$$

In the diagram (5.1), F denotes a maximal free submodule of M, for example, that generated by the elements $e_i + \mathcal{B}^{\perp}$, where e_i is the ith natural basis vector in $\mathcal{R}^{1,q}$, for each index i corresponding to an input component. The dual of M/F is $\mathcal{B}_{0,y}$, the dual of M/tM is $\mathcal{B}^c$, as already discussed, and the dual of $M/(tM \oplus F)$ is $\mathcal{B}^c \cap \mathcal{B}_{0,y} = (\mathcal{B}^c)_{0,y}$. Diagram (5.1) dualizes to (5.2).

$$

$$

Note that it is important not to confuse the zero-input behavior $(\mathcal{B}^c)_{0,y}$ with the behavior $(\mathcal{B}_{0,y})^c$. The latter is uninteresting as it is always zero, whereas the former in general is not, and we will henceforth write $\mathcal{B}^c_{0,y}$ for $(\mathcal{B}^c)_{0,y}$.

It is possible to regard the behavior $\mathcal{B}_{0,y}$ as the "pole module" of the system, though we feel that it would be more appropriate to give this name to the finitely generated module M/F to which $\mathcal{B}_{0,y}$ is dual. This terminology ties in loosely with that of Kalman [21], Conte and Perdon [6], and Wyman and Sain [45], and we could extend it to an "input decoupling zero module," etc., though there does not seem to be a strong link between the two sets of definitions. The significance of a "pole module" is that the pole points themselves are the points where the annihilator of the pole module vanishes. This interpretation is also possible in the earlier work of Kalman and others. The term "pole module," etc., has also been used by Bourlès and Fliess [4], where it is equivalent (for 1D systems) to the definition we have suggested; see also Pommaret and Quadrat [31].

One important consequence of our definitions is that the number of poles (and also the number of controllable poles and the number of uncontrollable poles) is finite. This follows from Theorem 4.7. Also, for any pole J, $V(J)$ is contained in the pole variety, and indeed the pole variety is the union of such $V(J)$'s, similarly for controllable and uncontrollable poles.

The following characterization of pole points is immediate from Theorem 4.4.

COROLLARY 5.2. *Let $\mathcal{B}$ be a behavior with a given input/output structure, and let $\underline{a}$ be a point in $\mathbb{C}^n$ $((\mathbb{C}\backslash 0)^n)$. Let $(-Q\ P)$ be a kernel representation of $\mathcal{B}$, where the submatrix P corresponds to the output variables. Then the following are equivalent:*

1. *$\underline{a}$ is a pole point of $\mathcal{B}$.*
2. *$P(\underline{a})$ has less than full column rank.*
3. *$\mathcal{B}_{0,y}$ contains a nonzero exponential trajectory of frequency $\underline{a}$.*

5.2. Controllable poles. The controllable poles (pole points, etc.) of $\mathcal{B}$ are poles (pole points, etc.) of the controllable part $\mathcal{B}^c$ of $\mathcal{B}$. Hence for any controllable pole point $\underline{a}$, there is an exponential trajectory $w(\underline{t}) \in \mathcal{B}^c_{0,y} \subseteq \mathcal{B}_{0,y}$ which can be concatenated with the zero trajectory in the sense of behavioral controllability, i.e., such a $w(\underline{t})$ can be controlled.

Recall that $\mathcal{B}^c$ is the unique minimal element of the transfer class of $\mathcal{B}$. Since there is a strong relationship between $\mathcal{B}^c$ and the transfer matrix G of $\mathcal{B}$, it is not surprising that the controllable pole points of a behavior are captured in the structure of its transfer matrix.

Not only the variety $V(\operatorname{ann} \mathcal{B}^c_{0,y})$ but also the ideal $\operatorname{ann} \mathcal{B}^c_{0,y}$ can be described via the transfer matrix, and this gives $\operatorname{ann} \mathcal{B}^c_{0,y}$ and also the corresponding coassociated primes a special structure.

THEOREM 5.3. *Let $\mathcal{B}$ be a behavior with a given input/output structure and transfer matrix G. Then we have*

$$\operatorname{ann} \mathcal{B}^c_{0,y} \;=\; \{r \in \mathcal{R} \;\mid\; rG \text{ is a polynomial matrix}\}. \tag{5.3}$$

In particular, $\operatorname{ann} \mathcal{B}^c_{0,y}$ *is principal, and indeed generated by the least common denominator of the entries of G. The controllable poles of $\mathcal{B}$ are also principal.*

Proof. Recall (3.6)

$$(\mathcal{B}^c_{0,y})^\perp \;=\; \{v \in \mathcal{R}^{1,p} \;\mid\; vG \in \mathcal{R}^{1,m}\}.$$

For any element v of $\mathcal{R}^{1,p}$, we therefore have

$$\operatorname{ann}\,(v + (\mathcal{B}^c_{0,y})^\perp) \;=\; \{r \in \mathcal{R} \;\mid\; (rv)G \in \mathcal{R}^{1,m}\}. \tag{5.4}$$

Taking the intersection of these sets for all $v \in \mathcal{R}^{1,p}$ gives us $\operatorname{ann} \mathcal{R}^{1,p}/(\mathcal{B}^c_{0,y})^\perp = \operatorname{ann} \mathcal{B}^c_{0,y}$, and thus we obtain (5.3). Furthermore, (5.4) also tells us that the annihilator of any $v + (\mathcal{B}^c_{0,y})^\perp$ is equal to (d), where d is the least common denominator of the entries of vG. In particular, each such annihilator is principal, including the coassociated primes of $\mathcal{B}^c_{0,y}$, which are the controllable poles. □

COROLLARY 5.4. *Let $\mathcal{B}$ be a behavior with a given input/output structure and transfer matrix G. Let $(-Q^c\ P^c)$ be a GFLP matrix such that $P^cG = Q^c$, e.g., P^c is square and $(P^c)^{-1}Q^c = G$ is a minor left coprime matrix fraction description of G, if such exists. Let $\underline{a} \in \mathbb{C}^n$ $((\mathbb{C}\backslash 0)^n)$. Then the following are equivalent:*

1. *$\underline{a}$ is a controllable pole point of $\mathcal{B}$.*
2. *$P^c(\underline{a})$ has less than full column rank.*
3. *The denominator of some entry of G vanishes at $\underline{a}$.*
4. *$\mathcal{B}^c_{0,y}$ contains a nonzero exponential trajectory with frequency $\underline{a}$.*

Proof. If $(-Q^c\ P^c)$ is GFLP and $P^cG = Q^c$, then $(-Q^c\ P^c)$ is a kernel representation of a controllable behavior with transfer matrix G, which is therefore the controllable part of $\mathcal{B}$. From [43, Cor. 7.9], any minor left prime matrix is GFLP, and therefore this situation particularly applies when $(P^c)^{-1}Q^c$ is a minor left coprime matrix fraction description of G.

P^c is then a kernel representation of $\mathcal{B}^c_{0,y}$ (up to trivial isomorphism), and the equivalence of 1, 2, and 4 now follows from Theorem 4.4. Condition 3 is immediate from (5.3) in Theorem 5.3. □

Note that the condition "the denominator of some entry of G vanishes at $\underline{a}$" can be expressed formally by the localization condition: $G \notin \mathcal{R}^{p,m}_{I(\underline{a})}$, where $I(\underline{a})$ is the maximal ideal corresponding to the point $\underline{a}$.

Corollary 5.4 also characterizes controllable pole points in terms of left matrix fraction descriptions (MFDs) of G; these must be minor left coprime for the characterization to apply, and not every transfer matrix has a minor left coprime MFD. The same characterization can be applied to right MFDs, since it is known that if $P^{-1}Q = \overline{Q}\overline{P}^{-1}$ are minor left coprime and minor right coprime MFDs of a transfer matrix, then $|P| = |\overline{P}|$ to within a unit [19, Thm. 2.12].

This correspondence between the controllable pole points and the transfer matrix is similar to the classical 1D characterization of transmission poles. However, transmission poles are defined with respect to a state-space representation, and so it is not accurate to identify controllable pole points with transmission poles. The nD behavioral equivalent of the classical transmission poles will be discussed in section 6.2.

5.3. Uncontrollable poles. The uncontrollable poles *are defined independently of any input/output structure*, i.e., a system has the same uncontrollable poles regardless of the input/output structure imposed. This is interesting only if we have a proper interpretation of an uncontrollable pole, but we will see that it corresponds in appropriate cases to the idea of an input decoupling zero.

The uncontrollable poles can be characterized as follows.

LEMMA 5.5. *Let $\mathcal{B} = D(M)$ be a behavior with a given input/output structure. The uncontrollable poles are the coassociated primes of*

$$\mathcal{B}/\mathcal{B}^c \quad \cong \quad \mathcal{B}_{0,y}/\mathcal{B}^c_{0,y} \quad \cong \quad D(tM). \tag{5.5}$$

The uncontrollable poles of $\mathcal{B}$ are precisely the nonzero coassociated primes of $\mathcal{B}$. Furthermore, a behavior is controllable if and only if it has no uncontrollable poles.

Proof. The duality $\mathcal{B}/\mathcal{B}^c \cong D(tM)$ is known (see (3.5) and the discussion following), and the isomorphism $\mathcal{B}/\mathcal{B}^c \cong \mathcal{B}_{0,y}/\mathcal{B}^c_{0,y}$ comes from the standard module isomorphism theorems; see also diagram (5.2). The uncontrollable poles of $\mathcal{B}$ are the associated primes of tM, and it is easy to see that these are the nonzero associated primes of M, i.e., the nonzero coassociated primes of $\mathcal{B}$. Finally, $\mathcal{B}$ has no uncontrollable poles if and only if tM has no associated primes, i.e., if and only if $tM = 0$, i.e., $\mathcal{B} = \mathcal{B}^c$. □

The last result of Lemma 5.5 is reminiscent of the result that a controllable state-space representation of a 1D system is precisely one with no input decoupling zeros. However it is not appropriate to identify the uncontrollable poles with input decoupling zeros, since the concept of an input decoupling zero only has meaning when inputs, outputs, and states are involved; we will develop this connection further in section 6.2.

We now consider the characterization of uncontrollable pole points in terms of properties of $\mathcal{B}$ and its representations.

THEOREM 5.6. *Let $\mathcal{B} = D(M)$ be a behavior with kernel representation E. Then*

1. *$\mathcal{B}$ is controllable if and only if it has no uncontrollable pole points.*

2. *Let $\underline{a} \in \mathbb{C}^n$ $((\mathbb{C}\backslash 0)^n)$, and write $I(\underline{a}) \subseteq \mathcal{R}$ for the ideal of polynomials vanishing at $\underline{a}$. We have that $\mathcal{B}\backslash\mathcal{B}^c$ contains a nonzero exponential trajectory with frequency $\underline{a}$:*

   $\Rightarrow$ *$\underline{a}$ is an uncontrollable pole point of $\mathcal{B}$*

   $\Rightarrow$ *E loses rank at $\underline{a}$, i.e.,* rank $E(\underline{a}) \lneq$ rank E, *or equivalently, the localization $M_{I(\underline{a})}$ is not free.*

3. *The statements in claim 2 are equivalent when $\mathcal{B}^c$ is strongly controllable, and, in particular, for a 1D system. More generally, if E^c is a kernel representation of $\mathcal{B}^c$, then the statements are equivalent for points $\underline{a}$ at which E^c does not lose rank. In particular, these statements are equivalent for points $\underline{a}$ which are not controllable pole points.*

4. *Suppose that $\underline{a}$ is not an uncontrollable pole point of $\mathcal{B}$. Then E loses rank at $\underline{a}$ if and only if E^c loses rank at $\underline{a}$.*

Proof.

1. $\mathcal{B}$ has no uncontrollable pole points if and only if ann $\mathcal{B}/\mathcal{B}^c = \mathcal{R}$, i.e., $\mathcal{B} = \mathcal{B}^c$.

2. Write $J = I(\underline{a})$, and suppose that $\mathcal{B}\backslash\mathcal{B}^c$ contains a nonzero exponential trajectory w with frequency $\underline{a}$. Then $Jw = 0 \in \mathcal{B}^c$, so $w + \mathcal{B}^c$ is an element of $\mathcal{B}/\mathcal{B}^c$ which is annihilated by J. By Theorem 4.4, $\underline{a}$ is a characteristic point of $\mathcal{B}/\mathcal{B}^c$, i.e., an uncontrollable pole point of $\mathcal{B}$. From this it follows that ann $tM \subseteq J$, or equivalently, by Theorem 4.7 that $t(M_J) = (tM)_J \neq 0$, i.e., M_J is not torsionfree. Hence M_J is not free, which by [24, Thm. 7.69] means that E loses rank at $\underline{a}$.

3. Now suppose that E loses rank at $\underline{a}$ but that E^c does not. Equivalently, $(M/tM)_J$ is free but M_J is not. Due to the exact sequence

$$0 \longrightarrow (tM)_J \longrightarrow M_J \longrightarrow (M/tM)_J \longrightarrow 0, \tag{5.6}$$

we must have $(tM)_J \neq 0$, and so by Theorem 4.7 ann $tM \subseteq J$, from which $\underline{a}$ is an uncontrollable pole point of $\mathcal{B}$. Next, if $\underline{a}$ is such a point, and furthermore E^c does not lose rank at $\underline{a}$, we again have the exact sequence (5.6). Since again $(M/tM)_J$ is free, (5.6) splits, and so we can tensor with $R_J/J_J = R/J$ to obtain the exact sequence

$$0 \longrightarrow tM/JtM \longrightarrow M/JM \longrightarrow M^c/JM^c \longrightarrow 0,$$

where M^c denotes M/tM and its dual

$$0 \longrightarrow [\mathcal{B}^c : J] \longrightarrow [\mathcal{B} : J] \xrightarrow{\rho} [\mathcal{B}/\mathcal{B}^c : J] \longrightarrow 0. \tag{5.7}$$

Since $\underline{a}$ is an uncontrollable pole point of $\mathcal{B}$, by Theorem 4.4 there exists a nonzero element v in $[\mathcal{B}/\mathcal{B}^c : J]$. From the exactness of (5.7), there must be an element $w \in [\mathcal{B} : J]$ with $\rho(w) = w + \mathcal{B}^c = v$. Since $v \neq 0$, we must have $w \notin \mathcal{B}^c$, and as J annihilates w, it is an exponential trajectory with frequency $\underline{a}$, as required. This proves the equivalence of the three conditions in claim 2 for points $\underline{a}$ at which E^c does not lose rank. If $E^c = (-Q^c \; P^c)$ is a decomposition of E^c with respect to an input/output structure, so that P^c is a kernel representation of $\mathcal{B}^c_{0,y}$, then we know that rank E^c = rank P^c. Now if $\underline{a}$ is not a controllable pole point of $\mathcal{B}$, so that by Corollary 5.4 P^c does not lose rank at $\underline{a}$, then E^c does not lose rank at $\underline{a}$, and the equivalence of the given statements applies.

If $\mathcal{B}^c$ is strongly controllable, then E^c is zero left prime, and so E^c loses rank nowhere. For a 1D system, $\mathcal{B}^c$ is always strongly controllable.

4. Again we have an exact sequence

$$0 \longrightarrow (tM)_J \longrightarrow M_J \longrightarrow (M/tM)_J \longrightarrow 0.$$

As in the proof of the previous claim, the condition that $\underline{a}$ is not an uncontrollable pole point of $\mathcal{B}$ means that $(tM)_J = 0$, from which $M_J \cong (M/tM)_J$. Hence M_J is free if and only if $(M/tM)_J$ is free. By [24, Thm. 7.69], an equivalent statement is that E loses rank at $\underline{a}$ if and only if E^c loses rank at $\underline{a}$. ∎

It is not true in general that an uncontrollable pole point of $\mathcal{B} = \ker_{\mathcal{A}} E$ is precisely a point where E loses rank. Consider the example

$$E \;=\; \begin{pmatrix} z_1 & 0 & z_2 \\ 0 & z_2 & z_3 \end{pmatrix}$$

and the corresponding behavior $\mathcal{B}$ with signal space $\mathcal{A} = \mathcal{C}^\infty(\mathbb{R}^3, \mathbb{C})$. The matrix E has a rank-loss point $(0, 0, a_3)$ for any $a_3 \in \mathbb{C}$, but it is minor left prime (i.e., the second-order minors have no common factor), and therefore GFLP by [43, Cor. 7.9]. $\mathcal{B}$ is therefore controllable by Theorem 3.8, and so by Theorem 5.6 it has no uncontrollable pole points.

Uncontrollable pole points can also be characterized in terms of other behaviors and representations.

THEOREM 5.7. *Let $\mathcal{B} = \ker_{\mathcal{A}} E$ be any behavior with controllable part $\mathcal{B}^c = \ker_{\mathcal{A}} E^c$. Let K be any polynomial matrix with $E = KE^c$, and let C be a minimal left annihilator of E^c; write*

$$L \;=\; \begin{pmatrix} K \\ C \end{pmatrix}.$$

Then L is a kernel representation of $E^c\mathcal{B} \cong \mathcal{B}/\mathcal{B}^c$, and the following are equivalent for any point $\underline{a} \in \mathbb{C}^n$ $((\mathbb{C}\backslash 0)^n)$:

1. *$\underline{a}$ is an uncontrollable pole point of $\mathcal{B}$.*
2. *$L(\underline{a})$ has less than full column rank.*
3. *$E^c\mathcal{B}$ contains a nonzero exponential trajectory with frequency $\underline{a}$.*

Proof. Given E, E^c, K, C, and L as described, it is easy to see that LE^c is a kernel representation of $\mathcal{B}$, and we also have $\ker_{\mathcal{A}} L \subseteq \operatorname{im}_{\mathcal{A}} E^c$. Now $w \in E^c\mathcal{B}$ implies

$Lw = 0$, and conversely $w \in \ker_{\mathcal{A}} L$ implies that $w = E^c v$ for some v, so $(LE^c)v = 0$, i.e., $v \in \mathcal{B}$. Hence $\ker_{\mathcal{A}} L = E^c\mathcal{B}$. As $E^c\mathcal{B} \cong \mathcal{B}/\mathcal{B}^c$, the uncontrollable pole points are the characteristic points of $E^c\mathcal{B}$, and the remaining assertions follow on applying Theorem 4.4. ∎

5.4. The uncontrollable–controllable decomposition. As implied by the nomenclature, poles are either uncontrollable poles or controllable poles (or possibly both), and similarly for pole points.

THEOREM 5.8.

1. *The union of the uncontrollable pole variety and the controllable pole variety is the pole variety.*

2. *The union of the set of uncontrollable poles and the set of controllable poles is the set of poles.*

Proof. From the commutative exact diagram (5.2), we have an exact sequence

$$0 \longrightarrow (\mathcal{B}^c)_{0,y} \longrightarrow \mathcal{B}_{0,y} \longrightarrow \mathcal{B} \,/\, \mathcal{B}^c \longrightarrow 0,$$

which is dual to a corresponding sequence of finitely generated modules in reverse order in the diagram (5.1). Applying Lemma 4.8 gives us the first claim concerning pole points immediately, and also the following:

$$\{\text{uncontrollable poles}\} \subseteq \{\text{poles}\} \subseteq \{\text{uncontrollable poles, controllable poles}\}.$$

It remains to show that every controllable pole is a pole. Write $M_{0,y}$ and $M^c_{0,y}$, respectively, for the modules to which $\mathcal{B}_{0,y}$ and $\mathcal{B}^c_{0,y}$ are dual. We now have the following:

$$\operatorname{Ass} M^c_{0,y} \subseteq \operatorname{supp} M^c_{0,y} \subseteq \operatorname{supp} M_{0,y}.$$

As $\operatorname{ann} M_{0,y} \neq 0$ (its dual is autonomous), $0 \notin \operatorname{supp} M_{0,y}$. Now by Theorem 5.3, every element of $\operatorname{Ass} M^c_{0,y}$ is principal and therefore has height 1. Each such element must therefore be minimal in $\operatorname{supp} M_{0,y}$, and so by Theorem 4.7 is therefore in $\operatorname{Ass} M_{0,y}$. This proves that $\operatorname{Ass} M^c_{0,y} \subseteq \operatorname{Ass} M_{0,y}$, i.e., the controllable poles are also poles, as required. ∎

In the proof above, the fact that every controllable pole is a pole relies on the fact that every controllable pole is principal (from Theorem 5.3). In section 6 we will encounter decompositions of sets of poles where such an observation does not apply, and therefore only partial results of this nature can be obtained.

Note that, contrary to the implication of the nomenclature, it is possible for a pole to be both a controllable pole and an uncontrollable pole, and similarly for pole points! A complete partitioning of poles into controllable and uncontrollable ones would require a suitable notion of multiplicity, which is beyond the scope of this paper.

5.5. The dimension of the characteristic variety. Another important question for an nD system is how "large" the poles are, in a geometric sense. For a 1D system, the pole variety is just a set of isolated points. For a 2D system, the pole variety may be a set of isolated points, or it may include curves. For a 3D system, there is the additional possibility that the pole variety may contain a 2D surface. The dimensions of the pole variety, controllable pole variety, and uncontrollable pole variety, or more generally of the characteristic variety, are therefore of interest.

LEMMA 5.9. *Let $\mathcal{B} = \ker_{\mathcal{A}} E$. Then*

1. *For $\mathcal{B} \neq 0$, the dimension of the characteristic variety of $\mathcal{B}$ is n minus the "right primeness degree" [43] of E.*

2. *$\mathcal{B}$ is finite-dimensional if and only if it has a finite number of characteristic points.*

3. *The controllable pole variety has dimension either -1 (it is empty) or $n-1$. The former case occurs if and only if the transfer matrix is a polynomial matrix. In the latter case, each maximal irreducible subvariety of the controllable pole variety has dimension $n-1$.*

4. *If the transfer matrix is not a polynomial matrix, the pole variety has dimension $n-1$.*

Proof. The first claim is immediate from Theorem 4.4 and the definition of the right primeness degree. The second claim is given in [26, 29].

From Theorem 5.3, ann $\mathcal{B}^c_{0,y}$ is principal, and it must therefore be either $\mathcal{R}$ or an ideal of height 1. Hence $V(\text{ann}\,\mathcal{B}^c_{0,y})$ is either empty or of dimension $n-1$. Again by Theorem 5.3, the former occurs precisely when the transfer matrix is polynomial. In the other case, Theorem 5.3 says further that every coassociated prime of $\mathcal{B}^c_{0,y}$, including the minimal prime divisors of ann $\mathcal{B}^c_{0,y}$, has height 1, so the maximal irreducible subvarieties of $V(\text{ann}\,\mathcal{B}^c_{0,y})$ have dimension $n-1$.

Claim 4 follows from claim 3, as the pole variety contains the controllable pole variety. ∎

The dimension of the characteristic variety (pole variety, etc.) can be found algorithmically, as discussed in [43]. For a system with signal space $k^{\mathbb{N}^n}$, this quantity can also be interpreted as a measure of the order of magnitude of the system's initial condition set, the "autonomy degree" [43]. The interpretation for systems with other signal spaces is still open.

When the transfer matrix is not a polynomial matrix, Lemma 5.9 states that every maximal irreducible subvariety of the controllable pole variety has dimension $n-1$. In consequence, every maximal irreducible subvariety of the pole variety having dimension less than $n-1$ must also be a maximal irreducible subvariety of the uncontrollable pole variety. This is also trivially true when the transfer matrix is a polynomial matrix.

6. Observable and unobservable poles. In this section we will look at the additional structure which occurs when the behavior is a latent variable representation of some other behavior. The principal example of this is when the latent variables are "state variables," e.g., in the context of the classical 1D theory. When the behavior is defined through a Rosenbrock system matrix (or "polynomial matrix description"), this additional structure allows us to relate certain submatrices to various sets of poles.

6.1. Observable and unobservable poles. Consider now a behavior $\mathcal{B}_{l,w}$ which is a latent variable description of some other behavior $\mathcal{B}_w$. The behavior $\mathcal{B}_w$ is called the *manifest behavior* of the *full behavior* $\mathcal{B}_{l,w}$, the variables of w are called *manifest variables*, and the variables of l are called *latent variables*. These ideas are described in [40] for the 1D case and [22, 32] for the 2D case. Formally, we have the following for some polynomial matrices E, F:

$$\mathcal{B}_{l,w} = \left\{ \begin{pmatrix} l \\ w \end{pmatrix} \in \mathcal{A}^{d+q} \;\middle|\; Ew = Fl \right\}, \tag{6.1}$$

$$\mathcal{B}_w = \left\{ w \in \mathcal{A}^q \;\middle|\; \exists\, l \in \mathcal{A}^d \text{ such that } \begin{pmatrix} l \\ w \end{pmatrix} \in \mathcal{B}_{l,w} \right\}. \tag{6.2}$$

It is easy to derive a kernel representation of $\mathcal{B}_w$: we construct a minimal left annihilator L of F, and we have $\mathcal{B}_w = \ker_{\mathcal{A}}(LE)$ [22], [24, p. 27]. There is also the behavior $\mathcal{B}_{l,0}$, which we will call the *unobservable behavior*, consisting of all elements of $\mathcal{B}_{l,w}$ with $w = 0$. $\mathcal{B}_{l,0}$ is isomorphic to $\ker_{\mathcal{A}} F$, and vanishes precisely when the latent variables are observable (in the behavioral sense) from the manifest variables. We can show that $\mathcal{B}_w$ is the factor module of $\mathcal{B}_{l,w}$ by $\mathcal{B}_{l,0}$, so we have an exact sequence

$$0 \longrightarrow \mathcal{B}_{l,0} \longrightarrow \mathcal{B}_{l,w} \longrightarrow \mathcal{B}_w \longrightarrow 0. \tag{6.3}$$

Now consider the pole structure of these behaviors. Take an input/output structure on $\mathcal{B}_{l,w}$ for which the number of inputs which are in the variables w is maximized. (When the latent variables are state variables, all the input variables can of course be taken to be manifest variables.) We will refer to such an input/output structure on $\mathcal{B}_{l,w}$ as a *maximally manifest input/output structure*. Divide the components w and l into input and output components, so $w = (w_1^T, w_2^T)^T$ and $l = (l_1^T, l_2^T)^T$, where $(l_1^T, w_1^T)^T$ is a complete input vector for $\mathcal{B}_{l,w}$. It follows that (w_1, w_2) is an input/output structure on $\mathcal{B}_w$ and (l_1, l_2) is one on $\mathcal{B}_{l,0}$. (It is for this reason that we restrict our consideration to input/output structures which are maximally manifest.) These input/output structures are called the *induced input/output structures* on $\mathcal{B}_w$ and $\mathcal{B}_{l,0}$.

The poles of $\mathcal{B}_{l,w}$ fall naturally into two categories. The first is the set of poles which are observable from the behavior $\mathcal{B}_w$ and the second is the set of poles which cannot be determined from the manifest behavior. (They are poles of the unobservable behavior.)

DEFINITION 6.1. *Let $\mathcal{B}_{l,w}$ be a behavior with latent variables l and a maximally manifest input/output structure with input variables (w_1, l_1) and output variables (w_2, l_2). Take the induced input/output structures on $\mathcal{B}_w$ and $\mathcal{B}_{l,0}$.*

1. *The* unobservable pole variety*,* unobservable pole points*, and* unobservable poles *of $\mathcal{B}_{l,w}$ are defined to be the pole variety, pole points, and poles of the unobservable behavior $\mathcal{B}_{l,0}$.*

2. *The* observable pole variety*,* observable pole points*, and* observable poles *of $\mathcal{B}_{l,w}$ are defined to be the pole variety, pole points, and poles of the manifest behavior $\mathcal{B}_w$.*

In effect we have defined the unobservable poles as the coassociated primes of the behavior $\mathcal{B}_{l_1=0,l_2,w_1=0,w_2=0}$ (notation interpreted in the obvious way) and the observable poles as those of the behavior $\mathcal{B}_{w_1=0,w_2} \subseteq \mathcal{B}_w$. The poles of $\mathcal{B}_{l,w}$ itself are the coassociated primes of $\mathcal{B}_{l_1=0,l_2,w_1=0,w_2}$, and $\mathcal{B}_{w_1=0,w_2}$ is the factor module of $\mathcal{B}_{l_1=0,l_2,w_1=0,w_2}$ by $\mathcal{B}_{l_1=0,l_2,w_1=0,w_2=0}$, so we have an exact sequence

$$0 \longrightarrow \mathcal{B}_{l_1=0,l_2,w_1=0,w_2=0} \longrightarrow \mathcal{B}_{l_1=0,l_2,w_1=0,w_2} \longrightarrow \mathcal{B}_{w_1=0,w_2} \longrightarrow 0. \tag{6.4}$$

THEOREM 6.2. *Let $\mathcal{B}_{l,w}$ be a behavior with latent variables l and a maximally manifest input/output structure. Then the poles/pole points of the full behavior $\mathcal{B}_{l,w}$ have the following properties:*

1. *A point $\underline{a}$ is an observable pole point if and only if there exists $(l, w) \in \mathcal{B}_{l,w}$ such that $w_1 = 0$ and w_2 is nonzero and exponential with frequency $\underline{a}$.*

2. *A point $\underline{a}$ is an unobservable pole point if and only if there exists $(l, w) \in \mathcal{B}_{l,w}$ such that $w = 0, l_1 = 0$ and l_2 is nonzero and exponential with frequency $\underline{a}$.*

3. *Suppose that the latent variables l contain no free variables, i.e., $\mathcal{B}_{l,0}$ is autonomous. Then $\mathcal{B}_{l,w}$ is observable if and only if it has no unobservable poles or, equivalently, no unobservable pole points.*

4. *The union of the unobservable pole variety and the observable pole variety is the pole variety.*

5. *Every observable pole is a pole. Every pole is either an unobservable pole or an observable pole (or both).*

Proof. The first two claims follow on applying Theorem 4.4 and the last two are immediate from Lemma 4.8 together with the exact sequence (6.4). For claim 3, the condition that $\mathcal{B}_{l,w}$ is observable is equivalent to the condition $\mathcal{B}_{l,0} = 0$, or alternatively, to the vanishing of the module to which $\mathcal{B}_{l,0}$ is dual. The result follows since a finitely generated module M is 0 precisely when it has no associated primes (Theorem 4.7), or equivalently, when $V(\operatorname{ann} M) = \emptyset$. ∎

We do not claim that every unobservable pole is a pole. Claim 3 of Theorem 6.2 is similar to the classical 1D result that a system in state-space form is observable if and only if it has no output decoupling zeros. Note that the condition on this last result is satisfied if the latent variables l are interpreted as states.

6.2. Complete classification of poles. We can combine the partitioning of pole points into unobservable and observable pole points with the partitioning into uncontrollable and controllable pole points. This involves the controllable part of $\mathcal{B}_{l,w}$ and its associated unobservable and manifest behaviors. We denote by $\mathcal{B}^c_{l,w}$ the controllable part of $\mathcal{B}_{l,w}$, by $\mathcal{B}^c_{l,0}$ the unobservable behavior of $\mathcal{B}^c_{l,w}$, by $\mathcal{B}^c_w$ the manifest behavior of $\mathcal{B}^c_{l,w}$, and so on. Care must be taken with this notation, as it is not generally the case that $\mathcal{B}^c_{l,0} = (\mathcal{B}_{l,0})^c$.

Our final refinement of the pole structure is defined as follows.

DEFINITION 6.3. *Let $\mathcal{B}_{l,w}$ be a behavior with latent variables l and a maximally manifest input/output structure. Then*

1. *The* unobservable uncontrollable pole variety*,* unobservable uncontrollable pole points*, and* unobservable uncontrollable poles *are the characteristic variety, characteristic points, and coassociated primes of $\mathcal{B}_{l,0}$ / $\mathcal{B}^c_{l,0}$.*

2. *The* unobservable controllable pole variety*,* unobservable controllable poles points*, and* unobservable controllable poles *are the pole variety, pole points, and poles of $\mathcal{B}^c_{l,0}$.*

3. *The* observable uncontrollable pole variety*,* observable uncontrollable pole points*, and* observable uncontrollable poles *are the characteristic variety, characteristic points, and coassociated primes of $\mathcal{B}_w$ / $\mathcal{B}^c_w$.*

4. *The* observable controllable pole variety*,* observable controllable pole points*, and* observable controllable poles *are the pole variety, pole points, and poles of $\mathcal{B}^c_w$.*

To show that the unobservable uncontrollable poles are meaningfully defined, we have to show that $(\mathcal{B}^c)_{l,0}$ is a subbehavior of $\mathcal{B}_{l,0}$, which is evident from the fact that $(\mathcal{B}^c)_{l,0} = \mathcal{B}_{l,0} \cap \mathcal{B}^c$. To show that the observable uncontrollable poles are meaningfully defined, we have to show that $(\mathcal{B}^c)_w$ is a subbehavior of $\mathcal{B}_w$, which follows by definition. In fact, a stronger claim is possible.

THEOREM 6.4. *Let $\mathcal{B}_{l,w}$ be a behavior with latent variables l. Then the manifest behavior of the controllable part of $\mathcal{B}_{l,w}$ is equal to the controllable part of the manifest behavior of $\mathcal{B}_{l,w}$.*

Proof. We write $\mathcal{B} = \mathcal{B}_{l,w}$ as usual. Clearly $(\mathcal{B}^c)_w$ is a subbehavior of $\mathcal{B}_w$. It is also clear from the definition of controllability that as $\mathcal{B}^c$ is controllable, so is $(\mathcal{B}^c)_w$. Now write E for any kernel representation of $\mathcal{B}$ and E^c for any kernel representation of $\mathcal{B}^c$. Since $\mathcal{B}$ and $\mathcal{B}^c$ have the same input/output structures, any submatrices comprised of corresponding columns of E and of E^c must have the same rank. In particular,

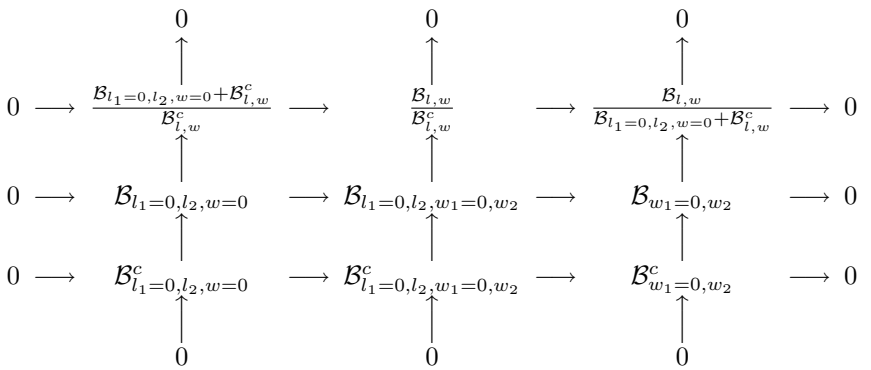

FIG. 6.1. *Exact commutative diagram for complete classification of poles. Note that the columns of this diagram are read upwards, contrary to convention; this is to achieve symmetry in Figure* 6.2.

$m(\mathcal{B}_{l,0}) = m((\mathcal{B}^c)_{l,0})$. Now we use the additivity of the number of free variables:

$$\begin{aligned} m((\mathcal{B}^c)_w) &= m((\mathcal{B}^c)_{l,w}) - m((\mathcal{B}^c)_{l,0}) \\ &= m(\mathcal{B}_{l,w}) - m(\mathcal{B}_{l,0}) \\ &= m(\mathcal{B}_w). \end{aligned}$$

Summarizing, $(\mathcal{B}^c)_w$ is a subbehavior of $\mathcal{B}_w$ which has the same number of free variables and is controllable. This suffices to prove that $(\mathcal{B}^c)_w$ is the controllable part of $\mathcal{B}_w$. ∎

Theorem 6.4 proves that the observable controllable poles are equal to the controllable poles of the manifest behavior (if you like, the "controllable observable poles"). This result also shows that we can use the notation $\mathcal{B}^c_w$ without fear of ambiguity.

Currently we have a pair of exact sequences of autonomous behaviors whose coassociated primes correspond to various sets of poles:

$$0 \longrightarrow \mathcal{B}_{l_1=0,l_2,w_1=0,w_2=0} \longrightarrow \mathcal{B}_{l_1=0,l_2,w_1=0,w_2} \longrightarrow \mathcal{B}_{w_1=0,w_2} \longrightarrow 0, \tag{6.5}$$

$$0 \longrightarrow \mathcal{B}^c_{l_1=0,l_2,w_1=0,w_2=0} \longrightarrow \mathcal{B}^c_{l_1=0,l_2,w_1=0,w_2} \longrightarrow \mathcal{B}^c_{w_1=0,w_2} \longrightarrow 0, \tag{6.6}$$

and each module in the sequence (6.6) is a submodule of the corresponding module in the upper sequence (6.5). Let us look at the corresponding factor modules. Since $\mathcal{B}^c_{l_1=0,l_2,w_1=0,w_2=0} = \mathcal{B}_{l_1=0,l_2,w_1=0,w_2=0} \cap \mathcal{B}^c_{l_1,l_2,w_1,w_2}$, the factor module is

$$\frac{\mathcal{B}_{l_1=0,l_2,w_1=0,w_2=0}}{\mathcal{B}_{l_1=0,l_2,w_1=0,w_2=0} \cap \mathcal{B}^c_{l_1,l_2,w_1,w_2}} \cong \frac{\mathcal{B}_{l_1=0,l_2,w_1=0,w_2=0} + \mathcal{B}^c_{l_1,l_2,w_1,w_2}}{\mathcal{B}^c_{l_1,l_2,w_1,w_2}}. \tag{6.7}$$

This is obviously a submodule of $\mathcal{B}_{l_1,l_2,w_1,w_2} \,/\, \mathcal{B}^c_{l_1,l_2,w_1,w_2}$, which by (5.5) is isomorphic to $\mathcal{B}_{l_1=0,l_2,w_1=0,w_2}/\mathcal{B}^c_{l_1=0,l_2,w_1=0,w_2}$. These behaviors are all shown in Figure 6.1. By the Snake lemma (e.g., [10, Ex. A3.10]), we also have an isomorphism

$$\frac{\mathcal{B}_{l_1,l_2,w_1,w_2}}{\mathcal{B}_{l_1=0,l_2,w_1=0,w_2=0} + \mathcal{B}^c_{l_1,l_2,w_1,w_2}} \cong \frac{\mathcal{B}_{w_1=0,w_2}}{\mathcal{B}^c_{w_1=0,w_2}}, \tag{6.8}$$

and the diagram in Figure 6.1 is commutative and exact.

Reading the nontrivial behaviors in Figure 6.1 from left to right and from top to bottom, we see that the coassociated primes are, respectively, the following: the

unobservable uncontrollable poles, the uncontrollable poles, the observable uncontrollable poles, the unobservable poles, the poles, the observable poles, the unobservable controllable poles, the controllable poles, and the observable controllable poles.

We now apply Lemma 4.8 again. This gives us the basic structure of the poles of a behavior given by a latent variable description.

1. The union of the unobservable uncontrollable pole variety and the observable uncontrollable pole variety is the uncontrollable pole variety. Every observable uncontrollable pole is an uncontrollable pole. Every uncontrollable pole is either an unobservable uncontrollable pole or an observable uncontrollable pole.

2. The union of the unobservable pole variety and the observable pole variety is the pole variety. Every observable pole is a pole. Every pole is either an unobservable pole or an observable pole.

3. The union of the unobservable controllable pole variety and the observable controllable pole variety is the controllable pole variety. Every observable controllable pole is a controllable pole. Every controllable pole is either an unobservable controllable pole or an observable controllable pole.

4. The union of the unobservable uncontrollable pole variety and the unobservable controllable pole variety is the unobservable pole variety. Every unobservable uncontrollable pole is an unobservable pole. Every unobservable pole is either an unobservable controllable pole or an unobservable uncontrollable pole.

5. The union of the uncontrollable pole variety and the controllable pole variety is the pole variety. The union of the set of uncontrollable poles and the set of controllable poles is the set of poles.

6. The union of the observable uncontrollable pole variety and the observable controllable pole variety is the observable pole variety. The union of the set of observable uncontrollable poles and the set of observable controllable poles is the set of observable poles.

In general, we do not expect the inclusions of sets of poles missing from the list above to hold (e.g., we do not expect every unobservable uncontrollable pole to be an uncontrollable pole). Note however that we are able to make a full decomposition in the last case of observable poles. This is possible because the observable controllable poles are a subset of the controllable poles, and are therefore principal by Theorem 5.3. We can therefore apply the same argument as in the proof of Theorem 5.8 to deduce that every observable controllable pole is an observable pole. This reasoning cannot be applied to cases 1–4.

We summarize the relationships between the various sets of poles in a conceptual exact diagram (Figure 6.2). This diagram should be interpreted as follows: if $0 \longrightarrow$ Set 1 $\longrightarrow$ Set 2 $\longrightarrow$ Set 3 $\longrightarrow 0$ is a row or column, then the union of the pole variety of Set 1 and the pole variety of Set 3 is the pole variety of Set 2. The corresponding statements for the poles themselves is slightly weaker, except for the middle and right-hand columns, for which an analogous law holds.

Example. Take the 2D behavior given by the following polynomial matrix:

$$\mathcal{B}_{l,u,y} = \ker_{\mathcal{A}} E_1,$$
$$E_1 = \left(\begin{array}{c|c|c} (z_1^2 - z_2)(z_1 + z_2)(z_1 - 1)z_2 & 0 & z_2^2(z_1^2 - z_2) \\ (z_1^2 - z_2)(z_1 + z_2)(z_1 - 1)z_1 & (z_1 + z_2)^2 & z_1 z_2 (z_1^2 - z_2) \end{array} \middle| \begin{array}{c} -(z_1^2 + z_2^2 - 1) \\ (z_1^2 + z_2^2 - 1) \end{array}\right).$$

The signal space $\mathcal{A}$ can be taken as $k^{\mathbb{N}^n}$, $\mathcal{C}^\infty(\mathbb{R}^n, k)$, or $\mathcal{D}'(\mathbb{R}^n, k)$ for $k = \mathbb{R}$ or $\mathbb{C}$; the ring $\mathcal{R} = k[\mathbf{z}]$. The behavior $\mathcal{B}_{l,u,y}$ has 2 inputs, 1 output, and 1 latent variable.

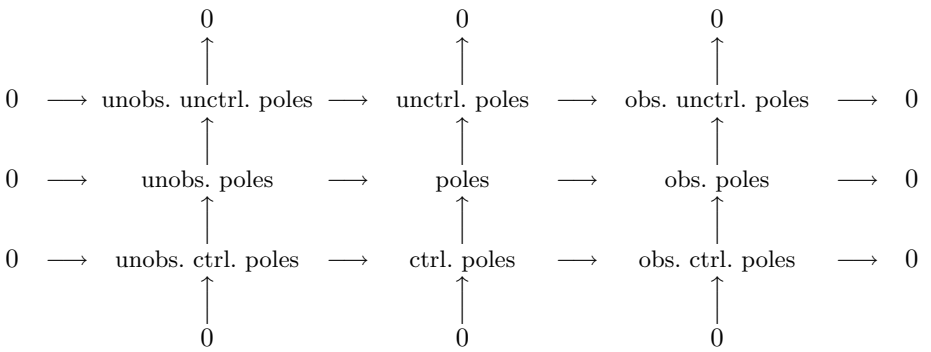

FIG. 6.2. *Relationships between sets of poles.*

We will now find the 9 pole varieties of this behavior. This requires constructing representations for 9 related behaviors—those appearing in Figure 6.1. To begin with, we have the zero-input and unobservable behaviors:

$$\mathcal{B}_{l,u=0,y} \cong \ker_{\mathcal{A}} E_2, \qquad E_2 = \left(\begin{array}{c|c} (z_1^2 - z_2)(z_1 + z_2)(z_1 - 1)z_2 & -(z_1^2 + z_2^2 - 1) \\ (z_1^2 - z_2)(z_1 + z_2)(z_1 - 1)z_1 & (z_1^2 + z_2^2 - 1) \end{array}\right),$$
$$\mathcal{B}_{l,u=0,y=0} \cong \ker_{\mathcal{A}} E_3, \qquad E_3 = \left(\begin{array}{c} (z_1^2 - z_2)(z_1 + z_2)(z_1 - 1)z_2 \\ (z_1^2 - z_2)(z_1 + z_2)(z_1 - 1)z_1 \end{array}\right).$$

Next, observe that we can write $E_1 = LE_4$, where L and E_4 are given by

$$L = \left(\begin{array}{cc} z_2 & -1 \\ z_1 & 1 \end{array}\right),$$
$$E_4 = \left(\begin{array}{c|cc|c} (z_1^2 - z_2)(z_1 + z_2)(z_1 - 1) & (z_1 + z_2) & z_2(z_1^2 - z_2) & 0 \\ 0 & (z_1 + z_2)z_2 & 0 & (z_1^2 + z_2^2 - 1) \end{array}\right).$$

Since E_4 is minor left prime, $\ker_{\mathcal{A}} E_4 = \mathcal{B}^c_{l,u,y}$. Hence we have the following representations:

$$\mathcal{B}^c_{l,u=0,y} \cong \ker_{\mathcal{A}} E_5, \qquad E_5 = \left(\begin{array}{c|c} (z_1^2 - z_2)(z_1 + z_2)(z_1 - 1) & 0 \\ 0 & (z_1^2 + z_2^2 - 1) \end{array}\right),$$
$$\mathcal{B}^c_{l,u=0,y=0} \cong \ker_{\mathcal{A}} E_6, \qquad E_6 = \left(\begin{array}{c} (z_1^2 - z_2)(z_1 + z_2)(z_1 - 1) \\ 0 \end{array}\right).$$

For the manifest behaviors of $\mathcal{B}_{l,u,y}$ and $\mathcal{B}^c_{l,u,y}$, we need minimal left annihilators of E_3 and E_6, and these are easily found to be the matrices $E_7 = (z_1 \ \ -z_2)$ and $E_8 = (0 \ \ 1)$, respectively. The zero-input manifest behaviors are now found by taking the appropriate submatrices of E_7E_1 and E_8E_4, respectively:

$$\mathcal{B}_{u=0,y} \cong \ker_{\mathcal{A}} E_9, \qquad E_9 = (-(z_1^2 + z_2^2 - 1)(z_1 + z_2)),$$
$$\mathcal{B}^c_{u=0,y} \cong \ker_{\mathcal{A}} E_{10}, \qquad E_{10} = (z_1^2 + z_2^2 - 1).$$

Since E_4 has full row rank, Theorem 5.7 tells us that a kernel representation of $E_4\mathcal{B}_{l,u,y} \cong \mathcal{B}_{l,u,y}/\mathcal{B}^c_{l,u,y}$ is the matrix L. Similarly, the representation found for $\mathcal{B}^c_{u,y}$ also has full row rank, and so a kernel representation for $\mathcal{B}_{u,y}/\mathcal{B}^c_{u,y}$ is the matrix $E_{11} =$

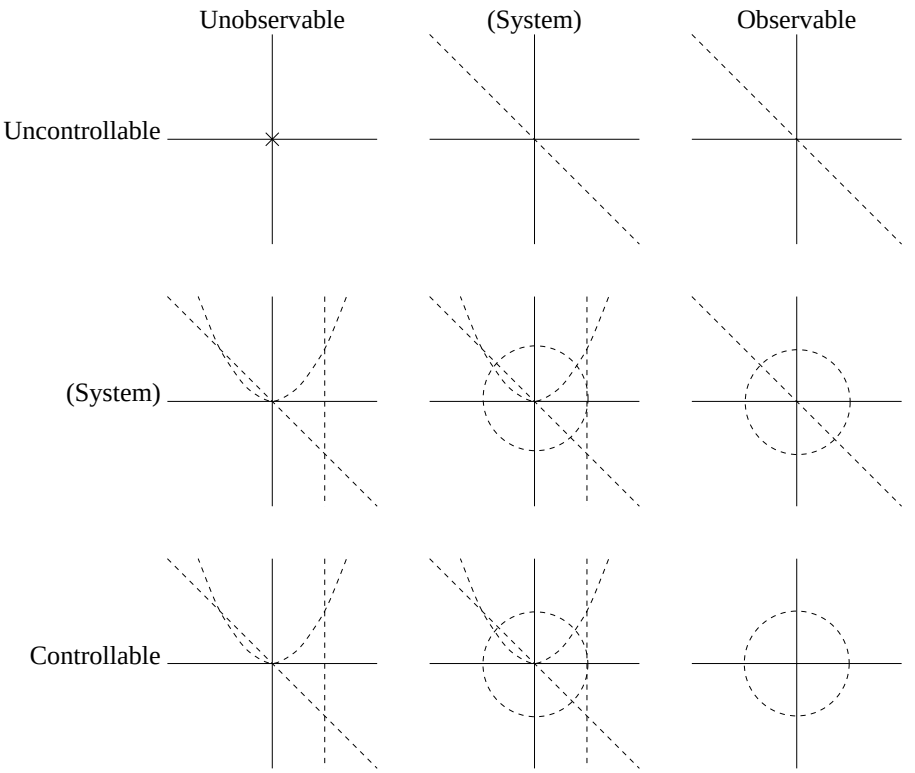

FIG. 6.3. *Example of pole varieties.*

$(-(z_1 + z_2))$. Using a similar trick, a kernel representation for $\mathcal{B}_{l,u=0,y=0}/\mathcal{B}^c_{l,u=0,y=0}$ is

$$E_{12} \;=\; \begin{pmatrix} z_2 \\ z_1 \end{pmatrix}.$$

Now the 9 sets of pole points, 9 behaviors of relevance, and 9 kernel representations are listed as follows:

Pole point set	Behavior	Rep. matrix
Unobservable uncontrollable pole points	$\mathcal{B}_{l,u=0,y=0}/\mathcal{B}^c_{l,u=0,y=0}$	E_{12}
Uncontrollable pole points	$\mathcal{B}_{l,u,y}/\mathcal{B}^c_{l,u,y}$	L
Observable uncontrollable pole points	$\mathcal{B}_{u,y}/\mathcal{B}^c_{u,y}$	E_{11}
Unobservable pole points	$\mathcal{B}_{l,u=0,y=0}$	E_3
(System) pole points	$\mathcal{B}_{l,u=0,y}$	E_2
Observable pole points	$\mathcal{B}_{u=0,y}$	E_9
Unobservable controllable pole points	$\mathcal{B}^c_{l,u=0,y=0}$	E_6
Controllable pole points	$\mathcal{B}^c_{l,u=0,y}$	E_5
Observable controllable pole points	$\mathcal{B}^c_{u=0,y}$	E_{10}

For this example, it is now easy to plot the various pole varieties as the rank-loss varieties of the corresponding matrices. (However in general we suspect that computation of the annihilator is a more efficient method.) These varieties are shown in Figure 6.3.

Note that the behavior $\mathcal{B}_{l,u=0,y=0}/\mathcal{B}^c_{l,u=0,y=0}$ giving the unobservable uncontrollable pole points has a single pole (z_1, z_2). We have conjectured that not every un-

observable uncontrollable pole is an uncontrollable pole. We can confirm this using the current example; we have to show that (z_1, z_2) is not an associated prime of $\mathrm{Coker}_{\mathcal{R}} L$, where L is the matrix given above. Equivalently, we show that no element of $\mathcal{R}^{1,2} \backslash \mathrm{Im}_{\mathcal{R}} L$ is taken into $\mathrm{Im}_{\mathcal{R}} L$ by the actions of z_1 and z_2. Let N denote the set of all elements x of $\mathcal{R}^{1,2}$ such that $z_1 x \in \mathrm{Im}_{\mathcal{R}} L$ and $z_2 x \in \mathrm{Im}_{\mathcal{R}} L$. Then N is the set of polynomial vectors corresponding to the first two components of the kernel (natural left action) of the matrix

$$K = \left(\begin{array}{cc|cccc} z_1 & 0 & z_2 & z_1 & 0 & 0 \\ 0 & z_1 & -1 & 1 & 0 & 0 \\ z_2 & 0 & 0 & 0 & z_2 & z_1 \\ 0 & z_2 & 0 & 0 & -1 & 1 \end{array} \right)^T.$$

However, it is possible to show that the kernel of this matrix is equal to the image of the matrix

$$\left(\begin{array}{cc|cccc} z_2 & -1 & -z_1 & 0 & -z_2 & 0 \\ z_1 & 1 & 0 & -z_1 & 0 & -z_2 \end{array} \right),$$

and hence $N = \mathrm{Im}_{\mathcal{R}} L$. This proves that (z_1, z_2) is not an associated prime of $\mathrm{Coker}_{\mathcal{R}} L$, and hence is not an uncontrollable pole of the behavior, although it is an unobservable uncontrollable pole.

6.3. Rosenbrock system matrices. One important class of representations of 1D and nD systems is the class of Rosenbrock system matrices, also called polynomial matrix descriptions; see, e.g., [33] for the 1D case and [19] for the nD case.

We write here x for the latent variables, u for the (manifest) free variables, and y for the remaining manifest variables. We can think of u as the input, x as the state, and y as the output. Since x is to be interpreted as a vector of state variables, it is assumed to contain no free variables, i.e., the behavior with zero input and zero output is assumed to be autonomous. We consider state-input-output behaviors given by the following classical system of equations:

$$T(\underline{\mathbf{z}}) x(\underline{t}) = U(\underline{\mathbf{z}}) u(\underline{t}), \tag{6.9}$$

$$y(\underline{t}) = V(\underline{\mathbf{z}}) x(\underline{t}) + W(\underline{\mathbf{z}}) u(\underline{t}). \tag{6.10}$$

We can write the resulting behavior in kernel form as follows:

$$\mathcal{B}_{x,u,y} = \ker_{\mathcal{A}} \left(\begin{array}{ccc} T & -U & 0 \\ V & W & -I \end{array} \right). \tag{6.11}$$

The submatrix $\left(\begin{smallmatrix} T & -U \\ V & W \end{smallmatrix} \right)$ is called a *Rosenbrock system matrix*. We define the *pole points of the Rosenbrock system matrix* to be the points where T fails to have full column rank. This is the definition previously given in the 1D case (e.g., in [20]).

Note that the standard input/output structure on $\mathcal{B}_{x,u,y}$ is trivially a maximally manifest input/output structure, with the states being treated as additional outputs in the behavioral sense.

LEMMA 6.5. *Let $\mathcal{B}_{x,u,y}$ be a differential or difference behavior given by a Rosenbrock system matrix* (6.9–6.10). *Then*

1. *The pole points of $\mathcal{B}_{x,u,y}$ are precisely the pole points of the Rosenbrock system matrix.*

2. *The unobservable pole points of* $\mathcal{B}_{x,u,y}$ *are precisely the points where the matrix* $(T^T\ V^T)^T$ *has less than full column rank.*

3. *Each uncontrollable pole point of* $\mathcal{B}_{x,u,y}$ *is a point where* $(T\ -U)$ *has less than its normal rank; the converse holds for* 1*D systems.*

4. *The observable controllable pole points of* $\mathcal{B}_{x,u,y}$ *are precisely the points* $\underline{a}$ *such that the denominator of some entry of the input-to-output transfer matrix of the Rosenbrock system matrix vanishes at* $\underline{a}$.

Proof.

1. A kernel representation of $\mathcal{B}_{x,0,y}$ is $\begin{pmatrix} T & O \\ V & -I \end{pmatrix}$ (to within isomorphism). By Corollary 5.2, the pole points are the points where this matrix, or equivalently T, fails to have full column rank.

2. The unobservable pole points are the characteristic points of $\mathcal{B}_{x,0,0} \cong \ker_{\mathcal{A}} \begin{pmatrix} T \\ V \end{pmatrix}$. By Theorem 4.4, the unobservable pole points are the points where this matrix fails to have full column rank.

3. By Theorem 5.6, in the 1D case the uncontrollable pole points are the points where the whole matrix $\begin{pmatrix} T & -U & 0 \\ V & W & -I \end{pmatrix}$ has less than its normal rank. These are equal to the rank-loss points of $(T\ -U)$.

4. By Theorem 6.4, the observable controllable pole points are the controllable pole points of $\mathcal{B}_{u,y}$, the transfer matrix of which is the input-to-output transfer matrix of the PMD. The claim now follows from Corollary 5.4. ∎

Lemma 6.5 is enough to prove that, in the 1D case, the pole points, unobservable pole points, uncontrollable pole points, and observable controllable pole points of $\mathcal{B}_{x,0,y}$ correspond, respectively, to the poles, output decoupling zeros, input decoupling zeros, and transmission poles of the system, as defined classically. Note also that, in the general nD case, we have proved in Theorems 5.6 and 6.2 that a behavior is controllable (resp., observable) if and only if it has no uncontrollable pole points (resp., no unobservable pole points).

We can readily apply our theory to characterize the pole points of special classes of nD systems, for example, systems governed by the Roesser or Fornasini–Marchesini state space models. In these cases we find that the pole points are the points where the "characteristic polynomial" vanishes, as has been anticipated by many other authors. Such an analysis is however beyond the scope of this paper.

7. Polar decomposition and integral representation. In this section we discuss a decomposition of a behavior that emerges from the theory of poles, and also the related integral representation theorem.

7.1. Polar and decoupling zero decompositions. In a 1D system, any trajectory with zero input can be written as a sum of polynomial exponential trajectories with frequencies corresponding to the system poles. This results from a decomposition of the behavior as a sum of certain subbehaviors, a decomposition which is dual to the classical algebraic "primary decomposition." We can apply the same principles in the nD case.

Consider the ring $\mathcal{R} = k[\underline{\mathbf{z}}]$ or $\mathcal{R} = k[\underline{\mathbf{z}}, \underline{\mathbf{z}}^{-1}]$ (or more generally any Noetherian ring) and a finitely generated $\mathcal{R}$-module L. Given a proper submodule N of L, N has a *primary decomposition* (e.g., [3, 5, 10]) into submodules of L containing N:

$$N = \bigcap_{i=1}^{l} N_i, \tag{7.1}$$

where each quotient L/N_i is J_i-coprimary for some prime J_i, i.e., Ass (L/N_i) consists

of the single prime J_i, and the J_i's include all the associated primes of L/N. The intersection can be taken to be such that the J_i's are precisely the associated primes of L/N, each occurring precisely once, in which case it is called a *minimal primary decomposition*. Such a decomposition is in general nonunique.

The dual of (7.1) allows us to express any behavior $\mathcal{B}$ as the sum of subbehaviors $\mathcal{B}_i$, where each $\mathcal{B}_i$ has a single coassociated prime, and these primes are precisely the coassociated primes of $\mathcal{B}$. This idea has two interesting applications.

THEOREM 7.1. *Let $\mathcal{B}$ be a differential or difference behavior. Then the zero-input behavior has a decomposition*

$$\mathcal{B}_{0,y} = \sum_{i=1}^{l} \mathcal{B}_i, \tag{7.2}$$

where each behavior $\mathcal{B}_i$ has only a single coassociated prime J_i, and the J_i's are precisely the poles of $\mathcal{B}$. We call this decomposition a polar decomposition *of $\mathcal{B}_{0,y}$.*

The behavior $\mathcal{B}$ itself also has a decomposition

$$\mathcal{B} = \mathcal{B}^c + \sum_{l=1}^{r} \mathcal{B}'_l, \tag{7.3}$$

where each behavior $\mathcal{B}'_l$ has only a single coassociated prime J'_l, and the J'_l's are precisely the uncontrollable poles of $\mathcal{B}$.

Proof. The first claim follows immediately by application of the dual version of (7.1) to the zero-input behavior $\mathcal{B}_{0,y}$. For the second part, assume first that $\mathcal{B}$ is not autonomous, since otherwise $\mathcal{B}^c = 0$, the uncontrollable poles are the coassociated primes of $\mathcal{B}$, and the result is immediate by the dual of (7.1). Hence by Theorem 3.3 M is not a torsion module and so 0 is an associated prime. Thus $\mathcal{B}^\perp$ has a minimal primary decomposition: $\mathcal{B}^\perp = \bigcap_{l=0}^{r} N_l$, where, in particular, N_0 is the module such that $\mathrm{Ass}\,(\mathcal{R}^{1,q}/N_0) = \{0\}$. Define $\mathcal{B}'_l = (N_l)^\perp$ for $l = 0, 1, \ldots, r$. This gives us

$$\mathcal{B} = \sum_{l=0}^{r} \mathcal{B}'_l. \tag{7.4}$$

Now by Lemma 5.5, the uncontrollable poles of $\mathcal{B} = D(M)$ are precisely the coassociated primes of the behaviors $\mathcal{B}'_l$ for $l = 1, \ldots, r$. Finally, $\mathcal{R}^{1,q}/N_0$ is 0-primary, or equivalently, torsionfree (e.g., on applying [10, Prop. 3.4]), and so by Theorem 3.8 $\mathcal{B}'_0$ is controllable. The sum $\sum_{l=1}^{r} \mathcal{B}'_l$ is autonomous as the sum of autonomous behaviors, and so by the controllable–autonomous decomposition $\mathcal{B}'_0$ is the controllable part of $\mathcal{B}$. This completes the proof. ∎

Note that the polar decomposition also leads to a decomposition of $\mathcal{B}$ itself, by combination with the controllable–autonomous decomposition. However such a decomposition of $\mathcal{B}$ must be redundant, since by (7.3) it is possible to do this using only the uncontrollable poles. Indeed, the uncontrollable pole decomposition of $\mathcal{B}$ is a refinement of the controllable–autonomous decomposition. The 2D polar decomposition is also similar to a decomposition discussed by Valcher [38], in which any 2D autonomous behavior can be decomposed into the sum of a finite-dimensional behavior and a behavior with a square kernel representation.

The annihilator of a finitely generated module M can be computed using Gröbner basis techniques; an algorithm has been presented in [43]. This is in general the closest we can get to computing the characteristic variety of a behavior. The decompositions

in Theorem 7.1 can be computed via the primary decomposition, algorithms for which have been given in the algebraic literature, for example, [1, 11, 17]. The construction of a primary decomposition necessarily includes an identification of the associated primes, i.e., the poles or uncontrollable poles.

7.2. The integral representation theorem. The integral representation theorem was originally formulated by Ehrenpreis in 1961 [9] and then proven in full generality by Palamodov [28, Thm. VI.4.1]. A simplified special case was presented by Björk in [2, Thm. 8.1.3]. Roughly, the integral representation theorem gives an explicit form for any $\mathcal{C}^\infty$ behavior, in which each trajectory is expressed as a sum of integrals of polynomial exponential functions which also lie in the behavior. In the following, we write $\langle \underline{a}, \underline{t} \rangle$ for the inner product of two vectors $\underline{a}, \underline{t}$. Using the language of the behavioral approach, Björk's statement of the theorem reads as follows.

THEOREM 7.2 (integral representation theorem). *Let $\mathcal{B}$ be a differential behavior with signal space $\mathcal{C}^\infty(\mathbb{R}^n, \mathbb{C})$. Then there exist polynomial vectors $p_1, \ldots, p_L$ in $2n$ variables with the following property. For any compact and convex subset $\mathcal{H}$ of $\mathbb{R}^n$ with nonempty interior $\mathcal{K}$, and for any trajectory $w \in \mathcal{B}$, there exists measures $\mu_1, \ldots, \mu_L$ on $\mathbb{C}^n$ for which*

$$w(\underline{t}) \;=\; \sum_{i=1}^{L} \int_{\mathbb{C}^n} p_i(\underline{a}, \underline{t}) e^{\langle \underline{a}, \underline{t} \rangle} \; d\mu_i(\underline{a}) \tag{7.5}$$

for all $\underline{t} \in \mathcal{H}$, and for which the following conditions also hold:

1. *Each function $p_i(\underline{a}, \underline{t}) e^{\langle \underline{a}, \underline{t} \rangle}$ is a polynomial exponential trajectory of $\mathcal{B}$ for any $\underline{a}$ in the support of the measure μ_i. In particular, the support of μ_i is contained in the characteristic variety of $\mathcal{B}$.*
2. *We have*

$$\int_{\mathbb{C}^n} e^{\mathcal{H}(\underline{a})} (1 + ||\underline{a}||^c) \, d|\mu_i|(\underline{a}) \;<\; \infty$$

for all c, where $\mathcal{H}(\underline{a}) = \sup_{\underline{t} \in \mathcal{H}} (\langle \Re e(\underline{a}), \underline{t} \rangle)$. In particular, the integrals on the right of (7.5) are absolutely convergent and can be differentiated with respect to $\underline{t}$ under the integral sign for $\underline{t} \in \mathcal{K}$.

The integral representation (7.5) can be broken down by first applying the decomposition (7.3) in Theorem 7.1 in order to write $\mathcal{B}$ as a sum of subbehaviors $\mathcal{B}_i$ each with a single coassociated prime. For each $\mathcal{B}_i$, we then obtain an integral representation, and when summed these give a representation of $\mathcal{B}$.

Assume therefore that $\mathcal{B}$ has a single coassociated prime J, or equivalently, that $\mathcal{R}^{1,q}/\mathcal{B}^\perp$ is a J-coprimary. Then according to [28, Cor. IV.4.2] or [2, Thm. 8.4.5], there is a $q \times L$ matrix $A(\underline{\mathbf{z}}, \partial/\partial \underline{\mathbf{z}})$ of differential operators with polynomial coefficients such that

$$\mathcal{B}^\perp \;=\; \{ v \in \mathcal{R}^{1,q} \mid A^T(\underline{a}, \partial/\partial \underline{a}) v^T(\underline{a}) = 0 \text{ for all } \underline{a} \in V \},$$

where V denotes the characteristic variety of $\mathcal{B}$. Such a matrix A is called a *Noetherian operator* for $\mathcal{B}^\perp \subseteq \mathcal{R}^{1,q}$, and we can show that, for all $\underline{a} \in V$,

$$E(\partial/\partial \underline{t})(A(\underline{a}, \underline{t}) e^{\langle \underline{a}, \underline{t} \rangle}) \;=\; (A^T(\underline{a}, \partial/\partial \underline{a}) E^T(\underline{a}) e^{\langle \underline{a}, \underline{t} \rangle})^T \;=\; 0,$$

i.e., that $A(\underline{a}, \underline{t}) e^{\langle \underline{a}, \underline{t} \rangle}$ is a trajectory of $\mathcal{B}$. The columns of $A(\underline{a}, \underline{t})$ then become the polynomial vectors $p_i(\underline{a}, \underline{t})$ in the right-hand side of (7.5); see [2, proof of Thm. 8.1.3].

It is easy to construct a Noetherian operator in the special case when we know in addition that $\operatorname{ann} \mathcal{R}^{1,q}/\mathcal{B}^\perp$ is a radical ideal, i.e., when the annihilator of $\mathcal{R}^{1,q}/\mathcal{B}^\perp$ is equal to its single associated prime. In this case, $M = \mathcal{R}^{1,q}/\mathcal{B}^\perp$ is a torsionfree $\mathcal{R}/J$-module. We write $\overline{\mathcal{R}} = \mathcal{R}/J$, and for any matrix Q over $\mathcal{R}$ we use the notation $\overline{Q}$ for the matrix over $\overline{\mathcal{R}}$ obtained by projection of each entry. Now consider a kernel representation $E \in \mathcal{R}^{g,q}$ of $\mathcal{B}$, and construct an $A \in \mathcal{R}^{q,L}$ such that

$$\operatorname{Im}_{\overline{\mathcal{R}}} \overline{E} \;=\; \operatorname{Ker}_{\overline{\mathcal{R}}} \overline{A},$$

which is possible as $\operatorname{Coker}_{\overline{\mathcal{R}}} \overline{E}$ is torsionfree over $\overline{\mathcal{R}}$. We now have

$$\begin{aligned}\mathcal{B}^\perp &= \operatorname{Im}_{\mathcal{R}} E \\ &= \{v \in \mathcal{R}^{1,q} \;\mid\; \overline{vA} = \overline{v}\overline{A} = 0 \in \overline{\mathcal{R}}^{1,L}\} \\ &= \{v \in \mathcal{R}^{1,q} \;\mid\; A^T(\underline{a})v^T(\underline{a}) = 0 \text{ for all } \underline{a} \in V(\operatorname{ann}\mathcal{B})\}.\end{aligned}$$

This proves that $A(\underline{z}, \partial/\partial\underline{z}) = A(\underline{z})$ is a Noetherian operator for M. The polynomial vectors in the integral representation are then extracted as the columns of A.

The preceding argument can be applied in the case where $\mathcal{B}$ is controllable (and with no other conditions). For it then holds that $\mathcal{B}$ has the single coassociated prime $\{0\}$, which is equal to $\operatorname{ann}\mathcal{B}$. The ring $\overline{\mathcal{R}}$ is simply equal to $\mathcal{R}$, and so the Noetherian operator A is just any matrix such that $\operatorname{Im}_{\mathcal{R}} E = \operatorname{Ker}_{\mathcal{R}} A$ or equivalently $\ker_{\mathcal{A}} E = \operatorname{im}_{\mathcal{A}} A$, i.e., A is any image representation of $\mathcal{B}$. Thus in the controllable case we obtain the following corollary.

COROLLARY 7.3. *Let $\mathcal{B}$ be a controllable differential behavior with signal space $\mathcal{C}^\infty(\mathbb{R}^n, \mathbb{C})$ and an image representation F. Let $F_1, \dots, F_L$ denote the columns of F. Then for any $\underline{a} \in \mathbb{C}^n$, $F_i(\underline{a})e^{\langle \underline{a}, \underline{t}\rangle}$ is an exponential trajectory of $\mathcal{B}$, and every trajectory w of $\mathcal{B}$ can be written*

$$w(\underline{t}) \;=\; \sum_{i=1}^{L} \int_{\mathbb{C}^n} F_i(\underline{a}) e^{\langle \underline{a}, \underline{t}\rangle} \; d\mu_i(\underline{a}) \tag{7.6}$$

for suitable measures $\mu_1, \dots, \mu_L$ as in Theorem 7.2.

COROLLARY 7.4. *Let $u \in \mathcal{A}^m$, $y \in \mathcal{A}^p$ satisfy*

$$P(\underline{\mathbf{z}})y \;=\; u,$$

where $\mathcal{A} = \mathcal{C}^\infty(\mathbb{R}^n, \mathbb{C})$ and P is a square nonsingular matrix. Then there are measures $\mu_1, \dots, \mu_p$ on $\mathbb{C}^n$ such that

$$y_j(\underline{t}) = \int_{\mathbb{C}^n} e^{\langle \underline{a}, \underline{t}\rangle} \, d\mu_j(\underline{a}), \qquad j = 1, \dots, p,$$

and

$$u(\underline{t}) = \sum_{i=1}^{p} \int_{\mathbb{C}^n} P_i(\underline{a}) e^{\langle \underline{a}, \underline{t}\rangle} \, d\mu_i(\underline{a})$$

as in Theorem 7.2, where P_i denotes the ith column of P.

Proof. This result is immediate from Corollary 7.3, since $(U^T \; I_p)^T$ is an image representation of $\ker_{\mathcal{A}} (-I_p \; U)$, the given controllable behavior. □

In the case of a finite-dimensional behavior $\mathcal{B}$, the characteristic variety is finite (see Lemma 5.9), and each integral in the summation of (7.5) can be taken as an evaluation of the integrand at a given characteristic point, multiplied by a suitable

constant. In this situation we can recover the result that every trajectory is a polynomial exponential trajectory [26], which generalizes the well-known decomposition of trajectories of 1D systems. Results for the case of a zero-dimensional characteristic variety are also given in [2, p. 365]. The general construction of Noetherian operators is addressed in [27].

ERRATUM: ASYNCHRONOUS STOCHASTIC APPROXIMATIONS*

VIVEK S. BORKAR†

PII. S0363012998345913

The proofs of Lemma 2.1 and Theorem 3.2 of [1] have a common error, the correction of which needs additional conditions: the use of l'Hôpital's rule in both equates the limiting ratio of derivatives of functions with the limiting ratio of the functions themselves, but this presupposes that the latter exist. Of these, the conclusions of Lemma 2.1 can simply be adopted as an additional assumption on stepsizes (a harmless one, as it is satisfied by all the usual examples). The proof of Theorem 3.2 will continue to hold if we make the following additional assumption.

For all $x > 0$ and

$$N(n,x) = \min\left\{ m > n : \sum_{k=n+1}^{m} \tilde{a}(k) > x \right\},$$

the limit

$$\lim_{n\to\infty} \frac{\sum_{k=\nu(n,i)}^{\nu(N(n,x),i)} a(k,i)}{\sum_{k=\nu(n,j)}^{\nu(N(n,x),j)} a(k,j)} \tag{1}$$

exists almost surely (a.s.) for all i, j.

Intuitively, this implies that the updating of different components is "evenly spread." Under this condition,

$$\lim_{t\to\infty} \frac{\int_0^x \mu_{t+y}(j)dy}{\int_0^x \mu_{t+y}(i)dy}$$

is guaranteed to exist a.s. a priori, justifying the use of l'Hôpital's rule.

Since $\{\tilde{a}(n)\}$ were defined after the artificial "unfolding" of iterates, (1) may look a little contrived. One can alternatively use the following condition defined in terms of the original stepsizes: for all $x > 0$ and

$$N(n,x) = \min\left\{ m > n : \sum_{k=n+1}^{m} \sum_{i} \bar{a}(k,i) I\{i \in Y_n\} > x \right\},$$

the limit

$$\lim_{n\to\infty} \frac{\sum_{k=\nu(n,i)}^{\nu(N(n,x),i)} a(k,i)}{\sum_{k=\nu(n,j)}^{\nu(N(n,x),j)} a(k,j)}$$

exists a.s. for all i, j.

Under this, an appropriate variant of Theorem 3.2 can be proved without the unfolding. See also Lemma 4.8, [2].

DYNAMIC L^p-HEDGING IN DISCRETE TIME UNDER CONE CONSTRAINTS*

HUYÊN PHAM†

Abstract. We consider a general discrete time process of a financial market with cone constraints on trading strategies. In this framework, we study the problem of minimizing the expected l_p-loss function of the shortfall of a given contingent claim in L^p. This stochastic control problem is solved by using results on superhedging and a convex duality approach.

Key words. hedging, superhedging, constrained portfolios, stochastic control problem, duality theory

1. Introduction. In a frictionless financial market which is free of arbitrage opportunities and complete, the problem of pricing and hedging is well understood. Any contingent claim H is attainable: starting from an initial wealth v_0, an agent can find a trading strategy θ^H that will allow his (self-financed) wealth V^{v_0,θ^H} to achieve exact replication of the claim at the expiration date T, $V_T^{v_0,\theta^H} = H$, almost surely (a.s.). The cost of replication v_0 is given by the expected value of the contingent claim under the unique equivalent martingale measure.

In an incomplete market and/or with constraints on trading strategies, not every contingent claim is attainable. However, it is still possible to hedge without risk the contingent claim H at time T, whenever one starts with a large enough initial wealth x:

$$V_T^{x,\theta} \geq H, \quad \text{a.s. for some trading strategy } \theta. \tag{1.1}$$

The least initial wealth v_0 allowing (1.1) is called superreplication cost of the contingent claim, and the corresponding strategy θ^H such that $V_T^{v_0,\theta^H} \geq H$, a.s. is called superhedging strategy of H. The superreplication cost v_0 is given by the supremum of the expected values over a suitable set of equivalent martingale measures; see El Karoui and Quenez [13], Kramkov [26], Schäl [36], Föllmer and Kabanov [14] in an incomplete market context, and Cvitanić and Karatzas [5] and Föllmer and Kramkov [15] in a continuous time model with convex constraints on trading strategies. But in many situations, the superhedging strategy is the trivial buy-and-hold strategy and the superreplication cost is too high; see, e.g., Eberlein and Jacod [11] and Cvitanić, Pham, and Touzi [7].

We consider the position of an agent who is unwilling to commit the initial amount required for a superhedging strategy. Then the contingent claim carries an intrinsic risk and the question is how to quantify this risk. Various criteria have been proposed in the literature. The mean-variance hedging approach, initiated by Duffie and Richardson [10] and studied by Schäl [35], Schweizer [38, 39], Monat and Stricker [29],

*Received by the editors June 25, 1998; accepted for publication (in revised form) September 22, 1999; published electronically February 24, 2000.

†Laboratoire de Probabilités et Modéles Aleatoires, UMR 7599, Université Paris 7, Case 7012, 2 Place Jussieu, 75251 Paris Cedex 05, France (pham@gauss.math.jussieu.fr).

Gouriéroux, Laurent, and Pham [18], and Rheinländer and Schweizer [31], among others, consists of approximating in $L^2(P)$-norm the contingent claim H by the terminal value of a self-financed wealth process:

$$\inf_\theta E\left[\left(H - V_T^{x,\theta}\right)^2\right]. \tag{1.2}$$

Expectation in (1.2) is under the objective probability P. The main criticism of this criterion is that it gives equal weight to upside and downside risks. In a general continuous time semimartingale model, Föllmer and Leukert [16] consider the problem of maximizing the probability of a hedge without risk,

$$\sup_\theta P\left[V_T^{x,\theta} \geq H\right], \tag{1.3}$$

by making use of the Neyman–Pearson lemma. This criterion does not take into account the size of the shortfall $(H - V_T^{x,\theta})^+$ but only the probability of its occurrence. In the context of a complete diffusion model and in the spirit of the paper of Artzner et al. [1], Cvitanić and Karatzas [6] study the following measure of the risk of the contingent claim H,

$$\inf_\theta E\left[\left(H - V_T^{x,\theta}\right)^+\right], \tag{1.4}$$

by adopting a convex duality approach. Notice that in both papers of Föllmer and Leukert [16, 17] and in Cvitanić and Karatzas [6], wealth processes have to satisfy a fixed lower bound requirement.

In this paper, we consider a general discrete time price process of a financial market. We also impose cone constraints on trading strategies. This includes the incomplete market case as well as the case of no short-selling constraints on portfolios. Given a contingent claim H in $L^p(P)$ and a loss function $l_p(x) = x^p/p$, $x \geq 0$, $p \in (1, \infty)$, we propose to measure the intrinsic risk of H by the quantity

$$J(x) = \inf_\theta E\left[l_p\left(\left(H - V_T^{x,\theta}\right)^+\right)\right]. \tag{1.5}$$

This is the smallest expected l_p-loss function of the shortfall of the contingent claim that can be achieved by trading in the financial market. Our purpose is to study this stochastic control problem (1.5) by deriving some properties of the value function J and by characterizing the trading strategy, if it exists, that attains the infimum. Recently, Föllmer and Leukert [17] have studied the problem of minimizing $E[l(H - V_T^{x,\theta})^+]$ for a general loss function l and in a general continuous time incomplete model, focusing on the Neyman–Pearson approach. In Cvitanić [3], convex duality approach is applied for a linear loss function, $l(x) = x$, in the context of an incomplete or constrained diffusion model.

We present in section 2 the model and the precise formulation of the problem. Within this $L^p(P)$-framework with cone constraints, we introduce in section 3 sets of martingale measures related to the no arbitrage condition and we state duality results on the superreplication cost. In section 4, we combine the technique of superhedging and a convex duality approach to solve the stochastic control problem (1.5). Our main result states that the optimal hedging strategy is given by the superhedging strategy of the modified contingent claim $H - l_q'(y^*(x)Z^*(y^*(x))$, where q is the conjugate of

p; i.e., $1/p + 1/q = 1$, $y^*(x) > 0$ is some Lagrange multiplier, and $Z^*(y^*(x))$ is a martingale measure, depending on H in general, solution of a dual problem whose existence is proved. Section 5 contains applications and examples of our results. We first show that the well-known equivalence between uniqueness of a martingale measure and attainability of every contingent claim in an unconstrained market can be extended to the case of symmetrical cone constraints on trading strategies. The determination of the optimal hedging strategy in this framework of complete market model is illustrated with the example of the Cox–Ross–Rubinstein model. In a second application, we note a case where H is attainable in a model with symmetrical cone constraints. Then, the dual problem leads to the problem of the so-called $L^q(P)$-optimal martingale measure, which does not depend on H. Finally, we consider the problem of hedging a riskless asset and we give an explicit example of computation of the optimal hedging strategy in a no short-selling constraints model.

2. Formulation of the problem. Let $(\Omega, \mathcal{F}, P)$ be a probability space with a filtration $\mathbb{F} = \{\mathcal{F}_k,\ k = 0, \dots, T\}$ for some $T \in \mathbb{N}$. For simplicity, we assume that $\mathcal{F}_0$ is trivial. The evolution of the discounted price process of d risky assets is modeled by an $\mathbb{R}^d$-valued $\mathbb{F}$-adapted stochastic process $S = \{S_k,\ k = 0, \dots, T\}$. A trading strategy is an $\mathbb{R}^d$-valued process $\theta = \{\theta_k,\ k = 1, \dots, T\}$, $\mathbb{F}$-predictable; i.e., θ_k is $\mathcal{F}_{k-1}$-measurable $\forall k = 1, \dots, T$. Here θ_k represents the number of units of risky assets held by the investor during $(k-1, k]$ $\forall k = 1, \dots, T$. We denote by Θ the set of all trading strategies. Given an initial wealth $x \in \mathbb{R}$ and a trading strategy $\theta \in \Theta$, we define the discounted (self-financed) wealth process $V^{x,\theta}$ by

$$V_k^{x,\theta} = x + \sum_{j=1}^{k} \theta_j . \Delta S_j, \quad k = 1, \dots, T,$$
$$V_0^{x,\theta} = x,$$

where $\Delta S_j = S_j - S_{j-1}$. Here given two elements $a, b \in \mathbb{R}^d$, $a.b$ denotes their Euclidean scalar product. When using discounted prices and a discounted self-financed wealth process, we assume there is an additional bank account whose interest rate is zero. This reduced form is explained in detail in Harrison and Kreps [19]. Notice that by considering discounted prices, we leave aside all problems related to the case of stochastic interest rate. These questions typically arise in the context of foreign exchange markets. This would certainly be an important extension of our model but is beyond the scope of the present paper.

Let us consider a nonempty closed convex cone C in $\mathbb{R}^d$. A trading strategy θ is called C-constrained if

$$\theta_k \in C, \qquad k = 1, \dots, T,\ P \text{ a.s.}$$

We denote by $\Theta(C)$ the set of all C-constrained trading strategies. The role of the convex cone C is to model some constraints on the trading strategies. We denote by C^o the polar cone of C. Since C is a cone, we have (see [32])

$$C^o = \{b \in \mathbb{R}^d : a.b \leq 0\ \forall a \in C\}.$$

The following are some examples of such constraints:

(a) *Unconstrained case*: $C = \mathbb{R}^d$. Then $C^o = \{0\}$.

(b) *Prohibition of short-selling of some risky assets*: $C = \{a \in \mathbb{R}^d : a^i \geq 0\ \forall i \in I\}$, where I is some subset of $\{1, \dots, d\}$. Then $C^o = \{b \in \mathbb{R}^d : b^i \leq 0\ \forall i \in I, b^i = 0 \text{ otherwise}\}$.

Consider now a contingent claim given by an $\mathcal{F}_T$-measurable random variable H. Given an initial wealth x and a trading strategy θ, the resulting shortfall of H, defined as the excess of the contingent claim over the final portfolio value, is $(H - V_T^{x,\theta})^+$. We are interested in the problem of minimizing the $L^p(P)$-norm $(1 < p < \infty)$ of the shortfall of a contingent claim $H \in L^p(P)$. We introduce the subset of trading strategies

$$\Theta_p(C) = \left\{ \theta \in \Theta(C) : \exists X \in L^p(P),\ V_T^{0,\theta} \geq X,\ P\ a.s. \right\},$$

and we consider the following optimization problem:

$$(\mathcal{P}_p(x))J(x) \ = \ \inf_{\theta \in \Theta_p(C)} E\left[l_p\left(\left(H - V_T^{x,\theta} \right)^+ \right) \right], \quad x \in \mathbb{R},$$

where l_p is a loss function defined on $\mathbb{R}_+$ by $l_p(y) = y^p/p$. In this L^p-framework, we shall assume that $S_k \in L^p(P)$, $k = 0, \ldots, T$. We mention that the main result of the paper remains valid under the more general case when S is locally in $L^p(P)$ (see Remark 3.1). We analyze problem $(\mathcal{P}_p(x))$ by combining the technique of superhedging in a L^p-framework under cone constraints with a convex duality approach.

Remark 2.1. Föllmer and Leukert [17] study the problem of minimizing $E[l(H - V_T^{x,\theta})^+]$ for a general loss function l and in a general continuous time incomplete model. They focus mainly on the Neyman–Pearson lemma approach as in their previous paper [16]. Cvitanić and Karatzas [6] and Cvitanić [3] analyze a similar problem for a linear loss function, $l(x) = x$, in a diffusion model including also constraints on strategies and margin requirements. Notice that in these papers a nonnegativity constraint and, more generally, a given lower bound constraint on the wealth process is imposed. Here, since we allow for contingent claims with a nonconstant sign, we consider a more general admissibility condition by requiring only a lower bound on the terminal wealth value by some arbitrary $L^p(P)$ random variable.

3. Martingale measures, arbitrage, and superhedging strategy. In an incomplete market model, there is a known duality relation between the superreplication cost of a contingent claim H, defined as the least initial wealth for hedging H without risk, and the largest arbitrage-free prices defined as the supremum of expectations of H under a set of martingale measures; see, e.g., Delbaen and Schachermayer [9], El Karoui and Quenez [13], Kramkov [26], Schäl [36], and Föllmer and Kabanov [14]. In markets with convex constraints on trading strategies, analogous results are generalized by Cvitanić and Karatzas [5] in a diffusion model and by Föllmer and Kramkov [15] in a general continuous time semimartingale model; see also Brannath [2] in a discrete time framework. Most of the cited papers consider the case of nonnegative contingent claims. For the sake of completeness and the purpose of our paper, we state similar results in a general discrete time model with cone constraints and for a contingent claim in $L^p(P)$.

Let us introduce some notations. By $L^{0,d}(\mathcal{F}_k, P)$, we denote the space of all $\mathbb{R}^d$-valued $\mathcal{F}_k$-measurable random variables. When $d = 1$, we shall omit exponent d. We consider the convex cone K of $L^0(P) := L^0(\mathcal{F}_T, P)$,

$$K = \left\{ V_T^{0,\theta} : \theta \in \Theta(C) \right\},$$

and we say that there is no arbitrage opportunity if

$$\text{(NA)} \quad K \cap L^0_+(P) = \{0\}.$$

In the unconstrained case on trading strategies, there is a basic result relating the no arbitrage condition (NA) to the existence of some equivalent martingale measure. This duality result, known as the fundamental theorem of asset pricing, was proved by Dalang, Morton and Willinger [8], Schachermayer [34], Kabanov and Kramkov [24], and Rogers [33] in a discrete time framework. Extensions of this result to the constrained case are proved by Jouini and Kallal [23] and Schürger [37] in a no short-selling constraints model, by Pham and Touzi [30] in the case of cone constraints on portfolios, and by Brannath [2] in the case of convex constraints. For the sake of completeness, we briefly recall these results.

In the rest of this paper, for any $p \in [1, \infty]$, we denote by $q \in [1, \infty]$ its conjugate, i.e., $1/p + 1/q = 1$. Given $p \in [1, \infty]$, we introduce the following set of martingale measures:

$$\mathcal{M}_q(P) = \left\{ Q \ll P : \frac{dQ}{dP} \in L^q(P), \text{ and } E^Q[\Delta S_k | \mathcal{F}_{k-1}] \in C^o,\ k = 1, \dots, T,\ Q \text{ a.s.} \right\},$$

$$\mathcal{M}_q^e(P) = \{ Q \sim P : Q \in \mathcal{M}_q(P) \}.$$

In the unconstrained case $C = \mathbb{R}^d$, $\mathcal{M}_q^e(P)$ is the set of equivalent probability measures with density in $L^q(P)$ under which S is a martingale. In the no short-selling constraints case $C = (0, \infty)^d$, $\mathcal{M}_q^e(P)$ is the set of equivalent probability measures with density in $L^q(P)$ under which S is a supermartingale. Writing that $V_k^{0,\theta} = V_{k-1}^{0,\theta} + \theta_k.\Delta S_k$, it is easily seen that for any $\theta \in \Theta_p(C)$, $V^{0,\theta}$ is a supermartingale under any $Q \in \mathcal{M}_q(P)$. Since $\Delta S_k \in L^p(P)$, $k = 1, \dots, T$, it is clear that $\mathcal{M}_q(P)$ is closed in $L^q(P)$ (when identifying a probability measure $Q \ll P$ with its Radon–Nikodym dQ/dP).

Remark 3.1. In the case where S is assumed only to be local in $L^p(P)$, one introduces the set

$$\mathcal{M}_q^{loc}(P) = \left\{ Q \ll P : \frac{dQ}{dP} \in L^q(P),\ E^Q[|\Delta S_k||\mathcal{F}_{k-1}] < \infty, \text{ and } E^Q[\Delta S_k | \mathcal{F}_{k-1}] \in C^o,\ k = 1, \dots, T,\ Q \text{ a.s.} \right\},$$

which is equal to $\mathcal{M}_q(P)$ when $S \in L^p(P)$. It can be proved that $\mathcal{M}_q^{loc}(P)$ is closed in $L^q(P)$.

As is now standard in the literature on arbitrage and superreplication, a key result is to state the closedness property of the set of dominated final payoffs, $K - L_+^0(P)$ for the topology of convergence in probability. While this property is satisfied in the unconstrained case (see, e.g., Schachermayer [34]), this does not hold true in the presence of constraints on strategies (see Brannath [2]). We shall then make a nondegeneracy assumption on the price process in order to ensure this closedness property. Let us introduce, $\forall k = 1, \dots, T$, the subsets of $L^{0,d}(\mathcal{F}_{k-1}, P)$:

$$N(k-1) = \left\{ \eta \in L^{0,d}(\mathcal{F}_{k-1}, P) : \eta.\Delta S_k = 0,\ P \text{ a.s.} \right\}.$$

We assume that

(B) $N(k-1) = \{0\}\ \forall k = 1, \dots, T$.

Remark 3.2. Notice that if $S \in L^2(P)$, then condition (B) is obviously implied by the nondegeneracy condition on the price process:

(B′) $\mathrm{Var}(S_k|\mathcal{F}_{k-1})$ is invertible $\forall k = 1, \ldots, T$.

Condition (B′) is satisfied by most models considered in the financial literature. For instance, suppose that $\{S_k, k = 1, \ldots, T\}$ is obtained from the geometric Brownian motion $dS_t = S_t(\mu dt + \sigma dW_t)$ as in the Black–Scholes model. Then, a straightforward calculation shows that

$$\mathrm{Var}\left(S_k|\mathcal{F}_{k-1}\right) = S_{k-1}^2 e^{2\mu}\left(e^{\sigma^2} - 1\right),$$

and the validity of the hypothesis of invertibility of $\mathrm{Var}\left(S_t|\mathcal{F}_{t-1}\right)$ is guaranteed whenever $\sigma > 0$. It is also easy to check that condition (B′) is satisfied in the Cox–Ross–Rubinstein model (see section 5).

Under condition (B), we have the dual characterization of the no arbitrage condition (NA): there is no arbitrage opportunity if and only if $\mathcal{M}_\infty^e(P) \neq \emptyset$ (see Pham and Touzi [30], Brannath [2]).

We define the superreplication cost of a contingent claim $H \in L^p(P)$, $p \in [1, \infty]$, by

$$v_0 = \inf\left\{x \in \mathbb{R} : \ \exists \theta \in \Theta_p(C),\ V_T^{x,\theta} \geq H,\ P \text{ a.s.}\right\}.$$

The next result provides a dual characterization of the superreplication cost in terms of martingale measures within a $L^p(P)$-framework in a general discrete time model with cone constraints portfolios. In what follows, to alleviate notations, we write $\mathcal{M}_q = \mathcal{M}_q(P)$.

THEOREM 3.1. *Assume that condition* (NA) *is satisfied and assumption* (B) *holds. Then the superreplication cost of a contingent claim $H \in L^p(P)$, $p \in [1, \infty]$, is given by*

$$v_0 = \sup_{Q \in \mathcal{M}_q^e} E^Q[H]. \tag{3.1}$$

In (3.1)*, the supremum can also be taken with respect to $\mathcal{M}_q$. Moreover, we have the following assertions:*

(1) *Suppose that $\sup_{Q \in \mathcal{M}_q^e} E^Q[H] < \infty$; then there exists $\theta^H \in \Theta_p(C)$ such that $V_T^{v_0,\theta^H} \geq H$, P a.s. θ^H is called superhedging strategy for H.*

(2) *Suppose that the supremum in* (3.1) *is attained for some $\hat{Q} \in \mathcal{M}_q^e$. Then the superhedging strategy θ^H is actually a replicating strategy, i.e., $V_T^{v_0,\theta^H} = H$, P a.s.*

Proof. See Appendix A. □

4. $L^p(P)$-hedging and dual formulation. In a first step, we reformulate the dynamic problem $(\mathcal{P}_p(x))$ into an equivalent static problem by using results of section 3 on superhedging strategy. For $p \in (1, \infty)$, $x \in \mathbb{R}$, and a given contingent claim H in $L^p(P)$, we denote

$$\mathcal{C}_p(x) = \left\{X \in L^p(P) : X \leq H,\ P \text{ a.s. and } E[ZX] \leq x\ \forall Z \in \mathcal{M}_q\right\}.$$

Here we identify a probability measure Q in $\mathcal{M}_q$ with its Radon–Nikodým density $Z = dQ/dP$. We consider then the static problem

$$(\mathcal{S}_p(x)) \quad \inf_{X \in \mathcal{C}_p(x)} E\left[l_p\left(H - X\right)\right].$$

PROPOSITION 4.1. *Assume that condition* (NA) *is satisfied and assumption* (B) *holds.*

(1) *The value functions of problems* $(\mathcal{P}_p(x))$ *and* $(\mathcal{S}_p(x))$, $x \in \mathbb{R}$, *coincide:*

$$J(x) = \inf_{\theta \in \Theta_p(C)} E\left[l_p\left(\left(H - V_T^{x,\theta}\right)^+\right)\right] = \inf_{X \in \mathcal{C}_p(x)} E\left[l_p\left(H - X\right)\right] \quad \forall\, x \in \mathbb{R}.$$

(2) *Assume that* $X^*(x)$ *is a solution to problem* $(\mathcal{S}_p(x))$. *Then there exists a superhedging strategy* $\theta^*(x)$ *for* $X^*(x)$ *and* $\theta^*(x)$ *solves the dynamic problem* $(\mathcal{P}_p(x))$.

(3) *Conversely, assume that* $\theta^*(x)$ *is a solution to problem* $(\mathcal{P}_p(x))$. *Then* $X^*(x) = H - (H - V_T^{x,\theta^*(x)})^+$ *solves problem* $(\mathcal{S}_p(x))$.

Proof. (1) Let $\theta \in \Theta_p(C)$. Then $X = H - (H - V_T^{x,\theta})^+ = \min(H, V_T^{x,\theta}) \in L^p(P)$. We have $X \le H$ and $X \le V_T^{x,\theta}$, so that by the supermartingale property of $V^{x,\theta}$ under $Q = Z.P \in \mathcal{M}_q$, $E[ZX] \le x$. It follows that $X \in \mathcal{C}_p(x)$. Denoting by $\bar{J}$ the value function of problem $(\mathcal{S}_p(x))$, $x \in \mathbb{R}$, we have

$$E\left[l_p\left(\left(H - V_T^{x,\theta}\right)^+\right)\right] = E\left[l_p\left(H - X\right)\right] \ge \bar{J}(x),$$

and therefore $J(x) \ge \bar{J}(x)$. Conversely, let $X \in \mathcal{C}_p(x)$. We then have

$$x_0 := \sup_{Z \in \mathcal{M}_q} E[ZX] \le x < \infty.$$

We deduce by Theorem 3.1 that there exists $\theta^X \in \Theta_p(C)$, superhedging strategy for X, such that

$$V_T^{x,\theta^X} \ge V_T^{x_0,\theta^X} \ge X, \tag{4.1}$$

and therefore, recalling that $X \le H$,

$$\left(H - V_T^{x,\theta^X}\right)^+ \le H - X. \tag{4.2}$$

Now, since the function l_p is nondecreasing, we obtain

$$J(x) \le E\left[l_p\left(\left(H - V_T^{x,\theta^X}\right)^+\right)\right] \le E\left[l_p\left(H - X\right)\right],$$

which proves that $J(x) \le \bar{J}(x)$ and finally the equality $J = \bar{J}$.

(2) As in (4.1)–(4.2), there exists a superhedging strategy $\theta^*(x)$ for $X^*(x)$, and we have

$$\left(H - V_T^{x,\theta^*(x)}\right)^+ \le H - X^*(x);$$

hence,

$$E\left[l_p\left(\left(H - V_T^{x,\theta^*(x)}\right)^+\right)\right] \le E\left[l_p\left(H - X^*(x)\right)\right] = J(x),$$

which proves that $\theta^*(x)$ solves problem $(\mathcal{P}_p(x))$.

(3) As in the proof of (1), the random variable $X^*(x) = H - (H - V_T^{x,\theta^*(x)})^+$ lies in $\mathcal{C}_p(x)$ and we have

$$E\left[l_p\left(H - X^*(x)\right)\right] = E\left[l_p\left(\left(H - V_T^{x,\theta^*(x)}\right)^+\right)\right] = J(x),$$

which proves that $X^*(x)$ solves problem $(\mathcal{S}_p(x))$. ∎

Remark 4.1. A trivial case where problem $(\mathcal{P}_p(x))$ is directly solved arises when the investor has an initial wealth larger than the superreplication cost of the contingent claim; i.e., $x \geq v_0 = \sup_{Z\in\mathcal{M}_q} E[ZH]$. Then the solution to problem $(\mathcal{S}_p(x))$ is obviously $X^*(x) = H$ and a solution to problem $(\mathcal{P}_p(x))$ is the superhedging strategy θ^H for H. In this case, the resulting shortfall of H is zero and $J(x) = 0$.

In Föllmer and Leukert [17], wealth processes are required to be nonnegative. This admissibility condition is crucial for solving the static problem associated to (1.3) thanks to the Neyman–Pearson lemma. Here in our L^p-framework, we do not impose a fixed lower bound on wealth process so that the static problem $(\mathcal{S}_p(x))$ can not be solved by using the Neyman–Pearson lemma. In what follows, we fix $p \in (1,\infty)$, $H \in L^p(P)$, and we study the static problem $(\mathcal{S}_p(x))$ for an initial capital $x < v_0$, by adopting a convex duality approach. Starting with the strictly convex function $x \mapsto l_p(H-x)$, defined on the random interval $(-\infty, H]$, we consider its stochastic Fenchel–Legendre transform:

$$\tilde{L}(y,\omega) = \max_{x\leq H}[-l_p(H-x) - xy] \;=\; l_q(y) - yH, \qquad y > 0. \tag{4.3}$$

The maximum in expression (4.3) is attained by the random $\mathcal{F}_T$-measurable function:

$$\chi(y,\omega) = H - l_q'(y), \quad y > 0. \tag{4.4}$$

We consider then the dual problem of $(\mathcal{S}_p(x))$:

$$(\mathcal{D}_q(y))\tilde{J}(y) \;=\; \inf_{Z\in\mathcal{M}_q} E\left[\tilde{L}(yZ,\omega)\right].$$

Notice that compared to the dual problem arising in the problem of maximizing the expected utility of terminal wealth in an incomplete market (see Karatzas et al. [25], He and Pearson [21], Cvitanić and Karatzas [4], and Kramkov and Schachermayer [27]), there is an additional term depending on the contingent claim in the formulation of the dual problem $(\mathcal{D}_q(y))$. We mention that Föllmer and Leukert [17] also use a convex duality approach in their context of nonnegative wealth processes.

The next proposition states the existence of a unique solution to the dual problem.

PROPOSITION 4.2. *Assume that $\mathcal{M}_q \neq \emptyset$. Then $\forall y > 0$, there exists a unique solution $Z^*(y)$ to the dual problem $(\mathcal{D}_q(y))$. Moreover, the function $\tilde{J}$ is differentiable and strictly convex on $(0,\infty)$, and we have*

$$\tilde{J}'(y) = -E\left[Z^*(y)\chi(yZ^*(y),\omega))\right], \quad y > 0. \tag{4.5}$$

Proof. Let $(Z_n)_n$ be a sequence in $\mathcal{M}_q$ such that

$$\lim_{n\to\infty} E\left[\tilde{L}(yZ_n,\omega)\right] = \tilde{J}(y). \tag{4.6}$$

Then, for n sufficiently large, we have

$$E\left[l_q(yZ_n) - yZ_nH\right] \leq \tilde{J}(y) + 1. \tag{4.7}$$

Since $\mathcal{M}_q \neq \emptyset$, we have $\tilde{J}(y) < \infty \;\forall\; y > 0$. By Hölder inequality and since $H \in L^p(P)$, we deduce from (4.7) that

$$\| Z_n \|^q_{L^q(P)} \leq \text{const.}\left(1 + \| Z_n \|_{L^q(P)}\right), \tag{4.8}$$

where const. is a positive constant independent of n. Since $q > 1$, inequality (4.8) proves that $(Z_n)_n$ is bounded in $L^q(P)$. This implies that Z_n converges weakly in $L^q(P)$ to some $Z^*(y)$, possibly along a subsequence. By Mazur's theorem (see Ekeland and Temam [12, Chap. I], there exists a sequence $\tilde{Z}_n \in \text{conv}(Z_n, Z_{n+1}, \ldots)$ such that $\tilde{Z}_n$ converges to $Z^*(y)$ in $L^q(P)$-norm. It is clear that $\tilde{Z}_n \in \mathcal{M}_q$. Moreover, $\mathcal{M}_q$ is closed in $L^q(P)$ and so $Z^*(y) \in \mathcal{M}_q$. From the convexity of the function $z \in \mathbb{R}_+ \mapsto \tilde{L}(yz, \omega)$, P a.s., we have

$$E\left[\tilde{L}(y\tilde{Z}_n, \omega)\right] \leq \sup_{k \geq n} E\left[\tilde{L}(yZ_k, \omega)\right],$$

so that by (4.6), and since $\tilde{L}(y\tilde{Z}_n, \omega)$ converges to $\tilde{L}(yZ^*(y), \omega)$ in $L^1(P)$,

$$E\left[\tilde{L}(yZ^*(y), \omega)\right] = \lim_{n \to \infty} E\left[\tilde{L}(y\tilde{Z}_n, \omega)\right] = \tilde{J}(y),$$

which proves that $Z^*(y)$ is solution to $(\mathcal{D}_q(y))$. The uniqueness of the solution to $(\mathcal{D}_q(y))$ follows from the strict convexity of the function $z \in \mathbb{R}_+ \mapsto \tilde{L}(yz, \omega)$, P a.s. $\forall\ y > 0$. The strict convexity of $\tilde{J}$ is proved by same arguments as in Kramkov and Schachermayer [27, Lemma 3.5] by using the strict convexity of the function $x \in \mathbb{R}_+ \mapsto \tilde{L}(x, \omega)$, P a.s.

Let $y > 0$. Then $\forall\ h > 0$, we have

$$\begin{aligned}\frac{\tilde{J}(y+h) - \tilde{J}(y)}{h} &\leq \frac{1}{h} E\left[\tilde{L}((y+h)Z^*(y), \omega) - \tilde{L}(yZ^*(y), \omega)\right] \\ &= \frac{l_q(y+h) - l_q(y)}{h} E\left[Z^*(y)^q\right] - E\left[Z^*(y)H\right].\end{aligned}$$

This shows that

$$\limsup_{h \searrow 0^+} \frac{\tilde{J}(y+h) - \tilde{J}(y)}{h} \leq -E\left[Z^*(y)\chi(yZ^*(y), \omega)\right]. \tag{4.9}$$

Similarly, $\forall h < 0$, $y + h > 0$, we have

$$\frac{\tilde{J}(y+h) - \tilde{J}(y)}{h} \geq \frac{l_q(y+h) - l_q(y)}{h} E\left[Z^*(y)^q\right] - E\left[Z^*(y)H\right],$$

which shows that

$$\liminf_{h \nearrow 0^-} \frac{\tilde{J}(y+h) - \tilde{J}(y)}{h} \geq -E\left[Z^*(y)\chi(yZ^*(y), \omega)\right]. \tag{4.10}$$

Finally, (4.9)–(4.10) and convexity of the function $\tilde{J}$ imply the differentiability of $\tilde{J}$ and provides the expression (4.5) of $\tilde{J}'$. □

Remark 4.2. Cvitanić [3] also uses a convex duality approach in the case of a linear loss function. In this context, the value function of the dual problem fails to be everywhere differentiable.

LEMMA 4.1. *Under the assumptions of Proposition* 4.2, $\forall x < v_0$, *there exists a unique* $y^*(x) > 0$ *satisfying* $\tilde{J}'(y^*(x)) = -x$, *i.e.,*

$$E\left[Z^*(y^*(x))\chi\left(y^*(x)Z^*(y^*(x)), \omega\right)\right] = x. \tag{4.11}$$

Proof. The function $y \mapsto f_x(y) = \tilde{J}(y) + xy$ is (strictly) convex on $(0,\infty)$. We have $f_x(0^+) = 0$. Moreover, by Jensen's inequality and since $E[Z^*(y)] = 1$, we have

$$\tilde{J}(y) \geq l_q(y) - yE\left[Z^*(y)H\right];$$

hence,

$$f_x(y) \geq l_q(y) - y\left(E\left[Z^*(y)H\right] - x\right).$$

Since $q > 1$, this shows that $f_x(y) \to \infty$ as y goes to infinity. Let us now check that there exists $y_0 > 0$ such that $f_x(y_0) < 0$. If not, we should have

$$E\left[l_q(yZ) - yZH\right] + xy \geq 0 \quad \forall y > 0,\ \forall Z \in \mathcal{M}_q;$$

hence,

$$\frac{l_q(y)}{y} E\left[Z^q\right] + x \geq E\left[ZH\right] \quad \forall y > 0,\ \forall Z \in \mathcal{M}_q.$$

By sending y to zero, and from Theorem 3.1, we obtain

$$x \geq \sup_{Z \in \mathcal{M}_q} E\left[ZH\right] = v_0,$$

which is in contradiction to the fact that $x < v_0$. We have thus proved the existence of $y^*(x) > 0$ which attains the infimum of $f_x(y)$ over $y > 0$. The uniqueness of $y^*(x)$ follows from the strict convexity of f_x. Finally, since $\tilde{J}$ (and so f_x) is differentiable, we have $f_x'(y^*(x)) = 0$ or $\tilde{J}'(y^*(x)) = -x$, which provides the relation (4.11) by (4.5). □

We now state the main result of this paper by proving the existence of a unique solution to the dynamic problem $(\mathcal{P}_p(x))$ and relating it to the solution of a dual problem. Recall that when $x \geq v_0$, a solution to the problem $(\mathcal{P}_p(x))$ is the superhedging strategy for H; see Remark 4.1. In the case $x < v_0$, we have the following result.

THEOREM 4.1. *Assume that condition* (NA) *is satisfied and assumption* (B) *holds.*

(1) *For all $x < v_0$, there exists a unique solution $X^*(x)$ to problem $(\mathcal{S}_p(x))$, and we have the dual relation*

$$X^*(x) = \chi\left(y^*(x)Z^*(y^*(x)), \omega\right) \ = \ H - \left(y^*(x)Z^*(y^*(x))\right)^{q-1}, \tag{4.12}$$

where $y^*(x)$ is given by (4.11) *and $Z^*(y^*(x))$ is the solution to the dual problem $(\mathcal{D}_q(y^*(x)))$. Let $\theta^*(x)$ denote the superhedging strategy for the contingent claim $X^*(x) \in L^p(P)$. Then $\theta^*(x)$ is a solution to problem $(\mathcal{P}_p(x))$.*

(2) *The function J is differentiable, strictly decreasing, and strictly convex on $(-\infty, v_0)$, and we have the dual relations*

$$J(x) = \max_{y>0}\left[-\tilde{J}(y) - xy\right], \quad x < v_0, \tag{4.13}$$

$$\tilde{J}(y) = \max_{x<v_0}\left[-J(x) - xy\right], \quad y > 0, \tag{4.14}$$

$$J'(x) = -y^*(x), \quad x < v_0. \tag{4.15}$$

Proof. (1) Fix some $y > 0$ and let Z be an arbitrary element of $\mathcal{M}_q$. Denote

$$Z_\varepsilon = (1-\varepsilon)Z^*(y) + \varepsilon Z, \quad \varepsilon \in (0,1).$$

We have $Z_\varepsilon \in \mathcal{M}_q$ so that

$$\begin{aligned} 0 &\leq \frac{1}{\varepsilon} E\left[\tilde{L}(yZ_\varepsilon, \omega) - \tilde{L}(yZ^*(y), \omega)\right] \\ &\leq yE\left[\left(l_q'(yZ_\varepsilon) - H\right)\left(Z - Z^*(y)\right)\right], \end{aligned}$$

where the second inequality follows from the convexity of the function $y \mapsto \tilde{L}(y, \omega)$ and the fact that its derivative is equal to $l_q'(y) - yH$. Therefore we obtain

$$E\left[l_q'(yZ_\varepsilon)\left(Z^*(y) - Z\right)\right] \leq E\left[H\left(Z^*(y) - Z\right)\right]. \tag{4.16}$$

Notice that $l_q'(yZ_\varepsilon)\left(Z^*(y) - Z\right) \geq l_q'(yZ)\left(Z^*(y) - Z\right) \geq -l_q'(y)Z^q$ which is integrable. Hence, by Fatou's lemma, sending ε to zero in (4.16), we get

$$E\left[l_q'(yZ^*(y))\left(Z^*(y) - Z\right)\right] \leq E\left[H\left(Z^*(y) - Z\right)\right].$$

This last relation shows that

$$E\left[Z\chi(yZ^*(y), \omega)\right] \leq x_y := E\left[Z^*(y)\chi(yZ^*(y), \omega)\right] \quad \forall Z \in \mathcal{M}_q. \tag{4.17}$$

Therefore, $\chi(yZ^*(y), \omega) \in \mathcal{C}_p(x_y)$. Moreover, by (4.3)–(4.4), we have $\forall X \in \mathcal{C}_p(x_y)$

$$\tilde{L}(yZ^*(y), \omega) = -l_p(H - \chi(yZ^*(y), \omega)) - yZ^*(y)\chi(yZ^*(y), \omega), \tag{4.18}$$

$$\geq -l_p(H - X) - yZ^*(y)X; \tag{4.19}$$

hence,

$$E\left[l_p(H - \chi(yZ^*(y), \omega))\right] \leq E\left[l_p(H - X)\right], \tag{4.20}$$

since $E[Z^*(y)X] \leq x_y$. This shows that $\chi(yZ^*(y), \omega)$ is solution to problem $(\mathcal{S}_p(x_y))$. Now, by noting that for $y = y^*(x)$, we have $x_{y^*(x)} = x$ (see relation (4.11)) and $\chi(y^*(x)Z^*(y^*(x)), \omega) = X^*(x)$, we have proved that $X^*(x)$ is a solution to the static problem $(\mathcal{S}_p(x))$. The uniqueness of the solution to problem $(\mathcal{S}_p(x))$ follows from the strict convexity of the function $x \leq H \mapsto l_p(H - x)$. Now, from Proposition 4.1(2), there exists a superhedging strategy $\theta^*(x)$ for $X^*(x)$, and $\theta^*(x)$ is a solution to the dynamic problem $(\mathcal{P}_p(x))$.

(2) Proof of the duality results (4.13)–(4.15) is standard in utility optimization problem and is proved by same arguments as in Föllmer and Leukert [17, Thm. 7.3] or Kramkov and Schachermayer [27]. □

Part (1) of Theorem 4.1 states that the problem of $L^p(P)$-hedging a contingent claim H, when one has in hand an initial wealth strictly smaller than the superreplication cost of H, is solved by superhedging a modified option $X^*(x)$ given in (4.12) and expressed as the difference of H and a nonnegative contingent claim related to the density of an appropriate martingale measure. In Föllmer and Leukert [17] where wealth processes are required to be nonnegative, the optimal hedging strategy is the superhedging strategy for a modified option of the form $(X^*(x))^+$. Part (2) of Theorem 4.1 gives some properties of the measure of risk J, related to those of Artzner et al. [1].

5. Applications and examples.

5.1. The complete market case. We say that a contingent claim $H \in L^p(P)$ is attainable if there exist $x \in \mathbb{R}$ and $\theta \in \Theta_p(C)$ such that $H = V_T^{x,\theta}$. In this case, θ^H is called perfect replicating strategy for H. In the unconstrained case, $C = \mathbb{R}^d$, it is well known that if the set of equivalent martingale measures is reduced to a singleton, then every contingent claim is attainable, and vice versa; see, e.g., Harrison and Pliska [20] and Jacka [22]. We extend such results in the case of cone constraints. We say that C is a symmetrical cone if $\forall y \in C$, $-y \in C$. An example of a symmetrical cone in the case $d = 2$ is $C = \{(x, y) \in \mathbb{R}^2 : xy \geq 0\}$. This means that the investor is constrained to have either short or long positions in both assets.

PROPOSITION 5.1. *Let $p \in [1, \infty]$ and assume that* (B) *holds.*

(1) *Suppose that $\mathcal{M}_q^e = \{\hat{P}\}$. Then every contingent claim $H \in L^p(P)$ is attainable.*

(2) *Assume that C is a symmetrical cone and condition* (NA) *is satisfied. Suppose that every contingent claim $H \in L^p(P)$, with $p \leq 2$, is attainable. Then $\mathcal{M}_q^e$ is reduced to a singleton and $\mathcal{M}_q^e = \mathcal{M}_q = \{\hat{P}\}$.*

Proof. (1) By Theorem 3.1, since $x_0 := \sup_{Q \in \mathcal{M}_q^e} E^Q[H] = E^{\hat{P}}[H] < \infty$, there exists $\theta^H \in \Theta_p(C)$ such that

$$V_T^{x_0,\theta^H} \geq H. \tag{5.1}$$

By the supermartingale property of $V^{x,\theta}$ under $\hat{P}$, we have

$$E^{\hat{P}}\left[V_T^{x_0,\theta^H} - H\right] \leq x_0 - E^{\hat{P}}[H] = 0. \tag{5.2}$$

Relations (5.1) and (5.2) imply that $H = V_T^{x_0,\theta}$, P a.s.

(2) Let $\hat{P} \in \mathcal{M}_q^e$, which is nonempty by condition (NA), and suppose that there exists $Q \neq \hat{P}$ in $\mathcal{M}_q$. Setting $\hat{Z} = d\hat{P}/dP$ and $Z^Q = dQ/dP$, it follows that the contingent claim $H = \hat{Z} - Z^Q \in L^q(P) \subset L^p(P)$ (since $p \leq 2$). Hence H is attainable and there exist $x \in \mathbb{R}$ and $\theta \in \Theta_p(C)$ such that

$$\hat{Z} - Z^Q = V_T^{x,\theta}, \quad P \text{ a.s.} \tag{5.3}$$

Under the condition that C is a symmetrical cone and by noting that $V_T^{-x,-\theta} = -H \in L^p(P)$, we deduce that $-\theta \in \Theta_p(C)$. Therefore by the supermartingale property of $V^{x,\theta}$ and $V^{-x,-\theta}$ under $\hat{P}$ and Q, we obtain that $V^{x,\theta}$ is a martingale under $\hat{P}$ and Q. Using (5.3), this implies that

$$E^{\hat{P}}\left[\hat{Z} - Z^Q\right] = E^Q\left[\hat{Z} - Z^Q\right] = x,$$

and therefore that $E[(\hat{Z} - Z^Q)^2] = 0$, which proves that $Q = \hat{P}$, which is a contradiction. □

Remark 5.1. This last proposition means that when C is a symmetrical cone and under condition (NA) and assumption (B), the following assertions, for $p \in [1, 2]$, are equivalent:

(i) $\mathcal{M}_q^e = \{\hat{P}\}$,

(ii) every contingent claim $H \in L^p(P)$ is attainable.

Notice also that in this case, $\mathcal{M}_q = \mathcal{M}_q^e = \{\hat{P}\}$. We shall say that the market is complete. This extends the characterization of market completeness of Harrison and Pliska [20] and Jacka [22] to the symmetrical cone constraints.

In the complete market case, when $x \geq v_0 = E^{\hat{P}}[H]$, a solution to problem $(\mathcal{P}_p(x))$ is the perfect replicating strategy for H. When $x < v_0$, we have the following result for the $L^p(P)$-hedging of a contingent claim H in $L^p(P)$.

THEOREM 5.1. *Assume that C is a symmetrical cone and assumption* (B) *holds, and suppose that $\mathcal{M}_q = \mathcal{M}_q^e = \{\hat{P}\}$, $p \in (1, \infty)$. Let $x < v_0 = E^{\hat{P}}[H]$. Then the solution to problem $(\mathcal{P}_p(x))$ is the perfect replicating strategy for the contingent claim:*

$$X^*(x) = H - \left(y^*(x)\hat{Z}\right)^{q-1}, \tag{5.4}$$

where $\hat{Z} = d\hat{P}/dP$ and

$$y^*(x) = \left(\frac{v_0 - x}{E[\hat{Z}^q]}\right)^{\frac{1}{q-1}}. \tag{5.5}$$

Proof. Since $\mathcal{M}_q = \{\hat{P}\}$, the solution to the dual problem $(\mathcal{D}_q(y))$ is $Z^*(y) = \hat{Z} = d\hat{P}/dP \ \forall \ y > 0$. Hence $y^*(x)$ in (4.11) is explicitly given by (5.5) and the solution $X^*(x)$ to problem $(\mathcal{S}_p(x))$ is given by (5.4). By Proposition 5.1(1), $X^*(x) \in L^p(P)$ is attainable and so the superhedging strategy $\theta^*(x)$ for $X^*(x)$ is in fact the perfect replicating strategy, and it is the solution to the dynamic problem $(\mathcal{P}_p(x))$ by Theorem 4.1. □

Remark 5.2. By Remark 5.1, if $\mathcal{M}_q^e = \{\hat{P}\}$, with $p \leq 2$, then $\mathcal{M}_q = \mathcal{M}_q^e = \{\hat{P}\}$.

In the unconstrained case, $C = \mathbb{R}^d$, the perfect replicating strategy for $X^*(x)$ is $\theta^*(x) = \theta^H - \tilde{\theta}(x)$, where θ^H is the perfect replicating strategy for H and $\tilde{\theta}(x)$ is the perfect replicating strategy for $(y^*(x)\hat{Z})^{q-1}$.

Example: The Cox–Ross–Rubinstein model. Given the price S_k at date k, the price S_{k+1} at date $k+1$ can jump either upward to the value $S_k u$ with a probability $\pi \in (0,1)$ or downward to the value $S_k d$, where $d < 1 < u$. The probability space is then $\Omega = \{u, d\}^T$ and for any $\omega = (\omega_1, \ldots, \omega_T) \in \Omega$, the price process is defined by $S_k(\omega) = S_0 \prod_{j=1}^k \omega_j$. $\mathcal{F}_k$ is the filtration $\sigma(S_1, \ldots, S_k)$ generated by the random variables $S_1, \ldots, S_k$. It is clear that condition (B′) is satisfied. It is well known that in the unconstrained case, $C = \mathbb{R}$, the market is complete and there is a unique equivalent martingale measure $\hat{P}$ whose probability transition is given by

$$\hat{P}\left[S_{k+1} = S_k u | \mathcal{F}_k\right] = \frac{1-d}{u-d}, \hat{P}\left[S_{k+1} = S_k d | \mathcal{F}_k\right] = \frac{u-1}{u-d}.$$

The density of $\hat{P}$ with respect to the objective probability P is then written as

$$\hat{Z} = \frac{d\hat{P}}{dP} = \left(\frac{1-d}{\pi(u-d)}\right)^N \left(\frac{u-1}{(1-\pi)(u-d)}\right)^{T-N},$$

where $N(\omega) = \sum_{k=1}^T 1_{\{\omega_k = u\}}$ follows a binomial law $\mathcal{B}(T, \pi)$. A straightforward calculation shows that

$$E\left[\hat{Z}^q\right] = \frac{1}{(u-d)^{qT}} \left(\pi \left(\frac{1-d}{\pi}\right)^q + (1-\pi)\left(\frac{u-1}{1-\pi}\right)^q\right)^T.$$

By Theorem 5.1 and Remark 5.2, the solution to problem $(\mathcal{P}_p(x))$, for $x < E^{\hat{P}}[H]$, is $\theta^H - \tilde{\theta}(x)$, where θ^H is the perfect replicating strategy for H and $\tilde{\theta}(x)$ is the perfect replicating strategy for $(y^*(x)\hat{Z})^{q-1}$.

5.2. The case of attainable contingent claims. In this paragraph, we assume that C is a symmetrical cone and we consider the $L^p(P)$-hedging of an attainable contingent claim $H \in L^p(P)$. There exist $c \in \mathbb{R}$ and $\theta \in \Theta_p(C)$ such that $H = V_T^{c,\theta}$. Since C is a symmetrical cone and $V_T^{-c,-\theta} = -H$, we have $-\theta \in \Theta_p(C)$. By the supermartingale property of $V^{c,\theta}$ and $V^{-c,-\theta}$ under any martingale measure in $\mathcal{M}_q$, we deduce that $E[ZH] = E[ZV_T^{c,\theta}] = c \ \forall Z \in \mathcal{M}_q$. Therefore the dual problem $(\mathcal{D}_q(y))$ can be written equivalently as

$$\inf_{Z \in \mathcal{M}_q} E[Z^q].$$

Hence, the solution Z_q^* of the dual problem does not depend on y and H. Notice that in the unconstrained case and for $q = 2$, Z_2^* is the variance-optimal martingale measure introduced by Schweizer [39]. We refer to this paper and to Laurent and Pham [28] for explicit computations of the variance-optimal martingale measure in different models of an incomplete market. By analogy, we call Z_q^* the $L^q(P)$-optimal martingale measure.

For $x < \sup_{Z \in \mathcal{M}_q} E[ZH]$, the Lagrange multiplier in (4.11) is explicitly given by

$$y^*(x) = \left(\frac{E[Z_q^* H] - x}{E[(Z_q^*)^q]} \right)^{\frac{1}{q-1}},$$

and the solution to problem $(\mathcal{P}_p(x))$ is the superhedging strategy for the contingent claim

$$X^*(x) = H - \left(y^*(x) Z_q^*\right)^{q-1}.$$

Remark 5.3. In the case of attainable claims, the solution of the primal optimization problem $(\mathcal{S}_p(x))$ can be directly solved without using the convex duality approach (see Appendix B).

5.3. $L^p(P)$-hedging of a riskless asset. In this paragraph, we consider the $L^p(P)$-hedging of the riskless asset $H = 1$. As in the previous paragraph, since $E[ZH] = E[Z] = 1 \ \ \forall \ \ Z \in \mathcal{M}_q$, the dual problem $(\mathcal{D}_q(y))$ can be written equivalently as

$$\inf_{Z \in \mathcal{M}_q} E[Z^q],$$

and the solution Z_q^* of this problem is still called $L^q(P)$-optimal martingale measure. The solution to problem $(\mathcal{P}_p(x))$, for $x < \sup_{Z \in \mathcal{M}_q} E[ZH] = 1$, is given by the superhedging strategy for the contingent claim:

$$X^*(x) = 1 - \frac{1 - x}{E[(Z_q^*)^q]} \left(Z_q^*\right)^{q-1}.$$

Example. We consider the case of no short-selling constraints, $C = [0, \infty)$, in a one-period binomial model. Given the initial value $S_0 = 1$, S_1 takes the values u and d, $d < u$, with objective probability π and $1 - \pi$, $\pi \in (0, 1)$. The probability space is $\Omega = \{u, d\}$ and $\mathcal{F}_1 = \sigma(S_1)$. In this context, problem $(\mathcal{P}_p(x))$ is written as

$$(\mathcal{P}_p(x)) \inf_{\theta \geq 0} E\left[l_p\left((1 - x - \theta \Delta S_1)^+ \right) \right].$$

Obviously, for $x \geq 1$, the solution of this problem is $\theta^*(x) = 0$. Fix now $x < 1$. A probability measure Q on $(\Omega, \mathcal{F}_1)$ is characterized by $\rho = Q(u) \in [0,1]$ and $Q \in \mathcal{M}_q$ if and only if $E^Q[S_1] \leq S_0$, i.e., $\rho \leq \hat{\pi} := (1-d)/(u-d)$. Assuming that $d < 1$, it follows that $\mathcal{M}_q^e \neq \emptyset$. The dual problem is written as

$$\min_{0 \leq \rho \leq \hat{\pi}} \left[\pi \left(\frac{\rho}{\pi} \right)^q + (1-\pi) \left(\frac{1-\rho}{1-\pi} \right)^q \right],$$

whose solution is given by

$$\rho^* = \begin{cases} \pi & \text{if } \pi \leq \hat{\pi}, \\ \hat{\pi} & \text{if } \pi > \hat{\pi}. \end{cases}$$

We shall therefore distinguish two cases:

Case 1. $\pi \leq \hat{\pi}$. The $L^q(P)$-optimal martingale measure is $Q^* = P$ and $Z^* = dQ^*/dP = 1$. Therefore $X^*(x) = x$ and so the solution to problem $(\mathcal{P}_p(x))$ is $\theta^*(x) = 0$.

Case 2. $\pi > \hat{\pi}$. This case implies that, in particular, we must have $u > 1$. The $L^q(P)$-optimal martingale measure is $Q^* = \hat{P}$, where $\hat{P}$ is the unique martingale measure in the unconstrained case and is characterized by $\hat{P}(u) = \hat{\pi}$. We have $Z^*(u) = \hat{\pi}/\pi$, $Z^*(d) = (1-\hat{\pi})/(1-\pi)$. The solution $\theta^*(x)$ to problem $(\mathcal{P}_p(x))$ is the superhedging strategy of $X^*(x) = 1 - (1-x)(Z^*)^{q-1}/E[(Z^*)^q]$, i.e., $x + \theta^*(x)\Delta S_1 \geq X^*(x)$. A straightforward calculation shows that $\theta^*(x)$ is in fact the perfect replicating strategy for $X^*(x)$ and is explicitly given by

$$\theta^*(x) = \frac{(\pi(u-1))^{q-1} - ((1-\pi)(1-d))^{q-1}}{\pi^{q-1}(u-1)^q - (1-\pi)^{q-1}(1-d)^q}(1-x).$$

Appendix A. Proof of Theorem 3.1. Let $x \in \mathbb{R}$ and $\theta \in \Theta_p(C)$ such that $V_T^{x,\theta} \geq H$, P a.s. Then, by the supermartingale property of $V^{x,\theta}$ under any $Q \in \mathcal{M}_q$, we have $\sup_{Q \in \mathcal{M}_q} E^Q[H] \leq x$ and therefore

$$\sup_{Q \in \mathcal{M}_q} E^Q[H] \leq v_0. \tag{A.1}$$

Consider now an arbitrary $x \in \mathbb{R}$ such that $x < v_0$. Then by definition of v_0, the element $H - x$ does not belong to K_p, where $K_p := (K - L^0_+(P)) \cap L^p(P)$. Now, by condition (B), the set $K - L^0_+(P)$ is closed for the topology of convergence in probability (see Brannath [2]) and so K_p is a closed convex cone in $L^p(P)$ containing 0. Therefore, by the Hahn–Banach separation theorem, there exists $Z \in L^q(P) \setminus \{0\}$ such that $\forall \theta \in \Theta(C)$, $Y \in L^0_+(P)$ with $V_T^{0,\theta} - Y \in L^p(P)$,

$$E[Z(V_T^{0,\theta} - Y)] \leq 0 < E[Z(H-x)]. \tag{A.2}$$

As usual, we can assume, without loss of generality, that $\Delta S_k \in L^1(P)$ $\forall k = 1, \ldots, T$. Indeed, if this is not the case, we can change P to an equivalent probability measure $\bar{P}$ with bounded density such that $\Delta S_k \in L^1(\bar{P})$ $\forall$ k (take, for example, $d\bar{P}/dP = \exp(-\max_k |\Delta S_k|)/E[\exp(-\max_k |\Delta S_k|)]$). Relation (A.2) for $\theta = 0$ and $Y = 1_A$, $A \in \mathcal{F}$, implies that $E[Z1_A] \geq 0$; hence $Z \geq 0$, P a.s. Let a be an arbitrary element of C, $A \in \mathcal{F}_{k-1}$ and $\theta \in \Theta(C)$ defined by $\theta_j = 0$ for $j \neq k$ and $\theta_k = a1_A$. Then $V_T^{0,\theta} = a.\Delta S_k 1_A \in L^p(P)$. Then, (A.2) and arbitrariness of $A \in \mathcal{F}_{k-1}$ imply that

$a.E[Z\Delta S_k|\mathcal{F}_{k-1}] \leq 0\ \forall a \in C$ and $k = 1, \ldots, T$. Defining the probability measure Q by $dQ/dP = Z/E[Z]$, it follows that $Q \in \mathcal{M}_q$ and by the right-hand side of (A.2), we have

$$x < E^Q[H]. \tag{A.3}$$

Now, from condition (NA), $\mathcal{M}^e_\infty \neq \emptyset$. Choose some $\tilde{Q} \in \mathcal{M}^e_\infty$ and set $Q_\varepsilon = (1-\varepsilon)Q + \varepsilon\tilde{Q}$, $\varepsilon \in (0,1)$. It is clear that $Q_\varepsilon \in \mathcal{M}^e_q$. Moreover, we have $E^{Q_\varepsilon}[H] \to E^Q[H]$ as ε goes to zero. Then, from (A.3), for a sufficiently small ε, we have $x < E^{Q_\varepsilon}[H]$. From the arbitrariness of $x < v_0$, this proves that

$$v_0 \leq \sup_{Q \in \mathcal{M}^e_q} E^Q[H]. \tag{A.4}$$

This last inequality combined with (A.1) proves (3.1), and also that the supremum can be taken over absolutely continuous martingale measures.

By noting that v_0 can also be written as

$$v_0 = \inf\left\{x \in \mathbb{R} :\ \exists U \in K - L^0_+(P),\ x + U = H,\ P \text{ a.s.}\right\}, \tag{A.5}$$

and since $(K - L^0_+(P)) \cap L^p(P)$ is closed in $L^p(P)$, we conclude that the infimum in (A.5) is attained whenever v_0 is finite, which proves assertion (1). Finally suppose that the supremum in (3.1) is attained for some $\hat{Q} \in \mathcal{M}^e_q$. Then v_0 is finite and there exists a superhedging strategy θ^H for H: $V_T^{v_0,\theta^H} - H \geq 0$ P a.s. By the supermartingale property of V^{v_0,θ^H} under $\hat{Q}$, we have $E^{\hat{Q}}[V_T^{v_0,\theta^H} - H] \leq v_0 - E^{\hat{Q}}[H] = 0$. Since $\hat{Q}$ is equivalent to P, we then conclude that $V_T^{v_0,\theta^H} = H$ P a.s.

Appendix B. Direct resolution in the case of attainable claims. In this paragraph, we directly derive the solution to the $L^p(P)$-hedging of an attainable contingent claim $H \in L^p(P)$, which then satisfies $E[ZH] = c\ \forall Z \in \mathcal{M}_q$. For $x \geq c = \sup_{Z \in \mathcal{M}_q} E[ZH]$, we already know that $X^*(x) = H$ is a solution to the static problem $(\mathcal{S}_p(x))$ associated to the $L^p(P)$-hedging problem $(\mathcal{P}_p(x))$. Fix now $x < c$, and consider the L^q-optimal martingale measure Z^*_q solution of

$$\inf_{Z \in \mathcal{M}_q} E[Z^q].$$

One easily obtains

$$E[(Z^*_q)^q] \leq E[Z(Z^*_q)^{q-1}] \quad \forall Z \in \mathcal{M}_q. \tag{B.1}$$

Now, let $X \in \mathcal{C}_p(x)$. By the Hölder inequality, we have $E[Z^*_q(H - X)] \leq (E[Z^*_q]^q)^{\frac{1}{q}}$ $(E[H - X]^p)^{\frac{1}{p}}$ and so

$$\frac{(c-x)^p}{\left(E[Z^*_q]^q\right)^{\frac{p}{q}}} \leq E[H - X]^p. \tag{B.2}$$

Now, set $y^*(x) = (\frac{c-x}{E[Z^*_q]^q})^{\frac{1}{q-1}}$, and define $X^*(x) = H - \left(y^*(x)Z^*_q\right)^{q-1}$. Then $X^*(x)$ $\leq H$ and $E[ZX^*(x)] = c - (y^*(x))^{q-1}\ E[Z(Z^*_q)^{q-1}] \leq c - (y^*(x))^{q-1}\ E[Z^*_q]^q = x$, by using (B.1) and definition of $y^*(x)$. Hence $X^*(x) \in \mathcal{C}_p(x)$. Moreover, we have

$$\begin{aligned} E[H - X^*(x)]^p \ &= \ (y^*(x))^q E[Z^*_q]^q = \frac{(c-x)^p}{\left(E[Z^*_q]^q\right)^{\frac{p}{q}}} \\ &\leq E[H - X]^p, \end{aligned}$$

by (B.2). This proves that $X^*(x)$ solves $(\mathcal{S}_p(x))$.

Acknowledgments. I would like to thank the anonymous referees for their helpful comments, and for pointing out the argument shown in Remark 5.3.

A MAX-PLUS-BASED ALGORITHM FOR A HAMILTON–JACOBI–BELLMAN EQUATION OF NONLINEAR FILTERING*

WENDELL H. FLEMING† AND WILLIAM M. McENEANEY‡

Abstract. The Hamilton–Jacobi–Bellman (HJB) equation associated with the robust/H_∞ filter (as well as the Mortensen filter) is considered. These filters employ a model where the disturbances have finite power. The HJB equation for the filter information state is a first-order equation with a term that is quadratic in the gradient. Yet the solution operator is linear in the max-plus algebra. This property is exploited by the development of a numerical algorithm where the effect of the solution operator on a set of basis functions is computed off-line. The precomputed solutions are stored as vectors of coefficients of the basis functions. These coefficients are then used directly in the real-time computations.

Key words. nonlinear filtering, robust, H_∞, max-plus algebra, nonlinear HJB equations

1. Introduction.

This paper is concerned with an algorithm for construction of viscosity solutions of a certain Hamilton–Jacobi–Bellman (HJB) equation. The solution of this partial differential equation (PDE) is a necessary step in the application of certain filtering techniques (such as robust filtering) to nonlinear systems. This will be discussed further below. First, we note that the PDE is first-order but nonlinear—possessing a term which is quadratic in the gradient. However, in the max-plus algebra, the solution operator is linear. The algorithm takes advantage of this linearity by using a max-plus basis representation of the solution. Propagation of the solution is reduced to a max-plus matrix multiplication on the coefficients of the basis representation.

We consider the problem of estimating the state of some system evolving continuously in time. The state space is $\Re^n$. The problem of estimating the current state based on knowledge (or lack thereof) of the initial state and the measurements up to the current moment is the filtering problem. One approach to the problem is to model the system via stochastic differential equations. This leads to the stochastic nonlinear filtering problem (we assume that the extended linear Kalman filter is not appropriate). The key step becomes the solution of a second-order stochastic partial differential–integral equation—the Kushner equation [19]—or a linear, second-order stochastic partial differential equation (SPDE)—the Zakai equation [6]. Alternatively, this can be reformulated via pathwise filtering, leading to a deterministic PDE parameterized by the measurement process [6], [11], [28].

One particular approach to the solution of the Zakai SPDE is the splitting method (see, for instance, [21]). If the measurements occur at discrete times, this approach

takes advantage of the linearity of the solution operator via a basis function representation of the solution of the SPDE. In the continuous-time measurements case, one takes a limit [21], [16].

An alternate approach is taken by robust/H_∞ filters [24], [9], [5] and the Mortensen filter [29]. In this case, the noise in the system dynamics is modeled by an L^2 process that is unknown a priori, but to which we do not associate a probability measure. The measurement process is also affected by an a priori unknown disturbance. In contrast to the Kalman filter approach, for nonlinear systems this problem necessitates solution of a *first-order* PDE. (Note that in the formulations considered here this is a finite-dimensional PDE.) This first-order nature has certain implications. The foremost is that one has a "range-of-dependence" property: a change in initial conditions at one point does not instantaneously affect the solution everywhere in $\Re^n$; the solution propagates with finite speed. This has certain numerical advantages, the most obvious of which is the applicability of generalized characteristic methods [24], [27]. Second, the solution, even in nondegenerate cases, is likely to be nonsmooth, leading to the use of viscosity solution definitions of solution. However, this first-order PDE is not linear; it possesses a quadratic term in the gradient.

In the max-plus algebra (which may more correctly be termed a commutative semifield), the "addition operation" is defined by $a \oplus b = \max\{a, b\}$, and the "multiplication operation" is defined by $a \otimes b = a + b$. Interestingly, the solution operator for the PDE associated with the robust/H_∞ filter is linear in the max-plus algebra. As noted above, the algorithm described herein takes advantage of this linearity and a max-plus basis representation of the solution. This approach is analogous to the splitting method described above for the Kalman filter. In fact, that method provided, by analogy, an early influence on this work.

Both the case of discrete-time measurements and the case of continuous-time measurements are considered. In the discrete-time measurements case, the solution of the PDE between measurement times (2.14b) is of the form discussed just above, and the above approach is used, leading to the algorithm discussed in section 6. In the case of continuous-time measurements, a proof of convergence of this algorithm as the measurement time-step goes to zero is presented in section 7.

Section 2 reviews the robust/H_∞ filter (and Mortensen filter) and provides motivation for the solution of the relevant HJB equations. In section 3, the max-plus algebra is described, and the max-plus linearity of the solution operator is proved. The basis representation will be obtained in the class of continuous, semiconvex functions. Proofs of the semiconvexity of the solution of the PDE (under two sets of assumptions) are given in section 4. A semiconvex duality-based representation of the solution is also included there. In section 5, the semiconvex duality representation is used to obtain the basis representation, and certain properties of this representation are also presented. Sections 6 and 7 are as discussed above.

2. Review of the robust filter. In this section, the robust filter (as well as the Mortensen filter) are briefly reviewed. For a fuller discussion, see [24], [9], [10], [29].

Let $x(t)$ denote the state to be estimated at time $t \geq 0$, with $x(t) \in \Re^n$. The state dynamics are

$$\frac{dx}{dt} = f(x) + \sigma(x)w, \tag{2.1}$$

where $w \in L_2^{loc}([0, \infty); \Re^m)$ is the disturbance in the dynamics and σ is an $n \times m$

matrix-valued function. First we will describe the case of continuous-time measurements. Let the observations, taking values in $\Re^k$, be given by

$$y(t) = h(x(t)) + \rho(x(t))v(t), \tag{2.2}$$

where $v \in L_2^{loc}([0,\infty);\Re^l)$ is the observation disturbance, ρ is a $k \times l$ matrix-valued function, and $k \le l$. Let $\phi(x_0)$ be a measure of our uncertainty about the initial state $x(0) = x_0$.

We will assume that

$$\begin{aligned} &f, \sigma, h, \text{ and } \rho \text{ are } C^2; \\ &f, \sigma, \text{ and } h \text{ are globally Lipschitz in } x. \end{aligned} \tag{A1}$$

The differentiability assumptions are required in certain calculus of variations arguments. We assume that there exists $M < \infty$ such that

$$|\sigma(x)| \le M \qquad \forall\, x \in \Re^n \tag{A2}$$

and define $a \doteq \sigma\sigma^T$. We will also assume that

$$\text{Range}(\rho(x)) = \Re^k \qquad \forall\, x \in \Re^n, \tag{A3a}$$

which guarantees that for any y, x there exists some v satisfying (2.2).

Finally, we define ρ^{-1} by

$$\rho^{-1}(x)b = \text{argmin}\{|v| :\ \rho(x)v = b\}. \tag{2.3}$$

Assume that ρ^{-1} is uniformly bounded, that is, that there exists $C_\rho < \infty$ such that

$$\begin{aligned} &|\rho^{-1}(x)b| \le C_\rho |b| \qquad \forall\, x \in \Re^n \ \ \forall\, b \in \Re^l, \\ &\rho^{-1} \in C^2. \end{aligned} \tag{A3b}$$

Note also that these assumptions imply that if we view the integral version of (2.1),

$$x_T \doteq x(T) = x_0 + \int_0^T f(x(t)) + \sigma(x(t))w(t)\, dt, \tag{2.4}$$

as a mapping from x_0 to x_T, then this mapping is one-to-one and onto for any $w \in \mathrm{L}_2$.

Let $\phi(x_0)$ be a measure of our uncertainty about the initial state x_0, and suppose there exists $D_1 < \infty$ such that

$$\begin{aligned} &\phi(x) \le D_1 \qquad \forall\, x \in \Re^n, \\ &\phi \text{ is locally Lipschitz.} \end{aligned} \tag{A4}$$

It should be noted here that the algorithm described in this paper will produce the solution of the HJB equation corresponding to the robust/H_∞ and Mortensen filters. The algorithm could also be used to solve similar HJB equations arising from different applications. If it is not obvious that the desired solution is the same as the solution for the robust filter, then one would want a result indicating uniqueness of the (viscosity) solution of the HJB equation in some class. This uniqueness is known under the additional assumption that ϕ satisfies a quadratic growth assumption (references are given below). Since this uniqueness is not required for the specific result here, we did not include a quadratic growth assumption on ϕ in the above.

Suppose we wish to estimate the state at time T. Consider a cost criterion of the form

$$J(T, x_T, w(\cdot)) = \phi(x_0) - \frac{1}{2}\int_0^T |w(t)|^2 + |v(t)|^2\, dt \tag{2.5a}$$

$$= \phi(x_0) - \frac{1}{2}\int_0^T |w(t)|^2 + |\rho^{-1}(x(t))[y(t) - h(x(t))]|^2\, dt, \tag{2.5b}$$

where x_0 is given by (2.4) for any particular w. The information state is given by

$$P(T, x_T) = \sup_{w \in L_2} J(T, x_T, w). \tag{2.6}$$

We now briefly discuss the extraction of filter estimates from the information state. After this, we will return to a detailed discussion of aspects of (and representations for) the above information state. Further details may be found in the references included below. Readers who are interested mainly in the computational algorithm may choose to skip this discussion.

Mortensen [29] developed an estimator based on this information state in the 1960s. Mortensen's estimate is $\widehat{x}_T \in \operatorname{argmax}_x P(T, x)$ (the existence of which follows easily under reasonable assumptions [24], [9]).

For a robust filter, one is interested in a state estimate for which one has a bound on the effect of the disturbances on our estimate error by the product of some constant and the disturbance energy (where one hopes that this constant is small). In particular, one would like an estimate, $\hat{e}_T$, such that for some $\gamma^2 < \infty$ [24],

$$|x(T) - \hat{e}_T|^2 \le \gamma^2 \left[-\phi(x_0) + \frac{1}{2}\int_0^T \left[|w_t|^2 + |v_t|^2 \right] dt \right] \tag{2.7}$$

for all x_0, w, v in the case of continuous-time measurements with an analogous inequality for discrete-time measurements. (Of course this would require an additional assumption that $\phi(x) \le -k|x - \overline{x}|^2$ for some $k > 0$ and $\overline{x} \in \Re^n$; see [24].) Under reasonable assumptions (see [24]), there exists $\gamma^* < \infty$ such that for all $\gamma \ge \gamma^*$, such a robust estimator is given by

$$\hat{e}_T \doteq \operatorname{argmin}_e \max_x \left[|x - e|^2 + \gamma^2 P(T, x) \right]. \tag{2.8}$$

It should perhaps be noted that there will generally be multiple estimates that yield disturbance attenuation (2.7), and in fact, under certain conditions, the Mortensen estimator is a robust estimator in this sense [9]. We also note that $\hat{e}_T$ (given by (2.8)) is the risk-averse limit of a risk-sensitive stochastic filter [10]. Some readers may note that the above information state differs from some which include an integral running cost term. Such an information state is particularly suited to the problem of H_∞ control under partial information as opposed to the problem of robust state estimation considered here; see [1], [17].

Now we turn to the promised further discussion of the information state, P, itself. It will be convenient to note the following.

LEMMA 2.1. *Let $T, R < \infty$, $|x_T| \le R$. There exists M_1 (depending on T, R) such that for $\epsilon \le 1$, ϵ-optimal w for problem (2.6) satisfies $\|w\|^2_{L_2[0,T]} \le M_1$. Further, there exists an optimal w^* and M_2 (depending on T, R) such that $|w^*(t)| \le M_2$ for all $t \in [0, T]$.*

Proof. The first assertion follows by the standard technique of comparison with $w^0 \equiv 0$. Let $x^0(\cdot)$ be the solution of (2.1) corresponding to w^0 and $x^0(T) = x_T$. By (A1), there exist $K, K_h < \infty$ such that $|f(x)| \le K(1+|x|)$ and $|h(x)| \le K_h(1+|x|)$. Then $\frac{d}{dt}|x^0|^2 \le K(3|x^0|^2+1)$, and by Gronwall's inequality, one obtains $|x^0(t)|^2 \le R_1^2 \doteq (R^2+KT)(1+3KTe^{3KT})$ for all $t \in [0,T]$.

Let $\mu(\rho) = \min\{\phi(x) : |x| \le \rho\}$ and note that $\mu(\rho) > -\infty$ for all $\rho < \infty$ by (A4). Then

$$J(T, x_T, w^0(\cdot)) \ge \mu(R_1) - \frac{C_\rho^2}{2}\left[2K_h^2(1+R_1^2) + \|y\|^2_{L_2[0,T]}\right] \doteq \overline{M}_1.$$

Consequently, for ϵ-optimal w^ϵ, $-\frac{1}{2}\int_0^T |w^\epsilon|^2\,dt \ge \overline{M}_1 - \epsilon$, which yields the first assertion. The second assertion then follows by the proof of [9, Lemma 2.1(a)]. □

The following theorem and remark are easily obtained in the case where $y(\cdot)$ is continuous, and we outline the proof in that case. They are not directly needed in the sequel, and so we do not prove them in the case where $y \in L_2 \setminus C$. (Of course, they could be needed in an adaptation of this algorithm to the solution of PDEs not necessarily arising from this application.) Extensions of viscosity solutions to cases where the time-dependency of the Hamiltonian is only measurable are well known but more technical (see, for instance, [4], [14], [22], [32]).

THEOREM 2.2. *P is a continuous viscosity solution of the HJB equation*

$$\begin{aligned} 0 &= P_T + f^T(x)\nabla_x P - \frac{1}{2}\nabla_x P^T a(x)\nabla_x P + \frac{1}{2}|\rho^{-1}(x)(y(T)-h(x))|^2, \\ P(0,x) &= \phi(x). \end{aligned} \tag{2.9}$$

Proof. Fix $R < \infty$ and let $|x_T| \le R$. By Lemma 2.1, the optimal trajectory $x^*(\cdot)$ terminating at x_T satisfies $|x^*(t)| \le R_1$ for some $R_1 < \infty$ (depending on T, R) for any $x_t \in B_R \doteq \{x \in \Re^n : |x| \le R\}$. Let

$$\widetilde{\phi}(x) = \begin{cases} \phi(x) & \text{if } |x| \le R_1, \\ \phi(R_1 x/|x|) & \text{if } |x| > R_1. \end{cases}$$

Let $\widetilde{P}$ be the value given by (2.6) with $\widetilde{\phi}$ replacing ϕ. Then, by standard results (for instance, [26]), $\widetilde{P}$ is a viscosity solution of (2.9) with $\widetilde{\phi}$ replacing ϕ. Since $\widetilde{P} = P$ on $[0,T] \times B_R$ and $\widetilde{\phi} = \phi$ on B_{R_1}, P is a viscosity solution of (2.9) on $[0,T] \times B_R$. Letting $R \to \infty$, one obtains the result. □

Remark 2.3. In the case where $\phi(x) \ge -D_2(1+|x|^2)$ for some $D_2 < \infty$ and σ is constant, uniqueness among the class of continuous, quadratically growing viscosity solutions was obtained in [25]. Recent results of Da Lio and McEneaney [7], Bardi and Da Lio [2], and Ishii [15] allow the removal of the constant σ assumption.

Let us also develop the information state in the discrete-time measurement case.

In the discrete-time measurement case, the dynamics (2.1) are unchanged, but the measurement model is as follows. Suppose that at each measurement time, $t_j > 0$, we receive an observation that is modeled as

$$y_j = h(x(t_j)) + \rho(x(t_j))v_j. \tag{2.10}$$

Let the number of measurements in time $[0,T]$ be N. One may adapt the cost criterion

(2.5) and information state (2.6) in the following manner. Let the cost criterion be

$$J(T, x_T, w(\cdot)) = \phi(x_0) - \frac{1}{2}\int_0^T |w(t)|^2\,dt - \frac{\delta}{2}\sum_{j=1}^N |v_j|^2 \tag{2.11a}$$

$$= \phi(x_0) - \frac{1}{2}\int_0^T |w(t)|^2\,dt - \frac{\delta}{2}\sum_{j=1}^N |\rho^{-1}(x(t_j))[y_j - h(x(t_j))]|^2, \tag{2.11b}$$

where δ is the time interval between measurements, and let the value again be given by

$$P(T, x_T) = \sup_{w\in L_2} J(T, x_T, w). \tag{2.12}$$

Due to the discrete nature of the measurements, it is helpful to recall the form of the dynamic programming principle for such a system. Let $P(t_j^+, x)$ be the value at time t_j just after measurement j, and $P(t_j^-, x)$ be the value at time t_j just before the measurement. If T is not a measurement time, and $t \in (t_{k-1}, t_k)$, we have

$$P(T,x) = \sup_{w\in L_2([t,T];\Re^m)} \left\{ P(t,x(t)) - \frac{1}{2}\int_t^T |w(r)|^2\,dr - \frac{\delta}{2}\sum_{j=k}^N |\rho^{-1}(x(t_j))[y_j - h(x(t_j))]|^2 \right\}, \tag{2.13a}$$

and when T occurs at the time of measurement j, we have

$$P(T^+, x) = P(T^-, x) - \frac{\delta}{2}|\rho^{-1}(x)[y_j - h(x)]|^2. \tag{2.13b}$$

The corresponding dynamic programming equations are

$$P(0,x) = \phi(x), \qquad t = 0, \tag{2.14a}$$

$$0 = P_t - \sup_{w\in\Re^m}\left\{ -[f(x) + \sigma(x)w]^T \nabla_x P - \frac{1}{2}|w|^2 \right\}, \qquad t \in (t_j, t_{j+1}),$$

$$= P_t + f^T(x)\nabla_x P - \frac{1}{2}(\nabla_x P)^T a(x) \nabla_x P, \qquad t \in (t_j, t_{j+1}), \tag{2.14b}$$

$$P(t_j^+, x) = P(t_j^-, x) - \frac{\delta}{2}|\rho^{-1}(x)[y_j - h(x)]|^2, \qquad t = t_j \text{ for some } j. \tag{2.14c}$$

As in the continuous-time measurements case, we have the following [24]. (Since y does not appear on the right-hand side of (2.14b), there is no difficulty with discontinuous y in this case.)

THEOREM 2.4. *The information state, P, given by* (2.13)*, is continuous and is a viscosity solution of* (2.14) *between measurement times.*

In the case where ϕ satisfies a quadratic growth condition, uniqueness follows in a similar manner as that discussed in Remark 2.3.

As in the continuous-time measurement case, one obtains the robust estimator from (2.8), and an attenuation inequality similar to (2.7) follows (with summation of v_j replacing the integral of v_t).

Finally, see [1], [5], and [18] for related work.

3. Max-plus linearity. Recall the definition of max-plus addition, $\oplus$, and multiplication, $\otimes$, for elements of $\Re$ as

$$\begin{aligned} a \oplus b &\doteq \max\{a, b\}, \\ a \otimes b &\doteq a + b. \end{aligned} \tag{3.1}$$

Define these operations for $-\infty$ in the obvious way. It is well known that $(\Re \cup \{-\infty\}, \oplus, \otimes)$ is a commutative semifield which is referred to as the max-plus algebra. See [3], [20], [13] for a fuller discussion. We remark that, although the commutative semifield lacks additive inverses, there is an extension which allows one to solve linear systems in a certain sense. This extension is accomplished via the notion of a "balance"; see [3]. However, for the robust/H_∞ and Mortensen filter applications, we are interested only in real-valued quantities, and so nothing is gained by this extension. Consequently, we will not pursue this here.) The authors have recently learned that Theorem 3.1 was previously reported in 1987 [23].

As noted earlier, we are interested only in the discrete-time measurements case in this section; the continuous-time measurements case will be discussed in section 7. Let $\mathcal{S}_T$ be the solution operator for HJB equation (2.14b). Specifically, given initial condition $P(t_0, \cdot)$, the solution to (2.14b) at time $t_0 + T$ is given by

$$P(t_0 + T, x) = \mathcal{S}_T[P(t_0, \cdot)](x). \tag{3.2}$$

From the dynamic programming principle (2.13a) (noting that there are no measurements in $(t_0, t_0 + T)$ in order for (2.14b) to be applicable), one has

$$\begin{aligned} \mathcal{S}_T[P(t_0, \cdot)](x) &= P(t_0 + T, x) \\ &= \sup_{w \in L_2([t_0, t_0+T]; \Re^m)} \left\{ P(t_0, x(t_0)) - \frac{1}{2} \int_{t_0}^{t_0+T} |w(r)|^2 \, dr \right\}, \end{aligned} \tag{3.3}$$

where $x(t_0)$ is given by (2.1) with $x(t_0 + T) = x$.

We now prove that $\mathcal{S}_T$ is linear in the max-plus algebra. Let $c \in \Re$ and let $\phi, \psi : \Re^n \to \Re$ be locally Lipschitz and bounded from above. By (3.3), one easily sees that for any $x \in \Re^n$

$$\mathcal{S}_T[c \otimes \phi](x) = \mathcal{S}_T[c + \phi](x) = c + \mathcal{S}_T[\phi] = c \otimes \mathcal{S}_T[\phi](x). \tag{3.4}$$

Also, for any $x \in \Re^n$,

$$\begin{aligned} \mathcal{S}_T[\phi \oplus \psi](x) &= \sup_{w \in L_2([0,T]; \Re^m)} \left\{ \max[\phi(x(0)), \psi(x(0))] - \frac{1}{2} \int_0^T |w(r)|^2 \, dr \right\} \\ &\geq \sup_{w \in L_2([0,T]; \Re^m)} \left\{ \phi(x(0)) - \frac{1}{2} \int_0^T |w(r)|^2 \, dr \right\} \\ &= \mathcal{S}_T[\phi](x). \end{aligned} \tag{3.5}$$

By symmetry, one obtains an analogous inequality for ψ. Consequently,

$$\mathcal{S}_T[\phi \oplus \psi](x) \geq \max\{\mathcal{S}_T[\phi](x), \mathcal{S}_T[\psi](x)\} = \mathcal{S}_T[\phi](x) \oplus \mathcal{S}_T[\psi](x). \tag{3.6}$$

Now let w^* be optimal in (3.5). (The existence of the optimizer is discussed in section 2.) Then

$$\mathcal{S}_T[\phi \oplus \psi](x) = \max[\phi(x(0)), \psi(x(0))] - \frac{1}{2}\int_0^T |w^*(r)|^2\, dr,$$

and, in the case where $\phi(x(0)) \geq \psi(x(0))$,

$$\begin{aligned} &= \phi(x(0)) - \frac{1}{2}\int_0^T |w^*(r)|^2\, dr \\ &\leq \mathcal{S}_T[\phi](x). \end{aligned}$$

Considering also the case where $\phi(x(0)) < \psi(x(0))$, one obtains

$$\mathcal{S}_T[\phi \oplus \psi](x) \leq \mathcal{S}_T[\phi](x) \oplus \mathcal{S}_T[\psi](x).$$

Combining this with (3.6) yields

$$\mathcal{S}_T[\phi \oplus \psi](x) = \mathcal{S}_T[\phi](x) \oplus \mathcal{S}_T[\psi](x). \tag{3.7}$$

By (3.4) and (3.7), one has the following theorem.

THEOREM 3.1. *The solution operator for* (2.14b) *is linear in the max-plus algebra.*

4. Semiconvexity. A function ψ is called *semiconvex* if for every $R < \infty$, there exists C_R such that

$$\widehat{\psi}(x) \doteq \psi(x) + \frac{C_R}{2}|x|^2 \tag{4.1}$$

is convex on the ball $B_R \doteq \{x \in \Re^n : |x| \leq R\}$. The infimum over such C_R will be known as the semiconvexity constant for ψ over B_R. Note that any real-valued semiconvex function is locally Lipschitz. In fact, if $\widehat{\psi}$ is convex on the ball B_R, then $\widehat{\psi}$ is Lipschitz on $B_{R/2}$ with a Lipschitz constant depending only on $\max_{|x|\leq R} \widehat{\psi}(x) - \min_{|x|\leq R} \widehat{\psi}(x)$ (see [8, p. 111]).

In this section, it will be shown that if either the initial information state is semiconvex, or if σ is nondegenerate, then the information state will be semiconvex for all $T > 0$. Next, the convex duality representation for convex functions is adapted to the semiconvex case. Then, since the information state is semiconvex, one sees that this provides a semiconvex duality representation for the information state. This representation will be used in section 5 to obtain the basis representation.

Recall from section 3 that the solution operator (in the absence of observations) is defined as

$$\begin{aligned} \mathcal{S}_T[\phi](x) &= \sup_{w \in L_2([0,T];\Re^m)} J^0(T, x; w(\cdot)), \\ J^0(T, x; w(\cdot)) &= \phi(x_0) - \frac{1}{2}\int_0^T |w(t)|^2\, dt, \end{aligned} \tag{4.2}$$

where $x_0 = x(0)$ given $x(T) = x$ and dynamics (2.1).

THEOREM 4.1. *If ϕ is semiconvex, then $\mathcal{S}_T[\phi]$ is semiconvex for each $T > 0$. In fact, there exists $\Gamma_R(T)$ such that for $0 \leq \tau \leq T$, $R > 0$, $\mathcal{S}_\tau[\phi](x) + \Gamma_R(T)|x|^2$ is convex on the ball B_R.*

Proof. Let

$$\widetilde{J}(\tau, x; w(\cdot)) = J^0(\tau, x; w(\cdot)) + \Gamma|x|^2,$$
$$J^0(\tau, x, w(\cdot)) = \phi(x_0) - \frac{1}{2}\int_0^\tau |w(t)|^2\, dt,$$

where $\Gamma = \Gamma_R(T)$ is to be chosen suitably. Since the supremum of any family of convex functions is a convex function, it suffices to show that $\widetilde{J}(\tau, \cdot; w(\cdot))$ is convex on B_R for each $w(\cdot)$.

By smoothing via convolution with approximations to the identity, we may assume that ϕ is smooth. Then semiconvexity of ϕ is equivalent to $v^T\phi_{xx}(x)v \geq -C_R|v|^2$ for all $v \in \Re^n$, when $|x| \leq R$. To show convexity of $\widetilde{J}$ it suffices to show that

$$v^T J^0_{xx}(\tau, x; w(\cdot))v \geq -2\Gamma \tag{4.3}$$

whenever $|x| \leq R$, $|v| = 1$, and $\|w\|^2 \leq M_1(T, R)$ (see Lemma 2.1). Let $\zeta^1(t), \zeta^2(t)$ denote the first and second derivatives of $x(t)$ in the direction v (considered as a function of $x = x(\tau)$). Then

$$v^T J^0_{xx}(\tau, x; w(\cdot))v = \phi_x(x_0) \cdot \zeta^2(0) + (\zeta^1(0))^T\phi_{xx}(x_0)\zeta^1(0).$$

By the "range-of-dependence" property (which follows directly from Lemma 2.1), $|x_0| \leq R_1$ for suitable R_1. If we can also obtain bounds on $|\zeta^1(0)|, |\zeta^2(0)|$ depending only on T, R, then we will have (4.3) for suitable $\Gamma = \Gamma_R(T)$, which will complete the proof. (In fact, one could explicitly compute $\Gamma_R(T)$ from these bounds if so desired.) Bounds on $\zeta^1(0), \zeta^2(0)$ are obtained as follows. Let

$$\dot{x}^h = f(x^h) + \sigma(x^h)w,$$
$$x^h(\tau) = x + hv.$$

Then with $\zeta^1(t) \doteq \frac{d}{dh}x^h(t)\big|_{h=0}$, one has

$$\dot{\zeta}^1 = f_x(x^0)\zeta^1 + [\sigma_x(x^0)\zeta^1]w,$$
$$\zeta^1(\tau) = v.$$

By Lemma 2.1, one has bounds on x^0, w, and then by (A1), this last equation yields a bound on $|\zeta^1(0)|$. □

Also, letting $\zeta^{1,h}(t) = \frac{d}{dh}x^h(t)$ for h not necessarily zero, one has $\zeta^2(t) = \frac{d}{dh}\zeta^{1,h}(t)\big|_{h=0}$. Then

$$\dot{\zeta}^2 = f_{xx}(x^0)\zeta^1 \cdot \zeta^1 + f_x(x^0)\zeta^2 + [\sigma_{xx}(x^0)\zeta^1 \cdot \zeta^1 + \sigma_x(x^0)\zeta^2]w,$$
$$\zeta^2(\tau) = 0.$$

Again, employing bounds from Lemma 2.1 and (A1) with this equation leads to a bound for $|\zeta^2(0)|$. □

Fundamental solutions. If we assume nondegeneracy of the disturbance term in (2.1), then $\mathcal{S}_T[\phi]$ is semiconvex for $T > 0$ without assuming semiconvexity of ϕ. (The authors wish to thank P. Dupuis for pointing this out.) By nondegeneracy we mean that $m \geq n$ and

(A5) $\sigma^{-1}(x)$ is bounded uniformly in x, and also assume $\sigma^{-1} \in C^2$,

where we define the inverse by

$$\sigma^{-1}(x)b \doteq \operatorname{argmin}\{|a| : \sigma(x)a = b\}$$

for any $b \in \Re^n$. Note that assumption (A5) is only required if the initial information function, ϕ, is not semiconvex.

Let us introduce the following function, $V(T, x_0, x_T)$, which we call a *fundamental solution* of the PDE (2.14b). For $x_0, x_T \in \Re^n$, $T > 0$, let

$$V(T, x_0, x_T) = \sup_{w \in L_2([0,T];\Re^m)} \left\{ -\frac{1}{2} \int_0^T |w(t)|^2 \, dt : x(0) = x_0,\ x(T) = x_T \right\}, \tag{4.4}$$

where $x(\cdot)$ satisfies (2.1). From (4.2),

$$\mathcal{S}_T[\phi](x) = \sup_{x_0 \in \Re^n} \{\phi(x_0) + V(T, x_0, x)\}. \tag{4.5}$$

We can rewrite V in terms of the following calculus of variations problem with fixed end conditions. Let

$$L(x, \dot{x}) = \tfrac{1}{2}|\sigma^{-1}(x)(\dot{x} - f(x))|^2,$$
$$I(T, x_0, x_T; x(\cdot)) = -\textstyle\int_0^T L(x(t), \dot{x}(t)) \, dt.$$

Then

$$V(T, x_0, x_T) = \sup\{I(T, x_0, x_T; x(\cdot)) : x(0) = x_0,\ x(T) = x_T\}$$

with $x(\cdot)$ given by (2.1). Equivalence of (4.4) and this calculus of variations version follows easily by noting that for each path, $x(\cdot)$, there is a corresponding unique minimal-norm $w(\cdot)$ given in feedback form with this definition of σ^{-1}.

LEMMA 4.2. *Assume* (A5). *Then* $V(T, x_0, \cdot)$ *is semiconvex. In fact, given* $0 < T_1 < T_2 < \infty$, R, R_0, *there exists* Δ *(depending on* T_1, T_2, R, R_0*) such that* $V(T, x_0, x) + \Delta|x|^2$ *is convex on the ball* $B_R \doteq \{x \in \Re^n : |x| \le R\}$ *for any* $T \in [T_1, T_2]$ *and any* $|x_0| \le R_0$.

Proof. Given x_0, x, there exists $x^*(\cdot)$ such that $x^*(0) = x_0$, $x^*(T) = x$, and

$$V(T, x_0, x) = I(T, x_0, x; x^*(\cdot)).$$

Now suppose $0 < T_1 \le T \le T_2$, $|x_0| \le R_0$, and $|x| \le R$. Some "range-of-dependence" estimates will be obtained. For comparison with the optimal trajectory, let $\overline{x}(t) \doteq x_0 + (t/T)(x - x_0)$. Then there exists $C < \infty$ (depending on R_0, R, T_1) such that

$$\left|\dot{\overline{x}} - f(\overline{x}(t))\right| \le C \qquad \forall\, t \in [0, T],$$

and then by (A5), there exists $M_i < \infty$ such that

$$-L(\overline{x}, \dot{\overline{x}}) \ge -\frac{1}{2} M_i^2 C^2.$$

Then by the optimality of x^*,

$$I(T, x_0, x; x^*(\cdot)) \ge -\frac{1}{2} M_i^2 C^2 T,$$

and using (A2), this yields

$$\int_0^T |\dot{x}^* - f(x^*(t))|^2\,dt \le M^2 M_i^2 C^2 T. \tag{4.6}$$

Then note that by (A1), there exists $K < \infty$ such that

$$\begin{aligned}\frac{d}{dt}|x^*|^2 &= 2(x^*)^T(f(x^*) + (\dot{x}^* - f(x^*)))\\ &\le 3K|x^*|^2 + K + 2|x^*||\dot{x}^* - f(x^*)|\\ &\le (3K+1)|x^*|^2 + K + |\dot{x}^* - f(x^*)|^2.\end{aligned}$$

Employing Gronwall's inequality and (4.6), one finds that there exist $R_1, \overline{M} < \infty$ (depending on R_0, R, T_1, T_2) such that $|x^*(t)| \le R_1$ for all $t \in [0,T]$ and $\|\dot{x}^*(\cdot)\|_{L_2[0,T]} \le \overline{M}$.

Next, consider any direction $v \in \Re^n$ ($|v| = 1$) and scalar $h \in [-1,1]$. Let

$$x^h(t) \doteq x^*(t) + \frac{t}{T}hv.$$

Then $x^h(0) = x_0$ and $x^h(T) = x + hv$. Moreover,

$$\begin{aligned}&\frac{d^2}{dh^2} I(T, x_0, x+hv; x^h(\cdot)) = v^T \Lambda^h v,\\ &\Lambda^h \doteq \frac{1}{T^2}\int_0^T \left[t^2 L^h_{xx} + 2tL^h_{x\dot{x}} + L^h_{\dot{x},\dot{x}}\right] dt,\end{aligned}$$

$L^h_{xx} = L_{xx}(x^h(t), \dot{x}^h(t))$, and the other derivatives defined similarly. Since $|x^h(t)|$ and $\|\dot{x}^h(\cdot)\|_{L_2[0,T]}$ are uniformly bounded,

$$\frac{d^2}{dh^2} I(T, x_0, x+hv; x^h(\cdot)) \ge -2\Delta$$

for some constant Δ depending on T_1, T_2, R, R_0. Then $I(T, x_0, x+hv; x^h(\cdot)) + \Delta h^2$ is a convex function of h for $|h| \le 1$. Then

$$\begin{aligned}&V(T, x_0, x+hv) + V(T, x_0, x-hv) - 2V(T, x_0, x)\\ &\ge I(T, x_0, x+hv; x^h(\cdot)) + I(T, x_0, x-hv; x^{-h}(\cdot)) - 2I(T, x_0, x; x^*(\cdot))\\ &\ge -2\Delta h^2.\end{aligned}$$

This implies that $V(T, x_0, x) + \Delta|x|^2$ is convex on the ball $\{x \in \Re^n : |x| \le R\}$. ∎

THEOREM 4.3. *Assume* (A5). *For any* $\phi \le 0$, $T > 0$, $\mathcal{S}_T[\phi]$ *is semiconvex.*

Proof. If $|x_T| \le R$, by the "range-of-dependence" property, it suffices to consider those $x(\cdot)$ such that $|x(t)| \le R_1$, where $x_0 = x(0)$. If $x = x_T$, then by (4.5)

$$\begin{aligned}&\mathcal{S}_T[\phi](x) = \sup_{x_0 \in \Re^n} \{\phi(x_0) + V(T, x_0, x)\},\\ &\mathcal{S}_T[\phi](x) + \Delta|x|^2 = \sup_{x_0 \in \Re^n} \left\{\phi(x_0) + V(T, x_0, x) + \Delta|x|^2\right\},\end{aligned}$$

with Δ as in Lemma 4.2 Since the supremum of any family of convex functions is convex, $\mathcal{S}_T[\phi](x) + \Delta|x|^2$ is convex on the ball $\{x \in \Re^n : |x| \le R\}$. ∎

Theorems 4.1 and 4.3 imply (under different assumptions) that the information state (in the absence of measurement updates) will be semiconvex. To complete this discussion, one also needs to show that the measurement updates (2.14c) maintain semiconvexity.

LEMMA 4.4. *Suppose ψ is semiconvex. Then $\psi(x) - \frac{1}{2}|\rho^{-1}(x)[y - h(x)]|^2$ is semiconvex for any $y \in \Re^k$.*

Proof. Let $G(x) \doteq |\rho^{-1}(x)[y - h(x)]|^2$. Fix $R < \infty$. Then, since ψ is semiconvex, there exists $C_R < \infty$ such that $\psi(x) + \frac{C_R}{2}|x|^2$ is convex. But by (A1) and (A3b), there exists $C_{R,y} < \infty$ such that $|G_{xx}(x)| \leq C_{R,y}$ for all $x \in B_R$. Consequently $\psi(x) - \frac{1}{2}|\rho^{-1}(x)[y - h(x)]|^2 + \frac{C_R + C_{R,y}}{2}|x|^2$ is convex. □

By Theorem 2.4, Lemma 4.4, and either Theorem 4.1 or Theorem 4.3, we know that, under the given assumptions, the information state, P, will be continuous and semiconvex. Consequently, we define

$$\mathcal{P} \doteq \{\psi : \Re^n \to \Re : \psi \text{ is continuous and semiconvex}\}.$$

The algorithm to follow will depend on a max-plus basis representation of any $\psi \in \mathcal{P}$. The starting point for this representation will be the convex dual.

Let $R > 0$ and (as above) $B_R \doteq \{x \in \Re^n : |x| \leq R\}$. Let $\widehat{\psi} : B_R \to \Re$ be convex and Lipschitz over B_R with Lipschitz constant $L(R)$, and let $\widehat{\psi}(x) = +\infty$ for all $x \notin B_R$. The following result is a minor variation of a standard result in convex duality (see, for instance, [30], [31]). The slight variation here is that, in this case, one has existence of the maximizers in the statement of the lemma, which is a result of the restrictive class of functions, $\widehat{\psi}$, being considered here.

LEMMA 4.5 (convex duality representation).

$$\widehat{\psi}(x) = \max_{p \in B_{L(R)}} [p^T x + \overline{a}_p] \qquad \forall\, x \in B_R,$$

where

$$\overline{a}_p = -\max_{x \in B_R} [p^T x - \widehat{\psi}(x)],$$

and note that $\overline{a}_p$ may be $-\infty$.

Consider any $\psi \in \mathcal{P}$ over some ball B_R. Let $c > 0$ be a constant such that

$$\widehat{\psi}(x) \doteq \begin{cases} \psi(x) + \frac{c}{2}|x|^2 & \text{if } x \in B_R \\ +\infty & \text{otherwise} \end{cases} \quad \text{is convex.} \tag{4.7}$$

(The existence of c is guaranteed by $\psi \in \mathcal{P}$.) As noted above, by [8, p. 111], $\widehat{\psi}$ is Lipschitz over B_R with some constant $L(R)$. Further, if $|\psi(x)| \leq D_2(1 + |x|^2)$ for some D_2, then it can be shown using the explicit local Lipschitz bound in [8] that $L(R) \leq D_3(1 + R)$ for some D_3. The convex duality representation of $\widehat{\psi}$ in Lemma 4.5 leads easily to the following representation for ψ.

THEOREM 4.6 (semiconvex duality representation).

$$\psi(x) = \max_{\widetilde{x} \in B_{L(R)/c}} \left[-\frac{c}{2}|x - \widetilde{x}|^2 + a_{\widetilde{x}}\right] = \max_{\widetilde{x} \in \Re^n} \left[-\frac{c}{2}|x - \widetilde{x}|^2 + a_{\widetilde{x}}\right] \qquad \forall\, x \in B_R,$$

where

$$a_{\widetilde{x}} = -\max_{x \in B_R} \left[-\frac{c}{2}|x - \widetilde{x}|^2 - \psi(x)\right].$$

Proof. For any $x \in B_R$,

$$\psi(x) = \widehat{\psi}(x) - \frac{c}{2}|x|^2,$$

which by Lemma 4.5

$$\begin{aligned} &= \max_{p \in B_{L(R)}} \left[p^T x - \frac{c}{2}|x|^2 + \overline{a}_p \right] \\ &= \max_{p \in B_{L(R)}} \left[-\frac{c}{2}|x - p/c|^2 + \frac{1}{2c}|p|^2 + \overline{a}_p \right], \end{aligned}$$

which by letting $\widetilde{x} = p/c$ becomes

$$\begin{aligned} &= \max_{\widetilde{x} \in B_{L(R)/c}} \left[-\frac{c}{2}|x - \widetilde{x}|^2 + \frac{c}{2}|\widetilde{x}|^2 + \overline{a}_{c\widetilde{x}} \right] \\ &= \max_{\widetilde{x} \in B_{L(R)/c}} \left[-\frac{c}{2}|x - \widetilde{x}|^2 + a_{\widetilde{x}} \right], \end{aligned}$$

where

$$\begin{aligned} a_{\widetilde{x}} &= \frac{c}{2}|\widetilde{x}|^2 + \overline{a}_{c\widetilde{x}} \\ &= -\max_{x \in B_R} \left[(c\widetilde{x})^T x - \widehat{\psi}(x) - \frac{c}{2}|\widetilde{x}|^2 \right], \end{aligned}$$

which by (4.7)

$$\begin{aligned} &= -\max_{x \in B_R} \left[(c\widetilde{x})^T x - \psi(x) - \frac{c}{2}|x|^2 - \frac{c}{2}|\widetilde{x}|^2 \right] \\ &= -\max_{x \in B_R} \left[-\frac{c}{2}|x - \widetilde{x}|^2 - \psi(x) \right]. \end{aligned}$$

□

5. Basis representation. In this section we modify the representation of $\psi \in \mathcal{P}$ given by Theorem 4.6 to obtain a countable basis representation. Again, let $\psi \in \mathcal{P}$ and $R > 0$ with corresponding $\overline{c}$ such that (4.7) holds.

Suppose we have some countable dense subset $\{x_i\}_{i=1}^{\infty} \subseteq \Re^n$. Let $\widehat{c} \in (\overline{c}, \infty)$. Let

$$g_i(x) = -\frac{\widehat{c}}{2}|x - x_i|^2 \tag{5.1a}$$

and

$$a_i = -\max_{x \in B_R} [g_i(x) - \psi(x)]. \tag{5.1b}$$

Let $c \in (\widehat{c}, \infty)$ and

$$\overline{g}_{\widetilde{x}}(x) = -\frac{c}{2}|x - \widetilde{x}|^2.$$

By Theorem 4.6,

$$\psi(x) = \max_{\widetilde{x} \in B_{L(R)/c}} [\overline{g}_{\widetilde{x}}(x) + a_{\widetilde{x}}] \qquad \forall\, x \in B_R,$$

where $a_{\widetilde{x}}$ is given in Theorem 4.6. It will next be shown that, in fact,

$$\psi(x) = \sup_i [a_i + g_i(x)] = \bigoplus_{i=1}^{\infty} [a_i \otimes g_i(x)] \qquad \forall\, x \in B_R,$$

where $\bigoplus_{i=1}^{\infty}$ indicates max-plus summation. Some additional properties of this basis function representation will also be obtained. Lemma 5.1 will be useful in the two theorems to follow.

LEMMA 5.1. *Given $\widetilde{x} \in B_{L(R)/c}$ and $\epsilon > 0$, there exists i such that*

$$\psi(x) \geq g_i(x) + a_i \geq \overline{g}_{\widetilde{x}}(x) + a_{\widetilde{x}} - \epsilon \qquad \forall\, x \in B_R.$$

Further, for any $\delta > 0$ one may specify $|x_i - \widetilde{x}| \leq \frac{c-\widehat{c}}{c\widehat{c}}(cR + L(R)) + \delta$.

Proof. Let $\widetilde{x}$ and $\epsilon > 0$ be given. By Theorem 4.6, there exists $\overline{x} \in B_R$ such that

$$a_{\widetilde{x}} - \frac{c}{2}|\overline{x} - \widetilde{x}|^2 = \psi(\overline{x}). \tag{5.2}$$

Choose $\widehat{x} \in \Re^n$ such that

$$-\widehat{c}(\overline{x} - \widehat{x}) = -c(\overline{x} - \widetilde{x}) \tag{5.3}$$

(so that the gradient of $-\frac{\widehat{c}}{2}|x - \widehat{x}|^2$ matches that of $\overline{g}_{\widetilde{x}}$ at $\overline{x}$). Note that this implies $|\widehat{x} - \widetilde{x}| \leq \frac{c-\widehat{c}}{c\widehat{c}}(cR + L(R))$. By the density of $\{x_i\}_{i=1}^{\infty}$, given $\delta > 0$, there exists i such that

$$|x_i - \widehat{x}| < \delta. \tag{5.4}$$

Let $\widehat{a}_i$ be such that

$$\psi(\overline{x}) = \widehat{a}_i - \frac{\widehat{c}}{2}|\overline{x} - x_i|^2. \tag{5.5}$$

Define

$$\psi^0(x) = \begin{cases} \psi(x) + \frac{\overline{c}}{2}|x - \overline{x}|^2 & \text{if } x \in B_R, \\ +\infty & \text{if } x \notin B_R, \end{cases}$$

so that ψ^0 is convex. By the definition of $\overline{x}$,

$$-c(\overline{x} - \widetilde{x})^T \in \partial\psi^0(\overline{x}),$$

and so by (5.3)

$$-\widehat{c}(\overline{x} - \widehat{x})^T \in \partial\psi^0(\overline{x}),$$

which, by the definition of subgradient and that $\psi^0(\overline{x}) = \psi(\overline{x})$, implies

$$\psi(\overline{x}) - \widehat{c}(\overline{x} - \widehat{x})^T(x - \overline{x}) \leq \psi^0(x) \qquad \forall\, x \in \Re^n. \tag{5.6}$$

It will next be shown that the a_i given by (5.1b) is not much smaller than $\widehat{a}_i$ given by (5.5). Define

$$F(x) \doteq \widehat{a}_i - \frac{\widehat{c}}{2}|x - x_i|^2 + \frac{\overline{c}}{2}|x - \overline{x}|^2 - [\psi(\overline{x}) - \widehat{c}(\overline{x} - \widehat{x})^T(x - \overline{x})]. \tag{5.7}$$

The maximum of F occurs at

$$x_0 = \overline{x} + \frac{\widehat{c}}{\widehat{c} - \overline{c}}(x_i - \widehat{x}),$$

and the maximum value is

$$F(x_0) = \frac{\widehat{c}^2}{2(\widehat{c} - \overline{c})}|x_i - \widehat{x}|^2,$$

which by (5.4)

$$< \frac{\widehat{c}^2}{2(\widehat{c} - \overline{c})}\delta^2. \tag{5.8}$$

We choose $\delta > 0$ sufficiently small such that

$$\frac{\widehat{c}^2}{2(\widehat{c} - \overline{c})}\delta^2 < \frac{\epsilon}{2}. \tag{5.9}$$

Then, by (5.7), (5.8), and (5.9),

$$\widehat{a}_i - \frac{\widehat{c}}{2}|x - x_i|^2 + \frac{\overline{c}}{2}|x - \overline{x}|^2 < \psi(\overline{x}) - \widehat{c}(\overline{x} - \widehat{x})^T(x - \overline{x}) + \frac{\epsilon}{2} \qquad \forall\, x \in \Re^n,$$

and so by (5.6),

$$\widehat{a}_i - \frac{\widehat{c}}{2}|x - x_i|^2 + \frac{\overline{c}}{2}|x - \overline{x}|^2 < \psi^0(x) + \frac{\epsilon}{2} \qquad \forall\, x \in \Re^n,$$

which, by the definition of ψ^0, implies

$$\widehat{a}_i - \frac{\widehat{c}}{2}|x - x_i|^2 < \psi(x) + \frac{\epsilon}{2} \qquad \forall\, x \in B_R.$$

Consequently, with a_i given by (5.1b), one has

$$a_i > \widehat{a}_i - \frac{\epsilon}{2}. \tag{5.10}$$

Now it will be shown that $a_i - \frac{\widehat{c}}{2}|x - x_i|^2 = a_i + g_i(x)$ is not more than ϵ below $a_{\widetilde{x}} + \overline{g}_{\widetilde{x}}(x)$ (for sufficiently small δ). Define

$$H(x) = a_{\widetilde{x}} - \frac{c}{2}|x - \widetilde{x}|^2 - \left(a_i - \frac{\widehat{c}}{2}|x - x_i|^2\right). \tag{5.11}$$

By (5.2),

$$H(\overline{x}) = \psi(\overline{x}) - \left(a_i - \frac{\widehat{c}}{2}|\overline{x} - x_i|^2\right),$$

which by (5.10) and (5.5)

$$< \frac{\epsilon}{2}.$$

By (5.11)

$$\frac{dH}{dx}(\overline{x}) = -c(\overline{x} - \widetilde{x})^T + \widehat{c}(\overline{x} - x_i)^T,$$

which by (5.3)

$$= -\widehat{c}(\overline{x} - \widehat{x})^T + \widehat{c}(\overline{x} - x_i)^T,$$

so that

$$\left|\frac{dH}{dx}(\overline{x})\right| \leq \widehat{c}|\widehat{x} - x_i|.$$

Also,

$$\frac{d^2H}{dx^2}(x) = (\widehat{c} - c)I < 0$$

(whereby the last inequality, we mean that $(\widehat{c}-c)I$ is negative definite). Consequently,

$$H(x) < \frac{\epsilon}{2} + \widehat{c}|\widehat{x} - x_i||x - \overline{x}| - \frac{c - \widehat{c}}{2}|x - \overline{x}|^2 \qquad \forall\, x \in \Re^n,$$

and taking the maximum of the right-hand side yields

$$H(x) < \frac{\epsilon}{2} + \frac{\widehat{c}^2}{2(c - \widehat{c})}|\widehat{x} - x_i|^2 \qquad \forall\, x \in \Re^n,$$

which by (5.4)

$$\leq \frac{\epsilon}{2} + \frac{\widehat{c}^2}{2(c - \widehat{c})}\delta^2 \qquad \forall\, x \in \Re^n,$$

and by possibly reducing the size of δ from that in (5.9), one can make this

$$< \epsilon. \tag{5.12}$$

By (5.11) and (5.12),

$$a_i - \frac{\widehat{c}}{2}|x - x_i|^2 \geq a_{\widetilde{x}} - \frac{c}{2}|x - \widetilde{x}|^2 - \epsilon \qquad \forall\, x \in \Re^n.$$

This is the desired right inequality, and the desired left inequality is a direct consequence of (5.1b). □

THEOREM 5.2.

$$\psi(x) = \sup_i [a_i + g_i(x)] = \bigoplus_{i=1}^{\infty} [a_i \otimes g_i(x)] \qquad \forall\, x \in B_R. \tag{5.13}$$

Further, for any $\delta > 0$ it is sufficient to consider only a set of $\{x_i\}$ which is a dense subset of $B_{\delta + L(R)/c}$.

Proof. Let $\overline{x} \in B_R$. By Theorem 4.6, there exists $\widetilde{x} \in \Re^n$ such that

$$\psi(\overline{x}) = \overline{g}_{\widetilde{x}}(\overline{x}) + a_{\widetilde{x}}$$

and by Lemma 5.1, given $\epsilon > 0$, there exists i such that

$$\leq g_i(\overline{x}) + a_i + \epsilon.$$

Since $\epsilon > 0$ was arbitrary,

$$\psi(\overline{x}) \leq \sup_i [g_i(\overline{x}) + a_i],$$

and the reverse follows by the definition of the a_i. Also, the last assertion follows from Theorem 4.6 and the density of the x_i. ∎

For the remainder of the section, let $\{x_i\}$ be dense over all of $\Re^n$ in order to reduce complication. One has the countable basis function representation (5.13) for any such countable dense set $\{x_i\}$ and particular choice of constant $\widehat{c} \in (\overline{c}, \infty)$, where $\overline{c}$ is any constant such that (4.7) holds. Some further guidance on appropriate choices of $\widehat{c}$ will now be obtained. Consider several possible choices of basis function sets indexed by j,

$$\mathcal{B}_j \doteq \left\{ g_{j,i}(x) = -\frac{\widehat{c}_j}{2}|x - x_i|^2 : \{x_i\}_{i=1}^{\infty} \right\}. \tag{5.14}$$

From Theorem 5.2, we know that

$$\psi(x) = \bigoplus_{i=1}^{\infty} [a_i \otimes g_{j,i}(x)] \tag{5.15}$$

for any j such that $\widehat{c}_j > \overline{c}$. Conceptually then, given some $\psi \in \mathcal{P}$ and $R > 0$, one could choose any set of basis functions $\mathcal{B}_j \in \{\mathcal{B}_j\}$ such that

$$\widehat{c}_j > \overline{c}. \tag{5.16}$$

It will now be shown that it is in some sense optimal to choose the set $\mathcal{B}_j$ with the smallest (loosely speaking) $\widehat{c}_j$ which satisfies (5.16). This may be rigorously stated as follows.

THEOREM 5.3. *Suppose $R > 0$ and $\psi \in \mathcal{P}$ with semiconvexity constant $\overline{c}$ (so that (4.7) is satisfied). Let $\mathcal{B}_{j_1}, \mathcal{B}_{j_2} \in \{\mathcal{B}_j\}$ be such that $\widehat{c}_{j_2} > \widehat{c}_{j_1} > \overline{c}$. Then, for any $n < \infty$ and $\epsilon > 0$, there exists $\{k_i\}_{i=1}^n$ such that*

$$\psi(x) \geq \bigoplus_{i=1}^{n} a_{j_1,k_i} \otimes g_{j_1,k_i}(x) \geq \bigoplus_{i=1}^{n} a_{j_2,i} \otimes g_{j_2,i}(x) - \epsilon \qquad \forall\, x \in B_R,$$

where $a_{j_1,i}, a_{j_2,i}$ are given by (5.1b) for all i.

Before proceeding with the proof, note that this implies that one can always do arbitrarily close to better by choosing the smaller choice of $\widehat{c}_j$, but that the particular order of x_i and the function ψ may affect this. Typically, of course, one would expect better performance with the smaller choice of $\widehat{c}_j$ since the result is obviously not true if $\widehat{c}_{j_2} < \widehat{c}_{j_1}$.

Proof. Let $1 \leq i \leq n < \infty$ and $\epsilon > 0$. It is sufficient to show that there exists $k_i < \infty$ such that

$$\psi(x) \geq a_{j_1,k_i} \otimes g_{j_1,k_i}(x) \geq a_{j_2,i} \otimes g_{j_2,i}(x) - \epsilon \qquad \forall\, x \in B_R. \tag{5.17}$$

But this is simply Lemma 5.1. ∎

Finally, we turn to motivation for the choice of coefficients a_i in the expansion. Specifically we motivate the choice given by (5.1b). Note that this theorem will be true independent of the particular choice of basis functions $\{g_i\}$ in (5.1a).

THEOREM 5.4. *Let $\{a_i\}_{i=1}^{\infty}$ be given by* (5.1b) *and let $\{\widetilde{a}_i\}_{i=1}^{\infty}$ be an alternative set of coefficients. If $\widetilde{a}_{i_0} > a_{i_0}$ for some i_0, then*

$$\max_{x\in B_R}\left|\bigoplus_{i=1}^{\infty}\widetilde{a}_i\otimes g_i(x)-\psi(x)\right|>0. \tag{5.18}$$

Alternatively, if $\widetilde{a}_i \le a_i$ for all i, then

$$\max_{x\in B_R}\left|\bigoplus_{i=1}^{n}\widetilde{a}_i\otimes g_i(x)-\psi(x)\right| \ge \max_{x\in B_R}\left|\bigoplus_{i=1}^{n}a_i\otimes g_i(x)-\psi(x)\right| \qquad \forall\, n. \tag{5.19}$$

Remark 5.5. Before proceeding to the proof, let us note that this theorem implies that of the possible choices for $\{a_i\}_{i=1}^{\infty}$ such that (5.13) holds, the choice given by (5.1b) is optimal. However, this does not imply that for any fixed $n<\infty$,

$$\max_{x\in B_R}\left|\bigoplus_{i=1}^{n}a_i\otimes g_i(x)-\psi(x)\right| \le \max_{x\in B_R}\left|\bigoplus_{i=1}^{n}\widetilde{a}_i\otimes g_i(x)-\psi(x)\right|.$$

That is, there may be better choices of $\{a_i\}_{i=1}^{n}$ for finite approximations, but such a choice cannot be extended to yield ψ in the limit without changing the a_i's for $i\le n$.

Proof. For the first part, note that by (5.1a), there exists $x_0\in B_R$ such that

$$\psi(x_0)-a_{i_0}\otimes g_{i_0}(x_0)=0,$$

and consequently,

$$\psi(x_0)-\bigoplus_{i=1}^{\infty}\widetilde{a}_i\otimes g_i(x_0)\le \psi(x_0)-\widetilde{a}_{i_0}\otimes g_{i_0}(x_0),$$

which since $\widetilde{a}_{i_0}>a_{i_0}$

$$<\psi(x_0)-a_{i_0}\otimes g_{i_0}(x_0)=0.$$

For the second part, note that for any $n\ge 1$ and any $x\in B_R$,

$$\begin{aligned}\psi(x)\ge\textstyle\bigoplus_{i=1}^{n}a_i\otimes g_i(x) &= \max_{1\le i\le n}[a_i+g_i(x)]\\ &\ge \max_{1\le i\le n}[\widetilde{a}_i+g_i(x)]=\bigoplus_{i=1}^{n}\widetilde{a}_i\otimes g_i(x).\end{aligned}$$

□

6. Algorithm. Before explicitly describing the computational algorithm, we discuss how one may combine basis representation (5.13) with the max-plus linearity of the solution operator (Theorem 3.1) to update the information state between measurement times. This is actually a general algorithm for solving HJB equations of the form (2.14b) with semiconvex initial conditions, and so is more general than the particular application considered in this paper.

Specific error estimates have not been included in this section. The goal of this paper is to outline a new approach to computations for the Mortensen and robust

nonlinear filters. Since this is a new and unusual approach, and since the paper is already of substantial length, error estimates are delayed to a future paper, where computational comparisons could also be examined.

Recall the discrete-time filter discussed in section 2. Suppose $P(t_l^+, \cdot)$ is semiconvex, and that we approximate it over some ball, B_R, by some finite number of elements of the basis representation (5.13), that is,

$$P(t_l^+, x) = \bigoplus_{i=1}^{\infty} [a_i \otimes g_{j_1,i}(x)] \simeq \bigoplus_{i=1}^{n} [a_i \otimes g_{j_1,i}(x)] \qquad \forall\, x \in B_R,$$

where

$$g_{j_1,i} = -\frac{\widehat{c}_{j_1}}{2}|x - x_i|^2$$

with appropriate choice of $\widehat{c}_{j_1}$ and with a_i given by (5.1b). Then $P(t_{l+1}{}^-, x)$ is given by $\mathcal{S}_\delta[P(t_l^+, \cdot)](x)$, where $\mathcal{S}_\delta$ is the solution operator for (2.14b), where $\delta = t_{l+1} - t_l$.

We know by Theorem 3.1 that

$$\begin{aligned} P(t_{l+1}{}^-, x) &= \mathcal{S}_\delta[P(t_l^+, \cdot)](x) \\ &\simeq \mathcal{S}_\delta \left[\bigoplus_{i=1}^{n} [a_i \otimes g_{j_1,i}(\cdot)] \right](x) \\ &= \bigoplus_{i=1}^{n} \{a_i \otimes \mathcal{S}_\delta[g_{j_1,i}](x)\}. \end{aligned} \tag{6.1}$$

It is assumed that one has precomputed $\mathcal{S}_\delta[g_{j,i}]$ for all appropriate j, i, where the solutions are represented in the form

$$\mathcal{S}_\delta[g_{j,i}](x) \simeq \bigoplus_{k=1}^{n} b_{k,i} \otimes g_{j_2,k}(x), \tag{6.2}$$

where $g_{j_2,k}(x) = -\frac{\widehat{c}_{j_2}}{2}|x - x_k|^2$, $\widehat{c}_{j_2}$ is greater than the largest semiconvexity constant over the set $\{\mathcal{S}_\delta g_{j_1,i}\}_{i=1}^n$, and $b_{k,i}$ is given by (5.1b), i.e., $b_{k,i} = -\max_{x \in B_R}[g_{j_2,k}(x) - \mathcal{S}_\delta[g_i](x)]$. (Note that one might choose to vary the set of interest, B_R, from one time to another, but for simplicity of notation, we do not include that here.) In other words, one has precomputed and stored the matrices $[b_{k,i}]$ for all appropriate j_1, j_2. Then by (6.1), (6.2)

$$\begin{aligned} P(t_{l+1}{}^-, x) &\simeq \bigoplus_{i=1}^{n} \{a_i \otimes \mathcal{S}_\delta[g_{j_1,i}](x)\} \\ &\simeq \bigoplus_{i=1}^{n} \left\{ a_i \otimes \left[\bigoplus_{k=1}^{n} b_{k,i} \otimes g_{j_2,k}(x) \right] \right\} \\ &= \bigoplus_{i=1}^{n} \bigoplus_{k=1}^{n} [b_{k,i} \otimes a_i \otimes g_{j_2,k}(x)] \\ &= \bigoplus_{k=1}^{n} \left[\left(\bigoplus_{i=1}^{n} (b_{k,i} \otimes a_i) \right) \otimes g_{j_2,k}(x) \right]. \end{aligned} \tag{6.3}$$

Let B be the $n \times n$ matrix $[b_{k,i}]$, and let A be the vector $[a_i]$. Define max-plus matrix multiplication in the natural way; that is, let $C = B \otimes A$ be given by $C = [c_k]$, where $c_k = \bigoplus_{i=1}^{n} [b_{k,i} \otimes a_i]$. Then,

$$P(t_{l+1}^-, x) = \bigoplus_{i=1}^{n} [c_i \otimes g_{j_2,i}(x)],$$

where

$$C = B \otimes A. \tag{6.4}$$

In other words, the update $P(t_{l+1}^-, x) = \mathcal{S}_\delta[P(t_l^+, \cdot)](x)$ is performed simply by the max-plus matrix multiplication (6.4).

Now we will outline the structure of the information state propagation numerical algorithm for the discrete-time measurement case. Assume that the measurements occur at fixed time intervals $t_l = l\delta$ for $l = 1, 2, \ldots$. Assume that $P(0^+, \cdot) = \phi(\cdot)$ is semiconvex. (If not, then we know from Theorem 4.3 that $P(\delta, \cdot)$ will be semiconvex for $\delta > 0$, under the nondegeneracy assumption discussed there.)

Let $l = 0$.

(1) Compute an estimate of the semiconvexity constant, $\bar{c}$, for $P(t_l^+, \cdot)$ over B_R. (Since $P(t_l^+, \cdot)$ will be known only on some finite set, this is estimated by second-order differences.)

(2) Choose a set of basis functions $\mathcal{B}_{j_1}$ with $\widehat{c}_{j_1} > \bar{c}$. (In actual operations, one may choose to use more than one set, $\{\mathcal{B}_{j_1}, \mathcal{B}_{j_2}, \ldots, \mathcal{B}_{j_n}\}$, but we require $\max_{j_m} \widehat{c}_{j_m} > \bar{c}$.) Also, determine the particular subset $\{x_i\}_{i=1}^n \subset \{x_i\}_{i=1}^\infty$ to use.

(3) Compute $A^l = [a_i^l]$ for $i = 1, 2, \ldots, n$ from (5.1b). One now has the approximation

$$P(t_l^+, x) \simeq \bigoplus_{i=1}^{n} [a_i^l \otimes g_{j_1,i}(x)],$$

where $g_{j_1,i}(x) = -\frac{\widehat{c}_{j_1}}{2}|x - x_i|^2$, and so the information state $P(t_l^+, \cdot)$ is represented simply by the vector A^l.

(4) Propagate the solution of (2.14b) forward in time to time t_{l+1}. From the above discussion, we see that this takes the form of the max-plus matrix multiplication

$$A^{l+1} = B \otimes A^l.$$

(5) Compute $P(t_{l+1}{}^-, \cdot)$ from

$$P(t_{l+1}{}^-, x) = \bigoplus_{i=1}^{n} \left[a_i^{l+1} \otimes g_{j_2,i}(x)\right].$$

This step takes the representation of the information state in the form A^{l+1} and converts it back to a function of x (actually evaluated only on some grid over B_R).

(6) Given measurement y_{l+1}, perform the measurement update

$$P(t_{l+1}{}^+, x) = P(t_{l+1}{}^-, x) - \frac{1}{2}|\rho^{-1}(x)[y_{l+1} - h(x)]|^2$$

(for all points on the grid over B_R).

(7) Increment l, and return to step 1.

It is interesting to note that in the absence of measurement updates, the solution could be propagated forward in time simply by a series of max-plus matrix multiplications. This would be the case if there were other applications where one was only interested in solution of an HJB equation of the form (2.14b) with semiconvex initial conditions or nondegenerate σ. However, in the robust filter application, the largest portion of the computational effort is likely to be expended in step 3, where one needs to compute the coefficients in the expansion. In many other types of expansions, the coefficients are computed by integration. Here, we see that the integration step is replaced by a maximization over the relevant portion of the state space, B_R.

7. Continuous-time measurements. Let us return to the case of continuous-time measurements satisfying (2.2), and let $P(T,x)$ be the information state given by (2.6). Let $P^\delta(T,x)$ be the discrete-time measurement information state with time-step δ. (To be specific, we take $P^\delta(t,\cdot)$ to be $P(t^+,\cdot)$ at the measurement times, although $P(t^-,\cdot)$ would work as well.) In this section, we will show that P is the limit of P^δ as $\delta \downarrow 0$ (Theorem 7.3). Section 6 described a numerical algorithm for finding $P^\delta(T,x)$ approximately, and hence for approximate solution of the HJB equation (2.9) for $P(T,x)$.

We use the simplest discretization of the problem, letting $t_l = l\delta$ for $l = 0, 1, 2 \ldots$. At each $l \geq 1$, the discrete approximation model receives a measurement y_l given by

$$y_l = \frac{1}{\delta} \int_{t_{l-1}}^{t_l} y(t)\, dt. \tag{7.1}$$

Given T, let N be the largest integer such that $t_N \leq T$, and let

$$J^\delta(T,x,w) = \phi(x_0) - \frac{1}{2}\int_0^T |w(t)|^2\, dt - \frac{\delta}{2}\sum_{l=1}^{N} |\rho^{-1}(x(t_l))[y_l - h(x(t_l))]|^2, \tag{7.2}$$

where $x_0 = x(0)$ given $x(T) = x$ and dynamics (2.1), and

$$P^\delta(T,x) = \sup_{w \in L_2} J^\delta(T,x,w). \tag{7.3}$$

Note that if $T = N\delta$, one has $P^\delta(T,x)$ being what was denoted as $P(T^+,x)$ in (2.13b) rather than $P(T^-,x)$.

It will first be shown that the semiconvexity constants for the approximations P^δ (which we recall affect the choice of basis functions in the algorithm of section 6) do not blow up as $\delta \downarrow 0$.

THEOREM 7.1. *Assume that ϕ is semiconvex. Then for any T^0, R, there exists a constant $\widehat{\Gamma}$ (depending on T^0, R) such that for any $T \in [0, T^0]$, $P^\delta(T,x) + \widehat{\Gamma}|x|^2$ is convex on B_R.*

Proof. Let

$$\begin{aligned} J^{\delta,0}(T,x,w) &= \phi(x_0) - \frac{1}{2}\int_0^T |w(t)|^2\, dt, \\ J^{\delta,1}(T,x,w) &= -\frac{\delta}{2}\sum_{l=1}^{N} |\rho^{-1}(x(t_l))[y_l - h(x(t_l))]|^2, \end{aligned}$$

so that $J^\delta = J^{\delta,0} + J^{\delta,1}$. In the proof of Theorem 4.1, one finds that given T^0, R, there exists Γ such that

$$v^T J^{\delta,0}_{xx}(x,T,w)v \geq -2\Gamma \tag{7.4}$$

for all $|x| \leq R$, $T \in [0,T^0]$, $|v| = 1$, and ϵ_0-optimal w with $\epsilon_0 \leq 1$. In particular, $\Gamma = \Gamma_R(T^0)$ is independent of δ. All that remains is to prove a similar result for $J^{\delta,1}$. It will now be shown that there exists $\overline{\Gamma}$ (depending on T^0, R) such that

$$v^T J^{\delta,1}_{xx}(x,T,w)v \geq -2\overline{\Gamma}$$

for all $|x| \leq R$, $T \in [0,T^0]$, $|v| = 1$, and ϵ_0-optimal w with $\epsilon_0 \leq 1$.

As in the proof of Theorem 4.1, let $\zeta^1(t), \zeta^2(t)$ denote the first and second derivatives of $x(t)$ in the direction v (considered as a function of $x = x(T)$). Then

$$\begin{aligned} v^T J^{\delta,1}_{xx}(x,T,w)v = -\frac{\delta}{2}\sum_{l=1}^{N}\Big\{ & \left(|\rho^{-1}(x)[y_l - h(x)]|^2\right)_x \Big|_{x=x(t_l)} \zeta^2(t_l) \\ & + \left[\left(|\rho^{-1}(x)[y_l - h(x)]|^2\right)_{xx} \Big|_{x=x(t_l)} \zeta^1(t_l)\right] \cdot \zeta^1(t_l)\Big\}. \end{aligned} \tag{7.5}$$

From Lemma 2.1, we know that there exists $R_1 = R_1(T^0, R)$ such that $|x(t)| \leq R_1 \, \forall t \in [0,T]$, which leads, via (A1), to bounds on all x-dependent terms in (7.5). That is, there exists $M_1 = M_1(T^0, R)$ such that

$$v^T J^{\delta,1}_{xx}(x,T,w)v \geq -\frac{\delta}{2}\sum_{l=1}^{N} C_\rho^2 \left\{\left(M_1 + |y_l|^2\right)\left(|\zeta^2(t_l)| + |\zeta^1(t_l)|^2\right)\right\}.$$

But as shown in the proof of Theorem 4.1, $|\zeta^2(t)|, |\zeta^1(t)|$ are bounded with bounds only dependent on T^0, R. Therefore, there exists $M_2 = M_2(T^0, R)$ such that

$$\begin{aligned} v^T J^{\delta,1}_{xx}(x,T,w)v &\geq -\frac{\delta}{2}\sum_{l=1}^{N}\left\{M_2(1 + |y_l|^2)\right\} \\ &= -\frac{\delta}{2}\sum_{l=1}^{N}\left\{M_2\left(1 + \left|\frac{1}{\delta}\int_{t_{l-1}}^{t_l} y(t)\,dt\right|^2\right)\right\} \\ &\geq -\frac{\delta}{2}\sum_{l=1}^{N}\left\{M_2\left(1 + \frac{1}{\delta}\int_{t_{l-1}}^{t_l} |y(t)|^2\,dt\right)\right\} \\ &\geq \frac{-M_2}{2}\left(T + \|y\|^2_{L_2[0,T]}\right), \end{aligned}$$

which we define to be

$$\doteq -2\overline{\Gamma}. \tag{7.6}$$

Combining (7.4) and (7.6), one has

$$v^T J^\delta_{xx}(x,T,w)v \geq -2(\Gamma + \overline{\Gamma})$$

for all $|x| \leq R$, ϵ_0-optimal w with $\epsilon_0 \leq 1$, where $\Gamma, \overline{\Gamma}$ are independent of δ. This implies the desired result. □

Remark 7.2. The P^δ satisfy a uniform (in δ) local Lipschitz condition in x. That is, given $R, T < \infty$, there exists $K = K(T,R)$ such that $|P^\delta(T,x) - P^\delta(T,\widetilde{x})| \le K|x - \widetilde{x}|$ for all $x, \widetilde{x} \in B_R$. This follows directly from the uniform semiconvexity; see [8, p. 111]

Finally, we obtain the convergence result.

THEOREM 7.3. *$P^\delta(T,x) \to P(T,x)$ as $\delta \downarrow 0$ for all $(T,x) \in [0,\infty) \times \Re^n$.*

Proof. Fix $T, \overline{R} < \infty$ and $x \in B_{\overline{R}}$. Let $\epsilon_0 \in [0,1]$. Let J be given by (2.5) and J^δ by (7.2). By Lemma 2.1 (and a similar result for the discrete case), we know ϵ_0-optimal w for either problem satisfies $\|w\|_{L_2[0,T]} \le M_{\overline{R},T}$ for appropriate $M_{\overline{R},T}$.

Let $\|w\|_{L_2[0,T]} \le M_{\overline{R},T}$. It is sufficient to show that

$$|J(T,x,w) - J^\delta(T,x,w)| \to 0$$

as $\delta \downarrow 0$ (with an estimate that is independent of w). We have

$$2|J(T,x,w) - J^\delta(T,x,w)| = \left| \int_0^T |\rho^{-1}(x(t))[y(t) - h(x(t))]|^2 \, dt - \delta \sum_{l=1}^{N} |\rho^{-1}(x(t_l))[y_l - h(x(t_l))]|^2 \right|. \tag{7.7}$$

We now show that given $\epsilon > 0$, the right-hand side of (7.7) can be made $< \epsilon$ for $\delta > 0$ sufficiently small. The proof will involve first an approximation of y by an L_∞ function, and then a mollification.

Let $R > 0$ and

$$y^R(t) \doteq \begin{cases} y(t) & \text{if } |y(t)| \le R, \\ 0 & \text{otherwise.} \end{cases}$$

Let $\Xi_R = \{t \in [0,T] : |y(t)| > R\}$. Then

$$\int_0^T \Big[|\rho^{-1}(x(t))[y(t) - h(x(t))]|^2 - |\rho^{-1}(x(t))[y^R(t) - h(x(t))]|^2 \Big] \, dt = \int_{\Xi_R} |\rho^{-1}(x(t))[y(t) - h(x(t))]|^2 dt,$$

which by (2.3), (A1), and Lemma 2.1

$$\le 2C_\rho^2 \int_{\Xi_R} (M_1 + |y(t)|^2) \, dt$$

for the proper choice of M_1, and then for R sufficiently large,

$$< \frac{\epsilon}{4}. \tag{7.8}$$

Also,

$$\delta\sum_{l=1}^{N}\left|\left|\rho^{-1}(x(t_l))\left[\frac{1}{\delta}\int_{t_{l-1}}^{t_l}y(t)\,dt-h(x(t_l))\right]\right|^2\right.$$
$$\left.-\left|\rho^{-1}(x(t_l))\left[\frac{1}{\delta}\int_{t_{l-1}}^{t_l}y^R(t)\,dt-h(x(t_l))\right]\right|^2\right|$$
$$\le\delta C_\rho^2\delta\sum_{l=1}^{N}\left|\frac{1}{\delta}\int_{t_{l-1}}^{t_l}(y(t)+y^R(t))\,dt-2h(x(t_l))\right|\left|\frac{1}{\delta}\int_{t_{l-1}}^{t_l}(y(t)-y^R(t))\,dt\right|,$$

and using Lemma 2.1 and Cauchy–Schwarz, one finds that for proper choice of M_2,

$$\le\delta C_\rho^2\delta\sum_{l=1}^{N}\left\{\frac{1}{\sqrt{\delta}}\left[\int_{t_{l-1}}^{t_l}|y(t)+y^R(t)|^2\,dt\right]^{\frac12}\frac{1}{\sqrt{\delta}}\left[\int_{t_{l-1}}^{t_l}|y(t)-y^R(t)|^2\,dt\right]^{\frac12}\right.$$
$$\left.+\frac{M_2}{\delta}\int_{t_{l-1}}^{t_l}|y(t)-y^R(t)|\,dt\right\},$$

which, using $2ab\le ca^2+b^2/c$ for any $c>0$,

$$\le C_\rho^2\left\{\frac{c}{2}\int_0^T|y+y^R|^2\,dt+\frac{1}{2c}\int_0^T|y-y^R|^2\,dt+M_2\int_0^T|y-y^R|\,dt\right\},$$

which for c sufficiently small and then R sufficiently large

$$<\frac{\epsilon}{4}. \tag{7.9}$$

From (7.7),

$$2|J(T,x,w)-J^\delta(T,x,w)|$$
$$\le\left|\int_0^T|\rho^{-1}(x(t))[y(t)-h(x(t))]|^2-|\rho^{-1}(x(t))[y^R(t)-h(x(t))]|^2,dt\right|$$
$$+\left|\int_0^T|\rho^{-1}(x(t))[y^R(t)-h(x(t))]|^2\,dt\right.$$
$$\left.-\sum_{l=1}^{N}\int_{t_{l-1}}^{t_l}\left|\rho^{-1}(x(t))\left[\frac{1}{\delta}\int_{t_{l-1}}^{t_l}y^R(r)\,dr-h(x(t))\right]\right|^2dt\right|$$
$$+\left|\sum_{l=1}^{N}\int_{t_{l-1}}^{t_l}\left\{\left|\rho^{-1}(x(t))\left[\frac{1}{\delta}\int_{t_{l-1}}^{t_l}y^R(r)\,dr-h(x(t))\right]\right|^2\right.\right.$$
$$\left.\left.-\left|\rho^{-1}(x(t_l))\left[\frac{1}{\delta}\int_{t_{l-1}}^{t_l}y^R(r)\,dr-h(x(t_l))\right]\right|^2\right\}dt\right|$$
$$+\left|\sum_{l=1}^{N}\delta\left\{\left|\rho^{-1}(x(t_l))\left[\frac{1}{\delta}\int_{t_{l-1}}^{t_l}y^R(r)\,dr-h(x(t_l))\right]\right|^2\right.\right.$$
$$\left.\left.-\left|\rho^{-1}(x(t_l))\left[\frac{1}{\delta}\int_{t_{l-1}}^{t_l}y(r)\,dr-h(x(t_l))\right]\right|^2\right\}dt\right|,$$

which by (7.8), (7.9), and some rearrangement is

$$
\begin{aligned}
&< \left| \sum_{l=1}^{N} \int_{t_{l-1}}^{t_l} \left\{ |\rho^{-1}(x(t))[y^R(t) - h(x(t))]|^2 \right.\right. \\
&\qquad \left.\left. - \left| \rho^{-1}(x(t)) \left[\frac{1}{\delta} \int_{t_{l-1}}^{t_l} y^R(r)\, dr - h(x(t)) \right] \right|^2 \right\} dt \Bigg| \\
&\quad + \left| \sum_{l=1}^{N} \int_{t_{l-1}}^{t_l} \left\{ \left| \rho^{-1}(x(t)) \left[\frac{1}{\delta} \int_{t_{l-1}}^{t_l} y^R(r)\, dr - h(x(t)) \right] \right|^2 \right.\right. \\
&\qquad \left.\left. - \left| \rho^{-1}(x(t_l)) \left[\frac{1}{\delta} \int_{t_{l-1}}^{t_l} y^R(r)\, dr - h(x(t_l)) \right] \right|^2 \right\} dt \Bigg| \\
&\quad + \int_{t_N}^{T} |\rho^{-1}(x(t))[y^R(t) - h(x(t))]|^2\, dt + \frac{\epsilon}{2},
\end{aligned}
$$

which by the continuity of $x(\cdot)$ over $[0,T]$ for $\|w\| < M_{\overline{R},T}$

$$
\begin{aligned}
&< \left| \sum_{l=1}^{N} \int_{t_{l-1}}^{t_l} \left\{ |\rho^{-1}(x(t))[y^R(t) - h(x(t))]|^2 \right.\right. \\
&\qquad \left.\left. - \left| \rho^{-1}(x(t)) \left[\frac{1}{\delta} \int_{t_{l-1}}^{t_l} y^R(r)\, dr - h(x(t)) \right] \right|^2 \right\} dt \right| + M_3\delta + \frac{3\epsilon}{4} \\
&= \left| \sum_{l=1}^{N} \int_{t_{l-1}}^{t_l} \left\{ \left| \rho^{-1}(x(t)) \left[\frac{1}{\delta} \int_{t_{l-1}}^{t_l} y^R(t)\, dr - h(x(t)) \right] \right|^2 \right.\right. \\
&\qquad \left.\left. - \left| \rho^{-1}(x(t)) \left[\frac{1}{\delta} \int_{t_{l-1}}^{t_l} y^R(r)\, dr - h(x(t)) \right] \right|^2 \right\} dt \right| + M_3\delta + \frac{3\epsilon}{4},
\end{aligned}
$$

which for proper choice of $\xi(t) \in B_R$ for all t,

$$
< 2C_\rho^2 \sum_{l=1}^{N} \int_{t_{l-1}}^{t_l} |\xi(t) - h(x(t))| \left| \frac{1}{\delta} \int_{t_{l-1}}^{t_l} (y^R(t) - y^R(r))\, dr \right| dt + M_3\delta + \frac{3\epsilon}{4},
$$

which for proper choice of $M_4 = M_4(R,T)$

$$
< M_4 \sum_{l=1}^{N} \int_{t_{l-1}}^{t_l} \left| \frac{1}{\delta} \int_{t_{l-1}}^{t_l} (y^R(t) - y^R(r))\, dr \right| dt + M_3\delta + \frac{3\epsilon}{4}. \tag{7.10}
$$

Now let $y^{R,\rho}$ be a C^∞ mollification of y^R such that $\|y^{R,\rho} - y^R\|_{L_1[0,T]} \to 0$ as $\rho \downarrow 0$. Rearranging (7.10) yields

$$
\begin{aligned}
&2|J(T,x,w) - J^{\delta}(T,x,w)| \\
&\quad < M_4 \sum_{l=1}^{N} \int_{t_{l-1}}^{t_l} \left| \frac{1}{\delta} \int_{t_{l-1}}^{t_l} (y^{R,\rho}(t) - y^{R,\rho}(r))\, dr \right| dt \\
&\qquad + M_4 \sum_{l=1}^{N} \int_{t_{l-1}}^{t_l} \left| \left| \frac{1}{\delta} \int_{t_{l-1}}^{t_l} (y^{R}(t) - y^{R}(r))\, dr \right| - \left| \frac{1}{\delta} \int_{t_{l-1}}^{t_l} (y^{R,\rho}(t) - y^{R,\rho}(r))\, dr \right| \right| dt \\
&\qquad + M_3\delta + \frac{3\epsilon}{4},
\end{aligned}
$$

and letting $\mu^{\rho}(\cdot)$ be the modulus of continuity of $y^{R,\rho}$, and using the inequality $\big||a-b| - |c-d|\big| \le |a-c| + |b-d|$ on the second sum, one finds that this is

$$
\begin{aligned}
&\le M_4 T \mu^{\rho}(\delta) + M_4 \delta \sum_{l=1}^{N} \left[\int_{t_{l-1}}^{t_l} |y^{R}(t) - y^{R,\rho}(t)|\, dt + \int_{t_{l-1}}^{t_l} |y^{R}(r) - y^{R,\rho}(r)|\, dr \right] \\
&\qquad + M_3\delta + \frac{3\epsilon}{4}, \\
&= M_4 T \mu^{\rho}(\delta) + 2M_4 \|y^{R} - y^{R,\rho}\|_{L_1[0,T]} + M_3\delta + \frac{3\epsilon}{4},
\end{aligned}
$$

which for ρ sufficiently small

$$
< M_4 T \mu^{\rho}(\delta) + M_3\delta + \frac{7\epsilon}{8},
$$

which for δ sufficiently small

$$
< \epsilon. \qquad \square
$$

Remark 7.4. In the case where $y(\cdot)$ is continuous, one can obtain an explicit estimate of the convergence rate. Specifically, using only the bound $\|w\|_{L_2[0,t]} \le M_{\overline{R},T}$, for ϵ_0-optimal disturbances for both continuous- and discrete-time problems with $\delta \le 1$, one can obtain an estimate of the form $|P^{\delta}(T,x) - P(T,x)| \le \mathcal{M}[\sqrt{\delta} + \mu(\delta)]$, where $\mu(\cdot)$ is the modulus of continuity for y. We expect that with additional effort, one can obtain a uniform L_∞ bound on the optimal disturbances for the discrete-time problems (in analogy with the continuous-time bound of Lemma 2.1). This would lead to an estimate of the form $|P^{\delta}(T,x) - P(T,x)| \le \mathcal{M}[\delta + \mu(\delta)]$. However, the effort would likely require more journal space than would seem appropriate for this initial exploration.

Acknowledgments. The authors would like to thank P. Dupuis and K. Ito for helpful suggestions.

CONTROLLABILITY AND STABILIZATION OF A CANAL WITH WAVE GENERATORS*

STÉPHANE MOTTELET†

Abstract. This paper deals with a physical system that can be represented by an abstract wave equation: a canal with wave generators.

We first study the various degrees of controllability that this system can enjoy, with two kinds of input operators and associated control spaces, corresponding to "flexible" and "rigid" generators. A counterexample to the exact controllability and a positive result for the approximate controllability are given for the flexible generator case. In the rigid case, we show that approximate controllability in finite time does not hold.

We also study the stability of the system when the elevation of the surface is measured at $x = 0$, and a static feedback is used to control a rigid generator. We show that strong stability holds (but with a nonuniform decay), although the perturbation caused by the feedback on the system operator is not dissipative in the natural topology.

Key words. boundary control, hyperbolic system, nonharmonic Fourier series, hydrodynamics

1. Statement of the problem.

The physical system under consideration is a canal where the behavior of floating bodies is studied from an experimental point of view. In such a canal, waves are created by means of plane generators which can be controlled.

This paper deals with the mathematical analysis of control problems involving this system and, more precisely, of various degrees of controllability and feedback stabilization.

Practical control problems involving this system have been studied, from a numerical and experimental point of view. For these aspects we refer to [14], [15], [7].

The paper is organized as follows : in section 2 we briefly introduce the model of the canal (for a more complete discussion of the model see [14]). In section 3 we reformulate the original model in the framework of Riesz-spectral systems. This will allow us to use the standard tools concerning these systems, especially for controllability tests.

In section 4 we focus on controllability problems, with two types of input operators, concerning two types of generators. For the case where the generator is "flexible," the input space is infinite-dimensional and we give a positive result for the approximate controllability and a counterexample to the exact controllability. For the case where the generator is "rigid," the input space is $\mathbf{R}$ and we will see that the spectral properties of the system operator are such that approximate controllability in finite time does not hold. This result has been obtained by means of results on the nonharmonic Fourier series.

In section 5 we consider a feedback stabilization problem which has been already set in [14], but the only type of stability we obtained was input-output stability. We

give here a strong stability result, which has been obtained by means of an ad hoc energy functional.

