf{R}_x^n \times \mathbf{R}_u^m$ onto $\mathbf{R}_x^n$, that is, $pr_x(x, u) = x$. $(pr_x - f)^{-1}(0)$ denotes the equilibrium set of system (4),

$$(pr_x - f)^{-1}(0) = \{(x, u) \in \mathbf{R}_x^n \times \mathbf{R}_u^m; \ \ x = f(x, u)\}.$$

System (4) is said to be continuously stabilizable at $(x^*, u^*) \in (pr_x - f)^{-1}(0)$ over a set $K \subset \mathrm{R}^n$ if there exists a continuous function $u = u(x)$, such that $u(x^*) = u^*$ and x^* is an asymptotically stable singular point of the closed loop system

$$x_{k+1} = f(x_k, u(x_k)), \tag{5}$$

and the domain of x^*-attraction contains K, i.e.,

$$\lim_{k \to +\infty} e^{kf} x = x^* \quad \forall \, x \in K \subset \mathbf{R}^n,$$

where $e^{kf}x$ is the solution of the closed loop system (5) with the initial condition $x_0 = x$. We say that x^* is stable if for any neighborhood W of x^* (open connected set containing x^*) there is a neighborhood V of x^*, such that

$$\forall \ \ k \in \mathbf{N} \quad e^{kf} V \subset W,$$

where $e^{kf}V = \{e^{kf}x; \ \ x \in V\}$.

A system that is continuously stabilizable at $(x^*, u^*) \in (pr_x - f)^{-1}(0)$ over $\mathbf{R}^n$ is said to be continuously stabilizable in the large.

The analogue of Theorem 3 for discrete-time systems is as follows.

THEOREM 6. *If* $f : \mathrm{R}_\mathrm{x}^\mathrm{n} \times \mathrm{R}_\mathrm{u}^\mathrm{m} \ \to \ \mathrm{R}^\mathrm{n}$ *is a smooth function and* $(pr_x - f)^{-1}(0)$ *is bounded, then the system* $x_{k+1} = f(x_k, u)$ *is not continuously stabilizable in the large at any point* $(x^*, u^*) \in (pr_x - f)^{-1}(0)$.

Proof. If $(pr_x - f)^{-1}(0)$ is bounded, then there is a positive real number r, such that

$$(pr_x - f)^{-1}(0) \subset \mathrm{Int}(B_r(0)).$$

Hence

$$f(x,u) \neq x \quad \forall u \in \mathrm{R}_u^m, \quad \mid x \mid = r,$$

and properties (1), (3) (Theorem 2) imply

$$d(P_x(\cdot) - f(\cdot, u(\cdot)), P_x(B_r(0)), 0) = d(P_x(\cdot) - f(x, \bar{u}), P_x(B_r(0)), 0) = 0,$$

where $\mid \bar{u} \mid = r$ and $u = u(x)$ is a continuous function, while

$$d(x - f(x, u(x)), P_x(B_r(0)), 0) = 1$$

whenever $u = u(x)$ is a continuous feedback stabilizing the system in the large. Thus the system cannot be continuously stabilized in the large at any point $(x^*, u^*) \in (pr_x - f)^{-1}(0)$; hence the theorem is proved. □

The analogue of Theorem 4 for discrete-time systems is as follows.

THEOREM 7. *Let* $f : \mathrm{R_x^n} \times \mathrm{R_u^m} \rightarrow \mathrm{R^n}$ *be a smooth function, and let* ω *be a connected component of* $(pr_x - f)^{-1}(0)$ *such that*

$$\mathrm{rank}\left(\mathrm{Id}_n - \frac{\partial}{\partial x} f(x,u), \frac{\partial}{\partial u} f(x,u)\right) = n \quad \forall \ (x,u) \in \omega,$$

where Id_n *is the identity matrix with* n *columns and* n *rows.*

If the system $x_{k+1} = f(x_k, u)$ *is continuously stabilizable in the large at* $(x^*, u^*) \in \omega$*, then* ω *is unbounded.*

Proof. If $u = v(x)$ is a continuous feedback stabilizing in the large the system $x_{k+1} = f(x_k, u)$ at a point $(x^*, u^*) \in \omega$ and ω is bounded, then there is $B_r(0)$ such that

$$\omega \subset \mathrm{Int}(B_r(0))$$

and

$$d(P_x(\cdot) - f(\cdot, v(\cdot)), P_x(B_r(0)), 0) = 1.$$

Note that

$$(pr_x - f)^{-1}(0) \cap \{(x,u) \in \mathrm{R}_x^n \times \mathrm{R}_u^m \ ; \ u = v(x)\} = \omega \cap \{(x,u) \in \mathrm{R}_x^n \times \mathrm{R}_u^m \ ; \ u = v(x)\}$$

and

$$\mid d(P_x(\cdot) - f(\cdot, v(\cdot)), P_x(B_r(0)), 0) \mid = \mid d((P_x - f, P_u - v \circ P_x), B_r(0), 0) \mid .$$

Making use of Lemma 1, we obtain the contradiction that proves the theorem. □

Theorems 6 and 7 have the same geometrical sense as Theorems 3 and 4 (Figure 1).

In order to formulate the analog of Theorem 5 for discrete-time systems we need to change the definition of natural parameterization.

Definition 4. *Let ζ be a segment of a connected component of $(pr_x - f)^{-1}(0)$, and let*

$$\operatorname{rank}\left(\mathrm{Id}_n - \frac{\partial}{\partial x}f(x,u), \frac{\partial}{\partial u}f(x,u)\right) = n \quad \forall \ (x,u) \in \zeta.$$

Then a parameterization

$$\zeta = \{(x_\zeta(\tau), u_\zeta(\tau)) \in \mathrm{R}^{\mathrm{n}}_{\mathrm{x}} \times \mathrm{R}_{\mathrm{u}} \quad ; \tau \in \mathrm{R}\}$$

of the segment will be called normal if

$$\det\begin{pmatrix} \frac{dx_\zeta(\tau)}{d\tau} & \frac{du_\zeta(\tau)}{d\tau} \\ \frac{\partial}{\partial x}f(x_\zeta(\tau), u_\zeta(\tau)) - \mathrm{Id}_n & \frac{\partial}{\partial u}f(x_\zeta(\tau), u_\zeta(\tau)) \end{pmatrix} > 0 \qquad \forall \tau \in \mathrm{R}.$$

The analogue of Theorem 5 for discrete-time systems is as follows.

Theorem 8. *Let $f(x,u)$ be such that*

$$\operatorname{rank}\left(\mathrm{Id}_n - \frac{\partial}{\partial x}f(x,u), \frac{\partial}{\partial u}f(x,u)\right) = n \quad \forall \ (x,u) \in \zeta,$$

where $\zeta \subset (pr_x - f)^{-1}(0)$ is a segment with a normal parameterization

$$\zeta = \{(x_\zeta(\tau), u_\zeta(\tau)) \in \mathrm{R}^{\mathrm{n}}_{\mathrm{x}} \times \mathrm{R}_{\mathrm{u}}; \ \ \tau \in \mathrm{R}\}.$$

Then the system $x_{k+1} = f(x_k, u)$ is not smoothly stabilizable in the large at a point $(x^*, u^*) \in \zeta$ whenever there is a connected component $\tilde{\omega} \subset (pr_x - f)^{-1}(0) \setminus \zeta$ such that one can find points $(\tilde{x}_2, \tilde{u}_2), (\tilde{x}_1, \tilde{u}_1) \in \tilde{\omega}$ such that

$$x_\zeta(\tau_1) = \tilde{x}_1, \qquad \tau_1 < \tau^*,$$

$$x_\zeta(\tau_2) = \tilde{x}_2, \qquad \tau_2 > \tau^*,$$

and

$$\begin{aligned} u_\zeta(\tau_1) &\geq \tilde{u}_1, \\ u_\zeta(\tau_2) &\leq \tilde{u}_2, \end{aligned} \tag{6}$$

where $\tau^* \in \mathrm{R}$ and $x_\zeta(\tau^*) = x^*, \quad u_\zeta(\tau^*) = u^*$.

The proof and geometrical illustration for this theorem coincide with that of Theorem 5 (Figure 3).

After a few technical modifications all topological necessary conditions of continuous stabilization also remain valid for discrete-time systems. Thus many discrete-time systems are not continuously stabilizable, and therefore we need to consider either piecewise-continuous or nonstationary stabilizing feedbacks. This fact serves as one of the main motivations for establishing the result presented in the next section. Moreover, the approach outlined in the next section can be effectively applied to design feedbacks subjected to state and control constraints.

3. Piecewise-constant stabilization criterion.

The goal of this section is to give the criterion of piecewise-constant stabilization. The proof of this criterion is constructive and can be used for feedback synthesis. Moreover, it is based on the general topology and therefore is valid for both discrete- and continuous-time systems. For the sake of brevity, only the criterion for continuous-time systems is presented.

Consider the system

$$\dot{x} = f(x,u), \tag{7}$$

where $x \in \mathrm{R}^{\mathrm{n}},\ u \in U\ \subset\ \mathrm{R}^{\mathrm{m}},\ U$ is a subset in R^{m}. $f(x,u)$ is a complete C^∞ vector field on R^{n} for every $u \in\ U\ \subset\ \mathrm{R}^{\mathrm{m}}$ fixed.

$PC(U)$ is the set of all piecewise-constant mappings form R^{n} into $U\ \subset\ \mathrm{R}^{\mathrm{m}}$. A function $u = u(x)$ is called piecewise-constant on some set Q if there exists a covering $Q \subseteq \bigcup_i V_i$ such that

(i) $V_i \cap V_j = \emptyset$ when $i \neq j$;

(ii) Int $V_i \neq \emptyset\ \forall i$;

(iii) the closure $\overline{\text{Int } V_i}$ of the interior Int V_i coincides with $\overline{V_i}$;

(iv) the restriction $u|_{V_i}$ of u to V_i is a constant from U.

Let $u(x) \in PC(U)$. Then we define the solution for the initial value problem

$$\dot{x} = f(x,u(x)), \quad x(0) = x_0 \tag{8}$$

as follows.

Definition 5. *A function of time $x_u(t,x_0)$ $(t > 0,\ \ t \in \mathrm{R})$ is called a solution for the initial value problem* (8) *if the following conditions hold:*

(i) *$x_u(t,x_0)$ is a continuous function of time,*

(ii) *$\forall\ T > 0$ the derivative $\frac{d}{dt}x_u(t,x_0)$ exists, and*

(iii)

$$\frac{d}{dt}x_u(t,x_0) = f(x_u(t,x_0), u(x_u(t,x_0)))$$

either $\forall t \in [0,T]$ or $\forall t \in [0,T]$ excluding a finite number of points.

Having fixed the feedback $u = u(x)$ such that $u(x) \in PC(U)$ and the solution for (7) exists for all $x_0 \in \mathrm{R}^{\mathrm{n}}$ we obtain the flow e^{tf} generated by the closed loop system

$$\dot{x} = f(x,u(x))$$

evolving over R^{n}. $e^{tf}x_0$ denotes the point into which the flow e^{tf} steers x_0 and $e^{tf}(V) = \{e^{tf}x_0; x_0 \in V\}$. V is called an invariant set of the system if and only if $e^{tf}V \subseteq V\ \forall t \geq 0$.

Definition 6. *A system $\dot{x} = f(x,u)$ is said to be piecewise-constantly stabilizable at $(x^*,u^*) \in f^{-1}(0)$ over a domain $K \subseteq \mathrm{R}^{\mathrm{n}}$, if there exists a piecewise-constant feedback $u = u(x)$ from $PC(U)$, such that $u(x^*) = u^*, x^*$ is an asymptotically stable equilibrium of* (8) *and $K \subseteq D(x^*)$, where $D(x^*)$ is the domain of x^*-attraction, i.e., for every $x_0 \in D(x^*)$ the solution $e^{tf}x_0$ of the closed loop system exists $\forall t \geq 0$ and $\lim_{t\to\infty} e^{tf}x_0 = x^*$.*

If $K = \mathrm{R}^{\mathrm{n}}$, then $\dot{x} = f(x,u)$ is called (completely) piecewise-constantly stabilizable at $(x^*,u^*) \in f^{-1}(0)$ (over R^{n} or in the large). If there exists a neighborhood $O(x^*)$ and $\dot{x} = f(x,u)$ is piecewise-constantly stabilizable in $(x^*,u^*) \in f^{-1}(0)$ over $O(x^*)$, then $\dot{x} = f(x,u)$ is said to be locally piecewise-constantly stabilizable at (x^*,u^*).

A control $u : [0,T] \to U$ is said to be piecewise constant if there exist time points $0 = t_0 < t_1 < t_2 < \cdots < t_N = T$ and $u_1, \ldots, u_N \in U$, such that $u(t) = u_i$ for $t_{i-1} \le t < t_i$ $(i < N)$ and $u(t) = u_N$ for $t_{N-1} \le t \le t_N$.

Definition 7. *We say that a point p can be piecewise-constantly steered into a point q, if there exist $0 < T < \infty$ and a piecewise-constant control $u : [0,T] \to U$, such that the solution $x_u(t,p)$ of the initial value problem*

$$\begin{aligned} \dot{x} &= f(x, u(t)), \\ x(0) &= p \end{aligned}$$

exists on the time interval $[0,T]$, is unique, and $x_u(T,p) = q$. If for every point $p \in K \subset \mathrm{R}^{\mathrm{n}}$ there exists $q \in V \subset \mathrm{R}^{\mathrm{n}}$, such that p is piecewise-constantly steered into q, then the set V is called piecewise-constantly accessible from the set K.

The piecewise-constant accessibility has a very important property formulated in the following lemma.

Lemma 2. *Let K be a compact subset in R^{n}. Let $V \subset \mathrm{R}^n$ be an open subset. Then if V is piecewise-constantly accessible from K there exist a natural number N, real number $T > 0$, and*

$$\{u_1, \ldots, u_N\} \in U^N = \underbrace{U \times \cdots \times U}_{N}$$

such that for each point $p \in K$ there exist a point $q \in V$ and $t_1 \ge 0, \ldots, t_N \ge 0$, $\sum_{i=1}^N t_i \le T$, such that

$$e^{-t_1 f(*,u_1)} \circ e^{-t_2 f(*,u_2)} \circ \cdots \circ e^{-t_N f(*,u_N)} q = p,$$

where $f(*, u_i)$ denotes the vector field $f(x, u_i)$ $(i = 1, 2, \ldots, N)$.

Proof. The set

$$V(n,u,T) = \left\{ e^{-t_1 f(*,u_1)} \circ e^{-t_2 f(*,u_2)} \circ \cdots \circ e^{-t_n f(*,u_n)} z : \right. \\ \left. t_i \ge 0 \ (i = 1, 2, \ldots, n) \sum_{i=1}^n t_i \le T, z \in V \right\}$$

is open $\forall n = 1, 2, \ldots,\ \ T > 0,\ u \in U^n$. The piecewise-constant accessibility of V from K implies

$$K \subset \bigcup_{n=1}^{\infty} \bigcup_{\substack{u \in U^n \\ T > 0}} V(n,u,T).$$

Thus it follows from the compactness of K that there exists a natural number μ such that

$$K \subset \bigcup_{i=1}^{\mu} V(n_i, u_i, T_i),$$

where $u_i = (u_{i1}, u_{i2}, \ldots, u_{in_i})$ $(i = 1, 2, \ldots, \mu)$. Therefore we can take $N = \sum_{i=1}^{\mu} n_i$,

$$\begin{aligned}&\{u_1, \dots, u_N\}\\&= \{u_{11}, u_{12}, \dots, u_{1n_1}, u_{21}, u_{22}, \dots, u_{2n_2}, \dots, u_{\mu n_\mu}\}\end{aligned}$$

and $T = \sum_{i=1}^{\mu} T_i$. □

To formulate the main result of this paper we need the following analogue of the Liapunov asymptotic stability.

DEFINITION 8. *An equilibrium $(x^*, u^*) \in f^{-1}(0)$ of $\dot{x} = f(x, u)$ is said to be Liapunov asymptotically stable if there exists $\Delta > 0$ such that for any $0 \le \varepsilon \le \Delta$ one can find $\delta > 0$ such that x^* is piecewise-constantly accessible from $B_\delta(x^*)$ without leaving $B_\varepsilon(x^*)$; i.e., for any $p \in B_\delta(x^*)$ there exist $0 < T \le \infty$ (T can be ∞) and a piecewise-constant control $u : [0, T) \to U$, such that the solution $x_u(t, p)$ of the initial value problem*

$$\begin{aligned}\dot{x} &= f(x, u(t)),\\ x(0) &= p\end{aligned}$$

exists on $[0, T)$, $x_u(t, p) \in B_\varepsilon(x^*)$ for any $t \in [0, T)$, and

$$\lim_{t \to T} x_u(t, p) = x^*.$$

THEOREM 9. *A system $\dot{x} = f(x, u)$ is piecewise-constantly stabilizable at its equilibrium $(x^*, u^*) \in f^{-1}(0)$ over a compact set K if and only if (x^*, u^*) is Liapunov asymptotically stable and x^* is piecewise-constantly accessible from K.*

Proof.

Necessity. If $u(x) \in PC(U)$ stabilizes $\dot{x} = f(x, u)$ at $(x^*, u^*) \in f^{-1}(0)$ over K, then (x^*, u^*) is evidently Liapunov asymptotically stable and x^* is piecewise-constantly accessible from K.

Sufficiency. Since $(x^*, u^*) \in f^{-1}(0)$ is Liapunov asymptotically stable, then there exists a sequence of positive real numbers $\{\varepsilon_n\}_{n=0}^{\infty}$ such that

$$\begin{gathered}\varepsilon_0 > \varepsilon_1 > \cdots > \varepsilon_n > \varepsilon_{n+1} > \cdots,\\ \lim_{n \to \infty} \varepsilon_n = 0\end{gathered}$$

and for any $n = 1, 2, 3, \dots$, $B_{\varepsilon_{n+1}}(x^*)$ is accessible from $B_{\varepsilon_n}(x^*)$ without leaving $B_{\varepsilon_{n-1}}(x^*)$.

Roughly speaking, the main idea of the proof is to design piecewise-constant feedbacks $u_0(x)$, $u_1(x)$, $u_2(x), \dots$ which steer the systems in accordance with the arrows marked in Figure 5.

The point x^* is piecewise-constantly accessible from K and therefore, for any $n = 0, 1, 2, \dots$, $B_{\varepsilon_n}(x^*)$ is piecewise-constantly accessible from K. Lemma 2 with V being the interior $\mathrm{Int}(B_{\varepsilon_2}(x^*))$ of the ball $B_{\varepsilon_2}(x^*)$ gives us the existence of a natural number N, real number $T > 0$, and

$$\{u_1, \dots, u_N\} \in U^N = \underbrace{U \times \cdots \times U}_{N}$$

such that for each point $p \in K$ there exist a point $q \in B_{\varepsilon_2}(x^*)$ and

$$t_1 \ge 0, \dots, t_N \ge 0, \qquad \sum_{i=1}^{N} t_i \le T$$

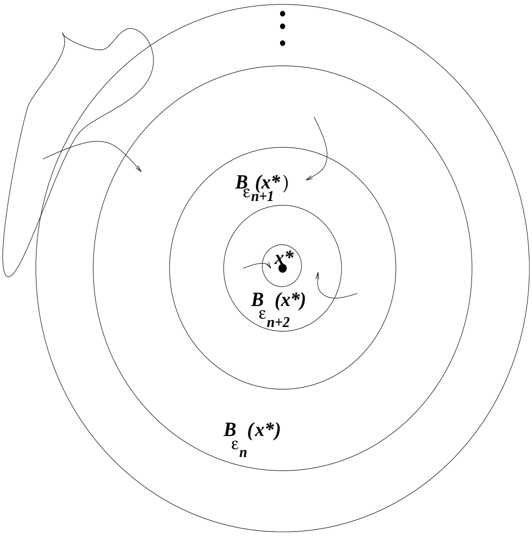

FIG. 5. *The closed loop system is supposed to move with respect to the sets* K, $\{B_{\varepsilon_n}(x^*)\}_{n=0}^{\infty}$ *in accordance with the arrows.*

such that

$$e^{-t_1 f(*,u_1)} \circ e^{-t_2 f(*,u_2)} \circ \cdots \circ e^{-t_N f(*,u_N)} q = p,$$

where $f(*, u_i)$ denotes the vector field $f(x, u_i)$ $(i = 1, 2, \ldots, N)$.

Consider the family of open sets generated by

$$V(t_1, t_2, \ldots, t_N) = e^{-t_1 f(*,u_1)} \circ e^{-t_2 f(*,u_2)} \circ \cdots \circ e^{-t_N f(*,u_N)} \mathrm{Int}(B_{\varepsilon_2}(x^*)),$$

where $t_1 \geq 0, \ldots, t_N \geq 0, \sum_{i=1}^{N} t_i \leq T$.

Due to Lemma 2

$$K \subset \bigcup_{t_1 \geq 0, \ldots, t_N \geq 0, \sum_{i=1}^{N} t_i \leq T} V(t_1, t_2, \ldots, t_N).$$

But K is a compact set, and hence one can choose a finite number of N-tuples $\{(t_{1j}, t_{2j}, \ldots, t_{Nj})\}_{j=1}^{\nu}$ such that

$$K \subset \bigcup_{j=1}^{\nu} V(t_{1j}, t_{2j}, \ldots, t_{Nj}). \tag{9}$$

The feedback $u_0(x) \in PC(U)$ which steers any point of $K \setminus B_{\varepsilon_2}(x^*)$ into the interior of the set $B_{\varepsilon_1}(x^*) \setminus B_{\varepsilon_2}(x^*)$ can be designed in the following way:

$$u_0(x) = u_N \text{ for } x \in \overline{\bigcup_{0<\tau\leq t_{N1}} V(0, \ldots, \tau)} \setminus B_{\varepsilon_2}(x^*),$$

$$u_0(x) = u_{N-1} \text{ for } x \in \overline{\bigcup_{0<\tau\leq t_{N-1\,1}} V(0, \ldots, \tau, t_{N1})} \setminus \left\{ \overline{\bigcup_{0<\tau\leq t_{N1}} V(0, \ldots, \tau)} \cup B_{\varepsilon_2}(x^*) \right\}$$

and so on until

$$\begin{aligned} u_0(x) = u_1 \text{ for } x \in {} & \overline{\bigcup_{0<\tau\le t_{11}} V(\tau, t_{21}, \dots, t_{N1})} \setminus \Bigg\{ \overline{\bigcup_{0<\tau\le t_{21}} V(0, \tau, \dots, t_{N1})} \\ & \bigcup \left(\overline{\bigcup_{0<\tau\le t_{31}} V(0, 0, \tau, \dots, t_{N1})} \right) \cup \cdots \cup \left(\overline{\bigcup_{0<\tau\le t_{N1}} V(0, \dots, \tau)} \right) \cup B_{\varepsilon_2}(x^*) \Bigg\}. \end{aligned}$$

Thus $u_0(x)$ is defined on the set

$$\begin{aligned} \Xi_1 = \Bigg[& \overline{\left(\bigcup_{0<\tau\le t_{11}} V(\tau, t_{21}, \dots, t_{N1}) \right)} \cup \overline{\left(\bigcup_{0<\tau\le t_{21}} V(0, \tau, \dots, t_{N1}) \right)} \\ & \cup \cdots \cup \overline{\left(\bigcup_{0<\tau\le t_{N1}} V(0, \dots, \tau) \right)} \Bigg] \setminus B_{\varepsilon_2}(x^*). \end{aligned}$$

If $K \setminus B_{\varepsilon_2}(x^*) \subseteq \Xi_1$, then the construction of $u_0(x)$ is completed. Otherwise, there exists $1 \le i \le \nu$ for which

$$V(t_{1i}, t_{2i}, \dots, t_{Ni}) \setminus B_{\varepsilon_2}(x^*) \not\subseteq \Xi_1.$$

We put

$$\begin{aligned} & u_0(x) = u_N \text{ for } x \in \overline{\bigcup_{0<\tau\le t_{Ni}} V(0, \dots, \tau,)} \setminus (\Xi_1 \cup B_{\varepsilon_2}(x^*)), \\ & u_0(x) = u_{N-1} \text{ for } x \in \overline{\bigcup_{0<\tau\le t_{N-1i}} V(0, 0, \dots, \tau, t_{Ni})} \setminus \Bigg\{ \Xi_1 \cup \overline{\left(\bigcup_{0<\tau\le t_{Ni}} V(0, \dots, \tau,) \right)} \\ & \qquad \qquad \cup B_{\varepsilon_2}(x^*) \Bigg\} \\ & \quad \vdots \\ & u_0(x) = u_1 \text{ for } x \in \overline{\bigcup_{0<\tau\le t_{1i}} V(\tau, t_{2i}, \dots, t_{Ni})} \setminus \Bigg\{ \Xi_1 \cup \overline{\left(\bigcup_{0<\tau\le t_{Ni}} V(0, \dots, \tau,) \right)} \\ & \qquad \cup \cdots \cup \overline{\left(\bigcup_{0<\tau\le t_{2i}} V(0, \tau, \dots, t_{Ni}) \right)} \cup B_{\varepsilon_2}(x^*) \Bigg\}. \end{aligned}$$

Thus we have defined $u_0(x)$ on the set

$$\Xi_2 = \left[\overline{\left(\bigcup_{0<\tau\le t_{1i}} V(\tau, \dots, t_{Ni}) \right)} \cup \overline{\left(\bigcup_{0<\tau\le t_{2i}} V(0, \tau, \dots, t_{Ni}) \right)} \cup \cdots \cup \Xi_1 \right] \setminus B_{\varepsilon_2}(x^*).$$

If $K \setminus B_{\varepsilon_2}(x^*) \subseteq \Xi_2$, then $u_0(x) \in PC(U)$ is constructed. Otherwise there exists j such that $j \ne 1, j \ne i$, and $V(t_{1j}, \dots, t_{Nj}) \setminus B_{\varepsilon_2}(x^*) \not\subseteq \Xi_2$. We can define the feedback

$u_0(x)$ on the set

$$\Xi_3 = \left[\overline{\left(\bigcup_{0<\tau\le t_{1j}} V(\tau,\dots,t_{Nj}) \right)} \cup \overline{\left(\bigcup_{0<\tau\le t_{2j}} V(0,\tau,\dots,t_{Nj}) \right)} \cup \dots \cup \Xi_2 \right] \setminus B_{\varepsilon_2}(x^*)$$

in the same way as it has been done on the set Ξ_2.

The existence of a natural number μ such that $K \setminus B_{\varepsilon_2}(x^*) \subseteq \Xi_\mu$ follows from (9). Thus the construction of $u_0(x)$ is completed after a finite number of steps. Let Λ_0 be the domain where $u_0(x)$ is defined. By construction, if a trajectory of the system closed by $u_0(x)$ starts at a point of Λ_0, then it will reach the set $B_{\varepsilon_1}(x^*) \setminus \mathrm{Int}(B_{\varepsilon_2}(x^*))$ in a finite time.

The set $B_{\varepsilon_1}(x^*) \setminus \mathrm{Int}(B_{\varepsilon_2}(x^*))$ is compact, and therefore we can employ the method used to construct $u_0(x)$ for designing $u_1(x) \in PC(U)$ which steers any point from $B_{\varepsilon_1}(x^*) \setminus \mathrm{Int}(B_{\varepsilon_2}x^*))$ into $\mathrm{Int}(B_{\varepsilon_2}(x^*)) \setminus B_{\varepsilon_3}(x^*)$. We denote by Λ_1 the domain where $u_1(x)$ is defined. Since (x^*, u^*) is Liapunov asymptotically stable, one can construct $u_1(x) \in PC(U)$ so that $\Lambda_1 \subset B_{\varepsilon_0}(x^*)$. Moreover, if a trajectory of the system closed by $u_1(x)$ starts at a point of Λ_1, then it will reach the set $B_{\varepsilon_2}(x^*) \setminus \mathrm{Int}(B_{\varepsilon_3}(x^*))$ in finite time.

We proceed in this way and obtain for each $n = 1, 2, 3, \dots$ the feedback $u_n(x) \in PC(U)$ defined on $\Lambda_n \subset B_{\varepsilon_{n-1}}(x^*)$ and $B_{\varepsilon_n}(x^*) \setminus \mathrm{Int}(B_{\varepsilon_{n+1}}(x^*)) \subset \Lambda_n$. The feedback $u_n(x)$ steers the system from any state in Λ_n into $\mathrm{Int}(B_{\varepsilon_{n+1}}(x^*)) \setminus B_{\varepsilon_{n+2}}(x^*)$.

Hence the function $u(x) \in PC(U)$ which stabilizes $\dot{x} = f(x, u)$ at x^* over the compact set K can be defined as

$$\lim_{n\to\infty} w_n(x) = u(x),$$

where $w_n(x)$ is given by

$$\begin{aligned} w_n(x) &= u_n(x) \quad \text{for } x \in \Lambda_n, \\ w_n(x) &= u_{n-1}(x) \quad \text{for } x \in \Lambda_{n-1} \setminus \Lambda_n, \\ &\vdots \\ w_n(x) &= u_0(x) \quad \text{for } x \in \Lambda_0 \setminus \bigcup_{j=1}^{n} \Lambda_j, \\ w_n(x) &= u^* \quad \text{for } x \notin \bigcup_{j=0}^{n} \Lambda_j. \end{aligned}$$

The proof is completed. □

Definitions 6, 7, and 8 and Lemma 2 admit natural formulations for discrete-time systems. Moreover, the main ideas in the proof of Theorem 9 are topological and, after minor technical adjustments, they lead us to the following analogue of Theorem 9 for discrete-time systems.

THEOREM 10. *A system $x_{k+1} = f(x_k, u)$ is piecewise-constantly stabilizable at its equilibrium $(x^*, u^*) \in (pr_x - f)^{-1}(0)$ over a compact set K if and only if (x^*, u^*) is Liapunov asymptotically stable and x^* is piecewise-constantly accessible from K.*

The proof of Theorem 9 remains valid for much more general objects than discrete-time systems. The method of the proof outlines a general framework which leads to the synthesis of control systems defined over a finite algebra, in particular Boolean algebra. Such systems very often are called algorithms and arise in numerous software engineering problems. To demonstrate the use of this framework in software engineering the author developed a simple game called Corners. (The Java version of Corners is posted at http://lagrange.la.asu.edu/docs/Corners.) The analysis of algorithms from the point of view of a control theorist is beyond the scope of this paper. Here we present only some examples of the synthesis of piecewise constant stabilizers.

Although in the next example the construction of the piecewise-constant feedback seems completely ad hoc, it contains an effective recipe which, if combined with topological methods developed in [10], leads us to an effective stabilizer synthesis procedure for two-dimensional affine nonlinear systems.

Example 3. Consider the linear system

$$\begin{aligned} \dot{x}_1 &= x_2, \\ \dot{x}_2 &= u, \end{aligned} \tag{10}$$

where $(x_1, x_2) \in \mathbf{R}^2$ and $u \in \mathbf{R}$. System (10) is continuously stabilizable at the origin by a linear feedback. Hence by Theorem 9 it is stabilizable by a piecewise-constant feedback as well. We look for a piecewise-constant feedback stabilizer having the following form:

$$u(x) = -k_1 \cdot \theta(x_1) - k_2 \cdot \theta(x_2) \quad \text{for } x \neq 0 \tag{11}$$

and

$$u(0) = 0,$$

where $\theta(\tau)$ is the function defined as

$$\theta(\tau) = \begin{cases} -1 & : \quad \tau < 0, \\ 1 & : \quad \tau \geq 0. \end{cases} \tag{12}$$

If the real numbers $k_1,\ k_2$ satisfy the inequality

$$k_1 > k_2 > 0,$$

then the feedback (11) globally stabilizes the system (10) at the origin. Indeed, one can show that the function

$$V(x_1, x_2) = k_1 \cdot \mid x_1 \mid + \frac{x_2^2}{2}$$

is monotonically decreasing along the trajectories of the system (10) closed by the feedback (11).

Example 3 combined with the topological methods from [10] allows us to construct a piecewise-constant stabilizer for any controllable affine nonlinear system

$$\dot{x}_1 = f_1(x_1, x_2) + b_1(x_1, x_2) \cdot u,$$
$$\dot{x}_2 = f_2(x_1, x_2) + b_2(x_1, x_2) \cdot u$$

satisfying the following conditions:

(i) $f_1(x_1, x_2), f_2(x_1, x_2), b_1(x_1, x_2), b_2(x_1, x_2)$ are continuously differentiable functions.

(ii)

$$\left(b_1(x_1,x_2)\cdot\frac{\partial}{\partial x_1}\varphi(x)+b_2(x_1,x_2)\cdot\frac{\partial}{\partial x_2}\varphi(x)\right)|_{x\in\varphi^{-1}(0)}\neq 0,$$

where

$$\varphi(x)=f_1(x_1,x_2)b_2(x_1,x_2)-f_2(x_1,x_2)b_1(x_1,x_2)$$

and

$$\varphi^{-1}(0)=\{x\in\mathbf{R}^2:\ \ \varphi(x)=0\}.$$

Example 4. In this example the system

$$\begin{array}{rcl}\dot{x}_1 & = & x_2,\\ \dot{x}_2 & = & a(x)+b(x)\cdot u\end{array}\tag{13}$$

is globally stabilized at the origin by means of a piecewise-constant feedback. We assume that $\forall x\in\mathbf{R}^2$ the functions $a(x)$ and $b(x)$ satisfy the following inequalities:

$$\mid a(x)\mid\leq a_+,$$
$$0<b_-\leq b(x)\leq b_+.$$

It is known [10] that system (13) can be stabilized by a time-dependent continuous feedback. Hence by Theorem 9 there exists a piecewise-constant stabilizer for (13). Choose positive real numbers α, β so that

$$\alpha\cdot b_->\beta\cdot b_+>0$$

and

$$\alpha\cdot b_->2\cdot a_++(2\cdot b_++a_+)\cdot\beta.$$

Then the piecewise-constant feedback

$$u(x)=\left\{\begin{array}{rcl}-k_1\theta(x_1)-k_2\theta(x_2) & : & x\neq 0,\\ -\frac{a(0)}{b(0)} & : & x=0,\end{array}\right.$$

with $\theta(\tau)$ being defined in (12) and

$$k_1=\frac{\alpha+\beta}{2},\qquad k_2=\frac{\alpha-\beta}{2},$$

globally stabilizes the system at the origin.

Indeed, the function

$$V(x)=\frac{\alpha\cdot b_--a_+\cdot\beta}{2}\mid x_1\mid+\frac{x_2^2}{2}$$

is monotonically decreasing along the trajectories of the closed loop system, and therefore the origin is globally asymptotically stable.

Using the topological methods based on so-called stable covering (see [10]) one can construct piecewise-constant stabilizers for a generic nonlinear affine system with an equilibrium set having several connected components.

The next example illustrates the use of Theorem 9 in the stabilizability analysis of a nonholonomic system.

Example 5. Consider the system

$$\begin{aligned} \dot{x}_1 &= u, \\ \dot{x}_2 &= v, \\ \dot{x}_3 &= x_1 v - x_2 u. \end{aligned} \tag{14}$$

It is stated in [2] that system (14) is not continuously stabilizable at the origin. Our goal is to analyze its piecewise-constant stabilizability.

Let us show that the origin is Liapunov asymptotically stable. Indeed, for any point $P = (x_1, x_2, x_3) \in \mathrm{R}^3$ the piecewise-constant control

$$\begin{aligned}
(u(t), v(t)) &= (-x_1, -x_2) \quad \text{for } t \in [0,1], \\
(u(t), v(t)) &= \left(\sqrt{\frac{|x_3|}{2}}, 0\right) \quad \text{for } t \in [1,2], \\
(u(t), v(t)) &= \left(0, -sign(x_3) \cdot \sqrt{\frac{|x_3|}{2}}\right) \quad \text{for } t \in [2,3], \\
(u(t), v(t)) &= \left(-\sqrt{\frac{|x_3|}{2}}, 0\right) \quad \text{for } t \in [3,4], \\
(u(t), v(t)) &= \left(0, sign(x_3) \cdot \sqrt{\frac{|x_3|}{2}}\right) \quad \text{for } t \in [4,5]
\end{aligned}$$

steers system (14) from the point P into the origin. First, this control moves the system from P into $(0, 0, x_3)$ along the straight line. Then $(x_1(t), x_2(t))$ traces the boundary of the square with the side of length $\sqrt{|x_3|/2}$ and moves system (14) from $(0, 0, x_3)$ into the origin.

Thus the origin is Liapunov asymptotically stable for system (14) and all conditions of Theorem 9 are satisfied. Hence system (14) is piecewise-constantly stabilizable at the origin over any compact set from R^3.

The next example illustrates the use of Theorem 10.

Example 6. Consider a discrete-time system of the form

$$\begin{aligned} x_1(k+1) &= \tfrac{1}{2}(1 + \sin(x_1^2(k) + u^2(k)))x_1(k), \\ x_2(k+1) &= 2 \cdot x_2(k) - u(k). \end{aligned} \tag{15}$$

Let us analyze stabilizability of system (15) at the origin. By Theorem 8 system (15) is not continuously stabilizable at the origin. On the other hand, for any x_1 one can find $\bar{u}$ such that $\sin(x_1^2 + \bar{u}^2) = -1$. Then on the next step $u = 2x_2$ will steer system (15) to the origin. Thus all conditions of Theorem 10 are satisfied and system (15) is piecewise-constantly stabilizable at the origin over any compact set from R^2.

4. Conclusion. This paper presents geometrical illustrations of the topological necessary conditions of continuous stabilization obtained in [10], [11]. It follows from these conditions that many systems are not stabilizable by continuous stationary feedbacks. Since in the majority of control applications one needs to implement a control system with the help of digital processors, it is natural to design piecewise-constant stabilizing feedbacks. We have proved the criterion of stabilization in the class of piecewise-constant feedbacks and discussed their synthesis for affine nonlinear two-dimensional systems.

It follows from Theorem 9 that any system that is stabilizable by a continuous feedback $u = u(t, x)$ also can be stabilized by a piecewise-constant feedback of the form $u = u(x)$. Moreover, the proof of Theorem 9 leads to the synthesis procedure for stabilizing feedbacks subjected to state and control constraints.

The approach proposed in this paper can be applied to deal with a wide variety of control objects that are much more general than those described by differential or discrete-time equations. For example, one can use this approach for software development projects. In fact, we already have tested the methodology provided by the proof of Theorem 9 and have developed a simple computer game. To use this methodology for computer algorithm synthesis one needs to choose some natural topology and then follow the proof of Theorem 9. In a computer game or a program where one needs to minimize some cost function this topology naturally is introduced by this cost function. In general the choice of an appropriate topology raises a number of difficult questions that can serve as topics for further research.

Acknowledgments. The author is grateful to Anton Nikitin for his editorial remarks and for reading the early version of this manuscript. The author is much obliged to anonymous referees for valuable suggestions. Some ideas presented in this paper were generated during (or shortly after) the author's visit to the University of Gent in June 1996. The author would like to thank Professor D. Aeyels for his kind support of this research and his hospitality.

BIFURCATION STABILIZATION WITH LOCAL OUTPUT FEEDBACK[*]

GUOXIANG GU[†], XIANG CHEN[‡], ANDREW G. SPARKS[§], AND SIVA S. BANDA[§]

Abstract. Local output feedback stabilization with smooth nonlinear controllers is studied for parameterized nonlinear systems for which the linearized system possesses either a simple zero eigenvalue or a pair of imaginary eigenvalues and the bifurcated solution is unstable at the critical value of the parameter. It is assumed that the unstable mode corresponding to the critical eigenvalue of the linearized system is not linearly controllable. Results are established for bifurcation stabilization using output feedback where the critical mode can be either linearly observable or linearly unobservable. The stabilizability conditions are characterized in explicit forms that can be used to synthesize stabilizing controllers. The results obtained in this paper are applied to rotating stall control for axial flow compressors as an application example.

Key words. nonlinear systems, bifurcations, projection method, bifurcation stabilization, linear controllability/observability

1. Introduction.

Stabilization of nonlinear control systems with smooth state feedback control has been studied by a number of people [4, 2, 3, 9, 19]. An interesting situation for nonlinear stabilization is the case when the linearized system has uncontrollable modes on the imaginary axis with the rest of the modes stable. This is the so-called *critical case* for which linearization theory is inadequate. It becomes more intricate if the underlying nonlinear system involves a real-valued parameter. At critical values of the parameter, the linearized system has unstable modes corresponding to eigenvalues on the imaginary axis and additional equilibrium solutions will be born. The bifurcated solutions may or may not be stable. The instability of the bifurcated solution may cause a "hysteresis loop" in bifurcation diagrams for both subcritical pitchfork bifurcations and Hopf bifurcations [11] and induce undesirable physical phenomena. This is manifested by rotating stall in axial flow compressors [1, 17, 18], which has received great attention for the past several years [5, 6, 7, 15, 16, 20]. Thus bifurcation stabilization is an important topic in nonlinear control.

Abed and Fu studied bifurcation stabilization using smooth local state feedback control [2, 3]. For a Hopf bifurcation, stabilization conditions were obtained for both the case where the critical modes of the linearized system are controllable and uncontrollable. For a stationary bifurcation, stabilization conditions were derived for the case where the critical mode of the linearized system is controllable. The uncontrollable case was investigated in [13], where normal forms of the nonlinear system are used. In this paper we study bifurcation stabilization via local output feedback

control laws that are smooth. Throughout the paper it is assumed that the critical mode of the linearized system is uncontrollable. Moreover only output measurement is available for feedback. It should be clear that measurement of all state variables is unrealistic in practice, especially when the underlying nonlinear system has a high order. Often some of state variables are more expensive or more difficult to measure than others. Hence the bifurcation stabilization problem studied in this paper has more engineering significance.

Two stabilization issues will be investigated. The first one is concerned with bifurcation stabilization where the critical mode of the linearized system is unobservable through linearized output measurement. Stabilizability conditions are established for both stationary bifurcations and Hopf bifurcations. Roughly speaking, it is shown that nonlinear controllers do not offer any advantage over the linear ones for bifurcation stabilization. Stabilizing controllers, if they exist, can be taken as linear ones. The second one is concerned with bifurcation stabilization where the critical mode of the linearized system is observable through linearized output measurement that includes state feedback as a special case. Stabilizability conditions are also obtained in this case. It is shown that linear controllers are adequate for stabilization of transcritical bifurcations and quadratic controllers are adequate for stabilization of pitchfork and Hopf bifurcations, respectively. It should be pointed out that the stabilization conditions obtained in this paper are characterized in an explicit form that provides synthesis procedures for design of stabilizing controllers, if they exist. Rotating stall control for axial flow compressors will be used as an application example to demonstrate the use of the stabilization results established in this paper.

The notation in this paper is standard. The collections of real and complex numbers are denoted by $\mathbf{R}$ and $\mathbf{C}$, respectively. If $c \in \mathbf{C}$, its complex conjugate is denoted by $\bar{c}$. The collection of real and complex vectors with size n are denoted by $\mathbf{R}^n$ and $\mathbf{C}^n$, respectively. A matrix M of size $p \times m$ can be viewed as a linear map from $\mathbf{C}^m$ to $\mathbf{C}^p$, and its transpose is denoted by M^T. For $m = p = n$, M is said to be stable if all its eigenvalues are in the open left half-plane. Notions such as linear controllability and linear observability can be found in [12].

2. Local bifurcation stability and projection method.

This section considers the stability issue for a bifurcated system using the projection method developed in [11]. The system under consideration is the following nth-order parametrized nonlinear system:

$$(1) \qquad \dot{x} = f(\gamma, x), \qquad f(\gamma, x_e) = 0 \;\; \forall\, \gamma \in (-\delta,\ \delta),$$

where $x \in \mathbf{R}^n$, γ is a real-valued parameter, and $\delta > 0$ is a sufficiently small real number. Without loss of generality, we can assume $x_e = 0$, i.e., $f(\gamma, 0) = 0$ in a small neighborhood of $\gamma = 0$, which is called the zero solution. The linearized system at the zero solution is given by

$$(2) \qquad \dot{x}_0 = L(\gamma)x_0, \qquad L(\gamma) = \left.\frac{df(\gamma, x)}{dx}\right|_{x=x_e=0}.$$

If $L(0)$ has one or more eigenvalues on the imaginary axis, then additional nonzero equilibrium solutions or bifurcated solutions will be born at $\gamma = 0$. It is assumed that $f(\cdot,\cdot)$ is sufficiently smooth such that the bifurcated solution $x_e \neq 0$, satisfying $f(\gamma, x_e) = 0$, is a smooth function of γ.

DEFINITION 2.1. *The nonlinear system in* (1) *is said to have local bifurcation stability if the bifurcated solution is locally asymptotically stable for sufficiently small* γ.

Two different types of bifurcations will be considered in this paper, and the determination of their local stability will be discussed in the following two subsections.

2.1. Local stability for stationary bifurcations. For stationary bifurcations, it is assumed that $L(\gamma)$ possesses a simple eigenvalue $\lambda(\gamma)$, depending smoothly on γ, satisfying

$$\lambda(0) = 0, \qquad \lambda'(0) = \frac{d\lambda}{d\gamma}(0) \neq 0, \tag{3}$$

while all other eigenvalues are stable in a neighborhood of $\gamma = 0$. It implies that the zero solution changes its stability as γ crosses 0. For instance, $\lambda'(0) < 0$ implies that the zero solution is locally stable for $\gamma > 0$ and becomes unstable for $\gamma < 0$. Furthermore additional equilibria $x_e \neq 0$ born at $\gamma = 0$ are smooth functions of γ by the smoothness of $f(\cdot,\cdot)$. Such bifurcated solutions are independent of time t and called stationary bifurcation. Thus $\gamma = 0$ is the critical value of the parameter and $\lambda(\gamma)$ is called the critical eigenvalue. The nonlinear system (1) at $\gamma = 0$ is referred to as the critical system. The bifurcated solution of the nonlinear system born at $\gamma = 0$ may or may not be locally stable. For simplicity, only double points [11] will be considered in this paper. A useful tool to determine local stability of the bifurcated solution and of the critical system is the projection method developed in [11] and advocated in [2, 11].

Let ℓ and r denote the left row and right column eigenvectors of $L(0)$, corresponding to the critical eigenvalue $\lambda(0) = 0$. Then $\ell r = 1$ by suitable normalization. Denote $\varepsilon = \ell x_e$, where $x_e \neq 0$ satisfying $f(\gamma, x_e) = 0$ is also an equilibrium solution of (1), or bifurcated solution in a small neighborhood of $\gamma = 0$. Then by [11] there exists a series expansion

$$\begin{bmatrix} x_e(\varepsilon) \\ \gamma(\varepsilon) \end{bmatrix} = \sum_{k=1}^{\infty} \begin{bmatrix} x_{ek} \\ \gamma_k \end{bmatrix} \varepsilon^k.$$

Since $f(\gamma, x)$ is sufficiently smooth, there exists a Taylor expansion near the origin of $\mathbf{R}^n$ of the form

$$\dot{x} = f(\gamma, x) = L(\gamma)x + Q(\gamma)[x, x] + C(\gamma)[x, x, x] + \cdots, \tag{4}$$

where $L(\gamma)x$, $Q(\gamma)[x, x]$, and $C(\gamma)[x, x, x]$ are vector-valued linear, quadratic, and cubic terms of $f(\gamma, x)$, respectively, having symmetric form in each of their entries, and can each be expanded into

$$L(\gamma)x = L_0 x + \gamma L_1 x + \gamma^2 L_2 x + \cdots, \qquad Q(\gamma)[x, x] = Q_0[x, x] + \gamma Q_1(x, x) + \cdots,$$

and $C(\gamma)[x, x, x] = C_0[x, x, x] + \gamma C_1[x, x, x] + \cdots$, where L_0, L_1, and L_2 are $n \times n$ constant matrices.

Let $\tilde{\lambda}(\gamma)$ be the critical eigenvalue of the linearized system matrix at the new (bifurcated) equilibrium close to the origin. Then $\tilde{\lambda}(0) = \lambda(0) = 0$ at $\gamma = 0$. There exists a series expansion [11]

$$\tilde{\lambda}(\varepsilon) = \sum_{i=1}^{\infty} \tilde{\lambda}_i \varepsilon^i = \tilde{\lambda}_1 \varepsilon + \tilde{\lambda}_2 \varepsilon^2 + \cdots.$$

The computation of the first two coefficients of $\tilde{\lambda}$ can proceed as follows [11, 2]:

- Step 1: Calculate $\lambda'(0) = \ell L_1 r$, where λ is a function of γ.
- Step 2: Set $x_{e1} = r$ and calculate $\gamma_1 = -\ell Q_0[r,r]/\lambda'(0)$.
- Step 3: Compute x_{e2} from equations $\ell x_{e2} = 0$ and $L_0 x_{e2} = -Q_0[r,r]$, and γ_2 from
$$\gamma_2 = -\frac{1}{\lambda'(0)}\left(\gamma_1 \ell L_1 x_{e2} + \gamma_1^2 \ell L_2 r + 2\ell Q_0[r,x_{e2}] + \gamma_1 \ell Q_1[r,r] + \ell C_0[r,r,r]\right).$$
- Step 4: Set $\tilde{\lambda}_1 = -\gamma_1\lambda'(0)$ and $\tilde{\lambda}_2 = -2\gamma_2\lambda'(0)$.

Local stability of a stationary bifurcation is given by the following lemma [3].

LEMMA 2.2. *Suppose that all eigenvalues of L_0 are stable except one critical eigenvalue. For the case $\gamma_1 \neq 0$, the branch of the bifurcated equilibrium solution is locally stable for γ sufficiently close to* 0 *if $\ell Q_0[r,r]\varepsilon < 0$ and unstable if $\ell Q_0[r,r]\varepsilon > 0$. For the case $\gamma_1 = 0$, the bifurcated solution is locally stable for γ sufficiently close to* 0 *if $\tilde{\lambda}_2 < 0$, and unstable if $\tilde{\lambda}_2 > 0$, where*
$$\tilde{\lambda}_2 = 2\ell\left(2Q_0[r,x_{e2}] + C_0[r,r,r]\right), \qquad x_{e2} = -(\ell^T\ell + L_0^T L_0)^{-1} L_0^T Q_0[r,r].$$

It should be clear that the local bifurcation for the case $\gamma_1 \neq 0$ is transcritical [21]. Thus the branch of the bifurcated solution at $\varepsilon > 0$ has the opposite stability property as the one at $\varepsilon < 0$. We are interested in the stabilization of the transcritical bifurcation for the branch of $\varepsilon > 0$, with no loss of generality. On the other hand, the local bifurcation for the case $\gamma_1 = 0$ and $\gamma_2 \neq 0$ is pitchfork [21], where both branches of the bifurcated solution share the same stability property.

2.2. Local stability for Hopf bifurcations. For a Hopf bifurcation, it is assumed that $L(\gamma)$ possesses a pair of complex eigenvalues $\lambda(\gamma), \bar{\lambda}(\gamma)$, dependent smoothly on γ, while all other eigenvalues are stable in a neighborhood of $\gamma = 0$. Denote $\lambda(\gamma) = \alpha(\gamma) + j\beta(\gamma)$ with $\alpha(\gamma), \beta(\gamma)$ real, and $j = \sqrt{-1}$ imaginary. It is assumed that

$$(5) \qquad \alpha(0) = 0, \qquad \beta(0) = \omega_c \neq 0, \qquad \alpha'(0) = \frac{d\alpha}{d\gamma}(0) \neq 0.$$

Thus $\lambda(\gamma)$ is a critical eigenvalue and so is its conjugate. It implies that the zero solution changes its stability as γ crosses 0. For instance $\alpha'(0) > 0$ implies that the zero solution is locally stable for $\gamma > 0$ and becomes unstable for $\gamma > 0$. Furthermore the Hopf bifurcation theorem asserts the existence of a one-parameter family $\{p_\varepsilon\}$, where $0 < \varepsilon \leq \varepsilon_0$, of nonconstant periodic solutions of (1) emerging from the zero solution at $\gamma = 0$. This is a nonstationary bifurcation. The positive real number ε is a measure of the amplitude of the periodic solution and ε_0 is sufficiently small. The periodic solutions $p_\varepsilon(t)$ have period near $2\pi/\omega_c$ and occur for parameter values γ given by a smooth function $\gamma(\varepsilon)$. Exactly one of the characteristic exponents of p_ε is near zero and is given by

$$(6) \qquad \tilde{\lambda}(\varepsilon) = \tilde{\lambda}_2\varepsilon^2 + \tilde{\lambda}_4\varepsilon^4 + \cdots = \sum_{i=1}^{\infty} \tilde{\lambda}_{2i}\varepsilon^{2i}.$$

Local stability of a Hopf bifurcation is hinged to the first nonzero coefficient of $\tilde{\lambda}(\varepsilon)$, denoted by $\tilde{\lambda}_{2N}$, $N \geq 1$. Generically $N = 1$.

Let the Taylor series of $f(\gamma, x)$ be of the form in (4) where $L_0 = L(0)$. An algorithm to compute $\tilde{\lambda}_2$ is quoted from [2]. See also [10].

- Step 1: Compute left row eigenvector ℓ and right column eigenvector r of L_0 corresponding to the critical eigenvalue of $\lambda(0) = j\omega_c$, normalized by setting $\ell r = 1$.
- Step 2: Solve column vectors μ and ν from the equations

$$-L_0\mu = \frac{1}{2}Q_0[r, \bar{r}], \qquad (2j\omega_c I - L_0)\nu = \frac{1}{2}Q_0[r, r], \qquad j = \sqrt{-1}.$$

- Step 3: The coefficient $\tilde{\lambda}_2$ is given by

$$\tilde{\lambda}_2 = 2\mathrm{Re}\left\{2\ell Q_0[r, \mu] + \ell Q_0[\bar{r}, \nu] + \frac{3}{4}\ell C_0[r, r, \bar{r}]\right\}.$$

Local stability of a Hopf bifurcation is given by the following lemma [3].

LEMMA 2.3. *Suppose all eigenvalues of L_0 are stable in a neighborhood of $\gamma = 0$ except the critical pair of complex eigenvalues. Then the Hopf bifurcation is stable if $\tilde{\lambda}_2 < 0$ and unstable if $\tilde{\lambda}_2 > 0$.*

3. Output feedback stabilization for stationary bifurcations.

We address the feedback stabilization problem for stationary bifurcations. The nonlinear control system under consideration has the form

$$\dot{x} = f(\gamma, x) + g(x, u), \qquad y = h(x), \qquad x \in \mathbf{R}^n, \tag{7}$$

where $f(\gamma, x)$ is the same as in (4), and $g(\cdot,\cdot)$ and $h(\cdot)$ are also smooth functions satisfying

$$g(x, 0) = 0 \ \forall x, \qquad h(0) = 0. \tag{8}$$

It is assumed that $u \in \mathbf{R}$, and $y \in \mathbf{R}^p$ with $p \geq 1$. Thus the nonlinear system (7) has only one control input, but may have more than one output measurement. Its Taylor series expansion is given by

$$\begin{aligned} \dot{x} = {} & L_0 x + \gamma L_1 x + \gamma^2 L_2 x + B_1 u + u\tilde{L}_1 x + Q_0[x, x] + B_2 u^2 + u\tilde{L}_{12}[x, x] \\ & + \gamma Q_1[x, x] + u^2\tilde{L}_2 x + u^2\tilde{Q}_1[x, x] + C_0[x, x, x] + B_3 u^3 + \cdots, \end{aligned} \tag{9}$$

where $\tilde{L}_1 x$ and $\tilde{Q}_1[x, x]$ are the linear and quadratic terms for the linear control component of $g(x, u)$, $\tilde{L}_2 x$ is the linear term for the quadratic control component and $\tilde{L}_{12}[x, x]$ is the quadratic term for the linear control component of $g(x, u)$, and B_1, B_2, and B_3 are the coefficient vectors of u, u^2, and u^3, respectively. It is assumed that L_0 has only one zero eigenvalue with the rest of the eigenvalues stable, and that the bifurcated solution born at $\gamma = 0$ is not locally stable. The assumption on stability of the nonzero eigenvalues of L_0 has no loss of generality. If some of the nonzero eigenvalues of L_0 are unstable, then any linear control method, such as pole placement [12], can be employed to stabilize those unstable modes corresponding to nonzero eigenvalues. It is the unstable mode corresponding to the critical eigenvalue $\lambda(0) = 0$ that renders linear control methods inadequate because of bifurcations.

We seek a smooth local output feedback control law of the form

$$u = K(y) = K_L y + K_Q[y, y] + K_C[y, y, y] + \cdots, \tag{10}$$

that stabilizes the bifurcated system (i.e., the closed-loop system admits bifurcation stability; see Definition 2.1), where $K_Q[\cdot,\cdot]$ and $K_C[\cdot,\cdot,\cdot]$ are the quadratic and cubic terms of $K(y)$, respectively, satisfying $K_Q[0,0] = K_C[0,0,0] = 0$. The output has a Taylor series expansion

$$y = h(x) = H_1x + H_2[x,x] + H_3[x,x,x] + \cdots, \tag{11}$$

where $H_1x, H_2[x,x]$, and $H_3[x,x,x]$ are the linear, quadratic, and cubic terms of $h(x)$, respectively, satisfying $H_2[0,0] = H_3[0,0,0] = 0$. Without loss of generality, it is assumed that linear, quadratic, and cubic terms of the feedback control law in (10) are of the form

$$\begin{aligned} K_Ly = K_1h(x), \qquad K_Q[y,y] &= K_2\tilde{H}_2[x,x] + K_2\tilde{H}_3[x,x,x] + \cdots, \\ K_C[y,y,y] &= K_3\tilde{\tilde{H}}_3[x,x,x] + \cdots, \end{aligned} \tag{12}$$

with K_1, K_2, and K_3 some constant matrices, and $\tilde{H}_2[0,0] = \tilde{H}_3[0,0,0] = \tilde{\tilde{H}}_3[0,0,0] = 0 \in \mathbf{R}^p$. Substituting the control law into (9), we get the closed-loop system equation in series form:

$$\dot{x} = L_0^*x + \gamma L_1^*x + Q_0^*[x,x] + \gamma^2 L_2^*x + \gamma Q_1^*[x,x] + C_0^*[x,x,x] + \cdots, \tag{13}$$

where the linear, quadratic, and cubic terms are given by

$$\begin{aligned} L_0^* = L_0 + B_1K_1H_1, \qquad L_1^* = L_1, \qquad L_2^* &= L_2, \qquad Q_1^*[x,x] = Q_1[x,x], \\ Q_0^*[x,x] &= Q_0[x,x] + B_1\left(K_1H_2[x,x] + K_2\tilde{H}_2[x,x]\right) + K_1H_1x\tilde{L}_1x + B_2(K_1H_1x)^2, \\ C_0^*[x,x,x] &= C_0[x,x,x] + \left(K_1H_2[x,x] + K_2\tilde{H}_2[x,x]\right)\tilde{L}_1x \\ &\quad + 2B_2K_1H_1x\left(K_1H_2[x,x] + K_2\tilde{H}_2[x,x]\right) \\ &\quad + (K_1H_1x)^2\tilde{L}_2x + B_1\left(K_1H_3[x,x,x] + K_2\tilde{H}_3[x,x,x] + K_3\tilde{\tilde{H}}_3[x,x,x]\right) \\ &\quad + K_1H_1x\tilde{L}_{12}[x,x] + K_1H_1x\tilde{Q}_1[x,x] + B_3(K_1H_1x)^3. \end{aligned}$$

Abed and Fu studied the same problem in [3] for the case of state feedback where the critical mode of the linearized system at $\gamma = 0$ is controllable. We will consider the case of output feedback where the critical mode of L_0 is linearly uncontrollable. It should be clear that, in practice, measurement of all state variables is unrealistic. Often only part of the state variables or a nonlinear function of part of the state variables is measurable. Under this circumstance, the critical mode of the linearized system may or may not be observable based on linearized output measurements. Hence the problem considered in this paper has more engineering significance than that of [3]. Because $y \in \mathbf{R}^p$ with $p \geq 1$, our results are also applicable to state feedback by taking $H_1 = I$ and $H_2 = H_3 = \cdots = 0$, which yields $y = x$. We will establish stabilizability conditions for bifurcated systems where the bifurcated solution is unstable near $\gamma = 0$ in the following two subsections.

3.1. Unobservable critical mode. Consider first when the critical mode of the linearized system corresponding to the zero eigenvalue at $\gamma = 0$ is not observable through the linearized output measurement H_1x. Note that by assumption the eigenvalue $\lambda(0) = 0$ is invariant under feedback control because of both uncontrollability and unobservability of the critical mode. Thus L_0^* also possesses the critical zero eigenvalue as L_0. Denote ℓ^* and r^* as the left row and right column eigenvectors for

L_0^* corresponding to the critical eigenvalue. Then it is easy to see that $\ell^* = \ell$ and $r^* = r$ again due to the uncontrollability and unobservability of the critical eigenvalue. This can be seen from the Popov, Belevitch, and Hautus (PBH) test [12]. Denote $\tilde{\lambda}^*$ as the critical eigenvalue of the linearized feedback system at the bifurcated solution. It is a function of $\varepsilon = \ell^* x_e = \ell x_e$ in the form of

$$\tilde{\lambda}^*(\varepsilon) = \tilde{\lambda}_1^*\varepsilon + \tilde{\lambda}_2^*\varepsilon^2 + \cdots . \tag{14}$$

Clearly the local feedback controller in (10) does not change the zero solution. Denote $L^*(\gamma)$ as the linearized system matrix for the closed-loop system at the zero solution. Its critical eigenvalue is denoted by $\lambda^*(\gamma)$. Since $L_1^* = L_1$,

$$\frac{d\lambda^*}{d\gamma}(0) = \lambda'(0) = \frac{d\lambda}{d\gamma}(0) \neq 0$$

is also invariant under feedback control. It follows that the bifurcated solution $x_e \equiv 0$ of the closed-loop system changes its stability and bifurcates at $\gamma = 0$ as well. The problem is whether or not the bifurcated solution can be stabilized with output feedback control. The next result is negative for the transcritical bifurcation.

THEOREM 3.1. *Consider the nonlinear control system* (9) *with output feedback control law* (10). *Suppose that the critical mode of* L_0 *is not linearly observable. Then for the case* $\tilde{\lambda}_1 > 0$, *there does not exist a feedback control law* $u = K(y)$ *that stabilizes the branch of the bifurcated solution at* $\varepsilon > 0$, *and* $\tilde{\lambda}_1^* = \tilde{\lambda}_1$ *is invariant under output feedback control in* (10).

Proof. Note that with the smooth feedback controller in (10), the closed-loop system is in the form of (13). The uncontrollability and unobservability of the critical mode for the linearized system at $\gamma = 0$ imply that both $\ell B_1 = 0$ and $H_1 r = 0$ by the PBH test [12]. Hence applying Lemma 2.2 to the nonlinear system in (13) gives the first coefficient of the critical eigenvalue for the branch of the bifurcated solution at $\varepsilon > 0$:

$$\begin{aligned}\tilde{\lambda}_1^* = \ell Q_0^*[r,r] &= \ell Q_0[r,r] + \ell B_1\left(K_1 H_2[r,r] + K_2\tilde{H}_2[r,r]\right)\\ &+ \ell K_1 H_1 r\tilde{L}_1 r + \ell B_2(K_1 H_1 r)^2 = \ell Q_0[r,r] = \tilde{\lambda}_1.\end{aligned}$$

It follows that the sign of $\tilde{\lambda}_1^*$ is the same as that of $\tilde{\lambda}_1$, which means we cannot alter the sign by feedback controller in (10). □

Although the stability property of a transcritical bifurcation with an unobservable critical mode cannot be altered by output feedback, the situation for pitchfork bifurcation is quite different. We have the following result.

THEOREM 3.2. *Consider the nonlinear control system* (9) *with output feedback control law* (10) *under the same hypothesis as in Theorem* 3.1. *For simplicity, assume in addition that* $\tilde{H}_2[r,r] = 0$. *Then for the case* $\tilde{\lambda}_1 = 0$, *there exists a smooth feedback control law* $u = K(y)$ *as in* (10) *that ensures* $\tilde{\lambda}_2^* < 0$, *i.e., stabilizes the bifurcated solutions, if and only if there exists a linear feedback control law* $u = K_1 y$ *that stabilizes the bifurcated solution. Moreover there exists a nonsingular matrix* $T \in \mathbf{R}^{n\times n}$ *such that*

$$TL_0T^{-1} = \begin{bmatrix} L_{00} & 0 \\ 0 & 0 \end{bmatrix}, \quad TB_1 = \begin{bmatrix} B_{11} \\ 0 \end{bmatrix}, \qquad \begin{bmatrix} H_1 \\ \ell \end{bmatrix} T^{-1} = \begin{bmatrix} H_{11} & 0 \\ 0 & 1 \end{bmatrix}, \tag{15}$$

where $L_{00} \in \mathbf{R}^{(n-1)\times(n-1)}$, $B_{11} \in \mathbf{R}^{(n-1)\times 1}$, *and* $H_{11} \in \mathbf{R}^{p\times(n-1)}$. *Denote* I_{n-1} *as* *the identity matrix of size* $(n-1)\times(n-1)$, *and*

$$\rho = 4\ell Q_0[r, (\ell^T\ell + L_0^T L_0)^{-1}L_0^T B_1] - 2\ell\tilde{L}_1 r, \qquad \beta = \begin{bmatrix} I_{n-1} & 0 \end{bmatrix} TQ_0[r,r]. \tag{16}$$

Then the existence of the stabilizing feedback control law is equivalent to that

$$\tilde{\lambda}_2^* = \tilde{\lambda}_2 + K_1\left(H_{11}L_{00}^{-1}(B_{11}\tilde{\lambda}_2 + \rho\beta) - \rho H_2[r,r]\right) < 0 \tag{17}$$

and that $L_{00} + B_{11}K_1H_{11}$ *is stable for some* $K_1 \neq 0$.

Proof. Let x_{e2} and x_{e2}^* be the unique solutions for

$$\begin{aligned} &\ell x_{e2} = 0, \qquad L_0 x_{e2} = -Q_0[r,r], \qquad \ell x_{e2}^* = 0, \\ &(L_0 + B_1K_1H_1)x_{e2}^* = -Q_0[r,r] - B_1K_1H_2[r,r]. \end{aligned} \tag{18}$$

By the proof of Theorem 3.1, and the condition $\ell B_1 = 0$, $H_1 r = 0$,

$$\begin{aligned} 4\ell Q_0^*[r, x_{e2}^*] &= 2\ell\left(2Q_0[r, x_{e2}^*] + K_1H_1x_{e2}^*\tilde{L}_1 r\right), \\ 2\ell C_0^*[r,r,r] &= 2\ell\left(C_0[r,r,r] + K_1H_2[r,r]\tilde{L}_1 r + K_2\tilde{H}_2[r,r]\tilde{L}_1 r\right). \end{aligned}$$

The formula governing the vector x_{e2}^* as in (18) can be readily verified by noting that $Q_0^*[r,r] = Q_0[r,r] + B_1K_1H_2[r,r]$ due to $\tilde{H}_2[r,r] = 0$, and $H_1 r = 0$. Applying Lemma 2.2 again yields

$$\begin{aligned} \tilde{\lambda}_2^* &= 2\ell\Big(2Q_0[r, x_{e2}^*] + K_1H_1x_{e2}^*\tilde{L}_1 r\Big) + 2\ell\Big(C_0[r,r,r] + K_1H_2[r,r]\tilde{L}_1 r + K_2\tilde{H}_2[r,r]\tilde{L}_1 r\Big) \\ &= \tilde{\lambda}_2 + 4\ell\left(Q_0[r, x_{e2}^*] - Q_0[r, x_{e2}]\right) + 2\ell\left(K_1H_1x_{e2}^* + K_1H_2[r,r] + K_2\tilde{H}_2[r,r]\right)\tilde{L}_1 r \\ &= \tilde{\lambda}_2 - 4\ell Q_0[r, x_{e2} - x_{e2}^*] + 2(\ell\tilde{L}_1 r)K_1\left(H_1x_{e2}^* + H_2[r,r]\right). \end{aligned}$$

It follows that the bifurcated solution is stabilized if and only if there exists $K_1 \neq 0$ such that $\tilde{\lambda}_2^* < 0$ holds and the nonzero eigenvalues of $L_0 + B_1K_1H_1$ lie in the open left half-plane. It remains to be shown that stabilizability of the bifurcated solution is equivalent to the existence of $K_1 \neq 0$ such that (17) holds, plus stability of $L_{00} + B_{11}K_1H_{11}$. From (18), the equations

$$\ell(x_{e2} - x_{e2}^*) = 0, \qquad L_0(x_{e2} - x_{e2}^*) = B_1K_1\left(H_1x_{e2}^* + H_2[r,r]\right)$$

are obtained. Thus the solutions x_{e2} and x_{e2}^* solved from (18) satisfy

$$x_{e2} - x_{e2}^* = (\ell^T\ell + L_0^TL_0)^{-1}L_0^TB_1K_1\left(H_1x_{e2}^* + H_2[r,r]\right).$$

The expression for $\tilde{\lambda}_2^*$ can now be written as

$$\begin{aligned} \tilde{\lambda}_2^* &= \tilde{\lambda}_2 - 4\ell Q_0[r, \bar{B}_1K_1(H_1x_{e2}^* + H_2[r,r])] + 2(\ell\tilde{L}_1 r)K_1\left(H_1x_{e2}^* + H_2[r,r]\right) \\ &= \tilde{\lambda}_2 - \rho K_1\left(H_1x_{e2}^* + H_2[r,r]\right), \qquad \bar{B}_1 = (\ell^T\ell + L_0^TL_0)^{-1}L_0^TB_1, \end{aligned} \tag{19}$$

where ρ is the same as in (16). Since the critical mode of the linearized system is uncontrollable and unobservable, there exists a nonsingular matrix $T \in \mathbf{R}^{n\times n}$, such that (15) is true by Kalman decomposition. Denoting $L_0^* = L_0 + B_1K_1H_1$, the last two equations of (18) yield

$$\begin{aligned} TL_0^*x_{e2}^* &= \begin{bmatrix} L_{00} + B_{11}K_1H_{11} & 0 \\ 0 & 0 \end{bmatrix} Tx_{e2}^* = -T\left(Q_0[r,r] + B_1K_1H_2[r,r]\right) \\ &= -TQ_0[r,r] - \begin{bmatrix} B_{11} \\ 0 \end{bmatrix} K_1H_2[r,r], \qquad \ell x_{e2}^* = \begin{bmatrix} 0 & \cdots & 0 & 1 \end{bmatrix} Tx_{e2}^* = 0, \end{aligned}$$

which implies that the last element of the column vector Tx_{e2}^* is zero. Denote

$$\alpha = \left[\begin{array}{cc} I_{n-1} & 0 \end{array}\right] Tx_{e2}^*, \qquad \beta = \left[\begin{array}{cc} I_{n-1} & 0 \end{array}\right] TQ_0[r,r],$$

where I_{n-1} is an identity matrix of size $(n-1)\times(n-1)$. Then x_{e2}^* is determined by α and T as

$$\text{(20)} \quad \alpha = -\left(L_{00} + B_{11}K_1H_{11}\right)^{-1}\left(\beta + B_{11}K_1H_2[r,r]\right), \qquad x_{e2}^* = T^{-1}\left[\begin{array}{c} \alpha \\ 0 \end{array}\right].$$

Applying (15) and (20) to the expression in (19) gives

$$\begin{aligned}
\text{(21)} \quad \tilde{\lambda}_2^* &= \tilde{\lambda}_2 - \rho K_1\left([H_1T^{-1}][Tx_{e2}^*] + H_2[r,r]\right) = \tilde{\lambda}_2 - \rho K_1\left(H_{11}\alpha + H_2[r,r]\right) \\
&= \tilde{\lambda}_2 + \rho K_1\Big(H_{11}\left(L_{00} + B_{11}K_1H_{11}\right)^{-1}\left(\beta + B_{11}K_1H_2[r,r]\right) - H_2[r,r]\Big) \\
&= \tilde{\lambda}_2 + \rho K_1H_{11}\left(L_{00} + B_{11}K_1H_{11}\right)^{-1}\beta \\
&\quad -\rho\Big(1 - K_1H_{11}\left(L_{00} + B_{11}K_1H_{11}\right)^{-1}B_{11}\Big)K_1H_2[r,r].
\end{aligned}$$

Denote $\bar{\lambda}_2 = \tilde{\lambda}_2 + \rho K_1H_{11}\left(L_{00} + B_{11}K_1H_{11}\right)^{-1}\beta$. Using the identity $\det(I+AB) = \det(I+BA)$ whenever the products AB and BA are compatible square matrices and $\det(A^{-1}) = 1/\det(A)$, the following sequence of equalities is true:

$$\begin{aligned}
\frac{\bar{\lambda}_2}{\tilde{\lambda}_2} &= \det\left(I + \frac{\rho}{\tilde{\lambda}_2}\left(L_{00} + B_{11}K_1H_{11}\right)^{-1}\beta K_1H_{11}\right) \\
&= \frac{1}{\det(L_{00} + B_{11}K_1H_{11})}\det\left(L_{00} + B_{11}K_1H_{11} + \frac{\rho}{\tilde{\lambda}_2}\beta K_1H_{11}\right) \\
&= \frac{\det(L_{00})}{\det(L_{00} + B_{11}K_1H_{11})}\det\left(I + \left(B_{11} + \frac{\rho}{\tilde{\lambda}_2}\beta\right)K_1H_{11}L_{00}^{-1}\right) \\
&= \frac{\det(L_{00})}{\det(L_{00} + B_{11}K_1H_{11})}\left(1 + K_1H_{11}L_{00}^{-1}\left(B_{11} + \frac{\rho}{\tilde{\lambda}_2}\beta\right)\right).
\end{aligned}$$

Similarly there holds

$$\begin{aligned}
1 - K_1H_{11}\left(L_{00} + B_{11}K_1H_{11}\right)^{-1}B_{11} &= \det\left(I - (L_{00} + B_{11}K_1H_{11})^{-1}B_{11}K_1H_{11}\right) \\
&= \frac{\det(L_{00})}{\det(L_{00} + B_{11}K_1H_{11})}.
\end{aligned}$$

Thus the expression of $\tilde{\lambda}_2^*$ in (21) can now be written as

$$\tilde{\lambda}_2^* = \frac{\det(L_{00})}{\det(L_{00} + B_{11}K_1H_{11})}\left(\tilde{\lambda}_2 + K_1\left(H_{11}L_{00}^{-1}(B_{11}\tilde{\lambda}_2 + \rho\beta) - \rho H_2[r,r]\right)\right).$$

Hence stabilization of a pitchfork bifurcation is equivalent to the existence of $K_1 \neq 0$ such that $L_{00} + B_{11}K_1H_{11}$ is stable, and

$$\tilde{\lambda}_2 + K_1\left(H_{11}L_{00}^{-1}(B_{11}\tilde{\lambda}_2 + \rho\beta) - \rho H_2[r,r]\right) < 0,$$

because stability of L_{00} and $L_{00} + B_{11}K_1H_{11}$ ensures that $\det(L_{00})$ and $\det(L_{00} + B_{11}K_1H_{11})$ have the same sign. This concludes the proof. □

Theorem 3.2 is surprising as it indicates that even though the critical mode of the linearized system is neither controllable nor observable, there exists an output feedback control law that stabilizes a pitchfork bifurcation under some mild conditions. This is in contrast to linear control theory. Moreover the nonlinear feedback control law does not offer any advantage over the linear ones as far as stabilization of stationary bifurcation is concerned. This is due to the fact that linear feedback control, though it has no influence on the stability of the linear term, changes the quadratic terms of the state-space equation that in turn determine the stability of the pitchfork bifurcation. It is worth pointing out that condition (17) in Theorem 3.2 is characterized in explicit form. It greatly simplifies the synthesis part for bifurcation stabilization. Indeed, all $K_1 \neq 0$ satisfying (17) can be easily parameterized and then substituted into $L_{00}^* = L_{00} + B_{11}K_1H_{11}$ to determine the right K_1 that ensures stability of L_{00}^*. To be specific for $p = 1$, K_1 satisfying (17) is a semi-infinite interval of the real line. Thus the stabilizing value of K_1 can be easily determined through root locus of

$$1 + K_1H_{11}(sI - L_{00})^{-1}B_{11} = 0, \tag{22}$$

where K_1 changes in the semi-infinite interval determined by inequality (17). If $p > 1$, then all stabilizing K_1's lie on one side of a hyper-plane in $\mathbf{R}^p$ that does not pass through the origin, as $K_1 = 0$ is not stabilizing. In this case one needs to search for the right K_1 on the given side of the hyperplane in $\mathbf{R}^p$ to ensure the stability of $L_{00}^* = L_{00} + B_{11}K_1H_{11}$, for which the parameterized root locus method can be used for (22). The assumption $\tilde{H}_2[r, r] = 0$ in Theorem 3.2 is not very restrictive if the critical mode of the linearized system is not observable through linearized output measurement. For instance, it holds for the case where the output measurement consists of linear combination of state variables. In the case $\tilde{H}_2[r, r] \neq 0$, the quadratic gain K_2 plays a role as well for stabilization of pitchfork bifurcation that will be illuminated further in the next subsection.

3.2. Observable critical mode.

This subsection is concerned with the case where the critical mode is linearly observable based on output measurement. Consider first the transcritical bifurcation. Without loss of generality, the branch of $\varepsilon > 0$ is assumed to be unstable for $\gamma > 0$. This is equivalent to $\tilde{\lambda}_1 > 0$. Our goal is to seek a controller of the form (10) that stabilizes the bifurcated solution for $\varepsilon > 0$ without changing the stability property of the zero solution. This problem is very different from past work [3] but has its significance in engineering application (see section 5). It is noted that by assumption the eigenvalue $\lambda(0) = 0$ is invariant under feedback control. Thus L_0^* also possesses the critical zero eigenvalue as L_0 does. Denote ℓ^* and r^* as the left row and right column eigenvectors for L_0^* corresponding to the critical eigenvalue. Then $\ell^* = \ell$ due to the uncontrollability of the critical eigenvalue. Denote $\tilde{\lambda}^*$ as the critical eigenvalue of L_0^* under feedback. It has the same form of the series expansion as in (14). However, $r^* \neq r$ in general due to $H_1r \neq 0$ by the observability of the critical mode. The next result concerns stabilization of transcritical bifurcations.

THEOREM 3.3. *Consider the nonlinear control system* (9) *with output feedback control law* (10)*. Suppose that the critical mode of the linearized system corresponding to the zero eigenvalue at $\gamma = 0$ is observable. Then for the case $\tilde{\lambda}_1 > 0$, i.e., $\ell Q_0[r, r] > 0$, there exists a nonlinear feedback control law $u = K(y)$ that stabilizes the given branch of the bifurcated solution at $\varepsilon > 0$ if and only if there exists a linear feedback control law that stabilizes the given branch of the bifurcated solution at $\varepsilon > 0$. Moreover* *there exists a nonsingular matrix $T \in \mathbf{R}^{n\times n}$ such that*

$$(23)\ TL_0T^{-1} = \begin{bmatrix} L_{00} & 0 \\ 0 & 0 \end{bmatrix}, \quad TB_1 = \begin{bmatrix} B_{11} \\ 0 \end{bmatrix}, \quad \begin{bmatrix} H_1 \\ \ell \end{bmatrix} T^{-1} = \begin{bmatrix} H_{11} & H_{12} \\ 0 & 1 \end{bmatrix},$$

where L_{00}, B_{11}, and H_{11} have the same sizes as in Theorem 3.2, respectively. Let ℓ_i be the ith element of ℓ, and $r^TQ_{0k}r$ be the kth element of $Q_0[r,r]$ with $Q_{0k} = Q_{0k}^T$ for $k = 1, 2, \ldots, n$. Partition

$$(T^{-1})^T\left(\sum_{k=1}^{n} \ell_k Q_{0k}\right)T^{-1} = \begin{bmatrix} \tilde{Q}_{00} & \tilde{Q}_{01} \\ \tilde{Q}_{10} & \tilde{Q}_{11} \end{bmatrix}, \qquad \tilde{Q}_{10} = \tilde{Q}_{01}^T, \qquad \tilde{Q}_{00} \in \mathbf{R}^{(n-1)\times(n-1)}.$$

Then $\tilde{Q}_{11} = \tilde{\lambda}_1 > 0$. The existence of a stabilizing feedback control law, subject to the same stability property for the zero solution, is equivalent to the existence of $K_1 \neq 0$ such that

(i) $\left(1 + K_1H_{11}L_{00}^{-1}B_{11}\right)\left(\tilde{\lambda}_1(1 + K_1H_{11}L_{00}^{-1}B_{11}) + aK_1H_{12}\right) + b(K_1H_{12})^2 < 0,$

(ii) $\lambda'(0)\left(\lambda'(0) + K_1(H_{11}\lambda'(0) - H_{12}d)L_{00}^{-1}B_{11}\right) > 0,$ *and*

(iii) $L_{00}^* = L_{00} + B_{11}K_1H_{11}$ *is stable,*

where $a = \tilde{d}_0 - 2\tilde{Q}_{10}L_{00}^{-1}B_{11}$, $b = \ell B_2 + ((L_{00}^{-1}B_{11})^T\tilde{Q}_{00} - \tilde{d})L_{00}^{-1}B_{11}$, $\begin{bmatrix} \tilde{d} & \tilde{d}_0 \end{bmatrix} = \ell\tilde{L}_1T^{-1}$with $\tilde{d}_0$ scalar, $d^T = \begin{bmatrix} I_{n-1} & 0 \end{bmatrix}(\ell L_1T^{-1})^T$, and $\lambda(\gamma)$ is the critical eigenvalue in (3).

Proof. From the proofs of Theorem 3.1 and of Lemma 2.2, the first nonzero coefficient of the critical eigenvalue for the feedback system has the expression

$$(24)\qquad \begin{aligned} \tilde{\lambda}_1^* &= \ell Q_0[r^*, r^*] + \ell B_1\left(K_1H_2[r^*, r^*] + K_2\tilde{H}_2[r^*, r^*]\right) \\ &\quad + \ell K_1H_1r^*\tilde{L}_1r^* + \ell B_2(K_1H_1r^*)^2 \\ &= \ell Q_0[r^*, r^*] + (\ell\tilde{L}_1r^*)(K_1H_1r^*) + \ell B_2(K_1H_1r^*)^2, \end{aligned}$$

due to $\ell B_1 = 0$ by the uncontrollability of the critical mode and the condition of the theorem. Because only the linear gain K_1 is present in the expression of $\tilde{\lambda}_1^*$, the existence of a stabilizing control law is equivalent to the existence of a linear stabilizing control law. It remains to be shown that conditions (i)–(iii) are equivalent to the existence of the stabilizing feedback control law with the same stability property for the zero solution retained. By Kalman decomposition a nonsingular matrix T exists such that (23) holds where the lower triangular Schur form of TL_0T^{-1} is used. The hypothesis on L_0 implies that $\det(L_{00}) \neq 0$, and thus $0 = \ell L_0 = (\ell T^{-1})(TL_0T^{-1})$ yields the form of ℓT^{-1} as in (23). Since

$$\ell r^* = (\ell T^{-1})(Tr^*) = 1, \quad L_0^*r^* = (L_0 + B_1K_1H_1)r^* = T(L_0 + B_1K_1H_1)T^{-1}(Tr^*) = 0,$$

the right eigenvector of L_0^* corresponding to the zero eigenvalue is found to be

$$(25)\quad r^* = T^{-1}\begin{bmatrix} \eta \\ 1 \end{bmatrix},$$

$$\eta = -(I_{n-1} + L_{00}^{-1}B_{11}K_1H_{11})^{-1}L_{00}^{-1}B_{11}K_1H_{12} = -\frac{L_{00}^{-1}B_{11}K_1H_{12}}{1 + K_1H_{11}L_{00}^{-1}B_{11}}.$$

By noticing that

$$K_1H_{11}\eta = -\frac{(K_1H_{11}L_{00}^{-1}B_{11})K_1H_{12}}{1+K_1H_{11}L_{00}^{-1}B_{11}} = -K_1H_{12} + \frac{K_1H_{12}}{1+K_1H_{11}L_{00}^{-1}B_{11}},$$

the expression for $K_1H_1r^*$ can be simplified as

$$\begin{aligned} K_1H_1r^* &= K_1(H_1T^{-1})(Tr^*) = K_1\begin{bmatrix} H_{11} & H_{12}\end{bmatrix}\begin{bmatrix}\eta \\ 1\end{bmatrix} \\ &= K_1H_{11}\eta + K_1H_{12} = \frac{K_1H_{12}}{1+K_1H_{11}L_{00}^{-1}B_{11}}. \end{aligned} \tag{26}$$

It is claimed that the condition (ii) is equivalent to the invariance of the stability property for the zero solution, provided that $L_{00}^* = L_{00} + B_{11}K_1H_{11}$ is stable. Indeed, denote λ^* as the critical eigenvalue of the linearized system under feedback control law $u = K(y)$. Then

$$\begin{aligned} \frac{d\lambda^*}{d\gamma}(0) &= \ell L_1r^* = (\ell L_1T^{-1})(Tr^*) = \begin{bmatrix} d & \lambda'(0)\end{bmatrix}\begin{bmatrix}\eta \\ 1\end{bmatrix} \\ &= d\eta + \lambda'(0), \qquad d = \ell L_1T^{-1}\begin{bmatrix} I_{n-1} \\ 0\end{bmatrix}, \end{aligned}$$

by the fact that if $K_1 = 0$, then $\eta = 0$, and thus $\lambda^*(\gamma)$ reduces to $\lambda(\gamma)$. Substituting the expression of η as in (25) yields that

$$\ell L_1r^* = -\frac{dL_{00}^{-1}B_{11}K_1H_{12}}{1+K_1H_{11}L_{00}^{-1}B_{11}} + \lambda'(0) = \frac{\lambda'(0) + K_1(H_{11}\lambda'(0) - H_{12}d)L_{00}^{-1}B_{11}}{1+K_1H_{11}L_{00}^{-1}B_{11}}.$$

It follows that (ii) is equivalent to ℓL_1r^* that has the same sign as $\lambda'(0)$ due to the stability assumption for L_{00}^* and L_{00}, that is in turn equivalent to that the zero solution for the feedback system changes its stability also at $\gamma = 0$, and shares the same stability property as that of an uncontrolled system. Thus the stability property of the zero solution is retained.

Similarly,

$$\ell\tilde{L}_1r^* = \frac{\tilde{d}_0 + K_1(H_{11}\tilde{d}_0 - H_{12}\tilde{d})L_{00}^{-1}B_{11}}{1+K_1H_{11}L_{00}^{-1}B_{11}}, \qquad \begin{bmatrix}\tilde{d} & \tilde{d}_0\end{bmatrix} = \ell\tilde{L}_1T^{-1},$$

with $\tilde{d}_0$ scalar. Combining with the expression in (26), there holds

$$\ell\tilde{L}_1r^*K_1H_1r^* = \left(\frac{\tilde{d}_0 + K_1(H_{11}\tilde{d}_0 - H_{12}\tilde{d})L_{00}^{-1}B_{11}}{(1+K_1H_{11}L_{00}^{-1}B_{11})^2}\right)K_1H_{12}. \tag{27}$$

For the term $\ell Q_0[r^*, r^*]$, there holds

$$\ell Q_0[r^*, r^*] = (Tr^*)^T(T^{-1})^TQ_\ell T^{-1}(Tr^*) = \begin{bmatrix}\eta^T & 1\end{bmatrix}\begin{bmatrix}\tilde{Q}_{00} & \tilde{Q}_{01} \\ \tilde{Q}_{10} & \tilde{Q}_{11}\end{bmatrix}\begin{bmatrix}\eta \\ 1\end{bmatrix}$$

for some real symmetric matrix Q_ℓ. To show that $\tilde{Q}_{11} = \tilde{\lambda}_1$, setting $K_1 = 0$, thus $a = 0$, leads to

$$\tilde{\lambda}_1 = \ell Q_0[r, r] = (Tr)^T(T^{-1})^TQ_\ell T^{-1}(Tr) = Q_{11},$$

because the last element of Tr is one, by $(\ell T^{-1})Tr = 1$. Therefore,

$$\ell Q_0[r^*, r^*] = \tilde{\lambda}_1 - \left(\frac{2\tilde{Q}_{10} L_{00}^{-1} B_{11}}{1 + K_1 H_{11} L_{00}^{-1} B_{11}} \right) K_1 H_{12} + \left(\frac{(L_{00}^{-1} B_{11})^T \tilde{Q}_{00} (L_{00}^{-1} B_{11})}{\left(1 + K_1 H_{11} L_{00}^{-1} B_{11}\right)^2} \right) (K_1 H_{12})^2. \tag{28}$$

Combining (26)–(28) with rearrangement yields the expression

$$\tilde{\lambda}_1^* \left(1 + K_1 H_{11} L_{00}^{-1} B_{11}\right)^2 = \tilde{\lambda}_1 \left(1 + K_1 H_{11} L_{00}^{-1} B_{11}\right)^2 + a \left(1 + K_1 H_{11} L_{00}^{-1} B_{11}\right) K_1 H_{12} + b (K_1 H_{12})^2,$$

which can be simplified to (i). The necessity of conditions (i)–(iii) is now clear. In brief, (iii) implies that $L_{00}^* = L_{00} + B_{11} K_1 H_{11}$ is stable. Hence

$$\left(1 + K_1 H_{11} L_{00}^{-1} B_{11}\right)^2 > 0.$$

Condition (i) then implies that $\tilde{\lambda}_1^* < 0$ ensures stability of the given branch of the bifurcated solution, while condition (ii) guarantees the invariance of the stability property of the zero solution under feedback. □

It is noticed that if $b = 0$, then (i) of Theorem 3.6 can be further simplified to

$$\tilde{\lambda}_1 (1 + K_1 H_{11} L_{00}^{-1} B_{11}) + a K_1 H_{12} < 0,$$

by the fact that condition (iii) and stability of L_{00} imply that

$$1 + K_1 H_{11} L_{00}^{-1} B_{11} = \frac{\det(L_{00} + B_{11} K_1 H_{11})}{\det(L_{00})} > 0.$$

Theorem 3.3 indicates that stabilization of a transcritical bifurcation is possible by using just a linear control law. More importantly the conditions (i)–(iii) also provide explicit formulas for synthesis of a stabilizing linear gain K_1. Indeed, for the case of $p = 1$, K_1 is scalar. The set of K_1 satisfying each of (i)–(iii) can be easily computed that are either finite intervals or semi-infinite intervals. In particular, the set of K_1 satisfying (iii) can be obtained through root locus. For the case $p > 1$, conditions (i)–(iii) offer more freedom for the synthesis of stabilizing linear gain K_1. On the other hand, the synthesis becomes more complex because there is more than one element for K_1.

REMARK 3.4. *Suppose that the linearized system has been transformed into the form of* (23). *Then the last entry of the state vector is the critical state variable. Measurement of this critical state variable corresponds to* $H_{12} \neq 0$. *Theorem* 3.6 *indicates that the feedback of the critical state variable is crucial. This is due to the fact that if* $H_{12} = 0$, *the sign of* $\tilde{\lambda}_1^*$ *remains the same as that of* $\tilde{\lambda}_1$, *and thus the given branch of the bifurcated solution at* $\varepsilon > 0$ *is not stabilizable that is exactly the result of Theorem* 3.1. *However, this fact does not imply that the measurement of noncritical state variables, which corresponds to* $H_{11} \neq 0$, *is unnecessary. By condition* (i) *of Theorem* 3.3, *the measurement of noncritical state variables becomes necessary if* $a = b = 0$. *If* $a \neq 0$ *and/or* $b < 0$, *however, the measurement of noncritical state variables are redundant and thus unnecessary for the purpose of bifurcation stabilization.*

Theorem 3.3 has implications for state feedback control:

$$u = K(x) = K_1 x + K_Q[x, x] + K_C[x, x, x] + \cdots,$$

with K_1 the linear state feedback gain and $K_Q[\cdot, \cdot]$ and $K_C[\cdot, \cdot, \cdot]$ the quadratic and cubic terms, respectively. The next result is a direct consequence of Theorem 3.3.

Corollary 3.5. *Suppose that all the hypotheses in Theorem* 3.3 *hold. Then there exists a nonlinear state feedback control law $u = K(x)$ that stabilizes the given branch of the bifurcated solution if and only if there exists a linear state feedback control law that stabilizes the given branch of the bifurcated solution. Moreover, with the same notation as in Theorem* 3.3, *the existence of stabilizing state feedback control law (subject to the same stability property for the zero solution) is equivalent to the existence of a* $K_1 = \left[\begin{array}{cc} K_{11} & K_{12} \end{array}\right] T \neq 0$ *such that*

$$\text{(i) } \left(1 + K_{11} L_{00}^{-1} B_{11}\right) \left(\tilde{\lambda}_1 (1 + K_{11} L_{00}^{-1} B_{11}) + a K_{12}\right) + b K_{12}^2 < 0,$$

$$\text{(ii) } \lambda'(0) \left(\lambda'(0) + (K_{11}\lambda'(0) - K_{12} d) L_{00}^{-1} B_{11}\right) > 0, \quad \textit{and}$$

$$\text{(iii) } L_{00}^* = L_{00} + B_{11} K_{11} \quad \textit{is stable.}$$

Proof. The theorem can be easily proven by setting $K_1 H_{11} \to K_{11}$, $K_1 H_{12} \to K_{12}$, and noting that

$$K_1 = \left[\begin{array}{cc} K_{11} & K_{12} \end{array}\right] T$$

with T the similarity transform, in the proof of Theorem 3.3. □

For a pitchfork bifurcation, i.e., $\tilde{\lambda}_1 = 0$, the situation is again different. We adopt an approach as in [3] by setting the linear term of the controller to zero. In fact, by the proof of Theorems 3.1 and 3.3, the nonzero gain K_1 will result in $\tilde{\lambda}_1^* \neq 0$, thereby changing the pitchfork bifurcation into a transcritical bifurcation for which only one branch of the bifurcated solution can be stable. Hence this is not a desirable situation other than some exceptional situations. It is noted that with $K_1 = 0$, the eigenvectors of L_0^* corresponding to the critical eigenvalue at $\gamma = 0$ satisfy $\ell^* = \ell$ and $r^* = r$. Hence both row and column eigenvectors of the critical eigenvalue are invariant under feedback control. Since $L_1^* = L_1$, there holds $\ell^* L_1^* r^* = \ell L_1 r = \lambda'(0)$. Thus the zero solution of the feedback system changes its stability at $\gamma = 0$ as well. The stabilizability of the bifurcated solution is given by the following result.

Theorem 3.6. *Consider the nonlinear control system* (9) *with output feedback control law* (10) *under the same hypothesis as in Theorem* 3.3. *Then for the case $\tilde{\lambda}_1 = 0$, there exists a feedback control law $u = K(y)$ subject to $K_1 = 0$, that ensures $\tilde{\lambda}_1^* = 0$ and $\tilde{\lambda}_2^* < 0$, i.e., changes the pitchfork bifurcation from subcritical into supercritical, if and only if*

$$\rho = 4\ell Q_0[r, (\ell^T \ell + L_0^T L_0)^{-1} L_0^T B_1] - 2\ell \tilde{L}_1 r \neq 0 \quad \textit{and} \quad \tilde{H}_2[r, r] \neq 0.$$

Note that the expression of ρ is the same as in (16).

Proof. By the proof of Theorem 3.2 and $\ell B_1 = 0$, there holds

$$\begin{aligned}
\tilde{\lambda}_2^* = 2\ell &\Big(2Q_0[r, x_{e2}^*] + C_0[r, r, r] + K_2 \tilde{H}_2[r, r] \tilde{L}_1 r \\
&+ \; K_1 H_1 r (\tilde{Q}_1[r, r] + K_1 H_1 r \tilde{L}_2 r + B_3 (K_1 H_1 r)^2)\Big) \\
&+ 2\ell K_1 \left((H_2[r, r] + H_1 x_{e2}^*) \tilde{L}_1 r + H_1 r \tilde{L}_1 x_{e2}^*\right) \\
&+ 4\ell B_2 K_1 H_1 r \left(K_1 (H_1 x_{e2}^* + H_2[r, r]) + K_2 \tilde{H}_2[r, r]\right).
\end{aligned}$$

Setting $K_1 = 0$ yields $\tilde{\lambda}_1^* = 0$. Since $Q_0^*[r,r] = Q_0[r,r] + B_1K_2\tilde{H}_2[r,r]$, x_{e2}^* can be solved from

$$L_0x_{e2}^* = -Q_0[r,r] - B_1K_2\tilde{H}_2[r,r], \qquad \ell x_{e2}^* = 0.$$

Combined with $\ell x_{e2} = 0$ and $L_0x_{e2} = -Q_0[r,r]$ yields

$$x_{e2}^* - x_{e2} = -(\ell^T\ell + L_0^TL_0)^{-1}L_0^TB_1K_2\tilde{H}_2[r,r].$$

Substituting the above into the expression of $\tilde{\lambda}_2^*$ gives

$$\begin{aligned}\tilde{\lambda}_2^* &= \tilde{\lambda}_2 + 4\ell Q_0[r, x_{e2}^* - x_{e2}] + 2\ell\tilde{L}_1rK_2\tilde{H}_2[r,r]\\ &= \tilde{\lambda}_2 - 4\ell Q_0[r,(\ell^T\ell + L_0^TL_0)^{-1}L_0^TB_1]K_2\tilde{H}_2[r,r] + 2\ell\tilde{L}_1rK_2\tilde{H}_2[r,r]\\ &= \tilde{\lambda}_2 - \left(4\ell Q_0[r,(\ell^T\ell + L_0^TL_0)^{-1}L_0^TB_1] - 2\ell\tilde{L}_1r\right)K_2\tilde{H}_2[r,r]\\ &= \tilde{\lambda}_2 - \rho K_2\tilde{H}_2[r,r].\end{aligned}$$

Since $\rho \neq 0$ and $\tilde{H}_2[r,r] \neq 0$, there exists $K_2 \neq 0$ such that $\tilde{\lambda}_2^* < 0$. Conversely, stability of the bifurcated solution implies that

$$\tilde{\lambda}_2^* = \tilde{\lambda}_2 - \rho K_2\tilde{H}_2[r,r] < 0,$$

which then implies that $\rho \neq 0$ and $\tilde{H}_2[r,r] \neq 0$ by the hypothesis that $\tilde{\lambda}_2 > 0$. □

It is noted that terms of order higher than two do not affect stability. Thus the stabilizing controllers can be taken as quadratic. Moreover if the output measurements consist of linear combinations of state variables, then the observability condition implies that $\tilde{H}_2[r,r] \neq 0$. In this case, stabilizability for pitchfork bifurcation is equivalent to $\rho \neq 0$. For bifurcation stabilization using state feedback in the case of a pitchfork bifurcation, the stabilizability condition is again equivalent to $\rho \neq 0$, because state feedback is a special case of output feedback satisfying observability.

4. Output feedback stabilization for Hopf bifurcation.

It is assumed that the linearized system matrix $L(\gamma)$ as in (2) has a pair of complex (critical) eigenvalues $\lambda(\gamma) = \alpha(\gamma) \pm j\beta(\gamma)$ such that $\alpha(0) = 0$ and $\alpha'(0) \neq 0$, while all other eigenvalues are stable. As explained in the previous section, this assumption has no loss of generality. The problem to be investigated in this section is the stabilization of Hopf bifurcations with output feedback control if the Hopf bifurcation born at $\gamma = 0$ for the nonlinear system in (1) is unstable. We consider first the case when the pair of critical modes corresponding to the pair of complex eigenvalues $\lambda(\gamma)$ are neither controllable nor observable. According to the PBH test [12], both left and right eigenvectors corresponding to the pair of critical eigenvalues satisfy

$$\ell B_1 = \bar{\ell}B_1 = H_1r = H_1\bar{r} = 0.$$

It follows that when the feedback controller (10) is employed, $L_0^* = L_0 + B_1K_1H_1$ retains the pair of critical eigenvalues $\pm j\omega_c$ at $\gamma = 0$. Denote ℓ^* and r^* as the left and right eigenvectors of L_0^* corresponding to the pair of critical eigenvalues, respectively. Then there holds $\ell^* = \ell$ and $r^* = r$, and thus a Hopf bifurcation is again born at $\gamma = 0$ for which the zero solution changes its stability as γ crosses zero [11]. The next result gives the condition on stabilizability of a Hopf bifurcation.

THEOREM 4.1. *Consider the nonlinear control system* (9) *with output feedback control law* (10). *Suppose that* $\tilde{\lambda}_2 > 0$ *with* $\tilde{\lambda}(\varepsilon)$ *as in* (6) *and the critical modes of* L_0

are neither controllable nor observable in the sense that $\ell B_1 = 0$ *and* $H_1 r = 0$*. For simplicity, assume in addition that* $\tilde{H}_2[r,r] = H_2[r,r] = 0$*. Let* $Q_0^*[x,x]$ *and* C_0^* *be as in the proof of Theorem* 3.1*. Let* μ *and* ν *be as in section* 2.2*, and define* μ^* *and* ν^* *by*

$$-L_0^*\mu^* = \frac{1}{2}Q_0^*[r,\bar{r}], \qquad (2j\omega_c I - L_0^*)\,\nu^* = \frac{1}{2}Q_0^*[r,r],$$

where $L_0^* = L_0 + B_1 K_1 H_1$*. Then there exists a feedback control law* $u = K(y)$ *that stabilizes the Hopf bifurcation if and only if there exists a linear feedback control law* $u = K_1 y$ *that stabilizes the Hopf bifurcation. Moreover the existence of a stabilizing feedback control law is equivalent to*

$$(29)\quad \tilde{\lambda}_2^* = \tilde{\lambda}_2 + \mathrm{Re}\left\{\frac{K_1H_1L_0^{-1}Q_0[r,\bar{r}]\theta}{1+K_1H_1L_0^{-1}B_1} + \frac{K_1H_1(L_0-2j\omega_c I)^{-1}Q_0[r,r]\phi}{1+K_1H_1(L_0-2j\omega_c I)^{-1}B_1}\right\} < 0,$$

and the noncritical eigenvalues of L_0^* *lie on open left half-plane for some* $K_1 \neq 0$*, where*

$$(30)\quad \theta = -\left(\ell\tilde{L}_1 r - 2\ell Q_0[r, L_0^{-1}B_1]\right), \quad \phi = \frac{1}{2}\left(\ell\tilde{L}_1\bar{r} - 2\ell Q_0[\bar{r}, (-2j\omega_c I + L_0)^{-1}B_1]\right).$$

Proof. Denote $\tilde{\lambda}^*(\varepsilon)$ as the function in (6) for the controlled system, and $\tilde{\lambda}_2^*$ as the first coefficient of $\tilde{\lambda}^*(\varepsilon)$. From the proof of Theorem 3.1,

$$Q_0^*[r,r] = Q_0[r,r], \qquad \ell Q_0^*[r,r] = \ell Q_0[r,r], \qquad \ell C_0^*[r,r,\bar{r}] = \ell C_0[r,r,\bar{r}],$$

by using $\ell B_1 = \bar{\ell}B_1 = 0$, $H_1 r = H_1\bar{r} = 0$, and $\tilde{H}_2[r,r] = H_2[r,r] = 0$. Thus there hold

$$\begin{aligned} -2(L_0 + B_1K_1H_1)\mu^* &= Q_0[r,\bar{r}],\ -2L_0\mu = Q_0[r,\bar{r}], \\ -2(-2j\omega_c I + L_0 + B_1K_1H_1)\nu^* &= Q_0[r,r],\ -2(-2j\omega_c I + L_0)\nu^* = Q_0[r,r]. \end{aligned}$$

The above equalities imply that

$$\mu^* - \mu = -L_0^{-1}B_1K_1H_1\mu^*, \qquad \nu^* - \nu = -(-2j\omega_c I + L_0)^{-1}B_1K_1\nu^*.$$

Although $Q_0^*[r,r] = Q_0[r,r]$, $Q_0^*[r,x] \neq Q_0[r,x]$ for $x \neq r$ due to the feedback term. In fact,

$$2\ell Q_0^*[r,\mu^*] = 2\ell Q_0[r,\mu^*] + \ell K_1H_1\mu^*\tilde{L}_1 r,\ 2\ell Q_0^*[\bar{r},\nu^*] = 2\ell Q_0[\bar{r},\nu^*] + \ell K_1H_1\nu^*\tilde{L}_1\bar{r}.$$

The coefficient $\tilde{\lambda}_2^*$ can now be computed as

$$\begin{aligned} \tilde{\lambda}_2^* &= \mathrm{Re}\left\{2\ell(2Q_0[r,\mu^*] + Q_0[\bar{r},\nu^*]) + 3C_0[r,r,\bar{r}]/4\right\} + K_1H_1\mathrm{Re}\left\{2\mu^*\ell\tilde{L}_1 r + \nu^*\ell\tilde{L}_1\bar{r}\right\} \\ &= \tilde{\lambda}_2 + \mathrm{Re}\left\{2\ell(2Q_0[r,\mu^*-\mu] + Q_0[\bar{r},\nu^*-\nu])\right\} + K_1H_1\mathrm{Re}\left\{2\mu^*\ell\tilde{L}_1 r + \nu^*\ell\tilde{L}_1\bar{r}\right\} \\ &= \tilde{\lambda}_2 + K_1H_1\mathrm{Re}\Big\{2\mu^*\left(\ell\tilde{L}_1 r - 2\ell Q_0[r, L_0^{-1}B_1]\right) \\ &\qquad\qquad + \nu^*\left(\ell\tilde{L}_1\bar{r} - 2\ell Q_0[\bar{r}, (-2j\omega_c I + L_0)^{-1}B_1]\right)\Big\}. \end{aligned}$$

By $\mu^* = -0.5(L_0+B_1K_1H_1)^{-1}Q_0[r,\bar{r}]$, and $\nu^* = -0.5(L_0+B_1K_1H_1-2j\omega_c I)^{-1}Q_0[r,r]$,

$$\tilde{\lambda}_2^* = \tilde{\lambda}_2 + K_1H_1\mathrm{Re}\left\{(L_0 + B_1K_1H_1)^{-1}Q_0[r,\bar{r}]\theta + (L_0 + B_1K_1H_1 - 2j\omega_c I)^{-1}Q_0[r,r]\phi\right\},$$

where θ and ϕ are as in (30). For any square nonsingular matrices M and $M+NF$,

$$F(M+NF)^{-1}G = F(I+M^{-1}NF)^{-1}M^{-1}G = \frac{FM^{-1}G}{1+FM^{-1}N}, \tag{31}$$

whenever $FM^{-1}N$ is a scalar. The expression for $\tilde{\lambda}_2^*$ as in (29) can now be verified. Hence stabilization of the Hopf bifurcation with the nonlinear controllers in (10) is equivalent to the existence of $K_1 \neq 0$ such that $\tilde{\lambda}_2^* < 0$, and the rest of the eigenvalues of L_0^* remain in the open left half plane. □

The result in Theorem 4.1 is similar to the stabilizability of a pitchfork bifurcation in Theorem 3.2 where nonlinear controllers do not offer any advantage over linear ones in terms of bifurcation stabilization. Hence if the pair of critical modes of the linearized system is uncontrollable and unobservable, linear controllers are adequate for bifurcation stabilization. Moreover a necessary condition for stabilizability of a Hopf bifurcation as in Theorem 4.1 is that

$$\|H_1 L_0^{-1} Q_0[r,\bar{r}]\theta\| + \|H_1(L_0 - 2j\omega_c I)^{-1} Q_0[r,r]\phi\| \neq 0,$$

where $\|\cdot\|$ denotes the Euclidean norm in $\mathbf{R}^p$. If the above holds, all K_1 such that $\tilde{\lambda}_2^* < 0$ can be easily parameterized, especially for scalar K_1 that are a collection of a limited number of finite intervals, or semi-infinite intervals, while stability of the noncritical eigenvalues of L_0 can be tested using root locus of (22) as argued in the previous section.

In the rest of the section, we study the case when the stabilizability condition in Theorem 4.1 is not satisfied. Clearly additional sensors must be deployed such that $H_1 r \neq 0$ is valid in order for a Hopf bifurcation to be stabilizable. Although linear controllers can be investigated, it is much easier to consider the class of nonlinear controllers in (10) with $K_1 = 0$ as discussed in [2]. The next result generalizes the result in [2] to output feedback stabilization.

THEOREM 4.2. *Consider the nonlinear control system* (9) *with output feedback control law in* (10) *subject to* $K_1 = 0$. *Suppose that* $\tilde{\lambda}_2 > 0$ *with* $\tilde{\lambda}(\varepsilon)$ *as* (6), μ, ν *as in section* 2.2, *and the critical mode of* L_0 *is observable through linearized output measurement* $y = H_1 x$. *Then there exists a feedback control law* $u = K(y)$ *that stabilizes the Hopf bifurcation if and only if*

$$\begin{aligned} \operatorname{Re}\Big\{ & \tilde{H}_2[r,\bar{r}]\ell\left(2Q_0[r, L_0^{-1}B_1] - \tilde{L}_1 r\right) \\ & + \tilde{H}_2[r,r]\ell\left(Q_0[\bar{r}, (2j\omega_c I - L_0)^{-1}B_1] - 0.5\tilde{L}_1\bar{r}\right)\Big\} \neq 0. \end{aligned} \tag{32}$$

If the above condition holds, stabilizing controllers can be taken as quadratic.

Proof. With $K_1 = 0$, both critical eigenvalues and left/right eigenvectors are invariant under feedback. Moreover

$$\begin{aligned} L_0^* = L_0, \qquad Q_0^*[x,z] &= Q_0[x,z] + B_1 K_2 \tilde{H}_2[x,z], \qquad \ell Q_0^*[x,z] = \ell Q_0[x,z] \\ 3\ell C_0^*[r,r,\bar{r}] &= 3\ell C_0[r,r,\bar{r}] + \ell K_2\left(\tilde{H}_2[r,r]\tilde{L}_1\bar{r} + 2\tilde{H}_2[r,\bar{r}]\tilde{L}_1 r\right) \end{aligned}$$

by $\ell B_1 = 0$. It follows that

$$\mu^* = -0.5L_0^{-1}\left(Q_0[r,\bar{r}] + B_1 K_2 \tilde{H}_2[r,\bar{r}]\right) = \mu + \Delta\mu, \qquad \Delta\mu = -0.5L_0^{-1}B_1 K_2 \tilde{H}_2[r,\bar{r}],$$

$$\nu^* = \nu + \Delta\nu, \qquad \Delta\nu = -0.5(2j\omega_c I - L_0)^{-1} B_1 K_2 \tilde{H}_2[r,\bar{r}].$$

By the property of the quadratic term,

$$Q_0[r,\mu+\Delta\mu] = Q_0[r,\mu] + Q_0[r,\Delta\mu] = Q_0[r,\mu] - 0.5K_2\tilde{H}_2[r,\bar{r}]Q_0[r,L_0^{-1}B_1],$$
$$Q_0[\bar{r},\nu+\Delta\nu] = Q_0[\bar{r},\nu] + Q_0[\bar{r},\Delta\nu] = Q_0[\bar{r},\nu] - 0.5K_2\tilde{H}_2[r,\bar{r}]Q_0[\bar{r},(2j\omega_c I - L_0)^{-1}B_1].$$

After lengthy calculations, we finally obtain

$$\begin{aligned}\tilde{\lambda}_2^* = \tilde{\lambda}_2 - K_2\mathrm{Re}\Big\{&\tilde{H}_2[r,\bar{r}]\ell\left(2Q_0[r,L_0^{-1}B_1] - \tilde{L}_1 r\right)\\ &+ \tilde{H}_2[r,r]\ell\left(Q_0[\bar{r},(2j\omega_c I - L_0)^{-1}B_1] - 0.5\tilde{L}_1\bar{r}\right)\Big\}.\end{aligned}$$

Because $\tilde{\lambda}_2 > 0$, the Hopf bifurcation of the uncontrolled system is unstable. Hence stabilization requires $\tilde{\lambda}_2^* < 0$ to hold, which implies the condition in (32). Conversely, if (32) holds, then there exists K_2 such that $\tilde{\lambda}_2^* < 0$, which ensures the stability of the Hopf bifurcation for the feedback system. Since only the quadratic term of the nonlinear controller is involved in determination of $\tilde{\lambda}_2^*$, the stabilizing controller can be taken as quadratic. □

It is worth pointing out that condition (32) in Theorem 4.2 reduces to that of [2] if $\tilde{H}_2[r,r] = \tilde{H}_2[r,\bar{r}]$ is a nonzero real number, which was derived for state feedback control laws.

5. Applications to rotating stall control. Rotating stall is a flow instability in axial flow compressors of gas turbines, induced by bifurcations. It cannot only lead to large penalties in performance, but also cause catastrophe. Hence there is a growing interest in suppression of rotating stall using feedback control in order to extend the stable operating range, and to improve turbine-based aeroengines for axial flow compressors. A number of control laws are proposed in [8, 14, 16, 20] using rotating stall control, and are shown to be effective based on the low-order Moore–Greitzer model [18]. In this section established results on stationary bifurcations in section 3 will be applied to the Moore–Greitzer model and are shown to yield identical results as in [8, 14, 16, 20], thereby validating our results on bifurcation stabilization. Clearly our results are more general and apply to broader bifurcation instability problems other than rotating stall.

The post-stall model developed by Moore and Greitzer is of the form

$$\dot{\Psi} = \frac{1}{\beta^2}\left(\Phi - (\gamma+u)\sqrt{\Psi} + 1\right), \tag{33}$$

$$\dot{\Phi} = -\Psi + \psi_c(\Phi) + 6c_3\Phi R, \qquad \psi_c(\Phi) = c_0 + c_1\Phi + c_3\Phi^3, \tag{34}$$

$$\dot{R} = \sigma R(1 - \Phi^2 - R), \tag{35}$$

where Φ is the average flow rate, Ψ the pressure rise, R the amplitude square of the disturbance flow ($R = A^2$), and u the actuating signal implemented with throttle, which are all nondimensionalized. An obvious equilibrium (Ψ_e, Φ_e, R_e) for $u = 0$ satisfies

$$R_e = 0, \qquad \Psi_e = \psi_c(\Phi_e), \qquad \Psi_e = \frac{1}{\gamma}(1+\Phi_e)^2. \tag{36}$$

It can be easily shown that there exists $\gamma_c > 0$ such that the above equilibrium is stable for $\gamma > \gamma_c$ but unstable for $\gamma < \gamma_c$ [17]. Denote

$$x = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} \Psi - \Psi_e \\ \Phi - \Phi_e \\ R \end{bmatrix}, \qquad g(x) = \begin{bmatrix} -1 \\ 0 \\ 0 \end{bmatrix} \frac{\sqrt{\Psi}}{\beta^2},$$

with $\Psi = x_1 + \Psi_e$. Then

$$\dot{x} = f(\delta\gamma, x) + g(x)u, \qquad \delta\gamma = \gamma - \gamma_c. \tag{37}$$

Thus the equilibrium in (36) is the local zero solution for $u = 0$, and both Ψ_e and Φ_e are functions of γ. Moreover the linearized system at the origin possesses exactly one zero eigenvalue at $\gamma = \gamma_c$, which implies that γ_c is the critical value. The equilibrium in (36) at the critical value of γ is determined as (see [16, 14, 20]):

$$R_c = 0, \qquad \Phi_c = 1, \qquad \Psi_c = \Psi_c(\Phi_c) = c_0 + c_1 + c_3,$$
$$\gamma_c = \frac{2}{\sqrt{\Psi_c}}, \qquad c_0 = 8/3, \qquad c_1 = 1.5, \qquad c_3 = -0.5.$$

Clearly the nonlinear system (37) can be expanded in the same form as (9) with

$$L_0 = \begin{bmatrix} -\frac{\gamma_c\beta^{-2}}{2\sqrt{\Psi_c}} & \beta^{-2} & 0 \\ -1 & 0 & 6c_3 \\ 0 & 0 & 0 \end{bmatrix}, \qquad B_1 = \begin{bmatrix} -1 \\ 0 \\ 0 \end{bmatrix} \frac{\sqrt{\Psi_c}}{\beta^2}, \tag{38}$$

$$Q_0[x,x] = \begin{bmatrix} \frac{\gamma_c}{8\beta^2\Psi_c^{\frac{3}{2}}} x_1^2 \\ 3c_3\Phi_c x_2^2 + 6c_3x_2x_3 \\ -\sigma x_3^2 - 2\sigma\Phi_c x_2 x_3 \end{bmatrix},$$

$$\tilde{L}_1 = \begin{bmatrix} -\frac{1}{2\beta^2\sqrt{\Psi_c}} & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \; C_0[x,x,x] = \begin{bmatrix} -\frac{\gamma_c}{16\beta^2\Psi_c^{\frac{5}{2}}} x_1^3 \\ c_3 x_2^3 \\ -\sigma x_2^2 x_3 \end{bmatrix}, \; r = \begin{bmatrix} 6c_3 \\ \frac{3c_3\gamma_c}{\sqrt{\Psi_c}} \\ 1 \end{bmatrix}, \tag{39}$$

and $\ell = \begin{bmatrix} 0 & 0 & 1 \end{bmatrix}$. Thus the critical mode of the linearized system is uncontrollable. By the assumption in [16, 14, 20], $\sigma > 0$ and $\beta > 0$. For the uncontrolled system,

$$\tilde{\lambda}_1 = \ell Q_0[r,r] = -\sigma\left(1 + \frac{6c_3\gamma_c}{\sqrt{\Psi_c}}\right) = -\sigma\left(1 + \frac{12c_3}{\Psi_c}\right) > 0, \quad \lambda'(0) = -2\sigma\sqrt{\Psi_c} < 0.$$

Therefore it is a transcritical bifurcation and the bifurcated solution for $R_e > 0$ is unstable. Corollary 3.5 is now applied to compute a linear state feedback gain K_1 that stabilizes the bifurcated solution at $R_e > 0$. Recall that R is the amplitude squared of the disturbance flow. Thus $R_e < 0$ has no physical meaning. Let T be the required similarity transformation as in (23). Then

$$K_1 = \begin{bmatrix} k_\Psi & k_\Phi & k_R \end{bmatrix} = \begin{bmatrix} K_{11} & K_{12} \end{bmatrix} T, \quad K_{11} = \begin{bmatrix} k_1 & k_2 \end{bmatrix}, \quad K_{12} = k_3. \tag{40}$$

Straightforward computation gives

$$T = \begin{bmatrix} 1 & 0 & -6c_3 \\ 0 & 1 & -\frac{3c_3\gamma_c}{\sqrt{\Psi_c}} \\ 0 & 0 & 1 \end{bmatrix}, \qquad L_{00} = \begin{bmatrix} -\frac{\gamma_c\beta^{-2}}{2\sqrt{\Psi_c}} & \beta^{-2} \\ -1 & c_2 + 3c_3\Phi_c^2 \end{bmatrix}, \qquad B_{11} = \begin{bmatrix} -\frac{\sqrt{\Psi_c}}{\beta^2} \\ 0 \end{bmatrix},$$

which yields $a = -2\sqrt{\Psi_c}\sigma$, $b = 0$, and $d = \tilde{d} = 0$. Thus (i)–(iii) of Corollary 3.5 are equivalent to

$$\text{(i) } -\sigma(1 - k_2\sqrt{\Psi_c})\left[\left(1 + \frac{12c_3}{\Psi_c}\right)(1 - k_2\sqrt{\Psi_c}) + 2\sqrt{\Psi_c}k_3\right] < 0, \tag{41}$$

$$\text{(ii) } \lambda'(0)\left(1 + K_{11}L_{00}^{-1}B_{11}\right) = \lambda'(0)(1 - k_2\sqrt{\Psi_c}) < 0 \tag{42}$$

$$\text{(iii) } k_1 > -\Psi_c^{-3/2}, \quad k_2 < \Psi_c^{-1/2}. \tag{43}$$

Note that (iii) implies that (ii) is true, and (i) is reduced to

$$(1 - 6/\Psi_c)\,(1-k_2\sqrt{\Psi_c})+2\sqrt{\Psi_c}k_3 > 0, \quad k_1 = k_\Psi,\;\; k_2 = k_\Phi,\;\; k_3 = -3k_\Psi-\frac{3}{\Psi_c}k_\Phi+k_R,$$

where $c_3 = -1/2$ is used. After simplification, the stabilizing state feedback gain satisfies

$$\text{(44)} \qquad \frac{6-\Psi_c}{\Psi_c^{3/2}} < -6k_\Psi - k_\Phi + 2k_R, \qquad k_\Phi < \Psi_c^{-1/2}, \qquad k_\Psi > -\Psi_c^{-3/2},$$

which are exactly the same as in [14]. Taking $k_R = k_\Phi = 0$ with $c_0 = 8/3$, $c_1 = 1.5$, and $c_3 = -0.5$ yields

$$-\frac{3}{11}\sqrt{\frac{3}{11}} = -\Psi_c^{-3/2} < k_\Psi < \frac{1}{6\sqrt{\Psi_c}} - \Psi_c^{-3/2} = -\frac{7}{66}\sqrt{\frac{3}{11}},$$

which is the same condition obtained in [8]. Taking $k_\Psi = k_\Phi = 0$ yields

$$k_R > 3\Psi_c^{-3/2} - \frac{1}{2\sqrt{\Psi_c}} = 0.1175,$$

which implies that $k_R = 0.5$ as in [16, 20] is a stabilizing gain too.

It should be pointed out that the results of [16, 20] can also be obtained from Theorem 3.6 directly. A more interesting case is that condition (44) can be obtained using Theorem 3.2 as well. Indeed, set $R = A^2$ with A the amplitude of disturbance flow. Then (35) can be written as

$$\text{(45)} \qquad \dot{A} = 0.5\sigma A(1 - \Phi^2 - A^2).$$

Together with (33) and (34), the Moore–Greitzer model has new coordinates (Ψ, Φ, A) and rotating stall corresponds to a subcritical pitchfork bifurcation that is unstable due to $\tilde{\lambda}_1 = 0$ and $\tilde{\lambda}_2 = -\sigma(\Psi_c - 6)/\Psi_c > 0$ [16, 20]. Let $x_1 = \Psi - \Psi_e$, $x_2 = \Phi - \Phi_e$, and $x_3 = A$, and let the output measurement be given by

$$y = H_1 x + H_2[x,x] = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ x_3^2 \end{bmatrix}.$$

Then it is easy to see that the critical mode of the linearized system at $\gamma = \gamma_c$ is neither controllable nor observable in light of

$$L_0 = \begin{bmatrix} -\frac{\gamma_c\beta^{-2}}{2\sqrt{\Psi_c}} & \beta^{-2} & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \qquad B_1 = \begin{bmatrix} -1 \\ 0 \\ 0 \end{bmatrix} \frac{\sqrt{\Psi_c}}{\beta^2},$$

$$H_1 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \qquad \ell^T = r = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix},$$

which are of the same form as in (15) with $T = I$. By Theorem 3.2, linear controllers suffice for stabilization which have the form

$$\text{(46)} \qquad u = K_1 y = K_1(H_1 x + H_2[x,x]) = k_\Psi x_1 + k_\Phi x_2 + k_{A^2} x_3^2.$$

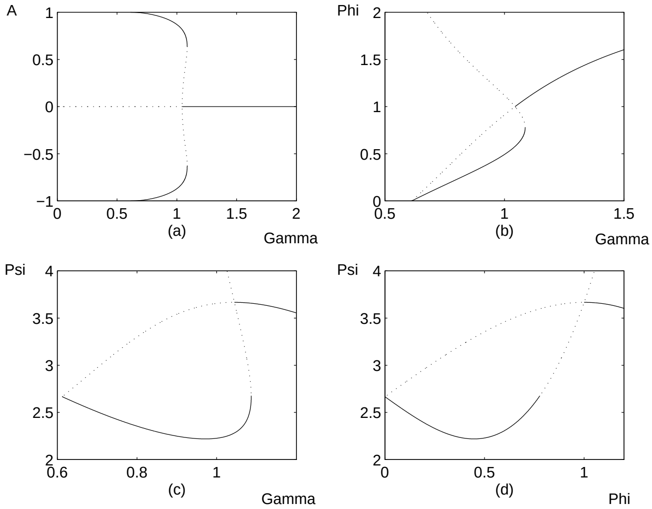

FIG. 1. *Bifurcation diagrams without feedback control.*

Direct computation gives

$$\rho = 2\sqrt{\Psi_c}, \qquad \beta = \begin{bmatrix} 0 \\ -2 \end{bmatrix}, \qquad H_{11}L_{00}^{-1}\left(B_{11}\tilde{\lambda}_2 + \rho\beta\right) = \begin{bmatrix} 6\sigma\sqrt{\Psi_c} \\ \sigma\sqrt{\Psi_c} \end{bmatrix}.$$

Hence the stabilizing conditions in Theorem 3.2 are equivalent to

$$-\frac{\Psi_c - 6}{\Psi_c^{3/2}} + 6k_\Psi + k_\Phi - 2k_{A^2} < 0, \qquad k_\Phi < \Psi_c^{-1/2}, \qquad k_\Psi > -\Psi_c^{-3/2},$$

which are exactly the same as in (44) as $k_R = k_{A^2}$ by $R = A^2$.

Numerical simulations. The compressor model with the following parameters [8, 16, 18, 20]:

$$\lambda = 1.75, \qquad H = 0.18, \qquad W = 0.25, \qquad B = 2, \qquad a = 1/3.5,$$
$$c_0 = 8/3, \qquad c_1 = 1.5, \qquad c_3 = -0.5, \qquad l_c = 8, \qquad l_F = \infty,$$

is used to illustrate the application of our results on bifurcation stabilization. Figure 1 shows four simulation plots for the uncontrolled compression system where (a) is the bifurcation diagram of A_e vs. γ with a solid line for stability and a dotted line for instability. It shows a subcritical pitchfork bifurcation associated with the hysteresis loop in rotating stall. The bifurcation diagrams in Figure 1(b)–(d) are obtained from Figure 1(a) using the relations satisfied for steady equilibrium solutions. The hysteresis loop in Figure 1(a) clearly has adverse effects when using the throttle as control actuator. This is seen from the fact that the operating points (Ψ_e, Φ_e, A_e) are not single-valued functions of γ.

We now apply control law (46) by choosing $K_\Phi = 0$ and $K_{A^2} = 0$. Then a stabilizing K_Ψ must lie in the interval of $(-\frac{3}{11}\sqrt{\frac{3}{11}}, -\frac{7}{66}\sqrt{\frac{3}{11}})$. Using a linear feedback control law with $K_\Psi = -0.0885$, the bifurcation plots are shown in Figure 2. This control law changes the pitchfork bifurcation in Figure 1(a) from subcritical to supercritical as shown in Figure 2(a). The bifurcation diagrams in Figure 2(b)–(d) show that the adverse effects of the hysteresis loop are eliminated, and (Ψ_e, Φ_e, A_e) are all single-valued functions of γ. The details can be found in [8].

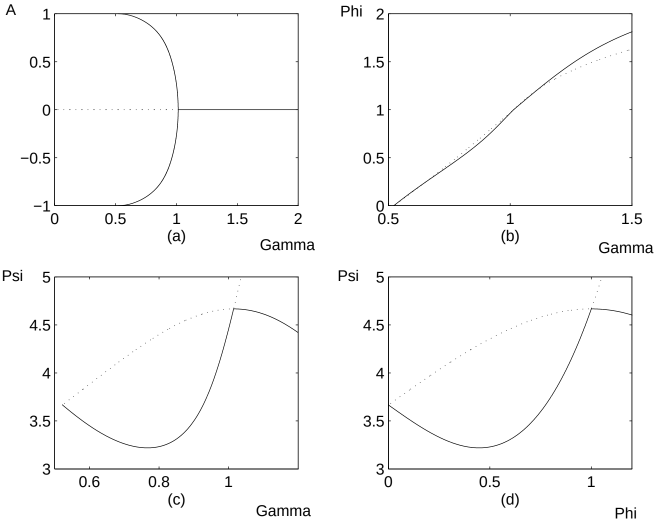

FIG. 2. *Bifurcation diagrams with feedback control.*

6. Conclusion. This paper investigated bifurcation stabilization using smooth local output feedback controllers for parameterized nonlinear systems where the critical mode of the linearized system is uncontrollable. Stabilizability conditions were established for both the case where the critical mode is linearly unobservable and the case where it is observable through output measurement. The latter case includes state feedback as a special case. It was shown that nonlinear controllers do not offer any advantage over the linear ones for bifurcation stabilization if the critical mode of the linearized system is unobservable. For the case that the critical mode of the linearized system is observable, it was shown that linear controllers are adequate for stabilization of transcritical bifurcation, and quadratic controllers are adequate for stabilization of pitchfork and Hopf bifurcations, respectively. Stabilization conditions for nonlinear bifurcations with single critical parameters were characterized in explicit form which can be used to synthesize stabilizing controllers, if they exist. The applicability of the bifurcation stabilization results was demonstrated for rotating stall control of axial flow compressors.

BACKSTEPPING CONTROLLER DESIGN FOR NONLINEAR STOCHASTIC SYSTEMS UNDER A RISK-SENSITIVE COST CRITERION*

ZIGANG PAN† AND TAMER BAŞAR‡

Abstract. This paper develops a methodology for recursive construction of optimal and near-optimal controllers for strict-feedback stochastic nonlinear systems under a risk-sensitive cost function criterion. The design procedure follows the integrator backstepping methodology, and the controllers obtained guarantee any desired achievable level of long-term average cost for a given risk-sensitivity parameter θ. Furthermore, they lead to closed-loop system trajectories that are bounded in probability, and in some cases asymptotically stable in the large. These results also generalize to nonlinear systems with strongly stabilizable zero dynamics. A numerical example included in the paper illustrates the analytical results.

Key words. stochastic differential equation, stochastic stability, risk-sensitive control, integrator backstepping, zero dynamics

1. Introduction.

The topic of designing globally stabilizing controllers for nonlinear systems has been an intense area of research in recent years. A class of nonlinear systems that have attracted particular interest consists of those that can be transformed into linear time-invariant systems under a state diffeomorphism and state feedback—to so-called feedback linearizable nonlinear systems [10]. For this class of nonlinear systems, a general and flexible control design strategy was introduced in the early 1990s [15], which is now known as *integrator backstepping*. This methodology provides a general recursive constructive tool to design controllers for nonlinear systems that are given in the *strict-feedback* form and for systems that are feedback equivalent to such systems. Since the early 1990s, several additional results have been obtained for strict-feedback nonlinear systems using the integrator backstepping method; some selective references in this area are [18], [26], and [12]. This methodology has also been used to design controllers for a class of nonholonomic nonlinear systems [14]. The recent book [19] contains an up-to-date coverage of this topic, with an extensive list of references.

The integrator backstepping methodology provides a considerable amount of flexibility in the design process. This is reflected in terms of the choice of the stabilizing control laws and the additive Lyapunov functions that can be prescribed at each step of the recursive construction. One of the interesting issues that arise in the application of backstepping methodology is the identification of appropriate choices of these

design flexibilities at each step of the recursion, so that an improved control design is achieved at the end of the recursive construction. One approach to this problem is the inverse optimal control design [6], [7]. In [7], for example, it has been shown that given a controlled Lyapunov function for a nonlinear system, one can construct a controller that is optimal for one out of a certain class of desirable cost functions.

Another approach for reducing the choices of integrator backstepping design is to design the controller to guarantee a prespecified level of performance with respect to a given cost criterion. In a recent paper [23], we have introduced such an approach and used the backstepping design tool for guaranteed disturbance attenuation in the framework of the worst-case design methodology. This has involved obtaining controllers that achieve a zero value for a particular parametrized nonlinear differential game.

It has been known for some time that differential game problems are closely related to risk-sensitive stochastic control problems with exponentiated cost [11], [13], [25], [28], [29]. In particular, it has been shown that a general nonlinear/nonquadratic risk-sensitive stochastic control problem for continuous diffusions has an equivalent representation as a stochastic differential game [1]. If the noise intensity vanishes, then a particular (large deviation) limit of the stochastic differential game (and also that of the risk-sensitive stochastic control problem) yields a deterministic differential game. All these connections have motivated, in recent years, accelerated research on the topic of risk-sensitive stochastic control.

Because of the connections alluded to above between deterministic worst-case designs and risk-sensitive stochastic control designs for nonlinear systems, the question arises as to whether the counterpart of the results of [23] can be obtained under a risk-sensitive control formulation, using an integrator backstepping methodology. Such a study would of course also require the development of a "backstepping" tool for stochastic systems. This is precisely the problem addressed in this paper.

To this end, we introduce a class of strict-feedback stochastic nonlinear systems, along with an exponential cost function to be optimized, which is parametrized by a risk-sensitivity parameter θ. For this system, we seek to design a controller that would guarantee any desired achievable level of long-term average cost. It turns out that the construction of a controller for the risk-sensitive cost function is quite different from that of the nonlinear H^∞ problem presented in [23], the reason being that the equivalence between the deterministic dynamic game and the exponential cost problem holds only as the intensity of the system noise diminishes to zero. We present here an explicit recursive construction for the nonlinear control laws that guarantee any prespecified level of long-term average cost and lead to boundedness in probability of the closed-loop system trajectory. Three special cases are discussed in detail. One case is that in which the vector fields for the disturbance vanish at the origin of the system; in this case, the control design can actually guarantee a zero long-term average cost, and the closed-loop system becomes asymptotically stable in the large. Another special case we discuss in the paper pertains to the limit when the risk-sensitivity parameter converges to zero—the case of the risk-neutral performance index. The third special case discussed is that in which the system noise level diminishes to zero, for which we show that the control design procedure converges (in some sense) to the H^∞ control design procedure of [23], uniformly on compact subsets of the entire state space. These results admit immediate extensions to a class of nonlinear systems with strongly stabilizable zero dynamics (section 6). The theoretical findings are further illustrated in section 7 on a second-order nonlinear system.

The paper is organized as follows. In section 2, we present a precise formulation for the problem of guaranteed cost control design and provide some general theorems regarding the uncontrolled version of the exponential cost problem. We discuss the recursive construction procedure for a guaranteed cost controller design in sections 3 and 4; the former discusses a single typical backstepping process for nonlinear systems, which serves as a building block for the more general derivation given in the latter. Extensive discussions of various limits and specializations of the results are included in section 5. In section 6, we extend the result to a class of more general nonlinear systems involving nontrivial zero dynamics. A numerical example is presented in section 7. The paper presents some conclusions and remarks on future research directions in section 8. An appendix includes proofs of two results that are utilized in the main body of the paper.

2. Problem formulation.

We consider the following noise-prone strict-feedback nonlinear system, given by the Itô stochastic differential equation (SDE):[1]

$$
\begin{aligned}
&\text{(2.1a)} && dx_1 = (x_2 + f_1(x_1))\,dt + h_1'(x_1)\,dw,\\
& && \vdots \qquad\quad \vdots\\
&\text{(2.1b)} && dx_{n-1} = (x_n + f_{n-1}(x_1,\dots,x_{n-1}))\,dt + h_{n-1}'(x_1,\dots,x_{n-1})\,dw,\\
&\text{(2.1c)} && dx_n = (f_n(x_1,\dots,x_n) + b(x_1,\dots,x_n)u)\,dt + h_n'(x_1,\dots,x_n)\,dw,\\
&\text{(2.1d)} && y = x_1\,.
\end{aligned}
$$

Here, $x := (x_1,\dots,x_n)'$ is the n-dimensional state vector, with a fixed initial value $x(0)$; u is the scalar control input; w is the q-dimensional vector-valued standard Wiener process; and y is the scalar output. In compact form, the SDE (2.1) can be expressed as

$$dx = (f(x) + G(x)u)\,dt + H(x)\,dw. \tag{2.2}$$

Note that, in addition to the strict-feedback form introduced in [15] in a deterministic setting, the above system incorporates additive stochastic disturbance inputs, where the nonlinear function multiplying the disturbance terms are also in triangular form. The underlying probability space is taken to be the triplet $(\Omega, \mathcal{F}, \boldsymbol{P})$, where Ω is the sample space, $\mathcal{F}$ is a filtration, and $\boldsymbol{P}$ is the probability measure.

For the nonlinear system (2.1), we make the following basic assumption as a starting point of our study.

Assumption A1. The nonlinear functions f_i and h_i are $\mathcal{C}^\infty$ in all their arguments (or simply are smooth), $i = 1,\dots,n$. The nonlinear functions b and $1/b$ are $\mathcal{C}^2$ in all their arguments. The functions f_i, $i = 1,\dots,n$, vanish at $x = 0$: $f_i(x_1,\dots,x_i)|_{x=0} = 0$, $i = 1,\dots,n$. □

The first part of Assumption A1 is a standard smoothness assumption for this class of nonlinear systems; the condition imposed on f_i at $x = 0$ is to ensure that the origin is an equilibrium point of the deterministic (unperturbed) part of the system.

The control input u depends on the current value of the state and hence is generated by

$$u(t) = \mu(x(t)), \tag{2.3}$$

[1] In a deterministic form, systems having the structure (2.1) arise in several applications (see [19]), one of which is robotic manipulators [27]. Here, we have taken the disturbance input to be a Wiener process instead of a deterministic unknown function. We should also note that stochastic systems in the state-space form (2.2) with general dynamics can be brought to the strict-feedback form (2.1) via a diffeomorphic transformation as shown in [22]. This therefore justifies the study of stochastic systems in the form of (2.1).

where the mapping $\mu : \mathbb{R}^n \to \mathbb{R}$ is locally Lipschitz. We denote the class of all such controllers by $\mathcal{M}$.

The objective of the controller design is to maintain a finite (and in fact arbitrarily small, positive) long-term average value for the following *risk-sensitive* cost function:

$$J_\theta(\mu) = \limsup_{t_f \to \infty} \frac{2}{\theta t_f} \ln \left\{ \boldsymbol{E} \left\{ \exp \left[\frac{\theta}{2} \left(\int_0^{t_f} y^2(t)\, dt \right) \right] \right\} \right\}, \tag{2.4}$$

where θ is the risk-sensitivity parameter. When θ is positive, the cost functional weights heavily the large deviations of y (from a base zero) through the exponential operator, which leads to a risk-averse control design. The larger θ is, the more conservative is the controller. On the other hand, if θ is negative, the optimization will lead to a risk-seeking controller design. If we take $\theta \to 0$, then the cost function converges to a standard integral cost, with the underlying stochastic control problem also known as a *risk-neutral* problem. In this paper, we will study only the case in which θ is positive. The risk-seeking case (i. e., with $\theta < 0$) can be studied analogously but will not be covered here.

An important point to note here is that in the performance function (2.4) there is no weighting on the control input, and hence control can be chosen arbitrarily large without incurring any cost. This, coupled with the strict-feedback structure, allows an arbitrarily small positive long-term average value to be guaranteed for the closed-loop system, for any given risk-sensitivity parameter θ—a result that will actually be established in this paper. The smaller the long-term average cost is, the larger the control effort will generally be. Similarly, the larger the value of θ is, the higher will be the induced weighting on large excursions of the output y, which implies a better systems response if the long-term average cost is maintained at a constant value, but at the expense of a larger control effort. Motivated by these considerations, we embed the original problem of minimizing (2.4) in a larger class of "cost-level satisfaction" problems, where the objective is to find a controller that leads to satisfaction of a given bound on the risk-sensitive cost. This is captured in the following definition.

DEFINITION 2.1. *Given a risk-sensitivity parameter θ, a controller μ is said to achieve a guaranteed risk-sensitive cost $R_c \geq 0$, if the following inequality holds:*

$$J_\theta(\mu) = \limsup_{t_f \to \infty} \frac{2}{\theta t_f} \ln \left\{ \boldsymbol{E} \left\{ \exp \left[\frac{\theta}{2} \left(\int_0^{t_f} (y^2(t) + l(x(t)))\, dt \right) \right] \right\} \right\} \leq R_c, \tag{2.5}$$

where the function $l(x(t))$ is nonnegative and is chosen by the designer.

Our objective, succinctly stated, is given $\theta > 0$ and any $R_c > 0$ ($R_c = 0$ under the additional assumption $H(0) = 0$), to construct a controller that achieves a risk-sensitive cost of R_c. To achieve this, our approach to the problem is recursive construction of the value function using the *integrator backstepping* procedure. To this end, we first present a result that deals with the issues of existence, uniqueness, stability, and performance of a control free risk-sensitive problem. Such a risk-sensitive problem will correspond to the closed-loop system of (2.1) under a particular smooth control design.

We note at this point that the nonlinear continuous-time risk-sensitive stochastic control problem has been treated before by many authors, including the work in [5], [3], [1], [4], and [25]. The most recent paper in this area is [20], in which the general risk-sensitive control problem has been treated in both finite- and infinite-horizon cases under some global Lipschitz conditions. Yet the results presented in all these references are not completely suitable for the class of problems under consideration in this paper, since we are considering here the infinite-horizon case with arbitrary (globally non-Lipschitzian) nonlinearities. In contradistinction with the early references, though, we are interested here in designing a suboptimal control strategy rather than an optimal one, which avoids the measure transformation that is commonly used for this type of a problem.

Let us now consider the SDE

$$dx = f(x)\,dt + H(x)\,dw \tag{2.6}$$

along with a risk-sensitive cost function:

$$J_\theta = \limsup_{t_f\to\infty} \frac{2}{\theta t_f} \ln\left\{\boldsymbol{E}\left\{\exp\left[\frac{\theta}{2}\int_0^{t_f} q(x(t))\,dt\right]\right\}\right\}. \tag{2.7}$$

Let us introduce the value function, $W(t_f - t; x)$, associated with the finite-horizon version of this problem (on interval $[t, t_f]$):

$$W(t_f - t; x) = \frac{2}{\theta}\ln\left\{\boldsymbol{E}\left\{\exp\left[\frac{\theta}{2}\int_t^{t_f} q(x(s))\,ds\right]\right\}\right\} \tag{2.8}$$

for a system with initial time-state pair (t, x). The Hamilton–Jacobi–Bellman (HJB) equation satisfied by W is [1]

$$\frac{\partial W}{\partial t} + \frac{\partial W}{\partial x} f(x) + \frac{\theta}{4}\frac{\partial W}{\partial x} H(x)H'(x)\left(\frac{\partial W}{\partial x}\right)' + \frac{1}{2}\mathrm{Tr}\left(\frac{\partial^2 W}{\partial x^2} H(x)H'(x)\right) + q(x) = 0. \tag{2.9}$$

Generally (and in particular if $H(x)H'(x) > \delta I\ \forall x \in \mathbb{R}^n$, for some $\delta > 0$), the value function $W(t_f - t; x)$ becomes unbounded as the terminal time t_f goes to infinity. The rate at which it goes to infinity corresponds to the long-term average cost for the infinite-horizon problem. Also in view of the results of [20], it is therefore reasonable to assume the following structure for W:

$$W(t_f - t; x) = V(x) + (t_f - t)R_c,$$

where R_c is a desired long-term average cost.

In terms of this constant, $V(x)$ satisfies the following HJB equation:

$$\frac{\partial V}{\partial x} f(x) + \frac{\theta}{4}\frac{\partial V}{\partial x} H(x)H'(x)\left(\frac{\partial V}{\partial x}\right)' + \frac{1}{2}\mathrm{Tr}\left(\frac{\partial^2 V}{\partial x^2} H(x)H'(x)\right) + q(x) = R_c. \tag{2.10}$$

Since we are interested in finding a controller that guarantees the desired long-term average cost R_c, we can relax the equality in (2.10) to an inequality, and thus search for a $V(x)$ that satisfies the following HJB inequality:

$$\frac{\partial V}{\partial x} f(x) + \frac{\theta}{4}\frac{\partial V}{\partial x} H(x)H'(x)\left(\frac{\partial V}{\partial x}\right)' + \frac{1}{2}\mathrm{Tr}\left(\frac{\partial^2 V}{\partial x^2} H(x)H'(x)\right) + q(x) = \Delta(x) \le R_c, \tag{2.11}$$

where R_c is the desired long-term average risk-sensitive cost that uniformly bounds the function $\Delta(x)$. We will prove that the existence of a $\mathcal{C}^2$ solution to the above

HJB inequality yields the desired existence, uniqueness, stability, and performance requirements for the original risk-sensitive control problem defined by (2.6) and (2.7).

First, we recall the stochastic process notions of *bounded in probability* and *asymptotic stability in the large*, as introduced in Chapter 1, Section 4 and Chapter 5, Section 4 of the classical book [17]. These notions will be useful in our development.

DEFINITION 2.2. *A stochastic process* $\{x(t), t \geq 0\}$ *is said to be* bounded in probability *if*

$$\lim_{c\to\infty} \sup_{0\leq t<\infty} \boldsymbol{P}\{|x(t)| > c\} = 0. \tag{2.12}$$

DEFINITION 2.3. *Consider the SDE* (2.6), *with* $H(0) = 0$. *The solution* $x(t) \equiv 0$ *of such an SDE is said to be* asymptotically stable in the large *if for any* $\epsilon > 0$,

$$\lim_{|x_0|\to 0} \boldsymbol{P}\{\sup_{t\geq 0} |x(t)| \geq \epsilon\} = 0 \tag{2.13}$$

and for any initial condition x_0,

$$\boldsymbol{P}\{\lim_{t\to\infty} x(t) = 0\} = 1. \tag{2.14}$$

DEFINITION 2.4. *A scalar function* $V : \mathbb{R}^n \to \mathbb{R}$ *is* positive definite *if* $V(0) = 0$ *and* $V(x) > 0\ \forall x \in \mathbb{R}^n \setminus \{0\}$. V *is* radially unbounded *if* $V(x) \to \infty$ *as* $|x| \to \infty$.

We are now in a position to state (and prove) the following theorem.

THEOREM 2.5. *Consider the SDE* (2.6) *with the risk-sensitive cost function* (2.7). *Let* $\theta > 0$ *and* $R_c \geq 0$ *be fixed. Assume that the vector field* $f(x)$ *and the matrix-valued function* $H(x)$ *are* $\mathcal{C}^1$ *in their arguments, and the function* $q(x)$ *is nonnegative definite and is* $\mathcal{C}^2$ *in its argument. Further assume that there exists a positive definite and radially unbounded* $\mathcal{C}^2$ *value function* $V(x)$ *satisfying the HJB inequality* (2.11). *Then the following statements are true.*

1. *There exists an almost surely (a.s.)* $\boldsymbol{P}$ *unique solution to the SDE* (2.6) *on* $[0, \infty)$.
2. *The cost* (2.7) *is upper bounded by* R_c.
3. *If, in addition,* $V(x)$ *and* $q(x)$ *satisfy the linear bound relationship*[2]

$$V(x) \leq c_1 q(x) + c_2 \qquad \forall x \in \mathbb{R}^n \tag{2.15}$$

for some positive constants c_1, c_2, *then the solution* $x(t)$ *to the SDE* (2.6) *is bounded in probability.*

4. *If* $R_c = 0$, $H(0) = 0$, *and the function* $q(x)$ *is positive definite, then the SDE* (2.6) *is asymptotically stable in the large.*

Proof. Consider the function $\tilde{W}(x) := V(x) + R_c$. By the HJB inequality (2.11), we have

$$\begin{aligned}\frac{\partial \tilde{W}}{\partial x} f(x) + \frac{1}{2}\mathrm{Tr}\left(\frac{\partial^2 \tilde{W}}{\partial x^2} H(x)H(x)'\right) &= -\frac{\theta}{4}\frac{\partial V}{\partial x} H(x)H(x)' \left(\frac{\partial V}{\partial x}\right)' - q(x) + \Delta(x)\\ &\leq \Delta(x) \leq R_c \leq \tilde{W}(x)\end{aligned}$$

for any $x \in \mathbb{R}^n$. Since the function $V(x)$ is radially unbounded, $\tilde{W}$ is also radially unbounded. Then, by Theorem 4.1 of Chapter 3 of [17], we conclude that there exists

[2] In section 4, we will provide an explicit construction for a function V that satisfies this bound.

a solution to the SDE (2.6) on the infinite interval $[0,\infty)$, and that the solution is a.s. $\boldsymbol{P}$ unique. This completes the proof of the first statement.

For the second statement, we apply Itô's rule to the stochastic process $V(x(t))$ generated by composing $V(\cdot)$ with the stochastic process $x(t),\ t\geq 0$:

$$\begin{aligned} dV(x(t)) &= \left(\frac{\partial V}{\partial x}f(x)+\frac{1}{2}\mathrm{Tr}\left(\frac{\partial^2 V}{\partial x^2}H(x)H'(x)\right)\right)dt+\frac{\partial V}{\partial x}H(x)\,dw \\ &= \frac{\partial V}{\partial x}H(x)\,dw-\left(\frac{\theta}{4}\frac{\partial V}{\partial x}H(x)H'(x)\left(\frac{\partial V}{\partial x}\right)'+q(x)-\Delta(x)\right)dt, \end{aligned}$$

where in the second line we have made use of (2.11).

Integrating both sides of this equation, we arrive at

$$\begin{aligned} \int_0^{t_f} q(x)\,dt &= \int_0^{t_f}\left(\frac{\partial V}{\partial x}H(x)\,dw-\left(\frac{\theta}{4}\frac{\partial V}{\partial x}H(x)H'(x)\left(\frac{\partial V}{\partial x}\right)'-\Delta(x)\right)dt\right) \\ &\quad +V(x(0))-V(x(t_f)) \\ &\leq V(x(0))+\int_0^{t_f}\left(\frac{\partial V}{\partial x}H(x)\,dw-\frac{\theta}{4}\frac{\partial V}{\partial x}H(x)H'(x)\left(\frac{\partial V}{\partial x}\right)'dt\right)+R_c t_f, \end{aligned}$$

where in the second line we have used the bound $\Delta(x)\leq R_c$ and replaced $V(x(t_f))$ by its lower bound 0. Using this expression in the cost function J_θ, we have

$$\begin{aligned} J_\theta \leq \limsup_{t_f\to\infty}\frac{2}{\theta t_f}\ln&\left\{\boldsymbol{E}\left\{\exp\left[\int_0^{t_f}\left(\frac{\theta}{2}\frac{\partial V}{\partial x}H(x)\,dw-\frac{\theta^2}{8}\left|H'(x)\left(\frac{\partial V}{\partial x}\right)'\right|^2 dt\right)\right]\right\}\right\} \\ &+R_c. \end{aligned}$$

The stochastic process

$$\zeta(t):=\exp\left[\int_0^t\left(\frac{\theta}{2}\frac{\partial V}{\partial x}H(x)\,dw-\frac{\theta^2}{8}\frac{\partial V}{\partial x}H(x)H'(x)\left(\frac{\partial V}{\partial x}\right)'dt\right)\right] \tag{2.16}$$

is almost surely positive and is a supermartingale (see the appendix). Hence,

$$\boldsymbol{E}(\zeta(t_f))\leq 1 \qquad \forall t_f>0.$$

Using this bound in the inequality for J_θ yields the desired bound

$$J_\theta\leq R_c.$$

This establishes the second statement of the theorem.

The third statement follows from Theorem 2 of Chapter 3, Section 13 of [8], which says that, for any $\delta>0$,

$$\sup_{0\leq t<\infty}\boldsymbol{P}\{V(x(t))>\delta\}\leq\frac{1}{\delta}\left(V(x(0))+\frac{c_2+R_c}{c_1}\right)$$

because of the HJB inequality (2.11).

Since V is a positive definite and radially unbounded function, there exists a continuous strictly increasing scalar function $\alpha : [0, \infty) \to [0, \infty)$ with the property $\lim_{s\to\infty} \alpha(s) = \infty$ such that (see Lemma 3.5 in [16])

$$V(x) \geq \alpha(|x|).$$

Consequently,

$$\begin{aligned}\sup_{0\leq t<\infty} \boldsymbol{P}\{|x(t)| > \delta\} &= \sup_{0\leq t<\infty} \boldsymbol{P}\{\alpha(|x|) > \alpha(\delta)\} \leq \sup_{0\leq t<\infty} \boldsymbol{P}\{V(x(t)) > \alpha(\delta)\} \\ &\leq \frac{1}{\alpha(\delta)} \left(V(x(0)) + \frac{c_2 + R_c}{c_1} \right).\end{aligned}$$

The third statement follows by taking the limit $\delta \to \infty$.

When $R_c = 0$, the last statement is a direct consequence of Theorem 4.4 of Chapter 5 of [17].

This completes the proof of the theorem. □

In the development to follow, we will make extensive use of an equivalent form of the HJB equation (2.11), which is made precise by the following proposition.

PROPOSITION 2.6. *A $\mathcal{C}^2$ function $V(x)$ satisfies the HJB equation* (2.11) *if and only if the following algebraic relationship holds:*

$$\begin{aligned}\frac{\partial V}{\partial x} f(x)\, dt + \frac{\partial V}{\partial x} H(x)\, dw + \frac{1}{2} \mathrm{Tr}\left(\frac{\partial^2 V}{\partial x^2} H(x) H'(x) \right) dt \\ = \sigma(x)\, dw - \left(\frac{\theta}{4} \sigma(x)\sigma'(x) + q(x) - \Delta(x) \right) dt,\end{aligned} \tag{2.17}$$

where $\sigma(x) = \frac{\partial V}{\partial x} H(x)$ for all $x \in \mathbb{R}^n$.

Proof. Sufficiency. By the hypothesis of the proposition, we have

$$\begin{aligned}\frac{\partial V}{\partial x} f(x)\, dt + \frac{\partial V}{\partial x} H(x)\, dw + \frac{1}{2} \mathrm{Tr}\left(\frac{\partial^2 V}{\partial x^2} H(x) H'(x) \right) dt \\ = \sigma(x)\, dw - \left(\frac{\theta}{4} \sigma(x)\sigma'(x) + q(x) - \Delta(x) \right) dt.\end{aligned} \tag{2.18}$$

Taking expectations on both sides of the equation, we get

$$\frac{\partial V}{\partial x} f(x)\, dt + \frac{1}{2} \mathrm{Tr}\left(\frac{\partial^2 V}{\partial x^2} H(x) H'(x) \right) dt = -\left(\frac{\theta}{4} \sigma(x)\sigma'(x) + q(x) - \Delta(x) \right) dt.$$

Therefore, by dividing both sides by dt, we have

$$\frac{\partial V}{\partial x} f(x) + \frac{\theta}{4} \sigma(x)\sigma'(x) + q(x) + \frac{1}{2} \mathrm{Tr}\left(\frac{\partial^2 V}{\partial x^2} H(x) H'(x) \right) = \Delta(x).$$

Since this holds for any initial condition $x \in \mathbb{R}^n$, the function $V(x)$ satisfies the HJB equation (2.11). Substituting this into (2.18), we have

$$\frac{\partial V}{\partial x} H(x)\, dw = \sigma(x)\, dw.$$

By Lemma A.2 in the appendix, we have

$$\frac{\partial V}{\partial x} H(x) = \sigma(x).$$

Then, it holds for all $x \in \mathbb{R}^n$. Substitution of this equality into (2.18) leads to the HJB equation (2.11).

This completes the proof of the sufficiency part of the proposition.

Necessity. Since the HJB equation (2.11) is satisfied by the $\mathcal{C}^2$ function $V(x)$,

$$\begin{aligned}\left(\frac{\partial V}{\partial x} f(x) + \frac{1}{2}\mathrm{Tr}\left(\frac{\partial^2 V}{\partial x^2} H(x)H'(x)\right)\right) dt + \frac{\partial V}{\partial x} H(x)\, dw \\ = \frac{\partial V}{\partial x} H(x)\, dw - \left(\frac{\theta}{4}\sigma(x)\sigma'(x) + q(x) - \Delta(x)\right) dt.\end{aligned}$$

This completes the proof of the necessity part of the proposition. □

REMARK 2.1. *We note that in Proposition* 2.6, *the left-hand side of* (2.6) *equals the Itô differential of the stochastic process $V(x(t))$ with $x(t)$ generated by the SDE*

$$dx = f(x)\, dt + H(x)\, dw, \qquad x(0) = x, \tag{2.19}$$

whenever it exists. As a consequence of the property that the function $V(x)$ satisfies the HJB equation (2.11), *the Itô differential of $V(x(t))$ exists under additional growth conditions delineated in Theorem* 2.5. *These growth conditions will automatically be satisfied by the recursive construction procedure to be described later. For notational simplicity, we henceforth identify $dV(x(t))$ with*

$$\left(\frac{\partial V}{\partial x} f(x) + \frac{1}{2}\mathrm{Tr}\left(\frac{\partial^2 V}{\partial x^2} H(x)H'(x)\right)\right) dt + \frac{\partial V}{\partial x} H(x)\, dw$$

for a candidate $\mathcal{C}^2$ value function $V(x)$ without verifying the existence of the Itô differential. The validity of this correspondence, which is equivalent to the existence of the Itô differential of $V(x(t))$, will be justified by a later application of Theorem 2.5.

We now turn, in the next two sections, to the development of a recursive construction procedure for a risk-sensitive controller with a desired guaranteed cost. In the next section, we first study a typical step in the recursive design, which provides a technical tool in the construction of a cost bounding controller for the full-order system.

3. Recursive design.

In this section, we present a systematic recursive design methodology for constructing a guaranteed cost controller for the risk-sensitive stochastic control problem.

Consider the following two-level problem:

$$d\eta = (f_1(\eta) + g_1(\eta)\xi)\, dt + H_1(\eta)\, dw, \tag{3.1a}$$

$$d\xi = (f_2(\eta, \xi) + v)\, dt + H_2(\eta, \xi)\, dw, \tag{3.1b}$$

where η is of dimension $n_1 > 0$, and ξ is a scalar. The exogenous disturbance process w is as defined in section 2. The scalar v is the control variable for this two-level system. All nonlinear functions involved are assumed to be smooth.

Suppose that the control design for the η system has been completed with ξ as the control input, and the first component of η as the output y. Further assume that this design has resulted in a smooth positive definite and radially unbounded value function $V_1(\eta)$ and a smooth control law $\alpha_1(\eta)$ (for ξ) when the running cost in (2.4) has an additional additive nonnegative term $q_1(\eta)$. Let a guaranteed time-average cost level be $R_1 \geq 0$, which can be picked as *zero* if $H_1(0) = 0$, and positive (but arbitrarily close to *zero*) otherwise. Further suppose that the following four induction hypotheses hold.

1. The equilibrium condition $\alpha_1(0) = 0$.
2. If $\xi = \alpha_1(\eta)$, the value function V_1 for this system satisfies the HJB inequality

$$\frac{\partial V_1}{\partial \eta}(f_1(\eta) + g_1(\eta)\alpha_1(\eta)) + \frac{\theta}{4}\frac{\partial V_1}{\partial \eta} H_1(\eta)H_1'(\eta)\left(\frac{\partial V_1}{\partial \eta}\right)' + y^2 + q_1(\eta) + \frac{1}{2}\mathrm{Tr}\left(\frac{\partial^2 V_1}{\partial \eta^2} H_1(\eta)H_1'(\eta)\right) =: \Delta_1(\eta) \leq R_1 \tag{3.2}$$

3. The weighting function $q_1(\eta)$ is smooth and positive definite, and there exist constants $c_1 > 0$, $c_2 > 0$, $c_3 > 0$, and $c_4 > 0$, such that

$$q_1(\eta) \geq c_1 \eta' \eta \qquad \forall |\eta| \leq c_2 \tag{3.3}$$

and

$$V_1(\eta) \leq c_3\, q_1(\eta) + c_4 \qquad \forall \eta \in \mathbb{R}^{n_1}. \tag{3.4}$$

4. When $H_1(0) = 0$, the value function V_1 and control law α_1 can be chosen in such a way to make the long-term average cost *zero* (i.e., $R_1 = 0$).

These hypotheses lead to the conclusion that the η system admits a guaranteed risk-sensitive cost R_1 with risk-sensitivity parameter θ, i.e.,

$$\limsup_{t_f \to \infty} \frac{2}{\theta t_f} \ln \left\{ \boldsymbol{E} \left\{ \exp\left[\frac{\theta}{2} \left(\int_0^{t_f} (y^2(t) + q_1(\eta(t)))\, dt \right) \right] \right\} \right\} \leq R_1$$

and is stochastically bounded, if we can set $\xi = \alpha_1(\eta)$. When $H_1(0) = 0$, the guaranteed cost R_1 is identically zero. In this case, the closed-loop system is asymptotically stable in the large.

Among the conditions above, we stress the importance of the quadratic growth condition on the function q_1 of the induction hypothesis 3. This growth condition is crucial for the function q_1 to bound the quadratic variation term that results from the ξ subsystem when R_2 is identically zero. This point will be elucidated shortly.

In the design of the control law α_1 and the value function V_1, we have taken ξ as a control input. In reality, ξ is the state of an SDE driven by the control input v. Hence, to complete the design process, we next consider the control design for the entire (η, ξ) system, based on the knowledge of the control design for the η subsystem just completed. Our objective for the design of the (η, ξ) system is to achieve the time-average cost bound

$$\limsup_{t_f \to \infty} \frac{2}{\theta t_f} \ln \left\{ \boldsymbol{E} \left\{ \exp\left[\frac{\theta}{2} \left(\int_0^{t_f} (y^2 + (1-\lambda) q_1(\eta) + q_2(\eta, \xi))\, dt \right) \right] \right\} \right\} \leq R_1 + R_2$$

and ensure stochastic boundedness of the closed-loop system, where the constant $\lambda \in (0,1)$ is a design constant. In the above, q_2 is another arbitrary nonnegative functional chosen by the control designer, and R_2 is a nonnegative constant, reflecting the design specification. Note further that $q_1(\eta)$ has been rescaled by a factor of $1-\lambda$. When $H_1(0) = 0$ and $H_2(0,0) = 0$, we take R_2 to be zero, which reflects our desire to guarantee an asymptotically stable (in the sense of Definition 2.3) closed-loop system for this special case. Otherwise, R_2 is taken to be positive.

To obtain a controller for the composite system, we consider the state transformation

$$z := \xi - \alpha_1(\eta), \tag{3.5}$$

where z represents the deviation of the random process ξ from its desired trajectory $\alpha_1(\eta)$.

Let us now introduce a convention that is adopted for the rest of this section. Any function symbol marked with an overbar will denote a function defined in terms of the transformed state variables $(\eta', z)'$, such as $\bar{a}$ denoting the equivalent form of function a (of $(\eta', \xi)'$) in terms of transformed state variables, $(\eta', z)'$.

In terms of this transformed state variable, we can rewrite the SDE (3.1) as follows:

$$\begin{aligned} d\eta &= (f_1 + g_1\alpha_1 + g_1 z)\, dt + H_1\, dw \\ dz &= \left(f_2 + v - \frac{\partial \alpha_1}{\partial \eta}(f_1 + g_1\alpha_1 + g_1 z) - \frac{1}{2}\mathrm{Tr}\left(\frac{\partial^2 \alpha_1}{\partial \eta^2} H_1 H_1' \right) \right) dt \\ &\quad + \left(H_2 - \frac{\partial \alpha_1}{\partial \eta} H_1 \right) dw. \end{aligned}$$

We introduce the following terms:

$$\begin{aligned} \bar{a}_2(\eta, z) &:= f_2 - \frac{\partial \alpha_1}{\partial \eta}(f_1 + g_1\alpha_1 + g_1 z) - \frac{1}{2}\mathrm{Tr}\left(\frac{\partial^2 \alpha_1}{\partial \eta^2} H_1 H_1' \right), \\ \bar{d}_2(\eta, z) &:= H_2 - \frac{\partial \alpha_1}{\partial \eta} H_1. \end{aligned}$$

We note here that the function $\bar{a}_2$ includes the quadratic variation of α_1 and does not vanish at $\eta = 0$, in general. Since $\bar{d}_2$ is a smooth (nonlinear) function of (η, z), we can rewrite it as follows, where $\bar{d}_{22}$ is also smooth:

$$\bar{d}_2(\eta, z) =: \bar{d}_{21}(\eta) + z\bar{d}_{22}(\eta, z).$$

Using the preceding notation, we have

$$dz = (\bar{a}_2 + v)\, dt + (\bar{d}_{21} + z\bar{d}_{22})\, dw.$$

Consider the following smooth function $V_2(\eta, \xi)$ as a candidate value function for the (η, ξ) system:

$$\bar{V}_2(\eta, z) := V_1(\eta) + \Xi(\eta) z^2, \tag{3.6}$$

where Ξ is some positive smooth function yet to be determined. In forming the value function V_2, we have added to the previous value function V_1 the term Ξz^2, instead of a simple z^2. This is motivated by the fact that the quadratic variation term of the difference $V_2 - V_1$ does not in general vanish at $z = 0$. To guarantee the desired long-term average performance, we have to introduce the Ξ function into the design, as will be clear shortly.

Using Itô's rule, the random process $\bar{V}_2(\eta(t), z(t))$ satisfies the following SDE: [3]

$$\begin{aligned} d\bar{V}_2(\eta(t), z(t)) &= dV_1(\eta(t)) + \begin{bmatrix} z^2 \left(\dfrac{\partial \Xi}{\partial \eta} \right)' \\ 2z\Xi \end{bmatrix}' \begin{bmatrix} (f_1 + g_1\alpha_1 + g_1 z)\, dt + H_1\, dw \\ (\bar{a}_2 + v)\, dt + (\bar{d}_{21} + z\bar{d}_{22})\, dw \end{bmatrix} \\ &\quad + \frac{1}{2}\mathrm{Tr}\left(\begin{bmatrix} z^2 \dfrac{\partial^2 \Xi}{\partial \eta^2} & 2z \left(\dfrac{\partial \Xi}{\partial \eta} \right)' \\ 2z \dfrac{\partial \Xi}{\partial \eta} & 2\Xi \end{bmatrix} \begin{bmatrix} H_1 \\ \bar{d}_{21} + z\bar{d}_{22} \end{bmatrix} \begin{bmatrix} H_1 \\ \bar{d}_{21} + z\bar{d}_{22} \end{bmatrix}' \right) dt \end{aligned}$$

[3] All these differentials exist, as the explicit construction of V_1, $\bar{V}_2$, ... will reveal.

Since the differential for $V_1(\eta(t))$ is

$$dV_1(\eta(t)) = -\left(\frac{\theta}{4}\frac{\partial V_1}{\partial \eta} H_1 H_1' \left(\frac{\partial V_1}{\partial \eta}\right)' + y^2 + q_1 - \frac{\partial V_1}{\partial \eta} g_1 z - \Delta_1\right) dt \\ + \frac{\partial V_1}{\partial \eta} H_1 \, dw,$$

we further have

$$\text{(3.7)}\quad d\bar{V}_2(\eta(t), z(t)) = -y^2\, dt - q_1\, dt + \bar{\sigma}_2\, dw - \frac{\theta}{4}\frac{\partial V_1}{\partial \eta} H_1 H_1' \frac{\partial V_1}{\partial \eta}'\, dt + \frac{\partial V_1}{\partial \eta} g_1 z\, dt \\ + \Delta_1\, dt + \begin{bmatrix} z^2 \left(\dfrac{\partial \Xi}{\partial \eta}\right)' \\ 2z\Xi \end{bmatrix}' \begin{bmatrix} f_1 + g_1\alpha_1 + g_1 z \\ \bar{a}_2 + v \end{bmatrix} dt \\ + \frac{1}{2}\mathrm{Tr}\left(\begin{bmatrix} z^2 \dfrac{\partial^2 \Xi}{\partial \eta^2} & 2z\left(\dfrac{\partial \Xi}{\partial \eta}\right)' \\ 2z\dfrac{\partial \Xi}{\partial \eta} & 2\Xi \end{bmatrix} \begin{bmatrix} H_1 H_1' & H_1 \bar{d}_2' \\ \bar{d}_2 H_1' & (\bar{d}_{21} + z\bar{d}_{22})(\bar{d}_{21} + z\bar{d}_{22})' \end{bmatrix} \right) dt,$$

where

$$\bar{\sigma}_2(\eta, z) := \begin{bmatrix} \dfrac{\partial \bar{V}_2}{\partial \eta} & \dfrac{\partial \bar{V}_2}{\partial z} \end{bmatrix} \begin{bmatrix} H_1 \\ \bar{d}_2 \end{bmatrix} \equiv \frac{\partial V_1}{\partial \eta} H_1 + \begin{bmatrix} z^2 \left(\dfrac{\partial \Xi}{\partial \eta}\right)' \\ 2z\Xi \end{bmatrix}' \begin{bmatrix} H_1 \\ \bar{d}_2 \end{bmatrix}.$$

We seek a control law α_2 such that $\bar{V}_2$ satisfies the following HJB inequality:

$$\text{(3.8)}\quad \begin{bmatrix} \dfrac{\partial V_2}{\partial \eta} \\ \dfrac{\partial V_2}{\partial \xi} \end{bmatrix}' \begin{bmatrix} f_1(\eta) + g_1(\eta)\xi \\ f_2(\eta, \xi) + \alpha_2(\eta, \xi) \end{bmatrix} + y^2 + (1-\lambda) q_1(\eta) + q_2(\eta, \xi) \\ + \frac{\theta}{4} \begin{bmatrix} \dfrac{\partial V_2}{\partial \eta} \\ \dfrac{\partial V_2}{\partial \xi} \end{bmatrix}' \begin{bmatrix} H_1(\eta) \\ H_2(\eta, \xi) \end{bmatrix} \begin{bmatrix} H_1(\eta) \\ H_2(\eta, \xi) \end{bmatrix}' \begin{bmatrix} \dfrac{\partial V_2}{\partial \eta} \\ \dfrac{\partial V_2}{\partial \xi} \end{bmatrix} \\ + \frac{1}{2}\mathrm{Tr}\left(\begin{bmatrix} \dfrac{\partial^2 V_2}{\partial \eta^2} & \dfrac{\partial^2 V_2}{\partial \eta \partial \xi} \\ \dfrac{\partial^2 V_2}{\partial \eta \partial \xi} & \dfrac{\partial^2 V_2}{\partial \xi^2} \end{bmatrix} \begin{bmatrix} H_1(\eta) \\ H_2(\eta, \xi) \end{bmatrix} \begin{bmatrix} H_1(\eta) \\ H_2(\eta, \xi) \end{bmatrix}' \right) \le R_1 + R_2$$

for some nonnegative function q_2, by making use of the equivalence given in Proposition 2.6. To this end, we add and subtract $\frac{\theta}{4}\bar{\sigma}_2(\eta, z)\bar{\sigma}_2'(\eta, z)\, dt$ and $\bar{\beta}(\eta, z) z^2\, dt$ to the right-hand side of (3.7). This yields

$$d\bar{V}_2(\eta(t), z(t)) = -y^2\, dt - q_1\, dt - \bar{\beta} z^2\, dt + \bar{\sigma}_2\, dw - \frac{\theta}{4}\bar{\sigma}_2\bar{\sigma}_2'\, dt + \Delta_1\, dt \\ + \bar{\beta} z^2\, dt + \frac{\theta}{4}\bar{\sigma}_2\bar{\sigma}_2'\, dt + \frac{\partial V_1}{\partial \eta} g_1 z\, dt - \frac{\theta}{4}\frac{\partial V_1}{\partial \eta} H_1 H_1' \frac{\partial V_1}{\partial \eta}'\, dt \\ + \begin{bmatrix} z^2 \left(\dfrac{\partial \Xi}{\partial \eta}\right)' \\ 2z\Xi \end{bmatrix}' \begin{bmatrix} f_1 + g_1\alpha_1 + g_1 z \\ \bar{a}_2 + v \end{bmatrix} dt$$

$$+\frac{1}{2}\mathrm{Tr}\left(\left[\begin{array}{cc} z^2\dfrac{\partial^2\Xi}{\partial\eta^2} & 2z\left(\dfrac{\partial\Xi}{\partial\eta}\right)' \\ 2z\dfrac{\partial\Xi}{\partial\eta} & 2\Xi \end{array}\right]\left[\begin{array}{cc} H_1H_1' & H_1\bar{d}_2' \\ \bar{d}_2H_1' & (\bar{d}_{21}+z\bar{d}_{22})(\bar{d}_{21}+z\bar{d}_{22})' \end{array}\right]\right) dt,$$

where the function $\bar{\beta}(\eta, z)$ is to be determined shortly.

By multiplying out various terms above, we arrive at

$$\begin{aligned} d\bar{V}_2(\eta(t), z(t)) &= -y^2\,dt - q_1\,dt + \bar{\sigma}_2\,dw - \frac{\theta}{4}\bar{\sigma}_2\bar{\sigma}_2'\,dt + \Delta_1\,dt - \bar{\beta}z^2\,dt \\ &+\bar{\beta}z^2\,dt + \frac{\theta}{4}\left[\begin{array}{c} z^2\left(\dfrac{\partial\Xi}{\partial\eta}\right)' \\ 2z\Xi \end{array}\right]'\left[\begin{array}{c} H_1 \\ \bar{d}_2 \end{array}\right]H_1'\left(\frac{\partial V_1}{\partial\eta}\right)'\,dt \\ &+\frac{\theta}{4}\frac{\partial V_1}{\partial\eta}H_1\left[\begin{array}{c} H_1 \\ \bar{d}_2 \end{array}\right]'\left[\begin{array}{c} z^2\left(\dfrac{\partial\Xi}{\partial\eta}\right)' \\ 2z\Xi \end{array}\right]dt + \frac{\partial V_1}{\partial\eta}g_1 z\,dt \\ &+\frac{\theta}{4}\left[\begin{array}{c} z^2\left(\dfrac{\partial\Xi}{\partial\eta}\right)' \\ 2z\Xi \end{array}\right]'\left[\begin{array}{c} H_1' \\ \bar{d}_2 \end{array}\right]\left[\begin{array}{c} H_1' \\ \bar{d}_2 \end{array}\right]'\left[\begin{array}{c} z^2\left(\dfrac{\partial\Xi}{\partial\eta}\right)' \\ 2z\Xi \end{array}\right]dt \\ &+\left[\begin{array}{c} z^2\left(\dfrac{\partial\Xi}{\partial\eta}\right)' \\ 2z\Xi \end{array}\right]'\left[\begin{array}{c} f_1+g_1\alpha_1+g_1z \\ \bar{a}_2+v \end{array}\right]dt + \frac{1}{2}\mathrm{Tr}\left(z^2\frac{\partial^2\Xi}{\partial\eta^2}H_1'H_1\right) \\ &+\frac{1}{2}\mathrm{Tr}\left(4z\left(\frac{\partial\Xi}{\partial\eta}\right)'\bar{d}_2H_1 + 2\Xi(z\bar{d}_{21}\bar{d}_{22}' + z\bar{d}_{22}\bar{d}_{21}' + z^2\bar{d}_{22}\bar{d}_{22}')\right)dt \\ &+\Xi\bar{d}_{21}\bar{d}_{21}'\,dt. \end{aligned}$$

In the above SDE, we can select the control to cancel out all terms except those on the first and last lines. The control law that accomplishes this is the following:

$$\begin{aligned} \text{(3.9)}\quad \bar{\alpha}_{2b}(\eta, z) = -\frac{1}{2\Xi}\Bigg(&\bar{\beta}z + \frac{\theta}{4}\left[\begin{array}{c} z\left(\dfrac{\partial\Xi}{\partial\eta}\right)' \\ 2\Xi \end{array}\right]'\left[\begin{array}{c} H_1 \\ \bar{d}_2 \end{array}\right]H_1'\left(\frac{\partial V_1}{\partial\eta}\right)' \\ &+\frac{\theta}{4}\frac{\partial V_1}{\partial\eta}H_1\left[\begin{array}{c} H_1 \\ \bar{d}_2 \end{array}\right]'\left[\begin{array}{c} z\left(\dfrac{\partial\Xi}{\partial\eta}\right)' \\ 2\Xi \end{array}\right] + \frac{\partial V_1}{\partial\eta}g_1 \\ &+\frac{\theta}{4}\left[\begin{array}{c} z\left(\dfrac{\partial\Xi}{\partial\eta}\right)' \\ 2\Xi \end{array}\right]'\left[\begin{array}{c} H_1 \\ \bar{d}_2 \end{array}\right]\left[\begin{array}{c} H_1 \\ \bar{d}_2 \end{array}\right]'\left[\begin{array}{c} z^2\left(\dfrac{\partial\Xi}{\partial\eta}\right)' \\ 2z\Xi \end{array}\right] \\ &+\left[\begin{array}{c} z\left(\dfrac{\partial\Xi}{\partial\eta}\right)' \\ 2\Xi \end{array}\right]'\left[\begin{array}{c} f_1+g_1\alpha_1+g_1z \\ \bar{a}_2 \end{array}\right] \\ &+\frac{1}{2}\mathrm{Tr}\left(z\frac{\partial^2\Xi}{\partial\eta^2}H_1H_1' + 4\left(\frac{\partial\Xi}{\partial\eta}\right)'\bar{d}_2H_1' + 2\Xi(\bar{d}_{21}\bar{d}_{22}' + \bar{d}_{22}\bar{d}_{21}' + z\bar{d}_{22}\bar{d}_{22}')\right)\Bigg). \end{aligned}$$

Even though this controller leads to a guaranteed risk-sensitive cost design, in general it fails to preserve the equilibrium at $(\eta, \xi) = (0,0)$, except for the case when $H_1(0) = 0$ and $H_2(0,0) = 0$. To preserve the equilibrium at the origin, we remove the bias term from (3.9) to arrive at the modified controller

$$v = \bar{\alpha}_2(\eta, z) := \bar{\alpha}_{2b}(\eta, z) - \frac{\Xi(0)}{\Xi(\eta)} \bar{\alpha}_{2b}(0,0), \tag{3.10}$$

which, by its construction, preserves the equilibrium at $(\eta, \xi) = (0,0)$.

Using this control law, the differential of $\bar{V}_2$ becomes

$$\begin{aligned} d\bar{V}_2(\eta(t), z(t)) = -y^2\,dt - q_1\,dt + \bar{\sigma}_2\,dw - \frac{\theta}{4}\bar{\sigma}_2\bar{\sigma}_2'\,dt + \Delta_1\,dt - \bar{\beta} z^2\,dt \\ + \Xi \bar{d}_{21}\bar{d}_{21}'\,dt + 2z\Xi(0)\bar{\alpha}_{2b}(0,0)\,dt, \end{aligned}$$

where the last term is due to the removal of the constant bias in the controller.

To establish the desired HJB inequality (3.8), we will first pick the function Ξ and then β in the following steps. The function $\bar{d}_{21}(\eta)$ is further decomposed into constant and η-dependent parts:

$$\begin{aligned} \bar{d}_{21c} &:= \bar{d}_{21}(0), \\ \bar{d}_{21v}(\eta) &:= \bar{d}_{21}(\eta) - \bar{d}_{21c}. \end{aligned}$$

We choose Ξ such that for any positive R_2 and $\forall \eta \in \mathbb{R}^{n_1}$,

$$\Xi(\eta)\bar{d}_{21}(\eta)\bar{d}_{21}'(\eta) \le \frac{R_2}{2} + \lambda q_1(\eta), \tag{3.11}$$

and furthermore,

$$\Xi(\eta)\bar{d}_{21v}(\eta)\bar{d}_{21v}'(\eta) \le \lambda q_1(\eta). \tag{3.12}$$

One possible choice of the function Ξ can be made in the following two steps. For the first step, we will select a function Ξ_1 such that the inequality (3.12) is satisfied with Ξ_1 instead of Ξ. Since $\bar{d}_{21v}(\eta)$ is a smooth function that vanishes at $\eta = 0$, it can be written as

$$\bar{d}_{21v}(\eta) = \eta' \bar{D}_{21v}(\eta),$$

where $\bar{D}_{21v}$ is a smooth matrix-valued function of appropriate dimension. Let $\lambda_M = \lambda_{\max}(\bar{D}_{21v}(0)\bar{D}_{21v}'(0))$, where $\lambda_{\max}(M)$ denotes the maximum eigenvalue of a symmetric matrix M. Note that the following function is smooth:

$$\chi_1(\eta) = \frac{\lambda q_1(\eta)}{1 + \bar{d}_{21v}(\eta)\bar{d}_{21v}'(\eta)}.$$

Then, by the smoothness of $\bar{D}_{21v}$, there exists a constant $c_5 \in (0, c_2]$ such that

$$\frac{\lambda c_1 \eta'\eta}{(0.5 + \lambda_M)\eta'\eta} - \chi_1(\eta) \ge \frac{\lambda c_1}{1 + \lambda_M} \quad \forall\ 0 < |\eta| \le c_5$$

and

$$\bar{d}_{21v}(\eta)\bar{d}_{21v}'(\eta) = \eta'\bar{D}_{21v}(\eta)\bar{D}_{21v}'(\eta)\eta \le (0.5 + \lambda_M)\eta'\eta \quad \forall\ |\eta| \le c_5.$$

We define the following function:

$$\chi_2(\eta) = \begin{cases} \exp\left(\dfrac{\eta'\eta}{\eta'\eta - c_5^2}\right), & |\eta| < c_5, \\ 0, & |\eta| \geq c_5, \end{cases}$$

which is clearly smooth. Then, Ξ_1 can be chosen as

$$\Xi_1(\eta), = \frac{\lambda c_1}{1+\lambda_M}\chi_2(\eta) + \chi_1(\eta). \tag{3.13}$$

Ξ_1 is smooth and

$$\begin{aligned} \Xi_1(\eta)\bar{d}_{21v}(\eta)\bar{d}'_{21v}(\eta) &\leq \left(\frac{\lambda c_1}{1+\lambda_M} + \chi_1(\eta)\right)\bar{d}_{21v}(\eta)\bar{d}'_{21v}(\eta) \\ &\leq \lambda c_1 \eta'\eta \frac{\bar{d}_{21v}(\eta)\bar{d}'_{21v}(\eta)}{(0.5+\lambda_M)\eta'\eta} \leq \lambda q_1(\eta) \qquad \forall 0 < |\eta| < c_5 \end{aligned}$$

and

$$\Xi_1(\eta)\bar{d}_{21v}(\eta)\bar{d}'_{21v}(\eta) \leq \chi_1(\eta)\bar{d}_{21v}(\eta)\bar{d}'_{21v}(\eta) \leq \lambda q_1(\eta) \qquad \forall |\eta| \geq c_5.$$

Furthermore, $\Xi_1(\eta) > 0$, $\forall \eta \in \mathbb{R}^{n_1}$. Therefore, we have

$$\Xi_1(\eta)\bar{d}_{21v}(\eta)\bar{d}'_{21v}(\eta) \leq \lambda q_1(\eta) \qquad \forall \eta \in \mathbb{R}^{n_1}.$$

For the second step, we will select the function Ξ based on Ξ_1 derived above. Let $C > 0$ be a constant such that

$$C\left(\bar{d}_{21c}\bar{d}'_{21c} + \sqrt{\bar{d}_{21c}\bar{d}'_{21c}}\right) \leq \frac{R_2}{2}.$$

Given the above choice of the function Ξ_1, we can then select the function Ξ as

$$\Xi(\eta) = \frac{C\Xi_1(\eta)}{\sqrt{\Xi_1^2(\eta) + C^2\left(1+\sqrt{\bar{d}_{21c}\bar{d}'_{21c}}\right)^2}}. \tag{3.14}$$

It is clear that Ξ is smooth, and it satisfies the inequalities (3.11) and (3.12) since

$$\begin{aligned} &\Xi(\eta) < \frac{\Xi_1(\eta)}{1+\sqrt{\bar{d}_{21c}\bar{d}'_{21c}}}, \qquad \Xi(\eta) < C, \qquad \Xi(\eta) > 0 \qquad \forall \eta \in \mathbb{R}^{n_1}, \\ &\bar{d}_{21}(\eta)\bar{d}'_{21}(\eta) = \bar{d}_{21c}\bar{d}'_{21c} + 2\bar{d}_{21c}\bar{d}'_{21v}(\eta) + \bar{d}_{21v}(\eta)\bar{d}'_{21v}(\eta) \\ &\qquad \leq \bar{d}_{21c}\bar{d}'_{21c} + \frac{\bar{d}_{21c}\bar{d}'_{21c}}{\sqrt{\bar{d}_{21c}\bar{d}'_{21c}}} + \bar{d}_{21v}(\eta)\bar{d}'_{21v}(\eta)\sqrt{\bar{d}_{21c}\bar{d}'_{21c}} + \bar{d}_{21v}(\eta)\bar{d}'_{21v}(\eta), \\ &\Xi(\eta)\bar{d}_{21}(\eta)\bar{d}'_{21}(\eta) \leq \Xi(\eta)\left(\bar{d}_{21c}\bar{d}'_{21c} + \sqrt{\bar{d}_{21c}\bar{d}'_{21c}}\right) \\ &\qquad +\Xi(\eta)\bar{d}_{21v}(\eta)\bar{d}'_{21v}(\eta), \left(1+\sqrt{\bar{d}_{21c}\bar{d}'_{21c}}\right) < \frac{R_2}{2} + \lambda q_1(\eta) \qquad \forall \eta \in \mathbb{R}^{n_1}. \end{aligned}$$

After fixing the choice of the function Ξ, we next choose the positive function β to be

$$\bar{\beta}(\eta, z) = \frac{2\Xi^2(0)\bar{\alpha}_{2b}^2(0,0)}{R_2} + \bar{\beta}_a(\eta, z), \tag{3.15}$$

$$\bar{\beta}_a(\eta, z) \geq c_6\Xi(\eta) + c_7, \tag{3.16}$$

where $c_6 > 0$ and $c_7 > 0$ are positive constants. Then, we have

$$2z\Xi(0)\bar{\alpha}_{2b}(0,0) \leq \frac{R_2}{2} + \bar{\beta}(\eta,z)z^2 - \bar{\beta}_a(\eta,z)z^2. \tag{3.17}$$

As a result of these steps,

$$\begin{aligned} d\bar{V}_2(\eta(t),z(t)) &= -y^2\,dt - q_1\,dt + \bar{\sigma}_2\,dw - \frac{\theta}{4}\bar{\sigma}_2\bar{\sigma}_2'\,dt + \Delta_1\,dt - \bar{\beta}z^2\,dt \\ &\quad + \Xi\bar{d}_{21}\bar{d}_{21}'\,dt + 2\Xi(0)\bar{\alpha}_{2b}(0,0)z\,dt \\ &=: -y^2\,dt - (1-\lambda)q_1\,dt - q_2\,dt + \bar{\sigma}_2\,dw - \frac{\theta}{4}\bar{\sigma}_2\bar{\sigma}_2'\,dt + \Delta_1\,dt + R_2\,dt, \end{aligned}$$

where q_2 is defined by

$$\begin{aligned} \bar{q}_2(\eta,z) &:= \lambda q_1(\eta) + \bar{\beta}(\eta,z)z^2 + R_2 - \Xi(\eta)\bar{d}_{21}(\eta)\bar{d}_{21}'(\eta) - 2\Xi(0)\bar{\alpha}_{2b}(0,0)z \\ &\geq \bar{\beta}_a(\eta,z)z^2. \end{aligned}$$

By Proposition 2.6, we conclude that the function V_2 satisfies the HJB inequality (3.8).

REMARK 3.1. *Consider the special case $H_1(0) = 0$ and $H_2(0,0) = 0$. In this case, $\bar{d}_{21c} = 0$. Therefore, any choice of the function Ξ that satisfies the inequality* (3.12) *satisfies the inequality* (3.11) *with $R_2 = 0$. Fix such a choice of Ξ. In this special case, we observe that $\bar{\alpha}_{2b}(0,0) = 0$. This implies that the choice for the function $\bar{\beta}$*

$$\bar{\beta}(\eta,z) = \bar{\beta}_a(\eta,z) \tag{3.18}$$

leads to satisfaction of the inequality (3.17) *with $R_2 = 0$. Hence, in this special case, the above choices of functions Ξ and $\bar{\beta}$ lead to a controller design with $R_2 = 0.0$*

We next check the satisfaction of the control law α_2 and value function V_2 with respect to the four induction hypotheses made at the beginning of this section.

1. The control law (3.10) is smooth and meets the equilibrium condition $\alpha_2(0,0) = 0$ by construction.

2. The function V_2 is smooth and satisfies the HJB inequality (3.8).

3. The inequality

$$(1-\lambda)q_1(\eta) + q_2(\eta,\xi) \geq (1-\lambda)c_1\eta'\eta + c_7z^2 \geq c_1'\left|\left[\begin{array}{c}\eta\\ \xi\end{array}\right]\right|^2 \quad \forall\left|\left[\begin{array}{c}\eta\\ \xi\end{array}\right]\right| \leq c_2' \tag{3.19}$$

holds for some constants $c_1' > 0$ and $c_2' > 0$, and the left-hand side is a smooth function. We also have the following inequality:

$$\bar{V}_2(\eta,z) \leq c_3q_1(\eta) + c_4 + \bar{\beta}_a(\eta,z)z^2 \leq c_3'((1-\lambda)q_1(\eta) + q_2(\eta,z)) + c_4, \tag{3.20}$$

which holds $\forall(\eta,z) \in \mathbb{R}^{n_1+1}$, for some $c_3' > 0$, because of (3.16).

4. In the special case of $H_1(0) = 0$ and $H_2(0,0) = 0$, by the induction hypothesis, there exist a control law α_1 and a corresponding value function V_1 to guarantee a desired long-term average cost $R_1 = 0$ for the η dynamics. By Remark 3.1, we have found the design to yield $R_2 = 0$. Hence the pair α_2 and V_2 are smooth and guarantee a zero long-term average cost (i.e., $R_1 + R_2 = 0$) for the two-level problem (3.1). Furthermore, the guaranteed incremental cost function for the two-level problem (3.1) is the smooth function $(1-\lambda)q_1 + q_2$.

Hence, the control law α_2 and value function V_2 meet all four induction hypotheses.

This completes the guaranteed cost design for this two-level problem. We summarize these findings in the following lemma.

LEMMA 3.1. *Consider the SDE equation* (3.1), *and assume the following.*

(i) *Given an arbitrary* $R_1 > 0$, *there exists a smooth positive definite and radially unbounded value function* $V_1(\eta)$ *and a smooth fictitious control law* $\alpha_1(\eta)$ *(for* ξ*), such that* V_1 *satisfies the HJB inequality* (3.2), *as well as the bounds* (3.3) *and* (3.4) *with a smooth incremental cost function* $q_1(\eta)$, *and* $\alpha_1(0) = 0$.

(ii) *When* $H_1(0) = 0$, *the guaranteed long-term average cost level* R_1 *can be chosen to be* 0.

Then, the following statements hold.

1. *There exist a smooth value function* $V_2(\eta, \xi)$ *and a smooth control law* $\alpha_2(\eta, \xi)$ *as given by* (3.6) *and* (3.10), *respectively, where the former satisfies the HJB inequality* (3.8) *with the additional positive constant* R_2.
2. *The weighting function* $(1-\lambda)q_1(\eta) + q_2(\eta, \xi)$ *satisfies the bounds* (3.19) *and* (3.20), *and is smooth.*
3. *The control law* $v = \alpha_2(\eta, \xi)$ *has the property* $\alpha_2(0,0) = 0$, *and under it the closed-loop system trajectory is bounded in probability.*
4. *If* $H_1(0) = 0$ *and* $H_2(0,0) = 0$, *the constant* $R_1 + R_2$ *can be chosen as zero, which further implies that the closed-loop system is asymptotically stable in the large.*

4. Controller design for the full-order system. By using the backstepping Lemma 3.1 that we have just derived, we can design a feedback controller that leads to a guaranteed risk-sensitive cost R_c, for an arbitrary positive R_c and risk-sensitivity parameter θ. The design follows n steps of integrator backstepping. As suggested by Lemma 3.1, at each step of the backstepping one has to accommodate some positive quadratic variation intrinsic to that particular step. Accordingly, we first split the desired risk-sensitive cost R_c into n pieces, each of which is positive. When $h_1(0) = \cdots = h_n(0, \ldots, 0) = 0$, the control design can actually guarantee a zero long-term average, i.e., $R_c = 0$. Let

$$R_c = R_1 + \cdots + R_n,$$

where $R_i > 0$, $i = 1, \ldots, n$. The controller design follows n steps of integrator backstepping, as elucidated below:

Step 1: Here, we are dealing with a scalar system:

$$dx_1 = (f_1(x_1) + x_2)\,dt + h_1'(x_1)\,dw.$$

The controller to be designed is to guarantee a risk-sensitive cost R_1.

For this purpose, we select the value function V_1 as

$$V_1(x_1) = \frac{1}{1 + 2h_{1c}'h_{1c}/R_1} x_1^2 =: \Xi_1 x_1^2,$$

where h_{1c} is the constant part of the function h_1:

$$h_1(x_1) = h_{1c} + h_{1v}(x_1)x_1.$$

Then, using Itô's rule for $V_1(x_1(t))$, we obtain the following relationship:

$$dV_1(x_1(t)) = 2\Xi_1 x_1(f_1(x_1) + x_2)\,dt + 2\Xi_1 x_1 h_1'(x_1)\,dw + \mathrm{Tr}(\Xi_1 h_1'(x_1)h_1(x_1))\,dt.$$

Choose the virtual control input to cancel out all the terms that involve a multiplier of x_1:

$$\alpha_{1b}(x_1) = -\frac{1}{2\Xi_1}x_1 - \frac{1}{2\Xi_1}\beta x_1 - f_1(x_1) - \frac{\theta\Xi_1}{2}h_1'(x_1)h_1(x_1)x_1$$
$$-\frac{1}{2}h_{1v}'(x_1)h_{1v}(x_1)x_1 - h_{1c}'h_{1v}(x_1),$$

where β is a constant to be chosen later.

To preserve the equilibrium at the origin, we define the control law as follows:

$$x_2 = \alpha_{1b}(x_1) - \alpha_{1b}(0) =: \alpha_1(x_1), \tag{4.1}$$

This choice of the virtual control input leads to

$$dV_1(x_1(t)) = 2\Xi_1 x_1 h_1'\,dw - (x_1^2 + \beta x_1^2 + \theta\Xi_1^2 h_1' h_1 x_1^2 + \Xi_1 h_{1c}' h_{1c} + 2\Xi_1\alpha_{1b}(0)x_1)\,dt.$$

Choose

$$\beta = \frac{4\Xi_1^2\alpha_{1b}^2(0)}{R_1} + c_2,$$

where $c_2 > 0$. Then, V_1 satisfies the HJB inequality (2.11) for the x_1 subsystem under α_1 with guaranteed cost R_1:

$$\frac{\partial V_1}{\partial x_1}(f_1 + \alpha_1) + \frac{\theta}{4}\frac{\partial V_1}{\partial x_1}h_1'h_1\left(\frac{\partial V_1}{\partial x_1}\right)' + x_1^2 + \frac{1}{2}\beta x_1^2 + \frac{1}{2}\mathrm{Tr}\left(\frac{\partial^2 V_1}{\partial x_1^2}h_1 h_1'\right) \le R_1.$$

It is easy to check to see that all four induction hypotheses are satisfied. This completes the first step of the integrator backstepping.

For Steps 2, 3, etc., we can repeatedly apply the backstepping lemma, Lemma 3.1. At a typical step i, we can design the risk-sensitive controller with the increase in the long-term average cost bounded by R_i. We then continue this process until the second to last step $n-1$, where we design the virtual control input

$$x_n = \alpha_{n-1}(x_1, \ldots, x_{n-1}).$$

At Step n, we let $v = bu$, and use the construction of Lemma 3.1 to lead to a smooth control law:

$$v = \alpha_n(x_1, \ldots, x_n).$$

Under the working assumption, A1, we finally obtain

$$u = \frac{1}{b(x_1, \ldots, x_n)}\,\alpha_n(x_1, \ldots, x_n). \tag{4.2}$$

This completes the construction of a risk-sensitive controller, guaranteeing any desired level of positive long-term average cost. This construction is now made precise in the following theorem.

THEOREM 4.1. *Consider the strict-feedback stochastic nonlinear system described by the SDE* (2.1), *satisfying Assumption* A1. *For any risk-sensitivity parameter* $\theta > 0$ *and any desired long-term average cost level* $R_c > 0$, *there exists a smooth nonlinear feedback control* (4.2) *that achieves the level* R_c. *Such a controller can be constructed* *using the integrator backstepping procedure and by a repeated application of Lemma* 3.1. *The resulting closed-loop system trajectory is bounded in probability.*

If the functions h_i, $i = 1, \dots, n$, vanish at $x = 0$, then the controller (4.2) *achieves a zero long-term average cost for the SDE* (2.1). *In this case, the closed-loop system is asymptotically stable in the large, in addition to being bounded in probability.*

Proof. The result is an immediate application of Theorem 2.5, in view of the backstepping construction outlined above. Since the existence (and construction) of function V satisfying the HJB inequality is implied by the construction presented before the statement of the theorem, the boundedness in probability follows immediately.

When h_i vanishes at $x = 0$, the construction implies that the constant R_c can be chosen to be zero, by Remark 3.1. Since the weighting function is chosen to be positive definite, by Theorem 2.5 the system is asymptotically stable in the large, in addition to being bounded in probability. □

5. Two special cases.

In this section, we discuss some implications of the results presented above as the design parameters approach specific limits. In particular, we are interested in two types of limiting processes. The first is known as the risk-neutral limit, with $\theta \downarrow 0$. The other process is known as the large deviation limit, where the noise intensity decreases to zero.

5.1. Risk-neutral case.

If $\theta \downarrow 0$, the limiting problem is the one with a risk-neutral cost function:

$$J_0(\mu) = \limsup_{t_f \to \infty} \frac{1}{t_f} \boldsymbol{E} \left\{ \int_0^{t_f} (y^2(t) + l(x(t)))\, dt \right\} \leq R_c, \tag{5.1}$$

where R_c is again the desired long-term average cost bound.

The control design procedure presented in the previous two sections equally applies here, leading to a controller

$$u = \mu(x)$$

and a value function $V(x)$ such that

$$\frac{\partial V}{\partial x} f^u(x) + \frac{1}{2} \mathrm{Tr} \left(\frac{\partial^2 V}{\partial x^2} H(x) H'(x) \right) + y^2 + l(x) = \Delta(x) \leq R_c, \tag{5.2}$$

where

$$f^u(x) = \begin{bmatrix} f_1(x_1) + x_2 \\ \vdots \\ f_{n-1}(x_1, \dots, x_{n-1}) + x_n \\ f_n(x_1, \dots, x_n) + b(x_1, \dots, x_n)\mu(x) \end{bmatrix} \quad H(x) = \begin{bmatrix} h_1'(x_1) \\ \vdots \\ h_n'(x_1, \dots, x_n) \end{bmatrix}.$$

This inequality immediately implies that the long-term average cost for the risk-neutral cost function (5.1) is bounded by R_c.

Therefore, we have the following corollary to Theorem 4.1.

Corollary 5.1. *Consider the strict-feedback stochastic nonlinear system* (2.1) *satisfying Assumption* A1, *along with the risk-neutral cost function* (5.1). *For any desired long-term average cost level $R_c > 0$, there exists a corresponding smooth nonlinear feedback control that guarantees it. Such a controller can be constructed using the integrator backstepping procedure presented in the previous two sections with the* *risk-sensitivity parameter set at $\theta = 0$. The resulting closed-loop system trajectories are bounded in probability.*

If the functions h_i, $i = 1, \ldots, n$, vanish at $x = 0$, then the controller μ can be chosen to guarantee $R_c = 0$. In this case, the closed-loop system is asymptotically stable in the large, in addition to being bounded in probability.

5.2. Large deviation limit. Another limiting scenario is that in which the noise intensity in the system dynamics asymptotically vanishes at the rate of ϵ, for some small positive parameter ϵ, while the cost function heavily penalizes any deviation of the output from zero at the rate of $1/\epsilon$. Letting $\theta = \frac{1}{\gamma^2\epsilon^2}$, for some positive design parameter γ (whose role and significance will become clear shortly), we now have the following problem formulation:

$$\text{(5.3a)} \qquad dx_1 = (x_2 + f_1(x_1))\,dt + \epsilon\tilde{h}_1'(x_1)\,dw,$$

$$\vdots \qquad\qquad \vdots$$

$$\text{(5.3b)} \qquad dx_{n-1} = (x_n + f_{n-1}(x_1, \ldots, x_{n-1}))\,dt + \epsilon\tilde{h}_{n-1}'(x_1, \ldots, x_{n-1})\,dw,$$

$$\text{(5.3c)} \qquad dx_n = (f_n(x_1, \ldots, x_n) + b(x_1, \ldots, x_n)u)\,dt + \epsilon\tilde{h}_n'(x_1, \ldots, x_n)\,dw,$$

$$\text{(5.3d)} \qquad y = x_1,$$

$$\text{(5.4)} \qquad J_\theta(\mu) = \limsup_{t_f \to \infty} \frac{2}{\theta t_f} \ln \left\{ \boldsymbol{E} \left\{ \exp\left[\frac{\theta}{2} \left(\int_0^{t_f} (y^2 + l(x(t)))\,dt \right) \right] \right\} \right\} \le R_c.$$

It is a well-known fact in the risk-sensitive optimal control literature (see [1] or [25]) that the large deviation limit, as $\epsilon \to 0$, of the optimal risk-sensitive controller for this problem leads exactly to the H^∞ central controller with disturbance attenuation parameter γ, provided that the solution to either one exists. For the problem at hand, the corresponding H^∞ control problem involves the state dynamics

$$\text{(5.5a)} \qquad \dot{x}_1 = x_2 + f_1(x_1) + \tilde{h}_1'(x_1)w,$$

$$\vdots \qquad\qquad \vdots$$

$$\text{(5.5b)} \qquad \dot{x}_{n-1} = x_n + f_{n-1}(x_1, \ldots, x_{n-1}) + \tilde{h}_{n-1}'(x_1, \ldots, x_{n-1})w,$$

$$\text{(5.5c)} \qquad \dot{x}_n = f_n(x_1, \ldots, x_n) + b(x_1, \ldots, x_n)u + \tilde{h}_n'(x_1, \ldots, x_n)w,$$

$$\text{(5.5d)} \qquad y = x_1$$

and the following worst-case (game) cost function:

$$\text{(5.6)} \qquad J_\gamma(\mu, \nu) = \int_0^\infty (y^2(t) + l(x(t)) - \gamma^2|w(t)|^2)\,dt,$$

where w is generated by some opponent through $w(t) = \nu(t, x(t))$.

This is precisely the problem that was addressed in [23]. The interesting question to ask here is whether the backstepping construction of risk-sensitive controllers for (5.3), (5.4), also converges to the backstepping construction for the H^∞ controller for (5.5), (5.6) presented in [23]. Since both the design procedures presented here and the ones in [23] are suboptimal schemes, the convergence cannot be guaranteed by the well-established large deviation limit for risk-sensitive optimal control problems.

It turns out that the answer to this question is still yes. We examine again the single-stage backstepping design presented in section 3. The difference between the recursive construction presented in [23] and that of this paper is as follows. First of all, the choice of Ξ is solely determined by the inequalities (3.11) and (3.12). For any fixed compact set K, Ξ can be chosen to be constant, say 1/2, on this compact set for sufficiently small $\epsilon > 0$, such that, $\forall \eta \in K$,

$$\mathrm{Tr}\left(\Xi(\eta)\bar{d}_{21}(\eta)\bar{d}_{21}'(\eta)\right) \leq \frac{1}{\epsilon^2}\left(\frac{R_2}{2} + \lambda q_1(\eta)\right)$$

and

$$\mathrm{Tr}\left(\Xi(\eta)\bar{d}_{21v}(\eta)\bar{d}_{21v}'(\eta)\right) \leq \frac{\lambda c_3 \eta'\eta}{\epsilon^2}.$$

This compact set expands to the entire state space as $\epsilon \downarrow 0$. On this compact set, the added value function in this case is exactly the same as that for the H^∞ problem. Consider the controller (3.9); all the terms on the first three lines are exactly the same as in the controller of the H^∞ problem. The function $\bar{a}_2$ is within $O(\epsilon^2)$ of its counterpart in the H^∞ problem. The terms on the last line are of $O(\epsilon^2)$. Therefore, on this compact set, the risk-sensitive design provides a $O(\epsilon^2)$ approximation to the H^∞ solution.

Hence, we can state the following remark to capture our observation.

Remark 5.1. *Consider the strict-feedback stochastic nonlinear system* (5.3) *satisfying Assumption* A1 *with the risk-sensitive cost function* (5.4). *For any desired long-term average cost level $R_c > 0$, there exists a corresponding nonlinear feedback control that guarantees it. Such a controller approximates the backstepping controller for the nonlinear H^∞ control problem* [23] *up to $O(\epsilon^2)$ on any given compact set $K \subset \mathbb{R}^n$.*

6. An extension.

We identify and present here an immediate (natural) extension of the results presented heretofore to a more general class of nonlinear systems, with nontrivial zero dynamics. Consider the class of nonlinear systems described by the following SDE:

$$\begin{aligned}
&(6.1\text{a}) \quad d\phi = f_0(\phi, x_1)\,dt + H_0(\phi, x_1)\,dw,\\
&(6.1\text{b}) \quad dx_1 = (b_1(\phi, x_1)x_2 + f_1(\phi, x_1))\,dt + h_1'(\phi, x_1)\,dw,\\
&\qquad\quad \vdots \qquad\quad \vdots\\
&(6.1\text{c})\, dx_{n-1} = (b_{n-1}(\phi, x_1, \ldots, x_{n-1})x_n + f_{n-1}(\phi, x_1, \ldots, x_{n-1}))\,dt\\
&\qquad\qquad\qquad + h_{n-1}'(\phi, x_1, \ldots, x_{n-1})\,dw,\\
&(6.1\text{d}) \quad dx_n = (f_n(\phi, x_1, \ldots, x_n) + b(\phi, x_1, \ldots, x_n)u)\,dt + h_n'(\phi, x_1, \ldots, x_n)\,dw,\\
&(6.1\text{e}) \quad y = p(\phi, x_1)
\end{aligned}$$

where ϕ is an n_0-dimensional state vector, which can be viewed as the state of the zero dynamics of the system (see Chapter 9 of [10]). We note that these ϕ dynamics are affected only by x_1 and not by the remaining components of the state x. Furthermore, the virtual control input variables $x_2, \ldots, x_n$ are premultiplied by nonlinear functions $b_1, \ldots, b_{n-1}$. For this class of nonlinear stochastic systems, we introduce the following two assumptions in addition to A1.

Assumption A2. The nonlinear functions f_0, H_0, b_i, and $1/b_i$ are $\mathcal{C}^\infty$ in all their arguments, $i = 1, \ldots, n-1$. The output function p is smooth. □

Assumption A3. Given a risk-sensitivity parameter $\theta_0 > 0$, there exists a smooth virtual control law $\alpha_0(\phi)$, with $\alpha_0(0) = 0$, and a positive definite and radially unbounded smooth value function $V_0(\phi)$, such that the following PDE is satisfied for some positive definite function $q_0(\phi)$:

$$\begin{aligned}(6.2)\ &\frac{\partial V_0}{\partial \phi} f_0(\phi, \alpha_0(\phi)) + \frac{\theta_0}{4}\frac{\partial V_0}{\partial \phi} H_0(\phi, \alpha_0(\phi)) H_0'(\phi, \alpha_0(\phi)) \left(\frac{\partial V_0}{\partial \phi}\right)' \\ &+ \frac{1}{2}\mathrm{Tr}\left(\frac{\partial^2 V_0}{\partial \phi^2} H_0(\phi, \alpha_0(\phi)) H_0'(\phi, \alpha_0(\phi))\right) + p^2(\phi, \alpha_0(\phi)) + q_0(\phi) = \Delta_0(\phi) \leq R_0.\end{aligned}$$

Furthermore, $q_0(\phi)$ is smooth and satisfies the assumptions of induction for the backstepping procedure, and the following growth conditions:

$$q_0(\phi) \geq c_1 \phi'\phi \qquad \forall |\phi| \leq c_2 \tag{6.3}$$

and

$$V_0(\phi) \leq c_3\, q_0(\phi) + c_4 \qquad \forall \phi \in \mathbb{R}^{n_0} \tag{6.4}$$

for some constants $c_1 > 0$, $c_2 > 0$, $c_3 > 0$, and $c_4 > 0$. □

We should note that A2 is quite a standard assumption for this class of nonlinear system, ensuring that the state variables $x_1, \ldots, x_n$ are completely controllable; A3, on the other hand, is a strong stabilizability condition on the ϕ dynamics, ensuring that there is a virtual control law for x_1 that guarantees a long-term average value of R_0 for the risk-sensitive cost function

$$\limsup_{t_f \to \infty} \frac{2}{\theta_0 t_f} \ln\left\{\boldsymbol{E}\left\{\exp\left[\frac{\theta_0}{2}\left(\int_0^{t_f} y^2(t)\, dt\right)\right]\right\}\right\}$$

for a given value of θ_0. This is stated as an assumption, because for a given $\theta_0 > 0$ there may not exist a control law (for x_1) to return an arbitrarily small value for the risk-sensitive cost function above. This is partly due to the appearance of both ϕ and x_1 as arguments of p.

Under these assumptions, it is possible to construct recursively a nonlinear feedback controller that achieves any given long-term average cost level $R_c > R_0$ for a given risk-sensitivity parameter $\theta \leq \theta_0$. We note that, as stated earlier, we may no longer be able to achieve an arbitrarily small long-term average cost for arbitrarily large values of the risk-sensitivity parameter. This performance limitation is solely due to the presence of the zero dynamics of the system.

This now brings us to the following theorem.

THEOREM 6.1. *Consider the class of stochastic nonlinear systems described by SDE* (6.1), *satisfying Assumptions* A1, A2, *and* A3. *For any risk-sensitivity parameter $\theta \leq \theta_0$ and any desired long-term average cost level $R_c > R_0$, there exists a nonlinear feedback control law μ, designed using the integrator backstepping procedure that achieves the level R_c. The resulting closed-loop system trajectory is bounded in probability.*

If $R_0 = 0$ is a feasible choice, and the nonlinear functions H_0, h_i, $i = 1, \ldots, n$, all vanish at the origin of the system, then the nonlinear controller constructed with $R_0 = 0$ achieves a zero long-term average cost for the SDE (6.1). *In this case, the closed-loop system is asymptotically stable in the large, in addition to being bounded in probability.*

Proof. We need only establish the result when $n = 1$. For the case when $n > 1$, the result follows directly from the recursive design procedure described in section 3.

Consider the following SDE:

$$\begin{aligned} d\phi &= f_0(\phi, x_1)\,dt + H_0(\phi, x_1)\,dw \\ dx_1 &= (b_1(\phi, x_1)u + f_1(\phi, x_1))\,dt + h_1'(\phi, x_1)\,dw \\ y &= p(\phi, x_1)\,. \end{aligned} \tag{6.5}$$

We will introduce the variable

$$v = b_1(\phi, x_1)u$$

and design a control for v, which, in turn, yields a control law for u, under the working Assumption A2.

By Assumption A3, the function V_0 satisfies the following HJB inequality for any $\theta \le \theta_0$:

$$\begin{aligned} &\frac{\partial V_0}{\partial \phi} f_0(\phi, \alpha_0(\phi)) + \frac{\theta}{4}\frac{\partial V_0}{\partial \phi} H_0(\phi, \alpha_0(\phi))H_0(\phi, \alpha_0(\phi))' \left(\frac{\partial V_0}{\partial \phi}\right)' \\ &+\frac{1}{2}\mathrm{Tr}\left(\frac{\partial^2 V_0}{\partial \phi^2} H_0(\phi, \alpha_0(\phi))H_0(\phi, \alpha_0(\phi))'\right) + p^2(\phi, \alpha_0(\phi)) + q_0(\phi) = \Delta_0(\phi) \le R_0. \end{aligned} \tag{6.6}$$

Given this, we introduce the transformed state variable

$$z = x_1 - \alpha_0(\phi).$$

Then, by Itô's rule of differentiation, we have

$$dz = (\bar{a}_1 + v)\,dt + \bar{d}_1\,dw,$$

where

$$\begin{aligned} \bar{a}_1(\phi, z) &= \bar{f}_1(\phi, z) - \frac{\partial \alpha_0}{\partial \phi}\bar{f}_0(\phi, z) - \frac{1}{2}\mathrm{Tr}\left(\frac{\partial^2 \alpha_0}{\partial \phi^2}\bar{H}_0(\phi, z)\bar{H}_0'(\phi, z)\right), \\ \bar{d}_1(\phi, z) &= \bar{h}_1'(\phi, z) - \frac{\partial \alpha_0}{\partial \phi}\bar{H}_0(\phi, z). \end{aligned}$$

Introduce a smooth function $\bar{V}_1$ as a candidate value function

$$\bar{V}_1(\phi, z) = V_0(\phi) + \Xi(\phi)z^2, \tag{6.7}$$

where Ξ is a positive smooth function yet to be determined. We again set up the proper conditions to prove that $\bar{V}_1$ satisfies the desired HJB inequality by using the equivalent form of Proposition 2.6.

Define the smooth functions $\bar{f}_{01}$, $\bar{H}_{01}$, $\bar{d}_{11}$, and $\bar{d}_{12}$ as follows:

$$\begin{aligned} &f_0(\phi, x_1) = f_0(\phi, \alpha_0(\phi)) + \bar{f}_{01}(\phi, z)z, \qquad H_0(\phi, x_1) = H_0(\phi, \alpha_0(\phi)) + \bar{H}_{01}(\phi, z)z, \\ &\bar{d}_{11}(\phi) = \bar{d}_1(\phi, 0), \qquad \bar{d}_1(\phi, z) = \bar{d}_1(\phi, 0) + \bar{d}_{12}(\phi, z)z. \end{aligned}$$

The Itô differential of $\bar{V}_1(\phi(t), z(t))$ is given by

$$\begin{aligned} d\bar{V}_1(\phi(t), z(t)) = {}&\left(\frac{\partial V_0}{\partial \phi} f_0(\phi, \alpha_0(\phi)) + \frac{1}{2}\mathrm{Tr}\left(\frac{\partial^2 V_0}{\partial \phi^2} H_0(\phi, \alpha_0(\phi))H_0'(\phi, \alpha_0(\phi))\right)\right) dt \\ &+z(\bar{m}(\phi, z) + 2\Xi(\phi)v)\,dt + \bar{\sigma}(\phi, z)\,dw + \mathrm{Tr}(\Xi(\phi)\bar{d}_{11}(\phi)\bar{d}_{11}'(\phi))\,dt, \end{aligned}$$

where

$$\begin{aligned}\bar{m}(\phi,z) &= \frac{\partial V_0}{\partial \phi}\bar{f}_{01} + \frac{1}{2}\mathrm{Tr}\left(\frac{\partial^2 V_0}{\partial \phi^2}(2H_0\bar{H}_{01}' + z\bar{H}_{01}\bar{H}_{01}')\right) + z\frac{\partial \Xi}{\partial \phi}\bar{f}_0 + 2\Xi\bar{a}_1 \\ &\quad + \frac{1}{2}\mathrm{Tr}\left(z\frac{\partial^2 \Xi}{\partial \phi^2}\bar{H}_0\bar{H}_0' + 4\frac{\partial \Xi}{\partial \phi}\bar{H}_0\bar{d}_1' + 4\Xi\bar{d}_{11}\bar{d}_{12}' + 2\Xi\bar{d}_{12}\bar{d}_{12}'z\right), \\ \bar{\sigma}(\phi,z) &= \frac{\partial V_0}{\partial \phi}H_0 + z\bar{\sigma}_{11}, \\ \bar{\sigma}_{11}(\phi,z) &= \frac{\partial V_0}{\partial \phi}\bar{H}_{01} + z\frac{\partial \Xi}{\partial \phi}\bar{H}_0 + 2\Xi\bar{d}_1.\end{aligned}$$

Using the HJB inequality (6.6), we arrive at the following stochastic differential inequality:

$$\begin{aligned}d\bar{V}_1(\phi(t),z(t)) &= \left(-p^2 - q_0 + \Delta_0 - \frac{\theta}{4}\bar{\sigma}\bar{\sigma}'\right)dt + \bar{\sigma}\,dw \\ &\quad + z\left(\bar{m} + \frac{\theta}{4}\left(2\frac{\partial V_0}{\partial \phi}H_0\bar{\sigma}_{11}' + z\bar{\sigma}_{11}\bar{\sigma}_{11}'\right) + 2\Xi v\right)dt + \mathrm{Tr}(\Xi\bar{d}_{11}\bar{d}_{11}')\,dt.\end{aligned}$$

We next define a smooth nonlinear function $\bar{p}_1$ by

$$p(\phi,x_1) = p(\phi,\alpha_0(\phi)) + \bar{p}_1(\phi,z)z\,,$$

and introduce the control law

$$v = \bar{\alpha}_1(\phi,z) = \bar{\alpha}_{1b}(\phi,z) - \frac{\Xi(0)}{\Xi(\phi)}\bar{\alpha}_{1b}(0,0), \tag{6.8}$$

where

$$\bar{\alpha}_{1b}(\phi,z) = \frac{1}{2\Xi}\left(-2p\bar{p}_1 - \bar{p}_1^2 z - \bar{\beta}z - \bar{m} - \frac{\theta}{4}\left(2\frac{\partial V_0}{\partial \phi}H_0\bar{\sigma}_{11}' + z\bar{\sigma}_{11}\bar{\sigma}_{11}'\right)\right)$$

and $\bar{\beta}(\phi,z)$ is a positive nonlinear function to be determined shortly.

Under this control law, the Itô differential of $\bar{V}_1(\phi(t),z(t))$ satisfies

$$\begin{aligned}d\bar{V}_1(\phi(t),z(t)) &= \left(-y^2 - q_0 - \bar{\beta}z^2 + \Delta_0 - \frac{\theta}{4}\bar{\sigma}\bar{\sigma}'\right)dt + \bar{\sigma}\,dw + 2z\Xi(0)\bar{\alpha}_{1b}(0,0)\,dt \\ &\quad + \mathrm{Tr}(\Xi\bar{d}_{11}\bar{d}_{11}')\,dt.\end{aligned}$$

Now, following a selection process similar to that of section 3 for the functions Ξ and $\bar{\beta}$, we can show that

$$d\bar{V}_1(\phi(t),z(t)) \le \left(-y^2 - q_1 + R_1 - \frac{\theta}{4}\bar{\sigma}\bar{\sigma}'\right)dt + \bar{\sigma}\,dw$$

for any $R_1 > R_0$, and the nonlinear weighting function q_1 is smooth and satisfies the induction assumptions of section 3. This then completes the construction for this first step of the backstepping procedure.

When $n > 1$, we can repeatedly apply Lemma 3.1 to construct the nonlinear cost-bounding controller for the overall system.

This completes the proof of the theorem. $\square$

7. An example. In this section, we illustrate the design procedure presented in the main body of the paper by a second-order example and compare the resulting control design with that of [23] and the risk neutral case as $\theta \downarrow 0$. The second-order system is taken as

$$\begin{bmatrix} dx_1 \\ dx_2 \end{bmatrix} = \begin{bmatrix} x_1^2 + x_2 \\ 0 \end{bmatrix} dt + \begin{bmatrix} 0 \\ 1 \end{bmatrix} u\, dt + \begin{bmatrix} 0 & 1 \\ 1 & x_1 \end{bmatrix} dw, \tag{7.1a}$$

$$y = x_1, \tag{7.1b}$$

where u is the control input and w is a two-dimensional standard Wiener process. For this SDE, we will consider two types of cost functions, namely, the risk-sensitive cost function and the risk-neutral cost function. We will take the risk-sensitivity parameter $\theta = 1$ and a desired guaranteed long-term average cost of $R_c = 4$. This corresponds to the following choice of design criterion for the risk-sensitive case:

$$J_{rs}(\mu) = \limsup_{t_f \to \infty} \frac{2}{t_f} \ln \left\{ \boldsymbol{E} \left\{ \exp \left[\frac{1}{2} \left(\int_0^{t_f} (y^2(t) + l(x(t)))\, dt \right) \right] \right\} \right\} \leq 4 \tag{7.2}$$

and the following one for the risk-neutral case:

$$J_{rn}(\mu) = \limsup_{t_f \to \infty} \frac{1}{t_f} \boldsymbol{E} \left\{ \int_0^{t_f} (y^2(t) + l(x(t)))\, dt \right\} \leq 4. \tag{7.3}$$

The corresponding nonlinear H^∞-control problem of [23] (see also (5.5) and (5.6) in subsection 5.2), on the other hand, is described by the following second-order dynamics:

$$\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} = \begin{bmatrix} x_1^2 + x_2 \\ 0 \end{bmatrix} + \begin{bmatrix} 0 \\ 1 \end{bmatrix} u + \begin{bmatrix} 0 & 1 \\ 1 & x_1 \end{bmatrix} w, \tag{7.4a}$$

$$y = x_1, \tag{7.4b}$$

where w is to be chosen by some opponent to disrupt the control objective. The associated (game-theoretic) cost function is

$$J_{rb}(\mu, \nu) = \int_0^\infty (y^2(t) + l(x(t)) - w'(t)w(t))\, dt. \tag{7.5}$$

Here we have picked $\epsilon = 1$ and $\gamma = 1$—a choice that is consistent with the specific choice $\theta = 1$ for the risk-sensitivity parameter, because of the relationship $\theta = \frac{1}{\epsilon^2\gamma^2}$.

Carrying out the risk-sensitive backstepping design procedure, we arrive at the following value function and control law:

$$V_{rs}(x) = 0.5x_1^2 + 0.0391251 \left(x_2 + 2.25x_1 + x_1^2\right)^2, \tag{7.6a}$$

$$\begin{aligned} \mu_{rs}(x) = {} & -4.93429x_2 - 19.9442x_1 - 7.02849x_1^2 - 2.26409x_1x_2 - 2.66023x_1^3 \\ & -0.176063x_1^2x_2 - 0.176063x_1^4. \end{aligned} \tag{7.6b}$$

An important observation to make here is that the constant multiplying the second term in the value function V_{rs} above is much smaller than that of the first term. This constant is determined by the bounds (3.11) and (3.12) for the recursive design.

Now, for the risk-neutral case, the counterparts of (7.6a) and (7.6b) are, respectively,

$$V_{rn}(x) = 0.5x_1^2 + 0.0406138 \left(x_2 + 2x_1 + x_1^2\right)^2, \tag{7.7a}$$

$$\mu_{rn}(x) = -4.47237x_2 - 17.2558x_1 - 4.47237x_1^2 - 2x_1x_2 - 2x_1^3. \tag{7.7b}$$

We observe that the assignment of the constant multipliers in the value function above is quite similar to that in the risk-sensitive case. The control law, however, is somewhat different; it does not include the high-order nonlinear terms that are part of the risk-sensitive design. This result corroborates the earlier statement that the risk neutral control design does not put weight on the higher (than second) order moments in the system output. Apart from the missing high-order nonlinear terms, the control design for this risk-neutral case is quite similar to that of the risk-sensitive case.

Finally, we design a control law for the worst-case disturbance attenuation problem (7.4a), (7.4b) and (7.5). In this case the value function and the control law are given as follows:

$$\text{(7.8a)} \quad V_{rb}(x) = 0.5x_1^2 + 0.5\left(x_2 + 1.75x_1 + x_1^2\right)^2,$$

$$\text{(7.8b)} \quad \mu_{rb}(x) = -3.26563x_2 - 4.52734x_1 - 9.35938x_1^2 - 2.25x_1^2x_2 - 4.62500x_1x_2 \\ -8.56250x_1^3 - 2.25x_1^4.$$

We observe that both the value function and the controller are quite different from their counterparts in the risk-sensitive and risk-neutral cases. Here, the gains of the linear control terms are relatively small compared with those of their stochastic counterparts, yet the gains on high-order nonlinear terms are significantly larger than those of the stochastic controllers.

The mesh plots of the value functions and the control laws for the three designs are depicted in Figures 7.1–7.3. Comparing these figures, we observe that both stochastic designs lead to smaller value functions than the worst-case design. The stochastic control laws are much softer than the worst-case control laws. In particular, in the region of the state space $x_1 < 0$, the stochastic control laws are much softer than the worst-case (nonlinear H^∞) control law.

We simulated the closed-loop system under these three controllers subject to two different types of disturbance inputs. The simulations were carried out using the Matlab Simulink software package. We chose the disturbance inputs to be sampled Gaussian white noise inputs with a sample rate of 10 Hz. Each of the noise channels had power 1. The simulation results are plotted in Figures 7.4–7.6. We observe from these figures that the stochastic control designs lead to smaller system outputs than the worst-case controller. A simple calculation yields that the $\mathcal{L}_2$ norm of the output for the risk-sensitive control design is the smallest among the three, which is 5.0058. Second best is the risk-neutral controller, whose output norm is 6.0840. The worst-case controller yields a norm of 7.0492 for its output. Regarding the control effort, we observe that the stochastic controllers use more control effort when the system states are small in norm. Yet the worst-case controller leads to larger peak control actions. A simple calculation yields that the $\mathcal{L}_2$ norms of the stochastic controllers are bounded by twice the amount of the worst-case controller.

Finally, we simulated the system response under the following sinusoidal disturbance inputs:

$$w_1(t) = 8\,\sin(t), \qquad w_2(t) = 8\,\sin(2t+1).$$

We tried various levels for the magnitudes of the sine waves. For smaller-magnitude sine waves, the stochastic controllers showed better performance than the worst-case controller. When the magnitudes were fixed at 8, the performances of the two stochastic controllers were very different. These simulation results are plotted in Figures 7.7–7.9. We observe from these figures that the risk-sensitive controller again leads to the

best overall system performance. A simple calculation yields that the $\mathcal{L}_2$ norm of the output for the risk-sensitive control design is the smallest among the three, which is 107.3. Second best is the worst-case controller, whose output norm is 122.3. The risk-neutral controller yields a norm of 479.4 for its output. Regarding the control effort, we observe that the worst-case controller uses the least amount of control effort. The risk-sensitive controller uses 33% more control effort when measured in $\mathcal{L}_2$ norm. The system performance for the risk-neutral controller is not satisfactory under this disturbance.

Overall, we observe that the risk-sensitive controller and the worst-case controller are quite satisfactory for this simple example. The risk-sensitive controller leads to a smaller output $\mathcal{L}_2$ norm in both of the simulations, at the expense of more control effort. This does not contradict the observation that the risk-sensitive controller has a smaller controller gain. It is generally observed that the behavior of the state variable x_2 is much better for the worst-case controller. Smaller control gain guarantees a smaller control effort only if the system states behave the same way.

8. Conclusion. In this paper, we have presented a recursive control design for strict-feedback stochastic nonlinear systems. Under an exponential (risk-sensitive) cost function, we have obtained controllers that guarantee any desired positive level of long-term average cost for a fixed risk-sensitivity parameter. Such an objective was feasible because (i) no weighting was attached to the control variable, (ii) the system was in the strict-feedback form, and (iii) there was weighting only on the output of the system. The construction presented here for the risk-sensitive control problem differs substantially from that of the H^∞ problem [23], which is to be expected since the equivalence between the two problems holds only as the noise intensity diminishes to zero. As a special case, the solution to the risk-neutral control problem has also been obtained by simply taking the limit as the risk-sensitivity parameter approaches zero. Another special case treated was that in which the vector fields for the disturbance vanish at the origin of the system; in this case, the control design can actually guarantee a *zero* long-term average cost. Furthermore, the closed-loop system becomes asymptotically stable in the large. These results have then been generalized to a class of nonlinear systems involving zero dynamics that are strongly stabilizable. The theoretical findings of the paper have been further illustrated in section 7 on a second-order nonlinear system.

Future research opportunities on this topic lie in several directions. One of these pertains to the parameter identification problem under a risk-sensitive performance criterion, to generalize the results of [2] and [24] to the stochastic case. Another interesting topic is the stochastic adaptive control design for strict-feedback systems, to achieve a desired risk-sensitive performance level for a given risk-sensitivity parameter; this would be a generalization of the results of [23] to the stochastic case.

Appendix.

In this appendix, we provide a proof of the fact (see Girsanov [9]) that the stochastic process $\zeta(t)$ defined in the proof of Theorem 2.5 is a supermartingale. The precise statement is as follows.

THEOREM A.1. *Let $w(t)$ be an m-dimensional vector-valued standard Wiener process on the time interval $[0, t_f]$ adapted to a filtration $\mathcal{F}$ on a probability space $(\Omega, \mathcal{F}, \boldsymbol{P})$. Further let a vector-valued stochastic process $f : [0, t_f] \times \Omega \to \mathbb{R}^m$ be adapted to the filtration $\mathcal{F}$. Define the scalar process*

$$\zeta_0^t(f) := \exp\left(\int_0^t f'(s)\,dw - \frac{1}{2}\int_0^t |f(s)|^2\,ds\right).$$

Then, we have $\boldsymbol{E}\left(\zeta_0^t(f)\right) \leq 1 \ \forall t \in [0, t_f]$.

Proof. Let each component of the mapping f be given by

$$f = \begin{bmatrix} f^1 & \cdots & f^m \end{bmatrix}'.$$

For each $n = 1, 2, \ldots$, define the function $f_n : [0, t_f] \times \Omega \to \mathbb{R}^m$ by

$$f_n = \begin{bmatrix} \max\{\min\{f^1, n\}, -n\} & \cdots & \max\{\min\{f^m, n\}, -n\} \end{bmatrix}'.$$

Clearly, we have

$$\lim_{n\to\infty} f_n = f \qquad \text{almost everywhere.}$$

It is easy to check that

$$\boldsymbol{E}\left(\exp\left(\frac{1}{2}\int_0^t |f_n(s)|^2\, ds\right)\right) \leq \exp\left(\frac{1}{2}n^2 t\right) < \infty.$$

By the result of [21], we have

$$\boldsymbol{E}\left(\zeta_0^t(f_n)\right) = 1 \qquad \forall\ t \in [0, t_f];\ n = 1, 2, \ldots .$$

By Fatou's lemma, we have

$$1 = \liminf_{n\to\infty} \boldsymbol{E}\left(\zeta_0^t(f_n)\right) \geq \boldsymbol{E}\left(\liminf_{n\to\infty} \zeta_0^t(f_n)\right) = \boldsymbol{E}\left(\zeta_0^t(f)\right).$$

This completes the proof of the theorem. □

Next, we present a lemma which is used in the proof of Proposition 2.6.

LEMMA A.2. *Let $w(t)$ be an m-dimensional vector-valued standard Wiener process on the time interval $[0, t_f]$ adapted to a filtration $\mathcal{F}$ on a probability space $(\Omega, \mathcal{F}, \boldsymbol{P})$. Let x and z be two constant m-dimensional vectors satisfying*

$$x'\, dw = z'\, dw$$

for some time instance $t_0 \geq 0$. Then, $x = z$.

Proof. Let x, z, and $w(t)$ be given by

$$x = \begin{bmatrix} x_1 & \cdots & x_m \end{bmatrix}' \quad z = \begin{bmatrix} z_1 & \cdots & z_m \end{bmatrix}' \quad w(t) = \begin{bmatrix} w_1(t) & \cdots & w_m(t) \end{bmatrix}'.$$

At t_0, we have

$$\sum_{i=1}^m x_i\, dw_i(t_0) = \sum_{i=1}^m z_i\, dw_i(t_0).$$

For each $i = 1, 2, \ldots, m$, we multiply both sides of this equation by $dw_i(t_0)$ and then take expectations on both sides of the equation. This leads to

$$x_i\, dt = z_i\, dt, \qquad i = 1, 2, \ldots, m \qquad \Rightarrow \qquad x_i = z_i, \qquad i = 1, 2, \ldots, m,$$

from which it follows that $x = z$. This completes the proof of the lemma. □

AVERAGING RESULTS AND THE STUDY OF UNIFORM ASYMPTOTIC STABILITY OF HOMOGENEOUS DIFFERENTIAL EQUATIONS THAT ARE NOT FAST TIME-VARYING*

JOAN PEUTEMAN[†] AND DIRK AEYELS[†]

Abstract. Within the Liapunov framework, a sufficient condition for uniform asymptotic stability of ordinary differential equations is proposed. Unlike with classical Liapunov theory, the time derivative of the V-function, taken along solutions of the system, may have positive and negative values. It is shown that the proposed condition is useful for the study of uniform asymptotic stability of homogeneous systems with order $\tau > 0$. In particular, it is established that asymptotic stability of the averaged homogeneous system implies local uniform asymptotic stability of the original time-varying homogeneous system. This shows that averaging techniques play a prominent role in the study of homogeneous—not necessarily fast time-varying—systems.

1. Introduction.

The classical Liapunov approach to uniform asymptotic stability of the null solution of a dynamical system $\dot{x}(t) = f(x,t)$ requires the existence of a positive definite, decrescent Liapunov function $V(x,t)$ whose derivative along the solutions of the system is negative definite. When this derivative is negative semidefinite, stability rather than asymptotic stability follows; in case the differential equation is autonomous, the Barbashin–Krasovskii theorem or LaSalle's invariance principle may be helpful in proving asymptotic stability. Extensions to periodic differential equations are possible. For nonperiodic systems, Narendra and Annaswamy [12] show that with $\dot{V}(x,t) \leq 0$ uniform asymptotic stability can be proven if there exists a $T \in \mathbb{R}^+$ such that $\forall t : V(x(t+T), t+T) - V(x(t),t) \leq -\gamma(\|x(t)\|) < 0$, where $\gamma(\cdot)$ is a strictly increasing continuous function on $\mathbb{R}^+$ which is zero at the origin and where $x(t+T)$ is the solution of the system at $t+T$ with initial condition $x(t)$ at t. Weaker conditions than the Narendra–Annaswamy conditions also leading to asymptotic stability have recently been obtained [1, 2, 3, 4]. The present paper and [3, 4] have been inspired by the result of Narendra–Annaswamy. We claim that in the asymptotic stability theorem of Narendra–Annaswamy, *the negative semidefiniteness condition on the time-derivative of the V-function can be dispensed with*: the null solution of a differential equation is uniformly asymptotically stable under the condition that for a positive definite decrescent $V(x,t)$, $\exists T > 0$, and a strictly increasing sequence of times t_k^* such that $V(x(t_{k+1}^*), t_{k+1}^*) - V(x(t_k^*), t_k^*) \leq -\gamma(\|x(t_k^*)\|)$ with $\gamma(\cdot) : \mathbb{R}^+ \to \mathbb{R}^+$ continuous, strictly increasing and passing through the origin and $t_{k+1}^* - t_k^* \leq T \ \forall k \in \mathbb{Z}$ and $t_k^* \to \infty$ as $k \to \infty$ and $t_k^* \to -\infty$ as $k \to -\infty$. Compared to [12], $\dot{V}(x,t) \leq 0$ is no longer required. Compared to [3], the condition on V needs to be satisfied only for a sequence t_k^*, not for all t. Unlike [4], this paper is focused upon uniform asymptotic stability, not exponential stability.

In section 2 of this paper, the classical theorem of Liapunov for discrete-time nonlinear systems is recalled. In section 3, we propose a sufficient condition which guarantees uniform asymptotic stability of a continuous-time nonlinear system. In section 4 and section 5, a proposition and a theorem are stated concerning uniform asymptotic stability of time-varying homogeneous systems $\dot{x}(t) = f(x, \alpha t)$ $(\forall \alpha \in \mathbb{R}_0^+)$ with order $\tau > 0$. It is shown that asymptotic stability of the averaged (*time-invariant* homogeneous) system guarantees local uniform asymptotic stability of the original *time-varying* homogeneous system. For stability results on time-invariant homogeneous systems, the reader is referred to [7, 9]. An important—perhaps surprising—feature of our result is that it is valid *independent of* α. This shows that averaging techniques play a prominent role in the study of time-varying—not necessarily fast time-varying—homogeneous systems of order $\tau > 0$.

As illustrated in section 6 and studied in [11], it is worthwhile mentioning that the averaging results for homogeneous systems with order $\tau = 0$ are different in the sense that they are valid only for α sufficiently large.

The region of attraction of the homogeneous system $\dot{x}(t) = f(x, \alpha t)$ $(\alpha \in \mathbb{R}_0^+)$ with order $\tau > 0$ depends on α. This region of attraction increases when α increases and grows unbounded as α goes to infinity.

2. Theorem of Liapunov for discrete-time systems. Consider the time-varying discrete-time system

$$x_{k+1} = g(x_k, k) \tag{1}$$

with $g : W_d \times \mathbb{Z} \to \mathbb{R}^n$, W_d open, $W_d \subset \mathbb{R}^n$. Let $g(0, k) = 0\ \forall\ k \in \mathbb{Z}$ and $0 \in W_d$.

PROPOSITION 1. *Consider a function $V : U_d \times \mathbb{Z} \to \mathbb{R}$, with U_d an open neighborhood of* 0. *We assume the following.*

Condition 1. *$V(x, k)$ is positive definite and decrescent; i.e., $V(0, k) = 0 \quad \forall k$ and $\forall x \in U_d : \alpha_V(\|x\|) \leq V(x, k) \leq \beta_V(\|x\|)$. The functions $\alpha_V(\cdot) : \mathbb{R}^+ \to \mathbb{R}^+$ and $\beta_V(\cdot) : \mathbb{R}^+ \to \mathbb{R}^+$ are strictly increasing continuous functions passing through the origin.*

Condition 2. *There exists a function $\gamma(\cdot) : \mathbb{R}^+ \to \mathbb{R}^+$, which is continuous, strictly increasing, and passing through the origin, and an open set $U'_d \subset U_d \cap W_d$, which contains the origin such that $\forall k \in \mathbb{Z}\ \forall x_k \in U'_d \setminus \{0\}$:*

$$V(x_{k+1}, k+1) - V(x_k, k) \leq -\gamma(\|x_k\|) < 0, \tag{2}$$

where $x_{k+1} = g(x_k, k)$.

Then the equilibrium point $x = 0$ of (1) *is locally uniformly asymptotically stable.*

Proof. The present proposition is the classical theorem of Liapunov for uniform asymptotic stability for discrete-time nonlinear time-varying systems. For the proof of this proposition, the reader is referred to [5, 8]. □

Remark 1. When the closed ball with radius ν centered at 0, $\overline{B}_\nu(0) \subset U'_d$ and $x_{k_0} \in B_{\nu'}(0)$ with $\nu' = \beta_V^{-1}(\alpha_V(\nu))$, then by (2), x_k exists and $x_k \in B_\nu(0) \subset U'_d\ \forall k_0$ and $\forall k \geq k_0$. The proof of Proposition 1, which is entirely analogous to the proof of the Liapunov theorem in the continuous-time case, implies that the open ball with radius ν' centered at 0, $B_{\nu'}(0)$ belongs to the region of attraction.

3. A sufficient condition for uniform asymptotic stability. In this section, a sufficient condition for uniform asymptotic stability of a continuous-time system is proposed. In classical Liapunov theory, the time derivative of the Liapunov function V along the solutions of the system is required to be negative definite. In the present case, the derivative of the V-function may have positive and negative values. The theorem requires only the existence of a positive definite and decrescent V-function and a sequence of times t_k^* such that the values of this V-function decrease when evaluated along the solutions at t_k^*.

Consider

$$\dot{x}(t) = f(x,t) \tag{3}$$

with $f : W_c \times \mathbb{R} \to \mathbb{R}^n$, W_c open, $W_c \subset \mathbb{R}^n$. Let $f(0,t) = 0 \ \forall\ t \in \mathbb{R}$ and $0 \in W_c$. Furthermore we assume that conditions are imposed on (3) such that existence and uniqueness of its solutions are secured. These conditions are imposed on all the differential equations mentioned in the present paper, and of these conditions we single out the local Lipschitz condition. This local Lipschitz condition will be used in the course of the proof of the propositions and the theorems hereafter: f is locally Lipschitz, i.e., for $\forall x \in W_c$, $\exists$ a neighborhood $\mathcal{N}(x) \subset W_c$, such that the restriction $f|_{\mathcal{N}(x)\times\mathbb{R}} \overset{not}{=} f|_{\mathcal{N}(x)}$ is Lipschitz with Lipschitz function $l_x(t)$. We assume that $l_x(t)$ is bounded $\forall\ t \in \mathbb{R}$. We are now ready to state a lemma and Proposition 2.

LEMMA 1. *Let $U \subset W_c$ be an open neighborhood of 0. Consider a closed ball $\overline{B}_\mu(0) \subset U$; then $\forall\ T > 0$, $\exists \mu' > 0$ such that $(x_0, t_0) \in B_{\mu'}(0) \times \mathbb{R}$ implies that $x(t) \in B_\mu(0)$ for $t \in [t_0, t_0 + T]$. Here $x(t)$ is the solution of (3) evaluated at t with initial condition x_0 at t_0. (The solutions are assumed to exist over the considered time interval.)*

Proof. The proof of the lemma is omitted. It can be found in [3]. □

Remark 2. The proof of the lemma shows that $\mu' = \mu e^{-KT}$ is an appropriate choice of μ'. K is the Lipschitz constant of (3) on $\overline{B}_\mu(0)$ [10, p. 70].

PROPOSITION 2. *Consider a function $V : U \times \mathbb{R} \to \mathbb{R}$, with U an open neighborhood of 0. We assume that the following additional conditions are satisfied.*

1. *Condition 1. $V(x,t)$ is positive definite and decrescent; i.e., $V(0,t) = 0 \ \ \forall t$ and $\forall x \in U : \alpha_V(\|x\|) \le V(x,t) \le \beta_V(\|x\|)$. The functions $\alpha_V(\cdot) : \mathbb{R}^+ \to \mathbb{R}^+$ and $\beta_V(\cdot) : \mathbb{R}^+ \to \mathbb{R}^+$ are strictly increasing continuous functions passing through the origin.*

2. *Condition 2. There exists an increasing sequence of times t_k^* ($k \in \mathbb{Z}$) with $t_k^* \to \infty$ as $k \to \infty$ and $t_k^* \to -\infty$ as $k \to -\infty$, $\exists$ finite $T > 0 : t_{k+1}^* - t_k^* \le T$ ($\forall k \in \mathbb{Z}$); there exists a function $\gamma(\cdot) : \mathbb{R}^+ \to \mathbb{R}^+$ which is continuous, strictly increasing, and passing through the origin and an open set $U' \subset U \cap W_c$ which contains the origin such that $\forall k \in \mathbb{Z}\ \forall x(t_k^*) \in U' \setminus \{0\}$:*

$$V(x(t_{k+1}^*), t_{k+1}^*) - V(x(t_k^*), t_k^*) \le -\gamma(\|x(t_k^*)\|) < 0, \tag{4}$$

where $x(t_{k+1}^*)$ is the solution of (3) at t_{k+1}^* with initial condition $x(t_k^*)$ at t_k^*.

Then the equilibrium point $x = 0$ of (3) is locally uniformly asymptotically stable.

Proof. By the continuous-time system $\dot{x} = f(x,t)$ and the sequence t_k^*, we define the discrete-time system $x_{k+1} = g(x_k, k)$ with $g(x_k, k) = x(t_{k+1}^*)\ \forall x_k \in U' = W_d$. Here $x(t_{k+1}^*)$ is the solution of (3) at t_{k+1}^* with initial condition $x(t_k^*) = x_k$ at t_k^*. The continuous times t_k^* are identified with the discrete times k ($\forall k \in \mathbb{Z}$) and the state $x(t_k^*)$ is equal to x_k ($\forall k \in \mathbb{Z}$).

Uniform asymptotic stability of $x_{k+1} = g(x_k, k)$. Condition 1 and Condition 2 of Proposition 2 imply that Condition 1 and Condition 2 of Proposition 1 are fulfilled with $W_d = U_d = U_d' = U'$, which implies local uniform asymptotic stability of $x_{k+1} = g(x_k, k)$.

We are set to prove local uniform asymptotic stability of (3). First uniform stability will be established and then uniform convergence will be established.

Uniform stability of $\dot{x} = f(x,t)$. Consider a closed ball $\overline{B}_\epsilon(0)$ centered at 0 and radius ϵ small enough such that $\overline{B}_\epsilon\ (0) \subset U'$. Let K be the Lipschitz constant of (3) on $\overline{B}_\epsilon(0)$. Define $\epsilon' := \epsilon\ e^{-KT}$. Define $\delta' := \beta_V^{-1}(\alpha_V(\epsilon'))$ and $\delta'' := e^{-KT}\delta'$.

Consider the open ball $B_{\delta''}(0)$. For all $(x(t_0), t_0) \in B_{\delta''}(0) \times \mathbb{R}$, there exists a $k_0 \in \mathbb{Z}$ such that $t^*_{k_0} - t_0 < T$. By Lemma 1 and Remark 2 with $\mu = \delta'$ and $\mu' = \delta''$, one obtains that $\forall t \in [t_0, t^*_{k_0}]$, $t - t_0 < T$ which implies that

$$\|x(t)\| < \delta' = \delta'' e^{KT} < \epsilon \qquad \forall t \in [t_0, t^*_{k_0}] \tag{5}$$

and $\|x(t^*_{k_0})\| < \delta'$.

By Proposition 1 and Remark 1 with $\nu = \epsilon'$ and $\nu' = \delta'$, it is clear that $\forall n \in \mathbb{N}$: x_{k_0+n} exists and $\|x_{k_0+n}\| < \epsilon'$, where x_{k_0+n} is the solution of $x_{k+1} = g(x_k, k)$ at $k_0 + n$ with initial condition $x_{k_0} = x(t^*_{k_0})$ at k_0.

For all $n \in \mathbb{N}$, x_{k_0+n} equals $x(t^*_{k_0+n})$, where $x(t^*_{k_0+n})$ is the solution of (3) at $t^*_{k_0+n}$ with initial condition $x(t^*_{k_0}) = x_{k_0}$ at $t^*_{k_0}$. This implies that $\forall n \in \mathbb{N} : \|x(t^*_{k_0+n})\| = \|x_{k_0+n}\| < \epsilon'$.

Notice that $\forall\ t \geq t^*_{k_0}$, $\exists n \in \mathbb{N}$ such that $t - t^*_{k_0+n} < T$. Since $\|x(t^*_{k_0+n})\| < \epsilon' = \epsilon e^{-KT}$ $\forall n \in \mathbb{N}$, Lemma 1 and Remark 2 with $\mu = \epsilon$ and $\mu' = \epsilon'$ imply that

$$\|x(t)\| < \epsilon \qquad \forall\ t \geq t^*_{k_0}. \tag{6}$$

By (5) and (6), $\|x(t)\| < \epsilon$ $\forall t \geq t_0$ when $(x(t_0), t_0) \in B_{\delta''}(0) \times \mathbb{R}$.

Uniform stability of (3) is established when

$$\forall \epsilon_c > 0, \exists \delta(\epsilon_c) > 0 : \|x(t_0)\| < \delta(\epsilon_c) \Rightarrow \|x(t)\| < \epsilon_c\ \ \forall t, t_0\ \text{ such that }\ t \geq t_0.$$

If $\overline{B}_{\epsilon_c} \subset U'$, then take $\epsilon = \epsilon_c$. If $\overline{B}_{\epsilon_c}(0) \not\subset U'$, then take ϵ small enough such that $\overline{B}_\epsilon(0) \subset U'$. Simply take $\delta(\epsilon_c) = \delta'' = e^{-KT}\beta_V^{-1}(\alpha_V(\epsilon e^{-KT}))$.

Uniform convergence of $\dot{x} = f(x,t)$. We prove the existence of an $\epsilon_1 > 0$ such that $\forall \epsilon_2 > 0$, there exists a $T(\epsilon_2) \geq 0$ such that $\|x(t_0)\| < \epsilon_1$ (t_0 arbitrary) implies $\|x(t)\| < \epsilon_2$ $\forall\ t \geq t_0 + T(\epsilon_2)$. Here $x(t)$ is the solution of (3) with initial condition $x(t_0)$ at t_0.

Take ϵ small enough such that $\overline{B}_\epsilon(0) \subset U'$. Let K be the Lipschitz constant of (3) on $\overline{B}_\epsilon(0)$. Take $\epsilon_1 = e^{-KT}\beta_V^{-1}(\alpha_V(\epsilon e^{-KT}))$. For all $(x(t_0), t_0) \in B_{\epsilon_1}(0) \times \mathbb{R}$, there exists a $k_0 \in \mathbb{Z}$ such that $t^*_{k_0} - t_0 < T$. Since $\|x(t_0)\| < \epsilon_1$, by Lemma 1 and Remark 2 with $\mu = \epsilon_1 e^{KT}$ and $\mu' = \epsilon_1$, one obtains that

$$\|x(t^*_{k_0})\| < \epsilon_1 e^{KT} = \beta_V^{-1}(\alpha_V(\epsilon e^{-KT})). \tag{7}$$

Take $\epsilon_{1d} := \beta_V^{-1}(\alpha_V(\epsilon))$. By the convergence property of $x_{k+1} = g(x_k, k)$, Proposition 1 and Remark 1 with $\nu = \epsilon$ and $\nu' = \epsilon_{1d}$ imply that $\forall \epsilon_{2d} : \exists k(\epsilon_{2d})$ such that $\|x_{k_0}\| < \epsilon_{1d}$ implies that $\|x_k\| < \epsilon_{2d}$ $\ \forall k \geq k_0 + k(\epsilon_{2d})$.

Since by (7) $\|x_{k_0}\| = \|x(t^*_{k_0})\| < \epsilon_{1d}$, one obtains by taking $\epsilon_{2d} = \epsilon_2 e^{-KT}$ that $\forall k \geq k_0 + k(\epsilon_{2d})$ that

$$\|x_k\| = \|x(t^*_k)\| < \epsilon_2 e^{-KT}. \tag{8}$$

By Lemma 1 and Remark 2 with $\mu = \epsilon_2$ and $\mu' = \epsilon_2 e^{-KT}$

$$\|x(t)\| < \epsilon_2 \qquad \forall\ t \geq t^*_{k_0+k(\epsilon_{2d})}. \tag{9}$$

Since $t^*_{k_0} - t_0 < T$ and since $t^*_{k_0+k(\epsilon_{2d})} - t^*_{k_0} \leq k(\epsilon_{2d})T$, $t^*_{k_0+k(\epsilon_{2d})} - t_0 < (k(\epsilon_{2d})+1)T$. Therefore $\|x(t)\| < \epsilon_2 \ \forall t \geq t_0 + T(\epsilon_2)$ with $T(\epsilon_2) := (k(\epsilon_2 e^{-KT}) + 1)T$. This implies uniform convergence to the origin and therefore also uniform asymptotic stability of (3). □

Remark 3. The proof of Proposition 2 shows that when $\overline{B}_\epsilon(0) \subset U'$ that $B_{\delta(\epsilon)}(0)$ with $\delta(\epsilon) = e^{-KT}\beta_V^{-1}(\alpha_V(\epsilon e^{-KT}))$ belongs to the region of attraction of (3).

Remark 4. If Condition 2 of Proposition 2 is replaced by the condition that there exists an increasing sequence of times t^*_k $(k \in \mathbb{Z})$ with $t^*_k \to \infty$ as $k \to \infty$ and $t^*_k \to -\infty$ as $k \to -\infty$, $\exists$ finite $T > 0 : t^*_{k+1} - t^*_k \leq T$ $(\forall k \in \mathbb{Z})$, there exists an open set $U' \subset U \cap W_c$ which contains the origin such that $\forall k \in \mathbb{Z}\ \forall x(t^*_k) \in U' \setminus \{0\}$,

$$V(x(t^*_{k+1}), t^*_{k+1}) - V(x(t^*_k), t^*_k) \leq 0,$$

then the equilibrium point $x = 0$ of (3) is locally uniformly stable.

4. Homogeneous systems. Proposition 2 introduces a sufficient condition for uniform asymptotic stability of a dynamical system. Because of Condition 2, it may be hard in general to verify uniform asymptotic stability by means of this proposition. This section and section 5 may be seen as an elaboration of the previous one. When considering homogeneous systems, we show that Condition 2 of Proposition 2 may be replaced by a condition *independent of* the flow.

DEFINITION 1. *The system $\dot{x}(t) = f(x,t)$ with $x = (x_1, ..., x_n)^T$ is homogeneous of order τ and with dilation $\delta(s,x) = (s^{r_1}x_1, ..., s^{r_n}x_n)^T$ $(\forall i \in \{1,...,n\} : 0 < r_i < \infty)$ if for each $i \in \{1,...,n\}$*

$$\forall x \in \mathbb{R}^n, \forall t, \forall s \geq 0 : f_i(s^{r_1}x_1, ..., s^{r_n}x_n, t) = s^{\tau+r_i} f_i(x_1, ..., x_n, t). \tag{10}$$

DEFINITION 2. *The homogeneous p-norm ρ_p with dilation $\delta(s,x)$ is a continuous map from $\mathbb{R}^n$ to $\mathbb{R}^+$, $x \to \rho_p(x)$ such that*

$$\rho_p(x) := \left(\sum_{i=1}^n |x_i|^{\frac{p}{r_i}}\right)^{\frac{1}{p}} \tag{11}$$

with $p \in \mathbb{R}^+_0$.

Remark 5. Calling the function ρ_p a "norm" is a misnomer. In general ρ_p does not satisfy the triangle inequality or the scale property.

PROPOSITION 3. *Consider the homogeneous system $\dot{x}(t) = f(x,t)$ of order $\tau > 0$ and with dilation $\delta(s,x) = (s^{r_1}x_1, ..., s^{r_n}x_n)^T$. f is locally Lipschitz, i.e., $\forall x$, $\exists$ neighborhood $\mathcal{N}(x)$ such that the restriction $f|_{\mathcal{N}(x)}$ is Lipschitz with Lipschitz function $l_x(t)$ and $l_x(t)$ is bounded $\forall t \in \mathbb{R}$.*

If there exists an increasing sequence of times t^*_k $(k \in \mathbb{Z})$ with $t^*_k \to \infty$ as $k \to \infty$ and $t^*_k \to -\infty$ as $k \to -\infty$, $\exists$ finite $T > 0 : t^*_{k+1} - t^*_k \leq T$ $(\forall k \in \mathbb{Z})$ and $\exists$ $K_1 > 0$ such that $\forall k$ and $\forall x$ with $\rho_r(x) = 1$ and $r > \max\{r_1, ..., r_n\}$

$$\frac{\partial V}{\partial x}(x) \int_{t^*_k}^{t^*_{k+1}} f(x,t)dt \leq -K_1 T, \tag{12}$$

where

1. *$V(x)$ is a positive definite continuous homogeneous function, i.e.,*

$$\forall x \in \mathbb{R}^n,\ \forall s \geq 0 :\ V(s^{r_1}x_1, ..., s^{r_n}x_n) = s^l V(x_1, ..., x_n) \tag{13}$$

for some $l > 0$, and

2. $\frac{\partial V}{\partial x}(x) := (\frac{\partial V}{\partial x_1}(x), ..., \frac{\partial V}{\partial x_n}(x))$ *is locally Lipschitz on* $\mathbb{R}^n$;
then $\dot{x} = f(x,t)$ *is locally uniformly asymptotically stable.*

Proof. Before starting the main part of the proof, we introduce some notation and we derive a number of inequalities to be used later on in the proof.

Define $S_\beta := \{x \in \mathbb{R}^n : \ |x_i| \leq \beta, \forall i \in \{1, ..., n\}\}$ $(\beta \in \mathbb{R}_0^+)$. If we use the norm $\|x\|_{\max} = \max_{1\leq i\leq n} |x_i|$, then $\forall x \in S_\beta : \ \|x\|_{\max} \leq \beta$. The max-norm is denoted as $\|\cdot\|_{\max}$ whereas the Euclidean norm is denoted as $\|\cdot\|$.

By the local Lipschitz property of $\dot{x} = f(x,t)$, it is Lipschitz on S_β with a Lipschitz constant which we denote as $K_{f\beta}$. Therefore, $\forall x, y \in S_\beta$ and $\forall\ i \in \{1, ..., n\}$

$$|f_i(x,t) - f_i(y,t)| \leq \|f(x,t) - f(y,t)\|_{\max} \leq K_{f\beta}\|x - y\|_{\max}. \tag{14}$$

The set $\{x \in \mathbb{R}^n | \rho_r(x) = 1\} \subset S_1$ and therefore if $i \in \{1, ..., n\}$ and $\rho_r(x) = 1$, then

$$|f_i(x,t)| \leq \|f(x,t)\|_{\max} \leq K_f\|x\|_{\max} \leq K_f \tag{15}$$

with $K_f := K_{f1}$. By the same argument, we obtain that $\forall x, y \in S_\beta$

$$\left\|\frac{\partial V}{\partial x}(x) - \frac{\partial V}{\partial x}(y)\right\|_{\max} \leq K_{V\beta}\|x - y\|_{\max}, \tag{16}$$

where $K_{V\beta}$ is the Lipschitz constant of $\frac{\partial V}{\partial x}$ on S_β. When $\rho_r(x) = 1$, then

$$\left\|\frac{\partial V}{\partial x}(x)\right\|_{\max} \leq K_V \tag{17}$$

with $K_V := K_{V1}$. The estimates (14), (15), (16), and (17) will be used in the following.

I. Evolution of the *V*-function with respect to the sequence t_k^*. The time-derivative of $V(x)$ along the solutions of the system $\dot{x}(t) = f(x,t)$ is given by

$$\dot{V}(x,t) = \frac{\partial V}{\partial x}(x)\dot{x} = \frac{\partial V}{\partial x}(x)f(x,t). \tag{18}$$

Consider

$$\Delta V(t_{k+1}^*, t_k^*) := \int_{t_k^*}^{t_{k+1}^*} \dot{V}(x,t)dt = \int_{t_k^*}^{t_{k+1}^*} \frac{\partial V}{\partial x}(x(t))f(x(t),t)dt, \tag{19}$$

which may be rewritten as

$$\int_{t_k^*}^{t_{k+1}^*} \frac{\partial V}{\partial x}(x(t_k^*))f(x(t_k^*),t)dt \tag{20}$$

$$+ \int_{t_k^*}^{t_{k+1}^*} \left(\frac{\partial V}{\partial x}(x(t))f(x(t),t) - \frac{\partial V}{\partial x}(x(t_k^*))f(x(t_k^*),t)\right) dt. \tag{21}$$

In order to evaluate (19), we successively estimate (20) and (21).

II. Estimate of (20). In order to invoke the homogeneity properties of $\dot{x} = f(x,t)$, we spell out (20) as

$$\sum_{i=1}^{n} \int_{t_k^*}^{t_{k+1}^*} \frac{\partial V}{\partial x_i}(x(t_k^*))f_i(x(t_k^*),t)dt. \tag{22}$$

By partially differentiating each member of (13) with respect to x_i, one obtains that $\forall x \in \mathbb{R}^n \setminus \{0\}$, $\forall i \in \{1, ..., n\}$, and $\forall s \geq 0$

$$\frac{\partial V}{\partial x_i}(s^{r_1}x_1, ..., s^{r_n}x_n) = s^{l-r_i}\frac{\partial V}{\partial x_i}(x_1, ..., x_n). \tag{23}$$

By (23) and the homogeneity of $f(x,t)$, one obtains that (22) can be written as

$$\rho_r^{\tau+l}(x(t_k^*))\int_{t_k^*}^{t_{k+1}^*}\sum_{i=1}^{n}\frac{\partial V}{\partial x_i}(\delta(\rho_r^{-1}(x(t_k^*)), x(t_k^*)))f_i(\delta(\rho_r^{-1}(x(t_k^*)), x(t_k^*)), t)dt \tag{24}$$

or as

$$\rho_r^{\tau+l}(x(t_k^*))\frac{\partial V}{\partial x}(\delta(\rho_r^{-1}(x(t_k^*)), x(t_k^*)))\int_{t_k^*}^{t_{k+1}^*} f(\delta(\rho_r^{-1}(x(t_k^*)), x(t_k^*)), t)dt. \tag{25}$$

Since $\delta(\rho_r^{-1}(x(t_k^*)), x(t_k^*))$ has a homogeneous norm equal to 1, (25) implies by (12) that

$$\int_{t_k^*}^{t_{k+1}^*}\frac{\partial V}{\partial x}(x(t_k^*))f(x(t_k^*), t)dt \leq -K_1 T\rho_r^{\tau+l}(x(t_k^*)). \tag{26}$$

The inequality (26) will force $\Delta V(t_{k+1}^*, t_k^*)$ to be negative definite. We show that (21) cannot account for a sign change when the initial state $x(t_k^*)$ is taken close enough to the origin. To prove this, we estimate an upper bound for the absolute value of (21).

III. Estimate of (21). By (23) and the homogeneity of $f(x,t)$, (21) can be written as

$$\rho_r^{\tau+l}(x(t_k^*))\int_{t_k^*}^{t_{k+1}^*} L_f V(\delta(\rho_r^{-1}(x(t_k^*)), x(t)), t) - L_f V(\delta(\rho_r^{-1}(x(t_k^*)), x(t_k^*)), t)dt, \tag{27}$$

where $\frac{\partial V}{\partial x}(x)f(x,t) =: L_f V(x,t)$.

In order to evaluate an upper bound for the absolute value of (27), we need the max-norm of

$$\delta(\rho_r^{-1}(x(t_k^*)), x(t)) - \delta(\rho_r^{-1}(x(t_k^*)), x(t_k^*)) = \delta(\rho_r^{-1}(x(t_k^*)), x(t) - x(t_k^*)) \tag{28}$$

since we use the Lipschitz property of $L_f V$. In III.1 we estimate the norm of (28) and in III.2 we estimate the Lipschitz constant corresponding to $L_f V$. In III.3 we use these results to estimate the absolute value of (21).

III.1. Estimate of the norm of (28). Since

$$x_i(t) - x_i(t_k^*) = \int_{t_k^*}^{t} f_i(x(s), s)ds, \tag{29}$$

one obtains by the homogeneity of $f(x,s)$ and by (15) that

$$|x_i(t) - x_i(t_k^*)| \leq \int_{t_k^*}^{t}\rho_r^{\tau+r_i}(x(s))K_f ds. \tag{30}$$

Since $\frac{\partial \rho_r}{\partial x_i}(s^{r_1}x_1, ..., s^{r_n}x_n) = s^{1-r_i}\frac{\partial \rho_r}{\partial x_i}(x_1, ..., x_n)$ and

$$\begin{aligned}\frac{d}{d\sigma}\rho_r(x(\sigma)) &= \sum\nolimits_{i=1}^{n}\frac{\partial \rho_r}{\partial x_i}(x(\sigma))f_i(x(\sigma), \sigma)\\ &= \rho_r^{\tau+1}(x(\sigma))\sum\nolimits_{i=1}^{n}\frac{\partial \rho_r}{\partial x_i}(y(\sigma))f_i(y(\sigma), \sigma)\end{aligned} \tag{31}$$

with $y(\sigma) = \delta(\rho_r^{-1}(x(\sigma)), x(\sigma))$. By defining $g(\sigma) := \sum_{i=1}^n \frac{\partial \rho_r}{\partial x_i}(y(\sigma)) f_i(y(\sigma), \sigma)$,

$$\frac{d}{d\sigma}\rho_r(x(\sigma)) = \rho_r^{\tau+1}(x(\sigma)) g(\sigma). \tag{32}$$

By direct substitution [6], it is clear that the solution of (32) equals

$$\rho_r(x(s)) = \frac{\rho_r(x(t_k^*))}{(1 - \tau\rho_r^\tau(x(t_k^*)) \int_{t_k^*}^s g(\sigma) d\sigma)^{\frac{1}{\tau}}} \tag{33}$$

under the assumption that

$$1 - \tau\rho_r^\tau(x(t_k^*)) \int_{t_k^*}^s g(\sigma) d\sigma > 0. \tag{34}$$

Since $r_i < r$, $\frac{\partial \rho_r}{\partial x_i}$ is continuous on the set $\{x \in \mathbb{R}^n | \rho_r(x) = 1\}$. Since $y(\sigma)$ belongs to this compact set ($\rho_r(y(\sigma)) = 1$), the continuity of $\frac{\partial \rho_r}{\partial x_i}$ and (15) imply boundedness of $g(\sigma)$. There exists a $g_m > 0$ such that $\forall \sigma$: $g(\sigma) \leq g_m$. This implies that

$$\rho_r(x(s)) \leq \frac{\rho_r(x(t_k^*))}{(1 - \tau\rho_r^\tau(x(t_k^*))(s - t_k^*) g_m)^{\frac{1}{\tau}}} < 2^{\frac{1}{\tau}} \rho_r(x(t_k^*)) \tag{35}$$

when $t \in [t_k^*, t_{k+1}^*]$ with $t_{k+1}^* - t_k^* \leq T$ $\forall k \in \mathbb{Z}$ and $\rho_r(x(t_k^*)) < (2\tau g_m T)^{-\frac{1}{\tau}} =: \rho'$. By (35), it is obvious that (30) implies that

$$|x_i(t) - x_i(t_k^*)| \leq 2^{\frac{\tau + r_i}{\tau}} K_f T \rho_r^{\tau + r_i}(x(t_k^*)). \tag{36}$$

Recall that

$$\|\delta(\rho_r^{-1}(x(t_k^*)), x(t)) - \delta(\rho_r^{-1}(x(t_k^*)), x(t_k^*))\|_{\max} = \max_{1 \leq i \leq n} \frac{|x_i(t) - x_i(t_k^*)|}{\rho_r^{r_i}(x(t_k^*))}. \tag{37}$$

Therefore, (36) and (37) imply the existence of a $\tilde{K} > 0$ such that

$$\|\delta(\rho_r^{-1}(x(t_k^*)), x(t)) - \delta(\rho_r^{-1}(x(t_k^*)), x(t_k^*))\|_{\max} \leq \tilde{K} T \rho_r^\tau(x(t_k^*)) \tag{38}$$

when $\rho_r(x(t_k^*)) < \rho'$ and $t \in [t_k^*, t_{k+1}^*]$.

Having estimated the norm of (28), we estimate the Lipschitz constant of $L_f V$ which will be used in the calculation of an upper bound for (21).

III.2. Estimate of the Lipschitz constant. Notice that

$$\begin{aligned} \delta(\rho_r^{-1}(x(t_k^*)), x(t)) = {} & \delta(\rho_r^{-1}(x(t_k^*)), x(t_k^*)) \\ & + \delta(\rho_r^{-1}(x(t_k^*)), x(t)) - \delta(\rho_r^{-1}(x(t_k^*)), x(t_k^*)) \end{aligned} \tag{39}$$

and

$$\begin{aligned} \|\delta(\rho_r^{-1}(x(t_k^*)), x(t))\|_{\max} \leq {} & \|\delta(\rho_r^{-1}(x(t_k^*)), x(t_k^*))\|_{\max} \\ & + \|\delta(\rho_r^{-1}(x(t_k^*)), x(t)) - \delta(\rho_r^{-1}(x(t_k^*)), x(t_k^*))\|_{\max} \end{aligned} \tag{40}$$

such that by (38)

$$\|\delta(\rho_r^{-1}(x(t_k^*)), x(t))\|_{\max} \leq 1 + \tilde{K} T \rho_r^\tau(x(t_k^*)) \leq 1 + \frac{\tilde{K}}{2\tau g_m} =: \tilde{\beta} \tag{41}$$

when $t \in [t_k^*, t_{k+1}^*]$ and $\rho_r(x(t_k^*)) < \rho' = (2\tau g_m T)^{-\frac{1}{\tau}}$. Therefore, (41) implies that $\delta(\rho_r^{-1}(x(t_k^*)), x(t)) \in S_{\tilde{\beta}}$.

Since $\forall x, y \in S_{\tilde{\beta}}$ and $\forall t$

$$\begin{aligned} L_f V(x,t) - & L_f V(y,t) \\ & = \frac{\partial V}{\partial x}(x)(f(x,t) - f(y,t)) + \left(\frac{\partial V}{\partial x}(x) - \frac{\partial V}{\partial x}(y)\right) f(y,t), \end{aligned} \tag{42}$$

the boundedness of $\frac{\partial V}{\partial x}$ and f on $S_{\tilde{\beta}}$, implied by (14) and (16), and the Lipschitz properties of $\frac{\partial V}{\partial x}$ and f imply the existence of a Lipschitz constant $K_{fV\tilde{\beta}}$ for $L_f V$ on $S_{\tilde{\beta}}$. Therefore, $\forall x, y \in S_{\tilde{\beta}}$, and $\forall t$

$$|L_f V(x,t) - L_f V(y,t)| \le K_{fV\tilde{\beta}} \|x - y\|_{\max}. \tag{43}$$

III.3. Estimate of (21). By (38) and (43), one obtains that

$$\begin{aligned} |L_f V(\delta(\rho_r^{-1}(x(t_k^*)), x(t)), t) - & L_f V(\delta(\rho_r^{-1}(x(t_k^*)), x(t_k^*)), t)| \\ & \le K_{fV\tilde{\beta}} \tilde{K} T \rho_r^{\tau}(x(t_k^*)). \end{aligned} \tag{44}$$

By (44), the absolute value of (27)–(21) is less than or equal to

$$K_{fV\tilde{\beta}} \tilde{K} T^2 \rho_r^{2\tau + l}(x(t_k^*)) \tag{45}$$

when $\rho_r(x(t_k^*)) < \rho'$.

IV. Estimate of (19). By (26) and (45), (19) is less than or equal to

$$\rho_r^{\tau + l}(x(t_k^*)) T(-K_1 + \tilde{K} K_{fV\tilde{\beta}} T \rho_r^{\tau}(x(t_k^*))). \tag{46}$$

Define $\rho := \min\{\rho', (\frac{K_1}{2K_{fV\tilde{\beta}}\tilde{K}T})^{\frac{1}{\tau}}\}$. This implies by (46) that $\forall x(t_k^*) \neq 0$ with $\rho_r(x(t_k^*)) < \rho$:

$$\Delta V(t_{k+1}^*, t_k^*) = V(x(t_{k+1}^*)) - V(x(t_k^*)) \le -\frac{K_1 T}{2} \rho_r^{\tau + l}(x(t_k^*)), \tag{47}$$

where $x(t_{k+1}^*)$ is the solution of $\dot{x}(t) = f(x,t)$ at t_{k+1}^* with initial condition $x(t_k^*)$ at t_k^*.

V. Uniform asymptotic stability. By (13), it is obvious that Condition 1 of Proposition 2 is fulfilled with $U = \mathbb{R}^n$. By (47), it is clear that Condition 2 of Proposition 2 is fulfilled with $U' = \{x | \rho_r(x) < \rho\}$. Therefore, Proposition 2 may be applied, which implies local uniform asymptotic stability of the homogeneous system $\dot{x} = f(x,t)$. □

Remark 6. Notice that r is taken to be larger than $\max\{r_1, ..., r_n\}$ (and not equal to $\max\{r_1, ..., r_n\}$) in order to avoid technical difficulties when taking the derivative of $\sum_{i=1}^n |y_i|^{\frac{r}{r_i}}$ with respect to time.

5. Uniform asymptotic stability of time-varying homogeneous systems. Having Proposition 3 available, it is now possible to establish that asymptotic stability of the averaged system of a time-varying homogeneous system implies local uniform asymptotic stability of the original time-varying homogeneous system. Because of the homogeneity and the order condition $\tau > 0$, this result is valid even when the system is not fast time-varying.

THEOREM 1. *Consider the homogeneous system $\dot{x}(t) = f(x,t)$ of order $\tau > 0$ and with dilation $\delta(s,x) = (s^{r_1}x_1, ..., s^{r_n}x_n)^T$. f is locally Lipschitz, i.e., $\forall x$, $\exists$ neighborhood $\mathcal{N}(x)$ such that the restriction $f|_{\mathcal{N}(x)}$ is Lipschitz with Lipschitz function $l_x(t)$ and $l_x(t)$ is bounded $\forall t \in \mathbb{R}$. If the following conditions hold:*

Condition 1. *The averaged system $\dot{x}(t) = \bar{f}(x)$ is asymptotically stable, where*

$$\bar{f}(x) := \lim_{T\to\infty} \frac{1}{2T} \int_{-T}^{+T} f(x,t)dt \tag{48}$$

is continuous in x;

Condition 2. *There exists a continuous function $M : [0, +\infty[\to [0, +\infty[$ with $\lim_{\sigma\to\infty} \sigma^{-1}M(\sigma) = 0$ such that $\forall t_1, t_2 \in \mathbb{R}$ $(t_2 > t_1)$*

$$\left\| \int_{t_1}^{t_2} (f(x,t) - \bar{f}(x))dt \right\| \leq M(t_2 - t_1) \tag{49}$$

when $\rho_r(x) = 1$ with $r > \max\{r_1, ..., r_n\}$.

Then $\dot{x}(t) = f(x,t)$ is locally uniformly asymptotically stable.

Proof. The proof of the theorem is based on Proposition 3. Definition (48) of the averaged system $\dot{x}(t) = \bar{f}(x)$ implies its homogeneity of order τ with dilation $\delta(s,x) = (s^{r_1}x_1, ..., s^{r_n}x_n)^T$. Definition (48) also implies that $\bar{f}(0) = 0$. By Condition 1, the homogeneous system $\dot{x} = \bar{f}(x)$ is asymptotically stable. Let p be a positive integer and let l be a real number larger than $p(\max_{1\leq i\leq n} r_i)$. Following Rosier [13], there exists a Liapunov function $V : \mathbb{R}^n \to \mathbb{R}$ such that

P1. $V(x)$ is of class C^∞ in $\mathbb{R}^n \setminus \{0\}$ and of class C^p in $\mathbb{R}^n$;

P2. $V(0) = 0$, $V(x) > 0$ $\forall$ $x \neq 0$ and $V(x) \to +\infty$ as $\|x\| \to +\infty$;

P3. V is homogeneous: $\forall x \in \mathbb{R}^n \setminus \{0\} : \forall s > 0 : V(s^{r_1}x_1, ..., s^{r_n}x_n) = s^l V(x_1, ..., x_n)$;

P4. $\forall x \neq 0 : \frac{\partial V}{\partial x}(x)\bar{f}(x) < 0$.

By P1, $\frac{\partial V}{\partial x}$ is continuous in $\mathbb{R}^n$ and the continuity of $\bar{f}(x)$ implies continuity of $\frac{\partial V}{\partial x}(x)\bar{f}(x)$ on the compact set $\{x|\rho_r(x) = 1\}$. This implies by P4 that $\exists\beta > 0$ such that $\forall x$ with $\rho_r(x) = 1$,

$$\frac{\partial V}{\partial x}(x)\bar{f}(x) \leq -\beta. \tag{50}$$

Take a $t_0^\circ \in \mathbb{R}$ and $\forall T'$ and $\forall x$ with $\rho_r(x) = 1$:

$$\frac{\partial V}{\partial x}(x) \int_{t_0^\circ}^{t_0^\circ+T'} f(x,t)dt = T'\frac{\partial V}{\partial x}(x)\bar{f}(x) + \frac{\partial V}{\partial x}(x) \int_{t_0^\circ}^{t_0^\circ+T'} (f(x,t) - \bar{f}(x))dt. \tag{51}$$

By the continuity of $\frac{\partial V}{\partial x}$ on the compact set $\{x|\rho_r(x) = 1\}$, $\exists M_V > 0$ such that

$$\left\| \frac{\partial V}{\partial x}(x) \right\| \leq M_V \tag{52}$$

when $\rho_r(x) = 1$. One obtains by Condition 2 that

$$\frac{\partial V}{\partial x}(x) \int_{t_0^\circ}^{t_0^\circ+T'} f(x,t)dt \leq T'\frac{\partial V}{\partial x}(x)\bar{f}(x) + M_V M(T') \tag{53}$$

$$\leq -\beta T' + M_V M(T') \tag{54}$$

when $\rho_r(x) = 1$. By Condition 2, $\lim_{T' \to \infty} \frac{M(T')}{T'} = 0$, which implies that $\exists T''$ such that $\forall T' \geq T'' : \frac{M(T')}{T'} < \frac{\beta}{M_V}$. Take such a T' and define a sequence of times $t_k^* := t_0^\circ + kT'$, then $\forall k \in \mathbb{Z}$ and $\forall x$ with $\rho_r(x) = 1$,

$$\frac{\partial V}{\partial x}(x) \int_{t_k^*}^{t_{k+1}^*} f(x,t)dt \leq -K_1 T' \tag{55}$$

with $K_1 = \beta - M_V \frac{M(T')}{T'} > 0$.

With $T = T'$ and $t_k^* = t_0^\circ + kT'$, (55) implies that (12) is satisfied and P3 implies that (13) is satisfied. With $p \geq 2$, $\frac{\partial V}{\partial x}$ is continuously differentiable and therefore also locally Lipschitz. By Proposition 3, one obtains local uniform asymptotic stability of the homogeneous system $\dot{x} = f(x,t)$. □

Remark 7. Theorem 1 is a result on asymptotic stability of a homogeneous system under a classical averaging condition, *without* requirements on the time-scale—typical for averaging results.

Remark 8. The proof of Theorem 1 is based on Proposition 3 and the crucial part of the proof of Proposition 3 is the negative definiteness of (19). This negative definiteness of (19) is guaranteed by the negative definiteness of (20) when (21) is sufficiently small. The expression (21) is small when, roughly, the variation of the flow $x(t) - x(t_k^*)$ is small in comparison with $x(t_k^*)$. This proportional variation can be reduced by reducing the size of the right-hand side $\rho_r^\tau(x(t_k^*))\tilde{K}T$ of (38). A first way of achieving this reduction is by a time-scale transformation. It is clear that when the homogeneous system $\dot{x} = f(x,t)$ satisfies the conditions of Theorem 1 with $T = T_f$, then $\forall \alpha > 0$: $\dot{x} = f(x, \alpha t)$ satisfies the conditions of Theorem 1 with $T = \frac{T_f}{\alpha}$. By increasing α, i.e., by decreasing $T = \frac{T_f}{\alpha}$, $\rho_r^\tau(x(t_k^*))\tilde{K}T$ can be made arbitrarily small. For any fixed time-scale, there is still a second possibility of reducing the size of $\rho_r^\tau(x(t_k^*))\tilde{K}T$ by reducing $\rho_r(x(t_k^*))$, i.e., by starting at initial conditions close enough to the origin. This is the technique that leads to Theorem 1.

In [4], where exponential stability is considered, and in [11], where homogeneous systems of order $\tau = 0$ are considered, there is a different situation. The effect of a decreasing proportional variation of the flow when starting close enough to the origin is not available. The only way to obtain a small proportional variation is by making α sufficiently large. This explains why the averaging results in [4] and [11] imply uniform asymptotic stability of *fast* time-varying systems.

6. A counterexample and an example.

The averaging result of Theorem 1, for not necessarily fast time-varying systems, is valid for homogeneous systems of order $\tau > 0$. As explained in Remark 8, the averaging result is not valid for homogeneous systems with an order $\tau = 0$.

This is easily illustrated. Consider the linear time-varying system $\dot{x}(t) = A(t)x(t)$ [10, p. 144] with

$$A(t) = \begin{pmatrix} -1 + 1.5\,\cos^2 t & 1 - 1.5\,\sin t\,\cos t \\ -1 - 1.5\,\sin t\,\cos t & -1 + 1.5\,\sin^2 t \end{pmatrix}. \tag{56}$$

The averaged system $\dot{x}(t) = \bar{A}x(t)$ with

$$\bar{A} = \begin{pmatrix} -0.25 & 1 \\ -1 & -0.25 \end{pmatrix} \tag{57}$$

is asymptotically stable but the original time-varying system $\dot{x}(t) = A(t)x(t)$ is unstable with transition matrix

$$\Phi(t,0) = \begin{pmatrix} e^{0.5t}\text{cos}t & e^{-t}\text{sin}t \\ -e^{0.5t}\text{sin}t & e^{-t}\text{cos}t \end{pmatrix}. \tag{58}$$

Since $\bar{A}$ is Hurwitz, there exists a positive definite matrix P such that $\bar{A}^TP + P\bar{A}$ is negative definite. Consider the homogeneous system $\dot{x}(t) = \|x(t)\|A(t)x(t)$ with positive order. The averaged system $\dot{x}(t) = \|x(t)\|\bar{A}x(t)$ is asymptotically stable since along its flow the derivative of x^TPx equals $\|x\|x^T(\bar{A}^TP + P\bar{A})x$, which is negative definite. By Theorem 1, asymptotic stability of $\dot{x}(t) = \|x(t)\|\bar{A}x(t)$ implies local uniform asymptotic stability of $\dot{x}(t) = \|x(t)\|A(t)x(t)$.

7. Semiglobal uniform asymptotic stability. The conditions of Theorem 1 imply local uniform asymptotic stability of the homogeneous time-varying system $\dot{x} = f(x,t)$ with order $\tau > 0$. These conditions also imply that $\forall\alpha > 0$: $\dot{x} = f(x,\alpha t)$ is locally uniformly asymptotically stable. No global stability property is obtained. In the present section, we prove that the region of attraction of the homogeneous system $\dot{x} = f(x,\alpha t)$ depends on α. We show that the bounded region of attraction increases when α increases and grows unbounded as α goes to infinity.

THEOREM 2. *The homogeneous system $\dot{x} = f(x,\alpha t)$ of order $\tau > 0$, where $\dot{x} = f(x,t)$ satisfies all the conditions of Theorem 1, is semiglobally uniformly asymptotically stable, i.e., $\forall R > 0$, $\exists\alpha_R > 0$, and also a class $\mathcal{KL}$-function $\beta_R(\cdot,\cdot)$ such that $\forall x_0$ with $\rho_r(x_0) < R$, $\forall t_0$, $\forall t \geq t_0$*

$$\rho_r(x_{\alpha_R}(t,t_0,x_0)) \leq \beta_R(\rho_r(x_0), t - t_0). \tag{59}$$

Here $x_{\alpha_R}(t,t_0,x_0)$ is the solution at t of the homogeneous system $\dot{x} = f(x,\alpha_R t)$ with initial condition x_0 at t_0.

Proof. The conditions imposed by Theorem 1 on $\dot{x} = f(x,t)$ are satisfied, which implies local uniform asymptotic stability of $\dot{x} = f(x,t)$. This is equivalent to the existence of a $\rho > 0$ and a class $\mathcal{KL}$-function $\beta_\rho(\cdot,\cdot)$ such that $\forall t_0$, $\forall t \geq t_0$, $\forall x_0$ with $\rho_r(x_0) < \rho$

$$\rho_r(x_1(t,t_0,x_0)) \leq \beta_\rho(\rho_r(x_0), t - t_0), \tag{60}$$

where $x_1(t,t_0,x_0)$ denotes the solution at t of $\dot{x} = f(x,t)$ with initial condition x_0 at t_0. We denote the solution of $\dot{x} = f(x,\alpha t)$ with initial condition x_0 at t_0 as $x_\alpha(t,t_0,x_0)$. The solutions of $\dot{x} = f(x,t)$ and $\dot{x} = f(x,\alpha t)$ are related, i.e., $\forall\alpha > 0$, $\forall t_0$, and $\forall t \geq t_0$

$$x_\alpha(t,t_0,x_0) = \delta(\sqrt[\tau]{\alpha}, x_1(\alpha t, \alpha t_0, \delta^{-1}(\sqrt[\tau]{\alpha}, x_0))). \tag{61}$$

Define $\alpha_R := (\frac{R}{\rho})^\tau$. For all x_0 with $\rho_r(x_0) < R$, $\forall t_0$, $\forall t \geq t_0$, by (61)

$$\rho_r(x_{\alpha_R}(t,t_0,x_0)) = \sqrt[\tau]{\alpha_R}\ \rho_r(x_1(\alpha_R t, \alpha_R t_0, \delta^{-1}(\sqrt[\tau]{\alpha_R}, x_0))). \tag{62}$$

Since $\rho_r(\delta^{-1}(\sqrt[\tau]{\alpha_R}, x_0)) < \rho$, applying (60) to the right-hand side of (62) implies that for all x_0 with $\rho_r(x_0) < R$, $\forall t_0$, $\forall t \geq t_0$

$$\rho_r(x_{\alpha_R}(t,t_0,x_0)) \leq \sqrt[\tau]{\alpha_R}\beta_\rho(\rho_r(\delta^{-1}(\sqrt[\tau]{\alpha_R}, x_0)), \alpha_R(t - t_0)) = \beta_R(\rho_r(x_0), t - t_0) \tag{63}$$

with the obvious definition of $\beta_R(\cdot,\cdot)$. □

8. Conclusions.

Proposition 2 gives a sufficient condition for uniform asymptotic stability of a differential equation. This result is related to the result of Narendra and Annaswamy [12], but negative semidefiniteness on $\dot{V}(x,t)$ is dispensed with.

This result is useful for the investigation of uniform asymptotic stability of homogeneous sytems with order $\tau > 0$. More precisely, averaging becomes a useful tool for studying uniform asymptotic stability: asymptotic stability of the averaged system implies local uniform asymptotic stability of the original time-varying system. It is important that this result is *not restricted to fast time-varying systems.* The region of attraction of $\dot{x} = f(x, \alpha t)$ increases with increasing α. The uniform asymptotic stability is semiglobal since by taking α large enough, every bounded region of attraction can be guaranteed.

Comparing these results with the results of M'Closkey and Murray [11], the following should be noted:

1. We are dealing with homogeneous systems of order $\tau > 0$ while M'Closkey and Murray are dealing with homogeneous systems of order $\tau = 0$.

2. Because of the order $\tau > 0$, asymptotic stability of the averaged system implies asymptotic stability, not exponential stability, of the original time-varying system. M'Closkey and Murray consider homogeneous systems of order $\tau = 0$ and therefore they are able to conclude exponential stability, with respect to the homogeneous norm, of the original time-varying system.

3. We obtain local asymptotic stability results for the homogeneous system $\dot{x} = f(x, \alpha t)$ with order $\tau > 0$ for every $\alpha > 0$. By setting $\sigma = \alpha t$ and $\epsilon = \frac{1}{\alpha}$, $\dot{x} = f(x, \alpha t)$ is equivalent to $\dot{x} = \epsilon f(x, \sigma)$. M'Closkey and Murray deal with homogeneous systems $\dot{x} = \epsilon f(x, \sigma, \epsilon)$ of order $\tau = 0$ and therefore, the stability results are valid only for ϵ sufficiently small.

Acknowledgments. The authors acknowledge the constructive comments of the anonymous reviewers.

NECESSARY OPTIMALITY CONDITIONS FOR CONTROL PROBLEMS AND THE STONE–ČECH COMPACTIFICATION[*]

NADIR ARADA[†] AND JEAN-PIERRE RAYMOND[†]

Abstract. This paper deals with optimal control problems of parabolic equations in the presence of pointwise state constraints. We consider bounded controls which act in the initial condition of the state equation. The state variable is a bounded continuous function on the domain $Q = \Omega\times]0,T[$ but is not continuous on $\overline{Q}$. In this case, the multiplier associated with state constraints is a regular bounded finitely additive measure on Q (but not a σ-additive one). Using some properties of the Stone–Čech compactification, we prove a decomposition theorem for this measure which allows us to interpret the adjoint equation in a classical sense. We obtain new optimality conditions for these kinds of problems, and we apply these results to the case of bilateral constraints.

Key words. optimal control, Stone–Čech compactification, semilinear parabolic equation, pointwise state constraint

1. Introduction.

Consider an optimal control problem governed by a partial differential equation, with state constraints of the form $y \in \mathcal{C}$, where $\mathcal{C}$ is a closed convex subset of a Banach space Z. It is well known that some conditions are needed on $\mathcal{C}$ to establish first order optimality conditions. For example, $\mathcal{C}$ must be of finite codimension in Z (which is satisfied if the interior of $\mathcal{C}$ is nonempty in Z). In this case, the adjoint state satisfies a partial differential equation in which appears a multiplier ζ belonging to Z', the topological dual of Z. Different cases where Z is separable are treated in [3], [4], [5], [9], [11], [14], [16]. There are situations in which Z is not separable. In such problems, the main drawback is that the adjoint equation cannot be interpreted in the sense of distributions and classical methods for partial differential equations cannot be used (to prove existence and uniqueness, and to study approximation). In this paper, we use some properties of the Stone–Čech compactification to derive optimality conditions.

Since the use of these tools is completely new in the context of optimal control problems, we have chosen a simple problem to illustrate such situations: we consider a control problem for a semilinear parabolic equation with a control in the initial condition, the cost functional depends only on the final observation and on the control, and pointwise state constraints are imposed on the whole domain. The problem is simple because there is only one control and because the control acts only in the initial condition. However, the same method may be applied to other control problems. In particular, the Stone–Čech compactification may be used to obtain new optimality conditions for problems with Dirichlet boundary controls in the presence of pointwise state constraints. (Such problems are considered in [10], [12], [13].) Some results have been presented in [1], and a complete analysis will be carried out in a forthcoming paper [2].

Consider the following semilinear parabolic equation:

$$(1)\qquad \frac{\partial y}{\partial t}+Ay+\Phi(\cdot,y)=0 \quad \text{in } Q,\qquad \frac{\partial y}{\partial n_A}+\Psi(\cdot,y)=0 \quad \text{on } \Sigma,\qquad y(\cdot,0)=w \quad \text{in } \Omega,$$

where $Q=\Omega\times]0,T[$, Ω is a bounded domain in $\mathbb{R}^N$, $\Sigma=\Gamma\times]0,T[$, Γ is the boundary of Ω, $T>0$, $w\in W_{ad}\subset L^\infty(\Omega)$ is a control in the initial condition, A is a second order elliptic operator of the form $Ay(x)=-\sum_{i,j=1}^N D_i(a_{ij}(x)D_jy(x))$ (D_i denotes the partial derivative with respect to x_i), $\frac{\partial y}{\partial n_A}$ denotes the conormal derivative with respect to A, and Φ and Ψ are Carathéodory functions (assumptions are specified in section 2.1). Constraints of the form

$$(2)\qquad g(y)\in\mathcal{C}$$

are imposed on the state variable y. (Here g is a continuous mapping from $C_b(\overline{Q}\setminus\overline{\Omega}_0)$ into $C_b(\overline{Q}\setminus\overline{\Omega}_0)$, $\mathcal{C}$ is a closed convex subset with a nonempty interior in $C_b(\overline{Q}\setminus\overline{\Omega}_0)$, and $\overline{\Omega}_0=\overline{\Omega}\times\{0\}$.) The paper is concerned with the control problem

$$(\mathrm{P})\qquad \inf\{J(y,w)\ \mid\ y\in C_b(\overline{Q}\setminus\overline{\Omega}_0),\ w\in W_{ad},\ \ (y,w) \text{ satisfies (1) and (2)}\},$$

where the cost functional is given by

$$J(y,w)=\int_\Omega L(x,y(x,T),w(x))\,dx.$$

Since the initial condition w belongs to $L^\infty(\Omega)$ (and not to $C(\overline{\Omega})$), the solution y_w of (1) belongs to $C_b(\overline{Q}\setminus\overline{\Omega}_0)$ (and not to $C(\overline{Q})$). Since $C_b(\overline{Q}\setminus\overline{\Omega}_0)$ is not separable, we are in the situation described at the beginning. One way to obtain optimality conditions is to proceed as in [12], [3]. We can associate with (P) a problem in which the state constraint (2) is penalized, we can write optimality conditions for the penalized problem, and, by passing to the limit with respect to the penalization parameter, we recover optimality conditions in which the adjoint state p obeys:

$$\int_Q\Big(-p\frac{\partial z}{\partial t}+\sum_{i,j=1}^N a_{ij}D_jpD_iz+\Phi'_y(x,t,\bar y)pz\Big)\,dxdt+\int_\Sigma\Psi'_y(s,t,\bar y)pz\,dsdt$$
$$+\int_\Omega\bar\alpha L'_y(x,\bar y(T),\bar w)z\,dx+\Big\langle g'(\bar y)^*\bar\zeta,z\Big\rangle_{(C_b(\overline{Q}\setminus\overline{\Omega}_0))'\times C_b(\overline{Q}\setminus\overline{\Omega}_0)}=0$$

for all $z\in C^1(\overline{Q})$ such that $z(0)=0$, where $(\bar y,\bar w)$ is an optimal solution for (P), $\bar\alpha$ is a multiplier of the cost functional, and $\bar\zeta\in(C_b(\overline{Q}\setminus\overline{\Omega}_0))'$ is a multiplier associated with the state constraint. As mentioned above, because of the term $g'(\bar y)^*\bar\zeta$, such an equation cannot be studied in the classical framework of partial differential equations. To overcome this difficulty, we identify $C_b(\overline{Q}\setminus\overline{\Omega}_0)$ with the space $C((\overline{Q}\setminus\overline{\Omega}_0)^\#)$, where $(\overline{Q}\setminus\overline{\Omega}_0)^\#$ is the Stone–Čech compactification of $\overline{Q}\setminus\overline{\Omega}_0$. Next, following an idea of DiPerna and Majda [7], we can associate with any $\zeta\in(C_b(\overline{Q}\setminus\overline{\Omega}_0))'\equiv\mathcal{M}((\overline{Q}\setminus\overline{\Omega}_0)^\#)$ an element of $\mathcal{M}(\overline{Q}\times(\overline{Q}\setminus\overline{\Omega}_0)^\#)$. In this way, we prove a decomposition theorem for elements of $(C_b(\overline{Q}\setminus\overline{\Omega}_0))'$ (Corollary 4.8). Each $\zeta\in(C_b(\overline{Q}\setminus\overline{\Omega}_0))'$ is represented by a "regular part," which is a bounded Radon measure on $\overline{Q}\setminus\overline{\Omega}_0$ and an additional part, which acts only on $\overline{\Omega}_0$. Due to this decomposition, we prove that only the regular part intervenes in the adjoint equation. The additional part intervenes in the optimality conditions. We state optimality conditions for (P) in Theorem 2.1. We give applications of these optimality conditions to the case of bilateral constraints in section 6. Notice that optimality conditions obtained in Corollary 6.2 are particularly simple.

The rest of the paper is organized as follows. Assumptions and the main result (Theorem 2.1) are stated in section 2. We have collected some results for the state and the adjoint equations in section 3. Results related to the Stone–Čech compactification are proved in section 4. The proof of the optimality conditions is given in section 5.

2. Assumptions. Main results. Throughout the paper, Ω denotes a bounded open subset in $\mathbb{R}^N$ $(N \geq 2)$ of class $C^{2+\gamma}$ for some $0 < \gamma \leq 1$. The coefficients a_{ij} of the operator A belong to $C^{1+\gamma}(\overline{\Omega})$ and satisfy the conditions

$$a_{ij}(x) = a_{ji}(x) \qquad \text{for every} \quad i,j \in \{1,\dots,N\}, \qquad m_0|\xi|^2 \leq \sum_{i,j=1}^{N} a_{ij}(x)\xi_i\xi_j$$

for all $\xi \in \mathbb{R}^N$ and all $x \in \overline{\Omega}$, with $m_0 > 0$. In (1), $\frac{\partial y}{\partial n_A}$ denotes the conormal derivative of y with respect to A, that is,

$$\frac{\partial y}{\partial n_A}(s,t) = \sum_{i,j} a_{ij}(s) D_j y(s,t) n_i(s),$$

where $n = (n_1,\dots,n_N)$ is the unit normal to Γ outward Ω.

For every $1 \leq \ell \leq \infty$, the usual norms in the spaces $L^\ell(\Omega)$, $L^\ell(Q)$, $L^\ell(\Sigma)$ will be denoted by $||\cdot||_{\ell,\Omega}$, $||\cdot||_{\ell,Q}$, $||\cdot||_{\ell,\Sigma}$. The Hilbert space

$$W(0,T;H^1(\Omega),(H^1(\Omega))') = \left\{ y \in L^2(0,T;H^1(\Omega)) \ \mid \ \frac{dy}{dt} \in L^2(0,T;(H^1(\Omega))') \right\}$$

will be denoted by $W(0,T)$. We introduce the space

$$Y_\infty = \left\{ y \in W(0,T) \ \mid \ \frac{\partial y}{\partial t} + Ay \in L^\infty(Q), \ \ \frac{\partial y}{\partial n_A} \in L^\infty(\Sigma), \ \text{ and } \ y(\cdot,0) \in L^\infty(\Omega) \right\}.$$

Endowed with the norm

$$y \longrightarrow ||y||_{W(0,T)} + ||\frac{\partial y}{\partial t} + Ay||_{\infty,Q} + ||\frac{\partial y}{\partial n_A}||_{\infty,\Sigma} + ||y(\cdot,0)||_{\infty,\Omega},$$

Y_∞ is a Banach space. Throughout what follows, $\langle \cdot,\cdot \rangle_{*,\overline{Q}\setminus\overline{\Omega}_0}$ denotes the duality pairing between the spaces $(C_b(\overline{Q} \setminus \overline{\Omega}_0))'$ and $C_b(\overline{Q} \setminus \overline{\Omega}_0)$. If $\mu \in \mathcal{M}_b(\overline{Q} \setminus \overline{\Omega}_0)$ (the space of bounded Radon measures on $\overline{Q}\setminus\overline{\Omega}_0$) and $y \in C_b(\overline{Q}\setminus\overline{\Omega}_0)$, we set $\langle \mu, y \rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} = \int_{\overline{Q}\setminus\overline{\Omega}_0} y(x,t)d\mu(x,t)$.

2.1. Assumptions. A1. For every $y \in \mathbb{R}$, $\Phi(\cdot,y)$ and $\Psi(\cdot,y)$ are, respectively, measurable on Q and Σ. For almost all $(x,t) \in Q$, $\Phi(x,t,\cdot)$ is of class C^1, and for almost all $(s,t) \in \Sigma$, $\Psi(s,t,\cdot)$ is of class C^1. Moreover, the following estimates hold:

$$|\Phi(x,t,0)| + |\Phi'_y(x,t,y)| \leq C_0, \quad |\Psi(s,t,0)| + |\Psi'_y(s,t,y)| \leq C_0 \ \text{ for some } C_0 \geq 0.$$

A2. For every $(y,w) \in \mathbb{R}^2$, $L(\cdot,y,w)$ is measurable on Ω. For almost all $x \in \Omega$, $L(x,\cdot,\cdot)$ is of class C^1. The following estimate holds:

$$|L(x,y,w)| + |L'_y(x,y,w)| + |L'_w(x,y,w)| \leq L_1(x,t)\eta(|w|)\eta(|y|),$$

where $L_1 \in L^1(\Omega)$ and η is a nondecreasing function from $\mathbb{R}^+$ into $\mathbb{R}^+$.

A3. W_{ad} is a closed convex subset in $L^\infty(\Omega)$.

A4. $g : C_b(\overline{Q} \setminus \overline{\Omega}_0) \longrightarrow C_b(\overline{Q} \setminus \overline{\Omega}_0)$ is of class C^1.

2.2. Statement of the main result. Define the following Hamiltonian function:

$$H(x,y,w,p,\alpha) = \alpha L(x,y,w) - pw \qquad \text{for all } (x,y,w,p,\alpha) \in \Omega \times \mathbb{R}^3 \times \mathbb{R}^+.$$

As mentioned in the introduction, every $\zeta \in (C_b(\overline{Q}\setminus\overline{\Omega}_0))'$ is identified with a measure $\hat{\hat{\zeta}} \in \mathcal{M}(\overline{Q}\times(\overline{Q}\setminus\overline{\Omega}_0)^{\#})$ (see section 4). For notational simplicity, $\hat{\hat{\zeta}}$ will also be denoted by ζ. The canonical projection from $\mathcal{M}(\overline{Q}\times(\overline{Q}\setminus\overline{\Omega}_0)^{\#})$ onto $\mathcal{M}(\overline{Q})$ is denoted by π and defined by

$$\pi : \zeta \in \mathcal{M}(\overline{Q}\times(\overline{Q}\setminus\overline{\Omega}_0)^{\#}) \longrightarrow \pi_\zeta \in \mathcal{M}(\overline{Q}),$$

$$\Big\langle \pi_\zeta, \phi \Big\rangle_{\mathcal{M}(\overline{Q})\times C(\overline{Q})} = \Big\langle \zeta, \phi \Big\rangle_{\mathcal{M}(\overline{Q}\times(\overline{Q}\setminus\overline{\Omega}_0)^{\#})\times C(\overline{Q}\times(\overline{Q}\setminus\overline{\Omega}_0)^{\#})} \qquad \text{for all } \phi \in C(\overline{Q}).$$

Throughout the following, for any $\zeta \in (C_b(\overline{Q}\setminus\overline{\Omega}_0))'$, $|\zeta|$ stands for the total variation of ζ. If $\mu \in \mathcal{M}_b(\overline{Q}\setminus\overline{\Omega}_0)$, we denote by $g'(\bar{y})^*\mu$ the Radon measure on $\overline{Q}\setminus\overline{\Omega}_0$ defined by

$$z \longrightarrow \Big\langle \mu, g'(\bar{y})z \Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} \qquad \text{for all } z \in C_0(\overline{Q}\setminus\overline{\Omega}_0).$$

Moreover, $[g'(\bar{y})^*\mu]_{|Q}$ denotes the restriction of $g'(\bar{y})^*\mu$ to Q, $[g'(\bar{y})^*\mu]_{|\Sigma}$ denotes the restriction of $g'(\bar{y})^*\mu$ to Σ, and $[g'(\bar{y})^*\mu]_{|\overline{\Omega}_T}$ denotes the restriction of $g'(\bar{y})^*\mu$ to $\overline{\Omega}\times\{T\}$.

Theorem 2.1. *If* A1–A4 *are fulfilled and if* $(\bar{y},\bar{w})$ *is a solution of* (P)*, then there exist* $\bar{\alpha} \geq 0$, $\bar{p} \in L^1(0,T;W^{1,1}(\Omega))$, $\bar{\zeta} \in (C_b(\overline{Q}\setminus\overline{\Omega}_0))'$, *and a bounded linear transformation* $\Lambda_{\bar{\zeta}} : C_b(\overline{Q}\setminus\overline{\Omega}_0) \longrightarrow L^\infty_{\pi_{|\bar{\zeta}|}}(\overline{Q})$, *such that the following conditions hold:*

Nontriviality condition:

$$(\bar{\zeta},\bar{\alpha}) \neq 0. \tag{3}$$

Complementary condition:

$$\Big\langle \bar{\zeta}, z - g(\bar{y}) \Big\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0} = \Big\langle \pi_{\bar{\zeta}}, z - g(\bar{y}) \Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} + \int_{\overline{\Omega}_0} \Lambda_{\bar{\zeta}}\Big(z - g(\bar{y})\Big)\, d\pi_{|\bar{\zeta}|} \leq 0 \tag{4}$$

for all $z \in \mathcal{C}$.

Adjoint equation:

$$\begin{cases} -\frac{\partial \bar{p}}{\partial t} + A\bar{p} + \Phi'_y(x,t,\bar{y})\bar{p} + [g'(\bar{y})^*\pi_{\bar{\zeta}}]_{|Q} = 0 & \text{in } Q, \\ \frac{\partial \bar{p}}{\partial n_A} + \Psi'_y(s,t,\bar{y})\bar{p} + [g'(\bar{y})^*\pi_{\bar{\zeta}}]_{|\Sigma} = 0 & \text{on } \Sigma, \\ \bar{p}(x,T) + \bar{\alpha}L'_y(x,\bar{y}(T),\bar{w}) + [g'(\bar{y})^*\pi_{\bar{\zeta}}]_{|\overline{\Omega}_T} = 0 & \text{on } \overline{\Omega}. \end{cases} \tag{5}$$

Optimality condition for $\bar{w}$:

$$\int_\Omega H'_w\Big(x,\bar{y}(T),\bar{w},\bar{p}(0),\bar{\alpha}\Big)(\bar{w}-w)\,dx + \int_{\overline{\Omega}_0} \Lambda_{\bar{\zeta}}\Big(g'(\bar{y})(z_{\bar{w}} - z_w)\Big) d\pi_{|\bar{\zeta}|} \leq 0 \tag{6}$$

for all $w \in W_{ad}$, *where* z_w *is the solution of:*

$$\frac{\partial z}{\partial t} + Az = 0 \quad \text{in } Q, \qquad \frac{\partial z}{\partial n_A} = 0 \quad \text{on } \Sigma, \qquad z(\cdot,0) = w \quad \text{in } \Omega. \tag{7}$$

Decomposition property of $\bar\zeta$*:*

$$\left\langle \bar\zeta, h\right\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0} = \left\langle \pi_{\bar\zeta}, h\right\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} + \int_{\overline{\Omega}_0} \Lambda_{\bar\zeta}(h)\, d\pi_{|\bar\zeta|} \quad \text{for all } h \in C_b(\overline{Q}\setminus\overline{\Omega}_0). \tag{8}$$

Property of the operator $\Lambda_{\bar\zeta}$*:*

$$\int_{\overline{\Omega}_0} \Lambda_{\bar\zeta}(h)\, d\pi_{|\bar\zeta|} = \left\langle \pi_{\bar\zeta}, h\right\rangle_{\mathcal{M}(\overline{\Omega}_0)\times C(\overline{\Omega}_0)} \quad \text{for all } h \in C(\overline{Q}). \tag{9}$$

Remark 2.2. *In the case when* $W_{ad} \subset C(\overline{\Omega})$ ($\mathcal{C}$ *is a closed convex subset of* $C(\overline{Q})$ *and* $g : C(\overline{Q}) \longrightarrow C(\overline{Q})$), *by using the property* (9) *satisfied by the operator* $\Lambda_{\bar\zeta}$, *the complementary condition is written as*

$$\left\langle \pi_{\bar\zeta}, z - g(\bar y)\right\rangle_{\mathcal{M}(\overline{Q})\times C(\overline{Q})} \le 0 \quad \text{for all } z \in \mathcal{C},$$

the optimality condition for $\bar w$ *is written as*

$$\int_\Omega H'_w\Big(x, \bar y(T), \bar w, \bar p(0), \bar\alpha\Big)(\bar w - w)\, dx + \left\langle [g'(\bar y)^*\pi_{\bar\zeta}]_{|\overline{\Omega}_0}, \bar w - w\right\rangle_{\mathcal{M}(\overline{\Omega})\times C(\overline{\Omega})} \le 0$$

for all $w \in W_{ad}$, *and the condition* $(\bar\zeta, \bar\alpha) \ne 0$ *is equivalent to* $(\pi_{\bar\zeta}, \bar\alpha) \ne 0$ (*it is a direct consequence of* (9)). *In this case, we recover optimality conditions proved in* [14] *and* [16].

Remark 2.3. *As in* [16], *we can recover optimality conditions in qualified form* (*that is, with* $\bar\alpha = 1$ *in* (5) *and* (6)) *under a strong stability condition.*

3. State equation and adjoint equation.

3.1. Existence, uniqueness, and regularity of the state variable. The following result is proved in [16, Proposition 3.4].

Proposition 3.1. *Let* (a, b) *be in* $L^\infty(Q) \times L^\infty(\Sigma)$ *satisfying* $||a||_{\infty,Q} \le C_0$ *and* $||b||_{\infty,\Sigma} \le C_0$. *For every* $(f, h, y_0) \in L^q(Q) \times L^r(\Sigma) \times L^\infty(\Omega)$ *(with* $q > \frac{N}{2} + 1$ *and* $r > N + 1$*), the solution* y *of*

$$\frac{\partial y}{\partial t} + Ay + ay = f \quad \text{in } Q, \quad \frac{\partial y}{\partial n_A} + by = h \quad \text{on } \Sigma, \quad y(0) = y_0 \quad \text{in } \Omega$$

belongs to $W(0, T) \cap C_b(\overline{Q}\setminus\overline{\Omega}_0)$. *Moreover, for every* $\tau \in]0, T]$, y *satisfies*

$$||y||_{\infty,Q} \le C\Big(||f||_{q,Q} + ||h||_{r,\Sigma} + ||y_0||_{\infty,\Omega}\Big),$$

$$||y||_{C(\overline{Q}_{\tau T})} \le C(\tau)\Big(||f||_{q,Q} + ||h||_{r,\Sigma} + ||y_0||_{2,\Omega}\Big)$$

for all $q > \frac{N}{2} + 1$ *and all* $r > N + 1$, *where* $C \equiv C(T, \Omega, N, C_0, q, r)$ *and* $C(\tau) \equiv C(T, \Omega, N, C_0, q, r, \tau)$.

Theorem 3.2 (see [15, Theorem 3.1]). *Let* w *be in* $L^\infty(\Omega)$*; then* (1) *admits a unique weak solution* y_w *in* $W(0, T) \cap C_b(\overline{Q}\setminus\overline{\Omega}_0)$. *This solution satisfies*

$$||y_w||_{\infty,Q} \le C_1(1 + ||w||_{\infty,\Omega}),$$

where $C \equiv C(T, \Omega, N, C_0)$. *Moreover, the mapping* $w \longrightarrow y_w$ *is continuous from* $L^\infty(\Omega)$ *into* $C_b(\overline{Q}\setminus\overline{\Omega}_0)$.

Theorem 3.3 (see [16, Corollary 3.1]). *For every $M > 0$ and every $\tau > 0$, there exist $C \equiv C(T, \Omega, N, C_0, M, \tau)$ and $\bar{\theta} > 0$ such that, for every $w \in W_{ad}$ satisfying $||w||_{\infty,\Omega} \leq M$, the weak solution y_w of* (1)*, corresponding to w, is Hölder continuous on $\overline{\Omega} \times [\tau, T]$ and satisfies*

$$||y_w||_{C^{\bar{\theta},\bar{\theta}/2}(\overline{\Omega}\times[\tau,T])} \leq C.$$

3.2. Adjoint equation. Let (a, b) be in $L^\infty(Q)\times L^\infty(\Sigma)$ such that $||a||_{\infty,Q} \leq C_0$ and $||b||_{\infty,\Sigma} \leq C_0$. We consider the following terminal boundary value problem:

$$(10) -\frac{\partial p}{\partial t} + Ap + ap = \mu_Q \quad \text{in } Q, \quad \frac{\partial p}{\partial n_A} + bp = \mu_\Sigma \quad \text{on } \Sigma, \quad p(T) = \mu_{\overline{\Omega}_T} \quad \text{on } \overline{\Omega},$$

where $\mu = \mu_Q + \mu_\Sigma + \mu_{\overline{\Omega}_T}$ is a bounded Radon measure on $\overline{Q}\setminus\overline{\Omega}_0$, μ_Q is the restriction of μ to Q, μ_Σ is the restriction of μ to Σ, and $\mu_{\overline{\Omega}_T}$ the restriction of μ to $\overline{\Omega} \times \{T\}$.

Definition 3.4. *A function $p \in L^1(0, T; W^{1,1}(\Omega))$ is a weak solution of* (10) *if and only if*

$$\int_Q \Big(p\frac{\partial z}{\partial t} + \sum_{i,j=1}^N a_{ij} D_j p D_i z + ayp\Big)\, dxdt + \int_\Sigma bpz\, dsdt = \Big\langle \mu, z\Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0}$$

for all $z \in C^1(\overline{Q})$ satisfying $z(0) = 0$ on $\overline{\Omega}$.

We recall an existence theorem for parabolic equations with measures as data stated in [14], [5].

Theorem 3.5. *Let (a, b) be in $L^\infty(Q)\times L^\infty(\Sigma)$ satisfying $||a||_{\infty,Q} \leq C_0$, $||b||_{\infty,\Sigma} \leq C_0$, and let μ be in $\mathcal{M}_b(\overline{Q} \setminus \overline{\Omega}_0)$. Equation* (10) *admits a unique solution p in $L^1(0, T; W^{1,1}(\Omega))$. For every (δ, d) satisfying $\delta > 1$, $d > 1$, $\frac{N}{2d} + \frac{1}{\delta} < \frac{1}{2}$, p belongs to $L^{\delta'}(0, T; W^{1,d'}(\Omega))$, and*

$$||p||_{L^{\delta'}(0,T;W^{1,d'}(\Omega))} \leq C||\mu||_{\mathcal{M}_b(\overline{Q}\setminus\overline{\Omega}_0)},$$

where $C \equiv C(\Omega, T, \delta, d, C_0)$ is a positive constant independent of a and b. Moreover, there exists a function in $L^1(\Omega)$, denoted by $p(0)$, such that

$$\int_Q \left(\frac{\partial z}{\partial t} + Az + az\right) p\, dxdt + \int_\Sigma \left(\frac{\partial z}{\partial n_A} + bz\right) p\, dsdt = \Big\langle \mu, z\Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} - \int_\Omega z(0)p(0)\, dx$$

for every $z \in Y_\infty = \{y \in W(0, T) \mid \frac{\partial y}{\partial t} + Ay \in L^\infty(Q),\ \frac{\partial y}{\partial n_A} \in L^\infty(\Sigma),$ and $y(0) \in L^\infty(\Omega)\}$.

Proof. The first part of the theorem is stated in [14], the only new result being the Green formula for test functions z belonging to Y_∞. (In [14], test functions belong to $Y_\infty \cap C(\overline{Q})$.) Let $z \in Y_\infty$ and set $f_z = \frac{\partial z}{\partial t} + Az + az$, $h_z = \frac{\partial z}{\partial n_A} + bz$, $k_z = z(0)$. Let $(z_{n0})_n$ be a sequence of regular functions converging to $z(0)$ for the weak-star topology of $L^\infty(\Omega)$ and for the strong topology of $L^2(\Omega)$. Let z_n be the solution of

$$\frac{\partial z_n}{\partial t} + Az_n + az_n = f_z \quad \text{in } Q, \quad \frac{\partial z_n}{\partial n_A} + bz_n = h_z \quad \text{on } \Sigma, \quad z_n(0) = z_{n0} \quad \text{in} \quad \Omega.$$

It is clear that $z_n \in C(\overline{Q})$. Moreover, the function $\phi = z_n - z$ is the solution of

$$\frac{\partial \phi}{\partial t} + A\phi + a\phi = 0 \quad \text{in } Q, \quad \frac{\partial \phi}{\partial n_A} + b\phi = 0 \quad \text{on } \Sigma, \quad \phi(0) = z(0) - z_{n0} \quad \text{in } \Omega$$

and satisfies (see Proposition 3.1)

$$||z_n - z||_{C_b(\overline{Q}\setminus\overline{\Omega}_0)} \le C||z_{n0} - z(0)||_{\infty,\Omega} \le C',$$

$$||z_n - z||_{C(\overline{Q}_{\tau T})} \le C(\tau)||z_{n0} - z(0)||_{2,\Omega} \quad \text{for every } \tau \in]0,T].$$

Therefore, $(z_n)_n$ converges to z uniformly on $\overline{Q}_{\tau T}$, for every $\tau \in]0,T]$. On the other hand, by using the Green formula stated in [14], it follows that

$$\int_Q \Big(\frac{\partial z_n}{\partial t} + Az_n + az_n\Big)p\,dxdt + \int_\Sigma \Big(\frac{\partial z_n}{\partial n_A} + bz_n\Big)p\,dsdt = \Big\langle \mu, z_n \Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} - \int_\Omega z_{n0}p(0)\,dx.$$

We claim that

$$\lim_{n\to\infty} \Big\langle \mu, z_n \Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} - \int_\Omega z_{n0}\ p(0)\,dx = \Big\langle \mu, z \Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} - \int_\Omega z(0)p(0)\,dx.$$

Indeed, for every $\epsilon > 0$, there exists $\tau_\epsilon > 0$ such that $|\mu|(\overline{\Omega}\times]0,\tau_\epsilon[) \le \frac{\epsilon}{C'}$. Thus,

$$\begin{aligned}
&\Big|\Big\langle \mu, z - z_n \Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} + \int_\Omega (z(0) - z_{n0})p(0)\,dx\Big| \\
&\le ||\mu||_{\mathcal{M}(\overline{Q}_{\tau_\epsilon})}\ ||z - z_n||_{C(\overline{Q}_{\tau_\epsilon})} + |\mu|\Big(\overline{\Omega}\times]0,\tau_\epsilon[\Big)\ ||z - z_n||_{C_b(\overline{\Omega}\times]0,\tau_\epsilon[)} \\
&+\Big|\int_\Omega (z(0) - z_{n0})p(0)\,dx\Big| \le C||z - z_n||_{C(\overline{Q}_{\tau_\epsilon})} + \epsilon + \Big|\int_\Omega (z(0) - z_{n0})p(0)\,dx\Big|.
\end{aligned}$$

By passing to the limit first when n tends to infinity, and next when ϵ tends to zero, we prove the above claim and the proof is complete. □

4. The Stone–Čech compactification. Let us introduce the compactification in the sense of Stone–Čech. Let $\mathcal{O}$ be a locally compact subset of $\overline{Q}$, and let $C_b(\mathcal{O})$ be the space of bounded continuous functions on $\mathcal{O}$. Denote by $(C_b(\mathcal{O}))'$ the topological dual of $C_b(\mathcal{O})$ and by B_0 the unit ball of $(C_b(\mathcal{O}))'$. For every $(x,t) \in \mathcal{O}$, consider $\nu_{(x,t)}$ in $(C_b(\mathcal{O}))'$ defined by

$$\Big\langle \nu_{(x,t)}, h \Big\rangle_{(C_b(\mathcal{O}))'\times C_b(\mathcal{O})} = h(x,t), \qquad h \in C_b(\mathcal{O}). \tag{11}$$

It is clear that

$$\sup_{(x,t)\in\mathcal{O}} \Big|\nu_{(x,t)}(h)\Big| = \sup_{(x,t)\in\mathcal{O}} \Big|\langle \nu_{(x,t)}, h\rangle_{(C_b(\mathcal{O}))'\times C_b(\mathcal{O})}\Big| = ||h||_{C_b(\mathcal{O})}.$$

Proposition 4.1 (see [6, p. 137]). *The mapping $(x,t) \longrightarrow \nu_{(x,t)}$ is a homeomorphism from $\mathcal{O}$ into a subset of B_0. (B_0 is endowed with the weak-star topology of $(C_b(\mathcal{O}))'$.)*

Let $\mathcal{O}^\#$ be the closure of the set $\{\nu_{(x,t)} \mid (x,t) \in \mathcal{O}\}$, for the weak-star topology of $(C_b(\mathcal{O}))'$. It is a Hausdorff compact space which, in view of the previous proposition, admits a dense subset homeomorphic to $\mathcal{O}$. This is called the Stone–Čech compactification of $\mathcal{O}$.

Proposition 4.2. *Each $h \in C_b(\mathcal{O})$ can be uniquely extended to a function $\tau(h) \in C(\mathcal{O}^\#)$, such that*

$$||\tau(h)||_{C(\mathcal{O}^\#)} = ||h||_{C_b(\mathcal{O})}.$$

Proof. With each $h \in C_b(\mathcal{O})$, we associate $\tau(h) \in C(\mathcal{O}^{\#})$ defined by

$$\tau(h)(q^{\#}) = \langle q^{\#}, h\rangle_{(C_b(\mathcal{O}))' \times C_b(\mathcal{O})} \qquad \text{for every } q^{\#} \in \mathcal{O}^{\#}.$$

We have $\sup_{q^{\#} \in \mathcal{O}^{\#}} |\tau(h)(q^{\#})| = \sup_{q^{\#} \in \mathcal{O}^{\#}} |\langle q^{\#}, h\rangle_{(C_b(\mathcal{O}))' \times C_b(\mathcal{O})}|$, and because the set $\mathcal{O}$ is identified with a dense subset of $\mathcal{O}^{\#}$, it follows that

$$\begin{aligned} ||\tau(h)||_{C(\mathcal{O}^{\#})} &= \sup_{q^{\#} \in \mathcal{O}^{\#}} \left|\tau(h)(q^{\#})\right| = \sup_{q^{\#} \in \mathcal{O}^{\#}} \left|\langle q^{\#}, h\rangle_{(C_b(\mathcal{O}))' \times C_b(\mathcal{O})}\right| \\ &= \sup_{(x,t) \in \mathcal{O}} \left|\nu_{(x,t)}(h)\right| = ||h||_{C_b(\mathcal{O})}. \end{aligned}$$

REMARK 4.3. *For every h_1, $h_2 \in C_b(\mathcal{O})$ and every real continuous function f, we have* (*see* [9, *pp.* 274 – 275])

$$\tau(h_1 h_2) = \tau(h_1)\tau(h_2), \qquad \tau(f(h)) = f(\tau(h)).$$

Moreover, there exists a continuous mapping i from $\mathcal{O}^{\#}$ into $\overline{\mathcal{O}}$, such that

$$\tau(\phi) = \phi \circ i \qquad \textit{for all } \phi \in C(\overline{\mathcal{O}}).$$

(*See* [8, *Theorem* 26, *p.* 278].)

The set $C(\overline{\mathcal{O}}) \otimes C(\mathcal{O}^{\#})$ of linear combinations of functions of the form $\phi\psi$ with $\phi \in C(\overline{\mathcal{O}})$ and $\psi \in C(\mathcal{O}^{\#})$ is a subspace of $C(\overline{\mathcal{O}} \times \mathcal{O}^{\#})$. The following result gives interesting properties for elements of $\mathcal{M}(\overline{\mathcal{O}} \times \mathcal{O}^{\#})$ (the topological dual of $C(\overline{\mathcal{O}} \times \mathcal{O}^{\#})$).

LEMMA 4.4. *Let η be a Radon measure on $\overline{\mathcal{O}} \times \mathcal{O}^{\#}$, let $\pi_\eta \in \mathcal{M}(\overline{\mathcal{O}})$ be the projection of η on $\overline{\mathcal{O}}$, and let $\pi_{|\eta|} \in \mathcal{M}^+(\overline{\mathcal{O}})$ be the projection of $|\eta|$ on $\overline{\mathcal{O}}$. There exists a bounded linear operator $\Lambda_\eta : C(\mathcal{O}^{\#}) \longrightarrow L^\infty_{\pi_{|\eta|}}(\overline{\mathcal{O}})$, such that*

$$\left\langle \eta, \phi\psi \right\rangle_{\#} = \int_{\overline{\mathcal{O}}} \phi \Lambda_\eta(\psi)\, d\pi_{|\eta|} \quad \textit{for all } (\phi, \psi) \in C(\overline{\mathcal{O}}) \times C(\mathcal{O}^{\#}), \tag{12}$$

where $\langle \cdot, \cdot \rangle_{\#}$ is the duality pairing between $\mathcal{M}(\overline{\mathcal{O}} \times \mathcal{O}^{\#})$ and $C(\overline{\mathcal{O}} \times \mathcal{O}^{\#})$.

Proof. Let η be in $\mathcal{M}(\overline{\mathcal{O}} \times \mathcal{O}^{\#})$. With notation of Lemma 4.4 we have

$$\left\langle \pi_\eta, \phi \right\rangle_{\mathcal{M}(\overline{\mathcal{O}}) \times C(\overline{\mathcal{O}})} = \left\langle \eta, \phi \right\rangle_{\#} \quad \text{for all } \phi \in C(\overline{\mathcal{O}}).$$

Let ψ be in $C(\mathcal{O}^{\#})$, and consider the Radon measure η_ψ on $\overline{\mathcal{O}}$ defined by

$$\left\langle \eta_\psi, \phi \right\rangle_{\mathcal{M}(\overline{\mathcal{O}}) \times C(\overline{\mathcal{O}})} = \left\langle \eta, \phi\psi \right\rangle_{\#}.$$

It satisfies

$$\left|\left\langle \eta_\psi, \phi \right\rangle_{\mathcal{M}(\overline{\mathcal{O}}) \times C(\overline{\mathcal{O}})}\right| \le ||\psi||_{C(\mathcal{O}^{\#})} \int_{\overline{\mathcal{O}}} |\phi|\, d\pi_{|\eta|}.$$

Thus, the measure η_ψ is absolutely continuous with respect to $\pi_{|\eta|}$ and, due to the Radon–Nikodým theorem, admits a representation of the form:

$$\left\langle \eta_\psi, \phi \right\rangle_{\mathcal{M}(\overline{\mathcal{O}}) \times C(\overline{\mathcal{O}})} = \int_{\overline{\mathcal{O}}} f_\psi \phi \, d\pi_{|\eta|} \quad \text{for all } \phi \in C(\overline{\mathcal{O}}), \quad \text{where } f_\psi \in L^1_{\pi_{|\eta|}}(\overline{\mathcal{O}}).$$

The integrand f_ψ linearly depends on ψ and defines a linear transformation Λ_η such that

$$\Big\langle \eta_\psi, \phi \Big\rangle_{\mathcal{M}(\overline{\mathcal{O}})\times C(\overline{\mathcal{O}})} = \int_{\overline{\mathcal{O}}} \Lambda_\eta(\psi)\phi \, d\pi_{|\eta|} \quad \text{for all } \phi \in C(\overline{\mathcal{O}}).$$

Observe that Λ_η is bounded in $L^\infty_{\pi_{|\eta|}}(\overline{\mathcal{O}})$. Indeed, since

$$\Big| \int_{\overline{\mathcal{O}}} \Lambda_\eta(\psi)\phi \, d\pi_{|\eta|} \Big| \le ||\psi||_{C(\mathcal{O}^\#)} \int_{\overline{\mathcal{O}}} |\phi| \, d\pi_{|\eta|} \quad \text{for all } \phi \in C(\overline{\mathcal{O}}),$$

and since $(L^1_{\pi_{|\eta|}}(\overline{\mathcal{O}}))' = L^\infty_{\pi_{|\eta|}}(\overline{\mathcal{O}})$, it follows that

$$||\Lambda_\eta(\psi)||_{L^\infty_{\pi_{|\eta|}}(\overline{\mathcal{O}})} = \sup_{\{\phi\in C(\overline{\mathcal{O}}) \mid \, ||\phi||_{L^1_{\pi_{|\eta|}}(\overline{\mathcal{O}})}=1\}} \Big| \int_{\overline{\mathcal{O}}} \Lambda_\eta(\psi)\phi \, d\pi_{|\eta|} \Big| \le ||\psi||_{C(\mathcal{O}^\#)}$$

for all $\psi \in C(\mathcal{O}^\#)$. The proof is complete. □

REMARK 4.5. *A measure $\zeta \in (C_b(\mathcal{O}))'$ can be identified with $\hat{\zeta} \in \mathcal{M}(\mathcal{O}^\#)$ via the formula*

$$(13) \quad \Big\langle \hat{\zeta}, \chi \Big\rangle_{\mathcal{M}(\mathcal{O}^\#)\times C(\mathcal{O}^\#)} = \Big\langle \zeta, \chi \circ \nu_{(\cdot)} \Big\rangle_{(C_b(\mathcal{O}))'\times C_b(\mathcal{O})} \qquad \textit{for all } \chi \in C(\mathcal{O}^\#)$$

(*where $\nu_{(\cdot)}$ is the evaluation measure defined by* (11)). *Additionally, elements of $(C_b(\mathcal{O}))'$ can be considered as elements of $\mathcal{M}(\overline{\mathcal{O}} \times \mathcal{O}^\#)$ (the topological dual of $C(\overline{\mathcal{O}} \times \mathcal{O}^\#)$). More precisely, with each $\hat{\zeta} \in \mathcal{M}(\mathcal{O}^\#)$ (defined by* (13)), *we associate $\hat{\hat{\zeta}} \in \mathcal{M}(\overline{\mathcal{O}} \times \mathcal{O}^\#)$ defined by*

$$(14) \quad \Big\langle \hat{\hat{\zeta}}, \psi \Big\rangle_{\#} = \Big\langle \hat{\zeta}, \psi \circ e \Big\rangle_{\mathcal{M}(\mathcal{O}^\#)\times C(\mathcal{O}^\#)} = \Big\langle \zeta, (\psi \circ e) \circ \nu_{(\cdot)} \Big\rangle_{(C_b(\mathcal{O}))'\times C_b(\mathcal{O})}$$

for all $\psi \in C(\overline{\mathcal{O}} \times \mathcal{O}^\#)$, where e is the continuous mapping from $\mathcal{O}^\#$ into $\overline{\mathcal{O}} \times \mathcal{O}^\#$, defined by

$$e(q^\#) = \Big(i(q^\#), q^\#\Big) \qquad q^\# \in \mathcal{O}^\#,$$

and where i is the continuous mapping defined in Remark 4.3.

LEMMA 4.6. *Let $\zeta \in (C_b(\mathcal{O}))'$, and let $\hat{\hat{\zeta}} \in \mathcal{M}(\overline{\mathcal{O}} \times \mathcal{O}^\#)$ be the associated measure defined by* (14). *Then*

$$(15) \quad \Big\langle \zeta, \phi h \Big\rangle_{(C_b(\mathcal{O}))'\times C_b(\mathcal{O})} = \Big\langle \hat{\hat{\zeta}}, \phi\tau(h) \Big\rangle_{\#} \qquad \textit{for all } (\phi, h) \in C(\overline{\mathcal{O}}) \times C_b(\mathcal{O}),$$

where τ is defined in Proposition 4.2. *Moreover, if ℓ is a continuous function with compact support in $\mathcal{O}$, then*

$$(16) \quad \Big\langle \hat{\hat{\zeta}}, \ell\phi\tau(h) \Big\rangle_{\#} = \Big\langle \pi_{\hat{\hat{\zeta}}}, \ell\phi h \Big\rangle_{\mathcal{M}(\overline{\mathcal{O}})\times C(\overline{\mathcal{O}})} \qquad \textit{for all } (\phi, h) \in C(\overline{\mathcal{O}}) \times C_b(\mathcal{O}).$$

Proof. Due to (13) and (14), for every $\phi \in C(\overline{\mathcal{O}})$ and every $h \in C_b(\mathcal{O})$, we have

$$\begin{aligned}&\Big\langle \zeta, \phi h \Big\rangle_{(C_b(\mathcal{O}))' \times C_b(\mathcal{O})} = \Big\langle \zeta, \tau(\phi h) \circ \nu_{(\cdot)} \Big\rangle_{(C_b(\mathcal{O}))' \times C_b(\mathcal{O})} = \Big\langle \hat{\zeta}, \tau(\phi h) \Big\rangle_{\mathcal{M}(\mathcal{O}^{\#}) \times C(\mathcal{O}^{\#})} \\ &= \Big\langle \hat{\zeta}, \tau(\phi)\tau(h) \Big\rangle_{\mathcal{M}(\mathcal{O}^{\#}) \times C(\mathcal{O}^{\#})} = \Big\langle \hat{\zeta}, (\phi \circ i)\ \tau(h) \Big\rangle_{\mathcal{M}(\mathcal{O}^{\#}) \times C(\mathcal{O}^{\#})} \\ &= \Big\langle \hat{\zeta}, (\phi\tau(h)) \circ e \Big\rangle_{\mathcal{M}(\mathcal{O}^{\#}) \times C(\mathcal{O}^{\#})} = \Big\langle \hat{\hat{\zeta}}, \phi\tau(h) \Big\rangle_{\#}.\end{aligned}$$

Therefore, we have proved (15). To prove (16), observe that, since $\ell\phi$ belongs to $C(\overline{\mathcal{O}})$, with (15) we have

$$\Big\langle \zeta, \ell\phi h \Big\rangle_{(C_b(\mathcal{O}))' \times C_b(\mathcal{O})} = \Big\langle \hat{\hat{\zeta}}, \ell\phi\tau(h) \Big\rangle_{\#}.$$

On the other hand, since $\ell\phi h$ belongs to $C(\overline{\mathcal{O}})$, from the definition of $\hat{\zeta}$ and $\hat{\hat{\zeta}}$, it follows that

$$\begin{aligned}&\Big\langle \zeta, \ell\phi h \Big\rangle_{(C_b(\mathcal{O}))' \times C_b(\mathcal{O})} = \Big\langle \zeta, \tau(\ell\phi h) \circ \nu_{(\cdot)} \Big\rangle_{(C_b(\mathcal{O}))' \times C_b(\mathcal{O})} \\ &= \Big\langle \hat{\zeta}, \tau(\ell\phi h) \Big\rangle_{\mathcal{M}(\mathcal{O}^{\#}) \times C(\mathcal{O}^{\#})} = \Big\langle \hat{\zeta}, (\ell\phi h) \circ i \Big\rangle_{\mathcal{M}(\mathcal{O}^{\#}) \times C(\mathcal{O}^{\#})} \\ &= \Big\langle \hat{\zeta}, (\ell\phi h) \circ e \Big\rangle_{\mathcal{M}(\mathcal{O}^{\#}) \times C(\mathcal{O}^{\#})} = \Big\langle \hat{\hat{\zeta}}, \ell\phi h \Big\rangle_{\#} = \Big\langle \pi_{\hat{\hat{\zeta}}}, \ell\phi h \Big\rangle_{\mathcal{M}(\overline{\mathcal{O}}) \times C(\overline{\mathcal{O}})}.\end{aligned}$$

The proof is complete. □

A very useful result is given in the following theorem.

THEOREM 4.7. *Let $\zeta \in (C_b(\mathcal{O}))'$, and let $\hat{\hat{\zeta}} \in \mathcal{M}(\overline{\mathcal{O}} \times \mathcal{O}^{\#})$ be the associated measure defined by* (14)*. There exists a bounded linear transformation $\Lambda_{\hat{\hat{\zeta}}} : C(\mathcal{O}^{\#}) \longrightarrow L^{\infty}_{\pi_{|\hat{\hat{\zeta}}|}}(\overline{Q})$, such that*

$$\Big\langle \zeta, h\phi \Big\rangle_{(C_b(\mathcal{O}))' \times C_b(\mathcal{O})} = \Big\langle \pi_{\hat{\hat{\zeta}}}, h\phi \Big\rangle_{\mathcal{M}_b(\mathcal{O}) \times C_b(\mathcal{O})} + \int_{\overline{\mathcal{O}} \setminus \mathcal{O}} \Lambda_{\hat{\hat{\zeta}}}\Big(\tau(h)\Big)\phi\, d\pi_{|\hat{\hat{\zeta}}|}$$

for all $(\phi, h) \in C(\overline{\mathcal{O}}) \times C_b(\mathcal{O})$. (In $\langle \pi_{\hat{\hat{\zeta}}}, \phi h\rangle_{\mathcal{M}_b(\mathcal{O}) \times C_b(\mathcal{O})}$, $\pi_{\hat{\hat{\zeta}}}$ denotes the restriction of $\pi_{\hat{\hat{\zeta}}}$ to $\mathcal{O}$.)

Proof. Due to (15) and Lemma 4.4, by setting $\psi = \tau(h)$ in (12), we obtain

$$\Big\langle \zeta, h\phi \Big\rangle_{(C_b(\mathcal{O}))' \times C_b(\mathcal{O})} = \Big\langle \hat{\hat{\zeta}}, \phi\tau(h) \Big\rangle_{\#} = \int_{\overline{\mathcal{O}}} \phi\Lambda_{\hat{\hat{\zeta}}}\Big(\tau(h)\Big) d\pi_{|\hat{\hat{\zeta}}|} \tag{17}$$

for all $(\phi, h) \in C(\overline{\mathcal{O}}) \times C_b(\mathcal{O})$. For $\phi \in C(\overline{\mathcal{O}})$, the integrals $\int_{\mathcal{O}} \phi\Lambda_{\hat{\hat{\zeta}}}(\tau(h))\, d\pi_{|\hat{\hat{\zeta}}|}$ and $\int_{\mathcal{O}} \phi h\, d\pi_{\hat{\hat{\zeta}}}$ are obtained by passing to the limit in $\int_{\mathcal{O}} \phi\ell_k\Lambda_{\hat{\hat{\zeta}}}(\tau(h))\, d\pi_{|\hat{\hat{\zeta}}|}$ and in $\int_{\mathcal{O}} \phi\ell_k h\ \, d\pi_{\hat{\hat{\zeta}}}$, where $(\ell_k)_k$ is a sequence of continuous functions with compact support in $\mathcal{O}$. From (16) and (17), we have

$$\Big\langle \hat{\hat{\zeta}}, \ell_k\phi\tau(h) \Big\rangle_{\#} = \Big\langle \pi_{\hat{\hat{\zeta}}}, \ell_k\phi h \Big\rangle_{\mathcal{M}(\overline{\mathcal{O}}) \times C(\overline{\mathcal{O}})} = \int_{\overline{\mathcal{O}}} \phi\ell_k\Lambda_{\hat{\hat{\zeta}}}\Big(\tau(h)\Big)\ \, d\pi_{|\hat{\hat{\zeta}}|}.$$

Therefore, we deduce that

$$\int_{\mathcal{O}} \phi \ell_k \Lambda_{\hat{\hat{\zeta}}}\Big(\tau(h)\Big)\ d\pi_{|\hat{\hat{\zeta}}|} = \int_{\mathcal{O}} \phi \ell_k h\ d\pi_{\hat{\hat{\zeta}}}.$$

By passing to the limit, when k tends to infinity, we obtain

$$\int_{\mathcal{O}} \phi \Lambda_{\hat{\hat{\zeta}}}\Big(\tau(h)\Big)\ d\pi_{|\hat{\hat{\zeta}}|} = \int_{\mathcal{O}} \phi h\ d\pi_{\hat{\hat{\zeta}}} = \Big\langle \pi_{\hat{\hat{\zeta}}}, \phi h \Big\rangle_{\mathcal{M}_b(\mathcal{O})\times C_b(\mathcal{O})}.$$

Consequently,

$$\int_{\overline{\mathcal{O}}} \phi \Lambda_{\hat{\hat{\zeta}}}\Big(\tau(h)\Big)\, d\pi_{|\hat{\hat{\zeta}}|} = \int_{\mathcal{O}} \phi \Lambda_{\hat{\hat{\zeta}}}\Big(\tau(h)\Big)\, d\pi_{|\hat{\hat{\zeta}}|} + \int_{\overline{\mathcal{O}}\setminus\mathcal{O}} \phi \Lambda_{\hat{\hat{\zeta}}}\Big(\tau(h)\Big)\, d\pi_{|\hat{\hat{\zeta}}|}$$

$$= \int_{\mathcal{O}} \phi h\, d\pi_{\hat{\hat{\zeta}}} + \int_{\overline{\mathcal{O}}\setminus\mathcal{O}} \phi \Lambda_{\hat{\hat{\zeta}}}\Big(\tau(h)\Big)\, d\pi_{|\hat{\hat{\zeta}}|}$$

for every $\phi \in C(\overline{\mathcal{O}})$ and every $h \in C_b(\mathcal{O})$. The proof is complete. □

COROLLARY 4.8. *Let $\zeta \in (C_b(\overline{Q} \setminus \overline{\Omega}_0))'$. There exists a bounded linear transformation $\Lambda_\zeta :\ C_b(\overline{Q} \setminus \overline{\Omega}_0) \longrightarrow L^\infty_{\pi_{|\zeta|}}(\overline{Q})$, such that*

$$\Big\langle \zeta, h\phi \Big\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0} = \Big\langle \pi_\zeta, h\phi \Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} + \int_{\overline{\Omega}_0} \Lambda_\zeta(h)\phi\, d\pi_{|\zeta|}$$

for all $h \in C_b(\overline{Q} \setminus \overline{\Omega}_0)$ and all $\phi \in C(\overline{Q})$. Moreover, for every $\tilde{h}$ in $C(\overline{Q})$, we have

$$\int_{\overline{\Omega}_0} \Lambda_\zeta(\tilde{h})\, d\pi_{|\zeta|} = \Big\langle \pi_\zeta, \tilde{h} \Big\rangle_{\mathcal{M}(\overline{\Omega}_0)\times C(\overline{\Omega}_0)}.$$

Proof. The first assertion is a direct consequence of Theorem 4.7, by setting $\mathcal{O} = \overline{Q}\setminus\overline{\Omega}_0$, $\Lambda_\zeta = \Lambda_{\hat{\hat{\zeta}}} \circ \tau$, and by identifying ζ with the measure $\hat{\hat{\zeta}}$, defined on $\overline{\mathcal{O}} \times \mathcal{O}^\#$, by (14). If $\tilde{h}$ belongs to $C(\overline{Q})$, by definition of π_ζ and with Theorem 4.7, we have

$$\Big\langle \zeta, \tilde{h} \Big\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0} = \Big\langle \pi_\zeta, \tilde{h} \Big\rangle_{\mathcal{M}(\overline{Q})\times C(\overline{Q})} = \Big\langle \pi_\zeta, \tilde{h} \Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} + \int_{\overline{\Omega}_0} \Lambda_\zeta(\tilde{h})\, d\pi_{|\zeta|}.$$

It follows that $\int_{\overline{\Omega}_0} \Lambda_\zeta(\tilde{h})\, d\pi_{|\zeta|} = \langle \pi_\zeta, \tilde{h} \rangle_{\mathcal{M}(\overline{\Omega}_0)\times C(\overline{\Omega}_0)}$. The proof is complete. □

COROLLARY 4.9. *Let ζ be a nonnegative measure belonging to $(C_b(\overline{Q} \setminus \overline{\Omega}_0))'$. There exists a bounded linear transformation $\Lambda_\zeta :\ C_b(\overline{Q} \setminus \overline{\Omega}_0) \longrightarrow L^\infty_{\pi_\zeta}(\overline{Q})$, such that*

$$\Big\langle \zeta, h\phi \Big\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0} = \Big\langle \pi_\zeta, h\phi \Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} + \int_{\overline{\Omega}_0} \Lambda_\zeta(h)\phi\, d\pi_\zeta$$

for all $(h, \phi) \in C_b(\overline{Q} \setminus \overline{\Omega}_0) \times C(\overline{Q})$. Moreover, if $\tilde{h}$ is a nonnegative function in $C_b(\overline{Q} \setminus \overline{\Omega}_0)$, then $\int_{\overline{\Omega}_0} \Lambda_\zeta(\tilde{h})\, d\pi_\zeta \geq 0$.

Proof. The equality $\pi_\zeta = \pi_{|\zeta|}$ is obvious. Let $\tilde{h}$ be a nonnegative function in $C_b(\overline{Q} \setminus \overline{\Omega}_0)$. Observe that the Radon measure $\zeta_{\tilde{h}}$ defined by

$$\Big\langle \zeta_{\tilde{h}}, \phi \Big\rangle_{\mathcal{M}(\overline{Q})\times C(\overline{Q})} = \Big\langle \zeta, \phi\tilde{h} \Big\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0} \qquad \phi \in C(\overline{Q}),$$

is nonnegative and that

$$\zeta_{\tilde{h}}(E) = \int_E \Lambda_\zeta(\tilde{h})\, d\pi_\zeta \qquad \text{for all Borel sets } E \subset \overline{Q}.$$

Therefore, $\int_{\overline{\Omega}_0} \Lambda_\zeta(\tilde{h})\, d\pi_\zeta = \zeta_{\tilde{h}}(\overline{\Omega}_0) \geq 0$. The proof is complete. □

For $\zeta \in (C_b(\overline{Q} \setminus \overline{\Omega}_0))'$ we denote by $(\pi_\zeta, \pi_{|\zeta|}, \Lambda_\zeta)$ the triplet corresponding to ζ defined in Corollary 4.8. The following result gives another property of the operator Λ_ζ often used later.

Proposition 4.10. *Let (a, b) be in $L^\infty(Q) \times L^\infty(\Sigma)$, let w be in $L^\infty(\Omega)$, and let z_1 and z_2 be solutions of*

$$\frac{\partial z_1}{\partial t} + Az_1 + az_1 = 0 \quad \text{in } Q, \qquad \frac{\partial z_1}{\partial n_A} + bz_1 = 0 \quad \text{on } \Sigma, \qquad z_1(\cdot, 0) = w \quad \text{in } \Omega,$$

$$\frac{\partial z_2}{\partial t} + Az_2 = 0 \quad \text{in } Q, \qquad \frac{\partial z_2}{\partial n_A} = 0 \quad \text{on } \Sigma, \qquad z_2(\cdot, 0) = w \quad \text{in } \Omega.$$

Then, for every $h \in C_b(\overline{Q} \setminus \overline{\Omega}_0)$, we have $\int_{\overline{\Omega}_0} \Lambda_\zeta(hz_1)\, d\pi_{|\zeta|} = \int_{\overline{\Omega}_0} \Lambda_\zeta(hz_2)\, d\pi_{|\zeta|}$.

Proof. Notice that the function $z_1 - z_2$ is the solution of

$$\frac{\partial z}{\partial t} + Az + az = -az_2 \quad \text{in } Q, \qquad \frac{\partial z}{\partial n_A} = -bz_2 \quad \text{on } \Sigma, \qquad z(\cdot, 0) = 0 \quad \text{in } \Omega,$$

and it belongs to $C_0(\overline{Q} \setminus \overline{\Omega}_0)$. It follows that, for every $h \in C_b(\overline{Q} \setminus \overline{\Omega}_0)$, the function $(z_1 - z_2)h$ belongs to $C_0(\overline{Q} \setminus \overline{\Omega}_0)$. From Corollary 4.8, we obtain

$$\begin{aligned} \Big\langle \zeta, (z_1 - z_2)h \Big\rangle_{*, \overline{Q} \setminus \overline{\Omega}_0} &= \Big\langle \pi_\zeta, (z_1 - z_2)h \Big\rangle_{b, \overline{Q} \setminus \overline{\Omega}_0} + \int_{\overline{\Omega}_0} \Lambda_\zeta((z_1 - z_2)h)\, d\pi_{|\zeta|} \\ &= \Big\langle \pi_\zeta, (z_1 - z_2)h \Big\rangle_{b, \overline{Q} \setminus \overline{\Omega}_0}. \end{aligned}$$

Thus, $\int_{\overline{\Omega}_0} \Lambda_\zeta(z_1 h)\, d\pi_{|\zeta|} = \int_{\overline{\Omega}_0} \Lambda_\zeta(z_2 h)\, d\pi_{|\zeta|}$. □

5. Optimality conditions.

5.1. Metric space of controls. Taylor expansions.

We endow W_{ad} with the distance $d(w_1, w_2) = ||w_1 - w_2||_{\infty, \Omega}$.

Lemma 5.1. *The metric space (W_{ad}, d) is complete. Moreover, the mapping which associates $(y_w, J(y_w, w), d_{\mathcal{C}}(g(y_w)))$ with the control w is continuous from (W_{ad}, d) into $C_b(\overline{Q} \setminus \overline{\Omega}_0) \times \mathbb{R} \times \mathbb{R}$.*

Proof. It is a direct consequence of Theorem 3.2. □

In the following, we consider control problems in which the state constraints (2) are penalized. For a given solution $\bar{w}$ of (P), the penalization is chosen so that $\bar{w}$ is an ϵ^2-solution of the penalized problem. To obtain optimality conditions for the penalized problem, we first establish Taylor expansions in the theorem below.

Theorem 5.2 (see [16, Theorem 4.1]). *Let ρ be such that $0 < \rho < 1$. For every w_1, $w_2 \in L^\infty(\Omega)$, if $w_\rho = w_1 + \rho w_2$, if y_ρ and y_1 are the solutions of* (1) *corresponding respectively to w_ρ and w_1, then we have*

$$\begin{aligned} y_\rho &= y_1 + \rho z + r_\rho \qquad \textit{with } \lim_{\rho \to 0} \frac{1}{\rho} ||r_\rho||_{C(\overline{Q})} = 0, \\ J(y_\rho, w_\rho) &= J(y_1, w_1) + \rho \Delta J + o(\rho), \end{aligned}$$

where z is the weak solution of

$$\frac{\partial z}{\partial t} + Az + \Phi'_y(\cdot, y_1)z = 0 \quad \textit{in } Q, \quad \frac{\partial z}{\partial n_A} + \Psi'_y(\cdot, y_1)z = 0 \ \ \textit{on } \Sigma, \quad z(0) = w_2 \ \ \textit{in } \Omega,$$

and

$$\Delta J = \int_\Omega \Big(L'_w(x, y_1(T), w_1)w_2 + L'_y(x, y_1(T), w_1)z(T) \Big)\, dx.$$

5.2. Approximate optimality conditions. Let $(\bar y, \bar w)$ be a solution of problem (P). For every $\epsilon > 0$, define

$$J_\epsilon(y, w) = \{[(J(y, w) - J(\bar y, \bar w) + \epsilon^2)^+]^2 + (d_{\mathcal{C}}(g(y)))^2\}^{\frac{1}{2}},$$

where $d_{\mathcal{C}}$ denotes the distance to $\mathcal{C}$ in $C_b(\overline{Q} \setminus \overline{\Omega}_0)$.

Due to Lemma 5.1, the functional $w \longrightarrow J_\epsilon(y_w, w)$ is continuous and bounded on the metric space (W_{ad}, d). Moreover, we have

$$J_\epsilon(y_w, w) > 0 \quad \text{for every } w \in W_{ad} \ \text{ and } \ J_\epsilon(\bar y, \bar w) = \epsilon^2 \leq \inf_{W_{ad}} J_\epsilon(y_w, w) + \epsilon^2.$$

Due to the Ekeland variational principle, there exists $w_\epsilon \in W_{ad}$ such that

$$\text{(18)} \qquad d(\bar w, w_\epsilon) \leq \epsilon \quad \text{and} \quad J_\epsilon(y_\epsilon, w_\epsilon) \leq J_\epsilon(y_w, w) + \epsilon d(w_\epsilon, w) \quad \text{for every } w \in W_{ad},$$

where y_ϵ is the solution of (1) corresponding to w_ϵ. The following theorem gives an approximate optimality condition for (y_ϵ, w_ϵ). Optimality conditions for $(\bar y, \bar w)$ will be recovered by passing to the limit, when ϵ tends to zero, in this approximate optimality condition.