2. Model of the canal. We consider the rectangular canal in Figure 2.1. This canal is supposed to be wide enough to consider that the waves created by generators located at each end are plane waves. This allows us to use a bidimensional model, where the domain Ω is the rectangle $[0, L] \times [0, h]$, represented in Figure 2.1. The boundary $\Gamma = \Gamma_s \cup \Gamma_f \cup \Gamma_1 \cup \Gamma_2$ is represented by

- the free surface $\Gamma_s = \{(x, h) \mid 0 < x < L\}$,
- the bottom of the canal $\Gamma_f = \{(x, 0) \mid 0 < x < L\}$,
- the left end $\Gamma_1 = \{(0, y) \mid 0 < y < h\}$,
- the right end $\Gamma_2 = \{(L, y) \mid 0 < y < h\}$.

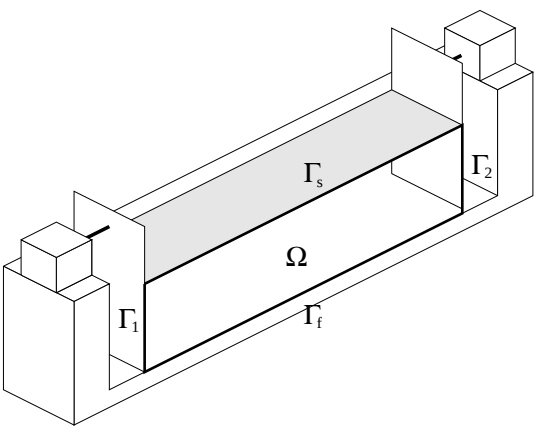

FIG. 2.1. *Definition of domain* Ω.

The fluid is supposed to be perfect, incompressible, and irrotational. Let $\vec{V}(x, y, t)$ be the velocity field at time t. From the hypothesis $\operatorname{curl} \vec{V} = 0$, there exists a potential ψ defined by

$$\vec{V}(x, y, t) = \vec{\nabla}\, \psi(x, y, t).$$

We now study the boundary conditions on Γ. The boundary condition on Γ_s is a dynamic condition. Let us call $\eta(x, t)$ the elevation of a point $M(x, h)$ of Γ_s with respect to its equilibrium position. From the hypothesis we have made the static pressure $P(x, y, t)$ is related to the velocity potential ψ by the Bernoulli condition

$$\frac{P}{\rho} + 1/2|\, \vec{\nabla}\, \psi|^2 + \dot{\psi} + g_0 \eta = \frac{P_a}{\rho}, \text{ on } \Gamma_s,$$

where ρ is the (constant) volumic mass, g_0 is the acceleration of gravity, and P_a is the atmospheric pressure (supposed to be constant). The Bernoulli condition expresses the continuity of pressure across the free surface and takes the following form:

$$1/2|\, \vec{\nabla}\, \psi|^2 + \dot{\psi} + g_0 \eta = 0, \text{ on } \Gamma_s.$$

Once linearized under the hypothesis of small fluid motion, this condition takes the form

$$\dot{\psi} + g_0\eta = 0, \text{ on } \Gamma_s. \tag{2.1}$$

The kinematic condition, which expresses the fact that the vertical component of the velocity of a fluid particle $M(x,h)$ of the free surface is equal to the time derivative of $\eta(x,t)$, takes the form

$$\dot{\eta} = \partial_n\psi, \text{ on } \Gamma_s. \tag{2.2}$$

One can eliminate η between (2.1) and (2.2) and obtain the so-called free surface condition,

$$\ddot{\psi} + g_0\partial_n\psi = 0, \text{ on } \Gamma_s, \tag{2.3}$$

where $\ddot{\psi}$ is the second time derivative of ψ with respect to time, and $\eta(x,t)$ takes the form

$$\eta(x,t) = -\frac{1}{g_0}\dot{\psi}(x,h,t). \tag{2.4}$$

The condition on the bottom Γ_f expresses the fact that the normal velocity of the fluid on Γ_f is zero. If one calls $\vec{n}$ the outer normal to Γ, we have

$$\partial_n\psi \equiv \vec{\nabla}\,\psi.\vec{n} = 0, \text{ on } \Gamma_f. \tag{2.5}$$

Finally, we obtain the following equations:

$$\begin{cases} \Delta\psi &= 0, & \text{in } \Omega\times[0,\tau], \\ \ddot{\psi} + g_0\partial_n\psi &= 0, & \text{on } \Gamma_s\times[0,\tau], \\ \partial_n\psi &= 0, & \text{on } \Gamma_f\times[0,\tau], \\ \partial_n\psi &= v_1, & \text{on } \Gamma_1\times[0,\tau], \\ \partial_n\psi &= v_2, & \text{on } \Gamma_2\times[0,\tau]. \end{cases}$$

As we will see in what follows, we only need to specify initial conditions on Γ_s:

$$\psi(0) = \varphi_0, \dot{\psi}(0) = \varphi_1, \text{ on } \Gamma_s. \tag{2.6}$$

The boundary conditions on Γ_1 and Γ_2 take into account the action of generators which can produce desired velocities $v_1(y,t)$ and $v_2(y,t)$. This kind of control will allow us to consider in section 4.1 an exact controllability problem. The devices to produce these velocities have to be some kind of "flexible" generators.

When the generators have a fixed "shape" described by the function $f(y)$, we consider the following form for the controls:

$$v_1(y,t) = f(y)u_1(t),$$
$$v_2(y,t) = f(y)u_2(t).$$

In this case, we will speak of "rigid" generators. We have scalar controls $u_1(t)$ and $u_2(t)$. When $f(y) = y$ these boundary conditions represent plane generators being able to rotate around an axis located at the bottom of the canal, with small angular velocities $u_1(t)$ and $u_2(t)$.

To simplify the notations in what follows and without loss of generality, we will take $g_0 = 1$, $L = \pi$, $h = 1$ and we will consider only one generator, at the left end of the canal; thus we will note

$$v := v_1,\ u := u_1,$$

and we will take $v_2 = 0$.

3. Mathematical analysis.

3.1. Regularity results. We now consider the following equations, corresponding to a canal of longitudinal section $\Omega =]0, \pi[\times]0, 1[$, with one generator on the left side:

$$\Delta\psi = 0, \text{ in } \Omega \times [0, \tau], \tag{3.1}$$

$$\ddot{\psi} + \partial_n \psi = 0, \text{ on } \Gamma_s \times [0, \tau], \tag{3.2}$$

$$\partial_n \psi = 0, \text{ on } (\Gamma_f \cup \Gamma_2) \times [0, \tau], \tag{3.3}$$

$$\partial_n \psi = v, \text{ on } \Gamma_1 \times [0, \tau]. \tag{3.4}$$

Let D denote the "Dirichlet map," i.e., the continuous map $\mathrm{D} : H^{1/2}(\Gamma_s) \to H^1(\Omega)$ defined by $\mathrm{D}\varphi = \Phi$ where

$$\left\{ \begin{array}{rcll} \Delta\Phi & = & 0, & \text{in } \Omega, \\ \Phi & = & \varphi, & \text{on } \Gamma_s, \\ \partial_n\Phi & = & 0, & \text{on } \Gamma_f \cup \Gamma_1 \cup \Gamma_2. \end{array} \right. \tag{3.5}$$

Let N denote the "Neumann map," i.e., the continuous map $\mathrm{N} : H^{-1/2}(\Gamma_s) \to H^1(\Omega)$ defined by $\mathrm{N}v = \Psi$ where

$$\left\{ \begin{array}{rcll} \Delta\Psi & = & 0, & \text{in } \Omega, \\ \Psi & = & 0, & \text{on } \Gamma_s, \\ \partial_n\Psi & = & 0, & \text{on } \Gamma_f \cup \Gamma_2, \\ \partial_n\Psi & = & v, & \text{on } \Gamma_1. \end{array} \right. \tag{3.6}$$

If we define $\varphi = \psi|_{\Gamma_s}$, then the original problem can be transformed in a one-dimensional problem on Γ_s,

$$\left\{ \begin{array}{rcll} \ddot{\varphi} + \mathcal{A}\varphi & = & \mathcal{B}v, & \text{on } \Gamma_s \times [0, \tau], \\ \varphi(x, 0) & = & \varphi_0(x), & \\ \dot{\varphi}(x, 0) & = & \varphi_1(x), & \end{array} \right. \tag{3.7}$$

where the operators $\mathcal{A}$ and $\mathcal{B}$ are defined by

$$\mathcal{A}\varphi = \partial_n \mathrm{D}\varphi|_{\Gamma_s}, \quad \mathcal{B}v = -\partial_n \mathrm{N}v|_{\Gamma_s}. \tag{3.8}$$

It is easy to see that this abstract formulation is related to the original equations by the fact that the velocity potential ψ and the two functions φ and v verify

$$\psi = \mathrm{D}\varphi + \mathrm{N}v. \tag{3.9}$$

The application of elementary theorems for elliptic problems allows us to claim that $\mathcal{A}$ is a linear unbounded operator in $H^{-1/2}(\Gamma_s)$ with domain $H^{1/2}(\Gamma_s)$. If we apply the results of Grisvard (see [5]) for $\varphi \in H^{3/2}(\Gamma_s)$ and the additional compatibility conditions

$$x^{-1/2}\varphi'(x) \in L^2(\Gamma_s), \ (\pi - x)^{-1/2}\varphi'(x) \in L^2(\Gamma_s), \tag{3.10}$$

we have $\mathrm{D}\varphi \in H^2(\Omega)$ (we will note this space $H_c^{3/2}(\Gamma_s)$). Thus we can consider $\mathcal{A}$ as a linear unbounded operator in $H^{1/2}(\Gamma_s)$ with domain $H_c^{3/2}(\Gamma_s)$.

As far as the operator $\mathcal{B}$ is concerned, the application of classical trace theorems (see [11]) and some basic inequalities allow us to claim that $\mathcal{B}$ is a bounded operator

from $H^{-1/2}(\Gamma_1)$ into $H^{-1/2}(\Gamma_s)$. We have the same kind of compatibility requirement for the boundary conditions of (3.6) : for $v \in H^{1/2}(\Gamma_1)$ with the additional condition (we will use the notation $H_c^{1/2}(\Gamma_1)$ to denote this space)

$$(1-y)^{-1/2}v(y) \in L^2(\Gamma_1), \tag{3.11}$$

we have $\mathrm{N}v \in H^2(\Omega)$, and so $\mathcal{B}$ is also bounded from $H_c^{1/2}(\Gamma_1)$ into $H^{1/2}(\Gamma_s)$.

Results of interpolation theory (see [11]) allow us to finally obtain the following theorem.

THEOREM 3.1.

i. *The operator $\mathcal{A}$ is a linear unbounded operator in $L^2(\Gamma_s)$ with domain $H^1(\Gamma_s)$.*

ii. *The operator $\mathcal{B}$ is a linear bounded operator from $L^2(\Gamma_1)$ into $L^2(\Gamma_s)$.*

When the generator is rigid with a shape $f \in L^2(\Gamma_1)$, the control $u(t)$ is a scalar and the state equation (3.7) takes the form

$$\ddot{\varphi} + \mathcal{A}\varphi = \beta(x)u(t),$$

where $\beta = \mathcal{B}f$. In this case the control operator is of rank one and bounded. In the particular case of rotating plane generators, i.e., $f(y) = y$, we can show from its Fourier coefficients that $\beta \in H^{1/2-\varepsilon}(\Gamma_s)\ \forall\ \varepsilon > 0$.

For some reasons that will appear clearly in what follows, we will work with zero mean functions. We define the Hilbert space

$$H = \left\{ \varphi \in L^2(\Gamma_s) \;\middle|\; \int_{\Gamma_s} \varphi(x)\,dx = 0 \right\} \equiv \tilde{L}^2(\Gamma_s)$$

and the domain of operator $\mathcal{A}$

$$D(\mathcal{A}) = \left\{ \varphi \in H^1(\Gamma_s) \;\middle|\; \int_{\Gamma_s} \varphi(x)\,dx = 0 \right\} \equiv \tilde{H}^1(\Gamma_s).$$

The fact that $D(\mathcal{A})$ is actually $\tilde{H}^1(\Gamma_s)$ results from the fact that the results of interpolation theory we used before remain valid for quotiented spaces (see [11]).

We have the following results on $\mathcal{A}$.

PROPOSITION 3.2. *The operator $\mathcal{A} : D(\mathcal{A}) \subset H \to H$ is strictly positive, self-adjoint, and $R(\lambda I + \mathcal{A}) = H$ for $\lambda > 0$.*

Proof. We have

$$\langle \mathcal{A}\varphi\,,\,\varphi\rangle = \|\nabla \mathrm{D}\varphi\|^2_{L^2(\Omega)} \geq 0,$$

where $\varphi \in D(\mathcal{A})$. Moreover $\mathcal{A}\xi = 0 \Rightarrow \xi = 0$ because of the particular choice of $D(\mathcal{A})$. This shows that $\mathcal{A}$ is strictly positive (the symmetry of $\mathcal{A}$ easily results from its definition).

For $\lambda > 0$, the operator $\lambda I + \mathcal{A}$ is trivially a bijection from $\tilde{H}^{1/2}(\Gamma_s)$ to $\tilde{H}^{-1/2}(\Gamma_s)$, and with the results of [5], we show that $\lambda I + \mathcal{A}$ is also a bijection from $\tilde{H}_c^{3/2}(\Gamma_s)$ to $\tilde{H}^{1/2}(\Gamma_s)$. We obtain the final result by applying interpolation theory (see [11]). □

This result ensures that the operator $\mathcal{A}^{1/2}$ is also well defined and we have

$$D(\mathcal{A}^{1/2}) = [D(\mathcal{A}), H]_{1/2} = \tilde{H}^{1/2}(\Gamma_s).$$

Unfortunately we don't have an explicit representation of $\mathcal{A}^{1/2}$, but we have for φ and w in $\tilde{H}^{1/2}(\Gamma_s)$

$$\langle \mathcal{A}\varphi\,,\,w\rangle_{\tilde{H}^{-1/2},\tilde{H}^{1/2}} = \left\langle \mathcal{A}^{1/2}\varphi\,,\,\mathcal{A}^{1/2}w \right\rangle = \int_\Omega \nabla \mathrm{D}\varphi.\nabla \mathrm{D}w.$$

3.2. Spectral analysis. The eigenvalues and associated eigenfunctions of $\mathcal{A}$, i.e., the nonzero functions $w_k(x) \in D(\mathcal{A})$ and the numbers λ_k such that $\mathcal{A}\, w_k = \lambda_k\, w_k$ for $k > 0$ integer, are obtained by solving the *Steklov problem*

$$\left\{\begin{array}{rcll} \Delta W_k &=& 0, & \text{in } \Omega, \\ \partial_n W_k &=& \lambda_k W_k, & \text{on } \Gamma_s, \\ \partial_n W_k &=& 0, & \text{on } \Gamma_f \cup \Gamma_1 \cup \Gamma_2, \end{array}\right. \tag{3.12}$$

where $w_k = W_k|_{\Gamma_s}$. By separation of variables one easily obtains the following form for W_k:

$$W_k = \alpha \cosh ky \cos kx,$$

where $\alpha \neq 0$ is an arbitrary constant. Thus we can choose

$$w_k(x) = \cos kx,\ x \in [0, \pi],\ k = 1, 2, \ldots,$$

and the eigenvalues λ_k are given by

$$\lambda_k = k \tanh k,\ k = 1, 2, \ldots.$$

In what follows, we will also consider the pair $(w_0 = 1, \lambda_0 = 0)$ which is not an eigenpair of $\mathcal{A}$ due to the choice of $D(\mathcal{A})$.

3.3. Formulation as a first-order system. We adopt the following abstract formulation of the original system:

$$\left\{\begin{array}{rcl} \dot{\xi} &=& A\xi + Bv, \\ \eta &=& C\xi, \\ \xi(0) &=& \xi_0 \in X. \end{array}\right. \tag{3.13}$$

The variable ξ is related to the original variables $\varphi = \psi|_{\Gamma_s}$ and $\dot{\varphi}$ in (3.7) by

$$\xi = \begin{pmatrix} \Pi_H \varphi \\ \Pi_H \dot{\varphi} \\ \Pi_{\mathbf{R}} \dot{\varphi} \end{pmatrix}, \tag{3.14}$$

where Π_H denotes the orthogonal projection on H and $\Pi_{\mathbf{R}}$ the orthogonal projection on the space of constant functions of x, i.e.,

$$\Pi_{\mathbf{R}} \varphi = \frac{1}{\pi} \int_0^\pi \varphi\, dx, \quad \Pi_H \varphi = \varphi - \Pi_{\mathbf{R}} \varphi.$$

The state space X is the following:

$$\begin{aligned} X &= D(\mathcal{A}^{1/2}) \times H \times \mathbf{R} \\ &= \tilde{H}^{1/2}(\Gamma_s) \times \tilde{L}^2(\Gamma_s) \times \mathbf{R}. \end{aligned}$$

The operators A, B, and C are defined as follows:

$$A\xi = \begin{pmatrix} \xi_2 \\ -\mathcal{A}\xi_1 \\ 0 \end{pmatrix},\ Bv = \begin{pmatrix} 0 \\ \Pi_H \mathcal{B} v \\ \Pi_{\mathbf{R}} \mathcal{B} v \end{pmatrix}, \tag{3.15}$$

$$C\xi = -(\xi_2 + \xi_3), \tag{3.16}$$

and the domain of A is given by

$$\begin{aligned} D(A) &= D(\mathcal{A}) \times D(\mathcal{A}^{1/2}) \times \mathbf{R} \\ &= \tilde{H}^1(\Gamma_s) \times \tilde{H}^{1/2}(\Gamma_s) \times \mathbf{R}. \end{aligned}$$

We define the inner product in X by

$$\begin{aligned} \langle \xi \, , \, \zeta \rangle_X &= \left\langle \mathcal{A}^{1/2}\xi_1 \, , \, \mathcal{A}^{1/2}\zeta_1 \right\rangle + \langle \xi_2 + \xi_3 \, , \, \zeta_2 + \zeta_3 \rangle \\ &= \int_\Omega \nabla \mathrm{D}\xi_1 . \nabla \mathrm{D}\eta_1 + \int_{\Gamma_s} (\xi_2 + \xi_3)(\zeta_2 + \zeta_3). \end{aligned} \tag{3.17}$$

We adopt the notation $\|.\|_X$ for the associated norm, which is defined by

$$\begin{aligned} \|\xi\|_X^2 &= |\mathcal{A}^{1/2}\xi_1|^2 + |\xi_2 + \xi_3|^2 \\ &= \int_\Omega |\nabla \mathrm{D}\xi_1|^2 + \int_{\Gamma_s} |\xi_2 + \xi_3|^2. \end{aligned}$$

This norm is related in some sense to the natural energy, in terms of the original potential ψ,

$$E(\psi, \dot{\psi}) = \frac{1}{2}\int_\Omega |\nabla \psi|^2 + \frac{1}{2}\int_{\Gamma_s} \dot{\psi}^2,$$

which is equal to the sum of kinetic and potential energies of the fluid.

Indeed, if we consider the definition of ξ given by (3.14) and the relation $\psi = \mathrm{D}\varphi + \mathrm{N}v$, then we can show that

$$\int_\Omega |\nabla \psi|^2 = \int_\Omega |\nabla \mathrm{D}\xi_1|^2 + \int_\Omega |\nabla \mathrm{N}v|^2.$$

Thus we will have $\frac{1}{2}\|\xi\|_X^2 = E(\psi, \dot{\psi})$, only if $v = 0$.

The main advantage of our abstract formulation is that the chosen energy is coercive on X, i.e., the only element such that $\|\xi\|_X^2 = 0$ is $\xi = 0$, whereas the natural energy is not coercive on the original energy space, since all solutions of the type

$$\psi = c, \ t \in [0, \infty)$$

verify $E(\psi, \dot{\psi}) = 0$.

3.4. Spectral analysis and semigroup generation. One can show that the eigenpairs $(\mu_k, \phi_k)_{k \in \mathbf{Z}}$ of operator A are given by $\mu_k = i\omega_k$, where $\omega_k = \sqrt{\lambda_k}$ for $k > 0$, $\omega_k = -\sqrt{\lambda_{-k}}$ for $k < 0$, and

$$\phi_k = \frac{1}{\sqrt{\pi}} \begin{pmatrix} \frac{1}{\mu_k} w_k \\ w_k \\ 0 \end{pmatrix}$$

for $k \in \mathbf{Z}^*$ and $\mu_0 = 0$,

$$\phi_0 = \begin{pmatrix} 0 \\ 0 \\ \frac{1}{\sqrt{\pi}} \end{pmatrix}.$$

The family ϕ_k can be shown to be an orthonormal basis of X, with $\|\phi_k\|_X = 1$. This means that A is a Riesz-spectral operator (for a complete theory of Riesz-spectral systems see [3]).

Remark 3.3. This property of spectrality would have been lost if we had considered the system $\dot{\xi} = A_0\xi$ with $\xi = (\dot{\varphi}, \varphi) \in H^{1/2}(\Gamma_s) \times L^2(\Gamma_s)$, where

$$A_0 = \begin{pmatrix} 0 & I \\ -\mathcal{A} & 0 \end{pmatrix},$$

with domain $D(A_0) = H^1(\Gamma_s) \times H^{1/2}(\Gamma_s)$, since in this case the eigenfunctions of A_0 do not form a basis of $H^{1/2}(\Gamma_s) \times L^2(\Gamma_s)$. Another possibility could have been to consider $\tilde{A}$ with the domain $\tilde{H}^1(\Gamma_s) \times \tilde{H}^{1/2}(\Gamma_s)$, but in this case, the mean value of $\dot{\varphi}$ is constrained to be zero, in spite of its contribution to the surface elevation η. In the system theoretic terminology, this corresponds to remove an observable part of the state ξ, which results in an alteration of the input-output map (from the control v to the surface elevation η). Thus, this other choice is not admissible either.

We have the following proposition.

PROPOSITION 3.4. *The operator A is the infinitesimal generator of a strongly continuous semigroup of contractions $T(t)$ on $X = \tilde{H}^{1/2}(\Gamma_s) \times \tilde{L}^2(\Gamma_s) \times \mathbf{R}$, given by the formula*

$$T(t)\xi = \sum_{k\in\mathbf{Z}} e^{i\omega_k t} \langle \xi\,,\, \phi_k\rangle_X \,\phi_k,$$

where $\omega_k^2 = \lambda_k$.

Proof. Since A is skew-adjoint for the inner product $\langle .\,,\, .\rangle_X$, i.e., $A^* = -A$, we have for $\xi \in D(A)$

$$\mathrm{Re}\ \langle A\xi\,,\, \xi\rangle_X = 0,$$

and the semigroup generation easily follows from the fact that A is Riesz-spectral (see [3, Theorem 2.3.5]). □

In the next two paragraphs we focus on controllability problems.

4. Controllability problems. We focus on the theoretical study of the following problem: given a control space U and a time $\tau > 0$, is it possible to find a control $v \in L^2(0,\tau;U)$ such that the surface of the canal is in a given state at time τ? We will consider the strong version of this question, where the state is to be reached exactly, and the weak version, where the state is reached approximately. The first version is an exact controllability problem. We will see that exact controllability can eventually be obtained if we consider flexible generators. In the case where the generators are rigid, only approximate controllability can eventually be obtained.

Let us first recall some definitions. Consider the system

$$\left\{ \begin{array}{rcl} \dot{\xi} & = & A\xi + Bv, \\ \xi(0) & = & \xi_0, \end{array} \right. \tag{4.1}$$

where A is an infinitesimal generator of a strongly continuous semigroup $T(t)$ on a Hilbert space X, and B is a bounded operator from U to X. At a given time t, the control $v(t)$ belongs to an infinite or finite dimensional space U.

DEFINITION 4.1. *The controllability map of system* (4.1) *on* $[0,\tau]$ *(for a finite* $\tau > 0$*) is the bounded map* $\mathcal{H}_\tau : L_2(0,\tau;U) \to X$ *defined by*

$$\mathcal{H}_\tau v = \int_0^\tau T(\tau - s)Bv(s)\,ds.$$

The natural definition of exact controllability follows.

DEFINITION 4.2. *The system* (4.1) *is exactly controllable on* $[0,\tau]$ *if every element of* X *can be reached from the origin at time* τ*, equivalently*

$$ran\ \mathcal{H}_\tau = X.$$

There are various methods to obtain this result. The classical approach works by showing an inverse inequality [3], [10].

THEOREM 4.3. *The system* (4.1) *is exactly controllable on* $[0,\tau]$ *if there exists* $\gamma > 0$ *such that*

$$\int_0^\tau \|B^*T^*(s)\xi\|_U^2\, ds \geq \gamma\|\xi\|_X^2 \tag{4.2}$$

for every $\xi \in X$.

When U is a finite dimensional space and B is bounded, exact controllability cannot hold, because in this case the map $\mathcal{H}_\tau$ is compact (see [3]).

The concept of exact controllability is often too strong, and sometimes the concept of approximate controllability is more adequate. It is defined as follows.

DEFINITION 4.4. *The system* (4.1) *is approximately controllable on* $[0,\tau]$ *(for a finite* $\tau > 0$*) if for* $\varepsilon > 0$*, it is possible to steer from the origin at a distance* ε *from all elements of* X *in a finite time* τ*, say*

$$\overline{ran\ \mathcal{H}_\tau} = X. \tag{4.3}$$

To show (4.3) one usually tries to show that H_τ^* is one-to-one [3, Theorem 4.1.7]:

$$B^*T(t)^*\xi = 0 \text{ on } [0,\tau] \Rightarrow \xi = 0. \tag{4.4}$$

In our application, we are first going to focus on the case where the generators are flexible.

4.1. Controllability with a flexible generator. In [14] and [6], we tried to attack the exact controllability problem by separating it in two subproblems. The first problem treated the same system with a distributed control on Γ_s, which was shown to be exactly controllable for any $\tau > 0$. The second problem is an elliptic problem, which was not exactly controllable, but only approximately (see Lemma 4.6).

This just allowed us to prove the approximate controllability of the original system in a rather complicated way. In this section we show that in fact exact controllability does not hold. We also give a simpler proof for the approximate controllability result.

In the following we will need to use the operator $\mathcal{B}^*$, the adjoint of $\mathcal{B}$. Let us recall that for $v \in L^2(\Gamma_1)$, $\mathcal{B}v$ is defined by $\mathcal{B}v = -\partial_n \mathrm{N}v|_{\Gamma_s}$, where N is the Neumann map defined by (3.6). In order to define $\mathcal{B}^*z$ for some $z \in L^2(\Gamma_s)$, let us take the auxiliary function Θ solution of

$$\left\{\begin{array}{rcll} \Delta\Theta & = & 0, & \text{in } \Omega, \\ \Theta & = & z, & \text{on } \Gamma_s, \\ \partial_n\Theta & = & 0, & \text{on } \Gamma_f \cup \Gamma_1 \cup \Gamma_2. \end{array}\right. \tag{4.5}$$

We write that $\langle \Delta \mathrm{N}v\,,\, \Theta\rangle_{L^2(\Omega)} = 0$, and applying Green's formula twice, we obtain that $\mathcal{B}^*z = \Theta|_{\Gamma_1}$, and if we consider the definition of the Dirichlet map given by (3.5), we have in fact

$$\mathcal{B}^*z = \mathrm{D}z|_{\Gamma_1}\,.$$

4.1.1. Counterexample to the exact controllability on $[0,\tau]$. We have the following theorem.

THEOREM 4.5. *Consider the system*

$$\dot{\xi} = A\xi + Bv, \tag{4.6}$$

where the definition of A and B has been given in section 3.3*, and $v \in L^2(0,\tau;L^2(\Gamma_1))$. Exact controllability on $[0,\tau]$ does not hold in X for any $\tau > 0$.*

Proof. The classical approach consists in using Theorem 4.3. We first need to identify B^* : using the definition of B given by (3.15) and the definition of the inner product $\langle .\,,\,. \rangle_X$ given by (3.17), we have for some $\xi \in X$ and some $v \in L^2(\Gamma_1)$

$$\begin{aligned}
\langle Bv\,,\,\xi\rangle_X &= \left\langle \begin{pmatrix} 0 \\ \Pi_H \mathcal{B}v \\ \Pi_{\mathbf{R}}\mathcal{B}v \end{pmatrix}\,,\, \begin{pmatrix} \xi_1 \\ \xi_2 \\ \xi_3 \end{pmatrix} \right\rangle_X \\
&= \langle \Pi_H \mathcal{B}v + \Pi_{\mathbf{R}}\mathcal{B}v\,,\,\xi_2+\xi_3\rangle \\
&= \langle \mathcal{B}v\,,\,\xi_2+\xi_3\rangle \\
&= \langle v\,,\,\mathcal{B}^*(\xi_2+\xi_3)\rangle_{L^2(\Gamma_1)}.
\end{aligned}$$

Thus the operator $B^* : L^2(\Gamma_s) \to U = L^2(\Gamma_1)$ is given by

$$B^*\xi = \mathcal{B}^*(\xi_2+\xi_3)$$

for $\xi \in X$. One considers the sequence

$$\xi^{(n)} = \phi_n,\ n > 0,$$

where ϕ_n is the nth eigenfunction of A. This sequence has the property $\|\xi^{(n)}\|_X^2 = 1$, and one can easily show that

$$\begin{aligned}
B^*T^*(t)\xi^{(n)} &= \sum_{k\in\mathbf{Z}} e^{-i\omega_k t}\left\langle \xi^{(n)}\,,\,\phi_k\right\rangle_X B^*\phi_k \\
&= B^*\phi_n e^{-i\omega_n t} \\
&= \frac{1}{\sqrt{\pi}}\mathcal{B}^* w_n e^{-i\omega_n t},
\end{aligned}$$

where w_n is the nth eigenfunction of $\mathcal{A}$. Using the definition of $\mathcal{B}^*$, one can express $\mathcal{B}^*w_n$ by using the problem (3.12) that has been used to obtain the eigenpairs of $\mathcal{A}$: this gives

$$\mathcal{B}^* w_n = \frac{\cosh ny}{\cosh n}. \tag{4.7}$$

It is easy to see that $\mathcal{B}^*w_n \to 0$ almost everywhere (a.e.) in $L^2(\Gamma_1)$, and a simple calculation applied to (4.7) gives

$$\|\mathcal{B}^*w_n\|^2_{L^2(\Gamma_1)} = \mathcal{O}(n^{-1}) \ \text{ as } n \to \infty.$$

Hence for fixed $\tau > 0$ one has

$$\lim_{n\to\infty} \frac{\int_0^\tau \|B^*T^*(s)\xi^{(n)}\|_U^2\,ds}{\|\xi^{(n)}\|_X^2} = 0.$$

So there does not exist $\gamma > 0$ such that (4.2) is verified. ∎

It is easy to see that the result $\mathcal{B}^* w_n \to 0$ would have been lost if we had considered convergence in $H^1(\Gamma_1)$. This could give some directions of search to identify the exactly controllable subspace. Similar problems have been addressed in [13].

4.1.2. Approximate controllability on $[0,\tau]$. We first show the following lemma.

LEMMA 4.6. *The range of $\mathcal{B}$ is dense in $L^2(\Gamma_s)$, or equivalently,*

$$\mathcal{B}^* z = 0 \Rightarrow z = 0, \text{ in } L^2(\Gamma_1).$$

Proof. Let us take $z \in L^2(\Gamma_s)$ such that $\mathcal{B}^* z = 0$. From (4.5), we have that

$$\left\{ \begin{array}{rcll} \Delta\Theta & = & 0, & \text{in } \Omega, \\ \Theta & = & z, & \text{on } \Gamma_s, \\ \Theta & = & 0, & \text{on } \Gamma_1, \\ \partial_n\Theta & = & 0, & \text{on } \Gamma_f \cup \Gamma_1 \cup \Gamma_2. \end{array} \right. \tag{4.8}$$

Since Θ is smooth enough (we have taken z in $L^2(\Gamma_s)$), the Holmgren's uniqueness theorem implies that $\Theta = 0$, since $\Theta = \partial_n\Theta = 0$ on Γ_1. So $z = \Theta|_{\Gamma_s} = 0$. This ends the proof. □

We are now able to show the following theorem.

THEOREM 4.7. *The system*

$$\dot{\xi} = A\xi + Bv, \tag{4.9}$$

with $v \in L^2(0,\tau; L^2(\Gamma_1))$, is approximately controllable on $[0,\tau]$ for any $\tau > 0$.

Proof. To show approximate controllability one has to show that the operator $\mathcal{H}_\tau^*$ is one-to-one, i.e.,

$$B^* T^*(s)\xi_0 = 0, \ s \in [0,\tau] \Rightarrow \xi_0 = 0. \tag{4.10}$$

Since $T^*(s) = T(-s)$, this is the same as showing that the solution of system

$$\left\{ \begin{array}{rcll} -\dot{\xi} & = & A\xi, \ t \in [0,\tau], \\ B^*\xi & = & 0, \\ \xi(0) & = & \xi_0 \in X, \end{array} \right. \tag{4.11}$$

with the supplementary condition

$$B^*\xi = 0, \ t \in [0,\tau], \tag{4.12}$$

is identically zero, i.e., $\xi_0 = 0$.

In order to clarify the abstract formulation, the system (4.11)–(4.12) can be rewritten in terms of the original equations (3.2)–(2.6) under the following form:

$$\left\{ \begin{array}{rcll} \Delta\psi & = & 0, \text{ in } \Omega \times [0,\tau], \\ \ddot{\psi} + \partial_n\psi & = & 0, \text{ on } \Gamma_s \times [0,\tau], \\ \partial_n\psi & = & 0, \text{ on } \Gamma_f \cup \Gamma_1 \cup \Gamma_2 \times [0,\tau], \end{array} \right. \tag{4.13}$$

with initial conditions

$$\psi(0) = \varphi_0 \in \tilde{H}^{1/2}(\Gamma_s), \ \dot{\psi}(0) = \varphi_1 \in L^2(\Gamma_s), \text{ on } \Gamma_s,$$

and the supplementary condition

$$\dot{\psi} = 0, \text{ on } \Gamma_1 \times [0, \tau].$$

We recall that ξ and ψ are related by $\varphi = \psi|_{\Gamma_s}$ and

$$\xi = \begin{pmatrix} \Pi_H \varphi \\ \Pi_H \dot{\varphi} \\ \Pi_{\mathbf{R}} \dot{\varphi} \end{pmatrix}, \ \xi_0 = \begin{pmatrix} \Pi_H \varphi_0 \\ \Pi_H \varphi_1 \\ \Pi_{\mathbf{R}} \varphi_1 \end{pmatrix}.$$

For the rest of the proof, we will use the abstract formulation (4.11)–(4.12). We first check what kind of information on ξ is given by (4.12), which is equivalent to

$$\mathcal{B}^*(\xi_2 + \xi_3) = 0.$$

By Lemma 4.6 this implies that $\xi_2 + \xi_3 = 0$. Since ξ_2 and ξ_3 belong to orthogonal subspaces (ξ_2 has zero mean and ξ_3 is a constant), we must have $\xi_2 = 0$ and $\xi_3 = 0$. From (4.11) we have that $-\dot{\xi}_1 = \xi_2 = 0$, so (4.11) reduces to

$$\mathcal{A}\xi_1 = 0, \ t \in [0, \tau],$$

with ξ_1 only depending of x. Since the kernel of $\mathcal{A}$ is reduced to $\{0\}$, this implies that $\xi_1 = 0 \ \forall t \in [0, \tau]$, and we can conclude that $\xi = 0 \ \forall t \in [0, \tau]$. □

As it is proved in [12, p. 522, Appendix B], the following theorem is an immediate corollary of Theorem 4.7 (the result in [12] is very general and can be directly applied to our case).

THEOREM 4.8. *Let E be any finite dimensional subspace of X. For any $\tau > 0$, for any $\varepsilon > 0$, and for any $\xi_0, \xi_d \in X$, there exists a control $v \in L^2(0, \tau; L^2(\Gamma_1))$ such that the solution of*

$$\left\{ \begin{array}{rcl} \dot{\xi} & = & A\xi + Bv, \ t \in [0, \tau], \\ \xi(0) & = & \xi_0 \end{array} \right.$$

satisfies

$$\left\{ \begin{array}{rcl} \Pi_E(\xi(\tau) - \xi_d) & = & 0, \\ ||\xi(\tau) - \xi_d||_X & < & \varepsilon, \end{array} \right.$$

where $\Pi_E \xi$ denotes the orthogonal projection of ξ over E.

4.2. Controllability with a rigid generator. We consider again the first order form of our system, but this time with a scalar control $u(t)$,

$$\dot{\xi} = A\xi + Bu. \tag{4.14}$$

We take this new definition for B :

$$Bu = bu, \quad b = \begin{pmatrix} 0 \\ \Pi_H \beta \\ \Pi_{\mathbf{R}} \beta \end{pmatrix} \in X, \tag{4.15}$$

where, as before, $\beta = \mathcal{B}f$. In what follows we will consider the set of generators with a "strategic" shape function f. This set is defined as follows.

DEFINITION 4.9. *We say that a shape function $f \in L^2(\Gamma_1)$ is strategic if the corresponding operator B, defined by ways of* (3.8)–(3.6) *and* (4.15)*, is such that* $B^*\phi_k \neq 0 \ \forall\, k \in \mathbf{Z}$.

As it is shown in the following lemma, the positivity of the shape function f on $[0,1]$, which includes the case of $f(y) = y$ (plane rotating generators), is a sufficient condition for f to be strategic.

LEMMA 4.10. *If the shape function $f(y)$ is positive for $y \in [0,1]$, then*

$$B^*\phi_k > 0 \quad \forall k \in \mathbf{Z}.$$

Proof. One has for $k \geq 0$

$$\begin{aligned} B^*\phi_k &= \langle \phi_k \,,\, b \rangle_X \\ &= \frac{1}{\sqrt{\pi}} \langle w_k \,,\, \beta \rangle \,, \end{aligned}$$

and $B^*\phi_{-k} = B^*\phi_k$. From the definition of β we have

$$\begin{aligned} \langle w_k \,,\, \beta \rangle &= \langle w_k \,,\, \mathcal{B} f \rangle \\ &= \langle \mathcal{B}^* w_k \,,\, f \rangle_{L^2(\Gamma_1)} \,, \end{aligned}$$

where $\mathcal{B}^* w_k$ is given by (4.7). Thus we have

$$B^*\phi_k \quad = \quad \tfrac{1}{\sqrt{\pi}\cosh k} \int_0^1 \cosh ky \, f(y)\, dy, \ k \geq 0. \tag{4.16}$$

Since $f(y)$ is a positive function on $[0,1]$, then it is obvious from (4.16) that $B^*\phi_k > 0 \ \forall k$. ∎

Remark 4.11. The strategic set is not limited to positive shapes. For example, if we consider a plane rotating generator with an axis located at $y = a$, $a \in [0,1]$, we can verify by means of (4.16) that the corresponding shape $f_a(y) = y - a$ will be strategic for $a \in [0,1] \setminus \left(\left\{ \tfrac{1}{2} \right\} \cup \left\{ \ 1 - \tfrac{1}{k} \tanh \tfrac{k}{2}, \ k \in \mathbf{N}^* \right\} \right)$.

In the following, we will need to know how f influences the regularity of β. For this purpose we define for an integer $p > 0$ the space

$$H_c^p(\Gamma_1) = \{ f \in H^p(\Gamma_1), \ f^{(q)}(1) = 0, \ q = 0 \ldots p-1 \},$$

and we take the convention $H_c^0(\Gamma_1) = L^2(\Gamma_1)$. We have the following lemma.

LEMMA 4.12. *If $f \in H_c^p(\Gamma_1)$, then there exists $C > 0$ such that the operator B has the property*

$$|B^*\phi_k| \leq \frac{C}{k^{p+\frac{1}{2}}}.$$

If $f \in H^p(\Gamma_1) \backslash H_c^p(\Gamma_1)$ for some $p > 0$ then there exists $C > 0$ and an integer q with $0 < q \leq p$ such that

$$k^q |B^*\phi_k| \to C$$

as $k \to \infty$.

Proof. We obtain the two results by means of repeated integration by parts on (4.16) and the Cauchy–Schwarz inequality. ∎

4.2.1. Lack of approximate controllability on an interval $[0,\tau]$**.** In fact the system (4.14) is not approximately controllable on $[0,\tau]$ for any $\tau>0$. This result was claimed in [6], but the proof was incomplete. The following lemma is crucial in the proof of our main result.

LEMMA 4.13.

1. *For any* $\tau>0$*, the system* $\left\{e^{iw_kt}\right\}_{k\in\mathbf{Z}}$ *is complete and linked in* $L^2(0,\tau)$.
2. *For any* $\tau>0$*, there exists a subset* $\mathcal{S}_\tau\subset\mathbf{Z}$ *such that* $\left\{e^{iw_kt}\right\}_{k\in\mathcal{S}_\tau}$ *is a Riesz basis of* $L^2(0,\tau)$.

For $k>0$, ω_k is given by $\omega_k=\sqrt{\lambda_k}$, where $\lambda_k>0$ are the eigenvalues of $\mathcal{A}$, given by $\lambda_k=k\tanh k$. Notice that we have taken $\omega_k=-\omega_{-k}$ for $k<0$ and $\omega_0=0$. We recall that the terminology "linked system" means that every element of the system is in the closed subspace spanned by the other elements.

Before giving the proof, let us recall the following theorem which is due to Young [18].

THEOREM 4.14 ($\frac{1}{4}$-theorem). *If* $\{\omega_k\}$ *is a sequence of real numbers for which*

$$|\omega_k-k|<\frac{1}{4},\ k\in\mathbf{Z},$$

then the system $\{e^{i\omega_kt}\}$ *is a (Riesz) basis of* $L^2(0,2\pi)$.

This result can be applied in $L^2(0,\tau)$, in which case the inequality to obtain is

$$\left|\omega_k-\frac{2k\pi}{\tau}\right|<\frac{\pi}{2\tau}.$$

We also need the following theorem.

THEOREM 4.15. *Let* $\{f_n\}_{n\in\mathbf{Z}}$ *be a Riesz basis of* $L^2(0,\tau)$. *Consider the family* $\{\tilde f_n\}$ *where* $\tilde f_n=g_n$ *for* $n<n_0$ *and* $\tilde f_n=f_n$ *otherwise, where the* g_n *are such that* $\{\tilde f_n\}$ *remains a basis of* $L^2(0,\tau)$. *Then* $\{\tilde f_n\}$ *remains a Riesz basis of* $L^2(0,\tau)$.

Proof. Since $\{f_n\}_{n\in\mathbf{Z}}$ is a Riesz basis of $L^2(0,\tau)$, there exists an isomorphism T and an orthonormal basis $\{e_n\}$ of $L^2(0,\tau)$ such that $Te_n=f_n,\ n\in\mathbf{Z}$. Since T is an isomorphism there exists $\rho>0$ such that $\|Tf\|\geq\rho\|f\|\ \forall\, f\in L^2(0,\tau)$. Then we have

$$\infty>\sum\|f_n-\tilde f_n\|^2=\sum\|Te_n-\tilde f_n\|^2\geq\rho^2\sum\|e_n-T^{-1}\tilde f_n\|^2,$$

showing that $\{e_n\}$ and $\{T^{-1}\tilde f_n\}$ are quadratically close. Then by Bari's theorem (see [18], p. 45), since $\{T^{-1}\tilde f_n\}$ is a basis, it is also a Riesz basis, and so is $\{\tilde f_n\}$ since T^{-1} is an isomorphism. □

Proof of Lemma 4.13. We take the sequence of integers $\{c_k\}$ with

$$c_k=\operatorname{Int}\left(\frac{4k^2\pi^2}{\tau^2}\right),k\geq0,$$

(the notation Int (.) denotes the integer part function) and we define $\mu_k=\sqrt{c_k}$ for $k\geq0$ and $\mu_k=-\sqrt{c_k}$ for $k<0$. It can be easily shown that this sequence has the property

$$\left|\mu_k-\frac{2k\pi}{\tau}\right|<\frac{1}{2|\mu_k|}\quad\forall k\in\mathbf{Z},$$

which shows that for a sufficiently large k, say k_0, one has $\left|\mu_k-\frac{2k\pi}{\tau}\right|<\frac{\pi}{2\tau}\ \forall|k|\geq k_0$, since $\{|\mu_k|\}$ is an increasing sequence. Since $\omega_p=\sqrt{p\tanh p}$, one has

$$\frac{\omega_p}{\sqrt{p}}\to1,\quad\text{as } p\to\infty,$$

which means that there exists $k_1 \geq k_0$ such that

$$\left|\omega_{c_k} - \frac{2k\pi}{\tau}\right| < \frac{\pi}{2\tau},\ \forall |k| \geq k_1.$$

Let us define the sequence $\{\mu_k\}_{k\in\mathbf{Z}}$ by

$$\mu_k = \begin{cases} \frac{2k\pi}{\tau}\ , & |k| < k_1, \\ \omega_{c_k}\ , & k \geq k_1, \\ -\omega_{c_k}\ , & k \leq -k_1. \end{cases}$$

One has by construction $|\mu_k - \frac{2k\pi}{\tau}| < \frac{\pi}{2\tau}\ \forall k \in \mathbf{Z}$, so by Theorem 4.14 the system $\{e^{i\mu_k t}\}$ is a Riesz basis of $L^2(0,\tau)$. If one replaces a finite number of μ_k by other numbers distinct from μ_k [16, Theorem 7, p. 135] the system remains a basis, and from Theorem 4.15 it is also a Riesz basis.

So one replaces μ_k by ω_{d_k} for $|k| < k_1$, where each d_k, $|k| < k_1$ are distinct and can be chosen such that $d_k \neq c_l$ for any l with $|l| \geq k_1$. We then define the set

$$\mathcal{S}_\tau = \{d_k, |k| < k_1\} \cup \{c_k, |k| \geq k_1\}.$$

By construction, the system $\{e^{i\omega_k t}\}_{k\in\mathcal{S}_\tau}$ is a Riesz basis. Hence, the system $\{e^{i\omega_k t}\}_{k\in\mathbf{Z}}$ cannot be linearly independent in $L^2(0,\tau)$ since it strictly contains a basis, and by a result of Schwartz [16, Theorem 4, p. 102], this system is linked. □

As announced above, we have the following controllability theorem.

THEOREM 4.16. *Suppose that the shape function $f \in H^p(\Gamma_1)\backslash H^p_c(\Gamma_1)$ is strategic. Then, the system* (4.14)–(4.15) *is not approximately controllable on* $[0,\tau]$ *for any* $\tau > 0$.

Proof. Since $f \in H^p(\Gamma_1)\backslash H^p_c(\Gamma_1)$ there exists an integer q and a constant $C > 0$ such that $k^q |B^*\phi_k| \to C$. Moreover, we have shown in Lemma 4.13 that the system $\{e^{i\omega_k t}\}_{k\in\mathcal{S}_\tau}$ is a Riesz basis of $L^2(0,\tau)$ and the set $\mathbf{Z}\backslash\mathcal{S}_\tau$ is not finite. Hence we can apply a result of Avdonin and Ivanov (see [1, Theorem II.6.6, p. 141], to claim that there exists a nonzero sequence $\{a_k\}_{k\in\mathbf{Z}}$ such that $\sum_{k\in\mathbf{Z}} |a_k|^2 |\omega_k|^{4q} < \infty$ and

$$\sum_{k\in\mathbf{Z}} a_k e^{i\omega_k t} = 0,\ \text{in } L^2(0,\tau).$$

Since $\omega_k = (k \tanh k)^{\frac{1}{2}}$ is equivalent to $k^{\frac{1}{2}}$, the series $\sum_{k\in\mathbf{Z}} |a_k|^2 |k|^{2q}$ is convergent. Hence, if we consider the vector ξ defined by

$$\xi = \sum_{k\in\mathbf{Z}} \frac{a_k}{B^*\phi_k}\phi_k,$$

we have $\xi \in X$ since the series

$$\sum_{k\in\mathbf{Z}} |\langle \xi\ ,\ \phi_k\rangle|^2 = \sum_{k\in\mathbf{Z}} \left|\frac{a_k}{B^*\phi_k}\right|^2$$

is convergent. Finally, we have by construction

$$B^*T^*(t)\xi = \sum_{k\in\mathbf{Z}} B^*\phi_k\, \langle \xi\ ,\ \phi_k\rangle\, e^{i\omega_k t} = 0,\ \text{in } L^2(0,\tau). \tag{4.17}$$

This ends the proof. □

This result is essentially due to the fact that there is no asymptotic gap between ω_k and ω_{k+1}, i.e., one has $\lim_{k\to\infty} |\omega_{k+1} - \omega_k| = 0$. Nevertheless, the hypothesis of "maximal regularity" for f is fundamental because the result of Avdonin and Ivanov cannot be applied if $\{a_k\}_{k\in\mathbf{Z}}$ is expected to have an exponential decay (see Theorem II.6.5, page 140 in [1]). Such a decay would be required if $|B^*\phi_k|$ already had an exponential decay. Lemma 4.12 shows that if $f \in H_c^p(\Gamma_1)$ for any $p > 0$, then the decay rate of $|B^*\phi_k|$ will be faster than any polynomial, but it is not clear whether this decay rate can be exponential or not.

In the next section we show that the system (4.14)–(4.15) is approximately controllable in the sense of a weaker definition.

4.2.2. Generic approximate controllability. One can define a generic concept of approximate controllability on $[0,\infty)$. This is the concept used by Curtain and Zwart [3]. Its definition follows.

DEFINITION 4.17. *Let us call* $\mathcal{R}$ *the reachable subspace*

$$\mathcal{R} = \bigcup_{\tau\in\mathbf{R}^+} Ran\,\mathcal{H}^\tau.$$

The system is approximately controllable on $[0,\infty)$ *if* $\overline{\mathcal{R}} = X$. □

As for the case where the controllability time is finite, this type of approximate controllability corresponds to an observability property on the dual system, i.e., approximate controllability on $[0,\infty)$ will hold if

$$B^*T^*(t)\xi = 0 \quad \forall t > 0 \Longrightarrow \xi = 0. \tag{4.18}$$

Since we have shown that A is a Riesz-spectral operator, we can use Theorem 4.2.3 in [3] which claims that (4.18) will hold if

$$B^*\phi_k \neq 0 \quad \forall k \in \mathbf{Z},$$

where ϕ_k, $k \in \mathbf{Z}$ are the eigenfunctions of operator A. The following proposition follows directly from Definition 4.9.

PROPOSITION 4.18. *Suppose that the shape function* f *is strategic. Then the system* (4.14)–(4.15) *is approximately controllable on* $[0,\infty)$.

4.3. Interpretation of controllability results. Since we have established some controllability results on an abstract formulation of the original problem, it is necessary to explain the meaning of these results in terms of the original system, posed in the bidimensional domain Ω,

$$\left\{\begin{array}{rcll} \Delta\psi &=& 0, & \text{in } \Omega\times[0,\tau],\\ \ddot{\psi}+\partial_n\psi &=& 0, & \text{on } \Gamma_s\times[0,\tau],\\ \partial_n\psi &=& v, & \text{on } \Gamma_1\times[0,\tau],\\ \partial_n\psi &=& 0, & \text{on } \Gamma_f\cup\Gamma_2\times[0,\tau]. \end{array}\right. \tag{4.19}$$

It must be well understood that the unknown of this system is not the pair $(\psi,\dot{\psi})$, but the pair $(\psi,\dot{\psi}|_{\Gamma_s})$, as it is clearly expressed in the natural energy norm

$$E(\psi,\dot{\psi}) = \frac{1}{2}\int_\Omega |\nabla\psi|^2 + \frac{1}{2}\int_{\Gamma_s}\dot{\psi}^2, \tag{4.20}$$

and we will take this into account in the following.

We have obtained an approximate controllability result for the abstract system, posed on the free surface Γ_s,

$$\left\{ \begin{array}{rcl} \dot{\xi} & = & A\xi + Bv, \\ \xi(0) & = & \xi_0, \end{array} \right. \tag{4.21}$$

where ξ is related to the original velocity potential ψ by

$$\xi = \begin{pmatrix} \Pi_H \psi|_{\Gamma_s} \\ \Pi_H \dot{\psi}|_{\Gamma_s} \\ \Pi_{\mathbf{R}} \dot{\psi}|_{\Gamma_s} \end{pmatrix}.$$

This abstract system is well posed, and for $v \in L^2(0,\tau;L^2(\Gamma_1))$ and $\xi_0 \in X$ we have $\xi \in C(0,\tau;X)$. This means that the pair $(\psi|_{\Gamma_s}, \dot{\psi}|_{\Gamma_s})$ is continuous in time for the norm of X while in general the pair $(\psi, \dot{\psi}|_{\Gamma_s})$ is not continuous for the energy norm since it would require that v is also continuous. We will see that it is not a problem in the context of approximate controllability.

Let us consider a target

$$(\psi_d, \eta_d) \in H^1(\Omega) \times L^2(\Gamma_s),$$

with $\Delta\psi_d = 0$, which is to be reached approximately in the sense of the energy norm, at $t = \tau$ by $(\psi, \dot{\psi}|_{\Gamma_s})$, i.e., we seek for a v such that

$$E(\psi(\tau) - \psi_d, \dot{\psi}(\tau)|_{\Gamma_s} - \eta_d) \leq \varepsilon. \tag{4.22}$$

In terms of the abstract system the target (ψ_d, η_d) corresponds to the abstract target

$$\xi_d = \begin{pmatrix} \Pi_H \psi_d|_{\Gamma_s} \\ \Pi_H \eta_d \\ \Pi_{\mathbf{R}} \eta_d \end{pmatrix}.$$

Hence, the meaning of Theorem 4.7 is that, given $\varepsilon > 0$, we can find a $v \in L^2(0,\tau;L^2(\Gamma_1))$ such that $\frac{1}{2}\|\xi(\tau) - \xi_d\|_X \leq \varepsilon$, i.e.,

$$\frac{1}{2} \left\| \begin{pmatrix} \Pi_H(\psi(\tau) - \psi_d)|_{\Gamma_s} \\ \Pi_H(\dot{\psi}(\tau)|_{\Gamma_s} - \eta_d) \\ \Pi_{\mathbf{R}}(\dot{\psi}(\tau)|_{\Gamma_s} - \eta_d) \end{pmatrix} \right\|_X \leq \varepsilon. \tag{4.23}$$

We have shown that the approximately reachable space for $\xi(\tau)$ is

$$\tilde{H}^{1/2}(\Gamma_s) \times \tilde{L}^2(\Gamma_s) \times \mathbf{R},$$

and thus

(4.24) *the approximately reachable space for* $\Pi_H \psi(\tau)|_{\Gamma_s}$ *is* $\tilde{H}^{1/2}(\Gamma_s)$,

and since the approximately reachable space for the pair $(\Pi_H \dot{\psi}(\tau)|_{\Gamma_s}, \Pi_{\mathbf{R}} \dot{\psi}(\tau)|_{\Gamma_s})$ is $\tilde{L}^2(\Gamma_s) \times \mathbf{R}$, and $\dot{\psi}(\tau)|_{\Gamma_s} = \Pi_H \dot{\psi}(\tau)|_{\Gamma_s} + \Pi_{\mathbf{R}} \dot{\psi}(\tau)|_{\Gamma_s}$, then

(4.25) *the approximately reachable space for* $\dot{\psi}(\tau)|_{\Gamma_s}$ *is* $L^2(\Gamma_s)$.

We can note that the final value of $\psi|_{\Gamma_s}$ is only reached up to an additive constant. This is related to the fact that in the whole domain Ω, the velocity potential ψ is itself defined up to an additive constant.

We must be very careful in extending the results (4.24) and (4.25) to the pair $(\psi, \dot{\psi}|_{\Gamma_s})$ in the whole domain Ω. Since we are only concerned with approximate controllability, by a density argument it is always possible to find

$$v \in \tilde{U} = \{u \in C(0,\tau; L^2(\Gamma_1)),\ u(\tau) = 0\},$$

such that the solution of (4.19) verifies (4.23). Moreover, when $v \in \tilde{U}$ then the energy norm and the abstract norm of the pair $(\psi(\tau), \dot{\psi}(\tau)|_{\Gamma_s})$ coincide, i.e.,

$$v \in \tilde{U} \Rightarrow \frac{1}{2}\|\xi(\tau) - \xi_d\|_X = E(\psi(\tau) - \psi_d, \dot{\psi}(\tau)|_{\Gamma_s} - \eta_d).$$

Thus, we can finally claim that when $v \in \tilde{U}$, the approximately reachable space for $\psi(\tau)$ is the set

$$\left\{\psi_d \in H^1(\Omega) \text{ such that } \Delta\psi_d = 0 \text{ in } \Omega,\ \partial_n\psi_d|_{\Gamma_1\cup\Gamma_2\cup\Gamma_f} = 0,\ \int_{\Gamma_s} \psi_d = 0\right\}.$$

5. Stabilization. As in the previous sections, we take $g_0 = 1$, $L = \pi$, $h = 1$, and we will consider only one generator at the left of the canal. We consider a "rigid" generator: we recall that the corresponding boundary condition is

$$\partial_n\psi = f(y)u, \quad \text{on } \Gamma_1,$$

where u is the velocity of the generator and $f \in L^2(\Gamma_1)$ is the "shape" of the generator. For the moment we will only require that f is a positive function on Γ_1.

It makes sense to measure the elevation of the surface at $x = 0$, i.e.,

$$\eta(0,t) = -\dot{\psi}(0,1,t),$$

and practically speaking, this requires a sensor installed on the generator itself. We use this measurement to construct a very simple feedback, under the form

$$u(t) = \eta(0,t).$$

This kind of feedback will require enough regularity for $\dot{\psi}$ on Γ_s, and this point will be clarified in section 5.1. Anyway, we are interested by the choices of $f(y)$ which will make the system (at least) strongly stable.

In terms of the original system (3.2)–(3.4), this feedback leads to the following equations:

$$\left\{\begin{array}{rcl} \Delta\psi &=& 0, \text{ in } \Omega\times[0,\infty),\\ \partial_n\psi + \ddot{\psi} &=& 0, \text{ on } \Gamma_s\times[0,\infty),\\ \partial_n\psi + f(y)\dot{\psi}(0,1) &=& 0, \text{ on } \Gamma_1\times[0,\infty),\\ \partial_n\psi &=& 0, \text{ on } \Gamma_f\cup\Gamma_2\times[0,\infty), \end{array}\right. \tag{5.1}$$

with initial conditions

$$\psi(0) = \varphi_0, \dot{\psi}(0) = \varphi_1, \text{ on } \Gamma_s.$$

We can already see that initial data of the form

$$\psi(0) = c, \dot{\psi}(0) = 0, \text{ on } \Gamma_s,$$

will stay invariant, i.e., we will have

$$\psi = c, \text{ in } \Omega \times [0, \infty).$$

Moreover, if we consider the natural energy of the system, i.e.,

$$E(\psi, \dot{\psi}) = \frac{1}{2} \int_\Omega |\nabla \psi|^2 + \frac{1}{2} \int_{\Gamma_s} \dot{\psi}^2,$$

we have $E(\psi, \dot{\psi}) = 0$ for such a solution. In order to have a correct framework for the stability analysis of the system (5.1), we will eliminate such initial data by choosing spaces adequately.

In the following we will show that for some choices of $f(y)$ the solution of the system (5.1) is strongly stable, although the natural energy is not decreasing: multiplying by $\dot{\psi}$ the first equation in (5.1) and integrating in Ω, we formally get that

$$\dot{E}(\psi, \dot{\psi}) = -\dot{\psi}(0,1) \int_{\Gamma_1} f(y) \dot{\psi}.$$

For the case of a plane rotating generator, we have $f(y) = y$ and if we take for example ψ such that for some t, $\dot{\psi}(t)|_{\Gamma_1} = \varepsilon - 1 + y$ for a sufficiently small $\varepsilon > 0$, it is easy to show that $\dot{E}(\psi, \dot{\psi}) > 0$ (for any $f(y)$ it is obviously possible to construct such a $\psi(t)$).

As a first intermediate step, and with the same notations as in section 3, we can reformulate (5.1) on Γ_s with a single unknown

$$\varphi = \psi|_{\Gamma_s},$$

which is the solution of

$$\ddot{\varphi} + \mathcal{A}\varphi + \beta \dot{\varphi}(0) = 0 \text{ on } \Gamma_s \times [0, \infty), \tag{5.2}$$

with initial conditions

$$\varphi(0) = \varphi_0, \dot{\varphi}(0) = \varphi_1, \tag{5.3}$$

where the operator $\mathcal{A}$ has the same definition as in section 3, i.e., $\mathcal{A}\varphi = \partial_n \mathrm{D}\varphi|_{\Gamma_s}$, where D is the Dirichlet map defined by (3.5). The function $\beta \in L^2(\Gamma_s)$ is defined by $\beta = \mathcal{B}f = \partial_n N f|_{\Gamma_s}$, where N is the Neumann map defined by (3.6). Finally, the original potential ψ is related to φ and f by the relation

$$\psi = \mathrm{D}\varphi + \dot{\varphi}(0)\mathrm{N}f,$$

and of course we still have $\varphi = \psi|_{\Gamma_s}$.

The next step consists in using the first order formulation of (5.2): as in section 3.3 we define a new unknown ξ, related to φ and $\dot{\varphi}$ by

$$\xi = \begin{pmatrix} \Pi_H \varphi \\ \Pi_H \dot{\varphi} \\ \Pi_{\mathbf{R}} \dot{\varphi} \end{pmatrix}, \ \xi_0 = \begin{pmatrix} \Pi_H \varphi_0 \\ \Pi_H \varphi_1 \\ \Pi_{\mathbf{R}} \varphi_1 \end{pmatrix}. \tag{5.4}$$

In order to exhibit the very general aspect of the method we will use to obtain our main result, we need to define an observation operator C such that $\eta(0)$, the elevation of the free surface at $x = 0$ (which is a feedback to the control), is obtained by $\eta(0) = C\xi$. Since we have $\eta(0) = -\dot{\varphi}(0)$, then (5.4) implies that C is defined by

$$C\xi = -(\xi_2(0) + \xi_3).$$

If we also consider the control operator B defined for $u \in \mathbf{R}$ by

$$Bu = bu, \text{ with } b = \begin{pmatrix} 0 \\ \Pi_H \beta \\ \Pi_{\mathbf{R}} \beta \end{pmatrix} \in X,$$

and the definition of the operator A given by

$$A\xi = \begin{pmatrix} \xi_2 \\ -\mathcal{A}\xi_1 \\ 0 \end{pmatrix},$$

then the problem (5.2), in terms of the new unknown ξ, is equivalent to the problem

$$\left\{ \begin{array}{rcl} \dot{\xi} & = & (A + BC)\xi, \ t > 0, \\ \xi(0) & = & \xi_0, \end{array} \right. \tag{5.5}$$

which appears as a perturbation of the original open-loop system. In the following, we will use the notation $A_f = A + BC$.

The stability of system (5.5) has been already studied in [14], for the case $f(y) = y$ (plane rotating generator), where it is shown that the eigenvalues of A_f have strictly negative real parts (in fact it is easily shown that this results will always hold if $f(y)$ is a positive function). But this reference does not give any result on the eventual generation of a semigroup.

The result on the real parts of A_f itself is not sufficient to conclude to strong stability, because we don't know if the eigenfunctions of A_f form a Riesz basis. One could apply a result of Lasiecka and Triggiani [9], [17] but the criterion is hard to apply, since one has to know the eigenvalues of A_f explicitly.

In the following we show that the solution of (5.5) is strongly stable by means of an ad hoc energy, and we will have to restrict ourselves to a particular choice of f, since the regularity of β will directly determine the energy space in which the stability result will hold.

5.1. Ad hoc energy. The ad hoc energy we propose is based on the bilinear form

$$B(\xi, \zeta) = \sum_{k \in \mathbf{Z}} d_k \, \langle \xi \, , \, \phi_k \rangle_X \, \overline{\langle \zeta \, , \, \phi_k \rangle}_X, \tag{5.6}$$

where the bar denotes the complex conjugate, ϕ_k denotes the kth eigenfunction of A, and

$$d_k = -\frac{C\phi_k}{\langle \phi_k \, , \, b \rangle_X}.$$

The definitions of C and b give

$$d_k = d_{-k} = \frac{w_k(0)}{\langle \beta \, , \, w_k \rangle} \text{ for } k \geq 0.$$

Since we only consider the case where $f(y)$ is positive, the positivity of d_k follows directly from Lemma 4.10.

Remark 5.1. The bilinear form $B(\xi,\zeta)$ is a reweighted form of the classical inner product associated with the open-loop system $\dot{\xi} = A\xi$, i.e.,

$$\begin{aligned}\langle \xi\,,\,\zeta\rangle_X &= \left\langle \mathcal{A}^{1/2}\xi_1\,,\,\mathcal{A}^{1/2}\zeta_1\right\rangle + \langle \xi_2+\xi_3\,,\,\zeta_2+\zeta_3\rangle \\ &= \sum_{k\in\mathbf{Z}} \langle \xi\,,\,\phi_k\rangle_X\,\overline{\langle \zeta\,,\,\phi_k\rangle}_X. \qquad \square\end{aligned}$$

The positivity of d_k allows us to claim that the bilinear form $B(.,.)$ defines a scalar product and

$$B(\xi,\xi) = \sum_{k\in\mathbf{Z}} d_k |\,\langle \xi\,,\,\phi_k\rangle_X\,|^2 \tag{5.7}$$

can be used as a norm defined on the associated energy space, which is to be identified.

Remark 5.2. The regularity of f will condition the asymptotic behavior of d_k, which will obviously determine the energy space. From an engineering point of view, it could be interesting to consider the case $f(y) = y$, since this corresponds to the most widely used device for wave generators. In this case the energy space can be identified as

$$H^1 \times H^{1/2} \times \mathbf{R},$$

but $b \notin H^1 \times H^{1/2} \times \mathbf{R}$, since for $f(y) = y$ we only have $\beta \in H^{1/2-\varepsilon}(\Gamma_s)\ \forall\ \varepsilon > 0$. This remark explains the particular choice we will make for f in what follows.

In the following, we will focus on the particular case when the "shape" of the generator is given by

$$f_\varepsilon(y) = \begin{cases} \frac{1}{1-\varepsilon}y, & \text{if} \quad 1-\varepsilon \geq y \geq 0, \\ \frac{1}{\varepsilon} - \frac{1}{\varepsilon}y, & \text{if} \quad 1 \geq y > 1-\varepsilon, \end{cases}$$

where $\varepsilon > 0$. We can see that $f_\varepsilon(y)$ is arbitrary close to the original shape, since $f_\varepsilon(y) \to y$ in $L^2(\Gamma_1)$, as $\varepsilon \to 0$. For this particular choice we have $f_\varepsilon \in H_c^{1/2}(\Gamma_1)$, and one can show from formulas (4.16) that

$$B^*\phi_k = \langle \phi_k\,,\,b\rangle_X = \frac{1}{\sqrt{\pi}}\,\langle w_k\,,\,\beta\rangle \tag{5.8}$$

$$= \frac{1}{\varepsilon\sqrt{\pi}\,k^2} + \frac{\cosh k(\varepsilon-1) - \varepsilon}{\varepsilon(\varepsilon-1)\sqrt{\pi}\,k^2\cosh k},\ k>0, \tag{5.9}$$

which gives

$$k^2 B^*\phi_k \to \frac{1}{\varepsilon\sqrt{\pi}},$$

when $k \to \infty$. Thus $\beta \in D(\mathcal{A})$.

PROPOSITION 5.3. *The energy space defined by the convergence of the series in* (5.7) *is equal to*

$$X_f = \tilde{H}_c^{3/2}(\Gamma_s) \times \tilde{H}^1(\Gamma_s) \times \mathbf{R}.$$

Proof. We recall that the natural energy space was

$$X = D(\mathcal{A}^{1/2}) \times H \times \mathbf{R},$$

and that the eigenvalues of $\mathcal{A}$ are given by $\lambda_k = k\tanh k$, for $k > 0$. If we use the expression of the eigenfunctions of A we have

$$B(\xi,\xi) = \frac{1}{\pi} d_0 \xi_3^2 + \frac{2}{\pi} \sum_{k>0} d_k \left(\lambda_k \langle \xi_1 \,,\, w_k \rangle^2 + \langle \xi_2 \,,\, w_k \rangle^2 \right), \tag{5.10}$$

and since we can easily show that

$$\lim_{k\to\infty} \frac{d_k}{\lambda_k^2} = \frac{1}{\varepsilon},$$

the series (5.10) is equivalent to the series

$$\frac{1}{\pi} d_0 \xi_3^2 + \frac{2}{\pi} \sum_{k>0} \lambda_k^3 \langle \xi_1 \,,\, w_k \rangle^2 + \lambda_k^2 \langle \xi_2 \,,\, w_k \rangle^2 .$$

Thus (5.10) will be convergent provided $\xi \in D(\mathcal{A}^{3/2}) \times D(\mathcal{A}) \times \mathbf{R}$, and we have

$$D(\mathcal{A}^{3/2}) = \left\{ \varphi \in D(\mathcal{A}),\ \mathcal{A}\varphi \in D(\mathcal{A}^{1/2}) \right\} = \tilde{H}_c^{3/2}(\Gamma_s). \qquad \square$$

PROPOSITION 5.4. *The domain of A_f is*

$$D(A_f) = \tilde{H}_c^2(\Gamma_s) \times \tilde{H}_c^{3/2}(\Gamma_s) \times \mathbf{R},$$

where the space $H_c^2(\Gamma_s)$ is defined by

$$\tilde{H}_c^2(\Gamma_s) = \left\{ \varphi \in \tilde{H}^2(\Gamma_s),\ \varphi'(0) = \varphi'(\pi) = 0 \right\}.$$

Proof. The domain of A_f is by definition

$$\begin{aligned} D(A_f) &= \{ \xi \in X_f,\ A_f \xi \in X_f \} \\ &= D(\mathcal{A}^2) \times D(\mathcal{A}^{3/2}) \times \mathbf{R}, \end{aligned}$$

where $D(\mathcal{A}^2) = \{ \varphi \in D(\mathcal{A}),\ \mathcal{A}\varphi \in D(\mathcal{A}) \}$. We can identify $D(\mathcal{A}^2)$ by making the following analysis: we will have $\varphi \in D(\mathcal{A}^2)$ if

$$\sum_{k>0} \lambda_k^4 \langle \varphi \,,\, \cos kx \rangle^2 < +\infty. \tag{5.11}$$

It is well known that the operator $-\frac{d}{dx^2}$ in $H = \tilde{L}^2(\Gamma_s)$ with the boundary conditions $\varphi'(0) = \varphi'(\pi) = 0$ has the eigenpairs $(k^2, \cos kx)$ for $k > 0$. Since λ_k^4 is equivalent to k^4, we can claim that the series in (5.11) will be convergent provided that φ is in the domain of this latter operator, which is exactly $\tilde{H}_c^2(\Gamma_s)$. $\square$

Hence, in the following, the space X_f will be endowed with the norm

$$\|\xi\|_f^2 \equiv B(\xi,\xi),$$

where $B(.,.)$ is defined by (5.6), and for $\xi, \zeta \in X_f$, the associated inner product will be

$$\langle \xi\,,\,\zeta\rangle_f \equiv B(\xi,\zeta),$$

and the superscript * will denote adjoint operators with respect to $\langle .\,,\,.\rangle_f$.

The last part of the paper relies on the following observation.

LEMMA 5.5. *The operators B and C verify*

$$B^* = -C,$$

where B^* is the adjoint operator of B, with respect to the inner product $\langle .\,,\,.\rangle_f$.

Proof. Let us take $\xi \in X_f$. We have

$$B^*\xi = \langle \xi\,,\,b\rangle_f, \text{ with } b = \begin{pmatrix} 0 \\ \Pi_H\beta \\ \Pi_{\mathbf{R}}\beta \end{pmatrix}.$$

But we have also

$$\begin{aligned}\langle \xi\,,\,b\rangle_f &= \sum_{k\in\mathbf{Z}} d_k \langle \xi\,,\,\phi_k\rangle \overline{\langle b\,,\,\phi_k\rangle} \\ &= -\sum_{k\in\mathbf{Z}} \frac{C\phi_k}{\langle b\,,\,\phi_k\rangle} \langle \xi\,,\,\phi_k\rangle \overline{\langle b\,,\,\phi_k\rangle} \\ &= -\sum_{k\in\mathbf{Z}} C\phi_k \langle \xi\,,\,\phi_k\rangle \\ &= -C\xi,\end{aligned}$$

where we have used the fact that $\langle b\,,\,\phi_k\rangle$ is a real quantity. □

The situation where $B^* = -C$ is often denoted by "collocation" of the sensor and the actuator, and there are many examples in the literature where such a property corresponds to a realizable actuator/sensor device (see e.g. [4] for the case of a beam with a piezoelectric actuator/sensor). It is interesting to see that the change of inner product has revealed a rather favorable situation, which was hidden in the original topology.

5.2. Strong stability. We note that the result given by Lemma 5.5 shows that C is bounded for the topology of X_f, although this operator was unbounded in the "natural" topology. We will use this fact in the proof of our main result.

THEOREM 5.6. *The system*

$$\left\{\begin{array}{rcl} \dot{\xi} &=& A_f\xi,\ t>0, \\ \xi(0) &=& \xi_0, \end{array}\right. \tag{5.12}$$

with an initial data ξ_0 in X_f, is strongly stable, i.e.,

$$\lim_{t\to\infty} \|\xi(t)\|_f = 0,$$

moreover, the decay rate of $\|\xi(t)\|_f$ cannot be uniform.

Proof. We first recall that $A_f = A + BC = A - BB^*$, and we can easily show that $A^* = -A$ for the inner product $\langle .\,,\,.\rangle_f$. Hence we have for $\xi \in D(A_f)$

$$\begin{aligned}\text{Re}\,\langle A_f\xi\,,\,\xi\rangle_f &= \text{Re}\,\langle A\xi\,,\,\xi\rangle_f - \langle BB^*\xi\,,\,\xi\rangle_f \\ &= -|B^*\xi|^2 \le 0,\end{aligned} \tag{5.13}$$

so that $A - BB^*$ is dissipative.

We then apply the result given in [2]: if A generates a contraction semigroup in X_f and has a compact resolvent, then $A - BB^*$ generates a strongly stable semigroup provided that the pair (A, B) is approximately controllable in the sense of Definition 4.14, i.e., $B^*\phi_k \neq 0 \ \ \forall k \in \mathbf{Z}$.

First, we see that $A - \lambda I$ is maximal in X_f for $\lambda > 0$, if $\mathcal{A} + \lambda^2 I$ is onto from $D(\mathcal{A})$ to $D(\mathcal{A}^2)$. Proposition 3.2 together with the definition of $D(\mathcal{A}^2)$ show that this last result is true. Hence, the resolvent $(\lambda I - A)^{-1}$: $X_f \to D(A_f)$ is bounded. It is also compact, since the injection of $D(A_f) = D(\mathcal{A}^2) \times D(\mathcal{A}^{3/2}) \times \mathbf{R}$ into $X_f = D(\mathcal{A}^{3/2}) \times D(\mathcal{A}) \times \mathbf{R}$ can be easily shown to be compact. Thus A generates a contraction semigroup in X_f and has a compact resolvent in X_f.

Second, for any $k \in \mathbf{Z}$ we have $B^*\phi_k = -C\phi_k = \frac{1}{\sqrt{\pi}}$.

Finally, the decay rate cannot be uniform since BB^* is compact in X_f (bounded and one-dimensional range in our case). □

Remark 5.7. The approach we have used to show the stability result cannot be applied if we use the real "shape" of the plane rotating generator, i.e., $f(y) = y$. In this case the perturbation operator BC is not A-bounded (see [8]) in the natural topology. This may suggest that uniform stability could eventually hold, but in this case, even the well-posedness of the feedback system seems not to be a trivial issue.

Acknowledgment. The author would like to thank Professor Hans Zwart for helpful discussions concerning the controllability problem in section 4.2.1.

EXACT BOUNDARY CONTROLLABILITY OF A MAXWELL PROBLEM*

N. WECK†

Abstract. We consider the problem of steering some initial state of the time-dependent Maxwell equations to rest by controlling the lateral boundary condition. Depending on the topology (Betti numbers) of the given domain Ω, we identify completely those subspaces which can be steered to rest and those which cannot. In the positive case it is shown that each time interval which is longer than diam Ω suffices. This result is almost sharp for the class of regions Ω which contain a segment of length diam Ω.

Key words. exact boundary controllability, Maxwell

1. Introduction. Consider a bounded domain $\Omega \subset \mathbb{R}^3$. An initial boundary value problem for Maxwell's equations may be written (formally) as follows:

$$\left.\begin{aligned} \varepsilon \partial_t E + \operatorname{curl}_x H &= 0 \\ \mu \partial_t H - \operatorname{curl}_x E &= 0 \end{aligned}\right\} \quad \text{in} \quad \mathbb{R}_+ \times \Omega,$$

$$\nu \wedge H = -J \quad \text{in} \quad \mathbb{R}_+ \times \partial\Omega,$$

$$E(0,\cdot) = E^0, \quad H(0,\cdot) = H^0 \quad \text{in} \quad \Omega.$$

Here ε, μ are given positive constants and ν is the exterior unit normal of Ω.

We want to investigate the problem whether it is possible to choose the "boundary control" J such that the given "initial state" (E^0, H^0) is driven to some desired "final state" (E^1, H^1) in a time interval $[0, T]$. This problem has been discussed for special regions Ω with restricted controls by D. L. Russell [23] and K. A. Kime [11] as well as for general regions and general controls by J. E. Lagnese [14], A. Bensoussan [5], O. Nalin [17], V. Komornik [12], and B. V. Kapitonov [10]. (Restricting controls gives a stronger result; therefore the last five results do not imply the first two.) For related results on corresponding stabilization problems see also [3] and [4].

However, the first three general results ([14], [5], and [17]) are based on an inequality in [13, Thm. 7.1] which does not hold in general. Nevertheless, the first two results are essentially true because by control-theoretic considerations the authors are led to consider mainly the special case of star-shaped domains where it *does* hold. The fourth [12] and fifth [10] address only the star-shaped and so-called "sub-star-shaped" cases trying to find an optimal time for exact controllability. On the other hand, spherical shells and tori are counterexamples, and these lead to interesting control-theoretic problems.

In the present paper we shall completely identify those initial states which can be controlled and those which cannot. Furthermore we shall show that in the positive

*Received by the editors November 12, 1998, accepted for publication (in revised form) June 28, 1999; published electronically February 29, 2000.

†Fachbereich 6-Mathematik und Informatik, Universität GH Essen, Universitätsstraße 2, D-45141 Essen, Germany (weck@uni-essen.de).

case any time interval of length larger than diam Ω suffices. Even in the star-shaped case this is at least as good as the result in [12], improves it in a variety of cases, and is almost sharp for a class of regions (see Remark 5 below).

We shall make extensive use of the theory of the Maxwell system as exhibited in [15] (and the literature therein). Though we shall not dwell upon this point, we remark that this theory would enable us to treat more general problems (nonsmooth boundaries, inhomogeneous anisotropic media, H. Weyl's [29] generalization of the Maxwell system to differential forms of arbitrary rank in $\Omega \subset \mathbb{R}^N$). For another suitable source of reference for our present simple setting see [6].

In order to keep the analytical efforts low we choose states and controls from convenient spaces. In particular, we strive to use only standard elliptic theory and standard results of the spectral calculus for the self-adjoint time-independent Maxwell operator (or semigroup theory [1, Thms. 4.8.1 and 4.8.2]). Concerning control theory, we use only the analogue of D. L. Russell's trick to obtain suitable boundary controls for the wave equation [20], [22].

Compared to [14], [5], [17], and [12] we need a slightly larger space of controls (with respect to regularity) or, conversely, have to impose stronger regularity upon the states. However, the simplicity of our argument as well as the more precise nature of our results seems to justify our approach. Furthermore, recent regularity results (see [24] and the literature cited there) give hope that this gap can be closed.

We introduce the following modifications and simplifications of our problem:

(i) $(E^1, H^1) = (0, 0)$ (without loss of generality because the family of evolution operators is a group);

(ii) $\varepsilon = \mu = 1$ (for the case of constant scalar dielectricity ε and permeability μ—which is considered in the previous literature—this may be achieved by a standard transformation);

(iii) as in [14] and [5], we assume Ω to be a bounded open set "lying on one side" of its C^∞-boundary $\partial\Omega =: \Gamma$ with exterior unit normal $\nu : \Gamma \to S^2$ (although C^2-regularity would be sufficient).

Hence (interchanging the roles of E and H) we say that (E, H) solves $\mathcal{P}(E^0, H^0; J)$ in the "time interval" $I := [\,0\,, T\,]$ or $I := [\,0\,, \infty\,)$ if (in a sense to be defined below)

$$\text{(IBVP)} \qquad \left.\begin{array}{lll} \partial_t E = \nabla_x \wedge H, \quad \partial_t H = -\nabla_x \wedge E & \text{in} & I \times \Omega \\ (E(0,\cdot), H(0,\cdot)) = (E^0, H^0) & & \\ \nu \wedge E = J & \text{on} & I \times \Gamma \end{array}\right\}.$$

2. Notation and a solution theory for the direct problem. For the convenience of the reader we want to exhibit an easily accessible theory of the direct problem tailored to fit the need of having a convenient description of the map "control to state." So we strive to use only the fact that the Maxwell operator is self-adjoint plus the corresponding spectral calculus. As mentioned in the introduction, this approach could be generalized in various directions.

We shall use the notation of [15]. In particular, spaces of $\mathbb{C}$-valued functions will be denoted by roman letters whereas script letters indicate spaces of $\mathbb{C}^3$-valued functions. Usually Ω will be fixed, so we shall indicate the dependence of our function spaces on the domain S only if it is different from Ω. Hence

$$L^2 := \{\, f : \Omega \to \mathbb{C} \;\mid\; f \quad \text{measurable and square integrable} \,\},$$
$$\mathcal{L}^2 := \left\{\, v : \Omega \to \mathbb{C}^3 \;\mid\; v_1, \ldots, v_3 \in L^2 \right\}.$$

Similarly, for $s \in \mathbb{R}$ we denote L^2-Sobolev spaces by H^s and $\mathcal{H}^s$ in the scalar, respectively, vector valued case and in the same spirit

$$C^\infty(S) := C^\infty(S, \mathbb{C}), \quad \mathcal{C}^\infty(S) := C^\infty(S, \mathbb{C}^3).$$

Furthermore, following [15] we introduce

$$\begin{aligned}
\mathcal{R} &:= \left\{ v \in \mathcal{L}^2 \quad \middle| \quad \nabla \wedge v := \operatorname{curl} v \in \mathcal{L}^2 \right\}, \\
\mathcal{D} &:= \left\{ v \in \mathcal{L}^2 \quad \middle| \quad \langle \nabla, v \rangle := \operatorname{div} v \in L^2 \right\}, \\
\mathcal{R}_0 &:= \{ v \in \mathcal{R} \quad | \quad \nabla \wedge v = 0 \}, \\
\mathcal{D}_0 &:= \{ v \in \mathcal{D} \quad | \quad \langle \nabla, v \rangle = 0 \}.
\end{aligned}$$

The following spaces, $\overset{0}{\mathcal{R}}$, $\overset{0}{\mathcal{D}}$, and $\overset{0}{H}{}^1$, generalize the boundary conditions $\nu \wedge v|_\Gamma = 0$, $\langle \nu,\ v|_\Gamma \rangle = 0$, and $f|_\Gamma = 0$, respectively:

$$\begin{aligned}
\overset{0}{\mathcal{R}} &:= \{ v \in \mathcal{R} \quad | \quad \langle \nabla \wedge v, \varphi \rangle = \langle v, \nabla \wedge \varphi \rangle \quad \text{for all} \quad \varphi \in \mathcal{R} \}, \\
\overset{0}{\mathcal{D}} &:= \left\{ v \in \mathcal{D} \quad | \quad \langle \operatorname{div} v, \varphi \rangle = -\langle v, \nabla \varphi \rangle \quad \text{for all} \quad \varphi \in H^1 \right\}, \\
\overset{0}{H}{}^1 &:= \left\{ f \in H^1 \quad \middle| \quad \langle \nabla f, \varphi \rangle = -\langle f, \operatorname{div} \varphi \rangle \quad \text{for all} \quad \varphi \in \mathcal{D} \right\}.
\end{aligned}$$

Here the natural scalar product both in L^2 and $\mathcal{L}^2$ is denoted by $\langle \cdot, \cdot \rangle$ (and by $\langle \cdot, \cdot \rangle_S$ if the domain S needs to be specified).

The space $\overset{0}{H}{}^1$ coincides with the closure of the test functions $\overset{0}{C}{}^\infty$ in H^1 and this is used to *define* $\overset{0}{H}{}^s(S)$ for an arbitrary $s \in \mathbb{R}$.

LEMMA 2.1 (see [15, pp. 144 ff.]). *The operator*

$$\begin{array}{rccc}
A & : & \overset{0}{\mathcal{R}} \times \mathcal{R} \subset \mathcal{L}^2 \times \mathcal{L}^2 & \longrightarrow & \mathcal{L}^2 \times \mathcal{L}^2, \\
 & & (E, H) & \longmapsto & (i\nabla \wedge H, -i\nabla \wedge E)
\end{array}$$

is self-adjoint with respect to the natural scalar product

$$\langle\langle (E^1, H^1), (E^2, H^2) \rangle\rangle := \langle E^1, E^2 \rangle + \langle H^1, H^2 \rangle.$$

For each $(\Phi^0, \Psi^0) \in D(A) = \overset{0}{\mathcal{R}} \times \mathcal{R}$ *the family*

$$(\Phi(t), \Psi(t)) := \exp(-itA)(\Phi^0, \Psi^0), \quad t \in \hat{I} := [\,0\,,\,\infty\,)$$

defines a strong solution

$$(\Phi, \Psi) \in C^0(\hat{I}, D(A)) \cap C^1(\hat{I}, \mathcal{L}^2 \times \mathcal{L}^2)$$

of (IBVP) *with* $J = 0$.

The strong solutions (Φ, Ψ) defined in Lemma 2.1 will be used as test functions in order to define weak solutions to (IBVP) with $J \neq 0$ in some finite interval $I := [\,0\,,\,T\,]$. We introduce

$$M := M(T) := (\,0\,,\,T\,) \times \Gamma, \quad Z := Z(T) := (\,0\,,\,T\,) \times \Omega$$

and for simplicity take the control from

$$\mathcal{U} := \mathcal{U}(T) := \mathcal{H}_\tau^{1/2}(M(T)).$$

Here (and in what follows) the index τ denotes spaces consisting of "tangential" vector fields, i.e., we require

$$\langle \nu(y),\, J(t,y)\rangle = 0 \quad \text{for} \quad (t,y)\in M, \quad J\in\mathcal{U},$$

in view of the boundary condition in (IBVP). Each $J\in\mathcal{U}$ may be represented by

$$\hat{J}\in \mathcal{H}^1(Z)$$

in the sense that $\mathcal{T}_\tau \hat{J} := \nu\wedge\mathcal{T}\hat{J} = J$ (on M), where here and in what follows $\mathcal{T}$ denotes the ordinary trace operator [25, Prop. 4.5].

LEMMA 2.2. *Let $(E^0,H^0)\in\mathcal{L}^2\times\mathcal{L}^2$ and $J\in\mathcal{U}$. Then there exists a unique $(E,H)\in C^0(I,\mathcal{L}^2\times\mathcal{L}^2)$ such that*

$$\begin{aligned}\langle\!\langle (E(t),H(t)),(\Phi(t),\Psi(t))\rangle\!\rangle - \langle\!\langle (E^0,H^0),(\Phi^0,\Psi^0)\rangle\!\rangle \\ = -\int_0^t\int_\Gamma \langle J(s,y),\,\Psi(s,y)\rangle d\mathbf{o}(y)ds\end{aligned} \tag{1}$$

for all $t\in I$ and all (Φ,Ψ) defined by

$$(\Phi(t),\Psi(t)) := \exp(-itA)(\Phi^0,\Psi^0), \quad (\Phi^0,\Psi^0)\in D(A).$$

Proof. First of all, we need an interpretation of the right-hand side of (1). This may be achieved with the aid of [8, Lem. VII.4.2] saying that there exists a unique continuous trace operator

$$\mathcal{T}_\tau \;:\; \mathcal{R} \;\longrightarrow\; \mathcal{H}_\tau^{-1/2}(\Gamma)$$

which extends the map $\psi\mapsto\nu\wedge\psi|_\Gamma$ from $\mathcal{C}^\infty(\overline{\Omega})$ into $\mathcal{C}^\infty_\tau(\Gamma)$, say. Therefore, from Lemma 2.1,

$$t\mapsto \mathcal{T}_\tau\Psi(t)\in C^0(I,\mathcal{H}_\tau^{-1/2}(\Gamma))\subset\mathcal{H}_\tau^{-1/2}(M),$$

and the right-hand side of (1) may be interpreted as $\langle \nu\wedge\mathcal{T}_\tau\overline{\Psi},\, J\rangle_{X',X}$, where $\langle\cdot,\cdot\rangle$ denotes the duality between the Banach space $X := \mathcal{H}_\tau^{1/2}(M)$ and its topological dual. Furthermore, $\mathcal{H}^{-1/2}(M)$ is identified with the dual of $\overset{0}{\mathcal{H}}{}^{1/2}(M) = \mathcal{H}^{1/2}(M)$ (see [25, Ex. 4.1.16]). Finally, the index τ in $\mathcal{H}_\tau^{-1/2}$ is defined in the weak sense:

$$\Psi\in\mathcal{H}_\tau^{-1/2}(M) :\Leftrightarrow \langle\Psi,\,\varphi\cdot\nu\rangle = 0 \quad \text{for all} \quad \varphi\in H^{1/2}(M).$$

Uniqueness of (E,H) is clear because $D(A)$ is dense in $\mathcal{L}^2\times\mathcal{L}^2$ and $t\mapsto\exp(-itA)$ is a group.

As to existence, we introduce a representation $\hat{J}\in\mathcal{H}^1(Z)\subset C^0(I,\mathcal{L}^2)$ of J (i.e., $J=\mathcal{T}_\tau\hat{J}$) and make the ansatz

$$(E,H) = (\tilde{E}+\hat{J},\tilde{H}),$$

which (formally) leads to

$$\begin{aligned}\partial_t\tilde{E} &= \nabla_x\wedge\tilde{H} - \partial_t\hat{J},\\ \partial_t\tilde{H} &= -\nabla_x\wedge\tilde{E} - \nabla_x\wedge\hat{J},\\ \nu\wedge\tilde{E}\Big|_\Gamma &= 0,\\ (\tilde{E}(0,\cdot),\tilde{H}(0,\cdot)) &\overset{!}{=} (E^0-\hat{J}(0,\cdot),H^0) =: (\tilde{E}^0,\tilde{H}^0).\end{aligned} \tag{2}$$

So we try

$$
\begin{aligned}
(E(t),H(t)) := {} & (\hat{J}\,(t,\cdot),0) \\
& + \exp(-itA)(\tilde{E}^0,\tilde{H}^0) \\
& + \int_0^t \exp(-i(t-s)A)(F(s),G(s))ds
\end{aligned} \tag{3}
$$

with

$$
(F,G) := (-\partial_t\,\hat{J}, -\nabla_x\wedge\,\hat{J}) \in L^2(I,\mathcal{L}^2\times\mathcal{L}^2). \tag{4}
$$

The spectral calculus (or semigroup theory) shows that indeed

$$
(E,H)\in C^0(I,\mathcal{L}^2\times\mathcal{L}^2).
$$

It remains to prove (1). To this end we put

$$
(\Phi(t),\Psi(t)) := \exp(-itA)(\Phi^0,\Psi^0), \qquad (\Phi^0,\Psi^0)\in D(A)
$$

and note that

$$
\langle\!\langle \exp(-itA)(\tilde{E}^0,\tilde{H}^0),(\Phi(t),\Psi(t))\rangle\!\rangle = \langle\!\langle(\tilde{E}^0,\tilde{H}^0),(\Phi^0,\Psi^0)\rangle\!\rangle \tag{5}
$$

because $\exp(-itA)$ is unitary. Furthermore,

$$
\begin{aligned}
&\left\langle\!\!\left\langle \int_0^t \exp(-i(t-s)A)(F(s),G(s))ds,(\Phi(t),\Psi(t))\right\rangle\!\!\right\rangle \\
&\quad = \left\langle\!\!\left\langle \int_0^t \exp(isA)(F(s),G(s))ds,(\Phi^0,\Psi^0)\right\rangle\!\!\right\rangle \\
&\quad = \int_0^t \langle\!\langle (F(s),G(s)),\exp(-isA)(\Phi^0,\Psi^0)\rangle\!\rangle ds \\
&\quad = \int_0^t \left(\langle -\partial_s\,\hat{J}\,(s,\cdot),\,\Phi(s,\cdot)\rangle - \langle\nabla_x\wedge\,\hat{J}\,(s,\cdot),\,\Psi(s,\cdot)\rangle\right) ds \\
&\quad = \int_0^t \left(\langle\hat{J}\,(s,\cdot),\,\partial_s\Phi(s,\cdot)\rangle - \langle\nabla_x\wedge\,\hat{J}\,(s,\cdot),\,\Psi(s,\cdot)\rangle\right) \\
&\qquad - \langle\hat{J}\,(t,\cdot),\,\Phi(t,\cdot)\rangle + \langle\hat{J}\,(0,\cdot),\,\Phi(0,\cdot)\rangle.
\end{aligned}
$$

Because of $\partial_s\Phi = \nabla_x\wedge\Psi$, the last integral yields the right-hand side of (1). Therefore, combining our last computation with (3) and (5) gives (1). □

In the following we shall refer to the solution (E,H) just introduced (defined by (3) and (2),(4)) as "the solution to $\mathcal{P}(E^0,H^0;J)$ in I." Two simple applications of the spectral calculus will be useful later on.

LEMMA 2.3. *Let $(\Phi^0,\Psi^0)\in N(A)$ (the null-space of A). Then*

$$
(\Phi(t),\Psi(t)) := \exp(-itA)(\Phi^0,\Psi^0) = (\Phi^0,\Psi^0)
$$

does not depend on t, and we have

$$
\begin{aligned}
&\langle\!\langle (E(t),H(t)),(\Phi^0,\Psi^0)\rangle\!\rangle - \langle\!\langle (E^0,H^0),(\Phi^0,\Psi^0)\rangle\!\rangle \\
&\qquad = -\int_0^t\int_\Gamma \langle J(\tau,y),\,\Psi^0(y)\rangle d\mathbf{o}(y)d\tau
\end{aligned} \tag{6}
$$

for all $t \in I$ and all solutions (E,H) of $\mathcal{P}(E^0,H^0;J)$ in I.

LEMMA 2.4. *Let $(F,G) \in C^1(I,\mathcal{L}^2\times\mathcal{L}^2)$. Then $(E(T),H(T)) \in D(A)$ for*

$$(E(T),H(T)) := \int_0^T \exp(itA)(F(t),G(t))dt.$$

In particular, if (E,H) solves $\mathcal{P}(E^0,H^0;J)$ in I with $(E^0,H^0)\in D(A)$ and J which is represented by $\hat{J}\in C^2(I,\mathcal{L}^2)\cap C^1(I,\mathcal{R})$ with $\hat{J}(T)\in\overset{0}{\mathcal{R}}$, then $(E(T),H(T))\in D(A)$.

3. Hodge–Helmholtz decompositions. Results on exact controllability are related to the topological nature of Ω via Hodge–Helmholtz decompositions. Furthermore, there are also some decompositions on $\partial\Omega$ which are needed to give a precise account of the space of controllable states. So in this section we shall provide these decompositions in classical terms. But as mentioned in the introduction, H. Weyl's generalization of the Maxwell system could be investigated in the same spirit. For references from the vast literature on this topic, see, e.g., [18], [19], or [6] and their references.

Here and in what follows, the symbols $\oplus$, $\ominus$, and $\perp$ indicate orthogonality in $\mathcal{L}^2$. We recall the following.

LEMMA 3.1 (Hodge–Helmholtz decomposition). *With $\mathcal{H}_D := \mathcal{R}_0\cap\mathcal{D}_0\cap\overset{0}{\mathcal{R}}$ and $\mathcal{H}_N := \mathcal{R}_0\cap\mathcal{D}_0\cap\overset{0}{\mathcal{D}}$ we have the following orthogonal decompositions:*

$$\mathcal{L}^2 = (\nabla\wedge\mathcal{R})\oplus\mathcal{H}_D\oplus(\nabla\overset{0}{H}{}^1) = \mathcal{D}_0\oplus(\nabla\overset{0}{H}{}^1), \tag{7}$$

$$\mathcal{L}^2 = (\nabla\wedge\overset{0}{\mathcal{R}})\oplus\mathcal{H}_N\oplus(\nabla H_1) = (\mathcal{D}_0\cap\overset{0}{\mathcal{D}})\oplus\nabla H_1. \tag{8}$$

Proof. Theorem 8.4 of [15] says that these decompositions hold in an arbitrary open set if we replace the intervening subspaces $\nabla\wedge\mathcal{R}$, etc. by their respective closures $\overline{\nabla\wedge\mathcal{R}}$, etc. However, if Ω enjoys the "Maxwell compactness property" (which is certainly true if $\partial\Omega$ is smooth [15, Thm. 8.6]), then $\nabla\wedge\mathcal{R} = \overline{\nabla\wedge\mathcal{R}}$, etc. (cf. [16]). □

Let us also mention that there are larger classes of (nonsmooth) regions for which this property holds [28], [26], [15], [30] and that Lemma 3.1 is a special case of a more general theory (cf., e.g., [25, section 5.9]).

The orthogonal projectors onto $\nabla\wedge\mathcal{R}$ and $\nabla\wedge\overset{0}{\mathcal{R}}$ will be denoted by P_D and P_N, respectively. They may be constructed by solving appropriate coercive boundary value problems which enjoy regularity properties (cf. [16]).

LEMMA 3.2. *The following boundary value problem is coercive:*

$$(P_D)\qquad \left.\begin{array}{l} \text{Find } v\in\mathcal{V}_D := (\nabla\wedge\overset{0}{\mathcal{R}})\cap\mathcal{R} \text{ such that} \\ \qquad\qquad \langle \operatorname{curl} v, \operatorname{curl}\varphi\rangle = \langle E, \operatorname{curl}\varphi\rangle \\ \text{for all } \varphi\in\mathcal{V}_D. \end{array}\right\}$$

Let

$$\begin{array}{rccc} G_D & : & \mathcal{L}^2 & \longrightarrow & \mathcal{V}_D, \\ & & E & \longmapsto & v \end{array}$$

denote its solution operator. Then $P_DE = \operatorname{curl} G_DE$.

The problem (P_D) has the regularity property: $E \in \mathcal{H}^k$ implies $G_D E \in \mathcal{H}^{k+1}$.

LEMMA 3.3. *The following boundary value problem is coercive:*

$$(P_N)\qquad \left.\begin{array}{l} \text{Find } w \in \mathcal{V}_N := (\nabla \wedge \mathcal{R}) \cap \overset{0}{\mathcal{R}} \text{ such that} \\ \qquad\qquad \langle \operatorname{curl} w, \operatorname{curl} \psi\rangle = \langle E, \operatorname{curl} \psi\rangle \\ \text{for all } \psi \in \mathcal{V}_N. \end{array}\right\}$$

Let

$$\begin{array}{rccc} G_N & : & \mathcal{L}^2 & \longrightarrow & \mathcal{V}_N, \\ & & E & \longmapsto & w \end{array}$$

denote its solution operator. Then $P_N E = \operatorname{curl} G_N E$.

The problem (P_N) has the regularity property: $E \in \mathcal{H}^k$ implies $G_N E \in \mathcal{H}^{k+1}$.

In order to obtain precise controllability results it is necessary to recall the construction and properties of the spaces $\mathcal{H}_D$ and $\mathcal{H}_N$ as well as to decompose ∇H^1 even further.

Standard elliptic theory (see, e.g., [25, Prop. 1.7]) shows the following.

LEMMA 3.4. *For $s \in [1/2, \infty)$ and $g \in H^s(\Gamma)$, define u as the solution of the Dirichlet problem $\Delta u = 0$, $\mathcal{T} u = g$. Then $u \in H^{s+1/2}$ and the operator $\hat{G}$ defined by*

$$\begin{array}{rccc} \hat{G} & : & H^s(\Gamma) & \longrightarrow & \mathcal{H}^{s-1/2} \cap \nabla H^1, \\ & & g & \longmapsto & \nabla u \end{array}$$

is continuous. Its null-space consists of $\operatorname{Lin}\{\mathbf{1}\}$*—the constant functions—and its range equals $\mathcal{H}^{s-1/2} \cap (\nabla H^1 \ominus \nabla \overset{0}{H}{}^1)$. Therefore, the operator*

$$\begin{array}{rccccc} G & : & \overset{\bullet}{H}{}^s(\Gamma) := \{u \in H^s(\Gamma) \colon \langle u, \mathbf{1}\rangle_\Gamma = 0\} & \longrightarrow & \mathcal{H}^{s-1/2} \cap (\nabla H^1 \ominus \nabla \overset{0}{H}{}^1), \\ & & g & \longmapsto & \nabla u \end{array}$$

is a topological isomorphism.

Let $K(\Gamma)$ denote the *locally* constant functions on Γ. Then $\mathcal{H}_D$ may be described in terms of G (cf. [16], [6]).

LEMMA 3.5. *We have $\mathcal{H}_D = G(K(\Gamma))$. More precisely (in the notation of Lemma* 3.4*),*

$$\begin{array}{rccc} G_0 & : & \overset{\bullet}{H}{}^s(\Gamma) \cap K(\Gamma) & \longrightarrow & \mathcal{H}_D, \\ & & g & \longmapsto & \nabla u \end{array}$$

is a topological isomorphism. Therefore, the space $\mathcal{H}_D$ of "Dirichlet fields" is finite-dimensional ($\dim \mathcal{H}_D = \beta_1$ *if there are $\beta_1 + 1$ connected components of Γ) and contained in $\mathcal{C}^\infty(\overline{\Omega})$.*

Similar results are known for $\mathcal{H}_N$. We only need the following lemma which may be deduced from [27, Thm. 2.2] (or cf. [9], [16], [6]).

LEMMA 3.6. *The space $\mathcal{H}_N$ of "Neumann fields" is finite-dimensional and contained in $\mathcal{C}^\infty(\overline{\Omega})$.*

REMARK 1. *There are elementary examples of regions Ω where $\mathcal{H}_D$ or $\mathcal{H}_N$ are nontrivial:*

(i) *If $\partial\Omega$ has two connected components Γ_0, Γ_1 (e.g., in the case of a spherical shell $\Omega := \{x \in \mathbb{R}^3 \colon 1 < |x| < 2\}$), then $\nabla u \in \mathcal{H}_D \setminus \{0\}$ if u is a solution to Dirichlet's boundary value problem for $\Delta u = 0$ with $u|_{\Gamma_0} = 0$ and $u|_{\Gamma_1} = 1$.*

(ii) *If Ω is invariant under rotations around the x_3-axis A and $A \cap \overline{\Omega} = \emptyset$, e.g., in the case of a torus*

$$\Omega := \left\{ x = \begin{bmatrix} x' \\ x_3 \end{bmatrix} \in \mathbb{R}^3 \colon \left| |x'|\, x - R x' \right| < r\, |x'| \right\}, \qquad 0 < r < R,$$

then $v \in \mathcal{H}_N \setminus \{0\}$ for

$$v(x) := (x_1^2 + x_2^2)^{-1} \begin{bmatrix} -x_2 \\ x_1 \\ 0 \end{bmatrix}.$$

These examples disprove the claims made in [13, *Thm.* 7.1], [14, *section* 2], [5, *section* 1.2], *and* [17, *section* 1].

DEFINITION 3.7. *For $\varphi \in C^\infty(\Gamma)$ we define the "surface gradient" $\nabla_o \varphi \in \mathcal{C}^\infty(\Gamma)$ by extending φ arbitrarily to some $\overset{\wedge}{\varphi} \in C^\infty(\mathbb{R}^3)$ and using the tangential components of $\nabla \overset{\wedge}{\varphi}$:*

$$\nabla_o \varphi := -\nu \wedge (\nu \wedge \nabla \overset{\wedge}{\varphi}).$$

The continuous extension of ∇_o to $H^1(\Gamma)$ will also be denoted by ∇_o and its adjoint (with respect to $\int_\Gamma \dots d\mathbf{o}$) by div_o.

REMARK 2. *Of course, both ∇_o and* div_o *may be defined intrinsically without reference to the embedding into $\mathbb{R}^3$. In fact, identifying scalar functions and tangential vector fields with differential forms of rank* 0 *and* 1, *respectively, we see that ∇_o and* div_o *correspond to the differential d and codifferential $*d*$.*

A compactness argument shows that $\nabla_o H^1(\Gamma)$ is closed in $\mathcal{L}^2(\Gamma)$. This proves the following lemma.

LEMMA 3.8. *With $\mathcal{D}_0(\Gamma) := \{U \in \mathcal{L}^2_\tau(\Gamma) \colon \operatorname{div}_o U = 0\}$ we have the following orthogonal decomposition:*

$$\mathcal{L}^2_\tau(\Gamma) = \mathcal{D}_0(\Gamma) \oplus \nabla_o H^1(\Gamma).$$

For $u \in H^t$ $(t > 3/2)$, we may define

$$\overset{\bullet}{\partial}\, u := \langle \mathcal{T} \nabla u,\, \nu \rangle \in H^{t-3/2}(\Gamma).$$

In particular,

$$\mathcal{Y} := \mathcal{Y}_s := \overset{\bullet}{H}{}^s(\Gamma) \cap \{\overset{\bullet}{\partial}\, u \colon \nabla u \in \mathcal{H}_D\}^\perp \qquad \text{(orthogonal complement in } L^2(\Gamma))$$

is a well-defined closed subspace of $\overset{\bullet}{H}{}^s(\Gamma)$ for $s \geq 0$.

LEMMA 3.9. *Let $s \in [\,1/2\,,\, \infty\,)$. Then*

$$\begin{array}{rccl} G_1 & : & \mathcal{Y}_s & \longrightarrow \quad \mathcal{X}_s := \mathcal{H}^{s-1/2} \cap \left(\nabla H^1 \ominus (\nabla \overset{0}{H}{}^1 \oplus \mathcal{H}_D) \right), \\ & & g & \longmapsto \qquad\qquad \nabla u \end{array}$$

is a topological isomorphism. In particular,

$$\nabla H^1 = \mathcal{X}_{1/2} \oplus \mathcal{H}_D \oplus \nabla \overset{0}{H}{}^1. \tag{9}$$

Proof. Let $g \in \overset{\bullet}{H}{}^s(\Gamma)$ and $c \in K(\Gamma)$ and define $\nabla v := Gg$ and $\nabla u := Gc$. By Green's formula,

$$\langle \nabla v, \nabla u \rangle = \langle g, \overset{\bullet}{\partial}\, u \rangle_\Gamma,$$

which implies (using Lemma 3.4)

$$G\mathcal{Y}_s \subset \mathcal{X}_s \quad \text{and} \quad G^{-1}\mathcal{X}_s \subset \mathcal{Y}_s$$

and thus our assertion. □

4. Boundary controllability. We now turn to the question of boundary controllability:

Given $(E^0, H^0), (E^1, H^1) \in \mathcal{L}^2 \times \mathcal{L}^2$ *and* $T \in \mathbb{R}^+$, *can we find* $J \in \mathcal{U}$ *such that* $(E(T), H(T)) = (E^1, H^1)$ *for the solution* (E, H) *of* $\mathcal{P}(E^0, H^0; J)$ *in* $I := [\,0\,,\,T\,]$*?*

If this is possible we say that "the state (E^0, H^0) can be steered into (E^1, H^1) in time T." In the special case $(E^1, H^1) = (0, 0)$ we say that "the state (E^0, H^0) can be steered to rest." It will be decisive for the analysis of this problem to decompose (E^0, H^0) according to the material of the preceding section. So we write

$$E^0 = \nabla \wedge D + \underline{U} + \underline{\nabla e}, \tag{10}$$

$$H^0 = \nabla \wedge B + W + \nabla v + \underline{V} + \underline{\nabla h} \tag{11}$$

with uniquely determined

$$D \in (\nabla \wedge \overset{0}{\mathcal{R}}) \cap \mathcal{R}, \quad U \in \mathcal{H}_D, \quad e \in \overset{0}{H}{}^1,$$
$$B \in (\nabla \wedge \mathcal{R}) \cap \overset{0}{\mathcal{R}}, \quad W \in \mathcal{H}_N$$

and (cf. Lemma 3.9)

$$\nabla v = Gg \subset \mathcal{X}_{1/2}(\Omega) \quad (g \in H^{1/2}(\Gamma)), \quad V \in \mathcal{H}_D, \quad h \in \overset{0}{H}{}^1.$$

We start with a negative answer.

THEOREM 4.1. *Let* $\hat{U} \in \mathcal{H}_D$. *Then* $\langle E, \hat{U} \rangle$ *and* $\langle H, \hat{U} \rangle$ *as well as* $\operatorname{div} E$ *and* $\operatorname{div} H$ *are not influenced by our boundary controls. More precisely: Let* $J \in \mathcal{U}$ *and* $(E^0, H^0) \in \mathcal{L}^2 \times \mathcal{L}^2$. *Then, for all* t,

$$\langle E(t), \hat{U} \rangle = \langle E^0, \hat{U} \rangle,$$
$$\langle H(t), \hat{U} \rangle = \langle H^0, \hat{U} \rangle,$$
$$\operatorname{div} E(t) = \operatorname{div} E^0,$$
$$\operatorname{div} H(t) = \operatorname{div} H^0$$

for the solution (E, H) *to* $\mathcal{P}(E^0, H^0; J)$ *in* I.

In particular, no state (E^0, H^0) *for which any of the underlined components in* (10), (11) *is different from zero can be steered to rest in any time.*

Proof. The states $(\hat{U}, 0)$ and $(0, \hat{U})$ belong to $N(A)$. Therefore, by Lemma 2.3,

$$\langle E(t), \hat{U}\rangle - \langle E^0, \hat{U}\rangle = 0,$$
$$\langle H(t), \hat{U}\rangle - \langle H^0, \hat{U}\rangle = \int_0^t \int_\Gamma \langle J(s,y), \nu(y) \wedge (\nu(y) \wedge \hat{U}(y))\rangle d\mathbf{o}(y) ds.$$

But the integral vanishes because $\nu \wedge \hat{U} = 0$. This proves the first two assertions. The next two are proved analogously with the aid of Lemma 2.3 by looking at

$$(\nabla\varphi, 0), (0, \nabla\varphi) \in N(A) \quad \text{for} \quad \varphi \in C_0^\infty.$$

Finally, the negative conclusion follows from (10),(11) and Lemma 3.1. □

REMARK 3. *This result disproves previous claims in the literature which do not assume star-shapedness* [14, *section* 4.3], [17].

For a positive result it is necessary to require that the underlined components (which in what follows will be called "noncontrollable components") in (10), (11) should vanish. Furthermore, in order to keep the analytical efforts low, we require some additional regularity of the initial states. Thus we introduce the following spaces of states:

$$\mathcal{S}_2 := (\nabla \wedge \mathcal{R}) \times \left((\nabla \wedge \overset{0}{\mathcal{R}}) \oplus \mathcal{H}_N \oplus \mathcal{X}_{1/2}(\Omega) \right),$$
$$\mathcal{S}_1 := (\nabla \wedge \mathcal{R}) \times \left((\nabla \wedge \overset{0}{\mathcal{R}}) \oplus \mathcal{H}_N \right),$$
$$\mathcal{S}_0 := (\nabla \wedge \mathcal{R}) \times (\nabla \wedge \overset{0}{\mathcal{R}}),$$
$$\mathcal{S}_k^1 := \left(\mathcal{H}^1 \times \mathcal{H}^1\right) \cap \mathcal{S}_k, \quad k = 0, 1, 2,$$
$$\mathcal{S}_k^D := D(A) \cap \mathcal{S}_k^1, \quad k = 0, 1, 2.$$

We are ready to formulate our main result.

MAIN THEOREM. *Let $T > \operatorname{diam}(\Omega)$. Then each state in $\mathcal{S}_2^1$ can be steered to rest in time T. In particular, each divergence-free state can be steered to rest in time T if $\partial\Omega$ is connected.*

This will be proved in four steps: The initial state $(E^0, H^0) \in \mathcal{S}_2^1$ may not be an element of $D(A)$. First we show that it takes arbitrarily short time to steer it into a state which *is* in $\mathcal{S}_2^D$. In the second and third steps we remove extra components of H^0 by steering into $\mathcal{S}_1^D$ and then into $\mathcal{S}_0^D$, again in arbitrarily short time. Finally, granted time $T > \operatorname{diam}(\Omega)$, the resulting state $(E^0, H^0) \in \mathcal{S}_0^D$ may be steered to rest by using the trick invented by D. L. Russell for the wave equation.

THEOREM 4.2. *Each state $(E^0, H^0) \in \mathcal{S}_2^1$ may be steered into a state in $\mathcal{S}_2^D$ in arbitrarily short time.*

Proof. Given $T \in \mathbb{R}^+$ choose $\chi \in C^\infty(\mathbb{R})$ such that $\operatorname{supp}\chi \subset (-\infty, T)$ and $\chi(0) = 1$. Then

$$J(s,y) := \chi(s) \cdot \mathcal{T}_\tau E^0(y), \quad (s,y) \in M,$$

defines an element of $\mathcal{U}$. Furthermore, J is represented by $\hat{J} \in C^\infty(I, \mathcal{H}^1)$, where

$$\hat{J}(s,x) = \chi(s) \cdot E^0(x), \quad (s,x) \in Z.$$

For $t = T$, the components of the solution formula (3) either vanish by construction or belong to $D(A)$ by Lemmas 2.1 and 2.4. Furthermore, according to Theorem 4.1, no noncontrollable components have been introduced by this control process.

It remains to be shown that the state stays in $\mathcal{H}^1 \times \mathcal{H}^1$: From $E(T) \in \overset{0}{\mathcal{R}} \cap \mathcal{D}_0$ we obtain $E(T) \in \mathcal{H}^1$ [15, Thm. 8.6].

Concerning $H(T)$, we decompose

$$H^0 = \nabla \wedge B + V + \nabla h, \quad B \in \overset{0}{\mathcal{R}}, \quad V \in \mathcal{H}_N, \quad h \in H^1.$$

Lemma 3.3 shows that additionally $B \in \mathcal{H}^2$ and therefore $h \in H^2$ (because $V \in \mathcal{C}^\infty(\overline{\Omega})$ by Lemma 3.6). We apply Lemma 2.3 with $(\Phi^0, \Psi^0) := (0, \nabla\psi)$ and an arbitrary $\psi \in H^1$ to obtain

$$\langle H(T) - H^0, \nabla\psi\rangle = -\int_0^T \chi(s) \left(\int_\Gamma \langle \mathcal{T}_\tau E^0(y), \nabla\psi(y)\rangle d\mathbf{o}(y) \right) ds.$$

Assuming additionally—as we may—that $\int_0^T \chi(s)ds = 0$, we see that in the decomposition

$$H(T) = \nabla \wedge \tilde{B} + \tilde{V} + \nabla h, \quad \tilde{B} \in \overset{0}{\mathcal{R}}, \quad \tilde{V} \in \mathcal{H}_N,$$

the third component remains unchanged in $\mathcal{H}^1$, whereas the second is still in $\mathcal{C}^\infty(\overline{\Omega})$ by Lemma 3.6. The first belongs to $\mathcal{D}_0 \cap \overset{0}{\mathcal{D}}$ and also to $\mathcal{R}$ (because of $(E(T), H(T)) \in D(A)$). This implies $\nabla \wedge \tilde{B} \in \mathcal{H}^1$ (by the analogue of [15, Thm. 8.6] or cf. [9, Lem. 4.2 and section 8]) and hence $H(T) \in \mathcal{H}^1$. □

THEOREM 4.3. *Each state $(E^0, H^0) \in \mathcal{S}_2^D$ may be steered into a state in $\mathcal{S}_1^D$ in arbitrarily short time.*

Proof. We have

$$H^0 = \nabla \wedge B + W + X, \quad B \in \overset{0}{\mathcal{R}}, \quad W \in \mathcal{H}_N, \quad X = \nabla v \in \mathcal{X}_{1/2}.$$

The sesquilinear form

$$B(h, \varphi) := \langle \nabla_o h, \nabla_o \varphi\rangle_\Gamma$$

is continuous and positive semidefinite on $H^1(\Gamma)$ with null-space $K(\Gamma)$. Furthermore, $\mathcal{Y}_1$ and $K(\Gamma)$ are complementary closed subspaces of $H^1(\Gamma)$ by Lemmas 3.4, 3.5, and 3.9. A standard compactness argument (using the compact embedding of $\overset{\bullet}{H}{}^1(\Gamma)$ in $L^2(\Gamma)$) shows that B is strictly coercive on $\mathcal{Y}_1$. Therefore, the problem to find $h \in \mathcal{Y}_1$ such that

$$\langle \nabla_o h, \nabla_o \varphi\rangle_\Gamma = -\langle X, G\varphi\rangle \quad \text{for all} \quad \varphi \in \mathcal{Y}_1$$

is uniquely solvable. Lemma 3.4 shows that the right-hand side defines a continuous antilinear functional on $H^{1/2}(\Gamma)$ and thus may be considered as an element of $H^{-1/2}(\Gamma)$. Therefore, elliptic regularity theory tells us that the solution h belongs to $H^{3/2}(\Gamma)$ and thus to $\mathcal{Y}_{3/2}$. (In fact, a closer look using $H^0 \in \mathcal{H}^1$ would show that $h \in H^{5/2}(\Gamma)$.) Let $\chi \in C^\infty(\mathbb{R})$ with

$$\operatorname{supp}\chi \subset (\,0\,,\,T\,) \quad \text{and} \quad \int_0^T \chi(t)dt = 1.$$

Then

$$J(t,y) := -\chi(t)\nabla_o h(y), \quad (t,y) \in M,$$

defines an element of $\mathcal{U}$. By the trace theorem, we may extend $\nu \wedge \nabla_o h \in \mathcal{H}^{1/2}(\Gamma)$ to some $j \in \mathcal{H}^1$ such that J is represented by

$$\hat{J}(t,x) := \chi(t) j(x), \quad (t,x) \in Z,$$

which satisfies

$$\hat{J} \in C^\infty([\,0\,,\,T\,],\mathcal{R}), \quad \hat{J}(0,\cdot) = \hat{J}(T,\cdot) = 0. \tag{12}$$

Let (E,H) be the solution to $\mathcal{P}(E^0,H^0;J)$. Theorem 4.1 implies that $(E(T),H(T))$ does not contain any noncontrollable components and (12) and Lemma 2.4 show that $(E(T),H(T)) \in D(A)$.

Let us apply Lemma 2.3 with $(\Phi^0,\Psi^0) := (0,G\varphi)$,$\varphi \in \mathcal{Y}_{3/2}$ (hence $G\varphi \in \mathcal{H}^1$). We compute

$$\begin{aligned}
&\langle H(T),\, G\varphi\rangle \\
&\quad = \langle H^0,\, G\varphi\rangle + \int_0^T \chi(t)\langle \nabla_o h,\, \mathcal{T}G\varphi\rangle_\Gamma dt \\
&\quad = \langle X,\, G\varphi\rangle - \langle \nu\wedge(\nu\wedge\nabla_o h),\, \mathcal{T}G\varphi\rangle_\Gamma \\
&\quad = \langle X,\, G\varphi\rangle - \langle \nabla_o h,\, \nu\wedge(\nu\wedge\mathcal{T}G\varphi)\rangle_\Gamma \\
&\quad = \langle X,\, G\varphi\rangle + \langle \nabla_o h,\, \nabla_o\varphi\rangle_\Gamma = 0.
\end{aligned}$$

We conclude (using Lemma 3.9 as well as the fact that $\mathcal{Y}_{3/2}$ is dense in $\mathcal{Y}_{1/2}$)

$$H(T) = \nabla\wedge\tilde{B} + \tilde{W} \in \mathcal{R}, \quad \tilde{B} \in \overset{0}{\mathcal{R}}, \quad \tilde{W} \in \mathcal{H}_N.$$

Thus $H(T) \in \mathcal{H}^1$ from Lemma 3.6 and [27, Thm. 2.2] and $(E(T),H(T)) \in \mathcal{S}_1^D$. ∎

THEOREM 4.4. *Each state $(E^0,H^0) \in \mathcal{S}_1^D$ may be steered into a state in $\mathcal{S}_0^D$ in arbitrarily short time by a control $J \in \mathcal{C}_\tau^\infty(\Gamma)$.*

Proof. Let π denote the orthogonal projector in $\mathcal{L}_\tau^2(\Gamma)$ onto $\mathcal{D}_0(\Gamma)$ along $\nabla_o H^1(\Gamma)$. Then

$$\sigma(V,W) := \langle \pi\mathcal{T}V,\, \pi\mathcal{T}W\rangle_\Gamma$$

is a true scalar product on $\mathcal{H}_N$. Namely, if $\pi\mathcal{T}V = 0$, then we have

$$\mathcal{T}V = \nabla_o g, \quad g \in C^\infty(\Gamma).$$

We solve Dirichlet's problem

$$\Delta u = 0, \quad u|_\Gamma = g$$

and find by direct computation

$$V - \nabla u \in \mathcal{H}_D.$$

Therefore, Lemma 3.5 implies $V \in \nabla H^1$ and thus $V = 0$ by Lemma 3.1.

So we can choose a basis $\{W_k\colon\ k=1,\dots,\beta_2\}$ of $\mathcal{H}_N$ which is orthonormal with respect to σ. We choose the control $J\in\mathcal{C}^\infty_\tau(M)$ defined by

$$J(t,y):=\chi(t)\cdot\sum_{k=1}^{\beta_2}\langle H^0,\,W_k\rangle\pi\mathcal{T}W_k(y),\qquad (t,y)\in M,$$

with χ as in the preceding proof and denote the solution to $\mathcal{P}(E^0,H^0;J)$ by (E,H). Again (by Theorem 4.1 and Lemma 2.4) no noncontrollable components are introduced and $(E(T),H(T))\in D(A)$. So $(E(T),H(T))\in\mathcal{S}_0^D$ as desired if we can show (recalling Lemma 3.9 and the regularity result [27, Thm. 2.2])

$$\langle H(T),\,W_l\rangle=0\quad\text{for all}\quad l\in\{1,\dots,\beta_2\},\tag{13}$$

$$\langle H(T),\,G\varphi\rangle=0\quad\text{for all}\quad \varphi\in\mathcal{Y}_{3/2}.\tag{14}$$

For (13) we apply Lemma 2.3 with $(\Phi^0,\Psi^0):=(0,W_l)$ and compute

$$\begin{aligned}&\langle H(T)-H^0,\,W_l\rangle\\&\quad=-\sum_k\langle H^0,\,W_k\rangle\langle\pi\mathcal{T}W_k,\,\mathcal{T}W_l\rangle_\Gamma\\&\quad=-\sum_k\langle H^0,\,W_k\rangle\langle\pi\mathcal{T}W_k,\,\pi\mathcal{T}W_l\rangle_\Gamma=-\langle H^0,\,W_l\rangle.\end{aligned}$$

For (14) we use Lemma 2.3 with $(\Phi^0,\Psi^0):=(0,G\varphi)$ and compute

$$\begin{aligned}&\langle H(T),\,G\varphi\rangle\\&\quad=\langle H^0,\,G\varphi\rangle-\sum_k\langle H^0,\,W_k\rangle\langle\pi\mathcal{T}W_k,\,\mathcal{T}G\varphi\rangle_\Gamma\\&\quad=0+\sum_k\langle H^0,\,W_k\rangle\langle\pi\mathcal{T}W_k,\,\nu\wedge(\nu\wedge\mathcal{T}G\varphi)\rangle_\Gamma\\&\quad=-\sum_k\langle H^0,\,W_k\rangle\langle\pi\mathcal{T}W_k,\,\nabla_o\varphi\rangle_\Gamma=0\end{aligned}$$

because $\pi\mathcal{T}W_k\in\big(\nabla_oH^1(\Gamma)\big)^\perp$. □

THEOREM 4.5. *Let $T>\operatorname{diam}(\Omega)$ and $I:=[\,0\,,\,T\,]$. Then each $(E^0,H^0)\in\mathcal{S}_0^D$ can be steered to rest in time T by a control $J\in C^0(I,\mathcal{H}_\tau^{1/2}(\Gamma))\cap\mathcal{U}$.*

Proof. We have

$$(E^0,H^0)=(\nabla\wedge D,\nabla\wedge B)\in\mathcal{H}^1\times\mathcal{H}^1,\qquad (D,B)\in\mathcal{R}\times\overset{0}{\mathcal{R}},$$

and additionally (in view of Lemmas 3.2 and 3.3) $D,B\in\mathcal{H}^2$. We use Calderon's extension theorem to extend D,B to $\hat{D},\hat{B}\in\mathcal{H}^2(\mathbb{R}^3)$ and with a cutoff technique we may assume that $\hat{D}$, $\hat{B}$ are supported in

$$\Omega_\rho:=\Omega+U(0,\rho),\qquad \rho:=T-\operatorname{diam}(\Omega).$$

Let $(\hat{E},\hat{H})$ be the solution of the Cauchy problem

$$\left.\begin{aligned}\partial_t\hat{E}&=+\nabla_x\wedge\hat{H}\\ \partial_t\hat{H}&=-\nabla_x\wedge\hat{E}\end{aligned}\right\}\quad\text{in}\quad[\,0\,,\,\infty\,)\times\mathbb{R}^3,$$

$$(\hat{E}(0,\cdot),\hat{H}(0,\cdot))=(\nabla\wedge\hat{D},\nabla\wedge\hat{B}).$$

We have $\operatorname{div} E(t,\cdot) = 0$ because $\operatorname{div} E(0,\cdot) = 0$. Using $\Delta = -\mathrm{curlcurl} + \nabla\mathrm{div}$, we may look upon $\hat{E}$ as the solution to a Cauchy problem for the wave equation:

$$\begin{aligned} \partial_t^2 \hat{E} - \Delta_x \hat{E} &= 0, \\ \hat{E}(0,\cdot) &= \nabla\wedge \hat{D} \in \mathcal{H}^1, \\ \partial_t \hat{E}(0,\cdot) &= \nabla \wedge (\nabla\wedge \hat{B}) \in \mathcal{H}^0. \end{aligned}$$

The regularity of the initial data implies that $\hat{E}$ is a "solution with finite energy" (cf. [31, p. 20]) and therefore $\hat{E} \in C^0([\,0\,,\infty\,), \mathcal{H}^1(\mathbb{R}^3)) \cap \mathcal{H}^1(Z)$. An application of the trace theorem shows

$$J := \mathcal{T}_\tau \hat{E} \in C^0(I, \mathcal{H}^{1/2}(\Gamma)) \cap \mathcal{U}.$$

Furthermore, by Huygens' principle [15, section 5.3],

$$\operatorname{supp}(\hat{E}(T,\cdot), \hat{H}(T,\cdot)) \cap \Omega = \emptyset.$$

Restricting everything to $[\,0\,,T\,] \times \overline{\Omega}$ shows that J steers (E^0, H^0) into rest. □

REMARK 4. *Replacing the trace theorem by the more sophisticated regularity result of* [24] *would enable us to work with controls in the space* $\mathcal{H}_\tau^{3/4}$.

REMARK 5. *Consider the class of regions* Ω *for which there exists an open segment*

$$S := \{\hat{x} + \tau p\colon\ \tau \in (\,0\,,L\,)\}, \quad \hat{x} \in \overline{\Omega}, \quad p \in S^2,$$

such that $S \subset \Omega$ *and length*$(S) = L = \operatorname{diam}\Omega$. *Then one can show that our Main Theorem is almost optimal in the sense that for* $T < \operatorname{diam}(\Omega)$, *even in* $\mathcal{S}_0^D$ *there are states which cannot be steered to rest in time* T. *This may be shown using the argument of* [7, *Thm.* 2.1] *and the sequence* u_k *from* [2, *Thm.* 3.2] *on a ray* $\gamma \subset [\,0\,,T\,] \times \Omega$ *corresponding to* S. *Namely, defining*

$$W_k := \nabla_x \wedge \begin{bmatrix} u_k \\ 0 \\ 0 \end{bmatrix}, \quad E_k := \nabla_x \wedge W_k, \quad H_k := \partial_t W_k$$

yields a sequence which contradicts exact controllability of $\mathcal{S}_0^D$.

REMARK 6. *Our results show that more precise topological criteria ("Betti numbers") rather than star-shapedness decide about null-controllability of divergence-free states. In the case of Remark* 1(i) *("spherical shell") the initial state* $(\nabla u, 0)$ *is not null-controllable whereas in case* (ii) *("torus") each divergence-free initial state is null-controllable because for this region* $\mathcal{H}_D = \{0\}$.

REMARK 7. *Our methods also allow us to obtain "partial controllability" results for problems where the control* J *is only allowed to be supported on part of the boundary (cf.* [21], [2], [17]*).*

FINITE-TIME STABILITY OF CONTINUOUS AUTONOMOUS SYSTEMS*

SANJAY P. BHAT† AND DENNIS S. BERNSTEIN‡

Abstract. Finite-time stability is defined for equilibria of continuous but non-Lipschitzian autonomous systems. Continuity, Lipschitz continuity, and Hölder continuity of the settling-time function are studied and illustrated with several examples. Lyapunov and converse Lyapunov results involving scalar differential inequalities are given for finite-time stability. It is shown that the regularity properties of the Lyapunov function and those of the settling-time function are related. Consequently, converse Lyapunov results can only assure the existence of continuous Lyapunov functions. Finally, the sensitivity of finite-time-stable systems to perturbations is investigated.

Key words. stability, finite-time stability, non-Lipschitzian dynamics

1. Introduction.

The object of this paper is to provide a rigorous foundation for the theory of finite-time stability of continuous autonomous systems and motivate a closer examination of finite-time stability as a possible objective in control design.

Classical optimal control theory provides several examples of systems that exhibit convergence to the equilibrium in finite time [17]. A well-known example is the double integrator with bang-bang time-optimal feedback control [2]. These examples typically involve dynamics that are discontinuous. Discontinuous dynamics, besides making a rigorous analysis difficult (see [9]), may also lead to chattering [10] or excite high frequency dynamics in applications involving flexible structures. Reference [8] considers finite-time stabilization using time-varying feedback controllers. However, it is well known that the stability analysis of time-varying systems is more complicated than that of autonomous systems. Therefore, with simplicity as well as applications in mind, we focus on continuous autonomous systems.

Finite-settling-time behavior of systems with continuous dynamics is considered in [3], [4], [11], [19], [21]. However, a detailed analysis of such systems has not been carried out. In particular, a precise formulation of finite-time stability is lacking, while little is known about the settling-time function. Furthermore, while references [3], [4], [11], [19] present Lyapunov conditions for finite-time stability, neither rigorous proofs nor converse results can be found. Reference [21] suggests, based on a scalar example, that systems with finite-settling-time dynamics possess better disturbance rejection and robustness properties. However, no precise results exist for multidimensional systems. This paper attempts to fill these gaps.

In section 2, we define finite-time stability for equilibria of continuous autonomous systems that have unique solutions in forward time. Continuity and forward uniqueness render the solutions continuous functions of the initial conditions, so that the

solutions define a continuous semiflow on the state space. Uniqueness also makes it possible to define the settling-time function. Certain useful properties of the settling time function are established. It is shown by example that it is possible for the settling time to be unbounded in every neighborhood of the origin even if all solutions converge to the origin in finite time. A different example shows that the settling-time function may be continuous without being Hölder continuous at the origin.

In section 3 we define finite-time repellers (called terminal repellers in [7], [23]), which are a special class of unstable equilibria that arise only in non-Lipschitzian systems. We show that a system having a finite-time repeller possesses multiple solutions starting at the finite-time repeller.

In section 4, we give a Lyapunov theorem for finite-time stability. Dini derivatives are used since Lyapunov functions are assumed to be only continuous. A converse result is shown to hold under the assumption that the settling-time function is continuous. In general, the converse result cannot be strengthened in its conclusion regarding the regularity of the Lyapunov function; that is, a system with a finite-time-stable equilibrium may not admit a Hölder continuous Lyapunov function. This is because Hölder continuity of the Lyapunov function necessarily implies Hölder continuity of the settling-time function at the origin. On the other hand, as mentioned above, there exist finite-time-stable systems with settling-time functions that are not Hölder continuous at the origin.

The existence of a Hölder continuous Lyapunov function assumes importance in section 5 where we investigate the sensitivity of stability properties to perturbations of systems with a finite-time-stable equilibrium under the assumption of the existence of a Lipschitz continuous Lyapunov function. Both persistent and vanishing perturbations are considered. It is shown that under certain conditions, finite-time-stable systems may exhibit better rejection of bounded persistent disturbances than Lipschitzian exponentially stable systems. It is also shown that finite-time stability is preserved under perturbations that are Lipschitz in the state.

2. Finite-time stability. Let $\|\cdot\|$ denote a norm on $\mathbb{R}^n$. The notions of openness, convergence, continuity, and compactness that we use refer to the topology generated on $\mathbb{R}^n$ by the norm $\|\cdot\|$. We use $\overline{\mathbb{R}}$, $\mathbb{R}_+$, and $\overline{\mathbb{R}}_+$ to denote the extended, nonnegative, and extended nonnegative, real numbers, respectively. We also use $\overline{\mathcal{A}}$ and $\operatorname{bd}\mathcal{A}$ to denote the closure and the boundary of the set $\mathcal{A}$, respectively. We will call a set $\mathcal{A} \subset \mathbb{R}^n$ bounded if $\overline{\mathcal{A}}$ is compact. Finally, we denote the composition of two functions $U : \mathcal{A} \to \mathcal{B}$ and $V : \mathcal{B} \to \mathcal{C}$ by $V \circ U : \mathcal{A} \to \mathcal{C}$.

Consider the system of differential equations

$$\dot{y}(t) = f(y(t)), \tag{2.1}$$

where $f\colon \mathcal{D} \to \mathbb{R}^n$ is continuous on an open neighborhood $\mathcal{D} \subseteq \mathbb{R}^n$ of the origin and $f(0) = 0$. A continuously differentiable function $y\colon I \to \mathcal{D}$ is said to be a *solution* of (2.1) on the interval $I \subset \mathbb{R}$ if y satisfies (2.1) for all $t \in I$. The continuity of f implies that, for every $x \in \mathcal{D}$, there exist $\tau_0 < 0 < \tau_1$ and a solution $y(\cdot)$ of (2.1) defined on (τ_0, τ_1) such that $y(0) = x$ [12, Thm. I.1.1]. A solution y is said to be *right maximally defined* if y cannot be extended on the right (either uniquely or nonuniquely) to a solution of (2.1). Every solution of (2.1) has an extension that is right maximally defined [12, Thm. I.2.1]. For later use, we state the following result on bounded solutions of (2.1). For a proof, see [12, pp. 17–18] or [22, Thm. 3.3, p. 12].

PROPOSITION 2.1. *If $y : [0, \tau) \to \mathcal{D}$ is a right maximally defined solution of* (2.1) *such that $y(t) \in \mathcal{K}$ for all $t \in [0, \tau)$, where $\overline{\mathcal{K}} \subset \mathcal{D}$ is compact, then $\tau = \infty$.*

We will assume that (2.1) possesses unique solutions in forward time for all initial conditions except possibly the origin in the following sense: for every $x \in \mathcal{D}\backslash\{0\}$ there exists $\tau_x > 0$ such that, if $y_1 : [0, \tau_1) \to \mathcal{D}$ and $y_2 : [0, \tau_2) \to \mathcal{D}$ are two right maximally defined solutions of (2.1) with $y_1(0) = y_2(0) = x$, then $\tau_x \leq \min\{\tau_1, \tau_2\}$ and $y_1(t) = y_2(t)$ for all $t \in [0, \tau_x)$. Without any loss of generality, we may assume that for each x, τ_x is chosen to be the largest such number in $\overline{\mathbb{R}}_+$. In this case, we denote by $\psi(\cdot, x)$ or, alternatively, $\psi^x(\cdot)$ the unique solution of (2.1) on $[0, \tau_x)$ satisfying $\psi(0, x) = x$. Note that ψ^x cannot be extended on the right uniquely to a solution of (2.1) because if $\tau_x < \infty$, then as $t \to \tau_x$, either $\psi(t, x)$ approaches bd $\mathcal{D}$ [12, Thm. I.2.1], in which case ψ^x cannot be extended on the right to a solution of (2.1), or $\psi(t, x)$ approaches 0 with (2.1) having nonunique solutions starting at 0, in which case ψ^x can be extended on the right to a solution of (2.1) in more than one way. If (2.1) has nonunique solutions in forward time for the initial condition 0, then ψ is defined on a relatively open subset of $\mathbb{R}_+ \times \mathcal{D}\backslash\{0\}$ onto $\mathcal{D}\backslash\{0\}$. If (2.1) possesses a unique solution in forward time for the initial condition 0, then ψ is defined on a relatively open subset of $\mathbb{R}_+ \times \mathcal{D}$ onto $\mathcal{D}$ and for each $x \in \mathcal{D}$, $\psi^x : [0, \tau_x) \to \mathcal{D}$ is the unique right maximally defined solution of (2.1) for the initial condition x. Uniqueness in forward time and the continuity of f imply that ψ is continuous on its domain of definition [12, Thm. I.3.4] and defines a *local semiflow* [6], [20, Ch. 2] on $\mathcal{D}\backslash\{0\}$ or $\mathcal{D}$, as the case may be. Various sufficient conditions for forward uniqueness in the absence of Lipschitz continuity can be found in [1], [9, sect. 10], [14], [22, sect. 1].

DEFINITION 2.2. *The origin is said to be a* finite-time-stable equilibrium *of* (2.1) *if there exists an open neighborhood $\mathcal{N} \subseteq \mathcal{D}$ of the origin and a function $T\colon \mathcal{N}\backslash\{0\} \to (0, \infty)$, called the* settling-time function*, such that the following statements hold:*

(i) *Finite-time convergence: For every $x \in \mathcal{N}\backslash\{0\}$, ψ^x is defined on $[0, T(x))$, $\psi^x(t) \in \mathcal{N}\backslash\{0\}$ for all $t \in [0, T(x))$, and $\lim_{t\to T(x)} \psi^x(t) = 0$.*

(ii) *Lyapunov stability: For every open neighborhood $\mathcal{U}_\varepsilon$ of 0 there exists an open subset $\mathcal{U}_\delta$ of $\mathcal{N}$ containing 0 such that, for every $x \in \mathcal{U}_\delta\backslash\{0\}$, $\psi^x(t) \in \mathcal{U}_\varepsilon$ for all $t \in [0, T(x))$.*

The origin is said to be a globally finite-time-stable equilibrium *if it is a finite-time-stable equilibrium with $\mathcal{D} = \mathcal{N} = \mathbb{R}^n$.*

The following proposition shows that if the origin is a finite-time-stable equilibrium of (2.1), then (2.1) has a unique solution on $\mathbb{R}_+$ for every initial condition in an open neighborhood of 0, including 0 itself.

PROPOSITION 2.3. *Suppose the origin is a finite-time-stable equilibrium of* (2.1). *Let $\mathcal{N} \subseteq \mathcal{D}$ and let $T : \mathcal{N}\backslash\{0\} \to (0, \infty)$ be as in Definition* 2.2. *Then, ψ is defined on $\mathbb{R}_+ \times \mathcal{N}$ and $\psi(t, x) = 0$ for all $t \geq T(x)$, $x \in \mathcal{N}$, where $T(0) \triangleq 0$.*

Proof. It can be shown that Lyapunov stability of the origin implies that $y \equiv 0$ is the unique solution y of (2.1) satisfying $y(0) = 0$. This proves that $\mathbb{R}_+ \times \{0\}$ is contained in the domain of definition of ψ and $\psi^0 \equiv 0$.

Now, let $\mathcal{N} \subseteq \mathcal{D}$ and T be as in Definition 2.2 and let $x \in \mathcal{N}\backslash\{0\}$. Define

$$\begin{aligned} y(t) &= \psi(t, x), \quad 0 \leq t < T(x), \\ &= 0, \qquad T(x) \leq t. \end{aligned} \tag{2.2}$$

By construction, y is continuously differentiable on $\mathbb{R}_+\backslash\{T(x)\}$ and satisfies (2.1) on $\mathbb{R}_+\backslash\{T(x)\}$. Also, it follows from the continuity of f that

$$\lim_{t\to T(x)^-} \dot{y}(t) = \lim_{t\to T(x)^-} f(y(t)) = 0 = \lim_{t\to T(x)^+} \dot{y}(t),$$

so that y is continuously differentiable at $T(x)$ and satisfies (2.1). Thus y is a solution of (2.1) on $\mathbb{R}_+$. To prove uniqueness, suppose z is a solution of (2.1) on $\mathbb{R}_+$ satisfying $z(0) = x$. Then by the uniqueness assumption, y and z agree on $[0, T(x))$. By continuity, y and z must also agree on $[0, T(x)]$ so that $z(T(x)) = 0$. Lyapunov stability now implies that $z(t) = 0$ for $t > T(x)$. This proves uniqueness. By the definition of ψ, it follows that $\psi^x \equiv y$. Thus ψ^x is defined on $\mathbb{R}_+$ and satisfies $\psi^x(t) = 0$ on $[T(x), \infty)$ for every $x \in \mathcal{N}$. This proves the result. □

Proposition 2.3 implies that if the origin is a finite-time-stable equilibrium of (2.1), then the solutions of (2.1) define a continuous *global semiflow* [20] on $\mathcal{N}$; that is, $\psi : \mathbb{R}_+ \times \mathcal{N} \to \mathcal{N}$ is a (jointly) continuous function satisfying

$$\psi(0, x) = x, \tag{2.3}$$

$$\psi(t, \psi(h, x)) = \psi(t + h, x) \tag{2.4}$$

for every $x \in \mathcal{N}$ and $t, h \in \mathbb{R}_+$. In addition, ψ satisfies

$$\psi(T(x) + t, x) = 0 \tag{2.5}$$

for all $x \in \mathcal{N}$ and $t \in \mathbb{R}_+$.

Proposition 2.3 also indicates that it is reasonable to extend T to all of $\mathcal{N}$ by defining $T(0) = 0$. With a slight abuse of terminology, we will also call this extension the *settling-time function*. It is easy to see from Definition 2.2 that, for all $x \in \mathcal{N}$,

$$T(x) = \inf\{t \in \mathbb{R}_+ : \psi(t, x) = 0\}. \tag{2.6}$$

To illustrate finite-time stability, as well as for later use, we consider a scalar system with a finite-time-stable equilibrium.

Example 2.1. The right-hand side of the scalar system

$$\dot{y}(t) = -k\operatorname{sign}(y(t))|y(t)|^\alpha, \tag{2.7}$$

where $\operatorname{sign}(0) = 0$, $k > 0$, and $\alpha \in (0, 1)$, is continuous everywhere and locally Lipschitz everywhere except the origin. Hence every initial condition in $\mathbb{R}\backslash\{0\}$ has a unique solution in forward time on a sufficiently small time interval. The global semiflow for (2.7) is easily obtained by direct integration as

$$\begin{aligned} \mu(t, x) &= \operatorname{sign}(x)\left[|x|^{1-\alpha} - k(1-\alpha)t\right]^{\frac{1}{1-\alpha}}, && t < \tfrac{1}{k(1-\alpha)}|x|^{1-\alpha}, && x \neq 0, \\ &= 0, && t \geq \tfrac{1}{k(1-\alpha)}|x|^{1-\alpha}, && x \neq 0, \\ &= 0, && t \geq 0, && x = 0. \end{aligned} \tag{2.8}$$

It is clear from (2.8) that (i) in Definition 2.2 is satisfied with $\mathcal{D} = \mathcal{N} = \mathbb{R}$ and the settling-time function $T : \mathbb{R} \to \mathbb{R}_+$ given by

$$T(x) = \frac{1}{k(1-\alpha)}|x|^{1-\alpha}. \tag{2.9}$$

Lyapunov stability follows by considering, for instance, the Lyapunov function $V(x) = x^2$. Thus the origin is a globally finite-time-stable equilibrium for (2.7). Note that T is Hölder continuous but not Lipschitz continuous at the origin.

The following proposition investigates the properties of the settling-time function of a finite-time-stable system.

PROPOSITION 2.4. *Suppose the origin is a finite-time-stable equilibrium of* (2.1). *Let $\mathcal{N} \subseteq \mathcal{D}$ be as in Definition* 2.2 *and let $T : \mathcal{N} \to \mathbb{R}_+$ be the settling-time function. Then the following statements hold.*

(i) *If $x \in \mathcal{N}$ and $t \in \mathbb{R}_+$, then*

$$T(\psi(t,x)) = \max\{T(x) - t, 0\}. \tag{2.10}$$

(ii) *T is continuous on $\mathcal{N}$ if and only if T is continuous at 0.*

(iii) *For every $r > 0$, there exists an open neighborhood $\mathcal{U}_r \subset \mathcal{N}$ of 0 such that, for every $x \in \mathcal{U}_r \backslash \{0\}$,*

$$T(x) > r\|x\|. \tag{2.11}$$

Proof. (i) The result follows from (2.6), (2.4), and (2.5).

(ii) Necessity is immediate. To prove sufficiency, suppose that T is continuous at 0.

Let $z \in \mathcal{N}$ and consider a sequence $\{z_m\}$ in $\mathcal{N}$ that converges to z. Let $\tau^- = \liminf_{m\to\infty} T(z_m)$ and $\tau^+ = \limsup_{m\to\infty} T(z_m)$. Note that both τ^- and τ^+ are in $\overline{\mathbb{R}}_+$ and

$$\tau^- \le \tau^+. \tag{2.12}$$

Next, let $\{z_l^+\}$ be a subsequence of $\{z_m\}$ such that $T(z_l^+) \to \tau^+$ as $l \to \infty$. The sequence $\{(T(z), z_l^+)\}$ converges in $\mathbb{R}_+ \times \mathcal{N}$ to $(T(z), z)$. By continuity and equation (2.5), $\psi(T(z), z_l^+) \to \psi(T(z), z) = 0$ as $l \to \infty$. Since T is assumed to be continuous at 0, $T(\psi(T(z), z_l^+)) \to T(0) = 0$ as $l \to \infty$. Using (2.10) with $t = T(z)$ and $x = z_l^+$, we obtain $\max\{T(z_l^+) - T(z), 0\} \to 0$ as $l \to \infty$. Thus $\max\{\tau^+ - T(z), 0\} = 0$, that is,

$$\tau^+ \le T(z). \tag{2.13}$$

Now, let $\{z_l^-\}$ be a subsequence of $\{z_m\}$ such that $T(z_l^-) \to \tau^-$ as $l \to \infty$. It follows from (2.12) and (2.13) that $\tau^- \in \mathbb{R}_+$. Therefore, the sequence $\{(T(z_l^-), z_l^-)\}$ converges in $\mathbb{R}_+ \times \mathcal{N}$ to (τ^-, z). Since ψ is continuous, it follows that $\psi(T(z_l^-), z_l^-) \to \psi(\tau^-, z)$ as $l \to \infty$. Equation (2.5) implies that $\psi(T(z_l^-), z_l^-) = 0$ for each l. Hence $\psi(\tau^-, z) = 0$ and, by (2.6),

$$T(z) \le \tau^-. \tag{2.14}$$

From (2.12), (2.13), and (2.14) we conclude that $\tau^- = \tau^+ = T(z)$ and hence $T(z_m) \to T(z)$ as $m \to \infty$.

(iii) Let $r > 0$. The function $\|f(\cdot)\|$ is continuous on $\mathcal{D}$ and $f(0) = 0$ so that the set $\Omega_r = \left\{x \in \mathcal{N} : \|f(x)\| < \frac{1}{r}\right\}$ is open and contains 0. By Lyapunov stability, there exists an open set $\mathcal{U}_r$ such that $0 \in \mathcal{U}_r \subset \mathcal{N}$ and $\psi(t,x) \in \Omega_r$ for every $t \in \mathbb{R}_+$ and $x \in \mathcal{U}_r$. Letting $x \in \mathcal{U}_r \backslash \{0\}$, we have

$$0 = \psi(T(x), x) = x + \int_0^{T(x)} f(\psi(t,x))dt,$$

so that

$$\|x\| = \left\| - \int_0^{T(x)} f(\psi(t,x))dt \right\| \le \int_0^{T(x)} \|f(\psi(t,x))\|dt < \frac{T(x)}{r},$$

which proves the result. ∎

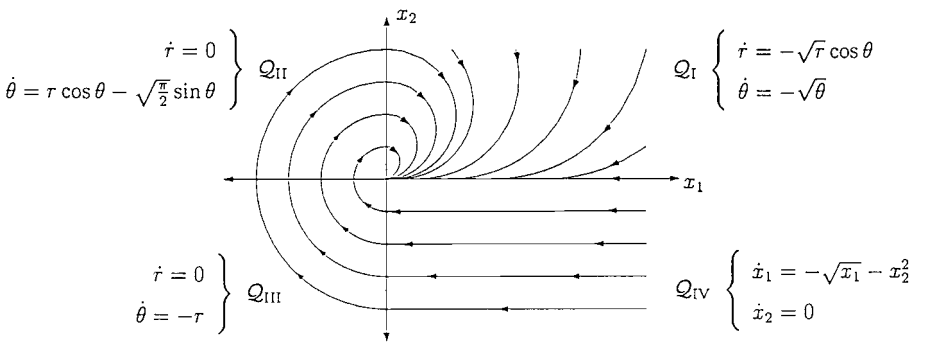

FIG. 2.1. *Finite-time stability with discontinuous settling-time function.*

Proposition 2.4 (ii) is significant because, in general, finite-time stability does not imply that the settling-time function T is continuous at the origin. Indeed, as the following example shows, the settling-time function can be unbounded in every neighborhood of the origin.

Example 2.2. Consider the system (2.1) where the vector field $f : \mathbb{R}^2 \to \mathbb{R}^2$ is defined on the quadrants

$$\begin{aligned} \mathcal{Q}_{\rm I} &= \{x \in \mathbb{R}^2 \backslash \{0\} : x_1 \geq 0, x_2 \geq 0\}, \quad \mathcal{Q}_{\rm II} = \{x \in \mathbb{R}^2 : x_1 < 0, x_2 \geq 0\}, \\ \mathcal{Q}_{\rm III} &= \{x \in \mathbb{R}^2 : x_1 \leq 0, x_2 < 0\}, \quad \mathcal{Q}_{\rm IV} = \{x \in \mathbb{R}^2 : x_1 > 0, x_2 < 0\}, \end{aligned}$$

as shown in Figure 2.1, with $f(0) = 0$, $r > 0$, $\theta \in [0, 2\pi)$, and $x = (x_1, x_2) = (r\cos\theta, r\sin\theta)$. It is easy to show that the vector field f is continuous on $\mathbb{R}^2$ and locally Lipschitz everywhere on $\mathbb{R}^2$ except on the positive x_1-axis, denoted by $\mathcal{X}_1^+$, the negative x_2-axis, denoted by $\mathcal{X}_2^-$, and the origin. Since the derivative of x_2^2 along the solutions of (2.1) is nonpositive in a sufficiently small neighborhood of every point $x \in \mathcal{X}_1^+$, every solution $y(\cdot)$ of (2.1) that satisfies $y(0) \in \mathcal{X}_1^+$ satisfies $y(t) \in \mathcal{X}_1^+$ for $t > 0$ sufficiently small, while on $\mathcal{X}_1^+$, f is simply given by $\dot{x}_1 = -\sqrt{x_1}$, $\dot{x}_2 = 0$ which is easily seen to have unique solutions for initial conditions in $\mathcal{X}_1^+$. In fact, by Example 2.1, solutions starting in $\mathcal{X}_1^+$ converge to the origin in finite time. The vector field f is also transversal to $\mathcal{X}_2^-$ at every point in $\mathcal{X}_2^-$. Hence it follows from [14, Prop. 2.2] or [9, Lem. 2, p. 107] that initial conditions in $\mathcal{X}_2^-$ possess unique solutions in forward time. Thus (2.1) possesses a unique solution in forward time for every initial condition in $\mathbb{R}^2 \backslash \{(0,0)\}$.

We show that the system given in Figure 2.1 has a globally finite-time-stable equilibrium at the origin and demonstrate a sequence $\{x_m\}$ in $\mathbb{R}^2$ such that $x_m \to 0$ and $T(x_m) \to \infty$, where T is the settling-time function.

Lyapunov stability of the origin is easily verified using the Lyapunov function $x_1^2 + x_2^2$. To show global finite-time convergence, we show that solutions starting in $\mathcal{Q}_{\rm IV}$ and $\mathcal{Q}_{\rm III} \cup \mathcal{Q}_{\rm II}$ enter $\mathcal{Q}_{\rm III}$ and $\mathcal{Q}_{\rm I}$, respectively, in a finite amount of time, while solutions starting in $\mathcal{Q}_{\rm I}$ converge to the origin in finite time.

On $\mathcal{Q}_{\rm IV}$, $\dot{x}_2 = 0$ and $\dot{x}_1 \leq -x_2^2 < 0$ so that after a finite amount of time (that depends on the initial condition) every solution starting in $\mathcal{Q}_{\rm IV}$ enters $\mathcal{Q}_{\rm III}$. Since $r\cos\theta - \sqrt{\frac{\pi}{2}}\sin\theta \leq \max\left\{-\sqrt{\frac{\pi}{2}}, -r\right\}$ for $r > 0$ and $\theta \in \left[\frac{\pi}{2}, \pi\right]$, it follows that $\dot{r} = 0$ and $\dot{\theta} \leq \max\left\{-\sqrt{\frac{\pi}{2}}, -r\right\} < 0$ on $\mathcal{Q}_{\rm III} \cup \mathcal{Q}_{\rm II}$ so that every solution starting in $\mathcal{Q}_{\rm III} \cup \mathcal{Q}_{\rm II}$ enters $\mathcal{Q}_{\rm I}$ after a finite amount of time. Now, $\mathcal{Q}_{\rm I}$ is positively invariant. Hence, if

a solution y starting in $\mathcal{Q}_{\mathrm{I}}$ does not converge to the origin for a sufficiently long time, then, since the scalar equation $\dot{\theta} = -\sqrt{\theta}$ has the origin as a finite-time-stable equilibrium by Example 2.1, y converges to $\mathcal{X}_1^+$ in finite time. We have already seen that solutions in $\mathcal{X}_1^+$ converge to the origin in finite-time. Thus the origin is a globally finite-time-stable equilibrium.

Now consider the sequence $\{x_m\}$, where $x_m = (x_{m1}, x_{m2}) = \left(0, -\frac{1}{m}\right)$, $m = 1, 2, \ldots$, in $\mathcal{X}_2^-$. Thus $\{x_m\}$ lies in $\mathcal{X}_2^-$ and $x_m \to 0$ as $m \to \infty$. Since $\dot{\theta} = -r$ on $\mathcal{Q}_{\mathrm{III}}$, for every m, the time taken by the solution y_m starting at x_m to enter $\mathcal{Q}_{\mathrm{II}}$ is equal to $\frac{\pi}{2\sqrt{x_{m1}^2 + x_{m2}^2}} = \frac{m\pi}{2}$. Since y_m must enter $\mathcal{Q}_{\mathrm{II}}$ before converging to the origin, it follows that $T(x_m) \geq \frac{m\pi}{2}$ for every m and hence $T(x_m) \to \infty$.

Proposition 2.4 (iii), which is equivalent to the statement that $\frac{\|x\|}{T(x)} \to 0$ as $x \to 0$, implies that the settling-time function is not Lipschitz continuous at the origin. This is consistent with Example 2.1 where the settling-time function is not Lipschitz continuous. However, as noted earlier, the settling-time function in Example 2.1 is Hölder continuous at the origin. In contrast, the following example shows that even if the settling-time function is continuous, it may not be Hölder continuous at the origin.

Example 2.3. Consider the system (2.1) with $\mathcal{D} = \{x \in \mathbb{R} : |x| < 1\}$ and $f : \mathcal{D} \to \mathbb{R}$ given by

$$\begin{aligned} f(x) &= -x(\ln|x|)^2, && x \in \mathcal{D}\backslash\{0\}, \\ &= 0, && x = 0. \end{aligned} \tag{2.15}$$

The system defined by (2.15) is continuous and has the global semiflow

$$\begin{aligned} \mu(t,x) &= \operatorname{sign}(x) e^{\frac{\ln|x|}{1+t\ln|x|}}, && t < -\tfrac{1}{\ln|x|}, && x \in \mathcal{D}\backslash\{0\}, \\ &= 0, && t \geq -\tfrac{1}{\ln|x|}, && x \in \mathcal{D}\backslash\{0\}, \\ &= 0, && t \geq 0, && x = 0. \end{aligned} \tag{2.16}$$

From the solution (2.16), it is clear that 0 is a finite-time-stable equilibrium in the neighborhood $\mathcal{N} = \mathcal{D}$ and the settling-time function, which is continuous, is given by

$$\begin{aligned} T(x) &= -\frac{1}{\ln|x|}, && x \in \mathcal{D}\backslash\{0\}, \\ &= 0, && x = 0. \end{aligned} \tag{2.17}$$

Since $\lim_{h\to 0^+} h^\gamma |\ln h| = 0$ for every $\gamma > 0$, it follows that for every $\gamma > 0$, $\frac{T(\cdot)}{|\cdot|^\gamma}$ is unbounded in every deleted neighborhood of 0. Thus T is not Hölder continuous at the origin.

3. Finite-time repellers. The results of this section do not depend upon the assumption of forward uniqueness.

If the origin is not Lyapunov stable, then there exists an open neighborhood $\mathcal{U}$ of the origin and solutions that start arbitrarily close to the origin and eventually leave $\mathcal{U}$. However, in the case of Lipschitzian dynamics, solutions are continuous in the initial condition over bounded time intervals so that solutions with initial conditions sufficiently close to the origin stay in $\mathcal{U}$ for arbitrarily large amounts of time. In the non-Lipschitzian case, where solutions need not be continuous in the initial condition even over a bounded time interval, it is natural to expect the existence of solutions that start arbitrarily close to the origin and yet leave a certain neighborhood in a fixed amount of time. We therefore have the following definition.

DEFINITION 3.1. *The origin is said to be a* finite-time repeller *if there exists a neighborhood* $\mathcal{U} \subset \mathcal{D}$ *of the origin and* $\tau > 0$ *such that, for every open neighborhood* $\mathcal{V} \subseteq \mathcal{U}$ *of the origin, there exists* $h \in (0, \tau]$ *and a solution* $y : [0, h] \to \mathcal{D}$ *of* (2.1) *such that* $y(0) \in \mathcal{V}$ *and* $y(h) \notin \mathcal{U}$. *The origin is said to be a* finite-time saddle *if the origin is a finite-time repeller in forward as well as reverse time.*

Definition 3.1 implies that solutions of (2.1) with initial conditions sufficiently close to a finite-time repeller do not depend continuously on the initial conditions over the bounded time interval $[0, \tau]$. In other words, a system is extremely sensitive to perturbations close to a finite-time repeller. As noted in section 2, under the assumption of uniqueness, solutions are continuous functions of the initial conditions and hence nonuniqueness is necessary for the existence of a finite-time repeller. The following proposition gives the precise connection between nonuniqueness and finite-time repellers.

PROPOSITION 3.2. *The origin is a finite-time repeller if and only if there exist more than one solution of* (2.1) *originating at the origin.*

Proof. Note that $z \equiv 0$ is a solution of (2.1) satisfying $z(0) = 0$. To prove sufficiency, suppose $y : [0, \tau] \to \mathcal{D}$, $\tau > 0$, is a solution of (2.1) such that $y(0) = 0$ and $y(\tau) \neq 0$. Then there exists an open set $\mathcal{U} \subset \mathcal{D}$ such that $0 \in \mathcal{U}$ and $y(\tau) \notin \mathcal{U}$. If $\mathcal{V} \subseteq \mathcal{U}$ is an open neighborhood of the origin, then $0 = y(0) \in \mathcal{V}$ and $y(h) \notin \mathcal{V}$ for $h = \tau$. Thus the origin is a finite-time repeller.

To prove necessity, suppose that the origin is a finite-time repeller and let $\mathcal{U}$ and τ be as in Definition 3.1. There exists a sequence $\{h_m\}$ of real numbers in $(0, \tau]$ and a sequence of solutions $y_m : [0, h_m] \to \mathcal{D}$ of (2.1) such that, $y_m(0) \to 0$ as $m \to \infty$ and $y_m(h_m) \notin \mathcal{U}$. Now suppose that $z \equiv 0$ is the unique solution of (2.1) satisfying $z(0) = 0$. Then there exists $N > 0$ such that for every $m > N$, y_m can be extended to a solution $\hat{y}_m$ of (2.1) defined on $[0, \tau]$ and $\hat{y}_m \to z$ uniformly on $[0, \tau]$ [12, Lem. I.3.1]. However, this contradicts the fact that, for every m, $h_m \in [0, \tau]$ and $\hat{y}_m(h_m) = y_m(h_m) \notin \mathcal{U}$. Hence we conclude that $z \equiv 0$ is not the unique solution of (2.1) satisfying $z(0) = 0$. □

Finite-time repellers are called terminal repellers in [7], [23] and some of the references therein. Reference [5] gives an example of a one-degree-of-freedom Lagrangian system having a finite-time saddle, while in [4] finite-time saddles arise in the controlled double integrator. Proposition 3.2 implies that a system exhibits spontaneous and unpredictable departure from an equilibrium state that is a finite-time repeller. This property of finite-time repellers was used in [5] as an example of indeterminacy in classical dynamics, while [23] and some of the references contained therein postulate finite-time repellers as models of irreversibility and unpredictability in complex systems. Finally, [7] proposed a fast global optimization algorithm which utilizes the tendency of solutions to rapidly escape from a neighborhood of a finite-time repeller.

Sections 3.25 and 3.26 in [1] contain sufficient conditions for (2.1) to possess multiple solutions with the initial value 0. In view of Proposition 3.2, these conditions can also be used to deduce whether the origin is a finite-time repeller. Therefore, sufficient Lyapunov conditions for the origin to be a finite-time repeller will not be considered in this paper.

4. Lyapunov theory. The upper right Dini derivative of a function $g : [a, b) \to \mathbb{R}$, $b > a$, is the function $D^+g : [a, b) \to \overline{\mathbb{R}}$ given by

$$(D^+g)(t) = \limsup_{h \to 0^+} \frac{1}{h}[g(t + h) - g(t)], \ t \in [a, b). \tag{4.1}$$

The function g is nonincreasing on $[a,b)$ if and only if $(D^+g)(t) \leq 0$ for all $t \in [a,b)$ [13, p. 84], [16, p. 347]. If g is differentiable at t, then $(D^+g)(t)$ is the ordinary derivative of g at t.

If the scalar differential equation $\dot{y}(t) = w(y(t))$ has the global semiflow $\mu : \mathbb{R}_+ \times \mathbb{R} \to \mathbb{R}$, where $w : \mathbb{R} \to \mathbb{R}$ is continuous, and $g : [a,b) \to \mathbb{R}$ is a continuous function such that $(D^+g)(t) \leq w(g(t))$ for all $t \in [a,b)$, then $g(t) \leq \mu(t, g(a))$ for all $t \in [a,b)$. Proofs and more general versions of this result, which is known as the comparison lemma, can be found in [13, sect. 5.2], [15, sect. 2.5], [16, Chap. IX], and [22, sect. 4]. The comparison lemma will be used along with the scalar system of Example 2.1 in the proofs of the main results of this section and the next.

The following lemma will prove useful in the rest of the development.

LEMMA 4.1. *Let $V : \mathcal{A} \to \mathbb{R}$ be a continuous function defined on the open set $\mathcal{A} \subseteq \mathbb{R}^n$. Let $\mathcal{B}$ be an open set such that $\overline{\mathcal{B}} \subset \mathcal{A}$, let $\Omega_\kappa = \{x \in \mathcal{B} : V(x) < \kappa\}$, where $\kappa < \inf_{z \in \text{bd } \mathcal{B}} V(z)$, and let $p : \mathbb{R} \to \mathbb{R}$ be a continuous function satisfying $p(\kappa) > 0$. If $y : [a,b) \to \mathcal{A}$ is a continuous function that satisfies $y(a) \in \overline{\Omega}_\kappa$ and satisfies*

$$(D^+(V \circ y))(t) \leq -p(V \circ y(t)) \tag{4.2}$$

for every $t \in [a,b)$ such that $y(t) \in \mathcal{B}$, then $y(t) \in \Omega_\kappa$ for all $t \in (a,b)$.

Proof. The assertion is vacuously true if Ω_κ is empty. Therefore, let $y : [a,b) \to \mathcal{A}$ be a continuous function satisfying the hypotheses in the statement of the lemma. Note that by the choice of κ and the continuity of V, bd $\Omega_\kappa \subseteq \{x \in \mathcal{B} : V(x) = \kappa\}$.

First suppose that $y(a) \in$ bd Ω_κ. Since p, V, and y are continuous and $p(V(y(a))) = p(\kappa) > 0$, it follows that there exists $s > 0$ such that $p(V(y(t))) > 0$ for all $t \in [a, a+s)$. Moreover, s may be chosen such that $y(t) \in \mathcal{B}$ for all $t \in [a, a+s)$. Equation (4.2) now implies that $V \circ y$ is strictly decreasing on $[a, a+s)$ so that $y(t) \in \Omega_\kappa$ for all $t \in (a, a+s)$.

Now suppose $y(h) \in \Omega_\kappa$ for some $h \in [a,b)$. If $y(t) \notin \Omega_\kappa$ for some $t \in [h,b)$, then, by continuity, there exists $\tau \in (h,b)$ such that $y(\tau) \in$ bd Ω_κ and $y(t) \in \Omega_\kappa$ for all $t \in [h,\tau)$. Therefore, y satisfies (4.2) on $[h,\tau)$. Since p, V, and y are continuous and $p(V(y(\tau))) = p(\kappa) > 0$, it follows that there exists $s > 0$ such that $p(V(y(t))) > 0$ for all $t \in [\tau - s, \tau)$. Equation (4.2) now implies that $V \circ y$ is nonincreasing on $[\tau - s, \tau)$ so that $\kappa = V(y(\tau)) \leq V(y(\tau - s)) < \kappa$, which is a contradiction. Hence we conclude that $y(t) \in \Omega_\kappa$ for all $t \in [h,b)$.

It follows from the above two facts that if $y(a) \in \overline{\Omega}_\kappa$, then $y(t) \in \Omega_\kappa$ for all $t \in (a,b)$. □

Given a continuous function $V : \mathcal{D} \to \mathbb{R}$, the upper-right Dini derivative of V along the solutions of (2.1) is a $\overline{\mathbb{R}}$-valued function $\dot{V}$ given by

$$\dot{V}(x) = (D^+(V \circ \psi^x))(0). \tag{4.3}$$

$\dot{V}(x)$ is defined for every $x \in \mathcal{D}$ for which ψ^x is defined. It is easy to see that $\dot{V}(0)$, if defined, is 0. Also, since ψ is a local semiflow, it can be shown that if $\psi^x(t)$ is defined, then

$$\dot{V}(\psi^x(t)) = (D^+(V \circ \psi^x))(t). \tag{4.4}$$

It can also be shown that if V is locally Lipschitz at $x \in \mathcal{D} \backslash \{0\}$, then [13, sect. 5.1], [16, p. 353], [22, p. 3]

$$\dot{V}(x) = \limsup_{h \to 0^+} \frac{1}{h}[V(x + hf(x)) - V(x)]. \tag{4.5}$$

If V is continuously differentiable on $\mathcal{D}\backslash\{0\}$, then (4.3) and (4.5) both yield the Lie derivative

$$\dot{V}(x) = \frac{d(V \circ \psi^x)}{dt}(0) = \frac{\partial V}{\partial x}(x) f(x), \ x \in \mathcal{D}\backslash\{0\}. \tag{4.6}$$

A function $V : \mathcal{D} \to \mathbb{R}$ is said to be *proper* if $V^{-1}(K)$ is compact for every compact set $K \subset \mathbb{R}$. Note that if $\mathcal{D} = \mathbb{R}^n$ and V is radially unbounded, then V is proper.

We are now ready to state the main result of this paper. Versions of this result have either appeared without proof or have been used implicitly in [3], [4], [11], [18], [19].

THEOREM 4.2. *Suppose there exists a continuous function $V\colon \mathcal{D} \to \mathbb{R}$ such that the following conditions hold:*

(i) *V is positive definite.*

(ii) *There exist real numbers $c > 0$ and $\alpha \in (0, 1)$ and an open neighborhood $\mathcal{V} \subseteq \mathcal{D}$ of the origin such that*

$$\dot{V}(x) + c(V(x))^\alpha \leq 0, \ x \in \mathcal{V}\backslash\{0\}. \tag{4.7}$$

Then the origin is a finite-time-stable equilibrium of (2.1). *Moreover, if $\mathcal{N}$ is as in Definition* 2.2 *and T is the settling-time function, then*

$$T(x) \leq \frac{1}{c(1-\alpha)} V(x)^{1-\alpha}, \ x \in \mathcal{N}, \tag{4.8}$$

and T is continuous on $\mathcal{N}$. If in addition $\mathcal{D} = \mathbb{R}^n$, V is proper, and $\dot{V}$ takes negative values on $\mathbb{R}^n\backslash\{0\}$, then the origin is a globally finite-time-stable equilibrium of (2.1).

Proof. Since V is positive definite and $\dot{V}$ takes negative values on $\mathcal{V}\backslash\{0\}$, it follows that $y \equiv 0$ is the unique solution of (2.1) on $\mathbb{R}_+$ satisfying $y(0) = 0$ [1, sect. 3.15] [22, Thm. 1.2, p. 5]. Thus every initial condition in $\mathcal{D}$ has a unique solution in forward time. Moreover, $\dot{V}(0) = 0$ and thus (4.7) holds on $\mathcal{V}$.

Let $\mathcal{U} \subseteq \mathcal{V}$ be a bounded open set such that $0 \in \mathcal{U}$ and $\overline{\mathcal{U}} \subset \mathcal{D}$. Then bd $\mathcal{U}$ is compact and $0 \notin$ bd $\mathcal{U}$. The continuous function V attains a minimum on bd $\mathcal{U}$ and by positive definiteness, $\min_{x \in \text{bd } \mathcal{U}} V(x) > 0$. Let $0 < \beta < \min_{x \in \text{bd } \mathcal{U}} V(x)$ and $\mathcal{N} = \{x \in \mathcal{U} : V(x) < \beta\}$. $\mathcal{N}$ is nonempty since $0 \in \mathcal{N}$, open since V is continuous, and bounded since $\mathcal{U}$ is bounded.

Now, consider $x \in \mathcal{N}$ and let c and α be as in the theorem statement above. By uniqueness, $\psi^x : [0, \tau_x) \to \mathcal{D}$ is the unique right maximally defined solution of (2.1) for the initial condition x. For every $t \in [0, \tau_x)$ such that $\psi^x(t) \in \mathcal{U}$, (4.4) and (4.7) yield

$$(D^+(V \circ \psi^x))(t) \leq -c(V \circ \psi^x(t))^\alpha. \tag{4.9}$$

Thus $y = \psi^x$ satisfies the hypotheses of Lemma 4.1 with $\mathcal{A} = \mathcal{D}$, $\mathcal{B} = \mathcal{U}$, $\kappa = \beta$, $\Omega_\kappa = \mathcal{N}$, and $p(h) = ch^\alpha$ for $h \in \mathbb{R}_+$. Therefore, by Lemma 4.1, $\psi^x(t) \in \mathcal{N}$ for all $t \in [0, \tau_x)$. Now ψ^x satisfies the hypotheses of Proposition 2.1 with $\mathcal{K} = \mathcal{N}$. Therefore, by Proposition 2.1, ψ^x is defined and satisfies (4.9) on $\mathbb{R}_+$. Thus $\psi : \mathbb{R}_+ \times \mathcal{N} \to \mathcal{N}$ is a continuous global semiflow satisfying (2.3) and (2.4).

Next, applying the comparison lemma to the differential inequality (4.9) and the scalar differential equation (2.7) yields

$$V(\psi(t, x)) \leq \mu(t, V(x)), \ t \in \mathbb{R}_+, \ x \in \mathcal{N}, \tag{4.10}$$

where μ is given by (2.8) with $k = c$. From (2.8), (4.10), and the positive-definiteness of V, we conclude that

$$\psi(t,x) = 0,\ t \geq \frac{1}{c(1-\alpha)}(V(x))^{1-\alpha},\ x \in \mathcal{N}. \tag{4.11}$$

Since $\psi(0,x) = x$ and ψ is continuous, $\inf\{t \in \mathbb{R}_+ : \psi(t,x) = 0\} > 0$ for $x \in \mathcal{N}\backslash\{0\}$. Also, it follows from (4.11) that $\inf\{t \in \mathbb{R}_+ : \psi(t,x) = 0\} < \infty$ for $x \in \mathcal{N}$. Define $T : \mathcal{N} \to \mathbb{R}_+$ by using (2.6). It is a simple matter to verify that T and $\mathcal{N}$ satisfy (i) of Definition 2.2 and thus T is the settling-time function on $\mathcal{N}$. Lyapunov stability follows by noting from (4.7) that $\dot{V}$ takes negative values on $\mathcal{V}\backslash\{0\}$. Equation (4.8) follows from (4.11) and (2.6). Equation (4.8) implies that T is continuous at the origin and hence, by Proposition 2.4, continuous on $\mathcal{N}$.

If $\mathcal{D} = \mathbb{R}^n$ and V is proper, then global finite-time-stability is proven in the same way that global asymptotic stability is proven using radially unbounded Lyapunov functions. See, for instance, [15, Thm. 3.2], [22, Thm. 11.5]. □

Remark 4.1. It is difficult to compute $\dot{V}$ by using (4.3) unless solutions to (2.1) are known. Thus, in practice, it will often be more convenient to apply Theorem 4.2 with a Lipschitz continuous or a continuously differentiable function V so that $\dot{V}$ is given by (4.5) or (4.6), respectively.

Theorem 4.2 implies that for a system with a finite-time-stable equilibrium and a discontinuous settling-time function, such as the system considered in Example 2.2, there does not exist a Lyapunov function satisfying the hypotheses of Theorem 4.2. In the case that the settling-time function is continuous, the following theorem provides a converse to the previous one.

THEOREM 4.3. *Suppose the origin is a finite-time-stable equilibrium of* (2.1) *and the settling-time function T is continuous at* 0. *Let $\mathcal{N}$ be as in Definition* 2.2 *and let $\alpha \in (0,1)$. Then there exists a continuous function $V : \mathcal{N} \to \mathbb{R}$ such that the following conditions are satisfied:*

(i) *V is positive definite.*

(ii) *$\dot{V}$ is real valued and continuous on $\mathcal{N}$ and there exists $c > 0$ such that*

$$\dot{V}(x) + c(V(x))^{\alpha} \leq 0,\ x \in \mathcal{N}.$$

Proof. By Proposition 2.4, the settling-time function $T\colon \mathcal{N} \to \mathbb{R}_+$ is continuous. Define $V : \mathcal{N} \to \mathbb{R}_+$ by $V(x) = (T(x))^{\frac{1}{1-\alpha}}$. Then V is continuous and positive definite and, by (2.5), $\dot{V}(0) = 0$. For $x \in \mathcal{N}\backslash\{0\}$, (2.10) implies that $V \circ \psi^x$ is continuously differentiable on $[0, T(x))$ so that (4.3) can be easily computed as $\dot{V}(x) = -\frac{1}{1-\alpha}(T(x))^{\frac{\alpha}{1-\alpha}} = -\frac{1}{1-\alpha}(V(x))^{\alpha}$. Thus $\dot{V}$ is real valued, continuous, and negative definite on $\mathcal{N}$ and satisfies $\dot{V}(x) + c(V(x))^{\alpha} = 0$ for all $x \in \mathcal{N}$ with $c = \frac{1}{1-\alpha}$. □

Equation (4.8) implies that if V in Theorem 4.2 is Hölder continuous at 0 then so is T. However, as shown by Example 2.3, the settling-time function need not be Hölder continuous at the origin. Thus the conclusion regarding the continuity of V in Theorem 4.3 cannot be strengthened to Hölder continuity. In particular, the scalar system considered in Example 2.3, where T is not Hölder continuous, does not admit a continuously differentiable or Lipschitz continuous Lyapunov function that satisfies the hypotheses of Theorem 4.2, since either Lipschitz continuity or differentiability implies Hölder continuity. As the next section shows, the existence of Lipschitz continuous Lyapunov functions is of importance in studying the behavior of finite-time-stable systems in the presence of perturbations.

5. Sensitivity to perturbations. In a realistic problem, (2.1) might represent a nominal model that is valid only under ideal conditions, while a more accurate description of the system might be provided by the perturbed model

$$\dot{y}(t) = f(y(t)) + g(t, y(t)), \tag{5.1}$$

where the perturbation term g results from disturbances, uncertainties, parameter variations, or modelling errors. In this section we investigate the sensitivity to perturbations of systems with a finite-time-stable equilibrium by studying the behavior of solutions of the perturbed system (5.1) in a neighborhood of the finite-time-stable equilibrium of the nominal system (2.1).

For simplicity, we consider only continuous perturbation terms $g : \mathbb{R}_+ \times \mathcal{D} \to \mathbb{R}^n$ so that the local existence of solutions of the perturbed system (5.1) is guaranteed. Right maximally defined solutions of (5.1) are defined as in section 2. We will need the following extension of Proposition 2.1 to time-varying systems. Proofs appear in [12, pp. 17–18], [22, Thm. 3.3, p. 12].

PROPOSITION 5.1. *If $y : [0, \tau) \to \mathcal{D}$ is a right maximally defined solution of* (5.1) *such that $y(t) \in \mathcal{K}$ for all $t \in [0, \tau)$, where $\overline{\mathcal{K}} \subset \mathcal{D}$ is compact, then $\tau = \infty$.*

If $y : [0, \tau) \to \mathcal{D}$ is a solution of (5.1) and $V : \mathcal{D} \to \mathbb{R}$ is Lipschitz continuous on $\mathcal{D}$ with Lipschitz constant M, then it can be shown that

$$(D^+(V \circ y))(t) \leq \dot{V}(y(t)) + M\|g(t, y(t))\|, \ t \in [0, \tau), \tag{5.2}$$

where $\dot{V}$ is computed along the solutions of the unperturbed system (2.1) using equation (4.3). See, for instance, the proof of Lemma X.5.1 in [12].

The following theorem concerns the behavior of finite-time-stable systems under bounded perturbations. Such perturbations, include, as a special case, bounded persistent disturbances of the form $g(t, y(t)) = v(t)$.

THEOREM 5.2. *Suppose there exists a function $V : \mathcal{D} \to \mathbb{R}$ such that V is positive definite and Lipschitz continuous on $\mathcal{D}$, and satisfies* (4.7), *where $\mathcal{V} \subseteq \mathcal{D}$ is an open neighborhood of the origin, $c > 0$ and $\alpha \in \left(0, \frac{1}{2}\right)$. Then there exist $\delta_0 > 0$, $l > 0$, $\Gamma > 0$, and an open neighborhood $\mathcal{U}$ of the origin such that, for every continuous function $g : \mathbb{R}_+ \times \mathcal{D} \to \mathbb{R}^n$ with*

$$\delta = \sup_{\mathbb{R}_+ \times \mathcal{D}} \|g(t, x)\| < \delta_0, \tag{5.3}$$

every right maximally defined solution y of (5.1) *with $y(0) \in \mathcal{U}$ is defined on $\mathbb{R}_+$ and satisfies $y(t) \in \mathcal{U}$ for all $t \in \mathbb{R}_+$ and*

$$\|y(t)\| \leq l\delta^\gamma, \ t \geq \Gamma, \tag{5.4}$$

where $\gamma = \frac{1-\alpha}{\alpha} > 1$.

Proof. By Theorem 4.2, the origin is a finite-time-stable equilibrium for (2.1). Let $\mathcal{N}$ be as in Definition 2.2 and let $T : \mathcal{N} \to \mathbb{R}^+$ be the settling-time function. By Proposition 2.4, there exists $r > 0$ and an open neighborhood $\mathcal{U}_r \subset \mathcal{N} \cap \mathcal{V}$ of 0 such that $T(x) \geq r\|x\|$ for $x \in \mathcal{U}_r$. Also, by Theorem 4.2, T satisfies (4.8). Without any loss of generality, we assume that $\overline{\mathcal{U}}_r$ is compact and $\overline{\mathcal{U}}_r \subset \mathcal{N} \cap \mathcal{V}$. Let $\mathcal{U} = \{x \in \mathcal{U}_r : V(x) < \beta\}$, where $0 < \beta < \min_{z \in \mathrm{bd}\ \mathcal{U}_r} V(z)$. Then $\mathcal{U}$ is nonempty, open, and bounded.

Let $M > 0$ be the Lipschitz constant of V and let $\delta_0 > 0$ satisfy $c\beta^\alpha - 2M\delta_0 > 0$. Suppose $g : \mathbb{R}_+ \times \mathcal{D} \to \mathbb{R}^n$ is a continuous function that satisfies (5.3) and consider a

right maximally defined solution $y : [0, \tau) \to \mathcal{D}$ of (5.1) with $x = y(0) \in \mathcal{U}$. Equations (4.7), (5.2), and (5.3) imply that for every $t \in [0, \tau)$ such that $y(t) \in \mathcal{U}_r$,

$$(D^+(V \circ y))(t) \leq -c(V(y(t)))^\alpha + M\delta. \tag{5.5}$$

Since $c\beta^\alpha - M\delta > c\beta^\alpha - 2M\delta > c\beta^\alpha - 2M\delta_0 > 0$, (5.5) implies that y satisfies the hypotheses of Lemma 4.1 with $\mathcal{A} = \mathcal{D}$, $\mathcal{B} = \mathcal{U}_r$, $\kappa = \beta$, $\Omega_\kappa = \mathcal{U}$, and $p(h) = ch^\alpha - M\delta$ for $h \in \mathbb{R}_+$. Therefore, Lemma 4.1 implies that $y(t) \in \mathcal{U}$ for $t \in [0, \tau)$. The right maximally defined solution y satisfies the hypotheses of Proposition 5.1 with $\mathcal{K} = \mathcal{U}$. Thus, by Proposition 5.1, y is defined on $\mathbb{R}_+$ and (5.5) holds on $\mathbb{R}_+$.

Now, let $\mathcal{W} = \{x \in \mathcal{U} : V(x) < (\frac{2M\delta}{c})^{\frac{1}{\alpha}}\}$. If $y(\tau) \in \overline{\mathcal{W}}$ for some $\tau > 0$, then (5.5) implies that y satisfies the hypotheses of Lemma 4.1 on $[\tau, \infty)$ with $\mathcal{A} = \mathcal{U}_r$, $\mathcal{B} = \mathcal{U}$, $\kappa = \left(\frac{2M\delta}{c}\right)^{\frac{1}{\alpha}}$, $\Omega_\kappa = \mathcal{W}$, and $p(h) = ch^\alpha - M\delta$ for $h \in \mathbb{R}_+$, and hence $y(t) \in \mathcal{W}$ for all $t > \tau$. Therefore, suppose $y(0) = x \notin \overline{\mathcal{W}}$ so that $y^{-1}(\mathcal{W})$, which is open by continuity, is of the form (t_x, ∞) with $t_x > 0$. Since $y(t) \notin \mathcal{W}$ for all $t \in [0, t_x]$, it follows that $V(y(t)) \geq \left(\frac{2M\delta}{c}\right)^{\frac{1}{\alpha}}$ for all $t \in [0, t_x]$. Equation (5.5) now implies that

$$(D^+(V \circ y))(t) \leq -\frac{1}{2}c(V(y(t)))^\alpha, \ t \in [0, t_x). \tag{5.6}$$

Applying the comparison principle to the differential inequality (5.6) and the scalar differential equation (2.7) we obtain

$$(V \circ y)(t) \leq \mu(t, V(x)), \ t \in [0, t_x), \tag{5.7}$$

where μ is given by (2.8) with $k = \frac{1}{2}c$. By continuity, the inequality (5.7) also holds for $t = t_x$. Since $V(y(t_x)) \geq \left(\frac{2M\delta}{c}\right)^{\frac{1}{\alpha}} > 0$, the comparison (5.7) yields $\mu(t_x, V(x)) > 0$. Equation (2.8) now gives $t_x < \frac{2}{c(1-\alpha)}(V(x))^{1-\alpha} < \frac{2}{c(1-\alpha)}\beta^{1-\alpha}$. Thus $V(y(t)) < \left(\frac{2M\delta}{c}\right)^{\frac{1}{\alpha}}$ for $t \geq \Gamma \triangleq \frac{2}{c(1-\alpha)}\beta^{1-\alpha}$. It now follows from (2.11) and (4.8) that for $t > \Gamma$,

$$\|y(t)\| \leq \frac{1}{rc(1-\alpha)}(V(y(t)))^{1-\alpha} \leq \frac{1}{rc(1-\alpha)}\left(\frac{2M\delta}{c}\right)^{\frac{1-\alpha}{\alpha}}.$$

Equation (5.4) now follows by choosing $l \triangleq \frac{1}{rc(1-\alpha)}\left(\frac{2M}{c}\right)^{\frac{1-\alpha}{\alpha}} > 0$. □

Note that in Theorem 4.3, α can be chosen to be arbitrarily small. Hence the requirement in Theorem 5.2 that α lie in $\left(0, \frac{1}{2}\right)$ is not restrictive. This choice of α leads to $\gamma > 1$ in (5.4) which implies that for δ in equation (5.3) sufficiently small, the ultimate bound (5.4) on the state is of higher order than the bound on the perturbation. In analogous theorems on exponential stability for Lipschitzian systems, α in equation (4.7) is at least 1 [15, Thm. 3.12], [22, Thm. 19.2] while γ in (5.4) is at most 1 [15, Lemma 5.2]. Thus for a Lipschitzian system with an exponentially stable equilibrium at the origin, the ultimate bound on the state can only be guaranteed to be of the same order of magnitude as the perturbation and not less. Consequently, finite-time stability of the origin leads to improved rejection of low-level persistent disturbances.

The following theorem deals with perturbations that are globally Lipschitz in the state variables uniformly in time. Such perturbations might represent model uncertainties.

THEOREM 5.3. *Suppose there exists a function $V : \mathcal{D} \to \mathbb{R}$ such that V is positive definite and Lipschitz continuous on $\mathcal{D}$, and satisfies* (4.7)*, where $\mathcal{V} \subseteq \mathcal{D}$ is an open neighborhood of the origin, $c > 0$ and $\alpha \in \left(0, \frac{1}{2}\right)$. Then, for every $L \geq 0$, there exists an open neighborhood $\mathcal{U}$ of the origin and $\Gamma > 0$ such that, for every continuous function $g : \mathbb{R}_+ \times \mathcal{D} \to \mathbb{R}^n$ satisfying*

$$\|g(t,x)\| \leq L\|x\|, \ (t,x) \in \mathbb{R}_+ \times \mathcal{D}, \tag{5.8}$$

every right maximally defined solution y of (5.1) *with $y(0) \in \mathcal{U}$ is defined on $\mathbb{R}_+$ and satisfies $y(t) \in \mathcal{U}$, for all $t \in \mathbb{R}_+$, and $y(t) = 0$ for all $t \geq \Gamma$.*

Proof. By Theorem 4.2, the origin is a finite-time-stable equilibrium for (2.1). Let $\mathcal{N}$ be as in Definition 2.2 and let $T : \mathcal{N} \to \mathbb{R}_+$ be the settling-time function. Fix $L \geq 0$ and let $r > 0$ be such that $c[r(1-\alpha)]^\alpha > (2ML)^{1-\alpha}$, where $M > 0$ is the Lipschitz constant of V. By Proposition 2.4, there exists an open set $\mathcal{U}_r \subset \mathcal{N} \cap \mathcal{V}$ such that $r\|x\| \leq T(x)$ for all $x \in \mathcal{U}_r$. Also, by Theorem 4.2, T satisfies (4.8). Without any loss of generality, we may assume that $\|x\| < 1$ for $x \in \mathcal{U}_r$ and $\overline{\mathcal{U}}_r \subset \mathcal{N} \cap \mathcal{V}$. Let $\mathcal{U} = \{x \in \mathcal{U}_r : V(x) < \beta\}$, where $0 < \beta < \min_{z \in \operatorname{bd} \mathcal{U}_r} V(z)$. Note that $\mathcal{U}$ is nonempty, open, and bounded. Also, $\frac{\alpha}{1-\alpha} < 1$ so that $\|x\| \leq \|x\|^{\frac{\alpha}{1-\alpha}}$ for $\|x\| < 1$. Therefore, (2.11) and (4.8) yield

$$2ML\|x\| \leq c[rc(1-\alpha)\|x\|]^{\frac{\alpha}{1-\alpha}} \leq c[c(1-\alpha)T(x)]^{\frac{\alpha}{1-\alpha}} \leq c(V(x))^\alpha, \ x \in \mathcal{U}_r. \tag{5.9}$$

Next, let $x \in \mathcal{U}$ and let $g : \mathbb{R}_+ \times \mathcal{D} \to \mathbb{R}^n$ be a continuous function satisfying (5.8). Consider a right maximally defined solution $y : [0, \tau) \to \mathcal{D}$ of (5.1) such that $y(0) = x$. For every $t \in [0, \tau)$ such that $y(t) \in \mathcal{U}_r$, (4.7), (5.2), and (5.8) yield

$$(D^+(V \circ y))(t) \leq -c(V \circ y(t))^\alpha + ML\|y(t)\|. \tag{5.10}$$

Using (5.9) in (5.10) we obtain

$$(D^+(V \circ y))(t) \leq -\frac{c}{2}(V \circ y(t))^\alpha, \ y(t) \in \mathcal{U}_r. \tag{5.11}$$

Lemma 4.1 now applies with $\mathcal{A} = \mathcal{D}$, $\mathcal{B} = \mathcal{U}_r$, $\kappa = \beta$, $\Omega_\kappa = \mathcal{U}$, and $p(h) = \frac{c}{2}h^\alpha$ for $h \in \mathbb{R}_+$ so that $y(t) \in \mathcal{U}$ for $t \in [0, \tau)$. The hypotheses of Proposition 5.1 are now satisfied by the right maximally defined solution y of (5.1) with $\mathcal{K} = \mathcal{U}$. Hence, by Proposition 5.1, $\tau = \infty$ and (5.11) holds on $\mathbb{R}_+$. Applying the comparison principle to the differential inequality (5.11) and the scalar differential equation (2.7) yields

$$(V \circ y)(t) \leq \mu(t, V(x)), \ t \in \mathbb{R}_+, \tag{5.12}$$

where μ is given by (2.8) with $k = \frac{1}{2}c$. Equation (2.8) and the inequality (5.12) imply that $y(t) = 0$ for $t \geq \Gamma \triangleq \frac{2\beta^{1-\alpha}}{c(1-\alpha)}$. ∎

The following theorem specializes Theorem 5.3 to time-invariant perturbations and shows that finite-time stability is preserved under Lipschitzian perturbations.

THEOREM 5.4. *Suppose there exists a function $V : \mathcal{D} \to \mathbb{R}$ such that V is positive definite and Lipschitz continuous on $\mathcal{D}$ and satisfies* (4.7)*, where $\mathcal{V} \subseteq \mathcal{D}$ is an open neighborhood of the origin, $c > 0$, and $\alpha \in \left(0, \frac{1}{2}\right)$. Let $g : \mathcal{D} \to \mathbb{R}^n$ be Lipschitz*

continuous on $\mathcal{D}$ and such that the differential equation

$$\dot{y}(t) = f(y(t)) + g(y(t)) \tag{5.13}$$

possesses unique solutions in forward time for initial conditions in $\mathcal{D}\backslash\{0\}$. Then the origin is a finite-time-stable equilibrium of (5.13).

Proof. Using steps similar to those used in deriving (5.11) above, it can be shown that $\dot{V}(x) \leq -\frac{c}{2}(V(x))^{\alpha}$ for all x in some open neighborhood of the origin, where $\dot{V}$ denotes the upper-right Dini derivative of V along the solutions of (5.13). Finite-time stability now follows from Theorem 4.2. □

The existence of a Lipschitz continuous function satisfying the hypotheses of Theorem 5.4 is sufficient but not necessary for the conclusions to hold. For instance, consider a scalar system of the form (5.13) where the nominal dynamics f are given by (2.15) in Example 2.3, and $g : \mathcal{D} \to \mathbb{R}$ is Lipschitz continuous on $\mathcal{D} = \{x \in \mathbb{R} : |x| < 1\}$ with Lipschitz constant L. As noted at the end of section 4, the nominal dynamics do not admit a Lipschitz continuous Lyapunov function satisfying the hypotheses of Theorem 5.4. However, the origin is still a finite-time-stable equilibrium for the perturbed system. This can be verified by considering the continuous Lyapunov function $V(x) = (\ln|x|)^{-2}$, $x \in \mathcal{D}\backslash\{0\}$, $V(0) = 0$. It is easy to compute $\dot{V}$ along the solutions of the perturbed system (5.13) for $x \neq 0$ and establish that $\dot{V}(x) < -\sqrt{V(x)}$ for $0 < |x| < e^{-\sqrt{2L}}$, thus proving finite-time stability by Theorem 4.2. This indicates that the main results of this section may be valid under the weaker assumption of finite-time stability with a continuous settling-time function. From the point of view of stability theory, proofs of these results under such weaker hypotheses are certainly of interest. However, as observed in Remark 4.1, the Lyapunov functions used to verify stability properties are often continuously differentiable in practice. In such a case, the results of this section are immediately applicable.

6. Conclusions. The notion of finite-time stability can be precisely formulated within the framework of continuous autonomous systems with forward uniqueness. These assumptions, however, do not imply any regularity properties for the settling-time function, which may be discontinuous or continuous yet Hölder discontinuous.

Lyapunov and converse Lyapunov results for finite-time stability naturally involve finite-time scalar differential inequalities. The regularity properties of a Lyapunov function satisfying such an inequality strongly depend on the regularity properties of the settling-time function.

Under the assumption of the existence of a Lipschitz continuous Lyapunov function, finite-time stability leads to better rejection of persistent as well as vanishing perturbations. Such an assumption, however, is not strictly necessary, as the discussion at the end of section 5 shows.

The paper thus raises certain questions that are important from the point of view of stability theory. In particular, conditions on the dynamics for the settling-time function to be Hölder continuous and conditions on the settling-time function that lead to a stronger converse result than Theorem 4.3 are of interest. Also of interest are results similar to those given in section 5 but with weaker hypotheses.

As mentioned earlier, a control system under the action of a time-optimal feedback controller yields a closed-loop system that exhibits finite-time convergence. Hence it would be interesting to explore the connections between finite-time-stability and time optimality and relate the results of this paper to results on the time-optimal control problem.

MESH-INDEPENDENCE FOR AN AUGMENTED LAGRANGIAN-SQP METHOD IN HILBERT SPACES*

S. VOLKWEIN†

Abstract. An augmented Lagrangian-SQP algorithm for optimal control of differential equations in Hilbert spaces is analyzed. This algorithm has second-order convergence rate provided that a second-order sufficient optimality condition is satisfied. The internal approximation of this method is investigated, and convergence results are presented. A mesh-independence principle for the augmented Lagrangian-SQP method is proved, which asserts that asymptotically the infinite dimensional algorithm and finite dimensional discretizations have the same convergence property. More precisely, for sufficiently small mesh-size there is at most a difference of one iteration step between the number of steps required by the infinite dimensional method and its discretization to converge within a given tolerance $\varepsilon > 0$. The theoretical results are demonstrated by two optimal control problems for the Burgers equation.

1. Introduction.

The numerical treatment of optimal control problems for nonlinear partial differential equations arising in diverse areas of science has received an increasing amount of attention in the recent past. We mention optimal control problems in combustion (see [Lio85] for control of parabolic explosive systems), in phase field modeling [CH91, HS94], in superconductivity [GHS91, Tin75], and in fluid dynamics (see [Gun95] and references therein). There is great interest for the numerical treatment of such problems.

In this work we study a general class of optimal control problems for nonlinear differential equations of the following type

$$\text{(P)} \qquad \text{minimize } J(x) \text{ subject to } e(x) = 0,$$

where $J : X \to \mathbb{R}$ and $e : X \to Y$ are sufficiently smooth functions; X and Y are Hilbert spaces. We assume that (P) has a local solution x^* and denote by λ^* the associated Lagrange multiplier.

To solve (P) we use the augmented Lagrangian-SQP (sequential quadratic programming) technique as developed in [IK96b]. In this method the differential equation is treated as an equality constraint which is realized by a Lagrangian term together with a penalty functional. We present an algorithm which has second-order convergence rate and depends upon a second-order sufficient optimality condition. In comparison with SQP methods, the augmented Lagrangian-SQP method has the advantage of a more global behavior. For certain examples we found it to be less sensitive with respect to the starting values, and the region for second-order convergence rate was reached earlier. We shall point out that the penalty term of the augmented Lagrangian functional need not to be implemented but rather that it can be realized by a first-order Lagrangian update.

Since the algorithm cannot be executed in infinite dimensional spaces, (P) is replaced by a family of internal approximations

$$(\mathrm{P}_h) \qquad \text{minimize } J_h(x_h) \text{ subject to } e_h(x_h) = 0,$$

indexed by some mesh-size parameter h, where now $J_h : X_h \to \mathbb{R}$, $e_h : X_h \to Y_h$, $\{X_h\}_{h>0}$, and $\{Y_h\}_{h>0}$ are given families of finite dimensional real Hilbert spaces. We propose the corresponding finite dimensional discretization of the augmented Lagrangian-SQP method. Using convergence properties in subspaces of X and Y, the existence of x^* solving (P) implies the existence of a solution to (P_h) for sufficiently small h. Convergence and rate of convergence results of the discretized algorithm are proved. Moreover, when the augmented Lagrangian-SQP algorithm and its finite dimensional discretization are stopped after the nth step, the difference between the iterates of the finite and the infinite dimensional methods can be estimated by the discretization error of the approximation scheme used. Since we have to solve a saddle-point problem at each level of the iteration process, these results depend on the discrete Babuška–Brezzi condition for the saddle-point problem.

We prove a mesh-independence principle for the augmented Lagrangian-SQP method. The proof is essentially based on the proof of the mesh-independence principle for the Newton method given in [ABPR86]. The mesh-independence principle asserts that, when the augmented Lagrangian-SQP method is applied to an optimal control problem in Hilbert spaces as well as to some finite dimensional discretization of that problem, then the behavior of the discretized process is asymptotically the same as that for the original problem. We shall give sufficient conditions for mesh-independence, provided the mesh-size is smaller than an explicitly given threshold parameter. The sufficient assumptions for mesh-independence are strongly related to the assumptions that are sufficient for the convergence of the discretized augmented Lagrangian-SQP algorithm.

Mesh-independence allows us to predict the convergence of the method applied to the discretized problem when the method has been analyzed for the infinite dimensional problem. Further, it can be used to improve the performance of the method. Since we are interested in the solution of an infinite dimensional problem, it is usually necessary to choose reasonably fine discretizations. This leads to a large number of variables in the discrete minimization problem and therefore to a large amount of work per iteration. If the method is fixed, the only possibility for reducing the total amount of work consists of a good choice in the starting value. For these problems it is obvious that we must use information from the coarse grids to obtain good starting values for the finer discretizations, which leads to mesh-refinement strategies. Mesh-independence is a theoretical justification for mesh-refinement strategies and, moreover, it can be used to design the refinement process and to predict the overall performance of the algorithm.

Let us put the present work into perspective with related research efforts. Polyak and Tret'yakov [PT73] give an elegant treatise of the augmented Lagrangian method. In the book of Fortin and Glowinski [FG83] augmented Lagrangian methods are developed systematically for equality constraints as a technique for solving nonlinear partial differential equations. In [IK90b] Ito and Kunisch apply a technique realized by an augmented Lagrangian formulation for parameter estimation in elliptic partial differential equations. An augmented Lagrangian method for the minimization of a nonlinear functional in the presence of an equality and an affine inequality constraint is considered in [IK90a]. Ito, Kroller, and Kunisch discuss their numerical experience with an augmented Lagrangian method for estimating the coefficient in an elliptic

equation from some given measurement [IKK91]. We refer to the paper [KP91], where Kunisch and Peichl develop an estimation procedure for the diffusion coefficient in a parabolic partial differential equation from the knowledge of the state. In [IK96b] Ito and Kunisch continue their efforts to develop stable and efficient techniques to solve parameter estimation problems formulated as nonlinear optimization problems. Such problems are ill-posed in the sense of a possible lack of continuous dependence of the minimizers with respect to perturbations of the problem. The authors concentrate on second-order methods and analyze the augmented Lagrangian-SQP technique with a second-order update of the Lagrange multiplier in a general Hilbert space setting. Quadratical convergence for smooth optimization problems satisfying the second-order sufficient optimality condition is proved. In [IK96a] the second-order sufficient optimality condition is analyzed and numerical test examples are given. We refer to the paper [KV97], where Kunisch and Volkwein study two augmented Lagrangian-SQP algorithms for optimal control of partial differential equations. The approximation of one of these methods is analyzed. Examples illustrate the theoretical investigations. Further, in [Vol99] the application of the augmented Lagrangian-SQP algorithm to optimal control problems for the stationary Burgers equation is studied. For some classes of nonlinear boundary value problems the mesh-independence principle for Newton's method is proved in [AM78] and [AMP79], and in [AM78], [ABM81], and [McC78] it is used for the construction of some mesh-refinement strategies. In [ABPR86] a proof of the mesh-independence principle for Newton's method is presented in its sharpest formulation for a general class of discretizations of nonlinear operator equations under fairly general and natural conditions on the operator and the discretizations. The paper combines the results of [AB87] with the procedure in [PR84]. Argyros extends the validity of the mesh-independence principle for nonlinear equations and their discretizations to include operators whose derivatives are only Hölder-continuous [Arg90]. In [Arg92] Argyros proved a mesh-independence principle for operator equations and the secant method. A mesh-independence result of Newton's method for generalized equations is achieved by Alt in [Alt95]. Kelley and Sachs prove a mesh-independence result for the Broyden–Fletcher–Goldfarb–Shanno (BFGS) method in Hilbert spaces and apply it to a class of unconstrained optimal control problems in [KS87]. In [KS91] Kelley and Sachs consider globally convergent modifications of Newton's method, such as the Armijo rule. It is shown that for proper discretization schemes the convergence behavior of the iteration is the same for the discrete problems as it is for the infinite dimensional problem. Optimal control problems and their discretizations are considered by Kelley and Sachs in [KS92]. To solve such discretized problems by the gradient projection method the finite identification of active constraints will be necessary. These authors prove a mesh-independence result using a proper condition on the convergence of the gradients. In [Hei93] Heinkenschloss extends the results of [ABPR86] to a norm constrained Gauss–Newton method using a somewhat different discretization scheme based on Galerkin approximations. Deuflhard and Potra present a theoretical characterization of the asymptotic mesh-independence of Newton's method [DP92]. The theory does not need any uniform Lipschitz assumptions. The results are obtained by means of a refined Newton–Mysovskii theorem in an affine invariant formulation. A theoretical refinement discussion is given in [Rhe80]. Further, refinement strategies are presented in [Axe93] for Newton-type methods, in [KS90] for quasi-Newton methods, and in [HLS91] for the Gauss–Newton method.

The paper is organized as follows. In section 2 the augmented Lagrangian-SQP method is proposed and a convergence result is presented, which states the second-order rate of convergence. In section 3 we treat the internal approximation of the

algorithm. We prove the converge and rate of convergence for the discretized version of the augmented Lagrangian-SQP method. The mesh-independence principle is developed in section 4. As an application we present numerical examples for optimal control problems for the Burgers equation in sections 5 and 6, where the cost functional is of tracking type.

It is appropriate to introduce some notations that will be used throughout the paper. Let $(V, \|\cdot\|_V)$ and $(W, \|\cdot\|_W)$ be a normed linear space. The set $B(v;r)$ denotes an open ball of radius $r > 0$ centered at the point $v \in V$. The open set $U \subset V$ is called a neighborhood of $v \in U$ if $B(v;r) \subset U$ for some $r > 0$. By $\mathcal{L}(V,W)$ we denote the normed linear space of all bounded linear operators from V into W and set $\mathcal{L}(V) = \mathcal{L}(V,V)$. For $A \in \mathcal{L}(V,W)$ the set $A(V) \subseteq W$ is called the range of A and is denoted by ran A. The set $\{v \in V : Av = 0\}$ is called the kernel of A and is denoted by ker A. For arbitrary $T > 0$ and B a Banach space $L^2(0,T;B)$ denotes the (equivalence class of) square integrable functions in the sense of Bochner.

2. The augmented Lagrangian-SQP method. We consider the constrained minimization problem

$$\text{(P)} \qquad \text{minimize } J(x) \text{ subject to } e(x) = 0,$$

where $J : X \to \mathbb{R}$, $e : X \to Y$ with X and Y real Hilbert spaces. For brevity we set $Z = X \times Y$. The space Z is endowed with the Hilbert space product topology. The Fréchet-derivatives with respect to the variable x will be denoted by primes. We do not distinguish by notation between a functional in the dual and its Riesz representation in the Hilbert space. Let us start with two examples that motivate our work.

Example 2.1. Let $\Omega = (0,1)$, $\Omega_\circ$ a nonempty subset of Ω with positive measure, and $f \in L^2(\Omega)$. For a control $u \in L^2(\Omega_\circ)$ the state $y \in H^1(\Omega)$ is given by the solution of the stationary Burgers equation

$$\begin{cases} -\nu y'' + yy' = f + Bu & \text{in } \Omega, \\ y(0) = y_l,\ y(1) = y_r, \end{cases}$$

where $B \in \mathcal{L}(L^2(\Omega_\circ), L^2(\Omega))$ is an extension operator defined by

$$Bq = \begin{cases} q & \text{in } \Omega_\circ, \\ 0 & \text{in } \Omega \setminus \Omega_\circ. \end{cases}$$

For controls $u \in L^2(\Omega_\circ)$ we associate the cost of tracking type

$$J(y,u) = \frac{1}{2} \int_\Omega |y - z|^2 \, dx + \frac{\alpha}{2} \int_{\Omega_\circ} |u|^2 \, dx,$$

where $z \in L^2(\Omega)$ and $\alpha > 0$ is fixed. We introduce the operator $e = (e_1, e_2, e_3) : H^1(\Omega) \times L^2(\Omega_\circ) \to H_0^1(\Omega) \times \mathbb{R}^2$ by

$$e(y,u) = \left((-\Delta)^{-1}(-\nu y'' + yy' - f - Bu), y(0) - y_l, y(1) - y_r\right),$$

where Δ denotes the Laplace operator from $H_0^1(\Omega)$ to $H^{-1}(\Omega)$. The resulting optimal control problem is in the form (**P**) with $X = H^1(\Omega) \times L^2(\Omega_\circ)$ and $Y = H^{-1}(\Omega) \times \mathbb{R}^2$.

Example 2.2. Let Ω be the interval $(0,1)$ and $Q = (0,T] \times \Omega$ for given $T > 0$. Moreover, let $f \in L^2(0,T;L^2(\Omega))$ and $\phi \in L^2(\Omega)$. We define the space $W(0,T)$ by

$$W(0,T) = \left\{\varphi : \varphi \in L^2(0,T;H_0^1(\Omega)),\ \varphi_t \in L^2(0,T;H^{-1}(\Omega))\right\},$$

which is a Hilbert space endowed with the common inner product. For a control $u \in L^2(0,T;L^2(\Omega))$ the state $y \in W(0,T)$ is given by the weak solution of the unsteady Burgers equation

$$\begin{aligned} y_t - \nu y_{xx} + y y_x &= f + u \quad \text{in } Q, \\ y(t,0) = y(t,1) &= 0 \quad \text{for } t \in (0,T) \text{ a.e.}, \\ y(0,x) &= \phi(x) \quad \text{for all } x \in \Omega, \end{aligned} \tag{2.1}$$

where $\nu > 0$ denotes the viscosity parameter. This equation was extensively developed by Burgers as a simplified fluid flow model which nevertheless exhibits some of the important aspects of turbulence [Bur40]. Later it was derived by Lighthill as a second-order approximation to the one-dimensional unsteady Navier–Stokes equations [Lig56].

With controls $u \in L^2(0,T;L^2(\Omega))$ we associate the cost of tracking type

$$J(y,u) = \frac{1}{2}\|y - z\|^2_{L^2(0,T;L^2(\Omega))} + \frac{\alpha}{2}\|u\|^2_{L^2(0,T;L^2(\Omega))},$$

where $z \in W(0,T)$ and $\alpha > 0$ is fixed. Setting $X = W(0,T) \times L^2(0,T;L^2(\Omega))$ and $Y = L^2(0,T;H_0^1(\Omega)) \times L^2(\Omega)$ and defining $e = (e_1, e_2)$ by

$$e(y,u) = \left((-\Delta)^{-1}\left(y_t - y_{xx} + y y_x - f - u\right), y(0,\cdot) - \phi\right),$$

where the Laplace operator Δ was introduced in Example 2.2, the optimal control problem can be written in the form (P).

ASSUMPTION 1. *Problem* (P) *has a local solution x^*; i.e., there exists an $\varepsilon > 0$ such that $J(x) \geq J(x^*)$ for all $x \in B(x^*;\varepsilon)$ satisfying $e(x) = 0$. Further, J and e are twice continuously Fréchet-differentiable, and the mappings J'' and e'' are Lipschitz-continuous in the neighborhood $U_1 \subset X$ of x^*.*

Remark 2.3. It is proved in [Vol97] that Assumption 1 holds for Example 2.2 and Example 2.1.

The Lagrangian functional $L : Z \to \mathbb{R}$ associated with (P) is given by

$$L(x,\lambda) = J(x) + \langle e(x), \lambda \rangle_Y,$$

where $\langle \cdot, \cdot \rangle_Y$ denotes the inner product in Y.

ASSUMPTION 2. *The linearization $e'(x^*)$ of e at x^* is surjective.*

Remark 2.4. Assumption 2 is satisfied for Examples 2.2 and 2.1; see [Vol97].

With Assumption 2 holding there exists a Lagrange multiplier $\lambda^* \in Y$ such that the following first-order necessary optimality condition is satisfied [Lue69]:

$$L'(x^*,\lambda^*) = 0\,, \quad e(x^*) = 0. \tag{2.2}$$

We also make use of the second-order sufficient optimality condition.

ASSUMPTION 3. *The operator $L''(x^*,\lambda^*)$ is coercive on the kernel of $e'(x^*)$; i.e., there exists a constant $\kappa > 0$ such that*

$$\langle L''(x^*,\lambda^*)v, v\rangle_X \geq \kappa \|v\|^2_X \text{ for all } v \in \ker e'(x^*),$$

where $\langle \cdot, \cdot \rangle_X$ denotes the inner product in X.

Remark 2.5. For Example 2.2 and Example 2.1 it is shown in [Vol97] that the second-order sufficient optimality condition is satisfied if the residues $\|y^* - z\|_{L^2(Q)}$ and $\|y^* - z\|_{L^2(\Omega)}$, respectively, are sufficiently small.

Let J and e be twice continuously Fréchet-differentiable in U_1. With Assumption 3 holding, the solution x^* of (2.2) is a locally unique solution to (P) [MZ79]. Due to Assumption 2 we can further assume that there exists a neighborhood $U_2 \subseteq U_1$ of x^* such that $e'(x)$ is surjective for all $x \in U_2$. Assumption 3 implies that there is a neighborhood $U_3 \subset Z$ of (x^*, λ^*) such that

$$\langle L''(x,\lambda)v, v\rangle_X \geq \kappa_\circ \|v\|_X^2 \text{ for all } v \in \ker e'(x)$$

for $(x,\lambda) \in U_3$ and for a constant $\kappa_\circ > 0$. Henceforth we denote by $U = U_X \times U_Y$ with $U_X \subset X$ and $U_Y \subset Y$ a neighborhood of (x^*, λ^*) such that

(a) J and e are twice Fréchet-differentiable on $\overline{U_X}$ and their second Fréchet-derivatives are Lipschitz-continuous,
(b) $e'(x)$ is surjective, and
(c) $L''(x,\lambda)$ is coercive on the kernel of $e'(x)$ for all $(x,\lambda) \in U$.

For any $c \geq 0$ the augmented Lagrangian functional is defined by

$$L_c(x,\lambda) = L(x,\lambda) + \frac{c}{2}\|e(x)\|_Y^2.$$

It will be convenient to introduce the matrix of operators

$$M(x,\lambda) = \begin{pmatrix} L''(x,\lambda) & e'(x)^* \\ e'(x) & 0 \end{pmatrix} \text{ for all } (x,\lambda) \in \overline{U}, \tag{2.3}$$

where $e'(x)^* : Y \to X$ denotes the adjoint of $e'(x)$ in $\overline{U_X}$. To find x^* numerically we observe that the first-order necessary optimality condition (2.2) implies that (x^*, λ^*) is a solution to

$$L_c'(x,\lambda) = L'(x, \lambda + ce(x)) = 0, \quad e(x) = 0 \quad \text{for all } c \geq 0. \tag{OS}$$

Remark 2.6. With Assumptions 1–2 holding, (x^*, λ^*) is a locally unique solution to (OS).

We solve problem (OS) by the Newton method, where we avoid the explicit calculation of the augmented Lagrangian functional and its derivatives [IK96b].

Algorithm 1.

(a) *Choose* $(x^0, \lambda^0) \in U$, $c \geq 0$ *and put* $n = 0$.
(b) *Set* $\tilde{\lambda}^n = \lambda^n + ce(x^n)$.
(c) *Solve for* $(\bar{x}, \bar{\lambda})$

$$M(x^n, \tilde{\lambda}^n)\begin{pmatrix} \bar{x} - x^n \\ \bar{\lambda} - \tilde{\lambda}^n \end{pmatrix} = -\begin{pmatrix} L'(x^n, \tilde{\lambda}^n) \\ e(x^n) \end{pmatrix}. \tag{2.4}$$

(d) *Set* $(x^{n+1}, \lambda^{n+1}) = (\bar{x}, \bar{\lambda})$, $n = n+1$ *and go back to* (b).

Remark 2.7.

(a) Since X and Y are Hilbert spaces, it can be shown that the update $(\bar{x}, \bar{\lambda})$ of Algorithm 1 can equivalently be obtained from

$$\begin{pmatrix} L_c''(x^n, \lambda^n) & e'(x^n)^* \\ e'(x^n) & 0 \end{pmatrix}\begin{pmatrix} \bar{x} - x^n \\ \bar{\lambda} - \lambda^n \end{pmatrix} = -\begin{pmatrix} L_c'(x^n, \lambda^n) \\ e(x^n) \end{pmatrix},$$

which corresponds to a Newton step applied to (OS). This form of the iteration requires the implementation of $e(x^n)^* e'(x^n)$, whereas steps (b) and (c) of Algorithm 1 do not. In the case of Examples 2.1 and 2.2 this implies an additional solve of the Poisson equation.

(b) If we set $c = 0$, Algorithm 1 becomes the SQP-method.

In each iteration of Algorithm 1 the saddle-point problem (2.4) needs to be solved. With Assumptions 2 and 3 holding, problem (2.4) has a unique solution $(\bar{x}, \bar{\lambda})$ for all $(x^n, \tilde{\lambda}^n) \in U$ (see [BF91]) and there exists a constant $\eta > 0$ satisfying

$$\|M^{-1}(x, \lambda)\|_{\mathcal{L}(Z)} \leq \eta \text{ for all } (x, \lambda) \in U.$$

To formulate the convergence result for Algorithm 1 we introduce the following constants. Let $r_{\max} > 0$ denote the largest radius of a ball centered at (x^*, λ^*) and contained in the neighborhood U, γ_e stands for the uniform Lipschitz-constant of e in U_X, and γ_M denotes the uniform Lipschitz-constant of M in U. Moreover, we set

$$r^* = \min\left(\frac{r_{\max}}{\sqrt{\max(2, 1 + 2c^2\gamma_e^2)}}, \frac{2}{\gamma_M \eta \max(2, 1 + 2c^2\gamma_e^2)}\right). \tag{2.5}$$

For the proof of the next theorem we refer the reader to [IK96b].

THEOREM 2.8. *Let Assumptions* 1, 2, *and* 3 *hold and let the starting value* (x^0, λ^0) *belong to the open ball* $B((x^*, \lambda^*); r^*)$. *Then Algorithm* 1 *is well-defined and*

$$\|(x^{n+1}, \lambda^{n+1}) - (x^*, \lambda^*)\|_Z \leq \widetilde{C} \, \|(x^n, \lambda^n) - (x^*, \lambda^*)\|_Z^2, \tag{2.6}$$

where $\widetilde{C} = \frac{1}{2} \gamma_M \eta \max(2, 1 + 2c^2\gamma_e^2)$.

Remark 2.9.

(a) With Assumptions 1–3 holding, Algorithm 1 has second-order rate of convergence, where the convergence rate factor $\widetilde{C}$ depends quadratically on c.

(b) We shall need the radius r^* in the formulation of Corollary 3.19.

(c) From (2.5) and (2.6) we derive that $(x^n, \lambda^n) \in U$ holds for all $n = 0, 1, \ldots$ and that the sequence $\{\|(x^n, \lambda^n) - (x^*, \lambda^*)\|_Z\}_{n \in \mathbb{N}}$ is strictly decreasing.

3. Internal approximation and convergence theorems. This section is devoted to the internal approximation of Algorithm 1. In many applications X and Y are infinite dimensional Hilbert spaces, which have to be discretized for numerical realization of (P); see Examples 2.2 and 2.1. For this purpose we suppose that we are given a family $\{h\}$, $h > 0$, with accumulation point zero and families $\{X_h\}_h$ and $\{Y_h\}_h$ of Hilbert spaces with finite dimension. In practice, the parameter h is called the mesh-size of the finite dimensional spaces and h varies over a sequence. To shorten notation we set $Z_h = X_h \times Y_h$ for every h.

Let $p_h^X \in \mathcal{L}(X_h, X)$ and $p_h^Y \in \mathcal{L}(Y_h, Y)$ be given injective prolongations. In addition, we introduce surjective restrictions $r_h^X \in \mathcal{L}(X, X_h)$ and $r_h^Y \in \mathcal{L}(Y, Y_h)$. For brevity we set $p_h = (p_h^X, p_h^Y)$ and $r_h = (r_h^X, r_h^Y)$. For every h the data (X_h, p_h^X, r_h^X), (Y_h, p_h^Y, r_h^Y), and (Z_h, p_h, r_h) are called approximations of the spaces X, Y, and Z, respectively.