THEOREM 5.3. *Let $w_\epsilon \in W_{ad}$ satisfy* (18)*. There exist $\alpha_\epsilon \geq 0$, $p_\epsilon \in L^1(0, T; W^{1,1}(\Omega))$, $\zeta_\epsilon \in (C_b(\overline{Q} \setminus \overline{\Omega}_0))'$, and a bounded linear transformation $\Lambda_\epsilon \equiv \Lambda_{\zeta_\epsilon} : C_b(\overline{Q} \setminus \overline{\Omega}_0) \longrightarrow L^\infty_{\pi_{|\zeta_\epsilon|}}(\overline{Q})$ such that*

$$\text{(19)} \qquad ||\zeta_\epsilon||^2_{(C_b(\overline{Q}\setminus\overline{\Omega}_0))'} + (\alpha_\epsilon)^2 = 1,$$

$$\text{(20)} \quad \Big\langle \zeta_\epsilon, z - g(y_\epsilon) \Big\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0} = \Big\langle \pi_{\zeta_\epsilon}, z - g(y_\epsilon) \Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} + \int_{\overline{\Omega}_0} \Lambda_\epsilon \Big(z - g(y_\epsilon) \Big)\, d\pi_{|\zeta_\epsilon|} \leq 0$$

for all $z \in \mathcal{C}$,

$$\text{(21)} \qquad \begin{cases} -\frac{\partial p_\epsilon}{\partial t} + Ap_\epsilon + \Phi'_y(x, t, y_\epsilon)p_\epsilon + [g'(y_\epsilon)^* \pi_{\zeta_\epsilon}]_{|Q} = 0 & \textit{in } Q, \\ \frac{\partial p_\epsilon}{\partial n_A} + \Psi'_y(s, t, y_\epsilon)\bar p_\epsilon + [g'(y_\epsilon)^* \pi_{\zeta_\epsilon}]_{|\Sigma} = 0 & \textit{on } \Sigma, \\ p_\epsilon(T) = -\alpha_\epsilon L'_y(x, y_\epsilon(T), w_\epsilon) - [g'(y_\epsilon)^* \pi_{\zeta_\epsilon}]_{|\overline{\Omega}_T} & \textit{on } \overline{\Omega}, \end{cases}$$

$$\text{(22)} \ \int_\Omega H'_w\Big(x, y_\epsilon(T), w_\epsilon, p_\epsilon(0), \alpha_\epsilon\Big)(w_\epsilon - w)\, dx + \int_{\overline{\Omega}_0} \Lambda_\epsilon\Big(g'(y_\epsilon)(z_{\epsilon,w_\epsilon} - z_{\epsilon,w})\Big)\, d\pi_{|\zeta_\epsilon|}$$

$$\leq C\epsilon\ (1 + ||w - w_\epsilon||_{\infty,\Omega}) \qquad \textit{for all } w \in W_{ad},$$

where $z_{\epsilon,\tilde w}$ *(with* $\tilde w = w_\epsilon$ *or* $\tilde w = w$*) is the weak solution of*

$$\frac{\partial z}{\partial t}+Az+\Phi'_y(\cdot,y_\epsilon)z=0 \ \textit{in } Q,\ \ \frac{\partial z}{\partial n_A}+\Psi'_y(\cdot,y_\epsilon)z=0 \ \textit{on } \Sigma,\quad z(0)=\tilde w \ \textit{in } \Omega. \tag{23}$$

Proof. Let (y_ϵ, w_ϵ) satisfy (18). Let us set

$$\begin{aligned} A_\epsilon = \Big\{&(z,\lambda)\in C_b(\overline{Q}\setminus\overline{\Omega}_0)\times\mathbb{R} \mid \exists w\in W_{ad},\ z=g(y_\epsilon)+g'(y_\epsilon)(z_{\epsilon,w}-z_{\epsilon,w_\epsilon}) \\ &\text{and } \lambda\ge J'_y(y_\epsilon,w_\epsilon)\ (z_{\epsilon,w}-z_{\epsilon,w_\epsilon})+J'_w(y_\epsilon,w_\epsilon)(w-w_\epsilon)+\epsilon\ d(w_\epsilon,w)\Big\}, \\ B = &\ \text{int}\ \mathcal{C}\times]-\infty,0[, \end{aligned}$$

where int $\mathcal{C}$ denotes the interior of $\mathcal{C}$. The sets A_ϵ and B are convex, and B is open. Let us prove that $A_\epsilon\cap B=\emptyset$. Suppose that there exists $w_o\in W_{ad}$, $\lambda_o\in\mathbb{R}$, such that

$$g(y_\epsilon)+g'(y_\epsilon)(z_{\epsilon,w_o}-z_{\epsilon,w_\epsilon})\in \text{int}\ \mathcal{C}, \tag{24}$$

$$0>\lambda_o\ge J'_y(y_\epsilon,w_\epsilon)\ (z_{\epsilon,w_o}-z_{\epsilon,w_\epsilon})+J'_w(y_\epsilon,w_\epsilon)(w_o-w_\epsilon)+\epsilon\ d(w_\epsilon,w_o). \tag{25}$$

Set $w^\rho_\epsilon = w_\epsilon+\rho(w_o-w_\epsilon)$, $z^\rho_\epsilon = g(y_\epsilon)+\frac{1}{\rho}(g(y^\rho_\epsilon)-g(y_\epsilon))$, and denote by y^ρ_ϵ the solution of (1) corresponding to w^ρ_ϵ. From (24), (25), and Theorem 5.2, it follows that

$$\lim_{\rho\searrow 0} z^\rho_\epsilon \in \text{int}\ \mathcal{C} \quad\text{and}\quad 0>\lim_{\rho\searrow 0}\Big(\frac{J(y^\rho_\epsilon,w^\rho_\epsilon)-J(y_\epsilon,w_\epsilon)}{\rho}+\epsilon\ \frac{d(w_\epsilon,w^\rho_\epsilon)}{\rho}\Big).$$

Therefore, there exists $\rho_o>0$ such that, for every $0<\rho\le\rho_o<1$, we have

$$g(y^\rho_\epsilon)=\rho\ z^\rho_\epsilon+(1-\rho)\ g(y_\epsilon)\in\ \text{int}\ \mathcal{C} \quad\text{and}\quad J(y^\rho_\epsilon,w^\rho_\epsilon)<J(y_\epsilon,w_\epsilon)-\epsilon\ d(w_\epsilon,w^\rho_\epsilon).$$

Observe that

$$\begin{aligned} J_\epsilon(y^\rho_\epsilon,w^\rho_\epsilon) &= (J(y^\rho_\epsilon,w^\rho_\epsilon)-J(\bar y,\bar w)+\epsilon^2)^+ = J(y^\rho_\epsilon,w^\rho_\epsilon)-J(\bar y,\bar w)+\epsilon^2 \\ &< J(y_\epsilon,w_\epsilon)-J(\bar y,\bar w)+\epsilon^2-\epsilon\ d(w_\epsilon,w^\rho_\epsilon)\le J_\epsilon(y_\epsilon,w_\epsilon)-\epsilon\ d(w_\epsilon,w^\rho_\epsilon). \end{aligned}$$

This contradicts (18) and proves that $A_\epsilon\cap B=\emptyset$. From a geometric version of the Hahn–Banach theorem, there exists $(\alpha_\epsilon,\zeta_\epsilon)\in\mathbb{R}\times(C_b(\overline{Q}\setminus\overline{\Omega}_0))'$, such that

$$\alpha_\epsilon\ \lambda_\epsilon+\Big\langle\zeta_\epsilon,z_\epsilon\Big\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0} > \alpha_\epsilon\ \lambda+\Big\langle\zeta_\epsilon,z\Big\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0} \text{ for all } (z_\epsilon,\lambda_\epsilon)\in A_\epsilon,\ \text{for all } (z,\lambda)\in B. \tag{26}$$

We can easily check that α_ϵ is nonnegative and that $(\alpha_\epsilon,\zeta_\epsilon)\neq 0$. By a normalization procedure, we can suppose that $(\alpha_\epsilon,\zeta_\epsilon)$ satisfies (19). Due to (26), we obtain

$$\alpha_\epsilon\ \lambda_\epsilon+\Big\langle\zeta_\epsilon,z_\epsilon\Big\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0} \ge \alpha_\epsilon\ \lambda+\Big\langle\zeta_\epsilon,z\Big\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0} \text{ for all } (z_\epsilon,\lambda_\epsilon)\in A_\epsilon,\ \text{for all } (z,\lambda)\in \overline{B}. \tag{27}$$

Therefore, by taking $z_\epsilon=g(y_\epsilon)$, $z\in\mathcal{C}$, and $\lambda_\epsilon=\lambda=0$, we deduce that

$$\Big\langle\zeta_\epsilon,z-g(y_\epsilon)\Big\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0}\le 0 \qquad \text{for all } z\in\mathcal{C}. \tag{28}$$

Due to Corollary 4.8, there exists a bounded linear transformation $\Lambda_\epsilon\equiv\Lambda_{\zeta_\epsilon}:\ C_b(\overline{Q}\setminus\overline{\Omega}_0)\longrightarrow L^\infty_{\pi_{|\zeta_\epsilon|}}(\overline{Q})$, such that

$$\Big\langle\zeta_\epsilon,h\Big\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0}=\Big\langle\pi_{\zeta_\epsilon},h\Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0}+\int_{\overline{\Omega}_0}\Lambda_\epsilon(h)\,d\pi_{|\zeta_\epsilon|} \qquad \text{for all } h\in C_b(\overline{Q}\setminus\overline{\Omega}_0).$$

Thus, (20) follows from (28). Let $w \in W_{ad}$; by setting $z_\epsilon = g(y_\epsilon) + g'(y_\epsilon)(z_{\epsilon,w} - z_{\epsilon,w_\epsilon})$, $\lambda_\epsilon = J'_y(y_\epsilon, w_\epsilon)\ (z_{\epsilon,w} - z_{\epsilon,w_\epsilon}) + J'_w(y_\epsilon, w_\epsilon)(w - w_\epsilon) + \epsilon\ d(w_\epsilon, w)$, $\lambda = 0$, and $z = g(\bar{y})$, in (27), with (18) and Proposition 3.1, we obtain

$$\begin{aligned}
(29) \qquad & \alpha_\epsilon\Big(J'_y(y_\epsilon, w_\epsilon)\ (z_{\epsilon,w} - z_{\epsilon,w_\epsilon}) + J'_w(y_\epsilon, w_\epsilon)(w - w_\epsilon)\Big) \\
& + \Big\langle \pi_{\zeta_\epsilon}, g'(y_\epsilon)(z_{\epsilon,w} - z_{\epsilon,w_\epsilon})\Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} + \int_{\overline{\Omega}_0} \Lambda_\epsilon\Big(g'(y_\epsilon)(z_{\epsilon,w} - z_{\epsilon,w_\epsilon})\Big)\, d\pi_{|\zeta_\epsilon|}, \\
& \geq -\alpha_\epsilon\ \epsilon\ d(w_\epsilon, w) + \Big\langle \zeta_\epsilon, g(\bar{y}) - g(y_\epsilon)\Big\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0} \geq -C\epsilon\ (1 + ||w - w_\epsilon||_{\infty,\Omega}),
\end{aligned}$$

where C is independent of ϵ. If p_ϵ is the solution of (21), with Theorem 3.5, we obtain

$$\begin{aligned}
(30) \qquad & \int_\Omega -\alpha_\epsilon L'_y(x, y_\epsilon(T), w_\epsilon)(z_{\epsilon,w} - z_{\epsilon,w_\epsilon})(T)\, dx - \Big\langle \zeta_\epsilon, g'(y_\epsilon)(z_{\epsilon,w} - z_{\epsilon,w_\epsilon})\Big\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0} \\
& = \int_\Omega p_\epsilon(0)(w - w_\epsilon)\, dx - \int_{\overline{\Omega}_0} \Lambda_\epsilon\Big(g'(y_\epsilon)(z_{\epsilon,w} - z_{\epsilon,w_\epsilon})\Big)\, d\pi_{|\zeta_\epsilon|}.
\end{aligned}$$

The optimality condition (22) follows from (29) and (30). □

5.3. Proof of optimality conditions. Theorem 3.5 gives

$$\begin{aligned}
||p_\epsilon||_{L^{\delta'}(0,T;W^{1,d'}(\Omega))} & \leq C\Big(||L'_y(\cdot, y_\epsilon(T), w_\epsilon)||_{1,\Omega} + ||g'(y_\epsilon)||_{\mathcal{L}(C_b(\overline{Q}\setminus\overline{\Omega}_0))}||\pi_{\zeta_\epsilon}||_{\mathcal{M}_b(\overline{Q}\setminus\overline{\Omega}_0)}\Big) \\
& \leq C\Big(||L'_y(\cdot, y_\epsilon(T), w_\epsilon)||_{1,\Omega} + ||g'(y_\epsilon)||_{\mathcal{L}(C_b(\overline{Q}\setminus\overline{\Omega}_0))}||\zeta_\epsilon||_{(C_b(\overline{Q}\setminus\overline{\Omega}_0))'}\Big)
\end{aligned}$$

for every $\delta > 1$, $d > 1$ satisfying $\frac{N}{2d} + \frac{1}{\delta} < \frac{1}{2}$ ($\mathcal{L}(C_b(\overline{Q} \setminus \overline{\Omega}_0))$ is the space of linear continuous mappings from $C_b(\overline{Q} \setminus \overline{\Omega}_0)$ into $C_b(\overline{Q} \setminus \overline{\Omega}_0)$). Since the sequences $(\zeta_\epsilon)_\epsilon$, $(y_\epsilon)_\epsilon$, and $(w_\epsilon)_\epsilon$ are bounded in $(C_b(\overline{Q} \setminus \overline{\Omega}_0))'$, $C_b(\overline{Q} \setminus \overline{\Omega}_0)$, and $L^\infty(\Omega)$ respectively, it follows that the sequence $(p_\epsilon)_\epsilon$ is bounded in $L^{\delta'}(0,T;W^{1,d'}(\Omega))$ for every (δ, d) satisfying $\frac{N}{2d} + \frac{1}{\delta} < \frac{1}{2}$. Then there exists a subsequence, still indexed by ϵ, and $\bar{p}$ such that $(p_\epsilon)_\epsilon$ converges to $\bar{p}$ weakly in $L^{\delta'}(0,T;W^{1,d'}(\Omega))$ for every (δ, d) satisfying $\frac{N}{2d} + \frac{1}{\delta} < \frac{1}{2}$. Moreover, due to classical imbeddings, $(p_\epsilon)_\epsilon$ converges to $\bar{p}$ weakly in $L^{q'}(Q)$ for all $q > \frac{N}{2} + 1$, and the sequence of traces $(p_{\epsilon|\Sigma})_\epsilon$ converges to $\bar{p}_{|\Sigma}$ weakly in $L^{r'}(\Sigma)$ for all $r > N + 1$. The sequence $(\alpha_\epsilon)_\epsilon$ (or at least a subsequence) converges to $\bar{\alpha} \geq 0$, $(w_\epsilon)_\epsilon$ converges to $\bar{w}$ in $L^\infty(\Omega)$, and $(y_\epsilon)_\epsilon$ converges to $\bar{y}$ in $C_b(\overline{Q} \setminus \overline{\Omega}_0)$.

From assumptions on Φ, Ψ and L, we can prove that the sequence $(\Phi'_y(\cdot, y_\epsilon), \Psi'_y(\cdot, y_\epsilon), L'_y(\cdot, y_\epsilon(T), w_\epsilon))_\epsilon$ converges to $(\Phi'_y(\cdot, \bar{y}), \Psi'_y(\cdot, \bar{y}), L'_y(\cdot, \bar{y}(T), \bar{w}))$ in $L^\theta(Q) \times L^\theta(\Sigma) \times L^1(\Omega)$ for every $\theta < \infty$. The sequence $(\zeta_\epsilon)_\epsilon$ is bounded in $(C_b(\overline{Q} \setminus \overline{\Omega}_0))'$. Then there exists a generalized sequence, still indexed by ϵ, such that $(\zeta_\epsilon)_\epsilon$ converges to a limit $\bar{\zeta}$ for the weak-star topology of $(C_b(\overline{Q} \setminus \overline{\Omega}_0))'$. Due to Corollary 4.8, there exists a bounded linear transformation $\Lambda_{\bar{\zeta}} :\ C_b(\overline{Q} \setminus \overline{\Omega}_0) \longrightarrow L^\infty_{\pi_{|\bar{\zeta}|}}(\overline{Q})$, such that

$$\Big\langle \bar{\zeta}, h\Big\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0} = \Big\langle \pi_{\bar{\zeta}}, h\Big\rangle_{b,\overline{Q}\setminus\bar{\Omega}_0} + \int_{\overline{\Omega}_0} \Lambda_{\bar{\zeta}}(h)\, d\pi_{|\bar{\zeta}|} \quad \text{for all } h \in C_b(\overline{Q} \setminus \overline{\Omega}_0).$$

For every $z \in C^1(\overline{Q})$ satisfying $z(0) = 0$, we have

$$\int_Q \left(p_\epsilon \frac{\partial z}{\partial t} + \sum_{i,j} a_{ij} D_i z D_j p_\epsilon + \Phi'_y(x,t,y_\epsilon) p_\epsilon z) \right) , dxdt + \int_\Sigma p_\epsilon \Psi'_y(s,t,y_\epsilon) z \, dsdt$$
$$+ \int_\Omega \alpha_\epsilon L'_y(x, y_\epsilon(T), w_\epsilon) z(x,T)\, dx = -\Big\langle \pi_{\zeta_\epsilon}, g'(y_\epsilon) z \Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} = -\Big\langle \zeta_\epsilon, g'(y_\epsilon) z \Big\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0}.$$

By passing to the limit in this variational formulation, it follows that:

$$\int_Q \left(\bar{p} \frac{\partial z}{\partial t} + \sum_{i,j} a_{ij} D_i z D_j \bar{p} + \Phi'_y(x,t,\bar{y}) \bar{p} z \right) dxdt + \int_\Sigma \bar{p} \Psi'_y(s,t,\bar{y}) z \, dsdt$$
$$+ \int_\Omega \bar{\alpha} L'_y(x, \bar{y}(T), \bar{w}) z(x,T)\, dx = -\Big\langle \bar{\zeta}, g'(\bar{y}) z \Big\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0} = -\Big\langle \pi_{\bar{\zeta}}, g'(\bar{y}) z \Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0}$$

for every $z \in C^1(\overline{Q})$ satisfying $z(0) = 0$. Therefore, $\bar{p}$ is the weak solution of equation (5). On the other hand, by using the Green formulas satisfied by $\bar{p}$ and p_ϵ, we have

$$(31) \qquad -\int_\Omega \alpha_\epsilon L'_y(x, y_\epsilon(T), w_\epsilon)(z_{\epsilon,w} - z_{\epsilon,w_\epsilon})(T)\, dx - \int_\Omega p_\epsilon(0)(w - w_\epsilon)\, dx$$
$$= \Big\langle \zeta_\epsilon, g'(y_\epsilon)(z_{\epsilon,w} - z_{\epsilon,w_\epsilon}) \Big\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0} - \int_{\overline{\Omega}_0} \Lambda_\epsilon\Big(g'(y_\epsilon)(z_{\epsilon,w} - z_{\epsilon,w_\epsilon}) \Big)\, d\pi_{|\zeta_\epsilon|}$$

and

$$(32) \qquad -\int_\Omega \bar{\alpha} L'_y(x, \bar{y}(T), \bar{w})(\bar{z}_w - \bar{z}_{\bar{w}})(T)\, dx - \int_\Omega \bar{p}(0)(w - \bar{w})(0)\, dx$$
$$= \Big\langle \bar{\zeta}, g'(\bar{y})(\bar{z}_w - \bar{z}_{\bar{w}}) \Big\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0} - \int_{\overline{\Omega}_0} \Lambda_{\bar{\zeta}}\Big(g'(\bar{y})(\bar{z}_w - \bar{z}_{\bar{w}}) \Big) d\pi_{|\bar{\zeta}|},$$

where $\bar{z}_{\tilde{w}}$ (for $\tilde{w} = \bar{w}$ or $\tilde{w} = w$) is the solution of

$$(33)\, \frac{\partial z}{\partial t} + Az + \Phi'_y(\cdot, \bar{y}) z = 0 \quad \text{in } Q, \quad \frac{\partial z}{\partial n_A} + \Psi'_y(\cdot, \bar{y}) z = 0 \;\; \text{on } \Sigma, \quad z(0) = \tilde{w} \;\; \text{in } \Omega.$$

Let us set

$$I_\epsilon = \int_\Omega \Big(p_\epsilon(0)(w - w_\epsilon) - \bar{p}(0)(w - \bar{w}) \Big)\, dx$$
$$- \int_{\overline{\Omega}_0} \Lambda_\epsilon\Big(g'(y_\epsilon)(z_w - z_{w_\epsilon}) \Big) d\pi_{|\zeta_\epsilon|} + \int_{\overline{\Omega}_0} \Lambda_{\bar{\zeta}}\Big(g'(\bar{y})(\bar{z}_w - \bar{z}_{\bar{w}}) \Big)\, d\pi_{|\bar{\zeta}|}.$$

From (31) and (32), it follows that

$$
\begin{aligned}
\Big|I_\epsilon\Big| \leq & \Big| \int_\Omega \bar\alpha L'_y(x,\bar y(T),\bar w)(\bar z_w - \bar z_{\bar w})(T)\,dx \\
& - \int_\Omega \alpha_\epsilon L'_y(x,y_\epsilon(T),w_\epsilon))(z_{\epsilon,w} - z_{\epsilon,w_\epsilon})(T)\,dx\Big| \\
& + \Big|\Big\langle \bar\zeta, g'(\bar y)(\bar z_w - \bar z_{\bar w})\Big\rangle_{*,\overline{Q}\backslash\overline{\Omega}_0} - \Big\langle \zeta_\epsilon, g'(y_\epsilon)(z_{\epsilon,w} - z_{\epsilon,w_\epsilon})\Big\rangle_{*,\overline{Q}\backslash\overline{\Omega}_0}\Big| \\
\leq & \Big|\Big|\bar\alpha L'_y(\cdot,\bar y(T),\bar w) - \alpha_\epsilon L'_y(\cdot,y_\epsilon(T),w_\epsilon)\Big|\Big|_{1,\Omega}\Big|\Big|z_{\epsilon,w} - z_{\epsilon,w_\epsilon}\Big|\Big|_{\infty,Q} \\
& + \Big|\Big|\bar\alpha L'_y(\cdot,\bar y(T),\bar w)\Big|\Big|_{1,\Omega}\Big|\Big|(z_{\epsilon,w} - z_{\epsilon,w_\epsilon}) - (\bar z_w - \bar z_{\bar w})\Big|\Big|_{\infty,Q} \\
& + \Big|\Big\langle \bar\zeta - \zeta_\epsilon, g'(\bar y)(\bar z_w - \bar z_{\bar w})\Big\rangle_{*,\overline{Q}\backslash\overline{\Omega}_0}\Big| \\
& + \Big|\Big|g'(\bar y)(z_w - z_{\bar w}) - g'(y_\epsilon)(z_{\epsilon,w} - z_{\epsilon,w_\epsilon})\Big|\Big|_{\infty,Q}.
\end{aligned}
$$

Since the generalized sequence $(\alpha_\epsilon, w_\epsilon, y_\epsilon, z_{\epsilon,w_\epsilon}, z_{\epsilon,w}, \zeta_\epsilon)_\epsilon$ converges to $(\bar\alpha, \bar w, \bar y, \bar z_{\bar w}, \bar z_w, \bar\zeta)$, we obtain $\lim_\epsilon I_\epsilon = 0$. Therefore, by passing to the limit in the approximate optimality conditions satisfied by w_ϵ, we obtain

$$
(34)\qquad \int_\Omega H'_w\Big(x,\bar y(T),\bar w,\bar p(0),\bar\alpha\Big)(\bar w - w)\,dx + \int_{\overline{\Omega}_0} \Lambda_{\bar\zeta}\Big(g'(\bar y)(\bar z_{\bar w} - \bar z_w)\Big)d\pi_{|\bar\zeta|} \leq 0
$$

for all $w \in W_{ad}$. Let $z_{\tilde w}$ (for $\tilde w = \bar w$ or $\tilde w = w$) be the solution of (7) corresponding to $\tilde w$. Due to Proposition 4.10, we have

$$
(35)\qquad \int_{\overline{\Omega}_0} \Lambda_{\bar\zeta}\Big(g'(\bar y)\bar z_{\tilde w}\Big)d\pi_{|\bar\zeta|} = \int_{\overline{\Omega}_0} \Lambda_{\bar\zeta}\Big(g'(\bar y)z_{\tilde w}\Big)d\pi_{|\bar\zeta|}.
$$

By taking (34) and (35) into account, we obtain (8). On the other hand, by passing to the limit in

$$
\Big\langle \zeta_\epsilon, z\Big\rangle_{*,\overline{Q}\backslash\overline{\Omega}_0} \leq \Big\langle \zeta_\epsilon, g(y_\epsilon)\Big\rangle_{*,\overline{Q}\backslash\overline{\Omega}_0} \qquad \text{for all } z \in \mathcal{C},
$$

we obtain condition (4). Finally, by passing to the limit in ${\alpha_\epsilon}^2 + (||\zeta_\epsilon||_{(C_b(\overline{Q}\backslash\overline{\Omega}_0))'})^2 = 1$, we obtain $\bar\alpha^2 + (\lim_\epsilon ||\zeta_\epsilon||_{(C_b(\overline{Q}\backslash\overline{\Omega}_0))'})^2 = 1$. If $\bar\alpha > 0$, the proof is complete. If $\bar\alpha = 0$, we must prove that $||\bar\zeta||_{(C_b(\overline{Q}\backslash\overline{\Omega}_0))'} > 0$. Since $\mathrm{int}_{C_b(\overline{Q}\backslash\overline{\Omega}_0)}\mathcal{C} \neq \emptyset$, there exists a ball $B(z,2\rho) \subset \mathcal{C}$ in $C_b(\overline{Q} \setminus \overline{\Omega}_0)$, with center z and radius $2\rho > 0$. We can choose $\tilde z_\epsilon \in B(0,2\rho)$ such that $\langle \zeta_\epsilon, \tilde z_\epsilon\rangle_{*,\overline{Q}\backslash\overline{\Omega}_0} = \rho||\zeta_\epsilon||_{(C_b(\overline{Q}\backslash\overline{\Omega}_0))'}$. Since $z + \tilde z_\epsilon \in \mathcal{C}$, we have

$$
\Big\langle \zeta_\epsilon, z + \tilde z_\epsilon - g(y_\epsilon)\Big\rangle_{*,\overline{Q}\backslash\overline{\Omega}_0} \leq 0.
$$

By passing to the limit, we obtain $\rho + \langle \bar\zeta, z - g(\bar y)\rangle_{*,\overline{Q}\backslash\overline{\Omega}_0} \leq 0$, and thus $\bar\zeta \neq 0$. □

6. Application of Theorem 2.1. Consider state constraints of the form

$$
(36)\qquad a(x,t) \leq y(x,t) \leq b(x,t) \quad \text{ for all } (x,t) \in \overline{Q} \setminus \overline{\Omega}_0,
$$

where a and b are two functions in $C(\overline{Q})$ satisfying $a(x,t) < b(x,t)$ on $\overline{Q}$. The state constraints (36) may be written in the form (2) by setting

$$y \in \mathcal{C} = \{z \in C_b(\overline{Q} \setminus \overline{\Omega}_0) \mid a \le z \le b\}. \tag{37}$$

Theorem 6.1. *Suppose that* A1–A4 *are fulfilled and that the state constraint* (2) *is defined by* (37). *Then there exist* $\bar\alpha \ge 0$, $\bar p \in L^1(0,T;W^{1,1}(\Omega))$, $\bar\zeta \in (C_b(\overline{Q} \setminus \overline{\Omega}_0))'$, *two bounded linear transformations* $\Lambda_+ : C_b(\overline{Q} \setminus \overline{\Omega}_0) \longrightarrow L^\infty_{\pi_{\bar\zeta^+}}(\overline{Q})$, *and* $\Lambda_- : C_b(\overline{Q} \setminus \overline{\Omega}_0) \longrightarrow L^\infty_{\pi_{\bar\zeta^-}}(\overline{Q})$ *such that*

$$(\pi_{\bar\zeta^-}, \pi_{\bar\zeta^+}, \bar\alpha) \neq 0, \tag{38}$$

$$\Big\langle \pi_{\bar\zeta^+}, \bar y \Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} = \Big\langle \pi_{\bar\zeta^+}, b \Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0}, \quad \int_{\overline{\Omega}_0} \Lambda_+(\bar y)\, d\pi_{\bar\zeta^+} = \Big\langle \pi_{\bar\zeta^+}, b \Big\rangle_{\mathcal{M}(\overline{\Omega}_0)\times C(\overline{\Omega}_0)}, \tag{39}$$

$$\Big\langle \pi_{\bar\zeta^-}, \bar y \Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} = \Big\langle \pi_{\bar\zeta^-}, a \Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0}, \quad \int_{\overline{\Omega}_0} \Lambda_-(\bar y)\, d\pi_{\bar\zeta^-} = \Big\langle \pi_{\bar\zeta^-}, a \Big\rangle_{\mathcal{M}(\overline{\Omega}_0)\times C(\overline{\Omega}_0)}, \tag{40}$$

$$\begin{cases} -\frac{\partial \bar p}{\partial t} + A\bar p + \Phi'_y(x,t,\bar y)\bar p + [\pi_{\bar\zeta^+} - \pi_{\bar\zeta^-}]_{|Q} = 0 & \text{in } Q, \\ \frac{\partial \bar p}{\partial n_A} + \Psi'_y(s,t,\bar y)\bar p + [\pi_{\bar\zeta^+} - \pi_{\bar\zeta^-}]_{|\Sigma} = 0 & \text{on } \Sigma, \\ \bar p(x,T) + \bar\alpha L'_y(x,\bar y(T),\bar w) + [\pi_{\bar\zeta^+} - \pi_{\bar\zeta^-}]_{|\overline{\Omega}_T} = 0 & \text{on } \overline{\Omega}, \end{cases} \tag{41}$$

$$\int_\Omega H'_w\Big(x, \bar y(T), \bar w, \bar p(0), \bar\alpha\Big)(\bar w - w)\, dx \tag{42}$$

$$+\Big\langle \pi_{\bar\zeta^+}, b \Big\rangle_{\mathcal{M}(\overline{\Omega}_0)\times C(\overline{\Omega}_0)} - \Big\langle \pi_{\bar\zeta^-}, a \Big\rangle_{\mathcal{M}(\overline{\Omega}_0)\times C(\overline{\Omega}_0)} \le \int_{\overline{\Omega}_0} \Lambda_+(z_w)\, d\pi_{\bar\zeta^+} - \int_{\overline{\Omega}_0} \Lambda_-(z_w)\, d\pi_{\bar\zeta^-}$$

for all $w \in W_{ad}$, *where* z_w *is the solution of* (7) *corresponding to* w.

Proof. Due to Theorem 2.1, there exist $\bar\alpha \ge 0$, $\bar p \in L^1(0,T;W^{1,1}(\Omega))$, $\bar\zeta \in (C_b(\overline{Q} \setminus \overline{\Omega}_0))'$, and a bounded linear transformation $\Lambda_{\bar\zeta} : C_b(\overline{Q} \setminus \overline{\Omega}_0) \longrightarrow L^\infty_{\pi_{|\bar\zeta|}}(\overline{Q})$, such that (3)–(8) are satisfied. We consider $\bar\zeta$ as an element of $\mathcal{M}(\overline{Q} \times (\overline{Q} \setminus \overline{\Omega}_0)^\#)$. The condition (4) may be rewritten as

$$\Big\langle \bar\zeta, \tau(z) - \tau(\bar y) \Big\rangle_\# \le 0 \qquad \text{for all } z \in \mathcal{C}$$

(that is, $\langle \bar\zeta, \tau(z) - \tau(\bar y)\rangle_\# \le 0$ for all $\tau(z) \in \hat{\mathcal{C}} = \{\hat z \in C((\overline{Q}\setminus\overline{\Omega}_0)^\#) \mid \tau(a) \le \hat z \le \tau(b)\}$), where $\langle\cdot,\cdot\rangle_\#$ denotes the duality pairing $\langle\cdot,\cdot\rangle_{\mathcal{M}(\overline{Q}\times(\overline{Q}\setminus\overline{\Omega}_0)^\#)\times C(\overline{Q}\times(\overline{Q}\setminus\overline{\Omega}_0)^\#)}$ and τ is the operator defined in Proposition 4.2. Therefore,

$$\Big\langle \bar\zeta, \tau(\tilde z) - \tau(\tilde y) \Big\rangle_\# \le 0 \quad \text{for all } -\frac{b-a}{2} \le \tilde z \le \frac{b-a}{2} \quad \left(\text{with } \tilde y = \bar y - \frac{b+a}{2}\right)$$

and

$$\Big\langle \bar\zeta, \tau(\tilde y) \Big\rangle_\# = \sup_{|\tilde z| \le \frac{b-a}{2}} \Big\langle \bar\zeta, \tau(\tilde z) \Big\rangle_\# = \sup_{|\phi|\le 1} \Big\langle \bar\zeta, \tau\Big(\frac{b-a}{2}\phi\Big) \Big\rangle_\#$$

$$= \sup_{\tau(|\phi|)\le\tau(1)} \Big\langle \bar\zeta, \tau\Big(\frac{b-a}{2}\Big)\tau(\phi)\Big\rangle_{\#} = \sup_{|\tau(\phi)|\le 1} \Big\langle \bar\zeta, \tau\Big(\frac{b-a}{2}\Big)\tau(\phi)\Big\rangle_{\#} = \Big\langle |\bar\zeta|, \tau\Big(\frac{b-a}{2}\Big)\Big\rangle_{\#}.$$

From the definition of $\tilde y$ and from the above equality, by a straightforward calculation, we obtain

$$\Big\langle \bar\zeta^+, \tau(\bar y - b)\Big\rangle_{\#} + \Big\langle \bar\zeta^-, \tau(a - \bar y)\Big\rangle_{\#} = 0.$$

From $a \le \bar y \le b$ (and thus $\tau(a) \le \tau(\bar y) \le \tau(b)$), we see that

$$\Big\langle \bar\zeta^+, \tau(\bar y - b)\Big\rangle_{\#} = 0, \qquad \Big\langle \bar\zeta^-, \tau(a - \bar y)\Big\rangle_{\#} = 0. \tag{43}$$

Due to Theorem 4.7, there exist two bounded linear transformations $\Lambda_{\bar\zeta^+} : C((\overline{Q} \setminus \overline{\Omega}_0)^{\#}) \longrightarrow L^\infty_{\pi_{\bar\zeta^+}}(\overline{Q})$ and $\Lambda_{\bar\zeta^-} : C((\overline{Q} \setminus \overline{\Omega}_0)^{\#}) \longrightarrow L^\infty_{\pi_{\bar\zeta^-}}(\overline{Q})$, such that

$$\Big\langle \bar\zeta^+, \tau(h)\Big\rangle_{\#} = \Big\langle \pi_{\bar\zeta^+}, h\Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} + \int_{\overline{\Omega}_0} \Lambda_{\zeta^+}(\tau(h))\, d\pi_{\bar\zeta^+}, \tag{44}$$

$$\Big\langle \bar\zeta^-, \tau(h)\Big\rangle_{\#} = \Big\langle \pi_{\bar\zeta^-}, h\Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} + \int_{\overline{\Omega}_0} \Lambda_{\zeta^-}(\tau(h))\, d\pi_{\bar\zeta^-} \tag{45}$$

for all $h \in C_b(\overline{Q} \setminus \overline{\Omega}_0)$. Let us set $\Lambda_+ = \Lambda_{\zeta^+} \circ \tau$ and $\Lambda_- = \Lambda_{\zeta^-} \circ \tau$. From (43), the results are

$$\Big\langle \pi_{\bar\zeta^+}, \bar y\Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} + \int_{\overline{\Omega}_0} \Lambda_+(\bar y)\, d\pi_{\bar\zeta^+} = \Big\langle \pi_{\bar\zeta^+}, b\Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} + \int_{\overline{\Omega}_0} \Lambda_+(b)\, d\pi_{\bar\zeta^+},$$

$$\Big\langle \pi_{\bar\zeta^-}, \bar y\Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} + \int_{\overline{\Omega}_0} \Lambda_-(\bar y)\, d\pi_{\bar\zeta^-} = \Big\langle \pi_{\bar\zeta^-}, b\Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} + \int_{\overline{\Omega}_0} \Lambda_-(a)\, d\pi_{\bar\zeta^-}.$$

Since $a \le \bar y \le b$, due to Corollary 4.9 with the above equalities, we have

$$0 \le \int_{\overline{\Omega}_0} \Lambda_+(b - \bar y)\, d\pi_{\bar\zeta^+} = \Big\langle \pi_{\bar\zeta^+}, \bar y - b\Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} \le 0,$$

$$0 \le \int_{\overline{\Omega}_0} \Lambda_-(\bar y - a)\, d\pi_{\bar\zeta^-} = \Big\langle \pi_{\bar\zeta^-}, a - \bar y\Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} \le 0.$$

Consequently, we have proved (39) and (40). We still must prove (42). With (44) and (45), it follows that

$$\begin{aligned}
&\int_{\overline{\Omega}_0} \Lambda_{\bar\zeta}(z)\, d\pi_{|\bar\zeta|} = \Big\langle \bar\zeta, \tau(z)\Big\rangle_{\#} - \Big\langle \bar\zeta, z\Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} = \Big\langle \bar\zeta, z\Big\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0} - \Big\langle \bar\zeta, z\Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} \\
&= \Big\langle \bar\zeta^+, z\Big\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0} - \Big\langle \bar\zeta^+, z\Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} - \Big\langle \bar\zeta^-, z\Big\rangle_{*,\overline{Q}\setminus\overline{\Omega}_0} + \Big\langle \bar\zeta^-, z\Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} \\
&= \int_{\overline{\Omega}_0} \Lambda_+(z)\, d\pi_{\bar\zeta^+} - \int_{\overline{\Omega}_0} \Lambda_-(z)\, d\pi_{\bar\zeta^-} \qquad \text{for all } z \in C_b(\overline{Q} \setminus \overline{\Omega}_0).
\end{aligned}$$

The optimality condition (42) follows from (6), from the above equality, and from

$$\int_{\overline{\Omega}_0} \Lambda_+(z_{\bar w} - \bar y)\, d\pi_{\bar\zeta^+} = \int_{\overline{\Omega}_0} \Lambda_-(z_{\bar w} - \bar y)\, d\pi_{\bar\zeta^-} = 0.$$

The proof is complete. □

Corollary 6.2. *Suppose that assumptions of Theorem* 6.1 *are satisfied. Suppose in addition that there exists* $\tilde w \in W_{ad}$ *satisfying* $a(x,0) + \tilde\epsilon \le \tilde w(x) \le b(x,0) - \tilde\epsilon$ *on* Ω (*for some* $\tilde\epsilon > 0$). *Then there exist* $\bar\alpha \ge 0$, $\bar p \in L^1(0,T;W^{1,1}(\Omega))$, $\bar\mu_a \in \mathcal{M}_b(\overline{Q}\setminus\overline{\Omega}_0)$, *and* $\bar\mu_b \in \mathcal{M}_b(\overline{Q}\setminus\overline{\Omega}_0)$ *such that*

$$\bar\mu_a \ge 0, \qquad \bar\mu_b \ge 0, \qquad (\bar\mu_a, \bar\mu_b, \bar\alpha) \ne 0, \tag{46}$$

$$\Big\langle \bar\mu_b, \bar y \Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} = \Big\langle \bar\mu_b, b \Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0}, \qquad \Big\langle \bar\mu_a, \bar y \Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0} = \Big\langle \bar\mu_a, a \Big\rangle_{b,\overline{Q}\setminus\overline{\Omega}_0}, \tag{47}$$

$$\bar p \textit{ satisfies } (41) \textit{ with } \pi_{\bar\zeta}{}_{|\overline{Q}\setminus\overline{\Omega}_0} \equiv \bar\mu_b - \bar\mu_a, \tag{48}$$

$$\int_\Omega H'_w\Big(x, \bar y(T), \bar w, \bar p(0), \bar\alpha\Big)(\bar w - w)\, dx \le 0 \tag{49}$$

for all $w \in W_{ad}$ *with* $a(0) \le w \le b(0)$.

Proof. Due to Theorem 6.1, there exist $\bar\alpha \ge 0$, $\bar p \in L^1(0,T;W^{1,1}(\Omega))$, $\bar\zeta \in (C_b(\overline{Q}\setminus\overline{\Omega}_0))'$, and a bounded linear transformation $\Lambda_{\bar\zeta} : C_b(\overline{Q}\setminus\overline{\Omega}_0) \longrightarrow L^\infty_{\pi_{\bar\zeta}}(\overline{Q})$ such that (38)–(42) are satisfied.

1. We claim that $(\pi_{\bar\zeta^+}{}_{|\overline{Q}\setminus\overline{\Omega}_0}, \pi_{\bar\zeta^-}{}_{|\overline{Q}\setminus\overline{\Omega}_0}, \bar\alpha) \ne 0$. Arguing by contradiction, we suppose that $(\pi_{\bar\zeta^+}{}_{|\overline{Q}\setminus\overline{\Omega}_0}, \pi_{\bar\zeta^-}{}_{|\overline{Q}\setminus\overline{\Omega}_0}, \bar\alpha) = 0$. It follows that $\bar p \equiv 0$. With (38), we have $(\pi_{\bar\zeta^-}{}_{|\overline{\Omega}_0}, \pi_{\bar\zeta^+}{}_{|\overline{\Omega}_0}) \ne 0$, and with (42), we deduce that

$$\int_{\overline{\Omega}_0} \Lambda_-(z_w)\, d\pi_{\bar\zeta^-} - \int_{\overline{\Omega}_0} \Lambda_+(z_w)\, d\pi_{\bar\zeta^+} \le \Big\langle \pi_{\bar\zeta^-}, a \Big\rangle_{\mathcal{M}(\overline{\Omega}_0)\times C(\overline{\Omega}_0)} - \Big\langle \pi_{\bar\zeta^+}, b \Big\rangle_{\mathcal{M}(\overline{\Omega}_0)\times C(\overline{\Omega}_0)}$$

for all $w \in W_{ad}$, where z_w is the solution of (7) corresponding to w. In particular,

$$\int_{\overline{\Omega}_0} \Lambda_-(z_{\tilde w})\, d\pi_{\bar\zeta^-} - \int_{\overline{\Omega}_0} \Lambda_+(z_{\tilde w})\, d\pi_{\bar\zeta^+} \le \langle \pi_{\bar\zeta^-}, a\rangle_{\mathcal{M}(\overline{\Omega}_0)\times C(\overline{\Omega}_0)} - \langle \pi_{\bar\zeta^+}, b\rangle_{\mathcal{M}(\overline{\Omega}_0)\times C(\overline{\Omega}_0)}. \tag{50}$$

With a comparison principle, we prove that

$$z_{a(0)+\tilde\epsilon}(x,t) \le z_{\tilde w}(x,t) \le z_{b(0)-\tilde\epsilon}(x,t) \quad \text{for all } (x,t) \in \overline{Q}\setminus\overline{\Omega}_0.$$

From Corollary 4.9, it follows that

$$\Big\langle \pi_{\bar\zeta^+}, a \Big\rangle_{\mathcal{M}(\overline{\Omega}_0)\times C(\overline{\Omega}_0)} + \tilde\epsilon\pi_{\bar\zeta^+}(\overline{\Omega}_0) \le \int_{\overline{\Omega}_0} \Lambda_+(z_{\tilde w})\, d\pi_{\bar\zeta^+} \le \Big\langle \pi_{\bar\zeta^+}, b \Big\rangle_{\mathcal{M}(\overline{\Omega}_0)\times C(\overline{\Omega}_0)} - \tilde\epsilon\pi_{\bar\zeta^+}(\overline{\Omega}_0),$$

$$\Big\langle \pi_{\bar\zeta^-}, a \Big\rangle_{\mathcal{M}(\overline{\Omega}_0)\times C(\overline{\Omega}_0)} + \tilde\epsilon\pi_{\bar\zeta^-}(\overline{\Omega}_0) \le \int_{\overline{\Omega}_0} \Lambda_-(z_{\tilde w})\, d\pi_{\bar\zeta^-} \le \Big\langle \pi_{\bar\zeta^-}, b \Big\rangle_{\mathcal{M}(\overline{\Omega}_0)\times C(\overline{\Omega}_0)} - \tilde\epsilon\pi_{\bar\zeta^-}(\overline{\Omega}_0),$$

and thus

$$\begin{aligned}&\Big\langle \pi_{\bar\zeta^-}, a\Big\rangle_{\mathcal{M}(\overline{\Omega}_0)\times C(\overline{\Omega}_0)} - \Big\langle \pi_{\bar\zeta^+}, b\Big\rangle_{\mathcal{M}(\overline{\Omega}_0)\times C(\overline{\Omega}_0)}\\ &\le \int_{\overline{\Omega}_0} \Lambda_-(z_{\tilde w})\, d\pi_{\bar\zeta^-} - \int_{\overline{\Omega}_0} \Lambda_+(z_{\tilde w})\, d\pi_{\bar\zeta^+} - \tilde\epsilon[\pi_{\bar\zeta^-}(\overline{\Omega}_0) + \pi_{\bar\zeta^+}(\overline{\Omega}_0)],\end{aligned}$$

which is in contradiction with (50). By setting $\bar\mu_a \equiv \pi_{\bar\zeta^-}{}_{|\overline{Q}\backslash\overline{\Omega}_0}$ and $\bar\mu_b \equiv \pi_{\bar\zeta^+}{}_{|\overline{Q}\backslash\overline{\Omega}_0}$, we obtain (46), (47), and (48).

2. Let $a(0) \le w \le b(0)$. With a comparison principle and Corollary 4.9, it follows that

$$\begin{aligned}&\int_{\overline{\Omega}_0} \Lambda_+(z_w)\, d\pi_{\bar\zeta^+} \le \int_{\overline{\Omega}_0} \Lambda_+(z_{b(0)})\, d\pi_{\bar\zeta^+} = \Big\langle \pi_{\bar\zeta^+}, b\Big\rangle_{\mathcal{M}(\overline{\Omega}_0)\times C(\overline{\Omega}_0)},\\ &\int_{\overline{\Omega}_0} \Lambda_-(z_{a(0)})\, d\pi_{\bar\zeta^-} = \Big\langle \pi_{\bar\zeta^-}, a\Big\rangle_{\mathcal{M}(\overline{\Omega}_0)\times C(\overline{\Omega}_0)} \le \int_{\overline{\Omega}_0} \Lambda_-(z_w)\, d\pi_{\bar\zeta^-}.\end{aligned}$$

Taking (42) into account, we obtain

$$\begin{aligned}&\int_\Omega H'_w(x, \bar y(T), \bar w, \bar p(0), \bar\alpha)(\bar w - w)\, dx\\ &\le \Big\langle \pi_{\bar\zeta^-}, a\Big\rangle_{\mathcal{M}(\overline{\Omega}_0)\times C(\overline{\Omega}_0)} - \Big\langle \pi_{\bar\zeta^+}, b\Big\rangle_{\mathcal{M}(\overline{\Omega}_0)\times C(\overline{\Omega}_0)} + \int_{\overline{\Omega}_0} \Lambda_+(z_w)\, d\pi_{\bar\zeta^+} - \int_{\overline{\Omega}_0} \Lambda_-(z_w)\, d\pi_{\bar\zeta^-}\\ &\le 0 \qquad \text{for all } w \in W_{ad} \text{ with } \ a(0) \le w \le b(0).\end{aligned}$$

The proof is complete. □

Acknowledgment. The authors would like to thank E. Casas for helpful remarks during the preparation of this paper.

ON THE WEAK CLOSURE OF SETS OF FEASIBLE STATES FOR LINEAR ELLIPTIC EQUATIONS IN THE SCALAR CASE*

ULDIS RAITUMS†

Abstract. A suitable description of the weak closure of feasible states is given for the family of equations

$$\mathrm{div} A(x)\nabla u = f(x) \text{ in } \Omega\ ,\ u \in H_0^1(\Omega),\ \Omega \subset \mathbf{R}^n,$$

with $A \in \mathcal{M}$, where the set $\mathcal{M}$ consists of all measurable symmetric matrices whose eigenvalues at almost every $x \in \Omega$ belong to a given finite set $\{(\lambda_1^1, \dots, \lambda_n^1); \dots; (\lambda_1^N, \dots, \lambda_n^N)\} \subset \mathbf{R}^n$ and which satisfy additional constraints on the measure of sets where the eigenvalues of A are equal to some $(\lambda_1^i, \dots, \lambda_n^i)$, $i = 1, \dots, N$. Applications to optimal control problems are also considered.

Key words. elliptic equation, optimal control, feasible states, weak closure

1. Introduction.

For optimal control problems of the type

$$I(u) \;\to\; \min,\ \ u \in H_0^1(\Omega),\ \ A \in \mathcal{M}, \tag{1.1}$$

$$\mathcal{A}u \;:=\; \mathrm{div} A\nabla u = f \ \text{ in } \Omega, \tag{1.2}$$

where $\mathcal{M}$ is a given set of measurable symmetric positive definite matrices and I is a weakly continuous functional, it is very natural to extend the set $\mathcal{M}$ to the set $G\mathcal{M}$ which corresponds to the G-closure of the set of admissible operators of the type (1.2) defined by $A \in \mathcal{M}$. Since analytical descriptions of $G\mathcal{M}$ are known only for a few cases, the problem of the G-closure can be substituted by a problem of finding another larger set $\mathcal{M}'$ of matrices, $\mathcal{M} \subset \mathcal{M}'$, such that the set $Z(\mathcal{M}', f)$ of all solutions of (1.2) with $A \in \mathcal{M}'$ is equal to the closure in the weak topology of $H_0^1(\Omega)$ of the set $Z(\mathcal{M}, f)$ of all solutions of (1.2) with $A \in \mathcal{M}$.

If such a set $\mathcal{M}'$ is found, then from the point of view of solving the problem (1.1)–(1.2) there is not a great difference if one uses the set $G\mathcal{M}$ or the set $\mathcal{M}'$. Only two questions remain: how to interpret an optimal solution from $\mathcal{M}'$ and how to construct a minimizing sequence for the original problem by using the knowledge of the optimal solution from $\mathcal{M}'$.

In this paper, we consider the problem (1.1)–(1.2) with $\mathcal{M} = \mathcal{M}(\mathbf{d})$, where $\mathcal{M}(\mathbf{d})$ is defined by means of a given finite set of matrices $\{D_1; \dots; D_N\} \subset \mathrm{R}^{n\times n}$, a vector $\mathbf{d} = (d_1, \dots, d_N) \in \mathrm{R}^N$, and

†Institute of Mathematics and Computer Science, University of Latvia, LV-1459 Riga, Latvia (raitums@cclu.lv).

$$\begin{aligned}\mathcal{M}(\mathbf{d}) \;=\; \Big\{ & A \in [L_2(\Omega)]^{n\times n} \mid \\ & A(x) = \sum_{i=1}^{N} \theta_i(x) Q_i(x) D_i Q_i^{-1}(x) \text{ almost everywhere (a.e.) } x \in \Omega, \\ & Q_i(x) \in \mathcal{O} \;\text{ a.e. } x \in \Omega, \\ & \theta_i(x) = 0 \text{ or } \;1,\; i = 1, \dots, N,\;\; \theta_1(x) + \cdots + \theta_N(x) \\ & = 1 \;\text{ a.e. } x \in \Omega, \\ & \int_\Omega \theta_i(x)dx \le d_i,\; i = 1, \dots, N \Big\}.\end{aligned}$$

Here $\mathcal{O}$ is the set of all orthogonal constant $n \times n$ matrices.

From the point of view of practical problems the matrices D_i play the role of properties of given N materials (not necessary isotropic) and the additional constraints on θ_i play the role of constraints on the volumes occupied by each material.

The above-formulated problem and its analogues have been studied by many authors. Most of these investigations were based on the evaluation of the G-closure of the set of admissible matrices. For problems without restrictions on volumes occupied by each material the corresponding G-closures were obtained by Frankfort and Murat [2] ($n = N = 2$, anisotropic materials) and Lurie and Cherkaev [4] (isotropic materials, arbitrary n and m). The characterization of mixtures using two isotropic materials in given proportions were given in Lurie and Cherkaev [4], [5], Murat and Tartar [8], and Tartar [12]. Many investigations have been devoted to bounds on effective properties of composites. We mention here Milton and Kohn [7], Milton [6], Nesi [9], Zhikov, Kozlov, and Oleinik [15], and references therein. Nevertheless, as far as we know, an analytical description of the G-closure for the case of N, $N \geq 3$, does not exist, given isotropic materials taken in prescribed proportion.

Various aspects of related optimal control problems are discussed in Lurie [3]. In Cherkaev [1] the idea was developed that from the point of view of optimization it is necessary to find out only a part of the G-closure which really defines the only candidates to optimality.

The first results different from pure extensions via the G-closure were obtained by Raitums [10] for the case without restrictions on the amounts of materials. Almost at the same time similar ideas were developed in Murat and Tartar [8] for the case of two isotropic materials, with restrictions on amounts of materials. In Tartar [13] it was indicated that these ideas in a natural way can be extended to the case of an arbitrary number of anisotropic materials.

We must especially mention the recently published paper by Tartar [14], who via a different approach obtained a successful extension of the set $\mathcal{M}(\mathbf{d})$ which coincides with the set $W\mathcal{M}(\mathbf{d})$ (see section 2 for the precise definition) described in our paper. The main difference between our approach and Tartar's [14] is that we give an explicit analytical procedure (proofs of Lemma 3.6 and Theorem 2.1 below) which describes how for a given pair $(A_*, u_*) \in W\mathcal{M}(\mathbf{d}) \times H_0^1(\Omega)$,

$$\operatorname{div} A_* \nabla u_* = f \text{ in } \Omega,$$

a sequence $\{A_k\} \subset \mathcal{M}(\mathbf{d})$ (rank 2 laminated structure) is constructed such that the corresponding sequence $\{u_k\}$ of solutions of

$$\operatorname{div} A_k \nabla u_k = f \text{ in } \Omega, \qquad k = 1, 2, \ldots,$$

converges to u_* weakly in $H_0^1(\Omega)$.

In the following sections we give an explicit description of a set of matrices $W\mathcal{M}(\mathbf{d})$ such that for every fixed $f \in H^{-1}(\Omega)$ the set $Z(W\mathcal{M}(\mathbf{d}), f)$ of all solutions of (1.2) with $A \in W\mathcal{M}(\mathbf{d})$ is equal to the closure in the weak topology of $H_0^1(\Omega)$ of the set of all solutions of (1.2) with $A \in \mathcal{M}(\mathbf{d})$. Moreover, we show that the set $W\mathcal{M}(\mathbf{d})$ defines a G-closed family of operators and that for every solution u_0 of (1.2) with some $A_0 \in W\mathcal{M}(\mathbf{d})$ there exists a sequence of matrices $\{A_k\} \subset \mathcal{M}(\mathbf{d})$ which defines a rank 2 laminated structure and G-converges to a matrix A_* such that

$$A_*(x)\nabla u_0(x) = A_0(x)\nabla u_0(x) \text{ a.e. } x \in \Omega.$$

2. Notation and statements of results. Let $n \geq 2$ be an integer, let R^n be the n-dimensional Euclidean space with elements $x = (x_1, \ldots, x_n)$, $\xi = (\xi_1, \ldots, \xi_n)$, and let $\Omega \subset \mathrm{R}^n$ be a bounded domain with a uniformly Lipschitz boundary $\partial\Omega$.

Throughout this paper we shall use the following notations:

$\lvert . \rvert, \langle . \rangle$	the norm and the scalar product in R^n, respectively.
$\lvert E\rvert$ or meas$E$	the Lebesgue measure of a measurable subset $E \subset \Omega$.
$\mathcal{O}$	the set of all constant $n \times n$ orthogonal matrices.
Q	a constant orthogonal matrix or a matrix function $Q = Q(x),\ x \in \Omega$, with values $Q(x) \in \mathcal{O}$ a.e. $x \in \Omega$.
ν, μ	fixed positive constants with $0 < \nu < \mu$.
$M(\nu, \mu)$	the set of all symmetric constant $n \times n$ matrices D such that $\langle D\xi, \xi\rangle \geq \nu\lvert\xi\rvert^2 \ \forall \xi \in \mathrm{R}^n, \quad \lvert D\xi\rvert \leq \mu\lvert\xi\rvert \ \forall \xi \in \mathrm{R}^n$.
$\mathcal{M}(\nu, \mu)$	the set $\{A \in [L_2(\Omega)]^{n\times n} \mid A(x) \in M(\nu,\mu) \text{ a.e. } x \in \Omega\}$.
$\lambda_j(A)(x)$	eigenvalues of a matrix $A \in \mathcal{M}(\nu,\mu)$ at a point x arranged in the increasing order, i.e., $\nu \leq \lambda_1(A)(x) \leq \cdots \leq \lambda_n(A)(x) \leq \mu$.
$\lambda_j(A)$	the corresponding functions with values at a point $x \in \Omega$ equal to $\lambda_j(A)(x),\ j = 1, \ldots, n$, respectively.
$\mathbf{l}_j$	vector functions with values in R^n.
$w$lim	the limit in the weak topology of $L_2(\Omega)$ or its Cartesian products.
G-limit	the limit in the sense of the G-convergence.
diag$(a_1, \ldots, a_n)$	a diagonal matrix $\begin{pmatrix} a_1 & & 0 \\ & \ddots & \\ 0 & & a_n \end{pmatrix}$.
$\mathbf{a} \leq \mathbf{b}$	for vectors $\mathbf{a} = (a_1, \ldots, a_n)$, $\mathbf{b} = (b_1, \ldots, b_n)$ the inequality $\mathbf{a} \leq \mathbf{b}$ means that $a_j \leq b_j,\ j = 1, \ldots, n$.
$A \leq B$	for matrices $A, B \in \mathcal{M}(\nu,\mu)$ the inequality $A \leq B$. means that $\langle (B(x) - A(x))\,\xi, \xi\rangle \geq 0 \ \forall \xi \in \mathrm{R}^n$ a.e. $x \in \Omega$.

Consider elliptic operators

$$\begin{aligned} \mathcal{A} &: H_0^1(\Omega) \to H^{-1}(\Omega), \\ \mathcal{A}u &:= \operatorname{div} A\nabla u \end{aligned} \tag{2.1}$$

defined by means of matrices $A \in \mathcal{M}(\nu, \mu)$. To emphasize that an operator $\mathcal{A}$ of the kind (2.1) is defined by a matrix A we shall use the notation $\mathcal{A}(A)$.

We shall say that a sequence of matrices $\{A_k\} \subset \mathcal{M}(\nu, \mu)$ G-converges to a matrix A_0 if and only if the corresponding sequence of operators $\{\mathcal{A}(A_k)\}$ G-converges to the operator $\mathcal{A}(A_0)$. For more details of the G-convergence see Zhikov, Kozlov, and Oleinik [15].

It is well known (see, for instance, Zhikov, Kozlov, and Oleinik [15] or Raitums [11]) that every subset $\mathcal{M} \subset \mathcal{M}(\nu, \mu)$ possesses a G-closure which belongs to $\mathcal{M}(\nu, \mu)$. We shall denote by $G\mathcal{M}$ the G-closure of a set $\mathcal{M} \subset \mathcal{M}(\nu, \mu)$. We remind the reader that $G\mathcal{M}$ consists of all matrices B such that there exists a sequence $\{A_k\} \subset \mathcal{M}$ which G-converges to B.

The G-convergence of a sequence of matrices $\{A_k\}$ to a matrix A_0 shall be denoted by

$$A_k \xrightarrow{G} A_0 \ \text{ or } \ A_0 = G - \text{limit} A_k.$$

We shall say that a matrix A_0 is a rank 1 composite (or that A_0 is obtained by means of a rank 1 laminated structure) if there exists a sequence of matrices A^s, $s = 1, 2, \dots$, such that

(i) $A^s \to A_0$ strongly in $[L_2(\Omega)]^{n \times n}$ as $s \to \infty$;

(ii) for every matrix A^s there exists a sequence $\{A_k^s\} \subset \mathcal{M}(\nu, \mu)$ of admissible matrices which G-converges to A^s and for almost every $x_0 \in \Omega$ there exists a neighborhood $E^s(x_0)$ of x_0 and a constant vector $\mathbf{l}^s \in \mathrm{R}^n$ such that

$$A_k^s(x) = A_k^s(\langle x, \mathbf{l}^s \rangle) \ \text{ in } \ E^s(x_0), \qquad k = 1, 2, \dots.$$

We shall say that a matrix A_0 is a rank 2 composite (or that A_0 is obtained by means of a rank 2 laminated structure) if A_0 is constructed from rank 1 composites in the same way as rank 1 composites are constructed from admissible matrices.

Let $N \geq 2$ be an integer, let $D_i \in M(\nu, \mu)$, $i = 1, \dots, N$, be diagonal matrices,

$$D_i = \text{diag}(\lambda_1(D_i), \dots, \lambda_n(D_i)), \ \ i = 1, \dots, N,$$

and let $\mathbf{d} = (d_1, \dots, d_N)$ be a vector with nonnegative components such that

$$d_1 + \dots + d_N \geq |\Omega|.$$

We introduce the following sets:

$$\begin{aligned} S = \{\theta \in [L_2(\Omega)]^N \ \ | \ \ & \theta = (\theta_1, \dots, \theta_N), \ \ \theta_i(x) = 0 \ \text{ or } 1, \ \ i = 1, \dots, N, \\ & \theta_1(x) + \dots + \theta_N(x) = 1 \ \text{ a.e. } x \in \Omega\}, \end{aligned}$$

$$\begin{aligned} \mathcal{K}(\mathbf{d}) = \Big\{ & \mathbf{p} \in [L_2(\Omega)]^N \ \ | \ \ \mathbf{p} = (p_1, \dots, p_N), \ \ p_i(x) \geq 0 \ \text{ a.e. } x \in \Omega, \ \ i = 1, \dots, N, \\ & p_1(x) + \dots + p_N(x) = 1 \ \text{ a.e. } \ x \in \Omega, \\ & \int_\Omega p_i(x) dx \leq d_i, \ \ i = 1, \dots, N \Big\}, \end{aligned}$$

$$\begin{aligned} \mathcal{M}(\mathbf{d}) = \Big\{ & A \in \mathcal{M}(\nu, \mu) \ \ | \ \ A(x) = \sum_{i=1}^{N} \theta_i(x) Q_i(x) D_i Q_i^{-1}(x) \ \text{ a.e. } x \in \Omega, \\ & \theta = (\theta_1, \dots, \theta_N) \in S, \ \ Q_i(x) \in \mathcal{O} \ \text{ a.e. } x \in \Omega, \ \ i = 1, \dots, N, \\ & \int_\Omega \theta_i(x) dx \leq d_i, \ \ i = 1, \dots, N \Big\}, \end{aligned}$$

$$\Lambda(\mathbf{p}) = \Bigg\{ (\lambda_1, \lambda_n) \in [L_2(\Omega)]^2 \quad | \quad \lambda_1(x) \le \lambda_n(x) \ \text{ a.e. } x \in \Omega,$$
$$\left(\frac{1}{\lambda_1(x)}, \lambda_n(x)\right) \le \left(\sum_{i=1}^{N} p_i(x) \frac{1}{\lambda_1(D_i)}, \ \sum_{i=1}^{N} p_i(x) \lambda_n(D_i)\right) \ \text{ a.e. } x \in \Omega \Bigg\},$$

$$\Lambda_0(\mathbf{p}) = \Bigg\{ (\lambda_1, \lambda_n) \in \Lambda(\mathbf{p}) \quad |$$
$$\left(\frac{1}{\lambda_1(x)}, \lambda_n(x)\right) = \left(\sum_{i=1}^{N} p_i(x) \frac{1}{\lambda_1(D_i)}, \ \sum_{i=1}^{N} p_i(x) \lambda_n(D_i)\right) \ \text{ a.e. } x \in \Omega \Bigg\},$$

$$\Lambda(\mathbf{d}) = \bigcup_{\mathbf{p} \in \mathcal{K}(\mathbf{d})} \Lambda(\mathbf{p}),$$
$$\Lambda_0(\mathbf{d}) = \bigcup_{\mathbf{p} \in \mathcal{K}(\mathbf{d})} \Lambda_0(\mathbf{p}).$$

By $\Lambda(\mathbf{p})(x)$ and $\Lambda_0(\mathbf{p})(x)$ we shall denote the sets of values defined by functions from $\Lambda(\mathbf{p})$ and $\Lambda_0(\mathbf{p})$ at a point x, respectively.

Consider the optimal control problem

$$\begin{aligned} &I(u) \to \min, \\ &\operatorname{div} A \nabla u = f \ \text{ in } \Omega, \ A \in \mathcal{M}(\mathbf{d}), \ \ u \in H_0^1(\Omega), \end{aligned} \tag{2.2}$$

where the element $f \in H^{-1}(\Omega)$ and the functional I are fixed. We always suppose that the functional I is weakly continuous on $H_0^1(\Omega)$.

Such problems correspond to the optimal layout of N given anisotropic materials described by means of matrices $D_1, \ldots, D_N$, respectively, with additional constraints on the volumes occupied by each material.

Together with the problem (2.2) we will consider the problem

$$\begin{aligned} &I(u) \to \min, \\ &\operatorname{div} A \nabla u = f \ \text{ in } \Omega, \ A \in G\mathcal{M}(\mathbf{d}), \ u \in H_0^1(\Omega), \end{aligned} \tag{2.3}$$

which is the extension of the problem (2.2) via the G-closure, and the problem

$$\begin{aligned} &I(u) \to \min, \\ &\operatorname{div} A \nabla u = f \ \text{ in } \Omega, \ \ A \in W\mathcal{M}(\mathbf{d}), \ u \in H_0^1(\Omega), \end{aligned} \tag{2.4}$$

where

$$W\mathcal{M}(\mathbf{d}) = \{A \in \mathcal{M}(\nu, \mu) \quad | \quad (\lambda_1(A), \lambda_n(A)) \in \Lambda(\mathbf{d})\}. \tag{2.5}$$

It is clear that problem (2.3) possesses an optimal solution.

For a given set of matrices $\mathcal{M} \subset \mathcal{M}(\nu, \mu)$ denote by $Z(\mathcal{M}, f)$ the set of all feasible states of the state equation

$$\operatorname{div} A \nabla u = f \ \text{ in } \Omega$$

with $A \in \mathcal{M}$, i.e.,

$$Z(\mathcal{M}, f) = \{u \in H_0^1(\Omega \mid \text{there exists a matrix } A \in \mathcal{M} \text{ such that } \operatorname{div} A\nabla u = f \text{ in } \Omega\}.$$

The main results of the paper are the following.

Theorem 2.1. *For every fixed $f \in H^{-1}(\Omega)$ the problems (2.3) and (2.4) have one and the same set of feasible states, i.e.,*

$$Z\left(G\mathcal{M}(\mathbf{d}), f\right) = Z\left(W\mathcal{M}(\mathbf{d}), f\right),$$

and the set $Z\left(W\mathcal{M}(\mathbf{d}), f\right)$ is closed in the weak topology of $H_0^1(\Omega)$.

Theorem 2.2. *The set $W\mathcal{M}(\mathbf{d})$ is G-closed.*

Theorem 2.3. *Problem (2.4) has at least one optimal solution $(A_0, u_0) \in W\mathcal{M}(\mathbf{d}) \times H_0^1(\Omega)$ and there exists a matrix $A_* \in G\mathcal{M}(\mathbf{d})$ such that*

$$A_*(x)\nabla u_0(x) = A_0(x)\nabla u_0(x) \text{ a.e. } x \in \Omega.$$

The pair (A_*, u_0) is an optimal solution of the problem (2.3) and the matrix A_* is a rank 2 composite constructed by means of matrices from $\mathcal{M}(\mathbf{d})$.

3. Properties of the set $W\mathcal{M}(\mathbf{d})$.

Lemma 3.1. *The set*

$$\Lambda = \left\{ \left(\frac{1}{\lambda_1(A)}, \lambda_n(A) \right) \in [L_2(\Omega)]^2 \mid A \in W\mathcal{M}(\mathbf{d}) \right\}$$

is convex and closed.

Proof. From the definitions of the sets $\Lambda(\mathbf{p})$, $\Lambda(\mathbf{d})$, and $W\mathcal{M}(\mathbf{d})$ it immediately follows that

$$\begin{aligned} \Lambda = \Bigg\{ &\left(\frac{1}{\lambda_1}, \lambda_n \right) \in [L_2(\Omega)]^2 \mid \lambda_1(x) \le \lambda_n(x) \text{ a.e. } x \in \Omega, \\ &\left(\frac{1}{\lambda_1(x)}, \lambda_n(x) \right) \le \left(\sum_{i=1}^N p_i(x) \frac{1}{\lambda_1(D_i)}, \sum_{i=1}^N p_i(x)\lambda_n(D_i) \right) \text{ a.e. } x \in \Omega, \\ &\mathbf{p} \in \mathcal{K}(\mathbf{d}) \Bigg\}. \end{aligned}$$

The set $\mathcal{K}(\mathbf{d})$ is convex and closed; therefore the set Λ is convex and closed too. □

Lemma 3.2. *Let $\mathbf{p} \in \mathcal{K}(\mathbf{d})$ and let the sequence $\{A_k\} \subset \mathcal{M}(\mathbf{d})$ be defined as*

$$\begin{aligned} &A_k(x) = \sum_{i=1}^N \theta_i^k(x) Q_i^k(x) D_i \left(Q_i^k(x)\right)^{-1} \text{ a.e. } x \in \Omega,\ k = 1, 2, \dots, \\ &Q_i^k(x) \in \mathcal{O} \text{ a.e. } x \in \Omega,\ i = 1, \dots, N,\ k = 1, 2, \dots, \qquad (3.1) \\ &\theta^k = (\theta_1^k, \dots, \theta_N^k) \in S,\ k = 1, 2, \dots, \\ &\theta^k \rightharpoonup \mathbf{p} \text{ weakly as } k \to \infty. \end{aligned}$$

If the sequence $\{A_k\}$ G-converges to a matrix A_0 then

$$(\lambda_1(A_0), \lambda_n(A_0)) \in \Lambda(\mathbf{p}).$$

Proof. Without loss of generality we can assume that the sequences $\{A_k\}$ and $\{A_k^{-1}\}$ weakly converge to A_+ and A_-^{-1}, respectively. It is well known (see, for instance, Zhikov, Kozlov, and Oleinik [15]) that

$$A_- \le A_0 \le A_+,$$

which gives that

$$\lambda_1(A_-)(x) \le \lambda_1(A_0)(x) \le \lambda_n(A_0)(x) \le \lambda_n(A_+)(x) \text{ a.e. } x \in \Omega. \tag{3.2}$$

On the other hand, for every fixed nonnegative $\varphi \in L_2(\Omega)$

$$\begin{aligned}&\int_\Omega \frac{1}{\lambda_1(A_-)}\varphi dx \le \lim_{k\to\infty}\int_\Omega \max_{|\xi(x)|\le 1}\langle A_k^{-1}(x)\xi(x),\xi(x)\rangle\varphi dx\\ &= \lim_{k\to\infty}\int_\Omega \max_{|\xi(x)|\le 1}\left\langle \sum_{i=1}^N \theta_i^k(x)Q_i^k(x)D_i^{-1}\left(Q_i^k(x)\right)^{-1}\xi(x),\xi(x)\right\rangle\varphi dx\\ &\le \lim_{k\to\infty}\int_\Omega \sum_{i=1}^N \theta_i^k\frac{1}{\lambda_1(D_i)}\varphi dx = \int_\Omega \sum_{i=1}^N p_i\frac{1}{\lambda_1(D_i)}\varphi dx.\end{aligned}$$

Analogously, for every nonnegative $\varphi \in L_2(\Omega)$,

$$\int_\Omega \lambda_n(A_+)\varphi dx \le \int_\Omega \sum_{i=1}^N p_i\lambda_n(D_i)\varphi dx.$$

Both these estimates together with (3.2) give that

$$\begin{gathered}\frac{1}{\lambda_1(A_0)(x)} \le \frac{1}{\lambda_1(A_-)(x)} \le \sum_{i=1}^N p_i(x)\frac{1}{\lambda_1(D_i)} \text{ a.e. } x\in\Omega,\\ \lambda_n(A_0)(x) \le \lambda_n(A_+)(x) \le \sum_{i=1}^N p_i(x)\lambda_n(D_i) \text{ a.e. } x\in\Omega,\end{gathered}$$

which proves the statement of Lemma 3.2. □

LEMMA 3.3. *Let $\mathbf{p} \in \mathcal{K}(\mathbf{d})$, let $(\lambda_1^0, \lambda_n^0) \in \Lambda_0(\mathbf{p})$, and let $(\mathbf{l}_1, \dots, \mathbf{l}_n)$ be an n-tuple of measurable vector functions orthonormed at a.e. $x \in \Omega$. Let the functions $\mathbf{p}, \mathbf{l}_1, \dots, \mathbf{l}_n$ be piecewise constant with one and the same partition $\Omega = \Omega_1 \cup \dots \cup \Omega_m$.*

Then there exists a sequence of matrices $A_k \in \mathcal{M}(\mathbf{d})$, $k = 1, 2, \dots$, of the type (3.1) such that

- (i) *$\{A_k\}$ G-converges to a matrix $A_0 \in G\mathcal{M}(\mathbf{d})$ and $(\lambda_1(A_0), \lambda_n(A_0)) = (\lambda_1^0, \lambda_n^0)$ in Ω, $A_0\mathbf{l}_j = \lambda_j(A_0)\mathbf{l}_j$ in Ω, $j = 1, \dots, n$;*
- (ii) *$A_k \rightharpoonup A_+$ weakly as $k \to \infty$ and $\lambda_n(A_+) = \lambda_n^0$ in Ω;*
- (iii) *$A_k^{-1} \rightharpoonup A_-^{-1}$ weakly as $k \to \infty$ and $\lambda_1(A_-) = \lambda_1^0$ in Ω;*
- (iv) *the functions θ^k in the representation (3.1) of matrices A_k satisfy $\int_{\Omega_r}\theta_i^k dx = \int_{\Omega_r} p_i dx$, $i = 1, \dots, N$, $r = 1, \dots, m$, $k = 1, 2, \dots$, $\theta^k \rightharpoonup \mathbf{p}$ weakly as $k \to \infty$;*
- (v) *in every Ω_r, $r = 1, \dots, m$, $A_k(x) = A_k(\langle x, \mathbf{l}_1(x)\rangle)$, $k = 1, 2, \dots$.*

Proof. Let $Q = Q(x)$, $x \in \Omega$, be a matrix such that its jth column is equal to $\mathbf{l}_j$, $j = 1, \dots, n$, respectively. It is obvious that $Q(x) \in \mathcal{O}$ a.e. $x \in \Omega$. Define the matrices A_k as

$$
\begin{aligned}
&A_k(x) = \sum_{i=1}^{N} \theta_i^k(x) Q(x) D_i Q^{-1}(x) \ \text{ a.e. } x \in \Omega,\\
&(\theta_1^k, \dots, \theta_N^k) = \theta^k \in S,\\
&\int_{\Omega_r} (\theta_i^k - p_i) dx = 0, \ \ i = 1, \dots, N, \ \ r = 1, \dots, m, \ \ k = 1, 2, \dots,\\
&\theta^k(x) = \theta^k(\langle x, \mathbf{l}_1(x)\rangle) \ \text{ a.e. } x \in \Omega,\\
&\theta^k \rightharpoonup \mathbf{p} \text{ weakly as } k \to \infty.
\end{aligned}
\tag{3.3}
$$

By construction $A_k \in \mathcal{M}(\mathbf{d})$, $k = 1, 2, \dots,$ and in every Ω_r, $r = 1, \dots, m$, $A_k(x) = A_k(\langle x, \mathbf{l}_1\rangle)$, $k = 1, 2, \dots$.

The function $\mathbf{l}_1$ is constant in every Ω_r, $r = 1, \dots, m$; therefore, by the well-known formulae for layered structures and by the locality properties of the G-convergence (see, for instance, Zhikov, Kozlov, and Oleinik [15]) the sequence $\{A_k\}$ defined by (3.3) has properties (i)–(v). □

LEMMA 3.4. *Let $\mathbf{p} \in \mathcal{K}(\mathbf{d})$, let $(\lambda_1^0, \lambda_n^0) \in \Lambda_0(\mathbf{p})$ and let $(\mathbf{l}_1, \dots, \mathbf{l}_n)$ be an n-tuple of measurable vector functions orthonormed at a.e. $x \in \Omega$. Then there exists a matrix $A_0 \in G\mathcal{M}(\mathbf{d})$ such that*

(i) *A_0 is the rank 1 composite defined by means of matrices from $\mathcal{M}(\mathbf{d})$;*

(ii) *$(\lambda_1(A_0), \lambda_n(A_0)) = (\lambda_1^0, \lambda_n^0)$ in Ω;*

(iii) *the eigenvectors of A_0 are equal to $\mathbf{l}_1, \dots, \mathbf{l}_n$, respectively, i.e.,*

$$A_0 \mathbf{l}_j = \lambda_j(A_0) \mathbf{l}_j \ \ \textit{in } \Omega, \ \ j = 1, \dots, n.$$

Proof. For every integer $s = 1, 2, \dots,$ there exist piecewise approximations $\mathbf{p}^s, \mathbf{l}_1^s, \dots, \mathbf{l}_n^s$ of $\mathbf{p}, \mathbf{l}_1, \dots, \mathbf{l}_n$, respectively, with one and the same partition

$$\Omega = \Omega_1^s \cup \dots \cup \Omega_{m_s}^s$$

(the corresponding approximations $(\lambda_1^s, \lambda_n^s)$ for $(\lambda_1^0, \lambda_n^0)$ are uniquely defined by $\mathbf{p}^s$) such that

$$
\begin{aligned}
&\mathbf{p}^s \to \mathbf{p} \ \text{ strongly as } \ s \to \infty,\\
&\mathbf{l}_j^s \to \mathbf{l}_j \ \text{ strongly as } s \to \infty, \ \ j = 1, \dots, n,\\
&\int_\Omega p_i^s dx = \int_\Omega p_i dx, \ \ i = 1, \dots, N, \ \ s = 1, 2, \dots,
\end{aligned}
\tag{3.4}
$$

such that $\mathbf{p}^s \in \mathcal{K}(\mathbf{d})$, $s = 1, 2, \dots,$ and such that every n-tuple $(\mathbf{l}_1^s, \dots, \mathbf{l}_n^s)$ is orthonormed at a.e. $x \in \Omega$. Our approximations satisfy the assumptions of Lemma 3.3; hence, there exist piecewise constant matrices $A^s \in G\mathcal{M}(\mathbf{d})$, $s = 1, 2, \dots,$ such that every matrix A_s is obtained by means of a rank 1 laminated structure from matrices from $\mathcal{M}(\mathbf{d})$ and

$$
\begin{aligned}
&\lambda_1(A_s) = \left(\sum_{i=1}^{N} p_i^s \frac{1}{\lambda_1(D_i)} \right)^{-1} \ \ \text{ in } \Omega,\\
&\lambda_j(A_s) = \sum_{i=1}^{N} p_i^s \lambda_j(D_i) \ \text{ in } \Omega, \ \ j = 2, \dots, n,\\
&A_s \mathbf{l}_j^s = \lambda_j(A_s) \mathbf{l}_j^s \ \text{ in } \Omega, \ \ j = 1, \dots, n,\\
&s = 1, 2, \dots.
\end{aligned}
$$

Here we have used the fact that the eigenvalues $\lambda_j(A_0),\ j=2,\dots,n$, in the construction of A_0 in the proof of Lemma 3.3 are the limits of the sequences $\{\lambda_j(A_k)\},\ j=2,\dots,n$, respectively.

Now, from the strong convergences (3.4) it follows immediately that the sequence $\{A_s\}$ converges strongly to a matrix A_0 which has the properties (i)–(iii). In turn, the standard diagonal process (matrices A_s are G-limit matrices for sequences from $\mathcal{M}(\mathbf{d})$) gives that $A_0 \in G\mathcal{M}(\mathbf{d})$. □

LEMMA 3.5. *The set $W\mathcal{M}(\mathbf{d})$ is G-closed.*

Proof. Let the sequence $\{A_k\} \subset W\mathcal{M}(\mathbf{d})$ G-converges to a matrix A_0. Without losing generality we can assume that

$$\begin{aligned}&A_k \rightharpoonup A_+ \text{ weakly as } k\to\infty,\\ &A_k^{-1} \rightharpoonup A_-^{-1} \text{ weakly as } k\to\infty.\end{aligned}$$

Since $(\lambda_1(A_k),\lambda_n(A_k)) \in \Lambda(\mathbf{p}^k)$ for some $\mathbf{p}^k \in \mathcal{K}(\mathbf{d}),\ k=1,2,\dots$, then

$$\left(\frac{1}{\lambda_1(A_k)},\lambda_n(A_k)\right) \le \left(\sum_{i=1}^N p_i^k \frac{1}{\lambda_1(D_i)},\sum_{i=1}^N p_i^k\lambda_n(D_i)\right) \text{ in } \Omega,\quad k=1,2,\dots. \tag{3.5}$$

Let $\mathbf{p}^k \rightharpoonup \mathbf{p}^0$ weakly as $k\to\infty$. Analogously to the proof of Lemma 3.2, from estimate (3.5) we obtain that

$$\left(\frac{1}{\lambda_1(A_0)},\lambda_n(A_0)\right) \le \left(\sum_{i=1}^N p_i^0 \frac{1}{\lambda_1(D_i)},\sum_{i=1}^N p_i^0\lambda_n(D_i)\right) \text{ in } \Omega.$$

The set $\mathcal{K}(\mathbf{d})$ is weakly closed; hence, $\mathbf{p}^0 \in \mathcal{K}(\mathbf{d})$ and $(\lambda_1(A_0),\lambda_n(A_0)) \in \Lambda(\mathbf{p}^0)$, which gives the inclusion $A_0 \in W\mathcal{M}(\mathbf{d})$. □

LEMMA 3.6. *Let $\mathbf{p} \in \mathcal{K}(\mathbf{d})$ and let $(\lambda_1^0,\lambda_n^0) \in \Lambda_0(\mathbf{p})$. Then there exists a pair of functions $(\alpha,\beta) = (\alpha(t,x),\beta(t,x)),(t,x) \in [0,1]\times\Omega$, such that these functions are continuous in t for a.e. $x\in\Omega$, measurable in x and that*

$$\begin{aligned}&(\alpha(t,x),\beta(t,x)) \in \Lambda(\mathbf{p})(x) \quad a.e.\ x\in\Omega,\quad 0\le t\le 1,\\ &(\alpha(0,x),\beta(0,x)) = \left(\lambda_1^0(x),\lambda_n^0(x)\right) \quad a.e.\ x\in\Omega,\\ &\alpha(1,x)=\beta(1,x) \quad a.e.\ x\in\Omega.\end{aligned}$$

In addition, for every fixed measurable-in-x function $\theta=\theta(x),x\in\Omega$, such that $0\le\theta(x)\le 1$ a.e. $x\in\Omega$, and every fixed measurable n-tuple $(\mathbf{l}_1,\dots,\mathbf{l}_n)$ of orthonormed at a.e. $x\in\Omega$ vector functions there exists a rank 2 composite $A_\theta \in G\mathcal{M}(\mathbf{d})$ such that

$$\begin{aligned}&(\lambda_1(A_\theta)(x),\lambda_n(A_\theta)(x)) = (\alpha(\theta(x),x),\beta(\theta(x),x)) \quad a.e.\ x\in\Omega,\\ &A_\theta\mathbf{l}_j = \lambda_j(A_\theta)\mathbf{l}_j \ in\ \Omega,\quad j=1,\dots,n.\end{aligned}$$

Proof. Let Q be a matrix such that its jth column is equal to $\mathbf{l}_j,\ j=1,\dots,n$. By virtue of Lemma 3.4 and Corollary 3.1 there exists a rank 1 composite $B_0 \in G\mathcal{M}(\mathbf{d})$

such that

$$\begin{aligned}
&B_0 = Q\mathrm{diag}\,(\lambda_1(B_0),\dots,\lambda_n(B_0))\,Q^{-1} \ \text{ in } \Omega,\\
&(\lambda_1(B_0),\lambda_n(B_0)) = (\lambda_1^0,\lambda_n^0) \ \text{ in } \Omega,\\
&B_0 = \text{G-limit} \sum_{i=1}^{N} \theta_i^k Q D_i Q^{-1},\\
&\int_\Omega \theta_i^k dx = \int_\Omega p_i dx, \ i=1,\dots,N, \ \ k=1,2,\dots,\\
&\theta^k \rightharpoonup \mathbf{p} \ \text{ weakly as } k\to\infty.
\end{aligned}$$

Analogously, if we use, instead of the matrices D_i, the clusters of matrices $\{\mathrm{diag}\,(\lambda_{j_1}(D_i),\dots,\lambda_{j_n}(D_i))\}$ with different order of eigenvalues on the diagonal and using layers orthogonal to $\mathbf{l}_1$ or $\mathbf{l}_n$ we obtain rank 1 composites $B_1, B_2 \in G\mathcal{M}(\mathbf{d})$ such that

$$\begin{aligned}
&B_1 = Q\mathrm{diag}(\lambda_1^0, a,\dots,a,\lambda_n^0)Q^{-1} \ \text{ in } \Omega,\\
&B_2 = Q\mathrm{diag}(\lambda_n^0, a,\dots,a,\lambda_1^0)Q^{-1} \ \text{ in } \Omega,\\
&a = \frac{1}{n-2}\,(\lambda_2(B_0)+\dots+\lambda_{n-1}(B_0)) \ \text{ in } \Omega.
\end{aligned}$$

Both matrices B_1 and B_2 locally at a.e. $x\in\Omega$ are the rank 1 composites constructed by means of the matrices D_i (and their rotations) taken in the proportions defined by $\mathbf{p}(x)$. The only difference is that the matrix B_1 is constructed by means of layers orthogonal to $\mathbf{l}_1$ (more precisely to approximations of $\mathbf{l}_1$) but the matrix B_2 is constructed by means of layers orthogonal to $\mathbf{l}_n$.

Hence, every matrix of the type

$$\begin{aligned}
&B = \theta B_2 + (1-\theta)B_1,\\
&\theta\in L_2(\Omega), \ \ \theta(x) = 0 \text{ or } 1 \ \text{ a.e. } x\in\Omega
\end{aligned}$$

has the same local distribution of involved matrices and B is a rank 1 composite constructed by means of matrices from $\mathcal{M}(\mathbf{d})$.

Let $Q_s, \lambda_1^s, a^s, \lambda_n^s, s = 1,2,\dots,$ be piecewise approximations in the norm of $[L_2(\Omega)]^{n\times n}$ or $L_2(\Omega)$ of the matrix Q and the functions $\lambda_1^0, a, \lambda_n^0$, respectively, with one and the same partition of Ω for a chosen s. Let $\mathbf{l}_1^s$ be the first column of Q_s and let

$$\begin{aligned}
&B_1^s = Q_s\mathrm{diag}(\lambda_1^s, a^s,\dots,a^s,\lambda_n^s)Q_s^{-1} \ \text{ in } \Omega,\\
&B_2^s = Q_s\mathrm{diag}(\lambda_n^s, a^s,\dots,a^s,\lambda_1^s)Q_s^{-1} \ \text{ in } \Omega.
\end{aligned}$$

For a given $\theta\in L_2(\Omega)$, $\ 0\le\theta(x)\le 1$ a.e. $x\in\Omega$, define the sequence

$$C_k^s = \theta_{ks}B_2^s + (1-\theta_{ks})B_1^s, \ \ k=1,2,\dots,$$

where

$$\begin{aligned}
&\theta_{ks}(x) = 0 \ \text{ or } 1 \ \text{ a.e. } x\in\Omega, \ \ k=1,2,\dots,\\
&\theta_{ks} \rightharpoonup \theta \text{ weakly as } k\to\infty, \ \ s=1,2,\dots,\\
&\theta_{ks}(x) = \theta_{ks}\left(\langle x, \mathbf{l}_1^s\rangle\right), \ \ k,s = 1,2,\dots.
\end{aligned}$$

For every fixed $s = 1, 2, \dots,$ the sequence $\{C^s_k\}$ G-converges as $k \to \infty$ to the matrix

$$C^s = Q_s \mathrm{diag}\left(\left(\frac{1-\theta}{\lambda_1^s} + \frac{\theta}{\lambda_n^s}\right)^{-1}, a^s, \dots, a^s, (1-\theta)\lambda_n^s + \theta\lambda_1^s\right) Q_s^{-1} \text{ in } \Omega.$$

In turn, the sequence $\{C^s\}$ converges strongly as $s \to \infty$ to the matrix

$$C_\theta = Q \mathrm{diag}\left(\left(\frac{1-\theta}{\lambda_1^0} + \frac{\theta}{\lambda_n^0}\right)^{-1}, a, \dots, a, (1-\theta)\lambda_n^0 + \theta\lambda_1^0\right) Q^{-1} \text{ in } \Omega. \tag{3.6}$$

The matrix C_θ belongs to $G\mathcal{M}(\mathbf{d})$ and C_θ is a rank 2 composite.

Let us represent the domain Ω as $\Omega = E_1 \cup E_2$, where

$$\begin{aligned} E_1 &= \{x \in \Omega \quad | \quad a(x) \le \left(\lambda_1^0(x)\, \lambda_n^0(x)\right)^{1/2}\}, \\ E_2 &= \{x \in \Omega \quad | \quad a(x) > \left(\lambda_1^0(x)\, \lambda_n^0(x)\right)^{1/2}\}. \end{aligned}$$

Define the function $h_1 = h_1(x), x \in \Omega$, as the solution of the equation

$$\frac{1-h_1}{\lambda_1^0(x)} + \frac{h_1}{\lambda_n^0(x)} = \frac{1}{a(x)}, \quad x \in \Omega;$$

the function $h_2 = h_2(x),\ x \in \Omega$, as the solution of the equation

$$(1-h_2)\lambda_n^0(x) + h_2\lambda_1^0(x) = a(x), \quad x \in \Omega;$$

and the functions h_-, h_+ as

$$\begin{aligned} h_+(x) &= \max\{h_1(x); h_2(x)\}, \quad x \in \Omega, \\ h_-(x) &= \min\{h_1(x); h_2(x)\}, \quad x \in \Omega. \end{aligned}$$

By construction

$$\begin{aligned} 0 \le h_-(x) = h_1(x) \le h_2(x) = h_+(x) \le 1 \ \text{ in } E_1, \\ 0 \le h_-(x) = h_2(x) \le h_1(x) = h_+(x) \le 1 \ \text{ in } E_2. \end{aligned}$$

Now we are able to define the functions α and β:

$$\begin{aligned} &(\alpha(t,x), \beta(t,x)) = \left(\left(\frac{1-t}{\lambda_1^0(x)} + \frac{t}{\lambda_n^0(x)}\right)^{-1}, (1-t)\lambda_n^0(x) + t\lambda_1^0\right), \\ &\qquad x \in \Omega, \quad 0 \le t \le h_-(x), \\ &(\alpha(t,x), \beta(t,x)) = \left(a(x), (1-t)\lambda_n^0(x) + t\lambda_1^0(x)\right), \\ &\qquad x \in E_1, \quad h_-(x) < t < h_+(x), \\ &(\alpha(t,x), \beta(t,x)) = \left(\left(\frac{1-t}{\lambda_1^0(x)} + \frac{t}{\lambda_n^0(x)}\right)^{-1}, a(x)\right), \\ &\qquad x \in E_2, \quad h_-(x) < t < h_+(x), \\ &(\alpha(t,x), \beta(t,x)) = (a(x), a(x)), \ x \in \Omega, \quad h_+(x) \le t \le 1. \end{aligned} \tag{3.7}$$

By construction the pair (α, β) has the desired properties and

$$(\lambda_1(C_\theta)(x), \lambda_n(C_\theta)(x)) = (\alpha(\theta(x), x), \beta(\theta(x), x)), \ x \in \Omega, \quad 0 \le \theta(x) \le h_+(x).$$

For $0 \le \theta(x) \le h_{\text{-}}(x)$ the eigenvectors $\mathbf{1}_1(x)$ and $\mathbf{1}_n(x)$ correspond to $\lambda_1(C_\theta)(x)$ and $\lambda_n(C_\theta)(x)$, respectively. However, for $h_{\text{-}}(x) \le \theta(x) \le h_t(x)$, in E_1 the eigenvectors $\mathbf{1}_j(x), j = 1, \dots, n-1$, and $\mathbf{1}_n(x)$ and in E_2 the eigenvectors $\mathbf{1}_1(x)$ and $\mathbf{1}_j(x)$, $j = 2, \dots, n$, respectively, correspond to $\lambda_1(C_\theta)(x)$ and $\lambda_n(C_\theta)(x)$.

Since the set $\mathcal{M}(\mathbf{d})$ is invariant with respect to rotations then together with the matrix $C_\theta \in G\mathcal{M}(\mathbf{d})$ the set $G\mathcal{M}(\mathbf{d})$ contains the matrix

$$A_\theta = Q\text{diag}\left(\lambda_1(C_\theta), \dots, \lambda_n(C_\theta)\right) Q^{-1} \ \text{ in } \Omega$$

which has the needed properties. It is obvious that the matrix A_θ is a rank 2 composite too. □

4. The extended problem. In this section we give the proofs of Theorems 2.1–2.3.

To begin with we will recall some properties of symmetric matrices.

Let $A \in \mathcal{M}(\nu, \mu)$ and let $\mathbf{a}, \mathbf{b} \in [L_2(\Omega)]^n$, $\mathbf{a}(x) \ne 0,\ \mathbf{b}(x) \ne 0$ a.e. $x \in \Omega$. Suppose that

$$A\mathbf{a} = \mathbf{b} \ \text{ in } \Omega.$$

Then there exists a matrix $A' \in \mathcal{M}(\nu, \mu)$ such that

$$\begin{gathered} \lambda_1(A') = \lambda_1(A), \ \ \lambda_2(A') = \dots = \lambda_n(A') \le \lambda_n(A) \ \text{ in } \Omega, \\ A'\mathbf{a} = \mathbf{b} \ \text{ in } \Omega. \end{gathered}$$

Furthermore, there exists a family of measurable symmetric $n \times n$ matrix functions $B_\tau,\ \tau < 0$, defined as

$$\begin{aligned} &\lambda_1(B_\tau)(x) = \tau F(x) + G(x) \ \text{ a.e. } x \in \Omega, \\ &\lambda_2(B_\tau)(x) = \dots = \lambda_n(B_\tau)(x) = -\frac{1}{\tau}F(x) + G(x) \ \text{ a.e. } x \in \Omega, \\ &\mathbf{l}_1(B_\tau) = \frac{\mathbf{b} - \lambda_n(B\tau)\mathbf{a}}{|\mathbf{b} - \lambda_n(B_\tau)\mathbf{a}|} \ \text{ in } \Omega, \\ &\mathbf{l}_n(B_\tau) = \frac{\mathbf{b} - \lambda_1(B_\tau)\mathbf{a}}{|\mathbf{b} - \lambda_1(B_\tau)\mathbf{a}|} \ \text{ in } \Omega, \end{aligned} \tag{4.1}$$

where

$$F(x) = \frac{\left(|\mathbf{a}(x)|^2|\mathbf{b}(x)|^2 - (\langle\mathbf{a}(x), \mathbf{b}(x)\rangle)^2\right)^{1/2}}{|\mathbf{a}(x)|^2} \ \text{ a.e. } x \in \Omega,$$

$$G(x) = \frac{\langle\mathbf{a}(x), \mathbf{b}(x)\rangle}{|\mathbf{a}(x)|^2} \ \text{ a.e. } x \in \Omega,$$

such that

$$B_\tau\mathbf{a} = \mathbf{b} \ \text{ in } \Omega.$$

In addition, for a.e. $x \in \Omega$ there exists $\tau = \tau(x)$ such that

$$B_{\tau(x)}(x) = A'(x).$$

Here by $\mathbf{l}_1(B_\tau)$ and $\mathbf{l}_n(B_\tau)$ we denote the eigenvectors of B_τ which correspond to $\lambda_1(B_\tau)$ and $\lambda_n(B_\tau)$, respectively. It is clear that for a.e. $x \in \Omega$ the vectors $\mathbf{a}(x)$ and $\mathbf{b}(x)$ belong to the linear hull of $(\mathbf{l}_1(B_\tau), \mathbf{l}_n(B_\tau))$.

All these results can be found in Raitums [10], [11].

Proof of Theorem 2.1. Because $\mathcal{M}(\mathbf{d}) \subset W\mathcal{M}(\mathbf{d})$ and the set $W\mathcal{M}(\mathbf{d})$ is G-closed then $G\mathcal{M}(\mathbf{d}) \subset W\mathcal{M}(\mathbf{d})$ and, as a consequence,

$$Z\left(G\mathcal{M}(\mathbf{d}), f\right) \subset Z\left(W\mathcal{M}(\mathbf{d}), f\right) \ \forall\, f \in H^{-1}(\Omega).$$

Let $u_0 \in Z\left(W\mathcal{M}(\mathbf{d}), f\right)$, i.e., there exists a matrix $A_0 \in W\mathcal{M}(\mathbf{d})$ such that

$$\mathrm{div} A_0 \nabla u_0 = f \ \text{ in } \Omega.$$

Since $A_0 \in W\mathcal{M}(\mathbf{d})$ then there exists a $\mathbf{p}^0 \in \mathcal{K}(\mathbf{d})$ such that $(\lambda_1(A_0), \lambda_n(A_0)) \in \Lambda(\mathbf{p}^0)$. Let $(\lambda_1^0, \lambda_n^0) \in \Lambda_0(\mathbf{p}^0)$. We point out that the pair $(\lambda_1^0, \lambda_n^0) \in \Lambda_0(\mathbf{p}^0)$ is uniquely defined by $\mathbf{p}^0$.

By virtue of Lemma 3.6 there exists a pair of functions $(\alpha, \beta) = (\alpha(t,x), \beta(t,x))$ such that these functions are continuous in t for a.e. $x \in \Omega$ and that for a.e. $x \in \Omega$ the curve $(\alpha(t,x), \beta(t,x))\,,\ 0 \le t \le 1$, connect the point $\big(\lambda_1^0(x), \lambda_n^0(x)\big)$ with the bisectrix $\lambda_1 = \lambda_n$. This curve belongs to $\Lambda(\mathbf{p}^0)(x)$.

On the other hand, there exists a family of matrices B_τ defined by formulae (4.1) with $\mathbf{a} = \nabla u_0,\ \mathbf{b} = A_0 \nabla u_0$ such that

$$B_\tau \nabla u_0 = A_0 \nabla u_0 \text{ in } \Omega,$$

and for some $\tau = \tau(x)$

$$\big(\lambda_1(B_{\tau(x)})(x), \lambda_n(B_{\tau(x)})(x)\big) \in \Lambda(\mathbf{p}^0)(x) \text{ a.e. } x \in \Omega.$$

The matrices B_τ continuously depend on τ for a.e. $x \in \Omega$.

Because the functions $\lambda_1(B_\tau)(x)$ and $\lambda_n(B_\tau)(x)$ are increasing then for a.e. $x \in \Omega$ the curves $(\alpha(t,x), \beta(t,x))$ and $(\lambda_1(B_\tau)(x), \lambda_n(B_\tau)(x))$ intersect, i.e., there exist measurable functions $\tau = \tau(x),\ t = t(x)$ such that

$$\big(\lambda_1(B_{\tau(x)})(x), \lambda_n(B_{\tau(x)})(x)\big) = \big(\lambda_1(C_{t(x)})(x), \lambda_n(C_{t(x)})(x)\big) \text{ a.e. } x \in \Omega$$

(the matrix $C_{t(.)}$ we take from the proof of Lemma 3.6) and that

$$B_{\tau(x)}(x) \nabla u_0(x) = A_0(x) \nabla u_0(x) \text{ a.e. } x \in \Omega.$$

We remind the reader that for a.e. $x \in \Omega$ the vectors $\nabla u_0(x)$ and $A_0(x) \nabla u_0(x)$ always belong to the linear hull of $\big(\mathbf{l}_1(B_{\tau(x)})(x), \mathbf{l}_n(B_{\tau(x)})(x)\big)$.

The set $GM(\mathbf{d})$ is invariant with respect to rotations; hence, $GM(\mathbf{d})$ contains a matrix C such that its eigenvalues coincide with the eigenvalues of $C_{t(.)}$, and its eigenvectors coincide with the eigenvectors of $B_{\tau(.)}$. Thus, we have obtained a matrix C such that

(1) $C \in G\mathcal{M}(\mathbf{d})$ and C is a rank 2 composite constructed by means of matrices from $\mathcal{M}(\mathbf{d})$;
(2) $(\lambda_1(C), \lambda_n(C)) \in \Lambda(\mathbf{p}^0)$ in Ω;
(3) $C \nabla u_0 = A_0 \nabla u_0$ in Ω.

The properties of the matrix C give that

$$\mathrm{div} C \nabla u_0 = f \ \text{ in } \Omega,$$

i.e., that $u_0 \in Z(G\mathcal{M}(\mathbf{d}), f)$. Hence, $Z(W\mathcal{M}(\mathbf{d}), f) = Z(G\mathcal{M}(\mathbf{d}), f)$ for every $f \in H^{-1}(\Omega)$. Since the set $Z(G\mathcal{M}(\mathbf{d}), f)$ is closed in the weak topology of $H_0^1(\Omega)$ then the set $Z(W\mathcal{M}(\mathbf{d}), f)$ is closed in the weak topology of $H_0^1(\Omega)$ too. □

Proof of Theorem 2.2. The statement of Theorem 2.2 is equal to the statement of Lemma 3.5. □

Proof of Theorem 2.3. Since the functional I in the problem (2.4) is weakly continuous on $H_0^1(\Omega)$ and the set $Z(W\mathcal{M}(\mathbf{d}), f)$ is closed in the weak topology of $H_0^1(\Omega)$ then the functional I attains its minimum on $Z(W\mathcal{M}(\mathbf{d}), f)$ at an element u_0. By the definition of $Z(W\mathcal{M}(\mathbf{d}), f)$ there exists a matrix $A_0 \in W\mathcal{M}(\mathbf{d})$ such that

$$\mathrm{div} A_0 \nabla u_0 = f \text{ in } \Omega.$$

Hence, the pair (A_0, u_0) is an optimal solution of the problem (2.4).

In turn, if we put $A_* = C$, where the matrix C is defined in the proof of Theorem 2.1, then A_* satisfies all demands of the statement of Theorem 2.3. □

In conclusion we point out only that Lemma 3.6 and the proof of Theorem 2.1 give a possibility of constructing a minimizing sequence for the initial problem (2.2) via the knowledge of an optimal solution (A_0, u_0) of the problem (2.4).

Indeed, the knowledge of the matrix A_0 gives a $\mathbf{p}^0 \in \mathcal{K}(\mathbf{d})$ with $(\lambda_1(A_0), \lambda_n(A_0)) \in \Lambda(\mathbf{p}^0)$ and the pair $(\lambda_1^0, \lambda_n^0) \in \Lambda_0(\mathbf{p}^0)$. Lemma 5.6 gives the construction for the pair (α, β). In reality the functions α and β do not depend on the eigenvectors of the matrix A_0. In turn, the knowledge of the pair $(\nabla u_0, A_0 \nabla u_0)$ gives the necessary data for the construction of the family $\{B_\tau\}$ in the proof of Theorem 2.1.

After computing intersection points $r(x)$ for the curves $(\alpha(t,x), \beta(t,x))$ and $(\lambda_1(B_\tau)(x), \lambda_n(B_\tau)(x))$ we will know the matrix C from the proof of Theorem 2.1. Finally, the construction of the matrices C_θ from the proof of Lemma 3.6 gives the matrices $A_k \in \mathcal{M}(\mathbf{d})$, $k = 1, 2, \ldots$, for the minimizing sequence $\{(A_k, u_k)\}$ in the problem (2.2).

From the point of view of applications it is more convenient from the very beginning to start with piecewise approximations of A_0 and ∇u_0. After that all steps in the construction of the minimizing sequence of controls $\{A_k\}$ become simple and clear, especially the construction of the rank 2 composites.

Acknowledgment. The author is indebted to unknown referees who considerably improved the exposition of this paper.

RISK-SENSITIVE CONTROL OF FINITE STATE MACHINES ON AN INFINITE HORIZON II*

WENDELL H. FLEMING† AND DANIEL HERNÁNDEZ-HERNÁNDEZ‡

Abstract. In this paper we present a sequel of [Fleming and Hernandez-Hernandez, *SIAM J. Control Optim.*, 35 (1997), pp. 1790–1810], extending those results to discrete time, output feedback (partial state information) systems. Our aim is to study both robust and risk-sensitive control of such systems on an infinite horizon. Appropriate information states are defined for each case, and dynamic programming results are obtained.

Key words. risk-sensitive control, robust control, dynamic games, information states

1. Introduction.

Risk-sensitive control provides a link between stochastic and robust control. Extensive literature can be found on this subject, covering different kinds of models. Jacobson [J] established for the first time this connection for linear systems, while for a continuous variable, finite time horizon, this idea was introduced by Whittle [W]. Nonlinear continuous variable models were considered in [F-McE, F-McE1], where Whittle's idea was given as a rigorous mathematical basis using viscosity solution methods. In addition, discrete time, finite horizon, output feedback systems were studied in [B-J, J-B-E], and the infinite horizon, state feedback case for finite state machines was treated in [F-HH]. See also [FG-M], where risk-sensitive control problems on a finite time horizon for hidden Markov models were considered.

In this paper we are concerned with the infinite horizon, partially observed, risk-sensitive control problem with finite state space and long run average cost. This problem is solved by defining an appropriate information state that turns out to be a sufficient statistic and an alternate risk-sensitive control problem with full state information. The optimal growth rate is expressed as the upper value of a stochastic dynamic game with average cost criteria. Introducing a discounted cost stochastic dynamic game (cf. [F-McE, HH-M]), we prove that its value function satisfies an Isaacs equation. By using the vanishing discount approach, it is shown that the risk-sensitive dynamic programming equation holds. We also derive an optimal output feedback control that is separated through the information state. See section 4.

It is well known that a partial state information dynamic game arises naturally when an output feedback H^{∞}-robust control is considered. In [B-J] (see also [J-B-E, J-B]) this game was studied for finite state systems on a finite time horizon. By introducing an information state, they define an equivalent dynamic game with complete state information. In section 5 we analyze this deterministic dynamic game with average cost per unit time criterion. Redefining the information state, we prove

the existence of a solution to the corresponding Isaacs equation without going through the small noise limit of the risk-sensitive dynamic programming equation, as was done in our previous work [F-HH]. When the upper value of this game is zero, it is shown that a robust output feedback control can be obtained from the Isaacs equation. We also analyze the case where the upper value is greater than zero, relating this fact to Dower and James's definition [D-J] of finite power gain.

The paper is organized as follows. To illustrate the ideas in a simple setting, in section 2 we consider uncontrolled finite state Markov chains. The risk-sensitive index is defined, and it is expressed in terms of a normalized information state. Also, it is characterized as the optimal value of a stochastic control problem with average cost criteria. Random perturbations of a finite state machine are considered in section 3, describing the strength of the perturbations through a parameter ε. The small noise limit is studied employing results from [F-HH]. In section 4 the partially observed risk-sensitive control problem is solved using estimates for products of random matrices. Finally, in section 5 we analyze the partial state information dynamic game described above.

2. The risk-sensitive index.

In this section we define the risk-sensitive index for a discrete time partially observed Markov process. Introducing an information state, we express the risk-sensitive index in terms of this completely observed state and study its related linear eigenvalue problem. Through this section no minimizing control is considered, and we postpone up to section 4 discussions involving risk-sensitive control problems.

Let $(\Omega, \mathcal{F}, \mathcal{P})$ be an underlying probability space, and let X be a finite set with N elements. On X consider a Markov chain $\{x_t\}$ with stationary transition probability matrix $P = (P_{xx'})$ and initial distribution θ_0. Further, let $\{y_t,\, t = 1, 2, \ldots\}$ be a stochastic process with state space Y, with Y a finite set with M elements, and with associated matrix $Q = (Q_{xy})$, where Q_{xy} is the probability of receiving message y when the state is x. The realizations of the process $\{y_t\}$ are referred to as the measurements (or observations) of the system. We denote by $\mathcal{Y}^t$ the σ-algebra $\sigma(y_1, \ldots, y_t)$, with $\mathcal{Y}^0 := \{\emptyset, \Omega\}$.

Throughout this section we assume the following.

(A) The transition matrix P is irreducible, and the matrix Q is positive (i.e., $Q_{xy} > 0$ for all x, y).

Given a nonnegative function l defined on X and the risk averse factor $\mu > 0$, the risk-sensitive index is defined by

$$\lambda := \lim_{T\to\infty} \frac{1}{\mu} \cdot \frac{1}{T} \log E_{\theta_0} \exp\left\{ \mu \sum_{t=0}^{T-1} l(x_t) \right\}. \tag{2.1}$$

Remark 2.1. Note that λ has nothing to do with the observation process, and therefore it could be studied by the methods developed in [F-HH]. However, in order to introduce the main ideas and make the presentation easier in section 4, we rewrite the expectation in (2.1) in terms of a normalized "information state" process θ_t and study by stochastic control methods its behavior as T goes to infinity. If $\theta_0 = \delta_x$ is a Dirac distribution, then (2.1) is the same as [F-HH, Formula (2.15)] with $\varepsilon = 1$.

Remark 2.2. In [B-J] (see also [J-B-E]) an output feedback risk-sensitive control problem on a finite horizon is considered, where an information state is derived that turns out to be a sufficient statistic. However, in order to solve the infinite horizon case, we have to introduce another statistic, which is just the normalization of the one introduced by Baras and James [B-J].

Let $\mathcal{G}^T$ be the σ-algebra $\sigma(x_0, \ldots, x_T; y_1, \ldots, y_T)$. Then (cf. [R-S]), there exists a probability measure $\mathcal{P}^+$ on $\mathcal{G}^T$ defined by

$$\mathcal{P}^+(x_0, x_1, \ldots, x_T; y_1, \ldots, y_T) = \prod_{t=0}^{T-1} \left[P_{x_t x_{t+1}} \cdot \frac{1}{M} \right] \theta_0(x_0) \tag{2.2}$$

such that $\mathcal{P}$ is absolutely continuous with respect to $\mathcal{P}^+$, with

$$\frac{d\mathcal{P}}{d\mathcal{P}^+} |_{\mathcal{G}^T} = \overline{L}_T =: \prod_{t=0}^{T-1} M Q_{x_{t+1} y_{t+1}}.$$

Moreover, under $\mathcal{P}^+$, y_t are independently and identically distributed random variables uniformly distributed, independent of $x_{t'}$ with $t' \leq t$, and x_t is a Markov chain with transition matrix P.

Let $V(\theta_0, T)$ be the expectation on the right-hand side of (2.1). Then, it can be written in terms of the probability measure $\mathcal{P}^+$ as

$$V(\theta_0, T) = E^+ \exp \left\{ \mu \sum_{t=0}^{T-1} l(x_t) \right\} \overline{L}_T.$$

Now we define the information state $\sigma_T \in \mathbb{R}^N$ by $\sigma_0 = \theta_0$ and

$$\sigma_T(x) = E^+ \left[I_{\{x_T = x\}} \exp \left\{ \mu \sum_{t=0}^{T-1} l(x_t) \right\} \overline{L}_T | \mathcal{Y}^T \right]. \tag{2.3}$$

It satisfies the recursion

$$\sigma_{T+1} = A(y_{T+1}) \sigma_T, \tag{2.4}$$

where $A(y)$ is the transpose matrix of $A^*(y)$ with entries

$$A^*(y)_{xx'} = M P_{xx'} Q_{x'y} e^{\mu l(x)}. \tag{2.5}$$

Then, relative to the norm $|\sigma| = \sum_{i=1}^N |\sigma^i|$, $\sigma \in \mathbb{R}^N$,

$$V(\theta_0, T) := E^+ |\sigma_T|. \tag{2.6}$$

Let $S := \{\theta \in \mathbb{R}^N : \theta^i \geq 0 \quad \text{and} \quad \sum_{i=1}^N \theta^i = 1\}$. We define $z_t := |\sigma_t|$ and the state information $\theta_t \in S$ by $\theta_t := \frac{\sigma_t}{|\sigma_t|}$, $t = 0, 1, \ldots$. Then, z_t and θ_t are solutions of the recursions

$$\begin{aligned} z_{t+1} &= z_t |A(y_{t+1}) \theta_t|, \\ z_0 &= 1, \end{aligned} \tag{2.7}$$

and

$$\theta_{t+1} = \frac{A(y_{t+1}) \theta_t}{|A(y_{t+1}) \theta_t|} =: F(\theta_t, y_{t+1}). \tag{2.8}$$

Therefore, defining $G(\theta, y) := \log |A(y)\theta|$, (2.6) can be rewritten in terms of $\{\theta_t\}$ and $\{y_t\}$ as

$$\begin{aligned} V(\theta_0, T) &= E^+ z_T \\ &= E^+ \exp \sum_{t=0}^{T-1} G(\theta_t, y_{t+1}). \end{aligned}$$

Thus, we have expressed $V(\theta_0, T)$ in terms of the completely observed state information $\{\theta_t\}$. On the other hand, with $\theta = \theta_0$,

$$V(\theta, T+1) = E^+ \left[e^{G(\theta, y_1)} V(\theta_1, T) \right]. \tag{2.9}$$

From (2.1), we expect that, for T large,

$$V(\theta, T) \approx \exp\{\rho T + W(\theta)\} \tag{2.10}$$

for some number ρ and function W. Then, from substituting formally (2.10) into (2.9), we should have

$$e^{\rho + W(\theta)} = E^+ \left[e^{G(\theta, y) + W(F(\theta, y))} \right]. \tag{2.11}$$

Note that, formally, e^W is a positive eigenfunction corresponding to the eigenvalue e^ρ of the operator

$$T\psi(\theta) = E^+ \left[e^{G(\theta, y)} \psi(F(\theta, y)) \right], \quad \psi \in C(S),$$

where $C(S)$ denotes the set of continuous functions on S.

On the other hand, if

$$\phi(x, T) := E_x \exp\left\{ \mu \sum_{t=0}^{T-1} l(x_t) \right\},$$

then (see [F-HH, Thm. 2.11])

$$\lambda = \lim_{T \to \infty} \frac{1}{\mu} \cdot \frac{1}{T} \log \phi(x, T).$$

In fact, from the Frobenius theory of positive matrices,

$$\phi(x, T) \approx e^{\mu \lambda T} \psi(x)$$

in the sense that the ratio tends to 1 as $T \to \infty$. Here ψ is a positive eigenvector corresponding to the eigenvalue $e^{\mu\lambda}$ of the matrix B with entries $B_{xx'} = e^{\mu l(x)} P_{xx'}$.

Hence,

$$V(\theta, T) = \langle \phi(\cdot, T), \theta \rangle \approx e^{\lambda T} \langle \psi, \theta \rangle,$$

and from (2.9) one gets that (2.11) holds with

$$\rho = \mu\lambda, \quad W(\theta) = \log\langle \psi, \theta \rangle.$$

Equation (2.11) has the following control interpretation. Let $P(Y)$ be the set of probability measures on Y, and define the set $\Pi \subset P(Y)$ by

$$\Pi := \left\{ \pi = (\pi^1, \dots, \pi^M) \in P(Y) : \pi^i > 0,\, i = 1, \dots, M \right\}.$$

Let ν be the uniform distribution on Y. We define the relative entropy function $I(\,\cdot\,\|\nu) : P(Y) \to \mathbb{R} \cup \{+\infty\}$ by

$$I(\pi \| \nu) = \begin{cases} \sum\limits_{i=1}^{M} \log(M \cdot \pi^i) \pi^i & \text{if} \quad \pi \in \Pi, \\ +\infty & \text{otherwise.} \end{cases}$$

Then, it can be proved that (see [D-E]), for any function $\psi : Y \to \mathbb{R}$,

$$\log \int e^{\psi} d\nu = \sup_{\pi \in \Pi} \left\{ \int \psi d\pi - I(\pi \| \nu) \right\}, \tag{2.12}$$

and the supremum is attained at the unique probability measure $\overline{\pi} \in \Pi$ given by

$$\overline{\pi}^i = \frac{\frac{1}{M} e^{\psi(y_i)}}{\int e^{\psi} d\nu}, \qquad i = 1, \ldots, M.$$

Therefore, using (2.12), and taking the logarithmic transformation on both sides of (2.11), the latter equation can be written as

$$\rho + W(\theta) = \sup_{\pi \in \Pi} \sum_{i=1}^{M} \left[W(F(\theta, y_i)) + G(\theta, y_i) - \log(M\pi^i) \right] \pi^i. \tag{2.13}$$

This equation corresponds to the dynamic programming equation of the following stochastic optimal control problem (cf. [F-HH]). The control set is Π, while the reward function is $K(\theta, \pi) = \sum_{i=1}^{M} \left[G(\theta, y_i) - \log(\pi^i M) \right] \pi^i$, with $(\theta, \pi) \in S \times \Pi$. An admissible control is a sequence $\tilde{\pi} = \{\tilde{\pi}_t\}$ of random variables taking values in Π such that $\tilde{\pi}_t$ is $\mathcal{Y}^t$-adapted for each $t = 0, 1, \ldots$. We denote by $\mathcal{A}$ the set of admissible controls. Given $\tilde{\pi} \in \mathcal{A}$, it induces a probability measure $\mathcal{P}^{\tilde{\pi}}$ on $(\Omega, \mathcal{Y}^{\infty})$ in the following way. For each cylinder set $A = [\omega \in \Omega | y_1(\omega) = i_1, \ldots, y_t(\omega) = i_t]$, we define

$$\mathcal{P}^{\tilde{\pi}}(A) := \tilde{\pi}_0(i_1) \cdot \tilde{\pi}_1(i_1)(i_2) \cdots \tilde{\pi}_{t-1}(i_1, \ldots, i_{t-1})(i_t).$$

Here $\tilde{\pi}_t$ is to be interpreted as the conditional probability distribution of y_t given $y_1, \ldots, y_{t-1}$. On the other hand, the stochastic dynamics of the state information θ_t are given by (2.8). Finally, the reward functional (to be maximized) is defined, for $\tilde{\pi} \in \mathcal{A}$ and $\theta \in S$ given, by

$$J^{\tilde{\pi}}(\theta) = \limsup_{T \to \infty} \frac{1}{T} E^{\tilde{\pi}} \sum_{t=0}^{T-1} \left[G(\theta_t, y_{t+1}) - I(\pi_{t+1} \| \nu) \right].$$

Actually, standard dynamic programming arguments show that

$$\rho = \sup_{\tilde{\pi} \in \mathcal{A}} J^{\tilde{\pi}}(\theta) \quad \text{for all} \quad \theta \in S.$$

LEMMA 2.3. *There exists a unique continuous solution (up to an additive constant) $W : S \to \mathbb{R}$ to the equation* (2.11).

Proof. As noted above, $W(\theta) = \log\langle \psi, \theta \rangle$ is one solution. Let $W_1, W_2 \in C(S)$ such that

$$e^{\rho + W_1(\theta)} = E^{+} \left[e^{G(\theta, y) + W_1(F(\theta, y))} \right]$$

and

$$e^{\rho + W_2(\theta)} = E^{+} \left[e^{G(\theta, y) + W_2(F(\theta, y))} \right].$$

Then, dividing the first equation by $e^{\rho + W_2(\theta)}$, we have that $Z(\cdot) := W_1(\cdot) - W_2(\cdot)$ satisfies the equation

$$e^{Z(\theta)} = \int e^{Z(F(\theta, y))} g(\theta, y) \nu(dy), \tag{2.14}$$

with $g(\theta, y) = \exp\{W_2(F(\theta, y)) - W_2(\theta) + G(\theta, y) - \rho\}$.

Let K be the stochastic kernel defined on S by

$$K(\theta, A) = \sum_{y \in Y} I_A(F(\theta, y))\nu(dy), \ \ \theta \in S, \ A \in \mathbb{B}(S).$$

In [K] it was proved that there exists a unique invariant measure $v \in P(S)$ corresponding to K. On the other hand, let $\tilde{K}$ be the stochastic kernel defined by

$$\tilde{K}(\theta, A) = \sum_{y \in Y} I_A(F(\theta, y))g(\theta, y)\nu(dy), \ \ \theta \in S, \ A \in \mathbb{B}(S).$$

Since $\tilde{K}$ is Feller and S is compact, there exists an invariant measure $\tilde{v} \in P(S)$ corresponding to this kernel (see Proposition 8.3.4 in [D-E]), and using the facts that v is unique and that $K(\theta, \cdot)$ is equivalent to $\tilde{K}(\theta, \cdot)$ for all $\theta \in S$, it follows that $\tilde{v}$ is unique. Then, from (2.14), we have that

$$e^{Z(\theta)} = \int e^Z \, d\tilde{v} \quad \text{for all} \quad \theta \in S. \qquad \square$$

3. Small noise limit. Let X and Y be the finite sets defined in section 2. Given the functions $f : X \to X$ and $g : X \to Y$, we consider the deterministic finite state machine

$$\left\{ \begin{array}{lcl} x_{t+1} & = & f(x_t), \ \ t = 0, 1, \ldots, \ x_0 = x, \\ y_{t+1} & = & g(x_{t+1}). \end{array} \right. \tag{3.1}$$

Further, we define a perturbed system $\sum$ by

$$\left\{ \begin{array}{lcl} x_{t+1} & = & b(x_t, \omega_t), \ \ t = 0, 1, \ldots, x_0 = x, \\ y_{t+1} & = & h(x_{t+1}, \omega_t), \end{array} \right. \tag{3.2}$$

where the exogenous inputs ω_t take values in a finite set Z and the functions $b : X \times Z \to X$ and $h : X \times Z \to Y$ are given. Also, in order to measure the magnitude of disturbances ω, we introduce the function $\vartheta : Z \to \mathbb{R}^+$.

Throughout this section we assume the following.

(A1) For each $x, x' \in X$ there exist T_1, $0 < T_1 < \infty$, and $\tilde{\omega} = (\omega_0, \ldots, \omega_{T_1 - 1}) \in Z^{T_1}$ such that for the initial condition $x_0 = x$ and input $\tilde{\omega}$, the system reaches x' after T_1 steps.

(A2) Given $x \in X$, $y \in Y$, there exists $\omega \in Z$ such that $y = h(x, \omega)$.

Let $\varphi_1 : X \times X \to \mathbb{R} \cup \{+\infty\}$ and $\varphi_2 : X \times Y \to \mathbb{R}$ be the functions defined by

$$\varphi_1(x, x') = \min_{\omega \in Z}\{\vartheta(\omega) : x' = b(x, \omega)\}$$

and

$$\varphi_2(x, y) = \min_{\omega \in Z}\{\vartheta(\omega) : y = h(x, \omega)\},$$

respectively, with the standard convention that the minimum over an empty set equals $+\infty$. The values $\varphi_1(x, x')$ and $\varphi_2(x', y)$ represent the minimum "magnitude" associated with the disturbances going from x to x' and x' to y in one time step.

We define the matrices $P^\varepsilon = (P^\varepsilon_{xx'})$, $Q^\varepsilon = (Q_{xy})$ by

$$P^\varepsilon_{xx'} = \frac{1}{Z_1^\varepsilon(x)} \exp \left\{ -\frac{\varphi_1(x,x')}{\varepsilon} \right\}$$

and

$$Q^\varepsilon_{xy} = \frac{1}{Z_2^\varepsilon(x)} \exp \left\{ -\frac{\varphi_2(x,y)}{\varepsilon} \right\},$$

where $\varepsilon > 0$ is a small noise parameter and $Z_1^\varepsilon, Z_2^\varepsilon$ are normalizing constants satisfying $\sum_{x'} P^\varepsilon_{xx'} = 1$ and $\sum_y Q^\varepsilon_{xy} = 1$, respectively.

Remark 3.1. Note that from (A1)–(A2), it follows that the matrices P^ε and Q^ε satisfy assumption (A) in section 2.

Let δ_x, $x \in X$ be the Dirac measure concentrated at x. The risk-sensitive index for $\sum$ is the real number defined by

$$\lambda^{\mu,\varepsilon} = \lim_{T\to\infty} \frac{\varepsilon}{\mu} \cdot \frac{1}{T} \log E_{\delta_x} \exp \left\{ \frac{\mu}{\varepsilon} \sum_{t=0}^{T-1} \ell(x_t) \right\}. \tag{3.3}$$

Then, Lemma 2.3 implies the existence of a unique continuous function $W^{\mu,\varepsilon} : S \to \mathbb{R}$, unique up to an additive constant, such that

$$\exp \left\{ \frac{\mu}{\varepsilon} \cdot \lambda^{\mu,\varepsilon} + W^{\mu,\varepsilon}(\theta) \right\} = E^+ \exp \{ W^{\mu,\varepsilon}(F^{\mu,\varepsilon}(\theta,y)) + G^{\mu,\varepsilon}(\theta,y) \}, \tag{3.4}$$

with $F^{\mu,\varepsilon}(\theta,y) := \frac{A^\varepsilon(y)\theta}{|A^\varepsilon(y)\theta|}$, and $G^{\mu,\varepsilon}(\theta,y) := \log |A^\varepsilon(y)\theta|$. Note that we have made explicit the dependence on the parameters ε, μ.

Now we make the following transformations. Let $\zeta : \mathbb{R}^N \to S$ defined by $\zeta_p := (\exp \frac{\mu}{\varepsilon} p)/|\exp \frac{\mu}{\varepsilon} p|$. Further, define the functions $\overline{W}^{\mu,\varepsilon} : \mathbb{R}^N \to \mathbb{R}$, $\overline{G}^{\mu,\varepsilon} : \mathbb{R}^N \times Y \to \mathbb{R}$ and $L^{\mu,\varepsilon} : \mathbb{R}^N \times Y \to \mathbb{R}^N$ by

$$\left\{ \begin{array}{lcl} \overline{W}^{\mu,\varepsilon}(p) & = & \frac{\varepsilon}{\mu} W^{\mu,\varepsilon}(\zeta_p), \\ \overline{G}^{\mu,\varepsilon}(p,y) & = & \frac{\varepsilon}{\mu} G^{\mu,\varepsilon}(\zeta_p, y), \\ L^{\mu,\varepsilon}(p,y) & = & \frac{\varepsilon}{\mu} \log A^\varepsilon(y) \exp\{\frac{\mu}{\varepsilon} p\}, \end{array} \right.$$

respectively. Here $\log p$ and e^p, for $p \in \mathbb{R}^N$, are understood to be componentwise.

Note that, for each $p \in \mathbb{R}^N$, $y \in Y$,

$$\begin{aligned} F^{\mu,\varepsilon}(\zeta_p, y) &= \frac{A^\varepsilon(y) e^{\frac{\mu}{\varepsilon} p}}{|A^\varepsilon(y) e^{\frac{\mu}{\varepsilon} p}|} \\ &= \frac{\exp\{\frac{\mu}{\varepsilon} L^{\mu,\varepsilon}(p,y)\}}{|\exp\{\frac{\mu}{\varepsilon} L^{\mu,\varepsilon}(p,y)\}|} \\ &= \zeta_{L^{\mu,\varepsilon}(p,y)}. \end{aligned}$$

Therefore, we can rewrite (3.4) as

$$\begin{aligned} \lambda^{\mu,\varepsilon} + \overline{W}^{\mu,\varepsilon}(p) = \frac{\varepsilon}{\mu} \log \sum_{y \in Y} \exp \Big\{ \frac{\mu}{\varepsilon} [\overline{W}^{\mu,\varepsilon}(L^{\mu,\varepsilon}(p,y)) \\ + \overline{G}^{\mu,\varepsilon}(p,y)] \Big\} \frac{1}{M}. \end{aligned} \tag{3.5}$$

Let $(p, q) := \sup_{x \in X}(p(x) + q(x))$ be the "sup-pairing" defined on $\mathbb{R}^N \times \mathbb{R}^N$. We define the functions $L^{\mu} : \mathbb{R}^N \times Y \to \mathbb{R}^N$ and $\overline{G}^{\mu} : \mathbb{R}^N \times Y \to \mathbb{R}$ by

$$L^{\mu}(p, y)(x') = \max_{x \in X} \left\{ \ell(x) - \frac{1}{\mu}[\varphi_1(x, x') + \varphi_2(x', y)] + p(x) \right\}$$

and

$$\overline{G}^{\mu}(p, y) = (L^{\mu}(p, y), 0) - (p, 0),$$

respectively. See [B-J].

Theorem 3.2.

(a) *$\varepsilon \to \lambda^{\mu,\varepsilon}$ is uniformly bounded.*

(b) *$L^{\mu,\varepsilon}(p, y) \to L^{\mu}(p, y)$ as $\varepsilon \to 0$ uniformly on compact subsets of $\mathbb{R}^N \times Y$.*

(c) *$\overline{G}^{\mu,\varepsilon}(p, y) \to \overline{G}^{\mu}(p, y)$ as $\varepsilon \to 0$ uniformly on compact subsets of $\mathbb{R}^N \times Y$.*

(d) *There exist a sequence $\{\varepsilon_n\}$, with $\varepsilon_n \to 0$, and a continuous function $\overline{W}^{\mu} : \mathbb{R}^N \to \mathbb{R}$, such that $\overline{W}^{\mu,\varepsilon_n}$ converges uniformly on compact subsets to $\overline{W}^{\mu}$.*

Proof. Equation (3.3) implies that $0 \leq \lambda^{\mu,\varepsilon} \leq \|\ell\|$, while part (b) follows from Theorem 3.4 in [B-J]. Let $p \in \mathbb{R}^N$, $y \in Y$. Then,

$$\begin{aligned} \overline{G}^{\mu,\varepsilon}(p, y) &= \frac{\varepsilon}{\mu} \log \left| A^{\varepsilon}(y) \cdot \frac{e^{\frac{\mu}{\varepsilon}p}}{|e^{\frac{\mu}{\varepsilon}p}|} \right| \\ &= \frac{\varepsilon}{\mu} \log |A^{\varepsilon}(y) e^{\frac{\mu}{\varepsilon}p}| - \frac{\varepsilon}{\mu} \log |e^{\frac{\mu}{\varepsilon}p}| \\ &\to (L^{\mu}(p, y), 0) - (p, 0) \quad \text{as } \varepsilon \to 0, \end{aligned}$$

where the convergence is due to the Laplace–Varadhan lemma [F-W] and part (b).

Now we shall prove part (d). Let $B^{\varepsilon} = [B^{\varepsilon}_{xx'}]$ be the matrix with entries $B^{\varepsilon}_{xx'} = e^{\frac{\mu}{\varepsilon}l(x)} P^{\varepsilon}_{xx'}$, and let $\psi^{\mu,\varepsilon}$ be the positive eigenvector (see section 2), with $\max_{x \in X} \psi(x) = 1$, corresponding to the dominant eigenvalue of B^{ε}. Then, from section 2, we may take

$$\begin{aligned} W^{\mu,\varepsilon}(\theta) &= \log\langle \psi^{\mu,\varepsilon}, \theta \rangle \\ &= \log\langle e^{\frac{\mu}{\varepsilon}\eta^{\mu,\varepsilon}}, \theta \rangle, \end{aligned} \tag{3.6}$$

with $\eta^{\mu,\varepsilon} = \frac{\mu}{\varepsilon} \log \psi^{\mu,\varepsilon}$. Moreover, Theorem 3.2 in [F-HH] implies that there exist a sequence $\{\varepsilon_n\}$, with $\varepsilon_n \to 0$, and a vector $\eta^{\mu} \in \mathbb{R}^N$ such that

$$\eta^{\mu,\varepsilon_n} \to \eta^{\mu} \quad \text{as } n \to \infty. \tag{3.7}$$

Therefore, using the Laplace–Varadhan lemma, (3.6)–(3.7) imply that

$$\overline{W}^{\mu,\varepsilon}(p) \to \overline{W}^{\mu}(p) := (p, \eta^{\mu}) - (p, 0) \tag{3.8}$$

uniformly on compact subsets of $\mathbb{R}^N$, where (p, q) is the sup-pairing. □

Theorem 3.3. *There exist a number λ^{μ} and a continuous function $\overline{W}^{\mu} : \mathbb{R}^N \to \mathbb{R}$ such that*

$$\lambda^{\mu} + \overline{W}^{\mu}(p) = \max_{y \in Y}\{\overline{W}^{\mu}(L^{\mu}(p, y)) + \overline{G}^{\mu}(p, y)\}. \tag{3.9}$$

Proof. Let $\{\varepsilon_n\}$ be a sequence as in Theorem 3.2(d). Then, part (a) of that theorem implies the existence of a subsequence of $\{\varepsilon_n\}$, which we denote again by

$\{\varepsilon_n\}$, such that $\lambda^{\mu,\varepsilon_n}$ converges to some number λ^μ as $n \to \infty$. Therefore, the Laplace–Varadhan lemma applied on the right-hand side of (3.5) yields that (3.9) holds. □

Remark 3.4. Since l is nonnegative, $\lambda^\mu \geq 0$. As seen in [F-HH, section 2] $\lambda^\mu = 0$ if and only if $\mu \leq \mu^*$, where $\mu^* > 0$ is the H^∞-norm. (Additional assumptions are needed to ensure that $\mu^* < \infty$.) Corresponding results for robust control with partial state information are discussed in section 5.

4. The risk-sensitive control problem. In this section we introduce the risk-sensitive control problem for partially observed Markov models. This problem shall be solved using the dynamic programming method. We prove the existence of a solution to the dynamic programming equation, which is a nonlinear eigenvalue problem. This equation can be transformed, using the variational formula (2.12), into the Isaacs equations for a stochastic dynamic game with average cost per unit time criterion.

Let X and Y be the same sets defined in section 1, and let U be a finite control set. Given an underlying probability space $(\Omega, \mathcal{F}, \mathcal{P})$, we shall consider controlled Markov processes x_t with state space X, initial distribution θ_0, and transition matrix $P(u) = [P(u)_{xx'}]$, with $u \in U$. The state process x_t is not observed directly, and instead, the observation process $\{y_t\}$ is available. This process takes values in Y, and its associated matrix is $Q = [Q_{xy}]$. Intuitively, $P(u)$ is the matrix of transitions from x_t to x_{t+1} if control u_t is used, and Q_{xy} is the probability of observing $y_{t+1} = y$ if $x_{t+1} = x$.

We denote by $\mathcal{U}$ the set of admissible control sequences $\widetilde{u} = \{u_t\}$, where u_t is a U-valued random variable adapted to the observations σ-field $\mathcal{Y}^t$, with $\mathcal{Y}^t = \sigma\{y_1, \dots, y_t\}$, $\mathcal{Y}^0 = \{\emptyset, \Omega\}$. Given an admissible control sequence $\widetilde{u}$, it defines a probability measure on $(\Omega, \mathcal{G}^t)$, with $\mathcal{G}^t = \sigma(x_0, \dots, x_t; y_1, \dots, y_t)$ such that

$$\mathcal{P}_{\theta_0}^{\tilde{u}}(x_0, \dots, x_t; y_1, \dots, y_t) = \prod_{t=0}^{t-1} P(u_t)_{x_t x_{t+1}} Q_{x_{t+1} y_{t+1}} \theta_0(x_0).$$

Throughout this section we assume the following.

(H) (a) There exists $T_1 > 0$ such that for every $u^{T_1} = (u_0, u_1, \dots, u_{T_1-1}) \in U^{T_1}$ and $x,\ x' \in X$ there exists $x^{T_1+1} = (x_0, x_1, \dots, x_{T_1}) \in X^{T_1}$ with $x_0 = x,\ x_{T_1} = x'$, and $\prod_{t=0}^{T_1-1} P(u_t)_{x_t x_{t+1}} > 0$.

(b) The matrix Q is positive.

Given the nonnegative cost per unit time function $l : X \times U \to \mathbb{R}$, for each $\widetilde{u} \in \mathcal{U}$ the cost functional (to be minimized) is the exponential growth criterion

$$\lambda(\tilde{u}) = \limsup_{T\to\infty} \frac{1}{T} \cdot \frac{1}{\mu} \log E_{\theta_0}^{\tilde{u}} \exp \mu \sum_{t=0}^{T-1} l(x_t, u_t), \tag{4.1}$$

where $\mu > 0$ is the risk averse parameter, and analogously to $E_{\theta_0}^{\tilde{u}}$, $\mathcal{P}_{\theta_0}^{\tilde{u}}$ denotes the probability induced by $\{x_t\}, \{y_t\}$, given $\widetilde{u} \in \mathcal{U}$ and the initial distribution θ_0.

Therefore, the goal is to find a control sequence $\widetilde{u}^*$ which minimizes $\lambda(\widetilde{u})$. We let

$$\Lambda = \inf_{\tilde{u} \in \mathcal{U}} \lambda(\widetilde{u}).$$

Paralleling section 2, we introduce an information state $\theta \in S$ and replace the original partially observed risk-sensitive control problem with an equivalent completely observed with state variable θ. Then, the dynamic programming method yields an optimal control for this original problem, which is separated through the information state.

Let $\mathcal{P}^+$ be the analogous probability measure on $\mathcal{G}^T$ given in (2.2). Under this probability measure, the controlled Markov chain $\{x_t\}$ and the observation process $\{y_t\}$ have the same properties mentioned in section 2.

Now we define, for $T = 1, 2, \dots,$

$$\sigma_T(x) = E^+ \left[I_{\{x_T = x\}} \exp\left[\mu \sum_{t=0}^{T-1} l(x_t, u_t) \right] \overline{L}_T | \mathcal{Y}^T \right],$$

and the information state $\theta_T \in S$ by

$$\theta_T = \frac{\sigma_T}{|\sigma_T|}.$$

Both σ_T and θ_T satisfy the recursions (2.4) and (2.8), substituting $A(y)$ with $A(y, u)$, which in this case has entries

$$A(y, u)_{xx'} = MP(u)_{x'x} Q_{xy} e^{\mu l(x', u)}.$$

Applying the same substitution in the definitions of G and F, one gets that (4.1) can be written as

$$\lambda(\widetilde{u}) = \limsup_{T \to \infty} \frac{1}{T} \frac{1}{\mu} \log E^+_\theta \exp\left\{ \sum_{t=1}^{T} G(\theta_{t-1}, u_{t-1}, y_t) \right\}.$$

The corresponding dynamic programming equation (cf. Thm. 4.6 in [F-HH]) for this control problem is given by

$$\exp\{\Upsilon + W(\theta)\} = \min_{u \in U} \left[E^+ \exp\{G(\theta, u, y) + W(F(\theta, u, y))\} \right]. \tag{4.2}$$

As in section 2, let ν denote the uniform distribution on Y.

THEOREM 4.1 (verification theorem). *Let $\Upsilon \in \mathbb{R}$, $W \in C(S)$ be a solution to the dynamic programming equation* (4.2). *Then*

(a) $\Upsilon \leq \mu\lambda(\widetilde{u})$ *for all* $\widetilde{u} \in \mathcal{U}$;

(b) *let* $\widetilde{u}^* = \{u_t^*\} \in \mathcal{U}$ *such that, for each* $t = 0, 1, \dots,$ $\tilde{u}_t^* = u^*(\theta_t)$, *where* $u^* : S \to U$ *is a function with*

$$u^*(\theta) \in \operatorname*{argmin}_{u \in U} [E^+ \exp\{W(F(\theta, u, y)) + G(\theta, u, y)\}].$$

Then $\Upsilon = \mu\lambda(\tilde{u}^*)$.

Proof. Given $\widetilde{u} \in \mathcal{U}$, $T > 0$, the dynamic programming principle implies that

$$\exp\{\Upsilon + W(\theta)\} \leq E^+ \exp\left\{ \sum_{t=0}^{T-1} G(\theta_t, u_t, y_{t+1}) + W(\theta_T) \right\},$$

with equality for the control $\widetilde{u}^*$. Now, take logs on both sides of this inequality, and divide by μT. Then, noting that $W(\theta_T)$ is bounded since θ_T is in the compact simplex S, letting $T \to \infty$ the theorem follows. □

THEOREM 4.2. *There exist a number Υ and a nonnegative continuous function $W : S \to \mathbb{R}$ such that* (4.2) *holds.*

In order to prove this theorem, we shall need some preliminary results. First, we shall introduce an infinite horizon, discounted cost stochastic game. Let W_β denote the upper value function of this game. Then, once we prove that $\{W_\beta; \beta \in (0, 1)\}$ is equicontinuous and $(1 - \beta)W_\beta(\theta^*)$ is uniformly bounded, where $\theta^* \in S$ is a reference point, the theorem follows in a straightforward way using the Arzelà–Ascoli theorem.

Stochastic dynamic game. The stochastic dynamics of the state θ_t for the controlled sequence (two players) is

$$\theta_{t+1} = F(\theta_t, u_t, y_{t+1}). \tag{4.3}$$

Here, the sequence $\{u_t\} \subset U$ represents the controls that the minimizer controller (player 1) chooses at each time step, while the maximizer controller (player 2) chooses a sequence $\{\pi_t\} \subset \Gamma$, where π_t is the distribution of y_{t+1}. The information available at each time t for both players is the history of observations $\{y_1, \ldots, y_t\}$. We shall make this precise using the following strategies.

Let $\mathcal{V} := \{\vec{u} = \{\overline{u}_t\} \mid \overline{u}_0 = u_0 \in U,\ \overline{u}_t : Y^t \times \Gamma^t \to U,\ t \geq 1\}$ be the set of strategies for player 1, and let $\mathcal{W} = \{\vec{\pi} = \{\overline{\pi}_t\} \mid \overline{\pi}_0 = \pi_0(u_0) \in \Gamma,\ \overline{\pi}_t : Y^t \times U^t \to \Gamma,\ t \geq 1\}$ be the set of strategies for player 2. Then, given the strategies $\vec{u}$, $\vec{\pi}$, we obtain the control sequences $\tilde{u} = \{\tilde{u}_t\}$, $\tilde{\pi} = \{\tilde{\pi}_t\}$, with $\tilde{u}_t$, $\tilde{\pi}_t$ $\mathcal{Y}^t$-adapted, determined by $\tilde{u}_0 = u_0$, $\tilde{\pi}_0 = \overline{\pi}_0(u_0)$, $\tilde{u}_1(y_1) = \overline{u}_1(y_1, \pi_1)$, $\tilde{\pi}_1(y_1) = \overline{\pi}_1(y_1, \tilde{u}_0, \tilde{u}_1(y_1)) \ldots$. Note that player 1 chooses first at each time step t (upper game). Moreover, $(\vec{u}, \vec{\pi})$ defines a probability measure $\mathcal{P}^{\vec{u},\vec{\pi}}$ on $\mathcal{Y}^\infty$, where $\mathcal{Y}^\infty$ is the σ-algebra generated by the "cylinder sets," in the following way:

$$P^{\vec{u},\vec{\pi}}(y_1, y_2, \ldots, y_n) = \tilde{\pi}_0(u_0)(y_1)\tilde{\pi}_1(y_1)(y_2) \cdots \tilde{\pi}_{n-1}(y_1, \ldots, y_{n-1})(y_n).$$

We denote by $E^{\vec{u},\vec{\pi}}$ the corresponding expectation operator. Finally, the reward per stage function is $K : S \times U \times \Gamma \to \mathbb{R}$, defined by $K(\theta, u, \pi) := \sum_{j=1}^{M} \pi^j [G(\theta, u, y^j) - \log(\pi^j M)]$.

Then, in order to prove Theorem 4.2, we shall introduce a sequence of infinite horizon discounted games. Let $\beta \in (0, 1)$ denote the discount factor. Given $\theta \in S$, $\vec{u} \in \mathcal{V}$, and $\vec{\pi} \in \mathcal{W}$, define the payoff functional

$$I_\beta(\theta, \vec{u}, \vec{\pi}) = E^{\vec{u},\vec{\pi}} \sum_{t=0}^{\infty} \beta^t K(\theta_t, u_t, \pi_t).$$

DEFINITION 4.3. *When there exists a pair of strategies $\vec{u}^*, \vec{\pi}^*$ such that*

$$I_\beta(\theta, \vec{u}^*, \vec{\pi}) \leq I_\beta(\theta, \vec{u}^*, \vec{\pi}^*) \leq I_\beta(\theta, \vec{u}, \vec{\pi}^*) \ \text{ for all } \ \vec{u}, \vec{\pi}, \tag{4.4}$$

the value $I_\beta(\theta, \vec{u}^*, \vec{\pi}^*)$ is called the upper value of the game, and $\vec{u}^*, \vec{\pi}^*$ are referred to as a saddle point. The upper value function of this game is denoted by $V_\beta(\theta)$.

Remark 4.4. In section 5 an Elliott–Kalton-type definition of value shall be used, since it is natural for the robust control interpretation. For stochastic differential systems the analogous definition was given by Fleming and Souganidis [F-S]. However, in this case, our present definition allows us to work out the problem without using the Elliott–Kalton definition of strategy.

LEMMA 4.5. *There is a unique concave continuous solution to the Isaacs equation*

$$\begin{aligned} V_\beta(\theta) \ &= \ \inf_{u \in U} \sup_{\pi \in \Gamma} \sum_{j=1}^{M} \pi^j \left[\beta V_\beta\left(F\left(\theta, u, y^j\right)\right)\right. \\ &\qquad \left. + G(\theta, u, y^j) - \log(M\pi^j)\right], \end{aligned} \tag{4.5}$$

and it is the upper value function defined above. Furthermore, the pair of strategies $\vec{u} = \{\overline{u}_t^*\}$, $\vec{\pi} = \{\overline{\pi}_t^*\}$, with $\overline{u}_t^*(y_1, \ldots, y_t, \pi_0, \ldots, \pi_{t-1}) = u^*(\theta_t)$ and $\overline{\pi}_t^*(y_1, \ldots, y_t, u_0, \ldots, u_t) = \pi^*(\theta_t, u_t)$, where

$$u^*(\theta) \in \operatorname*{argmin}_{u \in U} \int e^{\beta V_\beta(F(\theta,u,y)) + G(\theta,u,y)} \nu(dy)$$

and

$$\pi^*[\theta,u]^j = \frac{\frac{1}{M}\, e^{\beta V_\beta(F(\theta,u,y^j))+G(\theta,u,y^j)}}{\displaystyle\int e^{\beta V_\beta(F(\theta,u,y))+G(\theta,u,y)}\nu(dy)}$$

is a saddle point.

Sketch of proof. First, note that, using (2.12), we can write equation (4.5) as

$$V_\beta = \inf_{u\in U} \log \int \exp\{\beta V_\beta(F(\theta,u,y)) + G(\theta,u,y)\}\nu(dy).$$

Now define, for $\phi \in C(S)$, the operator

$$T\phi(\theta) = \inf_{u\in U} \log \int \exp\{\beta \phi(F(\theta,u,y)) + G(\theta,u,y)\}\nu(dy).$$

Then, straightforward calculations show that T is monotonic and contractive. Therefore, by the fixed point theorem, there exists a unique $V_\beta \in C(S)$ such that $TV_\beta = V_\beta$. Moreover, standard dynamic programming arguments show that V_β is the upper value function in Definition 4.3. It remains to see that V_β is concave. Let $\psi_0 = 1$, and define recursively

$$\psi_{n+1}(\theta) = \inf_{u\in U} \int |A(y,u)\theta|\psi_n^\beta(F(\theta,u,y))\nu(dy).$$

Then, from the above arguments, $\psi_n \nearrow \psi$ uniformly, with $\psi = e^{V_\beta}$. Thus, in order to prove that V_β is concave, it is sufficient to prove that ψ_n is concave for each $n = 0, 1, \ldots$. We shall prove this by induction. For $n = 0$ this is obvious. Then, provided ψ_n is concave, it follows, from Lemmas 1 and 2 in [A], that ψ_{n+1} is also concave. □

LEMMA 4.6. (a) *For each $\beta \in (0,1)$ and $\theta \in S$,*

$$|(1-\beta)V_\beta(\theta)| \le \|G\|.$$

(b) *The family of functions $\{V_\beta\}_{\beta\in(0,1)}$ is equicontinuous.*

Proof. Let $\vec{u}^* \in \mathcal{V}$ be as in Lemma 4.5, and take $\vec{\pi} = \{\tilde{\pi}_t\} \in \mathcal{W}$, with $\tilde{\pi}_t \equiv \nu$ for all $t = 0, 1 \ldots$. Then, from (4.4), it follows that

$$V_\beta(\theta) \ge -\frac{\|G\|}{1-\beta} \quad \text{for all } \theta \in S.$$

On the other hand, since $I(\cdot\,\|\nu) \ge 0$, $V_\beta(\theta) \le \frac{\|G\|}{1-\beta}$. This proves (a).

Let $T > 0$, and let Y^T, U^T be the set of multi-indices of length T on Y and U, respectively. Given $y^T = (y_1, \ldots, y_t) \in Y^T$, $u^T = (u_0, \ldots, u_{T-1}) \in U^T$, we define

$$h(\theta, u^T, y^T) := \frac{A(y_T, u_{T-1}) \cdots A(y_1, u_0)\theta}{|A(y_T, u_{T-1}) \cdots A(y_1, u_0)\theta|}.$$

Note that

$$\begin{aligned}\theta_T &= F(\theta_{T-1}, u_{T-1}, y_T)\\ &= h(\theta, u^T, y^T).\end{aligned}$$

The asymptotic behavior of the state process θ_T relies on estimations for random products of matrices. In particular, from assumption (A), it follows that there exist constants C and $r \in (0,1)$ such that

$$\|h(\theta, u^T, y^T) - h(\widetilde{\theta}, u^T, y^T)\| \leq Cr^T \|\theta - \widetilde{\theta}\| \tag{4.6}$$

for all $y^T \in Y^T$, $u^T \in U^T$, and $\theta, \widetilde{\theta} \in S$. We refer to [F-K] (see also [K, Lemma 6.2] and [A-M, Lemma 2.2]) for its proof.

Let $\vec{u} \in \mathcal{U}$, $\vec{\pi} \in \mathcal{W}$, and fix $\theta, \widetilde{\theta} \in S$. Then,

$$\begin{aligned}\|I_\beta(\theta, \vec{u}, \vec{\pi}) - I_\beta(\widetilde{\theta}, \vec{u}, \vec{\pi})\| &\leq E^{\vec{u},\vec{\pi}} \sum_{t=0}^{\infty} \beta^t |G(\theta_t, u_t, y_{t+1}) - G(\widetilde{\theta}_t, u_t, y_{t+1})| \\ &\leq \left\| \frac{dG}{d\theta} \right\| \cdot E^{\vec{u},\vec{\pi}} \sum_{t=0}^{\infty} \beta^t \|\theta_t - \widetilde{\theta}_t\| \\ &= \left\| \frac{dG}{d\theta} \right\| \left[\|\theta - \widetilde{\theta}\| + E^{\vec{u},\vec{\pi}} \sum_{t=1}^{\infty} \beta^t |h(\theta, u^t, y^t) - h(\widetilde{\theta}, u^t, y^t)| \right].\end{aligned}$$

Here $\tilde{\theta}_t$ is the solution of (4.3) with initial state $\tilde{\theta}_0 = \tilde{\theta}$.

Then, from (4.6), it follows that

$$\|I_\beta(\theta, \vec{u}, \vec{\pi}) - I_\beta(\widetilde{\theta}, \vec{u}, \vec{\pi})\| \leq \frac{c' \| \frac{dG}{d\theta} \|}{1 - r} \|\theta - \widetilde{\theta}\|,$$

for some suitable constant c' independent of $\vec{u}$, $\vec{\pi}$. Therefore, for each $\theta, \widetilde{\theta} \in S$,

$$|V_\beta(\theta) - V_\beta(\widetilde{\theta})| \leq \frac{c' \| \frac{dG}{d\theta} \|}{1 - r} \|\theta - \widetilde{\theta}\|.$$

This completes the proof of the lemma. □

Proof of Theorem 4.2. First note that, from (4.5), (2.15) can be rewritten as

$$e^{V_\beta(\theta)} = \inf_{u \in U} \int e^{\beta V_\beta(F(\theta,u,y)) + G(\theta,y)} \nu(dy). \tag{4.7}$$

Now, let $\theta_\beta \in \operatorname{argmin}_{\theta \in S}\{V_\beta(\theta\}$, and define $Z_\beta(\theta) := V_\beta(\theta) - V_\beta(\theta_\beta)$. From Lemma 4.5 we have that $\beta \to |(1-\beta)V_\beta(\theta_\beta)|$ is uniformly bounded, and the functions $\{Z_\beta\}$ are equicontinuous. Therefore, the Arzelà–Ascoli theorem implies the existence of a sequence $\beta_n \uparrow 1$ along which $(1-\beta_n)V_\beta(\theta_{\beta_n})$ converges to a limit Υ, and Z_{β_n} converges to a limit W uniformly. Then, writing (4.7) as

$$e^{(1-\beta)V_\beta(\theta_\beta) + Z_\beta(\theta)} = \inf_{u \in U} \int e^{\beta Z_\beta(F(\theta,u,y)) + G(\theta,u,y)} \nu(dy),$$

the theorem follows from an application of the dominated convergence theorem. □

5. Deterministic dynamic game and robust control. It is well known that the output feedback robust control problem can be recast as a partially observed dynamic game problem when the state space formulation is used. This dynamic game was studied by James and Baras [J-B] for finite state machines and finite horizon. Introducing an information state, they define an alternate deterministic dynamic game with completely observed information state. In this section we shall consider this dynamic game on an infinite horizon and average cost per unit time criterion and study its relationship with the robust control problem.

Consider the deterministic finite state controlled machine defined by

$$\left\{\begin{array}{lcl} x_{t+1} & = & f(x_t, u_t), \quad t = 0, \ldots;\ x_0 = x, \\ y_{t+1} & = & g(x_{t+1}), \end{array}\right. \tag{5.1}$$

where the state x_t evolves in the finite set X, the output y_t takes values in Y, u_t takes values in U, and the functions $f : X \times U \to X$ and $g : X \to Y$ are given. Also, in order to model the influence of disturbances, we introduce a deterministic perturbation of the system (5.1). Let $b : X \times U \times Z \to X$ and $h : X \times W \to Y$ be given functions that define the dynamics of the system $\sum^u$

$$\left\{\begin{array}{lcl} x_{t+1} & = & b(x_t, u_t, \omega_t), \quad t = 0, \ldots; x_0 = x, \\ y_{t+1} & = & h(x_{t+1}, \omega_{t+1}), \end{array}\right. \tag{5.2}$$

where ω_t takes values in the finite set Z, and $x_t,\ y_t$, and u_t evolve in $X,\ Y$, and U, respectively. We assume that there is a "null disturbance" $\omega_\phi \in Z$ such that, for all $x \in X,\ u \in U$,

$$b(x, u, \omega_\phi) = f(x, u),$$
$$h(x, \omega_\phi) = g(x).$$

We also assume the following.

(H1) There exists $T_1,\ 0 \leq T_1 < \infty$, with the following property: for each $x, x' \in X$ and $\tilde{u} = (u_0, \ldots, u_{T_1 - 1}) \in U^{T_1}$, there exists $\tilde{\omega} = (\omega_0, \ldots, \omega_{T_1-1}) \in Z^{T_1}$ such that $x_0 = x$ and $x_{T_1} = x'$.

(H2) Given $x \in X,\ \ y \in Y$, there exists $\omega \in Z$ such that $y = h(x, \omega)$.

In particular, if (H1) holds with $T_1 = 1$, the following stronger condition holds.

(H1$'$) Given $x,\ x' \in X$, and $u \in U$, there exists $\omega \in Z$ such that $x' = b(x, u, \omega)$.

Let $\vartheta_1, \vartheta_2 : Z \to \mathbb{R}^+$ be functions that measure the magnitude of disturbances, and define the functions $\varphi_1 : X \times U \times X \to \mathbb{R}$ and $\varphi_2 : X \times Y \to \mathbb{R}$ by

$$\varphi_1(x, u; x') = \min_{\omega \in Z}\{\vartheta_1(\omega) : \quad x' = b(x, u, \omega)\}$$

and

$$\varphi_2(x, y) = \min_{\omega \in Z}\{\vartheta_2(\omega) : \quad y = h(x, \omega)\},$$

respectively. We assume that

$$\vartheta_1(\omega_\phi) = \vartheta_2(\omega_\phi) = 0.$$

As in section 3 we use the convention that the minimum over the empty set equals $+\infty$. Assumption (H2) implies that $\varphi_2(x, y) < \infty$, and $\varphi_1(x, u; x')$ is always finite if (H1$'$) holds.

Let $l : X \times U \to \mathbb{R}^+$ be the cost per stage function, and define the function $\text{\L}^\mu : \mathbb{R}^N \times U \times Y \to \mathbb{R}^N$ by

$$\text{\L}^\mu(p, u, y)(x') = \max_{x \in X}\left\{ l(x, u) - \frac{1}{\mu}[\varphi_1(x, u; x') + \varphi_2(x', y)] + p(x) \right\}.$$

Assumptions (H1) and (H2) imply that $L^\mu(p, u, y)(x')$ is finite (not $-\infty$).

Consider the difference equation

$$\left\{ \begin{array}{l} p_{t+1} = \text{Ł}^{\mu}(p_t, u_t, y_{t+1}),\ t = 0, 1, \ldots, \\ p_0 = p \in \mathbb{R}^N, \end{array} \right. \tag{5.3}$$

where $\tilde{u} = \{u_t\}_{t=0}^{\infty}$ and $\tilde{y} = \{y_t\}_{t=1}^{\infty}$ are sequences on U and Y and play the role of controls for the minimizer and maximizer controllers respectively. We associate the finite-time payoff functional

$$J^{\mu}(p_0, T; \tilde{u}, \tilde{y}) = (p_T, 0), \quad T > 0,$$

with each pair of control sequences.

Now, following the Elliott–Kalton-type definition of upper value, we say that $\Gamma : Y^{\infty} \to U^{\infty}$ is a strategy for the minimizer controller if, given $\tilde{u} \in U^{\infty}, \tilde{y} \in Y^{\infty}$ such that $\Gamma(\tilde{y}) = \tilde{u}$, $\Gamma(\tilde{y})_t$ depends only on $y_1, \ldots, y_t$ for each $t \geq 1$, while u_0 does not depend on $\tilde{y}$. Let $V(p_0, T)$ denote the (upper) value of this dynamic game, defined by

$$V(p_0, T) = \inf_{\Gamma} \sup_{\tilde{y}} J^{\mu}(p_0, T; \Gamma, \tilde{y}).$$

In [B-J, Thm. 4.1] it was proved that, given a strategy for the minimizer controller,

$$\max_{\tilde{y} \in Y^{\infty}} (p_T, 0) = \max_{x_0, \tilde{\omega}} \left\{ p_0(x_0) + \sum_{t=0}^{T-1} \left[l(x_t, u_t) - \frac{1}{\mu} [\vartheta_1(\omega_t) + \vartheta_2(\omega_{t+1})] \right] \right\}. \tag{5.4}$$

Remark 5.1.

(a) In section 4 we considered *normalized* information states θ_t, with $\Sigma_{x \in X} \theta_t(x) = 1$, rather than unnormalized information states as in [B-J]. Similarly, in the deterministic case we can consider also information states p_t normalized by $(p_t, 0) = \max_{x \in X} p_t(x) = 0$.

(b) *Notation.* For $p \in \mathbb{R}^N,\ c \in \mathbb{R}$, we shall denote by $p + c \in \mathbb{R}^N$ the vector with components $p(x) + c,\ x \in X$.

Let $\Delta = \{\alpha \in \mathbb{R}^N : \max_{x \in X} \alpha(x) = 0\}$, and define the *normalized* information state $\alpha_t \in \Delta$ by

$$\alpha_t(x) = p_t(x) - (p_t, 0).$$

Moreover, let $G^{\mu} : \mathbb{R}^N \times U \times Y \to \mathbb{R}$ be defined by

$$G^{\mu}(p, u, y) = (\text{Ł}^{\mu}(p, u, y), 0) - (p, 0).$$

Then, noting that, for each $p \in \mathbb{R}^N,\ c \in \mathbb{R},\ G^{\mu}(p + c) = G^{\mu}(p)$, we get

$$J(\alpha_0, T; \tilde{u}, \tilde{y}) = \sum_{t=0}^{T-1} G^{\mu}(\alpha_t, u_t, y_{t+1}), \tag{5.5}$$

whenever $p_0 = \alpha_0 \in \Delta$. Further, defining $\overline{\text{Ł}}^{\mu} : \Delta \times U \times Y \to \Delta$ by

$$\overline{\text{Ł}}^{\mu}(\alpha, u, y) = \text{Ł}^{\mu}(\alpha, u, y) - G^{\mu}(\alpha, u, y),$$

we have that

$$\begin{aligned} \alpha_{t+1} &= \text{Ł}^{\mu}(\alpha_t, u_t, y_{t+1}) - G^{\mu}(\alpha_t, u_t, y_{t+1}) \\ &= \overline{\text{Ł}}^{\mu}(\alpha_t, u_t, y_{t+1}). \end{aligned} \tag{5.3$'$}$$

Let $\|\cdot\|$ denotes the supremum norm. The next lemma summarizes several elementary but important properties of G^{μ}, $Ł^{\mu}$, and $\overline{Ł}^{\mu}$.

LEMMA 5.2. *Assume* (H1), (H2). *For each* $p,\ \hat{p} \in \mathbb{R}^N,\ c \in \mathbb{R},\ y \in Y,\ u \in U,\ \alpha \in \Delta$, *the following holds.*

(a)

$$Ł^{\mu}(p + c, u, y) = Ł^{\mu}(p, u, y) + c.$$

(b)

$$\|Ł^{\mu}(p, u, y) - Ł^{\mu}(\hat{p}, u, y)\| \leq \|p - \hat{p}\|,$$

$$-\frac{1}{\mu}\|\varphi_2\| \leq G^{\mu}(p, u, y) \leq \|l\|,$$

$$0 \leq \max_{y \in Y} G^{\mu}(p, u, y) \leq \|l\|.$$

(c) *If* (H1$'$) *and* (H2) *hold, then*

$$(p, 0) - \frac{1}{\mu}[\|\varphi_1\| + \|\varphi_2\|] \leq Ł^{\mu}(p, u, y)(x) \leq \|l\| + (p, 0),$$

$$-[\|l\| + \frac{1}{\mu}(\|\varphi_1\| + \|\varphi_2\|)] \leq \overline{Ł}^{\mu}(\alpha, u, y)(x) \leq 0.$$

Sketch of proof. Part (a) and the first inequality in (b) are immediate from the definition of L^{μ}. For the rest of (b) it suffices to assume that $(p, 0) = 0$. Then

$$G^{\mu}(p, u, y) = \max_{x, x'} \left\{ l(x, u) - \frac{1}{\mu}[\varphi_1(x, u; x') + \varphi_2(x', y)] + p(x) \right\}.$$

One gets $-\mu^{-1}\|\varphi_2\| \leq G^{\mu}(p, u, y)$ by choosing x such that $p(x) = 0$ and $x' = b(x, u, \omega_{\phi})$. If $y = h(x', \omega_{\phi})$, then $0 \leq G^{\mu}(p, u, y)$. Clearly, $G^{\mu} \leq \|l\|$, and the inequalities in (c) are proved similarly. □

Note that, from part (b) of Lemma 5.2, it follows that, for each $T \geq 1$, $p_0, \tilde{p}_0 \in \mathbb{R}^N$, $\tilde{y}$, Γ,

$$\|p_T - \tilde{p}_T\| \leq \|p_0 - \tilde{p}_0\|, \tag{5.6}$$

$$\|J(p_0, T; \Gamma, \tilde{y}) - J(\tilde{p}_0, T; \Gamma, \tilde{y})\| \leq \|p_0 - \tilde{p}_0\|,$$

and therefore

$$|V(p_0, T) - V(\tilde{p}_0, T)| \leq \|p_0 - \tilde{p}_0\|. \tag{5.7}$$

Here $\tilde{p}_t$ is the solution to (5.3) with initial state $\tilde{p}_0$.

Now, in order to study the above dynamic game on an infinite horizon and average cost per unit time criterion, we shall consider first the discounted cost infinite horizon payoff.

Let $0 < \beta < 1$ be the discount factor, and define, for $p_0 \in \mathbb{R}^N, \tilde{y}, \Gamma$,

$$J_{\beta}(p_0; \Gamma, \tilde{y}) = \sum_{t=0}^{\infty} \beta^t[(p_{t+1}, 0) - (p_t, 0)] + (p_0, 0). \tag{5.8}$$

Then, using "summation by parts," for each $T > 0$,

$$\begin{aligned} J_\beta(p_0, T; \Gamma, \tilde{y}) &:= \sum_{t=0}^{T-1} \beta^t [(p_{t+1}, 0) - (p_t, 0)] + (p_0, 0) \\ &= \beta^T (p_T, 0) - \sum_{t=0}^{T-1} (\beta^{t+1} - \beta^t)(p_{t+1}, 0) \\ &= \beta^T (p_T, 0) + (1-\beta) \sum_{t=0}^{T-1} \beta^t (p_{t+1}, 0). \end{aligned}$$

Further, by (5.6),

$$\begin{aligned} |J_\beta(p_0, T; \Gamma, \tilde{y}) - J_\beta(\tilde{p}_0, T; \Gamma, \tilde{y})| &\le \beta^T \|p_0 - \tilde{p}_0\| + (1-\beta) \sum_{t=0}^{T-1} \beta^t \|p_0 - \tilde{p}_0\| \\ &\le (\beta^T + 1) \|p_0 - \tilde{p}_0\|. \end{aligned}$$

Therefore, letting $T \to \infty$, we get

$$|J_\beta(p_0; \Gamma, \tilde{y}) - J_\beta(\tilde{p}_0; \Gamma, \tilde{y})| \le \|p_0 - \tilde{p}_0\|. \tag{5.9}$$

Also, if $p_0 = \alpha_0 \in \Delta$, then, by (5.8) and the fact $(p_{t+1}, 0) - (p_t, 0) = G^\mu(p_t, u_t, y_{t+1})$,

$$(1-\beta)|J_\beta(\alpha_0)| \le \|G^\mu\|. \tag{5.10}$$

Let $W_\beta(\alpha)$ be the (upper) value of the game with discounted infinite horizon payoff. Then, (5.9)–(5.10) imply

$$|W_\beta(\alpha) - W_\beta(\tilde{\alpha})| \le \|\alpha - \tilde{\alpha}\| \quad \text{for all } \alpha, \alpha_0 \in \Delta, \tag{5.11}$$

and

$$0 \le (1-\beta) W_\beta(\cdot) \le \|G^\mu\|, \tag{5.12}$$

where the left-hand side inequality follows from Lemma 5.2(b).

The corresponding Isaacs equation for this game is

$$W_\beta(\alpha) = \min_{u \in U} \max_{y \in Y} [\beta W_\beta(\overline{\mathrm{L}}^\mu(\alpha, u, y)) + G^\mu(\alpha, u, y)], \tag{5.13}$$

and standard dynamic programming arguments show that the upper-value function W_β is the unique continuous solution to this equation.

If (H1$'$) and (H2) hold, then from Lemma 5.2(c), for arbitrary $\alpha_0 \in \Delta$, $\alpha_t \in K$ for all $t \ge 1$, where K is a fixed compact set. Hence, it suffices to consider $\alpha_0 \in K$. In fact, a similar property holds under the weaker assumptions (H1)–(H2).

Lemma 5.3. *Assume* (H1)–(H2). *Then there exists a compact set K such that, for arbitrary $\alpha_0 \in \Delta$, $\alpha_t \in K$ for all $t \ge T_1$.*

Proof. We write $x \to x'$ under u if $x' = b(x, u, \omega)$ for some ω. Let

$$C = \max_{x, x', u} \{\varphi_1(x, u; x') \mid x \to x' \text{ under } u\}.$$

Given x, x', and $\tilde{u}$, let $\tilde{\omega}$ be as in (H1). Then $x_t \to x_{t+1}$ under u_t for $t = 0, 1, \dots, T-1$. From (5.3)

$$p_t(x_t) - \frac{1}{\mu}(C + \|\varphi_2\|) \leq p_{t+1}(x_{t+1}) \leq \|l\| + (p_t, 0),$$

from which, since $x_0 = x,\ x_{T_1} = x'$,

$$p_0(x) - \frac{T_1}{\mu}(C + \|\varphi_2\|) \leq p_{T_1}(x') \leq T_1\|l\| + (p_0, 0).$$

Take $p_0 = \alpha_0$ and x such that $\alpha_0(x) = 0$. Then $\|p_{T_1}(x')\| \leq C_1$ which implies $\alpha_{T_1} \in K_1$ for some fixed compact set K_1. Then also $\alpha_{mT_1} \in K_1$ for $m = 1, 2, \dots,$ and $\alpha_t \in K$ for all $t \geq T_1$ for some compact K. □

Let $\alpha_\beta \in \operatorname{argmin}\{\ W_\beta(\alpha) \mid \alpha \in K\ \}$. Thus, (5.11)–(5.12) imply that, for a sequence $\beta_n \nearrow 1$,

$$\begin{gathered}(1-\beta_n)W_{\beta_n}(\alpha_{\beta_n}) \to \lambda^\mu,\\ W_{\beta_n}(\alpha) - W_{\beta_n}(\alpha_{\beta_n}) \to W^\mu(\alpha),\end{gathered}$$

uniformly on K, with $\min_K W(\alpha) = 0$.

Further, rewriting (5.13), with $\beta = \beta_n$, as

$$\begin{aligned}W_{\beta_n}(\alpha) - W_{\beta_n}(\alpha_{\beta_n}) = \min_u \max_y [&\beta_n(W_{\beta_n}(\bar{\mathbb{L}}^\mu(\alpha, u, y)) - W_{\beta_n}(\alpha_{\beta_n}))\\ &+ G^\mu(\alpha, u, y)] - (1-\beta_n)W_{\beta_n}(\alpha_{\beta_n}),\end{aligned}$$

and letting $n \to \infty$, we get

$$\lambda^\mu + W^\mu(\alpha) = \min_u \max_y [W^\mu(\bar{\mathbb{L}}^\mu(\alpha, u, y)) + G^\mu(\alpha, u, y)]. \tag{5.14}$$

We have proved the following.

THEOREM 5.4. *There exist a number* λ^μ *and a nonnegative continuous function* $W^\mu : K \to \mathbb{R}$ *such that* (5.14) *holds.*

On the other hand, a standard dynamic programming argument implies that, for $0 < T < \infty$,

$$W^\mu(\alpha) = \mathcal{UV}\left[\sum_{t=0}^{T-1}[G^\mu(\alpha_t, u_t, y_{t+1}) - \lambda^\mu] + W^\mu(\alpha_T)\right], \tag{5.15}$$

where $\mathcal{UV}$ denotes the upper value of the finite time game with running cost $G^\mu - \lambda^\mu$ and terminal cost $W^\mu(\alpha_T)$. Further, we also have by (5.4) that

$$V(\alpha, T) = \mathcal{UV}\left[\sum_{t=0}^{T-1} G^\mu(\alpha_t, u_t, y_{t+1})\right].$$

Since α_t belongs to the compact set K, we get, by dividing by T and letting $T \to \infty$, that

$$\lambda^\mu = \lim_{T\to\infty} \frac{V(\alpha, T)}{T}. \tag{5.16}$$

This shows, in particular, that λ^μ does not depend on the particular sequence $\{\beta_n\}$.

The next theorem follows in a way similar to [F-McE, sec. 8], and we omit its proof.

THEOREM 5.5. *The upper-value function of the dynamic game with payoff functional*

$$P(\alpha, \Gamma, \tilde{y}) = \limsup_{T\to\infty} \frac{1}{T} \sum_{t=0}^{T-1} G^{\mu}(\alpha_t, u_t, y_{t+1})$$

is equal to λ^{μ}.

Optimal stationary control policy. Let $u^* : K \to U$ such that

$$u^*(\alpha) \in \operatorname*{argmin}_{u}\{\max_{y}[W^{\mu}(\overline{Ł}^{\mu}(\alpha, u, y)) + G^{\mu}(\alpha, u, y)]\}. \tag{5.17}$$

Given $\alpha_0 \in K$, the policy $u^*(\cdot)$ determines a strategy Γ^* as follows. Given $\tilde{y} = (y_1, y_2, \ldots)$, define α_t^* by

$$\begin{aligned} \alpha_{t+1}^* &= \overline{Ł}^{\mu}(\alpha_t^*, u^*(\alpha_t^*), y_{t+1}), \\ \alpha_0^* &= \alpha_0. \end{aligned}$$

Now take

$$\Gamma^*(\tilde{y})_t = u_t^* = u^*(\alpha_t^*).$$

Then from (5.14), for all y, α,

$$\lambda^{\mu} + W^{\mu}(\alpha) \geq W^{\mu}(\overline{Ł}(\alpha, u^*(\alpha), y)) + G^{\mu}(\alpha, u^*(\alpha), y).$$

By iterating this inequality, we get, for all $\tilde{y}$, $T > 0$,

$$\lambda^{\mu} T + W^{\mu}(\alpha_0) \geq \sum_{t=0}^{T-1} G^{\mu}(\alpha_t^*, u_t^*, y_{t+1}) + W^{\mu}(\alpha_t^*).$$

Further, by (5.5), this can be rewritten as

$$\lambda^{\mu} T + W^{\mu}(\alpha_0) \geq (p_T^*, 0) + W^{\mu}(\alpha_T^*),$$

where

$$\begin{aligned} p_{t+1}^* &= Ł^{\mu}(p_t^*, u_t^*, y_{t+1}), \\ p_0^* &= \alpha_0. \end{aligned}$$

Hence, by (5.4), for all $x_0 \in X$, $\tilde{\omega} \in Z^{\infty}$, $T > 0$,

$$\begin{aligned} \sum_{t=0}^{T-1} l(x_t^*, u_t^*) + W^{\mu}(\alpha_T^*) \leq -\alpha_0(x_0) + \frac{1}{\mu} \sum_{t=0}^{T-1} [\vartheta_1(\omega_t) + \vartheta_2(\omega_{t+1})] \\ + \lambda^{\mu} T + W^{\mu}(\alpha_0), \end{aligned} \tag{5.18}$$

where

$$\begin{aligned} x_{t+1}^* &= b(x_t^*, u_t^*, \omega_t), \\ x_0^* &= x_0. \end{aligned}$$

Now, let us assume that $\lambda^{\mu} = 0$. In this case (5.18) becomes a kind of "dissipation inequality" (cf. (5.16) in [F-McE]). Suppose, moreover, that $W^{\mu}(\alpha_0) = \min_K W^{\mu}(\alpha)$. Then, inequality (5.18) implies that, for all $x_0,\ \tilde{\omega},\ T > 0$,

$$\sum_{t=0}^{T-1} l(x_t^*, u_t^*) \leq -\alpha_0(x_0) + \frac{1}{\mu}\sum_{t=0}^{T-1}[\vartheta_1(\omega_t) + \vartheta_2(\omega_{t+1})]. \tag{5.19}$$

Thus, the output feedback robust control is achieved with μ^{-1}, according to [B-J, Definition 2.12], provided $\beta = -\alpha_0$ (in their notation for $\beta(\cdot)$). If we assume that $l(x_\phi, u_\phi) = 0$ and $l(x, u) > 0$ for all $x \neq x_\phi$, then $\alpha_0(x_\phi) = 0$. To see this recall that $-\alpha_0(x_0) \geq 0$ with equality for some $\overline{x}_0$. Take $x_0 = \overline{x}_0$ and $\omega_t = 0$ for all t. By (5.19), $l(x_0^*, u_0^*) = l(\overline{x}_0, u_0^*) = 0$ and hence $\overline{x}_0 = x_\phi$.

On the other hand, since $V(p, T) \leq V(p, T+1)$,

$$\overline{W}(p) := \lim_{T\to\infty} V(p, T)$$

exists (maybe $+\infty$). In the case of $\overline{W}(p) < \infty$,

$$\overline{W}(p) = \min_u \max_y \overline{W}(\text{Ł}^{\mu}(p, u, y)).$$

This implies, particularly, since $\overline{W}(p + c) = \overline{W}(p) + c$ for all $p \in \mathbb{R}^N,\ c \in \mathbb{R}$, that

$$\begin{aligned}\overline{W}(\alpha_0) &= \mathcal{U}\mathcal{V}[\overline{W}(p_T)]\\ &= \mathcal{U}\mathcal{V}[\overline{W}(\alpha_T) + (p_T, 0)]\end{aligned}$$

whenever $p_0 = \alpha_0 \in \Delta$.

Replacing $\overline{W}(\alpha)$ by $W^{\mu}(\alpha)$, we can argue as before, with $\lambda^{\mu} = 0$ and u^* as in (5.17).

In order to ensure that $\lambda^{\mu} = 0$ for all sufficiently small μ, let us make (as in [B-J] and [F-HH]) additional assumptions about the existence of a "null" state and control $x_\phi,\ u_\phi$.

(H3)

$$\left\{\begin{array}{rcll} f(x_\phi, u_\phi) & = & x_\phi, & \\ l(x_\phi, u_\phi) & = & 0, & \\ l(x, u) & > & 0 & \text{for } (x, u) \neq (x_\phi, u_\phi). \end{array}\right.$$

(H4) There exists an integer T_0 such that for any initial condition $x_0 = x$, the solution to $x_{t+1} = f(x_t, u_\phi)$ reaches x_ϕ in T_0 steps.

If any constant control u is chosen, with $u_t = u$ for $t = 0, 1, \ldots$, then [F-HH, sect. 2] and section 3 above give a corresponding λ_u^{μ}. By either (5.16) or Theorem 5.5, $\lambda_u^{\mu} \geq \lambda^{\mu}$. In particular, take $u = u_\phi$. Then (H3) and (H4) imply that $\lambda_{u_\phi}^{\mu} = 0$ for $0 < \mu \leq \mu_\phi$, for suitable μ_ϕ. Hence $\lambda^{\mu} = 0$ for $0 < \mu \leq \mu_\phi$. Let

$$\mu^* = \sup\{\mu\ :\ \lambda^{\mu} = 0\}.$$

Then the crucial dissipation inequality (5.19) of robust control with partial state information can be achieved using the optimal control policy $u^*(\alpha)$, provided $\mu \leq \mu^*$.

Now let us assume that $\mu > \mu^*$, and hence $\lambda^{\mu} > 0$. In this case, (5.18) implies, since $W(\alpha_T^*)$ is bounded, that

$$\limsup_{T\to\infty}\left\{\frac{1}{T}\sum_{t-1}^{T-1} l(x_t^*, u_t^*) - \frac{1}{T}\cdot\frac{1}{\mu}\sum_{t=0}^{T-1}[\vartheta_1(\omega_t) + \vartheta_2(\omega_{t+1})]\right\} \leq q\lambda^{\mu}.$$

In terms of Definition 2.1 in [D-J], the above inequality means that the system Σ^{u^*} has finite power gain less than or equal to μ^{-1}.

Small noise limit. For each $u \in U$, analogously to section 3, define the matrices $P^\varepsilon(u)$ and Q^ε.

Then, replacing the matrices $P(u), Q$ in section 4 by $P^\varepsilon(u)$, Q^ε, Theorem 4.2 implies (in view of (H1-H2)) the existence of a number $\Lambda^{\mu,\varepsilon}$ and a nonnegative continuous function $W^{\mu,\varepsilon} : S \to \mathbb{R}$ such that

$$\exp\left\{\frac{\mu}{\varepsilon}\cdot\Lambda^{\mu,\varepsilon} + W^{\mu,\varepsilon}(\theta)\right\} = \min_{u\in U} E^{+}\exp\left\{G^{\mu,\varepsilon}(\theta,u,y) + W^{\mu,\varepsilon}(F^{\mu,\varepsilon}(\theta,u,y))\right\}, \tag{5.20}$$

where now $F^{\mu,\varepsilon}(\theta,u,y) = \frac{A^\varepsilon(u,y)\theta}{|A^\varepsilon(u,y)\theta|}$ and $G^{\mu,\varepsilon}(\theta,u,y) = \log|A^\varepsilon(u,y)\theta|$.

Now we proceed as in section 3 and define the functions $\overline{W}^{\mu,\varepsilon} : \mathbb{R}^N \to \mathbb{R}$, $\overline{G}^{\mu,\varepsilon} : \mathbb{R}^N \times U \times Y \to \mathbb{R}$, and $\text{Ł}^{\mu,\varepsilon} : \mathbb{R}^N \times U \times Y \to \mathbb{R}^N$ by

$$\left\{\begin{array}{l} \overline{W}^{\mu,\varepsilon}(p) = \frac{\varepsilon}{\mu}\overline{W}^{\mu,\varepsilon}(\zeta_p), \\ \overline{G}^{\mu,\varepsilon}(p,u,y) = \frac{\varepsilon}{\mu}\overline{G}^{\mu,\varepsilon}(\zeta_p,u,y), \\ \text{Ł}^{\mu,\varepsilon}(p,u,y) = \frac{\varepsilon}{\mu}\log A^\varepsilon(u,y)e^{\frac{\mu}{\varepsilon}p}, \end{array}\right.$$

Note that, from the above transformations, we can write (5.19) as

$$\begin{aligned} \Lambda^{\mu,\varepsilon} + \overline{W}^{\mu,\varepsilon}(p) \quad = \quad \min_{u\in U}\frac{\varepsilon}{\mu}\log\sum_{y\in Y}\exp\{&\overline{W}^{\mu,\varepsilon}(\text{Ł}^{\mu,\varepsilon}(p,u,y)) \\ &+ \overline{G}^{\mu,\varepsilon}(p,u,y)\}\cdot\frac{1}{M}. \end{aligned}$$

Then, using the same kind of arguments as in the proof of the Theorem 3.2, it follows that

(a) $\varepsilon \to \Lambda^{\mu,\varepsilon}$ is uniformly bounded,

(b) $\text{Ł}^{\mu,\varepsilon}(p,u,y) \to \text{Ł}^{\mu}(p,u,y)$ as $\varepsilon \to 0$ uniformly on compact sets of $\mathbb{R}^N \times U \times Y$,

(c) $\overline{G}^{\mu,\varepsilon}(p,u,y) \to G^{\mu}(p,u,y)$ as $\varepsilon \to 0$ uniformly on compact sets of $\mathbb{R}^N \times U \times Y$.

In fact, if there exists a sequence $\{\varepsilon_n\}$, with $\varepsilon_n \to 0$ as $n \to \infty$, such that $\Lambda^{\mu,\varepsilon_n}$ tends to some Λ^μ and $\overline{W}^{\mu,\varepsilon_n}$ converges uniformly on compact sets t o some function $W^\mu : \mathbb{R}^N \to \mathbb{R}$, the existence of a solution to (5.14) follows straightforwardly in view of (a)–(c) above. In order to obtain such a sequence ε_n, it would suffice to prove equicontinuity of the functions $\overline{W}^{\mu,\varepsilon}$, which we have not succeeded in doing. For the simpler situation in section 3 this difficulty was avoided by using the explicit form (3.6) of $W^{\mu,\varepsilon}$ and a corresponding convergence result [F-HH, Thm. 3.2] for the state feedback case.

Acknowledgments. We wish to thank Professor Steven Marcus for bringing to our attention several reprints of his work. D. Hernández-Hernández also expresses his gratitude to the Division of Applied Mathematics, Brown University, and the Institute for Systems Research, University of Maryland, for their hospitality and support.

NEWTON'S MESH INDEPENDENCE PRINCIPLE FOR A CLASS OF OPTIMAL SHAPE DESIGN PROBLEMS*

MANFRED LAUMEN†

Abstract. Many optimal shape design problems can be stated as infinite dimensional minimization problems. For deriving an implementable algorithm it has to be decided either to discretize the problem and to use a finite algorithm to solve the discrete problem or to state an algorithm in function space and to discretize this algorithm. This issue has yet to be addressed in the field of optimal shape design research. One big advantage for the latter procedure is a mesh independence behavior as it has been proven by Allgower et al. [*SIAM J. Numer. Anal.*, 23 (1986), pp. 160–169]. Since their assertions are not directly applicable to these specific kinds of problems, a modified version of their mesh independence principle is given here in order to derive more efficient algorithms for the resulting large scale problems.

Key words. Newton's method, optimal shape design, mesh independence principle

1. Introduction.

In 1986, Allgower et al. [3] published a general mesh independence proof for Newton's method in the context of nonlinear equations. The applications of their theoretical results to various mathematical problems are presented in the original paper and in the follow-up publication [2]. Heinkenschloss stated a similar mesh independence result for the Gauss–Newton method, which was applied to a parameter identification problem [21], [22], [23]. For quasi-Newton methods with Broyden update, Kelley and Sachs analyzed the influence of discretizations in [27].

Besides the advantage of the mesh independence principle for predicting the convergence of the computable method on the basis of the analyzed infinite dimensional convergence, there is a further important point for practical implementations. The mesh independence lays the theoretical foundation for the justification of refinement strategies and helps to design this refinement process (see, e.g., [2]). Since the focus is the infinite dimensional solution, a fine discretization scheme has to be chosen, so that the discrete solution approximates the infinite dimensional solution appropriately. However, a fine discretization also means that the finite problem consists of many variables, and therefore, an increased amount of work per iteration has to be expected. Keeping the numerical method fixed, the only possibility of reducing the total workload to obtain the discrete solution is to improve the starting point of the nonlinear iteration. Apparently, this can be done by using information from the coarse grid discretization leading to the concept of mesh refinement (respectively, nested iteration). Several numerical computations confirm the efficiency of this strategy for various algorithms (see, e.g., [17], [18]). The intention of this paper is to lay the foundation for using mesh refinement to solve the resulting large scale problems efficiently. This is done by proving an appropriately modified mesh independence principle.

Shape optimization is described by finding the geometry of a structure which is optimal in the sense of a given minimized cost function with respect to certain

constraints. Many-faceted problems naturally arise in engineering applications with the goal of designing a specific structure in an optimal sense, or alternatively, of understanding and determining the shape of a given structure. Typical applications are the design of a nozzle [35], a thermal diffuser [14], an airfoil boundary [36], or various beams and plates [20], [38], with respect to specific optimality conditions.

Several methods, e.g., the speed method [38], the boundary element method [35], the fictitious domain method [19], and the mapping method [8], have been developed for such problems in the past. In particular, in recent years the homogenization method has been the focus of research for solving such kinds of optimal shape design problems (see, e.g., [1], [9], [11], [25], [33]). The computation of the solution is a time consuming task for all of them because it normally leads to a large scale optimization problem, which requires the subsequent solution of many boundary value problems. We restrict our presentation to the mapping method which has the advantage that the theory also covers a class of optimal control problems, where the coefficients of the variational equation are influenced by the control. However, the mesh independence assertions presented here can also be applied to the other kinds of methods.

The considered class of optimal shape design problems that are extensively investigated in [30], [31] can be written as

$$\min_{u \in \mathcal{U}_{ad}} \tilde{J}(u, \tilde{y}, \tilde{z}). \tag{1.1}$$

The design, respectively, control, function $u \in \mathcal{U}_{ad}$ parametrizes the bounded domain

$$\tilde{\Omega} = \{\tilde{x} = (\tilde{x}_1, \tilde{x}_2)^T \in \mathbb{R}^2 \,|\, \tilde{x}_2 \in I := (0,1) \wedge \tilde{x}_1 \in (0, u(\tilde{x}_2))\} \tag{1.2}$$

and $\mathcal{U}_{ad}$ is a suitable subset of a function space $\mathcal{U}$. The state $\tilde{y} \in \tilde{\mathcal{V}}$, $\tilde{\mathcal{V}}$ Hilbert space, is the solution of an elliptic boundary value problem of the second kind on the domain $\tilde{\Omega}$, and the function $\tilde{z} \in \tilde{\mathcal{Z}}$, $\tilde{\mathcal{Z}}$ Hilbert space, has to be introduced to describe a desired state of the function $\tilde{y}$ or for handling inhomogeneous Dirichlet boundary conditions.

Since the boundary value problem is solved with the finite element method, the weak formulation in terms of a variational equation on the moving domain $\tilde{\Omega}$ is used from the beginning. Based on the boundary partition $\partial\tilde{\Omega} = \tilde{\Gamma}_0 \cup \tilde{\Gamma}_1$ with $\tilde{\Gamma}_0 \cap \tilde{\Gamma}_1 = \emptyset$, the space of the state is defined by

$$\tilde{\mathcal{V}} = \{\phi \in \mathcal{H}^1(\tilde{\Omega}) |\, \gamma_0 \phi|_{\tilde{\Gamma}_0} = 0\},$$

where the trace map $\gamma_0 \in \mathcal{L}(\mathcal{H}^1(\tilde{\Omega}), \mathcal{H}^{\frac{1}{2}}(\partial\tilde{\Omega}))$ of order zero is further omitted if the meaning is obvious.

The mapping method transforms the moving domain $\tilde{\Omega}$ to a fixed domain Ω leading to an optimal control problem that is defined on fixed Ω. Therefore, we assume that a suitable transformation $T = T(u)$ completely determined by a function $u \in \mathcal{U}_{ad}$ exists, which is the case for several kinds of transformations, as presented, for example, by Banks and Kojima [5]. Thus, by using the generalized substitution rule the optimal shape design problem (1.1) is modified to the optimal control problem

$$\min_{u \in \mathcal{U}_{ad}} J(u, y, z) \tag{1.3}$$

with a general variational equation

$$a(u; y, \eta) = l(u; \eta) \qquad \forall \eta \in \mathcal{V}, \tag{1.4}$$

where the $\mathcal{V}$-elliptic and continuous bilinear form $a(u;\cdot,\cdot):\mathcal{V}\times\mathcal{V}\to\mathbb{R}$ is given by

$$a(u;y,\eta)=\sum_{|i|,|j|\leq 1}\langle a_{ij}(u)D^i y, D^j\eta\rangle_{\mathcal{L}^2(\Omega)}+\langle b(u)y,\eta\rangle_{\mathcal{L}^2(\Gamma_1)},$$

and the linear functional $l(u;\cdot):\mathcal{V}\to\mathbb{R}$ is defined by

$$l(u;\eta)=\sum_{|i|\leq 1}\langle f_i(u),\eta\rangle_{\mathcal{L}^2(\Omega)}+\langle f(u),\eta\rangle_{\mathcal{L}^2(\Gamma_1)}.$$

This variational equation is described on the fixed domain Ω, where the coefficient functions now depend nonlinearly on the parameter function $u\in\mathcal{U}_{ad}$. The tilde indicating a function, boundary, etc., on the moving domain $\tilde{\Omega}$ is omitted, if the symbols are defined analogously on the fixed region Ω.

The derived minimization problem is further simplified by supposing initially the nonactivity of the constraint $u\in\mathcal{U}_{ad}$; i.e., the problem (1.3), respectively, (1.4), can be treated with the modified cost function

$$\min_{u\in\mathcal{U}} J(u,y,z). \tag{1.5}$$

This simplification is justified if the solution u_* is supposed to be an interior point of $\mathcal{U}_{ad}$, and if the starting point is near the solution, which is guaranteed, for instance, if a nested iteration is used.

By using the Lax–Milgram lemma, the equality constraint (1.4) can be eliminated by a solution operator $y=S(u)$. Hence, the constrained minimization problem (1.5) is modified to the unconstrained minimization problem

$$\min_{u\in\mathcal{U}} J(u,S(u),z(u)). \tag{1.6}$$

To handle the possible ill-posedness of the problems, a Tikhonov regularization term (see, e.g., [6], [7]) is sometimes added to this cost function if necessary. Thus, (1.6) is finally written as

$$\min_{u\in\mathcal{U}} F(u) \tag{1.7}$$

with $F(u):=J(u,S(u),z(u))+\frac{\varepsilon}{2}\|u-u_{\mathcal{T}}\|^2_{\mathcal{T}},\ \ \varepsilon\in\mathbb{R}$, and a function $u_{\mathcal{T}}$.

There are two different procedures for stating numerical methods based on the differentiability properties. One way is to derive the derivatives in function spaces and to discretize the algorithm afterward as will be presented here. The other procedure that is commonly used in the context of optimal shape design problems is to discretize the problem first and then to state numerical methods for the discrete problem.

It is a well-known fact that both procedures could lead to different algorithms. This fact is discussed in detail, for instance, by Chenais [12] in the context of optimal shape design problems and by Kelley and Sachs [26], [28] for solving continuous problems with quasi-Newton methods.

In contrast to the commonly used procedure for solving optimal shape design problems, the discretization of the infinite dimensional algorithm offers the possibility of improving approximation results by comparing the computable iterates with the underlying infinite dimensional ones. A typical question for the research in this context is the provability of a mesh independence principle. In other words, do all quantities of the method, such as iterates, solutions, and convergence constants, depend continuously on the discretization?

This illustrates impressively the demand of a mesh independence principle for this specific class of problems. The research of Allgower et al. concerning Newton's method is stated in the context of nonlinear equations. Their work can be transferred to our minimization problem by the necessary first order condition $F'(u) = 0$ in $\mathcal{U}'$. Then, Newton's method is defined by ($n \in \mathbb{N}$)

$$\begin{aligned} F''(u_{n-1})(w)(v) &= -F'(u_{n-1})(v) \qquad \forall v \in \mathcal{U}, \\ u_n &= u_{n-1} + w, \end{aligned} \tag{1.8}$$

where F, F', and F'' also depend on functions defined on the infinite dimensional Hilbert space $\mathcal{V}$. This method is discretized by the replacement of the infinite dimensional spaces $\mathcal{V}$ and $\mathcal{U}$ with the finite dimensional subspaces $\mathcal{V}^N$ and $\mathcal{U}^M$, leading to the discretized algorithm

$$\begin{aligned} F''_N(u^M_{n-1})(w^M)(v^M) &= -F'_N(u^M_{n-1})(v^M) \qquad \forall v^M \in \mathcal{U}^M, \\ u^M_n &= u^M_{n-1} + w^M. \end{aligned} \tag{1.9}$$

At first glance, one difficulty for applying their results directly to the optimal shape design problems under consideration arises from the fact that the uniform boundedness of a projection operator Π is required. This operator should map the infinite dimensional space $\mathcal{U}$ to the finite element space $\mathcal{U}^M$. Unfortunately, for our problems $\mathcal{U}$ is chosen to be only a Banach and not a Hilbert space, which means that the existence of such a projection cannot be assured. The lack of a Hilbert space can be overcome in two ways.

First, we could try to extend the formulation of the problem from the Banach space $\mathcal{U}$ to any Hilbert space, for example, $\mathcal{H}^1(I)$. However, the Fréchet-differentiability has to be proven in this larger space, which is far more complicated. Also, the extension strategy of Tröltzsch [39], who stated optimality conditions in a Hilbert space assuming the differentiability only with respect to a smaller Banach space, cannot be applied since it is not guaranteed that the extension of the derivative with respect to $\mathcal{H}^1(I)$ even exists.

Second, the Banach space $\mathcal{U}$ could be restricted to a smaller Hilbert space, for example, $\mathcal{H}^2(I)$. However, the mesh independence theorem has to be stated under rather strong regularity conditions limiting the application to real problems.

On closer inspection of the Allgower et al. mesh independence theorem, one can see that their assumptions on the projection operator $\Pi : \mathcal{U} \to \mathcal{U}^M$ are required only since they do not assume $\mathcal{U}^M \subset \mathcal{U}$. Since this inclusion is naturally satisfied for the finite element method that is commonly used for solving optimal shape design problems, their theorem could be modified without using such a projection operator.

Another problem for applying the results of Allgower et al. is caused by their consistency condition with respect to the derivatives of the cost function. For the considered problems it is not reasonable to expect such a required order of consistency.

These are the reasons for presenting a new modified mesh independence principle in the next section, which could be applied to these optimal shape design problems. The main assertion of the paper is given in Theorem 2.2. Since the derivation of the underlying complicated theory for the construction of Newton's method to solve the optimal shape design problems would be beyond the scope of this paper, we give only evidence for the necessity of the modified mesh independence theorem in section 3 and refer to the paper [31] for the theory. Finally, the discretization of the algorithm is given by the finite element method, and numerical results confirm the practical importance of the derived assertions.

2. Mesh independence principle. The modification of Newton's mesh independence theorem is adjusted to the notation of minimization problems and could be applied to the optimal shape design problems under consideration. For the nth iteration of Newton's method it leads to the estimate of the error $\|u_n - u_n^M\|_{\mathcal{U}}$ instead of the weaker assertion of the standard theorem based on the error $\|\Pi u_n - u_n^M\|_{\mathcal{U}}$. Throughout the proofs advantage is taken of the fact that the approximated function F_N is defined for all $u \in \mathcal{U}$, although it will be evaluated only for some points $u^M \in \mathcal{U}^M$.

Corresponding to the infinite dimensional convergence assertion, u_0 can be chosen to be in the ball $U_* := U(u_*, \rho_*) := \{u \in \mathcal{U} : \|u - u_*\|_{\mathcal{U}} \le \rho_*\}$ in order to guarantee the convergence to the solution u_*. Some further assumptions concerning the cost function F_N, which are assumed to hold on a possibly smaller ball $\hat{U}_* := \hat{U}(u_*, \hat{\rho}_*) := \{u \in \mathcal{U} : \|u - u_*\|_{\mathcal{U}} \le \hat{\rho}_*\}$ with $\hat{\rho}_* \le \rho_*$, will be stated in the following.

Assumption C1. Let the assumptions of the theorem on the q-quadratic convergence of Newton's method for the infinite dimensional problem be satisfied. In particular, with appropriate constants L and δ

$$\begin{aligned} \|F''(u) - F''(v)\|_{\mathcal{L}(\mathcal{U},\mathcal{L}(\mathcal{U},\mathbb{R}))} &\le L\|u - v\|_{\mathcal{U}} \qquad \forall u, v \in U_*, \\ \|F''(u_*)^{-1}\|_{\mathcal{L}(\mathcal{L}(\mathcal{U},\mathbb{R}),\mathcal{U})} &\le \delta. \end{aligned}$$

Assumption C2. There exist uniformly bounded Lipschitz constants $L_N^{(i)}$, $i = 1, 2$, such that

$$\begin{aligned} \|F_N'(u) - F_N'(v)\|_{\mathcal{L}(\mathcal{U},\mathbb{R})} &\le L_N^{(1)}\|u - v\|_{\mathcal{U}} \ \ \forall u, v \in \hat{U}_*, \forall N \in \mathbb{N}, \\ \|F_N''(u) - F_N''(v)\|_{\mathcal{L}(\mathcal{U},\mathcal{L}(\mathcal{U},\mathbb{R}))} &\le L_N^{(2)}\|u - v\|_{\mathcal{U}} \ \ \forall u, v \in \hat{U}_*, \forall N \in \mathbb{N}. \end{aligned}$$

Without loss of generality, we assume $L_N^{(i)} \le L$, $i = 1, 2$, for all N.

Assumption C3. There exists a sequence $\zeta_N^{(1)}$ with $\zeta_N^{(1)} \overset{N\to\infty}{\longrightarrow} 0$, such that

$$\begin{aligned} \|F_N'(u) - F'(u)\|_{\mathcal{L}(\mathcal{U},\mathbb{R})} &\le \zeta_N^{(1)} \qquad \forall u \in \hat{U}_*, \forall N \in \mathbb{N}, \\ \|F_N''(u) - F''(u)\|_{\mathcal{L}(\mathcal{U},\mathcal{L}(\mathcal{U},\mathbb{R}))} &\le \zeta_N^{(1)} \qquad \forall u \in \hat{U}_*, \forall N \in \mathbb{N}. \end{aligned}$$

Assumption C4. There exists a sequence $\zeta_M^{(2)}$ with $\zeta_M^{(2)} \overset{M\to\infty}{\longrightarrow} 0$, such that for all $M \in \mathbb{N}$ there exists a $\hat{u}^M \in \mathcal{U}^M \cap \hat{U}_*$, such that $\|\hat{u}^M - u_*\|_{\mathcal{U}} \le \zeta_M^{(2)}$.

Assumption C5. F_N' and F_N'' correspond to the derivatives of F_N.

Since the cost function F is assumed to be twice continuously Fréchet-differentiable, its first derivative is also Lipschitz continuous

$$\|F'(u) - F'(v)\|_{\mathcal{L}(\mathcal{U},\mathbb{R})} \le \hat{L}\|u - v\|_{\mathcal{U}} \qquad \forall u, v \in U_*,$$

where, without loss of generality, we also assume $\hat{L} \le L$.

Since $\|F''(u_*)^{-1}\|_{\mathcal{L}(\mathcal{U},\mathcal{L}(\mathcal{U},\mathbb{R}))} \le \delta$ and

$$\begin{aligned} &\delta\|F''(u_*) - F_N''(\hat{u}^M)\|_{\mathcal{L}(\mathcal{U},\mathcal{L}(\mathcal{U},\mathbb{R}))} \\ &\le \delta\|F''(u_*) - F''(\hat{u}^M)\|_{\mathcal{L}(\mathcal{U},\mathcal{L}(\mathcal{U},\mathbb{R}))} + \delta\|F''(\hat{u}^M) - F_N''(\hat{u}^M)\|_{\mathcal{L}(\mathcal{U},\mathcal{L}(\mathcal{U},\mathbb{R}))} \\ &\le \delta L\zeta_M^{(2)} + \delta\zeta_N^{(1)} \le \delta\hat{\zeta} < 1 \end{aligned}$$

hold for a constant $\hat{\zeta} \in \mathbb{R}$ if M and N are sufficiently large, the Banach lemma [24, Thm. V.2.4] yields the existence of $F''(\hat{u}^M)^{-1}$ with

$$\|F''(\hat{u}^M)^{-1}\|_{\mathcal{L}(\mathcal{U},\mathcal{L}(\mathcal{U},\mathbb{R}))} \leq \frac{\delta}{1-\delta\hat{\zeta}} =: \hat{\delta}.$$

Analogously, since it is known that $\rho_* \leq \frac{2}{3\delta L} < \frac{1}{\delta L}$ [37], the inequalities

$$\delta\|F''(u_i) - F''(u_*)\|_{\mathcal{L}(\mathcal{U},\mathcal{L}(\mathcal{U},\mathbb{R}))} \leq \delta L\|u_i - u_*\|_{\mathcal{U}} \leq \delta L\rho_* < 1$$

hold yielding the existence of $F''(u_i)^{-1}$ with

$$\|F''(u_i)^{-1}\|_{\mathcal{L}(\mathcal{L}(\mathcal{U},\mathbb{R}),\mathcal{U})} \leq \frac{\delta}{1-\delta L\rho_*} =: \hat{\delta}.$$

Therefore, possibly by redefining δ by the constant $\hat{\delta}$, it can be assumed that

$$\|F''(u_i)^{-1}\|_{\mathcal{L}(\mathcal{L}(\mathcal{U},\mathbb{R}),\mathcal{U})} \leq \delta \qquad \forall i \in \mathbb{N}, \tag{2.1}$$

$$\|F''_N(\hat{u}^M)^{-1}\|_{\mathcal{L}(\mathcal{L}(\mathcal{U},\mathbb{R}),\mathcal{U})} \leq \delta \qquad \forall \hat{u}^M, \forall N \in \mathbb{N}, \tag{2.2}$$

for M and N satisfying $\delta L\zeta_M^{(2)} + \delta\zeta_N^{(1)} \leq \delta\hat{\zeta} < 1$.

The next theorem presents sufficient conditions for the existence of a solution of the minimization problem

$$\min_{u^M \in \mathcal{U}^M} F_N(u^M) \tag{2.3}$$

and describes the convergence behavior of Newton's method for $M, N \to \infty$.

Theorem 2.1. *Let* (C1)–(C5) *be satisfied. Assume that the discretization parameters M and N fulfill the condition*

$$\zeta_{MN} := 2\delta\left(\max\{1,L\} + \frac{1}{2\delta}\right)\left(\zeta_N^{(1)} + \zeta_M^{(2)}\right) \leq \min\left\{\hat{\rho}_*, \frac{1}{\delta L}\right\}. \tag{2.4}$$

Then the discretized Newton's method has a local solution $u_*^M \in \hat{U}_*$, and the discretization error satisfies

$$\|u_*^M - u_*\|_{\mathcal{U}} \leq \zeta_{MN}.$$

Proof. The basic idea is to apply Kantorowitsch's theorem [24] to Newton's method with starting point $u_0^M = \hat{u}^M \in \hat{U}_*$ in order to obtain the existence of a solution u_*^M of the infinite dimensional minimization problem. The corresponding geometrical situation is sketched in Figure 2.1.

First, Assumptions C2–C4, equation (2.2), and the condition (2.4) yield the inequalities

$$\begin{aligned} 2h &:= 2\delta L\|F''_N(\hat{u}^M)^{-1}F'_N(\hat{u}^M)\|_{\mathcal{U}} \\ &\leq 2\delta L\|F''_N(\hat{u}^M)^{-1}\|_{\mathcal{L}(\mathcal{L}(\mathcal{U},\mathbb{R}),\mathcal{U})}\|F'_N(\hat{u}^M)\|_{\mathcal{L}(\mathcal{U},\mathbb{R})} \\ &\leq 2\delta^2 L\left(\|F'_N(\hat{u}^M) - F'(\hat{u}^M)\|_{\mathcal{L}(\mathcal{U},\mathbb{R})} + \|F'(\hat{u}^M) - F'(u^*)\|_{\mathcal{L}(\mathcal{U},\mathbb{R})}\right) \\ &\leq 2\delta^2 L\left(\zeta_N^{(1)} + L\|\hat{u}^M - u^*\|_{\mathcal{U}}\right) \\ &\leq 2\delta^2 L\max\{1,L\}\left(\zeta_N^{(1)} + \zeta_M^{(2)}\right) \qquad (2.5) \\ &\leq 2\delta^2 L\left(\max\{1,L\} + \frac{1}{2\delta}\right)\left(\zeta_N^{(1)} + \zeta_M^{(2)}\right) \leq \delta L\zeta_{MN} \leq 1, \end{aligned}$$

which imply the required assumption $h \leq \frac{1}{2}$.

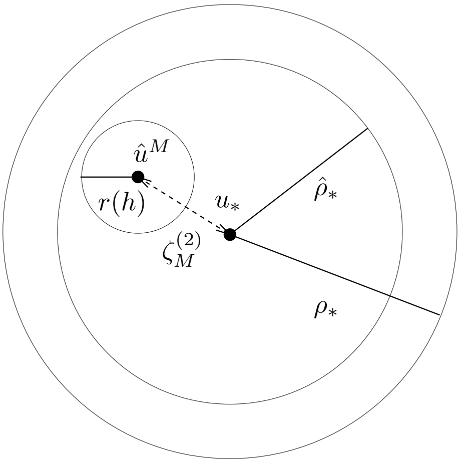

FIG. 2.1. *Balls used for the local convergence investigations.*

To be able to apply the Kantorowitsch theorem only the condition $U(\hat{u}^M, r(h)) \subset U(u_*, \hat{\rho}_*)$ remains to be checked. Because of Assumption C4 this condition can be rewritten as

$$r(h) := \frac{1}{\delta L}(1 - \sqrt{1-2h}) \leq \hat{\rho}_* - \zeta_M^{(2)}, \tag{2.6}$$

which is proven by using the given assumptions and inequality (2.6):

$$\begin{aligned} r(h) &\leq \frac{1}{\delta L}\left(1 - \sqrt{1 - 2\delta^2 L \max\{1, L\}\left(\zeta_N^{(1)} + \zeta_M^{(2)}\right)}\right) \\ &\leq \frac{2\delta \max\{1, L\}(\zeta_N^{(1)} + \zeta_M^{(2)})}{1 + \sqrt{1 - 2\delta^2 L \max\{1, L\}(\zeta_N^{(1)} + \zeta_M^{(2)})}} \\ &\leq 2\delta \max\{1, L\}\left(\zeta_N^{(1)} + \zeta_M^{(2)}\right) \\ &\leq 2\delta\left(\max\{1, L\} + \frac{1}{2\delta}\right)\left(\zeta_N^{(1)} + \zeta_M^{(2)}\right) - \zeta_M^{(2)} \\ &\leq \zeta_{MN} - \zeta_M^{(2)} \leq \hat{\rho}_* - \zeta_M^{(2)}. \end{aligned}$$

Finally, this yields the existence of a solution $u_*^M \in U(\hat{u}^M, r(h))$ and

$$\|u_*^M - u_*\|_{\mathcal{U}} \leq \|u_*^M - \hat{u}^M\|_{\mathcal{U}} + \|\hat{u}^M - u_*\|_{\mathcal{U}} \leq \zeta_{MN} - \zeta_M^{(2)} + \zeta_M^{(2)} = \zeta_{MN}. \qquad \square$$

Now we have proven that a solution $u_*^M \in U(\hat{u}^M, r(h)) \subset U(u_*, \hat{\rho}_*)$ of the discretized minimization problem exists. Next, the main theorem of the paper shows that the discretized Newton's method converges to the solution u_*^M for any $u_0^M \in U(u_*, \rho_1)$ for sufficiently small ρ_1.

THEOREM 2.2. *Let Assumptions* C1–C5 *be satisfied, and assume that the discretization parameters M and N satisfy the condition $\zeta_{MN} \leq \frac{1}{6}\min\left\{\frac{\hat{\rho}_*}{4}, \frac{1}{6L\delta+1}\right\}$. Then the discretized Newton's method converges to u_*^M for all $u_0^M \in U(u_*, \rho_1)$ with*

$\rho_1 = \frac{3}{4}\min\{\frac{1}{3L\delta}, \frac{\hat{\rho}_*}{2}\}$. *In addition, for all starting points satisfying the condition*

$$\|u_0^M - u_0\|_{\mathcal{U}} \le \tau$$

with $\tau = \frac{2(\frac{1}{2}+\|u_0-u_*\|_{\mathcal{U}})\zeta_{MN}}{b^2+\sqrt{b^2-6L\delta(\frac{1}{2}+\|u_0-u_*\|_{\mathcal{U}})\zeta_{MN}}}$ *and* $b = 1 + \frac{1}{2}\zeta_{MN} - 2\delta L\|u_0^M - u_*\|_{\mathcal{U}}$, *the following convergence properties hold* ($c_1, c_2, c_3, c_4 \in \mathbb{R}, n \in \mathbb{N}$)*:*

$$\|u_{n+1}^M - u_*^M\|_{\mathcal{U}} \le c_1\|u_n^M - u_*^M\|_{\mathcal{U}}^2, \tag{2.7}$$

$$\|u_n^M - u_n\|_{\mathcal{U}} \le c_2\zeta_{MN}, \tag{2.8}$$

$$\|F_N'(u_n^M) - F'(u_n)\|_{\mathcal{L}(\mathcal{U},\mathbb{R})} \le c_3\zeta_{MN}, \tag{2.9}$$

$$\|u_n^M - u_*^M\|_{\mathcal{U}} \le \|u_n - u_*\|_{\mathcal{U}} + c_4\zeta_{MN}. \tag{2.10}$$

Proof. The proof is divided into three parts. First, the convergence of the discretized Newton's method is proven for all u_0^M in a suitable ball around u_*. Then, the convergence of the iteration function u_n^M to the infinite dimensional iteration u_n is shown, and third, the proof is finished.

1. Since the assumptions of Theorem 2.1 are fulfilled, the existence of a solution $u_*^M \in \hat{U}_*$ is guaranteed. Now, it will be shown that the convergence of the discretized Newton's method to this solution is guaranteed, if u_0^M is chosen to be in $U(u_*, \rho_2)$ with $\rho_2 = \min\left\{\frac{1}{3L\delta}, \frac{\hat{\rho}_*}{2}\right\}$ and $\zeta_{MN} \le \min\left\{\frac{\hat{\rho}_*}{4}, \frac{1}{6L\delta+1}\right\}$.

   The inequalities

$$\begin{aligned}\|u_*^M - u_*\|_{\mathcal{U}} + \|u_0^M - u_*^M\|_{\mathcal{U}} &\le 2\|u_*^M - u_*\|_{\mathcal{U}} + \|u_0^M - u_*\|_{\mathcal{U}} \\ &\le 2\zeta_{MN} + \rho_2 \le \hat{\rho}_*\end{aligned}$$

   imply that $U(u_*^M, \|u_0^M - u_*^M\|_{\mathcal{U}}) \subset \hat{U}_*$, which means that Assumptions C1–C5 are also valid in $U(u_*^M, \|u_0^M - u_*^M\|_{\mathcal{U}})$.

   Since $\|F''(u_*)^{-1}\|_{\mathcal{L}(\mathcal{L}(\mathcal{U},\mathbb{R}),\mathcal{U})} \le \delta$ and since the definition of ζ_{MN} implies $\zeta_N^{(1)} \le \frac{1}{2\delta}\zeta_{MN}$, the following inequalities are obtained using Theorem 2.1:

$$\begin{aligned}&\delta\|F_N''(u_*^M) - F''(u_*)\|_{\mathcal{L}(\mathcal{U},\mathcal{L}(\mathcal{U},\mathbb{R}))} \\ &\le \delta\|F_N''(u_*^M) - F_N''(u_*)\|_{\mathcal{L}(\mathcal{U},\mathcal{L}(\mathcal{U},\mathbb{R}))} + \delta\|F_N''(u_*) - F''(u_*)\|_{\mathcal{L}(\mathcal{U},\mathcal{L}(\mathcal{U},\mathbb{R}))} \\ &\le \delta L\|u_*^M - u_*\|_{\mathcal{U}} + \delta\zeta_N^{(1)} \le \delta L\zeta_{MN} + \frac{1}{2}\zeta_{MN} \le \frac{\delta L + \frac{1}{2}}{6L\delta + 1} < 1.\end{aligned}$$

   Now the Banach lemma yields $\|F_N''(u_*^M)^{-1}\|_{\mathcal{L}(\mathcal{L}(\mathcal{U},\mathbb{R}),\mathcal{U})} \le \frac{\delta}{1-(\delta L+\frac{1}{2})\zeta_{MN}}$.

   So all assumptions of the theorem on the q-quadratic convergence of Newton's method are fulfilled, yielding the convergence to u_*^M for all u_0^M in a neighborhood of u_*^M. By applying a refined formulation of this theorem, which is given by Rheinboldt [3], [37], the convergence is even guaranteed for all $u_0^M \in U(u_*^M, r_*)$ with $r_* = \frac{2}{3L\|F_N''(u_*^M)^{-1}\|_{\mathcal{L}(\mathcal{L}(\mathcal{U},\mathbb{R}),\mathcal{U})}}$.

   Only $U(u_*, \rho_2) \subset U(u_*^M, r_*)$ remains to be proven in order to ensure the convergence for any $u_0^M \in U(u_*, \rho_2)$, which is implied by

$$\begin{aligned}\|u_0^M - u_*^M\|_{\mathcal{U}} &\leq \|u_0^M - u_*\|_{\mathcal{U}} + \|u_* - u_*^M\|_{\mathcal{U}} \\ &\leq \rho_2 + \zeta_{MN} \\ &\leq \frac{1 + 3L\delta\zeta_{MN}}{3L\delta} \\ &< \frac{2(1 - L\delta\zeta_{MN} - \frac{1}{2}\zeta_{MN})}{3L\delta} \\ &\leq \frac{2}{3L\|F_N''(u_*^M)^{-1}\|_{\mathcal{L}(\mathcal{L}(\mathcal{U},\mathbb{R}),\mathcal{U})}} =: r_*.\end{aligned}$$

To sum up, the discretized Newton's method converges to u_*^M for all $u_0^M \in U(u_*, \rho_2)$ with the q-quadratic convergence rate

$$\|u_{n+1}^M - u_*^M\|_{\mathcal{U}} \leq \delta L \|u_n^M - u_*^M\|_{\mathcal{U}}^2,$$

where $c_1 = \delta L$ is independent of the discretization parameters M and N.

2. In this part a proof by induction is used to show

$$\|u_n^M - u_n\|_{\mathcal{U}} \leq \tau \leq c_2\zeta_{MN} \tag{2.11}$$

for all $u_0^M \in U(u_*, \rho_1)$, $\rho_1 = \frac{3}{4}\rho_2$, and for all discretization parameters M and N fulfilling $\zeta_{MN} \leq \frac{1}{6}\min\left\{\frac{\hat{\rho}_*}{4}, \frac{1}{6L\delta+1}\right\}$, where τ is given by

$$\begin{aligned}\tau &= \frac{2(\frac{1}{2} + \|u_0 - u_*\|_{\mathcal{U}})\zeta_{MN}}{b^2 + \sqrt{b^2 - 6L\delta(\frac{1}{2} + \|u_0 - u_*\|_{\mathcal{U}})\zeta_{MN}}} \\ &\leq \frac{2(\frac{1}{2} + \|u_0 - u_*\|_{\mathcal{U}})\zeta_{MN}}{b^2} =: c_2\zeta_{MN}\end{aligned}$$

with $b = 1 + \frac{1}{2}\zeta_{MN} - 2\delta L\|u_0^M - u_*\|_{\mathcal{U}}$. The constant τ is well defined, since the inequalities

$$6L\delta\left(\frac{1}{2} + \|u_0 - u_*\|_{\mathcal{U}}\right)\zeta_{MN} \leq \frac{2L\delta + 1}{4(6L\delta + 1)} < \frac{1}{4} \text{ and } b \geq 1 - 2\delta L\rho_1 \geq \frac{1}{2}$$

imply $b^2 \geq \frac{1}{4} \geq 6L\delta\left(\frac{1}{2} + \|u_0 - u_*\|_{\mathcal{U}}\right)\zeta_{MN}$.

While the assertion (2.11) is fulfilled by assumption for $n = 0$, the induction step is based on the simple decomposition

$$\begin{aligned}u_{i+1}^M - u_{i+1} = F_N''(u_i^M)^{-1}\{&[F_N''(u_i^M)(u_i^M - u_i) - F_N'(u_i^M) + F_N'(u_i)] \\ &+[(F_N''(u_i^M) - F_N''(u_i))(F''(u_i)^{-1}F'(u_i))] \\ &+[F_N''(u_i)(F''(u_i)^{-1}F'(u_i)) - F'(u_i)] \\ &+[F'(u_i) - F_N'(u_i)]\}.\end{aligned} \tag{2.12}$$

Assumptions C1–C4, equation (2.1), and the definition of ζ_{MN} imply

$$\begin{aligned}&\delta\|F_N''(u_i^M) - F''(u_i)\|_{\mathcal{L}(\mathcal{U},\mathcal{L}(\mathcal{U},\mathbb{R}))} \\ &\leq \delta\|F_N''(u_i^M) - F_N''(u_i)\|_{\mathcal{L}(\mathcal{U},\mathcal{L}(\mathcal{U},\mathbb{R}))} + \delta\|F_N''(u_i) - F''(u_i)\|_{\mathcal{L}(\mathcal{U},\mathcal{L}(\mathcal{U},\mathbb{R}))} \\ &\leq \delta(L\tau + \zeta_N^{(1)}) \leq \delta L\tau + \frac{1}{2}\zeta_{MN} \leq \frac{\delta L\zeta_{MN} + 2\|u_0 - u_*\|_{\mathcal{U}}\delta L\zeta_{MN}}{1 - 2\delta L\|u_0 - u_*\|_{\mathcal{U}}} + \frac{1}{2}\zeta_{MN} \\ &\leq \frac{\frac{1}{3}\delta L + \frac{1}{4}}{6L\delta + 1} < 1\end{aligned}$$

resulting in the inequality $\|F_N''(u_i^M)^{-1}\|_{\mathcal{L}(\mathcal{L}(\mathcal{U},\mathbb{R}),\mathcal{U})} \leq \frac{\delta}{1-(L\delta\tau+\frac{1}{2}\zeta_{MN})}$. Using a standard argument [16, Lemma 2.4.2] we obtain

$$\|F_N''(u_i^M)(u_i^M-u_i)-F_N'(u_i^M)+F_N'(u_i)\|_{\mathcal{L}(\mathcal{U},\mathbb{R})} \leq \frac{1}{2}L\|u_i^M-u_i\|_{\mathcal{U}}^2 \leq \frac{1}{2}L\tau^2,$$

and the derived convergence assertion $\|u_i-u_*\|_{\mathcal{U}} \leq \|u_0-u_*\|_{\mathcal{U}}$ yields

$$\begin{aligned}&\|(F_N''(u_i^M)-F_N''(u_i))(F''(u_i)^{-1}F'(u_i))\|_{\mathcal{L}(\mathcal{U},\mathbb{R})}\\ &\leq L\|u_i^M-u_i\|_{\mathcal{U}}\|u_i-u_{i+1}\|_{\mathcal{U}} \leq 2L\tau\|u_0-u_*\|_{\mathcal{U}}.\end{aligned}$$

The assumptions of the theorem lead to

$$\begin{aligned}&\|F_N''(u_i)(F''(u_i)^{-1}F'(u_i))-F'(u_i)\|_{\mathcal{L}(\mathcal{U},\mathbb{R})}\\ &\leq \|-F_N''(u_i)(u_{i+1}-u_i)+F''(u_i)(u_{i+1}-u_i)\|_{\mathcal{L}(\mathcal{U},\mathbb{R})}\\ &\leq \|F_N''(u_i)-F''(u_i)\|_{\mathcal{L}(\mathcal{U},\mathcal{L}(\mathcal{U},\mathbb{R}))}\|u_{i+1}-u_i\|_{\mathcal{U}}\\ &\leq \zeta_N^{(1)}2\|u_0-u_*\|_{\mathcal{U}} \leq \frac{1}{\delta}\zeta_{MN}\|u_0-u_*\|_{\mathcal{U}}\end{aligned}$$

and $\|F'(u_i)-F_N'(u_i)\|_{\mathcal{L}(\mathcal{U},\mathbb{R})} \leq \zeta_N^{(1)} \leq \frac{1}{2\delta}\zeta_{MN}$. Using the decomposition (2.12) the last inequalities complete the induction proof by

$$\begin{aligned}&\|u_{i+1}^M-u_{i+1}\|_{\mathcal{U}}\\ &\leq \frac{\delta}{1-(L\delta\tau+\frac{1}{2}\zeta_{MN})}\left\{\frac{1}{2}L\tau^2+2L\|u_0-u_*\|_{\mathcal{U}}\tau+\left(\frac{1}{2}+\|u_0-u_*\|_{\mathcal{U}}\right)\frac{\zeta_{MN}}{\delta}\right\}\\ &=\tau.\end{aligned}$$

The last equality is based on the fact that τ is equal to the smallest solution of the quadratic equation $3L\delta\tau^2-2b\tau+2\zeta_{MN}(\frac{1}{2}+\|u_0-u_*\|_{\mathcal{U}})=0$.

3. Finally, inequality (2.9) is shown by

$$\begin{aligned}&\|F_N'(u_n^M)-F'(u_n)\|_{\mathcal{L}(\mathcal{U},\mathbb{R})}\\ &\leq \|F_N'(u_n^M)-F_N'(u_n)\|_{\mathcal{L}(\mathcal{U},\mathbb{R})}+\|F_N'(u_n)-F'(u_n)\|_{\mathcal{L}(\mathcal{U},\mathbb{R})}\\ &\leq L\|u_n^N-u_n\|_{\mathcal{U}}+\zeta_{MN} \leq (Lc_2+1)\zeta_{MN} =: c_3\zeta_{MN},\end{aligned}$$

and inequality (2.10) results from

$$\begin{aligned}&\|(u_n^M-u_*^M)-(u_n-u_*)\|_{\mathcal{U}} \leq \|u_n^M-u_n\|_{\mathcal{U}}+\|u_*^M-u_*\|_{\mathcal{U}}\\ &\leq c_2\zeta_{MN}+\zeta_{MN} \leq (c_2+1)\zeta_{MN} =: c_4\zeta_{MN}. \qquad \square\end{aligned}$$

At the end of this section, the influence of the derived convergence results on the required number of iterations is analyzed with respect to the stopping criterion

$$\begin{aligned}t_i &:= \|F''(u_i)(u_{i+1}-u_i)-F'(u_i)\|_{\mathcal{L}(\mathcal{U},\mathbb{R})} \leq \text{TOL},\\ t_i^{MN} &:= \|F_N''(u_i^M)(u_{i+1}^M-u_i^M)-F_N'(u_i^M)\|_{\mathcal{L}(\mathcal{U},\mathbb{R})} \leq \text{TOL}.\end{aligned}$$

The number $i(\text{TOL})$, respectively, $i^{MN}(\text{TOL})$, is defined to be the smallest iteration number satisfying the stopping criterion, i.e., $i^{MN}(\text{TOL}) := \min\{i : t_i^{MN} \leq \text{TOL}\}$, respectively, $i(\text{TOL}) := \min\{i : t_i \leq \text{TOL}\}$.

LEMMA 2.3. *Let the assumptions of Theorem* 2.2 *be satisfied. Then for every* $\text{TOL} > 0$ *and* $\epsilon > 0$, *there exist parameters* $\hat{M}, \hat{N} \in \mathbb{N}$ *such that*

$$\begin{aligned} &i(\text{TOL} + \epsilon) \leq i^{MN}(\text{TOL}) \leq i(\text{TOL}) \qquad \forall M \geq \hat{M}, N \geq \hat{N}, \text{ and} \\ &i^{MN}(\text{TOL}) = i(\text{TOL}) \qquad \forall M \geq \hat{M}, N \geq \hat{N}. \end{aligned}$$

Proof. By using the different assumptions and Theorem 2.2, the inequality

$$|t_i - t_i^{MN}| \leq c\zeta_{MN} \tag{2.13}$$

can easily be derived. The remaining part corresponds to the proof of Corollary 4.2.6 in [21]. Based on (2.13) it is possible to choose $\hat{M}$ and $\hat{N}$ such that the inequalities

$$\begin{aligned} |t_{i(\text{TOL})} - t_{i(\text{TOL})}^{MN}| \leq \text{TOL} - t_{i(\text{TOL})} \qquad \forall M \geq \hat{M}, N \geq \hat{N}, \\ |t_i - t_i^{MN}| \leq \epsilon \qquad \forall M \geq \hat{M}, N \geq \hat{N}, \end{aligned}$$

are fulfilled. Then, for all $M \geq \hat{M}, N \geq \hat{N}$,

$$t_{i(\text{TOL})}^{MN} \leq t_{i(\text{TOL})} + |t_{i(\text{TOL})} - t_{i(\text{TOL})}^{MN}| \leq \text{TOL}$$

implies $i^{MN}(\text{TOL}) \leq i(\text{TOL})$, and $i(\text{TOL} + \epsilon) \leq i^{MN}(\text{TOL})$ is derived using

$$t_{i^{MN}(\text{TOL})} \leq t_{i^{MN}(\text{TOL})}^{MN} + |t_{i^{MN}(\text{TOL})} - t_{i^{MN}(\text{TOL})}^{MN}| \leq \text{TOL}.$$

The definition of $i(\text{TOL})$ ensures that $t_{i(\text{TOL})-1} > \text{TOL}$. By choosing $\epsilon = \frac{t_{i(\text{TOL})-1} - \text{TOL}}{2}$ we get $\text{TOL} + \epsilon < t_{i(\text{TOL})-1}$. But to obtain a residual that is less than $t_{i(\text{TOL})-1}$, at least one more iteration is necessary, i.e.,

$$i(\text{TOL} + \epsilon) \geq (i(\text{TOL}) - 1) + 1. \qquad \square$$

This explains the frequently observed numerical behavior that the required iteration number is independent of the discretization parameters if these are large enough.

3. Optimal shape design problems. The computing of the first two derivatives of the cost function is based on the adjoint $p \in \mathcal{V}$ given by the solution of the equation

$$a(u; \eta, p) = J_y(u, S(u), z(u))(\eta) \qquad \forall \eta \in \mathcal{V}. \tag{3.1}$$

Some assumptions are listed here for the infinite dimensional problems in order to adapt the theorem of Newton's q-quadratic convergence rate. Although they could be weakened, for the sake of simplicity we have stated them in a rather general version.

ASSUMPTION A1. $\Omega \subset \mathbb{R}^2$ is Lipschitz continuous.

ASSUMPTION A2. $a(u; \cdot, \cdot)$ is a $\mathcal{V}$-elliptic bilinear form for all $u \in \mathcal{U}_{ad}$.

ASSUMPTION A3. The second Fréchet-derivatives of $f(u) \in \mathcal{V}'$, $a_{ij}(u) \in \mathcal{L}^\infty(\Omega)$, and $b(u) \in \mathcal{L}^\infty(\Gamma_1)$ exist and are Lipschitz continuous in u.

ASSUMPTION A4. $J : \mathcal{U}_{ad} \times \mathcal{V} \times \mathcal{Z} \otimes \mathbb{R}$ is twice continuously Fréchet-differentiable and $J_y(u, S(u), z(u)) \in \mathcal{V}'$, $J_{yu}(u, S(u), z(u))(v) \in \mathcal{V}'$ for all $v \in \mathcal{U}$, $J_{yy}(u, S(u), z(u)) \in (\mathcal{V} \times \mathcal{V})'$, $J_{yz}(u, S(u), z(u)) \in (\mathcal{V} \times \mathcal{Z})'$ are Lipschitz continuous with respect to all components.

Now, the well-known theorem can be written in the following version.

THEOREM 3.1. *Let Assumptions* A1–A4 *be satisfied. Let $z(u) \in \mathcal{Z}$ be twice continuously Fréchet-differentiable in an open neighborhood U of the solution u_*, and $z''(u)$, as well as all partial derivatives of J, be Lipschitz continuous. The existence of $F''(u_*)^{-1} \in \mathcal{L}(\mathcal{L}(\mathcal{U}, \mathbb{R}), \mathcal{U})$ and of the solution u_* in the interior of $\mathcal{U}_{ad}$ is further ensured.*

Then there exists a $\rho_* > 0$, such that the iterative sequence $\{u_n\}$ generated by Newton's method converges to the solution u_* for every initial value u_0 with $\|u_0 - u_*\|_{\mathcal{U}} \leq \rho_*$. Moreover, there is a suitable constant C depending on U and on the existing Lipschitz constant L of the second derivative of the cost function, such that

$$\|u_n - u_*\|_{\mathcal{U}} \leq C\|u_{n-1} - u_*\|_{\mathcal{U}}^2. \tag{3.2}$$

Proof. The theorem is stated in such a way that all the assumptions for stating the first derivative of the cost function are fulfilled (see [32], [31]). Hence, Newton's method is well defined and the desired assertion is derived as an application of the general theorem on Newton's q-quadratic convergence rate [40, p. 208]. □

The finite element method is used for the discretization of the variational equations in $\Omega \subset \mathbb{R}^2$, as well as for the calculation of Newton's equation in $I \subset \mathbb{R}$. Let $\{\psi_k\}_{k=1}^M, \psi_k \in \mathcal{U}^M$, be the one-dimensional spline basis functions and let $\{\phi_\tau\}_{\tau=1}^N, \phi_\tau \in \mathcal{V}^N$, be the two-dimensional spline basis functions, which are used to solve the distinct variational equations. In the following a vector consisting of the N or M basis coefficient is always denoted with an arrow on top of the same letter as the coefficient, e.g., $\vec{y}^N$.

For the optimal shape design problems Newton's equation is now written as

$$\langle F_N''(u^M)(w^M), v^M\rangle = \langle -F_N'(u^M), v^M\rangle \qquad \forall v^M \in \mathcal{U}^M, \tag{3.3}$$

which is equivalent to the linear system $H\vec{w}^M = d$, with the Hessian matrix $H = \langle F_N''(u^M)(\psi_i), \psi_j\rangle_{i,j=1}^M \in \mathbb{R}^{M\times M}$ and the vector $d = \langle -F_N'(u^M), \psi_i\rangle_{i=1}^M \in \mathbb{R}^M$. In [31] it has been proven that the right-hand side vector can be computed by

$$\begin{aligned} d = {} & \langle -J_u(u^M, y^N, z(u^M)) - J_z(u^M, y^N, z(u^M))z'(u^M), \psi_i\rangle_{i=1}^M \\ & -H_1\vec{p}^N - H_4(\vec{u}^M - \vec{u}_{\mathcal{T}}^M) \end{aligned}$$

and the required result of the matrix-vector multiplication $H\vec{w}^M$ is given by

$$H\vec{w}^M = H_1\vec{\hat{p}}^N + H_2\vec{\hat{y}}^N + H_3\vec{w}^M + H_4\vec{w}^M$$

for any vector $\vec{w}^M$, where $H_i, i = 1, \ldots, 4$, are specific sparse auxiliary matrices. The state y^N and the adjoint p^N, as well as the derivative of the state $\hat{y}^N = \hat{y}^N(w^M)$ and of the adjoint $\hat{p}^N = \hat{p}^N(w^M)$, are given by the solution of a variational problem of the kind (1.4).

Now, the question will be answered as to how the discretization parameter N influences the state, the adjoint, and the derivatives of the cost function. A detailed analysis is necessary, since the corresponding errors are influenced not only explicitly but also implicitly; for example, the error of the adjoint depends also on the error of the state. The term semidiscretized problem is used in the sense that the discretization is done only with respect to the parameter N, but not with respect to M. Nevertheless, since $\mathcal{U}^M \subset \mathcal{U}$, the approximation properties are also true for a fixed $u^M \in \mathcal{U}^M$.

THEOREM 3.2. *Let Assumptions* A1–A4 *be satisfied, $z(u) \in \mathcal{Z}$ be twice continuously Fréchet-differentiable, $J \in \mathcal{C}^2(\mathcal{U}, \mathcal{V}, \mathcal{Z})$, and $z''(u)$, as well as all partial derivatives of J, be further locally Lipschitz continuous with respect to all components, such that Newton's method is well defined.*

If the infinite dimensional solution $\chi \in \mathcal{V}$ of a variational equation with respect to the bilinear form $a(u; \chi, \eta)$, $u \in \mathcal{U}$ fixed, and the corresponding semidiscretized solution $\chi^N \in \mathcal{V}^N$ with respect to $a(u; \chi^N, \eta^N)$, satisfy the convergence condition ($c_\chi \in \mathbb{R}$)

$$\|\chi - \chi^N\|_{\mathcal{V}} \leq c_\chi \zeta(N) \qquad \text{as } N \to \infty,$$

then the following assertions for $N \to \infty$ are true ($c_1, c_2, c_3, c_4 \in \mathbb{R}$):

$$\begin{aligned} \|y - y^N\|_{\mathcal{V}} &\leq c_1 \zeta(N), \\ \|p - p^N\|_{\mathcal{V}} &\leq c_2 \zeta(N), \\ \|F'(u) - F'_N(u)\|_{\mathcal{L}(\mathcal{U},\mathbb{R})} &\leq c_3 \zeta(N), \\ \|F''(u) - F''_N(u)\|_{\mathcal{L}(\mathcal{U},\mathcal{L}(\mathcal{U},\mathbb{R}))} &\leq c_4 \zeta(N). \end{aligned}$$

Proof. As a direct implication of the given assumptions, the inequality

$$\|y - y^N\|_{\mathcal{V}} \leq c_y \zeta(N) \tag{3.4}$$

is derived for the exact and discretized state. Analogously, the inequality

$$\|p - \bar{p}^N\|_{\mathcal{V}} \leq c_p \zeta(N) \tag{3.5}$$

is obtained for the infinite adjoint p, and the solution, $\bar{p}^N$, of the equation

$$a(u^M; \bar{p}^N, \eta^N) = J_y(u^M; y)(\eta^N) \qquad \forall \eta^N \in \mathcal{V}^N.$$

Our main interest is not the solution $\bar{p}^N$, but the solution $p^N \in \mathcal{V}^N$ of the equation

$$a(u^M; p^N, \eta^N) = J_y(u^M; y^N)(\eta^N) \qquad \forall \eta^N \in \mathcal{V}^N,$$

which is completely discretized with respect to N. The last two equations imply

$$a(u^M; \bar{p}^N - p^N, \eta^N) = J_y(u^M; y)(\eta^N) - J_y(u^M; y^N)(\eta^N) \qquad \forall \eta^N \in \mathcal{V}^N.$$

Using the $\mathcal{V}$-ellipticity of the bilinear form yields the inequalities (L Lipschitz constant)

$$\begin{aligned} \|\bar{p}^N - p^N\|_{\mathcal{V}} &\leq c\|J_y(u^M; y) - J_y(u^M; y^N)\|_{\mathcal{V}'} \\ &\leq cL\|y - y^N\|_{\mathcal{V}} \\ &\leq c c_y L \zeta(N). \end{aligned} \tag{3.6}$$

This leads to an estimate of the infinite adjoint and of the semidiscretized adjoint

$$\begin{aligned} \|p - p^N\|_{\mathcal{V}} &\leq \|p - \bar{p}^N\|_{\mathcal{V}} + \|\bar{p}^N - p^N\|_{\mathcal{V}} \\ &\leq c_p \zeta(N) + c c_y L \zeta(N) \\ &=: c_2 \zeta(N) \end{aligned} \tag{3.7}$$

by exploiting (3.5) and (3.6). Finally, since every summand of $F'(u^M)$ depends Lipschitz continuously on at least y or p, the result is verified using the inequalities (3.4) and (3.7).

Since the proof for the second derivative of the cost function is nearly the same, it is omitted here. □

Theorem 3.2 reduces the approximation properties of the cost function derivatives to the approximation property of the discretized variational equation. This issue is well investigated in the research of finite elements. If the underlying mesh satisfies certain conditions, then the convergence is guaranteed (see, e.g., Ciarlet [13]).

COROLLARY 3.3. *Let Assumptions* A1–A4 *be satisfied,* $z(u^M) \in \mathcal{Z}$ *be twice continuously Fréchet-differentiable,* $J \in \mathcal{C}^2(\mathcal{U}, \mathcal{V}, \mathcal{Z})$*, and* $z''(u)$*, as well as all partial derivatives of* J*, be further locally Lipschitz continuous with respect to all components such that Newton's method is well defined.*

Consider a regular triangulation, where all finite elements are affine-equivalent to a reference element in the sense of Ciarlet [13]*. Then, the use of linear spline basis functions implies the following assertions for* $N \to \infty$*:*

$$\begin{aligned} \|y - y^N\|_{\mathcal{V}} &\to 0, \\ \|p - p^N\|_{\mathcal{V}} &\to 0, \\ \|F'(u) - F'_N(u)\|_{\mathcal{L}(\mathcal{U},\mathbb{R})} &\to 0, \\ \|F''(u) - F''_N(u)\|_{\mathcal{L}(\mathcal{U},\mathcal{L}(\mathcal{U},\mathbb{R}))} &\to 0. \end{aligned}$$

Proof. The assumptions concerning the finite element mesh and the finite element functions are defined in such a way that Theorem 18.2 of Ciarlet [13] can be applied. Thus, for fixed $u \in \mathcal{U}$, the solution of the semidiscretized variational equation converges to the infinite dimensional solution in the $\mathcal{V}$ norm. In other words, $\zeta(N) \to 0$ as $N \to \infty$, and a slight modification of Theorem 3.2 yields the desired result. □

For the optimal shape design problems in question, Assumptions C1 and C3 can now be replaced with the modified Assumptions D1 and D3 by using the implications of Theorem 3.1, Theorem 3.2, and Corollary 3.3, respectively.

ASSUMPTION D1. Let A1–A4 be satisfied. Let $z(u) \in \mathcal{Z}$ be twice continuously Fréchet-differentiable in U_*, and let $z''(u)$, as well as all partial derivatives of J, be Lipschitz continuous. Furthermore, let the existence of $F''(u_*)^{-1} \in \mathcal{L}(\mathcal{L}(\mathcal{U},\mathbb{R}),\mathcal{U})$ and of the solution u_* in the interior of $\mathcal{U}_{ad}$ be guaranteed.

ASSUMPTION D3. The infinite dimensional solution $\chi \in \mathcal{V}$ of a variational equation with respect to the bilinear form $a(u;\chi,\eta)$, $u \in \mathcal{U}$ fixed, and the corresponding semidiscretized solution $\chi^N \in \mathcal{V}^N$ with respect to $a(u;\chi^N,\eta^N)$, satisfy the convergence condition ($\zeta_N^{(1)} \overset{N\to\infty}{\longrightarrow} 0$): $\|\chi - \chi^N\|_{\mathcal{V}} \le \zeta_N^{(1)}$.

Assumption D3 means that a convergent discretization scheme has to be used to solve the variational equations. Corollary 3.3 translates this to the case of linear spline basis functions with a regular triangulation that is often used in computation.

It should further be mentioned that in the special case of $u_* \in \mathcal{C}^2(I)$, the inequality

$$\|I_M u_* - u_*\|_{\mathcal{W}^{1,\infty}} \le \frac{1}{M-1}\|u_*\|_{\mathcal{W}^{2,\infty}}$$

(see, e.g., [4, p. 218]) with respect to the linear interpolation operator $I_M : \mathcal{U} \to \mathcal{U}^M$ already guarantees C4 for linear spline basis functions by choosing $\hat{u}^M = I_M u_*$.

Assumption C5 has to be verified for the considered kind of discretization scheme as it has been demonstrated by Chenais [12] for a specific class of problems. This assumption could also be weakened by supposing the convergence of F'_N and F''_N to the derivatives of the discretized cost function with respect to $N, M \to \infty$. Several convergence assertions are given as an immediate consequence of Theorem 2.2.

LEMMA 3.4. *Let the assumptions of Theorem* 2.2 *be satisfied. Then for all starting points fulfilling* $\|u_0^M - u_0\|_{\mathcal{U}} \le \tau$ *the following assertions hold for the state* y*:*

$$\begin{aligned}
&\|y_*^N - y_*\|_{\mathcal{V}} \le \hat{c}_1\zeta_{MN},\\
&\|y_n^N - y_n\|_{\mathcal{V}} \le \hat{c}_2\zeta_{MN}, \ \text{and}\\
&\|y_n^N - y_*^N\|_{\mathcal{V}} \le \|y_n - y_*\|_{\mathcal{V}} + \hat{c}_3\zeta_{MN}.
\end{aligned}$$

Analogous results are true for the adjoint p*, as well as for the derivatives* $\hat{y}$ *and* $\hat{p}$*.*

Proof. Since the corresponding solution operators are proven to be Lipschitz continuous with respect to u, this is an easy implication of Theorem 2.2. □

4. Numerical results. The numerical results presented next correspond to the considered class of optimal shape design problems with the cost function ($\varepsilon = 10^{-5}$)

$$\min_{u\in\mathcal{U}} \int_\Omega (y-z)^2 u dx + \frac{\varepsilon}{2}\|u\|^2_{\mathcal{H}^1(I)}.$$

Based on the definition of the initial and exact control

$$u_0(x_2) = 1.1 \text{ and } u_*(x_2) = \begin{cases} 1 - 0.1x_2, & x_2 \le 0.5,\\ 0.9 + 0.1x_2, & x_2 > 0.5,\end{cases}$$

z is defined by $z = u_* x_1 e^{u_* x_1 x_2}\sin(u_* x_1\pi)\sin(x_2\pi)$. Since the state y is the solution of a boundary value problem with inhomogeneous Dirichlet condition, the splitting $y = \hat{y} + g_D(u)$ must be introduced. The function $g_D(u) = u x_1 e^{u x_1 x_2}\sin(u x_1 \pi)\sin(x_2\pi)$ is defined on the boundary and $\hat{y} = S(u)$ is the solution of the variational equation

$$a(u;\hat{y},\eta) = l(u;\eta) \qquad \forall \eta \in \mathcal{H}_0^1(\Omega),$$

where the bilinear form and the linear functional are defined by

$$\begin{aligned}
a(u;\hat{y},\eta) &= \int_\Omega \frac{1}{u}\left(e^{-ux_1x_2} + e^{ux_1x_2}x_1^2u'^2\right)\hat{y}_{x_1}\eta_{x_1} - e^{ux_1x_2}x_1u'\hat{y}_{x_1}\eta_{x_2}\\
&\quad - e^{ux_1x_2}x_1u'\hat{y}_{x_2}\eta_{x_1} + ue^{ux_1x_2}\hat{y}_{x_2}\eta_{x_2}\,dx,\\
l(u;\eta) &= \int_\Omega f(ux_1,x_2)u\,dx - a(u;g_D(u),\eta) \text{ with}\\
f(\tilde{x}_1,x_2) &= (\pi^2\tilde{x}_1 - x_2)\sin(\tilde{x}_1\pi)\sin(x_2\pi) - \pi(2+\tilde{x}_1x_2)\cos(\tilde{x}_1\pi)\sin(x_2\pi)\\
&\quad - e^{2\tilde{x}_1x_2}\left[(2\tilde{x}_1^3 - \tilde{x}_1\pi^2)\sin(\tilde{x}_1\pi)\sin(x_2\pi) + 3\pi\tilde{x}_1^2\sin(\tilde{x}_1\pi)\cos(x_2\pi)\right].
\end{aligned}$$

Each linearized optimal control problem has been solved by the SYMMLQ algorithm (see, e.g., [34]) with the stopping criterion $\|H\vec{w}^M - d\|_2 \le 10^{-9}$. Since for our example the variational equations consist of a symmetric bilinear form, the CG method with a hierarchical and a diagonal preconditioner is implemented to accelerate the expected convergence rate. This iterative method terminates if the $\mathcal{L}^2(\Omega)$ norm of the residual is less than or equal to 10^{-11}. This stopping criterion is rather small in order to exclude the influence of these errors on the observed convergence rate. However, the algorithm could be accelerated by taking advantage of the inexact Newton's method [15]. The $\|\cdot\|_{\mathcal{H}^1(I)}$ norm is used for the Tikhonov regularization term ($u_{\mathcal{T}} \equiv 0$, $\varepsilon = 10^{-4}$) and the nonlinear iteration is stopped if the norm of F_N' is less than 10^{-8}.

The convergence behavior of Newton's method is illustrated in Table 4.1. The discretization parameters M and N are increased simultaneously, where five levels and five iterations per level are considered. The first column gives the number of the nonlinear iterations. The second gives the required number of iterations of the SYMMLQ algorithm. Third, the required time, measured in seconds, for all iterations is specified. Right next to it, the $\mathcal{L}^2(I)$-norm of the step, the value of the cost function, the $\mathcal{L}^2(\Omega)$-norm of the gradient, and the $\mathcal{L}^2(I)$-norm of the control error $u_i - u_*$ are tabulated. Attention is drawn to the fact that u_i is the finite ith iteration, whereas u_* is the solution of the infinite dimensional problem without regularization. On account of this, q-quadratic convergence rate of these values cannot be expected.

The number of SYMMLQ-iterations increases to about two to three times that of the previous coarse level. In other words, the condition number of the Hessian matrix increases with the parameter M, which means that more variational equations must be solved. A preconditioner for Newton's equation could improve this behavior.

The convergence behavior is also improved for each increase in the discretization

parameters. However, the discretization error apparently influences the convergence rate. Although the q-quadratic convergence rate in the infinite dimensional setting cannot be directly observed, the fast reduction of the gradient norm and the cost function within the first iterations points to such a property. After the first iterations, the convergence rate is dominated by the large discretization error.

The analyzed behavior of Newton's method for increasing parameters M and N naturally leads to the idea of nested iteration. Since Newton's iteration on a coarse grid requires less time than on a fine grid, it could be expected that this yields a more efficient algorithm. Important issues in this context are how to control the increasing parameters and how to choose the ratio between the parameters M and N. Within the limitation of this report we deal with this problem only in passing.

The results of Table 4.2 are obtained by using four levels, $M = 9, 17, 33, 65$, with $N = M^2$, and each approximation is transferred to the finer grid by linear interpolation. The regularization parameter is decreased with respect to the different levels in order to handle the ill-posedness of the problem ($\varepsilon = 10^{-j}$, $j = 2, \ldots, 5$). Now, the accumulated time is listed in the second column.

To illustrate the applicability of the derived algorithm the starting approximation is chosen to be $u_0 = 1.8$, which is far away from the solution u_*. A further constraint

$u \geq 0.3$ has to be added since otherwise the control would become negative, which makes no sense for a domain. For simplicity, the projected gradient method with Armijo rule [10] is implemented on the coarse grid, where the stopping criterion is kept.

After the iterations on the coarse grid, the approximation is interpolated to the finer grid to carry out five Newton iterations. Then, the approximation is interpolated to the next finer grid and once again improved by five Newton iterations. This process proceeds until the finest grid ($M = 65$) is reached in order to compare the results with the presented method without nested iteration.

Although the starting point is further away from the solution this nested iteration method is faster than Newton's method on the fine grid. The bound 10^{-3} of the control is satisfied after the first iteration on the finest grid and the computation requires only about eight minutes. This has to be compared to 50 minutes for Newton's method without nested iteration, which is approximately required for computing a competitive approximation.

Finally, it can be observed that the control error at each level is unchanged at the last few iterations. Therefore, the refinement strategy could even be improved by using a modified stopping criterion at each level. Since the issue of choosing an appropriate stopping criterion is well discussed for various methods (see, e.g., [2], [23], [29]), we will not deal further with this topic.

To sum up, the computational experiments give evidence for the convergence assertions of the derived modified mesh independence theorem. It has been further illustrated that one key to constructing more efficient methods is to exploit the infinite dimensional information and to use a mesh refinement strategy.

ABSOLUTE STABILIZATION AND MINIMAX OPTIMAL CONTROL OF UNCERTAIN SYSTEMS WITH STOCHASTIC UNCERTAINTY*

V. A. UGRINOVSKII† AND I. R. PETERSEN†

Abstract. This paper is concerned with existence and optimality properties of so-called guaranteed cost controllers for an uncertain system subject to structured uncertainty. The uncertainty in the system is assumed to have a stochastic character and to satisfy certain stochastic integral constraints. It is shown that a minimax optimal guaranteed cost state feedback controller for a stochastic system can be synthesized as a state feedback controller absolutely stabilizing this system. For each initial state of the system, this controller can be found by parametric optimization of solutions of a parameter-dependent generalized matrix Riccati equation arising in stochastic H_∞ theory.

Key words. robust control, robust performance, structured uncertainty, stochastic H_∞ control, stochastic absolute stability, multiplicative noise

1. Introduction.

Recently, Petersen and James [16] introduced a new general framework to allow for both stochastic and deterministic uncertainty in a *discrete*-time system. The motivation for this has been to combine two alternative uncertainty models used commonly in control theory and applications. The one model considers uncertainty arising from unmodelled dynamics, modelling and linearization errors, and slow parameter deviations which are deterministic in nature. Another approach involves the use of stochastic processes to model dynamics driven by noise signals and uncertainties due to fast parameters variations. This framework involved defining a new class of stochastic uncertain systems in which the uncertainty was described by a *stochastic uncertainty constraint.*

This paper addresses the problem of developing a similar framework for *continuous*-time systems. We introduce a rather general model of stochastic uncertainty which naturally extends the deterministic structured uncertainty model (cf. [12, 15, 19, 20, 21, 22, 28]), allowing for stochastic perturbations. Thus, our uncertainty model is a continuous-time counterpart of the discrete-time stochastic uncertainty models introduced in [16]. However, we should emphasize the difference between the results of this paper and those of [16]. The results in [16] concern uncertain systems with additive noise perturbations. This paper deals with a multiplicative noise perturbation model. Structured stochastic uncertainties with multiplicative noise perturbations arise naturally in many control problems and are considered extensively in the literature (cf. [5, 7, 8, 9, 25, 30]). In what follows, we describe two examples that motivate the class of problems considered in this paper.

Technically and in its content, this paper is closely related to the paper of Savkin and Petersen [20]. The main problem addressed is finding a linear static state feedback controller yielding a prescribed level of performance in the face of stochastic structured uncertainty in the system. In [20], such a controller is found as a minimax optimal

controller which minimizes the maximum (over all admissible uncertainties) value of a cost functional. The class of controllers considered are static state feedback controllers, which absolutely stabilize the system. However, the key point of the controller proposed here is that its construction is based on the stabilizing solution of a *generalized* Riccati equation related to a stochastic H_∞ control problem and to a stochastic differential game considered recently in [26]. Our set up has required the results of [26] to be slightly modified. Therefore, we present these modifications in sections 2 and 3. Then, in section 4 we consider the auxiliary problem of stochastic absolute stabilizability of a system whose uncertainty satisfies a certain stochastic integral quadratic constraint. The main result is given in section 5. It establishes that the search for an minimax optimal controller can be reduced to a finite-dimensional optimization problem over the solutions to a generalized Riccati equation.

One more important feature which distinguishes stochastic problems from deterministic ones is as follows. The stochastic Ito equations which serve to give a mathematically rigorous description for system dynamics are nonautonomous equations in their nature. Technically, this is reflected in the fact that we have to take into account the difference between the effect of initial conditions posed at different times; i.e., roughly speaking, we cannot reduce a problem with initial condition $x(s) = h$, $s > 0$, to a problem with an initial condition imposed of time zero. That is why all systems and processes in this paper are considered with respect to the starting instant s, not 0. In particular, this allows us to readily integrate problems with random initial conditions [17] into our framework.

Notation. We use the notation $\mathbf{R}^n$, $\mathbf{R}^{n\times q}$ to denote the n-dimensional real Euclidian vector space and the space of real $n\times q$-matrices equipped with the Euclidian matrix norm. We shall use symbols $\|\cdot\|$ and $\langle\cdot,\cdot\rangle$ to denote, respectively, the norm of vectors and matrices and the inner product of vectors. Furthermore, given a positive symmetrical matrix $Q \in \mathbf{R}^{q\times q}$, $\mathrm{tr}\Theta_1 Q\Theta_2'$ defines an inner product on $\mathbf{R}^{n\times q}$. Hence, this space can be considered a subspace in the Hilbert space of Hilbert–Schmidt operators.

Let $\{\Omega, \mathcal{F}, \mathcal{P}\}$ be a complete probability space, and let $w_1(t)$, $w_2(t)$ be two mutually independent Wiener processes in $\mathbf{R}^{q_1}$, $\mathbf{R}^{q_2}$ with covariance matrices Q_1, Q_2, respectively. Let $\mathcal{F}_t$ denote the increasing sequence of Borel sub-σ-fields of $\mathcal{F}$, generated by $\{w_{1,2}(s), 0 \le s < t\}$. Also, let $\mathbf{E}$ and $\mathbf{E}\{\cdot|\mathcal{F}_t\}$ be the corresponding unconditional and conditional expectation operators, respectively, where the latter is the expectation with respect to $\mathcal{F}_t$.

Let L_2^s denote the Hilbert space $L_2(\Omega, \mathcal{F}_s, \mathcal{P}; \mathbf{R}^n)$ of $\mathcal{F}_s$-measurable random variables $\Omega \to \mathbf{R}^n$, which is complete with respect to the norm $\left(\mathbf{E}\|\cdot\|^2\right)^{1/2}$. For $T \le \infty$, let $L_2(s, T; \mathbf{R}^n)$ denote the Hilbert space generated by the (t,ω)-measurable $\{\mathcal{F}_t, t \ge 0\}$-nonanticipating processes $x(t,\omega)\colon [s,T] \times \Omega \to \mathbf{R}^n$ and complete with respect to the norm $|||\cdot||| = (\int_s^T \mathbf{E}\|\cdot\|^2 dt)^{1/2}$. We shall write $L_2(s; \mathbf{R}^n)$ for $L_2(s, +\infty; \mathbf{R}^n)$.

Given a symmetric positive definite $q \times q$-matrix Q, let $\mathbf{R}_Q^{n\times q}$ denote the Hilbert space of $n \times q$-matrices, with the inner product $\mathrm{tr}\Theta_1 Q\Theta_2'$.

We consider an uncertain stochastic system described by the following stochastic differential Ito equation:

$$\begin{aligned}(1)\quad & dx = (Ax(t) + B_1u(t) + B_2\xi(t))dt + (Hx(t) + P_1u(t))dw_1(t) + P_2\xi(t)dw_2(t),\\ & z(t) = Cx(t) + Du(t),\end{aligned}$$

where $x(t) \in \mathbf{R}^n$ is the state, $u(t) \in \mathbf{R}^{m_1}$ is the control input, $z(t) \in \mathbf{R}^p$ is a vector assembling all uncertainty outputs, and $\xi(t) \in \mathbf{R}^{m_2}$ is a vector assembling all uncertainty inputs. Here A, B_1, B_2, C, D are matrices of corresponding dimensions, and H, P_1, P_2 are linear bounded operators $\mathbf{R}^n \to \mathbf{R}_{Q_1}^{n\times q_1}$, $\mathbf{R}^{m_1} \to \mathbf{R}_{Q_1}^{n\times q_1}$, $\mathbf{R}^{m_2} \to \mathbf{R}_{Q_2}^{n\times q_2}$, respectively. In the sequel, we shall use the adjoint operators H^*, P_1^*, P_2^* defined by the following:

$$\begin{aligned}&\langle H^*\Theta_1, x\rangle = \mathrm{tr}\Theta_1 Q_1 (Hx)', \quad \langle P_1^*\Theta_1, u\rangle = \mathrm{tr}\Theta_1 Q_1 (P_1 u)',\\ &\langle P_2^*\Theta_2, \xi\rangle = \mathrm{tr}\Theta_2 Q_2 (P_2\xi)'\\ &\forall\, x\in\mathbf{R}^n,\ u\in\mathbf{R}^{m_1},\ \xi\in\mathbf{R}^{m_2},\ \Theta_1\in\mathbf{R}^{n\times q_1},\ \Theta_2\in\mathbf{R}^{n\times q_2}.\end{aligned}$$

1.1. System uncertainty. The uncertainty in the above system (1) is described by the equation

$$\xi(t) = \xi_\phi(t) := \phi(t, x(\cdot)|_0^t, u(\cdot)|_0^t). \tag{2}$$

We suppose this uncertainty to satisfy the following stochastic integral quadratic constraint.

Definition 1. *Let $\bar{R}\ge 0$, $\bar{G} > 0$, $W > 0$ be given matrices. Then an uncertainty of the form* (2) *is said to be admissible if the following conditions hold.*

1. *For any $s \ge 0$, if $u(\cdot) \in L_2(s, T; R^{m_1})$, then there exists a unique solution to* (1), (2) *that lies in $L_2(s, T; R^n)$;*

2. *There exists a sequence $\{t_j\}_{j=1}^\infty$ such that $t_j > s$, $t_j \to \infty$ as $j \to \infty$ and the following condition holds. If $u(\cdot) \in L_2([s, t_j]; R^{m_1})$ and $x(\cdot) \in L_2([s, t_j]; R^n)$, then $\xi_\phi(\cdot) \in L_2([s, t_j]; R^{m_2})$ and*

$$\int_s^{t_j} \mathbf{E}\left(\langle z(t), \bar{R}z(t)\rangle - \langle \xi_\phi(t), \bar{G}\xi_\phi(t)\rangle\right) dt \ge -\mathbf{E}\langle h, Wh\rangle, \quad h = x(s). \tag{3}$$

We use the notation $\Phi(\bar{R}, \bar{G}, W)$ to denote the set of admissible uncertainties. However, we will write Φ wherever it produces no confusion.

Observe that the trivial uncertainty $\phi \equiv 0$ satisfies the above constraint. In the sequel, we shall refer to the system corresponding to this uncertainty as the *nominal* system.

In a typical situation, the plant may contain several uncertain feedback loops. In our notation, this is described by the decomposition of uncertainty output vector z and uncertainty input vector ξ_ϕ into several blocks of reduced dimensions as follows:

$$z = [z_1', \dots, z_k']', \quad \xi_\phi = [\xi_{\phi,1}', \dots, \xi_{\phi,k}']'.$$

This in turn induces a corresponding block decomposition on the matrices C, D, B_2, and P_2 in (1). The version of Definition 1 that accounts for this structure of uncertainty proceeds from the assumption that each uncertainty loop satisfies its own stochastic integral quadratic constraint of the form of (3):

$$\int_s^{t_j} \mathbf{E}\left(\langle z_i(t), \bar{R}_i z_i(t)\rangle - \langle \xi_{\phi,i}(t), \bar{G}_i\xi_{\phi,i}(t)\rangle\right) dt \ge -\mathbf{E}\langle h, W_i h\rangle, \quad i = 1, \dots, k, \tag{4}$$

where $\bar{R}_i \ge 0$, $\bar{G}_i > 0$ and $W_i > 0$. Then for any numbers $\tau_1 > 0, \dots, \tau_k > 0$, we replace all of the constraints by a single stochastic integral quadratic constraint in the form of (3):

$$\int_s^{t_j} \mathbf{E}\left(\langle z(t), \bar{R}_\tau z(t)\rangle - \langle \xi_\phi(t), \bar{G}_\tau\xi_\phi(t)\rangle\right) dt \ge -\mathbf{E}\langle h, W_\tau h\rangle, \quad h = x(s), \tag{5}$$

where $\bar{R}_\tau$, $\bar{G}_\tau$ are the block diagonal matrices

$$\bar{R}_\tau = \mathrm{diag}[\tau_1\bar{R}_1, \ldots, \tau_k\bar{R}_k], \quad \bar{G}_\tau = \mathrm{diag}[\tau_1\bar{G}_1, \ldots, \tau_k\bar{G}_k],$$

and $W_\tau = \sum_{i=1}^k \tau_i W_i$.

A specific feature of the uncertainty description in the form of the integral quadratic constraint (3) or the structured integral quadratic constraints (4) is that this description employs a certain sequence $\{t_j\}_{j=1}^\infty$ of times. Obviously, in the particular case where $u(\cdot)$ is a *stabilizing* control input which guarantees that the uncertainty input $\xi(\cdot)$ of the form (2) and the solution $x(\cdot)$ to the system (1), driven by the control input $u(\cdot)$ and uncertainty input $\xi(\cdot)$, both exist on $[0,\infty)$ and belong to $L_2[0,\infty)$, there is no need in employing the sequence $\{t_j\}_{j=1}^\infty$ to describe the uncertainty. Indeed, given the constraint in the form (3) and stabilizing control input $u(\cdot)$, by passing to the limit in (3) as $t_j \to \infty$, one can replace the integral over $[0,t_j]$ in (3) by the integral over the infinite interval $[0,\infty)$. Furthermore, by then making use of the Parseval identity, one may proceed to consider the frequency domain version of the integral quadratic constraint (3); cf. [15]. However, at this stage, we have yet not determined that any control input $u(\cdot)$ is stabilizing. We wish to define the class of admissible uncertainties for a generic control input; therefore we ought to avoid referring to any particular stabilizing properties of the control input when the constraints on the uncertainty are being defined. As in the deterministic case (cf. [20, 21, 22]), this can be achieved by considering control inputs, uncertainty inputs, and the corresponding solutions defined on a sequence of expanding finite intervals $[0,t_j]$. To give the reader an idea on how conservative the uncertainty model described by Definition 1 is, note that if for a certain uncertainty input ξ_ϕ, there exists no sequence $\{t_j\}$ such that the constraint (3) is satisfied for suitable $\bar{R}$, $\bar{G}$, and $\bar{W}$, then this means that the considered uncertainty input is not locally (and hence globally) square integrable.

The uncertainty constraint given by (3) or (4) extends the integral quadratic constraints such as those given in [20, 21, 22] to stochastic systems with multiplicative noise. As in these references, this uncertainty description allows for the uncertainty input ξ to depend dynamically on the uncertainty outputs. Also, a constraint in the form of (3) or (4) represents an extension of the discrete stochastic sum constraint of [16] to the case of continuous-time stochastic systems. However, the results of [16] allow for additive noise rather than multiplicative noise. Note also that the uncertainty description in the form of the constraint (3) encompasses the standard norm-bounded uncertainty description. Indeed, if

$$\xi(t) = \Delta(t)z, \quad \|\Delta(t)\| \le 1,$$

i.e., $\phi(t,x,u) = \Delta(t)(Cx + Du)$, then the constraint (3) is satisfied with $\bar{R} = I$, $\bar{G} = I$, and any matrix $W > 0$ and sequence $\{t_j\}_{j=1}^\infty$, provided that $x(\cdot)$ and $u(\cdot)$ lie in the corresponding L_2 spaces. A corresponding observation is also true in the case of structured norm-bounded uncertainty.

Stochastic extensions to integral quadratic constraints may provide a possible approach to the problem of nonworst-case robust control design. Recall that the standard deterministic worst-case robust control design presumes that all uncertainties have an equal chance of occurring, so that one does not expect that certain uncertainty inputs are more or less likely than others. Although the worst-case design methodology has proved its efficacy in various engineering problems, it suffers from the disadvantage that the designer lacks the opportunity to discriminate between "expected" uncertainties and those uncertainties which are known to seldom occur. In

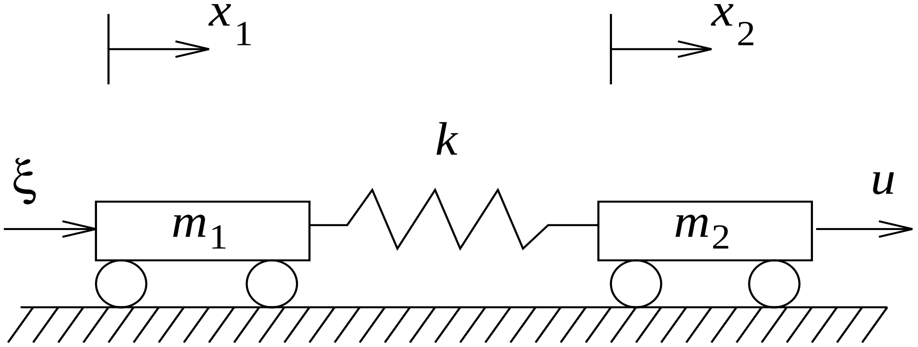

Fig. 1. *The two carts system.*

other words, the standard worst-case design methodology proceeds from the assumption that the values that the uncertainty may take, are equally likely; i.e., one can think of the uncertainty arising from a uniformly distributed random variable taking its values in the space of uncertainty inputs. However, this may not accurately represent the uncertainty in the system under consideration. For example, it may have been determined that the uncertainty inputs have a distribution other than the uniform distribution, and the designer may wish to make use of as much realistic a priori information about the distribution of uncertainty values as possible. The following example illustrates a situation in which this idea can be applied to go beyond the worst-case robust control design in the case where the distribution of uncertainties is Gaussian. In this case, we arrive at an underlying system of the form (1).

Suppose that the system to be controlled consists of two carts connected by a spring as shown in Figure 1. There is a disturbance ξ of the form (2) acting on the first cart. A control force u drives the second cart. The spring constant k has a specific nominal value $k_0 = 1.25$ but can vary and is considered uncertain. This may reflect the nonlinear nature of the true spring. A series of experiments was undertaken to determine values of the spring constant in various conditions. It was revealed that for each time instant t, the histogram of observed values is consistent with a stationary Gaussian distribution, with the mean k_0. It was also found in the experiments that k ranged over the interval $[0.5, 2]$. Assume that the masses of carts are $m_1 = m_2 = 1$. Then, the system is described by the equation

$$\dot{x} = (A + F\Delta(t)C)x + B_1 u + B_2 \xi,$$

where $x = [x_1\ x_2\ \dot{x}_1\ \dot{x}_2]' \in \mathbf{R}^4$, $\Delta(t) = k(t) - k_0$, and

$$A = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1.25 & 1.25 & 0 & 0 \\ 1.25 & -1.25 & 0 & 0 \end{bmatrix}, \quad B_1 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix}, \quad B_2 = \begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \end{bmatrix},$$

$$F = \begin{bmatrix} 0 \\ 0 \\ -1 \\ 1 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & -1 & 0 & 0 \end{bmatrix}. \tag{6}$$

Assume that for all $t \geq 0$, $\Delta(t)$ is the Gaussian white noise process with zero

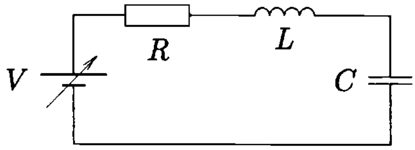

FIG. 2. *The uncertain electric circuit.*

mean and $E\Delta^2(t) = \sigma^2$. We can then choose the value of the parameter σ such that $k(t) = k_0 + \Delta(t)$ obeys the bounds $0.5 \leq k(t) \leq 2$ with a sufficiently high probability. For example, for $\sigma = 0.25$, we have $P(|k(t) - k_0| \leq 0.75) \geq 0.997$. This model of spring rate variations leads us to the uncertain stochastic system[1] of the form (1),

$$\begin{aligned} dx &= (Ax + B_1 u + B_2 \xi)dt + Hx dw_1(t), \\ z &= Cx + Du, \end{aligned}$$

where $H = \sigma FC$, and $w_1(\cdot)$ is the scalar Wiener process. Note that in this model, the probability $P(|k(t) - k_0| \leq 0.75)$ is increasing as $\sigma^2 \downarrow 0$. However, we shall always have $P(|k(t) - k_0| \leq 0.75) < 1$; i.e., the value of the spring rate $k(t)$ may exceed the presumed bounds on uncertainty $[0.5, 2]$ with nonzero probability. This phenomenon indicates the "soft" norm bound on the uncertainty.

Another example showing how the above uncertainty description may arise is given by the electric circuit shown in Figure 2. The differential equations describing the current and voltage dynamics in this circuit are the following:

$$\begin{aligned} \frac{di}{dt} &= -\frac{R}{L} i + \frac{1}{L}(V - V_C), \\ \frac{dV_C}{dt} &= \frac{1}{C} i, \end{aligned}$$

where i is the current flowing in the circuit and V_C is the capacitor voltage. One can control the system by applying the appropriate voltage V. In the circuit, the resistance R of the resistor and the inductance L of the inductor may vary as follows.

It is known that the resistance R may slowly vary from R^- to R^+ due to, e.g., the resistor temperature variations. That is, $R = R(t) = R_0 + R_1 \Delta R(t)$, where $R_0 = (R^+ + R^-)/2$ is the nominal value of the resistor, $R_1 = (R^+ - R^-)/2$, and $\Delta R(t)$ satisfies the standard norm-bounded uncertainty constraint, $|\Delta R(t)| \leq 1$. Also, it is known that nearby electrical devices may induce changes in the inductance value. That is, one may suppose that the inductance $L = L(t)$ is given by $L^{-1} = L_0^{-1} + L_1^{-1}\zeta(t)$, where $\zeta(t)$ is the Gaussian white noise with the mean 0 and the covariance 1, L_0 is the mean inductance. The value of L_1 can be determined by estimating the covariance of the reciprocal inductance.

Letting $x = [i, V_C] \in \mathbf{R}^2$, $z_1 = i$, $z_2 = V_C - V$, one can write a formal Langevin

[1] In this example, one relies on the fact that $(FC)^2 = 0$ when proceeding from the formal Langevin equation to a corresponding mathematically rigorous Ito equation. Conditions under which a solution of the Langevin equation satisfies also a corresponding Stratonovich equation and, consequently, an Ito equation are given in [24].

equation for the system in Figure 2:

$$\begin{aligned}
\dot{x} &= \begin{bmatrix} -R_0/L_0 & -1/L_0 \\ -1/C & 0 \end{bmatrix} x + \begin{bmatrix} 1/L_0 \\ 0 \end{bmatrix} V + \begin{bmatrix} -R_1/L_0 \\ 0 \end{bmatrix} \xi_1 \\
&\quad + \left(\begin{bmatrix} -R_0/L_1 & -1/L_1 \\ 0 & 0 \end{bmatrix} x + \begin{bmatrix} 1/L_1 \\ 0 \end{bmatrix} V + \begin{bmatrix} -R_1/L_1 \\ 0 \end{bmatrix} \xi_1 \right) \zeta(t), \\
z &= x + \begin{bmatrix} 0 \\ -1 \end{bmatrix} V, \qquad \xi_1 = \Delta R(t) z_1.
\end{aligned}$$

The rigorous mathematical description of the system is then given by the following Ito stochastic differential equation of the form (1):

$$\begin{aligned}
dx &= \left(\begin{bmatrix} -\frac{R_0}{L_0} + \frac{R_0^2}{2L_1^2} & -\frac{1}{L_0} + \frac{R_0}{2L_1^2} \\ -1/C & 0 \end{bmatrix} x + \begin{bmatrix} \frac{1}{L_0} - \frac{R_0}{2L_1^2} \\ 0 \end{bmatrix} V \right. \\
&\quad \left. + \begin{bmatrix} -\frac{R_1}{L_0} + \frac{R_0 R_1}{L_1^2} & \frac{R_1}{2L_1^2} & \frac{R_1^2}{2L_1^2} \\ 0 & 0 & 0 \end{bmatrix} \xi \right) dt \\
&\quad + \left(\begin{bmatrix} -R_0/L_1 & -1/L_1 \\ 0 & 0 \end{bmatrix} x + \begin{bmatrix} 1/L_1 \\ 0 \end{bmatrix} V + \begin{bmatrix} -R_1/L_1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \xi \right) dw(t), \\
z &= x + \begin{bmatrix} 0 \\ -1 \end{bmatrix} V, \qquad \xi = \Delta(t) z, \qquad \Delta(t) = \begin{bmatrix} \Delta R(t) & 0 \\ 0 & \Delta R(t) \\ (\Delta R(t))^2 & 0 \end{bmatrix}.
\end{aligned}$$

It is easy to see that $\Delta'\Delta \leq 2I$. As we have already mentioned, this constraint can be converted into a certain integral quadratic constraint of the form (3). It is also worth noting that in this example, the uncertainty is structured. Hence, the integral quadratic constraints on structured uncertainty of the form (4) can be used to describe the uncertainty in this example. It is known that the use of the structured integral quadratic constraints uncertainty description may lead to a potentially less conservative guaranteed robust performance. This motivates us to consider an optimal guaranteed cost control problem in section 5 for the system (1) with structured uncertainty.

1.2. Guaranteed cost control problem.

As has been mentioned above, the main problem addressed in this paper is to find a linear static state feedback controller resulting in an optimal performance in the face of stochastic uncertainty in the system (1). In this section, we set up this problem.

Let $R \in \mathbf{R}^{n \times n}$, $G \in \mathbf{R}^{m_1 \times m_1}$, $R' = R > 0$, $G' = G > 0$, be given matrices. Associated with the uncertain system (1), (2), consider the cost functional,

$$J^{s,h}(u(\cdot)) = \int_s^\infty \mathbf{E} \left(\langle x(t), Rx(t) \rangle + \langle u(t), Gu(t) \rangle \right) dt, \tag{7}$$

where $x(t)$ is the solution to (1), (2) satisfying the initial condition $x(s) = h$.

Definition 2. *Given a constant* $\gamma > 0$ *and the cost functional* (7), *the state feedback controller*

$$u^0 = Kx \tag{8}$$

is said to be a guaranteed cost controller *for the uncertain system* (1), (2), *with cost* *functional* (7) *and initial condition h, if it satisfies the following conditions:*

(i) *This controller stabilizes the nominal system, i.e., the resulting closed-loop nominal system,*

$$dx(t) = [A + B_1K]x(t)dt + [H + P_1K]x(t)dw_1(t), \quad x(s) = h, \tag{9}$$

is exponentially stable in a mean-square sense. That is, there exist constants $C > 0$, $\alpha > 0$ such that

$$\mathbf{E}\|x(t)\|^2 \leq C\mathbf{E}\|h\|^2 e^{-\alpha(t-s)}.$$

(ii) *For all $s > 0$ and $h \in L_2^s$, the corresponding solution to the closed-loop uncertain system* (1), (3), (8),

$$dx(t) = ([A + B_1K]x(t) + B_2\xi(t))\,dt + [H + P_1K]x(t)dw_1(t) + P_2\xi(t)dw_2(t), \tag{10}$$

$$\begin{pmatrix} z \\ u \end{pmatrix} = \begin{bmatrix} C + DK \\ K \end{bmatrix} x, \qquad x(s) = h,$$

with any admissible uncertainty input (2), *lies in $L_2(s, \mathbf{R}^n)$. Furthermore, as a consequence, the corresponding control input $u(\cdot)$ and admissible uncertainty input $\xi_\phi(\cdot)$ lie in $L_2(s, \mathbf{R}^{m_1})$, $L_2(s, \mathbf{R}^{m_2})$, respectively.*

(iii) *The corresponding value of the cost functional* (7) *is bounded by the constant γ for all admissible uncertainties:*

$$\sup_{\phi(\cdot)\in\Phi} J^{s,h}(u(\cdot)) \leq \gamma. \tag{11}$$

Note that in the case of the structured uncertainty, the definition remains virtually the same, with the obvious replacement of the constraint (3) by the structured constraints (4) (or their matrix version (5)).

We now introduce the set $\mathcal{K}$ of guaranteed cost controllers of the form (8). Note that the constant γ in Definition 2 describes the prespecified required level of robust performance of the closed-loop system. In the (nonoptimal) guaranteed cost control problem, it is satisfactory to obtain any controller satisfying the condition (11). In this paper, we address the optimal version of the guaranteed cost control problem, in which we seek to find a control guaranteeing the minimum upper bound on the worst-case performance of the uncertain closed-loop system driven by the uncertainty input ξ_ϕ, $\phi \in \Phi$:

$$\inf_{u(\cdot)\in\mathcal{K}} \sup_{\phi\in\Phi} J^{s,h}(u(\cdot)). \tag{12}$$

Note that in this minimax optimization problem, the admissible maximizers are those which satisfy the constraint (3) (or the constraints (4)). Thus, the optimization problem (12) is a constrained minimax optimization problem. The controller solving the constrained minimax optimization problem (12) will be referred to as a minimax optimal guaranteed cost controller.

2. Stochastic differential game. In this section we consider the stochastic linear quadratic differential game associated with (1). The set up is similar to that in [26], where the special case of $P_1 = P_2 = 0$ is considered. The results presented below extend in a straightforward manner those of [26]. This extension is of primary importance for the results of this paper and will be extensively used in what follows. Hence, for the sake of completeness, we include these extensions here.

As in [26], the consideration of the stochastic linear quadratic differential game in this section assumes that the underlying system has certain stability properties. In particular, we shall require in this section that the matrix A is stable. In the subsequent sections this assumption will be significantly weakened; see Assumption 2 in the next section.

Assumption 1. *The linear system*

$$dx(t) = Ax(t)dt + Hxdw_1(t), \qquad x(s) = h, \tag{13}$$

that corresponds to the system (1), *driven by the control input* $u(\cdot) = 0$ *and the uncertainty input* $\xi(\cdot) = 0$, *is exponentially stable in mean-square sense*; *i.e.*, *there exist constants* $C > 0,\ \alpha > 0$ *such that*

$$\mathbf{E}\|x(t)\|^2 \le Ce^{-\alpha(t-s)}\mathbf{E}\|h\|^2. \tag{14}$$

As a consequence, *the matrix* A *is a stability matrix.*

Remark. In order to check Assumption 1, one can use Lyapunov arguments reducing the stability test to finding a feasible solution Y to the linear matrix inequality

$$A'Y + YA + H^*YH \le -\bar{\epsilon}I, \qquad Y' = Y > 0,$$

for a certain constant $\bar{\epsilon} > 0$.

Consider the stochastic differential game defined by (1) and the cost functional

$$\begin{aligned} \Im^{s,h}(u,\xi) &= \int_s^{+\infty} \mathbf{E}\left\{F(x(t),u(t)) - \|\xi(t)\|^2\right\} dt, \\ F(x,u) &:= \langle x, Rx + Qu\rangle + \langle u, Q'x + Gu\rangle, \end{aligned} \tag{15}$$

where $R = R' \in R^{n\times n}$, $Q \in R^{n\times m_1}$, $G = G' \in R^{m_1\times m_1}$, $R \ge 0$, $G > 0$. In (15), $x(\cdot)$ denotes the solution to (1) satisfying the initial condition $x(s) = h$ and driven by the pair of inputs $(u(\cdot), \xi(\cdot))$. In this game, $u(\cdot) \in L_2(s, \mathbf{R}^{m_1})$ is the minimizing strategy, and $\xi(\cdot) \in L_2(s, \mathbf{R}^{m_2})$ is the maximizing strategy. Note that Assumption 1 assures that any pair of inputs $(u(\cdot), \xi(\cdot)) \in L_2(s, \mathbf{R}^{m_1}) \times L_2(s, \mathbf{R}^{m_2})$ result in a square-integrable solution on $[s, +\infty)$ for any initial condition; see, e.g., [3] and also Lemma 4 in Appendix A. This implies that the cost functional (15) is well defined on $L_2(s, \mathbf{R}^{m_1}) \times L_2(s, \mathbf{R}^{m_2})$. Also, in what follows we shall consider the finite horizon version of the cost functional (15) which is defined as follows:

$$\Im_T^{s,h}(u,\xi) = \int_s^T \mathbf{E}\left\{F(x(t),u(t)) - \|\xi(t)\|^2\right\} dt, \qquad s \le T < \infty. \tag{16}$$

Note that for $T = +\infty$, $\Im_\infty^{s,h}(u,\xi) = \Im^{s,h}(u,\xi)$.

In the stochastic differential game, we seek to find

$$V := \inf_{u(\cdot)\in L_2(s,\mathbf{R}^{m_1})} \sup_{\xi\in L_2(s,\mathbf{R}^{m_2})} \Im^{s,h}(u,\xi). \tag{17}$$

Lemma 1. *Suppose that Assumption* 1 *is satisfied. Also*, *suppose there exists a constant* $\varepsilon_2 > 0$ *such that*

$$\Im^{0,0}(0,\xi) \le -\varepsilon_2|||\xi|||^2 \qquad \forall\ \xi \in L_2(0, \mathbf{R}^{m_2}). \tag{18}$$

Then the following conditions hold:

(a) *For each* $s \geq 0$, $h \in L_2^s$, *there exists a unique* $\xi_2^s(\cdot) \in L_2(s; \mathbf{R}^{m_2})$ *such that*

$$\Im^{s,h}(0, \xi_2^s(\cdot)) = \sup_{\xi(\cdot) \in L_2(s, \mathbf{R}^{m_2})} \Im^{s,h}(0, \xi). \tag{19}$$

Also, there exists a unique optimal $\xi_{2T}^s(\cdot) \in L_2(s, T; \mathbf{R}^{m_2})$ *maximizing the cost function* $\Im_T^{s,h}(0, \xi(\cdot))$. *Moreover,*

$$|||\xi_{2T}^s(\cdot)|||^2 \leq c\mathbf{E}\|h\|^2, \qquad \Im_T^{s,h}(0, \xi_{2T}^s(\cdot)) \leq c\mathbf{E}\|h\|^2 \tag{20}$$

for some $c > 0$ *independent of* $s \leq T \leq +\infty$ *and* h.

(b) *There exists a symmetric nonnegative definite matrix* X_2 *such that*

$$\sup_{\xi(\cdot) \in L_2(s, \mathbf{R}^{m_2})} \Im^{s,h}(0, \xi) = \mathbf{E}\langle h, X_2 h\rangle. \tag{21}$$

(c) *For all* $T > 0$, *there exists a unique symmetric nonnegative definite solution* $X_{2T}(\cdot)$ *to the generalized Riccati equation*

$$\begin{aligned} &\frac{dX_{2T}}{dt} + A'X_{2T} + X_{2T}A + H^*X_{2T}H + R \\ &\qquad\qquad + X_{2T}B_2(I - P_2^*X_{2T}P_2)^{-1}B_2'X_{2T} = 0, \\ &X_{2T} = 0. \end{aligned} \tag{22}$$

This solution satisfies the conditions $0 \leq X_{2T}(s) \leq X_2$ *and* $I - P_2^* X_{2T}(s) P_2 > 0$. *The optimal input* $\xi_{2T}^s(\cdot)$ *maximizing the functional* (16) *can be expressed in the form of the feedback law*

$$\xi_{2T}^s(t) = (I - P_2^* X_{2T}(t) P_2)^{-1} B_2' X_{2T} x_{2T}^s(t), \tag{23}$$

where $x_{2T}^s(\cdot)$ *is the optimal trajectory satisfying the corresponding "closed-loop" equation*

$$\begin{aligned} dx(t) = {}& (A + B_2(I - P_2^* X_{2T}(t) P_2)^{-1} B_2' X_{2T}(t)) x dt + H x dw_1(t) \\ &+ P_2 (I - P_2^* X_{2T}(t) P_2)^{-1} B_2' X_{2T}(t) x dw_2(t), \quad x(s) = h. \end{aligned} \tag{24}$$

(d) *The matrix* X_2 *satisfying* (21) *is also the minimal solution to the generalized Riccati equation*

$$A'X_2 + X_2A + H^*X_2H + R + X_2B_2(I - P_2^*X_2P_2)^{-1}B_2'X_2 = 0, \tag{25}$$

such that

$$I - P_2^* X_2 P_2 > 0. \tag{26}$$

Proof. See Appendix B. □

Remark. As in [11], it can be proved that the matrix X_2 satisfying conditions (21), (25), and (26) is such that the system

$$\begin{aligned} dx(t) = {}& (A + B_2(I - P_2^* X_2 P_2)^{-1} B_2' X_2) x dt + H x dw_1(t) \\ &+ P_2 (I - P_2^* X_2 P_2)^{-1} B_2' X_2 x dw_2(t), \qquad x(s) = h \end{aligned} \tag{27}$$

is exponentially mean-square stable. Note that in the particular case where $H = 0$, $P_2 = 0$, (25) becomes a standard Riccati equation, with the stable matrix A. Hence in this case, the equation allows for a nonnegative definite stabilizing solution satisfying condition (26).

The problem of the solvability of a generalized ARE is known in the literature as a challenging problem; see, e.g., reference [18] and the references therein. This reference presents a numerical algorithm based on homotopy methods, which solves a general class of perturbed Riccati equations. The generalized algebraic Riccati equation (25) is virtually the same as those in [18]. Hence a useful idea toward solving (25) may be to apply the method of [18]. Also, it is worth noting that the solution X_2 to (25) and inequality (26) necessarily satisfies the linear matrix inequalities

$$\begin{bmatrix} -A'X_2 - X_2A - R - H^*X_2H & X_2B_2 \\ B_2'X_2 & I - P_2^*X_2P_2 \end{bmatrix} \geq 0, \qquad X_2 \geq 0.$$

Hence, the desired matrix X_2 exists only if the above linear matrix inequalitites (LMIs) are feasible.

THEOREM 1. *Suppose that Assumption* 1 *is satisfied and there exists a constant* $\varepsilon_2 > 0$ *such that condition* (18) *holds. Also, assume that there exists a constant* $\varepsilon_1 > 0$ *such that*

$$F(x,u) > \varepsilon_1\|u\|^2 \qquad \forall\, x \in R^n, u \in R^{m_1}. \tag{28}$$

Then the following conditions hold:

(a) *For each* $s \geq 0$, $h \in L_2^s$, *there exists a unique saddle point (minimax pair) for the cost function* (15) *in* $L_2(s,R^{m_1}) \times L_2(s,R^{m_2})$.

(b) *There exists a unique symmetric nonnegative definite solution* $X \in \mathbf{R}^{n\times n}$ *to the generalized game-type algebraic Riccati equation*

$$\begin{aligned} &A'X + XA + H^*XH + R \\ &-(XB_1 + H^*XP_1 + Q)(G + P_1^*XP_1)^{-1}(XB_1 + H^*XP_1 + Q)' \\ &+XB_2(I - P_2^*XP_2)^{-1}B_2'X = 0 \end{aligned} \tag{29}$$

such that $I - P_2^*XP_2 > 0$ *and*

$$V = \mathbf{E}\langle h, Xh\rangle. \tag{30}$$

(c) *The minimax pair can be expressed in the feedback form*

$$u = F_1x, \qquad \xi = F_2x,$$

where

$$F_1 = -(G + P_1^*XP_1)^{-1}(XB_1 + H^*XP_1 + Q)', \quad F_2 = (I - P_2^*XP_2)^{-1}B_2'X.$$

(d) *The stochastic closed-loop system*,

$$\begin{aligned} &dx = (A + B_1F_1 + B_2F_2)x + (H + P_1F_1)xdw_1(t) + P_2F_2xdw_2(t), \\ &x(s) = h, \end{aligned} \tag{31}$$

is exponentially stable in mean-square sense; *i.e.*,

$$\mathbf{E}\|x(t)\|^2 \leq C\mathbf{E}\|h\|^2e^{-\alpha(t-s)}. \tag{32}$$

As a consequence, *the matrix* $A + B_1F_1 + B_2F_2$ *is Hurwitz.*

Proof. The proof follows using arguments similar to those used in proving the corresponding theorem in [26] but with evident modifications due to the fact that we have $P_1 \neq 0$, $P_2 \neq 0$ in this case. See Appendix C. □

Remark. In the particular case of $H = P_1 = P_2 = 0$, (29) reduces to the Riccati equation known in deterministic H_∞ control. In another particular case in which $B_2 = 0$, $P_2 = 0$, this equation reduces to the generalized Riccati equation known in linear-quadratic stochastic optimization [2, 27]. □

3. Stochastic H_∞control with complete state measurement. In this section we consider a stochastic H_∞ control problem related to system (1). Again, this section adapts corresponding results of [26] to our more general set-up. From now on, we no longer assume that the system (13) is exponentially stable. That is, we no longer assume that Assumption 1 is satisfied, and hence we do not suppose the a priori stability of the matrix A in (1). In what follows, we shall use instead a property which is a stochastic counterpart to the detectability of a pair of matrices.

ASSUMPTION 2. *The system* (1) *is such that* $D'D > 0$, *the matrix* $\tilde{R} = C'(I - D(D'D)^{-1}D')C$ *is nonnegative definite, and there exists a matrix* $N \in R^{n\times m}$ *such that the matrix* $A - B_1(D'D)^{-1}D'C - N\tilde{R}^{1/2}$ *is stable, i.e.,* $\|\exp((A - B_1(D'D)^{-1}D'C - N\tilde{R}^{1/2})t)\| \le ae^{-\alpha t}$, *and*

$$\frac{a^2}{\alpha}\|H - P_1(D'D)^{-1}D'C\|^2_{Q_1} < 1. \tag{33}$$

Given the system (1), the associated stochastic H_∞ control problem is to find a matrix $K \in R^{m_1\times n}$ such that the state feedback controller $u = Kx$ satisfies the following conditions:

(i) The system

$$dx = (A + B_1K)xdt + (H + P_1K)xdw_1(t) \tag{34}$$

is exponentially stable in mean-square sense, and the matrix $A + B_1K$ is stable;

(ii) The closed-loop system, corresponding to system (1) with feedback control $u = Kx$,

$$dx = [(A + B_1K)x(t) + B_2\xi(t)]dt + (H + P_1K)x(t)dw_1(t) + P_2\xi(t)dw_2(t), \tag{35}$$

satisfies the following stochastic H_∞-norm condition: there exists a constant $\varepsilon > 0$ such that

$$\mathbf{E}\int_s^{+\infty} \left(\|(C + DK)x(t)\|^2 - \|\xi(t)\|^2\right)dt \le -\varepsilon\mathbf{E}\int_s^{+\infty} \|\xi(t)\|^2 dt \quad \text{for } x(s) = 0 \tag{36}$$

for each $\xi \in L_2(s; \mathbf{R}^{m_2})$.

Remark. The exponential stability of the nominal closed-loop system (34) is a sufficient condition for the system (35) to have solutions lying in $L_2(s; \mathbf{R}^n)$ for any $\xi(\cdot) \in L_2(s; \mathbf{R}^{m_2})$.

THEOREM 2. *Suppose Assumption* 2 *is satisfied. Then the stochastic* H_∞ *control problem defined above has a solution if and only if there exists a minimal nonnegative definite symmetric solution* X *to the generalized algebraic Riccati equation*

$$\begin{aligned} &A'X + XA + H^*XH + C'C \\ &-(XB_1 + H^*XP_1 + C'D)(D'D + P_1^*XP_1)^{-1}(B_1'X + P_1^*XH + D'C) \\ &+XB_2(I - P_2^*XP_2)^{-1}B_2'X = 0 \end{aligned} \tag{37}$$

such that $I - P_2^* X P_2 > 0$ *and the stochastic system*

$$\begin{aligned} dx &= (A - B_1(D'D + P_1^* X P_1)^{-1}(B_1'X + P_1^* XH + D'C) \\ &\quad + B_2(I - P_2^* X P_2)^{-1} B_2' X) x dt \\ &\quad + (H + P_1(D'D + P_1^* X P_1)^{-1}(B_1'X + P_1^* XH + D'C)) x dw_1 \\ &\quad + P_2(I - P_2^* X P_2)^{-1} B_2' X x dw_2(t) \end{aligned} \tag{38}$$

is exponentially stable in the mean-square sense. If this condition is satisfied, then the corresponding stabilizing feedback controller which solves the stochastic H_∞ *problem is given by*

$$K = -(D'D + P_1^* X P_1)^{-1}(B_1'X + P_1^* XH + D'C). \tag{39}$$

Conversely, if the stochastic H_∞ *control problem defined above has a solution, then the solution to the Riccati equation* (37) *satisfies the condition*

$$\mathbf{E}\langle h, Xh\rangle \le \sup_{\xi \in L_2(s;\mathbf{R}^{m_2})} \mathbf{E} \int_s^{+\infty} \left(\|Cx(t) + Du(t)\|^2 - \|\xi(t)\|^2 \right) dt \tag{40}$$

for any state feedback control $u(\cdot)$ *such that the closed-loop system corresponding to this feedback control has* L_2*-summable solutions for all* $\xi \in L_2(s;\mathbf{R}^{m_2})$, *and the supremum on the right-hand side in* (40) *is finite.*

Proof. The proof follows using arguments of the corresponding result of [26] which are readily extended to the statement above. See Appendix D. □

4. Stochastic absolute stabilization. In this section, we address to the problem of absolute stabilization via a static state feedback controller. We construct a stabilizing controller of the form (8) which leads to a closed-loop uncertain system (1), (2), (8) which is absolutely stable in the following sense.

Definition 3. *A controller of the form* (8) *is said to absolutely stabilize the uncertain system* (1), (2) *if the following conditions hold*:

(i) *The nominal closed-loop system is stable. That is, for any initial condition* $x(s) = h \in L_2^s$, *the system* (34) *is exponentially mean-square stable.*

(ii) *There exists a constant* $c > 0$, *independent of the initial condition and such that for any admissible uncertainty* ϕ, *the corresponding solution to the closed-loop system* (1), (2), (8) *belongs to* $L_2(s, \mathbf{R}^n)$, *the corresponding uncertain input* $\xi_\phi(\cdot)$ *belongs to* $L_2(s, \mathbf{R}^{m_2})$, *and*

$$|||x(\cdot)|||^2 + |||\xi_\phi(\cdot)|||^2 \le c\mathbf{E}\|h\|^2. \tag{41}$$

Given matrices $R \in \mathbf{R}^{n\times n}$, $G \in \mathbf{R}^{m_1 \times m_1}$, $R' = R > 0$, $G' = G > 0$, consider the generalized algebraic Riccati equation of the form of (37),

$$\begin{aligned} &A'X + XA + H^* XH + \bar{C}'\bar{C} \\ &-(XB_1 + H^* X P_1 + \bar{C}'\bar{D})(\bar{D}'\bar{D} + P_1^* X P_1)^{-1}(B_1'X + P_1^* XH + \bar{D}'\bar{C}) \\ &+X\bar{B}_2(I - \bar{P}_2^* X \bar{P}_2)^{-1} \bar{B}_2' X = 0, \end{aligned} \tag{42}$$

where

$$\bar{C} = \begin{bmatrix} R^{1/2} \\ 0 \\ \bar{R}^{1/2} C \end{bmatrix}, \quad \bar{D} = \begin{bmatrix} 0 \\ G^{1/2} \\ \bar{R}^{1/2} D \end{bmatrix}, \quad \bar{B}_2 = B_2 \bar{G}^{-1/2}, \quad \bar{P}_2 = P_2 \bar{G}^{-1/2}. \tag{43}$$

Also, associated with the uncertain system (1), (2), consider the cost functional (7).

THEOREM 3. *Suppose Assumption* 2 *is satisfied and suppose also that there exists a minimal nonnegative definite stabilizing solution X to the generalized Riccati equation* (42), *i.e., such that $I - \bar{P}_2^* X \bar{P}_2 > 0$ and that the system*

$$
\begin{aligned}
dx = {} & \big[A - B_1(\bar{D}'\bar{D} + P_1^* X P_1)^{-1}(B_1'X + P_1^* X H + \bar{D}'\bar{C}) \\
& + \bar{B}_2(I - \bar{P}_2^* X \bar{P}_2)^{-1}\bar{B}_2' X\big]\, xdt \\
& + \big[H - P_1(\bar{D}'\bar{D} + P_1^* X P_1)^{-1}(B_1'X + P_1^* X H + \bar{D}'\bar{C})\big]\, xdw_1(t) \\
& + \bar{B}_2(I - \bar{P}_2^* X \bar{P}_2)^{-1}\bar{B}_2' X x dw_2(t)
\end{aligned} \tag{44}
$$

is exponentially stable in mean-square sense, and as a consequence, the matrix

$$A - B_1(\bar{D}'\bar{D} + P_1^* X P_1)^{-1}(B_1'X + P_1^* X H + \bar{D}'\bar{C}) + \bar{B}_2(I - \bar{P}_2^* X \bar{P}_2)^{-1}\bar{B}_2' X$$

is stable. Then the controller given by

$$u^0(t) = Kx(t), \qquad K := -(\bar{D}'\bar{D} + P_1^* X P_1)^{-1}(B_1'X + P_1^* X H + \bar{D}'\bar{C}), \tag{45}$$

is an absolutely stabilizing controller for uncertain system (1), (2). *Furthermore, the corresponding value of the cost function* (7) *satisfies the bound*

$$\sup_{\phi \in \Phi} J^{s,h}(u^0(\cdot)) \le \mathbf{E}\langle h, (X + W)h\rangle. \tag{46}$$

Proof. Consider a stochastic differential game defined by the system

$$
\begin{aligned}
dx(t) = [Ax(t) + B_1 u(t) + \bar{B}_2 \bar{\xi}(t)]dt + (Hx(t) + P_1 u(t))dw_1(t) \\
+ \bar{P}_2 \bar{\xi}(t) dw_2(t),
\end{aligned} \tag{47}
$$

and the cost function

$$
\begin{aligned}
\Im^{s,h}(u(\cdot), \bar{\xi}(\cdot)) &= J^{s,h}(u(\cdot)) + \mathbf{E}\int_s^\infty \left(\langle z(t), \bar{R} z(t)\rangle - \|\bar{\xi}\|^2\right) dt \\
&= \mathbf{E}\int_s^\infty (\|\bar{C}x + \bar{D}u\|^2 - \|\bar{\xi}\|^2) dt,
\end{aligned} \tag{48}
$$

where matrices $\bar{B}_2$, $\bar{P}_2$, $\bar{C}$, and $\bar{D}$ are defined as in (43). Under Assumption 2, the conditions of the sufficiency part of Theorem 2 are satisfied for the system (47) and cost functional (48). This leads to the conclusion that the controller (45) solves the stochastic H_∞ control problem associated with (47), (48). That is, the system (34), where the matrix K is defined by (45), is exponentially stable in mean-square sense, and as a consequence, the matrix $A + B_1 K$ is stable. Furthermore, the controller (45) satisfies the following stochastic H_∞-norm condition: there exists a constant $\varepsilon > 0$ such that

$$
\begin{aligned}
\mathbf{E}\int_0^{+\infty} \left(\|(\bar{C} + \bar{D}K)x(t)\|^2 - \|\bar{\xi}(t)\|^2\right) dt \le -\varepsilon \mathbf{E}\int_0^{+\infty} \|\bar{\xi}(t)\|^2 dt \\
\text{for } x(0) = 0 \text{ and } \forall\ \bar{\xi}(\cdot) \in L_2(0, \mathbf{R}^{m_2}),
\end{aligned} \tag{49}
$$

where $x(\cdot)$ is a solution to the equation

$$
\begin{aligned}
dx(t) = ((A + B_1 K)x(t) + \bar{B}_2 \bar{\xi}(t))dt + (H + P_1 K)x(t)dw_1(t) \\
+ \bar{P}_2 \bar{\xi}(t) dw_2(t)
\end{aligned} \tag{50}
$$

obtained by the substitution of (45) into (47). This conclusion shows that the system (50) and functional (48) satisfy the conditions of Lemma 1. Using the result of this lemma, we obtain

$$\bar{\Im}^{s,h}(u^0(\cdot),\bar{\xi}(\cdot)) \leq \mathbf{E}\langle h, X_K h\rangle \quad \forall\ \bar{\xi}(\cdot) \in L_2(0,\mathbf{R}^{m_2}), \tag{51}$$

where the matrix X_K is the minimal solution to the following Riccati equation of the form (25):

$$\begin{aligned}&(A+B_1K)'X_K + X_K(A+B_1K) + (H+P_1K)^*X_K(H+P_1K)\\ &+(\bar{C}+\bar{D}K)'(\bar{C}+\bar{D}K) + X_K\bar{B}_2(I-\bar{P}_2^*X_K\bar{P}_2)^{-1}\bar{B}_2'X_K = 0,\\ &I-\bar{P}_2^*X_K\bar{P}_2 > 0.\end{aligned} \tag{52}$$

Also, one may observe that by using elementary transformations, (42) can be transformed into the following equation:

$$\begin{aligned}&(A+B_1K)'X + X(A+B_1K) + (H+P_1K)^*X(H+P_1K)\\ &+(\bar{C}+\bar{D}K)'(\bar{C}+\bar{D}K) + X\bar{B}_2(I-\bar{P}_2^*X\bar{P}_2)^{-1}\bar{B}_2'X = 0,\\ &I-\bar{P}_2^*X\bar{P}_2 > 0,\end{aligned} \tag{53}$$

which is the same as (52). Thus, the minimal solutions to these equations are equal, $X = X_K$, and consequently, one can replace X_K in (51) with the solution to the algebraic Riccati equation (42) to obtain

$$\bar{\Im}^{s,h}(u^0(\cdot),\bar{\xi}(\cdot)) \leq \mathbf{E}\langle h, Xh\rangle. \tag{54}$$

The subsequent proof requires the use of Theorem 3 of [5]. In [5] this result, referred to as the stochastic counterpart of the Kalman–Yakubovich lemma, established the existence of a solution to a certain linear matrix inequality related to the sign-indefinite linear-quadratic stochastic control problem considered in this reference. We wish to apply this result to the "control problem" $\sup_{\bar{\xi}(\cdot)} \Im^{s,h}(u^0,\bar{\xi}(\cdot))$, with the underlying system (50) and the stable system (34), with the matrix K given by (45). The conditions under which one can apply Theorem 3 in [5] to the above control problem are virtually the same as the conditions of Lemma 1. Note that Theorem 3 in [5] requires the cost functional in the above control problem to satisfy a certain condition of coercivity [5, 13]. In our case the fact that this condition is satisfied follows in a straightforward way from the stochastic H_∞ condition (49). Note also that Assumption 3 of [5] holds in our case, since we deal with finite-dimensional equations and operators. Since we have verified the conditions of Lemma 1 for the system (50) and functional (48), the application of Theorem 3 in [5] implies the existence of a symmetric matrix M and a positive constant ϵ satisfying the LMI

$$\begin{aligned}&-2\langle (A+B_1K)x + \bar{B}_2\bar{\xi}, Mx\rangle - \langle x, (H+P_1K)^*M(H+P_1K)x\rangle\\ &-\langle \bar{\xi}, \bar{P}_2^*M\bar{P}_2\bar{\xi}\rangle - \|(\bar{C}+\bar{D}K)x\|^2 + \|\bar{\xi}\|^2 \geq \epsilon(\|x\|^2+\|\bar{\xi}\|^2)\ \forall\ x\in\mathbf{R}^n, \bar{\xi}\in\mathbf{R}^{m_2}.\end{aligned} \tag{55}$$

The standard form for this LMI is the following:

$$\left[\begin{array}{cc} \begin{array}{c}-(A+B_1K)'M - M(A+B_1K)\\ -(H+P_1K)^*M(H+P_1K) - (\bar{C}+\bar{D}K)'(\bar{C}+\bar{D}K)\end{array} & -M\bar{B}_2 \\ -\bar{B}_2'M & I-\bar{P}_2M\bar{P}_2 \end{array}\right] > 0.$$

Recall that the nominal closed-loop system (34) corresponding to the system (50), driven by the uncertainty input $\xi_\phi(t) \equiv 0$, is exponentially stable in mean-square sense. Hence, $\mathbf{E}\|x(t)\|^2 \to 0$ as $t \to \infty$ in this particular case. Therefore, it follows from (55) that

$$\mathbf{E}\langle h, Mh\rangle \geq \epsilon_1 \mathbf{E}\int_s^\infty \|x(t)\|^2 dt,$$

and hence $M > 0$. To establish this fact, we have used the Ito formula along the solution to the system (34) on the interval $[s,t]$, with initial condition $x(s) = h$ and then sent t to ∞.

Now, let $\xi_\phi(\cdot)$ be the uncertainty input corresponding to an admissible uncertainty $\phi(\cdot) \in \Phi$. Then define

$$\bar{\xi}(t) = \begin{cases} \bar{G}^{1/2}\xi_\phi(t) = \bar{G}^{1/2}\phi(t, x|_s^t, Kx|_s^t), & t \in [s, t_j], \\ 0, & t > t_j, \end{cases}$$

where t_j is as defined in Definition 1. Also, let $x(t)$ be the corresponding solution to (50) satisfying the initial condition $x(s) = h$. Then it follows from inequality (55) that

$$\begin{aligned} -\mathbf{E}\langle x(t), Mx(t)\rangle|_s^{t_j} + \mathbf{E}\int_s^{t_j} (-\|(\bar{C}+\bar{D}K)x(t)\|^2 + \|\bar{\xi}(t)\|^2)dt& \\ \geq \epsilon \mathbf{E}\int_s^{t_j} (\|x(t)\|^2 + \langle \xi_\phi(t), \bar{G}\xi_\phi(t)\rangle)dt.& \end{aligned} \tag{56}$$

The Ito formula is used to derive (56) from (55). Hence, using (3) and the nonnegativeness of R, G, we obtain

$$\begin{aligned} &-\mathbf{E}\langle x(t), Mx(t)\rangle|_s^{t_j} + \mathbf{E}\langle x(s), Wx(s)\rangle \\ &\geq -\mathbf{E}\langle x(t), Mx(t)\rangle|_s^{t_j} - \mathbf{E}\int_s^{t_j} (\langle x(t), Rx(t)\rangle + \langle Kx(t), GKx(t)\rangle)dt \\ &-\mathbf{E}\int_s^{t_j} \left(\langle z(t), \bar{R}z(t)\rangle + \langle \xi_\phi(t), \bar{G}\xi_\phi(t)\rangle\right) dt \\ &\geq \epsilon_1 \mathbf{E}\int_s^{t_j} (\|x(t)\|^2 + \langle \xi_\phi(t), \bar{G}\xi_\phi(t)\rangle)dt. \end{aligned} \tag{57}$$

Since we have established that $M > 0$ and $x(s) = h$, (57) implies

$$\epsilon_1 \mathbf{E}\int_s^{t_j} (\|x(t)\|^2 + \langle \xi_\phi(t), \bar{G}\xi_\phi(t)\rangle)dt \leq \mathbf{E}\langle h, (M+W)h\rangle. \tag{58}$$

Thus, we see that the expression on the left in (58) is uniformly bounded with respect to t_j. Therefore, (58) implies that $x(\cdot) \in L_2(s, \mathbf{R}^n)$ for any admissible ϕ. Also, using the fact that $\bar{G} > 0$, it also follows that $\xi_\phi(\cdot) \in L_2(s, \mathbf{R}^{m_2})$ for any admissible ϕ. Therefore, for any admissible uncertainty ϕ, the input $\bar{\xi}(\cdot) = \bar{G}^{1/2}\xi_\phi(\cdot)$ is an admissible uncertainty input in the stochastic H_∞ control problem defined by the system (47) and cost functional (48). For this uncertainty input, we obtain from (48) and (54)

$$\begin{aligned} J^{s,h}(u^0) &\leq -\int_0^\infty \mathbf{E}\left(\langle z(t), \bar{R}z(t)\rangle - \langle \xi_\phi(t), \bar{G}\xi_\phi(t)\rangle\right) dt + \mathbf{E}\langle h, Xh\rangle \\ &\leq \mathbf{E}\langle h, (X+W)h\rangle. \qquad \square \end{aligned}$$

Remark. We have observed that the generalized algebraic Riccati equation (42) can be transformed into an algebraic Riccati equation of the form (25). Hence as in the case of (25), a possible approach to solving the algebraic Riccati equation (42) is to apply homotopy methods [18].

5. Minimax optimal state feedback controller. In this section we assume that the uncertainty in the system is structured and each uncertainty loop satisfies its own stochastic integral quadratic constraint of the form (4). As has been mentioned in the introduction, for any numbers $\tau_1 > 0, \ldots, \tau_k > 0$, we replace all of the constraints by a single stochastic integral quadratic constraint (5). For the uncertain stochastic system (1), with the uncertainty (2) satisfying this structured uncertainty constraint, we solve the corresponding minimax optimal guaranteed cost control problem. The main result of this section, Theorem 4, shows that the problem of finding the minimax optimal guaranteed cost controller can be reduced to a finite-dimensional optimization problem.

We shall assume in this section that the system (1) satisfies Assumption 2.

Let $\mathcal{T}$ denote the set of vectors $\tau \in \mathbf{R}_+^k$ such that the corresponding Riccati equation (42) has a nonnegative stabilizing solution X_τ; i.e.,

$$\mathcal{T} = \left\{ \tau \in \mathbf{R}^k\colon \begin{array}{l} \tau_1 > 0, \ldots, \tau_k > 0 \text{ and Riccati equation (42) with} \\ \bar{R} = \bar{R}_\tau, \bar{G} = \bar{G}_\tau, \text{ has a stabilizing solution} \\ X_\tau \geq 0 \text{ such that } \bar{G}_\tau - P_2^* X_\tau P_2 > 0. \end{array} \right\} \tag{59}$$

THEOREM 4.

(i) *Given $\gamma > 0$ and initial condition h, there exists a guaranteed cost controller for the uncertain system* (1), (2) *if and only if the set $\mathcal{T}$ defined in* (59) *is nonempty.*

(ii) *Suppose the set $\mathcal{T}$ is nonempty. Then*

$$\inf_{u(\cdot)\in\mathcal{K}} \sup_{\phi\in\Phi} J^{s,h}(u(\cdot)) = \inf_{\tau\in\mathcal{T}} \mathbf{E}\left[\langle h, (X_\tau + W_\tau)h\rangle\right]. \tag{60}$$

Furthermore, let $\tau^* \in \mathcal{T}$ attain the infimum on the right-hand side of (60). *Then the corresponding control $u^0_{\tau^*}$ defined by* (45) *with the matrix $X = X_{\tau^*}$ is the state feedback minimax optimal guaranteed cost control which minimizes the worst case of the cost functional* (48) *in the constrained stochastic optimization problem* (12) *subject to the stochastic integral quadratic constraint* (4) *and absolutely stabilizes the uncertain system* (1).

The proof of this theorem follows the same form as the proof of the main result of [20]. As in [20], we use the so-called S-procedure [15, 20, 21, 22, 29] to reduce our constrained optimization problem to a problem without constraints. However, in contrast to these papers, the system (1) is nonautonomous in nature due to the stochastic perturbations. This leads us to consider a special construction of shift operators in order to satisfy conditions of the S-procedure. This construction involves special metrical transitive transformations of stochastic processes. The basic properties of these transformations are given in Appendix A.

As in [20], we begin with a result establishing that a stabilizing guaranteed cost controller for the uncertain system (1), (2) exists if and only if the set $\mathcal{T}$ defined in (59) is nonempty.

LEMMA 2. *Given a positive constant γ and initial condition h, the following statements are equivalent*:

(i) *for the given $\gamma > 0$, there exists a guaranteed cost controller of the form* (8) *which guarantees that the closed-loop uncertain system* (1), (3), (8) *with the cost* *function* (7) *and given initial condition does not exceed the prescribed cost value*

$$\sup_{\phi\in\Phi} J^{s,h}(u(\cdot)) < \gamma; \tag{61}$$

(ii) *for a given initial condition, there exists a* $\tau \in \mathcal{T}$ *such that*

$$\mathbf{E}\langle h, (X_\tau + W_\tau)h\rangle < \gamma. \tag{62}$$

Proof of Lemma 2. (i)⇒(ii). First observe that since (8) corresponds to a guaranteed cost controller, then the nominal closed-loop system (9) is exponentially stable. This implies that for any $\xi(\cdot) \in L_2(s;\mathbf{R}^{m_2})$, the corresponding solution $x(\cdot)$ to (10) belongs to $L_2(s;\mathbf{R}^n)$. As a consequence, the corresponding uncertainty output $z(\cdot)$ lies in $L_2(s;\mathbf{R}^p)$ and the corresponding control input $u_\xi(\cdot)$ lies in $L_2(s;\mathbf{R}^{m_1})$.

Note that (61) implies the existence of a constant $\varepsilon > 0$ such that

$$(1+\varepsilon)J^{s,h}(u_\phi(\cdot)) \le \gamma - \varepsilon \quad \forall\ \phi \in \Phi(\bar{R}_1, \bar{G}_1, W_1, \ldots, \bar{R}_k, \bar{G}_k, W_k), \tag{63}$$

where $u_\phi(\cdot)$ is the control input generated by the closed-loop uncertain system (10), (2).

It follows from the above observation that the following quadratic functionals are well defined on $L_2(s;\mathbf{R}^{m_2})$:

$$\begin{aligned}&\mathcal{G}_0(\xi(\cdot)) := -(1+\varepsilon)J^{s,h}(u_\xi(\cdot)) + \gamma - \varepsilon,\\ &\mathcal{G}_i(\xi(\cdot)) := \mathbf{E}\int_0^\infty \left(\langle z_i(t), \bar{R}_i z_i(t)\rangle - \langle \xi_i(t), \bar{G}_i \xi_i(t)\rangle\right)dt + \mathbf{E}\langle h, W_i h\rangle,\end{aligned} \tag{64}$$

where $x(\cdot)$ and $z_i(\cdot)$ correspond to the solution of the closed-loop system (10) with uncertainty input $\xi(\cdot) \in L_2(s;\mathbf{R}^{m_2})$. Furthermore, since (8) corresponds to a guaranteed cost controller, then for any admissible uncertainty ϕ, the corresponding admissible uncertainty input $\xi_\phi(\cdot) \in L_2(s;\mathbf{R}^{m_2})$ and the corresponding uncertainty output $z(\cdot) \in L_2(s;\mathbf{R}^p)$. Therefore, since $t_j \to \infty$ as $j \to \infty$, it follows from (4) that

$$\mathcal{G}_i(\xi_\phi(\cdot)) \ge 0 \quad \forall\ \phi \in \Phi(\bar{R}_1, \bar{G}_1, W_1, \ldots, \bar{R}_k, \bar{G}_k, W_k) \qquad (i = 1, \ldots, k). \tag{65}$$

We now check that the quadratic functionals $\mathcal{G}_0, \mathcal{G}_1, \ldots, \mathcal{G}_k$ form an S-system in the terminology of [29]; i.e., we check that there exists a sequence of linear bounded operators $\mathbf{T}_j\colon L_2(s;\mathbf{R}^{m_2}) \to L_2(s;\mathbf{R}^{m_2})$, $j = 1, 2, \ldots$, such that this sequence weakly converges to zero in $\mathcal{L}(L_2(s;\mathbf{R}^{m_2}))$ and

$$\begin{aligned}J^{s,0}(u_j(\cdot)) \to J^{s,0}(u(\cdot)), \quad \mathcal{G}_i(\xi_j(\cdot)) \to \mathcal{G}_i(\xi(\cdot)) \quad &\text{as } j \to \infty\\ \forall\ \xi(\cdot) \in L_2(s;\mathbf{R}^{m_2}) \text{ and } i = 1, 2, \ldots, k&,\end{aligned} \tag{66}$$

where $u_j(\cdot)$ corresponds to the solution of (10) generated by the uncertainty input $\mathbf{T}_j\xi(\cdot)$ with zero initial condition. We choose the operators $\mathbf{T}_j$ as follows: for each $\xi(\cdot) \in L_2(s;\mathbf{R}^{m_2})$,

$$\xi_j(t,\omega) = (\mathbf{T}_j\xi)(t,\omega) := \begin{cases} 0, & s \le t < t_j,\\ \xi(t - t_j, \Gamma_{t_j}\omega), & t \ge t_j,\end{cases} \tag{67}$$

where t_j is the sequence from Definition 1, $t_j \to \infty$ as $j \to \infty$, and Γ_{t_j}, $j = 1, 2, \ldots$, are metrically transitive transformations from the translation semigroup generated by the Wiener process (w_1, w_2). (See Appendix A for details.) Given any two functions $\xi_1(\cdot), \xi_2(\cdot) \in L_2(s; \mathbf{R}^{m_2})$, the Cauchy inequality gives

$$\left|\mathbf{E}\int_s^\infty \langle (\mathbf{T}_j\xi_1)(t), \xi_2(t)\rangle dt\right|^2 = \left|\mathbf{E}\int_{t_j}^\infty \langle \xi_1(t-t_j, \Gamma_{t_j}\omega), \xi_2(t)\rangle dt\right|^2$$
$$\leq \mathbf{E}\int_s^\infty \|\xi_1(t)\|^2 dt\, \mathbf{E}\int_{t_j}^\infty \|\xi_2\|^2 dt$$

since Γ_{t_j} preserves probability measures, and $\mathbf{E}f(x(\Gamma_{t_j}\omega)) = \mathbf{E}f(x)$ for any Borel-measurable vector function f. However, the term $\mathbf{E}\int_{t_j}^\infty \|\xi_2\|^2 dt$ in the above inequality tends to 0 as $j \to \infty$. This implies $\mathbf{T}_j \to 0$ weakly.

Next, observe that Lemma 2 of [3] (see also Lemma 3 in Appendix A) states that the solution to the closed-loop system (10) with zero initial condition and corresponding to an uncertainty input $\mathbf{T}_j\xi$ is such that

$$x_j(t,\omega) = \begin{cases} 0, & s \leq t < t_j, \\ x(t-t_j, \Gamma_{t_j}\omega), & t \geq t_j, \end{cases} \tag{68}$$
$$u_j(t,\omega) = \begin{cases} 0, & s \leq t < t_j, \\ u(t-t_j, \Gamma_{t_j}\omega), & t \geq t_j, \end{cases}$$
$$z_j(t,\omega) = \begin{cases} 0, & s \leq t < t_j, \\ z(t-t_j, \Gamma_{t_j}\omega), & t \geq t_j. \end{cases}$$

Then, the substitution of (67) and (68) into (64) gives (66). Thus, we conclude that the family of functionals above forms an S-system. Furthermore, since $W_i > 0$, then for a given nonzero h, zero input $\xi(\cdot) \equiv 0$ gives $\mathcal{G}_i(0) > 0\ \forall\ i = 1, 2, \ldots, k$. This means that constraints are regular in terminology of [29]. Also, it follows from (63) and (65) that the condition $\mathcal{G}_1(\xi(\cdot)) \geq 0, \ldots, \mathcal{G}_k(\xi(\cdot)) \geq 0$ implies that $\mathcal{G}_0(\xi(\cdot)) \geq 0$. We have satisfied all conditions of Theorem 1 of [29]. Therefore, for a given nonzero h, there exist constants $\tau_1 \geq 0, \ldots, \tau_k \geq 0$ such that

$$\mathcal{G}_0(\xi) \geq \sum \tau_i \mathcal{G}_i(\xi) \quad \forall\ \xi(\cdot) \in L_2(s; \mathbf{R}^{m_2}). \tag{69}$$

Now, let us use these τ_i to define the functional

$$J_{\varepsilon,\tau}^{s,h}(\xi(\cdot)) := \varepsilon J^{s,h}(u_\xi(\cdot)) + \bar{\Im}^{s,h}(u_\xi(\cdot), \bar{G}_\tau^{1/2}\xi(\cdot)), \tag{70}$$

where the coefficients of $\bar{\Im}^{s,h}$ in (48) are defined as in (43):

$$\bar{\Im}^{s,h}(u(\cdot), \bar{G}_\tau^{1/2}\xi(\cdot)) = J^{s,h}(u(\cdot)) + \mathbf{E}\int_s^\infty \left(\langle z(t), \bar{R}_\tau z(t)\rangle - \langle \xi(t), \bar{G}_\tau \xi(t)\rangle\right) dt.$$

Then it follows from (69) that

$$J_{\varepsilon,\tau}^{s,h}(\xi(\cdot)) \leq \gamma - \varepsilon - \mathbf{E}\langle h, W_\tau, h\rangle \quad \forall\ \xi \in L_2(s; \mathbf{R}^{m_2}). \tag{71}$$

The same arguments as those in [20] (see Claims 1 and 2 in the proof of Lemma 3.2 of this reference) then give us

$$J_{\varepsilon,\tau}^{s,0}(\xi(\cdot)) \leq 0 \quad \forall\ \xi \in L_2(s; \mathbf{R}^{m_2}), \tag{72}$$

and also $\tau_i > 0\ \forall\ i = 1, \ldots, k$.

Next, let us show that the generalized Riccati equation (42) with $\bar{R} = \bar{R}_\tau$, $\bar{G} = \bar{G}_\tau$ has a nonnegative definite stabilizing solution X_τ such that $\bar{G}_\tau - P_2^* X_\tau P_2 > 0$, where constants $\tau_1, \ldots, \tau_k$ are as in (69). In terms of our notation, this will mean that $\tau \in \mathcal{T}$. Notice that (72) implies

$$\Im^{s,0}(u_\xi, \bar{G}^{1/2}\xi(\cdot)) \leq -\varepsilon J^{s,0}(u_\xi(\cdot)) \leq 0 \qquad \forall\, \xi \in L_2(s; \mathbf{R}^{m_2}). \tag{73}$$

Therefore, since $R > 0$, $G > 0$, $\bar{G}_\tau > 0$, it follows that there exists a constant $\alpha > 0$ such that

$$\mathbf{E}\int_s^\infty \left(\|\bar{C}x(t) + \bar{D}u_\xi(t)\|^2 - \|\bar{\xi}(t)\|^2\right) dt < -\alpha \mathbf{E}\int_s^\infty \|\bar{\xi}(t)\|^2 dt \qquad \forall\, \bar{\xi}(\cdot) \in L_2(s; \mathbf{R}^{m_2}) \tag{74}$$

for $h = 0$. To see this, suppose (74) does not hold; i.e., there exists a sequence $\{\bar{\xi}^l(\cdot)\}_{l=1}^\infty \subset L_2(s; \mathbf{R}^{m_2})$ such that

$$\lim_{l\to\infty} \frac{\mathbf{E}\int_s^\infty \|\bar{C}x^l(t) + \bar{D}u_{\bar{\xi}^l}(t)\|^2 dt}{|||\bar{\xi}^l(t)|||^2} = 1. \tag{75}$$

It is clear that we can choose this sequence such that $|||\bar{\xi}^l||| = 1$, since (10) is linear with respect to $\bar{\xi}$, and (70) is a quadratic functional with respect to $\bar{\xi}$. Then, using the weak compactness of a ball in Hilbert space [31], there exists a subsequence $\{\bar{\xi}^{l_\nu}\}_{\nu=1}^\infty$ such that $\bar{\xi}^{l_\nu} \to \bar{\xi}_*$ weakly as $\nu \to \infty$, $|||\bar{\xi}_*||| = 1$. Also, $x^{l_\nu} \to x_*$ weakly as $\nu \to \infty$, since (10) is linear and (9) is exponentially stable. Furthermore, we observe that (73) and (75) imply that $x^{l_\nu} \to 0$ strongly since $R > 0$. Indeed, from (73) we have

$$\Im^{s,0}(u_{\bar{\xi}^{l_\nu}}, \bar{\xi}^{l_\nu}(\cdot)) \leq -\varepsilon_1 \mathbf{E}\int_0^\infty \|x^{l_\nu}(t)\|^2 dt \leq 0. \tag{76}$$

From (75), the expression on the left-hand side of (76) tends to 0 as $l \to \infty$. Hence $x^{l_\nu} \to 0$ strongly. Then we have $|||\bar{C}x^{l_\nu} + \bar{D}u_{\bar{\xi}^{l_\nu}}||| \to 0$ which contradicts (75). Thus (74) must hold.

The inequality (74) implies that the given guaranteed cost control solves the stochastic H_∞ control problem for the system (1) and the cost function (48). Then, we conclude, using Theorem 2, that there exists a symmetric, nonnegative definite stabilizing solution X_τ to the Riccati equation (42), which is a minimal solution, and

$$\bar{G}_\tau - P_2^* X_\tau P_2 = \bar{G}_\tau^{1/2}(I - \bar{P}_2^* X_\tau \bar{P}_2)\bar{G}_\tau^{1/2} > 0.$$

Thus, $\tau \in \mathcal{T}$. Moreover, inequality (40), established in Theorem 2, and condition (71) imply that

$$\mathbf{E}\langle h, X_\tau h\rangle \leq \sup_{\bar{\xi}(\cdot)} \Im^{s,h}(u_\xi(\cdot), \bar{\xi}(\cdot)) \leq \sup_{\xi(\cdot)} J^{s,h}_{\varepsilon,\tau}(\xi(\cdot)) \leq \gamma - \varepsilon - \mathbf{E}\langle h, W_\tau h\rangle. \tag{77}$$

Hence, condition (62) holds.

(ii)⇒(i). This part of the proof follows immediately from Theorem 3. □

Proof of Theorem 4. The theorem follows immediately from Lemma 2. In particular, note that the absolute stabilizing properties of the minimax optimal guaranteed cost controller were established in the second part of the proof of Lemma 2, where we referred to Theorem 3. □

6. Conclusions.

This paper has been concerned with existence and optimality of a guaranteed cost controller for an uncertain system subject to structured uncertainty. The new class of uncertainty satisfying so-called stochastic integral quadratic constraints has been introduced. It has been shown that such constraints naturally describe some practically important classes of uncertainty.

In this paper, we have shown that for each initial state of the system, the linear static state feedback controller yielding an optimal worst-case performance in the face of stochastic structured uncertainty in the system, is found by parametric optimization of solutions of a parameter-dependent generalized matrix Riccati equation. The generalized Riccati equation is of the type arising in stochastic H_∞ theory and related stochastic differential games.

As in the deterministic case, the S-procedure has been used to convert the constrained stochastic optimization problem into a problem without constraints. However, due to the stochastic character of uncertainty, this has led us to consider a special construction of shift operators in order to satisfy conditions of the S-procedure. This construction has involved special metrical transitive transformations of stochastic processes.

Appendix A.

Let Ω be any space of elements ω. Let $\mathcal{P}$ be a probability measure defined on a Borel field $\mathcal{F}$ of ω sets. A transformation Γ, taking points of Ω into points of Ω, is called a one-to-one *measure-preserving point transformation* if it is one-to-one and has domain and range Ω and if it and its inverse take measurable sets into measurable sets of the same probability.

A set transformation Γ defined on the Borel field $\mathcal{F}$, taking sets of $\mathcal{F}$ into sets of $\mathcal{F}$, is called a *measure-preserving set transformation* if the following conditions are satisfied:

(i) Γ is single-valued, modulo sets of probability 0; i.e., if $\tilde{\Lambda}$ is an image of Λ under Γ, the class of all images of Λ is the class of all measurable sets differing from $\tilde{\Lambda}$ by sets of probability 0.

(ii) $\mathcal{P}(\Gamma\Lambda) = \mathcal{P}(\Lambda)$.

(iii) Neglecting ω sets of probability 0,

$$\Gamma(\Lambda_1 \cup \Lambda_2) = \Gamma\Lambda_1 \cup \Gamma\Lambda_2,$$
$$\Gamma(\bigcup_{i=1}^{\infty} \Lambda_i) = \bigcup_{i=1}^{\infty} \Gamma\Lambda_i,$$
$$\Gamma(\Omega - \Lambda) = \Omega - \Gamma\Lambda.$$

A one-to-one measure-preserving point transformation Γ induces a measure-preserving set transformation.

A measurable set is called *invariant* under a measure-preserving point or set transformation if it differs from its images by sets of probability 0. A measure-preserving point or set transformation is called *metrically* transitive if the only invariant sets are those which have probability 0 or 1.

A family $\{\Gamma_s, s \geq 0\}$ of transformations, taking points of Ω into points of Ω, is called a *translation semigroup of measure-preserving one-to-one point transformations* if each Γ_s is a one-to-one measure-preserving point transformation and if

$$\Gamma_{s+t} = \Gamma_s\Gamma_t \quad \forall\ s, t \geq 0. \tag{A.1}$$

The transformation Γ_0 will necessarily be the identity.

A family $\{\Gamma_s, s \geq 0\}$ of set transformations is called a *translation semigroup of measure-preserving set transformations* if (A.1) is true modulo the sets of probability 0. The transformation Γ_0 will be the identity in the sense that every image of a measurable set Λ under Γ_0 will differ from Λ by at most a set of probability 0. A translation semigroup of measure-preserving point or set transformations is called metrically transitive if the only invariant sets are those which have probability 0 or 1.

The scalar Wiener process is an example of a process generating a metrically transitive translation semigroup of measure-preserving set transformations [6]. These transformations are generated by time shifts of strictly stationary increments of the Wiener process. Also, it is known [6] that the semigroup of shifts of a strictly stationary process is metrically transitive if and only if the semigroup of shifts for the corresponding canonical process in the coordinate space is metrically transitive. For canonical processes, shifts are point transformations. This allows one to pass from considering the Wiener process over an abstract probability space to considering its canonical version for which metrically transitive shifts have a simple construction.

The canonical representation (see, e.g., [14]) for a scalar Wiener process is the probability space $(\overline{\Omega}, \overline{\mathcal{P}}, \overline{\mathcal{F}})$ and the process $\overline{w}(t)$, $t \geq 0$ such that

$\overline{\Omega}$ is the set of continuous functions $\omega(t)$: $[0, \infty) \to \mathbf{R}^1$, starting from zero at $t = 0$;

$\overline{\mathcal{F}}$ is the Borel σ-field generated by the cylindrical subsets in $\overline{\Omega}$;

$\overline{\mathcal{P}}$ is the Wiener probability measure on $(\overline{\Omega}, \overline{\mathcal{F}})$;

$\overline{w}(t)$ is a stochastic process defined as follows:

$$\overline{w}(t, \omega) = \omega(t) \quad (\omega \in \overline{\Omega}, t \geq 0).$$

As in [6], given any $s \geq 0$, each $\omega \in \overline{\Omega}$ has corresponding $\omega_1 \in \overline{\Omega}$ such that

$$\overline{w}(t, \omega_1) = \overline{w}(t + s, \omega) - \overline{w}(s, \omega) \qquad \forall\ t \geq 0.$$

The relation $\omega_1 = \Gamma_s \omega$ generates a metrically transitive translation semigroup of measure-preserving transformations.

Each of the above measure-preserving transformations induces a transformation of random variables, which takes $\bar{\mathcal{F}}_t$-measurable variables into $\bar{\mathcal{F}}_{t+s}$-measurable ones. Here $\{\bar{\mathcal{F}}_t, t \geq 0\}$ denotes the Borel filtration, generated by $\overline{w}(\theta)$, $0 \leq \theta < t$. When applied to diffusion processes satisfying linear Ito equations, this fact gives the following result.

LEMMA 3 (see Brusin [3]). *Let $x(t, \omega)$ and $y(t + s, \omega)$, $t \geq 0$, $s > 0$, be two $\mathbf{R}^n$-valued stochastic processes being the unique solutions to integral equations* (A.2) *and* (A.3) *below, respectively:*

$$\text{(A.2)} \qquad x(t, \omega) = h(\omega) + \int_0^t (Ax(\theta, \omega) + Bu(\theta, \omega))d\theta + \int_0^t (Hx(\theta, \omega) + Pu(\theta, \omega))dw(\theta),$$

$$\text{(A.3)} \qquad y(t + s, \omega) = g(\omega) + \int_s^{t+s} (Ay(\theta, \omega) + Bv(\theta, \omega))d\theta + \int_s^{t+s} (Hy(\theta, \omega) + Pv(\theta, \omega))dw(\theta),$$

$h \in L_2^0$, $g \in L_2^s$, $u \in L_2(0, \mathbf{R}^m)$, $v \in L_2(s, \mathbf{R}^m)$. If $u(t, \Gamma_s \omega) = v(t + s, \omega)$ and $g(\omega) = h(\Gamma_s \omega)$ with probability 1, *then*

$$y(t + s, \omega) = x(t, \Gamma_s \omega) \quad \textit{with probability } 1.$$

In section 2 and in the proof of Theorem 2, we have used another result of reference [3]. For the sake of completeness, we include this result here in the form adapted to the set-up of this paper. Note that in the particular case of a single input system of the form (1) with the matrix A in companion form and state dependent noise, a similar result was established in [23]. Theorem 2 in [23] dealt with an L_2-property of solutions with probability 1 while the result given below concerns the mean-square L_2-property.

Lemma 4 (see Brusin [3, Theorem 5]). *Suppose Assumption* 1 *is satisfied. Then, for any pair of inputs* $(u(\cdot), \xi(\cdot)) \in L_2(s, \mathbf{R}^{m_1}) \times L_2(s, \mathbf{R}^{m_2})$ *and any initial condition* $x(0) = h$, *the corresponding solution to* (1) *satisfies the condition:*

$$|||x(\cdot)|||^2 \leq c_0 \left(\mathbf{E}\|h\|^2 + |||u(\cdot)|||^2 + |||\xi(\cdot)|||^2\right), \tag{A.4}$$

where $c_0 > 0$ *is a constant independent of* h, $u(\cdot)$, *and* $\xi(\cdot)$.

Appendix B. Proof of Lemma 1. The problem (19) is a stochastic control problem with a sign-indefinite integrand in the cost function. Thus, it is natural to refer to the uncertainty inputs $\xi(\cdot)$ as "control" inputs in this control problem. A solution to this class of control problems has been given in [4]; see also [5], where the results of [4] were extended to the infinite-dimensional case. It is readily seen that the conditions of Theorem 1 in [4, 5] are satisfied in the case under consideration. Applying the result of Theorem 1 in [4, 5] to the control problem (19), it follows that the first part of claim (a) of Lemma 1 holds. The existence of a symmetric matrix X_2 satisfying condition (21) is also established by the above-mentioned result of [4, 5]. From the inequality $\Im^{s,h}(0,0) \geq 0$, it follows that $X_2 \geq 0$. Hence, claim (b) also holds.

The control problem

$$\sup_{\zeta \in L_2(s,T;\mathbf{R}^{m_2})} \Im_T^{s,h}(0,\zeta), \tag{B.1}$$

considered in the second part of claim (a) of Lemma 1, can be solved by the same method as that of [2, 11]. Reference [2] presents a solution to the standard finite horizon stochastic optimal control problem. The control problem (B.1) differs from control problems considered in reference [2] in that the integrand in (16) is sign-indefinite. Hence, one needs to extend the results of [2] to the case considered in this paper. This extension can be performed in the same fashion as has been done for similar maximization problems for deterministic time-varying systems [11].

We first note that the control problem (B.1) has a unique solution. Indeed, as in [2], it follows that the functional (16) is continuous. Also, in the same way as in [3, 4, 5], one can obtain using the Riesz representation theorem, that

$$\Im_T^{s,h}(0,\zeta) = -\pi(\zeta,\zeta) + 2\Upsilon(h,\zeta) + \Im_T^{s,h}(0,0),$$

where $\pi(\cdot,\cdot)$, $\Upsilon(\cdot,\cdot)$ are bilinear forms on the Hilbert product-spaces $L_2(s,T;\mathbf{R}^{m_2}) \times L_2(s,T;\mathbf{R}^{m_2})$, $L_2^s \times L_2(s,T;\mathbf{R}^{m_2})$, respectively. We now show that the bilinear form π is coercive [13]. Let $\Phi_{s,T}$ denote a linear bounded operator $L_2(s,T;\mathbf{R}^{m_2}) \to L_2(s,T;\mathbf{R}^n)$ mapping a given control input $\zeta(\cdot)$ into a corresponding solution of the equation

$$dx = (Ax(t) + B_2\zeta(t))dt + Hx(t)dw_1(t) + P_2\zeta(t)dw_2(t), \quad x(s) = 0. \tag{B.2}$$

Then, for any $s_2 \leq s_1 \leq T_1 \leq T_2$ and $\zeta(\cdot) \in L_2(s_1, T_1, \mathbf{R}^{m_2})$,

$$|||R^{1/2}\Phi_{s_1,T_1}\zeta|||^2 = |||R^{1/2}\Phi_{s_2,T_1}\tilde{\zeta}|||^2 \leq |||R^{1/2}\Phi_{s_2,T_2}\tilde{\zeta}|||^2,$$

where $\tilde{\zeta} \in L_2(s_2, T_2; \mathbf{R}^{m_2})$ is the extension of $\zeta(\cdot)$ to $[s_2; T_2]$ by zero. From this inequality and from (18), it follows that

$$-\pi(\zeta,\zeta) = |||R^{1/2}\Phi_{s,T}\zeta|||^2 - |||\zeta|||^2 \leq -\varepsilon_2|||\zeta|||^2 \tag{B.3}$$

for all $0 \leq s < T \leq +\infty$. That is, the form $\pi(\cdot,\cdot)$ is coercive. Then, Theorem 1.1 of [13] implies that the control problem (B.1) has a unique solution which is characterized by the equation

$$(\Phi^*_{s,T}R\Phi_{s,T} - \mathcal{I})\zeta^s_T = -\Phi^*_{s,T}Rx_{s,h},$$

where $x_{s,h}(\cdot)$ is the solution to (13), with the initial condition $x(s) = h$, and $\mathcal{I}$ denotes the identity operator. From (B.3), operators $R^{1/2}\Phi_{s,T}$ and $(\mathcal{I} - \Phi^*_{s,T}R\Phi_{s,T})^{-1}$ are uniformly bounded. Hence, conditions (20) are satisfied. This establishes the second part of claim (a) of Lemma 1.

As in Theorem 6.1 of [2], one can prove that the above facts imply the existence of a unique nonnegative definite solution to the Riccati equation (22). As in [2], we need the following claim.

Claim 1. *Let a symmetric nonnegative matrix $\hat{X}$ be given such that $I - P_2^*\hat{X}P_2 \geq \lambda I$, $\|(I - P_2^*\hat{X}P_2)^{-1}\| \leq 1/\lambda$. For any $\tilde{X}$ such that $\|\tilde{X} - \hat{X}\| \leq \lambda/(2\|P_2\|^2_Q)$, the matrix $I - P_2^*\tilde{X}P_2$ is positive definite and hence is boundedly invertible, and $\|(I - P_2^*\tilde{X}P_2)^{-1}\| \leq 2/\lambda$.*

Proof. The proof of this claim follows from the same arguments as those used in proving the corresponding fact in [2]. □

Let $\alpha > 0$ be a given constant. Consider a constant $\lambda > 0$ and a matrix-valued function $\mathcal{P}(t)$, $t \in [T-\alpha, T]$ such that $0 \leq \mathcal{P}(t) = \mathcal{P}'(t)$, $I - P_2^*\mathcal{P}(t)P_2 \geq \lambda I$ and hence $\sup_t \|(I - P_2^*\mathcal{P}(t)P_2)^{-1}\| \leq 1/\lambda$. As in [2], let us also consider the set of matrix-valued functions

$$\kappa^\alpha_{\mathcal{P}} = \left\{ \tilde{X}(t), t \in [T-\alpha, T]\colon \|\tilde{X} - \mathcal{P}\| \leq \frac{\lambda}{2\|P_2\|^2_Q} \right\}.$$

We define the distance on $\kappa^\alpha_{\mathcal{P}}$ by $\rho(\hat{X}, \tilde{X}) = \sup_{t\in[T-\alpha,T]} \|\tilde{X}(t) - \hat{X}(t)\|$. With this distance, the set $\kappa^\alpha_{\mathcal{P}}$ becomes a closed subset of the Banach space of continuous bounded matrix-valued functions. Let the mapping $\varphi(\cdot)$ be defined as follows:

$$\varphi(Z) \colon = A'Z + ZA + R + H^*ZH + ZB_2(I - P_2^*ZP_2)^{-1}B_2'Z.$$

It follows from Claim 1 that this mapping is well-defined on $\kappa^\alpha_{\mathcal{P}}$. Moreover, since $\mathcal{P}$ has been chosen as described above, it can be proved that the mapping

$$\mathcal{Q}(\tilde{X}(\cdot))(t) \colon = \mathcal{P} + \int_t^T \varphi(\tilde{X}(\theta))d\theta, \qquad \forall\ \tilde{X} \in \kappa^\alpha_{\mathcal{P}},$$

is a contraction on $\kappa^\alpha_{\mathcal{P}}$, provided α is chosen sufficiently small. The reader is referred to [2, Theorem 6.1] for details.

Let $\mathcal{P}(\cdot) = 0$. This choice agrees with the above conditions on the function $\mathcal{P}(\cdot)$. The choice of the constant λ is obvious. From the contraction mapping theorem, the contraction $\mathcal{Q}$ has a unique fixed point in $\kappa^{\alpha}_{\mathcal{P}\equiv 0}$. Denoting this point $X_{2T}(\cdot)$, we observe that $X_{2T}(\cdot)$ satisfies (22) on $[T-\alpha, T]$, and also from Claim 1 for a certain $\lambda_1 > 0$, $I - P_2^* X_{2T} P_2 \geq \lambda_1 I$ and hence is boundedly invertible. As in Lemma 2.2 of [11], this fact implies that

$$\sup_{\zeta \in L_2(s,T,\mathbf{R}^{m_2})} \Im_T^{s,h}(0,\zeta) = E\langle h, X_{2T}(s)h\rangle$$

for any $s \in [T-\alpha, T]$. Also, we see from the above equation that $0 \leq X_{2T}(s) \leq X_2$, and consequently, the operator X_{2T} is uniformly bounded on $[T-\alpha, T]$. Furthermore, it is straightforward to verify, using (22), that the unique optimal control is expressed in the feedback form

$$\xi^s_{2T}(t) = (I - P_2^* X_{2T}(t) P_2)^{-1} B_2' X_{2T} x^s_{2T}(t).$$

Claim (c) of Lemma 1 now follows by iterating the above procedure a finite number of steps, with $\mathcal{P}(t) \equiv X_{2T}(T-(i-1)\alpha)$ at the ith step.

To prove claim (d) of Lemma 1, we note that one can prove in a standard fashion that $X_{2T}(s)$ is monotone increasing in T. Hence, for all $s \geq 0$ there exists a matrix $\bar{X}_2(s) = \lim_{T\to\infty} X_{2T}(s)$. Hence $0 \leq \bar{X}_2(s) \leq X_2 \ \forall \ s \geq 0$. Consequently, $I - P_2^* \bar{X}_2(s) P_2 \geq 0$. Also, letting T approach ∞ in (22), it follows that $\bar{X}_2(s)$ satisfies this equation for all $s \in [0,\infty)$ such that $I - P_2^* \bar{X}_2(s) P_2$ is nonsingular. For all $s \in [0,\infty)$ such that $I - P_2^* \bar{X}_2(s) P_2$ is singular, we must have that either $\frac{d}{ds}\bar{X}_2(s) = \infty$ or $\bar{X}_2(s)$ is not differentiable.

On the other hand, from the second part of claim (a) of Lemma 1, it follows that

$$\Im_T^{s,h}(0, \xi_2^s(\cdot)) \leq \mathbf{E}\langle h, X_{2T}(s)h\rangle.$$

Letting T approach ∞, it follows from this inequality and (19), (21) that

$$\Im^{s,h}(0,\xi_2^s(\cdot)) \leq \mathbf{E}\langle h, \bar{X}_2(s)h\rangle \leq \mathbf{E}\langle h, X_2 h\rangle = \Im^{s,h}(0,\xi_2^s(\cdot)).$$

Hence, $\bar{X}_2(s) = X_2$, and $\frac{d}{ds}\bar{X}_2(s) = 0 \ \forall \ s \in [0,\infty)$. This implies that the matrix $I - P_2^* X_2 P_2$ is nonsingular. That is, condition (26) is satisfied.

Appendix C. Proof of Theorem 1. Note, that condition (28) of Theorem 1 implies that

$$\Im^{0,0}(u,0) \geq \varepsilon_1 \|u(t)\|_2^2 \qquad \forall \ u \in L_2([0,+\infty)\times\Omega; R^{m_1}). \tag{C.1}$$

Conditions (C.1) and (18) are convexity-concavity conditions which guarantee the existence of a unique minimax pair for the cost function (15) on $L_2(s,\mathbf{R}^{m_1}) \times L_2(s,\mathbf{R}^{m_2})$; see [1]. Let $u^s = u^s(h)$, $\xi^s = \xi^s(h)$ denote this saddle point.

The proof of the existence of an operator X satisfying (30) follows the lines of the corresponding result of linear-quadratic stochastic control [4, 5]. As in [4, 5], it can be shown that there exists a self-adjoint operator $\mathcal{X}_s \in \mathcal{L}(L_2^s, L_2^s)$ such that for all $h \in L_2^s$, $V = E\langle h, \mathcal{X}_s h\rangle$. By the Lebesgue–Nikodým theorem [31], it then follows that there exists a weakly measurable mapping $X_s = X_s(\omega)\colon \Omega \to R^{n\times n}$ such that

$$\langle g(\omega), X_s(\omega)h(\omega)\rangle = \langle g(\omega), (\mathcal{X}_s h)(\omega)\rangle \qquad \text{almost surely (a.s.)}$$

for all $h, g \in L_2^s$. Next, we establish that $X_s(\omega) = X_0(\Gamma_s\omega)$ a.s. where $\{\Gamma_s, s \geq 0\}$ is a translation semigroup generated by the Wiener process $(w_1(t), w_2(t))$ (see [6] and Appendix A). Since X_0 is weakly $\mathcal{F}_0$-measurable, then this operator is weakly invariant with respect to Γ_s. This leads to the existence of X satisfying (30).

The proof of the claim that the operator X satisfying (30) also satisfies (29) follows the same arguments as those used in proving Theorem 3.4 of [11]. This proof is based on certain facts of linear-quadratic stochastic control concerning the existence of nonnegative definite solutions to the generalized Riccati equation

$$\text{(C.2)}\quad \begin{aligned} &\frac{dX_{1T}}{dt} + A'X_{1T} + X_{1T}A + H^*X_{1T}H + R - (X_{1T}B_1 + H^*X_{1T}P_1 + Q) \\ &\qquad\qquad \times (G + P_1^*X_{1T}P_1)^{-1}(X_{1T}B_1 + H^*X_{1T}P_1 + Q)' = 0, \\ &X_{1T}(T) = 0, \end{aligned}$$

and the Riccati equation (22). Note that under the conditions of the theorem, the existence of a nonnegative definite solution to (22) is guaranteed by Lemma 1.

Equation (C.2) is a Riccati differential equation corresponding to the following standard stochastic control problem

$$\text{(C.3)}\quad \inf_{u\in L_2([s,T]\times\Omega;R^{m_1})} \Im_T^{s,h}(u,0).$$

For the particular case $Q = 0$, the solution to the control problem (C.3) can be found, e.g., in references [2, 27]. Note that under condition (28) of the theorem, the results of [2] are readily extended to the case $Q \neq 0$. The extension of Theorem 6.1 of [2] to the case $Q \neq 0$ implies that there exists a unique symmetric nonnegative definite bounded solution $X_{1T}(t)$ to (C.2) and that the feedback law $u_{1T} = -(G + P_1^*X_{1T}P_1)^{-1}(B_1'X_{1T} + P_1^*X_{1T}H + Q')x$ solves the control problem (C.3).

Now let us consider the stochastic differential game associated with (1) and the cost functional (16):

$$\text{(C.4)}\quad \inf_{u(\cdot)\in L_2(s,T,\mathbf{R}^{m_1})} \sup_{\xi\in L_2(s,T,\mathbf{R}^{m_2})} \Im_T^{s,h}(u,\xi).$$

Under conditions (28), (18), stochastic counterparts to Theorems 3.1 and 3.2 of [11] can be established.

Claim 2. *If conditions* (28), (18) *are satisfied, then the game problem* (C.4) *has a unique saddle point* (u_T, ξ_T). *Furthermore, there exists a unique nonnegative definite solution to the Riccati equation*

$$\text{(C.5)}\quad \begin{aligned} &\frac{dX_T(s)}{ds} + A'X_T + X_TA + H^*X_TH + R - (X_TB_1 + H^*X_TP_1 + Q) \\ &\qquad\qquad \times (G + P_1^*X_TP_1)^{-1}(X_TB_1 + H^*X_TP_1 + Q)' \\ &\qquad\qquad + X_TB_2(I - P_2^*X_TP_2)^{-1}B_2'X_T = 0, \\ &X_T(T) = 0, \end{aligned}$$

and the saddle point of the game (C.4) *is characterized by the feedback law*

$$\text{(C.6)}\quad u_T = F_{1T}x, \quad F_{1T} := -(G + P_1^*X_TP_1)^{-1}(B_1'X_T + P_1^*X_TH + Q'),$$

$$\text{(C.7)}\quad \xi_T = F_{2T}x, \quad F_{2T} := (I - P_2^*X_TP_2)^{-1}B_2'X_T.$$

Proof of Claim 2. The existence of a unique saddle point follows from the same concavity-convexity arguments as those used above and can be proved using the result of [1].

Suppose that a solution X_T to (C.5) exists on the interval $[T-\alpha, T]$. Let $s \in [T-\alpha, T]$ be given. Then, applying the Ito formula to the quadratic form $x(t)'X_T(t)x(t)$, where $x(t)$ satisfies (1), we obtain

$$\begin{aligned}\Im_T^{s,h}(u,\xi) = \mathbf{E}h'X_T(s)h + \mathbf{E}\int_s^T \|(G+P_1^*X_TP_1)^{1/2}\,(u(t)-F_{1T}x(t))\,\|^2dt \\ -\mathbf{E}\int_s^T \|(I-P_2^*X_TP_2)^{1/2}\,(\xi(t)-F_{2T}x(t))\,\|^2dt,\end{aligned}$$

where the matrices F_{1T} and F_{2T} are defined by (C.6), (C.7). Hence, we conclude that the pair (C.6), (C.7) satisfies the saddle point condition:

$$\Im_T^{s,h}(u_T,\xi) \le \Im_T^{s,h}(u_T,\xi_T) = \mathbf{E}h'X_T(s)h \le \Im_T^{s,h}(u,\xi_T). \tag{C.8}$$

It remains to prove that (C.5) has a solution as required. We can prove this claim in the same fashion as Lemma 1 by choosing α sufficiently small. Indeed for any $\mathcal{P}$ chosen as in the proof of Lemma 1, one can consider the closed set $\kappa_{\mathcal{P}}^{\alpha}$. Note that since $G + P_1^*\mathcal{P}P_1 \ge G \ge \bar{\lambda}I$, then $\|(G+P_1^*\mathcal{P}P_1)^{-1}\| \le 1/\bar{\lambda}$. As in Claim 1 (see also [2, Theorem 6.1]), we have that $\|(G+P_1^*\tilde{X}P_1)^{-1}\| \le 2/\bar{\lambda}$ for any $\tilde{X} \in \kappa_{\mathcal{P}}^{\alpha}$. This observation allows us to conclude that the mapping

$$\begin{aligned}\tilde{\varphi}(Z) := A'Z + ZA + R + H^*ZH + ZB_2(I-P_2^*ZP_2)^{-1}B_2'Z \\ -(ZB_1 + H^*ZP_1 + Q)(G+P_1^*ZP_1)^{-1}(B_1'Z + P_1^*ZH + Q')\end{aligned}$$

is well defined on $\kappa_{\mathcal{P}}^{\alpha}$ and that the mapping

$$\tilde{\mathcal{Q}}(\tilde{X}(\cdot))(t) := \mathcal{P} + \int_t^T \tilde{\varphi}(\tilde{X}(\theta))d\theta$$

is a contraction on $\kappa_{\mathcal{P}}^{\alpha}$ provided α is chosen sufficiently small. Then, fixed point arguments lead us to the conclusion that there exists a bounded solution $X_T(t)$ to (C.5) on $[T-\alpha, T]$, and also $I - P_2^*X_T(t)P_2 > 0$. Using (C.8), with this solution we have that $0 \le X_{1T}(s) \le X_T(s) \le X_{2T}(s) \le X_2 \ \forall \ s \in [T-\alpha, T]$. Thus, by partitioning the interval $[0, T]$ into subintervals not longer than α and iterating the above fixed point procedure, we can show the existence of a unique global solution to the Riccati equation (C.5). Since the considered game (C.4) has the unique saddle point and from (C.8), this saddle point is given by (C.6), (C.7). This completes the proof of Claim 2.

The remainder of the proof of Theorem 1 follows using arguments similar to those used in proving Theorem 3.4 in [11]. Consider a pair of inputs (C.6) and (C.7) extended to $[T, +\infty)$ by zero. This pair is again denoted by (u_T, ξ_T). By optimality we have

$$\Im_T^{s,h}(u_T,\xi^s) \le \Im_T^{s,h}(u_T,\xi_T) \le \Im_T^{s,h}(u^s,\xi_T) \le \Im^{s,h}(u^s,\xi^s). \tag{C.9}$$

Also, we have already shown that $X_T(s) \le X_2$. This bound on $X_T(s)$ holds for any $s < T$. On the other hand, it is readily seen that $X_T(s)$ is monotone increasing in T. Hence, for all $s \ge 0$, there exists $\bar{X}(s) = \lim_{T\to\infty} X_T(s)$. Consequently, $\bar{X}(s) \le X_2 \ \forall \ s \ge 0$ and this inequality and inequality (25) from Lemma 1 imply that $I - P_2^* \bar{X}(s) P_2 > 0$. This in turn implies that there exist bounded limits for $F_{1T}(s)$, $F_{2T}(s)$ as $T \to \infty$. Let $\bar{F}_1(s)$ and $\bar{F}_2(s)$ denote these limits, respectively. In the same fashion as in [11], we obtain that for any $T_0 > s$, $x_T(\cdot) \to \bar{x}(\cdot)$ strongly in $C([s, T_0], L_2(\Omega, P, R^n))$, $u_T(\cdot) \to \bar{u}(\cdot) = \bar{F}_1(\cdot)\bar{x}(\cdot)$ strongly in $C([s, T_0], L_2(\Omega, P, R^{m_1}))$, and $\xi_T(\cdot) \to \bar{\xi}(\cdot) = \bar{F}_2(\cdot)\bar{x}(\cdot)$ strongly in $C([s, T_0], L_2(\Omega, P, R^{m_2}))$, where $x_T(\cdot)$ is a solution to (1), driven by the pair u_T, ξ_T, and $\bar{x}(\cdot)$ is a solution to the equation

$$dx = (A + B_1\bar{F}_1(t) + B_2\bar{F}_2(t))xdt + (H + P_1\bar{F}_1(t))xdw_1(t) + P_2\bar{F}_1(t)xdw_2(t), \quad x(s) = h.$$

Also as in [11], it can be proved that the sequences $\{u_T\}$, $\{\xi_T\}$ are bounded in $L_2(s, \mathbf{R}^{m_1})$, $L_2(s, \mathbf{R}^{m_2})$, respectively. Thus, one can extract subsequences denoted again by $\{u_T\}$, $\{\xi_T\}$ such that $(u_T, \xi_T) \to (\tilde{u}, \tilde{\xi}) \in L_2(s, \mathbf{R}^{m_1}) \times L_2(s, \mathbf{R}^{m_2})$ weakly as $T \to \infty$. This leads us to the conclusion that $\bar{u}(\cdot) = \tilde{u}(\cdot)$, $\bar{\xi}(\cdot) = \tilde{\xi}(\cdot)$, which implies that $(\bar{u}, \bar{\xi}) \in L_2(s, \mathbf{R}^{m_1}) \times L_2(s, \mathbf{R}^{m_2})$.

Letting T approach ∞ in (C.9), we obtain

$$\Im^{s,h}(\bar{u}, \xi^s) \leq E\langle h, \bar{X}(s)h\rangle \leq \Im^{s,h}(u^s, \bar{\xi}) \leq \Im^{s,h}(u^s, \xi^s) \leq \Im^{s,h}(\bar{u}, \xi^s).$$

Thus, we have that $E\langle h, \bar{X}(s)h\rangle = \Im^{s,h}(u^s, \xi^s) = E\langle h, Xh\rangle$ and therefore

$$(u^s, \xi^s) = (\bar{u}, \bar{\xi}).$$

That is, the feedback representation of the saddle point holds. To see that the matrix X satisfies (29) one needs to pass to the limit as $T \to \infty$ in (C.5). Also, we see that $X = \lim_{T\to\infty} X_T$ is a minimal solution to (29) and this solution satisfies condition (30). It is clear that the solution satisfying these conditions is unique.

The claim that the system (31) is exponentially mean-square stable follows from the fact that for linear stochastic systems, stochastic L_2-stability is equivalent to stochastic exponential mean-square stability; see, e.g., [10].