Remark 3.1. Let us turn to Example 2.1. For $m \in \mathbb{N}$ the mesh-size $h = h(m)$ and the associated grid-points $x_i \in [0, 1]$ are given by $h = \frac{1}{m}$ and $x_i = ih$ for $i = 0, \ldots, m$, respectively. Let $\varphi_0, \ldots, \varphi_m \in H^1(0, 1)$ denote the well-known piecewise linear finite elements satisfying $\varphi_i(x_j) = \delta_{ij}$ for $0 \leq i, j \leq m$. We will restrict our discussions to the case that the set $\Omega_\circ = (a, b) \subseteq \Omega$ is an open interval. The numbers $i_a, i_b \in \{1, \ldots, m-1\}$ are defined by

$$a < x_{i_a} < x_{i_a+1} < \cdots < x_{i_b} < b.$$

For the approximation of the Hilbert spaces we set

$$\begin{aligned} X_h &= \operatorname{Span}\{\varphi_0, \dots, \varphi_m\} \times \operatorname{Span}\{\varphi_{i_a}, \dots, \varphi_{i_b}\}, \\ Y_h &= \operatorname{Span}\{\varphi_1, \dots, \varphi_{m-1}\} \times \mathbb{R}^2, \\ Z_h &= X_h \times Y_h. \end{aligned}$$

Now we are going to define the prolongations and restrictions. We set

$$p_h(y_h, u_h, \lambda_h, \mu, \xi) = (y_h, u_h, \lambda_h, \mu, \xi) \quad \text{for } (y_h, u_h) \in X_h \text{ and } (\lambda_h, \mu, \xi) \in Y_h.$$

Hence, the finite dimensional Hilbert spaces X_h and Y_h are endowed with the inner products and norms introduced in X and Y, respectively. We introduce the restriction

$$r_h(y, u, \lambda, \mu, \xi) = \left(\sum_{i=0}^{m} y(x_i)\varphi_i, \frac{1}{h} \sum_{i=i_a}^{i_b} \int_{x_i - \frac{h}{2}}^{x_i + \frac{h}{2}} u \, dx \, \varphi_i, \sum_{i=1}^{m-1} \lambda(x_i)\varphi_i, \mu, \xi \right)$$

for $(y, u) \in X$ and $(\lambda, \mu, \xi) \in Y$. Note that $u \in L^2(\Omega_\circ)$ holds so that $u(x_i)$ need not be meaningful.

With the prolongations we define discrete inner products and discrete norms in the following way.

Definition 3.2. *We introduce the* discrete inner product *in X_h by*

$$\langle x_h, \bar{x}_h \rangle_{X_h} = \langle p_h^X x_h, p_h^X \bar{x}_h \rangle_X$$

and the discrete norm *in X_h by*

$$\|x_h\|_{X_h} = \|p_h^X x_h\|_X$$

for all $x_h, \bar{x}_h \in X_h$. Analogously, for all $\lambda_h, \bar{\lambda}_h \in Y_h$ we define by

$$\langle \lambda_h, \bar{\lambda}_h \rangle_{Y_h} = \langle p_h^Y \lambda_h, p_h^Y \bar{\lambda}_h \rangle_Y, \quad \|\lambda_h\|_{Y_h} = \|p_h^Y \lambda_h\|_Y$$

the discrete inner product and discrete norm in Y_h. In Z_h the corresponding inner product is the sum of the inner products $\langle \cdot, \cdot \rangle_{X_h}$ and $\langle \cdot, \cdot \rangle_{Y_h}$ and the discrete norm is

$$\|(x_h, \lambda_h)\|_{Z_h} = \|p_h(x_h, \lambda_h)\|_Z \text{ for all } (x_h, \lambda_h) \in Z_h.$$

Remark 3.3. For these discrete norms p_h^X, p_h^Y, and p_h have norm 1.

Let us introduce the restriction $\hat{r}_h^X = (p_h^X)^* \in \mathcal{L}(X, X_h)$, i.e.,

$$\langle \hat{r}_h^X x, x_h \rangle_{X_h} = \langle x, p_h^X x_h \rangle_X \text{ for all } x \in X \text{ and } x_h \in X_h.$$

Analogously, $\hat{r}_h^Y$ is defined, and we put $\hat{r}_h = (\hat{r}_h^X, \hat{r}_h^Y)$. As p_h is injective and $\operatorname{ran} \hat{r}_h$ has finite dimension, we infer that $\hat{r}_h$ is surjective.

Lemma 3.4. *For every h the restriction $\hat{r}_h$ has the following properties:*

(a) *$\hat{r}_h p_h(x_h, \lambda_h) = (x_h, \lambda_h)$ for all $(x_h, \lambda_h) \in Z_h$ and*

(b) *$p_h \hat{r}_h$ is the orthogonal projector of Z onto the subspace* $\operatorname{ran} p_h$*, i.e.*

$$\|(x, \lambda) - p_h \hat{r}_h(x, \lambda)\|_Z = \inf_{(x_h, \lambda_h) \in Z_h} \|(x, \lambda) - p_h(x_h, \lambda_h)\|_Z \text{ for all } (x, \lambda) \in Z.$$

Proof.
(a) We derive from $\hat{r}_h = (p_h)^*$ and Definition 3.2 that

$$\langle \hat{r}_h p_h(x_h, \lambda_h), (\bar{x}_h, \bar{\lambda}_h) \rangle_{Z_h} = \langle (x_h, \lambda_h), (\bar{x}_h, \bar{\lambda}_h) \rangle_{Z_h}$$

for all $(x_h, \lambda_h), (\bar{x}_h, \bar{\lambda}_h) \in Z_h$. Hence, part (a) is shown.
(b) Any $(x, \lambda) \in Z$ can be expressed as

$$(x, \lambda) = [(x, \lambda) - p_h \hat{r}_h(x, \lambda)] + p_h \hat{r}_h(x, \lambda).$$

From $\hat{r}_h = (p_h)^*$ and part (a) we infer that

$$\langle (x, \lambda) - p_h \hat{r}_h(x, \lambda), p_h \hat{r}_h(x, \lambda) \rangle_Z = 0$$

such that $p_h \hat{r}_h$ is the orthogonal projector of Z onto the subspace ran p_h. □

Remark 3.5. The restrictions $\hat{r}_h^X$, $\hat{r}_h^Y$, and $\hat{r}_h$ are called the optimal restrictions associated with the prolongations p_h^X, p_h^Y, and p_h, respectively [Aub72]. Remark 3.3 implies that the norms of the optimal restrictions are equal to 1 [DL88].

DEFINITION 3.6. *The approximations (X_h, p_h^X, r_h^X) of X are called* convergent *if*

$$\lim_{h \to 0} \| x - p_h^X r_h^X x \|_X = 0 \text{ for all } x \in X.$$

Convergence of (Y_h, p_h^Y, r_h^Y) and (Z_h, p_h, r_h) is defined analogously.

ASSUMPTION 4. *The approximations (Z_h, p_h, r_h) of the Hilbert space Z are convergent, and $p_h r_h(x, \lambda) \in U$ holds for $(x, \lambda) \in U$ and all h sufficiently small.*

Remark 3.7. In Remark 3.1 we introduced approximations for Example 2.1, which are convergent [Aub72]. Hence, Assumption 4 is satisfied.

Remark 3.8. With Assumption 4 holding, $\| p_h r_h(x, \lambda) \|_Z$ is bounded for all $(x, \lambda) \in Z$. According to the principle of uniform boundedness [Wou79] there exists a constant $c_\circ > 0$ such that $\| p_h r_h \|_{\mathcal{L}(Z)} \leq c_\circ$ for all h.

Definition 3.6 leads directly to the following corollary.

COROLLARY 3.9. *The approximations (Z_h, p_h, r_h) of Z are convergent if and only if the approximations (X_h, p_h^X, r_h^X) of X and (Y_h, p_h^Y, r_h^Y) of Y are convergent.*

Now we define the following internal approximations of the cost functional J and the constraint e [Aub72]:

$$J_h = J\, p_h^X : X_h \to \mathbb{R}, \quad e_h = \hat{r}_h^Y\, e\, p_h^X : X_h \to Y_h. \tag{3.1}$$

Remark 3.10. Using (3.1) and $\hat{r}_h^Y = (p_h^Y)^*$ we have

$$\langle e_h(x_h), \lambda_h \rangle_{Y_h} = \langle e(p_h^X x_h), p_h^Y \lambda_h \rangle_Y \text{ for all } (x_h, \lambda_h) \in X_h \times Y_h. \tag{3.2}$$

From (3.2) we observe that the restriction $\hat{r}_h$ is more a theoretical tool, whereas the operator r_h is used in the numerical implementation.

Together with (P) we investigate the finite dimensional discrete problems

$$\text{minimize } J_h(x_h) \text{ subject to } e_h(x_h) = 0. \tag{P_h}$$

ASSUMPTION 5. *For every h there exist neighborhoods $V_h \subset X_h$ of $r_h^X x^*$ and $W_h \subset Y_h$ of $r_h^Y \lambda^*$ and a constant $r_{\min} > 0$ independent of h such that $p_h(U_h) \subset U$ and $B(r_h(x^*, \lambda^*); r_{\min})$ is a subset of $U_h = V_h \times W_h$ for all h.*

The Lagrangian for (P_h) is given by

$$L_h(x_h, \lambda_h) = J_h(x_h) + \langle e_h(x_h), \lambda_h \rangle_{Y_h}.$$

From $\hat{r}_h^Y = (p_h^Y)^*$ and (3.1) we derive that $L_h = L\, p_h$. Since all restrictions and prolongations are linear, we are able to differentiate the Lagrangian L_h with respect to the variable x_h for all $x_h \in V_h$ and $\lambda_h \in Y_h$:

$$L_h'(x_h, \lambda_h) = \hat{r}_h^X L'(p_h(x_h, \lambda_h)).$$

Both $L_h'(x_h, \lambda_h)$ and $e_h(x_h)$ are also continuously Fréchet-differentiable with respect to the variable x_h and their Fréchet-derivatives are Lipschitz-continuous. Explicitly, we get

$$L_h''(x_h, \lambda_h) = \hat{r}_h^X L''(p_h(x_h, \lambda_h)) p_h^X, \quad e_h'(x_h) = \hat{r}_h^Y e'(p_h^X x_h) p_h^X \tag{3.3}$$

for all $x_h \in V_h$ and $\lambda_h \in Y_h$. Further, we derive that

$$e_h'(x_h)^* = \hat{r}_h^X e'(p_h^X x_h)^* p_h^Y \text{ for all } x_h \in V_h.$$

For every h the matrix of operators M given in (2.3) is approximated by

$$M_h(x_h, \lambda_h) = \hat{r}_h\, M(p_h(x_h, \lambda_h))\, p_h = \begin{pmatrix} L_h''(x_h, \lambda_h) & e_h'(x_h)^* \\ e_h'(x_h) & 0 \end{pmatrix} \tag{3.4}$$

for all $(x_h, \lambda_h) \in U_h$. Since L'' is a self-adjoint operator in U we conclude that L_h'' is self-adjoint in U_h. Hence M_h is self-adjoint in U_h.

The approximation of (OS) is formulated as

$$L_h'(x_h, \lambda + c e_h(x_h)) = 0, \quad e_h(x_h) = 0 \quad \text{for all } c \geq 0, \tag{OS_h}$$

which is the first-order necessary optimality condition for (P_h).

We shall require a uniform Babuška–Brezzi condition in V_h.

Assumption 6. *There exists a constant $\beta^* > 0$ independent of h with*

$$\inf_{\bar{\lambda}_h \in Y_h} \sup_{\bar{x}_h \in X_h} \frac{\langle e_h'(x_h)^* \bar{\lambda}_h, \bar{x}_h \rangle_{X_h}}{\|\bar{x}_h\|_{X_h} \|\bar{\lambda}_h\|_{Y_h}} \geq \beta^* \text{ for all } x_h \in V_h \text{ and for all } h. \tag{3.5}$$

Remark 3.11. By closed range theory [Bre87] the uniform Babuška–Brezzi condition implies that the operator $e_h'(y_h, u_h)$ is surjective on V_h. Note that (3.5) leads to

$$\|e_h'(x_h)^* \lambda_h\|_{X_h} \geq \beta^* \|\lambda_h\|_{Y_h} \text{ for all } \lambda_h \in Y_h.$$

We refer the reader to [Vol99] for the proof of the uniform Babuška–Brezzi condition in the case of Example 2.1 and the piecewise linear approximations introduced in Remark 3.1.

We shall also make use of a uniform second-order sufficient optimality condition in U_h.

Assumption 7. *There exists $\kappa^* > 0$ independent of h such that*

$$\langle L_h''(x_h, \lambda_h) \bar{x}_h, \bar{x}_h \rangle_{X_h} \geq \kappa^* \|\bar{x}_h\|_{X_h}^2 \text{ for all } \bar{x}_h \in \ker e_h'(x_h)$$

for all $(x_h, \lambda_h) \in U_h$ and for all h.

Remark 3.12. Using (3.3) we have

$$\langle L_h''(r_h(x^*,\lambda^*))x_h, x_h\rangle_{X_h} = \langle L''(p_h r_h(x^*,\lambda^*))p_h^X x_h, p_h^X x_h\rangle_X \text{ for all } x_h \in X_h.$$

If the operator $L''(x^*,\lambda^*)$ is coercive on the whole space X and Assumption 4 holds, then Assumption 7 is satisfied in a neighborhood of $r_h(x^*,\lambda^*)$ if h is sufficiently small.

Now we consider the internal approximation of Algorithm 1.

ALGORITHM 2.

(a) *Choose* $(x_h^0,\lambda_h^0) \in U_h$, $c \geq 0$ *and put* $n = 0$.

(b) *Set* $\tilde{\lambda}_h^n = \lambda_h^n + ce_h(x_h^n)$.

(c) *Solve for* $(\bar{x}_h, \bar{\lambda}_h)$

$$M_h(x_h^n, \tilde{\lambda}_h^n)\begin{pmatrix} \bar{x}_h - x_h^n \\ \bar{\lambda}_h - \tilde{\lambda}_h^n \end{pmatrix} = -\begin{pmatrix} L_h'(x_h^n, \tilde{\lambda}_h^n) \\ e_h(x_h^n) \end{pmatrix}. \tag{3.6}$$

(d) *Set* $(x_h^{n+1}, \lambda_h^{n+1}) = (\bar{x}_h, \bar{\lambda}_h)$, $n = n+1$, *and go back to* (b).

Remark 3.13. Since the matrix M_h has the same structure as M we have to solve a saddle-point problem in (3.6). But now the linear system (3.6) has finite dimension.

LEMMA 3.14. *With Assumption* 6 *holding, the saddle-point problem*

$$M_h(x_h,\lambda_h)\begin{pmatrix} \bar{x}_h - x_h \\ \bar{\lambda}_h - \lambda_h \end{pmatrix} = -\begin{pmatrix} L_h'(x_h,\lambda_h) \\ e_h(x_h) \end{pmatrix}$$

has a unique solution $(\bar{x}_h, \bar{\lambda}_h)$ *for every* $(x_h,\lambda_h) \in U_h$.

For the proof we refer the reader to [GR92].

Remark 3.15. With Assumption 6 holding there exists a bound $\eta^* > 0$, which may depend on β^* or κ^*, but is independent of h satisfying

$$\|M_h^{-1}(r_h(x^*,\lambda^*))\|_{\mathcal{L}(Z_h)} \leq \eta^* \text{ for all } h. \tag{3.7}$$

Using Remark 3.5 and (3.1) we derive

$$\|e_h(x_h) - e_h(\bar{x}_h)\|_{Y_h} \leq \gamma_e \|x_h - \bar{x}_h\|_{X_h},$$

and from (3.4) we infer that

$$\|M_h(x_h,\lambda_h) - M_h(\bar{x}_h,\bar{\lambda}_h)\|_{\mathcal{L}(Z_h)} \leq \gamma_M \|(x_h,\lambda_h) - (\bar{x}_h,\bar{\lambda}_h)\|_{Z_h}$$

for all $(x_h,\lambda_h),(\bar{x}_h,\bar{\lambda}_h) \in U_h$. As a consequence, uniform Lipschitz-constants of e_h in V_h and M_h in U_h can be chosen of the uniform Lipschitz-properties of e and M in U_X and U, respectively.

In many applications it turns out that the solution (x^*,λ^*) of (OS) as well as the iterates (x^n,λ^n) of Algorithm 1 have "better smoothness" properties than the elements of Z. This is a motivation for the following assumption.

ASSUMPTION 8. *There are bounded subsets* $V \subset X$ *and* $W \subset Y$ *such that*

$$x^*,\ x^n,\ x^n - x^*,\ x^{n+1} - x^n \in V$$

and

$$\lambda^*,\ \lambda^n,\ \lambda^n - \lambda^*,\ \lambda^{n+1} - \tilde{\lambda}^n \in W$$

holds for all $n = 0, 1, \ldots$.

Moreover, there exists a bounded function $\rho : [0,1] \to [0,\infty)$ *which is right-continuous at* $h = 0$ *with* $\rho(0) = 0$ *satisfying*

$$\|(x,\lambda) - p_h r_h(x,\lambda)\|_Z \le \rho(h)$$

for all $(x,\lambda) \in V \times W$ *and for all* $h > 0$.

Let

$$F(x,\lambda) = \begin{pmatrix} L'(x,\lambda) \\ e(x) \end{pmatrix} \text{ and } F_h = \hat{r}_h F p_h. \tag{3.8}$$

The next lemma shows that the internal approximations of F and M given by F_h and M_h, respectively, are consistent of order $\rho(h)$.

LEMMA 3.16. *With Assumptions* 4 *and* 8 *holding, there exists a constant* $\tilde{C} > 0$ *independent of* h *such that*

$$\|\hat{r}_h F(x,\lambda) - F_h(r_h(x,\lambda))\|_{Z_h} \le \tilde{C}\rho(h)$$

and

$$\|\hat{r}_h M(x,\lambda)(\bar{x},\bar{\lambda})^T - M_h(r_h(x,\lambda))[r_h(\bar{x},\bar{\lambda})]^T\|_{Z_h} \le \tilde{C}\rho(h)$$

for all $(x,\lambda) \in (V \times W) \cap U$, $(\bar{x},\bar{\lambda}) \in V \times W$ *and for all* $h > 0$.

Proof. Let $x, \bar{x} \in V$ and $\lambda, \bar{\lambda} \in W$. By Assumption 8 we conclude

$$\|(x,\lambda) - p_h r_h(x,\lambda)\|_Z \le \rho(h) \text{ and } \|(\bar{x},\bar{\lambda}) - p_h r_h(\bar{x},\bar{\lambda})\|_Z \le \rho(h)$$

and $\|(\bar{x},\bar{\lambda})\|_Z \le \bar{c}$ for a constant $\bar{c} > 0$. Using Remark 3.5 and setting $\tilde{C} = \max(\gamma_F, \bar{c}\gamma_M + \eta_M)$, where $\gamma_F > 0$ denotes the Lipschitz-constant of F in U and η_M is a uniform upper bound of M in $\overline{U}$, we derive from (3.8) that

$$\|\hat{r}_h F(x,\lambda) - F_h(r_h(x,\lambda))\|_{Z_h} \le \gamma_F \|(x,\lambda) - p_h r_h(x,\lambda)\|_Z \le \tilde{C}\rho(h)$$

and by triangle inequality and (3.4) that

$$\begin{aligned}&\|\hat{r}_h M(x,\lambda)(\bar{x},\bar{\lambda})^T - M_h(r_h(x,\lambda))[r_h(\bar{x},\bar{\lambda})]^T\|_{Z_h} \\ &\quad \le \gamma_M \|(x,\lambda) - p_h r_h(x,\lambda)\|_Z \|(\bar{x},\bar{\lambda})\|_Z + \eta_M \|(\bar{x},\bar{\lambda}) - p_h r_h(\bar{x},\bar{\lambda})\|_Z \le \tilde{C}\rho(h). \quad \square\end{aligned}$$

Now we are going to formulate the convergence results.

THEOREM 3.17. *Let Assumptions* 1–8 *hold. Then there is a constant* $\bar{h} \in (0,1]$ *so that* (OS$_h$) *has a locally unique solution satisfying*

$$(x_h^*, \lambda_h^*) = r_h(x^*,\lambda^*) + O(\rho(h)) \text{ for all } h \in (0,\bar{h}]. \tag{3.9}$$

Proof. Since Algorithms 1 and 2 are equivalent to the Newton method applied to the operator equations (OS$_h$) and (OS), respectively, the theorem follows directly from Theorem 2 in [ABPR86]. $\square$

Remark 3.18. Since ρ is right-continuous at $h = 0$ with $\rho(0) = 0$, we derive from (3.9) that

$$\lim_{h\to 0} \|(x_h^*, \lambda_h^*) - r_h(x^*,\lambda^*)\|_{Z_h} = 0$$

holds.

From existence of (x_h^*, λ_h^*) the second-order convergence of Algorithm 2 is proved for starting values $(x_h^0, \lambda_h^0) = r_h(x^0, \lambda^0)$, where (x^0, λ^0) is the starting value of Algorithm 1 chosen in an appropriate neighborhood of (x^*, λ^*). This is formulated precisely in the next corollary. Note that we introduced the radius r^* in (2.5).

COROLLARY 3.19. *Let the assumptions of Theorem* 3.17 *hold. Then there exist* $\tilde{h} \in (0, \bar{h}]$ *and* $r_1 \in (0, r^*]$ *such that Algorithm* 2 *converges to* (x_h^*, λ_h^*) *for starting values* $(x_h^0, \lambda_h^0) = r_h(x^0, \lambda^0)$ *with* $(x^0, \lambda^0) \in (V \times W) \cap B((x^*, \lambda^*); r_1)$*, and the iterates satisfy*

$$\|(x_h^{n+1}, \lambda_h^{n+1}) - (x_h^*, \lambda_h^*)\|_{Z_h} \le C \, \|(x_h^n, \lambda_h^n) - (x_h^*, \lambda_h^*)\|_{Z_h}^2$$

for a constant $C > 0$ *independent of* $h \in (0, \tilde{h}]$ *and* n.

Proof. We shall apply Theorem 2.8 to the discrete Algorithm 2 in order to prove the claim of the corollary. From Theorem 3.17 we conclude the existence of a locally unique (x_h^*, λ_h^*) solving (OS_h), of a constant $\tilde{C} > 0$, and of $\bar{h} > 0$ such that

$$\|(x_h^*, \lambda_h^*) - r_h(x^*, \lambda^*)\|_{Z_h} \le \tilde{C} \, \rho(h) \text{ for every } h \in (0, \bar{h}]. \tag{3.10}$$

Applying the perturbation lemma (see [OR70]) we obtain that

$$\|M_h^{-1}(x_h, \lambda_h)\|_{\mathcal{L}(Z_h)} \le \frac{\eta^*}{1 - \eta^* \gamma_M \, \|(x_h, \lambda_h) - r_h(x^*, \lambda^*)\|_{Z_h}} < \frac{\eta^*}{2}$$

for all $(x_h, \lambda_h) \in B(r_h(x^*, \lambda^*), \frac{1}{2\eta^* \gamma_M})$. Let $(x^0, \lambda^0) \in U$ denote a starting value of Algorithm 1 satisfying

$$\|(x^0, \lambda^0) - (x^*, \lambda^*)\|_Z < \min\left(r^*, \frac{3r_{\min}}{8c_\circ \sqrt{\max(2, 1 + c^2\gamma_e^2)}}, \frac{2}{c_\circ \gamma_M \eta^* \max(2, 1 + c^2\gamma_e^2)} \right), \tag{3.11}$$

where the constant $c_\circ$ is specified in Remark 3.8. Since ρ is right-continuous at $h = 0$ there exists $\tilde{h} \in (0, \bar{h}]$ such that

$$\rho(h) \le \min\left(\frac{r_{\min}}{4\tilde{C}}, \frac{3r_{\min}}{8\tilde{C}\sqrt{\max(2, 1 + c^2\gamma_e^2)}}, \frac{2}{\gamma_M \eta^* \tilde{C} \max(2, 1 + c^2\gamma_e^2)} \right) \tag{3.12}$$

for all $h \in (0, \tilde{h}]$. Applying (3.11) yields

$$\|(x^0, \lambda^0) - (x^*, \lambda^*)\|_Z < \frac{3r_{\min}}{8c_\circ \sqrt{\max(2, 1 + c^2\gamma_e^2)}} < \frac{r_{\min}}{2c_\circ}. \tag{3.13}$$

From (3.10), (3.12), and (3.13) we infer that

$$\begin{aligned} &\|(x_h^0, \lambda_h^0) - (x_h^*, \lambda_h^*)\|_{Z_h} + \|(x_h^*, \lambda_h^*) - r_h(x^*, \lambda^*)\|_{Z_h} \\ &\qquad \le c_\circ \, \|(x^0, \lambda^0) - (x^*, \lambda^*)\|_Z + 2 \, \|(x_h^*, \lambda_h^*) - r_h(x^*, \lambda^*)\|_{Z_h} \le r_{\min}. \end{aligned}$$

By Assumption 5 it follows that

$$B((x_h^*, \lambda_h^*); \|(x_h^0, \lambda_h^0) - (x_h^*, \lambda_h^*)\|_{Z_h}) \subseteq U_h.$$

To apply Theorem 2.8 we set

$$\bar{r}^* = \min\left(\frac{3r_{\min}}{4\sqrt{\max(2, 1 + c^2\gamma_e^2)}}, \frac{4}{\gamma_M \eta^* \max(2, 1 + c^2\gamma_e^2)} \right)$$

(compare with (2.5)). From (3.10) and (3.12) we conclude that

$$\|(x_h^*, \lambda_h^*) - r_h(x^*, \lambda^*)\|_{Z_h} \leq \frac{r_{\min}}{4}$$

for every $h \in (0, \bar{h}]$. Moreover, it follows that $\bar{r}^* < \frac{3}{4} r_{\min}$. Consequently, we have

$$B((x_h^*, \lambda_h^*); \bar{r}^*) \subset U_h.$$

Then Theorem 2.8 yields

$$\lim_{n\to\infty} \|(x_h^n, \lambda_h^n) - (x_h^*, \lambda_h^*)\|_{Z_h} = 0$$

and

$$\begin{aligned} &\|(x_h^{n+1}, \lambda_h^{n+1}) - (x_h^*, \lambda_h^*)\|_{Z_h} \\ &\qquad \leq \frac{1}{\gamma_M \eta^*} \max(2, 1 + c^2\gamma_e^2) \, \|(x_h^n, \lambda_h^n) - (x_h^*, \lambda_h^*)\|_{Z_h}^2 \end{aligned} \tag{3.14}$$

for the sequence $\{(x_h^n, \lambda_h^n)\}_{n\in\mathbb{N}}$, which is generated by Algorithm 2 with initial value $r_h(x^0, \lambda^0)$, if $\|r_h(x^0, \lambda^0) - (x_h^*, \lambda_h^*)\|_{Z_h} < \bar{r}^*$; i.e.,

$$\|r_h(x^0, \lambda^0) - (x_h^*, \lambda_h^*)\|_{Z_h} < \frac{3r_{\min}}{4\sqrt{\max(2, 1 + c^2\gamma_e^2)}} \tag{3.15}$$

and

$$\|r_h(x^0, \lambda^0) - (x_h^*, \lambda_h^*)\|_{Z_h} < \frac{4}{\gamma_M \eta^* \max(2, 1 + c^2\gamma_e^2)} \, . \tag{3.16}$$

Using Remark 3.8, (3.11), (3.10), and (3.12) we derive that

$$\begin{aligned} \|r_h(x^0, \lambda^0) - (x_h^*, \lambda_h^*)\|_{Z_h} &\leq \|r_h[(x^0, \lambda^0) - (x^*, \lambda^*)]\|_{Z_h} \\ &\quad + \|r_h(x^*, \lambda^*) - (x_h^*, \lambda_h^*)\|_{Z_h} \\ &\leq c_\circ \, \|(x^0, \lambda^0) - (x^*, \lambda^*)\|_Z + \tilde{C}\rho(h) \\ &< \frac{3r_{\min}}{4\sqrt{\max(2, 1 + c^2\gamma_e^2)}} \, . \end{aligned} \tag{3.17}$$

Analogously, estimate (3.16) follows. □

Remark 3.20. We infer from the proof of Corollary 3.19 that the choice of r_1 guarantees that the sequence $\{\|(x_h^n, \lambda_h^n) - (x_h^*, \lambda_h^*)\|_{Z_h}\}_{n\in\mathbb{N}}$ is strictly decreasing.

When Algorithm 2 and Algorithm 1 are stopped after the nth step, the difference between the iterates of the finite dimensional and the infinite dimensional methods can be estimated by the discretization error of the approximation scheme used. This is the assertion of the following corollary following from Theorem 3.17 (see [ABPR86]).

COROLLARY 3.21. *Let the assumptions of Corollary* 3.19 *hold. By* $\{(x^n, \lambda^n)\}_{n\in\mathbb{N}}$ *we denote the sequence generated by Algorithm* 1. *Then there exist* $\hat{h} \in (0, \tilde{h}]$ *and a constant* $r_2 \in (0, r_1]$ *such that*

$$(x_h^n, \lambda_h^n) = r_h(x^n, \lambda^n) + O\left(\rho(h)\right), \tag{3.18}$$

$$F_h(x_h^n, \tilde{\lambda}_h^n) = \hat{r}_h F(x^n, \tilde{\lambda}^n) + O\left(\rho(h)\right), \tag{3.19}$$

$$(x_h^n - x_h^*, \lambda_h^n - \lambda_h^*) = r_h(x^n - x^*, \lambda^n - \lambda^*) + O\left(\rho(h)\right) \tag{3.20}$$

for $n = 0, 1, \ldots$, *for starting values* $(x^0, \lambda^0) \in (V \times W) \cap B((x^*, \lambda^*); r_2)$, *for the sequence* $\{(x_h^n, \lambda_h^n)\}_{n\in\mathbb{N}}$ *generated by Algorithm* 2 *using the starting value* $r_h(x^0, \lambda^0)$ *with* $h \in (0, \hat{h}]$.

Remark 3.22. We emphasize that the results presented also hold for $c = 0$. Hence the convergence is proved for internal approximations of SQP-methods in Hilbert spaces.

4. Mesh-independence. Now we present the mesh-independence principle in its sharpest formulation; i.e., we give sufficient conditions for mesh-independence provided the mesh-size is smaller than an explicitly given threshold parameter. The proof is based on Corollary 2 in [ABPR86]. Since $c = 0$ is allowed, the mesh-independence principle also applies to internal approximations of SQP methods.

Let $\varepsilon > 0$. We define

$$\ell(\varepsilon) = \min\{\ell_0 \in \mathbb{N} |\text{ for } \ell \geq \ell_0 : \|(x^\ell, \lambda^\ell) - (x^*, \lambda^*)\|_Z < \varepsilon\},$$
$$\ell_h(\varepsilon) = \min\{\ell_0 \in \mathbb{N} |\text{ for } \ell \geq \ell_0 : \|(x_h^\ell, \lambda_h^\ell) - (x_h^*, \lambda_h^*)\|_{Z_h} < \varepsilon\}.$$

Let us point out that $\ell(\varepsilon)$ and $\ell_h(\varepsilon)$ depend on the starting values (x^0, λ^0) and $(x_h^0, \lambda_h^0) = r_h(x^0, \lambda^0)$ of the infinite and finite dimensional method.

THEOREM 4.1. *Suppose that the hypotheses of Corollary* 3.21 *hold. Let* $\varepsilon > 0$ *be chosen. Then there exist* $h^* \in (0, \hat{h}]$ *and* $r_3 \in (0, r_2]$, *so that*

$$|\ell(\varepsilon) - \ell_h(\varepsilon)| \leq 1 \tag{4.1}$$

for all $h \in (0, h^*]$ *and* $(x^0, \lambda^0) \in (V \times W) \cap B((x^*, \lambda^*); r_3)$.

Remark 4.2. The constant h^* depends of course on the given tolerance ε.

5. Numerical example for Example 2.1. We present a numerical example which illustrates that mesh-independence can be observed numerically choosing the control interval $\Omega_\circ = (0, 0.1)$, the viscosity parameter $\nu = \frac{1}{25}$, the regularity parameter $\alpha = 1$, the right-hand side $f(x) = x$, and the desired state $z(x) = x$. The boundary values are given by $y_l = 0$ and $y_r = 1$. Then the optimal solution of (P) is $(y^*, u^*) = (z, 0)$. It follows from (2.2) that $(\lambda^*, \mu^*, \xi^*) = (0, 0, 0)$ hold. Note that $(y_h^*, u_h^*) = (z, 0)$ is also the optimal solution of the finite dimensional problem (P_h).

Assumptions 1–5 are satisfied; see sections 2 and 3. For the proof of the uniform Babuška–Brezzi condition we refer the reader to [Vol99]. Now we are going to verify the uniform second-order sufficient optimality condition (Assumption 7).

LEMMA 5.1. *Let* $(v_h, q_h) \in \ker e_h'(z, 0)$. *Then we have*

$$\|v_h\|_{H^1}^2 \leq c_{\ker}\ \|q_h\|_{L^2(\Omega_\circ)}^2$$

for a constant $c_{\ker} > 0$.

Proof. Using $z(x) = x$ the property $(v_h, q_h) \in \ker e_h'(z, 0)$ implies that $v_h \in H_0^1(\Omega)$ and

$$\begin{aligned}
0 &= \langle e_h'(z, 0)(v_h, q_h), (v_h, 0, 0)\rangle_{Y_h} = \langle e'(z, 0)(v_h, q_h), (v_h, 0, 0)\rangle_Y \\
&= \nu\ \|v_h'\|_{L^2}^2 + \int_0^1 (zv_h)' v_h\, dx - \int_{\Omega_\circ} q_h v_h\, dx \\
&= \nu\ \|v_h'\|_{L^2}^2 + \|v_h\|_{L^2}^2 + \frac{1}{2}\ xv_h^2\Big|_{x=0}^{x=1} - \frac{1}{2}\ \|v_h\|_{L^2}^2 - \int_{\Omega_\circ} q_h v_h\, dx \\
&\geq \min\left(\nu, \frac{1}{2}\right) \|v_h\|_{H^1}^2 - \|q_h\|_{L^2(\Omega_\circ)}\ \|v_h\|_{H^1}.
\end{aligned}$$

Setting $c_{\ker} = [\min(\nu, \frac{1}{2})]^{-2}$ the claim follows. ∎

TABLE 5.1
$\ell_h(\varepsilon)$ for different tolerance ε and mesh-size h.

m	200	250	300	350	400	450	500	1000	1800
$\varepsilon = 10^{0}$	13	14	13	13	13	13	13	13	13
$\varepsilon = 10^{-2}$	14	15	14	14	14	14	14	14	14
$\varepsilon = 10^{-4}$	15	15	15	15	15	15	15	15	15
$\varepsilon = 10^{-6}$	15	16	15	15	15	15	15	15	15
$\varepsilon = 10^{-8}$	16	16	16	16	16	15	15	15	15
$\varepsilon = 10^{-10}$	16	16	16	16	16	16	16	16	16

PROPOSITION 5.2. *The uniform second-order sufficient optimality condition is satisfied.*

Proof. We have $p_h r_h(y^*, u^*, \lambda^*, \mu^*, \xi^*) = (z, 0, 0, 0, 0)$. Hence,

$$\begin{aligned}\langle L_h''(r_h(y^*, u^*, \lambda^*, \mu^*, \xi^*))(v_h, q_h), (v_h, q_h)\rangle_{X_h} &= \langle L''(z, 0, 0, 0, 0)(v_h, q_h), (v_h, q_h)\rangle_X \\ &= \|v_h\|_{L^2}^2 + \|q_h\|_{L^2(\Omega_\circ)}^2 \\ &\geq \min\left(\frac{1}{2}, \frac{1}{2c_{\ker}}\right) \|(v_h, q_h)\|_{X_h}\end{aligned}$$

by Lemma 5.1. Thus, the operator $L_h''(r_h(y^*, u^*, \lambda^*, \mu^*, \xi^*))$ is coercive on the kernel of $e_h'(r_h(y^*, u^*))$. □

PROPOSITION 5.3. *The optimal solution of* (OS) *satisfies* $(y^*, u^*, \lambda^*) \in H^2(\Omega) \times H^2(\Omega_\circ) \times H^2(\Omega)$. *If* $(y^0, u^0, \lambda^0) \in H^2(\Omega) \times H^2(\Omega_\circ) \times H^2(\Omega)$ *holds, then we have* $y^n \in H^2(\Omega)$, $u^n \in H^2(\Omega_\circ)$, *and* $\lambda^n \in H^2(\Omega)$. *Furthermore, Assumption* 8 *is satisfied.*

Proof. Since the optimal solution solves (OS), the regularity result for (y^*, u^*, λ^*) follows. The second claim is proved by induction. Let $(y^n, u^n, \lambda^n) \in H^2(\Omega) \times H^2(\Omega_\circ) \times H^2(\Omega)$ for $n \geq 0$. Then we have $e(y^n, u^n) \in H^2(\Omega) \times \mathbb{R}^2$, which implies that $\tilde{\lambda}^n \in H^2(\Omega)$. The saddle-point problem (2.4) implies that

$$\begin{aligned} -\nu(\lambda^{n+1})'' &= -y^{n+1} + (\tilde{\lambda}^n)' y^{n+1} + y^n(\lambda^{n+1})' + x - y^n(\tilde{\lambda}^n)' && \text{in } \Omega, \\ u^{n+1} &= \lambda^{n+1} && \text{in } \Omega_\circ, \\ -\nu(y^{n+1})'' &= -(y^n y^{n+1})' + \overline{u^{n+1}} + x + y^n(y^n)' && \text{in } \Omega. \end{aligned} \tag{5.1}$$

The first and third equations imply that $y^{n+1}, \lambda^{n+1} \in H^2(\Omega)$ hold. Using the second equation of (5.1) we see that $u^{n+1} \in H^2(\Omega_\circ)$. As we use piecewise linear finite elements, we obtain

$$\|(y, u, \lambda, \mu, \xi) - r_h(y, u, \lambda, \mu, \xi)\|_Z \leq \check{C} h \, \|(y'', u', \lambda'')\|_{L^2 \times L^2(\Omega_\circ) \times L^2}$$

for all $(y, u, \lambda, \mu, \xi) \in H^2(\Omega) \times H^2(\Omega_\circ) \times H^2(\Omega) \times \mathbb{R}^2$, where the constant $\check{C} > 0$ does not depend on (y, u, λ, μ) and h. If the starting value y^0 is close to y^*, then $\|y^n\|_{H^1} \leq C^* + \|y^*\|_{H^1}$ for all n. Thus, we infer from (5.1) that $\|(y^n)''\|_{L^2}$ is bounded for all n. Analogously, we derive that $\|(\lambda^n)''\|_{L^2}$ is bounded for all n. Since $u^n = \lambda^n$ in $\Omega_\circ$, the sequence $\|(u^n)''\|_{L^2(\Omega_\circ)}$ is also bounded for all n. We conclude that Assumption 8 holds. □

Remark 5.4. Note that the previous proposition also holds for arbitrary $f \in L^2(\Omega)$.

The program was written in MATLAB version 5.1, and we used an IBM RS/6000 590-workstation. We chose $c = 1$, $y^0(x) = -x^2$, $u^0(x) = 0$, $\lambda^0(x) = -1.5x$, $\mu^0 = 0$, and $\xi^0 = 0$. For $c = 0$ divergence was observed numerically. Table 5.1 yields that

TABLE 6.1
$\ell_h(\varepsilon)$ for different tolerance ε and mesh-size h.

$1/h$	30	40	60	80	100	160	200	250
$\varepsilon = 10^{0}$	3	3	3	3	3	4	4	4
$\varepsilon = 10^{-2}$	5	5	6	6	6	6	5	5
$\varepsilon = 10^{-4}$	6	6	7	7	7	7	6	6
$\varepsilon = 10^{-6}$	6	7	7	7	7	7	7	6
$\varepsilon = 10^{-8}$	7	7	8	8	8	7	7	7
$\varepsilon = 10^{-10}$	7	7	8	8	8	8	7	7

there is at most a difference of one between the number of steps required to converge within a given tolerance $\varepsilon > 0$. We emphasize that the mesh-independence principle is satisfied for $h \leq 0.005$.

6. Numerical example for Example 2.2. Let $l \in \mathbb{N}$ be given. We introduce a discretization of the time interval $[0, T]$ by setting $k = \frac{T}{l}$ and $t_j = jk$ for $j = 0, \ldots, l$. We used the implicit Euler method for the time integration and piecewise linear finite elements introduced in Remark 3.1.

Let $T = 1$, $\Omega = (0, 1)$, $\alpha = 0.1$, and $\nu = 0.01$. Further, we put

$$z(t, x) = \left(\left(x - \frac{1}{2}\right)^2 - \frac{1}{4}\right)\left(\left(t - \frac{1}{2}\right)^2 - \frac{1}{4}\right)$$

and $f = z_t - \nu z_{xx} + z z_x$. Clearly, $(y^*, u^*) = (z, 0)$ is the optimal solution of the optimal control problem. For the augmented Lagrangian-SQP method we chose $c = 50$. In the computations we used a uniform mesh h for the time as well as for the spatial discretization. To solve the linear system (3.6) we applied the MATLAB function `gmres` with preconditioning. The starting values of Algorithm 2 were chosen to be $y_h^0 = -z$, $u_h^0 = \lambda_h^0 = 0$. Note that the iteration y_h^n has to "pass through" 0. In Table 6.1 we specify the smallest iteration number $\ell = \ell_h(\varepsilon)$ such that

$$\|(y_h^\ell, u_h^\ell, \lambda_h^\ell) - (y_h^*, u_h^*, \lambda_h^*)\|_{Z_h} < \varepsilon.$$

We proved in Theorem 4.1 that a strong mesh-independence principle is valid for $\ell_h(\varepsilon)$ and the corresponding iteration count $\ell(\varepsilon)$ of the infinite dimensional method. But the approximation scheme used does not generally satisfy the assumptions of Theorem 4.1. However, Table 6.1 illustrates that the asymptotic mesh-independence can be observed numerically for $h \leq \frac{1}{30}$.

EXISTENCE OF RIGHT AND LEFT REPRESENTATIONS OF THE GRAPH FOR LINEAR PERIODICALLY TIME-VARYING SYSTEMS*

MICHAEL CANTONI† AND KEITH GLOVER†

Abstract. The graph representation of a system (the set of all input-output pairs) has gained considerable attention in the control literature in view of its usefulness for the analysis of feedback systems. In this paper it is shown that the graph of any *stabilizable*, linear, periodically time-varying (LPTV), continuous-time system can be expressed as the range and kernel of bounded, causal, LPTV systems that are, respectively, left and right invertible by bounded, causal, LPTV systems. These so-called strong-right and strong-left representations are closely related to the perhaps more common notion of coprime factor representations. As an example of their usefulness, a neat characterization of closed-loop stability is obtained in terms of strong-right and strong-left representations of the plant and controller graphs. This in turn leads to a Youla-style parametrization of stabilizing controllers. All of the results obtained accommodate possibly infinite-dimensional input and output spaces and apply, as a special case, to sampled-data control-systems. Furthermore, they are particularly useful for robustness analysis in terms of the gap metric.

Key words. graphs, periodic time-variation, system representations, stabilizing controllers

1. Introduction.

Fractional system representations are useful for the analysis and design of feedback systems [7, 24, 6]. For example, it is well known that the fundamental objective of closed-loop stability can be neatly characterized in terms of the coprime factors (taken over a set of stable systems) of a closed-loop's component systems [23]. Furthermore, the coprime factorization framework is closely related to robustness analysis in the graph topology [22, 11, 19, 25], and it also lies at the heart of the H^∞-loopshaping design paradigm for linear, time-invariant systems [14].

The existence of coprime factors has been linked to stabilizability for several classes of systems. For linear, time-invariant systems that evolve in either continuous or discrete time, this result is often expressed in terms of the corresponding frequency-domain transfer-function and a factorization of this over the Hardy space H^∞ (see [20, 23] and references therein). Existence results are also available for linear, time-varying systems described by finite-dimensional, stabilizable, and detectable state-space realizations [18, 16].

In [5], an input-output perspective is taken to study linear, time-varying, discrete-time systems. More specifically, it is shown in [5] that a causal, linear, time-varying, discrete-time system is *stabilizable* if and only if its graph (the set of all input-output pairs) can be expressed as the range (respectively, kernel) of a bounded, causal, linear system that is left (respectively, right) invertible by another bounded, causal, linear system. This so-called strong-right (respectively, strong-left) representation of the graph is notionally equivalent to the representation of the system as the ratio of right-coprime (respectively, left-coprime) factors, because a strong-right (respectively,

strong-left) representation of the graph can be constructed straightforwardly from any right-coprime (respectively, left-coprime) factorization. Unfortunately, the results as developed in [5] do not extend directly to accommodate continuous-time systems.

In this paper, the input-output perspective described above is employed to study linear, periodically time-varying (LPTV), continuous-time systems. Such systems arise in sampled-data control [3] and the analysis of nonlinear systems along specified periodic trajectories, for example. The main results presented in this paper imply that the graph of a stabilizable, LPTV, continuous-time system can be expressed as the range (respectively, kernel) of a bounded, causal, LPTV system that is left (respectively, right) invertible by a bounded, causal, LPTV system. These so-called strong-right and strong-left representations of the graph facilitate a neat characterization of closed-loop stability, a parametrization of stabilizing controllers and, correspondingly, gap-metric robustness analysis of LPTV feedback-systems (see [4]). All of the results obtained accommodate possibly infinite-dimensional input and output spaces, and as such, apply to systems that are spatially distributed.

The paper has the following structure. Preliminary results from functional analysis and general systems theory are presented in the next section. Underpinning many of the results developed in this paper is the equivalence of LPTV, continuous-time systems to linear, shift-invariant (LSI), discrete-time systems. This equivalence implies that the graph of an LPTV system is isomorphic to a shift-invariant subspace of the Hardy space H^2. As such, section 3 is devoted to the characterization of shift-invariant subspaces. There, it is shown that if a shift-invariant subspace is shift-invariantly coordinatizable, then it can be expressed as the range and kernel of multiplication operators with symbols in H^∞. It is also shown that these range and kernel representations are, respectively, left and right invertible by multiplication operators with symbols in H^∞. Once certain causality issues have been addressed (as described in section 4), this extension of the Beurling–Lax–Halmos theorem is used to prove the existence of strong-right and strong-left representations of the graph for stabilizable, LPTV systems. Finally, in section 5 a neat characterization of closed-loop stability and a Youla-style parametrization of stabilizing, LPTV controllers for LPTV plants are given in terms of strong-right and strong-left representations of the plant and controller graphs.

2. Preliminaries. In this section, general notation and definitions used throughout the paper are introduced. Let $\mathbb{R}$, $\mathbb{Z}$, $\mathbb{R}^+$, $\mathbb{Z}^+$, $\mathbb{D}$, and $\mathbb{T}$ denote the reals, integers, nonnegative reals, nonnegative integers, open unit-disc, and unit-circle, respectively. For convenience, given a real number $h > 0$, the interval $[0, h) \subset \mathbb{R}$ is denoted by $\mathbb{H}$. In any Hilbert space $\mathcal{H}$, the inner-product is denoted by $\langle \cdot, \cdot \rangle_{\mathcal{H}}$ and the norm by $\| \cdot \|_{\mathcal{H}}$. For a subspace $\mathcal{U} \subset \mathcal{H}$, the orthogonal complement of $\mathcal{U}$ in $\mathcal{H}$ is denoted by $\mathcal{H} \ominus \mathcal{U}$ (or $\mathcal{U}^\perp$ when the ambient space $\mathcal{H}$ is clear from context) and the orthogonal projection onto $\mathcal{U}$ is denoted by $\mathbf{\Pi}_{\mathcal{U}}$.

Consider two closed subspaces $\mathcal{G}$ and $\mathcal{F}$ of a Hilbert space $\mathcal{H}$. If $\mathcal{G} \cap \mathcal{F} = \{0\}$ and $\mathcal{G} + \mathcal{F} = \mathcal{H}$, then $\mathcal{G}$ and $\mathcal{F}$ are said to induce a *coordinatization* of $\mathcal{H}$. In this case, any $h \in \mathcal{H}$ can be uniquely decomposed as the sum $h = g + f$, where $g \in \mathcal{G}$ and $f \in \mathcal{F}$ (see [8], for example). The bounded, linear operator $\mathbf{\Pi}_{\mathcal{G}\|\mathcal{F}} : h \mapsto g$ is called the parallel projection onto $\mathcal{G}$ along $\mathcal{F}$. Similarly, $\mathbf{\Pi}_{\mathcal{F}\|\mathcal{G}} : h \mapsto f$ is called the *parallel projection* onto $\mathcal{F}$ along $\mathcal{G}$.

Let $\mathcal{U}$ and $\mathcal{Y}$ be Hilbert spaces and consider a linear operator $P : \mathcal{D}_P \subset \mathcal{U} \to \mathcal{Y}$, where $\mathcal{D}_P := \{u \in \mathcal{U} : Pu \in \mathcal{Y}\}$ is called the domain of P. The range of P is defined to be $\mathcal{R}_P := \{Pu : u \in \mathcal{D}_P\}$, and $\mathcal{K}_P := \{u \in \mathcal{D}_P : Pu = 0\}$ is called the kernel of P.

The *graph* of P is defined to be the set of all input-output pairs

$$\mathcal{G}_P := \begin{bmatrix} I \\ P \end{bmatrix} \mathcal{D}_P \subset \mathcal{U} \oplus \mathcal{Y},$$

and for notational convenience the *inverse graph* is denoted by $\mathcal{G}_P^\sharp := [\begin{smallmatrix} 0 & I \\ I & 0 \end{smallmatrix}]\mathcal{G}_P$. Note that a (linear) subspace $\mathcal{G} \subset \mathcal{U} \oplus \mathcal{Y}$ corresponds to the graph of a linear operator if and only if $\left[\begin{smallmatrix} 0 \\ y \end{smallmatrix}\right] \in \mathcal{G}$ implies that $y = 0$. The symbol $\mathcal{B}_{\mathcal{U},\mathcal{Y}}$ is used to denote the Banach space of all bounded, linear operators $P : \mathcal{U} \to \mathcal{Y}$, that is, all such operators with $\mathcal{D}_P = \mathcal{U}$ and finite induced-norm

$$\|P\| := \sup_{\substack{u \in \mathcal{D}_P \\ u \neq 0}} \frac{\|Pu\|_{\mathcal{Y}}}{\|u\|_{\mathcal{U}}} < \infty.$$

Given an operator $P \in \mathcal{B}_{\mathcal{U},\mathcal{Y}}$, there exists a unique operator $P^* \in \mathcal{B}_{\mathcal{Y},\mathcal{U}}$ such that for all $u \in \mathcal{U}$ and $y \in \mathcal{Y}$,

$$\langle y, Pu \rangle_{\mathcal{Y}} = \langle P^* y, u \rangle_{\mathcal{U}}.$$

The operator P^* is called the (Hilbert space) adjoint. Note that for any $P \in \mathcal{B}_{\mathcal{U},\mathcal{Y}}$, $P = (P^*)^*$ and $\mathcal{R}_P$ is orthogonal to $\mathcal{K}_{P^*}$. An operator $P \in \mathcal{B}_{\mathcal{U},\mathcal{Y}}$ is called an isometry if $\langle Pu, Pu \rangle_{\mathcal{Y}} = \langle u, u \rangle_{\mathcal{U}}$ for all $u \in \mathcal{U}$ (or equivalently, $P^*P = I$).

2.1. Signals and systems. In this paper, a system is simply considered to be an operator mapping between signal-spaces. Primarily, attention is focused on systems mapping between continuous-time spaces of signals with finite-energy. Mathematically such signals can be thought of as functions in $\mathrm{L}^2_{\mathbb{R}^+}(\mathcal{H})$, the Hilbert space of $\mathcal{H}$-valued, (Lebesgue) square-integrable functions $f : \mathbb{R}^+ \to \mathcal{H}$. By virtue of the class of systems considered in the sequel and the analysis technique employed to study these systems, the following signal-spaces also play an important role: the discrete-time signal-space $\ell^2_{\mathbb{Z}^+}(\mathcal{H})$ of square-summable sequences $\mathsf{f} : \mathbb{Z}^+ \to \mathcal{H}$; and the frequency-domain signal-space $\mathrm{H}^2_{\mathbb{D}}(\mathcal{H})$ of functions $\varphi : \mathbb{D} \to \mathcal{H}$ that are analytic in $\mathbb{D}$ and satisfy

$$\int_0^{2\pi} \left\langle \varphi(re^{j\omega}), \varphi(re^{j\omega}) \right\rangle_{\mathcal{H}} d\omega < M$$

for some $M < \infty$ and all $0 \leq r < 1$. Note that $\mathrm{H}^2_{\mathbb{D}}(\mathcal{H})$ is isomorphic to $\ell^2_{\mathbb{Z}^+}(\mathcal{H})$ via the $\mathbf{Z}$-transform isomorphism [21, pp. 184–185], defined for all $\mathsf{f} \in \ell^2_{\mathbb{Z}^+}(\mathcal{H})$ by

$$(\mathbf{Z}\mathsf{f})(\lambda) := \sum_{i=0}^{\infty} \mathsf{f}_k \lambda^k, \quad \lambda \in \mathbb{D}.$$

Let $\mathcal{U}$ and $\mathcal{Y}$ be Hilbert spaces. For a linear, continuous-time system $P : \mathcal{D}_P \subset \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U}) \to \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{Y})$, the standard notion of causality can be expressed as follows: P is *causal* if for all $\tau \in \mathbb{R}^+$, $\mathbf{T}_\tau \mathcal{G}_P$ corresponds to the graph of a linear operator, where $\mathbf{T}_\tau$ is the projection that truncates a signal to zero after time τ. Given a real number $h > 0$, such a system P is called *periodically time-varying* (with period h) if $\mathbf{U}_{kh}\mathcal{G}_P \subset \mathcal{G}_P$ for all $k \in \mathbb{Z}^+$, where $\mathbf{U}_\tau$ denotes the unilateral (forward) shift on $\mathrm{L}^2_{\mathbb{R}^+}(\cdot)$.[1]

[1] According to this definition a linear, time-invariant system is also LPTV, since such a system must, by definition, satisfy $\mathbf{U}_\tau \mathcal{G}_P \subset \mathcal{G}_P$ for all $\tau \in \mathbb{R}^+$.

The following technical definitions are necessary to facilitate a precise definition of the class of systems considered in that which follows. A causal, linear, continuous-time system $P : \mathcal{D}_P \subset \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U}) \to \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U})$ is said to be *causally extendible* if $\mathbf{T}_\tau \mathcal{D}_P = \mathbf{T}_\tau \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U})$ for all $\tau < \infty$. In this way, the input to P can be chosen arbitrarily over any finite interval $[0, \tau)$ and then continued into $\mathcal{D}_P$. Since P is causal, the corresponding output over $[0, \tau)$ is defined *uniquely* by the input up to time τ. Accordingly, when P is causally extendible there is a one-to-one correspondence between P and a system $P_e : \mathrm{L}^{2,\mathrm{e}}_{\mathbb{R}^+}(\mathcal{U}) \to \mathrm{L}^{2,\mathrm{e}}_{\mathbb{R}^+}(\mathcal{Y})$ such that for all $u_e \in \mathrm{L}^{2,\mathrm{e}}_{\mathbb{R}^+}(\mathcal{U})$ and $\tau < \infty$, $\mathbf{T}_\tau P_e u_e = \mathbf{T}_\tau P_e \mathbf{T}_\tau u_e := \mathbf{T}_\tau P u$ for any $u \in \mathcal{D}_P$ that satisfies $\mathbf{T}_\tau u_e = \mathbf{T}_\tau u$, where $\mathrm{L}^{2,\mathrm{e}}_{\mathbb{R}^+}(\mathcal{H}) := \{f : \mathbb{R}^+ \to \mathcal{H} \,:\, \mathbf{T}_\tau f \in \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{H}) \;\forall\, \tau < \infty\}$ denotes the extended space associated with $\mathrm{L}^2_{\mathbb{R}^+}(\mathcal{H})$ for any Hilbert space $\mathcal{H}$. If P and P_e are related in this way, P_e is called the (causal) extension of P and it is said that P is induced by P_e. When P is causally extendible, its causal extension P_e is said to be *locally Lipschitz-continuous* if for all $\tau \in \mathbb{R}^+$,

$$\sup_{\substack{u_1, u_2 \in \mathrm{L}^{2,\mathrm{e}}_{\mathbb{R}^+}(\mathcal{U}) \\ \mathbf{T}_\tau u_1 \neq \mathbf{T}_\tau u_2}} \frac{\|\mathbf{T}_\tau (P u_1 - P u_2)\|_{\mathrm{L}^2_{\mathbb{R}^+}(\mathcal{Y})}}{\|\mathbf{T}_\tau (u_1 - u_2)\|_{\mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U})}} < \infty.$$

DEFINITION 2.1. *Given two Hilbert spaces $\mathcal{U}$ and $\mathcal{Y}$, let $\mathscr{P}_{\mathcal{U},\mathcal{Y}}$ denote the set of causal, LPTV (with period h), continuous-time systems*

$$P : \mathcal{D}_P \subset \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U}) \to \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{Y}),$$

with closed graphs.[2] *Furthermore, let $\mathscr{P}^e_{\mathcal{U},\mathcal{Y}} \subset \mathscr{P}_{\mathcal{U},\mathcal{Y}}$ denote the subset of causally extendible systems with locally Lipschitz-continuous extensions.*

A continuous-time system $P : \mathcal{D}_P \subset \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U}) \to \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{Y})$ is said to be stable if it is causal and $\mathcal{D}_P = \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U})$. If the system also has a closed graph, then $\|P\| < \infty$ by the closed graph theorem [2, p. 80]. Note that any stable system $P \in \mathscr{P}_{\mathcal{U},\mathcal{Y}}$ is an element of $\mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$.

Importantly, each system in $\mathscr{P}_{\mathcal{U},\mathcal{Y}}$ is equivalent (via the time-lifting isomorphism defined next) to a discrete-time system that is shift invariant [1]. Let $\mathbf{W} : \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{H}) \to \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{H}))$ denote the *time-lifting isomorphism* defined for each $f \in \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{H})$ by

$$\vec{\mathsf{f}}^{\circ}_k(\theta) := (\mathbf{W} f)_k = f(kh + \theta), \quad \theta \in \mathbb{H},$$

where $\mathrm{L}^2_{\mathbb{H}}(\mathcal{H}) := \mathbf{T}_h \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{H})$. Then given any system $P \in \mathscr{P}_{\mathcal{U},\mathcal{Y}}$, the time-lifted equivalent, discrete-time system

$$\mathsf{P} := \mathbf{W} P \mathbf{W}^{-1} : \mathcal{D}_{\mathsf{P}} \subset \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})) \to \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y}))$$

is causal and LSI in the sense that its graph is a shift-invariant (linear) subspace, meaning $\mathbf{S}\mathcal{G}_{\mathsf{P}} \subset \mathcal{G}_{\mathsf{P}} = \mathbf{W}\mathcal{G}_P$, and $\mathbf{T}_k \mathcal{G}_{\mathsf{P}}$ corresponds to the graph of a linear operator for all $k \in \mathbb{Z}^+$ (implying causality), where $\mathbf{S}$ denotes the unilateral (forward) shift on $\ell^2_{\mathbb{Z}^+}(\cdot)$, and $\mathbf{T}_k$ denotes the truncation to zero after time k.[3] The key here is that $\mathbf{S}^k \mathbf{W} = \mathbf{W} \mathbf{U}_{kh}$ for all $k \in \mathbb{Z}^+$, so that a shift by h in the continuous-time signal

[2] That a linear system has a closed graph is necessary for it to be stabilizable [10]. Hence, this is assumed.

[3] Throughout, the sans serif font (e.g., P) is used to distinguish objects associated with discrete-time signals/systems from continuous-time objects, for which Roman italics are used (e.g., P).

space $\mathrm{L}^2_{\mathbb{R}^+}(\cdot)$ corresponds to a shift by a single time-step in the isomorphic, discrete-time signal-space $\ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\cdot))$. Note that by representing each signal in $\ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\cdot))$ as a column vector with kth entry corresponding to the value of the signal at time k, the time-lifted equivalent system $\mathsf{P}(:=\mathbf{W}P\mathbf{W}^{-1})$ has lower-triangular, block-Toeplitz structure

$$\begin{bmatrix} \mathsf{P}_{[0]} & 0 & \cdots & \cdots & \cdots \\ \mathsf{P}_{[1]} & \mathsf{P}_{[0]} & 0 & \cdots & \cdots \\ \mathsf{P}_{[2]} & \mathsf{P}_{[1]} & \mathsf{P}_{[0]} & 0 & \cdots \\ \vdots & \ddots & \ddots & \ddots & \ddots \end{bmatrix},$$

which can be uniquely identified with the sequence $\{\mathsf{P}_{[i]}\}_{i=0}^{\infty}$. This representation plays a significant role in that which follows. If the original LPTV system P is causally extendible to a locally Lipschitz-continuous system, then each $\mathsf{P}_{[i]} \in \mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y})}$.

REMARK 2.2. *Given an LSI system* $\mathsf{P} : \mathcal{D}_{\mathsf{P}} \subset \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})) \to \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y}))$,[4] *the equivalent continuous-time system* $P(:=\mathbf{W}^{-1}\mathsf{P}\mathbf{W}$ *may not be locally causal in each* $[kh,(k+1)h)$ *interval of time. The equivalent system* P *is causal if and only if* $\mathsf{P}_{[0]}$ *(the first element of the sequence uniquely identifiable with the block-Toeplitz representation of* P*) is a causal mapping from* $\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})$ *to* $\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y})$*, in the sense that* $\mathbf{T}_\tau \mathcal{G}_{\mathsf{P}_{[0]}}$ *corresponds to the graph of a linear operator for all* $\tau \in \mathbb{H}$.

An LSI system $\mathsf{P} : \mathcal{D}_{\mathsf{P}} \subset \ell^2_{\mathbb{Z}^+}(\mathcal{U}) \to \ell^2_{\mathbb{Z}^+}(\mathcal{Y})$ is said to be stable if $\mathcal{D}_{\mathsf{P}} = \ell^2_{\mathbb{Z}^+}(\mathcal{U})$. If in addition $\mathcal{G}_{\mathsf{P}}$ is closed, then $\|\mathsf{P}\| < \infty$ by the closed graph theorem. Related to such operators is the Hardy space $\mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{U},\mathcal{Y}})$ of functions $\Phi : \mathbb{D} \to \mathcal{B}_{\mathcal{U},\mathcal{Y}}$ that are bounded and analytic in the open unit-disc. Given a function $\Phi \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{U},\mathcal{Y}})$, boundary values can be defined almost everywhere on the unit-circle $\mathbb{T}$, and the resulting boundary values $\Phi(e^{j\omega})$ are essentially bounded. A function $\Phi \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{U},\mathcal{Y}})$ is said to be inner if $\Phi(e^{j\omega})$ is an isometry almost everywhere on $\mathbb{T}$. Corresponding to each $\Phi \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{U},\mathcal{Y}})$ is a multiplication operator $\mathbf{M}_\Phi : \mathrm{H}^2_{\mathbb{D}}(\mathcal{U}) \to \mathrm{H}^2_{\mathbb{D}}(\mathcal{Y})$, defined by $(\mathbf{M}_\Phi\varphi)(\lambda)(:=\Phi(\lambda)\varphi(\lambda)$ for all $\varphi \in \mathrm{H}^2_{\mathbb{D}}(\mathcal{U})$ and $\lambda \in \mathbb{D}$.

PROPOSITION 2.3 (see [9, p. 235]). *Given a stable, LSI system* $\mathsf{P} : \ell^2_{\mathbb{Z}^+}(\mathcal{U}) \to \ell^2_{\mathbb{Z}^+}(\mathcal{Y})$ *with a closed graph, there exists a function* $\hat{\mathsf{P}} \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{U},\mathcal{Y}})$ *such that* $\mathsf{P} = \mathbf{Z}^{-1}\mathbf{M}_{\hat{\mathsf{P}}}\mathbf{Z}$. *Furthermore,* P *is an isometry if and only if the corresponding symbol* $\hat{\mathsf{P}}$ *is inner.*

2.2. Feedback systems. Consider the feedback configuration shown in Figure 2.1, and suppose that $P \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ and $C \in \mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$. Denote by P_e and C_e the respective locally Lipschitz-continuous causal extensions (which exist by assumption), and for notational convenience let $\mathcal{V}(:=\mathcal{U}\oplus\mathcal{Y}$. The closed-loop, denoted by $[P,C]$, is said to be well posed if the following three conditions hold:

(i) $\left[\begin{smallmatrix} I & C_e \\ P_e & I \end{smallmatrix}\right] : \mathrm{L}^{2,\mathrm{e}}_{\mathbb{R}^+}(\mathcal{V}) \to \mathrm{L}^{2,\mathrm{e}}_{\mathbb{R}^+}(\mathcal{V})$, the system mapping $\left[\begin{smallmatrix} u_1 \\ u_2 \end{smallmatrix}\right]$ to $\left[\begin{smallmatrix} d_1 \\ d_2 \end{smallmatrix}\right]$, is bijective, implying the existence of a *unique* solution to the functional equations that describe the closed-loop;

(ii) $H_e(P,C)(:=\left[\begin{smallmatrix} I & C_e \\ P_e & I \end{smallmatrix}\right]^{-1}$ is causal and locally Lipschitz-continuous;

(iii) The solution to the functional equations that describe the closed-loop is insensitive to very high frequency modeling errors, such as small transmission delays.

For further details and a discussion of the physical significance of well-posedness, the reader is referred to the seminal work of Willems [26, Chap. 4]. In addition to well-

[4] Since this system is only defined for positive time, shift-invariance implies causality.

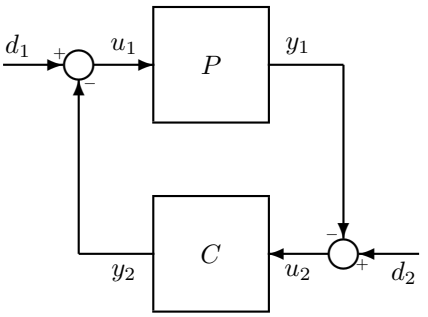

FIG. 2.1. *Standard feedback configuration.*

posedness, it is desirable for the system $H(P,C) : \mathcal{D}_{H(P,C)} \subset \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{V}) \to \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{V})$ induced by $H_e(P,C)$, to satisfy $\mathcal{D}_{H(P,C)} = \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{V})$. In this case, the closed-loop is said to be stable and P is said to be stabilized by C. Since P and C are both linear, it can be shown that this also implies closed-loop stability with finite-gain [26, p. 117]; that is, $\|H(P,C)\| < \infty$.

Given a plant $P \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ and a controller $C \in \mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$, note that

$$\begin{bmatrix} I & C \\ P & I \end{bmatrix} : \mathcal{D}_P \oplus \mathcal{D}_C \to \mathcal{G}_P + \mathcal{G}^\sharp_C.$$

Thus, if $[P,C]$ is well posed, then $\mathcal{G}_P \cap \mathcal{G}^\sharp_C = \{0\}$. Furthermore, observe that $\mathcal{D}_{H(P,C)} = \mathcal{G}_P + \mathcal{G}^\sharp_C$ and hence that the closed-loop is stable if and only if $\mathcal{G}_P + \mathcal{G}^\sharp_C = \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{V})$ (with $\mathcal{G}_P \cap \mathcal{G}^\sharp_C = \{0\}$). This useful geometric characterization of closed-loop stability is summarized in the following proposition, which has also appeared in [10, 12, 15] for other classes of systems.

PROPOSITION 2.4. *Given a well-posed plant/controller pair $P \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ and $C \in \mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$, the closed-loop $[P,C]$ is stable if and only if $\mathcal{G}_P$ and $\mathcal{G}^\sharp_C$ induce a coordinatization of $\mathrm{L}^2_{\mathbb{R}^+}(\mathcal{V})$. In this case, the parallel projections $\mathbf{\Pi}_{\mathcal{G}_P \| \mathcal{G}^\sharp_C}$ and $\mathbf{\Pi}_{\mathcal{G}^\sharp_C \| \mathcal{G}_P}$ are stable systems in $\mathscr{P}^e_{\mathcal{V},\mathcal{V}}$.*

REMARK 2.5. *Let the systems $P \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ and $C \in \mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$ constitute a well-posed plant/controller pair, and recall that $\mathcal{G}_P$ and $\mathcal{G}^\sharp_C$ are isomorphic to shift-invariant subspaces $\hat{\mathcal{G}}_{\mathsf{P}} := \mathbf{ZW}\mathcal{G}_P \subset \mathrm{H}^2_{\mathbb{D}}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{V}))$ and $\hat{\mathcal{G}}^\sharp_{\mathsf{C}} := \mathbf{ZW}\mathcal{G}^\sharp_C \subset \mathrm{H}^2_{\mathbb{D}}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{V}))$, respectively. It follows directly by Proposition 2.4 that the corresponding closed-loop $[P,C]$ is stable if and only if $\hat{\mathcal{G}}_{\mathsf{P}}$ and $\hat{\mathcal{G}}^\sharp_{\mathsf{C}}$ induce a coordinatization of $\mathrm{H}^2_{\mathbb{D}}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{V}))$.*

3. Shift-invariant subspaces. In view of Remark 2.5, shift-invariant subspaces arise somewhat naturally in the study of LPTV, continuous-time systems. Accordingly, this section is concerned with the characterization of shift-invariant subspaces.[5] To this end, the Beurling–Lax–Halmos theorem [13, 17, 9] is used, which states that any shift-invariant subspace of $\mathrm{H}^2_{\mathbb{D}}$ can be expressed as the range of a multiplication operator with inner symbol. This result is extended here, to show that if the shift-invariant subspace is also shift-invariantly coordinatizable, then it can be expressed as the kernel of a multiplication operator with symbol in $\mathrm{H}^\infty_{\mathbb{D}}$. Furthermore, it is shown

[5] A subspace of a Hilbert space is linear by definition. Furthermore, a shift-invariant subspace $\mathcal{G}$ satisfies $\mathbf{S}\mathcal{G} \subset \mathcal{G}$, by definition.

that these range and kernel representations are, respectively, right and left invertible by multiplication operators with symbols in $\mathrm{H}^\infty_{\mathbb{D}}$. Using this result, strong-right and strong-left representations of the graph of an LPTV, continuous-time system may be constructed as shown in section 4, provided the system is stabilizable.

Let $\mathcal{G} \subset \mathrm{H}^2_{\mathbb{D}}(\mathcal{H})$ be a closed, shift-invariant subspace, where $\mathcal{H}$ is a Hilbert space. Then $\mathcal{G}$ is said to be *shift-invariantly coordinatizable* if there exists a closed, shift-invariant subspace $\mathcal{F} \subset \mathrm{H}^2_{\mathbb{D}}(\mathcal{H})$ such that $\mathcal{G}$ and $\mathcal{F}$ induce a coordinatization of $\mathrm{H}^2_{\mathbb{D}}(\mathcal{H})$; that is, such that $\mathcal{G} \cap \mathcal{F} = \{0\}$ and $\mathcal{G} + \mathcal{F} = \mathrm{H}^2_{\mathbb{D}}(\mathcal{H})$. Recall that when two (closed) subspaces, $\mathcal{G}$ and $\mathcal{F}$ say, induce a coordinatization of $\mathrm{H}^2_{\mathbb{D}}(\mathcal{H})$, any $\eta \in \mathrm{H}^2_{\mathbb{D}}(\mathcal{H})$ can be uniquely decomposed as the sum $\eta = \gamma + \varphi$, where $\gamma \in \mathcal{G}$ and $\varphi \in \mathcal{F}$. Furthermore, recall that the operator $\mathbf{\Pi}_{\mathcal{G}\|\mathcal{F}} := \eta \mapsto \gamma$ is called the parallel projection onto $\mathcal{G}$ along $\mathcal{F}$ and similarly, that $\mathbf{\Pi}_{\mathcal{F}\|\mathcal{G}} := \eta \mapsto \varphi$ is called the parallel projection onto $\mathcal{F}$ along $\mathcal{G}$. Since $\mathcal{G}$ and $\mathcal{F}$ are closed subspaces it follows that the graphs of the parallel-projection operators are closed and thus, that the parallel-projection operators are bounded, by the closed graph theorem [2, p. 80]. If $\mathcal{G}$ and $\mathcal{F}$ are shift-invariant subspaces, then it follows immediately that the parallel-projection operators are LSI.

PROPOSITION 3.1 (Beurling–Lax–Halmos theorem [13, 17, 9]). *Given a shift-invariant subspace $\mathcal{L} \subset \mathrm{H}^2_{\mathbb{D}}(\mathcal{H})$, there exists an inner function $\Lambda_r \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{H}_1,\mathcal{H}})$ such that $\mathcal{L} = \Lambda_r \mathrm{H}^2_{\mathbb{D}}(\mathcal{H}_1)$, where $\mathcal{H}_1$ can be any Hilbert space isomorphic to $\mathcal{L} \ominus \mathbf{S}\mathcal{L}$.*

Let $\mathcal{G}$ and $\mathcal{F}$ be two shift-invariant subspaces that induce a coordinatization of $\mathrm{H}^2_{\mathbb{D}}(\mathcal{H})$. Then in view of Proposition 3.1, there exist *inner* functions $\Gamma_r \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{H}_1,\mathcal{H}})$ and $\Phi_r \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{H}_2,\mathcal{H}})$ such that $\mathcal{G} = \Gamma_r \mathrm{H}^2_{\mathbb{D}}(\mathcal{H}_1)$ and $\mathcal{F} = \Phi_r \mathrm{H}^2_{\mathbb{D}}(\mathcal{H}_2)$, where $\mathcal{H}_1$ is any Hilbert space isomorphic to $\mathcal{G} \ominus \mathbf{S}\mathcal{G}$ and $\mathcal{H}_2$ is any Hilbert space isomorphic to $\mathcal{F} \ominus \mathbf{S}\mathcal{F}$. Note that since $\mathbf{M}_{\Gamma_r}$ and $\mathbf{M}_{\Phi_r}$ are isometries (because their symbols are inner), the orthogonal projections $\mathbf{\Pi}_{\mathcal{G}}$ onto $\mathcal{G}$ and $\mathbf{\Pi}_{\mathcal{F}}$ onto $\mathcal{F}$ can be expressed as $\mathbf{M}_{\Gamma_r}(\mathbf{M}_{\Gamma_r})^*$ and $\mathbf{M}_{\Phi_r}(\mathbf{M}_{\Phi_r})^*$, respectively. This fact and the following technical result are used in the proof of the main theorem of this section.

LEMMA 3.2. *Given two closed, shift-invariant subspaces $\mathcal{G}$ and $\mathcal{F}$ that induce a coordinatization of $\mathrm{H}^2_{\mathbb{D}}(\mathcal{H})$, let $\Gamma_r \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{H}_1,\mathcal{H}})$ and $\Phi_r \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{H}_2,\mathcal{H}})$ be inner functions that satisfy $\mathcal{G} = \Gamma_r \mathrm{H}^2_{\mathbb{D}}(\mathcal{H}_1)$ and $\mathcal{F} = \Phi_r \mathrm{H}^2_{\mathbb{D}}(\mathcal{H}_2)$. Then the operators $(\mathbf{M}_{\Gamma_r})^* \mathbf{\Pi}_{\mathcal{G}\|\mathcal{F}}$ and $(\mathbf{M}_{\Phi_r})^* \mathbf{\Pi}_{\mathcal{F}\|\mathcal{G}}$ are bounded and LSI.*

Proof. It is only shown that $(\mathbf{M}_{\Gamma_r})^* \mathbf{\Pi}_{\mathcal{G}\|\mathcal{F}}$ is bounded and LSI. The proof that $(\mathbf{M}_{\Phi_r})^* \mathbf{\Pi}_{\mathcal{F}\|\mathcal{G}}$ is also bounded and LSI follows similarly. $(\mathbf{M}_{\Gamma_r})^* \mathbf{\Pi}_{\mathcal{G}\|\mathcal{F}}$ is clearly linear and bounded on $\mathrm{H}^2_{\mathbb{D}}(\mathcal{H})$, since it is the product of two bounded, linear operators. To see that it is also shift invariant, note that any $\eta \in \mathrm{H}^2_{\mathbb{D}}(\mathcal{H})$ is uniquely expressible as $\eta = \gamma + \varphi$, where $\gamma = \mathbf{\Pi}_{\mathcal{G}\|\mathcal{F}} \eta \in \mathcal{G}$ and $\varphi = \mathbf{\Pi}_{\mathcal{F}\|\mathcal{G}} \eta \in \mathcal{F}$, and since $\mathbf{M}_{\Gamma_r}$ is an isometry, that there exists a unique $\zeta \in \mathrm{H}^2_{\mathbb{D}}(\mathcal{H}_1)$ such that $\gamma = \mathbf{M}_{\Gamma_r} \zeta$. In fact, $\zeta = (\mathbf{M}_{\Gamma_r})^* \mathbf{\Pi}_{\mathcal{G}\|\mathcal{F}} \eta$. Now using the relationships $\mathbf{S}\eta = \mathbf{S}\gamma + \mathbf{S}\varphi$, $\mathbf{S}\gamma = \mathbf{M}_{\Gamma_r} \mathbf{S}\zeta \in \mathcal{G}$ and $\mathbf{S}\varphi \in \mathcal{F}$, it follows that

$$(\mathbf{M}_{\Gamma_r})^* \mathbf{\Pi}_{\mathcal{G}\|\mathcal{F}} \mathbf{S}\eta = (\mathbf{M}_{\Gamma_r})^* \mathbf{S}\gamma = \mathbf{S}\zeta = \mathbf{S}(\mathbf{M}_{\Gamma_r})^* \mathbf{\Pi}_{\mathcal{G}\|\mathcal{F}} \eta.$$

That is, $(\mathbf{M}_{\Gamma_r})^* \mathbf{\Pi}_{\mathcal{G}\|\mathcal{F}}$ is also shift invariant. ∎

The following theorem is the main result of this section. It is essentially an extension of the Beurling–Lax–Halmos theorem, in that it guarantees the existence of a kernel representation of a shift-invariant subspace if it is also shift-invariantly coordinatizable.

THEOREM 3.3. *Given a closed, shift-invariant subspace $\mathcal{G} \subset \mathrm{H}^2_{\mathbb{D}}(\mathcal{H})$ that is shift-invariantly coordinatizable, there exist functions $\Gamma_r \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{H}_1,\mathcal{H}})$, $\Gamma_l \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{H},\mathcal{H}_2})$,*

$\Phi_r \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{H}_2,\mathcal{H}})$, *and* $\Phi_l \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{H},\mathcal{H}_1})$ *such that*

$$\mathcal{G} = \mathcal{R}_{\mathbf{M}_{\Gamma_r}} = \mathcal{K}_{\mathbf{M}_{\Gamma_l}},$$

$$\begin{bmatrix}\mathbf{M}_{\Gamma_r} & \mathbf{M}_{\Phi_r}\end{bmatrix}\begin{bmatrix}\mathbf{M}_{\Phi_l}\\ \mathbf{M}_{\Gamma_l}\end{bmatrix} = \mathrm{I} \quad \textit{and} \quad \begin{bmatrix}\mathbf{M}_{\Phi_l}\\ \mathbf{M}_{\Gamma_l}\end{bmatrix}\begin{bmatrix}\mathbf{M}_{\Gamma_r} & \mathbf{M}_{\Phi_r}\end{bmatrix} = \begin{bmatrix}\mathrm{I} & 0\\ 0 & \mathrm{I}\end{bmatrix},$$

where $\mathcal{H}_1$ *can be any Hilbert space isomorphic to* $\mathcal{G} \ominus \mathbf{S}\mathcal{G}$, $\mathcal{H}_2$ *any Hilbert space isomorphic to* $\mathcal{F} \ominus \mathbf{S}\mathcal{F}$ *and* $\mathcal{F}$ *any closed, shift-invariant subspace that in conjunction with* $\mathcal{G}$ *induces a coordinatization of* $\mathrm{H}^2_{\mathbb{D}}(\mathcal{H})$.

Proof. By assumption there exists a shift-invariant subspace $\mathcal{F} \subset \mathrm{H}^2_{\mathbb{D}}(\mathcal{H})$ such that $\mathcal{G}$ and $\mathcal{F}$ induce a coordinatization of $\mathrm{H}^2_{\mathbb{D}}(\mathcal{H})$. Furthermore, by the Beurling–Lax–Halmos theorem, there exist inner functions $\Gamma_r \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{H}_1,\mathcal{H}})$ and $\Phi_r \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{H}_2,\mathcal{H}})$, with $\mathcal{H}_1 \sim \mathcal{G} \ominus \mathbf{S}\mathcal{G}$ and $\mathcal{H}_2 \sim \mathcal{F} \ominus \mathbf{S}\mathcal{F}$, such that $\mathcal{G} = \mathcal{R}_{\mathbf{M}_{\Gamma_r}}$ and $\mathcal{F} = \mathcal{R}_{\mathbf{M}_{\Phi_r}}$.

Now by Lemma 3.2, $(\mathbf{M}_{\Gamma_r})^*\mathbf{\Pi}_{\mathcal{G}\|\mathcal{F}}$ and $(\mathbf{M}_{\Phi_r})^*\mathbf{\Pi}_{\mathcal{F}\|\mathcal{G}}$ are bounded, LSI operators on $\mathrm{H}^2_{\mathbb{D}}(\mathcal{H})$. As such, by Proposition 2.3, there exist functions $\Phi_l \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{H},\mathcal{H}_1})$ and $\Gamma_l \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{H},\mathcal{H}_2})$, so that

$$\mathbf{M}_{\Phi_l} = (\mathbf{M}_{\Gamma_r})^*\mathbf{\Pi}_{\mathcal{G}\|\mathcal{F}} \quad \text{and} \quad \mathbf{M}_{\Gamma_l} = (\mathbf{M}_{\Phi_r})^*\mathbf{\Pi}_{\mathcal{F}\|\mathcal{G}}. \tag{3.1}$$

Since $\mathcal{R}_{\mathbf{\Pi}_{\mathcal{G}\|\mathcal{F}}} (= \mathcal{R}_{\mathbf{M}_{\Gamma_r}})$ is orthogonal to $\mathcal{K}_{(\mathbf{M}_{\Gamma_r})^*}$, it follows from (3.1) that $\mathcal{K}_{\mathbf{M}_{\Phi_l}} = \mathcal{K}_{\mathbf{\Pi}_{\mathcal{G}\|\mathcal{F}}} = \mathcal{F}$. Similarly, $\mathcal{K}_{\mathbf{M}_{\Gamma_l}} = \mathcal{G}$. Consequently it remains to show that

$$\begin{bmatrix}\mathbf{M}_{\Gamma_r} & \mathbf{M}_{\Phi_r}\end{bmatrix}\begin{bmatrix}\mathbf{M}_{\Phi_l}\\ \mathbf{M}_{\Gamma_l}\end{bmatrix} = \begin{bmatrix}\mathbf{M}_{\Phi_l}\\ \mathbf{M}_{\Gamma_l}\end{bmatrix}\begin{bmatrix}\mathbf{M}_{\Gamma_r} & \mathbf{M}_{\Phi_r}\end{bmatrix} = \begin{bmatrix}\mathrm{I} & 0\\ 0 & \mathrm{I}\end{bmatrix}.$$

To see this, first note that

$$\mathbf{\Pi}_{\mathcal{G}\|\mathcal{F}} = \mathbf{\Pi}_{\mathcal{G}}\mathbf{\Pi}_{\mathcal{G}\|\mathcal{F}} = \mathbf{M}_{\Gamma_r}(\mathbf{M}_{\Gamma_r})^*\mathbf{\Pi}_{\mathcal{G}\|\mathcal{F}} = \mathbf{M}_{\Gamma_r}\mathbf{M}_{\Phi_l}$$

and

$$\mathbf{\Pi}_{\mathcal{F}\|\mathcal{G}} = \mathbf{\Pi}_{\mathcal{F}}\mathbf{\Pi}_{\mathcal{F}\|\mathcal{G}} = \mathbf{M}_{\Phi_r}(\mathbf{M}_{\Phi_r})^*\mathbf{\Pi}_{\mathcal{F}\|\mathcal{G}} = \mathbf{M}_{\Phi_r}\mathbf{M}_{\Gamma_l}.$$

Using the relationship $\mathbf{\Pi}_{\mathcal{G}\|\mathcal{F}} + \mathbf{\Pi}_{\mathcal{F}\|\mathcal{G}} = \mathrm{I}$, it is then immediate that

$$\begin{bmatrix}\mathbf{M}_{\Gamma_r} & \mathbf{M}_{\Phi_r}\end{bmatrix}\begin{bmatrix}\mathbf{M}_{\Phi_l}\\ \mathbf{M}_{\Gamma_l}\end{bmatrix} = \mathrm{I}. \tag{3.2}$$

Now since $\mathcal{G} = \mathcal{R}_{\mathbf{M}_{\Gamma_r}} = \mathcal{K}_{\mathbf{M}_{\Gamma_l}}$, $\mathcal{F} = \mathcal{R}_{\mathbf{M}_{\Phi_r}} = \mathcal{K}_{\mathbf{M}_{\Phi_l}}$ and the subspaces $\mathcal{G}$ and $\mathcal{F}$ induce a coordinatization of $\mathrm{H}^2_{\mathbb{D}}(\mathcal{H})$, both $\begin{bmatrix}\mathbf{M}_{\Gamma_r} & \mathbf{M}_{\Phi_r}\end{bmatrix}$ and $\begin{bmatrix}\mathrm{M}_{\Phi_l}\\ \mathrm{M}_{\Gamma_1}\end{bmatrix}$ have zero kernel. Thus, they are the inverse of each other (see (3.2)) and

$$\begin{bmatrix}\mathbf{M}_{\Phi_l}\\ \mathbf{M}_{\Gamma_l}\end{bmatrix}\begin{bmatrix}\mathbf{M}_{\Gamma_r} & \mathbf{M}_{\Phi_r}\end{bmatrix} = \begin{bmatrix}\mathrm{I} & 0\\ 0 & \mathrm{I}\end{bmatrix}.$$

This completes the proof. ∎

REMARK 3.4. *The multiplication operator symbols in the last theorem are not unique. In fact, given any functions* $\Theta_0 \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{H}_2,\mathcal{H}_1})$, $\Theta_1(\Theta_1^{-1}) \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{H}_1,\mathcal{H}_1})$ *and* $\Theta_2(\Theta_2^{-1}) \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{H}_2,\mathcal{H}_2})$, *the functions*

$$\Gamma_{r\star} := \Gamma_r\Theta_1, \quad \Gamma_{l\star} := \Theta_2^{-1}\Gamma_l, \quad \Phi_{r\star} := (\Phi_r - \Gamma_r\Theta_0)\Theta_2,$$

and

$$\Phi_{l\star}{:=}\Theta_1^{-1}(\Phi_l+\Theta_0\Gamma_l)$$

satisfy $\mathcal{G}=\mathcal{R}_{\mathbf{M}_{\Gamma_{r\star}}}=\mathcal{K}_{\mathbf{M}_{\Gamma_{l\star}}}$,

$$\begin{bmatrix}\mathbf{M}_{\Gamma_{r\star}} & \mathbf{M}_{\Phi_{r\star}}\end{bmatrix}\begin{bmatrix}\mathbf{M}_{\Phi_{l\star}}\\ \mathbf{M}_{\Gamma_{l\star}}\end{bmatrix}=\mathrm{I},\quad \textit{and}\quad \begin{bmatrix}\mathbf{M}_{\Phi_{l\star}}\\ \mathbf{M}_{\Gamma_{l\star}}\end{bmatrix}\begin{bmatrix}\mathbf{M}_{\Gamma_{r\star}} & \mathbf{M}_{\Phi_{r\star}}\end{bmatrix}=\begin{bmatrix}\mathrm{I} & 0\\ 0 & \mathrm{I}\end{bmatrix}.$$

4. Stabilizability and existence of strong-right/left representations. Recall the standard closed-loop configuration shown in Figure 2.1, which is denoted by $[P,C]$. Also recall that a system $P\in\mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ is said to be stabilizable if there exists a system $C\in\mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$ such that the closed-loop $[P,C]$ is stable. In this section, it is shown that provided an LPTV system is stabilizable, there exist strong-right and strong-left representations of its graph. That is, it is shown that the graph of any stabilizable, LPTV system can be expressed as the range (respectively, kernel) of a stable, LPTV system that is left (respectively, right) invertible by a stable, LPTV system. In view of Proposition 2.4 and Remark 2.5, this result follows *almost* immediately by Theorem 3.3. The difficulty, however, is that the relevant multiplication operators shown to exist in Theorem 3.3 may correspond (via the **Z**-transform and time-lifting isomorphisms) to systems that are *not* locally causal in each $[kh,(k+1)h)$ interval of continuous-time (see Remark 2.2). Fortunately though, it is possible to exploit the nonuniqueness of these range and kernel representations (see Remark 3.4) to ensure causality, as detailed in the proof of the following theorem.

THEOREM 4.1. *Let* $\mathcal{U}$ *and* $\mathcal{Y}$ *be Hilbert spaces and for notational convenience define* $\mathcal{V}{:=}\mathcal{U}\oplus\mathcal{Y}$. *If* $P\in\mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ *can be stabilized by some* $C\in\mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$, *then there exist stable systems* $G_r\in\mathscr{P}^e_{\mathcal{U},\mathcal{V}}$, $G_l\in\mathscr{P}^e_{\mathcal{V},\mathcal{Y}}$, $K_l\in\mathscr{P}^e_{\mathcal{V},\mathcal{U}}$, *and* $K_r\in\mathscr{P}^e_{\mathcal{Y},\mathcal{V}}$ *such that*

$$\mathcal{G}_P=\mathcal{R}_{G_r}=\mathcal{K}_{G_l}$$

and

$$\begin{bmatrix}G_r & K_r\end{bmatrix}\begin{bmatrix}K_l\\ G_l\end{bmatrix}=\begin{bmatrix}K_l\\ G_l\end{bmatrix}\begin{bmatrix}G_r & K_r\end{bmatrix}=\begin{bmatrix}I & 0\\ 0 & I\end{bmatrix}.$$

Proof. Let $C\in\mathscr{P}^e_{\mathcal{Y},\mathcal{Y}}$ be a stabilizing controller for the plant P. Then by Remark 2.5 it follows that the shift-invariant subspaces $\hat{\mathcal{G}}_{\mathsf{P}}{:=}\mathbf{ZW}\mathcal{G}_P\subset\mathrm{H}^2_{\mathbb{D}}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{V}))$ and $\hat{\mathcal{G}}^{\sharp}_{\mathsf{C}}{:=}\mathbf{ZW}\mathcal{G}^{\sharp}_C\subset\mathrm{H}^2_{\mathbb{D}}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{V}))$ induce a coordinatization of $\mathrm{H}^2_{\mathbb{D}}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{V}))$. Correspondingly, there exist, by Theorem 3.3, functions

$$\hat{\mathsf{G}}_r\in\mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{H}_1,\mathrm{L}^2_{\mathbb{H}}(\mathcal{V})}),\quad \hat{\mathsf{G}}_l\in\mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{V}),\mathcal{H}_2}),\quad \hat{\mathsf{K}}_l\in\mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{V}),\mathcal{H}_1}),$$

and $\hat{\mathsf{K}}_r\in\mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{H}_2,\mathrm{L}^2_{\mathbb{H}}(\mathcal{V})})$ such that

$$\hat{\mathcal{G}}_{\mathsf{P}}=\mathcal{R}_{\mathbf{M}_{\hat{\mathsf{G}}_r}}=\mathcal{K}_{\mathbf{M}_{\hat{\mathsf{G}}_l}}$$

and

$$\begin{bmatrix}\mathbf{M}_{\hat{\mathsf{G}}_r} & \mathbf{M}_{\hat{\mathsf{K}}_r}\end{bmatrix}\begin{bmatrix}\mathbf{M}_{\hat{\mathsf{K}}_l}\\ \mathbf{M}_{\hat{\mathsf{G}}_l}\end{bmatrix}=\begin{bmatrix}\mathbf{M}_{\hat{\mathsf{K}}_l}\\ \mathbf{M}_{\hat{\mathsf{G}}_l}\end{bmatrix}\begin{bmatrix}\mathbf{M}_{\hat{\mathsf{G}}_r} & \mathbf{M}_{\hat{\mathsf{K}}_r}\end{bmatrix}=\begin{bmatrix}\mathrm{I} & 0\\ 0 & \mathrm{I}\end{bmatrix},$$

where $\mathcal{H}_1$ is any Hilbert space isomorphic to $\hat{\mathcal{G}}_{\mathsf{P}} \ominus \mathbf{S}\hat{\mathcal{G}}_{\mathsf{P}}$ and $\mathcal{H}_2$ is any Hilbert space isomorphic to $\hat{\mathcal{G}}_{\mathsf{C}}^{\sharp} \ominus \mathbf{S}\hat{\mathcal{G}}_{\mathsf{C}}^{\sharp}$. In fact, $\mathcal{H}_1$ may be taken to be $\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})$ and $\mathcal{H}_2$ to be $\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y})$, as is done in the rest of the proof. That this is possible is shown in Appendix A.

Now define

$$\mathsf{G}_r := \mathbf{Z}^{-1}\mathbf{M}_{\hat{\mathsf{G}}_r}\mathbf{Z}, \quad \mathsf{G}_l := \mathbf{Z}^{-1}\mathbf{M}_{\hat{\mathsf{G}}_l}\mathbf{Z}, \quad \mathsf{K}_l := \mathbf{Z}^{-1}\mathbf{M}_{\hat{\mathsf{K}}_r}\mathbf{Z},$$

and

$$\mathsf{K}_r := \mathbf{Z}^{-1}\mathbf{M}_{\hat{\mathsf{K}}_l}\mathbf{Z}.$$

Then $\mathcal{G}_{\mathsf{P}} = \mathbf{W}\mathcal{G}_P = \mathcal{R}_{\mathsf{G}_r} = \mathcal{K}_{\mathsf{G}_l}$ and

$$\begin{bmatrix}\mathsf{G}_r & \mathsf{K}_r\end{bmatrix}\begin{bmatrix}\mathsf{K}_l \\ \mathsf{G}_l\end{bmatrix} = \begin{bmatrix}\mathsf{K}_l \\ \mathsf{G}_l\end{bmatrix}\begin{bmatrix}\mathsf{G}_r & \mathsf{K}_r\end{bmatrix} = \begin{bmatrix}\mathrm{I} & 0 \\ 0 & \mathrm{I}\end{bmatrix}.$$

Furthermore, given any stable, LSI system

$$\mathsf{Q}_0 : \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})) \to \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y}))$$

and stable, LSI systems

$$\mathsf{Q}_1 : \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})) \to \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})) \quad \text{and} \quad \mathsf{Q}_2 : \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y})) \to \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y}))$$

with stable inverses, observe (as in Remark 3.4) that the stable, LSI systems

$$\mathsf{G}_{r\star} := \mathsf{G}_r\mathsf{Q}_1, \quad \mathsf{G}_{l\star} := \mathsf{Q}_2^{-1}\mathsf{G}_l, \quad \mathsf{K}_{r\star} := (\mathsf{K}_r - \mathsf{G}_r\mathsf{Q}_0)\mathsf{Q}_2,$$

and $\mathsf{K}_{l\star} := \mathsf{Q}_1^{-1}(\mathsf{K}_l + \mathsf{Q}_0\mathsf{G}_l)$ satisfy

$$\mathcal{G}_{\mathsf{P}} = \mathcal{R}_{\mathsf{G}_{r\star}} = \mathcal{K}_{\mathsf{G}_{l\star}}$$

and

$$\begin{aligned}
\begin{bmatrix}\mathsf{G}_{r\star} & \mathsf{K}_{r\star}\end{bmatrix}\begin{bmatrix}\mathsf{K}_{l\star} \\ \mathsf{G}_{l\star}\end{bmatrix} &:= \begin{bmatrix}\mathsf{G}_r\mathsf{Q}_1 & (\mathsf{K}_r - \mathsf{G}_r\mathsf{Q}_0)\mathsf{Q}_2\end{bmatrix}\begin{bmatrix}\mathsf{Q}_1^{-1}(\mathsf{K}_l + \mathsf{Q}_0\mathsf{G}_l) \\ \mathsf{Q}_2^{-1}\mathsf{G}_l\end{bmatrix} \\
&= \begin{bmatrix}\mathsf{Q}_1^{-1}(\mathsf{K}_l + \mathsf{Q}_0\mathsf{G}_l) \\ \mathsf{Q}_2^{-1}\mathsf{G}_l\end{bmatrix}\begin{bmatrix}\mathsf{G}_r\mathsf{Q}_1 & (\mathsf{K}_r - \mathsf{G}_r\mathsf{Q}_0)\mathsf{Q}_2\end{bmatrix} \\
&= \begin{bmatrix}\mathsf{Q}_1^{-1} & \mathsf{Q}_1^{-1}\mathsf{Q}_0 \\ 0 & \mathsf{Q}_2^{-1}\end{bmatrix}\begin{bmatrix}\mathsf{K}_l \\ \mathsf{G}_l\end{bmatrix}\begin{bmatrix}\mathsf{G}_r & \mathsf{K}_r\end{bmatrix}\begin{bmatrix}\mathsf{Q}_1 & -\mathsf{Q}_0\mathsf{Q}_2 \\ 0 & \mathsf{Q}_2\end{bmatrix} \\
&= \begin{bmatrix}\mathrm{I} & 0 \\ 0 & \mathrm{I}\end{bmatrix}. \qquad (4.1)
\end{aligned}$$

Consequently, if it were possible to choose Q_0, Q_1, and Q_2 to ensure that $(\mathsf{G}_r\mathsf{Q}_1)_{[0]}$, $(\mathsf{Q}_2^{-1}\mathsf{G}_l)_{[0]}$, $(\mathsf{Q}_1^{-1}(\mathsf{K}_l + \mathsf{Q}_0\mathsf{G}_l))_{[0]}$, and $((\mathsf{K}_r + \mathsf{G}_r\mathsf{Q}_0)\mathsf{Q}_2)_{[0]}$ are all causal mappings on the finite horizon $\mathbb{H}$, it would follow by Remark 2.2 that

$$G_{r\star} := \mathbf{W}^{-1}\mathsf{G}_{r\star}\mathbf{W}, \quad G_{l\star} := \mathbf{W}^{-1}\mathsf{G}_{l\star}\mathbf{W}, \quad K_{r\star} := \mathbf{W}^{-1}\mathsf{K}_{r\star}\mathbf{W},$$

and $K_{l\star} := \mathbf{W}^{-1}\mathsf{K}_{l\star}\mathbf{W}$ are all stable, LPTV systems satisfying

$$\mathcal{G}_P = \mathcal{R}_{G_{r\star}} = \mathcal{K}_{G_{l\star}}$$

and

$$\begin{bmatrix} G_{r\star} & K_{r\star} \end{bmatrix} \begin{bmatrix} K_{l\star} \\ G_{l\star} \end{bmatrix} = \begin{bmatrix} K_{l\star} \\ G_{l\star} \end{bmatrix} \begin{bmatrix} G_{r\star} & K_{r\star} \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix}.$$

Accordingly, the rest of the proof is dedicated to showing that this is possible.

Let

$$\begin{bmatrix} \mathsf{M}_{r[0]} \\ \mathsf{N}_{r[0]} \end{bmatrix} := \mathsf{G}_{r[0]} \quad \text{and} \quad \begin{bmatrix} -\mathsf{N}_{l[0]} & \mathsf{M}_{l[0]} \end{bmatrix} := \mathsf{G}_{l[0]},$$

where the partitioning is conformal with that of G_P and the subscript [0] denotes the first element of the sequence uniquely identifiable with the associated block-Toeplitz representation. Now recall that, by definition, $P \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ is causally extendible with locally Lipschitz-continuous extension. As such, it follows that both $\mathsf{M}_{r[0]} \in \mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})}$ and $\mathsf{M}_{l[0]} \in \mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y})}$ are bijective and hence, boundedly invertible by the open mapping theorem [2, p. 79]. To see this, first note that since P is causally extendible,

$$\mathcal{R}_{\mathsf{M}_{r[0]}} = \mathbf{T}_h \mathcal{D}_P = \mathrm{L}^2_{\mathbb{H}}(\mathcal{U}).$$

Consequently, $\mathsf{M}_{r[0]}$ is surjective. Suppose now that there exists some nonzero $\overset{\circ}{q} \in \mathrm{L}^2_{\mathbb{H}}(\mathcal{U})$ such that $\mathsf{M}_{r[0]}\, \overset{\circ}{q} = 0$. Then by causality of P it follows that $\mathsf{N}_{r[0]}\, \overset{\circ}{q}$ must also be zero. Since $\mathsf{K}_{l[0]}\mathsf{G}_{r[0]} = \mathrm{I}$, this implies that

$$0 = \mathsf{K}_{l[0]} \begin{bmatrix} \mathsf{M}_{r[0]} \\ \mathsf{N}_{r[0]} \end{bmatrix} \overset{\circ}{q} = \overset{\circ}{q},$$

which is a contradiction. Hence, the linear operator $\mathsf{M}_{r[0]}$ must be injective. This, and the fact that it is also surjective, implies that $\mathsf{M}_{r[0]}$ is bijective as claimed. Now consider $\mathsf{M}_{l[0]}$, and suppose that there exists a nonzero $\overset{\circ}{q} \in \mathrm{L}^2_{\mathbb{H}}(\mathcal{Y})$ such that $\mathsf{M}_{l[0]}\, \overset{\circ}{q} = 0$. Then since

$$\mathcal{K}_{\begin{bmatrix} -\mathsf{N}_{l[0]} & \mathsf{M}_{l[0]} \end{bmatrix}} = \mathbf{T}_h \mathcal{G}_P,$$

it follows that $\begin{bmatrix} 0 \\ \overset{\circ}{q} \end{bmatrix} \in \mathbf{T}_h \mathcal{G}_P$. But this contradicts the causality of P and hence $\overset{\circ}{q}$ must be 0. Consequently, $\mathsf{M}_{l[0]}$ has zero kernel and is thereby injective. Moreover, since $\mathsf{G}_{l[0]}\mathsf{K}_{r[0]} = \mathrm{I}$,

$$\mathcal{R}_{\begin{bmatrix} -\mathsf{N}_{l[0]} & \mathsf{M}_{l[0]} \end{bmatrix}} = \mathrm{L}^2_{\mathbb{H}}(\mathcal{Y}).$$

So for all $\overset{\circ}{e} \in \mathrm{L}^2_{\mathbb{H}}(\mathcal{Y})$, there exists a $\overset{\circ}{g} = \begin{bmatrix} \overset{\circ}{g}_1 \\ \overset{\circ}{g}_2 \end{bmatrix} \in \mathrm{L}^2_{\mathbb{H}}(\mathcal{V})$ such that

$$\overset{\circ}{e} = \begin{bmatrix} -\mathsf{N}_{l[0]} & \mathsf{M}_{l[0]} \end{bmatrix} \begin{bmatrix} \overset{\circ}{g}_1 \\ \overset{\circ}{g}_2 \end{bmatrix}.$$

In fact,

$$\overset{\circ}{e} = \begin{bmatrix} -\mathsf{N}_{l[0]} & \mathsf{M}_{l[0]} \end{bmatrix} \begin{bmatrix} \overset{\circ}{g}_1 + \overset{\circ}{u} \\ \overset{\circ}{g}_2 + \mathsf{P}_{[0]}\, \overset{\circ}{u} \end{bmatrix}$$

for all $\overset{\circ}{u} \in \mathbf{T}_h\mathcal{D}_P$. Since $\mathbf{T}_h\mathcal{D}_P = \mathrm{L}^2_{\mathbb{H}}(\mathcal{U})$, $\overset{\circ}{u}$ can be set to $-\overset{\circ}{g}_1$. Doing this gives $\overset{\circ}{e} = \mathsf{M}_{l[0]}(\overset{\circ}{g}_2 - \mathsf{P}_{[0]}\overset{\circ}{g}_1)$, from which it is evident that $\mathcal{R}_{\mathsf{M}_{l[0]}} = \mathrm{L}^2_{\mathbb{H}}(\mathcal{Y})$. Correspondingly, $\mathsf{M}_{l[0]}$ is bijective as claimed.

Having shown that both $\mathsf{M}_{r[0]}$ and $\mathsf{M}_{l[0]}$ are boundedly invertible, it is possible to construct the required Q_0, Q_1, and Q_2. Let Q_1 satisfy $\mathsf{Q}_{1[0]} = \mathsf{M}^{-1}_{r[0]}$ and $\mathsf{Q}_{1[i]} = 0$ for $i \neq 0$, where $\{\mathsf{Q}_{1[i]}\}_{i=0}^{\infty}$ denotes the sequence uniquely identifiable with the block-Toeplitz representation of Q_1. Then

$$(\mathsf{G}_r\mathsf{Q}_1)_{[0]} = \begin{bmatrix} \mathrm{I} \\ \mathsf{N}_{r[0]}\mathsf{M}^{-1}_{r[0]} \end{bmatrix},$$

which is causal on $\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})$, since P is a causal system. Now let $\begin{bmatrix}\mathsf{Y}_{l[0]} & \mathsf{X}_{l[0]}\end{bmatrix} := \mathsf{K}_{l[0]}$, where the partition is conformal with $\mathcal{G}_{\mathsf{P}}$, and construct Q_0 so that $\mathsf{Q}_{0[0]} = -\mathsf{X}_{l[0]}\mathsf{M}^{-1}_{l[0]}$ and $\mathsf{Q}_{0[i]} = 0$ for $i \neq 0$. Then since $\mathsf{N}_{r[0]}\mathsf{M}^{-1}_{r[0]} = \mathsf{M}^{-1}_{l[0]}\mathsf{N}_{l[0]} = \mathsf{P}_{[0]}$ and $\mathsf{Y}_{l[0]}\mathsf{M}_{r[0]} + \mathsf{X}_{l[0]}\mathsf{N}_{r[0]} = \mathrm{I}$, it follows that

$$\begin{aligned}(\mathsf{Q}_1^{-1}(\mathsf{K}_l + \mathsf{Q}_0\mathsf{G}_l))_{[0]} &= (\mathsf{Q}_1^{-1})_{[0]}\left(\mathsf{K}_{l[0]} + \mathsf{Q}_{0[0]}\begin{bmatrix}-\mathsf{N}_{l[0]} & \mathsf{M}_{l[0]}\end{bmatrix}\right) \\ &= \mathsf{M}_{r[0]}\begin{bmatrix}\mathsf{Y}_{l[0]} + \mathsf{X}_{l[0]}\mathsf{M}^{-1}_{l[0]}\mathsf{N}_{l[0]} & 0\end{bmatrix} \\ &= \mathsf{M}_{r[0]}\begin{bmatrix}\mathsf{M}^{-1}_{r[0]} & 0\end{bmatrix} = \begin{bmatrix}\mathrm{I} & 0\end{bmatrix},\end{aligned}$$

which is obviously causal on $\mathrm{L}^2_{\mathbb{H}}(\mathcal{V})$, as required. Finally, let $\left[\begin{smallmatrix}-\mathsf{X}_{r[0]} \\ \mathsf{Y}_{r[0]}\end{smallmatrix}\right] := \mathsf{K}_{r[0]}$. Then from (4.1), it follows that $\mathsf{M}_{r[0]}\mathsf{X}_{l[0]} - \mathsf{X}_{r[0]}\mathsf{M}_{l[0]} = 0$ and hence, that $\mathsf{Q}_{0[0]} = -\mathsf{X}_{l[0]}\mathsf{M}^{-1}_{l[0]} = \mathsf{M}^{-1}_{r[0]}\mathsf{X}_{r[0]}$. Defining Q_2 to satisfy $\mathsf{Q}_{2[0]} = \mathsf{M}_{l[0]}$ and $\mathsf{Q}_{2[i]} = 0$ for $i \neq 0$, gives $(\mathsf{Q}_2^{-1}\mathsf{G}_l)_{[0]} = [-\mathsf{M}^{-1}_{l[0]}\mathsf{N}_{l[0]} \quad \mathrm{I}]$ and $((\mathsf{K}_r + \mathsf{G}_r\mathsf{Q}_0)\mathsf{Q}_2)_{[0]} = \left[\begin{smallmatrix}0 \\ \mathrm{I}\end{smallmatrix}\right]$. As required, each is respectively causal on $\mathrm{L}^2_{\mathbb{H}}(\mathcal{V})$ and $\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y})$, completing the proof. ∎

REMARK 4.2. *Since G_r and G_l in Theorem 4.1 are, respectively, left and right invertible by stable, LPTV systems, they are called strong-right and strong-left representations of $\mathcal{G}_P$, respectively. Note that they are only unique up to invertible factors. That is, for any stable systems $Q_1(Q_1^{-1}) \in \mathscr{P}^e_{\mathcal{U},\mathcal{U}}$, and $Q_2(Q_2^{-1}) \in \mathscr{P}^e_{\mathcal{Y},\mathcal{Y}}$, the systems G_rQ_1 and $Q_2^{-1}G_l$ are also strong-right and strong-left representations of $\mathcal{G}_P$, respectively.*

5. Closed-loop stability and stabilizing controllers. The next result constitutes a useful characterization of closed-loop stability in terms of range and kernel representations of $\mathcal{G}_P$ and $\mathcal{G}^\sharp_C$. In turn, this result leads to a Youla-style parametrization of stabilizing controllers.

LEMMA 5.1. *Given a well-posed plant/controller pair $P \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ and $C \in \mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$, let $G_r \in \mathscr{P}^e_{\mathcal{U},\mathcal{V}}$ be any stable system with zero kernel such that $\mathcal{G}_P = \mathcal{R}_{G_r}$, and $K_l \in \mathscr{P}^e_{\mathcal{V},\mathcal{U}}$ be any stable system such that $\mathcal{R}_{K_l} = \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U})$ and $\mathcal{G}^\sharp_C = \mathcal{K}_{K_l}$. Then the following are equivalent:*

(i) *The closed-loop system $[P, C]$ is stable.*
(ii) *The stable, LPTV system K_lG_r is bijective (and hence boundedly invertible, although the inverse may not be causal).*

Furthermore, if $[P, C]$ is stable and G_r and K_l are, respectively, strong-right and strong-left representations of $\mathcal{G}_P$ and $\mathcal{G}^\sharp_C$, then $(K_lG_r)^{-1}$ is a stable system in $\mathscr{P}^e_{\mathcal{U},\mathcal{U}}$. That is, the inverse is also causal.

Proof. Since the closed-loop is well posed by assumption, it follows by Proposition 2.4 and the identities $\mathcal{G}_P = \mathcal{R}_{G_r}$ and $\mathcal{G}_C^\sharp = \mathcal{K}_{K_l}$ that

$$[P,C] \text{ is stable } \Leftrightarrow \mathcal{R}_{G_r} + \mathcal{K}_{K_l} = \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{V}) \text{ and } \mathcal{R}_{G_r} \cap \mathcal{K}_{K_l} = \{0\}.$$

Since $\mathcal{R}_{K_l} = \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U})$ and $\mathcal{K}_{G_r} = \{0\}$, it is clear that

$$\begin{gathered}\mathcal{R}_{G_r} + \mathcal{K}_{K_l} = \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{V}) \text{ and } \mathcal{R}_{G_r} \cap \mathcal{K}_{K_l} = \{0\} \\ \Downarrow \\ \mathcal{R}_{K_l G_r} = \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U}) \text{ and } \mathcal{K}_{K_l G_r} = \{0\}.\end{gathered}$$

To see that the converse is also true, let $\mathcal{R}_{K_l G_r} = \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U})$ and $\mathcal{K}_{K_l G_r} = \{0\}$. That $\mathcal{R}_{G_r} \cap \mathcal{K}_{K_l} = \{0\}$ is immediate. Now suppose that there exists a $v \in \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{V})$ such that $v \notin \mathcal{R}_{G_r} + \mathcal{K}_{K_l}$, and define $e{:=}K_l v$. Then since $\mathcal{R}_{K_l G_r} = \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U})$ and $\mathcal{K}_{K_l G_r} = \{0\}$, there exists a unique $q \in \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U})$ such that $e = K_l G_r q = K_l g$, where $g{:=}G_r q$. Consequently, $K_l(g - v) = 0$, which implies either $v = g$ or $(g - v) \in \mathcal{K}_{K_l}$. But this contradicts $v \notin \mathcal{R}_{G_r} + \mathcal{K}_{K_l}$, since $g \in \mathcal{R}_{G_r}$. Consequently, it follows that $[P,C]$ is stable if and only if the bounded linear operator $K_l G_r$ is bijective (and hence, boundedly invertible by the open mapping theorem [2, p. 79]). Note that $(K_l G_r)^{-1}$ is periodically time-varying but that it may not be locally causal on $\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})$.

It is now shown that if $[P,C]$ is stable and G_r and K_l are, respectively, strong-right and strong-left representations of $\mathcal{G}_P$ and $\mathcal{G}_C^\sharp$, then $(K_l G_r)^{-1} \in \mathscr{P}^e_{\mathcal{U},\mathcal{U}}$. First note that for any K_l and G_r that satisfy the original conditions of the lemma,

$$\mathbf{\Pi}_{\mathcal{G}_P \| \mathcal{G}_C^\sharp} = G_r (K_l G_r)^{-1} K_l. \tag{5.1}$$

To see this, note that since $[P,C]$ is stable, the subspaces $\mathcal{G}_P$ and $\mathcal{G}_C^\sharp$ induce a coordinatization of $\mathrm{L}^2_{\mathbb{R}^+}(\mathcal{V})$. Thereby, any $g \in \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{V})$ can be written uniquely as the sum $g = p + c$, where $p \in \mathcal{G}_P$ and $c \in \mathcal{G}_C^\sharp$. Furthermore, since $\mathcal{K}_{G_r} = \{0\}$ and $\mathcal{R}_{G_r} = \mathcal{G}_P$, there exists a unique $q \in \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U})$ such that $p = G_r q$. Consequently,

$$\begin{aligned}\left(\mathbf{\Pi}_{\mathcal{G}_P \| \mathcal{G}_C^\sharp} - G_r (K_l G_r)^{-1} K_l\right) g &= p - G_r (K_l G_r)^{-1} K_l p \\ &= p - G_r (K_l G_r)^{-1} K_l G_r q \\ &= p - G_r q = 0\end{aligned}$$

for all $g \in \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U})$, implying that $\mathbf{\Pi}_{\mathcal{G}_P \| \mathcal{G}_C^\sharp} = G_r (K_l G_r)^{-1} K_l$. Now take G_r and K_l to be *strong-right* and *strong-left* representations. Then, G_r and K_l satisfy the original conditions of the lemma and there exist stable systems $K_{l\star} \in \mathscr{P}^e_{\mathcal{V},\mathcal{U}}$ and $G_{r\star} \in \mathscr{P}^e_{\mathcal{U},\mathcal{V}}$ such that $K_{l\star} G_r = I$ and $K_l G_{r\star} = I$. Now from (5.1),

$$(K_l G_r)^{-1} = K_{l\star} \mathbf{\Pi}_{\mathcal{G}_P \| \mathcal{G}_C^\sharp} G_{r\star},$$

which since $\mathbf{\Pi}_{\mathcal{G}_P \| \mathcal{G}_C^\sharp} \in \mathscr{P}^e_{\mathcal{V},\mathcal{V}}$ (see Proposition 2.4) implies that $(K_l G_r)^{-1} \in \mathscr{P}^e_{\mathcal{U},\mathcal{U}}$. This completes the proof. ∎

REMARK 5.2. *Note that by interchanging the roles of P and C in Lemma 5.1, given any stable system $G_l \in \mathscr{P}^e_{\mathcal{Y},\mathcal{Y}}$ such that $\mathcal{R}_{G_l} = \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U})$ and $\mathcal{G}_P = \mathcal{K}_{G_l}$, and any stable system $K_r \in \mathscr{P}^e_{\mathcal{Y},\mathcal{V}}$ with zero kernel such that $\mathcal{G}_C^\sharp = \mathcal{R}_{K_r}$, the following are equivalent*:

(i) *The closed-loop system $[P,C]$ is stable.*

(ii) *The stable, LPTV system G_lK_r is bijective (and hence boundedly invertible, although the inverse may not be causal).*

Furthermore, if G_l and K_r are, respectively, strong-left and strong-right representations of $\mathcal{G}_P$ and $\mathcal{G}_C^\sharp$, and $[P, C]$ is stable, then $(G_lK_r)^{-1}$ is a stable system $\mathscr{P}^e_{\mathcal{Y},\mathcal{Y}}$.

Interestingly, given a system $P \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ and a stabilizing controller $C \in \mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$, strong-right and strong-left representations of $\mathcal{G}_C^\sharp$ can be constructed from strong-right and strong-left representations of $\mathcal{G}_P$ and the respective stable left and right inverses. This is analogous to necessity of the well-known Youla parametrization of stabilizing controllers for certain classes of systems [27, 7, 6, 5], as summarized in the following theorem.

THEOREM 5.3. *Given a stabilizable system $P \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ and stable systems $G_r \in \mathscr{P}^e_{\mathcal{U},\mathcal{V}}$, $G_l \in \mathscr{P}^e_{\mathcal{V},\mathcal{Y}}$, $K_l \in \mathscr{P}^e_{\mathcal{V},\mathcal{U}}$, and $K_r \in \mathscr{P}^e_{\mathcal{Y},\mathcal{V}}$ such that*

$$\mathcal{G}_P = \mathcal{R}_{G_r} = \mathcal{K}_{G_l}$$

and

$$\begin{bmatrix} G_r & K_r \end{bmatrix} \begin{bmatrix} K_l \\ G_l \end{bmatrix} = \begin{bmatrix} K_l \\ G_l \end{bmatrix} \begin{bmatrix} G_r & K_r \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix},$$

a system $C \in \mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$ stabilizes P only if there exists a stable $Q \in \mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$ such that

$$K_r - G_rQ$$

is a strong-right representation of $\mathcal{G}_C^\sharp$ and

$$K_l + QG_l$$

is a strong-left representation of $\mathcal{G}_C^\sharp$.

Proof. Let $C \in \mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$ denote a stabilizing controller for P. Then it follows by Theorem 4.1 that there exist stable systems $G_r \in \mathscr{P}^e_{\mathcal{U},\mathcal{V}}$, $G_l \in \mathscr{P}^e_{\mathcal{V},\mathcal{Y}}$, $K_l \in \mathscr{P}^e_{\mathcal{V},\mathcal{U}}$, and $K_r \in \mathscr{P}^e_{\mathcal{Y},\mathcal{V}}$ such that

$$\mathcal{G}_P = \mathcal{R}_{G_r} = \mathcal{K}_{G_l}$$

and

$$\begin{bmatrix} G_r & K_r \end{bmatrix} \begin{bmatrix} K_l \\ G_l \end{bmatrix} = \begin{bmatrix} K_l \\ G_l \end{bmatrix} \begin{bmatrix} G_r & K_r \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix}. \tag{5.2}$$

Furthermore, for any stable system $Q \in \mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$,

$$\begin{aligned} &\begin{bmatrix} G_r & (K_r - G_rQ) \end{bmatrix} \begin{bmatrix} (K_l + QG_l) \\ G_l \end{bmatrix} \\ &= \begin{bmatrix} (K_l + QG_l) \\ G_l \end{bmatrix} \begin{bmatrix} G_r & (K_r - G_rQ) \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix}. \end{aligned} \tag{5.3}$$

Now from (5.3),

$$(K_l + QG_l)(K_r - G_rQ) = 0,$$

implying that $\mathcal{R}_{(K_r - G_rQ)} \subset \mathcal{K}_{(K_l + QG_l)}$. To see that the opposite inclusion also holds, note from (5.3) that

$$(K_l + QG_l) \begin{bmatrix} G_r & (K_r - G_rQ) \end{bmatrix} = \begin{bmatrix} I & 0 \end{bmatrix}. \tag{5.4}$$

Now suppose there exists a nonzero $x \in \mathcal{K}_{(K_l+QG_l)}$ that is not in $\mathcal{R}_{(K_r-G_rQ)}$. Then since

$$\mathcal{K}\begin{bmatrix} G_r & (K_r - G_rQ)\end{bmatrix} = \{0\} \quad \text{and} \quad \mathcal{R}\begin{bmatrix} G_r & (K_r - G_rQ)\end{bmatrix} = \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{V}),$$

there exists a unique $u =: \left[\begin{smallmatrix} u_1 \\ u_2 \end{smallmatrix}\right] \in \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{V})$ such that

$$x = \begin{bmatrix} G_r & (K_r - G_rQ)\end{bmatrix}\begin{bmatrix} u_1 \\ u_2 \end{bmatrix}.$$

Furthermore, $0 = (K_l + QG_l)x = u_1$, which using (5.4), implies that $x \in \mathcal{R}_{(K_r-G_rQ)}$. This is a contradiction and, therefore, $\mathcal{K}_{(K_l+QG_l)} \subset \mathcal{R}_{(K_r-G_rQ)}$.

Since $[P, C]$ is stable (or equivalently C is stabilized P), it follows by Theorem 4.1 that there exist strong-right and strong-left representations of $\mathcal{G}_C$. Noting that $\mathcal{G}^\sharp_C := \left[\begin{smallmatrix} 0 & I \\ I & 0 \end{smallmatrix}\right]\mathcal{G}_C$, these give rise to strong-right and strong-left representations of $\mathcal{G}^\sharp_C$. Denote these by $K_{r\star} \in \mathscr{P}^e_{\mathcal{Y},\mathcal{V}}$ and $K_{l\star} \in \mathscr{P}^e_{\mathcal{V},\mathcal{U}}$, respectively. It then follows by Lemma 5.1 that $K_{l\star}G_r$ is boundedly invertible in $\mathscr{P}^e_{\mathcal{U},\mathcal{U}}$. Now define

$$Q := -(K_{l\star}G_r)^{-1}K_{l\star}K_r,$$

noting that Q is a stable system in $\mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$. Then using (5.2),

$$\begin{aligned} K_l - QG_l &= K_l + (K_{l\star}G_r)^{-1}K_{l\star}K_rG_l \\ &= K_l + (K_{l\star}G_r)^{-1}K_{l\star}(I - G_rK_l) \\ &= K_l - K_l + (K_{l\star}G_r)^{-1}K_{l\star} = (K_{l\star}G_r)^{-1}K_{l\star}, \end{aligned}$$

implying that $\mathcal{K}_{(K_l-QG_l)} = \mathcal{K}_{K_{l\star}}$. Since $\mathcal{R}_{(K_r+G_rQ)} = \mathcal{K}_{(K_l-QG_l)}$ and $\mathcal{R}_{K_{r\star}} = \mathcal{K}_{K_{l\star}}$, it also follows that $\mathcal{R}_{(K_r+G_rQ)} = \mathcal{R}_{K_{r\star}}$. That is, the strong-right and strong-left representations of $\mathcal{G}^\sharp_C$ are in the form required. □

REMARK 5.4. *If in Theorem* 5.3 *the choice of* Q *was restricted to the stable systems in* $\mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ *for which the subspace* $\mathcal{R}_{(K_r-G_rQ)} = \mathcal{K}_{(K_l+QG_l)}$ *corresponds to the inverse graph of a system* $C \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ *such that the closed-loop* $[P, C]$ *is well posed, then* C *would stabilize* P. *That is, Theorem* 5.3 *would also be sufficient. To see this, note from* (5.3) *that for such a* Q, *the system* $(K_l + QG_l)$ *is a strong-left representation of* $\mathcal{G}^\sharp_C$. *So by arguments similar to those used in the proof of Lemma* 5.1, *and the fact that* $(K_l + QG_l)G_r = I$ *is obviously invertible, it follows that* $[P, C]$ *is stable. Again from* (5.3), *and since* $\mathcal{R}_{(K_r-G_rQ)} = \mathcal{K}_{(K_l+QG_l)} = \mathcal{G}^\sharp_C$, *it also follows that* $(K_r - G_rQ)$ *is a strong-right representation of the inverse graph of a stabilizing controller.*

Appendix A. Supplement to the proof of Theorem 4.1. As required in Theorem 4.1, it is shown here that $\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})$ is isomorphic to $\hat{\mathcal{G}}_{\mathsf{P}} \ominus \mathbf{S}\hat{\mathcal{G}}_{\mathsf{P}}$ and that $\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y})$ is isomorphic to $\hat{\mathcal{G}}^\sharp_{\mathsf{C}} \ominus \mathbf{S}\hat{\mathcal{G}}^\sharp_{\mathsf{C}}$, where all of these objects are defined as in the proof of the theorem. Recall that there exists a function $\hat{\mathsf{G}}_r \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{H}_1,\mathrm{L}^2_{\mathbb{H}}(\mathcal{V})})$ such that

$$\hat{\mathcal{G}}_{\mathsf{P}} = \hat{\mathsf{G}}_r\mathrm{H}^2_{\mathbb{D}}(\mathcal{H}_1),$$

where $\mathcal{H}_1$ is a Hilbert space isomorphic to $\hat{\mathcal{G}}_{\mathsf{P}} \ominus \mathbf{S}\hat{\mathcal{G}}_{\mathsf{P}}$. Note that since $P \in \mathscr{P}_{\mathcal{U},\mathcal{Y}}$ is causally extendible, $\mathbf{T}_h\mathcal{D}_P = \mathrm{L}^2_{\mathbb{H}}(\mathcal{U})$ and hence

$$\mathsf{G}_{r[0]}\mathcal{H}_1 = \begin{bmatrix} \mathrm{I} \\ \mathsf{P}_{[0]} \end{bmatrix}\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}), \tag{A.1}$$

where $\mathsf{G}_{r[0]}(=\hat{\mathsf{G}}_r(0))$ and $\mathsf{P}_{[0]}$ denote the first elements of the sequences uniquely identifiable with the block-Toeplitz representations of $\mathsf{G}_r{:=}\mathbf{Z}^{-1}\mathbf{M}_{\hat{\mathsf{G}}_r}\mathbf{Z}$ and $\mathsf{P}{:=}\mathbf{W}P\mathbf{W}^{-1}$, respectively. Also recall that $\mathbf{M}_{\hat{\mathsf{G}}_r}$ has a left-inverse $\mathbf{M}_{\hat{\mathsf{K}}_l}$ with $\hat{\mathsf{K}}_l \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{V}),\mathcal{H}_1})$. As such, $\mathsf{K}_{l[0]} = \hat{\mathsf{K}}_l(0)$ is a bounded left-inverse of $\mathsf{G}_{r[0]}$.[6] Define

$$\mathsf{Q}{:=}\mathsf{K}_{l[0]}\begin{bmatrix}\mathrm{I}\\ \mathsf{P}_{[0]}\end{bmatrix} : \mathrm{L}^2_{\mathbb{H}}(\mathcal{U}) \to \mathcal{H}_1.$$

Then since $\begin{bmatrix}\mathrm{I}\\ \mathsf{P}_{[0]}\end{bmatrix}$ has zero kernel and $\mathsf{K}_{l[0]}\mathsf{G}_{r[0]} = \mathrm{I}$, it follows from (A.1) that Q is a bijective mapping. Hence, $\mathsf{Q}(\mathsf{Q}^*\mathsf{Q})^{-\frac{1}{2}}$ is an isomorphism between $\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})$ and $\mathcal{H}_1$. Correspondingly, $\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})$ is isomorphic to $\hat{\mathcal{G}}_{\mathsf{P}} \ominus \mathbf{S}\hat{\mathcal{G}}_{\mathsf{P}} \sim \mathcal{H}_1$. It can be shown in a similar manner that $\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y})$ is isomorphic to $\hat{\mathcal{G}}^\sharp_{\mathsf{C}} \ominus \mathbf{S}\hat{\mathcal{G}}^\sharp_{\mathsf{C}}$.

GAP-METRIC ROBUSTNESS ANALYSIS OF LINEAR PERIODICALLY TIME-VARYING FEEDBACK SYSTEMS*

MICHAEL CANTONI† AND KEITH GLOVER†

Abstract. Quantitative robust stability results are established in this paper for feedback systems that evolve in continuous-time and exhibit linear, periodically time-varying (LPTV) behavior. The results presented are analogous to results known to hold for linear, time-invariant (LTI) systems, although they do not follow directly from these. System uncertainty is measured using the gap metric, which quantifies the distance between systems in terms of the aperture between their graphs (the subspaces corresponding to all input-output pairs for each system). The main robustness result characterizes the largest gap-ball of LPTV plants stabilized by a nominal LPTV feedback controller known to stabilize a nominal LPTV plant at the center of this ball. A key step in the proof of this result makes use of a formula derived for the directed gap between LPTV systems. This formula is essentially a generalization of Georgiou's for LTI systems. Importantly, all of the results presented apply to a class of sampled-data control systems, as a special case.

Key words. gap metric, robust stability, periodic time-variation, sampled-data systems

1. Introduction.

The motivation for this paper stems from a desire to characterize the robustness properties of sampled-data (SD) control systems. Such systems are invariably time-varying, but often the time-variation is periodic [6]. As such, the approach taken here is to study general linear, periodically time-varying (LPTV) feedback systems.

Most systematic frameworks for control system design are model based. Correspondingly, it is imperative to account for the uncertainty that may be associated with any mathematical model of a physical process. Importantly, feedback systems can be made robust to uncertainty of this kind. In fact, this property is the principal reason for using feedback in control systems. The uncertainty that feedback systems can tolerate may be qualified mathematically by introducing a *suitable* topology on the set of systems concerned and quantified in terms of any metric that induces such a topology. Consider the standard closed-loop configuration shown in Figure 1.1. This is said to be stable if $H(P,C) := \left[\begin{smallmatrix} I & C \\ P & I \end{smallmatrix}\right]^{-1}$ is causal and bounded. A topology suitable for robustness analysis is defined in [25, 23] (for quite clear reasons) as one that satisfies the following properties: Given any plant P in some set of interest and a stabilizing controller C, there exists a neighborhood of P (in this topology on the set of plants) such that all plants in this neighborhood are also stabilized by C and the mapping $P \mapsto H(P,C)$ is continuous at P (with respect to this topology and the induced-norm topology on the corresponding set of stable closed loops). That is, for any sequence $\{P_i\}_{i=0}^{\infty}$ converging to P (with respect to a topology with these properties), all but a finite number of the plants in the sequence must be stabilized by C and $H(P_i,C) \to H(P,C)$ in the induced-norm topology. Put more simply,

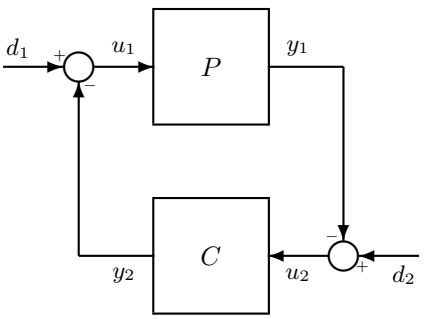

FIG. 1.1. *Standard closed-loop configuration.*

closed-loop stability is maintained in sufficiently small neighborhoods and closed-loop performance changes gradually in the face of tolerable uncertainty.

For stable systems, a topology suitable for studying robustness is the induced-norm topology. This framework lies at the heart of H^∞ control theory as developed in the seminal paper of Zames [30]. A shortcoming of the induced-norm topology is the inability to consider (explicitly) unstable components of a given closed loop. This shortcoming was addressed by defining the so-called graph topology as described below (see also [31, 23, 24]). For certain classes of system, a topology satisfying the properties described above can be characterized explicitly in terms of the graph representation of systems (the subspace of all input-output pairs) [23]. Such a topology is correspondingly referred to as the graph topology. Qualitatively, two systems are "close" in the graph topology if their graph subspaces are "close." For systems known to admit fractional representations that are coprime (such as LTI systems [24, 21], for example), a basis for the graph topology can be constructed by additively perturbing range and kernel representations of the graph, which can be constructed from the coprime factors [24]. It is also shown in [24] that for such systems, the graph topology (defined in terms of the basis described above) is the weakest with respect to which closed-loop performance varies continuously and closed-loop stability is a robust property.

The topological aspects of robustness analysis described so far qualify the types of uncertainty that are tolerable in a feedback sense. To quantify a level of robustness in these terms, a metric to induce the graph topology is required. For LTI systems a number of metrics have this property, including the graph metric [23], the gap metric [13], and the ν-gap metric [26]. Correspondingly, there are many well-known quantitative robustness results expressed in terms of these metrics for LTI systems [23, 31, 9, 13, 14, 19, 26].

All of the robust stability results derived in this paper for LPTV feedback systems are expressed in terms of the gap metric. Given two systems, the gap between them is defined to be the aperture between their corresponding graph subspaces [16]. It is well known that the gap between two subspaces is the maximum of two directed gaps [17] and, correspondingly, the gap between two systems is also the maximum of two directed gaps. In this paper, a formula is derived for the directed gap between two LPTV systems. The formula characterizes the directed gap in terms of a two-block H^∞-optimization problem involving a particular representation of the graph. As such, it is essentially a generalization of that given in [13] for LTI systems. The formula derived is used in a key step of the main robustness result further on, and, importantly,

it can be used to derive an algorithm for computing the gap [4, Chap. 5].

The quantitative robust stability results derived in this paper for LPTV feedback systems are, to a large extent, analogous to the results of [14] for LTI systems and to those of [12] for linear, time-varying (LTV) systems. However, the LPTV results do not follow directly from either the LTI or the LTV results. In particular, problems concerning causality are not addressed in [12], and although the periodic nature of the time-variation considered here imparts a high degree of structure to the analysis, it is somewhat more involved than in the time-invariant case. As for LTI systems, it can be shown that for a general class of LPTV systems, the gap metric induces the weakest topology with respect to which closed-loop performance varies continuously and closed-loop stability is a robust property. This result is not presented explicitly here but can be found in [4, Chap. 4]. All of the results obtained accommodate possibly infinite-dimensional input and output spaces and, importantly, can be applied to LPTV SD control systems as a special case.

The paper has the following structure. In section 2, the notation, terminology, and preliminary mathematics used throughout the paper are introduced. Section 3 is devoted to the gap metric, with the main result being a formula for the directed gap between two LPTV systems. In section 4, quantitative robustness results are obtained in terms of the gap metric. The main result characterizes the largest gap-ball of LPTV plants centered at a nominal plant that a nominal stabilizing LPTV controller is guaranteed to stabilize. In addition to this, robustness to simultaneous gap-perturbations of both the nominal plant and the controller is considered. To conclude this section, the main robustness result is specialized to SD control systems in which the sampling and hold devices are synchronized and periodic.

2. Preliminaries. In this section, general notation and definitions used throughout the paper are introduced. Let $\mathbb{R}$, $\mathbb{Z}$, $\mathbb{R}^+$, $\mathbb{Z}^+$, $\mathbb{D}$, and $\mathbb{T}$ denote the reals, integers, nonnegative reals, nonnegative integers, open unit-disc, and unit-circle, respectively. For convenience, given a real number $h > 0$, the interval $[0, h) \subset \mathbb{R}$ is denoted by $\mathbb{H}$. In any Hilbert space $\mathcal{H}$, the inner-product is denoted by $\langle \cdot, \cdot \rangle_{\mathcal{H}}$ and the norm by $\| \cdot \|_{\mathcal{H}}$. For a subspace $\mathcal{U} \subset \mathcal{H}$, the orthogonal complement of $\mathcal{U}$ in $\mathcal{H}$ is denoted by $\mathcal{H} \ominus \mathcal{U}$ (or $\mathcal{U}^\perp$, when the ambient space $\mathcal{H}$ is clear from context), and the orthogonal projection onto $\mathcal{U}$ is denoted by $\mathbf{\Pi}_{\mathcal{U}}$.

Consider two closed subspaces $\mathcal{G}$ and $\mathcal{F}$ of a Hilbert space $\mathcal{H}$. If $\mathcal{G} \cap \mathcal{F} = \{0\}$ and $\mathcal{G} + \mathcal{F} = \mathcal{H}$, then $\mathcal{G}$ and $\mathcal{F}$ are said to induce a *coordinatization* of $\mathcal{H}$. In this case, any $h \in \mathcal{H}$ can be uniquely decomposed as the sum $h = g + f$, where $g \in \mathcal{G}$ and $f \in \mathcal{F}$ (see [7], for example). The bounded, linear operator $\mathbf{\Pi}_{\mathcal{G}\|\mathcal{F}} : h \mapsto g$ is called the *parallel projection* onto $\mathcal{G}$ along $\mathcal{F}$. Similarly, $\mathbf{\Pi}_{\mathcal{F}\|\mathcal{G}} : h \mapsto f$ is called the parallel projection onto $\mathcal{F}$ along $\mathcal{G}$.

Let $\mathcal{U}$ and $\mathcal{Y}$ be arbitrary Hilbert spaces and consider a linear operator $P : \mathcal{D}_P \subset \mathcal{U} \to \mathcal{Y}$, where $\mathcal{D}_P := \{u \in \mathcal{U} : Pu \in \mathcal{Y}\}$ is called the domain of P. The range of P is defined to be $\mathcal{R}_P := \{Pu : u \in \mathcal{D}_P\}$ and $\mathcal{K}_P := \{u \in \mathcal{D}_P : Pu = 0\}$ is called the kernel of P. The *graph* of P is defined to be the totality of all input-output pairs

$$\mathcal{G}_P := \begin{bmatrix} I \\ P \end{bmatrix} \mathcal{D}_P \subset \mathcal{U} \oplus \mathcal{Y},$$

and for notational convenience the *inverse graph* is denoted by $\mathcal{G}_P^\sharp := \left[\begin{smallmatrix} 0 & I \\ I & 0 \end{smallmatrix}\right] \mathcal{G}_P$. Note that a (linear) subspace $\mathcal{G} \subset \mathcal{U} \oplus \mathcal{Y}$ corresponds to the graph of a linear operator if and only if $\left[\begin{smallmatrix} 0 \\ y \end{smallmatrix}\right] \in \mathcal{G}$ implies that $y = 0$. The symbol $\mathcal{B}_{\mathcal{U},\mathcal{Y}}$ is used to denote the

Banach space of all bounded, linear operators $P : \mathcal{U} \to \mathcal{Y}$; that is, all such operators with $\mathcal{D}_P = \mathcal{U}$ and finite induced-norm

$$\|P\| := \sup_{\substack{u \in \mathcal{D}_P \\ u \neq 0}} \frac{\|Pu\|_{\mathcal{Y}}}{\|u\|_{\mathcal{U}}} < \infty.$$

Given an operator $P \in \mathcal{B}_{\mathcal{U},\mathcal{Y}}$, there exist a unique operator $P^* \in \mathcal{B}_{\mathcal{Y},\mathcal{U}}$ such that for all $u \in \mathcal{U}$ and $y \in \mathcal{Y}$,

$$\langle y, Pu \rangle_{\mathcal{Y}} = \langle P^* y, u \rangle_{\mathcal{U}}.$$

The operator P^* is called the (Hilbert space) adjoint. Note that for any $P \in \mathcal{B}_{\mathcal{U},\mathcal{Y}}$, $P = (P^*)^*$ and $\mathcal{R}_P$ is orthogonal to $\mathcal{K}_{P^*}$. An operator $P \in \mathcal{B}_{\mathcal{U},\mathcal{Y}}$ is called an isometry if $\langle Pu, Pu \rangle_{\mathcal{Y}} = \langle u, u \rangle_{\mathcal{U}}$ for all $u \in \mathcal{U}$ (or equivalently, $P^*P = I$).

2.1. Signals and systems. In this paper, a system is simply considered to be an operator mapping between signal-spaces. Primarily, attention is focused on systems mapping between continuous-time spaces of signals with finite energy. Mathematically such signals can be thought of as functions in $\mathrm{L}^2_{\mathbb{R}^+}(\mathcal{H})$, the Hilbert space of $\mathcal{H}$-valued, (Lebesgue) square-integrable functions $f : \mathbb{R}^+ \to \mathcal{H}$. By virtue of the class of systems considered in what follows and the analysis technique employed to study these systems, the following signal-spaces also play an important role: the discrete-time signal-space $\ell^2_{\mathbb{Z}^+}(\mathcal{H})$ of square-summable sequences $\mathsf{f} : \mathbb{Z}^+ \to \mathcal{H}$, and the frequency-domain signal-space $\mathrm{H}^2_{\mathbb{D}}(\mathcal{H})$ of functions $\varphi : \mathbb{D} \to \mathcal{H}$ that are analytic in $\mathbb{D}$ and satisfy

$$\int_0^{2\pi} \left\langle \varphi(re^{j\omega}), \varphi(re^{j\omega}) \right\rangle_{\mathcal{H}} d\omega < M$$

for some $M < \infty$ and all $0 \leq r < 1$. Note that $\mathrm{H}^2_{\mathbb{D}}(\mathcal{H})$ is isomorphic to $\ell^2_{\mathbb{Z}^+}(\mathcal{H})$ via the $\mathbf{Z}$-transform isomorphism [22, pp. 184–185], defined for all $\mathsf{f} \in \ell^2_{\mathbb{Z}^+}(\mathcal{H})$ by

$$(\mathbf{Z}\mathsf{f})(\lambda) := \sum_{i=0}^{\infty} \mathsf{f}_k \lambda^k, \quad \lambda \in \mathbb{D}.$$

Let $\mathcal{U}$ and $\mathcal{Y}$ be Hilbert spaces. For a linear, continuous-time system $P : \mathcal{D}_P \subset \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U}) \to \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{Y})$, the standard notion of causality can be expressed as follows: P is *causal* if for all $\tau \in \mathbb{R}^+$, $\mathbf{T}_\tau \mathcal{G}_P$ corresponds to the graph of a linear operator, where $\mathbf{T}_\tau$ is the projection that truncates a signal to zero after time τ. Given a real number $h > 0$, such a system P is called *periodically time-varying* (with period h) if $\mathbf{U}_{kh} \mathcal{G}_P \subset \mathcal{G}_P$ for all $k \in \mathbb{Z}^+$, where $\mathbf{U}_\tau$ denotes the unilateral (forward) shift on $\mathrm{L}^2_{\mathbb{R}^+}(\cdot)$.[1]

The following technical definitions are necessary to facilitate a precise definition of the class of systems considered in what follows. A causal, linear, continuous-time system $P : \mathcal{D}_P \subset \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U}) \to \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U})$ is said to be *causally extendible* if $\mathbf{T}_\tau \mathcal{D}_P = \mathbf{T}_\tau \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U})$ for all $\tau < \infty$. In this way, the input to P can be chosen arbitrarily over any finite interval $[0, \tau)$ and then continued into $\mathcal{D}_P$. Since P is causal, the corresponding output over $[0, \tau)$ is defined *uniquely* by the input up to time τ. Accordingly, when P is causally extendible there is a one-to-one correspondence between P and a system $P_e : \mathrm{L}^{2,\mathrm{e}}_{\mathbb{R}^+}(\mathcal{U}) \to \mathrm{L}^{2,\mathrm{e}}_{\mathbb{R}^+}(\mathcal{Y})$ such that for all $u_e \in \mathrm{L}^{2,\mathrm{e}}_{\mathbb{R}^+}(\mathcal{U})$ and

[1] According to this definition an LTI system is also LPTV, since such a system must, by definition, satisfy $\mathbf{U}_\tau \mathcal{G}_P \subset \mathcal{G}_P \ \forall\ \tau \in \mathbb{R}^+$.

$\tau < \infty$, $\mathbf{T}_\tau P_e u_e = \mathbf{T}_\tau P_e \mathbf{T}_\tau u_e := \mathbf{T}_\tau P u$ for any $u \in \mathcal{D}_P$ that satisfies $\mathbf{T}_\tau u_e = \mathbf{T}_\tau u$, where $\mathrm{L}^{2,\mathrm{e}}_{\mathbb{R}^+}(\mathcal{H}) := \{f : \mathbb{R}^+ \to \mathcal{H} \ : \ \mathbf{T}_\tau f \in \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{H}) \text{ for all } \tau < \infty\}$ denotes the extended space associated with $\mathrm{L}^2_{\mathbb{R}^+}(\mathcal{H})$ for any Hilbert space $\mathcal{H}$. If P and P_e are related in this way, P_e is called the (causal) extension of P, and it is said that P is induced by P_e. When P is causally extendible, its causal extension P_e is said to be *locally Lipschitz-continuous* if for all $\tau \in \mathbb{R}^+$,

$$\sup_{\substack{u_1,u_2 \in \mathrm{L}^{2,\mathrm{e}}_{\mathbb{R}^+}(\mathcal{U}) \\ \mathbf{T}_\tau u_1 \neq \mathbf{T}_\tau u_2}} \frac{\|\mathbf{T}_\tau(P_e u_1 - P_e u_2)\|_{\mathrm{L}^2_{\mathbb{R}^+}(\mathcal{Y})}}{\|\mathbf{T}_\tau(u_1 - u_2)\|_{\mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U})}} < \infty.$$

Furthermore, a causally extendible system P is said to be *strongly causal* if its causal extension P_e satisfies the following property: Given any $\tau \in \mathbb{R}^+$, $\epsilon > 0$ and $\tau_1 \leq \tau$ ($\tau_1 \in \mathbb{R}^+$), there exists a $\delta > 0$ such that for all $u_1, u_2 \in \mathrm{L}^{2,\mathrm{e}}_{\mathbb{R}^+}(\mathcal{U})$ with $\mathbf{T}_\tau u_1 = \mathbf{T}_\tau u_2$,

$$\|\mathbf{T}_{(\tau_1+\delta)}(P_e u_1 - P_e u_2)\|_{\mathrm{L}^2_{\mathbb{R}^+}(\mathcal{Y})} \leq \epsilon \|\mathbf{T}_{(\tau_1+\delta)}(u_1 - u_2)\|_{\mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U})}.$$

Basically, a strongly causal system cannot respond instantaneously to inputs. Naturally, similar definitions to those above hold for systems defined on the discrete-time signal-space $\ell^2_{\mathbb{Z}^+}(\cdot)$.

DEFINITION 2.1. *Given two Hilbert spaces $\mathcal{U}$ and $\mathcal{Y}$, let $\mathscr{P}_{\mathcal{U},\mathcal{Y}}$ denote the set of causal LPTV (with period h, say) continuous-time systems*

$$P : \mathcal{D}_P \subset \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U}) \to \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{Y})$$

with closed graphs.[2] *Furthermore, let $\mathscr{P}^e_{\mathcal{U},\mathcal{Y}} \subset \mathscr{P}_{\mathcal{U},\mathcal{Y}}$ denote the subset of causally extendible systems with locally Lipschitz-continuous extensions, and let $\mathscr{P}^{e,sc}_{\mathcal{U},\mathcal{Y}}$ denote the subset of systems that are also strongly causal.*

A continuous-time system $P \in \mathscr{P}_{\mathcal{U},\mathcal{Y}}$ is said to be *stable* if it is causal and $\mathcal{D}_P = \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U})$. Since it is assumed (by definition) that all systems in $\mathscr{P}_{\mathcal{U},\mathcal{Y}}$ have closed graphs, this implies that $\|P\| < \infty$ by the closed graph theorem [3, p. 80]. Note that any stable system $P \in \mathscr{P}_{\mathcal{U},\mathcal{Y}}$ is an element of $\mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$.

Importantly, each system in $\mathscr{P}_{\mathcal{U},\mathcal{Y}}$ is equivalent (via the time-lifting isomorphism defined next) to a discrete-time system that is shift invariant [2]. Let $\mathbf{W} : \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{H}) \to \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{H}))$ denote the *time-lifting isomorphism* defined for each $f \in \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{H})$ by

$$\overset{\circ}{\mathsf{f}}_k(\theta) := (\mathbf{W}f)_k = f(kh + \theta), \quad \theta \in \mathbb{H},$$

where $\mathrm{L}^2_{\mathbb{H}}(\mathcal{H}) := \mathbf{T}_h \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{H})$. Then given any system $P \in \mathscr{P}_{\mathcal{U},\mathcal{Y}}$, the time-lifted equivalent, discrete-time system

$$\mathsf{P} := \mathbf{W} P \mathbf{W}^{-1} : \mathcal{D}_{\mathsf{P}} \subset \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})) \to \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y}))$$

is causal and linear shift-invariant (LSI) in the sense that its graph is a shift-invariant subspace, meaning $\mathbf{S}\mathcal{G}_{\mathsf{P}} \subset \mathcal{G}_{\mathsf{P}} = \mathbf{W}\mathcal{G}_P$, and $\mathbf{T}_k \mathcal{G}_{\mathsf{P}}$ corresponds to the graph of a linear operator for all $k \in \mathbb{Z}^+$ (implying causality), where $\mathbf{S}$ denotes the unilateral (forward) shift on $\ell^2_{\mathbb{Z}^+}(\cdot)$ and $\mathbf{T}_k$ denotes the truncation to zero after time k.[3] The key here is

[2] That a linear system has a closed graph is necessary for it to be stabilizable [12]. Hence, this is assumed.

[3] Throughout, the sans serif font (e.g., P) is used to distinguish objects associated with discrete-time signals and systems from continuous-time objects, for which italics are used (e.g., P).

that $\mathbf{S}^k\mathbf{W} = \mathbf{W}\mathbf{U}_{kh}$ for all $k \in \mathbb{Z}^+$, so that a shift by h in the continuous-time signal space $\mathrm{L}^2_{\mathbb{R}^+}(\cdot)$ corresponds to a shift by a single time-step in the isomorphic, discrete-time signal-space $\ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\cdot))$. Note that by representing each signal in $\ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\cdot))$ as a column vector with kth entry corresponding to the value of the signal at time k, the time-lifted equivalent system $\mathsf{P}(:=\mathbf{W}P\mathbf{W}^{-1})$ has lower-triangular, block-Toeplitz structure

$$\begin{bmatrix} \mathsf{P}_{[0]} & 0 & \cdots & \cdots & \cdots \\ \mathsf{P}_{[1]} & \mathsf{P}_{[0]} & 0 & \cdots & \cdots \\ \mathsf{P}_{[2]} & \mathsf{P}_{[1]} & \mathsf{P}_{[0]} & 0 & \cdots \\ \vdots & \ddots & \ddots & \ddots & \ddots \end{bmatrix},$$

which can be uniquely identified with the sequence $\{\mathsf{P}_{[i]}\}_{i=0}^{\infty}$. This representation plays a significant role in the sequel. If the original LPTV system P is causally extendible to a locally Lipschitz-continuous system, then each $\mathsf{P}_{[i]} \in \mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y})}$.

REMARK 2.2. *Given a (causal) LSI system* $\mathsf{P} : \mathcal{D}_P \subset \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})) \to \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y}))$,[4] *the equivalent continuous-time system* $P:=\mathbf{W}^{-1}\mathsf{P}\mathbf{W}$ *may not be locally causal in each* $[kh,(k+1)h)$ *interval of time. The equivalent system* P *is causal if and only if* $\mathsf{P}_{[0]}$ *(the first element of the sequence uniquely identifiable with the block-Toeplitz representation of* P*) is a causal mapping from* $\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})$ *to* $\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y})$*, in the sense that* $\mathbf{T}_\tau\mathcal{G}_{\mathsf{P}_{[0]}}$ *corresponds to the graph of a linear operator for all* $\tau \in \mathbb{H}$.

A (causal) LSI system $\mathsf{P} : \mathcal{D}_{\mathsf{P}} \subset \ell^2_{\mathbb{Z}^+}(\mathcal{U}) \to \ell^2_{\mathbb{Z}^+}(\mathcal{Y})$ is called stable if $\mathcal{D}_{\mathsf{P}} = \ell^2_{\mathbb{Z}^+}(\mathcal{U})$. If in addition $\mathcal{G}_{\mathsf{P}}$ is closed, then $\|\mathsf{P}\| < \infty$ by the closed-graph theorem. Related to such operators is the Hardy space $\mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{U},\mathcal{Y}})$ of functions $\Phi : \mathbb{D} \to \mathcal{B}_{\mathcal{U},\mathcal{Y}}$ that are bounded and analytic in the open unit-disc. The norm of a function $\Phi \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{U},\mathcal{Y}})$ is defined as

$$\|\Phi\|_\infty := \sup_{\lambda\in\mathbb{D}} \|\Phi(\lambda)\|.$$

Given a function $\Phi \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{U},\mathcal{Y}})$, boundary values can be defined almost everywhere on the unit-circle $\mathbb{T}$. The resulting boundary values $\Phi(e^{j\omega})$ are essentially bounded on $\mathbb{T}$, and $\|\Phi\|_\infty = \operatorname{ess\,sup}_{\omega\in[0,2\pi)}\|\Phi(e^{j\omega})\|$. A function $\Phi \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{U},\mathcal{Y}})$ is called inner if $\Phi(e^{j\omega})$ is an isometry almost everywhere on $\mathbb{T}$. Corresponding to each $\Phi \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{U},\mathcal{Y}})$ is a multiplication operator $\mathbf{M}_\Phi : \mathrm{H}^2_{\mathbb{D}}(\mathcal{U}) \to \mathrm{H}^2_{\mathbb{D}}(\mathcal{Y})$, defined by $(\mathbf{M}_\Phi\varphi)(\lambda):=\Phi(\lambda)\varphi(\lambda)$ for all $\varphi \in \mathrm{H}^2_{\mathbb{D}}(\mathcal{U})$ and $\lambda \in \mathbb{D}$.

PROPOSITION 2.3 (see [11], p. 235). *Let* $\mathcal{U}$ *and* $\mathcal{Y}$ *be arbitrary Hilbert spaces. Then given a stable, LSI system* $\mathsf{P} : \ell^2_{\mathbb{Z}^+}(\mathcal{U}) \to \ell^2_{\mathbb{Z}^+}(\mathcal{Y})$ *with closed graph, there exists a function* $\hat{\mathsf{P}} \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{U},\mathcal{Y}})$ *such that* $\mathsf{P} = \mathbf{Z}^{-1}\mathbf{M}_{\hat{\mathsf{P}}}\mathbf{Z}$*. Furthermore,* P *is an isometry if and only if the corresponding symbol* $\hat{\mathsf{P}}$ *is inner. Moreover, given any* $\Phi \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathcal{U},\mathcal{Y}})$*, the multiplication operator* $\mathbf{M}_\Phi : \mathrm{H}^2_{\mathbb{D}}(\mathcal{U}) \to \mathrm{H}^2_{\mathbb{D}}(\mathcal{Y})$ *is bounded and LSI*[5] *with* $\|\mathbf{M}_\Phi\| = \|\Phi\|_\infty$.

2.2. Feedback systems. Consider the closed-loop configuration shown in Figure 1.1, and suppose that $P \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ and $C \in \mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$. Denote by P_e and C_e the respective locally Lipschitz-continuous causal extensions, and for notational convenience, let $\mathcal{V}:=\mathcal{U}\oplus\mathcal{Y}$. The closed loop, denoted by $[P,C]$, is said to be well-posed if the following three conditions hold.

[4]Since this system is defined only for positive time, shift-invariance implies causality.

[5]The unilateral shift $\mathbf{S}$ on $\mathrm{H}^2_{\mathbb{D}}(\cdot)$ corresponds to multiplication by λ.

(i) $\left[\begin{smallmatrix} I & C_e \\ P_e & I \end{smallmatrix}\right] : \mathrm{L}^{2,\mathrm{e}}_{\mathbb{R}^+}(\mathcal{V}) \to \mathrm{L}^{2,\mathrm{e}}_{\mathbb{R}^+}(\mathcal{V})$, the system mapping $\left[\begin{smallmatrix} u_1 \\ u_2 \end{smallmatrix}\right]$ to $\left[\begin{smallmatrix} d_1 \\ d_2 \end{smallmatrix}\right]$, is bijective, implying the existence of a *unique* solution to the functional equations that describe the closed loop.

(ii) $H_e(P,C) := \left[\begin{smallmatrix} I & C_e \\ P_e & I \end{smallmatrix}\right]^{-1}$ is causal and locally Lipschitz-continuous.

(iii) The solution to the functional equations that described the closed loop is insensitive to very high frequency modeling errors, such as small transmission delays.

A sufficient condition for well-posedness is that P or C is strongly causal.[6] For further details and a discussion of the physical significance of well-posedness, the reader is referred to the seminal work of Willems [28, Chap. 4]. In addition to well-posedness, it is desirable for the system $H(P,C) : \mathcal{D}_{H(P,C)} \subset \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{V}) \to \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{V})$ induced by $H_e(P,C)$ to satisfy $\mathcal{D}_{H(P,C)} = \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{V})$. In this case, the closed loop is said to be stable and P is said to be stabilized by C. Since P and C are both linear it can be shown that this also implies closed loop stability with finite gain [28, p. 117]; that is, $\|H(P,C)\| < \infty$.

Given a plant $P \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ and a controller $C \in \mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$, note that

$$\begin{bmatrix} I & C \\ P & I \end{bmatrix} : \mathcal{D}_P \oplus \mathcal{D}_C \to \mathcal{G}_P + \mathcal{G}_C^\sharp.$$

Thus, if $[P,C]$ is well-posed, then $\mathcal{G}_P \cap \mathcal{G}_C^\sharp = \{0\}$. Furthermore, observe that $\mathcal{D}_{H(P,C)} = \mathcal{G}_P + \mathcal{G}_C^\sharp$ and hence that the closed loop is stable if and only if $\mathcal{G}_P + \mathcal{G}_C^\sharp = \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{V})$ (with $\mathcal{G}_P \cap \mathcal{G}_C^\sharp = \{0\}$). This useful geometric characterization of closed-loop stability is summarized in the following proposition, which has also appeared in [12, 15, 19] for other classes of systems.

PROPOSITION 2.4. *Given a well-posed plant/controller pair $P \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ and $C \in \mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$, the closed-loop $[P,C]$ is stable if and only if the graph of the plant and the inverse graph of the controller induce a coordinatization of $\mathrm{L}^2_{\mathbb{R}^+}(\mathcal{V})$, that is, if and only if $\mathcal{G}_P \cap \mathcal{G}_C^\sharp = \{0\}$ and $\mathcal{G}_P + \mathcal{G}_C^\sharp = \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{V})$. In this case,the parallel projections $\mathbf{\Pi}_{\mathcal{G}_P \| \mathcal{G}_C^\sharp}$ and $\mathbf{\Pi}_{\mathcal{G}_C^\sharp \| \mathcal{G}_P}$ are stable systems in $\mathscr{P}^e_{\mathcal{V},\mathcal{V}}$. In fact,*

$$\mathbf{\Pi}_{\mathcal{G}_P \| \mathcal{G}_C^\sharp} = \begin{bmatrix} I & 0 \\ 0 & -I \end{bmatrix} H(P,C) + \begin{bmatrix} 0 & 0 \\ 0 & I \end{bmatrix}$$

and

$$\mathbf{\Pi}_{\mathcal{G}_C^\sharp \| \mathcal{G}_P} = \begin{bmatrix} -I & 0 \\ 0 & I \end{bmatrix} H(P,C) + \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix}.$$

2.3. Representations of the graph. The following results, concerning the existence of particular representations of the graph, are fundamental to all of the results presented in the sequel. These results can be found in [5], and accordingly they are stated here without proof.

THEOREM 2.5. *If $P \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ can be stabilized by some $C \in \mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$, then there exist stable systems $G_r \in \mathscr{P}^e_{\mathcal{U},\mathcal{V}}$, $G_l \in \mathscr{P}^e_{\mathcal{V},\mathcal{Y}}$, $K_l \in \mathscr{P}^e_{\mathcal{V},\mathcal{U}}$, and $K_r \in \mathscr{P}^e_{\mathcal{Y},\mathcal{V}}$ such that*

$$\mathcal{G}_P = \mathcal{R}_{G_r} = \mathcal{K}_{G_l}$$

[6] This is not the weakest such condition. For example, that the product of the instantaneous gains is strictly less than 1 is also sufficient [28, Chap. 4].

and

$$\begin{bmatrix} G_r & K_r \end{bmatrix} \begin{bmatrix} K_l \\ G_l \end{bmatrix} = \begin{bmatrix} K_l \\ G_l \end{bmatrix} \begin{bmatrix} G_r & K_r \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix}.$$

G_r and G_l in Theorem 2.5 are called *strong-right* and *strong-left* representations of $\mathcal{G}_P$, respectively. Note that they are unique only up to invertible factors. That is, for any stable systems $Q_1(Q_1^{-1}) \in \mathscr{P}^e_{\mathcal{U},\mathcal{U}}$, and $Q_2(Q_2^{-1}) \in \mathscr{P}^e_{\mathcal{Y},\mathcal{Y}}$, the systems G_rQ_1 and $Q_2^{-1}G_l$ are also strong-right and strong-left representations of $\mathcal{G}_P$, respectively.

LEMMA 2.6. *Given a well-posed plant/controller pair $P \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ and $C \in \mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$, let $G_r \in \mathscr{P}^e_{\mathcal{U},\mathcal{V}}$ be any stable system with zero kernel such that $\mathcal{G}_P = \mathcal{R}_{G_r}$, and let $K_l \in \mathscr{P}^e_{\mathcal{V},\mathcal{U}}$ be any stable system such that $\mathcal{R}_{K_l} = \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U})$ and $\mathcal{G}^\sharp_C = \mathcal{K}_{K_l}$. Then the following are equivalent.*

(i) *The closed-loop $[P, C]$ is stable.*

(ii) *The stable, linear system K_lG_r is bijective (and hence boundedly invertible, although the inverse may not be causal).*

Furthermore, if $[P, C]$ is stable and G_r and K_l are, respectively, strong-right and strong-left representations of $\mathcal{G}_P$ and $\mathcal{G}^\sharp_C$, then $(K_lG_r)^{-1}$ is a stable system in $\mathscr{P}^e_{\mathcal{U},\mathcal{U}}$.

A similar result to Lemma 2.6 holds with the right representation of $\mathcal{G}_P$ replaced by a left representation, and similarly for the inverse graph of the controller.

REMARK 2.7. *Note that with P, C, G_r, and K_l defined as in the first part of Lemma* 2.6*, the following useful identity holds:*

$$\mathbf{\Pi}_{\mathcal{G}_P \| \mathcal{G}^\sharp_C} = G_r(K_lG_r)^{-1}K_l.$$

Now, let

$$\mathsf{P} := \mathbf{W}P\mathbf{W}^{-1}, \quad \mathsf{C} := \mathbf{W}C\mathbf{W}^{-1}, \quad \mathsf{G}_r := \mathbf{W}G_r\mathbf{W}^{-1}, \quad \textit{and} \quad \mathsf{K}_l := \mathbf{W}K_l\mathbf{W}^{-1}$$

so that $\mathcal{G}_{\mathsf{P}} = \mathcal{R}_{\mathsf{G}_r}$, $\mathcal{R}_{\mathsf{K}_l} = \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}))$, and $\mathcal{G}^\sharp_{\mathsf{C}} = \mathcal{K}_{\mathsf{K}_l}$. Then the closed-loop $[P, C]$ is stable if and only if the bounded linear operator $\mathsf{K}_l\mathsf{G}_r$ is boundedly invertible. In this case, $(\mathsf{K}_l\mathsf{G}_r)^{-1}$ is a stable LSI system and hence equivalent (via $\mathbf{Z}$) to a multiplication operator with symbol in $\mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})})$ (cf. Proposition 2.3*). Moreover, $\mathbf{\Pi}_{\mathcal{G}_{\mathsf{P}} \| \mathcal{G}^\sharp_{\mathsf{C}}} = \mathsf{G}_r(\mathsf{K}_l\mathsf{G}_r)^{-1}\mathsf{K}_l$.*

3. The gap metric. In this section, the gap metric is formally introduced. The main result of the section is a formula for the directed gap between LPTV systems. The formula is essentially a generalization of Georgiou's result for LTI systems [13], and it facilitates the use of function theoretic arguments in a key step of the proof of the main robustness result in the next section.

The gap (or aperture) between two (closed) subspaces $\mathcal{H}_0$ and $\mathcal{H}_1$ of a Hilbert space $\mathcal{H}$ is defined by (see [16, pp. 197–200], for example)

$$\delta(\mathcal{H}_0, \mathcal{H}_1) := \|\mathbf{\Pi}_{\mathcal{H}_0} - \mathbf{\Pi}_{\mathcal{H}_1}\|.$$

From this it follows that $\delta(\cdot, \cdot)$ is a metric. It can be shown, as in [17, Sect. 15.3], that

$$\delta(\mathcal{H}_0, \mathcal{H}_1) = \max\{\vec{\delta}(\mathcal{H}_0, \mathcal{H}_1), \vec{\delta}(\mathcal{H}_1, \mathcal{H}_0)\},$$

where

$$\vec{\delta}(\mathcal{H}_i, \mathcal{H}_j) = \|\mathbf{\Pi}_{\mathcal{H}_j^\perp}\mathbf{\Pi}_{\mathcal{H}_i}\| \quad (i, j = 0, 1)$$

is called the directed gap. Note hence that $0 \le \delta(\mathcal{H}_0, \mathcal{H}_1) \le 1$.

PROPOSITION 3.1 (see [17]). *For $i = 0, 1$ let $\mathcal{H}_i$ be a closed subspace of a Hilbert space $\mathcal{H}$. Then $\mathbf{\Pi}_{\mathcal{H}_1}$ is a bijective mapping from $\mathcal{H}_0$ to $\mathcal{H}_1$ if and only if $\delta(\mathcal{H}_0, \mathcal{H}_1) < 1$. Moreover, if $\delta(\mathcal{H}_0, \mathcal{H}_1) < 1$, then*

$$\delta(\mathcal{H}_0, \mathcal{H}_1) = \vec{\delta}(\mathcal{H}_0, \mathcal{H}_1) = \vec{\delta}(\mathcal{H}_1, \mathcal{H}_0).$$

The gap between two (closed) operators P_0 and P_1 is defined to be the gap between their graphs as follows:

$$\delta_g(P_0, P_1) := \delta(\mathcal{G}_{P_0}, \mathcal{G}_{P_1}),$$

with the directed gap being defined similarly [16, pp. 197–200]. Measuring the distance between systems in this way was first introduced into the control literature in [31] and considered further in the work of several others, notably [13, 14, 20, 12, 10].

Consider a system $P_0 \in \mathscr{P}_{\mathcal{U},\mathcal{Y}}$ and recall that $\mathcal{G}_{P_0}$ is isomorphic to both $\mathcal{G}_{\mathsf{P}_0}$ and $\hat{\mathcal{G}}_{\mathsf{P}_0} := \mathbf{Z}\mathcal{G}_{\mathsf{P}_0}$, where $\mathsf{P}_0 := \mathbf{W}P_0\mathbf{W}^{-1}$. Now given another system $P_1 \in \mathscr{P}_{\mathcal{U},\mathcal{Y}}$,

$$\delta_g(P_0, P_1) = \delta(\mathcal{G}_{P_0}, \mathcal{G}_{P_1}) = \delta(\hat{\mathcal{G}}_{\mathsf{P}_0}, \hat{\mathcal{G}}_{\mathsf{P}_1})$$

holds for the gap and

$$\vec{\delta}_g(P_i, P_j) = \vec{\delta}(\mathcal{G}_{P_i}, \mathcal{G}_{P_j}) = \vec{\delta}(\hat{\mathcal{G}}_{\mathsf{P}_i}, \hat{\mathcal{G}}_{\mathsf{P}_j}) \quad (i, j = 0, 1)$$

holds for the directed gap. The next corollary of Proposition 3.1 constitutes a useful characterization of when the gap between two systems is strictly less than 1 (see [20] and [27] for the LTI analogue).

COROLLARY 3.2. *Given two systems P_0 and P_1 in $\mathscr{P}_{\mathcal{U},\mathcal{Y}}$ for $i = 0, 1$ let $\hat{\mathsf{G}}_{ri}$ be any inner function in $\mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y})})$ such that $\hat{\mathcal{G}}_{\mathsf{P}_i} := \mathbf{ZW}\mathcal{G}_{P_i} = \hat{\mathsf{G}}_{ri}\mathrm{H}^2_{\mathbb{D}}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}))$.[7] Then the following are equivalent.*

(i) $\delta_g(P_0, P_1) = \delta(\hat{\mathcal{G}}_{\mathsf{P}_0}, \hat{\mathcal{G}}_{\mathsf{P}_1}) < 1$.

(ii) *The bounded linear operator $(\mathbf{M}_{\hat{\mathsf{G}}_{r1}})^*\mathbf{M}_{\hat{\mathsf{G}}_{r0}}$ is bijective (and hence boundedly invertible).*

Proof. Since $\mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_i}} = \mathbf{M}_{\hat{\mathsf{G}}_{ri}}(\mathbf{M}_{\hat{\mathsf{G}}_{ri}})^*$, $\hat{\mathcal{G}}_{\mathsf{P}_i} = \mathcal{R}_{\mathbf{M}_{\hat{\mathsf{G}}_{ri}}}$, and $\mathcal{K}_{\mathbf{M}_{\hat{\mathsf{G}}_{ri}}} = \{0\}$, it follows by Proposition 3.1 that $\delta(\hat{\mathcal{G}}_{\mathsf{P}_0}, \hat{\mathcal{G}}_{\mathsf{P}_1}) < 1$ if and only if $\mathbf{M}_{\hat{\mathsf{G}}_{r1}}(\mathbf{M}_{\hat{\mathsf{G}}_{r1}})^*\mathbf{M}_{\hat{\mathsf{G}}_{r0}}$ is a bijective mapping from $\mathrm{H}^2_{\mathbb{D}}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}))$ to $\hat{\mathcal{G}}_{\mathsf{P}_1}$ (see also [18, p. 201] for a similar result). Using again the fact that $\hat{\mathcal{G}}_{\mathsf{P}_i} = \mathcal{R}_{\mathbf{M}_{\hat{\mathsf{G}}_{ri}}}$ and $\mathcal{K}_{\mathbf{M}_{\hat{\mathsf{G}}_{ri}}} = \{0\}$, this is equivalent to

$$\mathcal{R}_{(\mathbf{M}_{\hat{\mathsf{G}}_{r1}})^*\mathbf{M}_{\hat{\mathsf{G}}_{r0}}} = \mathrm{H}^2_{\mathbb{D}}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})) \text{ and } \mathcal{K}_{(\mathbf{M}_{\hat{\mathsf{G}}_{r1}})^*\mathbf{M}_{\hat{\mathsf{G}}_{r0}}} = \{0\}.$$

That is, $\delta(\hat{\mathcal{G}}_{\mathsf{P}_0}, \hat{\mathcal{G}}_{\mathsf{P}_1}) < 1$ if and only if $(\mathbf{M}_{\hat{\mathsf{G}}_{r1}})^*\mathbf{M}_{\hat{\mathsf{G}}_{r0}}$ is bijective (and hence boundedly invertible by the open mapping theorem [3, p. 79]). ∎

Importantly, it is possible to express the directed gap between two LPTV systems in terms of a two-block optimization problem over $\mathrm{H}^\infty_{\mathbb{D}}$ and a specific representation of the corresponding graphs. This formula is essentially a generalization of Georgiou's [13] for the directed gap between two finite-dimensional LTI systems (see also [29, Thm. 1] and [20, Cor. 4.4]). The resultant formula is fundamental to the robust

[7] Such $\hat{\mathsf{G}}_{ri}$ exist by the Beurling–Lax–Halmos theorem. See [5] for further details.

stability results derived in the next section, and it gives rise to an algorithm for computing the gap between LPTV systems [4, Chap. 5].

THEOREM 3.3. *Given two systems P_0 and P_1 in $\mathscr{P}_{\mathcal{U},\mathcal{Y}}$ for $i = 0, 1$ let $\hat{\mathsf{G}}_{ri}$ be an inner function in $\mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{V})})$ such that $\hat{\mathcal{G}}_{\mathsf{P}_i} = \mathbf{ZW}\mathcal{G}_{P_i} = \hat{\mathsf{G}}_{ri}\mathrm{H}^2_{\mathbb{D}}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}))$. Then*

$$\vec{\delta}_g(P_0, P_1) := \vec{\delta}(\hat{\mathcal{G}}_{\mathsf{P}_0}, \hat{\mathcal{G}}_{\mathsf{P}_1}) = \inf_{\hat{\mathsf{Q}} \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})})} \|\hat{\mathsf{G}}_{r0} - \hat{\mathsf{G}}_{r1}\hat{\mathsf{Q}}\|_\infty.$$

Proof. The proof follows that of an H^∞ optimization result in [11, p. 248], using the commutant lifting theorem. For the full proof see Appendix A. □

4. Quantitative robustness analysis. An important property of feedback systems is that closed-loop stability can be desensitized to reasonable perturbations of the plant and the controller. In the subsections to follow, this property is quantitatively analyzed in terms of the gap metric for LPTV, feedback systems that evolve in continuous-time. First gap-metric perturbations to the plant alone are considered. Then robustness in the face of simultaneous gap-metric perturbations to both the plant and the controller is investigated.

4.1. Plant perturbations. In this subsection, the robustness of closed-loop stability is studied within the context of plant perturbations measured in the gap metric. Before going on, however, it is convenient to make the following definition.

DEFINITION 4.1. *Given a stable closed-loop $[P, C]$ with $P \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ and $C \in \mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$, define*

$$b^{-1}_{P,C} := \|\mathbf{\Pi}_{\mathcal{G}_P \| \mathcal{G}^\sharp_C}\| = \|\mathbf{\Pi}_{\mathcal{G}_\mathsf{P} \| \mathcal{G}^\sharp_\mathsf{C}}\|. \tag{4.1}$$

For reasons that will become apparent shortly, $b_{P,C}$ is called the robust-stability margin.

The robust stability result derived next characterizes the largest gap-ball of LPTV plants centered at a nominal plant that a nominal stabilizing LPTV controller is guaranteed to stabilize. To a large extent, the result is analogous to the LTI result of [14] and the general LTV result of [12]. Note, however, that it does not follow directly from either of these. In particular, considerable effort is required to prove necessity, where the approach taken is to construct a *causal* plant P_1 of appropriate gap distance from the nominal plant so that $[P_1, C]$ is well-posed but not stable.

THEOREM 4.2. *Let $[P_0, C]$ be a stable, closed-loop system, where $P_0 \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ and $C \in \mathscr{P}^{e,sc}_{\mathcal{Y},\mathcal{U}}$. Then, the following are equivalent.*

(i) $b_{P_0,C} \geq \beta$.

(ii) *$[P_1, C]$ is stable for all $P_1 \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ that satisfy $\delta_g(P_0, P_1) < \beta$.*

Proof of (i) $\Rightarrow$ (ii). Assume that (i) holds so that $b^{-1}_{P_0,C} \leq \beta^{-1}$. Now consider any system $P_1 \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ such that $\delta_g(P_0, P_1) := \delta(\mathcal{G}_{\mathsf{P}_0}, \mathcal{G}_{\mathsf{P}_1}) < \beta$, where $\mathsf{P}_i = \mathbf{W}P_i\mathbf{W}^{-1}$ for $i = 0, 1$. Since P_i is LPTV, P_i is LSI and, correspondingly, $\mathcal{G}_{\mathsf{P}_i}$ is a shift-invariant subspace of $\ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{V}))$.[8] Thus, it follows by the Beurling–Lax–Halmos theorem (see [11, p. 239]) that for each $i = 0, 1$, there exists an LSI isometry $\mathsf{G}_{ri} : \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})) \to \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{V}))$ such that $\mathcal{G}_{\mathsf{P}_i} = \mathcal{R}_{\mathsf{G}_{ri}}$.[9] As G_{ri} is an isometry, $\mathbf{\Pi}_{\mathcal{G}_{\mathsf{P}_i}} = \mathsf{G}_{ri}(\mathsf{G}_{ri})^*$ and hence

[8] Recall that for notational convenience $\mathcal{V} := \mathcal{U} \oplus \mathcal{Y}$.

[9] For a discussion on the existence of such representations of the graph, see [5].

$$\delta(\mathcal{G}_{\mathsf{P}_0}, \mathcal{G}_{\mathsf{P}_1}) = \|\mathbf{\Pi}_{\mathcal{G}_{\mathsf{P}_0}} - \mathbf{\Pi}_{\mathcal{G}_{\mathsf{P}_1}}\| = \|\mathsf{G}_{r0}\mathsf{G}_{r0}^* - \mathsf{G}_{r1}\mathsf{G}_{r1}^*\| < \beta. \tag{4.2}$$

Now since $[P_0, C]$ is stable, it follows by Theorem 2.5 that there exists a stable LSI system $\mathsf{K}_l : \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y})) \to \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}))$ satisfying $\mathcal{K}_{\mathsf{K}_l} = \mathcal{G}^\sharp_{\mathsf{C}}$ and $\mathcal{R}_{\mathsf{K}_l} = \ell^2_{\mathbb{Z}^+}(\mathcal{U})$. Furthermore, $\mathbf{\Pi}_{\mathcal{G}_{\mathsf{P}_0}\|\mathcal{G}^\sharp_{\mathsf{C}}} = \mathsf{G}_{r0}(\mathsf{K}_l\mathsf{G}_{r0})^{-1}\mathsf{K}_l$ (see Remark 2.7). Correspondingly,

$$b^{-1}_{P_0,C} = \|(\mathsf{K}_l\mathsf{G}_{r0})^{-1}\mathsf{K}_l\| \le \beta^{-1}, \tag{4.3}$$

since G_{r0} is an isometry. Combining equations (4.2) and (4.3) yields

$$\|(\mathsf{K}_l\mathsf{G}_{r0})^{-1}\mathsf{K}_l(\mathsf{G}_{r0}\mathsf{G}_{r0}^* - \mathsf{G}_{r1}\mathsf{G}_{r1}^*)\| < 1.$$

This implies that

$$\|\mathrm{I} - (\mathsf{K}_l\mathsf{G}_{r0})^{-1}\mathsf{K}_l\mathsf{G}_{r1}\mathsf{G}_{r1}^*\mathsf{G}_{r0}\| \le \|\mathsf{G}_{r0}^* - (\mathsf{K}_l\mathsf{G}_{r0})^{-1}\mathsf{K}_l\mathsf{G}_{r1}\mathsf{G}_{r1}^*\| \cdot \|\mathsf{G}_{r0}\| < 1$$

and hence that $(\mathsf{K}_l\mathsf{G}_{r0})^{-1}\mathsf{K}_l\mathsf{G}_{r1}(\mathsf{G}_{r1}^*\mathsf{G}_{r0})$ has bounded inverse. Since $\delta_g(P_0, P_1) < 1$, the operator $\mathsf{G}_{r1}^*\mathsf{G}_{r0}$ has bounded inverse (see Corollary 3.2) and, correspondingly, it follows that $\mathsf{K}_l\mathsf{G}_{r1}$ is also boundedly invertible. By Lemma 2.6 and Remark 2.7, this implies stability of the closed-loop $[P_1, C]$, completing the proof of (i) $\Rightarrow$ (ii).

Proof of (i) $\Leftarrow$ (ii). Suppose that (ii) holds for some $1 \ge \beta > b_{P_0,C}$.[10] Under this hypothesis it is sufficient to construct a system $P_1 \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ such that $\delta_g(P_0, P_1) < \beta$ and $[P_1, C]$ is well-posed but not stable. Now let G_{r0} and K_l be defined as in the proof of (i) $\Rightarrow$ (ii). Then by Proposition 2.3, G_{r0} and K_l are equivalent (via $\mathbf{Z}$) to multiplication operators with symbols $\hat{\mathsf{G}}_{r0} \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y})})$ and $\hat{\mathsf{K}}_l \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})})$, respectively. Furthermore, $(\hat{\mathsf{K}}_l\hat{\mathsf{G}}_{r0})^{-1} \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})})$ (see Lemma 2.6). Hence,

$$\hat{\mathsf{K}}_{l\star} := (\hat{\mathsf{G}}_{r0}\hat{\mathsf{K}}_l)^{-1}\hat{\mathsf{K}}_l \in \mathrm{H}^\infty_{\mathbb{D}}\left(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})}\right)$$

and $\mathsf{K}_{l\star} := \mathbf{Z}^{-1}\mathbf{M}_{\hat{\mathsf{K}}_{l\star}}\mathbf{Z} : \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y})) \to \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}))$ is a stable LSI system satisfying $\mathcal{K}_{\mathsf{K}_{l\star}} = \mathcal{G}^\sharp_{\mathsf{C}}$ and $\mathcal{R}_{\mathsf{K}_{l\star}} = \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}))$. In fact, by definition,

$$b^{-1}_{P_0,C} := \|\mathsf{G}_{r0}\mathsf{K}_{l\star}\| = \|\mathsf{K}_{l\star}\| = \|\hat{\mathsf{K}}_{l\star}\|_\infty = \sup_{\lambda\in\mathbb{D}} \|\hat{\mathsf{K}}_{l\star}(\lambda)\|, \tag{4.4}$$

where the second equality holds because G_{r0} is an isometry. Since the function $\hat{\mathsf{K}}_{l\star}(\lambda)$ is analytic in $\mathbb{D}$, $\|\hat{\mathsf{K}}_{l\star}(\lambda)\|$ satisfies a maximum principle on any connected, open subset of $\mathbb{D}$ (see [1]). Using this property and (4.4), it follows that for any $\epsilon_0 > 0$ and $\epsilon_1 > 0$, there exists a $\lambda_{0,\epsilon_0} \in \mathbb{A}_{\epsilon_0} := \{\lambda : (1-\epsilon_0) \le |\lambda| < 1\}$ such that

$$(b_{P_0,C} + \epsilon_1)^{-1} \le \|\hat{\mathsf{K}}_{l\star}(\lambda_{0,\epsilon_0})\| \le b^{-1}_{P_0,C}.$$

Now for any $\epsilon_2 > \epsilon_1$ it is possible to construct an operator $\Delta_{0,\epsilon_2} \in \mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y})}$ such that

$$\|\Delta_{0,\epsilon_2}\| \le (b_{P_0,C} + \epsilon_2) \tag{4.5}$$

[10] Since $\delta_g(P_0, P_1) \le 1$ for all $P_1 \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$, it is without loss of generality that β is taken to be less than or equal to 1; otherwise there is an obvious contradiction to what is being proved.

and $(\mathrm{I}+\hat{\mathsf{K}}_{l\star}(\lambda_{0,\epsilon_0})\Delta_{0,\epsilon_2})$ is not invertible in $\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})}$.[11] Defining

$$\hat{\Delta}_{\epsilon_2}(\lambda):=\frac{\lambda}{\lambda_{0,\epsilon_0}}\Delta_{0,\epsilon_2}\in \mathrm{H}^\infty_{\mathbb{D}}\left(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{V})}\right), \tag{4.6}$$

it follows that

$$\|(\mathrm{I}+\hat{\mathsf{K}}_{l\star}(\lambda)\hat{\Delta}_{\epsilon_2}(\lambda))^{-1}\|\to\infty$$

as $\lambda\to\lambda_{0,\epsilon_0}$, since $(\mathrm{I}+\hat{\mathsf{K}}_{l\star}\hat{\Delta})$ is continuous on $\mathbb{D}$ and $(\mathrm{I}+\hat{\mathsf{K}}_{l\star}(\lambda_{0,\epsilon_0})\Delta_{0,\epsilon_2})$ is not invertible.[12] Clearly then, $(\mathrm{I}+\hat{\mathsf{K}}_{l\star}\hat{\Delta}_{\epsilon_2})$ is not invertible in $\mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})})$.

For some $\hat{\mathsf{Q}}_1(\hat{\mathsf{Q}}_1^{-1})\in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})})$ let

$$\hat{\mathsf{G}}_{r1}:=(\hat{\mathsf{G}}_{r0}+\hat{\Delta}_{\epsilon_2})\hat{\mathsf{Q}}_1,$$

and note that

$$\hat{\mathsf{K}}_{l\star}\hat{\mathsf{G}}_{r1}=(\mathrm{I}+\hat{\mathsf{K}}_{l\star}\hat{\Delta}_{\epsilon_2})\hat{\mathsf{Q}}_1.$$

Clearly, the function $\hat{\mathsf{K}}_{l\star}\hat{\mathsf{G}}_{r1}$ is not invertible in $\mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})})$. Consequently, with $\mathsf{G}_{r1}:=\mathbf{Z}^{-1}\mathbf{M}_{\hat{\mathsf{G}}_{r1}}\mathbf{Z}$, the stable LSI system $\mathsf{K}_{l\star}\mathsf{G}_{r1}:\ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}))\to\ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}))$ is not boundedly invertible. So provided that

(a) $\mathcal{K}_{\mathsf{G}_{r1}}=\{0\}$,
(b) $\mathcal{R}_{\mathsf{G}_{r1}}$ is isomorphic (via $\mathbf{W}$) to the graph of a system $P_1\in\mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$, and
(c) $\delta_g(P_0,P_1)<\beta$,

a contradiction to the initial hypothesis that (ii) holds for some $1\geq\beta>b_{P_0,C}$ can be established using Lemma 2.6 and Remark 2.7. Accordingly, the remainder of the proof is devoted to showing that by appropriate choice of ϵ_0, ϵ_2, and $\hat{\mathsf{Q}}_1$, conditions (a), (b), and (c) can be satisfied.

First note that $\mathsf{G}_{r1}=(\mathsf{G}_{r0}+\Delta_{\epsilon_2})\mathsf{Q}_1$, where

$$\mathsf{G}_{r0}:=\mathbf{Z}^{-1}\mathbf{M}_{\hat{\mathsf{G}}_{r0}}\mathbf{Z},\ \ \Delta_{\epsilon_2}:=\mathbf{Z}^{-1}\mathbf{M}_{\hat{\Delta}_{\epsilon_2}}\mathbf{Z},\ \text{ and }\ \mathsf{Q}_1:=\mathbf{Z}^{-1}\mathbf{M}_{\hat{\mathsf{Q}}_1}\mathbf{Z}.$$

Furthermore, note that $\hat{\Delta}_{\epsilon_2}(\lambda)$ has continuous extension to the closed unit-disc and hence that $\|\hat{\Delta}_{\epsilon_2}\|_\infty=\max_{\omega\in[0,2\pi)}\|\hat{\Delta}_{\epsilon_2}(e^{j\omega})\|$. As such, it follows by Proposition 2.3 and from (4.5) and (4.6) that

$$\|\Delta_{\epsilon_2}\|=\|\hat{\Delta}_{\epsilon_2}\|_\infty=\frac{1}{|\lambda_{0,\epsilon_0}|}\|\Delta_{0,\epsilon_2}\|\leq\frac{b_{P_0,C}+\epsilon_2}{1-\epsilon_0}.$$

[11] To see this, let A denote a bounded, linear operator in $\mathcal{B}_{\mathcal{U},\mathcal{Y}}$. Then for any $\epsilon>0$, it follows by definition of the induced norm that there exists a $u\in\mathcal{U}$ (which is taken to have unit norm) such that with $y:=Au$,

$$\|A\|\geq\|y\|_{\mathcal{Y}}\geq\|A\|-\epsilon.$$

Defining $\Delta:\mathcal{Y}\to\mathcal{U}$ to be the operator that maps αy to $-\alpha u$ for all $\alpha\in\mathbb{C}$ and every other direction orthogonal to this in $\mathcal{Y}$ to 0, it follows that

$$\|\Delta\|\leq\frac{1}{\|A\|-\epsilon},$$

and that $y\in\mathcal{K}_{(I+A\Delta)}$. Correspondingly, $(I+A\Delta)$ is not invertible.

[12] See [8, Lemma 4.3] (only if part) for a similar result.

By hypothesis $(\beta - b_{P_0,C}) > 0$ and setting $\epsilon_2 = (\beta - b_{P_0,C})/2 > 0$, $\epsilon_1 < \epsilon_2$ and $\epsilon_0 < \epsilon_2/2\beta$, gives

$$\|\Delta_{\epsilon_2}\| < \beta \leq 1. \tag{4.7}$$

Hence, since G_{r0} is an isometry, it follows that there exists a constant $c > 0$ such that $\|\mathsf{G}_{r1}\,\overline{\mathsf{q}}^{\circ}\|_{\ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{V}))} \geq c\|\,\overline{\mathsf{q}}^{\circ}\|_{\ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}))}$ for all $\overline{\mathsf{q}}^{\circ} \in \ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}))$. Correspondingly, $\mathcal{R}_{\mathsf{G}_{r1}}$ is closed and $\mathcal{K}_{\mathsf{G}_{r1}} = \{0\}$. That is, condition (a) is satisfied.

$\hat{\mathsf{Q}}_1 \in \mathrm{H}^{\infty}_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})})$ is now constructed so that $\mathcal{R}_{\mathsf{G}_{r1}}$ is isomorphic (via $\mathbf{W}$) to the graph of a system $P_1 \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$. First let

$$\begin{bmatrix}\mathsf{M}_{r1}\\ \mathsf{N}_{r1}\end{bmatrix} := \mathsf{G}_{r1} \text{ and } \begin{bmatrix}\mathsf{M}_{r0}\\ \mathsf{N}_{r0}\end{bmatrix} := \mathsf{G}_{r0},$$

where the partitioning is conformal with $\mathcal{G}_{\mathsf{P}_0}$. By construction, $\Delta_{[0]} = 0$, where the subscript [0] denotes the first term in the sequence uniquely identifiable with the block-Toeplitz representation of Δ. Thus, $\mathsf{G}_{r1[0]} = (\mathsf{G}_{r0}\mathsf{Q}_1)_{[0]}$ and

$$\begin{bmatrix}\mathsf{M}_{r1[0]}\\ \mathsf{N}_{r1[0]}\end{bmatrix} = \left(\begin{bmatrix}\mathsf{M}_{r0}\\ \mathsf{N}_{r0}\end{bmatrix}\mathsf{Q}_1\right)_{[0]} = \begin{bmatrix}\mathsf{M}_{r0[0]}\\ \mathsf{N}_{r0[0]}\end{bmatrix}\mathsf{Q}_{1[0]}. \tag{4.8}$$

Since $\mathcal{R}_{\mathsf{G}_{r0}}$ is isomorphic to $\mathcal{G}_{P_0}$ and $P_0 \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$, it can be shown that $\mathsf{M}_{r0[0]} \in \mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})}$ is boundedly invertible (for the details of this see the proof of Theorem 4.1 in [5]). So by the assumed invertibility of Q_1 and (4.8), $\mathsf{M}_{r1[0]}$ is also invertible in $\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})}$. Consequently, M_{r1} has zero kernel, which confirms that $\mathcal{R}_{\mathsf{G}_{r1}}$ is the graph of a linear operator. In fact, it is isomorphic to the graph of an LPTV system P_1 defined on a subspace of $\mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U})$. It is sufficient therefore to select $\hat{\mathsf{Q}}_1$ to ensure that P_1 is causal and that it has locally Lipschitz-continuous extension. To this end, set $\hat{\mathsf{Q}}_1 = \mathsf{M}^{-1}_{r0[0]}$ (which is clearly an invertible element in $\mathrm{H}^{\infty}_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})})$) so that $\mathsf{Q}_{1[0]} = \mathsf{M}^{-1}_{r0[0]}$ and

$$\mathsf{G}_{r1[0]} = \begin{bmatrix}\mathsf{M}_{r1[0]}\\ \mathsf{N}_{r1[0]}\end{bmatrix} = (\mathsf{G}_{r0}\mathsf{Q}_1)_{[0]} = \begin{bmatrix}\mathrm{I}\\ \mathsf{N}_{r0[0]}\mathsf{M}^{-1}_{r0[0]}\end{bmatrix}.$$

Since $\mathsf{P}_{0[0]} = \mathsf{N}_{r0[0]}\mathsf{M}^{-1}_{r0[0]}$ is causal on $\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})$, this implies that $\mathsf{G}_{r1[0]}$ is a causal map on $\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})$. So in view of Remark 2.2, $\left[\begin{smallmatrix}M_{r1}\\ N_{r1}\end{smallmatrix}\right] := G_{r1} = \mathbf{W}^{-1}\mathsf{G}_{r1}\mathbf{W}$ is a stable system in $\mathscr{P}^e_{\mathcal{U},\mathcal{V}}$. This, in turn, implies that P_1 is itself causal. To see this, suppose that P_1 is not causal. Then by definition, there exists a point $\left[\begin{smallmatrix}u\\ y\end{smallmatrix}\right] \in \mathcal{G}_{P_1} = \mathcal{R}_{G_{r1}}$ and a $\tau_1 \in \mathbb{R}^+$ such that

$$\mathbf{T}_{\tau_1}\begin{bmatrix}u\\ y\end{bmatrix} = \begin{bmatrix}0\\ \tilde{y} \neq 0\end{bmatrix}.$$

That is, there exists a $q \in \mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U})$ such that $\tilde{y} = \mathbf{T}_{\tau_1}N_{r1}q$ and $0 = \mathbf{T}_{\tau_1}M_{r1}q$. Since

M_{r1} is causal,

$$\begin{aligned}\mathbf{T}_{\tau_1} M_{r1} q &= \mathbf{T}_{\tau_1}\mathbf{W}^{-1}\mathbf{T}_n \mathsf{M}_{r1}\mathbf{W}q \\ &= \mathbf{T}_{\tau_1}\mathbf{W}^{-1}\begin{bmatrix}\underbrace{\begin{bmatrix}\mathsf{M}_{r1[0]}(=\mathrm{I}) & 0 & \cdots & 0\\ \mathsf{M}_{r1[1]} & \ddots & \ddots & \vdots\\ \vdots & \ddots & \ddots & 0\\ \mathsf{M}_{r1[n]} & \cdots & \mathsf{M}_{r1[1]} & \mathsf{M}_{r1[0]}\end{bmatrix}}_{:=\tilde{\mathsf{M}}_n} \begin{bmatrix}\overset{\circ}{\mathsf{q}}_0\\ \overset{\circ}{\mathsf{q}}_1\\ \vdots\\ \vdots\\ \overset{\circ}{\mathsf{q}}_n\end{bmatrix}\\ 0\\ \vdots\end{bmatrix},\end{aligned} \tag{4.9}$$

where $\overset{\circ}{\mathsf{q}}(=:k\mapsto\overset{\circ}{\mathsf{q}}_k):=\mathbf{W}q$, $n=\lfloor\frac{\tau_1}{h}\rfloor$ and $\lfloor\cdot\rfloor$ denotes the integer part of a real number. Note that $\tilde{\mathsf{M}}_i$ is boundedly invertible for all finite i and, correspondingly, that it has zero kernel and full range.[13] So if $0=\mathbf{T}_{\tau_1}M_{r1}q$, it follows from (4.9) that $\overset{\circ}{\mathsf{q}}_0=\overset{\circ}{\mathsf{q}}_1=\cdots=\overset{\circ}{\mathsf{q}}_{n-1}=0$ and $\mathbf{T}_{(\tau_1-nh)}\overset{\circ}{\mathsf{q}}_n=0$. Equivalently, $\mathbf{T}_{\tau_1}q=0$. Now since N_{r1} is causal, this implies that $\tilde{y}=\mathbf{T}_{\tau_1}N_{r1}q=0$, which is a contradiction. Consequently, P_1 must be causal. This line of reasoning also leads to the conclusion that P_1 is causally extendible to a locally Lipschitz-continuous operator on $\mathrm{L}^{2,\mathrm{e}}_{\mathbb{R}^+}(\mathcal{U})$. To see this note that, since $\tilde{\mathsf{M}}_i$ has full range for all finite i, given any $\tau<\infty$

$$\mathbf{T}_\tau\mathcal{D}_{P_1}=\mathbf{T}_\tau\mathcal{R}_{M_{r1}}=\mathbf{T}_\tau\mathbf{W}^{-1}\begin{bmatrix}\mathcal{R}_{\tilde{\mathsf{M}}_n}\\ 0\end{bmatrix}=\mathbf{T}_\tau\mathrm{L}^2_{[0,(n+1)h)}(\mathcal{U})=\mathbf{T}_\tau\mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U}),$$

where $n=\lfloor\frac{\tau}{h}\rfloor$. Correspondingly, P_1 is causally extendible (by definition). Now denote the extension of P_1 by P_{1e} and observe that

$$\sup_{\substack{u_1,u_2\in\mathrm{L}^{2,\mathrm{e}}_{\mathbb{R}^+}(\mathcal{U})\\ \mathbf{T}_\tau u_1\neq\mathbf{T}_\tau u_2}}\frac{\|\mathbf{T}_\tau(P_{1e}u_1-P_{1e}u_2)\|_{\mathrm{L}^2_{\mathbb{R}^+}(\mathcal{Y})}}{\|\mathbf{T}_\tau(u_1-u_2)\|_{\mathrm{L}^2_{\mathbb{R}^+}(\mathcal{U})}}\le\sup_{\substack{\mathsf{u}\in\mathbf{T}_n\ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}))\\ \mathsf{u}\neq0}}\frac{\|\tilde{\mathsf{N}}_n\tilde{\mathsf{M}}_n^{-1}\mathsf{u}\|_{\mathbf{T}_n\ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{Y}))}}{\|\mathsf{u}\|_{\mathbf{T}_n\ell^2_{\mathbb{Z}^+}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}))}},$$

where

$$\tilde{\mathsf{N}}_n:=\begin{bmatrix}\mathsf{N}_{r1[0]} & 0 & \cdots & 0\\ \mathsf{N}_{r1[1]} & \ddots & \ddots & \vdots\\ \vdots & \ddots & \ddots & 0\\ \mathsf{N}_{r1[n]} & \cdots & \mathsf{N}_{r1[1]} & \mathsf{N}_{r1[0]}\end{bmatrix}.$$

Then, since $\tilde{\mathsf{N}}_i$ and $\tilde{\mathsf{M}}_i^{-1}$ are both bounded for all finite i, it follows (by definition) that P_{1e} is locally Lipschitz-continuous as claimed.

It remains to show that $\delta_g(P_0,P_1)<\beta$. First it is shown that $\vec{\delta}_g(P_0,P_1)<\beta$ and then that $\delta_g(P_0,P_1)=\vec{\delta}_g(P_0,P_1)<\beta$. Note that $\hat{\mathcal{G}}_{\mathsf{P}_1}:=\mathbf{Z}\mathbf{W}\mathcal{G}_{\mathsf{P}_1}$ is a shift-invariant subspace of $\mathrm{H}^2_{\mathbb{D}}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{V}))$. Correspondingly, by the Beurling–Lax–Halmos theorem [11, p. 239], there exists an inner function $\hat{\mathsf{G}}_{r\star}\in\mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{V})})$ such that $\hat{\mathcal{G}}_{\mathsf{P}_1}=\hat{\mathsf{G}}_{r1\star}\mathrm{H}^2_{\mathbb{D}}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}))$. Moreover, since $\mathcal{R}_{\mathbf{M}_{\hat{\mathsf{G}}_{r1}}}=\mathcal{R}_{\mathbf{M}_{\hat{\mathsf{G}}_{r1\star}}}$ and $\mathcal{K}_{\mathbf{M}_{\hat{\mathsf{G}}_{r1}}}=\{0\}$, there

[13] In fact $\tilde{\mathsf{M}}_i^{-1}$ here is block-lower-triangular with identities down the diagonal.

exists a $\hat{\mathsf{Q}}_\star(\hat{\mathsf{Q}}_\star^{-1}) \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})})$ such that $\hat{\mathsf{G}}_{r1\star}\hat{\mathsf{Q}}_\star = \hat{\mathsf{G}}_{r1} = (\hat{\mathsf{G}}_{r0} + \hat{\Delta})\hat{\mathsf{Q}}_1$ (see Corollary IX.2.2 of the Beurling–Lax–Halmos theorem in [11]). Now by Theorem 3.3,

$$\begin{aligned}\vec{\delta}_g(P_0,P_1) = \vec{\delta}(\hat{\mathcal{G}}_{\mathsf{P}_0},\hat{\mathcal{G}}_{\mathsf{P}_1}) &= \inf_{\hat{\mathsf{Q}}\in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})})} \|\hat{\mathsf{G}}_{r0} - \hat{\mathsf{G}}_{r1\star}\hat{\mathsf{Q}}\|_\infty \\ &= \inf_{\hat{\mathsf{Q}}\in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})})} \|\hat{\mathsf{G}}_{r0} - (\hat{\mathsf{G}}_{r0} + \hat{\Delta}_{\epsilon_2})\hat{\mathsf{Q}}_1\hat{\mathsf{Q}}_\star^{-1}\hat{\mathsf{Q}}\|_\infty \\ &\le \|\hat{\Delta}_{\epsilon_2}\|_\infty < \beta,\end{aligned}$$

where the third inequality follows from the fact that $\hat{\mathsf{Q}}_\star\hat{\mathsf{Q}}_1^{-1} \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})})$ and the last inequality follows from (4.7).

Now for any $\varphi \in \mathrm{H}^2_{\mathbb{D}}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}))$, consider the projection of $\mathbf{M}_{\hat{\mathsf{G}}_{r1}}\varphi \in \hat{\mathcal{G}}_{\mathsf{P}_1}$ onto $\hat{\mathcal{G}}_{\mathsf{P}_0}$. Since $\mathbf{M}_{\hat{\mathsf{G}}_{r0}}$ is an isometry, $\mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_0}} = \mathbf{M}_{\hat{\mathsf{G}}_{r0}}(\mathbf{M}_{\hat{\mathsf{G}}_{r0}})^*$ and the projection described above can be expressed as

$$\mathbf{M}_{\hat{\mathsf{G}}_{r0}}\left(\mathbf{M}_{\hat{\mathsf{G}}_{r0}}\right)^*\left(\mathbf{M}_{\hat{\mathsf{G}}_{r0}} + \mathbf{M}_{\hat{\Delta}_{\epsilon_2}}\right)\mathbf{M}_{\hat{\mathsf{Q}}_1}\varphi = \mathbf{M}_{\hat{\mathsf{G}}_{r0}}\zeta,$$

where

$$\zeta := \left(\mathrm{I} + \left(\mathbf{M}_{\hat{\mathsf{G}}_{r0}}\right)^*\mathbf{M}_{\hat{\Delta}_{\epsilon_2}}\right)\mathbf{M}_{\hat{\mathsf{Q}}_1}\varphi.$$

Furthermore,

$$\|\left(\mathbf{M}_{\hat{\mathsf{G}}_{r0}}\right)^*\mathbf{M}_{\hat{\Delta}_{\epsilon_2}}\| \le \|\mathbf{M}_{\hat{\mathsf{G}}_{r0}}\| \cdot \|\mathbf{M}_{\hat{\Delta}_{\epsilon_2}}\| < \beta \le 1.$$

Thus, $(\mathrm{I} + (\mathbf{M}_{\hat{\mathsf{G}}_{r0}})^*\mathbf{M}_{\hat{\Delta}_\epsilon})$ is a *one-to-one* mapping *onto* $\mathrm{H}^2_{\mathbb{D}}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}))$ and since $\mathbf{M}_{\hat{\mathsf{Q}}_1}$ is bijective, it follows that the projection described above is also bijective. So by Proposition 3.1,

$$\vec{\delta}(\hat{\mathcal{G}}_{\mathsf{P}_0},\hat{\mathcal{G}}_{\mathsf{P}_1}) = \vec{\delta}(\hat{\mathcal{G}}_{\mathsf{P}_1},\hat{\mathcal{G}}_{\mathsf{P}_0}) = \delta(\hat{\mathcal{G}}_{\mathsf{P}_0},\hat{\mathcal{G}}_{\mathsf{P}_1})$$

and hence $\delta_g(P_0,P_1) = \delta(\hat{\mathcal{G}}_{\mathsf{P}_0},\hat{\mathcal{G}}_{\mathsf{P}_1}) = \vec{\delta}(\hat{\mathcal{G}}_{\mathsf{P}_0},\hat{\mathcal{G}}_{\mathsf{P}_1}) < \beta$, as required. This completes the proof. □

Consider a closed-loop $[P_0, C]$ with $P_0 \in \mathscr{P}^{e,sc}_{\mathcal{U},\mathcal{Y}}$ and $C \in \mathscr{P}^{e}_{\mathcal{Y},\mathcal{U}}$. Since the plant P_0 is strongly causal, the closed-loop $[P_0, C]$ is well-posed. Similarly, if the set of permissible perturbed plants were restricted to be a subset of $\mathscr{P}^{e,sc}_{\mathcal{U},\mathcal{Y}}$, well-posedness would be maintained. Now note that by the way the destabilizing plant P_1 is constructed in the proof of Theorem 4.2, $\mathsf{P}_{0[0]} = \mathsf{P}_{1[0]}$. Correspondingly, the instantaneous behavior of the nominal plant and the plant constructed to destabilize the closed loop is the same. As such, if P_0 were strongly causal, then P_1 would also be strongly causal. Consequently, (ii) ⇒ (i) in Theorem 4.2 would still hold if permissible perturbed plants were restricted to strongly causal ones only. This is summarized below.

COROLLARY 4.3. *Given a stable, closed-loop system* $[P_0, C]$ *with* $P_0 \in \mathscr{P}^{e,sc}_{\mathcal{U},\mathcal{Y}}$ *and* $C \in \mathscr{P}^{e}_{\mathcal{Y},\mathcal{U}}$, *the following are equivalent.*

(i) $b_{P_0,C} \ge \beta$.

(ii) $[P_1, C]$ *is stable for all* $P_1 \in \mathscr{P}^{e,sc}_{\mathcal{U},\mathcal{Y}}$ *that satisfy* $\delta_g(P_0,P_1) < \beta$.

Similarly, although it is very difficult to characterize analytically, restricting the set of permissible perturbations to all of those which do not cause ill-posedness[14] leads to the following restatement of Theorem 4.2.

[14]This is necessary for (i) ⇒(ii) to hold.

COROLLARY 4.4. *Given a stable, closed-loop system* $[P_0, C]$ *with* $P_0 \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ *and* $C \in \mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$, *the following are equivalent.*

(i) $b_{P_0,C} \geq \beta$.

(ii) $[P_1, C]$ *is stable for all* $P_1 \in \mathscr{P}^e_{\mathcal{U},\mathcal{Y}}$ *such that* $\delta_g(P_0, P_1) < \beta$ *and* $[P_1, C]$ *is well-posed.*

4.2. Simultaneous plant and controller perturbations. The maximum combined perturbation to both P and C that does not cause instability is quantified in terms of the gap metric in this subsection. As a corollary of Theorem 4.2, it is first shown that a given controller C stabilizes a gap-ball centered at P if and only if P is stabilized by all controllers in a gap-ball of the same radius and centered at C. The maximum combined gap-perturbation (as a sum) to P and C that the closed loop can tolerate is then considered. The results presented are analogous to the LTI results of [14, Sect. VI] and the LTV results of [12, Sect. 4]. Before continuing, it is instructive to recall the following results.

PROPOSITION 4.5 (see [7]). *Suppose that two (closed) manifolds* $\mathcal{F}$ *and* $\mathcal{G}$ *induce a coordinatization of a Hilbert space* $\mathcal{H}$. *If* $\mathcal{F}$ *is linear, then*

$$\|\mathbf{\Pi}_{\mathcal{F}\|\mathcal{G}}\| = \|\mathbf{\Pi}_{\mathcal{G}\|\mathcal{F}}\|.$$

COROLLARY 4.6. *Given a stable closed-loop* $[P, C]$ *with* $P \in \mathscr{P}_{\mathcal{U},\mathcal{Y}}$ *and* $C \in \mathscr{P}_{\mathcal{Y},\mathcal{U}}$,

$$b_{P,C} = b_{C,P}.$$

Proof. Note that (see Definition 4.1)

$$b_{C,P} := \|\mathbf{\Pi}_{\mathcal{G}_C\|\mathcal{G}_P^\sharp}\| = \left\| \begin{bmatrix} 0 & I \\ I & 0 \end{bmatrix} \mathbf{\Pi}_{\mathcal{G}_C^\sharp\|\mathcal{G}_P} \begin{bmatrix} 0 & I \\ I & 0 \end{bmatrix} \right\| = \|\mathbf{\Pi}_{\mathcal{G}_C^\sharp\|\mathcal{G}_P}\|.$$

Now since $[P, C]$ is stable, $\mathcal{G}_P$ and $\mathcal{G}_C^\sharp$ induce a coordinatization of $\mathrm{L}^2_{\mathbb{R}^+}(\mathcal{V})$ (see Proposition 2.4). So by Proposition 4.5, $b_{C,P} = \|\mathbf{\Pi}_{\mathcal{G}_C^\sharp\|\mathcal{G}_P}\| = \|\mathbf{\Pi}_{\mathcal{G}_P\|\mathcal{G}_C^\sharp}\| = b_{P,C}$. ∎

In view of Corollary 4.6, the following result, which characterizes robustness to gap-metric perturbations of the controller, is an immediate consequence of Theorem 4.2.

COROLLARY 4.7. *Let* $[P_0, C_0]$ *be a stable, closed-loop system with* $P_0 \in \mathscr{P}^{e,sc}_{\mathcal{U},\mathcal{Y}}$ *and* $C_0 \in \mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$. *Then the following are equivalent.*

(i) $[P_1, C_0]$ *is stable for all* $P_1 \in \mathscr{P}^{e,sc}_{\mathcal{U},\mathcal{Y}}$ *such that* $\delta_g(P_0, P_1) < \beta$.

(ii) $[P_0, C_1]$ *is stable for all* $C_1 \in \mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$ *such that* $\delta_g(C_0, C_1) < \beta$.

REMARK 4.8. *As with Corollaries* 4.3 *and* 4.4, *Corollary* 4.7 *can be restated with various constraints on the strength of causality of the plants and the controllers.*

Now, with this established, it is possible to quantitatively characterize robustness to perturbations of both P and its stabilizing controller C.

THEOREM 4.9. *Consider a stable closed-loop system* $[P_0, C_0]$ *with* $P_0 \in \mathscr{P}^{e,sc}_{\mathcal{U},\mathcal{Y}}$ *and* $C_0 \in \mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$. *The following are equivalent.*

(i) $\beta \leq b_{P_0,C_0}$.

(ii) $[P_1, C_1]$ *is stable for all* $P_1 \in \mathscr{P}^{e,sc}_{\mathcal{U},\mathcal{Y}}$ *and* $C_1 \in \mathscr{P}^e_{\mathcal{Y},\mathcal{U}}$ *such that*

$$\delta_g(P_0, P_1) + \delta_g(C_0, C_1) < \beta.$$

Proof. The proof follows directly from Corollary 4.3 of Theorem 4.2 and Corollary 4.7, in exactly the same way as the corresponding result [14, Thm. 7]. Assume that

(i) holds, so that by Corollaries 4.3 and 4.7, $[P_0, C_1]$ is stable for all $C_1 \in \mathscr{B}^{\mathrm{e}}_{\delta_g}(C_0, \beta)$, where

$$\mathscr{B}^{\mathrm{e}}_{\delta_g}(F, \epsilon) := \{\grave{F} \in \mathscr{P}^{e}_{\mathcal{Y},\mathcal{U}} \ : \ \delta_g(F, \grave{F}) < \epsilon\}.$$

Consider a controller $C_1 \in \mathscr{P}^{e}_{\mathcal{Y},\mathcal{U}}$, which satisfies $\tau := \delta_g(C_0, C_1) < \beta$. By the metric property of the gap, it follows that $\mathscr{B}^{\mathrm{e}}_{\delta_g}(C_1, \beta - \tau) \subset \mathscr{B}^{\mathrm{e}}_{\delta_g}(C_0, \beta)$ and hence that $[P_0, C_2]$ is stable for all $C_2 \in \mathscr{B}^{\mathrm{e}}_{\delta_g}(C_1, \beta - \tau)$. Using Corollary 4.7, it is then possible to conclude that $[P_1, C_1]$ is stable for all $P_1 \in \mathscr{B}^{\mathrm{e,sc}}_{\delta_g}(P_0, \beta - \tau)$, where

$$\mathscr{B}^{\mathrm{e,sc}}_{\delta_g}(F, \epsilon) := \{\grave{F} \in \mathscr{P}^{e,sc}_{\mathcal{Y},\mathcal{U}} \ : \ \delta_g(F, \grave{F}) < \beta\}.$$

Since this holds for any $C_1 \in \mathscr{P}^{e}_{\mathcal{U},\mathcal{Y}}$ satisfying $\delta_g(C_0, C_1) < \beta$, it is clear that (ii) holds. That (ii) $\Rightarrow$ (i) is immediate, since (ii) here implies (i) in Corollary 4.3. This is precisely $\beta \le b_{P_0,C_0}$. ∎

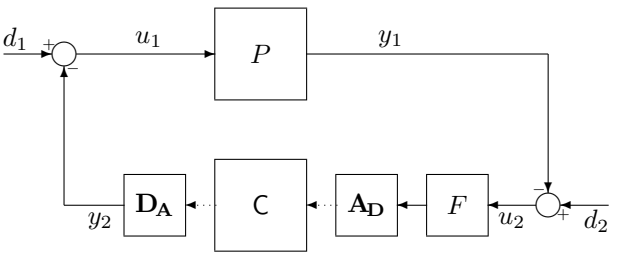

FIG. 4.1. *Sampled-data control system.*

4.3. Robustness of SD control systems. In this subsection, the robustness results obtained in preceding subsections are specialized to the SD case. Set $\mathcal{U} = \mathbb{R}^m$ and $\mathcal{Y} = \mathbb{R}^p$, and consider the feedback configuration shown in Figure 4.1. Let the plant P be in $\mathscr{P}^{e}_{\mathcal{U},\mathcal{Y}}$; the controller $\mathsf{C} : \mathcal{D}_{\mathsf{C}} \subset \ell^2_{\mathbb{Z}_+}(\mathcal{Y}) \to \ell^2_{\mathbb{Z}_+}(\mathcal{U})$ be an LSI, discrete-time system; $\mathbf{A_D}$ be an ideal h-periodic sampling-device; $\mathbf{D_A}$ be a zero-order hold device synchronized with $\mathbf{A_D}$; and F be a stable, low-pass LTI filter required to ensure boundedness of the sampling device. Note that $F \in \mathscr{P}^{e,sc}_{\mathcal{Y},\mathcal{Y}}$ and hence that $C^{sd} := \mathbf{D_A}\mathsf{C}\mathbf{A_D}F \in \mathscr{P}^{e,sc}_{\mathcal{Y},\mathcal{U}}$. Accordingly, Theorem 4.2 applies as summarized in the following corollary.

COROLLARY 4.10. *Consider the stable closed-loop system $[P_0, C^{sd}]$ described above. The following are equivalent.*

(i) $b_{P_0,C^{sd}} \ge \beta$.

(ii) $[P_1, C^{sd}]$ *is stable for all* $P_1 \in \mathscr{P}^{e}_{\mathcal{U},\mathcal{Y}}$ *that satisfy* $\delta_g(P_0, P_1) < \beta$.

REMARK 4.11. *The results presented in subsection* 4.2 *concerning simultaneous perturbations to the plant and controller also apply. Such a result is a useful for characterizing the effect of approximating an LTI continuous-time controller with an SD controller, for example.*

Appendix A. Proof of Theorem 3.3. As mentioned, the proof of Theorem 3.3 follows that of an H^∞ optimization result in [11, p. 248], using the commutant lifting theorem. Note that (for $i = 0, 1$) $\hat{\mathsf{G}}_{\mathsf{P}_i}$ is a shift-invariant subspace of $\mathrm{H}^2_{\mathbb{D}}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{V}))$. As such, it follows by the Beurling–Lax–Halmos theorem (see [11, p. 239]) that there exist inner functions $\hat{\mathsf{G}}_{ri} \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}),\mathrm{L}^2_{\mathbb{H}}(\mathcal{V})})$ such that $\hat{\mathsf{G}}_{\mathsf{P}_i} = \hat{\mathsf{G}}_{ri}\mathrm{H}^2_{\mathbb{D}}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}))$ ($i =$

$0,1$).[15] Correspondingly (for $i=0,1$), $\mathbf{M}_{\hat{\mathsf{G}}_{ri}}$ is an isometry and hence it follows that $\mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_i}} = \mathbf{M}_{\hat{\mathsf{G}}_{ri}}(\mathbf{M}_{\hat{\mathsf{G}}_{ri}})^*$. Correspondingly,

$$\vec{\delta}(\hat{\mathcal{G}}_{\mathsf{P}_0}, \hat{\mathcal{G}}_{\mathsf{P}_1}) = \|\mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \mathbf{M}_{\hat{\mathsf{G}}_{r0}} \left(\mathbf{M}_{\hat{\mathsf{G}}_{r0}}\right)^* \| = \|\mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \mathbf{M}_{\hat{\mathsf{G}}_{r0}}\|,$$

where the last equality follows from the fact that $\mathbf{M}_{\hat{\mathsf{G}}_{r0}}$ is an isometry. Now recall that $\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp} := \mathrm{H}^2_{\mathbb{D}}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{V})) \ominus \hat{\mathcal{G}}_{\mathsf{P}_1}$ and take any $\eta \in \mathrm{H}^2_{\mathbb{D}}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{V}))$, which may be expressed as $\eta = \gamma + \varphi$, where $\gamma = \mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}} \eta$ and $\varphi = \mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \eta$. Note that $\mathbf{S}\eta = \mathbf{S}\gamma + \mathbf{S}\varphi$ and that

$$\begin{aligned} \mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \mathbf{S}\eta &= \mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \mathbf{S}\gamma + \mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \mathbf{S}\varphi \\ &= \mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \mathbf{S}\varphi, \end{aligned}$$

where the second equality follows from the fact that $\mathbf{S}\hat{\mathcal{G}}_{\mathsf{P}_1} \subset \hat{\mathcal{G}}_{\mathsf{P}_1}$. That is,

$$\mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \mathbf{S}\eta = \mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \mathbf{S}\mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \eta = \mathbf{S}_\star \mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \eta, \tag{A.1}$$

where

$$\mathbf{S}_\star := \mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \mathbf{S}|_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \ : \ \hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp} \to \hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}.$$

The unilateral shift $\mathbf{S}$ is an isometric dilation (lifting) of $\mathbf{S}_\star$ in that $\mathbf{S}_\star^n = \mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \mathbf{S}^n|_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}}$ for all $n \geq 0$. In fact, by the way $\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}$ is defined and since $\hat{\mathcal{G}}_{\mathsf{P}_1}$ is shift-invariant, it follows that $\mathbf{S}$ is the minimal, isometric dilation of $\mathbf{S}_\star$ in the sense that $\mathrm{H}^2_{\mathbb{D}}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{V}))$ is the smallest shift-invariant space that contains $\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}$.[16] Furthermore, from (A.1) it follows that

$$\mathbf{S}_\star \mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} = \mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \mathbf{S}.$$

Consequently, with the generalized Hankel operator $\mathbf{H}_{\hat{\mathsf{G}}_{r0}}$ defined to be

$$\mathbf{H}_{\hat{\mathsf{G}}_{r0}} := \mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \mathbf{M}_{\hat{\mathsf{G}}_{r0}}, \tag{A.2}$$

it follows that

$$\mathbf{S}_\star \mathbf{H}_{\hat{\mathsf{G}}_{r0}} = \mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \mathbf{S}\mathbf{M}_{\hat{\mathsf{G}}_{r0}} = \mathbf{H}_{\hat{\mathsf{G}}_{r0}} \mathbf{S}.$$

Since $\mathbf{S}$ is a minimal, isometric dilation of $\mathbf{S}_\star$, it follows by the commutant lifting theorem (cf. [11, Chap. VII] and [22]) that there exists an LSI operator $\mathsf{H} : \mathrm{H}^2_{\mathbb{D}}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U})) \to \mathrm{H}^2_{\mathbb{D}}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{V}))$, which satisfies $\mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \mathsf{H} = \mathbf{H}_{\hat{\mathsf{G}}_{r0}}$ and

$$\|\mathsf{H}\| = \|\mathbf{H}_{\hat{\mathsf{G}}_{r0}}\|. \tag{A.3}$$

Furthermore, by Proposition 2.3, the operator H can be expressed as a multiplication operator with symbol $\hat{\mathsf{H}} \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}), \mathrm{L}^2_{\mathbb{H}}(\mathcal{V})})$, and

$$\|\mathsf{H}\| = \|\hat{\mathsf{H}}\|_\infty. \tag{A.4}$$

[15] See [5] for a more detailed discussion concerning representations of the graph.