Appendix D. Proof of Theorem 2. With the substitution

$$v = u + (D'D)^{-1}D'Cx \tag{D.1}$$

into (1), the stochastic system under consideration becomes

$$\begin{aligned} dx &= (\tilde{A}x(t) + B_1 v(t) + B_2\xi(t))dt + (\tilde{H}x(t) + P_1 v(t))dw_1(t) \\ &\quad + P_2\xi(t)dw_2(t), \\ \tilde{z} &= \tilde{C}x + \tilde{D}v. \end{aligned} \tag{D.2}$$

Here the following notation is used:

$$\begin{aligned} &\tilde{A} = A - B_1(D'D)^{-1}D'C, \qquad \tilde{H} = H - P_1(D'D)^{-1}D'C, \\ &\tilde{C} = \begin{bmatrix} \tilde{R}^{1/2} \\ 0 \end{bmatrix}, \qquad \tilde{D} = \begin{bmatrix} 0 \\ D \end{bmatrix}, \end{aligned} \tag{D.3}$$

and the matrix $\tilde{R}$ is as defined in Assumption 2. Note that if the matrix K is a solution to the stochastic H_∞ problem defined in section 3, then $\tilde{K} = K + (D'D)^{-1}D'C$ solves a corresponding stochastic H_∞ problem associated with the system (D.2), and vice versa. The stochastic H_∞ control problem associated with the system (D.2) is defined in the same fashion as the original H_∞ control problem; i.e., given the system (D.2), find a matrix $\tilde{K} \in R^{m_1 \times n}$ such that the state feedback controller $v = \tilde{K}x$ satisfies the following conditions:

(i$'$) The system

$$dx = (\tilde{A} + B_1\tilde{K})xdt + (\tilde{H} + P_1\tilde{K})xdw_1(t) \tag{D.4}$$

is exponentially stable in the mean-square sense and the matrix $\tilde{A} + B_1\tilde{K}$ is stable.

(ii$'$) The closed-loop system corresponding to system (D.2) with feedback control $v = \tilde{K}x$,

$$dx = [(\tilde{A} + B_1\tilde{K})x(t) + B_2\xi(t)]dt + (\tilde{H} + P_1\tilde{K})x(t)dw_1(t) + P_2\xi(t)dw_2(t), \tag{D.5}$$

satisfies the following stochastic H_∞-norm condition: there exists a constant $\tilde{\varepsilon} > 0$ such that

$$E\int_s^{+\infty} \left(\|(\tilde{C} + \tilde{D}\tilde{K})x(t)\|^2 - \|\xi(t)\|^2\right)dt \le -\tilde{\varepsilon}\mathbf{E}\int_s^{+\infty} \|\xi(t)\|^2 dt \quad \text{for } x(s) = 0 \tag{D.6}$$

for each $\xi \in L_2(s; \mathbf{R}^{m_2})$.

Note that the problem (i$'$), (ii$'$) is simpler than the original problem because we have $\tilde{C}'\tilde{D} = 0$, $\tilde{D}'\tilde{D} = D'D > 0$ in this case. Also by Assumption 2, there exists a matrix N such that the matrix $\tilde{A} - N\tilde{C}$ is a Hurwitz matrix and

$$\|\exp((\tilde{A} - N\tilde{C})t)\| \le ae^{-\alpha t}, \qquad \frac{a^2}{\alpha}\|\tilde{H}\|^2_{Q_1} < 1. \tag{D.7}$$

This observation implies that the system

$$dy = (\tilde{A} - N\tilde{C})ydt + \tilde{H}ydw_1(t), \qquad y(s) = y_0 \in L_2^s, \tag{D.8}$$

is exponentially mean-square stable. In the particular case where $\tilde{H} = 0$, this fact amounts to the pair $(\tilde{C}, \tilde{A})$ being detectable.

First, we solve the problem (i$'$), (ii$'$).

Lemma 5.

(a) *If the stochastic H_∞ state feedback control problem* (i$'$), (ii$'$) *has a solution, then there exists a symmetric nonnegative definite minimal solution X to the generalized algebraic Riccati equation*

$$\begin{aligned} &\tilde{A}'X + X\tilde{A} + \tilde{H}^*X\tilde{H} + \tilde{C}'\tilde{C} \\ &-(XB_1 + \tilde{H}^*XP_1)(\tilde{D}'\tilde{D} + P_1^*XP_1)^{-1}(B_1'X + P_1^*X\tilde{H}) \\ &+XB_2(I - P_2^*XP_2)^{-1}B_2'X = 0, \end{aligned} \tag{D.9}$$

such that $I - P_2^*XP_2 > 0$ and the stochastic system

$$dx = (\tilde{A} + B_1\tilde{F}_1 + B_2\tilde{F}_2)xdt + (H + P_1\tilde{F}_1)xdw_1(t) + P_2\tilde{F}_2xdw_2(t), \tag{D.10}$$

where

$$\begin{aligned} \tilde{F}_1 &= -(\tilde{D}'\tilde{D} + P_1^*XP_1)^{-1}(B_1'X + P_1^*X\tilde{H}), \\ \tilde{F}_2 &= (I - P_2^*XP_2)^{-1}B_2'Xx, \end{aligned} \tag{D.11}$$

is exponentially stable in the mean-square sense. Also,

$$\mathbf{E}\langle h, Xh\rangle \le \sup_{\xi \in L_2(s;\mathbf{R}^{m_2})} E\int_s^{+\infty} \left(\|\tilde{C}x(t) + \tilde{D}\hat{v}(t)\|^2 - \|\xi(t)\|^2\right)dt \tag{D.12}$$

for any state feedback control $\hat{v}(\cdot)$ such that the closed-loop system corresponding to (D.2) *and this control has L_2-summable solutions for all $\xi \in L_2(s; \mathbf{R}^{m_2})$, and the supremum on the left-hand side of* (D.12) *is finite.*

(b) *Conversely, if there exists a symmetric nonnegative definite solution X to* (D.9) *such that $I - P_2^* X P_2 > 0$ and the stochastic system* (D.10) *is exponentially stable, then the stochastic H_∞ state feedback control problem* (i′), (ii′) *has a solution. The corresponding stabilizing feedback controller which solves this stochastic H_∞ problem is given by*

$$\tilde{K} = -(\tilde{D}'\tilde{D} + P_1^* X P_1)^{-1}(B_1' X + P_1^* X \tilde{H}). \tag{D.13}$$

Proof of Lemma 5. We shall use the following notation: $\tilde{A}_K = \tilde{A} + B_1\tilde{K}$, $\tilde{C}_K = \tilde{C} + \tilde{D}\tilde{K}$, $\tilde{H}_K = \tilde{H} + P_1\tilde{K}$.

(b)⇒(a). Let X be a symmetric nonnegative solution to (D.9) such that (D.10) is exponentially mean-square stable. Let $\tilde{K}$ be given by (D.13). We wish to establish that X and $\tilde{K}$ satisfy conditions (i′), (ii′).

Let us prove the stability of the system (D.4). Note that using (D.13), (D.9) can be transformed as follows:

$$\begin{aligned}\tilde{A}_K' X + X\tilde{A}_K + \tilde{H}_K^* X \tilde{H}_K + \tilde{C}'\tilde{C} + \tilde{K}'(\tilde{D}'\tilde{D})\tilde{K}& \\ + X B_2 (I - P_2^* X P_2)^{-1} B_2' X = 0.&\end{aligned} \tag{D.14}$$

This implies that

$$\tilde{A}_K' X + X\tilde{A}_K + \tilde{H}_K^* X \tilde{H}_K + \tilde{C}'\tilde{C} + \tilde{K}'(\tilde{D}'\tilde{D})\tilde{K} \le 0. \tag{D.15}$$

We now proceed as in [10, Lemma 4.6]. Letting $x(t)$ be the solution to (D.4), first we note that from (D.15),

$$\mathbf{E}\int_0^\infty \left(\|\tilde{C}x(t)\|^2 + \|\tilde{D}\tilde{K}x(t)\|^2\right) dt \le \mathbf{E} h' X h < \infty,$$

and hence $\tilde{C}x(\cdot)$ and $\tilde{K}x(\cdot)$ are square integrable (the latter holds since $\tilde{D}'\tilde{D} > 0$). Next, note that $\|\tilde{H} + P_1\tilde{K}\|_{Q_1}^2 \le (1+\nu)\|\tilde{H}\|_{Q_1}^2 + (1+\frac{1}{\nu})\|P_1\tilde{K}\|_{Q_1}^2$ for any $\nu > 0$. From (D.7), ν can be chosen sufficiently small in order to guarantee that

$$\frac{(1+\nu)a^2}{\alpha}\|\tilde{H}\|_{Q_1}^2 < 1. \tag{D.16}$$

This observation allows us to obtain in the same way as in [10, Lemma 4.6] that $\mathbf{E}\|x(t)\|^2 \in L_1[0,\infty)$. This implies that (i′) holds.

We will now prove that condition (ii′) is also satisfied. From (D.14), we have that

$$\begin{aligned}&\mathbf{E}\langle x(t), X x(t)\rangle + \mathbf{E}\int_0^t \{\|\tilde{C}_K x(t)\|^2 - \|\xi\|^2\} dt \\ &\quad = -\mathbf{E}\int_0^t \|(I - P_2^* X P_2)^{1/2}(\xi - (I - P_2^* X P_2)^{-1} B_2' X x)\|^2 dt,\end{aligned} \tag{D.17}$$

where $x(\cdot)$ is the solution to (D.5) corresponding to the initial condition $x(0) = 0$.

Note, that the substitution $\xi = \zeta + (I - P_2^* X P_2)^{-1} B_2' X x$ into (D.5) leads to the following equation:

$$\begin{aligned} dx &= ((\tilde{A}_K + B_2(I - P_2^* X P_2)^{-1} B_2' X)x + B_2\zeta(t))dt + \tilde{H}_K x dw_1(t) \\ &\qquad + P_2(\zeta + (I - P_2^* X P_2)^{-1} B_2' X x) dw_2, \\ x(0) &= 0. \end{aligned} \tag{D.18}$$

In particular, the input $\zeta(t) = 0$ corresponds to the stable system (D.10). This implies (see, e.g., [3] and also Lemma 4 in Appendix A) that solutions of (D.18) satisfy the condition $|||x||| \le c_0|||\zeta|||$, where $c_0 > 0$ is a constant independent of ζ. That is, the mapping $\zeta(\cdot) \to x(\cdot)$ and, consequently, the mapping $\zeta(\cdot) \to \xi(\cdot) = \zeta(\cdot) + (I - P_2XP_2)^{-1}B_2'Xx(\cdot)$ generated by (D.18) are bounded mappings $L_2(0;\mathbf{R}^{m_2}) \to L_2(0;\mathbf{R}^n)$, $L_2(0;\mathbf{R}^{m_2}) \to L_2(0;\mathbf{R}^{m_2})$, respectively. Thus, there exists a constant $c > 0$ such that

$$|||\xi(\cdot)||| \le c|||\zeta(\cdot)||| \quad \forall\, \zeta \in L_2(0;\mathbf{R}^{m_2}).$$

Note that the restriction of any solution of (D.18) to an interval $[0,t]$ is equal to the restriction of a corresponding solution of (D.5). Since $X \ge 0$ and $I - P_2^*XP_2 > 0$, then (D.17) implies that

$$\mathbf{E}\int_0^\infty \{\|(\tilde{C} + \tilde{D}\tilde{K})x(t)\|^2 - \|\xi\|^2\}dt \le -\epsilon\mathbf{E}\int_0^\infty \|\zeta\|^2dt \le -\frac{\epsilon}{c^2}\mathbf{E}\int_0^\infty \|\xi\|^2dt.$$

(a)⇒(b). Given a matrix $\tilde{K}$ satisfying conditions (i′) and (ii′), we wish to prove that there exists a solution to (D.9) stabilizing the system (D.10).

Let $\delta \in (0, \bar{\delta}]$ be a given constant. Consider the stochastic differential game of the form (17) associated with the system

$$\text{(D.19)} \qquad \begin{aligned} &dx = (\tilde{A}_Kx + B_1v + B_2\xi)dt + (\tilde{H}_Kx + P_1v)dw_1(t) + P_2\xi dw_2(t),\\ &\tilde{z} = \tilde{C}_Kx + \tilde{D}v \end{aligned}$$

and cost functional

$$\text{(D.20)} \qquad \Im_\delta^{s,h}(v,\xi) = \int_s^{+\infty} \mathbf{E}\left\{\|\tilde{C}_Kx(t) + \tilde{D}v(t)\|^2 + \delta\|v(t)\|^2 - \|\xi(t)\|^2\right\}dt.$$

By the condition (i′), (D.4) is stable, and hence the system (D.19) satisfies Assumption 1. Also, it follows from (ii′) that the system (D.5) satisfies condition (18) of Lemma 1 and Theorem 1 with $\varepsilon_2 = \tilde{\varepsilon}$. In particular, Lemma 1 defines a matrix X_2 such that $I - P_2^*X_2P_2 > 0$. Note that this matrix is independent of δ.

Condition (28) of Theorem 1 is also satisfied with $\varepsilon_1 = \delta$. It follows from this theorem that for each $\delta \in (0, \bar{\delta}]$, the equation

$$\text{(D.21)} \qquad \begin{aligned} \tilde{A}_K'X + X\tilde{A}_K + \tilde{H}_K^*X\tilde{H}_K + \tilde{C}_K\tilde{C}_K &- (XB_1 + \tilde{H}_K^*XP_1 + \tilde{C}_K'\tilde{D})\\ &\times (\tilde{D}'\tilde{D} + \delta I + P_1^*XP_1)^{-1}(B_1'X + P_1^*X\tilde{H}_K + \tilde{D}'\tilde{C}_K)\\ &+ XB_2(I - P_2^*XP_2)^{-1}B_2'X = 0 \end{aligned}$$

has a symmetric nonnegative definite minimal solution X^δ such that the system

$$\text{(D.22)} \qquad \begin{aligned} dx = (\tilde{A}_K + B_1F_{1,\delta} + B_2F_{2,\delta})xdt &+ (\tilde{H}_K + P_1F_{1,\delta})xdw_1(t)\\ &+P_2F_{2,\delta}xdw_2(t) \end{aligned}$$

is exponentially mean-square stable. In (D.22),

$$\begin{aligned} &F_{1,\delta} = -(\tilde{D}'\tilde{D} + \delta I + P_1^*X^\delta P_1)^{-1}(B_1'X^\delta + P_1^*X^\delta\tilde{H}_K + \tilde{C}_K'\tilde{D}),\\ &F_{2,\delta} = (I - P_2^*X^\delta P_2)^{-1}B_2'X^\delta. \end{aligned}$$

As we have shown when proving Theorem 1, $X^\delta \le X_2$ and hence $I - P_2^*X^\delta P_2 > 0$.

As in reference [11, Theorem 4.2], it follows that there exists a matrix $X{:}=\lim_{\delta\downarrow 0} X^\delta$, $X=X'\geq 0$ which satisfies (D.9). To verify this fact, one must take into account the fact that $\tilde{C}'\tilde{D}=0$. Also, we note that since X_2 is independent of δ, $X\leq X_2$ and hence $I-P_2^*XP_2>0$. Next, letting $\delta\downarrow 0$ in (D.21), we obtain that the above defined matrix X satisfies (D.9). Also, there exist the limits

$$\begin{aligned}F_{1,K}&=\lim_{\delta\downarrow 0}F_{1,\delta}=-\tilde{K}-(\tilde{D}'\tilde{D}+P_1^*XP_1)^{-1}(B_1'X+P_1'X\tilde{H})=\tilde{F}_1-\tilde{K},\\ F_{2,K}&=\lim_{\delta\downarrow 0}F_{2,\delta}=(I-P_2^*XP_2)^{-1}B_2'X=\tilde{F}_2.\end{aligned}$$

Note that X is defined as the limit of a sequence of minimal solutions, hence it represents the minimal solution to (D.9).

We now show that the system (D.10) is exponentially mean-square stable. Consider solutions $x_\delta(\cdot)$ and $x(\cdot)$ to (D.22) and (D.10), respectively, that correspond to the initial condition $x_\delta(s)=x(s)=h$. Note that

$$\text{(D.23)}\qquad \begin{aligned}0\leq \Im_\delta^{s,h}(F_{1,\delta}x_\delta,0)\leq \mathbf{E}h'X^\delta h&=\Im_\delta^{s,h}(F_{1,\delta}x_\delta,F_{2,\delta}x_\delta)\\ &\leq \Im^{s,h}(0,F_{2,\delta}x_\delta)\leq \mathbf{E}h'X_2h,\end{aligned}$$

where the matrix X_2 has been defined above. Hence, $F_{2,\delta}x_\delta(\cdot)$ is bounded. This fact is established in the same fashion as that in the proof of Theorem 1. Furthermore, from (D.23), $\Im_\delta^{s,h}(F_{1,\delta}x_\delta,F_{2,\delta}x_\delta)$ is bounded. Since $F_{2,\delta}x_\delta(\cdot)$ is bounded, this then implies that $\tilde{C}x_\delta(\cdot)$ and $(\tilde{K}+F_{1,\delta})x_\delta(\cdot)$ are bounded in the corresponding space $L_2[s,\infty)$. Again, we have used the fact that $\tilde{C}'\tilde{D}=0$ and $\tilde{D}'\tilde{D}>0$ to reach this conclusion. Hence, one can extract subsequences which have weak limit points in corresponding L_2-spaces. These limits are L_2-summable functions on $[s,+\infty)\times\Omega$. Also, as in the proof of Theorem 1, for any $T_0>s$, $x_\delta(\cdot)\to x(\cdot)$ in $C([s,T_0];L_2(\Omega,P,R^n))$. Therefore, for any $T_0>s$, the restrictions of the functions $\tilde{C}x(\cdot)$, $(\tilde{K}+F_{1,K})x(\cdot)=\tilde{F}_1x(\cdot)$, and $\tilde{F}_2x(\cdot)$ to the interval $[s,T_0]$ are equal to restrictions of the corresponding weak limit points. Hence $\tilde{C}x(\cdot)$, $\tilde{F}_1x(\cdot)$, $\tilde{F}_2x(\cdot)$ are square-integrable functions on $[s,+\infty)\times\Omega$.

Let us rewrite (D.10) in the following form:

$$\begin{aligned}dx=((\tilde{A}-N\tilde{C})x+B_1\tilde{F}_1x(t)+B_2\tilde{F}_2x(t)+N\tilde{C}x(t))dt+(\tilde{H}+P_1\tilde{F}_1)xdw_1(t)\\ +P_2\tilde{F}_2xdw_2(t),\end{aligned}$$

where N is the matrix defined in Assumption 2. Since (D.8) is stable and inputs $\tilde{F}_1x(\cdot)$, $\tilde{F}_2x(\cdot)$, and $\tilde{C}x(\cdot)$ are square integrable on $[s,\infty)\times\Omega$, then $x(\cdot)\in L_2(s;\mathbf{R}^n)$. Hence, (D.10) is exponentially mean-square stable.

To see that (D.12) holds, let us consider the finite horizon version of the functional (D.20):

$$\Im_{\delta,T}^{s,h}(v,\xi)=\int_s^T\mathbf{E}\left\{\|\tilde{C}_Kx(t)+\tilde{D}v(t)\|^2+\delta\|v(t)\|^2-\|\xi(t)\|^2\right\}dt,$$

with $v\in L_2(s,T;\mathbf{R}^{m_1})$, $\xi\in L_2(s,T;\mathbf{R}^{m_2})$. As in the infinite horizon case, we obtain from Claim 2 (cf. [11, Theorem 4.1]), that there exists a matrix $X_T=\lim_{\delta\downarrow 0}X_T^\delta$, satisfying the matrix Riccati equation

$$\text{(D.24)}\qquad \frac{dX_T(s)}{ds}+\tilde{A}_K'X_T+X_T\tilde{A}_K+\tilde{H}_K^*X_T\tilde{H}_K+\tilde{C}_K'\tilde{C}_K$$

$$\begin{aligned}
&\quad - (X_T B_1 + \tilde{H}_K^* X_T P_1 + \tilde{C}_K' \tilde{D})(\tilde{D}'\tilde{D} + P_1^* X_T P_1)^{-1} \\
&\quad \times (X_T B_1 + \tilde{H}_K^* X_T P_1 + \tilde{C}_K' \tilde{D})' \\
&\quad + X_T B_2 (I - P_2^* X_T P_2)^{-1} B_2' X_T = 0, \\
&X_T(T) = 0.
\end{aligned}$$

Let $\hat{v}(\cdot)$ be any state feedback controller such that the closed-loop system obtained from (D.2) has L_2-summable trajectories for all L_2-summable uncertainty inputs. Then, the corresponding closed-loop system obtained from (D.19), with state feedback $v(\cdot) = \hat{v}(\cdot) - \tilde{K}x$ has also L_2-summable trajectories for all L_2-summable uncertainty inputs. Hence, if $\xi \in L_2(s, T; \mathbf{R}^{m_2})$ and $\tilde{\xi}(\cdot)$ denotes its extension to the interval $[T, \infty)$ by zero, then (D.24) implies

$$\begin{aligned}
\mathbf{E}\langle h, X_T(s)h\rangle &\leq \sup_{\xi \in L_2(s,T;\mathbf{R}^{m_2})} \int_s^T \mathbf{E}\left\{\|\tilde{C}_K x(t) + \tilde{D}v(t)\|^2 - \|\xi(t)\|^2\right\} dt \\
&\leq \sup_{\xi \in L_2(s,T;\mathbf{R}^{m_2})} \int_s^\infty \mathbf{E}\left\{\|\tilde{C}_K x(t) + \tilde{D}v(t)\|^2 - \|\tilde{\xi}(t)\|^2\right\} dt \\
&\leq \sup_{\xi \in L_2(s;\mathbf{R}^{m_2})} \int_s^\infty \mathbf{E}\left\{\|\tilde{C}_K x(t) + \tilde{D}v(t)\|^2 - \|\xi(t)\|^2\right\} dt \\
&= \sup_{\xi \in L_2(s;\mathbf{R}^{m_2})} \int_s^\infty \mathbf{E}\left\{\|\tilde{C} x(t) + \tilde{D}\hat{v}(t)\|^2 - \|\xi(t)\|^2\right\} dt.
\end{aligned}$$

Also, note that $X_T \to X$ as $T \to \infty$, since X is a minimal solution. Thus, (D.12) holds. □

We now are in a position to finish the proof of Theorem 2. One can observe that letting

$$K = \tilde{K} - (D'D)^{-1} D'C$$

and using the notation (D.3), (D.9) and (D.10) are transformed into (37) and (38), respectively, and the feedback matrix (D.13) is transformed into the matrix (39). Hence the theorem follows from Lemma 5. □

CONTROL OF THE STOCHASTIC BURGERS MODEL OF TURBULENCE*

GIUSEPPE DA PRATO[†] AND ARNAUD DEBUSSCHE[‡]

Abstract. We consider a control problem for a stochastic Burgers equation. This problem is motivated by a model from the control of Turbulence (see [Choi et al., *J. Fluid Mech.*, 253 (1993), pp. 509–543]). We study a sequence of approximated Hamilton–Jacobi equations by using dynamic programming.

Key words. stochastic Burgers equations, turbulence, Hamilton–Jacobi equations, dynamic programming

1. Introduction.

It has been shown in [3] that the stochastic Burgers equation is a good and simple model with which to study turbulence phenomena. The mathematical study of this equation has been the object of several papers [2], [9], [10], [17], [21].

This model also has been used in [6] to test a numerical algorithm for reducing the cost function in the very important problem of the control of turbulence.

In this paper we consider the stochastic Burgers equation with distributed parameter controls. The cost function has the same form as in [6] and contains the analogue of the kinetic energy. The problem is as follows: minimize

$$J(z) = \mathbb{E}\left(\int_0^T \left[\left|\frac{\partial X}{\partial \xi}\right|^2_{L^2(0,1)} + \frac{1}{2}\ |z(s)|^2_{L^2(0,1)}\right] ds + \frac{1}{2}\ |X(T)|^2_{L^2(0,1)}\right),$$

where the control z is in $L^2(\Omega \times [0,T] \times [0,1])$, and $X(t,\xi),\ \xi \in [0,1],\ t \in [0,T]$, is the solution of the controlled Burgers equation

$$\left\{\begin{array}{l} dX = \left(\dfrac{\partial^2 X}{\partial \xi^2} + \dfrac{\partial}{\partial \xi}(X^2)\right) dt + \sqrt{Q} z dt + \sqrt{Q} dW,\ \xi \in [0,1],\ t \geq 0, \\ X(t,0) = X(t,1) = 0,\ t \geq 0, \\ X(0,\xi) = x(\xi),\ \xi \in [0,1], \end{array}\right. \tag{1.1}$$

where $x \in L^2(0,1)$.

Here W is a cylindrical Wiener process on $L^2(0,1)$ (in other words $\frac{dW}{dt}$ is the "space–time white noise") and is adapted to a stochastic basis $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}_{t\geq 0}, \mathbb{P})$ (of course the control z has to be adapted to the filtration $\{\mathcal{F}_t\}_{t\geq 0}$). Moreover Q is a symmetric linear operator on $L^2(0,1)$. In (1.1) the operator $\sqrt{Q}$ acts both on the noise and on the control. This is essential in our work: it enables us to use a Hopf

transform on the Hamilton–Jacobi equation (see below). This might be a restriction in the applications. However, this assumption is not artificial. It can be interpreted as a control acting on the solution in the same way as the noise or as a noise acting on the control.

It is easy to see that the cost functional J cannot have finite values unless Q is a nuclear operator. This is a simple consequence of the Ito formula.

In this paper we study this control problem following the dynamic programming approach. We solve the associated Hamilton–Jacobi equation and prove that it has a solution that coincides with the value function. More precisely, let A be the unbounded operator on $L^2(0,1)$ defined by

$$Ax = \frac{\partial^2 x}{\partial \xi^2},\ D(A) = H^2(0,1) \cap H_0^1(0,1),$$

and F, g are the nonlinear functions:

$$F(x) = \frac{\partial (x^2)}{\partial \xi},\quad g(x) = \left| \frac{\partial x}{\partial \xi} \right|^2_{L^2(0,1)}.$$

Then we can associate our control problem with the Hamilton–Jacobi equation

$$\left\{ \begin{aligned} u_t(t,x) &= \frac{1}{2}\ \mathrm{Tr}\ [Qu_{xx}(t,x)] + (Ax + F(x), u_x(t,x)) \\ &\quad - \frac{1}{2}\ |\sqrt{Q}\ u_x(t,x)|^2 + g(x), \\ u(0,x) &= \frac{1}{2}\ |x|^2_{L^2(0,1)} \end{aligned} \right. \tag{1.2}$$

for $x \in L^2(0,1)$, $t \in [0,T]$.

We prove below that there exists a solution u and that

$$u(T,x) = \inf_z J(z). \tag{1.3}$$

Moreover, for each control z and its associated solution X of (1.1), the fundamental identity holds:

$$u(T,x) + \frac{1}{2}\mathbb{E} \int_0^T |\sqrt{Q}\ u_x(T-s, X(s,x)) + z(s)|^2_{L^2(0,1)} ds = J(z). \tag{1.4}$$

We prove that the *closed loop equation*

$$\left\{ \begin{array}{l} dX^* = \left(\dfrac{\partial^2 X^*}{\partial \xi^2} + \dfrac{\partial}{\partial \xi}(X^{*2}) - Qu_x(T-t, X^*(t)) \right) dt + \sqrt{Q}\ dW, \\ X^*(t,0) = X^*(t,1) = 0,\ t \geq 0, \\ X^*(0,\xi) = x(\xi),\ \xi \in [0,1] \end{array} \right. \tag{1.5}$$

has a unique solution. It follows that there exists a unique optimal control given by

$$z^*(t) = -\sqrt{Q}\ u_x(T-t, X^*(t)). \tag{1.6}$$

To prove the existence of a solution to the Hamilton–Jacobi equation (1.2) we use a Hopf transform

$$u = -\ln v.$$

The function v satisfies

$$v_t(t,x) = \frac{1}{2}\,\mathrm{Tr}\,[Qv_{xx}(t,x)] + (Ax + F(x), v_x(t,x)) - g(x)v \tag{1.7}$$

so that using the Feynmann–Kac formula we have an explicit representation for u,

$$u(t,x) = -\ln \mathbb{E}\left(\exp\left[-\frac{1}{2}\,|Y(t)|^2_{L^2(0,1)} - \int_0^t g(Y(s))ds\right]\right), \tag{1.8}$$

where Y is the solution to the uncontrolled equation

$$\begin{cases} dY = \left(\dfrac{\partial^2 Y}{\partial \xi^2} + \dfrac{\partial}{\partial \xi}(Y^2)\right)dt + \sqrt{Q}dW,\ \xi \in [0,1],\ t \geq 0, \\ Y(t,0) = Y(t,1) = 0,\ t \geq 0, \\ Y(0,\xi) = x(\xi),\ \xi \in [0,1]. \end{cases} \tag{1.9}$$

The study of second-order Hamilton–Jacobi equations has been the object of several articles. Existence and uniqueness in finite and infinite dimensions have been obtained using semigroups methods (see [1], [8], [4], [5], [13], [14], [15]) and also using the concept of viscosity solution (see [7], [12], [19], [20], [16]). However, these results do not cover our case. Indeed here we simultaneousy have a non-Lipschitz Hamiltonian $H(u) = \frac{1}{2}\,|\sqrt{Q}\,u_x|^2$, a singular term in the cost functional $g(x) = \frac{1}{2}\,|\frac{\partial}{\partial\xi}X|^2_{L^2(0,1)}$, and the nonlinear term $f(x) = \frac{\partial}{\partial\xi}(X^2)$ coming from the Burgers equation.

All the formula described above can be derived formally; we use an approximation technique to justify them. We consider an approximate problem which is finite dimensional by using a Galerkin approximation and in which g and f are replaced by bounded and Lipschitz functions. We obtain a control problem which we can solve easily and a sequence $\{u^m\}$ of approximations of the solution to (1.2). We derive several a priori estimates and prove convergence of the approximation. The main difficulty is that we are not able to obtain an a priori estimate in the space of C^1 bounded functions on u^m. We have only the estimates

$$|u^m(t,x)| \leq \frac{1}{2}\,\left(|x|^2_{L^2(0,1)} + \ \mathrm{Tr}\ tQ\right),$$
$$|u^m_x(t,x)| \leq Ce^{\frac{1}{2}\,(|x|^2_{L^2(0,1)} + \ \mathrm{Tr}\ tQ)}$$

and a similar estimate on $u^m_{xx}(t)$.

However, we are able to prove that u^m converges to a C^2 function u which is a solution of (1.2), that the formulas (1.1) and (1.3) hold, and that the closed loop equation (1.5) has a unique solution. Thus the original control problem is completely solved.

2. Preliminaries and main results.

Let $H = L^2(0,1)$ endowed with the usual norm and inner product denoted by $|\cdot|$ and $(\cdot,\cdot)$. We define a linear operator A in H by setting

$$Ax = \frac{\partial^2 x}{\partial \xi^2},\ x \in D(A) = H^2(0,1) \cap H^1_0(0,1).$$

As usual, $H^k(0,1),\ k \in \mathbb{N}$, is the Sobolev space of all functions in H whose derivatives up to the order k belong to H, and $H_0^1(0,1)$ is the subspace of $H^1(0,1)$ of all functions whose traces at 0 and 1 vanish.

The operator A is self-adjoint and strictly negative and has a compact inverse. We can define $(-A)^s$ and $D((-A)^s)$ for any $s \in \mathbb{R}$. For $s = \frac{1}{2}$, we have $D((-A)^{1/2}) = H_0^1(0,1)$ and its norm and inner product are denoted by

$$\|x\| = |(-A)^{1/2}x|,\ ((x,y)) = \left((-A)^{1/2}x, (-A)^{1/2}y\right),\ x,y \in H_0^1(0,1).$$

The sequence of eigenvalues of A is

$$\lambda_k = -k^2\pi^2,\ k \in \mathbb{N},$$

and it is associated with the orthonormal basis of eigenvectors $\{e_k\}_{k\in\mathbb{N}}$,

$$e_k = \sqrt{2/\pi}\ \sin k\xi,\ k \in \mathbb{N},\ \xi \in [0,1].$$

For any positive integer m we denote by P_m the orthogonal projector on the space spanned by $e_1, \dots, e_m$.

We also consider a linear operator Q which is assumed to be symmetric, nonnegative, and of trace class; and a cylindrical Wiener process W on H associated with a stochastic basis $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}_{t\geq 0}, \mathbb{P})$. (The reader is referred to [11] for precise definitions.) Let $L_W^2(\Omega \times [0,T]; H)$ be the space of all square integrable and adapted processes with values in $L^2(0,T;H)$. For $x \in H_0^1(0,1)$ we set

$$F(x) = \frac{\partial}{\partial \xi}(x^2).$$

The control problem we want to study is

$$\tag{2.1} \left\{ \begin{array}{l} \text{Minimize} \\ J(z) = \mathbb{E}\left(\displaystyle\int_0^T \left(\|X(t)\|^2 + \frac{1}{2}\,|z(t)|^2\right) dt + \frac{1}{2}\,|X(T)|^2\right) \\ \text{over all}\ \ z \in L_W^2(\Omega \times [0,T]; H), \end{array} \right.$$

where X is the solution of the controlled Burgers equation

$$\tag{2.2} \left\{ \begin{array}{l} dX = (AX + F(X) + \sqrt{Q}\ z)dt + \sqrt{Q}\ dW, \\ X(0) = x \end{array} \right.$$

and the initial datum x is in H.

For any $z \in L_W^2(\Omega \times [0,T]; H)$, (2.2) has a unique solution. More precisely, its solution can be constructed as the limit of Galerkin approximations. For $m \in \mathbb{N}$, we define F_m by

$$F_m(x) = \frac{\partial}{\partial \xi}\left(f_m(x)\right),\ x \in H_0^1(0,1),$$

where

$$f_m(\alpha) = \frac{m\alpha^2}{m + \alpha^2},\ \alpha \in \mathbb{R},$$

and we consider the following Galerkin approximation of (2.2):

$$\begin{cases} dX_m = (AX_m + P_m F_m(X_m) + P_m \sqrt{Q}\, z_m)dt + P_m \sqrt{Q}\, dW, \\ X_m(0) = x_m, \end{cases} \tag{2.3}$$

where $z_m \in L^2_W(\Omega \times [0,T]; P_m H)$ and $x_m \in P_m H$. The existence and uniqueness of X_m follow from the classical theory of finite dimensional stochastic differential equations.

We will need a lemma, whose proof is given in the appendix.

LEMMA 2.1. *Let $\{x_m\}_{m\in\mathbb{N}}, \{z_m\}_{m\in\mathbb{N}}$ be such that $x_m \to x$ in H and $z_m \to z$ in $L^2_W(\Omega \times [0,T]; H)$ and almost surely in $L^2([0,T]\times H)$. Let X_m be the solution of* (2.3). *Then $\{X_m\}_{m\in\mathbb{N}}$ is convergent to the unique solution X of* (2.2) *in*

$$L^2(\Omega \times [0,T]; H^1_0(0,1)) \cap L^2(\Omega; C([0,T]; H))$$

and almost surely in $L^2([0,T]\times H)$.

As mentioned in the introduction, we can formally associate the following Hamilton–Jacobi equation with the control problem (2.1)–(2.2):

$$\begin{cases} u_t(t,x) = \dfrac{1}{2}\,\mathrm{Tr}\,[Qu_{xx}(t,x)] + (Ax + F(x), u_x(t,x)) \\ \qquad\qquad - \dfrac{1}{2}\,|\sqrt{Q}\, u_x(t,x)|^2 + \|x\|^2, \\ u(0,x) = \dfrac{1}{2}\,|x|^2, \end{cases} \tag{2.4}$$

for $t \in [0,T], x \in H$. Using the Hopf transformation

$$u = -\ln v,$$

v formally satisfies

$$v_t(t,x) = \frac{1}{2}\,\mathrm{Tr}\,[Qv_{xx}(t,x)] + (Ax + F(x), v_x(t,x)) - \|x\|^2 v, \tag{2.5}$$

and so, by the Feynmann–Kac formula,

$$v(t,x) = \mathbb{E}\left(\exp\left[-\frac{1}{2}\,|Y(t)|^2 - \int_0^t \|Y(s)\|^2 ds\right]\right), \tag{2.6}$$

where Y is the solution to the uncontrolled Burgers equation

$$\begin{cases} dY = (AY + F(Y))dt + \sqrt{Q}\, dW, \\ Y(0) = x. \end{cases} \tag{2.7}$$

It is classical that Y is two times differentiable with respect to x. More precisely, we have the following lemma, whose proof is given in the appendix.

LEMMA 2.2. *The function v defined by* (2.6)–(2.7) *is two times differentiable with respect to $x \in H$. For any $(x,h) \in H \times H$, its derivative at x in the direction of h is given by*

$$v_x(t,x)h = -\mathbb{E}\left[\left((Y(t), \eta^h(t)) + 2\int_0^t ((Y(s), \eta^h(s)))ds\right) e^{-\frac{1}{2}|Y(t)|^2 - \int_0^t \|Y(s)\|^2 ds}\right], \tag{2.8}$$

where η^h is the solution of

$$\begin{cases} \dfrac{d\eta^h}{dt} = A\eta^h + 2\dfrac{\partial}{\partial \xi}\left(Y\eta^h\right), \\ \eta^h(0) = h. \end{cases} \tag{2.9}$$

Moreover, its second derivative is given by

$$\begin{aligned} v_{xx}(t,x)(h,h) = -\mathbb{E}\Bigg[\Bigg(&|\eta^h(t)|^2 + 2\int_0^t \|\eta^h(s)\|^2 ds + (Y(t),\zeta^h(t)) \\ &+ 2\int_0^t ((Y(s),\zeta^h(s)))ds\Bigg) e^{-\frac{1}{2}|Y(t)|^2 - \int_0^t \|Y(s)\|^2 ds}\Bigg] \\ +\mathbb{E}\Bigg[\Bigg((Y(t),\eta^h(t)) + 2\int_0^t ((Y(s),\eta^h(s)))ds\Bigg)^2 & e^{-\frac{1}{2}|Y(t)|^2 - \int_0^t \|Y(s)\|^2 ds}\Bigg], \end{aligned} \tag{2.10}$$

where ζ^h is the solution of

$$\begin{cases} \dfrac{d\zeta^h}{dt} = A\zeta^h + 2\dfrac{\partial}{\partial \xi}\left(Y\zeta^h + (\eta_h)^2\right), \\ \zeta^h(0) = 0. \end{cases} \tag{2.11}$$

We will also consider the Galerkin approximation of (2.9),

$$\begin{cases} \dfrac{d\eta_m^h}{dt} = A\eta_m^h + P_m\dfrac{\partial}{\partial \xi}\left(f_m'(Y_m)\eta_m^h\right), \\ \eta_m^h(0) = P_m h, \end{cases} \tag{2.12}$$

and of (2.11),

$$\begin{cases} \dfrac{d\zeta_m^h}{dt} = A\zeta_m^h + P_m\dfrac{\partial}{\partial \xi}\left(f_m'(Y_m)\zeta_m^h + f_m''(Y_m)(\eta_m^h)^2\right), \\ \zeta_m^h(0) = 0, \end{cases} \tag{2.13}$$

where Y_m is the solution to

$$\begin{cases} dY_m = (AY_m + F_m(Y_m))dt + P_m\sqrt{Q}\, dW, \\ Y_m(0) = x_m \end{cases} \tag{2.14}$$

and $x_m \in P_m H,\ h \in P_m h$.

LEMMA 2.3. *Let $\{x_m\}_{m\in\mathbb{N}}$ be such that $x_m \to x$ in H; then*

$$\sup_{h\in H, |h|=1} \left|\eta_m^{P_m h} - \eta^h\right|^2_{L^2(0,T;H_0^1(0,1))} \to 0,$$

$$\sup_{h\in H, |h|=1} \left|\eta_m^{P_m h} - \eta^h\right|_{C([0,T];H)} \to 0,$$

$$\sup_{h\in H, |h|=1} \left|\zeta_m^{P_m h} - \zeta^h\right|^2_{L^2(0,T;H_0^1(0,1))} \to 0,$$

$$\sup_{h\in H, |h|=1} \left|\zeta_m^{P_m h} - \zeta^h\right|_{C([0,T];H)} \to 0$$

almost surely when $m \to \infty$. The proof of this lemma is given in the appendix.

In section 4 we will prove, by an approximation technique, that v given by (2.6) is a strict solution of (2.5). By strict solution we mean that v is a C^2 function with respect to x; that for any $x \in D(A)$, $t \to v(t,x)$ is a C^1 function; and that (2.5) holds for any $(t,x) \in D(A) \times [0,T]$. We will also obtain that $u = \ln v$ is a strict solution of (2.4).

Then, again by approximation, we show that the fundamental identity (1.4) holds.

It remains to be proved that the closed loop equation (1.5) has a unique solution X^*. The difficulty here is that we have only a rather bad estimate on u_x. We will consider this problem in section 5.

The main result of this paper, whose proof is presented in sections 4 and 5, is the following.

THEOREM 2.4. *Let v be defined by* (2.6)–(2.7) *and $u = -\ln v$; then u is a strict solution to the Hamilton–Jacobi equation* (2.4). *Moreover for any $z \in L^2_W(\Omega \times [0,T]; H)$, we have*

$$u(T,x) + \frac{1}{2}\mathbb{E}\int_0^T |\sqrt{Q}\, u_x(T-s, X(s,x)) + z(s)|^2 ds = J(z),$$

where X is the solution of (2.2) *and J is defined by* (2.1).

The control problem (2.1) *has a unique solution given by*

$$z^*(t) = -\sqrt{Q}\, u_x(T-t, X^*(t)),$$

where X^* is the unique solution to the closed loop equation

$$\begin{cases} dX^* = (AX^* + F(X^*)dt - Qu_x(T-t, X^*(t)))\, dt + \sqrt{Q}\, dW, \\ X^*(0) = x. \end{cases}$$

Remark 2.5. In fact we prove a little bit more. Indeed, we show that the optimal control z^* and the optimal state X^* are the limits of an approximated finite dimensional problem.

3. Approximations.

We already have introduced the Galerkin approximation (2.3) of (2.2). We also need to approximate the terms $\|\cdot\|^2$ and $\frac{1}{2}|\cdot|^2$ in the functional J. If $l \in \mathbb{N}$, we set

$$\varphi_l(x) = \frac{1}{2}\,\frac{l|x|^2}{l + |x|^2},\ x \in H, \quad g_l(x) = \frac{l\|x\|^2}{l + \|x\|^2},\ x \in H_0^1(0,1).$$

The approximated control problem is

$$(3.1) \qquad \begin{cases} \text{Minimize} \\ J_{l,m}(z_m) = \mathbb{E}\left(\int_0^T (g_l(X_m(t)) + \frac{1}{2}\,|z_m(t)|^2)dt + \varphi_l(x_m(T))\right) \\ \text{over all } \ z_m \in L^2_W(\Omega \times [0,T]; P_mH), \end{cases}$$

where X_m is the solution of (2.3).

We define for $l, m \in \mathbb{N}$, $x_m \in P_mH$, $t \in [0,T]$

$$v^{l,m}(t, x_m) = \mathbb{E}\left(e^{-\varphi_l(Y_m(t)) - \int_0^t g_l(Y_m(s))ds}\right),$$

where Y_m is the solution of (2.14). It defines a two times continuously differentiable function with respect to $x_m \in P_mH$, and for $h \in P_mH$ we have

$$\begin{aligned} v^{l,m}_{x_m}(t,x)h &= -\mathbb{E}\Bigg[\bigg(\big(D_x\varphi_l(Y_m(t)),\eta^h_m(t)\big) + \int_0^t \big(D_x g_l(Y_m(s)),\eta^h_m(s)\big)\,ds\bigg) \\ &\qquad e^{-\varphi_l(Y_m(t))-\int_0^t g_l(Y_m(s))ds}\Bigg], \end{aligned} \tag{3.2}$$

where η^h_m is the solution of (2.12) and

$$\begin{aligned} v^{l,m}_{x_mx_m}(t,x)(h,h) &= -\mathbb{E}\Bigg[\bigg(\big(D_x\varphi_l(Y_m(t)),\zeta^h_m(t)\big) + \int_0^t \big(D_x g_l(Y_m(s)),\zeta^h_m(s)\big)\,ds \\ &+D^2_x\varphi_l(Y_m(t))(\eta^h_m(t),\eta^h_m(t)) + \int_0^t D^2_x g_l(Y_m(s))(\eta^h_m(s),\eta^h_m(s))ds\bigg) \\ &\qquad \times e^{-\varphi_l(Y_m(t))-\int_0^t g_l(Y_m(s))ds}\Bigg] \\ &+\mathbb{E}\Bigg[\bigg(\big(D_x\varphi_l(Y_m(t)),\eta^h_m(t)\big) + \int_0^t \big(D_x g_l(Y_m(s)),\eta^h_m(s)\big)\,ds\bigg)^2 \\ &\qquad \times e^{-\varphi_l(Y_m(t))-\int_0^t g_l(Y_m(s))ds}\Bigg], \end{aligned} \tag{3.3}$$

where ζ^h_m is the solution of (2.13). By the Feynman–Kac formula we know that $v^{l,m}$ satisfies the equation

$$\begin{cases} v^{l,m}_t = \dfrac{1}{2}\,\mathrm{Tr}\,[P_mQv^{l,m}_{x_m,x_m}] + \big(Ax_m + P_mF_m(x_m), v^{l,m}_{x_m}\big) - g_l(x_m)v^{l,m}, \\ v^{l,m}(0,x_m) = e^{-\varphi_l(x_m)} \end{cases} \tag{3.4}$$

on $P_mH \times [0,T]$. Also, clearly

$$v^{l,m}(t,x_m) \geq e^{-l(\frac{1}{2}+T)}. \tag{3.5}$$

Therefore the function

$$u^{l,m} = -\ln v^{l,m}$$

is two times continuously differentiable and it can be checked that it is a solution of the Hamilton–Jacobi equation associated with (3.1):

$$\begin{cases} u^{l,m}_t(t,x) &= \dfrac{1}{2}\,\mathrm{Tr}\,[P_mQu^{l,m}_{x_m,x_m}] + \big(Ax_m + P_mF_m(x_m), u^{l,m}_{x_m}\big) \\ &- \dfrac{1}{2}\,|P_m\sqrt{Q}\,u^{l,m}_{x_m}|^2 + g_l(x_m), \\ u^{l,m}(0,x_m) &= \varphi_l(x_m). \end{cases} \tag{3.6}$$

A standard computation using Ito's formula shows that

$$\begin{aligned} u^{l,m}(T,x_m) &+ \frac{1}{2}\int_0^T \left|\sqrt{Q}\, u^{l,m}_{x_m}(T-t,X_m(t)) + z_m(t)\right|^2 dt \\ &= \varphi_l(X_m(T)) + \int_0^T \left(g_l(X_m(t)) + \frac{1}{2}\,|z_m(t)|^2\right) dt \\ &+ \int_0^T \left(u^{l,m}_{x_m}(T-t,X_m(t)), P_m\sqrt{Q}\, dW(t)\right). \end{aligned} \tag{3.7}$$

Taking the expectation, we obtain the fundamental identity

$$u^{l,m}(T,x_m) + \frac{1}{2}\mathbb{E}\int_0^T \left|\sqrt{Q}\, u^{l,m}_{x_m}(T-t,X_m(t)) + z_m(t)\right|^2 dt = J_{l,m}(z_m). \tag{3.8}$$

We deduce that if $X^*_{l,m}$ is the solution to the closed loop equation

$$\left\{\begin{array}{l} dX^*_{l,m} = \left(AX^*_{l,m} + P_m F_m(X^*_{l,m}) - P_m Q u^{l,m}_{x_m}(T-t,X^*_{l,m})\right) dt + P_m\sqrt{Q}\, dW, \\ X^*_{l,m}(0) = x_m, \end{array}\right. \tag{3.9}$$

then there exists a unique optimal control $z^*_{l,m}$ for (3.1) which is given by the feedback formula

$$z^*_{l,m}(t) = -\sqrt{Q}\, u^{l,m}_{x_m}(T-t,X^*_{l,m}). \tag{3.10}$$

We will see below (see Lemma 4.1) that $v^{l,m}_{x_m}(T-t,X^*_{l,m})$ is a globally Lipschitz and bounded function so that by (3.5) the same holds for $u^{l,m}_{x_m}(T-t,X^*_{l,m})$ and we know that $X^*_{l,m}$ exists and is unique. We also have

$$J_{l,m}(z^*_{l,m}) = u^{l,m}(T,x_m) = \inf_{z_m} J_{l,m}(z_m) = -\ln\mathbb{E}\left(e^{-\varphi_l(y_m(T)) - \int_0^T g_l(Y_m(s))ds}\right), \tag{3.11}$$

where Y_m satisfies (2.14).

We will also use the function

$$v^m(t,x_m) = \mathbb{E}\left(e^{-\frac{1}{2}|Y_m(t)|^2 - \int_0^t \|Y_m(s)\|^2 ds}\right), \tag{3.12}$$

where Y_m is the solution of (2.14), with first and second derivatives given by

$$\begin{aligned} &v^m_{x_m}(t,x_m)h \\ &= -\mathbb{E}\left[\left((Y_m(t),\eta^h_m(t)) + 2\int_0^t ((Y_m(s),\eta^h_m(s)))ds\right) e^{-\frac{1}{2}|Y_m(t)|^2 - \int_0^t \|Y_m(s)\|^2 ds}\right], \end{aligned} \tag{3.13}$$

$$\begin{aligned} v^m_{x_m x_m}(t,x)(h,h) &= -\mathbb{E}\left[\left((Y_m(t),\zeta^h_m(t)) + 2\int_0^t ((Y_m(s),\zeta^h_m(s)))ds\right.\right. \\ &\left.\left. + |\eta^h_m(t)|^2 + 2\int_0^t \|\eta^h_m(s)\|^2 ds\right) e^{-\frac{1}{2}|Y_m(t)|^2 - \int_0^t \|Y_m(s)\|^2 ds}\right] \\ &+ \mathbb{E}\left[\left((Y_m(t),\eta^h_m(t)) + 2\int_0^t ((Y_m(s),\eta^h_m(s)))ds\right)^2 e^{-\frac{1}{2}|Y_m(t)|^2 - \int_0^t \|Y_m(s)\|^2 ds}\right], \end{aligned} \tag{3.14}$$

where η_m^h and ζ_m^h are defined by (2.12), (2.13).

In the next two sections, c denotes any constant depending only on the data A, Q, T. We always use the same symbol c although the constants have different values. Sometimes, we use a constant depending on $\omega \in \Omega$, or $m \in \mathbb{N}, \dots$, in which case we will write $C(\omega)$ or $k_m, \dots$.

Also, when f is a C^1 (resp., C^2) function from H or P_mH to $\mathbb{R}$, we will identify its first (resp., second) differential f_x (resp., f_{xx}) with the gradient (resp., the Hessian) of f; i.e., we use the two notations

$$f_x(x)h = (f_x(x), h),\ x, h \in H$$

and

$$f_{xx}(x)(h,h) = (f_{xx}(x)h, h),\ x, h \in H,$$

respectively.

4. Passing to the limit. We take the limit in our approximation in two steps. We first proceed to the limit $l \to \infty$, then, using a priori estimates on the Galerkin approximation, we take the limit $m \to \infty$. We first bound $v^{l,m}$ uniformly in l.

LEMMA 4.1. *For any $m \in \mathbb{N}$ there exists a constant $k_m$depending on m and on A, Q, T such that for any $x_m \in P_mH, t \in [0,T]$*

$$\text{(i)}\quad |v^{l,m}_{x_m}(t, x_m)| \le k_m,$$
$$\text{(ii)}\quad |v^{l,m}_{x_m x_m}(t, x_m)|_{\mathcal{L}(P_mH)} \le k_m.$$

Proof. We have the following inequalities:

$$|(-A)^{1/2} D_x g_l(y)|^2 \le 4 g_l(y),\quad y \in H_0^1(0,1), \tag{4.1}$$

$$|D_x \varphi_l(y)|^2 \le 4 \varphi_l(y),\quad y \in H, \tag{4.2}$$

$$|D_x^2 g_l(y)(\eta,\eta)| \le 6\|\eta\|^2,\quad y, \eta \in H_0^1(0,1), \tag{4.3}$$

$$|D_x^2 \varphi_l(y)(\eta,\eta)| \le 6|\eta|^2,\quad y, \eta \in H. \tag{4.4}$$

Since f_m' is bounded by $\sqrt{m}$ and (2.12) is a linear system of ordinary differential equations, there exists a constant $c(m,T)$ such that

$$|\eta_m^h(t)| \le c(m,T)|h|,\ h \in H. \tag{4.5}$$

Similarly we have for the solution of (2.13)

$$|\zeta_m^h(t)| \le c(m,T)|h|^2,\ h \in H. \tag{4.6}$$

By (3.2), (4.1), (4.2), and the Cauchy–Schwarz inequality, for $x_m, h \in P_mH, t \in [0,T]$,

$$\begin{aligned}
&|v^m_{x_m}(t, x_m)h| \\
&\le c(m,T)\mathbb{E}\left[\left(\varphi_l(Y_m(t)) + \int_0^t g_l(Y_m(s))ds\right)^{1/2} e^{-\varphi_l(Y_m(t)) - \int_0^t g_l(Y_m(s))ds}\right]|h| \\
&\le C(m,T)|h|,
\end{aligned}$$

since $\sqrt{x}e^{-x}$ is bounded. This proves (i). Similarly (ii) follows from (3.3), (4.1)–(4.4), and elementary inequalities. □

Using (4.1)–(4.4) and the dominated convergence theorem it can be seen that for any $x_m \in P_mH,\ t \in [0,T]$,

$$\begin{aligned} &v^{l,m}(t,x_m) \to v^m(t,x_m), \\ &v^{l,m}_{x_m}(t,x_m) \to v^m_{x_m}(t,x_m) \text{ in } P_mH, \\ &v^{l,m}_{x_mx_m}(t,x_m) \to v^m_{x_mx_m}(t,x_m) \text{ in } \mathcal{L}(P_mH) \end{aligned} \tag{4.7}$$

when $l \to \infty$. Also, using Lemma 4.1 and with another application of the dominated convergence theorem, it follows that v_m is a solution of

$$\begin{cases} v^m_t = \dfrac{1}{2}\operatorname{Tr}\left[P_mQv^m_{x_m,x_m}\right] + \left(Ax_m + P_mF_m(x_m), v^m_{x_m}\right) - \|x_m\|^2v^m, \\ \\ v^m(0,x_m) = e^{-\frac{1}{2}|x_m|^2}. \end{cases} \tag{4.8}$$

From Lemma 4.1 we deduce the following estimates on

$$u^{l,m} = -\ln v^{l,m}.$$

Lemma 4.2. *For any $m \in \mathbb{N}$, there exists a constant $k_m$depending on m and on A, Q, T such that for any $x_m \in P_mH, t \in [0,T]$*

(i) $|u^{l,m}(t,x_m)| \le \frac{1}{2}\ \left(|x_m|^2 + T\ Tr\,Q\right)$,

(ii) $|u^{l,m}_{x_m}(t,x_m)| \le k_m\ e^{\frac{1}{2}\ \left(|x_m|^2+T\ Tr\ Q\right)}$,

(iii) $|u^{l,m}_{x_mx_m}(t,x_m)|_{\mathcal{L}(P_mH)} \le k_me^{\frac{1}{2}\ \left(|x_m|^2+T\ Tr\ Q\right)} + k_m^2e^{|x_m|^2+T\ Tr\ Q}$.

Proof. By Jensen's inequality we have

$$v^{l,m}(t,x_m) \ge e^{-\mathbb{E}(\varphi_l(Y_m(t))+\int_0^t g_l(Y_m(s))ds)} \ge e^{-\mathbb{E}(\frac{1}{2}|Y_m(t)|^2+\int_0^t \|Y_m(s)\|^2ds)}.$$

By Ito's formula we have

$$\begin{aligned} \frac{1}{2}|Y_m(t)|^2 + \int_0^t \|Y_m(s)\|^2ds = &\int_0^t \left(Y_m(s), \sqrt{Q}\ dW(s)\right) \\ &+ \frac{1}{2}\ \left(|x_m|^2 +\ t\operatorname{Tr}\left(P_mQ\right)\right), \end{aligned}$$

since $(F_m(Y_m), Y_m) = 0$. Thus

$$v^{l,m}(t,x_m) \ge e^{-\frac{1}{2}\left(|x_m|^2+t\operatorname{Tr}\,(P_mQ)\right)} \ge e^{-\frac{1}{2}\left(|x_m|^2+T\operatorname{Tr}\,(P_mQ)\right)}.$$

Now (i) follows from the definition of $u^{l,m}$, and (ii), (iii) from the chain rule. □

Let us define

$$u^m = -\ln v^m.$$

Then by (4.7) for any $x_m \in P_mH,\ t \in [0,T]$,

$$\begin{aligned} &u^{l,m}(t,x_m) \to u^m(t,x_m), \\ &u^{l,m}_{x_m}(t,x_m) \to u^m_{x_m}(t,x_m) \text{ in } P_mH, \\ &u^{l,m}_{x_mx_m}(t,x_m) \to u^m_{x_mx_m}(t,x_m) \text{ in } \mathcal{L}(P_mH), \end{aligned} \tag{4.9}$$

and by (4.8) u_m is a solution of

$$\left\{\begin{aligned} u_t^m(t,x) &= \frac{1}{2}\,\mathrm{Tr}\,[P_mQu^m_{x_m,x_m}] + \big(Ax_m + P_mF_m(x_m), u^m_{x_m}\big)\\ &\quad -\frac{1}{2}\,|P_m\sqrt{Q}u^m_{x_m}|^2 + \|x_m\|^2,\\ u^m(0,x_m) &= \frac{1}{2}|x_m|^2. \end{aligned}\right. \tag{4.10}$$

Using Ito's formula we have for any $z_m \in L^2(\Omega\times[0,T];P_mH)$, $x_m \in P_mH$,

$$\begin{aligned} u^m(T,x_m) &+ \frac{1}{2}\int_0^T \left|\sqrt{Q}\;u^m_{x_m}(T-t,X_m(t)) + z_m(t)\right|^2 dt\\ &= \frac{1}{2}\,|X_m(T)|^2 + \int_0^T \left(\|X_m(t)\|^2 + \frac{1}{2}\,|z_m(t)|^2\right) dt\\ &+ \int_0^T \left(u^m_{x_m}(T-t,X_m(t)), P_m\sqrt{Q}\;dW(t)\right). \end{aligned} \tag{4.11}$$

We now derive some a priori estimates uniform in m in order to take the limit $m\to\infty$.

LEMMA 4.3. *There exists a constant k_1 depending on A,Q,T such that for any $x_m \in P_mH, t\in[0,T]$*

$$\text{(i)}\quad |v^m_{x_m}(t,x_m)| \le k_1,$$
$$\text{(ii)}\quad |v^m_{x_mx_m}(t,x_m)|_{\mathcal{L}(P_mH)} \le k_1.$$

Remark 4.4.

- We are not able to give an a priori estimate on $v^{l,m}$ independently of m. This explains why we take the limit in two steps.
- We do not have a lower bound on v^m such as in (3.5) for $v^{l,m}$. Thus we do not know whether u^m has a bounded derivative. Formally u^m and v^m are associated to the control problem in which the cost functional $J_{l,m}$ is replaced by

$$J_m(z_m) = \mathbb{E}\left(\int_0^T \left(\|X_m(t)\|^2 + \frac{1}{2}\,|z_m(t)|^2\right)dt + \frac{1}{2}\,|X_m(t)|^2\right). \tag{4.12}$$

We shall prove in section 5 that the corresponding closed loop equation has a unique solution.

Proof of Lemma 4.3. Let us first note that

$$f''_m(\alpha) \le 2,\ \alpha\in\mathbb{R}. \tag{4.13}$$

Let $h\in P_mH$. We take the scalar product of (2.12) with η^h_m and obtain

$$\begin{aligned} \frac{1}{2}\,\frac{d}{dt}|\eta^h_m|^2 + \|\eta^h_m\|^2 &= \left(P_m\frac{\partial}{\partial\xi}(f'_m(Y_m)\eta^h_m), \eta^h_m\right)\\ &= \frac{1}{2}\int_0^1 f''_m(Y_m)\left(\frac{\partial}{\partial\xi}Y_m\right)(\eta^h_m)^2 d\xi\\ &\le \|Y_m\|\;|\eta^h_m|^2_{L^4(0,1)} \end{aligned} \tag{4.14}$$

by integration by parts and Hölder's inequality. Using interpolation and the Sobolev embedding theorem, we have

$$|\eta_m^h|^2_{L^4(0,1)} \leq c|\eta_m^h|^{3/2}\ \|\eta_m^h\|^{1/2}. \tag{4.15}$$

Hence, using Young's inequality,

$$\frac{1}{2}\ \frac{d}{dt}\ |\eta_m^h|^2 + \|\eta_m^h\|^2 \leq c\|Y_m\|^{4/3}|\eta_m^h|^2 + \frac{1}{2}\ \|\eta_m^h\|^2,$$

and, by Gronwall's lemma,

$$\begin{cases} |\eta_m^h(t)|^2 \leq e^{c\int_0^t \|Y_m(s)\|^{4/3}ds}|h|^2, \\ \displaystyle\int_0^t \|\eta_m^h(s)\|^2 ds \leq e^{c\int_0^t \|Y_m(s)\|^{4/3}ds}|h|^2. \end{cases} \tag{4.16}$$

We infer from (3.13) and the Cauchy–Schwarz inequality that

$$|v_{x_m}^m(t,x_m)h| \leq \mathbb{E}\left[\left(|Y_m(t)|^2 + 2\int_0^t \|Y_m(s)\|^2 ds\right)^{1/2} \right.$$
$$\left. e^{-\frac{1}{2}|Y_m(t)|^2 - \int_0^t \|Y_m(s)\|^2 ds + c\int_0^t \|Y_m(s)\|^{4/3}ds}\right]|h|$$

and (i) follows from elementary inequalities.

For the second estimate we take the scalar product of (2.13) with ζ_m^h and obtain

$$\frac{1}{2}\ \frac{d}{dt}|\zeta_m^h|^2 + \|\zeta_m^h\|^2 = \left(P_m\frac{\partial}{\partial\xi}(f_m'(Y_m)\zeta_m^h), \zeta_m^h\right) + \left(P_m\frac{\partial}{\partial\xi}(f_m''(Y_m)(\eta_m^h)^2), \zeta_m^h\right)$$

and use

$$\left|\left(P_m\frac{\partial}{\partial\xi}(f_m'(Y_m)\zeta_m^h), \zeta_m^h\right)\right| \leq C\|Y_m\|^{4/3}|\zeta_m^h|^2 + \frac{1}{4}\ \|\zeta_m^h\|^2$$

and

$$\left|\left(P_m\frac{\partial}{\partial\xi}(f_m''(Y_m)(\eta_m^h)^2), \zeta_m^h\right)\right| = \left|\int_0^1 f_m''(Y_m)(\eta_m^h)^2\frac{\partial}{\partial\xi}\zeta_m^h d\xi\right|$$
$$\leq 2|\eta_m^h|^2_{L^4(0,1)}\|\zeta_m^h\| \leq C|\eta_m^h|^4_{L^4(0,1)} + \frac{1}{4}\ \|\zeta_m^h\|^2.$$

We deduce

$$\frac{d}{dt}\ |\zeta_m^h|^2 + \|\zeta_m^h\|^2 \leq c\|Y_m\|^{4/3}|\zeta_m^h|^2 + c\|\eta_m^h\|^4_{L^4(0,1)}$$

and by (4.15), (4.16), and Gronwall's lemma

$$\begin{cases} |\zeta_m^h(t)|^2 \leq e^{c\int_0^t \|Y_m(s)\|^{4/3}ds}|h|^4, \\ \displaystyle\int_0^t \|\zeta_m^h(s)\|^2 ds \leq e^{c\int_0^t \|Y_m(s)\|^{4/3}ds}\ |h|^4. \end{cases} \tag{4.17}$$

By the Cauchy–Schwarz inequality, (3.14), (4.16), (4.17), we obtain

$$|v^m_{x_m x_m}(t, x_m)(h, h)| \le c\mathbb{E}\left[\left(1 + |Y_m(t)|^2 + \int_0^t \|Y_m(s)\|^2 ds\right)\right.$$

$$\left. e^{-\frac{1}{2}|Y_m(t)|^2 - \int_0^t \|Y_m(s)\|^2 ds + c\int_0^t \|Y_m(s)\|^{4/3} ds}\right] |h|^2,$$

and (ii) follows. □

Applying Lemma 2.1 with $z_m = 0$ and $x_m = P_m x$, we easily prove that for each $x \in H, t \in [0, T]$

$$v^m(t, P_m x) \to v(t, x) \tag{4.18}$$

when $m \to \infty$. Also, we have for any $x \in H,\ t \in [0, T]$,

$$\begin{aligned} &|v_{x_m}(t, P_m x) - v_x(t, x)| \\ &= \sup_{|h|=1} (v_{x_m}(t, P_m x), P_m h) - (v_x(t, x), h) \\ &= \sup_{|h|=1} \mathbb{E}\Bigg[\left((Y_m(t), \eta_m^{P_m h}(t)) + 2\int_0^t ((Y_m(s), \eta_m^{P_m h}(s)))ds\right) e^{-\frac{1}{2}|Y_m(t)|^2 - \int_0^t ||Y_m(s)||^2 ds} \\ &\qquad -\left((Y(t), \eta(t)) + 2\int_0^t ((Y(s), \eta(s)))ds\right) e^{-\frac{1}{2}|Y(t)|^2 - \int_0^t ||Y(s)||^2 ds}\Bigg] \\ &\le \mathbb{E}\Bigg[\sup_{|h|=1} \Bigg|\left((Y_m(t), \eta_m^{P_m h}(t)) + 2\int_0^t ((Y_m(s), \eta_m^{P_m h}(s)))ds\right) e^{-\frac{1}{2}|Y_m(t)|^2 - \int_0^t ||Y_m(s)||^2 ds} \\ &\qquad -\left((Y(t), \eta(t)) + 2\int_0^t ((Y(s), \eta(s)))ds\right) e^{-\frac{1}{2}|Y(t)|^2 - \int_0^t ||Y(s)||^2 ds}\Bigg|\Bigg]. \end{aligned}$$

It follows from Lemma 2.2 and Lemma 2.3 that the quantity inside of the expectation of the right-hand side above almost surely goes to zero. We infer from the dominated convergence theorem and estimate (4.16) that

$$v^m_{x_m}(t, P_m x) \to v_x(t, x) \text{ in } H. \tag{4.19}$$

By a similar argument, we prove that for any $x \in H,\ t \in [0, T]$,

$$v^m_{x_m x_m}(t, P_m x) \to v_{xx}(t, x) \text{ in } \mathcal{L}(H) \tag{4.20}$$

when $m \to \infty$. (The expressions of v, v_x, v_{xx} are given in (2.6), (2.8), (2.10).) Integrating (4.8), we have for $x \in H, t \in [0, T]$,

$$\begin{aligned} &v^m(t, P_m x) = e^{-\frac{1}{2}|P_m x|^2} \\ &+ \int_0^t \Big[\frac{1}{2} \text{ Tr } \big(P_m Q v^m_{x_m x_m}(s, P_m x)\big) + \big(P_m A x + P_m F_m(P_m x), v^m_{x_m}(s, P_m x)\big) \\ &\qquad -\|P_m x\|^2 v^m(s, P_m x)\Big] ds. \end{aligned}$$

We choose $x \in D(A)$. Using Lemma 4.3, we have for any $s \in [0,T]$

$$\Bigg|\frac{1}{2}\ \mathrm{Tr}\ \left(P_m Q v^m_{x_m x_m}(s, P_m x)\right) + \left(P_m A x + P_m F_m(P_m x), v^m_{x_m}(s, P_m x)\right)$$

$$-\|P_m x\|^2 v^m(s, P_m x)\Bigg|$$

$$\leq \frac{1}{2}\ k_1\ \mathrm{Tr}\ Q + k_1 \left(|Ax|^2 + c|x|^{1/2}\|x\|^{3/2}\right) + \|x\|^2.$$

We have used inequalities

$$0 \leq v^m(s, P_m x) \leq 1$$

and the following consequence of Agmon's inequality:

$$|P_m F_m(P_m x)| \leq |F_m(P_m x)| \leq |f'_m(P_m x)\frac{\partial}{\partial \xi} P_m x|$$

$$\leq 2|P_m x|_{L^\infty(0,1)}\|P_m x\| \leq c|P_m x|^{1/2}\|P_m x\|^{3/2} \leq c|x|^{1/2}\|x\|^{3/2}.$$

We deduce from (4.18), (4.19), (4.20), and the dominated convergence theorem that for $x \in D(A), t \in [0,T]$,

$$v(t,x) = e^{-\frac{1}{2}|x|^2}$$

$$+ \int_0^t \left[\frac{1}{2}\ \mathrm{Tr}\ (Q v^m_{xx}(s,x)) + (Ax + F(x), v_x(s,x)) - \|x\|^2 v(s,x)\right] ds.$$

Since v, v_x, v_{xx} are continuous with respect to t, it follows that $t \mapsto v(t,x)$ is a C^1 function for $x \in D(A)$, and for $x \in D(A), t \in [0,T]$,

$$v_t(t,x) = \frac{1}{2}\ \mathrm{Tr}\ [Q v_{xx}(t,x)] + (Ax + F(x), v_x(t,x)) - \|x\|^2 v(t,x),$$

so that v is a strict solution of (2.5). The following lemma is an easy consequence of Lemma 4.2, Lemma 4.3, and (4.9).

LEMMA 4.5. *For any $x_m \in P_m H, t \in [0,T]$ we have*

(i) $0 \leq |u^m(t, x_m)| \leq \frac{1}{2}\ \left(|x_m|^2 + T\ \mathrm{Tr}\ Q\right)$,

(ii) $|u^m_{x_m}(t, x_m)| \leq k_1\ e^{\frac{1}{2}\ \left(|x_m|^2 + T\ \mathrm{Tr}\ Q\right)}$,

(iii) $|u^m_{x_m x_m}(t, x_m)|_{\mathcal{L}(P_m H)} \leq k_1 e^{\frac{1}{2}\ \left(|x_m|^2 + T\ \mathrm{Tr}\ Q\right)} + k_1^2 e^{|x_m|^2 + T\ \mathrm{Tr}\ Q}$.

From (4.18), (4.19), and (4.20) we have for $x \in H, t \in [0,T]$,

$$\begin{aligned} & u^m(t, P_m x) \to u(t,x), \\ (4.21) \qquad & u^m_{x_m}(t, P_m x) \to u_x(t,x) \text{ in } H, \\ & u^m_{x_m x_m}(t, P_m x) P_m \to u_{xx}(t,x) \text{ in } \mathcal{L}(H). \end{aligned}$$

Arguing as above we see that $t \mapsto u(t,x)$ is a C^1 function for $x \in D(A)$, and for $x \in D(A), t \in [0,T]$,

$$u_t(t,x) = \frac{1}{2}\ \mathrm{Tr}\ [Q u_{xx}(t,x)] + (Ax + F(x), u_x(t,x)) - \frac{1}{2}\ |\sqrt{Q} u_x(t,x)|^2 + \|x\|^2,$$

and u is a strict solution of the Hamilton–Jacobi equation (2.4).

We now want to take the limit $m \to \infty$ in (4.11).

LEMMA 4.6. *Let $x \in H$ and $z \in L^2_W(\Omega \times [0,T]; H)$, let X be the solution of* (2.2) *and X_m the solution of* (2.3), *with $x_m = P_m x, z_m = P_m z$. Then*

$$u^m_{x_m}(T-t, X_m(t)) \to u_x(T-t, X(t))$$

in $L^2(0,T;H)$ $\mathbb{P}$–almost surely.

Proof. It is shown in the proof of Lemma 2.1 that X_m is almost surely bounded in $L^\infty(0,T;H)$ and it converges almost surely in $L^2(0,T;H)$ to X. By the mean value theorem and Lemma 4.5(iii) it follows

$$u^m_{x_m}(T-t, X_m(t)) - u^m_{x_m}(T-t, P_m X(t)) \to 0$$

in $L^2(0,T;H)$ almost surely. Also by (4.21)

$$u^m_{x_m}(T-t, P_m X(t)) - u_x(T-t, X(t)) \to 0$$

in H for any $t \in [0,T]$, and by Lemma 4.5(ii) and the dominated convergence theorem we deduce that this convergence holds in $L^2(0,T;H)$. □

Let $x \in H$ and $z \in L^2_W(\Omega \times [0,T]; H)$. We take $x_m = P_m x, z_m = P_m z$ in (4.11). Then thanks to Lemma 2.1, (4.21), and Lemma 4.6 we can take the limit and deduce that

$$\begin{aligned} u(T,x) &+ \frac{1}{2}\int_0^T \left|\sqrt{Q}\, u_x(T-t,X(t)) + z(t)\right|^2 dt \\ &= \frac{1}{2}\,|X(T)|^2 + \int_0^T \left(\|X(t)\|^2 + \frac{1}{2}\,|z(t)|^2\right) dt \\ &+ \int_0^T \left(u_x(T-t,X(t)), \sqrt{Q}\, dW(t)\right). \end{aligned} \tag{4.22}$$

From (3.8) we have

$$\begin{aligned} &\mathbb{E}\left(\int_0^T |\sqrt{Q}\, u^{l,m}_{x_m}(T-t, X_m(t))|^2 dt\right) \\ &\le 4J_{l,m}(z_m) + 2\mathbb{E}\int_0^T |z_m|^2 dt. \end{aligned}$$

By Ito's formula, for $t \in [0,T]$

$$\begin{aligned} &\frac{1}{2}\mathbb{E}|X_m(t)|^2 + \int_0^t ||X_m(s)||^2 ds \\ &= \mathbb{E}\int_0^t (X_m(s), z_m(s))ds + \frac{1}{2}|x_m|^2 + \frac{1}{2}t \text{ Tr } P_m Q \\ &\le \frac{1}{2}\int_0^t |X_m(s)|^2 ds + \frac{1}{2}s\int_0^t |z(s)|^2 ds + \frac{1}{2}|x|^2 + \frac{1}{2}T \text{ Tr } Q. \end{aligned}$$

By the Gronwall lemma it follows easily that

$$J_{l,m}(z_m) \le c\left(|x|^2 + T \text{ Tr } (Q) + \mathbb{E}\int_0^T |z|^2 dt\right)$$

and

$$\mathbb{E}\left(\int_0^T |\sqrt{Q}\, u^{l;m}_{x_m}(T-t,X_m(t))|^2 dt\right) \le c\left(|x|^2 + T \text{ Tr }(Q) + \mathbb{E}\int_0^T |z|^2 dt\right).$$

It follows that $\sqrt{Q}\, u^{l;m}_{x_m}(T-t,X_m(t))$ is bounded in $L^2(\Omega\times[0,T])$. Since it converges pointwise to $\sqrt{Q}\, u_x(T-t,X(t))$ we have by Fatou's lemma

$$\mathbb{E}\left(\int_0^T |\sqrt{Q}\, u_x(T-t,X(t))|^2 dt\right) \le c\left(|x|^2 + T \text{ Tr }(Q) + 2\mathbb{E}\int_0^T |z|^2 dt,\right)$$

and $\sqrt{Q}\, u_x(T-t,X(t))$ belongs to $L^2(\Omega\times[0,T])$. Therefore we can take the expectation in (4.22) and obtain the fundamental identity

$$u(T,x) + \frac{1}{2}\,\mathbb{E}\int_0^T |\sqrt{Q}\, u_x(T-t,X(t)) + z(t)|^2 dt = J(z). \tag{4.23}$$

5. Existence of a solution to the closed loop equation.

We now consider the closed loop equation

$$\begin{cases} dX^* = (AX^* + F(X^*)dt - Qu_x(T-t,X^*(t)))\,dt + \sqrt{Q}\,dW, \\ X^*(0) = x. \end{cases} \tag{5.1}$$

We first note that thanks to Lemma 4.5 and (4.21)

$$|u_x(t,x)| \le k_1\, e^{\frac{1}{2}\,\left(|x|^2 + T \text{ Tr } Q\right)},\ x\in H, \tag{5.2}$$

$$|u_{xx}(t,x)|_{\mathcal{L}(H)} \le 2k_1^2\, e^{\left(|x|^2 + T \text{ Tr } Q\right)},\ x\in H. \tag{5.3}$$

Hence u_x is locally Lipschitz in x. This is the main ingredient in the proof of the following result.

Lemma 5.1. *There exists at most one solution of* (5.1) *with trajectories in*

$$L^\infty(0,T;H)\cap L^2(0,T;H^1_0(0,1)).$$

Proof. Let X_1, X_2 be two solutions of (5.1) and $X = X_1 - X_2$. We have

$$\frac{dX}{dt} = AX + F(X_1) - F(X_2) - Q\left(u_x(T-t,X_1(t)) - u_x(T-t,X_2(t))\right).$$

It follows that $\frac{dX}{dt}\in L^2(0,T;H^{-1}(0,1))$ and

$$\frac{1}{2}\,\frac{d}{dt}|X|^2 + \|X\|^2 = (F(X_1)-F(X_2),X) - (Qu_x(T-t,X_1) - Qu_x(T-t,X_2),X)$$

$$\le \frac{1}{2}\,\|X\|^2 + c\left(|X_1|^2_{L^\infty(0,1)} + |X_2|^2_{L^\infty(0,1)}\right)|X|^2 + 4k_1^4 e^{2\left(M_1^2 + T \text{ Tr } Q\right)}|X|^2,$$

where

$$M_1 = \max\{|X_1|_{L^\infty(0,T;H)}, |X_2|_{L^\infty(0,T;H)}\}.$$

By the Sobolev embedding theorem

$$|X_i|_{L^\infty(0,1)} \le c\|X_i\|, \quad i = 1, 2.$$

Thus by Gronwall's lemma

$$|X(t)|^2 \le e^{c\int_0^T (\|X_1\|^2+\|X_2\|^2)ds+M_2T}|X(0)|^2,$$

with

$$M_2 = 4k_1^4 e^{2\left(M_1^2+T \text{ Tr } Q\right)}.$$

The result follows since $X(0) = 0$. □

We prove the existence of X^* by approximation. Let $X^*_{l,m}$ be the solution of (3.9) with $x_m = P_m x$.

Lemma 5.2. *There exists a constant k_2 depending only on A, Q, T such that for any $l, m \in \mathbb{N}$*

$$\mathbb{E}\left(\sup_{t\in[0,T]} |X^*_{l,m}(t)|^2\right) \le k_2\left(|x|^2 + \text{ Tr } Q\right).$$

Proof. First we have

$$J_{l,m}(z^*_{l,m}) \le J_{l,m}(0) \le \frac{1}{2}\left(|x_m|^2 + t \text{ Tr } Q\right)$$

by Ito's formula, where $z^*_{l,m}$ is defined in (3.10). It follows that

$$\mathbb{E}\left(\int_0^T |z^*_{l,m}(t)|^2 dt\right) \le |x_m|^2 + t \text{ Tr } Q \le |x|^2 + t \text{ Tr } Q. \tag{5.4}$$

By Ito's formula

$$\begin{aligned}
&\frac{1}{2}|X^*_{l,m}(t)|^2 + \int_0^t \|X^*_{l,m}(s)\|^2 ds \\
&= \int_0^t \left(\sqrt{Q}\, z^*_{l,m}(s), X^*_{l,m}(s)\right) ds + \int_0^t \left(X^*_{l,m}(s), \sqrt{Q}\, dW(s)\right) \\
&+\frac{1}{2}\left(|x_m|^2 + t \text{ Tr } (P_m Q)\right) \\
&\le c\int_0^T |z^*_{l,m}(s)|^2 ds + \frac{1}{2}\int_0^T \|X^*_{l,m}(s)\|^2 ds \\
&+ \sup_{t\in[0,T]} \int_0^t \left(X^*_{l,m}(s), \sqrt{Q}\, dW(s)\right) + \frac{1}{2}\left(|x|^2 + t \text{ Tr } Q\right).
\end{aligned}$$

The result follows by the application of a Martingale inequality. □

We deduce that there exists $\overline{X}_m$ in $L^2(\Omega; L^\infty(0,T;H))$ such that

$$\mathbb{E}\left(\sup_{t\in[0,T]} |\overline{X}_m(t)|\right) \le k_2\left(|x|^2 + \text{ Tr } Q\right)$$

and

$$X^*_{l,m} \rightharpoonup \overline{X}_m \text{in } L^2(\Omega; L^\infty(0,T;H)), \text{ weak star.}$$

We now derive a pathwise estimate for solutions of (3.9).

LEMMA 5.3. *Let $k(\omega)$ be a random variable. For any $m \in \mathbb{N}$, there exist random times t^m_k and constants c^m_k such that if $\widetilde{X}_{l,m}$ is a solution of* (3.9) *satisfying*

$$|\widetilde{X}_{l,m}(0)| \le k, \ \mathbb{P}\text{–almost surely,}$$

then

$$\sup_{t\in[0,t^m_k]} |\widetilde{X}_{l,m}(t)|^2 + \int_0^{t_k} \|\widetilde{X}_{l,m}(s)\|^2 ds \le c^m_k, \ \mathbb{P}\text{–almost surely}$$

Proof. Let

$$W^m_A(t) = \int_0^t e^{(t-s)A} P_m \sqrt{Q}\, dW(s)$$

and

$$\overline{X}_{l,m} = \widetilde{X}_{l,m} - W^m_A.$$

Then

$$\frac{d}{dt}\overline{X}_{l,m} = A\overline{X}_{l,m} + P_m F_m(\overline{X}_{l,m} + W^m_A) - Qu^{l,m}_{x_m}(T-t, \overline{X}_{l,m} + W^m_A).$$

Using similar arguments as in the proofs of Lemmas 2.1 and 4.2 we can prove

$$\begin{aligned} \frac{d}{dt}|\overline{X}_{l,m}|^2 &+ \|\overline{X}_{l,m}\|^2 \le c|W^m_A|^{4/3}_{L^4(0,1)}|\overline{X}_{l,m}|^2 + ck_m e^{2|\overline{X}_{l,m}|^2+2|W^m_A|^2+T\ \mathrm{Tr}\ Q} \\ &+ c|W^m_A|^4_{L^4(0,1)}. \end{aligned}$$

We set

$$\begin{aligned} F_m(t) &= e^{-c\int_0^t |W^m_A(s)|^{4/3}_{L^4(0,1)}ds}|\overline{X}_{l,m}|^2, \\ g_m &= 2e^{c\int_0^t |W^m_A(s)|^{4/3}_{L^4(0,1)}ds}, \\ h_m &= ck_m e^{\sup_{t\in[0,T]}|W^m_A(t)|^2+T\ \mathrm{Tr}\ Q}, \\ k_m &= c\sup_{t\in[0,T]}|W^m_A(t)|^4. \end{aligned}$$

It is easy to obtain

$$\frac{d}{dt}\,F_m \le h_m e^{g_m F_m} + k_m$$

so that

$$e^{-g_m F_m(t)} \ge -\left(h_m + k_m\right)t + e^{-g_m k^2},$$

and if we take

$$t_k^m = \frac{1}{2(h_m + k_m)}\, e^{-g_m k^2}$$

we have

$$F_m(t) \le \frac{1}{g_m}\, \ln 2 + k^2$$

for $t \in [0, t_k^m]$. Now the proof can be completed easily. □

It is not difficult to use the estimate in Lemma 5.3 and to prove that, for almost all $\omega \in \Omega$, a subsequence $\{X_{l,m}^*\}$ converges to X_m^* a solution of

$$(5.5)\quad \begin{cases} dX_m^* = (AX_m^* + P_m F_m(X_m^*) - P_m Q u_{x_m}^m (T-t, X_m^*))dt + P_m\sqrt{Q}\, dW, \\ \\ X_m^*(0) = x_m \end{cases}$$

on the interval $[0, t_m^k]$ whenever $|x_m| \le k$. Arguing as in Lemma 5.1, (5.5) has at most one solution so that the whole sequence converges.

We take

$$k = |\overline{X}_m|_{L^\infty(0,T;H)}.$$

Since $\{X_{l,m}^*\}$ converges pointwise to X_m^* and in $L^2(\Omega; L^\infty(0,T;H))$ weak star to $\overline{X}_m$, we have $X_m^* = \overline{X}_m$ $\mathbb{P}$−almost surely on $[0, t_k^m]$. It follows $|X_m^*(t_k^m)| \le k$, so that our construction can be reiterated and X_m^* can be prolonged to a solution of (5.5) on the interval $[0,T]$. Moreover, by Lemma 5.2 if $x_m = P_m x$

$$\mathbb{E}\left(\sup_{t\in[0,T]} |X_m^*|^2\right) \le k_2\left(|x|^2 + T\ \mathrm{Tr}\ Q\right).$$

Arguing as in the proof of Lemma 5.3 and using Lemma 4.5 and the uniform boundedness of W_A^m in $L^\infty(0,T;L^4(0,1))$, we prove the following pathwise estimate on X_m^*.

Lemma 5.4. *Let $k(\omega)$ be a random variable; there exists a random time t_k and a constant c_k such that if $\widetilde{X}_m$ is a solution of* (5.5) *satisfying*

$$|\widetilde{X}_m(0)| \le k, \ \textit{almost surely,}$$

then

$$\sup_{t\in[0,t_k]} |\widetilde{X}_m(t)|^2 + \int_0^{t_k} \|\widetilde{X}_m(s)\|^2 ds \le c_k, \ \textit{almost surely.}$$

Now we can repeat the argument that we have used to construct X_m^* and obtain X^*, a solution of (5.1) on $[0,T]$ such that

$$\mathbb{E}\left(\sup_{t\in[0,T]} |X^*(t)|^2\right) \le k_2\left(|x|^2 + T\ \mathrm{Tr}\ Q\right).$$

It remains to prove that

$$z^*(t) = -\sqrt{Q}\, u_x(T-t, X^*(t))$$

is an admissible control, i.e., that $z^* \in L^2_W(\Omega \times [0,T]; H)$.

Arguing as in Lemma 4.6 we have

$$u^{l,m}_{x_m}(T-t, X^*_{l,m}(t)) \overset{l\to\infty}{\to} u^m_{x_m}(T-t, X^*_m(t)) \overset{m\to\infty}{\to} u_x(T-t, X^*(t))$$

in $L^2(0,T;H)$ $\mathbb{P}$–almost surely. Thus by (5.4) we have $u_x(T-t, X^*(t)) \in L^2_W(\Omega \times [0,T]; H)$ and

$$\mathbb{E}\left(\int_0^T |z^*(t)|^2 dt\right) \le |x|^2 + T \operatorname{Tr} Q.$$

This ends the proof of Theorem 2.4. □

Appendix A.

A.1. Proof of Lemma 2.1. For any $m \in N$ we set

$$W^m_A(t) = \int_0^t e^{(t-s)A} P_m \sqrt{Q}\, dW(s);$$

it is the unique solution of

$$\begin{cases} dW^m_A = AW^m_A dt + P_m \sqrt{Q}\, dW, \\ W^m_A(0) = 0. \end{cases}$$

Also

$$W_A(t) = \int_0^t e^{(t-s)A} \sqrt{Q}\, dW(s)$$

is the unique solution (see [11]) of

$$\begin{cases} dW_A = AW_A dt + \sqrt{Q}\, dW, \\ W_A(0) = 0. \end{cases}$$

It is not difficult to see that W^m_A converges to W_A in $L^4([0,T] \times [0,1])$ almost surely.

Let X_m be the solution to (2.3). We set

$$\overline{X}_m = X_m - W^m_A;$$

thus

$$\text{(A.1)} \qquad \begin{cases} \dfrac{d\overline{X}_m}{dt} = A\overline{X}_m + P_m F_m(\overline{X}_m + W^m_A) + P_m \sqrt{Q}\, z_m, \\ \overline{X}_m(0) = x_m. \end{cases}$$

To derive an a priori estimate, we take the scalar product of (A.1) by $\overline{X}_m$. Using integration by parts, interpolation inequality, Sobolev embedding theorem, and Young's inequality, we have

$$\begin{aligned}&\left(P_mF_m(\overline{X}_m+W_A^m),\overline{X}_m\right)=-\int_0^1\left(f_m(\overline{X}_m+W_A^m)-f_m(\overline{X}_m)\right)\frac{\partial}{\partial\xi}\overline{X}_m d\xi\\&\leq 2\int_0^1|2\overline{X}_m+W_A^m|\,|W_A^m|\left|\frac{\partial}{\partial\xi}\overline{X}_m\right|d\xi\\&\leq 2\left(2|\overline{X}_m|_{L^4(0,1)}+|W_A^m|_{L^4(0,1)}\right)|W_A^m|_{L^4(0,1)}\|\overline{X}_m\|\\&\leq c|W_A^m|_{L^4(0,1)}|\overline{X}_m|^{3/4}\|\overline{X}_m\|^{5/4}+\frac{1}{8}\,\|\overline{X}_m\|^2+8|W_A^m|^4_{L^4(0,1)}\\&\leq c|W_A^m|^{8/3}_{L^4(0,1)}|\overline{X}_m|^2+\frac{1}{4}\,\|\overline{X}_m\|^2+8|W_A^m|^4_{L^4(0,1)}.\end{aligned}$$

We deduce

$$\frac{d}{dt}\,|\overline{X}_m|^2+\|\overline{X}_m\|^2\leq c|W_A^m|^{8/3}_{L^4(0,1)}|\overline{X}_m|^2+16|W_A^m|^4_{L^4(0,1)}+c|\sqrt{Q}\,z_m|^2$$

and

$$\begin{aligned}&|\overline{X}_m(t)|^2+\int_0^t\|\overline{X}_m(s)\|^2ds\\&\leq e^{c\int_0^t|W_A^m(s)|^{8/3}_{L^4(0,1)}ds}|x_m|^2\\&\quad+\int_0^t e^{c\int_s^t|W_A^m(r)|^{8/3}_{L^4(0,1)}dr}\left(16|W_A^m(s)|^4_{L^4(0,1)}+c+|\sqrt{Q}\,z_m|^2\right)\,ds.\end{aligned}$$

This proves that for fixed $\omega\in\Omega$, $\{\overline{X_m}\}$ is a bounded sequence in $L^\infty(0,T;L^2(0,1))$ and $L^2(0,T;H_0^1(0,1))$. By standard arguments based on compactness and the uniqueness of the limit (see [18]), we deduce that $\{\overline{X}_m\}$ converges almost surely to $\overline{X}$ in $L^2([0,T]\times[0,1])$, the unique solution of

$$\begin{cases}\dfrac{d\overline{X}}{dt}=A\overline{X}+F(\overline{X}+W_A)+\sqrt{Q}\,z,\\ \overline{X}(0)=x.\end{cases}$$

We set $X=\overline{X}+W_A$ and have

$$\begin{cases}dX=(AX+F(X)+\sqrt{Q}\,z)dt+\sqrt{Q}\,dW,\\ X(0)=x.\end{cases}$$

We apply Ito's formula to $|X^m|^2$ and take the expectation

$$\begin{aligned}&\frac{1}{2}\,\mathbb{E}|X^m(t)|^2+\mathbb{E}\int_0^t\|X^m(s)\|^2ds=\frac{1}{2}\,|x_m|^2\\&\qquad+\mathbb{E}\left(\int_0^t\left(\sqrt{Q}\,z_m,X^m\right)ds+\frac{1}{2}\,t\mathrm{Tr}\,[P_mQ]\right).\end{aligned}\tag{A.2}$$

Hence

$$\mathbb{E}|X^m(t)|^2+\mathbb{E}\int_0^t\|X^m\|^2ds\leq\ |x_m|^2+c\mathbb{E}\left(\int_0^t|\sqrt{Q}\,z_m|^2ds+t\mathrm{Tr}\ Q\right),$$

which proves that X^m is bounded in $L^2(\Omega, L^2(0,T; H_0^1(0,1)))$ and $X^m(t)$ in $L^2(\Omega, L^2(0,1))$. It is classical that this implies

$$\begin{aligned} &X^m \rightharpoonup X \text{ in } L^2(\Omega, L^2(0,T; H_0^1(0,1)) \text{ weak}, \\ &X^m(t) \rightharpoonup X(t) \text{ in } L^2(\Omega, L^2(0,1)) \text{ weak}. \end{aligned} \tag{A.3}$$

Since z_m converges to z in $L^2(\Omega, L^2(0,T; L^2(0,1)))$ strongly, we also have

$$\mathbb{E}\int_0^t \left(\sqrt{Q}\, z_m, X^m\right) ds \to \mathbb{E}\int_0^t \left(\sqrt{Q}\, z, X\right) ds. \tag{A.4}$$

By Ito's formula for $|X|^2$, we also have

$$\frac{1}{2}\,\mathbb{E}|X(t)|^2 + \mathbb{E}\int_0^t \|X(s)\|^2 ds = \frac{1}{2}\,|x|^2 + \mathbb{E}\int_0^t \left(\sqrt{Q}\, z, X\right) ds + \frac{1}{2}\, t \operatorname{Tr} Q,$$

and by $(A.2)$, $(A.4)$

$$\frac{1}{2}\,\mathbb{E}|X^m(t)|^2 + \mathbb{E}\int_0^t \|X^m(s)\|^2 ds \to \frac{1}{2}\,\mathbb{E}|X(t)|^2 + \mathbb{E}\int_0^t \|X(s)\|^2 ds$$

so that convergences in $(A.3)$ hold in the strong topology.

Let us write Ito's formula for $\frac{1}{2}\,|X^m - P_m X|^2$:

$$\begin{aligned} &\frac{1}{2}\,|X^m - P_m X|^2 + \int_0^t \|X^m - P_m X\|^2 ds \\ &= \int_0^t \left(\sqrt{Q}\,(z^m - P_m z), X^m - P_m X\right) ds \\ &\quad + \int_0^t (P_m F_m(X^m) - P_m F(X), X^m - P_m X)\, ds \\ &\le c\int_0^t |\sqrt{Q}\,(z^m - P_m z)|^2 ds + c\int_0^t |f_m(X^m) - X^2|^2 ds + \frac{1}{2}\int_0^t \|X^m - P_m X\|^2 ds. \end{aligned}$$

We deduce

$$\begin{aligned} \mathbb{E}\left(\sup_{t\in[0,T]} |X^m - P_m X|\right) &\le c\mathbb{E}\left(\int_0^T |\sqrt{Q}\,(z_m - P_m z)|^2 ds\right)^{1/2} \\ &+ c\mathbb{E}\left(\int_0^T |f_m(X^m) - X^2|^2 ds\right)^{1/2}. \end{aligned}$$

By standard estimates based on Ito's formula it can be seen that $\{X^m\}$ is bounded in $L^p(\Omega, C([0,T]; L^2(0,1)))$ for any $p \ge 1$. By Sobolev's embedding theorem and the strong convergence of X^m to X in $L^2(\Omega, L^2(0,T; H_0^1(0,1)))$, we can prove

$$\mathbb{E}\left[\left(\int_0^T |f_m(X^m) - X^2|^2 ds\right)^{1/2}\right] \to 0,$$

implying

$$\mathbb{E}\left(\sup_{t\in[0,T]} |X^m - P_m X|\right) \to 0.$$

Since X^m is bounded in any $L^p(\Omega, C([0,T]; L^2(0,1)))$, the conclusion follows. □

A.2. Proof of Lemma 2.2. The existence of η^h and ζ^h solutions of (2.9) and (2.11) is classical. Let Y^x (resp., Y^{x+h}) be the solution of (2.7) with initial datum $x \in H$ (resp., $x+h \in H$). We set

$$r = Y^{x+h} - Y^x - \eta^h.$$

r satisfies the equation

$$\begin{aligned}\frac{dr}{dt} &= Ar + \frac{\partial}{\partial \xi}\left((Y^{x+h})^2 - (Y^x)^2 - 2Y^x\eta^h\right)\\ &= Ar + \frac{\partial}{\partial \xi}\left((Y^{x+h} - Y^x)^2 + 2Y^x r\right).\end{aligned}$$

By similar arguments as in the proof of Lemma 4.3, we have

$$|Y^{x+h}(t) - Y^x(t)|^2 + \int_0^t \|Y^{x+h}(s) - Y^x(s)\|^2 ds \le ce^{c\int_0^t \|Y^x(s)\|^{4/3}ds}\,|h|^2 \tag{A.5}$$

and

$$\begin{aligned}&|r(t)|^2 + \int_0^t \|r(s)\|^2 ds\\ &\le ce^{c\int_0^t \|Y^x(s)\|^{4/3}ds}\int_0^t |Y^{x+h}(s) - Y^x(s)|^3 \|Y^{x+h}(s) - Y^x(s)\| ds.\end{aligned}$$

It follows that

$$|r(t)|^2 + \int_0^t \|r(s)\|^2 ds \le ce^{c\int_0^t \|Y^x(s)\|^{4/3}ds}|h|^4. \tag{A.6}$$

We have

$$\begin{aligned}&|v(t,x+h) - v(t,x) - v_x(t,x)h|\\ &= \mathbb{E}\Bigg(e^{-\frac{1}{2}|Y^{x+h}(t)|^2 - \int_0^t \|Y^{x+h}(s)\|^2 ds} - e^{-\frac{1}{2}|Y^x(t)|^2 - \int_0^t \|Y^x(s)\|^2 ds}\\ &\qquad + \left((Y^x(t), \eta^h(t)) + 2\int_0^t (Y^x(s), \eta^h(s))ds\right) e^{-\frac{1}{2}|Y^x(t)|^2 - \int_0^t \|Y^x(s)\|^2 ds}\Bigg)\\ &= \mathbb{E}\Bigg(\Big(e^{-\frac{1}{2}(|Y^{x+h}(t)|^2 - |Y^x(t)|^2) - \int_0^t (\|Y^{x+h}(s)\|^2 - \|Y^x(s)\|^2)ds}\\ &\qquad -1 + \left(Y^x(t), Y^{x+h}(t) - Y^x(t)\right) + 2\int_0^t \left(Y^x(s), Y^{x+h}(s) - Y^x(s)\right) ds\\ &\qquad -(Y^x(t), r(t)) - 2\int_0^t (Y^x(s), r(s))\, ds\Big) e^{-\frac{1}{2}|Y^x(t)|^2 - \int_0^t \|Y^x(s)\|^2 ds}\Bigg).\end{aligned}$$

By (A.5), (A.6), and elementary inequalities we obtain

$$\begin{aligned}&|v(t,x+h) - v(t,x) - v_x(t,x)h|\\ &\le c\mathbb{E}\Bigg[\left(1 + |Y^x(t)|^2 + \int_0^t \|Y^x(s)\|^2 ds\right)\\ &\qquad\qquad e^{-\frac{1}{2}|Y^x(t)|^2 - \int_0^t \|Y^x(s)\|^2 ds + c\int_0^t \|Y^x(s)\|^{4/3}ds}\Bigg]\,|h|^2.\end{aligned}$$

This proves the differentiability of v. The proof that v is twice differentiable is similar. □

A.3. Proof of Lemma 2.3. We define

$$e_m^h = \eta_m^{P_m h} - P_m \eta^h.$$

By integration by parts, Hölder's inequality, and Agmon's inequality

$$|x|_{L^\infty(0,1)} \le c|x|^{1/2}\|x\|^{1/2},\ x \in H_0^1(0,1),$$

we have

$$\begin{aligned}
&\frac{1}{2}\ \frac{d}{dt}\ |e_m^h|^2 + \|e_m^h\|^2 = -\int_0^1 \Bigg[\big((f_m'(Y_m) - f_m'(Y))\eta_m^h \\
&+f_m'(Y)e_m^h + f_m'(Y)\left((P_m - I)\right)\eta^h + (f_m'(Y) - 2Y)\eta^h\big)\ \frac{\partial}{\partial\xi}e_m^h\Bigg] d\xi \\
&\le \frac{1}{2}\ \|e_m^h\|^2 + c|\eta_m^{P_m h}|\ \|\eta_m^{P_m h}\|\ |Y_m - Y|^2 + c|Y|\|Y\|(|e_m^h|^2 + |(I - P_m)\eta^h|^2) \\
&+c|\eta^h|\ \|\eta^h\|\ |f_m'(Y) - 2Y|^2.
\end{aligned}$$

Thus by Gronwall's lemma

$$\begin{aligned}
&|e_m^h|^2 + \int_0^t \|e_m^h(s)\|^2 ds \le ce^{c\int_0^t |Y(s)|\ \|Y(s)\| ds} \\
&\left(\int_0^t |\eta_m^{P_m h}|\ \|\eta_m^{P_m h}\|\ |Y_m - Y|^2 ds + \int_0^t |Y(s)|\ \|Y(s)\|\ |(I - P_m)\eta^h|^2 ds\right. \\
&\qquad \left. + \int_0^t |\eta^h|\ \|\eta^h\|\ |f_m'(Y) - 2Y|^2 ds\right).
\end{aligned}$$

We write

$$|(I - P_m)\eta^h|^2 \le c\|(I - P_m)\|^2_{\mathcal{L}(D((-A)^{1/4}),H)}|\eta^h|\ \|\eta^h\|,$$

and since Y is almost surely in

$$L^\infty(0,T;L^2(0,1)) \cap L^2(0,T;H_0^1(0,1)),$$

by (4.16) and a similar estimate on η we have

$$\begin{aligned}
&|e_m^h(t)|^2 + \int_0^t \|e_m^h(s)\|^2 ds \le c(\omega)\Bigg(\sup_{t\in[0,T]} |Y_m - Y|^2 \\
&+|I - P_m|_{\mathcal{L}(D((-A)^{1/4}),H)} + c\left(\int_0^T |f_m'(Y) - 2Y|^4 ds\right)^{1/2}\Bigg)|h|^2.
\end{aligned}$$

We have

$$\begin{aligned}
&|f_m'(Y) - 2Y|^4 = \left|\frac{2}{m}\ \frac{Y^3}{(1 + \frac{1}{m}Y^2)^2} - \frac{2}{m^2}\ \frac{Y^4}{(1 + \frac{1}{m}Y^2)^2}\right|^4 \\
&\le \frac{c}{m^2}\ |Y|^8_{L^4(0,1)} \le \frac{c}{m^2}\ |Y|^6\|Y\|^2,
\end{aligned}$$

so that

$$|e_m^h|^2 + \int_0^t \|e_m^h(s)\|^2 ds \le c(\omega)\Bigg(\sup_{t\in[0,T]} |Y_m - Y|^2$$
$$+|I - P_m|_{\mathcal{L}(H)} + \frac{c}{m}\Bigg) |h|^2.$$

The first part of the lemma follows by Lemma 2.1. The proof of the second part goes along the same line. □

BEYOND MONOTONICITY IN REGULARIZATION METHODS FOR NONLINEAR COMPLEMENTARITY PROBLEMS[*]

FRANCISCO FACCHINEI[†] AND CHRISTIAN KANZOW[‡]

Abstract. Regularization methods for the solution of nonlinear complementarity problems are standard methods for the solution of monotone complementarity problems and possess strong convergence properties. In this paper, we replace the monotonicity assumption by a P_0-function condition. We show that many properties of regularization methods still hold for this larger class of problems. However, we also provide some counterexamples which indicate that not all results carry over from monotone to P_0-function complementarity problems.

Key words. nonlinear complementarity problem, regularization method, P_0-function, mountain pass theorem

1. Introduction.

We consider the *nonlinear complementarity problem* which is to find a vector in $\mathbb{R}^n$ satisfying the conditions

$$x \geq 0, \;\; F(x) \geq 0, \;\; x^T F(x) = 0;$$

here all inequalities are taken componentwise and $F : \mathbb{R}^n \to \mathbb{R}^n$ is any given function which we assume to be continuously differentiable throughout this paper.

There exist several methods for the solution of the complementarity problem NCP(F); see, e.g., the recent paper [12]. The particular class of methods to be considered in this paper are the so-called *regularization methods*, which are designed to handle *ill-posed* problems. In fact, regularization-type methods have recently been used very successfully in order to improve the robustness of several complementarity solvers on difficult test problems; see [1, 2]. For a detailed discussion of ill-posedness in mathematical programming, we refer the reader to [8]. Very roughly speaking, an ill-posed problem may be difficult to solve since small errors in the computations can lead to a totally wrong solution.

Regularization methods try to circumvent this difficulty by substituting the solution of the original problem with the solution of a sequence of well-posed (i.e., nicely behaved) problems whose solutions form a trajectory converging to the solution of the original problem. In the context of complementarity problems, if we consider the so-called *Tikhonov-regularization*, this scheme consists of solving a sequence of complementarity problems NCP(F_ε)

$$x \geq 0, \;\; F_\varepsilon(x) \geq 0, \;\; x^T F_\varepsilon(x) = 0,$$

where $F_\varepsilon(x) := F(x) + \varepsilon x$ and ε is a positive parameter converging to 0.

Regularization methods for complementarity problems have already been considered in the literature; see, e.g., [28] and [6, Theorem 5.6.2 (b)]. The basic results that can be established in the monotone case and that parallel the classical results for regularization methods for convex optimization problems (see [8] or [25]) are as follows:

(a) The regularized problem NCP(F_ε) has a unique solution $x(\varepsilon)$ for every $\varepsilon > 0$.

(b) The trajectory $x(\varepsilon)$ is continuous for $\varepsilon > 0$.

(c) For $\varepsilon \to 0$, the trajectory $x(\varepsilon)$ converges to the least l_2-norm solution of NCP(F) if NCP(F) has a nonempty solution set; otherwise it diverges.

In this paper, we try to generalize as much as possible the above results to the larger class of P_0 nonlinear complementarity problems. Actually, such a scheme has already been considered in the case of P_0 linear complementarity problems in [32] (see also [6]) and in [9]. These results will be discussed in section 2, where we also show, by an example, the rather counterintuitive fact that if F is a nonlinear P_0-function, then F_ε is not necessarily a uniform P-function. This fact makes the extension of some known results for linear problems to nonlinear problems more difficult than one would expect. In this paper we accomplish this task by an approach based on Fischer's function and the mountain pass theorem. In section 3, we then extend item (a) to the class of P_0-function complementarity problems, whereas section 4 is devoted to the (partial) generalization of items (b) and (c). In section 5 we investigate an algorithm which requires only an approximate solution of the perturbed problems; as far as we are aware of, this is the first implementable algorithm which guarantees that a solution of a P_0 complementarity problem can be computed under the mere assumption that the solution set is nonempty and bounded. We conclude with some final remarks in section 6.

2. Preliminaries.

We first restate some basic definitions.

DEFINITION 2.1. *A matrix $M \in \mathbb{R}^{n\times n}$ is called*

(a) *a P_0-matrix if, for every $x \in \mathbb{R}^n$ with $x \neq 0$, there is an index $i_0 = i_0(x)$ with*

$$x_{i_0} \neq 0 \quad \textit{and} \quad x_{i_0}[Mx]_{i_0} \geq 0;$$

(b) *a P-matrix if, for every $x \in \mathbb{R}^n$ with $x \neq 0$, it holds that*

$$\max_i x_i[Mx]_i > 0;$$

(c) *an R_0-matrix if $x = 0$ is the only solution of NCP(F) for $F(x) := Mx$.*

We refer the reader to the excellent book [6] by Cottle, Pang, and Stone for a discussion of several properties of these classes of matrices. Some nonlinear generalizations of these classes are defined in the following.

DEFINITION 2.2. *The function $F : \mathbb{R}^n \to \mathbb{R}^n$ is called a*

(a) *P_0-function if, for all $x, y \in \mathbb{R}^n$ with $x \neq y$, there is an index $i_0 = i_0(x, y)$ with*

$$x_{i_0} \neq y_{i_0} \quad \textit{and} \quad (x_{i_0} - y_{i_0})[F_{i_0}(x) - F_{i_0}(y)] \geq 0;$$

(b) *P-function if, for all $x, y \in \mathbb{R}^n$ with $x \neq y$, it holds that*

$$\max_i (x_i - y_i)[F_i(x) - F_i(y)] > 0;$$

(c) *uniform P-function if there is a constant $\mu > 0$ such that*

$$\max_i (x_i - y_i)[F_i(x) - F_i(y)] \geq \mu \|x - y\|^2$$

holds for all $x, y \in \mathbb{R}^n$.

Obviously, every uniform P-function is a P-function and every P-function is a P_0-function. Moreover, an affine mapping $F(x) := Mx+q$ is a P_0-function (P-function) if and only if M is a P_0-matrix (P-matrix). Moreover, the class of P_0-functions includes the class of monotone functions. For further discussion, we refer the reader to Moré and Rheinboldt [23].

In the affine case, there are some known results for regularization methods which partially generalize the properties (a) and (c) illustrated in the introduction from monotone to P_0 problems. We summarize these results in the following theorem.

Theorem 2.3. *Assume that $F(x) = Mx + q$ with $M \in \mathbb{R}^{n \times n}$ being a P_0-matrix and $q \in \mathbb{R}^n$. Then*

(a) *the regularized problem NCP(F_ε) has a unique solution $x(\varepsilon)$ for every $\varepsilon > 0$.*

(b) *if M is also an R_0-matrix, then the sequence $x(\varepsilon)$ is bounded for $\varepsilon \to 0$, and every limit point is a solution of NCP(F).*

A proof of these results can be found in [6, Theorem 5.6.2 (a)]. Note also that, in [32], item (b) is proved under an assumption which implies that the original problem has a unique solution. A relaxation of the R_0-condition is also discussed in the recent paper [9] by Ebiefung. In the linear case the proof of statement (a) is quite simple because if M is a P_0-matrix, then $M + \varepsilon I$ is a P-matrix by Theorem 3.4.2 in [6], so that NCP(F_ε) has a unique solution by Theorem 3.3.7 in [6].

Therefore, in an attempt to extend the previous results from the linear to the nonlinear case, the following question seems very natural: Is F_ε a uniform P-function for every fixed $\varepsilon > 0$ if F itself is a P_0-function? If the answer to this question were in the affirmative, then item (a) above could readily be extended, since a complementarity problem with a uniform P-function has a unique solution ([21, Corollary 3.2]). Unfortunately, the following example shows that F_ε is not necessarily a uniform P-function over $\mathbb{R}^n_+$ when F is nonlinear.

Example 2.4. *Consider the function F: $\mathbb{R}^2 \to \mathbb{R}^2$ defined by*

$$F(x) := F(x_1, x_2) := \begin{pmatrix} 0 \\ -e^{x_1} \end{pmatrix}.$$

Since the Jacobian

$$F'(x) = \begin{pmatrix} 0 & 0 \\ -e^{x_1} & 0 \end{pmatrix}$$

is obviously a P_0-matrix for all $x \in \mathbb{R}^2$, the function F itself is a P_0-function by Corollary 5.3 *in* [23]. *Now let $\varepsilon > 0$ and define*

$$F_\varepsilon(x) = F(x) + \varepsilon x = \begin{pmatrix} \varepsilon x_1 \\ \varepsilon x_2 - e^{x_1} \end{pmatrix}.$$

We want to show that F_ε is not a uniform P-function on $\mathbb{R}^n_+$. This means that we want to show that, given a fixed value ε, we can find, for every fixed value μ, two points in $\mathbb{R}^n_+$ (possibly depending on μ) for which the definition of a uniform P-function is not satisfied with that μ.

We will actually show that F_ε is not a uniform P-function for every positive ε. So suppose that $\varepsilon > 0$ is fixed. Choose a positive μ. Consider the following point $x = (x_1, x_2)$:

$$x_1 = 1, \quad x_2 = \sqrt{\frac{\varepsilon}{\mu}}(c-1), \tag{2.1}$$

where c is a constant such that

$$c \geq 2, \tag{2.2}$$

$$\frac{\varepsilon^2}{\mu}(c-1)^2 - \sqrt{\frac{\varepsilon}{\mu}}(e^c - e^1) \leq \varepsilon. \tag{2.3}$$

Note that it is always possible to choose c large enough so that (2.3) *is satisfied; in fact the second term on the left-hand side of* (2.3) *is negative and decreases exponentially with c and hence dominates the first term. Multiplying* (2.3) *by $(c-1)^2$, we also obtain*

$$\frac{\varepsilon^2}{\mu}(c-1)^4 - \sqrt{\frac{\varepsilon}{\mu}}(c-1)^2(e^c - e^1) \leq \varepsilon(c-1)^2. \tag{2.4}$$

We also have, by (2.1),

$$\varepsilon(c-1)^2 < \mu + \varepsilon(c-1)^2 = \mu\left(1 + \frac{\varepsilon}{\mu}(c-1)^2\right) = \mu(x_1^2 + x_2^2). \tag{2.5}$$

Set $y = cx$. Then

$$\begin{aligned}
&\max_{i\in\{1,2\}} (x_i - y_i)[F_{\varepsilon,i}(x) - F_{\varepsilon,i}(y)] \\
&= \max\left\{\varepsilon(x_1-y_1)^2, \varepsilon(x_2-y_2)^2 + (x_2-y_2)(e^{y_1} - e^{x_1})\right\} \\
&= \max\left\{\varepsilon(c-1)^2 x_1^2, \varepsilon(c-1)^2 x_2^2 - (c-1)x_2(e^{cx_1} - e^{x_1})\right\} \\
&\overset{(2.1)}{=} \max\left\{\varepsilon(c-1)^2, \frac{\varepsilon^2}{\mu}(c-1)^4 - \sqrt{\frac{\varepsilon}{\mu}}(c-1)^2(e^c - e^1)\right\} \\
&\overset{(2.4)}{=} \varepsilon(c-1)^2 \\
&\overset{(2.5)}{<} \mu(x_1^2 + x_2^2) \\
&= \frac{\mu}{(c-1)^2}\|x-y\|_2^2 \\
&\overset{(2.2)}{\leq} \mu\|x-y\|_2^2.
\end{aligned}$$

Hence F_ε is not a uniform P-function.

In the next section we shall show that, in spite of the fact that F_ε is not necessarily a uniform P-function, the regularized problems NCP(F_ε) have a unique solution $x(\varepsilon)$ for every $\varepsilon > 0$. However, due to Example 2.4, the analysis is more complicated than one would expect.

3. Existence of regularized solutions. In this section, we want to prove that the regularized problem NCP(F_ε) has a unique solution $x(\varepsilon)$ for every $\varepsilon > 0$. The main tool for proving this result is the (nonsmooth) function $\varphi : \mathbb{R}^2 \to \mathbb{R}$ defined by

$$\varphi(a,b) := \sqrt{a^2 + b^2} - a - b.$$

This function was introduced by Fischer [13] and plays a central role in the design of several nonsmooth Newton-type methods for the solution of NCP(F); see, e.g., [11, 7, 5]. Here, however, we use this function as a theoretical tool. To this end, let us introduce the operator $\Phi : \mathbb{R}^n \to \mathbb{R}^n$ by

$$\Phi(x) := \begin{pmatrix} \varphi(x_1, F_1(x)) \\ \vdots \\ \varphi(x_n, F_n(x)) \end{pmatrix}$$

as well as the corresponding merit function $\Psi : \mathbb{R}^n \to \mathbb{R}$ by

$$\Psi(x) := \frac{1}{2}\Phi(x)^T\Phi(x) = \frac{1}{2}\|\Phi(x)\|^2.$$

We summarize some of the elementary properties of these functions in the following result (see, e.g., [14, 11, 7]).

PROPOSITION 3.1. *The following statements hold:*

(a) *$x^* \in \mathbb{R}^n$ solves NCP(F) if and only if x^* solves the nonlinear system of equations $\Phi(x) = 0$.*

(b) *The merit function Ψ is continuously differentiable on the whole space $\mathbb{R}^n$.*

(c) *If F is a P_0-function, then every stationary point of Ψ is a solution of NCP(F).*

For the regularized problem, we define the corresponding operator and the corresponding merit function similarly by

$$\Phi_\varepsilon(x) := \begin{pmatrix} \varphi(x_1, F_{\varepsilon,1}(x)) \\ \vdots \\ \varphi(x_n, F_{\varepsilon,n}(x)) \end{pmatrix}$$

and

$$\Psi_\varepsilon(x) := \frac{1}{2}\Phi_\varepsilon(x)^T\Phi_\varepsilon(x),$$

where $F_{\varepsilon,i}$ denotes the ith component function of F_ε. The main result of this section is based on the following three preliminary results.

LEMMA 3.2. *Let $\varepsilon > 0$ be arbitrary. Then the Jacobian matrices $F'_\varepsilon(x)$ are P-matrices for all $x \in \mathbb{R}^n$. In particular, the function $F_\varepsilon : \mathbb{R}^n \to \mathbb{R}^n$ is a P-function.*

Proof. Since F is a P_0-function, the Jacobian matrices $F'(x)$ are P_0-matrices for all $x \in \mathbb{R}^n$ by Theorem 5.8 in [23]. In view of Theorem 3.4.2 in [6], the Jacobian matrices $F'_\varepsilon(x) = F'(x) + \varepsilon I$ are therefore P-matrices for all $x \in \mathbb{R}^n$. Hence F_ε is a P-function by Theorem 5.2 in [23]. □

A proof of the following simple result can be found in [18].

LEMMA 3.3. *Let $\{a^k\}, \{b^k\} \subseteq \mathbb{R}$ be any two sequences such that $a^k, b^k \to +\infty$ or $a^k \to -\infty$ or $b^k \to -\infty$. Then $|\varphi(a^k, b^k)| \to \infty$.*

The following proposition contains the main step in order to prove the existence of a solution of the regularized problems NCP(F_ε).

PROPOSITION 3.4. *Suppose that F is a P_0-function and $\varepsilon > 0$. Then the merit function Ψ_ε is coercive, i.e.,*

$$\lim_{\|x\|\to\infty} \Psi_\varepsilon(x) = +\infty.$$

Proof. Suppose by contradiction that the theorem is false. Then we can find an unbounded sequence $\{x^k\}$ such that $\{\Psi_\varepsilon(x^k)\}$ is bounded. Since the sequence $\{x^k\}$ is unbounded, the index set $J := \{i \in \{1,\dots,n\} | \{x_i^k\} \text{ is unbounded}\}$ is nonempty. Subsequencing if necessary, we can assume without loss of generality that $\{|x_j^k|\} \to +\infty$ for all $j \in J$. Let $\{y^k\}$ denote the bounded sequence defined in the following way:

$$y_i^k := \begin{cases} 0 & \text{if } i \in J, \\ x_i^k & \text{if } i \notin J. \end{cases}$$

From the definition of $\{y^k\}$ and the assumption that F is a P_0-function, we get

$$\begin{array}{rcl} 0 & \le & \max_{1\le i\le n}(x_i^k - y_i^k)[F_i(x^k) - F_i(y^k)] \\ & = & \max_{i\in J} x_i^k[F_i(x^k) - F_i(y^k)] \\ & = & x_j^k[F_j(x^k) - F_j(y^k)], \end{array} \tag{3.1}$$

where j is one of the indices for which the max is attained, which we have, without loss of generality, assumed to be independent of k. Since $j \in J$, we have that

$$\{|x_j^k|\} \to \infty. \tag{3.2}$$

We now consider two cases.

Case 1. $x_j^k \to +\infty$. In this case, since $F_j(y^k)$ is bounded by the continuity of F_j, (3.1) implies that $F_j(x^k)$ does not tend to $-\infty$. This in turn implies

$$\left\{\sqrt{(x_j^k)^2 + (F_j(x^k) + \varepsilon(x_j^k))^2} - x_j^k - (F_j(x^k) + \varepsilon x_j^k)\right\} \to +\infty$$

by Lemma 3.3 since $F_j(x^k) + \varepsilon x_j^k$ tends to $+\infty$.

Case 2. $x_j^k \to -\infty$. In this case it follows immediately from Lemma 3.3 that

$$\left\{\sqrt{(x_j^k)^2 + (F_j(x^k) + \varepsilon(x_j^k))^2} - x_j^k - (F_j(x^k) + \varepsilon x_j^k)\right\} \to +\infty$$

(both if $F_j(x^k) + \varepsilon x_j^k$ is unbounded or not).

In either case we get $\Psi_\varepsilon(x^k) \to +\infty$, thus contradicting the boundedness of the sequence $\{\Psi_\varepsilon(x^k)\}$. □

Note that Proposition 3.4 can also be stated in an equivalent way by saying that the level sets $\mathcal{L}_\varepsilon(c) := \{x \in \mathbb{R}^n |\, \Psi_\varepsilon(x) \le c\}$ are compact for every $c \in \mathbb{R}^n$. We are now in a position to prove the following existence and uniqueness result.

THEOREM 3.5. *Assume that F is a P_0-function. Then the regularized complementarity problem NCP(F_ε) has a unique solution $x(\varepsilon)$ for every $\varepsilon > 0$.*

Proof. Let $\varepsilon > 0$. Then F_ε is a P-function by Lemma 3.2. Therefore NCP(F_ε) has at most one solution by Theorem 2.3 in [22].

In order to prove the existence of a solution, let $x^0 \in \mathbb{R}^n$ be arbitrary and define $c := \Psi_\varepsilon(x^0)$. Because of Proposition 3.4, the corresponding level set $\mathcal{L}_\varepsilon(c)$ is nonempty and compact. Hence the continuous function Ψ_ε attains a global minimum x_ε on $\mathcal{L}(c)$ which, in view of the definition of the level set, is also a global minimum of Ψ_ε on $\mathbb{R}^n$. Therefore x_ε is a stationary point of Ψ_ε. However, F_ε is a P-function; in particular, F_ε

itself is a P_0-function, so that x_ε must be a solution of NCP(F_ε) because of Proposition 3.1 (c). ◻

Remark 3.6. It was pointed out to us by Gowda [15] (see also [27]) that the existence of the regularized solutions $x(\varepsilon)$ can also be deduced, with a possibly marginally shorter proof, by Theorem 3.4 in [20]. This offers an interesting alternative point of view. The approach we use here is more algorithmically oriented and Proposition 3.4 has a great practical significance, as will become clear in section 5.

4. Behavior of the solution path. The aim of this section is to study the properties of the solution path $\mathcal{P} := \{x(\varepsilon) | \, \varepsilon > 0\}$ and, in particular, conditions under which $x(\varepsilon)$ remains bounded when $\varepsilon \to 0$. We are interested in the boundedness of $x(\varepsilon)$ because the following easily verifiable result holds.

THEOREM 4.1. *Let $\{\varepsilon_k\}$ be a sequence of positive values converging to* 0. *If $\{x(\varepsilon_k)\}$ converges to a point $\bar{x}$, then $\bar{x}$ solves NCP(F).*

The first noteworthy property we can establish is the continuity of $x(\varepsilon)$.

LEMMA 4.2. *Assume that F is a P_0-function. Then the mapping $\varepsilon \mapsto x(\varepsilon)$ is continuous at any $\varepsilon > 0$.*

Proof. By Lemma 3.2, the Jacobian matrix $F'_\varepsilon(x)$ is a P-matrix for every $\varepsilon > 0$ and every $x \in \mathbb{R}^n$; in particular, $M := F'_\varepsilon(x(\varepsilon))$ is a P-matrix. This immediately implies that every principal submatrix of M is again a P-matrix. Moreover, using the same technique of proof as for Lemma 2.3 in [3], it is easy to see that any Schur-complement of a P-matrix is also a P-matrix. Hence the assertion follows from Theorem 3.1 in Kyparisis [19]. ◻

Note that Lemma 4.2 does not say anything about the continuity of the mapping $\varepsilon \mapsto x(\varepsilon)$ at $\varepsilon = 0$. Continuity at 0 is equivalent to convergence of the solution path $x(\varepsilon)$ when ε goes to 0. As discussed in the introduction, this result holds if F is monotone and the complementarity problem admits a solution. In the more general setting we are considering, we are no longer able to prove such a strong result. However, we can state the following result.

THEOREM 4.3. *Let F be a P_0-function and assume that the solution set $\mathcal{S}$ of NCP(F) is nonempty and bounded. Then the path $\mathcal{P}_{\bar{\varepsilon}} = \{x(\varepsilon) | \, \varepsilon \in (0, \bar{\varepsilon}]\}$ is bounded for any positive $\bar{\varepsilon}$ and*

$$\lim_{\varepsilon \downarrow 0} \operatorname{dist}(x(\varepsilon) | \mathcal{S}) = 0.$$

We postpone the proof of this theorem until the next section, where it will follow from a more general result.

We next state two immediate consequences of Theorem 4.3.

COROLLARY 4.4. *Let F be a P_0-function and assume that NCP(F) has a unique solution $\bar{x}$. Then $\lim_{\varepsilon \downarrow 0} x(\varepsilon) = \bar{x}$.*

Due to a recent result in [10], the uniqueness of a solution of NCP(F) is, for P_0 complementarity problems, equivalent to the existence of an isolated solution of NCP(F). Hence, alternatively, we could have stated Corollary 4.4 under the assumption that NCP(F) has a locally isolated solution.

COROLLARY 4.5. *Let $F(x) = Mx + q$ be an affine mapping with $M \in \mathbb{R}^{n \times n}$ being a P_0- and R_0-matrix. Then the path $\mathcal{P}_{\bar{\varepsilon}}$ is bounded for any positive $\bar{\varepsilon}$ and*

$$\lim_{\varepsilon \downarrow 0} \operatorname{dist}(x(\varepsilon) | \mathcal{S}) = 0.$$

Proof. Since the solution set of NCP(F) is known to be nonempty and bounded under the stated assumptions (see [6]), the result follows immediately from Theorem 4.3. □

Note that Corollary 4.5 is already known (see Theorem 5.6.2 (a) in [6], restated in Theorem 2.3 of this paper); however, our proof is completely different from the one given in [6]. Moreover, it is easy to see that Corollary 4.5 can easily be extended to nonlinear functions F if we assume that F is a P_0-function and an R_0-function. The definition of the latter class of functions as well as some of its properties are given in the recent paper [4]; see also [31].

The following counterexample shows that it is not possible to remove the boundedness assumption of the solution set $\mathcal{S}$ in Theorem 4.3 without destroying the boundedness of the path $\mathcal{P}$. This contrasts sharply with what happens in the case of monotone complementarity problems, where we always have the boundedness of the trajectory if the solution set is nonempty.

Example 4.6. *Let $F : \mathbb{R}^2 \to \mathbb{R}^2$ be defined by $F(x) := Mx + q$, where*

$$M := \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} \quad \text{and} \quad q := \begin{pmatrix} -1 \\ 0 \end{pmatrix}.$$

Obviously, F is a P_0-function. The solution set $\mathcal{S}$ is given by

$$\mathcal{S} := \{(x_1, x_2) \,|\, (x_1, 1), x_1 \geq 0\} \cup \{(x_1, x_2) \,|\, (0, x_2), x_2 \geq 1\},$$

i.e., the solution set is unbounded. It is easy to see that $x(\varepsilon) := (1/\varepsilon, 0)$ is the unique solution of the corresponding regularized problem NCP(F_ε). Obviously, $x(\varepsilon)$ is neither convergent nor bounded for $\varepsilon \to 0$. Even worse, the distance of $x(\varepsilon)$ to the solution set $\mathcal{S}$ does not go to zero since dist$(x(\varepsilon)|\mathcal{S}) = 1$ for every $\varepsilon > 0$.

5. Inexact regularization methods.

In the previous section, we illustrated several properties of the trajectory $\mathcal{P}$ which suggest that the original problem NCP(F) can be solved by calculating the exact solutions of a sequence of regularized problems NCP(F_ε) for a sequence of parameters ε converging to 0. From a practical point of view, however, it is usually not possible to solve the regularized problems NCP(F_ε) exactly for each $\varepsilon > 0$. In the following, we therefore present an algorithm which only requires inexact solutions of these subproblems and which nevertheless preserves all the convergence properties of its exact counterpart.

Algorithm 5.1 (inexact regularization method).

(S.0) *Choose $\varepsilon_0 > 0, \alpha_0 \geq 0$, and set $k := 0$.*

(S.1) *Compute an approximate solution $x^k \in \mathbb{R}^n$ of NCP(F_{ε_k}) such that*

$$\Psi_{\varepsilon_k}(x^k) \leq \alpha_k.$$

(S.2) *Terminate the iteration if a suitable stopping criterion is satisfied.*

(S.3) *Choose $\varepsilon_{k+1} > 0, \alpha_{k+1} \geq 0$, set $k \leftarrow k+1$, and go to (S.1).*

Obviously, if we take $\alpha_k = 0$ at each iteration, we have $x^k = x(\varepsilon_k)$. Note that a point x^k satisfying $\Psi_{\varepsilon_k}(x^k) \leq \alpha_k$ can easily be obtained by, e.g., applying any unconstrained minimization technique to Ψ_{ε_k}. In fact, the level sets of Ψ_{ε_k} are compact and every stationary point $\bar{x}$ of Ψ_{ε_k} is such that $\Psi_{\varepsilon_k}(\bar{x}) = 0$. Therefore, every suitable minimization algorithm will produce a minimizing sequence and the point x^k can be surely determined in a finite number of steps. This situation reflects the fact that the perturbed problems are well-posed and this, in turn, is one of the main motivations for using regularization methods.

To establish a result generalizing Theorem 4.3 to Algorithm 5.1 we need some further technical results.

LEMMA 5.2. *Let $C \subset \mathbb{R}^n$ be a compact set. Then, for every $\delta > 0$, there exists a $\bar{\varepsilon} > 0$ such that*

$$|\Psi_\varepsilon(x) - \Psi(x)| \leq \delta$$

for all $x \in C$ and all $\varepsilon \in [0, \bar{\varepsilon}]$.

Proof. The function $\Psi_\varepsilon(x)$ viewed as a function of both x and ε is continuous on the compact set $C \times [0, \bar{\varepsilon}]$. The lemma is then an immediate consequence of the fact that every continuous function on a compact set is uniformly continuous there. □

Finally, we also restate a version of the famous mountain pass theorem which is suitable for our purposes and which can easily be derived from standard statements of this theorem; see, e.g., Theorem 9.2.7 in [24].

THEOREM 5.3. *Let $f : \mathbb{R}^n \to \mathbb{R}$ be continuously differentiable and coercive. Let $C \subset \mathbb{R}^n$ be a nonempty and compact set and define m to be the least value of f on the (compact) boundary of C:*

$$m := \min_{x \in \partial C} f(x).$$

Assume further that there are two points $a \in C$ and $b \notin C$ such that $f(a) < m$ and $f(b) < m$. Then there exists a point $c \in \mathbb{R}^n$ such that $\nabla f(c) = 0$ and $f(c) \geq m$.

In the convergence analysis of Algorithm 5.1, we will implicitly assume that Algorithm 5.1 generates an infinite sequence so that the termination criterion in step $(S.2)$ is never active. The following result is our main convergence theorem for Algorithm 5.1. To the authors' knowledge this convergence theorem is new even for monotone complementarity problems.

THEOREM 5.4. *Let F be a P_0-function and assume that the solution set $\mathcal{S}$ of NCP(F) is nonempty and bounded. Suppose that a sequence $\{x^k\}$ is generated according to Algorithm 5.1. If $\varepsilon_k \to 0$ and $\alpha_k \to 0$, then $\{x^k\}$ remains bounded, and every accumulation point of $\{x^k\}$ is a solution of NCP(F).*

Proof. We first note that it follows from a simple continuity argument that every accumulation point of the sequence $\{x^k\}$ is a solution of NCP(F). Hence it remains to be shown that $\{x^k\}$ is a bounded sequence. Assume that the sequence $\{x^k\}$ is not bounded. Then, subsequencing if necessary, we have $\{\|x^k\|\} \to \infty$. Hence there exists a compact set $C \subset \mathbb{R}^n$ with $\mathcal{S} \subset \text{int}C$ and

$$x^k \notin C \tag{5.1}$$

for all k sufficiently large. Let $a \in \mathcal{S}$ be an arbitrary solution of NCP(F). Then we have

$$\Psi(a) = 0.$$

Since

$$\bar{m} := \min_{x \in \partial C} \Psi(x) > 0,$$

we can apply Lemma 5.2 with $\delta := \bar{m}/4$ and conclude that

$$\Psi_{\varepsilon_k}(a) \leq \frac{1}{4}\bar{m} \tag{5.2}$$

and

$$m := \min_{x \in \partial C} \Psi_{\varepsilon_k}(x) \geq \frac{3}{4}\bar{m} \tag{5.3}$$

for all k sufficiently large. Since $\Psi_{\varepsilon_k}(x^k) \leq \alpha_k$ by step $(S.1)$ of Algorithm 5.1, we have

$$\Psi_{\varepsilon_k}(x^k) \leq \frac{1}{4}\bar{m} \tag{5.4}$$

for all k large enough since $\alpha_k \to 0$ by our assumption. Now let us fix an index k such that (5.1)–(5.4) hold. Applying the mountain pass Theorem 5.3 with $b := x^k$, we obtain the existence of a vector $c \in \mathbb{R}^n$ such that

$$\nabla \Psi_{\varepsilon_k}(c) = 0 \quad \text{and} \quad \Psi_{\varepsilon_k}(c) \geq \frac{3}{4}\bar{m} > 0.$$

In view of Proposition 3.1(c), however, the stationary point c of Ψ_{ε_k} must be a global minimizer of Ψ_{ε_k} which gives us the desired contradiction. □

Obviously, Theorem 4.3 follows from Theorem 5.4 by taking $\alpha_k = 0$ for all k and using Theorem 4.1. Also, Corollaries 4.4 and 4.5 can easily be extended to the inexact framework.

Corollary 5.5. *Assume that F is a P_0-function and suppose that a sequence $\{x^k\}$ is generated according to Algorithm* 5.1. *Suppose that $\varepsilon_k \to 0$ and $\alpha_k \to 0$. Then, if NCP(F) has a unique solution $\bar{x}$, we have*

$$\lim_{\varepsilon_k \to 0} x^k = \bar{x}.$$

Corollary 5.6. *Let $F(x) = Mx + q$ be an affine mapping with $M \in \mathbb{R}^{n \times n}$ being a P_0- and R_0-matrix. Assume that $\{x^k\}$ is any sequence generated by Algorithm* 5.1 *such that $\varepsilon_k \to 0$ and $\alpha_k \to 0$. Then the sequence $\{x^k\}$ is bounded, and every accumulation point of the sequence $\{x^k\}$ is a solution of NCP(F).*

If F is a monotone function such that NCP(F) is strictly feasible (i.e., there exists a vector $\hat{x} \in \mathbb{R}^n$ such that $\hat{x} > 0$ and $F(\hat{x}) > 0$), then it is known ([17, Theorem 3.4]) that NCP(F) has a nonempty and bounded solution set. Hence we also obtain the following corollary from our main result (Theorem 5.4) of this section.

Corollary 5.7. *Assume that F is a monotone function such that NCP(F) is strictly feasible. Suppose that $\varepsilon_k \to 0$ and $\alpha_k \to 0$. Then any sequence $\{x^k\}$ generated by Algorithm* 5.1 *remains bounded, and every accumulation point of $\{x^k\}$ is a solution of NCP(F).*

We finally stress that, as far as we know, the inexact regularization method, Algorithm 5.1, investigated in this section is the first (implementable) algorithm which guarantees that a solution of a P_0-function complementarity problem with a bounded and nonempty solution set can actually be computed.

6. Final remarks. In this paper we have shown that, under appropriate assumptions, regularization methods can be successfully applied to P_0 complementarity problems. However, some properties that hold in the monotone case are lost. In particular, when the solution set of the problem is unbounded we can no longer guarantee that the trajectory generated by the regularization method is bounded. There is an open question which we think could be interesting to investigate further. When the solution trajectory $x(\varepsilon)$ is bounded, does it converge and, if it does converge, to which element? In the monotone case, $x(\varepsilon)$ always converges to the least l_2-norm solution of NCP(F). In the P_0 case, the least l_2-norm solution can even be not unique, since the solution set is not necessarily convex.

After the completion of this paper, several contributions appeared on these issues. In particular, in [30] it has been shown that every limit point of $x(\varepsilon)$ is a weak Pareto minimal element of $\mathcal{S}$ and that $x(\varepsilon)$ actually converges if F is polynomial. We also mention that several results presented in this paper have been carefully examined and generalized to a wider class of problems in [16, 26, 27] and that the results of section 5 made it possible to develop superlinearly convergent algorithms for the solution of P_0 complementarity problems with bounded solution sets; see [26, 29].

MAXIMUM PRINCIPLE FOR A HYBRID SYSTEM VIA SINGULAR PERTURBATIONS[*]

G. GRAMMEL[†]

Abstract. We prove a maximum principle of Pontryagin type for the time optimal control of a hybrid system. The system is nonlinear and consists of a controlled coupled ODE/PDE. The control input acts via the boundary and the interior of the domain. Systems of this type frequently arise in modeling population dynamics in a contaminated environment. For the regularization we use Ekeland's variational principle along with a singular perturbation technique. For this purpose we introduce a new trajectory on an additional exterior domain, whose size may be considered as a singular perturbation parameter. It turns out that the maximum principle is stable with respect to the size of the additional exterior domain. The technique allows us to obtain necessary optimality conditions without involving measure boundary data.

Key words. time optimal boundary control, Pontryagin's maximum principle, Ekeland's variational principle, Ekeland metric, singular perturbation

1. Introduction.

This paper is concerned with necessary optimality conditions for parabolic boundary control problems. Its main purpose is to provide a regularization technique via singular perturbations to obtain optimality conditions for the time optimal control problem.

In order to obtain a Pontryagin type maximum principle, one usually has to study equations with measure boundary data. The reason is that, for nonlinear or nonconvex problems with state restrictions, one cannot manage without strong variations (or spike perturbations) of the control. This necessarily leads to Dirac measures in the variational system describing the directional derivatives; see [6]. In contrast to nonlinear ODE, where the Dirac impulse just causes a jump of the trajectory, there is no similar interpretation for the boundary control of a parabolic equation. Furthermore, Dirac impulses in the boundary data cause technical difficulties (see [6]) and obviously reduce the regularity of the solutions. For *linear* systems, the explicit representation of the solutions via Green's functions (see, e.g., [7]) still allows us to overcome these difficulties; see [5], [6]. But for *nonlinear* systems, boundary element methods seem to be not as far developed. The situation becomes even more serious when pointwise state constraints are considered (see [10], [3]). Then the adjoint system necessarily has Dirac data, and duality considerations cannot be carried through when the variational system is not smooth enough. For this reason another type of variation recently has been introduced in [10], [3]. Here the variation is not concentrated locally around one point but somehow distributed over the domain, with the effect that the variational system is smooth and even looks like the variational system of a weak variation (L^∞-perturbation) of the control. This technique leads to an integrated form of the maximum principle, which, under slight continuity assumptions, can be transformed into a pointwise maximum principle.

We propose a different method to derive a maximum principle without involving measure boundary data in the variational system. The basic idea is quite simple: since it doesn't cause too much trouble to deal with strong variations for ODEs we interpret the boundary term as the steady state of a fast trajectory of an additional ODE. So, instead of investigating the original system, we approximate it by a singularly perturbed augmented system, obtain necessary optimality conditions for the singularly perturbed system via strong variations, and later let the singular perturbation tend to zero.

The proposed regularization procedure is demonstrated by a hybrid model of mathematical biology, introduced in [2], [1], but it is by far not restricted to this model. Roughly speaking, it works for any boundary control problem which is well-posed with respect to L^1-perturbations (with a common L^∞-bound) of the boundary data—a property which is easily derived (also for semilinear parabolic equations) whenever the boundary problem is well-posed with respect to Ekeland- *and* L^∞-perturbations of the boundary data. In contrast, the standard approach requires well-posedness for the case where L^1-data converge in the distributional sense to a Dirac measure.

The mathematical model of the present paper consists of a coupled pair of a (linear) parabolic equation with Neumann type boundary conditions and a (nonlinear) ODE in a Banach space:

$$(1)\qquad \left\{\begin{array}{rcl} \frac{\partial}{\partial t}Y(x,t) &=& \Delta Y(x,t),\\ \frac{\partial}{\partial N(y)}Y(y,t) &=& \int_\Omega K(x,y,u(t))^T Z(x,t)dx,\\ \frac{\partial}{\partial t}Z(x,t) &=& f(Z(x,t),Y(x,t),u(t)),\\ Y(x,0) &=& Y^0(x),\\ Z(x,0) &=& Z^0(x), \end{array}\right.$$

where $x \in \Omega$, $y \in \partial\Omega$, $t \in (0,T]$ and $\frac{\partial}{\partial N(y)}$ denotes the outer normal derivative. Thus the control input $u(t) \in U$ acts via the boundary and the interior of the domain. We are interested in the following *time optimal control problem.*

Given a function $L : L^1(\Omega; R^n) \to R$, find the control function that steers $Z(\cdot,t) \in L^1(\Omega; R^n)$ in minimal time to the target set, which is given by

$$\{Z \in L^1(\Omega; R^n) : L(Z) = 0\}.$$

The singular perturbation technique is based on the introduction of a new fast boundary trajectory $X(y,t)$, which leads to the *singularly perturbed system*

$$(2)\qquad \left\{\begin{array}{rcl} \frac{\partial}{\partial t}Y(x,t) &=& \Delta Y(x,t),\\ \frac{\partial}{\partial N(y)}Y(y,t) &=& X(y,t) - Y(y,t),\\ Y(x,0) &=& Y^0(x), \end{array}\right.$$

$$(3)\qquad \left\{\begin{array}{rcl} \epsilon(y)\frac{\partial}{\partial t}X(y,t) &=& \int_\Omega K(x,y,u(t))^T Z(x,t)dx - (X(y,t) - Y(y,t)),\\ \frac{\partial}{\partial t}Z(x,t) &=& f(Z(x,t),Y(x,t),u(t)),\\ X(y,0) &=& 0,\\ Z(x,0) &=& Z^0(x). \end{array}\right.$$

Here $\epsilon(y) > 0$ is assumed to be small in order to reflect that, for a given "slow" control u, $X(y,t)$ moves fast towards its (control dependent) equilibrium, which is given by

$$X(y,t) = \int_\Omega K(x,y,u(t))^T Z(x,t)dx + Y(y,t).$$

Note that, in general, the approximation of a nonlinear control system by singularly perturbed systems causes delicate problems, since a “fast” control may force the fast trajectory to perform oscillations, and more general averaging techniques are required; see, e.g., [8], [13], [9]. Nevertheless, to prove the maximum principle via singular perturbations, we can still manage with the steady state approach à la Tychonov (see, e.g., [12]) for two reasons: first, by the linearity of the artificial fast equation for X in (3); second, by the condition of the maximum principle itself that an optimal control for the original time optimal problem *exists*.

Surely, our proposed method is not the only possibly one. First, by the linearity of the diffusion equation, strong variations together with boundary element methods (see, e.g., [6]) seem to be applicable, even if the proof that the nonsmooth variational system really describes the directional derivatives seems to be quite involved. Second, the method of “distributed variations,” as in [3], [10], could be applicable, even for semilinear diffusions, but with the obstacle of constructing a suitable location for the perturbation, which should be quite complicated considering the coupled dynamics. The advantage of our method is that the analysis towards necessary optimality conditions involves a singularly perturbed variational system without Dirac data. This approach is extendable to semilinear diffusions and easily manages complicated coupled dynamics. Furthermore, the singular perturbation parameter has a physical meaning and the regularization method hence implies a sensitivity analysis for the maximum principle against model errors.

Interpretation of the model. Models of this kind appear when modeling population dynamics in a contaminated environment. For example, $Z(x,t) \in R$ could be a population density or, more generally, if in R^n, the densities of several characteristics of a population, that cause an environmental contamination density $Y(x,t)$ by polluting the boundary area. $Y(x,t)$ enters the domain via the boundary and its dynamics within the domain are described by a diffusion. On the other hand, the contamination causes changes in the population characteristics and the circle is closed. In [1] a slightly simpler model is investigated to describe the dynamics of viral diseases. There it is assumed that the infectious agent is transported via diffusion and necessary optimality conditions for optimal control problems *without* terminal state restrictions are derived.

There is a crucial difficulty in connection with the hybrid character of the system (1). Whereas the ODE describes different characteristics of a population distribution, it clearly defines a domain $\Omega \subset R^2$ of interest. In [1] the area consists of a city at the seashore. But if, additionally, a diffusion process is considered, it is not obvious how to relate it to the domain Ω. By this reason any reasonable model should be stable with respect to parameters describing the boundary conditions.

In our singular perturbation approach, we divide the environment into two parts. First, we have the domain Ω, in which the differential equations for $Y(x,t)$, the density of the diffusing material, and for $Z(x,t)$, the characteristics of the population, hold. It is separated by the boundary $\partial\Omega$ from a new outer domain, in which $X(y,t)$, the new outer density of the diffusing material, is assumed to be “radially constant”: every boundary point $y \in \partial\Omega$ corresponds to a line of length $\epsilon(y) > 0$ in the outer domain on which the density is spatially constant. If the outer domain is thin, i.e., if $\epsilon(y) > 0$ is small, the density $X(y,t)$ changes rapidly with respect to time. When $\epsilon(y)$ tends to zero, the density $X(y,t)$ converges rapidly towards its equilibrium. The flow through the boundary $\partial\Omega$ is then determined by the difference $X(y,t) - Y(y,t)$ of outer and inner concentrations. Whereas the term $\int_\Omega K(x,y,u(t))^T Z(x,t)dx$ generates an outer concentration $X(y,t)$, which naturally changes faster, the smaller the size $\epsilon(y)$ of the outer domain. Thus the singular perturbation approach also gives an interpretation for the source term $\int_\Omega K(x,y,u(t))^T Z(x,t)dx$. It measures just the absolute quantity of contaminated material transported to the boundary area. Finally, we remark that a meaningful functional L, describing the terminal set $L(Z) = 0$, is given by $L(Z) = \int_\Omega Z^i(x)dx - k$, for $i = 1, \dots, n$, and a natural number $k \in N$. In the model above, $Z^i(x,t) \in R$ could be the density of the *affected* population, and thus the optimal control problem would consist of reducing the number of affected individuals to a given number $k \in N$ in minimal time.

Organization of the paper. Section 2 contains the setting and the maximum principles for the singularly perturbed system (2), (3) and for the original system (1). In section 3 we briefly show the unique existence of solutions for the singularly perturbed system. The variational system for the singularly perturbed system is introduced in section 4. The last two sections contain the proofs of the maximum principles.

2. Preliminaries and main results.

Throughout the paper we assume the following:

- The admissible control functions $u \in L^\infty([0,T];U)$ are measurable with values in a compact subset $U \subset R^m$ and are equipped with the Ekeland metric (λ denotes the Lebesgue measure on $[0,T]$):

$$d(u_1, u_2) = \lambda\{t \in [0,T] : u_1(t) \neq u_2(t)\}.$$

- The domain $\Omega \subset R^2$ is bounded with smooth boundary $\partial\Omega$.
- The function $f \in C^{1,1,0}(R^n \times R \times R^m; R^n)$ is continuous, bounded, and continuously differentiable with respect to the first and second arguments with bounded derivative. For all $Y \in R$ and $v \in U$ the components of $f(0,Y,v) \in R^n$ are nonnegative.
- The function $\epsilon(\cdot) \in C(\partial\Omega; R)$ is positive and continuous.
- The kernel $K \in C(\overline{\Omega} \times \partial\Omega \times R^m; R^n)$ is continuous with nonnegative components.
- The initial distribution $Y^0 \in C(\overline{\Omega}; R_0)$ is nonnegative and continuous.
- The initial distribution $Z^0 \in L^\infty(\Omega; R^n)$ is measurable, essentially bounded with essentially nonnegative components.
- The function $L : L^1(\Omega, R^n) \to R$ is continuously Frechet differentiable.

Remark 2.1. We did not make any attempts to optimize this setting. There are possibly many ways to weaken the regularity conditions above. In particular, we mention that the space dimension for the domain Ω could be any natural number; in just the special model it is 2. The control range U could be any compact metric space so that more complicated controls, also depending on the spatial variable, could be taken into consideration.

In order to formulate the Pontryagin maximum principle, we define the *adjoint system* with terminal conditions

$$(4) \quad \left\{ \begin{array}{rcl} \frac{\partial}{\partial t}P(x,t) & = & -\Delta P(x,t) - f_Y(Z_0(x,t), Y_0(x,t), u(t))^T Q(x,t), \\ \frac{\partial}{\partial N(y)}P(y,t) & = & 0, \\ \frac{\partial}{\partial t}Q(x,t) & = & -f_Z(Z_0(x,t), Y_0(x,t), u(t))^T Q(x,t) \\ & & - \int_{\partial\Omega} K(x,y,u(t))P(y,t)dy, \\ P(x,T) & = & 0, \\ Q(x,T) & = & \Lambda. \end{array} \right.$$

We denote solutions of the system (1) by Y_0, Z_0 and solutions of the adjoint system by P_0, Q_0. The maximum principle for the time optimal control problem then becomes the following theorem.

THEOREM 2.1. *If $u_0^* : [0, T_0] \to U$ is a time optimal control function for the system* (1) *with arrival time $T = T_0$, then there is a terminal condition $\Lambda \in L^\infty(\Omega; R^n)$ for the adjoint system* (4), *such that for almost all times $s \in [0, T_0]$ and all control values $v \in U$ the maximum condition*

$$\begin{aligned} 0 \leq & \int_{\partial\Omega} \int_{\Omega} (K(x, y, v) - K(x, y, u_0^*(s)))^T Z_0(x, s) P_0(y, s) dx dy \\ & + \int_{\Omega} Q_0(x, s)^T (f(Z_0(x, s), Y_0(x, s), v) - f(Z_0(x, s), Y_0(x, s), u_0^*(s)) dx \end{aligned}$$

is valid. The multiplier Λ fulfills the transversality condition

$$\Lambda = \operatorname{sgn}(L(Z^0)) \nabla L(Z_0(\cdot, T_0)(u_0^*)) \in L^\infty(\Omega; R^n).$$

We prove this Pontryagin maximum principle by regularizing the original system by singularly perturbed systems, so naturally we introduce a *singularly perturbed adjoint system* with terminal conditions:

$$(5) \qquad \left\{ \begin{array}{rcl} \frac{\partial}{\partial t} P(x, t) & = & -\Delta P(x, t) - f_Y(Z_\epsilon(x, t), Y_\epsilon(x, t), u(t))^T Q(x, t), \\ \frac{\partial}{\partial N(y)} P(y, t) & = & R(y, t) - P(y, t), \\ \epsilon(y) \frac{\partial}{\partial t} R(y, t) & = & R(y, t) - P(y, t), \\ \frac{\partial}{\partial t} Q(x, t) & = & -f_Z(Z_\epsilon(x, t), Y_\epsilon(x, t), u(t))^T Q(x, t) \\ & & - \int_{\partial\Omega} K(x, y, u(t)) R(y, t) dy, \\ P(x, T) & = & 0, \\ R(y, T) & = & 0, \\ Q(x, T) & = & \Lambda. \end{array} \right.$$

Throughout the paper, we will denote trajectories of the singularly perturbed system (2), (3) by $Y_\epsilon, X_\epsilon, Z_\epsilon$ and trajectories of the singularly perturbed adjoint system (5) by $P_\epsilon, R_\epsilon, Q_\epsilon$. Although we do not need it for the proof of Theorem 2.1, we also state the maximum principle for the singularly perturbed system because we obtain the proof of the following theorem as a byproduct.

THEOREM 2.2. *If $u^* : [0, T] \to U$ is a time optimal control function for the singularly perturbed system* (2), (3) *with arrival time $T \geq 0$, then there is a terminal condition $\Lambda \in L^\infty(\Omega; R^n)$ for the singularly perturbed adjoint system* (5), *such that for almost all times $s \in [0, T]$ and all control values $v \in U$ the maximum condition*

$$\begin{aligned} 0 \leq & \int_{\partial\Omega} \int_{\Omega} (K(x, y, v) - K(x, y, u^*(s)))^T Z_\epsilon(x, s) R_\epsilon(y, s) dx dy \\ & + \int_{\Omega} Q_\epsilon(x, s)^T (f(Z_\epsilon(x, s), Y_\epsilon(x, s), v) - f(Z_\epsilon(x, s), Y_\epsilon(x, s), u^*(s))) dx \end{aligned}$$

is valid. The multiplier Λ fulfills the transversality condition

$$\Lambda = \operatorname{sgn}(L(Z^0)) \nabla L(Z_\epsilon(\cdot, T)(u^*)) \in L^\infty(\Omega; R^n).$$

The regularization procedure via singular perturbations requires some explanation, especially since the system under consideration is *nonlinear.* For nonlinear singularly perturbed control systems, it is known that, even if the fast subsystem has an exponentially stable equilibrium for any control value $v \in U$ and any frozen slow state, the correct limit system is richer than the one obtained with the standard Tychonov approach. The explanation for this nonlinear phenomenon is that open-loop controls that oscillate between two values can force the fast motion to oscillate, if the oscillation of the open-loop control becomes faster as the perturbation becomes smaller. On the other hand, by the nonlinearity of the system, oscillations of the fast motions produce additional averaged dynamics of the slow motions, which are not captured by the steady state approach à la Tychonov. Hence, in general, the original system (1) is not rich enough to contain all limits of Y_ϵ, Z_ϵ trajectories of the singularly perturbed system (2), (3), as the perturbation tends to zero. A correct limit system for (2), (3) should take into account fast oscillations and could be considered as a generalized relaxed system.

However, in connection with the maximum principle, these difficulties do not occur, since we are interested in only one special control, namely, the optimal control of the time optimal problem. We do not need to care about the possible better trajectories of the singularly perturbed system and their limits (which would be trajectories of a generalized relaxed system) simply by the fact that the maximum principle presumes the existence of an optimal control.

3. Unique solutions of the singularly perturbed systems. In this section we sketch a proof for the unique existence of solutions of the singularly perturbed (adjoint) system and continuous dependence on the control. The corresponding statements for the original (adjoint) system are implicitly proved in Lemma 6.1 in the last section. We introduce appropriate function spaces

$$\begin{aligned} Y_\epsilon, P_\epsilon, Y_0, P_0 &\in C([0,T]; C(\overline{\Omega}; R)) \cap L^2((0,T); H^1(\Omega)),\\ X_\epsilon, R_\epsilon &\in C([0,T]; C(\partial\Omega; R)),\\ Z_\epsilon, Q_\epsilon, Z_0, Q_0 &\in C([0,T]; L^\infty(\Omega; R^n)). \end{aligned}$$

All function spaces are equipped with the standard topology.

PROPOSITION 3.1. *The singularly perturbed system* (2), (3) *and adjoint system* (5) *have unique solutions* $(Y_\epsilon, X_\epsilon, Z_\epsilon)(u)$ *for any* $T \geq 0$ *and any control function* $u \in L^\infty([0,T]; U)$. *The solutions depend continuously on the control function.*

Proof. In order to show the unique existence of solutions $(Y_\epsilon, X_\epsilon, Z_\epsilon)$ of (2), (3), we define the solution operators

$$S_Y : C([0,T]; C(\partial\Omega; R) \times L^\infty(\Omega; R^n)) \to C([0,T]; C(\overline{\Omega}; R)) \cap L^2((0,T); H^1(\Omega)),$$

which map trajectories (X, Z) to solutions Y of the PDE (2). Conversely, we define

$$S^u_{(X,Z)} : C([0,T]; C(\overline{\Omega}; R)) \cap L^2((0,T); H^1(\Omega)) \to C([0,T]; C(\partial\Omega; R) \times L^\infty(\Omega; R^n)),$$

which map trajectories Y (for a given control function u) to solutions (X, Z) of the ODE (3). Note that the operator $S^u_{(X,Z)}$ also depends on the size $\epsilon(y) > 0$ of the additional boundary region. For $T \geq 0$ small enough, the composition

$$S^u_{(X,Z)} \circ S_Y : C([0,T]; C(\partial\Omega; R) \times L^\infty(\Omega; R^n)) \to C([0,T]; C(\partial\Omega; R) \times L^\infty(\Omega; R^n))$$

is a (continuously differentiable) contraction for any control $u \in L^\infty([0,T];U)$: the operator S_Y is affine linear and continuous (see [11] or [3]), thus continuously differentiable and Lipschitz. A standard application of the Gronwall lemma also shows that the nonlinear operator $S^u_{(X,Z)}$ is continuously differentiable and Lipschitz since f is. The Lipschitz constant of the operator $S^u_{(X,Z)}$ defined by the integral equation

$$\begin{cases} X(y,t) &= \int_0^t (\int_\Omega K(x,y,u(\tau))^T Z(x,\tau)dx - (X(y,\tau)+Y(y,\tau)))d\tau, \\ Z(x,t) &= Z^0(x) + \int_0^t f(Z(x,\tau),Y(x,\tau),u(\tau))d\tau \end{cases}$$

becomes arbitrary small, as the time horizon $[0,T]$ becomes smaller. We conclude that, for $T \geq 0$ small enough, the singularly perturbed system (2), (3) has for any control function $u \in L^\infty([0,T];U)$ a unique solution $(X_\epsilon, Z_\epsilon)(u)$, which is just the fixed point of the contraction $S^u_{(X,Z)} \circ S_Y$. Similarly, $Y_\epsilon(u)$ is the fixed point of the contraction $S_Y \circ S^u_{(X,Z)}$. A standard application of the Gronwall lemma shows that the nonlinear operator $S^u_{(X,Z)}$ depends continuously on $u \in L^\infty([0,T];U)$ (in the sense of pointwise convergence). Thus, also, the fixed point of the contraction $S^u_{(X,Z)} \circ S_Y$ depends continuously on $u \in L^\infty([0,T];U)$. For arbitrary $T \geq 0$ we can subdivide the interval $[0,T]$ into smaller subintervals and construct appropriate contractions on each subinterval to show successively the existence of a unique solution on the whole time interval. The corresponding statement for the adjoint system can be proved in essentially the same way and the proof is finished. □

4. The singularly perturbed variational system. The main advantage of our singular perturbation approach is that the variational system, which describes the variations or directional derivatives of the trajectories corresponding to strong variations of the control, contains Dirac impulses only in the ODE part. An investigation of the more complicated variational system for the original system (1) is no longer necessary. In the following we introduce the variational system for the singularly perturbed system and manifest its connections with the singularly perturbed adjoint system.

We use the strong variation for control functions. For a control value $v \in U$, a time $s \in (0,T]$ and $h \in (0,s]$, the strong variation u^h of the control function u is defined by

$$u^h(t) := \begin{cases} v & \text{for almost all } t \in [s-h,s], \\ u(t) & \text{for almost all } t \in [0,s-h] \cup [s,T]. \end{cases} \tag{6}$$

Then the *singularly perturbed variational system* for the limits

$$(V_\epsilon, U_\epsilon, W_\epsilon) = \lim_{h \to 0+} \frac{1}{h}((Y_\epsilon, X_\epsilon, Z_\epsilon)(u^h) - (Y_\epsilon, X_\epsilon, Z_\epsilon)(u)) \tag{7}$$

becomes for $t \in [s,T]$

$$\begin{cases} \frac{\partial}{\partial t}V(x,t) &= \Delta V(x,t), \\ \frac{\partial}{\partial N(y)}V(y,t) &= U(y,t) - V(y,t), \\ \epsilon(y)\frac{\partial}{\partial t}U(y,t) &= \int_\Omega K(x,y,u(t))^T W(x,t)dx - (U(y,t)-V(y,t)), \\ \frac{\partial}{\partial t}W(x,t) &= f_Z(Z_\epsilon(x,t),Y_\epsilon(x,t),u(t))W(x,t), \\ & \quad +f_Y(Z_\epsilon(x,t),Y_\epsilon(x,t),u(t))V(x,t) \\ V(x,s) &= 0, \\ U(y,s) &= \frac{1}{\epsilon(y)}\int_\Omega (K(x,y,v)-K(x,y,u(s)))^T Z(x,s)dx, \\ W(x,s) &= f(Z_\epsilon(x,s),Y_\epsilon(x,s),v) - f(Z_\epsilon(x,s),Y_\epsilon(x,s),u(s)). \end{cases} \tag{8}$$

For $t \in [0, s)$ the variation $(V_\epsilon, U_\epsilon, W_\epsilon)$ is obviously equal to zero; thus, we have the usual jump at time $t = s$, which is caused by a Dirac impulse. We show that the solution of the singularly perturbed variational system (8) in fact describes the variation of the trajectories with respect to the strong variation of the control. The function spaces for the trajectories of the variational system are

$$\begin{aligned} V_\epsilon &\in C([s,T]; C(\overline{\Omega}; R)) \cap L^2((0,T); H^1(\Omega)), \\ U_\epsilon &\in C([s,T]; C(\partial\Omega; R)), \\ W_\epsilon &\in C([s,T]; L^\infty(\Omega; R^n)). \end{aligned}$$

All function spaces are equipped with the standard topology. We omit showing the unique existence of solutions to (8), since the proof is completely analogous to the proof of Proposition 3.1.

LEMMA 4.1. *Let $u^h \in L^\infty([0,T]; U)$ be the strong variation of the control $u \in L^\infty([0,T]; U)$. Then the limit* (7) *exists and is a solution of the singularly perturbed variational system* (8).

Proof. Since the operator $S^u_{(X,Z)} \circ S_Y$ is continuously differentiable, we can write (again for $T > 0$ small enough)

$$\begin{aligned} &\frac{1}{h}((X_\epsilon, Z_\epsilon)(u^h) - (X_\epsilon, Z_\epsilon)(u)) \\ &\quad = \frac{1}{h}\left(S^{u^h}_{(X,Z)} \circ S_Y((X_\epsilon, Z_\epsilon)(u^h)) - S^u_{(X,Z)} \circ S_Y((X_\epsilon, Z_\epsilon)(u))\right) \\ &\quad = \frac{1}{h}\left(S^{u^h}_{(X,Z)} \circ S_Y((X_\epsilon, Z_\epsilon)(u^h)) - S^{u^h}_{(X,Z)} \circ S_Y((X_\epsilon, Z_\epsilon)(u))\right) \\ &\qquad + \frac{1}{h}\left(S^{u^h}_{(X,Z)} \circ S_Y((X_\epsilon, Z_\epsilon)(u)) - S^u_{(X,Z)} \circ S_Y((X_\epsilon, Z_\epsilon)(u))\right) \\ &\quad = D_{(X,Z)}\left(S^{u^h}_{(X,Z)} \circ S_Y((X_\epsilon, Z_\epsilon)(u))\right)\left[\frac{1}{h}((X_\epsilon, Z_\epsilon)(u^h) - (X_\epsilon, Z_\epsilon)(u))\right] + \frac{o(h)}{h} \\ &\qquad + \frac{1}{h}\left(S^{u^h}_{(X,Z)} \circ S_Y - S^u_{(X,Z)} \circ S_Y\right)((X_\epsilon, Z_\epsilon)(u)). \end{aligned}$$

A standard application of the Gronwall lemma shows the convergence

$$\lim_{h \to 0+} \frac{1}{h}\left(S^{u^h}_{(X,Z)} \circ S_Y - S^u_{(X,Z)} \circ S_Y\right)((X_\epsilon, Z_\epsilon)(u)) = (U_2, W_2)$$

in $C([s,T]; C(\partial\Omega; R) \times C(\overline{\Omega}; R^n))$, where (U_2, W_2) fulfill the differential equation

$$\left\{ \begin{array}{rcl} \epsilon(y)\frac{\partial}{\partial t}U_2(y,t) &=& \int_\Omega K(x,y,u(t))^T W_2(x,t)dx - U_2(y,t), \\ \frac{\partial}{\partial t}W_2(x,t) &=& f_Z(Z_\epsilon(x,t), Y_\epsilon(x,t), u(t))W_2(x,t), \\ U_2(y,s) &=& \frac{1}{\epsilon(y)}\int_\Omega (K(x,y,v) - K(x,y,u(s)))^T Z_\epsilon(x,s)dx, \\ W_2(x,s) &=& f(Z_\epsilon(x,s), Y_\epsilon(x,s), v) - f(Z_\epsilon(x,s), Y_\epsilon(x,s), u(s)). \end{array} \right.$$

At the same time we have the convergence of the bounded linear operator (in the sense of the operator norm)

$$\lim_{h \to 0+} D_{(X,Z)}\left(S^{u^h}_{(X,Z)} \circ S_Y((X_\epsilon, Z_\epsilon)(u))\right) = D_{(X,Z)}\left(S^u_{(X,Z)} \circ S_Y((X_\epsilon, Z_\epsilon)(u))\right),$$

where the limit operator maps $(U,W)\in C([s,T];C(\partial\Omega;R)\times L^\infty(\Omega;R^n))$ to solutions (U_1,W_1) of the system

$$\left\{\begin{array}{rcl} \frac{\partial}{\partial t}V(x,t) & = & \Delta V(x,t),\\ \frac{\partial}{\partial N}V(y,t) & = & (U(y,t)-V(y,t)),\\ \epsilon(y)\frac{\partial}{\partial t}U_1(y,t) & = & \int_\Omega K(x,y,u(t))^T W_1(x,t)dx-(U_1(y,t)-V(y,t)),\\ \frac{\partial}{\partial t}W_1(x,t) & = & f_Z(Z_\epsilon(x,t),Y_\epsilon(x,t),u(t))W_1(x,t)\\ & & +f_Y(Z_\epsilon(x,t),Y_\epsilon(x,t),u(t))V(x,t),\\ V(x,s) & = & 0,\\ U_1(y,s) & = & 0,\\ W_1(x,s) & = & 0. \end{array}\right.$$

Thus $\frac{1}{h}((X_\epsilon,Z_\epsilon)(u^h)-(X_\epsilon,Z_\epsilon)(u))$ is a fixed point of a contraction that depends continuously on h. Note that the contraction constant does not depend on h! We conclude that the limit $(U_\epsilon,W_\epsilon)=\lim_{h\to 0+}\frac{1}{h}((X_\epsilon,Z_\epsilon)(u^h)-(X_\epsilon,Z_\epsilon)(u))$ exists and fulfills the equation

$$(U_\epsilon,W_\epsilon)=D_{(X,Z)}\left(S^u_{(X,Z)}\circ S_Y((X_\epsilon,Z_\epsilon)(u))\right)[(U,W)]+(U_2,W_2).$$

It follows that $(U_\epsilon,W_\epsilon)=(U_1,W_1)+(U_2,W_2)$ is a solution of the variational system and the proof is finished. □

We close this section with a lemma describing the relationship between the singularly perturbed variational system (8) and the singularly perturbed adjoint system (5).

Lemma 4.2. *For all times $s\in(0,T]$, all times $t\in[s,T]$, and all control values $v\in U$ the trajectories of the singularly perturbed variational system* (8) *and of the singularly perturbed adjoint system* (5) *fulfill*

$$\begin{aligned} &\int_\Omega (P_\epsilon(x,s)V_\epsilon(x,s)+Q_\epsilon(x,s)^T W_\epsilon(x,s))dx+\int_{\partial\Omega}\epsilon(y)R_\epsilon(y,s)U_\epsilon(y,s)dy\\ &\qquad=\int_\Omega (P_\epsilon(x,t)V_\epsilon(x,t)+Q_\epsilon(x,t)^T W_\epsilon(x,t))dx+\int_{\partial\Omega}\epsilon(y)R_\epsilon(y,t)U_\epsilon(y,t)dy\\ &\qquad=\int_\Omega Q_\epsilon(x,T)^T W_\epsilon(x,T)dx. \end{aligned}\tag{9}$$

Proof. We can formally calculate

$$\begin{aligned} &\frac{d}{dt}\int_\Omega P_\epsilon(x,t)V_\epsilon(x,t)dx\\ &\qquad=\int_\Omega\left(\frac{\partial}{\partial t}P_\epsilon(x,t)V_\epsilon(x,t)+P_\epsilon(x,t)\frac{\partial}{\partial t}V_\epsilon(x,t)\right)dx\\ &\qquad=\int_\Omega(-\Delta P_\epsilon(x,t)V_\epsilon(x,t)+P_\epsilon(x,t)\Delta V_\epsilon(x,t))dx\\ &\qquad\quad-\int_\Omega f_Y(Z_\epsilon(x,t),Y_\epsilon(x,t),u(t))^T Q_\epsilon(x,t)V_\epsilon(x,t)dx\\ &\qquad=\int_{\partial\Omega}\left(\frac{\partial}{\partial N(y)}V_\epsilon(y,t)P_\epsilon(y,t)-V_\epsilon(y,t)\frac{\partial}{\partial N(y)}P_\epsilon(y,t)\right)dy\\ &\qquad\quad-\int_\Omega f_Y(Z_\epsilon(x,t),Y_\epsilon(x,t),u(t))^T Q_\epsilon(x,t)V_\epsilon(x,t)dx \end{aligned}$$

$$
\begin{aligned}
&= \int_\Omega (U_\epsilon(y,t)P_\epsilon(y,t) - V_\epsilon(y,t)R_\epsilon(y,t))dy \\
&\quad - \int_\Omega f_Y(Z_\epsilon(x,t), Y_\epsilon(x,t), u(t))^T Q_\epsilon(x,t)V_\epsilon(x,t)dx
\end{aligned}
$$

and

$$
\begin{aligned}
&\frac{d}{dt}\int_{\partial\Omega} \epsilon(y)R_\epsilon(y,t)U_\epsilon(y,t)dy \\
&\quad = \int_{\partial\Omega} \epsilon(y)\left(\frac{\partial}{\partial t}R_\epsilon(y,t)U_\epsilon(y,t) + R_\epsilon(y,t)\frac{\partial}{\partial t}U_\epsilon(y,t)\right)dy \\
&\quad = \int_{\partial\Omega} (R_\epsilon(y,t)V_\epsilon(y,t) - P_\epsilon(y,t)U_\epsilon(y,t))dy \\
&\qquad + \int_{\partial\Omega} R_\epsilon(y,t)\int_\Omega K(x,y,u(t))^T W_\epsilon(x,t)dxdy
\end{aligned}
$$

and

$$
\begin{aligned}
&\frac{d}{dt}\int_\Omega Q_\epsilon(x,t)^T W_\epsilon(x,t)dx \\
&\quad = \int_\Omega \left(\frac{\partial}{\partial t}Q_\epsilon(x,t)^T W_\epsilon(x,t) + Q_\epsilon(x,t)^T\frac{\partial}{\partial t}W_\epsilon(x,t)\right)dx \\
&\quad = -\int_\Omega\int_{\partial\Omega} K(x,y,u(t))^T R_\epsilon(y,t)dyW_\epsilon(x,t)dx \\
&\qquad + \int_\Omega Q_\epsilon(x,t)^T f_Y(Z_\epsilon(x,t), Y_\epsilon(x,t), u(t))V_\epsilon(x,t)dx.
\end{aligned}
$$

For the present this calculation is justified for smooth control functions and data (cf. [7]). We conclude that for times $t \in (s,T]$

$$
\frac{d}{dt}\left(\int_\Omega (P_\epsilon(x,t)V_\epsilon(x,t) + Q_\epsilon(x,t)^T W_\epsilon(x,t))dx + \int_{\partial\Omega} \epsilon(y)R_\epsilon(y,t)U_\epsilon(y,t)dy\right) = 0
$$

holds, from which it follows that

$$
\begin{aligned}
&\int_\Omega (P_\epsilon(x,t)V_\epsilon(x,t) + Q_\epsilon(x,t)^T W_\epsilon(x,t))dx + \int_{\partial\Omega} \epsilon(y)R_\epsilon(y,t)U_\epsilon(y,t)dy \\
&\quad = \int_\Omega (P_\epsilon(x,s)V_\epsilon(x,s) + Q_\epsilon(x,s)^T W_\epsilon(x,s))dx + \int_{\partial\Omega} \epsilon(y)R_\epsilon(y,s)U_\epsilon(y,s)dy
\end{aligned}
$$

is constant for all $t \in [s,T]$. Since we can approximate any admissible control function with respect to the Ekeland metric by continuous control functions, and the terminal condition Λ and initial condition Z^0 by smooth functions, we conclude that the expression above is constant and the proof of the lemma is finished. □

5. Proof of Theorem 2.2.

The proof of the Pontryagin maximum principle for the singularly perturbed system is standard and mainly follows the unifying concept of [5], with the only differences being that by introducing the adjoint variables our maximum principle has the familiar form and that the (smooth) target set gives more information on the terminal adjoint state.

Let u^* be the optimal control for the singularly perturbed system (2), (3) and $T>0$ the arrival time. We take a sequence of times $t_n \in [0,T)$ with $t_n \to T$ and define on $L^\infty((0,T);U)$ the (positive) functional

$$F_n(u) := |L(Z_\epsilon(\cdot,t_n)(u))|.$$

We define $\delta_n := F_n(u^*) > 0$. By Ekeland's variational principle (cf. [4]), there is a control u_n with

$$d(u_n,u^*) \le \sqrt{\delta_n}, \qquad F_n(u) \ge F_n(u_n) - \sqrt{\delta_n} d(u,u_n).$$

The second inequality holds especially for the strong variation u_n^h of the control function u_n; see (6). Then the inequality can be written as

$$\frac{|L(Z_\epsilon(\cdot,t_n)(u_n^h))| - |L(Z_\epsilon(\cdot,t_n)(u_n))|}{h} \ge -\sqrt{\delta_n}\frac{d(u_n^h,u_n)}{h}.$$

Taking the limit $h\to 0+$ we obtain

$$\frac{L(Z_\epsilon(\cdot,t_n)(u_n))}{|L(Z_\epsilon(\cdot,t_n)(u_n))|}\langle \nabla L(Z_\epsilon(\cdot,t_n)(u_n), W_\epsilon(\cdot,t_n)(u_n)\rangle \ge -\sqrt{\delta_n}, \tag{10}$$

where $W_\epsilon(u_n)$ is the strong variation of the trajectory $Z_\epsilon(u_n)$; see (6). The inequality above holds for all $v\in U$ and all Lebesgue points $s\in[0,T]$ of u_n, thus for all $s\in A(n)\subset[0,T]$, where $A(n)$ is a set of full Lebesgue measure in $[0,T]$. Taking a subsequence, we can assume that $d(u_n,u^*)\le 2^{-n}$. Then we can take the limit $n\to\infty$ in (10) and get

$$\operatorname{sgn}(L(Z^0))\langle \nabla L(Z_\epsilon(\cdot,T)(u^*)), W_\epsilon(\cdot,T)(u^*)\rangle \ge 0, \tag{11}$$

where $W_\epsilon(u^*)$ is the strong variation of the trajectory $Z_\epsilon(u^*)$. Now we define the terminal condition of the adjoint system as

$$\Lambda = \operatorname{sgn}(L(Z^0))\nabla L(Z_\epsilon(\cdot,T)(u^*)).$$

Then the maximum condition (11) can be written as

$$\operatorname{sgn}(L(Z^0))\int_\Omega Q_\epsilon(x,T)(u^*)^T W_\epsilon(x,T)(u^*)dx \ge 0,$$

and using Lemma 4.2 and the initial conditions at time $t=s$ of the variational system (8) we finish the proof. □

6. Proof of Theorem 2.1. The proof of Theorem 2.1 is based on an approximation of the system (1) by the singularly perturbed system (2), (3). For this reason we need a stability statement for small perturbations $\epsilon(y)=\epsilon_n>0$ *and* controls that are close to a given nominal control.

The following lemma is a key tool. It states that, if the perturbation of the control is adapted to the singular perturbation of the system, the trajectories of the singularly perturbed system converge to trajectories of the (unperturbed) system.