[16] See [11, Chap. VI] or [22, Chaps. I–II] for a precise definition and treatment of minimal dilations.

Thus,

$$\mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \mathbf{M}_{\hat{\mathsf{H}}} = \mathbf{H}_{\hat{\mathsf{G}}_{r0}} = \mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \mathbf{M}_{\hat{\mathsf{G}}_{r0}},$$

which implies that $\mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} (\mathbf{M}_{\hat{\mathsf{H}}} - \mathbf{M}_{\hat{\mathsf{G}}_{0r}}) = 0$. Equivalently, since $\hat{\mathcal{G}}_{\mathsf{P}_1} = \hat{\mathsf{G}}_{r1} \mathrm{H}^2_{\mathbb{D}}(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}))$

$$(\hat{\mathsf{H}} - \hat{\mathsf{G}}_{r0}) \mathrm{H}^2_{\mathbb{D}} \left(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}) \right) \subset \hat{\mathsf{G}}_{r1} \mathrm{H}^2_{\mathbb{D}} \left(\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}) \right).$$

Correspondingly, by Corollary IX.2.2 in [11, pp. 239–240] (a corollary of the Beurling–Lax–Halmos theorem) and since $\hat{\mathsf{G}}_{r1}$ is inner, there exists a $\hat{\mathsf{Q}}_\star \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}), \mathrm{L}^2_{\mathbb{H}}(\mathcal{U})})$ such that

$$\hat{\mathsf{H}} - \hat{\mathsf{G}}_{r0} = -\hat{\mathsf{G}}_{r1} \hat{\mathsf{Q}}_\star.$$

Hence, $\hat{\mathsf{H}} = \hat{\mathsf{G}}_{r0} - \hat{\mathsf{G}}_{r1} \hat{\mathsf{Q}}_\star$ and

$$\|\hat{\mathsf{G}}_{r0} - \hat{\mathsf{G}}_{r1} \hat{\mathsf{Q}}_\star\|_\infty = \|\mathbf{H}_{\hat{\mathsf{G}}_{r0}}\| = \|\mathbf{H}_{\hat{\mathsf{G}}_{r0} - \hat{\mathsf{G}}_{r1} \hat{\mathsf{Q}}}\| \leq \inf_{\hat{\mathsf{Q}} \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}), \mathrm{L}^2_{\mathbb{H}}(\mathcal{U})})} \|\hat{\mathsf{G}}_{r0} - \hat{\mathsf{G}}_{r1} \hat{\mathsf{Q}}\|_\infty,$$

where the first equality follows from (A.3) and (A.4), the second by the fact that $\mathbf{H}_{\hat{\mathsf{G}}_{r1} \hat{\mathsf{Q}}} = \mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \mathbf{M}_{\hat{\mathsf{G}}_{r1} \hat{\mathsf{Q}}} = 0$ for all $\hat{\mathsf{Q}}$, and (finally) the third inequality follows by the fact that $\|\mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}}\| \leq 1$. Clearly, equality holds when $\hat{\mathsf{Q}} = \hat{\mathsf{Q}}_\star$. In conclusion,

$$\|\mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_0}}\| = \|\mathbf{\Pi}_{\hat{\mathcal{G}}_{\mathsf{P}_1}^{\perp}} \mathbf{M}_{\hat{\mathsf{G}}_{r0}}\| = \|\mathbf{H}_{\hat{\mathsf{G}}_{r0}}\| = \inf_{\hat{\mathsf{Q}} \in \mathrm{H}^\infty_{\mathbb{D}}(\mathcal{B}_{\mathrm{L}^2_{\mathbb{H}}(\mathcal{U}), \mathrm{L}^2_{\mathbb{H}}(\mathcal{U})})} \|\hat{\mathsf{G}}_{r0} - \hat{\mathsf{G}}_{r1} \hat{\mathsf{Q}}\|_\infty,$$

which completes the proof. □

A HIGH-ORDER GENERALIZED LOCAL MAXIMUM PRINCIPLE*

URSZULA LEDZEWICZ† AND HEINZ SCHÄTTLER‡

Abstract. We derive a generalized local maximum principle which gives necessary conditions for optimality of abnormal trajectories in optimal control problems. In this theorem the multiplier associated with the objective is nonzero. Our results provide a complete hierarchy of primal constructions of high-order approximating cones (consisting of tangent directions for equality constraints, feasible directions for inequality constraints, and directions of decrease for the objective) and dual characterizations of empty intersection properties of these cones. The essential tool in our construction is a generalization of the Lyusternik theorem which describes the structure of high-order tangent directions to an operator equality constraint in a Banach space at a point where the operator is not regular (i.e., its Fréchet derivative is not onto). The results and procedure are illustrated with several examples.

Key words. optimal control, maximum principle, high-order approximations, nonregular equality constraints, abnormal trajectories

1. Introduction.

We consider an optimal control problem on $\mathbb{R}^n$ with fixed terminal time and terminal constraints. The control set is a closed and convex subset of $\mathbb{R}^m$ with nonempty interior. We develop necessary conditions for optimality of *abnormal extremals*. Recall that an abnormal extremal is an admissible input-trajectory pair which satisfies the conditions of the Pontryagin maximum principle [28] for which the multiplier at the objective vanishes. Although the word "abnormal," which has its origins in the calculus of variations [7], seems to suggest that these types of extremals are an aberration, for optimal control problems this is not the case. The phenomenon is quite general and can be observed in a multitude of problems, and abnormal extremals cannot be excluded from optimality a priori. For instance, there exist optimal abnormal trajectories for the standard textbook problem of stabilizing the harmonic oscillator time optimally in minimum time, a simple time-invariant linear system. Recently there has been a strong interest in locally length minimizing abnormal geodesics in sub-Riemannian manifolds, and it has been found that abnormal minimizers are ubiquitous rather than exceptional. These have been investigated from an optimal control perspective for instance by Liu and Sussmann [23, 24] and by Agrachev and Sarychev [1, 2].

In the abnormal case conventional necessary conditions for optimality provide conditions which only describe the structure of the constraints. For example, if there are no control constraints, then these conditions only involve the equality constraint defined by the dynamics and terminal conditions as zero set of an operator $F : Z \to$

Y between Banach spaces. If the Fréchet derivative $F'(z_*)$ at a point $z_* \in Z$ is onto (the so-called surjectivity or regularity condition), then the classical Lyusternik theorem describes the tangent space to the equality constraint at z_* as the kernel of $F'(z_*)$. Together with approximations of the inequality constraints (feasible cones) and the directions of decrease for the functional to be minimized (cones of decrease), Lagrange multiplier type necessary conditions for optimality in terms of a generalized Euler–Lagrange function can be derived (see, for instance [12]). If $F'(z_*)$ is not onto but closed (and this is always the case for the optimal control problem), then these multiplier rules can be satisfied trivially by choosing a multiplier which annihilates the image of $F'(z_*)$ and setting all other multipliers to zero. However, the corresponding necessary conditions are independent of the objective and describe only the structure of the constraint, yielding little information about the optimality of the abnormal trajectory. Although in some cases these conditions may be helpful, in general this situation is unsatisfactory, and it seems relevant to find other necessary conditions for optimality which are specifically tailored to abnormal processes and involve the objective in a nontrivial way.

The main reason why conventional necessary conditions fail for abnormal cases is that they, like the maximum principle, use only linear approximations for the equality constraint. This is woefully inadequate near abnormal points z_* when the kernel of the operator $F'(z_*)$ contains many directions which are *not* tangent to the equality constraint. Much of the difficulty in analyzing abnormal points in extremum problems can be traced back to the fact that the equality constraint is typically no longer a manifold near abnormal points. For illustrative purposes, simply consider the problem to minimize a functional $I : \mathbb{R}^n \to \mathbb{R}$, $z \mapsto I(z)$, subject to $F(z) = 0$, where $F : \mathbb{R}^n \to \mathbb{R}^k$. The trivial example to minimize a function $I(z_1, z_2)$ subject to $z_1 z_2 = 0$ illustrates the point perfectly well. Clearly the origin is a local minimizer if and only if zero is a local minimizer for both functions $I(z_1, 0)$ and $I(0, z_2)$. Hence, if one aims to develop necessary and/or sufficient conditions for optimality of abnormal extremals, it is imperative to analyze different branches of the zero-set of F. In an ideal situation one can hope that the subproblems of minimizing I over the branches are regular and thus can be analyzed with standard methods. But finding these branches precisely is at the heart of the matter.

In our research we have pursued this direction. Generalizing a result of Avakov [4, 5] in [21], we derived a high-order generalization of the classical Lyusternik theorem which for general $p \in \mathbb{N}$ describes the structure of p-order tangent directions to an operator equality constraint in a Banach space also for nonregular operators under a more general surjectivity assumption involving the first p derivatives of the operator. The underlying idea is simply to analyze the operator F further using higher-order derivatives and thus to replace linear approximations by polynomial approximations of degree p if the Fréchet derivative $F'(z_*)$ is not onto. Based on the results in [21], p-order tangent cones to the equality constraint can explicitly be calculated along critical directions which comprise the low-order terms. Combining these cones with standard constructions of high-order cones of decrease for the functional and high-order feasible cones to inequality constraints, all taken along critical directions, we can derive generalized necessary conditions for optimality for extremum problems in Banach spaces which allow incorporation of the objective with a nonzero multiplier. In [22] an abstract formulation of these results was presented for minimization problems in Banach spaces. Characteristic of these results is that they are parametrized by critical directions as it is *natural* near abnormal points. The main result of [22,

Theorem 7.1] gives a dual characterization for the empty intersection property of the various approximating cones along critical directions, but primal arguments using the cones themselves are often equally effective. The dependence of our results on critical directions, however, is viewed as a necessity of the problem rather than a weakness of the results.

In this paper we apply the abstract results of [22] to the optimal control problem, but we only consider the so-called weak or local version of the maximum principle. This result is weaker than the Pontryagin maximum principle [28] in the sense that the Pontryagin maximum principle asserts that the Hamiltonian of the control problem is indeed minimized over the control set at every time along the reference trajectory by the reference control. The local version only gives the necessary conditions for optimality for this property. However, it is well known how to use an argument of Dubovitskii to derive the Pontryagin maximum principle from the local version [12, Lecture 13], and in this sense the local maximum principle can be considered a first step in the derivation of the complete result. We will consider strong formulations of our results elsewhere. (A preliminary version is given in [20].)

Our research is part of a currently active research direction which aims at developing theories which are tailored to abnormal processes. Milyutin [25] introduced a method known as "weakening equality constraints" which has been developed further by Dmitruk [8]. In the papers by Avakov [4, 5] and by Arutyunov [3] both necessary and sufficient conditions for optimality of abnormal extremals are given based on quadratic approximations. In earlier papers we embedded Avakov's work into a Dubovitskii–Milyutin framework using the concept of second-order approximating cones [17] and derived a second-order generalized maximum principle [18]. Izmailov [15] also considers quadratic approximations, but for problems with inequality constraints. While mostly optimization related techniques are used in these papers, on a different level Agrachev and Sarychev [1] use differential geometric techniques to develop a theory of the second variation for abnormal extremals. They give both necessary and sufficient conditions for so-called corank 1 abnormal extremals (extremals for which there exists a unique multiplier) in terms of the Jacobi equation and related Morse indices and nullity theorems. While our results are not as far reaching, Agrachev and Sarychev's underlying necessary condition for optimality [1, Theorem 3.4] naturally fits into our framework, and we show how it can be rederived with our methods. Also, our results do apply to arbitrary abnormal extremals, and we give examples to show how our main result provides nontrivial conditions also in cases when the multiplier is no longer unique. In these examples the reference extremals have both normal and abnormal multipliers, but this is of no consequence for our approximations. In one of the examples we derive the classical accessory type necessary condition for optimality for the normal multiplier, i.e., $\mathcal{L}''_{xx}(\lambda_0, \lambda, z_*) \geq 0$, where $\mathcal{L}(\lambda_0, \lambda, z_*) = \lambda_0 I'(z_*) + \lambda F'(z_*)$ denotes the standard Lagrangian, but only on a subspace of $\ker F'(z_*)$ which consists of actual tangent directions. In general, it is easily seen that it is *not* a necessary condition for optimality of z_* that $\mathcal{L}''_{xx}$ is positive semidefinite on $\ker F'(z_*)$ when the multiplier is not unique. Second-order necessary conditions for optimality in the type of accessory problem results without normality assumptions have first been given by Gilbert and Bernstein [11]. Stefani and Zezza [29] also derive results without making normality assumptions.

This brief survey of the literature given focuses on research on the maximum principle related to normality conditions. Obviously the Pontryagin maximum principle has literally hundreds of extensions too numerous to be discussed here. We want

to mention only a few, among them a recently developed general formulation of the theorem by Sussmann which is valid under very weak differentiability assumptions and applies to many even classical problems for which the standard version is inadequate [30]. High-order approximations also have a long history in connection with the maximum principle and we mention only the papers by Krener [16] and Gabasov and Kirillova [9] for the smooth case or the recent papers by Páles and Zeidan [26, 27] under nonsmooth assumptions.

The main result of this paper, a p-order local maximum principle has been announced in [19], but no proof is given there. Also, the formulation in [19] allows for p-order abnormality in the sense that it includes the more degenerate case when the multiplier for the objective is allowed to vanish. Here we give conditions under which this multiplier will be nonzero which guarantee the nontriviality of this p-order extension. Our results provide a complete hierarchy of primal constructions of high-order approximating directions and dual characterizations of empty intersection properties of these approximating cones. Thus the theory developed in [22] and here gives necessary conditions for optimality for increasingly more degenerate structures.

2. Problem formulation. We consider an optimal control problem in Bolza form with fixed terminal time: (OC) Minimize the functional

$$I(x,u) = \int_0^T L(x(t),u(t),t)dt + \ell(x(T)) \tag{2.1}$$

subject to the constraints

$$\dot{x}(t) = f(x(t),u(t),t), \tag{2.2}$$

$$x(0) = 0, \qquad q(x(T)) = 0, \tag{2.3}$$

$$u(\cdot) \in \mathcal{U} = \{u \in L^r_\infty(0,T) : \ u(t) \in U \text{ almost everywhere (a.e.)}\}. \tag{2.4}$$

The terminal time T is fixed and we make the following *regularity assumptions* on the data: $L : \mathbb{R}^n \times \mathbb{R}^m \times [0,T] \to \mathbb{R}$ and $f : \mathbb{R}^n \times \mathbb{R}^m \times [0,T] \to \mathbb{R}^n$ are C^∞ in (x,u) for every $t \in [0,T]$; both functions and their derivatives are measurable in t for every (x,u) and the functions and all partial derivatives are bounded on compact subsets of $\mathbb{R}^n \times \mathbb{R}^m \times [0,T]$; $\ell : \mathbb{R}^n \to \mathbb{R}$ and $q : \mathbb{R}^n \to \mathbb{R}^k$ are C^∞ and the rows of the Jacobian matrix q_x (i.e., the gradients of the equations defining the terminal constraint) are linearly independent; $U \subset \mathbb{R}^m$ is a closed and convex set with nonempty interior.

We model this problem in the framework of optimization theory as a minimization problem in a Banach space under equality and inequality constraints. Let $W^n_{11}(0,T)$ denote the Banach space of all absolutely continuous functions $x : [0,T] \to \mathbb{R}^n$ with norm $|x| = ||x(0)|| + \int_0^T ||\dot{x}(s)||ds$ and let $\overline{W}^n_{11}(0,T) = W^n_{11}(0,T) \cap \{x \in W^n_{11}(0,T)$: $x(0) = 0\}$. Then the problem is to minimize the functional I over a class $\mathcal{A}$ of input-trajectory pairs $(x,u) \in \overline{W}^n_{11}(0,T) \times L^m_\infty(0,T)$ which is defined by equality constraints and the convex inequality constraint $u \in \mathcal{U}$. The equality constraints can be modelled as $\mathcal{F} = \{(x,u) \in \overline{W}^n_{11}(0,T) \times L^m_\infty(0,T)$: $F(x,u) = 0\}$, where F is the operator

$$\begin{aligned} F &: \overline{W}^n_{11}(0,T) \times L^m_\infty(0,T) \to \overline{W}^n_{11}(0,T) \times \mathbb{R}^k, \\ &(x,u) \mapsto F(x,u) = \left(x(\cdot) - \int_0^{(\cdot)} f(x(s),u(s),s)ds, \ q(x(T)) \right). \end{aligned} \tag{2.5}$$

It is easy to see that the operator F has continuous Fréchet derivatives of arbitrary order. For instance,

$$F'(x,u)(\eta,\xi) = \left(\eta(\cdot) - \int_0^{(\cdot)} f_x(x,u,s)\eta + f_u(x,u,s)\xi ds, q_x(x(T))\eta(T)\right) \tag{2.6}$$

acting on $(\eta,\xi) \in \overline{W}^n_{11}(0,T) \times L^m_\infty(0,T)$. All partial derivatives of f are evaluated along a reference input-trajectory pair $(x,u) \in \mathcal{A}$. The formulas for higher-order derivatives are given by equally straightforward multilinear forms.

3. Regularity of the operator. We first describe the image of the operator $F'(x_*,u_*)$ for a reference input-trajectory pair (x_*,u_*). For notational simplicity, let

$$A(t) = f_x(x_*(t),u_*(t),t), \qquad B(t) = f_u(x_*(t),u_*(t),t), \tag{3.1}$$

and denote the fundamental matrix of the variational equation by $\Phi(t,s)$, i.e.,

$$\frac{\partial}{\partial t}\Phi(t,s) = A(t)\Phi(t,s), \qquad \Phi(s,s) = \mathrm{Id}. \tag{3.2}$$

Furthermore, let $R \subset \mathbb{R}^n$ denote the reachable subspace of the linearized system

$$\dot{h}(t) = A(t)h + B(t)v, \quad h(0) = 0, \tag{3.3}$$

at time T, i.e.,

$$R = \left\{\eta(T) = \int_0^T A(s)\eta(s) + B(s)\xi(s)ds = \int_0^T \Phi(T,s)B(s)\xi(s)ds : \xi \in L^m_\infty(0,T)\right\}. \tag{3.4}$$

It is well known that R is a linear subspace of $\mathbb{R}^n$ and that $R = \mathbb{R}^n$ if and only if (3.3) is completely controllable. In general we have the following.

LEMMA 3.1.

$$\operatorname{Im} F'(x_*,u_*) = \left\{(a,b) \in \overline{W}^n_{11}(0,T) \times \mathbb{R}^k : b \in q_x(x_*(T))\left(\int_0^T \Phi(T,s)\dot{a}(s)ds + R\right)\right\}. \tag{3.5}$$

$\operatorname{Im} F'(x_*,u_*)$ is closed and of finite codimension given by

$$\operatorname{co\,dim} \operatorname{Im} F'(x_*,u_*) = k - \dim\left[R \cap \ker q_x(x_*(T))^\perp\right].$$

In particular, $F'(x_*,u_*)$ is onto if and only if

$$\ker q_x(x_*(T)) + R = \mathbb{R}^n. \tag{3.6}$$

Proof. Given an arbitrary function $a \in \overline{W}^n_{11}(0,T)$, the unique solution $\overline{h} \in \overline{W}^n_{11}(0,T)$ to the equation

$$\overline{h}(t) - \int_0^t A(s)\overline{h}(s)ds = a(t) = \int_0^t \dot{a}(s)ds$$

is given by $\overline{h}(t) = \int_0^t \Phi(t,s)\dot{a}(s)ds$. This function can be superimposed with any other solution h to (3.3), say

$$h(t) = \int_0^t A(s)h(s) + B(s)v(s)ds,$$

without changing the first component of $\operatorname{Im} F'(x_*, u_*)$. Thus, if $\eta = \overline{h} + h$ and $\xi = v$, then

$$F'(x_*, u_*)(\eta, \xi) = \left(a, q_x(x_*(T))\left(\int_0^T \Phi(T,s)\dot{a}(s)ds + h(T)\right)\right)$$

and $h(T) \in R$. Conversely, if $(a, b) = F'(x_*, u_*)(\eta, \xi)$, then $b = q_x(x_*(T))\eta(T)$, and

$$\begin{aligned}\eta(T) - \int_0^T \Phi(T,s)\dot{a}(s)ds &= \int_0^T [A(t)\eta(t) + B(t)\xi(t)]dt + a(T) \\ &\quad - \int_0^T [A(t)\overline{h}(t) + \dot{a}(t)]dt \\ &= \int_0^T A(t)[\eta(t) - \overline{h}(t)] + B(t)\xi(t)dt \in R,\end{aligned}$$

verifying (3.5). It follows that $\operatorname{Im} F'(x_*, u_*)$ is the direct sum of the closed subspace

$$\widetilde{W} = \left\{\left(a, q_x(x_*(T))\int_0^T \Phi(T,s)\dot{a}(s)ds\right) \in \overline{W}^n_{11}(0,T) \times \mathbb{R}^k : a \in \overline{W}^n_{11}(0,T)\right\},$$

which is isomorphic to $\overline{W}^n_{11}(0,T)$ and the finite-dimensional subspace $\widetilde{R} = \{0\} \times q_x(x_*(T))R$. Thus $\operatorname{Im} F'(x_*, u_*)$ is closed and of finite codimension given by the codimension of $q_x(x_*(T))R$. Since the linear map $q_x(x_*(T)) : \mathbb{R}^n \to \mathbb{R}^k$ is an isomorphism when it is restricted to the orthogonal complement of $\ker q_x(x_*(T))$, it follows that the codimension is given by

$$\operatorname{co\,dim} \operatorname{Im} F'(x_*, u_*) = k - \dim(R \cap \ker q_x(x_*(T))^\perp). \tag{3.7}$$

In particular, $F'(x_*, u_*)$ is onto if and only if R contains $\ker \psi_x(x_*(T))^\perp$ which is equivalent to (3.6). □

The operator F gives the state-space representation of the dynamical system for the optimal control problem. Equivalently, and this is used for instance by Agrachev and Sarychev in [1], one could use the input-output map

$$Q : L^m_\infty(0,T) \to \mathbb{R}^k, \qquad u \mapsto q(x(T)), \tag{3.8}$$

where x is the solution to $\dot{x} = f(x, u(t), t)$, $x(0) = 0$. These formulations are equivalent and it is easily seen that the codimension of $\operatorname{Im} Q'(u)$ is given by (3.7). The input-output map has the advantage that it is clear that the image of $Q'(u)$ is closed, in fact finite dimensional. The state-representation leads to calculations which, although not intrinsic, are quite transparent and require only simple differentiations of data directly given.

It is well known how to characterize that (3.3) is not completely controllable. If h is a solution of (3.3) corresponding to control v and λ is a solution to the corresponding adjoint equation

$$\dot{\lambda}(t) = -\lambda(t)A(t), \tag{3.9}$$

(which we write as row-vector $\lambda \in (\mathbb{R}^n)^*$ denoting the space of row-vectors in $\mathbb{R}^n$ by $(\mathbb{R}^n)^*$), then

$$\lambda(T)h(T) = \int_0^T \dot{\lambda}(t)h(t) + \lambda(t)\dot{h}(t)dt = \int_0^T \lambda(t)B(t)v(t)dt. \tag{3.10}$$

Hence, if (3.3) is not completely controllable, then any vector $\lambda(T) \perp R$ defines a solution λ of (3.9) which satisfies $\lambda(t)B(t) \equiv 0$ on $[0,T]$, and, conversely, any solution λ with this property satisfies $\lambda(T) \perp R$. Thus the codimension of R is given by the number of linearly independent solutions to $\dot{\lambda}(t) = -\lambda(t)A(t)$ which satisfy $\lambda(t)B(t) \equiv 0$ on $[0,T]$. Consequently, we have the following well-known characterization.

PROPOSITION 3.2. *The codimension of $F'(x_*, u_*)$ is given by the number of linearly independent solutions to $\dot{\lambda}(t) = -\lambda(t)A(t)$ which satisfy $\lambda(t)B(t) \equiv 0$ on $[0,T]$ and for which $\lambda(T)$ is orthogonal to $\ker q_x(x_*(T))$.*

The nonregularity of the operator F at an input-trajectory pair (x_*, u_*) can be characterized in terms of the conditions of the so-called local maximum principle. Let

$$H(\lambda_0, \lambda, x, u, t) = \lambda_0 L(x, u, t) + \lambda f(x, u, t) \tag{3.11}$$

be the Hamiltonian for the control problem. If the input-trajectory pair (x_*, u_*) is optimal for problem (OC), then the local maximum principle [12] states that there exists a constant $\lambda_0 \geq 0$, an absolutely continuous function $\lambda : [0,T] \to (\mathbb{R}^n)^*$, and a row-vector $\nu \in (\mathbb{R}^k)^*$ such that the following conditions hold:

1. nontriviality of the multipliers: $(\lambda_0, \lambda(t)) \neq 0$ for all $t \in [0,T]$;
2. adjoint equation:

$$\begin{aligned} \dot{\lambda}(t) &= -\lambda_0 L_x(x_*(t), u_*(t), t) - \lambda(t) f_x(x_*(t), u_*(t), t) \\ &= -H_x(\lambda_0, \lambda(t), x_*(t), u_*(t), t); \end{aligned} \tag{3.12}$$

3. transversality condition:

$$\lambda(T) = \lambda_0 \ell_x(x_*(T)) + \nu q_x(x_*(T)); \tag{3.13}$$

4. local minimum condition:

$$\langle H_u(\lambda_0, \lambda(t), x_*(t), u_*(t), t), v - u_*(t) \rangle \geq 0 \qquad \text{for all } v \in U. \tag{3.14}$$

We call input-trajectory pairs (x_*, u_*) for which multipliers λ_0, λ, and ν exist such that these conditions are satisfied *(weak) extremals*. If $\lambda_0 > 0$, then it is possible to normalize $\lambda_0 = 1$ and the extremal is called normal while extremals with $\lambda_0 = 0$ are called *abnormal*.

PROPOSITION 3.3. *The operator F is nonregular at $\Gamma = (x_*, u_*)$ if and only if Γ is an abnormal weak extremal which satisfies $H_u(0, \lambda(t), x_*(t), u_*(t), t) \equiv 0$ on $[0,T]$.*

Proof. If F is nonregular at $\Gamma = (x_*, u_*)$, then there exists a nontrivial solution λ to the equation $\dot{\lambda}(t) = -\lambda(t)A(t)$ which satisfies $\lambda(t)B(t) \equiv 0$ on $[0,T]$ and $\lambda(T)$ is orthogonal to $\ker q_x(x_*(T))$. Since the rows of $q_x(x_*(T))$ are linearly independent, it follows that $\lambda(T)$ is a linear combination of the rows of $q_x(x_*(T))$, i.e., there exists a row-vector $\nu \in (\mathbb{R}^k)^*$ such that $\lambda(T) = \nu q_x(x_*(T))$. If we choose $\lambda_0 = 0$, it follows that Γ is an abnormal weak extremal which satisfies $H_u(0, \lambda(t), x_*(t), u_*(t), t) \equiv 0$ on $[0,T]$. Conversely, if Γ is an abnormal weak extremal which satisfies $H_u(0, \lambda(t), x_*(t), u_*(t), t) \equiv 0$ on $[0,T]$, then λ satisfies the conditions of Proposition 3.2 since $\nu q_x(x_*(T)$ is orthogonal to $\ker q_x(x_*(T))$. ∎

For variational type problems where the control set is the full space, $U = \mathbb{R}^m$, or more generally when the extremal control takes values in the interior of the control set, the condition $H_u \equiv 0$ is automatically satisfied and nonregular equality constraints thus correspond to abnormal extremals. For example, if the problem is also in Mayer form, i.e., $L \equiv 0$, then every terminal point x_* where $\ell_x(x_*)$ is a linear combination of the rows of $q_x(x_*)$ generates an abnormal extremal with nonregular equality constraint.

4. High-order directional derivatives. We introduce a formalism to describe higher derivatives [21]. Let $F : Z \to Y$ be an operator between Banach spaces which is sufficiently often continuously Fréchet differentiable in a neighborhood of $z_* \in Z$, and consider the Taylor expansion of F along a curve $\gamma(\varepsilon) = z_* + \sum_{i=1}^m \varepsilon^i h_i$. We have

$$F\left(z_* + \sum_{i=1}^m \varepsilon^i h_i\right) = F(z_*) + \sum_{i=1}^m \varepsilon^i \nabla^i F(z_*)(h_1, \dots, h_i) + \widetilde{r}(\varepsilon), \tag{4.1}$$

where

$$\nabla^i F(z_*)(h_1, \dots, h_i) \doteq \sum_{r=1}^i \frac{1}{r!} \left(\sum_{j_1+\cdots+j_r=i} F^{(r)}(z_*)(h_{j_1}, \dots, h_{j_r}) \right) \tag{4.2}$$

and $\widetilde{r}(\varepsilon)$ is a function of order $o(\varepsilon^m)$ as $\varepsilon \to 0$. Note that $\nabla^i F(z_*)(h_1, \dots, h_i)$ simply collects the ε^i terms in this expansion. These terms, which we call the *ith-order directional derivatives of F along the sequence* $H_i = (h_1 \dots, h_i)$, $1 \le i \le m$, are easily calculated by straightforward Taylor expansions. For example,

$$\nabla^1 F(z_*)(H_1) = F'(z_*)h_1, \quad \nabla^2 F(z_*)(H_2) = F'(z_*)h_2 + \frac{1}{2}F''(z_*)(h_1, h_1),$$
$$\nabla^3 F(z_*)(H_3) = F'(z_*)h_3 + F''(z_*)(h_1, h_2) + \frac{1}{6}F'''(z_*)(h_1, h_1, h_1),$$

and so on. The higher-order directional derivative $\nabla^i F(z_*)$ is homogeneous of degree i in the directions in the sense that

$$\nabla^i F(z_*)(\varepsilon h_1, \dots, \varepsilon^i h_i) = \varepsilon^i \nabla^i F(z_*)(h_1, \dots, h_i). \tag{4.3}$$

In particular, no indices j_1 and j_2 with $j_1 + j_2 > i$ can occur together as arguments in any of the terms in $\nabla^i F(z_*)$. Thus all the vectors h_j whose index satisfies $2j > i$ appear linearly in $\nabla^i F(z_*)$ and are multiplied by terms which are homogeneous of degree $i - j$. In fact, there exist linear operators $G_k = G_k[F](z_*; H_{k-1})$, $k \in \mathbb{N}$, depending on the derivatives up to order k of F in the point z_* (the k-jet of F in z_*) and on the vectors $H_{k-1} = (h_1, \dots, h_{k-1})$, which describe the contributions of these components. We have $G_1[F](z_*) = F'(z_*)$ and in general $G_k = G_k[F](z_*; H_{k-1})$: $Z \to Y$, $v \longmapsto G_k(v)$ is given by

$$G_k[F](z_*; H_{k-1})(v) = \sum_{r=1}^{k-1} \frac{1}{r!} \left(\sum_{j_1+\cdots+j_r=k-1} F^{(r+1)}(z_*)(h_{j_1}, \dots, h_{j_r}, v) \right). \tag{4.4}$$

These operators $G_k[F](z_*; H_{k-1})$ are simply the Fréchet derivatives of the $(k-1)$th directional derivative of F at z_* along H_{k-1}. Note that these terms are homogeneous

of degree $k-1$. For simplicity of notation we often suppress the arguments. For example, we write

$$G_1(v) = F'(z_*)v, \qquad G_2(v) = F''(z_*)(h_1, v),$$
$$G_3(v) = F''(z_*)(h_2, v) + \frac{1}{2}F'''(z_*)(h_1, h_1, v).$$

Given an order $p \in \mathbb{N}$, it follows that we can separate the linear contributions of the vectors $h_p, \dots, h_{2p-1}$ in derivatives of orders p through $2p-1$, and for $i = 1, \dots, p$, we have an expression of the form

$$\nabla^{p-1+i}F(z_*)(H_{p-1+i}) = \sum_{k=1}^{i} G_k[F](z_*; H_{k-1})h_{p+i-k} + R_{p-1+i}[F](z_*; H_{p-1}). \tag{4.5}$$

Here, amongst all terms which are homogeneous of degree $p-1+i$, the sum gives the terms which contain one of the vectors $h_p, \dots, h_{p-1+i}$, and the remainder R combines all other terms which only include vectors of index $\le p-1$. Similar to the operators G_k, the remainders R depend on the $(p-1+i)$-jet of the operator F at z_*, but if the map is clear we omit it in the notation. The general structure of these remainders is given by

$$R_q[F](z_*; H_\ell) = \sum_{r=2}^{q} \frac{1}{r!} \left(\sum_{\substack{j_1+\cdots+j_r=q,\\ 1\le j_k\le \ell,\ 1\le k\le r}} F^{(r)}(z_*)(h_{j_1}, \dots, h_{j_r}) \right). \tag{4.6}$$

Thus $R_q(H_\ell)$ consists of the terms which are homogeneous of degree q, but only involve vectors from H_ℓ. For example,

$$R_4[F](z_*; H_2) = \frac{1}{2}F''(z_*)(h_2, h_2) + \frac{1}{2}F^{(3)}(z_*)(h_1, h_1, h_2) + \frac{1}{24}F^{(4)}(z_*)(h_1, h_1, h_1, h_1).$$

Note that the remainders only have contributions from derivatives of at least order two. These operators allow to formalize high-order approximations to an equality constraint at nonregular points [22]. In the next section we give the conditions under which such approximations exist.

5. Critical directions. We first describe the set of critical directions along which high-order tangent approximations to the equality constraint $\mathcal{F}$ can be set up. For a given admissible process $z_* = (x_*, u_*) \in \mathcal{A}$ and a finite sequence $H_{p-1} = (h_1, \dots, h_{p-1}) \in Z^{p-1}$, let

$$Y_i = \sum_{k=1}^{i} \operatorname{Im} G_k[F](z_*; H_{k-1}), \quad i = 1, \dots, p. \tag{5.1}$$

We need to impose the following conditions:

(i) the first $p-1$ directional derivatives of F along H_{p-1} vanish,

$$\nabla^i F(z_*)(H_i) = 0 \quad \text{for all } \ i = 1, \dots, p-1; \tag{5.2}$$

(ii) and the compatibility conditions

$$R_{p-1+i}[F](z_*; H_{p-1}) \in Y_i, \quad i = 1, \dots, p-1, \tag{5.3}$$

are satisfied.

In these equations all partial derivatives of f are evaluated along the reference trajectory. Both conditions (i) and (ii) are necessary for the existence of a p-order tangent vector along H_{p-1}. For instance, if $p = 2$, then (i) says $F'(z_*)h_1 = 0$ and (ii) states that $F''(z_*)(h_1, h_1) \in \operatorname{Im} F'(z_*)$. If the second condition does not hold, then the quadratic term in

$$F(z_* + \varepsilon h_1 + \varepsilon^2 h_1 + \cdots) = F(z_*) + \varepsilon F'(z_*)h_1 + \varepsilon^2 \left(F'(z_*)h_2 + \frac{1}{2} F''(z_*)(h_1, h_1) \right) + \cdots$$

cannot be made zero with any choice of $h_2 \in Z$. Conditions (i) and (ii) are sufficient for the existence of p-order approximations along H_{p-1} under the following regularity condition.

DEFINITION 5.1. *Let $F : Z \to Y$ be an operator between Banach spaces. We say the operator F is* p-regular *at z_* in direction of the sequence $H_{p-1} \in Z^{p-1}$ if the following conditions are satisfied:*

(A1) *$F : Z \to Y$ is $(2p-1)$ times continuously Fréchet differentiable in a neighborhood of z_*;*

(A2) *the subspaces Y_i, $i = 1, \ldots, p$, are closed;*

(A3) *the map $\mathcal{G}_p = \mathcal{G}_p[F](z_*; H_{p-1})$*

$$\mathcal{G}_p : Z \to Y_1 \times Y_2/Y_1 \times \cdots \times Y/Y_{p-1} \qquad v \mapsto \mathcal{G}_p(v) = (G_1(v), \pi_1 G_2(v), \ldots, \pi_{p-1} G_p(v)), \tag{5.4}$$

where $\pi_i : Y_{i+1} \to Y_{i+1}/Y_i$ denotes the canonical projection onto the quotient space, is onto.

In the sense of this definition, 1-regularity corresponds to the classical Lyusternik condition while 2-regularity is similar to Avakov's definition [5]. It is shown in [21, Theorem 1] and [22, Corollary 3.3] that the set of all directions h_p for which $H_p = (h_1, \ldots, h_{p-1}; h_p)$ is tangent to $\{z \in Z : F(z) = 0\}$ at z_* is a nonempty affine subspace if F is p-regular in direction of $H_{p-1} = (h_1, \ldots, h_{p-1})$ and H_{p-1} satisfies (i) and (ii).

Example (see [1]). Suppose $\operatorname{Im} F'(z_*)$ has codimension 1 and let λ_* be the (up to nonzero multiples) unique annihilator of $\operatorname{Im} F'(z_*)$, $\lambda_* F'(z_*)h = 0$ for all $h \in Z$. If the quadratic form $\lambda_* F''(z_*)(h, h)$ is indefinite on $\ker F'(z_*)$, then there exist linearly independent vectors h_+ and h_- in $\ker F'(z_*)$ such that F is 2-regular in direction of $h_\pm$ and such that the compatibility condition $F''(z_*)(h_\pm, h_\pm) \in \operatorname{Im} F'(z_*)$ is satisfied.

For, since $\lambda_* F''(z_*)(h, h)$ is indefinite on $\ker F'(z_*)$, there exist vectors h_α and h_β in $\ker F'(z_*)$ so that $\lambda_* F''(z_*)(h_\alpha, h_\alpha) = -1$ and $\lambda_* F''(z_*)(h_\beta, h_\beta) = 1$. If we take nontrivial convex combinations of h_α and h_β and of h_α and $-h_\beta$, it follows that there exist two linearly independent directions h_+ and h_- in $\ker F'(z_*)$ such that $\lambda_* F''(z_*)(h_\pm, h_\pm) = 0$. Since λ_* is the unique annihilator of $\operatorname{Im} F'(z_*)$, this is equivalent to $F''(z_*)(h_\pm, h_\pm) \in \operatorname{Im} F'(z_*)$. Hence $h_\pm$ satisfy conditions (i) and (ii) for $p = 2$. Furthermore, F is 2-regular along $h_\pm$ if there exists a vector $h \in Z$ (not necessarily in $\ker F'(z_*)$) such that $\pi G_2(z_*)(h_\pm, h) \neq 0$, where $\pi : Z \to Y/\operatorname{Im} F'(z_*)$ is the canonical projection. But again, since $\operatorname{Im} F'(z_*)$ has codimension 1, this is equivalent to $\lambda_* F''(z_*)(h_\pm, h) \neq 0$. This condition is satisfied since indeed we have $\lambda_* F''(z_*)(h_+, h_-) \neq 0$. For, if this were not true, then it would follow that $\lambda_* F''(z_*)(h, h) = 0$ for all h in the linear span of h_+ and h_-. But this is not possible since h_α and h_β lie in this span. □

It therefore follows from [22, Corollary 3.3] that h_+ and h_- in $\ker F'(z_*)$ are tangent directions to the set $\{z \in Z : F(z) = 0\}$. (In fact, except for scalar multiples

these are the only tangent directions in the two-dimensional subspace of $\ker F'(z_*)$ spanned by h_α and h_β.) Hence, if the objective is to minimize some functional $I : Z \to \mathbb{R}$ over $\{z \in Z : F(z) = 0\}$, then it is a necessary condition for optimality of z_* that $I'(z_*)h_\pm = 0$. This in its essence (combined with a perturbation argument) is the reasoning of Agrachev and Sarychev, who proved the result below.

PROPOSITION 5.2 (see [1, Theorem 3.4]). *Consider the problem to minimize a functional $I : Z \to \mathbb{R}$ over the set $\{z \in Z : F(z) = 0\}$. Suppose $\operatorname{Im} F'(z_*)$ has codimension 1 and let λ_* be a nonzero annihilator of $\operatorname{Im} F'(z_*)$. If the quadratic form $\lambda_* F''(z_*)(h,h)$ is indefinite on $\ker F'(z_*)$, then it is a necessary condition for optimality of z_* that the codimension of $\operatorname{Im}(F'(z_*), I'(z_*))$ is 2, i.e., that $I'(z_*)h = 0$ for all $h \in \ker F'(z_*)$.*

As described above, this result naturally fits into our framework of high-order approximations near nonregular points. In a certain sense these are still the least degenerate cases.

We now proceed to include the critical directions for the objective I. We will focus on the least degenerate critical case and therefore make the following assumption:

(iii) $I'(z_*)$ is not identically zero and $\nabla^i I(z_*)(H_i) = 0$ for $i = 1, \dots, p-1$.

Assuming $I'(z_*) \neq 0$ excludes some cases in which Theorem 6.1 below could be satisfied with a trivial choice of multipliers. However, rather than including this as a degenerate case, in this case the better way is to analyze the objective further by considering higher derivatives of I. This can be done easily, but the formulas for the cones of decrease and their duals (which enter into the formulation of Theorem 6.1) become different. Here we just give the nondegenerate formulation. The other assumption that the first $p-1$ directional derivatives vanish is directly tied in with optimality. If there exists a first nonzero directional derivative $\nabla^j I(z_*)(H_j)$ with $j < i$ which is positive, then z_* indeed is a local minimum for any curve $z(\varepsilon) = z_* + \sum_{i=1}^{p} \varepsilon^i h_i + o(\varepsilon^p)$, $\varepsilon > 0$, and none of the directions H_{p-1} is of any use in improving the value. In other words, the p-order cone of decrease along H_{p-1} is empty and the empty intersection property of approximating cones holds trivially. Note that we restrict to $\varepsilon \geq 0$ since we also want to include inequality constraints. On the other hand, if $\nabla^j I(z_*)(H_j) < 0$, then H_j is indeed a direction of decrease, and arbitrary high-order extensions of this sequence will give better values. Thus the p-order cone of decrease will be the full space. In this case our conditions below apply, but they simplify in the sense that the multiplier ν_0 in Theorem 6.1 must vanish. The truly critical case is when all these derivatives vanish.

We also need to define the critical directions for the inequality constraint $\mathcal{U}$ in the optimal control problem. More generally, we define a p-order feasible set to an inequality constraint in a Banach space.

DEFINITION 5.3. *Let $S \subset Z$ be a subset with nonempty interior. We call v a p-order feasible vector for S at z_* in direction of $H_{p-1} = (h_1, \dots, h_{p-1}) \in Z^{p-1}$ if there exist an $\varepsilon_0 > 0$ and a neighborhood V of v so that for all $0 < \varepsilon \leq \varepsilon_0$,*

$$z_* + \sum_{i=1}^{p-1} \varepsilon^i h_i + \varepsilon^p V \subset S.$$

The collection of all p-order feasible vectors v for S at z_* in direction of the sequence H_{p-1} will be called the p-order feasible set to S at z_* in direction of the sequence H_{p-1} and will be denoted by $FS^{(p)}(S; z_*, H_{p-1})$.

It follows from this definition that $FS^{(p)}(S; z_*, H_{p-1})$ is open (since any vector in the neighborhood V of v also lies in $FS^{(p)}(S; z_*, H_{p-1})$). It is also clear that

$FS^{(p)}(S; z_*, H_{p-1})$ is convex, if S is. Furthermore, if $h_j \in FS^{(j)}(S; z_*, H_{j-1})$ for some integer $j < p$, then any vector v is allowed as a p-order feasible direction and thus trivially $FS^{(p)}(S; z_*, H_{p-1}) = X$.

For the optimal control problem and $H_{p-1} = ((\eta_1, \xi_1); \dots, (\eta_{p-1}, \xi_{p-1}))$ let $V_{p-1} = (\xi_1, \dots, \xi_{p-1}) \in L^m_\infty(0,1)^p$ denote the sequence of controls. Then the critical feasible directions for the convex inequality constraint $\mathcal{U}$ in $L^m_\infty(0,1)$ consist of all H_{p-1} for which

(iv) $FS^{(p)}(\mathcal{U}; u_*, V_{p-1})$ is nonempty.

DEFINITION 5.4. *We call a direction H_{p-1} a* p-regular critical direction *for the extremum problem at z_* if the operator F is p regular at z_* along H_{p-1} and if conditions* (i)–(iv) *are satisfied.*

6. The *p*-order local maximum principle. Theorem 6.1 below gives a generalized p–order version of the maximum principle obtained from a dual characterization of the fact that if (x_*, u_*) is optimal, then the p-order tangent cones to the set $\{F = 0\}$, the p-order feasible cone to $\mathcal{U}$ and the p-order cone of decrease for the functional I cannot intersect. This theorem generalizes a result which was derived from quadratic approximations in [18, Theorem 4.1] to the case of general p-order approximations. Notice that we write covectors like ψ as row vectors. This is consistent with a multiplier interpretation of the adjoint variable. We also denote partial derivatives by subscripts. For instance, if $\nabla^i f(H_i)$ denotes the ith directional derivative of $f = f(x,u,t)$ with respect to the sequence H_i, then $\left(\nabla^i f(H_i)\right)_x$ denotes its partial derivative in x. For example, suppose $H_1 = (\eta_1, \xi_1)$. Then

$$\nabla^1 f(H_1) = f_x(x,u,t)\eta_1 + f_u(x,u,t)\xi_1,$$

and thus

$$\left(\nabla^1 f(H_1)\right)_x = f_{xx}(x,u,t)\eta_1 + f_{ux}(x,u,t)\xi_1$$

and

$$\left(\nabla^1 f(H_1)\right)_u = f_{xu}(x,u,t)\eta_1 + f_{uu}(x,u,t)\xi_1.$$

THEOREM 6.1 (p-order local maximum principle). *Suppose the admissible process (x_*, u_*) is optimal for the optimal control problem (OC). Then for every p-regular critical direction H_{p-1} there exist a number $\nu_0 = \nu_0(H_{p-1}) \geq 0$, vectors $a_i = a(H_{p-1}) \in (\mathbb{R}^k)^*$, $i = 0, 1, \dots, p-1$, and absolutely continuous functions $\psi(\cdot) = \psi(H_{p-1})(\cdot)$ and $\rho_i(\cdot) = \rho_i(H_{p-1})(\cdot)$, $i = 1, \dots, p-1$, from $[0,T]$ into $(\mathbb{R}^n)^*$, which satisfy the following conditions along the optimal trajectory $(x_*(t), u_*(t), t)$:*

(a) *nontriviality condition: ν_0 and the functional $\lambda : L^m_\infty(0,T) \to \mathbb{R}$ given by*

$$\lambda(\xi) = \int_0^T \left\langle \nu_0 L_u + \psi f_u + \sum_{i=1}^{p-1} \rho_i \left(\nabla^i f(H_i)\right)_u, \xi \right\rangle dt \tag{6.1}$$

do not both vanish identically.

(b) *extended adjoint equation:*

$$\dot{\psi}(t) = -\nu_0 L_x - \psi(t) f_x - \sum_{i=1}^{p-1} \rho_i(t) \left(\nabla^i f(H_i)\right)_x \tag{6.2}$$

with terminal condition

$$\psi(T) = \nu_0 \ell_x(x_*(T)) + a_0 q_x(x_*(T)) + \sum_{i=1}^{p-1} a_i \left(\nabla^i q(x_*(T); H_i)\right)_x . \tag{6.3}$$

(c) *orthogonality conditions on the additional multipliers: The functions* $\rho_i(\cdot)$, $i = 1, \dots, p-1$, *satisfy*

$$\dot\rho_i(t) = -\rho_i(t) f_x, \quad \rho_i(t) f_u \equiv 0, \quad \rho_i(T) = a_i q_x(x_*(T)), \tag{6.4}$$

and for $j = 1, \dots, i-1$, *the following conditions are satisfied for a.e.* $t \in [0,T]$*:*

$$\rho_i(t) \left(\nabla^j f(H_j)\right)_x = 0, \quad \rho_i(t) \left(\nabla^j f(H_j)\right)_u = 0, \quad a_i \left(\nabla^j q((x_*(1); H_j)\right)_x = 0. \tag{6.5}$$

(d) *separation condition: for all* $\xi \in FS^{(p)}(\mathcal{U}; u_*, V_{p-1})$, *we have that*

$$\begin{aligned} 0 \le{}& \nu_0 R_p[\ell](H_{p-1}) + a_0 R_p[q](H_{p-1}) + \sum_{i=1}^{p-1} a_i R_{p+i}[q](H_{p-1}) \\ &+ \int_0^T \left\langle \nu_0 L_u + \psi f_u + \sum_{i=1}^{p-1} \rho_i(t) \left(\nabla^i f(H_i)\right)_u , \xi \right\rangle dt \\ &+ \int_0^T \left(\nu_0 R_p[L](H_{p-1}) + \psi(t) R_p[f](H_{p-1}) + \sum_{i=1}^{p-1} \rho_i(t) R_{p+i}[f](H_{p-1}) \right) dt. \end{aligned} \tag{6.6}$$

COROLLARY 6.2. *The separation condition* (d) *implies the following p-order local minimum condition: along* $(x_*(t), u_*(t), t)$ *we have for every* $u \in U$ *and a.e.* $t \in [0,T]$

$$\left\langle \nu_0 L_u(x_*, u_*) + \psi(t) f_u + \sum_{i=1}^{p-1} \rho_i(t) \left(\nabla^i f(H_i)\right)_u , u - u_*(t) \right\rangle \ge 0. \tag{6.7}$$

7. Proof. Let $z_* = (x_*, u_*)$. Since H_{p-1} is a p-regular critical direction, Theorem 7.1 of [22] applies in its nondegenerate form. The control constraint has the form $\mathcal{Z} = \overline{W}^n_{11}(0,T) \times \mathcal{U}$, where $\mathcal{U} = \{u \in L^m_\infty(0,T) : u(t) \in U \text{ a.e. on } (0,T)\}$ is convex. Since the constraint is active only in the control variable u, $FS^{(p)}(\mathcal{Z}; z_*, H_{p-1})$ is trivially the full space $\overline{W}^n_{11}(0,T)$ in the first coordinate. Thus the p-order feasible set to $\mathcal{Z}$ at z_* in direction of H_{p-1} takes the form

$$FS^{(p)}(\mathcal{Z}; z_*, H_{p-1}) = \overline{W}^n_{11}(0,T) \times FS^{(p)}(\mathcal{U}; u_*, V_{p-1}).$$

Hence by (iv) this set is nonempty. Note also that, if $(\overline\lambda, \mu)$ defines a supporting hyperplane to $FS^{(p)}(\mathcal{Z}; z_*, H_{p-1})$, i.e.,

$$\left\langle \overline\lambda, (\eta, \xi) \right\rangle + \mu \ge 0 \quad \text{for} \quad (\eta, \xi) \in FS^{(p)}(\mathcal{Z}; z_*, H_{p-1}),$$

then $\overline\lambda$ is of the form $\overline\lambda = (0, \lambda)$ and (λ, μ) defines a supporting hyperplane to $FS^{(p)}(\mathcal{U}; u_*, V_{p-1})$.

It therefore follows from [22, Theorem 7.1] that there exists a Lagrange multiplier $\nu_0 \geq 0$, functionals $(y_i^*, w_i^*) \in Y_{i-1}^{\perp_i},\ i = 1, \dots, p$, and a supporting hyperplane (λ, μ) to $FS^{(p)}(\mathcal{U}; u_*, V_{p-1})$, all depending on the sequence H_{p-1}, such that the multipliers ν_0 and λ do not both vanish, and

$$(0, \lambda) \equiv \nu_0 I'(z_*) + \sum_{i=1}^{p} G_i^*[F_1](z_*; H_{i-1}) y_i^* + \sum_{i=1}^{p} G_i^*[F_2](z_*; H_{i-1}) w_i^*, \tag{7.1}$$

$$\begin{aligned} \mu \leq \nu_0 R_p[I](z_*; H_{p-1}) &+ \sum_{i=1}^{p} \langle y_i^*, R_{p-1+i}[F_1](z_*; H_{p-1}) \rangle \\ &+ \sum_{i=1}^{p} \langle w_i^*, R_{p-1+i}[F_2](z_*; H_{p-1}) \rangle. \end{aligned} \tag{7.2}$$

In these formulas F_1 and F_2 denote the components of the operator F, $[F_i]$, respectively, $[I]$ indicates that the operators G or R are taken on F_i, respectively, I, and $*$ denotes the dual map. Also $Y_{i-1}^{\perp_i}$ denotes the annihilator of Y_{i-1} in Y_i^*, i.e., $Y_{i-1}^{\perp_i} = \{z^* \in Y_i^* :\ \langle z^*, v \rangle = 0\ \forall\ v \in Y_{i-1}\}$ and we formally set $Y_0 = \{0\}$, so that $Y_0^{\perp_1} \cong Y_1^*$.

We now analyze these equations. Conditions (b) and (c) of the theorem follow from the Euler–Lagrange equation (7.1). For simplicity of notation we omit the arguments $(z_*; H_i)$. We then have for arbitrary $(\eta, \xi) \in \overline{W}_{11}^n(0,T) \times L_\infty^m(0,T)$ that

$$\lambda(\xi) \equiv \nu_0 I'(\eta, \xi) + \sum_{i=1}^{p} \langle y_i^*, G_i[F_1](\eta, \xi) \rangle + \sum_{i=1}^{p} \langle w_i^*, G_i[F_2](\eta, \xi) \rangle\,. \tag{7.3}$$

The (y_i^*, w_i^*) are continuous linear functionals on the spaces Y_i which extend to continuous linear functionals $(\overline{y}_i^*, \overline{w}_i^*)$ in the full space $\overline{W}_{11}^n(0,T)^* \times (\mathbb{R}^k)^*$. Using the representations of continuous linear functionals in $\overline{W}_{11}^n(0,T)^*$ [14, p. 21], it follows that there exist functions $\psi,\ \rho_i \in L_\infty^m(0,T),\ i = 1, \dots, p-1$, such that for all $(\eta, \xi) \in \overline{W}_{11}^n(0,T) \times L_\infty^m(0,T)$,

$$\langle y_1^*, G_1[F_1](\eta, \xi) \rangle = \langle \overline{y}_1^*, G_1[F_1](\eta, \xi) \rangle = -\int_0^T \psi(t) \frac{d}{dt} \left(G_1[F_1](\eta, \xi) \right) dt, \tag{7.4}$$

and for $i = 2, \dots, p$,

$$\langle y_i^*, G_i[F_1](\eta, \xi) \rangle = \langle \overline{y}_i^*, G_i[F_1](\eta, \xi) \rangle = -\int_0^T \rho_{i-1}(t) \frac{d}{dt} \left(G_i[F_1](\eta, \xi) \right) dt. \tag{7.5}$$

Similarly, we represent the second factor by row-vectors a_{i-1}(note the shift in index),

$$\langle w_i^*, G_i[F_2](\eta, \xi) \rangle = \langle \overline{w}_i^*, G_i[F_2](\eta, \xi) \rangle = a_{i-1} G_i[F_2](\eta, \xi). \tag{7.6}$$

Since we consider extensions of the functionals (y_i^*, w_i^*) from Y_i to the full space Y, the multipliers ψ, ρ_i, and a_i are not unique but depend on these extensions except for (ρ_{p-1}, a_{p-1}) which corresponds to the functional (y_p^*, w_p^*) which already is defined on the full space. We shall show below that the particular extension away from Y_i, although it may give rise to different multipliers in the statement of the theorem, still has no influence in the conditions of the theorem. For the moment, we just pick one

representation. Thus we have for all $(\eta,\xi)\in \overline{W}^n_{11}(0,T)\times L^m_\infty(0,T)$ that

(7.7)
$$\begin{aligned}\lambda(\xi) &= \nu_0\int_0^T (L_x\eta + L_u\xi)ds + \nu_0\ell_x(x_*(T))\eta(T) - \int_0^T \psi(t)\frac{d}{dt}\left(G_1[F_1](\eta,\xi)\right)dt\\ &\quad - \sum_{i=1}^{p-1}\int_0^T \rho_i(t)\frac{d}{dt}\left(G_{i+1}[F_1](\eta,\xi)\right)dt + a_0G_1[F_2](\eta,\xi) + \sum_{i=1}^{p-1}\langle a_i, G_{i+1}[F_2](\eta,\xi)\rangle.\end{aligned}$$

We need to evaluate the time derivatives $\frac{d}{dt}G_i[F](z_*;H_{p-1})$ of the G-operators along the reference trajectory. Since the operator F splits as $F=(F_1,F_2)$, also the operators G_i defined in (4.4) are applied componentwise. Note that we have $F_1(x,u)=x-I(f)(x,u)$, where $I(f)$ is the integral operator $I(f)(x,u)=\int_0^{(\cdot)} f(x(s),u(s),s)ds$. The linear term x will enter only the first operator G_1 but not the operators $G_i,\ i\geq 2$, which depend only on higher derivatives. And the time-derivative will simply cancel the integration. We can use the definition of the ith order directional derivative at a point $\varsigma\in Z$ along the sequence H_i for an arbitrary operator $\Phi: Z\to Y$ between Banach spaces to write the general formula concisely: let $\nabla^i\Phi: Z\to Y,\ i\in\mathbb{N}$,

$$\begin{aligned}&\nabla^i\Phi(\varsigma;H_i): Z\to Y,\\ &\varsigma\mapsto\ \nabla^i\Phi(\varsigma;H_i) = \sum_{r=1}^{i}\frac{1}{r!}\left(\sum_{j_1+\cdots+j_r=i}\Phi^{(r)}(\varsigma)(h_{j_1},\dots,h_{j_r})\right).\end{aligned}\tag{7.8}$$

It then follows for $i=2,\dots,p$ that

$$\begin{aligned}&\frac{d}{dt}\left(G_i[F_1](z_*;H_{i-1})\cdot(\eta,\xi)\right)\\ &\quad= \frac{d}{dt}\left[\sum_{r=1}^{i-1}\frac{1}{r!}\sum_{j_1+\cdots+j_r=i-1}\left(-\int_0^t\frac{\partial f^{(r)}}{\partial x}(z_*)(\eta_{j_1},\xi_{j_1};\dots;\eta_{j_r},\xi_{j_r})\eta\right.\right.\\ &\qquad\left.\left.+\frac{\partial f^{(r)}}{\partial u}(z_*)(\eta_{j_1},\xi_{j_1};\dots;\eta_{j_r},\xi_{j_r})\xi ds\right)\right]\\ &\quad= -\left(\nabla^{i-1}f\right)_x(z_*;H_{i-1})\eta - \left(\nabla^{i-1}f\right)_u(z_*;H_{i-1})\xi.\end{aligned}\tag{7.9}$$

With this notation for $i=2,\dots,p$ we also have that

$$G_i[F_2](z_*;H_{i-1})(\eta,\xi) = \left(\nabla^{i-1}q(x_*(T);H_{i-1})\right)_x\cdot\eta(T).\tag{7.10}$$

Using these formulas we thus obtain for all $(\eta,\xi)\in\overline{W}^n_{11}(0,T)\times L^m_\infty(0,T)$ that

$$\begin{aligned}\lambda(\xi) &= \int_0^T\left(\left(\nu_0L_x+\psi f_x+\sum_{i=1}^{p-1}\rho_i\left(\nabla^i f(H_i)\right)_x\right)\eta-\psi\dot\eta\right)dt\\ &\quad+\int_0^T\left\langle\nu_0L_u+\psi f_u+\sum_{i=1}^{p-1}\rho_i\left(\nabla^i f(H_i)\right)_u,\xi\right\rangle dt\\ &\quad+\nu_0\ell_x(x_*(T))\eta(T)+a_0q_x(x_*(T))\eta(T)+\sum_{i=1}^{p-1}\langle a_i\left(\nabla^i q(H_i)\right)_x,\eta(T)\rangle.\end{aligned}\tag{7.11}$$

Conditions (b)–(c) of the theorem follow from here using the following version of the classical DuBois–Raymond lemma. A proof is given, for instance, in [18].

LEMMA 7.1 (see [18]). *Suppose $\alpha, \beta \in L_1^n(0,T), c \in \mathbb{R}^n$, and for all $h \in \overline{W}_{11}^n(0,T)$ we have*

$$\int_0^T \alpha(t)h(t) + \beta(t)\dot{h}(t)dt = \langle c, h(T)\rangle. \tag{7.12}$$

Then

$$\beta(t) = c - \int_t^T \alpha(s)ds. \tag{7.13}$$

In particular, if necessary after changing β on a set of measure zero, $\beta \in \overline{W}_{11}^n(0,T)$.

Equations (6.2) and (6.3) directly follow if we take $\xi \equiv 0$ in (7.11). The extra conditions on the multipliers ρ_i and a_i follow from the orthogonality relations $(y_{i+1}^*, w_{i+1}^*) \in Y_i^{\perp_{i+1}}$, $i = 1, \dots, p-1$. Since the multiplier (y_{i+1}^*, w_{i+1}^*) is orthogonal to $\operatorname{Im} G_j$ for $j = 1, \dots, i$, we have for all $(\eta, \xi) \in \overline{W}_{11}^n(0,T) \times L_\infty^m(0,T)$ and $j = 1, \dots, i$ that

$$0 = \left\langle y_{i+1}^*, G_j[F_1](\eta,\xi)\right\rangle + \langle w_{i+1}^*, G_j[F_2](\eta,\xi)\rangle. \tag{7.14}$$

For $j = 1$, this yields

$$0 = \int_0^T \rho_i \left(f_x\eta + f_u\xi - \dot{\eta}\right) dt + a_i q_x(x_*(T))\eta(T), \tag{7.15}$$

and for $j = 2, \dots, i$,

$$0 = \int_0^T \rho_i \left(\left(\nabla^{j-1} f(H_{j-1})\right)_x \eta + \left(\nabla^{j-1} f(H_{j-1})\right)_u \xi\right) dt + a_i \left(\nabla^{j-1} q\right)_x (x_*(T))\eta(T). \tag{7.16}$$

Conditions (6.4) and (6.5) are consequences of these relations using Lemma 7.1. For instance, setting $\xi = 0$ in the second equation, we obtain that

$$\int_t^T \rho_i \left(\nabla^{j-1} f(H_{j-1})\right)_x ds = -a_i \left(\nabla^{j-1} q(H_{j-1})\right)_x (x_*(T)) = \text{const}, \tag{7.17}$$

and from this (6.5) follows.

If we set $\eta = 0$ in (7.11), we obtain a representation for the functional λ: for all $\xi \in L_\infty^m(0,T)$,

$$\lambda(\xi) = \int_0^T \left\langle \nu_0 L_u + \psi f_u + \sum_{i=1}^{p-1} \rho_i \left(\nabla^i f(H_i)\right)_u, \xi \right\rangle dt. \tag{7.18}$$

Since (λ, μ) is a supporting hyperplane to $FS^{(p)}(\mathcal{U}; u_*, V_{p-1})$, it follows that $\lambda(\xi) + \mu \geq 0$ for all $\xi \in FS^{(p)}(\mathcal{U}; u_*, V_{p-1})$. But (7.2) states that

$$\mu \leq \nu_0 R_p[I] + \sum_{i=1}^p \langle y_i^*, R_{p-1+i}[F_1]\rangle + \sum_{i=1}^p \langle w_i^*, R_{p-1+i}[F_2]\rangle,$$

and by definition and using the representations of these functionals, we have

$$R_p[I] = \int_0^T R_p[L](H_{p-1})dt + R_p[\ell](H_{p-1}), \tag{7.19}$$

$$\begin{aligned}\langle y_1^*, R_p[F_1]\rangle &= -\int_0^T \left\langle \psi(t), \frac{d}{dt}\left(R_p[F_1](H_{p-1})\right)\right\rangle dt \\ &= \int_0^T \psi(t) R_p[f](H_{p-1})dt, \end{aligned} \tag{7.20}$$

$$\begin{aligned}\langle y_i^*, R_{p-1+i}[F_1]\rangle &= -\int_0^T \left\langle \rho_{i-1}(t), \frac{d}{dt}\left(R_{p-1+i}[F_1](H_{p-1})\right)\right\rangle dt \\ &= \int_0^T \rho_{i-1}(t) R_{p-1+i}[f](H_{p-1})dt, \end{aligned} \tag{7.21}$$

$$\langle w_i^*, R_{p-1+i}[F_2]\rangle = a_{i-1} R_{p-1+i}[q](H_{p-1}). \tag{7.22}$$

Using the representation (7.18) for λ, we therefore obtain condition (6.6). This proves the result. □

The corollary is a direct consequence of the fact that (λ, μ) is a supporting hyperplane to $FS^{(p)}(\mathcal{U}; u_*, V_{p-1})$ since this implies that λ is a supporting functional to $\mathcal{U}$ at u_* [22, Corollary 6.3]. Hence the minimum condition (6.7) follows from Example 10.5 in [12]. We include it since this is the common form of the local minimum principle, but the separation condition is stronger (see the section with examples below).

Remark: Nontriviality of the extension. If H_{p-1} satisfies conditions (i)–(iv) in the definition of critical directions, but the operator F is not p-regular along H_{p-1}, then the conditions of Theorem 6.1 can be satisfied with a trivial choice of multipliers for which both $\nu_0 = 0$ and $\lambda \equiv 0$. Now the nontriviality statement is only on all multipliers which is significantly weaker than the strong nontriviality statement (a) of Theorem 6.1. In fact, in this case the conditions can be satisfied by choosing all the new multipliers zero and for (ν_0, ψ) the multipliers of the local maximum principle. This, of course, defeats the purpose of our extension. The p-regularity eliminates this choice of multipliers and thus gives us a nontrivial extension.

Remark: On the uniqueness of multipliers. There are two sources for nonuniqueness of the multipliers, one essential, the other unimportant. Different multipliers can arise from the existence of linearly independent supporting functionals $(\overline{\lambda} = (0, \lambda), \mu)$ to $FS^{(p)}(\mathcal{Z}; z_*, H_{p-1})$, and this is just one aspect of the particular problem to be considered. However, given λ and ν_0, since the operator $\mathcal{G}_p$ is onto, the functionals $(y_i^*, w_i^*) \in Y_{i-1}^{\perp_i}$, $i = 1, \dots, p$, in the generalized Euler–Lagrange equation (7.1) are uniquely determined. The multipliers ψ, ρ_i, and a_i in Theorem 6.1 are determined by representations obtained for these functionals after extending the (y_i^*, w_i^*) to continuous linear functionals on the full space. Naturally they depend on these extensions, and different independent solutions to conditions (b) and (c) can exist which all represent the same functionals (y_i^*, w_i^*). On the other hand, these extensions should be irrelevant and indeed the nonuniqueness caused in this way has no effect on *the separation condition* (d) *which is invariant* for all these multipliers in the sense that the value of the right-hand side in (6.6) does not depend on the choice of the specific representative from this class of multipliers.

If $\psi + \widehat{\psi}$, $\rho_i + \widehat{\rho}_i$ for $i = 1, \dots, p-2$, and $a_i + \widehat{a}_i$ for $i = 0, \dots, p-2$ are also multipliers which represent these functionals, then $(\widehat{\psi}, \widehat{a}_0)$ defines a functional $(\widehat{y}_1^*, \widehat{w}_1^*)$ in the annihilator of Y_1, and the $(\widehat{\rho}_i, \widehat{a}_i)$ define functionals $(\widehat{y}_{i+1}^*, \widehat{w}_{i+1}^*)$ in

the annihilator of Y_{i+1}, $i = 1, \dots, p-2$. (The last multipliers (ρ_{p-1}, a_{p-1}) are unique since no extensions need to be taken.) It therefore follows for all $(\eta, \xi) \in \overline{W}^n_{11}(0,T) \times L^m_\infty(0,T)$ that

$$
\begin{aligned}
0 &= \langle \widehat{y}_1^*, G_1[F_1](\eta,\xi)\rangle + \langle \widehat{w}_1^*, G_1[F_2](\eta,\xi)\rangle \\
&= -\int_0^T \widehat{\psi}(t)\frac{d}{dt}\left(G_1[F_1](\eta,\xi)\right) dt + \widehat{a_0} G_1[F_2](\eta,\xi)
\end{aligned} \tag{7.23}
$$

and

$$
\begin{aligned}
0 &= \langle \widehat{y}_{i+1}^*, G_{i+1}[F_1](\eta,\xi)\rangle + \langle \widehat{w}_{i+1}^*, G_{i+1}[F_2](\eta,\xi)\rangle \\
&= -\int_0^T \widehat{\rho}_i(t)\frac{d}{dt}\left(G_{i+1}[F_1](\eta,\xi)\right) dt + \widehat{a}_i G_{i+1}[F_2](\eta,\xi).
\end{aligned} \tag{7.24}
$$

In particular, the multipliers $(\widehat{\psi}, \widehat{a_0})$ satisfy analogous orthogonality conditions as the multiplier (ρ_1, a_1) and for $i = 2, \dots, p-2$, $(\widehat{\rho}_i, \widehat{a}_i)$ satisfies analogous orthogonality conditions as (ρ_{i+1}, a_{i+1}). Thus we have

$$
\dot{\widehat{\psi}}(t) = -\widehat{\psi}(t) f_x, \quad \widehat{\psi}(t) f_u \equiv 0, \quad \widehat{\psi}(T) = \widehat{a_0} q_x(x_*(T)), \tag{7.25}
$$

and for $j = 1, \dots, i$, the following conditions are satisfied for a.e. $t \in [0,T]$:

$$
\widehat{\rho}_i(t)\left(\nabla^j f(H_j)\right)_x = 0, \quad \widehat{\rho}_i(t)\left(\nabla^j f(H_j)\right)_u = 0, \quad \widehat{a}_i\left(\nabla^j q((x_*(1); H_j)\right)_x = 0. \tag{7.26}
$$

Note that, different from the orthogonality conditions (c) in Theorem 6.1, here the last index is $j = i$. Therefore we obtain, for example,

$$
\nu_0 L_u + \left(\psi + \widehat{\psi}\right) f_u + \sum_{i=1}^{p-1} (\rho_i + \widehat{\rho}_i)\left(\nabla^i f(H_i)\right)_u = \nu_0 L_u + \psi f_u + \sum_{i=1}^{p-1} \rho_i \left(\nabla^i f(H_i)\right)_u \tag{7.27}
$$

since $\widehat{\psi} f_u \equiv 0$ and also still $\widehat{\rho}_i \left(\nabla^i f(H_i)\right)_u \equiv 0$. As it should be, the extended adjoint equation and its terminal condition are not affected with such a choice. Furthermore, by the compatibility condition (ii) we have $R_{p-1+i}[F](z_*; H_{p-1}) \in Y_i$, and thus it also follows that

$$
\begin{aligned}
0 &= \langle \widehat{y}_1^*, R_p[F_1]\rangle + \langle \widehat{w}_1^*, R_p[F_2]\rangle \\
&= \int_0^T \widehat{\psi}(t) R_p[f](H_{p-1}) dt + \widehat{a_0} R_p[q](H_{p-1}),
\end{aligned} \tag{7.28}
$$

and for $i = 2, \dots, p-1$,

$$
\begin{aligned}
0 &= \langle \widehat{y}_i^*, R_{p-1+i}[F_1]\rangle + \langle \widehat{w}_i^*, R_{p-1+i}[F_2]\rangle \\
&= \int_0^T \widehat{\rho}_i(t) R_{p+i}[f](H_{p-1}) dt + \widehat{a}_i R_{p+i}[q](H_{p-1}).
\end{aligned} \tag{7.29}
$$

Hence we have

$$
\begin{aligned}
0 = {} & \widehat{a}_0 R_p[q](H_{p-1}) + \sum_{i=1}^{p-1} \widehat{a}_i R_{p+i}[q](H_{p-1}) \\
& + \int_0^T \left\langle \widehat{\psi} f_u + \sum_{i=1}^{p-1} \widehat{\rho}_i(t) \left(\nabla^i f(H_i)\right)_u, \xi \right\rangle dt \\
& + \int_0^T \left(\widehat{\psi}(t) R_p[f](H_{p-1}) + \sum_{i=1}^{p-1} \widehat{\rho}_i(t) R_{p+i}[f](H_{p-1}) \right) dt.
\end{aligned} \tag{7.30}
$$

Thus the separation condition (d) is independent of the extensions of the linear functionals $(y_i^*, w_i^*) \in Y_{i-1}^{\perp_i},\ i = 1, \dots, p-1$.

In the case of a Lagrangian minimization problem which has no control constraints, the functional λ vanishes identically. In this case we can normalize $\nu_0 = 1$ and the multipliers $(y_i^*, w_i^*) \in Y_{i-1}^{\perp_i},\ i = 1, \dots, p$, in the generalized Euler–Lagrange equation (7.1) are unique since $\mathcal{G}_p^*$ is one-to-one. In this case we therefore obtain the following corollary.

COROLLARY 7.2 (p-order local maximum principle for Lagrangian problems). *Consider the problem (OC) without control constraints ($U = \mathbb{R}^m$), and suppose the admissible process (x_*, u_*) is optimal. Then for every p-regular critical direction H_{p-1}, there exist vectors $a_i = a(H_{p-1}) \in (\mathbb{R}^k)^*$, $i = 0, 1, \dots, p-1$, and absolutely continuous functions $\psi(\cdot) = \psi(H_{p-1})(\cdot)$ and $\rho_i(\cdot) = \rho_i(H_{p-1})(\cdot)$, $i = 1, \dots, p-1$, from $[0, T]$ into $(\mathbb{R}^n)^*$, which satisfy the conditions* (b)–(d) *of Theorem* 6.1 *along the optimal trajectory $(x_*(t), u_*(t), t)$ for $\nu_0 = 1$. In particular, we thus have*

$$
L_u(x_*, u_*) + \psi(t) f_u + \sum_{i=1}^{p-1} \rho_i(t) \left(\nabla^i f(H_i)\right)_u \equiv 0. \tag{7.31}
$$

Furthermore, for any multipliers which satisfy conditions (b) *and* (c)*, the value of the right-hand side in* (6.6) *is the same.*

8. Approximations of order r in the p-regular case, $r > p$. Theorem 6.1 is based on p-order approximations. If these remain inconclusive, higher-order approximations can now easily be set up. Suppose H_{p-1} is a p-regular critical direction, and consider higher-order approximations H_{r-1}, $r > p$, whose first $p-1$ components are given by H_{p-1}. Several simplifications occur. For instance, since $FS^{(p)}(\mathcal{U}; u_*, V_{p-1})$ is nonempty, arbitrary higher-order approximations for the control constraint can be made, i.e., $FS^{(r)}(\mathcal{U}; u_*, V_{r-1}) = L_\infty^m(0, T)$. More importantly, F is trivially r-regular at (x_*, u_*) in direction of H_{r-1} since already the first p components of the map $\mathcal{G}_r$ are onto. In this case, all the quotient spaces Y_{i+1}/Y_i are $\{0\}$ for $i = p, \dots, r-1$. In particular, all the multipliers associated with these terms are zero, and therefore no additional multipliers arise in higher-order approximations. Thus only the operator $\mathcal{G}_p$ needs to be considered.

We show now that the required higher-order expansions for the tangent directions can easily be made by solving linear equations for the operator $\mathcal{G}_p$. We first analyze the higher-order approximations to the constraint $\mathcal{F} = \{z \in Z : F(z) = 0\}$ in a Banach

space Z. For $i = 0, \dots, p-1$, the term at ε^{p+i} in the expansion of $F(z_* + \sum_{j=1}^{p+i} \varepsilon^j h_j)$ can be expressed as

$$\nabla^{p+i} F(z_*; H_\ell) = \sum_{k=1}^{i+1} G_k[F](z_*; H_{k-1}) h_{p+i+1-k} + R_{p+i}[F](z_*; H_{p-1}), \tag{8.1}$$

and for $\ell \geq 2p$, we get

$$\nabla^{\ell} F(z_*; H_\ell) = \sum_{k=1}^{p} G_k[F](z_*; H_{k-1}) h_{\ell+1-k} + R_{\ell}[F](z_*; H_{\ell-p}). \tag{8.2}$$

($\nabla^\ell F$ collects all terms for which the indices of the directions h sum to ℓ. The operators G_k are used to write contributions of the h vectors with highest index separately. But for our construction the vectors in H_{p-1} are given and only terms with higher indices need to be chosen. Therefore, in the terms of orders p through $2p-1$, we consider only the vectors $h_p, \dots, h_\ell$ as free and restrict the range of the operators G_k, while for terms of orders $\geq 2p$, we always step down the full length p.) There are simple relations between these operators which follow directly from the definition of the R operators. For example, for $\ell = p, \dots, 2p-1$,

$$G_{\ell+1-p}[F](z_*; H_{\ell-p}) h_p + R_\ell[F](z_*; H_{p-1}) = R_\ell[F](z_*; H_p). \tag{8.3}$$

Here $R_\ell[F](z_*; H_p)$ consists of all terms which are homogeneous of degree ℓ, but involve only vectors from H_p. On the left-hand side these terms are split into those which contain h_p and those which don't. Since the total order is less than $2p$, h_p can enter linearly only with terms which must be homogeneous of degree $\ell - p$. These are given by $G_{\ell+1-p}[F](z_*; H_{\ell-p})$.

The construction of higher-order approximating sequences is inductive and requires only solution of *linear* equations in every step. It is shown in [22, Corollary 3.3] that the p-order tangent directions h_p to $\mathcal{F}$ at z_* along a sequence H_{p-1} (which satisfies conditions (i) and (ii) and along which F is p-regular) are given by the solutions to the linear equation

$$\mathcal{G}_p[F](z_*; H_{p-1}) h_p + \mathcal{R}_{p-1}[F](z_*, H_{p-1}) = 0, \tag{8.4}$$

where $\mathcal{R}_{p-1}[F](z_*, H_{p-1}) \in Y_1 \times Y_2/Y_1 \times \cdots \times Y/Y_{p-1}$ is the point with components

$$\left(R_p[F](z_*; H_{p-1}), \pi_1 R_{p+1}[F](z_*; H_{p-1}), \dots, \pi_{p-1} R_{2p-1}[F](z_*; H_{p-1})\right). \tag{8.5}$$

This vector is well defined by the compatibility condition. In the next step we need to choose h_{p+1} so that amongst other conditions we have

$$\begin{aligned} \nabla^{p+1} F(z_*; H_p) &= G_1(z_*) h_{p+1} + \underbrace{G_2(z_*; H_1) h_p + R_{p+1}[F](z_*; H_{p-1})}_{} \\ &= G_1(z_*) h_{p+1} + \qquad R_{p+1}[F](z_*; H_p) = 0. \end{aligned}$$

By the choice of h_p as a p-order tangent direction the required necessary condition $R_{p+1}[F](z_*; H_p) \in Y_1$ is satisfied since h_p already solves the equation $\nabla^{p+1} F(z_*; H_p) = 0$ in the quotient space Y_2/Y_1, i.e., except possibly for a remaining term in Y_1. (See [21] for more detailed explanations on calculating p-order tangent directions.) Similarly, the necessary conditions $R_{p+i}[F](x_*; H_p) \in Y_i$ are satisfied for all the other components, and we can inductively solve for h_{p+1} while preserving the required necessary

conditions for setting up higher-order approximations. Note that these conditions are essential since only in this way can we actually assert that H_{p+1} is a $(p+1)$-order tangent direction. In general we have the following.

PROPOSITION 8.1. *Let H_{p-1} be a $(p-1)$-order tangent direction to $\mathcal{F}$ at z_*, and suppose F is p-regular at z_* in direction of H_{p-1}. Let H_{r-1} be an extension of H_{p-1} to an $(r-1)$-order tangent direction to $\mathcal{F}$ at z_* (i.e., $\nabla^i F(z_*)(H_i) = 0$ for $i = p, \dots, r-1$, and the compatibility conditions $R_{r-1+i}[F](z_*; H_{r-1}) \in Y_i$ for $i = 1, \dots, p-1$ are satisfied), and let $\mathcal{R}_{r-1}[F](z_*; H_{r-1})$ be the point with components*

$$(R_r[F](z_*; H_{r-1}), \pi_1 R_{r+1}[F](z_*; H_{r-1}), \dots, \pi_{p-1} R_{r+p-1}[F](z_*; H_{r-1})). \tag{8.6}$$

Then the set of all r-order tangent directions to $\mathcal{F}$ at z_* along H_{r-1}, $TS^{(r)}(\mathcal{F}; z_*, H_{r-1})$, is a nonempty affine variety given by the solutions to the equation

$$\mathcal{G}_p[F](z_*; H_{p-1}) h_r + \mathcal{R}_{r-1}[F](z_*; H_{r-1}) = 0. \tag{8.7}$$

Proof. In the state-space Z the vectors h_r which extend H_{r-1} to r-order tangent directions are the solutions to the following equations:

$$\begin{aligned}
\nabla^r F(z_*; H_{r-1}) &= G_1(z_*) h_r + R_r[F](z_*; H_{r-1}) = 0, \\
\nabla^{r+1} F(z_*; H_{r-1}) &= G_1(z_*) h_{r+1} + G_2(z_*; h_1) h_r + R_{r+1}[F](z_*; H_{r-1}) \in Y_1 \\
&\dots \\
\nabla^{r+i} F(z_*; H_{r-1}) &= \sum_{k=1}^{i+1} G_k(z_*; H_{k-1}) h_{r+i+1-k} + R_{r+i}[F](z_*; H_{r-1}) \in Y_i
\end{aligned}$$

for $i = 0, \dots, p-1$, and the vectors h_j for $j > r$ are left undetermined in this step. By assumption (guaranteed by the inductive steps of the construction) we have

$$R_{r+i}[F](z_*; H_{r-1}) \in Y_{i+1},$$

and therefore, since the operator $\mathcal{G}_p$ is onto, we can choose h_r so that

$$G_{i+1}(z_*; H_i) h_r + R_{r+i}[F](z_*; H_{r-1}) \in Y_i. \tag{8.8}$$

These vectors are precisely the solutions to (8.7). It follows similar to the proof of the main approximation lemma in [21] that any such vector defines an r-order tangent direction. The only change is that the order of approximation needs to be raised to r. ∎

Note that we need only to solve *linear* equations, but in every step a system of p equations needs to be solved since the operator F is only p-regular. As in [22, section 2] we define the r-order tangent cone to $\mathcal{F}$ at z_* in direction of H_{r-1}, $TC^{(r)}(\mathcal{F}; z_*, H_{r-1})$, as the cone in $Z \times \mathbb{R}$ generated by the vectors $(v, 1)$ with $v \in TS^{(r)}(\mathcal{F}; z_*, H_{r-1})$. The dual or polar cone consists of all continuous linear functionals which are nonnegative on $TC^{(r)}(\mathcal{F}; z_*, H_{r-1})$. Since the operator $\mathcal{G}_p$ is used in each of these higher-order approximations, the structure of the dual cone directly follows from [22, Proposition 3.6].

PROPOSITION 8.2. *The dual or polar r-order tangent cone consists of all linear functionals* $(\lambda, \mu) \in X^* \times \mathbb{R}$ *which can be represented in the following form: there exist functionals* $y_i^* \in Y_{i-1}^{\perp_i}$, $i = 1, \dots, p$, *and a number* $s \geq 0$ *such that*

$$\lambda = \sum_{i=1}^{p} G_i^*[F](z_*; H_{i-1}) y_i^* \ , \tag{8.9}$$

$$\mu = \sum_{i=1}^{p} \langle y_i^*, R_{r-1+i}[F](z_*; H_{r-1}) \rangle + s. \tag{8.10}$$

Thus, given a p-regular tangent direction, it is possible to set up higher-order approximations of arbitrary order. Now consider the problem to minimize a functional $I : Z \to \mathbb{R}$ over the set $\mathcal{F}$. If there exists an integer $j \leq r$ such that $\nabla^j I(z_*; H_j) < 0$ while $\nabla^i I(z_*; H_i) = 0$ for $i = 1, \dots, j-1$, then z_* is not optimal since there exist j-order tangent directions to $\mathcal{F}$ for which I will produce better values than at z_*. Thus it is a necessary condition for optimality of z_* that the first nonzero derivative of $\nabla^i I(z_*; H_i)$ is positive. Once this happens, it is clear that no higher-order approximations which extend H_i are useful in obtaining necessary conditions for optimality. Therefore the r-order critical directions for the objective are those which satisfy

(iii-r) $\nabla^i I(z_*)(H_i) = 0$ for $i = p, \dots, r-1$.

THEOREM 8.3. *Suppose the admissible process* (x_*, u_*) *is optimal for the optimal control problem* (OC), *and let* H_{p-1} *be a p-regular critical direction. Let* H_{r-1} *be an extension of* H_{p-1} *to an* $(r-1)$*-order tangent direction to the equality constraint which is r-order critical for the objective. Then there exist vectors* $a_i = a(H_{p-1}) \in (\mathbb{R}^k)^*$, $i = 0, 1, \dots, p-1$, *and absolutely continuous functions* $\psi(\cdot) = \psi(H_{p-1})(\cdot)$ *and* $\rho_i(\cdot) = \rho_i(H_{p-1})(\cdot)$, $i = 1, \dots, p-1$, *from* $[0, T]$ *into* $(\mathbb{R}^n)^*$, *which satisfy conditions* (b) *and* (c) *of Theorem* 6.1 *with* $\nu_0 = 1$ *and are such that*

$$\begin{aligned} 0 \leq\ & R_r[\ell](H_{r-1}) + a_0 R_r[q](H_{r-1}) + \sum_{i=0}^{p-1} a_i R_{r+i}[q](H_{r-1}) \\ & + \int_0^T \left(R_r[L](H_{r-1}) + \psi(t) R_r[f](H_{r-1}) + \sum_{i=1}^{p-1} \rho_i(t) R_{r+i}[f](H_{r-1}) \right) dt. \end{aligned} \tag{8.11}$$

The value of the right-hand side in (8.11) *is the same independent of the choice of multipliers* a_i, ψ, *and* ρ_i *which satisfy conditions* (b) *and* (c).

Proof. Let $z_* = (x_*, u_*)$. Under these conditions the r-order tangent cone and the r-order cone of decrease are nonempty. Since the feasible cone is the full space, it is therefore a necessary condition for optimality that these cones do not intersect. The r-order cone of decrease of the functional I at z_* in direction of H_{r-1}, $DC^{(r)}(I; z_*, H_{r-1})$, is given by [22, Proposition 4.1] as

$$DC^{(r)}(I; z_*, H_{r-1}) = \{(w, \gamma) \in X \times \mathbb{R} : \gamma > 0, I'(z_*)w + \gamma R_r[I](z_*; H_{r-1}) < 0\} \tag{8.12}$$

and thus is nonempty, open, and convex. Its dual cone is given by [22, Proposition 4.2] as

$$\Big(DC^{(r)}(I;z_*,H_{r-1})\Big)^* = \Big\{(\lambda,\mu)\in X^*\times\mathbb{R}:\ \exists\ \alpha_1\le 0,\ \alpha_2\ge 0 \text{ such that } \begin{pmatrix}\lambda\\ \mu\end{pmatrix} = \begin{pmatrix} I'(z_*) & 0\\ R_r[I](z_*;H_{r-1}) & 1\end{pmatrix}\begin{pmatrix}\alpha_1\\ \alpha_2\end{pmatrix}\Big\}. \tag{8.13}$$

Hence it follows from the Dubovitskii–Milyutin lemma [12] that there exist *nontrivial* continuous linear functionals in the dual cones, $\big(TC^{(r)}(\mathcal{F};z_*,H_{r-1})\big)^*$ and $\big(DC^{(r)}(I;z_*,H_{r-1})\big)^*$, whose sum vanishes identically. Thus there exist functionals $(y_i^*,w_i^*)\in Y_{i-1}^{\perp_i},\ i=1,\dots,p$, such that

(8.14)
$$0\equiv I'(z_*)+\sum_{i=1}^{p} G_i^*[F_1](z_*;H_{i-1})y_i^*+\sum_{i=1}^{p} G_i^*[F_2](z_*;H_{i-1})w_i^*,$$

(8.15)
$$0\le R_r[I](z_*;H_{r-1})+\sum_{i=1}^{p}\langle y_i^*,R_{r-1+i}[F_1](z_*;H_{r-1})\rangle+\sum_{i=1}^{p}\langle w_i^*,R_{r-1+i}[F_2](z_*;H_{r-1})\rangle.$$

The first equation is the Euler–Lagrange equation (7.1) for the case $\lambda\equiv 0$ and $\nu_0=1$. Thus conditions (b) and (c) of Theorem 6.1 follow. The second-order condition (8.15) gives (8.11). In this derivation only the index changes from p to r. Furthermore, as in the case of a Lagrangian extremum problem the multipliers $(y_i^*,w_i^*)\in Y_{i-1}^{\perp_i}$ are unique, and the degrees of freedom brought into the representation by using extensions to the full space do not affect the values (since $R_{r-1+i}[F](z_*;H_{r-1})\in Y_i$ for $i=1,\dots,p-1$, and the freedom in the multipliers is only within functionals which annihilate Y_i). This proves the result. □

Remark. Note that we cannot assert in general that the multipliers in Theorem 8.3 are the same ones as the multipliers which arise in Theorem 6.1. In fact, if λ is not identically zero, they are not. If, however, $\lambda\equiv 0$, then (except for the possible but inconsequential freedom in the extensions) these multipliers are the same since $\mathcal{G}_p^*$ is $1-1$. This applies to the Lagrangian problem.

Corollary 8.4 (Lagrangian problems). *Consider the optimal control problem* (OC) *without control constraints ($U=\mathbb{R}^m$), and suppose the admissible process (x_*,u_*) is optimal. Let H_{p-1} be p-regular critical direction and let $a_i=a(H_{p-1})$, $i=0,1,\dots,p-1$, $\psi(\cdot)$ and $\rho_i(\cdot)$, $i=1,\dots,p-1$, be multipliers which satisfy the conditions of Theorem* 6.1 *along the optimal trajectory $(x_*(t),u_*(t),t)$ for $\nu_0=1$. Then* (8.11) *holds for any extension of H_{p-1} to an $(r-1)$-order tangent direction to the equality constraint which is r-order critical.*

Our theorems equally apply to the regular case, i.e., $p=1$, but then they reduce to classical results. Yet on this level the relations between these results are easiest explained. For $p=1$, Theorem 6.1 is the local maximum principle (e.g., [12, Theorem 12.1]) and the separation condition is simply the statement that there exists a supporting hyperplane to $\mathcal{U}$ at u_*. For the Lagrangian minimization problem and

$r = 2$, Theorem 8.3 gives the accessory problem. For, in this case, (8.11) becomes

$$
\begin{aligned}
0 &\le R_2[\ell](H_1) + a_0 R_2[q](H_1) + \int_0^T R_2[L](H_1) + \psi(t) R_2[f](H_1) dt \\
&= \frac{1}{2}\ell_{xx}(x_*(T))(\eta(T),\eta(T)) + \frac{1}{2}a_0 q_{xx}(x_*(T))(\eta(T),\eta(T)) \\
&\quad + \int_0^T (\eta,\xi) \begin{pmatrix} L_{xx} & L_{xu} \\ L_{ux} & L_{uu} \end{pmatrix} \begin{pmatrix} \eta \\ \xi \end{pmatrix} + \left\langle \psi, (\eta,\xi) \begin{pmatrix} f_{xx} & f_{xu} \\ f_{ux} & f_{uu} \end{pmatrix} \begin{pmatrix} \eta \\ \xi \end{pmatrix} \right\rangle dt \qquad (8.16) \\
&= \frac{1}{2}\ell_{xx}(x_*(T))(\eta(T),\eta(T)) + \frac{1}{2}a_0 q_{xx}(x_*(T))(\eta(T),\eta(T)) \\
&\quad + \int_0^T (\eta,\xi) \begin{pmatrix} H_{xx} & H_{xu} \\ H_{ux} & H_{uu} \end{pmatrix} \begin{pmatrix} \eta \\ \xi \end{pmatrix} dt,
\end{aligned}
$$

where $H = L + \psi f$. This holds for all $(\eta,\xi) \in \ker F'(x_*,u_*)$ for which $I'(x_*,u_*) = 0$. But $(\eta,\xi) \in \ker F'(x_*,u_*)$ if and only if η is a solution to the variational equation

$$
\dot\eta = f_x(x_*(t),u_*(t),t)\eta + f_u(x_*(t),u_*(t),t)\xi, \quad \eta(0) = 0, \tag{8.17}
$$

with terminal constraint $q_x(x_*(T))\eta(T) = 0$. These are the conditions for the domain of the accessory problem. In its typical formulation, however, no reference is made to the condition $I'(x_*,u_*) = 0$. But this is badly misleading. For, if this does not hold, then it follows immediately that (x_*,u_*) cannot be an extremal since it violates the local maximum principle. Thus the condition $I'(x_*,u_*) = 0$ is hidden in the statement that the accessory problem is taken along an extremal. In this sense our primal approach of determining high-order admissible directions results in the proper set of necessary conditions which these directions have to satisfy to be critical of a certain level. Then, if we choose $r = 3$, Theorem 8.3 gives additional necessary conditions for optimality, but only for those directions for which linear or quadratic approximations have been inconclusive, namely second-order critical directions. In this sense, our results provide a complete hierarchy of results which through primal constructions of higher-order approximating directions and dual characterizations of empty intersection properties of approximating cones give necessary conditions for optimality for increasingly more degenerate structures.

9. Examples. In this section we give several examples which illustrate how Theorem 6.1 can be used to eliminate abnormal candidates from optimality. We consider two cases. The first illustrates the case when $\mathrm{Im}(F'(z_*), I'(z_*))$ has codimension 1 and in the second example $\mathrm{Im}(F'(z_*), I'(z_*))$ has codimension 2. In these examples the order p will be arbitrary. However, we use the same equality constraint so that the analysis of high-order tangent directions only needs to be done once.

We consider the problems to minimize the functional

$$
I_\pm(x,u) = \int_0^T \left[(x_1 - 1)^2 + x_2^p + (x_3 \pm 1)^2 - 2\right] dt \tag{9.1}
$$

over all $(x,u) \in \overline{W}^3_{11}(0,T) \times L^2_\infty(0,T)$ subject to the dynamics

$$
\dot x(t) = A(x) + Bu = \begin{pmatrix} 0 \\ x_1^p \\ \alpha x_2^{p-1} x_3 \end{pmatrix} + \begin{pmatrix} 0 & 1 \\ -1 & 0 \\ 0 & -1 \end{pmatrix} \begin{pmatrix} u_1 \\ u_2 \end{pmatrix}, \tag{9.2}
$$

initial condition $x(0) = 0$, and terminal constraints $x_1(T) = 0$ and $x_3(T) = 0$. Here p is an integer, $p \geq 2$, and α is an arbitrary real number. For simplicity we have not imposed any control constraints. A related example which has bounded controls is given in [20].

We first show that the reference trajectory $\Gamma = (x_*, u_*) \equiv (0, 0)$ is an abnormal extremal for each problem. If Γ is optimal, then by the weak local maximum principle there exist a constant $\lambda_0 \geq 0$ and an absolutely continuous function $\lambda : [0, T] \to (\mathbb{R}^3)^*$ such that $(\lambda_0, \lambda(t)) \neq 0$ for all $t \in [0, T]$, $\dot\lambda(t) = \lambda_0(2, 0, \mp 2)$, $\lambda(T) = (\nu_1, 0, \nu_3)$, and the local minimum conditions $\lambda_2(t) \equiv 0$ and $\lambda_1(t) \equiv \lambda_3(t)$ are satisfied. For the problem to minimize I_+ we get

$$\lambda_1(t) - \lambda_3(t) = \nu_1 - \nu_3 + 4\lambda_0(t - T),$$

and this vanishes if and only if $\nu_1 = \nu_3$ and $\lambda_0 = 0$. Thus in this case Γ is a corank 1 abnormal extremal whose unique multiplier is given by $\lambda_0 = 0$ and $\lambda(t) \equiv (\nu, 0, \nu)$ for some nonzero constant ν. If, however, we minimize I_-, then we have

$$\lambda_1(t) - \lambda_3(t) = \nu_1 - \nu_3,$$

and the minimum condition $\lambda_1(t) \equiv \lambda_3(t)$ is automatically satisfied if $\nu_1 = \nu_3 = \nu$. In this case the extremal Γ has two linearly independent multipliers, one normal, the other abnormal, given by $\lambda_0 = 0$ and $\lambda(t) \equiv (1, 0, 1)$ and $\lambda_0 = 1$ and $\lambda(t) \equiv (2(t - T), 0, 2(t - T))$.

In either case the generalized Legendre–Clebsch condition [6] is trivially satisfied: since the multipliers are at most linear functions in t, we have for any positive integer k that

$$\frac{d^{2k}}{dt^{2k}} H_u(\lambda_0, \lambda(t), 0, 0) \equiv 0,$$

and thus the controls are singular of infinite order. For the case when there is a unique multiplier further necessary conditions for optimality of multi-input control systems are given by Goh [13]. In its simplified version [13, section 4.3] these conditions are satisfied trivially here since the control vector fields are constant and thus commute. The stronger condition stated in the "fundamental theorem" in [13] in addition requires that the matrix $B^T H_{xx}(0, \lambda(t), 0, 0,)B$ is positive semidefinite. For $p > 2$, this holds trivially since $H_{xx}(0, \lambda(t), 0, 0,) \equiv 0$, but for $p = 2$, this excludes the optimality of Γ. We have $H(0, \lambda, x, u,) = \lambda_2 x_1^2 + \lambda_3 \alpha x_2 x_3 + Bu$, and thus using $\lambda_2(t) \equiv 0$ and $\lambda_3(t) \equiv \nu$, we get that

$$\begin{aligned} B^T H_{xx}(0, \lambda(t), 0, 0,)B &= \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & -1 \end{pmatrix} \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & \alpha\nu \\ 0 & \alpha\nu & 0 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ -1 & 0 \\ 0 & -1 \end{pmatrix} \\ &= \alpha\nu \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \end{aligned} \tag{9.3}$$

which is indefinite for $\alpha \neq 0$. In this case the optimality of Γ can also be excluded using the result of Agrachev and Sarychev [1, Theorem 3.4] recalled in Proposition 5.2: It is clear from above that $\operatorname{Im} F'(0, 0)$ has codimension 1. More specifically, the variational equation is given by the linear system $\dot h(t) = B\xi$, $h(0) = 0$, and thus its reachable set is simply the image of B. Hence

$$\operatorname{Im} F'(0, 0) = \left\{ (a, b) \in \overline{W}{}^3_{11}(0, T) \times \mathbb{R}^2 : b^{[1]} + b^{[3]} = a^{[1]}(T) + a^{[3]}(T) \right\}, \tag{9.4}$$

where the superscripts denote the components. Also,

$$\ker F'(0,0) = \Big\{(\eta,\xi) \in \overline{W}^3_{11}(0,T) \times L^2_\infty(0,T) : \dot\eta(t) = B\xi, \eta(0) = 0, \\ \eta^{[1]}(T) = 0 \text{ and } \eta^{[3]}(T) = 0\Big\}. \tag{9.5}$$

Note that for $(\eta,\xi) \in \ker F'(0,0)$

$$I'_\pm(0,0)(\eta,\xi) = -2\int_0^T \eta^{[1]}(t) \mp \eta^{[3]}(t)dt = -2(1 \pm 1)\int_0^T \eta^{[1]}(t)dt, \tag{9.6}$$

and thus we have $I'_-(0,0)(\eta,\xi) \equiv 0$ for all $(\eta,\xi) \in \ker F'(0,0)$ while this quantity can be made nonzero for I_+. Hence the codimension of $\operatorname{Im}(F'(0,0), I'_-(0,0))$ is 2, while the codimension of $\operatorname{Im}(F'(0,0), I'_+(0,0))$ is 1. A nontrivial annihilator λ^* of $\operatorname{Im} F'(0,0)$ is determined by the abnormal costate λ of the weak maximum principle, and since $\lambda(t) = (\nu, 0, \nu)$, it follows that

$$\begin{aligned}\lambda^* F''(0,0)((\eta,\xi);(\eta,\xi)) &= \langle y^*, F_1''(0,0)\,((\eta,\xi),(\eta,\xi))\rangle + \langle w^*, F_2''(0,0)\,((\eta,\xi),(\eta,\xi))\rangle \\ &= \int_0^T \lambda(t)A_{xx}(0)(\eta(t),\eta(t))dt + 0 \\ &= \nu\int_0^T 2\alpha\eta^{[2]}(s)\eta^{[3]}(s)ds, \end{aligned} \tag{9.7}$$

where $\eta^{[i]}$ denotes the ith component of η. This quantity can be made both positive and negative for $(\eta,\xi) \in \ker F'(0,0)$. For instance, choose $\eta^{[3]}(t) = \sin(\pi\frac{t}{T})$ and $\eta^{[2]}(t) = \pm\eta^{[3]}(t)$. Hence $\lambda^* F''(0,0)$ is indefinite on $\ker F'(0,0)$, and thus Γ is not optimal.

For $p > 2$ or for the problem to minimize I_-, however, these results do not apply. We now show how Theorem 6.1 can be used to obtain additional information. We first consider the problem to minimize I_+ and show how to eliminate the optimality of Γ for any $p \geq 2$ using Theorem 6.1. For this we first need to find an appropriate p-regular critical direction

$$H_{p-1} = ((\eta_1,\xi_1);\dots;(\eta_{p-1},\xi_{p-1})) \in \Big(\overline{W}^3_{11}(0,T) \times L^2_\infty(0,T)\Big)^{p-1}.$$

Since the components of f are homogeneous polynomials of degree p and the terminal constraints are linear, it follows that for $i = 1,\dots,p-1$, the directional derivatives $\nabla^i F(z_*)(H_i)$ are simply given by

$$\nabla^i F(z_*)(H_i) = F'(0,0)(\eta_i,\xi_i), \tag{9.8}$$

and thus these derivatives vanish provided $(\eta_i,\xi_i) \in \ker F'(0,0)$ for $i = 1,\dots,p-1$. Since the dynamics involves only p-order terms it seems reasonable to consider only first- and pth-order approximations. We therefore choose H_{p-1} of the form

$$H_{p-1} = ((\eta_1,\xi_1);(0,0);\dots;(0,0)) \tag{9.9}$$

with $(\eta_1,\xi_1) \in \ker F'(0,0)$. With this choice of directions the compatibility conditions (ii) simplify considerably and reduce to the first condition only,

$$R_p[F](\Gamma;H_{p-1}) = \frac{1}{p!}F^{(p)}(0,0)\,((\eta_1,\xi_1);\dots;(\eta_1,\xi_1)) \in \operatorname{Im} F'(0,0). \tag{9.10}$$

The conditions for $i = 2, \dots, p-1$, are satisfied since $R_{p-1+i}[F](\Gamma; H_{p-1}) = 0$. Condition (9.10) is equivalent to

$$(1,0,1) \cdot \int_0^T D_x^{(p)} A(0)(\eta_1, \dots, \eta_1) ds = 0,$$

where $D_x^{(p)} A(0)(\eta_1, \dots, \eta_1)$ denotes the 3-vector whose ith entry is given by the values of the multilinear form $D_x^{(p)} A_i(0)$ acting on the vector η_1 in every component. In particular, since $A_1(x) \equiv 0$ in the example, we must therefore have

$$\int_0^T D_x^{(p)} A_3(0)(\eta_1, \dots, \eta_1) ds = 0. \tag{9.11}$$

If, as above, we denote the components of $\eta_1$by $\eta_1^{[j]}$, $j = 1, 2, 3$, then for $A_3(x) = \alpha x_2^{p-1} x_3$ this requires that

$$\int_0^T \left(\eta_1^{[2]}\right)^{p-1} \left(\eta_1^{[3]}\right) ds = 0. \tag{9.12}$$

We satisfy this by choosing $\eta_1^{[3]} = -\eta_1^{[1]} \equiv 0$ (i.e., $\xi_1^{[2]} \equiv 0$). Then choosing a nonzero $\eta_1^{[2]}$ with zero boundary conditions defines a nontrivial vector H_{p-1} of the form (9.9) for which conditions (i) and (ii) in the definition of p-regular critical directions are satisfied. The operator F is p-regular in this direction if the operator $\mathcal{G}_p(\Gamma; H_{p-1})$ is onto. Because of the homogeneity properties of A, the pth component G_p of $\mathcal{G}_p$ is given by

$$G_p[F](\Gamma; H_{p-1})(\widetilde{\eta}, \widetilde{\xi}) = \frac{1}{(p-1)!} F^{(p)}(0,0) \left((\eta_1, \xi_1); \dots; (\eta_1, \xi_1); (\widetilde{\eta}, \widetilde{\xi}) \right),$$

while all operators G_i for $i = 2, \dots, p-1$, vanish. Thus $\mathcal{G}_p(\Gamma; H_{p-1})$ is onto if there exists a direction $(\widetilde{\eta}, \widetilde{\xi}) \in \overline{W}^3_{11}(0,T) \times L^2_\infty(0,T)$ such that $G_p[F](\Gamma; H_{p-1})(\widetilde{\eta}, \widetilde{\xi}) \notin \operatorname{Im} F'(0,0)$. Like above, this is equivalent to

$$\int_0^T D_x^{(p)} A_3(0)(\eta_1, \dots, \eta_1, \widetilde{\eta}) ds \neq 0, \tag{9.13}$$

and thus

$$\int_0^T \left(\eta_1^{[2]}\right)^{p-2} \left[\left(\eta_1^{[2]}\right) \left(\widetilde{\eta}^{[3]}\right) + (p-1) \left(\eta_1^{[3]}\right) \left(\widetilde{\eta}^{[2]}\right) \right] ds \neq 0. \tag{9.14}$$

Since we have $\eta_1^{[3]} \equiv 0$ in our chosen direction H_{p-1}, this can simply be satisfied by choosing $\widetilde{\eta}^{[3]} = \eta_1^{[2]}$ if p is even or $\widetilde{\eta}^{[3]} = (\eta_1^{[2]})^2$ if p is odd. Hence F is p-regular in direction of H_{p-1} at Γ. Finally, these directions are also critical for the objective: by (9.6) we have $I'_+(0,0)(\eta_1, \xi_1) = 0$ and furthermore

$$\begin{aligned} \nabla^2 I_+(0,0)(H_2) &= \frac{1}{2} I''_+(0,0)((\eta_1, \xi_1); (\eta_1, \xi_1)) \\ &= \int_0^T \left(\eta_1^{[1]}\right)^2 + \left(\eta_1^{[3]}\right)^2 ds = 0, \end{aligned}$$

provided $p > 2$. Since no other I_+-derivatives arise in the directional derivatives $\nabla^i I_+(0,0)(H_i)$ for $i = 3, \dots, p-1$, the direction $H_{p-1} = ((\eta_1, \xi_1); (0,0); \dots; (0,0))$ with $\eta_1^{[1]} = \eta_1^{[3]} \equiv 0$ and a nonzero $\eta_1^{[2]}$ is a nonzero p-regular critical direction for the problem to minimize I_+ subject to $F = 0$ for any $p \geq 2$.

We thus can apply Theorem 6.1. Since there are no control constraints we can normalize the multipliers so that $\nu_0 = 1$. The additional multipliers ρ_i, $i = 1, \dots, p-1$, are associated with elements in the dual spaces of the quotients Y_{i+1}/Y_i. But here $Y_i = \operatorname{Im} F'(0,0)$ for $i = 1, \dots, p-1$, and Y_p is the full space. Thus we have $\rho_i \equiv 0$ for $i = 1, \dots, p-2$, and the only nonzero multipliers are ψ and ρ_{p-1} which for simplicity of notation we just call ρ. Now (6.4) of Theorem 6.1 states that ρ is an adjoint multiplier for which the conditions of the weak local maximum principle for an abnormal extremal are satisfied. Since this multiplier is unique, we must have $\rho(t) = (\nu, 0, \nu)$, but $\nu \in \mathbb{R}$ could now be zero. To write down the extended adjoint equation and minimum condition (6.7), we need to evaluate the directional derivatives $\nabla^{p-1} f(x,u)(H_i)$, where $f(x,u) = A(x) + Bu$. Note that all partial derivatives of order at least two which contain one u-derivative vanish. Thus we need only to calculate the actual x-partials. The leading term in $\nabla^{p-1} f(x,u)(H_i)$ is therefore given by

$$D_x^{(p-1)} A(x)(\eta_1, \dots, \eta_1) = \begin{pmatrix} 0 \\ p! \left(\eta_1^{[1]}\right)^{p-1} x_1 \\ (p-1)! \left[(p-1) \left(\eta_1^{[2]}\right)^{p-2} \left(\eta_1^{[3]}\right) x_2 + \left(\eta_1^{[2]}\right)^{p-1} x_3 \right] \end{pmatrix}.$$

All other terms come from lower derivatives and contain at least quadratic terms in the x_i. After taking another derivative and evaluating at zero all these terms will vanish. Since we also have $\eta_1^{[1]} = \eta_1^{[3]} \equiv 0$, we therefore get

$$\left(\nabla^{p-1} f(0,0)(H_i)\right)_x = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & \left(\eta_1^{[2]}\right)^{p-1} \end{pmatrix} \tag{9.15}$$

and

$$\left(\nabla^{p-1} f(0,0)(H_i)\right)_u \equiv 0. \tag{9.16}$$

Thus the extended minimum condition reduces to $\psi B \equiv 0$, the minimum condition of the weak maximum principle. Hence also $\psi_2(t) \equiv 0$ and $\psi_1(t) = \psi_3(t)$. But now the extended adjoint equation is given by

$$\dot{\psi}(t) = (2, 0, -2) - \rho \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & \left(\eta_1^{[2]}\right)^{p-1} \end{pmatrix}, \tag{9.17}$$

and thus

$$4 = \dot{\psi}_1(t) - \dot{\psi}_3(t) - \nu \left(\eta_1^{[2]}(t)\right)^{p-1} = -\nu \left(\eta_1^{[2]}(t)\right)^{p-1}. \tag{9.18}$$

But we can certainly choose $\eta_1^{[2]}$ nonconstant to violate this condition. This contradiction proves that Γ cannot be optimal for the problem to minimize I_+ for any $p \geq 2$.

We now consider the problem to minimize I_- for which the codimension of $\mathrm{Im}(F'(0,0), I'_-(0,0))$ is 2. This becomes a harder problem in some aspects but an easier problem in others. Essentially, since there exist two linearly independent multipliers which satisfy the weak local maximum principle, conditions (a)–(c) of Theorem 6.1 can be satisfied in a straightforward way using these multipliers where (ν_0, ψ) is the normal multiplier and $\rho \equiv 0$. Hence these conditions will give nothing new. On the other hand, since the codimension is 2, the restrictions on the critical directions are less stringent since any direction $(\eta, \xi) \in \ker F'(0,0)$ is automatically critical for the objective as well. Hence more directions are critical and the separation condition (d) becomes stronger. The details follow.

We first assume $p > 2$ and consider the same p-regular tangent directions as above. Note that these directions remain p-order critical for the objective and thus are p-regular critical directions. The only difference to the analysis above is that the extended adjoint equation now reads

$$\dot{\psi}(t) = (2,0,2) - \rho \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & \left(\eta_1^{[2]}(t)\right)^{p-1} \end{pmatrix}, \tag{9.19}$$

and thus we get

$$0 = \dot{\psi}_1(t) - \dot{\psi}_3(t) - \nu \left(\eta_1^{[2]}(t)\right)^{p-1} = -\nu \left(\eta_1^{[2]}(t)\right)^{p-1}. \tag{9.20}$$

But this equation can be satisfied with $\nu = 0$ implying $\rho \equiv 0$. The separation condition (d) reduces to

$$0 \le \int_0^T R_p[L](H_{p-1}) + \psi(t) R_p[f](H_{p-1}) dt. \tag{9.21}$$

Since $\eta_1^{[1]} \equiv \eta_1^{[3]} \equiv 0$, we have

$$R_p[f](H_{p-1}) = \begin{pmatrix} 0 \\ \left(\eta_1^{[2]}\right)^p \\ 0 \end{pmatrix}, \tag{9.22}$$

and this term will be annihilated by $\psi_2(t) \equiv 0$; and $R_p[L](H_{p-1})$ only generates the term $(\eta_1^{[2]}(t))^p$ as nonzero term. Thus it is a necessary condition for optimality of Γ that

$$0 \le \int_0^T \left(\eta_1^{[2]}(t)\right)^p dt \tag{9.23}$$

for any p-regular critical direction which satisfies $\eta_1^{[1]} \equiv \eta_1^{[3]} \equiv 0$. But we can multiply these directions by -1, and thus Γ is not optimal if p is odd.

If p is even, (9.23) will always be satisfied and these directions do not give rise to better values of the objective. In fact, if $H_{p-1} = ((\eta_1, \xi_1), (\eta_2, \xi_2), \dots, (\eta_{p-1}, \xi_{p-1}))$ is any p-order tangent direction for which $\eta_1^{[3]} \neq 0$, then, since by (9.8) necessarily $(\eta_2, \xi_2) \in \ker F'(0,0)$, we get

$$\begin{aligned} \nabla^2 I_-(0,0)(H_2) &= I'_-(0,0)(\eta_2, \xi_2) + \frac{1}{2} I''_-(0,0)((\eta_1, \xi_1), (\eta_1, \xi_1)) \\ &= \int_0^T \left(\eta_1^{[1]}\right)^2 + \left(\eta_1^{[3]}\right)^2 ds > 0. \end{aligned} \tag{9.24}$$

Hence no p-order tangent direction can lead to an improved value of the objective. Indeed, it can be shown that no improvement of the objective is possible for any tangent direction. These calculations strongly suggest that Γ is locally optimal if p is even and $p \geq 4$, but we are not aware of sufficient conditions for optimality which would apply to this situation.

The case $p = 2$ is the most interesting one. As above, in this case 2-regular critical directions for which $\eta_1^{[1]} \equiv \eta_1^{[3]} \equiv 0$ cannot be used to exclude the optimality of Γ. However, now any direction in $\ker F'(0,0)$ is critical, and thus any nontrivial $(\eta, \xi) \in \ker F'(0,0)$ which satisfies the compatibility condition

$$\int_0^T \eta^{[2]}(s)\eta^{[3]}(s)ds = 0 \tag{9.25}$$

defines a 2-regular critical direction. It is easily seen from (9.14) that the operator F is 2-regular at Γ in direction of (η, ξ) by choosing $\widetilde{\eta}^{[3]} = \eta_1^{[2]}$ and $\widetilde{\eta}^{[2]} = \eta_1^{[3]}$. Hence any direction $(\eta, \xi) \in \ker F'(0,0)$ which satisfies (9.25) is a 2-regular critical direction. The fact that $\operatorname{co\,dim}(\operatorname{Im} I'_-(0,0), \operatorname{Im} F'(0,0)) = 2$ allows for this *large* class of critical directions H_1. The separation condition (d) of Theorem 6.1 in conjunction with Corollary 7.2 and the fact that $\rho \equiv 0$ therefore implies that the quadratic form

$$\mathcal{Q} = \frac{1}{2}\int_0^T L^{(2)}(0,0)(H_1, H_1) + \psi(t)f^{(2)}(0,0)(H_1, H_1)dt \tag{9.26}$$

is positive semidefinite on the set of all 2-regular critical directions H_1. Note that (9.26) takes the form of the accessory problem for the normal multiplier $(1, \psi)$, but that the domain is restricted to the actual tangent directions to the equality constraint. In this case we have $\psi_3(t) = \nu + 2(t-T)$, $\nu = \psi_3(T)$. Note that in accordance with our remark on the uniqueness of multipliers the one degree of freedom in the multipliers is taken by the multipliers $(\nu, 0, \nu)$ from the annihilator of $\operatorname{Im} F'(0,0)$. But, as stated in Corollary 7.2, this freedom does not enter into the value of the quadratic form:

$$\begin{aligned}
\mathcal{Q} &= \int_0^T \left(\eta^{[1]}\right)^2 + \left(\eta^{[2]}\right)^2 + \left(\eta^{[3]}\right)^2 + \psi_3(t)\alpha\eta^{[2]}\eta^{[3]}dt \\
&= \int_0^T \left(\eta^{[2]}\right)^2 + 2\left(\eta^{[3]}\right)^2 + (\nu + 2(t-T))\,\alpha\eta^{[2]}\eta^{[3]}dt \\
&= \int_0^T \left(\eta^{[2]}\right)^2 + 2\left(\eta^{[3]}\right)^2 + 2t\alpha\eta^{[2]}\eta^{[3]}dt. \qquad (9.27)
\end{aligned}$$

Regardless of the value of ν, the quadratic form $\mathcal{Q}$ takes the same value for all possible multipliers because of the compatibility condition (9.25).

Now we pick a suitable subset of 2-regular critical directions H_1. Let C denote the space of all twice continuously differentiable functions $h : [0,T] \to \mathbb{R}$ which satisfy zero boundary conditions $h(0) = h(T) = 0$. Since

$$\int_0^T \dot{h}(t)h(t)dt = \frac{1}{2}h(t)^2\Big|_0^T = 0,$$

C is isomorphic to a subspace of critical directions defined by

$$\eta^{[3]}(t) = -\eta^{[1]}(t) = h(t), \quad \eta^{[2]}(t) = \dot{h}(t) \tag{9.28}$$

and

$$\xi^{[1]}(t) = \ddot{h}(t), \quad \xi^{[2]}(t) = -\dot{h}(t). \tag{9.29}$$

Hence it is a necessary condition for optimality that the quadratic form

$$\begin{aligned} \mathcal{Q} &= \int_0^T \left(\dot{h}(t)\right)^2 + 2\left(h(t)\right)^2 + 2\alpha t\dot{h}(t)h(t)dt \\ &= \int_0^T \left(\dot{h}(t)\right)^2 + (2-\alpha)\left(h(t)\right)^2 dt \end{aligned} \tag{9.30}$$

is positive semidefinite on C. It follows from the Jacobi equation [10] that $\mathcal{Q}$ is positive definite on C for $\alpha < 2 + \left(\frac{T}{\pi}\right)^2$, positive semidefinite for $\alpha = 2 + \left(\frac{T}{\pi}\right)^2$, and indefinite for $\alpha > 2 + \left(\frac{T}{\pi}\right)^2$. Thus Γ is not optimal for $\alpha > 2 + \left(\frac{T}{\pi}\right)^2$.

10. Conclusion. These examples illustrate the hierarchy of results derived in this paper which give necessary conditions for optimality of abnormal extremals. This extension is nontrivial in the sense that the multiplier at the objective does not vanish. The results apply regardless of whether the multiplier is unique or not, whether additional multipliers are normal or not, etc. The key idea behind our results is to characterize the directions which are actually tangent to the constraint set, and this question has been answered conclusively in [21]. Hence it is possible to set up high-order constructions. Naturally, near abnormal points, the resulting necessary conditions for optimality will take a different look since the constraint typically is no longer a manifold and intersecting branches need to be analyzed separately. Our constructions provide an approach for doing this.

The local version of the extended maximum principle presented in this paper, besides its intrinsic interest for Lagrangian problems when the reference control takes values in the interior of the control set, can also be considered a first step in the derivation of a more general version analogous to the Pontryagin maximum principle. This theorem will apply to more general problems in the sense that the control set can be arbitrary and consequently no differentiability assumptions need to be made on the control. Also the terminal time will be free. For the case $p = 2$, this transition, which is accomplished by a technique of variable time transformations (introduced by Dubovitskii in this context) has already been carried out in [18]. Its generalization to the general p-order maximum principle is a logical next step. This result has already been formulated in [20] with an outline of the proof.

Acknowledgments. We would like to thank the associate editor who was handling this paper and two anonymous referees for many valuable suggestions which helped us clarify our results.

STABILIZATION OF NONHOLONOMIC SYSTEMS USING ISOSPECTRAL FLOWS*

ANTHONY M. BLOCH†, SERGEY V. DRAKUNOV‡, AND MICHAEL K. KINYON§

Abstract. In this paper we derive and analyze a discontinuous stabilizing feedback for a Lie algebraic generalization of a class of kinematic nonholonomic systems introduced by Brockett [*New Directions in Applied Mathematics*, P. Hilton and G. Young, eds., Springer-Verlag, New York, 1982, pp. 11–27]. The algorithm involves discrete switching between isospectral and norm-decreasing flows. We include a rigorous analysis of the convergence.

1. Introduction.

In this paper we present a stabilization algorithm for a Lie algebraic generalization of a class of nonholonomic systems originally introduced by Brockett [11]. These are the systems of the general form $\dot{x} = B(x)u$ in which the dimension of the control vector u is smaller than that of the state vector x, but the system is nonetheless controllable. Such systems are sometimes referred to as kinematic nonholonomic systems (as opposed to dynamic nonholonomic systems which arise from a Lagrangian—see, e.g., Bloch and Crouch [2] or Bloch, Krishnaprasad, Marsden, and Murray [9]). Following standard usage, we will simply refer to kinematic nonholonomic systems as nonholonomic.

A prototypical system in the class we study here is the Heisenberg system or nonholonomic integrator (Brockett [11], [12]):

$$\dot{x} = u, \tag{1.1}$$

$$\dot{y} = v, \tag{1.2}$$

$$\dot{z} = xv - yu, \tag{1.3}$$

where $x, u, y, v, z \in \mathbb{R}$. If we identify the variable z with the skew-symmetric matrix $Y = \left(\begin{smallmatrix} 0 & z \\ -z & 0 \end{smallmatrix}\right)$, and observe that

$$\begin{pmatrix} x \\ y \end{pmatrix}(u, v) - \begin{pmatrix} u \\ v \end{pmatrix}(x, y) = \begin{pmatrix} 0 & xv - yu \\ -xv + yu & 0 \end{pmatrix},$$

then a generalization of (1.1)–(1.3) immediately suggests itself. This is the $so(n)$ system (see Brockett [11]):

$$\dot{x} = u, \tag{1.4}$$

$$\dot{Y} = xu^T - ux^T, \tag{1.5}$$

where x, u are column vectors in $\mathbb{R}^n$ and $Y \in so(n)$, $n \geq 2$. Here $so(n)$ is the Lie algebra of $n \times n$ skew-symmetric matrices: $Y^T = -Y$.

The importance of the $so(n)$ system (1.4)–(1.5) is that it is a canonical form for a class of controllable systems of the form $\dot{x} = B(x)u$, $u \in \mathbb{R}^n$, $x \in \mathbb{R}^{n(n+1)/2}$. The class in question is the controllable systems of this type, where the first derived algebra of control vector fields spans the tangent space $T\mathbb{R}^{n(n+1)/2}$ at any point. (Recall that if E^0 is the subbundle of the tangent bundle spanned by the control fields, then the first derived algebra is given by $E^1 = E^0 + [E^0, E^0]$.) Brockett showed that such a system can be transformed to the form (1.4)–(1.5) up to a suitable order in the neighborhood of a given point such as the origin (see Brockett [11]). (In the terminology of Bloch, Reyhanoglu, and McClamroch [10], for example, this is a controllable nonholonomic kinematic system of nonholonomy degree 1.)

A different generalization of the Heisenberg system (1.1)–(1.3) is obtained by identifying the vectors $(x, y)^T$ and $(u, v)^T$ with the matrices $X = \frac{1}{\sqrt{2}}\left(\begin{smallmatrix} x & -y \\ -y & -x \end{smallmatrix}\right)$ and $U = \frac{1}{\sqrt{2}}\left(\begin{smallmatrix} u & -v \\ -v & -u \end{smallmatrix}\right)$, respectively. Then we have

$$[U, X] = UX - XU = \begin{pmatrix} 0 & xv - yu \\ -(xv - yu) & 0 \end{pmatrix}.$$

This suggests the following matrix system occurring in the Lie algebra $sl(n, \mathbb{R})$ of $n \times n$ matrices with trace 0:

$$\dot{X} = U, \tag{1.6}$$

$$\dot{Y} = [U, X], \tag{1.7}$$

where $X, U \in sym_0(n, \mathbb{R})$ and $Y \in so(n)$. Here $sym_0(n, \mathbb{R})$ is the space of $n \times n$ real symmetric matrices with trace zero. Note that $sl(n, \mathbb{R}) = sym_0(n, \mathbb{R}) \oplus so(n)$, a direct sum.

The system we study in this paper generalizes both the $so(n)$ system (1.4)–(1.5) and the $sl(n, \mathbb{R})$ system (1.6)–(1.7). Let $\mathfrak{g}$ be a Lie algebra. Assume $\mathfrak{g}$ has a direct sum decomposition $\mathfrak{g} = \mathfrak{m} \oplus \mathfrak{h}$ such that $\mathfrak{h}$ is a Lie subalgebra, $[\mathfrak{h}, \mathfrak{m}] \subseteq \mathfrak{m}$, and $[\mathfrak{m}, \mathfrak{m}] = \mathfrak{h}$. The exact hypotheses will be given in section 3; for now, we note that every simple Lie algebra with a Cartan decomposition is of this type. We will consider the following system in $\mathfrak{g}$:

$$\dot{x} = u, \tag{1.8}$$

$$\dot{Y} = [u, x], \tag{1.9}$$

where $x, u \in \mathfrak{m}$, $Y \in \mathfrak{h}$.

Clearly the $sl(n, \mathbb{R})$ system (1.6)–(1.7) has the form (1.8)–(1.9). In addition, the $so(n)$ system (1.4)–(1.5) can also be written in this form as we now show. Let $\mathfrak{h} = so(n)$ and let $\mathfrak{m} = \mathbb{R}^n$. For $x, u \in \mathfrak{m}$, define $[u, x] \equiv xu^T - ux^T \in \mathfrak{h}$. For $Y \in \mathfrak{h}$, $x \in \mathfrak{m}$, define $[Y, x] = -[x, Y] \equiv Yx$. Then the Lie algebra $\mathfrak{g} \equiv \mathfrak{m} + \mathfrak{h}$ is isomorphic to $so(n + 1)$. Indeed, this is clear if we make the identifications

$$\mathfrak{h} \cong \left\{ \begin{pmatrix} 0 & 0 \\ 0 & Y \end{pmatrix} : Y \in so(n) \right\} \quad \text{and} \quad \mathfrak{m} \cong \left\{ \begin{pmatrix} 0 & -x^T \\ x & 0 \end{pmatrix} : x \in \mathbb{R}^n \right\}.$$

It is easy to check that the desired commutation relations hold, and, with these particular identifications, that the adjoint action of $\mathfrak{h}$ on $\mathfrak{m}$ agrees with the standard

action of $so(n)$ on $\mathbb{R}^n$. (Incidentally, that the Heisenberg system (1.1)–(1.3) can be viewed as either an $sl(2,\mathbb{R})$ system or an $so(3)$ system is just a consequence of the fact that $sl(2,\mathbb{R})$ and $so(3)$ are isomorphic Lie algebras.)

We have already noted that the $so(n)$ system (1.4)–(1.5) is a canonical form for those controllable nonholonomic systems for which the first derived algebra $E^1 = E^0 + [E^0, E^0]$ of the control subbundle E^0 spans the tangent space at each point and for which the dimensions of E^0 and E^1 are arithmetically related in a particular way (see Brockett [11]). As partial motivation for considering the more general Lie algebra system (1.8)–(1.9), we expect that this system will turn out to be a canonical form for a wider class of controllable nonholonomic systems satisfying conditions which suitably generalize those characterizing the $so(n)$ system, including certain symmetry conditions. In particular, we suspect that (1.8)–(1.9) is a canonical form for nonholonomic systems occurring in certain homogeneous spaces, such as symmetric spaces.

The problem we consider herein is that of finding a stabilizing control for the general system (1.8)–(1.9). Since the dimension of $\mathfrak{m}$, which is where the control u takes its values, is less than the dimension of the state space $\mathfrak{g}$, the system fails Brockett's necessary condition for the existence of a continuous feedback law (see Brockett [12]). Previous work on the stabilization problem for nonholonomic systems such as the Heisenberg and $so(n)$ systems has focused mainly on the development of either smooth dynamic feedback or nonsmooth static feedback. For the former approach, see Coron [15] and also Pomet [28] and M'Closkey and Murray [25]. A discontinuous, discrete-time approach can be found in Bloch, Reyhanoglu, and McClamroch [10] and Kolmanovsky and McClamroch [23]. Brockett [14], on the other hand, used a stochastic approach. Other interesting work includes that of Liu and Sussmann [24], Sontag [30], Hespanha [21], Khennouf and Canudas de Wit [22], Morse [26], and others. The role of differential flatness in these systems is also interesting; see the work of Sira-Ramirez [29] and of Fliess et al. [19].

In this paper we present a new discontinuous feedback law and an algorithm for its implementation. We also give a rigorous analysis of the convergence of the algorithm. This completely solves the stabilization problem for (1.8)–(1.9), which is more general than the systems considered by others. We stress, however, that our results are new even for the well-known $so(n)$ system (1.4)–(1.5). Our present results are related to our earlier work on the Heisenberg system (1.1)–(1.3) (see Bloch and Drakunov [4], [5], [6]), the $so(n)$ system (1.4)–(1.5) (see Bloch and Drakunov [7]), and the general system (1.8)–(1.9) (see Bloch, Drakunov and Kinyon [8]). However, this paper is not so much an extension of our earlier work as it is a completely new approach to the stabilization problem. In addition we provide insights into the natural geometric structure of the problem.

Stabilizing (1.8)–(1.9), even locally, is a nontrivial task, since, as can be easily seen, linearization in the vicinity of the origin $0 \in \mathfrak{g}$ gives the noncontrollable system

$$\begin{aligned} \dot{x} &= u, \\ \dot{Y} &= 0. \end{aligned}$$

The main difficulty with (1.8)–(1.9) is the fact that stabilization of x leads to the right-hand side of (1.9) being 0. Therefore Y cannot be directly steered to zero when $x = 0$. This simple observation implies that to stabilize the system one needs to make Y converge "faster" than x. The feedback law and algorithm we present in sections 4 and 5 satisfy this criterion. The idea is as follows: we switch back and forth between flows which decrease one of the variables x and Y in norm, while at the same time leaving

the other variable as "unchanged" as possible. One of the most remarkable features of our feedback law is what "unchanged" turns out to mean; for not only does the nondecreasing variable remain constant in norm, it turns out to evolve *isospectrally*. For matrix Lie algebras, the meaning of this is clear; for general Lie algebras, the adjoint representation of the variable in question evolves with constant spectrum.

In the case of the $so(n)$ system, we have an additional feature. As will be seen in sections 4 and 6, in those parts of the algorithm where the skew-symmetric matrix Y is decreasing in norm (as x evolves isospectrally), all of the eigenvalues of Y^TY except for the largest one remain constant. The results in section 4 suggest that this *partial isospectrality* of Y probably generalizes to other Lie algebras.

We conclude this introduction with an outline of what follows. In section 2, we consider the Heisenberg system (1.1)–(1.3). We introduce our control law for this special case and we show that it stabilizes the system. As might be expected, the feedback is a prototype for the more general ones to follow.

In section 3 we introduce the general Lie algebraic setting. We give the specific hypotheses on the Lie algebra $\mathfrak{g}$ and we show that in a certain sense, these hypotheses cannot be weakened in order to have a stabilization problem that can be solved. We prove certain useful operator identities in $\mathfrak{g}$, and we also verify two crucial inequalities which play a role in the proof of the convergence of the stabilization algorithm. The proof of one of the inequalities, (3.12), is rather delicate and relies on the structure of the Lie algebra $\mathfrak{g}$ in an essential way. This turns out to be somewhat obscured in the setting of specific Lie algebras, and provides another justification for considering the general system (1.8)–(1.9) instead of just, say, the $so(n)$ system.

In section 4 we present our discontinuous controls and we analyze the various cases between which we will be switching in our algorithm. As mentioned above, we show that in each of the main cases, one variable decreases in norm while the other evolves isospectrally. We also verify (4.22), which, in $so(n)$, is the key to the previously mentioned partial isospectrality of Y in the case when it is the norm-decreasing variable.

In section 5 we present the stabilization algorithm and we give a rigorous proof of its convergence. Again, the estimates are rather delicate and are most easily seen in the general setting, not in the setting of specific Lie algebras. It is here, as well as in section 3, where it will be shown that the generalization to the Lie algebraic setting is not as straightforward as it seems.

Finally, in section 6 we apply our results to the $so(n)$ system. We show that stabilization will be achieved in, at most, $\lfloor \frac{n}{2} \rfloor$ iterations of our algorithm. We show some numerics in $so(3)$ to illustrate our results.

2. Stabilization of the Heisenberg system. To illustrate part of our full algorithm for stabilization of the system (1.8)–(1.9), we discuss it in the context of the Heisenberg system or nonholonomic integrator (1.1)–(1.3), which we repeat here for convenience:

$$\dot{x} = u, \tag{2.1}$$

$$\dot{y} = v, \tag{2.2}$$

$$\dot{z} = xv - yu. \tag{2.3}$$

The usefulness of stabilization for this system may be illustrated by an application to the kinematics of a knife edge in point contact with a plane surface or the motion of a rolling wheel—the simplest form of "mobile robot" (see, for example, Bloch and

Drakunov [5], Bloch, Reyhanoglu, and McClamroch [10], and Murray and Sastry [27]). One may transform these systems to one of Heisenberg type.

Our model for the control of (2.1)–(2.3) is the following (slightly incomplete) control law:

$$u = -\alpha x + \beta\, z\, y, \tag{2.4}$$

$$v = -\alpha y - \beta\, z\, x, \tag{2.5}$$

where α and β are positive constants. With this choice, the system (2.1)–(2.3) becomes

$$\dot{x} = -\alpha x + \beta z y, \tag{2.6}$$

$$\dot{y} = -\alpha y - \beta z x, \tag{2.7}$$

$$\dot{z} = -\beta z(x^2 + y^2). \tag{2.8}$$

Let $V = x^2 + y^2$. Then

$$\dot{V} = 2(x\dot{x} + y\dot{y}) = 2(\beta x z y - \beta y z x - \alpha x^2 - \alpha y^2) = -2\alpha V. \tag{2.9}$$

There are a number of strategies for choosing α and β to stabilize the system. It is clear from (2.8) that if we initially choose $\alpha = 0$ and $\beta > 0$, then for x or y not equal to zero, z will be driven asymptotically to 0, while (2.9) shows that V will remain fixed. On the other hand for $\alpha > 0$ and $\beta = 0$, V will be driven to 0. All stabilization strategies to be discussed later are generalizations of this simple observation.

Note also from (2.8) the following: for $\alpha = 0$ the rate of convergence for the variable z depends on the initial conditions for V. The greater the value of $V|_{t=0}$, the faster will be the convergence. On the other hand, if $V|_{t=0} = 0$, i.e., if the initial state belongs to the z-axis, then the variable z will not converge at all. In order to initialize motion in this case, one may apply any nonzero control for a short period of time. It may be a constant nonzero vector or any other suitable control. One possibility is to use

$$u = -\alpha(x - x_1),$$
$$v = -\alpha(y - y_1),$$

with some x_1, y_1 such that $x_1^2 + y_1^2 \neq 0$. With this control the state will leave the z-axis. Then the control (2.4), (2.5) can be used with $\alpha = 0$, $\beta > 0$. When the state reaches an ϵ-neighborhood of $z = 0$ (observe that the derivative of z in this mode is just a constant times $-z$), we can switch to $\alpha > 0$, $\beta = 0$; thus stabilizing the state to the origin.

Let us note here that because of the switchings, the above strategy assumes that the control input is a discontinuous function of the state variables. Thus the existence of the corresponding solution of the differential equations (off of the z-axis only) should be understood in the sense of the Filippov definition (see Filippov [18]). In such systems sliding mode behavior (motion along a discontinuity set) is possible, which can be used to stabilize the system (see DeCarlo, Zak, and Drakunov [16] and a generalization of the sliding mode concept in Drakunov and Utkin [17]). In Bloch and Drakunov [4], [5], [7] several methods are given for achieving stability of (2.1)–(2.3) using sliding mode theory.

Similar considerations apply in the general case discussed here, although we will not discuss explicitly sliding mode behavior; only the discrete switching pattern is needed to obtain stability.

3. The general setting. We now consider the general situation. Let $\mathfrak{g}$ be a real semisimple Lie algebra, and let $B : \mathfrak{g} \times \mathfrak{g} \to \mathbb{R}$ be the Killing form of $\mathfrak{g}$. Assume that $\mathfrak{g}$ has a direct sum decomposition $\mathfrak{g} = \mathfrak{h} \oplus \mathfrak{m}$, where $\mathfrak{h}$ is a compactly imbedded subalgebra and the subspace $\mathfrak{m}$ is the orthogonal complement of $\mathfrak{h}$ relative to B. (In the terminology of Helgason [20], $\mathfrak{g}$ is a semisimple orthogonal symmetric Lie algebra. See this reference, especially Chapter V, for subsequent assertions about Lie algebras.) Under these assumptions, the commutation relations $[\mathfrak{h}, \mathfrak{m}] \subseteq \mathfrak{m}$ and $[\mathfrak{m}, \mathfrak{m}] \subseteq \mathfrak{h}$ hold, and the restriction $B|_{\mathfrak{h}\times\mathfrak{h}}$ of the Killing form B to $\mathfrak{h} \times \mathfrak{h}$ is negative definite. In addition, assume that no ideal of $\mathfrak{g}$ is contained in $\mathfrak{h}$. The Jacobi identity together with the commutation relations for $\mathfrak{h}$ and $\mathfrak{m}$ imply that $[\mathfrak{m}, \mathfrak{m}] \oplus \mathfrak{m}$ is an ideal of $\mathfrak{g}$, and thus so is its orthogonal complement relative to B. But this complement is contained in $\mathfrak{h}$, and therefore $[\mathfrak{m}, \mathfrak{m}] = \mathfrak{h}$. In particular, the representation of $\mathfrak{h}$ on $\mathfrak{m}$ is faithful (because the kernel of this representation is B-orthogonal in $\mathfrak{h}$ to $[\mathfrak{m}, \mathfrak{m}]$).

We will consider stabilization of the system (1.8)–(1.9) in $\mathfrak{g}$, which we repeat here for convenience:

$$\dot{x} = u, \tag{3.1}$$

$$\dot{Y} = [u, x], \tag{3.2}$$

where $x, u \in \mathfrak{m}$, $Y \in \mathfrak{h}$. We first show that this system can be analyzed without loss of generality in a more specialized type of Lie algebra.

Under the given hypotheses on $\mathfrak{g}$, there exist B-orthogonal ideals $\mathfrak{g}_+$ and $\mathfrak{g}_-$ with the following properties: (i) $\mathfrak{g} = \mathfrak{g}_+ \oplus \mathfrak{g}_-$ (direct sum), (ii) $\mathfrak{h}_\pm = \mathfrak{g}_\pm \cap \mathfrak{h}$ is compactly imbedded in $\mathfrak{g}_\pm$ and contains no ideal of $\mathfrak{g}_\pm$, and (iii) $\mathfrak{g}_+ = \mathfrak{h}_+ \oplus \mathfrak{m}_+$ is of noncompact type and $\mathfrak{g}_- = \mathfrak{h}_- \oplus \mathfrak{m}_-$ is of compact type, where $\mathfrak{m}_\pm = \mathfrak{g}_\pm \cap \mathfrak{m}$. If we let $x = x_+ + x_-$, $u = u_+ + u_-$, and $Y = Y_+ + Y_-$ denote the corresponding decompositions, then the system (3.1)–(3.2) decomposes into the systems

$$\dot{x}_\pm = u_\pm, \tag{3.3}$$

$$\dot{Y}_\pm = [u_\pm, x_\pm]. \tag{3.4}$$

It follows that to stabilize the system (3.1)–(3.2) in $\mathfrak{g}$, it is enough to stabilize simultaneously the systems (3.3)–(3.4).

We thus assume from now on without loss of generality that $\mathfrak{g}$ is either of noncompact type or of compact type. This implies that the restriction $B|_{\mathfrak{m}\times\mathfrak{m}}$ of B to $\mathfrak{m}$ is positive definite if $\mathfrak{g}$ is of noncompact type and negative definite if $\mathfrak{g}$ is of compact type.

We should stress here that all simple Lie algebras satisfy our assumptions when $\mathfrak{g} = \mathfrak{h} \oplus \mathfrak{m}$ is a Cartan decomposition. Thus the results we obtain in this paper for our general class of Lie algebras apply to many important cases. It is also worth noting that we would gain no generality by weakening our assumptions that $\mathfrak{g}$ is semisimple and that $\mathfrak{h}$ contains no ideal of $\mathfrak{g}$. For example, if we were to assume merely that $\mathfrak{g}$ is effective, that is, that $\mathfrak{h}$ does not contain any elements of the center of $\mathfrak{g}$, then it would follow that $\mathfrak{g}$ would have an additional ideal $\mathfrak{g}_0 = \mathfrak{h}_0 + \mathfrak{m}_0$ of Euclidean type (see Helgason [20]). But in such an ideal, $[u_0, x_0] = 0$, which would imply that Y_0 is constant. Thus stabilization would not be possible. This would still be the case even if we were to keep the semisimplicity, but not the assumption that $\mathfrak{h}$ contains no ideal of $\mathfrak{g}$.

In order to discuss the compact and noncompact cases simultaneously, let

$$\epsilon = \begin{cases} 1 & \text{if } \mathfrak{g} \text{ is of noncompact type,} \\ -1 & \text{if } \mathfrak{g} \text{ is of compact type.} \end{cases} \tag{3.5}$$

We will use the inner product on $\mathfrak{g}$ defined by the Killing form

$$\langle x_1 + Y_1, x_2 + Y_2 \rangle \equiv \epsilon B(x_1, x_2) - B(Y_1, Y_2) \tag{3.6}$$

for $x_1, x_2 \in \mathfrak{m}$, $Y_1, Y_2 \in \mathfrak{h}$. The corresponding norm will be denoted by $\|\cdot\|$.

Now for $x \in \mathfrak{m}$, let

$$M(x) = \epsilon(\text{ad } x)^2|_{\mathfrak{h}}. \tag{3.7}$$

Then $M(x)$ is a nonnegative symmetric operator on $\mathfrak{h}$ relative to the inner product. To see this, note that ad x is B-symmetric if $\mathfrak{g}$ is noncompact and B-skew-symmetric if $\mathfrak{g}$ is compact. In either case, $(\text{ad } x)^2$ is B-symmetric, and thus so is $M(x)$. Note that $(\text{ad } x)^2$ is nonnegative if $\mathfrak{g}$ is noncompact and nonpositive if $\mathfrak{g}$ is compact, and thus introducing ϵ into the definition of $M(x)$ guarantees that it is a nonnegative operator.

Next, for $Y \in \mathfrak{h}$, let

$$N(Y) = -(\text{ad } Y)^2|_{\mathfrak{m}}. \tag{3.8}$$

Then $N(Y)$ is a nonnegative symmetric operator on $\mathfrak{m}$ relative to the inner product. This follows from the fact that ad Y is B-skew-symmetric.

We will make frequent use of two identities relating the operators $M(x)$ and $N(Y)$. First, the Jacobi identity implies

$$[Y, M(x)Y] = \epsilon[x, N(Y)x] \tag{3.9}$$

for all $x \in \mathfrak{m}$, $Y \in \mathfrak{h}$. Second, the invariance of the Killing form implies

$$\langle Y, M(x)Y \rangle = \|[Y, x]\|^2 = \langle x, N(Y)x \rangle \tag{3.10}$$

for all $x \in \mathfrak{m}$, $Y \in \mathfrak{h}$.

We will also require two estimates arising from $M(x)$ and $N(Y)$. First, since $\mathfrak{m}$ and $\mathfrak{h}$ are each invariant under $(\text{ad } x)^2$ for every $x \in \mathfrak{m}$, we have

$$\begin{aligned} \|x\|^2 &= \epsilon \text{tr}((\text{ad } x)^2) = \epsilon \text{tr}((\text{ad } x)^2|_{\mathfrak{m}}) + \epsilon \text{tr}((\text{ad } x)^2|_{\mathfrak{h}}) \\ &= \epsilon \text{tr}((\text{ad } x)^2|_{\mathfrak{m}}) + \text{tr}(M(x)). \end{aligned}$$

This implies the following inequality:

$$\text{tr}(M(x)) \leq \|x\|^2 \tag{3.11}$$

for all $x \in \mathfrak{m}$.

Our second estimate is the following: there exists a constant $0 < \eta < 1$ such that

$$\text{tr}(N(Y)) > \eta \|Y\|^2 \tag{3.12}$$

for all $Y \in \mathfrak{h}$. This fact, which will be crucial for our discussion of the convergence of our algorithm, is probably part of Lie algebra folklore, but the authors are unaware of any reference. We conclude this section with a proof of this result. Since the discussion that follows is somewhat far afield from our stabilization problem, the reader who is more interested in the control-theoretic aspects might wish to skip ahead to section 4.

In addition to the restriction of the Killing form B, the Lie algebra $\mathfrak{h}$ has two other natural invariant forms:

$$B_{\mathfrak{h}}(Y_1, Y_2) = \text{tr}((\text{ad } Y_1)(\text{ad } Y_2)|_{\mathfrak{h}}), \tag{3.13}$$

$$B_{\mathfrak{m}}(Y_1, Y_2) = \text{tr}((\text{ad } Y_1)(\text{ad } Y_2)|_{\mathfrak{m}}) \tag{3.14}$$

for $Y_1, Y_2 \in \mathfrak{h}$. The form $B_\mathfrak{h}$ is just the Killing form of $\mathfrak{h}$ itself, while the form $B_\mathfrak{m}$ is the natural trace form associated with the representation of $\mathfrak{h}$ on $\mathfrak{m}$. All three invariant forms are related by

$$B(Y_1, Y_2) = B_\mathfrak{h}(Y_1, Y_2) + B_\mathfrak{m}(Y_1, Y_2) \tag{3.15}$$

for $Y_1, Y_2 \in \mathfrak{h}$. Also notice that

$$\operatorname{tr}(N(Y)) = -B_\mathfrak{m}(Y, Y) \tag{3.16}$$

for all $Y \in \mathfrak{h}$.

We have already noted that the restriction of B to $\mathfrak{h}$ is negative definite since $\mathfrak{h}$ is compactly imbedded in $\mathfrak{g}$. In addition, $B_\mathfrak{m}$ is negative definite. Indeed, suppose $B_\mathfrak{m}(Z, Z) = 0$ for some $Z \in \mathfrak{h}$. Then the nonpositive symmetric operator $(\operatorname{ad} Z)^2|_\mathfrak{m}$ must be the zero operator (because all of its nonpositive eigenvalues must be 0). Now for all $x \in \mathfrak{m}$, we have $0 = \langle [Z, [Z, x]], x\rangle = -\langle [Z, x], [Z, x]\rangle$, and thus $[Z, x] = 0$. Since $\mathfrak{h}$ acts faithfully on $\mathfrak{m}$, $Z = 0$.

Letting $\mathfrak{z}(\mathfrak{h})$ denote the center of $\mathfrak{h}$, we have

$$\mathfrak{h} = \mathfrak{z}(\mathfrak{h}) + [\mathfrak{h}, \mathfrak{h}], \tag{3.17}$$

a direct sum, which is orthogonal relative to $\langle \cdot, \cdot \rangle$ (that is, relative to B). Indeed, if Z is orthogonal to $[\mathfrak{h}, \mathfrak{h}]$ relative to $\langle \cdot, \cdot \rangle$, then $0 = \langle Z, [Y_1, Y_2]\rangle = -\langle [Y_1, Z], Y_2\rangle$ for all $Y_1, Y_2 \in \mathfrak{h}$. Thus $[Y_1, Z] = 0$ for all $Y_1 \in \mathfrak{h}$, i.e., $Z \in \mathfrak{z}(\mathfrak{h})$. By a similar computation, the subspaces $\mathfrak{z}(\mathfrak{h})$ and $[\mathfrak{h}, \mathfrak{h}]$ are also orthogonal relative to $B_\mathfrak{h}$ and it therefore follows from (3.15) that they are orthogonal relative to $B_\mathfrak{m}$.

The restriction of $B_\mathfrak{h}$ to $[\mathfrak{h}, \mathfrak{h}]$ is negative definite. Indeed, if $B_\mathfrak{h}(Z, Z) = 0$, then the nonpositive symmetric operator $(\operatorname{ad} Z)^2|_\mathfrak{h}$ must be the zero operator. Now for all $Y \in \mathfrak{h}$, we have $0 = \langle [Z, [Z, Y]], Y\rangle = -\langle [Z, Y], [Z, Y]\rangle$, and thus $[Z, Y] = 0$. Therefore $Z \in \mathfrak{z}(\mathfrak{h})$. Since the restriction of $B_\mathfrak{h}$ to $[\mathfrak{h}, \mathfrak{h}]$ is just the Killing form of $[\mathfrak{h}, \mathfrak{h}]$ itself (because $[\mathfrak{h}, \mathfrak{h}]$ is an ideal of $\mathfrak{h}$), it follows that $[\mathfrak{h}, \mathfrak{h}]$ is compact semisimple.

Now since the restrictions of both B and $B_\mathfrak{m}$ to $[\mathfrak{h}, \mathfrak{h}]$ are negative definite and invariant, it follows that each is a positive multiple of $B_\mathfrak{h}$. Thus there exist $c_1, c_2 > 0$ such that

$$B_\mathfrak{m}(Y_1, Y_2) = c_1 B_\mathfrak{h}(Y_1, Y_2) \quad \text{and} \quad B(Y_1, Y_2) = c_2 B_\mathfrak{h}(Y_1, Y_2)$$

for all $Y_1, Y_2 \in [\mathfrak{h}, \mathfrak{h}]$. The relation (3.15) implies $c_2 = 1 + c_1$. Thus let

$$\eta = \frac{c_1}{c_2} = \frac{c_1}{1 + c_1}. \tag{3.18}$$

Then we have the relation

$$B_\mathfrak{m}(Y_1, Y_2) = \eta B(Y_1, Y_2) \tag{3.19}$$

for all $Y_1, Y_2 \in [\mathfrak{h}, \mathfrak{h}]$.

For $Y, Z \in \mathfrak{h}$, write $Y = Y_c + Y_s$ and $Z = Z_c + Z_s$ for the decompositions into $\mathfrak{z}(\mathfrak{h})$ and $[\mathfrak{h}, \mathfrak{h}]$ ("c" = center, "s" = semisimple). Using the orthogonality relative to all three forms as well as (3.15) and (3.19), we compute

$$\begin{aligned} B_\mathfrak{m}(Y, Z) &= B_\mathfrak{m}(Y_c, Z_c) + B_\mathfrak{m}(Y_s, Z_s) \\ &= B(Y_c, Z_c) - B_\mathfrak{h}(Y_c, Z_c) + \eta B(Y_s, Z_s) \\ &= B(Y_c, Z_c) + \eta B(Y_s, Z_s), \end{aligned} \tag{3.20}$$

where we have used the vanishing of $B_{\mathfrak{h}}$ on $\mathfrak{z}(\mathfrak{h})$ to obtain (3.20). Now since $0 < \eta < 1$ and B is *negative* definite, (3.20) and the orthogonality yield

$$\begin{aligned} B_{\mathfrak{m}}(Y,Z) &< \eta B(Y_c,Z_c) + \eta B(Y_s,Z_s) \\ &= \eta B(Y,Z). \end{aligned} \tag{3.21}$$

If we specialize (3.21) to the case $Y = Z$, we obtain

$$B_{\mathfrak{m}}(Y,Y) < \eta B(Y,Y).$$

Multiplying through by -1 (and noting (3.16)) gives (3.12) for all $Y \in \mathfrak{h}$.

4. Controls. We now present our controls for the system (3.1)–(3.2). These are given by

$$\begin{aligned} u &= -\alpha x + \beta[Y,x] - \gamma[Y,[Y,x]] \\ &= -\alpha x + \beta[Y,x] + \gamma N(Y)x, \end{aligned} \tag{4.1}$$

where $\alpha, \beta, \gamma : \mathfrak{g} \to \mathbb{R}$ are functions. We will assume that $\alpha, \gamma \geq 0$ and $\beta\epsilon \leq 0$.

With (4.1) as our choice of u (and using (3.9)), the system (3.1)–(3.2) becomes

$$\dot{x} = -\alpha x + \beta[Y,x] + \gamma N(Y)x, \tag{4.2}$$

$$\begin{aligned} \dot{Y} &= \beta\epsilon M(x)Y + \gamma[N(Y)x,x] \\ &= \beta\epsilon M(x)Y - \gamma\epsilon[Y,M(x)Y]. \end{aligned} \tag{4.3}$$

Using (4.2), we compute

$$\begin{aligned} \frac{d}{dt}\|x\|^2 &= 2\langle x,\dot{x}\rangle \\ &= -2\alpha\langle x,x\rangle + 2\beta\langle x,[Y,x]\rangle + 2\gamma\langle x,N(Y)x\rangle \\ &= -2\alpha\|x\|^2 + 2\gamma\langle x,N(Y)x\rangle. \end{aligned} \tag{4.4}$$

Here the last equality of (4.4) follows because ad Y is B-skew-symmetric. Now let λ_* denote the largest eigenvalue of the symmetric operator $N(Y)$. Then $\langle x,N(Y)x\rangle \leq \lambda_*\|x\|^2$ for all $x \in \mathfrak{m}$, and thus the right-hand side of (4.4) is nonpositive if $\lambda_*\gamma \geq \alpha$. In this case $\|x\|$ is nonincreasing, and we also have that $\|x\|$ is constant if $\alpha = \gamma = 0$.

Using (4.3), we compute

$$\begin{aligned} \frac{d}{dt}\|Y\|^2 &= 2\langle Y,\dot{Y}\rangle \\ &= 2\beta\epsilon\langle Y,M(x)Y\rangle - 2\gamma\epsilon\langle Y,[Y,M(x)Y]\rangle \\ &= 2\beta\epsilon\langle Y,M(x)Y\rangle. \end{aligned} \tag{4.5}$$

Since $\beta\epsilon \leq 0$ and $M(x)$ is a nonnegative operator, it follows that the right-hand side of (4.5) is nonpositive. Thus $\|Y\|$ is nonincreasing in general and is constant if $\beta = 0$.

Our stabilization algorithm will be (necessarily) discontinuous and will require switching of the control (4.1) between the following three cases: (i) $\alpha > 0$, $\beta = \gamma = 0$; (ii) $\alpha = \kappa\lambda_*$, $\gamma = \kappa$, and $\beta = 0$, where, as above, λ_* is the largest eigenvalue of $N(Y)$ and where κ is a positive function; (iii) $\alpha = \gamma = 0$, $\beta\epsilon < 0$. We now discuss the dynamical behavior of the system (4.2)–(4.3) in each of these cases.

Case I. $\alpha > 0$, $\beta = \gamma = 0$.

In this case, the system (4.2)–(4.3) is

$$\dot{x} = -\alpha x, \tag{4.6}$$

$$\dot{Y} = 0. \tag{4.7}$$

The dynamics here are quite clear: x is driven to 0 radially while Y remains fixed. The remarks made in section 2 regarding the Heisenberg system hold here as well; if Y was not already 0 in the first place, implementing the control (4.1) with these parameter values will render the system unstabilizable. Thus this case will only be used if $Y \equiv 0$.

Case II. $\alpha = \kappa\lambda_*$, $\gamma = \kappa$, $\beta = 0$.

As noted above, $\kappa > 0$. In this case, the control (4.1) has the form

$$u = -\kappa\ (\lambda_* x - N(Y)x), \tag{4.8}$$

while the system (4.2)–(4.3) is

$$\dot{x} = -\kappa(\lambda_* x - N(Y)x), \tag{4.9}$$

$$\dot{Y} = -\kappa\epsilon[Y, M(x)Y]. \tag{4.10}$$

In this case, $\|Y\|$ is constant. In addition, (4.10) is a Lax equation in Y. It follows that the spectrum of ad Y is constant. Therefore the spectrum of the operator $N(Y)$ is constant, as are the dimensions of its eigenspaces. In particular, the eigenvalue λ_*, which occurs in (4.9), is constant.

Let $0 \le \lambda_0 < \lambda_1 < \cdots < \lambda_s = \lambda_*$ denote those eigenvalues of $N(Y)$ which are distinct. (Thus $s \le \dim \mathfrak{m} - 1$.) Let $x = x_0 + x_1 + \cdots + x_s$ be the unique decomposition of x into the eigenspaces of $N(Y)$. Then the differential equation (4.9) decouples into the following system of equations in $\mathfrak{m}$:

$$\begin{aligned} \dot{x}_0 &= -\kappa(\lambda_* - \lambda_0)x_0, \\ \dot{x}_1 &= -\kappa(\lambda_* - \lambda_1)x_1, \\ &\vdots \\ \dot{x}_{s-1} &= -\kappa(\lambda_* - \lambda_{s-1})x_{s-1}, \\ \dot{x}_s &= 0. \end{aligned} \tag{4.11}$$

Since $\kappa(\lambda_* - \lambda_j) > 0$ for $j = 0, 1, \ldots, s-1$, it follows that $x_j \to 0$ asymptotically. If we let x_* denote the projection of x onto the λ_*-eigenspace of $N(Y)$, that is, $x_* = x_s$, then noting that $x_* \equiv x_*|_{t=0}$ is constant, we conclude that

$$x \to x_*$$

asymptotically.

Note that (4.9)–(4.10) and (3.9) imply the following:

$$\dot{Y} = -\kappa[x, N(Y)x] = [x, \dot{x}]. \tag{4.12}$$

Since x is converging to a λ_*-eigenvector of $N(Y)$, the right-hand side of (4.9) is converging to 0, and thus $\dot{x}$ is converging to 0. Therefore (4.12) implies that $\dot{Y}$ is converging to 0.

Summarizing this case, we have that Y evolves isospectrally with constant norm and asymptotically vanishing velocity, while x is driven to x_*, its (constant) projection onto the λ_*-eigenspace of $N(Y)$.

Case III. $\alpha = \gamma = 0$, $\beta\epsilon < 0$.
The system (4.2)–(4.3) for this case is

$$\dot{x} = \beta[Y, x], \tag{4.13}$$

$$\dot{Y} = \beta\epsilon M(x)Y. \tag{4.14}$$

In this case, $\|x\|$ is constant. In addition, (4.13) is a Lax equation in x, and thus ad x has constant spectrum. Therefore the spectrum of the operator $M(x)$ is constant, as are the dimensions of its eigenspaces. Let $0 \leq \mu_0 < \mu_1 < \cdots < \mu_r$ denote those eigenvalues of $M(x)$ which are distinct. (Thus $r \leq \dim \mathfrak{h} - 1$.) For $Y \in \mathfrak{h}$, let $Y = Y_0 + \cdots + Y_r$ denote the unique decomposition of Y into the eigenspaces of $M(x)$. Then the differential equation (4.14) decouples into the following system of equations in $\mathfrak{h}$:

$$\begin{aligned} \dot{Y}_0 &= \beta\epsilon\mu_0 Y_0, \\ \dot{Y}_1 &= \beta\epsilon\mu_1 Y_1, \\ &\vdots \\ \dot{Y}_r &= \beta\epsilon\mu_r Y_r. \end{aligned} \tag{4.15}$$

Since $\beta\epsilon\mu_j < 0$ for $j = 1, \ldots, r$, we have that $Y_j \to 0$ asymptotically. If $\mu_0 > 0$, then the same applies to Y_0. Otherwise, if $M(x)$ has $\mu_0 = 0$ as an eigenvalue, then Y_0 remains constant. Thus we have either $Y \to 0$ or $Y \to Y_0$ asymptotically, where $Y_0 \equiv Y_0|_{t=0}$ is constant. In either case, if we let $Y_\#$ denote the projection of Y onto the nullspace of $M(x)$, then noting that $Y_\# \equiv Y_\#|_{t=0}$ is constant, we conclude that

$$Y \to Y_\#$$

asymptotically.

Using system (4.13)–(4.14), we can derive the following equation:

$$\frac{d}{dt}M(x)^n Y = \beta\epsilon[Y, M(x)^n Y] + \beta\epsilon M(x)^{n+1} Y \tag{4.16}$$

for every nonnegative integer n. Indeed, the case $n = 0$ is just (4.14). Using the induction hypothesis, we have for $n > 0$,

$$\begin{aligned} \tfrac{d}{dt}M(x)^n Y = {} & \epsilon[\dot{x}, [x, M(x)^{n-1}Y]] + \epsilon[x, [\dot{x}, M(x)^{n-1}Y]] \\ & + M(x)(\beta\epsilon[Y, M(x)^{n-1}Y] + \beta\epsilon M(x)^n Y). \end{aligned} \tag{4.17}$$

Now

$$[\dot{x}, [x, M(x)^{n-1}Y]] = \beta[[Y, x], [x, M(x)^{n-1}Y]] \tag{4.18}$$

and

$$[x, [\dot{x}, M(x)^{n-1}Y]] = \beta[x, [[Y, x], M(x)^{n-1}Y]], \tag{4.19}$$

while applying the Jacobi identity repeatedly gives

$$\begin{aligned} M(x)[Y, M(x)^{n-1}Y] = {} & [Y, M(x)^n Y] + \epsilon[[x, Y], [x, M(x)^{n-1}Y]] \\ & + \epsilon[x, [[x, Y], M(x)^{n-1}Y]]. \end{aligned} \tag{4.20}$$

Substituting (4.18), (4.19), and (4.20) into (4.17) and simplifying gives (4.16).

Then from (4.16) immediately follows

$$\frac{d}{dt}f(M(x))Y = \beta\epsilon[Y, f(M(x))Y] + \beta\epsilon f(M(x))M(x)Y \tag{4.21}$$

for every real analytic function f. As an interesting special case of this, let $p(\mu)$ be the minimal polynomial of $M(x)$ and assume that $\mu_0 = 0$ is an eigenvalue of $M(x)$ (so that Y does not converge to 0). Then $p(\mu) = \mu q(\mu)$ for some polynomial q. Taking $f = q$ in (4.21) gives

$$\frac{d}{dt}q(M(x))Y = \beta\epsilon[Y, q(M(x))Y]. \tag{4.22}$$

This is a Lax equation, and it follows that the spectrum of $q(M(x))Y$ remains constant. We will see in section 6 what we suggested in the introduction, namely, that in the $so(n)$ case, the constancy of the spectrum of $q(M(x))Y$ implies that Y itself evolves partially isospectrally.

Summarizing this case, we have that x evolves isospectrally with constant norm, Y is driven to $Y_\#$, its (constant) projection onto the nullspace of $M(x)$, and $q(M(x))Y$ evolves with constant spectrum.

As an aside, it is interesting to compare the system of equations in Case III with the double bracket equations discussed in Brockett [13] and Bloch, Brockett, and Ratiu [1], for example. In these papers the isospectral flow $\dot{L} = [L, [L, N]]$ was considered, where L, N live in a compact Lie algebra and N is fixed. This flow is the gradient flow of $\langle L, N\rangle$ on an adjoint orbit of the corresponding Lie group with respect to the so-called normal metric. The second equation of system (4.13)–(4.14) is, on the other hand, of the form $\dot{Y} = \beta\epsilon[X, [X, Y]]$. This equation is *not* isospectral (although it is coupled to the isospectral equation (4.13)), and we have a different function, $\langle Y, Y\rangle$, decreasing along its flow. This, of course, is precisely what we want in the present context. We note also that in this system there is an interesting coupling between two equations involving brackets. This is reminiscent of Bloch and Crouch [3], although there the coupling is between two Lax equations and the overall flow is Hamiltonian.

5. The stabilization algorithm. We now describe our feedback strategy. As before, λ_* denotes the largest eigenvalue of the operator $N(Y)$, x_* denotes the projection of x onto the λ_*-eigenspace of $N(Y)$, and $Y_\#$ denotes the projection of Y onto the nullspace of $M(x)$. Let $\delta > 0$ be a prescribed error tolerance. In an informal pseudocode, our algorithm can be described as follows.

begin

while $\|Y\| \geq \delta$.

1. Let $r = \|x\|$. Implement the control (4.1) with $\alpha = \lambda_*\kappa$, $\gamma = \kappa$, and $\beta = 0$. Then Y evolves isospectrally with constant norm, while x converges to the constant x_*. If $x_* \neq 0$, then go to Step 3.
2. Let z_* denote a fixed λ_*-eigenvector of $N(Y)$ with $\|z_*\| = r\,(1 - 1/\dim\,\mathfrak{m})^{1/2}$. Let $u = -\alpha(x - z_*)$, where $\alpha > 0$. Then x converges to z_*, while Y remains constant.
3. Implement the control (4.1) with $\alpha = \gamma = 0$, $\beta\epsilon < 0$. Then x evolves isospectrally with constant norm, while Y converges to the constant $Y_\#$.

end while

if $\|x\| \geq \delta$, **then**

4. implement the control (4.1) with $\alpha > 0$, $\beta = \gamma = 0$. Then x will converge to 0 radially, while Y remains 0.

end

In Step 1, if α is a constant, then x will converge to x_* in infinite time; if, for example, $\alpha = 1/\|x - x_*\|$, then x will converge in finite time. Similarly, in Step 3, if β is a constant, then Y will converge to $Y_\#$ in infinite time; if, for example, $\beta = 1/\|Y - Y_\#\|$, then Y will converge in finite time. To establish the convergence claim made in Step 2, we simply note that in this case $x(t)$ has the form $x(t) = f(t)z_*$, where $f(t)$ is a scalar-valued function satisfying $\dot{f} = -\alpha(f-1)$, $f(0) = 0$. (For instance, if $\alpha > 0$ is constant, we have $f(t) = 1-e^{-\alpha t}$.) It follows from (3.2) that $\dot{Y} = [u, x] = 0$, so that Y is constant as claimed.

Step 2 is implemented if x converges to 0 in Step 1. One instance where this could happen is if the initial value of x is 0, in which case the first implementation of Step 1 is trivial. More generally, the case where the projection of x onto the λ_*-eigenspace of $N(Y)$ is 0 seems to be the natural higher-dimensional analog of the situation in the Heisenberg system (2.1)–(2.3), where the initial value starts on the z-axis. As in Steps 1 and 3, Step 2 can also be implemented in finite time.

The λ_*-eigenspace of $N(Y)$ will, in general, have dimension greater than 1 (since the nonzero eigenvalues of the B-skew-symmetric operator ad Y come in complex conjugate pairs). Thus there is no unique choice of eigenvector z_* in Step 2. Any lexicographic ordering of the eigenvectors relative to a coordinate basis will suffice as a selection scheme. The rationale behind the particular normalization of z_* will be explained below. (Choices of this type occur naturally in stabilizing nonholonomic systems; see Sontag [30] for comments on this and related robustness issues.)

We will now show that our algorithm successfully stabilizes the system (3.1)–(3.2) by showing that each of $\|x\|$ and $\|Y\|$ can be brought to within the prescribed error tolerance. Note that as soon as the test condition of the while loop fails, that is, as soon as $\|Y\| < \delta$, then the system will be stabilized whether Step 4 needs to be executed or not. Thus we may assume that the initial value of Y satisfies $\|Y\| \geq \delta$ so that the while loop will be executed at least once. If Y ever converges to 0 in Step 3 because $Y_\# = 0$, then the test condition of the while loop will eventually fail. As noted, this is enough to guarantee that the system is stabilizable.

Assume that for every iteration of Step 3, we have $Y_\# \neq 0$. We will show that after finitely many iterations of the while loop, the test condition will fail. In other words, the projection of Y onto the nullspace of $M(x)$ is eventually arbitrarily small in norm. In fact, we will show a stronger result, for when this situation occurs, then it turns out that $\|x\|$ is simultaneously brought to within the error tolerance. Thus as soon as the while loop's test condition fails, the test condition of the if-then statement (Step 4) will also fail, and the system will already be stabilized.

Assume first that Step 3 is about to be executed. Since Step 1 and possibly Step 2 have already been executed, the initial values $x(0) = x_*$ and $Y(0) = Y_*$ satisfy $N(Y_*)x_* = \lambda_* x_*$. As before, let Y_j denote the projection of Y onto the μ_j-eigenspace of $M(x)$. Recall that $Y_\# = Y_0 \equiv Y_0(0)$ throughout Step 3 and that $Y(t) \to Y_\#$ asymptotically. Using the orthogonality of the eigenspaces, we compute

$$\begin{aligned} \|Y_\#\|^2 &= \|Y_*\|^2 - \textstyle\sum_{j=1}^r \|Y_j(0)\|^2 \\ &\leq \|Y_*\|^2 - \frac{1}{\sum_{j=0}^r \mu_j} \textstyle\sum_{j=0}^r \mu_j \|Y_j(0)\|^2. \end{aligned} \tag{5.1}$$

Note that we are using $\mu_0 = 0$. Now using the orthogonality once again, we compute

$$\sum_{j=0}^{r} \mu_j \|Y_j(0)\|^2 = \langle Y_*, \sum_{j=0}^{r} \mu_j Y_j(0) \rangle = \langle Y_*, M(x_*) Y_* \rangle$$

$$= \langle x_*, N(Y_*) x_* \rangle \tag{5.2}$$

$$= \lambda_* \|x_*\|^2. \tag{5.3}$$

Here we have used (3.10) to obtain (5.2). In addition, using (3.11), we have

$$\sum_{j=1}^{r} \mu_j \leq \operatorname{tr}(M(x_*)) \leq \|x_*\|^2. \tag{5.4}$$

Applying (5.3) and (5.4) to (5.1) yields

$$\|Y_\#\|^2 \leq \|Y_*\|^2 - \lambda_*. \tag{5.5}$$

Now using (3.12), we have

$$\lambda_* \geq \frac{1}{\dim \mathfrak{m}} \operatorname{tr}(N(Y_*)) > \frac{\eta}{\dim \mathfrak{m}} \|Y_*\|^2. \tag{5.6}$$

Applying (5.6) to (5.5) gives our final estimate for Step 3

$$\|Y_\#\|^2 < \left(1 - \frac{\eta}{\dim \mathfrak{m}}\right) \|Y_*\|^2. \tag{5.7}$$

Now assume that Step 3 has already been executed and that Step 1 is about to be executed again. Then the initial values $x(0) = x_\#$ and $Y(0) = Y_\#$ in Step 1 satisfy $M(x_\#)Y_\# = 0$. By (3.10), this implies $\langle x_\#, N(Y_\#)x_\# \rangle = 0$. As before, let x_j denote the projection of x into the λ_j-eigenspace of $N(Y)$. Recall that $x_* = x_s \equiv x_s(0)$ throughout Step 1 and that $x(t) \to x_*$ asymptotically. Using the orthogonality of the eigenspaces, we compute

$$\begin{aligned} \|x_*\|^2 &= \|x_\#\|^2 - \textstyle\sum_{j=0}^{s-1} \|x_j(0)\|^2 \\ &\leq \|x_\#\|^2 - \frac{1}{\sum_{j=0}^{s} (\lambda_s - \lambda_j)} \sum_{j=0}^{s} (\lambda_s - \lambda_j) \|x_j(0)\|^2. \end{aligned} \tag{5.8}$$

Using orthogonality again, we compute

$$\sum_{j=0}^{s} (\lambda_s - \lambda_j) \|x_j(0)\|^2 = \lambda_s \|x_\#\|^2 - \langle x_\#, \sum_{j=0}^{s} \lambda_s x_j(0) \rangle$$

$$= \lambda_s \|x_\#\|^2 - \langle x_\#, N(Y_\#) x_\# \rangle$$

$$= \lambda_s \|x_\#\|^2. \tag{5.9}$$

Also

$$\sum_{j=0}^{s} (\lambda_s - \lambda_j) = s\lambda_s - \sum_{j=0}^{s-1} \lambda_j. \tag{5.10}$$

Applying (5.9) and (5.10) to (5.8) gives

$$\|x_*\|^2 \leq \left(1 - \frac{\lambda_s}{s\lambda_s - \sum_{j=0}^{s-1} \lambda_j}\right) \|x_\#\|^2. \tag{5.11}$$

Finally,

$$\frac{\lambda_s}{s\lambda_s - \sum_{j=0}^{s-1}\lambda_j} \geq \frac{1}{s} \geq \frac{1}{\dim\,\mathfrak{m}}, \tag{5.12}$$

and applying (5.12) to (5.11) gives our final estimate for Step 1

$$\|x_*\|^2 \leq \left(1 - \frac{1}{\dim\,\mathfrak{m}}\right)\|x_\#\|^2. \tag{5.13}$$

Now assume Step 2 is executed because $x = 0$ (that is, $x_* = 0$ in Step 1). Rename $x_* = z_*$, where z_* is the chosen λ_*-eigenvector. Then the normalization of z_* described in Step 2 immediately implies (5.13) holds as an equality.

Define two sequences of real numbers as follows: Let a_j and b_j denote, respectively, the initial values of $\|x\|^2$ and $\|Y\|^2$ prior to the $(j+1)$st iteration of the while loop, where $j = 0, 1, \ldots$. Recall that $\|Y\|$ remains constant during Steps 1 and 2 and $\|x\|$ remains constant during Step 3. Our estimates (5.7) and (5.13) imply that the sequences $\{a_j\}$ and $\{b_j\}$ satisfy

$$a_{j+1} \leq \left(1 - \frac{1}{\dim\,\mathfrak{m}}\right)a_j, \tag{5.14}$$

$$b_{j+1} < \left(1 - \frac{\eta}{\dim\,\mathfrak{m}}\right)b_j. \tag{5.15}$$

Since

$$0 < 1 - \frac{1}{\dim\,\mathfrak{m}} < 1 - \frac{\eta}{\dim\,\mathfrak{m}} < 1, \tag{5.16}$$

it follows from (5.14)–(5.15) that the sequences $\{a_j\}$ and $\{b_j\}$ each converge to 0. In particular, it is immediate that each of $\|x\|$ and $\|Y\|$ can be brought to within the prescribed error tolerance $\delta > 0$ in finitely many iterations of the while loop.

In summary, we have proven the following result.

THEOREM 5.1. *The algorithm globally stabilizes the system* (3.1)–(3.2).

We remark while we have used the error tolerance δ above to indicate how the stabilization algorithm works in practice, the formal proof of stability follows from letting δ limit to zero.

6. Example: *so(n).* We consider the $so(n)$ systems (1.4)–(1.5). Let $\mathfrak{g} = so(n+1)$, the Lie algebra of $(n+1)\times(n+1)$ skew-symmetric matrices. As in section 1, we identify the Lie subalgebra

$$\mathfrak{h} \equiv \left\{ \begin{pmatrix} 0 & 0 \\ 0 & Y \end{pmatrix} : Y \in so(n) \right\}$$

with $so(n)$ and the subspace

$$\mathfrak{m} \equiv \left\{ \begin{pmatrix} 0 & -x^T \\ x & 0 \end{pmatrix} : x \in \mathbb{R}^n \right\}$$

with $\mathbb{R}^n$, and the adjoint action of $so(n)$ on $\mathbb{R}^n$ is the standard action. Since $\mathfrak{g}$ is of compact type, $\epsilon = -1$. For $x \in \mathbb{R}^n$, the operator $M(x) : so(n) \to so(n)$ is given by

$$M(x)Y = -[x,[x,Y]] = xx^TY + Yxx^T. \tag{6.1}$$

This satisfies the following minimal polynomial equation:

$$M(x)^2 Y = (x^T x) M(x) Y. \tag{6.2}$$

For $Y \in so(n)$, the operator $N(Y) : \mathbb{R}^n \to \mathbb{R}^n$ is given by

$$N(Y)x = Y^T Y x. \tag{6.3}$$

The control (4.1) in this setting is given by

$$u = -\alpha x + \beta Y x + \gamma Y^T Y x \tag{6.4}$$

for $x \in \mathbb{R}^n$, $Y \in so(n)$, and thus the system (4.2)–(4.3) is

$$\dot{x} = -\alpha x + \beta Y x + \gamma Y^T Y x, \tag{6.5}$$

$$\dot{Y} = -\beta(x x^T Y + Y x x^T) + \gamma(Y^T Y x x^T - x x^T Y^T Y). \tag{6.6}$$

In Case III, with $\alpha = \gamma = 0$, we know from (4.22) that the matrix $M(x)Y - (x^T x)Y$ evolves with constant spectrum. Since $x^T x$ remains constant throughout this case, this means that

$$Y - \frac{1}{x^T x} M(x) Y \tag{6.7}$$

has constant spectrum. Assume now that the system is in its initial configuration for Step 3. Then $Y^T Y x = \lambda_* x$, where λ_* is the largest eigenvalue of $N(Y) = Y^T Y$. Observe that

$$\begin{aligned} M(x)Y &= x x^T Y + Y x x^T = x x^T Y + \tfrac{1}{\lambda_*} Y x x^T Y^T Y \\ &= (x x^T + \tfrac{1}{\lambda_*} Y x x^T Y^T) Y. \end{aligned}$$

We claim the symmetric operator $\frac{1}{x^T x}(x x^T + \frac{1}{\lambda_*} Y x x^T Y^T)$ is actually an orthogonal projector onto the subspace of $\mathbb{R}^n$ spanned by x and Yx. Indeed, using the antisymmetry of Y, we compute

$$\begin{aligned} (x x^T + \tfrac{1}{\lambda_*} Y x x^T Y^T)^2 &= (x^T x) x x^T + \tfrac{1}{\lambda_*^2} Y x x^T Y^T Y x x^T Y^T \\ &= (x^T x)(x x^T + \tfrac{1}{\lambda_*} Y x x^T Y^T). \end{aligned}$$

This establishes our claim. It follows that the operator given by (6.7) is the composition of the orthogonal projector onto the orthogonal complement of the subspace spanned by x and Yx with Y.

In particular, suppose v is an eigenvector of $Y^T Y$ corresponding to a nonzero eigenvalue $\lambda \neq \lambda_*$. Then Yx is also such an eigenvector and $Yv \pm \lambda^{1/2} i v$ are complex eigenvectors of Y itself corresponding to the eigenvalues $\pm \lambda^{1/2} i$, respectively. Both v and Yv are orthogonal to the subspace spanned by x and Yx. The preceding discussion shows that

$$\begin{aligned} (Y - \tfrac{1}{x^T x} M(x) Y) v &= Yv, \\ (Y - \tfrac{1}{x^T x} M(x) Y) Y v &= Y^2 v = -\lambda v. \end{aligned}$$

It follows that

$$\left(Y - \frac{1}{x^T x} M(x)Y\right)(Yv \pm \lambda^{1/2} iv) = \pm\lambda^{1/2} i(Yv \pm \lambda^{1/2} iv),$$

and thus $\pm\lambda^{1/2}i$ are eigenvalues of $Y - \frac{1}{x^T x}M(x)Y$. (Similarly, if v is an eigenvector of Y^TY corresponding to the possible eigenvalue 0, then consideration of Yv shows that 0 is an eigenvalue of $Y - \frac{1}{x^T x}M(x)Y$.) On the other hand, we have

$$(Y - \tfrac{1}{x^T x}M(x)Y)x = 0,$$

$$(Y - \tfrac{1}{x^T x}M(x)Y)Yx = Y^2x + \lambda_* x = 0.$$

We see that the eigenvalues of Y other than $\pm{\lambda_*}^{1/2}i$ are also eigenvalues of $Y - \frac{1}{x^T x}M(x)Y$ with the same multiplicities. It follows that throughout Step 3, the other eigenvalues of Y, and hence Y^TY, will remain constant. (While the preceding discussion seems to assume implicitly that λ_* has multiplicity 1, it is easy to see that the same result applies if there are additional eigenvectors corresponding to λ_*.)

In Step 3, the eigenvalue of Y^TY, whose initial value is λ_*, is the only one that is evolving nontrivially and it will in fact converge to 0. To see this, recall that Y converges to $Y_\#$, the projection of Y onto the nullspace of $M(x)$. It follows that $\frac{1}{x^T x}M(x)Y = \frac{1}{x^T x}(\mu_0 Y_0 + \cdots + \mu_r Y_r)$ will converge to 0, for if $Y_\# = Y_0 \neq 0$, then $\mu_0 = 0$. But as we have just seen, $\pm{\lambda_*}^{1/2}i$ are the only nonzero eigenvalues of $\frac{1}{x^T x}M(x)Y$ at time $t = 0$, and thus they must converge to 0 asymptotically.

These considerations also tell us how many times we can expect the stabilization algorithm to iterate. Indeed, since Y^TY can have at most $\lfloor \frac{n}{2} \rfloor$ distinct positive eigenvalues, stabilization will be achieved in at most $\lfloor \frac{n}{2} \rfloor$ iterations.

Specializing further, let us consider the case $so(3)$. Here Y^TY has only one nonzero eigenvalue, which has multiplicity 2. It follows that after one execution of Step 3, Y will converge to 0. Thus the algorithm will stabilize the system with just one iteration of the while loop.

As a numerical example of this, consider the 6th order system

$$\dot{x} = u, \tag{6.8}$$

$$\dot{Y} = xu^T - ux^T, \tag{6.9}$$

where $x, u \in R^3$, $Y \in so(3)$ with the following initial conditions:

$$x(0) = \begin{pmatrix} 0.2 \\ 1.1 \\ 1.1 \end{pmatrix},$$

$$Y(0) = \begin{pmatrix} 0 & 0.1 & -0.2 \\ -0.1 & 0 & 3.0 \\ 0.2 & -3.0 & 0 \end{pmatrix}.$$

The spectrum of $Y(0)^TY(0)$ is $\{9.05, 9.05, 0\}$.

After we apply Step 1 (with $u = -\lambda_* x + Y^TYx$) over the interval $[0, t_1]$ with $t_1 = 2$ sec, x and Y become, respectively,

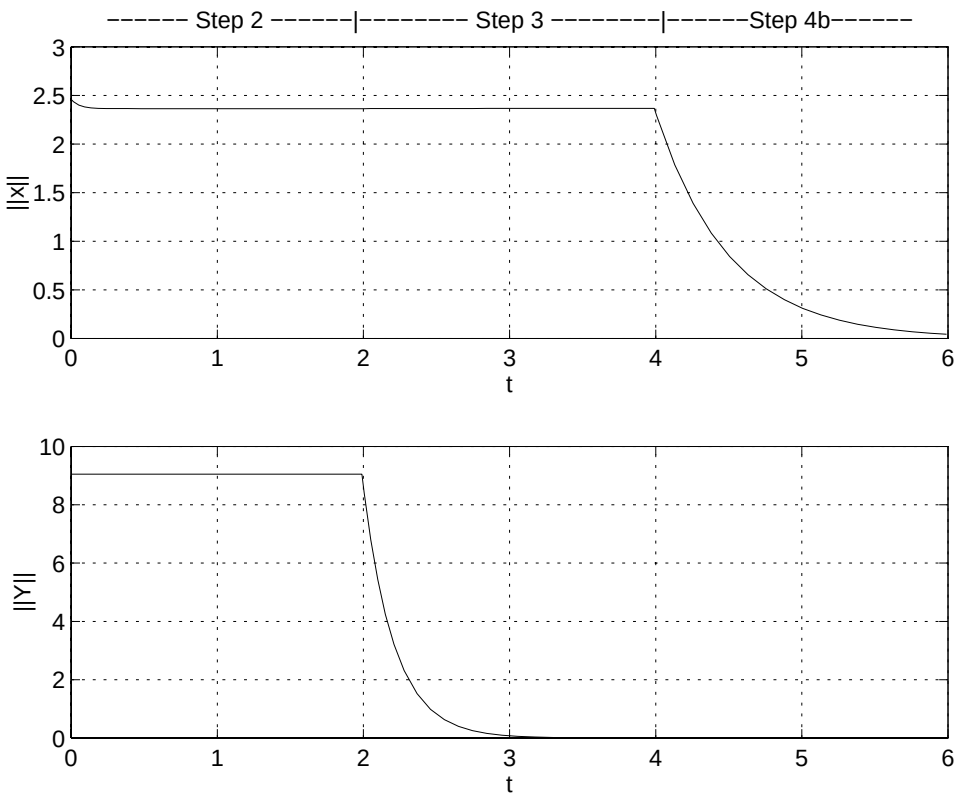

FIG. 6.1. *Numerical example.*

$$x(t_1) = \begin{pmatrix} -0.1076 \\ 1.0966 \\ 1.0726 \end{pmatrix},$$

$$Y(t_1) = \begin{pmatrix} 0 & 0.4359 & 0.1346 \\ -0.4359 & 0 & 2.9738 \\ -0.1346 & -2.9738 & 0 \end{pmatrix}.$$

The spectrum of $Y(t_1)^T Y(t_1)$ remains constant $\{9.05, 9.05, 0\}$ with good accuracy, but as expected, the vector $x(t_1)$ is now the eigenvector corresponding to the eigenvalue $\lambda = 9.05$.

Application of Step 3 (with $u = Yx$) over the interval $[t_1, t_2]$ ($t_2 = 4$ sec) results in the fast decay of $\|Y(t)\|$ to zero as $\|x(t)\|$ remains constant. At the end of this interval, the eigenvalues of $Y(t_2)^T Y(t_2)$ become very small: $\{0.0007, 0.0007, 0\}$.

Finally, Step 4 is executed (with $u = -x$). As expected, x converges to 0 as the value of Y remains unchanged.

Time plots of $\|x(t)\|^2$ and $\|Y(t)\|^2$ are shown in Figure 6.1. The decrease in these magnitudes is clearly seen.

Acknowledgments. We would like to thank Roger Brockett for useful discussions on this material. We would also like to thank the referees for their help in improving the paper.

A CLASS OF TEAM PROBLEMS WITH DISCRETE ACTION SPACES: OPTIMALITY CONDITIONS BASED ON MULTIMODULARITY*

PETER R. DE WAAL†‡ AND JAN H. VAN SCHUPPEN†

Abstract. In this paper we discuss a class of team problems with discrete action spaces. We introduce multimodularity into team theory as a natural alternative to convexity in continuous spaces. The main result relates coordinatewise-optimal (cw-optimal) points to the optimal team decision for a class of team problems. The method is based on a characterization of coordinatewise minima of multimodular functions.

Key words. team theory, multimodularity, person-by-person optimality

1. Introduction.

In 1955 Marschak introduced in [6] *team problems* as a mathematical model for cooperative decision making. In a team problem there are two or more decision makers or controllers who receive a common reward as the joint result of their decisions. The fact that the decision makers have a common objective sets it apart from the models that are usually encountered in game theory. Team problems differ from ordinary decision problems with one controller, since the controllers may have different information on which they have to base their decision. The role of information in control problems is discussed in Witsenhausen [11, 12] and Ho and Chu [3]. For some examples and a tutorial introduction to team problems see Ho [4].

The applications of team problems were at first found in the area of decision making in organizations (see Marschak [6]). Recently the attention in team theory has acquired a new impulse from the area of load balancing in distributed computer systems (see, for instance, Wang and Morris [10]). The environment of high-performance computer networking provides a typical example of a complex and highly-distributed system for which decentralized control and team theory appear to provide the right framework.

Despite a history of more than forty years, there are not that many fundamental results in team theory. The verification of the optimality of a team strategy, for instance, is equivalent to a minimization over a function space, and this is infeasible without additional assumptions. To the best of our knowledge, there are only two papers in the literature that present conditions for optimality of team strategies. Radner presents in [7] a sufficient condition that guarantees optimality: if the cost is a convex function of the decision variables and the expected cost is locally finite and stationary for a given team strategy, then this strategy is optimal. Stationarity is defined as a first-order property of the conditional expectation of the cost given the different information patterns. In the case of a convex cost function stationarity of a strategy implies that it is person-by-person optimal (pbpo). This means that the

expected cost cannot be improved by any player alone if the other team members keep using the same strategy. The importance of this result is twofold. First, it provides a way to verify the optimality of a strategy, and second, it suggests an algorithm to search for the optimal strategy. The local finiteness condition of Radner is relaxed by Krainak, Speyer, and Marcus [5] and replaced with a weaker condition. Both results, however, rely on the fact that the cost function is defined on a continuous space and that it is convex. The continuity makes it possible to compare the expected costs of any two team strategies by effectively constructing a randomization of the strategies. The expected cost of the randomized strategy is then a convex function of the randomization weight and the equivalence of local and global optimality for this one-dimensional convex function ensures the optimality of the stationary strategy.

The primary motivation for our research comes from decentralized control in distributed computer systems. These systems consist of a large number of computers that are interconnected by a network, and they allow sharing of resources and processors. Typically one computer is able to generate processes or tasks that can be performed on the computer itself, or they can be delegated to another processor. In the framework of team theory each computer (or more accurately each process scheduler) is a team player that has to decide for each process that is generated locally where the task has to be performed, locally or on another processor. The action space for such a team problem is intrinsically discrete, and it also does not allow a straightforward extension to a continuous action space. This property prohibits applying the results of [7] and [5].

The aim of this paper is to introduce a framework for team problems with a discrete action space and to present preliminary results for the existence and uniqueness of optima. For the cost function we consider a discrete space analogy for convexity, namely multimodularity. The specific results that were obtained for a class of two-person team problems are as follows:

- we present a characterization of the set of pbpo strategies;
- we give a procedure to check, for any pbpo strategy, in which direction to look for the optimal strategy. Not only does this provide us with an efficient search procedure, but it also enables us to check the optimality of a strategy.

The outline of this paper is as follows. In section 2 we introduce the team problem. A special class of team problems is described in section 3 and we present the optimality conditions for this class. For these conditions we rely on some results on the minima of multimodular functions. These results are summarized in the appendix.

2. Team problems. In this section we introduce our general formulation of the team decision problem. We restrict our attention to a nondynamical team problem.

The following definition of a team problem is based on the definitions of Radner [7] and Krainak, Speyer, and Marcus [5]. We use an underlying probability space $(\Omega, \mathcal{F}, \mathcal{P})$, with Ω the space of elementary events, $\mathcal{F}$ a sigma field of subsets of Ω, and $\mathcal{P}$ a known probability measure on $\mathcal{F}$. We use the letter ω to denote an event, but we do not really distinguish between events and states. In fact we also refer to Ω as the underlying, unobserved, state space, and we also call ω the *state* when it represents an outcome.

A *team* is a set of N decision makers or players. Each player i can choose a decision a_i from a set A_i, the action set. In this paper we assume that the action sets are subsets of $\mathbf{Z}$. Here $\mathbf{Z}$ indicates the set of integers, and $\mathbf{N}$ indicates the set of natural numbers, including 0. If the players choose the action vector $a = (a_1, \ldots, a_N)$ and the state is ω, then a cost $C(a, \omega)$ is incurred. C is a real-valued function that is

measurable with respect to the sigma field generated on the product space $(\mathbf{Z}^m \times \Omega)$ by the Borel sets $\mathcal{B}(\mathbf{Z}^m)$ of $\mathbf{Z}^m$ and by the σ-algebra $\mathcal{F}$. On discrete spaces the σ-algebras are not necessary, but they are retained to simplify the notation and to emphasize the analogy with the case of continuous spaces.

Contrary to a conventional optimal decision problem, we assume that each player has his own observation of the underlying event space. This is implemented as follows. We assume that for each player i there exists an observation space Y_i, a given sigma field $\mathcal{Y}_i$ of subsets of Y_i, and a function $h_i : \Omega \to Y_i$ that is $\mathcal{Y}_i$-measurable. If the event ω occurs, then player i will observe $h_i(\omega)$, and thus each function h_i is a random variable on $(\Omega, \mathcal{F}, \mathcal{P})$. We refer to $\mathcal{Y}_i$ as the *information subfield* of player i, and we define $\mathcal{F}^{h_i} = \{h_i^{-1}(A) \mid A \in \mathcal{Y}_i\}$ as the sigma field that is induced by h_i. The decision that player i makes can depend only on its observation, and thus the set of admissible control laws $\mathcal{U}_i$ for player i is defined by the set of $\mathbf{Z}$-valued functions that are $\mathcal{Y}_i$-measurable. We let $\mathcal{U} = \mathcal{U}_1 \times \cdots \times \mathcal{U}_N$ denote the set of admissible team strategies.

Note that under a strategy γ the team action a is by definition a function of the state ω, i.e., $a = \gamma(h(\omega))$ with $h(\omega) = (h_1(\omega), \ldots, h_N(\omega))$. Under a strategy γ the expected cost of the strategy $J(\gamma)$ is now defined as

$$J(\gamma) = E\{C(\gamma(h(\omega)), \omega)\}, \tag{2.1}$$

where E denotes the expectation with respect to $\mathcal{P}$.

DEFINITION 2.1. *A strategy $\gamma^* \in \mathcal{U}$ is* optimal *if*

$$J(\gamma^*) \leq J(\gamma), \qquad \gamma \in \mathcal{U}. \tag{2.2}$$

The next definition is a variation on the concept of cw-optimality as was introduced in Radner [7]. In that paper a strategy γ is called pbpo if $J(\gamma)$ cannot be improved by changing the strategy for one player alone. The idea that lies behind this definition is that under some extra conditions on the cost function C there exists only one pbpo strategy and this strategy is by the conditions on the cost function then also optimal. As an extra bonus the computation of a pbpo strategy is much easier than for the globally optimal strategy, since the optimization problem in a sense becomes separable. In our model with discrete action spaces we introduce the same concept of pbpo. This is done in a way that is different from [7] and [5], where stationarity is defined by means of the differential of a conditional expectation with respect to the individual decisions. An example of the use of pbpo strategies to determine an optimal solution for a detection problem can be found in [9].

DEFINITION 2.2. *A team strategy $\overline{\gamma} \in \mathcal{U}$ is pbpo if $J(\overline{\gamma}) < \infty$ and for each player i, $i = 1, \ldots, N$,*

$$E\Big[C(\overline{\gamma}(h(\omega)), \omega) \mid \mathcal{F}^{h_i}\Big] \leq E\Big[C(\gamma(h(\omega)), \omega) \mid \mathcal{F}^{h_i}\Big], \qquad (\mathcal{P} - a.s.) \tag{2.3}$$

for all team strategies $\gamma \in \mathcal{U}$ with

$$\gamma_j \equiv \overline{\gamma}_j \text{ for all } j = 1, \ldots, N, \text{ with } j \neq i.$$

A team strategy is called strictly pbpo if the $\leq$ sign in (2.3) *is replaced by a strict inequality ($<$).*

Note that the inequality (2.3) is well defined, since both conditional expectations are random variables on the same probability space. In fact, this implies that the

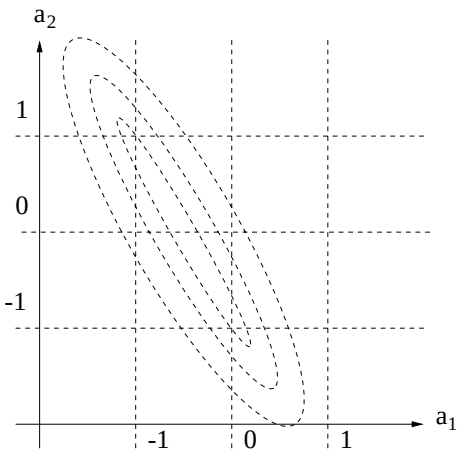

FIG. 2.1. *An example of a continuous convex function restricted to a discrete space.*

inequalities can be replaced by the usual stochastic order (cf. Shaked and Shanthikumar [8, pp. 3, 5]).

If the formulation of the team problem is such that there exists a natural continuation $\overline{C}$ of the cost function from $\mathbf{Z}^N \times \Omega$ to $\mathbf{R}^N \times \Omega$, and $\overline{C}$ is a convex, differentiable and locally finite function, then this continuous version of the problem has a unique optimal solution and this solution is also the only pbpo solution (see Radner [7]). There is no guarantee that restriction to a discrete action space leads to an optimal solution that is in the "neighborhood" of the continuous solution. By neighborhood we mean that the discrete solution is close to the continuous solution, in the usual metric of $\mathbf{R}^N$. Consider for example the cost function

$$C(a_1, a_2, \omega) = (a_1 + 0.5 - \sqrt{3}a_2)^2 + 2(\sqrt{3}(a_1 + 0.5) + a_2)^2 \tag{2.4}$$

for a team problem with only one possible outcome ω, i.e., a deterministic team or an ordinary minimization problem. From the picture of the contour lines as in Figure 2.1, we can see that the continuous minimum is in $(a_1, a_2) = (-0.5, 0)$, while the two integer valued minima are in $(a_1, a_2) = (-1, 1)$ and $(0, -1)$. This example can be modified, however, such that the "discrete" solution is arbitrarily far from the "continuous" solution. Note also that the discrete nature of the problem in this case allows *two* solutions.

In many problems the continuation of C to $\mathbf{R}^N$ may not be as straightforward as in the example. If that is the case, then we might try to construct one. This is where the idea of multimodularity comes in, and it is shown in detail in Hajek [2]. Hajek constructs atoms that span the space $\mathbf{R}^N$. Each atom contains exactly $m+1$ extreme points, and these points lie in $\mathbf{Z}^N$. The continuation $\overline{C}$ of C is piecewise affine on all the atoms. If the function C is multimodular on $\mathbf{Z}^N$, then the continuation of the function is convex in $\mathbf{R}^N$. Unfortunately this continuation is not differentiable, so the results of Radner [7] and Krainak, Speyer, and Marcus [5] cannot be applied here (see also the example in [7, p. 802]). For a justification of the use of multimodular cost functions see the remarks in [2, p. 546] and Bartroli and Stidham [1]. The discussion of multimodularity and its relation to convexity is presented in the appendix.

3. Solution of a class of team problems. In this section we investigate a special class of team problems. It is intended as an example for team problems with

discrete action spaces. It will also serve to indicate the possibilities of using multimodularity properties in solving this kind of team problem. We shall discuss various properties of optimal and cw-optimal strategies. These properties can be used in a procedure to search for the optimal team strategy.

We first need to introduce multimodular functions. For this we consider functions defined on $\mathbf{Z}^m$. We define the vectors $v_0, v_1, \ldots, v_m$ in $\mathbf{Z}^m$ as

$$\begin{aligned} v_0 &= (-1, 0, \ldots, 0), \\ v_1 &= (1, -1, 0, \ldots, 0), \\ v_2 &= (0, 1, -1, 0, \ldots, 0), \\ &\vdots \\ v_{m-1} &= (0, \ldots, 1, -1), \\ v_m &= (0, \ldots, 0, 1), \end{aligned}$$

and we let $\mathcal{V} = \{v_0, v_1, \ldots, v_m\}$. Note that any subset of m vectors of $\mathcal{V}$ is a basis for $\mathbf{Z}^m$, and furthermore we remark that

$$v_0 + v_1 + \cdots + v_m = (0, \ldots, 0). \tag{3.1}$$

DEFINITION 3.1. *A function f on $\mathbf{Z}^m$ for $m \geq 2$ is said to be* multimodular *if for all $z \in \mathbf{Z}^m$,*

$$g(z + v_i) + g(z + v_j) \geq g(z) + g(z + v_i + v_j) \tag{3.2}$$

for any $v_i, v_j \in \mathcal{V}$ and $v_i \neq v_j$.

For a function f on $\mathbf{Z}^m$, $n \in \{1, \ldots, m\}$ and $z \in \mathbf{Z}^m$, we denote the first-order n-difference of f at z as

$$\Delta_n f(z) := f(z + e_n) - f(z), \tag{3.3}$$

where e_n denotes the nth unit vector.

DEFINITION 3.2. *Let f be a real-valued function defined on $\mathbf{Z}^m$. A point $z \in \mathbf{Z}^m$ is called* minimal *for f if $f(z) \leq f(y)$ for all $y \in \mathbf{Z}^m$, $y \neq z$, and it is called* coordinatewise minimal (cw-minimal) *if $f(z) \leq f(z + \lambda e_i)$ for any $i \in \{1, \ldots, m\}$ and any $\lambda \in \mathbf{Z}$, $\lambda \neq 0$. We define a point $z \in \mathbf{Z}^m$ to be* strictly minimal *or* strictly cw-minimal *if these inequalities are replaced by strict inequalities.*

With these definitions we can now introduce the class of team problems that we want to describe. We consider a problem with two players. The underlying event space Ω has three elements, numbered as $\Omega = \{1, 2, 3\}$, and each element occurs with the same probability. We assume that $\mathcal{F}$ is the sigma algebra generated by $\{\{1\}, \{2\}, \{3\}\}$. The action sets for both players are $\mathbf{Z}$.

We assume that the two players have distinctly different information patterns. Player 1 cannot distinguish between events 1 and 2, so $\mathcal{F}^{h_1} = \sigma(\{\{1, 2\}, \{3\}\})$, while player 2 cannot distinguish between events 2 and 3, so $\mathcal{F}^{h_2} = \sigma(\{\{1\}, \{2, 3\}\})$.

For the cost structure we assume the following.

ASSUMPTION 3.3. *For each possible outcome ω, the cost function $C(u_1, u_2, \omega)$ is multimodular as a function of the decision variables $(u_1, u_2) \in \mathbf{Z}^2$.*

In this section we shall discuss the properties of pbpo strategies. For this we shall make use of the classification of cw-minimal points of multimodular functions on $\mathbf{Z}^2$. The following lemma is a direct consequence of the results of Appendix A, but we specifically state it here for easy reference.

LEMMA 3.4. *If $g : \mathbf{Z}^2 \to \mathbf{R}$ is a multimodular function and $y = (y_1, y_2)$ and $z = (z_1, z_2)$ are two distinct strictly cw-minimal points of g, where $z_1 \geq y_1$, then there is some $B > 0$ such that*

1. *$(z_1, z_2) = (y_1 + B, y_2 - B)$;*
2. *for all b, $0 < b < B$, $(y_1 + b, y_2 - b)$ is also cw-minimal;*
3. *if $g(z) > g(y)$, then the minimum of g cannot be in the set $\{(y_1+b, y_2-b)|b \geq B\}$;*
4. *if both y and z, for some $B \geq 0$, are minimal for g, then $(y_1 + b, y_2 - b)$ is minimal for all $0 \leq b \leq B$;*
5. *if both $g(y_1 + 1, y_1 - 1) \geq g(y_1, y_2)$ and $g(y_1 - 1, y_1 + 1) \geq g(y_1, y_2)$, then (y_1, y_2) is minimal; if the inequalities are strict, then the minimum is also unique.*

Proof. See Appendix A, Lemma A.10. □

Note that (strict) multimodularity of a function does not guarantee that the minimum is unique. It can take the form of a line segment $\{(y_1+z, y_2-z) \mid 0 \leq z \leq B\}$ for some $(y_1, y_2) \in \mathbf{Z}^2$ and $B \geq 0$. There can be only one such segment, however.

We now introduce the notation for a team decision strategy. We already saw in section 2 that the observations of the players can be modelled by functions that are defined on the event space. The observations of player 1 are given by a function $h_1 : \Omega \to \{1, 3\}$ of the state, where

$$h_1(\omega) = \begin{cases} 1 & \text{if } \omega = 1, 2, \\ 3 & \text{if } \omega = 3. \end{cases} \tag{3.4}$$

Similarly, we represent the information pattern of player 2 by a function h_2, which is defined as

$$h_2(\omega) = \begin{cases} 1 & \text{if } \omega = 1, \\ 3 & \text{if } \omega = 2, 3. \end{cases} \tag{3.5}$$

With this definition we can now represent a team decision function as $\gamma = (\gamma_{11}, \gamma_{13}, \gamma_{21}, \gamma_{23}) \in \mathbf{Z}^4$, where γ_{ij} represent the action that γ prescribes when player i gets observation j. Finally, we can now write the expected cost $J(\gamma)$ as a function of the team decision rule γ as

$$J(\gamma_{11}, \gamma_{13}, \gamma_{21}, \gamma_{23}) = \frac{1}{3}C(\gamma_{11}, \gamma_{21}, 1) + \frac{1}{3}C(\gamma_{11}, \gamma_{23}, 2) + \frac{1}{3}C(\gamma_{13}, \gamma_{23}, 3). \tag{3.6}$$

In principle, this makes finding the optimal strategy an optimization problem on $\mathbf{Z}^4$.

The properties that γ has to satisfy for optimality and cw-optimality are summarized in the following lemma.

LEMMA 3.5. *A team decision strategy $\gamma^* = ({\gamma_{11}}^*, {\gamma_{13}}^*, {\gamma_{21}}^*, {\gamma_{23}}^*)$ is minimal if*

$$({\gamma_{11}}^*, {\gamma_{13}}^*, {\gamma_{21}}^*, {\gamma_{23}}^*) = \underset{(\gamma_{11}, \gamma_{13}, \gamma_{21}, \gamma_{23}) \in \mathbf{Z}^4}{\arg\min} J(\gamma_{11}, \gamma_{13}, \gamma_{21}, \gamma_{23}), \tag{3.7}$$

or, in other words, if γ^* is a minimum for J. A strategy $\gamma = (\overline{\gamma}_{11}, \overline{\gamma}_{13}, \overline{\gamma}_{21}, \overline{\gamma}_{23})$ is strictly pbpo if J is strictly cw-minimal in γ, or

$$J(\overline{\gamma}_{11}, \overline{\gamma}_{13}, \overline{\gamma}_{21}, \overline{\gamma}_{23}) < J(u_{11}, \overline{\gamma}_{13}, \overline{\gamma}_{21}, \overline{\gamma}_{23}) \text{ for all } u_{11} \in \mathbf{Z}, u_{11} \neq \overline{\gamma}_{11}, \tag{3.8}$$

$$J(\overline{\gamma}_{11}, \overline{\gamma}_{13}, \overline{\gamma}_{21}, \overline{\gamma}_{23}) < J(\overline{\gamma}_{11}, u_{13}, \overline{\gamma}_{21}, \overline{\gamma}_{23}) \text{ for all } u_{13} \in \mathbf{Z}, u_{13} \neq \overline{\gamma}_{13}, \tag{3.9}$$

$$J(\overline{\gamma}_{11}, \overline{\gamma}_{13}, \overline{\gamma}_{21}, \overline{\gamma}_{23}) < J(\overline{\gamma}_{11}, \overline{\gamma}_{13}, u_{21}, \overline{\gamma}_{23}) \text{ for all } u_{21} \in \mathbf{Z}, u_{21} \neq \overline{\gamma}_{21}, \tag{3.10}$$

$$J(\overline{\gamma}_{11}, \overline{\gamma}_{13}, \overline{\gamma}_{21}, \overline{\gamma}_{23}) < J(\overline{\gamma}_{11}, \overline{\gamma}_{13}, \overline{\gamma}_{21}, u_{23}) \text{ for all } u_{23} \in \mathbf{Z}, u_{23} \neq \overline{\gamma}_{23}. \tag{3.11}$$

Proof. The first statement is immediate from the definition of optimality. The second statement follows from the fact that, by definition, a team strategy $\overline{\gamma} = (\overline{\gamma}_{11}, \overline{\gamma}_{13}, \overline{\gamma}_{21}, \overline{\gamma}_{23})$ is strictly pbpo if it satisfies the following set of equations:

$$C(\overline{\gamma}_{11}, \overline{\gamma}_{21}, 1) + C(\overline{\gamma}_{11}, \overline{\gamma}_{23}, 2) < C(\gamma_{11}, \overline{\gamma}_{21}, 1) + C(\gamma_{11}, \overline{\gamma}_{23}, 2), \tag{3.12}$$

$$C(\overline{\gamma}_{13}, \overline{\gamma}_{23}, 3) < C(\gamma_{13}, \overline{\gamma}_{23}, 3), \tag{3.13}$$

$$C(\overline{\gamma}_{11}, \overline{\gamma}_{21}, 1) < C(\overline{\gamma}_{11}, \gamma_{21}, 1), \tag{3.14}$$

$$C(\overline{\gamma}_{11}, \overline{\gamma}_{23}, 2) + C(\overline{\gamma}_{13}, \overline{\gamma}_{23}, 3) < C(\overline{\gamma}_{11}, \gamma_{23}, 2) + C(\overline{\gamma}_{13}, \gamma_{23}, 3) \tag{3.15}$$

for all $\gamma_{11}, \gamma_{13}, \gamma_{21}, \gamma_{23} \in \mathbf{Z}$. For instance, inequality (3.12) is immediate from the definition of pbpo and the fact that $\mathcal{F}^{h_1} = \sigma(\{\{1,2\},\{3\}\})$. Since $C(\overline{\gamma}_{13}, \overline{\gamma}_{23}, 3)$ is independent of $\overline{\gamma}_{11}$, (3.12) thus implies that $J(\overline{\gamma}_{11}, \overline{\gamma}_{13}, \overline{\gamma}_{21}, \overline{\gamma}_{23}) < J(\gamma_{11}, \overline{\gamma}_{13}, \overline{\gamma}_{21}, \overline{\gamma}_{23})$ for all $\gamma_{11} \in \mathbf{Z}$. In a similar way, one can prove the cw-minimality of J for the other components of $\overline{\gamma}$. □

In the remainder of this section we shall exploit the special nature of multimodular functions to derive properties of optima and cw-optima. We show how one can search for other (coordinatewise) minima starting from a cw-minimum. The main result is as follows.

THEOREM 3.6. *If $\alpha = (\alpha_{11}, \alpha_{13}, \alpha_{21}, \alpha_{23})$ and $\beta = (\beta_{11}, \beta_{13}, \beta_{21}, \beta_{23})$ are both strictly pbpo strategies, then they have to satisfy either $M\beta^T \leq M\alpha^T$ or $M\beta^T \geq M\alpha^T$ for*

$$M = \begin{pmatrix} 0 & 1 & 1 & 1 \\ 1 & 0 & 1 & 1 \\ -1 & -1 & 0 & -1 \\ -1 & -1 & -1 & 0 \end{pmatrix}. \tag{3.16}$$

The vector inequality $\leq$ is to be interpreted componentwise, i.e., $z \leq y$ if and only if $z_i \leq y_i$ for all i.

Proof. For any strategy $z = (z_{11}, z_{13}, z_{21}, z_{23})$, the expected cost $J(z)$ for this strategy is

- multimodular in (z_{11}, z_{21}) if (z_{13}, z_{23}) is fixed,
- multimodular in (z_{11}, z_{23}) if (z_{13}, z_{21}) is fixed,
- multimodular in (z_{13}, z_{21}) if (z_{11}, z_{23}) is fixed,
- multimodular in (z_{13}, z_{23}) if (z_{11}, z_{21}) is fixed.

Now assume that α is strictly pbpo. This implies that $\Delta_{11}J(\alpha) > 0$. Using the fact that J is multimodular in (z_{11}, z_{21}) for (z_{13}, z_{23}) fixed, we get that $\Delta_{11}J(\alpha_{11}+m, z_{13}, \alpha_{21}-m, \alpha_{23}) > 0$ for all $m \geq 0$ and all $z_{13} \in \mathbf{Z}$. Note that $\Delta_{11}J(z)$ is independent of z_{13}. Next use the multimodularity of J in (z_{11}, z_{23}) for (z_{13}, z_{21}) fixed to get $\Delta_{11}J(\alpha_{11} + m+n, z_{13}, \alpha_{21}-m, \alpha_{23}-n) > 0$ for all $m, n \geq 0$ and all z_{13}. Finally, use the fact that for any multimodular function f defined on $\mathbf{Z}^2$, $\Delta_i f(x) \leq \Delta_i f(x+e_j)$ for $x \in \mathbf{Z}^2$ and $i, j = 1, 2$, to prove that $\Delta_{11}J(z) > 0$ for all z in

$$\mathcal{G}_{11+} := \{(\alpha_{11} + m + n + i, z_{13}, \alpha_{21} - m + j, \alpha_{23} - n + k) \mid i, j, k, m, n \geq 0, z_{13} \in \mathbf{Z}\}.$$

Specifically, this means that the points in the interior of $\mathcal{G}_{11+}$ cannot be pbpo. With the interior of $\mathcal{G}_{11+}$ we mean the points z with $z_{11} + z_{21} + z_{23} > \alpha_{11} + \alpha_{21} + \alpha_{23}$. Analogously, we can exploit the fact that $\Delta_{11}J(\alpha_{11} - 1, \alpha_{13}, \alpha_{21}, \alpha_{23}) < 0$ to show that $\Delta_{11}J(z) < 0$ for z in

$$\mathcal{G}_{11-} := \{(\alpha_{11} - 1 - m - n - i, z_{13}, \alpha_{21} + m - j, \alpha_{23} + n - k) \mid i, j, k, m, n \geq 0, z_{13} \in \mathbf{Z}\}.$$

In the same manner, we also find that the fact that α is strictly pbpo implies $\Delta_{13}J(z) > 0$ for all z in

$$\mathcal{G}_{13+} := \{(z_{11}, \alpha_{13} + m + n + i, \alpha_{21} - m + j, \alpha_{23} - n + k) \mid i, j, k, m, n \geq 0, z_{13} \in \mathbf{Z}\},$$

and $\Delta_{13}J(z) < 0$ for z in

$$\mathcal{G}_{13-} := \{(z_{11}, \alpha_{13} - 1 - m - n - i, \alpha_{21} + m - j, \alpha_{23} + n - k) \mid i, j, k, m, n \geq 0, z_{11} \in \mathbf{Z}\}.$$

For the decisions of player 2, we get, in a similar manner, $\Delta_{21}J(z) > 0$ for z in

$$\mathcal{G}_{21+} := \{(\alpha_{11} - m + j, \alpha_{13} - n + k, \alpha_{21} + m + n + i, z_{23},) \mid i, j, k, m, n \geq 0, z_{23} \in \mathbf{Z}\},$$

and $\Delta_{21}J(z) < 0$ for all z in

$$\mathcal{G}_{21-} := \{(\alpha_{11} + m - j, \alpha_{13} + n - k, \alpha_{21} - 1 - m - n - i, z_{23},) \mid i, j, k, m, n \geq 0, z_{23} \in \mathbf{Z}\},$$

and finally $\Delta_{23}J(z) > 0$ for z in

$$\mathcal{G}_{23+} := \{(\alpha_{11} - m + j, \alpha_{13} - n + k, z_{21}, \alpha_{23} + m + n + i,) \mid i, j, k, m, n \geq 0, z_{21} \in \mathbf{Z}\},$$

and $\Delta_{23}J(z) < 0$ for z in

$$\mathcal{G}_{23-} := \{(\alpha_{11} + m - j, \alpha_{13} + n - k, z_{21}, \alpha_{23} - 1 - m - n - i,) \mid i, j, k, m, n \geq 0, z_{21} \in \mathbf{Z}\}.$$

Observe that, by the same reasoning as for $\mathcal{G}_{11+}$, there cannot be other pbpo strategies in the interior of any of the $\mathcal{G}$'s.

Now assume that β is also pbpo and $\beta_{11} > \alpha_{11}$. Since β cannot lie in $\mathcal{G}_{11+}$, this implies that

$$\beta_{11} + \beta_{21} + \beta_{23} \leq \alpha_{11} + \alpha_{21} + \alpha_{23}. \tag{3.17}$$

This proves the second inequality of $M\beta^T \leq M\alpha^T$. Since $\beta_{11} > \alpha_{11}$, it also implies that $\beta_{21} + \beta_{23} \leq \alpha_{21} + \alpha_{23}$. This in itself implies that at least one of the inequalities $\beta_{21} \leq \alpha_{21}$ and $\beta_{23} \leq \alpha_{23}$ hold. We shall prove that, in fact, both inequalities hold. Assume that $\beta_{21} > \alpha_{21}$. Since β is pbpo, it cannot lie in the interior of $\mathcal{G}_{21+}$, and thus $\beta_{11} + \beta_{13} + \beta_{21} < \alpha_{11} + \alpha_{13} + \alpha_{21}$. Because of the assumptions on β_{11} and β_{21}, we conclude that $\beta_{13} < \alpha_{13}$. Now β is also outside the interior of $\mathcal{G}_{13-}$, so $\beta_{13} + \beta_{21} + \beta_{23} \geq \alpha_{13} + \alpha_{21} + \alpha_{23}$. This contradicts $\beta_{13} < \alpha_{13}$ and $\beta_{21} + \beta_{23} \leq \alpha_{21} + \alpha_{23}$. We can thus conclude that both $\beta_{21} \leq \alpha_{21}$ and $\beta_{23} \leq \alpha_{23}$.

Since $\beta_{21} \leq \alpha_{21}$ and β is outside of the interior of $\mathcal{G}_{21-}$, this implies

$$\beta_{11} + \beta_{13} + \beta_{21} \geq \alpha_{11} + \alpha_{13} + \alpha_{21}, \tag{3.18}$$

and this proves the fourth component of the matrix inequality. Analogously to the reasoning above, we conclude from this that $\beta_{13} \geq \alpha_{13}$. This, together with the fact that β is outside of the interior of $\mathcal{G}_{13+}$, implies

$$\beta_{13} + \beta_{21} + \beta_{23} \leq \alpha_{13} + \alpha_{21} + \alpha_{23}, \tag{3.19}$$

the first inequality, and finally $\beta_{23} \leq \alpha_{23}$ leads us to

$$\beta_{11} + \beta_{13} + \beta_{23} \geq \alpha_{11} + \alpha_{13} + \alpha_{23}, \tag{3.20}$$

the third inequality.

If we start with $\beta_{11} < \alpha_{11}$, then this same reasoning gives us $M\beta^T \geq M\alpha^T$. The case where $\beta_{11} = \alpha_{11}$ is treated in the following lemma. □

Note that the proof of Theorem 3.6 does not depend on the particular information patterns of this problem. It is based solely on the additive structure of the expected cost and on the multimodularity of the cost function.

Theorem 3.6 provides us with a characterization of the areas around a known pbpo strategy, where we might find other pbpo strategies. If we want to design a search procedure, then we may want to know in which direction we have to search in the immediate neighborhood of α. By immediate neighborhood of α we refer to those strategies β, with $|\beta_{ij} - \alpha_{ij}| \leq 1$ for all coefficients β_{ij}. The following lemmas provide us with the necessary results.

LEMMA 3.7. *If $\alpha = (\alpha_{11}, \alpha_{13}, \alpha_{21}, \alpha_{23})$ and $\beta = (\beta_{11}, \beta_{13}, \beta_{21}, \beta_{23})$ are both strictly pbpo strategies and $\alpha \neq \beta$, then*

- *if $\alpha_{11} = \beta_{11}$, then $\alpha_{21} = \beta_{21}$,*
- *if $\alpha_{23} = \beta_{23}$, then $\alpha_{13} = \beta_{13}$.*

Proof. Assume that $\alpha_{11} = \beta_{11}$. Define $g(z_{13}, z_{21}, z_{23}) := J(\alpha_{11}, z_{13}, z_{21}, z_{23})$; then

$$g(z_{13}, z_{21}, z_{23}) = \frac{1}{3}\Big[C(\alpha_{11}, z_{21}, 1)\Big] + \frac{1}{3}\Big[C(\alpha_{11}, z_{23}, 2) + C(z_{13}, z_{23}, 3)\Big].$$

It is clear that g is a convex function of z_{21} on $\mathbf{Z}$, and that $\alpha_{21} = \arg\min_{z_{21} \in \mathbf{Z}} g(z_{13}, z_{21}, z_{23})$ is independent of z_{13} and z_{23}. Since both α and β are pbpo, they are cw-minimal for g and thus $\alpha_{21} = \beta_{21}$. The proof for $\alpha_{23} = \beta_{23}$ proceeds analogously. □

Lemma 3.7 does not tell us what happens if $\alpha_{13} = \beta_{13}$ or $\alpha_{21} = \beta_{21}$. It appears that we can construct two strictly pbpo strategies α and β that have some components in common. All these possibilities are summarized in the next lemma.

LEMMA 3.8. *If $\alpha = (\alpha_{11}, \alpha_{13}, \alpha_{21}, \alpha_{23})$ and $\beta = (\beta_{11}, \beta_{13}, \beta_{21}, \beta_{23})$ are two distinct strictly pbpo strategies, then one of the following possibilities holds:*

1. *α and β differ in at least two components,*
2. $(\alpha_{11}, \alpha_{13}) \neq (\beta_{11}, \beta_{13})$,
3. $(\alpha_{21}, \alpha_{23}) \neq (\beta_{21}, \beta_{23})$,
4. $(\alpha_{11}, \alpha_{23}) \neq (\beta_{11}, \beta_{23})$.

Proof. Part 1. Assume that the statement is false and that, for instance, α_{11} and β_{11} are the only two coefficients that are different. This implies $C(\alpha_{11}, \alpha_{21}, 1) + C(\alpha_{11}, \alpha_{23}, 2) < C(\beta_{11}, \alpha_{21}, 1) + C(\beta_{11}, \alpha_{23}, 2) = C(\beta_{11}, \beta_{21}, 1) + C(\beta_{11}, \beta_{23}, 2) < C(\alpha_{11}, \beta_{21}, 1) + C(\alpha_{11}, \beta_{23}, 2)$. This gives a contradiction, since $\alpha_{21} = \beta_{21}$ and $\alpha_{23} = \beta_{23}$.

Parts 2 and 3. Assume $(\alpha_{11}, \alpha_{13}) = (\beta_{11}, \beta_{13})$. Consider the function $g(z_{21}, z_{23})$ defined as $J(\alpha_{11}, \alpha_{13}, z_{21}, z_{23})$, so

$$g(z_{21}, z_{23}) = \frac{1}{3}\Big[C(\alpha_{11}, z_{21}, 1) + C(\alpha_{11}, z_{23}, 2) + C(\alpha_{13}, z_{23}, 3)\Big] =: g_1(z_{21}) + g_2(z_{23}).$$

Since α is a strictly pbpo strategy, $(\alpha_{21}, \alpha_{23})$ must be cw-minimal for g. The function g is multimodular in (z_{21}, z_{23}), and thus g_1 and g_2 are convex functions of z_{21} and z_{23}, respectively. This implies that g has a unique minimum, so $\alpha = \beta$.

Part 4. From Lemma 3.7, we see that $\alpha_{11} = \beta_{11}$ implies $\alpha_{21} = \beta_{21}$ and $\alpha_{23} = \beta_{23}$ implies $\alpha_{13} = \beta_{13}$. □

Now assume that we have found a pbpo strategy α, and we want to check the strategies in the neighborhood of α to see whether they are pbpo. Among the pbpo

strategies we can then check the value of the expected cost J for optimality. The neighborhood of a strategy α is the set

$$\{(\beta_{11}, \beta_{13}, \beta_{21}, \beta_{23}) \mid |\beta_{ij} - \alpha_{ij}| \leq 1, \quad i = 1, 2, \ j = 1, 3\}.$$

Note that there are 80 strategies (excluding α) in this set. If we combine the results of Theorem 3.6 and Lemmas 3.7 and 3.8, the following corollary shows how 68 of these strategies can be eliminated.

COROLLARY 3.9. *If $\alpha = (\alpha_{11}, \alpha_{13}, \alpha_{21}, \alpha_{23})$ is a strictly pbpo strategy, then the set of possible pbpo strategies in the neighborhood of α are the strategies of the form $\beta = \alpha \pm \epsilon$ with $\epsilon \in \{(1, 0, -1, 0), (0, 1, 0, -1), (1, 0, 0, -1), (1, 0, -1, -1), (1, 1, 0, -1), (1, 1, -1, -1)\}$. Outside of this set there cannot be pbpo strategies in the neighborhood of α.*

Proof. We sketch the proof in three steps.

1. Assume that a pbpo strategy $\beta = \alpha + \epsilon$ is of the form $\epsilon = (1, -1, \epsilon_{21}, \epsilon_{23})$ for any $\epsilon_{21}, \epsilon_{23} \in \{-1, 0, 1\}$. We show that β cannot satisfy $M\beta^T \leq M\alpha^T$, since then the third and fourth matrix inequalities imply that $\alpha_{21} \leq \beta_{21}$ and $\alpha_{23} \leq \beta_{23}$. These again imply via the first and last inequalities that $\alpha_{11} \geq \beta_{11}$ and $\alpha_{13} \geq \beta_{13}$, and this gives a contradiction with the assumption on the signs of the first two coefficients of ϵ. The inequality $M\beta^T \geq M\alpha^T$ gives a similar contradiction. Analogously, we can show that ϵ cannot be of the form $\epsilon = (-1, 1, \epsilon_{21}, \epsilon_{23})$ or $\pm(\epsilon_{11}, \epsilon_{13}, 1, -1)$.

2. Assume that a pbpo strategy $\beta = \alpha + \epsilon$ is of the form $\epsilon = (1, \epsilon_{13}, \epsilon_{21}, 1)$ for any ϵ_{13}, $\epsilon_{21} \in \{-1, 0, -1\}$. If β were to satisfy $M\beta^T \leq M\alpha^T$, then this would imply $\epsilon_{21} \leq 2$, while $M\beta^T \geq M\alpha^T$ would imply $\epsilon_{21} \geq 2$. Both contradictions show that the ϵ cannot be of the proposed form. Similarly, we can show that ϵ cannot be of the forms $\pm(1, \epsilon_{13}, 1, \epsilon_{23})$, $\pm(\epsilon_{11}, 1, 1, \epsilon_{23})$, or $\pm(\epsilon_{11}, 1, \epsilon_{21}, 2)$.

3. Combine 1 and 2 to get the possible candidates of ϵ. ∎

Note that within this set there are pairs of strategies that differ in exactly one coefficient, and thus of these pairs only one can be strictly pbpo. Furthermore, for any ϵ in the set of Corollary 3.9, both $\alpha + \epsilon$ and $\alpha - \epsilon$ can be pbpo, but at most one of these two strategies can have an expected cost smaller than $J(\alpha)$ (see Lemma A.6). Finally, if it turns out that $J(\alpha + \epsilon) \geq J(\alpha)$ for some ϵ, then the same lemma ensures that $J(\alpha + k\epsilon) \geq J(\alpha)$ for all $k \in \mathbf{N}$, and thus these points cannot be minimal. In immediate consequence of this is the following, which can be proven analogously to part 5 of Lemma 3.4.

COROLLARY 3.10. *If α is a strictly pbpo strategy and for all ϵ as in Corollary 3.9 we have $J(\alpha+\epsilon) \geq J(\alpha)$ and $J(\alpha-\epsilon) \geq J(\alpha)$, then α is minimal. If all the inequalities are strict, then α is the unique optimal strategy.*

This concludes our exploration of this class of team problems. We have developed a check for the optimality of a team strategy, and we have given the description of a procedure to search for the optimal strategy.

4. Conclusions. In this paper we have discussed team problems with discrete action spaces. Inspired by known results for problems on continuous spaces with convex cost functions, we have introduced multimodularity as a natural abstraction of convexity onto discrete spaces.

In the class of team problems of section 3, we have seen that multimodularity of the cost function translates to properties for the expected cost as a function of the strategy. These properties allow us to check for optimality of a strategy, and they indicate how the complexity of a search for the optimum can be reduced. The example, however, indicates that the complexity is still rather high, and we feel that it must be

possible to reduce it even more by exploiting the multimodularity even further. This is a topic for future research.

If we extend the results of section 3 to a model with a larger observation space for both players, then most of the results of the section remain valid. The proof of Theorem 3.6 relies only on the multimodularity of the cost function and not on the structure of the information patterns. This means that it is a straightforward exercise to extend the results of Theorem 3.6 to a larger observation space. In Lemmas 3.7 and 3.8, the particular structure of the information patterns *is* used, and any extension in this direction has to be done on an ad hoc basis.

Extending the team problem to more than two players is not a trivial task. If we try to mimic the proof of Theorem 3.6 for an example with three players, then even for small observation spaces it is not clear if a matrix inequality of the form $M\alpha^T \leq M\beta^T$ will hold and what the form of M will be.

Appendix A. Multimodular functions and optimality.

In this appendix, we introduce the concept of multimodular functions. Furthermore, we define cw-optimality for this class of functions, and we show its relation to ordinary optimality. We present a classification of cw-optimal points, and we specify a procedure to search for the optimum. For a more elaborate introduction to multimodular functions, we refer to Hajek [2].

We consider functions defined on $\mathbf{Z}^m$. We define the vectors $v_0, v_1, \ldots, v_m$ in $\mathbf{Z}^m$ as

$$\begin{aligned} v_0 &= (-1, 0, \ldots, 0), \\ v_1 &= (1, -1, 0, \ldots, 0), \\ v_2 &= (0, 1, -1, 0, \ldots, 0), \\ &\vdots \\ v_{m-1} &= (0, \ldots, 1, -1), \\ v_m &= (0, \ldots, 0, 1), \end{aligned}$$

and we let $\mathcal{V} = \{v_0, v_1, \ldots, v_m\}$. Note that any subset of m vectors of $\mathcal{V}$ is a basis for $\mathbf{Z}^m$, and furthermore we remark that

$$v_0 + v_1 + \cdots + v_m = (0, \ldots, 0). \tag{A.1}$$

Definition A.1. *A function f on $\mathbf{Z}^m$ for $m \geq 2$ is said to be* multimodular *if for all $z \in \mathbf{Z}^m$,*

$$g(z + v_i) + g(z + v_j) \geq g(z) + g(z + v_i + v_j) \tag{A.2}$$

for any $v_i, v_j \in \mathcal{V}$, and $v_i \neq v_j$.

For a function f on $\mathbf{Z}^m$, $n \in \{1, \ldots, m\}$, and $z \in \mathbf{Z}^m$ we denote the first-order n-difference of f at z as

$$\Delta_n f(z) := f(z + e_n) - f(z), \tag{A.3}$$

where e_n denotes the nth unit vector.

Definition A.2. *Let f be a real-valued function defined on $\mathbf{Z}^m$. A point $z \in \mathbf{Z}^m$ is called* minimal *for f if $f(z) \leq f(y)$ for all $y \in \mathbf{Z}^m$, $y \neq z$, and it is called* coordinatewise minimal (cw-minimal) *if $f(z) \leq f(z + \lambda e_i)$ for any $i \in \{1, \ldots, m\}$ and any $\lambda \in \mathbf{Z}$, $\lambda \neq 0$. We define a point $z \in \mathbf{Z}^m$ to be* strictly minimal *or* strictly cw-minimal *if these inequalities are replaced by strict inequalities.*

Note that of course a minimal point is also cw-minimal. The following lemma gives an indication of the properties of cw-optimal points of a multimodular function.

LEMMA A.3. *Let z^* be a strictly cw-minimal point of a multimodular function f, let z be any point in $\mathbf{Z}^m$, and let the coordinates of $z - z^*$ with respect to the bases $\{v_1, \ldots, v_m\}$ and $\{v_0, \ldots, v_{m-1}\}$ be*

$$z - z^* = k_1 v_1 + k_2 v_2 + \cdots + k_m v_m \tag{A.4}$$

and

$$z - z^* = l_0 v_0 + l_1 v_1 + \cdots + l_{m-1} v_{m-1}, \tag{A.5}$$

respectively.

A. *If $k_i > 0$ for all $i = 1, \ldots, m$, then $0 < \Delta_1 f(z - e_1)$, and thus z is not cw-minimal.*
B. *If $k_i < 0$ for all $i = 1, \ldots, m$, then $\Delta_1 f(z) < 0$, and z is not cw-minimal.*
C. *If $l_i > 0$ for all $i = 0, \ldots, m-1$, then $\Delta_m f(z) < 0$, and z is not cw-minimal.*
D. *If $l_i < 0$ for all $i = 0, \ldots, m-1$, then $0 < \Delta_m f(z - e_1)$, and z is not cw-minimal.*

Proof. For statement A we assume, without loss of generality, that $z^* = 0$, and let $z \in \mathbf{Z}^m$ be $z = k_1 v_1 + \cdots + k_m v_m$. From the definition of multimodularity, we get, by taking $v_i = v_0 = (-1, 0, \ldots, 0)$:

$$f(u - e_1) - f(u) \geq f(u - e_1 + v_j) - f(u + v_j)$$

for all $u \in \mathbf{Z}^m$ and all $v_j \in \mathcal{V}, v_j \neq v_0$. Since u is arbitrary, we can rewrite this as

$$\Delta_1 f(u) \leq \Delta_1 f(u + v_j), \quad u \in \mathbf{Z}^m,\ v_j \in \mathcal{V},\ v_j \neq v_0. \tag{A.6}$$

Note that $-e_1 = v_0 = -v_1 - v_2 - \cdots - v_m$, so

$$z - e_1 = (k_1 - 1)v_1 + (k_2 - 1)v_2 + \cdots + (k_m - 1)v_m,$$

where, by assumption, $k_i - 1 \geq 0$ for all i. By repeated application of (A.6), we thus get

$$\Delta_1 f(z - e_1) \geq \Delta_1 f(0) > 0.$$

From $\Delta_1 f(z - e_1) > 0$ follows that z cannot be a cw-minimal point, and this proves A.

For statement B we note that if $z^* = 0$ is a strictly cw-minimal point, then $\Delta_1 f(-e_1) < 0$, and

$$\begin{aligned} \Delta_1 f(z) &= \Delta_1 f(k_1 v_1 + \cdots + k_m v_m) \\ &= \Delta_1 f(-e_1 + (k_1 + 1)v_1 + \cdots + (k_m + 1)v_m) \\ &\leq \Delta_1 f(-e_1) \\ &< 0, \end{aligned}$$

so z is not cw-minimal.

For statements C and D, note that $v_m = e_m$, so the proof is analogous to cases A and B by showing that (A.6) now becomes

$$\Delta_m f(u) \geq \Delta_m f(u + v_j), \quad u \in \mathbf{Z}^m,\ v_j \in \mathcal{V},\ v_j \neq v_m.$$

This concludes the proof. □

To continue with a classification of cw-optimal points, we introduce the following definition of cones and atoms.

DEFINITION A.4. *For $z \in \mathbf{Z}^m$, define the following polyhedral cones:*

$$C_{0+}(z) = \{u \in \mathbf{Z} \mid u = z + k_1 v_1 + \cdots + k_m v_m,\ k_i \in \mathbf{Z},\ k_i > 0\}, \tag{A.7}$$

$$C_{0-}(z) = \{u \in \mathbf{Z} \mid u = z + k_1 v_1 + \cdots + k_m v_m,\ k_i \in \mathbf{Z},\ k_i < 0\}, \tag{A.8}$$

$$C_{m+}(z) = \{u \in \mathbf{Z} \mid u = z + k_0 v_0 + \cdots + k_{m-1} v_{m-1},\ k_i \in \mathbf{Z},\ k_i > 0\}, \tag{A.9}$$

$$C_{m-}(z) = \{u \in \mathbf{Z} \mid u = z + k_0 v_0 + \cdots + k_{m-1} v_{m-1},\ k_i \in \mathbf{Z},\ k_i < 0\}. \tag{A.10}$$

We let $C(z)$ denote the union

$$C(z) = C_{0+}(z) \cup C_{0-}(z) \cup C_{m+}(z) \cup C_{m-}(z). \tag{A.11}$$

From Lemma A.3 we know that if z is a strictly cw-minimal point, then there are no other cw-minimal points in $C(z)$. This means that if we start from a known cw-minimal point z, then we have to search only the complement of $C(z)$ for other possible cw-minimal points. This complement can be characterized by means of a simplicial decomposition of $\mathbf{R}^m$. We now continue with a brief introduction to this decomposition. For a detailed discussion, we refer to Hajek [2].

DEFINITION A.5. *We let Σ denote the set of permutations of $\{0, \ldots, m\}$. Let $\sigma \in \Sigma$ and $z \in \mathbf{Z}^m$. The set $\{u_0, \ldots, u_m\}$ of extreme points of the atom $S(z, \sigma)$ is defined as follows:*

$$\begin{aligned} u_0 &= z, \\ u_1 &= u_0 + v_{\sigma(1)}, \\ u_2 &= u_1 + v_{\sigma(2)}, \\ &\vdots \\ u_m &= u_{m-1} + v_{\sigma(m)}; \end{aligned}$$

hence $u_0 = u_m + v_{\sigma(0)}$. The atom $S(z, \sigma) \subset \mathbf{R}^m$ is thus the set of convex combinations of $\{u_0, \ldots, u_m\}$: $S(z, \sigma) = \{\sum_{i=0}^m a_i u_i \in \mathbf{Z}^m \mid a_i \in \mathbf{R}_+, \sum_{i=0}^m a_i = 1\}$. We denote $S(z, \sigma) = \langle u_0, \ldots, u_m \rangle$.

Each atom is in fact a simplex, since it contains exactly $m + 1$ extreme points in $\mathbf{Z}^m$. Examples of atoms in two and three dimensions are depicted in Figure A.1. In $\mathbf{R}^2$ the atoms are triangles. In $\mathbf{R}^3$ each atom is bounded by four triangles, and each of the triangles that belong to the same atom share exactly one side.

The atoms allow the following alternative characterization of multimodularity. Every atom S contains exactly $m + 1$ points $\{u_0, \ldots, u_m\}$, so for any function f defined on $\mathbf{Z}^m$, there is a unique affine function $L_S(z)$ that agrees with f on the $m + 1$ extreme points. If f is multimodular, then $L_S(z) \leq f(z)$ for $z \in \mathbf{Z}^m$ (see Hajek [2, Lemma 4.2]). The entire $\mathbf{R}^m$ can be decomposed uniquely into atoms of the form $S(z, \sigma)$, and for a function f defined on $\mathbf{Z}^m$ we can thus uniquely construct a continuous function $\underline{f}$ on $\mathbf{R}^m$ that is piecewise affine on all the atoms $S(z, \sigma)$, $z \in \mathbf{Z}^m$. If f is a multimodular on $\mathbf{Z}^m$, then this $\underline{f}$ is a convex function on $\mathbf{R}^m$.

The next property of multimodular functions will be used a couple of times in this paper, so for this reason we state it here explicitly.

LEMMA A.6. *If f is a multimodular function, then $f(z + ke_i)$ is a convex function of $k \in \mathbf{Z}$ for any $z \in \mathbf{Z}$ and unit vector e_i, $i = 1, \ldots, m$.*

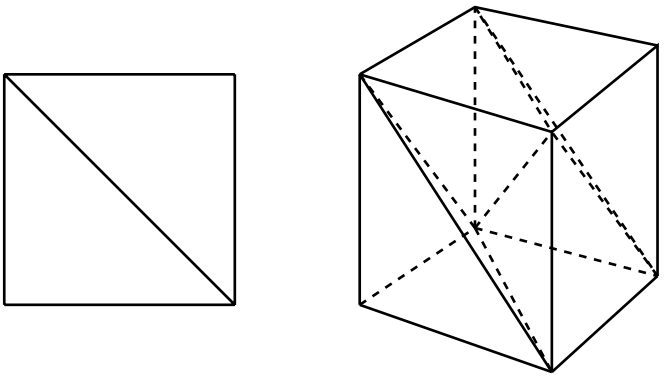

FIG. A.1. *Atoms in two and three dimensions.*

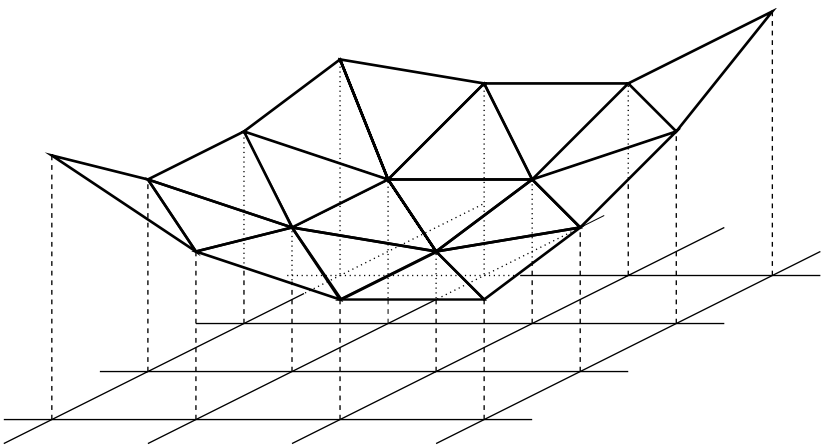

FIG. A.2. *Example of a multimodular function in* $\mathbf{Z}^2$.

Proof. Let $z \in \mathbf{Z}^m$ and e_i be some unit vector. Let S be an atom that contains both z and $z + e_i$. Such an atom exists, since $e_i = v_i + \cdots + v_m$. Using $L_S(z) \leq f(z)$ for this atom, we get

$$\Delta_i f(z) = f(z + e_i) - f(z) = L_S(z + e_i) - L_S(z) = L_S(z + 2e_i) - L_S(z + e_i)$$

$$\leq f(z + 2e_i) - f(z + e_i) = \Delta_i f(z + e_i).$$

The third equality is due to the fact that L_S is affine. □

In a similar manner, we may conclude that in fact for any vector $v \in \mathcal{V}$ and for any $z \in \mathbf{Z}$, the function $f(z + kv)$ is convex in $k \in \mathbf{Z}$.

For an example of a multimodular function on $\mathbf{Z}^2$, see Figure A.2. The atoms that decompose $\mathbf{R}^2$ were depicted in Figure A.1.

DEFINITION A.7. *For an atom* $S(z, \sigma)$, $z \in \mathbf{Z}^m$, $\sigma \in \Sigma$, *we define* $C_\sigma(z)$ *as the polyhedral cone in* $\mathbf{Z}^m$:

$$C_\sigma(z) = \Big\{ u \in \mathbf{Z}^m \mid u = z + k_1(u_1 - u_0) + \cdots + k_m(u_m - u_0), k_i \in \mathbf{N}, S(z, \sigma) = \langle u_0, \ldots, u_m \rangle \Big\}.$$

Define Σ^* *to be the following subset of permutations:*

$$\Sigma^* = \{\sigma \in \Sigma \mid \sigma(0) \neq 0,\ \sigma(0) \neq m,\ \sigma(1) \neq 0,\ \sigma(1) \neq m\},$$

and

$$C_{\Sigma^*}(z) := \bigcup_{\sigma \in \Sigma^*} C_\sigma(z),$$

$$\underline{C}_{\Sigma^*}(z) := \{u \in C_{\Sigma^*}(z) \mid u \neq z + ke_i \text{ for all } k \in \mathbf{Z}, i = 1, \ldots, m\}.$$

Finally, we define $P(z)$ *as the plane through* z *that has normal vector* $(1, \ldots, 1)$, *i.e.,*

$$P(z) := \{u \in \mathbf{Z}^m | u_1 + u_2 + \cdots + u_m = z_1 + z_2 + \cdots + z_m\}.$$

Note in this definition that for the case of $m = 2$, the set Σ^* is empty, and thus $C_{\Sigma^*}(z)$ and $\underline{C}_{\Sigma^*}(z)$ are also empty.

In the remainder of this section, we shall use these definitions to build a characterization of the set of cw-minimal points. The following lemma gives us the necessary preliminary results.

LEMMA A.8. *For any* $z \in \mathbf{Z}$,

$$C(z) \cap C_{\Sigma^*}(z) = \emptyset, \tag{A.12}$$

$$\mathbf{Z}^m = C(z) \cup C_{\Sigma^*}(z) \cup P(z). \tag{A.13}$$

Proof. First consider (A.12). If $m = 2$, then $C_{\Sigma^*}(z) = \emptyset$ and the result is immediate. For $m > 2$, assume that we have $z \in \mathbf{Z}^m$ and $y \in C_\sigma(z)$ for some $\sigma \in \Sigma^*$. This means that we can write $y - z$ as

$$y - z = k_1(u_1 - u_0) + \cdots + k_m(u_m - u_0)$$

or

$$y - z = k_1 v_{\sigma(1)} + k_2(v_{\sigma(1)} + v_{\sigma(2)}) + \cdots + k_m(v_{\sigma(1)} + v_{\sigma(2)} + \cdots + v_{\sigma(m)}), \tag{A.14}$$

and thus

$$\begin{array}{rcl} y - z & = & (k_1 + k_2 + \cdots + k_m)v_{\sigma(1)} \\ & + & (k_2 + k_3 + \cdots + k_m)v_{\sigma(2)} \\ & \vdots & \\ & + & k_m v_{\sigma(m)}. \end{array} \tag{A.15}$$

Note that all $k_i \geq 0$. Since $\sigma \in \Sigma^*$, we know that $\sigma(j) = 0$ for some $j \neq 0,\ 1$. Using (A.1) and subtracting $(k_j + k_{j+1} + \cdots + k_m)(v_0 + \cdots + v_m)$ from (A.15), we get

$$\begin{array}{rcl} y - z & = & (k_1 + \cdots + k_{j-1})v_{\sigma(1)} \\ & + & (k_2 + \cdots + k_{j-1})v_{\sigma(2)} \\ & \vdots & \\ & + & k_{j-1}v_{\sigma(j-1)} \\ & - & k_j v_{\sigma(j+1)} \\ & - & (k_j + k_{j+1})v_{\sigma(j+2)} \\ & \vdots & \\ & - & (k_j + k_{j+1} + \cdots + k_{m-1})v_{\sigma(m)}. \end{array}$$

Recall that $\{v_{\sigma(1)}, \ldots, v_{\sigma(j-1)}, v_{\sigma(j+1)}, \ldots, v_{\sigma(m)}\}$ is a basis for $\mathbf{Z}^m$, so this representation is unique. Since $k_i \geq 0$, we see that y is neither in $C_{0+}(z)$ nor in $C_{0-}(z)$. Analogously, one can prove that $z \notin C_{m+}(z)$ and $z \notin C_{m-}(z)$, and thus $z \notin C(z)$. This proves that $C(z)$ and $C_{\Sigma^*}(z)$ are disjoint.

To prove (A.13), assume that $y \in \mathbf{Z}^m$ and $y \notin C_{\Sigma^*}(z)$. We have to prove that y is in $C(z)$ or $P(z)$. The set $\{S(z,\sigma) \mid z \in \mathbf{Z}^m, \sigma \in \Sigma\}$ forms a partition of $\mathbf{Z}^m$, so there must be a permutation σ of $\{0, \ldots, m\}$, such that $y \in C_\sigma(z)$. Since $y \notin C_{\Sigma^*}(z)$, σ is not in Σ^*, and we must have $\sigma(0) = 0$ or m, or $\sigma(1) = 0$ or m. We shall deal with the case of $\sigma(1) = 0$ first. According to the definition of $C_\sigma(z)$, we can write $y - z$ as

$$y - z = (k_1 + k_2 + \cdots + k_m)v_0 + (k_2 + \cdots + k_m)v_{\sigma(2)} + \cdots + k_m v_{\sigma(m)} \tag{A.16}$$

for some $k_i \geq 0$. We now have to distinguish between the three following cases.

1: $k_1 > 0$. Use (A.1) to show that

$$\begin{aligned} y - z &= -k_1 v_{\sigma(2)} \\ &- (k_1 + k_2)v_{\sigma(3)} \\ &\vdots \\ &- (k_1 + \cdots + k_{m-1})v_{\sigma(m)} \\ &- (k_1 + \cdots + k_m)v_{\sigma(0)}. \end{aligned}$$

Since k_1 is strictly positive, this means that $y \in C_{0-}(z)$.

2: $k_1 = 0$, $\sigma(0) = m$. We first show that $k_m > 0$. Assume that $k_m = 0$. Construct a permutation τ as follows: $\tau(1) = \sigma(2)$, $\tau(2) = \sigma(1) = 0$, $\tau(m) = \sigma(0) = m$, $\tau(0) = \sigma(m)$, and $\tau(i) = \sigma(i)$ for $i = 3, \ldots, m-1$. This makes $\tau \in \Sigma^*$. From (A.16), using $k_1 = k_m = 0$, we get

$$\begin{aligned} y - z &= (k_2 + \cdots + k_m)v_{\tau(1)} \\ &+ (k_2 + \cdots + k_m)v_{\tau(2)} \\ &\vdots \\ &+ k_{m-1}v_{\tau(m-1)}, \end{aligned}$$

which implies that $y \in C_{\Sigma^*}(z)$, and this contradicts $y \notin C_{\Sigma^*}(z)$. We may conclude that the assumption $k_m = 0$ is incorrect, and then it is immediate from (A.16) that $y \in C_{m+}(z)$.

3: $k_1 = 0$ and $\sigma(0) \neq m$. Define the permutation τ by $\tau(1) = \sigma(2)$, $\tau(2) = \sigma(1)$ and $\tau(i) = \sigma(i)$, $i = 3, \ldots, m$. From (A.16), we have

$$\begin{aligned} y - z &= (k_2 + \cdots + k_m)v_{\tau(1)} \\ &+ (k_2 + \cdots + k_m)v_{\tau(2)} \\ &\vdots \\ &+ k_m v_{\tau(m)}, \end{aligned} \tag{A.17}$$

and thus $y \in C_\tau(z)$. Now assume that $\tau(1) \neq m$, then $\tau \in \Sigma^*$, and thus $y \in C_{\Sigma^*}(z)$, which contradicts the assumption that $y \notin C_{\Sigma^*}(z)$. We conclude that $\tau(1) = m$. Since $v_{\tau(1)} = v_m$ and $v_{\tau(2)} = v_0$, we may conclude from (A.17) that the coefficients of $y - z$ sum up to zero, and thus $y \in P(z)$.

The case where $\sigma(1) = m$ is proven analogously, with the roles of v_0 and v_m interchanged. The case where $\sigma(0) = 0$ (or $\sigma(0) = m$) proceeds as follows. Again, use (A.1) by substituting

$$v_{\sigma(1)} + v_{\sigma(2)} + \cdots + v_{\sigma(j)} = -v_{\sigma(j+1)} - \cdots - v_{\sigma(m)} - v_{\sigma(0)} \tag{A.18}$$

into each line of (A.14) to get

$$\begin{aligned} y - z \quad = \quad & -(k_1 + \cdots + k_m)v_{\sigma(0)} \\ & -(k_1 + \cdots + k_{m-1})v_{\sigma(m)} \\ & -(k_1 + \cdots + k_{m-2})v_{\sigma(m-1)} \\ & \vdots \\ & -k_1 v_{\sigma(2)}. \end{aligned} \tag{A.19}$$

This brings $y - z$ in a form similar to (A.15), with the exception that now all the coefficients of the v_is become negative. The proof concludes analogously to the case where $\sigma(1) = 0$. □

Note that the three sets $C(z)$, $C_{\Sigma^*}(z)$, and $P(z)$ are not mutually disjoint. $C(z)$ and $P(z)$ are disjoint, but $C_{\Sigma^*}(z)$ and $P(z)$ have a nonempty intersection. The immediate consequence of Lemma A.8 is summarized in the following theorem, which is the main result of this section.

THEOREM A.9. *If $z \in \mathbf{Z}^m$ is a strictly cw-minimal point of a multimodular function f, then there can be other cw-minimal points only in $\underline{C}_{\Sigma^*}(z)$ or in the plane $P(z)$.*

Proof. It is immediate from Lemma A.8 that the only other cw-minimal points must lie in $C_{\Sigma^*}(z)$ or in $P(z)$. Actually, we do not need to include the entire set $C_{\Sigma^*}(z)$ as a possibility for other coordinatewise minima. It may contain an axis of the form $\{z + ke_i \mid k \in \mathbf{Z}\}$ for some unit vector e_i, $i = 1, \ldots, m$. Since z is strictly cw-minimal and f is convex along this axis (see Lemma A.6), it is immediately obvious that there cannot be other coordinatewise minima on this axis. □

Theorem A.9 not only gives a characterization of the set of cw-minimal points, but it also enables us to search for the minimum in an efficient manner. In the two-dimensional case, for instance, the theorem means that if $z \in \mathbf{Z}^2$ is strictly cw-minimal, then the possible other coordinatewise minima must lie on the line $\{(z_1 + k, z_2 - k) \mid k \in \mathbf{Z}\}$. For an indication of the implications of Theorem A.9, take a look at Figure A.3. We assume that 0 (the center of the cube) is strictly cw-minimal. The points indicated with a bold filled circle are the points on the unit cube that are in both $\underline{C}_{\Sigma^*}(0)$ and in $P(0)$. The bold open circles are the points of $\underline{C}_{\Sigma^*}(0)$ that are not in $P(0)$. The bold open diamonds are the points $P(0)$ that are not in $\underline{C}_{\Sigma^*}(0)$.

We conclude this appendix with the proof of Lemma 3.4. It summarizes the results of Theorem A.9 for multimodular functions defined on $\mathbf{Z}^2$.

LEMMA A.10. *If $g : \mathbf{Z}^2 \to \mathbf{R}$ is a multimodular function and $y = (y_1, y_2)$ and $z = (z_1, z_2)$ are two distinct strictly cw-minimal points of g where $z_1 \geq y_1$, then*

1. *$(z_1, z_2) = (y_1 + B, y_2 - B)$ for some $B > 0$;*
2. *for all b, $0 < b < B$, $(y_1 + b, y_2 - b)$ is also cw-minimal;*
3. *if $g(z) > g(y)$, then the minimum of g cannot be in the set $\{(y_1 + b, y_2 - b) | b \geq B\}$;*
4. *if both y and $z = (y_1 + B, y_2 - B)$ for some $B \geq 0$ are minimal, then $(y_1 + b, y_2 - b)$ is minimal for all $0 \leq b \leq B$;*
5. *if both $g(y_1 + 1, y_1 - 1) \geq g(y_1, y_2)$ and $g(y_1 - 1, y_1 + 1) \geq g(y_1, y_2)$, then (y_1, y_2) is minimal; if the inequalities are strict, then the minimum is also unique.*

Proof. The proof follows immediately from Theorem A.9. Note that if $m = 2$, then there exist no permutations σ of $\{0, 1, 2\}$ with both $\sigma(0) \neq 0, 1$ and $\sigma(1) \neq 0, 1$, so $C_{\Sigma^*}(z) = \emptyset$ for all $z \in \mathbf{Z}^2$. This means that if z is a strictly cw-minimal point, then

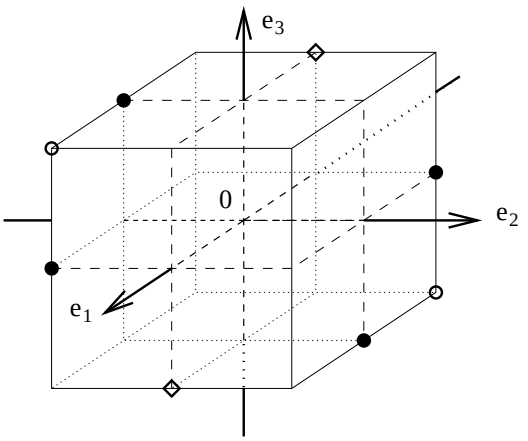

FIG. A.3. *The cone* $C_{\Sigma^*}(0)$ *and the plane* $P(0)$.

the only other cw-minimal points must lie in $P(z) = \{(z_1 + b, z_2 - b) \mid b \in \mathbf{Z}\}$. This proves 1.

To prove 2, note that y strictly cw-minimal implies that $\Delta_1 g(y) > 0$. Since g is multimodular, this implies that $\Delta_1 g(y_1 + b, y_2 - b) > 0$ for $b \geq 0$. In the same manner, $\Delta_1 g(z_1 - 1, z_2) < 0$, and by multimodularity $\Delta_1 g(z_1 - 1 - b, z_2 + b) < 0$ for all $b > 0$. Analogously, one can show that $\Delta_2 g(z_1 - b, z_2 + b) > 0$ and $\Delta_2 g(y_1 + b, y_2 - 1 - b) < 0$ for all $b \geq 0$, and these equalities combined prove 2.

For 3, 4, and 5, note that $f(z) := g(y_1 + z, y_2 - z)$ is a convex function of $z \in \mathbf{Z}$ by the remark below Lemma A.6. □

APPROXIMATION OF THE KUSHNER EQUATION FOR NONLINEAR FILTERING*

KAZUFUMI ITO† AND BORIS ROZOVSKII‡

Abstract. In this paper we discuss the well-posedness and approximation of solutions to the Kushner equation in nonlinear filtering problems. We develop and analyze a time integration method based on the operator splitting. Also, we discuss its relation to the operator-splitting method for the Zakai equation.

Key words. Kushner equation, operator-splitting method

1. Introduction.

In this paper we consider time discretization schemes for the Kushner equation

$$\begin{aligned} d\pi(t) + A\pi(t)\,dt &= (h - \pi_t[h])\pi(t)\,(dy(t) - \pi_t[h]\,dt)\,, \\ \pi(0) &= p_0, \end{aligned} \tag{1.1}$$

where $\pi_t[h] = \int_{R^d} h(x)\pi(t,x)\,dx$ and

$$-A\phi(x) = \frac{\partial}{\partial x_i}\left(a_{i,j}(x)\frac{\partial}{\partial x_j}\phi(x)\right) - \frac{\partial}{\partial x_i}\left(a_i(x)\phi(x)\right). \tag{1.2}$$

The Kushner equation (1.1) arises in nonlinear filtering of diffusion-type processes (see, e.g., [13], [17], [20]). More specifically, assume that the (unobserved) system process $x(t) \in R^d$ is a solution to the Ito equation

$$dx(t) = g(x(t))\,dt + \sigma(x(t))\,dw_1(t), \quad x(0) = x_0, \tag{1.3}$$

and the observation process $y(t) \in R^p$ is of the form

$$y(t) = \int_0^t h(x(s))\,ds + w_2(t), \tag{1.4}$$

where w_1 and w_2 are Brownian motions. In addition, it is assumed that w_2 is independent of $x(t)$ and x_0 is a random variable with density function $p_0 \in L^2(R^d)$. Throughout what follows $g : R^d \to R^d$, $\sigma : R^d \to R^{d\times d}$, and $h : R^d \to R^p$ are bounded continuous functions and g and σ are also Lipschitz continuous.

The diffusion processes $x(t), y(t)$ are considered on a complete probability space $(\Omega, \mathcal{F}, P)$. Let us denote by $\mathcal{F}_t^y$ the P-completed σ-field generated by the observations $\{y(s), 0 \le s \le t\}$.

It is a standard fact that for a bounded function ϕ, the best mean square estimator of $\phi(x(t))$ based on the observations $\{y(s), 0 \le s \le t\}$ is given by $\pi[\phi] = E[\phi(x(t))|\mathcal{F}_t^y]$. Moreover, a fundamental result of filtering theory (see, e.g., [7], [17]) says that if $\phi \in C_b^2(R^d)$, then $\pi_t[\phi]$ admits the stochastic differential

$$d\pi_t[\phi] = -\pi_t[A^*\phi]\,dt + (\pi_t[h\phi] - \pi_t[\phi]\pi_t[h])(dy(t) - \pi_t[h]\,dt), \tag{1.5}$$

where A^* is the operator formally adjoint to A with $a_{i,j} = (\frac{1}{2}\sigma\sigma^*)_{i,j}$ and $a_i = g_i - \frac{\partial}{\partial x_j}a_{i,j}$. If the measure $\pi_t(dx) = E[I(x(t) \in dx)|\mathcal{F}_t^y]$ admits a smooth density $\pi(t,x)$ with respect to the Lebesgue measure, it is readily checked that $\pi(t,x)$ verifies the Kushner equation (1.1).

It is also a standard fact (e.g., see [2], [19], [20]) that

$$E\,[\phi(x(t))|\mathcal{F}_t^y] = \frac{\int \phi(x)p(t,x)\,dx}{\int p(t,x)\,dx}, \tag{1.6}$$

where the function $p(t,x)$, usually referred to as the unnormalized filtering density, satisfies the Zakai equation

$$dp(t) + Ap(t)\,dt = hp(t)\,dy(t), \quad p(0) = p_0. \tag{1.7}$$

There is a substantial body of results on numerical approximations of the equations of nonlinear filtering (see, e.g., [1], [2], [3], [4], [5], [6], [8], [9], [11], [14], [16], and the references therein). The overwhelming majority of these numerical schemes deals with the Zakai equation. The rationale for this choice is usually twofold.

1. The Kushner and Zakai equations are equivalent in that their solutions are related by the simple formulas

$$\begin{aligned} &\pi(t,x) = p(t,x)/\textstyle\int p(t,x)\,dx, \\ &p(t,x) = \pi(t,x)\exp\{\textstyle\int_0^t \pi_s[h]\,dy(s) - \frac{1}{2}\int_0^t |\pi_s[h]|^2\,ds\}. \end{aligned} \tag{1.8}$$

2. In contrast to the Kushner equation, the Zakai equation is linear, and this of course greatly simplifies its analysis.

Unfortunately, in spite of its popularity, the Zakai equation has serious deficiencies as a computational tool. These include the following: (a) fast dissipation of the solution as the number of time steps grows, and (b) the effect of intermittency which manifests itself in the appearance of rare but very large peaks. On the contrary, it appears that Kushner's equation of nonlinear filtering is not subject to the aforementioned problems.

In this paper we develop time discretization schemes that apply directly to the Kushner equation (1.1). These schemes belong to the class of splitting-up approximations. The idea of splitting an operator into simpler parts according to different physical properties has been widely used in applied analysis. For example, different alternating directions schemes were developed for the heat equation (see [18] and [10] for a survey of the various operator-splitting schemes). In the case of discrete time observation, Kushner's and Zakai's equations automatically split into two parts: the prediction term that corresponds to the (deterministic) operator A and the correction term related to the (stochastic) operator $B = hp(t)\,\dot{y}(t)$. In [14] (see also [15] and the references therein) Kushner proposed a Markov chain approximation for continuous time equations of nonlinear filtering and proved its weak convergence in the space of measures. Owing to the discrete time nature of the Markov chain approximation, it

is, naturally, of the splitting-up type. Splitting-up time discretization of the Zakai equation in L^2 spaces was pioneered by Bensoussan, Glowinski, and Rascanu [3] and further developed in [8], [11]. In particular, the first estimates of the rate of convergence of the splitting-up approximations for the Zakai equation were obtained in these papers.

In this paper we prove weak and strong convergence in L^2 spaces of the approximations to the solution of (1.1) and estimate the approximation errors.

To avoid the effects of fast dissipation and intermittency, numerical approximations to Zakai's equation are often normalized on every step. It was established experimentally that this procedure is quite efficient. However, the effect of the normalization on the convergence of the approximation has never been studied rigorously. In this paper we derive the rate of convergence of normalized splitting-up approximations to Zakai's equation from the rate of convergence of the splitting-up approximation of Kushner's equation.

2. Well-posedness and difference approximations.

2.1. Zakai and Kushner equations in weighted Sobolev spaces. Weighted Sobolev spaces are of central importance for the approximation results we will be developing below. The analytical theory of Zakai and Kushner equations in standard Sobolev spaces is well understood (see, e.g., [20] and the references therein). However, much less is known about the extensions of this theory to weighted spaces. In this section we will recall some important results in nonlinear filtering and extend them to the case of weighted Sobolev spaces.

The Zakai theory is based on the change of probability measure [2], [20]. Let η_t be a stochastic process defined by

$$\eta_t = \exp\left(-\int_0^t h(x(s))\,dy(s) + \frac{1}{2}\int_0^t |h(x(s))|^2\,ds\right). \tag{2.1}$$

Define a probability measure $\tilde{P}$ on $(\Omega, \mathcal{F})$ by

$$\frac{d\tilde{P}}{dP} = \eta_t. \tag{2.2}$$

In what follows $\tilde{E}$ stands for the expectation with respect to measure $\tilde{P}$. It is a standard fact that under the assumptions we made above the measures P and $\tilde{P}$ are mutually absolutely continuous.

By Girsanov's theorem, the observation process $y(t)$ is an $\mathcal{F}_t^y$ -adapted Wiener process with covariance I on $(\Omega, \mathcal{F}, \tilde{P})$.

Denote $S = (\Omega \times [0,T], \mathcal{F} \times \mathcal{B}, dP \times dt)$ and $\tilde{S} = (\Omega \times [0,T], \mathcal{F} \times \mathcal{B}, d\tilde{P} \times dt)$, where $\mathcal{B}$ is the Borel σ-algebra in $[0,T]$. Set $H = L^2(R^d)$ and $V = H^1(R^d)$ and denote by V^* the strong dual to V. H^* is identified with H so that $V \subset H = H^* \subset V^*$. The inner product $(\cdot,\cdot)$ in H is defined by

$$(\phi, \psi) = \int_{R_d} \phi(x)\psi(x)\,dx.$$

The dual product in $V^* \times V$ is denoted by $\langle \cdot, \cdot \rangle_H$.

Let us denote by X the Hilbert space $L^2(R^d; \varphi(|x|)\,dx)$ equipped with the inner product

$$(\phi, \psi)_X = \int_{R^d} \phi(x)\psi(x)\,\varphi(|x|)\,dx,$$

where the positive weight $\varphi \in H^1_{\ell oc}(R^+)$, which is bounded on every compact in R^+, and so that $\varphi(s) \geq 1$,

$$\varphi'(s) \leq \gamma\, \varphi(s) \ \text{ almost everywhere (a.e.)}, \quad s \in R,$$

and $\varphi^{-1} \in L^1(R^+)$. For example, one can choose $\varphi(s) = e^{\gamma\, s},\ s \geq 0$.

Note that X is continuously embedded into $L^1(R^d)$, i.e.,

$$|\phi|_{L^1} \leq |\varphi|^{\frac{1}{2}}_{L^1} |\phi|_X \quad \text{for } \ \phi \in X.$$

Let $\widetilde{V}$ be the completion of $C^1_0(R^d)$ with respect to the norm

$$|\phi|^2_{\widetilde{V}} = (\nabla\phi, \nabla\phi)_X + |\phi|^2_X.$$

Obviously $\widetilde{V}$ is a Hilbert space. Denote by $\widetilde{V}^*$ its dual with respect to the scalar product in H. It is readily checked that $\widetilde{V} \subset V \subset H$ and that the imbeddings are continuous. The duality between $\widetilde{V}$ and $\widetilde{V}^*$ is denoted by $\langle , \rangle_X$.

Throughout what follows we assume that the initial condition $p_0 \in X$.

DEFINITION 2.1. *A function $p(t)$ is a (generalized) solution of the Zakai equation* (1.7) *if $p(t)$ is a predictable process in V such that $\int_0^T |p(t)|^2_V\, dt < \infty$ (almost surely (a.s.)) and for all $\phi \in C^\infty_0(R^d)$, the equality*

$$\begin{aligned}(p(t), \phi) = (p_0, \phi) &+ \int_0^t \left[\left(-\frac{\partial}{\partial x_i} p(s) a_{i,j}, \frac{\partial}{\partial x_j}\phi\right) + \left(p(s) a_i, \frac{\partial}{\partial x_i}\phi\right)\right] ds \\ &+ \int_0^t (hp(s), \phi)\, dy(s)\end{aligned} \tag{2.3}$$

holds dtdP a.e.

DEFINITION 2.2. *A function $\pi(t)$ is a (generalized) solution of the Kushner equation* (1.1) *if $\pi(t)$ is a predictable process in V such that $\int_0^T |p(t)|^2_V\, dt < \infty$ (a.s.) and for all $\phi \in C^\infty_0(R^d)$, the equality*

$$\begin{aligned}(\pi(t), \phi) = (p_0, \phi) &+ \int_0^t \left[\left(-\frac{\partial}{\partial x_i} \pi(s) a_{i,j}, \frac{\partial}{\partial x_j}\phi\right) + \left(\pi(s) a_i(x), \frac{\partial}{\partial x_i}\phi\right)\right] ds \\ &+ \int_0^t [(\pi(s), h\phi) - (\pi(s), \phi)(\pi(s), h)](dy(s) - (\pi(s), h)\, ds)\end{aligned} \tag{2.4}$$

holds dtdP a.e.

It is well known (see, e.g., [20], [21]) that both the Kushner and Zakai equations have unique generalized solutions; these solutions are nonnegative, $p(t) \in L^1(R^d)$, and formulas (1.6), (1.8) hold. If, as assumed in this paper, the initial condition $p_0 \in X$, the solutions to the Kushner and Zakai equations belong to $\widetilde{V}$. More specifically, the following result holds.

THEOREM 2.3. (i) *The generalized solution to the Zakai equation* (1.7) $p \in L^2(\tilde{S}; \widetilde{V}) \cap L^2(\Omega, \tilde{P}, C(0, T; X))$.

(ii) *The generalized solution to the Kushner equation* (1.1) $\pi \in L^1(S; \widetilde{V}) \cap L^1(\Omega, P, C(0, T; X))$.

Proof. To begin with we will extend the operator A to a linear continuous operator from V to V^* by the formula

$$\langle A\phi, \psi\rangle = (A_0\nabla\phi - a\phi, \nabla\psi) \quad \text{for all} \quad \phi, \psi \in V,$$

where A_0 denotes the symmetric matrix $\{a_{i,j}\}$. We will use the same notation, A, for the extension. Due to the assumptions on the coefficients g, h, and σ, it can be shown that $A \in \mathcal{L}(V, V^*)$, the space of linear continuous operators from V into V^*, and there exist constants $\beta > 0$ and $0 \le \rho < \infty$ such that

$$\langle A\phi, \phi\rangle + \rho|\phi|_H^2 \ge \frac{1}{2}\beta|\phi|_V^2 \quad \text{for all } \phi \in V, \tag{2.5}$$

where $|\phi|_V^2 = (\nabla\phi, \nabla\phi) + |\phi|_H^2$.

The operator A can also be extended to the linear continuous operator from $\widetilde{V}$ to $\widetilde{V}^*$ given by

$$\begin{aligned}\langle A\phi, \psi\rangle_X &= (A\phi, \varphi\psi)\\ &= (A_0\nabla\phi - \phi\, a, \varphi\,\nabla\psi + \psi\,\nabla\varphi) \quad \text{for all} \quad \phi \in \widetilde{V},\ \psi \in C_0^\infty(R^d),\end{aligned} \tag{2.6}$$

where $\varphi(x) = \varphi(|x|)$ and

$$\nabla\varphi = \varphi'(|x|)\,\frac{x}{|x|}.$$

This extension still will be denoted by A.

It is readily checked that there exist constants $\tilde{\rho}, C < \infty$ and $\beta > 0$ so that

$$|Ax|_{\widetilde{V}^*} \le C\,|x|_{\widetilde{V}}^2 \quad \text{and} \quad \langle A\phi, \phi\rangle_X + \tilde{\rho}\,|\phi|_X^2 \ge \frac{\beta}{2}\,|\phi|_{\widetilde{V}}^2. \tag{2.7}$$

Let us consider the operator equation

$$p(t) = p_0 - \int_0^t Ap(s)\,ds + \int_0^t Bp(s)\,dy(s), \tag{2.8}$$

where A is the operator defined by (2.6) and B maps $\widetilde{V}$ into the space of Hilbert–Schmidt operators $\mathcal{L}_2(R^p, X)$ by the formula $Bf = h(x)\,f$. We will consider (2.8) on $(\Omega, \mathcal{F}, \tilde{P})$ and will interpret it as an equation in $\widetilde{V}$. The latter means (see [20]) that a function $p(t)$ is a solution of (2.8) if $p(t)$ is a predictable process in $\widetilde{V}$ such that $\int_0^T |p(t)|_{\widetilde{V}}^2\,dt < \infty$ (a.s.) and for all $v \in C_0^\infty(R^d)$,

$$(p(t), v)_X = (p_0, v)_X - \int_0^t \langle Ap(s), v\rangle_X\,ds + \int_0^t (Bp(s), v)_X\,dy(s). \tag{2.9}$$

Owing to (2.7) it is easy to show that there exist constants $K,\ C \in R_+$, and $\beta > 0$ so that for all $x \in V$,

$$-2\,\langle Ax, x\rangle_X + |Bx|_X^2 \le K\,|x|_X^2 - \frac{\beta}{2}\,|x|_{\widetilde{V}}^2 \ \text{ and } \ |Ax|_{\widetilde{V}^*} \le C|x|_{\widetilde{V}}.$$

Thus (2.8) satisfies the assumptions of Theorem 3.1.4 in [20] and so there exists a unique solution of this equation, $p(t, x)$, and

$$p \in L^2(\tilde{S}, \widetilde{V}) \cap L^2(\Omega, \tilde{P}, C(O, T; X)). \tag{2.10}$$

Let ψ be an arbitrary function from $C_0^\infty(R^d)$. Then $\varphi^{-1}\psi \in \widetilde{V}$. Now taking $v = \varphi^{-1}\psi$, we can rewrite (2.9) in the form

$$(p(t),\psi) = (p_0,\psi) - \int_0^t (A_0\nabla\phi - a\phi, \nabla\psi)\,ds + \int_0^t (hp(s),\psi)\,dy(s). \tag{2.11}$$

Thus we proved that $p(t)$ is a generalized solution of the Zakai equation, and we know that this solution is unique. From this and Proposition 3.1 and Theorem 3.1 in [21] it follows that under our assumptions for any $f \in L^\infty(R^d)$,

$$E\left[f(x(t))|\mathcal{F}_t^y\right] = \int_{R^d} f(x)\pi(t,x)\,dx \ \text{ a.s.}$$

and $\pi(t,x)$ is a unique generalized solution of the Kushner equation (1.1). Moreover, $\pi(t,x) = p(t,x)/\rho_t$, where

$$\rho_t = \exp\left(\int_0^t \pi_s[h]\ dy(s) - \frac{1}{2}\int_0^t |\pi_s[h]|^2\ ds\right) = \langle p(t),1\rangle \ \text{ a.s.} \tag{2.12}$$

Since for any $q \geq 1$, $\rho(t)^q$ is a nonnegative supermartingale with respect to the filtration $(\Omega,\mathcal{F},\{\mathcal{F}_t^y\}_{t\leq T},\tilde{P})$, it follows from (2.10) and (2.12) that $\pi \in L^1(S,\widetilde{V}) \cap L^1(\Omega,P,C(O,T;X))$. Indeed, by the Schwarz inequality,

$$E\int_0^T |\pi(s)|_{\widetilde{V}}\,dt = \tilde{E}\int_0^T \rho_t^{-1}\eta_t^{-1}|p(t)|_{\widetilde{V}}\,dt$$

$$\leq \left(\tilde{E}\int_0^T |p(t)|_{\widetilde{V}}^2\,dt\right)^{\frac{1}{2}}\left(\tilde{E}\int_0^T \rho_t^{-2}\eta_t^{-2}\,dt\right)^{\frac{1}{2}} < \infty.$$

The inclusion $\pi \in L^1(\Omega,P,C(O,T;X))$ can be proved similarly. □

We conclude this section by deriving some auxiliary results needed below to justify the splitting up approximations. Let us consider the equation

$$\pi + \lambda A\pi = \phi, \tag{2.13}$$

where $\phi \in H$ and $\lambda > 0$ is a scalar.

DEFINITION 2.4. *We say that π is a solution of* (2.13) *if it belongs to V and the equality*

$$(\pi,\psi) + \lambda(A_0\nabla\pi - a\,\pi,\nabla\psi) = (\phi,\psi)$$

holds for all $\psi \in V$.

LEMMA 2.5. *Assume that $\lambda > 0$ is sufficiently small and $\phi \in H$ and is nonnegative a.e. in R^d. Then* (2.13) *has a unique solution and it is nonnegative (a.e. in R^d).*

Proof.[1] By standard arguments (see [22]) one can derive from (2.5) that if $\rho\lambda \leq 1$, $J_\lambda = (I + \lambda A)^{-1} \in \mathcal{L}(V^*,V)$ and (2.13) has a unique solution $\pi = J_\lambda\phi$, where ϕ is an H-valued random variable. By definition, $\pi \in V$ and satisfies

$$(\pi,\psi) + \lambda\left((A_0\nabla\pi,\nabla\psi) - (a\,\pi,\nabla\psi)\right) = (\phi,\psi)$$

[1]This result is well known; however, for the sake of completeness we give a short proof.

for all $\psi \in V$.

Let $\psi = \min(\pi, 0)$. Then $\psi \in V$ and

$$|\psi|_H^2 + \lambda\,((A_0\nabla\psi, \nabla\psi) - (a\,\psi, \nabla\psi)) = (\phi, \psi) \le 0.$$

It follows from (2.5) that

$$(1 - \lambda\rho)\,|\psi|_H^2 + \frac{\lambda\beta}{2}\,|\psi|_V^2 \le 0,$$

which implies that $|\psi|_H = 0$, and thus $\pi \ge 0$ a.e. in R^d. □

Of course it follows from Lemma 2.5 that for sufficiently small $\lambda > 0$, the system (2.17) has a unique nonnegative solution.

LEMMA 2.6. *If in addition to the assumptions of Lemma* 2.5 $\phi \in X$, *then a solution to* (2.13) *belongs to* $\widetilde{V}$.

Proof. The same arguments as in Lemma 2.5 yield that if $\tilde{\rho}\lambda \le 1$, then the equation

$$(\pi, v)_X + \lambda\,(A_0\nabla\pi - \pi\,a, \varphi\,\nabla v + v\nabla\varphi) = (\pi, v)_X \text{ for all } v \in \widetilde{V} \tag{2.14}$$

has a unique solution in $\widetilde{V}$. Now we will prove that a solution to (2.14) is also a solution to (2.13). This will give us the desired result since according to Lemma 2.5, a solution to the latter equation is unique.

Let ψ be an arbitrary function from $C_0^\infty(R^d)$. Then $\varphi\psi \in \widetilde{V}$. Now taking $v = \varphi^{-1}\psi$, we can rewrite (2.14) as follows:

$$(\pi, \psi) + \lambda\,((A_0\nabla\pi, \nabla\psi) - (a\,\pi, \nabla\psi)) = (\phi, \psi) \text{ for all } \psi \in C_0^\infty(R^d).$$

Since $C_0^\infty(R^d)$ is dense in V, we conclude that π is indeed a solution to (2.13). □

2.2. Operator-splitting approximations for the Kushner and Zakai equations. The operator splitting is an effective and natural approach to time discretization of the Zakai equation. In fact, it mimics the exact recursive formula which holds in the case of discrete time observations. In this subsection we define explicit and implicit operator-splitting approximations for the Kushner equation and discuss their relation to the splitting-up approximation of the Zakai equation.

For $T \in R_+$ and $m, k \in \mathbf{Z}$, set $\lambda = T/m$, $t_k = k\lambda$, $y_k = y(t_k)$, and $\Delta y_k = y_k - y_{k-1}$. The splitting-up discretization for the Zakai equation can be defined by the formulas[2]

$$\begin{aligned} &\alpha^k = \exp(h(x)\Delta y_k - \tfrac{\lambda}{2}|h(x)|^2)p^{k-1}, \\ &p^k - \alpha^k + \lambda A p^k = 0, \quad k = 1, 2, \ldots, \quad p^0 = p_0. \end{aligned} \tag{2.15}$$

This splitting-up scheme for the Zakai equation was introduced in [2]. The rate of convergence of this scheme and its higher-order modifications were studied in [8] and [11]; see also the references therein.

In practice, to avoid possible complications related to the fast dissipation of p^k and the effect of intermittency as the number of time steps grows, this scheme is often

[2]It is shown in Lemma 2.5 that for sufficiently small $\lambda > 0$ the inverse operator $(I + \lambda A)^{-1}$ is well defined.

modified as follows:

$$\begin{aligned} &\alpha^k = \exp(h(x)\Delta y_k - \tfrac{\lambda}{2}|h(x)|^2)\tilde{p}^{k-1}, \\ &\delta^k = \alpha^k / \textstyle\int \alpha^k \, dx, \text{ and} \\ &\tilde{p}^k - \delta^k + \lambda A \tilde{p}^k = 0,\ k = 1, 2, \dots,\ \tilde{p}^0 = p_0. \end{aligned} \tag{2.16}$$

As we mentioned before, in contrast to the former splitting-up scheme, the convergence of the latter one has never been studied rigorously.

Now let us consider two operator splitting-up approximations to the Kushner equation. We begin with the explicit one:

$$\begin{aligned} &\xi^k = \exp\left((h - \pi^{k-1}[h])(\Delta y_k - \pi^{k-1}[h]\lambda) - \tfrac{1}{2}|h(x) - \pi^{k-1}[h]|^2\lambda\right)\pi^{k-1}, \\ &\pi^k - \xi^k + \lambda A \pi^k = 0,\ k = 1, 2, \dots, \quad \pi^0 = p_0, \end{aligned} \tag{2.17}$$

where

$$\pi^{k-1}[h] = \frac{\int h(x)\pi^{k-1}\, dx}{\int \pi^{k-1}\, dx}. \tag{2.18}$$

Note that $\xi^k = \xi^k(t_k)$, where $\xi^k(\cdot)$ satisfies

$$\xi^k(t) = \pi^{k-1} + \int_{t_{k-1}}^{t} (h - \pi^{k-1}[h])\xi^k(s)(dy(s) - \pi^{k-1}[h]\, ds),\ t \in [t_{k-1}, t_k]. \tag{2.19}$$

Obviously, π^k is not necessarily a probability density and $\pi^{k-1}[h]$ defines the mean of h with respect to the normalizations of π^{k-1}.

Similarly, one can consider the implicit version of (2.17):

$$\begin{aligned} &\tilde{\xi}^k = \tilde{\pi}^{k-1} + \textstyle\int_{t_{k-1}}^{t_k} (h - \langle \tilde{\xi}_t, h\rangle)\tilde{\xi}(t)(dy(t) - \langle \tilde{\xi}_t, h\rangle\, dt), \\ &\tilde{\pi}^k - \tilde{\xi}^k + \lambda\, A\tilde{\pi}^k = 0. \end{aligned} \tag{2.20}$$

That is, $\tilde{\xi}^k = \tilde{\xi}(t_k)$, where $\tilde{\xi}(\cdot)$ satisfies the stochastic integro-differential equation

$$d\tilde{\xi}_t = (h - \langle \tilde{\xi}_t, h\rangle)\tilde{\xi}_t(dy(t) - \langle \tilde{\xi}_t, h\rangle\, dt), \quad \tilde{\xi}(t_{k-1}) = \tilde{\pi}^{k-1}, \tag{2.21}$$

on the interval $(t_{k-1}, t_k]$. By Ito's lemma a solution to this equation is given by the formula[3]

$$\tilde{\xi}_t = \beta_t / \langle \beta_t, 1\rangle,$$

where $\beta_t = \beta_t(x)$ is a solution to the stochastic equation

$$d\beta_t(x) = h(x)\beta_t(x)\, dy(t),\ \beta_{t_{k-1}} = \tilde{\pi}^{k-1}.$$

[3]Everywhere below, $\langle , \rangle$ denotes the duality between $L^1(R^d)$ and $L^\infty(R^d)$. In particular, $\langle \beta_t, 1\rangle = \int_{R^d} \beta_t(x)\, dx$.

The implicit approximation to the Kushner equation given by (2.20) is equivalent to the splitting-up scheme (2.16) for the Zakai equation with normalization at each step. Indeed, setting up $\beta^k = \beta(t_k)$, we can rewrite (2.21) as follows:

$$\begin{aligned} &\beta^k = \exp\left(h(x)\Delta y_k - \frac{\lambda}{2}|h(x)|^2\right)\tilde{\pi}^{k-1}\,,\ \gamma^k = \frac{\beta^k}{\langle \beta^k, 1\rangle}, \\ &\tilde{\pi}^k - \gamma^k + \lambda\, A\tilde{\pi}^k = 0,\ k = 1, 2, \ldots,\ \tilde{\pi}^0 = p_0. \end{aligned} \tag{2.22}$$

Obviously Lemmas 2.5 and 2.6 yield that the sequences $\{\pi^k\}$ and $\{\tilde{\pi}^k\}$ are well defined. The discretized solution map (2.15) for the Zakai equation is given by

$$p^k = (I + \lambda\, A)^{-1}\alpha^k, \quad \text{where } \alpha^k = \gamma^k_{k-1}p^{k-1}, \tag{2.23}$$

where

$$\gamma^k_{k-1} = \exp\left(h\,\Delta y_k - \frac{\lambda}{2}|h(x)|^2\right) \text{ and } \Delta y_k = y(t_k) - y(t_{k-1}).$$

Set

$$q^k_{k-1} = \exp\left(\pi^{k-1}[h]\,\Delta y_k - \frac{\lambda}{2}|\pi^{k-1}[h]|^2\right).$$

Since q^k_{k-1} does not depend on x, a solution to the approximation (2.17) can be written as

$$\pi^k = (q^k_{k-1})^{-1}(I + \lambda\, A)^{-1}\gamma^k_{k-1}\pi^{k-1}.$$

By induction we have the following relation between π^n and p^n:

$$\pi^n = (q^n)^{-1}\, p^n, \quad \text{where} \quad q^n = \Pi^n_{k=1}\, q^k_{k-1.} \tag{2.24}$$

Of course, (2.24) implies that $\langle \pi^n, 1\rangle = (q^n)^{-1}\ \langle p^n, 1\rangle$, and so for any $f \in X^*$,

$$\pi^n\,[f] = p^n\,[f]\,. \tag{2.25}$$

For $s \in (t_{k-1}, t_k]$, write

$$\gamma_k(s) = \exp\{h(x)\,(y(s) - y(t_{k-1})) - (s - t_{k-1})\,|h(x)|^2/2\}$$

and set

$$\begin{aligned} &p^k(s,x) = (I + \lambda A)^{-1}\,\alpha^k(s,x), \\ &\alpha^k(s,x) = \gamma_k(s)p^{k-1}(x),\ \text{and } p^0(s) = p_0. \end{aligned} \tag{2.26}$$

Obviously, $\gamma_k(t_k) = \gamma^k_{k-1}$ and $\alpha^k(t_k, x) = \alpha^k(x)$. Define the function $\alpha^\lambda_t(x) = \alpha^k(t,x)$ for $t \in [t_{k-1}, t_k)$.

LEMMA 2.7. *For every k,*

$$\begin{aligned} \langle p^k, 1\rangle = \langle p^{k-1}, 1\rangle \exp\left\{\int_{t_{k-1}}^{t_k} \alpha^k_s\,[h]\ dy(s) - \frac{1}{2}\int_{t_{k-1}}^{t_k} |\alpha^k_s\,[h]\,|^2\, ds\right\} \\ = \exp\left\{\int_0^{t_k} a^\lambda_s\,[h]\, dy(s) - \frac{1}{2}\int_0^{t_k} \left|\alpha^\lambda_s\,[h]\right|^2\, ds\right\} \end{aligned}$$

P—a.e., where $\alpha_s^k[h] = \langle \alpha^k(s), h\rangle / \langle \alpha^k(s), 1\rangle$ *and* $\alpha_t^\lambda[h] = \alpha_t^k[h]$ *for* $t \in (t_{k-1}, t_k]$.

Proof. Owing to (2.26) we have $(I + \lambda A)\, p^k(s,x) = \alpha^k(s,x)$. Note also that for every $f \in H^1(R^d)$,

$$\int_{R^d} \nabla(A_0 \nabla f - af)\, dx = 0.$$

Therefore,

$$\langle p^k(s), 1\rangle = \langle \alpha^k(s), 1\rangle = \int_{R^d} \gamma_k(s,x) p^{k-1}(x)\, dx. \tag{2.27}$$

Since for $t \in (t_{k-1}, t_k]$, $d\gamma_k(t) = h(x)\gamma_k(t)\, dy(t)$, $\gamma_k(t_{k-1}) = 1$, it follows from (2.27) that

$$\begin{aligned}
\langle p^k(t), 1\rangle &= \langle p^{k-1}, 1\rangle + \textstyle\int_{t_{k-1}}^t \int_{R^d} h(x)\gamma_k(s,x) p^{k-1}(x)\, dx\, dy(s) \\
&= \langle p^{k-1}, 1\rangle + \textstyle\int_{t_{k-1}}^t \langle p^k(s), 1\rangle \int_{R^d} h(x)\gamma_k(s,x) p^{k-1}(x)\, dx \langle \alpha^k(s), 1\rangle^{-1}\, dy(s) \\
&= \langle p^{k-1}, 1\rangle + \textstyle\int_{t_{k-1}}^t \langle p^k(s), 1\rangle \langle \alpha^k(s), h\rangle \langle \alpha^k(s), 1\rangle^{-1}\, dy(s).
\end{aligned}$$

Hence

$$\langle p^k(t), 1\rangle = \langle p^{k-1}, 1\rangle \exp\left\{ \int_{t_{k-1}}^t \alpha_s^k[h]\, dy(s) - \frac{1}{2}\int_{t_{k-1}}^t \left|\alpha_s^k[h]\right|^2 ds \right\},$$

which completes the proof. □

3. Convergence of splitting-up approximations.

3.1. Convergence in $L^1(\Omega, \mathcal{F}, P)$. In this section we will establish weak and strong convergence of the splitting-up approximation (2.17) to the solution of the Kushner equation. Since the differences in the proof of the main results for the sequences $\{\pi^k\}$ and $\{\tilde\pi^k\}$ are minimal, note that

$$\tilde\pi^n = (\tilde q^n)^{-1} p^n \ \text{ with } \ \tilde q^n = \exp\left(\sum_{k=1}^n \int_{t_{k-1}}^{t_k} \left(\tilde\xi_t[h]\, dy(t) - \frac{1}{2} |\tilde\xi_t[h]|^2\, dt \right) \right);$$

we will consider here only the former one and leave the latter to the interested reader.

Define the functions $\pi_\lambda(t)$ and p_t^λ by

$$\pi_\lambda(t) = \pi^k \ \text{ and } \ p_t^\lambda = p^k \quad \text{for} \quad t \in [k\lambda, (k+1)\lambda)\ k \ge 0.$$

Also, for $t \in [k\lambda, (k+1)\lambda)$, set $\rho_t^\lambda = \exp\{\int_0^{t_k} \alpha_s^k[h]\, dy(s) - \frac{1}{2}\int_0^{t_k} \left|\alpha_s^k[h]\right|^2 ds\}$. Owing to Lemma 2.7, we have

$$\rho_t^\lambda = \langle p_t^\lambda, 1\rangle. \tag{3.1}$$

First we will establish two auxiliary results, Lemma 3.1 and Theorem 3.2.

LEMMA 3.1. *Let* $\mu_1(t)$ *and* $\mu_2(t)$ *be* $\mathcal{F}_t^y$*-adapted processes so that*

$$\sup_t (|\mu_1(t)|^2 + |\mu_2(t)|) \le C|h|_\infty^2.$$

Write $\theta_t = \exp\{\int_0^t \mu_1(s)dy(s) + \int_0^t \mu_2(s)ds\}$. *For all* $f \in L^\infty(R^d)$ *and any* $q \geq 1$, *there exist constants* $M(q)$ *and* $c(q)$ *such that*

$$E\theta_t |\langle p_t^\lambda - p(t), f\rangle|^q \leq M(q) \exp\left(c(q)|h|_\infty^2 t\right) |f|_\infty^q \left|\varphi^{-1}\right|_1^{\frac{1}{2}} (\tilde{E}\,|p_t^\lambda - p(t)|_X^2)^{\frac{1}{2}}.$$

Proof. Assume that $t \in [k\lambda, (k+1)\lambda)$. Changing the probability law according to (2.2), applying the Schwarz inequality, and using (2.12) and (3.1), we get

$$\begin{aligned} E\theta_t |\langle p_t^\lambda - p(t), f\rangle|^q &= \tilde{E}\eta_t^{-1}\theta_t |\langle p_t^\lambda - p(t), f\rangle|^q \\ &\leq |f|_\infty^{q-1} \tilde{E}\left[\eta_t^{-1}\theta_t |\rho_t^\lambda + \rho_t|^{q-1} |\langle p_t^\lambda - p(t), f\rangle|\right] \\ &\leq |f|_\infty^q \left|\varphi^{-1}\right|_1^{\frac{1}{2}} \tilde{E}\left[\eta_t^{-1}\theta_t |\rho_t^\lambda + \rho_t|^{q-1} |p_t^\lambda - p(t)|_X\right] \\ &\leq |f|_\infty^q \left|\varphi^{-1}\right|_1^{\frac{1}{2}} (\tilde{E}|p_\lambda(t) - p(t)|_X^2)^{\frac{1}{2}} (\tilde{E}(\eta_t^{-2}\theta_t^2 |\rho_t^\lambda + \rho_t|^{2q-2}))^{\frac{1}{2}}. \end{aligned} \tag{3.2}$$

It follows from (2.1), (2.12), and (3.1) that

$$(\eta_t^{-2}\theta_t^2 |\rho_t^\lambda + \rho_t|^{2q-2}) \leq M(q)\left(I_t^\lambda + I_t\right),$$

where

$$I_t^\lambda = \exp(\int_0^t 2((q-1)\alpha_s^\lambda[h]1_{\{s<(k+1)\lambda\}} + h(x(s)) + \mu_1(s))\, dy(s)$$

$$-\tfrac{1}{2}\int_0^t 4|(q-1)\alpha_s^\lambda[h]1_{\{s<(k+1)\lambda\}} + h(x(s)) + \mu_1(s)|^2\, ds)$$

and

$$I_t = \exp(\int_0^t 2((q-1)\pi_s[h] + h(x(s)) + \mu_1(s))\, dy(s)$$

$$-\tfrac{1}{2}\int_0^t 4|(q-1)\pi_s[h] + h(x(s)) + \mu_1(s)|^2\, ds).$$

Since $\pi_s[h] \leq |h|_\infty$ and $\alpha_s^\lambda[h] \leq |h|_\infty$, I_t and I_t^λ are martingales with respect to the filtration $(\Omega, \mathcal{F}, \{\mathcal{F}_t^y\}_{t\leq T}, \tilde{P})$. Therefore,

$$\tilde{E}\eta_t^{-2}\theta_t |\rho_t^\lambda + \rho_t|^{2q-2} \leq M(q) \exp(c(q)|h|_\infty^2 t), \tag{3.3}$$

which implies the desired estimate. □

The following result follows in exactly the same manner as in [11].

THEOREM 3.2. *The following estimate holds uniformly in* λ :

$$\sup_{t\leq T} \tilde{E}|p_t^\lambda|_X^2 + \tilde{E}\int_0^T |p_t^\lambda|_{\widetilde{V}}^2\, dt < \infty.$$

Moreover,

$$\sup_{t\leq T}\ \tilde{E}|p_t^\lambda - p(t)|_X^2 + \tilde{E}\int_0^T |p_t^\lambda - p(t)|_{\widetilde{V}}^2 \to 0 \text{ as } \lambda \to 0.$$

The main results of this section are given in the following two theorems.

THEOREM 3.3. *For every $f \in L^\infty(R^d)$ and $q \geq 1$,*

$$E\,|\pi_\lambda(t)[f] - \pi_t[f]|^q \to 0 \text{ as } \lambda \to 0.$$

Moreover, there exist constants M and c (which do not depend on q) so that

$$\sup_{t\leq T} E\,|\pi_\lambda(t)[f] - \pi_t[f]|^q \leq M \exp\{cT\,|h|^2_\infty\}\,\left|\varphi^{-1}\right|_1^{\frac{1}{2}}\,|f|^q_\infty \sup_{t\leq T}(\tilde{E}\,|p^\lambda_t - p(t)|^2_X)^{\frac{1}{2}}.$$

Proof. Since $|\pi_\lambda(t)[f] - \pi(t)[f]| \leq |f|_\infty$, it suffices to prove the theorem only for $q = 1$. It follows from (2.25) that for $f \in L^\infty(R^d)$,

$$\begin{aligned}\pi_\lambda(t)[f] - \pi(t)[f] &= \frac{\langle p^\lambda_t, f\rangle}{\langle p^\lambda_t, 1\rangle} - \frac{\langle p(t), f\rangle}{\langle p(t), 1\rangle} \\ &= -\rho_t^{-1}(\langle p(t) - p^\lambda_t, f\rangle + p^\lambda_t[f]\langle p^\lambda_t - p(t), 1\rangle).\end{aligned} \tag{3.4}$$

By Lemma 3.1, we have

$$\begin{aligned}&E\,|\rho_t^{-1}\langle p(t) - p^\lambda_t, f\rangle| \\ &\quad\leq \tfrac{M}{2}\,\exp\{c\,|h|^2_\infty\,t\}\,\left|\varphi^{-1}\right|_1^{\frac{1}{2}}\,|f|_\infty\,(\tilde{E}\,|p^\lambda_t - p(t)|^2_X)^{\frac{1}{2}}.\end{aligned} \tag{3.5}$$

Since $|p^\lambda_t[f]| \leq |f|_\infty$, Lemma 3.1 yields

$$\begin{aligned}&E|\rho_t^{-1}p^\lambda_t[f]\langle\, p^\lambda_t - p(t), 1\rangle| \\ &\quad\leq \tfrac{M}{2}\,\exp\{c\,|h|^2_\infty\,t\}\,\left|\varphi^{-1}\right|_1^{\frac{1}{2}}\,|f|_\infty(\tilde{E}\,|p^\lambda_t - p(t)|^2_X)^{\frac{1}{2}}.\end{aligned} \tag{3.6}$$

The result follows now from Theorem 3.2. □

THEOREM 3.4. *The function π^λ converges to π, the solution of the Kushner equation* (1.1)*, strongly in $L^1((0,T)\times\Omega, \widetilde{V})$ as $\lambda \to 0$. Moreover, the following estimate holds:*

$$E\int_0^T |\pi_\lambda(t) - \pi(t)|_{\widetilde{V}}\,dt \leq C\left[\left(\tilde{E}\int_0^T |p^\lambda_t - p(t)|^2_{\widetilde{V}}dt\right)^{\frac{1}{2}} + \left(\int_0^T (\tilde{E}|p^\lambda_t - p(t)|^2_X)^{\frac{1}{2}}dt\right)^{\frac{1}{2}}\right].$$

Proof. Note that

$$\pi_\lambda(t) - \pi(t) = \rho_t^{-1}(p^\lambda_t - p(t)) + p^\lambda_t(\rho_t\rho^\lambda_t)^{-1}\,\langle p^\lambda_t - p(t), 1\rangle, \tag{3.7}$$

and thus

$$\begin{aligned}E\int_0^T |\pi_\lambda(t) - \pi(t)|_{\widetilde{V}}\,dt &\leq E\int_0^T \rho_t^{-1}|p_t - p^\lambda_t|_{\widetilde{V}}\,dt \\ &\quad + E\int_0^T |p^\lambda_t|_{\tilde{V}}(\rho_t\rho^\lambda_t)^{-1}|\,\langle p^\lambda_t - p(t), 1\rangle\,|\,dt.\end{aligned}$$

Now changing the probability law according to (2.2) and applying the Schwarz inequality, we get

$$E\int_0^T \rho_t^{-1}|p^\lambda_t - p(t)|_{\widetilde{V}}\,dt = \left(\tilde{E}\int_0^T |\eta_t^{-1}\rho_t{}^{-1}|^2\,dt\right)^{\frac{1}{2}}\left(\tilde{E}\int_0^T |p^\lambda_t - p(t)|^2_{\widetilde{V}}\,dt\right)^{\frac{1}{2}}. \tag{3.8}$$

Write $\zeta_t^\lambda = (\eta_t \rho_t \rho_t^\lambda)^{-1}$. Now by the Schwarz inequality and Lemma 3.1 we have

$$
\begin{aligned}
&E \int_0^T |p_t^\lambda|_{\widetilde{V}} (\rho_t \rho_t^\lambda)^{-1} |\, \langle p_t^\lambda - p(t), 1 \rangle |\, dt \\
&\leq \left(\tilde{E} \int_0^T |\zeta_t^\lambda \langle p_t^\lambda - p(t), 1 \rangle|^2 \, dt \right)^{\frac{1}{2}} \left(\tilde{E} \int_0^T |p_t^\lambda|_{\widetilde{V}}^2 \, dt \right)^{\frac{1}{2}} \qquad (3.9) \\
&\leq C \left(\int_0^T (\tilde{E} |p_t^\lambda - p(t)|_X^2)^{\frac{1}{2}} \, dt \right)^{\frac{1}{2}} \left(\tilde{E} \int_0^T |p_t^\lambda|_{\widetilde{V}}^2 \, dt \right)^{\frac{1}{4}}.
\end{aligned}
$$

Obviously,

$$
\tilde{E} \int_0^T |\eta_t^{-1} \rho_t^{-1}|^2 \, dt < \infty. \qquad (3.10)
$$

The statement follows now from Theorem 3.2 and (3.8)–(3.10). □

COROLLARY 3.5. *The following estimate holds:*

$$
E|\pi^n - \pi(t_n)|_X \leq C \left[1 + \left(\tilde{E} |p^n|_X^4 \right)^{\frac{1}{4}} \right] \left(\tilde{E} |p^n - p(t_n)|_X^2 \right)^{\frac{1}{2}}. \qquad (3.11)
$$

Proof. From (3.7) and Hölder's inequality,

$$
\begin{aligned}
E|\pi^n - \pi(t_n)|_X \leq |\varphi|_2^{\frac{1}{2}} \Big[&\left(\tilde{E} |(\eta(t_n) \rho(t_n)^{-1}|^2 \right)^{\frac{1}{2}} \left(\tilde{E} |p^n - p(t_n)|_X^2 \right)^{\frac{1}{2}} \\
&+ \left(\tilde{E} |p^n|_X^4 \right)^{\frac{1}{4}} \left(\tilde{E} |\eta(t_n) (\rho(t_n) \rho^n)^{-1}|^4 \right)^{\frac{1}{4}} \left(\tilde{E} |p^n - p(t_n)|_X^2 \right)^{\frac{1}{2}} \Big],
\end{aligned}
$$

which shows the estimate. □

In section 4 we establish a bound on $(\tilde{E}|p^n|_X^4)^{\frac{1}{4}}$ and the convergence estimate for $(\tilde{E}|p^n - p(t_n)|_X^2)^{\frac{1}{2}}$. It will be shown that

$$
\sup_n E|\pi^n - \pi(t_n)|_X \leq C \lambda \qquad (3.12)
$$

provided that $p(t)$ satisfies an appropriate regularity condition.

3.2. Convergence in $L^2(\Omega, F, \tilde{P})$. In this section we show that $\pi_\lambda(\cdot)$ converges strongly in $L^2(\tilde{S}; \widetilde{V})$. First we derive some preliminary estimates for π^k. Multiplying (2.17) by π^k, we obtain

$$
(\pi^k - \xi^k, \pi^k)_X + \lambda \langle A\pi^k, \pi^k \rangle_X = 0.
$$

Now completing the square, we obtain

$$
\frac{1}{2} (|\pi^k|_X^2 - |\xi^k|_X^2 + |\pi^k - \xi^k|_X^2) + \lambda \langle A\pi^k, \pi^k \rangle_X = 0,
$$

and thus from (2.7)

$$
(1 - 2\lambda\tilde{\rho}) \tilde{E} |\pi^k|_X^2 + \tilde{E} |\pi^k - \xi^k|_X^2 + \lambda\beta \tilde{E} |\pi^k|_{\widetilde{V}}^2 \leq \tilde{E} |\xi^k|_X^2. \qquad (3.13)
$$

Since $p_0 \geq 0$ a.e., it follows from Lemma 2.5 that the sequence $\{\pi^k\}$ generated by (2.17) satisfies $\pi^k \geq 0$ a.e. for each $k \geq 0$. Thus

$$|h - \pi^{k-1}[h]|_\infty \leq |h|_\infty \quad \text{and} \quad |\pi^{k-1}[h]|_\infty \leq |h|_\infty.$$

It follows from (2.19) and Ito's lemma that for $t \in [t_{k-1}, t_k]$,

$$\tilde{E}\,|\xi^k(t)|_X^2 - \tilde{E}\,|\pi^{k-1}|_X^2 = \tilde{E}\int_{t_{k-1}}^t \left(2(h - \pi^{k-1}[h])\pi^{k-1}[h] + (h - \pi^{k-1}[h])^2\right)\,|\xi^k(s)|_X^2\,ds$$

$$\leq \int_{t_{k-1}}^t 3|h|_\infty^2\,\tilde{E}\,|\xi(s)|_X^2\,ds.$$

From Gronwall's lemma,

$$\tilde{E}\,|\xi^k|_X^2 \leq e^{3|h|_\infty^2 \lambda}\,\tilde{E}\,|\pi^{k-1}|_X^2.$$

Thus from (3.13), we obtain

$$e^{-\tilde{\omega}\lambda}\,\tilde{E}\,|\pi^k|_X^2 + e^{-3\lambda\,|h|_\infty^2}\,(\tilde{E}\,|\pi^k - \xi^k|_X^2 + \lambda\beta\,\tilde{E}\,|\pi^k|_{\widetilde{V}}^2) \leq \tilde{E}\,|\pi^{k-1}|_X^2,$$

where $\tilde{\omega} = 1 + 2\,\tilde{\rho} + 3\,|h|_\infty^2$. (To obtain the latter inequality we used the fact that $e^{-\lambda(1+2\tilde{\rho})} \leq 1 - 2\lambda\tilde{\rho}$ for sufficiently small $\lambda > 0$.) Multiplying this by $e^{-\tilde{\omega}\,t_{k-1}}$, we have for $k \geq 1$

$$e^{-\tilde{\omega}t_k}\,(\tilde{E}\,|\pi^k|_X^2 + \tilde{E}\,|\pi^k - \xi^k|_X^2 + \lambda\beta\,\tilde{E}\,|\pi^k|_{\widetilde{V}}^2) \leq e^{-\tilde{\omega}t_{k-1}}\,\tilde{E}\,|\pi^{k-1}|_X^2.$$

Summing up both sides of the inequality in k, we obtain

$$e^{-\tilde{\omega}t_m}\,\tilde{E}\,|\pi^m|_X^2 + \tilde{E}\sum_{k=1}^m e^{-\tilde{\omega}t_k}\,(|\pi^k - \xi^k|_X^2 + \lambda\beta\,|\pi^k|_{\widetilde{V}}^2) \leq \tilde{E}\,|\pi^0|_X^2. \tag{3.14}$$

Assume that $p_0 \in X$. Then it follows from (3.14) that

$$\sup_{t\in[0,T]} \tilde{E}\,|\pi_\lambda(t)|_X^2 + \beta\int_0^T \tilde{E}\,|\pi_\lambda(t+\lambda)|_{\widetilde{V}}^2\,dt \leq e^{\tilde{\omega}\,T}\,\tilde{E}\,|p_0|_X^2. \tag{3.15}$$

In addition, since from Lemma 2.5 $\pi^k \geq 0$ a.e., we have $\pi_\lambda(t) \geq 0$ a.e. in $\tilde{S}$.

Next we show that $\pi_\lambda(t)$ converges weakly to $\pi(t)$ in $L^2(\tilde{S};\widetilde{V})$.

THEOREM 3.6. *The sequence $\{\pi^\lambda(t)\}$ converges weakly in $L^2(\tilde{S};\widetilde{V})$ and weakly star in $L^\infty(0,T,L^2(\Omega,\tilde{P};X))$ to the unique solution $\pi(t)$ of the Kushner equation*

$$\pi(t) = p_0 - \int_0^t A\pi(s)\,ds + \int_0^t (h - \pi[h](s))\pi(s)(dy(s) - \pi[h](s)\,ds) \quad \text{in } \widetilde{V}^*. \tag{3.16}$$

Proof. From (3.15) there exists a subsequence of $\{\pi_\lambda\}$, which will be denoted by the same symbol, such that $\pi_\lambda \to \pi$ weakly in $L^2(\tilde{S};\widetilde{V})$ and weakly star in $L^\infty(0,T;L^2(\Omega;\tilde{P},X))$, where $\pi(t) \in L^2(\tilde{S};\widetilde{V}) \cap sL^\infty(0,T;L^2(\Omega,\tilde{P},X))$ can be chosen

to be predictable. Moreover, $\pi \geq 0$ a.e. in $\tilde{S}$. If $[s]$, $s \in R$, denotes the largest integer j such that $j \leq s$, then from (2.17) we have

$$\begin{aligned}\pi_\lambda(t) = p_0 &- \int_0^{[t/\lambda]\lambda} A\pi_\lambda(s+\lambda)\,ds \\ &+ \int_0^{[t/\lambda]\lambda} (F(\pi_\lambda(s))\pi_\lambda(s) + r_\lambda(s))\,(dy(s) - \pi_\lambda[h](s)\,ds),\end{aligned} \tag{3.17}$$

where the operator F on X is defined by

$$F(\pi) = (h - \pi[h]) \quad \text{for } \pi \in X.$$

The residual function $r_\lambda(\cdot)$ is defined by

$$r_\lambda(t) = F(\pi_\lambda(t))(\xi_\lambda(t) - \pi_\lambda(t)),$$

where

$$\xi_\lambda = \xi^k(t) \quad \text{if} \quad t \in ((k-1)\lambda, k\lambda], \quad k \geq 1,$$

and

$$\xi^k(t) = \pi^{k-1} + \int_{t_{k-1}}^t (h - \pi^{k-1}[h])\xi^k(s)(dy(s) - \pi^{k-1}[h]\,ds).$$

Note that

$$(\phi, \psi)_H = (\phi, \varphi^{-1}\psi)_X \quad \text{and} \quad |\varphi^{-1}\psi|_X \leq |\varphi^{-1}|_1^{\frac{1}{2}} |\psi|_\infty$$

for $\psi \in L^\infty(R^d)$. Thus $(\pi_\lambda, \psi) \in L^2(\tilde{S}; R)$. Moreover, as proved in section 3.1,

$$\pi_\lambda[h] \to \pi[h] \quad \text{in } L^q(\tilde{S}; R) \tag{3.18}$$

for $h \in L^\infty(R^d)$ and $2 \leq q < \infty$. Thus it follows from the Lebesgue-dominated convergence theorem that

$$F(\pi_\lambda)\pi_\lambda \to F(\pi)\pi \quad \text{weakly in } L^2(\tilde{S}, X). \tag{3.19}$$

By Ito's lemma we have for $t \in [t_{k-1}, t_k]$

$$\begin{aligned}&\tilde{E}\,|\xi_\lambda(t) - \pi_\lambda(t)|_X^2 \\ &= \tilde{E} \int_{t_{k-1}}^t 2((h - \pi_\lambda[h])\,\xi_\lambda(s), \xi_\lambda(s) - \pi_\lambda(s) + |(h - \pi_\lambda[h])\,\xi_\lambda(s)|_X^2)\,ds \\ &\leq \int_{t_{k-1}}^t |h|_\infty^2\,\tilde{E}\,|\xi_\lambda(s) - \pi_\lambda(s)|_X^2 + 2\tilde{E}\,|(h - \pi_\lambda[h])\,\xi_\lambda(s)|_X^2\,ds.\end{aligned} \tag{3.20}$$

It follows from Gronwall's lemma that

$$\tilde{E}\,|\xi_\lambda(t) - \pi_\lambda(t)|_X^2 \leq 2|h|_\infty^2 e^{|h|_\infty^2\,(t - t_{k-1})} \int_{t_{k-1}}^t \tilde{E}\,|\xi_\lambda(s)|_X^2\,ds \leq M\,(t - t_{k-1}) \tag{3.21}$$

for $t \in [t_{k-1}, t_k]$ and some $M > 0$ independent of $\lambda > 0$, where we used the fact that

$$\tilde{E}\,|\xi_\lambda(t)|_X^2 \le e^{\tilde{\omega} t_k}\,\tilde{E}\,|p_0|_X^2.$$

Hence we have

$$\tilde{E}\int_0^T |r_\lambda(t)|_X^2\,dt \le |h|_\infty^2\,\tilde{E}\int_0^T |\xi_\lambda(t)-\pi_\lambda(t)|_X^2\,dt \le M\,\lambda. \tag{3.22}$$

It thus follows from (3.15)–(3.22) that for almost all (t,ω) a continuous modification of $\pi(t) \in L^2(\tilde{S};\widetilde{V})$ in X (see [12, Theorem 3.2]) satisfies (3.16) and $\pi \ge 0$. Note that $1 \in X^*$ and

$$\begin{aligned}(\pi(t),1)_H &= (p_0,1)_H + \int_0^t ((\pi(s),h)_H - \pi[h](s)(\pi(s),1))(dy(s) - \pi[h](s)\,ds)_H \\ &= (p_0,1)_H = 1\end{aligned} \tag{3.23}$$

a.s. Thus the random probability density $\pi(\cdot) \in L^2(\tilde{S};\widetilde{V}) \cap L^\infty(\tilde{S};X)$ satisfies the Kushner equation (1.1) in the sense that (3.16) is satisfied a.e. in $\tilde{S}$. □

Finally we show that $\pi_\lambda(t)$ converges strongly to $\pi(t)$ in $L^2(\tilde{S};\widetilde{V})$.

THEOREM 3.7. *The sequence $\{\pi^\lambda(t)\}$ converges strongly in $L^2(\tilde{S};\widetilde{V})$ to the unique solution $\pi(t)$ of the Kushner equation* (3.16).

Proof. Note that (3.17) is equivalently written as

$$\pi^k + \lambda\,A\pi^k - \lambda\,G(\pi^{k-1})\pi^{k-1} = \pi^{k-1} + F(\pi^{k-1})\pi^{k-1}\,\Delta y_k + e^k,$$

where

$$G(\pi) = \pi[h]\,(h - \pi[h]) \quad \text{for } \pi \in X$$

and

$$e^k = \int_{t_{k-1}}^{t_k} r_\lambda(s)(dy(s) - \pi^{k-1}[h]\,ds).$$

Multiplying this by π^k we have

$$\begin{aligned}&\frac{1}{2}\,(|\pi^k|_X^2 + |\pi^k - \pi^{k-1}|_X^2 - |\pi^{k-1}|_X^2) + \lambda\,(\langle A\pi^k,\pi^k\rangle_X - G(\pi^{k-1})\pi^k,\pi^k) \\ &\quad = (e^k - \lambda\,G(\pi^{k-1})(\pi^k - \pi^{k-1}),\pi^k) + (F(\pi^{k-1})\pi^{k-1}\,\Delta y_k,\pi^k).\end{aligned}$$

Since

$$\tilde{E}\,(F(\pi^{k-1})\pi^{k-1}\,\Delta y_k,\pi^{k-1}) = 0,$$

we have

$$\tilde{E}\,(F(\pi^{k-1})\pi^{k-1}\,\Delta y_k,\pi^k) \le \frac{1}{2}\,(\tilde{E}\,|\pi^k - \pi^{k-1}|_X^2 + \tilde{E}\,|F(\pi^{k-1})\pi^{k-1}\,\Delta y_k|_X^2).$$

Thus we obtain

$$\begin{aligned}&\tilde{E}\,|\pi^k|_X^2 + 2\lambda\,\tilde{E}\,(\langle A\pi^k,\pi^k\rangle_X - G(\pi^{k-1})\pi^k,\pi^k) \\ &\le \tilde{E}\,|\pi^{k-1}|_X^2 + \lambda\,\tilde{E}\,|F(\pi^{k-1})\pi^{k-1}|_X^2 + 2\,\tilde{E}\,(e^k - \lambda\,G(\pi^{k-1})(\pi^k - \pi^{k-1}),\pi^k).\end{aligned} \tag{3.24}$$

First, we note that

$$2\langle A\pi,\pi\rangle_X - 2(G(\pi^{k-1})\pi,\pi) - |F(\pi)\pi|^2 + \tilde{\omega}\,|\pi|_X^2 \geq \beta\,|\pi|_{\widetilde{V}}^2 \quad \text{for } \pi \in \widetilde{V}. \tag{3.25}$$

Second, we note that since

$$\tilde{E}\,|\pi^k - \pi^{k-1}|_X^2 \leq 2(\tilde{E}\,|\pi^k - \xi^k|_X^2 + \tilde{E}\,|\xi^k - \pi^{k-1}|_X^2),$$

it follows from (3.14)–(3.21) that

$$\sum_{k=1}^{m} \tilde{E}\,|\pi^k - \pi^{k-1}|_X^2 \leq \text{const.} \tag{3.26}$$

It follows from (3.22) that

$$\sum_{k=1}^{m} \tilde{E}\,|e^k|_X^2 \leq \text{const}\,\lambda. \tag{3.27}$$

Multiplying (3.24) by c^{k-1} with $c = 1 - \lambda\tilde{\omega}$, we obtain for $k \geq 1$

$$\begin{aligned} &c^k \tilde{E}\,|\pi^k|_X^2 - c^{k-1}\tilde{E}\,|\pi^{k-1}|_H^2 \\ &\qquad + \lambda c^{k-1}\,\tilde{E}\,(2\langle A\pi^k,\pi^k\rangle - 2(G(\pi^{k-1})\pi^k,\pi^k) - |F(\pi^{k-1})\pi^{k-1}|^2) \\ &\quad \leq 2c^{k-1}\tilde{E}\,(e^k - \lambda\,(G(\pi^{k-1})(\pi^k - \pi^{k-1}),\pi^k)). \end{aligned}$$

Summing up this in k, we obtain

$$\begin{aligned} &c^m \tilde{E}\,(|\pi_\lambda(T)|_X^2 + \lambda\,|F(\pi_\lambda(T))\pi_\lambda(T)|_X^2) - \tilde{E}\,(|p_0|_X^2 + \lambda\,|F(p_0)p_0|_X^2) + T_\lambda \\ &\qquad \leq 2\sum_{k=1}^{m} c^{k-1}\tilde{E}\,(e^k - \lambda\,(G(\pi^{k-1})(\pi^k - \pi^{k-1}),\pi^k)), \end{aligned} \tag{3.28}$$

where

$$\begin{aligned} T_\lambda = \int_0^T & e_\lambda(t)\,\tilde{E}\,(2\langle A\pi_\lambda(t+\lambda),\,\pi_\lambda(t+\lambda)\rangle + \tilde{\omega}\,|\pi_\lambda(t+\lambda)|_X^2 \\ & - 2(G(\pi_\lambda(t))\pi_\lambda(t+\lambda),\pi_\lambda(t+\lambda)) - |F(\pi_\lambda(t+\lambda))\pi_\lambda(t+\lambda)|^2)\,dt, \end{aligned} \tag{3.29}$$

where

$$e_\lambda(t) = c^k \quad \text{for } t \in (t_{k-1}, t_k].$$

It follows from (3.22) and (3.26) that

$$\sum_{k=1}^{m} c^{k-1}\,\tilde{E}\,(e^k - \lambda\,G(\pi^{k-1})(\pi^k - \pi^{k-1}),\pi^k) \to 0$$

as $\lambda \to 0$. Define

$$\begin{aligned} S_\lambda = \int_0^T & e_\lambda(t)\,\tilde{E}(2\langle A\pi_\lambda(t+\lambda) - A\pi(t), \pi(t+\lambda) - \pi(t)\rangle + \tilde{\omega}\,|\pi(t+\lambda) - \pi(t)|_X^2 \\ & - 2(G(\pi_\lambda(t))(\pi_\lambda(t+\lambda) - \pi(t)), \pi_\lambda(t+\lambda) - \pi(t)) \\ & - |F(\pi_\lambda(t+\lambda)(\pi_\lambda(t+\lambda) - \pi(t))|_X^2)\,dt. \end{aligned} \tag{3.30}$$

It then follows from (3.24) that

$$S_\lambda \geq \beta \int_0^T e_\lambda(t)\, \tilde{E}\, |\pi_\lambda(t+\lambda) - \pi(t)|^2_{\widetilde{V}}\, dt. \tag{3.31}$$

On the other hand, it follows from (3.16) and Ito's lemma that

$$\begin{aligned} & e^{-\tilde{\omega}T}\, \tilde{E}\, |\pi(T)|^2_X - \tilde{E}\, |p_0|^2_X \\ & + \int_0^T e^{-\tilde{\omega}t} \tilde{E}\, (2\langle A\pi(t), \pi(t)\rangle + \tilde{\omega}\, |\pi(t)|^2_X - 2(G(\pi(t))\pi(t), \pi(t)) \\ & - |F(\pi(t))\pi(t)|^2_X)\, dt = 0. \end{aligned} \tag{3.32}$$

Note that $|e_\lambda(t) - e^{-\tilde{\omega}t}| \to 0$ as $\lambda \to 0$ uniformly on $[0, T]$. Hence, since from (3.29)–(3.30),

$$\begin{aligned} & \int_0^T e^{-\tilde{\omega}t} \tilde{E}\, (-2\, \langle A\pi(t), \pi(t)\rangle - \tilde{\omega}\, |\pi(t)|^2_X + 2(G(\pi(t))\pi(t), \pi(t)) + |F(\pi(t))\pi(t)|^2_X)\, dt \\ & \qquad + \liminf\ T_\lambda = \liminf\ S_\lambda \geq 0, \end{aligned}$$

it follows from (3.28)–(3.32) that as $\lambda \to 0$,

$$\begin{aligned} & \int_0^T e^{-\tilde{\omega}t}\, \tilde{E}\, (-2\, \langle A\pi(t),\, \pi(t)\rangle - \tilde{\omega}\, |\pi(t)|^2_X + 2(G(\pi(t))\pi(t), \pi(t)) + |F(\pi(t))\pi(t)|^2_X)\, dt \\ & \qquad + \tilde{E}|p_0|^2_X - e^{-\tilde{\omega}T}\ \limsup\ \tilde{E}\, |\pi_\lambda(T)|^2_X \geq 0. \end{aligned} \tag{3.33}$$

Combining (3.32)–(3.33), we obtain

$$e^{-\tilde{\omega}T}\, (\tilde{E}\, |\pi(T)|^2_X - \limsup\ \tilde{E}\, |\pi_\lambda(T)|^2_X) \geq 0.$$

Since $\pi_\lambda(T)$ converges weakly to $\pi(T)$ (without loss of generality), $\tilde{E}\, |\pi(T)|^2_X - \liminf \tilde{E}\, |\pi_\lambda(T)|^2_X \leq 0$ and thus we have

$$\tilde{E}\, |\pi_\lambda(T) - \pi(T)|^2_X \to 0 \quad \text{as } \lambda \to 0.$$

Moreover, $\liminf\ S_\lambda = 0$ and from (3.31)

$$\tilde{E}\, |\pi_\lambda(t) - \pi(t)|_{L^2(0,T;\widetilde{V})} \to 0 \quad \text{as } \lambda \to 0. \qquad \square$$

4. Convergence rate. In this section we establish the convergence estimate (3.12) of π^λ_t to $\pi(t)$ by Corollary 3.5. First, we have the following estimate.

LEMMA 4.1. *For all m and $\lambda = T/m$,*

$$\sup_{1 \leq k \leq m} \tilde{E} : |p^k|^4_X \leq C\, \tilde{E} : |p_0|^4_X.$$

Proof. Note that in (2.15) $\alpha^k = \alpha^k(t_k)$, where

$$\alpha^k(t) = p^{k-1} + \int_{t_{k-1}}^t h\alpha^k(s)\, dy(s) \quad t \in [t_{k-1}, t_k]. \tag{4.1}$$

Multiplying (2.15) by $p_k|p_k|_X^2$, we obtain

(4.2)
$$\frac{1}{4}\left(|p^k|_X^4 - |\alpha^k|_X^4 + (|p_k|_X^2 - |\alpha^k|_X^2)^2\right) + \frac{1}{2}\,|p^k|_X^2|p^k - \alpha^k|_X^2 + \lambda\,\langle Ap^k, p^k\rangle\,|p^k|_X^2 = 0.$$

From (4.1) and Ito's lemma

$$d|\alpha^k(t)|_X^2 = 2\,(h\,\alpha^k(t), \alpha^k(t))_X\,dy(t) + |h\,\alpha^k(t)|_X^2\,dt.$$

Thus, by Ito's lemma,

$$\tilde{E}\,|\alpha^k(t)|_X^4 - \tilde{E}\,|p^{k-1}|_X^4 = \tilde{E}\int_{t_{k-1}}^{t} (4\,|(h\,\alpha^k(s), \alpha^k(s))_X|^2 + 2\,|h\,\alpha^k(s)|_X^2|\alpha^k(s)|_X^2)\,ds$$

$$\leq \int_{t_{k-1}}^{t} 6|h|_\infty^2\,\tilde{E}\,|\alpha^k(s)|_X^4\,ds.$$

By Gronwall's lemma,

$$\tilde{E}\,|\alpha^k|_X^4 \leq e^{6|h|_\infty^2\lambda}\,\tilde{E}\,|p^{k-1}|_X^4.$$

As shown in section 3.2, it follows from (2.7) and (4.3) that

$$e^{-\tilde{\omega}\lambda}\tilde{E}\,|p^k|_X^4 + 2e^{-6\lambda|h|_\infty^2}\beta\,\tilde{E}\,|p^k|_{\widetilde{V}}^2|p^k|_X^2 \leq \tilde{E}\,|p^{k-1}|_X^4,$$

where $\tilde{\omega} = 1 + 4\tilde{\rho} + 6\,|h|_\infty^2$. Hence we obtain

$$\sup_k \tilde{E}\,|p^k|_X^4 + \sum_{k=1}^{m} \tilde{E}\,\beta\,|p^k|_{\widetilde{V}}^2|p^k|_X^2 \leq e^{-\tilde{\omega}T}\,\tilde{E}\,|p_0|_X^4. \qquad \square \tag{4.3}$$

Next, we have the convergence estimate.

THEOREM 4.2. *Assume that the solution $p(t)$ of (1.7) satisfies the following regularity:*

$$\tilde{E}\,|A(hp(t))|_X^2 + \tilde{E}\,|Ap(t)|_X^2 \leq M \tag{4.4}$$

for some $M > 0$ and all $t \in [0, T]$. Then for all m and $\lambda = T/m$,

$$\sup_{1\leq k\leq m} \tilde{E}\,|p^k - p(t_k)|_X^2 + \beta\sum_{k=1}^{m} |p^k - p(t_k)|_{\widetilde{V}}^2 \leq C\,\lambda^2.$$

Proof. For $k \geq 0$ define the approximation error ϵ_k by

$$\epsilon_k = \int_{t_{k-1}}^{t_k} A(p(t) - p(t_k))\,dt - \int_{t_{k-1}}^{t_k} h(p(t) - \bar{\alpha}(t))\,dy(t), \tag{4.5}$$

where $p(t)$ is the unique solution to the Zakai equation (1.7) and $\bar{\alpha}(t)$ satisfies

$$d\bar{\alpha}(t) = h(x)\bar{\alpha}(t)\,dy(t), \quad \bar{\alpha}(t_{k-1}) = p(t_{k-1})$$

on $[t_{k-1}, t_k]$. Since (1.7) is equivalently written as

$$p(t_k) - p(t) + \int_t^{t_k} Ap(s)\, ds = \int_t^{t_k} hp(s)\, dy(s), \tag{4.6}$$

we have $\epsilon_k = \epsilon_k^{(1)} - \epsilon_k^{(2)}$ with

$$\begin{aligned} \epsilon_k^{(1)} &= \int_{t_{k-1}}^{t_k} \int_t^{t_k} A^2 p(s)\, ds\, dt, \\ \epsilon_k^{(2)} &= \int_{t_{k-1}}^{t_k} \int_t^{t_k} A(hp(s))\, dy(s)\, dt + \int_{t_{k-1}}^{t_k} h(p(t) - \bar\alpha(t))\, dy(t). \end{aligned} \tag{4.7}$$

Since from (4.5)–(4.6),

$$p(t_k) - p(t_{k-1}) + Ap(t_k) = \int_{t_{k-1}}^{t_k} h\bar\alpha(t)\, dy(t) - \epsilon_k,$$

the error function $\delta p_k = p^k - p(t_k)$ satisfies

$$\delta p_k - \delta p_{k-1} + \lambda\, A\delta p_k = \int_{t_{k-1}}^{t_k} h\delta\alpha_k(t)\, dy(t) + \epsilon_k, \tag{4.8}$$

where $\delta\alpha_k(t) = \alpha^k(t) - \bar\alpha(t)$ on $[t_{k-1}, t_k)$. Multiplying (4.4) by δp_k, we obtain

$$\begin{aligned} &\frac{1}{2}\left(|\delta p_k|_X^2 - |\delta p_{k-1}|_X^2 + |\delta p_k - \delta p_{k-1}|_X^2\right) + \langle \lambda\, A\delta p_k - \epsilon_k^{(1)},\, \delta p_k\rangle_X \\ &\quad = (\delta p_k, \gamma_k - \epsilon_k^{(2)}), \end{aligned} \tag{4.9}$$

where

$$\gamma_k = \int_{t_{k-1}}^{t_k} h\delta\alpha_k(t)\, dy(t).$$

Since $\tilde E\,(\delta p_{k-1}, \gamma_k - \epsilon_k^{(2)}) = 0$, we have

$$\tilde E\,(\delta p_k, \gamma_k + \epsilon_k^{(2)}) \le \frac{1}{2}\,(\tilde E\,|\delta p_k - \delta p_{k-1}|_X^2 + \tilde E\,|\gamma_k - \epsilon_k^{(2)}|_X^2),$$

and from (4.9) and (2.7),

$$\begin{aligned} &(1 - 2\lambda\tilde\rho)\,\tilde E\,|\delta p_k|_X^2 - \tilde E\,|\delta p_{k-1}|_X^2 \\ &\qquad \le -\lambda\beta\,|\delta p_k|_{\widetilde V}^2 + 2\tilde E\,\langle \epsilon_k^{(1)},\, \delta p_k\rangle_X + \tilde E\,|\gamma_k - \epsilon_k^{(2)}|_X^2 \\ &\qquad \le -\frac{\beta\lambda}{2}\,|\delta p_k|_{\widetilde V}^2 + \frac{2\lambda}{\beta}\left|\frac{\epsilon^{(1)}}{\lambda}\right|_{\widetilde V^*}^2 + 2\,(\tilde E\,|\gamma_k|_X^2 + \tilde E\,|\epsilon_k^{(2)}|_X^2). \end{aligned} \tag{4.10}$$

Note that

$$\tilde E\,|\gamma_k|^2 \le |h|_\infty^2 \int_{t_{k-1}}^{t_k} \tilde E\,|\delta\alpha^k(s)|^2\, ds \le |h|_\infty^2 e^{|h|_\infty^2 \lambda}\lambda\,\tilde E\,|\delta p_{k-1}|^2 \tag{4.11}$$

since $\delta\alpha_k$ satisfies $d\delta\alpha_k(t) = h\,\delta\alpha_k(t)\,dy(t)$ with $\delta\alpha_k(t_{k-1}) = \delta p_{k-1}$. Now we evaluate the error terms $\tilde{E}\,|\epsilon^{(2)}|_X^2$ and $\tilde{E}\,|\epsilon^{(1)}|_{\widetilde{V}^*}^2$. To this end we use

$$\tilde{E}\left|\int_{t_{k-1}}^{t}\eta(s)\,ds\right|^2 \le e\,(t-t_{k-1})\int_{t_{k-1}}^{t}\tilde{E}\,|\eta(s)|^2\,ds \tag{4.12}$$

for any square integrable $\mathcal{F}_t$-adapted process η and $t > t_{k-1}$. In fact if $\phi(t) = \int_{t_{k-1}}^{t}\eta(s)\,ds$, then

$$\tilde{E}|\phi(t)|^2 = 2\int_{t_{k-1}}^{t}\tilde{E}(\phi(s),\eta(s))\,ds \le \int_{t_{k-1}}^{t}\left(\frac{1}{t-t_{k-1}}\tilde{E}\,|\phi(s)|^2 + (t-t_{k-1})\tilde{E}\,|\eta(s)|^2\right)ds.$$

Thus (4.12) follows from Gronwall's lemma. From (4.12),

$$\begin{aligned}\tilde{E}\,|\epsilon^{(1)}|_{\widetilde{V}^*}^2 &\le e\lambda\int_{t_{k-1}}^{t_k}\tilde{E}\left|\int_t^{t_k}Ap(s)\,ds\right|_{\widetilde{V}^*}^2 dt\\ &\le (e\lambda)^2\int_{t_{k-1}}^{t_k}\int_t^{t_k}\tilde{E}\,|Ap(s)|_{\widetilde{V}^*}^2\,ds\,dt \le \frac{1}{2}(e\lambda^2)^2\max_{s\in[0,T]}\tilde{E}\,|Ap(s)|_{\widetilde{V}^*}^2\end{aligned}$$

and

$$\begin{aligned}\tilde{E}\left|\int_{t_{k-1}}^{t_k}\int_t^{t_k}A(hp(s))\,dy(s)\,dt\right|_X^2 &\le e\lambda\int_{t_{k-1}}^{t_k}\tilde{E}\left|\int_t^{t_k}A(hp(s))\,dy(s)\right|_X^2 dt\\ &\le e\lambda\int_{t_{k-1}}^{t_k}\int_t^{t_k}\tilde{E}\,|A(hp(s))|_X^2 \le \frac{1}{2}e\lambda^3\max_{s\in[0,T]}\tilde{E}\,|A(hp(s))|_X^2.\end{aligned}$$

Note that

$$d(p(t)-\bar{\alpha}(t)) = h\,(p(t)-\bar{\alpha}(t))\,dy(t) + Ap(t)\,dt$$

and thus by Ito's lemma and the Hölder inequality,

$$\tilde{E}\,|p(t)-\bar{\alpha}(t)|_X^2 \le \int_{t_{k-1}}^{t}\left(\lambda\,\tilde{E}\,|Ap(t)|_X^2 + \left(\frac{1}{\lambda}+|h|_\infty^2\right)\tilde{E}\,|p(s)-\bar{\alpha}(s)|_X^2\right)ds.$$

By Gronwall's lemma,

$$\tilde{E}\,|p(t)-\bar{\alpha}(t)|_X^2 \le e^{1+|h|_\infty^2\lambda}\,\lambda^2\max_{s\in[0,T]}\tilde{E}\,|Ap(s)|_X^2$$

and thus

$$\begin{aligned}\tilde{E}\left|\int_{t_{k-1}}^{t_k}h(p(t)-\bar{\alpha}(t))\,dy(t)\right|_X^2 &\le |h|_\infty^2\int_{t_{k-1}}^{t_k}\tilde{E}\,|p(t)-\bar{\alpha}(t)|_X^2\\ &\le e^{1+|h|_\infty^2\lambda}\,|h|_\infty^2\lambda^3\max_{s\in[0,T]}\tilde{E}\,|Ap(s)|_X^2.\end{aligned}$$

Hence there exists a constant c_2 such that

$$\frac{2}{\lambda}\,\tilde{E}\,|\epsilon^{(2)}|_X^2 + \frac{1}{\beta}\,\tilde{E}\,\left|\frac{\epsilon^{(1)}}{\lambda}\right|_{\widetilde{V}^*}^2 \le c_2\,\lambda^2 \tag{4.13}$$

provided that (4.4) holds. It thus follows from (4.10)–(4.13) that

$$(1-2\tilde{\rho}\lambda)\,(\tilde{E}\,|\delta p_k|_X^2 + \beta\,\tilde{E}\,|\delta p_k|_{\widetilde{V}}^2) \le (1+c\lambda)\,\tilde{E}\,|\delta p_{k-1}|_X^2 + c_2\,\lambda^3$$

for some positive constants c. Thus we obtain

$$\sup_{1\le k\le m}\ \tilde{E}\,|\delta p_k|_X^2 + \beta\sum_{k=1}^{m}\lambda\tilde{E}\,|\delta p_k|_{\widetilde{V}}^2 \le M\frac{e^{\tilde{c}T}-1}{\tilde{c}}\,\lambda^2$$

for $\tilde{c} = 1 + c + 2\tilde{\rho}$. □

The regularity assumption (4.4) of the solution to (1.7) can be verified under certain smoothness assumptions on the functions f, σ, h, and the initial condition p_0 (e.g., see [20]). Now the estimate (3.12) follows from Corollary 3.5, Lemma 4.1, and Theorem 4.2.

REGULARITY RESULTS FOR THE MINIMUM TIME FUNCTION OF A CLASS OF SEMILINEAR EVOLUTION EQUATIONS OF PARABOLIC TYPE*

PAOLO ALBANO†, PIERMARCO CANNARSA†, AND CARLO SINESTRARI†

Abstract. Under suitable controllability and smoothness assumptions, the minimum time function $T(x)$ of a semilinear control system is proved to be locally Lipschitz continuous and semiconcave on the controllable set. These properties are then applied to derive optimality conditions relating optimal trajectories to the superdifferential of T.

Key words. time optimal control, semilinear parabolic problem, semiconcavity, optimality conditions

1. Introduction.

In this paper we study a time optimal control problem for the system

$$y'(t) = Ay(t) + f(y(t)) + u(t) \quad (t > 0), \quad y(0) = x.$$

Here y belongs to a real separable Banach space X, A is the generator of an analytic semigroup of negative type, f is a Lipschitz perturbation, and $u(\cdot)$ is a control taking values in a closed set $U \subset X$. A model problem for such an equation is a semilinear parabolic system under the action of a distributed control.

The time optimal control problem associated with this system consists of finding, for any initial condition $x \in X$, the trajectories reaching in minimum time a given set $K \subset X$, called the target set. If such a trajectory exists, it is called optimal for the point x.

The history of this problem dates back to the works [17], [18], [20], [21], [5], [16], [22] (see also [24]), where it was studied for linear systems ($f \equiv 0$) using the Pontryagin maximum principle. The linear problem is also considered in [12] from the point of view of dynamic programming. Nonlinear time optimal control problems in infinite dimensions were treated in [6], [7], [14], [15] following the dynamic programming approach. A comprehensive description of many of these results is given in [23].

In this paper we restrict our attention to the case where both the control set U and the target K are closed balls in X. In addition, we require that the control set be large enough to ensure local controllability on ∂K. Our approach can possibly be extended to more general control systems, where K and U are smooth bounded sets with nonempty interior, but we do not treat such cases here.

The main object of our analysis is the minimum time function $T(x)$ of the above system, defined as the infimum of the time taken to steer the trajectories of the state equation from x to K. It is well known that this function provides the basis of the dynamic programming method in optimal control. In section 3 we give the

†Dipartimento di Matematica, Università di Roma "Tor Vergata", Via della Ricerca Scientifica, 00133 Roma, Italy (albano@mat.uniroma2.it, cannarsa@mat.uniroma2.it, sinestra@mat.uniroma2.it).

precise definition and state some basic properties of $T(x)$. In section 4 we analyze the regularity of the minimum time function. Our main result (Theorem 4.3) is that T satisfies a semiconcavity estimate of the form

$$T(x) + T(y) - 2T\left(\frac{x+y}{2}\right) \leq C|x-y|^{1+\alpha}$$

for some $C \geq 0$, $\alpha \in]0,1]$. This result holds under suitable regularity assumptions on the norm of the space X and on the nonlinear term f which appears in the state equation. We have to assume, in fact, that the norm of X is sufficiently smooth away from 0 and that, roughly speaking, f is of class $C^{1,\alpha}$ as a function from Y to X, where $Y \subset X$ is the domain of a suitable fractional power of $-A$. We could just assume $f \in C^{1,\alpha}(X,X)$, but this would be too restrictive for the application to the model problem mentioned at the beginning. A similar semiconcavity result was obtained by two of the authors in [11] for a finite dimensional setting; the main ideas in the proof are similar, but the extension of the technique of [11] to infinite dimensions requires a substantial improvement of the method.

Once we have proved the semiconcavity of T, we are in a position to apply the regularity results on semiconcave functions proved in [2]. These results are recalled in section 2 of this paper and concern the set of nondifferentiability (or singular set) of a semiconcave function. In particular, the singular set can be covered by a countable family of Lipschitz surfaces in X. Moreover, it is possible to give conditions for the propagation of singularities starting from a given point of nondifferentiability. In the case of the minimum time function, these results become interesting in connection with the optimality conditions that we derive in section 5 of this paper. Our main result (see Corollary 5.12 and Theorem 5.13) states that there is a one-to-one correspondence between the optimal trajectories starting at a given point x and the elements of a suitable generalized differential of T at x. In particular, it follows that the differentiability points of T are exactly the starting points of a unique time optimal trajectory. Therefore, the aforementioned result on the singular sets of T implies that the initial conditions of multiple time optimal trajectories form a "small" set in X. On the other hand, this set is in general nonempty even for a system associated with a parabolic equation (see [1]).

2. Preliminaries. Throughout this paper we denote by X a *real separable* Banach space with *separable dual* X^*, and by

$$E = \{e_j\}_{j\in\mathbb{N}}$$

a dense subset of X. Then, X is an Asplund space and, in particular, X possesses an equivalent norm that is Fréchet differentiable on $X \setminus \{0\}$. We denote by $|\cdot|$ such a norm, by $\langle\cdot,\cdot\rangle$ the duality pairing between X and X^*, and by $\|\cdot\|$ the standard norm of a linear operator between Banach spaces. For any $R > 0$ and $x \in X$, we set

$$B_R(x) = \{y \in X : |x-y| < R\},$$

and we abbreviate $B_R = B_R(0)$.

Let $\Omega \subset X$ be an open set and W another Banach space. We denote by $C(\Omega;W)$ the space of all continuous functions $g : \Omega \to W$, and by $C^1(\Omega;W)$ the space of all functions that are Fréchet differentiable in Ω with continuous derivative Dg. Furthermore, for any $\theta \in [0,1]$, $C^{1,\theta}(\Omega;W)$ stands for the set of all functions $g \in C^1(\Omega;W)$ with Hölder continuous derivative; that is

$$\|Dg(x) - Dg(z)\| \leq C|x-z|^\theta \quad \forall x,z \in \Omega$$

for some constant $C > 0$. Finally, in the above notation, we drop the arrival set when $W = \mathbb{R}$.

We now recall the definition of a semiconcave function in Ω, a notion that is classical in finite dimensions and that was applied to infinite dimensional problems in [26], [8].

DEFINITION 2.1. *Given $\alpha \in]0,1]$, a function $g \in C(\Omega)$ is said to be* semiconcave *with exponent α if, for any point $x_0 \in \Omega$, there exist $\rho > 0$ and $C \geq 0$ such that*

$$g(x) + g(y) - 2g\left(\frac{x+y}{2}\right) \leq C|x-y|^{1+\alpha}$$

for all $x, y \in B_\rho(x_0)$. We denote by $SC^\alpha(\Omega)$ the set of all functions $g : \Omega \to \mathbb{R}$ which are semiconcave with exponent α and we set $SC(\Omega) = \cup_{\alpha \in]0,1]} SC^\alpha(\Omega)$.

Semiconcave functions share many properties with concave functions. For instance, arguing as in the finite dimensional case (see e.g., [3]), it is easy to show that any semiconcave function in Ω is locally Lipschitz continuous. Consequently, g is Fréchet differentiable on a dense set by a result of [28], and the gradient Dg is locally bounded. Now, let us denote by $D_*g(x)$ the set of all points $p \in X^*$ for which a sequence $\{x_k\}_{k\in\mathbb{N}} \subset \Omega$ exists such that

(i) $x = \lim_{k\to\infty} x_k$,

(ii) g is Fréchet differentiable at x_k,

(iii) $Dg(x_k)$ weakly–* converges to p as $k \to \infty$.

In view of the above remarks we have that $D_*g(x) \neq \emptyset$ for any $x \in \Omega$.

Just like the concave case, semiconcave functions possess a natural notion of generalized gradient, given by the *superdifferential*

$$D^+g(x) = \left\{ p \in X^* \,:\, \limsup_{y\to x} \frac{g(y) - g(x) - \langle p, y-x\rangle}{|y-x|} \leq 0 \right\} \quad \forall x \in \Omega.$$

Actually, a similar generalization of the gradient is the *subdifferential* of g defined as

$$D^-g(x) = \left\{ p \in X^* \,:\, \liminf_{y\to x} \frac{g(y) - g(x) - \langle p, y-x\rangle}{|y-x|} \geq 0 \right\}.$$

However, for a semiconcave function, the superdifferential plays a more important role than the subdifferential. Indeed, in view of the proposition below, D^+g is nonempty at every point. Therefore, given any $x \in \Omega$, either $D^-g(x)$ is empty, or g is differentiable at x.

PROPOSITION 2.2. *Let $g \in SC^\alpha(\Omega)$ for some $\alpha \in]0,1]$ and let $x_0 \in \Omega$. Then $D^+g(x_0)$ is nonempty and satisfies*

$$D^+g(x_0) = \overline{\text{co}}\, D_*g(x_0), \tag{2.1}$$

where $\overline{\text{co}}$ denotes the closed convex hull. Moreover, there exist $R, C > 0$ such that

$$g(y) - g(x) - \langle p, y-x\rangle \leq C|y-x|^{1+\alpha} \quad \forall\, y, x \in B_R(x_0),\ p \in D^+g(x), \tag{2.2}$$

$$\langle p-q, y-x\rangle \leq 2C|y-x|^{1+\alpha} \quad \forall\, y, x \in B_R(x_0),\ p \in D^+g(y),\ q \in D^+g(x). \tag{2.3}$$

For the proof of the above proposition the reader is referred to [8] for semiconcave functions with exponent $\alpha = 1$, the argument in the general case being similar.

We now introduce the singular sets of a semiconcave function on X. Let P be a subspace of X^* and $r > 0$. We denote by B_r^P the ball with radius r and center at 0 in P. We say that B is a *ball of dimension* $n \in \mathbb{N}$ in X^* if there exist a subspace $P \subset X^*$, with $\dim P = n$, a covector $p \in X^*$, and a radius $r > 0$ such that

$$B = p + B_r^P. \tag{2.4}$$

Similarly, we say that B is a *ball of codimension* n in X^* if (2.4) holds for a subspace P such that $\operatorname{codim} P = n$. Let $g : \Omega \to \mathbb{R}$ be a semiconcave function. We introduce the following singular sets of g.

DEFINITION 2.3. *The set of all points $x \in \Omega$ such that $D^+g(x)$ fails to be a singleton is called the* singular set *of g and is denoted by $\Sigma(g)$. The points of $\Sigma(g)$ are called the* singular points *of g. Moreover, for any $n \in \mathbb{N}$, $n > 0$ we denote by $\Sigma_n(g)$ (resp., $\Sigma_{\infty-n}(g)$) the set of all points $x \in \Omega$ such that $D^+g(x)$ contains a ball of dimension n (resp., codimension n).*

To study the singular set we will need the following definition (see e.g., [19]).

DEFINITION 2.4. *We will say that a set $\Sigma \subset X$ is n* rectifiable *iff a bounded set $A \subset \mathbb{R}^n$ and a Lipschitz function, f, exist so that*

$$f : A \to \Sigma$$

is surjective. Moreover, we will say that a set $\Sigma \subset X$ is countably n rectifiable *iff*

$$\Sigma = \bigcup_{j \in \mathbb{N}} Q_j \tag{2.5}$$

where the sets $Q_j \subset X$, $j \in \mathbb{N}$, are n rectifiable.

By analogy with the previous definition, we will say that $\Sigma \subset X$ is $\infty - n$ rectifiable if a subspace $Y \subset X$, of codimension n, and a bounded set $A \subset Y$ exist so that Σ is the image of A under a Lipschitz map f. Similarly, we will say that Σ is countably $\infty - n$ rectifiable if it can be represented as in (2.5) for some family of $\infty - n$ rectifiable sets $\{Q_j\}$. The following theorem is proved in [2].

THEOREM 2.5. *Let $g \in SC(\Omega)$ and fix $n \in \mathbb{N}$, $n > 0$. Then,*

(i) *$\Sigma_n(g)$ is countably $\infty - n$ rectifiable;*

(ii) *$\Sigma_{\infty-n}(g)$ is countably n rectifiable.*

The following theorem, again proved in [2], describes the propagation of singularities of a semiconcave function with exponent 1.

THEOREM 2.6. *Let X be a Hilbert space, let $g \in SC^1(\Omega)$, and let $x_0 \in \Sigma(g)$. Let*

$$p_0 \in D^+g(x_0) \setminus D_*g(x_0)\,, \tag{2.6}$$

and suppose that, for some vector $q \in X \setminus \{0\}$ and some $T_0 > 0$,

$$p_0 + tq \notin D^+g(x_0) \quad \forall 0 < t \le T_0\,. \tag{2.7}$$

Then, a number $0 < T \le T_0$ and two Lipschitz arcs $x, p : [0, T] \to X$ exist so that

$$\text{(i)} \quad \langle x(t) - x_0, q\rangle < 0 \ \ \forall 0 < t \le T,$$

$$\text{(ii)} \quad (x(0), p(0)) = (x_0, p_0),$$

$$\text{(iii)} \quad (x(t), p(t)) \in \Sigma(g) \times D^+g(x(t)) \quad \forall t \in [0, T]\,.$$

A point $x_0 \in \Sigma(g)$ for which x and p as above exist will be called a *propagation point* of $\Sigma(g)$.

3. A time optimal control problem. Let us consider the controlled evolution equation in X

$$\begin{cases} y'(t) = Ay(t) + f(y(t)) + u(t), & t > 0, \\ y(0) = x, \end{cases} \tag{3.1}$$

under the following assumptions:

(H1) $A : D(A) \subset X \to X$ is the infinitesimal generator of an analytic semigroup of bounded linear operators on X, e^{tA}, satisfying

$$\|e^{tA}\| \le e^{-\omega t} \quad \forall t \ge 0 \tag{3.2}$$

for some constant $\omega > 0$;

(H2) $f : X \to X$ is a Lipschitz continuous function satisfying

$$|f(x) - f(y)| \le L|x - y| \quad \forall x, y \in X,$$
$$f(0) = 0.$$

We assume that the *control set* U is a closed ball in X of the form

$$U = \overline{B}_r \tag{3.3}$$

for some given $r > 0$. A measurable function $u : [0, +\infty[\to U$ will be called a *control strategy* (or, simply a *control*). We denote by $\mathcal{U}$ the set of all control strategies. It is well known that, for any $x \in X$ and any control u, state equation (3.1) has a unique mild solution. We recall that a mild solution of (3.1) is a function $y \in C([0, \infty[; X)$ satisfying

$$y(t) = e^{tA}x + \int_0^t e^{(t-s)A}[f(y(s)) + u(s)]ds\,, \quad t \ge 0. \tag{3.4}$$

Such a solution is called the *trajectory* of system (3.1) starting from x with control u and is denoted by $y(\cdot; x, u)$.

Remark 3.1. The assumption that ω in (H1) is positive is not restrictive, as one can always reduce the system to this case by adding a bounded linear term to f.

Remark 3.2. Assumption (H1) implies (see e.g., [27]) that the *fractional powers* of $-A$, denoted by $(-A)^\theta$, are well defined for any $\theta \in [0, 1]$ and satisfy

$$|(-A)^\theta e^{tA}x| \le \frac{M_\theta}{t^\theta}|x| \quad \forall x \in X, t > 0, \tag{3.5}$$

$$|x| \le M'_\theta|(-A)^\theta x| \quad \forall x \in D((-A)^\theta) \tag{3.6}$$

for suitable constants $M_\theta, M'_\theta > 0$. Moreover, a well-known interpolation inequality (see e.g., [27]) ensures that, for any $\theta \in [0, \frac{1}{2}]$, there exists $\kappa_\theta > 0$ such that

$$|(-A)^\theta x| \le |(-A)^{\frac{1}{2}}x| + \kappa_\theta|x| \qquad \forall x \in D((-A)^{\frac{1}{2}})\,. \tag{3.7}$$

We are interested in the time optimal control problem for system (3.1) with a closed ball $\overline{B}_R$ as a target. More precisely, for any $x \in X$ and any control strategy u we denote by

$$\tau(x, u) = \min\{t \ge 0 : y(t; x, u) \in \overline{B}_R\} \in [0, +\infty] \tag{3.8}$$

the transition time from x to $\overline{B}_R$. We define the *controllable set* $\mathcal{R}$ to be the set of all points x such that $\tau(x,u) < +\infty$ for some u. Then, for all $x \in \mathcal{R}$, the time optimal control problem consists of minimizing $\tau(x,u)$ over all controls u. A control u at which $\tau(x,\cdot)$ attains the minimum is said to be optimal for x and the corresponding solution $y(\cdot;x,u)$ of (3.1) is called an optimal trajectory.

The dynamic programming approach to the above problem is based on the properties of the *value function* — called minimum time function in this case — defined as

$$T : \mathcal{R} \to [0,+\infty[\,, \quad T(x) = \inf_{u\in\mathcal{U}} \tau(x,u). \tag{3.9}$$

The minimum time function encompasses most of the information about the control problem. An important property of this function is the dynamic programming principle which says that, for any $x \in \mathcal{R}$ and any control u,

$$T(x) \le t + T(y(t;x,u)) \qquad \forall t \in [0,\tau(x,u)]\,. \tag{3.10}$$

Furthermore, equality holds in (3.10) iff u is optimal for x.

Our goal is to relate the optimal trajectories of the above problem to the structure of superdifferentials of T. Such generalized differentials enjoy the properties that we have described in the previous section, once it is shown that T is semiconcave. Therefore, one of the main steps of our analysis will be to prove the semiconcavity of T, which we do in the next section. For this purpose we impose, in addition to (H1) and (H2), the conditions below.

(H3) The constants ω, L, r, R which appear in (H1), (H2), (3.3), and (3.8), resp., satisfy

$$0 < (L-\omega)R < r.$$

(H4) There exists $\alpha \in]0,1]$ such that the norm in X is of class $C^{1,\alpha}(X \setminus \overline{B}_M)$, for any $M > 0$.

(H5) The function f is Gâteaux differentiable at all points $x \in X$. The Gâteaux differential $\delta f(x)$ satisfies the following property: there exist $\theta_1 \in]0,1/2[$, $\beta \in]0,1]$, and $\hat{C} > 0$ such that

$$|f(x+y) - f(x) - \delta f(x)y| \le \hat{C}|(-A)^{\theta_1} y|^{1+\beta} \tag{3.11}$$

for all $x, y \in D((-A)^{\theta_1})$. Moreover, the map $x \mapsto \delta f(x)$ is strongly continuous on X; that is, for any sequence $\{x_n\}$ in X,

$$\lim_{n\to\infty} x_n = x_\infty \quad \Rightarrow \quad \lim_{n\to\infty} \delta f(x_n)x = \delta f(x_\infty)x \ \ \forall x \in X. \tag{3.12}$$

Remark 3.3. The rightmost inequality in (H3) is a controllability assumption and will ensure that $\mathcal{R}$ is an open neighbourhood of $\overline{B}_R$. The first inequality holds provided $L > \omega$ and has been assumed only in order to simplify the exposition. In fact, all the results of this paper hold in the case of $L \le \omega$ as well, and some of them even in a stronger form. For instance, if $L \le \omega$, one could prove that $\mathcal{R} = X$.

Remark 3.4. Let us denote by $d(x)$ the distance of x from the target

$$d(x) = \inf_{y\in\overline{B}_R} |y - x| = (|x| - R)^+\,.$$

Then, from (H4) and the identity

$$|x+h|+|x-h|-2|x|=\int_0^1 \langle D|x+th|-D|x-th|,h\rangle dt,$$

it follows that d is semiconcave on $X\setminus \overline{B}_R$ with exponent α. In addition, the numbers C,ρ in Definition 2.1 can be chosen independently on $x_0\in X\setminus \overline{B}_R$.

Condition (H4) holds true in several important examples. For instance, let $X=L^p(\mathcal{O})$ where $p\in]1,\infty[$ and $\mathcal{O}$ is a bounded domain $\mathbb{R}^n$. Then, it is well known that the norm satisfies (H4) with $\alpha=p-1$ if $p\in]1,2[$ and with $\alpha=1$ if $p\in[2,\infty[$.

Remark 3.5. Hypothesis (H5) is trivially satisfied when $f\in C^{1,\beta}(X;X)$, since we can take in this case $\delta f=Df$ and any $\theta_1\in]0,1/2[$. However, there are interesting examples where f satisfies our assumptions without being Fréchet differentiable, as shown in the next example. Let us also observe that the Lipschitz continuity of f and property (3.11) imply that, for some constant $L^*>0$,

$$|f(x)+f(y)-2f(z)|\le L^*(|(-A)^{\theta_1}(x-y)|^{1+\beta}+|x+y-2z|) \tag{3.13}$$

for all $x,y,z\in D((-A)^{\theta_1})$.

Example. Let $\mathcal{O}$ be a bounded domain in $\mathbb{R}^n$ with sufficiently smooth boundary, and let $\phi\in \mathrm{Lip}(\mathbb{R})\cap C^{1,1}(\mathbb{R})$ be such that $\phi(0)=0$. In this example we show that the control system associated with the *parabolic* state equation

$$\begin{cases} y_t(t,\xi)=\Delta y(t,\xi)+\phi(y(t,\xi))+u(t,\xi), & (t,\xi)\in]0,+\infty[\times\mathcal{O}\,,\\ y(t,\xi)=0, & (t,\xi)\in]0,+\infty[\times\partial\mathcal{O}\,,\\ y(0,\xi)=x(\xi), & \xi\in\mathcal{O}, \end{cases} \tag{3.14}$$

rewritten in abstract form, satisfies (H1), (H2), and (H5).

Let us set $X=L^2(\mathcal{O})$, and define $A:D(A)\subset X\to X$ as

$$D(A)=W^{2,2}(\mathcal{O})\cap W_0^{1,2}(\mathcal{O})\,;\qquad Ax(\xi)=\Delta x(\xi)\quad(\xi\in\mathcal{O},x\in D(A)).$$

Moreover, consider the composition map $f:X\to X$ defined by

$$f(x)(\xi)=\phi(x(\xi)),\quad(\xi\in\mathcal{O},x\in X).$$

Then, (3.1) is the abstract version of system (3.14). The fact that A satisfies (H1) is well known; (H2) is immediate to check. Let us show that (H5) is also satisfied. It is well known (see e.g., [4]) that f is Gâteaux differentiable with

$$\delta f(y)(z)(\xi)=\phi'(y(\xi))z(\xi)\text{ for any }y,z\in X\,,\ \xi\in\mathcal{O},$$

but f is nowhere Fréchet differentiable unless ϕ is linear. On the other hand, if L and M are the Lipschitz constants of ϕ and ϕ', then, for any $\beta\in[0,1]$, we have that

$$\begin{aligned} &||f(x+y)-f(x)-\delta f(x)y||^2_{L^2(\mathcal{O})}\\ &=\int_\Omega y^2(\xi)\left(\int_0^1(\phi'(x(\xi)+\lambda y(\xi))-\phi'(x(\xi)))\,d\lambda\right)^2 d\xi\\ &\le\int_\Omega y^2(\xi)\left(\int_0^1(|\phi'(x(\xi)+\lambda y(\xi))|+|\phi'(x(\xi))|)\,d\lambda\right)^{2-2\beta}\left(\int_0^1 M\lambda|y(\xi)|d\lambda\right)^{2\beta}d\xi\\ &\le(2L)^{2-2\beta}(M/2)^{2\beta}\int_\Omega|y(\xi)|^{2+2\beta}d\xi=C||y||^{2(1+\beta)}_{L^{2+2\beta}(\mathcal{O})}. \end{aligned}$$

Recalling that, by the Sobolev embedding theorem,

$$D((-A)^\theta) \subset W^{2\theta,2}(\mathcal{O}) \subset L^{2n/(n-4\theta)}(\mathcal{O}),$$

we obtain property (3.11) with

$$\beta = 1\,, \quad \theta_1 = \frac{3}{8} \quad \text{if} \quad n \le 3,$$

and with

$$\beta \in \left]0, \frac{1}{n-1}\right[\,, \quad \theta_1 = \frac{1}{4} \quad \text{if} \quad n > 3.$$

Finally, property (3.12) follows from the Lebesgue dominated convergence theorem.

In the next lemma we collect some basic properties about the trajectories of (3.1).

LEMMA 3.6. *Assume* (H1) *and* (H2). *Then the following properties hold.*

(i) *For any $x \in X$ a control strategy u^* exists such that the corresponding trajectory of* (3.1) *satisfies*

$$|y(t;x,u^*)| \le e^{(L-\omega)t}\left(|x| - \frac{r}{L-\omega}\right) + \frac{r}{L-\omega} \tag{3.15}$$

for any $0 \le t \le \omega^{-1}\log(1 + r^{-1}\omega|x|)$.

(ii) *For any $x \in X$ and any control strategy u the corresponding trajectory of* (3.1) *satisfies*

$$|y(t;x,u)| \le e^{(L-\omega)t}\left(|x| + \frac{r}{L-\omega}\right) - \frac{r}{L-\omega} \quad \forall t \ge 0\,. \tag{3.16}$$

(iii) *For any $x, z \in X$ and any control strategy u we have that*

$$|y(t;x,u) - y(t;z,u)| \le e^{(L-\omega)t}|x-z| \quad \forall t \ge 0. \tag{3.17}$$

(iv) *Let $\theta \in [0,1[$ be given. Then the trajectories of* (3.1) *belong to the domain of $(-A)^\theta$ for any $t > 0$, and*

$$|(-A)^\theta y(t;x,u)| \le \frac{M_\theta}{t^\theta}|x| + \int_0^t \frac{M_\theta}{(t-s)^\theta}(L|y(s;x,u)| + r)ds. \tag{3.18}$$

Moreover, for any $T_0 > 0$, a constant $K = K(\theta, T_0) > 0$ exists such that

$$|(-A)^\theta(y(t;x,u) - y(t;z,u))| \le \frac{K}{t^\theta}|x-z| \tag{3.19}$$

for any $x, z \in X$ and $t \in [0, T_0]$.

(v) *If in addition* (H5) *holds, then, for any $T_0 > 0$, a constant $k > 0$ exists such that*

$$|y(t;x+h,u) + y(t;x-h,u) - 2y(t;x,u)| \le k|h|^{1+\beta} \tag{3.20}$$

for every $x, h \in X$ and $t \in [0, T_0]$.

Proof. (i): Given $x \in X$, $x \neq 0$, let us set, for $t \geq 0$,

$$u^*(t) = -\frac{r}{|x|} e^{t(A+\omega I)} x.$$

By (3.2), $|u^*(t)| \leq r$ for any t, and thus u^* is an admissible control strategy. From (3.4) we compute

$$y(t) = \left(1 - \frac{r}{|x|} \frac{e^{\omega t} - 1}{\omega}\right) e^{tA} x + \int_0^t e^{(t-s)A} f(y(s))\, ds.$$

Let us set

$$\phi(t) = e^{\omega t} |y(t)|\,.$$

Then, for any $t \leq \omega^{-1} \log(1 + r^{-1}\omega|x|)$,

$$\begin{aligned} \phi(t) &\leq \left[|x| - \frac{r}{\omega}\left(e^{\omega t} - 1\right)\right] + \int_0^t e^{\omega s} |f(y(s))|\, ds \\ &\leq |x| + \int_0^t \left[L\phi(s) - r e^{\omega s}\right] ds. \end{aligned}$$

Here we have used the Lipschitz assumption (H2) on f. We can now apply the Gronwall inequality to obtain

$$\phi(t) \leq e^{Lt}|x| + \frac{r}{L - \omega}\left(e^{\omega t} - e^{Lt}\right),$$

which implies (3.15).
(ii)–(iii): These assertions can be derived by similar computations to those of (i).
(iv): Inequality (3.18) is a straightforward consequence of (3.4) and (3.5). In order to prove (3.19), we apply properties (3.5) and (3.17) to obtain

$$\begin{aligned} |(-A)^\theta (y(t;x,u) - y(t;z,u))| &\leq \frac{M_\theta}{t^\theta}|x - z| + \int_0^t \frac{M_\theta}{(t-s)^\theta} |y(s;x,u) - y(s;z,u)| ds \\ &\leq \frac{M_\theta}{t^\theta}|x - z| + M_\theta |x - z| \int_0^t \frac{e^{(L-\omega)s}}{(t-s)^\theta} ds \\ &\leq M_\theta |x - z| \left[\frac{1}{t^\theta} + e^{(L-\omega)T_0} \frac{T_0^{1-\theta}}{1-\theta}\right]. \end{aligned}$$

(v): By (3.2), (3.13), and (3.19), we obtain

$$\begin{aligned} &|y(t;x+h,u) + y(t;x-h,u) - 2y(t;x,u)| \\ &= \left| \int_0^t e^{(t-s)A} (f(y(s;x+h,u)) + f(y(s;x-h,u)) - 2f(y(s;x,u)))ds \right| \\ &\leq L^* \int_0^t e^{-\omega(t-s)} \{|y(s;x+h,u) + y(s;x-h,u) - 2y(s;x,u)| \\ &\qquad + |(-A)^{\theta_1}(y(s;x+h,u) - y(s;x-h,u))|^{1+\beta}\} ds \end{aligned}$$

$$\leq L^* \int_0^t e^{-\omega(t-s)} |y(s;x+h,u) + y(s;x-h,u) - 2y(s;x,u)| ds$$

$$+L^* \int_0^t e^{-\omega(t-s)} \frac{K(\theta_1, T_0)^{1+\beta}}{s^{(1+\beta)\theta_1}} |h|^{1+\beta} ds$$

$$\leq L^* \int_0^t e^{-\omega(t-s)} |y(s;x+h,u) + y(s;x-h,u) - 2y(s;x,u)| ds + K'|h|^{1+\beta}$$

for some $K' > 0$. We conclude our proof by the Gronwall inequality. ∎

Remark 3.7. From (ii) above and (H2) we conclude that, for any $\rho > 0$, a constant $C_\rho > 0$ exists such that

$$|f(y(t;x,u))| \leq C_\rho \quad \forall t \in [0,1]$$

for any $|x| \leq \rho$ and any control strategy u. Therefore, all trajectories starting from $x \in B_\rho$ may be estimated from below as follows:

$$|y(t;x,u)| \geq |e^{tA}x| - (C_\rho + r)t \quad \forall t \in [0,1]\,.$$

The last inequality, together with the strong continuity of e^{tA}, implies that $T(x) > 0$ for any $x \in \mathcal{R} \setminus \overline{B}_R$.

The following proposition shows that, in a neighbourhood of the target, the minimum time function is bounded above by the distance function.

PROPOSITION 3.8. *Assume* (H1), (H2), *and* (H3). *Then, there exists a number* $\rho \in]0, r/(L-\omega) - R[$ *such that*

$$T(x) \leq \frac{d(x)}{r - (R+\rho)(L-\omega)} \tag{3.21}$$

for all points x *satisfying* $d(x) \leq \rho$. *Moreover,* $\mathcal{R}$ *is an open subset of* X.

Proof. First of all, we fix $\rho \in]0, r/(L-\omega) - R[$ so that

$$\frac{1}{L-\omega} \log \frac{\frac{r}{L-\omega} - R}{\frac{r}{L-\omega} - |x|} \leq \omega^{-1} \log(1 + r^{-1}\omega|x|) \tag{3.22}$$

for any $x \in X$ such that $0 < d(x) \leq \rho$. The existence of such a number ρ follows from the fact that, taking the limit as $|x| \to R$, the left-hand side of (3.22) tends to 0 while the right-hand side tends to $\omega^{-1} \log(1 + r^{-1}\omega R) > 0$.

Now, let $x \in X$ be fixed so that $0 < d(x) \leq \rho$, and let u^* be the corresponding control strategy, given by Lemma 3.6(i). Defining

$$t^* = \frac{1}{L-\omega} \log \frac{\frac{r}{L-\omega} - R}{\frac{r}{L-\omega} - |x|}\,,$$

we can apply (3.15) with $t = t^*$ in light of (3.22), obtaining $|y(t^*;x,u^*)| \leq R$. Therefore, by an easy computation,

$$T(x) \leq t^* \leq \frac{d(x)}{r - |x|(L-\omega)}.$$

This estimate, together with (3.17), easily implies that $\mathcal{R}$ is open. ∎

In section 6 we will use the following proposition. For a proof of this standard result see, e.g., [23, p. 68].

PROPOSITION 3.9. *Assume* (H1), (H2), (H5)*, and let y be a trajectory of* (3.1)*. Then, there exists a unique strongly continuous map $G : \Delta \to \mathcal{L}(X)$, where $\Delta := \{(t,s) : 0 \le s \le t \le T\}$, such that*

$$\begin{cases} G(t,t) = I & \forall t \in [0,T] \\ G(t,r)G(r,s) = G(t,s) & \forall r,s,t : 0 \le s \le r \le t \le T, \end{cases} \tag{3.23}$$

and

$$\begin{aligned} G(t,s)x &= e^{(t-s)A}x + \int_s^t e^{(t-r)A}\delta f(y(r))G(r,s)x\,dr \\ &= e^{(t-s)A}x + \int_s^t G(t,r)\delta f(y(r))e^{(r-s)A}x\,dr \end{aligned}$$

for $0 \le s \le t \le T$, $x \in X$.

Remark 3.10. By standard techniques one can show that the operator G above is the evolution operator of the linearization of (3.1) along the trajectory y. Equivalently, if $y(\cdot) = y(\cdot; x, u)$, then, for any $h \in X$, we have that

$$y(t; x+h, u) - y(t; x, u) = G(t,0)h + o(|h|)\,. \tag{3.24}$$

4. Regularity of the minimum time function. In this section we prove that the minimum time function T, defined in (3.9), is semiconcave. We begin showing a preliminary regularity result, which yields, in particular, the local Lipschitz continuity of T.

THEOREM 4.1. *Assume* (H1), (H2), (H3)*, and let $x_0 \in \mathcal{R} \setminus \overline{B}_R$ be fixed. Then, for some $\delta > 0$,*

$$0 < m(\delta) := \inf_{x \in B_\delta(x_0)} T(x) \le \sup_{x \in B_\delta(x_0)} T(x) =: M(\delta) < +\infty\,. \tag{4.1}$$

Moreover, for any $\theta \in [0,1[$ a constant $K_\theta = K_\theta(x_0)$ exists such that

$$|T(x) - T(z)| \le K_\theta |(-A)^{-\theta}(x-z)| \qquad \forall x, z \in B_\delta(x_0). \tag{4.2}$$

Proof. We first prove the rightmost inequality of (4.1); that is, we show that T is bounded from above in some neighborhood of x_0. Let u_0 be a control such that $\tau_0 := \tau(x_0, u_0) < \infty$. Recalling (3.17), we have that, for any $x \in X$,

$$d(y(\tau_0; x, u_0)) \le |y(\tau_0; x, u_0) - y(\tau_0; x_0, u_0)| \le e^{(L-\omega)\tau_0}|x - x_0|\,.$$

Now, let

$$\delta_0 = \rho e^{(\omega - L)\tau_0},$$

where $\rho \in]0, r/(L-\omega) - R[$ is given by Proposition 3.8. Then, from the dynamic programming principle and (3.21) we obtain

$$T(x) \le \tau_0 + T(y(\tau_0; x, u_0)) < \tau_0 + \frac{\rho}{r - (R+\rho)(L-\omega)} \qquad \forall x \in B_{\delta_0}(x_0),$$

and this shows that $M(\delta_0) < +\infty$. We now show that there exist numbers $\delta_1 \in]0, \delta_0]$ and $C > 0$ such that

$$|T(x) - T(z)| \le C|x - z| \qquad \forall x, z \in B_{\delta_1}(x_0)\,. \tag{4.3}$$

Let us define

$$\delta_1 = \min\left\{\frac{\rho}{2}e^{(\omega - L)M(\delta_0)}, \delta_0\right\}$$

and consider two points $x, z \in B_{\delta_1}(x_0)$ with $T(x) < T(z)$. Then, for any $\varepsilon \in]0, T(z) - T(x)[$ a control u_ε exists such that

$$\tau(x, u_\varepsilon) < T(x) + \varepsilon < T(z) \le M(\delta_0).$$

Let us set for simplicity $x' = y(\tau(x, u_\varepsilon); x, u_\varepsilon)$, $z' = y(\tau(x, u_\varepsilon); z, u_\varepsilon)$. From the dynamic programming principle it follows that

$$|T(z) - T(x)| = T(z) - T(x) \le T(z') + \varepsilon\,. \tag{4.4}$$

Now, estimate (3.17) gives

$$d(z') \le |x' - z'| \le e^{(L-\omega)M(\delta_0)}|x - z| < \rho.$$

Then we can apply Proposition 3.8 to obtain

$$\begin{aligned} |T(z) - T(x)| &\le T(z') + \varepsilon \le \frac{|x' - z'|}{r - (R + \rho)(L - \omega)} + \varepsilon \\ &\le \frac{e^{(L-\omega)M(\delta_0)}}{r - (R + \rho)(L - \omega)}|x - z| + \varepsilon\,. \end{aligned} \tag{4.5}$$

Since ε is arbitrary, (4.3) follows. We note that (4.3) is a special case of (4.2), namely (4.2) for $\theta = 0$. Recalling Remark 3.7, such a Lipschitz estimate yields the lower bound in (4.1) for a suitably small $\delta \in]0, \delta_1[$.

In order to complete the proof it remains to prove (4.2) for $\theta \in]0, 1[$. For this purpose, we note that, taking x, z, and u_ε as above,

$$\begin{aligned} &|y(t; x, u_\varepsilon) - y(t; z, u_\varepsilon)| \\ &\le \int_0^t e^{-\omega(t-s)}|f(y(s; x, u_\varepsilon)) - f(y(s; z, u_\varepsilon))|ds + |e^{tA}(x - z)| \\ &\le L\int_0^t e^{-\omega(t-s)}|y(s; x, u_\varepsilon) - y(s; z, u_\varepsilon)|ds + \frac{M_\theta}{t^\theta}|(-A)^{-\theta}(x - z)|\,. \end{aligned}$$

Then, applying the Gronwall inequality, we obtain

$$\begin{aligned} |y(t; x, u_\varepsilon) - y(t; z, u_\varepsilon)| &\le \left[\frac{M_\theta}{t^\theta} + LM_\theta\int_0^t \frac{e^{(L-\omega)(t-s)}}{s^\theta}ds\right]|(-A)^{-\theta}(x - z)| \\ &\le \left[\frac{M_\theta}{m(\delta)^\theta} + \frac{LM_\theta}{1 - \theta}M(\delta)^{1-\theta}e^{(L-\omega)M(\delta)}\right]|(-A)^{-\theta}(x - z)| \end{aligned}$$

for all $t \in [T(x), \tau(x, u_\varepsilon)]$. For $t = \tau(x, u_\varepsilon)$, the left-hand side of the inequality is $|x' - z'|$. Arguing as in (4.5), we then conclude that

$$|T(x) - T(z)| \le K_\theta |(-A)^{-\theta}(x - z)| + \varepsilon$$

for some $K_\theta > 0$. Since ε is arbitrary, the proof is complete. □

Remark 4.2. From estimate (4.2) it is easy to deduce that $D^+T(x) \subset D((-A^*)^\theta)$ for all $\theta \in [0, 1[$. Moreover, if $D((-A)^\theta)$ is compactly embedded into X for some $\theta \in]0, 1[$, then (4.2) implies that T is sequentially weakly continuous near x_0.

We can now prove our semiconcavity result for the minimum time function.

THEOREM 4.3. *Let assumptions* (H1), (H2), (H3), (H4), *and* (H5) *be satisfied, and let* α *and* β *be as in* (H4) *and* (H5), *resp. Then the minimum time function* T *belongs to* $SC^\gamma(\mathcal{R} \setminus \overline{B}_R)$, *where* $\gamma = \min\{\alpha, \beta\}$.

Proof. Let $\overline{x} \in \mathcal{R} \setminus \overline{B}_R$ be fixed. By (4.3) we can choose $m^*, M^*, \delta^* > 0$ such that

$$0 < m^* \le \inf_{x \in B_{\delta^*}(\overline{x})} T(x) < \sup_{x \in B_{\delta^*}(\overline{x})} T(x) \le M^* < +\infty \tag{4.6}$$

and

$$2\delta^* < \rho e^{M^*(\omega - L)}\,, \tag{4.7}$$

where ρ is given by Proposition 3.8. From (3.17) we obtain that, for all $x, z \in B_{\delta^*}(\overline{x})$ and all $u \in \mathcal{U}$,

$$|y(t; x, u) - y(t; z, u)| < \rho\,, \qquad t \in [0, M^*]\,. \tag{4.8}$$

Moreover, by (3.18), for any $\theta \in [0, 1[$ there exists $C_\theta > 0$ such that

$$|(-A)^\theta y(t; x, u)| \le C_\theta \tag{4.9}$$

for all $x \in B_{\delta^*}(\overline{x})$, all $u \in \mathcal{U}$, and all $t \in [m^*/2, T(x)]$.

Let us now take $x, x + h, x - h \in B_\delta(\overline{x})$, where $\delta \in]0, \delta^*]$ is a number which will be specified later in the proof. We have to prove that

$$T(x + h) + T(x - h) - 2T(x) \le C|h|^{1+\gamma} \tag{4.10}$$

for some constant $C > 0$ independent of x, h.

Without loss of generality, we can assume the existence of an optimal control, u, for x, i.e.,

$$T(x) = \tau(x, u)\,.$$

In the general case the conclusion follows by an approximation argument, as in the proof of Proposition 4.1.

We observe that, if $T(x) \ge \max\{\tau(x - h, u), \tau(x + h, u)\}$, then (4.10) is trivial as

$$T(x + h) + T(x - h) - 2T(x) \le \tau(x - h, u) + \tau(x + h, u) - 2T(x) \le 0\,.$$

Therefore, it is enough to consider the two cases $T(x) \le \min\{\tau(x - h, u), \tau(x + h, u)\}$ and $\tau(x - h, u) < T(x) < \tau(x + h, u)$. We will denote by $c_0, c_1, \ldots$ positive constants, independent of x and h.

Case 1. Suppose that

$$T(x) \le \min\{\tau(x - h, u), \tau(x + h, u)\}. \tag{4.11}$$

Let us set

$$x_0 = y(T(x); x+h, u), \quad x_1 = y(T(x); x, u), \quad x_2 = y(T(x); x-h, u).$$

Then, by definition, $x_1 \in \partial B_R$. From the dynamic programming principle, Proposition 3.8, and property (4.8), we obtain

$$T(x+h) + T(x-h) - 2T(x) \le T(x_0) + T(x_2) \le \frac{d(x_0) + d(x_2)}{r - (R+\rho)(L-\omega)}.$$

In addition, from (3.17), (3.20), and the semiconcavity of d in $X \setminus \overline{B}_R$ (see Remark 3.4) we deduce

$$\begin{aligned} d(x_0) + d(x_2) &\le 2d\left(\frac{x_0+x_2}{2}\right) + c_0|x_0 - x_2|^{1+\alpha} \\ &\le |x_0 + x_2 - 2x_1| + c_0|x_0 - x_2|^{1+\alpha} \le c_1|h|^{1+\beta} + c_2|h|^{1+\alpha}. \end{aligned}$$

This proves (4.10) in this case.

Case 2. Suppose that

$$\tau(x-h, u) < T(x) < \tau(x+h, u). \tag{4.12}$$

Before starting our analysis let us point out that the main ideas of the proof are basically the same of the previous case. We will again exploit the regularity of f, the semiconcavity of the distance function, and the estimate of T near the target given by Proposition 3.8. However, if we proceed as in Case 1 and let the points $x-h$ and $x+h$ evolve according to a control u which is optimal for x, we obtain no useful information. We have to use instead controls which are suitable rescalings of u; this choice takes into account the fact that, by (4.12), the points $x-h$ and $x+h$ require a different amount of time to approach the target. For this reason, the analysis of this case is longer and requires more delicate estimates than the previous one.

Let us first set

$$\tau_0 = \frac{1}{2}\tau(x-h, u)$$

and

$$z_0 = y(\tau_0; x-h, u), \quad z_1 = y(\tau_0; x, u), \quad z_2 = y(\tau_0; x+h, u)\,.$$

We note that, for $j = 0, 1, 2$, $z_j \in D((-A)^\theta)$ for all $\theta \in [0, 1[$ in light of (4.9). In fact, this gain in regularity is the reason why we replace the points $x-h, x, x+h$ with z_0, z_1, z_2. By definition, we have that

$$T(z_0) \le \tau_0.$$

From the dynamic programming principle and (4.12) we obtain

$$\tau_0 + T(z_1) = T(x) > 2\tau_0 \ge \tau_0 + T(z_0),$$

and so

$$T(z_1) > T(z_0)\,. \tag{4.13}$$

Let us abbreviate

$$T_j = T(z_j), \quad j = 0, 1, 2.$$

Again by dynamic programming, we deduce that

$$T(x-h) + T(x+h) - 2T(x) \le T_0 + T_2 - 2T_1\,. \tag{4.14}$$

If $T_2 - T_1 \le T_1 - T_0$, then (4.10) follows from (4.14). Assume, on the contrary, that $T_2 - T_1 > T_1 - T_0$. Then a number a exists such that

$$a \in \left]\frac{T_1 - T_0}{T_1}, \frac{T_2 - T_1}{T_1}\right[\bigcap\,]0, 1[\,. \tag{4.15}$$

Indeed the above set can be empty only if $(T_1 - T_0)/T_1 \ge 1$ or if $(T_2 - T_1)/T_1 \le 0$. But both possibilities are excluded since $T_0 > 0$ and $T_2 - T_1 > T_1 - T_0 > 0$ by (4.13).

Next, having fixed a as in (4.15), we define

$$u_1(t) = u(t + \tau_0), \qquad u_0(t) = u_1\left(\frac{t}{1-a}\right), \qquad u_2(t) = u_1\left(\frac{t}{1+a}\right),$$

and

$$z_j(t) = y(t; z_j, u_j)\,, \quad j = 0, 1, 2.$$

Notice that, by (4.15), $(1+a)T_1 < T_2$ and $(1-a)T_1 < T_0$. We now claim that

$$d(z_2((1+a)T_1)) \le \rho, \qquad d(z_0((1-a)T_1)) \le \rho\,. \tag{4.16}$$

Assuming for a moment that (4.16) holds, we deduce from Proposition 3.8 and from the semiconcavity of d that

$$\begin{aligned} T_2 + T_0 - 2T_1 &\le T(z_2((1+a)T_1)) + T(z_0((1-a)T_1)) \\ &\le \frac{1}{r - (R+\rho)(L-\omega)}[d(z_2((1+a)T_1)) + d(z_0((1-a)T_1))] \\ &\le \frac{1}{r - (R+\rho)(L-\omega)} 2d\left(\frac{z_2((1+a)T_1) + z_0((1-a)T_1)}{2}\right) \\ &\quad + c_1 |z_2((1+a)T_1) - z_0((1-a)T_1)|^{1+\alpha}\,. \end{aligned} \tag{4.17}$$

Let us now prove our claim (4.16). To this end, define

$$\zeta_1(t) = z_2((1+a)t) - z_1(t), \quad \zeta_2(t) = z_0((1-a)t) - z_1(t)\,. \tag{4.18}$$

We note that $\zeta_1(t)$ is the solution of the problem

$$\begin{cases} \zeta_1'(t) &= (1+a)\,\{Az_2((1+a)t) + f(z_2((1+a)t)) + u_1(t)\} \\ &\quad - \{Az_1(t) + f(z_1(t)) + u_1(t)\}\,, \\ \zeta_1(0) &= z_2 - z_1\,. \end{cases}$$

Hence, we have that

$$\begin{aligned} \zeta_1(t) = e^{tA}(z_2 - z_1) &+ \int_0^t e^{(t-s)A}\{f(z_2((1+a)s)) - f(z_1(s))\}\,ds \\ &+ a\int_0^t e^{(t-s)A}\{Az_2((1+a)s) + f(z_2((1+a)s)) + u_1(s)\}\,ds\,, \end{aligned}$$

which yields

$$|\zeta_1(t)| \le e^{-\omega t}|z_2 - z_1| + L\int_0^t e^{-\omega(t-s)}|\zeta_1(s)|ds + a\varphi(t), \tag{4.19}$$

where we have set $\varphi(t) = \int_0^t e^{(t-s)A}\left(Az_2((1+a)s) + f(z_2((1+a)s)) + u_1(s)\right)ds$. Using (4.9), we obtain

$$\begin{aligned}|\varphi(t)| &\le \int_0^t \left(\frac{C_{1-\theta}M_\theta}{(t-s)^\theta} + e^{-\omega(t-s)}(LC_0 + r)\right)ds \\ &\le \frac{C_{1-\theta}M_\theta}{1-\theta}t^{1-\theta} + t(LC_0 + r) \le c_2(1+t)\end{aligned}$$

for some $c_2 > 0$. Now, the Gronwall inequality gives

$$\begin{aligned}|\zeta_1(t)| &\le e^{-\omega t}|z_2 - z_1| + ac_2(1+t) \\ &\quad + L\int_0^t e^{(L-\omega)(t-s)}\left(e^{-\omega s}|z_2 - z_1| + ac_2(1+s)\right)ds\,,\end{aligned} \tag{4.20}$$

whence, by (3.17),

$$|\zeta_1(T_1)| \le 2\delta e^{M^*(L-\omega)} + ac_2(1+M^*) + LM^*e^{(L-\omega)M^*}\left\{2\delta e^{M^*(L-\omega)} + ac_2(1+M^*)\right\}.$$

The above inequality can be rewritten as

$$|\zeta_1(T_1)| \le c_3(\delta + a) \tag{4.21}$$

for some $c_3 > 0$. Recalling that $T_1 = T(x) - \frac{1}{2}\tau(x-h,u)$ we obtain from (4.12)

$$T_1 \ge \frac{1}{2}T(x) \ge \frac{1}{2}m^*.$$

The Lipschitz continuity of $T(\cdot)$, together with (4.15) and (3.17), yields

$$a \le \frac{T_2 - T_1}{T_1} \le \frac{c_4|z_2 - z_1|}{m^*} \le c_5|h| \le 2c_5\delta. \tag{4.22}$$

Thus, from inequality (4.21) we conclude that if $\delta \in]0, \delta^*]$ is fixed small enough, then

$$|\zeta_1(T_1)| \le \rho.$$

This inequality implies our claim (4.16) as far as $z_2(\cdot)$ is concerned. To obtain the conclusion for $z_0(\cdot)$, it suffices to replace ζ_1 by ζ_2 in the above argument.

It now remains to estimate the right-hand side in (4.17). We first observe that the inequalities in (4.22) imply that both a and $|z_2 - z_1|$ are of order $O(|h|)$. From inequality (4.20) we deduce that

$$|\zeta_1(t)| < c_6|h|, \qquad t \in [0, T_1]. \tag{4.23}$$

An analogous property holds for $|\zeta_2(t)|$, $t \in [0, T_1]$. We then obtain

$$|z_2((1+a)t) - z_0((1-a)t)|^{1+\alpha} = |\zeta_1(t) - \zeta_2(t)|^{1+\alpha} \le 4c_6|h|^{1+\alpha} \tag{4.24}$$

for any $t \in [0, T_1]$. In view of (4.17), our proof will be concluded if we show that

$$d\left(\frac{z_2((1+a)T_1) + z_0((1-a)T_1)}{2}\right) \le c|h|^{1+\beta} \tag{4.25}$$

for some constant $c > 0$. As a first step we show that, for some $c_7 > 0$,

$$|(-A)^{\theta_1}(z_2((1+a)t) - z_0((1-a)t))| \le c_7|h|t^{-\theta_1}\,, \ \forall t \in [0, T_1], \tag{4.26}$$

with θ_1 as in (3.13). Indeed, set $\eta(t) = z_2((1+a)t) - z_0((1-a)t)$, and observe that

$$\begin{aligned}
\eta(t) &= \zeta_1(t) - \zeta_2(t) \\
&= e^{tA}(z_2 - z_0) + \int_0^t e^{(t-s)A}\{f(z_2((1+a)s)) - f(z_0((1-a)s))\}ds \\
&\quad + a\int_0^t e^{(t-s)A}A(z_2((1+a)s) - z_0((1-a)s))ds \\
&\quad + a\int_0^t e^{(t-s)A}\{2u_1(s) + f(z_2((1+a)s)) + f(z_0((1-a)s))\}ds\,.
\end{aligned}$$

Then

$$\begin{aligned}
|(-A)^{\theta_1}\eta(t)| &\le \frac{M_{\theta_1}}{t^{\theta_1}}|z_2 - z_0| + LM_{\theta_1}\int_0^t \frac{|\eta(s)|}{(t-s)^{\theta_1}}\,ds \\
&\quad + a\int_0^t |(-A)^{1+\theta_1}e^{(t-s)A}(z_2((1+a)s) + z_0((1-a)s))|ds \\
&\quad + a\int_0^t |(-A)^{\theta_1}e^{(t-s)A}(f(z_2((1+a)s)) + f(z_0((1-a)s)))|ds \\
&\quad + 2a\int_0^t |(-A)^{\theta_1}e^{(t-s)A}u_1(s)|ds. \qquad (4.27)
\end{aligned}$$

We recall that both $|z_2 - z_1|$ and a are of order $O(|h|)$. The last two integrals in (4.27) are easily estimated using (3.5) and the boundedness of z_0, z_2, u_1. In addition, we have, by (3.5) and (4.9),

$$\begin{aligned}
&a\int_0^t |(-A)^{1+\theta_1}e^{(t-s)A}(z_2((1+a)s) + z_0((1-a)s))|ds \\
&\le a\int_0^t |(-A)^{\frac{1+\theta_1}{2}}e^{(t-s)A}(-A)^{\frac{1+\theta_1}{2}}(z_2((1+a)s) + z_0((1-a)s))|ds \\
&\le a\int_0^t c_8(t-s)^{-\frac{1+\theta_1}{2}}ds \le c_9 a.
\end{aligned}$$

Finally, equality (4.24) shows that $|\eta(t)| = O(|h|)$, and our claim (4.26) follows.

Let us now define $\xi(t) = z_0((1-a)t) + z_2((1+a)t) - 2z_1(t)$ and note that, by (3.20) we have $\xi(0) \le c_{10}|h|^{1+\beta}$ for some $c_{10} > 0$. Moreover,

$$\begin{aligned}\xi'(t) &= (1-a)\{Az_0((1-a)t) + f(z_0((1-a)t)) + u_1(t)\}\\ &\quad + (1+a)\{Az_2((1+a)t) + f(z_2((1+a)t)) + u_1(t)\}\\ &\quad -2\{Az_1(t) + f(z_1(t)) + u_1(t)\}\\ &= A\xi(t) + a\{A(z_2((1+a)t) - z_0((1-a)t)) + f(z_2((1+a)t)) - f(z_0((1-a)t))\}\\ &\quad + (f(z_0((1-a)t)) + f(z_2((1+a)t)) - 2f(z_1(t)).\end{aligned}$$

Hence,

$$\begin{aligned}\xi(t) &= e^{tA}\xi(0) + \int_0^t 2e^{(t-s)A}\left\{f\left(\frac{z_0((1-a)t) + z_2((1+a)t)}{2}\right) - f(z_1(s))\right\}ds\\ &+ \int_0^t e^{(t-s)A}\{f(z_0((1-a)s)) + f(z_2((1+a)s))\\ &\qquad -2f\left(\frac{z_0((1-a)t) + z_2((1+a)t)}{2}\right)\Big\}ds\\ &+ a\int_0^t e^{(t-s)A}(f(z_0((1-a)s)) - f(z_2((1+a)s))ds + a\int_0^t e^{(t-s)A}A\eta(s)ds.\end{aligned}$$

Recalling the Lipschitz continuity of f and formula (3.13), we obtain

$$\begin{aligned}|\xi(t)| &\le c_{10}|h|^{1+\beta} + L\int_0^t |\xi(s)|ds + \int_0^t L^*|(-A)^{\theta_1}\eta(s)|^{1+\beta}\,ds\\ &\quad + aL\int_0^t |\eta(s)|ds + M_{1-\theta_1}\int_0^t \frac{1}{(t-s)^{1-\theta_1}}|(-A)^{\theta_1}\eta(s)|ds\,.\end{aligned}$$

Now, using (4.24), (4.26), and the Gronwall inequality, we conclude that

$$|\xi(t)| \le c_{11}|h|^{1+\beta}, \qquad t \in [0, T_1], \tag{4.28}$$

which implies (4.25) and completes our proof. □

Since the minimum time function T is semiconcave, its singular set enjoys the properties stated in Theorem 2.5. In the next section, we will use Theorem 2.6 to derive a criterion for the propagation of the singularities of T.

5. Optimality conditions. In this section we use the fact that T is semiconcave to derive some optimality conditions for the minimum time problem. From now on, we will suppose that all assumptions (H1)–(H5) are satisfied, and, moreover, that

(H6) X is a Hilbert space;

(H7) e^{tA} is a compact operator for every $t > 0$;

(H8) A is self-adjoint;

(H9) a constant $\hat{L} > 0$ exists such that

$$|[\delta f(x) - \delta f(y)]z| \le \hat{L}|(-A)^{\theta_1}(x-y)||(-A)^{\theta_1}z| \quad \forall x, y, z \in D((-A)^{\theta_1}), \tag{5.1}$$

where θ_1 is given by (H5). In what follows we omit recalling the above hypotheses.

Remark 5.1. We note that, if (H6) holds, then assumption (H4) is satisfied with $\alpha = 1$. Moreover, (H9) yields estimate (3.11) in (H5) with $\beta = 1$. In addition, (H1) implies that

$$\langle Ax, x\rangle \le -\omega|x|^2 \qquad \forall x \in D(A). \tag{5.2}$$

Remark 5.2. It is well known that the parabolic system (3.14) satisfies (H7) and (H8). Moreover, (H9) holds if $n \le 3$. In fact, in this case, $\theta_1 \in]0, 1/2[$ exists such that $W^{2\theta_1,2}(\mathcal{O}) \subset L^4(\mathcal{O})$. Then

$$|[\delta f(x) - \delta f(y)]z| \le L'||x-y||_{L^4(\mathcal{O})}||z||_{L^4(\mathcal{O})} \le \hat{L}||x-y||_{W^{2\theta_1,2}(\mathcal{O})}||z||_{W^{2\theta_1,2}(\mathcal{O})}.$$

We will now begin to analyze properties of optimal controls and optimal trajectories for problem (3.9). The existence of such optimal pairs can be proved, arguing as in [7, p. 365]. Let then $y(\cdot)$ be an optimal trajectory starting from a given point $x \in \mathcal{R}$. We consider the *adjoint system* associated with y

$$p'(t) = -Ap(t) - (\delta f(y(t)))^* p(t), \qquad t \in]0, T(x)] \tag{5.3}$$

together with the *transversality condition*

$$p(T(x)) = \frac{y(T(x))}{rR + |(-A)^{\frac{1}{2}} y(T(x))|^2 - \langle f(y(T(x))), y(T(x))\rangle}\,. \tag{5.4}$$

We observe that the right-hand side of (5.4) is well defined. In fact, $y(T(x)) \in D((-A)^{1/2})$ by Lemma 3.6(iv); in addition, by (H2), (H3), and (5.2), we have that

$$\begin{aligned} &rR + |(-A)^{\frac{1}{2}} y(T(x))|^2 - \langle f(y(T(x))), y(T(x))\rangle \\ &\ge rR + (\omega - L)|y(T(x))|^2 = R(r + (\omega - L)R) > 0. \end{aligned}$$

Moreover, applying Proposition 3.9, we can check easily that problem (5.3)–(5.4) has a unique solution given by

$$p(t) = \frac{G^*(T(x), t)y(T(x))}{rR + |(-A)^{\frac{1}{2}} y(T(x))|^2 - \langle f(y(T(x))), y(T(x))\rangle}. \tag{5.5}$$

Such a solution will be called the *dual arc* associated with $y(\cdot)$. The following inclusion is interesting in itself and has several important consequences.

THEOREM 5.3. *Let $y(\cdot) = y(\cdot; x, u)$ be a time optimal trajectory for x and p be the dual arc associated with $y(\cdot)$. Then*

$$p(t) \in D^+ T(y(t))$$

for any $t \in [0, T(x)[$.

To prove the above theorem we need a technical lemma.

LEMMA 5.4. *Let $\alpha \in [0, 1[$, $\theta \in]0, 1-\alpha[$ and $\overline{T} > 0$ be fixed. Then a constant $C > 0$ exists such that*

$$|(-A)^\alpha (y(t; \overline{x}, u)) - \overline{x})| \le C(1 + |(-A)^{\theta+\alpha}\overline{x}|)t^\theta \tag{5.6}$$

for all $\overline{x} \in D((-A)^{\theta+\alpha}) \cap B_{2R}$, for all controls $u \in \mathcal{U}$ and for all $t \in [0, \overline{T}]$.

Proof. First of all we note that

$$|(-A)^\alpha(y(t;\overline{x},u))-\overline{x})| \le |(-A)^\alpha(e^{tA}-I)\overline{x})| + \left|\int_0^t (-A)^\alpha e^{(t-s)A}(f(y(s;\overline{x},u))+u(s))ds\right|.$$

In addition we have, using (3.5),

$$\begin{aligned}|(-A)^\alpha(e^{tA}-I)\overline{x})| &= \left|\int_0^t (-A)^{1+\alpha}e^{\sigma A}\overline{x}d\sigma\right| \\ &= \left|\int_0^t (-A)^{1-\theta}e^{\sigma A}(-A)^{\theta+\alpha}\overline{x}d\sigma\right| \\ &\le M_{1-\theta}|(-A)^{\theta+\alpha}\overline{x}|\frac{t^\theta}{\theta}.\end{aligned}$$

On the other hand, using (H2) and (3.16), we obtain that there exists $c_1>0$ such that $|f(y(s;\overline{x},u))+u(s)|<c_1$ for any $\overline{x}\in B_{2R}$, $s\in[0,\overline{T}]$ and $u\in\mathcal{U}$. Therefore, using again (3.5), we find

$$\left|\int_0^t (-A)^\alpha e^{(t-s)A}(f(y(s;\overline{x},u))+u(s))ds\right| \le M_\alpha c_1\int_0^t \frac{ds}{s^\alpha} \le c_2 t^\theta,$$

which implies the conclusion. □

Proof of Theorem 5.3. It is enough to prove the result for the initial time $t=0$. In fact, if $t_0\in]0,T(x)[$, then, by the dynamic programming principle, the restriction of $y(\cdot)$ to the interval $[t_0,T(x)]$ is an optimal trajectory for the point $y(t_0)$ and the restriction of $p(\cdot)$ to the same interval is the associated dual arc. Thus, knowing that the inclusion holds for the initial time yields that $p(t_0)\in D^+T(y(t_0))$.

Therefore it suffices to show that $p(0)\in D^+T(x)$, or, equivalently, that

$$T(x+h)-T(x)-\langle p(0),h\rangle \le o(|h|).$$

For simplicity we set

$$T:=T(x) \quad\text{and}\quad \sigma := rR+|(-A)^{\frac{1}{2}}y(T)|^2-\langle f(y(T)),y(T)\rangle.$$

Then, by (5.5), $\langle p(0),h\rangle = \langle \sigma^{-1}y(T), G(T,0)h\rangle$. Therefore, all we need to show is the fact that

$$T(x+h)-T(x)-\left\langle \frac{y(T)}{\sigma}, G(T,0)h\right\rangle \le o(|h|), \tag{5.7}$$

where $h\in X$ is sufficiently small. Let us consider the trajectories $y_h(t):=y(t;x+h,u)$. In order to prove (5.7), we have to distinguish two cases.

Case 1. Suppose that

$$\tau(x+h,u)=:t_h<T(x).$$

Then

$$0<T-t_h\le T(x)-T(x+h)=O(|h|). \tag{5.8}$$

We note that

$$d(y(t_h)) = \Big\langle \frac{y(T)}{R}, y(t_h) - y(T) \Big\rangle + O(|y(t_h) - y(T)|^2). \tag{5.9}$$

Now, Lemma 5.4 (with $\alpha = 0$ and $\overline{x} = y(t_h)$) implies that $|y(T) - y(t_h)| = O((T - t_h)^\theta)$ for some $\theta > 1/2$, and so $|y(T) - y(t_h)|^2 = o(|h|)$. Moreover, we have that

$$\begin{aligned}
\Big\langle \frac{y(T)}{R}, y(t_h) - y(T) \Big\rangle &= -\int_{t_h}^T \frac{d}{dt} \Big\langle \frac{y(T)}{R}, y(t) \Big\rangle \, dt \\
&= -\int_{t_h}^T \Big\langle \frac{y(T)}{R}, Ay(t) + f(y(t)) + u(t) \Big\rangle \, dt \\
&\le -\int_{t_h}^T \left\{ \Big\langle \frac{y(T)}{R}, Ay(t) + f(y(t)) \Big\rangle - r \right\} dt \\
&= (T - t_h) \left\{ \frac{|(-A)^{\frac{1}{2}} y(T)|^2}{R} - \frac{\langle y(T), f(y(T)) \rangle}{R} + r \right\} \\
&\quad - \int_{t_h}^T \Big\langle (-A)^{\frac{3}{4}} \frac{y(T)}{R}, (-A)^{\frac{1}{4}} (y(T) - y(t)) \Big\rangle \, dt \\
&\quad + \int_{t_h}^T \Big\langle \frac{y(T)}{R}, f(y(T)) - f(y(t)) \Big\rangle \, dt = (\mathrm{I})_h + (\mathrm{II})_h + (\mathrm{III})_h \, .
\end{aligned}$$

From Lemma 5.4 we obtain that $|(-A)^\alpha (y(t) - y(T))| \to 0$ as $t \to T$ for any $\alpha \in [0, 1/2[$. Since $T - t_h = O(|h|)$ by (5.8), we have that $(\mathrm{II})_h + (\mathrm{III})_h = o(|h|)$ as $h \to 0$. Thus (5.9) implies that

$$d(y(t_h)) \le \frac{(T - t_h)\sigma}{R} + o(|h|) \, .$$

Then, we obtain from (5.8)

$$T(x + h) - T(x) \le t_h - T \le -\frac{R \, d(y(t_h))}{\sigma} + o(|h|) \, . \tag{5.10}$$

Next, by (3.24),

$$\begin{aligned}
d(y(t_h)) &= \Big\langle \frac{y_h(t_h)}{R}, y(t_h) - y_h(t_h) \Big\rangle + O(|y(t_h) - y_h(t_h)|^2) \\
&= \Big\langle \frac{y(T)}{R}, y(t_h) - y_h(t_h) \Big\rangle + \Big\langle \frac{y(t_h) - y(T)}{R}, y(t_h) - y_h(t_h) \Big\rangle \\
&\quad + O(|y(t_h) - y_h(t_h)|^2) \\
&= -\Big\langle \frac{y(T)}{R}, G(t_h, 0)h \Big\rangle + o(|h|) = -\Big\langle \frac{y(T)}{R}, G(T, 0)h \Big\rangle + o(|h|),
\end{aligned}$$

which, together with (5.10), proves claim (5.7) in this case.

Case 2. Suppose that

$$\tau(x+h,u) > T(x).$$

For simplicity we set $x_h = y(T(x); x+h, u)$, and we note that $x_h \notin \overline{B}_R$. Then, the dynamic programming principle gives

$$T(x+h) - T(x) \le T(x_h).$$

Our goal is to estimate $T(x_h)$ with $d(x_h)$. Since $x_h = y(T(x)) + G(T(x),0)h + o(|h|)$ by (3.24), we have

$$d(x_h) = \Big\langle \frac{y(T(x))}{R}, G(T(x),0)h \Big\rangle + o(|h|).$$

Therefore, to prove (5.7) in this case, we only need to show that

$$T(x_h) \le \frac{R\, d(x_h)}{\sigma} + o(|h|)\,. \tag{5.11}$$

For this purpose, we consider the problem

$$\begin{cases} \overline{y}_h'(t) = A\overline{y}_h(t) + f(\overline{y}_h(t)) + u^*(t), & t > 0, \\ \overline{y}_h(0) = x_h\,, \end{cases} \tag{5.12}$$

where u^* is a feedback control of the form $u^*(t) = -r\overline{y}_h(t)/|\overline{y}_h(t)|$. We are interested in studying the solution of system (5.12) only for $|\overline{y}_h(t)| \ge R$; hence we can consider the system as a semilinear evolution equation with a Lipschitz nonlinearity. First of all, observe that, by (H2) and (5.2),

$$\begin{aligned} \frac{d}{dt}\frac{|\overline{y}_h(t)|^2}{2} &= \langle A\overline{y}_h(t) + f(\overline{y}_h(t)), \overline{y}_h(t)\rangle - r|\overline{y}_h(t)| \\ &\le (L-\omega)|\overline{y}_h(t)|^2 - r|\overline{y}_h(t)|. \end{aligned}$$

If $|h|$ is small enough, then $|x_h| \le r + |y(T(x)) - x_h| < R$. Then, from (H3) and the above inequality it follows that $\tau(x_h, u^*) < +\infty$ for $|h|$ small, and that $\tau(x_h, u^*) \to 0$ as $h \to 0$. Let us set, for simplicity, $\tau_h = \tau(x_h, u^*)$. Then,

$$\begin{aligned} d(x_h) &= \Big\langle \frac{\overline{y}_h(\tau_h)}{R}, x_h - \overline{y}_h(\tau_h) \Big\rangle + O(|x_h - \overline{y}_h(\tau_h)|^2) \\ &= -\int_0^{\tau_h} \frac{d}{dt}\Big\langle \frac{\overline{y}_h(\tau_h)}{R}, \overline{y}_h(t) \Big\rangle\, dt + O(|x_h - \overline{y}_h(\tau_h)|^2) \\ &= -\int_0^{\tau_h} \Big\langle \frac{\overline{y}_h(\tau_h)}{R}, A\overline{y}_h(t) + f(\overline{y}_h(t)) - r\frac{\overline{y}_h(t)}{|\overline{y}_h(t)|} \Big\rangle\, dt + O(|x_h - \overline{y}_h(\tau_h)|^2). \end{aligned}$$

Arguing as in Case 1 and applying Lemma 5.4, we obtain

$$d(x_h) = \int_0^{\tau_h} \frac{\sigma}{R}\, dt + o(|h|) = \frac{\tau_h\, \sigma}{R} + o(|h|)\,,$$

which implies (5.11) and concludes our proof. □

We now state the Pontryagin maximum principle for our control system.

PROPOSITION 5.5. *Let $y(\cdot) = y(\cdot; x, u)$ be an optimal trajectory for x and $p(t)$ be the corresponding dual arc. Then, $p(t) \neq 0$ for all $t \in [0, T(x)[$, and*

$$u(t) = -r\frac{p(t)}{|p(t)|} \tag{5.13}$$

for almost everywhere (a.e.) $t \in [0, T(x)]$.

Proof. The maximum principle is a classical result in the theory of optimal control. For the minimum time problem, it is well known (see e.g., [7, p. 367]) that there exists at least one arc $p(\cdot)$ solution of (5.3) such that (5.13) holds. In our particular case, since the target set is a ball, we can prescribe the final condition for $p(\cdot)$ to be a normal vector to the ball at the terminal point of the trajectory, i.e., any scalar multiple of $y(T(x))$. This can be proved as in the finite dimensional case (see [9]). The normalization in the transversality condition (5.4) is chosen in such a way that Theorem 5.3 holds.

The fact that $p(t) \neq 0$ for any t is not obvious a priori. In fact, (5.3) is, in general, ill posed forward in time as $-A$ fails to be the generator of a C_0 semigroup. Nevertheless, a forward uniqueness property is proved in [10, Theorem A.1] for such equations, which ensures that $p(t)$ never vanishes if the final condition is nonzero, as in (5.4). □

Coupling state equation (3.1) with the adjoint system (5.3) and using (5.13), we obtain the Hamiltonian form of the maximum principle

$$\begin{cases} y'(t) = Ay(t) + f(y(t)) - r\dfrac{p(t)}{|p(t)|} \\ \\ p'(t) = -Ap(t) - (\delta f(y(t)))^* p(t)\,. \end{cases} \tag{5.14}$$

Once again, we note that the Cauchy problem for the above system is, in general, ill posed. However, as we show in the next proposition, the system satisfies a forward uniqueness property like the one recalled in the previous proof for the adjoint equation (5.3).

PROPOSITION 5.6. *Given $x, q \in X$, with $q \neq 0$ and $T > 0$, there exists at most one pair $(y, p) : [0, T] \to X \times (X \setminus \{0\})$ which solves system (5.14) in $[0, T[$, and satisfies the initial conditions*

$$\begin{cases} y(0) = x \\ p(0) = q\,. \end{cases} \tag{5.15}$$

The following proof uses a technique introduced by [25]; this method was adapted to systems by [13], in a different situation from the one of interest in this paper.

Proof. Suppose that there exist two solutions, say $(y_1(t), p_1(t))$ and $(y_2(t), p_2(t))$, of problem (5.14)–(5.15). Define $\bar{y}(t) := y_2(t) - y_1(t)$ and $\bar{p}(t) := p_2(t) - p_1(t)$. We note that the pair $(\bar{y}(t), \bar{p}(t))$ is a solution of the system

$$\begin{cases} \bar{y}'(t) = A\bar{y}(t) + f(y_2(t)) - f(y_1(t)) - r\dfrac{p_2(t)}{|p_2(t)|} + r\dfrac{p_1(t)}{|p_1(t)|}, \\ \\ \bar{p}'(t) = -A\bar{p}(t) - \delta f(y_2(t))^* p_2(t) + \delta f(y_1(t))^* p_1(t) \end{cases} \tag{5.16}$$

for $t \in]0, T[$, with initial conditions

$$\begin{cases} \bar{y}(0) = 0, \\ \bar{p}(0) = 0. \end{cases} \tag{5.17}$$

Now, let us take a function $\theta \in C^1(\mathbb{R})$ such that $\theta(t) = 1$ for $0 \le t \le \frac{T}{2}$, $\theta(t) = 0$ for $t = T$ and $|\theta'(t)| \le \frac{4}{T}$. We set

$$z(t) := e^{\frac{k(t-T)^2}{2}}\theta(t)\bar{y}(t) \qquad \text{and} \qquad q(t) := e^{\frac{k(t-T)^2}{2}}\theta(t)\bar{p}(t).$$

We have that

$$\begin{cases} z'(t) = Az(t) + k(t-T)z(t) + \phi_1(t)\,, \\ z(0) = z(T) = 0, \\ q'(t) = -Aq(t) + k(t-T)q(t) + \phi_2(t)\,, \\ q(0) = q(T) = 0, \end{cases} \tag{5.18}$$

where

$$\phi_1(t) = e^{\frac{k(t-T)^2}{2}}\theta(t)\left(f(y_2(t)) - f(y_1(t)) - r\frac{p_2(t)}{|p_2(t)|} + r\frac{p_1(t)}{|p_1(t)|}\right) + e^{\frac{k(t-T)^2}{2}}\theta'(t)\bar{y}(t) \tag{5.19}$$

and

$$\phi_2(t) = e^{\frac{k(t-T)^2}{2}}\theta(t)(\delta f(y_1(t))^* p_1(t) - \delta f(y_2(t))^* p_2(t)) + e^{\frac{k(t-T)^2}{2}}\theta'(t)\bar{p}(t)\,. \tag{5.20}$$

Then, multiplying the first equation of system (5.18) by $z'(t)$ and the second equation by $q'(t)$ we get

$$|z'(t)|^2 = \frac{1}{2}\frac{d}{dt}\{\langle Az(t), z(t)\rangle + k(t-T)|z(t)|^2\} - \frac{k}{2}|z(t)|^2 + \langle \phi_1(t), z'(t)\rangle$$

and

$$|q'(t)|^2 = \frac{1}{2}\frac{d}{dt}\{\langle -Aq(t), q(t)\rangle + k(t-T)|q(t)|^2\} - \frac{k}{2}|q(t)|^2 + \langle \phi_2(t), q'(t)\rangle.$$

Integrating the equations above on $[0,T]$ and recalling that z and q vanish at the endpoints, we obtain

$$\int_0^T \Big(|z'(t)|^2 + \frac{k}{2}|z(t)|^2\Big)dt \le \frac{1}{2}\int_0^T (|z'(t)|^2 + |\phi_1(t)|^2)dt$$

and

$$\int_0^T \Big(|q'(t)|^2 + \frac{k}{2}|q(t)|^2\Big)dt \le \frac{1}{2}\int_0^T (|q'(t)|^2 + |\phi_2(t)|^2)dt.$$

Hence,

$$k\int_0^T (|z(t)|^2 + |q(t)|^2)dt \le \int_0^T (|\phi_1(t)|^2 + |\phi_2(t)|^2)dt\,. \tag{5.21}$$

We have now to estimate the right-hand side of (5.21). Let us first note that, by Proposition 5.5,

$$e^{k(t-T)^2}\theta^2(t)\left|\frac{p_2(t)}{|p_2(t)|} - \frac{p_1(t)}{|p_1(t)|}\right|^2 \le C_1|q(t)|^2$$

for some $C_1 > 0$. Here and in the remainder of the proof $C_1, C_2, \dots$ denote positive numbers independent of k. We have

$$\begin{aligned}|\phi_1(t)|^2 &\le 2L^2|z(t)|^2 + 4e^{k(t-T)^2}|\theta'(t)\bar{y}(t)|^2 \\ &\quad + 4r^2 e^{k(t-T)^2}\theta^2(t)\left|\frac{p_2(t)}{|p_2(t)|} - \frac{p_1(t)}{|p_1(t)|}\right|^2 \\ &\le 2L^2|z(t)|^2 + 4e^{k(t-T)^2}|\theta'(t)\bar{y}(t)|^2 + C_2|q(t)|^2\end{aligned}$$

for some $C_2 > 0$. Moreover,

$$|\phi_2(t)|^2 \le 2e^{k(t-T)^2}|\theta'(t)\bar{p}(t)|^2 + 2e^{k(t-T)^2}\theta^2(t)|\delta f(y_1(t))^* p_1(t) - \delta f(y_2(t))^* p_2(t)|^2.$$

Now, the interpolation inequality (3.7) and assumption (5.1) yield

$$\begin{aligned}&|\delta f(y_1(t))^* p_1(t) - \delta f(y_2(t))^* p_2(t)| \\ &\le |[\delta f(y_1(t))^* - \delta f(y_2(t))^*]p_2(t) + \delta f(y_1(t))^*(p_1(t) - p_2(t))| \\ &\le C_3\{|(-A)^{\theta_1}(y_2(t) - y_1(t))||(-A)^{\theta_1}p_2(t)| + |p_1(t) - p_2(t)|\} \\ &\le C_4\{|(-A)^{\theta_1}(y_2(t) - y_1(t))| + |p_1(t) - p_2(t)|\} \\ &\le C_4\{|(-A)^{\frac{1}{2}}(y_2(t) - y_1(t))| + \kappa_{\theta_1}|y_2(t) - y_1(t)| + |p_1(t) - p_2(t)|\}\end{aligned}$$

for some $C_3, C_4 > 0$. Therefore, we obtain

$$|\phi_2(t)|^2 \le 2e^{k(t-T)^2}|\theta'(t)\bar{p}(t)|^2 + C_5(|(-A)^{\frac{1}{2}}z(t)|^2 + |z(t)|^2 + |q(t)|^2)$$

for some $C_5 > 0$. Multiplying by $z(t)$ the first equation of (5.18) and integrating, we obtain

$$\begin{aligned}\int_0^T |(-A)^{\frac{1}{2}}z(t)|^2 dt &\le \frac{1}{2}\int_0^T (|z(t)|^2 + |\phi_1(t)|^2)dt \\ &\le \frac{1}{2}\int_0^T ((1+2L^2)|z(t)|^2 + 4e^{k(t-T)^2}|\theta'(t)\bar{y}(t)|^2 + C_2|q(t)|^2)dt.\end{aligned}$$

Plugging the estimates of $|\phi_1(\cdot)|$ and $|\phi_2(\cdot)|$ into (5.21), we find

$$\begin{aligned}&k\int_0^T (|z(t)|^2 + |q(t)|^2)dt \\ &\le C_6\int_0^T (|z(t)|^2 + |q(t)|^2)dt + C_7\int_0^T e^{k(t-T)^2}|\theta'(t)|^2(|\bar{y}(t)|^2 + |\bar{p}(t)|^2)\,dt \\ &= C_6\int_0^T (|z(t)|^2 + |q(t)|^2)dt + C_7\int_{\frac{T}{2}}^T e^{k(t-T)^2}|\theta'(t)|^2(|\bar{y}(t)|^2 + |\bar{p}(t)|^2)\,dt \\ &\le C_6\int_0^T (|z(t)|^2 + |q(t)|^2)dt + C_7\frac{16}{T^2}e^{k\frac{T^2}{4}}\int_0^T (|\bar{y}(t)|^2 + |\bar{p}(t)|^2)\,dt\end{aligned}$$

for some $C_6, C_7 > 0$. On the other hand, if $k > C_6$,

$$(k - C_6)\int_0^T (|z(t)|^2 + |q(t)|^2)dt \ge (k - C_6)e^{k\frac{T^2}{4}}\int_0^{\frac{T}{2}} (|\bar{y}(t)|^2 + |\bar{p}(t)|^2)\,dt,$$

and therefore

$$\int_0^{\frac{T}{2}} (|\bar{y}(t)|^2 + |\bar{p}(t)|^2)dt \le \frac{16C_7}{(k - C_6)T^2} \int_0^T (|\bar{y}(t)|^2 + |\bar{p}(t)|^2)\, dt\,. \tag{5.22}$$

Sending $k \to \infty$, we obtain $|\bar{y}(t)| = |\bar{p}(t)| = 0$ on $[0, \frac{T}{2}]$. The conclusion follows by an easy iteration argument. □

The singular points of T can be characterized in terms of optimal trajectories. Before proving this fact, we need a preliminary result.

LEMMA 5.7. *Let x and x_n be given points of $\mathcal{R}\setminus\overline{B}_R$ such that $x_n \to x$ as $n \to \infty$. Let $y_n : [0, T(x_n)] \to X$ be optimal trajectories for x_n and let $p_n : [0, T(x_n)] \to X$ be the corresponding dual arcs. Then there exists a subsequence, $\{y_{n_k}(\cdot)\}$, converging uniformly on any interval $[0, T']$, with $T' < T(x)$, to a trajectory $y(\cdot)$, optimal for x. In addition, $\lim_{k\to\infty} p_{n_k}(t) = p(t)$ for all $t \in [0, T(x)[$, where $p(\cdot)$ is the dual arc associated with $y(\cdot)$.*

Proof. Let us denote by $u_n(\cdot)$ the optimal controls corresponding to $y_n(\cdot)$, and let us set for simplicity $T_n = T(x_n)$, $T = T(x)$. After extracting a subsequence, we find that there exists $u : [0, T] \to B_r$ such that $u_n \overset{*}{\rightharpoonup} u$ in $L^\infty([0, T'], B_r)$ for any $T' < T$. Then, using the compactness of the operators e^{tA}, we can see easily that $y(\cdot) := y(\cdot; x, u)$ is an optimal trajectory for x and that $y_n(\cdot) \to y(\cdot)$ uniformly in $[0, T']$ for any $T' < T$.

It remains to prove that $p_n(t) \to p(t)$ for all $t \in [0, T(x)[$. To this purpose, let us first show that $(-A)^{1/2}y_n(T_n)$ tends to $(-A)^{1/2}y(T)$. We have

$$\begin{aligned}|(-A)^{\frac{1}{2}}(y_n(T_n) - y(T))| &\le |(-A)^{\frac{1}{2}}(y_n(T_n) - y(T_n; x_n, u))| \\ &\quad + |(-A)^{\frac{1}{2}}(y(T_n; x_n, u) - y(T_n))| + |(-A)^{\frac{1}{2}}(y(T_n) - y(T))|.\end{aligned}$$

Using the representation formula (3.4) and property (3.5), we obtain that the first term on the right-hand side tends to 0 as $n \to \infty$. The second and third term also tend to 0, thanks to inequality (3.19) and to Lemma 5.4, resp. Thus we have that $(-A)^{1/2}y_n(T_n) \to (-A)^{1/2}y(T)$, and this implies, by (5.4), (H2), and (3.6), that $p_n(T_n) \to p(T)$.

Let us now prove that $p_n(t) \to p(t)$ for any $t \in [0, T(x)[$. To fix ideas, we suppose that $T_n > T$ for all n. Then we have, by (H5),

$$\begin{aligned}|p_n(t) - p(t)| &\le |e^{(T_n - t)A}(p_n(T_n) - p(T))| + |(e^{(T_n - t)A} - e^{(T-t)A})p(T)| \\ &\quad + \int_t^T |e^{(s-t)A}\delta f(y_n(s))^*(p_n(s) - p(s))|ds \\ &\quad + \int_T^{T_n} |e^{(s-t)A}\delta f(y_n(s))^* p_n(s)|ds \\ &\quad + \int_t^T |e^{(s-t)A}(\delta f(y_n(s))^* - \delta f(y(s))^*)p(s)|ds \\ &\le L\int_t^T |p_n(s) - p(s)|ds + o(1) \quad \text{as } n \to \infty.\end{aligned}$$

Then the conclusion follows by applying Gronwall's inequality. □

The following theorem provides a characterization of the singular points of T as the initial points of multiple time optimal trajectories.

THEOREM 5.8. *A point $x \in \mathcal{R} \setminus \overline{B}_R$ is a differentiability point for the minimum time function T iff there exist a unique optimal trajectory for system* (3.1) *with initial point x.*

Proof. Suppose first that T is differentiable at x. Let $y(\cdot)$ be any optimal trajectory starting at x, and let $p(\cdot)$ be the associated dual arc. Then, by (5.3), (5.13), and Theorem 5.3, we have that (y, p) is a solution of system (5.14) with initial conditions $y(0) = x, p(0) = DT(x)$. But Proposition 5.6 states that there exists at most a unique pair (y, p) with these properties. Therefore, x is the starting point of a unique optimal trajectory.

Conversely, let us assume that there exists a unique optimal trajectory starting at x, which we denote by $y(\cdot)$. We note that $D^+T(x) \neq \emptyset$ as the minimum time function is semiconcave. If we prove that $D^-T(x)$ is also nonempty, we obtain that T is differentiable at x. Hence, to conclude the proof it is enough to show that

$$p(0) \in D^-T(x), \tag{5.23}$$

where $p(\cdot)$ is the dual arc associated with $y(\cdot)$. For this purpose, let us consider a sequence x_k converging to x as $k \to \infty$ such that

$$\lim_{k\to\infty} \frac{T(x_k) - T(x) - \langle p(0), x_k - x\rangle}{|x_k - x|} = \liminf_{x'\to x} \frac{T(x') - T(x) - \langle p(0), x' - x\rangle}{|x' - x|}.$$

Now let $y_k(\cdot)$ be optimal trajectories for the points x_k, and let $p_k(\cdot)$ be the dual arcs associated with $y_k(\cdot)$. Since $y(\cdot)$ is the unique optimal trajectory for x, Lemma 5.7 implies that $y_k \to y$ and that $p_k \to p$ as $k \to \infty$. Using Theorem 5.3 and property (2.2) of semiconcave functions, we obtain

$$\begin{aligned}
&T(x_k) - T(x) - \langle p(0), x_k - x\rangle \\
&= T(x_k) - T(x) - \langle p_k(0), x_k - x\rangle - \langle p(0) - p_k(0), x_k - x\rangle \\
&\geq -C|x_k - x|^2 - |p(0) - p_k(0)|\,|x_k - x|\,.
\end{aligned}$$

Hence,

$$\lim_{k\to\infty} \frac{T(x_k) - T(x) - \langle p(0), x_k - x\rangle}{|x_k - x|} \geq 0,$$

and the proof is complete. □

We now proceed to show that, for the control systems under investigation, the minimum time function is differentiable along any optimal trajectory, except for the end points. For this purpose, we use the Hamilton–Jacobi–Bellman equation

$$r|DT(x)| - \langle DT(x), Ax\rangle - \langle DT(x), f(x)\rangle = 1. \tag{5.24}$$

The next lemma shows that the above equation is satisfied, in a suitable sense, along any optimal trajectory.

LEMMA 5.9. *Let $y(\cdot) = y(\cdot; x, u)$ be a time optimal trajectory for a point $x \in \mathcal{R} \setminus \overline{B}_R$. Then, for any $t \in]0, T(x)[\,, \theta \in]0, 1[$, and $q \in D^+T(y(t))$, we have that*

$$\langle (-A)^{1-\theta} q, (-A)^{\theta} y(t)\rangle - \langle q, f(y(t))\rangle + r|q| = 1. \tag{5.25}$$

Proof. First we observe that all the terms in (5.25) are well defined since, by Remark 4.2 and Lemma 3.6(iv), both q and $y(t)$ belong to $D((-A)^\theta)$ for any $\theta \in [0,1[$. Now, having fixed $t \in]0,T(x)[$, $\theta \in]0,1[$ and $q \in D^+T(y(t))$, we note that, for all $h>0$,

$$\frac{1}{h}\langle q, y(t)-y(t-h)\rangle$$

$$= \frac{1}{h}\langle q, (e^{hA}-I)y(t-h)\rangle + \frac{1}{h}\int_0^h \langle e^{(h-s)A}q, f(y(t+s-h))+u(t+s-h)\rangle ds.$$

Hence,

$$\lim_{h\downarrow 0}\frac{1}{h}\langle q,(e^{hA}-I)y(t-h)\rangle = -\lim_{h\downarrow 0}\frac{1}{h}\int_0^h \langle (-A)^{1-\theta}q, (-A)^\theta e^{sA}y(t-h)\rangle ds$$

$$= -\langle (-A)^{1-\theta}q, (-A)^\theta y(t)\rangle\,.$$

Moreover, we have that

$$\limsup_{h\downarrow 0}\frac{1}{h}\int_0^h \langle e^{(h-s)A}q, f(y(t+s-h))+u(t+s-h)\rangle ds \geq \langle q, f(y(t)\rangle - r|q|.$$

From the dynamic programming principle we obtain

$$1 = \lim_{h\downarrow 0}\frac{1}{h}\{T(y(t-h))-T(y(t))\} \leq \liminf_{h\downarrow 0}\frac{1}{h}\langle q, y(t-h)-y(t)\rangle$$

$$\leq \langle (-A)^{1-\theta}q, (-A)^\theta y(t)\rangle - \langle q, f(y(t))\rangle + r|q|. \tag{5.26}$$

To prove the converse inequality, we introduce the control

$$\tilde{u}(s) = \begin{cases} u(s) & \text{if } s \leq t,\\ -rq/|q| & \text{if } s > t.\end{cases}$$

Let us set $\tilde{y}(s) = y(s;x,\tilde{u})$. Arguing as in the first part of the proof we obtain

$$\lim_{h\downarrow 0}\frac{1}{h}\langle q, \tilde{y}(t+h)-\tilde{y}(t)\rangle = -\langle (-A)^{1-\theta}q, (-A)^\theta y(t)\rangle + \langle q, f(y(t))\rangle - r|q|.$$

Again by the dynamic programming principle, we have that

$$-1 \leq \liminf_{h\downarrow 0}\frac{1}{h}\{T(\tilde{y}(t+h))-T(\tilde{y}(t))\} \leq \liminf_{h\downarrow 0}\frac{1}{h}\langle q, \tilde{y}(t+h)-\tilde{y}(t)\rangle$$

$$= -\langle (-A)^{1-\theta}q, (-A)^\theta y(t)\rangle + \langle q, f(y(t))\rangle - r|q|\,,$$

which, together with (5.26), yields the conclusion. □

We also need the following easy result.

LEMMA 5.10. *Let $x \in D((-A)^\theta)$ for some $\theta \in]0,1[$, and let $\Gamma \subset D((-A)^{1-\theta})$ be a nonempty convex set such that*

$$-\langle (-A)^{1-\theta}q, (-A)^\theta x\rangle + \langle q, f(x)\rangle - r|q| = 1 \tag{5.27}$$

for any $q \in \Gamma$. Then Γ is a singleton.

Proof. Suppose on the contrary that Γ contains two distinct elements q_1 and q_2. Then, since Γ is convex, equality (5.27) holds with $q = \lambda q_1 + (1-\lambda)q_2$, for all $\lambda \in [0,1]$. This implies

$$|\lambda q_1 + (1-\lambda)q_2| = \lambda|q_1| + (1-\lambda)|q_2| \qquad \forall \lambda \in [0,1].$$

This is possible only if $q_2 = \alpha q_1$ for some $\alpha > 0$. But then (5.27), which is not homogeneous in q, cannot be satisfied both by q_1 and by q_2. □

The differentiability of T along any optimal trajectory follows as a corollary.

PROPOSITION 5.11. *Let $y(\cdot) = y(\cdot; x, u)$ be a time optimal trajectory for a point $x \in \mathcal{R} \setminus \overline{B}_R$. Then T is differentiable at any point of the form $y(t)$ for $t \in]0, T(x)[$.*

Proof. The two previous lemmas show that $D^+T(y(t))$ is a singleton for any $t \in]0, T(x)[$. On the other hand, a semiconcave function is differentiable at any point where its superdifferential is a singleton. Since T is semiconcave, the conclusion follows. □

From the above proposition we immediately obtain the following corollary.

COROLLARY 5.12. *Let $y(\cdot) = y(\cdot; x, u)$ be a time optimal trajectory for a point $x \in \mathcal{R} \setminus \overline{B}_R$ and p be the corresponding dual arc. Then*

$$p(0) \in D_*T(x).$$

Corollary 5.12, together with the following result, completes Theorem 5.8, giving a characterization of all time optimal trajectories starting at singular points of T.

THEOREM 5.13. *Let $x \in \mathcal{R} \setminus \overline{B}_R$. Then, for any $q \in D_*T(x)$, there exists a unique solution (y, p) of the Cauchy problem*

$$\begin{cases} y'(t) = Ay(t) + f(y(t)) - r\dfrac{p(t)}{|p(t)|}, & y(0) = x, \\ \\ p'(t) = -Ap(t) - (\delta f(y(t)))^* p(t), & p(0) = q. \end{cases} \tag{5.28}$$

Moreover, $y(\cdot)$ is a time optimal trajectory for x, and $p(\cdot)$ is the associated dual arc.

Proof. Given $q \in D_*T(x)$, let $\{x_n\}$ be a sequence of differentiability points for T such that $x_n \to x$ and $DT(x_n) \rightharpoonup q$. For any n, let us denote by $y_n(\cdot)$ the unique optimal trajectory for x_n and by $p_n(\cdot)$ the corresponding dual arc. By Theorem 5.3, we have that $p_n(0) = DT(x_n)$. By Lemma 5.7 we obtain that, after possibly extracting a subsequence, $y_n(\cdot) \to y(\cdot)$ and $p_n(\cdot) \to p(\cdot)$ pointwise, where $y(\cdot)$ is an optimal trajectory for x and $p(\cdot)$ is the associated dual arc. In particular, $p(0) = \lim p_n(0) = q$. Moreover, recalling the Hamiltonian form of the maximum principle (5.14), we conclude that (y, p) is a solution of (5.28). Finally, (y, p) is the unique solution of this problem in light of Proposition 5.6. □

The above proof shows that, if $q \in D_*T(x)$ for some x, then there exists $x_n \to x$ such that $DT(x_n) \to q$ in the strong topology, not only in the weak topology as required by the definition of D_*T. We remark that such a property would not hold without the compactness assumption on e^{tA} in (H7).

We will conclude this section with a propagation result for the singular set of T. For this purpose we need a lemma showing that the Hamilton–Jacobi–Bellman equation (5.24) is satisfied on a dense set.

LEMMA 5.14. *Let $\theta \in]0,1[$ and $x \in D((-A)^\theta) \cap (\mathcal{R} \setminus \overline{B}_R)$. Then, for all $p \in D_*T(x)$,*

$$\langle (-A)^{1-\theta} p, (-A)^\theta x \rangle - \langle p, f(x) \rangle + r|p| = 1. \tag{5.29}$$

Proof. Given $q \in D_*T(x)$, Theorem 5.13 yields the existence of a trajectory $y(\cdot) = y(\cdot; x, u)$, time optimal for x, such that the associated dual arc $p(\cdot)$ satisfies $p(0) = q$. Then,

$$\begin{aligned}
&|(-A)^\theta(y(t) - x)| \\
&= \left|(-A)^\theta \left((e^{tA} - I)x + \int_0^t e^{(t-s)A}(f(y(s)) + u(s))ds\right)\right| \\
&\le \left|(e^{tA} - I)(-A)^\theta x\right| + \int_0^t \frac{M_\theta}{(t-s)^\theta}|f(y(s)) + u(s)|ds \to 0
\end{aligned}$$

as $t \to 0$. Analogously, we find that

$$\begin{aligned}
|(-A)^{1-\theta}(p(t) - q)| \le &\left|\left(e^{(T-t)A} - e^{TA}\right)(-A)^{1-\theta}p(T)\right| \\
&+ \int_0^t |(-A)^{1-\theta}e^{sA}\delta f(y(s))^* p(s)|\, ds \\
&+ \int_t^T \left|(-A)^{1-\theta}\left(e^{(s-t)A} - e^{sA}\right)\delta f(y(s))^* p(s)\right| ds \to 0
\end{aligned}$$

as $t \to 0$. In addition, by Theorem 5.3 and Lemma 5.9, we have that

$$\langle(-A)^{1-\theta}p(t), (-A)^\theta y(t)\rangle - \langle p(t), f(y(t))\rangle + r|p(t)| = 1$$

for any $t > 0$. Letting $t \to 0$, we obtain the conclusion. □

We are now in a position to prove the aforementioned propagation result.

THEOREM 5.15. *Let $x_0 \in \Sigma(T)$. If x_0 belongs to $D((-A)^\theta)$ for some $\theta \in]0, 1]$, then x_0 is propagation point of $\Sigma(T)$.*

Proof. From Theorem 4.3 we know that T belongs to the class $SC^1(\mathcal{R} \setminus \overline{B}_R)$. We claim that, under the above assumptions, $D_*T(x_0)$ is a proper subset of $D^+T(x_0)$, i.e., assumption (2.6) of Theorem 2.6 holds. Let us argue by contradiction and suppose that $D^+T(x_0) = D_*T(x_0)$. Then, since $D^+T(x_0)$ is a convex set, we deduce, from Lemmas 5.10 and 5.14, that $D^+T(x_0)$ is a singleton. But this is impossible, since $x_0 \in \Sigma(T)$.

Having fixed $p_0 \in D^+T(x_0) \setminus D_*T(x_0)$, it remains to exhibit a vector q satisfying condition (2.7) of Theorem 2.6. For this purpose it suffices to take any $q \in X \setminus D((-A)^\theta)$. In fact, since $D^+T(x_0) \subset D((-A)^\theta), \theta \in [0, 1[$, we immediately obtain that $p_0 + tq \notin D^+T(x_0)$ for every $t \neq 0$. The proof is then completed applying Theorem 2.6. □

In this paper we include no example to show that the minimum time function may well possess a nonempty singular set. Such examples are well known in the literature: a typical case is that of the distance function from a closed set. One may wonder, however, whether the minimum time function associated with a parabolic system like (3.14) may be singular at some point. The affirmative answer to this question follows from an example of [1].

ABDERRAHIM JOURANI†

Abstract. Our aim is to present sufficient conditions ensuring Hoffman's error bound for lower semicontinuous nonconvex inequality systems and to analyze its impact on the local controllability, implicit function theorem for (non-Lipschitz) multivalued mappings, generalized equations (variational inequalities), and sensitivity analysis and on other problems like Lipschitzian properties of polyhedral multivalued mappings as well as weak sharp minima or linear conditioning. We show how the information about our sufficient conditions can be used to provide a computable constant such that Hoffman's error bound holds. We also show that this error bound is nothing but the classical Farkas lemma for linear inequality systems. In the latter case our constant may be computed explicitly.

Key words. subdifferentials, Hoffman's bound, implicit function theorem, generalized equations, controllability, sensitivity analysis

1. Introduction.

Consider the inequality system

$$f(x) \leq 0, \tag{1.1}$$

where $f : X \to R \cup \{\infty\}$ is an extended real-valued lower semicontinuous function and X is a Banach space.

Let S be a set of solutions to (1.1). Hoffman's error bound holds (globally) for (1.1) if there exists $a > 0$ such that

$$d(x, S) \leq a f_+(x) \quad \forall x \in X, \tag{1.2}$$

where $d(x, S) = \inf_{u \in S} \|x - u\|$, $f_+(x) = \max(f(x), 0)$ and $\| \ \|$ denotes the norm on X.

Hoffman's result [11] states that if f is a maximum of a finite number of affine functions in R^n, then (1.2) holds.

Various extensions in finite dimension of Hoffman's result were obtained for general convex inequality systems (see, for example, [36], [37], [12], [34], [35], [56]). For other related error bound results, see [4], [38], [13], [49]. Robinson [49] showed that in infinite dimension the error bound (1.2) holds for any convex differentiable inequality system which satisfies the Slater constraint qualification condition and where S is bounded. In [13], Ioffe gave a local version of (1.2) for nonconvex and nondifferentiable Lipschitz inequality system in infinite dimension. He used his result to obtain a new proof of Hoffman's inequality in linear programming in infinite dimension. Recently, Deng [9] studied any system of convex inequality in a reflexive Banach space which has an unbounded solution set.

In this paper we study the parametric inequality systems

$$f(x, y) \leq 0, \tag{1.1$'$}$$

where $f : X \times Y \to R \cup \{\infty\}$ is an extended real-valued lower semicontinuous function and Y is a Banach space.

For each y we let $S(y)$ be a set of solutions to (1.1′). We are concerned with the following analogous Hoffman's error bound: there exists $a > 0$ such that

$$d(x, S(y)) \leq a f_+(x, y) \quad \forall x \in X, \quad \forall y \in Y. \tag{1.2′}$$

Our aim is to present sufficient conditions ensuring (1.2′) for lower semicontinuous nonconvex inequality systems and to analyze its impact on the local controllability, sensitivity analysis, implicit function theorem for non-Lipschitz multivalued mappings, and generalized equations (variational inequalities) and on other problems like Lipschitzian properties of polyhedral multivalued mappings as well as weak sharp minima or linear conditioning. As in [9] and [13] we can show how the information about our sufficient condition can be used to provide a computable constant a such that (1.2′) holds. We also show that relation (1.2) is nothing but the classical Farkas lemma for linear inequality systems. In the latter case our constant may be computed explicitly. Note that the present paper is an infinite dimensional extension of [22] and a continuation of [18], published in *Mathematical Programming* in 1994, in which I indicate (see the end of section 3 of [18]) that we may use the partial approximate subdifferential (which works in any Banach spaces and more and the proposed proof works for any presubdifferential [55] as is noted in [24, Theorem 6.1]) and introduce similar regularity conditions to ensure metric regularity of systems defined by inclusions.

Our notation is basically standard. For any Banach space X and its topological dual X^* we denote by B_X and B_{X^*} their closed unit balls. As usual, $\mathrm{dom} f$ and $\mathrm{epi} f$ of an arbitrary extended real-valued function f stand for the domain and the epigraph

$$\begin{aligned} \mathrm{dom} f &= \{x : \quad f(x) < +\infty\}, \\ \mathrm{epi} f &= \{(x, r) : \quad f(x) \leq r\}. \end{aligned}$$

2. Error bound: The nonconvex case. In this section we present sufficient condition in terms of an abstract subdifferential. The partial subdifferential (as in [55]), in x with respect to y, on X is any operator ∂_x which satisfies the following properties.