LEMMA 6.1. *For any sequence $\epsilon_n\to 0$ and $u_n\in B_{\epsilon_n^2}(u)$ we have the convergence*

$$\begin{cases} Z_{\epsilon_n}(u_n)\to Z_0(u) & \text{in} \quad C([0,T_0];L^\infty(\Omega;R^n)),\\ Y_{\epsilon_n}(u_n)\to Y_0(u) & \text{in} \quad C([0,T_0];C(\overline{\Omega};R))\cap L^2((0,T);H^1(\Omega)),\end{cases} \tag{12}$$

$$(13) \qquad \begin{cases} Q_{\epsilon_n}(u_n) \to Q_0(u) & \text{in} \quad C([0,T_0];L^\infty(\Omega;R^n)), \\ R_{\epsilon_n}(u_n) \to P_0(u) & \text{in} \quad C([0,T_0];C(\partial\Omega;R)). \end{cases}$$

Proof. We will show (12). We consider the (ϵ_n-dependent) solution operator $S^u_{(X,Z)}$, which maps trajectories Y to solutions (X,Z) of (3). For the fixed control function u we can write

$$\begin{cases} Z(x,t) &= Z^0(x) + \int_0^t f(Z(x,r),Y(x,r),u(r))dr, \\ X(y,t) &= \int_0^t \frac{e^{-(t-r)/\epsilon_n}}{\epsilon_n}(\int_\Omega K(x,y,u(r))Z(x,r)dx + Y(y,r))dr. \end{cases}$$

We note that $r \mapsto \frac{e^{-(t-r)/\epsilon_n}}{\epsilon_n}$ serves as mollifier, since, as $\epsilon_n \to 0$, we have

$$\int_0^t \frac{e^{-(t-r)/\epsilon_n}}{\epsilon_n}dr = 1 - e^{-t/\epsilon_n} \to 1, \qquad \int_{t-\sqrt{\epsilon_n}}^t \frac{e^{-(t-r)/\epsilon_n}}{\epsilon_n}dr = 1 - e^{-1/\sqrt{\epsilon_n}} \to 1.$$

Thus, as $\epsilon_n \to 0$, we have the convergence in $L^1((0,T_0);C(\partial\Omega;R))$

$$\left(t \mapsto \int_0^t \frac{e^{-(t-r)/\epsilon_n}}{\epsilon_n}\left(\int_\Omega K(x,y,u(r))Z(x,r)dx + Y(y,r)\right)dr\right)$$
$$\to \left(t \mapsto \int_\Omega K(x,y,u_n(t))Z(x,t)dx + Y(y,t)\right).$$

We now take into account variations of the control function. First, we note that, as $\epsilon_n \to 0$,

$$\int_{t-{\epsilon_n}^2}^t \frac{e^{-(t-r)/\epsilon_n}}{\epsilon_n}dr = 1 - e^{-\sqrt{\epsilon_n}} \to 0.$$

Thus, if we take $u_n \in B_{\epsilon_n^2}(u)$, we still have

$$\left|\int_0^t \frac{e^{-(t-r)/\epsilon_n}}{\epsilon_n}\int_\Omega (K(x,y,u(r))) - K(x,y,u(r))Z(x,r)dxdr\right| = O(\sqrt{\epsilon_n}).$$

Hence, as $\epsilon_n \to 0$, we get the convergence in $L^1((0,T_0);C(\partial\Omega;R))$

$$\left(t \mapsto \int_0^t \frac{e^{-(t-r)/\epsilon_n}}{\epsilon_n}\left(\int_\Omega K(x,y,u_n(r))Z(x,r)dx + Y(y,r)\right)dr\right)$$
$$\to \left(t \mapsto \int_\Omega K(x,y,u(t))Z(x,t)dx + Y(y,t)\right).$$

Note that both the converging sequence and the limit are (uniformly bounded) in $L^\infty((0,T_0);C(\partial\Omega;R))$. With respect to the natural topology of $L^\infty((0,T_0);C(\partial\Omega;R))$ for X the solution operator S_Y, which maps trajectories (X,Z) to solutions Y of (2), is continuous. Also with respect to the Ekeland topology of $L^\infty((0,T_0);C(\partial\Omega;R))$ for X we get continuity of S_Y (see Theorem 5.1 in [3]). Both continuity properties imply continuity of S_Y with respect to the $L^1((0,T_0);C(\partial\Omega;R))$ topology for X! Just use the fact that a sequence X_n in $L^\infty((0,T_0);C(\partial\Omega;R))$, which converges in $L^1((0,T_0);C(\partial\Omega;R))$, necessarily uniformly approximates the limit on a sequence of sets $A_n \subset (0,T_0)$ with increasing Lebesgue measure $\lambda(A_n) \to T_0$. All in all, we conclude that the fixed point of the contraction $S_Y \circ S^{u_n}_{(X,Z)}$ tends in $L^1([0,T];C(\partial\Omega)) \times$

$C([0,T]; L^\infty(\Omega; R^n))$ to $t \mapsto (\int_\Omega K(x,y,u)Z_0(x,t)(u)dx + Y_0(y,t)(u), Z_0(x,t)(u))$, and similarly the fixed point of the contraction $S^{u_n}_{(X,Z)} \circ S_Y$ tends to $Y_0(u)$. The proof of (13) is completely analogous. We just have to take into account that the equation for R in the singularly perturbed adjoint system is stable in backwards time and the same singular perturbation technique works again. The proof of the lemma is finished. □

Let u_0^* be the optimal control for the system (1) and $T_0 > 0$ the arrival time. We take sequences of times $t_n \in [0, T_0)$ and of perturbation parameters $\epsilon_n > 0$, with $t_n \to T_0$ and $\epsilon_n \to 0$, as $n \to \infty$. We define the functional

$$F_n(u) := |L(Z_{\epsilon_n}(\cdot, t_n)(u))|$$

obtained with the trajectory $Z_{\epsilon_n}(u)$ of the singularly perturbed system (2), (3) with $\epsilon(y) := \epsilon_n > 0$ for all $y \in \partial\Omega$.

Lemma 6.2. *For every sequence $t_n \to T_0$, $t_n \in [0, T_0)$, there is a sequence $\epsilon_n \to 0$, $\epsilon_n > 0$, and a sequence of radii $\mu_n \to 0$, $\mu_n > 0$, such that, for $n \in N$ large enough, the functional F_n is positive on the ball $B_{\mu_n}(u_0^*)$. $\delta_n := F_n(u_0^*)$ especially is positive, for $n \in N$ large enough. Furthermore $\delta_n := F_n(u_0^*) \to 0$, as $n \to \infty$.*

Proof. According to Lemma 6.1, applied to $u = u_0^*$, we have

$$Z_{\epsilon_n}(u_n) \to Z_0(u_0^*)$$

if $u_n \in B_{\epsilon_n^2}(u_0^*)$. It follows that

$$L(Z_{\epsilon_n}(\cdot, t_n)(u_n)) \to L(Z_0(\cdot, t_n)(u_0^*))$$

uniformly in $t_n \in [0, T_0]$, if $u_n \in B_{\epsilon_n^2}(u_0^*)$. By optimality of u_0^* we have

$$|L(Z_0(\cdot, t_n)(u_0^*))| > 0$$

for every $t_n \in [0, T_0)$. Thus, if we choose $0 < \mu_n \le \epsilon_n^2$ small enough, the functional F_n is positive on $B_{\mu_n}(u_0^*)$. It also follows that $\delta_n \to 0$ and the proof of the lemma is finished. □

Since $\delta_n = F_n(u_0^*)$ is positive, for $n \in N$ large enough, we get, as in the proof of Theorem 2.2 for a $u_n \in B_{\mu_n}(u_0^*) \cap B_{\sqrt{\delta_n}}(u_0^*)$,

$$\frac{L(Z_{\epsilon_n}(\cdot, t_n)(u_n))}{|L(Z_{\epsilon_n}(\cdot, t_n)(u_n))|} \langle \nabla L(Z_{\epsilon_n}(\cdot, t_n)(u_n)), W_{\epsilon_n}(\cdot, t_n)(u_n) \rangle \ge -\sqrt{\delta_n},$$

where $W_{\epsilon_n}(u_n)$ is the strong variation of the trajectory $Z_{\epsilon_n}(u_n)$; see (7). We conclude by Lemma 4.2 and by the initial conditions of (8) that

$$\begin{aligned} -\sqrt{\delta_n} \le {} & \int_\Omega Q_{\epsilon_n}(x,s)\,(f(Z_{\epsilon_n}(x,s), Y_{\epsilon_n}(x,s), v) - f(Z_{\epsilon_n}(x,s), Y_{\epsilon_n}(x,s), u_n(s)))\,dx \\ & + \int_{\partial\Omega} R_{\epsilon_n}(y,s) \int_\Omega (K(x,y,v) - K(x,y,u_n(s)))Z_{\epsilon_n}(x,s)dy, \end{aligned} \tag{14}$$

where $Q_{\epsilon_n} = Q_{\epsilon_n}(u_n)$ and $R_{\epsilon_n} = R_{\epsilon_n}(u_n)$ are solutions of the adjoint system

$$(15) \quad \left\{ \begin{array}{rcl} \frac{\partial}{\partial t}P(x,t) & = & -\Delta P(x,t) - f_Y(Z_{\epsilon_n}(x,t), Y_{\epsilon_n}(x,t), u_n(t))^T Q(x,t), \\ \frac{\partial}{\partial N(y)}P(y,t) & = & R(y,t) - P(y,t), \\ \epsilon(y)\frac{\partial}{\partial t}R(y,t) & = & R(y,t) - P(y,t), \\ \frac{\partial}{\partial t}Q(x,t) & = & -f_Z(Z_{\epsilon_n}(x,t), Y_{\epsilon_n}(x,t), u(t))^T Q(x,t) \\ & & - \int_{\partial\Omega} K(x,y,u_n(t))R(y,t)dy, \\ P(x,t_n) & = & 0, \\ R(y,t_n) & = & 0, \\ Q(x,t_n) & = & \mathrm{sgn}(L(Z^0))\nabla L(Z_{\epsilon_n}(\cdot,t_n)(u_n)) \end{array} \right.$$

obtained with terminal conditions at time $t = t_n$, with the control u_n and with $\epsilon(y) = \epsilon_n$. Since, as a slight adaptation of the proof of Lemma 6.1 shows, we have the convergence of the trajectories of (15) to the trajectories of (4), obtained with terminal conditions at time $t = T_0$ and with the control u_0^*, thus the maximum principle follows from (14) and the proof is finished. □

PRIMAL-DUAL STRATEGY FOR CONSTRAINED OPTIMAL CONTROL PROBLEMS*

MAÏTINE BERGOUNIOUX[†], KAZUFUMI ITO[‡], AND KARL KUNISCH[§]

Abstract. An algorithm for efficient solution of control constrained optimal control problems is proposed and analyzed. It is based on an active set strategy involving primal as well as dual variables. For discretized problems sufficient conditions for convergence in finitely many iterations are given. Numerical examples are given and the role of the strict complementarity condition is discussed.

Key words. active set, augmented Lagrangian, primal-dual method, optimal control

1. Introduction and formulation of the problem.

In the recent past significant advances have been made in efficiently solving nonlinear optimal control problems. Most of the proposed methods are based on variations of the sequential quadratic programming (SQP) technique; see for instance [HT, KeS, KuS, K, T] and the references therein. The SQP-algorithm is sequential and each of its iterations requires the solution of a quadratic minimization problem subject to linearized constraints. If these auxiliary problems contain inequality constraints with infinite dimensional image space, then their solution is still a significant challenge.

In this paper we propose an algorithm for the solution of infinite dimensional quadratic problems with linear equality constraints and pointwise affine inequality constraints. It is based on an active set strategy involving primal and dual variables. It thus differs significantly from conventional active set strategies that involve primal variables only; see [Sch] for example. In practice the proposed algorithm behaves like an infeasible one. The iterates of the algorithm violate the constraints up to the next-to-last iterate. The algorithm stops at a feasible and optimal solution.

Within this paper we do not aim for generality but rather we treat as a model problem a unilateral control constraint optimal control problem related to elliptic partial differential equations. The distributed nature of this problem, which is reflected in the fact that it behaves like an obstacle problem for the biharmonic equation, makes it difficult to analyze.

Let us briefly outline the contents of the paper. The algorithm will be presented in section 2. We prove that if the algorithm produces the same active set in two consecutive iterates, then the optimal solution has been obtained. In section 3 we shall give sufficient conditions which guarantee that an augmented Lagrangian functional behaves as a decreasing merit function for the algorithm. In practice this implies finite

step convergence of the discretized problem. Section 4 is devoted to showing that for a minor modification of the algorithm the cost functional is increasing until the feasible optimal solution is reached. In section 5 several numerical examples are given. For most examples the algorithm behaves extremely efficiently and typically converges in less than five iterations. Thus, to present interesting cases the majority of the test examples is in some sense extreme: either the strict complementarity condition is violated or the cost of the control is nearly zero.

To describe the problem, let Ω be an open, bounded subset of $\mathbb{R}^N$, $N \leq 3$, with smooth boundary Γ and consider the following distributed optimal control problem:

$$(\mathcal{P}) \qquad \min \quad J(y,u) = \frac{1}{2}\int_\Omega (y - z_d)^2\, dx + \frac{\alpha}{2}\int_\Omega (u - u_d)^2\, dx,$$

$$(1.1) \qquad -\Delta y = u \text{ in } \Omega, \quad y = 0 \quad \text{on } \Gamma,$$

$$(1.2) \qquad u \in U_{ad} \subset L^2(\Omega),$$

where $z_d,\ u_d \in L^2(\Omega),\ \alpha > 0$, and $U_{ad} = \{\ u \in L^2(\Omega) \mid u(x) \leq b(x) \text{ a.e. in } \Omega\},\ b \in L^\infty(\Omega)$.

It is well known that for every $u \in L^2(\Omega)$ system (1.1) has a unique solution $y = \mathcal{T}(u)$ in $H^2(\Omega) \cap H^1_o(\Omega)$.

REMARK 1.1. *To emphasis the basic ideas of the proposed approach we treated the rather simple problem* $(\mathcal{P})$. *Many generalizations are possible. In particular, the analysis of this paper can be extended to the case where* $-\Delta$ *in* (1.1) *is replaced by any strictly elliptic second order differential operator. The algorithm itself can be easily adapted to other optimal control problems involving, for example, ordinary differential equations. Its numerical efficiency as well as the convergence analysis require some additional research.*

It is standard that problem $(\mathcal{P})$ has a unique solution (y^*, u^*) characterized by the following optimality system:

$$\begin{cases} -\Delta y^* = u^* \text{ in } \Omega, \quad y^* \in H^1_o(\Omega), \\ -\Delta p^* = z_d - y^* \text{ in } \Omega, \quad p^* \in H^1_o(\Omega), \\ (\alpha(u^* - u_d) - p^*, u - u^*) \geq 0 \qquad \text{for all } u \in U_{ad}, \end{cases}$$

where $(\cdot,\cdot)$ denotes the $L^2(\Omega)$-inner product.

Let us give an equivalent formulation for this optimality system, which is essential to motivate the forthcoming algorithm.

THEOREM 1.1. *The unique solution* (y^*, u^*) *to problem* $(\mathcal{P})$ *is characterized by*

$$(\mathcal{S}) \qquad \begin{cases} -\Delta y^* = u^* \ \text{in } \Omega, \quad y^* \in H^1_o(\Omega), \\ -\Delta p^* = z_d - y^* \ \text{in } \Omega, \quad p^* \in H^1_o(\Omega), \\ u^* = u_d + \dfrac{p^* - \lambda^*}{\alpha}, \\ \lambda^* = c\left[u^* + \dfrac{\lambda^*}{c} - \Pi\left(u^* + \dfrac{\lambda^*}{c}\right)\right] = c \max\left(0, u^* + \dfrac{\lambda^*}{c} - b\right) \end{cases}$$

for every $c > 0$. *Here* Π *denotes the projection of* $L^2(\Omega)$ *onto* U_{ad}.

Proof. We refer to [IK]. □

We point out that the last equation in $(\mathcal{S})$,

$$\lambda^* = c\left[u^* + \frac{\lambda^*}{c} - \Pi\left(u^* + \frac{\lambda^*}{c}\right)\right], \tag{1.3}$$

is equivalent to

$$\lambda^* \in \partial I_{U_{ad}}(u^*), \tag{1.4}$$

where ∂I_C denotes the subdifferential of the indicator function I_C of a convex set C. This follows from general properties of convex functions (see [IK] for example) and can also easily be verified directly for the convex function $I_{U_{ad}}$. The replacement of the well-known differential inclusion (1.4) [B] in the optimality system for $(\mathcal{P})$ by (1.3) is an essential ingredient of the algorithm that we shall propose.

Here and below, order relations like "max" and "$\leq$" between elements of $L^2(\Omega)$ are understood in the pointwise almost everywhere (a.e.) sense.

Let us interpret the optimality system $(\mathcal{S})$. From $-\Delta y^* = u_d + \frac{p^*-\lambda^*}{\alpha}$ it follows that $p^* = \alpha[-\Delta y^* - u_d] + \lambda^*$ and hence

$$-\alpha\Delta y^* - \Delta^{-1}y^* + \lambda^* = \alpha\ u_d - \Delta^{-1}z_d.$$

It follows that

$$\begin{aligned} \alpha u^* + \Delta^{-2}u^* + \lambda^* &= \alpha u_d - \Delta^{-1}z_d\ , \\ \lambda^* &= c\max\left(0, u^* + \frac{\lambda^*}{c} - b\right) \qquad \text{for all } c > 0, \end{aligned}$$

which implies the highly distributed nature of the optimal control. Setting $\mathcal{H} = \alpha I + \Delta^{-2}$ and $f = \alpha u_d - \Delta^{-1}z_d$, system $(\mathcal{S})$ can be expressed as

$$(\mathcal{S}_1) \quad \left\{ \begin{aligned} \mathcal{H}u^* + \lambda^* &= f, \\ \lambda^* &= c\max\left(0, u^* + \frac{\lambda^*}{c} - b\right) \qquad \text{for all } c > 0. \end{aligned} \right.$$

We observe that by setting $u = -\Delta y$, system $(\mathcal{S})$ constitutes an optimality system for the variational inequality,

$$\left\{ \begin{array}{l} \min \dfrac{\alpha}{2}\displaystyle\int_\Omega |\Delta y|^2 dx + \dfrac{1}{2}\displaystyle\int_\Omega |y - (z_d - \alpha\ \Delta u_d)|^2 dx, \\ y \in H_o^1(\Omega) \cap H^2(\Omega), \\ -\Delta y \leq b, \end{array} \right.$$

the regularity of which was studied in [BS].

2. Presentation of the algorithm. In this section we present the primal-dual active set algorithm and discuss some of its basic properties. Let us introduce the active and inactive sets for the solution to $(\mathcal{P})$ and define

$$\mathcal{A}^* = \{\ x \mid u^*(x) = b \ \text{ a.e. }\} \text{ and } \mathcal{I}^* = \{\ x \mid u^*(x) < b \ \text{ a.e. }\}.$$

The proposed strategy is based on (1.3). Given (u_{n-1}, λ_{n-1}) the active set for the current iterate is chosen as

$$\mathcal{A}_n = \left\{\ x \mid u_{n-1}(x) + \frac{\lambda_{n-1}(x)}{c} > b \ \text{ a.e. } \right\}.$$

We recall that $\lambda^* \geq 0$ and in the case of strict complementarity $\lambda^* > 0$ on $\mathcal{A}^*$. The complete algorithm is specified next.

Algorithm.

1. Initialization: choose $y_o,\ u_o$, and λ_o and set $n = 1$.
2. Determine the following subsets of Ω:

$$\mathcal{A}_n = \left\{\ x \mid u_{n-1}(x) + \frac{\lambda_{n-1}(x)}{c} > b\ \right\},\ \mathcal{I}_n = \left\{\ x \mid u_{n-1}(x) + \frac{\lambda_{n-1}(x)}{c} \le b\ \right\}.$$

3. If $n \ge 2$ and $\mathcal{A}_n = \mathcal{A}_{n-1}$, then STOP.
4. Else, find $(y_n, p_n) \in H^1_o(\Omega) \times H^1_o(\Omega)$ such that

$$-\Delta y_n = \begin{cases} b & \text{in } \mathcal{A}_n, \\ u_d + \dfrac{p_n}{\alpha} & \text{in } \mathcal{I}_n, \end{cases}$$
$$-\Delta p_n = z_d - y_n \quad \text{in } \Omega$$

and set

$$u_n = \begin{cases} b & \text{in } \mathcal{A}_n, \\ u_d + \dfrac{p_n}{\alpha} & \text{in } \mathcal{I}_n. \end{cases}$$

5. Set $\lambda_n = p_n - \alpha(u_n - u_d)$, update $n = n + 1$, and goto 2.

The existence of the triple (y_n, u_n, p_n) satisfying the system of step 4 of the algorithm follows from the fact that it constitutes the optimality system for the auxiliary problem

$$(\mathcal{P}_{aux}) \qquad \min\ \{\ J(y,u) \mid y \in H^1_o(\Omega),\ -\Delta y = u \text{ in } \Omega,\ u = b \text{ on } \mathcal{A}_n\ \},$$

which has (y_n, u_n) as unique solution.

We may use different initialization schemes. The one that was used most frequently is the following:

$$\text{(2.1)} \qquad \begin{cases} u_o = b, \\ -\Delta y_o = u_o,\ y_o \in H^1_o(\Omega), \\ -\Delta p_o = z_d - y_o,\ p_o \in H^1_o(\Omega), \\ \lambda_o = \max(0, \alpha(u_d - b) + p_o). \end{cases}$$

This choice of initialization has the property of feasibility. Alternatively, we tested the algorithm with initialization as the solution of the unconstrained problem, i.e.,

$$\text{(2.2)} \qquad \begin{cases} \lambda_o = 0, \\ -\Delta y_o = u_d + \dfrac{p_o}{\alpha}, & y_o \in H^1_o(\Omega), \\ -\Delta p_o = z_d - y_o, & p_o \in H^1_o(\Omega), \\ u_o = u_d + \dfrac{p_o}{\alpha}. \end{cases}$$

For all examples the first initialization behaved better than or equal to the second.

The initialization process (2.1) has the property that the first set $\mathcal{A}_1$ is always included in the active set $\mathcal{A}^*$ of problem $(\mathcal{P})$. More precisely we have the following lemma.

Lemma 2.1. *If (u_o, y_o, λ_o) are given by (2.1) with $u_o \ge u^*$, then $\lambda_o \le \lambda^*$. In addition, if $u_o = b$, then $\mathcal{A}_1 \subset \mathcal{A}^*$.*

Proof. The proof is the construction

$$\lambda_o = \max(0, \alpha(u_d - u_o) + p_o) = \max(0, \alpha(u_d - u_o) + \Delta^{-1}(y_o - z_d))$$

and as a consequence of $(\mathcal{S})$,

$$\lambda^* = \alpha(u_d - u^*) + p^* = \alpha(u_d - u^*) + \Delta^{-1}(y^* - z_d) = \alpha(u_d - u^*) - \Delta^{-2}u^* - \Delta^{-1}z_d \ \geq 0.$$

It follows that $\lambda^* - \lambda_o = \lambda^* \geq 0$ if $\alpha(u_d - u_o) + \Delta^{-1}(y_o - z_d) \leq 0$, and $\lambda^* - \lambda_o = \alpha(u_o - u^*) + \Delta^{-2}(u_o - u^*) + \alpha(u_d - u_o) + \Delta^{-1}(y_o - z_d)$ else.

If $u_o \geq u^*$, the maximum principle yields $\Delta^{-2}(u_o - u^*) \geq 0$ and

$$\lambda^* - \lambda_o \begin{cases} = \ \lambda^* \geq 0 & \text{if } \alpha(u_d - u_o) + \Delta^{-1}(y_o - z_d) \leq 0, \\ \geq \alpha(u_d - u_o) + \Delta^{-1}(y_o - z_d) \geq 0 & \text{else.} \end{cases}$$

Therefore $\lambda_o \leq \lambda^*$.

In addition, if $u_o = b$, then $u_o + \frac{\lambda_o}{c} = b + \frac{\lambda_o}{c} > b$ on $\mathcal{A}_1$. Consequently $\lambda_o > 0$ on $\mathcal{A}_1$ and $\lambda^* > 0$. It follows that $\mathcal{A}_1 \subset \mathcal{A}^*$ and the proof is complete. □

A first convergence result which also justifies the stopping criterion in step 3 is given in the following theorem.

Theorem 2.1. *If there exists $n \in \mathbb{N} - \{0\}$ such that $\mathcal{A}_n = \mathcal{A}_{n+1}$, then the algorithm stops and the last iterate satisfies*

$$(\mathcal{S}_n) \qquad \begin{cases} -\Delta y_n = u_n = \begin{cases} b & \textit{in } \mathcal{A}_n, \\ u_d + \dfrac{p_n}{\alpha} & \textit{in } \Omega - \mathcal{A}_n, \end{cases} \\ -\Delta p_n = z_d - y_n \quad \textit{in } \Omega, \\ \lambda_n = p_n - \alpha(u_n - u_d), \ u_n \in U_{ad}, \end{cases}$$

with

$$\lambda_n = 0 \ \textit{on } \mathcal{I}_n \qquad \textit{and} \qquad \lambda_n > 0 \ \textit{on } \mathcal{A}_n. \tag{2.3}$$

Therefore, the last iterate is the solution of the original optimality system $(\mathcal{S})$.

Proof. If there exists $n \in \mathbb{N} - \{0\}$ such that $\mathcal{A}_n = \mathcal{A}_{n+1}$, then it is clear that the algorithm stops and the last iterate satisfies $(\mathcal{S}_n)$ by construction, except possibly for $u_n \in U_{ad}$. Thus we have to prove $u_n \in U_{ad}$ and (2.3).

- On $\mathcal{I}_n$ we have $\lambda_n = 0$ by step 5 of the algorithm. Moreover, $u_n + \frac{\lambda_n}{c} = u_n \leq b$, since $\mathcal{I}_n = \mathcal{I}_{n+1}$.
- On $\mathcal{A}_n$ we get $u_n = b$ and $u_n + \frac{\lambda_n}{c} > b$ since $\mathcal{A}_n = \mathcal{A}_{n+1}$. Therefore $\lambda_n > 0$ on $\mathcal{A}_n$ and $u_n \in U_{ad}$.

To prove that the last iterate is a solution of the original optimality system $(\mathcal{S})$, it remains to show that

$$\lambda_n = c\left[u_n + \frac{\lambda_n}{c} - \Pi\left(u_n + \frac{\lambda_n}{c}\right)\right].$$

- On $\mathcal{I}_n$ we have $\lambda_n = 0$ and $u_n + \frac{\lambda_n}{c} = u_n \leq b$. It follows that

$$u_n + \frac{\lambda_n}{c} - \Pi\left(u_n + \frac{\lambda_n}{c}\right) = u_n - \Pi(u_n) = 0 = \lambda_n.$$

- On $\mathcal{A}_n$ we get $u_n = b$, $\lambda_n > 0$ and therefore

$$c\left[u_n + \frac{\lambda_n}{c} - \Pi\left(u_n + \frac{\lambda_n}{c}\right)\right] = c\left[b + \frac{\lambda_n}{c} - b\right] = \lambda_n. \qquad \square$$

Now we give a structural property of the algorithm.

LEMMA 2.2. *If u_n is feasible for some $n \in \mathbb{N} - \{0\}$ (i.e., $u_n \le b$), then $\mathcal{A}_{n+1} \subset \mathcal{A}_n$.*

Proof. On $\mathcal{I}_n$ we get $\lambda_n = 0$ by construction so that $u_n + \frac{\lambda_n}{c} = u_n \le b$ (because of feasibility). This implies $\mathcal{I}_n \subset \mathcal{I}_{n+1}$ and consequently $\mathcal{A}_{n+1} \subset \mathcal{A}_n$. □

Note that Theorem 2.1 and in particular (2.3) do not utilize or imply strict complementarity. In fact, if (2.3) holds, then the set of x for which $u_n(x) = b$ and $\lambda_n(x) = 0$ is contained in $\mathcal{I}_n$.

We end this section with simple cases, where we may conclude easily that the algorithm is convergent.

THEOREM 2.2. *For initialization* (2.1), *the algorithm converges in one iteration in the following cases:*

1. $z_d \le 0,\ u_d = 0,\ b \ge 0$ *and the solution to* $-\alpha\Delta u - \Delta^{-1}u = z_d$ *is nonpositive.*

2. $z_d \ge 0,\ b \le 0,\ u_d > b$ *or* $z_d \ge 0,\ b \le 0,\ u_d \ge b$ *and* $z_d + \Delta^{-1}b$ *is not zero as element in* $L^2(\Omega)$.

Proof. Let us first examine case 1. The maximum principle implies that $-\Delta^{-1}u_o \ge 0$. Consequently $z_d + \Delta^{-1}u_o \le 0$ and by a second application of the maximum principle

$$-\Delta^{-1}(z_d + \Delta^{-1}u_o) \le 0.$$

Together with the fact that $u_d - b = -b \le 0$, this implies

$$\lambda_o = \max(0, \alpha(u_d - b) - \Delta^{-1}(z_d + \Delta^{-1}u_o)) = 0.$$

Therefore $\mathcal{A}_1 = \emptyset$ and $\mathcal{I}_1 = \Omega$.

Using the first iteration we obtain $u_1 = \frac{p_1}{\alpha}$ in Ω. Moreover, $-\Delta y_1 = u_1$ and $-\Delta p_1 = z_d - y_1$ imply that

$$-\alpha\Delta u_1 - \Delta^{-1}u_1 = z_d.$$

By assumption u_1 is feasible. Therefore $\mathcal{A}_2 = \mathcal{A}_1 = \emptyset$ and by Theorem 2.1 the algorithm stops at the solution to $(\mathcal{P})$.

Now we consider case 2. By assumption and due to (2.1) we have $z_d \ge 0,\ b \le 0,\ \lambda_o \ge 0$, and $\mathcal{A}_1 = \{\ \lambda_o > 0\ \}$. Due to the maximum principle $-\Delta^{-1}u_o \le 0$ and

$$p_o = -\Delta^{-1}(z_d - y_o) = -\Delta^{-1}[z_d - (-\Delta^{-1}u_o)] \ge 0.$$

Moreover, if $z_d + \Delta^{-1}b$ is not the zero element in $L^2(\Omega)$, then $p_o > 0$ in Ω and $\alpha(u_d - b) + p_o > \alpha(u_d - b)$.

If $u_d > b$ or ($u_d = b$ and $z_d + \Delta^{-1}b \ne 0$), then $\lambda_o = \max(0, \alpha(u_d - b) + p_o) > 0$ in Ω (and $\lambda_o = 0$ on $\partial\Omega$). Consequently $\mathcal{A}_1 = \Omega$ and $u_1 = b$, $\lambda_1 = -\Delta^{-1}(z_d + \Delta^{-1}b) + \alpha(u_d - b) > 0$. This yields $\mathcal{A}_2 = \mathcal{A}_1 = \Omega$ and the algorithm stops. □

3. Convergence analysis.

3.1. The continuous case. The convergence analysis of the algorithm is based on the decrease of appropriately chosen merit functions. For that purpose we define the following augmented Lagrangian functions:

$$L_c(y, u, \lambda) = J(y, u) + (\lambda, \hat{g}_c(u, \lambda)) + \frac{c}{2}\|\hat{g}_c(u, \lambda)\|^2 \quad \text{and} \quad \hat{L}_c(y, u, \lambda) = L_c(y, u, \lambda^+),$$

where $(\cdot,\cdot)$ is the $L^2(\Omega)$-inner product, $\|\cdot\|$ is the $L^2(\Omega)$-norm, $\lambda^+ = \max(\lambda, 0)$, and $\hat{g}_c(u, \lambda) = \max(g(u), -\frac{\lambda}{c})$ with $g(u) = u - b$. Further $(\cdot,\cdot)_{|S}$ and $\|\cdot\|_{|S}$ denote the L^2-inner product and norm on a measurable subset $S \subset \Omega$. Note that the mapping

$$u \mapsto (\lambda, \hat{g}_c(u, \lambda)) + \frac{c}{2}\|\hat{g}_c(u, \lambda)\|^2$$

is $\mathcal{C}^1$, which is not the case for the function given by

$$u \mapsto (\lambda, g(u)) + \frac{c}{2}\|\max(g(u),0)\|^2.$$

The following relationship between primal and dual variables will be essential.

LEMMA 3.1. *For all $n \in \mathbb{N} - \{0\}$ and $(y,u) \in H^1_o(\Omega) \times L^2(\Omega)$ satisfying $-\Delta y = u$ we have*

$$J(y_n,u_n) - J(y,u) = -\frac{1}{2}\|y-y_n\|^2 - \frac{\alpha}{2}\|u-u_n\|^2 + (\lambda_n, u-u_n)_{|\mathcal{A}_n}\,. \tag{3.1}$$

Proof. Using $\|a\|^2 - \|b\|^2 = -\|a-b\|^2 + 2\,(a-b,a)$ and steps 4 and 5 of the algorithm, we find that

$$\begin{aligned}J(y_n,u_n)-J(y,u) &= -\frac{1}{2}\|y-y_n\|^2-\frac{\alpha}{2}\|u-u_n\|^2+(y_n-y,y_n-z_d)+\alpha\,(u_n-u,u_n-u_d)\\ &= -\frac{1}{2}\|y-y_n\|^2-\frac{\alpha}{2}\|u-u_n\|^2+(\Delta(y_n-y),p_n)+\alpha\,(u_n-u,u_n-u_d)\\ &= -\frac{1}{2}\|y-y_n\|^2-\frac{\alpha}{2}\|u-u_n\|^2+(u_n-u,-p_n+\alpha(u_n-u_d))\\ &= -\frac{1}{2}\|y-y_n\|^2-\frac{\alpha}{2}\|u-u_n\|^2+(u-u_n,\lambda_n)\,.\end{aligned}$$

Because $\lambda_n = 0$ on $\mathcal{I}_n$ the result follows. □

Let us define

$$\mathcal{S}_{n-1} = \{\ x \in \mathcal{A}_{n-1} \mid \lambda_{n-1}(x) \le 0\ \} \ \text{ and } \mathcal{T}_{n-1} = \{\ x \in \mathcal{I}_{n-1} \mid u_{n-1}(x) > b(x)\ \}.$$

These two sets can be paraphrased by calling $\mathcal{S}_{n-1}$ the set of elements that the active set strategy predicts to be active at level $n-1$ but the Lagrange multiplier indicates should be inactive and by calling $\mathcal{T}_{n-1}$ the set of elements that was predicted to be inactive but the $(n-1)$st iteration level corrects it to be active. We note that

$$\Omega = (\mathcal{I}_{n-1}\backslash\mathcal{T}_{n-1}) \cup \mathcal{T}_{n-1} \cup \mathcal{S}_{n-1} \cup (\mathcal{A}_{n-1}\backslash\mathcal{S}_{n-1}) \tag{3.2}$$

defines a decomposition of Ω in mutually disjoint sets. Moreover, we have the following relation between these sets at each level n:

$$\mathcal{I}_n = (\mathcal{I}_{n-1}\backslash\mathcal{T}_{n-1}) \cup \mathcal{S}_{n-1}, \qquad \mathcal{A}_n = (\mathcal{A}_{n-1}\backslash\mathcal{S}_{n-1}) \cup \mathcal{T}_{n-1}. \tag{3.3}$$

In fact, as $\Omega = \mathcal{I}_n \cup \mathcal{A}_n$ it is sufficient to prove that

$$(\mathcal{I}_{n-1}\backslash\mathcal{T}_{n-1}) \cup \mathcal{S}_{n-1} \subset \mathcal{I}_n \qquad \text{and} \qquad (\mathcal{A}_{n-1}\backslash\mathcal{S}_{n-1}) \cup \mathcal{T}_{n-1} \subset\ \mathcal{A}_n,$$

that is

$$\mathcal{S}_{n-1} \subset \mathcal{I}_n \quad \text{and} \quad \mathcal{T}_{n-1} \subset\ \mathcal{A}_n.$$

Since $\mathcal{S}_{n-1} \subset \mathcal{A}_{n-1}$ we find $u_{n-1} = b$ on $\mathcal{S}_{n-1}$. From the definition of $\mathcal{S}_{n-1}$ we conclude that $\lambda_{n-1} \le 0$ so that $u_{n-1} + \frac{\lambda_{n-1}}{c} \le b$. This implies $\mathcal{S}_{n-1} \subset \mathcal{I}_n$. The verification of $\mathcal{T}_{n-1} \subset\ \mathcal{A}_n$ is quite similar.

For the convenience of the reader we present these sets in Figure 3.1.

In Figure 3.1 the shaded region depicts $\mathcal{I}_n$ and the white region is $\mathcal{A}_n$. Table 3.1 depicts the signs of primal and dual variables for two consecutive iteration levels.

Below, $\|\Delta^{-1}\|$ will denote the operator norm of Δ^{-1} in $\mathcal{L}(L^2(\Omega))$.

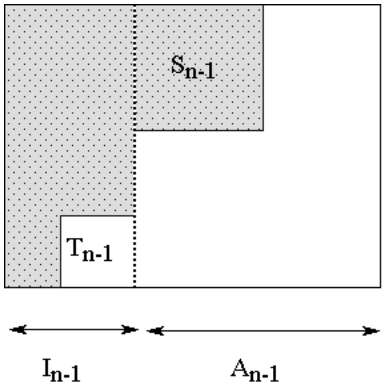

FIG. 3.1. *Decomposition of Ω at levels $n-1$ and n.*

TABLE 3.1

	λ_{n-1}	λ_n	u_{n-1}	u_n
$\mathcal{T}_{n-1} = \mathcal{I}_{n-1} \cap \mathcal{A}_n$	0		$> b$	$= b$
$\mathcal{S}_{n-1} = \mathcal{A}_{n-1} \cap \mathcal{I}_n$	≤ 0	0	$= b$	
$\mathcal{I}_{n-1} \backslash \mathcal{T}_{n-1}$ $(\subset \mathcal{I}_n)$	0	0	$\leq b$	
$\mathcal{A}_{n-1} \backslash \mathcal{S}_{n-1}$ $(\subset \mathcal{A}_n)$	> 0		$= b$	$= b$

THEOREM 3.1. *If $\mathcal{A}_n \neq \mathcal{A}_{n-1}$ and*

$$\alpha + \gamma \leq c \leq \alpha - \frac{\alpha^2}{\gamma} + \frac{\alpha^2}{\|\Delta^{-1}\|^2} \tag{3.4}$$

for some $\gamma > 0$, then $\hat{L}_c(y_n, u_n, \lambda_n) \leq \hat{L}_c(y_{n-1}, u_{n-1}, \lambda_{n-1})$. In addition, if the second inequality of (3.4) *is strict, then either $\hat{L}_c(y_n, u_n, \lambda_n) < \hat{L}_c(y_{n-1}, u_{n-1}, \lambda_{n-1})$ or the algorithm stops at the solution to* $(\mathcal{S})$*.*

Proof. A short computation gives

$$(\lambda, \hat{g}_c(u, \lambda)) + \frac{c}{2}\|\hat{g}_c(u, \lambda)\|^2$$

$$= \left(\frac{1}{\sqrt{c}}\lambda, \sqrt{c}\ \hat{g}_c(u, \lambda)\right) + \frac{1}{2}\left(\sqrt{c}\ \hat{g}_c(u, \lambda), \sqrt{c}\ \hat{g}_c(u, \lambda)\right)$$

$$= \frac{1}{2}\ \left\|\sqrt{c}\max\left(g(u), -\frac{\lambda}{c}\right) + \frac{1}{\sqrt{c}}\lambda\right\|^2 - \frac{1}{2c}\|\lambda\|^2$$

$$= \frac{1}{2}\left\|\max\left(\sqrt{c}\ g(u), -\frac{\lambda}{\sqrt{c}}\right) + \frac{1}{\sqrt{c}}\ \lambda\right\|^2 - \frac{1}{2c}\|\lambda\|^2$$

$$= \frac{1}{2c}\|\max(c\ g(u) + \lambda, 0)\|^2 - \frac{1}{2c}\|\lambda\|^2.$$

Moreover, for all (y, u, λ) we find

$$L_c(y, u, \lambda) = J(y, u) + \frac{1}{2c}\|\max(c\,g(u) + \lambda, 0)\|^2 - \frac{1}{2c}\|\lambda\|^2. \tag{3.5}$$

By assumption $\mathcal{A}_n \neq \mathcal{A}_{n-1}$ and hence $\mathcal{S}_{n-1} \cup \mathcal{T}_{n-1} \neq \emptyset$. Using (3.5) we get

$$\begin{aligned}
&\hat{L}_c(y_n, u_n, \lambda_n) - \hat{L}_c(y_{n-1}, u_{n-1}, \lambda_{n-1})\\
&= J(y_n, u_n) - J(y_{n-1}, u_{n-1})\\
&+\frac{1}{2c}\left[\|\max(c\;g(u_n) + \lambda_n^+, 0)\|^2 - \|\lambda_n^+\|^2 - \|\max(c\;g(u_{n-1}) + \lambda_{n-1}^+, 0)\|^2 + \|\lambda_{n-1}^+\|^2\right]
\end{aligned}$$

and by (3.1)

$$\begin{aligned}
&\hat{L}_c(y_n, u_n, \lambda_n) - \hat{L}_c(y_{n-1}, u_{n-1}, \lambda_{n-1})\\
&= -\frac{1}{2}\|y_{n-1} - y_n\|^2 - \frac{\alpha}{2}\|u_{n-1} - u_n\|^2 + (u_{n-1} - u_n, \lambda_n)_{\mathcal{T}_{n-1}}\\
&+\frac{1}{2c}\left[\|\max(c\;g(u_n) + \lambda_n^+, 0)\|^2 - \|\lambda_n^+\|^2 - \|\max(c\;g(u_{n-1}) + \lambda_{n-1}^+, 0)\|^2 + \|\lambda_{n-1}^+\|^2\right].
\end{aligned} \tag{3.6}$$

It will be convenient to introduce

$$\begin{aligned}
d(x) = |\max(c\,g(u_n(x)) + \lambda_n^+(x), 0)|^2 - |\lambda_n^+(x)|^2 - |\max(c\,g(u_{n-1}(x))\\
+ \lambda_{n-1}^+(x), 0)|^2 + |\lambda_{n-1}^+(x)|^2.
\end{aligned}$$

Let us estimate d on the four distinct subsets of Ω according to (3.2).

1. On $\mathcal{I}_{n-1}\backslash\mathcal{T}_{n-1}$ we have $\lambda_n(x) = \lambda_{n-1}(x) = 0,\ u_{n-1}(x) \leq b(x)\ (g(u_{n-1}(x)) \leq 0)$, and

$$d(x) = |\max(c\,g(u_n(x)), 0)|^2 - |\max(c\,g(u_{n-1}(x)), 0)|^2 \leq c^2|u_n(x) - u_{n-1}(x)|^2.$$

Moreover, as $\lambda_n = p_n - \alpha(u_n - u_d) = 0$ and $\lambda_{n-1} = p_{n-1} - \alpha(u_{n-1} - u_d) = 0$ we have $u_n(x) - u_{n-1}(x) = \frac{p_n(x) - p_{n-1}(x)}{\alpha}$ so that

$$|u_n(x) - u_{n-1}(x)| \leq \frac{1}{\alpha}|p_n(x) - p_{n-1}(x)| \quad \text{on } \mathcal{I}_{n-1}\backslash\mathcal{T}_{n-1}.$$

2. On $\mathcal{S}_{n-1}$, $\lambda_n(x) = 0$, $\lambda_{n-1}(x) \leq 0$, $g(u_{n-1}(x)) = 0$ so that $d(x) = |\max(c\,g(u_n(x)), 0)|^2$. Here we used the positivity of λ^+ to get $\lambda_{n-1}^+(x) = 0$. To estimate $d(x)$ in detail we consider first the case where $u_n(x) \geq b(x)$. Since $x \in \mathcal{S}_{n-1} \subset \mathcal{I}_n$ we obtain $\lambda_n(x) = p_n(x) - \alpha[u_n(x) - u_d(x)] = 0$ and hence $u_n(x) = \frac{p_n(x)}{\alpha} + u_d(x)$. Moreover, $\lambda_{n-1}(x) = p_{n-1}(x) - \alpha[u_{n-1}(x) - u_d(x)] \leq 0$ so that $u_d(x) - b(x) \leq -\frac{p_{n-1}(x)}{\alpha}$, where we used $u_{n-1}(x) = b(x)$. Since by assumption $u_n(x) \geq b$ these estimates imply

$$\begin{aligned}
|u_n(x) - u_{n-1}(x)| &= u_n(x) - b(x)\\
&= \frac{p_n(x)}{\alpha} + u_d(x) - b(x) \leq \frac{p_n(x)}{\alpha} - \frac{p_{n-1}(x)}{\alpha} = \frac{1}{\alpha}\,|p_n(x) - p_{n-1}(x)|.
\end{aligned}$$

In addition it is clear that on the set $\mathcal{I}_n$

$$d(x) = |\max(c\,g(u_n(x)), 0)|^2 \leq c^2|u_n(x) - u_{n-1}(x)|^2.$$

In the second case, $u_n(x) < b(x)$ so that $\max(c\,g(u_n(x)), 0) = 0$ and $d(x) = 0$. Finally, we have a precise estimate on the whole set $\mathcal{I}_n$. Let us denote

$$\mathcal{I}_n^* = \mathcal{I}_{n-1}\backslash\mathcal{T}_{n-1} \cup \{x \in \mathcal{S}_{n-1} \mid u_n(x) \geq b(x)\} \;= \mathcal{I}_n\backslash\{x \in \mathcal{S}_{n-1} \mid u_n(x) < b(x)\};$$

then

$$\int_{\mathcal{I}_n} d(x)\;dx = \int_{\mathcal{I}_n^*} d(x)\;dx = c^2\|\max(g(u_n), 0)\|^2_{\mathcal{I}_n^*} \leq c^2\;\|u_n - u_{n-1}\|^2_{\mathcal{I}_n^*}. \tag{3.7}$$

We note that we have proved in addition that

$$\|u_n - u_{n-1}\|_{\mathcal{I}_n^*} \le \frac{\|\Delta^{-1}\|}{\alpha}\|y_n - y_{n-1}\|. \tag{3.8}$$

3. On $\mathcal{A}_{n-1}\backslash\mathcal{S}_{n-1}$ we have $g(u_{n-1}(x)) = g(u_n(x)) = 0,\ \lambda_{n-1}(x) > 0$ and hence

$$d(x) = |\max(\lambda_n^+(x), 0)|^2 - |\lambda_n^+(x)|^2 \le 0. \tag{3.9}$$

4. On $\mathcal{T}_{n-1}$ we have $\lambda_{n-1}(x) = 0,\ g(u_n(x)) = 0,\ g(u_{n-1}(x)) > 0$ and thus

$$d(x) = -c^2|g(u_{n-1}(x))|^2 = -c^2|u_n(x) - u_{n-1}(x)|^2. \tag{3.10}$$

Next we estimate the term $(\lambda_n, u_{n-1} - u_n)_{\mathcal{T}_{n-1}}$ in (3.6):

$$\begin{aligned}(\lambda_n, u_{n-1} - u_n)_{\mathcal{T}_{n-1}} &= (\lambda_n - \lambda_{n-1}, u_{n-1} - u_n)_{\mathcal{T}_{n-1}}\\ &= (p_n - p_{n-1}, u_{n-1} - u_n)_{\mathcal{T}_{n-1}} + \alpha\|u_n - u_{n-1}\|^2_{\mathcal{T}_{n-1}}\end{aligned}$$

and therefore

$$\begin{aligned}&(\lambda_n, u_{n-1} - u_n)_{\mathcal{T}_{n-1}}\\ &\qquad \le \|\Delta^{-1}\|\ \|y_n - y_{n-1}\|_\Omega\|u_n - u_{n-1}\|_{\mathcal{T}_{n-1}} + \alpha\|u_n - u_{n-1}\|^2_{\mathcal{T}_{n-1}}.\end{aligned} \tag{3.11}$$

Inserting (3.7)–(3.11) into (3.6) we find

$$\begin{aligned}&\hat{L}_c(y_n, u_n, \lambda_n) - \hat{L}_c(y_{n-1}, u_{n-1}, \lambda_{n-1})\\ &\le -\frac{1}{2}\|y_{n-1} - y_n\|^2 - \frac{\alpha}{2}\|u_{n-1} - u_n\|^2_{\mathcal{I}_n^*} - \frac{\alpha}{2}\|u_{n-1} - u_n\|^2_{\mathcal{I}_n\backslash\mathcal{I}_n^*} - \frac{\alpha}{2}\|u_{n-1} - u_n\|^2_{\mathcal{T}_{n-1}}\\ &+\|\Delta^{-1}\|\ \|y_n - y_{n-1}\|_\Omega\|u_n - u_{n-1}\|_{\mathcal{T}_{n-1}} + \alpha\|u_n - u_{n-1}\|^2_{\mathcal{T}_{n-1}}\\ &+\frac{c}{2}\|u_{n-1} - u_n\|^2_{\mathcal{I}_n^*} - \frac{c}{2}\|u_{n-1} - u_n\|^2_{\mathcal{T}_{n-1}}.\end{aligned} \tag{3.12}$$

Using $ab \le \frac{1}{2}(\frac{a^2}{\rho} + \rho b^2)$ for every $\rho > 0$ and relation (3.8), we get for $c \ge \alpha$

$$\begin{aligned}&\hat{L}_c(y_n, u_n, \lambda_n) - \hat{L}_c(y_{n-1}, u_{n-1}, \lambda_{n-1})\\ &\le -\frac{1}{2}\|y_{n-1} - y_n\|^2 + \frac{(c-\alpha)}{2}\|u_{n-1} - u_n\|^2_{\mathcal{I}_n^*} + \frac{(\alpha - c)}{2}\|u_{n-1} - u_n\|^2_{\mathcal{T}_{n-1}}\\ &+\frac{\|\Delta^{-1}\|}{2\rho}\|y_{n-1} - y_n\|^2 + \frac{\rho\|\Delta^{-1}\|}{2}\|u_{n-1} - u_n\|^2_{\mathcal{T}_{n-1}}\\ &\le -\frac{1}{2}\|y_{n-1} - y_n\|^2 + \frac{(c-\alpha)\|\Delta^{-1}\|^2}{2\alpha^2}\|y_{n-1} - y_n\|^2\\ &+\frac{\alpha - c + \rho\|\Delta^{-1}\|}{2}\|u_{n-1} - u_n\|^2_{\mathcal{T}_{n-1}} + \frac{\|\Delta^{-1}\|}{2\rho}\|y_{n-1} - y_n\|^2\\ &= \frac{1}{2}\left[(c-\alpha)\frac{\|\Delta^{-1}\|^2}{\alpha^2} + \frac{\|\Delta^{-1}\|}{\rho} - 1\right]\|y_{n-1} - y_n\|^2\\ &+\frac{1}{2}(\alpha + \rho\|\Delta^{-1}\| - c)\|u_{n-1} - u_n\|^2_{\mathcal{T}_{n-1}}.\end{aligned}$$

Setting $\gamma = \rho\|\Delta^{-1}\|$, then $\hat{L}_c(y_n, u_n, \lambda_n) \le \hat{L}_c(y_{n-1}, u_{n-1}, \lambda_{n-1})$ provided that

$$\left[\left[\frac{(c-\alpha)}{\alpha^2} + \frac{1}{\gamma}\right]\|\Delta^{-1}\|^2 - 1\right] \le 0 \quad \text{and} \quad \alpha + \gamma - c \le 0.$$

The latter condition is equivalent to

$$\alpha + \gamma \leq c \leq \alpha - \frac{\alpha^2}{\gamma} + \frac{\alpha^2}{\|\Delta^{-1}\|^2}. \tag{3.4}$$

If the second inequality is strict, then $\hat{L}_c(y_n, u_n, \lambda_n) < \hat{L}_c(y_{n-1}, u_{n-1}, \lambda_{n-1})$ except if $y_n = y_{n-1}$. In this latter case $u_n = u_{n-1}$ and the algorithm stops at the solution to $(\mathcal{S})$. □

REMARK 3.1. *Note that for the choice $\gamma = \alpha$ condition* (3.4) *is equivalent to*

$$2\,\alpha \leq c \leq \frac{\alpha^2}{\|\Delta^{-1}\|^2}. \tag{3.13}$$

REMARK 3.2. *If there exists γ such that* (3.4) *holds, then necessarily*

$$c > \alpha \geq 2\|\Delta^{-1}\|^2$$

holds. Indeed, assume that $\alpha < 2\|\Delta^{-1}\|^2$. Then

$$\alpha + \gamma < \alpha - \frac{\alpha^2}{\gamma} + 2\alpha,$$

that is

$$\gamma^2 - 2\alpha\gamma + \alpha^2 = (\gamma - \alpha)^2 < 0,$$

which is a contradiction.

3.2. The discrete case. So far we have given a sufficient condition for $\hat{L}_c$ to act as a merit function for which the algorithm has a strict descent property. In particular this eliminates the possibility of chattering of the algorithm: it will not return to the same active set a second time. If the control and state spaces are discretized, then the descent property can be used to argue convergence in a finite number of steps. More precisely, assume that a finite difference or finite element–based approximation to $(\mathcal{P})$ results in

$$(\mathcal{P}^{N,M}) \qquad \begin{array}{l} \min \quad J^{N,M}(Y,U) = \frac{1}{2}\|M_1^{\frac{1}{2}}(Y - Z_d)\|_{\mathbb{R}^N}^2 + \frac{\alpha}{2}\|M_2^{\frac{1}{2}}(U - U_d)\|_{\mathbb{R}^M}^2, \\ S\,Y = M_3\,U, \\ U \leq B. \end{array}$$

Here Y and Z_d denote vectors in $\mathbb{R}^N$ corresponding to the discretization of y and z_d, and U, U_d, and B denote vectors in $\mathbb{R}^M$, corresponding to the discretizations of u, u_d, and b. Furthermore M_1, S, and M_2 are, respectively, $N \times N$, $N \times N$, and $M \times M$ positive definite matrices while M_3 is an $N \times M$ matrix. The norms in $(\mathcal{P}^{N,M})$ denote Euclidean norms and the inequality is understood coordinatewise. Finally, it is assumed that M_2 is a diagonal matrix. It is simple to argue the existence of a solution (Y^*, U^*) to $(\mathcal{P}^{N,M})$. A first order optimality system is given by

$$\left\{ \begin{array}{rcl} S\,Y^* &=& M_3\,U^*, \\ S\,P^* &=& -M_1(Y^* - Z_d), \\ U^* &=& U_d + \frac{1}{\alpha}M_2^{-1}(M_3^\top P^* - \Lambda^*), \\ \Lambda^* &=& c\max\left(0, U^* + \frac{1}{c}\Lambda^* - B\right), \end{array} \right. \tag{3.14}$$

with $(P^*, \Lambda^*) \in \mathbb{R}^N \times \mathbb{R}^M$ for every $c > 0$. Here max is understood coordinatewise. The algorithm for the discretized problem is given next.

Discretized algorithm.

1. Initialization: choose Y^o, U^o, and Λ^o, and set $n = 1$.
2. Determine the following subsets of $\{1, \dots, M\}$:

$$A_n = \left\{ i \mid U_i^{n-1} + \frac{1}{c}\Lambda_i^{n-1} > B_i \right\}, \quad I_n = \{1, \dots, M\} \backslash A_n.$$

3. If $n \geq 2$ and $A_n = A_{n-1}$, then STOP.
4. Else, find $(Y^n, P^n) \in \mathbb{R}^N \times \mathbb{R}^N$ such that

$$\begin{aligned} S\,Y^n &= M_3 \begin{cases} B & \text{in } A_n, \\ U_d + \dfrac{1}{\alpha} M_2^{-1} M_3^\top \; P^n & \text{in } I_n, \end{cases} \\ S\,P^n &= -M_1(Y^n - Z_d) \end{aligned}$$

and set

$$U^n = \begin{cases} B & \text{in } A_n, \\ U_d + \dfrac{1}{\alpha} M_2^{-1} M_3^\top \; P^n & \text{in } I_n. \end{cases}$$

5. Set $\Lambda^n = M_3^\top P^n - \alpha M_2 (U^n - U_d)$, update $n = n + 1$, and goto 2.

The following corollary describing properties of the discretized algorithm can be obtained with techniques analogous to those utilized above for analyzing the continuous algorithm. We shall denote

$$\underline{m_2} = \min_i (M_2)_{i,i}, \qquad \overline{m_2} = \max_i (M_2)_{i,i}, \qquad \text{and } K = \|M_2^{-1} M_3^\top\| \; \|S^{-1} M_1\|.$$

Corollary 3.1. *If*

$$\overline{m_2}\,(\alpha + \gamma) \leq c < \alpha\,\underline{m_2} - \frac{\alpha^2}{\gamma} + \frac{\alpha^2 \|M_1\|}{K} \tag{3.15}$$

holds for some $\gamma > 0$, then the discretized algorithm converges in finitely many steps to the solution of $(\mathcal{P}^N)$.

Proof. First we observe that if the discretized algorithm stops in step 3, then the current iterate gives the unique solution. Then we show with an argument analogous to that of the proof of Theorem 3.1 that with (3.15) holding, we have $L_c^{N,M}(Y_n, U_n, \Lambda_n) < L_c^{N,M}(Y_{n-1}, U_{n-1}, \Lambda_{n-1})$ or $(Y_n, U_n) = (Y_{n-1}, U_{n-1})$, where the discretized merit function is given by

$$\begin{aligned} L_c^{N,M}(Y, U, \Lambda) = {} & \frac{1}{2} \|M_1^{\frac{1}{2}} \; (Y - Z_d)\|^2_{\mathbb{R}^N} \\ & + \frac{\alpha}{2} \|M_2^{\frac{1}{2}} \; (U - U_d)\|^2_{\mathbb{R}^M} \\ & + (\Lambda, \hat{g}_c(U, \Lambda))_{\mathbb{R}^M} + \frac{c}{2} \|\hat{g}_c(U, \Lambda)\|^2_{\mathbb{R}^M} \end{aligned}$$

with $\hat{g}_c(U, \Lambda) = (\max(U_1 - B_1, -\frac{\Lambda_1}{c}), \dots, \max(U_M - B_M, -\frac{\Lambda_M}{c}))^\top$. If $(Y_n, U_n) = (Y_{n-1}, U_{n-1})$, then $A_{n+1} = A_n$ and the discretized algorithm stops at the solution. The case $L_c^{N,M}(Y_n, U_n, \Lambda_n) < L_c^{N,M}(Y_{n-1}, U_{n-1}, \Lambda_{n-1})$ cannot occur for infinitely many n since there are only finitely many different combinations of active index sets. In fact, assume that there exists $p < n$ such that $A_n = A_p$ and $I_n = I_p$. Since (Y_n, U_n)

is a solution of the optimality system of step 4 if and only if (Y_n, U_n) is the unique solution of

$$\min\{\ J^{N,M}(y,u) \mid S\ Y = M_3\ U,\ U = B \ \text{ in } A_n\ \},$$

it follows that $Y_n = Y_p$, $U_n = U_p$, and $\Lambda_n = \Lambda_p$. This contradicts $L_c^{N,M}(Y_n, U_n, \Lambda_n) < L_c^{N,M}(Y_p, U_p, \Lambda_p)$ and ends the proof. □

REMARK 3.3. *Note that for* $\gamma = \frac{\alpha}{\underline{m_2}}$ *condition* (3.15) *is satisfied if*

$$\overline{m_2}\,\alpha\left(1 + \frac{1}{\underline{m_2}}\right) \le c < \frac{\alpha^2 \|M_1\|}{K}.$$

Therefore, one can choose $c = \overline{m_2}\,\alpha\,(1 + \frac{1}{\underline{m_2}})$ *for any*

$$\alpha > \frac{\overline{m_2} K}{\|M_1\|}\left(1 + \frac{1}{\underline{m_2}}\right).$$

4. Ascent properties of the algorithm. In the previous section sufficient conditions for convergence of the algorithm in terms of α, c, and $\|\Delta^{-1}\|$ were given. Numerical experiments showed that the algorithm converges also for values of α, c, and $\|\Delta^{-1}\|$ which do not satisfy the conditions of Theorem 3.1. In fact the only possibility of constructing an example for which the algorithm has some difficulties (which will be made precise in the following section) is based on violating the strict complementarity condition.

Thus one is challenged to further justify theoretically the efficient behavior of the algorithm. In the tests that were performed it was observed that the cost functional was always increasing so that in practice the algorithm behaves like an infeasible algorithm. To parallel theoretically this behavior of the algorithm as far as possible, we slightly modify the algorithm. For the modified algorithm an ascent property of the cost J will be shown.

MODIFIED ALGORITHM.

1. Initialization: choose u_o, y_o, and λ_o; set $n = 1$.
2. (a) Determine the following subsets of Ω:

$$\mathcal{A}_n = \left\{\ x \mid u_{n-1}(x) + \frac{\lambda_{n-1}(x)}{c} > b \right\},\quad \mathcal{I}_n = \left\{\ x \mid u_{n-1}(x) + \frac{\lambda_{n-1}(x)}{c} \le b \right\},$$

(b) and find $(\tilde{y}, \tilde{p}) \in H_o^1(\Omega) \times H_o^1(\Omega)$ such that

$$\begin{aligned} -\Delta \tilde{y} &= \begin{cases} b & \text{in } \mathcal{A}_n, \\ u_d + \dfrac{\tilde{p}}{\alpha} & \text{in } \mathcal{I}_n, \end{cases} \\ -\Delta \tilde{p} &= z_d - \tilde{y} \ \text{ in } \Omega, \end{aligned}$$

and set

$$\tilde{u} = \begin{cases} b & \text{in } \mathcal{A}_n, \\ u_d + \dfrac{\tilde{p}}{\alpha} & \text{in } \mathcal{I}_n. \end{cases}$$

3. $\tilde{\lambda} = \tilde{p} - \alpha(\tilde{u} - u_d)$.

4. Set

$$\widetilde{\mathcal{A}} = \left\{ x \mid \tilde{u}(x) + \frac{\tilde{\lambda}(x)}{c} > b \right\}.$$

If $\widetilde{\mathcal{A}} = \mathcal{A}_n$, then STOP, else goto 5.

5. Check for $J(\tilde{y}, \tilde{u}) > J(y_{n-1}, u_{n-1})$.
   (a) If $J(\tilde{y}, \tilde{u}) > J(y_{n-1}, u_{n-1})$, then

   $n = n+1,\ y_n = \tilde{y},\ u_n = \tilde{u},\ \lambda_n = \tilde{\lambda}$, and goto 2(a).

   (b) Otherwise, determine

$$\mathcal{T}_{n-1} = \{\ x \in \mathcal{I}_{n-1} \mid u_{n-1}(x) > b\ \}.$$

   - If measure of $\mathcal{T}_{n-1}$ is null, then STOP;
   - else set

$$\mathcal{A}_n = \mathcal{A}_{n-1} \cup \mathcal{T}_{n-1}, \quad \mathcal{I}_n = \mathcal{I}_{n-1} \backslash \mathcal{T}_{n-1},$$

   then goto 2(b).

THEOREM 4.1. *If the modified algorithm stops in step* 4, *then* $(\tilde{u}, \tilde{y}, \tilde{\lambda})$ *is the solution to* $(\mathcal{S})$. *If it never stops in step* 5(b), *then the sequence* $J(y_n, u_n)$ *(*$n \geq 2$*) is strictly increasing and converges to some* J^*.

Proof. Let us first assume that the algorithm stops in step 4. In case $\mathcal{A}_n$ is calculated from 2(a), then $(\tilde{u}, \tilde{y}, \tilde{\lambda})$ is the solution to $(\mathcal{S})$ by Theorem 2.1. If $\mathcal{A}_n$ is determined from 5(b), then an argument analogous to that used in the proof of Theorem 2.1 allows us to argue that again $(\tilde{u}, \tilde{y}, \tilde{\lambda})$ is the solution to $(\mathcal{S})$.

Next we assume that the algorithm never stops in step 4. Let us consider an iteration level, where the check for ascent in step 5(a) is not passed. Consequently $\mathcal{A}_n$ and $\mathcal{I}_n$ are redefined according to step 5(b) and $(\tilde{y}, \tilde{u})$ are recalculated from 2(b). We have already noticed that $(\tilde{y}, \tilde{u})$ is a solution of the optimality system of step 2(b) if and only if $(\tilde{y}, \tilde{u})$ is the unique solution of

$$(\mathcal{P}_{aux}) \qquad \min\{\ J(y,u) \mid -\Delta y = u \text{ in } \Omega, y \in H^1_o(\Omega),\ u = b \text{ in } \mathcal{A}_n\ \}.$$

Since $\mathcal{A}_n = \mathcal{A}_{n-1} \cup \mathcal{T}_{n-1}$ strictly contains $\mathcal{A}_{n-1}$ it necessarily follows that

$$(4.1) \qquad J(y_{n-1}, u_{n-1}) \leq J(\tilde{y}, \tilde{u}).$$

It will be shown next that equality in (4.1) is impossible. In fact if $J(\tilde{y}, \tilde{u}) = J(y_{n-1}, u_{n-1})$, then due to uniqueness of the solution to $(\mathcal{P}_{aux})$ it follows that $(\tilde{y}, \tilde{u}) = (y_{n-1}, u_{n-1})$ and consequently $\tilde{\lambda} = \lambda_{n-1}$. On $\mathcal{A}_n = \mathcal{A}_{n-1} \cup \mathcal{T}_{n-1}$, we get $\tilde{u} = b = u_{n-1}$. This implies that $u_{n-1} = b$ on $\mathcal{T}_{n-1}$ and gives a contradiction to the assumption that the measure of $\mathcal{T}_{n-1}$ is non-null. Hence $J(y_{n-1}, u_{n-1}) = J(\tilde{y}, \tilde{u})$ is impossible. Together with (4.1) it follows that $J(y_{n-1}, u_{n-1}) < J(\tilde{y}, \tilde{u})$ and thus the sequence $\{J(y_n, u_n)\}$ generated by the modified algorithm is strictly increasing. The pair (y_b, b) with $-\Delta y_b = b$ in Ω is feasible for all $(\mathcal{P}_{aux})$ so that $J(y_n, u_n) \leq J(y_b, b)$. It follows that $J(y_n, u_n)$ is convergent to some J^*.

We note in addition that $\tilde{u}$ is feasible since $\tilde{u} = u_{n-1} = u_{n-1} + \frac{\lambda_{n-1}}{c} \leq b$ on $\mathcal{I}_n$ $(\lambda_{n-1} = \tilde{\lambda} = 0$ on $\mathcal{I}_n)$. □

The previous result can be strengthened in the case where $(\mathcal{P})$ is discretized as in subsection 3.1.

Corollary 4.1. *If the modified algorithm is discretized as described in the previous section and if it never stops in step* 5(b), *then the (discretized) solution is obtained in finitely many steps.*

Proof. Unless the algorithm stops in step 4, the values of $J^N(Y_n, U_n)$ $(n \geq 2)$ are strictly increasing. As argued in the proof of Corollary 3.1, at each level of the iteration the minimization is carried out over an active set different from all those that have been computed before. As there are only finitely many different possibilities for active sets, the modified algorithm terminates in step 4 at the unique solution of $(\mathcal{S})$. □

We have not found a numerical example in which the modified algorithm terminates in step 5(b).

5. Numerical experiments. In this section we report on numerical tests with the proposed algorithm. For these tests we chose $\Omega =]0,1[\times]0,1[$ and the five-point finite difference approximation of the Laplacian. Unless otherwise specified the discretization was carried out on a uniform mesh with grid size 1/50.

For the chosen dimension $\|\Delta^{-1}\| = \frac{1}{2\pi^2}$ so that $\frac{1}{\|\Delta^{-1}\|^2} = 4\pi^4 \simeq 390$. Relation (3.13), which is required for the applicability of Theorem 3.1, is satisfied if $\alpha \geq 5.\ 10^{-3}$ to get the convergence via Theorem 3.1. Nevertheless we have also tested the method for smaller values of α.

The tests were performed on a Hewlett-Packard workstation using the MATLAB package.

5.1. Example 1. We set

$$z_d(x_1, x_2) = \sin\ (2\pi x_1)\ \sin\ (2\pi x_2)\ \exp(2x_1)/6, \quad b \equiv 0.$$

Several tests for different values for α, c, and u_d were performed. We present two of them. In the first one (3.13) is satisfied with strict inequalities; see Table 5.1.

Plots of the optimal state and optimal control are shown in Figure 5.1.

We present in Table 5.2 a second example where (3.13) is not fulfilled because α is too small; in addition u_d has been chosen infeasible.

Although the size of the set $\mathcal{A}_n$, in the sense of number of grid points, in $\mathcal{A}_n$ is increasing, the sequence $\mathcal{A}_n$ does not increase monotonically. More precisely, points in $\mathcal{A}_n$ at iteration n may not belong to $\mathcal{A}_{n+1}$ at iteration $n+1$.

We observe numerically that the algorithm stops as soon as an iterate is feasible. Thus the sequence of iterates is not feasible until it reaches the solution. We could say that we have an "outer" method. We must also underline that unlike with classical primal active set methods, the primal-dual method that we propose can move a lot of points from one iteration to the next.

We compared the new algorithm to an Uzawa method for the augmented Lagrangian with Gauss–Seidel splitting. For convenience we recall that algorithm.

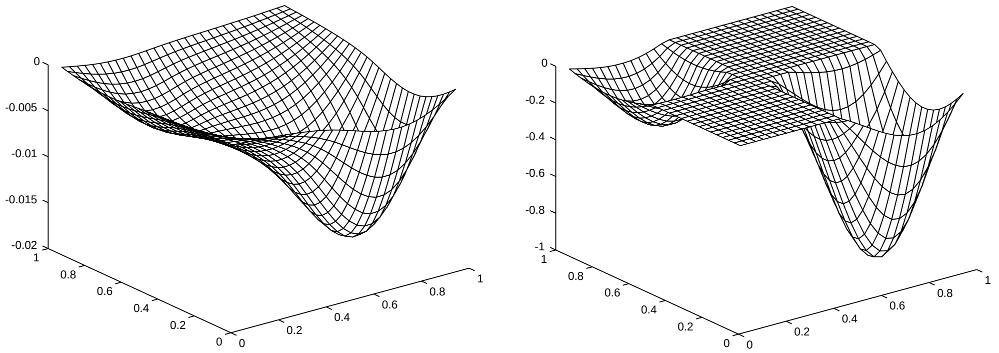

FIG. 5.1. *Optimal state (left), optimal control (right).*

ALGORITHM UGS.

- Step 1. Initialization: Set $n = 1$ and choose $\gamma > 0$.
  Choose $q_o \in L^2(\Omega)$ and $u_{-1} \in L^2(\Omega)$.
- Step 2. Choose $k_n \in \mathbb{N}$, set $u_n^{-1} = u_{n-1}$, and for $j = 0, \ldots, k_n$

$$\begin{aligned} y_n^j &= \text{ Arg min } \{\ L_\gamma(y, u_n^{j-1}, q_n) \mid y \in H^2(\Omega) \cap H_o^1(\Omega)\ \}, \\ u_n^j &= \text{ Arg min } \{\ L_\gamma(y_n^j, u, q_n) \mid u \in U_{ad}\ \}. \end{aligned}$$

  End of the inner loop: $y_n = y_n^{k_n}, u_n = u_n^{k_n}$.
- Step 3.

$$q_{n+1} = q_n + \frac{\rho}{k_n + 1} \sum_{j=0}^{k_n} (Ay_n^j - u_n^j), \qquad \text{where } \rho \in (0, 2\gamma],$$

where

$$L_\gamma(y, u, q) = J(y, u) + (q, Ay - u)_{L^2(\Omega)} + \frac{\gamma}{2} \|Ay - u\|_{L^2(\Omega)}^2.$$

For this algorithm a detailed convergence analysis was given in [BK]. Due to the splitting technique the second constrained minimization in Step 2 can be carried out by a simple algebraic manipulation. Algorithm UGS is an iterative algorithm that approximates the solution (y^*, u^*), whereas the new algorithm obtains the exact (discretized) solution. For Example 1(a) (Table 5.1) the computing time was 61

Table 5.3
$u_o \equiv 0\ (\equiv b)$.

Iteration	$\max(u_n - b)$	size of $\mathcal{A}_n$	$J(y_n, u_n)$	$L_c(y_n, u_n, \lambda_n)$	$\hat{L}_c(y_n, u_n, \lambda_n)$
1	4.4409e-15	1385	4.296739e-02	4.296739e-02	4.296739e-02

seconds whereas Algorithm UGS with accuracy set at 10^{-3} was stopped after 105 minutes. At that moment the difference between the algorithm and Algorithm UGS was

$$|J_{ugs} - J(y^*, u^*)| \approx 4.10^{-8},\ \|y_{ugs} - y^*\|_{L^\infty} \approx 8.10^{-7},\ \text{and}\ \|u_{ugs} - u^*\|_{L^\infty} \approx 4.10^{-6},$$

where the index "ugs" refers to the result from Algorithm UGS. For Example 1(b) (Table 5.2) the algorithm took 191 seconds whereas Algorithm UGS was stopped after 120 minutes.

5.2. Example 2. The desired state z_d, b is set as in the previous example and $\alpha = 10^{-2}$, $c = 10^{-1}$. See Table 5.3. This example has been constructed such that there is no strict complementarity at the solution. More precisely we have set $u_d = b - \frac{1}{\alpha}[-\Delta^{-1} z_d + \Delta^{-2} b]$ so that the exact solution of problem $(\mathcal{P})$ is $u^* = b = 0$ and $\lambda^* = 0$ and hence λ^* is not positive where the constraint is active. This example was considered by means of the optimality system $(\mathcal{S})$ of Theorem 1.1.

In this example the canonical initial guess u_o coincides with the solution u^*. From Table 5.3 we observe that u_n, $J(y_n, u_n)$, $L_c(y_n, u_n)$, and $\hat{L}_c(y_n, u_n)$ remain constant while the active sets $\mathcal{A}_n$ chatter. For different initial guesses for u_o the same type of behavior is observed, the algorithm always reaches the optimal value for u and J in one iteration, and if the stopping criterion of the algorithm was based on the coincidence of two consecutive values of J, it would stop after one iteration. The chattering of active sets is due to lack of strict complementarity and machine precision. Let us briefly consider this phenomenon and note at first that the signs in the algorithm are set such that at the limit we should have $\Omega = \mathcal{I}^*$ (all inactive with $\lambda^* = u^* = 0$). If $x \in \mathcal{A}_{n-1}$, then $u_{n-1}(x) = 0$ by step 4 and $\lambda_{n-1}(x) = \pm\varepsilon$, with ε equal to the computer epsilon, will decide whether $x \in \mathcal{A}_n$ or $\mathcal{I}_n$, although for numerical purposes the exact pair for (u, λ) is already obtained. If $x \in \mathcal{I}_{n-1}$, then $\lambda_{n-1} = 0$ and $u_{n-1}(x) = \pm\varepsilon$ will decide whether $x \in \mathcal{A}_n$ or $\mathcal{I}_n$, while the influence of this choice on J or L_c is of the order of ε^2, i.e., it is numerically zero. Therefore we decided to replace "$> b$" in the definition of $\mathcal{A}_n$ by "$> b - \varepsilon$ " (and $\mathcal{I}_n = \Omega \backslash \mathcal{A}_n$): the algorithm now behaves as expected and stops after two iterations.

5.3. Example 3. We have seen with Example 1 (Tables 5.1 and 5.2) that the augmented Lagrangian function decreases during iterations. We show with this example that the augmented Lagrangian function may not decrease although the method is convergent and provides the exact solution. Let us precise the data:

$$z_d = \begin{cases} 200\ x_1 x_2\ (x_1 - \frac{1}{2})^2\ (1 - x_2) & \text{if } 0 < x_1 \le 1/2, \\ 200\ x_2\ (x_1 - 1)(x_1 - \frac{1}{2})^2\ (1 - x_2) & \text{if } 1/2 < x_1 \le 1, \end{cases}$$

$$u_d \equiv 0,\ b \equiv 1,\ c = 10^{-2}.$$

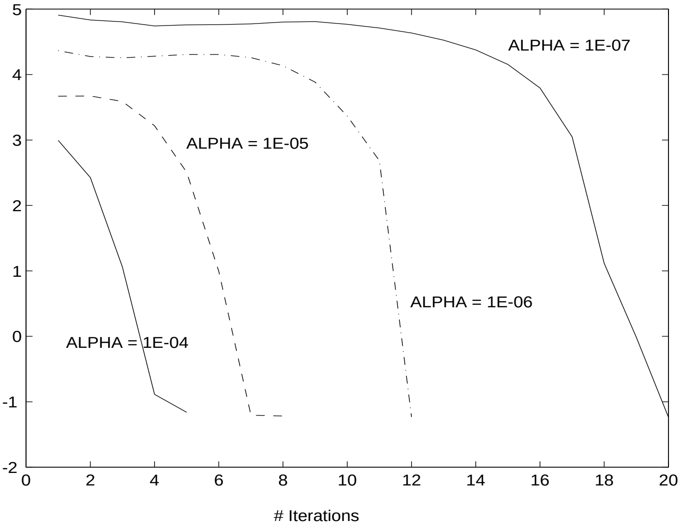

Fig. 5.2. *Influence of α on the behavior of L_c (logarithmic scale).*

See Table 5.4. The solution was obtained in 210 seconds.

The plot in Figure 5.2 shows the influence of α on the behavior of the Lagrangian function L_c.

We see that during the first iterations the augmented Lagrangian function does not decrease if α is too small.

However, if the initialization point is close enough to the solution, then this function decreases. We have tested initialization points different from b which were closer to the solution and obtained decrease of L_c. As an example we give in Table 5.5 the results for $\alpha = 10^{-10}$ with an initialization according to (2.1) but with u_o the solution for $\alpha = 10^{-5}$.

Note that the total number of iterations including the initialization with $\alpha = 10^{-5}$ to obtain the solution corresponding to $\alpha = 10^{-10}$ is equal to 18. If one computes the solution with initialization $u_o = b$, the number of iterations is 27 and L_c decreases

TABLE 5.5
Example 3(b): $\alpha = 10^{-10}$, u_o *given by the solution to* $(\mathcal{P})$ *for* $\alpha = 10^{-5}$.

Iteration	$\max(u_n - b)$	Size of $\mathcal{A}_n$	$J(y_n, u_n)$	$L_c(y_n, u_n, \lambda_n)$

9	0.0000e+00	2182	5.795061e-02	5.795061e-02
10	0.0000e+00	2182	5.795061e-02	5.795061e-02

after iteration 12. Thus a good initial guess can decrease the number of iterations to obtain the solution. This process was repeated successfully for smaller values of α up to $\alpha = 10^{-15}$ as well.

REGULARITY OF THE MINIMUM TIME FUNCTION AND MINIMUM ENERGY PROBLEMS: THE LINEAR CASE[*]

FAUSTO GOZZI[†] AND PAOLA LORETI[‡]

Abstract. We prove new results on the continuity properties and on reachable sets of the minimum time function associated with a linear dynamical system in a separable Hilbert space H. Part of the results are new also in the finite dimensional case. The regularity results are stated thanks to the result we obtain on the connection between the minimum time function and the minimum energy.

Key words. null controllability, minimum time function, minimum energy problems

1. Introduction.

This paper is devoted to the study of continuity properties of the minimum time function associated with a linear dynamical system in finite and infinite dimensions. We consider a separable Hilbert space H (the state space) with norm $|\cdot|$ and scalar product $\langle\cdot,\cdot\rangle$ and we consider a controlled dynamical system in H whose behavior is described by the following linear Cauchy problem in H:

$$\begin{cases} y'(t) = Ay(t) + Bu(t); \quad t > 0, \\ y(0) = x \in H, \end{cases} \tag{1}$$

where $A : D(A) \subset H \to H$ is a closed linear operator that generates a strongly continuous semigroup e^{tA} on H. Moreover, $u : [0, +\infty[\to U$ is a measurable function with values in another Hilbert space U (the space of control parameters) and $B : U \to H$ is a continuous linear operator. Given $u \in L^1_{loc}(0, +\infty; U)$, there exists a unique mild solution to (1) in $[0, +\infty)$ given by (see, e.g., Pazy [28])

$$y(t; x, u) = e^{tA}x + \int_0^t e^{(t-s)A}Bu(s)ds. \tag{2}$$

Now we assume that the control strategies $u(\cdot)$ are taken in a given set of admissibility $\mathcal{U}_{ad}$ and consider the following minimum time problem:

Given $x \in H$, find the minimal time needed to bring x to 0 *by applying an admissible control strategy.*

The function $T(x)$ giving the minimal time to bring x to 0 is set equal to $+\infty$ when it is not possible to steer x to 0 in finite time by applying admissible control strategies, and it is called the Bellman function of the system (1). Obviously, the function T will depend on the set $\mathcal{U}_{ad}$ of admissible control strategies. We will consider the case where $\mathcal{U}_{ad}$ is a ball centered at $x = 0$ of the space $L^p(0, +\infty; U)$, $p \in (1, +\infty]$ and

call the associated Bellman function $T_p(x)$. The regularity properties of the Bellman function give important information on the system (1) and have been studied in many papers when the dimension of H is finite and $p = +\infty$.

Petrov [29] studied more general classes of admissible controls and stated that a necessary and sufficient condition for the continuity of the minimal time function is the local null controllability. In our context this is equivalent to the so-called Kalman condition, i.e., that the matrix $[B, AB, ..., A^{n-1}B]$ is full rank.

Petrov also describes necessary and sufficient conditions under which the Bellman function is Lipschitz continuous in a neighborhood of the origin. Other papers related to Lipschitz continuity of the Bellman function $T_\infty(x)$ are, e.g., Cannarsa and Sinestrari [8, 9], which study various properties of the minimum time function in the case when the state equation is nonlinear, and Hajek [20], which studies the case of linear systems.

On the other hand, in many cases the minimal time function is neither differentiable nor Lipschitz continuous. The Hölder continuity was investigated by Liverovskii [23, 24], Petrenko [30], Ranguin [32, 33], and by Gyurkovics [19] who showed that, when the system (1) satisfies the Kalman condition, the Hölder exponent of T_∞ is related to the minimum number $k \leq n-1$ such that the matrix $[B, AB, ..., A^k B]$ has full rank. We refer moreover to Bacciotti [1, sections 25, 33] and to Bianchini and Stefani [6] and the references therein for a discussion of the relationship between the Hölder continuity of the minimum time function and geometrical properties of the system also in the nonlinear case.

Other papers related to regularity properties of $T_\infty(x)$ in finite dimension are Bardi and Soravia [5] concerning Hölder continuity in the nonlinear case; Rampazzo and Sartori [31] concerning the case of L^1 controls; Bardi [4] concerning the dynamic programming equation for T_∞; and Conti [10]. See also Hermes and Lasalle; Lee and Markus; and Li and Yong [21, 22, 25] for a wider exposition of the argument.

The minimum time problem has been studied also in the case when the dimension of H is infinite and $p = +\infty$. Carja [12] proved the continuity of the Bellman function T_∞ and various properties of the reachable set when the system is linear and null controllable, while in Carja [14] the linear case with $B = I$ is considered. In Carja [13, 15] Hölder continuity results of T_∞ in the linear case are proved. In these last two papers Hölder continuity results for T_p, $p < +\infty$ are also proved; however, part of the method used to prove these results seems to be incorrect (see our section 3.2). We also recall Tauraso [38] which contains continuity results for the minimum time function of linear systems such as (1) in the case of $p = 2$ in connection with controllability properties of the system.

Other papers on the minimum time problem in infinite dimension are, e.g., Fattorini [17] and Krabs [26, 27], which study existence and properties of optimal controls that we will use in this paper. We recall also the papers of Barbu [2, 3] in which the dynamic programming equation and the maximum principle in some infinite dimensional case are studied.

The aim of this paper is to study the continuity properties of the Bellman function T_p, $p \in (1, +\infty]$, in the case when the state space H is a separable Hilbert space by generalizing the results of the papers mentioned above. We point out that in finite dimension the natural approach (used in the papers mentioned above) is to connect the continuity properties of T_p in a neighborhood of $x = 0$ with the minimum number $k \leq n-1$ such that the matrix $[B, AB, ..., A^k B]$ has full rank. Since in infinite dimension this is not possible, we use a different approach: we prove (see Theorem

4.1) that the function T_p is implicitly defined by the minimum energy function (that we will introduce later; see also section 2); we prove new regularity results for the minimum energy function and we use them to prove various continuity properties of T_p.

The connection between minimum time problems and minimum energy problems has been observed in [38], where the case $p = 2$ is studied and a lower semicontinuity result for T_2 is proved, and in [15, Remark 3.1], where it is used to prove Hölder continuity of T_∞ in some particular cases. However, in both cases, a precise formulation of this connection and of its consequences is not given. Here the mentioned relationship is established in a precise way for $p \in (1, +\infty]$ (see Theorem 4.1). To well exploit this connection we study the regularity properties of the minimum energy. Some results of this kind are available in the literature (see section 3.1) but we were able to prove more. Our new results on the minimum energy are interesting also in themselves and we gather them in section 3.2, Theorem 3.7. Then, using these new results we get an estimate of the growth rate of $T_p(x)$ in a neighborhood of $x = 0$ (see Theorem 4.6) which can be seen as an estimate of the modulus of continuity (and in some cases of the Hölder exponent) near this point. This estimate is then exploited in a different way when $p \in (1, +\infty)$ and when $p = +\infty$.

If $p = +\infty$ via the dynamic programming principle, the estimate of Theorem 4.6 can be transferred (locally) to the whole reachable sets obtaining local uniform continuity, an estimate of the local modulus and, in somes case, of the local Hölder exponent. The fact that T_∞ is locally uniformly continuous is already shown in [15] where some estimates of the modulus of continuity are given, too. Here the estimate proved in Theorem 4.6 gives a way to estimate the modulus of continuity of T_∞ in more general cases by using estimates for the minimum energy as $t \searrow 0$. In general it is not easy to find such estimates, but in some cases it can be done, as shown in section 5.

If $1 \leq p < +\infty$, the dynamic programming principle does not hold, in general, as shown in Example 5.14. If $p \in (1, +\infty)$, by using directly Theorem 4.1, we prove that the function T_p is continuous (Theorem 4.8) and that the reachable sets enjoy useful properties (Theorem 4.10). Moreover, by adding a new variable to the problem (i.e., the radius of the ball of admissible strategies) we can also prove a version of the dynamic programming principle which allows us again to transfer (with a different method) the estimate of Theorem 4.6 to the whole reachable sets obtaining local uniform continuity, an estimate of the local modulus and, in some cases, of the local Hölder exponent. In particular, in the finite dimensional case, using results of Seidman and Yong [35, 37] (see Theorem 3.6) that give sharp estimates for the minimum energy as $t \searrow 0$, we obtain precise estimates of the local Hölder exponent of T_p that seem to be completely new.

We remark that the case $p = 1$ is the most difficult since the space L^1 is not reflexive nor a dual and so we cannot use the characterization of controllability given in section 2. This case is not treated in this paper (see [31] for results in this direction).

Finally we recall that the behavior of the minimum energy function, in the case $p = 2$, is related to the regularity properties of the stochastic diffusion process that solves (1), where the control u is substituted by a white noise $\dot{W}$. In particular, the Kolmogorov equation associated with the process y enjoys good regularity properties depending on the behavior of the singularity of the minimum energy as $t \searrow 0$ (see [16, Chapter 9] for an extensive treatment of the subject). So, in this paper, by proving Theorem 4.1 we have indirectly shown a connection between the continuity properties of $T_2(x)$ in a neighborhood of $x = 0$ and the regularity properties of the solutions of suitable second order partial differential equations (for results in this direction in the finite dimensional case see, e.g., [18]).

The plan of the paper is the following. First we give some preliminaries and the statement of the problem in section 2. Then we recall known results about null controllability and minimum energy problems in section 3.1, while in section 3.2 we give new results about continuity and monotonicity of the minimum energy that are used in the rest of the paper. Section 4 is devoted to a statement and proof of the main results, while in section 5 we discuss the uniform continuity (and in some cases the Hölder continuity) of T_p and give some examples.

2. Preliminaries.

This section is devoted to introducing the basic concepts that will be used in the paper, i.e., the null controllability, the minimum time problem, and the minimum energy problem. Consider the control system (1), where we assume the following.

HYPOTHESIS 2.1.

1. *H and U are real separable Hilbert spaces.*
2. *$A : D(A) \subset H \to H$ is a closed linear operator that generates a C_0 semigroup e^{tA} on H satisfying $\|e^{tA}\| \leq Me^{\omega t}$ for given $M \geq 1$ and $\omega \in \mathbb{R}$.*
3. *$u : [0, +\infty) \to U$ is a locally integrable function.*
4. *$B : U \to H$ is a continuous linear operator.*

The unique mild solution (2) is continuous and can be written as

$$y(t; x, u) = e^{tA}x + \mathcal{L}_t u, \tag{3}$$

where the operator $\mathcal{L}_t$ is defined as

$$\mathcal{L}_t : L^p(0, +\infty; U) \to H, \qquad \mathcal{L}_t u = \int_0^t e^{(t-s)A}Bu(s)ds. \tag{4}$$

We will assume that the control strategies belong to a given set of admissibility $\mathcal{U}_{ad} \subset L^1_{loc}(0, +\infty; U)$ which will vary depending on the context. We begin by taking, for $p \in [1, +\infty]$, $\mathcal{U}_{ad} = \mathcal{U}_p \overset{def}{=} L^p(0, +\infty; U)$ and by considering the following null controllability problem:

Given $T > 0$ and $x \in H$, find an admissible control strategy u such that $y(T; x, u) = 0$.

In the literature we refer to [39] for the various concepts of controllability, in particular the null controllability. We now give the definition of p-null controllability.

DEFINITION 2.2. *Let $T > 0$, $x \in H$, and $p \in [1, +\infty]$. If there exists a strategy $u \in \mathcal{U}_p$ such that $y(T; x, u) = 0$, then the point x is said to be p-null controllable in time T. If this happens for every $x \in H$, then the system* (1) *is said to be p-null controllable in time T. If this happens for every $T > 0$ and $x \in H$, then the control system* (1) *is said to be simply p-null controllable.*

DEFINITION 2.3. *Given $T > 0$, $x \in H$, and $p \in [1, +\infty]$ we will denote by $\mathcal{M}(p, T, x)$ the (possibly empty) set of control strategies $u \in L^p(0, +\infty; U)$ such that $y(T; x, u) = 0$.*

Remark 2.4. The set $\mathcal{M}(p, T, x)$ is convex and closed and is nonempty if and only if x is p-null controllable in time T. Moreover, by (3) and (4) it follows that x is p-null controllable in time T if and only if $e^{TA}x \in \mathcal{L}_T(\mathcal{U}_p)$. Since $\mathcal{L}_T(\mathcal{U}_q) \subset \mathcal{L}_T(\mathcal{U}_p)$ for $q > p$, then, if a point x is q-null controllable in time T, it is also p-null controllable in time T for every $p < q$.

Finally, the set $\mathcal{L}_t(\mathcal{U}_p)$ is increasing in the variable t. This remain true if we consider, for any $\rho > 0$, the set $\mathcal{L}_t\left(\{u \in \mathcal{U}_p, \|u\|_p \leq \rho\}\right)$.

We now take by $\mathcal{U}_{ad}$ the following subset of controls:

$$\mathcal{U}_{ad} = \mathcal{U}_{p,\rho} = \{u \in \mathcal{U}_p : |u|_p \leq \rho\},$$

where ρ is a positive number. We denote by $\mathcal{R}_{p,\rho}(t)$ the set of states controllable to the rest within time t by some controls in $\mathcal{U}_{p,\rho}$. More precisely,

$$\mathcal{R}_{p,\rho}(t) = \{x \in H : \exists u \in \mathcal{U}_{p,\rho}\, s.t.\, y(t,x,u) = 0\}.$$

We observe that since H is a reflexive space, then $\mathcal{R}_{p,\rho}(t)$ is a closed set. We set

$$\mathcal{R}_{p,\rho} = \bigcup_{t \geq 0} \mathcal{R}_{p,\rho}(t)$$

and we define the minimum time function as

$$T_{p,\rho}(x) = \inf\{t \geq 0 : x \in \mathcal{R}_{p,\rho}(t)\}, \text{if } x \in \mathcal{R}_{p,\rho} \tag{5}$$

and $T_{p,\rho}(x) = +\infty$ otherwise. In some cases we will take for simplicity $\rho = 1$ and we will write T_p instead of $T_{p,1}$ and $\mathcal{R}_p$ instead of $\mathcal{R}_{p,1}$.

We recall that the continuity of the minimal time function in the origin is equivalent to the p-null controllability of system (1) as the following result, proved in [15], shows.

THEOREM 2.5. *Assume that Hypothesis* 2.1 *holds and let* $p \in (1, +\infty]$, $\rho > 0$. *Then the system* (1) *is p-null controllable if and only if the corresponding minimal time function* $T_{p,\rho}$ *is continuous at the origin.*

This result drives us to study only the case when the system (1) is p-null controllable. We end the section with the definition of the minimum energy problem.

DEFINITION 2.6. *Given* $T > 0$, $x \in H$, *and* $p \in [1, +\infty]$, *define the p-energy of a control strategy* $u \in \mathcal{M}(p, T, x)$ *as the quantity*

$$\mathcal{E}_p(u) = \left(\int_0^{+\infty} |u(s)|_U^p ds\right)^{\frac{1}{p}}, \qquad p \in [1, +\infty),$$

$$\mathcal{E}_\infty(u) = \sup_{t \geq 0} |u(t)|_U,$$

and the minimum p-energy to bring x *to* 0 *as*

$$\mathcal{E}_p^*(T, x) \overset{def}{=} \inf_{u \in \mathcal{M}(p,T,x)} \mathcal{E}_p(u).$$

The minimum p-energy problem is

find the minimum p-energy needed to bring x *to* 0 *in time* T.

We observe that the second extremum of the integral can be taken as T, since the control $u(s) = 0$ for $s > T$ is admissible and it does not modify the value of the minimum.

3. Null controllability and minimum energy.

3.1. Known results. In this section we recall some known results about null controllability and minimum energy that we will use in the rest of the paper. We start with the following if and only if conditions for the 2-null controllability of the system (1) (see, e.g., [39, Part IV, Chapter 1]).

THEOREM 3.1. *Assume Hypothesis* 2.1.

(i) *A point* $x \in H$ *is* 2*-null controllable in time* $T > 0$ *if and only if* $e^{TA}x \in Q_T^{\frac{1}{2}}(H)$, *where* $Q_T = \int_0^T e^{sA}BB^*e^{sA^*}ds$.

(ii) *The system* (1) *is* 2*-null controllable if and only if* $e^{TA}(H) \subset Q_T^{\frac{1}{2}}(H)$ $\forall T > 0$.

(iii) *The condition* (ii) *above is equivalent to*

$$\text{For every } T > 0 \text{ there exists a constant } C(T) > 0$$
$$\text{such that } |e^{TA^*}x| \leq C(T)|Q_T^{1/2}x| \ \forall x \in H.$$

In this case the operator $\Gamma(T) = Q_T^{-1/2}e^{TA}$ *is well defined and bounded on* H *and* $\|\Gamma(T)\|_{\mathcal{L}(H)}$ *is the infimum of the constants* $C(T)$ *such that condition* (iii) *holds.*

(iv) *If* $H = \mathbb{R}^n$, *then the system* (1) *is* 2*-null controllable if and only if*

$$\text{rank}\,[B, AB, A^2B, ..., A^{n-1}B] = n. \tag{6}$$

Remark 3.2. In the finite dimensional case all concepts of p-null controllability coincide with (6) which is the well-known Kalman condition.

If $p \in [1, +\infty]$, then (i), (ii) of the above theorem still hold true with the operator $\mathcal{L}_T : \mathcal{U}_p \to H$ in place of $Q_T^{\frac{1}{2}}$. Moreover, if $p \in (1, +\infty)$, then condition (iii) is true in the following form (see, e.g., [11, Theorem 2.2]):

The system (1) *is* p*-null controllable if and only if for every* $T > 0$ *there exists a constant* $C(T) > 0$ *such that*

$$|e^{TA^*}x| \leq C(T)|\mathcal{L}_T^*x| = C(T)\left(\int_0^T |B^*e^{(T-s)A^*}x|^q ds\right)^{\frac{1}{q}} \qquad \forall x \in H, \tag{7}$$

where $\frac{1}{q} + \frac{1}{p} = 1$. As in the case $p = 2$ the smallest $C(T)$ is decreasing with respect to T and blows up as $T \searrow 0$. If $p = 1, +\infty$ the equivalence above is still true when A generates a group but in general is false. In this case we have only that p-null controllability implies (7) (see, e.g., [11]).

We now give a result about existence of optimal controls that, in the case $p = 2$, gives an explicit formula for the optimal strategy. The proof can be found, e.g., in [39, Part IV, Chapter 1] for the case $p = 2$. The case $p \neq 2$ can be obtained exactly by repeating the same argument and we omit it. The case $p = +\infty$ can be proved using the same argument of [17].

THEOREM 3.3. *Let* $p \in (1, +\infty)$. *Assume Hypothesis* 2.1 *and let the system* (1) *be* p*-null controllable. Then the problem*

$$\min\left\{\int_0^T |u(s)|^p ds, u \in L^p(0, +\infty; U) : \ y(T; x, u) = 0\right\}$$

admits only one optimal solution which, in the case $p = 2$, *is given by*

$$u_{T,x}^*(s) = -\overline{B^*e^{(T-s)A^*}Q_T^{-\frac{1}{2}}}\Gamma(T)x$$

and in this case the value of the minimum is $|\Gamma(T)x|^2$*;* $\overline{B^* e^{(T-s)A^*} Q_T^{-\frac{1}{2}}}$ *denotes the closure of the operator* $B^* e^{(T-s)A^*} Q_T^{-\frac{1}{2}}$.

Let $p = +\infty$*. Assume Hypothesis* 2.1 *and let the system* (1) *be* ∞*-null controllable. Then the problem*

$$\min\{||u||_\infty, u \in L^\infty(0,+\infty;U) : \; y(T;x,u) = 0\}$$

admits at least one optimal solution.

Remark 3.4. The operator $B^* e^{(T-s)A^*} Q_T^{-\frac{1}{2}}$ is not a priori well defined on all H. However, its closure is well defined on H due to the 2-null controllability assumption (see [39, Part IV, Chapter 1]).

Moreover, we recall that if $p = 1$, in general an optimal control strategy for the minimum energy problem does not exists. For example, one can take the one dimensional case when $A = a \neq 0$ and $B = 1$.

The behavior of $\mathcal{E}_p^*(t,x)$ when $t \to 0^+$ plays an important role in the rest of the paper. We recall the following result, which is immediately provable taking the control $u(s) = -(1/T)B^{-1}e^{sA}x$. (See [16, Appendix B] for the case $p = 2$.)

PROPOSITION 3.5. *Assume that Hypothesis* 2.1 *holds and that B is onto. Then, for every* $p \in [1,+\infty]$ *the system* (1) *is p-null controllable and for every fixed* T_0 *there exists a suitable constant* $C(T_0) > 0$ *such that*

$$\mathcal{E}_p^*(T,x) \leq C(T_0)|x|T^{-1+1/p}, \qquad T \in (0,T_0].$$

In finite dimension we have the following sharp result given by Seidman [35] and by Seidman and Yong [37].

THEOREM 3.6. *If* $H = \mathbb{R}^n$*,* $p \in [1,+\infty]$*, then, for almost every* $x \in H$ *(setting* $1/p = 0$ *when* $p = +\infty$*)*

$$\mathcal{E}_p^*(t,x) \sim t^{-k-1+1/p}|x| \qquad \textit{as } t \to 0^+,$$

where k is the first integer such that rank $[B, AB, \dots, A^k B] = n$.

This theorem shows that the singularity of $\mathcal{E}_p^*(t,x)$ as $t \to 0^+$ can have only a finite range of behaviors. When the dimension of H is infinite this is not true as can be deduced by the example given in [16, pp. 275–277] which shows that, in the case $p = 2$ for every $\beta \geq 1$, we can find diagonal operators A, B such that $\|\Gamma(t)\| = o(t^{\frac{\beta}{2}})$ as $t \to 0$.

3.2. New results. The following result about the regularity of the minimal energy is interesting in itself and will be a key tool for proving properties of the minimum time function and of reachable sets. For simplicity we will write L^p for $L^p(0,+\infty;U)$.

THEOREM 3.7. *Let* $p \in (1,+\infty]$*. Assume that Hypothesis* 2.1 *is satisfied and that the system is p-null controllable. Then*

(i) *the function* $\mathcal{E}_p^*(t,\cdot)$ *is homogeneus of degree* 1 *for every* $t > 0$*;*

(ii) *the function* $\mathcal{E}_p^*(\cdot,x)$ *is strictly decreasing for every* $x \in H$*;*

(iii) *if* $p \in (1,+\infty)$*, then the function* $\mathcal{E}_p^*$ *is continuous. Moreover, for every* $\varepsilon > 0$ *there exists* C_ε *such that*

$$|\mathcal{E}_p^*(t,x_1) - \mathcal{E}_p^*(t,x_2)| \leq C_\varepsilon |x_1 - x_2| \tag{8}$$

for every $t \geq \varepsilon$, $x_1, x_2 \in H$, *and*

$$|\mathcal{E}_p^*(t_1,x) - \mathcal{E}_p^*(t_2,x)| \leq C_\varepsilon \left[|x|(t_2-t_1) + \left| x - e^{(t_2-t_1)A}x \right| \right] \tag{9}$$

for every $x \in H$, $t_2 > t_1 > \varepsilon$.

To prove the above theorem, we need first a useful representation lemma that uses a minimax theorem to give a different representation of the minimum energy function.

LEMMA 3.8. *Given* $p \in (1, +\infty)$ *consider the function*

$$L_p : [0,+\infty) \times H \times L^p \times H \mapsto \mathbb{R}, \qquad L_p(t,x;u,y) = \|u\|_p^p + \langle y, \mathcal{L}_t u + e^{tA}x \rangle.$$

Then, for every $(t,x) \in [0,+\infty) \times H$ *we have*

$$\mathcal{E}_p^*(t,x)^p = \inf_{u \in L^p} \sup_{y \in H} L_p(t,x;u,y) = \sup_{y \in H} \inf_{u \in L^p} L_p(t,x;u,y)$$

and

$$\mathcal{E}_p^*(t,x)^p = \sup_{y \in H} \left\{ \langle y, e^{tA}x \rangle - c_p \|\mathcal{L}_t^* x\|_{L^q}^q \right\}, \tag{10}$$

where $1/p + 1/q = 1$ *and* $c_p = (1/q)[1/p]^{q/p}$.

Proof of Lemma 3.8. First we observe that

$$\sup_{y \in H} L_p(t,x;u,y) = \begin{cases} \|u\|_p^p & \text{if } e^{tA}x + \mathcal{L}_t u = 0, \\ 0 & \text{otherwise} \end{cases}$$

so that

$$\inf_{u \in L^p} \sup_{y \in H} L_p(t,x;u,y) = \inf_{u \in \mathcal{M}(p,t,x)} \|u\|_p^p = \mathcal{E}_p^*(t,x)^p.$$

The proof of the other equality

$$\mathcal{E}_p^*(t,x)^p = \sup_{y \in H} \inf_{u \in L^p} L_p(t,x;u,y)$$

is much more difficult. Let us call, for brevity,

$$G_1(t,x) = \inf_{u \in L^p} \sup_{y \in H} L_p(t,x;u,y) = \mathcal{E}_p^*(t,x)^p$$

and

$$G_2(t,x) = \sup_{y \in H} \inf_{u \in L^p} L_p(t,x;u,y).$$

We want to prove that $G_1 = G_2$. We begin by observing that, by easy verification,

$$\inf_{u \in L^p} \sup_{y \in H} L_p(t,x;u,y) \geq \sup_{y \in H} \inf_{u \in L^p} L_p(t,x;u,y),$$

so $G_1 \geq G_2$ and we have only to prove the reverse inequality. Since the function L_p does not satisfy usual assumptions of minimax theorems, we consider for $\varepsilon > 0$ the approximating function $L_{p,\varepsilon}(t,x;u,y) = L_p(t,x;u,y) - \varepsilon |x|^2$. It can be easily verified that the function $L_{p,\varepsilon}$ satisfies assumptions of [7, Proposition 1] (see also [38, Chapter IV]) and so there exists a point $(u_\varepsilon, y_\varepsilon)$ (a so-called "saddle point") such that

$$\max_{y\in H}\inf_{u\in L^p(0,+\infty;U)} L_{p,\varepsilon}(t,x;u,y) = L_{p,\varepsilon}(t,x;u_\varepsilon,y_\varepsilon) = \min_{u\in L^p}\sup_{y\in H} L_{p,\varepsilon}(t,x;u,y)$$

which gives, for every $u \in L^p$ and $y \in H$,

$$L_p(t,x;u_\varepsilon,y) - \varepsilon|y|^2 \le L_p(t,x;u_\varepsilon,y_\varepsilon) - \varepsilon|y_\varepsilon|^2 \le L_p(t,x;u,y_\varepsilon) - \varepsilon|y_\varepsilon|^2$$

so that

$$\begin{aligned} L_p(t,x;u_\varepsilon,y_\varepsilon) &\le \inf_{u\in L^p} L_p(t,x;u,y_\varepsilon) \le \sup_{y\in H}\inf_{u\in L^p} L_p(t,x;u,y_\varepsilon) \\ &= G_2(t,x) \le \mathcal{E}_p^*(t,x)^p < +\infty. \end{aligned}$$

The above two inequalities give

$$0 \le \|u_\varepsilon\|_p^p = L_p(t,x;u_\varepsilon,0) \le L_p(t,x;u_\varepsilon,y_\varepsilon) - \varepsilon|y_\varepsilon|^2 \le G_2(t,x)$$

so that the set $\{u_\varepsilon;\ \varepsilon > 0\}$ is bounded and so there exists $u_0 \in L^p$ and a sequence $\{\varepsilon_n\}_{n\in\mathbb{N}}$ converging to 0 as $n \to +\infty$ such that

$$u_{\varepsilon_n} \longrightarrow u_0 \quad \text{weakly in } L^p.$$

Passing to the limit on this sequence we then obtain

$$L_p(t,x;u_0,y) \le \liminf_{n\to+\infty} L_p(t,x;u_{\varepsilon_n},y) \le \liminf_{n\to+\infty} [L_p(t,x;u_{\varepsilon_n},y) - \varepsilon_n|y|^2]$$

$$\le \liminf_{n\to+\infty} [L_p(t,x;u_{\varepsilon_n},y_{\varepsilon_n}) - \varepsilon_n|y_{\varepsilon_n}|^2] \le \liminf_{n\to+\infty} L_p(t,x;u_{\varepsilon_n},y_{\varepsilon_n}) \le G_2(t,x)$$

so that

$$G_1(t,x) \le \inf_{u\in L^p}\sup_{y\in H} L_p(t,x;u,y) \le \sup_{y\in H} L_p(t,x;u_0,y) \le G_2(t,x)$$

which gives the claim $G_1 = G_2$.

Finally, to prove the last equality of the claim it is enough to observe that, by standard calculations, we get

$$\sup_{y\in H}\inf_{u\in L^p} L_p(t,x;u,y)$$

$$= \sup_{y\in H}\left\{\langle y, e^{tA}x\rangle + \inf_{u\in L^p}\left[\|u\|_p^p + \langle y, \mathcal{L}_t u\rangle\right]\right\}.$$

Now, since $\mathcal{L}_t^* : H \mapsto L^q$, $[\mathcal{L}_t^* y](s) = B^* e^{(t-s)A^*} y$, we have

$$\|u\|_p^p + \langle y, \mathcal{L}_t u\rangle = \|u\|_p^p + \langle \mathcal{L}_t^* y, u\rangle_{\langle L^q, L^p\rangle}$$

and

$$\inf_{u\in L^p}\left[\|u\|_p^p + \langle y, \mathcal{L}_t u\rangle\right] = -\sup_{u\in L^p}\left[-\|u\|_p^p - \langle \mathcal{L}_t^* y, u\rangle\right]$$

which is the convex conjugate function (see, e.g., [34, p. 104]) of $\|u\|_p^p$ calculated at $-\mathcal{L}_t^* y$ which, by standard calculations, is equal to $c_p \|\mathcal{L}_t^* y\|_q^q$, where $c_p = (1/q)[1/p]^{q/p}$. It follows that

$$\inf_{u \in L^p} \left[\|u\|_p^p + \langle y, \mathcal{L}_t u \rangle \right] = -c_p \|\mathcal{L}_t^* y\|_q^q$$

which gives the claim. □

Remark 3.9.

(i) We observe that, in general, we cannot say that the map

$$H \mapsto \mathbb{R}, \qquad y \mapsto \langle y, e^{tA} x \rangle - c_p \|\mathcal{L}_t^* x\|_{L^q}^q$$

has a maximum point. However, if the system (1) is exactly controllable, then there exists a unique maximum point (see, e.g., [38, Chapter IV]).

(ii) From the proof of Theorem 3.7 and from Remark 3.2 we can easily deduce that a point $x \in H$ is p-null controllable in time $t > 0$ if and only if

$$G_2(t, x) = \sup_{y \in H} \left\{ \langle y, e^{tA} x \rangle - c_p \|\mathcal{L}_t^* x\|_{L^q}^q \right\} < +\infty.$$

We are now ready to give the proof of Theorem 3.7.

Proof of Theorem 3.7. (i) It is a straightforward consequence of the definition of minimum energy and of the observation that

$$\mathcal{M}(p, t, \lambda x) = \lambda \mathcal{M}(p, t, x).$$

(ii) Given $p \in (1, +\infty]$, $t_1 \geq 0$, and $x \in H$ it is clear that, if u_0 is the minimum p-energy control at (t_1, x), then for every $t_2 > t_1$ the control $\overline{u}$ defined as $\overline{u}(r) = u_0(r)$ for $r \in [0, t_1]$ and $\overline{u}(r) = 0$ for $r \in (t_1, t_2]$ belongs to $\mathcal{M}(p, t_2, x)$. This implies, in particular, that $\mathcal{E}_p^*(t_1, x) \geq \mathcal{E}_p^*(t_2, x)$ for $t_2 > t_1$.

We now want to prove the strict inequality starting from the case $p \in (1, +\infty)$. In this case we in fact have existence and uniqueness of the minimum p-energy control, so to prove the strict inequality it is enough to prove that the above control $\overline{u}$ is not optimal for $t_2 > t_1$. To this end we observe that, for $p \in (1, +\infty)$, $t \geq 0$, $x \in H$, and $u \in \mathcal{M}(p, t, x)$, we can write

$$\mathcal{M}(p, t, x) = u + \text{Ker } \mathcal{L}_t.$$

In particular, the control of minimum p-energy u^* is such that, for any given $w \in \text{Ker } \mathcal{L}_t$,

$$\|u^*\|_{L^p} = \min_{\lambda \in \mathbb{R}} \|u^* + \lambda w\|_{L^p}$$

so that, by differentiating, we get

$$\langle |u^*|^{p-2} u^*, w \rangle_{\langle L^q(0,t;U), L^p(0,t;U) \rangle} = 0.$$

Suppose now by contradiction that the control $\overline{u}$ defined above is optimal at time $t_2 > t_1$. Then, for every $w \in \text{Ker } \mathcal{L}_{t_2}$, we have

$$\langle |\overline{u}|^{p-2} \overline{u}, w \rangle_{\langle L^q(0,t_2;U), L^p(0,t_2;U) \rangle} = 0.$$

Choosing $u_1 \in L^p(0,t_2-t_1;U)$ such that

$$\mathcal{L}_{t_2-t_1}u_1 = e^{(t_2-t_1)A}\mathcal{L}_{t_1}u_0$$

(this is always possible thanks to the p-null controllability of the system (1)) the control w_1 defined as $w_1(s)=u_0(s)$ for $s\in[0,t_1]$ and $w_1(s)=u_1(s-t_1)$ for $s\in(t_1,t_2]$ belongs to Ker $\mathcal{L}_{t_2}$ and is such that

$$\langle|\overline{u}|^{p-2}\overline{u},w\rangle_{\langle L^q(0,t_2;U),L^p(0,t_2;U)\rangle} = \|u_0\|_{L^p(0,t_1;U)} > 0,$$

which is a contradiction.

Consider now the case $p=+\infty$. In this case we do not have uniqueness of the optimal control, in general, so the above argument is not a straightforward application. As before, let $0<t_1<t_2$, $x\in H$, and let u_0 be the minimum ∞-energy control at (t_1,x). Consider the control $u_\lambda\in L^\infty(0,t_1;U)$ defined as $u_\lambda(r)=(1-\lambda)u_0(r)$ for $r\in[0,t_1]$. Then $y(t_1;xu_\lambda)=\lambda e^{t_1A}x$. Now, from the ∞-null controllability assumption we know that $e^{(t_2-t_1)A}(H)\subset\mathcal{L}_{t_2-t_1}(\mathcal{U}_\infty)$ so that (see [16, Appendix B]) for every $\varepsilon>0$ there exists $\delta>0$ such that

$$e^{(t_2-t_1)A}(\{|x|<\delta\})\subset\mathcal{L}_{t_2-t_1}(\{\|u\|_\infty<\varepsilon\}).$$

Now we choose $0<\varepsilon<\|u_0\|_\infty$, $\lambda>0$ such that

$$\lambda|e^{t_1A}x|\le\delta$$

and $\hat{u}$ such that $\|\hat{u}\|_\infty<\varepsilon$, $\mathcal{L}_{t_2-t_1}\hat{u}=e^{(t_2-t_1)A}\left[\lambda e^{t_1A}x\right]$. Then the control $u_1\in L^p(0,t_2;U)$ defined as $u_1(s)=\lambda u_0(s)$ for $s\in[0,t_1]$ and $u_1(s)=\hat{u}(s-t_1)$ for $s\in(t_1,t_2]$ belong to $\mathcal{M}(\infty,t_2,x)$ and $\|u_1\|_\infty<\|u_0\|_\infty$, the claim follows.

(iii) We use the representation given in (10)

$$\mathcal{E}_p^*(t,x)^p=\sup_{y\in H}\left\{\langle y,e^{tA}x\rangle-c_p\|\mathcal{L}_t^*y\|_{L^q}^q\right\}.$$

Using this, we have for brevity $G(t,x)=\mathcal{E}_p^*(t,x)^p$, and taking $x_1\neq x_2$, with $G(t,x_1)>G(t,x_2)$,

$$\begin{aligned}G(t,x_1)-G(t,x_2)=&\sup\nolimits_{y\in H}\left\{\langle y,e^{tA}x_1\rangle-c_p\|\mathcal{L}_t^*y\|_{L^q}^q\right\}\\&-\sup\nolimits_{y\in H}\left\{\langle y,e^{tA}x_2\rangle-c_p\|\mathcal{L}_t^*y\|_{L^q}^q\right\}\end{aligned}$$

which, taking y_ε such that

$$G(t,x_1)\le\varepsilon+\langle y_\varepsilon,e^{tA}x_1\rangle-c_p\|\mathcal{L}_t^*y_\varepsilon\|_{L^q}^q,$$

implies

$$G(t,x_1)-G(t,x_2)\le\varepsilon+\langle e^{tA^*}y_\varepsilon,x_1-x_2\rangle\le\varepsilon+|e^{tA^*}y_\varepsilon||x_1-x_2|. \tag{11}$$

By the p-null controllability assumption and by Remark 3.2 we have

$$|e^{tA^*}y_\varepsilon|\le C(t)|\mathcal{L}_t^*y_\varepsilon|_{L^q} \tag{12}$$

so that, taking $\varepsilon\le G(t,x_1)$ (if $x_1=0$ we take the reverse inequality) we have

$$0\le\langle e^{tA^*}y_\varepsilon,x_1\rangle-c_p\|\mathcal{L}_t^*y_\varepsilon\|_{L^q}^q\le|e^{tA^*}y_\varepsilon||x_1|-c_p\|\mathcal{L}_t^*y_\varepsilon\|_{L^q}^q$$

$$\leq C(t)|\mathcal{L}_t^* y_\varepsilon|_{L^q}|x_1| - c_p\|\mathcal{L}_t^* y_\varepsilon\|_{L^q}^q$$

and, by Young's inequality, for any $\sigma > 0$ there exists $C_\sigma > 0$ such that

$$0 \leq \sigma|\mathcal{L}_t^* y_\varepsilon|_{L^q}^q + C_\sigma[C(t)|x_1|]^p - c_p|\mathcal{L}_t^* y_\varepsilon|_{L^q}^q$$

which finally gives, taking $\sigma = c_p/2$,

$$c_p/2|\mathcal{L}_t^* y_\varepsilon|_{L^q}^q \leq C_{c_p/2}C(t)^p|x_1|^p \tag{13}$$

and then, by (12),

$$|e^{tA^*}y_\varepsilon| \leq C(t)\left[\frac{2}{c_p}C_{c_p/2}C(t)^p|x_1|^p\right]^{1/q} = \left[\frac{2}{c_p}\right]^{1/q} C_{c_p/2}^{1/q}C(t)^p|x_1|^{p-1}.$$

By substituting the last inequality into (11) we get, taking also ε sufficiently small,

$$G(t,x_1)-G(t,x_2) \leq \varepsilon+\left[\frac{2}{c_p}\right]^{1/q} C_{c_p/2}^{1/q}C(t)^p|x_1|^{p-1}|x_1-x_2| \leq C_1(p)C(t)^p|x_1|^{p-1}|x_1-x_2|, \tag{14}$$

where $C_1(p)$ is a suitable constant depending only on p. Now we observe that, given $a > b \geq 0$ and $p \in (1,+\infty)$, we have

$$a - b \leq a^{1-p}\left[a^p - b^p\right]$$

so that, in our case,

$$\begin{aligned} \mathcal{E}_p^*(t,x_1) - \mathcal{E}_p^*(t,x_2) &\leq \mathcal{E}_p^*(t,x_1)^{1-p}\left[G(t,x_1) - G(t,x_2)\right] \\ &= G(t,x_1)^{-1/q}\left[G(t,x_1) - G(t,x_2)\right]. \end{aligned} \tag{15}$$

By (10) and (12) we get

$$G(t,x_1) \leq \sup_{y\in H}\{C(t)\|\mathcal{L}_t^* y\|_{L^q}|x_1| - c_p\|\mathcal{L}_t^* y\|_{L^q}^q\} \tag{16}$$

which gives, by standard calculations,

$$G(t,x_1) \leq c_p^{1-p}c_qC(t)^p|x_1|^p$$

so that putting the last equation and (14) into (15), we obtain

$$\mathcal{E}_p^*(t,x_1) - \mathcal{E}_p^*(t,x_2)$$

$$\leq \left[c_p^{1-p}c_qC(t)^p|x_1|^p\right]^{-1/q}C_1(p)C(t)^p|x_1|^{p-1}|x_1-x_2| = C_2(p)C(t)|x_1-x_2|,$$

where $C_2(p) = C_1(p)[c_p^{1-p}c_q]^{-1/q}$. Then (8) follows by repeating the same argument, exchanging the roles of x_1 and x_2.

To prove (9) we use a similar argument. First we fix $t_1 < t_2$ and we consider y_ε such that

$$G(t_1,x) \leq \varepsilon + \langle y_\varepsilon, e^{t_1A}x\rangle - c_p\|\mathcal{L}_{t_1}^* y_\varepsilon\|_{L^q}^q.$$

Then, reasoning as in the above proof, we have

$$G(t_1,x)-G(t_2,x)\le \varepsilon+\langle y_\varepsilon,e^{t_1A}x\rangle-c_p\|\mathcal{L}^*_{t_1}y_\varepsilon\|^q_{L^q}-\langle y_\varepsilon,e^{t_2A}x\rangle+c_p\|\mathcal{L}^*_{t_2}y\|^q_{L^q}$$

$$=\ \langle e^{t_1A^*}y_\varepsilon,x-e^{(t_2-t_1)A}x\rangle+c_p\int_{t_1}^{t_2}|B^*e^{sA^*}y_\varepsilon|^q ds$$

$$\le C(t_1)\|\mathcal{L}^*_{t_1}y_\varepsilon\|_{L^q}|x-e^{(t_2-t_1)A}x|+c_p|B^*|^q\int_{t_1}^{t_2}\|\mathcal{L}^*_s y_\varepsilon\|^q_{L^q}ds.$$

Now, arguing as in (13), we get

$$|\mathcal{L}^*_{t_1}y_\varepsilon|^q_{L^q}\le\frac{2}{c_p}C_{c_p/2}C(t_1)^p|x|^p$$

and

$$\sup_{s\in[t_1,t_2]}\|\mathcal{L}^*_s y_\varepsilon\|^q_{L^q}\le\|\mathcal{L}^*_{t_2}y_\varepsilon\|^q_{L^q}\le\frac{2}{c_p}C_{c_p/2}C(t_2)^p|x|^p$$

so that

$$G(t_1,x)-G(t_2,x)\le\varepsilon+C_3(p)\left[C(t_1)^p|x|^{p-1}|x-e^{(t_2-t_1)A}x|+(t_2-t_1)C(t_2)^p|x|^p\right]$$

$$\le\varepsilon+C_3(p)C(t_1)^p|x|^{p-1}\left[|x-e^{(t_2-t_1)A}x|+|x|(t_2-t_1)\right],$$

where we have used that $C(t_2)\le C(t_1)$. Finally, reasoning as in (15) and using the analogue of (16),

$$\mathcal{E}^*_p(t_1,x)\ -\mathcal{E}^*_p(t_2,x)\le\mathcal{E}^*_p(t_1,x)^{1-p}\left[G(t_1,x)-G(t_2,x)\right]$$

$$=G(t_1,x)^{-1/q}\left[G(t_1,x)-G(t_2,x)\right]$$

$$\le\left[C_4(p)C(t_1)^p|x|^p\right]^{-1/q}C_3(p)C(t_1)^p|x|^{p-1}\left[|x-e^{(t_2-t_1)A}x|+|x|(t_2-t_1)\right]$$

$$\le C_5(p)C(t_1)\left[|x-e^{(t_2-t_1)A}x|+|x|(t_2-t_1)\right]$$

which gives the claim. □

Remark 3.10. From the proof of (ii) it follows that, for $t_1<t_2$, there exists $\varepsilon(t_2-t_1)>0$ such that

$$e^{(t_2-t_1)A}\mathcal{L}_{t_1}(\mathcal{U}_{p,\rho})\subset\mathcal{L}_{t_2}(\mathcal{U}_{p,\rho-\varepsilon}).$$

Moreover, it also follows that, for $(t,x)\in(0,+\infty)\times H$, the optimal trajectory $y(\cdot;x,u^*)$ corresponding to the minimum p-energy control u^* arrives at 0 only at the final time t. Finally, it is easy to find a one dimensional example ($A=0$, $B=1$), where the minimum 1-energy is constant with respect to t. So the case $p=1$ cannot satisfy our claims.

4. Main results. In this section we state and prove the following main results of the paper: Theorem 4.1, where we prove that the minimum time is implicitly defined by the minimum energy; Theorem 4.6, where we show that the growth rate of the minimum time $T_{p,\rho}(x)$ near $x = 0$ is connected to the explosion rate of the minimum energy $\mathcal{E}_p^*(t,x)$ as $t \searrow 0$; Theorem 4.8, where we prove the continuity of the minimum time and give an estimate of the modulus of local uniform continuity (and of the Hölder exponent); and Theorem 4.10, where we prove topological properties of reachable sets.

THEOREM 4.1. *Let $p \in (1, +\infty]$ and $\rho > 0$ be fixed. Assume that the system* (1) *satisfies Hypothesis* 2.1 *and is p-null controllable. Then the minimal time function $T_{p,\rho}$ is defined implicitly by the equation*

$$\mathcal{E}_p^*(T_p(x), x) = \rho. \tag{17}$$

For the proof of this theorem we need two lemmas that are interesting in themselves. The first one states existence of optimal controls for the minimum time problem while the second one states a "maximum principle" for the optimal control.

LEMMA 4.2. *Let $p \in (1, +\infty]$ and assume that the system* (1) *satisfies Hypothesis* 2.1*. Then there exists an optimal control for the minimum time problem.*

Proof. We give the proof only for the case $p \in (1, +\infty)$, as the case $p = +\infty$ can be found in [17]. For brevity we will set $\rho = 1$ along this proof. Then let $p \in (1, +\infty)$ and $x \in \mathcal{R}_p$. By definition of $T_p(x)$, there exists a sequence of controls $u_n \in \mathcal{U}_{p,1}$ and a sequence of times $T_n \downarrow T_p(x)$ such that $T_n \leq 2T_p(x)$ and

$$y(T_n; x, u_n) = 0.$$

The control strategy u_n can be taken equal to 0 out of $[0, T_n]$, and by passing to a subsequence (which we still denote by u_n) it converges weakly to an element $u_0 \in \mathcal{U}_{p,1}$. Now we can write, for every $h \in H$,

$$0 = \langle y(T_n; x, u_n), h\rangle$$

$$= \langle e^{T_n A}x, h\rangle + \int_0^{2T_p(x)} \langle u_n(s), \chi_{[0,T_n]}(s) B^* e^{(T_n - s)A^*} h\rangle ds.$$

By the strong continuity of $\{e^{tA^*},\ t \geq 0\}$, it follows that for every $h \in H$ the map $s \to \chi_{[0,T_n]}(s)B^* e^{(T_n-s)A^*} h$ is measurable and bounded and converges strongly in $L^q(0, +\infty; U)$ as $n \to +\infty$ for $q = \frac{p}{p-1}$. Then, by the weak convergence of u_n to u_0 we have, for every $h \in H$,

$$0 = \lim_{n \to +\infty} \langle y(T_n; x, u_n), h\rangle\ =\ \langle y(T_p(x); x, u_0), h\rangle.$$

This gives $y(T; x, u_0) = 0$ and so the claim follows. □

LEMMA 4.3. *Let $p \in (1, +\infty]$. Assume that the system* (1) *satisfies Hypothesis* 2.1 *and is p-null controllable. Then any optimal control u^* for the minimum time problem satisfies the following "maximum principle":*

$$\|u^*\|_p = \rho.$$

Proof. For brevity we will set $\rho = 1$ along this proof. Let $x \in H$ and assume by contradiction that $\|u^*\|_p = a < 1$. Then we prove that $T_p(x)$ is not optimal.

We observe first that, given $u \in \mathcal{U}_p$, $x \in H$, and $0 < s < t$, we can write

$$\mathcal{L}_t u = e^{sA}\mathcal{L}_{t-s}u + \mathcal{L}_s[u(t-s+\cdot)]$$

so that, setting $z(t-s) = y(t-s;x,u) - x$ and $\overline{u}(r) = u(t-s+r)$, we have

$$y(t;x,u) = e^{tA}x + \mathcal{L}_t u = e^{sA}x + e^{sA}[e^{(t-s)A}x - x] + e^{sA}\mathcal{L}_{t-s}u + \mathcal{L}_s[u(t-s+\cdot)]$$

$$= e^{sA}x + \mathcal{L}_s[u(t-s+\cdot)] + e^{sA}z(t-s) = y(s;x,\overline{u}) + e^{sA}z(t-s).$$

Then taking in the above equation $t = T_p(x)$ and u an optimal control for the minimum time problem we have that, for $0 < s < t$,

$$y(s;x,\overline{u}) + e^{sA}z(t-s) = 0,$$

where $\overline{u}$ and $z(t-s)$ are defined as above. Now, by the p-null controllability assumption we have $e^{sA}(H) \subset \mathcal{L}_s\mathcal{U}_p$, which implies (see, e.g., [11]) that, for every $s_0 > 0$, $\varepsilon > 0$, there exists $\delta > 0$ such that

$$e^{sA}\{|x| \le \delta\} \subset \mathcal{L}_s\mathcal{U}_{p,\varepsilon} \quad \forall s \ge s_0.$$

Now fix $\varepsilon = (1-a)/2$ and $s_0 = T_p(x)/2$. Take δ as above and $s_0 \le s < T_p(x)$ such that $|z(t-s)| \le \delta$. Then there exists a control $\widehat{u}$ such that $\|\widehat{u}\|_p \le \frac{1-a}{2}$ and $e^{sA}z(t-s) = \mathcal{L}_s\widehat{u}$ so that

$$y(s;x,\overline{u}+\widehat{u}) = e^{sA}x + \mathcal{L}_s[\overline{u}+\widehat{u}] = e^{sA}x + \mathcal{L}_s\overline{u} + e^{sA}z(t-s) = 0.$$

The claim follows by contradiction. □

Proof of Theorem 4.1. We argue by contradiction, setting for brevity $\rho = 1$. If $\mathcal{E}_p^*(T_p(x),x) = a > 1$, then every control driving x to 0 in time $T_p(x)$ has p-energy strictly greater than 1 and so it is not admissible. This is impossible due to the existence of the optimal control stated in Lemma 4.2.

Conversely, assume that $\mathcal{E}_p^*(T_p(x),x) = a < 1$. Then, by Theorem 3.3 there exists a control driving x to 0 in time $T_p(x)$ with energy $a < 1$. This contradicts the "maximum principle" stated above. Finally we observe that if $t \ne T(x)$, then $\mathcal{E}_p^*(t,x) \ne 1$, since the minimum energy is strictly decreasing in the variable t. □

Remark 4.4. Observe that, by definition of $T_p(x)$, $\mathcal{E}_p^*(T,x) \le 1$ when $T > T_p(x)$. Similarly we have that $\mathcal{E}_p^*(T,x) \ge 1$ when $T < T_p(x)$. Then, in the case $p \in (1,+\infty)$, the claim of Theorem 4.1 follows also by the continuity and the strict monotonicity of $\mathcal{E}_p^*(T,x)$ with respect to T (see Theorem 3.7).

Remark 4.5. The control u of minimal energy at time $T_p(x)$ satisfies also $\mathcal{E}_p(u) = 1$ and so it is optimal also for the minimum time problem. In particular, when $p \in (1,+\infty)$, this implies the uniqueness of the optimal control for the minimum time problem. Observe that if $p = 1$, we do not have existence of the minimum time optimal control; it is enough to take the one dimensional case with $A = 0$, $B = 1$.

The representation given above allows us to connect the behavior of T_p near 0 with L^p estimates of controls bringing a given state x to 0.

THEOREM 4.6. *Let* $p \in (1,+\infty]$. *Assume that the system* (1) *satisfies Hypothesis* 2.1 *and is p-null controllable. Let* $f : \mathbb{R}^+ \to \mathbb{R}^+$ *be a continuous strictly decreasing function such that* $\lim_{t\to 0^+} f(t) = +\infty$. *Then there exists* $T_0 > 0$ *such that*

$$\mathcal{E}_p^*(T,x) \le f(T)|x| \qquad \forall x \in H, \quad T \in]0,T_0] \tag{18}$$

if and only if*, taking as f^{-1} the inverse of f, we have*

$$T_{p,\rho}(x) \le f^{-1}(\rho/|x|)$$

in a suitable neighborhood of $x = 0$. The same holds with the reverse inequalities.

Proof. For brevity we will set $\rho = 1$ along this proof. We start by proving the "only if" part. Let $0 < T < T_0$ and $x \in H$. By Theorem 3.3, it follows that there exists a control $u_{T,x} \in \mathcal{M}(p, T, x)$ such that $\|u_{T,x}\|_p \le f(T)|x|$. If $f(T)|x| \le 1$, then the control $u_{T,x}$ belongs to $\mathcal{U}_{p,1}$ and is admissible for the minimum time problem. It follows that for every $x \in H$, such that $1/|x| \in \operatorname{Im} f$, the time $\overline{T}(x) = f^{-1}(1/|x|)$ satisfies $\overline{T}(x) \ge T_p(x)$ and the claim follows.

Conversely, assume that there exists $R_1 > 0$ such that $T_p(x) \le f^{-1}(1/|x|)$ $\forall |x| \le R_1$. This fact, together with the monotonicity of f^{-1}, implies that, given $t > 0$, all points x satisfying $|x| \le R_1$ and

$$f^{-1}(1/|x|) \le t \Longleftrightarrow |x| \le 1/f(t)$$

are controllable to 0 in time t with controls in $\mathcal{U}_{p,1}$. It follows that, taking t such that $1/f(t) \le R_1$,

$$e^{tA}\left\{|x| \le 1/f(t)\right\} \subset \mathcal{L}_t \left\{\|u\|_p \le 1\right\}$$

which is equivalent to (see [11])

$$e^{tA}\left\{|x| \le r\right\} \subset \mathcal{L}_t \left\{\|u\|_p \le f(t)r\right\} \qquad \forall r > 0$$

which gives the claim. The proof in the case of the reverse inequalities is completely similar and we omit it. □

Remark 4.7. From the above proof we can infer that

$$\mathcal{R}_{p,\rho} = \left\{x \in H : \lim_{t\to+\infty} \mathcal{E}_p^*(t,x) < \rho\right\}$$

and that, setting $g(t) = \mathcal{E}_p^*(t,x)$, g is invertible and $T_{p,\rho}(x) = g^{-1}\left(\rho/|x|\right)$.

Moreover, if we have $f(T) = CT^{-\beta}$ for suitable $C > 0$, then by the previous theorem we get that $\mathcal{E}_p^*(T,x) \le CT^{-\beta}|x|$ for T in a neighborhood of $t = 0$ and x in a neighborhood of $x = 0$ *if and only if* $T_p(x) \le C_0[|x|/\rho]^{1/\beta}$ in another neighborhood of $x = 0$. The same holds for the reverse inequalities. This means that the explosion rate of $\mathcal{E}_p^*(t,x)$ at $t = 0$ *characterizes* the Hölder continuity exponent of $T_{p,\rho}(x)$ at $x = 0$. So, in the finite dimensional case this exponent is completely determined thanks to the sharp result of [35, 37] (see Theorem 3.6).

The main consequence of Theorem 4.1 is the following result on the local uniform continuity (and the Hölder continuity) of $T_{p,\rho}$ in the case $p \in (1, +\infty)$ (the continuity of T_∞ is already known and is proved in [15]).

THEOREM 4.8. *Let $p \in (1, +\infty)$. Assume that the system* (1) *satisfies Hypothesis* 2.1 *and is p-null controllable. Then $T_p(\rho, \cdot)$ is locally uniformly continuous in $x \in \mathcal{R}_{p,\rho}$. Assume also that, for a given decreasing function $f : \mathbb{R}^+ \to \mathbb{R}^+$ with $\lim_{r\to0^+} f(r) = +\infty$, condition* (18) *is satisfied. Then a modulus of continuity of $T_p(\rho, \cdot)$ on $\mathcal{R}_{p,\rho}(t) \cap \{|x| \le K\}$ is given by $r \mapsto g\left(Me^{\omega t}[1 + K]r^{1-1/p}\right)$, where $g(r) = f^{-1}(\rho/r)$.*

More precisely, for every x_1, $x_2 \in \mathcal{R}_{p,\rho}(t) \cap \{|x| \le K\}$ we have

$$|T_p(\rho, x_1) - T_p(\rho, x_2)| \le g\left(Me^{\omega t}[1 + K]\left|(x_1 - x_2)\right|^{1-\frac{1}{p}}\right). \tag{19}$$

In particular, if we can choose $f(r) = C/r^{\beta}$ *for suitable* $C > 0$*,* $\beta \geq 1$*, then the minimum time function* T_p *is locally Hölder continuous with exponent* $(q\beta)^{-1}$*, where* $q^{-1} + p^{-1} = 1$*.*

We will give the proof of the above theorem in section 5.2.

Remark 4.9. A representation of the minimum time function such as (17) and a "maximum principle" such as the one of Lemma 4.3 can be found in [38] for the case $p = 2$ but no consequence of these results is given there. Moreover, Lemma 4.3 could be seen as a consequence of the following fact: fixed $x \in H$ and $p \in (1, +\infty]$, the set-valued map $t \to \mathcal{M}(p, t, x)$ is left lower semicontinuous (see [38] for the proof of this fact in the case $p = 2$).

Finally, the fact that $T_{p,\rho}$ is lower semicontinuous in H (also without assuming p-null controllability) has been given in [38] for the case $p = 2$ by a topological argument that can be generalized to the case $p \in (1, +\infty)$.

For the reachable sets we have the following theorem which generalizes to the case $p \in (1, +\infty)$ a result given in [12] for the case $p = \infty$.

THEOREM 4.10. *Assume that Hypothesis* 2.1 *holds and let* $p \in (1, +\infty)$*,* $\rho > 0$*.*

(i) *The system* (1) *is p-null controllable if and only if* $0 \in \operatorname{Int} \mathcal{R}_{p,\rho}(t)$ *for every* $t > 0$*.*

(ii) *The system* (1) *is p-null controllable if and only if* $\mathcal{R}_{p,\rho}(t_1) \subset \operatorname{Int} \mathcal{R}_{p,\rho}(t_2)$ *for every* $t_1 < t_2$*.*

(iii) *If the system* (1) *is p-null controllable, then* $\mathcal{R}_{p,\rho}$ *is open and* $\lim_{y \to x} T_{p,\rho}(y) = +\infty \ \forall x \in \operatorname{Fr} \mathcal{R}_{p,\rho}$*.*

(iv) *If the system* (1) *is p-null controllable, then* $\mathcal{R}_{p,\rho}(t) = \{x : T_{p,\rho}(x) \leq t\}$*,* $\operatorname{Int} \mathcal{R}_{p,\rho}(t) = \{x : T_{p,\rho}(x) < t\}$*, and* $\operatorname{Fr} \mathcal{R}_{p,\rho}(t) = \{x : T_{p,\rho}(x) = t\}$*.*

Before we prove the above theorem we give a lemma that is interesting in itself since it allows us to use the properties of the functions $\mathcal{E}_p^*$ and $T_{p,\rho}$ to study $\mathcal{R}_{p,\rho}(t)$.

LEMMA 4.11. *Assume that Hypothesis* 2.1 *holds and let* $p \in (1, +\infty)$*. If the system* (1) *is p-null controllable, then*

(i) $\mathcal{R}_{p,\rho}(t) = \{x : \mathcal{E}_p^*(t, x) \leq \rho\} = \{x : T_{p,\rho}(x) \leq t\}$,

(ii) $\operatorname{Int} \mathcal{R}_{p,\rho}(t) = \{x : \mathcal{E}_p^*(t, x) < \rho\} = \{x : T_{p,\rho}(x) < t\}$,

(iii) $\operatorname{Fr} \mathcal{R}_{p,\rho}(t) = \{x : \mathcal{E}_p^*(t, x) = \rho\} = \{x : T_{p,\rho}(x) = t\}$.

Proof of Lemma 4.11. For brevity we set $\rho = 1$ and drop the dependence on ρ writing $\mathcal{R}_p, T_p$ instead of $\mathcal{R}_{p,\rho}, T_{p,\rho}$. We prove only the identities $\mathcal{R}_p(t) = \{x : \mathcal{E}_p^*(t, x) \leq 1\}$, $\operatorname{Int} \mathcal{R}_p(t) = \{x : \mathcal{E}_p^*(t, x) < 1\}$, and $\operatorname{Fr} \mathcal{R}_p(t) = \{x : \mathcal{E}_p^*(t, x) = 1\}$ since the other ones, $\{x : \mathcal{E}_p^*(t, x) \leq 1\} = \{x : T_p(x) \leq t\}$, $\{x : \mathcal{E}_p^*(t, x) < 1\} = \{x : T_p(x) < t\}$, and $\{x : \mathcal{E}_p^*(t, x) = 1\} = \{x : T_p(x) = t\}$, easily follow from Theorem 4.1 and the strict decreasing property of the function $t \to \mathcal{E}_p^*(t, x)$ for every $x \in H$.

For the first identity we observe that, by definition of $\mathcal{R}_p(t)$, we have

$$\mathcal{R}_p(t) = \{x : \mathcal{M}(p, t, x) \cap \mathcal{U}_{p,1} \neq \emptyset\}.$$

Now, if $x \in \mathcal{R}_p(t)$ it is clear by the definition that $\mathcal{E}_p^*(t, x) \leq 1$. Conversely, if $\mathcal{E}_p^*(t, x) \leq 1$ then, by the existence of the optimal control for the minimum energy problem, we have $x \in \mathcal{R}_p(t)$.

For the second identity, first let $\mathcal{E}_p^*(t, x) < 1$. Then, by the continuity of the map $x \to \mathcal{E}_p^*(t, x)$ we have that, for y in a suitable neighborhood of x, $\mathcal{E}_p^*(t, y) < 1$ and so $x \in \operatorname{Int} \mathcal{R}_p(t)$. Conversely, let $x \in \operatorname{Int} \mathcal{R}_p(t)$. By the first identity we have $\mathcal{E}_p^*(t, x) \leq 1$. If by contradiction we have $\mathcal{E}_p^*(t, x) = 1$, then by the homogeneity of degree 1 of $\mathcal{E}_p^*(t, \cdot)$ (see Theorem 3.7) it follows that for every $\lambda > 1$ we have $\mathcal{E}_p^*(t, \lambda x) > 1$ and so $\lambda x \notin \mathcal{R}_p(t)$, which is a contradiction.

For the third identity it is enough to recall that $\mathcal{R}_p(t)$ is closed and so

$$\mathrm{Fr}\,\mathcal{R}_p(t) = \mathcal{R}_p(t) - \mathrm{Int}\,\mathcal{R}_p(t) = \{x : \mathcal{E}_p^*(t,x) = 1\}. \qquad \square$$

Proof of Theorem 4.10. As in the proof above we set $\rho = 1$ and drop the dependence on ρ. We first observe that from the existence of optimal control we have, also without assuming p-null controllability, $\mathcal{R}_p(t) = \{x : T_p(x) \le t\}$ $\forall t > 0$. Then to prove (i) it is enough to observe that, by Theorem 2.5 (see [15]), the p-null controllability of the system (1) is equivalent to the continuity of T_p at $x = 0$ and thus equivalent to the fact that the set $\{T_p \le t\}$ is a neighborhood of $x = 0$ for every $t > 0$.

We now prove (ii). First, if $\mathcal{R}_p(t_1) \subset \mathrm{Int}\,\mathcal{R}_p(t_2)$ for every $t_1 < t_2$, then given any $t > 0$ we have $0 \in \mathcal{R}_p(\frac{t}{2}) \subset \mathrm{Int}\,\mathcal{R}_p(t)$ and thus have p-null controllability by part (i). Conversely, if p-null controllability holds true, then, by Lemma 4.11, for every $t_1 < t_2$ we have

$$\mathcal{R}_p(t_1) = \{x : T_p(x) \le t_1\} \subset \{x : T_p(x) < t_2\} = \mathrm{Int}\,\mathcal{R}_p(t_2).$$

We prove (iii). First we observe that $\mathcal{R}_p = \cup_{t>0}\{T_p < t\}$ and so it is open. Moreover, take $x \in \mathrm{Fr}\,\mathcal{R}_p$ and a sequence $(x_n) \subset \mathrm{Int}\,\mathcal{R}_p$ such that $x_n \to x$. From (ii) it follows that, for every $t > 0$, $\mathcal{R}_p(t) \subset \mathrm{Int}\,\mathcal{R}_p$. So, since $\mathcal{R}_p(t)$ is closed, we have definitively $x_n \notin \mathcal{R}_p(t)$ which means $T_p(x_n) > t$. The claim follows since t is arbitrary.

Statement (iv) follows from Lemma 4.11. $\square$

5. Uniform continuity and Hölder continuity.

In this section we are concerned with Hölder continuity properties of the Bellman function T_p. In the above section we obtained an estimate of the growth rate of T_p in a neighborhood of $x = 0$ in connection with the explosion rate of the minimum energy at $t = 0$. Here we discuss the possibility of extending such an estimate out of $x = 0$.

In the case $p = +\infty$ we use the results of the previous section and the dynamic programming principle, recalled below, to derive local Hölder continuity of the function T_∞ in some cases by extending results of [15].

In the case $p \in (1, +\infty)$ (where no results are available in the literature even in finite dimension) we observe, giving also an example, that the dynamic programming principle does not hold in general. Then, letting ρ be a new state variable of the problem, we prove a version of the dynamic programming principle which allows us again to transfer (with a different method) the estimate of Theorem 4.6 to the whole reachable sets obtaining local uniform continuity, an estimate of the local modulus and, in some cases, of the local Hölder exponent.

We then discuss a finite dimensional example where, for a given $T_0 > 0$, we have $\|\Gamma(t)\| \le Ct^{-3/2}$, $0 < t \le T_0$, and $T_{2,1}$ is locally Hölder continuous with exponent $1/3$ and without higher exponents.

5.1. The case $p = +\infty$.

For simplicity we set $\rho = 1$ and drop the dependence on ρ writing $\mathcal{R}_p, T_p$ instead of $\mathcal{R}_{p,\rho}, T_{p,\rho}$.

We start by recalling the dynamic programming principle for the minimum time problem if $p = +\infty$ (proved, e.g., in [15]): *For every $t \le T_\infty(x)$, for all $x \in \mathcal{R}_\infty$ we have*

$$T_\infty(x) = \inf\{t + T_\infty(y(t; x, u));\ u \in \mathcal{U}_{\infty,1}\}.$$

We observe that the dynamic programming principle is very important for studying the regularity of T_∞. In fact it allows us to estimate the continuity modulus of T_∞ by its behavior in a neighborhood of 0 (see [15] for the proof).

The above result, together with the result of the previous section, gives as a consequence the following corollary (see [15] for the proof).

COROLLARY 5.1. *Assume that the system* (1) *satisfies Hypothesis* 2.1 *and is* ∞*-null controllable. Then the minimum time function* T_∞ *is locally uniformly continuous. Assume also that, for a given decreasing function* $f : \mathbb{R}^+ \to \mathbb{R}^+$ *with* $\lim_{r\to 0^+} f(r) = +\infty$, *condition* (18) *is satisfied. Then a modulus of continuity of* T_∞ *is given by*

$$|T_\infty(x_1) - T_\infty(x_2)| \leq g\left(Me^{\omega t}\left|(x_1 - x_2)\right|\right),$$

where $g(r) = f^{-1}(1/r)$. *In particular, if we can choose* $f(r) = C/r^\beta$ *for suitable* $C > 0$, $\beta \geq 1$, *then the minimum time function* T_∞ *is locally Hölder continuous with exponent* $1/\beta$.

Remark 5.2. The claim of Corollary 5.1 is a consequence of the dynamic programming principle. This renders the case $p = +\infty$ easier to treat when we want to prove continuity properties of the minimum time function. We will see that, even for simple cases, for $p < +\infty$ the dynamic programming principle does not hold (see Example 5.14).

At this point, to prove local Hölder continuity of T_∞ we can simplify the problem to find good L^∞ estimates on the controls that bring to 0 the points x belonging to a neighborhood of 0. We remark that the best thing to do would be to calculate the minimal ∞-energy needed to bring x to 0. We now show some situations where this estimate can be given. Some of them (as we will specify below) are already given in the literature, but our results allow us to see them in a unified approach.

We start by estimating the ∞-norm of the control of minimal 2-energy $u^*_{T,x}$ defined in Theorem 3.3, since this norm is surely greater than the minimal ∞-energy needed to bring x to 0.

PROPOSITION 5.3. *Assume that Hypothesis* 2.1 *holds, that the system* (1) *is* 2*-null controllable, and that* A *generates a group. Then the system* (1) *is also* ∞*-null controllable. Moreover, if there exists* $C > 0$ *such that* $\|\Gamma(t)\| \leq Ct^{-\beta/2}$ *as* $t \to 0^+$, *then* T_∞ *is locally Hölder continuous of exponent* $\frac{1}{\beta}$. *If the dimension of* H *is finite, then* T_∞ *is locally Hölder continuous of exponent* $2/(1+\beta)$.

Proof. We first remark that by Theorem 3.3 the control $u^*_{T,x}(r) = \Gamma_r(T)^*\Gamma(T)x$, where $\Gamma_r(T) = Q_T^{-\frac{1}{2}}S(T-r)B$ transfer x to 0 in time T. We now show that $u^*_{T,x}$ is bounded and we estimate $\|u^*_{T,x}\|_\infty$. Since A generates a group, then we can write $\Gamma_r(T) = \Gamma(T)S(-r)B$, which gives

$$\|u^*_{T,x}\|_\infty \leq \sup_{r\in[0,T]} \|\Gamma(T)\|^2 \|S(-r)B\| |x|$$

and the first part of the claim easily follows.

When the dimension of H is finite it is enough to use the results of Seidman and Yong [37] contained in Theorem 3.6 for the case $p = +\infty$.

Remark 5.4. In the case of finite dimension the results of Gyurkovics [19] state that T_∞ is locally Hölder continuous exactly of exponent $1/(k+1)$, where k is the first integer such that rank $[B, AB, \ldots, A^kB] = n$. By Theorem 3.6 it then follows that the relationship between the singularity of $\|\Gamma(T)\|$ as $T \to 0$ and the continuity properties of T_∞ when $H = \mathbb{R}^n$ is the following: If $\|\Gamma(t)\| \leq Ct^{-\beta/2}$, then T_∞ is locally Hölder continuous of exponent $2/(1+\beta)$. This result confirms the one of Proposition 5.3. The same result can be deduced by the estimate of the ∞-minimum energy given in Theorem 3.6 (see [37]).

Remark 5.5. By the proof of Proposition 5.3, it follows that in the general case an estimate of the ∞-minimum energy needed to steer a state x to 0 (and so of the modulus of continuity of T_∞) is given by an estimate of the norm of the operator $\Gamma_r(T)^*\Gamma(T)$. In Proposition 5.3 such an estimate is given for the case when A is a group or H is finite dimensional. In fact, in some special cases, also when A does not generate a group, an estimate of this kind can be proved (see [16, Appendix B]). In particular, when B is onto it can be easily proved that $\sup_{r\in[0,T]}\|\Gamma_r(T)^*\Gamma(T)\| \leq C/T$ for a suitable constant C and so that $\|u^*_{T,x}\|_\infty \leq C|x|/T$. This follows also from Proposition 3.5 and proves local Lipschitz continuity of T_∞ when B is onto.

Remark 5.6. If we have for a given decreasing function $f : \mathbb{R}^+ \to \mathbb{R}^+$ $\|\Gamma(T)\| \leq f(T)$, then we obtain an estimate of the continuity modulus of T_∞. For example, for known boundary control problems (see, e.g., [36]) the best estimate is $f(T) = e^{1/T}$. This case is not treated in this paper. However, such estimates suggest that for boundary control problems the function T_∞ should not be Hölder continuous.

Remark 5.7. The result of the latter proposition is useful in the infinite dimensional case when it is possible to give an estimate of $\|\Gamma(t)\|$ as $t \searrow 0$. This is not a simple task but can be done, for example, when the system (1) is an abstract wave equation. This case has already been treated by Krabs [26] who found that $\|\Gamma(t)\| \sim t^{-3/2}$ as $t \searrow 0$ and by Carja [13] who applied this estimate to prove that T_∞ is locally Hölder continuous of exponent 1/3.

We now consider a diagonal case where the relation between the Hölder exponent of T_∞ and the singularity of $\|\Gamma(t)\|$ as $t \searrow 0$ is the same as the finite dimensional case. Assume the following.

HYPOTHESIS 5.8. *Let H be a separable Hilbert space and let $\{e_k\}$ be a complete orthonormal system in H. We assume here that A and B are of the following form:*

$$Ae_k = -\alpha_k e_k, \quad Be_k = b_k e_k, \quad k \in \mathbb{N}, \tag{20}$$

where $\{\alpha_k\}$ is an increasing (to $+\infty$) sequence of positive numbers and $\{b_k\}$ is a bounded sequence of positive numbers.

Under Hypothesis 5.8 we have, for $k \in \mathbb{N}$, $Q_t e_k = (1 - e^{-2\alpha_k t})b_k^2/(2\alpha_k)$ and, for every $t > 0$,

$$\|\Gamma(t)\|^2 = \sup_{k\in\mathbb{N}} \frac{2\alpha_k e^{-2\alpha_k t}}{b_k^2(1 - e^{-2\alpha_k t})} = \sup_{k\in\mathbb{N}} \frac{2\alpha_k}{b_k^2(e^{2\alpha_k t} - 1)}. \tag{21}$$

By Theorem 3.1 the system is 2-null controllable if and only if

$$\|\Gamma(t)\|^2 = \sup_{k\in\mathbb{N}} \frac{2\alpha_k}{b_k^2(e^{2\alpha_k t} - 1)} < +\infty. \tag{22}$$

In this case the control of minimum energy $u^*_{T,x}$ is given by

$$u^*_{T,x}(s) = \sum_{k=1}^{+\infty} \frac{2\alpha_k}{b_k} \frac{e^{-(2T-s)\alpha_k}}{1 - e^{-2T\alpha_k}} x_k e_k.$$

This control is bounded if and only if

$$\sup_{k\in\mathbb{N}} \frac{2\alpha_k}{b_k} \frac{1}{e^{2T\alpha_k} - 1} < +\infty$$

and in this case

$$\|u^*_{T,x}\|_\infty \leq \sup_{k\in\mathbb{N}} \frac{2\alpha_k}{b_k}\frac{1}{e^{2T\alpha_k}-1}|x|.$$

The estimates above depend on the behavior at infinity of the sequence $(b_k)_{k\in\mathbb{N}}$. Let us consider the particular case when $b_k = \alpha_k^{-\frac{r}{2}}$ for some $r \geq 0$ (the case $b_k \sim \alpha_k^{-\frac{r}{2}}$ would give the same results). Then (22) is fulfilled since

$$\|\Gamma(t)\|^2 = \sup_{n\in\mathbf{N}} \frac{2\alpha_k^{1+r}}{e^{2\alpha_k t}-1} \leq \frac{1}{t^{1+r}} \sup_{s>0} \frac{2s^{1+r}}{e^{2s}-1} \tag{23}$$

so that $\|\Gamma(t)\| \leq \sqrt{C(r)}t^{-(1+r)/2}$, where $C(r) = \sup_{s>0} 2s^{1+r}/(e^{2s}-1)$. Similarly we can prove that, for a suitable positive constant $c(r)$, $\|\Gamma(t)\| \geq \sqrt{c(r)}t^{-(1+r)/2}$ for t sufficiently small so that $\|\Gamma(t)\| \sim t^{-(1+r)/2}$ as $t \searrow 0$. Using the same arguments we can also show that $\|u^*_{T,x}\|_\infty \sim T^{-1-r/2}$. This allows us to extend to a diagonal infinite dimensional case the finite dimensional results of Gyurkovics [19] (see Proposition 5.3 and Remark 5.4).

Example 5.9. An example in which Hypothesis 5.8 is satisfied is the following. Let $C_N = [0,\pi]^N$ and $X = L^2(C_N)$, $N \leq 3$, and take the Laplace operator with Dirichlet conditions at the boundary defined as

$$D(A) = H^2(C_N) \cap H^1_0(C_N), Ax = \Delta x \text{ for } x \in D(A).$$

The operator A satisfies Hypothesis 2.1 and it generates an analytic semigroup of compact operators. Moreover, A satisfies Hypothesis 5.8 by taking, for $(n_1,\dots,n_N) \in \mathbb{N}^N$,

$$e_{n_1,\dots,n_N}(\xi) = \left(\frac{2}{\pi}\right)^{\frac{N}{2}} \sin n_1\xi_1 \cdots \sin n_N\xi_N$$

and $\alpha_{n_1,\dots,n_N}(\xi) = n_1^2 + \cdots + n_N^2$ so that, by ordering the eigenvalues, we obtain $\alpha_k \approx k^{\frac{2}{N}}$ as $k \to +\infty$. If we take $B = A^{-\frac{r}{2}}$, $r \geq 0$, then we have exactly the case introduced above.

We now proceed by estimating the sup norm of a different control bringing x to 0 (a similar idea, yielding different results, is used in [15]).

HYPOTHESIS 5.10.

(i) *For every* $t > 0$, $e^{tA}(H) \subset B(H)$.

(ii) *For some* $C, \alpha > 0$ $|B^{-1}e^{sA}x| \leq Cs^{-\alpha}|x|$, *where* B^{-1} *denotes the pseudo-inverse of* B *(see, e.g.,* [16, p. 407]*).*

Remark 5.11.

(i) Under Hypothesis 5.10(i), given $x \neq 0$ such that $e^{tA}x \neq 0$ for all $t > 0$, the map $t \to 1/|B^{-1}e^{tA}x|$ is locally integrable on $(0,+\infty)$ since $|B^{-1}e^{tA}x| > |e^{tA}x|/\|B\|$ and $\{e^{tA},\ t \geq 0\}$ is strongly continuous.

(ii) Hypothesis 5.10(i) implies that Ker $B^* = 0$ and so $B(H)$ is dense.

Let $\overline{u}_x(s) = -B^{-1}e^{sA}x/|B^{-1}e^{sA}x|$ (we take $\overline{u}_x(s) = 0$ if $e^{sA}x = 0$). In this case we have that $\overline{u}_x \in \mathcal{U}_{\infty,1}$ and

$$y(t;x,\overline{u}_x) = e^{tA}x\left[1 - \int_0^t \frac{1}{|B^{-1}e^{sA}x|}ds\right]$$

so, if $T > 0$ is such that

$$\int_0^T \frac{1}{|B^{-1}e^{sA}x|} ds = 1,$$

then $T_\infty(x) \le T$. Now thanks to Hypothesis 5.10(ii) we have, for $t > 0$,

$$\int_0^t \frac{1}{|B^{-1}e^{sA}x|} ds \ge \int_0^t \frac{s^\alpha}{C}|x| ds.$$

Since

$$\int_0^t \frac{s^\alpha}{C}|x| ds = 1 \Longleftrightarrow t = [C(\alpha+1)]^{\frac{1}{\alpha+1}} |x|^{\frac{1}{\alpha+1}}$$

we have, by Hypothesis 5.10(ii),

$$T_\infty(x) \le C_1 |x|^{\frac{1}{\alpha+1}} \quad \text{for some } C_1 > 0$$

which gives, by Theorem 4.6, that T_∞ is locally Hölder continuous of exponent $\frac{1}{\alpha+1}$. We have thus proved the following.

PROPOSITION 5.12. *Assume that Hypotheses* 2.1 *and* 5.10 *hold true. Then the system* (1) *is* ∞*-null controllable and* T_∞ *is locally Hölder continuous with exponent* $1/(\alpha+1)$.

Remark 5.13. If the system (1) is 2-null controllable and Im $\{Q_t^{\frac{1}{2}}\} \subset$ Im $\{B\}$ $\forall t > 0$, then we can write

$$|B^{-1}e^{sA}x| = |B^{-1}Q_s^{\frac{1}{2}}\Gamma(s)x| \le |B^{-1}Q_s^{\frac{1}{2}}||\Gamma(s)x|.$$

So, if we assume that, for a given constant $C > 0$ and for s in a neighborhood of 0 we have $|\Gamma(s)x| \le Cs^{-\beta/2}|x|$, then, to apply Proposition 5.12 we have only to estimate $|B^{-1}Q_s^{\frac{1}{2}}|$. This can be done, for example, in the diagonal case described above yielding the same results obtained there.

A framework where Proposition 5.12 can be used is the following. Let A be the generator of an analytic semigroup on H such that $A^{-1} \in \mathcal{L}(H)$. Assume also that B can be written as $A^{-r}B_0$, where B_0 is continuous and onto (so that B_0^{-1} is also continuous).

Then we clearly have, by the analyticity of the semigroup, $e^{tA}(H) \subset D(A^r) = B(H)$ and, for every $t > 0$, $x \in H$, and a suitable constant $C > 0$,

$$|B^{-1}e^{tA}x| = |B_0^{-1}A^r e^{tA}x| \le \|B_0^{-1}\| \, \|A^r e^{tA}\| \, |x| \le Ct^{-r}|x|.$$

This implies that T_∞ is locally Hölder continuous with exponent $1/(1+r)$.

5.2. The case $p \in (1, +\infty)$. In the following we construct an example for the case $p = 2$, showing that the dynamic programming principle does not apply. This difference is crucial when studying regularity properties of the minimum time function. Then we will consider the minimum time problem where the radius ρ of the set of admissible controls is variable. For this problem we prove the dynamic programming principle and then we use it to get local estimates of the modulus of uniform continuity of the Bellman function.

Applying the same argument used in the proof of Theorem 4.6 we obtain that, in the case $p = 2$,

$$\begin{gathered} \|\Gamma(t)\| \leq C_1 t^{-\beta/2}|x| \text{ in a right neighborhood of } t = 0 \\ \Downarrow \\ T_{2,\rho}(x) \leq C_2[|x|/\rho]^{2/\beta} \text{ in a neighborhood of } x = 0 \end{gathered}$$

and, by the dynamic programming principle,

$$\begin{gathered} T_{2,\rho}(x) \leq C_2[|x|/\rho]^{\frac{2}{\beta}} \text{ in a neighborhood of } x = 0 \\ \Updownarrow \\ T_{2,\rho}(x_1) - T_{2,\rho}(x_2) \leq [C_3/\rho^{2/\beta}]|x_1 - x_2|^{\frac{2}{\beta}} \quad \forall x_1, x_2 \in \mathcal{R}_2, |x_1 - x_2| \text{ sufficiently small.} \end{gathered}$$

In particular this would imply that, when $B = I$, the function T_2 is constant, which is not true as can be seen by the following example.

Example 5.14. Let $H = \mathbb{R}$ and the state equation be

$$y' = y + u; \qquad y(0) = x.$$

Then $Q_t = \int_0^t e^{2s} ds = \frac{e^{2t}-1}{2}$ and $\Gamma(t) = Q_t^{-\frac{1}{2}} e^{tA} = \frac{\sqrt{2}}{\sqrt{e^{2t}-1}} e^t$ so that

$$|\Gamma(t)x| = \frac{\sqrt{2}}{\sqrt{1 - e^{-2t}}}|x| \text{ and, in particular, } |\Gamma(t)x| \approx \frac{C}{t^{\frac{1}{2}}}.$$

By Theorem 4.1 we have $|\Gamma(T_2(x))x| = \rho$, so we obtain by easy calculations that $\mathcal{R}_{2,\rho} = (-\frac{\rho}{\sqrt{2}}, \frac{\rho}{\sqrt{2}})$ and $T_{2,\rho}(x) = -\frac{1}{2}\log(1 - 2x^2/\rho^2)$.

Remark 5.15. This example is in contrast with the result given in [15, Lemma 2.1]. In fact the proof of this lemma seems to be incorrect in the case $p < +\infty$. From the proof of the dynamic programming principle it can be seen that for $p \in (1, +\infty)$ only the following inequality holds: $T_p(x) \geq \inf\{t + T_p(y(t; x, u)),\ u \in \mathcal{U}_{p,1}\}$.

Consider now, for $p \in (1, +\infty]$, the minimum time problem, where the radius ρ of the set of admissible controls is a state variable that represents the amount of p-energy left to consume. Then ρ clearly follows the equation

$$\frac{d}{dt}\rho^p(t) = |u(t)|^p; \qquad \rho(0) = \rho_0$$

which can be written in integral form as (denoting as $\rho(t; \rho_0, u)$ the unique solution of the above equation)

$$\rho^p(t; \rho_0, u) = \rho_0^p - \int_0^t |u(s)|^p ds.$$

The latter equation, coupled with (1), gives the state equation of the new problem (with state variables ρ and y); the Bellman function will depend now on (ρ, x) and we will denote it by $T_p(\rho, x)$. We have the following result (which is the main advantage of taking the ρ variable).

THEOREM 5.16. *Let $p \in (1, +\infty)$ and $(\rho_0, x_0) \in (0, +\infty) \times R_{p,\rho_0}$. For every $t \leq T_p(\rho_0, x_0)$ we have*

$$T_p(x) = \inf\left\{t + T_p(\rho(t; \rho_0, u), y(t; x_0, u));\ u \in \mathcal{U}_{\infty,\rho_0}\right\}.$$

Proof. The proof follows along the same line of the proof given in [15] after taking account of the variability of ρ. Fix $x \in H$. The first step of the proof is to show

$$T_p(\rho_0, x_0) \le t + T_p(\rho(t;\rho_0,u), y(t;x_0,u)) \quad \forall u \in \mathcal{U}_{\infty,\rho_0}.$$

If $y(t;x_0,u)$ is not in $\mathcal{R}_{p,\rho_0}$, then $T_p(\rho(t;\rho_0,u), y(t;x_0,u)) = +\infty$ and there is nothing to prove. Hence, we can assume that $y(t;x_0,u) \in \mathcal{R}_{p,\rho(t;\rho_0,u)}$ and this is equivalent to saying that $T_p(\rho(t;\rho_0,u), y(t;x_0,u)) < +\infty$. Let $s \ge T_p(\rho(t;\rho_0,u), y(t;x_0,u))$. Then $y(t;x_0,u) \in \mathcal{R}_{p,\rho(t;\rho_0,u)}(s)$, i.e., $y(s, y(t;x_0,u), \hat{u}) = 0$ for some $\hat{u} \in \mathcal{U}_{\infty,\rho(t;\rho_0,u)}$. We then have

$$e^{sA}\left[e^{tA}x_0 + e^{sA}\int_0^t e^{(t-s)A}Bu(s)ds\right] + \int_0^s e^{(s-r)A}B\hat{u}(r)dr = 0$$

which means

$$e^{(s+t)A}x_0 + \int_0^{t+s} e^{(t+s-r)A}Bu^*(r)dr = 0,$$

where $u^* \in \mathcal{U}_{\infty,\rho_0}$ is defined as $u^*(r) = u(r)$ for $0 \le r \le t$ and $u^*(r) = \hat{u}(r-t)$ for $t \le r \le s+t$. This implies that $x_0 \in \mathcal{R}_{p,\rho_0}(s+t)$ and then

$$T_p(\rho_0, x_0) \le t + s \qquad \forall s \ge T_p(\rho(t;\rho_0,u), y(t;x_0,u)).$$

Hence

$$T_p(\rho_0, x_0) \le t + T_p(\rho(t;\rho_0,u), y(t;x_0,u)) \qquad \forall u \in \mathcal{U}_{\infty,\rho_0}.$$

This ends the first step. To prove the claim it remains to show that for every $\varepsilon > 0$ there exists $u \in \mathcal{U}_{\infty,\rho_0}$ such that

$$T_p(\rho_0, x_0) \ge t + T_p(\rho(t;\rho_0,u), y(t;x_0,u)) - \varepsilon \qquad \text{for } t \le T_p(\rho_0, x_0).$$

Fix $\varepsilon > 0$. By definition of T_p there exists $s < T_p(\rho_0, x_0) + \varepsilon$ such that $x_0 \in \mathcal{R}_{p,\rho_0}(s)$. Since $x_0 \in \mathcal{R}_{p,\rho_0}(s)$, we have

$$e^{sA}x_0 + \int_0^s e^{(s-r)A}Bv(r)dr = 0 \tag{24}$$

for some $v \in \mathcal{U}_{p,\rho_0}$. By assumption we have $t \le T_p(\rho_0, x_0)$. This implies $t \le s$. We consider $t < s$ (otherwise everything is clear) and we rewrite (24) as

$$e^{(s-t)A}e^{tA}x_0 + e^{(s-t)A}\int_0^t e^{(t-r)A}Bv(r)dr + \int_t^s e^{(s-r)A}Bv(r)dr = 0$$

which yields

$$e^{(s-t)A}y(t;x_0,v) + \int_0^{s-t} e^{(s-t-r)A}Bv(t+r)dr = 0.$$

Since we have $v(t+\cdot) \in \mathcal{U}_{p,\rho(t;\rho_0,v)}$ the latter implies that $y(t;x_0,v) \in \mathcal{R}_{p,\rho(t;\rho_0,v)}(s-t)$ and so that $T_p(\rho(t;\rho_0,v), y(t;x_0,v)) \le s - t$, i.e.,

$$t + T_p(\rho(t;\rho_0,v), y(t;x_0,v)) \le s \le T_p(\rho_0, x_0) + \varepsilon.$$

This ends the proof. $\square$

The key consequence of the above theorem is Theorem 4.8 which we prove below.

Proof of Theorem 4.8. Let $\rho_0 > 0$, $x_1, x_2 \in H$, and $T_p(\rho_0, x_1) > T_p(\rho_0, x_2)$. For simplicity we will prove the claim when $|x_1 - x_2| \leq 1/2$, as the estimate (19) for the case $|x_1 - x_2| > 1/2$ follows by simply using the local boundedness of $T_p(\rho_0, \cdot)$ on $\mathcal{R}_{p,\rho_0} \cap \{|x| \leq K\}$. Let t be such that $T_p(\rho_0, x_1) > t$. By the dynamic programming principle

$$T_p(\rho_0, x_1) \leq t + T_p(\rho(t; \rho_0, u), y(t; x_1, u)) \qquad \forall u \in \mathcal{U}_{p,\rho_0}. \tag{25}$$

Taking $t = T_p(\rho_0, x_2)$ in (25) we find

$$T_p(\rho_0, x_1) - T_p(\rho_0, x_2) \leq T_p\left(\rho(T_p(\rho_0, x_2); \rho_0, u), y\left(T_p(\rho_0, x_2); x_1, u\right)\right) \qquad \forall u \in \mathcal{U}_{p,\rho_0}$$

so that, using Theorem 4.6 and calling $g(r) = f^{-1}(\rho_0/r)$ (which is a strictly increasing function),

$$T_p(\rho_0, x_1) - T_p(\rho_0, x_2) \leq g\left(\frac{\rho_0 y\left(T_p(\rho_0, x_2); x_1, u\right)}{\rho(T_p(\rho_0, x_2); \rho_0, u)}\right) \qquad \forall u \in \mathcal{U}_{p,\rho_0}. \tag{26}$$

Now let $\lambda \in (0, 1)$, let u_2 be the optimal control for $T_p(\rho_0, x_2)$, and choose $u_\lambda = \lambda u_2$ in the above inequality. We then have, by easy calculations,

$$\rho(T_p(\rho_0, x_2); \rho_0, u_\lambda) = \rho_0[1 - \lambda^p]^{1/p} > \rho_0[1 - \lambda]^{1/p}. \tag{27}$$

Moreover, since $y(T_p(\rho_0, x_2); x_2, u_2) = 0$, we have

$$\int_0^{T_p(\rho_0,x_2)} e^{(T_p(\rho_0,x_2)-s)A} B u_2(s) ds = -e^{T_p(\rho_0,x_2)A} x_2$$

and so

$$\begin{aligned} y(T_p(\rho_0, x_2); x_1, u_\lambda) &= e^{T_p(\rho_0,x_2)A} x_1 - \lambda e^{T_p(\rho_0,x_2)A} x_2 \\ &\leq M e^{\omega T_p(\rho_0,x_2)} |x_1 - x_2| + (1 - \lambda) M e^{\omega T_p(\rho_0,x_2)} |x_2|. \end{aligned} \tag{28}$$

Hence, putting (27) and (28) into (26) we can write

$$T_p(\rho_0, x_1) - T_p(\rho_0, x_2) \leq g\left(\frac{M e^{\omega T_p(\rho_0,x_2)}[|x_1 - x_2| + (1 - \lambda)|x_2|]}{[1 - \lambda]^{1/p}}\right).$$

Setting $\lambda = 1 - |x_1 - x_2|$ we then have

$$T_p(\rho_0, x_1) - T_p(\rho_0, x_2) \leq g\left(M e^{\omega T_p(\rho_0,x_2)} [1 + |x_2|] |x_1 - x_2|^{1-1/p}\right)$$

which gives the claim by interchanging the roles of x_1 and x_2. $\square$

In the finite dimensional case an answer about the local Hölder continuity of T_p follows immediately from the following corollary and the result of Seidman and Yong [35, 37] recalled in Theorem 3.6.

Corollary 5.17. *Assume that the system* (1) *is p-null controllable* ($p \in (1, +\infty)$) *and that $H = \mathbb{R}^n$. Let k be the minimum integer such that the matrix $\left[B, AB, ..., A^k B\right]$ is full rank. Then the minimum time function $T_p(\rho, \cdot)$ is Hölder continuous of exponent $[1 + kq]^{-1}$, where $q^{-1} + p^{-1} = 1$.*

We now give a finite dimensional example where the exponent $[1+kq]^{-1}$ stated above is sharp.

Example 5.18. Let $\mathrm{n}=2$, $\mathcal{U}=\mathcal{U}_{2,1}$, and take the system (1) with

$$A=\begin{pmatrix}0 & 0\\ 1 & 0\end{pmatrix}\ B=\begin{pmatrix}1 & 0\\ 0 & 0\end{pmatrix}.$$

We have rank $[B, AB]=2$ so 2-null controllability holds. By easy calculations we get that the control of minimum energy $u^*_{t,x}(r)=-B^*e^{(t-r)A^*}Q_t^{-1}e^{tA}x$ is given by

$$u^*_{t,x}(r)=-\frac{2}{t}\left[\left(2-\frac{3r}{t}\right)x_1+\frac{3}{t}\left(1-\frac{2r}{t}\right)x_2\right]$$

and the minimum energy by

$$|\Gamma(t)x|^2=\frac{4}{t^2}\left[tx_1^2+\frac{3}{t}x_2^2+3x_1x_2\right].$$

Now to compute $T_2(x)$ we solve $|\Gamma(T_2(x))x|^2=1$ which gives

$$T_2(x)=\frac{2^{\frac{2}{3}}}{3}\left[2^{\frac{4}{3}}x_1^2+2^{\frac{2}{3}}x_1(4x_1^3+9x_2)^{\frac{1}{3}}+(4x_1^3+9x_2)^{\frac{2}{3}}\right].$$

Now it is not hard to show that $T_2(x)$ is locally Hölder continuous with exponent 1/3. In fact, it is the sum of three functions: the first is locally Lipschitz continuous, the second is locally Hölder continuous with exponent 1/3, and the third is locally Hölder continuous with exponent 2/3. Moreover, $T_2(x)$ is not locally Hölder continuous with higher exponents because it can be easily verified that the second function is not locally Hölder continuous with exponents greater than 1/3.

Acknowledgments. The authors wish to thank P. Cannarsa for suggesting the idea of adding the new variable ρ to prove the uniform and Hölder continuities in the case $p\in(1,\infty)$; I. C. Dolcetta for suggesting the problem; A. Cutrí, V. Komornik, and J. Zabczyk for discussions and comments; and the referees for suggestions which improved the presentation of the paper.

ON THE CONVERGENCE AND APPLICATIONS OF GENERALIZED SIMULATED ANNEALING[*]

P. DEL MORAL[†] AND L. MICLO[†]

Abstract. The convergence of the generalized simulated annealing with time-inhomogeneous communication cost functions is discussed. This study is based on the use of log-Sobolev inequalities and semigroup techniques in the spirit of a previous article by one of the authors. We also propose a natural test set approach to study the global minima of the virtual energy. The second part of the paper is devoted to the application of these results. We propose two general Markovian models of genetic algorithms and we give a simple proof of the convergence toward the global minima of the fitness function. Finally we introduce a stochastic algorithm that converges to the set of the global minima of a given mean cost optimization problem.

Introduction. Let E be a finite state space and q an irreducible Markov kernel. The main purpose of this paper is to study the limiting behavior of a large class of time-inhomogeneous Markov processes controlled by two parameters $(\gamma,\beta)\in\mathbb{R}_+^2$ and associated with a family of Markov kernels $Q_{\gamma,\beta}(x,y)$ having the following property:

$$\exists k>0\ :\quad k^{-1}\, q(x,y)e^{-\beta V_\gamma(x,y)} \leq Q_{\gamma,\beta}(x,y) \leq k\ \ q(x,y)e^{-\beta V_\gamma(x,y)}, \tag{1}$$

where $V:\mathbb{R}_+\times E^2\to\mathbb{R}_+\cup\{\infty\}$, $V_\gamma(x,y)<+\infty \iff q(x,y)>0$, and for any $x,y\in E$, $(\gamma,\beta)\to Q_{\gamma,\beta}(x,y)\in C^1$.

For a discussion on the origins of this problem the reader is referred to the introduction of Trouvé [12], who studies the asymptotic behavior of such chains, with time-homogeneous function $V(x,y)$, using large deviation techniques. The fundamental notions here are those of the log-Sobolev constant $a(\gamma,\beta)$ of $Q_{\gamma,\beta}$ and the relative entropy of a measure with respect to another measure. Other complementary results relating to time-inhomogeneous communication cost function can be found in Frigerio–Grillo [7], Younes [13], and more recently in Löwe [9], where Sobolev inequalities rather than log-Sobolev inequalities are used for classical models where q is assumed to be reversible and V_γ is associated with an a priori potential depending on γ.

For a probability measure m on E, inverse-freezing schedule $\beta\in C^1(\mathbb{R}_+,\mathbb{R}_+)$ and $\gamma\in C^1(\mathbb{R}_+,\mathbb{R}_+)$, we denote (Ω,P,F_t,X_t) as the canonical process associated with the family of generators $(L_{\gamma_t,\beta_t})_{t\geq 0}=(Q_{\gamma_t,\beta_t}-I)_{t\geq 0}$ whose initial condition is $m_0=m$, and we denote m_t as the distribution of X_t.

The aim of section 1.1 is to give several conditions on the rate of increase of $\gamma_t,\beta_t\to+\infty$ to ensure the entropy of m_t with respect to π_{γ_t,β_t} converges to 0. We shall examine as much of the theory as possible in a form applicable to general optimization problems and applicable in particular to mean cost optimization problems.

To illustrate our results we will restrict attention to various special classes of generalized simulated annealing. We will commence with a detailed analysis of general Markov kernels of the form

$$Q_\beta(x,y) = \sum_{u \in U} \overline{q}_\beta(x,u,y) e^{-\beta \overline{V}(x,u,y)}, \tag{2}$$

where U is a given finite set, $\overline{V} : E \times U \times E \to \mathbb{R}_+$, and $\overline{q}_\beta : E \times U \times E \to \mathbb{R}_+$, $\beta \in \mathbb{R}_+$, is a family of functions satisfying some continuity and irreducibility conditions. This situation can be formulated in the general form (1). We will settle this question and provide the explicit computation of the corresponding communication cost function V. In a final stage we will give several conditions on the rate of decrease of the cooling schedule to ensure the convergence in probability of the corresponding canonical process X_t, as $t \to +\infty$, to the set of global minima of the virtual energy associated with V.

Another application is the situation in which the Markov kernel $Q_{\gamma,\beta}$ has the form

$$Q_{\gamma,\beta}(x,y) = q_\beta(x,y)\ e^{\beta V_\gamma(x,y)}$$

with

$$\lim_{\gamma \to +\infty} V_\gamma(x,y) = V(x,y), \qquad \lim_{\beta \to +\infty} q_\beta(x,y) = q(x,y)$$

for some Markov kernel q and some function $V : E \times E \to \mathbb{R}^+$. In this situation, let π_β be the unique invariant probability measure of the Markov generator $L_\beta = Q_\beta - I$, where

$$Q_\beta(x,y) = q(x,y)\ e^{-\beta\, V(x,y)}.$$

We will give several conditions on the rate of decrease of the cooling schedule and on the rate of convergence $\lim_{t \to +\infty} V_{\gamma_t} = V$ to ensure the entropy of m_t with respect to π_{β_t} converges to 0.