For any lower semicontinuous function $f : X \times Y \to R \cup \{\infty\}$, any locally Lipschitz function $g : X \times Y \to R \cup \{\infty\}$, any $x \in X$, and any $y \in Y$,

(P_1) $\partial_x f(x, y) \subset X^*$ and $\partial_x f(x, y) = \emptyset$ if $f(x, y) = \infty$;

(P_2) $\partial_x g(x, y)$ coincides with the partial subdifferential in the sense of convex analysis whenever $g(\cdot, y)$ is convex, that is,

$$\partial_x g(x, y) = \{x^* \in X^* : \langle x^*, u - x \rangle \leq g(u, y) - g(x, y) \quad \forall u \in X\};$$

(P_3) $0 \in \partial_x f(x, y)$ whenever x is a local minimum for f with respect to y;

(P_4) $\partial_x f(x, y) = \partial_x w(x, y)$ whenever f and w coincide around (x, y);

(P_5)

$$\partial_x (f + g)(x, y) \subset \partial_x f(x, y) + \partial_x g(x, y).$$

In the case where $f(x, y) = f(x)$ for all $(x, y) \in X \times Y$, our subdifferential will be denoted by $\partial f(x)$.

Before stating our main results of this section, let us give some examples of partial subdifferentials.

Example 2.1 (partial limiting Fréchet subdifferential). Let X be an *Asplund space*, i.e., a Banach space on which every continuous convex function is Fréchet differentiable at a dense set of points. We refer the reader, for example, to the papers by Phelps [48]. The partial Fréchet ε-subdifferential of f at x with respect to y is the set

$$\partial_x^{\varepsilon} f(x,y) = \left\{ x^* \in X^* : \liminf_{h \to 0} \frac{f(x+h,y) - f(x,y) - \langle x^*, h \rangle}{\| h \|} \geq -\varepsilon \right\}$$

if $(x,y) \in \mathrm{dom} f$ and $\partial_x^{\varepsilon} f(x,y) = \emptyset$ if $(x,y) \notin \mathrm{dom} f$. *The partial limiting Fréchet subdifferential* $\partial_x^F f(x,y)$, which is first introduced in finite dimension by Jourani and Thibault [22], of f at x with respect to y is the set

$$\partial_x^F f(x,y) = \text{seq-} \limsup_{\substack{(u,v) \xrightarrow{f} (x,y) \\ \varepsilon \longrightarrow 0^+}} \partial_x^{\varepsilon} f(u,v).$$

In the case where $f(x,y) = f(x)$, this subdifferential (Kruger–Mordukhovich [30]) is an infinite dimensional extension of the nonconvex construction by Mordukhovich [39], [40] (see also [44]).

We may show that the partial limiting Fréchet subdifferential has the same properties as the limiting Fréchet subdifferential (see Kruger–Mordukhovich [31] and Kruger [29]) and hence it satisfies properties (P_1)–(P_5).

Example 2.2 (partial approximate subdifferential). The partial Dini subdifferential of f at x with respect to y is the set

$$\partial_x^- f(x,y) = \left\{ x^* \in X^* : \langle x^*, h \rangle \leq \liminf_{\substack{t \to 0^+ \\ u \to h}} t^{-1}(f(x+tu,y) - f(x,y)) \quad \forall h \in X \right\}$$

if $(x,y) \in \mathrm{dom} f$ and $\partial_x^- f(x,y) = \emptyset$ if $(x,y) \notin \mathrm{dom} f$.

The partial approximate subdifferential of f at x with respect to y is the set

$$\partial_x^A f(x,y) = \bigcap_{L \in \mathcal{F}(X)} \limsup_{(u,v) \xrightarrow{f} (x,y)} \partial_x^- f_{u+L}(u,v),$$

where $f_S(x,y) = f(x,y)$ if $x \in S$ and $f_S(x,y) = +\infty$ otherwise and $\mathcal{F}(X)$ denotes the collection of all finite dimensional subspaces of X.

In the case where $f(x,y) = f(x)$, this subdifferential (Ioffe [14], [15]) is an infinite dimensional extension of the nonconvex construction by Mordukhovich [39], [40]. In fact, Ioffe [16] showed that in finite dimensional spaces the approximate subdifferential and the limiting Fréchet subdifferentials coincide. Ioffe [14] used this representation to introduce the approximate subdifferential in infinite dimensional spaces. We have to note that the subdifferentials in Examples 2.1 and 2.2 are generally different in infinite dimensional case.

We may show that the partial approximate subdifferential has the same properties as the approximate subdifferential (see Ioffe [14], [15]) and hence it satisfies properties (P_1)–(P_5).

Example 2.3 (partial Clarke's subdifferential). Let f be locally Lipschitzian around (x,y). The partial Clarke's generalized directional derivative of f at x with respect to y in the direction $h \in X$ is given by

$$d_x^0 f((x,y);h) = \limsup_{\substack{(u,v) \longrightarrow (x,y) \\ t \to 0^+}} \frac{f(u+th,v) - f(u,v)}{t}.$$

The partial Clarke's subdifferential of f at x with respect to y is the set

$$\partial_x^C f(x,y) = \{x^* \in X^* : \quad \langle x^*, h\rangle \le d_x^0 f((x,y);h) \quad \forall h \in X\}.$$

We may show that the partial Clarke's subdifferential has the same properties as the Clarke's subdifferential (see Clarke [6]) and hence it satisfies properties (P_1)–(P_5) for locally Lipschitzian functions.

All these partial subdifferentials coincide, for a continuous convex function f, with the partial subdifferential in the sense of convex analysis

$$\partial_x f(x,y) = \{x^* \in X^* : \quad \langle x^*, h-x\rangle \le f(h,y) - f(x,y) \quad \forall h \in X\}.$$

We suppose in the following that our partial subdifferential ∂ satisfies (P_1)–(P_5).

Our proof is similar to that given by Ioffe in [13] in the local situation and in the case where f is locally Lipschitzian. We begin with the global error bound result.

THEOREM 2.4. *Let $f : X \times Y \to R \cup \{\infty\}$ be an extended real-valued function such that for each $y \in Y$, $f(\cdot, y)$ is lower semicontinuous. Suppose that*

$$\text{(2.1)} \qquad \text{there exists } a > 0 \quad \forall x \in X, \quad \forall y \notin S^{-1}(x), \quad d(0, \partial_x f(x,y)) \ge \frac{1}{a}.$$

Then (1.2′) *holds.*

Proof. Suppose that our relation (1.2′) is not valid. Then there exists $x' \in X$ and $y' \in Y$ such that

$$\text{(2.2)} \qquad d(x', S(y')) > a f_+(x', y').$$

Note that $x' \notin S(y')$. Then $f_+(x', y') > 0$. Set $\varepsilon = f(x', y')$ and $\lambda = (a+\alpha) f(x', y')$ where $\alpha > 0$ is such that $\lambda < d(x', S(y'))$. Then

$$f_+(x', y') \le \inf_{x \in X} f_+(x, y') + \varepsilon.$$

By the lower semicontinuity of $f(\cdot, y')$, the Ekeland's variational principle ensures the existence of $x \in X$ satisfying

$$\text{(2.3)} \qquad \|x - x'\| \le \lambda$$

$$\text{(2.4)} \qquad f_+(x, y') \le f_+(u, y') + \frac{\varepsilon}{\lambda}\|u - x\| \quad \forall u \in X.$$

Note that, by (2.2)–(2.3), $x \notin S(y')$. Since $f(\cdot, y')$ is lower semicontinuous, it coincides with $f_+(\cdot, y')$ in a neighborhood of x and hence by (2.4) and properties (P_1)–(P_5) we get

$$0 \in \partial_x f(x, y') + \frac{1}{(a+\alpha)} B_{X^*}$$

and this contradicts relation (2.1). □

Remark. Theorem 2.4 has been established by Clarke [5] (see also [7]) in Hilbert space using the decrease principle.

The proof of the following local result is similar to the previous one. It extends the result by Ioffe [13] to the non-Lipschitz case.

THEOREM 2.5. *Let $f : X \times Y \to R \cup \{\infty\}$ be an extended real-valued function such that for each $y \in Y$, $f(\cdot, y)$ is lower semicontinuous and let $\overline{x} \in S(\overline{y})$ for some $\overline{y} \in Y$. Suppose that there exist $r > 0$ and $a > 0$ such that*

$$(2.5) \qquad \forall x \in \overline{x} + rB_X,\ \forall y \notin S^{-1}(x) \text{ with } y \in \overline{y} + rB_Y, \quad d(0, \partial_x f(x,y)) \geq \frac{1}{a}.$$

Then

$$d(x, S(y)) \leq a f_+(x,y) \quad \forall x \in \overline{x} + \frac{r}{2}B_X,\ \forall y \in \overline{y} + rB_Y.$$

Remark. Note that Theorems 2.4 and 2.5 remain valid if Y is a metric space.

In the following corollary we give a sufficient condition for the solvability of inclusions: Given $(\overline{x}, \overline{y})$ with $\overline{y} \in F(\overline{x})$, find for each y in some neighborhood of $\overline{y}$ a point $x(y)$ near $\overline{x}$, solution of the inclusion

$$y \in F(x),$$

where $F : X \to 2^Y$ is a multivalued mapping.

COROLLARY 2.6. *Let $F : X \to 2^Y$ be a multivalued mapping with closed graph GrF containing $(\overline{x}, \overline{y})$. Suppose that*

$$\text{there exist } r > 0, a > 0 \quad \forall x \in \overline{x} + rB_X,\ \forall y \notin F(x) \text{ with } y \in \overline{y} + rB_Y,$$
$$d(0, \partial_x d(x, y; GrF)) \geq \frac{1}{a}.$$

Then

$$d(x, F^{-1}(y)) \leq a d(x, y; GrF) \quad \forall x \in \overline{x} + \frac{r}{2}B_X,\ \forall y \in \overline{y} + rB_Y.$$

Proof. Set $f(x,y) = d(x, y; \mathrm{Gr}F)$ and apply Theorem 2.5.

The following corollary gives us different characterizations of our sufficient condition in Corollary 2.6 for partial limiting Fréchet subdifferential in finite dimension.

COROLLARY 2.7. *Let X and Y be finite dimensional spaces and let $F : X \to 2^Y$ be a multivalued mapping with closed graph GrF containing $(\overline{x}, \overline{y})$. Then the following assertions are equivalent:*

(1) *if $(0, y^*) \in \partial^F d(\overline{x}, \overline{y}; GrF)$, then $y^* = 0$;*

(2) *there exist $r > 0$ and $a > 0$ $\forall x \in \overline{x} + rB_X$, $\forall y \notin F(x)$, with $y \in \overline{y} + rB_Y$,*

$$d(0, \partial_x^F d(x, y; GrF)) \geq \frac{1}{a};$$

(3) *(Graphical metric regularity) there exist $r > 0$ and $a > 0$ such that*

$$d(x, F^{-1}(y)) \leq a d(x, y; GrF) \quad \forall x \in \overline{x} + rB_X,\ \forall y \in \overline{y} + rB_Y;$$

(4) *(Metric regularity) there exist $r > 0$ and $a > 0$ such that*

$$d(x, F^{-1}(y)) \leq a d(y, F(x)) \quad \forall x \in \overline{x} + rB_X,\ \forall y \in \overline{y} + rB_Y.$$

Proof. (2) $\Longrightarrow$ (3) follows from Corollary 2.6.

(3) $\Longrightarrow$ (4) is obvious.

(4) $\Longrightarrow$ (1): see Mordukhovich [41], [42] and Jourani [18].

The proof of the implication (1) $\Longrightarrow$ (2) is similar to that of Theorem 3.14 in Jourani [18]. □

Remarks. (1) Recently Thibault [53] showed (by a direct method) that the equivalence (3) $\Longleftrightarrow$ (4) holds in any normed spaces.

(2) We may show that the corollary holds in infinite dimensional spaces for a special class of multivalued mappings (see for some applications of this type of result the papers by Ioffe [17], Mordukhovich and Shao [45], [46], and Jourani and Thibault [23], [24], [25], [26], [27], [18], [19], [20], [21]).

Suppose in addition to (P_1)–(P_5) that our subdifferential satisfies the following closedness assumption:

$$(P_6) \qquad \partial_x f(x,y) = \limsup_{\substack{(u,v)\to(x,y)\\ f(u,v)\to f(x,y)}} \partial_x f(u,v)$$

and

$$\partial_x f(x,y) = seq- \limsup_{\substack{(u,v)\to(x,y)\\ f(u,v)\to f(x,y)}} \partial_x f(u,v)$$

if X is Asplund.

Remarks. (1) Property (P_6) is satisfied for partial limiting Fréchet subdifferential (in Asplund spaces) and for partial approximate subdifferential for any lower semicontinuous function f and for partial Clarke's subdifferential for any locally Lipschitz function f.

(2) With these properties, our subdifferential satisfies the following inclusions for any locally Lipschitz function f around x uniformly in y (in some neighborhood V_y of y):

$$\partial_x^F f(x,y) \subset \partial_x^A f(x,y) \subset \partial_x f(x,y).$$

COROLLARY 2.8. *Let f be as in Theorem 2.5 and let $\overline{x} \in S(\overline{y})$ for some $\overline{y} \in Y$. Suppose that f is continuous around $(\overline{x},\overline{y})$, (P_6) is satisfied, and*

$$0 \notin \partial_x f(\overline{x},\overline{y}). \tag{2.6}$$

Then there exist $r > 0$ and $a > 0$ such that

$$d(x, S(y)) \le a f_+(x,y) \quad \forall x \in \overline{x} + rB_X,\ \forall y \in \overline{y} + rB_Y. \tag{2.7}$$

Proof. It suffices to show that (2.6) implies (2.5) and to apply Theorem 2.5. Indeed suppose that (2.5) is false. Then there are sequences $((x_n,y_n))$ and (x_n^*) such that $x_n \notin S(y_n)$ and $x_n^* \in \partial_x f(x_n,y_n)$ with $(x_n,y_n) \to (\overline{x},\overline{y})$ and $x_n^* \to 0$. Thus, by (P_6), $0 \in \partial_x f(\overline{x},\overline{y})$ and this contradiction completes the proof. □

3. Error bound: The convex case. We start this section by giving a characterization of Hoffman's error bound (see the excellent paper by Burke and Ferris [3]).

PROPOSITION 3.1. *Suppose X is a Hilbert space and f is convex and proper. If S is closed, then the following are equivalent:*

(i) *Relation* (1.2) *holds;*

(ii) $\partial d(S,x) \subset a\partial f_+(x) \quad \forall x \in S.$

In the following proposition we present a classical condition ensuring relation (1.2) which also can be obtained as a consequence of the results in [50] and [51].

PROPOSITION 3.2. *Suppose f is convex and $f(x_0) < 0$. Then for all $x \in X$*

$$d(x, S) \leq \frac{f_+(x)}{-f(x_0)} \|x - x_0\|.$$

If in addition there exists a nonempty set $C \subset X$, $\alpha > 0$, and $\gamma \geq 1$ such that

$$f(x) - f(x_0) \geq \alpha \|x - x_0\|^\gamma \quad \forall x \in C,$$

then

$$d(x, S) \leq \frac{f_+(x)}{\alpha} \quad \forall x \in C.$$

Let $g : X \to R \cup \{\infty\}$ be a function. The recession function g^∞ of g is defined by

$$\text{epi} g^\infty = (\text{epi} g)^\infty,$$

where $A^\infty = \{x : \quad A + x \subset A\}$. If g is convex, proper, and lower semicontinuous, then

$$g^\infty(u) = \sup_{x \in \text{dom} g} \{g(u + x) - g(x)\}.$$

The following result extends that of Deng [9], established in reflexive Banach spaces, to general Banach spaces.

THEOREM 3.3. *Let $g : X \to R \cup \{\infty\}$ be a convex, proper, and lower semicontinuous function and C be a closed convex subset of X such that $\text{dom} g \cap C \neq \emptyset$. Consider the solution set*

$$S' = \{x \in C : \quad g(x) \leq 0\}.$$

Suppose that

(i) *for all $\overline{x} \in \text{dom} g \cap C$, $\overline{x} \notin S'$,*

$$\partial(g + \Psi_C)(\overline{x}) = \partial g(\overline{x}) + N(C, \overline{x}),$$

where Ψ_C denotes the indicator function of C;

(ii) *there exist $a > 0$ and $\hat{x} \in C^\infty$ with $\|\hat{x}\| = 1$ such that*

$$g^\infty(\hat{x}) \leq \frac{-1}{a}.$$

Then

$$d(x, S') \leq a g_+(x) \quad \forall x \in C.$$

Proof. Put $f = g + \Psi_C$. It is an easy exercise to show that (i) and (ii) imply (2.1) and Theorem 2.4 completes the proof. □

Remarks. (1) In [9], Deng assumed that the function g is continuous and this is crucial in his proof.

(2) Deng [9] established this result in reflexive Banach space and for a finite number of inequality

$$g_i(x) \leq 0, \quad i = 1, \ldots, m.$$

But it suffices to put $g(x) = \max\{g_i(x) : \ i = 1, \ldots, m\}$ and it is easy to show that the assertion (ii) is satisfied.

(3) We know that the formula in (i) is valid under some constraint qualifications and there are many constraint qualifications in the literature ensuring this relation. It is valid, for example, when g is continuous.

4. Error bound: The linear case. In this section we are concerned with the linear equality-inequality systems

$$Ax = 0, \quad \langle x_i^*, x\rangle + b_i \le 0, \quad i = 1, \dots, m, \tag{4.1}$$

where $A : X \to Y$ is a linear continuous mapping such that $R(A)$, the rank of A, is closed, Y is a Banach space, $b_i \in R$, and $x_i^* \in X^*$ with $\|x_i^*\| = 1$.

We begin by showing that in the case of linear inequality systems, Hoffman's error bound is equivalent to the classical Farkas lemma. To do this, some notations are needed. We set

$\Delta_m = \{1, \dots, m\}$,
$I_m = \{E \subset \Delta_m : \quad (x_i^*)_{i\in E}$ are linearly independent $\}$,
$\forall E \in I_m$, $S_E = \cap_{i\in E} S_i$ and $f_E(x) = \sum_{i\in E} d(x, S_i)$ and
$\forall i \in \Delta_m$, $S_i = \{x \in H : \quad \langle x_i^*, x\rangle + b_i \le 0\}$.

THEOREM 4.1. *Consider the linear inequality system*

$$\langle x_i^*, x\rangle + b_i \le 0, \quad i = 1, \dots, m$$

with solution set S, $x_i^* \in H$, where H is a Hilbert space. Then the two following properties hold and are equivalent:

(i) *there exists $\alpha > 0$ depending only on $(x_i^*)_{i\in\Delta_m}$ such that*

$$d(x, S) \le \alpha f(x) \quad \forall x \in X.$$

(ii) *(Farkas lemma) for all u in S, $N(S, u) = R_+\partial f(u)$, where*

$$f(x) = \sum_{i=1}^{m} d(x, S_i) \qquad \text{and} \qquad N(S, u) = R_+\partial d(u, S).$$

Proof. The implication (i) $\Longrightarrow$ (ii) is obvious.

We establish the reverse implication in three steps.

First step. Let $E \in I_m$. Since $(x_i^*)_{i\in E}$ are linearly independent,

$$\min\left\{\left\|\sum_{i\in E}\lambda_i x_i^*\right\| : \quad 1 \ge \lambda_i \ge 0, i \in E, \sum_{i\in E}\lambda_i \ge 1\right\} > 0,$$

and hence for all $x \notin S_E$

$$d(0, \partial f_E(x)) \ge \frac{1}{\alpha_E},$$

where

$$\frac{1}{\alpha_E} = \min\left\{\left\|\sum_{i\in E}\lambda_i x_i^*\right\| : \quad 1 \ge \lambda_i \ge 0, i \in E, \sum_{i\in E}\lambda_i \ge 1\right\}.$$

So, by Theorem 2.4,

$$d(x, S_E) \le \alpha_E f_E(x) \quad \forall x \in H.$$

Second step. We will show that for each $x \notin S$ there exists $E \in I_m$ such that

$$d(x, S) = d(x, S_E).$$

Indeed, let $x \notin S$; then there exists u in S such that

$$d(x, S) = \|x - u\|$$

or, equivalently,

$$x - u \in N(S, u).$$

By (ii), $x-u \in R_+ \partial f(u)$ and as $\partial d(u, S_i) \subset [0, 1]x_i^*$, for $i \in \Delta_m$, there exist $1 \geq \lambda_i \geq 0$, $i \in \Delta_m$, not all equal to zero, such that

$$x - u = \sum_{i \in \Delta_m} \lambda_i x_i^*.$$

If $(x_i^*)_{i \in \Delta_m}$ are linearly independent the result follows from the first step. So suppose there exist $\mu_i \in R$, $i \in \Delta_m$, not all equal to zero such that

$$\sum_{i \in \Delta_m} \mu_i x_i^* = 0.$$

Hence for all $t \in R$

$$\sum_{i \in \Delta_m} (\lambda_i + t\mu_i) x_i^* = x - u.$$

Our problem is to find $t \geq 0$ and $i_0 \in \Delta_m$ such that $\lambda_{i_0} + t\mu_{i_0} = 0$ and $\lambda_i + t\mu_i \geq 0$ for $i \neq i_0$. Set $J = \{i \in \Delta_m : \quad \mu_i < 0\}$ and suppose that $J \neq \emptyset$. Set $t = \min_{i \notin J} \frac{-\lambda_i}{\mu_i}$. Then there exists $i_0 \in \Delta_m$ such that

$$\lambda_{i_0} + t\mu_{i_0} = 0 \quad \text{and} \quad \lambda_i + t\mu_i \geq 0 \quad \forall i \neq i_0.$$

By induction we show that $x - u$ is a positive combination of the linearly independent family of $(x_i^*)_{i \in E}$ and hence $x - u \in N(S_E, u)$, or equivalently, $\|x - u\| = d(x, S_E)$.

Third step. By the second step we have for each $x \notin S$ the existence of $E \in I_m$ such that

$$d(x, S) = d(x, S_E),$$

and by the first step we have

$$d(x, S) \leq \alpha_E f_E(x) \leq \alpha_E f(x).$$

Thus the proof is complete by taking

$$\alpha = \max_{E \in I_m} \alpha_E. \qquad \square$$

Remark. One of the referees pointed out that when the dimension of H is finite, a general result was proved by D. Klatte [28].

We use Theorem 4.1 to get a Lipschitzian property of polyhedral multivalued mappings. A multivalued mapping F from X into Y is polyhedral if its graph is the union of a finite (possibly empty) collection of polyhedral convex sets.

COROLLARY 4.2 (see [49]). *Let F be a multivalued mapping from X into Y. Suppose that Y is a Hilbert space and F is polyhedral. Then F is locally upper Lip-*

schitzian, i.e., there exists $a > 0$ such that for all $x \in X$ there exists $r > 0$ such that for all $x' \in x + rB_X$,

$$F(x') \subset F(x) + a\|x - x'\|B_Y.$$

Proof. Let $\mathrm{Gr}F$ be the graph of F. Then there are polyhedral sets $P_1, \dots, P_k \subset X \times Y$ such that $\mathrm{Gr}F = \cup\{P_i : \quad i = 1, \dots, k\}$. For each $i = 1, \dots, k$ there are $(b_{i,j})_{j=1,\dots,k_i} \subset R$, $(x^*_{i,j})_{j=1,\dots,k_i} \subset X^*$, and $(y^*_{i,j})_{j=1,\dots,k_i} \subset Y^*$ such that

$$P_i = \{(x, y) \in X \times Y : \quad \langle x^*_{i,j}, x\rangle + \langle y^*_{i,j}, y\rangle + b_{i,j} \le 0, \quad j = 1, \dots, k_i\}.$$

For each i let F_i be the multivalued mapping whose graph is P_i. for all $i = 1, \dots, k$ and $x \in X$, $F_i(x)$ is a polyhedral subset of Y.

If for all $i = 1, \dots, k$, $F_i(x)$ is empty, then there exists $r > 0$ such that for all $x' \in x + rB_X$ and for all $i = 1, \dots, k$, $F_i(x')$ are empty. So suppose that there exists i such that $F_i(x)$ is nonempty; then by Theorem 4.1, there exists $a_i > 0$, depending only on $(y^*_{i,j})_{j=1,\dots,k_i}$, such that for all $y \in Y$,

$$d(y, F_i(x)) \le a_i g^i(x, y),$$

where $g^i(x, y) = \sum_{j=1}^{k_i}(\langle x^*_{i,j}, x\rangle + \langle y^*_{i,j}, y\rangle + b_{i,j})_+$. So for all $x' \in X$ and for all $y \in F_i(x')$

$$d(y, F_i(x)) \le a_i g^i(x, y) \le a_i K_i \|x - x'\|,$$

where $K_i = \sum_{j=1}^{k_i} \|x^*_{i,j}\|$, and hence

$$F_i(x') \subset F_i(x) + a_i K_i \|x - x'\| B_Y.$$

Set $a = \max\{a_i K_i : \quad i = 1, \dots, k\}$. Then for all $x \in X$, there exists $r > 0$ such that for all $x' \in x + rB_X$

$$F(x') \subset F(x) + a\|x - x'\|B_Y. \qquad \square$$

Remark. If in Corollary 4.2 we have $F(x) \neq \emptyset$ for all x in some neighborhood V of x_0, then for all $x, x' \in V$

$$F(x') \subset F(x) + a\|x - x'\|B_Y.$$

The following result is due to Ioffe [13]. It extends that of Hoffman [11] from finite dimensional spaces to infinite dimensional ones.

THEOREM 4.3. *Let S be the solution set of the system* (4.1). *Then there exists $a > 0$ such that*

$$d(x, S) \le a f(x) \quad \forall x \in X,$$

where $f(x) = \|Ax\| + \sum_{i=1}^{m}(\langle x^*_i, x\rangle + b_i)_+$.

Proof. It suffices to show that the assumptions of Theorem 2.4 are satisfied (see Ioffe [13]). $\square$

5. Implicit function theorem and generalized equations. Let X be the product of two finite dimensional spaces U and V, and Y stands for a Banach space (in fact all the results of this section hold for Y a metric space) and let $F : U \times Y \to V$ be a multivalued mapping. Consider the inclusion

$$0 \in F(u, y).$$

We wish to solve this inclusion for u as a function of y around $(\overline{u}, \overline{y})$ at which this inclusion holds. Again our important results (Theorems 2.4 and 2.5) permit us to establish the implicit function theorem for non-Lipschitz multivalued mappings. Note that the infinite dimensional case will be studied in a forthcoming paper.

THEOREM 5.1. *Suppose that the graph GrF of the multivalued mapping F is closed and that*

$$(0, v^*) \in \partial^F_{(u,v)} h(\overline{u}, 0, \overline{y}) \quad \Longrightarrow \quad v^* = 0, \tag{5.1}$$

where $h(u, v, y) = d(u, v, GrF_y)$ and $F_y : u \to F(u, y)$. Suppose also that the multivalued mapping $y \to F_y(u)$ is pseudo-Lipschitzian around $\overline{y}$ uniformly in u in some neighborhood of $\overline{u}$, that is there exist $a > 0$ and $r > 0$ such that for all $y, y' \in \overline{y} + rB_Y$ and $u \in \overline{u} + rB_U$,

$$F_y(u) \cap rB_V \subset F_{y'}(u) + a\|y - y'\|B_V.$$

Then the multivalued mapping $(y, v) \to F_y^{-1}(v)$ is pseudo-Lipschitzian around $(\overline{y}, 0, \overline{u})$. Hence there exist $\alpha > 0$ and a Lipschitz continuous mapping $\phi : (\overline{y} + \alpha B_Y) \times \alpha B_V \to U$ with $\phi(\overline{y}, 0) = \overline{u}$ such that for all $(y, v) \in (\overline{y} + \alpha B_Y) \times \alpha B_V$,

$$v \in F(\phi(y, v), y).$$

Proof. For the first part, apply Theorem 2.5 to the function h with (u, v) playing the role of x. □

The proof of the second part follows from the following selection lemma.

LEMMA 5.2. *Let G be a multivalued mapping from some Banach space Z into R^m. Suppose that G is pseudo-Lipschitzian around $(\overline{z}, 0)$, that is, there exist $k_G > 0$ and $r > 0$ such that for all $z, z' \in \overline{z} + rB_Z$*

$$G(z) \cap rB_{R^m} \subset G(z') + k_G\|z - z'\|B_{R^m}.$$

Suppose also that for all $z \in \overline{z} + rB_Z$, $G(z)$ is closed. Then G admits a Lipschitz selection g near $\overline{z}$ with $g(\overline{z}) = 0$.

Proof. Without loss of generality we assume that $m = 1$. Set $s = r(1 + 2k_G)$ and consider the mappings $\overline{G} : \overline{z} + rB_Z \to [-s, s]$ defined by

$$\overline{G}(z) = G(z) \cap sB_R.$$

Then there exist $a > 0$ and $b > 0$ such that for all $z, z' \in \overline{z} + aB_Z$

$$\overline{G}(z) \cap bB_R \subset \overline{G}(z') \cap bB_R + k_G\|z - z'\|B_R.$$

Define the mapping $g : \overline{z} + aB_Z \to [-s, s]$ by

$$g(z) = \inf \overline{G}(z) \cap bB_R := \inf\{p : \quad p \in \overline{G}(z) \cap bB_R\}.$$

Then g is locally Lipschitzian near $\overline{z}$ and as $\overline{G}(z)$ is compact, $g(z) \in \overline{G}(z)$. □

Remarks. (1) Theorem 5.1 remains valid if Y is finite dimensional and if relation (5.1) is replaced by

$$(0, y^*, v^*) \in \partial^F d(\overline{u}, \overline{y}, 0; GrF) \quad \Longrightarrow \quad v^* = 0, \quad y^* = 0.$$

(2) The theorem is false if the uniform pseudo-Lipschitzness assumption is omitted. Indeed, consider the real-valued function F defined on R^2 by

$$F(u, y) = (\sqrt{|y|} + 1)u.$$

It is simple to see that all the hypotheses of the theorem are satisfied except the fact that the mapping

$$y \to F_y(u)$$

is not pseudo-Lipschitz around 0 uniformly in u in some neighborhood of 0 and the conclusion is that the mapping $(y, v) \to F_y^{-1}(v) = \frac{v}{\sqrt{|y|}+1}$ is not locally Lipschitz around $(0, 0)$.

(3) One of the referees pointed out that the first part of Theorem 5.1 was derived in [32] for infinite dimensional Fréchet smooth spaces and this is true. In my opinion their result is not an implicit function theorem but a metric regularity one. However, the authors of [32] may consult the paper by Jourani and Thibault [22], published in *Mathematical Programming* in 1990, established in finite dimensional spaces. In this paper we established a graphical metric regularity result but, as noted by Thibault [53], metric regularity and graphical metric regularity are equivalent. The present paper is an infinite dimensional extension of [22] and a continuation of the paper [18], published in *Mathematical Programming* in 1994, in which I indicate (see the end of section 3) that we may use the partial approximate subdifferential (which works in any Banach spaces and the proposed proof works for any subdifferential satisfying (P_1)–(P_6) as is noted in the paper [24, Theorem 6.1]) and introduce similar regularity conditions to ensure metric regularity of systems defined by inclusions. I am persuaded that the authors of the paper [32] might not be aware of the existence of the papers [22] and [18].

Now we consider the generalized equation of the form

$$0 \in f(u, y) + G(u), \tag{5.2}$$

where $f : U \times Y \to V$ is a mapping and $G : U \to V$ is a multivalued mapping of a closed graph. We are concerned with properties of the solution set

$$S(y) := \{u \in U : \quad 0 \in f(u, y) + G(u)\}$$

near a reference point. These questions are addressed to local sensitivity analysis of the generalized equation (5.2) under parameter perturbation y. There are many publications devoted to the study of the sensitivity analysis of generalized equations in forms (5.2) or in the form

$$0 \in f(u, y) + N(C, u),$$

where $N(C, u)$ is the normal cone operator in the sense of convex analysis [51], then in the latter case the generalized equation is reduced to the parametric variational inequality

$$\text{find} \quad u \in C \quad \text{such that} \quad \langle f(u, y), u - u' \rangle \geq 0 \quad \forall u' \in C.$$

For more details concerning these equations and their consequences, the reader can consult, for example, the works by Robinson [49], Mordukhovich [42], and references therein.

Most of the obtained results in the literature assume that f is differentiable. Our aim is to apply Theorem 2.5 in order to show that sensitivity analysis of these generalized equations may be established for f locally Lipschitzian in u uniformly in y around $(\overline{u}, \overline{y})$ solution of (5.2). Note that our result extends that of Mordukhovich [42] in which he assumes that f admits a so-called strong approximation.

THEOREM 5.3. *Let f be locally Lipschitzian around the point $(\overline{u}, \overline{y})$ solution of* (5.2). *Suppose that*

$$0 \in \partial_u^F (v^* \circ f)(\overline{u}, \overline{y}) + D^*G(\overline{u}, -f(\overline{u}, \overline{y})(v^*) \quad \Longrightarrow \quad v^* = 0,$$

where $D^*G(u,v)(v^*) = \{u^* \in U^* : \quad (u^*, -v^*) \in R_+ \partial^F d(u, v, GrG)\}$ is the coderivative multivalued mapping of G at (u,v). Then the multivalued mapping S is pseudo-Lipschitzian around $(\overline{u}, \overline{y})$, that is, there exist $r > 0$ and $b > 0$ such that for all $y, y' \in \overline{y} + rB_Y$

$$S(y) \cap (\overline{u} + rB_U) \subset S(y') + b\|y - y'\|B_U.$$

Proof. Apply Theorem 2.5 to the function $g(u,y) = d(u, -f(u,y), GrG)$ and use subdifferential calculus of composite functions for partial limiting Fréchet subdifferential which is the same as limiting Fréchet subdifferential. □

Remark. Theorem 5.3 may be obtained from Theorem 5.1 by setting $F(u,y) = f(u,y) + G(u)$.

When $G(u) = \{0\}$ for all u we obtain the following implicit function theorem for mappings which can be considered as a generalization of that of Clarke [6] since the partial limiting Fréchet subdifferential is smaller than Clarke's.

COROLLARY 5.4. *Let f be locally Lipschitzian around the point $(\overline{u}, \overline{y})$ solution of*

$$f(u,y) = 0.$$

Suppose that

$$0 \in \partial_u^F (v^* \circ f)(\overline{u}, \overline{y}) \quad \Longrightarrow \quad v^* = 0.$$

Then there exist $r > 0$ and a Lipschitz continuous mapping $\phi : (\overline{y} + rB_Y) \to U$ with $\phi(\overline{y}) = \overline{u}$ such that for all $y \in \overline{y} + rB_Y$

$$f(\phi(y), y) = 0.$$

6. Local controllability. Given a multivalued mapping $F : [0,1] \times R^n \to 2^{R^n}$ and a set $C_0 \subset R^n$, we call x a trajectory for F with respect to C_0 if it satisfies

$$(6.1) \quad x(0) \in C_0 \quad \text{and} \quad x'(t) \in F(t, x(t)) \quad \text{almost everywhere (a.e.) on } [0,1].$$

We denote by S the set of all trajectories of (6.1). We suppose in what follows this section that *S is a closed and nonempty subset* of the space $\mathcal{C}([0,1], R^n)$ of continuous functions on $[0,1]$ with values in R^n.

The parametrized reachable set of (6.1) (with parameter $z \in \mathcal{C}([0,1], R^n)$) is given by

$$R(z) = \{x(1) : \ x + z \in S\}.$$

The target is a closed nonempty subset of R^n and is denoted by C_1. Let A be the multivalued mapping from $R^n \times \mathcal{C}([0,1],R^n)$ into $\mathcal{C}([0,1],R^n)$ defined by

$$A(y,z) = \{x \in \mathcal{C}([0,1],R^n): \quad x(1)+y \in C_1,\ x+z \in S\}.$$

Let w be the linear continuous functional from $\mathcal{C}([0,1],R^n)$ into R^n defined by $w(x) = x(1)$ and let w^* be its adjoint functional. We denote by Ψ_C the indicator function of C.

Finally we shall say that the system is strongly locally controllable (s.l.c.) if there exists $r>0$ such that for all $z \in rB_{\mathcal{C}([0,1],R^n)}$,

$$rB_{R^n} \subset R(z) - C_1$$

and is locally controllable if this later holds for $z=0$.

There are many publications devoted to local controllability (see, for example, [10], [6], and bibliographies therein). Most works in the area conduct a local controllability under conditions expressed, in primal space in terms of Clarke's tangent cone or some derivative of multivalued mappings, or in dual space in terms of Clarke's normal cone. Our aim in this section is to present sufficient conditions in terms of the approximate subdifferential of the distance function ensuring strong local controllability. Note that the approximate subdifferential of locally Lipschitz functions is usually much smaller than Clarke's. It turns out that the sufficient condition below (6.6) is much more restrictive than the same one expressed in terms of Clarke's subdifferential and this latter does not hold for a broad class of sets C_1 and S important for applications (see, for example, [19]).

THEOREM 6.1. *Let $\overline{x} \in S$ with $\overline{x}(1) \in C_1$. Suppose that*

$$w^*(\partial^A d(\overline{x}(1),C_1)) \cap (-\partial^A \Psi_S(\overline{x})) = \{0\}. \tag{6.2}$$

Then there exist $r>0$ and $a>0$ such that for all $x \in \overline{x}+rB_{\mathcal{C}([0,1],R^n)}$, $y \in rB_{R^n}$, $z \in rB_{\mathcal{C}([0,1],R^n)}$,

$$d(x,A(y,z)) \le a(d(x(1)+y,C_1)+d(x+z,S)) \tag{6.3}$$

and hence the system is s.l.c.

Proof. It is not difficult to show that when $u \notin C_1$

$$\partial^A d(u,C_1) \subset S_{R^n}, \tag{6.4}$$

where $S_{R^n} = \{x^* \in R^n: \quad \|x^*\| = 1\}$. Set $f(x,y,z) = d(x(1)+y,C_1)+\Psi_S(x+z)$. We will show that (2.5) holds, and we apply Theorem 2.5. So, suppose the contrary. Then there are $(x_k,y_k,z_k) \to (\overline{x},0,0)$ and (x_k^*), with $\|x_k^*\| \to 0$ such that $x_k \notin A(y_k,z_k)$ and $x_k^* \in \partial_x^A f(x_k,y_k,z_k)$, for all integer k. By the definition of f and the subdifferential calculus we get $\partial_x^A f(x_k,y_k,z_k) \subset w^*(\partial^A d(x_k(1)+y_k,C_1)) + \partial_A \Psi_S(x_k+z_k)$. Then $x_k+z_k \in S$ and hence $x_k(1)+y_k \notin C_1$ and by (6.4) there exist $u_k^* \in \partial^A d(x_k(1)+y_k,C_1)$, with $\|u_k^*\| = 1$, and $v_k^* \in \partial^A \Psi_S(x_k+z_k)$ such that

$$x_k^* = w^*(u_k^*) + v_k^*.$$

We may suppose that $u_k^* \to u^*$, with $u^* \in \partial^A d(\overline{x}(1),C_1)$ and, by (6.4), $\|u^*\| = 1$ and $v_k^* \to v^*$, with $v^* \in \partial^A d(\overline{x},S)$ and

$$w^*(u^*) + v^* = 0,$$

and this contradicts (6.2) since $\|w^*(u^*)\| = 1$. □

Remark. In fact we showed that for all $x \in \overline{x} + rB_{\mathcal{C}([0,1],R^n)}$, $y \in rB_{R^n}$, $z \in rB_{\mathcal{C}([0,1],R^n)}$

$$d(x, A(y,z)) \le a(d(x(1)+y, C_1) + \Psi_S(x+z)) \tag{6.5}$$

for all $x \in \overline{x} + rB_{\mathcal{C}([0,1],R^n)}$, $y \in rB_{R^n}$, $z \in rB_{\mathcal{C}([0,1],R^n)}$, but this is equivalent (use Proposition 2.4.3 in [6]) to relation (6.3) with another constant a_1 instead of a.

In the following theorem we show that in relation (6.2), we may replace $\partial^A \Psi_S(\overline{x})$ by $\partial^A d(S, \overline{x})$.

THEOREM 6.2. *Theorem* 6.1 *remains valid if we replace* (6.2) *with*

$$w^*(\partial^A d(\overline{x}(1), C_1)) \cap (-\partial^A d(S, \overline{x})) = \{0\}. \tag{6.6}$$

Proof. Suppose that (6.5) does not hold. Then there are sequences $(x_k, y_k, z_k) \to (\overline{x}, 0, 0)$ such that $x_k + z_k \in S$ and

$$d(x_k, A(y_k, z_k)) > k d(x_k(1) + y_k, C_1). \tag{6.7}$$

Set $g_k(x) = d(x(1)+y_k, C_1)$ and $\varepsilon_k = \sqrt{g_k(x_k)}$. Note that by (6.7) $\varepsilon_k > 0$ and $\varepsilon_k \to 0$. Set $\lambda_k = \min(k\varepsilon_k^2, \varepsilon_k)$ and $s_k = \frac{\varepsilon_k^2}{\lambda_k} = \max(\frac{1}{k}, \varepsilon_k)$. Then

$$g_k(x_k) \le \inf_{x \in S - z_k} g_k(x) + \varepsilon_k^2$$

and hence by Ekeland's variational principle there exists $u_k \in S - z_k$ such that

$$\|u_k - x_k\| \le \lambda_k \tag{6.8}$$

and

$$g_k(u_k) \le g_k(x) + s_k \|x - u_k\| \quad \forall x \in S - z_k,$$

and hence u_k is a local minimum of the function

$$x \to g_k(x) + s_k\|x - u_k\| + (1 + s_k) d(x + z_k, S).$$

Thus

$$0 \in \partial^A g_k(u_k) + (1+s_k)\partial^A d(u_k + z_k, S) + s_k B_{(\mathcal{C}([0,1],R^n))^*}.$$

Note that by (6.8) $u_k(1) + y_k \notin C_1$ and hence by (6.4) there exist $u_k^* \in \partial^A d(u_k(1) + y_k, C_1)$, with $\|u_k^*\| = 1$, and $x_k^* \in (1+s_k)\partial^A d(u_k + z_k, S)$ such that

$$\|w^*(u_k^*) + x_k^*\| \le s_k,$$

and as in the proof of Theorem 6.1 we arrive at a contradiction with (6.6). □

In order to give other conditions ensuring relation (6.3), we give an estimate of the approximate subdifferential of the distance function to the solution set of the differential inclusion (6.1). We begin with some definitions and notations. A multivalued mapping $G : R^n \to R^n$ is said to be Lipschitz on a set A (of rank k) provided that for all $x, u \in A$

$$G(x) \subset G(u) + k\|x - u\| B_{R^n},$$

where $\|\cdot\|$ denotes the euclidean norm. Let Δ and Ω_t be the sets defined by

$$\Delta = \{t: \quad (t,x) \in \Omega\}$$
$$\Omega_t = \{x: \quad (t,x) \in \Omega\}.$$

Following Clarke [6], Ω is called a tube provided the set Δ is an interval (say, $\Delta = [0,1]$) and provided there exist a continuous function $\omega(t)$ and a continuous positive function ε on $[0,1]$ such that $\Omega_t = \omega(t) + \varepsilon(t)B_{R^n}$ for all $t \in [0,1]$. We call such tube a tube on $[0,1]$. If x is a given continuous function on $[0,1]$, the ε-tube about x, denoted $T(x,\varepsilon)$, is the tube on $[0,1]$ obtained by setting

$$\Omega = \{(t,u): \quad 0 \le t \le 1,\ u \in x(t) + \varepsilon B_{R^n}\}.$$

Let Ω be a tube on $[0,1]$. We say [6] that F is measurably Lipschitz on Ω provided that the following hold.

(i) For each $x \in R^n$, the mutivalued mapping $t \to F(t,x)$ is measurable on $[0,1]$.

(ii) There exists an integrable function $k(t)$ on $[0,1]$ such that for each $t \in [0,1]$ the multivalued mapping $x \to F(t,x)$ is nonempty and Lipschitz of rank $k(t)$ on Ω_t.

We assume in the following that F *is measurably Lipschitz on* Ω. To the multivalued mapping F we associate the quantities

$$\rho(t,x,y) = d(y,F(t,x)), \quad \rho_F(x) = I_F(x,x') = \int_0^1 \rho(t,x(t),x'(t))dt,$$

and we set $K = \exp(\int_0^1 k(t)dt)$. The set AC will refer to the set of absolutely continuous functions $x: [0,1] \to R^n$.

Now we may compute the subdifferential of the solution set of (6.1).

PROPOSITION 6.3. *Let S be the solution set of* (6.1) *and let $\overline{x} \in S$ and $\varepsilon > 0$ such that $T(\overline{x},\varepsilon) \subset \Omega$. Suppose that the values of F are closed. Then*

$$\partial^A d(\overline{x},S) \subset 2\partial^A[K\rho_F(\cdot) + (K\ln K + 1)d(u(\cdot),C_0)](\overline{x}),$$

where $u: x \to x(0)$.

The proof of this proposition is a consequence of the following lemma.

LEMMA 6.4 (compare with [6, Lemma 2, p. 124]). *Let $f: AC \to R$ be a locally Lipschitz function around $\overline{x}$, with constant $K_f > 0$, and let $\overline{x}$ be a local solution of the problem of minimizing f over S. Then $\overline{x}$ is a local solution of the problem*

$$\min\{f(x) + K_f K\rho_F(x) + K_f(K\ln K + 1)d(x(0),C_0): \quad x \in AC\}.$$

Remark. We may apply Theorem 2.4 in order to obtain $K_f(K+1)$ instead of $K_f(K\ln K + 1)$, since

$$d(x,u^{-1}(C_0)) \le d(u(x),C_0) \quad \forall x \in \mathcal{C}([0,1],R^n).$$

Proof of Proposition 6.3. Let $x^* \in \partial^A d(\overline{x},S)$. Then [15] for all $L \in \mathcal{F}(AC)$ there are nets $(x_i) \subset S$, $\varepsilon_i > 0$, and $x_i^* \in (1+\varepsilon_i)B_{(AC)^*}$ such that $x_i \to \overline{x}$, $x_i^* \to x^*$, $\varepsilon_i \to 0^+$ and such that the function

$$x \to -\langle x_i^*, x - x_i\rangle + \varepsilon_i\|x - x_i\| + (1+\varepsilon_i)d(x,x_i + L)$$

attains a local minimum at x_i on S. Then, by Lemma 6.4, the function

$$x \to -\langle x_i^*, x - x_i\rangle + \varepsilon_i\|x - x_i\| + (1+\varepsilon_i)d(x, x_i + L) + (2+2\varepsilon_i) \times [K\rho_F(x) + (K\ln K + 1)d(x(0), C_0)]$$

attains a local minimum at x_i. Thus

$$x_i^* \in (2+2\varepsilon_i)\partial^A[K\rho_F(\cdot) + (K\ln K+1)d(u(\cdot), C_0)](x_i) + \varepsilon_i B_{(AC)^*} + (1+\varepsilon_i)\partial^A d(x_i, x_i + L)$$

and hence

$$x^* \in 2\partial^A[K\rho_F(\cdot) + (K\ln K+1)d(u(\cdot), C_0)](\overline{x})$$

and the proof is complete. □

Set $K_1 = 2(K\ln K + 1)$. Then, with the help of Proposition 6.3, we have the following result.

COROLLARY 6.5. *Let F be as in Proposition* 6.3. *Suppose that*

$$if\ (v'(t), v(t)) \in K_1\partial^C\rho(t, \overline{x}(t), \overline{x}'(t)) \quad a.e.$$

with

$$v(0) \in K_1\partial^A d(\overline{x}(0), C_0),\ v(1) \in \partial^A d(\overline{x}(1), C_1), \quad then\ v(1) = 0.$$

Then the conclusion of Theorem 6.2 *holds.*

Here $\partial^C\rho$ refers to the Clarke's subdifferential of ρ with respect to the variables $(\overline{x}(t), \overline{x}'(t))$ for t fixed.

Proof. It suffices to show that (6.6) holds and to apply Theorem 6.2. Indeed consider (as in Thibault [54]) the mappings $\alpha : R^n \times L^1([0,1], R^n) \to R^n \times R^n$ and $\beta : R^n \times L^1([0,1], R^n) \to L^1([0,1], R^n) \times L^1([0,1], R^n)$ defined by

$$\alpha(x(0), x') = (x(0), x(1)), \quad \beta(x(0), x') = (x, x').$$

Let $b \in \partial^A d(\overline{x}(1), C_1)$ with $-w^*(b) \in \partial^A(\overline{x}, S)$. By Proposition 6.3 there exist $a \in K_1\partial^A d(\overline{x}(0), C_0)$ and $(u, v) \in K_1\partial^A I_L(\overline{x}, \overline{x}')$ such that

$$-\alpha^*(a, b) = \beta^*(u, v)$$

and hence (see Thibault [54])

$$b = -v(1), \quad a = v(0), \quad \text{and} \quad u(t) = v'(t) \text{ a.e.},$$

and hence $b = 0$ and the proof is complete. □

As a consequence, we obtain the following result which gives us an upper estimate of the solution set of (6.1).

COROLLARY 6.6. *There exist $a > 0$ and $r > 0$ such that*

$$d(x, B(z, v)) \le a(d(x(0) + z, C_0) + \rho_F(x + v))$$

for all $x \in \overline{x} + rB_{AC}$, $z \in rB_{R^n}$, and $v \in rB_{AC}$.

Here

$$B(z, v) = \{x \in AC : \quad x(0) + z \in C_0,\ x'(t) + v'(t) \in F(t, x(t) + v(t)),\ a.e.\}.$$

Corollary 6.5 may be stated in the following general form. The proof of this result is omitted since it is similar to those of Theorems 6.1 and 6.2. Note that in the following result, the perturbation appears only on the left-hand side of the differential inclusion.

THEOREM 6.7. *Under the assumptions of Corollary* 6.5 *there exist* $a := a(\overline{x}) > 0$ *and* $r > 0$ *such that*

$$d(x, C(y,z,v)) \le a(d(x(0)+z, C_0) + \hat{\rho}_F(x+v) + d(x(1)+y, C_1))$$

for all $x \in \overline{x} + rB_{AC}$, $z, y \in rB_{R^n}$, *and* $v \in rB_{AC}$.

Here

$$C(y,z,v) = \{x \in AC : \quad x(1)+y \in C_1,\ x(0)+z \in C_0,\ x'(t)+v'(t) \in F(t,x(t)), \text{ a.e.}\}$$

and

$$\hat{\rho}_F(x+v) = \int_0^1 d(x'(t)+v'(t), F(t,x(t)))dt.$$

This theorem implies in particular that there exist $a > 0$ and $r > 0$ such that for all $(y,z) \in r(B_{R^n} \times B_{R^n})$ and $v \in rB_{AC}$ there exists $u \in AC$ such that

$$u(0)+z \in C_0, \quad u(1)+y \in C_1, \quad u'(t)+v'(t) \in F(t,u(t)), \quad \text{and}$$
$$\|\overline{x}-u\|_{AC} \le a[\|z\| + \|y\| + \|v\|_{AC}].$$

7. Applications to sensitivity analysis. Throughout this section X and Y will be Banach spaces. Suppose that an optimization problem (P) is given in the following abstract form:

$$\min\{f(x) : \quad g(x) \le 0\}.$$

It often happens that (P) lends itself naturally to parametric perturbation, so that (P) is embedded in a family of optimization problems (P_y) indexed by a parameter y

$$\min\{f(x,y) : \quad g(x,y) \le 0\}.$$

The value of the problem (P_y) is denoted $v(y)$, and v is called the value function. For each y in the domain of v we consider the set of minimizers

$$S(y) := \{x \in X : \quad g(x,y) \le 0, f(x,y) = v(y)\}.$$

We proceed to examine a few typical properties of v that have a bearing on (P). We begin by the Lipschitzian property of v. For this we introduce a compactness assumption which will assure the stability of the parametrized problems (P_y). A stability assumption (SA) holds if $S(y) \neq \emptyset$ for y near 0 and

$$\text{if } y_n \to 0 \text{ and } x_n \in S(y_n)\ \forall n, \text{ then } (x_n) \text{ has an accumulation point.}$$

THEOREM 7.1. *Suppose that*

(i) $S(0)$ *is nonempty,*

(ii) f *(resp., g) is lower semicontinuous and locally Lipschitzian near each point* $(x_0, 0)$, *with Lipschitz constant* $k_f(x_0)$, *(resp., near* 0 *uniformly around* x_0*) for* $x_0 \in S(0)$,

(iii) (SA) *holds,*

(iv) *the Hoffman error bound holds at each point* x_0 *in* $S(0)$*, i.e., there exist* $a(x_0) > 0$ *and* $r > 0$ *such that*

$$d(x, \{u : \ g(u, y) \le 0\}) \le a(x_0) g_+(x, y) \quad \forall x \in x_0 + rB_X, \quad \forall y \in rB_Y.$$

Then v *is locally Lipschitzian near* 0*.*

Proof. First we show that v is continuous at 0. Since v is upper semicontinuous it suffices to show that it is s.l.c. at 0. So suppose the contrary; then there exist $\varepsilon > 0$ and a sequence (y_n) converging to 0 such that for n large enough

$$v(0) > v(y_n) + \varepsilon.$$

By (iii), there exists $x_n \in S(y_n)$, which we assume converging to some x_0 with, by (ii), $x_0 \in S(0)$ and hence by the lower semicontinuity of f, we get

$$v(0) \ge v(0) + \varepsilon$$

which leads to a contradiction. So v is s.l.c. at 0.

Now we proceed to show that v is locally Lipschitzian around 0. So suppose the contrary; then there are sequences $y_n \to 0$ and $y'_n \to 0$ such that for n large enough

$$|v(y_n) - v(y'_n)| > n\|y_n - y'_n\|.$$

We may assume that the set $I = \{n : \ v(y_n) - v(y'_n) > n\|y_n - y'_n\|\}$ is infinite (because (y_n) and (y'_n) play a symmetric role). For all $n \in I$ there exists, by (iii), $x'_n \in S(y'_n)$, which we suppose converges to $x_0 \in S(0)$ (by the continuity of v). Now, by (iv), for $n \in I$ large enough

$$d(x'_n, \{u : \ g(u, y_n) \le 0\}) \le a g_+(x'_n, y_n)$$

and hence there exists x_n, with $g(x_n, y_n) \le 0$, such that

$$\|x'_n - x_n\| \le a g_+(x'_n, y_n)$$

and since g is locally Lipschitzian near 0 uniformly in x'_n, with constant $k_g = k_g(x_0)$

$$\|x'_n - x_n\| \le a(g_+(x'_n, y_n) - g_+(x'_n, y'_n)) \le a k_g \|y_n - y'_n\|.$$

So if k_f is a Lipschitz constant of f around $(x_0, 0)$, then for all $n \in I$ sufficiently large

$$n\|y_n - y'_n\| < f(x_n, y_n) - f(x'_n, y'_n) \le k_f(1 + a k_g)\|y_n - y'_n\|,$$

and this contradiction completes the proof. ∎

We have the following estimate of the subdifferential of v.

THEOREM 7.2. *Suppose, in addition to the assumptions of Theorem* 7.1*, that* g *is locally Lipschitzian near each point* $(x_0, 0)$*, with* $x_0 \in S(0)$*. Then*

- $\forall x_0 \in S(0)$, $\partial^A v(0) \cap M^A(x_0) \ne \emptyset$,
- $\partial^A v(0) \subset M^A(0)$.

Where

$$M^A(x_0) = \{y^* + z^* : \ (x^*, y^*) \in \partial^A f(x_0, 0), \ (-x^*, z^*) \in \alpha(x_0)[0, 1]\partial^A g(x_0, 0)\},$$

$$M^A(0) = \bigcup_{x_0 \in S(0)} M^A(x_0)$$

$\alpha(x_0) = (k_v + k_f(x_0))a(x_0)$ and k_v is a Lipschitz constant of v near 0.

Proof. The proof of the second part is omitted because it is similar to that given by Jourani in [19] for the so-called G-subdifferential.

For all $x_0 \in S(0)$ we have, by Theorem 7.1, that the function

$$(x, y) \to f(x, y) - v(y) + \alpha(x_0)g_+(x, y)$$

attains a local minimum at $(x_0, 0)$ and hence $(x_0, 0, v(0))$ is a local minimum of the function

$$(x, y, t) \to f(x, y) - t + \alpha(x_0)g_+(x, y)$$

over the set $\{(x, y, t) : \quad v(y) = t\}$, and the result follows by using Fritz–John necessary optimality conditions for approximate subdifferential. □

The previous result may be applied to produce estimates of the subdifferential of the marginal function

$$m(y, z) = \inf\{f(x(0), x(1)) : \quad x(1) + y \in C_1,\ x(0) + z \in C_0,\\ x'(t) \in F(t, x(t)),\ \text{a.e.}\}$$

Let $S(y, z)$ be the set of feasible points x satisfying $m(y, z) = f(x(0), x(1))$.

COROLLARY 7.3. *Suppose that for all $\overline{x} \in S(0, 0)$, the assumptions of Theorem 6.7 hold, f is locally Lipschitzian around $(\overline{x}(0), \overline{x}(1))$ with constant $k_f(\overline{x})$, and suppose that the multivalued mapping $(y, z) \to S(y, z)$ satisfies some compactness assumption like (SA). Then*

- *m is locally Lipschitzian around $(0, 0)$ (with constant k_m),*
- *$\forall \overline{x} \in S(0, 0)$, $\partial^A m(0, 0) \cap N(\overline{x}) \neq \emptyset$,*
- *$\partial^A m(0, 0) \subset N(0, 0)$.*

Where $K_1(\overline{x}) = (k_f(\overline{x}) + k_m)a(\overline{x})$, $a(\overline{x})$ is as in Theorem 6.7,

$$N(0, 0) = \bigcup_{\overline{x} \in S(0,0)} N(\overline{x}),$$

and $N(\overline{x})$ is the set of elements $(a, b) \in K_1(\overline{x})\partial^A d((\overline{x}(0), \overline{x}(1)), C_0 \times C_1)$ for which there exist $(c, d) \in \partial^A f(\overline{x}(0), \overline{x}(1))$ and v such that

$$(v'(t), v(t)) \in K_1(\overline{x})\partial^C \rho(t, \overline{x}(t), \overline{x}'(t)),\ \text{a.e.}$$

with

$$a + c = v(0) \quad \text{and} \quad b + d = -v(1).$$

Proof. Apply Theorem 7.2 with $g(x, y, z) = d(x(1)+y, C_1)+d(x(0)+z, C_0)+\rho_F(x)$ and use the formulae on generalized gradients of integral functionals [6]. □

8. Further results: Farkas lemma for quadratic inequality systems and weak sharp minima (or linear conditioning). We will use the previous results and the result by Mangasarian [37] to obtain a Farkas lemma for quadratic inequality system

$$x \in C, \quad \frac{1}{2}\langle x, Bx\rangle + \langle b, x\rangle + c \leq 0, \tag{8.1}$$

where C is polyhedral in R^n and $B \in R^{n\times m}$ is symmetric and positive semidefinite. We let S be a solution set to this system.

We use the description of the solution set of a convex program established in [37]. See [33] for a simple proof of the following proposition in the case where f is locally Lipschitz.

PROPOSITION 8.1. *Let D be the solution set to the problem*

$$\min_{x\in C} f(x),$$

where both $f : R^n \to R$ and $C \subset R^n$ are convex with f differentiable. Let $u \in D$. Then

$$D = \{x \in C : \quad \nabla f(x) = \nabla f(u),\ \langle \nabla f(u), x - u\rangle = 0\}.$$

Now we are able to present a Farkas lemma for (8.1).

PROPOSITION 8.2. *Let u be a boundary point in S and $B_i, i = 1, \dots, m$, be vector lines of B. Set $g(x) = \frac{1}{2}\langle x, Bx\rangle + \langle b, x\rangle + c$. Then*

$$N(S,u) \subset N(C,u) + R_+\partial g_+(u) \text{ or } N(S,u) \subset N(C,u) + \operatorname{span}\{B_1, \dots, B_m, b\}.$$

Proof. First case. If there exists $u_0 \in C$ such that $g(u_0) < 0$, then, by Proposition 3.2, we have

$$d(x,S) \le \frac{f_+(x)}{-g(u_0)}\|x - u_0\| \quad \forall x \in R^n,$$

where $f(x) = g(x) + \Psi_C(x)$, or, equivalently,

$$d(x,S) \le \frac{g_+(x)}{-g(u_0)}\|x - u_0\| \quad \forall x \in C.$$

This ensures that

$$N(S,u) \subset N(C,u) + R_+\partial g_+(u).$$

Second case. For all $x \in C$, $g(x) \ge 0$. In this case S is the set of solutions of the problem

$$\min_{x\in C} g(x).$$

Thus, by Proposition 8.1, $S = \{x \in C : \quad A(x - u) = 0\}$, where $A = (B, b)$ and Theorem 4.3 implies the existence of $a > 0$ such that

$$d(x,S) \le a\|A(x - u)\| \quad \forall x \in C.$$

Thus

$$N(S,u) \subset N(C,u) + \operatorname{span}\{B_1, \dots, B_m, b\}.$$

This completes the proof. □

Remark. Proposition 8.2 may be obtained as a consequence of the well-known results in convex analysis (see [51]).

Consider a function $g : X \to R \cup \{\infty\}$ and a subset C of X. We say that $S := \arg\min_C g$ is a set of weak sharp minima for g relative to C with modulus $b > 0$ if

$$g(x) \geq g(u) + bd(x, S) \quad \forall x \in C, \quad \forall u \in S.$$

As we can see that this is equivalent to Hoffman's error bound

$$d(x, S) \leq \frac{1}{b} f_+(x) \quad \forall x \in X,$$

where $f(x) = g(x) - g(u) + \Psi_C(x)$ for some $u \in S$. To simplify we assume that $C = X$.

THEOREM 8.3. *Let f be lower semicontinuous, $b > 0$, and $S := \arg\min f$ be nonempty. Consider the following statements.*

(i) $(\partial f)^{-1}(x^*) \subset S \ \forall x^* \in X^*$ *with* $\|x^*\| < b$.

(ii) $\forall x \in \mathrm{dom} f$, $x \notin S \quad d(0, \partial f(x)) \geq b$.

(iii) S *is a set of weak sharp minima for f on X with modulus b.*

Then (i) $\Longleftrightarrow$ (ii) $\Longrightarrow$ (iii). *If in addition f is proper and convex, statements* (i), (ii), *and* (iii) *are equivalent. Here* $(\partial f)^{-1}(x^*) := \{x \in X : \quad x^* \in \partial f(x)\}$.

Proof. The equivalence (i) $\Longleftrightarrow$ (ii) is obvious. The implication (ii) $\Longrightarrow$ (iii) follows from Theorem 2.4. Theorem 5.1 in [8] ensures the implication (iii) $\Longrightarrow$ (i). □

Remark. One of the referees pointed out that the nonparametric version of Theorem 2.4 and the equivalence of (ii) and (iii) were obtained independently and presented at a meeting in Dallas in 1997 by J. V. Burke and S. Deng.

Acknowledgment. The author wishes to acknowledge the comments of the referees, which helped to correct and improve the presentation of the paper.

ANY DOMAIN OF ATTRACTION FOR A LINEAR CONSTRAINED SYSTEM IS A TRACKING DOMAIN OF ATTRACTION*

FRANCO BLANCHINI† AND STEFANO MIANI‡

Abstract. In the stabilization problem for systems with control and state constraints a domain of attraction is a set of initial states that can be driven to the origin by a feedback control without incurring constraints violations. If the problem is that of tracking a reference signal, that converges to a constant constraint-admissible value, a tracking domain of attraction is a set of initial states from which the reference signal can be asymptotically approached without constraints violation during the transient. Clearly, since the zero signal is an admissible reference signal, any tracking domain of attraction is a domain of attraction. We show that the opposite is also true. For constant reference signals we establish a connection between the convergence speed of the stabilization problem and tracking convergence which turns out to be independent of the reference signal. We also show that the tracking controller can be inferred from the stabilizing (possibly nonlinear) controller associated with the domain of attraction.

Key words. constrained control, domain of attraction, Lyapunov functions, tracking, convex analysis

1. Introduction.

In this paper we consider linear systems with state and control constraints. For this class of systems we say that a certain convex and compact set including the origin in its interior is a domain of attraction to the origin if there exists a feedback control such that for any initial state in this set the state is driven asymptotically to the origin without constraints violation. Several previous references have dealt with the construction of such domains (see for instance [3], [6], [11], [12], [17], [18], [19], [20], [21], [26], [28]).

Here we consider the problem of tracking a reference signal including the zero one. We assume that the system is square (i.e., it has as many inputs as outputs) and that it is free of invariant zeros at one in the discrete-time case (or it is free from zeros at the origin in the continuous-time case). We define a set of reference vectors which are constraints-compatible in the sense that they are associated with state vectors which are in the interior of the domain of attraction to the origin and to feasible input vectors. The only condition required for the signal to be tracked is that it asymptotically converges to a value which is in this set. A signal satisfying the above requirement will be said to be admissible. We stress that the signal, during the transient, may assume values outside this set and it is a goal of the control to avoid constraints violations. For the zero reference signal, such a goal can be achieved only if the initial state is inside a domain of attraction to the origin. Any initial state from which we can track asymptotically an admissible reference signal is said to belong to a tracking domain of attraction. The question which hence arises is whether there are initial states inside the domain of attraction to the origin from which we cannot

solve the problem of tracking an admissible reference signal. Put in other words this means to verify whether or not the largest tracking domain of attraction is a proper subset of the assigned domain of attraction. We show that the answer is negative.

The basic ideas we develop here are related to previously published results [2], [15], [14], [16]. The main difference relies on the fact that in those references it is assumed that a stabilizing linear nominal compensator (often referred to as precompensator) is applied to the system. To this nominal compensator the so called reference governor is added which is a device that possibly attenuates the effect of the reference signal in order to avoid violations. This is basically equivalent to considering a stable system (i.e., a system to which a precompensator is applied) and to managing the reference for this system. Although this assumption is quite reasonable, it turns out that the resulting constructed invariant sets depend on the precompensator. Therefore, an unsuitable choice of the compensator can produce a very small domain of attraction.

Conversely, here *we do not assume the existence of any precompensator* and thus we may take as a domain of attraction the largest one in absolute in the sense that, if the initial state is outside that region, there is no guarantee that constraints violation can be avoided, even for zero reference signal. We show that this is a tracking domain of attraction, in the sense that there is a (possibly nonlinear) compensator, which is not a priori fixed, that solves the tracking problem for any initial state in this region. Furthermore, we show that the control strategy can be inferred from the original stabilizing controller associated with the given domain of attraction. We use as a technical support a Lyapunov function suitably constructed by "reshaping" the one associated with such a domain.

Finally we show that, for constant reference signals and symmetric domains, the speed of convergence can be estimated a priori from the speed of convergence achieved by the stabilizing controller, and it does not depend on the particular reference.

The paper is organized as follows. In section 2 we provide the basic definitions. In section 3 we state the main results which will be proven later in section 4 and section 5. We particularize the results to domains of attraction of special shapes in section 6. We show how to extend the results to nonsquare systems in section 7. We finally present two examples in section 8 to illustrate the method, and we derive our conclusions in section 9.

2. Definitions and problem statement. In what follows we denote by $int\mathcal{P}$ the interior of a set $\mathcal{P}$ and by $\partial\mathcal{P}$ its boundary. With the term C-set we denote a convex and compact set containing the origin as an interior point. It is known that any C-set $\mathcal{P}$ induces a positively homogeneous convex function which is known as Minkowski functional (see [22]):

$$\psi_{\mathcal{P}}(x) = \inf\{\xi \geq 0 : x \in \xi\mathcal{P}\}. \tag{2.1}$$

The function $\psi_{\mathcal{P}}(x) \geq 0$ is such that $\psi_{\mathcal{P}}(x) = 0$ iff $x = 0$, and $\psi_{\mathcal{P}}(\lambda x) = \lambda\psi_{\mathcal{P}}(x)$ for any $\lambda \geq 0$. If $\mathcal{P}$ is 0-symmetric (i.e., $x \in \mathcal{P}$ implies $-x \in \mathcal{P}$), then $\psi_{\mathcal{P}}$ is a norm. The index $\mathcal{P}$ will be omitted for brevity when the inducing set $\mathcal{P}$ of $\psi_{\mathcal{P}}$ is clear from the context.

In the following we consider both discrete and continuous-time square systems

$$\begin{array}{rcl} \delta x(t) & = & Ax(t) + Bu(t) \\ y(t) & = & Cx(t) + Du(t), \end{array} \tag{2.2}$$

where δ represents the shift operator $\delta x(t) = x(t+1)$ in the discrete-time case and the derivative operator in the continuous-time case. The vector $y(t) \in \mathbb{R}^q$ is the system

output, the vector $x(t) \in \mathbb{R}^n$ is the system state, and $u(t) \in \mathbb{R}^q$ is the control input. We assume that (A, B) is stabilizable and that x and u are subject to the constraints

$$x(t) \in \mathcal{X}, \tag{2.3}$$

$$u(t) \in \mathcal{U}, \tag{2.4}$$

where $\mathcal{X} \subset \mathbb{R}^n$ and $\mathcal{U} \subset \mathbb{R}^q$ are assigned C-sets.

Due to the presence of the constraints, the solution of the stabilization problem implies restrictions on the admissible initial conditions.

DEFINITION 2.1. *The C-set $\mathcal{S} \subset \mathcal{X}$ is a domain of attraction for the system* (2.2) *if there exists a continuous feedback control function $u(t) = \phi(x(t))$ such that any trajectory $x(t)$ with initial condition $x(0) \in \mathcal{S}$ is such that $x(t) \in \mathcal{S}$, $u(t) \in \mathcal{U}$, and*

$$\lim_{t \to \infty} x(t) = 0.$$

It is well known that the above definition is fundamental for the stabilization problem under constraints. An initial condition can be driven to the origin without constraints violations iff it belongs to a domain of attraction. However, in practice, simple convergence is not enough, but it is important to provide an index of the speed of convergence to the origin. Thus we introduce the following two definitions.

DEFINITION 2.2. *The C-set $\mathcal{S} \subset \mathcal{X}$ is a domain of attraction with speed of convergence λ for the* discrete-time *system* (2.2) *if there exists $0 \leq \lambda < 1$ and a continuous feedback control function $u(t) = \phi(x(t))$ such that any trajectory $x(t)$ with initial condition $x(0) \in \mathcal{S}$ is such that*

$$\psi_{\mathcal{S}}(x(t)) \leq \lambda^t \psi_{\mathcal{S}}(x(0)).$$

If we take $\lambda = 1$, the set $\mathcal{S}$ is simply said to be positively invariant (often referred to as controlled–invariant). We say that $\mathcal{S}_\lambda \subset \mathcal{X}$ is the largest domain of attraction if for any domain of attraction $\mathcal{S}$ in $\mathcal{X}$ with speed of convergence λ we have $\mathcal{S} \subset \mathcal{S}_\lambda$.

DEFINITION 2.3. *The C-set $\mathcal{S} \subset \mathcal{X}$ is a domain of attraction with speed of convergence β for the* continuous-time *system* (2.2) *if there exists $\beta > 0$ and a continuous feedback control function $u(t) = \phi(x(t))$ such that any trajectory $x(t)$ with initial condition $x(0) \in \mathcal{S}$ is such that*

$$\psi_{\mathcal{S}}(x(t)) \leq e^{-\beta t} \psi_{\mathcal{S}}(x(0))$$

If we take $\beta = 0$, the set $\mathcal{S}$ is simply said to be positively invariant (often referred to as controlled-invariant). We say that $\mathcal{S}_\beta \subset \mathcal{X}$ is the largest domain of attraction if for any domain of attraction $\mathcal{S}$ in $\mathcal{X}$ with speed of convergence β we have $\mathcal{S} \subset \mathcal{S}_\beta$.

A stabilizable system always admits a domain of attraction $\mathcal{P} \subset \mathcal{X}$. The knowledge of such a domain is fundamental in the stabilization problem under constraints, since if $x(0) \in \mathcal{P}$, then the conditions $x(t) \in \mathcal{P} \subset \mathcal{X}$ for $t \geq 0$, and $x(t) \to 0$ as $t \to \infty$ can be assured. Thus, once we have computed a domain of attraction $\mathcal{P}$ to solve the problem (possibly the largest one [4], [6], [7]), we can replace the constraint $x(t) \in \mathcal{X}$ by the new constraint

$$x(t) \in \mathcal{P}.$$

In this paper we deal with the problem of tracking a certain class of reference signals. To this aim we make the assumption that the system is free from zeros at one (zeros at the origin).

ASSUMPTION 2.1. *The square matrix*

$$M_d = \begin{bmatrix} A-I & B \\ C & D \end{bmatrix} \left(\textit{resp.}, \; M_c = \begin{bmatrix} A & B \\ C & D \end{bmatrix} \right)$$

is invertible.

The general case in which M_d (M_c) is not invertible or even nonsquare will be considered in section 7. Under Assumption 2.1 the system has the property that for any constant reference $r \in \mathbb{R}^q$ there is an unique state-input equilibrium pair $(\bar{x}, \bar{u})$ such that the corresponding equilibrium output is r. Such a pair is the unique solution of the equation

$$M_d \begin{bmatrix} \bar{x}(r) \\ \bar{u}(r) \end{bmatrix} = \begin{bmatrix} 0 \\ r \end{bmatrix} \left(\text{resp.}, \; M_c \begin{bmatrix} \bar{x}(r) \\ \bar{u}(r) \end{bmatrix} = \begin{bmatrix} 0 \\ r \end{bmatrix} \right).$$

Thus we can define the set of admissible constant reference vectors

$$\mathcal{R} = \{ r \in \mathbb{R}^q : \; \bar{u}(r) \in \mathcal{U}, \; \bar{x}(r) \in \mathcal{P} \}.$$

Being that $\mathcal{P}$ and $\mathcal{U}$ are both bounded, $\mathcal{R}$ is also bounded. The set $\mathcal{R}$ is of fundamental importance. It is the set of all reference vectors for which the corresponding input and state equilibrium pairs do not violate the constraints $\bar{u} \in \mathcal{U}$ and $\bar{x} \in \mathcal{P}$. While the reason for imposing the former is obvious, the second deserves some explanation. Indeed we have imposed $x \in \mathcal{X}$. However, note that if $\bar{x}(r)$ is not included in a domain of attraction, then the condition $x(t) \to \bar{x}(r)$ can cause a violation of the constraints if, for instance, after a sufficiently long period, the reference $r(t)$ switches to zero.

We are now going to introduce the set of all the admissible signals to be tracked, formed by the signals $r(t)$ having a finite limit r_∞, with the condition that r_∞ has some admissibility condition with respect to the constraints.

DEFINITION 2.4. *Assume that a small* $0 < \epsilon < 1$ *is given. A reference signal* $r(t)$ *is admissible if it is continuous*[1] *and if it is such that*

$$\lim_{t \to \infty} r(t) = r_\infty \in (1-\epsilon)\mathcal{R} \doteq \mathcal{R}_\epsilon.$$

The parameter ϵ, as we will see later, is introduced to avoid singularities in the control. Such ϵ may be arbitrarily small, and thus it does not practically affect the problem. We stress that an admissible reference signal *does not need to assume its values in* $\mathcal{R}_\epsilon$, but only its limit r_∞ needs to do this. Now we can state the following basic definition.

DEFINITION 2.5. *The set* $\mathcal{P} \subset \mathcal{X}$ *is a tracking domain of attraction if there exists a (possibly nonlinear) feedback control*

$$u(t) = \Phi(x(t), r(t))$$

such that for any $x(0) \in \mathcal{P}$ *and for every admissible reference signal* $r(t)$

(i) $x(t) \in \mathcal{P}$ *and* $u(t) \in \mathcal{U}$,

(ii) $y(t) \to r_\infty$ *as* $t \to \infty$.

[1]The continuity requirement for the function $r(t)$ is limited to the continuous-time case only. It is not essential but avoids unnecessary complications.

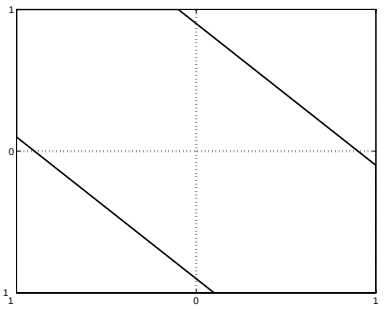

FIG. 1. *The largest domain of attraction when* $\lambda = .9$.

Since $r(t) = 0$ is an admissible reference signal, any tracking domain of attraction is a domain of attraction. The main result of this paper is that of showing that every domain of attraction $\mathcal{P}$ is also a tracking domain of attraction. The importance of this assertion lies in the fact that the tracking problem can be solved once one has found a domain of attraction. Since the latter operation is a well-established topic, this allows for the solution of a more general problem.

REMARK 2.1. *Note that under Assumption* 2.1 *the condition* $y(t) \to r_\infty$ *as* $t \to \infty$ *is equivalent to the two conditions* $x(t) \to \bar{x}_\infty \doteq \bar{x}(r_\infty)$ *and* $u(t) \to \bar{u}_\infty \doteq \bar{u}(r_\infty)$.

2.1. A simple example. Consider the discrete-time system

$$A = \begin{bmatrix} 1 & -1 \\ 1 & 1 \end{bmatrix} \quad B = \begin{bmatrix} 1 \\ 0 \end{bmatrix} \quad C = \begin{bmatrix} 0 & 1 \end{bmatrix},$$

together with the constraints sets $\mathcal{X} = \{x : \|x\|_\infty \leq 1\}$ and $\mathcal{U} = \{u : |u| \leq 1.2\}$. The largest domain of attraction with speed of convergence λ for $\lambda \geq 0.9$ is given by

$$\mathcal{P} = \{x : |x_1| \leq 1,\ |x_2| \leq 1,\ |x_1 + x_2| \leq \lambda\}$$

and is reported in Figure 1 for $\lambda = .9$. Such a domain is associated with the polyhedral function $\psi(x) = \max\{|x_1|, |x_2|, |x_1 + x_2|/\lambda\}$.

If we take $\lambda < 1$ we assure that $\mathcal{P}$ is a domain of attraction. Note that for λ approaching 1 the set $\mathcal{P}$ approaches the largest invariant set. Therefore there is a tradeoff between the choice of the largest invariant set and the convergence speed. Once this tradeoff is fixed by a choice of λ, we have that there exists a stabilizing control which avoids constraints violation for all initial states inside $\mathcal{P}$. Now if we want to track a reference signal $r(t)$ the situation is different. For a given fixed $\bar{r}$, the corresponding state input pair is

$$\begin{bmatrix} \bar{x} \\ \bar{u} \end{bmatrix} = \begin{bmatrix} A - I & B \\ C & 0 \end{bmatrix}^{-1} \begin{bmatrix} 0 \\ \bar{r} \end{bmatrix}.$$

If our goal were asymptotic tracking only, in view of the linearity of the system we could just use the translated Lyapunov function

$$\psi(x - \bar{x}) = \max\{|x_1 - \bar{x}_1|, |x_2 - \bar{x}_2|, |x_1 - \bar{x}_1 + x_2 - \bar{x}_2|/\lambda\}.$$

But in this way the constraints could not be satisfied. The basic idea we pursue is to "deform" the function ψ in such a way that the surface of level one is unchanged and the minimum point (the zero) is assumed on $\bar{x}$.

The set $\mathcal{R}_\epsilon$ is the interval

$$\mathcal{R}_\epsilon = \{r : \ |r| \leq \lambda - \epsilon\}.$$

For every reference signal $r(t) \to \bar{r} \in \mathcal{R}_\epsilon$ and $x(0) \in \mathcal{P}$, our goal is that of letting $y(t) \to \bar{r}$ and $x(t) \in \mathcal{P}$. According to Remark 2.1, for the first condition it is necessary and sufficient that $x(t) \to \bar{x} = [0 \ \ r]^T$ and $u(t) \to r$ (in this case $\bar{u}(r) = r$).

3. Main results. We will now introduce the functions which will subsequently be used for tracking every admissible reference signal. Suppose that a C-set $\mathcal{P}$, which is a domain of attraction, is given and consider its Minkowski functional which, from (2.1), can be rewritten as

$$\psi_{\mathcal{P}}(x) = \inf\{\alpha > 0 \ : \ \frac{1}{\alpha} x \in \mathcal{P}\}. \tag{3.1}$$

For every $\bar{x} \in \text{int}\mathcal{P}$ and $x \in \mathcal{P}$, we introduce the following function:

$$\Psi_{\mathcal{P}}(x, \bar{x}) = \inf\{\alpha > 0 \ : \ \bar{x} + \frac{1}{\alpha}(x - \bar{x}) \in \mathcal{P}\}. \tag{3.2}$$

It is immediate that the just introduced function Ψ recovers the values of ψ when $\bar{x} = 0$, say $\Psi_{\mathcal{P}}(x, 0) = \psi_{\mathcal{P}}(x)$. For fixed $\bar{x}$, $\Psi_{\mathcal{P}}(x, \bar{x})$ is convex. Furthermore, the function $\Psi_{\mathcal{P}}(x, \bar{x})$ for $(x, \bar{x}) \in \mathcal{P} \times \text{int}\mathcal{P}$ is such that

$$\Psi_{\mathcal{P}}(x, \bar{x}) = 0 \quad \text{iff} \quad x = \bar{x}, \tag{3.3}$$

$$\Psi_{\mathcal{P}}(x, \bar{x}) < 1 \quad \text{iff} \quad x \in \mathcal{P}, \tag{3.4}$$

$$\Psi_{\mathcal{P}}(x, \bar{x}) = 1 \quad \text{iff} \quad x \in \partial\mathcal{P}. \tag{3.5}$$

A sketch of the function $\Psi_{\mathcal{P}}(x, \bar{x})$ for fixed $\bar{x}$ is in Fig. 2. One further relevant property of this function is that $\Psi_{\mathcal{P}}$ is Lipschitz in x and positively homogeneous of order one with respect to the variable $z = x - \bar{x} \in \mathbb{R}^n$, $\bar{x} \in \text{int}\mathcal{P}$, i.e.,

$$\Psi_{\mathcal{P}}(\xi z + \bar{x}, \bar{x}) = \xi \Psi_{\mathcal{P}}(z + \bar{x}, \bar{x}). \tag{3.6}$$

In view of property (3.3) we have that the function is a suitable Lyapunov candidate for tracking, and from (3.4)–(3.5) we have that this function is suitable to prevent constraints violations, as we will show later.

Let us now consider the function $\Psi_{\mathcal{P}}(x, \bar{x})$ and for every $x \in \mathcal{P}$ and $\bar{x} \in \text{int}\mathcal{P}$, with $x \neq \bar{x}$, set

$$\tilde{x} \doteq \bar{x} + (x - \bar{x}) \frac{1}{\Psi_{\mathcal{P}}(x, \bar{x})} \in \partial\mathcal{P}.$$

The vector $\tilde{x}$ is the intersection of $\partial\mathcal{P}$ with the half line starting from $\bar{x}$ and passing through x (see Fig. 2). Assume that $\mathcal{P}$ is a given domain of attraction and that $\phi(x)$ is the control law associated with this set. As shown in [4], [7], there exists always a positively homogeneous control of order 1 which can be associated with such a domain. Therefore, without restriction, we introduce the following assumption.

ASSUMPTION 3.1. *The stabilizing control law $\phi(x)$ associated with the domain of attraction $\mathcal{P}$ is Lipschitz and positively homogeneous of order* 1*, i.e., $\phi(\alpha x) = \alpha\phi(x)$ for $\alpha \geq 0$ and $x \in \mathcal{P}$.*

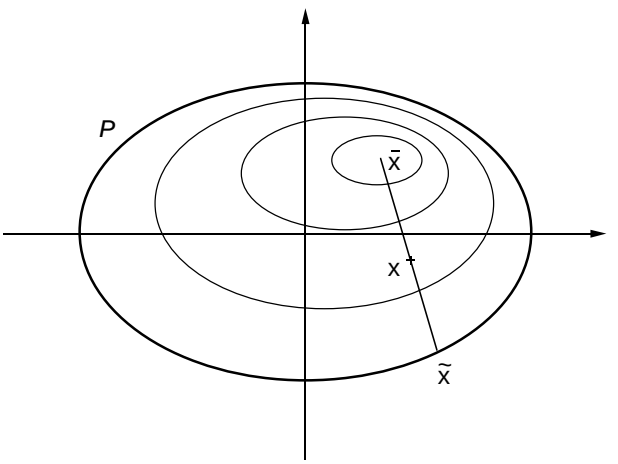

FIG. 2. *The function $\Psi_{\mathcal{P}}(x,\bar{x})$ for fixed $\bar{x}$.*

The next step in the derivation of a feedback control law $\Phi(x,r)$ is the definition of a saturation map $\Gamma : \mathbb{R}^q \to \mathcal{R}_\epsilon$ as follows:

$$\Gamma(r) = \begin{cases} r\psi_{\mathcal{R}_\epsilon}(r)^{-1} & \text{when} \quad \psi_{\mathcal{R}_\epsilon}(r) > 1 \\ r & \text{otherwise} \end{cases}$$

say

$$\Gamma(r) = r * sat\left(\frac{1}{\psi_{\mathcal{R}_\epsilon}(r)}\right),$$

where $sat(\cdot)$ is the saturation function. Note that $\Gamma(r)$ is the identity if we restrict $r \in \mathcal{R}_\epsilon$. Conversely, for $r \notin \mathcal{R}_\epsilon$, $\Gamma(r)$ is the intersection of $\partial\mathcal{R}_\epsilon$ and the segment having extrema 0 and r.

The control we propose has the form

$$\Phi(x,r) = \phi(\tilde{x})\Psi_{\mathcal{P}}(x,\bar{x}) + (1 - \Psi_{\mathcal{P}}(x,\bar{x}))\bar{u}, \tag{3.7}$$

where

$$\begin{bmatrix} \bar{x}(\bar{r}) \\ \bar{u}(\bar{r}) \end{bmatrix} \doteq M_d^{-1} \begin{bmatrix} 0 \\ \bar{r} \end{bmatrix} \left(\text{resp.,} \begin{bmatrix} \bar{x}(\bar{r}) \\ \bar{u}(\bar{r}) \end{bmatrix} \doteq M_c^{-1} \begin{bmatrix} 0 \\ \bar{r} \end{bmatrix}\right) \tag{3.8}$$

and

$$\bar{r} = \Gamma(r). \tag{3.9}$$

Note that, for $r \in \mathcal{R}_\epsilon$, (3.9) does not play any role. Note also that, since $\bar{r} = \Gamma(r) \in \mathcal{R}_\epsilon$, then $\bar{x} \in int\mathcal{P}$, thus the term $\Psi_{\mathcal{P}}(x,\bar{x})$ in (3.7) is defined. However, the expression (3.7) is not defined for $x = \bar{x}$ because of the critical term $\phi(\tilde{x})\Psi_{\mathcal{P}}(x,\bar{x})$. Nevertheless, in view of the homogeneity of ϕ and from the expression of $\tilde{x}$, we have that

$$\phi(\tilde{x})\Psi_{\mathcal{P}}(x,\bar{x}) = \phi(\Psi_{\mathcal{P}}(x,\bar{x})\tilde{x}) = \phi\left(x + (\Psi_{\mathcal{P}}(x,\bar{x}) - 1)\bar{x}\right). \tag{3.10}$$

Then $\phi(\tilde{x})\Psi_{\mathcal{P}}(x,\bar{x}) \to 0$ as $x \to \bar{x}$ so that we can extend the function by continuity by assuming

$$\phi(\tilde{x})\Psi_{\mathcal{P}}(\bar{x},\bar{x}) = 0.$$

The introduced control law inherits most of the properties from $\phi(x)$ according to the next proposition which assures existence and uniqueness of the solution of (2.2) when the control $\Phi(x,r)$ is used, provided that the admissible reference signal $r(t)$ is measurable.

PROPOSITION 3.1. *Suppose $\phi(x)$ is Lipschitz and homogeneous of order 1. Then $\Phi(x,r):\mathcal{P}\times\mathbb{R}^q\to\mathcal{U}$, defined as in (3.7)–(3.9), is continuous and it is Lipschitz with respect to x.*

To have an idea of how this control works, note that as long as the condition

$$\Psi_{\mathcal{P}}(x(t),\bar{x}(t))\le 1 \tag{3.11}$$

is satisfied, we have that $x(t)\in\mathcal{P}$. Moreover, for $\bar{x}\in int\mathcal{P}$, the control is just a *convex combination* of the control $\bar{u}(\bar{r})$ and $\phi(\tilde{x})$. By construction, $\bar{u}(\bar{r})\in\mathcal{U}$ and $\phi(\tilde{x})\in\mathcal{U}$; thus $\Phi(x,r)\in\mathcal{U}$.

Our effort will be devoted to proving that the proposed control law guarantees (3.11) as well as the limit condition

$$\Psi_{\mathcal{P}}(x(t),\bar{x}(r_\infty))\to 0, \tag{3.12}$$

where $\bar{x}(r_\infty)$ is the steady state associated with $r_\infty\in\mathcal{R}_\epsilon$ (note that $\Gamma(r_\infty)=r_\infty$). Indeed such a limit condition implies $x(t)\to\bar{x}(r_\infty)$ and, from (3.7) and (3.10), $\Phi(x(t),r(t))\to\Phi(\bar{x}(r_\infty),r_\infty)=\bar{u}(r_\infty)$. Therefore if (3.12) holds, we have that $y(t)\to r_\infty$.

For evident practical reasons, we introduce an extended concept of speed of convergence, appropriate for the condition (3.12). In the continuous-time case, given a *fixed* $\bar{x}\in int\mathcal{P}$ we say that the speed of convergence is $\beta>0$ if the Lyapunov derivative $\dot{\Psi}_{\mathcal{P}}(x(t),\bar{x})$ of $\Psi_{\mathcal{P}}(x(t),\bar{x})$ is such that

$$\dot{\Psi}_{\mathcal{P}}(x,\bar{x},u)\doteq\lim_{h\to 0^+}\frac{\Psi_{\mathcal{P}}(x+h(Ax+Bu),\bar{x})-\Psi_{\mathcal{P}}(x,\bar{x})}{h}\le-\beta\Psi_{\mathcal{P}}(x,\bar{x}),$$

where the existence of the limit is assured by the convexity of $\Psi_{\mathcal{P}}$ with respect to x. In the discrete-time case we say that the speed of convergence is $\lambda<1$ if

$$\Psi_{\mathcal{P}}(Ax+Bu,\bar{x})\le\lambda\Psi_{\mathcal{P}}(x,\bar{x}).$$

We start by considering a special case, namely the one in which the reference signal is constant. In this case we can show that, if we have a domain of attraction to the origin with a certain speed of convergence, we can achieve the tracking goal without constraints violation for all the initial states in such a domain. Furthermore, for symmetric domains, we can guarantee a speed of convergence which is *independent of the reference input.*

THEOREM 3.2. *Let $\mathcal{P}$ be a domain of attraction with speed of convergence λ for the discrete-time dynamic system (2.2) associated with the control $\phi(x)$ satisfying Assumption 3.1. Then, for every admissible constant reference signal $r(t)=\bar{r}$, the control law (3.7)–(3.8) is such that for every initial condition $x(0)\in\mathcal{P}$ we have that $x(t)\in\mathcal{P}$ and $u(t)\in\mathcal{U}$ for every $t\ge 0$ and $\lim_{t\to\infty}y(t)=\bar{r}$. Moreover, if $\mathcal{P}$ is 0-symmetric, the speed of convergence $\lambda_{TR}=\frac{\lambda+1}{2}$ is guaranteed.*

The next theorem is the continuous-time version of the above.

THEOREM 3.3. *Let $\mathcal{P}$ be a domain of attraction with speed of convergence β for the continuous-time dynamic system (2.2) associated with the control $\phi(x)$ satisfying Assumption 3.1. Then, for every admissible constant reference signal $r(t)=\bar{r}$, the*

control law (3.7)–(3.8) *is such that for every initial condition* $x(0) \in \mathcal{P}$, *we have that* $x(t) \in \mathcal{P}$ *and* $u(t) \in \mathcal{U}$ *for every* $t \geq 0$ *and* $\lim_{t\to\infty} y(t) = \bar{r}$. *Moreover, if* $\mathcal{P}$ *is* 0*-symmetric, the speed of convergence is at least* $\beta_{TR} = \frac{\beta}{2}$.

The proposed control law can be successfully used even when the reference $r(t)$ is allowed to vary provided that it is admissible according to Definition 2.4.

THEOREM 3.4. *Let* $r(t)$ *be admissible as in Definition* 2.4. *Any domain of attraction* $\mathcal{P}$, *with speed of convergence* $\beta > 0$ $(0 \leq \lambda < 1)$, *for system* (2.2) *is a tracking domain of attraction. Moreover, the control law in* (3.7)–(3.9) *assures the conditions* (i) *and* (ii) *of Definition* 2.5.

REMARK 3.1. *If we consider a constant reference* $r \in \mathcal{R}_\epsilon$ *and the corresponding steady state vectors derived from* $\bar{x}$ *and* $\bar{u}$ *by means of* (3.8), *then we can apply a state and control translation by considering the system* $\delta\hat{x} = A\hat{x} + B\hat{u}$ *with the new constraints* $\hat{u} = u - \bar{u} \in \mathcal{U} - \bar{u} = \hat{\mathcal{U}}$ *and* $\hat{x} = x - \bar{x} \in \mathcal{X} - \bar{x} = \hat{\mathcal{X}}$. *From this algebraic point of view, our result amounts to proving that the largest domain of attraction of the translated problem is just achieved by translating the original largest domain of attraction as* $\hat{\mathcal{P}} = \mathcal{P} - \bar{x}$.

4. Properties of the function $\Psi(x, \bar{x})$. To prove the results of the previous section we first need to present some properties of the function $\Psi(x, \bar{x})$. First we prove its continuity. For the simple notation we will drop the index $\mathcal{P}$.

LEMMA 4.1. *For* $(x, \bar{x}) \in \mathcal{P} \times int\mathcal{P}$, *the function* $\Psi(x, \bar{x})$ *is continuous.*

Proof. Consider the case $x \neq \bar{x}$. Take any point $(x, \bar{x})$ and a close pair $(x', \bar{x}')$. Assume that $x' \in V_x$ and $\bar{x}' \in V_{\bar{x}} \subset int\mathcal{P}$ where V_x and $V_{\bar{x}}$ are close neighborhoods of x and $\bar{x}$ such that $V_x \bigcap V_{\bar{x}} = \emptyset$, the empty set. This implies that $\|x' - \bar{x}'\| \geq M$ for some positive M. Assume now $x' \in \mathcal{P}$ and take $\alpha > 0$ (which exists because $\bar{x}' \in int\mathcal{P}$) such that $\bar{x}' + (x' - \bar{x}')/\alpha \in \mathcal{P}$. Then $\|(x' - \bar{x}')/\alpha\| \leq m$, for some positive m. This means that $\alpha \geq M/m$; thus it is lower bounded. From (3.2) we have

$$\Psi(x', \bar{x}') = \inf\left\{\alpha > 0 : \ \bar{x}' + \frac{1}{\alpha}(x' - \bar{x}') \in \mathcal{P}\right\} \tag{4.1}$$

$$= \inf\left\{\alpha > 0 : \ \bar{x} + \frac{1}{\alpha}(x - \bar{x}) \in \mathcal{P} + \underbrace{(\bar{x} - \bar{x}')\left(1 - \frac{1}{\alpha}\right) + \frac{1}{\alpha}(x - x')}_{=z}\right\},$$

where $\mathcal{P} + z \doteq \{y = x + z, \quad x \in \mathcal{P}\}$. Since α as in (4.1) is lower bounded by M/m, then $\|z\| \to 0$ as $(x', \bar{x}') \to (x, \bar{x})$.

Moreover, $\mathcal{P}$ is a C-set; thus for every $0 < \hat{\epsilon} < 1$ there exists δ such that if $\|x - x'\| \leq \delta$ and $\|\bar{x} - \bar{x}'\| \leq \delta$, then

$$(1 - \hat{\epsilon})\mathcal{P} \subset \mathcal{P} + z \subset (1 + \hat{\epsilon})\mathcal{P}. \tag{4.2}$$

Consider the following function:

$$\alpha(\epsilon) = \inf\left\{\alpha > 0 : \quad \bar{x} + \frac{1}{\alpha}(x - \bar{x}) \in (1 + \epsilon)\mathcal{P}\right\}.$$

The inclusion (4.2) assures that for $\hat{\epsilon}$ and δ as above

$$\alpha(\hat{\epsilon}) \leq \Psi(x', \bar{x}') \leq \alpha(-\hat{\epsilon}),$$

and from (3.2) we have

$$\alpha(\hat{\epsilon}) \leq \Psi(x, \bar{x}) \leq \alpha(-\hat{\epsilon}).$$

Thus, if we show that $\alpha(\epsilon)$ is continuous at 0, we have $|\alpha(\hat{\epsilon}) - \alpha(-\hat{\epsilon})| \to 0$, as $\hat{\epsilon} \to 0$, and we have completed the proof.

Since $\bar{x} \in int\mathcal{P}$, there exists $0 < \bar{\epsilon} < 1$ such that $\bar{x} \in int\{(1+\epsilon)\mathcal{P}\}$ for all $|\epsilon| < \bar{\epsilon}$.

The set of all points of the form $\bar{x} + (x - \bar{x})/\alpha$, $\alpha > 0$ is a ray originating from $\bar{x}$ which, for $|\epsilon| \leq \bar{\epsilon}$, intersects the boundary of $(1+\epsilon)\mathcal{P}$ at the unique point $\bar{x} + (x - \bar{x})/\alpha(\epsilon)$. We can write this condition as

$$\psi\left(\bar{x} + (x - \bar{x})/\alpha(\epsilon)\right) = 1 + \epsilon. \tag{4.3}$$

Note also that for $\alpha > \alpha(\epsilon)$ the point $\bar{x} + (x - \bar{x})/\alpha \in int\{(1+\epsilon)\mathcal{P}\}$; thus the function $\alpha(\epsilon)$ is strictly decreasing on $[-\bar{\epsilon}, \bar{\epsilon}]$, and so it is invertible. From (4.3) its inverse is the function

$$\epsilon(\alpha) \doteq \psi\left(\bar{x} + (x - \bar{x})/\alpha\right) - 1$$

which is continuous (actually convex). Then $\alpha(\epsilon)$ is continuous.

In the case $x = \bar{x} \in int\mathcal{P}$, say $\Psi(x, \bar{x}) = 0$ it is very easy to show from (3.2) that $\Psi(x', \bar{x}') \to 0$ as $(x', \bar{x}') \to (\bar{x}, \bar{x})$, and we skip the proof for brevity. □

The function $\Psi(x, \bar{x})$ is not necessarily differentiable and then, to use it as a candidate Lyapunov function, we invoke the theory of subdifferentials. Given a convex function $F(x)$, the subdifferential of F in x is defined as the set [23]

$$\nabla F(x) = \{w : \langle w, z - x\rangle \leq F(z) - F(x) \quad \text{for all} \quad z \in \mathbb{R}^n\}.$$

Each element w of ∇F is called subgradient. In what follows we denote by $\nabla\Psi(x, \bar{x})$ the subdifferential of the function $\Psi(x, \bar{x})$ with respect to x (i.e., $\bar{x}$ is assumed constant):

$$\nabla\Psi(x, \bar{x}) = \{w : \langle w, z - x\rangle \leq \Psi(z, \bar{x}) - \Psi(x, \bar{x})\}.$$

If $\Psi(x, \bar{x})$ is differentiable with respect to x, then $\nabla\Psi(x, \bar{x})$ is a singleton including the gradient vector

$$\nabla\Psi(x, \bar{x}) \doteq \left[\frac{\partial\Psi(x, \bar{x})}{\partial x_1}, \ldots, \frac{\partial\Psi(x, \bar{x})}{\partial x_n}\right]^T.$$

For constant $\bar{x}$, the Lyapunov derivative of the function $\Psi(x, \bar{x})$, along the system trajectory of the system (2.2), is given by

$$\dot{\Psi}(x, \bar{x}, u) = \lim_{\tau \to 0^+} \frac{\Psi(x + \tau(Ax + Bu), \bar{x}) - \Psi(x, \bar{x})}{\tau}. \tag{4.4}$$

From [23, Th. 23.4], we have that

$$\dot{\Psi}(x, \bar{x}, u) = \sup_{w \in \nabla\Psi(x, \bar{x})} \langle w, Ax + Bu\rangle. \tag{4.5}$$

This fact implies that the condition

$$\dot{\Psi}(x, \bar{x}, u) \leq -\beta\Psi(x, \bar{x})$$

is equivalent to

$$\langle w, Ax + Bu\rangle \;\leq\; -\beta\Psi(x, \bar{x}) \quad \text{for all} \quad w \in \nabla\Psi(x, \bar{x}).$$

The next lemma will show some fundamental properties concerning the subdifferentiability of Ψ. Its importance will be evident later when we deal with continuous-time systems.

LEMMA 4.2. *Assume that $\bar{x} \in int\mathcal{P}$ is fixed. Then*

(i) *Its subdifferential is constant over any ray emanating from* $\bar{x}$

$$\nabla\Psi(\bar{x}+\mu y,\bar{x}) = \nabla\Psi(\bar{x}+y,\bar{x}) \quad \textit{for all} \;\; \mu \geq 0; \tag{4.6}$$

(ii) *The equality*

$$\Psi(x,\bar{x}) = \langle \hat{w}, x-\bar{x}\rangle$$

holds for all $\hat{w} \in \nabla\Psi(x,\bar{x})$.

(iii) *For every* $x \in \partial\mathcal{P}$ *the positive cones generated by the subdifferentials* $\nabla\psi(x)$ *and* $\nabla\Psi(x,\bar{x})$ *coincide. This means that each* $w \in \nabla\psi(x)$ *is aligned with some* $\hat{w} \in \nabla\Psi(x,\bar{x})$ *and vice-versa. Furthermore, if* $\mathcal{P}$ *is 0-symmetric (i.e.,* $\mathcal{P} = -\mathcal{P}$*) for every* $\bar{x} \in (1-\epsilon)\mathcal{P}$ *and* $x \in \partial\mathcal{P}$*, the aligning factor* $\gamma(\hat{w},w)$ *such that*

$$\hat{w} = \gamma(\hat{w},w)w, \qquad \hat{w} \in \nabla\Psi(x,\bar{x}), \quad w \in \nabla\psi(x)$$

satisfies the inequality

$$\gamma(\hat{w},w) \geq \frac{1}{2-\epsilon} \geq \frac{1}{2}. \tag{4.7}$$

Proof. Property (i) is a straightforward derivation from the definition of the subdifferential once we have established that $\tilde{\psi}(y) = \Psi(\bar{x}+y,\bar{x})$ is a positively homogeneous function of order 1 according to (3.6). Property (ii) follows from the following properties of the positively homogeneous functions of order 1 (see the appendix)

$$\tilde{\psi}(y) = \langle w, y\rangle \quad \text{for all} \;\; w \in \nabla\tilde{\psi}(y). \tag{4.8}$$

To prove (iii), let $\bar{x} \in int\mathcal{P}$ be fixed. From (3.4)–(3.5) the unit balls of the functions $\Psi(x,\bar{x})$ and $\psi(x)$ are both equal to $\mathcal{P}$. For $x \in \partial\mathcal{P}$, the normal cone [13] to this set is given by

$$\mathcal{N} = \{z \in \mathbb{R}^n : \langle z, x'-x\rangle \leq 0 \;\; \text{for all} \;\; x' \in \mathcal{P}\}.$$

Since the normal cone for $x \in \partial\mathcal{P}$ is the convex positive cone generated by any of the two subdifferentials $\nabla\Psi(x,\bar{x})$ and $\nabla\psi(x)$, we have the alignment of any element of the former with an element of the latter and the existence of a positive real $\gamma(\hat{w},w)$ such that $\hat{w} = \gamma w$, with $\hat{w} \in \nabla\Psi(x,\bar{x})$ and $w \in \nabla\psi(x)$.

To prove (4.7) consider $x \in \partial\mathcal{P}$ so that $\Psi(x,\bar{x}) = 1$ with $\bar{x} \in (1-\epsilon)\mathcal{P}$. Let $\hat{w} \in \nabla\Psi(x,\bar{x})$ and $w \in \nabla\psi(x)$ be as above. From property (ii)

$$\Psi(x,\bar{x}) = 1 = \langle \hat{w}, x-\bar{x}\rangle = \gamma\langle w, x-\bar{x}\rangle.$$

Then, since $w \in \nabla\psi(x)$, $\psi(x) = \langle w,x\rangle = 1$ and by the symmetry of $\mathcal{P}$, $\psi(-\bar{x}) = \psi(\bar{x}) \leq 1-\epsilon$ we get

$$\frac{1}{\gamma} = \langle w, x-\bar{x}\rangle = \langle w, -\bar{x}-x\rangle + 2\langle w,x\rangle \tag{4.9}$$

$$\leq \psi(-\bar{x}) - \psi(x) + 2 = \psi(-\bar{x}) + 1 \leq 2-\epsilon \tag{4.10}$$

which is equivalent to (4.7). ∎

REMARK 4.1. *If symmetry is removed, it is possible to show that there exists* $m_\epsilon > 0$ *such that* $\gamma(\hat{w}, w) \geq m_\epsilon > 0$, *although no lower bounds can be provided a priori.*

We recall that if $\mathcal{P}$ is a convex set in a real normed space X, then it is possible to define on the dual space X^* the support functional $h(x^*)$ of $\mathcal{P}$

$$h(x^*) = \sup_{x \in \mathcal{P}} \langle x, x^* \rangle. \tag{4.11}$$

If the set contains the origin as an interior point, then $h(x^*)$ is positive definite, and if the set is compact, there exists a finite constant K such that $h(x^*) \leq K\|x^*\|$ for every x^*. Once $h(\cdot)$ is known, it is possible to describe a closed convex set as the intersection of all the half-spaces that contain it:

$$\mathcal{P} = \bigcap_{x^*} \{x : \langle x, x^* \rangle \leq h(x^*)\}. \tag{4.12}$$

For every x belonging to a C-set $\mathcal{P}$ we have that $-h(-x^*) \leq \langle x, x^* \rangle \leq h(x^*)$ for every $x^* \in X^*$. If $\mathcal{P}$ is 0-symmetric, then $h(-x^*) = h(x^*)$ for all x^*. The next lemma characterizes $\Psi(x, \bar{x})$ in terms of h.

LEMMA 4.3. *Let* $h(\cdot)$ *be the support functional of* $\mathcal{P}$. *Then*

$$\Psi(x, \bar{x}) = \sup_{\|x^*\|=1} \frac{\langle x^*, x - \bar{x} \rangle}{h(x^*) - \langle x^*, \bar{x} \rangle}. \tag{4.13}$$

Proof. By a proper scaling of the vectors x^* in (4.12), we know that $x \in \mathcal{P}$ iff $\langle x, x^* \rangle \leq h(x^*)$ for every x^* such that $\|x^*\| = 1$. Then from (3.2)

$$\begin{aligned} \Psi(x, \bar{x}) &= \inf \left\{ \alpha \ : \langle \bar{x} + \frac{1}{\alpha}(x - \bar{x}), x^* \rangle \ \leq \ h(x^*), \ \text{ for all } \ \|x^*\| = 1 \right\} \\ &= \inf \left\{ \alpha \ : \frac{1}{\alpha} \langle (x - \bar{x}), x^* \rangle \ \leq \ h(x^*) - \langle \bar{x}, x^* \rangle, \ \text{ for all } \ \|x^*\| = 1 \right\}. \end{aligned}$$

from which follows (4.13). ∎

The next lemma we present gives an upper bound to the values of the function $\Psi(x, \bar{x})$ when $(x, \bar{x}) \in \alpha\mathcal{P} \times int\mathcal{P}$. It will be useful to guarantee a convergence speed in the discrete-time case.

LEMMA 4.4. *Suppose* $\mathcal{P}$ *is* 0*-symmetric and let* $x \in \alpha\mathcal{P}$ *and* $\bar{x} \in int\mathcal{P}$. *Then*

$$\Psi(x, \bar{x}) \leq \frac{\alpha + 1}{2}. \tag{4.14}$$

Proof. From Lemma 4.3 we need to prove that

$$\frac{\langle x^*, x - \bar{x} \rangle}{h(x^*) - \langle x^*, \bar{x} \rangle} \leq \frac{1 + \alpha}{2} \tag{4.15}$$

for every x^* such that $\|x^*\| = 1$. For every such x^* we have that $\langle x, x^* \rangle \leq \alpha h(x^*)$ whenever $x \in \alpha\mathcal{P}$. Thus

$$\begin{aligned} \frac{\langle x^*, x - \bar{x} \rangle}{h(x^*) - \langle x^*, \bar{x} \rangle} &\leq \frac{\alpha h(x^*) - \langle x^*, \bar{x} \rangle}{h(x^*) - \langle x^*, \bar{x} \rangle} \\ &= \frac{\alpha - \frac{\langle x^*, \bar{x} \rangle}{h(x^*)}}{1 - \frac{\langle x^*, \bar{x} \rangle}{h(x^*)}} \end{aligned} \tag{4.16}$$

for every $\|x^*\| = 1$ (note that $h(x^*) \neq 0$). Now we notice that, since $\mathcal{P}$ is 0-symmetric,

$$-1 \leq \frac{\langle x^*, \bar{x} \rangle}{h(x^*)} \leq 1.$$

Thus expression (4.16) is bounded by the extrema of the function

$$f(\xi) = \frac{\alpha - \xi}{1 - \xi} \quad \text{with} \quad |\xi| \leq 1.$$

Simple algebra shows that $f(\xi)$ is continuous and decreasing thus attaining its maximum at $\xi = -1$. This proves (4.15). □

REMARK 4.2. *The previous lemma gives a specific upper bound for $\Psi(x, \bar{x})$ for $\bar{x} \in int\mathcal{P}$ and $x \in \alpha\mathcal{P}$. If symmetry is removed, we have that there exists $m_\alpha < 1$ such that $\Psi(x, \bar{x}) \leq m_\alpha < 1$, although no upper bounds can be guaranteed a priori.*

5. Proofs of the main results. For brevity, the next proofs will consider the case of a symmetric $\mathcal{P}$ only. The general proofs follow immediately by considering Remarks 4.1 and 4.2.

Proof of Proposition 3.1. In view of the homogeneity of $\phi(x)$ we have that

$$\begin{aligned} \Phi(x, r) &= \phi(\tilde{x})\Psi(x, \bar{x}) + (1 - \Psi(x, \bar{x}))\bar{u} \\ &= \phi(\Psi(x, \bar{x})\bar{x} + x - \bar{x}) + (1 - \Psi(x, \bar{x}))\bar{u}. \end{aligned} \tag{5.1}$$

By exploiting the Lipschitz condition on $\phi(x)$ and the triangular inequality we get

$$\begin{aligned} \|\Phi(x_1, r) - \Phi(x_2, r)\| \leq L\|\Psi(x_1, \bar{x})\bar{x} + x_1 - \bar{x} - \Psi(x_2, \bar{x})\bar{x} - x_2 + \bar{x}\| \\ + \|(1 - \Psi(x_1, \bar{x}))\bar{u} - (1 - \Psi(x_2, \bar{x}))\bar{u}\|; \end{aligned}$$

therefore, after proper rearrangement,

$$\|\Phi(x_1, r) - \Phi(x_2, r)\| \leq L\|x_1 - x_2\| + (L\|\bar{x}\| + \|\bar{u}\|)\|\Psi(x_1, \bar{x}) - \Psi(x_2, \bar{x})\|.$$

Let $L_\mathcal{P}$ be the Lipschitz constant of the function $\Psi(x, \bar{x})$ and let K be a constant such that $L\|\bar{x}\| + \|\bar{u}\| \leq K$ so that we can finally obtain

$$\|\Phi(x_1, r) - \Phi(x_2, r)\| \leq (L + L_\mathcal{P} K)\|x_1 - x_2\|.$$

The Lipschitz constant of $\Phi(x, r)$ is then $L_\Phi = (L + L_\mathcal{P} K)$.

The continuity of $\Phi(x, r)$ can be inferred easily by considering expression (5.1) which, in view of Lemma 4.1 and the Lipschitz condition of ϕ, is continuous with respect to x, $\bar{x}$, and $\bar{u}$. Now $\bar{x}$ and $\bar{u}$ are linear functions of $\bar{r} = \Gamma(r)$, and Γ is continuous. This completes the proof. □

Proof of Theorem 3.2. We have already noticed that $\Phi(x, r) \in \mathcal{U}$, which is an immediate consequence of the convexity of $\mathcal{U}$ and the fact that the control $\Phi(x, r)$ as in (3.7)–(3.9) is the convex combination of $\phi(\tilde{x})$ and $\bar{u}$, both belonging to $\mathcal{U}$. The condition $x \in \mathcal{P}$ for every $t \geq 0$ will be proved by showing that $\Psi(x, \bar{x})$ is a Lyapunov function for system (2.2). Consider $x \in \mathcal{P}$, $x \neq \bar{x}$ and let

$$\begin{aligned} y &= Ax + B\Phi(x, r) \\ &= A(\tilde{x}\Psi(x, \bar{x}) + (1 - \Psi(x, \bar{x}))\bar{x}) + B(\phi(\tilde{x})\Psi(x, \bar{x}) + (1 - \Psi(x, \bar{x})\bar{u}) \\ &= \Psi(x, \bar{x})(A\tilde{x} + B\phi(\tilde{x})) + (1 - \Psi(x, \bar{x})(A\bar{x} + B\bar{u}) \\ &= \Psi(x, \bar{x})(A\tilde{x} + B\phi(\tilde{x})) + (1 - \Psi(x, \bar{x}))\bar{x}, \end{aligned}$$

where we have replaced $A\bar{x} + B\bar{u} = \bar{x}$ due to the fact that $(\bar{x}, \bar{u})$ is an equilibrium pair. Define now $\tilde{y} = A\tilde{x} + B\phi(\tilde{x})$, since $\mathcal{P}$ is domain of attraction as in definition 2.2. Then $\psi(A\tilde{x} + B\phi(\tilde{x})) \leq \lambda\psi(\tilde{x}) = \lambda$, and thus $\tilde{y} \in \lambda\mathcal{P}$. By virtue of (3.6),

$$\begin{aligned}\Psi(y, \bar{x}) &= \Psi(\tilde{y}\Psi(x, \bar{x}) + (1 - \Psi(x, \bar{x}))\bar{x}, \bar{x}) \\ &= \Psi((\tilde{y} - \bar{x})\Psi(x, \bar{x}) + \bar{x}, \bar{x}) \\ &= \Psi(x, \bar{x})\Psi(\tilde{y}, \bar{x}) \leq \frac{1 + \lambda}{2}\Psi(x, \bar{x}),\end{aligned}$$

where the inequality comes from Lemma 4.4. Thus

$$\Psi(Ax + B\Phi(x, r), \bar{x}) \leq \lambda_{TR}\Psi(x, \bar{x}). \qquad \square$$

Proof of Theorem 3.3 Let $x \in \mathcal{P}$ and $\bar{x} \in (1 - \epsilon)\mathcal{P}$. From (4.5) we need to prove that $\dot{\Psi}(x, \bar{x}) \leq -\beta/2\Psi(x, \bar{x})$, which is true if

$$\langle \hat{w}, Ax + B\Phi(x, r)\rangle \leq -\frac{\beta}{2}\Psi(x, \bar{x}) < 0 \tag{5.2}$$

is satisfied for all $\hat{w} \in \nabla\Psi(x, \bar{x})$ and $x \neq \bar{x}$. Let, then, $x \neq \bar{x}$. Note that

$$\begin{aligned}&\langle \hat{w}, Ax + B\Phi(x, r)\rangle \\ &= \langle\ \hat{w}\ ,\ A(\Psi(x, \bar{x})\tilde{x} + (1 - \Psi(x, \bar{x}))\bar{x}) + B(\Psi(x, \bar{x})\phi(\tilde{x}) + (1 - \Psi(x, \bar{x}))\bar{u}\ \rangle \\ &= \langle\ \hat{w}\ ,\ [A\tilde{x} + B\phi(\tilde{x})]\,\Psi(x, \bar{x}) + (1 - \Psi(x, \bar{x}))\,[A\bar{x} + B\bar{u}]\ \rangle.\end{aligned}$$

We remind the reader that in the continuous-time case we have that $A\bar{x} + B\bar{u} = 0$ and that (i) of Lemma 4.2 holds so that $\hat{w} \in \nabla\Psi(x, \bar{x})$, iff $\hat{w} \in \nabla\Psi(\tilde{x}, \bar{x})$. Since $\tilde{x} \in \partial\mathcal{P}$, then, by virtue of (iii) of Lemma 4.2, $\hat{w} = \gamma(\hat{w}, w)w$, with $w \in \nabla\psi(\tilde{x})$ and $\gamma(\hat{w}, w) \geq 1/(2 - \epsilon)$. Therefore

$$\begin{aligned}\langle \hat{w}, Ax + B\Phi(x, r)\rangle &= \Psi(x, \bar{x})\langle \hat{w}, A\tilde{x} + B\phi(\tilde{x})\rangle \\ &= \gamma(\hat{w}, w)\ \langle w, A\tilde{x} + B\phi(\tilde{x})\rangle\ \Psi(x, \bar{x}).\end{aligned}$$

Due to the fact that $\mathcal{P}$ is a domain of attraction, we have that

$$\langle w, A\tilde{x} + B\phi(\tilde{x})\rangle \leq -\beta \quad \text{for all} \quad w \in \nabla\psi(x).$$

From (iii) of Lemma 4.2 we have that, if $\mathcal{P}$ is symmetric, $\gamma(\hat{w}, w) \geq 1/(2 - \epsilon) \geq 1/2$, and thus we have (5.2). $\square$

REMARK 5.1. *According to Remarks* 4.1 *and* 4.2*, for nonsymmetric domains we have that* $\lambda_{TR} = m_\alpha < 1$ *and* $\beta_{TR} = \beta m_\epsilon > 0$.

Proof of Theorem 3.4 We will consider the control law (3.7)–(3.9) and we will prove the result for the continuous-time case only, as the discrete-time version can be obtained by following a similar argument.

To show that the proposed control law maintains the state inside $\mathcal{P}$ for every $x(0) \in \mathcal{P}$, we need to show its positive invariance for the closed-loop system. But this is immediate because we can just consider the original Lyapunov function $\psi(x)$. For $x \in \partial\mathcal{P}$ we have that $\Phi(x, r) = \phi(x)$, and thus the Lyapunov derivative of the system with the tracking control is

$$\dot{\psi}(x(t)) = \sup_{w \in \nabla\psi(x)} \langle w, Ax + B\phi(x)\rangle,$$

which is the same as the Lyapunov derivative of the system with original stabilizing control associated with $\mathcal{P}$. By Definition 2.3, the derivative for $x \in \partial\mathcal{P}$ is such that

$$\dot{\psi}(x) \leq -\beta,$$

which obviously prevents the state $x(t)$ from leaving $\mathcal{P}$ [1].

The fact that the control $\Phi(x, r) \in \mathcal{U}$ has been shown at the beginning of the proof of Theorem 3.2 (we remind the reader that $\bar{u}$ is computed with respect to the "saturated" reference $\bar{r} = \Gamma(r)$).

To complete the proof we need now to show that $y(t)$ approaches r_∞ when $t \to \infty$. In view of Remark 2.1, this amounts to showing that $x(t) \to \bar{x}_\infty$, say $\Psi(x, \bar{x}_\infty) \to 0$.

Let $\Phi(x(t), r(t))$ and $\Phi(x(t), r_\infty)$ be the control actions associated with the reference values $r(t)$ and r_∞, resp., so that we can write

$$\dot{x} = Ax + B\Phi(x, r) = Ax + B\Phi(x, r_\infty) + B[\Phi(x, r) - \Phi(x, r_\infty)].$$

To show that $x(t) \to \bar{x}_\infty$ we consider the candidate Lyapunov function $\Psi(x(t), \bar{x}_\infty)$. Take any vector $w \in \nabla\Psi(x(t), \bar{x}_\infty)$. Then

$$\begin{aligned}\langle w, Ax + B\Phi(x, r)\rangle &= \langle w, Ax + B\Phi(x, r_\infty)\rangle + \underbrace{\langle w, B[\Phi(x, r) - \Phi(x, r_\infty)]\rangle}_{z} \\ &\leq -\frac{\beta}{2}\Psi(x(t), \bar{x}_\infty) + |z(t)|,\end{aligned}$$

where we have exploited the condition $\langle w, Ax + B\Phi(x, r_\infty)\rangle \leq -\frac{\beta}{2}\Psi(x(t), \bar{x}_\infty)$ proven in Theorem 3.3. As the above inequality holds for all $w \in \nabla\Psi(x(t), \bar{x}_\infty)$, from (4.5) we get

$$\dot{\Psi}(x(t), \bar{x}_\infty, \Phi(x(t), r(t))) \leq -\beta/2\Psi(x(t), \bar{x}_\infty) + |z(t)|.$$

The vector $w \in \nabla\Psi(x(t), \bar{x}_\infty)$ is bounded due to the fact that $\Psi(x, \bar{x}_\infty)$ is Lipschitz with respect to the first argument x. Since $r(t) \to r_\infty \in \mathcal{R}_\epsilon$, there exists T_1 such that $r(t) \in \mathcal{R}_{\frac{\epsilon}{2}}$ for $t \geq T_1$. $\Phi(x, r)$ is continuous, thus it is uniformly continuous on $\mathcal{P} \times \mathcal{R}_\epsilon$. This means that $z(t) \to 0$ as $\bar{r}(t) \to r_\infty$. Standard Lyapunov arguments lead to the conclusion that $\Psi(x(t), \bar{x}_\infty) \to 0$, say $x(t) \to \bar{x}_\infty$. □

6. Special domains of attraction. The proofs of the preceding sections have allowed us to show that every domain of attraction is indeed a tracking domain. The actual implementation of the proposed control law requires the computation of the functions $\Psi(x, \bar{x})$ and $\psi_{\mathcal{R}_\epsilon}(r)$. In the next subsections we will see how the above arguments apply when we consider different families of domains.

6.1. Ellipsoidal domains. Ellipsoids are very popular candidate domains of attraction. They have been deeply investigated in literature, see for instance [18], [21]. A detailed exposition on the properties of such sets can be found in [10]. Assume that an ellipsoidal domain of attraction

$$\mathcal{P} = \{x : x^T Q x \leq 1\}, \quad Q > 0,$$

is available and this domain is associated with the linear control law $\phi(x) = Kx$.

Since by Assumption 2.1 M_c (resp., M_d) is invertible we denote with K_{xr} and K_{ur}, resp., the first n lines and the last m lines of M_c^{-1} (resp., M_d) so that $\bar{x}(r) = K_{xr}r$ and $\bar{u} = K_{ur}r$. The set $\mathcal{R}$ is the intersection of the sets

$$\mathcal{R}_x = \{r : r^T K_{xr}^T Q K_{xr} r \leq 1\}$$

and

$$\mathcal{R}_u = \{r : K_{ur} r \in \mathcal{U}\}.$$

The Minkowski functional of $\mathcal{R}_\epsilon = (1-\epsilon)\mathcal{R}$ is easily computable. For instance, if $\mathcal{U}$ is the unit ball of some norm $\|\cdot\|_{\mathcal{U}}$, then $\mathcal{R}_u = \{r : \ \|K_{ur} r\|_{\mathcal{U}} \le 1\}$ so that

$$\psi_{\mathcal{R}_\epsilon} = (1-\epsilon)^{-1} \max\{(r^T K_{xr}^T Q K_{xr} r)^{1/2}, \|K_{ur} r\|_{\mathcal{U}}\}.$$

With the choice of an ellipsoidal tracking domain, denoting by $y = x - \bar{x}$, the expression of $\Psi(x, \bar{x})$ reduces to the following:

$$\Psi(x, \bar{x}) = \frac{\bar{x}^T Q y + [(\bar{x}^T Q y)^2 + y^T Q y (1 - \bar{x}^T Q \bar{x})]^{\frac{1}{2}}}{1 - \bar{x}^T Q \bar{x}};$$

thus its computation essentially involves the computation of the three quantities $x^T Q \bar{x}$, $x^T Q y$ and $y^T Q y$.

The operations involved on-line in the implementation of the proposed control law are hence the following:

1. Compute the "constrained" reference value $r_c = \Gamma(r)$;
2. Compute $\bar{x} = K_{xr} r_c$ and $\bar{u} = K_{ur} r_c$;
3. Compute $\Psi(x, \bar{x})$;
4. Set

$$\Phi(x, r) = Kx + (1 - \Psi(x, \bar{x}))(\bar{u} - K\bar{x}).$$

Although we have explicitly considered the case in which the original controller is linear, we can easily consider the case in which such a controller is nonlinear. The price we pay is a less neat expression of the controller.

6.2. Polyhedral domains. Polyhedral invariant sets have been deeply investigated for constrained stabilization problems [3], [11], [12], [17], [19], [20], [26], [28]. The basic reason is that if linear state and control constraints are considered, the largest domain of attraction can be arbitrarily closely approximated by a polyhedral set which is a domain of attraction. Such a result holds for both discrete-time [17], [19] and continuous-time systems [7]. It is also known that once such a domain of attraction is available, a feedback stabilizing control law can be inferred. Therefore, in the constrained stabilization problem, considering polyhedral sets as candidate domains of attraction is not restrictive.

We consider now the implementation of a tracking control strategy for a polyhedral domain of attraction. A polyhedral C-set $\mathcal{P}$ can be represented as

$$\mathcal{P} = \{x : \ \ F_i x \le 1, \ \ i = 1, 2, \ldots, s\} = \{x : \ \ Fx \le \bar{1}\},$$

where F is the matrix whose rows are F_i, while $\bar{1} \doteq [1 \ 1 \ \ldots \ 1]^T$. The Minkowski functional associated with $\mathcal{P}$ is given by [5], [28]

$$\psi(x) = \max_i \ F_i x.$$

From the above expression it is evident that in this particular case the set is the intersection of a finite number of half-spaces, thus if we consider the function $\Psi(x, \bar{x})$, its expression is given by

$$\Psi(x, \bar{x}) \doteq \max_i \frac{F_i(x - \bar{x})}{1 - F_i \bar{x}}, \quad x \in (1-\epsilon)\mathcal{P},$$

where $\epsilon > 0$ is a small number. Note that $1 - F_i\bar{x} \geq \epsilon$, so singularities are avoided.

The construction of a polyhedral domain of attraction is a well-established topic and allows the designer to derive a Lipschitz piecewise linear control law of the form $u = K(x)x$ according to [4], [17], which is positively homogeneous of order 1. Once such a domain is known, the expression of the control can be derived by means of (5.1) with the provided expression of Ψ.

After the determination of the value of Ψ, as for the other families considered here, the first step necessary for the implementation of the tracking control (3.7)–(3.9) concerns the evaluation of the function

$$\psi_{\mathcal{R}_\epsilon}(r) = (1-\epsilon)^{-1} \max\{\psi(K_{xr}r), \|K_{ur}r\|_{\mathcal{U}}\}$$

(we remind the reader that $\bar{x} = K_{xr}r$ and $\bar{u} = K_{ur}r$), whose computation is needed for the determination of the "constrained" reference value $r_c = \Gamma(r)$.

6.3. Smoothed domains. In this section we consider the family of domains of attraction whose Minkowski functional is given by

$$\psi(x) = \left(\sum_{i=1}^{s} \sigma_{2p}(F_i x) \right)^{\frac{1}{2p}}$$

where

$$\sigma_r(x) = \begin{cases} x^r \text{ if } x \geq 0, \\ 0 \text{ otherwise.} \end{cases}$$

This family has been analyzed in [9] for the constrained stabilization problem. Similar functions have been used for tracking constant signals for continuous-time systems in the presence of state constraints only in [8]. It is helpful to recall that, although the functions used in [8] are similar to those proposed here, they are essentially different. Their definition is based on an analytic expression and such definition does not apply to the Minkowski function of a generic C-set. In particular the unitary level surface is not invariant when the reference is allowed to vary. They are unsuitable for the cases in which there are control constraints and variable reference signals.

Here we reconsider this class for tracking purposes for continuous-time systems and we assume that the input constraints are of the form $\mathcal{U} = \{u \ : \|u\|_\infty \leq 1\}$. The reason for considering this class of functions comes from the fact that the differentiability of this class of functions together with the assumption on $\mathcal{U}$ to be a box allows for the determination of an explicit control law (as opposed to the control law which can be associated with a polyhedral domain which is general implicit). Indeed it can be shown that to every such domain of attraction $\mathcal{P}$ can be associated the Lipschitz control function

$$\phi(x) = -sat(k(B^T F^T \Gamma(x)^T))\psi(x)$$

where

$$\Gamma(x) \doteq \psi(x)^{(1-2p)} \begin{bmatrix} (F_1 x)^{2p-1} & \dots & (F_s x)^{2p-1} \end{bmatrix}$$

and k is a computable positive constant (see [9]). The drawback of the capability of determining an explicit control law is given anyway by the fact that it is not possible to give an explicit expression for $\Psi(x, \bar{x})$, but this has to be computed by bisection on the parameter α in (3.2).

Again, the control action requires the computation on-line of $\Psi(x(t), \bar{x}(t))$ and the application of (5.1).

7. Nonsquare systems. So far we have considered the case in which the system has as many inputs as outputs. It is not difficult to extend the results to nonsquare systems. Consider the nonsquare matrix M_c and the equation

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix} \begin{bmatrix} \bar{x}(r) \\ \bar{u}(r) \end{bmatrix} = \begin{bmatrix} 0 \\ \bar{r} \end{bmatrix}.$$

It is well known that, if the above equation does not admit an unique solution, two cases are possible: for a given $\bar{r}$ there may be infinitely many solutions, or there may be none. In the first case one has to choose one vector $[\bar{x}(r)^T \ \bar{u}(r)^T]$ among the solutions. One obvious choice is to consider the minimum (possibly weighted) norm solution given by

$$\begin{bmatrix} \bar{x}(r) \\ \bar{u}(r) \end{bmatrix} = \begin{bmatrix} A & B \\ C & D \end{bmatrix}^{\dagger} \begin{bmatrix} 0 \\ \bar{r} \end{bmatrix}, \tag{7.1}$$

where $M_c^{\dagger}$ is the Moore–Penrose inverse of M_c.

In the case in which there are no solutions, the obvious extension, the least square solution, is not suitable since for tracking purpose we need the steady-state condition

$$\begin{bmatrix} A & B \end{bmatrix} \begin{bmatrix} \bar{x}(r) \\ \bar{u}(r) \end{bmatrix} = 0 \tag{7.2}$$

to be satisfied exactly, a condition which is in general not satisfied by the solution (7.1). In this case we may take, among all the equilibrium points satisfying (7.2), those which minimize $\|\bar{y} - \bar{r}\|$. This is obtained by first parameterizing all the elements of the kernel of $[A\ B]$ as $x = Nz$, $u = Mz$, where $AN + BM = 0$ and then choosing for a given reference r the least square solution of

$$\min_z \ \|[CN + DM]z - r\|.$$

Since the minimum is obtained for $z = [CN + DM]^{\dagger} r$ we finally obtain

$$\begin{bmatrix} \bar{x}(r) \\ \bar{u}(r) \end{bmatrix} = \begin{bmatrix} N[CN + DM]^{\dagger} r \\ M[CN + DM]^{\dagger} r \end{bmatrix}.$$

Once the linear relation above is established, all the theory developed in the previous chapters remains valid. Clearly in the over-determined (i.e., no exact solution) case, asymptotic tracking, even for a constant signal, is not possible in general.

8. Examples.

8.1. Continuous-time example: linear state feedback. As a first example we consider the following continuous-time system:

$$\dot{x}(t) = \begin{bmatrix} 1 & .4 \\ .8 & .5 \end{bmatrix} x(t) + \begin{bmatrix} 0 \\ 1 \end{bmatrix} u(t)$$
$$y(t) = \begin{bmatrix} .2 & .1 \end{bmatrix} x(t).$$

We derived for this system a linear state feedback compensator $u = Kx$ which is such to stabilize the closed loop system while guaranteeing that for every initial state $\|x(0)\| \leq 1$ we have $\|Kx\| \leq U_{max}$ along the system trajectory. By solving the

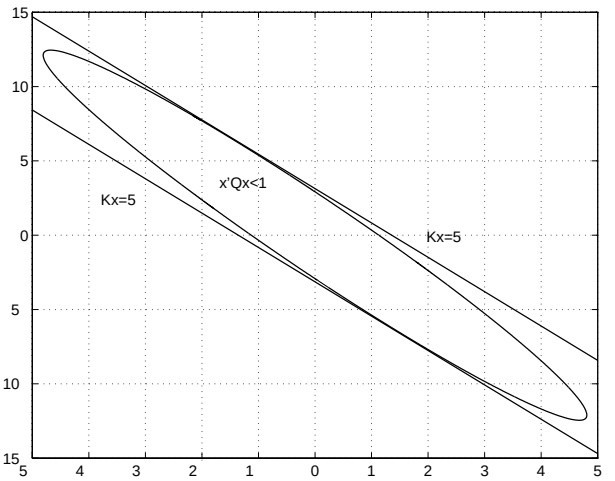

FIG. 3. *Domain of attraction.*

corresponding set of linear matrix inequalities (LMI) [10] for $U_{max} = 5$, we obtained the gain

$$K = \begin{bmatrix} -3.6845 & -1.5943 \end{bmatrix}$$

which corresponds to the ellipsoidal domain of attraction (with speed of convergence $\beta = .0001$) $\mathcal{P} = \{x \ : x^T Q x \leq 1\}$, where

$$Q = \begin{bmatrix} .7859 & .2950 \\ .2950 & .1172 \end{bmatrix}.$$

The set $\mathcal{P}$ is the ellipse depicted in Figure 3 and is by construction contained in the region where $|Kx| \leq U_{max}$ (also reported in Figure 3); thus the constraints on the reference value $\bar{r}$ can be derived by the set $\mathcal{P}$ alone and result in $|\bar{r}| \leq .2403$. We slightly reduced this value to .24 to guarantee that $\bar{x}(\bar{r})$ belongs to the interior of $\mathcal{P}$. This means that $\bar{r} = \Gamma(r) = 0.24\ sat(r/0.24)$.

We report in Figure 4 the zero initial state time evolution of the output corresponding to the reference signal (dashed line)

$$r(t) = \begin{cases} 0.40 & \text{for } \ 0 \leq t \leq 100, \\ 0.20 + 0.20e^{-(t-100)/10} & \text{for } \ 100 < t \end{cases}$$

and we report in Figure 5 the state space evolution.

8.2. Discrete-time example: linear variable structure state feedback. As a second example we consider the discrete-time system

$$x(k+1) = \begin{bmatrix} 1 & .3 \\ -1 & 1 \end{bmatrix} x(k) + \begin{bmatrix} .5 \\ 1 \end{bmatrix} u(k)$$
$$y(k) = \begin{bmatrix} -.1 & .3 \end{bmatrix} x(k)$$

with the state and control constraint sets, resp., given by

$$\mathcal{X} = \{x \ : \|x\|_\infty \leq 1\}$$

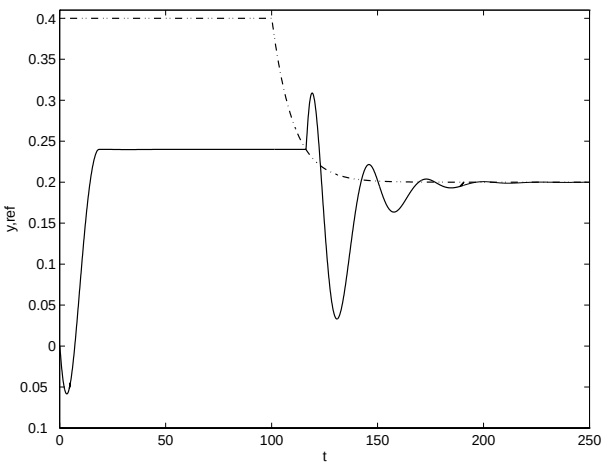

FIG. 4. *Output and reference (dashed) time evolution.*

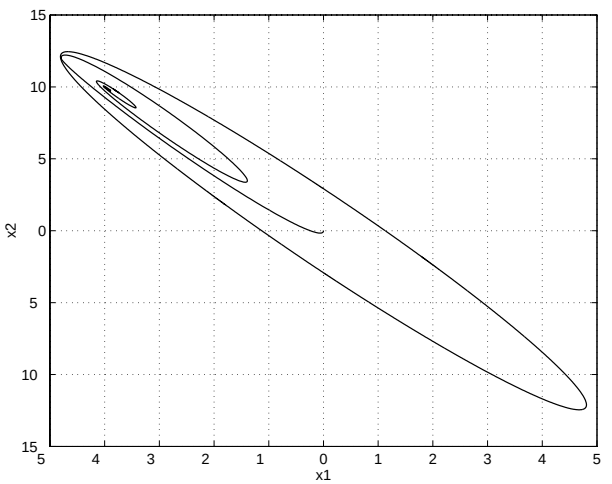

FIG. 5. *Domain of attraction and state space evolution.*

and

$$\mathcal{U} = \{u \ : |u| \leq 1\}.$$

For this system we computed a symmetric polyhedral domain of attraction $\mathcal{P} = \{x \ : \ \|Fx\|_\infty \leq 1\}$ with speed of convergence $\lambda = .9$ (which is the polyhedral region in Figure 6), where

$$F = \begin{bmatrix} 0 & 1 \\ 1.8160 & -0.2421 \\ 1.3140 & 0.1932 \end{bmatrix}.$$

In this case the constraints on the reference value derive from the constraint that $\bar{x} \in \mathcal{P}$ and translate in $|\bar{r}| \leq .27$. The linear variable structure controller associated with $\mathcal{P}$ is given by $u(x) = k_i x$ with $i = \arg\max_j |f_j x|$, where f_i and k_i are the ith

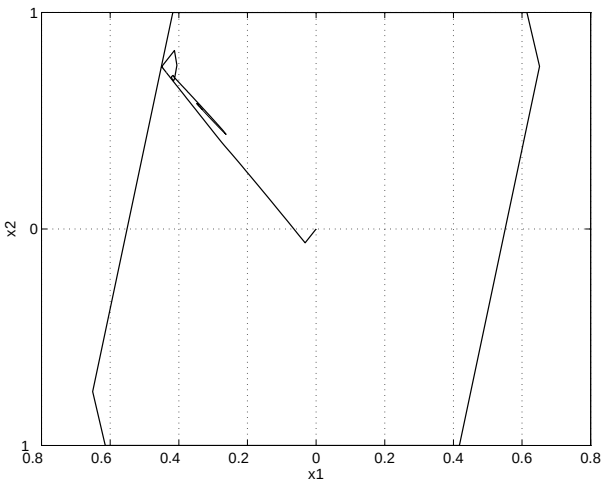

FIG. 6. *Polyhedral domain of attraction and state space evolution.*

rows of F and K, resp., where

$$K = \begin{bmatrix} -0.4690 & -0.7112 \\ -0.6355 & -0.7806 \\ -1.3140 & -0.1931 \end{bmatrix}.$$

We applied the control law proposed in section 6.2 with $\epsilon = .01$, starting from zero initial state, for the reference signal

$$r(t) = 0.2 + 0.4 * \sin(0.01 * t) * e^{-0.005 * t}.$$

Figure 7 depicts the time evolution of the output and the reference value, and Figure 6 shows the corresponding state space trajectory.

9. Conclusions. In this paper it was shown that every set of initial states which can be brought to the origin while assuring that no control and state constraints are violated is indeed a tracking domain. This amounts to saying that it is possible to track a given reference value only if its corresponding state and input equilibrium pair belongs to a domain of attraction, whereas if this condition is not met the state is not "trackable." We have provided this result based on the system structure, without assuming the existence of a stabilizing compensator, by furnishing a Lyapunov function which is derived by the domain of attraction and which allows us to derive a tracking strategy that avoids state and input constraints yet guarantees an a priori speed of convergence. Future directions in this area concern the possibility of deriving stabilizing tracking strategies capable of maintaining the tracking error within prespecified bounds and of improving the speed of convergence.

The presented approach can be applied as well to systems with control constraints only. In this case the domain of attraction can be computed by considering a fictitious (sufficiently large) state constraints region and by applying the techniques suggested in [9], [17], [20]. We finally remind the reader that for systems with no state constraints and free from eigenvalues in the open right half plane (or with no eigenvalues outside the closed unit disk) a completely different approach can be used for global

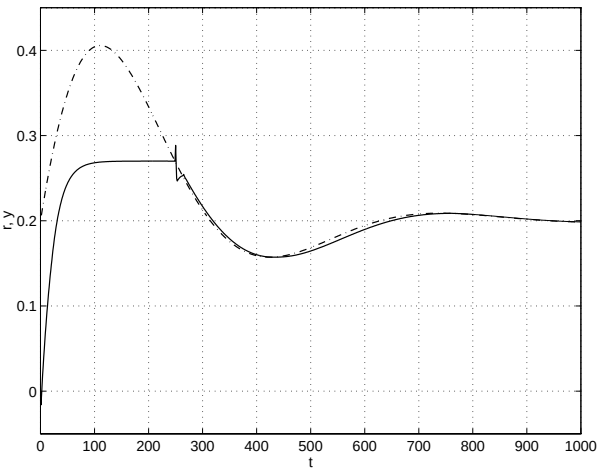

FIG. 7. *Output and reference time-evolution.*

stabilization [25] or semiglobal stabilization [24], [27]. In this case those approaches can be successfully applied to the solution of the tracking problem with an arbitrarily large initial condition set.

Appendix. Given a differentiable positively homogeneous function of order 1 $F : \mathbb{R}^n \to \mathbb{R}$ it is well known that $\langle \nabla F(y), y \rangle = F(y)$. This property can be extended easily to our case of nondifferentiable functions under the convexity assumption.

Proof of the equality (4.8). Let $F : \mathbb{R}^n \mapsto \mathbb{R}$ be a convex and positively homogeneous function of order 1. Then for any y and any $w \in \nabla F(y)$, we have $\langle w, y \rangle = F(y)$.

For $y = 0$ the property is obvious. So let $y \neq 0$. By definition any $w \in \nabla F(y)$ is such that

$$F(z) - F(y) \geq \langle w, z - y \rangle$$

for all $z \in \mathbb{R}^n$, that is

$$F(z) - \langle w, z \rangle \geq F(y) - \langle w, y \rangle.$$

Now let $z = \lambda y$ with $\lambda > 0$. Then

$$\lambda \left[F(y) - \langle w, y \rangle \right] \geq F(y) - \langle w, y \rangle \quad \text{for all} \quad \lambda > 0,$$

which necessarily implies

$$F(y) - \langle w, y \rangle = 0. \qquad \square$$

SELECTION OF BEST ORTHONORMAL RATIONAL BASIS*

PER BODIN†, LARS F. VILLEMOES‡, AND BO WAHLBERG§

Abstract. This contribution deals with the problem of structure determination for generalized orthonormal basis models used in system identification. The model structure is parameterized by a prespecified set of poles representing a finite-dimensional subspace of $\mathcal{H}^2$. Given this structure and experimental data, a model can be estimated using linear regression techniques. Since the variance of the estimated model increases with the number of estimated parameters, one objective is to find coordinates, or a basis, for the finite-dimensional subspace giving as compact or parsimonious a system representation as possible. In this paper, a best basis algorithm and a coefficient decomposition scheme are derived for the generalized orthonormal rational bases. Combined with linear regression and thresholding this leads to compact transfer function representations. The methods are demonstrated with several examples.

1. Introduction.

Over the last few years, the use of orthonormal rational basis functions in system identification has received considerable attention. The idea is to approximate the transfer function of a linear time-invariant system with a linear combination of orthonormal basis functions having fixed poles. Given a finite collection of asymptotically stable filters, the basis functions can be constructed from a Gram–Schmidt orthogonalization of the given filters using all-pass filters with balanced state space realizations. Orthogonality in $\mathcal{H}^2$ is defined with respect to the inner product (2.2). The resulting family of orthonormal functions then forms a basis for the finite-dimensional subspace of $\mathcal{H}^2$ consisting of all possible transfer functions having the poles given at hand. Depending on the order in which the orthogonalization is performed, different bases are obtained. These represent different selections of coordinate systems for the finite-dimensional subspace.

Given input/output data from a linear time invariant system, the system transfer function can be approximated in the given finite-dimensional subspace by estimating the expansion coefficients associated with the selected coordinate system. Supposing that the output data is corrupted by noise, the estimated coefficients also can be considered noisy. In particular, small coefficients will be more or less hidden in noise and thus the system estimate actually benefits from discarding them. In this way, selection of the coordinate system becomes an important issue. Since the bases are orthogonal, the energy of the coefficients will always be exactly the same independent of the selection of coordinates. If all coefficients below some magnitude are discarded, a coordinate system concentrating the energy into a few large and many small coef-

ficients results in a smaller error than a selection having a more evenly distributed energy. This can be viewed as selecting a coordinate system where some of the basis functions are close to, or resemble, the system being identified. Coefficient concentration can, for example, be measured by the entropy or the ℓ^1-norm of the coefficients. The following example demonstrates the consequence of orthogonalization order. Let a transfer function be given by

$$G(z) = \frac{3z + 1/\sqrt{2}}{5z(z - 1/\sqrt{2})}. \tag{1.1}$$

Using a Gram–Schmidt orthogonalization of the two functions $\frac{1}{z}$ and $\frac{1}{z-1/\sqrt{2}}$, the orthonormal pair of functions

$$\psi_1(z) = \frac{1}{z} \quad \text{and} \quad \psi_2(z) = \frac{1/\sqrt{2}}{z(z - 1/\sqrt{2})} \tag{1.2}$$

is constructed. The transfer function $G(z)$ can then be written $G(z) = g_1\psi_1(z) + g_2\psi_2(z)$, where

$$g_1 = \frac{3}{5} \quad \text{and} \quad g_2 = \frac{4}{5}. \tag{1.3}$$

On the other hand, if the orthogonalization is performed the other way around, the orthonormal pair

$$\tilde{\psi}_1(z) = \frac{1/\sqrt{2}}{z - 1/\sqrt{2}} \quad \text{and} \quad \tilde{\psi}_2(z) = \frac{1 - z/\sqrt{2}}{z(z - 1/\sqrt{2})} \tag{1.4}$$

is obtained so that $G(z)$ can be written $G(z) = \tilde{g}_1\tilde{\psi}_1(z) + \tilde{g}_2\tilde{\psi}_2(z)$, with

$$\tilde{g}_1 = \sqrt{\frac{49}{50}} \quad \text{and} \quad \tilde{g}_2 = \frac{1}{\sqrt{50}}. \tag{1.5}$$

In the first case, the two expansion coefficients g_1 and g_2 have almost equal size, while in the second case $\tilde{g}_1$ is much larger than $\tilde{g}_2$. In this way, almost all of the "energy" is concentrated in the coefficient $\tilde{g}_1$. The ℓ^1-norms in these two cases satisfy

$$|g_1| + |g_2| = \frac{7}{5} > \sqrt{2}\frac{4}{5} = |\tilde{g}_1| + |\tilde{g}_2|. \tag{1.6}$$

In general, under the constraint that $g_1^2 + g_2^2$ is constant, $|g_1| + |g_2|$ is minimized when one of the coefficients is zero so that the other term becomes the system $G(z)$ itself. The ℓ^1-norm is maximized when the two coefficients are equal so that the energy is maximally spread out. The example illustrates the importance of selecting coordinates. The coefficient energy becomes concentrated into few coefficients if the coordinates are selected as close as possible to the expanded function.

The contribution of this paper deals with the selection of the best coordinates, or basis. The orthogonalization procedure results in many different possible bases. However, a specific basis function can belong to many different bases. In fact, the overlap can be tremendous. If for example the dimension of the subspace is n, and if all the initially given filters have different poles, there will be $n!$ different orthogonal bases, each one resulting from a different orthogonalization order. However, all of these different bases are constructed from only $n2^{n-1}$ different basis functions. For example,

$n = 10$ gives 3,628,800 bases constructed from only 5,120 basis functions. This observation leads to a scheme for selecting the very best coordinates, where "best" is in terms of concentration of the expansion coefficients, measured by entropy, ℓ^1-norm, or some other cost. Moreover, if expansion coefficients are estimated in one single basis, the coefficients belonging to all the other basis functions can be calculated using local orthogonal transformations. Thus, a total framework is developed for decomposition into all possible expansion coefficients and then selection of the best basis. All of this is performed in the same complexity as the number of basis functions. In this meaning, the scheme is "fast." Several examples of applications of the best-basis selection scheme are given in section 5.

Construction of orthonormal rational bases is by no means new. In [33], it was investigated how the Laguerre basis could be used for system identification. This basis can be generated from identical first order all-pass filters, and the results were generalized to the second order Kautz functions in [34]. Further generalizations were made in [16, 15, 14] and [21]. In [5], it is demonstrated how general orthonormal rational bases can be generated in a simple manner from all-pass filters with balanced state space realizations. This result is mainly due to [20, 27], but similar basis constructions appear in the literature as early as 1925 in [31]. The historical background of these constructions is investigated in [2].

In order to have an efficient representation of a system using an orthonormal rational expansion, it is important that the basis functions be calibrated to the system being identified. This corresponds to selecting an approximating subspace of $\mathcal{H}^2$ and determines the rate of convergence of the expansion coefficients; see [36]. Calibration can be made by incorporating a priori knowledge about the poles of the system in the construction of the basis. As already mentioned, the mean squared error of the estimate is further reduced if coefficients with magnitudes less than the corresponding variance error are set to zero. This way of thresholding was investigated in [5], where ideas from [9] were applied to rational bases. Model sets based on orthonormal functions have nice properties in terms of least squares estimates of the coefficients since if many coefficients are discarded in the final estimate, the least squares estimate of the kept coefficients remains the same; see [13].

In the best basis selection scheme developed in this paper, the observation that the number of basis functions is much smaller than the number of different bases is crucial for the existence of an efficient best basis algorithm. This situation is similar to the wavelet packet best-basis selection methods suggested in [7], and the same best basis criteria can be used in the case of the best rational basis as well. Another best basis criterion was suggested in [10]. In this paper the cost function is related to the entropy cost of [8].

More precisely, the parallel to the wavelet packet transform can briefly be described in the following way. In the wavelet packet case, a signal is made finite dimensional through sampling. The finite-dimensional space to work with then becomes $\mathbb{R}^n$ or $\mathbb{C}^n$, where n is the number of samples. The basis in which the signal is described is the canonical Dirac basis. The signal is then transformed into all the wavelet packet coefficients using a low-complexity implementation of the transform. The best wavelet packet basis can then be selected. This is illustrated in Figure 1.1. The number of different bases is approximately 1.5^n, while the number of basis functions is only $n(\log_2(n) + 1)$.

In the case of choosing the best rational basis, a collection of filters is given. The finite-dimensional space is then identified with the span of the poles of these filters

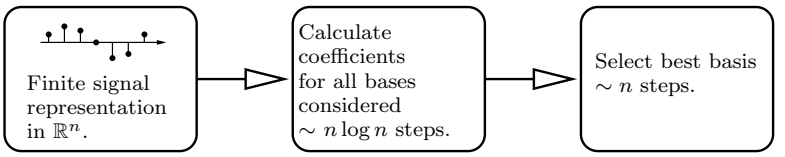

FIG. 1.1. *Wavelet packet best basis decomposition.*

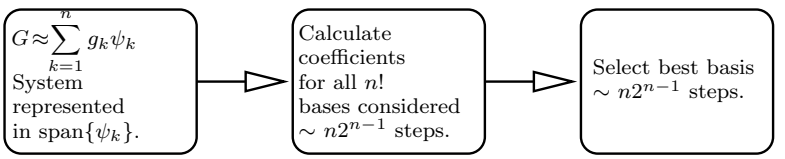

FIG. 1.2. *Best rational basis decomposition.*

and the system is approximated in this space by estimating the coefficients for a basis given by some ordering of the filters. This basis can then be called the canonical basis. All the coefficients needed for all the other orderings of the filters can then be calculated from the canonical coefficients. As mentioned above, if all n filters are different, the number of bases is $n!$ while the number of different coefficients and steps for calculating them is $n2^{n-1}$. As in the case of wavelet packet best basis selection, the best rational basis can now be selected. This can be done in $n2^{n-1}$ steps as well. Figure 1.2 illustrates the scheme.

Connections between wavelets and orthonormal rational basis functions have previously been studied in [11] and frames of rational wavelets for system identification were examined in [25, 24] with promising results, but where one conclusion is that bases of rational wavelets can never be orthogonal.

The paper is organized as follows. In section 2, the background for rational basis construction and system identification is given. Section 3 presents the best basis selection scheme while the procedure for calculating all possible expansion coefficients is derived in section 4. Different examples are given in section 5 and finally in section 6, some conclusions are made. The two main results of the paper are the best basis selection scheme presented in section 3.3 and the coefficient generation of section 4.2.

2. Background. This section presents the background for construction of orthonormal rational basis functions and for their use in system identification. Section 2.1 gives a convenient way to construct rational bases from a cascade of all-pass filters with balanced state space realizations. In section 2.2, it is shown how thresholding can be applied when using these bases in system identification.

2.1. An orthonormal family in $\mathcal{H}^2$. Assume that a strictly proper asymptotically stable linear time-invariant dynamical system is described by

$$y(t) = G(q)u(t), \tag{2.1}$$

where $\{u(t)\}$ is the input sequence, $\{y(t)\}$ is the output sequence, and q is the forward shift operator. The transfer function $G(z)$ is assumed to be asymptotically stable so that the system will belong to $\mathcal{H}^2$, being the Hardy space of functions analytical outside, and square integrable on the unit circle. See, e.g., [1, 28]. Since $G(z)$ is

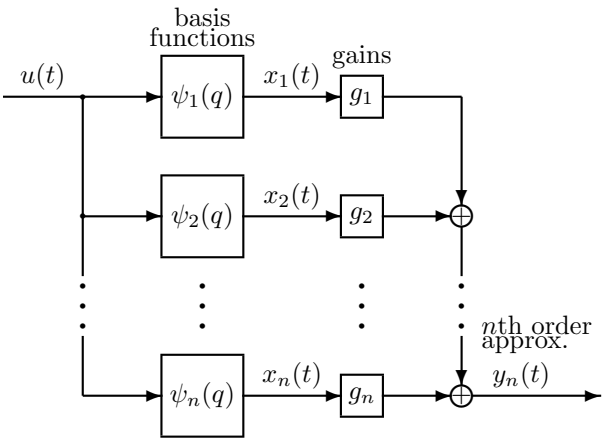

FIG. 2.1. *The approximate system* $G_n(z)$.

assumed to be strictly proper, only the part of $\mathcal{H}^2$ with functions fulfilling $G(\infty) = 0$ is considered.

Let $\{\psi_k(z)\}_{k=1}^{\infty}$ be an orthonormal family of functions in $\mathcal{H}^2$ such that $\langle \psi_k, \psi_l \rangle = \delta_{k,l}$, where the inner product is defined as

$$\langle f, g \rangle = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(e^{i\omega}) \overline{g(e^{i\omega})} d\omega \tag{2.2}$$

for any pair of functions $f, g \in \mathcal{H}^2$, and where $\delta_{k,l} = 1$ if $k = l$ and 0 otherwise. Suppose now that $G(z)$ can be represented as

$$G(z) = \sum_{k=1}^{\infty} g_k \psi_k(z). \tag{2.3}$$

The simplest example of such a family of orthonormal functions is the standard basis

$$\psi_k(z) = z^{-k}, \qquad k = 1, 2, \ldots . \tag{2.4}$$

Since the transfer function $G(z)$ belongs to $\mathcal{H}^2$, the expansion coefficient sequence $\{g_k\}$ will be square summable so that $g_k \to 0$ as $k \to \infty$. Therefore, the sequence can be truncated in order to obtain an approximation $G_n(z)$ of $G(z)$, where

$$G_n(z) = \sum_{k=1}^{n} g_k \psi_k(z). \tag{2.5}$$

Due to orthonormality, the expansion coefficients for both (2.3) and (2.5) will be given by the least squares generalized Fourier coefficients $g_k = \langle G, \psi_k \rangle$. Assume now that the functions $\psi_k(z)$ are state transfer functions of the approximating system $G_n(z)$. This is illustrated in Figure 2.1. A state space realization of $G_n(z)$ is written

$$\begin{aligned} \mathbf{x}(t+1) &= \mathbf{A}_n \mathbf{x}(t) + \mathbf{B}_n u(t), \\ y(t) &= \mathbf{C}_n \mathbf{x}(t), \qquad \mathbf{C}_n = (g_1 \ldots g_n), \end{aligned} \tag{2.6}$$

for which the functions $\{\psi_k\}_{k=1}^n$ correspond to

$$\psi_k(z) = \mathbf{e}_k^T \left(z\mathbf{I} - \mathbf{A}_n\right)^{-1} \mathbf{B}, \qquad k = 1, \ldots, n, \tag{2.7}$$

where $\mathbf{e}_k = (0 \ldots 1 \ldots 0)^T$ is a unit vector with 1 in position k and where $\mathbf{I}$ is the identity matrix. Assume that the system matrix $\mathbf{A}_n$ has all its eigenvalues strictly inside the unit circle so that the system (2.6) is asymptotically stable. Then, the family of functions (2.7) has mutual inner products $\langle \psi_k, \psi_l \rangle = \mathbf{e}_k^T \mathbf{P} \mathbf{e}_l$, where $\mathbf{P}$ is the unique solution of the discrete Lyapunov equation

$$\mathbf{A}_n \mathbf{P} \mathbf{A}_n^T + \mathbf{B}_n \mathbf{B}_n^T = \mathbf{P}. \tag{2.8}$$

This follows from the fact that the inner products can be written

$$\begin{aligned} \langle \psi_k, \psi_l \rangle &= \frac{1}{2\pi} \int_{-\pi}^{\pi} \left[\mathbf{e}_k^T \left(\mathbf{I}e^{i\omega} - \mathbf{A}_n\right)^{-1} \mathbf{B}_n\right] \left[\mathbf{e}_l^T \left(\mathbf{I}e^{-i\omega} - \mathbf{A}_n\right)^{-1} \mathbf{B}_n\right] d\omega \\ &= \mathbf{e}_k^T \left\{ \frac{1}{2\pi} \int_{-\pi}^{\pi} \left[\left(\mathbf{I}e^{i\omega} - \mathbf{A}_n\right)^{-1} \mathbf{B}_n\right] \left[\left(\mathbf{I}e^{-i\omega} - \mathbf{A}_n\right)^{-1} \mathbf{B}_n\right]^T d\omega \right\} \mathbf{e}_l =: \mathbf{e}_k^T \mathbf{P} \mathbf{e}_l . \end{aligned} \tag{2.9}$$

It is then well known that the controllability Gramian $\mathbf{P}$ satisfies the Lyapunov equation (2.8) and that $\mathbf{P}$ is unique and positive definite if $\mathbf{A}_n$ is stable. It is easy to conclude that the family $\{\psi_k\}_{k=1}^n$ becomes orthonormal if and only if

$$\mathbf{A}_n \mathbf{A}_n^T + \mathbf{B}_n \mathbf{B}_n^T = \mathbf{I}. \tag{2.10}$$

In this way, the parameters available for constructing an orthonormal family are $(\mathbf{A}_n, \mathbf{B}_n)$ under the constraint (2.10), and $\mathbf{A}_n$ is asymptotically stable. However, if n is large (2.10) might be complicated to solve and if the family is to be expanded to, say, order $n+1$, it would be convenient to do this in some structured way.

A state space realization satisfying (2.10) is said to be input balanced. In [20, 27], a way of constructing orthonormal families from serial connections of all-pass filters with such realizations was given. This kind of construction has previously been presented in [5, 2] and similar ideas have also been discussed in [39, 6, 21].

Crucial for all of these constructions is the concept of orthogonal all-pass filters defined as follows.

DEFINITION 2.1 (orthogonal all-pass filter). *A scalar transfer function $H(z)$ is said to be all-pass if*

$$H(z)H(1/z) \equiv 1, \tag{2.11}$$

and it is said to be orthogonal if its state-space realization $(\mathbf{A}, \mathbf{B}, \mathbf{C}, D)$ is input balanced, i.e., if it fulfills

$$\mathbf{A}\mathbf{A}^T + \mathbf{B}\mathbf{B}^T = \mathbf{I}. \tag{2.12}$$

It is straightforward to verify [27] that a filter $H(z)$ with state space realization $(\mathbf{A}, \mathbf{B}, \mathbf{C}, D)$ is orthogonal and all-pass if and only if

$$\mathbf{F} := \begin{bmatrix} \mathbf{A} & \mathbf{B} \\ \mathbf{C} & D \end{bmatrix} \tag{2.13}$$

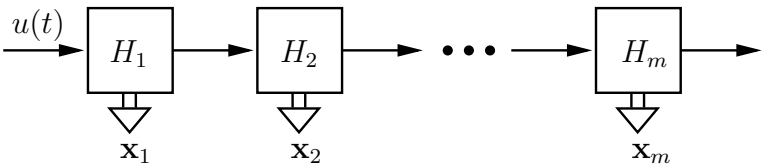

FIG. 2.2. *A cascade of all-pass filters with input balanced realizations generating an orthonormal family.*

is an orthogonal matrix, $\mathbf{F}\mathbf{F}^T = \mathbf{I}$.

The key result in [27, sect. 10.4] is that the orthogonality and all-pass properties are preserved through several different connections of such filters. One such operation is the serial, or cascade, connection. More formally, let $H_1(z)$ and $H_2(z)$ be two orthogonal all-pass filters with states $\mathbf{x}_1$ and $\mathbf{x}_2$, respectively. Then, the serial connection $H_1(z)H_2(z)$ of the two filters with the state vector $(\mathbf{x}_1^T \ \mathbf{x}_2^T)^T$ is also orthogonal and all-pass.

This follows from the fact that if $H_1(z)$ and $H_2(z)$ have the state space realizations $(\mathbf{A}_1, \mathbf{B}_1, \mathbf{C}_1, D_1)$ and $(\mathbf{A}_2, \mathbf{B}_2, \mathbf{C}_2, D_2)$ respectively, and if the matrices

$$\mathbf{F}_1 := \begin{bmatrix} \mathbf{A}_1 & \mathbf{B}_1 \\ \mathbf{C}_1 & D_1 \end{bmatrix} \quad \text{and} \quad \mathbf{F}_2 := \begin{bmatrix} \mathbf{A}_2 & \mathbf{B}_2 \\ \mathbf{C}_2 & D_2 \end{bmatrix} \tag{2.14}$$

are defined, the serial connection will have the corresponding matrix

$$\mathbf{F}_3 := \left[\begin{array}{cc|c} \mathbf{A}_1 & \mathbf{0} & \mathbf{B}_1 \\ \mathbf{B}_2\mathbf{C}_1 & \mathbf{A}_2 & \mathbf{B}_2 D_1 \\ \hline D_2\mathbf{C}_1 & \mathbf{C}_2 & D_2 D_1 \end{array}\right] = \begin{bmatrix} \mathbf{I} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{A}_2 & \mathbf{B}_2 \\ \mathbf{0} & \mathbf{C}_2 & D_2 \end{bmatrix} \begin{bmatrix} \mathbf{A}_1 & \mathbf{0} & \mathbf{B}_1 \\ \mathbf{0} & \mathbf{I} & \mathbf{0} \\ \mathbf{C}_1 & \mathbf{0} & D_1 \end{bmatrix} \tag{2.15}$$

for the state $(\mathbf{x}_1^T \ \mathbf{x}_2^T)^T$. It is then trivial to verify that if $\mathbf{F}_1$ and $\mathbf{F}_2$ are orthogonal matrices, the factors of $\mathbf{F}_3$ are also orthogonal, making their product orthogonal as well.

From this result it is easy to see that, given a family of stable all-pass filters $\{H_k\}_{k=1}^m$ with McMillan degrees $\{n_k\}_{k=1}^m$, an orthonormal family in $\mathcal{H}^2$ can be generated by serially connecting the filters in an array as shown in Figure 2.2.

The orthonormal functions $\{\psi_k\}_{k=1}^n$ are then simply given as the state transfer functions from the input to the cascade to each of the components of the states of the filters, making $n = \sum_{k=1}^m n_k$. More specifically let $\mathbf{x}_k$, defined as the states of $H_k(z)$ and shown in Figure 2.2, have components

$$\mathbf{x}_k(t) = \begin{bmatrix} x_{k,1}(t) \\ x_{k,2}(t) \\ \vdots \\ x_{k,n_k}(t) \end{bmatrix}, \tag{2.16}$$

where n_k is the McMillan degree of the filter $H_k(z)$. The transfer functions $\psi_{k,l}(z)$, defined by $x_{k,l}(t) = \psi_{k,l}(q)u(t)$, then satisfy $\langle \psi_{i,j}, \psi_{k,l} \rangle = \delta_{i,k}\delta_{j,l}$.

Define

$$\Psi_k(z) = \begin{bmatrix} \psi_{k,1}(z) \\ \psi_{k,2}(z) \\ \vdots \\ \psi_{k,n_k}(z) \end{bmatrix}, \qquad k = 1, \ldots, m, \tag{2.17}$$

and let $H_k(z)$ have the state transfer function $\Phi_k(z)$. Then the $\Psi_k(z)$'s obtained from the m ordered filters in the cascade are given by

$$\Psi_k(z) = \Phi_k(z) \prod_{l=1}^{k-1} H_l(z), \qquad k = 1, \ldots, m. \tag{2.18}$$

Some special cases should be mentioned here. If all the all-pass filters fulfill $H_k(z) = H(z)$ with McMillan degree n and have state transfer functions $\Phi_k(z) = \Phi(z)$, the construction of [15, 14] is obtained. In this case, the basis functions become

$$\Psi_k(z) = \Phi(z) \left[H(z)\right]^{k-1}, \qquad k = 1, 2, \ldots . \tag{2.19}$$

Moreover, equal first order filters result in the Laguerre basis suggested for system identification already in [17]. The Laguerre basis was also suggested for time series modeling in [35]. Identical second order filters give the Kautz basis. None of these constructions provides any flexibility in coordinate selection since they are constructed from only one kind of all-pass filter. Explicit expressions for balanced state space realizations for the Laguerre and Kautz bases can be found in, e.g., [14]. The approximation properties of both the first order filter-based Laguerre basis and the second order Kautz basis are thoroughly investigated in [36]. These results are generalized to the Hambo construction of [14] in [23].

Historical remarks on the construction of orthonormal rational bases can be found in [2]. The first such constructions were made almost simultaneously by Takenaka in [31] and by Malmquist; see [37].

The completeness condition for the family (2.18) with $k = 1, \ldots, \infty$ is very mild. Basically, it spans the subspace of all possible strictly proper transfer functions in $\mathcal{H}^2$ if the poles of $\Psi_k(z)$ do not (if at all) converge too fast to the unit circle when $k \to \infty$. This was shown in [30] in a paper that only considers the case of poles with single multiplicity. The more general result can be found in [37, chap. 10]. The condition automatically provides completeness for the Laguerre, Kautz, and Hambo constructions.

2.2. System identification and thresholding. The general orthonormal basis functions (2.18) are now possible to use for system identification. As mentioned earlier, one of the major advantages with such a model structure is that it is linear in the parameters. If the measurements are noisy, the estimated expansion coefficients will be contaminated with noise as well. One way to regularize the system estimate is then to discard small coefficients. This way of thresholding the estimate was suggested in [9] and is efficient when the basis is able to give a sparse representation of the system, but not the noise. The motivation is that if this is the case, small coefficients will mostly consist of noise so that the estimation error is reduced if these are replaced with zeros.

Let the system identification problem be defined as

$$y(t) = G(q)u(t) + e(t), \qquad t = 1, \ldots, N, \tag{2.20}$$

where $\{y(t)\}_{t=1}^N$ is the output sequence, $\{u(t)\}_{t=1}^N$ is the input sequence, and $\{e(t)\}_{t=1}^N$ is a white Gaussian measurement noise with zero mean and variance σ^2. The system is assumed to be asymptotically stable and strictly proper so that it belongs to $\mathcal{H}^2$. Define the vector valued least squares expansion coefficients $\mathbf{g}_k := \langle G, \Psi_k \rangle$, $k = 1, \ldots, m$, so that

$$\mathbf{g}_k = \begin{bmatrix} g_{k,1} \\ g_{k,2} \\ \vdots \\ g_{k,n_k} \end{bmatrix} = \begin{bmatrix} \langle G, \psi_{k,1} \rangle \\ \langle G, \psi_{k,2} \rangle \\ \vdots \\ \langle G, \psi_{k,n_k} \rangle \end{bmatrix}. \tag{2.21}$$

Suppose that the functions $\Psi_k(z)$ are generated by the cascade shown in Figure 2.2, where all-pass filter k has McMillan degree n_k. Let $n = \sum_{k=1}^m n_k$ and define the nth order approximation of $G(z)$ as

$$G_n(z) := \sum_{k=1}^m \mathbf{g}_k^T \Psi_k(z), \tag{2.22}$$

which minimizes the approximation error $\|G - G_n\|_2$. Let the parameter vector Θ be defined by

$$\Theta := \begin{bmatrix} \mathbf{g}_1 \\ \vdots \\ \mathbf{g}_m \end{bmatrix}. \tag{2.23}$$

The least squares estimate of Θ resulting from N measurements then becomes

$$\hat{\Theta} := \mathbf{R}_N^{-1} \mathbf{f}_N, \tag{2.24}$$

where

$$\mathbf{R}_N = \frac{1}{N} \sum_{t=1}^N \mathbf{X}(t) \mathbf{X}^T(t), \qquad \mathbf{f}_N = \frac{1}{N} \sum_{t=1}^N \mathbf{X}(t) y(t) \tag{2.25}$$

with

$$\mathbf{X}(t) = \begin{bmatrix} \mathbf{x}_1(t) \\ \mathbf{x}_2(t) \\ \vdots \\ \mathbf{x}_m(t) \end{bmatrix} \tag{2.26}$$

and where $\mathbf{x}_k$ is defined by (2.16). It is well known (see, e.g., [19, chap. 8]) that $\hat{\Theta} \to \Theta^*$ with probability one (w.p.1) as $N \to \infty$, where

$$\Theta^* := \arg\min_{\Theta} \frac{1}{2\pi} \int_{-\pi}^{\pi} \left| G(e^{i\omega}) - G_n(e^{i\omega}) \right|^2 \phi_u(e^{i\omega}) d\omega, \tag{2.27}$$

where ϕ_u is the power spectral density of the input sequence $\{u(t)\}_{t=1}^N$. In this way, if the input has a constant mean spectrum such as the realizations of white noise, $\hat{\Theta}$

will converge to the true least-squares gains Θ. The asymptotic distribution of the gains becomes

$$\sqrt{N}(\hat{\Theta} - \Theta^*) \sim \mathrm{AsN}(\mathbf{0}, \mathbf{R}_N^{-1}\sigma^2), \tag{2.28}$$

where σ^2 is the variance of the measurement noise. From the orthonormality of the basis functions, $\mathbf{R}_N$ will asymptotically become the identity matrix w.p.1 so that the asymptotic distribution of the coefficients $\hat{\Theta}$ will be independently and identically distributed (i.i.d.) Define the nth order approximation of $G(z)$ using the estimated least squares gains $\hat{\Theta}$ as

$$\hat{G}_n(z) := \sum_{k=1}^{m} \hat{\mathbf{g}}^T \Psi_k(z). \tag{2.29}$$

Let $\{u(t)\}_{t=1}^N$ be a realization of a white noise. The least-squares error then satisfies

$$\|G - \hat{G}_n\|_2 \to \|G - G_n\|_2 \quad \text{w.p.1} \quad \text{as } N \to \infty. \tag{2.30}$$

From the orthonormality of the basis functions, the squared error can now be written

$$\|G - \hat{G}_n\|_2^2 = \sum_{k=1}^{m} \|\mathbf{g}_k - \hat{\mathbf{g}}_k\|_2^2 + \sum_{k=m+1}^{\infty} \|\mathbf{g}_k\|_2^2 \tag{2.31}$$

so that the error is divided into two terms. The first part, $\sum_{k=1}^m \|\mathbf{g}_k - \hat{\mathbf{g}}_k\|_2^2$, is minimized given the first m all-pass filters by the least-squares estimate $\hat{\Theta}$ of the coefficients Θ, while the second term is completely determined by the choice of the first m filters. It would be desirable to make this part as small as possible for fixed m, but in general this leads to a difficult nonlinear optimization problem. However, a priori knowledge about the true system can often be used when selecting the filters $\{H_k\}_{k=1}^m$.

A systematic iterative scheme for selecting the all-pass filter for the construction in [14] is suggested in [16, 15]. In this case, when the basis is generated from one single repeated all-pass filter, a model is identified using a basis generated from some initial all-pass filter. The model is then reduced by means of balanced model reduction to some lower-order system, which is used to construct a new all-pass filter. The steps above are then repeated until a refined low order model is obtained. The method seems to converge in many cases and reduces the tail contribution of the error to almost zero after only three or four iterations. If the model order for the all-pass filter is selected as the true order of $G(z)$, the poles of the all-pass filter converge to the poles of $G(z)$ making only the first basis function necessary. However, in some cases the method diverges, especially in the presence of substantial measurement noise.

In [5], it was suggested that the thresholding rule of [9] should be used to regularize the system estimate if measurement noise is present. The suggestion builds on the observation that if, for some k and l,

$$(\hat{g}_{k,l} - g_{k,l})^2 > g_{k,l}^2, \tag{2.32}$$

a smaller error in the estimate is obtained by simply replacing $\hat{g}_{k,l}$ with 0. In this case the true coefficient $g_{k,l}$ is totally "drowned" in noise. Since we hope the system is well described with only a few basis functions while the noise is difficult to express in the basis, the threshold algorithm described in section 3.2 could be applied to this kind of basis function as well. Then, the problem is reduced to finding the proper

threshold level in order to detect when (2.32) happens. From (2.28), the asymptotic distribution of the coefficients is known. Suppose that the input sequence $\{u(t)\}$ has zero mean and constant power spectral density σ_u^2 and that the measurement noise $\{v(t)\}$ is white stationary zero mean with variance σ^2. Then

$$\sqrt{N}(\hat{g}_{k,l} - g_{k,l}) \sim \mathrm{AsN}(0, \sigma^2/\sigma_u^2). \tag{2.33}$$

Furthermore they are asymptotically independent for different (k, l). The threshold rule suggested in [9] then relies on the fact that

$$\mathrm{Prob}\left(\max_{\substack{1\le k\le m\\ 1\le l\le n_k}} |\hat{g}_{k,l} - g_{k,l}| > \frac{\sigma}{\sigma_u}\sqrt{\frac{2\log n}{N}} \right) \to 0 \tag{2.34}$$

as $m \to \infty$. This follows from a result in [18] which was used in [9].

Assume the problem formulation of (2.20), where the input sequence $\{u(t)\}_{t=1}^N$ has constant power spectral density σ_u^2 and zero mean. Let the measurement noise be defined as above so that (2.34) results in the following regularization scheme:

1. Choose a rational orthonormal basis constructed from a cascade of orthonormal all-pass filters $\{H_k\}_{k=1}^m$ with McMillan degrees n_k, respectively.
2. Calculate the least squares estimates $\hat{\Theta}$ of the least squares coefficients Θ as in (2.24).
3. Let

$$\hat{g}_{k,l}^s = \begin{cases} \hat{g}_{k,l} & \text{if } |\hat{g}_{k,l}| \ge \tau\frac{\sigma}{\sigma_u}, \\ 0 & \text{if } |\hat{g}_{k,l}| < \tau\frac{\sigma}{\sigma_u}, \end{cases} \qquad \begin{matrix} k = 1, \dots, m, \\ l = 1, \dots, n_k, \end{matrix} \tag{2.35}$$

where

$$\tau = \sqrt{\frac{2\log n}{N}}. \tag{2.36}$$

4. Form the thresholded transfer function estimate

$$\hat{G}_n^{(s)}(z) = \sum_{k=1}^{m}\sum_{l=1}^{n_k} \hat{g}_{k,l}^s \psi_{k,l}(z). \tag{2.37}$$

The algorithm results in only significant coefficients being kept. In order for it to work well, the system $G(z)$ should be as compressible as possible in the basis chosen. It is therefore important to incorporate as much a priori information as possible when selecting the all-pass filters $H_k(z)$. However, even when the all-pass filters have been selected, their ordering in the cascade has to be selected as well. The compressibility of a collection of all-pass filters can differ significantly depending on the order in which the filters appear. In parallel to the best basis selection of wavelet packets, given a collection of all-pass filters, a similar problem of best basis, or ordering, can be stated for rational orthonormal functions. In the following section, a scheme for selecting a suitable such basis is presented.

3. Best basis selection. As mentioned in the previous section, a collection of orthonormal all-pass filters can be used to construct an orthonormal rational basis. Different orderings of these filters will then correspond to different coordinate selections for the same subspace of $\mathcal{H}^2$. In this section, a scheme is given for selecting

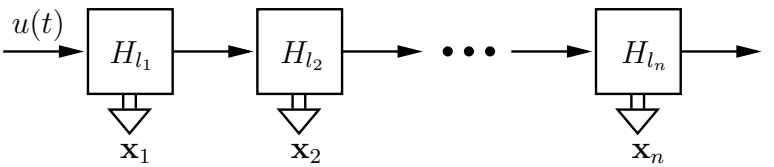

FIG. 3.1. *Cascade of orthogonal all-pass filters.*

the best among all possible coordinates. The outline is as follows. In section 3.1, the number of different bases and different basis functions is given. Section 3.2 considers different criteria for optimality. The selection scheme is derived in section 3.3 and finally, in section 3.4, some implementation issues are discussed.

3.1. Combinatorial observations. Using notation similar to that in section 2.1, a basis is associated with a collection of n balanced all-pass filters placed in an array as shown in Figure 3.1. Let the all-pass filter $H_k(z)$ have state transfer function $\Phi_k(z)$ and McMillan degree n_k. Suppose that there is a total of p *different* filters, represented by the family $\{H_l(z)\}_{l=1}^p$, and that the filter $H_l(z)$ appears exactly κ_l times for $l = 1, \ldots, p$. The number of filters n in the array then becomes

$$n = \sum_{l=1}^{p} \kappa_l. \tag{3.1}$$

Given the array in Figure 3.1, the vector valued basis functions will be

$$\Psi_k(z) = \Phi_{l_k}(z) \prod_{i=1}^{k-1} H_{l_i}(z), \qquad k = 1, \ldots, n, \tag{3.2}$$

for some ordering $\{l_k\}_{k=1}^n$. Define the finite-dimensional space

$$\mathcal{H}_n := \operatorname{span} \{\Psi_k\}_{k=1}^n \subset \mathcal{H}^2, \tag{3.3}$$

which is independent of the ordering of the filters since they will all have the same finite fractional expansions. Thus, each ordering of the functions will correspond to a selection of coordinates for $\mathcal{H}_n$. The number of different such choices is given by the following proposition, first presented in [4].

PROPOSITION 3.1 (number of bases). *Given the different orthogonal all-pass filters* $\{H_l(z)\}_{l=1}^p$ *and multiplicities* $\{\kappa\}_{l=1}^p$ *with* $n = \sum_{l=1}^p \kappa_l$, *the number of arrangements of these filters is*

$$\binom{n}{\kappa_1, \kappa_2, \ldots, \kappa_p} := \frac{n!}{\kappa_1! \cdot \kappa_2! \cdots \kappa_p!}. \tag{3.4}$$

Proof. The result is obtained from simple counting; see for example [12]. ∎

The number of bases can be described combinatorially as the number of "words" that can be written using the "letters" $\{H_l\}_{l=1}^p$, where each letter $H_l(z)$ appears κ_l times. A number of special cases can now be examined.

All filters equal. This results in the construction of [14] with the Laguerre or Kautz bases as special cases. Of course, there is only one way to arrange a number of equal filters and consequently, with $p = 1$ and $\kappa_1 = n$, Proposition 3.1 gives only $\binom{n}{n} = 1$ basis.

All filters different. This problem is identical to the number of arrangements of n distinct objects and is equal to $n!$, which is exactly what Proposition 3.1 gives with $p = n$ and $\kappa_l = 1$ for $l = 1, \ldots, n$.

Each filter appears κ times. This case can be viewed as starting with the construction of [14] with κ equal filters, where each of the filters has p factors. Then, Proposition 3.1 gives the number of bases that can be constructed by splitting up each filter into its factors and rearranging them. With $\kappa_l = \kappa$ for $l = 1, \ldots, p$ this results in $n!/(\kappa!)^p$ bases. For example, if each filter appears twice, the number of bases will be $n!/2^{n/2}$.

Two different filters. With only two different all-pass filters, the number of bases becomes $\binom{n}{\kappa}$, where κ is the number of filters $H_1(z)$ so that $H_2(z)$ appears $n-\kappa$ times.

Observe that a vector valued basis function, defined as in (3.2), depends on the state transfer function of its output filter $H_{l_k}(z)$ and on which filters precede it in the cascade, but not on their ordering. Obviously, there will be an overlap in which *different* basis functions there are in all the bases given by Proposition 3.1. The number of different basis functions is determined by the following proposition.

PROPOSITION 3.2 (number of basis functions). *Given different orthogonal all-pass filters $\{H_l(z)\}_{l=1}^p$ with multiplicities $\{\kappa_l\}_{l=1}^p$ and $n = \sum_{k=1}^p \kappa_l$, the number of vector valued basis functions as defined in* (3.2) *that can be constructed from these filters is*

$$\sum_{l=1}^{p} \left[\kappa_l \prod_{\substack{m \neq l \\ m=1}}^{p} (\kappa_m + 1) \right]. \tag{3.5}$$

Proof. A basis function is uniquely defined by the output filter $H_l(z)$ (or actually its state transfer function $\Phi_l(z)$) together with the p-tuple

$$(k_1, k_2, \ldots, k_p), \qquad \text{where} \quad \begin{cases} 0 \le k_m \le \kappa_m, & m \neq l, \\ 0 \le k_l \le \kappa_l - 1 & \text{otherwise,} \end{cases} \tag{3.6}$$

denoting that the array of filters preceding the output filter contains $H_m(z)$ k_m times for $m = 1, \ldots, p$. Each filter $H_m(z)$ can appear from 0 up to κ_m times in this array except for $H_l(z)$, which can appear only from 0 up to $\kappa_l - 1$ times, since the filter $H_l(z)$ is used as an output filter. Simple counting then gives a total of

$$(\kappa_1 + 1)(\kappa_2 + 1) \cdots (\kappa_{l-1} + 1)\, \kappa_l\, (\kappa_{l+1} + 1) \cdots (\kappa_p + 1) = \kappa_l \prod_{\substack{m \neq l \\ m=1}}^{p} (\kappa_m + 1) \tag{3.7}$$

basis functions having $H_l(z)$ as their output filter. The total number of functions (3.5) is then obtained as the sum over all possible output filters. ∎

The number of basis functions can now be calculated for the special cases considered above.

All filters equal. With $p = 1$ and $\kappa_1 = n$, (3.5) gives n. This is of course expected since there is only one basis.

All filters different. With $p = n$ and $\kappa_l = 1$ for $l = 1, \ldots, p$, the number of basis functions becomes $n2^{n-1}$. This can be checked since the filters preceding the output filter can be represented by an $(n-1)$-position binary number, which can take 2^{n-1} values, and since there are n possible output filters.

Each filter appears κ times. In this case, with $\kappa_l = \kappa$ for $l = 1, \ldots, p$, the number of functions will be $p\kappa(\kappa+1)^{n-1}$, according to (3.5).

Two different filters. With $H_1(z)$ appearing κ times, the number of basis functions will be $2\kappa(n-\kappa)+n$. This expression degenerates to n for $\kappa = 0$ or $\kappa = n$, which corresponds to the case when all the filters are equal. It is maximized for $\kappa = n/2$, where there are equally many of the two different filters. In this case, the number of functions is $n(n+2)/2$. This should be compared to the number of bases, which is $\binom{n}{n/2} \approx 2^{n+1/2}/\sqrt{\pi n}$ according to Stirling's formula. In this way there is an exponentially growing number of bases containing only a quadratically growing number of basis functions.

Propositions 3.1 and 3.2 show that in many cases, the number of basis functions is dramatically smaller than the number of orthonormal basis functions that can be constructed from these, while in other cases the difference is more modest. If, e.g., all the filters are equal and $n = 10$, the total number of bases is $n! = 3,628,800$ while the number of basis functions becomes only $n2^{n-1} = 5,120$. If there are 5 of each of 2 different all-pass filters, the number of bases is 252 while the number of functions is 60. In both these cases, the number of basis functions is smaller than the number of bases that can be constructed from them. In section 3.3, it will be shown that in the case of rational basis functions, a fast algorithm also exists that permits selection of the best basis.

3.2. Best basis criteria. In order for the thresholding of section 2.2 to work as an efficient regularization method in system identification, it is necessary to have a basis that provides a sparse system description. This situation is similar to wavelet-packet best basis selection. In the case of rational basis functions, the best ordering of the all-pass filters has to be found. This section discusses different optimality criteria or cost functions for determining what is meant by the best basis. The same cost functions were used for wavelet packet best basis selection in [7, 8, 10].

Let $\{g_k\}_{k\in\mathcal{B}}$ be the expansion coefficients of a finite orthonormal rational basis expansion, where $\mathcal{B}$ are the indices of n basis functions formed from all the state outputs from an array of all-pass filters. Let all possible $\mathcal{B}$ denote the bases that can be formed by permuting the ordering of the all-pass filters. In this way, a finite library of bases is obtained. In [8], it was suggested that the entropy of the expansion coefficients should be used as a cost function for best basis selection. This is defined by

$$V_e(\mathcal{B}) = -\sum_{k\in\mathcal{B}} |g_k|^2 \log |g_k| \tag{3.8}$$

and is a well-known data compression measure; see [38]. Another possible criterion for best basis selection is the ℓ^α-cost

$$V_\alpha(\mathcal{B}) = \sum_{k\in\mathcal{B}} |g_p|^\alpha \tag{3.9}$$

with $0 < \alpha < 2$. In particular, $\alpha = 1$ is often considered. Both these cost functions have the property that for free minimization subject only to the constraint

$$\sum_{k\in\mathcal{B}} |g_k|^2 = \text{Constant}, \tag{3.10}$$

they result in all g_k but one equal to zero. The corresponding maximization problem gives all $|g_k|$ equal. This indicates the ability to measure compression. However, for

best basis selection, the minimization is also constrained by the requirement that the coefficients of all different bases also must describe the same system.

A third cost function,

$$V(\mathcal{B},\tau)=\sum_{k\in\mathcal{B}}\min(|g_k|^2,\tau^2\sigma^2), \tag{3.11}$$

was suggested in [10]. This function is strongly connected to denoising by thresholding using the threshold level $\tau\sigma$, thus involving this parameter also in the best basis selection process. A more general form of (3.11) was suggested for speech denoising using wavelet packets in [3], where colored noise was taken into account.

The cost function (3.11) relates to the entropy cost and the ℓ^1-cost via the following result.

THEOREM 3.3. *Let $V_e(\mathcal{B})$, $V_1(\mathcal{B})$, and $V(\mathcal{B},\tau)$ be defined by* (3.8), (3.9), *and* (3.11), *respectively. Let*

$$C:=\sqrt{\sum_{k\in\mathcal{B}}|g_k|^2}, \tag{3.12}$$

which is constant for any choice of orthonormal basis. Then

$$V_e(\mathcal{B})=\int_0^{C/\sigma}V(\mathcal{B},\tau)\frac{d\tau}{\tau}-\frac{1}{2}C^2-C^2\log C \tag{3.13}$$

and

$$V_1(\mathcal{B})=\frac{1}{2\sigma}\int_0^{\infty}V(\mathcal{B},\tau)\frac{d\tau}{\tau^2}. \tag{3.14}$$

Proof. Integration of one term of $V(\mathcal{B})$ results in

$$\begin{aligned}
&\int_0^{C/\sigma}\min(|g_k|^2,\tau^2\sigma^2)\frac{d\tau}{\tau}=\sigma^2\int_0^{C/\sigma}\min\left(\frac{|g_k|^2}{\sigma^2},\tau^2\right)\frac{d\tau}{\tau}\\
&=\sigma^2\left\{\int_0^{|g_k|/\sigma}\tau^2\frac{d\tau}{\tau}+\int_{|g_k|/\sigma}^{C/\sigma}\frac{|g_k|^2}{\sigma^2}\frac{d\tau}{\tau}\right\}\\
&=\sigma^2\left\{\frac{1}{2}\frac{|g_k|^2}{\sigma^2}+\frac{|g_k|^2}{\sigma^2}\log\frac{C}{\sigma}-\frac{|g_k|^2}{\sigma^2}\log\frac{|g_k|}{\sigma}\right\}\\
&=\frac{1}{2}|g_k|^2+|g_k|^2\log C-|g_k|^2\log|g_k|.
\end{aligned} \tag{3.15}$$

Summation over $k\in\mathcal{B}$ of the left- and right-hand sides gives (3.13). Similarly,

$$\begin{aligned}
&\int_0^{\infty}\min(|g_k|^2,\tau^2\sigma^2)\frac{d\tau}{\tau^2}=\sigma^2\int_0^{\infty}\min\left(\frac{|g_k|^2}{\sigma^2},\tau^2\right)\frac{d\tau}{\tau^2}\\
&=\sigma^2\left\{\int_0^{|g_k|/\sigma}\tau^2\frac{d\tau}{\tau^2}+\int_{|g_k|/\sigma}^{\infty}\frac{|g_k|^2}{\sigma^2}\frac{d\tau}{\tau^2}\right\}=2\sigma|g_k|,
\end{aligned} \tag{3.16}$$

which via summation over $k\in\mathcal{B}$ results in (3.14). ∎

The theorem shows that the entropy and ℓ^1-cost in fact are weighted versions of (3.11), where the weight is taken (integrated) over many threshold levels.

The cost function (3.11) also has an interpretation in terms of rate distortion. If a signal is decomposed in the best basis according to this cost and reconstructed using only coefficients with a magnitude greater than τ, then the ℓ^2 reconstruction error is minimal over all bases in the library for any construction using the selected number of coefficients. See [26, 32].

The cost functions discussed above can now be used for selecting the best rational basis.

3.3. Selection scheme. In section 3.1, it was concluded that the number of bases that can be constructed from an array of all-pass filters in most cases is much larger than the number of basis functions forming these bases. Using wavelet packet terminology, there is a library of bases containing only a few different basis functions. This section provides a scheme for selecting the best among all possible bases in the library. The search is made in a complexity no larger than the number of different basis functions so that in this sense, the search can be called "fast."

In section 3.2, different criteria for best-basis selection were discussed. Which criterion to use is up to the user, but important for all these methods is that they describe compression so that a basis with the energy concentrated in few coefficients is selected. Supposing that the true system is well described by only a few coefficients in the finite-dimensional subspace $\mathcal{H}_n$ but that noise is present, a denoising scheme such as the one described in section 2.2 can be applied. This was suggested for orthonormal rational bases in [5]. Since only coefficients above the threshold level are kept, as few such coefficients as possible would give a smaller variance for the system estimate. This is a result of fewer parameters being estimated; see [22].

The selection criteria from wavelet packet basis selection presented in section 3.2 are directly applicable to the selection of the best orthonormal rational basis as well. The selection algorithm, however, becomes different. As for wavelet packets, it is crucial that the cost function be additive for the algorithm derived here. The following terminology will be used.

DEFINITION 3.4 (collection and word). *An m-collection is a set of m all-pass filters, where the filter $H_l(z)$ appears k_l times for $l = 1, \dots, p$. The m-collection is represented by the p-tuple*

$$(k_1, k_2, \dots, k_p), \qquad \text{where} \quad \sum_{l=1}^{p} k_l = m. \tag{3.17}$$

An m-word is an ordered m-collection.

The vector valued basis functions (3.2) are thus fully defined by the output filter together with a *collection* of preceding filters. A basis for $\mathcal{H}_n$, on the other hand, is defined by the *word* of all-pass filters constituting the array. With this terminology an algorithm for selection of the best basis can now be formulated. The algorithm is recursive: If the best m-word and its cost are known for each different m-collection, the best $(m+1)$-word and its cost can be calculated for all different $(m+1)$-collections. Formally, this can be written as follows.

ALGORITHM 3.5 (best basis selection). *The algorithm selects the best basis constructed from an array of n orthogonal all-pass filters. The given filters are $\{H_l(z)\}_{l=1}^{p}$ with multiplicities $\{\kappa_l\}_{l=1}^{p}$, where $n = \sum_{l=1}^{p} \kappa_l$. In other words, the output of the algorithm is the best n-word constructed from these filters.*

1. *If $m = 1$, all the best 1-words and their costs are trivial.*
2. *For all $(m+1)$-collections:*

(a) *For every l where $k_l \neq 0$ in the current $(m+1)$-collection: Construct the basis function having $H_l(z)$ as output filter preceded by the remaining m-collection. Calculate the cost of the expansion coefficient corresponding to each such basis function.*

(b) *For each basis function: Add its cost to the known best cost of the corresponding m-collection and select the best. The corresponding best $(m+1)$-word is given by the best m-word for the current m-collection with the selected output filter appended.*

3. *Terminate if $m = n-1$. Otherwise, increment m by one and return to step* 2.

The single n-word resulting from the algorithm will correspond to the globally optimal basis with respect to the chosen cost function. From the way the algorithm is constructed, it is important that the cost function be additive in the sense that the sum of the costs for two disjoint subsets of the coefficients is equal to the cost of the union of these two coefficient sets. This is fulfilled for all the cost functions considered in section 3.2. Additivity of the cost then implies that a suboptimal m-word cannot result in an optimal $(m+1)$-word, and in this way the resulting n-word has to be globally optimal. The number of steps for Algorithm 3.5 is given by the following theorem.

THEOREM 3.6 (algorithmic complexity). *The order of complexity of Algorithm* 3.5 *with respect to n and $\{\kappa_l\}_{l=1}^{p}$ is*

$$\sum_{l=1}^{p} \left[\kappa_l \prod_{\substack{m \neq l \\ m=1}}^{p} (\kappa_m + 1) \right], \tag{3.18}$$

which is the same as the number of basis functions given by Proposition 3.2.

Proof. The steps 2(a) and 2(b) of Algorithm 3.5 are performed once for each l having $k_l \neq 0$ in the current m-collection. Step 3.3 is performed once for each $(m+1)$-collection. These steps are repeated for $m = 1, \ldots, n-1$. The initial step takes p operations. In total this gives

$$\begin{aligned} p + \sum_{m=1}^{n-1} \left(\sum_{\substack{\forall (k_1,\ldots,k_p) \\ \sum k_l = m+1 \\ 0 \leq k_l \leq \kappa_l}} \left[\sum_{\substack{i=1 \\ k_i \neq 0}}^{p} 1 \right] \right) &= \sum_{\substack{i=1 \\ k_i \neq 0}}^{p} \left(\sum_{m=0}^{n-1} \left[\sum_{\substack{\forall (k_1,\ldots,k_p) \\ \sum k_l = m+1 \\ 0 \leq k_l \leq \kappa_l}} 1 \right] \right) \\ = \sum_{\substack{i=1 \\ k_i \neq 0}}^{p} \#\{(k_1, \ldots, k_p) | k_i \neq 0\} &= \sum_{l=1}^{p} \kappa_l \prod_{\substack{i=1 \\ i \neq l}}^{p} (1 + \kappa_i). \end{aligned} \tag{3.19}$$

∎

REMARK 3.7. *In the proof, the change of order of summation avoids using the number of $(m+1)$-collections. Due to the constraints imposed by the κ_l's, this number cannot be explicitly calculated. However, for given values of the κ_l's, the number of m-collections is the coefficient in front of x^m in the generating function $\prod_{l=1}^{p} \sum_{k=0}^{\kappa_l} x^k$.*

As will be shown in the next section, the $(m+1)$-collections can recursively be calculated from the m-collections without knowing in advance how many these are for a certain $m+1$. In this way, no search for the $(m+1)$-collections has to be made.

Theorem 3.6 shows that, as in the case of wavelet packet best basis selection, the number of algorithmic steps for selecting the best orthonormal rational basis is

the same as the number of different basis functions in all bases considered. The next section demonstrates how to recursively calculate m-collections and how to implement the algorithm.

3.4. Implementation. Algorithm 3.5, defined in section 3.3, performs the inner iteration once for each $(m+1)$-collection with respect to the multiplicities $\{\kappa_l\}_{l=1}^{p}$. The constraints imposed by the κ_l's result in difficulties in explicitly calculating all $(m+1)$-collections for a given m without having to search over all the collections with all different lengths. However, the following algorithm shows how all $(m+1)$-collections can be calculated recursively given all the m-collections.

ALGORITHM 3.8 (recursive collection generation). *Given all m-collections $(k_1, \ldots, k_p)$ with $0 \le k_l \le \kappa_l$ for $l = 1, \ldots, p$ so that $\sum_{l=1}^{p} k_l = m$, the following steps generate all $(m+1)$-collections.*

For each m-collection $(k_1, \ldots, k_p)$:

1. $l \leftarrow 0$
2. $l \leftarrow l + 1$
   (a) *If $k_l = 0$, increment k_l by 1 to generate an $(m+1)$-collection and repeat step 2 if $l < p$. Stop otherwise.*
   (b) *If $0 < k_l < \kappa_l$, increment k_l by 1 to generate an $(m+1)$-collection and stop.*
   (c) *Stop if $k_l = \kappa_l$.*

Proof. The following arguments show that the mapping performed by Algorithm 3.8 from all m-collections to the $(m+1)$-collections is onto: First of all, it is evident that if there is any output from the algorithm, it will be an $(m+1)$-collection, and the only time when there is no output is when $k_l = \kappa_l$ for all $l = 1, \ldots, p$. It then remains to show that any $(m+1)$-collection always comes from the algorithm: Take an arbitrary $(m+1)$-collection $(k_1, \ldots, k_p)$. If $k_1 > 0$, it comes from $(k_1 - 1, k_2, \ldots, k_p)$ via Algorithm 3.8. If $k_1 = 0$ and $k_2 > 0$, it comes from the m-collection $(0, k_2 - 1, k_3, \ldots, k_p)$ via the algorithm. If $k_1 = k_2 = 0$ and $k_3 > 0$ it comes from $(0, 0, k_3 - 1, \ldots, k_p)$, and so on. Thus, any $(m+1)$-collection was generated from the algorithm and the mapping is onto. This inversion also shows that no $(m+1)$-collection is produced more than once by the algorithm. Note here that, in step 2(a), the $l < p$ condition is only needed if $m = 0$. ∎

The algorithm above provides a fast way to recursively calculate collections with different number sums. For implementation of the best basis selection algorithm, it is also convenient to have some systematic addressing of the collections. This is to say that an integer must be assigned to each of the collections in a unique way. The total number of collections, or p-tuples $(k_1, \ldots, k_p)$, with $0 \le k_l \le \kappa_l$ for $l = 1, \ldots, p$ becomes $\prod_{l=1}^{p}(\kappa_l+1)$. Thus, the collections can be numbered from 0 to $\prod_{l=1}^{p}(\kappa_l+1)-1$ in the following way.

DEFINITION 3.9 (addressing). *Let $0 \le k \le \kappa_l$ for $l = 1, \ldots, p$ and denote a collection by*

$$\mathbf{c}_q = (k_1, \ldots, k_p), \tag{3.20}$$

where q is an integer in $\{0, 1, \ldots, \prod_{l=1}^{p}(\kappa_l + 1) - 1\}$, calculated as

$$q := \sum_{l=1}^{p} k_l \prod_{j=1}^{l-1}(1 + \kappa_j), \tag{3.21}$$

and where the product over no elements is defined as 1.

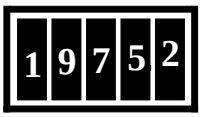

FIG. 3.2. *Counter.*

This way of numbering the collections is in fact a multibase representation with respect to the κ_l's. One interpretation of the numbering is that the collection $\mathbf{c}_q$ can be viewed as the qth number on the counter shown in Figure 3.2, where the lth wheel is numbered from 0 to κ_l. This is also quite the same as the numbering of time, where for example hours, days, and weeks all have different numbers of their respective subquantities minutes, hours, and days. The numbering and recursive collection calculation is demonstrated with the following example.

EXAMPLE 3.10. *Let* $p = 3$ *with* $\kappa_1 = 3$, $\kappa_2 = 1$, *and* $\kappa_3 = 2$. *The total number of collections is then* 24 *and with the addressing of Definition* 3.9, *they become*

$$
\begin{array}{lll}
\mathbf{c}_0 = (0,0,0), & \mathbf{c}_8 = (0,0,1), & \mathbf{c}_{16} = (0,0,2),\\
\mathbf{c}_1 = (1,0,0), & \mathbf{c}_9 = (1,0,1), & \mathbf{c}_{17} = (1,0,2),\\
\mathbf{c}_2 = (2,0,0), & \mathbf{c}_{10} = (2,0,1), & \mathbf{c}_{18} = (2,0,2),\\
\mathbf{c}_3 = (3,0,0), & \mathbf{c}_{11} = (3,0,1), & \mathbf{c}_{19} = (3,0,2),\\
\mathbf{c}_4 = (0,1,0), & \mathbf{c}_{12} = (0,1,1), & \mathbf{c}_{20} = (0,1,2),\\
\mathbf{c}_5 = (1,1,0), & \mathbf{c}_{13} = (1,1,1), & \mathbf{c}_{21} = (1,1,2),\\
\mathbf{c}_6 = (2,1,0), & \mathbf{c}_{14} = (2,1,1), & \mathbf{c}_{22} = (2,1,2),\\
\mathbf{c}_7 = (3,1,0), & \mathbf{c}_{15} = (3,1,1), & \mathbf{c}_{23} = (3,1,2).
\end{array}
\tag{3.22}
$$

The recursion of Algorithm 3.8 *can be cranked with the trivial collection* $\mathbf{c}_0$. *This gives*

$m=0$	$m=1$	$m=2$	$m=3$	$m=4$	$m=5$	$m=6$
$\mathbf{c}_0$	$\mathbf{c}_1$	$\mathbf{c}_2$	$\mathbf{c}_3$	$\mathbf{c}_7$	$\mathbf{c}_{15}$	$\mathbf{c}_{23}$
	$\mathbf{c}_4$	$\mathbf{c}_5$	$\mathbf{c}_6$	$\mathbf{c}_{11}$	$\mathbf{c}_{19}$	
	$\mathbf{c}_8$	$\mathbf{c}_9$	$\mathbf{c}_{10}$	$\mathbf{c}_{14}$	$\mathbf{c}_{22}$	
		$\mathbf{c}_{12}$	$\mathbf{c}_{13}$	$\mathbf{c}_{18}$		
		$\mathbf{c}_{16}$	$\mathbf{c}_{17}$	$\mathbf{c}_{21}$		
			$\mathbf{c}_{20}$			

(3.23)

It is easily checked that in each column of (3.23), *the collections have the same number sum* $\sum_{k=1}^{3} k_l$.

The addressing of Definition 3.9 gives a convenient representation of the collections when implementing Algorithm 3.5. In step 2 of this algorithm, the $(m+1)$-collections are recursively calculated using Algorithm 3.8. In step 2(a), the remaining m-collection for the current l is obtained by reducing the current k_l with 1 from the current $(m+1)$-collection. Using the addressing of Definition 3.9, this reduction can be made directly simply by subtracting $\prod_{j=1}^{l-1}(1+\kappa_j)$ from the address of the current $(m+1)$-collection. This results in the address to the corresponding m-collection. The subtracted products are found as the addresses for $m = 1$. In this way, the collections will not have to be explicitly represented by anything other than the addresses. In step 2(a), $k_l \neq 0$ can be checked for the addresses by successively dividing by the κ_l's in order to examine if these are contained as factors in the remainder of the current $(m+1)$-collection. This is shown in more detail in Appendix A. For example (from

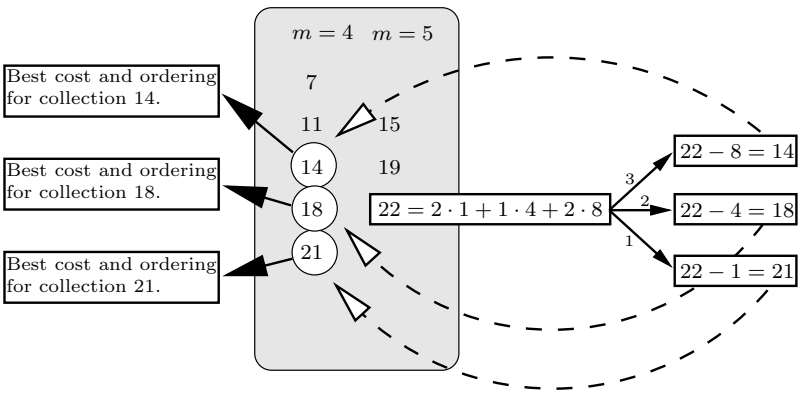

FIG. 3.3. *Addressing in Algorithm* 3.5.

Example 3.10 above), by subtracting 1, 4, and 8 respectively, the address 22 with number sum $m = 5$ will then directly point to the addresses 21, 18, and 14, all having number sums $m = 4$. This is illustrated in Figure 3.3.

Several implementation aspects were treated in this section, which concludes the derivation of a best basis selection scheme. The following section provides a way to calculate the expansion coefficients associated with each of the different basis functions. These coefficients are the essential input to Algorithm 3.5.

4. Decomposition. The expansion coefficients of a system can be obtained using system identification as described in section 2.2. This results in the coefficients for only one fixed basis. The selection scheme derived in section 3, however, needs the coefficients for all possible basis functions. In this section, an algorithm is given that uses the expansion coefficients in one single basis in order to produce all the coefficients needed for the best basis selection scheme. The algorithm uses local block two-by-two orthogonal matrix transformations and has the same complexity as the best basis selection scheme of section 3.

The local orthogonal transformations are derived in section 4.1 where a method is also given for generating coefficients in the case where all the all-pass filters are different from each other. The latter is provided for understanding of the general coefficient-generation scheme presented in section 4.2.

4.1. Calculating coefficients by orthonormal transformations. Suppose that the expansion coefficients are given in one basis. This can be achieved with the system-identification approach presented in section 2.2. Then, there is an orthonormal, and thus well-conditioned, matrix transformation of these coefficients to the coefficients of any other possible basis. Using the inherent recursive structure of the rational basis functions, this orthonormal transformation can be decomposed into local (block) two-by-two orthonormal transformations.

Given a family of different all-pass filters $\{H_k\}_{k=1}^n$, the basis functions for an ordering $\{l_k\}_{k=1}^n$ of the filters can then be written as in (3.2). Consider two basis functions of consecutive order

$$\Psi_k(z) = \Phi_{l_k}(z) \prod_{i=1}^{k-1} H_{l_i}(z), \tag{4.1}$$

$$\Psi_{k+1}(z) = \Phi_{l_{k+1}}(z) H_{l_k}(z) \prod_{i=1}^{k-1} H_{l_i}(z). \tag{4.2}$$

By interchanging the order of the output filter of $\Psi_k(z)$ and the output filter of $\Psi_{k+1}(z)$, two basis functions of a basis defined by another ordering are obtained. The functions can be written

$$\tilde{\Psi}_k(z) = \Phi_{l_{k+1}}(z) \prod_{i=1}^{k-1} H_{l_i}(z), \tag{4.3}$$

$$\tilde{\Psi}_{k+1}(z) = \Phi_{l_k}(z) H_{l_{k+1}}(z) \prod_{i=1}^{k-1} H_{l_i}(z). \tag{4.4}$$

The two pairs of functions relate via the linear transformation $\mathbf{T}(l_k, l_{k+1})$ as

$$\begin{bmatrix} \Psi_k(z) \\ \Psi_{k+1}(z) \end{bmatrix} = \mathbf{T}(l_k, l_{k+1}) \begin{bmatrix} \tilde{\Psi}_k(z) \\ \tilde{\Psi}_{k+1}(z) \end{bmatrix}. \tag{4.5}$$

Denote the outer product between two column vector valued functions $\Phi_j(z)$ and $\Phi_k(z)$ with possibly different dimension by

$$\langle \Phi_j, \Phi_k \rangle := \frac{1}{2\pi} \int_{-\pi}^{\pi} \Phi_j(e^{i\omega}) \left[\Phi_k(e^{i\omega})\right]^H d\omega, \tag{4.6}$$

where H denotes transposition and complex conjugation. Then, from the orthonormality of the basis functions, the transformation matrix $\mathbf{T}$ becomes

$$\mathbf{T}(l_k, l_{k+1}) = \begin{bmatrix} \langle \Psi_k, \tilde{\Psi}_k \rangle & \langle \Psi_k, \tilde{\Psi}_{k+1} \rangle \\ \langle \Psi_{k+1}, \tilde{\Psi}_k \rangle & \langle \Psi_{k+1}, \tilde{\Psi}_{k+1} \rangle \end{bmatrix}, \tag{4.7}$$

and since all the four basis functions have the common factor $\prod_{i=1}^{k-1} H_{l_i}$, T can be rewritten as

$$\mathbf{T}(l_k, l_{k+1}) = \begin{bmatrix} \langle \Phi_{l_k}, \Phi_{l_{k+1}} \rangle & \langle \Phi_{l_k}, \Phi_{l_k} H_{l_{k+1}} \rangle \\ \langle \Phi_{l_{k+1}} H_{l_k}, \Phi_{l_{k+1}} \rangle & \langle \Phi_{l_{k+1}} H_{l_k}, \Phi_{l_k} H_{l_{k+1}} \rangle \end{bmatrix}. \tag{4.8}$$

Rewriting (4.7) as (4.8) is crucial for the existence of a fast coefficient transformation scheme. Let $\mathbf{T}(j,k)$ be partitioned into blocks as

$$\mathbf{T}(j,k) = \begin{bmatrix} \mathbf{t}_{11}(j,k) & \mathbf{t}_{12}(j,k) \\ \mathbf{t}_{21}(j,k) & \mathbf{t}_{22}(j,k) \end{bmatrix}, \tag{4.9}$$

where the four blocks, given by

$$\mathbf{t}_{11}(j,k) = \langle \Phi_j, \Phi_k \rangle, \tag{4.10}$$

$$\mathbf{t}_{12}(j,k) = \langle \Phi_j, \Phi_j H_k \rangle, \tag{4.11}$$

$$\mathbf{t}_{21}(j,k) = \langle \Phi_k H_j, \Phi_k \rangle, \tag{4.12}$$

$$\mathbf{t}_{22}(j,k) = \langle \Phi_k H_j, \Phi_j H_k \rangle, \tag{4.13}$$

are orthonormal, i.e., the matrix satisfies $\mathbf{T}(j,k)\mathbf{T}^T(j,k) = \mathbf{I}$. (This is shown in Appendix B, where the orthonormality follows because the two pairs of orthonormal functions $\{\Phi_j, \Phi_k H_j\}$ and $\{\Phi_k, \Phi_j H_k\}$ have the same span.)

The transformation matrix $\mathbf{T}$ can be calculated as the solution of a Lyapunov-like equation. Define

$$\mathbf{X}_{j,k}(z) := \begin{bmatrix} \Phi_j(z) \\ \Phi_k(z) H_j(z) \end{bmatrix} \tag{4.14}$$

so that $\mathbf{T}(j,k) = \langle \mathbf{X}_{j,k}, \mathbf{X}_{k,j} \rangle$. Let $H_j(z)$ and $H_k(z)$ have the state-space realizations $(\mathbf{A}_j, \mathbf{B}_j, \mathbf{C}_j, D_j)$ and $(\mathbf{A}_k, \mathbf{B}_k, \mathbf{C}_k, D_k)$ respectively. From (2.15), $\mathbf{X}_{j,k}(z)$ has the (balanced) state-space realization

$$(\mathbf{A}_{j,k}, \mathbf{B}_{j,k}) = \left(\begin{bmatrix} \mathbf{A}_j & \mathbf{0} \\ \mathbf{B}_k \mathbf{C}_j & \mathbf{A}_k \end{bmatrix}, \begin{bmatrix} \mathbf{B}_j \\ \mathbf{B}_k D_j \end{bmatrix} \right). \tag{4.15}$$

In this way, $\mathbf{T}(j,k)$ can be written

$$\begin{aligned} \mathbf{T}(j,k) &= \langle \mathbf{X}_{j,k}, \mathbf{X}_{k,j} \rangle \\ &= \frac{1}{2\pi} \int_{-\pi}^{\pi} \left(\mathbf{I} e^{i\omega} - \mathbf{A}_{j,k} \right)^{-1} \mathbf{B}_{j,k} \left[\left(\mathbf{I} e^{-i\omega} - \mathbf{A}_{k,j} \right)^{-1} \mathbf{B}_{k,j} \right]^T d\omega \\ &= \sum_{n=0}^{\infty} \sum_{m=0}^{\infty} \mathbf{A}_{j,k}^n \mathbf{B}_{j,k} \left\{ \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{-i\omega(n-m)} d\omega \right\} \mathbf{B}_{k,j}^T (\mathbf{A}_{k,j}^T)^m \\ &= \sum_{n=0}^{\infty} \mathbf{A}_{j,k}^n \mathbf{B}_{j,k} \mathbf{B}_{k,j}^T (\mathbf{A}_{k,j}^T)^n, \end{aligned} \tag{4.16}$$

which solves the equation

$$\mathbf{A}_{j,k} \mathbf{T}(j,k) \mathbf{A}_{k,j}^T + \mathbf{B}_{j,k} \mathbf{B}_{k,j}^T = \mathbf{T}(j,k). \tag{4.17}$$

As shown in Appendix C, this equation can easily be transformed into a Sylvester equation using bilinear transformations. This equation can then be solved with standard methods. Such equations are often used in feedback design of large-scale multivariable systems; see, e.g., [29].

In terms of the block components of $\mathbf{T}(j,k)$, this equation can be divided into the four coupled matrix equations

$$\mathbf{t}_{11} = \mathbf{A}_j \mathbf{t}_{11} \mathbf{A}_k^T + \mathbf{B}_j \mathbf{B}_k^T, \tag{4.18}$$

$$\mathbf{t}_{12} = \mathbf{A}_j \mathbf{t}_{11} \mathbf{C}_k^T \mathbf{B}_j^T + \mathbf{A}_j \mathbf{t}_{12} \mathbf{A}_j^T + \mathbf{B}_j D_k \mathbf{B}_j^T, \tag{4.19}$$

$$\mathbf{t}_{21} = \mathbf{B}_k \mathbf{C}_j \mathbf{t}_{11} \mathbf{A}_k^T + \mathbf{A}_k \mathbf{t}_{21} \mathbf{A}_k^T + \mathbf{B}_k D_j \mathbf{B}_k^T, \tag{4.20}$$

$$\begin{aligned} \mathbf{t}_{22} &= \mathbf{B}_k \mathbf{C}_j \mathbf{t}_{11} \mathbf{C}_k^T \mathbf{B}_j^T + \mathbf{B}_k \mathbf{C}_j \mathbf{t}_{12} \mathbf{A}_j^T \\ &\quad + \mathbf{A}_k \mathbf{t}_{21} \mathbf{C}_k^T \mathbf{B}_j^T + \mathbf{A}_k \mathbf{t}_{22} \mathbf{A}_j^T + \mathbf{B}_k D_j D_k \mathbf{B}_j^T, \end{aligned} \tag{4.21}$$

where the argument (j,k) of $\mathbf{t}_{11}$, $\mathbf{t}_{12}$, $\mathbf{t}_{21}$, and $\mathbf{t}_{22}$ was suppressed. The equations can either be solved "top-down" due to their triangular structure or as the total solution to (4.17). The following gives an example of a transformation matrix $\mathbf{T}(j,k)$.

EXAMPLE 4.1 (generalized Laguerre functions). *The generalized Laguerre functions with real poles*

$$\psi_k(z) = \frac{\sqrt{1-a_k^2}}{z - a_k} \prod_{j=1}^{k-1} \frac{1 - a_j z}{z - a_j}, \qquad k = 1, 2, \ldots, \tag{4.22}$$

are obtained from an array built of different first order all-pass filters. The transformation matrix (4.8) *becomes*

$$\mathbf{T}(j,k) = \frac{1}{1-a_j a_k}\begin{bmatrix} \sqrt{1-a_j^2}\sqrt{1-a_k^2} & a_j - a_k \\ a_k - a_j & \sqrt{1-a_j^2}\sqrt{1-a_k^2} \end{bmatrix}. \tag{4.23}$$

Suppose now that $\Psi_k(z)$ and $\Psi_{k+1}(z)$, defined by (4.1), have the respective expansion coefficients $\mathbf{g}_k$ and $\mathbf{g}_{k+1}$. Using (4.5), the expansion coefficients associated with the basis functions $\tilde{\Psi}_k(z)$ and $\tilde{\Psi}_{k+1}(z)$ are then given by

$$\begin{bmatrix} \tilde{\mathbf{g}}_k \\ \tilde{\mathbf{g}}_{k+1} \end{bmatrix} = \mathbf{T}^T(l_k, l_{k+1}) \begin{bmatrix} \mathbf{g}_k \\ \mathbf{g}_{k+1} \end{bmatrix}. \tag{4.24}$$

In this way, given the expansion coefficients of a pair of functions in one basis, the expansion coefficients for the functions obtained from alternating the two last all-pass filters can be obtained by a block two-by-two transformation. The question is whether the coefficients of all possible basis functions can be reached by repeating such transformations. Next, it will be shown that this is the case, but in order to facilitate the description, a more compact notation for the expansion coefficients will be introduced.

DEFINITION 4.2 (expansion-coefficient notation). *Given a family of different all-pass filters* $\{H_k(z)\}_{k=1}^n$, *an expansion coefficient associated with a basis function constructed from these filters can then be denoted by* $\mathbf{g}(p,k)$, *where* p *denotes the address to the subset of preceding all-pass filters and* k *is the number associated with the output filter. The addressing is performed as in Definition* 3.9, *which in the case where all the filters are different reduces to*

$$p = \sum_{l=1}^{n} d_l 2^{l-1}, \tag{4.25}$$

where d_l *is either* 1 *or* 0 *denoting whether or not the filter* $H_l(z)$ *is included in the set. The output filter* $H_k(z)$ *cannot belong to the subset* p.

Before introducing the scheme for calculating all the coefficients, the idea for coefficient generation will be illustrated with an example.

EXAMPLE 4.3 (coefficient generation). *Suppose that all coefficients belonging to functions generated from the filters* $H_1(z)$, $H_2(z)$, *and* $H_3(z)$ *are known. Suppose also that* $\mathbf{g}(\{1,2,3\},4)$ *is known. Here, the subset address is replaced by the subset itself in order to make the description easier to follow. To start with, all the coefficients generated from arrays of maximum length* 4 *become*

$$\begin{aligned}
\mathbf{g}(\{1,2,4\},3) &= \begin{bmatrix} \mathbf{t}_{12}^T & \mathbf{t}_{22}^T \end{bmatrix} \begin{bmatrix} \mathbf{g}(\{1,2\},3) \\ \mathbf{g}(\{1,2,3\},4) \end{bmatrix}, \\
\mathbf{g}(\{1,3,4\},2) &= \begin{bmatrix} \mathbf{t}_{12}^T & \mathbf{t}_{22}^T \end{bmatrix} \begin{bmatrix} \mathbf{g}(\{1,3\},2) \\ \mathbf{g}(\{1,2,3\},4) \end{bmatrix}, \\
\mathbf{g}(\{2,3,4\},1) &= \begin{bmatrix} \mathbf{t}_{12}^T & \mathbf{t}_{22}^T \end{bmatrix} \begin{bmatrix} \mathbf{g}(\{2,3\},1) \\ \mathbf{g}(\{1,2,3\},4) \end{bmatrix}, \\
\mathbf{g}(\{1,2\},4) &= \begin{bmatrix} \mathbf{t}_{11}^T & \mathbf{t}_{21}^T \end{bmatrix} \begin{bmatrix} \mathbf{g}(\{1,2\},3) \\ \mathbf{g}(\{1,2,3\},4) \end{bmatrix},
\end{aligned}$$

$$\mathbf{g}(\{1,3\},4) = \begin{bmatrix}\mathbf{t}_{11}^T & \mathbf{t}_{21}^T\end{bmatrix}\begin{bmatrix}\mathbf{g}(\{1,3\},2)\\ \mathbf{g}(\{1,2,3\},4)\end{bmatrix},$$

$$\mathbf{g}(\{2,3\},4) = \begin{bmatrix}\mathbf{t}_{11}^T & \mathbf{t}_{21}^T\end{bmatrix}\begin{bmatrix}\mathbf{g}(\{2,3\},1)\\ \mathbf{g}(\{1,2,3\},4)\end{bmatrix}.$$

*Next, coefficients coming from length-*3 *arrays are produced by*

$$\mathbf{g}(\{1,4\},2) = \begin{bmatrix}\mathbf{t}_{12}^T & \mathbf{t}_{22}^T\end{bmatrix}\begin{bmatrix}\mathbf{g}(\{1\},2)\\ \mathbf{g}(\{1,2\},4)\end{bmatrix},$$

$$\mathbf{g}(\{2,4\},1) = \begin{bmatrix}\mathbf{t}_{12}^T & \mathbf{t}_{22}^T\end{bmatrix}\begin{bmatrix}\mathbf{g}(\{2\},1)\\ \mathbf{g}(\{1,2\},4)\end{bmatrix},$$

$$\mathbf{g}(\{1,4\},3) = \begin{bmatrix}\mathbf{t}_{12}^T & \mathbf{t}_{22}^T\end{bmatrix}\begin{bmatrix}\mathbf{g}(\{1\},3)\\ \mathbf{g}(\{1,3\},4)\end{bmatrix},$$

$$\mathbf{g}(\{3,4\},1) = \begin{bmatrix}\mathbf{t}_{12}^T & \mathbf{t}_{22}^T\end{bmatrix}\begin{bmatrix}\mathbf{g}(\{3\},1)\\ \mathbf{g}(\{1,3\},4)\end{bmatrix},$$

$$\mathbf{g}(\{2,4\},3) = \begin{bmatrix}\mathbf{t}_{12}^T & \mathbf{t}_{22}^T\end{bmatrix}\begin{bmatrix}\mathbf{g}(\{2\},3)\\ \mathbf{g}(\{2,3\},4)\end{bmatrix},$$

$$\mathbf{g}(\{3,4\},2) = \begin{bmatrix}\mathbf{t}_{12}^T & \mathbf{t}_{22}^T\end{bmatrix}\begin{bmatrix}\mathbf{g}(\{3\},2)\\ \mathbf{g}(\{2,3\},4)\end{bmatrix},$$

$$\mathbf{g}(\{1\},4) = \begin{bmatrix}\mathbf{t}_{11}^T & \mathbf{t}_{21}^T\end{bmatrix}\begin{bmatrix}\mathbf{g}(\{1\},2)\\ \mathbf{g}(\{1,2\},4)\end{bmatrix},$$

$$\mathbf{g}(\{2\},4) = \begin{bmatrix}\mathbf{t}_{11}^T & \mathbf{t}_{21}^T\end{bmatrix}\begin{bmatrix}\mathbf{g}(\{2\},3)\\ \mathbf{g}(\{2,3\},4)\end{bmatrix},$$

$$\mathbf{g}(\{3\},4) = \begin{bmatrix}\mathbf{t}_{11}^T & \mathbf{t}_{21}^T\end{bmatrix}\begin{bmatrix}\mathbf{g}(\{3\},1)\\ \mathbf{g}(\{1,3\},4)\end{bmatrix}.$$

*Finally, the length-*2 *arrays give the coefficients*

$$\mathbf{g}(\{4\},1) = \begin{bmatrix}\mathbf{t}_{12}^T & \mathbf{t}_{22}^T\end{bmatrix}\begin{bmatrix}\mathbf{g}(\{\emptyset\},1)\\ \mathbf{g}(\{1\},4)\end{bmatrix},$$

$$\mathbf{g}(\{4\},2) = \begin{bmatrix}\mathbf{t}_{12}^T & \mathbf{t}_{22}^T\end{bmatrix}\begin{bmatrix}\mathbf{g}(\{\emptyset\},2)\\ \mathbf{g}(\{2\},4)\end{bmatrix},$$

$$\mathbf{g}(\{4\},3) = \begin{bmatrix}\mathbf{t}_{12}^T & \mathbf{t}_{22}^T\end{bmatrix}\begin{bmatrix}\mathbf{g}(\{\emptyset\},3)\\ \mathbf{g}(\{3\},4)\end{bmatrix},$$

$$\mathbf{g}(\{\emptyset\},4) = \begin{bmatrix}\mathbf{t}_{11}^T & \mathbf{t}_{21}^T\end{bmatrix}\begin{bmatrix}\mathbf{g}(\{\emptyset\},1)\\ \mathbf{g}(\{1\},4)\end{bmatrix}.$$

The reason the total $\mathbf{T}$ *is not used in the transforms is to avoid too many coefficients being generated. Note that above,* $\begin{bmatrix}\mathbf{t}_{11}^T & \mathbf{t}_{21}^T\end{bmatrix}$ *is used fewer times than* $\begin{bmatrix}\mathbf{t}_{12}^T & \mathbf{t}_{22}^T\end{bmatrix}$. *The number of coefficients known is* $3 \cdot 2^2 + 1 = 13$ *and the total number of coefficients associated with* 4 *filters is* $4 \cdot 2^3 = 32$. *In the example,* 19 *coefficients were generated, which is exactly the difference.*

It is now possible to formulate a coefficient generation scheme for the case where the all-pass filters are different. Assume as in the example above that all the coefficients associated with basis functions constructed from the filters $H_1(z), \ldots, H_{m-1}(z)$ are known. Furthermore, assume that $\mathbf{g}(2^{m-1}-1, m)$ also is known. Then, the rest of the coefficients associated with the basis functions constructed from the filters $H_1(z), \ldots, H_m(z)$ are generated by the following algorithm.

ALGORITHM 4.4 (recursive step for coefficient generation).

1. *Let* $l = m - 1$.
2. *For all possible* l*-collections* p_l *that can be constructed from the all-pass filters* $H_1(z), \ldots, H_{m-1}(z)$, *let*

$$\mathbf{g}(p_l - 2^{k-1} + 2^{m-1}, k) = \begin{bmatrix}\mathbf{t}_{12}^T(k,m) & \mathbf{t}_{22}^T(k,m)\end{bmatrix}\begin{bmatrix}\mathbf{g}(p_l - 2^{k-1}, k)\\ \mathbf{g}(p_l, m)\end{bmatrix}$$

for all k in the current l-collection.

3. *For all possible $(l-1)$-collections p_{l-1} that can be constructed from the all-pass filters $H_1(z), \ldots, H_{m-1}(z)$: Pick one k such that $H_k(z)$ does not belong to the current $(l-1)$-collection and let*

$$\mathbf{g}(p_{l-1}, m) = \begin{bmatrix} \mathbf{t}_{11}^T(k,m) & \mathbf{t}_{21}^T(k,m) \end{bmatrix} \begin{bmatrix} \mathbf{g}(p_{l-1}, k) \\ \mathbf{g}(p_{l-1} + 2^{k-1}, m) \end{bmatrix}.$$

4. *Terminate if $l = 1$, decrease l by 1 otherwise, and go to step 2.*

The following theorem guarantees that all coefficients can be generated given the coefficients for one basis.

THEOREM 4.5 (coefficient generation). *Given the coefficients $\mathbf{g}(2^{m-1}-1, m)$, $m = 1, \ldots, n$ of the canonical basis, all the other $n2^{n-1} - n$ coefficients are generated by performing Algorithm 4.4 recursively for $m = 1, \ldots, n$.*

Proof. Steps 2 and 3 of Algorithm 4.4 trivially generate coefficients not known before. It then remains to check that the number of coefficients generated equals $n2^{n-1} - n$. Step 2 is performed $\binom{m-1}{l} l$ times while step 4.4 is performed $\binom{m-1}{l-1}$ times. Thus for fixed m, Algorithm 4.4 generates

$$\sum_{l=1}^{m-1} \binom{m-1}{l} l + \binom{m-1}{l-1} = (m-1)2^{m-2} + 2^{m-1} - 1 \tag{4.26}$$

coefficients. Then, the algorithm is performed for $m = 1, \ldots, n$ so that the total number of coefficients produced becomes

$$\sum_{m=1}^{n} (m-1)2^{m-2} + 2^{m-1} - 1 = n2^{n-1} - n, \tag{4.27}$$

which is exactly the number of coefficients needed. ∎

The following section extends the coefficient generation procedure to cover the general rational basis case.

4.2. General coefficient calculation. Using the same two-by-two transformations as in the previous section, the coefficient generation scheme can now be derived for the general basis case where the all-pass filters can have multiplicities.

Given a family of all-pass filters $\{H_l\}_{l=1}^p$ with balanced realizations and multiplicities $\{\kappa_l\}_{l=1}^p$ denoting that each filter $H_l(z)$ appears κ_l times, the total number of filters is $n := \sum_{l=1}^p \kappa_l$. As in the previous section, denote an expansion coefficient $\mathbf{g}(\beta, l)$, meaning that the output filter in the corresponding basis function is $H_l(z)$ and that the filter is preceded by the collection of filters with address β. The addressing of the collections of filters is performed as suggested in Definition 3.9.

Suppose now that the expansion coefficients

$$\mathbf{g}(\beta_k, l_k), \qquad k = 1, \ldots, n, \tag{4.28}$$

for one basis are given. The basis is defined by the ordering $\{l_k\}_{k=1}^n$ of the filters in the array. In this way, β_k is a $(k-1)$-collection. The first collection will have the address $\beta_1 = 0$ and the other addresses are given by

$$\beta_{k+1} = \beta_k + \prod_{j=1}^{l_k - 1} (\kappa_j + 1), \qquad k = 1, \ldots, (n-1). \tag{4.29}$$

The following algorithm is now suggested for generating all the other coefficients that are obtained by rearranging the array of all-pass filters in all possible different ways.

ALGORITHM 4.6 (general coefficient generation). *Given the expansion coefficients for one basis, as described above, repeat the following steps for* $m = 2, \dots, n$*:*

1. *Let* $k \leftarrow m-1$ *and* $a_1 \leftarrow \beta_m$.
2. *For each* a_j*:*
   - *For every different* $H_l(z)$ *in the collection represented by* a_j *except for the filter* $H_{l_m}(z)$*:*

   (a) *Let*

$$\mathbf{g}\left(a_j - \prod_{i=1}^{l-1}(\kappa_i+1) + \prod_{i=1}^{l_m-1}(\kappa_i+1), l\right) = \begin{bmatrix}\mathbf{t}_{12}^T(l,l_m) & \mathbf{t}_{22}^T(l,l_m)\end{bmatrix}\begin{bmatrix}\mathbf{g}(a_j - \prod_{i=1}^{l-1}(\kappa_i+1), l) \\ \mathbf{g}(a_j, l_m)\end{bmatrix}. \tag{4.30}$$

   (b) *Let* $\tilde{a}_{j,l} \leftarrow a_j - \prod_{i=1}^{l-1}(\kappa_i+1)$.
3. *Delete all* a_j *and assign a new* $a_{j'} \leftarrow \tilde{a}_{j,l}$ *for each unique* $\tilde{a}_{j,l}$.
4. *For each* a_j*, pick one* $H_l(z)$ *from the collection represented by* $\beta_m - a_j$ *and let*

$$\mathbf{g}(a_j, l_m) = \begin{bmatrix}\mathbf{t}_{11}^T(l,l_m) & \mathbf{t}_{21}^T(l,l_m)\end{bmatrix}\begin{bmatrix}\mathbf{g}(a_j, l) \\ \mathbf{g}(a_j + \prod_{i=1}^{l-1}(\kappa_i+1), l_m)\end{bmatrix}. \tag{4.31}$$

5. *Terminate if* $k = 1$*, decrease* k *by* 1 *otherwise, delete all* $\tilde{a}_{j,l}$*, and go to step* 2.

Before the algorithm is proved, a couple of examples of how it is executed will be given. A different number of steps is performed for each m depending on the initially given ordering of the all-pass filters.

EXAMPLE 4.7 (general coefficient generation). *Let* $p = 3$ *and let* $\kappa_1 = 3$, $\kappa_2 = 1$, *and* $\kappa_3 = 2$. *The case is the same as in Example* 3.10. *Two different initial orderings will be examined in order to demonstrate how the algorithm executes for different cases. First, let the given basis be defined by the ordering*

$$\begin{pmatrix} l_1 & l_2 & l_3 & l_4 & l_5 & l_6 \end{pmatrix} = \begin{pmatrix} 1 & 1 & 1 & 2 & 3 & 3 \end{pmatrix}. \tag{4.32}$$

Then, Algorithm 4.6 *produces*

(0 0 0):1	(1 0 0):1	(2 0 0):1	(3 0 0):2	(3 1 0):3	(3 1 1):3
(0 0 0):2 (6)	(1 0 0):2 (4)	(2 0 0):2 (2)	(2 1 0):1 (1)	(2 1 1):1 (7)	(2 1 2):1 (24)
(0 0 0):3 (23)	(0 1 0):1 (5)	(1 1 0):1 (3)	(2 1 0):3 (9)	(3 0 1):2 (8)	(3 0 2):2 (25)
	(0 1 0):3 (19)	(1 1 0):3 (14)	(3 0 0):3 (10)	(2 1 1):3 (26)	
	(1 0 0):3 (20)	(2 0 0):3 (15)	(1 1 1):1 (11)	(3 0 1):3 (27)	
	(0 0 1):2 (21)	(0 1 1):1 (16)	(2 0 1):2 (12)	(1 1 2):1 (28)	
	(0 0 1):1 (22)	(1 0 1):2 (17)	(2 0 1):1 (13)	(2 0 2):2 (29)	
	(0 0 1):3 (40)	(1 0 1):1 (18)	(1 1 1):3 (31)	(2 0 2):1 (30)	
		(0 1 1):3 (36)	(2 0 1):3 (32)		
		(1 0 1):3 (37)	(0 1 2):1 (33)		
		(0 0 2):2 (38)	(1 0 2):2 (34)		
		(0 0 2):1 (39)	(1 0 2):1 (35)		

where the entries

$$(k_1\ k_2\ k_3) : l\ (\ j) \tag{4.33}$$

denote a coefficient for the basis function with l *as output filter, preceded by* k_i *filters* $H_i(z)$, $i = 1, 2, 3$. *The number* j *denotes that the entry is the* j*th coefficient generated by the algorithm. Grey-shaded entries are generated in step* 4 *of the algorithm while the nonshaded are produced in step* 2(a).

Let now the initially known coefficients be defined by the ordering

$$\begin{pmatrix} l_1 & l_2 & l_3 & l_4 & l_5 & l_6 \end{pmatrix} = \begin{pmatrix} 1 & 2 & 3 & 1 & 3 & 1 \end{pmatrix}. \tag{4.34}$$

The algorithm then executes as

(0 0 0):1	(1 0 0):2	(1 1 0):3	(1 1 1):1	(2 1 1):3	(2 1 2):1
(0 0 0):2 (2)	(0 1 0):1 (1)	(0 1 1):1 (3)	(2 0 1):2 (10)	(1 1 2):1 (17)	(3 0 2):2 (29)
(0 0 0):3 (9)	(0 1 0):3 (5)	(1 0 1):2 (4)	(2 1 0):3 (11)	(2 0 2):2 (18)	(3 1 1):3 (30)
	(1 0 0):3 (6)	(1 0 1):1 (12)	(1 1 1):3 (19)	(2 0 2):1 (31)	
	(0 0 1):2 (7)	(1 1 0):1 (13)	(2 0 1):3 (20)	(2 1 1):1 (32)	
	(0 0 1):1 (8)	(2 0 0):3 (14)	(0 1 2):1 (21)	(3 0 1):3 (33)	
	(1 0 0):1 (16)	(2 0 0):2 (15)	(1 0 2):2 (22)	(3 0 1):2 (34)	
	(0 0 1):3 (28)	(0 1 1):3 (24)	(1 0 2):1 (23)	(3 1 0):3 (35)	
		(1 0 1):3 (25)	(2 0 1):1 (36)		
		(0 0 2):2 (26)	(2 1 0):1 (37)		
		(0 0 2):1 (27)	(3 0 0):3 (38)		
		(2 0 0):1 (40)	(3 0 0):2 (39)		

which corresponds to a different execution pattern. In both cases, all 40 *coefficients are generated given the* 6 *coefficients in one basis. From Proposition* 3.2, *this is exactly the number of different basis functions in all the bases that can be constructed from the* 6 *all-pass filters.*

With the example above in mind, Algorithm 4.6 can now be proved.

Proof. Consider a fixed m in step 1 of the algorithm and suppose that all the coefficients in the previous steps have been calculated. Say now that the collection with address β_m has k_l filters $H_l(z)$, $l = 1, \ldots, p$. Then for fixed m, l_m is added to this collection. The new coefficients to be calculated will then be those based on exactly $k_{l_m} + 1$ filters $H_{l_m}(z)$, where the output filter also is counted. These can be divided into three parts:

(i) The new known coefficient $\mathbf{g}(\beta_m, l_m)$.
(ii) All the other $\mathbf{g}(a, l_m)$ where the collection a has k_{l_m} filters $H_{l_m}(z)$.
(iii) All coefficients $\mathbf{g}(b, l)$ where the collection b has $k_{l_m} + 1$ filters $H_{l_m}(z)$ and consequently $l \neq l_m$.

By construction, the coefficients of type (ii) are recursively generated in step 4 of the algorithm while the coefficients of type (iii) are generated recursively by step 2(a). That all coefficients are obtained is guaranteed by the fact that for each k in the algorithm the number of filters, except H_{l_m}, is reduced by 1 in all possible ways. □

REMARK 4.8. *The total number of coefficients of types* (i) *and* (ii) *becomes*

$$\prod_{\substack{j=1 \\ j \neq l_m}}^{p} (k_j + 1) \tag{4.35}$$

while the number of coefficients of type (iii) *is*

$$\sum_{\substack{l=1 \\ l \neq l_m}}^{p} k_l \prod_{\substack{j=1 \\ j \neq l \\ j \neq l_m}}^{p} (k_j + 1). \tag{4.36}$$

In this way the total number of new coefficients generated for a fixed m is the sum of (4.35) *and* (4.36)*, which does not depend on the number of the filter $H_{l_m}(z)$ in the array.*

This concludes the contributions of this paper. A complete scheme for decomposing a system in the coefficients of a large number of orthonormal bases and for selecting the best has been given. In the following section, the best basis scheme is examined for a number of examples.

5. Examples. The procedure for selecting the best orthonormal rational basis can now be investigated in some examples. The first example concerns an exact finite description in order to demonstrate the consequences of selecting different all-pass filter orderings. Section 5.2 then examines pole selection in a noise-free setting. Finally, in section 5.3, best basis selection is applied to delay estimation.

5.1. Finite description. In order to demonstrate best rational basis selection, this example assumes that the system is exactly described by a finite number of basis functions. This means that the poles of the system are exactly the poles of the basis functions. In this way, the problem is reduced to a pure problem of calculating the best basis with respect to some cost function, while the estimation procedure can be omitted. Let the system transfer function be

$$G(z) = \sum_{k=1}^{n} c_k \frac{\sqrt{1 - a_k^2}}{z - a_k}, \tag{5.1}$$

where all the a_k's are real and different with magnitude less than one, and where the square-root factor normalizes the norm of each of the terms to $|c_k|$. Choose as bases the different generalized Laguerre systems constructed with the very same poles. The all-pass filters will thus be

$$H_k(z) = \frac{1 - a_k z}{z - a_k}, \qquad k = 1, \ldots, n, \tag{5.2}$$

while the state transfer functions become

$$\phi_k(z) = \frac{\sqrt{1 - a_k^2}}{z - a_k}, \qquad k = 1, \ldots, n. \tag{5.3}$$

The basis functions for some given ordering $\{k_l\}_{l=1}^{n}$ are then given by

$$\psi_l(z) = \phi_{k_l}(z) \prod_{j=1}^{l-1} H_{k_j}(z), \qquad l = 1, \ldots, n. \tag{5.4}$$

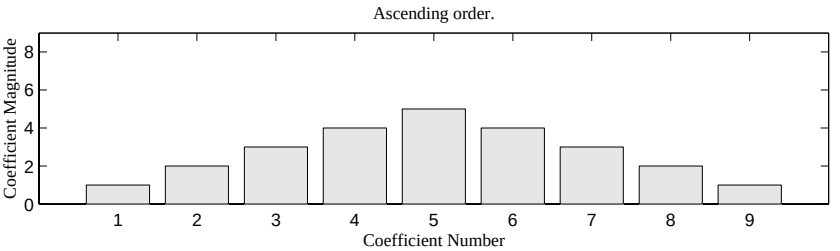

FIG. 5.1. *Coefficients for the ascending pole order.*

In this way, the system can now exactly be described by any of the $n!$ different bases that can be constructed. For fixed ordering, the expansion is written

$$G(z) = \sum_{l=1}^{n} g_l \psi_l(z), \tag{5.5}$$

where the coefficients $g_l = \langle G, \psi_l \rangle$ are explicitly calculated as

$$\begin{aligned} \langle G, \psi_l \rangle &= \frac{1}{2\pi} \int_{-\pi}^{\pi} G(e^{i\omega}) \psi_l(e^{-i\omega}) d\omega \\ &= \sqrt{1 - a_{k_l}^2} \sum_{m=1}^{n} c_m \frac{\sqrt{1 - a_m^2}}{1 - a_{k_l} a_m} \prod_{j=1}^{l-1} \frac{a_m - a_{k_j}}{1 - a_{k_j} a_m} \end{aligned} \tag{5.6}$$

for $l = 1, \ldots, n$.

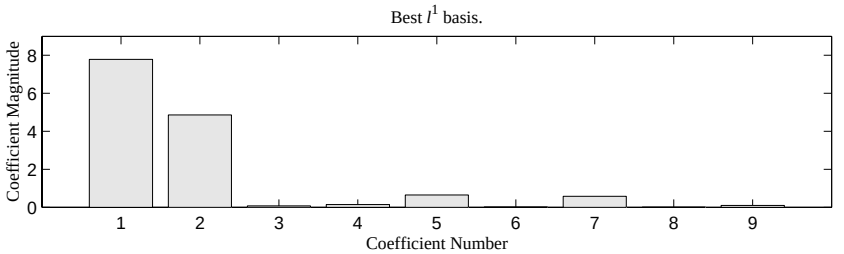
The best basis selection was performed with $n = 9$ and $a_k = k/10$, $k = 1, \ldots, 9$. In this way, $362,880$ bases are searched in $2,304$ steps. Two different cases were examined: In the first case, c_l was chosen so that $g_l = 5 - |l - 5|$ for the ascending pole ordering $n_l = l$, $l = 1, \ldots, 9$. Figure 5.1 shows the expansion coefficients for the ascending pole ordering. Two different cost functions were considered: the ℓ^1-cost

$$\sum_{l=1}^{n} |g_l| \tag{5.7}$$

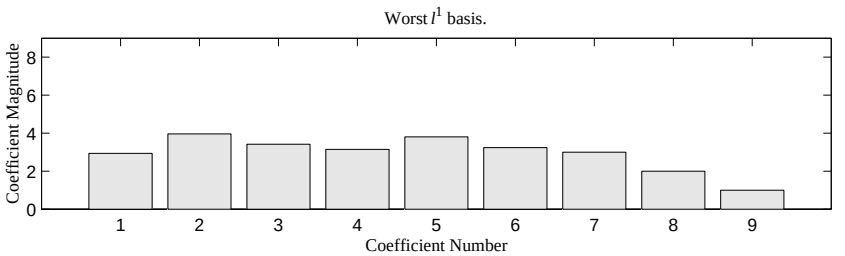
and the entropy

$$-\sum_{l=1}^{n} |g_l|^2 \log |g_l|. \tag{5.8}$$

The magnitude of the best and worst ℓ^1 expansion coefficients are shown in Figure 5.2. In the same way, this is shown for the best and worst entropy expansions in Figure 5.3. The second case considered is constructed so that $g_l = 1$ for the ascending order $k_l = l$, $l = 1, \ldots, 9$. The best and worst ℓ^1 expansion coefficients are displayed in Figure 5.4. For the entropy cost, exactly the same best and worst respective bases are selected as in the ℓ^1 case. The resulting costs and orderings for the two different cases are shown in Table 5.1. For case 1, the best expansions differ while the worst give the same result. As mentioned above, in case 2 both the best and the worst expansions match for the two different cost functions. Also the worst expansions for case 2 become the



(a) Best expansion.



(b) Worst expansion.

FIG. 5.2. *Best and worst ℓ^1 expansion coefficients for case* 1.

same. The latter should not be surprising since in this case, the solution is feasible and optimal for the two optimization problems

$$\min_{g_l} \sum_{l=1}^{n} |g_l| \quad \text{subject to} \quad \sum_{l=1}^{n} |g_l|^2 = \text{Constant} \tag{5.9}$$

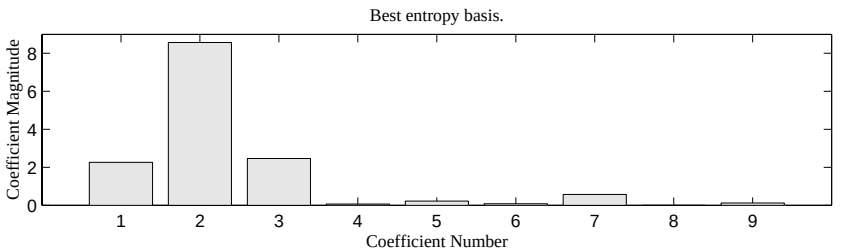
and

$$\min_{g_l} \sum_{l=1}^{n} |g_l|^2 \log |g_l|, \qquad \text{subject to} \quad \sum_{l=1}^{n} |g_l|^2 = \text{Constant}. \tag{5.10}$$

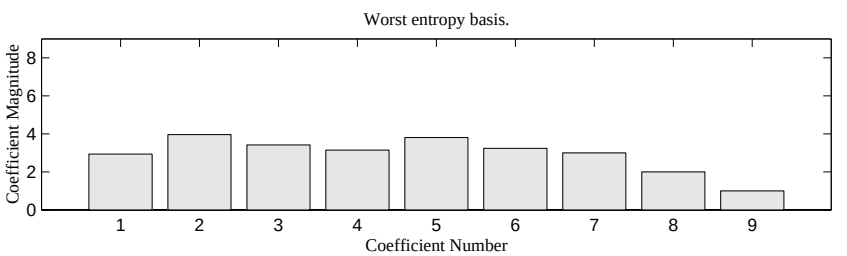
This example shows the difference in coefficient compression between different choices of basis and, in this way, the importance of selecting the order of the all-pass filters in the array properly.

5.2. Noise-free estimation. In this case, the system is estimated without measurement noise. As a priori information, three different alternatives are given for the complex poles of the system while the real pole is assumed to be known. One of the complex poles is identical to the true one and the other two are somewhat displaced. The system is given by

$$G(z) = C \frac{b_1(z) b_2(z)}{(z - K) a(z)^2}, \tag{5.11}$$



(a) Best expansion.



(b) Worst expansion.

FIG. 5.3. *Best and worst entropy expansion coefficients for case* 1.

TABLE 5.1
Costs and orderings for the two cases.

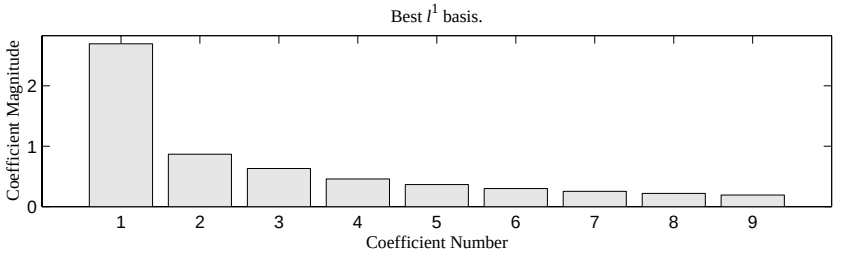
Case 1			
Type	ℓ^1-cost	Entropy cost	Ordering $k_1, \ldots, k_9$
Best ℓ^1	14.22	−161.21	9, 8, 2, 1, 7, 6, 3, 4, 5
Worst ℓ^1	26.53	−101.16	6, 4, 2, 1, 3, 5, 7, 8, 9
Best entropy	14.37	−167.00	5, 9, 7, 8, 1, 2, 4, 3, 6
Worst entropy	26.53	−101.16	6, 4, 2, 1, 3, 5, 7, 8, 9

Case 2			
Type	ℓ^1-cost	Entropy cost	Ordering $k_1, \ldots, k_9$
Best ℓ^1	5.99	−6.28	9, 8, 7, 6, 5, 4, 3, 2, 1
Worst ℓ^1	9.00	0.00	1, 2, 3, 4, 5, 6, 7, 8, 9
Best entropy	5.99	−6.28	9, 8, 7, 6, 5, 4, 3, 2, 1
Worst entropy	9.00	0.00	1, 2, 3, 4, 5, 6, 7, 8, 9

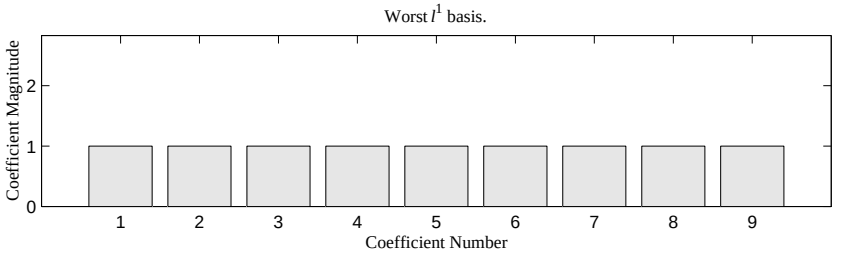
where

$$b_1(z) = z^2 - 2r\cos(\phi + \Delta\phi)z + r^2,$$
$$b_2(z) = z^2 - 2r\cos(\phi - \Delta\phi)z + r^2,$$
$$a(z) = z^2 - 2r\cos(\phi)z + r^2,$$

with $r = 0.80$, $\phi = 1.30\,\pi/4$, $\Delta\phi = 0.20\,\pi/4$, and $K = 0.50$. C is a normalizing constant achieving $G(1) = 1$. The system output y is generated as $y(t) = G(q)u(t)$, $t = 1, \ldots, N$, where q is the forward shift operator and the input sequence $\{u(t)\}_{t=1}^{N}$ is a unit pseudorandom binary signal (PRBS). The number of samples N is chosen



(a) Best expansion.



(b) Worst expansion.

FIG. 5.4. *Best and worst ℓ^1 expansion coefficients for case* 2. *These also match the best and worst entropy expansions for case* 2.

to be $1,024$.

The orthonormal basis used for estimation is constructed from the four different filters H_1, H_2, H_3, and H_4, where H_1 is a Laguerre filter with a pole in 0.50, H_2 is a Kautz filter with the same poles as the roots of $z^2 - 2r\cos(\phi_{d_1})z + r_d^2$, H_3 is a Kautz filter with the same poles as the roots of $z^2 - 2r\cos(\phi_{d_2})z + r_d^2$, and H_4 is a Kautz filter with the same poles as $a(z)$.

The displaced parameters ϕ_{d_1}, ϕ_{d_2}, and r_d are disturbed by 5% from the original so that $\phi_{d_1} = 1.05\,\phi$, $\phi_{d_2} = 0.95\,\phi$, and $r_d = 1.05\,r$. The corresponding multiplicities for the filters are

$$\begin{pmatrix} \kappa_1 & \kappa_2 & \kappa_3 & \kappa_4 \end{pmatrix} = \begin{pmatrix} 1 & 2 & 2 & 2 \end{pmatrix}. \tag{5.12}$$

With this setting, the best basis among 630 is chosen in 135 steps. The idea is to see if the best basis selection scheme chooses the correct complex pole over the displaced parameters so that the first three filters in the best array are H_1, H_4, and H_4, while the other basis functions have zero coefficients. The initial ordering of the filters was chosen as

$$\begin{pmatrix} l_1 & \cdots & l_7 \end{pmatrix} = \begin{pmatrix} 1 & 2 & 3 & 4 & 2 & 3 & 4 \end{pmatrix} \tag{5.13}$$

and estimation of the corresponding coefficients was performed as in (2.24) from section 2.2. The resulting coefficients are shown in Figure 5.5. Calculation of all the other possible coefficients and selection of the best basis was performed with the given conditions. For simplicity of the presentation, only the ℓ^1-cost was considered. The

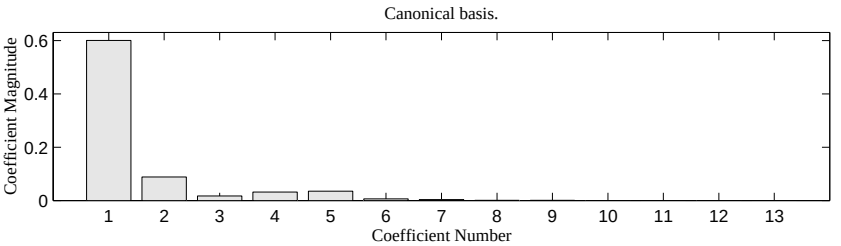


FIG. 5.5. *Estimated coefficients for the initial ordering of the all-pass filters.*

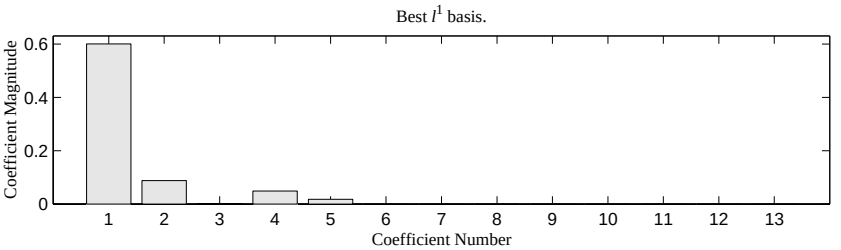

FIG. 5.6. *Coefficients for the best ℓ^1-ordering of the all-pass filters.*

TABLE 5.2
Costs and orderings for the initial, best, and worst bases.

Type	ℓ^1-cost	Ordering $l_1, \ldots, l_7$
Initial	0.786	$1, 2, 3, 4, 2, 3, 4$
Best ℓ^1	0.757	$1, 4, 4, 2, 3, 3, 2$
Worst ℓ^1	1.742	$2, 3, 2, 3, 4, 4, 1$

resulting coefficients are shown in Figure 5.6 while the ordering and cost are presented in Table 5.2. In the table, the worst cost and ordering are also shown.

The corresponding worst coefficients can be found in Figure 5.7. As intended, the best basis selection scheme chooses a basis constructed from an array starting with H_1, H_4, and H_4. This means that the system is exactly described by the first five coefficients. With the initial ordering, on the other hand, more coefficients are needed. One can also note that, not surprisingly, the worst basis has the first order all-pass filter last in the array.

This example shows how the coefficient calculation and selection scheme chooses a suitable ordering of the all-pass filters.

5.3. Multiple delays. In this example, estimation of a system with multiple delays is examined. The system is shown in Figure 5.8. The purpose is to estimate the delays from choosing the best basis. Thus, for clarity, the poles are assumed to be known so that

$$G_j(z) = \frac{1 - a_j}{z - a_j}, \qquad j = 1, 2, 3, \tag{5.14}$$

with $a_1 = 0.30$, $a_2 = 0.40$, and $a_3 = 0.50$. The delays are $d_1 = 5$, $d_2 = 10$, and $d_3 = 10$, and are unknown. The system can be viewed as echo measurements with two additional bounces.

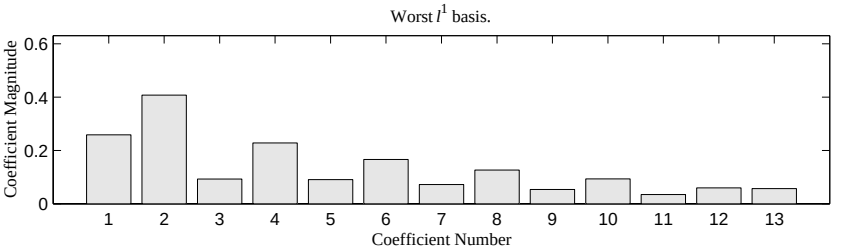

FIG. 5.7. *Coefficients for the worst ℓ^1-ordering of the all-pass filters.*

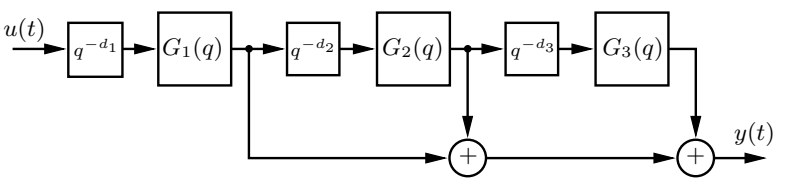

FIG. 5.8. *System with three delays.*

Simulations were performed with $\{u(t)\}_{t=1}^{1,024}$ chosen as PRBS; Gaussian measurement noise with standard deviation 1.00 was added to the output and the system was estimated in a basis consisting of the four different filters

$$H_j(z) = \frac{1 - a_j z}{z - a_j}, \qquad j = 1, 2, 3, \tag{5.15}$$

and

$$H_4(z) = z^{-1}. \tag{5.16}$$

The multiplicities of these filters were

$$\begin{pmatrix} \kappa_1 & \kappa_2 & \kappa_3 & \kappa_4 \end{pmatrix} = \begin{pmatrix} 1 & 1 & 1 & 35 \end{pmatrix}. \tag{5.17}$$

With a large number of delays in the bases, and with the remaining dynamics similar to that of the system, the best basis selection scheme should be able to identify the proper delays. The total number of possible bases is 50,616 while the number of different basis functions is only 712. Figure 5.9 shows the magnitude of the best and worst ℓ^1-coefficients.

Although the measurement noise is quite large, the best basis shows significantly larger coefficients in positions 6, 17, and 28. The corresponding filters are H_1, H_2, and H_3, respectively so that the rest of the all-pass filters are the unit delays H_4. The number of delays before coefficient 6 is 5 and corresponds to d_1. Between the coefficients 6 and 17 the number of delays is 10, corresponding to d_2. Finally, the number of delays between the coefficients 28 and 17 is 10, which is the same as d_3. The three different delays can thus be identified in this way. The ordering of the worst basis starts with H_3 and H_2 followed by 4 unit delays, which are followed by H_1. All the rest of the filters are delays.

The example shows that, for a system with this delay structure, the delays can be estimated by selecting the best orthonormal rational basis expansion even when substantial measurement noise is present.

(b) Worst expansion.

FIG. 5.9. *Best and worst ℓ^1-expansion coefficients for the system shown in Figure* 5.8.

6. Concluding remarks. This paper gives a method for calculating coefficients and selecting the best basis among a large number of different orthonormal rational bases.

The number of possible bases was first derived and the observation that a basis function can be a member of many different bases was made. This was exploited in order to derive a scheme for selecting the best orthonormal basis. The selection scheme is fast in the sense that the best basis is selected in a number of steps with a complexity no larger than the number of different basis functions. A similar scheme was then derived for calculating all possible different expansion coefficients, providing the coefficients in only one basis. The method is based on recursive local orthonormal transformations of the already calculated coefficients.

These two main results give a complete method for separately calculating all the possible coefficients and then selecting the best basis in an order of complexity which is the same as the number of different basis functions rather than the number of different bases. This property is very similar to that of the wavelet packet best basis methods of [7].

As indicated in the beginning of section 1, the different bases can be viewed as results from Gram–Schmidt orthogonalizations of simple filters having the given poles. Depending on the order in which the orthogonalization is performed, different bases for the finite-dimensional subspace are received. In this way, the best basis selection of Algorithm 3.5 is not only applicable to subspaces in $\mathcal{H}^2$ but can in fact be applied to any finite-dimensional space. However, the issue of multiplicities as well as the coefficient calculation of Algorithm 4.6 becomes specific to the construction of rational bases.

Appendix A. Address to collection conversion. Given an address

$$q = \sum_{l=1}^{p} k_l \prod_{j=1}^{l-1} (1 + \kappa_j)$$

to a collection $(k_1, \ldots, k_p)$ with respect to the multiplicities $\{\kappa_l\}_{l=1}^{p}$, the numbers $\{k_l\}_{l=1}^{p}$ are extracted from q by the following pseudocode:

for $l = 1, \ldots, p$
    $k_l \leftarrow \mathrm{rem}(q, \kappa_l + 1)$
    $q \leftarrow (q - k_l)/(\kappa_l + 1)$
end

Appendix B. Orthonormality of $\mathbf{T}(j,k)$. The matrix $\mathbf{T}(j,k)$ defined by (4.8) fulfills $\mathbf{T}(j,k)\mathbf{T}^T(j,k) = \mathbf{I}$ since

$$\mathrm{span}\{\Phi_j, \Phi_k H_j\} = \mathrm{span}\{\Phi_k, \Phi_j H_k\}. \tag{B.1}$$

These two pairs of functions have the same span since they both have the same poles and are strictly proper, and thus have the same partial fractional expansions.

Appendix C. Transforming $\mathbf{A_1 X A_2^T + B_1 B_2^T = X}$. Given the matrix equation

$$\mathbf{A}_1 \mathbf{X} \mathbf{A}_2^T + \mathbf{B}_1 \mathbf{B}_2^T = \mathbf{X}, \tag{C.1}$$

introduce

$$\tilde{\mathbf{A}}_k = (\mathbf{A}_k + \mathbf{I})^{-1}(\mathbf{A}_k - \mathbf{I}), \tag{C.2}$$

$$\tilde{\mathbf{B}}_k = \sqrt{2}(\mathbf{A}_k + \mathbf{I})^{-1}\mathbf{B}_k \tag{C.3}$$

for $k = 1, 2$. Then, $\mathbf{X}$ solves the Sylvester equation

$$\tilde{\mathbf{A}}_1 \mathbf{X} + \mathbf{X} \tilde{\mathbf{A}}_2^T + \tilde{\mathbf{B}}_1 \tilde{\mathbf{B}}_2^T = \mathbf{0}. \tag{C.4}$$

LINEAR SYSTEMS WITH PRESCRIBED SIMILARITY STRUCTURAL INVARIANTS*

I. BARAGAÑA†, V. FERNÁNDEZ†, AND I. ZABALLA‡

Abstract. The problem of the existence of linear systems $\dot{x}(t) = Ax(t) + Bu(t)$ with prescribed structural invariants for system similarity is studied. Namely, we solve the problem of the existence of such a system with prescribed controllability indices, Hermite indices, and invariant factors when the invariant factors of A (which are also invariants under system similarity) are given.

Key words. system similarity, controllability indices, Hermite indices, Brunovsky indices, invariant factors, majorization

1. Introduction, notation, and preliminary results.

Let us assume that $A \in \mathbb{F}^{n\times n}$ and $B \in \mathbb{F}^{n\times m}$, $\mathbb{F}$ being the field of real or complex numbers. In the study of the structure of linear control systems

$$\dot{x}(t) = Ax(t) + Bu(t) \tag{1.1}$$

under systems similarity—(TAT^{-1}, TB), with T invertible—several systems of invariants can be found. In [12] Popov gave a complete system of independent invariants for system similarity but this is not the only complete system of invariants that one can obtain (see, for example, [9, p. 494], [5, p. 191], or [20]). An interesting feature of all these systems is that they are formed by two types of subsystems that, following [11, p. 48], we can call *invariants of structure* and *numerical invariants*. The former ones are nonnegative integers, and the latter ones are real or complex numbers depending on the underlying field where the elements of A and B are.

The most mentioned structural invariants are the controllability and the Hermite indices [9, Chap. 6], [5]. Both come up when searching for a basis of the controllability subspace, i.e., the one generated by the columns of the controllability matrix, $\mathcal{C}(A,B) = [B \;\; AB \;\; \dots \;\; A^{n-1}B]$, in the following table:

$$\begin{array}{ccccc} b_1 & b_2 & b_3 & \dots & b_m \\ Ab_1 & Ab_2 & Ab_3 & \dots & Ab_m \\ A^2b_1 & A_2b_2 & A^2b_3 & \dots & A^2b_m \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ A^{n-1}b_1 & A^{n-1}b_2 & A^{n-1}b_3 & \dots & A^{n-1}b_m, \end{array}$$

where $b_i \in \mathbb{F}^{n\times 1}$ is the ith column of B. If $\operatorname{rank}\mathcal{C}(A,B) = r$ and we select by columns (from left to right) the first r linearly independent columns of the table and we write them as

$$b_1, \ldots, A^{h_1-1}b_1, \ldots, b_m, \ldots, A^{h_m-1},$$

then $h_1, h_2, \ldots, h_m$ are the Hermite indices of the system. Actually, as pointed out in [9, p. 476], these indices are the degrees of the polynomials appearing in the diagonal of the Hermite normal form of the right denominator of the transfer $(sI_n - A)^{-1}B$. This is why they were called Hermite indices in [20] (see also [14]). If we proceed similarly but searching by rows from top to bottom and we rearrange the indices in nonincreasing order, then we come up with the controllability indices [4] or input structural indices as they are called in [3, p. 156].

It is also worth noting that system similarity implies similarity of the corresponding state matrices. It is well known (see, for example, [6]) that two square matrices A_1 and A_2 are similar if and only if their corresponding characteristic matrices $sI - A_1$ and $sI - A_2$ are equivalent; i.e., they have the same invariant factors (the invariant factors of A being those of $sI - A$ as a polynomial matrix). Thus the invariant factors of the state matrix are invariants under system similarity. Furthermore, if we call invariant factors of (A, B) or of system (1.1) those of the polynomial matrix $[sI_n - A \quad B]$, then these polynomials are also invariants under system similarity. Notice that the invariant factors of system (1.1) are all equal to 1 if and only if the system is controllable [13].

The well-known Rosenbrock's theorem [13] on eigenstructure assignment under state feedback can be seen as a result of the relationship between the invariant factors of the state matrix A, i.e., those of $sI_n - A$, and the controllability indices of a controllable system (A, B). Similarly, the generalization of Rosenbrock's theorem to noncontrollable systems [17, 18] provides a characterization of the possible controllability indices and invariant factors of system (A, B) for a given matrix A. Following these ideas, the study of the relationship between the controllability and the Hermite indices of a given pair as well as the relationship between the invariant factors of A and the Hermite indices and invariant factors of (A, B) for all possible choices of B was carried out in [20]. In this paper, the four systems of invariants are considered together. Namely, we will deal with the following.

PROBLEM 1. *Let $A \in \mathbb{F}^{n\times n}$ and $\alpha_1 \mid \ldots \mid \alpha_n$ its invariant factors. Let $k_1 \geq \cdots \geq k_m > 0$ be positive integers, $h_1 \geq \cdots \geq h_m \geq 0$ nonnegative integers, and $\gamma_1 \mid \ldots \mid \gamma_n$ monic polynomials. Under what conditions does there exist a matrix $B \in \mathbb{F}^{n\times m}$ such that (A, B) has $k_1, \ldots, k_m$ as controllability indices, $h_1, \ldots, h_m$ as Hermite indices, and $\gamma_1, \ldots, \gamma_n$ as invariant factors?*

Our results will be of an algebraic nature and so we will not impose any restrictions on $\mathbb{F}$ that from now on will be considered arbitrary. We will use Greek letters to denote polynomials, $\alpha \mid \beta$ will mean that α divides β, and $d(\alpha)$ will be the degree of α.

As said before, the controllability indices are invariant under system similarity but in the case when (A, B) is controllable, they form a complete system of invariants for the feedback equivalence. Following Brunovsky [4], two matrix pairs $(A, B), (\hat{A}, \hat{B}) \in \mathbb{F}^{n\times n} \times \mathbb{F}^{n\times m}$ are said to be feedback equivalent if there are nonsingular matrices $P \in \mathbb{F}^{n\times n}$ and $Q \in \mathbb{F}^{m\times m}$ and a matrix $R \in \mathbb{F}^{m\times n}$ such that $(\hat{A}, \hat{B}) = (PAP^{-1} + PBR, PBQ)$. If (A, B) is not completely controllable, a complete system of invariants is given by the controllability indices and the invariant factors of (A, B).

The paper is organized as follows: in the next section we give a solution to the posed problem when the system is controllable, and in the following one when

this condition is not satisfied. Our proofs, although involved, are constructive and decidable.

Throughout this paper we will refer several times to the Brunovsky indices of a pair of matrices. We call Brunovsky indices of (A, B) to the components of the conjugate partition of that of the controllability indices; i.e., if $(k_1, \ldots, k_m)$ is the partition of the controllability indices of (A, B), then, by defining $r_j = \#\{i : k_i \geq j\}$, we have that $r_1, \ldots, r_n$ are its Brunovsky indices (or its r-numbers as they were called in [4]).

In general, if $a = (a_1, \ldots, a_n)$ is a partition of nonnegative integers, we will use $\bar{a} = \overline{(a_1, \ldots, a_n)}$ to mean its conjugate partition. Thus

$$(r_1, \ldots, r_n) = \overline{(k_1, \ldots, k_m)}.$$

We will consider that the components in each partition are arranged in nonincreasing order. Following [8], we say that a is majorized by b, and we write $a \prec b$ if

$$\sum_{j=1}^{k} a_j \leq \sum_{j=1}^{k} b_j, \ 1 \leq k < n,$$

and

$$\sum_{j=1}^{n} a_j = \sum_{j=1}^{n} b_j.$$

It can be proved that if $a \prec b$, then $\bar{b} \prec \bar{a}$ [10].

Before going into a solution of Problem 1, let us notice that this problem is equivalent, in the sense of Proposition 1.1 given below, to the following one.

PROBLEM 2. *Let $(A, B) \in \mathbb{F}^{n\times n} \times \mathbb{F}^{n\times m}$, and let $k_1 \geq \cdots \geq k_m > 0$ and $\gamma_1 \mid \ldots \mid \gamma_n$ be its controllability indices and invariant factors, respectively. Let $\alpha_1 \mid \ldots \mid \alpha_n$ and $h_1 \geq \cdots \geq h_m \geq 0$ be monic polynomials and nonnegative integers. Find necessary and sufficient conditions for the existence of a static state feedback matrix $F \in \mathbb{F}^{m\times n}$ and a nonsingular matrix $Q \in \mathbb{F}^{m\times m}$ such that $A + BF$ has $\alpha_1, \ldots, \alpha_n$ as invariant factors and $(A+BF, BQ)$ has $h_1, \ldots, h_m$ as Hermite indices.*

It should be remarked that a solution of this problem will provide us with a generalization of Rosenbrock's theorem. In fact we are characterizing not only the invariant factors that can be assigned by state feedback but also some additional invariants (the Hermite indices) of the similarity class where the closed loop system $(A + BF, BQ)$ may lie.

As said before the equivalence of Problems 1 and 2 is based on the following proposition.

PROPOSITION 1.1. *Let $A \in \mathbb{F}^{n\times n}$ and $\alpha_1 \mid \ldots \mid \alpha_n$ its invariant factors. Let $(\hat{A}, \hat{B}) \in \mathbb{F}^{n\times n} \times \mathbb{F}^{n\times m}$ with $k_1 \geq \cdots \geq k_m > 0$ and $\gamma_1 \mid \ldots \mid \gamma_n$ as controllability indices and invariant factors, respectively, and let $h_1 \geq \cdots \geq h_m \geq 0$ be nonnegative integers. Then there exists a matrix $B \in \mathbb{F}^{n\times m}$ such that (A, B) is feedback equivalent to $(\hat{A}, \hat{B})$ and has $h_1, \ldots, h_m$ as Hermite indices if and only if there are matrices $F \in \mathbb{F}^{m\times n}$ and $Q \in \mathbb{F}^{m\times m}$, nonsingular, such that $\hat{A} + \hat{B}F$ is similar to A and $(\hat{A}+\hat{B}F, \hat{B}Q)$ has $\gamma_1, \ldots, \gamma_n$ as invariant factors and $h_1, \ldots, h_m$ as Hermite indices.*

Proof. Assume that there is B so that (A, B) is feedback equivalent to $(\hat{A}, \hat{B})$ and has $h_1, \ldots, h_m$ as Hermite indices. Let us show that there are matrices F and

Q, nonsingular, such that $(\hat{A}+\hat{B}F, \hat{B}Q)$ is similar to (A, B). This is enough to prove that $(\hat{A}+\hat{B}F, \hat{B}Q)$ has $h_1, \ldots, h_m$ as Hermite indices and $\gamma_1, \ldots, \gamma_n$ as invariant factors because these two sequences are invariant under system similarity. In fact, since (A, B) and $(\hat{A}, \hat{B})$ are feedback equivalent, there are nonsingular matrices P and T and a matrix R such that

$$A = P(\hat{A}+\hat{B}RP)P^{-1} \quad \text{and} \quad B = P\hat{B}T.$$

So, $F = RP$ and $Q = T$ are the desired matrices.

Conversely, if A is similar to $\hat{A}+\hat{B}F$ for some matrix F, then there is an invertible matrix P such that $A = P(\hat{A}+\hat{B}F)P^{-1}$. Define $B = P\hat{B}Q$. Thus (A, B) and $(\hat{A}+\hat{B}F, \hat{B}Q)$ are system similar matrix pairs and so they have the same invariant factors $\gamma_1, \ldots, \gamma_n$ and the same Hermite indices $h_1, \ldots, h_m$. Furthermore, as $(\hat{A}, \hat{B})$ and $(\hat{A}+\hat{B}F, \hat{B}Q)$ are feedback equivalent, we conclude that (A, B) and $(\hat{A}, \hat{B})$ have the same controllability indices $k_1, \ldots, k_m$. ∎

From now on we will deal with Problem 1. A consequence of the next lemma is that we can substitute A with any matrix in its similarity class.

LEMMA 1.2. *Let $A \in \mathbb{F}^{n\times n}$. Let $k_1 \geq \cdots \geq k_m > 0$ and $h_1 \geq \cdots \geq h_m \geq 0$ be nonnegative integers and $\gamma_1, \ldots, \gamma_n$ monic polynomials. Suppose that $A \overset{s}{\sim} \hat{A}$. Then there exists $B \in \mathbb{F}^{n\times m}$ such that (A, B) has $k_1, \ldots, k_m$ as controllability indices, $h_1, \ldots, h_m$ as Hermite indices, and $\gamma_1, \ldots, \gamma_n$ as invariant factors if and only if there exists $\hat{B} \in \mathbb{F}^{n\times m}$ such that $(\hat{A}, \hat{B})$ has $k_1, \ldots, k_m$ as controllability indices, $h_1, \ldots, h_m$ as Hermite indices, and $\gamma_1, \ldots, \gamma_n$ as invariant factors.*

Proof. The proof is straightforward. ∎

Given a controllable matrix pair $(A, B) \in \mathbb{F}^{n\times n} \times \mathbb{F}^{n\times m}$, we are going to give a canonical form for the similarity of matrix pairs associated with the Hermite indices (see [9]).

LEMMA 1.3. *Let $(A, B) \in \mathbb{F}^{n\times n} \times \mathbb{F}^{n\times m}$ be a controllable pair and let $h_1 \geq \cdots \geq h_p > 0 = h_{p+1} = \cdots = h_m$ be its Hermite indices. Then there exists a nonsingular matrix $P \in \mathbb{F}^{n\times n}$ such that*

$$(PAP^{-1}, PB) = (A_c, B_c),$$

where

$$A_c = (A_{ij}) \begin{matrix} i = 1, \ldots, p, \\ j = 1, \ldots, p, \end{matrix} \qquad B_c = (B_{ij}) \begin{matrix} i = 1, \ldots, p, \\ j = 1, \ldots, m, \end{matrix}$$

are the blocks

$$A_{ii} = \begin{pmatrix} \begin{bmatrix} 0 & 0 & \ldots & 0 & x_{ii0} \\ 1 & 0 & \ldots & 0 & x_{ii1} \\ 0 & 1 & \ldots & 0 & x_{ii2} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \ldots & 1 & x_{iih_i-1} \end{bmatrix} \end{pmatrix} \in \mathbb{F}^{h_i\times h_i}, \ 1 \leq i \leq p,$$

$$A_{ij} = \begin{pmatrix} \begin{bmatrix} 0 & 0 & \ldots & 0 & x_{ji0} \\ 0 & 0 & \ldots & 0 & x_{ji1} \\ 0 & 0 & \ldots & 0 & x_{ji2} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \ldots & 0 & x_{jih_i-1} \end{bmatrix} \end{pmatrix} \in \mathbb{F}^{h_i\times h_j}, \ 1 \leq i < j \leq p,$$

$$A_{ij} = 0 \in \mathbb{F}^{h_i \times h_j},\ 1 \le j < i \le p,$$

$$B_{ii} = \begin{bmatrix} 1 & 0 & \dots & 0 \end{bmatrix}^T \in \mathbb{F}^{h_i \times 1},\ 1 \le i \le p,$$

$$B_{ij} = \begin{bmatrix} 0 & 0 & \dots & 0 \end{bmatrix}^T \in \mathbb{F}^{h_i \times 1},\ 1 \le i, j \le p,\ i \ne j,$$

$$B_{ij} = \begin{bmatrix} x_{ji0} & x_{ji1} & \dots & x_{jih_i-1} \end{bmatrix}^T \in \mathbb{F}^{h_i \times 1},\ 1 \le i \le p,\ p+1 \le j \le m.$$

2. The controllable case. In this section, we will deal with Problem 1 in the controllable case. The following two results provide necessary conditions for the problem to have a solution, i.e., for the existence of a matrix $B \in \mathbb{F}^{n\times m}$ such that (A, B) has prescribed controllability and Hermite indices for a given $A \in \mathbb{F}^{n\times n}$.

LEMMA 2.1 (see [20]). *Let $A \in \mathbb{F}^{n\times n}$, and let $\alpha_1 \mid \dots \mid \alpha_n$ be its invariant factors. Let $h_1 \ge \dots \ge h_m \ge 0$ be nonnegative integers . Then there exists a matrix $B \in \mathbb{F}^{n\times m}$, $m \le n$, such that (A, B) is controllable and has $h_1, \dots, h_m$ as Hermite indices if and only if there are m monic polynomials $\beta_1, \dots, \beta_m$ such that $d(\beta i) = h_i,\ 1 \le i \le m$, and*

$$\alpha_i = 1, \quad 1 \le i \le n - m, \tag{2.1}$$

$$\alpha_{n-m+1} \dots \alpha_{n-m+k} \mid g.c.d.\{\beta_{i_1} \dots \beta_{i_k} : 1 \le i_1 < \dots < i_k \le m\},$$

$$1 \le k \le m - 1, \tag{2.2}$$

$$\alpha_1 \dots \alpha_n = \beta_1 \dots \beta_m. \tag{2.3}$$

LEMMA 2.2 (see [20]). *Let $(A, B) \in \mathbb{F}^{n\times n} \times \mathbb{F}^{n\times m}$ be a controllable matrix pair. Let $k_1 \ge \dots \ge k_m \ge 0$ be its controllability indices, and let $h_1, \dots, h_m$ be its Hermite indices. Then*

$$(k_1, \dots, k_m) \prec (h_1, \dots, h_m). \tag{2.4}$$

The rest of this section is dedicated to show that conditions (2.1)–(2.4) are also sufficient for a matrix $B \in \mathbb{F}^{n\times m}$ to exist so that for a given matrix $A \in \mathbb{F}^{n\times n}$ the pair (A, B) is controllable and has prescribed controllability and Hermite indices. This will be shown as a consequence of several lemmas.

LEMMA 2.3 (see [2]). *Let $(A_1, B_1) \in \mathbb{F}^{n_1\times n_1} \times \mathbb{F}^{n_1\times m_1}$ and $(A_2, B_2) \in \mathbb{F}^{n_2\times n_2} \times \mathbb{F}^{n_2\times m_2}$ be two controllable matrix pairs, and let $r_1 \ge \dots \ge r_{n_1}$ and $m_2 = s_1 \ge \dots \ge s_{n_2}$ be their Brunovsky indices, respectively. Let $k_1 \ge \dots \ge k_{s_1}$ be the controllability indices of (A_2, B_2), and put $n = n_1 + n_2$. Assume that $t_1 = r_1 + m_2$ and that $t_1 \ge \dots \ge t_n$ are nonnegative integers. Then there exist matrices $X \in \mathbb{F}^{n_1\times n_2}$ and $Y \in \mathbb{F}^{n_1\times m_2}$ such that $t_1, \dots, t_n$ are the Brunovsky indices of*

$$\left(\begin{bmatrix} A_1 & X \\ 0 & A_2 \end{bmatrix}, \begin{bmatrix} B_1 & Y \\ 0 & B_2 \end{bmatrix} \right)$$

if and only if the following conditions hold:

$$\sum_{j=1}^{n_1} r_j + \sum_{j=1}^{n_2} s_j = \sum_{j=1}^{n} t_j, \tag{2.5}$$

$$t_j \le r_j + s_1,\ 1 \le j \le n, \tag{2.6}$$

$$t_j \ge s_j,\ 1 \le j \le n, \tag{2.7}$$

$$\sum_{j=1}^{d_p} (t_j - r_j - p) \ge \sum_{j=p+1}^{s_1} k_j,\ 1 \le p \le s_1, \tag{2.8}$$

$$\sum_{j=1}^{i} r_j \le (i-q)(t_q - s_q) + \sum_{j=1}^{q} (t_j - s_j), \quad 1 \le q \le k_1; \quad q+1 \le i \le n, \tag{2.9}$$

where $d_p = \max\{j : t_j - r_j \ge p\}$, $1 \le p \le s_1$.

Remark. Notice that when $s_1 = \cdots = s_{k_1}$, (2.5)–(2.8) imply $t_j = r_j + s_1$, $1 \le j \le k_1$, and (2.9) holds.

LEMMA 2.4 (see [1]). *Let* $(A, B) \in \mathbb{F}^{n\times n} \times \mathbb{F}^{n\times m}$ *be a controllable matrix pair, and let* $r_1 \ge \cdots \ge r_n$ *be its Brunovsky indices. Let* $t_1 = r_1 + s \ge \cdots \ge t_n$ *be nonnegative integers. Then there exists a matrix* $C \in \mathbb{F}^{n\times s}$ *such that* $t_1, \ldots, t_n$ *are the Brunovsky indices of* $(A, [B\ C])$ *if and only if the following conditions hold:*

$$\sum_{j=1}^{n} t_j = \sum_{j=1}^{n} r_j, \tag{2.10}$$

$$t_j \le r_j + s,\ 1 \le j \le n, \tag{2.11}$$

$$\sum_{j=1}^{d_p} (t_j - r_j - p) \ge 0,\ 1 \le p \le s, \tag{2.12}$$

where $d_p = \max\{j : t_j - r_j \ge p\}$, $1 \le p \le s$.

LEMMA 2.5. *Let* $k_1 \ge \cdots \ge k_m > 0$ *and* $h_1 \ge \cdots \ge h_m \ge 0$ *be nonnegative integers, and let* $(v_1, v_2, \ldots, v_n) = \overline{(h_1, \ldots, h_m)}$, $(t_1, \ldots, t_n) = \overline{(k_1, \ldots, k_m)}$ *and* $(v'_1, \ldots, v'_n) = \overline{(h_1, \ldots, h_{m-1})}$. *Assume that* (2.4) *holds and let*

$$r_i = m - 1,\ 1 \le i \le k_m,$$

and

$$r_i = \min\left\{ m - 1, t_i + \sum_{j=1}^{i-1} (t_j - r_j) - h_m \right\},\ k_m < i \le n.$$

Then the following conditions are satisfied:

$$r_1 \geq \cdots \geq r_n \geq 0, \tag{2.13}$$

$$(v_1', \ldots, v_n') \prec (r_1, \ldots, r_n), \tag{2.14}$$

$$t_j \leq r_j + 1,\ 1 \leq j \leq n, \tag{2.15}$$

$$\sum_{j=1}^{d_1} (t_j - r_j - 1) = 0, \tag{2.16}$$

where $d_1 = \max\{j : t_j - r_j \geq 1\}$.

Proof. We can assume without loss of generality that $k_m < n$.

Notice first that $t_i \leq m-1$, $k_m < i \leq n$, and $\sum_{j=1}^{k_m}(t_j - r_j) - h_m = k_m - h_m \geq 0$. Moreover, as $r_i \leq t_i + \sum_{j=1}^{i-1}(t_j - r_j) - h_m$, $k_m < i \leq n$, we have that $\sum_{j=1}^{i-1}(t_j - r_j) - h_m \geq 0$ for $k_m + 1 < i \leq n$. Hence,

$$r_i \geq t_i,\ k_m < i \leq n.$$

Therefore, $d_1 = k_m$ and (2.15)–(2.16) hold.

We will prove next that for some $i \in \{k_m + 1, \ldots, n\}$,

$$r_i = t_i + \sum_{j=1}^{i-1}(t_j - r_j) - h_m.$$

In fact, assume that

$$r_i \neq t_i + \sum_{j=1}^{i-1}(t_j - r_j) - h_m,\ k_m + 1 \leq i \leq n;$$

then

$$r_n = m - 1 < t_n + \sum_{j=1}^{n-1}(t_j - r_j) - h_m = \sum_{j=1}^{m-1} h_j - (n-1)(m-1).$$

So

$$n(m-1) < \sum_{j=1}^{m-1} h_j \leq n(m-1),$$

which is a contradiction.

Let $g = \min\{i \in \{k_m + 1 \ldots, n\} : r_i = t_i + \sum_{j=1}^{i-1}(t_j - r_j) - h_m\}$. Then

$$r_i = m - 1,\ 1 \leq i \leq g - 1,$$

$$r_g = \sum_{j=1}^{g} t_j - (g-1)(m-1) - h_m,$$

and

$$r_i = t_i,\ g < i \leq n.$$

Therefore,

$$r_{g-1} = m - 1 \geq r_g \geq t_g \geq t_{g+1} = r_{g+1},$$

and (2.13) follows.

On the other hand,

$$\begin{array}{l} v'_i = v_i - 1,\ 1 \leq i \leq h_m, \\ v'_i = v_i,\ h_m < i \leq n, \end{array}$$

and, bearing in mind that $h_m \leq k_m < g$, we have that

$$\sum_{j=1}^{i} r_j = (m-1)i \geq \sum_{j=1}^{i} v'_j,\ 1 \leq i < g,$$

$$\sum_{j=1}^{i} r_j = \sum_{j=1}^{i} t_j - h_m \geq \sum_{j=1}^{i} v_j - h_m = \sum_{j=1}^{i} v'_j,\ g \leq i \leq n,$$

and

$$\sum_{j=1}^{n} r_j = \sum_{j=1}^{n} t_j - h_m = \sum_{j=1}^{n} v_j - h_m = \sum_{j=1}^{n} v'_j,$$

from which we obtain (2.14). □

LEMMA 2.6. *Let $h_1 \geq \cdots \geq h_p > 0$ positive integers, and let*

$$(A_{ii}, B_{ii}) = \left(\begin{bmatrix} 0 & 0 & \dots & 0 & x_{ii0} \\ 1 & 0 & \dots & 0 & x_{ii1} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \dots & 1 & x_{iih_i-1} \end{bmatrix}, \begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix} \right) \in \mathbb{F}^{h_i \times hi} \times \mathbb{F}^{h_i \times 1},\ i = 1, \dots, p.$$

Let $k_1 \geq \cdots \geq k_m > 0$ be positive integers. If condition (2.4) *is satisfied, then there exist matrices $X_{ij} \in \mathbb{F}^{h_i \times h_j}$, $Y_{ij} \in \mathbb{F}^{h_i \times 1}$, $1 \leq i \leq p-1$, $i+1 \leq j \leq p$, and $Y_{ip+1} \in \mathbb{F}^{h_i \times (m-p)}$, $1 \leq i \leq p$, such that*

$$\left(\begin{bmatrix} A_{11} & X_{12} & \dots & X_{1p} \\ 0 & A_{22} & \dots & X_{2p} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & A_{pp} \end{bmatrix}, \begin{bmatrix} B_{11} & Y_{12} & \dots & Y_{1p} & Y_{1p+1} \\ 0 & B_{22} & \dots & Y_{2p} & Y_{2p+1} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \dots & B_{pp} & Y_{pp+1} \end{bmatrix} \right)$$

has $k_1, k_2, \dots, k_m$ as controllability indices.

Proof. If $m = 1$, then $k_1 = h_1$, and there is nothing to prove.

Assume now that condition (2.4) is sufficient for $m-1$, and let us show that it is sufficient for m.

From (2.4) we have that $m \geq p$ and $k_m \geq h_m$.

Let $(v_1, v_2, \ldots, v_n) = \overline{(h_1, \ldots, h_m)}$, $(t_1, \ldots, t_n) = \overline{(k_1, \ldots, k_m)}$, and $(v'_1, \ldots, v'_n) = \overline{(h_1, \ldots, h_{m-1})}$. From Lemma 2.5 there exist nonnegative integers $r_1, \ldots, r_n$ satisfying conditions (2.13)–(2.16) and $r_1 = m - 1$.

Let $(k'_1, \ldots, k'_{m-1}) = \overline{(r_1, \ldots, r_n)}$. Then $k'_{m-1} > 0$, and condition (2.14) is equivalent to

$$(k'_1, \ldots, k'_{m-1}) \prec (h_1, \ldots, h_{m-1}). \tag{2.17}$$

Moreover, from (2.4) and (2.14), we obtain

$$\sum_{j=1}^{n} r_j + h_m = \sum_{j=1}^{n} t_j, \tag{2.18}$$

and, since $k_1 \geq k_m \geq h_m$,

$$t_j \geq 1,\ 1 \leq j \leq h_m. \tag{2.19}$$

If $m = p$, from (2.17) and the induction hypothesis, there are matrices $X_{ij} \in \mathbb{F}^{h_i \times h_j}$, $Y_{ij} \in \mathbb{F}^{h_i \times 1}$, $1 \leq i \leq m-2$, $i+1 \leq j \leq m-1$, such that the matrix pair

$$(A', B') = \left(\begin{bmatrix} A_{11} & X_{12} & \ldots & X_{1m-1} \\ 0 & A_{22} & \ldots & X_{2m-1} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & A_{m-1m-1} \end{bmatrix}, \begin{bmatrix} B_{11} & Y_{12} & \ldots & Y_{1m-1} \\ 0 & B_{22} & \ldots & Y_{2m-1} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & B_{m-1m-1} \end{bmatrix} \right)$$

has $k'_1, \ldots, k'_{m-1}$ as controllability indices (and therefore $r_1, \ldots, r_n$ as Brunovsky indices). The Brunovsky indices of (A_{mm}, B_{mm}) are $1, \ldots, 1$ (h_m times).

From (2.15), (2.16), (2.18), and (2.19), by Lemma 2.3, there exist matrices $X \in \mathbb{F}^{(n-h_m) \times h_m}$, $Y \in \mathbb{F}^{(n-h_m) \times 1}$ such that the matrix pair

$$\left(\begin{bmatrix} A' & X \\ 0 & A_{mm} \end{bmatrix}, \begin{bmatrix} B' & Y \\ 0 & B_{mm} \end{bmatrix} \right)$$

has $k_1, \ldots, k_m$ as controllability indices.

If $m > p$, from (2.17) and the induction hypothesis, there are matrices $X_{ij} \in \mathbb{F}^{h_i \times h_j}$, $Y_{ij} \in \mathbb{F}^{h_i \times 1}$, $1 \leq i \leq p-1$, $i+1 \leq j \leq p$, and $Y_{ip+1} \in \mathbb{F}^{h_i \times (m-1-p)}$, $1 \leq i \leq p$, such that

$$(A', B') = \left(\begin{bmatrix} A_{11} & X_{12} & \ldots & X_{1p} \\ 0 & A_{22} & \ldots & X_{2p} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & A_{pp} \end{bmatrix}, \begin{bmatrix} B_{11} & Y_{12} & \ldots & Y_{1p} & Y_{1p+1} \\ 0 & B_{22} & \ldots & Y_{2p} & Y_{2p+1} \\ \vdots & \vdots & \ddots & \vdots & \\ 0 & 0 & \ldots & B_{pp} & Y_{pp+1} \end{bmatrix} \right)$$

has $r_1, \ldots, r_n$ as Brunovsky indices.

As $m > p$, it follows that $h_m = 0$. From (2.15), (2.16), and (2.18), by Lemma 2.4, there exists $y_{p+1} \in \mathbb{F}^{n \times 1}$ such that the matrix pair

$$\left(A', \begin{bmatrix} B' & y_{p+1} \end{bmatrix} \right)$$

has $k_1, \ldots, k_m$ as controllability indices. □

LEMMA 2.7. *Let $(A_i, B_i), (\hat{A}_i, \hat{B}_i) \in \mathbb{F}^{n_i \times n_i} \times \mathbb{F}^{n_i \times m_i}$, $i = 1, 2$, and assume that (A_i, B_i) is feedback equivalent to $(\hat{A}_i, \hat{B}_i)$, $i = 1, 2$. Let $m \geq m_1 + m_2$ and $k_1 \geq$*

$\cdots \geq k_m \geq 0$ *be nonnegative integers. Then there exist matrices* $X \in \mathbb{F}^{n_1 \times n_2}, Y_1 \in \mathbb{F}^{n_1 \times m_2}$, $Y_2 \in \mathbb{F}^{n_1 \times (m-m_1-m_2)}$, $Y_3 \in \mathbb{F}^{n_2 \times (m-m_1-m_2)}$ *such that*

$$(A, B) = \left(\begin{bmatrix} A_1 & X \\ 0 & A_2 \end{bmatrix}, \begin{bmatrix} B_1 & Y_1 & Y_2 \\ 0 & B_2 & Y_3 \end{bmatrix} \right)$$

has $k_1, \ldots, k_m$ *as controllability indices if and only if there exist matrices* $\hat{X} \in \mathbb{F}^{n_1 \times n_2}$, $\hat{Y}_1 \in \mathbb{F}^{n_1 \times m_2}$, $\hat{Y}_2 \in \mathbb{F}^{n_1 \times (m-m_1-m_2)}$, $\hat{Y}_3 \in \mathbb{F}^{n_2 \times (m-m_1-m_2)}$ *such that*

$$(\hat{A}, \hat{B}) = \left(\begin{bmatrix} \hat{A}_1 & \hat{X} \\ 0 & \hat{A}_2 \end{bmatrix}, \begin{bmatrix} \hat{B}_1 & \hat{Y}_1 & \hat{Y}_2 \\ 0 & \hat{B}_2 & \hat{Y}_3 \end{bmatrix} \right)$$

has $k_1, \ldots, k_m$ *as controllability indices.*

Proof. Assume that

$$(A, B) = \left(\begin{bmatrix} A_1 & X \\ 0 & A_2 \end{bmatrix}, \begin{bmatrix} B_1 & Y_1 & Y_2 \\ 0 & B_2 & Y_3 \end{bmatrix} \right)$$

has $k_1, \ldots, k_m$ as controllability indices.

There are nonsingular matrices $P_i \in \mathbb{F}^{n_i \times n_i}$ and $Q_i \in \mathbb{F}^{m_i \times m_i}$ and matrices $R_i \in \mathbb{F}^{m_i \times n_i}$, $i = 1, 2$, such that

$$(\hat{A}_i, \hat{B}_i) = (P_i A_i P_i^{-1} + P_i B_i R_i, P_i B_i Q_i), \quad i = 1, 2.$$

Put

$$P := \begin{bmatrix} P_1 & 0 \\ 0 & P_2 \end{bmatrix}, \quad Q := \begin{bmatrix} Q_1 & 0 & 0 \\ 0 & Q_2 & 0 \\ 0 & 0 & I_{m-m_1-m_2} \end{bmatrix}, \quad \text{and} \quad R := \begin{bmatrix} R_1 & 0 \\ 0 & R_2 \\ 0 & 0 \end{bmatrix}.$$

Then

$$(PAP^{-1} + PBR, PBQ) = \left(\begin{bmatrix} \hat{A}_1 & \hat{X} \\ 0 & \hat{A}_2 \end{bmatrix}, \begin{bmatrix} \hat{B}_1 & \hat{Y}_1 & \hat{Y}_2 \\ 0 & \hat{B}_2 & \hat{Y}_3 \end{bmatrix} \right),$$

where $\hat{X} = P_1 X P_2^{-1} + P_1 Y_1 R_2$, $\hat{Y}_1 = P_1 Y_1 Q_2$, $\hat{Y}_2 = P_1 Y_2$, and $\hat{Y}_3 = P_2 Y_3$. ∎

LEMMA 2.8. *Let* $(A_1, B_1) \in \mathbb{F}^{n_1 \times n_1} \times \mathbb{F}^{n_1 \times m_1}$ *be a controllable matrix pair,* $A_2 \in \mathbb{F}^{n_2 \times n_2}$ *and* $A_3 \in \mathbb{F}^{n_1 \times n_2}$. *Then there exist* $R \in \mathbb{F}^{m_1 \times n_2}$ *and* $L \in \mathbb{F}^{n_1 \times n_2}$ *such that*

$$A_1 L + B_1 R - L A_2 = A_3.$$

Proof. Let $k_1 \geq k_2 \geq \cdots \geq k_r$ be the controllability indices of the matrix pair (A_1, B_1), then [16] there exist nonsingular matrices $P \in \mathbb{F}^{n_1 \times n_1}$ and $Q \in \mathbb{F}^{m_1 \times m_1}$ and a matrix $F \in \mathbb{F}^{m_1 \times n_1}$ such that

$$P A_1 P^{-1} + P B_1 F = \hat{A}_1, \quad P B_1 Q = \hat{B}_1,$$

where

$$\hat{A}_1 = \operatorname{diag}(A_{11}, A_{12}, \ldots, A_{1r}), \quad \hat{B}_1 = \begin{bmatrix} B_{11} \\ B_{12} \\ \vdots \\ B_{1r} \end{bmatrix}$$

and

$$A_{1i} = \begin{bmatrix} 0 & I_{k_i-1} \\ 0 & 0 \end{bmatrix} \in \mathbb{F}^{k_i \times k_i},\ B_{1i} = \begin{bmatrix} 0 \\ e_i \end{bmatrix} \in \mathbb{F}^{k_i \times m_1},\ i = 1, \dots, r,$$

where e_i is the ith row of the identity matrix I_{m_1}.

Let us put

$$\hat{A}_3 = PA_3 = \begin{bmatrix} A_{31} \\ A_{32} \\ \vdots \\ A_{3r} \end{bmatrix},\quad A_{3i} \in \mathbb{F}^{k_i \times n_2},\ i = 1, \dots, r.$$

By Lemma 2.10 of [16], for $i = 1, \dots, r$ there are matrices $L_i \in \mathbb{F}^{k_i \times n_2}$, $d_i \in \mathbb{F}^{1 \times n_2}$ such that $-A_{1i}L_i + A_{3i} + L_iA_2 = \left[\begin{smallmatrix} 0 \\ d_i \end{smallmatrix}\right] \in \mathbb{F}^{k_i \times n_2}$.

Let

$$\hat{L} = \begin{bmatrix} L_1 \\ L_2 \\ \vdots \\ L_r \end{bmatrix}.$$

As all the elements of B_{1i} are zero except the one in position (k_i, i), it is easy to prove that there exists a matrix $\hat{R} \in \mathbb{F}^{m_1 \times n_2}$ such that $-\hat{A}_1\hat{L} + \hat{A}_3 + \hat{L}A_2 + \hat{B}_1\hat{R} = 0$.

Therefore,

$$-PA_1P^{-1}\hat{L} - PB_1F\hat{L} + PA_3 + \hat{L}A_2 + PB_1Q\hat{R} = 0,$$

and if we put $L = P^{-1}\hat{L}$ and $R = F\hat{L} - Q\hat{R}$, the lemma follows. □

LEMMA 2.9. *Let*

$$(A, B) = \left(\begin{bmatrix} A_{11} & A_{12} & \dots & A_{1p} \\ 0 & A_{22} & \dots & A_{2p} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & A_{pp} \end{bmatrix}, \begin{bmatrix} B_{11} & 0 & \dots & 0 \\ 0 & B_{22} & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & B_{pp} \end{bmatrix} \right),$$

with $(A_{ii}, B_{ii}) \in \mathbb{F}^{n_i \times n_i} \times \mathbb{F}^{n_i \times m_i}$ *controllable,* $1 \le i \le p-1$ *and* $(A_{pp}, B_{pp}) \in \mathbb{F}^{n_p \times n_p} \times \mathbb{F}^{n_p \times m_p}$. *Let* $m \ge \sum_{i=1}^{p} m_i$ *and* $k_1 \ge \cdots \ge k_m \ge 0$ *be nonnegative integers. Then there exist matrices* $Z_{ij} \in \mathbb{F}^{n_i \times m_j}$, $1 \le i \le p-1$, $i+1 \le j \le p$, *and* $Z_{ip+1} \in \mathbb{F}^{n_i \times (m - \sum_{i=1}^{p} m_i)}$, $1 \le i \le p$, *such that*

$$(A^{(p)}, B^{(p)}) = \left(\begin{bmatrix} A_{11} & A_{12} & \dots & A_{1p} \\ 0 & A_{22} & \dots & A_{2p} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & A_{pp} \end{bmatrix}, \begin{bmatrix} B_{11} & Z_{12} & \dots & Z_{1p} & Z_{1p+1} \\ 0 & B_{22} & \dots & Z_{2p} & Z_{2p+1} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \dots & B_{pp} & Z_{pp+1} \end{bmatrix} \right)$$

has $k_1, \dots, k_m$ *as controllability indices if and only if there exist matrices* $X_{ij} \in \mathbb{F}^{n_i \times n_j}, Y_{ij} \in \mathbb{F}^{n_i \times m_j}$, $1 \le i \le p-1$, $i+1 \le j \le p$, *and* $Y_{ip+1} \in \mathbb{F}^{n_i \times (m - \sum_{i=1}^{p} m_i)}$, $1 \le i \le p$, *such that*

$$(\hat{A}^{(p)}, \hat{B}^{(p)}) = \left(\begin{bmatrix} A_{11} & X_{12} & \dots & X_{1p} \\ 0 & A_{22} & \dots & X_{2p} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & A_{pp} \end{bmatrix}, \begin{bmatrix} B_{11} & Y_{12} & \dots & Y_{1p} & Y_{1p+1} \\ 0 & B_{22} & \dots & Y_{2p} & Y_{2p+1} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \dots & B_{pp} & Y_{pp+1} \end{bmatrix} \right)$$

has $k_1, \dots, k_m$ *as controllability indices.*

Proof. We will show by induction on p that if there exist matrices $X_{ij} \in \mathbb{F}^{n_i \times n_j}$, $Y_{ij} \in \mathbb{F}^{n_i \times m_j}$, $1 \leq i \leq p-1$, $i+1 \leq j \leq p$, and $Y_{ip+1} \in \mathbb{F}^{n_i \times (m - \sum_{i=1}^{p} m_i)}$, $1 \leq i \leq p$, such that $(\hat{A}^{(p)}, \hat{B}^{(p)})$ has $k_1, \ldots, k_m$ as controllability indices, then there exist matrices $Z_{ij} \in \mathbb{F}^{n_i \times m_j}$, $1 \leq i \leq p-1$, $i+1 \leq j \leq p$, and $Z_{ip+1} \in \mathbb{F}^{n_i \times (m - \sum_{i=1}^{p} m_i)}$, $1 \leq i \leq p$, such that $(A^{(p)}, B^{(p)})$ has $k_1, \ldots, k_m$ as controllability indices.

If $p = 1$, the proposition is trivial.

We will assume that it is true up to $p-1$, and let us prove that it also holds for p.

Let us suppose that there are matrices $X_{ij} \in \mathbb{F}^{n_i \times n_j}$, $Y_{ij} \in \mathbb{F}^{n_i \times m_j}$, $1 \leq i \leq p-1$, $i+1 \leq j \leq p$, and $Y_{ip+1} \in \mathbb{F}^{n_i \times (m - \sum_{i=1}^{p} m_i)}$, $1 \leq i \leq p$, such that $(\hat{A}^{(p)}, \hat{B}^{(p)})$ has $k_1, \ldots, k_m$ as controllability indices. By the induction hypothesis there exist matrices $Z_{ij} \in \mathbb{F}^{n_i \times m_j}$, $1 \leq i \leq p-1$, $i+1 \leq j \leq p-1$, such that

$$(A^{(p-1)}, B^{(p-1)}) = \left(\begin{bmatrix} A_{11} & A_{12} & \ldots & A_{1p-1} \\ 0 & A_{22} & \ldots & A_{2p-1} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & A_{p-1p-1} \end{bmatrix}, \begin{bmatrix} B_{11} & Z_{12} & \ldots & Z_{1p-1} \\ 0 & B_{22} & \ldots & Z_{2p-1} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & B_{p-1p-1} \end{bmatrix} \right)$$

has the same controllability indices as

$$(\hat{A}^{(p-1)}, \hat{B}^{(p-1)}) = \left(\begin{bmatrix} A_{11} & X_{12} & \ldots & X_{1p-1} \\ 0 & A_{22} & \ldots & X_{2p-1} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & A_{p-1p-1} \end{bmatrix}, \begin{bmatrix} B_{11} & Y_{12} & \ldots & Y_{1p-1} \\ 0 & B_{22} & \ldots & Y_{2p-1} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & B_{p-1p-1} \end{bmatrix} \right).$$

Furthermore, as (A_{ii}, B_{ii}) is controllable, $1 \leq i \leq p-1$; then the pairs $(A^{(p-1)}, B^{(p-1)})$ and $(\hat{A}^{(p-1)}, \hat{B}^{(p-1)})$ are controllable, and so they are feedback equivalent.

Let us assume that

$$X_p = \begin{bmatrix} X_{1p} \\ \vdots \\ X_{p-1p} \end{bmatrix} \in \mathbb{F}^{\sum_{i=1}^{p-1} n_i \times n_p}, \qquad Y_p = \begin{bmatrix} Y_{1p} \\ \vdots \\ Y_{p-1p} \end{bmatrix} \in \mathbb{F}^{\sum_{i=1}^{p-1} n_i \times m_p},$$

and

$$Y_{p+1} = \begin{bmatrix} Y_{1p+1} \\ \vdots \\ Y_{p-1p+1} \end{bmatrix} \in \mathbb{F}^{\sum_{i=1}^{p-1} n_i \times (m - \sum_{i=1}^{p} m_i)}$$

are matrices such that

$$(\hat{A}^{(p)}, \hat{B}^{(p)}) = \left(\begin{bmatrix} \hat{A}^{(p-1)} & X_p \\ 0 & A_{pp} \end{bmatrix}, \begin{bmatrix} \hat{B}^{(p-1)} & Y_p & Y_{p+1} \\ 0 & B_{pp} & Y_{pp+1} \end{bmatrix} \right)$$

has $k_1, \ldots, k_m$ as controllability indices.

By Lemma 2.7 there exist $\hat{X}_p, \hat{Y}_p, \hat{Y}_{p+1}, \hat{Y}_{pp+1}$ such that

$$\left(\begin{bmatrix} A^{(p-1)} & \hat{X}_p \\ 0 & A_{pp} \end{bmatrix}, \begin{bmatrix} B^{(p-1)} & \hat{Y}_p & \hat{Y}_{p+1} \\ 0 & B_{pp} & \hat{Y}_{pp+1} \end{bmatrix} \right)$$

is feedback equivalent to $(\hat{A}^{(p)}, \hat{B}^{(p)})$.

Because $(A^{(p-1)}, B^{(p-1)})$ is controllable, by Lemma 2.8 there exist matrices $L \in \mathbb{F}^{\sum_{i=1}^{p-1} n_i \times n_p}$ and $R \in \mathbb{F}^{\sum_{i=1}^{p-1} m_i \times n_p}$ such that

$$A^{(p-1)}L - LA_{pp} + B^{(p-1)}R = \hat{X}_p - A_p,$$

where

$$A_p = \begin{bmatrix} A_{1p} \\ \vdots \\ A_{p-1p} \end{bmatrix} \in \mathbb{F}^{\sum_{i=1}^{p-1} n_i \times n_p}.$$

Put

$$T = \begin{bmatrix} I & L \\ 0 & I \end{bmatrix}, \quad F = \begin{bmatrix} 0 & -R \\ 0 & 0 \\ 0 & 0 \end{bmatrix}.$$

Then

$$T \begin{bmatrix} A^{(p-1)} & \hat{X}_p \\ 0 & A_{pp} \end{bmatrix} T^{-1} + T \begin{bmatrix} B^{(p-1)} & \hat{Y}_p & \hat{Y}_{p+1} \\ 0 & B_{pp} & \hat{Y}_{pp+1} \end{bmatrix} F = \begin{bmatrix} A^{(p-1)} & A_p \\ 0 & A_{pp} \end{bmatrix} = A^{(p)}$$

and

$$T \begin{bmatrix} B^{(p-1)} & \hat{Y}_p & \hat{Y}_{p+1} \\ 0 & B_{pp} & \hat{Y}_{pp+1} \end{bmatrix} = \begin{bmatrix} B^{(p-1)} & \hat{Y}_p + LB_{pp} & \hat{Y}_{p+1} + L\hat{Y}_{pp+1} \\ 0 & B_{pp} & \hat{Y}_{pp+1} \end{bmatrix}.$$

Write $Z_{pp+1} = \hat{Y}_{pp+1}$ and

$$\hat{Y}_p + LB_{pp} = \begin{bmatrix} Z_{1p} \\ \vdots \\ Z_{p-1p} \end{bmatrix}, \quad \hat{Y}_{p+1} + L\hat{Y}_{pp+1} = \begin{bmatrix} Z_{1p+1} \\ \vdots \\ Z_{p-1p+1} \end{bmatrix},$$

where $Z_{ip} \in \mathbb{F}^{n_i \times m_p}, 1 \le i \le p-1$, and $Z_{ip+1} \in \mathbb{F}^{n_i \times (m - \sum_{i=1}^{p} m_i)}, 1 \le i \le p-1$. Put

$$B^{(p)} = \begin{bmatrix} B^{(p-1)} & \hat{Y}_p + LB_{pp} & \hat{Y}_{p+1} + L\hat{Y}_{pp+1} \\ 0 & B_{pp} & \hat{Y}_{pp+1} \end{bmatrix}.$$

Then $(A^{(p)}, B^{(p)})$ is feedback equivalent to $(\hat{A}^{(p)}, \hat{B}^{(p)})$, and therefore it has $k_1, \ldots, k_m$ as controllability indices. □

Finally, the following lemma, whose proof is straightforward, allows us to perform some transformations on matrix B without altering the Hermite indices of pair (A, B).

LEMMA 2.10. *Let $A \in \mathbb{F}^{n \times n}$ and $b_i \in \mathbb{F}^{n \times 1}, 1 \le i \le m$. Let $h_1, \ldots, h_m$ be the Hermite indices of the pair (A, B), where $B = [b_1, \ldots, b_m]$. Let t be a nonnegative integer and $l \in \{2, \ldots, m\}$. Put $b'_l = b_l + \sum_{j=0}^{t} \sum_{i=1}^{l-1} c_{ij} A^j b_i$, where $c_{ij} \in \mathbb{F}$ are arbitrary. Then, $h_1, \ldots, h_m$ are the Hermite indices of the matrix pair (A, B'), where $B' = [b_1, \ldots, b'_l, \ldots, b_m]$.*

As a consequence of this result, we have that the matrix pair

$$(A_c, B'_c) = \left(\begin{bmatrix} A_{11} & A_{12} & \ldots & A_{1p} \\ 0 & A_{22} & \ldots & A_{2p} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & A_{pp} \end{bmatrix}, \begin{bmatrix} B_{11} & Z_{12} & \ldots & Z_{1p} & Z_{1p+1} \\ 0 & B_{22} & \ldots & Z_{2p} & Z_{2p+1} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \ldots & B_{pp} & Z_{pp+1} \end{bmatrix} \right)$$

for arbitrary $Z_{ij} \in \mathbb{F}^{h_i \times 1}$, $1 \le i \le p-1$, $i+1 \le j \le p$, and $Z_{ip+1} \in \mathbb{F}^{h_i \times (m-p)}$, $1 \le i \le p$, has $h_1, \dots, h_m$ as Hermite indices.

Now we can prove our main result.

THEOREM 2.11. *Let $A \in \mathbb{F}^{n\times n}$, and let $\alpha_1 \mid \dots \mid \alpha_n$ be its invariant factors. Let $k_1 \ge \cdots \ge k_m > 0$ and $h_1 \ge \cdots \ge h_m \ge 0$ be nonnegative integers. Then there exists a matrix $B \in \mathbb{F}^{n\times m}$ such that (A, B) is controllable and has $k_1, \dots, k_m$ as controllability indices and $h_1, \dots, h_m$ as Hermite indices if and only if there are m monic polynomials $\beta_1, \dots, \beta_m$ such that $d(\beta_i) = h_i$, $1 \le i \le m$, and conditions* (2.1), (2.2), (2.3), *and* (2.4) *are satisfied.*

Proof. The necessity is a direct consequence of Lemmas 2.1 and 2.2.

Assume now that a matrix $A \in \mathbb{F}^{n\times n}$ is given with $\alpha_1 \mid \dots \mid \alpha_n$ as invariant factors. By Lemma 2.1 conditions (2.1)–(2.3) are sufficient for the existence of a matrix $B \in \mathbb{F}^{n\times m}$ such that (A, B) has $h_1, \dots, h_m$ as Hermite indices. By Lemma 1.3 (A, B) is similar to (A_c, B_c), where this pair has the form exhibited in that lemma. From Lemmas 2.6, 2.9, and 2.10 we have that if condition (2.4) is fulfilled, then there are matrices $Z_{ij} \in \mathbb{F}^{h_i \times 1}$, $1 \le i \le p-1$, $i+1 \le j \le p$, and $Z_{ip+1} \in \mathbb{F}^{h_i \times (m-p)}$, $1 \le i \le p$, such that

$$(A_c, B_c') = \left(\begin{bmatrix} A_{11} & A_{12} & \dots & A_{1p} \\ 0 & A_{22} & \dots & A_{2p} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & A_{pp} \end{bmatrix}, \begin{bmatrix} B_{11} & Z_{12} & \dots & Z_{1p} & Z_{1p+1} \\ 0 & B_{22} & \dots & Z_{2p} & Z_{2p+1} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \dots & B_{pp} & Z_{pp+1} \end{bmatrix} \right)$$

has $k_1, \dots, k_m$ as controllability indices and $h_1, \dots, h_m$ as Hermite indices. As A and A_c are similar matrices, there is a nonsingular matrix $P \in \mathbb{F}^{n\times n}$ such that $A = PA_cP^{-1}$. Put $B = PB_c'$. Then (A, B) has $k_1, \dots, k_m$ and $h_1, \dots, h_m$ as controllability and Hermite indices, respectively, and the theorem follows. ∎

It is worth noting that if $\mathbb{F}$ is algebraically closed in [20], it has been shown that conditions (2.1), (2.2), and (2.3) are equivalent to (2.1) and

$$(h_1, \dots, h_m) \prec (d(\alpha_n), \dots, d(\alpha_{n-m+1})). \tag{2.20}$$

Thus, in this case, we have the following consequence of Theorem 2.11.

COROLLARY 2.12. *Let $\mathbb{F}$ be an algebraically closed field. Let $A \in \mathbb{F}^{n\times n}$, and let $\alpha_1 \mid \dots \mid \alpha_n$ be its invariant factors. Let $k_1 \ge \cdots \ge k_m > 0$ and $h_1 \ge \cdots \ge h_m \ge 0$ be nonnegative integers. Then there exists a matrix $B \in \mathbb{F}^{n\times m}$ such that (A, B) is controllable and has $k_1, \dots, k_m$ as controllability indices and $h_1, \dots, h_m$ as Hermite indices if and only if conditions* (2.1), (2.20), *and* (2.4) *are satisfied.*

3. The noncontrollable case. Now we will generalize Theorem 2.11 to the noncontrollable case. It is well known (see, for example, [9, p. 361]) that if (A, B) is not completely controllable, then there is a nonsingular matrix P such that

$$PAP^{-1} = \begin{bmatrix} A_1 & A_2 \\ 0 & A_3 \end{bmatrix}, \quad PB = \begin{bmatrix} B_1 \\ 0 \end{bmatrix}, \tag{3.1}$$

where $(A_1, B_1) \in \mathbb{F}^{r\times r}$ is controllable and $r = \operatorname{rank} C(A, B)$. Furthermore, the invariant factors of (A, B) different from 1 and those of A_3 coincide [17].

As the Hermite indices and the controllability indices are invariant under similarity tranformations, it follows that the Hermite indices and the controllability indices of (A, B) are those of the matrix pair (A_1, B_1) in the decomposition of (A, B) as in (3.1).

The generalization of Lemma 2.1 to the noncontrollable case is given by the following lemma.

LEMMA 3.1 (see [20]). *Let $A \in \mathbb{F}^{n\times n}$, and let $\alpha_1 \mid \ldots \mid \alpha_n$ be its invariant factors. Let $h_1, \ldots, h_m$ and $\gamma_1, \ldots, \gamma_n$ be nonnegative integers and monic polynomials, respectively, such that $d(\gamma_1) + \cdots + d(\gamma_n) = q$. Let $r = n - q$. Then there exists a matrix $B \in \mathbb{F}^{n\times m}$, $m \le r$, such that (A, B) has $h_1, \ldots, h_m$ as Hermite indices and $\gamma_1, \ldots, \gamma_n$ as invariant factors if and only if there are m monic polynomials $\tau_1, \ldots, \tau_m$ such that $d(\tau_i) = h_i$, $1 \le i \le m$, and*

$$\alpha_{i-m} \mid \gamma_i \mid \alpha_i, \ 1 \le i \le n, \tag{3.2}$$

$$\sigma_1 \ldots \sigma_{r-m+j} \mid \text{g.c.d.}\{\tau_{i_1} \ldots \tau_{i_j} : 1 \le i_1 < \cdots < i_j \le m\}, \ 1 \le j \le m, \tag{3.3}$$

$$\sigma_1 \ldots \sigma_r = \tau_1 \ldots \tau_m, \tag{3.4}$$

where we agree that $\alpha_i := 1$ for $i < 1$ and $\sigma_j = \frac{\beta^j}{\beta^{j-1}}$, $1 \le j \le r$, and $\beta^j = \prod_{i=1}^{n+j} l.c.m.(\gamma_{i-j}, \alpha_{i-r})$, $0 \le j \le r$.

With the help of this result we can generalize Theorem 2.11 to give a complete solution to Problem 1.

THEOREM 3.2. *Let $A \in \mathbb{F}^{n\times n}$, and let $\alpha_1 \mid \ldots \mid \alpha_n$ be its invariant factors. Let $k_1 \ge \cdots \ge k_m > 0$ and $h_1 \ge \cdots \ge h_m \ge 0$ be nonnegative integers and $\gamma_1, \ldots, \gamma_n$ monic polynomials, such that $d(\gamma_1) + \cdots + d(\gamma_n) = q$. Let $r = n - q$. Then there exists a matrix $B \in \mathbb{F}^{n\times m}$, $m \le r$, such that (A, B) has $h_1, \ldots, h_m$ as Hermite indices, $k_1, \ldots, k_m$ as controllability indices, and $\gamma_1, \ldots, \gamma_n$ as invariant factors if and only if there are m monic polynomials $\tau_1, \ldots, \tau_m$ such that $d(\tau_i) = h_i$, $1 \le i \le m$, and the conditions* (3.2)–(3.4) *and* (2.4) *are satisfied.*

Proof of Theorem 3.2.

Necessity. If there exists B such that (A, B) has $k_1, \ldots, k_m$ as controllability indices, $h_1, \ldots, h_m$ as Hermite indices, and $\gamma_1, \ldots, \gamma_n$ as invariant factors, by Lemma 3.1 conditions (3.2)–(3.4) hold. Moreover, there exists a matrix P such that (3.1) holds and the controllability indices and the Hermite indices of (A, B) are those of the pair (A_1, B_1). Then, by Lemma 2.2 condition (2.4) holds.

Sufficiency. By Lemma 3.1, if conditions (3.2), (3.3), and (3.4) hold, there exists a matrix $B \in \mathbb{F}^{n\times m}$ such that (A, B) has $h_1, \ldots, h_m$ as Hermite indices and $\gamma_1, \ldots, \gamma_n$ as invariant factors.

If we assume that $h_1 \ge \cdots \ge h_p > 0 = h_{p+1} = \cdots = h_m$, then there exists a matrix P such that

$$PAP^{-1} = \begin{bmatrix} A_c & A_2 \\ 0 & A_3 \end{bmatrix} \qquad PB = \begin{bmatrix} B_c \\ 0 \end{bmatrix},$$

where $(A_c, B_c) \in \mathbb{F}^{r\times r} \times \mathbb{F}^{r\times m}$ has the structure of that of Lemma 1.3 with $h_1, \ldots, h_m$ as Hermite indices and $\gamma_{r+1}, \ldots, \gamma_n$ are the invariant factors of A_3.

Now, as in the proof of Theorem 2.11, if conditions (3.2)–(3.4) and (2.4) hold, then there exists B_c' such that

$$\left(\begin{bmatrix} A_c & A_2 \\ 0 & A_3 \end{bmatrix}, \begin{bmatrix} B_c' \\ 0 \end{bmatrix} \right)$$

has $k_1, \ldots, k_m$ as controllability indices, $h_1, \ldots, h_m$ as Hermite indices, and $\gamma_1, \ldots, \gamma_n$ as invariant factors.

As

$$A \overset{s}{\sim} \begin{bmatrix} A_c & A_2 \\ 0 & A_3 \end{bmatrix},$$

by applying Lemma 1.2, the theorem follows. □

COROLLARY 3.3. *Let $A \in \mathbb{F}^{n\times n}$, and let $\alpha_1 \mid \ldots \mid \alpha_n$ be its invariant factors, $\mathbb{F}$ algebraically closed. Let $k_1 \geq \cdots \geq k_m > 0$, $h_1 \geq \cdots \geq h_m \geq 0$ be nonnegative integers and $\gamma_1, \ldots, \gamma_n$ monic polynomials such that $d(\gamma_1) + \cdots + d(\gamma_n) = q$. Let $r = n - q$. Then there exists a matrix $B \in \mathbb{F}^{n\times m}$, $m \leq r$, such that (A, B) has $k_1, \ldots, k_m$ as controllability indices, $h_1, \ldots, h_m$ as Hermite indices, and $\gamma_1, \ldots, \gamma_n$ as invariant factors if and only if the conditions* (3.2), (2.4), *and*

$$(h_1, \ldots, h_m) \prec (d(\sigma_r), \ldots, d(\sigma_1)) \tag{3.5}$$

are satisfied.

A consequence of this corollary and Proposition 1.1 is the following theorem.

THEOREM 3.4. *Let $(A, B) \in \mathbb{F}^{n\times n} \times \mathbb{F}^{n\times m}$ be a matrix pair with $k_1 \geq \cdots \geq k_m > 0$ and $\gamma_1 \mid \ldots \mid \gamma_n$ as controllability indices and invariant factors, respectively. Let $\alpha_1 \mid \ldots \mid \alpha_n$ and $h_1 \geq \cdots \geq h_m \geq 0$ be monic polynomials and nonnegative integers. Then there exist a state feedback matrix $F \in \mathbb{F}^{m\times n}$ and a nonsingular matrix $Q \in \mathbb{F}^{m\times m}$ such that $A + BF$ has $\alpha_1, \ldots, \alpha_n$ as invariant factors and $(A + BF, BQ)$ has $h_1, \ldots, h_m$ as Hermite indices if and only if conditions* (3.2), (2.4), *and* (3.5) *hold.*

Acknowledgment. Thanks are given to the referees for their valuable suggestions for improving this paper. The authors are specially indebted to one of the referees for suggesting the equivalence of Problems 1 and 2.

MINIMIZING EXPECTED LOSS OF HEDGING IN INCOMPLETE AND CONSTRAINED MARKETS*

JAKŠA CVITANIĆ†

Abstract. We study the problem of minimizing the expected discounted loss

$$E\left[e^{-\int_0^T r(u)du}(C - X^{x,\pi}(T))^+\right]$$

when hedging a liability C at time $t = T$, using an admissible portfolio strategy $\pi(\cdot)$ and starting with initial wealth x. The existence of an optimal solution is established in the context of continuous-time Ito process *incomplete* market models, by studying an appropriate dual problem. It is shown that the optimal strategy is of the form of a knock-out option with payoff C, where the "domain of the knock-out" depends on the value of the optimal dual variable. We also discuss a dynamic measure for the risk associated with the liability C, defined as the supremum over different scenarios of the minimal expected loss of hedging C.

Key words. expected loss, hedging, incomplete markets, portfolio constraints, dynamic measures of risk

1. Introduction.

In a *complete* financial market which is free of arbitrage opportunities, any sufficiently integrable random payoff (*contingent claim*) C, whose value has to be delivered and is known at time $t = T$, can be hedged perfectly: starting with a large enough initial capital x, an agent can find a trading strategy π that will allow his wealth $X^{x,\pi}(\cdot)$ to hedge the liability C *without risk* at time $t = T$, that is,

$$X^{x,\pi}(T) \geq C \quad \text{almost surely (a.s.)} \quad \text{for some portfolio } \pi(\cdot), \tag{1.1}$$

while maintaining "solvency" throughout $[0, T]$. (For an overview of standard results in complete and some incomplete markets in continuous-time Ito process models, see, for example, Cvitanić (1997), or a recent book by Karatzas and Shreve (1998).) This is either no longer possible or too expensive to accomplish in a market which is incomplete due to various "market frictions," such as insufficient number of assets available for investment, transaction costs, portfolio constraints, problems with liquidity, presence of a "large investor," and so on. In this paper we concentrate on the case in which incompleteness arises due to some assets not being available for investment and the more general case of portfolio constraints. Popular approaches to the problem of hedging a claim C in such contexts have been to either maximize the expected utility of the difference $-D := X^{x,\pi}(T) - C$ or minimize the risk of D. In particular, one of the most studied approaches is to minimize $E[D^2]$, so-called quadratic hedging of Föllmer–Schweizer–Sondermann (for recent results and references see Pham,

Rheinländer, and Schweizer (1998), for example). An obvious disadvantage of this approach is that one is penalized for high profits and not just high losses. On the other hand, Artzner, Delbaen, Eber, and Heath (1999) have shown in a static hedging setting that the only measure of risk that satisfies certain natural "coherence" properties is of the type $E[\bar{D}^+]$ (or a supremum of these over a set of probability measures), where $\bar{D}^+$ is the discounted value of the positive part of D. Motivated by this work, Cvitanić and Karatzas (1999) solve the problem of minimizing $E[\bar{D}^+]$ in a context of a *complete* continuous-time Ito process model for the financial market. We solve in this paper the same problem in a more difficult context of incomplete or constrained markets. Recently, Pham (1998) has solved the problem of minimizing $E[(D^+)^p]$ for $p > 1$ in discrete-time models and under cone constraints. Moreover, independently from Pham and the present paper, Föllmer and Leukert (1999b) analyze the problem of minimizing $E[l(D^+)]$ for a general loss function l and in general incomplete semimartingale models, emphasizing the Neyman–Pearson lemma approach, as opposed to the duality approach. The former approach was used by the same authors in Föllmer and Leukert (1999a) to solve the problem of maximizing the probability of perfect hedge $P[D \leq 0]$. Some early work on problems like these is presented in Dembo (1997), in a one-period setting. A very general study of the the duality approach and its use in the utility maximization context can be found in Kramkov and Schachermayer (1999).

As mentioned above, another approach would be to try to hedge away all the risk of the agent by superreplicating the claim he has to deliver at time T, namely to have $X^{x,\pi}(T) \geq C$, a.s. This has been done in the framework of constraints by Cvitanić and Karatzas (1993), Broadie, Cvitanić, and Soner (1998), and Cvitanić, Pham, and Touzi (1999). However, the cost $x = x_C$ of the least expensive strategy accomplishing the superreplication is typically very high, and hence the strategy is appropriate neither for pricing nor for hedging purposes. For example, if the agent sells a call option C on one share of stock S, and he cannot borrow money, then his cost of superreplicating the option is equal to the price of one share of S. Nobody would pay this much for the option if they can buy the stock itself. More interesting examples include newly deregulated energy markets, reinsurance markets, and emerging markets. The cost of superreplication in these markets is usually too high (even infinite), and one is forced to introduce preferences, typically in terms of a loss or a utility function. This is the approach taken also in this paper, with a linear loss function.

Suppose now that, in addition to the genuine risk that the liability C represents, the agent also faces some uncertainty regarding the model for the financial market itself. Following Cvitanić and Karatzas (1999), we capture such uncertainty by allowing a family $\mathcal{P}$ of possible "real-world probability measures," instead of just one measure. Thus, the "max-min" quantity

$$\underline{V}(x) := \sup_{P \in \mathcal{P}} \inf_{\pi} E^P[\bar{D}^+] \tag{1.2}$$

represents the maximal risk that the agent can encounter when faced with the "worst possible scenario" $P \in \mathcal{P}$. In the special case of incomplete markets and under the condition that all equivalent martingale measures are included in the set of possible real-world measures $\mathcal{P}$, we show that

$$\underline{V}(x) = \overline{V}(x) := \inf_{\pi} \sup_{P \in \mathcal{P}} E^P[\bar{D}^+]. \tag{1.3}$$

In other words, the corresponding fictitious "stochastic game" between the market and the agent has a value. The trading strategy attaining this value is shown to be

the one that corresponds to borrowing just enough money from the bank at time $t = 0$ as to be able to have at least the amount C at time $t = T$.

We describe the market model in section 2 and introduce the optimization problem in section 3. As is by now standard in financial mathematics, we define a dual problem, whose optimal solution determines the optimal terminal wealth $X^{x,\hat{\pi}}(T)$. It turns out that this terminal wealth is of the "knock-out" option type—namely, it is either equal to C or to 0 or to a certain (random) value $0 \leq B \leq C$, depending on whether the optimal dual variable is less than, larger than, or equal to one, respectively. What makes the dual problem more difficult than in the usual utility optimization problems (as in Cvitanić and Karatzas (1992)) is that the objective function fails to be everywhere differentiable, and the optimal dual variable (related to the Radon–Nikodym derivative of an "optimal change of measure") can be zero with positive probability. Nevertheless, we are able to solve the problem using nonsmooth optimization techniques for infinite dimensional problems, which can be found in Aubin and Ekeland (1984). We discuss in section 4 the stochastic game associated with (1.2) and (1.3).

2. The market model. We recall here the standard Ito process model for a financial market $\mathcal{M}$. It consists of one *bank account* and d *stocks*. Price processes $S_0(\cdot)$ and $S_1(\cdot), \ldots, S_d(\cdot)$ of these instruments are modeled by the equations

$$\begin{aligned} &dS_0(t) = S_0(t)r(t)dt\ , \quad S_0(0) = 1, \\ &dS_i(t) = S_i(t)\left[b_i(t)dt + \sum_{j=1}^{d} \sigma_{ij}(t)dW^j(t)\right], \quad S_i(0) = s_i > 0\ ;\ i = 1, \ldots, d. \end{aligned} \tag{2.1}$$

Here $W(\cdot) = (W^1(\cdot), \ldots, W^d(\cdot))'$ is a standard d-dimensional Brownian motion on a complete probability space $(\Omega, \mathcal{F}, P)$, endowed with a filtration $\mathbf{F} = \{\mathcal{F}(t)\}_{0 \leq t \leq T}$, the P-augmentation of $\mathcal{F}^W(t) := \sigma(W(s);\ 0 \leq s \leq t)\ ,\ \ 0 \leq t \leq T$, the filtration generated by the Brownian motion $W(\cdot)$. The *coefficients* $r(\cdot)$ (interest rate), $b(\cdot) = (b_1(\cdot), \ldots, b_d(\cdot))'$ (vector of stock return rates) and $\sigma(\cdot) = \{\sigma_{ij}(\cdot)\}_{1 \leq i,j \leq d}$ (matrix of stock-volatilities) of the model $\mathcal{M}$ are all assumed to be progressively measurable with respect to $\mathbf{F}$. Furthermore, the matrix $\sigma(\cdot)$ is assumed to be invertible, and all processes $r(\cdot)$, $b(\cdot)$, $\sigma(\cdot)$, $\sigma^{-1}(\cdot)$ are assumed to be bounded uniformly in $(t, \omega) \in [0, T] \times \Omega$.

The "risk premium" process

$$\theta_0(t) := \sigma^{-1}(t)[b(t) - r(t)\tilde{\mathbf{1}}]\ ,\ \ 0 \leq t \leq T, \tag{2.2}$$

where $\tilde{\mathbf{1}} = (1, \ldots, 1)' \in \mathbb{R}^d$, is then bounded and $\mathbf{F}$-progressively measurable. Therefore, the process

$$Z_0(t) := \exp\left[-\int_0^t \theta_0'(s)dW_0(s) - \frac{1}{2}\int_0^t ||\theta_0(s)||^2 ds\right],\ 0 \leq t \leq T, \tag{2.3}$$

is a P-martingale, and

$$P_0(\Lambda) := E[Z_0(T)1_\Lambda], \quad \Lambda \in \mathcal{F}(T) \tag{2.4}$$

is a probability measure equivalent to P on $\mathcal{F}(T)$. Under this *risk-neutral equivalent martingale measure* P_0, the discounted stock prices $\frac{S_1(\cdot)}{S_0(\cdot)}, \ldots, \frac{S_d(\cdot)}{S_0(\cdot)}$ become martingales, and the process

$$W_0(t)\ :=\ W(t) + \int_0^t \theta_0(s)ds\ ,\ \ 0 \leq t \leq T, \tag{2.5}$$

becomes Brownian motion, by the Girsanov theorem.

Consider now an agent who starts out with initial capital x and can decide, at each time $t \in [0,T]$, what proportion $\pi_i(t)$ of his (nonnegative) wealth to invest in each of the stocks $i = 1, \ldots, d$. However, the portfolio process $(\pi_1(\cdot), \ldots, \pi_d(\cdot))'$ has to take values in a given closed convex set $K \subset \mathbb{R}^d$ of constraints, for almost everywhere (a.e.) $t \in [0,T]$, a.s. We will also assume that K contains the origin. For example, if the agent can hold neither short nor long positions in the last $d-m$ stocks $S_{m+1}(\cdot), \ldots, S_d(\cdot)$, we get a typical example of an incomplete market, in the sense that not all square-integrable payoffs can be exactly replicated. (One of the best known examples of incomplete markets, the case of stochastic volatility, is included in this framework.) Another typical example is the case of an agent who has limits on how much he can borrow from the bank, or how much he can go short or long in a particular stock.

With $\pi(t) = (\pi_1(t), \ldots, \pi_d(t))' \in K$ chosen, the agent invests the amount $X(t)(1 - \sum_{i=1}^d \pi_i(t))$ in the bank account, at time t, where we have denoted $X(\cdot) \equiv X^{x,\pi,\kappa}(\cdot)$ his wealth process. Moreover, for reasons of mathematical convenience, we allow the agent to spend money outside of the market, and $\kappa(\cdot) \geq 0$ denotes the corresponding *cumulative consumption process*. The resulting wealth process satisfies the equation

$$\begin{aligned} dX(t) &= -d\kappa(t) + \left[X(t)(1 - \sum_{i=1}^d \pi_i(t))\right] r(t)dt \\ &\quad + \sum_{i=1}^d \pi_i(t)X(t)\left[b_i(t)dt + \sum_{j=1}^d \sigma_{ij}(t)dW^j(t)\right] \\ &= -d\kappa(t) + r(t)X(t)dt + \pi'(t)\sigma(t)X(t)dW_0(t); \quad X(0) = x. \end{aligned}$$

Denoting

$$\bar{X}(t) = e^{-\int_0^t r(u)du} X(t), \tag{2.6}$$

the discounted version of a process $X(\cdot)$, we get the equivalent equation

$$d\bar{X}(t) = -e^{-\int_0^t r(u)du} d\kappa(t) + \pi'(t)\sigma(t)\bar{X}(t)dW_0(t)\ ; \quad X(0) = x. \tag{2.7}$$

It follows that $\bar{X}(\cdot)$ is a nonnegative local P_0-supermartingale, hence also a P_0-supermartingale, by Fatou's lemma. Therefore, if τ_0 is defined to be the first time it hits zero, we have $X(t) = 0$ for $t \geq \tau_0$, so that the portfolio values $\pi(t)$ are irrelevant after that happens. Accordingly, we can and do set $\pi(t) = 0$ for $t \geq \tau_0$.

More formally, we have the following definition.

DEFINITION 2.1. (i) *A portfolio process* $\pi : [0,T] \times \Omega \to \mathbb{R}^d$ *is* $\mathbf{F}$*-progressively measurable and satisfies* $\int_0^T ||\pi(t)||^2 dt < \infty$*, a.s., as well as*

$$\pi(t) \in K \quad \text{for a.e. } t \in [0,T] \tag{2.8}$$

a.s. A consumption process $\kappa(\cdot)$ *is a nonnegative, nondecreasing, progressively measurable process with right-continuous with left limits (RCLL) paths, with* $\kappa(0) = 0$ *and* $\kappa(T) < \infty$.

(ii) *For a given portfolio and consumption processes* $\pi(\cdot)$, $\kappa(\cdot)$, *the process* $X(\cdot) \equiv X^{x,\pi,\kappa}(\cdot)$ *defined by* (2.7) *is called the wealth process corresponding to strategy* (π, κ) *and initial capital* x.

(iii) *A portfolio-consumption process pair* $(\pi(\cdot),\kappa(\cdot))$ *is called admissible for the initial capital* x*, and we write* $(\pi,\kappa)\in\mathcal{A}(x)$*, if*

$$X^{x,\pi,\kappa}(t)\geq 0,\qquad 0\leq t\leq T, \tag{2.9}$$

holds a.s.

We refer to the lower bound of (2.9) as a *margin requirement*. The no-arbitrage price of a contingent claim C in a complete market is unique and is obtained by multiplying ("discounting") the claim by $H_0(T):=Z_0(T)/S_0(T)$ and taking expectation. Since the market here is incomplete, there are more relevant *stochastic discount factors* other than $H_0(T)$. We identify them along the lines of Cvitanić and Karatzas (1993), hereafter [CK93], and Karatzas and Kou (1996), hereafter [KK96], as follows: Introduce the *support function*

$$\delta(\nu):=\sup_{\pi\in K}\{-\pi'\nu\} \tag{2.10}$$

of the set $-K$, as well as its *barrier cone*

$$\tilde{K}:=\{\nu\in\mathbb{R}^d\ /\ \delta(\nu)<\infty\}. \tag{2.11}$$

For the rest of the paper we assume the following mild conditions.

Assumption 2.2. The closed convex set $K\subset\mathbb{R}^d$ contains the origin; in other words, the agent is allowed not to invest in stocks at all. In particular, $\delta(\cdot)\geq 0$ on $\tilde{K}$. Moreover, the set K is such that $\delta(\cdot)$ is continuous on the barrier cone $\tilde{K}$ of (2.11).

Denote by $\mathcal{D}$ the set of all *bounded* progressively measurable process $\nu(\cdot)$ taking values in $\tilde{K}$ a.e. on $\Omega\times[0,T]$. In analogy with (2.2)–(2.5), introduce

$$\theta_\nu(t):=\sigma^{-1}(t)[\nu(t)+b(t)-r(t)\tilde{\mathbf{1}}]\ ,\quad 0\leq t\leq T, \tag{2.12}$$

$$Z_\nu(t):=\exp\left[-\int_0^t\theta_\nu'(s)dW(s)-\frac{1}{2}\int_0^t||\theta_\nu(s)||^2ds\right],\ 0\leq t\leq T, \tag{2.13}$$

$$P_\nu(\Lambda):=E[Z_\nu(T)1_\Lambda],\quad \Lambda\in\mathcal{F}(T), \tag{2.14}$$

$$W_\nu(t)\ :=\ W(t)+\int_0^t\theta_\nu(s)ds\ ,\quad 0\leq t\leq T, \tag{2.15}$$

a P_ν-Brownian motion. Also denote

$$H_\nu(t):=e^{-\int_0^t\delta(\nu(u))du}Z_\nu(t). \tag{2.16}$$

Note that

$$dZ_\nu(t)=-Z_\nu(t)\theta_\nu'(t)dW(t). \tag{2.17}$$

From this and (2.7) we get, by Ito's rule,

$$\begin{aligned}d(H_\nu(t)\bar{X}(t))=&-e^{-\int_0^t r(u)du}H_\nu(t)d\kappa(t)-[\delta(\nu(t))+\pi'(t)\nu(t)]H_\nu(t)\bar{X}(t)dt\\&+[\pi'(t)\sigma(t)-\theta_\nu(t)]H_\nu(t)\bar{X}(t)dW(t)\ ;\quad X(0)=x\end{aligned} \tag{2.18}$$

for all $\nu\in\mathcal{D}$. Therefore, $H_\nu(\cdot)\bar{X}(\cdot)$ is a P-local supermartingale (note that $\delta(\nu)+\pi'\nu\geq 0$ for $\pi\in K$ and $\nu\in\tilde{K}$), and from (2.9) thus also a P-supermartingale, by Fatou's lemma. Consequently,

$$E[H_\nu(T)\bar{X}^{x,\pi,\kappa}(T)]\leq x\quad\forall\ (\pi,\kappa,\nu)\ \in\ \mathcal{A}(x)\times\mathcal{D}\ . \tag{2.19}$$

3. The minimization problem and its dual. Suppose now that, at time $t = T$, the agent has to deliver a payoff given by a contingent claim C, a random variable in $\mathbf{L}^2(\Omega, \mathcal{F}(T), P)$, with

$$P[C \geq 0] = 1 \quad \text{and} \quad P[C > 0] > 0. \tag{3.1}$$

Introduce a (possibly infinite) process

$$\bar{C}(t) := ess \sup_{\nu \in \mathcal{D}} E\left[H_\nu(T)\bar{C} \;\middle|\; \mathcal{F}(t) \right], \qquad 0 \leq t \leq T, \tag{3.2}$$

a.s., the discounted version of the process

$$C(\cdot) := S_0(\cdot)\bar{C}(\cdot). \tag{3.3}$$

We have denoted

$$\bar{C} := \frac{C}{S_0(T)} \tag{3.4}$$

the discounted value of the $\mathcal{F}(T)$-measurable random variable C. We impose the following assumption throughout the rest of the paper (see Remark 3.14 for a discussion on the relevance of this assumption).

Assumption 3.1. We assume

$$C(0) = \sup_{\nu \in \mathcal{D}} E[H_\nu(T)\bar{C}] < \infty. \tag{3.5}$$

The following theorem is taken from the literature on constrained financial markets (see, for example, [CK93], [KK96], or Cvitanić (1997)).

THEOREM 3.2. (Cvitanić and Karatzas (1993)). *Let $C \geq 0$ be a given contingent claim. Under Assumption* 3.1*, the process $C(\cdot)$ of* (3.3) *is finite, and it is equal to the minimal admissible wealth process hedging the claim C. More precisely, there exists a pair $(\pi_C, \kappa_C) \in \mathcal{A}(C(0))$ such that*

$$C(\cdot) \equiv X^{C(0),\pi_C,\kappa_C}(\cdot), \tag{3.6}$$

and, if for some $x \geq 0$ and some pair $(\pi, \kappa) \in \mathcal{A}(x)$ we have

$$X^{x,\pi,\kappa}(T) \geq C, \;\; P - a.s., \tag{3.7}$$

then

$$X^{x,\pi,\kappa}(t) \geq C(t), \quad 0 \leq t \leq T, \;\; P - a.s.$$

Consequently, if $x \geq C(0)$, there exists then an admissible pair $(\pi, \kappa) \in \mathcal{A}(x)$ such that $X^{x,\pi,\kappa}(T) \geq C$. Achieving a "hedge without risk" is not possible for $x < C(0)$. Motivated by results of Artzner et al. (1999) (and similarly as in a complete market setting of Cvitanić and Karatzas (1999)) we choose the following risk function to be minimized:

$$V(x) \equiv V(x; C) := \inf_{(\pi,\kappa) \in \mathcal{A}(x)} E\left[\bar{C} - \bar{X}^{x,\pi,\kappa}(T)\right]^+. \tag{3.8}$$

In other words, we are minimizing the expected discounted net loss, over all admissible trading strategies.

If $x \geq C(0)$, we have $V(x) = 0$, because, as mentioned above, we can find a wealth process that hedges C. Moreover, the margin requirement (2.9) implies that $x \geq 0$, so we assume from now on that

$$0 < x < C(0). \tag{3.9}$$

Note that we can (and do) assume $X^{x,\pi,\kappa}(T) \leq C$, $P-$a.s., in our optimization problem (3.8), since the agent can always consume down to the value of C, in case he has more than C at time T. In particular, if $C(\omega) = 0$, we can (and do) assume $X^{x,\pi,\kappa}(T,\omega) = 0$, too. This means that the set $\{C = 0\} \in \mathcal{F}(T)$ is not relevant for the problem (3.8), which motivates us to define a new probability measure

$$P^C(\Lambda) = \frac{1}{E[\bar{C}]} E[\bar{C}\mathbf{1}_\Lambda], \quad \Lambda \in \mathcal{F}(T) \tag{3.10}$$

(see also Remark 3.14 (ii)). Denote by E^C the associated expectation operator.

The problem (3.8) has then an equivalent formulation

$$V(x) = E[\bar{C}] \inf_{(\pi,\kappa)\in\mathcal{A}(x)} E^C \left[1 - \frac{X^{x,\pi,\kappa}(T)}{C}\right]^+. \tag{3.11}$$

We approach the problem (3.11) by recalling familiar tools of convex duality: starting with the convex loss function $R(y) = (1-y)^+$, consider its Legendre–Fenchel transform

$$\tilde{R}(z) := \min_{0\leq y\leq 1} [R(y) + yz] = z \wedge 1, \qquad z \geq 0 \tag{3.12}$$

(where $z \wedge 1 = \min\{z, 1\}$). The minimum in (3.12) is attained by any number $I(z;b)$ of the form

$$I(z;b) := \left\{ \begin{array}{lll} 0 & ; & z > 1 \\ 1 & ; & 0 \leq z < 1 \\ b & ; & z = 1 \end{array} \right\}, \tag{3.13}$$

where $0 \leq b \leq 1$.

Consequently, denoting

$$Y^{x,\pi,\kappa} := \frac{X^{x,\pi,\kappa}(T)}{C},\ P^C - a.s., \tag{3.14}$$

we conclude from (3.12) that for any initial capital $x \in (0, C(0))$ and any $(\pi,\kappa) \in \mathcal{A}(x)$, $\nu \in \mathcal{D}$, $z \geq 0$ we have

$$(1 - Y^{x,\pi,\kappa})^+ \geq \tilde{R}(zH_\nu(T)) - zH_\nu(T)Y^{x,\pi,\kappa},\ P^C - a.s. \tag{3.15}$$

Thus, multiplying by $E[\bar{C}]$, taking expectations, and in conjunction with (2.19), we obtain

$$\begin{aligned} E[\bar{C}]E^C\left[1 - Y^{x,\pi,\kappa}\right]^+ &\geq E[\bar{C}]E^C\left[\tilde{R}(zH_\nu(T))\right] - zE[\bar{C}]E^C\left[H_\nu(T)Y^{x,\pi,\kappa}\right] \\ &\geq E[\bar{C}]E^C\left[\tilde{R}(zH_\nu(T))\right] - xz. \end{aligned} \tag{3.16}$$

This is a type of a duality relationship that has proved to be very useful in constrained portfolio optimization studied in Cvitanić and Karatzas (1992). The difference here is that we have to extend it to the random variables in the set

$$\mathcal{H} := \{H \in \mathbf{L}^1(\Omega, \mathcal{F}(T), P^C) \ / \ H \geq 0 \ P^C - a.s., \\ E[\bar{C}]E^C[HY^{x,\pi,\kappa}] \leq x, \ \forall \ (\pi,\kappa) \in \mathcal{A}(x)\}. \tag{3.17}$$

Remark 3.3. As the referee points out, it should be noted that the set $\mathcal{H}$ does not actually depend on x. This is because $X^{x,\pi,\kappa}(\cdot) = xX^{1,\pi,\kappa/x}(\cdot)$, so that the inequality in the definition (3.17) of $\mathcal{H}$ is equivalent to

$$E[\bar{C}]E^C[HY^{1,\pi,\kappa}] \leq 1 \quad \forall \ (\pi,\kappa) \in \mathcal{A}(1). \tag{3.18}$$

It is clear that $\mathcal{H}$ is a convex set. It is also closed in $\mathbf{L}^1(\Omega, \mathcal{F}(T), P^C)$. Indeed, if $H_n \to H$ in $\mathbf{L}^1(\Omega, \mathcal{F}(T), P^C)$, then there exists a (relabeled) subsequence $\{H_n\}_{n\in\mathbb{N}}$ converging to H, P^C-a.s.; therefore $H \geq 0$, $P^C - a.s.$, and, by Fatou's lemma, $E[\bar{C}]E^C[HY^{x,\pi,\kappa}] \leq x \quad \forall (\pi,\kappa) \in \mathcal{A}(x)$.

By Theorem 3.2 we have $C(\cdot) = X^{C(0),\pi_C,\kappa_C}(\cdot)$ for some $(\pi_C, \kappa_C) \in \mathcal{A}(x)$. Consequently, we have $Y^{C(0),\pi_C,\kappa_C} = 1$, $P^C - a.s.$, and therefore

$$E[\bar{C}]E^C[H] = E[\bar{C}H] \leq C(0) \quad \forall \ H \in \mathcal{H}, \tag{3.19}$$

where we extend a random variable H to the probability space $(\Omega, \mathcal{F}(T), P)$ by setting $H = 0$ on $\{C = 0\}$. Similarly, since $0 \in K$, taking $\tilde{X}^{x,0,0}(T) = x$ in the definition (3.17) of $\mathcal{H}$, we see that

$$E[\bar{C}]E^C[H/C] = E[H] \leq 1 \quad \forall \ H \in \mathcal{H}. \tag{3.20}$$

Moreover, since $E[\bar{C}]E^C[H_\nu(T)] \leq C(0) < \infty \quad \forall \nu \in \mathcal{D}$, and by (2.19), we get

$$\mathcal{H}_{\mathcal{D}} := \{H_\nu(T) \ / \ \nu \in \mathcal{D}\} \ \subset \ \mathcal{H}. \tag{3.21}$$

Remark 3.4. The idea of introducing the set $\mathcal{H}$ is similar to and inspired by the approach of Kramkov and Schachermayer (1999), who work with the set of all nonnegative processes $G(\cdot)$ such that $G(\cdot)\tilde{X}(\cdot)$ is a P-supermartingale for all admissible wealth processes $X(\cdot)$.

Next, arguing as above (when deducing (3.16)), we obtain

$$E[\bar{C}]E^C\left[1 - Y^{x,\pi,\kappa}\right]^+ \geq E[\bar{C}]E^C\left[\tilde{R}(zH)\right] - xz =: \tilde{J}(H;z) - xz \quad \forall \ H \in \mathcal{H}, \ z \geq 0, \tag{3.22}$$

where we have denoted

$$\tilde{J}(H;z) := E[\bar{C}]E^C[(zH) \wedge 1]. \tag{3.23}$$

It is easily seen that $-\tilde{J}(\cdot;z) : \mathbf{L}^1(\Omega, \mathcal{F}(T), P^C) \to \mathbb{R}$ is a convex, lower-semicontinuous and proper functional, in the terminology of convex analysis; see, for example, Aubin and Ekeland (1984), henceforth [AE84].

Remark 3.5. It is straightforward to see that the inequality of (3.22) holds as equality for some $(\hat{\pi}, \hat{\kappa}) \in \mathcal{A}(x)$ and $\hat{z} \geq 0$, $\hat{H} \in \mathcal{H}$, *if and only if* we have

$$E[\bar{C}]E^C\left[\hat{H}Y^{x,\hat{\pi},\hat{\kappa}}\right] = x \tag{3.24}$$

and

$$Y^{x,\hat{\pi},\hat{\kappa}} = I(\hat{z}\hat{H};\hat{B}) = 1_{\{\hat{z}\hat{H}<1\}} + \hat{B}1_{\{\hat{z}\hat{H}=1\}},\ P^C - a.s. \tag{3.25}$$

for some $\mathcal{F}(T)$-measurable random variable $\hat{B}$ that satisfies $0 \le \hat{B} \le 1$, P^C- a.s. We also set

$$Y^{x,\hat{\pi},\hat{\kappa}} = 0 \ \text{ on } \ \{C = 0\}.$$

If (3.24) and (3.25) are satisfied, then $(\hat{\pi},\hat{\kappa})$ is optimal for the problem (3.11), under the "change of variables" (3.14), since the lower bound of (3.22) is attained. Moreover, $\hat{H} \in \mathcal{H}$ is optimal for the auxiliary dual problem

$$\tilde{V}(z) = \sup_{H\in\mathcal{H}} \tilde{J}(H;z) \tag{3.26}$$

with $z = \hat{z}$. If we let

$$X^{x,\hat{\pi},\hat{\kappa}}(T) = CY^{x,\hat{\pi},\hat{\kappa}}, \quad P - a.s., \tag{3.27}$$

the conditions (3.24) and (3.25) become

$$E\left[\hat{H}\bar{X}^{x,\hat{\pi},\hat{\kappa}}(T)\right] = x \tag{3.28}$$

and

$$X^{x,\hat{\pi},\hat{\kappa}}(T) = C\left(1_{\{\hat{z}\hat{H}<1\}} + \hat{B}1_{\{\hat{z}\hat{H}=1\}}\right),\ P - a.s. \tag{3.29}$$

for some $\mathcal{F}(T)$-measurable random variable $\hat{B}$ that satisfies $0 \le \hat{B} \le 1$, a.s., and $X^{x,\hat{\pi},\hat{\kappa}}(T)$ is the terminal wealth of the strategy $(\hat{\pi},\hat{\kappa})$ which is optimal for the problem (3.8). □

In light of the preceding remark, our approach will be the following: we will try to find a number $\hat{z} > 0$, a solution $\hat{H}$ to the auxiliary dual problem (3.26) with $z = \hat{z}$, a number $\hat{z} > 0$, a random variable $\hat{B}$ as above, and a pair $(\hat{\pi},\hat{\kappa}) \in \mathcal{A}(x)$ such that (3.24) and (3.25) (or, equivalently, (3.28) and (3.29)) are satisfied.

THEOREM 3.6. *For any given $z > 0$, there exists an optimal solution $\hat{H} = \hat{H}_z \in \mathcal{H}$ for the auxiliary dual problem* (3.26).

Proof. Let $H_n \in \mathcal{H}$ be a sequence that attains the supremum in (3.26), so that

$$\lim_n \tilde{J}(H_n;z) = \tilde{V}(z).$$

Note that, by (3.19), $\mathcal{H}$ is a bounded set in $\mathbf{L}^1(\Omega,\mathcal{F}(T),P^C)$, so that by Komlós theorem (see Schwartz (1986), for example) there exists a random variable $\hat{H} \in \mathbf{L}^1(\Omega,\mathcal{F}(T),P^C)$ and a (relabeled) subsequence $\{H_i\}_{i\in\mathbb{N}}$ such that

$$G_n := \frac{1}{n}\sum_{i=1}^n H_i \to \hat{H}, \quad P^C - a.s.$$

Fatou's lemma then implies $\hat{H} \in \mathcal{H}$. Since $0 \le (zG_n) \wedge 1 \le 1$, by the dominated convergence theorem and concavity of $\tilde{J}(\cdot;z)$ we get

$$\tilde{J}(\hat{H};z) = \lim_n \tilde{J}\left(\frac{1}{n}\sum_{i=1}^n H_i;z\right) \ge \lim_n \left[\frac{1}{n}\sum_{i=1}^n \tilde{J}(H_i;z)\right] = \tilde{V}(z).$$

Thus, $\hat{H} \in \mathcal{H}$ is optimal. □

LEMMA 3.7. *The function $\tilde{V}(z)$ is continuous on $[0,\infty)$.*

Proof. Let $H \in \mathcal{H}$ and assume first $z_1, z_2 > 0$. We have

$$\begin{aligned}\tilde{J}(H;z_1) &= E[\bar{C}]E^C[(z_1H)\wedge 1] = E[\bar{C}]E^C\big[(z_2H)\wedge 1 + (z_1H)\wedge 1 - (z_2H)\wedge 1\big]\\ &= \tilde{J}(H;z_2) + E[\bar{C}]E^C\big[H(z_1-z_2)\mathbf{1}_{\{z_1H<1,z_2H<1\}} + (z_1H-1)\mathbf{1}_{\{z_1H<1,z_2H\geq 1\}}\\ &\qquad + (1-z_2H)\mathbf{1}_{\{z_1H\geq 1,z_2H<1\}}\big]\\ &\leq \tilde{V}(z_2) + 2E[\bar{C}](1-z_2/z_1)^+.\end{aligned}$$

Taking the supremum over $H \in \mathcal{H}$ we get $\tilde{V}(z_1)-\tilde{V}(z_2) \leq 2E[\bar{C}](1-z_2/z_1)^+$. Since we can do the same while interchanging the roles of z_1 and z_2, we have shown continuity on $(0,\infty)$. To prove continuity at $z_2 = 0$, note that, by duality and (3.20), we have

$$\tilde{J}(H;z_1) = E[\bar{C}]E^C[(z_1H)\wedge 1] \leq E[(\bar{C}-y)^+] + yz_1E[H] \leq E[(\bar{C}-y)^+] + yz_1$$

for all $z_1 > 0, y > 0$. Choosing first y large enough and then z_1 small enough, we can make the two terms on the right-hand side arbitrarily close to zero, uniformly in $H \in \mathcal{H}$. □

PROPOSITION 3.8. *For every $0 < x < C(0)$ there exists $\hat{z} = \hat{z}_x \in (0,\infty)$ that attains the supremum $\sup_{z\geq 0}[\tilde{V}(z) - xz]$.*

Proof. Denote

$$\alpha(z) := \tilde{V}(z) - xz.$$

Note that $\alpha(0) = 0$. It is clear that

$$\limsup_{z\to\infty} \alpha(z) < 0, \tag{3.30}$$

so that the supremum of $\alpha(z)$ over $[0,\infty)$ cannot be attained at $z = \infty$. Consequently, being continuous by Lemma 3.7, function $\alpha(z)$ either attains its supremum at some $\hat{z} > 0$, or else $\alpha(z) \leq \alpha(0) = 0$ for all $z > 0$. Suppose that the latter is true. We have then

$$x \geq \frac{\tilde{V}(z)}{z} \geq E[\bar{C}]E^C\left[H \wedge \frac{1}{z}\right] \tag{3.31}$$

for all $z > 0$ and $H \in \mathcal{H}$. In particular, we can use the dominated convergence theorem while letting $z \to 0$ to get

$$x \geq E[H\bar{C}]$$

for all $H \in \mathcal{H}_{\mathcal{D}}$. Taking the supremum over $H \in \mathcal{H}_{\mathcal{D}}$ we obtain $x \geq C(0)$, a contradiction. □

Denote $\hat{H} = \hat{H}_{\hat{z}}$ the optimal dual variable for problem (3.26), corresponding to $z = \hat{z}$ of Proposition 3.8. We want to show that there exists an $\mathcal{F}(T)$-measurable random variable $0 \leq \hat{B} \leq 1$ such that the optimal wealth for the primal problem is given by $CI(\hat{z}\hat{H}, \hat{B})$, where $I(z;b)$ is given in (3.13). In order to do that, we recall some notions and results from convex analysis, as presented, for example, in [AE84].

First, introduce the space

$$\mathbf{L} := \mathbf{L}^1(\Omega, \mathcal{F}(T), P^C) \times \mathbb{R} \tag{3.32}$$

with the norm

$$\|(Z,z)\| := E[\bar{C}]E^C|Z| + |z|$$

and its subset

$$\mathcal{G} := \{(zH,z) \in \mathbf{L} \ / \ z \geq 0, H \in \mathcal{H}\}. \tag{3.33}$$

It is easily seen that $\mathcal{G}$ is convex, by the convexity of $\mathcal{H}$. It is also closed in $\mathbf{L}$. Indeed, if we are given subsequences $z_n \geq 0$ and $H_n \in \mathcal{H}$ such that $(z_nH_n, z_n) \to (Z,z)$ in $\mathbf{L}$, then $z_n \to z$; we also have, from (3.19),

$$E^C|z_nH_n - zH_n| \leq |z_n - z|E^C[H_n] \leq \frac{C(0)}{E[\bar{C}]}|z_n - z|,$$

so that $zH_n \to Z$ in $\mathbf{L}^1(\Omega, \mathcal{F}(T), P^C)$. If $z = 0$ we get $Z = 0$, and we are done. If $z > 0$, we get $H_n \to Z/z$ in $\mathbf{L}^1(\Omega, \mathcal{F}(T), P^C)$, therefore $Z/z \in \mathcal{H}$ because $\mathcal{H}$ is closed in $\mathbf{L}^1(\Omega, \mathcal{F}(T), P^C)$, and we are done again. The closedness of $\mathcal{G}$ has been confirmed.

We now define a functional $\tilde{U} : \mathbf{L} \to \mathbb{R}$ by

$$\tilde{U}(Z,z) := -E[\bar{C}]E^C[Z \wedge 1] + xz = -\tilde{J}(Z;1) + xz. \tag{3.34}$$

It is easy to check that $\tilde{U}$ is convex, lower-semicontinuous, and proper on $\mathbf{L}$. Moreover, since we have

$$\begin{aligned}\tilde{J}(\hat{H},\hat{z}) - x\hat{z} &= \tilde{V}(\hat{z}) - x\hat{z} \geq \tilde{V}(z) - xz \\ &\geq \tilde{J}(H,z) - xz \ \ \forall\ (H,z) \in \mathcal{H} \times [0,\infty)\end{aligned}$$

from Proposition 3.8 and in the notation of Theorem 3.6, it follows that the pair $\hat{G} := (\hat{z}\hat{H}, \hat{z}) \in \mathcal{G}$ is optimal for the *dual problem*

$$\inf_{(Z,z)\in\mathcal{G}} \tilde{U}(Z,z). \tag{3.35}$$

Let $\mathbf{L}^* := \mathbf{L}^\infty(\Omega, \mathcal{F}(T), P^C) \times \mathbb{R}$ be the dual space to $\mathbf{L}$ and let $N(\hat{z}\hat{H}, \hat{z})$ be the *normal cone* to the set $\mathcal{G}$ at the point $(\hat{z}\hat{H}, \hat{z})$, given by

$$N(\hat{z}\hat{H},\hat{z}) = \{(Y,y) \in L^* \ / \ E[\bar{C}]E^C[\hat{z}\hat{H}Y] + \hat{z}y = \max_{(zH,z)\in\mathcal{G}}(E[\bar{C}]E^C[zHY] + zy)\} \tag{3.36}$$

by Proposition 4.1.4 in [AE84]. Let $\partial\tilde{U}(\hat{z}\hat{H},\hat{z})$ denote the subdifferential of $\tilde{U}$ at $(\hat{z}\hat{H},\hat{z})$, which, by Proposition 4.3.3 in [AE84], is given by

$$\begin{aligned}\partial\tilde{U}(\hat{z}\hat{H},\hat{z}) = \{(Y,y) \in \mathbf{L}^* \ / \ &\tilde{U}(\hat{z}\hat{H},\hat{z}) - \tilde{U}(Z,z) \\ &\leq E[\bar{C}]E^C[Y(\hat{z}\hat{H} - Z)] + y(\hat{z} - z) \quad \forall\ (Z,z) \in \mathbf{L}\}.\end{aligned} \tag{3.37}$$

Then, by Corollary 4.6.3 in [AE84], since $(\hat{z}\hat{H},\hat{z})$ is optimal for the problem (3.35), we obtain the following proposition.

PROPOSITION 3.9. *The pair $(\hat{z}\hat{H},\hat{z}) \in \mathcal{G}$ is a solution to*

$$0 \in \partial\tilde{U}(\hat{z}\hat{H},\hat{z}) + N(\hat{z}\hat{H},\hat{z}). \tag{3.38}$$

In other words, there exists a pair $(\hat{Y}, \hat{y}) \in \mathbf{L}^*$ *which belongs to the normal cone* $N(\hat{z}\hat{H}, \hat{z})$ *and such that* $-(\hat{Y}, \hat{y})$ *belongs to the subdifferential* $\partial\tilde{U}(\hat{z}\hat{H}, \hat{z})$.

From (3.36) and (3.37), this is equivalent to

$$E[\bar{C}]E^C[\hat{z}\hat{H}\hat{Y}] + \hat{z}\hat{y} \geq E[\bar{C}]E^C[zH\hat{Y}] + z\hat{y} \quad \forall z \geq 0, H \in \mathcal{H}, \tag{3.39}$$

and

$$\begin{aligned} &E[\bar{C}]E^C[\hat{Y}(\hat{z}\hat{H} - Z)] + \hat{y}(\hat{z} - z) \\ &\quad \leq E[\bar{C}]E^C[(\hat{z}\hat{H}) \wedge 1] - E[\bar{C}]E^C[Z \wedge 1] + x(z - \hat{z}) \quad \forall\ (Z, z) \in \mathbf{L}. \end{aligned} \tag{3.40}$$

It is clear from (3.40) (by letting $z \to \pm\infty$ while keeping Z fixed) that, necessarily,

$$\hat{y} = -x.$$

On the other hand, if we let $\hat{z} = z$ in (3.39), we get

$$E^C[\hat{Y}\hat{H}] \geq E^C[\hat{Y}H] \quad \forall H \in \mathcal{H}. \tag{3.41}$$

Moreover, letting $z = (\hat{z} + \varepsilon)$ for some $\varepsilon > 0$, $H = \hat{H}$ in (3.39), and recalling $\hat{y} = -x$, we obtain

$$x \geq E[\bar{C}]E^C[\hat{Y}\hat{H}].$$

Similarly, we get the reverse inequality by letting $\hat{z} = z - \varepsilon$ and $H = \hat{H}$ in (3.39) (recall that $\hat{z} > 0$ by Proposition 3.8), to obtain, finally,

$$E[\bar{C}]E^C[\hat{Y}\hat{H}] = x. \tag{3.42}$$

This last equality will correspond to (3.24) with $\hat{Y} = Y^{x,\hat{\pi},\hat{\kappa}}$, if we can show the following result and recall (3.14).

PROPOSITION 3.10. *There exists an admissible pair* $(\hat{\pi}, \hat{\kappa}) \in \mathcal{A}(x)$ *such that*

$$X^{x,\hat{\pi},\hat{\kappa}}(T) = C\hat{Y},\ P - a.s.$$

and such that (3.28) *is satisfied.*

(Here we set $\hat{Y} = 0$ on $\{C = 0\}$.)

Proof. This follows immediately from (3.41) and (3.42), which can be written as

$$x = E[\bar{C}\hat{Y}\hat{H}] = \sup_{H \in \mathcal{H}} E[\bar{C}\hat{Y}H]$$

(with $H = 0$ on $\{C = 0\}$). Indeed, Theorem 3.2 tells us that the right-hand side is no smaller than the minimal amount of initial capital needed to hedge $C\hat{Y}$; thus, there exists a pair $(\hat{\pi}, \hat{\kappa}) \in \mathcal{A}(x)$ that does the hedge. □

In order to "close the loop," it only remains to show (3.25).

PROPOSITION 3.11. *Let* $-(Y, y) \in \partial\tilde{U}(\hat{z}\hat{H}, \hat{z})$. *Then* $y = -x$ *and* Y *is of the form*

$$Y = 1_{\{\hat{z}\hat{H} < 1\}} + B1_{\{\hat{z}\hat{H} = 1\}}\ ,\ P^C - a.s. \tag{3.43}$$

for some $\mathcal{F}(T)$*-measurable random variable* B *that satisfies* $0 \leq B \leq 1$, P^C *a.s.*

Proof. We have already seen that $y = -x$. Define a random variable A by

$$Y = \mathbf{1}_{\{\hat{z}\hat{H}<1\}} + A. \tag{3.44}$$

From (3.40) with $\hat{y} = -x$ and $\hat{Y} = Y$, we get

$$\begin{aligned} &E^C[A(\hat{z}\hat{H} - Z)] - E^C[Z\mathbf{1}_{\{\hat{z}\hat{H}<1\}}] \\ &\quad \le E^C[\mathbf{1}_{\{\hat{z}\hat{H}\ge 1\}}] - E^C[Z \wedge 1] \quad \forall\ Z \in \mathbf{L}^1(\Omega, \mathcal{F}(T), P^C). \end{aligned} \tag{3.45}$$

Let $Z \in \mathbf{L}^1(\Omega, \mathcal{F}(T), P^C)$ be such that

$$\{\hat{z}\hat{H} < 1\} = \{Z < 1\}.$$

Then,

$$E^C[A(\hat{z}\hat{H} - Z)] = E^C[A(\hat{z}\hat{H} - Z)\mathbf{1}_{\{\hat{z}\hat{H}<1\}}] + E^C[A(\hat{z}\hat{H} - Z)\mathbf{1}_{\{\hat{z}\hat{H}\ge 1\}}] \le 0, \tag{3.46}$$

by (3.45). This implies

$$A \le 0 \ \text{ on } \ \{\hat{z}\hat{H} < 1\}, \quad A \ge 0 \ \text{ on } \ \{\hat{z}\hat{H} \ge 1\}, \quad P^C - a.s., \tag{3.47}$$

for otherwise we could make Z arbitrarily small (respectively, large) on $\{\hat{z}\hat{H} < 1\} \cap \{A > 0\}$ (respectively, on $\{\hat{z}\hat{H} \ge 1\} \cap \{A < 0\}$) to get a contradiction in (3.46).

Suppose now that $P^C[A < 0, \hat{z}\hat{H} < 1] > 0$. There exists then $\delta > 0$ such that $E^C[A(\hat{z}\hat{H} - 1)\mathbf{1}_{\{\hat{z}\hat{H}<1\}}] > \delta$, because of (3.47). For a given $\varepsilon > 0$, let $Z = 1 - \varepsilon$ on $\{\hat{z}\hat{H} < 1\}$ and $Z = 1$ on $\{\hat{z}\hat{H} \ge 1\}$, in (3.46). This gives

$$E^C[A(\hat{z}\hat{H} - 1 + \varepsilon)\mathbf{1}_{\{\hat{z}\hat{H}<1\}}] + E^C[A(\hat{z}\hat{H} - 1)\mathbf{1}_{\{\hat{z}\hat{H}\ge 1\}}] \le 0. \tag{3.48}$$

The left-hand side is greater than $\delta + \varepsilon E^C[A\mathbf{1}_{\{\hat{z}\hat{H}<1\}}]$ for all $\varepsilon > 0$ (recall (3.47) again), a contradiction to (3.48). Thus, we have shown

$$A = 0 \ \text{ on } \ \{\hat{z}\hat{H} < 1\}, \quad P^C - a.s. \tag{3.49}$$

Going back to (3.46), this implies

$$E^C[A(\hat{z}\hat{H} - Z)\mathbf{1}_{\{\hat{z}\hat{H}\ge 1\}}] \le 0 \tag{3.50}$$

for all $Z \in \mathbf{L}^1(\Omega, \mathcal{F}(T), P^C)$ such that $\{Z < 1\} = \{\hat{z}\hat{H} < 1\}$. If we set now $Z = 1$ on $\{\hat{z}\hat{H} \ge 1\}$, we get from (3.50) and (3.47)

$$A = 0 \ \text{ on } \ \{\hat{z}\hat{H} > 1\}, \quad P^C - a.s. \tag{3.51}$$

Using (3.49) and (3.51) in (3.45), we obtain

$$\begin{aligned} &E^C[A(1 - Z)\mathbf{1}_{\{\hat{z}\hat{H}=1\}}] - E^C[Z(\mathbf{1}_{\{\hat{z}\hat{H}<1\}} - \mathbf{1}_{\{Z<1\}})] \\ &\quad \le E^C[\mathbf{1}_{\{\hat{z}\hat{H}\ge 1\}} - \mathbf{1}_{\{Z\ge 1\}}] \quad \forall\ Z \in \mathbf{L}^1(\Omega, \mathcal{F}(T), P^C). \end{aligned} \tag{3.52}$$

Suppose now that $P^C[A > 1, \hat{z}\hat{H} = 1] > 0$. There exists then $\delta > 0$ such that $E^C[A\mathbf{1}_{\{\hat{z}\hat{H}=1, A>1\}}] > \delta + P^C[\hat{z}\hat{H} = 1, A > 1]$. Setting $Z = 0$ on $\{\hat{z}\hat{H} = 1, A > 1\}$, $Z = 1$ on $\{\hat{z}\hat{H} = 1, A \le 1\}$, and $Z = 1 - \varepsilon$ otherwise (for a given $\varepsilon > 0$), (3.52) implies

$$\begin{aligned} &E^C[A\mathbf{1}_{\{\hat{z}\hat{H}=1, A>1\}}] - (1 - \varepsilon)E^C[\mathbf{1}_{\{\hat{z}\hat{H}<1\}} - \mathbf{1}_{\{\hat{z}\hat{H}\ne 1\}}] \\ &\quad \le P^C[\hat{z}\hat{H} \ge 1] - P^C[\hat{z}\hat{H} = 1, A \le 1]. \end{aligned} \tag{3.53}$$

The left-hand side is greater than $\delta + P^C[\hat{z}\hat{H} = 1, A > 1] + (1-\varepsilon)(P^C[\hat{z}\hat{H} \neq 1] - P^C[\hat{z}\hat{H} < 1])$, so that from (3.53) we conclude $\delta - \varepsilon(P^C[\hat{z}\hat{H} \neq 1] - P^C[\hat{z}\hat{H} < 1]) \leq 0$ for all $\varepsilon > 0$, a contradiction. Therefore,

$$A \leq 1 \ , \quad \text{on} \ \ \{\hat{z}\hat{H} = 1\}, \quad P^C - a.s. \tag{3.54}$$

Together with (3.44), (3.47), (3.49), and (3.51), this completes the proof. □

We now state the main result of the paper.

THEOREM 3.12. *For any initial wealth x with $0 < x < C(0) < \infty$, there exists an optimal pair $(\hat{\pi}, \hat{\kappa}) \in \mathcal{A}(x)$ for the problem* (3.8) *of minimizing the expected loss of hedging the claim C. It can be taken as that strategy for which the terminal wealth $X^{x,\hat{\pi},\hat{\kappa}}(T)$ is given by* (3.29)*, i.e.,*

$$X^{x,\hat{\pi},\hat{\kappa}}(T) = C\left(1_{\{\hat{z}\hat{H}<1\}} + \hat{B}1_{\{\hat{z}\hat{H}=1\}}\right) \ , \ P - a.s. \tag{3.55}$$

Here $(\hat{z}, \hat{H})$ is an optimal solution for the dual problem (3.35)*, and $\hat{B}$ can be taken as the random variable B in Proposition* 3.11*, with (Y, y) replaced by some $(\hat{Y}, \hat{y}) \in \{-\partial\tilde{U}(\hat{z}\hat{H}, \hat{z}) \cap N(\hat{z}\hat{H}, \hat{z})\}$, which exists by Proposition* 3.9.

Proof. It follows from Remark 3.5. Indeed, it was observed in that remark that a pair $(\hat{\pi}, \hat{\kappa}) \in \mathcal{A}(x)$ is optimal for the problem (3.8) if it satisfies (3.28) and (3.55) for some $\mathcal{F}(T)$-measurable random variable $\hat{B}$, $0 \leq \hat{B} \leq 1$, and some $\hat{z} \geq 0$, $\hat{H} \in \mathcal{H}$. The existence of such a pair $(\hat{\pi}, \hat{\kappa}) \in \mathcal{A}(x)$ was established in Proposition 3.10 in conjunction with Proposition 3.11, with $\hat{B}$, $\hat{z}$, and $\hat{H}$ as in the statement of the theorem. □

The following simple example is mathematically interesting from several points of view. It shows that the optimal dual variable $\hat{H}$ can be equal to zero with positive probability, unlike the case of classical utility maximization under constraints (as in Cvitanić and Karatzas (1992)). Moreover, $\hat{z}\hat{H}$ can be equal to one with positive probability, so that the use of nonsmooth optimization techniques and subdifferentials for the dual problem is really necessary. It also shows why it can be mathematically convenient to allow nonzero consumption. Finally, it confirms that condition (3.5) is not always necessary for the dual approach to work.

Example 3.13. Suppose $r(\cdot) \equiv 0$ for simplicity, and let $C \geq 0$ be any contingent claim such that $P[C \geq x] > 0$. We consider the trivial primal problem for which $K = \{0\}$, so that there is only one possible admissible portfolio strategy $\hat{\pi}(\cdot) \equiv 0$ (in other words, the agent can invest only in the riskless asset). We do not assume condition (3.5), which, for these constraints, is equivalent to C being bounded. It is clear that the value $V(x)$ of the primal problem is $E[C - x]^+$, and duality implies

$$E[C - x]^+ \geq E[C((zH) \wedge 1)] - xz \tag{3.56}$$

for all $z \geq 0$, $H \in \mathcal{H}$ (see (3.22)). Here we can take $\mathcal{H}$ to be the set of all nonnegative random variables such that $E[H] \leq 1$. Let $\hat{z} := P[C \geq x] > 0$ and $\hat{z}\hat{H} := \mathbf{1}_{\{C \geq x\}}$. It is then easily checked that $\hat{H} \in \mathcal{H}$ and that the pair $(\hat{H}, \hat{z})$ attains equality in (3.56), so that the pair $(\hat{z}\hat{H}, \hat{z}) \in \mathcal{G}$ is optimal for the dual problem (3.35). One possible choice for the optimal terminal wealth is

$$X^{x,\hat{\pi},\hat{\kappa}}(T) = x\mathbf{1}_{\{C \geq x\}} + C\mathbf{1}_{\{C<x\}}.$$

According to (3.55), this corresponds to $\hat{B} = x/C$ on $\{C \geq x\}$, and $\hat{\kappa}(t) = 0$ for $t < T$, while $\hat{\kappa}(T) = (x - C)\mathbf{1}_{\{C<x\}}$.

Remark 3.14. (i) Assumption 3.1 is satisfied, for example, if C is bounded. We need it in order to get existence for the dual problem (3.35), due to our use of the Komlós theorem. Example 3.13 shows that this assumption is not always necessary: in this example the dual problem has a solution and there is no gap between the primal and the dual problem, even when (3.5) is not satisfied.

(ii) If we, in fact, assumed that C is bounded, the switch to the equivalent formulation (3.11) from (3.8) would not be necessary. (The reason for this is that the dual spaces of $\mathbf{L}^1(\Omega, \mathcal{F}(T), P)$ and $\mathbf{L}^1(\Omega, \mathcal{F}(T), P^C)$ are then the same, up to the equivalence class determined by the set $\{C = 0\}$.)

Remark 3.15. Since there are almost no examples with explicit solutions to this problem, it is of interest to study possible numerical algorithms. In Markovian continuous-time models this would involve solving Hamilton–Jacobi–Bellman PDEs, while in discrete models one could apply standard linear or convex programming techniques; see Blumenstein (1999) for some of these issues.

4. Dynamic measures of risk. Suppose now that we are not quite sure whether our subjective probability measure P is equal to the real-world measure. We would like to measure the risk of hedging the claim C under constraints given by set K, and under uncertainty about the real-world measure. According to Artzner et al. (1999), and Cvitanić and Karatzas (1999), it makes sense to consider the following quantities as the lower and upper bounds for the measure of such a risk, where we denote by $\mathcal{P}$ a set of possible real-world measures:

$$\underline{V}(x) := \sup_{Q \in \mathcal{P}} \inf_{(\pi,\kappa) \in \mathcal{A}(x)} E^Q \left[\bar{C} - \bar{X}^{x,\pi,\kappa}(T) \right]^+, \tag{4.1}$$

the *maximal risk that can be incurred, over all possible real-world measures*, dominated by its "min-max" counterpart

$$\overline{V}(x) := \inf_{(\pi,\kappa) \in \mathcal{A}(x)} \sup_{Q \in \mathcal{P}} E^Q \left[\bar{C} - \bar{X}^{x,\pi,\kappa}(T) \right]^+, \tag{4.2}$$

the upper-value of a fictitious *stochastic game* between an agent (who tries to choose $(\pi, \kappa) \in \mathcal{A}(x)$ so as to minimize his risk) and "the market" (whose "goal" is to choose the real-world measure that is least favorable for the agent). Here, E^Q is expectation under measure Q. A question is whether the "upper-value" (4.2) and the "lower-value" (4.1) of this game coincide and, if they do, to compute this common value. We shall answer this question only in a very specific setting as follows. Let P be the "reference" probability measure, as in the previous sections. We first change the margin requirement (2.9) to a more flexible requirement

$$\bar{X}^{x,\pi,\kappa}(t) \geq -k, \qquad 0 \leq t \leq T, \quad P - a.s., \tag{4.3}$$

where k is a constant such that $\infty > k \geq C(0) - x > 0$. We still assume $0 < x < C(0)$, and we look at the special case of the constraints given by

$$K = \{\pi \in \mathbb{R}^d \ / \ \pi_{m+1} = \cdots = \pi_d = 0\} \tag{4.4}$$

for some $m < d$. In other words, we only consider the case of a market which is incomplete due to the insufficient number of assets available for investment. In this case,

$$\tilde{K} = \{\nu \in \mathbb{R}^d \ / \ \nu_1 = \cdots = \nu_m = 0\}$$

and

$$\mathcal{D} = \{\text{bounded progress. meas. processes } \nu(\cdot) \ / \ \nu_1(\cdot) \equiv \cdots \equiv \nu_m(\cdot) \equiv 0\}.$$

We define the set $\mathcal{P}$ of possible real-world probability measures as follows. Let $\mathcal{E}$ be a set of progressively measurable and bounded processes $\nu(\cdot)$ and such that

$$\mathcal{D} \subset \mathcal{E}. \tag{4.5}$$

We set

$$\mathcal{P} := \{P_\nu \ / \ \nu \in \mathcal{E}\}, \tag{4.6}$$

in the notation of (2.14) (note that the reference measure P is not necessarily in $\mathcal{P}$). In other words, our set of all possible real-world probability measures includes all the "equivalent martingale measures" for our market, corresponding to bounded "kernels" $\nu(\cdot)$. This way, under a possible real-world probability measure $P_\nu \in \mathcal{P}$, the model $\mathcal{M}$ of (2.1) becomes

$$\begin{aligned} dS_0(t) &= S_0(t)r(t)dt, \quad S_0(0) = 1, \\ dS_i(t) &= S_i(t)\left[(r(t) - \nu_i(t))dt + \sum_{j=1}^{d} \sigma_{ij}(t)dW_\nu^j(t)\right], \\ S_i(0) &= s_i \in (0,\infty) \ ; \quad i = 1, \ldots, d, \end{aligned} \tag{4.7}$$

in the notation of (2.15). The resulting modified model $\mathcal{M}_\nu$ is similar to that of (2.1); now $W_\nu(\cdot)$ plays the role of the driving Brownian motion (under P_ν), but the stock return rates are different for different "model measures" P_ν.

The following theorem shows that, if the uncertainty about the real-world probability measure is large enough (in the sense that all equivalent martingale measures corresponding to bounded kernels are possible candidates for the real-world measure), then the optimal thing to do in order to minimize the expected risk of hedging a claim C in the market is the following: *borrow exactly as much money from the bank as is needed to hedge C.*

THEOREM 4.1. *Under the above assumptions we have*

$$\overline{V}(x) = \underline{V}(x) = C(0) - x. \tag{4.8}$$

In other words, the stochastic game defined by (4.1) *and* (4.2) *has a value that is equal to the expected loss of the strategy which borrows $C(0) - x$ from the bank and then invests according to the least expensive strategy for hedging the claim C.*

Proof. Let (π^*, κ^*) be the strategy from the statement of the theorem, namely the one for which we have

$$\bar{X}^*(t) := \bar{X}^{x,\pi^*,\kappa^*}(t) = \bar{C}(t) - (C(0) - x), \ P - a.s.,$$

in the notation of (3.2). Such a strategy exists by Theorem 3.2. It is clear that (4.3) is then satisfied, so that $(\pi^*, \kappa^*) \in \mathcal{A}(x)$. Since for this strategy $E^Q[\bar{C} - \bar{X}^{x,\pi^*,\kappa^*}(T)]^+ = C(0) - x$ for all $Q \in \mathcal{P}$, it also follows that

$$\overline{V}(x) \leq C(0) - x. \tag{4.9}$$

On the other hand, we have here $\delta(\nu) = 0$ for $\nu \in \tilde{K}$, so that $H_\nu(\cdot) = Z_\nu(\cdot)$ for $\nu \in \mathcal{D}$, and Ito's rule gives, in analogy to (2.7) and in the notation of (2.15),

$$d\bar{X}^*(t) = -e^{-\int_0^t r(u)du} d\kappa^*(t) + (\pi^*(t))'\sigma(t)\bar{X}^*(t)dW_\nu(t) \ ; \quad X^*(0) = x \tag{4.10}$$

for all $\nu \in \mathcal{D}$, since $\nu'(\cdot)\pi^*(\cdot) \equiv 0$. Therefore, $\bar{X}^*(\cdot)$ is a P_ν-local supermartingale bounded from below, thus also a P_ν-supermartingale, by Fatou's lemma. Consequently,

$$E_\nu[\bar{X}^*(T)] \leq x \quad \forall\, \nu \ \in \ \mathcal{D}, \tag{4.11}$$

where E_ν is the expectation under P_ν measure. Since $P_\nu \in \mathcal{P}$ for all $\nu \in \mathcal{D}$, (4.11) and Jensen's inequality imply

$$\underline{V}(x) \geq \sup_{\nu\in\mathcal{D}} \inf_{(\pi,\kappa)\in\mathcal{A}(x)} (E_\nu[\bar{C}] - x)^+ = \sup_{\nu\in\mathcal{D}} (E_\nu[\bar{C}] - x)^+ = C(0) - x. \tag{4.12}$$

Since $\underline{V}(x) \leq \overline{V}(x)$, (4.8) is a consequence of (4.9) and (4.12). □

Acknowledgments. I wish to thank Ioannis Karatzas for suggesting the use of Komlós theorem and for providing me with the reference Schwartz (1986), as well for thorough readings and helpful comments on the paper. Thanks are also due to the two anonymous referees for useful suggestions and comments.

DISCONTINUOUS SOLUTIONS OF THE HAMILTON–JACOBI EQUATION FOR EXIT TIME PROBLEMS*

J. J. YE†

Abstract. In general, the value function associated with an exit time problem is a discontinuous function. We prove that the lower (upper) semicontinuous envelope of the value function is a supersolution (subsolution) of the Hamilton–Jacobi equation involving the proximal subdifferentials (superdifferentials) with subdifferential-type (superdifferential-type) mixed boundary condition. We also show that if the value function is upper semicontinuous, then it is the maximum subsolution of the Hamilton–Jacobi equation involving the proximal superdifferentials with the natural boundary condition, and if the value function is lower semicontinuous, then it is the minimum solution of the Hamilton–Jacobi equation involving the proximal subdifferentials with a natural boundary condition. Futhermore, if a compatibility condition is satisfied, then the value function is the unique lower semicontinuous solution of the Hamilton–Jacobi equation with a natural boundary condition and a subdifferential type boundary condition. Some conditions ensuring lower semicontinuity of the value functions are also given.

1. Introduction.

In this paper we study the exit time problem (also called the control problem with a boundary condition as in [10]). In its simplest form, the exit time problem involves a given open set E in R^n, and asks for choices for the time $t^* \geq 0$ and the measurable function u on $[0, t^*)$ which will

$$\begin{aligned} \text{minimize} \quad & J(x,u) := \int_0^{t^*} e^{-\lambda s} f(y(s), u(s)) ds + e^{-\lambda t^*} h(y(t^*)) \\ \text{subject to (s.t.)} \quad & \dot{y}(t) = g(y(t), u(t)) \quad \text{a.e. } t \in [0, t^*], \\ & u(t) \in U \quad \text{a.e. } t \in [0, t^*), \\ & y(0) = x, y(t) \in E, 0 \leq t < t^*, y(t^*) \notin E. \end{aligned}$$

By the classical Hamilton–Jacobi (H–J) theory (or the so-called dynamic programming theory), if the value function V is continuously differentiable, then it is the unique solution of the following H–J equation:

$$\lambda V(x) + H(x, -\nabla V(x)) = 0 \quad \forall x \in E, \tag{1}$$

where the Hamiltonian $H(x,p) := \max\{p \cdot g(x,u) - f(x,u) : u \in U\}$, with the natural boundary condition

$$V(x) = h(x) \quad \forall x \in \partial E.$$

Due to the complicated behavior of the trajectories at the boundary of the state space, the value function for the exit time problem is in general discontinuous, even

if all the problem data are Lipschitz continuous, unless some nontangency condition is imposed on the boundary (see, e.g., [12, 23, 10] for the Lipschitz continuity of the value function). Solving the H–J equation (1) with appropriate boundary conditions in some nonclassical sense has become an active research area. Gonzalez and Rofman [13] proved that the value function is an upper bound of a suitable set of subsolutions of the H–J equation. Dempster and Ye [10] characterized the Lipschitz value function as a solution of the H–J equation involving the Clarke generalized gradient. Bardi and Soravia [2], Barles and Perthame [4, 5], Blanc [6], Ishii [14], and Soravia [17, 18] have studied the solution of the H–J equation (1) with various boundary conditions in the framework of the viscosity solutions first introduced by Crandall and Lions [9] for continuous functions and later defined for discontinuous functions by Ishii [14, 15] and modified by Barron and Jenson [3] for the case of convex Hamiltonians. The reader is also referred to the recent monograph of Bardi and Capuzzo-Dolcetta [1] for the history and the recent development of the H–J equation using the viscosity approach.

Under assumptions that reduce the exit time problem to a generalized optimal stopping time problem, Ye and Zhu [24] showed that the value function of the exit time problem with relaxed controls is the unique lower semicontinuous solution of the H–J equation with the usual gradient replaced by the proximal subdifferential $\partial_p V(x)$ (see Definition 2.1) with the natural boundary condition

$$V(x) = h(x) \ \forall x \in E^c,$$

where E^c denotes the complement of the state space E and the subdifferential type boundary condition, i.e.,

$$\lambda V(x) + H(x, -\partial_p V(x)) \leq 0 \quad \forall x \in \partial E.$$

The purpose of this paper is to extend the H–J theory using the equivalence between the invariance and the H–J equation to treat exit time problems under assumptions that are much more general than those in [24]. In particular, we allow the discount rate λ to be zero and the exit cost h to be unbounded. In Theorem 2.2 we show that the lower (upper) semicontinuous envelope of the value function is a supersolution (subsolution) of the H–J equation involving the proximal subdifferentials (superdifferentials) with subdifferential-type (superdifferential-type) mixed boundary condition. In Theorems 2.3 and 2.4 we show that if the value function is upper semicontinuous, then it is the maximum subsolution of the H–J equation involving the proximal superdifferentials with the natural boundary condition, and if the value function is lower semicontinuous, then it is the minimum solution of the H–J equation involving the proximal subdifferentials with a natural boundary condition. Some conditions ensuring lower semicontinuity of the value functions are given in Proposition 2.5.

The technique of treating semicontinuous solutions to the H–J equation by using equivalence between the invariance property and the H–J equation was first introduced by Subbotin [19] for differential games (see also Subbotin [20]) and has been used in [8, 11] for finite horizon problems and in [22] for minimal time problems. The equivalence of the various concepts of the solution to the H–J equation in an open set was also given in [8].

We arrange the paper as follows: In the next section we state the problem formulation for the exit time problem and our main results. In section 3 we establish the equivalence among the optimality principle, the invariance property, and the H–J equations. The proofs of the main results are contained in section 4.

2. The exit time problems and the H–J equation. Let U be a compact subset of R^m and Prob(U) the set of all Borel probability measures on U. Consider Prob(U) as a subset of the dual of $C(U)$ endowed with the weak star topology, where $C(U)$ is the Banach space of continuous functions on U with the supremum norm. For any $\phi \in C(U)$ and $u \in$ Prob(U), we denote the pairing of ϕ and u by $\phi(u) := \int_U \phi(r)u(dr)$. Let $\mathcal{U}$ be the set of all Lebesgue measurable mappings from R to Prob(U). For finite real numbers $a < b$, define $\mathcal{U}_{[a,b]} := \{u|_{[a,b]} : u \in \mathcal{U}\}$. Then $\mathcal{U}_{[a,b]}$ is a weak star compact subset of $L^1([a,b]; C(U))^*$. We endow $\mathcal{U}$ with the following topology: u^n converges to u in $\mathcal{U}$ provided that $u^n|_{[a,b]}$ converges to $u|_{[a,b]}$ in $\mathcal{U}_{[a,b]}$ for any finite real numbers $a < b$. The set $\mathcal{U}_{[a,b]}$ is the collection of relaxed control functions defined in Warga [21]. It is the compactification of the set of usual control functions in the weak star topology of $L^1([a,b]; C(U))^*$. Elements of $\mathcal{U}_{[a,b]}$ are called relaxed controls. Using the set of relaxed controls ensures the existence of the optimal solution and also ensures the convexity of the velocity set so that the invariance theorems can be used. Any relaxed control can be approximated by usual controls. We refer to [21] for more details.

Let the state space E be an open subset of R^d, $\bar{E}$ be the closure of E, and O be an open set containing $\bar{E}$. Assume that $g : O \times U \to R^d$ satisfies the following condition.

(H1) $g(x,u)$ is continuous, bounded, and Lipschitz in x uniformly in $u \in U$.

Under such a condition, for each $x \in O$ and $u \in \mathcal{U}$, the differential equation

$$\dot{y}(s) = g(y(s), u(s)) \quad \text{a.e.}$$

has a unique solution defined on R that satisfies the side condition $y(0) = x$. We denote this solution by $y[x,u](\cdot)$ to indicate its dependence on x and u.

For each initial state $x \in E$ and control function u, define the exit time $t^*[x,u]$ to be the first time the trajectory starting from $x \in E$ corresponding to the control u exits from the state space E, or infinity if it never exits the state space; i.e.,

$$t^*[x,u] := \inf\{t > 0 : y[x,u](t) \notin E\},$$

where $\inf \emptyset = \infty$ by convention. For any $x \in E^c$, we define $t^*[x,u] := 0$. Where there is no confusion, we will simply use t^* instead of $t^*[x,u]$.

Let $\lambda \geq 0$ be the discount rate. Consider the following exit time problem:

$$P_x \quad \text{minimize} \quad J(x,u) := \int_0^{t^*} e^{-\lambda s} f(y[x,u](s), u(s))ds + e^{-\lambda t^*} h(y[x,u](t^*))$$
$$\text{s.t.} \quad u \in \mathcal{U}.$$

We state some further basic assumptions:

(H2) The running cost $f(x,u) : O \times U \to R^d$ is continuous, bounded, and Lipschitz in x uniformly in $u \in U$. The exit cost $h(x) : O \to R$ is lower semicontinuous. Furthermore, when $t^*[x,u] = \infty$ the integral $\int_0^{t^*} e^{-\lambda s} f(y[x,u](s), u(s))ds$ converges and the limit $e^{-\lambda\infty} h(y[x,u](\infty)) := \lim_{r\to\infty} e^{-\lambda r} h(y[x,u](r))$ exists and is finite.

REMARK 1. *The exit time problem we consider in this paper is more general than that usually considered in the literature (see, e.g.,* [1, 6]*) in that we allow the discount rate λ to be zero and the exit cost h to be unbounded. Notice that under the assumption that f is bounded, the integral $\int_0^\infty e^{-\lambda s} f(y[x,u](s), u(s))ds$ converges*

automatically for the case $\lambda > 0$ *so the assumption* (H2) *is mainly for the case when* $\lambda = 0$.

Under our assumptions, it is known that there exists an optimal control for the exit time problem for each $x \in E$. Define the value function of the family of problems P_x as

$$V(x) := \min \left\{ \int_0^{t^*} e^{-\lambda s} f(y[x,u](s), u(s)) ds + e^{-\lambda t^*} h(y[x,u](t^*)) : u \in \mathcal{U} \right\}.$$

Unlike a standard free end point optimal control problem whose value function is continuous if the terminal cost is continuous, the value function for the exit time problem is in general discontinuous even in the case where the terminal cost h is smooth. To see this we examine two simple examples.

EXAMPLE 1. *Let* $E = (0,1)$ *be the state space and the control set* $U = \{-1\}$. *Consider the following exit time problem where* $f(x,u) \equiv 0, g(x,u) = u, h(x) = x$, $\lambda = 0$:

$$\begin{aligned} \min \quad & y(t^*) \\ s.t. \quad & \dot{y} = u, u(t) = -1, \\ & y(0) = x. \end{aligned}$$

It is easy to see that the value function

$$V(x) = \begin{cases} 0 & \text{if } x \in [0,1), \\ x & \text{if } x \notin [0,1) \end{cases}$$

is upper semicontinuous with discontinuity at $x = 1$.

EXAMPLE 2. *In Example* 1, *change the control set to* $U = \{1\}$. *Then the value function becomes*

$$V(x) = \begin{cases} 1 & \text{if } x \in (0,1], \\ x & \text{if } x \notin (0,1], \end{cases}$$

which is lower semicontinuous with discontinuity at $x = 0$.

In order to see the connections between the value function and the H–J equations we define the lower and upper semicontinuous envelopes of a function $W : O \to R$ as

$$W_*(x) := \liminf_{y \to x} W(y)$$

and

$$W^*(x) := \limsup_{y \to x} W(y),$$

respectively. Then it is easy to see that W_* is lower semicontinuous and W^* is upper semicontinuous.

We will use the concept of proximal subdifferentials (superdifferentials) for any lower (upper) semicontinuous functions defined as follows.

DEFINITION 2.1 (see, e.g., Clarke [7] and Loewen [16]). *Let* $\phi : R^d \to (-\infty, \infty]$ *be an extended-valued lower semicontinuous function. The proximal subdifferential of* ϕ *at* $x \in R^d$ *where* $\phi(x) \neq \infty$ *is a set-valued map defined by*

$$\begin{aligned} \partial_p \phi(x) := \{ \xi \in R^d : & \exists \sigma > 0, \delta > 0 \\ & s.t.\ \phi(y) \geq \phi(x) - \sigma \|y - x\|^2 + \langle \xi, y - x \rangle \quad \forall y \in x + \delta B \}, \end{aligned}$$

where $\langle a, b\rangle$ denotes the inner product of the vectors a and b and B denotes the open unit ball. Let $\phi : R^d \to [-\infty, \infty)$ be an extended-valued upper semicontinuous function. The proximal superdifferential of ϕ at x where $\phi(x) \neq \infty$ is defined by

$$\partial^p \phi(x) := -\partial_p(-\phi)(x),$$

i.e.,

$$\partial^p \phi(x) := \{\xi \in R^d : \exists \sigma > 0, \delta > 0 \quad \text{s.t. } \phi(y) \leq \phi(x) + \sigma\|y - x\|^2 + \langle \xi, y - x\rangle \quad \forall x + \delta B\}.$$

REMARK 2. *Since the function $y \to \phi(x) - \sigma\|y - x\|^2 + \langle \xi, y - x\rangle$ in the right-hand side of the inequality in the definition of the proximal subdifferential is a quadratic, it is easy to see that $\xi \in \partial_p \phi(x)$ if and only if there is a parabola fitting under the epigraph of ϕ at $(x, \phi(x))$ with ξ as the slope of ϕ at x. Hence, in the case where there does not exist a parabola fitting under the epigraph of ϕ at $(x, \phi(x))$, the proximal subdifferential of ϕ at x may be empty (e.g., $\phi(x) = -|x|$ has an empty proximal subdifferential at 0). Similarly the proximal superdifferential may be empty. However, we shall see later that the emptiness of the proximal subdifferential (superdifferential) is actually an advantage.*

We now state our main results. The first result gives the connection between the semicontinuous envelopes of the value function and the H–J inequalities.

THEOREM 2.2. *Under assumptions* (H1)–(H2) *the lower semicontinuous envelope of the value function $V_*(x)$ is a supersolution of the H–J equation involving the proximal subdifferentials (in E), i.e.,*

$$\lambda V_*(x) + H(x, -\partial_p V_*(x)) \geq 0 \quad \forall x \in E \tag{2}$$

with the subdifferential-type mixed boundary condition

$$\max\{V_*(x) - h(x), \lambda V_*(x) + H(x, -\partial_p V_*(x))\} \geq 0 \quad \forall x \in \partial E, \tag{3}$$

and the upper semicontinuous envelope of the value function $V^*(x)$ is a subsolution of the H–J equation involving the proximal superdifferentials (in E), i.e.,

$$\lambda V^*(x) + H(x, -\partial^p V^*(x)) \leq 0 \quad \forall x \in E, \tag{4}$$

with the superdifferential-type mixed boundary condition

$$\min\{V^*(x) - h^*(x), \lambda V^*(x) + H(x, -\partial^p V^*(x))\} \leq 0 \quad \forall x \in \partial E, \tag{5}$$

where ∂E denotes the boundary of E.

REMARK 3. *Equation* (2) *should be understood in the following sense: At any point $x \in E$ where $\partial_p V_*(x) \neq \emptyset$,*

$$\lambda V_*(x) + H(x, -\xi) \geq 0 \quad \forall \xi \in \partial_p V_*(x).$$

Hence the points x where $\partial_p V_*(x) = \emptyset$ can be neglected. Equation (4) *is understood in a similar way. Equation* (3) *means that if $x \in \partial E$ is a point where $V_*(x) < h(x)$ and $\partial_p V_*(x) \neq \emptyset$, then*

$$\lambda V_*(x) + H(x, -\xi) \geq 0 \quad \forall \xi \in \partial_p V_*(x).$$

Similarly, (5) *means that if* $x \in \partial E$ *is a point where* $V^*(x) > h^*(x)$ *and* $\partial^p V^*(x) \neq \emptyset$, *then*

$$\lambda V^*(x) + H(x, -\xi) \leq 0 \quad \forall \xi \in \partial^p V^*(x).$$

Note that a similar result was given in Theorem 2.9 *of Blanc* [6] *in the viscosity solution sense for the case* $\lambda > 0$ *and bounded exit cost* h. *In general, as in Remark* 2.7 *of Blanc* [6], *we do not expect to have a unique function that satisfies* (2)–(5).

When the value function has a semicontinuity property, the following two theorems give connections between the value function (instead of its semicontinuous envelopes) and the H–J equation with natural boundary condition (instead of the mixed boundary condition).

THEOREM 2.3. *In additions to assumptions* (H1)–(H2), *assume that the value function is upper semicontinuous. Then it is the maximum upper semicontinuous function that is a subsolution of the H–J equation involving the proximal superdifferentials* (*in* E), *i.e.,*

$$\lambda W(x) + H(x, -\partial^p W(x)) \leq 0 \quad \forall x \in E,$$

with the natural boundary condition

$$W(x) = h(x) \quad \forall x \in \partial E.$$

THEOREM 2.4. *In additions to assumptions* (H1)–(H2), *assume that the value function is lower semicontinuous. Then it is the minimum lower semicontinuous solution of the H–J equation involving the proximal subdifferentials* (*in* E), *i.e.,*

$$\lambda W(x) + H(x, -\partial_p W(x)) = 0 \quad \forall x \in E,$$

with the natural boundary condition

$$W(x) = h(x) \quad \forall x \in \partial E.$$

We now give some conditions which ensure lower semicontinuity of the value function. First we state the required assumptions.

(A) $\forall\ x \in \partial E$ and $u \in \mathcal{U}$ such that $y[x,u](t) \in \bar{E} \quad \forall t \in [0,\infty)$, the limit $\lim_{r\to\infty} e^{-\lambda r} h(y[x,u](r))$ exists. Also, $\forall x \in \partial E$, all controls $u \in \mathcal{U}$ and $r \geq 0$ such that $y[x,u](t) \in \bar{E} \forall t \in [0,r], y[x,u](r) \in \partial E$, or $r = \infty$,

$$h(x) \leq \int_0^r e^{-\lambda s} f(y[x,u](s), u(s)) ds + e^{-\lambda r} h(y[x,u](r)).$$

PROPOSITION 2.5. *In addition to assumptions* (H1)–(H2), *if* (A) *is satisfied, then the value function* $V(x)$ *is lower semicontinuous on* $\bar{E}$.

Proof. Let $x \in \bar{E}$ and $x_n \in \bar{E}, x_n \to x$. By definition of the value function for each n, there exists $u^n \in \mathcal{U}$ and $t^*[x_n, u_n] := t_n^*$ such that

$$V(x_n) = \int_0^{t_n^*} e^{-\lambda s} f(y[x_n,u_n](s), u_n(s)) ds + e^{-\lambda t_n^*} h(y[x_n,u_n](t_n^*)). \tag{6}$$

We now consider two cases.

Case 1. The sequence $\{t_n^*\}$ is bounded. Without loss of generality we may assume that t_n^* converges to r, $t_n^* \in [0, r+1]$ and $u_n|_{[0,r+1]}$ converges to $u \in \mathcal{U}_{[0,r+1]}$ in the

topology of $\mathcal{U}_{[0,r+1]}$. Then $y[x_n,u_n](s)$ uniformly converges to $y[x,u](s)$ in $[0,r+1]$. Since $\bar{E}$ and ∂E are closed, $y[x,u](t)\in\bar{E}\ \forall t\in[0,r]$ and $y[x,u](r)\in\partial E$. Taking lim inf in (6) when $n\to\infty$ yields by virtue of lower semicontinuity of h

$$\begin{aligned}\liminf_{n\to\infty} V(x_n) &\geq \int_0^r e^{-\lambda s} f(y[x,u](s),u(s))ds + e^{-\lambda r} h(y[x,u](r))\\ &= \int_0^{t^*} e^{-\lambda s} f(y[x,u](s),u(s))ds\\ &\quad + \int_{t^*}^r e^{-\lambda s} f(y[x,u](s),u(s))ds + e^{-\lambda r} h(y[x,u](r))\\ &\geq \int_0^{t^*} e^{-\lambda s} f(y[x,u](s),u(s))ds + e^{-\lambda t^*} h(y[x,u](t^*))\\ &\qquad\qquad \text{(by assumption (A))}\\ &\geq V(x).\end{aligned}$$

Case 2. The sequence $\{t_n^*\}$ is unbounded. Without loss of generality we may assume that $t_n^*\to\infty$. For each integer $m>0$, consider the restriction of u_n to $[0,m]$. Since $\mathcal{U}_{[0,m]}$ is compact we can extract a convergent subsequence from $\{u_n|_{[0,m]}\}$. Using the diagonal method we can choose a subsequence $\{u_{n_i}\}$ of $\{u_n\}$ and an element $u\in\mathcal{U}$ such that $u_{n_i}|_{[0,m]}$ converges to $u|_{[0,m]}$ in $\mathcal{U}|_{[0,m]}$ for any m. We may assume that

$$\lim_{i\to\infty} V(x_{n_i}) = \liminf_{n\to\infty} V(x_n).$$

Taking lim inf in (6) when $n_i\to\infty$ yields in the case $t^*[x,u]=\infty$ that

$$\begin{aligned}\liminf_{i\to\infty} V(x_{n_i}) &\geq \int_0^{\infty} e^{-\lambda s} f(y[x,u](s),u(s))ds + e^{-\lambda\infty} h(y[x,u](\infty))\\ &\geq V(x)\end{aligned}$$

and in the case $t^*[x,u]<\infty$ that

$$\begin{aligned}\liminf_{i\to\infty} V(x_{n_i}) &\geq \int_0^{\infty} e^{-\lambda s} f(y[x,u](s),u(s))ds + e^{-\lambda\infty} h(y[x,u](\infty))\\ &= \int_0^{t^*} e^{-\lambda s} f(y[x,u](s),u(s))ds\\ &\quad + \int_{t^*}^{\infty} e^{-\lambda s} f(y[x,u](s),u(s))ds + e^{\lambda\infty} h(y[x,u](\infty))\\ &\geq \int_0^{t^*} e^{-\lambda s} f(y[x,u](s),u(s))ds + e^{-\lambda t^*} h(y[x,u](t^*))\\ &\qquad\qquad \text{(by assumption (A))}\\ &\geq V(x).\end{aligned}$$

The proof of the proposition is complete. □

REMARK 4. *In its essentials the above result says that if we allow the trajectory to continue after the first exit time but assume that it is cheaper to stop at the first exit time than to continue until the trajectory reaches the boundary again, then the value function is lower semicontinuous. The assumption* (A) *is not satisfied at the boundary*

point $x = 1$ for Example 1 since the only r in this case is $r = 1$ and the trajectory starting at $x = 1$ using the only control $u = -1$ reaches the boundary state $x = 0$ at time $r = 1$, but $1 = h(1) \not\leq h(y[1, u](1)) = 0$. On the other hand, the assumption (A) *is satisfied by Example 2 and hence the value function is lower semicontinuous.*

Combining Theorem 2.4 and Proposition 2.5, we have the following corollary.

COROLLARY 2.6. *Under assumptions* (H1), (H2), *and* (A), *the value function is the minimum lower semicontinuous solution of the H–J equation involving the proximal subdifferentials (in E), i.e.,*

$$\lambda W(x) + H(x, -\partial_p W(x)) = 0 \quad \forall x \in E, \tag{7}$$

with the natural boundary condition

$$W(x) = h(x) \quad \forall x \in \partial E. \tag{8}$$

One may wonder whether the natural boundary condition (8) is enough for the uniqueness of the solution to (7). The following example gives a negative answer.

EXAMPLE 3. *Let $E = R^2 \backslash \{0\}$ be the state space and the control set $U = [-1, 1]$. Consider the exit time problem where $f(x, u) \equiv 1, g(x, u) = (u, 0), h(x) = 0, \lambda = 1$. It is easy to see that*

$$V(x) = \begin{cases} \int_0^{|x_1|} e^{-s} ds = 1 - e^{-|x_1|} & \text{if } x_2 = 0, \\ \int_0^{\infty} e^{-s} ds = 1 & \text{if } x_2 \neq 0, \end{cases}$$

$$H(x, p) = \max\{p_1 u : u \in [-1, 1]\} - 1 = |p_1| - 1,$$

and

$$\partial_p V(x_1, 0) = \begin{cases} (e^{-x_1}, 0) & \text{if } x_1 > 0, \\ (-e^{x_1}, 0) & \text{if } x_1 < 0, \\ [-1, 1] \times \{0\} & \text{if } x_1 = 0. \end{cases}$$

Hence the value function is a lower semicontinuous solution of the H–J equation (7) *with the natural boundary condition* (8). *However, the function $W(x) = 1$ if $x \neq 0$ and $W(0) = 0$ is also a lower semicontinuous solution of* (7), (8). *Indeed, by Corollary 2.6, the value function is the minimum solution of the H–J equation* (7) *with the natural boundary condition $V(0) = 0$.*

The above example shows that the natural boundary condition (8) may not be enough to ensure the uniqueness of the solution to the H–J equation involving the proximal subdifferentials (7). However, V satisfies the subdifferential-type boundary condition

$$\lambda V(0) + H(x, -\partial_p V(0)) \leq 0$$

while $W(x)$ does not satisfy the above boundary condition. (Note $\partial_p W(0) = R^2$.) We now give a compatibility condition stronger than assumption (A) under which the value function is not only lower semicontinuous but also a unique lower semicontinuous solution to the H–J equation involving the proximal subdifferentials with the natural boundary condition and the subdifferential-type boundary condition.

(H3) $\forall\, x \in O \setminus E$, all controls $u \in \mathcal{U}$

$$h(x) \leq \int_0^r e^{-\lambda s} f(y[x, u](s), u(s)) ds + e^{-\lambda r} h(y[x, u](r)) \quad \forall 0 \leq r < \tau^*, \tag{9}$$

where

$$\tau^* := \inf\{t > 0 : y[x,u](t) \notin O \setminus E\}$$

and when

$$\tau^* = \infty, \int_0^{\tau^*} e^{-\lambda s} f(y[x,u](s), u(s))ds$$

converges and the limit $\lim_{r\to\infty} e^{-\lambda r} h(y[x,u])(r))$ exists and is finite.

REMARK 5. *When $E = R^d$ and $h = 0$ the exit time problem becomes an infinite horizon problem and assumption* (H3) *is satisfied vacuously. If $f \geq 0$ and $h = 0$, then assumption* (H3) *is also satisfied. This includes the time optimal control problem since solving a time optimal control problem is equivalent to solving an exit time problem with $f = 1$ and $h = 0$. Note that* (H3) *is a local version of the assumption* (5.8) *in Bardi and Capuzzo-Dolcetta* [1] *and* (H3′) *in Ye and Zhu* [24].

The statement of the following theorem is known from Corollary 4.5 of Ye and Zhu [24] for the case where $\lambda > 0$ and h is bounded under the assumption that (9) is satisfied globally $\forall x \in R^d$. However, the proof we give here is independent and different.

THEOREM 2.7. *Under assumptions* (H1)–(H3), *the value function $V(x)$ is a unique lower semicontinuous solution of the H–J equation involving the proximal subdifferentials (in E), i.e.,*

$$\lambda V(x) + H(x, -\partial_p V(x)) = 0 \quad \forall x \in E$$

with the natural boundary condition

$$V(x) = h(x) \qquad \forall x \in O \setminus E$$

and the subdifferential-type boundary condition, i.e.,

$$\lambda V(x) + H(x, -\partial_p V(x)) \leq 0 \forall x \in \partial E.$$

REMARK 6. *Note that a similar result was proved in Theorem* 5.5 *of Bardi and Capuzzo-Dolcetta* [1] *for the lower semicontinuous envelope of the value function in the viscosity solution sense in the case where $\lambda > 0$ and h is bounded under the assumption that* (9) *is satisfied globally $\forall x \in R^d$.*

3. Optimality principle, invariance, and the H–J equation.

DEFINITION 3.1. *Let $W(x) : G :\to R$ where $G \subseteq R^d$ is an open set. We say that $W(x)$ satisfies*

(a) *the* superoptimality principle *in G if and only if $\forall x \in G$ there exists a control $u \in \mathcal{U}$ such that*

$$W(x) \geq \int_0^{\tau} e^{-\lambda s} f(y[x,u](s), u(s))ds + e^{-\lambda\tau} W(y[x,u](\tau)) \quad \forall 0 \leq \tau < \tau^*;$$

(b) *the* suboptimality principle *in G if and only if $\forall x \in G$ and $\forall u \in \mathcal{U}$,*

$$W(x) \leq \int_0^{\tau} e^{-\lambda s} f(y[x,u](s), u(s))ds + e^{-\lambda\tau} W(y[x,u](\tau)) \qquad \forall 0 \leq \tau < \tau^*.$$

Here $\tau^* := \inf\{t > 0 : y[x,u](t) \notin G\}$ *is the exit time from set* G.

The following facts are well known from the Bellman optimality principle.

PROPOSITION 3.2. *The value function* $V(x)$ *satisfies the superoptimality principle in* E *and suboptimality principle in* E.

Furthermore, the following results indicate that not only the value function but also its lower (upper) semicontinuous envelope satisfies the superoptimality (suboptimality) principle in E.

PROPOSITION 3.3. *The lower semicontinuous envelope of the value function* $V_*(x)$ *satisfies the superoptimality principle in* E *and the upper semicontinuous envelope of the value function* $V^*(x)$ *satisfies the suboptimality principle in* E.

Proof. Fix $x \in E$, and suppose $V_*(x) = \lim_{n\to\infty} V(x_n)$ where $\lim_{n\to\infty} x_n = x, x_n \in E$. Then by Proposition 3.2, there exists $u_n \in \mathcal{U}$ and $t^*[x_n, u_n] = t_n^*$ such that

$$V(x_n) \geq \int_0^\tau e^{-\lambda s} f(y[x_n,u_n](s), u_n(s))ds + e^{-\lambda\tau} V(y[x_n,u_n](\tau)) \quad \forall 0 \leq \tau < t_n^*.$$

Without loss of generality assume that $t_n^* \to t^*$ where t^* may be finite or infinity. Let $0 \leq \tau < t^*$. Hence, for n large enough $\tau \leq t_n^*$. Taking limits and using the compactness of relaxed controls, we find a control $u \in \mathcal{U}$ such that

$$V_*(x) \geq \int_0^\tau e^{-\lambda s} f(y[x,u](s), u(s))ds + e^{-\lambda\tau} V_*(y[x,u](\tau)) \quad \forall 0 \leq \tau < t^*.$$

Similarly we can prove that $V^*(x)$ satisfies the suboptimality principle. □

In the following proposition, we show that either semicontinuity on $\bar{E}$ and the optimality principle in E or the suboptimality principle in an open set containing $\bar{E}$ gives the comparison results.

PROPOSITION 3.4.

(a) *Suppose that* W *satisfies the superoptimality principle in* E. *If* W *is lower semicontinuous on* $\bar{E}$ *and*

$$W(x) \geq h(x) \quad \forall x \in \partial E,$$

then $W(x) \geq V(x) \quad \forall x \in \bar{E}$.

(b) *Suppose that* W *satisfies the suboptimality principle in* E. *If* W *is upper semicontinuous on* $\bar{E}$ *and*

$$W(x) \leq h(x) \quad \forall x \in \partial E,$$

then $W(x) \leq V(x) \quad \forall x \in \bar{E}$.

(b′) *Suppose that* W *satisfies the suboptimality principle in the open set* O *containing* $\bar{E}$ *and*

$$W(x) \leq h(x) \quad \forall x \in \partial E.$$

Then $W(x) \leq V(x) \quad \forall x \in \bar{E}$.

Proof. (a) Suppose that W satisfies the superoptimality in E and $W(x) \geq h(x)\ \forall x \in \partial E$. Then $\forall x \in E$ there exists $u \in \mathcal{U}$ such that $\forall \tau_n \in [0, t^*)$.

$$W(x) \geq \int_0^{\tau_n} e^{-\lambda s} f(y[x,u](s), u(s))ds + e^{-\lambda\tau_n} W(y[x,u](\tau)).$$

Without loss of generality, assume that $\tau_n \to t^*$. Taking limits in the above inequality, we have by the compactness of relaxed controls and the lower semicontinuity of the function W that

$$\begin{aligned} W(x) &\geq \int_0^{t^*} e^{-\lambda s} f(y[x,u](s), u(s))ds + e^{-\lambda t^*} W(y[x,u](t^*)) \\ &\geq \int_0^{t^*} e^{-\lambda s} f(y[x,u](s), u(s))ds + e^{-\lambda t^*} h(y[x,u](t^*)) \\ &\geq V(x). \end{aligned}$$

Similarly we can prove (b).

(b′) Now suppose W satisfies the suboptimality in O and $W(x) \leq h(x)\ \forall x \in \partial E$. If $x \in \partial E$, then $W(x) \leq h(x) = V(x)$. If $x \in E$, then $\forall u \in \mathcal{U}$ we have

$$W(x) \leq \int_0^{t^*} e^{-\lambda s} f(y[x,u](s), u(s))ds + e^{-\lambda t^*} W(y[x,u](t^*)) \tag{10}$$

$$\leq \int_0^{t^*} e^{-\lambda s} f(y[x,u](s), u(s))ds + e^{-\lambda t^*} h(y[x,u](t^*)). \tag{11}$$

Hence $W(x) \leq V(x)$. □

Definition 3.5 (see [22, Definition 3.1]). *Suppose $\Omega \subset R^n$ is nonempty, $\Theta \subset R^n$ is open, and $\Gamma : R^n \Longrightarrow R^n$ is a set-valued map.*

(a) *Then (Γ, Ω) is weakly invariant in Θ provided that $\forall x \in \Omega \cap \Theta$, there exists an absolutely continuous function $y(\cdot)$ that satisfies $\dot{y}(s) \in \Gamma(y(s))$ a.e., $y(0) = x$, and*

$$y(s) \in \Omega \quad \forall s \in [0, \tau^*).$$

(b) *Then (Γ, Ω) is strongly invariant in Θ provided that $\forall x \in \Omega \cap \Theta$ and for any absolutely continuous function $y(\cdot)$ that satisfies $\dot{y}(s) \in \Gamma(y(s))$ a.e., $y(0) = x$ one has*

$$y(s) \in \Omega \quad \forall s \in [0, \tau^*)$$

where $\tau^* := \inf\{t > 0 : y(t) \notin \Theta\}$.

Define

$$\begin{aligned} F(s,x,r) &:= \{(g(x,u), -e^{-\lambda s} f(x,u)) : u \in U\}, \\ \widetilde{F}(s,x,r) &:= \{(g(x,u), e^{-\lambda s} f(x,u)) : u \in U\}. \end{aligned}$$

We write $\{1\} \times F$ for the set-valued map defined as

$$(\{1\} \times F)(s,x,r) := \{(1, g(x,u), -e^{-\lambda s} f(x,u)) : u \in U\}.$$

Similarly, we define $\{1\} \times \widetilde{F}$ and $\{-1\} \times \{-F\}$. Let $W : G \to R$. We denote the epigraph of the function $e^{-\lambda t} W(x)$ by X_W, i.e.,

$$X_W := \{(t,x,r) : r \geq e^{-\lambda t} W(x)\}.$$

The following results show that the optimality principles are equivalent to the invariance properties.

Proposition 3.6 (equivalence of optimality principles and invariances). *Let G be an open set in R^d.*

(a) *A function W satisfies the superoptimality principle in G if and only if $(\{1\}\times F, X_W)$ is weakly invariant in $R\times G\times R$;*

(b) *A function W satisfies the suboptimality principle in G if and only if either $(\{1\}\times\{\widetilde{F}\}, X_{-W})$ is strongly invariant in $R\times G\times R$ or $(\{-1\}\times\{-F\}, X_W)$ is strongly invariant in $R\times G\times R$.*

Proof. Since the proof is straightforward by using definitions, we prove only the second part of (b). Let $(t,x,r)\in X_W\cap R\times G\times R$. Then $x\in G$ and $r\ge e^{-\lambda t}W(x)$. By suboptimality principle, we have $\forall u\in\mathcal{U}$,

$$e^{\lambda\tau}W(y[x,u](-\tau))\le\int_{-\tau}^{0}e^{-\lambda s}f(y[x,u](s),u(s))ds+W(x)\quad\forall 0\le\tau\le\tau^*,$$

where $\tau^*:=\inf\{t>0: y[x,u](-\tau)\notin G\}$. Let $z_0(\tau)=-\tau+t$, $z(\tau)=y[x,u](-\tau)$, $z_{d+1}(\tau)=r-\int_0^{-\tau}e^{-\lambda(t+s)}f(y[x,u](s),u(s))ds$. Then $z_0(0)=t, z(0)=y[x,u](0)=x, z_{d+1}(0)=r$, $(\dot z_0,\dot z,\dot z_{d+1})(s)\in(\{-1\}\times\{-F\})(z_0(s),z(s))$, and

$$\begin{aligned}z_{d+1}(\tau)&=r-\int_0^{-\tau}e^{-\lambda(t+s)}f(y[x,u](s),u(s))ds\\&\ge e^{-\lambda t}W(x)-\int_0^{-\tau}e^{-\lambda(t+s)}f(y[x,u](s),u(s))ds\\&=e^{-\lambda t}(W(x)-\int_0^{-\tau}e^{-\lambda s}f(y[x,u](s),u(s))ds)\\&\ge e^{-\lambda(t-\tau)}W(y[x,u](-\tau))\\&=e^{-\lambda z_0(\tau)}W(z(\tau)).\end{aligned}$$

That is, $(z_0,z,z_{d+1})(\tau)\in X_W\ \forall 0\le\tau<\tau^*$. So $(\{-1\}\times\{-F\},X_W)$ is strongly invariant in $R\times G\times R$. Conversely, we can show that if $(\{-1\}\times\{-F\},X_W)$ is strongly invariant in $R\times G\times R$, then W satisfies the suboptimality principle in G. □

In the case when the function satisfying the optimality principles has semicontinuity properties, the invariances can be described by the H–J equations in the following way.

PROPOSITION 3.7 (equivalence of invariances and the H–J equations). *Let G be an open subset in R^d.*

(a) *Let $W: G\to R$ be a lower semicontinuous function. Then $(\{1\}\times F, X_W)$ is weakly invariant in $R\times G\times R$ if and only if*

$$\lambda W(x)+H(x,-\partial_p W(x))\ge 0\quad\forall x\in G.$$

(b) *Let $W: G\to R$ be an upper semicontinuous function. Then $(\{1\}\times\widetilde{F}, X_{-W})$ is strongly invariant in $R\times G\times R$ if and only if*

$$\lambda W(x)+H(x,-\partial^p W(x))\le 0\quad\forall x\in G.$$

(b′) *Let $W: G\to R$ be a lower semicontinuous function. Then $(\{-1\}\times\{-F\},X_W)$ is strongly invariant in $R\times G\times R$ if and only if*

$$\lambda W(x)+H(x,-\partial_p W(x))\le 0\quad\forall x\in G.$$

The proof is based on the following lemmas. We denote $N^p_\Omega(x) = \partial_p \delta_\Omega(x)$, where δ_Ω is the indicator function of a set Ω defined by

$$\delta_\Omega(x) = \begin{cases} 0 & \text{if } x \in \Omega, \\ +\infty & \text{if } x \notin \Omega. \end{cases}$$

LEMMA 3.8 (see, e.g., [22, Theorem 3.1]). *Suppose that for each $x \in R^n$, $\Gamma(x)$ is not empty, convex, and compact, and the graph $gph\Gamma := \{(x,v) : v \in \Gamma(x)\}$ is closed in R^{2n}. Let $\Omega \subseteq R^n$ be closed and $\Theta \subseteq R^n$ be open.*

(a) *Then (Γ, Ω) is weakly invariant in Θ if and only if*

$$\min\{\langle v, \xi\rangle : v \in \Gamma(x)\} \le 0 \quad \forall x \in \Omega \cap \Theta, \xi \in N^p_\Omega(x),$$

where $N^p_\Omega(x)$ is the proximal normal cone to Ω at $x \in \Omega$ defined by

$$N^p_\Omega(x) := \{\xi \in R^n : \exists M > 0 \text{ s.t. } \langle \xi, x' - x\rangle \le M\|x' - x\|^2 \ \ \forall x' \in \Omega\}.$$

(b) *In addition, assume that Γ is Lipschitz continuous; i.e., for each compact subset $C \subset R^n$, there exists $K > 0$ so that*

$$\Gamma(x) \subset \Gamma(y) + K\|x - y\|B \quad \forall x, y \in C.$$

Then (Γ, Ω) is strongly invariant in Θ if and only if

$$\max\{\langle v, \xi\rangle : v \in \Gamma(x)\} \le 0 \quad \forall x \in \Omega \cap \Theta, \xi \in N^p_\Omega(x).$$

LEMMA 3.9. *Suppose that for each $x \in R^n$, $\Gamma(x)$ is not empty, convex, and compact, and the graph $gph\Gamma := \{(x,v) : v \in \Gamma(x)\}$ is closed in R^{2n}. Let θ be a lower semicontinuous function and Θ be an open subset of R^n. Then*

(a)

$$\begin{aligned} &\min\{\langle v_1, \eta\rangle + v_2\rho : (v_1, v_2) \in \Gamma(z, r)\} \le 0 \quad \forall (z, r) \in epi\theta \cap \Theta, \\ &\qquad\qquad (\eta, \rho) \in N^p_{epi\theta}(z, r) \end{aligned} \tag{12}$$

if and only if

$$\min\{\langle v_1, \eta\rangle - v_2 : (v_1, v_2) \in \Gamma(z, \theta(z))\} \le 0 \quad \forall z \in \Theta, \eta \in \partial_p\theta(z). \tag{13}$$

(b) *In addition, assume that Γ is Lipschitz continuous. Then*

$$\begin{aligned} &\max\{\langle v_1, \eta\rangle + v_2\rho : (v_1, v_2) \in \Gamma(z, \theta(z))\} \le 0 \quad \forall (z, r) \in epi\theta \cap \Theta, \\ &\qquad\qquad (\eta, \rho) \in N^p_{epi\theta}(z, r) \end{aligned} \tag{14}$$

if and only if

$$\max\{\langle v_1, \eta\rangle - v_2 : (v_1, v_2) \in \Gamma(z, \theta(z)))\} \le 0 \quad \forall z \in \Theta, \eta \in \partial_p\theta(z). \tag{15}$$

Proof. Since an equivalent definition of the proximal subdifferential of ϕ at z is that

$$\eta \in \partial_p\theta(z) \text{ if and only if } (\eta, -1) \in N^p_{epi\theta}(z, \theta(z)),$$

(13) and (15) are (12) and (14) with $r = \theta(z)$ and $\rho = -1$, respectively. So it suffices to prove that (13) and (15) imply (12) and (14), respectively.

We first suppose that (13) holds. Let $(z,r) \in epi\theta \cap \Theta, (\eta,\rho) \in N^p_{epi\theta}(z,r)$. Then by the nature of epigraphs, we have $\rho \le 0$. Let us assume first that $\rho < 0$ from which it follows that $r = \theta(z)$. Since $N^p_{epi\theta}(z,\theta(z))$ is a cone, we have $(-\frac{\eta}{\rho}, -1) \in N^p_{epi\theta}(z,\theta(z))$ and consequently $-\frac{\eta}{\rho} \in \partial_p\theta(z)$. By (13), we have

$$\min\left\{-\left\langle v_1, \frac{\eta}{\rho}\right\rangle - v_2 : (v_1,v_2) \in \Gamma(z,\theta(z))\right\} \le 0.$$

Since $\rho < 0$, we have

$$\min\{\langle v_1,\eta\rangle + v_2\rho : (v_1,v_2) \in \Gamma(z,\theta(z))\} \le 0.$$

That is, (12) holds $\forall\ \rho < 0$.

We see that $(\eta,\rho) = 0$ trivially satisfies (12). Now suppose $\rho = 0$ and $\eta \ne 0$, from which it follows that $(\eta,0) \in N^p_{epi\theta}(z,\theta(z))$. By definition (cf. [16]), η is in the singular limiting subdifferential of θ at z. So there exists $\{z_i\}, \{\eta_i\}$, and $\{\rho_i\}$ so that $z_i \to z, \theta(z_i) \to \theta(z), \eta_i \to \eta, \rho_i < 0, \rho_i \uparrow 0$, and $-\frac{\eta_i}{\rho_i} \in \partial_p\theta(z_i)$. By (13), we have

$$\min\left\{-\left\langle v_1, \frac{\eta_i}{\rho_i}\right\rangle - v_2 : (v_1,v_2) \in \Gamma(z_i,\theta(z_i))\right\} \le 0.$$

So there exist $(v_1^i, v_2^i) \in \Gamma(z_i,\theta(z_i))$ such that

$$\langle v_1^i, \eta_i\rangle + v_2^i\rho_i \le 0.$$

Without loss of generality, assume that $v_1^i \to v_1, v_2^i \to v_2$. Then $(v_1,v_2) \in \Gamma(z,\theta(z))$ and

$$\langle v_1,\eta\rangle + v_2 \cdot 0 \le 0 \quad \forall (\eta,0) \in N_{epi\theta}(z,\theta(z)),$$

which is (12) when $\rho = 0$.

Now suppose (15) holds. Let $(\eta,\rho) \in N^p_{epi\theta}(z,r), (z,r) \in epi\theta \cap \Theta$. Then $\rho \le 0$. If $\rho < 0$, then the proof is similar to that in (a). If $\rho = 0$, then $r = \theta(z), (\eta,0) \in N^p_{epi\theta}(z,\theta(z))$. So there exist $\{z_i\}, \{\eta_i\}$, and $\{\rho_i\}$ such that $z_i \to z, \theta(z_i) \to \theta(z), \eta_i \to \eta, \rho_i < 0, \rho_i \uparrow 0$, and $-\frac{\eta_i}{\rho_i} \in \partial_p\theta(z_i)$. By (15), we have

$$\max\left\{-\left\langle v_1, \frac{\eta_i}{\rho_i}\right\rangle - v_2 : (v_1,v_2) \in \Gamma(z_i,\theta(z_i))\right\} \le 0.$$

That is,

$$\max\{\langle v_1,\eta_i\rangle + v_2\rho_i : (v_1,v_2) \in \Gamma(z_i,\theta(z_i))\} \le 0.$$

Since Γ is Lipschitz continuous, letting $(v_1,v_2) \in \Gamma(z_i,\theta(z_i))$, we have

$$\Gamma(z_i,\theta(z_i)) \subset \Gamma(z,\theta(z)) + K(\|z - z_i\|^2 + |\theta(z) - \theta(z_i)|^2)^{1/2}B.$$

Therefore there exists $(v_1^i, v_2^i) \in \Gamma(z,\theta(z))$ such that

$$(v_1,v_2) = (v_1^i, v_2^i) + K(\|x_1 - z_i\|^2 + |\theta(x_1) - \theta(z_i)|^2)^{1/2}e,$$

where $\|e\| \le 1$. Hence

$$\begin{aligned}\langle v_1,\eta_i\rangle + v_2\rho_i &= \langle v_1^i,\eta_i\rangle + v_2^i\rho_i + \langle\lambda_i e_1,\eta_i\rangle + \langle\lambda_i e_2,\rho_i\rangle\\ &\le \langle\lambda_i e_1,\eta_i\rangle + \langle\lambda_i e_2,\rho_i\rangle,\end{aligned}$$

where $\lambda_i = K(\|x_1 - z_i\|^2 + |\theta(x_1) - \theta(z_i)|^2)^{1/2} \to 0$ as $i \to \infty$. Taking limits, we have

$$\langle v_1, \eta \rangle + v_2 \cdot 0 \le 0 \quad \forall (\eta, 0) \in N_{epi\theta}(x_1, \theta(x_1)).$$

That is, (14) when $\rho = 0$. □

LEMMA 3.10 (see [24, Lemma 4.1]). *Let W be an extended-valued lower semicontinuous function. Then*

$$\partial_p(e^{-\lambda t}W(x)) = \{-\lambda e^{-\lambda t}W(x)\} \times \{e^{-\lambda t}\partial_p W(x)\}.$$

Proof of Proposition 3.7. By virtue of (a) in Lemmas 3.8 and 3.9, $(\{1\} \times F, X_W)$ is weakly invariant in $R \times G \times R$ if and only if

$$\min\{\xi_1 + \xi_2 \cdot g(x,u) + e^{-\lambda t}f(x,u) : u \in U\} \le 0 \quad \forall x \in G, \xi \in \partial_p(e^{-\lambda t}W(x)).$$

By Lemma 3.10, that is,

$$\min\{-\lambda W(x) + \eta \cdot g(x,u) + f(x,u) : u \in U\} \le 0 \quad \forall x \in G, \eta \in \partial_p W(x).$$

Hence

$$\lambda W(x) + H(x, -\eta) \ge 0 \quad \forall x \in G, \eta \in \partial_p W(x).$$

By virtue of (b) in Lemmas 3.8 and 3.9, $(\{1\} \times \widetilde{F}, X_{-W})$ is strongly invariant in $R \times G \times R$ if and only if

$$\max\{\xi_1 + \xi_2 \cdot g(x,u) - e^{-\lambda t}f(x,u) : u \in U\} \le 0 \quad \forall x \in G, \xi \in \partial_p(-e^{-\lambda t}W(x)).$$

By Lemma 3.10, that is,

$$\max\{\lambda W(x) - \eta \cdot g(x,u) - f(x,u) : u \in U\} \le 0 \quad \forall x \in G, \eta \in \partial_p(-W(x)).$$

Hence

$$\lambda W(x) + H(x, -\eta) \le 0 \quad \forall x \in G, \eta \in \partial^p W(x).$$

By virtue of (b) in Lemmas 3.8 and 3.9, $(\{-1\} \times \{-F\}, X_W)$ is strongly invariant in $R \times G \times R$ if and only if

$$\max\{-\xi_1 - \xi_2 \cdot g(x,u) - e^{-\lambda t}f(x,u) : u \in U\} \le 0 \quad \forall x \in G, \xi \in \partial_p(e^{-\lambda t}W(x)).$$

By Lemma 3.10, that is,

$$\max\{\lambda W(x) - \eta \cdot g(x,u) - f(x,u) : u \in U\} \le 0 \quad \forall x \in R^d, \eta \in \partial_p W(x).$$

Hence

$$\lambda W(x) + H(x, -\eta) \le 0 \quad \forall x \in G, \eta \in \partial_p W(x). \qquad \square$$

We now derive from Propositions 3.6 and 3.7 the equivalence between the optimality principles and the H–J equations.

PROPOSITION 3.11 (equivalence of optimality principles and the H–J equations). *Let G be an open subset of R^d.*

(a) *Let $W : G \to R$ be a lower semicontinuous function. Then it satisfies the superoptimality principle in G if and only if it is a supersolution of the H–J equation involving the proximal subdifferentials in G; i.e.,*

$$\lambda W(x) + H(x, -\partial_p W(x)) \geq 0 \quad \forall x \in G.$$

(b) *Let $W : G \to R$ be an upper semicontinuous function. Then it satisfies the suboptimality principle in G if and only if it is a subsolution of the H–J equation involving the proximal superdifferentials in G; i.e.,*

$$\lambda W(x) + H(x, -\partial^p W(x)) \leq 0 \quad \forall x \in G.$$

(b′) *Let $W : G \to R$ be a lower semicontinuous function. Then it satisfies the suboptimality principle in G if and only if it is a subsolution of the H–J equation involving the proximal subdifferentials in G; i.e.,*

$$\lambda W(x) + H(x, -\partial_p W(x)) \leq 0 \quad \forall x \in G.$$

4. Proof of main results.

Proof of Theorem 2.2. By Proposition 3.3, $V_*(x)$ satisfies the superoptimality principle in E. So by (a) of Proposition 3.11, it is a supersolution of the H–J equation involving the proximal subdifferentials in E.

We now prove that V_* satisfies the boundary condition

$$\max\{V_*(x) - h(x), \lambda V_*(x) + H(x, -\partial_p V_*(x))\} \geq 0 \quad \forall x \in \partial E. \tag{16}$$

If $V_*(x) - h(x) \geq 0 \ \forall x \in \partial E$, then the boundary condition (16) holds. Otherwise suppose that there exists $x \in \partial E$ such that $V_*(x) < h(x)$.