The above results imply that the canonical process X_t converges in law to the set of the global minima $V^\star$ of a virtual energy V. This leads us to investigate more closely the properties of such function. Section 1.2 introduces a natural test set approach to study $V^\star$. Specifically, we will give a condition for a given subset $H \subset E$ to contain $V^\star$.

Section 2 is devoted to application of these results, an area of which is the situation in which Q_β is the transition probability kernel of a genetic algorithm. Such algorithms can be formulated by a Markov process with state space $E = S^N$ ($N > 1$ and S a finite set) and whose transition probabilities Q_β includes a mutation transition $Q_\beta^{(1)}$ and a selection mechanism $Q_\beta^{(2)}$. More precisely the mutation transition is modeled by independent motion of each particle and the selection mechanism chooses randomly in the previous population according to a given fitness function. The first convergence result was obtained by Cerf [2] in the case in which $Q_\beta = Q_\beta^{(1)} Q_\beta^{(2)}$ and the mutations vanish, that is, $\lim_{\beta \to +\infty} Q_\beta^{(1)}(x,y) = 1_x(y)$.

In section 2.1 we will use the results of section 1.1 and the test set approach introduced in section 1.2 to derive a new and simple proof of the convergence in probability of such algorithms to the set of the global minima of the fitness function in the following situations:

$$Q_\beta = Q_\beta^{(1)} Q_\beta^{(2)} \quad \text{and} \quad Q_\beta = \alpha\, Q_\beta^{(1)} + (1-\alpha)\, Q_\beta^{(2)}, \quad 0 < \alpha < 1.$$

Finally, in subsection 2.2 we will apply the results of the first section to mean cost optimization problems. However, here we touch upon a slightly different aspect of the theory. Namely, the object will be to find the global minima of a function $U : E \to \mathbb{R}_+$ defined by

$$U(x) = E(L(Z, x)),$$

where Z is a random variable taking values in a finite set F and $L : F \times E \to \mathbb{R}_+$. We will solve this optimization problem by an original method based on the use of Monte Carlo simulations coupled with simulated annealing. This special case will require specific developments because the corresponding function V_γ will necessarily behave as a random process. We will present a time-inhomogeneous Markov process which converges to the global minima of U.

1. General results.

The purpose of this section is to study the limiting behavior of time-inhomogeneous Markov chains controlled by two parameters $(\gamma, \beta) \in \mathbb{R}_+^2$ and associated with a family of Markov kernels $Q_{\gamma,\beta}(x, y)$ having the property (1), with the assumptions given in the introduction. This is in keeping with our second objective, which is to introduce some areas in which such results are useful.

The reader who is especially interested in genetic algorithms has to consult Corollary 1 and Propositions 3 and 4. Finally, the numerical solving of mean cost optimization problems requires only the use of Theorem 2 or Corollary 4.

1.1. Relative entropy convergence.

Our analysis will be based entirely on considerations of the time-continuous semigroup associated with the Markov kernels $Q_{\gamma,\beta}(x, y)$ introduced in (1). Namely, define for $f : E \to \mathbb{R}$

$$L_{\gamma,\beta} f(x) = \sum_{y \in E} (f(y) - f(x))\, Q_{\gamma,\beta}(x, y).$$

For a probability measure m on E, an inverse-freezing schedule $\beta \in C^1(\mathbb{R}_+, \mathbb{R}_+)$, and $\gamma \in C^1(\mathbb{R}_+, \mathbb{R}_+)$, we denote (Ω, P, F_t, X_t) as the canonical process associated with the family of generators $(L_{\gamma_t,\beta_t})_{t \geq 0} = (Q_{\gamma_t,\beta_t} - I)_{t \geq 0}$ whose initial condition is $m_0 = m$, and we write m_t the distribution of X_t.

Whenever X is time-homogeneous (i.e., $\beta_t = \beta$ and $\gamma_t = \gamma$) it is well known that $L_{\gamma,\beta}$ has a unique invariant probability measure $\pi_{\gamma,\beta}$ so that

$$\forall f : E \to \mathbb{R} \qquad \pi_{\gamma,\beta}(L_{\gamma,\beta} f) = 0$$

and $\pi_{\gamma,\beta}$ charges all the points. It is also convenient to recall the notion of log-Sobolev constant of $Q_{\gamma,\beta}$. Namely,

$$a(\gamma, \beta) \overset{\text{def}}{=} \min \left\{ \mathcal{E}_{\gamma,\beta}(f, f) / \mathcal{L}_{\gamma,\beta}(f),\ \mathcal{L}_{\gamma,\beta}(f) \neq 0 \right\},$$

where the Dirichlet form $\mathcal{E}_{\gamma,\beta}$ and $\mathcal{L}_{\gamma,\beta}$ are defined by

$$\mathcal{E}_{\gamma,\beta}(f, g) = -\langle L_{\gamma,\beta} f, g \rangle_{\pi_{\gamma,\beta}} = -\sum_{x \in E} L_{\gamma,\beta} f(x)\, g(x)\, \pi_{\gamma,\beta}(x),$$

$$\mathcal{L}_{\gamma,\beta}(f) = \sum_{x \in E} f(x)^2 \log \left(f(x)^2 / \|f\|_{2,\pi_{\gamma,\beta}}^2 \right) \pi_{\gamma,\beta}(x).$$

Let us recall the notion of relative entropy of a measure m with respect to a measure π charging all the points

$$\mathrm{Ent}_{\pi}(m) = \sum_{x\in E} m(x)\ \log\left(m(x)/\pi(x)\right).$$

Using this notation, whenever X is time-homogeneous, one has the following basic inequality (for instance, see Miclo [10]):

$$\frac{d}{dt}\mathrm{Ent}_{\pi_{\gamma,\beta}}(m_t) \leq -2\ a(\gamma,\beta)\ \mathrm{Ent}_{\pi_{\gamma,\beta}}(m_t). \tag{3}$$

For an expository paper on log-Sobolev constants for the general Markov chain on finite spaces the reader is referred to Diaconis–Saloff-Costes [5]. Holley and Stroock [8] use Sobolev and log-Sobolev inequalities to study the standard simulated annealing. For another approach using only spectral gap estimates the reader should consult [4]. Using log-Sobolev inequalities, one of the authors addressed the convergence of a simulated annealing associated with a Markov transition kernel of the form using the entropy distance to stationarity (see [10]). The purpose of this section is to extend these results to general Markov transition kernels of form (1).

What follows is an exposition of some basic results regarding the description of $\pi_{\gamma,\beta}$, by Bott–Mayberry [1] and also exposed in Freidlin–Wentzell [6]. For $x \in E$ we denote $G_E(x)$, or $G(x)$ when there are no possible confusions, as the set of x-graphs. We shall also use the following notations for $x \in E$ and $g \in G(x)$:

$$R_{\gamma,\beta}(x) = \sum_{g\in G(x)} Q_{\gamma,\beta}(g), \qquad Q_{\gamma,\beta}(g) = \prod_{(y\to z)\in g} Q_{\gamma,\beta}(y,z),$$
$$V_{\gamma}(g) = \sum_{(y\to z)\in g} V_{\gamma}(y,z), \qquad \mathbf{Q}_{\gamma,\beta}(x,y) = q(x,y)\ e^{-\beta\, V_{\gamma}(x,y).}$$

Then, whenever X is time-homogeneous, its invariant distribution $\pi_{\gamma,\beta}$ is given by

$$\pi_{\gamma,\beta}(x) = R_{\gamma,\beta}(x)/\sum_{z\in E} R_{\gamma,\beta}(z).$$

Similarly, let $\mu_{\gamma,\beta}$ be the invariant probability measure of

$$\mathbf{L}_{\gamma,\beta} f(x) = \sum_{y\in E} (f(y) - f(x))\ \mathbf{Q}_{\gamma,\beta}(x,y).$$

If $\mathbf{a}(\gamma,\beta)$ is the log-Sobolev constant of $\mathbf{Q}_{\gamma,\beta}$, then under assumption (1) there exists some constant $k_1 > 0$ such that

$$k_1^{-1}\mu_{\gamma,\beta}(x) \leq \pi_{\gamma,\beta}(x) \leq k_1 \mu_{\gamma,\beta}(x). \tag{4}$$

Now, from the very definition of $\mu_{\gamma,\beta}$ and (4), we have the estimate

$$-\beta^{-1}\ \log \pi_{\gamma,\beta}(x) \xrightarrow[\beta\,\to\,+\infty]{} V_{\gamma}(x) - \min_{z\in E} V_{\gamma}(z) \quad \text{with} \quad V_{\gamma}(x) \overset{\text{def}}{=} \min_{g\in G(x)} V_{\gamma}(g).$$

As a direct consequence of Lemma 3.3, Diaconis–Saloff-Costes [5], and the inequalities (1) and (4) there exists some constant $B > 0$ such that

$$B^{-1}\ \mathbf{a}(\gamma,\beta) \leq a(\gamma,\beta) \leq B\ \mathbf{a}(\gamma,\beta).$$

Finally, by Theorem 3.23 of Holley–Stroock [8] and the inequalities stated in Miclo [10], we have the following proposition.

PROPOSITION 1. *There exists some constant $A > 0$ such that $a(\gamma,\beta) \geq A\,\frac{e^{-\beta\,c(\gamma)}}{1+\beta}$, where $c(\gamma)$ is the critical height associated with the communication cost V_γ given by*

$$c(\gamma) = \max_{x,y\in E}\left(\min_{p\in\mathcal{S}_{x,y}} e_\gamma(p) - V_\gamma(x) - V_\gamma(y)\right) + \min_{z\in E} V_\gamma(z),$$
$$e_\gamma(p) = \max_{1\leq i\leq n} \min\left(V_\gamma(p_{i-1}) + V_\gamma(p_{i-1},p_i), V_\gamma(p_i) + V_\gamma(p_i,p_{i-1})\right),$$

where $\mathcal{S}_{x,y}$ is the set of all the finite sequences from x to y and $e_\gamma(p)$ denotes elevation of a path. It can also be shown that

$$c(\gamma) = \max_{x,y\in E}\left(\min_{p\in C_{x,y}} \tilde{e}_\gamma(p) - V_\gamma(x) - V_\gamma(y)\right) + \min_{z\in E} V_\gamma(z),$$

where

$$\tilde{e}_\gamma(p) = \max_{1\leq i\leq n} V_\gamma(p_{i-1}) + V_\gamma(p_{i-1},p_i)$$

and $C_{x,y}$ is the set of all paths (admissible for q) from x to y.

By choosing $t \to (\gamma_t,\beta_t)$ to go to infinity and using (3) we arrive at

$$\frac{d}{dt}\mathrm{Ent}_{\pi_{\gamma_t,\beta_t}}(m_t) \leq -2\,A\,\frac{e^{-\beta_t\,c(\gamma_t)}}{1+\beta_t}\mathrm{Ent}_{\pi_{\gamma_t,\beta_t}}(m_t) - \sum_{x\in E} m_t(x)\frac{d}{dt}\log\pi_{\gamma_t,\beta_t}(x). \tag{5}$$

Therefore it remains to estimate the derivatives $d\pi_{\gamma,\beta}/d\beta$ and $d\pi_{\gamma,\beta}/d\gamma$. For this purpose, write

$$\overline{Q}_{\gamma,\beta}(g) = Q_{\gamma,\beta}(g)/\sum_{h\in I_x} Q_{\gamma,\beta}(h), \qquad I_x = \left\{g\in G(x)\ :\ \prod_{(y\to z)\in g} q(y,z) > 0\right\}.$$

By a simple analysis it is easily checked that

$$\frac{d}{d\beta}\log R_{\gamma,\beta}(x) = \sum_{g\in I_x} \overline{Q}_{\gamma,\beta}(g)\frac{d}{d\beta}\log Q_{\gamma,\beta}(g),$$
$$\frac{d}{d\beta}\log \pi_{\gamma,\beta}(x) = \sum_{z\in E}\left(\frac{d}{d\beta}\log R_{\gamma,\beta}(x) - \frac{d}{d\beta}\log R_{\gamma,\beta}(z)\right)\pi_{\gamma,\beta}(z).$$

In order to derive a useful inequality we assume there exist two functions $d_1,\ d_2 : \mathbb{R}_+ \to \mathbb{R}_+$ such that

$$\sup_{g\in\cup_x I_x}\frac{d}{d\beta}\log Q_{\gamma,\beta}(g) - \inf_{g\in\cup_x I_x}\frac{d}{d\beta}\log Q_{\gamma,\beta}(g) \leq d_1(\gamma), \tag{6}$$

$$\sup_{g\in\cup_x I_x}\frac{d}{d\gamma}\log Q_{\gamma,\beta}(g) - \inf_{g\in\cup_x I_x}\frac{d}{d\gamma}\log Q_{\gamma,\beta}(g) \leq d_2(\beta). \tag{7}$$

Note that by the very definitions of the sets I_x it clearly suffices to have

$$\left|\frac{d}{d\beta}\log Q_{\gamma,\beta}(x,y)\right| \leq \tilde{d}_1(\gamma), \qquad \left|\frac{d}{d\gamma}\log Q_{\gamma,\beta}(x,y)\right| \leq \tilde{d}_2(\beta)$$

for every $q(x,y) > 0$ and two functions $\tilde{d}_1,\ \tilde{d}_2 : \mathbb{R}_+ \to \mathbb{R}_+$. Now we are ready to apply the following technical lemma.

LEMMA 1 (Stroock [11]). *If μ is a probability measure and $\theta \in L^1(\mu)^+$ satisfies $\int \theta d\mu = 1$, then for every $\phi \in L^\infty(\mu)$ satisfying $\int \phi d\mu = 0$ one has*

$$\left| \int \phi\, \theta\, d\mu \right| \leq \sqrt{2}\, \|\phi\|_{L^\infty(\mu)} \left(\int \theta\, \log \theta\, d\mu \right)^{1/2}.$$

Using this lemma with $\mu = \pi_{\gamma,\beta}$, $\phi = d \log \pi_{\gamma,\beta}/d\beta$ (resp., $\phi = d \log \pi_{\gamma,\beta}/d\gamma$), and $\theta = m_t/\pi_{\gamma_t,\beta_t}$ and writing

$$I_t \overset{\mathrm{def}}{=} (\mathrm{Ent}_{\pi_{\gamma_t,\beta_t}}(m_t))^{1/2}$$

we see from (5) that

$$\frac{dI_t}{dt} \leq -A_0\, \frac{e^{-\beta_t\, c(\gamma_t)}}{1+\beta_t} I_t + A_1\, d_1(\gamma_t) \left| \frac{d\beta_t}{dt} \right| + A_2\, d_2(\beta_t) \left| \frac{d\gamma_t}{dt} \right| \tag{8}$$

for some constants $A_0, A_1, A_2 > 0$. Hence by taking, for t sufficiently large, an inverse-temperature schedule of the form $\beta_t = K^{-1} \log t$ we obtain

$$\frac{dI_t}{dt} \leq -A_t\, I_t + B_t$$

with

$$A_t = A_0\, t^{-c(\gamma_t)/K} (1 + K^{-1} \log t)^{-1} \quad \text{and} \quad B_t = A_1 \frac{d_1(\gamma_t)}{Kt} + A_2\, d_2(K^{-1} \log t) \left| \frac{d\gamma_t}{dt} \right|.$$

Now, it is well known that

$$\exists t_0 \in \mathbb{R}_+ \quad \int_{t_0}^{+\infty} A_s\, ds = +\infty, \qquad \lim_{t \to +\infty} \frac{B_t}{A_t} = 0 \Longrightarrow \lim_{t \to +\infty} I_t = 0.$$

We can now summarize the entire consideration in the following way.

THEOREM 1. *Assume that $c = \limsup_{\gamma \to +\infty} c(\gamma) < +\infty$ and the conditions*

$$\sup_{x \in E} \left| \frac{d}{d\beta} \mu_{\gamma,\beta}(x) \right| \leq d_1(\gamma), \qquad \sup_{x \in E} \left| \frac{d}{d\gamma} \mu_{\gamma,\beta}(x) \right| \leq d_2(\beta)$$

are satisfied for two nonnegative functions $d_1,\ d_2$.

When the inverse-freezing schedule has parametric form $\beta_t = K^{-1} \log t$, for t sufficiently large and $K > c$, we have

$$\lim_{t \to +\infty} \mathrm{Ent}_{\pi_{\gamma_t,\beta_t}}(m_t) = 0 \tag{9}$$

whenever

$$\frac{d\gamma_t}{dt} = o\left(1/(d_2(\log t^{1/K}) t^{c/K} \log t) \right), \qquad d_1(\gamma_t)/t = o\left(1/(t^{c/K} \log t) \right). \tag{10}$$

Remark. The hypothesis above might seem difficult to check; we shall see in fact that in many cases it is indeed fulfilled. In practice the Markov kernels $Q_{\gamma,\beta}$ are known and it clearly suffices to check that

$$\sup_{g\in\cup_x I_x}\frac{d}{d\beta}\log Q_{\gamma,\beta}(g)-\inf_{g\in\cup_x I_x}\frac{d}{d\beta}\log Q_{\gamma,\beta}(g)\leq d_1(\gamma),$$

$$\sup_{g\in\cup_x I_x}\frac{d}{d\gamma}\log Q_{\gamma,\beta}(g)-\inf_{g\in\cup_x I_x}\frac{d}{d\gamma}\log Q_{\gamma,\beta}(g)\leq d_2(\beta).$$

Because of the general orientation provided in this section we can proceed immediately to review the most important special class of generalized simulated annealing, which we shall study later. Let us consider the transition probability kernels

$$Q_\beta(x,y)=\sum_{u\in U}\overline{q}_\beta(x,u,y)e^{-\beta\overline{V}(x,u,y)}, \tag{11}$$

where U is a given finite set, $\overline{V}:U\times E^2\to\mathbb{R}_+$, and $\overline{q}_\beta(x,u,y)\geq 0$. The proof of Theorem 1 shows it is important that the Markov kernel q is irreducible. For this purpose we will assume the existence of nonnegative functions $\overline{q}(x,u,y)$ so that

$$(\mathcal{C})\qquad \overline{q}_\beta(x,u,y)>0\Longleftrightarrow\overline{q}(x,u,y)>0,\qquad \lim_{\beta\to+\infty}\overline{q}_\beta(x,u,y)=\overline{q}(x,u,y),$$

and we will work with the following irreducibility condition:

$$(\mathcal{I})\,\forall x,y\in E\quad \exists(p_k,u_k)_{1\leq k\leq r}:\ \ p_0=x,\quad p_k\in E\ u_k\in U\ p_r=y\ \overline{q}(p_k,u_k,p_{k+1})>0.$$

Our immediate goal is to prove the following consequence of Theorem 1 which gives conditions assuring the convergence stated in Theorem 1 for a time-inhomogeneous Markov chain with transitions (11). This corollary is applied in section 2 to the convergence of genetic algorithms

COROLLARY 1. *Assume $\overline{q}_\beta$ and $\overline{q}$ satisfy the continuity and irreducibility conditions* ($\mathcal{C}$) *and* ($\mathcal{I}$). *Then, the transition probabilities*

$$Q_\beta(x,y)=\sum_{u\in U}\overline{q}_\beta(x,u,y)e^{-\beta\overline{V}(x,u,y)} \tag{12}$$

satisfy the inequalities (1) *with*

$$V(x,y)=\min_{u\in U(x,y)}\overline{V}(x,u,y),\qquad U(x,y)=\{u\in U\ :\ \overline{q}(x,u,y)>0\},$$

$$q(x,y)=\sum_{u\in U^\star(x,y)}\overline{q}(x,u,y),\qquad U^\star(x,y)=\{u\in U(x,y)\ :\ \overline{V}(x,u,y)=V(x,y)\}.$$

Let V be the virtual energy function corresponding to the above communication cost function

$$V(x)=\min_{g\in G(x)}\sum_{(y\to z)}V(y,z)$$

and let c be the corresponding critical height. In addition, suppose that for every $\overline{q}(x,u,y)>0$ and for some $\beta_0\geq 0$

$$\sup_{\beta\geq\beta_0}\left|\frac{d\log\overline{q}_\beta}{d\beta}(x,u,y)\right|<+\infty. \tag{13}$$

In this case, if m is a probability measure on E and if β_t assumes the parametric form $\beta_t = K^{-1}\log t$, for sufficiently large t, with $K > c$, then

$$\lim_{t\to+\infty} Ent_{\pi_{\beta_t}}(m_t) = 0 \qquad \textit{and} \qquad \lim_{t\to+\infty} P(X_t \in V^\star) = 1,$$

where (Ω, P, F_t, X_t) is the canonical process associated with the family of generators $(L_{\beta_t})_{t\geq 0} = (Q_{\beta_t} - I)_{t\geq 0}$ whose initial condition is $m_0 = m$, m_t is the distribution of X_t, π_β is the unique invariant probability measure of L_β, and

$$V^\star = \{x \in E \ : \ V(x) = \min_E V\}.$$

Proof. Using the form of $\overline{q}_\beta$ we have for some suitable function $\epsilon(\beta) \to 0$, as $\beta \to +\infty$,

$$(1 - \epsilon(\beta))\, K_\beta(x,y) \leq Q_\beta(x,y) \leq (1 + \epsilon(\beta))\, K_\beta(x,y), \tag{14}$$

where

$$K_\beta(x,y) = \sum_{u\in U(x,y)} \overline{q}(x,u,y)e^{-\beta\overline{V}(x,u,y)}.$$

But now we have that

$$\begin{aligned} K_\beta(x,y) = &\sum_{u\in U^\star(x,y)} \overline{q}(x,u,y)\; e^{-\beta V(x,y)} \\ &+ e^{-\beta V(x,y)} \sum_{u\in U(x,y)-U^\star(x,y)} \overline{q}(x,u,y)\; e^{-\beta(\overline{V}(x,u,y)-V(x,y))} \\ = q(x,y)&e^{-\beta V(x,y)} + e^{-\beta V(x,y)} \sum_{u\in U(x,y)-U^\star(x,y)} \overline{q}(x,u,y)\; e^{-\beta(\overline{V}(x,u,y)-V(x,y))}. \end{aligned}$$

Thus, condition $(\mathcal{I})$ implies that q is irreducible. Furthermore, if we write

$$\begin{aligned} I &= \{(x,y) \in E^2 \ : \ U(x,y) \neq \emptyset\}, \\ J &= \{(x,u,y) \in E \times U \times E \ : \ (x,y) \in I \ \ u \in U(x,y)\} \end{aligned}$$

and

$$\begin{aligned} h_1 &= \min_{(x,y)\in I} \sum_{u\in U(x,y)-U^\star(x,y)} \overline{q}(x,u,y)/q(x,y), \\ h_2 &= \min_{(x,u,y)\,:\, u\notin U^\star(x,y)} \overline{V}(x,u,y) - V(x,y), \end{aligned}$$

then using (14) we get the system of inequalities

$$(1-\epsilon(\beta))\; q(x,y)\; e^{\beta V(x,y)} \leq Q_\beta(x,y) \leq (1+\epsilon(\beta))\; (1 + h_1\; e^{-\beta h_2})q(x,y)\; e^{\beta V(x,y)}.$$

To end the proof it remains to check condition (6). Choose $q(x,y) > 0$; after some computations we find

$$\left|\frac{d\log Q_\beta(x,y)}{d\beta}\right| \leq \sup_{u\in U(x,y)} \left|\frac{d\log \overline{q}_\beta}{d\beta}(x,u,y)\right| + \sup_{u\in U(x,y)} \overline{V}(x,u,y).$$

Thus (13) implies (6), and using Theorem 1 the proof of the first assertion is complete. Examination of the invariant distribution of L_β soon yields that $\forall x \notin V^\star$ we have $\lim_{\beta\to+\infty}\pi_\beta(x) = 0$. Then, to prove the last assertion it is enough to recall the basic inequality

$$\|m_t - \pi_{\beta_t}\|_{TV}^2 \leq 2\,\mathrm{Ent}_{\pi_{\beta_t}}(m_t),$$

where $\|.\|_{TV}$ is the distance in total variation given by

$$\|\mu - \nu\|_{TV} = 2\sup_{A\subset E}|\mu(A) - \nu(A)|. \qquad \square$$

It is quite clear from definition (12) that the following situations are covered:

$$Q_\beta = Q_\beta^{(1)}Q_\beta^{(2)} \quad\text{and}\quad Q_\beta = \alpha\,Q_\beta^{(1)} + (1-\alpha)\,Q_\beta^{(2)}, \quad 0<\alpha<1.$$

In section 2 we will develop properties of both class of chains which we shall find includes, as a special case, the evolutionary processes studied by Cerf in [2]. For the sake of unity and to highlight issues specific to evolutionary processes, we give some examples to suggest how these results translate in this special situation.

Examples.

1. If $d_1(\gamma) = \gamma^p$ and $d_2(\beta) = \beta^q$ for some $p \geq 0$ and $q > 0$, it clearly suffices to choose $\gamma_t = \log t$.
2. Let us study a way to combine the transitions $Q_\beta^{(1)}, \dots, Q_\beta^{(r)}$ given by

$$Q_\beta^{(k)}(x,y) = q_\beta^{(k)}(x,y)\,e^{-\beta V^{(k)}(x,y)}, \qquad V^{(k)} : E^2 \to \mathbb{R}_+, \qquad q_\beta^{(k)}(x,y) \geq 0.$$

It is clear from (11) that the following situation is covered:

$$\text{(a)}\ \ Q_\beta(x,y) = Q_\beta^{(1)}\dots Q_\beta^{(r)}(x,y) = \sum_{z_1,\dots,z_{r-1}\in E} Q_\beta^{(1)}(x,z_1)\dots Q_\beta^{(r)}(z_{r-1},y).$$

This situation can be formulated in the form (11) with $U = E^{r-1}$ and

$$\overline{q}_\beta(x,u,y) = q_\beta^{(1)}(x,u_1)\dots q_\beta^{(r)}(u_{r-1},y),$$
$$\overline{V}(x,u,y) = V^{(1)}(x,u_1) + \cdots + V^{(r)}(u_{r-1},y).$$

Also from (11), the following situation is covered:

$$\text{(b)}\ \ \tilde{Q}_\beta(x,y) = \sum_{k=1}^r \alpha_k\,Q_\beta^{(k)}(x,y) \qquad\text{with}\qquad \sum_{k=1}^r \alpha_k = 1.$$

This situation can be formulated in the form (11) with $E = \{1,\dots,r\}$ and

$$\overline{q}_\beta(x,u,y) = \alpha_u\,q_\beta^{(u)}(x,y), \qquad \overline{V}(x,u,y) = V^{(u)}(x,y).$$

Probabilistically and in precise language 1(a) has the interpretation of being the transition of a chain obtained through overlapping $r-1$ other chains, and 1(b) has the interpretation of being the transition of a chain obtained through choosing randomly at each step among r chains. Let us remark, by way of illustration, that it is also possible to consider a way of combining 1(a) and 1(b) that subsumes such parallel and series combinations. For instance, each transition probability $Q_\beta^{(k)}$ in the expression (a) may be of type (b) and conversely. As a result one has a great freedom in the design and the physical construction of the transition probabilities $Q_{\gamma,\beta}$, and they appear ideally suited to describe a large class of processes encountered in applications.

3. Let us examine the above example when $r = 2$. In this situation we introduce the irreducibility condition $(\mathcal{I})'$

$$q^{(1)} \quad \text{irreducible} \quad \text{and} \quad \forall x \in E \qquad q^{(2)}(x,x) > 0 \tag{15}$$

and the continuity condition $(\mathcal{C})'$

$$\lim_{\beta \to +\infty} q_\beta^{(k)}(x,y) = q^{(k)}(x,y), \quad q_\beta^{(k)}(x,y) = 0 \Longleftrightarrow q^{(k)}(x,y) = 0 \quad \forall k = 1, 2, \tag{16}$$

where $q^{(k)}(x,y)$ are transition probability kernels such that

$$q^{(k)}(x,y) = 0 \Longleftrightarrow V^{(k)}(x,y) = +\infty \qquad \forall k = 1, 2.$$

In this situation the conditions $(\mathcal{C})$ and $(\mathcal{I})$ of Corollary 1 are satisfied. In addition, if we assume that for every $k = 1, 2$ and $q^{(k)}(x,y)$

$$\left| \frac{d \log q_\beta^{(2)}}{d\beta}(x,y) \right| < +\infty,$$

then the last condition (13) introduced in Corollary 1 is satisfied.

COROLLARY 2. *Suppose the Markov kernel of the chain has the form*

$$Q_{\gamma,\beta} = q_\beta(x,y) e^{-\beta V_\gamma(x,y)}$$

with

$$q_\beta(x,y) = 0 \Longleftrightarrow q(x,y) = 0, \qquad \lim_{\beta \to +\infty} q_\beta(x,y) = q(x,y)$$

and assume the following conditions are satisfied for every $\beta, \gamma \in \mathbb{R}_+$ and some constant $d > 0$:

$$c = \sup_\gamma c(\gamma) < +\infty, \qquad \sup_{g \in \cup_x I_x} V_\gamma(g) - \inf_{g \in \cup_x I_x} V_\gamma(g) \le d,$$

$$\sup_{g \in \cup_x I_x} \frac{d}{d\beta} \log q_\beta(g) - \inf_{g \in \cup_x I_x} \frac{d}{d\beta} \log q_\beta(g) \le d \sup_{g \in \cup_x I_x} \frac{d}{d\gamma} V_\gamma(g) - \inf_{g \in \cup_x I_x} \frac{d}{d\gamma} V_\gamma(g) \le d.$$

When the inverse freezing schedule has parametric form $\beta_t = K^{-1} \log t$, for t sufficiently large and $K > c$, we have

$$\lim_{t \to +\infty} \mathrm{Ent}_{\pi_{\gamma_t, \beta_t}}(m_t) = 0 \qquad \textit{whenever} \quad \frac{d\gamma_t}{dt} = o(1/(t^{c/K} \log^2 t)).$$

As a consequence we have the well-known corollary that follows.

COROLLARY 3 (Miclo [10]). *Suppose the Markov kernel of the chain has the form*

$$Q_{\gamma,\beta} = q(x,y) e^{-\beta V(x,y)} \overset{\text{def}}{=} Q_\beta(x,y).$$

When the inverse freezing schedule has parametric form $\beta_t = K^{-1} \log t$, for t sufficiently large and $K > c$, we have

$$\lim_{t \to +\infty} \mathrm{Ent}_{\pi_{\beta_t}}(m_t) = 0,$$

where π_β is the unique invariant probability measure of the Markov generator $Q_\beta - I$.

The usefulness of Theorem 1 will now be illustrated in the case where the transition probabilities $Q_{\gamma,\beta}$ converge to a transition probability kernel Q_β as $\gamma \to +\infty$.

THEOREM 2. *Let $Q_\beta(x,y)$ be a Markov kernel such that $Q_\beta(x,y) = 0 \iff q(x,y) = 0$. Suppose the assumptions of Theorem 1 are satisfied and for every $q(x,y) > 0$*

$$\lim_{t\to+\infty} |\log Q_{\gamma_t,\beta_t}(x,y) - \log Q_{\beta_t}(x,y)| = 0. \tag{17}$$

Then

$$\lim_{t\to+\infty} \mathrm{Ent}_{\pi_{\beta_t}}(m_t) = 0, \tag{18}$$

where π_β is the unique invariant probability measure of the Markov generator $Q_\beta - I$.

Proof. By the same line of argument as before π_β may be described as follows:

$$\pi_\beta(x) = \frac{R_\beta(x)}{\sum_{z\in E} R_\beta(z)} \quad \text{with} \quad R_\beta(x) = \sum_{g\in I_x} Q_\beta(g) \quad \text{and} \quad Q_\beta(g) = \prod_{(y\to z)\in g} Q_\beta(y,z). \tag{19}$$

It follows that

$$\begin{aligned}\log\frac{\pi_{\gamma,\beta}}{\pi_\beta}(x) &= -\log\left(\sum_{g\in I_x}\prod_{(y\to z)\in g}(Q_\beta Q_{\gamma,\beta}^{-1})(y,z)\,\overline{Q}_{\gamma,\beta}(g)\right)\\ &\quad -\log\left(\sum_{x'\in E, g\in I_{x'}}\prod_{(y\to z)\in g}(Q_{\gamma,\beta}Q_\beta^{-1})(y,z)\,\tilde{Q}_\beta(g)\right),\end{aligned}$$

where

$$\overline{Q}_{\gamma,\beta}(g) = Q_{\gamma,\beta}(g)/\sum_{h\in I_x} Q_{\gamma,\beta}(h) \qquad \text{and} \qquad \tilde{Q}_\beta(g) = Q_\beta(g)/\sum_{z\in E, h\in I_z} Q_\beta(h).$$

By Jensen's inequality, we have

$$\log\frac{\pi_{\gamma,\beta}}{\pi_\beta}(x) \le 2\sup_{g\in\cup_z I_z} |\log Q_{\gamma,\beta}(g) - \log Q_\beta(g)|.$$

Finally, we obtain

$$\mathrm{Ent}_{\pi_{\beta_t}}(m_t) \le \mathrm{Ent}_{\pi_{\gamma_t,\beta_t}}(m_t) + 2\sup_{g\in\cup_x I_x} |\log Q_{\gamma_t,\beta_t}(g) - \log Q_{\beta_t}(g)|. \tag{20}$$

Using (9) the proof is complete. □

We now make the above observations precise by considering more specific, although general, transitions $Q_{\gamma,\beta}$.

COROLLARY 4. *Let V be a nonnegative function $V: E\times E \to \mathbb{R}_+$ and $Q_{\gamma,\beta}(x,y) = q_\beta(x,y)\, e^{\beta V_\gamma(x,y)}$. Suppose the assumptions of Corollary 2 are satisfied and, for every $q(x,y) > 0$,*

$$|V_{\gamma_t}(x,y) - V(x,y)| = o(1/\log t). \tag{21}$$

When the inverse-freezing schedule has parametric form $\beta_t = K^{-1}\log t$, for t sufficiently large and $K > c$, we have

$$\lim_{t\to+\infty} Ent_{\pi_{\beta_t}}(m_t) = 0 \qquad \textit{and} \qquad \lim_{t\to+\infty} P(X_t \in V^\star) = 1, \tag{22}$$

where π_β is the unique invariant probability measure of the Markov generator $Q_\beta - I$ with

$$Q_\beta(x,y) = q(x,y)\, e^{-\beta V(x,y)}, \qquad V^\star = \{x \in E :\ V(x) = \min_E V\},$$

and

$$V(x) = \min_{g\in G(x)} \sum_{(y\to z)\in g} V(y,z).$$

If $V_{\gamma_t}(x,y) = (U_t(y) - U_t(x))^+$ with $U_t : E \to \mathbb{R}_+$ and $\lim_{t\to+\infty} U_t(x) = U(x)$, condition (21) takes the form

$$\lim_{t\to+\infty} \log t\ |U_t(x) - U(x)| = 0.$$

The following examples illustrate the results and the conditions stated in the above theorems.

Examples.

1. Let us now turn our attention to the transition probability kernel

$$Q_{\gamma,\beta}(x,y) = q(x,y)\, e^{-\beta V_\gamma(x,y)},$$

where

$$V_\gamma(x,y) = (U_\gamma(y) - U_\gamma(x))^+ \ \text{ if } q(x,y) > 0 \text{ and } \ +\infty \ \text{ otherwise.}$$

In this case conditions (6) and (7) take the form

$$\sup_{x\in E} U_\gamma(x) - \inf_{x\in E} U_\gamma(x) \le d_1(\gamma), \qquad \sup_{x\in E} \frac{d}{d\gamma} U_\gamma(x) - \inf_{x\in E} \frac{d}{d\gamma} U_\gamma(x) \le d_2(\beta)/\beta.$$

In addition, if

$$\sup_{x,\gamma} U_\gamma(x) < +\infty, \qquad \sup_{x,\gamma} \frac{d}{d\gamma} U_\gamma(x) < +\ infty,$$

then we can choose $d_2(\beta) = \beta\, d_2$ and $d_1(\gamma) = d_1 < +\infty$ $(d_1, d_2 > 0)$ and the condition (10) takes the form

$$\frac{d\gamma_t}{dt} = o(1/(t^{c/K}(\log t)^2)).$$

2. Let us examine the above example with time-inhomogeneous potential given by

$$U_\gamma(x) = \theta(\gamma)^{-1} \int_0^{\theta(\gamma)} C(s,x)\, ds$$

with $C : \mathbb{R}_+ \times E \to \mathbb{R}_+$ bounded and $\frac{d}{d\gamma} \log \theta(\gamma) < +\infty$.
From the boundedness of C we can choose constants $d_1, d_2 > 0$ so that $d_1(\gamma) = d_1$ and $d_2(\beta) = \beta\ d_2$ satisfy the required conditions. Finally, if $\gamma_t = A\ \log t$ and $\theta(\gamma) = e^\gamma$, then we have

$$\frac{d\gamma_t}{dt} = A/t = o\left(1/(t^{c/K}(\log t)^2)\right), \qquad \frac{d}{d\gamma} \log \theta(\gamma) = 1,$$

and

$$U_{\gamma_t}(x) = \frac{1}{t^A} \int_0^{t^A} C(s, x)\ ds.$$

1.2. General results on the virtual energy. In section 1 we proved the convergence in probability of a class of stochastic algorithms to the set of the global minima $V^\star$ of a virtual energy function V. The crucial need of course is to estimate $V^\star$. In the case where q is symmetric and $V(x, y) = (U(y) - U(x))^+$ with $U : E \to \mathbb{R}_+$ it is well known that $V^\star = U^\star$. For a generalization of this see Trouvé [12]. The situation becomes considerably more involved when the above assumptions are dispensed with. The purpose of this section is to introduce a natural test set approach to study $V^\star$. More precisely, we will give several conditions for a given subset $H \subset E$ to contain $V^\star$.

Let us recall some basic definitions. Let E be a finite set and q an irreducible Markov kernel. Assume that a given function $V : E \times E \to \overline{\mathbb{R}}_+$ satisfies

$$V(x, y) < +\infty \Longleftrightarrow q(x, y) > 0.$$

Let us write $C_{x,y}$ the paths p in E joining x and y, that is,

$$\forall k \in \{0, \ldots, |p| - 1\} \quad q(p_k, p_{k+1}) > 0 \quad \text{and} \quad p_0 = x, p_{|p|} = y,$$

where $|p|$ is the length of p. For $x, y \in E$, $p \in C_{x,y}$, and $g \in G(x)$ we note

$$V(p) = \sum_{k=0}^{|p|-1} V(p_k, p_{k+1}), \qquad V(g) = \sum_{(y \to z) \in g} V(y, z), \qquad V(x) = \min_{g \in G(x)} V(g).$$

For $H \subset E$ and g an x-graph over H (that is, $g \in G_H(x)$) it is convenient to define a new communication cost V_H by making the set H a *taboo* set. Namely, for every $x, y \in H$

$$\begin{aligned} V_H(x, y) &= \min\{V(p)\ :\ p \in C_{x,y} \text{ with } \forall k \in \{1, \ldots, |p| - 1\}\ p_k \notin H\}, \\ V_H(g) &= \sum_{(y \to z) \in g} V_H(y, z). \end{aligned}$$

It is also convenient to define the virtual energy function associated with V_H:

$$\forall x \in H \qquad V_H(x) = \min_{g \in G_H(x)} V_H(g) - \min_{y \in H, h \in G_H(y)} V_H(h).$$

Finally, let us write

$$V(H) = \min_{x \in H} V(x) \qquad \text{and} \qquad V_H^\star = \left\{x \in H\ :\ V_H(x) = \min_H V_H\right\}.$$

LEMMA 2. *$\forall x \in H,\ V_H(x) = V(x) - V(H)$.*

Lemma 2 is an easy consequence of the following lemma.

LEMMA 3. *Let Q be an irreducible transition probability over E with invariant measure μ. Let X be a Markov chain with transition probability Q and initial measure m such that $m(x) > 0\ \forall x \in E$. Given a subset $H \subset E$ define*

$$T_1 = \inf\{n \geq 1\ :\ X_n \in H\} \qquad \tilde{Q} = P(X_{T_1} = y/X_0 = x).$$

Then $\tilde{Q}$ is an irreducible Markov kernel over H and its invariant probability measure is given by

$$\tilde{\mu}(x) = \mu(x)/\mu(H).$$

There are several ways to prove Lemmas 2 and 3. The following may be the shortest in this context.

Proof of Lemma 3. The proof is a consequence of the law of large numbers. Let us set by induction on the parameter $n \geq 1$

$$T_{n+1} = \inf\{k > T_n\ :\ X_k \in H\}, \qquad n \geq 1.$$

Now, under the above conditions, the random process $Y = (Y_n)_{n\geq 0}$ defined by

$$Y_0 = X_0, \qquad Y_n = X_{T_n}, \qquad n \geq 1,$$

is an irreducible Markov chain over H with transition probability kernel $\tilde{Q}$. Let $\tilde{\mu}$ be its invariant probability measure. First we note that P-almost surely

$$\forall x \in E \qquad \frac{1}{n}\sum_{i=1}^{n} 1_x(Y_i) \underset{n \to +\infty}{\longrightarrow} \tilde{\mu}(x)$$

On the other hand we have

$$\frac{1}{n}\sum_{i=1}^{n} 1_x(Y_i) = \frac{T_n}{n}\left(\frac{1}{T_n}\sum_{i=1}^{T_n} 1_x(X_i)\right), \qquad \frac{n}{T_n} = \frac{1}{T_n}\sum_{i=1}^{T_n} 1_H(X_i),$$

and

$$\frac{1}{T_n}\sum_{i=1}^{T_n} 1_x(X_i) \underset{n \to +\infty}{\longrightarrow} \mu(x), \qquad \frac{1}{T_n}\sum_{i=1}^{T_n} 1_H(X_i) \underset{n \to +\infty}{\longrightarrow} \mu(H)$$

P-almost everywhere (P.a.e.). The lemma follows immediately. □

We come to the proof of Lemma 2.

Proof of Lemma 2. We shall give a sketch of the proof. Let us denote by Q_β the Markov kernel over E given by

$$Q_\beta(x,y) = \begin{cases} |E|^{-1}\ \exp -\beta V(x,y) & \text{if } x \neq y, \\ 1 - |E|^{-1}\ \sum_{z\in E\,:z\neq x} \exp -\beta V(x,z) & \text{otherwise.} \end{cases}$$

Let μ_β be the invariant measure of Q_β. From the description of μ_β in terms of x-graphs over E it is clear that

$$\mu_\beta(x) \underset{\beta \to +\infty}{\sim} C(x)\ \exp -\beta V(x)$$

for some nonnegative function $C : E \to \mathbb{R}_+^*$. If one now defines $\tilde{Q}_\beta$ as in Lemma 3, by elementary large deviation arguments one sees the equivalence

$$\tilde{Q}_\beta(x,y) \underset{\beta \to +\infty}{\sim} \tilde{q}(x,y)\ \exp -\beta V_H(x,y) \qquad \forall x,y \in H$$

for some irreducible Markov kernel $\tilde{q} : E \times E \to \mathbb{R}_+$. Therefore if $\tilde{\mu}_\beta$ is the invariant measure of $\tilde{Q}_\beta$ one has for some nonnegative function $\tilde{C} : E \to \mathbb{R}_+^*$

$$\tilde{\mu}_\beta(x) \underset{\beta \to +\infty}{\sim} \tilde{C}(x)\ \exp -\beta V_H(x),$$

from which our claim follows easily. □

We now give a definition that we will use in our formulation of our test set approach to understand the limiting behavior of a generalized simulated annealing.

DEFINITION 1. *Let H be a subset of E. We say that a partition $\mathcal{H} = \{H_1, \ldots, H_n\}$ of H is a V-partition if for every $1 \le i \le n$ and $x, y \in H_i$, $x \ne y$, there exists a path $p \in C_{x,y}$ such that*

$$\forall 0 \le k < |p| \qquad p_k \in H_i \quad \textit{and} \quad V(p_k, p_{k+1}) = 0.$$

We observe that for a given subset $H \subset E$, one can always obtain a V-partition. For instance

$$\mathcal{H} = \{\{x\} \ :\ x \in H\}$$

is a V-partition. Given a V-partition $\mathcal{H} = \{H_1, \ldots, H_n\}$ of $H \subset E$, it is convenient to define a new communication cost function $V_{\mathcal{H}}$ by setting for every $x \in H_i$ and $y \in H_j$, $1 \le i, j \le n$

$$\begin{aligned} V_{\mathcal{H}}(x,y) = \{V(p) \ :\ p \in C_{x,y} \ \ &\exists 0 \le n_1 < n_2 \le |p| \\ &\forall 0 \le k \le n_1, p_k \in H_i, \quad \forall n_1 < k < n_2, p_k \notin H, \quad \forall n_2 \le k \le |p| p_k \in H_j\}. \end{aligned}$$

It is easily seen that $V_{\mathcal{H}}(x,y)$ does not depend on the choice of $x \in H_i$ and $y \in H_j$. Moreover we note that if $\mathcal{H} = \{\{x\} \ :\ x \in H\}$, then $V_{\mathcal{H}} = V_H$.

Let $V_{\mathcal{H}}$ be the virtual energy function associated with the communication cost function $V_{\mathcal{H}}$, namely,

$$\forall x \in H \qquad V_{\mathcal{H}}(x) = \min_{g \in G_H(x)} V_{\mathcal{H}}(g) \qquad \text{with} \quad V_{\mathcal{H}}(g) = \sum_{(y \to z) \in g} V_{\mathcal{H}}(y,z).$$

As usual, we also put

$$V_{\mathcal{H}}^\star = \left\{ x \in H \ :\ V_{\mathcal{H}}(x) = \min_H V_{\mathcal{H}} \right\}.$$

PROPOSITION 2. *If $\mathcal{H}$ is a V-partition of a subset $H \subset E$, then we have $V_{\mathcal{H}} = V_H$.*

Proof. Let us prove that for every $x \in H$

$$\min_{g \in G_H(x)} V_H(g) = \min_{g \in G_H(x)} V_{\mathcal{H}}(g).$$

Because $\mathcal{H} = \{H_1, \ldots, H_n\}$ is a V-partition it is clear that $V_{\mathcal{H}} \leq V_H$. So our claim will follow provided that for every $g \in G_H(x)$ we can build a new $\tilde{g} \in G_H(x)$ such that $V_{\mathcal{H}}(g) \geq V_H(\tilde{g})$. For this purpose let $g \in G_H(x)$ for some $x \in H$ and let $i \in \{1, \ldots, n\}$ such that $x \in H_i$. We will construct an x-graph $\tilde{g} \in G_H(x)$ such that $V_{\mathcal{H}}(g) \geq V_H(\tilde{g})$. For this we introduce the set

$$\Gamma = \{(j \to k) \ : \ \exists (y, z) \in g \text{ such that } \ y \in H_j \text{ and } z \in H_k\}.$$

Obviously Γ is not an i-graph over $\{1, \ldots, n\}$ but examination of Γ soon yields that it contains at least one i-graph G_i. Now for $j \neq i$ and $(j \to k) \in G_i$ (unique) there exists an arrow $(y_j \to z_k) \in g$ such that $y_j \in H_j$ and $z_k \in H_k$.

On the other hand, from the definition of $V_{\mathcal{H}}$ there exists a path $p \in C_{y_j, z_k}$ and $0 \leq n_1 < n_2 \leq |p|$ such that

$$\forall 0 \leq l \leq n_1 \quad p_l \in H_j, \qquad \forall n_1 < l < n_2 \quad p_l \notin H, \qquad \forall n_2 \leq l \leq |p| \quad p_l \in H_k,$$

and $V(p) = V_{\mathcal{H}}(y_j, z_k)$. Given such a path $p \in C_{y_j, z_k}$ let us set

$$\tilde{y}_j = p_{n_1}, \qquad \tilde{z}_k = p_{n_2}.$$

Finally, because $\mathcal{H}$ is a V-partition there exists for every $1 \leq i \leq n$ a $\tilde{y}_j$-graph $\tilde{g}_j \in G_{H_j}(\tilde{y}_j)$ such that $V(\tilde{g}_j) = 0$, with the convention $\tilde{y}_i = x$.

Using the above construction it is easily seen that the set of arrows

$$\tilde{g} = \bigcup_{i=1}^{n} \tilde{g}_i \ \bigcup \ \bigcup_{(j \to k) \in G_i} \{(\tilde{y}_j \to \tilde{z}_k)\}$$

is an x-graph over H and, from the construction of g, it follows that

$$V_{\mathcal{H}}(g) \geq V_{\mathcal{H}}(\tilde{g}) = \sum_{(j \to k) \in G_i} V_{\mathcal{H}}(\tilde{y}_j, \tilde{z}_k) = \sum_{(j \to k) \in G_i} V_H(\tilde{y}_j, \tilde{z}_k) = V_H(\tilde{g}).$$

This ends the proof. □

The following concept of λ-stability leads to a natural test set approach to study $V^\star$.

Definition 2. *Let λ be a nonnegative real number. A subset $H \subset E$ is called λ-stable with respect to a communication cost function V when the following conditions are satisfied:*

1. $\forall x \in H \ \ \forall y \notin H, \qquad V(x, y) > \lambda,$
2. $\forall x \notin H \ \ \exists y \in H, \qquad V(x, y) \leq \lambda.$

The importance of the notion of λ-stability resides in the following result, which extends Lemma 4.1 of Freidlin–Wentzell [6].

Proposition 3. *Let λ be a nonnegative real number and $H \subset E$. Any λ-stable subset H with respect to V contains $V^\star$ and $V_H = V_{/H}$*

Proof. Let H be a λ-stable subset of E. Let $x \notin H$ and let g be an element of $G(x)$ such that $V(g) = V(x)$. There exists almost one $y \in H$ such that $V(x, y) \leq \lambda$. Now we note p the exit path from y to x extracted from g, that is,

$$p_0 = y, p_{|p|} = x \quad \text{and} \quad \forall k = 0, \ldots, |p| - 1, \quad (p_k \to p_{k+1}) \in g.$$

Write $k_0 = \inf\{k = 0, \ldots, |p| - 1 \quad : \quad p_k \notin H\}$. Let $\overline{g}$ be the graph obtained from g by replacing the arrow $(p_{k_0 - 1} \to p_{k_0})$ by $(x \to y)$. Then we have $\overline{g} \in G(p_{k_0 - 1})$ and

$$V(x) = V(g) > V(\overline{g}) \geq V(p_{k_0 - 1}), \qquad p_{k_0 - 1} \in H.$$

This completes the proof of the first assertion. The last assertion is a clear consequence of Lemma 2. □

Let us now reduce all of the results of this section to a proposition which we shall use for later reference.

PROPOSITION 4. *Let A be a 0-stable subset of E with respect to V and let $\mathcal{A}$ be a V-partition of A. If H is a λ-stable subset of A with respect to $V_{\mathcal{A}}$ for some $\lambda \geq 0$, then $V^\star \subset H$.*

Proof. Using Proposition 3 it is easily seen that $V^\star \subset A$, $V_A = V_{/A} = V_{\mathcal{A}}$, and $V_{\mathcal{A}}^\star \subset H$. Thus one gets $V^\star = V_{\mathcal{A}}^\star = V_{\mathcal{A}}^\star \subset H$, and the proof of Proposition 4 is completed. □

2. Applications.

In this section we examine two applications. In section 2.1 we use the results of the first section to derive a new and simple proof of the convergence of the genetic algorithms. We shall prove this important result in a way different from the original proof of Cerf [2]. The proof splits quite naturally into two distinct parts:

1. We use the relative entropy convergence results stated in the first section to prove the convergence of the algorithm.
2. Then we investigate the test set approach, introduced in the second part of section 1, to prove that the set of the global minima of the virtual energy is contained in the product of the set of the global minima of the fitness function.

In section 2.2 we apply Corollary 4 to construct a stochastic algorithm for the numerical solving of a general mean cost optimization problem.

2.1. Genetic algorithms.

A genetic algorithm is a discrete time Markov process $\widehat{x} = (\widehat{x}_n)_n$ with state space $E = S^N$ ($N > 1$ and S a finite set) and whose transition probabilities G_n include a mutation M_n and a selection S_n mechanism. The N-tuple of elements of S, i.e., the points of the set E, are called particle systems and most will be denoted by the letters x, y, z. In what follows, we shall distinguish two kinds of combinations, namely,

$$\text{(a)} \qquad P\left(\widehat{x}_n \in dx \,/\widehat{x}_{n-1} = z\,\right) = \int_E M_n(z, dy)\; S_n(y, dx),$$

$$\text{(b)} \qquad P\left(\widehat{x}_n \in dx \,/\widehat{x}_{n-1} = z\,\right) = \alpha\; M_n(z, dx) + (1-\alpha)\;\; S_n(z, dx), \qquad 0 < \alpha < 1.$$

Mutations. The mutation transition is modeled by independent motion of each particle, that is,

$$M_n(z, dy) = \prod_{p=1}^{N} \; K_n(z^p, dy^p),$$

where K_n is a Markov kernel over S, $z = (z^p)_{1 \leq p \leq N}$, and $y = (y^p)_{1 \leq p \leq N}$.

Selection. In the selection transition the particles are chosen randomly and independently in the previous population according to a given selection function $F_n : S \to \mathbb{R}^+$, namely,

$$S_n(y, dx) = \prod_{p=1}^{N} \sum_{i=1}^{N} \frac{F_n(y^i)}{\sum_{j=1}^{N} F_n(y^j)} \;\; 1_{y^i}(dx^p).$$

The study of the convergence, as $N \to +\infty$ or $n \to +\infty$, of such algorithms requires specific developments because each individual particle is no longer Markovian and it is difficult to produce mean error estimates. In [3] one of the authors applied and extended such algorithms to nonlinear filtering problems. An apparent difficulty in establishing a convergence result as $n \to +\infty$ is finding a candidate invariant measure that enables us to describe some aspects of the limiting behavior of the algorithm. To our knowledge, Cerf gives in his Ph.D. dissertation [2] the first convergence result $n \to +\infty$ for a genetic algorithm to converge in probability to the global minima of a given fitness function. More precisely, he studies the following situation:

1. The state space S is finite and $G_n = M_n\, S_n$.
2. The mutation Markov transition kernels $K_n(x^1, y^1)$ are governed by a parameter a and a cooling schedule $\beta(n) : \mathbb{N} \to \mathbb{R}^+$, namely,

$$M_n(x,y) = Q^{(1)}_{\beta(n)}(x,y) \overset{\text{def}}{=} \prod_{p=1}^{N} k_{\beta(n)}(x^p, y^p) \tag{23}$$

with

$$k_\beta(x^1,y^1) \overset{\text{def}}{=} \begin{cases} k(x^1,y^1)\, e^{-a\,\beta} & \text{if} \quad x^1 \neq y^1, \\ 1 - \sum\limits_{z^1 \neq x^1} k(x^1,z^1)\, e^{-a\,\beta} & \text{if} \quad x^1 = y^1, \end{cases} \tag{24}$$

where k is a given irreducible Markov kernel on the space S.

3. The selection operator is built with a fitness function $f : S \to \mathbb{R}^+$ and a cooling schedule $\beta(n) : \mathbb{N} \to \mathbb{R}^+$, namely,

$$S_n(x,y) = Q^{(2)}_{\beta(n)}(x,y) \overset{\text{def}}{=} \prod_{p=1}^{N} \sum_{i=1}^{N} \frac{e^{-\,\beta(n)\, f(x^i)}}{\sum\limits_{j=1}^{N} e^{-\,\beta(n)\, f(x^j)}}\, 1_{x^i}(y^p). \tag{25}$$

Cerf gives several conditions on the rate of decrease of the cooling schedule $\beta(n) \to +\infty$ to ensure all the particles visit the set of global minima, as times goes on, when the number of particles is greater than a critical value. He carries out in a discrete time setting a precise study using large deviation techniques and the powerful tools developed by Trouvé [12]. Simplifying and extending techniques of Cerf and Trouvé, our results are obtained by using the relative entropy convergence result stated in Corollary 1 and by investigating the test set approach introduced in section 1.2.

2.1.1. General results and notations. In this section we will consider genetic algorithms described by the transition probability kernel

$$Q_\beta = Q^{(1)}_\beta Q^{(2)}_\beta \quad \text{or} \quad \tilde{Q}_\beta = \alpha_1\, Q^{(1)}_\beta + \alpha_2\, Q^{(2)}_\beta \quad \text{with} \quad \alpha_1 + \alpha_2 = 1 \quad \text{and} \quad 0 < \alpha_1 < 1 \tag{26}$$

and nonnecessarily vanishing mutations. More precisely, we assume that the mutation transition kernels k_β in (24) have the property

$$\exists b > 0, \qquad b^{-1}\;\; k(x_1,x_2)\, e^{-\beta\, a(x_1,x_2)} \leq k_\beta(x_1,x_2) \leq b\;\; k(x_1,x_2)\, e^{-\beta\, a(x_1,x_2)}, \tag{27}$$

where $a : S^2 \to \overline{\mathbb{R}}_+$, $a(x,y) < +\infty \iff k(x,y) > 0$, k is an irreducible Markov kernel, and the relation on S defined by

$$x_1 \sim x_2 \iff a(x_1,x_2) = 0$$

is an equivalence relation. This leads us naturally to consider the partition $S_1, \ldots, S_{n(a)}$, $n(a) \geq 1$, induced by $\sim$. If x_1 is a typical element of S, then the equivalence class of x_1 will be denoted by $S(x_1)$:

$$S(x_1) = \{x_2 \in S \;:\; x_1 \sim x_2\}.$$

We further require that

$$a(x_1, x_2) = 0 \Longrightarrow f(x_1) = f(x_2)$$

and for some $\beta_0 > 0$

$$\forall x_1, x_2 \in S \qquad \sup_{\beta \geq \beta_0} |d \log k_\beta(x_1, x_2)/d\beta| < +\infty. \tag{28}$$

To our knowledge the models of evolutionary processes (26) have not been covered by the literature of genetic algorithms.

Examples. The following mutation transition kernels have the properties (27) and (28):

1. $k_\beta(x_1, x_2) = \begin{cases} k(x_1, x_2)\, e^{-\beta\, a(x_1, x_2)} & \text{if} \quad a(x_1, x_2) > 0, \\ |S(x_1)|^{-1} \left(1 - \sum_{y_1 \notin S(x_1)} k(x_1, y_1)\, e^{-\beta\, a(x_1, y_1)}\right) & \text{otherwise.} \end{cases}$
2. $k_\beta(x_1, x_2) = \dfrac{e^{-\beta\, a(x_1, x_2)}\; k(x_1, x_2)}{\sum_{y_1 \in S} e^{-\beta\, a(x_1, y_1)}\; k(x_1, y_1)} \qquad \forall (x_1, x_2) \in S^2.$

Finally, let us note that if a is given by

$$a(x_1, x_2) = a\,(1 - 1_{x_1}(x_2)) \qquad \forall (x_1, x_2) \in S^2 \;:\; k(x_1, x_2) > 0,$$

then the first transition probability kernel is clearly the same as the mutation transition probability kernel (24) studied by Cerf.

In this special situation, the first model $Q_\beta = Q_\beta^{(1)} Q_\beta^{(2)}$ is of course identical to Cerf's model of a genetic algorithm.

Let us recall some terminology introduced by Cerf in [2]. The cardinality of a set will be denoted by $|.|$. If x and y belong to $E = S^N$ and $f : S \to \mathbb{R}^+$, we write

$$[x] = \{x_k \;:\; 1 \leq k \leq N\}, \qquad f^\star = \{x_1 \in S \;:\; f(x_1) = \min_S f\},$$

$$\widehat{x} = \{k \;:\; 1 \leq k \leq N\,,\; f(x_k) = \widehat{f}(x)\}, \qquad \widehat{f}(x) = \min_{1 \leq k \leq N} f(x_k),$$

$$x(y_1) = \text{Card}\{k \;:\; 1 \leq k \leq N\,,\; x_k = y_1\}.$$

Using these notations, an easy calculation shows that for $k = 1$ or $k = 2$

$$Q_\beta^{(k)}(x, y) = q_\beta^{(k)}(x, y)\; e^{-\beta V^{(k)}(x, y)}, \qquad q_\beta^{(k)}(x, y) = q^{(k)}(x, y)\; \theta_\beta^{(k)}(x, y),$$

where

$$q^{(1)}(x, y) = \prod_{i : a(x_i, y_j) > 0} k(x_i, y_i), \qquad q^{(2)}(x, y) = \prod_{i=1}^N \frac{x(y_i)}{|\widehat{x}|},$$

$$V^{(1)}(x, y) = \sum_{i=1}^N a(x_i, y_i) \quad \text{if} \quad q^{(1)}(x, y) > 0,$$

$$V^{(2)}(x,y) = \sum_{i=1}^{N} \left(f(y_i) - \widehat{f}(x) \right) \quad \text{if} \quad q^{(2)}(x,y) > 0,$$
$$\theta_\beta^{(1)}(x,y) = \prod_{i:a(x_i,y_i)=0} k_\beta(x_i,y_i),$$
$$\theta_\beta^{(2)}(x,y) = \left(1 + |\widehat{x}|^{-1} \sum_{k \notin \widehat{x}} \exp -\beta(f(x_k) - \widehat{f}(x)) \right)^{-N} .$$

As usual, we will use the convention

$$\forall k \in \{1,2\} \qquad V^{(k)}(x,y) = +\infty \Longleftrightarrow q^{(k)}(x,y) = 0.$$

The asymptotic mutation dynamics of the genetic algorithms is governed by the kernel k and the function a. The irreducibility condition on the kernel k and the fact that a is an equivalence relation are sufficient conditions to allow the system of particles to visit all the state space E. Thus, using the above notations, it is easily checked that

- $q^{(1)}$ is irreducible and $q^{(2)}(x,x) > 0$ for every $x \in E$;
- for every $k = 1,2$ and $q^{(k)}(x,y) > 0$ we have $\sup_{\beta \geq \beta_0} |d \log \theta_\beta^k(x,y)/d\beta| < +\infty$ for some $\beta_0 \geq 0$.

Then, returning to our general model (12), the conditions introduced in Corollary 1 are satisfied in both situations:

1. $$Q_\beta(x,y) \overset{\text{def}}{=} Q_\beta^{(1)} \, Q_\beta^{(2)}(x,y) = \sum_{u \in U} \overline{q}_\beta(x,u,y) e^{-\beta \overline{V}(x,u,y)}$$
   with $U = E, \overline{V}(x,u,y) = V^{(1)}(x,u) + V^{(2)}(u,y), \overline{q}(x,u,y) = q^{(1)}(x,u) q^{(2)}(u,y)$, and $\theta_\beta(x,u,y) = \theta_\beta^{(1)}(x,u) \, \theta_\beta^{(2)}(u,y), \overline{q}_\beta(x,u,y) = \theta_\beta(x,u,y)\overline{q}(x,u,y)$.
2. $$\tilde{Q}_\beta(x,y) \overset{\text{def}}{=} \alpha_1 \, Q_\beta^{(1)}(x,y) + \alpha_2 \, Q_\beta^{(2)}(x,y) = \sum_{u \in U} \overline{q}_\beta(x,u,y) e^{-\beta \overline{V}(x,u,y)}$$
   with $U = \{1,2\}, \overline{V}(x,u,y) = V^{(u)}(x,y), \overline{q}(x,u,y) = \alpha_u \; q^{(u)}(x,y)$, and $\theta_\beta(x,u,y) = \theta_\beta^{(u)}(x,y), \overline{q}_\beta(x,u,y) = \theta_\beta(x,u,y)\overline{q}(x,u,y)$.

2.1.2. A convergence theorem. To clarify the notations, in the remainder of section 2 we will use the diacritic $(\tilde{\cdot})$ to distinguish the communication cost functions, the virtual energy function, and the critical height associated with the transition probability kernels Q_β from those associated with $\tilde{Q}_\beta$.

From the above observations and Corollary 1, choosing β of the form

$$\beta_t = K^{-1} \, \log t, \quad \text{where} \quad K > c \quad (\text{resp., } K > \tilde{c}),$$

for t sufficiently large yields that the canonical process (Ω, P, F_t, X_t) associated with the family of generators $(L_{\beta_t})_{t \geq 0} = (Q_{\beta_t} - I)_{t \geq 0}$ (resp., $(\tilde{Q}_{\beta_t} - I)_{t \geq 0}$) converges in probability to the set of the global minima $V^\star$ (resp., $\tilde{V}^\star$) of the virtual energy V (resp., $\tilde{V}$) associated with Q_β (resp., $\tilde{Q}_\beta$) and described in Corollary 1. One open problem is to compare c and $\tilde{c}$. Let us remark that $\tilde{c}$ does not depend on the choice of the parameter $\alpha \in]0,1[$. In view of these observations the bulk of the proof rests on showing that $V^\star$ and $\tilde{V}^\star$ are subsets of $(f^\star)$, where $(f^\star)$ is the set in E defined by

$$(f^\star) = \left\{ x \in E \ : \ \widehat{f}(x) = \min_E f \right\}.$$

The main purpose of this section is to prove a more general result. We will prove that $V^\star$ and $\tilde{V}^\star$ are subsets of $(f^\star) \cap A$, where A is the set in E defined by

$$A = \{x \in E \ : \ x_k \sim x_l \quad \forall 1 \leq k, l \leq N\}.$$

By $\mathcal{A}$ we will denote the partition of A induced by the equivalence relation $\sim$

$$\mathcal{A} = \{A_1, \ldots, A_{n(a)}\}, \qquad A_i = \{x \in E \ : \ [x] \subset S_i\} \qquad \forall 1 \leq i \leq n(a).$$

As usual we associate with each typical element $x = (x_1, \ldots, x_N) \in A$ the subset

$$A(x) = \{y \in E \ : \ [y] \subset S(x_1)\}.$$

Note that A is 0-stable with respect to V and $\tilde{V}$. Moreover, from our constructions, a routine proof yields that $\mathcal{A}$ is a V and $\tilde{V}$-partition of A. In view of Propositions 2 and 3 it follows that $V^\star \subset A$, $\tilde{V}^\star \subset A$, and

$$\forall x \in A \qquad V(x) = \min_{g \in G_A(x)} V_{\mathcal{A}}(g), \qquad \tilde{V}(x) = \min_{g \in G_A(x)} \tilde{V}_{\mathcal{A}}(g).$$

Now, from Proposition 4, to prove that $V^\star$ and $\tilde{V}^\star$ are subsets of $(f^\star)$ it clearly suffices to find a constant λ such that the subset $(f^\star) \cap A$ is λ-stable with respect to $V_{\mathcal{A}}$ and $\tilde{V}_{\mathcal{A}}$.

As we will see such results hold when the size N of the particle systems is greater that a critical value which depends on the functions a and f. We shall study this critical size now, beginning with two important lemmas.

Before proceeding we need to introduce some additional notations.

By Γ_{x_1,x_2}, $x_1, x_2 \in S$, we denote the paths q in S joining x_1 and x_2, that is,

$$\forall 0 \leq l < |q| \qquad k(x_l, x_{l+1}) > 0, \qquad q_0 = x_1, \quad q_{|q|} = x_2.$$

We will also denote $R(a)$ as the smallest integer such that for every $x_1, x_2 \in S$ in two different classes there exists a path joining x_1 and x_2 with length $|q| \leq R(a)$. More precisely,

$$R(a) = \max_{1 \leq i,j \leq n(a)} \min_{(x_i,x_j) \in S_i \times S_j} \min_{q \in \Gamma_{x_i,x_j}} |q|.$$

It also will be convenient to use the following definitions:

$$\begin{array}{ll} \triangle a = \min\{a(x_1,x_2) \ : \ a(x_1,x_2) \neq 0\}, & \triangle f = \min\{|f(x_1) - f(x_2)| \ : \ f(x_1) \neq f(x_2)\}, \\ \delta(a) = \sup\{a(x_1,x_2) \ : \ x_1, x_2 \in S\}, & \delta(f) = \sup\{|f(x_1) - f(x_2)| \ : \ x_1, x_2 \in S\}. \end{array}$$

LEMMA 4. *For every $x, y \in A$ such that $\widehat{f}(x) \geq \widehat{f}(y)$ we have*

$$\tilde{V}_{\mathcal{A}}(x,y) \leq \delta(a)\ R(a). \tag{29}$$

Moreover, for every $x \in A$ there exists a state $y \in (f^\star) \cap A$ such that

$$V_{\mathcal{A}}(x,y) \leq (\delta(a) + \delta(f))\ R(a). \tag{30}$$

LEMMA 5. *For every $x, y \in A$ such that $\widehat{f}(x) < \widehat{f}(y)$ we have*

$$V_{\mathcal{A}}(x,y) \geq \min(\Delta a, \Delta f)\ N \quad \text{and} \quad \tilde{V}_{\mathcal{A}}(x,y) \geq \min(\Delta a, \Delta f)\ N. \tag{31}$$

Let us write

$$\lambda(a,f) = (\delta(a)+\delta(f))\,R(a), \qquad \tilde{\lambda}(a,f) = \delta(a)\,R(a),$$
$$N(a,f) = \lambda(a,f)/\min(\Delta a, \Delta f), \qquad \tilde{N}(a,f) = \tilde{\lambda}(a,f)/\min(\Delta a, \Delta f).$$

Combining Lemmas 4 and 5 one easily gets

$$N > N(a,f) \Longrightarrow (f^\star)\cap A \text{ is } \lambda(a,f)\text{-stable with respect to } V_{\mathcal{A}},$$
$$N > \tilde{N}(a,f) \Longrightarrow (f^\star)\cap A \text{ is } \tilde{\lambda}(a,f)\text{-stable with respect to } \tilde{V}_{\mathcal{A}}.$$

These results and Proposition 4 combine to yield the following theorem.

THEOREM 3. *We denote (Ω, P, F_t, X_t) as the canonical process associated with the family of generators $(L_{\beta_t})_{t\geq 0} = (Q_{\beta_t} - I)_{t\geq 0}$ (resp., $(\tilde{Q}_{\beta_t} - I)_{t\geq 0}$), c (resp., $\tilde{c}$) the critical height associated with the communication cost function V (resp., $\tilde{V}$), and m_t the distribution of X_t. If β_t assumes the parametric form $\beta_t = K^{-1}\log t$, for sufficiently large t, with $K > c$ and if $N > N(a,f)$ (resp., $\tilde{N}(a,f)$), then we have*

$$\lim_{t\to+\infty} \mathrm{Ent}_{\pi_{\beta_t}}(m_t) = 0 \qquad \text{and} \qquad \lim_{t\to+\infty} P(X_t \in (f^\star)\cap A) = 1,$$

where π_β is the invariant probability measure of $L_\beta = Q_\beta - I$ (resp., $\tilde{Q}_\beta - I$).

We come to the proof of Lemmas 4 and 5.

Proof of Lemma 4. Let $x = (x_1, \dots, x_N)$ and $y = (y_1, \dots, y_N)$ be two elements of A such that $\widehat{f}(x) \geq \widehat{f}(y)$. First let us remark that

$$x_1 \sim y_1 \Longrightarrow \forall 1 \leq k \leq N, \quad a(x_k, y_k) = 0 \Longrightarrow \forall 1 \leq k \leq N, \quad f(x_k) = f(y_k).$$

In this situation, a routine proof yields

$$V_{\mathcal{A}}(x,y) = 0 \qquad \text{and} \qquad \tilde{V}_{\mathcal{A}}(x,y) = 0.$$

If $a(x_1, y_1) > 0$ then the irreducibility condition implies the existence of a path $q \in \Gamma_{x_1,y_1}$ and a pair of integers $0 \leq n_1 < n_2 \leq |q|$ such that

$$\forall 0 \leq k \leq n_1,\ q_k \in S(x_1), \quad \forall n_1 < k < n_2,\ q_k \notin S(x_1), \quad \forall n_2 \leq k \leq |q|,\ q_k \in S(y_1). \tag{32}$$

Let us prove (29). For this, let $p \in \tilde{C}_{x,y}$ be the path defined by

$$\forall 0 \leq k \leq |q|, \qquad p_k = (q_k, x_2, \dots, x_N), \qquad p_{|q|+1} = (y_1), \qquad p_{|q|+2} = y.$$

From the definition of q we have

$$\forall 0 \leq k \leq n_1,\ p_k \in A(x), \quad \forall n_1 < k \leq |q|,\ p_k \notin A, \quad \forall k \in \{|q|+1, |q|+2\},\ p_k \in A(y). \tag{33}$$

Moreover, it follows that

$$0 \leq \sum_{k=0}^{n_1-1} \tilde{V}(p_k, p_{k+1}) \leq \sum_{k=0}^{n_1-1} V^{(1)}(p_k, p_{k+1}) = 0,$$
$$0 \leq \tilde{V}(p_{|q|}, p_{|q|+1}) \leq V^{(2)}(p_{|q|}, p_{|q|+1}) = 0, \quad \text{and}$$
$$\tilde{V}(p_{|q|+1}, p_{|q|+2}) = V^{(1)}(p_{|q|+1}, p_{|q|+2}) = 0.$$

Now, it appears from the proceeding that

$$\begin{aligned}\tilde{V}(p) &\leq \sum_{k=0}^{n_1-1} \tilde{V}(p_k, p_{k+1}) + \sum_{k=n_1}^{|q|-1} \tilde{V}(p_k, p_{k+1}) + \tilde{V}(p_{|q|}, p_{|q|+1}) + \tilde{V}(p_{|q|+1}, p_{|q|+2}) \\ &= \sum_{k=n_1}^{|q|-1} \tilde{V}(p_k, p_{k+1}) \leq \delta(a)|q|.\end{aligned}$$

Therefore $\tilde{V}(x,y) \leq \delta(a)\ R(a)$ and the proof of (29) is completed.

The proof of (30) is just a little more complicated.

Suppose $x \in A$ and y' is an element of A such that $\widehat{f}(x) \geq \widehat{f}(y') = \min_S f$ and $a(x_1, y'_1) > 0$. Let q be the path joining x_1 and y'_1 and defined as in (32). Using the above notations, let $(t_m)_m$ be the sequence of integers defined by

$$t_0 = n_1, \qquad t_m = \inf\left\{k > t_{m-1}\ :\ f(q_k) < f(q_{t_{m-1}})\right\} \qquad \forall m \geq 1.$$

Using the assumption $\widehat{f}(x) \geq \widehat{f}(y') = \min_S f$, examination of q soon yields that there exists an $m_0 \geq 1$ such that $t_{m_0} \leq n_2$ and $f(q_{t_{m_0}}) = \min_S f$. Consequently, we have constructed a sequence of states $(q_{t_m})_{0 \leq m \leq m_0}$ such that

$$\widehat{f}(x) = f(q_{t_0}) > f(q_{t_1}) > \cdots > f(q_{t_m}) > \cdots > f(q_{t_{m_0}}) = \widehat{f}(y), \tag{34}$$

where $y = (q_{t_{m_0}}, \ldots, q_{t_{m_0}}) \in A \cap (f^\star)$. With each state q_{t_m} we associate a state $p_m \in E$, $0 \leq m \leq m_0$, by setting

$$p_{t_0} = (q_{t_0}, x_2, \ldots, x_N), \qquad p_{t_m} = (q_{t_m}, \ldots, q_{t_m}, x_N) \quad \forall 1 \leq m \leq m_0.$$

First we note that $p_{t_m} \notin A\ \forall 1 \leq m \leq m_0$ and

$$\widehat{f}(x) = \widehat{f}(p_{t_0}) > \widehat{f}(p_{t_1}) > \cdots > \widehat{f}(p_{t_m}) > \cdots > \widehat{f}(p_{t_{m_0}}) = \min_S f = \widehat{f}(y).$$

Our next task is to construct a sequence of paths $(p^{(m)})_{0 \leq m \leq m_0+1}$ such that

$$p^{(0)} \in C_{x, p_{t_0}}, \qquad p^{(m)} \in C_{p_{t_{m-1}}, p_{t_m}}, \quad \forall 1 \leq m \leq m_0 \qquad p^{(m_0+1)} \in C_{p_{t_{m_0}}, y},$$

and

- the path $p^{(0)}$ has length $|p^{(0)}| = t_0$ and for every $0 \leq k \leq t_0$ the states $p_k^{(0)}$ belong to $A(x)$;
- for every $1 \leq m \leq m_0$, $p^{(m)}$ is a path joining $p_{t_{m-1}}$ and p_{t_m} in time

  $$|p^{(m)}| = t_m - t_{m-1},$$

  and for every $0 \leq k \leq t_m - t_{m-1}$ the states $p_k^{(m)}$ do not belong to A except the first initial state $p_0^{(1)} = p_{t_0} \in A(x)$;
- $p^{(m_0+1)} = (p_{t_{m_0}}, y)$.

It is straightforward to see that any path $p^{(0)}$ satisfying the above conditions has null cost, that is, $V(p^{(0)}) = 0$. Then, to obtain the desired upper bound it clearly suffices to have

$$\forall 1 \leq m \leq m_0 \qquad V(p^{(m)}) \leq (t_m - t_{m-1})\ (\delta(a) + \delta(f)).$$

We proceed to define $(p^{(m)})_{0 \leq m \leq m_0+1}$ as follows:

1. In view of (32) and (34) it is natural to define the initial path $p^{(0)} \overset{\text{def}}{=} (p_0, \dots, p_{t_0})$ by setting

$$\forall 0 \leq k \leq t_0 = n_1 \qquad p_k = (q_k, x_2, \dots, x_N) \in A(x).$$

As has already been noted, a simple calculation shows that

$$V(p^{(0)}) = \sum_{k=0}^{t_0-1} V^{(1)}(p_k, p_{k+1}) + V^{(2)}(p_{k+1}, p_{k+1}) = 0.$$

2. Taking into account that t_1 is the first time k such that $f(q_k) < \widehat{f}(x)$ we are lead to define $p^{(1)} \overset{\text{def}}{=} (p_{t_0}, p_{t_0+1}, \dots, p_{t_1})$ by setting

$$\forall t_0 \leq k < t_1 \qquad p_k = (q_k, x_2, \dots, x_N), \qquad p_{t_1} = (q_{t_1}, \dots, q_{t_1}, x_N).$$

Let us write $\overline{p}_{t_1} = (q_{t_1}, x_2, \dots, x_N)$. In this situation $p_k \notin A \; \forall t_0 < k \leq t_1$ and it is easy to verify that

$$\begin{aligned} V(p^{(1)}) \leq & \sum_{k=t_0}^{t_1-2} V^{(1)}(p_k, p_{k+1}) + V^{(2)}(p_{k+1}, p_{k+1}) + V^{(1)}(p_{t_1-1}, \overline{p}_{t_1}) \\ & + V^{(2)}(\overline{p}_{t_1}, p_{t_1}) \\ \leq & \, (t_1 - t_0)(\delta(a) + \delta(f)). \end{aligned}$$

3. As for item 2, we define the paths $p^{(m)} \overset{\text{def}}{=} (p_{t_{m-1}}, p_{t_{m-1}+1}, \dots, p_{t_m})$ for $2 \leq m \leq m_0$ by setting

$$\forall t_{m-1} \leq k < t_m p_k = (q_k, q_{t_{m-1}}, \dots, q_{t_{m-1}}, x_N), \quad p_{t_m} = (q_{t_m}, \dots, q_{t_m}, x_N).$$

Here again we have $p_k \notin A \; \forall t_{m-1} \leq k \leq t_m$. Let us introduce a new state $\overline{p}_{t_m} = (q_{t_m}, q_{t_{m-1}}, \dots, q_{t_{m-1}}, x_N)$. It is then an elementary matter to prove the inequalities

$$\begin{aligned} V(p^{(m)}) \leq & \sum_{k=t_{m-1}}^{t_m-2} \Big(V^{(1)}(p_k, p_{k+1}) + V^{(2)}(p_{k+1}, p_{k+1}) \Big) \\ & + V^{(1)}(p_{t_m-1}, \overline{p}_{t_m}) + V^{(2)}(\overline{p}_{t_m}, p_{t_m}) \\ \leq & \, (t_m - t_{m-1} - 1) \; (\delta(a) + 2\,\delta(f)) + \delta(a) + \delta(f) \\ \leq & \, (t_m - t_{m-1}) \; (\delta(a) + \delta(f)). \end{aligned}$$

4. Finally, let us note that

$$0 \leq V(p^{(m_0+1)}) \leq V^{(1)}(p_{t_{m_0}}, p_{t_{m_0}}) + V^{(2)}(p_{t_{m_0}}, y) = 0.$$

Consider the path $p = (p^{(0)}, \dots, p^{(m_0+1)}) \in C_{x,y}$ obtained by joining end to end all these paths. From the above inequalities it follows easily that $V(p) \leq |q| \; (\delta(a) + \delta(f))$. As a clear consequence one gets

$$V_{\mathcal{A}}(x, y) \leq (\delta(a) + \delta(f)) \; R(a).$$

This ends the proof of Lemma 4. □

Much more is true. In view of our assumptions on the function a and the constructions given in the proof of Lemma 4 we observe easily that

$$\forall x \in A \qquad \forall y \in A \cap (f^{\star}) \qquad V_{\mathcal{A}}(x,y) \leq (\delta(a) + \delta(f))\, R(a).$$

Proof of Lemma 5. Let (x,y) be a pair of points of A such that $\widehat{f}(x) < \widehat{f}(y)$. Now, let p belong to $\tilde{C}_{x,y}$. Note that since $\widehat{f}(x) < \widehat{f}(y)$ there exists a real number λ such that $\widehat{f}(x) < \lambda < \widehat{f}(y)$. Let us set

$$\forall 0 \leq l \leq |q| \qquad I_l = \left\{ i \in \{1, \dots, N\} \;:\; f(p_l^i) > \lambda \right\} \quad \text{and} \quad n_l = |I_l|.$$

It follows easily that $n_0 = 0$ and $n_{|p|} = N$.

Now, let T_k, $0 \leq k \leq N$, be the first time $l \geq 0$ such that $n_l \geq k$. More precisely,

$$T_k = \inf \{ l \in \{0, \dots, |p|\} \;:\; n_l \geq k \} \qquad \forall 0 \leq k \leq N.$$

Clearly it appears from the above that

$$T_0 = 0, \qquad T_N \leq |p|, \qquad n_{T_N} = N, \qquad n_{T_0} = n_0 = 0. \tag{35}$$

By definition of the communication cost function $V^{(1)}$ we can see that

$$V^{(1)}(p_{T_k-1}, p_{T_k}) \geq \sum_{i \in I_{T_k} - I_{T_{k-1}}} a(p^i_{T_k-1}, p^i_{T_k}) \geq (n_{T_k} - n_{T_k-1})\, \Delta a \qquad \forall 1 \leq k \leq N. \tag{36}$$

More precisely, p_{T_k-1} contains n_{T_k-1} individuals $p^i_{T_k-1}$ such that $f(p^i_{T_k-1}) > \lambda$ and p_{T_k} contains n_{T_k} individuals $p^j_{T_k}$ such that $f(p^j_{T_k}) > \lambda$. Therefore, if $V^{(1)}(p_{T_k-1}, p_{T_k}) < +\infty$, then the transition $p_{T_k-1} \to p_{T_k}$ necessarily involves at least $(n_{T_k} - n_{T_k-1})$ individual mutations.

Similarly, if $V^{(2)}(p_{T_k-1}, p_{T_k}) < +\infty$, then the system p_{T_k} contains at least $(n_{T_k} - n_{T_k-1})$ new individuals $p^i_{T_k} \in [p_{T_{k-1}}]$ such that $f(p^i_{T_k}) > \lambda$. Thus a discussion similar to that above leads to

$$V^{(2)}(p_{T_k-1}, p_{T_k}) \geq (n_{T_k} - n_{T_k-1})\, \Delta f. \tag{37}$$

Finally, by definition of $\tilde{V}$, we have

$$\tilde{V}(q) \geq \tilde{V}(p_{T_1-1}, p_{T_1}) + \cdots + \tilde{V}(p_{T_N-1}, p_{T_N}).$$

Let us remark that

$$n_{T_k-1} \leq k - 1 \leq n_{T_{k-1}} \quad \forall 1 \leq k \leq N.$$

Thus, combining (36) and (37) , we arrive at

$$\tilde{V}(q) \geq N \, \min(\Delta a, \Delta f).$$

Taking the minimum of all $p \in \tilde{C}_{x,y}$ and taking into account that $V \geq \tilde{V}$ we obtain

$$V(x,y) \geq \tilde{V}(x,y) \geq N \, \min(\Delta a, \Delta f).$$

Finally we have

$$\tilde{V}_{\mathcal{A}}(x,y) \geq \tilde{V}(x,y) \geq N \, \min(\Delta a, \Delta f) \quad \text{and} \quad V_{\mathcal{A}}(x,y) \geq V(x,y) \geq N \, \min(\Delta a, \Delta f).$$

This ends the proof of Lemma 5. $\square$

Remark. Lemmas 4 and 5 show that the costs of good transitions are bounded whereas the costs of the bad ones increase at least linearly with the size of the system. On the basis of the definition of V and $\tilde{V}$ and in view of the proof of these lemmas it is clear that the above result is easier to establish for the cost function $\tilde{V}$. It also turns out that the estimate of the cost of bad transitions with respect to $\tilde{V}$ provides a quick and natural way to estimate their costs with respect to V.

In [2] an inductive proof of this result is presented for the genetic algorithm associated with V and without the equivalence relation considered here. The main contribution here is the extension of the results presented in [2] to any equivalence relation a and to the genetic algorithm associated with the cost function $\tilde{V}$.

On the other hand and in contrast to the inductive proof presented in [2], the approach described here is based on a precise study of the cost of bad or good paths.

The constants $\lambda(a,f), \tilde{\lambda}(a,f)$ represent the difficulty for a population to travel from an equivalence class to better ones. In connection with this remark it is interesting to note that $\tilde{\lambda}(a,f)$ does not depend on the fitness function f and

$$\lambda(a,f) > \tilde{\lambda}(a,f).$$

In other words, it is more difficult for the genetic algorithm associated with V to move from one configuration to a better one. The above observations also imply that the critical value $N(a,f)$ is greater than $\tilde{N}(a,f)$.

Examples. Let us see what happens when our second general model (26) is specialized for the case where the state is

$$S = \{-1,+1\}^{\mathcal{S}}, \qquad \mathcal{S} = [-n,n]^p, \qquad p \geq 1,$$

and the fitness function $f : S \to \mathbb{R}$ is given by

$$f(x) = \frac{1}{2} \sum_{s\in\mathcal{S}} \sum_{s'\in V_s} x(s)\, x(s') + \frac{1}{2} \sum_{s\in\mathcal{S}} x(s),$$

where

$$\forall s \in \mathcal{S} \qquad V_s = \{s' \in \mathcal{S} \ : \ |s_k - s'_k| \leq 1, \ \ 1 \leq k \leq p\}.$$

Let k be the Markovian mutation kernel on S given by

$$k(x_1,x_2) = \frac{1}{|\mathcal{V}(x_1)|}\, 1_{\mathcal{V}(x_1)}(x_2),$$

$$\mathcal{V}(x_1) \overset{\text{def}}{=} \{x_2 \in S \ : \ \text{Card}\{s \in \mathcal{S} \ : \ x_1(s) \neq x_2(s)\} \leq 1\}.$$

Suppose that the function a is given by

$$a(x_1,x_2) = (1 - 1_{x_1}(x_2)) \qquad \forall (x_1,x_2) \in S^2 \ : \ k(x_1,x_2) > 0.$$

Then, one can check that

$$R(a) \leq \max_{x,y} \min_{q\in C_{x,y}} |q| = \text{card}(\mathcal{S}) = (2n+1)^p \qquad \text{and} \qquad \delta(a) = \Delta(a) = 1.$$

Let N be an integer that $N > (2n+1)^p$. The above theorem shows that N individuals will solve the optimization problem when using the genetic algorithm associated with $\tilde{Q}_\beta$.

2.2. Mean cost optimization. In this section we discuss the ways in which the results of section 1 are applied in mean cost optimization problems. Namely, the object will be to find the global minima of a function $V : E \to \mathbb{R}_+$ given by

$$V(x) = E(\mathcal{U}(Z, x)) \qquad \text{or} \qquad V(x) = \min_{g \in G(x)} \sum_{(y,z) \in g} E(\mathcal{V}(Z; y, z)),$$

where

- E is a finite set and $G(x)$ is the set of x-graphs over E,
- Z is a random variable taking value in a finite set F (we denote μ its distribution),
- $U : F \times E \to \mathbb{R}_+$, and $\mathcal{V} : F \times E \times E \times \to \mathbb{R}_+$.

We have seen how to construct a stochastic algorithm converging in probability to global minima of the virtual energy associated with a communication cost function. It is clear from the description above that the appropriate communication cost function is given by

$$V(x, y) = (E(\mathcal{U}(Z; y)) - E(\mathcal{U}(Z; x)))^+ \qquad \text{or} \qquad V(x, y) = E(\mathcal{V}(Z; y, z)).$$

Unfortunately the huge size of the set F often precludes the use of such an algorithm, and the essential problem is to compute a mean cost function at each step. Therefore it is natural to choose, for instance, a Markovian kernel K which ensures that

$$V_{\gamma_t}(x, y) = \frac{1}{t^A} \int_0^{t^A} \mathcal{V}(Z_s; x, y)\, ds \xrightarrow[t \to +\infty]{} V(x, y) = E(\mathcal{V}(Z; x, y)) \qquad \text{P.a.e.}$$

$$\text{or } V_{\gamma_t}(x, y) = \left(\frac{1}{t^A} \int_0^{t^A} \mathcal{U}(Z_s; y)\, ds - \frac{1}{t^A} \int_0^{t^A} \mathcal{U}(Z_s; x)\, ds \right)^+$$

$$\xrightarrow[t \to +\infty]{} V(x, y) = (E(\mathcal{U}(Z; y)) - E(\mathcal{U}(Z; x)))^+ \qquad \text{P.a.e.},$$

where

- $V_\gamma \overset{\text{def}}{=} 1/e^\gamma \int_0^{e^\gamma} \mathcal{V}(Z_s; x, y)\, ds$ or
  $V_\gamma \overset{\text{def}}{=} \left(\frac{1}{e^\gamma} \int_0^{e^\gamma} \mathcal{U}(Z_s; y)\, ds - \frac{1}{e^\gamma} \int_0^{e^\gamma} \mathcal{U}(Z_s; x)\, ds \right)^+$,
- $\gamma_t = A \log t$,
- Z_s is a time-homogeneous Markov process associated with the generator $\mathcal{L} = K - I$,
- μ is an invariant measure of $\mathcal{L}$.

Before starting the description of our stochastic algorithm, we give some details about the above convergences.

LEMMA 6. *Let K be a an irreducible transition kernel with unique invariant measure μ. For every $x, y \in E$ and $A > 0$ we have*

$$\lim_{t \to +\infty} \sqrt{\frac{t^A}{\log t}}\, |V_{\gamma_t}(x, y) - V(x, y)| = 0 \qquad \textit{P.a.e.}$$

Proof. In this situation it is well known that for every $x, y \in E$ there exists a bounded function $F(.; x, y)$ such that

$$\mathcal{V}(.; x, y) - \mu(\mathcal{V}(.; x, y)) = \mathcal{L}(\mathrm{F}(.; x, y)) \qquad \text{and} \qquad \mu(\mathrm{F}(.; x, y) = 0.$$

This equation is the Poisson equation associated with $\mathcal{V}(.;x,y)$ and $\mathcal{L}$. Thus, one gets the decomposition

$$\frac{1}{t}\int_0^t (\mathcal{V}(Z_s;x,y)-\mu(\mathcal{V}(.;x,y)))\,ds=\frac{1}{t}(F(Z_t;x,y)-F(Z_0;x,y)-M(x,y)_t),$$

where $M(x,y)$ is a martingale with angle bracket $\langle M(x,y)\rangle$ given by

$$\langle M(x,y)\rangle_t=\sum_{z\in F}\int_0^t (F(z;x,y)-F(Z_s;x,y))^2\,K(Z_s,z)\,ds.$$

Since the function F is bounded we have $\langle M(x,y)\rangle_t \le c\ t$ for some nonnegative constant. Finally, by the standard iterated-log law and since jumps are bounded, it follows that

$$\frac{1}{t}M(x,y)_t\le\frac{\sqrt{2\,c\,t\log\log(c\,t)}}{t}$$

and thus $\lim_{t\to+\infty}\sqrt{\frac{t}{\log t}}\left|\frac{1}{t}M(x,y)_t\right|=0$. This ends the proof. □

Remark. The Poisson equation is a standard tool in the study of Markov processes. For instance it was also used by Younes [13] to study the convergence of a stochastic gradient algorithm to a maximum likelihood estimator. The context of Younes is more complex than those considered here, and the speed of convergence cannot be obtained by a mere application of the iterated logarithm law as before. But Younes also noticed that if the convergence is fast enough (in a negative power in time), then one can couple the estimation procedure to a simulated annealing algorithm (with the classical reversibility conditions) to get the global minima of a function depending on the parameter to be estimated. To do this, Younes uses the Dobrushin coefficients, but the entropy approach enables one to get more precise results on the admissible logarithmic schedules of temperature (the constant c given below).

Let us fix some terminology.

- Let $(\Omega^{(Z)},P^{(Z)},F_t^{(Z)},Z_t)$ be the canonical process associated with the generator $\mathcal{L}$.
- For a given probability measure m on E, $\beta,\gamma\in C^1(\mathbb{R}_+,\mathbb{R}_+)$ and given the Markov process Z we note $(\Omega_{(Z)},P_{(Z)},F_{(Z),t},X_t)$ the canonical process associated with the family of generators $(L_{\gamma_t,\beta_t})_{t\ge0}=(Q_{\gamma_t,\beta_t}-I)_{t\ge0}$ whose initial condition is $m_0=m$, and we note m_t the distribution of X_t, where

$$Q_{\gamma,\beta}(x,y)=q(x,y)\,e^{-\beta\,V_\gamma(x,y)}\qquad\text{with}\quad q\ \text{irreducible.}$$

- To capture all randomness we note $\Omega=\Omega^{(Z)}\times\Omega_{(Z)}$, $F_t=F_t^{(Z)}\times F_{(Z),t}$, and we define P as follows:

$$\forall A\in F_{(Z),t}\in\qquad\forall B\in F_t^{(Z)}\qquad P(A\times B)=\int_B P_{(Z)}(A)\,dP^{(Z)}.$$

The above lemma and Corollary 4 lead us to the following proposition.

PROPOSITION 5. *Let us set* $c=\limsup_{\gamma\to+\infty}c(\gamma)<+\infty$ *P.a.e., where* $c(\gamma)$ *is the critical height associated with the communication cost* V_γ.

When the inverse-freezing schedule has parametric form $\beta_t=K^{-1}\log t$, *for* t *sufficiently large and* $K>c$, *we have*

$$\lim_{t\to+\infty}Ent_{\pi_{\beta_t}}(m_t)=0\quad P.a.e.\qquad\text{and}\qquad\lim_{t\to+\infty}P(X_t\in V^\star)=1,\tag{38}$$

where π_β is the unique invariant probability of $L_\beta = Q_\beta - I$ with

$$Q_\beta(x,y) = q(x,y)\, e^{-\beta V(x,y)}.$$

In many practical situations we also want a quantitative measure of the convergence (38). Unfortunately our method of proof is not suitable for estimating such quantitative behavior. In our settings a natural alternative approach is to look at the convergence of the mean value of the process $t \to \mathrm{Ent}_{\pi_{\beta_t}}(m_t)$ with respect to the random media (given by Z). In view of the inequality (20) we immediately observe that the speed of convergence of the mean value is related to the speed of convergence of the mean values of $\mathrm{Ent}_{\pi_{\gamma_t,\beta_t}}(m_t)$ and $|V_{\gamma_t}(x,y) - V(x,y)|$. The first term, linked to the critical height $c(\gamma_t)$ and to the derivative of γ_t, depends in a complicated way on the constant A, but we know that it is a nondecreasing function of the parameter A. On the other hand, the second term is a nonincreasing function of the parameter A. If we know how these quantities are linked to A a good adjustment of this parameter is then related to a classical minimization problem. We will examine this quantitative behavior in a forthcoming paper.

ON THE TOPOLOGICAL DERIVATIVE IN SHAPE OPTIMIZATION*

J. SOKOŁOWSKI† AND A. ŻOCHOWSKI‡

Abstract. In this paper the topological derivative for an arbitrary shape functional is defined. Examples are provided for elliptic equations and the elasticity system in the plane. The topological derivative can be used for solving shape optimization problems in structural mechanics.

Key words. shape optimization, shape derivative, elasticity system, topological derivative, asymptotic expansion

1. Introduction.

The topological derivative for a shape functional is defined in the following way [10].

Assume that $\Omega \subset \mathbb{R}^N$ is an open set and that there is given a shape functional

$$\mathcal{J} \ : \ \Omega \setminus K \to \mathbb{R}$$

for any compact subset $K \subset \overline{\Omega}$. We denote by $B_\rho(x), x \in \Omega$, the ball of radius $\rho > 0$, $B_\rho(x) = \{y \in \mathbb{R}^N | \|y - x\| < \rho\}$, $\overline{B_\rho(x)}$ is the closure of $B_\rho(x)$, and assume that there exists the following limit

$$\mathfrak{T}(x) = \lim_{\rho \downarrow 0} \frac{\mathcal{J}(\Omega \setminus \overline{B_\rho(x)}) - \mathcal{J}(\Omega)}{|\overline{B_\rho(x)}|},$$

which can be defined in an equivalent way by

$$\tilde{\mathfrak{T}}(x) = \lim_{\rho \downarrow 0} \frac{\mathcal{J}(\Omega \setminus \overline{B_\rho(x)}) - \mathcal{J}(\Omega)}{\rho^N}.$$

The function $\mathfrak{T}(x), x \in \Omega$ is called the topological derivative of $\mathcal{J}(\Omega)$ and provides the information on the infinitesimal variation of the shape functional $\mathcal{J}$ if a small hole is created at $x \in \Omega$. We shall show in the sequel that the method is constructive; i.e., the topological derivative can be evaluated for shape functionals depending on solutions of elliptic equations defined in Ω.

The partial differential equation for $u_\rho = u_{\Omega_\rho}$ is called the state equation for the shape optimization problems under consideration. We show that for a class of shape functionals it is sufficient to solve in the unperturbed domain Ω the state equation as well as the appropriate adjoint state equation in order to evaluate the topological

derivative $\mathfrak{T}(x), x \in \Omega$. This means that the derivative can be used in shape optimization for broad classes of shape functionals and partial differential equations. Some examples, where the derivative is explicitly given for model problems, are provided.

Our results can be described in the following way. For the shape functional $\mathcal{J}(\Omega \setminus \overline{B_\rho(x)})$ we introduce the function of the small parameter $\rho \geq 0$ of the form $J(\rho) = \mathcal{J}(\Omega \setminus \overline{B_\rho(x)})$ and determine for $N = 2$ the second-order derivative $J''(0^+)$. Therefore, the following expansion is obtained:

$$\mathcal{J}(\Omega_\rho) = \mathcal{J}(\Omega) + \frac{\rho^2}{2} J''(0^+) + o(\rho^2) \ .$$

In the very special case of the energy functional, the so-called compliance functional in linear elasticity, the topological derivative is in fact considered in [8]. The derivative is used in numerical methods of optimal design for the specific choice of shape functional [8]. In order to differentiate the energy functional with respect to the variations of the boundary of the domain of integration the knowledge of the shape derivative of the state equation with respect to the boundary variations is not required. Therefore, the results obtained for the particular case of the energy functional cannot be directly generalized to the case of an arbitrary shape functional.

In this paper the derivative is defined for an arbitrary shape functional and evaluated for solutions of scalar elliptic equations and the system of elasticity in the plane.

2. Elliptic equation in $\mathbb{R}^2$. Assume that $\Omega \subset \mathbb{R}^2$ is a bounded domain with the boundary $\partial\Omega = \Gamma_1 \cup \Gamma_2$, $0 \in \Omega$. Let $K = [k_{ij}]_{2\times 2}, k_{ij} \in \mathbb{R}, i, j = 1, 2$, be a symmetric positive definite matrix.

We consider the following elliptic equation with nonhomogeneous Dirichlet–Neumann boundary conditions:

$$\begin{aligned} \operatorname{div}(K \cdot \nabla u) &= f \quad \text{in} \quad \Omega, \\ u &= g \quad \text{on} \quad \Gamma_1, \\ \frac{\partial u}{\partial n_K} &= h \quad \text{on} \quad \Gamma_2. \end{aligned} \tag{2.1}$$

Let λ_1, λ_2 be the eigenvalues of K, ξ^1, $\xi^2 \in \mathbb{R}^2$ the corresponding eigenvectors, i.e., $K \cdot \xi^i = \lambda_i \xi^i$, $i = 1, 2$, and $R_\lambda = [\xi^1, \xi^2]_{2\times 2}$, a rotation matrix consisting of the eigenvectors. Using the matrix R_λ the following ellipse $E_\rho \subset \mathbb{R}^2$ depending on the small parameter $\rho > 0$ is defined:

$$E_\rho = \left\{ x = (x_1, x_2) \,|\, x = R_\lambda \cdot y \ , \ y = (y_1, y_2) \ , \ \frac{y_1^2}{\lambda_1} + \frac{y_2^2}{\lambda_2} \leq \rho^2 \right\}.$$

For sufficiently small $\rho > 0$ it is always possible to remove $\overline{E_\rho}$ from Ω, obtaining

$$\Omega_\rho = \Omega \setminus \overline{E_\rho} \ , \quad \partial\Omega_\rho = \partial\Omega \cup \partial E_\rho.$$

In such a domain we define the following system:

$$(\mathcal{P}(\Omega_\rho)) \qquad \left\{ \begin{array}{ccl} \operatorname{div}(K \cdot \nabla u_\rho) & = & f \quad \text{in} \quad \Omega_\rho, \\ u_\rho & = & g \quad \text{on} \quad \Gamma_1, \\ \frac{\partial u_\rho}{\partial n_K} & = & h \quad \text{on} \quad \Gamma_2, \\ \frac{\partial u_\rho}{\partial n_K} & = & 0 \quad \text{on} \quad \Gamma_\rho = \partial E_\rho, \end{array} \right.$$

which coincides with (2.1) for $\rho = 0$.

The shape functionals we shall consider have the following form:

$$\mathcal{J}_1(\Omega_\rho) = J_u(\rho) = \int_{\Omega_\rho} F(u_\rho)\, d\Omega, \tag{2.2}$$

$$\mathcal{J}_2(\Omega_\rho) = J_g(\rho) = \int_{\Omega_\rho} [\nabla u_\rho \cdot K \cdot \nabla u_\rho]^p\, d\Omega, \tag{2.3}$$

where $p \geq 1$ is selected in such a way that (2.3) is well defined, and F is a C^2 function of its argument, and, e.g., $|F(u)| \leq C_1|u|^2, |F''(u)| \leq C_2$, to assure the differentiability of the functional (2.2). The value of p depends on the types of admissible domains and the regularity of boundary data. We distinguish two typical cases of nonsmooth domains for which the results are applicable.

(A1) Pure cracks are admissible, even having different types of boundary conditions on both edges (i.e., Neumann and Dirichlet). Then $p = 1$ and g, h must be compatible with $u \in H^1(\Omega)$, which means that the boundary data g, h are selected in such a way that the solution to (2.1) is a weak solution in the Sobolev space $H^1(\Omega)$.

(A2) Reentrant corners with $\alpha < 2\pi$ are admissible and the same types of boundary conditions on both edges (Neumann–Neumann or Dirichlet–Dirichlet) are prescribed. Then $p = 2$ and g, h must be compatible with $u \in W^1_4(\Omega)$.

We refer the reader to [2] for the regularity of solutions to the elliptic equations in nonsmooth domains. Observe that the interior regularity of u in Ω is determined by the regularity of the right-hand side f for elliptic equations. The rather restrictive assumption $f \in C^1(\Omega)$ is sufficient for our purposes, but it is not optimal. On the other hand the formulas (2.4), (2.5), defined below at $x_0 = 0$, formally can be used to define functions $J''_u(x), J''_g(x), x \in \Omega$, which have the following property:

$$J''_u(x), J''_g(x) \in L^1_{\text{loc}}(\Omega)$$

for $u, v, w \in H^1(\Omega)$, $p = 1$, and $f \in L^2(\Omega)$.

The following form of topological derivatives is obtained.

Theorem 2.1. *Assume that $f \in C^1(\Omega)$ and the boundary data (g, h) satisfy* (A1) *or* (A2); *then*

$$J''_u(0) = -2\pi\sqrt{\lambda_1\lambda_2}[\,F(u(0)) + f(0)w(0) + 2\nabla u \cdot K \cdot \nabla w|_{x=0}\,], \tag{2.4}$$

and

$$J''_g(0) = -2\pi\sqrt{\lambda_1\lambda_2}[k(p)\|\nabla u \cdot K \cdot \nabla u\|^{2p}_{x=0} + f(0)v(0) + 2(\nabla u \cdot K \cdot \nabla v)|_{x=0}], \tag{2.5}$$

where the coefficient $k(p)$ takes the values

$$k(1) = 2, \qquad k(2) = 6.$$

The functions w, v are the adjoint state variables defined by (2.28), (2.29), *respectively.*

Remark 1. From (2.4), (2.5) it follows that the topological derivatives for the shape functionals (2.2), (2.3) take the form at $x = 0$,

$$\mathfrak{T}_1(0) = -\sqrt{\lambda_1\lambda_2}[\,F(u(0)) + f(0)w(0) + 2\nabla u \cdot K \cdot \nabla w|_{x=0}\,],$$

and

$$\mathfrak{T}_2(0) = -\sqrt{\lambda_1\lambda_2}[k(p)\|\nabla u \cdot K \cdot \nabla u\|^{2p}_{x=0} + f(0)v(0) + 2\nabla u \cdot K \cdot \nabla v|_{x=0}] \ ,$$

respectively.

Proof. The proof is divided into three steps. The first step consists in transformation of $(\mathcal{P}(\Omega_\rho))$ defined in $\Omega_\rho = \Omega \setminus \overline{E_\rho}$, into the simpler elliptic equation defined in the domain $\Omega_\rho = \Omega \setminus \overline{B_\rho}$ by using an appropriate change of variables. Here we denote $B_\rho = B_\rho(0)$, $0 \in \Omega$. In the second and third steps the formulas are derived for the latter equation and then translated to the original problem by the inverse change of variables.

Step 1. Let us make the substitution $y = Bx$, where $B = \Lambda^{-1/2}R_\lambda$, and $\Lambda = \operatorname{diag}(\lambda_1, \lambda_1)$. Since $\nabla_x = B^T\nabla_y$, (2.1) is transformed to the Laplace equation, the ellipse E_ρ is transformed onto the ball B_ρ centered at 0, and the resulting domain is $\Omega_\rho = \Omega \setminus \overline{B_\rho}$. To keep notation simple, we shall use the same notation for the transformed problem as for (2.1). Therefore, the transformed state equation takes the following form:

$$\begin{aligned} \Delta u &= f \quad \text{in} \quad \Omega, \\ u &= g \quad \text{on} \quad \Gamma_1, \\ \frac{\partial u}{\partial n} &= h \quad \text{on} \quad \Gamma_2. \end{aligned} \tag{2.6}$$

The corresponding equation in the domain Ω_ρ with the hole B_ρ has the form

$$\begin{aligned} \Delta u_\rho &= f \quad \text{in} \quad \Omega_\rho, \\ u_\rho &= g \quad \text{on} \quad \Gamma_1, \\ \frac{\partial u_\rho}{\partial n} &= h \quad \text{on} \quad \Gamma_2, \\ \frac{\partial u_\rho}{\partial n} &= 0 \quad \text{on} \quad \Gamma_\rho = \partial B_\rho. \end{aligned} \tag{2.7}$$

The resulting shape functionals after the change of variables take the form

$$J_u(\rho) = \sqrt{\lambda_1\lambda_2}\int_{\Omega_\rho} F(u_\rho)\, d\Omega, \tag{2.8}$$

$$J_g(\rho) = \sqrt{\lambda_1\lambda_2}\int_{\Omega_\rho} [\nabla u_\rho \cdot \nabla u_\rho]^p\, d\Omega. \tag{2.9}$$

This is due to the fact that $K = R_\lambda \Lambda R_\lambda^T$. To make the notation still simpler, we shall compute derivatives of the following functionals:

$$I_u(\rho) = \int_{\Omega_\rho} F(u_\rho)\, d\Omega, \tag{2.10}$$

$$I_g(\rho) = \int_{\Omega_\rho} [\nabla u_\rho \cdot \nabla u_\rho]^p\, d\Omega. \tag{2.11}$$

Step 2. In the sequel we denote by $(\cdot)'$ the derivative $\partial(\cdot)/\partial\rho$, which can be considered as a particular case of the shape derivative. We refer the reader to [9] for the details on the shape differentiability of integral shape functionals and solutions to partial differential equations of elliptic type.

By an application of (C.2) it follows that

$$I_u'(\rho) = \int_{\Omega_\rho} F_u'(u_\rho)u_\rho' \, d\Omega - \int_{\Gamma_\rho} F(u_\rho)\, dS, \tag{2.12}$$

$$I_g'(\rho) = \int_{\Omega_\rho} 2p||\nabla u_\rho||^{2p-2}(\nabla u_\rho \cdot \nabla u_\rho')\, d\Omega - \int_{\Gamma_\rho} \left(\frac{\partial u_\rho}{\partial \tau}\right)^{2p} dS. \tag{2.13}$$

The weak solution $u_\rho \in H_g^1(\Omega_\rho)$ to (2.7) satisfies the integral identity

$$\int_{\Omega_\rho} \nabla u_\rho \cdot \nabla \phi \, d\Omega = \int_{\Gamma_2} h\phi \, dS - \int_{\Omega_\rho} f\phi \, d\Omega \quad \forall \phi \in H_{\Gamma_1}^1(\Omega_\rho), \tag{2.14}$$

where for $\rho \geq 0$ such that $B_\rho \subset \Omega$,

$$H_g^1(\Omega_\rho) = \{\psi \in H^1(\Omega_\rho) \mid \psi = g \quad \text{on} \quad \Gamma_1\},$$

$$H_{\Gamma_1}^1(\Omega_\rho) = \{\psi \in H^1(\Omega_\rho) \mid \psi = 0 \quad \text{on} \quad \Gamma_1\},$$

and we use the convention that the restriction to Ω_ρ of a function $\phi \in H_{\Gamma_1}^1(\Omega)$ is denoted by ϕ.

The strong shape derivative u_ρ' of the solution u_ρ to (2.14) is defined by the relation

$$u_\rho' = \dot{u}_\rho - \nabla u_\rho \cdot V \ ,$$

where $\dot{u}_\rho$ is the material derivative, and V is an appropriate vector field [9]. Furthermore, $u_\rho' \in H_{\Gamma_1}^1(\Omega_\rho)$ satisfies the integral identity [9],

$$\int_{\Omega_\rho} \nabla u_\rho' \cdot \nabla \phi \, d\Omega - \int_{\Gamma_\rho} \frac{\partial u_\rho}{\partial \tau}\frac{\partial \phi}{\partial \tau}\, dS = \int_{\Gamma_\rho} f\phi \, dS, \tag{2.15}$$

for all test functions $\phi \in H_{\Gamma_1}^1(\Omega_\rho) \cup H^2(\Omega_\rho)$. The regularity of u_ρ' is determined by the regularity of $\dot{u}_\rho$ and the gradient ∇u_ρ since V is sufficiently regular.

The adjoint state equation for the functional I_u is defined as follows: find $w_\rho \in H_{\Gamma_1}^1(\Omega_\rho)$ such that

$$-\int_{\Omega_\rho} \nabla w_\rho \cdot \nabla \phi \, d\Omega = \int_{\Omega_\rho} F_u'(u_\rho)\phi \, d\Omega \quad \forall \phi \in H_{\Gamma_1}^1(\Omega_\rho); \tag{2.16}$$

and for the functional I_g, find $v_\rho \in H_{\Gamma_1}^1(\Omega_\rho)$ such that

$$-\int_{\Omega_\rho} \nabla v_\rho \cdot \nabla \phi \, d\Omega = \int_{\Omega_\rho} 2p||\nabla u_\rho||^{2p-2}(\nabla u_\rho \cdot \nabla \phi)\, d\Omega \quad \forall \phi \in H_{\Gamma_1}^1(\Omega_\rho). \tag{2.17}$$

The strong shape derivative $w_\rho' \in H_{\Gamma_1}^1(\Omega_\rho)$ of the solution w_ρ to (2.16) satisfies the following integral identity [9]:

$$-\int_{\Omega_\rho} \nabla w_\rho' \cdot \nabla \phi \, d\Omega + \int_{\Gamma_\rho} \frac{\partial w_\rho}{\partial \tau}\frac{\partial \phi}{\partial \tau}\, dS = \int_{\Omega_\rho} F_u''(u_\rho)u_\rho'\phi \, d\Omega - \int_{\Gamma_\rho} F_u'(u_\rho)\phi \, dS \tag{2.18}$$

for all test functions $\phi \in H^1_{\Gamma_1}(\Omega_\rho) \cup H^2(\Omega_\rho)$.

The strong shape derivative $v'_\rho \in H^1_{\Gamma_1}(\Omega_\rho)$ of the solution v_ρ to (2.17) is defined in the similar way:

$$\begin{aligned}(2.19)\quad -\int_{\Omega_\rho} \nabla v'_\rho \cdot \nabla \phi \, d\Omega + \int_{\Gamma_\rho} \frac{\partial v_\rho}{\partial \tau}\frac{\partial \phi}{\partial \tau}\, dS = -\int_{\Gamma_\rho} 2p\|\nabla u_\rho\|^{2p-2}\frac{\partial u_\rho}{\partial \tau}\frac{\partial \phi}{\partial \tau}\, dS \\ + \int_{\Omega_\rho} 2p||\nabla u_\rho||^{2p-2}(\nabla u'_\rho \cdot \nabla \phi)\, d\Omega \\ + \int_{\Omega_\rho} 2p(2p-2)||\nabla u_\rho||^{2p-4}(\nabla u'_\rho \cdot \nabla u_\rho)(\nabla u_\rho \cdot \nabla \phi)\, d\Omega\end{aligned}$$

for all test functions $\phi \in H^1_{\Gamma_1}(\Omega_\rho) \cup H^2(\Omega_\rho)$. Using $\phi = u'_\rho \in H^1_{\Gamma_1}(\Omega_\rho)$ as a test function, the following form of the derivatives (2.12), (2.13) is obtained:

$$(2.20)\qquad I'_u(\rho) = -\int_{\Gamma_\rho} \left[F(u_\rho) + f w_\rho + \frac{\partial u_\rho}{\partial \tau}\frac{\partial w_\rho}{\partial \tau}\right] dS,$$

$$(2.21)\qquad I'_g(\rho) = -\int_{\Gamma_\rho} \left[\left(\frac{\partial u_\rho}{\partial \tau}\right)^{2p} + f v_\rho + \frac{\partial u_\rho}{\partial \tau}\frac{\partial v_\rho}{\partial \tau}\right] dS.$$

Since all integrands are bounded,

$$(2.22)\qquad \lim_{\rho \to 0+} I'_u(\rho) = \lim_{\rho \to 0+} I'_g(\rho) = 0.$$

By differentiating (2.21) once more, in view of (C.1) we get

$$\begin{aligned} I''_u(\rho) &= \int_{\Gamma_\rho} \left[\frac{\partial F(u_\rho)}{\partial n} + \frac{\partial (f w_\rho)}{\partial n} + \frac{\partial}{\partial n}\left(\frac{\partial u_\rho}{\partial \tau}\frac{\partial w_\rho}{\partial \tau}\right)\right] dS \\ &- \int_{\Gamma_\rho} \left[F'_u(u_\rho)u'_\rho + f w'_\rho + \left(\frac{\partial u_\rho}{\partial \tau}\frac{\partial w_\rho}{\partial \tau}\right)'\right] dS \\ &- \frac{1}{\rho}\int_{\Gamma_\rho} \left[F(u_\rho) + f w_\rho + \frac{\partial u_\rho}{\partial \tau}\frac{\partial w_\rho}{\partial \tau}\right] dS \\ (2.23)\qquad &= I_1(\rho) + I_2(\rho) + I_3(\rho). \end{aligned}$$

Observe, that $\frac{\partial}{\partial n} = -\frac{\partial}{\partial r}$ on Γ_ρ. Now, according to (A.4),

$$(2.24)\qquad \frac{\partial u_\rho}{\partial \tau} = \frac{1}{r}\frac{\partial u_\rho}{\partial \theta} = -a\left(\frac{\rho^2}{r^2} + 1\right)\sin\theta + b\left(\frac{\rho^2}{r^2} + 1\right)\cos\theta + O(\rho^{1-\epsilon}).$$

Hence

$$\frac{\partial}{\partial n}\frac{\partial u_\rho}{\partial \tau} = -2a\frac{\rho^2}{r^3}\sin\theta + 2b\frac{\rho^2}{r^3}\cos\theta + O(\rho^{-\epsilon}) \underset{r=\rho}{=} -\frac{2a}{\rho}\sin\theta + \frac{2b}{\rho}\cos\theta + O(\rho^{-\epsilon}).$$

Similarly,

$$\frac{\partial}{\partial \rho}\left(\frac{\partial u_\rho}{\partial \tau}\right) = -2a\frac{\rho}{r^2}\sin\theta + 2b\frac{\rho}{r^2}\cos\theta + O(\rho^{-\epsilon}) \underset{r=\rho}{=} -\frac{2a}{\rho}\sin\theta + \frac{2b}{\rho}\cos\theta + O(\rho^{-\epsilon}).$$

Taking this into account leads to

$$\frac{\partial}{\partial n}\left(\frac{\partial u_\rho}{\partial \tau}\frac{\partial w_\rho}{\partial \tau}\right) - \left(\frac{\partial u_\rho}{\partial \tau}\frac{\partial w_\rho}{\partial \tau}\right)' = O(\rho^{-\epsilon}),$$

and the first two integrals cancel out,

$$\lim_{\rho\to 0+}[I_1(\rho) + I_2(\rho)] = 0.$$

We use for w_ρ the following expansion, the existence of which is proven in the Appendix:

$$w_\rho = w(0) + c\left(\frac{\rho^2}{r} + r\right)\cos\theta + d\left(\frac{\rho^2}{r} + r\right)\sin\theta + O(\rho^{2-\epsilon}). \tag{2.25}$$

Taking into account (2.24),

$$\lim_{\rho\to 0+} I_3(\rho) = -2\pi F(u(0)) - 2\pi f(0)w(0) - 4\pi(ac + bd).$$

As a result

$$I_u''(0) = -2\pi[\, F(u(0)) + f(0)w(0) + 2(\nabla u \cdot \nabla w)|_{x=0}\,], \tag{2.26}$$

and similarly

$$I_g''(0) = -2\pi[\, k(p)\,||\nabla u(0)||^{2p} + f(0)v(0) + 2(\nabla u \cdot \nabla v)|_{x=0}\,], \tag{2.27}$$

where the coefficient $k(p)$ takes on the values $k(1) = 2$, $k(2) = 6$. For $\rho = 0$ the adjoint state variables w, v, satisfy the integral identities

$$w \in H^1_{\Gamma_1}(\Omega) : \int_\Omega \nabla w \cdot \nabla\phi \, d\Omega = -\int_\Omega F_u'(u)\phi \, d\Omega, \tag{2.28}$$

$$v \in H^1_{\Gamma_1}(\Omega) : \int_\Omega \nabla v \cdot \nabla\phi \, d\Omega = -\int_\Omega 2p||\nabla u||^{2p-2}(\nabla u \cdot \nabla\phi)\, d\Omega \tag{2.29}$$

for all test functions $\phi \in H^1_{\Gamma_1}(\Omega)$.

In a special case, for $p = 1$, $\Gamma_2 = \emptyset$, and $g = 0$, it follows that

$$\int_\Omega \nabla v \cdot \nabla\phi \, d\Omega = \int_\Omega f\phi \, d\Omega \quad \forall\phi \in H^1_0(\Omega);$$

hence $v = 2u$. The function $k(p)$ is obtained by the integration

$$\int_0^{2\pi} (-2a\sin\theta + 2b\cos\theta)^{2p}\, d\theta = k(p)(a^2 + b^2)^p.$$

Step 3. The proof is completed by the change of variables $x = B^{-1}y$. □

The matrix K in the definition of J_g may be replaced in fact by an arbitrary matrix, say H. However, in such a case it is not possible in general to get a simple closed form of the expression

$$A(u,p) = \lim_{\rho\to 0+}\frac{1}{\rho}\int_{\Gamma_\rho} [\nabla u_\rho \cdot \tilde{H} \cdot \nabla u_\rho]^p \, dS,$$

where $\tilde{H} = BHB^T$. We must introduce locally the orthogonal coordinate system (e_r, e_θ); see the expansions in elasticity in the Appendix. Denote $c = \cos\theta,\ s = \sin\theta$; it follows that in this frame of reference the matrix $\tilde{H}$ transforms like a second-order tensor $\tilde{H} \to \hat{H} = R(\theta)\tilde{H}R(\theta)^T$, where

$$R(\theta) = \left[\begin{array}{cc} c & -s \\ s & c \end{array}\right].$$

After substituting the expansion for u_ρ and keeping in mind that $\frac{\partial u_\rho}{\partial r} = 0$ on Γ_ρ, so that $\nabla u_\rho = [0, \frac{\partial u_\rho}{\partial \tau}]^T$ on Γ_ρ, we get

$$A(u,p) = 4\int_0^{2\pi} [\hat{h}_{22}(-as+bc)^2]^p \, d\theta$$
$$= 4\int_0^{2\pi} [(\tilde{h}_{11}c^2 - 2\tilde{h}_{12}cs + \tilde{h}_{22}s^2)(-as+bc)^2]^p \, d\theta.$$

Having computed the integral, we must again express it in terms of H. The assumption $\tilde{H} = I$ is adopted in the paper in order to simplify the obtained formulas.

Remark 2. Let us note that the condition $J'(0) = 0$ depends on the shape functional. If a shape functional depends actually on the boundary $\partial\Omega$ of the domain Ω, then in general $J'(0) \neq 0$. For $\mathcal{J}(\partial\Omega) = \int_{\partial\Omega} = |\partial\Omega|$ we have $\mathcal{J}(\partial\Omega_\rho) = |\partial\Omega| + 2\pi\rho$ and

$$\frac{\mathcal{J}(\partial\Omega_\rho) - \mathcal{J}(\partial\Omega)}{|\partial B_\rho(x)|} = 1\ .$$

Remark 3. The following function is used for the definition of the so-called Morrey spaces $L^{p,\lambda}(\Omega)$, $p \geq 1, \lambda \geq 0$,

$$\mathfrak{g}(x) = \sup_{0<\rho<1} \rho^{-\lambda} \int_{B_\rho(x)} |u|^p dx = \sup_{0<\rho<1} \rho^{-\lambda} \left[\int_\Omega |u|^p dx - \int_{\Omega\setminus\overline{B_\rho(x)}} |u|^p dx\right]$$

for $u \in L^p(\Omega)$; see, e.g., [1] for details. However, the function $\mathfrak{g}(x)$ is not useful in applications to the shape optimization.

Let us point out that the difference between the topological derivative and the function $\mathfrak{g}(x)$ is substantial, since for our applications the function $u = u_\rho$ is given by a solution of the partial differential equation defined in the domain $\Omega_\rho = \Omega \setminus \overline{B_\rho(x)}$ and we would rather consider, e.g., the function

$$\mathfrak{h}(x) = \sup_{0<\rho<1} \rho^{-\lambda} \left[\int_\Omega |u_\Omega|^p dx - \int_{\Omega_\rho} |u_{\Omega_\rho}|^p dx\right]\ .$$

3. Test cases for Laplace equation. The explicit formulas for the derivatives obtained in the previous section are presented for three examples.

Example 1. Let $\Omega = B_R(0)$, and $u(x,y) = x$, so that

$$\Delta u = 0 \quad \text{in} \ \ \Omega, \qquad u = x \quad \text{on} \ \ \partial\Omega.$$

The solution u_ρ to $(\mathcal{P}(\Omega_\rho))$ takes the form

$$u_\rho = \frac{R^2}{R^2+\rho^2}\left(\frac{\rho^2}{r} + r\right)\cos\theta,$$

and the adjoint state w is given by

$$w = \frac{1}{4}(r^3 - R^2 r)\cos\theta$$

for the functional

$$J_u(\rho) = \int_{\Omega_\rho} u_\rho^2 \, d\Omega.$$

Hence

$$J_u(\rho) = \pi \left(\frac{R^2}{R^2+\rho^2}\right)^2 \left[\rho^4(\ln R - \ln\rho) + \rho^2 R^2 - \frac{5}{4}\rho^4 + \frac{1}{4}R^4\right]$$

and simple calculations show that

$$J_u''(0) = \pi\, R^2.$$

Notice that $\nabla u(0) = [1,0]$, $\nabla w(0) = [-1/4R^2, 0]$, so according to (2.4),

$$J_u''(0) = (-4\pi)(-1/4\, R^2) = \pi R^2.$$

In general, the expression for J_u'' has the form

$$J_u'' = -2\pi \left[x^2 + \frac{1}{2}(3x^2 + y^2 - R^2)\right] = -\pi\,[5x^2 + y^2 - R^2].$$

Hence the level set $J_u'' \leq 0$ is an ellipse with the boundary

$$5x^2 + y^2 - R^2 = 0.$$

Consider the second functional

$$J_g(\rho) = \int_{\Omega_\rho} ||\nabla u_\rho||^2 \, d\Omega$$

in this case with the adjoint state variable $v = 0$, in view of $f = 0$. Thus (2.5) leads to

$$J_g''(0) = -4\pi\, ||\nabla u(0)||^2 = -4\pi.$$

On the other hand,

$$J_g(\rho) = 2\pi \left(\frac{R^2}{R^2+\rho^2}\right)^2 \left[\frac{1}{2}R^2 - \frac{1}{2}\rho^4 R^{-2}\right] \quad \text{thus} \quad J_g''(0) = -4\pi$$

and the inequality $J_g'' < 0$ holds in Ω.

This example is generic, since any regular scalar function resembles in the small neighborhood of the point an inclined plane. Since here $u(x,y) = x = r\cos\theta$, we may write u_ρ as

$$u_\rho = u + \frac{\rho^2}{r}\cos\theta - \frac{\rho^2}{R^2+\rho^2}\left(\frac{\rho^2}{r} + r\right)\cos\theta,$$

which agrees with the expansion (A.3), with $a = 1$ and $b = 0$. The pointwise convergence holds in $\Omega \setminus \{0\}$. In the 1-D case the equivalent problem would be

$$u'' = 0 \quad \text{in} \quad (-1, 1), \qquad u(-1) = -1, \;\; u(1) = 1,$$

so that $u(x) = x$. However, here u_ρ is defined by

$$u''_\rho = 0 \quad \text{in} \quad (-1, -\rho), \qquad u(-1) = -1, \;\; u'(-\rho) = 0,$$

$$u''_\rho = 0 \quad \text{in} \quad (\rho, 1), \qquad u'(\rho) = 0, \;\; u(1) = 1.$$

Therefore,

$$u_\rho(x) = \begin{cases} -1 & \text{for } x \in [-1, -\rho], \\ 1 & \text{for } x \in [\rho, 1], \end{cases}$$

and no convergence in $\Omega \setminus \{0\}$ takes place. This shows that the asymptotic expansion is valid only in higher dimensions.

Example 2. Let us consider the equation

$$\Delta u = -1, \qquad u = 0 \quad \text{on} \quad \partial\Omega,$$

where $\Omega = B_R(0)$. Hence

$$u = \frac{1}{4}(R^2 - r^2),$$

$$u_\rho = u + \frac{1}{2}\rho^2 \,\ln(r/R).$$

Observe that (A.3) holds, since $\nabla u(0) = [0, 0]$. The adjoint state w is given by

$$w = -\frac{1}{32}\,r^4 + \frac{1}{8}\,R^2 r^2 - \frac{3}{32}\,R^4.$$

Hence the gradient of w vanishes at 0 and from (2.4) it follows that

$$J''_u(0) = -2\pi \left[\left(\frac{1}{4}R^2\right)^2 + (-1)\left(-\frac{3}{32}\,R^4\right) \right] = -\frac{5}{16}\,\pi R^4.$$

Explicit computations give the same result.

Again, we may compute the general expression for J''_u. After appropriate transformations,

$$J''_u = -\frac{1}{16}\pi R^4 \left[7\left(\frac{r}{R}\right)^4 - 16\left(\frac{r}{R}\right)^2 + 5 \right];$$

hence the level set $J''_u \leq 0$ is the circle $r \leq 0.6R$.

The gradient of the functional J_g is obtained after some simple calculations. We have $v = 2u$, so that $\nabla v(0) = [0, 0]$ as well. In addition

$$||\nabla u||^2 = \left(\frac{\partial u_\rho}{\partial r}\right)^2 = -\frac{r^2 - \rho^2}{2r};$$

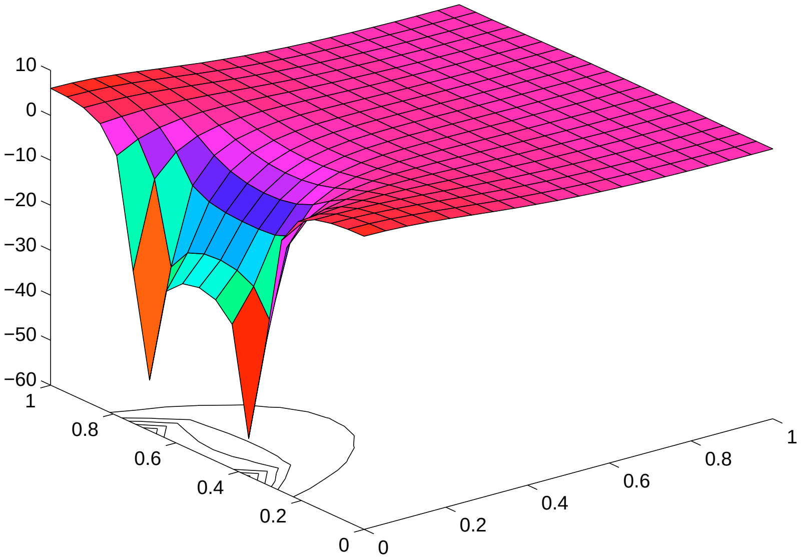

FIG. 3.1. *A graph of J_u'' and its* 0*-level line.*

hence

$$J_g''(0) = \pi R^2.$$

From our formula

$$J_g''(0) = -2\pi \left[(-1) \left(\frac{1}{2} R^2 \right) \right] = \pi R^2.$$

In general,

$$J_g'' = -4\pi \, [r^2 - R^2/4],$$

and the level set of $J_g'' \geq 0$ is the ring $r \geq R/2$.

Example 3. Let us consider the homogeneous Laplace equation $\Delta u = 0$ in $\Omega = [0,1] \times [0,1]$. The boundary conditions are prescribed as follows:

$$\begin{aligned} u = 0 \quad &\text{on} \quad \Gamma_0 = \partial\Omega - \{0\} \times [0,1], \\ u = 1 \quad &\text{on} \quad \Gamma_1 = \{0\} \times [0.3, 0.7], \\ \frac{\partial u}{\partial n} = 0 \quad &\text{on} \quad \Gamma_n = \partial\Omega \setminus (\Gamma_0 \cup \Gamma_1). \end{aligned}$$

The functional $J_u(\rho) = \int_{\Omega_\rho} u_\rho^2$ is defined for $\Omega_\rho = \Omega \setminus B_\rho(x)$; here $x \in \Omega$ stands for the center of the ball $B_\rho(x)$. The distribution of its second derivative as a function of $x \in \Omega$, computed numerically, is shown in Figure 3.1.

4. Plane elasticity problems. Let us consider the elasticity equations in the plane

$$\begin{aligned} A^T DAu = f \quad &\text{in} \quad \Omega, \\ u = g \quad &\text{on} \quad \Gamma_1, \\ B^T DAu = h \quad &\text{on} \quad \Gamma_2, \end{aligned} \tag{4.1}$$

and the same system in the domain with the circular hole $B_\rho(x_0) \subset \Omega$ centered at $x_0 \in \Omega$, $\Omega_\rho = \Omega \setminus \overline{B_\rho(x_0)}$,

$$\begin{aligned} A^T DAu^\rho &= f \quad \text{in} \quad \Omega_\rho, \\ u^\rho &= g \quad \text{on} \quad \Gamma_1, \\ B^T DAu^\rho &= h \quad \text{on} \quad \Gamma_2, \\ B^T DAu^\rho &= 0 \quad \text{on} \quad \Gamma_\rho. \end{aligned} \tag{4.2}$$

Assuming that $0 \in \Omega$, we can consider the case $x_0 = 0$. Here $u = (u_1, u_2)^T$ denotes the displacement field, g is a given displacement field on the fixed part Γ_1 of the boundary, and h is a traction given on the loaded part Γ_2 of the boundary. Finally, the volume forces are denoted by f. In addition, the differential operator is introduced,

$$A = \begin{bmatrix} \frac{\partial}{\partial x_1} & , & 0 \\ 0 & , & \frac{\partial}{\partial x_2} \\ \frac{\partial}{\partial x_1} & , & \frac{\partial}{\partial x_1} \end{bmatrix},$$

and the matrix of material (Lame) coefficients is denoted by

$$D = \begin{bmatrix} \lambda + 2\mu & , & \lambda & , & 0 \\ \lambda & , & \lambda + 2\mu & , & 0 \\ 0 & , & 0 & , & \mu \end{bmatrix}.$$

The following matrix is used for the Neumann boundary conditions:

$$B^T = \begin{bmatrix} n_1 & , & 0 & , & n_2 \\ 0 & , & n_2 & , & n_1 \end{bmatrix},$$

where $n = [n_1, n_2]^T$ is the unit outward normal vector on $\partial\Omega_\rho$. In this notation the stress tensor is replaced by the vector $\sigma = [\sigma_{11}, \sigma_{22}, \sigma_{12}]^T$, strain tensor is given by the vector $\varepsilon = [\varepsilon_{11}, \varepsilon_{22}, \gamma_{12}]^T$ (observe that $\gamma_{12} = 2\varepsilon_{12}$), and the surface tractions are defined by the formulas

$$\varepsilon = A \cdot u, \quad \sigma = D \cdot \varepsilon, \quad t = B \cdot \sigma. \tag{4.3}$$

The principal stresses associated with the displacement field u are denoted by $\sigma_I(u), \sigma_{II}(u)$; the trace of the stress tensor $\sigma(u)$ is denoted by $\text{tr}\sigma(u) = \sigma_I(u) + \sigma_{II}(u)$.

The first shape functional under consideration depends on the displacement field

$$J_u(\rho) = \int_{\Omega_\rho} F(u^\rho)\, d\Omega, \qquad F(u^\rho) = (u^\rho \cdot H \cdot u^\rho)^p = ((u^\rho)^T H u^\rho)^p\ . \tag{4.4}$$

In fact, F may be any C^2 function, similar to the case of the Laplace equation. It is also useful in the framework of elasticity to introduce the yield functional of the form

$$J_\sigma(\rho) = \int_{\Omega_\rho} [\sigma(u^\rho) \cdot S \cdot \sigma(u^\rho)]^p\, d\Omega = \int_{\Omega_\rho} [\sigma(u^\rho)^T S \sigma(u^\rho)]^p\, d\Omega, \tag{4.5}$$

where S is an isotropic matrix. Isotropicity means here that S may be expressed as

$$S = [s_{ij}] = \begin{bmatrix} l + 2m & l & 0 \\ l & l + 2m & 0 \\ 0 & 0 & 4m \end{bmatrix},$$

where l, m are any real constants. Their values for particular yield criteria are given in numerical examples. The following assumptions assure that J_u, J_σ are well defined for solutions of the elasticity system.

(B1) Pure cracks are admissible, even having different types of boundary conditions prescribed on both edges (i.e., tractions and displacements). Then $p = 1$ and g, h must be compatible with $u \in H^1(\Omega; \mathbb{R}^2)$.

(B2) Reentrant corners with $\alpha < 2\pi$ and the same types of boundary conditions are prescribed on both edges of each corner (traction–traction or displacement–displacement). Then $p = 2$ and g, h must be compatible with $u \in W_4^1(\Omega; \mathbb{R}^2)$.

The interior regularity of u in Ω is determined by the regularity of the right-hand side f of the elasticity system. For simplicity the following notation is used for functional spaces:

$$\begin{aligned} H_g^1(\Omega_\rho) &= \{\psi = (\psi_1, \psi_2) \in H^1(\Omega_\rho; \mathbb{R}^2) \mid \psi = g \quad \text{on} \quad \Gamma_1\}, \\ H_{\Gamma_1}^1(\Omega_\rho) &= \{\psi = (\psi_1, \psi_2) \in H^1(\Omega_\rho; \mathbb{R}^2) \mid \psi = 0 \quad \text{on} \quad \Gamma_1\}, \\ H_{\Gamma_1}^1(\Omega) &= \{\psi = (\psi_1, \psi_2) \in H^1(\Omega; \mathbb{R}^2) \mid \psi = 0 \quad \text{on} \quad \Gamma_1\}; \end{aligned}$$

here we use the convention that, e.g., $H_g^1(\Omega_\rho)$ stands for the Sobolev space of vector functions $H_g^1(\Omega_\rho; \mathbb{R}^2)$.

The weak solutions to the elasticity systems are defined as follows.

Find $u^\rho \in H_g^1(\Omega_\rho)$ such that, for every $\phi \in H_{\Gamma_1}^1(\Omega)$,

$$-\int_{\Omega_\rho} (Au^\rho)^T DA\phi \, d\Omega + \int_{\Gamma_2} h^T \phi \, dS = \int_{\Omega_\rho} f^T \phi \, d\Omega. \tag{4.6}$$

The adjoint state equations for the functional J_u are introduced.

Find $w^\rho \in H_{\Gamma_1}^1(\Omega_\rho)$ such that, for every $\phi \in H_{\Gamma_1}^1(\Omega)$,

$$-\int_{\Omega_\rho} (Aw^\rho)^T DA\phi \, d\Omega = \int_{\Omega_\rho} F_u'(u^\rho)^T \phi \, d\Omega. \tag{4.7}$$

Finally, $v^\rho \in H_{\Gamma_1}^1(\Omega_\rho)$ is the adjoint state for J_σ and satisfies for all test functions $\phi \in H_{\Gamma_1}^1(\Omega)$ the following integral identity:

$$-\int_{\Omega_\rho} (Av^\rho)^T DA\phi \, d\Omega = 2p \int_{\Omega_\rho} [\sigma(u^\rho)^T S \sigma(u^\rho)]^{(p-1)} \sigma(u^\rho)^T SDA\phi \, d\Omega. \tag{4.8}$$

Now we may formulate the following result.

THEOREM 4.1. *Assume that the distributed force is sufficiently regular*, $f \in C^1 (\Omega; \mathbb{R}^2)$, *and* (B1) *or* (B2) *is satisfied; then*

$$J_u''(0) = -2\pi \left[F(u) + f^T w + \frac{1}{E}(a_u a_w + 2 b_u b_w \cos 2\delta) \right]_{x=x_0}, \tag{4.9}$$

$$J_\sigma''(0) = -2\pi \left[s_{22}^p K_p(a_u, b_u) + f^T v + \frac{1}{E}(a_u a_v + 2 b_u b_v \cos 2\delta) \right]_{x=x_0}. \tag{4.10}$$

Some of the terms in (4.9), (4.10) require explanation. The function K_p takes the values

$$K_p(a, b) = \begin{cases} a^2 + 2b^2 & \text{for } p = 1, \\ a^4 + 6b^4 + 12a^2b^2 & \text{for } p = 2. \end{cases}$$

We denote

$$\begin{aligned} a_u &= \mathrm{tr}\sigma(u), & b_u &= \sigma_I(u) - \sigma_{II}(u),\\ a_w &= \mathrm{tr}\sigma(w), & b_w &= \sigma_I(w) - \sigma_{II}(w),\\ a_v &= \mathrm{tr}\sigma(v), & b_v &= \sigma_I(v) - \sigma_{II}(v). \end{aligned}$$

Finally, the angle δ denotes the angle between principal stress directions for displacement fields u and w in (4.9) and for displacement fields u and v in (4.10).

Proof. Let us calculate the derivatives of the functional $J_u(\rho)$ with respect to the parameter ρ, which determines the size of the hole B_ρ, by using the material derivative method. This leads to

$$J'_u(\rho) = \int_{\Omega_\rho} F'_u(u^\rho)^T u^{\rho\prime}\, d\Omega - \int_{\Gamma_\rho} F(u^\rho)\, dS, \tag{4.11}$$

and in the same way for the state equation

$$-\int_{\Omega_\rho} (Au^{\rho\prime})^T DA\phi\, d\Omega + \int_{\Gamma_\rho} (Au^\rho)^T DA\phi\, dS = -\int_{\Gamma_\rho} f^T\phi\, dS, \tag{4.12}$$

where $u^{\rho\prime}$ is the shape derivative.

After substitution of the test functions $\phi = w^\rho$ in the state equation, $\phi = u^{\rho\prime}$ in the adjoint state equation, we get

$$\begin{aligned} J'_u(\rho) &= -\int_{\Gamma_\rho} [(Au^\rho)^T DAw^\rho + F(u^\rho) + f^T w^\rho]\, dS \\ &= -\int_{\Gamma_\rho} \left[\frac{1}{E}\sigma_{\theta\theta}(w^\rho)\sigma_{\theta\theta}(u^\rho) + F(u^\rho) + f^T w^\rho\right] dS, \end{aligned} \tag{4.13}$$

since for the displacement fields u^ρ, w^ρ the boundary conditions $\sigma_{\theta\theta} = \tau_{r\theta} = 0$ on Γ_ρ are prescribed; here $\sigma_{\theta\theta}, \tau_{r\theta}$ denote the components of the stress tensor in the reference frame tied with normal and tangent unit vectors on Γ_ρ.

It is obvious that

$$J'_u(\rho) \underset{\rho\to 0+}{\longrightarrow} 0;$$

therefore, we compute the second derivative

$$J''_u(\rho) = I_1(\rho) - I_2(\rho) - I_3(\rho), \tag{4.14}$$

where

$$\begin{aligned} I_1(\rho) &= \int_{\Gamma_\rho} \frac{\partial}{\partial n}\left[\frac{1}{E}\sigma_{\theta\theta}(w^\rho)\sigma_{\theta\theta}(u^\rho) + F(u^\rho) + f^T w^\rho\right] dS,\\ I_2(\rho) &= \int_{\Gamma_\rho} \left[\frac{1}{E}(\sigma_{\theta\theta}(w^\rho)\sigma_{\theta\theta}(u^\rho))' + F'_u(u^\rho)u^{\rho\prime} + f^T w^{\rho\prime}\right] dS,\\ I_3(\rho) &= \frac{1}{\rho}\int_{\Gamma_\rho} \left[\frac{1}{E}\sigma_{\theta\theta}(w^\rho)\sigma_{\theta\theta}(u^\rho) + F(u^\rho) + f^T w^\rho\right] dS. \end{aligned}$$

Taking into account that $\frac{\partial}{\partial n} = -\frac{\partial}{\partial r}$ on Γ_ρ and using the expansion (B.6), we obtain

$$\frac{\partial}{\partial n}\sigma_{\theta\theta}(u^\rho) = \left[a_u\frac{\rho^2}{r^3} - 6b_u\frac{\rho^4}{r^5}\cos 2\theta\right] + O(\rho^{-\epsilon}) \underset{r=\rho}{=} a_u\frac{1}{\rho} - 6b_u\frac{1}{\rho}\cos\theta + O(\rho^{-\epsilon}).$$

Similarly,

$$\frac{\partial}{\partial \rho}\sigma_{\theta\theta}(u^\rho) = \left[a_u \frac{\rho}{r^2} - 6b_u \frac{\rho^3}{r^4}\cos 2\theta\right] + O(\rho^{-\epsilon}) \underset{r=\rho}{=} a_u \frac{1}{\rho} - 6b_u \frac{1}{\rho}\cos\theta + O(\rho^{-\epsilon}).$$

This means that the singular terms cancel out

$$\frac{\partial}{\partial n}\sigma_{\theta\theta}(u^\rho) - \frac{\partial}{\partial \rho}\sigma_{\theta\theta}(u^\rho) = O(\rho^{-\epsilon})$$

and

$$I_1(\rho) - I_2(\rho) \underset{\rho\to 0+}{\longrightarrow} 0.$$

Now we express the asymptotic expansion for $\sigma_{\theta\theta}(w^\rho)$ in the reference frame tied with principal stress directions for the displacement field u_ρ, and *not* with its own field w_ρ:

$$\sigma_{\theta\theta}(w^\rho) = \frac{1}{2}a_w\left(1 + \frac{\rho^2}{r^2}\right) - \frac{1}{2}b_w\left(1 + 3\frac{\rho^4}{r^4}\right)\cos 2(\theta - \delta) + O(\rho^{1-\epsilon}). \tag{4.15}$$

This leads to

$$\begin{aligned}
&\lim_{\rho\to 0+}\int_0^{2\pi} \sigma_{\theta\theta}(u^\rho)\sigma_{\theta\theta}(w^\rho)\, d\theta \\
&\quad = \int_0^{2\pi} [a_u - 2b_u\cos 2\theta][a_w - 2b_w\cos 2(\theta - \delta)]\, d\theta \\
&\quad = 2\pi[a_u a_w + 2b_u b_w \cos 2\delta],
\end{aligned} \tag{4.16}$$

and the final expression for the second derivative of J_u results.

In the case of J_σ the integral terms become

$$I_1(\rho) = \int_{\Gamma_\rho} \frac{\partial}{\partial n}\left[\frac{1}{E}\sigma_{\theta\theta}(v^\rho)\sigma_{\theta\theta}(u^\rho) + (s_{22}\sigma_{\theta\theta}(u^\rho)^2)^p + f^T v^\rho\right] dS,$$

$$I_2(\rho) = \int_{\Gamma_\rho} \left[\frac{1}{E}(\sigma_{\theta\theta}(v^\rho)\sigma_{\theta\theta}(u^\rho))' + +2ps_{22}^p\sigma_{\theta\theta}(u^\rho)^{2p-1}\sigma_{\theta\theta}(u^\rho)' + f^T v^{\rho\prime}\right] dS,$$

$$I_3(\rho) = \frac{1}{\rho}\int_{\Gamma_\rho} \left[\frac{1}{E}\sigma_{\theta\theta}(v^\rho)\sigma_{\theta\theta}(u^\rho) + (s_{22}\sigma_{\theta\theta}(u^\rho)^2)^p + f^T v^\rho\right] dS.$$

Again, in the same way as before,

$$I_1(\rho) - I_2(\rho) \underset{\rho\to 0+}{\longrightarrow} 0.$$

The function K_p is defined by the expression

$$K_p(a, b) = \frac{1}{2\pi}\int_0^{2\pi} (a - 2b\cos 2\theta)^{2p}\, d\theta.$$

The proof of Theorem 4.1 is completed. □

Remark 4. The matrix in the definition of J_σ, in fact, may be arbitrary, similar to the case of the scalar equation, and not only isotropic. However, it is difficult to imagine such a need for the isotropic material. Anyway, in the general case, we would have to transform S according to the known rules determined by the rotation of the reference frame. Then in the definition of $I_3(\rho)$ instead of s_{22} we would have an expression containing all the elements of S and trigonometric functions of θ. The integration is again possible but leads to more complicated formulas.

5. Examples for plane elasticity.

Example 4. Let us take the square domain, with the side length a. It is fixed on small segments of the length $a/10$ at the lower and upper part of the left side. The elastic body is pulled by the downward force distributed over the segment of the length $a/3$ located in the middle of the right side. The initial and distorted configurations are shown in Figure 5.1. The material Lame coefficients satisfy relation $\lambda = \mu$. We consider the functional J_u with $p = 8$ (approximating maximal displacement) and the following three types of J_σ, corresponding to the following yield criteria.

1. The elastic energy yield criterion (rarely used), which is equivalent modulo a proportionality factor (assuming $\lambda = \mu$ for Lame coefficients) to the following relation:

$$\sigma_{red}^2 = 3\sigma_{11}^2 + 3\sigma_{22}^2 - 2\sigma_{11}\sigma_{22} + 8\sigma_{12}^2. \tag{5.1}$$

This in turn corresponds to the isotropic matrix S with $l = -1$, $m = 2$, and J_σ given by (4.5).

2. The Huber yield criterion (frequently used), which is equivalent modulo a proportionality factor to the following relation:

$$\sigma_{red}^2 = 2\sigma_{11}^2 + 2\sigma_{22}^2 - 2\sigma_{11}\sigma_{22} + 6\sigma_{12}^2. \tag{5.2}$$

This in turn corresponds to the isotropic matrix S with $l = -1$, $m = 3/2$, and J_σ given by (4.5).

3. The maximal shear stress yield criterion (often used), which is equivalent modulo proportionality factor to the following relation:

$$\sigma_{red}^2 = \sigma_{11}^2 + \sigma_{22}^2 - 2\sigma_{11}\sigma_{22} + 4\sigma_{12}^2. \tag{5.3}$$

This in turn corresponds to the isotropic matrix S with $l = -1$, $m = 1$, and J_σ given by (4.5).

The second derivatives of these functionals are shown in Figures 5.1–5.4. The displacement functional here has the form $J_u = \int_\Omega (u_1^2 + u_2^2)^4 \, d\Omega$. The energy yield criterion is similar to the compliance functional considered in [8]. The level lines are distributed uniformly across the range of functions, and the lighter shades denote smaller values. The distributions of integrand functions and the densities of the second derivatives of functionals look similar; they are not, however, proportional to each other. The regions where the values of J'' are the smallest constitute the possible locations of holes. The same comments apply to the next example.

Example 5. Let us take the elongated rectangle, fixed on both left and right sides and loaded by the downward force over the small segment in the middle of the upper side. Its initial and distorted configuration are shown in Figure 5.5. Again we consider the same yield functions under assumption $\lambda = \mu$. The numerical results are shown in Figures 5.5–5.8.

Appendix A. Asymptotic expansions for Laplace equation in $\mathbb{R}^2$. Let us consider the equation

$$\begin{aligned} \Delta u &= f \quad \text{in} \quad \Omega, \\ u &= g \quad \text{on} \quad \Gamma_1, \\ \frac{\partial u}{\partial n} &= h \quad \text{on} \quad \Gamma_2, \end{aligned} \tag{A.1}$$

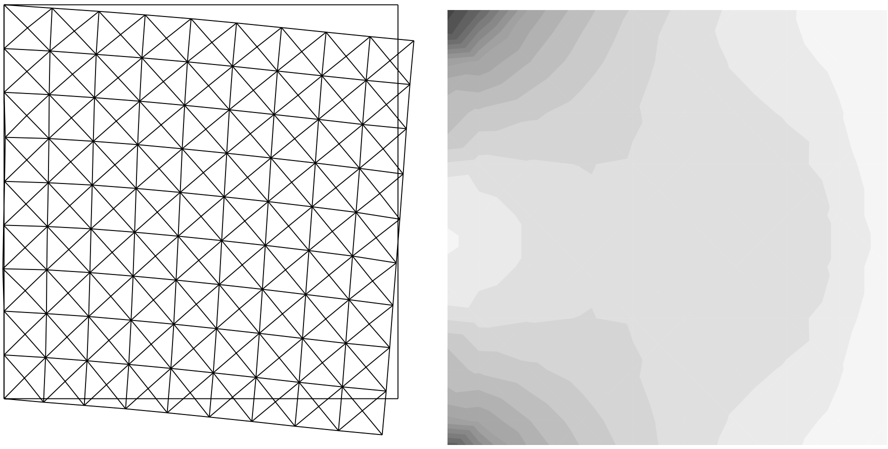

FIG. 5.1. *The square (original and distorted) and the distribution of the J''_u density.*

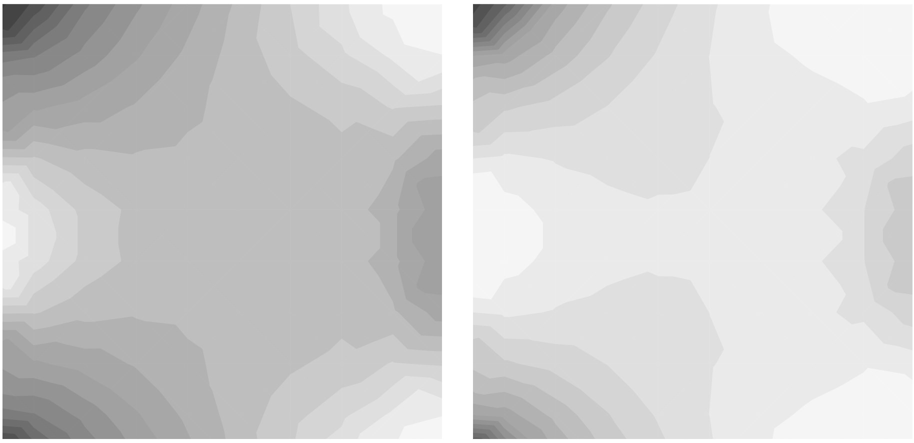

FIG. 5.2. *The distribution of the elastic energy function* (5.1) *and the corresponding J''_σ density.*

with $f \in C^1(\Omega)$ thus the solution $u \in C^3(\Omega)$. We drill a hole at $x_0 \in \Omega$, denoted $B_\rho(x_0),\ \rho < d(x_0, \Gamma)$, and define the set $\Omega_\rho = \Omega \setminus \overline{B_\rho(x_0)}$. Now consider

$$\begin{aligned} \Delta u_\rho &= f \quad \text{in} \quad \Omega_\rho, \\ u_\rho &= g \quad \text{on} \quad \Gamma_1, \\ \frac{\partial u_\rho}{\partial n} &= h \quad \text{on} \quad \Gamma_2, \\ \frac{\partial u_\rho}{\partial n} &= 0 \quad \text{on} \quad \Gamma_\rho = \partial B_\rho(x_0). \end{aligned} \tag{A.2}$$

Assume for simplicity that $x_0 = 0$. Then we have the following asymptotic expansion relations. Denote

$$\nabla u|_{x=0} = [a, b]^T.$$

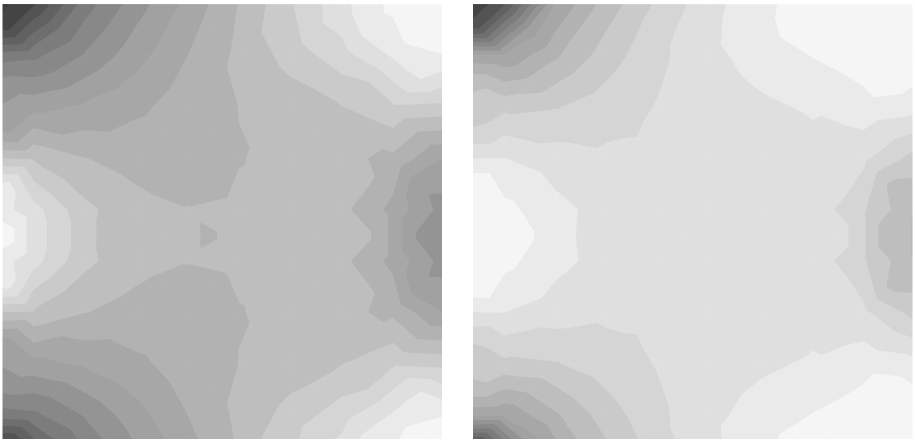

FIG. 5.3. *The distribution of the Huber yield function* (5.2) *and the corresponding* J''_σ *density.*

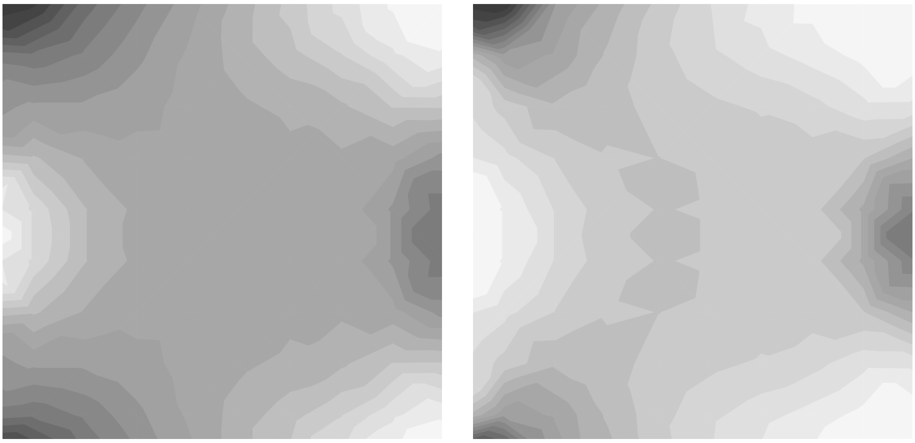

FIG. 5.4. *The distribution of the maximal shear stress yield function* (5.3) *and the corresponding* J''_σ *density.*

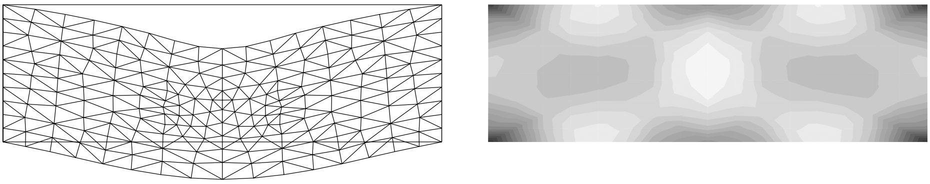

FIG. 5.5. *The object (original and distorted) and the distribution of the* J''_u *density.*

The solution u as a function of r, θ, can be expressed for $r \geq \rho$ as follows (see [5], Satz 4, and [3], [6]):

$$u_\rho = u + a\frac{\rho^2}{r}\cos\theta + b\frac{\rho^2}{r}\sin\theta + \mathcal{R}, \tag{A.3}$$

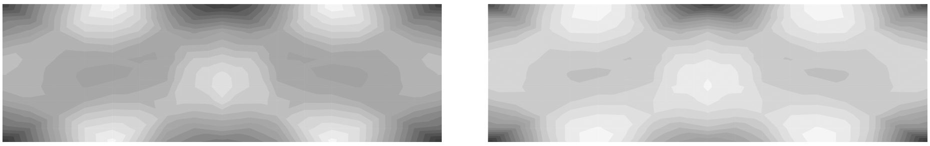

FIG. 5.6. *The distribution of the elastic energy function* (5.1) *and the corresponding* J''_σ *density.*

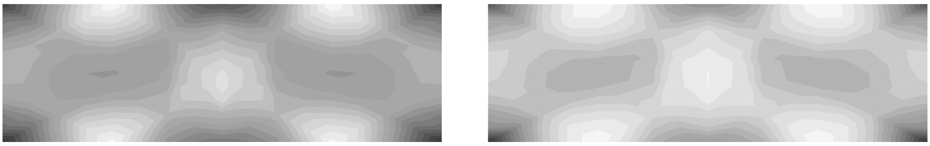

FIG. 5.7. *The distribution of the Huber yield function* (5.2) *and the corresponding* J''_σ *density.*

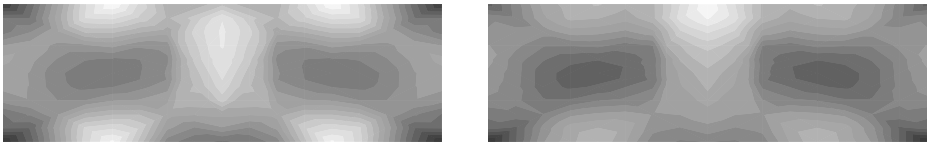

FIG. 5.8. *The distribution of the maximal shear stress yield function* (5.3) *and the corresponding* J''_σ *density.*

where

$$\mathcal{R} = \rho^2 \left[O\left(\frac{\rho}{r}\right) + l(\rho, r) \right],$$

and $l(\rho, r)$ may contain finite powers of $\ln\rho, \ln r$. Hence $\mathcal{R} = O(\rho^{2-\epsilon})$ for any $\epsilon > 0$.

The above formula gives the asymptotic expansion in the function space to which u belongs, the solution to (A.1). Besides, for smooth $f \in C^1(\Omega)$, u is three times continuously differentiable in an open neighborhood of B_ρ.

Therefore, in the ring $\rho \leq r \leq 2\rho$, taking into account the regularity of u in the neighborhood of $x_0 = 0$, we have the expansion

$$u_\rho = u(0) + a\left(\frac{\rho^2}{r} + r\right)\cos\theta + b\left(\frac{\rho^2}{r} + r\right)\sin\theta + O(\rho^{2-\epsilon}) \ , \tag{A.4}$$

where $u(0)$ denotes the value at x_0 of the solution to (A.1).

The above formulas are given in the polar coordinate system with the center at $x_0 = 0$, which coincides with the center of the ball B_ρ. In particular, from (A.4) it follows that

$$\left.\frac{\partial u_\rho}{\partial \tau}\right|_{r=\rho} = \left.\frac{1}{\rho}\frac{\partial u_\rho}{\partial \theta}\right|_{r=\rho} = 2(-a\sin\theta + b\cos\theta) + O(\rho^{1-\epsilon}). \tag{A.5}$$

Appendix B. Asymptotic expansions for the elasticity system in $\mathbb{R}^2$. Let us consider the systems (4.1) and (4.2) and assume that the coordinate system is aligned with the principal stress directions, so that $\sigma_{12} = 0$. Denote also

$$a_u = [\sigma_I(u) + \sigma_{II}(u)]|_{x=0}, \tag{B.1}$$

$$b_u = [\sigma_I(u) - \sigma_{II}(u)]|_{x=0}. \tag{B.2}$$

Let us introduce the polar coordinate system (r, θ). At each point in the plane we define also the orthogonal coordinate axes, still denoted by (r, θ), and defined by the unit vectors e_r, e_θ, directed along r and perpendicular to it, counterclockwise. Given the displacement field u, we may compute the components of the strain field (in the orthogonal system and using the polar coordinates):

$$\begin{aligned} \varepsilon_{rr} &= \frac{\partial u_r}{\partial r}, \\ \varepsilon_{\theta\theta} &= \frac{u_r}{r} + \frac{1}{r}\frac{\partial u_\theta}{\partial \theta}, \\ \gamma_{r\theta} &= \frac{1}{r}\frac{\partial u_r}{\partial \theta} + \frac{\partial u_\theta}{\partial r} - \frac{u_\theta}{r}. \end{aligned} \tag{B.3}$$

The corresponding isotropic Hook law has the form

$$\begin{aligned} \varepsilon_{rr} &= \frac{1}{E}(\sigma_{rr} - \nu\sigma_{\theta\theta}), \\ \varepsilon_{\theta\theta} &= \frac{1}{E}(\sigma_{\theta\theta} - \nu\sigma_{rr}), \\ \gamma_{r\theta} &= \frac{1}{G}\tau_{r\theta}, \end{aligned} \tag{B.4}$$

where $G = E/2(1+\nu)$. Then, similar to the Laplace case, the following expansion holds (see, e.g., [4] and [6]) in the ring $\rho \le r \le 2\rho$:

$$\begin{aligned} u_r^\rho = u_r(0) &+ \frac{a_u}{8Gr}[(\kappa-1)r^2 + 2\rho^2] \\ &+ \frac{b_u}{4Gr}\left[(\kappa+1)\rho^2 + r^2 - \frac{\rho^4}{r^2}\right]\cos 2\theta + O(\rho^{2-\epsilon}), \\ u_\theta^\rho = u_\theta(0) &- \frac{b_u}{4Gr}\left[(\kappa-1)\rho^2 + r^2 + \frac{\rho^4}{r^2}\right]\sin 2\theta + O(\rho^{2-\epsilon}), \end{aligned} \tag{B.5}$$

where $\kappa = (3-\nu)/(1+\nu)$ for plane stress and

$$\begin{aligned} u_r(0) &= \lim_{r\to 0} u_r(r,\theta), \\ u_\theta(0) &= \lim_{r\to 0} u_\theta(r,\theta). \end{aligned}$$

The corresponding expressions for the stresses have the form

$$\begin{aligned} \sigma_{rr}(u^\rho) &= \frac{1}{2}\left[a_u\left(1 - \frac{\rho^2}{r^2}\right) + b_u\left(1 - 4\frac{\rho^2}{r^2} + 3\frac{\rho^4}{r^4}\right)\cos 2\theta\right] + O(\rho^{1-\epsilon}), \\ \sigma_{\theta\theta}(u^\rho) &= \frac{1}{2}\left[a_u\left(1 + \frac{\rho^2}{r^2}\right) - b_u\left(1 + 3\frac{\rho^4}{r^4}\right)\cos 2\theta\right] + O(\rho^{1-\epsilon}), \\ \tau_{r\theta}(u^\rho) &= -\frac{1}{2}b_u\left(1 + 2\frac{\rho^2}{r^2} - 3\frac{\rho^4}{r^4}\right)\sin 2\theta + O(\rho^{1-\epsilon}). \end{aligned} \tag{B.6}$$

Observe that due to the free edge condition on the boundary of the hole, we have

$$\sigma_{rr}(u^\rho) = \tau_{r\theta}(u^\rho) = 0 \quad \text{on} \quad \partial B_\rho.$$

Appendix C. Derivatives of general functionals. Denote $(\cdot)'_\rho = \partial(\cdot)/\partial\rho$. Then we know [9] that for general G,

$$\left[\int_{\Gamma_\rho} G(u_\rho)\, dS\right]'_\rho = \int_{\Gamma_\rho} \left[G'_u(u_\rho)u'_\rho - \frac{\partial G(u_\rho)}{\partial n}\right] dS + \frac{1}{\rho}\int_{\Gamma_\rho} G(u_\rho)\, dS, \tag{C.1}$$

$$\left[\int_{\Omega_\rho} G(u_\rho)\, d\Omega\right]'_\rho = \int_{\Omega_\rho} G'_u(u_\rho)u'_\rho\, d\Omega - \int_{\Gamma_\rho} G(u_\rho)\, dS. \tag{C.2}$$

The formulas (C.1), (C.2) follow from the general formulas for the shape derivatives of integral functionals; we refer the reader to [9] for the details.

Appendix D. Asymptotic expansions for the adjoint function. The adjoint variable w_ρ satisfies the boundary value problem

$$\begin{aligned} \Delta w_\rho &= F'(u_\rho) \quad \text{in} \quad \Omega_\rho,\\ w_\rho &= 0 \quad \text{on} \quad \Gamma_1,\\ \frac{\partial u_\rho}{\partial n} &= 0 \quad \text{on} \quad \Gamma_2 \cup \Gamma_\rho. \end{aligned} \tag{D.1}$$

We know also that

$$u_\rho = u + \psi_\rho(r)\cdot(a\cos\theta + b\sin\theta) + \mathcal{R},$$

where $\psi_\rho(r) = \rho^2/r$ for $r \geq \rho$. Let us neglect for a moment $\mathcal{R}$, which is proportional to a higher power of ρ. Then, due to the regularity of F,

$$F'(u_\rho) = F'_u(u) + F''(u)\psi_\rho(r)\cdot(a\cos\theta + b\sin\theta) + O(\psi_\rho^2).$$

Again, we neglect the last term, quadratic with respect to ρ. The function $\psi_\rho(r)\cdot(a\cos\theta + b\sin\theta)$ may be smoothly extended to $\bar\psi_\rho$, defined on the whole Ω by putting

$$\bar\psi_\rho = \begin{cases} \frac{1}{2}(3\rho - r^2/\rho)\cdot(a\cos\theta + b\sin\theta) & \text{if } r < \rho,\\ \psi_\rho(r)\cdot(a\cos\theta + b\sin\theta) & \text{if } r \geq \rho. \end{cases}$$

In the next step we consider the problems

$$\begin{aligned} &\Delta p = F'_u(u) \quad \text{in} \quad \Omega, \qquad p = 0 \quad \text{on} \quad \Gamma_1, \quad \frac{\partial p}{\partial n} = 0 \quad \text{on} \quad \Gamma_2,\\ &\Delta q = \bar\psi_\rho\cdot F''_u(u) \quad \text{in} \quad \Omega, \quad q = 0 \quad \text{on} \quad \Gamma_1, \quad \frac{\partial q}{\partial n} = 0 \quad \text{on} \quad \Gamma_2. \end{aligned}$$

The function p is equal to the adjoint variable in the domain without a hole and, therefore, has the expansion

$$p_\rho = p + \psi_\rho(r)\cdot(c\cos\theta + d\sin\theta) + \mathcal{R},$$

where $[c, d] = \nabla p(0)$. There remains to analyze the expansion of q. We shall use here the results of [2, Chapter 2], and [7, Chapter 2].

Let $2\delta < \operatorname{dist}(0, \Gamma) - \rho$ and Ω_δ correspond to the domain Ω with the balls of radii δ centered around the boundary corner points removed. Then, due to the regularity of $\bar{\psi}_\rho$,

$$\begin{aligned} \|q\|_{H^2(\Omega_{2\delta})} &\leq C_\delta \|\bar{\psi}_\rho\|_{L^2(\Omega_{2\delta})}, \\ \|q\|_{H^3(\Omega_{2\delta})} &\leq C_\delta \|\bar{\psi}_\rho\|_{H^1(\Omega_{2\delta})}, \end{aligned}$$

and therefore both q and ∇q are pointwise bounded in $\Omega_{2\delta}$. Moreover, it may be checked by direct computations that

$$\begin{aligned} &\|\bar{\psi}_\rho\|_{L^2(\Omega_{2\delta})} \leq \rho^2(\Lambda_1 + \Lambda_2 |\ln \rho|) = O(\rho^{2-\epsilon}), \\ &\|\bar{\psi}_\rho\|_{H^1(\Omega_{2\delta})} \leq \Lambda\rho. \end{aligned}$$

Hence

$$q(0) = O(\rho^{2-\epsilon}), \qquad |\nabla q(0)| = O(\rho). \tag{D.2}$$

In the last step we consider the expansion of q with respect to the hole $B_{\rho_1}(0)$. It has the form

$$q_{\rho_1} = q(0) + \left(1 + \frac{\rho_1^2}{r^2}\right)(\nabla q(0) \cdot x) + O(\rho_1^{2-\epsilon}),$$

where $x = [r \cos\theta, r \sin\theta]$. By putting $\rho_1 = \rho$ and taking into account (D.2) we get

$$q_\rho = O(\rho^{2-\epsilon}),$$

and therefore the leading part of the expansion of w_ρ coincides with the expansion of p_ρ, i.e., the adjoint variable with a fixed right-hand side. The neglected parts contribute only to the higher order terms.

PONTRYAGIN MAXIMUM PRINCIPLE FOR OPTIMAL CONTROL OF VARIATIONAL INEQUALITIES*

MAÏTINE BERGOUNIOUX[†] AND HOUSNAA ZIDANI[‡]

Abstract. In this paper we investigate optimal control problems governed by variational inequalities. We present a method for deriving optimality conditions in the form of Pontryagin's principle. The main tools used are the Ekeland's variational principle combined with penalization and spike variation techniques.

Key words. variational inequalities, optimal control, Pontryagin principle

1. Introduction.

The purpose of this paper is to present a method for deriving a Pontryagin-type maximum principle as a first-order necessary condition of optimal controls for problems governed by variational inequalities. We allow various kinds of constraints to be imposed on the state. To be more precise, we consider the following variational inequality:

$$\frac{\partial y}{\partial t} + Ay + f(y) + \partial\varphi(y) \ni u \quad \text{in } Q = \Omega \times]0, T[, \tag{1.1a}$$

$$y = 0 \qquad \text{on } \Sigma = \Gamma \times]0, T[, \tag{1.1b}$$

$$y(0) = y_o \quad \text{in } \Omega, \tag{1.1c}$$

where $\Omega \subset \mathbb{R}^n$, $T > 0$, u is a distributed control, A is a second-order elliptic operator, and $\frac{\partial y}{\partial t}$ denotes the derivative of y with respect to t; $\partial\varphi(y)$ is the subdifferential of the function φ at y. We shall give all the definitions we need in section 3 and (1.1) will be made clear as well. The control variable u and the state variable y must satisfy constraints of the form

(1.2a)
$$u \in U_{ad} = \{\ u \in L^p(Q) \mid u(x,t) \in \mathcal{K}_U(x,t) \text{ almost everywhere (a.e.) in } Q\ \} \subset L^p(Q),$$

where $\mathcal{K}_U$ is a measurable set-valued mapping from Q with closed values in $\mathcal{P}(\mathbb{R})$ ($\mathcal{P}(\mathbb{R})$ being the set of all subsets of $\mathbb{R}$), and where

$$\Phi(y) \in \mathcal{C} \tag{1.2b}$$

with $1 < p < \infty$, Φ is a $\mathcal{C}^1$ mapping from $C(\overline{Q})$ into $C(\overline{Q})$, and $\mathcal{C} \subset C(\overline{Q})$ is a closed convex subset with finite codimension.

The control problem is

$$(\mathcal{P}) \qquad \inf\{J(y,u) \mid y \in C(\overline{Q}), u \in U_{ad}, (y,u) \text{ satisfies } (1.1),(1.2)\},$$

where the cost functional is defined by

$$(1.3) \qquad J(y,u) = \int_Q F(x,t,y(x,t),u(x,t))\,dx\,dt + \int_\Omega L(x,y(x,T))dx.$$

Many authors (for example, Barbu [2], Mignot–Puel [17], Yong [23], Bonnans–Tiba [6], Bonnans–Casas [5], and Bergounioux [3]) have already considered control problems for variational inequalities from the theoretical or numerical point of view. Here we are interested in optimality conditions in the form of Pontryagin's principle. The existence of an optimal solution is assumed a priori. The novelty of this paper is twofold: We obtain the optimality conditions in Pontryagin's form and we think that our hypotheses seem to be minimal. In essence we ask for the state equation to be well posed and assume differentiability of data with respect to the state. We allow various kinds of constraints to be added on the control u and on the state. However, we restrict the study to the case in which φ is the indicator function of the closed convex set $K_o = \{z \in C(\overline{Q}) \mid z \geq 0\}$ so that the variational inequality (1.1) becomes the so-called obstacle problem.

To get Pontryagin's principle, we use a method based on penalization of state constraints and on Ekeland's principle combined with diffuse perturbations [16, 20]. These techniques already have been used by many authors in the case of optimal control of parabolic or elliptic equations [5, 16, 21]. Some of these techniques also have been used for control problems governed by variational inequalities [5, 23, 4]. In those papers, the variational inequality is approximated via the Moreau–Yosida approximation of the maximal monotone operator $\partial\varphi$.

Here we use another idea based on the formulation of (1.1) with a slackness variable and the regularity of its solution. In fact, the solution of (1.1) is also a weak solution of

$$(1.4) \qquad \frac{\partial y}{\partial t} + Ay + f(y) = u + \xi \quad \text{in } Q, \qquad y = 0 \quad \text{on } \Sigma, \qquad y(0) = y_o \quad \text{in } \Omega,$$

where ξ is the Lagrange multiplier associated with the variational inequality and is introduced as an additional control variable. Therefore we obtain a problem $(\widetilde{\mathcal{P}})$ equivalent to $(\mathcal{P})$, with constraints on both the control variable and the state variable as well as coupled state-control constraints. We first give a Pontryagin's principle for $(\widetilde{\mathcal{P}})$. For this, we adapt the proof given in [21, 24, 7] to problem $(\widetilde{\mathcal{P}})$. Next we derive optimality conditions for $(\mathcal{P})$ from those for $(\widetilde{\mathcal{P}})$.

2. Assumptions.

Let Ω be an open, smooth (with a $\mathcal{C}^2$ boundary Γ for example), and bounded domain of $\mathbb{R}^n$ $(2 \leq n)$. In this paper we suppose that

$$p > n.$$

Remark 2.1. We must emphasize that this choice of p is not optimal. Indeed, we should distinguish the integers p (for the L^p-space of the distributed control u) and q (for the L^q-space of the initial value y_o). The optimal choice should be $u \in L^p(Q)$ with $p > \frac{n}{2} + 1$ and $y_o \in W_o^{1,q}(\Omega)$ with $q > n$; at each occurrence we note how the assumptions that follow could be weakened from this point of view. To make the presentation clearer we simply assume that $p = q > n$.

In addition we make the following assumptions.

(A1) A is a linear elliptic differential operator defined by

$$\begin{gathered} Ay = -\sum_{i,j=1}^{n} \partial_{x_i}(a_{ij}(x)\partial_{x_j} y) + a_0(x)y \quad \text{with} \\ a_{ij} \in \mathcal{C}^2(\overline{\Omega}) \ for\ i,j = 1 \cdots n, \\ a_0 \in L^\infty(\Omega), \sum_{i,j=1}^{n} a_{ij}(x)\xi_i\xi_j \geq m_o \sum_{i=1}^{n} \xi_i^2 \ \ \forall x \in \overline{\Omega}, \forall \xi \in \mathbb{R}^{\mathrm{n}}, m_o > 0. \end{gathered} \tag{2.1}$$

(A2) $f\ : \mathbb{R} \to \mathbb{R}$ is a monotone increasing, globally Lipschitz $\mathcal{C}^1$-function.

Remark 2.2. The monotonicity assumption on f can be relaxed and replaced by

$$\exists c_o \in \mathbb{R} \qquad f'_y \geq c_o.$$

An appropriate translation shows that we retrieve the case where f is monotonically increasing, so we assume this for the sake of simplicity.

On the other hand one could consider a mapping f from $\mathbb{R} \times \mathbb{R}$ to $\mathbb{R}$ depending on both y and u. The method would work in the same way. (In what follows, we denote the real function $f : \mathbb{R} \to \mathbb{R}$ and the Nemytski operator associated to $f : y(\cdot) \mapsto f(y(\cdot))$ in $L^p(Q)$ by the same symbol f.)

(A3) $\varphi\ : W^{1,p}_o(\Omega) \to \mathbb{R} \cup \{+\infty\}$ is a proper (i.e., nonidentically equal to $+\infty$), convex, lower semicontinuous function such that $0 \in \text{dom } \varphi$.

(A4) $y_o \in \text{dom } \varphi$.

(A5) For every $(y,u) \in \mathbb{R}^2$, $F(\cdot,y,u)$ is measurable on Q. For almost every $(x,t) \in Q$, for every $u \in \mathbb{R}$, $F(x,t,\cdot,u)$ is $\mathcal{C}^1$ on $\mathbb{R}$. For almost every $(x,t) \in Q$, $F(x,t,\cdot)$ and $F'_y(x,t,\cdot)$ are continuous on $\mathbb{R}^2$. The following estimate holds:

$$|F(x,t,y,u)| + |F'_y(x,t,y,u)| \leq (M_1(x,t) + m_1|u|^p)\eta(|y|),$$

where $M_1 \in L^1(Q)$, $m_1 \geq 0$, and η is a nondecreasing function from $\mathbb{R}^+$ to $\mathbb{R}^+$.

(A6) For every $y \in \mathbb{R}$, $L(\cdot,y)$ is measurable on Ω. For almost every $x \in \Omega$, $L(x,\cdot)$ is $\mathcal{C}^1$ on $\mathbb{R}$. The following estimate holds:

$$|L(x,y)| + |L'_y(x,y)| \leq M_2(x)\eta(|y|),$$

where $M_2 \in L^1(\Omega)$, η is as in (A5).

(A7) Φ is a $\mathcal{C}^1$ mapping from $C(\overline{Q})$ into $C(\overline{Q})$, and $\mathcal{C}$ is a closed convex subset of $C(\overline{Q})$ with finite codimension.

We recall that for $p \in \mathbb{N}$

$$W^{1,p}(\Omega) = \{y \in L^p(\Omega) \mid \nabla y \in L^p(\Omega)^n \ \} \ \text{ and}$$
$$W^{2,1,p}(Q) = \left\{ y \in L^p(Q) \mid Dy,\ D^2y,\ \frac{\partial y}{\partial t} \in L^p(Q) \right\}.$$

3. Existence and regularity of solutions to the variational inequality. Let V and H be Hilbert spaces such that $V \subset H \subset V'$ with continuous and dense injections. We denote by $(\cdot,\cdot)_V$ the V-scalar product, $\langle \cdot,\cdot \rangle$ the duality product between V and V', and $\|\cdot\|_V$ the V-norm. We consider a linear, continuous V-elliptic operator $\mathcal{A}$ from V to V' and ϕ a convex, proper, and lower semicontinuous function from V to $\mathbb{R} \cup \{+\infty\}$. Then we may define the variational inequality

$$\begin{cases} \dfrac{\partial y}{\partial t}(t) + \mathcal{A}y(t) + \partial\phi(y)(t) \ni u(t) \text{ a.e. t in } [0,T], \\ y(0) = y_o \end{cases} \tag{3.1}$$

in the following (variational) sense:

$$\left\langle \frac{\partial y}{\partial t}(t) + \mathcal{A}y(t), y(t) - z \right\rangle + \phi(y(t)) - \phi(z) \leq \langle\, f(t), y(t) - z\rangle \quad \text{a.e. } t \in (0,T)\ \forall z \in V. \tag{3.2}$$

Here $\partial\phi(y(t))$ denotes the subdifferential of ϕ at $z = y(t) \in V$ [8]:

$$\partial\phi(z) = \{\ z^* \in V' \mid \phi(z) - \phi(\zeta) \leq \langle z - \zeta, z^*\rangle\ \forall \zeta \in V\ \}. \tag{3.3}$$

Now we set $V = H^1_o(\Omega)$ and $H = L^2(\Omega)$; we let g be a primitive function of f (such that $g(0) = 0$ for example) and define

$$\phi = \varphi + g, \tag{3.4}$$

where φ is given by (A3). Then $\partial\phi = g' + \partial\varphi = f + \partial\varphi$ (g is the regular part of ϕ). Therefore (1.1) makes sense in the (3.1) form with $\mathcal{A} = A$ and we may give a first existence and regularity result as in the following theorem.

THEOREM 3.1. *Set $p \geq 2$; let $u \in L^p(Q)$ and $y_o \in W^{1,p}_o(\Omega)$. Assume that*

$$\exists \gamma \in L^p(\Omega) \cap \partial\varphi(y_o); \tag{3.5}$$

then (1.1) *has a unique solution $y \in W^{2,1,p}(Q)$.*

Proof. We first use a result of Tiba [22, Theorem 4.5, p. 26] that ensures that if β is a maximal monotone graph $\subset \mathbb{R} \times \mathbb{R}$, $u \in L^p(Q)$ and $y_o \in W^{1,p}_o(\Omega)$, then the parabolic variational inequality

$$\begin{cases} \dfrac{\partial y}{\partial t} + Ay + \beta(y) & \ni u \quad \text{a.e. in } Q,\\ y(0,x) & = y_o(x) \quad \text{a.e. on } \Omega,\\ y(t,x) & = 0 \quad \text{a.e. on } \Sigma \end{cases}$$

has a unique solution in $W^{2,1,p}(Q)$ if the compatibility relation

$$\begin{gathered} 0 \in \text{ dom } \beta,\ y_o(x) \in \text{ dom } \beta \text{ a.e. in } \Omega,\\ \exists \gamma \in L^p(\Omega) \text{ such that } \gamma(x) \in \beta(y_o(x)) \text{ a.e. in } \Omega \end{gathered} \tag{3.6}$$

is fulfilled. One can apply this result to $\beta = f + \partial\varphi$, which is a maximal monotone graph since f is monotone increasing and φ is convex, lower semicontinuous, and proper. It remains to check (3.6), that is,

$$\exists \gamma \in L^p(\Omega) \text{ such that } \gamma(x) \in f(y_o(x)) + \partial\varphi(y_o(x)) \ \text{ a.e. in } \Omega.$$

This is equivalent to

$$\exists \gamma \text{ such that } \gamma + f(y_o) \in L^p(\Omega), \text{ and } \gamma(x) \in \partial\varphi(y_o(x)) \text{ a.e. in } \Omega.$$

Since f is globally Lipschitz then $f(y_o) \in L^p(\Omega)$ and we get the result. □

We set

$$\xi = u - \frac{\partial y}{\partial t} - Ay - f(y) \in L^p(Q)$$

(since f is globally Lipschitz and $y \in W^{2,1,p}(Q)$). In addition, $\xi(t) \in \partial\varphi(y(t))$ almost everywhere in $]0,T[$; using the characterization of the subdifferential of a function in Banach spaces this gives

$$\varphi(y(t)) + \varphi^*(\xi(t)) - \langle y(t), \xi(t) \rangle = 0 \text{ a.e in }]0,T[. \tag{3.7}$$

In this last relation $\langle , \rangle$ denotes the duality product between $V = W_o^{1,p}(\Omega)$ and V', and φ^* is the conjugate function of φ. For more details refer to Barbu–Precupanu [1] or Ekeland–Temam [13]. It follows that the variational inequality (1.1) is equivalent to

$$\begin{aligned} \frac{\partial y}{\partial t} + Ay + f(y) &= u + \xi && \text{in } Q, \\ y &= 0 && \text{on } \Sigma, \\ y(x,0) &= y_o(x) && \text{in } \Omega \end{aligned} \tag{3.8}$$

and (3.7). Because $y_o \in W_o^{1,p}(\Omega)$ and $(u,\xi) \in L^p(Q) \times L^p(Q)$, the solution y of equation (3.8) belongs to $C(\overline{Q}) \cap W^{2,1,p}(Q)$. More precisely, we have the following theorem.

THEOREM 3.2. (i) *If $p > n/2+1$ and $(u,\xi,y_o) \in L^p(Q) \times L^p(Q) \times \mathcal{C}(\overline{\Omega})$, then* (3.8) *has a unique weak solution $y_{u\xi}$ in $W(0,T) \cap C(\overline{Q})$ which satisfies*

$$\|y_{u\xi}\|_{\infty,Q} \le C_1(\|u\|_{p,Q} + \|\xi\|_{p,Q} + \|y_o\|_{\infty,\Omega} + 1),$$

where $C_1 = C_1(T,\Omega,m_0,n,p)$. Moreover, for every $\varepsilon > 0$, $y_{u\xi}$ is Hölder continuous on $[\varepsilon,T] \times \overline{\Omega}$ and belongs to $W^{2,1,p}(\Omega \times]\varepsilon,T[)$.
(ii) *If $p > n$ and $(u,\xi,y_o) \in L^p(Q) \times L^p(Q) \times W_o^{1,p}(\Omega)$,* (3.8) *has a unique weak solution $y_{u\xi}$ in $W^{2,1,p}(Q) \cap C(\overline{Q})$.*

Proof. The existence of a unique weak solution $y_{u\xi}$ in $W(0,T) \cap C(\overline{Q})$ for (3.8) can be proved as in the case of the Robin boundary condition (see Raymond–Zidani [20, 21]). The Hölder continuity result holds thanks to [9]. Point (ii) can be found in Bergounioux–Tröltzsch [4]. □

4. Optimal control of the obstacle problem.

4.1. The obstacle problem. Now we focus on the very case of control of the obstacle problem, where

$$K_o = \{ z \in W_o^{1,p}(\Omega) \mid z \ge 0 \text{ a.e. in } \Omega \ \} \tag{4.1}$$

and φ is the indicator function of K_o:

$$\varphi(z) = \begin{cases} 0 & \text{if } z \in K_o, \\ +\infty & \text{else.} \end{cases}$$

It is clear that $0 \in \text{dom } \varphi = K_o$. Moreover, the compatibility condition (3.5) is fulfilled with $\gamma = 0$ so that Theorem 3.1 is valid. On the other hand, the (classical) calculus of φ^* shows that relation (3.7) is equivalent to

$$\begin{gathered} y(t) \ge 0 \text{ in } \Omega \quad \forall t \in]0,T[\ , \quad \xi(t) \ge 0 \text{ in } \Omega, \\ \text{and } \int_\Omega y(t,x)\ \xi(t,x)\ dx = 0 \ \text{ a.e. } t \in]0,T[, \end{gathered} \tag{4.2}$$

that is, at last

$$y \geq 0 \text{ in } Q \ , \xi \geq 0 \text{ a.e. in } Q, \text{ and } \int_Q y(t,x)\ \xi(t,x)\ dx\ dt = 0.$$

We may summarize in the following theorem.

THEOREM 4.1. *Assume $p > n$, $(u, y_o) \in L^p(Q) \times W_o^{1,p}(\Omega)$; then the variational inequality*

$$\frac{\partial y}{\partial t} + Ay + f(y) + \partial\varphi(y) \ni u \quad \text{in } Q, \quad y = 0 \quad \text{on } \Sigma, \quad y(0) = y_o \quad \text{in } \Omega, \tag{4.3}$$

where φ is the indicator function of K_o, has a unique solution $y \in \mathcal{C}(\overline{Q}) \cap W^{2,1,p}(Q)$. Moreover, it is equivalent to

$$\begin{cases} \dfrac{\partial y}{\partial t} + Ay + f(y) = u + \xi \quad \text{in } Q, \quad y = 0 \quad \text{on } \Sigma, \quad y(x,0) = y_o(x) \quad \text{in } \Omega, \\ \xi \geq 0, \quad y \geq 0, \quad \displaystyle\int_Q y(t,x)\ \xi(t,x)\ dx\ dt = 0. \end{cases} \tag{4.4}$$

In the following we denote

$$V_{ad} = \{\xi \in L^p(Q) \mid \xi \geq 0 \text{ a.e. in } Q\ \}. \tag{4.5}$$

4.2. Pontryagin principle. Now we consider the following problem $(\widetilde{\mathcal{P}})$: Minimize $J(y, u)$ subject to

$$\frac{\partial y}{\partial t} + Ay + f(y) = u + \xi \text{ in } Q, \quad y = 0 \text{ on } \Sigma,\ y(.,0) = y_o \text{ in } \Omega, \tag{4.6a}$$

$$\tilde{\Phi}(y) \in \widetilde{\mathcal{C}} \qquad (\text{“pure” state constraint}), \tag{4.6b}$$

$$(u, \xi) \in U_{ad} \times V_{ad} \qquad (\text{“pure” control constraints}), \tag{4.6c}$$

$$\int_Q y(t,x)\ \xi(t,x)\ dx\ dt = 0 \qquad (\text{mixed state-control integral constraints}), \tag{4.6d}$$

where

$$\tilde{\Phi}(y) = (\Phi(y), y) \text{ and } \widetilde{\mathcal{C}} = \mathcal{C} \times \{y \in \mathcal{C}(\overline{Q}) \mid y \geq 0\ \}. \tag{4.7}$$

The results of section 3 yield that problems $(\mathcal{P})$ and $(\widetilde{\mathcal{P}})$ are equivalent. In particular if $(\bar{y}, \bar{u})$ is a solution of $(\mathcal{P})$, then there exists $\bar{\xi} \in L^p(Q)$ such that $(\bar{y}, \bar{u}, \bar{\xi})$ is an optimal solution of $(\widetilde{\mathcal{P}})$ with $\bar{\xi} = \partial\bar{y}/\partial t + A\bar{y} + f(\bar{y}) - \bar{u}$. Let us mention that we are interested not in existence results (although we will give an example in the last section of this paper) but in optimality conditions for $(\bar{y}, \bar{u})$. Consequently, we study optimality conditions for $(\bar{y}, \bar{u}, \bar{\xi})$ to get those for $(\bar{y}, \bar{u})$.

Let us define the Hamiltonian functions by

$$H_1(x,t,y,u,q,\nu) = \nu F(x,t,y,u) + q\ u \tag{4.8}$$

for every $(x,t,y,u,q,\nu) \in Q \times \mathbb{R}^4$, and

$$H_2(y,\xi,q,\lambda) = q\ \xi + \lambda\ y\ \xi \tag{4.9}$$

for every $(y,\xi,q,\lambda) \in \mathbb{R}^4$.

THEOREM 4.2 (Pontryagin principle for $(\widetilde{\mathcal{P}})$). *If* (A1)−(A7) *are fulfilled and if* $(\bar{y},\bar{u},\bar{\xi})$ *is a solution of* $(\widetilde{\mathcal{P}})$*, then there exist* $\bar{q} \in L^1(0,T;W_o^{1,1}(\Omega))$*,* $\bar{\nu} \in \mathbb{R}$*,* $\bar{\lambda} \in \mathbb{R}$*, and* $(\bar{\mu},\bar{\theta}) \in \mathcal{M}(\overline{Q}) \times \mathcal{M}(\overline{Q})$ *(*$\mathcal{M}(\overline{Q})$ *is the space of Radon measures on* $\overline{Q}$*), such that*

$$(\bar{\nu},\bar{\lambda},\bar{\mu},\bar{\theta}) \neq 0, \quad \bar{\nu} \geq 0, \tag{4.10a}$$

$$\forall z \in \{ z \in \mathcal{C}(\overline{Q}) \mid z \geq 0 \}\ \ \langle \bar{\mu}, z - \bar{y} \rangle_{\overline{Q}} \leq 0,\ \ \textit{and}\ \forall z \in \mathcal{C}\ \ \langle \bar{\theta}, z - \Phi(\bar{y}) \rangle_{\overline{Q}} \leq 0, \tag{4.10b}$$

$$\begin{cases} -\dfrac{\partial \bar{q}}{\partial t} + A^*\bar{q} + f'_y(\bar{y})\bar{q} = \bar{\nu}F'_y(x,t,\bar{y},\bar{u}) + \bar{\mu}|_Q + [\Phi'(\bar{y})^*\bar{\theta}]|_Q + \bar{\lambda}\bar{\xi} & \textit{in } Q, \\ \bar{q} = 0 \quad \textit{on } \Sigma, \qquad \bar{q}(T) = \bar{\nu}L'_y(x,\bar{y}(T)) + \bar{\mu}|_{\overline{\Omega}_T} + [\Phi'(\bar{y})^*\bar{\theta}]|_{\overline{\Omega}_T} & \textit{in } \Omega, \end{cases} \tag{4.10c}$$

$$\bar{q} \in L^{\delta'}(0,T;W_o^{1,d'}(\Omega)) \qquad \textit{for every } (\delta,d) \textit{ satisfying } \frac{n}{2d} + \frac{1}{\delta} < \frac{1}{2}, \tag{4.10d}$$

$$\begin{aligned} H_1(x,t,\bar{y}(x,t),\bar{u}(x,t),\bar{q}(x,t),\bar{\nu}) = \min_{u \in \mathcal{K}_U(x,t)} \\ H_1(x,t,\bar{y}(x,t),u(x,t),\bar{q}(x,t),\bar{\nu}) \quad \textit{a.e. in } Q, \end{aligned} \tag{4.10e}$$

$$H_2(\bar{y}(x,t),\bar{\xi}(x,t),\bar{q}(x,t),\bar{\lambda}) = \min_{\xi \in \mathbb{R}^+} H_2(\bar{y}(x,t),\xi,\bar{q}(x,t),\bar{\lambda}) \qquad \textit{a.e. in } Q, \tag{4.10f}$$

where $\bar{\mu}|_Q$ *(resp.,* $[\Phi'(\bar{y})^*\bar{\theta}]|_Q$*) is the restriction of* $\bar{\mu}$ *(resp.,* $[\Phi'(\bar{y})^*\bar{\theta}]$*) to* Q*,* $\bar{\mu}|_{\overline{\Omega}_T}$ *(resp.,* $[\Phi'(\bar{y})^*\bar{\theta}]|_{\overline{\Omega}_T}$*) is the restriction of* $\bar{\mu}$ *(resp.,* $[\Phi'(\bar{y})^*\bar{\theta}]$*) to* $\overline{\Omega} \times \{T\}$*,* $\langle \cdot,\cdot \rangle_{\overline{Q}}$ *denotes the duality product between* $\mathcal{M}(\overline{Q})$ *and* $C(\overline{Q})$*,* A^* *is the adjoint operator of* A*, and* $\frac{1}{d} + \frac{1}{d'} = 1$*.*

Remark 4.1. We briefly describe these relations: $(\bar{\mu},\bar{\theta})$ are the multipliers associated with the state constraints; $\bar{\mu}$ corresponds to $y \geq 0$; and an immediate consequence of relation (4.10b) is the complementarity result $\bar{\mu} \leq 0$, $\langle \bar{\mu}, \bar{y} \rangle_{\overline{Q}} = 0$. $\bar{\theta}$ is associated to the (general) constraint $\Phi(y) \in \mathcal{C}$. $\bar{\lambda}$ is the multiplier associated to the integral constraint $\int_Q y(t,x)\ \xi(t,x)\ dx\ dt = 0$, and $\bar{q}$ is the classical adjoint state which takes into account the cost functional via $\bar{\nu}$.

Condition (4.10a) is a nontriviality condition. We must emphasize that we get (a priori) *nonqualified* optimality conditions. If $\bar{\nu} \neq 0$, the problem is qualified.

Remark 4.2. One may note that if $\bar{\xi} = 0$, then it could happen that $\bar{\nu} = \bar{\mu} = \bar{\theta} = 0$ and $\bar{\lambda} \neq 0$, so that $\bar{q} = 0$; therefore, the optimality system could appear to be useless. However, this is the case where the solution $(\bar{y},\bar{u})$ is the solution of a control problem governed by a classical semilinear parabolic equation, since we have

$\partial\bar y/\partial t + A\bar y + f(\bar y) = \bar u$ and the associated optimality systems are well known for this kind of problem. We refer for instance to [20].

Theorem 4.3 (Pontryagin principle for $(\mathcal{P})$). *If* (A1)–(A7) *are fulfilled and if* $(\bar y, \bar u)$ *is a solution of* $(\mathcal{P})$*, then there exists* $\bar q \in L^1(0,T;W_o^{1,1}(\Omega))$*,* $\bar\nu \in \mathbb{R}$*,* $\bar\lambda \in \mathbb{R}$*,* $(\bar\mu,\bar\theta) \in \mathcal{M}(\overline{Q}) \times \mathcal{M}(\overline{Q})$ *such that* (4.10a), (4.10b), (4.10d), *and* (4.10e) *hold. Moreover, we have*

(4.11a)

$$\begin{cases} -\dfrac{\partial \bar q}{\partial t} + A^*\bar q + f_y'(\bar y)\bar q = \bar\nu F_y'(x,t,\bar y,\bar u) + \bar\mu_{|Q} \\ \qquad +[\Phi'(\bar y)^*\bar\theta]_{|Q} + \bar\lambda\left(\dfrac{\partial \bar y}{\partial t} + A\bar y + f(\bar y) - \bar u\right) \quad \textit{in } Q, \\ \qquad \bar q = 0 \quad \textit{on } \Sigma, \qquad \bar q(T) = \bar\nu L_y'(x,\bar y(T)) + \bar\mu|_{\overline{\Omega}_T} + [\Phi'(\bar y)^*\bar\theta]|_{\overline{\Omega}_T} \quad \textit{in } \Omega, \end{cases}$$

$$\text{(4.11b)} \qquad \bar q(x,t)\left(\frac{\partial \bar y}{\partial t} + A\bar y + f(\bar y) - \bar u\right)(x,t) = 0 \quad \textit{a.e. } (x,t) \in Q.$$

Remark 4.3. Relation (4.11b) is a pointwise complementarity condition. Therefore, $\bar q$ may be viewed as a Lagrange multiplier associated with the pointwise constraint

$$\left(\frac{\partial y}{\partial t} + Ay + f(y) - u\right)(x,t) \geq 0.$$

Let us recall a regularity result for a weak solution of parabolic equation with measures as data, as follows.

Proposition 4.1. *Let* μ *be in* $\mathcal{M}_b(\overline{Q} \setminus (\overline{\Omega} \times \{0\} \cup \overline{\Sigma}))$ *and let* a *be in* $L^p(Q)$ *satisfying*

$$a \geq C_0, \quad \|a\|_{L^p(Q)} \leq M,$$

where $M > 0$*. Consider the equation*

$$\text{(4.12)} \quad -\frac{\partial q}{\partial t} + A^*q + aq = \mu_Q \quad \textit{in } Q, \qquad q = 0 \quad \textit{on } \Sigma, \qquad q(T) = \mu_{\overline{\Omega}_T} \quad \textit{on } \overline{\Omega},$$

where $\mu = \mu_Q + \mu_{\overline{\Omega}_T}$ *is a bounded Radon measure on* $\overline{Q} \setminus (\overline{\Omega} \times \{0\} \cup \overline{\Sigma})$*,* μ_Q *is the restriction of* μ *to* Q*, and* $\mu_{\overline{\Omega}_T}$ *is the restriction of* μ *to* $\overline{\Omega} \times \{T\}$*. Equation* (4.12) *admits a unique weak solution* $q \in L^1(0,T;W_o^{1,1}(\Omega))$*. For every* (δ, d) *satisfying* $d > 2$*,* $\delta > 2$*,* $\frac{n}{2d} + \frac{1}{\delta} < \frac{1}{2}$*,* $q \in L^{\delta'}(0,T;W_o^{1,d'}(\Omega))$*, and we have*

$$\|q\|_{L^{\delta'}(0,T;W_o^{1,d'}(\Omega))} \leq C_2 \|\mu\|_{\mathcal{M}_b(\overline{Q}\setminus(\overline{\Omega}\times\{0\}\cup\overline{\Sigma}))},$$

where $C_2 = C_2(T,\Omega,n,C_0,M,p,\delta,d)$ *is independent of* a*. Moreover, there exists a function* $q(0) \in L^1(\Omega)$ *such that*

$$\int_Q q\left\{\frac{\partial y}{\partial t} + Ay + ay\right\} dxdt = \langle y, \mu\rangle_b - \langle y(0), q(0)\rangle_{C(\overline{\Omega})\times\mathcal{M}(\overline{\Omega})}$$

for every $y \in Y = \{y \in W(0,T) \cap C(\overline{Q}) \mid \frac{\partial y}{\partial t} + Ay \in L^p(Q), y = 0 \textit{ in } \Sigma\}$*, where* $\langle\cdot,\cdot\rangle_b$ *denotes the duality product between* $C_b(\overline{Q} \setminus (\overline{\Omega} \times \{0\} \cup \overline{\Sigma}))$ *and* $\mathcal{M}_b(\overline{Q} \setminus (\overline{\Omega} \times \{0\} \cup \overline{\Sigma}))$*.*

($C_b(\overline{Q}\setminus(\overline{\Omega}\times\{0\}\cup\overline{\Sigma}))$ denotes the space of bounded continuous functions on $\overline{Q}\setminus(\overline{\Omega}\times\{0\}\cup\overline{\Sigma})$, while $\mathcal{M}_b(\overline{Q}\setminus(\overline{\Omega}\times\{0\}\cup\overline{\Sigma}))$ denotes the space of bounded Radon measures on $\overline{Q}\setminus(\overline{\Omega}\times\{0\}\cup\overline{\Sigma})$, that is, the topological dual of $C_o(\overline{Q}\setminus(\overline{\Omega}\times\{0\}\cup\overline{\Sigma}))$.)

Proof. The proof is the same as the one given in [19] for the Neumann boundary conditions (see also [7]). An easy adaptation of this proof yields the previous result. However, for the convenience of the reader we recall that q is the weak solution of (4.12) if and only if q belongs to $L^1(0,T;W_o^{1,1}(\Omega))$, $aq\in L^1(Q)$, and for every $\varphi\in C^1(\overline{Q})$ satisfying $\varphi(x,0)=0$ on $\overline{\Omega}$ and $\varphi(\cdot)=0$ on Σ we have

$$\int_Q\left\{q\frac{\partial\varphi}{\partial t}+\Sigma_{i,j}a_{ij}D_j\varphi D_iq+a\varphi q\right\}dx\,dt=\langle\varphi,\mu\rangle_b.$$

As in [7], we can prove that the weak solution q belongs to $L^{\delta'}(0,T;W_o^{1,d'}(\Omega))$ for every (δ,d) satisfying the condition

$$d>2,\quad \delta>2,\quad \frac{n}{2d}+\frac{1}{\delta}<\frac{1}{2}. \tag{4.13}$$

We remark that the set of pairs (δ,d) satisfying the above condition is nonempty. We remark also that if (δ,d) satisfies (4.13), if a belongs to $L^p(Q)$, and if q belongs to $L^{\delta'}(0,T;W_o^{1,d'}(\Omega))$, then $aq\in L^1(Q)$. Now, since $q\in L^{\delta'}(0,T;W_o^{1,d'}(\Omega))$ (where (δ,d) satisfies (4.24)), and since

$$\mathrm{div}_{xt}\left((\Sigma_j a_{ij}D_jq)_{1\le i\le n},q\right)=\frac{\partial q}{\partial t}-Aq \text{ belongs to } \mathcal{M}_b(Q),$$

then we can define the normal trace of the vector field $((\sum_j a_{ij}D_jq)_{1\le i\le n},q)$ in the space $W^{\frac{-1}{m},m}(\partial Q)$ (for some $1<m<\frac{n+1}{n}$). If we denote by $\gamma_o((\sum_j a_{ij}D_jq)_{1\le i\le n},q)$ this normal trace, we can prove (see Theorem 4.2 in [19]) that this normal trace belongs to $\mathcal{M}(\partial Q)$ and the restriction of $\gamma_o((\sum_j a_{ij}D_jq)_{1\le i\le n},q)$ to $\overline{\Omega}\times\{T\}$ is equal to $\mu_{\overline{\Omega}_T}$, and if $q(0)$ is the measure on $\overline{\Omega}$ which satisfies the Green formula of our Theorem 3.2, then $-q(0)$ is the restriction of $\gamma_o((\sum_j a_{ij}D_jq)_{1\le i\le n},q)$ to $\overline{\Omega}\times\{0\}$. In fact, it can be proved that $q(0)$ belongs to $L^1(\Omega)$ (see Theorem 4.3 in [19]). □

4.3. Proof of Theorems 4.2–4.3. First we assume that Theorem 4.2 is valid. As mentioned before, if $(\bar y,\bar u)$ is an optimal solution for $(\mathcal{P})$, then $(\bar y,\bar u,\bar\xi)$ is a solution for $(\widetilde{\mathcal{P}})$, where $\bar\xi=\frac{\partial\bar y}{\partial t}+A\bar y+f(\bar y)-\bar u\ \in L^p(Q)$. Thanks to Theorem 4.2, there exist $(\bar\nu,\bar\lambda,\bar\mu,\bar q)$ such that (4.10) holds. Replacing $\bar\xi$ by its value in (4.10c) obviously leads to (4.11a). Furthermore, relation (4.10f) implies

$$(\bar q(x,t)+\bar\lambda\bar y(x,t))\ (\bar\xi(x,t)-\xi)\le 0\quad\text{a.e. } (x,t)\in Q\ \forall\xi\in\mathbb{R}^+,$$

which gives

$$(\bar q(x,t)+\bar\lambda\bar y(x,t))\ \bar\xi(x,t)=0\quad\text{a.e. } (x,t)\in Q.$$

Since $\bar y(x,t)\,\bar\xi(x,t)=0$ a.e. in Q we obtain (4.11b). This concludes the proof of Theorem 4.3. □

It remains to show that Theorem 4.2 is valid. Note that Pontryagin's principle for a control problem with unbounded controls, with pointwise state constraints, and with state-control constraints in integral form already have been studied in [7]. For the convenience of the reader, we give the main ideas of the proof.

Step 1: *Metric space of controls.* In this paper we shall consider control problems for which the state constraints (4.6b) and the state-control integral constraints (4.6d) are penalized. These problems are constructed in such a way to make $(\bar y, \bar u, \bar\xi)$ an approximate solution. The idea is to apply the Ekeland variational principle next. For this we have to define a metric space of controls, endowed with the so-called Ekeland distance d, to make the mapping $(u,\xi) \longmapsto y_{u\xi}$ continuous from this metric space into $\mathcal{C}(\overline{Q})$. Thanks to Theorem 3.2, this continuity condition will be realized if convergence in the metric space of controls implies convergence in $L^p(Q) \times L^p(Q)$. Here, since we deal with (generally) unbounded controls, the convergence in $(U_{ad} \times V_{ad}, d)$ does not imply the convergence in $L^p(Q) \times L^p(Q)$ (see [14, p. 227]). To overcome this difficulty, as in [24, 20], we define a new metric as follows. For $0 < k < \infty$, we set

$$U_{ad}(\bar u, k) = \{u \in U_{ad} \mid |u(x,t) - \bar u(x,t)| \le k \quad \text{a.e. } (x,t) \in Q\},$$

$$V_{ad}(\bar \xi, k) = \{\xi \in V_{ad} \mid |\xi(x,t) - \bar \xi(x,t)| \le k \quad \text{a.e. } (x,t) \in Q\}.$$

We endow the control space with Ekeland's metric:

$$d((u_1,\xi_1),(u_2,\xi_2)) = \mathcal{L}^{n+1}(\{(x,t \mid u_1(x,t) \neq u_2(x,t)\}) + \mathcal{L}^{n+1}(\{(x,t) \mid \xi_1(x,t) \neq \xi_2(x,t)\}),$$

where $\mathcal{L}^{n+1}$ denotes the Lebesgue measure in $\mathbb{R}^{n+1}$. Then, as in [24, 20], we can prove the following lemma.

LEMMA 4.1. *$(U_{ad}(\bar u, k) \times V_{ad}(\bar\xi, k), d)$ is a complete metric space for the distance d, and the mapping which associates $(y_{u\xi}, J(y_{u\xi}, u))$ with (u,ξ) is continuous from $(U_{ad}(\bar u, k) \times V_{ad}(\bar\xi, k), d)$ into $\mathcal{C}(\overline{Q}) \times \mathbb{R}$.*

In [7], the authors have used another method to build the metric space of controls. This construction was adapted to the type of constraints they have considered.

Step 2: *Penalized problems.* Since $\mathcal{C}(\overline{Q})$ is separable, there exists a norm $|\cdot|_{\mathcal{C}(\overline{Q})}$, which is equivalent to the norm $\|\cdot\|_{\mathcal{C}(\overline{Q})}$ such that $(\mathcal{C}(\overline{Q}), |\cdot|_{\mathcal{C}(\overline{Q})})$ is strictly convex and $\mathcal{M}(\overline{Q})$, endowed with the dual norm of $|\cdot|_{\mathcal{C}(\overline{Q})}$ (denoted by $|\cdot|_{\mathcal{M}(\overline{Q})}$), also is strictly convex (see [11, Corollary 2, p. 148, or Corollary 2, p. 167]). Let $\mathbb{K}$ be a convex subset of $\mathcal{C}(\overline{Q})$. We define the distance function to $\mathbb{K}$ (for the new norm $|\cdot|_{\mathcal{C}(\overline{Q})}$) by

$$\delta_{\mathbb{K}}(\zeta) = \inf_{z \in \mathbb{K}} |\zeta - z|_{\mathcal{C}(\overline{Q})}.$$

Since $\mathbb{K}$ is convex, then $\delta_{\mathbb{K}}$ is convex and Lipschitz of rank 1, and we have

$$\limsup_{\substack{\rho \searrow 0, \\ \zeta' \to \zeta}} \frac{\delta_{\mathbb{K}}(\zeta' + \rho z) - \delta_{\mathbb{K}}(\zeta')}{\rho} = \max\{\langle \xi, z\rangle_{\overline{Q}} \mid \xi \in \partial\delta_{\mathbb{K}}(\zeta)\} \tag{4.14}$$

for every $\zeta, z \in \mathcal{C}(\overline{Q})$, where $\partial\delta_{\mathbb{K}}(\zeta)$ is the subdifferential of $\delta_{\mathbb{K}}$ at (ζ). Moreover, as $\mathbb{K}$ is a closed convex subset of $\mathcal{C}(\overline{Q})$ it is proved in [16, Lemma 3.4] that for every $\zeta \notin \mathbb{K}$, and every $\xi \in \partial\delta_{\mathbb{K}}(\zeta)$, $|\xi|_{\mathcal{M}(\overline{Q})} = 1$. Since $\partial\delta_{\mathbb{K}}(\zeta)$ is convex in $\mathcal{M}(\overline{Q})$ and $(\mathcal{M}(\overline{Q}), |\cdot|_{\mathcal{M}(\overline{Q})})$ is strictly convex, then if $\zeta \notin \mathbb{K}$, $\partial\delta_{\mathbb{K}}(\zeta)$ is a singleton and $\delta_{\mathbb{K}}$ is Gâteaux-differentiable at ζ. Let us notice that when $\mathbb{K} := \{z \in \mathcal{C}(\overline{Q}) \mid z \ge 0\}$, the distance function to $\mathbb{K}$ is given by $\delta_{\mathbb{K}}(\zeta) = |\zeta^-|_{\mathcal{C}(\overline{Q})}$, where $\zeta^- = \min(0,\zeta)$.
Endowing $\mathcal{C}(\overline{Q}) \times \mathcal{C}(\overline{Q})$ with the product norm we have similarly $\delta_{\widetilde{\mathcal{C}}}(\tilde\Phi(y))^2 = |y^-|^2_{\mathcal{C}(\overline{Q})} + \delta_{\mathcal{C}}(\Phi(y))^2$ ($\widetilde{\mathcal{C}}$ is defined by (4.7)). Let us consider the penalized functional

$$J_\varepsilon(y,u,\xi) = \left\{ \left[\left(J(y,u) - J(\bar y, \bar u) + \varepsilon^2\right)^+ \right]^2 + \delta_{\widetilde{\mathcal{C}}}(\tilde\Phi(y))^2 + \left(\int_Q y(x,t)\xi(x,t)\,dx\,dt \right)^2 \right\}^{\frac{1}{2}}.$$

With such a choice, for every $\varepsilon > 0$ and $k > 0$, $(\bar{y}, \bar{u}, \bar{\xi})$ is a ε^2-solution of the penalized problem

$$(\mathcal{P}_{k,\varepsilon}) \quad \inf\{J_\varepsilon(y,u,\xi) \mid y \in \mathcal{C}(\overline{Q}), (u,\xi) \in U_{ad}(\bar{u},k)\times V_{ad}(\bar{\xi},k),\ (y,u,\xi) \text{ satisfies } (4.6a)\},$$

i.e.,

$$\inf(\mathcal{P}_{k,\varepsilon}) \le J_\varepsilon(\bar{y},\bar{u},\bar{\xi}) \le \inf(\mathcal{P}_{k,\varepsilon}) + \varepsilon^2$$

(since $\inf(\mathcal{P}_{k,\varepsilon}) \ge 0$ and $J_\varepsilon(\bar{y},\bar{u},\bar{\xi}) = \varepsilon^2$).

For every $k > 0$, we choose $\varepsilon(k) = \varepsilon_k \le \frac{1}{k^{2p}}$ and we denote by $(\mathcal{P}_k)$ the penalized problem $(\mathcal{P}_{k,\varepsilon_k})$. Thanks to Ekeland's principle [13, p. 30], for every $k \ge 1$ there exists $(u_k, \xi_k) \in U_{ad}(\bar{u},k) \times V_{ad}(\bar{\xi},k)$ such that

$$d((u_k,\xi_k),(\bar{u},\bar{\xi})) \le \varepsilon_k \le \frac{1}{k^{2p}}, \tag{4.15a}$$

$$J_{\varepsilon_k}(y_k,u_k,\xi_k) \le J_{\varepsilon_k}(y_{u\xi},u,\xi) + \varepsilon_k\ d((u_k,\xi_k),(u,\xi)) \tag{4.15b}$$

for every $(u,\xi) \in U_{ad}(\bar{u},k) \times V_{ad}(\bar{\xi},k)$ (y_k and $y_{u\xi}$ being the states corresponding respectively to (u_k,ξ_k) and (u,ξ)). In view of the definition of ε_k, we have $\lim_k \|u_k - \bar{u}\|_{p,Q} = \lim_k \|\xi_k - \bar{\xi}\|_{p,Q} = 0$. Indeed, $\mathcal{L}^{n+1}(\{(x,t) \mid u_k(x,t) \ne \bar{u}(x,t)\}) + \mathcal{L}^{n+1}(\{(x,t) \mid \xi_k(x,t) \ne \bar{\xi}(x,t)\}) \le \frac{1}{k^{2p}}$, and $|u_k(x,t) - \bar{u}(x,t)| \le k$, $|\xi_k(x,t) - \bar{\xi}(x,t)| \le k$ a.e. on Q. Thus $\|u_k - \bar{u}\|_{p,Q} \le \frac{1}{k}$, $\|\xi_k - \bar{\xi}\|_{p,Q} \le \frac{1}{k}$.

To exploit the approximate optimality conditions (4.15), we introduce a particular perturbation of (u_k,ξ_k).

Step 3: *Diffuse perturbations.* For fixed (u_o,ξ_o) in $U_{ad} \times V_{ad}$, we denote by (u_{ok},ξ_{ok}) $(k > 0)$ the pair of functions in $U_{ad}(\bar{u},k) \times V_{ad}(\bar{\xi},k)$ defined by

$$u_{ok}(x,t) = \begin{cases} u_o(x,t) & \text{if } |u_o(x,t) - \bar{u}(x,t)| \le k, \\ \bar{u}(x,t) & \text{if not,} \end{cases} \tag{4.16a}$$

$$\xi_{ok}(x,t) = \begin{cases} \xi_o(x,t) & \text{if } |\xi_o(x,t) - \bar{\xi}(x,t)| \le k, \\ \bar{\xi}(x,t) & \text{if not.} \end{cases} \tag{4.16b}$$

Observe that for every $k \ge 1$, (u_{ok},ξ_{ok}) belongs to $U_{ad}(\bar{u},k) \times V_{ad}(\bar{\xi},k)$, and that $(u_{ok},\xi_{ok})_k$ converges to (u_o,ξ_o) in $L^p(Q) \times L^p(Q)$. Applying Theorem 4.1 of [7] (see also [24, 21] for more details), we deduce the existence of measurable sets E^k_ρ with $\mathcal{L}^{n+1}(E^k_\rho) = \rho\mathcal{L}^{n+1}(Q)$, such that if we denote by (u^ρ_k,ξ^ρ_k) the pair of controls defined by

(4.17)
$$u^\rho_k(x,t) = \begin{cases} u_k(x,t) & \text{on } Q \setminus E^k_\rho, \\ u_{ok}(x,t) & \text{on } E^k_\rho, \end{cases} \qquad \xi^\rho_k(x,t) = \begin{cases} \xi_k(x,t) & \text{on } Q \setminus E^k_\rho, \\ \xi_{ok}(x,t) & \text{on } E^k_\rho \end{cases}$$

and if y^ρ_k is the state corresponding to (u^ρ_k,ξ^ρ_k), then we have

$$y^\rho_k = y_k + \rho z_k + r^\rho_k, \qquad \lim_{\rho\to 0} \frac{1}{\rho}|r^\rho_k|_{\mathcal{C}(\overline{Q})} = 0, \tag{4.18a}$$

$$J(y^\rho_k,u^\rho_k) = J(y_k,u_k) + \rho\Delta_k J + o(\rho), \tag{4.18b}$$

$$\int_Q y_k^\rho \xi_k^\rho \, dx\ dt = \int_Q y_k \xi_k \, dx\ dt + \rho \int_Q \left[z_k \xi_k + y_k(\xi_{ok} - \xi_k) \right] \, dx\ dt + o(\rho), \tag{4.18c}$$

where z_k is the weak solution of

$$\frac{\partial z_k}{\partial t} + A z_k + f'_y(y_k) z_k = u_k - u_{ok} + \xi_k - \xi_{ok} \quad \text{in } Q, \qquad z_k = 0 \quad \text{on } \Sigma, \qquad z_k(0) = 0 \quad \text{in } \Omega,$$

and

$$\Delta_k J = \int_Q \Big[F'_y(x,t,y_k,u) z_k + F(x,t,y_k,u_{ok}) - F(x,t,y_k,u_k) \Big] \, dx\ dt + \int_\Omega L'_y(x, y_k(T)) z_k(T) \, dx.$$

Setting $(u, \xi) = (u_k^\rho, \xi_k^\rho)$ in (4.15b), it follows that

$$\limsup_{\rho \to 0} \frac{J_{\varepsilon_k}(y_k, u_k, \xi_k) - J_{\varepsilon_k}(y_k^\rho, u_k^\rho, \xi_k^\rho)}{\rho} \le \varepsilon_k \mathcal{L}^{n+1}(Q). \tag{4.19}$$

Taking (4.18) and the definition of J_{ε_k} into account, we get

(4.20)
$$-\nu_k \Delta_k J - \langle \mu_k, z_k \rangle_{\overline{Q}} - \langle \theta_k, \Phi'(y_k) z_k \rangle_{\overline{Q}} - \lambda_k \Big[\langle \xi_k, z_k \rangle_{\overline{Q}} + \langle y_k, \xi_{ok} - \xi_k \rangle_{\overline{Q}} \Big] \le \varepsilon_k \mathcal{L}^{n+1}(Q),$$

where

$$\nu_k = \frac{(J(y_k,u_k) - J(\bar y, \bar u) + \varepsilon_k^2)^+}{J_{\varepsilon_k}(y_k,u_k,\xi_k)}, \lambda_k = \frac{\left(\displaystyle\int_Q y_k(x,t) \xi_k(x,t) \, dx\ dt \right)}{J_{\varepsilon_k}(y_k,u_k,\xi_k)},$$

$$\mu_k = \begin{cases} \dfrac{|y_k^-|_{\mathcal{C}(\overline{Q})} \nabla |y_k^-|_{\mathcal{C}(\overline{Q})}}{J_{\varepsilon_k}(y_k,u_k,\xi_k)} & \text{if } |y_k^-|_{\mathcal{C}(\overline{Q})} \neq 0, \\ 0 & \text{otherwise,} \end{cases}$$

$$\theta_k = \begin{cases} \dfrac{\delta_{\mathcal{C}}(\Phi(y_k) \nabla \delta_{\mathcal{C}}(\Phi(y_k))}{J_{\varepsilon_k}(y_k,u_k,\xi_k)} & \text{if } \delta_{\mathcal{C}}(\Phi(y_k)) \neq 0, \\ 0 & \text{otherwise.} \end{cases}$$

For every $k > 0$, we consider the weak solution q_k of

(4.21)
$$\begin{cases} -\dfrac{\partial q_k}{\partial t} + A^* q_k + f'_y(y_k) q_k = \nu_k F'_y(x,t,y_k,u_k) + \mu_k|_Q + [\Phi'(y_k)^* \theta_k]|_Q + \lambda_k \xi_k \quad \text{in } Q, \\ \quad q_k = 0 \quad \text{on } \Sigma, \qquad q_k(T) = \nu_k L'_y(x, y_k(T)) + [\Phi'(y_k)^* \theta_k]|_{\overline{\Omega}_T} + \mu_k|_{\overline{\Omega}_T} \quad \text{in } \Omega, \end{cases}$$

where $\mu_k|_Q$ (resp., $[\Phi'(y_k)^*\theta_k]|_Q$) is the restriction of μ_k (resp., $[\Phi'(y_k)^*\theta_k]$) to Q, and $\mu_k|_{\overline{\Omega}_T}$ (resp., $[\Phi'(y_k)^*\theta_k]|_{\overline{\Omega}_T}$) is the restriction of μ_k (resp., $[\Phi'(y_k)^*\theta_k]$) to $\overline{\Omega} \times \{T\}$. By using the Green formula of Proposition 4.1 with z_k, we obtain

$$\int_Q \nu_k F'_y(x,t,y_k,u_k) z_k \, dx \, dt + \lambda_k \int_Q z_k(x,t) \xi_k(x,t) \, dx \, dt + \int_\Omega \nu_k L'_y(x, y_k(T)) z_k(T) \, dx$$
$$+ \langle \mu_k, z_k \rangle_{\overline{Q}} + \langle \theta_k, \Phi'(y_k) z_k \rangle_{\overline{Q}} = \int_Q q_k \left(u_{ok} - u_k + \xi_{ok} - \xi_k \right) \, dx \, dt.$$

With this equality, (4.20), and the definition of $\Delta_k J$, we get

$$\begin{aligned}&\int_Q [\nu_k F(x,t,y_k,u_k) + q_k u_k + q_k \xi_k + \lambda_k y_k \xi_k]\, ds\ dt\\ &\qquad \le \int_Q [\nu_k F(s,t,y_k,u_{ok}) + q_k u_{ok} + q_k \xi_{ok} + \lambda_k y_k \xi_{ok}]\, ds\, dt + \frac{1}{k^{2p}} \mathcal{L}^{n+1}(Q)\end{aligned} \tag{4.22}$$

for every $k > 0$ and every $(u_o, \xi_o) \in U_{ad} \times V_{ad}$ (where (u_{ok}, ξ_{ok}) is defined with respect to (u_o, ξ_o)).

Step 4. *Convergence of sequence $(\nu_k, \lambda_k, \mu_k, \theta_k, q_k)_k$; Pontryagin principle.* Observing that $\nu_k^2 + \lambda_k^2 + |\mu_k|^2_{\mathcal{M}(\overline{Q})} + |\theta_k|^2_{\mathcal{M}(\overline{Q})} = 1$, there exist $(\bar\nu, \bar\lambda, \bar\mu, \bar\theta) \in \mathbb{R}^+ \times \mathbb{R}^+ \times \mathcal{M}(\overline{Q}) \times \mathcal{M}(\overline{Q})$ and a subsequence, still denoted by $(\nu_k, \lambda_k, \mu_k, \theta_k)_k$, such that

$$\nu_k \to \bar\nu, \quad \lambda_k \to \bar\lambda, \quad \mu_k \rightharpoonup \bar\mu \text{ and } \ \theta_k \rightharpoonup \bar\theta \ \text{ weak}^* \text{ in } \mathcal{M}(\overline{Q}).$$

With the same arguments as in [21, Section 6.2, Step 4], we prove that $(q_k)_k$, or at least a subsequence of $(q_k)_k$, weakly converges to $\bar q$ in $L^{\delta'}(0,T; W_0^{1,d'}(\Omega))$ for every (δ, d) such that $\frac{n}{2d} + \frac{1}{\delta} < \frac{1}{2}$. Recall that $(u_k, \xi_k)_k$ converges to $(\bar u, \bar\xi)$ in $L^p(Q) \times L^p(Q)$. Hence y_k also converges to $\bar y$. Passing to the limit when k tends to infinity in (4.22) gives

$$\int_Q \big[H_1(x,t,\bar y, \bar u, \bar q, \bar\nu) + H_2(\bar y, \bar\xi, \bar q, \bar\lambda)\big]\, dx\ dt \le \int_Q \big[H_1(x,t,\bar y, u, \bar q, \bar\nu) + H_2(\bar y, \xi, \bar q, \bar\lambda)\big]\, dx\ dt$$

for every $(u, \xi) \in U_{ad} \times V_{ad}$. This inequality is equivalent to

$$\begin{aligned}&\int_Q H_1(x,t,\bar y(x,t), \bar u(x,t), \bar q(x,t), \bar\nu)\, dx\, dt\\ &\qquad = \min_{u \in U_{ad}} \int_Q H_1(x,t,\bar y(x,t), u(x,t), \bar q(x,t), \bar\nu)\, dx\, dt\end{aligned} \tag{4.23a}$$

$$\int_Q H_2(\bar y(x,t), \bar\xi(x,t), \bar q(x,t), \bar\lambda)\, dx\ dt = \min_{\xi \in V_{ad}} \int_Q H_2(\bar y(x,t), \xi(x,t), \bar q(x,t), \bar\lambda)\, dx\ dt. \tag{4.23b}$$

Now, by using Lebesgue's points argument (see [21, 24]), we obtain (4.10e) and (4.10f). On the other hand, it is clear that $\bar\nu \ge 0$. Moreover, from the definitions of μ_k and θ_k, we deduce

$$\langle \mu_k, z - y_k\rangle_{\overline{Q}} \le 0 \ \ \forall z \in \{z \in \mathcal{C}(\overline{Q}) \mid z \ge 0\} \quad \text{and } \langle \theta_k, z - \Phi(y_k)\rangle_{\overline{Q}} \le 0 \ \ \forall z \in \mathcal{C}. \tag{4.24}$$

When k tends to infinity, we obtain (4.10b) and a part of (4.10a). It remains to prove that $(\bar\nu, \bar\lambda, \bar\mu, \bar\theta)$ is nonzero; for this, we recall that $\nu_k^2 + \lambda_k^2 + |\mu_k|^2_{\mathcal{M}(\overline{Q})} + |\theta_k|^2_{\mathcal{M}(\overline{Q})} = 1$.

If $(\bar\nu, \bar\lambda) \neq 0$, then the proof is complete. If not, we can prove that $|\bar\mu|_{\mathcal{M}(\overline{Q})} + |\bar\theta|_{\mathcal{M}(\overline{Q})} > 0$.

First we recall that $\mathcal{C}$ has a finite codimension in $\mathcal{C}(\overline{Q})$ and that $\{z \in \mathcal{C}(\overline{Q}) \mid z \geq 0\}$ is a subset of $\mathcal{C}(\overline{Q})$ with a nonempty interior. Then $\widetilde{\mathcal{C}}$ is a subset of $\mathcal{C}(\overline{Q}) \times \mathcal{C}(\overline{Q})$ with a finite codimension. Moreover, from (4.24) we deduce that for every $(z_1, z_2) \in \widetilde{\mathcal{C}}$

$$\begin{aligned}\langle \mu_k, z_2 - \bar{y}\rangle_{\overline{Q}} + \langle \theta_k, z_1 - \Phi(\bar{y})\rangle_{\overline{Q}} &\leq \langle \mu_k, y_k - \bar{y}\rangle_{\overline{Q}} \\ +\langle \theta_k, \Phi(y_k) - \Phi(\bar{y})\rangle_{\overline{Q}} &\leq |y_k - \bar{y}|_{\mathcal{C}(\overline{Q})} + |\Phi(y_k) - \Phi(\bar{y})|_{\mathcal{C}(\overline{Q})}.\end{aligned}$$

The last right-hand side quantity tends to 0 as $k \to +\infty$. With this estimate and using $\lim_k |\mu_k|_{\mathcal{M}(\overline{Q})} + \lim_k |\theta_k|_{\mathcal{M}(\overline{Q})} = 1$, thanks to Lemma 3.6 of [16], we conclude that $(\bar{\mu}, \bar{\theta}) \neq 0$ when $(\bar{\nu}, \bar{\lambda}) = 0$. □

5. Examples. Let us consider the following optimal control problem where the cost functional is defined by

$$J(y, u) = \int_0^T [g(t, y(t)) + h(u(t))]\, dt + \psi(y(T)), \tag{5.1}$$

where

(A5*) the function $h : L^2(\Omega) \to \mathbb{R} \cup \{+\infty\}$ is convex and lower semicontinuous and there exist $c_1 > 0,\ c_2 \in \mathbb{R}$ such that

$$\forall u \in L^2(\Omega) \qquad h(u) \geq c_1 |u|^2_{L^2(\Omega)} - c_2, \tag{5.2}$$

(A6*) the function $g : [0, T] \times L^2(\Omega) \to \mathbb{R} \cup \{+\infty\}$ is measurable in t, $g(.,0) \in L^1(0, T)$, and for every $r > 0$ there exists $\gamma_r > 0$ independent of t such that

$$\begin{gathered}\forall t \in [0, T] \qquad |y|_{L^2(\Omega)} + |z|_{L^2(\Omega)} \leq r, \\ |g(t, y) - g(t, z)| + |\psi(y) - \psi(z)| \leq \gamma_r |y - z|_{L^2(\Omega)}.\end{gathered} \tag{5.3}$$

Conditions on g and ψ could be weakened. For more details one can refer to Barbu [2, p. 317].

Now we consider

$$(\mathcal{P}) \qquad \begin{cases}\text{Minimize } J(y(y_o, u), u), \\ u \in U_{ad}, \\ y(y_o, u) \text{ is the solution of (4.3),}\end{cases}$$

where U_{ad} is a nonempty, convex subset of $L^p(Q)$, closed for the $L^2(Q)$-topology, and p is an integer such that $n < p$. Although we are especially interested in optimality conditions for solutions of problem $(\mathcal{P})$, we give an existence result in the following theorem.

THEOREM 5.1. *For any $y_o \in K_o$ (defined by* (4.1)*), problem* $(\mathcal{P})$ *has at least one solution u. Moreover, the corresponding state belongs to $\mathcal{C}(\overline{Q}) \cap W^{2,1,p}(Q)$.*

Proof. One can find this result in Barbu [2, Proposition 1.1., p. 319] when $U_{ad} = L^2(Q)$. This is easily adapted to the case where U_{ad} is a closed convex subset of $L^2(Q)$. A priori estimations do not change so that we get the "suitable" convergence in the "suitable" spaces. The only modification concerns the cluster points of the control sequences. Because U_{ad} is convex and closed for the $L^2(Q)$-topology these points belong to U_{ad}. Because $U_{ad} \subset L^p(Q)$, we can use regularity results of Theorem 4.1. □

Remark 5.1. The assumption that U_{ad} has to be a convex subset of $L^p(Q)$ (for some $p > n$) closed for the $L^2(Q)$-topology may be difficult to ensure: for example

$U_{ad} = L^p(Q)$ is not suitable. However, we give more precise example sets U_{ad} in what follows. Let us refine the example. We set

$$J(y,u) = \frac{1}{2}\int_\Omega (y(x,T) - z_d(x))^2\,dx + \frac{N}{2}\int_Q u(x,t)^2\,dx\,dt \tag{5.4}$$

(with $N > 0$) so that with the previous notations we get

$$F(x,t,y,u) = \frac{N}{2}\,u^2,\ h(u(t)) = \frac{N}{2}\|u(t)\|^2_{L^2(\Omega)},$$
$$L(x,y) = \frac{1}{2}(y - z_d(x))^2,\ g(t,y(t)) \equiv 0,\ \psi(y(T)) = \frac{1}{2}\|y(T) - z_d\|^2_{L^2(\Omega)}.$$

It is easy to see that both (A5*) and (A6*) are fulfilled for such a choice of $h,\ g,\ \psi$. Therefore the optimal control problem

$$(\mathcal{P}_2)\qquad \begin{cases} \min\ J(y,u), \\ \dfrac{\partial y}{\partial t} + Ay + f(y) \geq u \ \text{ in } Q, \quad y = 0 \text{ on } \Sigma, \quad y(0) = y_o \text{ in } \Omega, \\ u \in U_{ad}, \\ y(x,t) \geq 0\ \forall (x,t) \in \overline{Q}, \end{cases}$$

where $y_o \in W^{1,p}_o(\Omega), y_o \geq 0,\ z_d \in L^2(\Omega)$, and U_{ad} is a nonempty, convex subset of $L^p(Q)$ closed for the $L^2(Q)$-topology, has an optimal solution.

We always assume, of course, that (A1) and (A2) are valid (one may choose $A = -\Delta$ for instance, where Δ is the Laplacian operator); we have already seen that (A3) and (A4) are fulfilled with the special choice of φ and y_o. It is also easy to see that (A5) and (A6) are ensured with F and L defined as above. Thus we may give optimality conditions for $(\mathcal{P}_2)$, as follows.

THEOREM 5.2. *Assume* (A1) *and* (A2) *are valid. Then problem* $(\mathcal{P}_2)$ *has an optimal solution* $(\bar y, \bar u) \in [W^{2,1,p}(Q) \cap \mathcal{C}(\overline{Q})] \times L^p(Q)$. *Moreover, there exist* $(\bar\nu, \bar\lambda, \bar\mu, \bar q) \in \mathbb{R} \times \mathbb{R} \times \mathcal{M}(\overline{Q}) \times L^1(0,T; W^{1,1}_o(\Omega))$ *such that the following optimality system holds:*

$$(\bar\nu, \bar\lambda, \bar\mu) \neq 0, \quad \bar\nu \geq 0, \tag{5.5a}$$

$$\forall z \in \{ z \in \mathcal{C}(\overline{Q}) \mid z \geq 0 \},\ \ \langle \bar\mu, z - \bar y\rangle_{\overline{Q}} \leq 0, \tag{5.5b}$$

$$\begin{cases} \dfrac{\partial \bar y}{\partial t} + A\bar y + f(\bar y) = \bar u + \bar\xi \quad \text{in } Q, \\ \bar y = 0 \quad \text{on } \Sigma, \qquad \bar y(0) = y_o \quad \text{in } \Omega, \end{cases} \tag{5.5c}$$

$$\bar y \geq 0,\ \bar\xi \in V_{ad},\ \bar u \in U_{ad}, \int_\Omega \bar y(t)\ \bar\xi(t)\ dx = 0 \quad \text{a.e. on } [0,T], \tag{5.5d}$$

$$\begin{cases} -\dfrac{\partial \bar q}{\partial t} + A^*\bar q + f'(\bar y)\bar q = \bar\mu_{|Q} + \bar\lambda\ \bar\xi \quad \text{in } Q, \\ \bar q = 0 \quad \text{on } \Sigma, \qquad \bar q(T) = \bar\nu[\bar y(T) - z_d] + \bar\mu_{|\overline{\Omega}_T} \quad \text{in } \Omega, \end{cases} \tag{5.5e}$$

$$([(\bar\nu N\bar u + \bar q)(u - \bar u)](x,t)) \le 0 \quad \forall\, u \in U_{ad}, \quad \textit{and a.e. } (x,t) \in Q, \tag{5.5f}$$

$$\bar q(x,t)\ \bar\xi(x,t) = 0 \quad \textit{a.e. } (x,t) \in Q, \tag{5.5g}$$

where $\bar\xi = \dfrac{\partial \bar y}{\partial t} + A\bar y + f(\bar y) - \bar u$.

Proof. This is a direct consequence of Theorem 4.2 where $\Phi = Id$ and $\mathcal{C}$ is the whole space. Considering the Hamiltonian functions and relations (4.10e) and (4.10f) give (5.5e) and (5.5f) immediately. □

We end this section with two examples for U_{ad}.

5.1. Case where U_{ad} is bounded in $L^\infty(Q)$.

Let us set

$$U_{ad} = \{\ u \in L^\infty(Q) \mid a(x,t) \le u(x,t) \le b(x,t) \ \text{ in } Q\ \},$$

where $a, b \in L^\infty(Q)$. U_{ad} is of course a convex subset of $L^p(Q)$ for any $p > n$. Moreover, we get the following lemma.

LEMMA 5.1. *U_{ad} is closed for the $L^2(Q)$-topology.*

Proof. Let $u_n \in U_{ad}$ converging to u in $L^2(Q)$. Then $u_n(x,t)$ converges to $u(x,t)$ a.e. in Q so that we get $a(x,t) \le u(x,t) \le b(x,t)$ a.e. in Q. Thus $u \in L^\infty(Q)$. It is clear that $u \in U_{ad}$. □

Therefore, in view of Remark 5.1, we get the result stated in the next theorem for $y_o = 0$ and

$$J(y,u) = \frac{1}{2}\int_\Omega (y(x,T) - z_d(x))^2\, dx + \frac{N}{2}\int_Q u^2(x,t)\, dx\ dt.$$

THEOREM 5.3. *Assume* (A1) *and* (A2) *are valid. Then problem* ($\mathcal{P}_2$) *has an optimal solution* $(\bar y, \bar u) \in [W^{2,1,p}(Q) \cap \mathcal{C}(\overline{Q})] \times L^p(Q)$ *for any* $p > n$. *Moreover there exists* $(\bar\nu, \bar\lambda, \bar\mu, \bar q) \in \mathbb{R} \times \mathbb{R} \times \mathcal{M}(\overline{Q}) \times L^1(0,T; W_o^{1,1}(\Omega))$ *such that* (5.5a)–(5.5d) *and* (5.5g) *hold with*

$$\begin{cases} -\dfrac{\partial \bar q}{\partial t} + A^*\bar q + f'(\bar y)\bar q = \bar\mu_{|Q} + \bar\lambda\ \bar\xi \quad \textit{in } Q, \\ \bar q = 0 \quad \textit{on } \Sigma, \qquad \bar q(T) = \bar\nu[\bar y(T) - z_d] + \bar\mu_{|\overline{\Omega}_T} \quad \textit{in } \Omega, \end{cases} \tag{5.6}$$

$$[(\bar\nu N\bar u + \bar q)(u - \bar u)](x,t) \le 0 \quad \forall\, u \in U_{ad} \quad \textit{and a.e. } (x,t) \in Q. \tag{5.7}$$

5.2. Case where $U_{ad} = \{u \in L^p(Q) \mid u(x,t) \ge 0$ a.e. in $Q\}$.

When $U_{ad} = \{u \in L^p(Q) \mid u(x,t) \ge 0$ a.e. in $Q\}$ and $y_o \ge 0$ in Ω, thanks to the maximum principle for parabolic equations, the constraint $y \ge 0$ is automatically fulfilled in (4.6b) so that the corresponding multiplier $\bar\mu$ is equal to 0 (or at least does not appear). Therefore the corresponding Pontryagin optimality system consists of (5.5a) and (5.5c)–(5.5g), where (5.5e) is replaced by

$$\begin{cases} -\dfrac{\partial \bar q}{\partial t} + A^*\bar q + f'(\bar y)\bar q = \bar\lambda\ \bar\xi \quad \text{in } Q, \\ \bar q = 0 \quad \text{on } \Sigma, \qquad \bar q(T) = \bar\nu[\bar y(T) - z_d] \quad \text{in } \Omega. \end{cases} \tag{5.8}$$

This implies in particular that $\bar q \in W^{2,1,p}(Q) \cap \mathcal{C}(\overline{Q})$.

For this simple example we can see that the optimality conditions (5.2) are not trivial because we cannot have $\bar\nu = \bar\lambda = 0$.

6. Conclusion. The optimality conditions we have obtained are given in a nonqualified form. So far it is difficult to compare precisely these results with those already existing, since they usually are in a qualified form [6, 5, 17] or they concern elliptic variational inequalities. Nevertheless we must emphasize that in this paper we obtain interesting informations about optimal solutions (at least in simple cases). Indeed, we have seen in Example 5 that (5.5e) provides precise information on the structure of the multipliers $\bar{\mu} + \bar{\xi}\ \bar{\lambda}$ for the distributed multiplier, for instance, and the adjoint state $\bar{q}$: the regular part of this adjoint state belongs to $\mathcal{C}(\overline{Q})$ while the nonsmooth part belongs to $L^1(0,T;W_o^{1,1}(\Omega))$. This information seems new, compared with that in Barbu [2, Section 5.1.4, p. 331], for example.

The method developed in [5, 23] for elliptic variational inequalities is still true for the parabolic case, but we think that this method does not allow the condition (4.11b) to be obtained. However, in [23, 5] the authors give a qualification assumption under which they can derive Pontryagin's principle in qualified form.

Since we now can preview the generic form of the Lagrange multipliers, we can check optimal control problems where the variational inequality is more general than the obstacle type or occurs on the boundary, with boundary control.

RELAXATION OF CONTROL SYSTEMS UNDER STATE CONSTRAINTS*

HÉLÈNE FRANKOWSKA† AND FRANCO RAMPAZZO‡

Abstract. In this paper we provide a relaxation result for control systems under both equality and inequality constraints involving the state and the control. In particular, we show that the Mangasarian–Fromowitz constraint qualification allows us to rewrite constrained systems as differential inclusions with locally Lipschitz right-hand side. Then the Filippov–Ważewski relaxation theorem may be applied to show that ordinary solutions are dense in the set of relaxed solutions. If, besides agreeing with the above constraints, the state has to remain in a control-independent set K, then the Mangasarian–Fromowitz condition cannot hold. This case is investigated as well by means of a condition on the feasible velocities on the boundary of K.

Key words. control under state constraints, differential inclusion, relaxation

1. Introduction.

Let us consider a control system of the form

$$x'(t) = f(t, x(t), u(t)), \quad u(t) \in U, \tag{1}$$

where the time parameter t belongs to an interval $[t_0, T]$, the state x takes values in $\mathbf{R}^n$, U (the *control set*) is a subset of a complete separable metric space $\mathcal{Z}$, and the function f maps $[t_0, T] \times \mathbf{R}^n \times \mathcal{Z}$ into $\mathbf{R}^n$. The trajectory-control pairs are subject to the constraints

$$h(t, x(t), u(t)) \leq 0, \quad g(t, x(t), u(t)) = 0 \quad \text{almost everywhere (a.e.) in } [t_0, T], \tag{2}$$

where

$$h = (h_1, \dots, h_m) : [t_0, T] \times \mathbf{R}^n \times \mathcal{Z} \mapsto \mathbf{R}^m \quad \text{and} \quad g : [t_0, T] \times \mathbf{R}^n \times \mathcal{Z} \mapsto \mathbf{R}^p.$$

In this paper we study the closure of the solution set of the control system (1) under state constraints (2). A classical way to investigate this problem relies on the study of the feedback set-valued map

$$G(t, x) \; = \; \{u \in U \mid h(t, x, u) \leq 0, \;\; g(t, x, u) = 0\}$$

(see, for instance, [6, 7]). In fact, observe that a trajectory-control pair (x, u) solves (1), (2) if and only if

$$u(t) \in G(t, x(t)) \quad \text{a.e in } [t_0, T].$$

More generally, one can consider a set-valued map $G : [t_0, T] \times \mathbf{R}^n \mapsto U$ and the control system

$$\begin{cases} x'(t) = f(t, x(t), u(t)), \quad u(t) \in G(t, x(t)), \quad t \in [t_0, T], \\ x(t_0) = x_0. \end{cases} \tag{3}$$

In several dynamic optimization problems it is interesting to answer the following two questions:

$\mathcal{Q}1$. *Is the set of solutions to the system* (3) (in particular, to (1), (2)) *precompact in the space of continuous functions?*

$\mathcal{Q}2$. *What is its closure?*

While the answer to the first question comes from functional analysis (via a standard application of the Ascoli theorem), the answer to the second one can be provided in different ways. One can use for instance *generalized curves*, which were introduced within the context of calculus of variations by L. C. Young and extended to control systems by J. Warga [22] and E. J. McShane [16] (see also [23] and references therein). Generalized curves are defined as the trajectories corresponding to *relaxed controls.* To be more precise, let f satisfy some standard regularity assumptions (see section 3), and let $\mathcal{M}(U)$ denote the set of probability measures on U. $\mathcal{M}(U)$ can be regarded as a subset of $C(U)^*$, the dual of the space $C(U)$ of continuous real functions defined on U. Define the space of admissible relaxed controls as

$$\widehat{\mathcal{U}}^{adm}(t_0,T) = \{\mu \in L^\infty([t_0,T];\mathcal{M}(U)) | \text{ for a.e. } t \in [t_0,T],\ \operatorname{supp}(\mu_t) \subset G(t,x(t))\},$$

where $\operatorname{supp}(\mu_t)$ denotes the support of $\mu(t,\cdot)$, and $x(\cdot)$ is the unique continuous solution to the integral equation

$$x(t) = x(t_0) + \int_{t_0}^{t}\int_U f(s,x(s),u)\mu(s,du)ds.$$

It turns out that such a solution is absolutely continuous. It is called a *generalized curve* of (3). Under standard assumptions, if a sequence $x_n(\cdot)$ of solutions to (3) converges uniformly to some $x(\cdot)$, then $x(\cdot)$ is a generalized curve.

The second approach goes back to papers by L. Cesari [8], A. Lasota and C. Olech [14], and C. Olech [18] (see also the bibliography of [7] and [6]). It relies on Mazur's theorem and uses the convex hull of the right-hand side of (3). Absolutely continuous functions satisfying

$$x'(t) \in \overline{co}\, f(t,x(t),G(t,x(t))) \quad \text{a.e. in } [t_0,T]$$

are called *relaxed solutions of* (3). The above system is the relaxed (convexified) differential inclusion corresponding to (3) (of course, the meanings given here to expressions like *relaxed control*, *generalized curve*, and *relaxed solutions* are purely conventional). It is well known that under standard hypotheses the uniform limit of solutions to (3) is a relaxed trajectory. Actually, under general assumptions the set of generalized curves coincides with the set of relaxed trajectories (see also Theorem 3.4 below). Therefore the set of relaxed curves (or, equivalently, of generalized curves) contains the closure of the solutions to (3). In order to complete the answer to question $\mathcal{Q}2$, one has to solve the following problem:

$\mathcal{Q}3$. *Can we approximate every relaxed solution by "ordinary" trajectories of the control system* (3)*?*

A general answer to this question is contained in the celebrated Filippov–Ważewski theorem, in the framework of differential inclusions. For control systems, a partial answer is given, e.g., in [6, 7], where only the case when the set-valued map $G(\cdot,\cdot)$ is independent of the state is investigated.

E. N. Barron and J. Jensen have recently published a paper [5] concerning a related question. They studied the Mayer problem

$$\text{minimize } \psi(x(T))$$

over solutions to the constrained system (1), (2) satisfying $x(t_0) = x_0$ in the case when $g = 0$ (i.e., only inequality constraints are present). They were looking for an enlarged class of trajectories that should be considered in order for the above control problem to have a solution, and the infimum of the original problem was the same as the minimum of the relaxed problem. Let us remark that an answer to this problem does not necessarily imply a positive answer to question $\mathcal{Q}3$ (while, by virtue of the continuity of the map $x(\cdot) \mapsto \psi(x(T))$ the converse implication holds true), the latter being outside the declared goal of [5]. Actually our aim is to introduce a *strong extension* of the problem (see [21]), while the objective in [5] is to obtain a *weak extension* (see [9]). Incidentally, since our hypotheses are more general than those assumed in [5], our results show that the extension provided by E. N. Barron and J. Jensen is in fact strong. Under a rank condition recalled below and some technical assumptions, E. N. Barron and J. Jensen proposed the following answer to their problem.

Let $\widehat{\mathcal{U}}(t_0,T) = L^\infty([t_0,T];\mathcal{M}(U))$. The space of admissible relaxed controls is defined by

$$\widehat{\mathcal{U}}_h(t_0,T) = \left\{\mu \in \widehat{\mathcal{U}}(t_0,T) |\text{ for a.e. } t \in [t_0,T],\ \mu - \text{ess sup}_{u\in U}\ h(t,x(t),u) \le 0\right\},$$

where $x(\cdot)$ is the generalized curve corresponding to the relaxed control μ. The relaxed problem is

$$\text{minimize } \psi(x(T))$$

over all generalized curves satisfying $x(t_0) = x_0$. They showed that, under usual technical assumptions, the set of generalized curves of (1), (2) (with $g = 0$) starting at x_0 is compact, and so the relaxed problem has a solution. Next they proved that the value functions of the original and the relaxed problems coincide. For this aim they checked that these value functions solve the same Hamilton–Jacobi boundary value problem, which, in turn, has a unique solution.

Let us briefly recall the rank condition used by E. N. Barron and J. Jensen. Let $u \in G(t,x)$ and let us denote the set of all "active" indices by

$$I(t,x,u) = \left\{i_1 < \cdots < i_k \mid \forall\, 1 \le j \le k,\ h_{i_j}(t,x,u) = 0 \text{ and } h_q(t,x,u) \ne 0\, \forall\ q \ne i_j\right\}.$$

Define the map $h_{I(t,x,u)} = (h_{i_1},\ldots,h_{i_k})$. It is assumed in [5] that the rank of the matrix

$$\frac{\partial h_{I(t,x,u)}}{\partial u}(t,x,u)$$

is equal to the number of elements in $I(t,x,u)$ (to be more precise, the authors restrict their investigation to the case where the maps $h_1,\ldots,h_{m-1}$ do not depend on (t,x)). This rank condition is often met in the optimal control theory of the Bolza problem (see, for instance, [6, p. 36], where the author also considered the problem (1), (2) in the case when $g = 0$) but apparently there are no results in the literature answering in the whole generality the above-mentioned question $\mathcal{Q}3$, although a tool providing an answer has existed since 1962 in the form of the Filippov–Ważewski relaxation theorem for differential inclusions. Namely, to get a positive answer it is enough to assume that the set-valued map $x \rightsquigarrow f(t,x,G(t,x))$ is locally Lipschitz. On the other hand an example provided by Pliś [19] shows that the Lipschitz condition cannot be weakened to a continuity condition.

The first aim of this paper is to investigate questions $\mathcal{Q}1$–$\mathcal{Q}3$ in the presence of both equality and inequality constraints. We show that the Mangasarian–Fromowitz constraint qualification (of which the above rank condition is a particular case) yields the local Lipschitz continuity of the map $x \rightsquigarrow G(t,x)$. The crucial argument to achieve this result is a careful application of an inverse mapping theorem (extending a result from [11] for maps defined on a metric space. Once the Lipschitz continuity of $x \rightsquigarrow G(t,x)$ is established, if $f(t,\cdot,\cdot)$ is locally Lipschitz, the above mentioned Filippov–Ważewski theorem may be applied and question $\mathcal{Q}3$ may be positively answered.

The last part of the paper is devoted to the relaxation problem in a situation when the Mangasarian–Fromowitz constraint qualification is not verified, namely, when we add a state constraint of the form $k(x) \leq 0$ to the above constraints (2). Nevertheless we can provide a result concerning this case by assuming a generalization (provided in [17]) of a condition originally proposed—for relaxation purposes—by P. Loreti [15].

The outline of the paper is as follows. In section 2 we provide some preliminaries on set-valued inverse mapping theorems and differential inclusions. Section 3 is devoted to relaxation of (1), (2) under the Mangasarian–Fromowitz condition. Section 4 covers a case where this condition is violated. A concluding short section provides a simple application concerning the value function of the Mayer problem.

2. Preliminaries.

2.1. Inverse mapping theorems. This section is basically an adaptation of some results from [11] to the form we need in this paper. We denote by $B_\delta(x)$ and $B(x,\delta)$ the closed ball of center x and radius δ; by $\overset{o}{B}$ and B the open and closed unit balls, respectively; by Graph(G) the graph of the set-valued map $G : X \rightsquigarrow Y$,

$$\mathrm{Graph}(G) = \{(x,y) \in X \times Y \mid y \in G(x)\}\,;$$

and by Dom(G) its domain

$$\mathrm{Dom}(G) = \{x \in X \mid G(x) \neq \emptyset\}\,.$$

Observe the following simple fact.

Proposition 2.1. *Let φ be a map from a metric space X to a normed space Y and $\rho > 0$, $\varepsilon > 0$, $\delta > 0$, $\overline{x} \in X$ be given. Then, the following two statements are equivalent:*

i. *φ satisfies the uniform open mapping principle at $\overline{x}$: $\forall\ x \in B_\delta(\overline{x})$ and $0 \leq h \leq \varepsilon$, $\varphi(x) + \rho h \overset{o}{B} \subset\ \varphi(B_h(x))$.*

ii. *The inverse map φ^{-1} is pseudo-Lipschitz at $\varphi(\overline{x})$: $\forall\ x \in B_\delta(\overline{x})$ and $y \in Y$ satisfying $\|y - \varphi(x)\| < \rho\varepsilon$,*

$$\mathrm{dist}\left(x,\ \varphi^{-1}(y)\right) \leq \frac{1}{\rho}\ \|\varphi(x) - y\|\,.$$

Pseudo-Lipschitz maps were introduced in [1]. The proof of Proposition 2.1 is straightforward. Most recently they have been called Aubin continuous maps.

Definition 2.2 (see [11]). *The* upper variation *of $\varphi : X \mapsto Y$ at x is the closed subset of Y defined by*

$$\varphi^{\sharp 1}(x) = \mathrm{Limsup}_{h\to 0+}\ \frac{\varphi(B_h(x)) - \varphi(x)}{h}.$$

In other words $v \in \varphi^{\sharp 1}(x)$ if and only if there exist sequences $h_i \to 0+$, $v_i \to v$ such that $\varphi(x) + h_i v_i \in \varphi(B_{h_i}(x))$.

Let X be a Banach space, $K \subset X$, and $x \in K$. The *contingent cone* to K at x is defined by

$$T_K(x) = \mathrm{Limsup}_{h \to 0+} \frac{K - x}{h}$$

(see, for instance, [4, Chapter 4]).

Let X, Y be Banach spaces and $\varphi : X \mapsto Y$ be a Fréchet differentiable map (or locally Lipschitz and Gâteaux differentiable map). Consider a subset $K \subset X$, $\overline{x} \in K$, and let $\varphi_{|K}$ denote the restriction of φ to K. Then it is not difficult to check that

$$\varphi'(\overline{x})(T_K(\overline{x}) \cap B) \subset \left(\varphi_{|K}\right)^{\sharp 1}(\overline{x}), \tag{4}$$

so that

$$\varphi'(\overline{x})(\overline{co}\ (T_K(\overline{x}) \cap B)) \subset \overline{co}\ \left(\varphi_{|K}\right)^{\sharp 1}(\overline{x})$$

and, in particular,

$$\varphi'(\overline{x})(B) \subset \varphi^{\sharp 1}(\overline{x}). \tag{5}$$

THEOREM 2.3. *Consider a complete metric space (X, d_X), a Banach space Y with the norm Gâteaux differentiable away from zero and a continuous map $\varphi : X \mapsto Y$. Let $\overline{x} \in X$ and assume that for some $\varepsilon > 0$, $\rho > 0$*

$$\rho B \subset \bigcap_{x \in B_\varepsilon(\overline{x})} \overline{co}\, \varphi^{\sharp 1}(x).$$

Then for every $x \in B_{\varepsilon/2}(\overline{x})$ and $y \in Y$ satisfying $\|y - \varphi(x)\| < \rho\varepsilon/2$,

$$\mathrm{dist}\ \left(x,\ \varphi^{-1}(y)\right) \leq \frac{1}{\rho}\ \|\varphi(x) - y\|\,.$$

In order to prove Theorem 2.3 we shall make use of Ekeland's variational principle (see, e.g., [3, 4]), which we recall for the reader's convenience.

THEOREM 2.4. *Let (X, d) be a complete metric space and $f : X \mapsto \mathbf{R} \cup \{+\infty\}$ be an extended lower semicontinuous bounded from below function. Consider $x_0 \in X$ such that $f(x_0) \neq +\infty$ and $\varepsilon > 0$. Then there exists $\overline{x} \in X$, a solution to*

$$\begin{cases} \text{i.} & f(\overline{x}) + \varepsilon d(x_0, \overline{x}) \leq f(x_0), \\ \text{ii.} & \forall\, x \neq \overline{x},\ \ f(\overline{x}) < f(x) + \varepsilon d(x, \overline{x}). \end{cases}$$

Proof of Theorem 2.3. By Proposition 2.1 we have to show that for every $x_1 \in B_{\varepsilon/2}(\overline{x})$, $0 \leq h \leq \varepsilon/2$

$$\varphi(x_1) + \rho h \overset{o}{B} \subset \varphi(B_h(x_1)).$$

We fix such x_1, h and pick $y \in Y$ satisfying $\|y - \varphi(x_1)\| < \rho h$. We define $0 < \theta < 1$ by

$$\theta^2 = \|y - \varphi(x_1)\| / \rho h.$$

Applying Theorem 2.4 to the complete metric space $B_h(x_1)$ and the continuous function $x \mapsto \|y - \varphi(x)\|$, we prove the existence of $x_2 \in B_{\theta h}(x_1) \subset B_\varepsilon(\overline{x})$ such that

$$\forall\, x \in B_h(x_1),\ \ \|\varphi(x_2) - y\| \leq \|\varphi(x) - y\| + \theta\rho d_X(x, x_2). \tag{6}$$

It remains to show that y is equal to $\varphi(x_2)$. Indeed, assume for a moment that $y \neq \varphi(x_2)$. By differentiability of the norm, there exists $p \in Y^\star$ of $\|p\|_\star = 1$ such that $\forall h > 0,\ v \in Y$

$$\|\varphi(x_2) + hv - y\| = \|\varphi(x_2) - y\| + \langle p, hv\rangle + o_v(h), \tag{7}$$

where $\lim_{h\to 0+} o_v(h)/h = 0$. We fix $v \in \varphi^{\sharp 1}(x_2)$ and let $h_j \to 0+,\ v_j \to v$ be such that $\varphi(x_2) + h_j v_j \in \varphi(B_{h_j}(x_2))$. Then from (6) and (7) we obtain

$$0 \leq \langle p, h_j v\rangle + h_j \|v_j - v\| + \theta\rho h_j + o_v(h_j).$$

Dividing by h_j and taking the limit yields $\langle p, v\rangle \geq -\theta\rho$. Since $v \in \varphi^{\sharp 1}(x_2)$ is arbitrary we proved that

$$\forall\, v \in \overline{co}\left(\varphi^{\sharp 1}(x_2)\right), \quad \langle p, v\rangle \geq -\theta\rho. \tag{8}$$

By the assumption of the theorem, $\rho B \subset \overline{co}\left(\varphi^{\sharp 1}(x_2)\right)$. Thus (8) yields $-\rho \geq -\theta\rho$. Since $0 < \theta < 1$ and $\rho > 0$, we derived a contradiction. Consequently $\varphi(x_2) = y$. □

2.2. Relaxation of differential inclusions. Consider a set-valued map F from $[t_0, T] \times \mathbf{R}^n$ into subsets of $\mathbf{R}^n$ and the differential inclusion

$$x' \in F(t, x). \tag{9}$$

An absolutely continuous function $x : [t_0, T] \mapsto \mathbf{R}^n$ is called a *solution* to (9) if

$$x'(t) \in F(t, x(t)) \ \text{ a.e. in } \ [t_0, T]. \tag{10}$$

Denote by $\mathcal{S}_{[t_0,T]}(x_0)$ the set of solutions to (9) starting at $x_0 \in \mathbf{R}^n$ at time t_0 and defined on the time interval $[t_0, T]$. Let us recall a result concerning the density of the set of solutions to the differential inclusion

$$\left\{ \begin{array}{lcl} x'(t) & \in & F(t, x(t)) \ \text{ a.e. in } \ [t_0, T], \\ x(t_0) & = & x_0 \end{array} \right. \tag{11}$$

into the set of solutions to the convexified (relaxed) differential inclusion

$$\left\{ \begin{array}{lcl} x'(t) & \in & \overline{co}\, F(t, x(t)) \ \text{ a.e. in } \ [t_0, T], \\ x(t_0) & = & x_0. \end{array} \right. \tag{12}$$

Assume

$$\left\{ \begin{array}{ll} \text{i.} & \forall\, (t, x) \in [t_0, T] \times \mathbf{R}^n, \ \ F(t, x) \ \text{ is closed,} \\ \text{ii.} & \forall\, x \in \mathbf{R}^n, \ F(\cdot, x) \text{ is measurable,} \\ \text{iii.} & \exists\, \gamma \in L^1(t_0, T), \ \text{for a.e. } t \in [t_0, T], \forall\, x \in \mathbf{R}^n, \ \sup_{v \in F(t,x)} \|v\| \leq \gamma(t)(1 + \|x\|). \end{array} \right. \tag{13}$$

Observe that if F satisfies (13), then so does the set-valued map $(t, x) \rightsquigarrow \overline{co}\,(F(t, x))$. If in addition for almost every t, $F(t, \cdot)$ is upper semicontinuous, then it is well known, thanks to the Dunford–Pettis criterion, the Mazur theorem, and the convergence theorem (see, for instance, [4, 6, 7]) that under assumptions (13) the set of solutions to (12) is compact in the space of continuous functions $C(t_0, T)$. This and the Filippov–Ważewski theorem (see, for instance, [2] for the time-independent case, [4, p. 402], or [12]) yield the following well-known result.

THEOREM 2.5. *Suppose* (13) *and that*

$$\left\{ \begin{array}{l} \forall\, \rho > 0, \exists\, k \in L^1(t_0, T) \ \textit{ such that for almost all } \ t \in [t_0, T], \\ \textit{the map } \ F(t, \cdot) \ \textit{ is } \ k(t) - \textit{Lipschitz on } \ B_\rho(0). \end{array} \right. \tag{14}$$

Then the closure of $\mathcal{S}_{[t_0,T]}(x_0)$ *in* $C(t_0,T)$ *is compact and equal to the set of solutions to the relaxed inclusion* (12).

Remark. The convergence theorem can be found, e.g., in [4] for time-independent maps. However it can be extended with exactly the same proof to all measurable with respect to time set-valued maps. □

2.3. Control systems with state-dependent control sets. Let $\mathcal{Z}$ be a complete separable metric space, let $G : [t_0,T] \times \mathbf{R}^n \rightsquigarrow \mathcal{Z}$ be a given set-valued map, and consider the control system

$$x' = f(t,x,u), \quad u \in G(t,x), \quad t \in [t_0,T]. \tag{15}$$

Such systems were considered, e.g., in [6, 7]. An absolutely continuous function $x : [t_0,T] \mapsto \mathbf{R}^n$ is called a solution to (15) if for some measurable selection $u(t) \in G(t,x(t))$ we have

$$x'(t) = f(t,x(t),u(t)) \text{ a.e. in } [t_0,T].$$

We introduce the set-valued map $F : [t_0,T] \times \mathbf{R}^n \rightsquigarrow \mathbf{R}^n$ defined by

$$F(t,x) = f(t,x,G(t,x)) = \{f(t,x,v) \mid v \in G(t,x)\},$$

and replace (15) by the differential inclusion (10). We impose the following assumptions:

$$\begin{cases} \forall\,(x,u) \in \mathbf{R}^n \times \mathcal{Z}, \ f(\cdot,x,u) \text{ is measurable,} \\ \forall\, t \in [t_0,T], \ f(t,\cdot,\cdot) \text{ is continuous,} \\ G \text{ is upper semicontinuous and has closed nonempty images.} \end{cases} \tag{16}$$

Observe that if in addition $G(t,x)$ are compact, then F has compact images.

From the measurable selection theorem (see, for instance, [4, Chapter 8]), Theorem 2.6 follows.

THEOREM 2.6. *If* (16) *holds true, then the sets of solutions to control system* (15) *and differential inclusion* (10) *do coincide.*

Thanks to the above result Theorem 2.5 can be applied to the control system (15) whenever the map $x \rightsquigarrow f(t,x,G(t,x))$ satisfies the required Lipschitz property. This holds, for example, whenever $G(\cdot,\cdot)$ is locally Lipschitz and $f(t,\cdot,\cdot)$ is $k(t)$-Lipschitz for some $k \in L^1$. On the other hand it is well known that if the Lipschitz property fails, then the conclusion of Theorem 2.5 may fail as well. A corresponding example was provided by Pliś in 1962.

Example (derived from [19, Pliś]). We recall first the Pliś construction.

Consider the map $F : \mathbf{R}^2 \rightsquigarrow \mathbf{R}^2$

$$F(x_1,x_2) = \left\{(v_1,v_2) \mid v_1 \in \{-1,+1\}\,,\ v_2 = \sqrt{|x_2|} + |x_1|\right\}.$$

This map is continuous but not locally Lipschitz around zero. For every $x \in \mathcal{S}_{[0,T]}(0)$ solving (11) for $t_0 = 0$ and $x_0 = 0$ we have $x_2(t) \geq t^2/4$, while $x \equiv 0$ solves the relaxed inclusion (12). Thus the conclusion of Theorem 2.5 is not valid in this case (trajectories of the original inclusion are not dense in the trajectories of the convexified one).

Consider a C^∞-map $g : \mathbf{R}^2 \times \mathbf{R}^2 \mapsto \mathbf{R}$ such that $g(x,u) = 0$ if and only if $u \in F(x)$. Such a map exists since the set Graph(F) is closed. Let $f(t,x,u) = u$ and $G(t,x) = \{u \mid g(x,u) = 0\}$. Then $F(x) = f(t,x,G(t,x))$. This implies that solutions to

$$x'(t) = f(t,x(t),u(t)), \quad g(x(t),u(t)) = 0, \quad x(0) = 0$$

are not dense in the solutions to

$$x'(t) \in \overline{co}\, f(t, x, G(t, x)), \;\; x(0) = 0.$$

3. Solutions of control systems under constraints. In this section we study relaxation of control systems under constraints. Speaking of the *closure* of the solution's set of a given Cauchy problem we always mean the closure in the space of continuous functions $C(t_0, T)$ endowed with the supremum norm. Consider a complete separable metric space $\mathcal{Z}$, real numbers $t_0 < T$, a map (describing the dynamics)

$$f : [t_0, T] \times \mathbf{R}^n \times \mathcal{Z} \mapsto \mathbf{R}^n,$$

and the control set $U \subset \mathcal{Z}$. We associate with this data the control system

$$x'(t) = f(t, x(t), u(t)), \quad u(t) \in U. \tag{17}$$

Consider the maps defining state-control constraints

$$h = (h_1, \dots, h_m) : [t_0, T] \times \mathbf{R}^n \times \mathcal{Z} \mapsto \mathbf{R}^m \;\text{ and }\; g : [t_0, T] \times \mathbf{R}^n \times \mathcal{Z} \mapsto \mathbf{R}^p.$$

We investigate solutions to (17) under additional constraints

$$h(t, x(t), u(t)) \le 0, \quad g(t, x(t), u(t)) = 0 \quad \text{a.e. in } [t_0, T]. \tag{18}$$

A way to study the above problem is to introduce the set-valued map

$$G(t, x) = \{u \in U \mid h(t, x, u) \le 0, \;\; g(t, x, u) = 0\}, \tag{19}$$

where $h(t, x, u) \le 0$ means $h_i(t, x, u) \le 0$ for every $i = 1, \dots, m$.

Observe that if a trajectory-control pair (x, u) solves (17), (18), then

$$u(t) \in G(t, x(t)) \quad \text{a.e. in } [t_0, T]. \tag{20}$$

Naturally, the converse statement holds true as well, if (x, u) satisfies (17) and (20), then (18) is satisfied.

Another type of problem that will be considered in this section is the one with equality constraints independent of controls. Let $\varphi : [t_0, T] \times \mathbf{R}^n \mapsto \mathbf{R}^p$. The state constraints are given by

$$\varphi(t, x(t)) = 0, \;\; h(t, x(t), u(t)) \le 0. \tag{21}$$

Observe that if (x, u) solves (17), (21), and φ is differentiable, then for almost all $t \in [t_0, T]$ we have

$$\frac{\partial \varphi}{\partial t}(t, x(t)) + \frac{\partial \varphi}{\partial x}(t, x(t)) f(t, x(t), u(t)) = 0.$$

Setting

$$G_1(t, x) = \left\{ u \in U \mid \frac{\partial \varphi}{\partial t}(t, x) + \frac{\partial \varphi}{\partial x}(t, x) f(t, x, u) = 0, \; h(t, x, u) \le 0 \right\}$$

we deduce that $u(t) \in G_1(t, x(t))$ a.e.

PROPOSITION 3.1. *Assume that φ is differentiable and locally Lipschitz and let (x, u) be a trajectory-control pair of* (17) *such that $u(t) \in G_1(t, x(t))$ a.e. If $\varphi(t_0, x(t_0)) = 0$, then (x, u) satisfies the state-control constraints* (21). *Conversely, every trajectory-control pair (x, u) to* (17), (21) *verifies $u(t) \in G_1(t, x(t))$ a.e.*

In order to prove this proposition it is enough to differentiate the map $t \mapsto \varphi(t, x(t))$.

Observe that the above result reduces the constrained system (17), (21) to the constrained system (17), (18) with g given by

$$g(t,x,u) = \frac{\partial \varphi}{\partial t}(t,x) + \frac{\partial \varphi}{\partial x}(t,x) f(t,x,u). \tag{22}$$

We shall next provide sufficient conditions for Lipschitz continuity of the map $x \rightsquigarrow G(t,x)$. Recall that in view of the Example of section 2 such a property is needed to build a satisfactory relaxation theory.

3.1. Control-dependent constraints. In this section $\mathcal{Z}$ is a Banach space and $U = \mathcal{Z}$. Set

$$\mathbf{R}^k_+ = \{(\alpha_1, \ldots, \alpha_k) |\ \alpha_i \geq 0\ \forall\, i = 1, \ldots, k\},$$

and consider the set-valued map $G : [t_0, T] \times \mathbf{R}^n \rightsquigarrow \mathcal{Z}$ defined by (19). With every (t,x,u) we associate the set of all "active" indices

$$I(t,x,u) = \left\{ i_1 < \cdots < i_k \mid \forall\, 1 \leq j \leq k,\ h_{i_j}(t,x,u) = 0 \ \text{ and } \ h_q(t,x,u) \neq 0\, \forall\, q \neq i_j \right\},$$

and define

$$h_{I(t,x,u)}(s,y,v) = \left(h_{i_1}, \ldots, h_{i_k}\right)(s,y,v) \quad \forall\, (s,y,v) \in [t_0,T] \times \mathbf{R}^n \times \mathcal{Z}.$$

Assume that the constraints satisfy the Mangasarian–Fromowitz-type conditions:

$$\begin{cases} \frac{\partial h}{\partial u},\ \frac{\partial g}{\partial u} \ \text{ are continuous,} \\ \forall\, u \in G(t,x),\ \frac{\partial g}{\partial u}(t,x,u) \ \text{ is surjective,} \\ \forall\, u \in G(t,x),\ \exists\, v \in U,\ \ \frac{\partial h_{I(t,x,u)}}{\partial u}(t,x,u)(v) < 0,\ \ \frac{\partial g}{\partial u}(t,x,u)(v) = 0. \end{cases} \tag{23}$$

Remark. In [5] a relaxation problem is considered where only inequality constraints act on the system. The main assumption made in [5] is a rank condition, which is stronger than (23). In fact, assume that there is no g in (18) and, $\forall u \in G(t,x)$, denote by $k(t,x,u)$ the number of elements in $I(t,x,u)$. The rank condition states that the rank of the matrix

$$\frac{\partial h_{I(t,x,u)}}{\partial u}(t,x,u)$$

is equal to $k(t,x,u)$. This means that the linear operator

$$\frac{\partial h_{I(t,x,u)}}{\partial u}(t,x,u) : U \to \mathbf{R}^{k(t,x,u)}$$

is surjective. Hence there exists $v \in U$ as in (23). The converse statement in general does not hold. □

We also assume that

$$\begin{cases} & \forall\, (\bar t, \bar x) \in [t_0,T] \times \mathbf{R}^n,\ \exists\, r > 0,\ \varepsilon > 0,\ L > 0\ \forall\, (t,x) \in B_\varepsilon(\bar t, \bar x), \\ \text{i.} & \{u \in U \mid h(t,x,u) \leq r,\ \|g(t,x,u)\| \leq r\} \quad \text{is compact,} \\ \text{ii.} & \forall\, u \in U,\ (h,g)(\cdot,\cdot,u) \text{ is L-Lipschitz on } B_\varepsilon(\bar t, \bar x), \\ \text{iii.} & \forall \text{ bounded } K \subset U,\ \exists\, M > 0 \text{ such that } \forall\, (t,x) \in B_\varepsilon(\bar t, \bar x), \\ & h(t,x,\cdot) \ \text{ is M-Lipschitz on } \ K. \end{cases} \tag{24}$$

We claim that G is upper semicontinuous (see, for instance, [2] for the definition). By (24.i) it has compact images. Clearly its graph is closed. We check next that its domain is closed as well. Indeed if $(t,x) \in \overline{\mathrm{Dom}(G)}$, then there exist $(t_i,x_i) \to (t,x)$ and $u_i \in G(t_i,x_i)$. Because of assumption (24.ii) $\forall i$ large enough

$$\|g(t,x,u_i)\| = \|g(t,x,u_i) - g(t_i,x_i,u_i)\| \le r,$$

$$h(t,x,u_i) \le h(t,x,u_i) - h(t_i,x_i,u_i) \le r.$$

We deduce from (24.i) that the sequence u_i has an accumulation point u. Then $h(t,x,u) \le 0,\ g(t,x,u) = 0$ and therefore (t,x) is in the domain of G.

We next fix $(\bar t,\bar x) \in \mathrm{Dom}(G)$. By (24.ii), for some $\delta > 0$ and $\forall (t,x) \in B_\delta(\bar t,\bar x) \cap \mathrm{Dom}(G)$ we have

$$G(t,x) \subset \{u \in U \mid h(\bar t,\bar x,u) \le r,\ \ \|g(\bar t,\bar x,u)\| \le r\}\,.$$

Since the set-valued map G has a closed graph and since $\forall (t,x) \in B_\delta(\bar t,\bar x) \cap \mathrm{Dom}(G)$ it takes its values in a compact set, we deduce that G is upper semicontinuous at $(\bar t,\bar x)$. The domain of G being closed and the point $(\bar t,\bar x) \in \mathrm{Dom}(G)$ being arbitrary, we conclude that G is upper semicontinuous.

THEOREM 3.2. *Assume that* (23), (24) *hold true and that* $\mathrm{Dom}(G) \neq \emptyset$. *Then* $\mathrm{Dom}(G) = [t_0,T] \times \mathbf{R}^n$ *and G is locally Lipschitz on* $[t_0,T] \times \mathbf{R}^n$.

Proof. We first observe that assumption (23) yields

$$\forall\, u \in G(t,x),\ \ \mathrm{Im}\left(\frac{\partial h_{I(t,x,u)}}{\partial u}, \frac{\partial g}{\partial u}\right)(t,x,u) + \mathbf{R}^k_+ \times 0 = \mathbf{R}^{k+p}, \tag{25}$$

where k denotes the number of elements in $I(t,x,u)$. It is enough to show that G has nonempty values and is locally Lipschitz continuous on a neighborhood of every point of its domain. In particular, since we already know that this domain is closed, we deduce that it is equal to $[t_0,T] \times \mathbf{R}^n$.

We fix $(\bar t,\bar x) \in \mathrm{Dom}(G)$, and consider the compact set

$$Z(\bar t,\bar x) = \{u \in G(\bar t,\bar x) \mid I(\bar t,\bar x,u) \neq \emptyset\} \subset G(\bar t,\bar x).$$

Let $\varepsilon, r > 0, L > 0$ be as in assumption (24) and $\bar u \in Z(\bar t,\bar x)$. Consider $\rho(\bar u) > 0$ such that

$$4\rho(\bar u)B \subset \left(\frac{\partial h_{I(\bar t,\bar x,\bar u)}}{\partial u}, \frac{\partial g}{\partial u}\right)(\bar t,\bar x,\bar u)(B) + \big(\mathbf{R}^k_+ \cap B\big) \times \{0\}\,.$$

It exists because of (25) and the separation theorem. Since $\frac{\partial h}{\partial u}$ and $\frac{\partial g}{\partial u}$ are continuous, there exists $\varepsilon > \delta(\bar u) > 0$ such that

$$\begin{cases} \forall\,(t,x) \in B_{\delta(\bar u)}(\bar t,\bar x)\ \ \forall\, u \in B_{\delta(\bar u)}(\bar u), \\ 2\rho(\bar u)B \subset \left(\frac{\partial h_{I(\bar t,\bar x,\bar u)}}{\partial u}, \frac{\partial g}{\partial u}\right)(t,x,u)(B) + \big(\mathbf{R}^k_+ \cap B\big) \times \{0\}\,. \end{cases}$$

By continuity of h and g, for some $0 < \nu(\bar u) \le \delta(\bar u)$ we have

$$\begin{cases} \forall\,(t,x) \in B_{\nu(\bar u)}(\bar t,\bar x)\ \forall\, u \in B_{\nu(\bar u)}(\bar u), \\ \big\|h_{I(\bar t,\bar x,\bar u)}(t,x,u)\big\| + \|g(t,x,u)\| < \rho(\bar u)\delta(\bar u)/2, \\ \forall\, i \notin I(\bar t,\bar x,\bar u),\ h_i(t,x,u) < 0. \end{cases} \tag{26}$$

Since $Z(\bar{t},\bar{x})$ is compact, there exist $u_i \in Z(\bar{t},\bar{x}),\ i=1,\dots,s$, satisfying

$$Z(\bar{t},\bar{x}) \subset \mathcal{O} := \bigcup_{i=1}^{s} \overset{o}{B}(u_i, \nu(u_i)/8).$$

Furthermore, for some $\mu > 0$ and all $u \in G(\bar{t},\bar{x}) \setminus \mathcal{O}, h(\bar{t},\bar{x},u) \le -2\mu$. The last inequality means that $h_j(\bar{t},\bar{x},u) \le -2\mu\, \forall j$.

Using that $\frac{\partial g}{\partial u}$ is continuous, by (25) we can find $\hat{\varepsilon} > 0$ and $\rho_0 > 0$ such that

$$\forall\ (t,x) \in B_{\hat{\varepsilon}}(\bar{t},\bar{x})\ \forall\ u \in G(\bar{t},\bar{x}) + \hat{\varepsilon}B,\ \ \rho_0 B \subset \frac{\partial g}{\partial u}(t,x,u)(B).$$

Moreover, for some $0 < \bar{\varepsilon} < \hat{\varepsilon}$

$$\forall\ (t,x) \in B_{\bar{\varepsilon}}(\bar{t},\bar{x})\ \forall\ u \in G(\bar{t},\bar{x}) + \bar{\varepsilon}B,\ \ \|g(t,x,u)\| < \rho_0\hat{\varepsilon}/2.$$

Set

$$\bar{\rho} = \min\left\{\rho_0,\ \rho(u_i) \mid i=1,\dots,s\right\},\quad \bar{\nu} = \min\left\{\bar{\varepsilon},\ \nu(u_i) \mid i=1,\dots,s\right\},$$

and let M be a Lipschitz constant (independent of $(t,x) \in B_{\varepsilon}(\bar{t},\bar{x})$) of $h(t,x,\cdot)$ on $G(\bar{t},\bar{x}) + \hat{\varepsilon}B$, which exists by (24.iii)). Since G is upper semicontinuous and h is continuous, we can find $0 < \delta < \frac{\bar{\nu}}{8}$ such that

$$\forall\ (t,x) \in B_{\delta}(\bar{t},\bar{x}),\ \ G(t,x) \subset G(\bar{t},\bar{x}) + B(0,\bar{\nu}/8)$$

and

$$2L\delta < \bar{\rho}\hat{\varepsilon}/2,\ \ L\delta < \bar{\rho}\bar{\nu},\ \ L\delta(1+M/\bar{\rho}) < \mu$$

$$\forall\ u \in G(t,x) \setminus \mathcal{O},\ \ h(t,x,u) \le -\mu.$$

Consider $(t_1,x_1),\ (t_2,x_2) \in B_\delta(\bar{t},\bar{x})$, and $y_1 \in G(t_1,x_1)$, i.e., $g(t_1,x_1,y_1) = 0$. If $y_1 \in G(t_1,x_1) \setminus \mathcal{O}$, then $h(t_1,x_1,y_1) \le -\mu$. From (5) and Theorem 2.3 applied to the map $\varphi = g(t_2,x_2,\cdot),\ \varepsilon = \hat{\varepsilon}/2,\ y=0,\ \bar{x} = y_1$, using that $G(t_2,x_2)$ is compact, we deduce that there exists $y_2 \in U$ such that $g(t_2,x_2,y_2) = 0$ and

$$\|y_2 - y_1\| \le \frac{1}{\bar{\rho}}\|g(t_2,x_2,y_1)\| \le \frac{L}{\bar{\rho}}\left(|t_2-t_1| + \|x_2-x_1\|\right).$$

Therefore

$$h(t_2,x_2,y_2) \le h(t_1,x_1,y_1) + L\delta\left(1 + \frac{M}{\bar{\rho}}\right) \le -\mu + \mu = 0$$

and $y_2 \in G(t_2,x_2)$. Consider next the case $-\mu < h(t_1,x_1,y_1) \le 0$. Then $y_1 \in G(t_1,x_1) \cap \mathcal{O}$. Thus for some i

$$y_1 \in B(u_i,\nu(u_i)/8) + B(0,\nu(u_i)/8) = B(u_i,\nu(u_i)/4),$$

where $u_i \in Z(\bar{t},\bar{x})$. Furthermore

$$\left\|h_{I(\bar{t},\bar{x},u_i)}(t_2,x_2,y_1)\right\| + \|g(t_2,x_2,y_1)\| < \rho(u_i)\delta(u_i)/2.$$

Let k denote the number of elements in $I(\bar{t},\bar{x},u_i)$. By applying Theorem 2.3 to the function $\varphi : U \times \mathbf{R}_+^k \mapsto \mathbf{R}^{k+p}$ defined by

$$\varphi(z,\alpha) := (h_{I(\bar{t},\bar{x},u_i)}, g)(t_2,x_2,z) + (\alpha,0)$$

with

$$\varepsilon = \delta(u_i),\ y = (h_{I(\bar t,\bar x,u_i)}(t_1,x_1,y_1),0),\ \bar x = u_i,\ x = (y_1,0),$$

we deduce from (4) that there exist $y_2 \in U$ and $\alpha \in \mathbf{R}^k_+$ such that

$$(h_{I(\bar t,\bar x,u_i)},g)(t_2,x_2,y_2) = (h_{I(\bar t,\bar x,u_i)}(t_1,x_1,y_1) - \alpha,0)$$

and

$$\begin{aligned}&\|y_2 - y_1\|\\ &\le \rho(u_i)^{-1}\left(\left\|h_{I(\bar t,\bar x,u_i)}(t_2,x_2,y_1) - h_{I(\bar t,\bar x,u_i)}(t_1,x_1,y_1)\right\| + \|g(t_2,x_2,y_1)\|\right)\\ &\le 2L(\bar\rho)^{-1}\left(|t_2-t_1| + \|x_2-x_1\|\right).\end{aligned}$$

In particular, $y_2 \in G(t_2,x_2)$; therefore $G(\cdot,\cdot)$ is $\frac{2L}{\bar\rho}$-Lipschitz on $B_\delta(\bar t,\bar x)$. □

We impose the following assumptions on f:

$$(27)\quad \begin{cases}\text{i.} & \forall\, x,u,\ f(\cdot,x,u) \text{ is measurable,}\\ \text{ii.} & \forall\,\rho>0,\ \exists\, k\in L^1(t_0,T) \text{ such that for almost all } t\in[t_0,T],\\ & \text{the map } f(t,\cdot,\cdot) \text{ is } k(t)\text{-Lipschitz on } B_\rho(0)\times U,\\ \text{iii.} & \exists\,\gamma\in L^1(t_0,T), \text{ such that for a.e. } t\in[t_0,T],\\ & \forall\, x\in\mathbf{R}^n,\ \sup_{u\in U}\|f(t,x,u)\| \le \gamma(t)(1+\|x\|).\end{cases}$$

Consider the case $\mathrm{Dom}(G)\neq\emptyset$. Then, by Theorem 3.2, the sets $F(t,x) = f(t,x,G(t,x))$ are nonempty and compact, the set-valued map F is measurable in t and locally Lipschitz in x in the sense of (14). By subsection 2.3 the control system (15) may be rewritten as the differential inclusion (10).

THEOREM 3.3. *Under assumptions* (23), (24), *and* (27) *the closure of solutions to* (17), (18) *starting at x_0 is compact and equal to the set of solutions to the differential inclusion*

$$\begin{cases} x' & \in & \overline{co}\, f(t,x,G(t,x)),\\ x(t_0) & = & x_0.\end{cases}$$

Notice that if $\mathrm{Dom}(G)=\emptyset$, then the above result holds true. When $\mathrm{Dom}(G)\neq\emptyset$ it follows from Theorems 2.5 and 3.2.

For control problems without constraints one of the approaches to the relaxation theory uses probability measures (i.e., relaxed controls see, e.g., [23]). It has also been used by E. N. Barron and J. Jensen [5] for the problem with inequality constraints. Actually, Theorem 3.3 can be reformulated in terms of relaxed controls, so that it implies, in particular, the result from [5].

More precisely, let $\mathcal{M}(U)$ denote the set of probability measures on U and set

$$\widehat{\mathcal{U}}(t_0,T) = L^\infty([t_0,T];\mathcal{M}(U)).$$

The set $\mathcal{M}(U)$ is endowed with the weak star topology of $\mathcal{C}(U)^*$, the dual of the space $\mathcal{C}(U)$ of continuous real functions defined on U. Generalizing the definition given in [5] to the case involving equality constraints as well, we define the space of admissible relaxed controls as

$$\begin{aligned}\widehat{\mathcal{U}}_{hg}(t_0,T) \ :=\ &\{\mu\in\widehat{\mathcal{U}}(t_0,T) \mid \text{for almost all } t\in[t_0,T],\\ &\mu - \text{ess}\sup_{u\in U} h(t,x(t),u)\le 0,\ \ \mu - \text{ess}\sup_{u\in U}\|g(t,x(t),u)\| = 0\},\end{aligned}$$

where $x(\cdot)$ is the (unique) continuous solution of the integral equation

$$x(t) = x(t_0) + \int_{t_0}^{t} \int_U f(s, x(s), u)\mu(s, du)ds.$$

$x(\cdot)$ is called the *generalized curve of* (17) *corresponding to the relaxed control* μ. From assumptions (27) it follows that x is absolutely continuous.

COROLLARY 3.4. *Under assumptions* (23), (24), (27) *the closure of solutions to* (17), (18) *starting at* x_0 *is compact and equal to the set of generalized curves of the control system* (17) *starting at* x_0 *and corresponding to the admissible relaxed controls* $\widehat{\mathcal{U}}_{hg}(t_0, T)$.

Proof. This result is an immediate consequence of Theorem 3.3. We provide its proof for the sake of completeness. By the very definition of admissible relaxed controls,

$$\mu\left(t, \{u \in U \mid h(t, x(t), u) > 0 \quad \text{or} \quad g(t, x, u) \neq 0\}\right) = 0$$

for almost all $t \in [t_0, T]$. Thus, for almost all $s \in [t_0, T]$,

$$\int_U f(s, x(s), u)\mu(s, du) = \int_{G(s,x(s))} f(s, x(s), u)\mu(s, du).$$

Let $p \in \mathbf{R}^n,\ t \in [t_0, T]$. Then

$$\langle p, x(t) - x(t_0)\rangle \leq \int_{t_0}^{t} \max_{u \in G(s,x(s))} \langle p, f(s, x(s), u)\rangle\, ds$$

and consequently, from the separation theorem,

$$x(t) - x(t_0) \in \int_{t_0}^{t} \overline{co}\, f(s, x(s), G(s, x(s)))ds.$$

Because x is absolutely continuous, we deduce from the mean value theorem (see [2, p. 21]) that $x'(s) \in \overline{co}\, f(s, x(s), G(s, x(s)))$ a.e.

Conversely, consider a solution x to the differential inclusion

$$x'(t) \in \overline{co}\, f(t, x(t), G(t, x(t))), \quad x(t_0) = x_0.$$

There exists then measurable functions $\lambda_i : [t_0, T] \mapsto [0, 1]$ and measurable selections $v_i(s) \in f(s, x(s), G(s, x(s))),\ i = 0, \dots, n$, such that

$$\sum_{i=0}^{n} \lambda_i(s) = 1,\ \sum_{i=0}^{n} \lambda_i(s)v_i(s) = x'(s) \quad \text{a.e. in} \quad [t_0, T]$$

(see, for instance, [4, Chapter 8]). Consider measurable selections $u_i(s) \in G(s, x(s))$ such that $\forall i = 0, \dots, n,\ v_i(s) = f(s, x(s), u_i(s))$ and set

$$\mu(s, u) = \begin{cases} \lambda_i(s) & \text{if } u = u_i(s),\ i = 0, \dots, n, \\ 0 & \text{otherwise.} \end{cases}$$

Then $\mu \in \widehat{\mathcal{U}}_{hg}(t_0, T)$ and x is the corresponding generalized curve. □

3.2. Control-independent equality constraints. By the results from the beginning of section 3, when the equality constraints are control independent, the problem can be reduced to the one considered in subsection 3.1. We translate the results of subsection 3.1 for such situation. For the sake of simplicity we assume here that there are no inequality constraints, which is equivalent to setting $h = -1$. It is straightforward to extend the following considerations to the case where actual inequality constraints $h(t, x, u) \leq 0$ (and even supplementary equality constraints $g(t, x, u) = 0$) are considered as well.

Consider a continuously differentiable $\varphi : [t_0, T] \times \mathbf{R}^n \mapsto \mathbf{R}^p$ and let $\mathcal{Z}$ be a Banach space, $U = \mathcal{Z}$. We introduce the set-valued map

$$G(t,x) = \left\{ u \in U \mid \frac{\partial \varphi}{\partial t}(t,x) + \frac{\partial \varphi}{\partial x}(t,x) f(t,x,u) = 0 \right\}. \tag{28}$$

Thanks to Proposition 3.1 we know that the system (17) subject to the constraint

$$\varphi(t, x(t)) = 0 \tag{29}$$

is equivalent to (17), (18) with g defined by (22) and $h = -1$.

Thus we may apply the results of subsection 3.1. For this aim assume that

$$\left\{ \begin{array}{l} (\frac{\partial \varphi}{\partial t}, \frac{\partial \varphi}{\partial x}) \;\text{ is locally Lipschitz,} \\ f \;\text{ is differentiable with respect to } u, \; \frac{\partial f}{\partial u} \;\text{ is continuous, and} \\ \forall\, u \in G(t,x), \quad \frac{\partial \varphi}{\partial x}(t,x) \frac{\partial f}{\partial u}(t,x,u) \;\text{ is surjective,} \end{array} \right. \tag{30}$$

$$\left\{ \begin{array}{l} \forall\, (\bar t, \bar x) \in [t_0, T] \times \mathbf{R}^n, \exists\, \varepsilon > 0, \; r > 0 \; \forall\, (t,x) \in B_\varepsilon(\bar t, \bar x), \text{ such that the set} \\ \{u \in U \mid \| \frac{\partial \varphi}{\partial x}(t,x) f(t,x,u) \| \leq r - \| \frac{\partial \varphi}{\partial t}(t,x) \| \} \text{ is compact,} \\ \exists\, L > 0 \; \forall\, u \in U, \; f(\cdot, \cdot, u) \;\text{ is L-Lipschitz on } B_\varepsilon(\bar t, \bar x). \end{array} \right. \tag{31}$$

Under these conditions, by Theorem 3.2, the set-valued map $G(\cdot, \cdot)$ is locally Lipschitz and so we have similar relaxation theorems. Applying Theorem 3.3 with $h = -1$ we get the following result.

THEOREM 3.5. *Under assumptions* (27), (30), (31) *the closure of solutions to* (17), (29) *starting at x_0 is compact and equal to the set of solutions to the differential inclusion*

$$\left\{ \begin{array}{rcl} x' & \in & \overline{co}\, f(t, x, G(t,x)), \\ x(t_0) & = & x_0. \end{array} \right.$$

Define the set of admissible relaxed controls $\widehat{\mathcal{U}}_\varphi(t_0, T) = \widehat{\mathcal{U}}_{hg}(t_0, T)$ as in subsection 3.1 with $h = -1$ and g as above. Corollary 3.4 yields the following.

COROLLARY 3.6. *Under assumptions* (27), (30), (31) *the closure of solutions to* (17), (29) *starting at x_0 is compact and equal to the set of generalized curves of the control system* (17) *starting at x_0 and corresponding to the admissible relaxed controls $\widehat{\mathcal{U}}_\varphi(t_0, T)$.*

3.3. Constrained control sets. In this section we assume that U is a closed subset of a finite-dimensional space $\mathcal{Z} = \mathbf{R}^m$. For every $u \in U$, let $C_U(u)$ denote the Clarke tangent cone to U at u. It is well known (see, for instance, [4, Chapter 4]) that

$$\operatorname{Liminf}_{u' \to_U u} T_U(u') = C_U(u) \tag{32}$$

and that $C_U(u)$ is convex.

First, we consider the constrained control system (17), (18). Define $G(t,x)$ by (19) and assume that (24) holds true. The surjectivity assumption (23) has to be replaced by the following one:

$$(33)\begin{cases} \frac{\partial h}{\partial u},\ \frac{\partial g}{\partial u} \text{ are continuous and } \forall\, u \in G(t,x),\ \frac{\partial g}{\partial u}(t,x,u)(C_U(u)) = \mathbf{R}^p \\ \forall\, u \in G(t,x), \exists\, v \in C_U(u),\ \ \frac{\partial h_{I(t,x,u)}}{\partial u}(t,x,u)(v) < 0,\ \ \frac{\partial g}{\partial u}(t,x,u)(v) = 0. \end{cases}$$

Exactly in the same way as in subsection 3.1 we check that G is upper semicontinuous, has compact images, and that its domain is closed.

PROPOSITION 3.7. *Under assumptions* (24) and (33), $G(\cdot,\cdot)$ *is locally Lipschitz on* $[t_0,T]\times\mathbf{R}^n$.

Proof. Observe that (33) and the separation theorem yield

$$(34)\qquad \left(\frac{\partial h_{I(t,x,u)}}{\partial u}, \frac{\partial g}{\partial u}\right)(t,x,u)(C_U(u)) + \mathbf{R}^k_+ \times 0 = \mathbf{R}^{k+p},$$

where k is the number of elements in $I(t,x,u)$. Let $Z(\bar t,\bar x)$ have the same meaning as in the proof of Theorem 3.2, and fix $\bar u \in Z(\bar t,\bar x)$. Using the separation theorem it is not difficult to show that (34) implies the existence of $\rho(\bar u) > 0$, $v_i \in C_U(\bar u)$, $i = 1,\ldots,s \le m+1$, such that $\|v_i\| \le 1$ and

$$8\rho(\bar u)B \subset \left(\frac{\partial h_{I(\bar t,\bar x,\bar u)}}{\partial u}, \frac{\partial g}{\partial u}\right)(\bar t,\bar x,\bar u)\left(\overline{co}\,\{v_1,\ldots,v_s\}\right) + (\mathbf{R}^k_+ \cap B, 0).$$

From (32) we deduce that for some $\delta(\bar u) > 0$ and $\forall u \in U \cap B_{\delta(\bar u)}(\bar u)$

$$4\rho(\bar u)B \subset \left(\frac{\partial h_{I(\bar t,\bar x,\bar u)}}{\partial u}, \frac{\partial g}{\partial u}\right)(\bar t,\bar x,\bar u)\left(\overline{co}\,(T_U(u)\cap B)\right) + (\mathbf{R}^k_+ \cap B, 0).$$

By continuity of the derivative, we can choose $\delta(\bar u)$ in such a way that $\forall (t,x) \in B_{\delta(\bar u)}(\bar t,\bar x)$ and $u \in G(t,x)\cap B_{\delta(\bar u)}(\bar u)$

$$2\rho(\bar u)B \subset \left(\frac{\partial h_{I(\bar t,\bar x,\bar u)}}{\partial u}, \frac{\partial g}{\partial u}\right)(t,x,u)\left(\overline{co}\,(T_U(u)\cap B)\right) + (\mathbf{R}^k_+ \cap B, 0).$$

Using (4) and applying exactly the same arguments as those in the proof of Theorem 3.2 we conclude. □

Arguing as in Theorem 3.3 we deduce the following theorem.

THEOREM 3.8. *Under assumptions* (24), (27), and (33) *the closure of solutions to* (17), (18) *starting at* x_0 *is compact and equal to the set of solutions to the differential inclusion*

$$\begin{cases} x' &\in& \overline{co}\, f(t,x,G(t,x)), \\ x(t_0) &=& x_0. \end{cases}$$

Observe that Corollary 3.4 is still valid in this new situation. Define the set of admissible relaxed controls $\widehat{\mathcal{U}}_{hg}(t_0,T)$ as in subsection 3.1 with U as above.

COROLLARY 3.9. *Under assumptions* (24), (27), *and* (33) *the closure of solutions to* (17), (18) *starting at* x_0 *is compact and equal to the set of generalized curves of the control system* (17) *starting at* x_0 *and corresponding to the admissible relaxed controls* $\widehat{\mathcal{U}}_{hg}(t_0,T)$.

Consider next equality constraints (29) and the set-valued map (28). Assume that

$$\left\{\begin{array}{l} (\frac{\partial\varphi}{\partial t},\frac{\partial\varphi}{\partial x}) \text{ is locally Lipschitz,} \\ f \text{ is differentiable with respect to } u,\ \frac{\partial f}{\partial u} \text{ is continuous, and} \\ \forall\, u\in G(t,x),\quad \frac{\partial\varphi}{\partial x}(t,x)\frac{\partial f}{\partial u}(t,x,u)(C_U(u)) = \mathbf{R}^p. \end{array}\right. \tag{35}$$

Define g by (22). From Theorem 3.8 we get the following theorem.

THEOREM 3.10. *Under assumptions* (27), (31), *and* (35), *the closure of solutions to* (17), (29) *starting at* x_0 *is compact and equal to the set of solutions to the differential inclusion*

$$\left\{\begin{array}{rcl} x' & \in & \overline{co}\, f(t,x,G(t,x)), \\ x(t_0) & = & x_0. \end{array}\right.$$

Define the set of admissible relaxed controls $\widehat{\mathcal{U}}_\varphi(t_0,T)=\mathcal{U}_{hg}(t_0,T)$ as in subsection 3.1 with U as above, $h=-1$, and g given by (22). Then we have the corollary below.

COROLLARY 3.11. *Under assumptions* (27), (31), *and* (35), *the closure of solutions to* (17), (29) *starting at* x_0 *is compact and equal to the set of generalized curves of the control system* (17) *starting at* x_0 *and corresponding to the admissible relaxed controls* $\widehat{\mathcal{U}}_\varphi(t_0,T)$.

4. Control-independent inequality constraints. In this section we subject the control-trajectories pairs to the constraints

$$x\in\overline{\Theta},\quad h(t,x,u)\le 0,\quad g(t,x,u)=0, \tag{36}$$

where $\Theta\subseteq\mathbf{R}^n$ is an open subset and $\overline{\Theta}$ denotes its closure (in view of subsection 3.2 the case of a constraint of the form $\varphi(t,x)=0$ is already covered by this formulation). Observe that Θ is control independent. For instance, it may be given by

$$\overline{\Theta}:=\{x\in\mathbf{R}^n\ :\ k(x)\le 0\},$$

with $k\in C(\mathbf{R}^n)$. Since $\frac{\partial k}{\partial u}(x)=0\ \forall x\in\mathbf{R}^n$, we cannot apply any longer the techniques of section 3. To relax (17), (36) we use a result from [17] on the existence of admissible trajectories which keep a controlled distance from a given (generally not admissible) trajectory. Consider a set-valued map F from $[t_0,T]\times\mathbf{R}^n$ into the subsets of $\mathbf{R}^n$, and let F verify hypotheses (13) and (14). For each subset $A\subseteq\mathbf{R}^n$ and each constant $\rho\ge 0$, let $B(A,\rho)$ denote the set $\{y\in\mathbf{R}^n\mid d(y,A)\le\rho\}$. Let us consider assumption (H) below on the behavior of F near $\partial\Theta$.

Hypothesis (H).

1. $\Theta=\Theta_1\cap\Theta_2$, where Θ_1 and Θ_2 are open subsets verifying the following conditions, respectively:

2. there exist constants η,q,r and a continuous selection $\alpha(t,x)\in F(t,x)$ defined on $[t_0,T]\times B(\partial\Theta_1,\eta)$ such that at any $(t,x)\in[t_0,T]\times(\Theta_1\cap B(\partial\Theta_1,\eta))$ one has

$$B(x+s\alpha(t,x),sr)\subset\Theta_1$$

$\forall s\in]0,q]$;

3. $\forall(t,x)\in[t_0,T]\times\partial\Theta_2$ one has $0\in F(t,x)$; moreover, there is $\delta>0$ such that $\forall(t,x)\in[t_0,T]\times\partial\Theta_2$ there exists a closed proper cone V and $\varepsilon>0$ such that

$$(x+V_\varepsilon)\cap B(x,\delta)\cap\overline{\Theta}_2=\{x\}\quad\text{and}\quad F(s,y)\subseteq V$$

$\forall (s,y) \in B((t,x);\delta) \cap ([t_0,T] \times \overline{\Theta}_2)$, where V_ε denotes the ε-conical neighborhood of V; i.e.,

$$V_\varepsilon := \left\{ \lambda \left(\frac{v}{\|v\|} + B(0,\varepsilon) \right), \quad \lambda > 0, \quad v \in V \backslash \{0\} \right\}.$$

Remark. Condition H1 is a generalization of a condition originally introduced by M. Soner [20]. For a control system with fixed control set and for a smooth Θ he used such a condition to prove the continuity of the value function of an infinite horizon problem. Later the condition was adapted to nonsmooth constraint sets by H. Ishii and S. Koike [13], while the generalization to differential inclusion is provided in [10]. In the same framework as Soner's, condition H2 was used by P. Loreti [15] for relaxation purposes as well. Finally, condition H3 has been introduced in [17]. □

THEOREM 4.1 (see [17]). *Let the map F be locally Lipschitz (in both variables) with compact values and let hypothesis* (H) *be in force. Then, for any compact subset $Q \subseteq \overline{\Theta}$ there exists a positive constant C such that $\forall x_0 \in Q$, and for any solution $x(\cdot)$ of the Cauchy problem*

$$x'(t) \in F(t,x(t)), \qquad x(t_0) = x_0$$

(*possibly violating the constraint $x(t) \in \overline{\Theta}$*) *there is a solution $z(\cdot)$ of the same Cauchy problem such that*

$$z(t) \in \overline{\Theta} \quad \forall\, t \in [t_0,T] \quad \textit{and} \quad \sup_{t\in[t_0,T]} \|x(t) - z(t)\| \le C \sup_{t\in[t_0,T]} d(x(t),\Theta).$$

As a corollary of Theorem 4.1 we obtain the following analogue of the Filippov–Ważewski theorem for differential inclusion with state constraints. Denote by $\mathcal{S}^{\overline{\Theta}}_{[t_0,T]}(x_0)$ the set of solutions to the differential inclusion (11) that verify the state constraint $x(t) \in \overline{\Theta}$ for every $t \in [t_0,T]$.

THEOREM 4.2. *Let the map F be locally Lipschitz with compact values and let hypothesis* (H) *be in force. Then the closure of $\mathcal{S}^{\overline{\Theta}}_{[t_0,T]}(x_0)$ is compact and equal to the set of solutions to the relaxed inclusion* (12) *that verify the constraint $x(t) \in \overline{\Theta}$ for every $t \in [t_0,T]$.*

Remark. By assuming a smoothness hypothesis on $\partial\Theta$, it is possible to replace the Lipschitz condition on F with the weaker conditions (13), (14) (see [17]). Similarly, when the boundary is smooth, the Lipschitz hypothesis on f in all theorems below can be replaced by the weaker conditions (27). □

Proof. Since $\mathcal{S}^{\overline{\Theta}}_{[t_0,T]}(x_0) \subseteq \mathcal{S}_{[t_0,T]}(x_0)$, from Theorem 2.5 it follows that the closure of $\mathcal{S}^{\overline{\Theta}}_{[t_0,T]}(x_0)$ is compact and is contained in the set of the solutions to the relaxed inclusion (12) that verify the constraint $x(t) \in \overline{\Theta}$ for every $t \in [t_0,T]$. Let us prove the converse inclusion. We may assume that the constant C appearing in Theorem 4.1 is greater than or equal to 1. Let us choose an $\varepsilon > 0$ and a trajectory $y(\cdot)$ of the relaxed inclusion (12) satisfying the constraint $y(t) \in \overline{\Theta}$. By the Filippov–Ważewski theorem (Theorem 2.5) one can find a trajectory $x(\cdot)$ of the differential inclusion (11) such that $\|x(t) - y(t)\| \le \varepsilon/2C$ for every $t \in [t_0,T]$. Observe that in general $x(\cdot)$ violates the constraints. However, in view of Theorem 4.1 a trajectory $z \in \mathcal{S}^{\overline{\Theta}}_{[t_0,T]}(x_0)$ can be found that verifies $\|z(t) - x(t)\| \le Cd$ for every $t \in [t_0,T]$, with $d := \sup\{d(x(t),\Theta) | t \in [t_0,T]\}$. Since $d \le \|x(t) - y(t)\|$ for all $t \in [t_0,T]$, we obtain that $\|z(t) - y(t)\| \le \varepsilon/2 + \varepsilon/2C \le \varepsilon$, so concluding the proof. □

In particular, we obtain the theorem below.

THEOREM 4.3. *Let us assume* (24), (33) *and that for every compact* $K \subset \mathbf{R}^n$*, there exists a constant* $L > 0$ *such that* $\forall u \in U$, $f(\cdot, \cdot, u)$ *is L-Lipschitz on* $[t_0, T] \times K$*, and let* $F(t,x) := f(t, x, G(t,x))$ *have compact values and verify hypothesis* (H)*. Then the closure of solutions to* (17), (36) *is compact and equal to the set of solutions to*

$$\begin{cases} x' & \in & \overline{co}\, f(t, x, G(t,x)), \\ x(t_0) & = & x_0, \ \ x(t) \in \overline{\Theta}. \end{cases}$$

Of course, by means of arguments quite similar to those exploited in the proof of Corollary 3.4 it is possible to reformulate the above theorem in terms of relaxed controls. Let us define the set $\widehat{\mathcal{U}}_{hg}^{\overline{\Theta}}(t_0, T)$ of relaxed controls by setting

$$\widehat{\mathcal{U}}_{hg}^{\overline{\Theta}}(t_0, T) := \{\mu \in \widehat{\mathcal{U}}(t_0, T) \mid x([t_0, T]) \subset \overline{\Theta}, \text{and, for almost all } \ t \in [t_0, T], \\ \mu - \text{ess sup}_{u \in U} \ h(t, x(t), u) \leq 0, \ \ \mu - \text{ess sup}_{u \in U} \ \|g(t, x(t), u)\| = 0\},$$

where x is a generalized curve of (17) corresponding to the relaxed control μ.

COROLLARY 4.4. *Under all the assumptions of Theorem* 4.3 *the closure of solutions to* (17), (36) *is compact and equal to the set of generalized curves of the control system* (17) *starting at* x_0 *and corresponding to the admissible relaxed controls* $\widehat{\mathcal{U}}_{hg}^{\overline{\Theta}}(t_0, T)$.

5. Applications. As an application of the results of the previous sections one finds that under suitable hypotheses the value function of the Mayer problem coincides with the value function of the relaxed Mayer problem. This was in fact the main motivation of the paper by E. N. Barron and J. Jensen [5].

Let us consider a function $\psi : \mathbf{R}^n \mapsto \mathbf{R}$ and the constrained control system

$$x'(t) = f(t, x(t), u(t)), \quad u(t) \in U, \tag{37}$$

$$h(t, x(t), u(t)) \leq 0, \quad g(t, x(t), u(t)) = 0 \quad \text{a.e. in } \ [t_0, T], \tag{38}$$

$$x(t) \in \overline{\Theta} \quad \text{in } \ [t_0, T], \tag{39}$$

where $f : [0, T] \times \mathbf{R}^n \times \mathcal{Z} \mapsto \mathbf{R}^n$ and h, g, $\mathcal{Z}$, U, Θ are as in Theorem 4.3. We consider the following minimization problem:

$$V(t_0, x_0) := \inf \ \{\psi(x(T)) \mid x \ \text{ solves } \ (37), \ (38), \ (39), \ x(t_0) = x_0\}.$$

The map V is called the *value function.* Consider the set-valued map $G(\cdot, \cdot)$ defined by (19) and the relaxed differential inclusion

$$x'(t) \in \overline{co}\, f(t, x, G(t,x)). \tag{40}$$

The value function of the relaxed problem is defined by

$$V^{co}(t_0, x_0) := \inf \ \{\psi(x(T)) \mid x \ \text{solves } \ (39), \ (40), \ x(t_0) = x_0\}. \tag{41}$$

THEOREM 5.1. *Let* ψ *be continuous and let the hypothesis of Theorem* 4.3 *be verified. Then the infimum in* (41) *is attained and* $V = V^{co}$*. Moreover,* V *is continuous.*

Proof. The existence of an optimal trajectory for the relaxed problem (41) is a standard result, which can be obtained via the so-called direct method (of course, for this purpose it is sufficient to assume that ψ is lower bounded and lower semicontinuous). As for the equality $V = V^{co}$, it is a straightforward consequence of Theorem 4.3 and of the continuity of ψ. The continuity of V was proved in [17]. □

Obviously, in view of the results of section 4, this theorem can be reformulated in terms of relaxed controls as well.

ERRATUM: "EXISTENCE OF MARKOV CONTROLS AND CHARACTERIZATION OF OPTIMAL MARKOV CONTROLS"*

THOMAS G. KURTZ† AND RICHARD H. STOCKBRIDGE‡

Abstract. A compactness condition used to establish the equivalence of infinite-dimensional linear programming problems with stochastic control problems in [*SIAM J. Control Optim.*, 36 (1998), pp. 609–653.] was misstated. The correct statement of the condition is given, as well as an example to show that the erroneous condition is not sufficient to obtain equivalence.

PII. S0363012998343033

An important condition in [2] is misstated, resulting in an error that may be seriously misleading to users of the results. Expression (6.1) on p. 644, which reads

$$\psi(u) \le a + bc(x,u) \quad \text{or} \quad \psi(u) \le a + bc(s,x,u), \tag{1}$$

should read

$$\psi(u) \le a + bc(x,u)^\beta \quad \text{or} \quad \psi(u) \le a + bc(s,x,u)^\beta, \tag{2}$$

where $0 < \beta < 1$, or slightly more generally,

$$\Phi(\psi(u)) \le a + bc(x,u) \quad \text{or} \quad \Phi(\psi(u)) \le a + bc(s,x,u), \tag{3}$$

where Φ is a *Young function*; that is, $\Phi : [0,\infty) \to [0,\infty)$, Φ is nondecreasing, and $\lim_{r\to\infty} \frac{\Phi(r)}{r} = \infty$.

Condition (vi) of the paper (p. 612) requires that for each $f \in \mathcal{D}(A)$, there exist constants a_f and b_f such that

$$|Af(x,u)| \le a_f + b_f\psi(u). \tag{4}$$

If $\mu_n \in \mathcal{P}(E \times U)$, $\mu_n \to \mu$ weakly, and $\sup_n \int_{E\times U} c(x,u)\mu_n(dx \times du) < \infty$, then (4), together with either (2) or (3), implies

$$\lim_{n\to\infty} \int_{E\times U} Af(x,u)\mu_n(dx \times du) = \int_{E\times U} Af(x,u)\mu(dx \times du). \tag{5}$$

In general, (5) will not hold if (2) and (3) are replaced by the weaker condition (1) as stated in the paper. The conclusion (5) is used explicitly and implicitly throughout section 6 of the paper.

We are, in fact, in the process of writing a second paper that will cover the situations in which (1) is satisfied but not (2) or (3). Such situations arise naturally in the context of singular control, where the conclusions of section 6 are not valid (or it would not be singular control). As a simple example, consider the classical linear regulator, $U = E = \mathbb{R}$, $\mathcal{D}(A) = C_c^2(\mathbb{R})$,

$$Af(x,u) = \frac{1}{2}f''(x) + uf'(x),$$

with running cost

$$c(x,u) = |x| + |u|.$$

The optimal solution to this problem, say for long run average cost, is reflecting Brownian motion on an interval $[-b, b]$. (See, for example, Karatzas [1].) An asymptotically optimal sequence of regular feedback controls is given by

$$u_n(x) = nI_{(-\infty,-b]}(x) - nI_{[b,\infty)}(x).$$

LAGRANGE MULTIPLIERS FOR NONCONVEX GENERALIZED GRADIENTS WITH EQUALITY, INEQUALITY, AND SET CONSTRAINTS[*]

JAY S. TREIMAN[†]

Abstract. A Lagrange multiplier rule for finite dimensional Lipschitz problems that uses a nonconvex generalized gradient is proven. This result uses either both the linear generalized gradient and the generalized gradient of Mordukhovich or the linear generalized gradient and a qualification condition involving the pseudo-Lipschitz behavior of the feasible set under perturbations. The optimization problem includes equality constraints, inequality constraints, and a set constraint. This result extends known nonsmooth results for the Lipschitz case.

Key words. Lagrange multipliers, nonsmooth analysis, generalized gradients, optimality conditions

1. Introduction.

In this paper we derive necessary conditions for a finite dimensional constrained optimization problem. The main differences between this and other work is that a small nonconvex generalized gradient is used in conjunction with the generalized gradient of Mordukhovich or with a geometric condition for problems with equality, inequality, and set constraints.

The basic tools used in this paper are the linear generalized gradient (LGG), [21, 22] and the generalized gradient of Mordukhovich and Ioffe (MGG) [7, 8, 9, 11, 13, 14, 15, 16, 17]. In finite dimensions both of these generalized gradients are defined through proximal subgradients. The LGG is always contained in the gradient of Mordukhovich. Both have a nice calculus, with that for LGG involving mostly Lipschitz functions. These generalized gradients are closely related to well known convex generalized gradients. For Lipschitz functions the closed convex hull of the LGG is the generalized gradient of Michel and Penot (MPGG) [10, 12, 19, 20], and the closed convex hull of MGG is the Clarke generalized gradient (CGG) [3, 4, 5].

Since LGG and MGG are generally not convex, they are smaller, respectively, than the generalized gradients of Michel and Penot and Clarke. In particular, this implies that any multiplier rules using these generalized gradients will be sharper when they apply.

There are several important differences between LGG and MGG. One major difference between these generalized gradients is that MGG is upper-semicontinuous (usc) as a multifunction [14], whereas LGG is not. Another difference is that if a function is Fréchet differentiable, then LGG is a singleton [22]. The corresponding condition for MGG is that MGG is a singleton if and only if a function is strictly differentiable [14].

When comparing the multiplier results in this paper with those involving MPGG or CGG it is often useful to consider situations where one generalized gradient is single valued. In order to do this we will use the facts that CGG is a singleton if

[†] Department of Mathematics and Statistics, Western Michigan University, Kalamazoo, MI 49008 (treiman@math-stat.wmich.edu).

and only if a function is strictly differentiable and MPGG is a singleton if a function is Gâteaux differentiable. This will be used to show that the results in this paper may be sharper than those using only MPGG, MGG, or CGG for finite dimensional Lipschitz problems. The basic problem considered in this paper is

$$(*) \qquad \begin{array}{lll} \min f(x) \quad \text{subject to} & g_i(x) \leq 0, & i = 1, 2, \ldots, m, \\ & h_j(x) = 0, & j = 1, 2, \ldots, k, \quad \text{and} \\ & x \in U. & \end{array}$$

Here all of the functions are Lipschitz functions from $\mathbb{R}^n$ to $\mathbb{R}$ and U is a closed subset of $\mathbb{R}^n$. This is a fairly general problem that includes the problem in [21] and the finite dimensional version of the problem in [10]. It is not as general as the problem considered by Mordukhovich [14] since the functions are Lipschitz.

The main optimality condition presented in this paper is a Lagrange multiplier result that uses both LGG and MGG or LGG and a geometric condition. It is sharper than the results of Mordukhovich for (*), but it is weaker in the sense that lower-semicontinuous (lsc) functions are not included. In one version of the result, the MGG is used for the equality constraints and LGG is used for all other functions. Under a pseudo-Lipschitz condition on the behavior of the feasible sets for the equality constraints, one can replace MGG with LGG for the equality constraints. This condition on the constraints is similar to conditions used by Mordukhovich and others.

The pseudo-Lipschitz condition used in this paper is equivalent to a condition using MGG. Our emphasis on the geometric condition makes it clearer that the results involving only LGG do not require the upper-semicontinuity of MGG.

The first section of this paper is an introduction to the definitions and calculus of LGG and MGG. In the second section several technical results showing how equality constraints relate to generalized gradients are proven. The third section is devoted to the main result and several of its corollaries and to a discussion of the relationship with other results. Finally it is shown how one can use our results in a natural setting, bilevel programming.

2. Basic definitions and results.

In order to prove the Lagrange multiplier results we use some calculus results for the generalized gradients in this paper. The proofs of the multiplier results in this paper use the definitions and most of the results in this section. They are all proven elsewhere. *For the results involving MGG the reference* [14] *is usually cited, although many of the results are also in* [16] *and other papers of Ioffe and Mordukhovich.* The basic objects used to define both the LGG and the MGG are the proximal normal and proximal subgradient. For our purposes the definition is restricted to $\mathbb{R}^n$. There are similar ways to define the MGG in Banach spaces. First we define proximal normals and proximal subgradients.

DEFINITION 2.1. *Let $C \subset \mathbb{R}^n$ be a closed set and let $f : \mathbb{R}^n \to \mathbb{R}$ be lsc. A $v \in \mathbb{R}^n$ is a proximal normal to C at $x \in C$ if, for some $\lambda > 0$,*

$$C \cap \bar{B}(x + \lambda v, \lambda\|v\|) = \{x\}.$$

Here $\bar{B}(x, \rho)$ is the closed ball centered at x with radius ρ. A $w \in \mathbb{R}^n$ is a proximal subgradient to f at x if, for some μ,

$$f(y) \geq f(x) + \langle w, y - x\rangle - \mu\|y - x\|^2$$

on a neighborhood of x.

These definitions have been used to characterize a number of generalized gradients and normal cones [3, 4, 5, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22]. They are also used, through normal cone definitions, to define co-derivatives [14, 15, 16, 17, 21, 22]. An element of the normal cone of Mordukhovich is defined as the limit of a sequence of proximal normals [11, 14]. To define the linear normal cone one restricts which sequences of proximal normals are allowed.

Definition 2.2. *A sequence of proximal normals $v^k \to v$ to a closed set $C \subset \mathbb{R}^n$ at $x^k \to \bar{x}$ is linear if either $x^k \neq \bar{x}$ for all k and, for some $\lambda > 0$ and all sufficiently large k,*

$$C \cap \bar{B}\left(x^k + \lambda \|x^k - \bar{x}\| v^k, \lambda \|x^k - \bar{x}\| \, \|v^k\|\right) = \{x^k\},$$

or $x^k = \bar{x}$ for all k.

This simply says that the size of the balls defining the proximal normals can be taken as a constant times the distance from x^k to $\bar{x}$. The effect of this is similar to the restriction on the length of vectors when defining MPGG.

With this definition we now define the normal cones.

Definition 2.3. *Let C be a closed subset of $\mathbb{R}^n$. The linear normal cone LNC to C at $\bar{x}$* [22] *is*

$$N_\ell C\bar{x} := \mathrm{cl}\{v : v \textit{ is the limit of a linear sequence of proximal normals to } C \textit{ for } \bar{x}\}.$$

The Mordukhovich normal cone MNC to C at $\bar{x}$ [14] *is*

$$N_M C\bar{x} := \{v : v \textit{ is the limit of a sequence of proximal normals to } C \textit{at } x^k \to \bar{x}\}.$$

It is clear from this definition that MNC always contains LNC. One may also note that MNC is closed without taking the closure of the set of limits of proximal normals. Now we define the generalized gradients. Here $x^k \to_f x$ means that $x^k \to x$ and $f(x^k) \to f(x)$. In what follows, $\|x - y\|_f = \|x - y\| + |f(x) - f(y)|$.

Definition 2.4. *A sequence of proximal subgradients $v^k \to v$ to a lsc f at $x^k \to \bar{x}$ is linear for $\bar{x}$ or linear if either $x^k = \bar{x}$ for all k or $x^k \to_f \bar{x}$, $x^k \neq \bar{x}$ and there exist $\mu, \delta > 0$ such that*

$$f(x^k + h) \geq f(x^k) + \langle v^k, h \rangle - \frac{\mu}{\|x^k - \bar{x}\|_f} \|h\|^2$$

on $B(x^k, \delta \|x^k - \bar{x}\|_f)$.

As with the normal cone, the definition of the linear generalized gradient uses this restricted convergence. One removes this restriction on sequences of proximal subgradients to get MGG.

Definition 2.5 (see [14, 22]). *Let $f : \mathbb{R}^n \to \mathbb{R}$ be lsc. The LGG to f at $\bar{x}$ is the set*

$$\partial_\ell f(\bar{x}) := \mathrm{cl}\{v : v \textit{ is the limit of a linear sequence of proximal subgradients to } f \textit{ for } \bar{x}\}.$$

The MGG to f at $\bar{x}$ is the set

$$\partial_M f(\bar{x}) := \mathrm{cl}\{v : v \textit{ is the limit of a sequence of proximal subgradients to } f \textit{ at } x^k \to \bar{x}\}.$$

As was stated in the introduction, if a function is Fréchet differentiable at a point, LGG is a singleton. This means that for some problems our results will be finer than those using MGG or CGG.

In addition, this generalized gradient can be smaller than MPGG. A simple example is $f(x) = -|x|$. For this function MPGG is $[-1, 1]$ whereas LGG is $\{-1, 1\}$. This means that results using LGG are different than those using MPGG for equality or inequality constraints. Additionally, since LGG is not convex, it can be used more successfully for set constraints. A simple set is the graph of $f(x) = |x|$. At the corner in the graph of $f(x) = |x|$ the normal cone for MPGG is $\mathbb{R}^2$, whereas the LNC is $\{(x, y) : |y| = |x| \text{ or } y \leq |x|\}$. The results for LGG do not coincide with MPGG multiplier results in finite dimensions.

As one hopes, there is a close relationship between these generalized gradients and the corresponding normal cones. In what follows, $\delta_C(x)$ is the indicator function of C,

$$\delta_C(x) = \begin{cases} 0 & \text{if } x \in C, \\ +\infty & \text{otherwise,} \end{cases}$$

and $d(C, x)$ is the distance from x to C.

Theorem 2.6 (see [14, 22]). *Let C be a closed subset of $\mathbb{R}^n$. Then*

$$\partial_\ell \delta_C(\bar{x}) = N_\ell C \bar{x}$$

and

$$\partial_M \delta_C(\bar{x}) = N_M C \bar{x}.$$

Theorem 2.7 (see [14, 22]). *If C is a closed set in $\mathbb{R}^n$, then*

$$N_\ell C \bar{x} = \mathrm{cl} \cup_{\lambda \geq 0} \lambda \partial_\ell d(C; \bar{x})$$

and

$$N_M C \bar{x} = \cup_{\lambda \geq 0} \lambda \partial_M d(C; \bar{x}).$$

Even with the restriction to linear convergence, the calculus for LGG is fairly rich. It includes a sum rule, a chain rule, and a variety of other results. Only a few results are stated here. It is important to note that some kind of Lipschitz behavior is used in all of these results. The results for MGG are valid in more general situations than those stated here.

Theorem 2.8 (see [7, 14, 22]). *Let f be a lsc function from $\mathbb{R}^n$ to $\mathbb{R}$ and let g be a Lipschitz function from $\mathbb{R}^n$ to $\mathbb{R}$. Then if $f(\bar{x})$ is finite,*

$$\partial_\ell (f + g)(\bar{x}) \subset \partial_\ell f(\bar{x}) + \partial_\ell g(\bar{x})$$

and

$$\partial_M(f+g)(\bar{x}) \subset \partial_M f(\bar{x}) + \partial_M g(\bar{x}).$$

There are rules for positive multiples of a function.

PROPOSITION 2.9 (see [14, 22]). *Let f be a lsc function from $\mathbb{R}^n$ to $\mathbb{R}$ and let $\alpha \geq 0$. Then if $f(\bar{x})$ is finite,*

$$\partial_\ell(\alpha f)(\bar{x}) = \alpha \partial_\ell f(\bar{x})$$

and

$$\partial_M(\alpha f)(\bar{x}) = \alpha \partial_M f(\bar{x}).$$

The following rule will be used in the next section to get an inclusion for the normal cone to the product of sets.

THEOREM 2.10 (see [14, 22]). *Let $f : \mathbb{R}^n \to \mathbb{R}$ be lsc and let $g : \mathbb{R}^m \to \mathbb{R}$ be locally Lipschitz. If f is finite at $\bar{x}$, then*

$$\partial_\ell(f(\bar{x}) + g(\bar{y})) \subset \partial_\ell f(\bar{x}) \times \partial_\ell g(\bar{y})$$

and

$$\partial_M(f(\bar{x}) + g(\bar{y})) = \partial_M f(\bar{x}) \times \partial_M g(\bar{y}).$$

The most basic optimality condition holds for the LGG. Without this result a generalized gradient is not very useful for optimization. We, of course, need it in the proof of the main result.

PROPOSITION 2.11 (see [14, 22]). *If $f : \mathbb{R}^n \to \mathbb{R}$ is lsc and $\bar{x}$ is a local minimizer of f, then*

$$0 \in \partial_\ell f(\bar{x}) \quad \textit{and} \quad 0 \in \partial_M f(\bar{x}).$$

The next result concerns the LGG for the maximum of a finite collection of functions. This type of result is often used to prove calculus rules and Lagrange multiplier rules [21]. It is important in the proof of the main theorem. A similar result holds for MGG [14].

THEOREM 2.12. [21] *Let $g_1, g_2, \ldots, g_n$ be a finite collection of Lipschitz functions from $\mathbb{R}^m$ to $\mathbb{R}$. Then*

$$\partial_\ell \max_{i=1,2,\ldots,n} g_i(x) \subset \left\{ \sum_{i=1,2,\ldots,n} \lambda_i \partial_\ell g_i(x) : \lambda_i \geq 0,\ \lambda_i = 0 \textit{ if } i \notin I(x) \textit{ and } \sum_{i \in I(x)} \lambda_i = 1 \right\},$$

where $I(x) = \{i : g_i(x) = \max_{j=1,\ldots,n} g_j(x)\}$.

3. Equalities and generalized gradients. The basic technique for handling equality constraints in this paper is to rewrite the equality constraints as indicator functions of level sets for the functions. If one can rewrite the generalized gradients of these indicator functions in terms of the generalized gradients of the original functions, one can prove Lagrange multiplier results. This is what we do.

In this section we relate the normal cone to the level set of a function and the generalized gradient of that function. This result is a generalization of the standard result that a normal to the intersection of the level sets of a finite number of C^1 functions with linearly independent derivatives is a linear combination of their derivatives. As is noted by Rockafellar [18], this type of result is not very useful when a generalized gradient is convex.

The basic result we wish to prove is that the normal cone to a set of the form $\{x : h_j(x) = 0,\ j = 1, 2, \ldots, m\}$ is contained in the positive linear combinations of the generalized gradients of the h_j's. This result is not true without some condition. The condition used here corresponds to the linear independence of the derivatives in classical results.

First we look at the case of a single function. The classical result is that the normal cone is the multiples of the gradient of h if $\nabla h(x) \neq 0$. Since $\partial h(x) \neq -\partial(-h)(x)$, it is not surprising that the classical condition $\nabla h(x) \neq 0$ is replaced by the condition that $0 \notin \partial h(x) \cup \partial(-h)(x)$.

We prove only the results in this section for LGG. The same or similar results hold for MGG with simpler proofs. The results for MGG are stated without proofs.

PROPOSITION 3.1. *Assume h is a Lipschitz function from $\mathbb{R}^n$ to $\mathbb{R}$ with $h(\bar{x}) = 0$. Let $C = \{x : h(x) = 0\}$. If $0 \notin \partial_\ell h(\bar{x}) \cup \partial_\ell(-h)(\bar{x})$, then*

$$N_\ell C\bar{x} \subset \cup_{\alpha\in\mathbb{R}} \partial_\ell(\alpha h)(\bar{x}).$$

If $0 \notin \partial_M h(\bar{x}) \cup \partial_M(-h)(\bar{x})$, then [14]

$$N_M C\bar{x} \subset \cup_{\alpha\in\mathbb{R}} \partial_M(\alpha h)(\bar{x}).$$

Proof. Note that $P = \partial_\ell h(\bar{x}) \cup \partial_\ell(-h)(\bar{x})$ is a closed set since h is Lipschitz and all proximal subgradients must have norm at most L, the Lipschitz constant for h. Since $0 \notin P$, P is bounded away from zero. Thus $P' = \cup_{\alpha\geq 0}\alpha P$ is a closed cone. If the set of all limits of linear sequences of proximal normals to C at $\bar{x}$ is in P', the result follows.

Let $v \notin P'$ be the nonzero limit of a linear sequence of proximal normals to C at $\bar{x}$. Then there are $v^k \to v$ such that either each v^k is a proximal normal to C at $\bar{x}$ or the v^k's form a linear sequence of proximal normals to C at $x^k \to \bar{x}$ with $x^k \neq \bar{x}$. The two cases are similar. Only the latter, more difficult case is considered.

Since $v \neq 0$, one may assume that $v^k \neq 0$ for all k. Assume that for some $\mu > 0$,

$$C \cap \bar{B}(x^k + \mu_k v^k, \mu_k\|v^k\|) = \{x^k\}$$

where $\mu_k = \mu\|x^k - \bar{x}\|$. Since h is continuous and nonzero on $B(x^k + \mu_k v^k, \mu_k\|v^k\|)$, it has constant sign there. Assume h is positive on this set. If it is negative, work with $-h$.

To simplify notation, let $z^k = x^k + \mu_k v^k/2$ and $\rho_k = \mu_k\|v^k\|/2$.

For each k define a function $r^k_{\delta,\omega}$,

$$r^k_{\delta,\omega}(x) = \omega + \begin{cases} 0 & \text{if } 0 \leq \|x - z^k\| < \rho_k, \\ -\frac{(\|x-z^k\|-\rho_k)^2}{\rho_k \delta} & \text{if } \rho_k \leq \|x - z^k\| < (1 + L\delta)\rho_k, \\ -L^2(\|x - z^k\| - (1 + L\delta)\rho_k) - L^2\delta\rho_k & \text{otherwise.} \end{cases}$$

By definition, when $\omega \leq 0$, $r^k_{\delta,0}(x)$ is less than h if $x \in B(z^k, \rho_k)$ or $\|x - z^k\| > (1 + L\delta)\rho_k$. Let U^k_δ be the set

$$U^k_\delta = \bar{B}(z^k, (1 + L\delta)\rho_k)\backslash B(x^k + \mu_k v^k, \mu_k\|v^k\|).$$

Note that for each k the gradient of $r^k_{\delta,\omega}$ at any x is either zero or in the direction from x to z^k. As $\delta \searrow 0$, the gradients of $r^k_{\delta,\omega}$ on U^k_δ are independent of ω and converge uniformly to points on the line segment $[0, 2L] \cdot \frac{v^k}{\|v^k\|}$.

For each k, there is a maximum $\omega_k \leq 0$ such that $r^k_{\delta,\omega_k}(x) \leq h(x)$ for all x. For this ω_k, if $r^k_{\delta,\omega_k}(y^k) = h(y^k)$, then the gradient w^k of r^k_{δ,ω_k} at y^k is a proximal subgradient to h at y^k. In addition, the w^k's form a linear sequence of proximal subgradients to h at $y^k \to \bar{x}$.

For a fixed δ, by passing to a subsequence, one can assume that the w^k's converge to some $w^\delta \in \partial_\ell h(\bar{x})$. Since $0 \notin \partial_\ell h(\bar{x})$, the w^δ's are bounded away from 0. Taking a sequence of δ's converging to zero and passing if necessary to a subsequence, there is a $w \in \partial_\ell h(\bar{x})$ such that $v = \lambda w$ for some $\lambda > 0$.

This completes the proof by contradicting that $v \notin P'$. □

If one assumes the function h is Fréchet differentiable at $\bar{x}$, this result reduces to the conculsion that the LNC to $C = \{x : h(x) = h(\bar{x})\}$ at $\bar{x}$ is a single line if $\nabla h(\bar{x}) \neq 0$.

The following proposition is needed for the main technical result of this section, Proposition 3.4. It relates the normal cone to the product of sets to the product of the normal cones. Unlike MNC, this will not be an equality except for special sets where one can control convergence rates for all sets and sequences at the same time.

PROPOSITION 3.2. *Let $C_1, C_2, \ldots, C_k$ be closed subsets of $\mathbb{R}^n$ and let $C_0 = C_1 \times C_2 \times \cdots \times C_k \subset \mathbb{R}^{nk}$. Then*

$$N_\ell C_0(x, x, \ldots, x) \subset N_\ell C_1 x \times N_\ell C_2 x \times \cdots \times N_\ell C_k x$$

and [14]

$$N_M C_0(x, x, \ldots, x) = N_M C_1 x \times N_M C_2 x \times \cdots \times N_M C_k x.$$

Proof. The first part can be proven by a simple direct argument using the fact that $\|x_i\| \leq \|(x_1, x_2, \ldots, x_n)\|$ to generate linear sequences of proximal normals for each C_i from a linear sequence of proximal normals to C_0. The result for $N_M Cx$ has a simple direct proof in the reference. □

In Proposition 3.4 the normal cone to an intersection of sets is expressed in terms of the sum of the normal cones to the original sets. Simple examples show that some condition on the sets is required for this type of result.

Example 3.1. Let $X = \mathbb{R}^2$ and take $C_1 = \bar{B}((0, 1), 1) \cup \bar{B}((0, -1), 1)$ and $C_2 = \{(x, 0) : x \in \mathbb{R}\}$. Here C_1 is the union of two closed balls that are tangent and intersect at the origin. The tangent to the balls at the origin is C_2. This means that $C = C_1 \cap C_2 = \{(0,0)\}$, $N_\ell C_1(0,0) = \{(0,0)\}$, $N_M C_1(0,0) = N_\ell C_2(0,0) = N_M C_2(0,0) = \{(0,y) : y \in \mathbb{R}\}$, and $N_\ell C(0,0) = N_M C(0,0) = \mathbb{R}^2$. Clearly the sum of the normal cones does not contain the normal cone of the intersection.

The condition used in this paper involves the behavior of all of the level sets near the point of interest. There are different ways of expressing this condition. Each is interesting in its own right.

Take $C_1, C_2, \ldots, C_k$ to be closed subsets of $\mathbb{R}^n$. Let $\Phi(v)$ be the set valued function from $\mathbb{R}^{nk}$ to $\mathbb{R}^n$ defined by

$$\Phi(v) = \cap_{i=1}^k (C_i + v_i).$$

The condition is that Φ is pseudo-Lipschitz at $(0, \bar{x})$. Aubin [2] introduced the concept of a pseudo-Lipschitz multifunction. A multifunction $\Omega(v)$ is pseudo-Lipschitz at (v, z) with $z \in \Omega(v)$ if there are neighborhoods V of v and Z of z and a $c > 0$ such that for any v_1 and v_2 in V,

$$\Omega(v_1) \cap Z \subset \Omega(v_2) + c\|v_1 - v_2\|\, B(0,1).$$

Among other things, this implies that Ω is nonempty on V.

If, in our problem, there is only one equality or set constraint, the multifunction Φ is automatically pseudo-Lipschitz. This is easy to see since $\Phi(v)$ will be a linear translation of a single set. Another situation where Φ is pseudo-Lipschitz is where there is no set constraint, all of the equality constraints are C^1, and their gradients are linearly independent. This is a classical constraint qualification.

This pseudo-Lipschitz condition on Φ can also be expressed as saying the set valued function

$$\Psi(w) = D \cap \big((C_1 + w_1) \times (C_2 + w_2) \times \cdots \times (C_k + w_k)\big),$$

with $D = \{(x, x, \ldots, x) \in \mathbb{R}^{nk} : x \in \mathbb{R}^k\}$, is pseudo-Lipschitz at $\bar{x}^k = \big((0,0,\ldots,0), (\bar{x}, \bar{x}, \ldots, \bar{x})\big)$. We use this version of the pseudo-Lipschitz condition in the proofs of Propositions 3.3 and 3.4. In this setting it is easier to relate the normal cone of the intersection to the normal cones of the individual sets.

This type of condition and its relationship to MGG and MNC are discussed in [15, 17]. Using Theorem 4.1 in [17], one can show that a sufficient condition for $\Phi(v)$ to be pseudo-Lipschitz is

$$N(D, \bar{x}^k) \cap N_M \mathrm{gph} H \bar{x}^k = \{0\},$$

where $H(x) = (h_1(x), h_2(x), \ldots, h_k(x))$. One can also use the following sufficient condition for Φ to be pseudo-Lipschitz:

$$N(D, \bar{x}^k) \cap N_M C_1 \times C_2 \times \cdots \times C_k \bar{x}^k = \{0\},$$

where $\bar{x}^k = (\bar{x}, \bar{x}, \ldots, \bar{x})$. Rewriting this yields

$$\sum\nolimits_{i=1,2,\ldots,k}^{v_i \in N_M C_i \bar{x}} v_i = 0 \quad \text{implies} \quad v_i = 0, \quad i = 1, 2, \ldots, k.$$

These conditions involving MNC are versions of the standard condition used in Mordukhovich's multiplier rule [14]. They are also used by other authors.

It turns out that this is also a necessary condition for $\Phi(v)$ to be pseudo-Lipschitz. We will use the next result throughout the rest of the paper in proofs and to state results in terms of the pseudo-Lipschitz property.

PROPOSITION 3.3. *Let Φ be as above. The multifunction Φ is pseudo-Lipschitz at $\bar{x}$ if and only if*

$$(\mathcal{C}) \qquad N(D,\bar{x}^k)\cap N_M C_1\times C_2\times\cdots\times C_k\bar{x}^k=\{0\}.$$

Proof. The sufficiency follows from Theorem 4.1 of [17] using $F:\mathbb{R}^k\times\mathbb{R}^n\to\mathbb{R}^{nk}$ defined by

$$F(x_1,\dots,x_k,y)=(y-x_1-C_1,\dots,y-x_k-C_k),$$

$\lambda=\{0\}$, and $\Omega=\mathbb{R}^k\times\mathbb{R}^n\times\mathbb{R}^{nk}$. It can also be proven directly by noting that if Ψ is not pseudo-Lipschitz at $\bar{x}$, then there exist $x^p\to\bar{x}$ such that

$$\frac{d(C_1\times\cdots\times C_k,x^p)}{d(D\cap(C_1\times\cdots\times C_k),x^p)}\to 0.$$

Applying a variational argument yields a sequence of proximal normals to $C_1\times\cdots\times C_k$ at $y^p\to\bar{x}$ such that $\|v^p\|=1$ for all p and $v^p|_D\to 0$. The sufficiency follows. To prove the necessity we work with Ψ instead of Φ. Assume there is a

$$v\in N(D,\bar{x}^k)\cap N_M C_1\times C_2\times\cdots\times C_k\bar{x}^k\backslash\{0\}.$$

Then there are sequences v^j and x^j such that $x^j\to\bar{x}^k$, $v^j\to v$, and v^j is a proximal normal to $C_1\times C_2\times\cdots\times C_k$ at x^j. Note that $0\in\Psi(-x^j)$. If the rate of change of $d(0,\Psi(-x^j-\alpha v^j))$ as α increases from 0 can be made arbitrarily large for large j, then Ψ, and hence Φ, are not pseudo-Lipschitz at $\bar{x}$. Since v^j is a proximal normal to $C_1\times C_2\times\cdots\times C_k$ at x^j, $D\cap B(r_jv^j-\alpha v^j,r_j\|v^j\|)\cap\Psi(-x^j-\alpha v^j)=\emptyset$ for some fixed $r_j>0$ and for all $\alpha>0$. This implies, if θ_j is the angle between v^j and D, the rate of change of $d(0,\Psi(-x^j-\alpha x^j))$ as α increases at $\alpha=0$ is at least $\|v^j\|\tan(\theta_j)$. Since $\theta_j\to\pi/2$ as $j\to\infty$, Ψ is not pseudo-Lipschitz at $\bar{x}^k$. □

See Mordukhovich's work [13, 14, 15, 16] for more details and examples of this type of equivalence. The next result is the most important of this section. It and its corollary are used in the next section.

PROPOSITION 3.4. *Let $C_1,C_2,\dots,C_k$ be closed subsets of $\mathbb{R}^n$ and let $C=\cap_{j=1}^k C_j$. If $\Phi(v)$ is pseudo-Lipschitz at $(0,\bar{x})$, then*

$$N_\ell C\bar{x}\subset\sum_{j=1}^k N_\ell C_j\bar{x}$$

and

$$N_M C\bar{x}\subset\sum_{j=1}^k N_M C_j\bar{x}.$$

Proof. The proofs are almost identical for the LNC and MNC. Therefore, as usual, only the proof for the LNC is given. Using Theorem 2.6 we can work with the LGG of δ_{C_0} and δ_C rather than with the LNC. In addition, we work with $C_0=C_1\times C_2\times\cdots\times C_k$

and D. The case when there are proximal subgradients to δ_C at $\bar{x}$ is omitted because it is similar to what follows. Let $v \in N_\ell C\bar{x}$ and let $v^k \to v$ be a linear sequence of proximal subgradients to δ_C at $x^k \to \bar{x}$, $x^k \neq \bar{x}$. Take $y \in \mathbb{R}^{nk}$, $y^k = (x^k, x^k, \dots, x^k)$, $\bar{y} = (\bar{x}, \bar{x}, \dots, \bar{x})$, and $w^k = (v^k, v^k, \dots, v^k)$. Then, for some μ and ρ,

$$\delta_{C_0}(y) \geq \delta_{C_0}(y^k) + \langle w^k, y - y^k\rangle - \rho_k \|y - y^k\|^2$$

if $y \in D$, $\|y - y^k\| \leq \mu_k = \mu\|y^k - \bar{y}\|$, and $\rho_k = \rho/\|y^k - \bar{y}\|$. It is relatively simple to show that if the conditions of the proposition are met, there are $\lambda, \beta > 0$ such that, if $z^k = (z, z, \dots, z) \in C_0$ and $D \cap C_0 \cap (z^k + (0, \beta\mu\|z^k\|] \cdot \bar{B}(w^k, \lambda)) = \emptyset$, then

$$C_0 \cap (z^k + (0, \beta\mu\|z^k\|] \cdot \bar{B}(w^k, \lambda)) = \emptyset$$

for any z in the intersection of C and some neighborhood of $\bar{x}$. Fix $\epsilon > 0$. One may assume that the gradient of $\rho_k\|y - y^k\|^2 < \epsilon$ if $\|y - y^k\| < 2\beta\mu_k(\|v^k\| + \lambda)$. Choose an $\eta > 0$ such that if $d(y, D) = \lambda\mu_k\beta/2$ and $\|y_D - y^k\| \leq \beta\mu_k(\|v^k\| + \lambda)$, then

$$r_k(y) = \langle w^k, y - y^k\rangle - \rho_k\|y_D - y^k\|^2 - \eta_k(d(y, D))^2 < 0, \tag{3.1}$$

where y_D is the orthogonal projection of y onto D and $\eta_k = \eta/\|y^k - \bar{y}\|$.

This means that the function r_k in (3.1) is less than zero on the boundary of $S = B(y^k, \beta\mu_k(\|v^k\| + \lambda) \cap \{y : d(y, D) \leq \lambda\mu_k\beta/2\}$. Thus, for some $\omega < 0$, $r^k(y) + \omega \leq \delta_{C_0}(y)$ on S and equals $\delta_{C_0}(y)$ at some point z^k in the interior of S. The gradients of r^k at $z^k \to \bar{y}$ form a linear sequence of proximal subgradients to δ_{C_0}. Taking a subsequence, if necessary, one may assume that these converge to a v_ϵ such that the orthogonal projection of v_ϵ onto D satisfies $\|v_\epsilon - v\| \leq \epsilon$.

There are two situations. If, as $\epsilon \searrow 0$, a sequence of the v_ϵ's is bounded, then there is a $v_0 \in \partial_\ell\delta_{C_0}(\bar{y})$ whose orthogonal projection onto D is v. On the other hand, if no bounded sequence exists, then, by renorming to unit lengths, there is a $v_1 \in \partial_\ell\delta_{C_0}(\bar{y}) \subset \partial_M\delta_{C_0}(\bar{y})$ such that v_1 is orthogonal to D. This contradicts the condition involving the Mordukhovich cone before the propositions and hence contradicts our assumptions. This means that v_0 exists.

Since $N_\ell C_0\bar{y} \subset N_\ell C_1\bar{x} \times N_\ell C_2\bar{x} \times \cdots \times N_\ell C_k\bar{x}$ and the normal cone to D is $\{(w^1, w^2, \dots, w^k) : \sum_{i=1}^k w^i = 0\}$, the result follows. □

Finally comes the result that yields the multiplier rules in the next section. It relates the normal cone to a set defined by equality constraints to the generalized gradients of the constraints. An arbitrary set constraint is included to match the optimization problem in this paper.

Theorem 3.5. *Let $h_1, h_2, \dots, h_k$ be Lipschitz functions from $\mathbb{R}^n$ to $\mathbb{R}$ and let C_{k+1} be a closed subset of $\mathbb{R}^n$. Assume that $h_j(\bar{x}) = 0$ for $j = 1, 2, \dots, k$. Take $C_j = \{x : h_j(x) = 0\}$ and take $\Phi(v)$ as in Proposition* 3.5. *Assume $\Phi(v)$ is pseudo-Lipschitz at $(0, \bar{x})$. If $0 \notin \partial_\ell h_j(\bar{x}) \cup \partial_\ell(-h_j)(\bar{x})$ for $j = 1, 2, \dots, k$, then*

$$N_\ell C\bar{x} \subset \sum\nolimits_{\alpha_j \in \mathbb{R}}^{j=1,2\dots k} \partial_\ell(\alpha h_j)(\bar{x}) + N_\ell C_{k+1}\bar{x}.$$

If $0 \notin \partial_M h_j(\bar{x}) \cup \partial_M(-h_j)(\bar{x})$ for $j = 1, 2, \dots, k$, then [14]

$$N_M C\bar{x} \subset \sum\nolimits_{\alpha_j \in \mathbb{R}}^{j=1,2\dots k} \partial_M(\alpha h_j)(\bar{x}) + N_M C_{k+1}\bar{x}.$$

Proof. Apply Propositions 3.1 and 3.4 to the sets defined in the theorem. □

4. The main results. In this section Lagrange multiplier rules are given for the LGG that include equality constraints. Recall that the problem being considered is

$$\begin{aligned} &(4.1) \qquad && \min f(x) \quad \text{subject to} \quad && g_i(x) \leq 0, \quad i = 1, 2, \ldots, m, \\ &(*) && && h_j(x) = 0, \quad j = 1, 2, \ldots, k, \\ &(4.2) && && x \in U. \end{aligned}$$

All of the functions are Lipschitz functions from $\mathbb{R}^n$ to $\mathbb{R}$ and U is a closed subset of $\mathbb{R}^n$.

The main result in this section is related to Theorem 6.1.1 of Clarke [5], the theorem of Ioffe [10], and the generalized gradient interpretation of Theorem 7.5 of Mordukhovich [14]. All of those results state that if $\bar{x}$ is a minimizer of (*), then for some constants $\beta \geq 0$, $\lambda_i \geq 0$, $i = 1, 2, \ldots, m$, and α_J, $j = 1, 2, \ldots, k$, not all zero, one has

$$0 \in \partial \left(\beta f_0 + \sum_{i=1}^{m} \lambda_i g_i + \sum_{j=1}^{k} \alpha_J h_j \right) (\bar{x}) + N(U, \bar{x}).$$

Here ∂ represents either the CGG, the MPGG, or the MGG. The results of Clarke and Penot assume that all functions are Lipschitz. Clarke's results are finite dimensional, Ioffe's require that U is convex, and Mordukhovich only assumes that the functions are lsc. Mordukhovich's result is sharper than Clarkes since the CGG always contains the MGG. The results in this section are stronger than Theorem 7.5 of Mordukhovich [14] in that the LGG is used. On the other hand, the results are weaker because only Lipschitz functions are allowed. The results are sharper than the finite dimensional restriction of the theorem of Ioffe [10] in the sense that convexity is not required. For the result that only involves LGG the pseudo-Lipschitz behavior of $\Phi(v)$ is invoked instead of using the upper-semicontinuity of MGG or the convexity of MPGG. This means that the results do not compare directly with previous results. The Lagrange multiplier rule is now stated and a proof given. We again take $C_j = \{x : h_j(x) = 0\}$ for $j = 1, 2, \ldots, k$, $C = \cap_{j=1,2,\ldots,k} C_j \cap U$, and

$$\Phi(v) = \cap_{j=1,2,\ldots,k} (C_j + v_j) \cap (U + v_{k+1}).$$

THEOREM 4.1. *Let $\bar{x}$ be a minimizer of (*). Then there exist $\beta \geq 0$, $\lambda_i \geq 0$ and α_j, not all zero, such that $\lambda_i g_i(\bar{x}) = 0$ for all i and*

$$0 \in \beta \partial_\ell f(\bar{x}) + \sum_{i=1}^{m} \lambda_i \partial_\ell g_i(\bar{x}) + \sum_{j=1}^{k} \partial_M (\alpha_j h_j)(\bar{x}) + N_M U \bar{x}.$$

Proof. Apply Theorems 2.6, 2.8, and 2.12 to the function

$$\max\{f(x) - f(\bar{x}), g_1(x), g_2(x), \ldots, g_m(x)\} + \delta_C(x)$$

to get that

$$\begin{aligned} 0 &\in \beta \partial_\ell f(\bar{x}) + \sum_{i=1}^{m} \lambda_i \partial_\ell g_i(\bar{x}) + N_\ell C \bar{x} \\ &\subset \beta \partial_\ell f(\bar{x}) + \sum_{i=1}^{m} \lambda_i \partial_\ell g_i(\bar{x}) + N_M C \bar{x}, \end{aligned}$$

where either β or one of the λ's is not zero and $\lambda_i g_i(\bar{x}) = 0$ for all i. If $0 \in \partial_M h_j(\bar{x}) \cup \partial_M(-h_j)(\bar{x})$ for some j, the result is true. If

$$0 \notin \sum\nolimits_{(\alpha_1 \ldots \alpha_k) \neq 0}^{j=1^k} \partial_M(\alpha h_j)(\bar{x}) + N_M U\bar{x},$$

Theorem 3.5 applies to $N_M C\bar{x}$ since $\Phi(v)$ must be pseudo-Lipschitz. This also means that the result holds. □

Since $\partial_\ell s(x) \subset \partial_M s(x)$ for any function, one can replace the LGG in Theorem 4.1 with MGG to get the following restriction of Theorem 7.5 of Mordukhovich [14].