Let $x_n \to x, V(x_n) \to V_*(x)$. We may assume without loss of generality that $x_n \in E \ \forall n$. Indeed, if there exists a subsequence $\{x_p\}$ of $\{x_n\}$ such that $x_p \in \partial E \ \forall p$, then, by definition of the value function on the boundary of E and the lower semicontinuity of the exit cost h, we have

$$V_*(x) = \lim_{n\to\infty} V(x_n) = \lim_{p\to\infty} V(x_p) = \lim_{p\to\infty} h(x_p) \geq h(x),$$

which contradicts the assumption that $V_*(x) < h(x)$.

Now by the Bellman optimality principle, there exists a control $u_n \in \mathcal{U}$, $t_n^* := t^*[x_n, u_n] > 0$ such that

$$V(x_n) \geq \int_0^r e^{-\lambda s} f(y[x_n, u_n](s), u_n(s))ds + e^{-\lambda \tau_n} V(y[x_n, u_n](r)) \ \ \forall 0 \leq r \leq t_n^*.$$

Now let $\bar{r} = \liminf t_n^*$. We must have $\bar{r} > 0$, since otherwise we can find a subsequence of $\{t_n^*\}$ such that $t_n^* \to 0$ so that

$$\begin{aligned} V_*(x) &= \lim_{n\to\infty} V(x_n) \\ &\geq \liminf_{n\to\infty} \int_0^{t_n^*} e^{-\lambda s} f(y[x_n, u_n](s), u_n(s))ds + \liminf_{n\to\infty} e^{-\lambda t_n^*} h(y[x_n, u_n](t_n^*)) \\ &\geq h(x) \quad \text{since } h \text{ is lower semicontinuous,} \end{aligned}$$

which is a contradiction. Now by the compactness of relaxed controls on $[0, \bar{r}]$, there exists $u = \lim_{n\to\infty} u_n$ such that

$$V_*(x) \geq \int_0^r e^{-\lambda s} f(y[x, u](s), u(s))ds + e^{-\lambda r} V_*(y[x, u](r)) \ \ \forall r \in (0, \bar{r}].$$

Let $\xi \in \partial_p V_*(x)$. Then there exist $\sigma > 0, \delta > 0$ such that

$$V_*(x') - V_*(x) + \sigma\|x' - x\|^2 \geq \langle \xi, x' - x\rangle \quad \forall x' \in x + \delta B.$$

Let $x' = y[x,u](r)$ where $r \in [0, \bar{r}]$ is fixed. Then

$$\begin{aligned}\langle \xi, y[x,u](r) - x\rangle &\leq \sigma\|y[x,u](r) - x\|^2 + V_*(y[x,u](r)) - V_*(x)\\ &\leq \sigma\|y[x,u](r) - x\|^2 - e^{\lambda r}\int_0^r e^{-\lambda s} f(y[x,u](s), u(s))ds\\ &\quad + e^{\lambda r}V_*(x) - V_*(x).\end{aligned}$$

Since $y[x,u](r) - x = \int_0^r g(y[x,u](s), u(s))ds$, one has

$$\begin{aligned}&\int_0^r [\langle -\xi, g(y[x,u](s), u(s))\rangle - f(y[x,u](s), u(s))]ds\\ &+ \int_0^r [(1 - e^{\lambda(r-s)})f(y[x,u](s), u(s))]ds + (e^{\lambda r} - 1)V_*(x) \geq -\sigma\|y[x,u](r) - x\|^2.\end{aligned}$$

By virtue of the boundedness of g and the Lipschitz continuity of g, f uniformly in $u \in U$, one has

$$\begin{aligned}&\|y[x,u](r) - x\| \leq M_g r\\ &(\|\xi\|L_g + L_f)M_g s + \langle \xi, g(x, u(s))\rangle - f(x, u(s))\\ &\quad \geq \langle \xi, g(y[x,u](s), u(s))\rangle - f(y[x,u](s), u(s)),\end{aligned}$$

where M_g, L_g, L_f denote the bound of g and the Lipschitz constants of g, f, respectively. Therefore, one has

$$\begin{aligned}&\int_0^r [\langle -\xi, g(x, u(s))\rangle - f(x, u(s))]ds + (e^{\lambda r} - 1)V_*(x)\\ &\geq o(r) - \int_0^r [(1 - e^{\lambda(r-s)})f(y[x,u](s), u(s))]ds\\ &\geq o(r) - \int_0^r (1 - e^{\lambda(r-s)})M_f ds,\end{aligned}$$

where $o(r)$ indicates a function $g(r)$ such that $\lim_{t\to 0^+} |g(r)|/r = 0$ and M_f is the bound of f. Since the term in the square bracket in the first integral is bounded from above by

$$H(x, -\xi) = \max\{\langle -\xi, g(x,u)\rangle - f(x,u) : u \in U\},$$

(17) implies that

$$H(x, -\xi)r + (e^{\lambda r} - 1)V_*(x) \geq o(r) - \int_0^r (1 - e^{\lambda(r-s)})M_f ds.$$

Dividing the above inequality by r and letting $r \to 0$, we have

$$\lambda V_*(x) + H(x, -\partial_p V_*(x)) \geq 0.$$

Similarly by Proposition 3.3, $V^*(x)$ satisfies the suboptimality principle. So by Proposition 3.6, $(\{-1\} \times \{-F\}, X_{V^*})$ is strongly invariant in $R \times E \times R$. Hence, by

Proposition 3.7, V^* is a proximal subsolution of the H–J equation. The boundary condition can be proved similarly. □

Proof of Theorem 2.3. By Proposition 3.2, the value function $V(x)$ satisfies the suboptimality principle in E. Since $V(x)$ is upper semicontinuous, by (b) of Proposition 3.11, it is a subsolution of the H–J equation involving the proximal superdifferentials, i.e.,

$$\lambda V(x) + H(x, -\partial^p V(x)) \leq 0 \quad \forall x \in E.$$

Conversely, let $W(x)$ be an upper semicontinuous function such that

$$\begin{aligned} \lambda W(x) + H(x, -\partial^p W(x)) &\leq 0 \quad \forall x \in E \\ W(x) &\leq h(x) \quad \forall x \in \partial E. \end{aligned}$$

Then by (b) of Proposition 3.11, W satisfies the suboptimality principle in E. By (b) of Proposition 3.4, $W(x) \leq V(x)\ \forall x \in \bar{E}$. □

Proof of Theorem 2.4. By Proposition 3.2, the value function V satisfies both the superoptimality principle in E and the suboptimality principle in E. Since the value function is assumed to be lower semicontinuous, by the equivalence of the optimality principles and the H–J equations ((a) and (b′) of Proposition 3.11), the value function is both a supersolution and subsolution (hence a solution) of the H–J equation involving the proximal subdifferentials. Now if $W(x)$ is a lower semicontinuous solution of the H–J equation involving the proximal subdifferentials in E with the natural boundary condition $W(x) = h(x)\ \forall x \in \partial E$, then by (a) of Proposition 3.4, $W(x) \geq V(x)\ \forall x \in E$. □

Proof of Theorem 2.7. By Proposition 3.2, the value function V satisfies both the superoptimality principle in E and the suboptimality principle in E. Observing that $V(x) = h(x)\ \forall x \in E^c$ we have by assumption (H3) that the value function also satisfies the suboptimality principle in O which contains $\bar{E}$. Since by Proposition 2.5 the value function is lower semicontinuous, by (a) and (b′) of Proposition 3.11,

$$\lambda V(x) + H(x, -\partial_p V(x)) \geq 0 \quad \forall x \in E, \tag{17}$$

$$\lambda V(x) + H(x, -\partial_p V(x)) \leq 0 \quad \forall x \in O. \tag{18}$$

Now suppose W is a lower semicontinuous function that satisfies (17), (18), and the natural boundary condition $W(x) = h(x)\ \forall x \in O \backslash E$. Then by Proposition 3.11, W satisfies both the superoptimality principle in E and the suboptimality principle in O. Hence by (a) and (b′) of Proposition 3.4, $W(x) = V(x)\ \forall x \in \bar{E}$. □

LONG TIME BEHAVIOR FOR SOME DYNAMICAL NOISE FREE NONLINEAR FILTERING PROBLEMS*

FRÉDÉRIC CÉROU†

Abstract. A possible approach to studying the accuracy of optimal nonlinear filtering is to look at the conditional law on an arbitrary neighborhood of the current (unknown) state as the time goes to infinity. This paper is devoted to a restricted class of systems with a deterministic state equation, and under additional assumptions, results concerning the concentration of the conditional law are shown, as is how estimating the current state could be different from estimating the initial condition. The assumptions on the system could seem quite restrictive; however, they concern only the "observability" of the system, without any reference to ergodicity as in previous works.

Key words. nonlinear filtering, long time behavior, measure concentration

AMS subject classifications. 93E11, 60G35

1. Introduction.

The optimal filtering of nonlinear systems, in particular in the framework of stochastic differential equations of Itô type, is now a well-studied problem: the conditional law of the current state, given the past observations, is the solution of the Kushner–Stratonovitch equation. For numerical purposes, the Zakai equation, which gives an unnormalized conditional law, is also used. See, for instance, [14] for a review on nonlinear filtering. Nevertheless, a crucial question is still open concerning the "accuracy" of the filtering: that is, as time increases and as we obtain more and more observations, what can we say about the conditional law of the current state? What are the conditions to be imposed on the system in order to control in some sense the filtering error?

Some results have been proved in [8] and [9] by Kunita when the state process is ergodic. Let us also mention that the results presented in [8] have been extended to the noncompact case in [7] by Ji. If we look at this problem as an asymptotic stability problem of the Kushner–Stratonovitch equation (which can be considered as a stochastic dynamical system on the infinite dimensional space of probability measures on the state space), it becomes clear that it is closely related to the sensitivity of the filter to the prior distribution. That is, given an erroneous initial distribution, does the filter give results close to the ones obtained with the correct initialization, as the time goes to infinity? Using again ergodicity arguments, Ocone and Pardoux [13] showed some results concerning this topic. Note that this question about stability was already addressed in the linear case by Bucy and Joseph [2].

Nevertheless, it seems natural that without any ergodicity, only some good fitting between the dynamics and the observations should be sufficient (related to some "observability" notion) to control the filtering error, say, to make it asymptotically bounded for large time. This has been an open problem since the early developments of the theory and may be considered as both challenging for the scientist and crucial for practical purposes.

The aim of the present paper is to deal with such problems, in the restricted framework of noise free dynamics, that is, with identically zero diffusion coefficient

on the state equation. This is a much simpler but nontrivial model, used with success in some applications (such as passive target tracking), and for which well-adapted numerical algorithms have been developed (see [1] and [3] for details). In fact we can adopt a direct approach here: as we can write an explicit formula for the conditional unnormalized density, under some assumptions ensuring a uniform good "observability," we can directly estimate the long time behavior of the conditional law. More precisely we will show that for any ball of fixed radius centered at the current state (and also moving with it), the integral of the conditional density on the ball converges in probability to 1 as time goes to infinity. This criterion comes from practice—say tracking problems—when the output consists of confidence regions, and it will ensure that these regions will be included at large times in arbitrarily small neighborhoods of the current state. We will investigate the general case without special behavior of the dynamics, for which we need good observations on the whole space, and the linear Gaussian case, for which we can give the behavior of the conditional covariance matrix. Even though the assumptions imposed on the coefficients still seem too restrictive for practical use, the main purpose of this work is to illustrate that the ergodicity conditions are not needed to study the accuracy of the filter at large times.

Before studying the filtering problem we present a particular approach to an estimation problem, keeping in mind that the method developed will be useful in what follows.

2. Estimation. We consider the following estimation problem:

$$dY(t) = S\,(t, X_0)\,dt + dB_t,$$

where S is a measurable function from $\mathbb{R} \times \mathbb{R}^d$ into $\mathbb{R}^m$, $X_0 \in \mathbb{R}^d$ is a random vector, and B denotes standard m-dimensional Brownian motion. We denote by P_0 the law of X_0. For all $x \in \mathbb{R}^d$ we take the notation

$$g(t, x) = S(t, x) - S(t, X_0).$$

We assume that X_0 and B are independent. This section is devoted to the study of the asymptotic behavior of the conditional law of X_0, given the observations $\{Y_s,\, s \le t\}$, as $t \to +\infty$. This is a well-studied problem (see [6], for instance) but the standard approach is difficult to use for related filtering problems that we will study in the next sections, so we present here some methods that will be useful later. Assume that the following hypotheses are fulfilled, ensuring the existence of a conditional density with respect to P_0 given by a Bayes formula. Let $\{\mathcal{F}_t^Y,\, t \ge 0\}$ be the filtration of the process Y, and $\forall\ t \ge 0$

$$\forall x \in \mathbb{R}^d,\ \int_0^t \|S(s, x)\|\,ds < \infty, \tag{1}$$

$$P\left(\int_0^t \|S(s, X_0)\|^2\,ds < \infty\right) = 1, \tag{2}$$

and

$$P\left(\int_0^t \left\|E\left[S(s, X_0) \,|\, \mathcal{F}_s^Y\right]\right\|^2 ds < \infty\right) = 1. \tag{3}$$

Then by [12, Theorem 7.23, p. 289], the Bayes formula gives for all bounded continuous ψ

$$E\left[\psi(X_0)\,|\,\mathcal{F}_t^Y\right] = G\int_{\mathbb{R}^d}\psi(x)\,\exp\left[-\frac{1}{2}\int_0^t S^2(s,x)\,ds + \int_0^t S(s,x)\,dY_s\right]\,P_0(dx),$$

where G is a $\mathcal{F}_t^Y$ measurable normalizing factor. After dividing G and multiplying the integral term by $\exp\left[-\frac{1}{2}\int_0^t S^2(s,X_0)\,ds - \int_0^t S(s,X_0)\,.\,dB_s\right]$, we get the following form for the unnormalized a posteriori law ν_t^0:

$$\nu_t^0(A) = \int_A f_t(x)\,P_0(dx) = \int_A \exp\left[\int_0^t g(s,x).dB_s - \frac{1}{2}\int_0^t g^2(s,x)ds\right]P_0(dx) \tag{4}$$

for all Borel sets A. Let us denote by μ_t^0 the normalized conditional law. In the whole section we suppose that the following hypothesis is fulfilled.

(H1). There are two functions v and V from $\mathbb{R}_+$ into $\mathbb{R}_+$ and a positive constant C such that $1 \leq \frac{V(t)}{v(t)} \leq C$ and

$$\forall (x_1,x_2)\in\mathbb{R}^d\times\mathbb{R}^d,\quad v(t)\|x_1-x_2\|^2 \leq \int_0^t \|S(s,x_1)-S(s,x_2)\|^2 ds \leq V(t)\|x_1-x_2\|^2.$$

Notice that it is reasonable to assume that $\int_0^t \|S(s,x)\|^2\,ds < \infty$ for some x and that then assumption (H1) is much stronger than (1)–(3).

Main result. We have the following proposition concerning the concentration of the conditional law.

PROPOSITION 2.1. *Let us denote*

$$\mathcal{B}_a^0 = \{x\in\mathbb{R}^d,\ \|x-X_0\|\leq a\}.$$

Assume that (H1) *is fulfilled, and* $\lim_{t\to+\infty} V(t) = +\infty$. *Then* $\forall\ a>0$

$$\mu_t^0\left(\mathcal{B}_a^0\right) \xrightarrow{P} 1 \quad as \quad t\to+\infty.$$

Moreover, we have the following estimate concerning the rate of convergence:

$$\forall\ 0<\beta<\frac{a^2}{4C},\quad \exp(\beta V(t))\left(1-\mu_t^0\left(\mathcal{B}_a^0\right)\right)\xrightarrow{P} 0 \quad as \quad t\to+\infty.$$

To prove this proposition, we will need some auxiliary results to control the stochastic integral which appears in the likelihood function f_t.

PROPOSITION 2.2. *Assume that the upper estimate in* (H1) *is valid. Then there exists* $A_1>0$ *such that* $\forall\ a>0$,

$$E\left[\sup_{\|x-X_0\|\leq a}\left|\int_0^t g(s,x).dB_s\right|\right] \leq A_1 a\sqrt{V(t)}.$$

Proof. We note

$$\mathcal{B}_a^0 = \left\{x\in\mathbb{R}^d/\|x-X_0\|\leq a\right\}.$$

Since X_0 and B are independent, we can assume that $P = P_{X_0}\otimes P_B$ on some probability space $\Omega_{X_0}\times\Omega_B$. We denote by E_{X_0} (resp., E_B) the expectation over Ω_{X_0} (resp.,

Ω_B). Given X_0, the integral in the supremum is a Gaussian process, so [11, Theorem 11.17, p. 321] gives the estimate

$$E\left[\sup_{\|x-X_0\|\le a}\left|\int_0^t g(s,x).dB_s\right|\right] = 2\,E_{X_0}E_B\left[\sup_{\|x-X_0\|\le a}\int_0^t g(s,x).dB_s\right]$$
$$\le 48E_{X_0}\left[\int_0^\infty \left(\log N\left(\mathcal{B}_a^0, d_{U_t};\zeta\right)\right)^{\frac{1}{2}} d\zeta\right],$$

where d_{U_t} the pseudometric given by

$$d_{U_t}(x_1,x_2) = \|U_t(x_1,x_2)\|_{L^2(\Omega)}$$
$$= \left[\int_0^t |S(s,x_1)-S(s,x_2)|^2 ds\right]^{\frac{1}{2}}$$

with

$$U_t(x_1,x_2) = \int_0^t \left(S(s,x_1)-S(s,x_2)\right).dB_s$$

and $N\left(\mathcal{B}_a^0, d_{U_t};\zeta\right)$ is the smallest number of balls of radius ζ, for the pseudometric d_{U_t}, needed to cover $\mathcal{B}_a^0$. The hypothesis above gives

$$d_{U_t}(x_1,x_2) \le (V(t))^{\frac{1}{2}}\|x_1-x_2\| \le K(V(t))^{\frac{1}{2}}\|x_1-x_2\|_\infty,$$

where K comes from the equivalence of the norms in $\mathbb{R}^d$. So we get

$$N\left(\mathcal{B}_a^0, d_{U_t};\zeta\right) \le N\left(\mathcal{B}_a^0, K(V(t))^{\frac{1}{2}}\|.\|_\infty;\zeta\right)$$
$$= N\left(\mathcal{B}_a^0, \|.\|_\infty; \frac{\zeta}{K(V(t))^{\frac{1}{2}}}\right)$$
$$\le \left(\frac{2aK(V(t))^{\frac{1}{2}}}{\zeta}+1\right)^d.$$

From this follows

$$\int_0^\infty \left(\log N\left(\mathcal{B}_a^0, d_{U_t};\zeta\right)\right)^{\frac{1}{2}} d\zeta$$
$$\le \int_0^\infty \left(\log N\left(\mathcal{B}_a^0, \|.\|_\infty; \frac{\zeta}{K(V(t))^{\frac{1}{2}}}\right)\right)^{\frac{1}{2}} d\zeta$$
$$\le \int_0^{2aK(V(t))^{\frac{1}{2}}} d^{\frac{1}{2}}\left(\log\left(\frac{2aK(V(t))^{\frac{1}{2}}}{\zeta}+1\right)\right)^{\frac{1}{2}} d\zeta$$
$$= d^{\frac{1}{2}}2aK(V(t))^{\frac{1}{2}}\int_0^1 \left(\log\left(1+\frac{1}{u}\right)\right)^{\frac{1}{2}} du$$

with the change of variables

$$u = \frac{\zeta}{2aK(V(t))^{\frac{1}{2}}}.$$

As $0 \leq \left(\log\left(1+\frac{1}{u}\right)\right)^{\frac{1}{2}} \leq \frac{1}{\sqrt{u}}$, the last integral is convergent, and the proposition is proved. □

PROPOSITION 2.3. *Assume that the upper estimate in* (H1) *is valid. Then there exists* $A_2 > 0$ *such that* $\forall\ a > 0$,

$$E\left[\sup_{\|x-X_0\|\geq a}\left|\frac{\int_0^t g(s,x).dB_s}{\|x-X_0\|^2}\right|\right] \leq A_2 a^{-1}\sqrt{V(t)}.$$

Proof. Let n_0 be the greatest relative integer such that $2^{n_0} \leq a$. The triangular inequality gives

$$\begin{aligned}
E\left[\sup_{\|x-X_0\|\geq a}\frac{\left|\int_0^t g(s,x).dB_s\right|}{\|x-X_0\|^2}\right] &\leq \sum_{n\geq n_0}\frac{1}{2^{2n}}E\left[\sup_{2^n\leq\|x-X_0\|\leq 2^{n+1}}\left|\int_0^t g(s,x).dB_s\right|\right] \\
&\leq \sum_{n\geq n_0}\frac{1}{2^{2n}}E\left[\sup_{\|x-X_0\|\leq 2^{n+1}}\left|\int_0^t g(s,x).dB_s\right|\right] \\
&\leq A_1(V(t))^{\frac{1}{2}}\sum_{n\geq n_0}\frac{2^{n+1}}{2^{2n}} \quad \text{(Proposition 2.2)} \\
&\leq A_1(V(t))^{\frac{1}{2}}2^{-n_0}\sum_{p\geq 0}\frac{2^{p+1}}{2^{2p}} \\
&\leq A_1(V(t))^{\frac{1}{2}}\frac{2}{a}\sum_{p\geq 0}\frac{2^{p+1}}{2^{2p}}.
\end{aligned}$$

Because $2^{n_0} \leq a \leq 2^{n_0+1}$, the convergence of the series concludes the proof. □

Proof of Proposition 2.1. First note that it is sufficient to show that $\forall a > 0$ and $0 < \beta < \frac{a^2}{4C}$,

$$\exp(\beta V(t))\frac{\int_{\mathcal{B}_a^{0,c}} f_t(x)P_0(dx)}{\int_{\mathcal{B}_a^0} f_t(x)P_0(dx)} \xrightarrow{P} 0 \quad \text{as} \quad t \to +\infty. \tag{5}$$

We note that it is equivalent to show that convergence (5) holds for every increasing sequence of positive times t_k with $\lim_{k\to+\infty} t_k = +\infty$. We will use the characterization of the convergence in probability in terms of almost sure convergence. That is, from any subsequence t_ℓ we have to extract a subsubsequence t_n on which (5) holds almost surely (a.s.). From Propositions 2.2 and 2.3, as $\lim_{t\to+\infty} V(t) = +\infty$, we obviously have

$$\frac{1}{V(t)}\sup_{\|x-X_0\|\leq a}\left|\int_0^t g(s,x).dB_s\right| \xrightarrow{P} 0 \quad \text{as} \quad t \to +\infty$$

and

$$\frac{1}{V(t)} \sup_{\|x-X_0\|\geq a} \left| \frac{\int_0^t g(s,x).dB_s}{\|x-X_0\|^2} \right| \xrightarrow{P} 0 \quad \text{as} \quad t \to +\infty.$$

Thus, from any t_ℓ we can extract an increasing sequence of positive times t_n, with $\lim_{n\to+\infty} t_n = +\infty$, such that the two previous convergences hold a.s. Then we need to show only that on this sequence, convergence (5) holds a.s. as well. Using (H1), we get

$$\begin{aligned}
&\int_{\mathcal{B}_a^{0,c}} f_{t_n}(x) P_0(dx) \\
&\leq \int_{\mathcal{B}_a^{0,c}} \exp\left[-\frac{1}{2} v(t_n) \|x-X_0\|^2 + \int_0^{t_n} g(s,x).dB_s \right] P_0(dx) \\
&\leq \int_{\mathcal{B}_a^{0,c}} \exp\left[-V(t_n)\|x-X_0\|^2 \left(\frac{1}{2C} - \frac{1}{V(t_n)} \sup_{x\in\mathcal{B}_a^{0,c}} \left| \frac{\int_0^{t_n} g(s,x).dB_s}{\|x-X_0\|^2} \right| \right) \right] P_0(dx) \\
&\leq \int_{\mathcal{B}_a^{0,c}} \exp\left[-\frac{V(t_n)}{4C} \|x-X_0\|^2 \right] P_0(dx) \\
&\leq \int_{\mathcal{B}_a^{0,c}} \exp\left[-\frac{V(t_n)}{4C} a^2 \right] P_0(dx)
\end{aligned}$$

for n large enough. Thus we obtain

$$\int_{\mathcal{B}_a^{0,c}} f_{t_n}(x) P_0(dx) \leq \exp\left[-\frac{a^2 V(t_n)}{4C} \right].$$

On the other hand, $\forall\ 0 < a_0 \leq a$,

$$\begin{aligned}
\int_{\mathcal{B}_a^0} f_{t_n}(x) P_0(dx) &\geq \int_{\mathcal{B}_{a_0}^0} \exp\left[-\frac{1}{2} V(t_n) \|x-X_0\|^2 + \int_0^{t_n} g(s,x).dB_s \right] P_0(dx) \\
&\geq \int_{\mathcal{B}_{a_0}^0} \exp\left[-V(t_n) \left(\frac{a_0^2}{2} + \frac{1}{V(t_n)} \sup_{x\in\mathcal{B}_a^0} \left| \int_0^{t_n} g(s,x).dB_s \right| \right) \right] P_0(dx) \\
&\geq \exp\left[-a_0^2 V(t_n) \right] P_0(\mathcal{B}_{a_0}^0)
\end{aligned}$$

for n large enough. Note that X_0 is a.s. in the support of P_0, thus a.s. we have $P_0(\mathcal{B}_{a_0}^0) > 0$. Then we get

$$\exp\left(\beta V(t_n)\right) \frac{\int_{\mathcal{B}_a^{0,c}} f_{t_n}(x) P_0(dx)}{\int_{\mathcal{B}_a^0} f_{t_n}(x) P_0(dx)} \leq \frac{1}{P_0(\mathcal{B}_{a_0}^0)} \exp\left[V(t_n) \left(\beta + a_0^2 - \frac{a^2}{4C} \right) \right],$$

which goes to 0 provided we took $a_0 < \sqrt{\frac{a^2}{4C} - \beta}$. □

3. Dynamical noise free filtering: general case. We consider now a slightly different situation where we are given a dynamical noise free filtering problem:

$$\left\{ \begin{array}{rcl} dX_t &=& b(X_t)dt, \\ dY_t &=& h(X_t)dt + dB_t, \end{array} \right. \tag{6}$$

where X_t takes values in $\mathbb{R}^d$ and Y_t in $\mathbb{R}^m$, X_0 is a random vector with the given law P_{X_0}, and B_t is an m-dimensional Wiener process independent of X_0. From now on, we will assume that P_0 has a density with respect to Lebesgue measure denoted by p_0. In the following, $\Phi_t(x)$ will denote the (deterministic) flow of the state equation; it is the state reached by the system at time t, starting from x at $t = 0$. We will assume that it is well defined for every time t and every initial condition x_0. If we want to estimate the initial state, we have a particular case of the previous problem with

$$S(t, .) = h(\Phi_t(.)).$$

Thus, in order to estimate X_0, we can apply the previous section and study the estimation problem. But here the term "filtering" means that we are interested in the current state X_t. So the object to be estimated is also moving, and we will say that the filtering algorithm gives good results if the conditional law of X_t concentrates on arbitrary balls centered at X_t (and also moving with it). The purpose of this section is to find sufficient conditions imposed on the system (6) to have such a behavior of the conditional law. So, to transpose the previous results on the current state X_t, we will assume in addition that the flow verifies the next hypothesis.

(H2). $\|\Phi_t(x_1) - \Phi_t(x_2)\| \leq \alpha(t)\,\|x_1 - x_2\|\ \forall\ x_1,\ x_2$ in $\mathbb{R}^d$ and $\forall\ t > 0$ and for some monotonous function α from $\mathbb{R}_+$ into $\mathbb{R}_+$.

REMARK 3.1. *Note that the monotonous character of the function α is not restricting as we can always transform it in a nondecreasing function by taking* $\sup_{0\leq s\leq t} \alpha(s)$.

We are interested in the concentration of the a posteriori law μ_t of X_t on sets of the form

$$\mathcal{B}_a^t = \left\{x \in \mathbb{R}^d / \|x - X_t\| \leq a\right\}.$$

Let $\{\mathcal{F}_t^Y,\ t \geq 0\}$ be the filtration of the process Y. For all test functions ψ we have

$$E\left[\psi(X_t) \,|\, \mathcal{F}_t^Y\right] = E\left[\psi \circ \Phi_t(X_0) \,|\, \mathcal{F}_t^Y\right]$$

$$= \int_{\mathbb{R}^d} \psi \circ \Phi_t(\xi)\, \mu_t^0(d\xi)\,.$$

Thus

$$\mu_t\left(\mathcal{B}_a^t\right) = \int_{\mathbb{R}^d} \mathbf{1}_{\mathcal{B}_a^t}\left(\Phi_t^{-1}(\xi)\right)\, \mu_t^0(d\xi)$$

$$= \mu_t^0\left(\Phi_t^{-1}\left(\mathcal{B}_a^t\right)\right)\,,$$

which we rewrite as

$$\mu_t\left(\mathcal{B}_a^t\right) = \frac{\int_{\Phi_t^{-1}(\mathcal{B}_a^t)} f_t(x)\, p_0(x)\, dx}{\int_{\mathbb{R}^d} f_t(x)\, p_0(x)\, dx}. \tag{7}$$

This expression will converge to 1 in probability if and only if

$$\frac{\int_{\Phi_t^{-1}(\mathcal{B}_a^t)^c} f_t(x)\, p_0(x)\, dx}{\int_{\Phi_t^{-1}(\mathcal{B}_a^t)} f_t(x)\, p_0(x)\, dx} \to 0 \quad \text{in probability as} \quad t \to +\infty. \tag{8}$$

It is clear that in the case where the flow is contracting (i.e., $\lim_{t\to+\infty}\alpha(t)=0$), the a priori law of X_t concentrates on the current true position, as does the conditional law. We will come back to this case later; let us begin with the most interesting case where the flow is not contracting but the observations are "good enough" so that the filter gives good results.

THEOREM 3.2. *Assume that* (H1) *and* (H2) *are fulfilled and* p_0 *is continuous, bounded. Assume moreover that*

$$\frac{V(t)}{\alpha(t)^2}\longrightarrow+\infty \tag{9}$$

and α *is bounded away from zero. Then* $\forall\ a>0$

$$\mu_t\left(\mathcal{B}_a^t\right)\xrightarrow{P}1\quad as\quad t\to+\infty.$$

Moreover, we have the following estimate concerning the rate of convergence:

$$\forall\ 0<\beta<\frac{a^2}{4C},\quad \exp\left[\beta\frac{V(t)}{\alpha^2(t)}\right]\left(1-\mu_t\left(\mathcal{B}_a^t\right)\right)\xrightarrow{P}0\quad\text{as}\quad t\to+\infty.$$

In order to prove this theorem we will need the next lemma.

LEMMA 3.3. *Let* $K(t)$ *and* $a(t)$ *be two functions from* $\mathbb{R}_+$ *into* $\mathbb{R}_+$ *such that*

$$\lim_{t\to+\infty}K(t)a(t)^2=+\infty.$$

Then $\forall\ d\in\mathbb{N}^*$, *there exists* $T_d>0$ *such that* $\forall\ t>T_d$

$$a(t)^{-d}\int_{a(t)}^{+\infty}\exp(-K(t)r^2)r^{d-1}dr\le\frac{1}{K(t)a(t)^2}\exp(-K(t)a(t)^2).$$

Proof. A simple change of variables gives

$$a(t)^{-d}\int_{a(t)}^{+\infty}\exp\left[-K(t)r^2\right]r^{d-1}\,dr=\frac{1}{2}\frac{1}{\left(a(t)^2K(t)\right)^{\frac{d}{2}}}\int_{a(t)^2K(t)}^{+\infty}e^{-z}z^{\frac{d}{2}-1}\,dz.$$

Then we conclude by observing that for $m\le 0$,

$$\int_\lambda^{+\infty}e^{-z}z^m\,dz\le e^{-\lambda}\lambda^m\qquad\forall\lambda\in\mathbb{R}_+,$$

and for $m>0$

$$\lim_{\lambda\to+\infty}\frac{\int_\lambda^{+\infty}e^{-z}z^m\,dz}{e^{-\lambda}\lambda^m}=1.\qquad\square$$

Proof of Theorem 3.2. Assume first that $\alpha(t)$ is bounded, say $\forall t\ge0$, $\alpha(t)\le A$. Then obviously

$$\mu_t\left(\mathcal{B}_a^t\right)=\mu_t^0\left(\Phi_t^{-1}\left(\mathcal{B}_a^t\right)\right)\ge\mu_t^0\left(B^0_{\frac{a}{\alpha(t)}}\right)\ge\mu_t^0\left(B^0_{\frac{a}{A}}\right),$$

and in this case the result is a direct consequence of Proposition 2.1.

Thus from now on we consider that $\alpha(t) \to +\infty$. From Propositions 2.2 and 2.3 and (H2) we have $\forall\ a > 0$

$$\frac{\alpha(t)^2}{V(t)} \sup_{\|x-X_0\| \leq \frac{a}{\alpha(t)}} \left| \int_0^t g(s,x)\, dB_s \right| \xrightarrow{P} 0$$

and

$$\frac{1}{V(t)} \sup_{\|x-X_0\| \geq \frac{a}{\alpha(t)}} \left| \frac{\int_0^t g(s,x)\, dB_s}{\|x-X_0\|^2} \right| \xrightarrow{P} 0$$

as $t \to +\infty$. We use the same kind of argument as we used in Proposition 2.1. Again, let t_n be an increasing sequence of times such that $\lim_{n\to+\infty} t_n = +\infty$, and for which the previous convergences hold a.s., and note that it is sufficient to show that $\forall a > 0$, $0 < \beta < \frac{a^2}{4C}$,

$$\exp\left[\beta \frac{V(t_n)}{\alpha(t_n)^2}\right] \frac{\int_{\Phi_{t_n}^{-1}\left(\mathcal{B}_a^{t_n,c}\right)} f_{t_n}(x)\, p_0(x)\, dx}{\int_{\Phi_{t_n}^{-1}\left(\mathcal{B}_a^{t_n}\right)} f_{t_n}(x)\, p_0(x)\, dx} \xrightarrow{\text{a.s.}} 0 \quad \text{as } n \to +\infty. \tag{10}$$

By (H2) we have $\forall\ t \geq 0$ and $a > 0$

$$\Phi_t^{-1}\left(\mathcal{B}_a^{t,c}\right) \subset \mathcal{B}^{0,c}_{\frac{a}{\alpha(t)}}$$

and

$$B^0_{\frac{a}{\alpha(t)}} \subset \Phi_t^{-1}\left(\mathcal{B}_a^t\right).$$

Then, using (H1) and (H2) and the fact that p_0 is bounded, say, by $K > 0$,

$$\begin{aligned}
&\int_{\Phi_t^{-1}\left(B_a^{t_n,c}\right)} f_{t_n}(x)\, p_0(x)\, dx \\
&\leq \int_{B^{0,c}_{\frac{a}{\alpha(t_n)}}} \exp\left[-\frac{V(t_n)}{C}\|x-X_0\|^2 \left(\frac{1}{2} \right.\right. \\
&\quad \left.\left. -\frac{C}{V(t_n)} \sup_{\|x'-X_0\| \geq \frac{a}{\alpha(t_n)}} \left| \frac{\int_0^{t_n} g(s,x')\, dB_s}{\|x'-X_0\|^2} \right| \right) \right] p_0(x)\, dx \Bigg] p_0(x)\, dx \\
&\leq K \int_{B^{0,c}_{\frac{a}{\alpha(t_n)}}} \exp\left[-\frac{V(t_n)}{4C}\|x-X_0\|^2 \right] dx
\end{aligned}$$

for n large enough, by definition of t_n. Using polar coordinates we obtain

$$\int_{\Phi_t^{-1}\left(B_a^{t_n,c}\right)} f_{t_n}(x)\, p_0(x)\, dx \leq K S_d \int_{\frac{a}{\alpha(t_n)}}^{+\infty} \exp\left[-\frac{V(t_n)}{4C} r^2 \right] r^{d-1}\, dr,$$

where S_d is the surface of the unit sphere in $\mathbb{R}^d$, with the convention $S_1 = 2$.

On the other hand, for any a_1 such that $0 < a_1 \leq a$,

$$\int_{\Phi_{t_n}^{-1}(\mathcal{B}_a^t)} f_{t_n}(x)\, p_0(x)\, dx$$

$$\geq \int_{B^0_{\frac{a_1}{\alpha(t_n)}}} \exp\left[-\frac{V(t_n)}{\alpha(t_n)^2}\left(\frac{a_1^2}{2} + \frac{\alpha(t_n)^2}{V(t_n)} \sup_{\|x'-X_0\|\leq \frac{a_1}{\alpha(t_n)}} \left|\int_0^{t_n} g(s,x')\, dB_s\right|\right)\right] p_0(x)\, dx$$

$$\geq \exp\left[-\frac{V(t_n)}{\alpha(t_n)^2}\, a_1^2\right] \int_{B^0_{\frac{a_1}{\alpha(t_n)}}} p_0(x)\, dx$$

for n large enough. As P_0 has a continuous density p_0, $p_0(X_0)$ is a.s. nonzero, and there is a small $a_2 > 0$ such that $\forall\, x \in \mathcal{B}^0_{a_2}$, $p_0(x) \geq \frac{1}{2} p_0(X_0)$. As $\alpha(t_n) \to +\infty$, for n large enough we have also that $\mathcal{B}^0_{\frac{a_1}{\alpha(t_n)}} \subset \mathcal{B}^0_{a_2}$, and thus

$$\int_{\mathcal{B}^0_{\frac{a_1}{\alpha(t_n)}}} p_0(x)\, dx \geq \frac{1}{2} p_0(X_0) \int_{\mathcal{B}^0_{\frac{a_1}{\alpha(t_n)}}} dx \geq \frac{1}{2} p_0(X_0)\, K_d \left(\frac{a_1}{\alpha(t_n)}\right)^d,$$

where K_d is the Lebesgue's measure of the unit ball in $\mathbb{R}^d$. Finally, using Lemma 3.3, we get for n large enough

$$\exp\left[\beta \frac{V(t_n)}{\alpha(t_n)^2}\right] \frac{\int_{\Phi_{t_n}^{-1}(\mathcal{B}_a^{t_n,c})} f_{t_n}(x)\, p_0(x)\, dx}{\int_{\Phi_{t_n}^{-1}(\mathcal{B}_a^{t_n})} f_{t_n}(x)\, p_0(x)\, dx}$$

$$\leq \exp\left[(\beta + a_1^2)\frac{V(t_n)}{\alpha(t_n)^2}\right] \frac{2KS_d}{K_d p_0(X_0)} \left[\frac{a}{a_1}\right]^d \left[\frac{\alpha(t_n)}{a}\right]^d \int_{\frac{a}{\alpha(t_n)}}^{+\infty} \exp\left[-\frac{V(t_n)}{4C} r^2\right] r^{d-1}\, dr$$

$$\leq \frac{2KS_d}{K_d p_0(X_0)} \left[\frac{a}{a_1}\right]^d \frac{4C\alpha(t_n)^2}{a^2 V(t_n)} \exp\left[\frac{V(t_n)}{\alpha(t_n)^2}\left(-\frac{a^2}{4C} + a_1^2 + \beta\right)\right],$$

which concludes the proof, provided we chose $a_1 < \sqrt{\frac{a^2}{4C} - \beta}$. □

Some remarks on other cases. Now let us come back to the case $\alpha(t) \to 0$. With no observation the concentration speed around the true position follows the ratio

$$\frac{\int_{\Phi_t^{-1}(\mathcal{B}_a^t)^c} p_0(x)\, dx}{\int_{\Phi_t^{-1}(\mathcal{B}_a^t)} p_0(x)\, dx} \simeq \int_{\Phi_t^{-1}(\mathcal{B}_a^t)^c} p_0(x)\, dx$$

because the denominator converges to 1 a.s. If we have observations and (H1) is fulfilled, we can show a faster convergence in probability. Let t_n be a sequence with the same properties as in the previous proof. Choose a_2 such that

$$a > \frac{a}{2\sqrt{C}} > a_2 > 0.$$

Using the same notations and arguments as in the proof of the previous theorem and using the following notations:

$$N_n = \int_{\Phi_{t_n}^{-1}(\mathcal{B}_a^{t_n})^c} f_{t_n}(x)\, dx\,,$$

$$D_n = \int_{\Phi_{t_n}^{-1}(\mathcal{B}_a^{t_n})} f_{t_n}(x)\, dx\,,$$

we get, for n large enough,

$$N_n \leq \int_{\Phi_{t_n}^{-1}(\mathcal{B}_a^t)^c} \exp\left[\frac{v(t_n)\alpha(t_n)}{a}\|x-X_0\|^2\left(-\frac{1}{2}\frac{a}{\alpha(t_n)}\right.\right.$$
$$\left.\left.+\frac{a}{\alpha(t_n)}\frac{1}{v(t_n)}\sup_{x'\in\mathcal{B}^{0,c}_{\frac{a}{\alpha(t_n)}}}\frac{\left|\int_0^{t_n} g(s,x').dB_s\right|}{\|x'-X_0\|^2}\right)\right] p_0(x)\,dx$$
$$\leq \exp\left[-\frac{1}{4}v(t_n)\frac{a^2}{\alpha(t_n)^2}\right]\int_{\Phi_{t_n}^{-1}(\mathcal{B}_a^t)^c} p_0(x)\,dx$$

and

$$D_n \geq \int_{\mathcal{B}^0_{\frac{a_2}{\alpha(t_n)}}} \exp\left[-\frac{1}{2}\frac{V(t_n)a_2^2}{\alpha(t_n)^2} - \sup_{x'\in\mathcal{B}^0_{\frac{a_2}{\alpha(t_n)}}}\left|\int_0^{t_n} g(s,x').dB_s\right|\right] p_0(x)\,dx$$
$$\geq \int_{\mathcal{B}^0_{\frac{a_2}{\alpha(t_n)}}} \exp\left[\frac{V(t_n)a_2}{\alpha(t_n)}\left(-\frac{1}{2}\frac{a_2}{\alpha(t_n)}\right.\right.$$
$$\left.\left.-\frac{\alpha(t_n)}{a_2V(t_n)}\sup_{x'\in\mathcal{B}^0_{\frac{a_2}{\alpha(t_n)}}}\left|\int_0^{t_n} g(s,x').dB_s\right|\right)\right] p_0(x)\,dx$$
$$\geq \exp\left[-C\frac{v(t_n)a_2^2}{\alpha(t_n)^2}\right]\int_{\mathcal{B}^0_{\frac{a_2}{\alpha(t_n)}}} p_0(x)\,dx$$
$$\geq \frac{1}{2}\exp\left[-C\frac{v(t_n)a_2^2}{\alpha(t_n)^2}\right].$$

By taking the two last inequalities we have

$$\frac{N_n}{D_n} \leq 2\exp\left[\frac{v(t_n)}{\alpha(t_n)^2}\left(-\frac{a^2}{4}+Ca_2^2\right)\right]\int_{\Phi_{t_n}^{-1}(\mathcal{B}_a^t)^c} p_0(x)\,dx.$$

So the convergence, this time in probability, is sped up by the exponential term.

Finally, consider some cases when the filter does not give good results. More precisely, consider the opposite of (H2).

$$(\overline{H2}). \qquad \|\Phi_t(x_1)-\Phi_t(x_2)\| \geq \alpha(t)\,\|x_1-x_2\|$$

$\forall\ x_1,\ x_2$ in $\mathbb{R}^d$ and $\forall\ t>0$ and for some nondecreasing function α from $\mathbb{R}_+$ into $\mathbb{R}_+$. We can show the following proposition (opposite of Theorem 3.2).

PROPOSITION 3.4. *Assume that* (H1) *and* ($\overline{\text{H2}}$) *are fulfilled,* p_0 *is continuous, bounded. Moreover assume that*

$$\frac{V(t)}{\alpha(t)^2} \longrightarrow 0 \tag{11}$$

and

$$\alpha(t) \longrightarrow +\infty \tag{12}$$

as $t \to +\infty$. *Then* $\forall\ a > 0$

$$\mu_t\left(\mathcal{B}_a^t\right) \xrightarrow{P} 0 \quad as \quad t \to +\infty.$$

Proof. We will show equivalently that

$$\frac{\int_{\Phi_t^{-1}(\mathcal{B}_a^t)^c} f_t(x)dx}{\int_{\Phi_t^{-1}(\mathcal{B}_a^t)} f_t(x)dx} \xrightarrow{P} +\infty \quad \text{as} \quad t \to +\infty.$$

Note that in this case it is reasonable to suppose (12); otherwise (11) would imply that $V(t) \to 0$, that is, by (H1), h is constant. From Propositions 2.2 and 2.3, using (11), we have

$$\frac{1}{\alpha(t)^2} \sup_{\|x'-X_0\| \geq \frac{a}{\alpha(t)}} \frac{\left|\int_0^t g(s,x').dB_s\right|}{\|x'-X_0\|^2} \xrightarrow{P} 0$$

and

$$\sup_{\|x'-X_0\| \leq \frac{a}{\alpha(t)}} \left|\int_0^t g(s,x').dB_s\right| \xrightarrow{P} 0\ .$$

Let t_n be a sequence of positive real numbers, increasing to $+\infty$, and such that the above convergences take place a.s. For any $b > a$ let

$$\mathcal{A}_n = \left\{x \in \mathbb{R}^d\ :\ \frac{a}{\alpha(t_n)} \leq \|x - X_0\| \leq \frac{b}{\alpha(t_n)}\right\}\ .$$

We obtain $\forall\ b > a$

$$\begin{aligned}
N_n &= \int_{\Phi_{t_n}^{-1}(B_a^{t_n,c})} f_{t_n}(x)\,dx \\
&\geq \int_{\mathcal{A}_n} \exp\left[\alpha(t_n)^2\|x-X_0\|^2\left(-\frac{V(t_n)}{2\alpha(t_n)^2}\right.\right. \\
&\qquad \left.\left. -\frac{1}{\alpha(t_n)^2}\sup_{\|x'-X_0\| \geq \frac{a}{\alpha(t_n)}} \frac{\left|\int_0^{t_n} g(s,x').dB_s\right|}{\|x'-X_0\|^2}\right)\right] p_0(x)\,dx \\
&\geq \int_{\mathcal{A}_n} \exp\left[b^2\left(-\frac{V(t_n)}{2\alpha(t_n)^2} - \frac{1}{\alpha(t_n)^2}\sup_{\|x'-X_0\| \geq \frac{a}{\alpha(t_n)}} \frac{\left|\int_0^{t_n} g(s,x').dB_s\right|}{\|x'-X_0\|^2}\right)\right] p_0(x)\,dx \\
&\geq \frac{1}{2}\int_{\mathcal{A}_n} p_0(x)\,dx
\end{aligned}$$

for n large enough. Using (12) and the continuity of p_0 we get

$$N_n \geq \frac{p_0(X_0)}{4} K_d \frac{b^d - a^d}{\alpha(t_n)^d} .$$

On the other hand,

$$\begin{aligned} D_n &= \int_{\Phi_{t_n}^{-1}(B_a^{t_n})} f_{t_n}(x)\, dx \\ &\leq \int_{\left\{ \|x - X_0\| \leq \frac{a}{\alpha(t_n)} \right\}} \exp\left[\sup_{\|x' - X_0\| \leq \frac{a}{\alpha(t_n)}} \left| \int_0^{t_n} g(s, x').dB_s \right| \right] p_0(x)\, dx \\ &\leq 2 p_0(X_0)\, K_d \frac{a^d}{\alpha(t_n)^d} , \end{aligned}$$

again for n large. Then, for arbitrary large $M > 0$, we have that for n large enough,

$$\frac{N_n}{D_n} \geq \frac{1}{8} \frac{b^d - a^d}{a^d} \geq M ,$$

provided we chose

$$b \geq a\, (8M + 1)^{\frac{1}{d}} . \qquad \square$$

4. Linear Gaussian case. The solution of the Riccati equation below and some ideas of this small section are taken from [4]. We consider throughout this section the following linear system:

$$\left\{ \begin{array}{rcll} dX_t &=& A X_t\, dt, & \\ dY_t &=& C\, X_t\, dt + dB_t, & \text{with } X_0 \simeq N(m_0, P_0), \end{array} \right.$$

where A and C are matrices of respective dimensions $d \times d$ and $d \times m$, and X_0 and B are independent. We will investigate conditions ensuring that the conditional covariance given by the Kalman–Bucy filter tends to 0 as $t \to +\infty$. It is well known that in this case the conditional law is Gaussian, so the above convergence is equivalent to the concentration of the law around the true position. See [10] or [14] for a general presentation of the Kalman–Bucy filter.

Denote by P_t the conditional covariance. In our particular case we can write the Riccati equation for P_t as

$$\dot{P}_t = A\, P_t + P_t\, A^* - P_t\, C^*\, C\, P_t, \tag{13}$$

where $*$ denotes the transpose and the dot the differential with respect to t, P_0 being the initial condition. We can solve this equation explicitly. First we state the following lemma.

LEMMA 4.1. *Let M and N be two symmetric positive semidefinite $h \times h$ matrices (i.e., $\langle N\, x,\, x \rangle \geq 0$ and $\langle M\, x,\, x \rangle \geq 0\ \forall\ x$). Then if M or N is invertible, $I + MN$ is also invertible.*

Proof. Suppose N is invertible (the case M invertible is similar). Then $N > 0$ and so is N^{-1}. Thus $N^{-1} + M > 0$ and we conclude that $(N^{-1} + M)N = I + MN$ is also invertible. $\square$

Now we can solve (13). This is the purpose of the next lemma.

LEMMA 4.2. *If P_0 is invertible, then P_t is also and*

$$P_t = e^{tA}\ \left(P_0^{-1} + Q(t)\right)^{-1}\ e^{tA^*}$$

with

$$Q(t) = \int_0^t e^{rA^*}\, C^*\, C\, e^{rA}\, dr.$$

Proof. The solution is unique because $P \mapsto F(P) = AP + PA^* - PC^*CP$ is locally Lipschitz. As P_0 is invertible, by Lemma 4.1, $I + Q(t)P_0$ is also invertible and so is P_t rewritten as

$$P_t = e^{tA}\, P_0\ (I + Q(t)\, P_0)^{-1}\ e^{tA^*}\ .$$

Then a simple computation shows that P_t is a solution of (13). ∎

Now we can state the result.

PROPOSITION 4.3. *Assume that P_0 is invertible. Then $P_t \to 0$ as $t \to +\infty$ if and only if the pair (A, C) is detectable, and for any eigenvalue λ of A, $\Re\mathrm{e}(\lambda) \leq 0$.*

Proof. First recall that P_t is symmetric positive definite. As P_t is diagonalizable, with real positive eigenvalues, showing the convergence of P_t is equivalent to the following: $\forall x \in \mathbb{R}^d$, $x^* P_t^{-1} x \to +\infty$, or more simply for x in a basis of $\mathbb{R}^d$. Note that it is also equivalent to consider complex vectors: take $x = x_1 + ix_2$ with x_1 and x_2 in $\mathbb{R}^d$, and write

$$x^*\, P_t^{-1}\, x = (x_1^* - ix_2^*)\, P_t^{-1}\, (x_1 + ix_2) = x_1^*\, P_t^{-1}\, x_1 + x_2^*\, P_t^{-1}\, x_2.$$

So throughout the proof we will work in $\mathbb{C}^d$.

Consider the Jordan form of the matrix A, say J, and call T the corresponding basis transformation. Then $x^* P_t^{-1} x \to +\infty\ \forall x \in \mathbb{C}^d$ if and only if $u_i^* P_t^{-1} u_i \to +\infty\ \forall u_i$ in the Jordan basis.

We have two cases. First assume that u_i is in the stable subspace of A, i.e., associated with a submatrix J_k of the Jordan form and an eigenvalue λ_k with strictly negative real part. Then obviously

$$u_i^*\, P_t^{-1}\, u_i \geq u_i^*\, e^{-tA^*}\, P_0^{-1}\, e^{-tA}\, u_i = \left\|e^{-tA}\, u_i\right\|^2_{P_0^{-1}} \to +\infty.$$

Second case: u_i is in the unstable subspace of A, i.e., associated with a Jordan submatrix with pure imaginary eigenvalue. In this case we write

$$\begin{aligned} u_i^*\, P_t^{-1}\, u_i &\geq \int_0^t u_i^*\, e^{-(t-s)A^*}\, C^*\, C\, e^{-(t-s)A}\, u_i\, ds \\ &= \int_0^t \left\|C\, e^{-(t-s)A}\, u_i\right\|^2 ds \\ &= \int_0^t \left\|C\, T\, e^{-(t-s)J}\, T^{-1}\, u_i\right\|^2 ds. \end{aligned} \tag{14}$$

Let m_k be the dimension of the subblock corresponding to u_i, k_0 the rank of the first term of the subblock, and ℓ the rank of u_i in the corresponding basis of the eigenspace.

J and $e^{-(t-s)J}$ are block diagonal (see [10] or [5] for precisions on the Jordan form). Denoting by J_k the corresponding subblock, we have

$$e^{-(t-s)J_k} = e^{-\lambda_k(t-s)} \begin{bmatrix} 1 & \dots & \frac{-(t-s)^{m_k-1}}{(m_k-1)!} \\ & \ddots & \vdots \\ 0 & & 1 \end{bmatrix}.$$

Then observe that, M being the number of subblocks,

$$\begin{aligned} &\|C\,T\,e^{-(t-s)J}\,(T^{-1}\,u_i)\|^2 \\ &= \left\| C\,T \begin{bmatrix} e^{-(t-s)J_1} & & & & \\ & \ddots & & 0 & \\ & & e^{-(t-s)J_k} & & \\ & 0 & & \ddots & \\ & & & & e^{-(t-s)J_M} \end{bmatrix} \cdot \begin{bmatrix} 0 \\ \vdots \\ 0 \\ 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix} \right\|^2 \\ &\geq \|C\,u_{k_0}\|^2 \left(\frac{(t-s)^{\ell-1}}{(\ell-1)!} \right)^2 - \sum_{q=1}^{l-1} \|C\,u_{k_0+q}\|^2 \left(\frac{(t-s)^{q-1}}{(q-1)!} \right)^2. \end{aligned}$$

Remark that u_{k_0} is an eigenvector of A, so, by the dual version of the Hautus lemma[1] (see [15, pp. 93 and 200]) and the assumption that (A, C) is detectable, $u_{k_0} \notin \ker C$. Thus $\|Cu_{k_0}\| > 0$ and for t large enough, (14) is bigger than, say, $K_i \int_0^t (t-s)^{2\ell-2}\,ds$ for some $K_i > 0$. This gives the divergence to $+\infty$.

Now we prove the converse. We again have two cases. First assume that there is some eigenvalue of A, say λ_i, with $\Re\mathrm{e}(\lambda_i) > 0$. Let u_i be a normalized associated eigenvector. Then

$$u_i^*\,e^{-tA^*}\,P_0^{-1}\,e^{-tA}\,u_i \longrightarrow 0$$

and

$$\int_0^t \left\| C\,e^{-(t-s)A}\,u_i \right\|^2 ds \leq \|C\|^2 \int_0^t e^{-2(t-s)\Re\mathrm{e}(\lambda_i)}\,ds < +\infty,$$

which proves that $P_t \not\to 0$.

Finally, consider the second case: assume that all the eigenvalues of A have non-positive real parts but that the pair (A, C) is not detectable. Then, again using the Hautus lemma, there exists an eigenvector u_i of A associated to some eigenvalue λ_i such that $u_i \in \ker C$ and $\Re\mathrm{e}(\lambda_i) = 0$. Then we have

$$u_i^*\,e^{-tA^*}\,P_0^{-1}\,e^{-tA}\,u_i \leq \|u_i\|^2_{P_0^{-1}}$$

and

$$\int_0^t \left\| C\,e^{-(t-s)A} u_i \right\|^2 ds = 0,$$

[1] Which tells us that (A, C) is observable if and only if $\begin{bmatrix} \lambda_i I - A \\ C \end{bmatrix}$ is full rank $\forall\ \lambda_i$ eigenvalues of A. Here we apply this to the unstable part of the system.

which concludes the proof. □

REMARK 4.4. *Keeping in mind that P_t is diagonalizable, the last proof shows that when P_t goes to 0 and the unstable subspace of A is nontrivial, the smallest eigenvalue of P_t^{-1} is at least of order t (take $\ell = 1$), that is, the largest eigenvalue of P_t is at most of order $1/t$, which gives an estimate on the order of convergence.*

Acknowledgments. I would like to thank Étienne Pardoux and Fabien Campillo for their support and interest during this work and Alexander Davie and Jean-Baptiste Pomet for valuable discussions about possible generalizations. I am also very grateful to Daniel Ocone for suggesting some improvements to this paper. Finally let me thank the reviewers for their interest in this work.

ON THE MINIMIZING PROPERTY OF A SECOND ORDER DISSIPATIVE SYSTEM IN HILBERT SPACES*

FELIPE ALVAREZ†

Abstract. We study the asymptotic behavior at infinity of solutions of a second order evolution equation with linear damping and convex potential. The differential system is defined in a real Hilbert space. It is proved that if the potential is bounded from below, then the solution trajectories are minimizing for it and converge weakly towards a minimizer of Φ if one exists; this convergence is strong when Φ is even or when the optimal set has a nonempty interior. We introduce a second order proximal-like iterative algorithm for the minimization of a convex function. It is defined by an implicit discretization of the continuous evolution problem and is valid for any closed proper convex function. We find conditions on some parameters of the algorithm in order to have a convergence result similar to the continuous case.

Key words. dissipative system, linear damping, asymptotic behavior, weak convergence, convexity, implicit discretization, iterative-variational algorithm

1. Introduction.

Consider the following differential system defined in a real Hilbert space H:

$$u'' + \gamma u' + \nabla\Phi(u) = 0, \tag{1.1}$$

where $\gamma > 0$ and $\Phi : H \to \mathbb{R}$ is differentiable. It is customary to call this equation *nonlinear oscillator with damping*. Here, the damping or friction has a linear dependence on the velocity. This is a particular case of the so-called dissipative systems. In fact, given u solution of (1.1) define $E(t) := \frac{1}{2}|u'|^2 + \Phi(u)$; it is direct to check that $E' = -\gamma|u'|^2$. Thus, the *energy* of the system is dissipated as t increases. Although (1.1) appears in various contexts with different physical interpretations, the motivation for this work comes from the dynamical approach to optimization problems.

Roughly speaking, any iterative algorithm generating a sequence $\{x_k\}_{k\in\mathbb{N}}$ may be considered as a discrete dynamical system. If it is possible to find a continuous version for the discrete procedure, one expects that the properties of the corresponding continuous dynamical system are close to those of the discrete one. This occurs, for instance, for the now classical proximal method for convex minimization: given $x_0 \in H$, solve the iterative scheme

$$\frac{x_{k+1} - x_k}{\lambda_k} + \partial f(x_{k+1}) \ni 0, \tag{Prox}$$

where $\lambda_k > 0$, $f : H \to \mathbb{R} \cup \{\infty\}$ is a closed proper convex function and ∂f denotes the usual subdifferential in convex analysis. (Prox) is an implicit discretization for the steepest descent method, which consists of solving the following differential inclusion:

$$x' + \partial f(x) \ni 0. \tag{SD}$$

Under suitable conditions, both the trajectory $\{x(t) : t \to \infty\}$ defined by (SD) and the sequence $\{x_k\}$ generated by (Prox) converge toward a particular minimizer of f (see [5, 6, 7] for (SD) and [18] for (Prox); see also [12] for a survey on these and new results). The dynamical approach to iterative methods in optimization has many advantages. It provides a deep insight into the expected behavior of the method, and sometimes the techniques used in the continuous case can be adapted to obtain results for the discrete algorithm. On the other hand, a continuous dynamical system satisfying nice properties may suggest new iterative methods.

This viewpoint has motivated increasing attention in recent years; see, e.g., [1, 2, 3, 4, 8, 13, 14]. In [3], Attouch, Goudou, and Redont deal with nonconvex functions that have, a priori, many local minima. The idea is to exploit the dynamics defined by (1.1) to explore critical points of Φ (i.e., solutions of $\nabla\Phi(x) = 0$). If Φ is coercive (bounded level sets) and of class C^1 with a locally Lipschitz gradient, then it is possible to prove that for any u solution of (1.1) we have $\nabla\Phi(u(t)) \to 0$ as $t \to \infty$. The convergence of the trajectory $\{u(t) : t \to \infty\}$ is a more delicate problem. When Φ is coercive, an obvious sufficient condition for the convergence of the trajectory is that the critical points, also known as equilibrium points, are isolated. Certainly, this is not necessary. In one dimension ($H = \mathbb{R}$) and without additional conditions, the solution always converges toward an equilibrium (see, e.g., [10]). The proof relies on topological arguments that are not generalizable to higher dimensions. Indeed, this is no longer true even in two dimensions: it is possible to construct a coercive C^1 function defined on $\mathbb{R}^2$ whose gradient is locally Lipschitz and for which at least one solution of (1.1) does not converge as $t \to \infty$ (see [3]). Thus, a natural question is to find general conditions under which the trajectory converges in the degenerate case, that is, when the set of equilibrium points of Φ contains a nontrivial connected component. A positive result in this direction has recently been given by Haraux and Jendoubi [11], where convergence to an equilibrium is established when Φ is *analytic*. However, this assumption is very restrictive from the optimization point of view.

Motivated by the previous considerations, in this work we focus our attention on the asymptotic behavior as $t \to \infty$ of the solutions of (1.1) when Φ is assumed to be convex. The paper is organized as follows. In section 2 we prove that if Φ is convex and bounded from below, then the trajectory $\{u(t) : t \to \infty\}$ is minimizing for Φ. If the infimum of Φ on H is attained, then $u(t)$ converges weakly towards a minimizer of Φ. The convergence is strong when Φ is even or when the optimal set has a nonempty interior. In section 2.2 we give a localization result for the limit point, analogous to the corresponding result for the steepest descent method [13]. In section 2.4 we generalize the convergence result to cover the equation $u'' + \Gamma u' + \nabla\Phi(u) = 0$, where $\Gamma : H \to H$ is a bounded self-adjoint linear operator which we assume to be elliptic: there is $\gamma > 0$ such that for any $x \in H$, $\langle \Gamma x, x\rangle \geq \gamma|x|^2$. We refer to this equation as nonlinear oscillator with *anisotropic damping*. This equation appears to be useful to diminish oscillations or even eliminate them, and also to accelerate the convergence of the trajectory. In section 2.3 we give an heuristic motivation of the above mentioned facts, which is based on an analysis of a quadratic function. Still under the convexity condition on Φ, section 3 deals with the discretization of (1.1). Here, we consider the *implicit* scheme

$$\frac{u_{k+1} - 2u_k + u_{k-1}}{h^2} + \gamma\frac{u_{k+1} - u_k}{h} + \nabla\Phi(u_{k+1}) = 0,$$

where $h > 0$. Since Φ is convex, the latter is equivalent to the following variational problem:

$$u_{k+1} = \operatorname{argmin}\left\{\Phi(x) + \frac{1+\gamma h}{2h^2}\,|x - z_k|^2 : x \in H\right\},$$

where $z_k = u_k + \frac{1}{1+\gamma h}(u_k - u_{k-1})$. This procedure does not require Φ to be differentiable and allows us to introduce the following more general iterative-variational algorithm:

$$\frac{1}{\lambda_k}(u_{k+1} - (1+\alpha_k)u_k + \alpha_k u_{k-1}) + \partial_{\epsilon_k} f(u_{k+1}) \ni 0, \tag{1.2}$$

where $\epsilon_k, \lambda_k > 0$, $\alpha_k \in [0,1[$, $f : H \to \mathbb{R} \cup \{\infty\}$ is a closed proper convex function and $\partial_\epsilon f$ is the ϵ-approximate subdifferential in convex analysis. We call (1.2) the *inertial proximal method*. We find conditions on the parameters α_k, ϵ_k, and λ_k in order to have a convergence result similar to the continuous case. Finally, in section 4 we state some of the questions opened by this work. Let us mention that the first to consider (1.1) for finite dimensional optimization problems was B. T. Polyack [16]. He studied a two-step discrete algorithm called the "heavy-ball with friction" method, which may be interpreted as an *explicit* discretization of (1.1). Both approaches are complementary; however, the analysis and the type of results in the implicit and explicit cases are different.

2. Dissipative differential system. Throughout this paper, H is a real Hilbert space, $\langle\cdot,\cdot\rangle$ denotes the associated inner product, and $|\cdot|$ stands for the corresponding norm. We are interested in the behavior at infinity of $u : [0,\infty[\to H$, a solution of the following abstract evolution equation:

$$(E_\gamma; u_0, v_0) \qquad \begin{cases} u'' + \gamma u' + \nabla\Phi(u) = 0, \\ u(0) = u_0,\ u'(0) = v_0, \end{cases}$$

where $\gamma > 0$, $\Phi : H \to \mathbb{R}$, and $u_0, v_0 \in H$ are given. Note that if we assume that the gradient $\nabla\Phi$ is locally Lipschitz, then the existence and uniqueness of a local solution for $(E_\gamma; u_0, v_0)$ follow from standard results of differential equations theory. In that case, to prove that u is infinitely extendible to the right, it suffices to show that its derivative u' is bounded. Set

$$E(t) := \frac{1}{2}|u'(t)|^2 + \Phi(u(t)).$$

Since $E'(t) = -\gamma|u'(t)|^2$, the function E is nonincreasing. If we suppose that Φ is bounded from below, then u' is bounded.

2.1. Asymptotic convergence. In that which follows, we suppose the existence of a global solution of $(E_\gamma; u_0, v_0)$. We write $\inf\Phi$ for the infimum value of Φ on H; thus, $\inf\Phi > -\infty$ will mean that Φ is bounded from below. We denote by $\operatorname{Argmin}\Phi$ the set $\{x \in H : \Phi(x) = \inf\Phi\}$. On the nonlinearity we shall assume

$$(h_\Phi) \qquad \Phi \in C^1(H;\mathbb{R}) \text{ is convex and } \inf\Phi > -\infty.$$

THEOREM 2.1. *Suppose that (h_Φ) holds. If $u \in C^2([0,\infty[;H)$ is a solution of $(E_\gamma; u_0, v_0)$, then $u' \in L^2([0,\infty[;H)$, $u'(t) \to 0$ as $t \to \infty$, and*

$$\lim_{t\to\infty} \Phi(u(t)) = \inf\Phi. \tag{2.1}$$

Furthermore, if $\operatorname{Argmin}\Phi \neq \emptyset$, then there exists $\widehat{u} \in \operatorname{Argmin}\Phi$ such that $u(t) \rightharpoonup \widehat{u}$ weakly in H as $t \to \infty$.

We begin by noticing that u' is bounded (see the argument above). In order to prove the minimizing property (2.1), it suffices to prove that

$$\limsup_{t\to\infty} \Phi(u(t)) \le \Phi(x)$$

for any $x \in H$. Fix $x \in H$ and define the auxiliary function $\varphi(t) := \frac{1}{2}|u(t)-x|^2$. Since u is a solution of (E_γ), it follows that

$$\varphi'' + \gamma\varphi' = \langle \nabla\Phi(u), x-u\rangle + |u'|^2,$$

which together with the convexity inequality $\Phi(u) + \langle \nabla\Phi(u), x-u\rangle \le \Phi(x)$ yields

$$\varphi'' + \gamma\varphi' \le \Phi(x) - \Phi(u) + |u'|^2. \tag{2.2}$$

We do not have information on the behavior of $\Phi(u(t))$ but we know that $E(t)$ is nonincreasing. Thus, we rewrite (2.2) as

$$\varphi'' + \gamma\varphi' \le \Phi(x) - E(t) + \frac{3}{2}|u'|^2.$$

Given $t > 0$, for all $\tau \in [0,t]$ we have

$$\varphi''(\tau) + \gamma\varphi'(\tau) \le \Phi(x) - E(t) + \frac{3}{2}|u'(\tau)|^2.$$

After multiplication by $e^{\gamma\tau}$ and integration we obtain

$$\varphi'(t) \le e^{-\gamma t}\varphi'(0) + \frac{1}{\gamma}(1-e^{-\gamma t})[\Phi(x) - E(t)] + \frac{3}{2}\int_0^t e^{-\gamma(t-\tau)}|u'(\tau)|^2 d\tau.$$

We write this equation with t replaced by θ, and use the fact that $E(t)$ decreases and integrate once more to obtain

$$\varphi(t) \le \varphi(0) + \frac{1}{\gamma}(1-e^{-\gamma t})\varphi'(0) + \frac{1}{\gamma^2}(\gamma t - 1 + e^{-\gamma t})[\Phi(x) - E(t)] + h(t), \tag{2.3}$$

where

$$h(t) := \frac{3}{2}\int_0^t \int_0^\theta e^{-\gamma(\theta-\tau)}|u'(\tau)|^2 d\tau d\theta.$$

Since $E(t) \ge \Phi(u(t))$, (2.3) gives

$$\frac{1}{\gamma^2}(\gamma t - 1 + e^{-\gamma t})\Phi(u(t)) \le \varphi(0) + \frac{1}{\gamma}(1-e^{-\gamma t})\varphi'(0) + \frac{1}{\gamma^2}(\gamma t - 1 + e^{-\gamma t})\Phi(x) + h(t).$$

Dividing this inequality by $\frac{1}{\gamma^2}(\gamma t - 1 + e^{-\gamma t})$ and letting $t \to \infty$ we get

$$\limsup_{t\to\infty} \Phi(u(t)) \le \Phi(x) + \limsup_{t\to\infty} \frac{\gamma}{t} h(t).$$

It suffices to show that $h(t)$ remains bounded as $t \to \infty$. By Fubini's theorem

$$h(t) = \frac{3}{2}\int_0^t \int_\tau^t e^{-\gamma(\theta-\tau)}|u'(\tau)|^2 d\theta d\tau = \frac{3}{2\gamma}\int_0^t |u'(\tau)|^2(1-e^{-\gamma(t-\tau)})d\tau.$$

Note that from the equality $E' = -\gamma|u'|^2$ it follows that

$$\frac{1}{2}|u'|^2 + \Phi(u) + \gamma \int_0^t |u'(\tau)|^2 d\tau = E_0,$$

and in particular,

$$\int_0^t |u'(\tau)|^2 d\tau \leq \frac{E_0 - \inf \Phi}{\gamma} < \infty.$$

Then $u' \in L^2([0,\infty[; H)$, and

$$h(t) \leq \frac{3}{2\gamma} \int_0^t |u'(\tau)|^2 d\tau \leq \frac{3}{2\gamma} \int_0^\infty |u'(\tau)|^2 d\tau < \infty.$$

On the other hand, since $E(\cdot)$ is nonincreasing and bounded from below by $\inf \Phi$, it converges as $t \to \infty$. If $\lim_{t\to\infty} E(t) > \inf \Phi$, then $\lim_{t\to\infty} |u'(t)| > 0$ because of (2.1). This contradicts the fact that $u' \in L^2$. Therefore, $\lim_{t\to\infty} E(t) = \inf \Phi$, hence $u'(t) \to 0$ as $t \to \infty$.

The task now is to establish the weak convergence of $u(t)$ when $\operatorname{Argmin} \Phi \neq \emptyset$. For this purpose, we shall apply the Opial lemma [15], which holds interest in that it allows one to prove convergence without knowing the limit point. We state it as follows.

LEMMA (Opial). *Let H be a Hilbert space, let $\{u(t) : t \to \infty\} \subset H$ be a trajectory, and denote by W the set of its weak limit points*

$$W := \{y \in H : \exists t_k \to \infty \ s.t. \ u(t_k) \rightharpoonup y\}.$$

If there exists $\emptyset \neq S \subset H$ such that

$$\forall z \in S, \ \lim_{t\to\infty} |u(t) - z| \ exists, \tag{2.4}$$

then $W \neq \emptyset$. Moreover, if $W \subset S$, then $u(t)$ converges weakly toward $\widehat{u} \in S$ as $t \to \infty$.

In order to apply the above result, we must find an adequate set S. Suppose that there exists $\widehat{u} \in H$ such that $u(t_k) \rightharpoonup \widehat{u}$ for a suitable sequence $t_k \to \infty$. The function Φ is weak lower-semicontinuous, because Φ is convex and continuous; hence

$$\Phi(\widehat{u}) \leq \liminf_{k\to\infty} \Phi(u(t_k)) = \lim_{t\to\infty} \Phi(u(t)) = \inf \Phi,$$

and therefore $\widehat{u} \in \operatorname{Argmin} \Phi$. According to the Opial lemma, we have only to prove that

$$\forall z \in \operatorname{Argmin} \Phi, \ \lim_{t\to\infty} |u(t) - z| \ \text{ exists.}$$

For this, fix $z \in \operatorname{Argmin} \Phi$ and define $\varphi(t) := \frac{1}{2}|u(t) - z|^2$. The following lemma provides a sufficient condition on $[\varphi']_+$, the positive part of the derivative, in order to ensure convergence for φ.

LEMMA 2.2. *Let $\theta \in C^1([0,\infty[; \mathbb{R})$ be bounded from below. If $[\theta']_+ \in L^1([0,\infty[; \mathbb{R})$, then $\theta(t)$ converges as $t \to \infty$.*

Proof. Set

$$w(t) := \theta(t) - \int_0^t [\theta'(\tau)]_+ d\tau.$$

Since $w(t)$ is bounded from below and $w'(t) \leq 0$, then $w(t)$ converges as $t \to \infty$, and consequently $\theta(t)$ converges as $t \to \infty$. □

On account of this result, it suffices to prove that $[\varphi']_+$ belongs to $L^1(0,\infty)$. Of course, to obtain information on φ' we shall use the fact that $u(t)$ is solution of (E_γ). Due to the optimality of z, it follows from (2.2) that

$$\varphi'' + \gamma\varphi' \leq |u'|^2. \tag{2.5}$$

LEMMA 2.3. *If $\omega \in C^1([0,\infty[;\mathbb{R})$ satisfies the differential inequality*

$$\omega' + \gamma\omega \leq g(t) \tag{2.6}$$

with $\gamma > 0$ and $g \in L^1([0,\infty[;\mathbb{R})$, then $[\omega]_+ \in L^1([0,\infty[;\mathbb{R})$.

Proof. We can certainly assume that $g \geq 0$, for if not, we replace g by $|g|$. Multiplying (2.6) by $e^{\gamma t}$ and integrating we get

$$\omega(t) \leq e^{-\gamma t}\omega(0) + \int_0^t e^{-\gamma(t-\tau)} g(\tau)\, d\tau.$$

Thus

$$[\omega(t)]_+ \leq e^{-\gamma t}[\omega(0)]_+ + \int_0^t e^{-\gamma(t-\tau)} g(\tau)\, d\tau,$$

and Fubini's theorem gives $\int_0^\infty \int_0^t e^{-\gamma(t-\tau)} g(\tau)\, d\tau dt = \frac{1}{\gamma}\int_0^\infty g(\tau)\, d\tau < \infty$. □

Recalling that $|u'|^2 \in L^1([0,\infty[;\mathbb{R})$, the proof of the theorem is completed by applying Lemma 2.3 to (2.5). □

We say that $\nabla\Phi$ is *strongly monotone* if there exists $\beta > 0$ such that for any $x, y \in H$ we have

$$\langle \nabla\Phi(x) - \nabla\Phi(y), x - y\rangle \geq \beta |x - y|^2.$$

A weaker condition is the strong monotonicity over bounded sets, that is to say, for all $K > 0$ there exists $\beta_K > 0$ such that for any $x, y \in B[0,K]$ we have

$$\langle \nabla\Phi(x) - \nabla\Phi(y), x - y\rangle \geq \beta_K |x - y|^2. \tag{2.7}$$

If the latter property holds, then we have strong convergence for $u(t)$ when the infimum of Φ is attained. The argument is standard: let $\widehat{u}$ be the (unique) minimum point for Φ and set $K := \max\{\sup_{t\geq 0} |u(t)|, |\widehat{u}|\}$; then from (2.7) we deduce

$$\Phi(\widehat{u}) + \frac{\beta_K}{2}|u(t) - \widehat{u}|^2 \leq \Phi(u(t)). \tag{2.8}$$

Since we have proven that $\lim_{t\to\infty} \Phi(u(t)) = \inf \Phi = \Phi(\widehat{u})$, estimate (2.8) implies $u(t) \to \widehat{u}$ strongly in H. Note that we do not need to apply the Opial lemma.

The latter is the case of a nondegenerate minimum point. When Φ admits multiple minima, it is not possible to obtain strong convergence without additional assumptions on Φ or the space H. For instance, we have the following.

THEOREM 2.4. *Under the hypotheses of Theorem* 2.1, *if either*

(i) $\operatorname{Argmin}\Phi \neq \emptyset$ *and* Φ *is even*

or

(ii) $\operatorname{int}(\operatorname{Argmin}\Phi) \neq \emptyset$,
then

$$u(t) \to \widehat{u} \text{ strongly in } H \text{ as } t \to \infty,$$

where $\widehat{u} \in \operatorname{Argmin}\Phi$.

Proof. The proof is adapted from the corresponding results for the steepest descent method; see [7] for the analogous hypothesis of (i) and [6] for (ii).

(i) Fix $t_0 > 0$ and define $g : [0, t_0] \to \mathbb{R}$ by

$$g(t) := |u(t)|^2 - |u(t_0)|^2 - \frac{1}{2}|u(t) - u(t_0)|^2.$$

Then $g'(t) = \langle u'(t), u(t) + u(t_0)\rangle$ and $g''(t) = \langle u''(t), u(t) + u(t_0)\rangle + |u'(t)|^2$. Consequently

$$g''(t) + \gamma g'(t) = \langle -\nabla\Phi(u(t)), u(t) + u(t_0)\rangle + |u'(t)|^2.$$

Since $E(t) = \frac{1}{2}|u'(t)|^2 + \Phi(u(t))$ is decreasing and Φ is even, we deduce that

$$E(t) \geq \frac{1}{2}|u'(t_0)|^2 + \Phi(-u(t_0))$$

for all $t \in [0, t_0]$. By the convexity of Φ we conclude that

$$E(t) \geq \frac{1}{2}|u'(t_0)|^2 + \Phi(u(t)) + \langle \nabla\Phi(u(t)), -u(t) - u(t_0)\rangle$$

and hence that

$$\frac{1}{2}|u'(t)|^2 \geq \langle -\nabla\Phi(u(t)), u(t) + u(t_0)\rangle.$$

Thus

$$g''(t) + \gamma g'(t) \leq \frac{3}{2}|u'(t)|^2.$$

The standard integration procedure yields

$$g(t_0) - g(t) \leq \frac{1}{\gamma}(e^{-\gamma t} - e^{-\gamma t_0})g'(0) + \frac{3}{2}\int_t^{t_0}\int_0^{\theta} e^{-\gamma(\theta-\tau)}|u'(\tau)|^2 d\tau d\theta.$$

Therefore, for all $t \in [0, t_0]$ we have that

$$\frac{1}{2}|u(t) - u(t_0)|^2 \leq |u(t)|^2 - |u(t_0)|^2 + \frac{1}{\gamma}(e^{-\gamma t} - e^{-\gamma t_0})g'(0) + h(t_0) - h(t), \tag{2.9}$$

where

$$h(t) = \frac{3}{2}\int_0^t \int_0^{\theta} e^{-\gamma(\theta-\tau)}|u'(\tau)|^2 d\tau d\theta.$$

On the other hand, in the proof of Theorem 2.1 we have shown that $h(t)$ is convergent as $t \to \infty$. We also proved that for all $z \in \operatorname{Argmin}\Phi$ the $\lim_{t\to\infty}|u(t) - z|$ exists. Since Φ is convex and even, we have $0 \in \operatorname{Argmin}\Phi$ whenever the infimum is realized.

In that case, $|u(t)|$ is convergent as $t \to \infty$ and we infer from (2.9) that $\{u(t) : t \to \infty\}$ is a Cauchy net. Hence $u(t)$ converges strongly as $t \to \infty$ and, by Theorem 2.1, the limit belongs to $\operatorname{Argmin} \Phi$.

(ii) Let $z_0 \in \operatorname{int}(\operatorname{Argmin} \Phi)$. There exists $\rho > 0$ such that for every $z \in H$ with $|z - z_0| \leq \rho$, then $z \in \operatorname{int}(\operatorname{Argmin} \Phi)$. In particular, if $|z - z_0| \leq \rho$, then $\nabla\Phi(z) = 0$. Consequently,

$$\langle \nabla\Phi(x), x - z_0 \rangle \geq \langle \nabla\Phi(x), z - z_0 \rangle$$

for every $x \in H$ and z with $|z - z_0| \leq \rho$. Hence,

$$\langle \nabla\Phi(x), x - z_0 \rangle \geq \rho |\nabla\Phi(x)|$$

for every $x \in H$. Applying this inequality to $x = u(t)$ we deduce that

$$-\langle u'' + \gamma u', u - z_0 \rangle \geq \rho |u'' + \gamma u'|.$$

Set $\varphi(t) := \frac{1}{2}|u(t) - z_0|^2$. We thus obtain

$$-\varphi'' + |u'|^2 - \gamma\varphi' \geq \rho |u'' + \gamma u'|.$$

Integrating this inequality yields

$$\varphi'(0) - \varphi'(t) + \int_0^t |u'(\tau)|^2 d\tau + \gamma(\varphi(0) - \varphi(t)) \geq \rho \int_0^t |u''(\tau) + \gamma u'(\tau)| d\tau.$$

We have already proved that the $\lim_{t\to\infty} \varphi(t)$ exists and $\lim_{t\to\infty} \varphi'(t) = 0$. Moreover, $u' \in L^2(0, \infty; H)$. As a conclusion, $u'' + \gamma u' \in L^1(0, \infty; H)$. We deduce that the $\lim_{t\to\infty} u'(t) + \gamma u(t)$ exists, which finishes the proof because $u'(t) \to 0$ as $t \to \infty$. □

2.2. Localization of the limit point. In the proof of Theorem 2.1 we have used the differential inequality (2.2), which in some sense measures the evolution of the system. A simpler but analogous inequality appears in the asymptotic analysis for the steepest descent inclusion (SD). This was used by B. Lemaire in [13] to *locate* the limit point of the trajectories of (SD). Following this approach, in this section we give a localization result of the limit point of the solutions of (E_γ). For simplicity of notation, set $S := \operatorname{Argmin} \Phi$ and we denote by $\operatorname{proj}_S : H \to S$ the projection operator onto the closed convex set S.

PROPOSITION 2.5. *Let u be solution of $(E_\gamma; u_0, v_0)$ and $\widehat{u} \in S$ be such that $u(t) \rightharpoonup \widehat{u}$ weakly as $t \to \infty$. Then, for all $x \in S$*

$$|\widehat{u} - x| \leq |u_0 + \frac{1}{\gamma} v_0 - x| + \frac{1}{\gamma} \delta(u_0), \tag{2.10}$$

where $\delta(u_0) = \sqrt{2}[\Phi(u_0) - \inf \Phi]^{1/2}$. Consequently

$$\text{(i)} \qquad |\widehat{u} - \operatorname{proj}_S(u_0 + \frac{1}{\gamma} v_0)| \leq d(u_0 + \frac{1}{\gamma} v_0, S) + \frac{1}{\gamma} \delta(u_0),$$

where $d(u_0, S)$ is the distance between u_0 and the set S.

(ii) *If S is an affine subspace of H, then*

$$|\widehat{u} - \operatorname{proj}_S(u_0 + \frac{1}{\gamma} v_0)| \leq \frac{1}{\gamma} \delta(u_0).$$

If, moreover, Φ is a quadratic form, then

$$u(t) \to \operatorname{proj}_S(u_0 + \frac{1}{\gamma}v_0) \text{ strongly in } H \text{ as } t \to \infty.$$

Proof. Let $x \in S$ and set $\varphi(t) := \frac{1}{2}|u(t) - x|^2$. The inequality (2.2) and the optimality of x give $\varphi'' + \gamma\varphi' \le |u'|^2$. Hence

$$\varphi(t) \le \varphi(0) + \frac{1}{\gamma}(1 - e^{-\gamma t})\varphi'(0) + \int_0^t \int_0^\theta e^{-\gamma(\theta-\tau)}|u'(\tau)|^2 d\tau d\theta.$$

Due to the weak lower-semicontinuity of the norm and Fubini's theorem, we can let $t \to \infty$ to obtain

$$\frac{1}{2}|\widehat{u} - x|^2 \le \frac{1}{2}|u_0 - x|^2 + \frac{1}{\gamma}\langle v_0, u_0 - x\rangle + \frac{1}{\gamma}\int_0^\infty |u'(\tau)|^2 d\tau. \tag{2.11}$$

On the other hand, from the energy equation

$$\frac{1}{2}|u'|^2 + \Phi(u) + \gamma\int_0^t |u'(\tau)|^2 d\tau = \frac{1}{2}|v_0|^2 + \Phi(u_0),$$

it follows that

$$\int_0^\infty |u'(\tau)|^2 d\tau \le \frac{1}{\gamma}\Big[\frac{1}{2}|v_0|^2 + \Phi(u_0) - \inf\Phi\Big].$$

Replacing the last estimate in (2.11), it easy to show that (2.10) holds.

For (i), it suffices to take $x = \operatorname{proj}_S(u_0 + \frac{1}{\gamma}v_0)$ in (2.10).

For (ii), let $e := \widehat{u} - \operatorname{proj}_S(u_0 + \frac{1}{\gamma}v_0)$. If $e \neq 0$, then set

$$x_r := \operatorname{proj}_S\Big(u_0 + \frac{1}{\gamma}v_0\Big) - rd\Big(u_0 + \frac{1}{\gamma}v_0, S\Big)\frac{e}{|e|},$$

which belongs to S. An easy computation shows that

$$\Big|u_0 + \frac{1}{\gamma}v_0 - x_r\Big| - |\widehat{u} - x_r| = \Big(\sqrt{1+r^2} - r\Big)d\Big(u_0 + \frac{1}{\gamma}v_0 - x, S\Big) - |e|,$$

which together with (2.10) yields

$$|e| \le \Big(\sqrt{1+r^2} - r\Big)d\Big(u_0 + \frac{1}{\gamma}v_0 - x, S\Big) + \frac{1}{\gamma}\delta(u_0).$$

Letting $r \to \infty$ we get the result.

Finally, suppose that $\Phi(x) = \frac{1}{2}\langle Ax, x\rangle$ where $A : H \to H$ is a positive and self-adjoint bounded linear operator. Then $S = \{x \in H \mid Ax = 0\}$ the null space of A. Let $z \in S$; for all $t \ge 0$ we have that

$$\begin{aligned}\langle u'(t) - v_0, z\rangle + \gamma\langle u(t) - u_0, z\rangle &= \int_0^t \langle u''(\tau) + \gamma u'(\tau), z\rangle d\tau \\ &= \int_0^t \langle -Au(\tau), z\rangle d\tau \\ &= \int_0^t -\langle u(\tau), Az\rangle d\tau = 0.\end{aligned}$$

Since $u'(t) \to 0$ and $u(t) \to \widehat{u} \in S$ strongly (Φ is even) as $t \to \infty$, we can deduce that

$$\Big\langle \widehat{u} - \Big(u_0 + \frac{1}{\gamma}v_0\Big), z\Big\rangle = 0$$

for all $z \in S$, which completes the proof. ∎

2.3. Linear system: Heuristic comparison. Before proceeding further, it is interesting from the optimization viewpoint to compare the behavior of the trajectories defined by

$$(E_\gamma) \qquad u'' + \gamma u' + \nabla\Phi(u) = 0,$$

with the steepest descent equation

$$(\mathrm{SD}) \qquad u' + \nabla\Phi(u) = 0,$$

and with the continuous Newton's method

$$(\mathrm{N}) \qquad u' + \nabla^2\Phi(u)^{-1}\nabla\Phi(u) = 0.$$

For simplicity, in this section we restrict ourselves to the associated linearized systems in a finite dimensional space. We shall consider $H = \mathbb{R}^N$ and assume that $\Phi \in C^2(\mathbb{R}^N;\mathbb{R})$. Related to (SD), we have the linearized system around some $x_0 \in \mathbb{R}^N$, which is defined by

$$(\mathrm{LSD}) \qquad x' + \nabla^2\Phi(x_0)(x - x_0) + \nabla\Phi(x_0) = 0.$$

We assume that the Hessian matrix $\nabla^2\Phi(x_0)$ is positive definite. An explicit computation shows that $x(t) \to \widehat{x} := x_0 - \nabla^2\Phi(x_0)^{-1}\nabla\Phi(x_0)$ as $t \to \infty$. In fact, the solutions of (LSD) are of the form $y(t) = \widehat{x} + \eta(t)$, where η solves the homogeneous equation $\eta' + \nabla^2\Phi(x_0)\eta = 0$. Take a matrix P such that $P^{-1}\nabla^2\Phi(x_0)P = \mathrm{diag}(\lambda_1, \ldots, \lambda_N)$, where $\lambda_i > 0$, and set $P\xi = \eta$. We obtain the system $\xi_i' + \lambda_i\xi_i = 0$, whose solutions are $\xi_i(t) = C_i e^{-\lambda_i t}$. Generally speaking, if there is a $\lambda_i << 1$, we will have a relative slow convergence towards the solution; on the other hand, when dealing with large λ_i's the numerical integration by an approximate method will present stability problems. Thus we see that the numerical performance of (SD) is strongly determined by the *local geometry* of the function Φ.

We turn now to the linearized version of (N), given by

$$(\mathrm{LN}) \qquad y' + y - \widehat{x} = 0.$$

The solutions are of the form $y(t) = \widehat{x} + e^{-t}y(0)$, which are much better than the previous ones. The major properties are (1) the straight-line geometry of the trajectories; (2) that the rate of convergence is independent of the quadratic function to be minimized. Certainly, this is just a local approximation of the original function and the global behavior of the trajectory may be complicated. Nevertheless, this outstanding *normalization* property of Newton's system makes it effective in practice, due to the fact that the associated trajectories are easy to follow by a discretization method. Of course, an important disadvantage of (N) is the computation of the inverse of the Hessian matrix, which may be involved for a numerical algorithm.

Finally, we consider

$$(LE_\gamma) \qquad z'' + \gamma z' + \nabla^2\Phi(x_0)(z - x_0) + \nabla\Phi(x_0) = 0.$$

For this equation we have $z(t) = \widehat{x} + \epsilon(t)$, where ϵ solves the homogeneous problem $\epsilon'' + \gamma\epsilon' + \nabla^2\Phi(x_0)\epsilon = 0$. Setting $P\delta = \epsilon$ with P as above, then δ_i satisfies $\delta_i'' + \gamma\delta_i' + \lambda_i\delta_i = 0$. It is a simple matter to show that $|\delta_i(t)| \le C_i e^{-\mu_i(\gamma)t}$ with $\mu_i :]0,\infty[\to]0,\infty[$ continuous and C_i a constant independent of γ. In fact, $\mu_i(\gamma) = \frac{\gamma}{2}$ if $\gamma \in]0, 2\sqrt{\lambda_i}]$ and

$\mu_i(\cdot)$ is nonincreasing on $]2\sqrt{\lambda_i},\infty[$. Moreover, if $\gamma \geq 2\sqrt{\lambda_i}$, then the corresponding $\delta_i(t)$ does not present oscillations. Thus the choice $\gamma = 2\sqrt{\lambda_i}$ gives $\mu_i = \sqrt{\lambda_i}$, the greatest rate that can be obtained. But we can get any value in the interval $]0,\sqrt{\lambda_i}]$; for instance, when $\lambda_i > 1$ we obtain $\mu_i = 1$ either with $\gamma = 2$ or $\gamma = \lambda_i + 1$. The last choice has the advantage that the associated trajectory is not oscillatory, which is interesting by numerical reasons. Note that we should take a different parameter γ according to the corresponding eigenvalue λ_i.

Therefore, the presence of the damping parameter γ gives us a control on the behavior of the solutions of (E_γ) and, in particular, on some qualitative properties of the associated trajectories. For a general Φ we must take into account that (a) a careful selection of the damping parameter γ should depend on the local geometry of the function Φ, leading to a nonautonomous damping; (b) this selection could give a different value of γ for some particular directions, leading to an anisotropic damping. No attempt has been made here to develop a theory in order to guide these choices.

2.4. Linear and anisotropic damping. In the preceding section we have seen that it may be of interest to consider an anisotropic damping. With the aim of contributing to this issue, in this section we establish the asymptotic convergence for the solutions of the following system:

$$(E_\Gamma; u_0, v_0) \qquad \begin{cases} u'' + \Gamma u' + \nabla\Phi(u) = 0, \\ u(0) = u_0,\ u'(0) = v_0, \end{cases}$$

where $\Gamma : H \to H$ is a bounded self-adjoint linear operator, which we assume to be elliptic:

$$(h_\Gamma) \qquad \text{there exists } \gamma > 0 \text{ such that for any } x \in H,\ \langle \Gamma x, x\rangle \geq \gamma |x|^2.$$

THEOREM 2.6. *Suppose (h_Φ) and (h_Γ) hold. If $u \in C^2([0,\infty[;H)$ is a solution of $(E_\Gamma; u_0, v_0)$, then it satisfies $u' \in L^2([0,\infty[;H)$, $u'(t) \to 0$ as $t \to \infty$, and*

$$\lim_{t\to\infty} \Phi(u(t)) = \inf \Phi. \tag{2.12}$$

Furthermore, if $\operatorname{Argmin}\Phi \neq \emptyset$, *then there exists* $\widehat{u} \in \operatorname{Argmin}\Phi$ *such that* $u(t) \rightharpoonup \widehat{u}$ *weakly in* H *as* $t \to \infty$.

Proof. We only need to adapt the proof of Theorem 2.1. First, note that the properties of existence, uniqueness, and infinite extendibility to the right of the solution follow by similar arguments. Likewise, the energy $E(t) := \frac{1}{2}|u'(t)|^2 + \Phi(u(t))$ satisfies $E' = -\langle \Gamma u', u'\rangle$, and we can deduce that $u' \in L^2$.

Next, define the operator $A : H \to H$ by $Ax := \Gamma x - \gamma x$, with $\gamma > 0$ given by (h_Γ). Fix $x \in H$ and set $\varphi(t) := \frac{1}{2}|u(t) - x|^2$ and $\rho(t) := \frac{1}{2}\langle A(u(t) - x), u(t) - x\rangle$, in such a way that

$$\varphi'' + \gamma\varphi' + \rho' = \langle \nabla\Phi(u), x - u\rangle + |u'|^2. \tag{2.13}$$

As in the proof of Theorem 2.1, (2.13) gives

$$\varphi'(t) + \int_0^t e^{-\gamma(t-\tau)}\rho'(\tau)d\tau \leq e^{-\gamma t}\varphi'(0) + \frac{1}{\gamma}(1 - e^{-\gamma t})[\Phi(x) - E(t)] + r(t), \tag{2.14}$$

with

$$r(t) := \frac{3}{2}\int_0^t e^{-\gamma(t-\tau)}|u'(\tau)|^2 d\tau,$$

the only difference being the term $\int_0^t e^{-\gamma(t-\tau)}\rho'(\tau)d\tau$. An integration by parts yields

$$\int_0^t e^{-\gamma(t-\tau)}\rho'(\tau)d\tau = \rho(t) - e^{-\gamma t}\rho(0) - \gamma\int_0^t e^{-\gamma(t-\tau)}\rho(\tau)d\tau.$$

Setting $f(t) := \int_0^t e^{-\gamma(t-\tau)}\rho(\tau)d\tau$, we have

$$\int_0^t e^{-\gamma(t-\tau)}\rho'(\tau)d\tau = f'(t) - e^{-\gamma t}\rho(0).$$

Thus, we can rewrite (2.14) as

$$\varphi'(t) + f'(t) \le e^{-\gamma t}(\varphi'(0) + \rho(0)) + \frac{1}{\gamma}(1 - e^{-\gamma t})[\Phi(x) - E(t)] + r(t).$$

We leave it to the reader to verify that the minimizing property (2.12) can now be established as in Theorem 2.1. The proof of $u'(t) \to 0$ as $t \to \infty$ is analogous.

When $\operatorname{Argmin}\Phi \neq \emptyset$, we fix $z \in \operatorname{Argmin}\Phi$ and consider the corresponding functions φ and ρ as above (with x replaced by z). Using the optimality of z, it follows that

$$\varphi'(t) + f'(t) \le e^{-\gamma t}(\varphi'(0) + \rho(0)) + \int_0^t e^{-\gamma(t-\tau)}|u'(\tau)|^2 d\tau, \tag{2.15}$$

with f associated with ρ as above. Integrating this inequality we conclude that $\varphi(t)$ stays bounded as $t \to \infty$, but we cannot deduce its convergence. Then, we rewrite (2.15) in the form

$$\varphi'(t) + \int_0^t e^{-\gamma(t-\tau)}\rho'(\tau)d\tau \le e^{-\gamma t}\varphi'(0) + \int_0^t e^{-\gamma(t-\tau)}|u'(\tau)|^2 d\tau,$$

and we conclude that $[\varphi'(t) + \int_0^t e^{-\gamma(t-\tau)}\rho'(\tau)d\tau]_+ \in L^1([0,\infty[;\mathbb{R})$. We note that

$$\varphi'(t) + \int_0^t e^{-\gamma(t-\tau)}\rho'(\tau)d\tau = \mu'(t) + \xi'(t),$$

where

$$\mu(t) := \frac{1}{2\gamma}\langle \Gamma(u(t) - z), u(t) - z\rangle,$$

and

$$\xi(t) := -\frac{1}{\gamma}\int_0^t e^{-\gamma(t-\tau)}\rho'(\tau)d\tau.$$

By virtue of Lemma 2.2, if we show that $\xi(t)$ is bounded from below, then $\mu(t) + \xi(t)$ converges as $t \to \infty$. Since $\rho'(t) = \langle Au'(t), u(t) - z\rangle$, there exists a constant $M > 0$ independent of t such that $|\rho'(t)| \le M|u'(t)|\sqrt{\varphi(t)}$ for any $t > 0$. We conclude that $\rho'(t) \to 0$ as $t \to \infty$. From this fact it follows easily that $\xi(t) \to 0$ as $t \to \infty$. Therefore, $\mu(t) + \xi(t)$ converges as $t \to \infty$, hence $\mu(t)$ converges as well.

The proof is completed by applying the Opial lemma to the trajectory $\{u(t) : t \to \infty\}$, where the Hilbert space H is endowed with the inner product $\langle\langle \cdot, \cdot\rangle\rangle : H \times H \to \mathbb{R}$ defined by $\langle\langle x, y\rangle\rangle := \frac{1}{\gamma}\langle \Gamma x, y\rangle$ and its associated norm. □

Remark 1. In Theorems 2.1, 2.4, and 2.6 we do not require any coerciveness assumption on Φ. When $\operatorname{Argmin}\Phi \neq \emptyset$, the dissipativeness in the dynamics suffices for the convergence of the solutions. If the infimum value is not realized, the trajectory may be unbounded as in the one-dimensional equation $u'' + \gamma u' + e^u = 0$, whose solutions $u \in C^2([0,\infty[;\mathbb{R})$ are so that $u(t) \to -\infty$ and $u'(t) \to 0$ as $t \to \infty$. In any case, our results assert that the dynamical system defined by (E_γ) (or more generally by (E_Γ)) is dissipative in the sense that every trajectory evolves towards a minimum of the energy. Certainly, there is a strong connection with the concept of point dissipativeness or ultimately boundedness in the theory of dynamical systems, where the Lyapunov function associated with the semigroup is usually supposed to be coercive (cf. [9, gradient systems]).

Remark 2. To ensure local existence and uniqueness of a classical solution for the differential equation, it suffices to require a local Lipschitz property on $\nabla\Phi$. Actually, in some situations this hypothesis is not necessary and the existence may be established by other arguments. For instance, that is the case of the Hille–Yosida theorem for evolution equations governed by monotone operators and the theory of linear and nonlinear semigroups for partial differential equations. Note that such a Lipschitz condition on the gradient is not used in the asymptotic analysis of the trajectories. Therefore, the previous asymptotic results remain valid for other classes of infinite dimensional dissipative systems provided the existence of a global solution. It is not our purpose to develop this point here for the continuous system because it exceeds the scope of this paper. However, in the next section we consider an implicit discretization of the continuous system. As we will see, the existence of the discrete trajectory is ensured by variational arguments. This will allow us to apply the discrete scheme to nonsmooth convex functions and to adapt the asymptotic analysis to this case.

3. Discrete approximation method. Once we have established the existence of a solution of an initial value problem, we are interested in its numerical values. We must accept that most differential equations cannot be solved explicitly; we are thus led to work with approximate methods. An important class of these methods is based on the approximation of the exact solution over a discrete set $\{t_n\}$: associated with each point t_n we compute a value u_n, which approximates $u(t_n)$ the exact solution at t_n. Generally speaking, these procedures have the disadvantage that a large number of calculations has to be done in order to keep the discretization error $e_n := u_n - u(t_n)$ sufficiently small. In addition to this, the estimates for the errors strongly depend on the length of the discretization range for the t variable. It turns out that these methods are not well adapted to the approximation of the exact solution on an unbounded domain.

Nevertheless, there is an important point to note here. If our objective is the asymptotic behavior of the solutions as t goes to ∞, then the accurate approximation of the whole trajectory becomes immaterial. We present a discrete method whose feature is that no attempt is made to approximate the exact solution over a set of points but that the discrete values are sought only to preserve the asymptotic behavior of the solutions.

3.1. Implicit iterative scheme. Dealing with the discretization of a first order differential equation $y' = F(y)$, it is classical to consider the implicit iterative scheme

$$\frac{y_{k+1} - y_k}{h} = F(y_{k+1}), \tag{3.1}$$

where $h > 0$ is a parameter called step size. In the case of equation (E_γ), or more precisely its first order equivalent system, (3.1) corresponds to recursively solve

$$\frac{u_{k+1} - 2u_k + u_{k-1}}{h^2} + \gamma \frac{u_{k+1} - u_k}{h} + \nabla\Phi(u_{k+1}) = 0. \tag{3.2}$$

Since Φ is convex, (3.2) is equivalent to the following variational problem:

$$u_{k+1} = \operatorname{argmin}\left\{\Phi(x) + \frac{1+\gamma h}{2h^2}\,|x - z_k|^2 : x \in H\right\},$$

where $z_k = u_k + \frac{1}{1+\gamma h}(u_k - u_{k-1})$. This motivates the introduction of the more general iterative procedure

$$u_{k+1} = \operatorname{argmin}\left\{\Phi(x) + \frac{1}{2\lambda}\,|x - z_k|^2 : x \in H\right\},$$

where $z_k = u_k + \alpha(u_k - u_{k-1})$, λ and α are positive. Note that when $\alpha = 0$, we recover the standard (Prox) iteration. If $\alpha > 0$, the starting point for the next iteration is computed as a development in terms of the *velocity* of the already generated sequence. Therefore, this iterative scheme defines a second order dynamics, while (Prox) is actually of a first order nature.

We have been working under the assumption that Φ is differentiable. However, for the above iterative variational method this regularity is no longer necessary. Thus, in that which follows $f : H \to \mathbb{R} \cup \{\infty\}$ denotes a closed proper convex function (see [17]), which eventually realizes the value ∞, and we consider

$$u_{k+1} = \operatorname{argmin}\left\{f(x) + \frac{1}{2\lambda}\,|x - z_k|^2 : x \in H\right\}, \tag{3.3}$$

where $z_k = u_k + \alpha(u_k - u_{k-1})$. In terms of the stationary condition, (3.3) is equivalent to

$$\frac{1}{\lambda}(u_{k+1} - (1+\alpha)u_k + \alpha u_{k-1}) + \partial f(u_{k+1}) \ni 0,$$

where ∂f is the standard convex subdifferential [17].

3.2. Convergence for the variational algorithm. By numerical reasons, it is natural to consider the following approximate iterative scheme:

$$\frac{1}{\lambda_k}(u_{k+1} - (1+\alpha_k)u_k + \alpha_k u_{k-1}) + \partial_{\epsilon_k} f(u_{k+1}) \ni 0, \tag{3.4}$$

where α_k is nonnegative, λ_k is positive, and $\partial_\epsilon f$ is the ϵ-subdifferential. Note that a sequence $\{u_k\} \subset H$ satisfying (3.4) always exists. Indeed, given $u_{k-1}, u_k \in H$, we can take u_{k+1} as the unique solution of the strongly convex problem $\min\{f(x) + \frac{1}{2\lambda_k}|x - z_k|^2 : x \in H\}$ with z_k as above.

THEOREM 3.1. *Assume that f is closed proper convex and bounded from below. Let $\{u_k\} \subset H$ be a sequence generated by* (3.4)*, where*

(i) $0 \le \alpha_k \le 1$ *and* $\{\lambda_k\}$ *is bounded from below by a positive constant,*

(ii) *the sequence* $\{\alpha_k/\lambda_k\}$ *is nonincreasing and* $\sum \lambda_k \epsilon_k < \infty$.

Then

$$\lim_{k\to\infty} \frac{1}{\lambda_k}(u_{k+1} - (1+\alpha_k)u_k + \alpha_k u_{k-1}) = 0, \tag{3.5}$$

and in particular $\lim_{k\to\infty} d(0,\partial_{\epsilon_k} f(u_{k+1})) = 0$.

When $\operatorname{Argmin} f \neq \emptyset$, *assume in addition that*

(iii) *there exists* $\bar{\alpha} \in]0,1[$ *such that* $0 \leq \alpha_k \leq \bar{\alpha}$, *and* $\{\lambda_k\}$ *is bounded from above if there is at least one* $\alpha_k > 0$.

Then, there exists $\widehat{u} \in \operatorname{Argmin} f$ *such that* $u_k \rightharpoonup \widehat{u}$ *weakly as* $k \to \infty$.

Proof. The proof consists of adapting the analysis done for the differential equation (E_γ). We begin by defining the discrete energy by

$$E_{k+1} = \frac{\alpha_k}{2\lambda_k}|u_{k+1} - u_k|^2 + f(u_{k+1}),$$

and we study the successive difference $E_{k+1} - E_k$. Since $\alpha_k/\lambda_k \leq \alpha_{k-1}/\lambda_{k-1}$,

$$E_{k+1} - E_k \leq \frac{\alpha_k}{2\lambda_k}\left(|u_{k+1} - u_k|^2 - |u_k - u_{k-1}|^2\right) + f(u_{k+1}) - f(u_k).$$

By definition of $\partial_{\epsilon_k} f$, (3.4) yields

$$f(u_{k+1}) - f(u_k) \leq -\frac{1}{\lambda_k}\langle u_{k+1} - (1+\alpha_k)u_k + \alpha_k u_{k-1}, u_{k+1} - u_k\rangle + \epsilon_k.$$

As we can write

$$\langle u_{k+1} - (1+\alpha_k)u_k + \alpha_k u_{k-1}, u_{k+1} - u_k\rangle = |u_{k+1} - u_k|^2 - \alpha_k\langle u_k - u_{k-1}, u_{k+1} - u_k\rangle,$$

we have

$$E_{k+1} - E_k \leq -\frac{\alpha_k}{2\lambda_k}|u_{k+1} - 2u_k + u_{k-1}|^2 - \frac{1-\alpha_k}{\lambda_k}|u_{k+1} - u_k|^2 + \epsilon_k,$$

and consequently

$$\sum_{k=1}^{N}\left[\frac{\alpha_k}{2\lambda_k}|u_{k+1} - 2u_k + u_{k-1}|^2 + \frac{1-\alpha_k}{\lambda_k}|u_{k+1} - u_k|^2\right] \leq E_1 - E_{N+1} + \sum_{k=1}^{N}\epsilon_k.$$

Noting that

$$E_1 - E_{N+1} + \sum_{k=1}^{N}\epsilon_k \leq E_1 - \inf f + \sum \epsilon_k < \infty,$$

and because $0 \leq \alpha_k \leq 1$, we deduce that

$$\sum \frac{\alpha_k}{2\lambda_k}|u_{k+1} - 2u_k + u_{k-1}|^2 < \infty$$

and

$$\sum \frac{1-\alpha_k}{\lambda_k}|u_{k+1} - u_k|^2 < \infty. \tag{3.6}$$

As $0 \leq \alpha_k \leq 1$ and λ_k is bounded from below by a positive constant, we have

$$\lim_{k\to\infty}\frac{\alpha_k}{\lambda_k}|u_{k+1} - 2u_k + u_{k-1}| = \lim_{k\to\infty}\frac{(1-\alpha_k)}{\lambda_k}|u_{k+1} - u_k| = 0.$$

Writing

$$u_{k+1} - (1+\alpha_k)u_k + \alpha_k u_{k-1} = \alpha_k(u_{k+1} - 2u_k + u_{k-1}) + (1-\alpha_k)(u_{k+1} - u_k),$$

we conclude that (3.5) holds.

Suppose now that $\operatorname{Argmin} f \neq \emptyset$. We apply the Opial lemma to prove the weak convergence of $\{u_k\}$. On account of (3.5), it is sufficient to show that for any $z \in \operatorname{Argmin} f$, the sequence of positive numbers $\{|u_k - z|\}$ is convergent. Fix $z \in \operatorname{Argmin} f$; since u_{k+1} satisfies (3.4), we have

$$f(u_{k+1}) - \frac{1}{\lambda_k}\langle u_{k+1} - (1+\alpha_k)u_k + \alpha_k u_{k-1}, z - u_{k+1}\rangle \leq f(z) + \epsilon_k,$$

and by the optimality of z

$$\langle u_{k+1} - u_k, u_{k+1} - z\rangle - \alpha_k\langle u_k - u_{k-1}, u_{k+1} - z\rangle \leq \lambda_k\epsilon_k. \tag{3.7}$$

Set $\varphi_k := \frac{1}{2}|u_k - z|^2$. It is direct to check that for any $k \in \mathbb{N}$

$$\varphi_{k+1} = \varphi_k + \langle u_{k+1} - u_k, u_{k+1} - z\rangle - \frac{1}{2}|u_{k+1} - u_k|^2.$$

Since $\langle u_k - u_{k-1}, u_{k+1} - z\rangle = \langle u_k - u_{k-1}, u_k - z\rangle + \langle u_k - u_{k-1}, u_{k+1} - u_k\rangle$, (3.7) shows that

$$\varphi_{k+1} - \varphi_k - \alpha_k\left(\varphi_k - \varphi_{k-1} + \frac{1}{2}|u_k - u_{k-1}|^2 + \langle u_k - u_{k-1}, u_{k+1} - u_k\rangle\right) \leq \lambda_k\epsilon_k,$$

and therefore

$$\varphi_{k+1} - (1+\alpha_k)\varphi_k + \alpha_k\varphi_{k-1} \leq \delta_k,$$

where $\delta_k = \alpha_k|u_k - u_{k-1}|^2 + \frac{\alpha_k}{2}|u_{k+1} - u_k|^2 + \lambda_k\epsilon_k$. Using (iii) and (3.6) it follows that $\sum |u_{k+1} - u_k|^2 < \infty$, thus $\sum \delta_k < \infty$. Set $\theta_k := \varphi_k - \varphi_{k-1}$; the above inequality implies

$$[\theta_{k+1}]_+ \leq \bar{\alpha}[\theta_k]_+ + \delta_k.$$

Thus

$$[\theta_{k+1}]_+ \leq \bar{\alpha}^k[\theta_1]_+ + \sum_{j=0}^{k-1}\bar{\alpha}^j\delta_{k-j},$$

which yields

$$\sum_{k=0}^{\infty}[\theta_{k+1}]_+ \leq \frac{1}{1-\bar{\alpha}}\left([\theta_1]_+ + \sum_{k=1}^{\infty}\delta_k\right) < \infty.$$

Set $w_k := \varphi_k - \sum_{j=1}^{k}[\theta_j]_+$. Since $\varphi_k \geq 0$ and $\sum[\theta_j]_+ < \infty$, w_k is bounded from below. As $\{w_k\}$ is nonincreasing we have that it converges. Hence $\{\varphi_k\}$ converges, which completes the proof of the theorem. □

For simplicity, we have considered in this section the isotropic damping system. However, a similar analysis can be done for the anisotropic damping associated with

an elliptic self-adjoint linear operator $\Gamma : H \to H$. The variational problem associated with the implicit discretization is

$$u_{k+1} = \operatorname{argmin}\left\{\Phi(x) + \frac{1}{2h^2}\,|x - z_k|^2_{(I+h\Gamma)} : x \in H\right\},$$

where $z_k = u_k + (I + h\Gamma)^{-1}(u_k - u_{k-1})$ and for any $y \in H$,

$$|y|_{(I+h\Gamma)} := \sqrt{\langle (I + h\Gamma)y, y\rangle}.$$

For a function $f : H \to \mathbb{R} \cup \{\infty\}$ closed proper and convex, the latter motivates the scheme

$$R(u_{k+1} - (I + S)u_k + Su_{k-1}) + \partial f(u_{k+1}) \ni 0,$$

where $R : H \to H$ is a linear positive definite operator and $S : H \to H$ is linear and positive semidefinite. If we assume both R and $I - S$ are elliptic, it is possible to obtain a convergence result like the previous one. It suffices to adapt the main arguments. Since the basic ideas are contained in the proof of Theorems 2.6 and 3.1, we shall go no further in this matter.

4. Some open problems. In the case of multiple optimal solutions, our convergence results do not provide additional information on the point attained in the limit. A possible approach to overcome this disadvantage may be to couple the dissipative system with approximation techniques such as regularization, interior-barrier or globally defined penalizations, and viscosity methods. In the continuous case, this alternative has been considered with success for the steepest descent equation in [2] and for Newton's method in [1], giving a characterization for the limit point under suitable assumptions on the approximate scheme. On account of these results, one may conjecture that this can be done for the equations considered in the present work.

On the other hand, we have seen that the behavior of the trajectories depends on a relation between the damping and the local geometry of the function we wish to minimize. This remark leads us to the obvious problem of the choice of the damping parameter, made in order to have a better control on the trajectory. This is also a problem in the discrete algorithm. Usually we have an incomplete knowledge of the objective function, which makes the question more difficult. We think that a first step in this direction may be the study of more general damped equations, with nonlinear and/or nonautonomous damping.

Acknowledgments. I wish to express my gratitude to the Laboratoire d'Analyse Convexe de l'Université Montpellier II for their hospitality and support, and especially to Professor Hedy Attouch. I gratefully acknowledge financial support through a French Foreign Scholarship grant from the French Ministry of Education and a Chilean National Scholarship grant from the CONICYT of Chile. I wish to thank a referee for helpful comments concerning Theorems 2.2 and 3.1.

TIME-VARYING AND ADAPTIVE INTEGRAL CONTROL OF INFINITE-DIMENSIONAL REGULAR LINEAR SYSTEMS WITH INPUT NONLINEARITIES*

H. LOGEMANN† AND E. P. RYAN†

Abstract. Closing the loop around an exponentially stable, single-input, single-output, regular linear system—subject to a globally Lipschitz, nondecreasing actuator nonlinearity and compensated by an integral controller with time-dependent gain $k(t)$—is shown to ensure asymptotic tracking of a constant reference signal r, provided that (a) the steady-state gain of the linear part of the system is positive, (b) the reference value r is feasible in an entirely natural sense, and (c) the function $t \mapsto k(t)$ monotonically decreases to zero at a sufficiently slow rate. This result forms the basis of a simple adaptive control strategy that ensures asymptotic tracking under conditions (a) and (b).

Key words. adaptive control, infinite-dimensional regular systems, input nonlinearities, integral control, saturation, robust tracking

1. Introduction.

The paper has, as a precursor, the article [9] which contains an extension, to infinite-dimensional systems with input nonlinearities, of the well-known principle (see, for example, [5], [13], and [17]) that closing the loop around a stable, linear, finite-dimensional, continuous-time, single-input, single-output plant, with transfer function $\mathbf{G}(s)$ compensated by a pure integral controller $\mathbf{C}(s) = k/s$, will result in a stable closed-loop system that achieves asymptotic tracking of arbitrary constant reference signals, provided that $|k|$ is sufficiently small and $\mathbf{G}(0)k > 0$. In particular, in [9] it is shown that the above principle may remain valid if the plant to be controlled is a single-input, single-output, continuous-time, infinite-dimensional, regular (as defined in section 2 below) linear system subject to an input nonlinearity ϕ. More precisely, if ϕ is globally Lipschitz and nondecreasing, if $\mathbf{G}(0) > 0$, and if the constant reference signal r is feasible (in the sense that $[\mathbf{G}(0)]^{-1}r$ is in the closure of the image of ϕ), then there exists $k^* > 0$ such that, $\forall k \in (0, k^*)$, the output $y(t)$ of the closed-loop system (shown in Figure 1) converges to r as $t \to \infty$. Therefore, if a (regular) plant is known to be stable, if the input nonlinearity is of the above class, if $\mathbf{G}(0) \neq 0$, and if the sign of $\mathbf{G}(0)$ is known (in principle, the latter information can be obtained from plant step response data), then the problem of tracking feasible signals r by low-gain integral control reduces to that of tuning the gain parameter k. In a nonadaptive, linear, finite-dimensional context, one such controller design approach ("tuning regulator theory"[5]) has been successfully applied in process control (see, for example, [4] and [14]). Furthermore, the problem of tuning the integrator gain adaptively has been addressed recently in a number of papers: see, for example, [3] and [15], [16] for the finite-dimensional case (with input constraints treated in [15]), and [10], [11], [12] for the linear infinite-dimensional case.

The present paper addresses aspects of adaptive tuning of the integrator gain

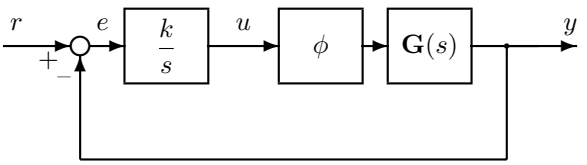

FIG. 1. *Low-gain control with input nonlinearity.*

for infinite-dimensional regular linear systems (with transfer function $\mathbf{G}$), subject to input nonlinearities ϕ of the same class as considered in its precursor [9]. In [9], the constant-gain case is treated; there, the existence of a value $k^* > 0$, with the property that asymptotic tracking of feasible reference signals r is ensured for every *fixed* gain $k \in (0, k^*)$, is established. Let k^{**} denote the supremum of all such k^*. In [9], it is shown that $k^{**} \geq \kappa^*/\lambda$, where $\lambda > 0$ is a Lipschitz constant for ϕ and κ^* denotes the supremum of all numbers $\kappa > 0$ such that

$$1 + \kappa \operatorname{Re} \frac{\mathbf{G}(s)}{s} \geq 0 \quad \forall\ s \text{ with } \operatorname{Re} s > 0.$$

For lower bounds and formulae for κ^* in terms of plant data, we refer to [8]. In general, k^{**} is a function of the plant data and so, in the presence of uncertainty, may fail to be computable. In such cases, it is natural to consider time-dependent gain strategies $t \mapsto k(t) > 0$ capable of attaining sufficiently small values. Theorem 3.8 has the following flavor: if $k(\cdot)$ monotonically decreases to zero *sufficiently slowly*, then asymptotic tracking of feasible reference signals is achieved. The practical utility of this result is limited insofar as the gain function is selected a priori: no use is made of the instantaneous output information $y(t)$ from the plant to update the gain. Utilizing the available output information, Theorem 3.13 establishes the efficacy of the simple adaptive gain strategy

$$k(t) = \frac{1}{l(t)}, \qquad \text{where} \quad \dot{l}(t) = |r - y(t)|,\ \ l(0) = l_0 > 0,$$

and shows that, if the reference signal r is such that $[\mathbf{G}(0)]^{-1} r \in \operatorname{im} \phi$ is not a critical value of ϕ, then the monotone function $t \mapsto k(t) > 0$ converges to a positive limit as $t \to \infty$.

2. Preliminaries on regular linear systems. We assemble some fundamental facts pertaining to regular linear systems and tailored to later requirements; the reader is referred to [20], [21], [22], [23], [24], and [9] for full details. This section is prefaced with the remark that the class of regular linear infinite-dimensional systems is rather general: it includes most distributed parameter systems and all time-delay systems (retarded and neutral) which are of interest in applications. Although there exist abstract examples of well-posed, infinite-dimensional systems that fail to be regular, the authors are of the opinion that any physically motivated, well-posed, linear, continuous-time, autonomous control system is regular.

First, some notation: for a Hilbert space H and any $\tau \geq 0$, $\mathbf{R}_\tau$ denotes the operator of right-shift by τ on $L^p_{\mathrm{loc}}(\mathbb{R}_+, H)$, where $\mathbb{R}_+ := [0, \infty)$; the truncation operator $\mathbf{P}_\tau : L^p_{\mathrm{loc}}(\mathbb{R}_+, H) \to L^p(\mathbb{R}_+, H)$ is given by $(\mathbf{P}_\tau u)(t) = u(t)$ if $t \in [0, \tau]$ and $(\mathbf{P}_\tau u)(t) = 0$ otherwise; for $\alpha \in \mathbb{R}$, we define the exponentially weighted L^p-space $L^p_\alpha(\mathbb{R}_+, H) := \{f \in L^p_{\mathrm{loc}}(\mathbb{R}_+, H) |\ f(\cdot) \exp(-\alpha\, \cdot) \in L^p(\mathbb{R}_+, H)\}$; $\mathcal{B}(H_1, H_2)$ denotes

the space of bounded linear operators from a Hilbert space H_1 to a Hilbert space H_2; for $\alpha \in \mathbb{R}$, $\mathbb{C}_\alpha := \{s \in \mathbb{C} \,|\, \operatorname{Re} s > \alpha\}$; the Laplace transform is denoted by $\mathcal{L}$.

Well-posed systems. The concept of a well-posed linear system was introduced by Weiss [24]. An equivalent definition can be found in [19].

DEFINITION 2.1. *Let U, X, and Y be real Hilbert spaces. A well-posed linear system with state space X, input space U, and output space Y is a quadruple $\boldsymbol{\Sigma} = (\mathbf{T}, \boldsymbol{\Phi}, \boldsymbol{\Psi}, \mathbf{F})$, where $\mathbf{T} = (\mathbf{T}_t)_{t\geq 0}$ is a C_0-semigroup of bounded linear operators on X; $\boldsymbol{\Phi} = (\boldsymbol{\Phi}_t)_{t\geq 0}$ is a family of bounded linear operators from $L^2(\mathbb{R}_+, U)$ to X such that, $\forall\, \tau, t \geq 0$,*

$$\boldsymbol{\Phi}_{\tau+t}(\mathbf{P}_\tau u + \mathbf{R}_\tau v) = \mathbf{T}_t \boldsymbol{\Phi}_\tau u + \boldsymbol{\Phi}_t v \quad \forall\, u, v \in L^2(\mathbb{R}_+, U)\,;$$

$\boldsymbol{\Psi} = (\boldsymbol{\Psi}_t)_{t\geq 0}$ is a family of bounded linear operators from X to $L^2(\mathbb{R}_+, Y)$ such that $\boldsymbol{\Psi}_0 = 0$ and, $\forall\, \tau, t \geq 0$,

$$\boldsymbol{\Psi}_{\tau+t} x_0 = \mathbf{P}_\tau \boldsymbol{\Psi}_\tau x_0 + \mathbf{R}_\tau \boldsymbol{\Psi}_t \mathbf{T}_\tau x_0 \quad \forall\, x_0 \in X;$$

and $\mathbf{F} = (\mathbf{F}_t)_{t\geq 0}$ is a family of bounded linear operators from $L^2(\mathbb{R}_+, U)$ to $L^2(\mathbb{R}_+, Y)$ such that $\mathbf{F}_0 = 0$ and, $\forall\, \tau, t \geq 0$,

$$\mathbf{F}_{\tau+t}(\mathbf{P}_\tau u + \mathbf{R}_\tau v) = \mathbf{P}_\tau \mathbf{F}_\tau u + \mathbf{R}_\tau(\boldsymbol{\Psi}_t \boldsymbol{\Phi}_\tau u + \mathbf{F}_t v) \quad \forall\, u, v \in L^2(\mathbb{R}_+, U).$$

For an input $u \in L^2_{\mathrm{loc}}(\mathbb{R}_+, U)$ and initial state $x_0 \in X$, the associated state function $x \in C(\mathbb{R}_+, X)$ and output function $y \in L^2_{\mathrm{loc}}(\mathbb{R}_+, Y)$ of $\boldsymbol{\Sigma}$ are given by

$$x(t) = \mathbf{T}_t x_0 + \boldsymbol{\Phi}_t \mathbf{P}_t u, \tag{1a}$$

$$\mathbf{P}_t y = \boldsymbol{\Psi}_t x_0 + \mathbf{F}_t \mathbf{P}_t u. \tag{1b}$$

$\boldsymbol{\Sigma}$ is said to be *exponentially stable* if the semigroup $\mathbf{T}$ is exponentially stable:

$$\omega(\mathbf{T}) := \lim_{t\to\infty} \frac{1}{t} \ln \|\mathbf{T}_t\| < 0.$$

$\boldsymbol{\Psi}_\infty$ and $\mathbf{F}_\infty$ will denote the unique operators $X \to L^2_{\mathrm{loc}}(\mathbb{R}_+, Y)$ and $L^2_{\mathrm{loc}}(\mathbb{R}_+, U) \to L^2_{\mathrm{loc}}(\mathbb{R}_+, Y)$, respectively, satisfying

$$\boldsymbol{\Psi}_\tau = \mathbf{P}_\tau \boldsymbol{\Psi}_\infty, \quad \mathbf{F}_\tau = \mathbf{P}_\tau \mathbf{F}_\infty \quad \forall\, \tau \geq 0. \tag{2}$$

If $\boldsymbol{\Sigma}$ is exponentially stable, then the operators $\boldsymbol{\Phi}_t$ and $\boldsymbol{\Psi}_t$ are uniformly bounded; $\boldsymbol{\Psi}_\infty$ is a bounded operator from X into $L^2(\mathbb{R}_+, Y)$, and $\mathbf{F}_\infty$ maps $L^2(\mathbb{R}_+, U)$ boundedly into $L^2(\mathbb{R}_+, Y)$. Since $\mathbf{P}_\tau \mathbf{F}_\infty = \mathbf{P}_\tau \mathbf{F}_\infty \mathbf{P}_\tau\, \forall\, \tau \geq 0$, $\mathbf{F}_\infty$ is a *causal* operator.

Regularity. Weiss [20] has established that, if $\alpha > \omega(\mathbf{T})$ and $u \in L^2_\alpha(\mathbb{R}_+, U)$, then $\mathbf{F}_\infty u \in L^2_\alpha(\mathbb{R}_+, Y)$ and there exists a unique holomorphic $\mathbf{G} : \mathbb{C}_{\omega(\mathbf{T})} \to \mathcal{B}(U, Y)$ such that

$$\mathbf{G}(s)(\mathcal{L}u)(s) = [\mathcal{L}(\mathbf{F}_\infty u)](s) \quad \forall\, s \in \mathbb{C}_\alpha,$$

where $\mathcal{L}$ denotes Laplace transform. In particular, $\mathbf{G}$ is bounded on $\mathbb{C}_\alpha\ \forall\ \alpha > \omega(\mathbf{T})$. The function $\mathbf{G}$ is called the *transfer function* of $\boldsymbol{\Sigma}$.

$\boldsymbol{\Sigma}$ and its transfer function $\mathbf{G}$ are said to be *regular* if there exists a linear operator D such that

$$\lim_{s\to\infty,\, s\in\mathbb{R}} \mathbf{G}(s)u = Du \quad \forall\, u \in U,$$

in which case, by the principle of uniform boundedness, it follows that $D \in \mathcal{B}(U, Y)$. The operator D is called the *feedthrough operator* of $\mathbf{\Sigma}$.

Generating operators. The generator of $\mathbf{T}$ is denoted by A with domain $\mathrm{dom}(A)$. Let X_1 be the space $\mathrm{dom}(A)$ endowed with the graph norm. The norm on X is denoted by $\|\cdot\|$, whilst $\|\cdot\|_1$ denotes the graph norm. Let X_{-1} be the completion of X with respect to the norm $\|x\|_{-1} = \|(\lambda I - A)^{-1}x\|$, where $\lambda \in \varrho(A)$ is any fixed element of the resolvent set $\varrho(A)$ of A. Then $X_1 \subset X \subset X_{-1}$ and the canonical injections are bounded and dense. The semigroup $\mathbf{T}$ can be restricted to a C_0-semigroup on X_1 and extended to a C_0-semigroup on X_{-1}. The exponential growth constant is the same on all three spaces. The generator on X_{-1} is an extension of A to X (which is bounded as an operator from X to X_{-1}). We shall use the same symbol $\mathbf{T}$ (respectively, A) for the original semigroup (respectively, its generator) and the associated restrictions and extensions. With this convention, we may write $A \in \mathcal{B}(X, X_{-1})$. Considered as a generator on X_{-1}, the domain of A is X.

By a representation theorem due to Salamon [19] (see also Weiss [22, 23]), there exist unique operators $B \in \mathcal{B}(U, X_{-1})$ and $C \in \mathcal{B}(X_1, Y)$ (the *control operator* and the *observation operator* of $\mathbf{\Sigma}$, respectively) such that, $\forall\, t \geq 0$, $u \in L^2_{\mathrm{loc}}(\mathbb{R}_+, U)$ and $x_0 \in X_1$,

$$\mathbf{\Phi}_t \mathbf{P}_t u = \int_0^t \mathbf{T}_{t-\tau} B u(\tau)\, d\tau \quad \text{and} \quad (\mathbf{\Psi}_\infty x_0)(\mathrm{t}) = C\mathbf{T}_{\mathrm{t}} x_0.$$

B is said to be *bounded* if it is so as a map from the input space U to the state space X; otherwise, B is said to be *unbounded*. C is said to be *bounded* if it can be extended continuously to X; otherwise, C is said to be *unbounded*. If $\mathbf{T}$ is exponentially stable, then there exist constants β, $\gamma > 0$ such that, $\forall\, t \geq 0$, $u \in L^2(\mathbb{R}_+, U)$, and $x_0 \in X_1$,

$$\|\mathbf{\Phi}_t \mathbf{P}_t u\| = \left\| \int_0^t \mathbf{T}_{t-\tau} B u(\tau)\, d\tau \right\| \leq \beta \|u\|_{L^2(0,t;U)}, \tag{3}$$

$$\|\mathbf{\Psi}_\infty x_0\|_{L^2(0,t;Y)} = \left(\int_0^t \|C\mathbf{T}_\tau x_0\|^2 d\tau \right)^{1/2} \leq \gamma \|x_0\|, \tag{4}$$

wherein, with slight abuse of notation, we write $\|u\|_{L^2(0,t;U)}$ and $\|\mathbf{\Psi}_\infty x_0\|_{L^2(0,t;Y)}$ to denote $\|\mathbf{P}_t u\|_{L^2(\mathbb{R}_+;U)}$ and $\|\mathbf{P}_t \mathbf{\Psi}_\infty x_0\|_{L^2(\mathbb{R}_+;U)}$, respectively. The *Lebesgue extension* of C was adopted in [23] and is defined by

$$C_L x_0 = \lim_{t \to 0} C \frac{1}{t} \int_0^t \mathbf{T}_\tau x_0\, d\tau,$$

where $\mathrm{dom}(C_L)$ is the set of all those $x_0 \in X$ for which the above limit exists. Clearly $X_1 \subset \mathrm{dom}(C_L) \subset X$. Furthermore, for any $x_0 \in X$, we have that $\mathbf{T}_t x_0 \in \mathrm{dom}(C_L)$ for almost all (a.a.) $t \geq 0$ and

$$(\mathbf{\Psi}_\infty x_0)(t) = C_L \mathbf{T}_t x_0 \quad \text{a.a. } t \geq 0. \tag{5}$$

If $\mathbf{\Sigma}$ is regular, then for any $x_0 \in X$ and $u \in L^2_{\mathrm{loc}}(\mathbb{R}_+, U)$, the functions $x(\cdot)$ and $y(\cdot)$, defined by (1a), satisfy the equations

$$\dot{x}(t) = Ax(t) + Bu(t), \quad x(0) = x_0, \tag{6a}$$

$$y(t) = C_L x(t) + Du(t) \tag{6b}$$

for a.a. $t \geq 0$ (in particular $x(t) \in \mathrm{dom}(C_L)$ for a.a. $t \geq 0$). The derivative on the left-hand side of (6a) has, of course, to be understood in X_{-1}. In other words, if we consider the initial-value problem (6a) in the space X_{-1}, then for any $x_0 \in X$ and $u \in L^2_{\mathrm{loc}}(\mathbb{R}_+, U)$, (6a) has unique strong solution (in the sense of Pazy [18, p. 109]) given by the variation of parameters formula

$$t \mapsto x(t) = \mathbf{T}_t x_0 + \int_0^t \mathbf{T}_{t-\tau} B u(\tau)\, d\tau. \tag{7}$$

It has been demonstrated in [20] that if $\mathbf{\Sigma}$ is regular, then $(sI - A)^{-1}BU \subset \mathrm{dom}(C_L)$ $\forall\, s \in \varrho(A)$, and the transfer function $\mathbf{G}$ can be expressed as

$$\mathbf{G}(s) = C_L(sI - A)^{-1}B + D \qquad \forall\, s \in \mathbb{C}_{\omega(\mathbf{T})},$$

which is familiar from finite-dimensional systems theory. The operators A, B, C, and D are called the *generating operators* of $\mathbf{\Sigma}$.

Two technical lemmas. In essence, part (a) of the following lemma provides an estimate, in the $L^2(\mathbb{R}_+, X)$ topology, for the solution of the initial-value problem (6a) with initial data $x_0 \in X$ and input $u \in L^2(\mathbb{R}_+, U)$, part (b) asserts that the solution is in $L^\infty(\mathbb{R}_+, X)$ whenever $x_0 \in X$ and $u \in L^\infty(\mathbb{R}_+, U)$, whilst part (c) establishes that the initial-value problem, again with initial data $x_0 \in X$, has a convergent-input, convergent-state property. Parts (a) and (c) constitute Lemma 2.2 of [9]; proof of part (b) is implicit in the argument establishing Lemma 2.2 of [9].

LEMMA 2.2. *Let (A, B, C, D) be the generating operators of an exponentially stable regular system $\mathbf{\Sigma} = (\mathbf{T}, \mathbf{\Phi}, \mathbf{\Psi}, \mathbf{F})$.*

(a) *There exist constants $\alpha_0, \alpha_1 > 0$ such that $\forall\, (x_0, u) \in X \times L^2(\mathbb{R}_+, U)$, the solution $x(\cdot)$ of the initial-value problem* (6a) *satisfies*

$$\|x\|_{L^2(\mathbb{R}_+, X)} \leq \alpha_0 \|x_0\| + \alpha_1 \|u\|_{L^2(\mathbb{R}_+, U)}.$$

(b) *$\forall\, (x_0, u) \in X \times L^\infty(\mathbb{R}_+, U)$, the solution $x(\cdot)$ of the initial-value problem* (6a) *satisfies*

$$x \in L^\infty(\mathbb{R}_+, X).$$

(c) *If $u \in L^\infty(\mathbb{R}_+, U)$ and $\lim_{t\to\infty} u(t) = u_\infty$ exists, then, $\forall\, x_0 \in X$, the solution $x(\cdot)$ of the initial-value problem* (6a) *satisfies*

$$\lim_{t\to\infty} \|x(t) + A^{-1}Bu_\infty\| = 0.$$

The next lemma shows that, for finite-dimensional U and Y, the impulse response of an exponentially stable regular system with bounded B (or bounded C) is the sum of a weighted L^1-function and a point mass at 0.

LEMMA 2.3. *Let (A, B, C, D) be the generating operators of an exponentially stable regular system $\mathbf{\Sigma} = (\mathbf{T}, \mathbf{\Phi}, \mathbf{\Psi}, \mathbf{F})$. Assume that either B or C is bounded.*

(a) *There exists $\alpha < 0$ such that, $\forall\, u \in U$,*

$$\mathcal{L}^{-1}(\mathbf{G}(\cdot)u - Du) \in L^1_\alpha(\mathbb{R}_+, Y).$$

(b) *If $U = \mathbb{R}^m$ and $Y = \mathbb{R}^p$, then*

$$\mathcal{L}^{-1}(\mathbf{G}) \in L^1_\alpha(\mathbb{R}_+, \mathbb{R}^{p\times m}) + (\mathbb{R}^{p\times m})\, \delta_0,$$

where δ_0 denotes the unit point mass at 0.

Proof. Suppose that B is bounded, and set $\mathbf{G}_0(s) := \mathbf{G}(s) - D = C(sI - A)^{-1}B$. Fix $u \in U$ and choose $(b_n) \subset X_1$ such that $\lim_{n\to\infty} \|Bu - b_n\| = 0$ (such a sequence exists by denseness of X_1 in X). Consequently, $\mathbf{\Psi}_\infty Bu$, $\mathbf{\Psi}_\infty b_n \in L^2(\mathbb{R}_+, Y)$, and

$$\lim_{n\to\infty} \|\mathbf{\Psi}_\infty Bu - \mathbf{\Psi}_\infty b_n\|_{L^2(\mathbb{R}_+,Y)} = 0.$$

Hence, $\forall\ s \in \mathbb{C}_0$,

$$\mathbf{G}_0(s)u = \lim_{n\to\infty} C(sI - A)^{-1}b_n = \lim_{n\to\infty} \int_0^\infty (\mathbf{\Psi}_\infty b_n)(t)e^{-st}\,dt = [\mathcal{L}(\mathbf{\Psi}_\infty Bu)](s).$$

Note that, by exponential stability, $\mathbf{\Psi}_\infty Bu \in L^2_\beta(\mathbb{R}_+, Y)$ for some $\beta < 0$, and hence $\mathbf{\Psi}_\infty Bu \in L^1_\alpha(\mathbb{R}_+, Y)\ \forall\ \alpha \in (\beta, 0)$, which yields part (a) in the case of bounded B. This result together with the duality between admissible control and observation operators (see [23]) yields part (a) in the case of bounded C. Part (b) is an immediate consequence of part (a). ∎

3. Integral control of regular systems with input nonlinearities. The problem of tracking constant reference signals r will be addressed in a context of uncertain single-input ($u(t) \in \mathbb{R}$), single-output ($y(t) \in \mathbb{R}$) linear systems, having a nonlinearity ϕ in the input channel:

$$\begin{aligned} \dot{x}(t) &= Ax(t) + B\phi(u(t)), \quad x(0) = x_0 \in X, \\ y(t) &= C_L x(t) + D\phi(u(t)). \end{aligned} \tag{8}$$

We consider quadruples (A, B, C, D), with C having Lebesgue extension C_L, of class $\mathcal{R}$ defined below.

DEFINITION 3.1. *Let $\mathcal{R}$ denote the class of quadruples (A, B, C, D) which are the generating operators of a regular linear system $\mathbf{\Sigma}$, with state space X, input space $\mathbb{R}$, output space $\mathbb{R}$, and transfer function $\mathbf{G}$, satisfying*

$$\text{(a)}\quad \mathbf{\Sigma} \text{ is exponentially stable}; \qquad \text{(b)}\quad \mathbf{G}(0) > 0.$$

The following property of $\mathcal{R}$ is readily verified.

PROPOSITION 3.2. *If $(A, B, C, D) \in \mathcal{R}$, then $(A + \varepsilon I, B, C, D) \in \mathcal{R}\ \ \forall \varepsilon > 0$ sufficiently small.*

Admissible input nonlinearities are those functions ϕ of class $\mathcal{N}$ defined below.

DEFINITION 3.3. *Let $\mathcal{N}$ be the class of functions $\phi : \mathbb{R} \to \mathbb{R}$ with the properties* (a) *ϕ is monotone nondecreasing;* (b) *ϕ satisfies a global Lipschitz condition (with Lipschitz constant λ), that is, for some λ, $|\phi(u) - \phi(v)| \le \lambda|u - v|\,\forall\, u, v \in \mathbb{R}$.*

As an example of $\phi \in \mathcal{N}$, consider the input nonlinearity in Figure 2 below.

Let $(\varepsilon_n) \subset (0, \infty)$ be a sequence with $\varepsilon_n \downarrow 0$ as $n \to \infty$. For each $\phi \in \mathcal{N}$, define $\phi^\diamond : \mathbb{R} \to \mathbb{R}$ by

$$\phi^\diamond(\xi) = \limsup_{n\to\infty} \frac{\phi(\xi + \varepsilon_n) - \phi(\xi)}{\varepsilon_n}.$$

Note that $0 \le \phi^\diamond(\xi) \le \lambda\ \ \forall\ \xi \in \mathbb{R}$, where λ is a Lipschitz constant for ϕ. Moreover, as the (pointwise) upper limit of a sequence of continuous functions, $\phi^\diamond$ is Borel measurable, and so its composition $\phi^\diamond \circ u$ with a Lebesgue measurable function u is Lebesgue measurable; furthermore, by the same argument as used in proving Lemma 3.5 of [9], a chain rule applies to such compositions, which we now record.

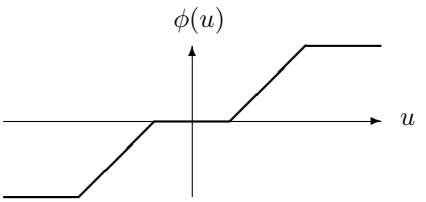

FIG. 2. *Nonlinearity with saturation and dead zone.*

PROPOSITION 3.4. *Let $\phi \in \mathcal{N}$ and let $u : \mathbb{R}_+ \to \mathbb{R}$ be absolutely continuous. Then, $\phi \circ u$ is absolutely continuous and*

$$(\phi \circ u)'(t) = \phi^\diamond(u(t))\dot{u}(t) \quad \text{for a.a. } t \in \mathbb{R}_+.$$

The Clarke [2] directional derivative $\phi^o(u; v)$ of $\phi \in \mathcal{N}$ at u in direction v is given by

$$\limsup_{\substack{w \to u \\ h \downarrow 0}} \frac{\phi(w + hv) - \phi(w)}{h}.$$

Define $\phi^-(\cdot) := -\phi^o(\cdot; -1)$. By upper semicontinuity of ϕ^o, ϕ^- is lower semicontinuous. By definition of $\phi^\diamond$ and monotonicity of $\phi \in \mathcal{N}$ (with Lipschitz constant λ), we have

$$0 \le \phi^-(u) \le \phi^\diamond(u) \le \lambda \quad \forall\, u. \tag{9}$$

$u \in \mathbb{R}$ is said to be a *critical point* (and $\phi(u)$ is said to be a *critical value*) of ϕ if $\phi^-(u) = 0$.

3.1. Integral control with time-varying gain. Let $(A, B, C, D) \in \mathcal{R}$, $\phi \in \mathcal{N}$, and $k \in L^\infty(\mathbb{R}_+, \mathbb{R})$. We denote, by $r \in \mathbb{R}$, the value of the constant reference signal to be tracked by the output $y(t)$. In Proposition 3.6 of [9], it is shown that the following condition is necessary for solvability of the tracking problem: $[\mathbf{G}(0)]^{-1} r \in \operatorname{clos}(\operatorname{im} \phi)$. Reference values r satisfying this condition are referred to as *feasible*.

We will investigate integral control action

$$u(t) = u_0 + \int_0^t k(\tau)[r - C_L x(\tau) - D\phi(u(\tau))]\, d\tau,$$

with time-varying gain $k(\cdot)$, leading to the following nonlinear system of differential equations:

$$\dot{x}(t) = Ax(t) + B\phi(u(t)), \quad x(0) = x_0 \in X, \tag{10a}$$

$$\dot{u}(t) = k(t)[r - C_L x(t) - D\phi(u(t))], \quad u(0) = u_0 \in \mathbb{R}. \tag{10b}$$

For $a \in (0, \infty]$, a continuous function

$$[0, a) \to X \times \mathbb{R}, \quad t \mapsto (x(t), u(t))$$

is a *solution* of (10) if $(x(\cdot), u(\cdot))$ is absolutely continuous as a $(X_{-1} \times \mathbb{R})$-valued function, $x(t) \in \operatorname{dom}(C_L)$ for a.a. $t \in [0, a)$, $(x(0), u(0)) = (x_0, u_0)$, and the differential

equations in (10) are satisfied almost everywhere (a.e.) on $[0, a)$, where the derivative in (10a) should be interpreted in the space X_{-1}.[1]

An application of a well-known result on abstract Cauchy problems (see Pazy [18, Theorem 2.4, p. 107]) shows that a continuous $(X \times \mathbb{R})$-valued function $(x(\cdot), u(\cdot))$ is a solution of (10) if and only if it satisfies the following integrated version of (10):

$$x(t) = \mathbf{T}_t x_0 + \int_0^t \mathbf{T}_{t-\tau} B\phi(u(\tau))\, d\tau, \tag{11a}$$

$$u(t) = u_0 + \int_0^t k(\tau)[r - C_L x(\tau) - D\phi(u(\tau))]\, d\tau. \tag{11b}$$

The next result asserts that (10) has a unique solution: the proof is contained in the appendix.

LEMMA 3.5. *Let $(A, B, C, D) \in \mathcal{R}$, $\phi \in \mathcal{N}$, $k \in L^\infty(\mathbb{R}_+)$, and $r \in \mathbb{R}$. For each $(x_0, u_0) \in X \times \mathbb{R}$, there exists a unique solution $(x(\cdot), u(\cdot))$ of (10) defined on $\mathbb{R}_+$.*

In [9], the constant-gain case is considered in the context of systems $(A, B, C, D) \in \mathcal{R}$ with input nonlinearities $\phi \in \mathcal{N}$: there, the existence of a value $k^* > 0$, with the property that asymptotic tracking of feasible reference signals r is ensured for all fixed gains $k \in (0, k^*)$, is established. However, k^* is, in general, a function of the plant data and so, in the presence of plant uncertainty, may fail to be computable in practice. In such circumstances, one might be led naïvely to consider a time-dependent gain strategy $t \mapsto k(t) > 0$ with $k(t)$ approaching zero as t tends to infinity.

The main result of this section is contained in the following two theorems which confirm the validity of the above naïvety provided that the gain approaches zero sufficiently slowly. In particular, Theorem 3.6 proves that if $t \mapsto k(t) > 0$ is chosen to be bounded and monotone decreasing to zero, then the unique solution of (10) is such that both $x(\cdot)$ and $\phi(u(\cdot))$ converge. The essence of Theorem 3.8 is the assertion that if, in addition, r is feasible and $k(\cdot)$ approaches zero sufficiently slowly, then $\phi(u(\cdot))$ converges to the value $\phi_r := [\mathbf{G}(0)]^{-1} r$, thereby ensuring asymptotic tracking of r.

THEOREM 3.6. *Let $(A, B, C, D) \in \mathcal{R}$, $\phi \in \mathcal{N}$, and $r \in \mathbb{R}$. Let $k : \mathbb{R}_+ \to (0, \infty)$ be a bounded, monotone function with $k(t) \downarrow 0$ as $t \to \infty$. $\forall\ (x_0, u_0) \in X \times \mathbb{R}$, the unique solution $(x(\cdot), u(\cdot))$ of (10) satisfies*

(a) $\lim_{t\to\infty} \phi(u(t))$ *exists and is finite, and*
(b) $\lim_{t\to\infty} \|x(t) + A^{-1} B\phi^*\| = 0$, *where* $\phi^* := \lim_{t\to\infty} \phi(u(t))$.

Proof. Let $(x_0, u_0) \in X \times \mathbb{R}$ be arbitrary. Let λ be a Lipschitz constant for $\phi \in \mathcal{N}$ (and so $0 \le \phi^\diamond(u) \le \lambda \ \ \forall\ u \in \mathbb{R}$). By Lemma 3.5, there exists a unique solution of (10) on $\mathbb{R}_+$. We denote this solution by $(x(\cdot), u(\cdot))$ and introduce new variables by writing $\phi_r = [\mathbf{G}(0)]^{-1} r$ and defining

$$z(t) := x(t) + A^{-1} B\phi(u(t)), \quad v(t) := \phi(u(t)) - \phi_r \quad \forall\ t \in \mathbb{R}_+. \tag{12}$$

By regularity, it follows that $z(t) \in \mathrm{dom}(C_L)$ for a.a. $t \in \mathbb{R}_+$. Moreover, by Proposition 3.4, $\dot{v}(t) = \phi^\diamond(u(t))\dot{u}(t)$ for a.a. $t \in \mathbb{R}_+$. Since (z, v) is absolutely continuous as

[1] Being a Hilbert space, $X_{-1} \times \mathbb{R}$ is reflexive, and hence any absolutely continuous $(X_{-1} \times \mathbb{R})$-valued function is a.e. differentiable and can be recovered from its derivative by integration; see [1, Theorem 3.1, p. 10].

an $(X_{-1} \times \mathbb{R})$-valued function, we obtain by direct calculation

$$\dot{z} = Az - k\phi^\diamond(u)A^{-1}B(C_L z + \mathbf{G}(0)v), \tag{13a}$$
$$z(0) = x_0 + A^{-1}B\phi(u_0),$$
$$\dot{v} = -k\phi^\diamond(u)(C_L z + \mathbf{G}(0)v), \tag{13b}$$
$$v(0) = \phi(u_0) - \phi_r.$$

We claim that there exist positive constants γ_1, γ_2, and σ_1 such that, $\forall\ t, s$ with $\sigma_1 \le s \le t$,

$$\int_s^t |C_L z|\,|k\phi^\diamond(u)v| \le \gamma_1 \|z(s)\| \left(\int_s^t k^2\phi^\diamond(u)v^2\right)^{1/2} + \gamma_2 \int_s^t k^2\phi^\diamond(u)v^2. \tag{14}$$

In order to prove (14), let us first estimate $\int_s^t |C_L z|^2$. For notational convenience, write $w = \phi^\diamond(u)\,[C_L z + \mathbf{G}(0)v]$. As a solution of (13$a$), $z(\cdot)$ satisfies

$$z(\tau) = \mathbf{T}_{\tau - s}z(s) - A^{-1}\int_s^\tau \mathbf{T}_{\tau-\xi}Bk(\xi)w(\xi)\,d\xi$$

$\forall\ s$ with $0 \le s \le \tau$. Invoking (4) and (5) and noting that $C_L A^{-1}$ maps X boundedly into $\mathbb{R}$, there exist constants $\alpha_0, \alpha_1 > 0$ such that

$$\int_s^t |C_L z(\tau)|^2 d\tau \le \alpha_0 \|z(s)\|^2 + \alpha_1 \int_s^t \left\| \int_s^\tau \mathbf{T}_{\tau-\xi}Bk(\xi)w(\xi)d\xi \right\|^2 d\tau \tag{15}$$

$\forall\, 0 \le s \le t$. By Lemma 2.2 (part (a)), interpreted in the context of the initial-value problem

$$\dot{\zeta} = A\zeta + Bkw, \quad \zeta(s) = 0,$$

we have

$$\left(\int_s^t \left\| \int_s^\tau \mathbf{T}_{\tau-\xi}Bk(\xi)w(\xi)d\xi \right\|^2 d\tau\right)^{1/2} \le \alpha_2 \left(\int_s^t |kw|^2\right)^{1/2}$$

for some constant α_2. Therefore, by (15) and monotonicity of k, it follows that, for some constants $\alpha_3, \alpha_4 > 0$,

$$\left(\int_s^t |C_L z|^2\right)^{1/2} \le \alpha_3\|z(s)\| + k(s)\alpha_4 \left(\int_s^t |\phi^\diamond(u)|^2 |C_L z|^2\right)^{1/2}$$
$$+ \alpha_4 \mathbf{G}(0) \left(\int_s^t |k\phi^\diamond(u)v|^2\right)^{1/2} \quad \forall\ 0 \le s \le t. \tag{16}$$

Fix $\sigma_1 > 0$ such that $\delta := k(\sigma_1)\alpha_4\lambda < 1$. Then,

$$k(s)\alpha_4 \left(\int_s^t |\phi^\diamond(u)|^2 |C_L z|^2\right)^{1/2} \le \delta \left(\int_s^t |C_L z|^2\right)^{1/2} \quad \forall\ \sigma_1 \le s \le t,$$

and so, by (16),

$$\left(\int_s^t |C_L z|^2\right)^{1/2} \le \beta_1\|z(s)\| + \beta_2 \left(\int_s^t k^2\phi^\diamond(u)v^2\right)^{1/2} \quad \forall\ \sigma_1 \le s \le t, \tag{17}$$

with $\beta_1 = \alpha_3/(1-\delta)$ and $\beta_2 = \alpha_4 \mathbf{G}(0)\sqrt{\lambda}/(1-\delta)$. We may now deduce that, $\forall\ t, s$ with $\sigma_1 \le s \le t$,

$$\int_s^t |C_L z|\,|k\phi^\diamond(u)v| \le \left(\int_s^t |C_L z|^2\right)^{1/2} \left(\int_s^t |k\phi^\diamond(u)v|^2\right)^{1/2}$$
$$\le \beta_1\sqrt{\lambda}\|z(s)\| \left(\int_s^t k^2\phi^\diamond(u)v^2\right)^{1/2} + \beta_2\sqrt{\lambda}\int_s^t k^2\phi^\diamond(u)v^2,$$

which is (14) with $\gamma_1 = \beta_1\sqrt{\lambda}$ and $\gamma_2 = \beta_2\sqrt{\lambda}$. By (13b), for a.a. $t \ge 0$,

$$v(t)\dot{v}(t) = -k(t)\mathbf{G}(0)\phi^\diamond(u(t))v^2(t) - k(t)\phi^\diamond(u(t))v(t)C_L z(t), \tag{18}$$

and hence

$$v(t)\dot{v}(t) \le -k(t)\mathbf{G}(0)\phi^\diamond(u(t))v^2(t) + |C_L z(t)|\,|k(t)\phi^\diamond(u(t))v(t)|.$$

Integrating this inequality and using (14) and monotonicity of k yields, $\forall\ t, s$ with $\sigma_1 \le s \le t$,

$$v^2(t) \le v^2(s) + 2\gamma_1\sqrt{k(s)}\|z(s)\| \left(\int_s^t k\phi^\diamond(u)v^2\right)^{1/2}$$
$$+ 2\int_s^t (k\gamma_2 - \mathbf{G}(0))k\phi^\diamond(u)v^2. \tag{19}$$

By positivity of $\mathbf{G}(0)$ and monotonicity of $k(\cdot)$, there exists $\sigma \ge \sigma_1$ such that, $\forall\,\tau \ge \sigma$, $(k(\tau)\gamma_2 - \mathbf{G}(0)) \le -\frac{1}{2}\mathbf{G}(0) < 0$. Therefore, it follows from (19) that

$$0 \le v^2(\sigma) + 2\gamma_1\sqrt{k(\sigma)}\|z(\sigma)\| \left(\int_\sigma^t k\phi^\diamond(u)v^2\right)^{1/2} - \mathbf{G}(0)\int_\sigma^t k\phi^\diamond(u)v^2 \quad \forall\, t \ge \sigma,$$

and so

$$\int_\sigma^\infty k\phi^\diamond(u)v^2 < \infty. \tag{20}$$

Moreover, by (14) we deduce that

$$\int_\sigma^\infty |C_L z|\,|k\phi^\diamond(u)v| < \infty. \tag{21}$$

Combining (18), (20), and (21) shows that there exists a number $\nu \in \mathbb{R}_+$ such that

$$\lim_{t\to\infty} v^2(t) = v^2(\sigma) + 2\lim_{t\to\infty}\int_\sigma^t v\dot{v} = \nu,$$

whence assertion (a) of the theorem. Assertion (b) now follows by Lemma 2.2 (part (c)). ∎

Let $\mathcal{M}$ denote the space of finite signed Borel measures on $\mathbb{R}_+$.

LEMMA 3.7. *Let $(A, B, C, D) \in \mathcal{R}$, $\phi \in \mathcal{N}$, and $(x_0, u_0) \in X \times \mathbb{R}$. Assume that $\mathcal{L}^{-1}(\mathbf{G}) \in \mathcal{M}$. Let $k : \mathbb{R}_+ \to (0,\infty)$ be bounded and such that $\int_0^t k =: K(t) \to \infty$ as $t \to \infty$. Let $r \in \mathbb{R}$ be feasible, that is, $\phi_r := [\mathbf{G}(0)]^{-1}r \in \operatorname{clos}(\operatorname{im}\phi)$. Let $(x(\cdot), u(\cdot)) : \mathbb{R}_+ \to X \times \mathbb{R}$ be the unique solution of* (10).

If $\lim_{t\to\infty}\phi(u(t))$ exists and is finite, then the following statements hold:

(a) $\lim_{t\to\infty}\phi(u(t))=\phi_r$,
(b) $\lim_{t\to\infty}\|x(t)+A^{-1}B\phi_r\|=0$,
(c) $\lim_{t\to\infty}[r-y(t)+(\mathbf{\Psi}_\infty x_0)(t)]=0$, *where* $y(t)=C_Lx(t)+D\phi(u(t))$,
(d) *if* $\phi_r\in\operatorname{im}\phi$, *then* $\lim_{t\to\infty}\operatorname{dist}(u(t),\phi^{-1}(\phi_r))=0$, *and*
(e) *if* $\phi_r\in\operatorname{int}(\operatorname{im}\phi)$, *then* $u(\cdot)$ *is bounded.*

Proof. By hypothesis, there exists $\phi^*\in\mathbb{R}$ such that $\lim_{t\to\infty}\phi(u(t))=\phi^*$. The essence of the proof is to show that $\phi^*=\phi_r$. Setting

$$y_0(t)=(\mathbf{\Psi}_\infty)(x_0)(t),\quad y_1(t)=(\mathcal{L}^{-1}(\mathbf{G})\star\phi(u))(t),$$

we have

$$\dot u(t)=k(t)[\mathbf{G}(0)(\phi_r-\phi^*)-y_0(t)-(y_1(t)-\mathbf{G}(0)\phi^*)].$$

Seeking a contradiction, suppose that $|\phi_r-\phi^*|\neq 0$. Since $\lim_{t\to\infty}\phi(u(t))=\phi^*$ and $\mathcal{L}^{-1}(\mathbf{G})\in\mathcal{M}$, it follows that $\lim_{t\to\infty}y_1(t)=\mathbf{G}(0)\phi^*$ (see [7, Theorem 6.1, part (ii), p. 96]). Let $s>0$ be such that

$$|y_1(t)-\mathbf{G}(0)\phi^*|\le\tfrac12\mathbf{G}(0)|\phi_r-\phi^*|\quad\forall\ t\ge s.$$

As a consequence we obtain

$$\begin{aligned}-\tfrac12k(t)\mathbf{G}(0)|\phi_r-\phi^*|-k(t)|y_0(t)|&\le\dot u(t)-k(t)\mathbf{G}(0)(\phi_r-\phi^*)\\&\le\tfrac12k(t)\mathbf{G}(0)|\phi_r-\phi^*|+k(t)|y_0(t)|\quad\forall\ t\ge s.\end{aligned}\tag{22}$$

Since $\phi_r\neq\phi^*$, either $\phi_r>\phi^*$ or $\phi_r<\phi^*$. If $\phi_r>\phi^*$, then

$$\tfrac12k(t)\mathbf{G}(0)(\phi_r-\phi^*)-k(t)|y_0(t)|\le\dot u(t)\quad\forall\ t\ge s,$$

which, on integration, yields

$$\tfrac12\mathbf{G}(0)(K(t)-K(s))(\phi_r-\phi^*)-\int_s^t k(\tau)|y_0(\tau)|d\tau\le u(t)-u(s)\quad\forall\ t\ge s.$$

By exponential stability, $y_0\in L^2_\alpha(\mathbb{R}_+,\mathbb{R})$ for some $\alpha<0$, and thus $y_0\in L^1(\mathbb{R}_+,\mathbb{R})$, which in turn implies that $ky_0\in L^1(\mathbb{R}_+,\mathbb{R})$. Since $K(t)\to\infty$ as $t\to\infty$, we conclude that $u(t)\to\infty$ as $t\to\infty$, whence the contradiction

$$\phi_r\le\sup\phi=\lim_{t\to\infty}\phi(u(t))=\phi^*<\phi_r.$$

If $\phi_r<\phi^*$, then

$$\dot u(t)\le k(t)|y_0(t)|-\tfrac12k(t)\mathbf{G}(0)|\phi_r-\phi^*|\quad\forall\ t\ge s,$$

which, on integration, yields $u(t)\to-\infty$ as $t\to\infty$ and the contradiction

$$\phi_r<\phi^*=\lim_{t\to\infty}\phi(u(t))=\inf\phi\le\phi_r.$$

Therefore, we may conclude that $\lim_{t\to\infty}\phi(u(t))=\phi_r$, which is assertion (a). Assertion (b) follows from Lemma 2.2, part (c); assertion (c) is a consequence of assertion (a), together with the identity

$$r-y(t)+(\mathbf{\Psi}_\infty x_0)(t)=\mathbf{G}(0)\phi_r-(\mathcal{L}^{-1}(\mathbf{G})\star\phi(u))(t),$$

and the fact that $\lim_{t\to\infty}(\mathcal{L}^{-1}(\mathbf{G}) \star \phi(u))(t) = \mathbf{G}(0)\phi_r$.

To prove assertion (d), let $\phi_r \in \operatorname{im}\phi$ and suppose that the claim is false. Then there exists a sequence $(t_n) \subset \mathbb{R}_+$ with $\lim_{n\to\infty} t_n = \infty$ and $\varepsilon > 0$ such that

$$\operatorname{dist}(u(t_n), \phi^{-1}(\phi_r)) \geq \varepsilon \quad \forall\ n. \tag{23}$$

If the sequence $(u(t_n))$ is bounded, we may assume without loss of generality that it converges to a finite limit u_∞. By continuity of ϕ and assertion (a), we have that $\phi(u_\infty) = \phi_r$, and thus $u_\infty \in \phi^{-1}(\phi_r)$. This contradicts (23). So, suppose that $(u(t_n))$ is unbounded. Without loss of generality, we may then assume that $\lim_{n\to\infty} u(t_n) = \infty$. By monotonicity and assertion (a), it follows that $\phi_r = \sup\phi$. Since $\phi_r \in \operatorname{im}\phi$, there exists ξ^* such that $\phi(\xi^*) = \phi_r = \sup\phi = \max\phi$. By monotonicity of ϕ, $\phi(\xi) = \phi_r = \max\phi \ \ \forall\ \xi \geq \xi^*$. In particular, we see that $u(t_n) \in \phi^{-1}(\phi_r)$ for all sufficiently large n, which contradicts (23).

Now, assume that $\phi_r \in \operatorname{int}(\operatorname{im}\phi)$ and, for contradiction, suppose that assertion (e) is false. Then there exists a sequence $(t_n) \subset (0,\infty)$ with $t_n \to \infty$ and $|u(t_n)| \to \infty$ as $n \to \infty$. Without loss of generality, we may assume that $\lim_{n\to\infty} u(t_n) = \infty$. By monotonicity, it then follows that $\phi_r = \lim_{n\to\infty}\phi(u(t_n)) = \sup\phi$, contradicting the assumption that $\phi_r \in \operatorname{int}(\operatorname{im}\phi)$. □

For $\alpha \in \mathbb{R}$, we define the exponentially weighted space $\mathcal{M}_\alpha$ as the set of all locally finite signed Borel measures μ on $\mathbb{R}_+$ (see, e.g., [6]) with the property that the weighted measure $E \mapsto \int_E e^{-\alpha t}\mu(dt)$ belongs to $\mathcal{M}$.

THEOREM 3.8. *Let $(A,B,C,D) \in \mathcal{R}$, $\phi \in \mathcal{N}$, and $(x_0,u_0) \in X \times \mathbb{R}$. Assume that $\mathcal{L}^{-1}(\mathbf{G}) \in \mathcal{M}$. Let $k : \mathbb{R}_+ \to (0,\infty)$ be bounded, monotone, and such that $k(t) \downarrow 0$ and $\int_0^t k =: K(t) \to \infty$ as $t \to \infty$. Let $r \in \mathbb{R}$ be feasible, that is, $\phi_r := [\mathbf{G}(0)]^{-1}r \in \operatorname{clos}(\operatorname{im}\phi)$.*

The unique solution $(x(\cdot),u(\cdot)) : \mathbb{R}_+ \to X \times \mathbb{R}$ of (10) satisfies

(a) $\lim_{t\to\infty}\phi(u(t)) = \phi_r$,

(b) $\lim_{t\to\infty}\|x(t) + A^{-1}B\phi_r\| = 0$,

(c) $\lim_{t\to\infty}[r - y(t) + (\mathbf{\Psi}_\infty x_0)(t)] = 0$, *where* $y(t) = C_L x(t) + D\phi(u(t))$,

(d) *if* $\phi_r \in \operatorname{im}\phi$, *then* $\lim_{t\to\infty}\operatorname{dist}(u(t),\phi^{-1}(\phi_r)) = 0$,

(e) *if* $\phi_r \in \operatorname{int}(\operatorname{im}\phi)$, *then $u(\cdot)$ is bounded, and*

(f) *if* $\phi_r \in \operatorname{im}\phi$ *is not a critical value of ϕ, then the convergence in* (a) *and* (b) *is of order* $\exp(-\rho K(t))$ *for some $\rho > 0$; moreover, the convergence in* (c) *is of the same order, provided that* $\mathcal{L}^{-1}(\mathbf{G}) \in \mathcal{M}_\alpha$ *for some $\alpha < 0$.*

REMARK 3.9. (i) *The assumption that* $\mathcal{L}^{-1}(\mathbf{G}) \in \mathcal{M}$ *(or that* $\mathcal{L}^{-1}(\mathbf{G}) \in \mathcal{M}_\alpha$ *for some $\alpha < 0$) is not very restrictive and seems to be satisfied in all practical examples of exponentially stable systems. In particular, this assumption is satisfied if B or C is bounded (see Lemma* 2.3*).*

(ii) *Since* $(\mathbf{\Psi}_\infty x_0)(t)$ *converges exponentially to* 0 *as* $t \to \infty\ \forall\ x_0 \in X_1 = \operatorname{dom}(A)$, *it follows from* (c) *that the error* $e(t) = r - y(t)$ *converges to* 0 $\forall\ x_0 \in \operatorname{dom}(A)$. *(Moreover, the convergence is of order* $\exp(-\rho K(t))$ *if the extra assumptions in* (f) *are satisfied.) If C is bounded, then this statement is true $\forall\ x_0 \in X$. If C is unbounded and* $x_0 \notin \operatorname{dom}(A)$, *then $e(t)$ does not necessarily converge to* 0 *as* $t \to \infty$. *However, $e(t)$ is small for large t in the sense that $e(t) = e_1(t) + e_2(t)$, where the function e_1 is bounded with* $\lim_{t\to\infty} e_1(t) = 0$ *and* $e_2 \in L^2_\alpha(\mathbb{R}_+,\mathbb{R})$ *for some $\alpha < 0$.*

(iii) *In particular,* (d) *asserts that $u(t)$ converges as $t \to \infty$ if the set* $\phi^{-1}(\phi_r)$ *is a singleton, which, in turn, will be true if* $\phi_r \in \operatorname{im}\phi$ *is not a critical value of ϕ.*

Proof. Assertions (a)–(e) follow immediately from Theorem 3.6 combined with Lemma 3.7. It remains only to establish assertion (f). By hypothesis, $\phi_r \in \operatorname{im}\phi$ is

not a critical value of ϕ, and so, by monotonicity, its preimage $\phi^{-1}(\phi_r)$ is a singleton $\{u_r\}$ and

$$\phi^{\diamond}(u_r) \geq \phi^{-}(u_r) =: \phi_r^{-} > 0.$$

Therefore, by assertion (d), $u(t) \to u_r$ as $t \to \infty$. By lower semicontinuity of ϕ^{-}, there exists $\sigma_1 > 0$ such that

$$\phi^{\diamond}(u(t)) \geq \phi^{-}(u(t)) \geq \tfrac{1}{2}\phi_r^{-} > 0 \quad \forall\, t \geq \sigma_1. \tag{24}$$

Define $\rho := \frac{1}{4}\mathbf{G}(0)\phi_r^{-} > 0$, and introduce exponentially weighted variables given by

$$z_e(t) := \exp(\rho K(t))[x(t) + A^{-1}B\phi(u(t))], \tag{25a}$$

$$v_e(t) := \exp(\rho K(t))[\phi(u(t)) - \phi_r] \tag{25b}$$

$\forall\, t \in \mathbb{R}_+$. Since (z_e, v_e) is absolutely continuous as an $(X_{-1} \times \mathbb{R})$-valued function, and using Proposition 3.4, we obtain by direct calculation

$$\begin{aligned} &\dot{z_e} = (A + \rho k I)z_e - k\phi^{\diamond}(u)A^{-1}B(C_L z_e + \mathbf{G}(0)v_e), \\ &z_e(0) = x_0 + A^{-1}B\phi(u_0), \end{aligned} \tag{26a}$$

$$\begin{aligned} &\dot{v}_e = -k\phi^{\diamond}(u)(C_L z_e + \mathbf{G}(0)v_e) + \rho k v_e, \\ &v_e(0) = \phi(u_0) - \phi_r. \end{aligned} \tag{26b}$$

For each (t, s) with $0 \leq s \leq t$, define

$$\mathbf{U}(t, s) := \exp(\rho[K(t) - K(s)])\mathbf{T}_{t-s}. \tag{27}$$

We briefly digress to prove a technicality.

LEMMA 3.10. *Let $s \in \mathbb{R}_+$, $u \in L^2_{\mathrm{loc}}(\mathbb{R}_+)$, and, on $[s, \infty)$, define a function p by*

$$p(t) := \int_s^t \mathbf{U}(t, \xi)Bu(\xi)d\xi.$$

Then, $\forall\, t$, $p(t) \in X$ and, as an X_{-1}-valued function, p is absolutely continuous with

$$\dot{p}(t) = (A + \rho k(t)I)p(t) + Bu(t) \quad \text{a.e.}$$

Proof. On $[s, \infty)$, define a function q by

$$q(t) := e^{-\rho K(t)}p(t) = \int_s^t \mathbf{T}_{t-\xi}Be^{-\rho K(\xi)}u(\xi)\, d\xi.$$

Clearly, $q(t) \in X\ \forall\, t$ and so $p(t) \in X\ \forall\, t$. Moreover, q is absolutely continuous as an X_{-1}-valued function and, by Pazy [18, Theorem 2.9, p. 109], for a.a. $t \geq s$,

$$\dot{q}(t) = Aq(t) + e^{-\rho K(t)}Bu(t).$$

Thus, as an X_{-1}-valued function, p is absolutely continuous with

$$\dot{p}(t) = \rho k(t)e^{\rho K(t)}q(t) + e^{\rho K(t)}\dot{q}(t) = (A + \rho k(t)I)p(t) + Bu(t)$$

for a.a. $t \geq s$. ∎

Returning to the proof of the theorem, for notational convenience write

$$w_e := \phi^{\diamond}(u)\left[C_L z_e + \mathbf{G}(0)v_e\right].$$

Let $s \in \mathbb{R}_+$ and, on $[s,\infty)$, define $f := f_1 - A^{-1}f_2$ with

$$f_1(t) := \mathbf{U}(t,s)z_e(s), \quad f_2(t) := \int_s^t \mathbf{U}(t,\xi)Bk(\xi)w_e(\xi)d\xi.$$

Clearly, $f_1(t) \in X \ \forall\ t$ and, as an X_{-1}-valued function, f_1 is absolutely continuous with

$$\dot{f}_1(t) = (A + \rho k(t)I)f_1(t) \quad \text{a.e.}$$

By Lemma 3.10, it now follows that $f(t) \in X \ \forall\ t$ and, as an X_{-1}-valued function, f is absolutely continuous with

$$\begin{aligned}\dot{f}(t) &= (A + \rho k(t)I)f_1(t) - A^{-1}\left((A + \rho k(t)I)f_2(t) + Bw_e(t)\right)\\ &= (A + \rho k(t)I)f(t) - A^{-1}Bw_e(t) \quad \text{a.e.}\end{aligned}$$

In view of (26a) (together with uniqueness of solutions), we may now conclude that

$$z_e(t) = \mathbf{U}(t,s)z_e(s) - A^{-1}\int_s^t \mathbf{U}(t,\xi)Bk(\xi)w_e(\xi)\,d\xi \quad \forall\ t,s \text{ with } 0 \le s \le t. \tag{28}$$

By exponential stability of the semigroup $\mathbf{T}$, there exist constants $N,\ \nu > 0$ such that $\|\mathbf{T}_t\| \le N\exp(-\nu t)\ \forall\ t \in \mathbb{R}_+$. Let $\varepsilon \in (0,\nu)$ be sufficiently small such that $(A + \varepsilon I, B, C, D) \in \mathcal{R}$ (recall Proposition 3.2). Fix $\sigma_2 > \sigma_1$ such that

$$k(\sigma_2) < \min\{\varepsilon/\rho, \nu/(\rho N)\}. \tag{29}$$

Again, we digress to prove a technicality.

LEMMA 3.11. *There exists constant $\gamma > 0$ such that, $\forall\ u \in L^2_{\mathrm{loc}}(\mathbb{R}_+)$,*

$$\left(\int_s^t \left\|\int_s^\tau \mathbf{U}(\tau,\xi)Bu(\xi)d\xi\right\|^2 d\tau\right)^{\frac{1}{2}} \le \gamma\left(\int_s^t u^2(\xi)d\xi\right)^{\frac{1}{2}} \quad \forall\ s,t \ge \sigma_2 \text{ with } s \le t.$$

Proof. Let $s \ge \sigma_2$ and let $u \in L^2_{\mathrm{loc}}(\mathbb{R}_+)$ be arbitrary. On $[s,\infty)$ define (as before) the function $p : t \mapsto \int_s^t \mathbf{U}(t,\xi)Bu(\xi)d\xi$. By Lemma 3.10, for a.a. $t \ge s$, we have $\dot{p}(t) = Ap(t) + \rho k(t)p(t) + Bu(t)$. Therefore,

$$p(t) = \int_s^t \mathbf{T}_{t-\xi}\rho k(\xi)p(\xi)\,d\xi + \int_s^t \mathbf{T}_{t-\xi}Bu(\xi)\,d\xi \quad \forall\ t \ge s.$$

Using exponential stability of the semigroup $\mathbf{T}$, monotonicity of k, and Lemma 2.2 (part (a)), we may conclude

$$\left(\int_s^t \|p(\xi)\|^2 d\xi\right)^{\frac{1}{2}} \le \rho N\nu^{-1}k(\sigma_2)\left(\int_s^t \|p(\xi)\|^2 d\xi\right)^{\frac{1}{2}} + \alpha_1\left(\int_s^t u^2(\xi)\,d\xi\right)^{\frac{1}{2}} \quad \forall\ t \ge s.$$

By (29), $1 - \rho N\nu^{-1}k(\sigma_2) > 0$, and the result follows. ∎

Once more, we return to the proof of the theorem. By monotonicity of k, $K(t) - K(s) \le k(s)(t-s)\,\forall\, t, s$ with $0 \le s \le t$. Since $k(\sigma_2) \le \varepsilon/\rho$, it follows that

$$\exp(\rho[K(t) - K(s)]) \le \exp(\varepsilon[t-s]) \quad \forall\ t, s \text{ with } \sigma_2 \le s \le t. \tag{30}$$

Observe that, $\forall\, t, s$ with $\sigma_2 \le s \le t$,

$$\begin{aligned} |C_L \mathbf{U}(t,s) z_e(s)| &= |C_L \mathbf{T}_{t-s} z_e(s)| \exp(\rho[K(t) - K(s)]) \\ &\le |C_L \mathbf{T}_{t-s} \exp(\varepsilon[t-s]) z_e(s)|. \end{aligned}$$

Invoking (4), (5) (in the context of the regular system $(A + \varepsilon I, B, C, D)$), (28), and Lemma 3.11, and recalling that $C_L A^{-1}$ maps X boundedly into $\mathbb{R}$, there exist constants $\alpha_2, \alpha_3 > 0$ such that

$$\begin{aligned} \left(\int_s^t |C_L z_e|^2 \right)^{1/2} \le \alpha_2 \|z_e(s)\| + k(s)\alpha_3 \left(\int_s^t |\phi^\diamond(u)|^2 |C_L z_e|^2 \right)^{1/2} \\ + \alpha_3 \mathbf{G}(0) \left(\int_s^t |k\phi^\diamond(u) v_e|^2 \right)^{1/2} \end{aligned} \tag{31}$$

$\forall\, t, s$ with $\sigma_2 \le s \le t$.

Inequality (31) is the exponentially weighted version of (16). Following the argument in the proof of Theorem 3.6, (31) may be used to derive an exponentially weighted version of (14), i.e., there exist positive constants $\gamma_1, \gamma_2 > 0$ and $\sigma_3 \ge \sigma_2$ such that

$$\int_s^t |C_L z_e|\, |k\phi^\diamond(u) v_e| \le \gamma_1 \|z_e(s)\| \left(\int_s^t k^2 \phi^\diamond(u) v_e^2 \right)^{1/2} + \gamma_2 \int_s^t k^2 \phi^\diamond(u) v_e^2 \tag{32}$$

$\forall\ t, s$ with $\sigma_3 \le s \le t$.

By (26b), for a.a. $t \ge 0$,

$$v_e(t)\dot{v}_e(t) = -k(t)\mathbf{G}(0)\phi^\diamond(u(t))v_e^2 + \rho k(t) v_e^2(t) - k(t)\phi^\diamond(u(t)) v_e(t) C_L z_e(t). \tag{33}$$

By (24), $\mathbf{G}(0)\phi^\diamond(u(t)) - \rho \ge \frac{1}{2}\mathbf{G}(0)\phi_r^- - \rho = \rho > 0\ \forall\ t \ge \sigma_3$. Hence, we have

$$v_e(t)\dot{v}_e(t) \le -\tfrac{1}{2}\rho k(t) v_e^2(t) + |C_L z_e(t)|\, |k(t)\phi^\diamond(u(t)) v_e(t)| \quad \text{for a.a. } t \ge \sigma_3.$$

Integrating this inequality and using (32) and monotonicity of k yields, $\forall\ t, s$ with $t \ge s \ge \sigma_3$,

$$v_e^2(t) \le v_e^2(s) + 2\gamma_1 \sqrt{\lambda k(s)} \|z_e(s)\| \left(\int_s^t k v_e^2 \right)^{1/2} - \int_s^t (\rho - 2k\gamma_2\lambda) k v_e^2. \tag{34}$$

Fix $\sigma \ge \sigma_3$ such that $\rho - 2k(t)\gamma_2\lambda > \frac{1}{2}\rho\ \forall\ t \ge \sigma$. From (34) and (32), we deduce

$$\int_\sigma^\infty k v_e^2 < \infty.$$

Hence, by (34), $v_e(\cdot) = \exp(\rho K(\cdot))[\phi(u(\cdot)) - \phi_r]$ is bounded and so the convergence in (a) is of order $\exp(-\rho K(t))$. We proceed to prove that the convergence in (b) is of the same order. Define $x_r := -A^{-1}B\phi_r$, and introduce a new variable given by

$$x_e(t) = \exp(\rho K(t))[x(t) - x_r] \quad \forall\ t \ge 0.$$

It suffices to show that $x_e(\cdot)$ is bounded. By (8) and (25), we have

$$\dot{x}_e = (A + \rho k I)x_e + Bv_e, \quad x_e(0) = x_0 - x_r,$$

and so, $\forall\ t \geq \sigma$,

$$x_e(t) = \mathbf{T}_{t-\sigma}x_e(\sigma) + \int_\sigma^t \mathbf{T}_{t-\xi}Bv_e(\xi)\,d\xi + \int_\sigma^t \mathbf{T}_{t-\xi}\rho k(\xi)x_e(\xi)\,d\xi.$$

Therefore, by boundedness of v_e together with Lemma 2.2 (part (b)) and exponential stability of $\mathbf{T}$, there exists a constant $\beta > 0$ such that

$$\sup_{s\in[\sigma,t]} \|x_e(s)\| \leq \beta + \rho N \nu^{-1} k(\sigma) \sup_{s\in[\sigma,t]} \|x_e(s)\| \quad \forall\ t \geq \sigma.$$

Since $\sigma \geq \sigma_2$, we have, by (29), $\rho N \nu^{-1} k(\sigma) < 1$, and hence we may conclude boundedness of x_e. Therefore, the convergence in part (b) is of order $\exp(-\rho K(t))$.

It remains only to prove that the convergence in (c) is also of order $\exp(-\rho K(t))$, provided that $\mu := \mathcal{L}^{-1}(\mathbf{G}) \in \mathcal{M}_\alpha$ for some $\alpha < 0$. Denoting the unit-step function by θ, we have $\forall\ t \geq 0$

$$|r - y(t) + (\mathbf{\Psi}_\infty x_0)(t)| \leq |[\mu \star (\phi(u) - \phi_r\theta)(t)]| + |\phi_r[(\mu \star \theta)(t) - \mathbf{G}(0)]|. \tag{35}$$

For convenience we set $w(t) = \exp(\rho K(t))\ \forall\ t \geq 0$. We have already shown that the function $t \mapsto w(t)|\phi(u(t)) - \phi_r|$ remains bounded as $t \to \infty$. If we extend w to a function defined on $\mathbb{R}$ by setting $w(t) = 1\ \forall\ t < 0$, then it is easy to show that w is a submultiplicative weight function in the sense of [7, p. 118]. Moreover, since $\mu \in \mathcal{M}_\alpha$, the measure $\mu_w : E \mapsto \int_E w(t)\mu(dt)$ belongs to $\mathcal{M}$. Hence, by [7, Theorem 3.5, part (i), p. 119], we may conclude that the function $t \mapsto w(t)[\mu\star(\phi(u)-\phi_r\theta)](t)$ is bounded on $\mathbb{R}_+$.

Since $\mu_w \in \mathcal{M}$ (a space of finite measures), $\int_0^\infty w(t)|\mu|(dt)$, where $|\mu|$ denotes the total variation of μ. Hence

$$|w(t)[(\mu \star \theta)(t) - \mathbf{G}(0)]| = w(t)\left|\int_t^\infty \mu(d\tau)\right| \leq \int_0^\infty w(\tau)|\mu|(d\tau) < \infty,$$

showing that the function $t \mapsto w(t)[(\mu\star\theta)(t)-\mathbf{G}(0)]$ is bounded on $\mathbb{R}_+$. Consequently, appealing to (35), we deduce that the function

$$\mathbb{R}_+ \to \mathbb{R}, \quad t \mapsto \exp(\rho K(t))|r - y(t) + (\mathbf{\Psi}_\infty x_0)(t)|$$

is bounded. □

3.2. Adaptive gain. Whilst Theorem 3.8 identifies conditions under which the tracking objective is achieved through the use of a monotone gain function, the resulting control strategy is somewhat unsatisfactory insofar as the gain function is selected a priori: no use is made of the output information from the plant to update the gain. We now consider the possibility of exploiting this output information to generate, by feedback, an appropriate gain function. In particular, let the gain $k(\cdot)$ be generated by the law:

$$k(t) = \frac{1}{l(t)}, \quad \dot{l}(t) = |r - y(t)|, \quad l(0) = l_0 > 0, \tag{36}$$

which yields the feedback system

$$\dot{x}(t) = Ax(t) + B\phi(u(t)), \quad x(0) = x_0 \in X, \tag{37a}$$

$$\dot{u}(t) = (1/l(t))[r - C_L x(t) - D\phi(u(t))], \quad u(0) = u_0 \in \mathbb{R}, \tag{37b}$$

$$\dot{l}(t) = |r - C_L x(t) - D\phi(u(t))|, \quad l(0) = l_0 \in (0, \infty). \tag{37c}$$

The concept of a solution of this feedback system is the obvious modification of the solution concept defined in subsection 3.1. The proof of the following existence and uniqueness result can be found in the appendix.

LEMMA 3.12. *Let* $(A, B, C, D) \in \mathcal{R}$, $\phi \in \mathcal{N}$, *and* $r \in \mathbb{R}$. *For each* $(x_0, u_0, l_0) \in X \times \mathbb{R} \times (0, \infty)$, *the initial-value problem given by* (37) *has a unique solution defined on* $\mathbb{R}_+$.

We now arrive at the main adaptive control result.

THEOREM 3.13. *Let* $(A, B, C, D) \in \mathcal{R}$, $\phi \in \mathcal{N}$, *and let* $r \in \mathbb{R}$ *be such that* $\phi_r := [\mathbf{G}(0)]^{-1} r \in \operatorname{clos}(\operatorname{im} \phi)$. *Assume that* $\mathcal{L}^{-1}(\mathbf{G}) \in \mathcal{M}$.

$\forall\ (x_0, u_0, l_0) \in X \times \mathbb{R} \times (0, \infty)$, *the unique solution of the initial-value problem given by* (37) *is such that assertions* (a) *to* (e) *of Theorem* 3.8 *hold. Moreover, if* $\phi_r \in \operatorname{im} \phi$ *is not a critical value and* $\mathcal{L}^{-1}(\mathbf{G}) \in \mathcal{M}_\alpha$ *for some* $\alpha < 0$, *then the monotone gain* k *converges to a positive value.*

Proof. Set $k(t) = 1/l(t)$. Since $l(\cdot)$ is monotone increasing, either $l(t) \to \infty$ as $t \to \infty$ (Case 1), or $l(t) \to l^* \in (0, \infty)$ as $t \to \infty$ (Case 2). We consider these two cases separately.

Case 1. In this case, $k(t) \downarrow 0$ as $t \to \infty$ and the hypotheses of Theorem 3.6 are satisfied. Therefore, $(\phi(u))(\cdot)$ converges. It follows that $\lim_{t\to\infty}(\mathcal{L}^{-1}(\mathbf{G}) \star \phi(u))(t)$ converges (and so, in particular, is a bounded function). Moreover, by exponential stability, $\mathbf{\Psi}_\infty x_0 \in L^1(\mathbb{R}_+, \mathbb{R})$, and it follows from

$$\dot{l}(t) = |r - y(t)| \le |r - (\mathcal{L}^{-1}(\mathbf{G}) \star \phi(u))(t)| + |(\mathbf{\Psi}_\infty x_0)(t)|,$$

via integration that

$$k(t) = \frac{1}{l(t)} \ge \frac{1}{\alpha + \beta t} \quad \forall\ t \ge 0, \tag{38}$$

where

$$\alpha := l_0 + \int_0^\infty |\mathbf{\Psi}_\infty x_0(\tau)|\, d\tau, \quad \beta \ge \sup_{t \ge 0} |r - (\mathcal{L}^{-1}(\mathbf{G}) \star \phi(u))(t)|.$$

Therefore, assertions (a) to (e) of Theorem 3.8 hold.

Case 2. In this case, $k(t) \to k^* := 1/l^* > 0$ as $t \to \infty$. By boundedness of $l(\cdot)$ and (36), we may conclude that $e(\cdot) := r - C_L x(\cdot) - D\phi(u(\cdot)) \in L^1(\mathbb{R}_+)$ and so (by (10b)) $u(t)$ converges to a finite limit as $t \to \infty$. Consequently, $\phi(u(t))$ converges to a finite limit as $t \to \infty$, and hence, by Lemma 3.7, assertions (a) to (e) of Theorem 3.8 hold.

Finally, assume that $\phi_r \in \operatorname{im} \phi$ is not a critical value and that $\mathcal{L}^{-1}(\mathbf{G}) \in \mathcal{M}_\alpha$ for some $\alpha < 0$. We will show that the monotone gain k converges to a positive value. Seeking a contradiction, suppose that the monotone function l is unbounded (equivalently, $k(t) \downarrow 0$ as $t \to \infty$). Then the hypotheses of Theorem 3.6 are satisfied and so (38) holds. By Theorem 3.8, $\phi(u(\cdot))$ converges to ϕ_r, and $y(\cdot) - (\mathbf{\Psi}_\infty x_0)(\cdot)$

converges to r; moreover, the convergence is of order $\exp(-\rho K(t))$ for some $\rho > 0$; that is, there exists constant $L > 0$ such that

$$|r - y(t) + (\mathbf{\Psi}_\infty x_0)(t)| \leq L \exp(-\rho K(t)) \quad \forall\, t \in \mathbb{R}_+. \tag{39}$$

Choose $\gamma \geq \beta$ such that $\rho/\gamma < 1$. By (38), $k(t) = 1/l(t) \geq (\alpha + \gamma t)^{-1}\ \forall\ t \in \mathbb{R}_+$. Therefore,

$$K(t) = \int_0^t k \ \geq\ \ln[((\alpha + \gamma t)/\alpha)^{1/\gamma}] \quad \forall\, t \geq 0.$$

Consequently for a.a. $t \geq 0$,

$$\dot{l}(t) = |r - y(t)| \leq L \exp(-\rho K(t)) + |(\mathbf{\Psi}_\infty x_0)(t)| \leq M(\alpha + \gamma t)^{-\eta} + |(\mathbf{\Psi}_\infty x_0)(t)|,$$

where $\eta = \rho/\gamma \in (0, 1)$ and $M = L\alpha^\eta$. Since, by exponential stability, $\mathbf{\Psi}_\infty x_0 \in L^1(\mathbb{R}_+, \mathbb{R})$, integration gives

$$l(t) \leq N(\alpha + \gamma t)^{1-\eta} \quad \forall\, t \geq 0,$$

for some suitable constant $N > 0$. It follows that

$$-K(t) = -\int_0^t k \leq -(N\gamma\eta)^{-1} \left[(\alpha + \gamma t)^\eta - \alpha^\eta\right] \quad \forall\, t \geq 0.$$

Therefore, $\exp(-\rho K(\cdot))$ is of class $L^1(\mathbb{R}_+, \mathbb{R})$, and, by (39), it follows that $|r - y(\cdot) + (\mathbf{\Psi}_\infty x_0)(\cdot)|$ is also of class $L^1(\mathbb{R}_+, \mathbb{R})$. Since $\mathbf{\Psi}_\infty x_0 \in L^1(\mathbb{R}_+, \mathbb{R})$, we have $|r - y(\cdot)| \in L^1(\mathbb{R}_+, \mathbb{R})$. This contradicts the supposition of unboundedness of $l(\cdot)$. Therefore, $l(\cdot)$ is bounded. □

4. Example: Controlled diffusion process with output delay. Consider a diffusion process (with diffusion coefficient $a > 0$ and with Dirichlet boundary conditions), on the one-dimensional spatial domain $I = [0, 1]$, with scalar nonlinear pointwise control action (applied at point $x_b \in I$, via a nonlinearity ϕ with Lipschitz constant $\lambda > 0$) and delayed (delay $h \geq 0$) pointwise scalar observation (output at point $x_c \in I$). We formally write this single-input, single-output system (previously considered, in a nonadaptive control context, in the precursor [9] to the present paper) as

$$z_t(t, x) = a z_{xx}(t, x) + \delta(x - x_b)\phi(u(t)), \quad y(t) = z(t - h, x_c),$$

$$z(t, 0) = 0 = z(t, 1) \quad \forall\, t > 0.$$

For simplicity, we assume zero initial conditions:

$$z(t, x) = 0 \quad \forall\ (t, x) \in [-h, 0] \times [0, 1].$$

With input $\phi(u(\cdot))$ and output $y(\cdot)$, this example qualifies as a regular linear system with transfer function given by

$$\mathbf{G}(s) = \frac{e^{-sh/a} \sinh(x_b\sqrt{s}\,) \sinh((1 - x_c)\sqrt{s}\,)}{a\sqrt{s} \sinh\sqrt{s}}.$$

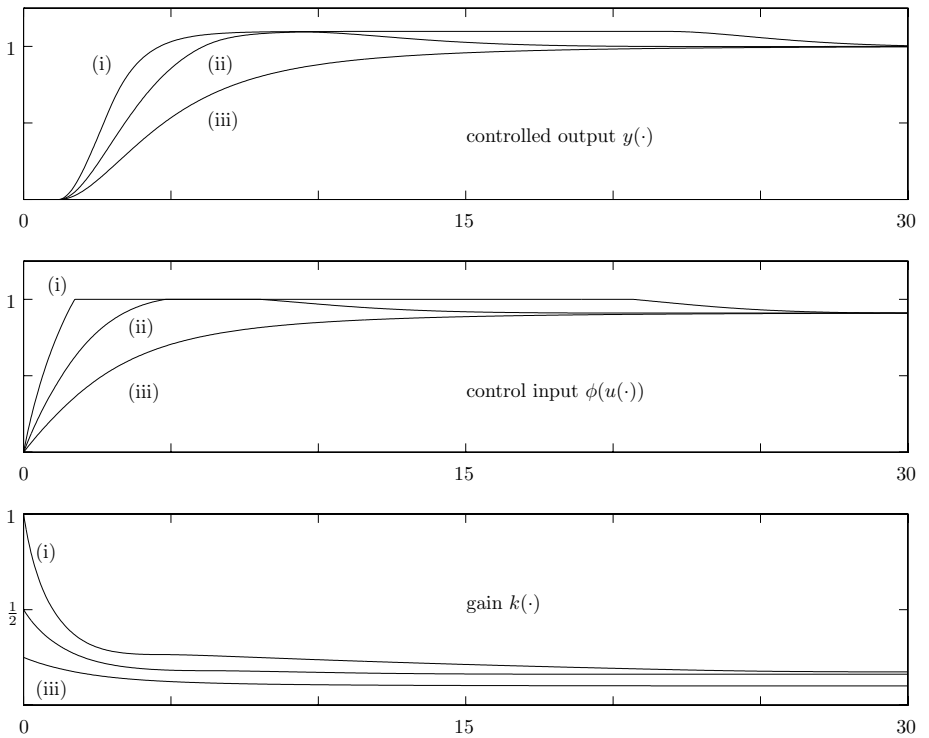

FIG. 3. *Controlled output, control input, and adapting gain.*

Therefore, by Theorem 3.8, the adaptive integral control

$$u(t) = \int_0^t k(t)[r - y(t)]\,dt, \qquad k(t) = \frac{1}{l(t)},$$

where the evolution of $l(t)$ is given by the adaptation law

$$\dot{l}(t) = |r - y(t)|, \quad l(0) = l_0 > 0,$$

guarantees asymptotic tracking of every constant reference signal r satisfying

$$\frac{r}{\mathbf{G}(0)} = \frac{ar}{x_b(1 - x_c)} \in \operatorname{clos}(\operatorname{im}\phi).$$

For purposes of illustration, we adopt the following values:

$$a = 0.1, \quad x_b = \frac{1}{3}, \quad x_c = \frac{2}{3}, \quad h = 0.1.$$

We consider a nonlinearity ϕ of saturation type, defined as follows

$$u \mapsto \phi(u) := \begin{cases} 1, & u \geq 1, \\ u, & u \in (0, 1), \\ 0, & u \leq 0, \end{cases}$$

in which case $\lambda = 1$. For unit reference signal $r = 1$, we have

$$\frac{r}{\mathbf{G}(0)} = \frac{a}{x_b(1 - x_c)} = 0.9 \in \operatorname{int}(\operatorname{im}\phi).$$

Figure 3 depicts the behavior of the system (with reference $r = 1$) under adaptive integral control in each of the following three cases:

$$\text{(i) } l_0 = 1, \quad \text{(ii) } l_0 = 2, \quad \text{(iii) } l_0 = 4.$$

This figure was generated using SIMULINK simulation software within MATLAB wherein a truncated eigenfunction expansion, of order 10, was adopted to model the diffusion process.

5. Appendix: Proof of Lemmas 3.5 and 3.12. In proving Lemmas 3.5 and 3.12, we will first study an abstract Volterra integrodifferential equation. Let $\alpha \geq 0$, and let $w_\alpha \in C([0,\alpha],\mathbb{R}^n)$. Consider the initial-value problem

$$\dot{w}(t) = (Vw)(t), \quad t \geq \alpha, \tag{40a}$$

$$w(t) = w_\alpha(t), \quad t \in [0,\alpha], \tag{40b}$$

where the operator $V : C(\mathbb{R}_+,\mathbb{R}^n) \to L^1_{\text{loc}}(\mathbb{R}_+,\mathbb{R}^n)$ is causal and *weakly Lipschitz* in the following sense.

$\forall\ \alpha \geq 0$, $\delta > 0$, $\rho > 0$, and $\theta \in C([0,\alpha],\mathbb{R}^n)$, there exists a continuous function $f : [0,\delta] \to \mathbb{R}_+$, with $f(0) = 0$, such that

$$\int_\alpha^{\alpha+\varepsilon} \|(Vv)(t) - (Vw)(t)\|\, dt \leq f(\varepsilon) \sup_{\alpha \leq t \leq \alpha+\varepsilon} \|v(t) - w(t)\|$$

$\forall\ \varepsilon \in [0,\delta]$ and $\forall\ v, w \in \mathcal{C}(\alpha,\delta,\rho,\theta)$, where

$$\mathcal{C}(\alpha,\delta,\rho,\theta) := \{w \in C([0,\alpha+\delta],\mathbb{R}^n) |\ w(t) = \theta(t)\ \forall\ t \in [0,\alpha], \\ \|w(t) - \theta(\alpha)\| \leq \rho\ \forall\ t \in [\alpha,\alpha+\delta]\}.$$

A *solution* of the initial-value problem (40) on an interval $[0,\beta)$, where $\beta > \alpha$, is a function $w \in C([0,\beta),\mathbb{R}^n)$, with $w(t) = w_\alpha(t)\ \forall\ t \in [0,\alpha]$, such that w is absolutely continuous on $[\alpha,\beta)$ and (40a) is satisfied for a.a. $t \in [\alpha,\beta)$.

Strictly speaking, to make sense of (40), we have to give a meaning to $(Vw)(t)$, $t \in [0,\beta)$, when w is a continuous function defined on a *finite* interval $[0,\beta)$ (recall that V operates on the space of continuous functions defined on the *infinite* interval $\mathbb{R}_+$). This can be done easily using causality of V: $\forall\ t \in [0,\beta)$, $(Vw)(t) := (Vw^*)(t)$, where $w^* : \mathbb{R}_+ \to \mathbb{R}^n$ is any continuous function with $w^*(s) = w(s)\ \forall\ s \in [0,t]$.

PROPOSITION 5.1. *For every $\alpha \geq 0$ and every $w_\alpha \in C([0,\alpha],\mathbb{R}^n)$, there exists a unique solution $w(\cdot)$ of (40) defined on a maximal interval $[0,t_{\max})$, with $t_{\max} > \alpha$. Moreover, if $t_{\max} < \infty$, then*

$$\limsup_{t \to t_{\max}} |w(t)| = \infty. \tag{41}$$

Proof. Fix $\alpha \geq 0$, $w_\alpha \in C([0,\alpha],\mathbb{R}^n)$ arbitrarily. Define a continuous extension $w^*_\alpha : \mathbb{R}_+ \to \mathbb{R}^n$ of w_α by setting $w^*_\alpha(t) = w_\alpha(\alpha)\ \forall\ t > \alpha$. For later convenience, we introduce the continuous function

$$\varepsilon \mapsto g(\varepsilon) := \int_\alpha^{\alpha+\varepsilon} \|(Vw^*_\alpha)(t)\|\, dt.$$

We proceed in three steps.

Step 1. Existence and uniqueness on a small interval.

For each $\varepsilon \in (0,1)$, define

$$\mathcal{C}_\varepsilon := \mathcal{C}(\alpha, \varepsilon, 1, w_\alpha),$$

which, endowed with the metric

$$(v,w) \mapsto \sup_{\alpha \le t \le \alpha+\varepsilon} \|v(t) - w(t)\|,$$

is a complete metric space.

Existence and uniqueness of a solution on a small interval is proved by showing that

$$(\Gamma w)(t) := \begin{cases} w_\alpha(t), & 0 \le t \le \alpha, \\ w_\alpha(\alpha) + \displaystyle\int_\alpha^t (Vw)(\tau)\, d\tau, & \alpha \le t \le \alpha + \varepsilon \end{cases}$$

defines a contraction on $\mathcal{C}_\varepsilon$ for sufficiently small $\varepsilon > 0$.

By the weak Lipschitz property of V, there exists a continuous function $f : [0,1] \to \mathbb{R}_+$ with $f(0) = 0$, such that, $\forall\ \varepsilon \in (0,1)$, $v, w \in \mathcal{C}_\varepsilon$, and $t \in [\alpha, \alpha+\varepsilon]$,

$$\begin{aligned} \|(\Gamma w)(t) - w_\alpha(\alpha)\| &\le \int_\alpha^{\alpha+\varepsilon} \|(Vw)(\tau)\|\, d\tau \\ &\le g(\varepsilon) + \int_\alpha^{\alpha+\varepsilon} \|(Vw)(\tau) - (Vw^*_\alpha)(\tau)\|\, d\tau \\ &\le g(\varepsilon) + f(\varepsilon) \\ &\le 1 \qquad \text{for all sufficiently small } \varepsilon > 0 \end{aligned} \tag{42}$$

and

$$\begin{aligned} \|(\Gamma v)(t) - (\Gamma w)(t)\| &\le \int_\alpha^{\alpha+\varepsilon} \|(Vv)(\tau) - (Vw)(\tau)\|\, d\tau \\ &\le f(\varepsilon) \sup_{\alpha \le \tau \le \alpha+\varepsilon} \|v(\tau) - w(\tau)\| \\ &\le \tfrac{1}{2} \sup_{\alpha \le \tau \le \alpha+\varepsilon} \|v(\tau) - w(\tau)\| \quad \text{for all sufficiently small } \varepsilon > 0. \end{aligned} \tag{43}$$

By (42), $\Gamma(\mathcal{C}_\varepsilon) \subset \mathcal{C}_\varepsilon$ for all sufficiently small $\varepsilon > 0$. Consequently, we obtain from (43) that Γ is a contraction on $\mathcal{C}_\varepsilon$ for all sufficiently small $\varepsilon > 0$.

Step 2. Extended uniqueness.

Let $v : [0, \beta_1) \to \mathbb{R}^n$ and $w : [0, \beta_2) \to \mathbb{R}^n$, $\beta_1, \beta_2 > \alpha$, be solutions of (40) (existence of v and w is ensured by Step 1).

We claim that $v(t) = w(t)\ \forall\ t \in [0, \beta)$, where $\beta = \min\{\beta_1, \beta_2\}$. Seeking a contradiction, suppose that there exists $t \in (0, \beta)$ such that $v(t) \ne w(t)$. Defining

$$t^* = \inf\{t \in (0,\beta) \,|\, v(t) \ne w(t)\},$$

it follows that $t^* > \alpha$ (by Step 1), $t^* < \beta$ (by supposition), and $v(t^*) = w(t^*)$ (by continuity of v and w). Clearly, the initial-value problem

$$\dot{z}(t) = (Vz)(t),\ \ t \ge t^*\,; \quad z(t) = v(t),\ \ t \in [0, t^*]$$

is solved by v and w. This implies (by the argument in Step 1) that there exists an $\varepsilon > 0$ such that $v(t) = w(t)\ \forall\ t \in [0, t^* + \varepsilon)$, which contradicts the definition of t^*.

Step 3. Continuation of solutions.

Let $\alpha \geq 0$ and $w_\alpha \in C([0,\alpha], \mathbb{R}^n)$ be arbitrary and, as before, let w_α^* be the continuous extension of w_α with $w_\alpha^*(t) = w_\alpha(\alpha)\ \forall\ t > \alpha$.

Let w be a solution of (40) on the interval $[0,\beta)$, $\alpha < \beta < \infty$. In order to prove that w can be extended to a maximal solution (which satisfies (41) if $t_{\max} < \infty$), it is sufficient to show that w can be continued to the right (beyond β) if w is bounded on $[0,\beta)$. Suppose that w is bounded. Set $\delta := \beta - \alpha$ and $\rho =: \sup\{\|w(\tau) - w_\alpha(\alpha)\| \mid \alpha < \tau < \beta\}$. By the weak Lipschitz property of V, there exists continuous $f : [0,\delta] \to \mathbb{R}_+$, with $f(0) = 0$, such that $\forall\ \varepsilon \in (0,\delta)$

$$\int_\alpha^{\alpha+\varepsilon} \|(Vw)(\tau)\|\, d\tau \leq g(\varepsilon) + \rho f(\varepsilon),$$

implying, by boundedness of g and f on $[0,\delta]$, that $Vw \in L^1([0,\beta], \mathbb{R}^n)$ and so the following limit exists:

$$\lim_{t\uparrow\beta} \int_\alpha^t (Vw)(\tau)\, d\tau =: L \in \mathbb{R}^n,$$

whence

$$L + w_\alpha(\alpha) = \lim_{t\uparrow\beta} (\Gamma w)(t).$$

Now $w(t) = (\Gamma w)(t)\ \forall\ t \in [0,\beta)$. Therefore, defining $w(\beta) = L + w_\alpha(\alpha)$ we can extend w into a continuous function on $[0,\beta]$. Finally, by the argument in Step 1, the initial-value problem

$$\dot z(t) = (Vz)(t),\ \ t \geq \beta\,; \quad z(t) = w(t),\ \ t \in [0,\beta]$$

has a unique solution w^* on $[0,\beta+\varepsilon)$ for some $\varepsilon > 0$. By causality of V, the function w^* is a solution of (40) on $[0,\beta+\varepsilon)$, and so w^* is a proper right continuation of w. □

REMARK 5.2. *In what follows, we shall invoke Proposition* 5.1 *only in the special case* $\alpha = 0$. *Note, however, that Steps* 2 *and* 3 *in the above proof of the proposition required the local existence and uniqueness result in the more general context of* $\alpha \geq 0$.

In the following, Proposition 5.1 will be used to prove Lemmas 3.5 and 3.12. First note that, by setting $k(t) = 1/l(t)$, the adaptive feedback system (37) (with $(A,B,C,D) \in \mathcal{R}$) can be written in the following form which will be more convenient for our purposes:

$$\dot x(t) = Ax(t) + B\phi(u(t)), \quad x(0) = x_0 \in X, \tag{44a}$$

$$\dot u(t) = k(t)[r - C_L x(t) - D\phi(u(t))], \quad u(0) = u_0 \in \mathbb{R}, \tag{44b}$$

$$\dot k(t) = -k^2(t)|r - C_L x(t) - D\phi(u(t))|, \quad k(0) = k_0 \in (0,\infty). \tag{44c}$$

The feedback systems (10) and (44) are both of the form

$$\dot x(t) = Ax(t) + B\phi(u(t)), \quad x(0) = x_0 \in X \tag{45a}$$

$$\dot u(t) = \kappa(t)\theta(t)[r - C_L x(t) - D\phi(u(t))], \quad u(0) = u_0 \in \mathbb{R}, \tag{45b}$$

$$\dot\theta(t) = h(\theta(t))|r - C_L x(t) - D\phi(u(t))|, \quad \theta(0) = \theta_0 \in \mathbb{R}, \tag{45c}$$

where $\kappa \in L^\infty(\mathbb{R}_+, \mathbb{R})$ and $h : \mathbb{R} \to \mathbb{R}$ is locally Lipschitz. To recover (10) from (45), set $h(\theta) \equiv 0$ and $\theta_0 = 1$ (in this case $\kappa(\cdot)$ plays the role of the gain function $k(\cdot)$). Considering the special case $\kappa(t) \equiv 1$ and $h(\theta) = -\theta^2$ gives the adaptive feedback equations (44) (with $k(\cdot) = \theta(\cdot)$).

For $a \in (0, \infty]$, a continuous function

$$[0, a) \to X \times \mathbb{R} \times \mathbb{R}, \quad t \mapsto (x(t), u(t), \theta(t))$$

is a *solution* of (45) if $(x(\cdot), u(\cdot), \theta(\cdot))$ is absolutely continuous as a $(X_{-1} \times \mathbb{R} \times \mathbb{R})$-valued function, $x(t) \in \mathrm{dom}(\mathrm{C_L})$ for a.a. $t \in [0, a)$, $(x(0), u(0), \theta(0)) = (x_0, u_0, \theta_0)$, and the differential equations in (45) are satisfied almost everywhere on $[0, a)$, where the derivative in (45a) should be interpreted in the space X_{-1}.

On noting that $C_L x(t) + D\phi(u(t)) = (\mathbf{\Psi}_\infty x_0)(t) + (\mathbf{F}_\infty \phi(u))(t)$ (with $\mathbf{\Psi}_\infty$ and $\mathbf{F}_\infty$ defined by (2)), the variable $x(t)$ can be eliminated from (45b) and (45c) to obtain

$$\dot{u}(t) = \kappa(t)\theta(t)[r - (\mathbf{\Psi}_\infty x_0)(t) - (\mathbf{F}_\infty \phi(u))(t)], \quad u(0) = u_0, \tag{46a}$$

$$\dot{\theta}(t) = h(\theta(t))|r - (\mathbf{\Psi}_\infty x_0)(t) - (\mathbf{F}_\infty \phi(u))(t)|, \quad \theta(0) = \theta_0. \tag{46b}$$

In order to proceed we need the following lemma.

LEMMA 5.3. *$\forall\ \alpha \geq 0$, $v \in C([0, \alpha], \mathbb{R})$, $\delta > 0$, and $\rho > 0$, there exist $\gamma_1, \gamma_2 > 0$ such that $\forall\ \varepsilon \in [0, \delta]$ and $u, w \in \mathcal{C}(\alpha, \delta, \rho, v)$*

$$\int_\alpha^{\alpha+\varepsilon} |(\mathbf{F}_\infty \phi(u))(\tau) - (\mathbf{F}_\infty \phi(w))(\tau)|\, d\tau \leq \varepsilon\gamma_1 \sup_{\alpha \leq \tau \leq \alpha+\varepsilon} |u(\tau) - w(\tau)|, \tag{47}$$

$$\int_\alpha^{\alpha+\varepsilon} |(\mathbf{F}_\infty \phi(u))(\tau)|\, d\tau \leq \varepsilon\gamma_1\rho + \sqrt{\varepsilon}\gamma_2. \tag{48}$$

Proof. Let $\alpha \geq 0$, $v \in C([0, \alpha], \mathbb{R})$, $\delta > 0$, $\rho > 0$, and $u, w \in \mathcal{C}(\alpha, \delta, \rho, v)$. Let λ be a Lipschitz constant for $\phi \in \mathcal{N}$. Then, using the Cauchy–Schwarz inequality and the boundedness of $\mathbf{F}_\infty$ as an operator from $L^2(\mathbb{R}_+, \mathbb{R})$ into $L^2(\mathbb{R}_+, \mathbb{R})$, we obtain $\forall\ \varepsilon \in [0, \delta]$,

$$\begin{aligned}
\int_\alpha^{\alpha+\varepsilon} |\mathbf{F}_\infty \phi(u) - \mathbf{F}_\infty \phi(w)| &\leq \sqrt{\varepsilon} \left(\int_\alpha^{\alpha+\varepsilon} |\mathbf{F}_\infty \phi(u) - \mathbf{F}_\infty \phi(w)|^2 \right)^{1/2} \\
&\leq \sqrt{\varepsilon}\lambda \|\mathbf{F}_\infty\| \left(\int_\alpha^{\alpha+\varepsilon} |u - w|^2 \right)^{1/2} \\
&\leq \varepsilon\lambda \|\mathbf{F}_\infty\| \sup_{\alpha \leq \tau \leq \alpha+\varepsilon} |u(\tau) - w(\tau)|,
\end{aligned}$$

which is (47) with $\gamma_1 = \lambda\|\mathbf{F}_\infty\|$.

To establish (48), define a continuous extension $v^* : \mathbb{R}_+ \to \mathbb{R}$ of v by setting $v^*(t) = v(\alpha)\ \forall\ t > \alpha$. Applying (47), it follows $\forall\ \varepsilon \in [0, \delta]$ that

$$\begin{aligned}
\int_\alpha^{\alpha+\varepsilon} |(\mathbf{F}_\infty \phi(u))(\tau)|\, d\tau &\leq \int_\alpha^{\alpha+\varepsilon} |(\mathbf{F}_\infty \phi(v^*))(\tau)|\, d\tau + \varepsilon\gamma_1 \sup_{\alpha \leq \tau \leq \alpha+\varepsilon} |u(\tau) - v^*(\tau)| \\
&\leq \sqrt{\varepsilon} \left(\int_\alpha^{\alpha+\delta} |(\mathbf{F}_\infty \phi(v^*))(\tau)|^2 \right)^{1/2} d\tau + \varepsilon\gamma_1\rho,
\end{aligned}$$

which yields (48) with $\gamma_2 := (\int_\alpha^{\alpha+\delta} |(\mathbf{F}_\infty\phi(v^*))(\tau)|^2\,d\tau)^{1/2}$. □

Lemmas 3.5 and 3.12 are special cases of the following corollary.

COROLLARY 5.4. *Let $(A,B,C,D) \in \mathcal{R}$, $\phi \in \mathcal{N}$, $r \in \mathbb{R}$, $\kappa \in L^\infty(\mathbb{R}_+,\mathbb{R})$, and let $h : \mathbb{R} \to \mathbb{R}$ be locally Lipschitz. If $h(\theta) \le 0\ \forall\ \theta \in \mathbb{R}$ and $h(0) = 0$, then $\forall$ $(x_0,u_0,\theta_0) \in X \times \mathbb{R} \times (0,\infty)$, the initial-value problem given by* (45) *has a unique solution defined on $\mathbb{R}_+$.*

Proof. Let $(x_0,u_0,\theta_0) \in X\times\mathbb{R}\times(0,\infty)$. It is clear that the map $V : C(\mathbb{R}_+,\mathbb{R}^2) \to L^1_{\mathrm{loc}}(\mathbb{R}_+,\mathbb{R}^2)$ given by

$$V\begin{pmatrix}u\\ \theta\end{pmatrix}(t) = \begin{pmatrix}\kappa(t)\theta(t)[r - (\mathbf{\Psi}_\infty x_0)(t) - (\mathbf{F}_\infty\phi(u))(t)]\\ h(\theta(t))|r - (\mathbf{\Psi}_\infty x_0)(t) - (\mathbf{F}_\infty\phi(u))(t)|\end{pmatrix}$$

is causal, and it follows from Lemma 5.3 via a routine argument that it is also weakly Lipschitz. Hence it follows from Proposition 5.1 that the initial-value problem (46) has a unique solution (u,θ) on a maximal interval of existence $[0,t_{\max})$. To prove that $t_{\max} = \infty$, we first show that θ is bounded on $[0,t_{\max})$. Note that since $h \le 0$, $\theta(\cdot)$ is nonincreasing, and combining this with the assumption that $\theta_0 > 0$, we see that boundeness of $\theta(\cdot)$ follows if we can show that $\theta(t) > 0\ \forall\ t \in [0,t_{\max})$. Seeking a contradiction, suppose that there exists a $t^* \in (0,t_{\max})$ such that $\theta(t^*) = 0$. Consider the following initial-value problem on $[0,t_{\max})$:

$$\dot\zeta(t) = h(\zeta(t))|e(t)|, \quad \zeta(t^*) = 0, \tag{49}$$

where $e(t) = r - (\mathbf{\Psi}_\infty x_0)(t) - (\mathbf{F}_\infty\phi(u))(t)$. Then $\theta(\cdot)$ is a solution of (49). Since $h(0) = 0$, the function $\zeta \equiv 0$ is also a solution of (49). By uniqueness it follows that $\theta \equiv 0$, which is in contradiction to $\theta_0 > 0$. Therefore, the function $\theta(\cdot)$ is bounded on $[0,t_{\max})$ and hence there exists a constant $\gamma > 0$ such that

$$|\kappa(t)\theta(t)| \le \gamma \quad \forall\, t \in [0,t_{\max}).$$

Let $[0,T)$ be an arbitrary interval with $[0,T) \subset [0,t_{\max})$ and $T < \infty$. Multiplying (46a) by u and estimating we obtain that, $\forall\ \tau \in [0,T)$,

$$u(\tau)\dot u(\tau) \le \gamma[r^2 + (\mathbf{\Psi}_\infty x_0)^2(\tau) + u^2(\tau) + |(\mathbf{F}_\infty\phi(u))(\tau)u(\tau)|\,]. \tag{50}$$

Integrating (50) from 0 to t and combining the estimate

$$\int_0^t |(\mathbf{F}_\infty\phi(u))u| \le \int_0^t |\mathbf{F}_\infty(\phi(u)-\phi(0))|\,|u| + \frac{1}{2}\left(\int_0^t (\mathbf{F}_\infty\phi(0))^2 + \int_0^t u^2\right),$$

the Cauchy–Schwarz inequality, and the global Lipschitz property of ϕ, we can show readily that there exist positive constants α and β such that, $\forall\ t \in [0,T)$,

$$u^2(t) \le \alpha + \beta\int_0^t u^2(\tau)\,d\tau.$$

An application of Gronwall's lemma then shows that $u^2(t) \le \alpha e^{\beta t}\ \forall\ t \in [0,T)$. Hence u is bounded on $[0,T)$. Since this holds $\forall\ T$ with $T \le t_{\max}$ and $T < \infty$, it follows by Proposition 5.1 that $t_{\max} = \infty$.

Finally, to obtain a solution of (45), *define*

$$x(t) = \mathbf{T}_t x_0 + \int_0^t \mathbf{T}_{t-\tau}B\phi(u(\tau))\,d\tau. \tag{51}$$

By well-posedness, x is a continuous X-valued function, and moreover, since A, considered as a generator on X_{-1}, is in $\mathcal{B}(X, X_{-1})$, the function $t \mapsto Ax(t)$ is a continuous X_{-1}-valued function. Consequently, by Pazy [18, Theorem 2.4, p. 107], we have that in X_{-1}

$$\dot{x}(t) = Ax(t) + B\phi(u(t)) \quad \forall\, t \in \mathbb{R}_+.$$

It follows that (x, u, θ) is the unique solution of (45) defined on $\mathbb{R}_+$. □

EXACT BOUNDARY CONTROLLABILITY OF MAXWELL'S EQUATIONS IN HETEROGENEOUS MEDIA AND AN APPLICATION TO AN INVERSE SOURCE PROBLEM*

SERGE NICAISE†

Abstract. We examine the question of control of Maxwell's equations in a heterogeneous medium with a nonsmooth boundary by means of control currents on the boundary of that medium. This requires the introduction and analysis of some functions spaces. Some energy estimates are established which allow us to get the control results owing to the Hilbert uniqueness method. We finally give an application to an inverse source problem.

Key words. Maxwell's equations, interface problems, singularities, control, inverse problem

1. Introduction. Recently the controllability and stabilization of Maxwell's equations gave rise to many works. To obtain the controllability results, four approaches are commonly used, namely the method of moments, the energy decay method of Russell, the skew symmetric operators method of Bensoussan and the Hilbert uniqueness method (HUM) of Lions [23]. The method of moments [31, 19] consists in reducing the control problem to the question of finding solutions to a countable set of moment problems related to some eigenfunctions and is only convenient for particular regions. The energy decay method [18, 1] uses the so-called Russell's "controllability via stability" principle. The skew symmetric operators method takes advantage of the purely imaginary point spectrum to obtain (sufficient) algebraic characterization of the exact controllability, algebraic conditions which are checked for the Maxwell's equations by the multiplier method [4]. The HUM is based on observation estimates (or energy estimates) of the adjoint problem. Such estimates are obtained either by the multiplier method [22, 20] or by microlocal analysis [24, 29, 30]. The above-mentioned papers require regularity properties of the solutions which are satisfied if the electric permittivity ε and the magnetic permeability μ are smooth (mainly for the sake of simplicity they assume that $\varepsilon = \mu = 1$) and the involved domain Ω is smooth. Our first goal is then to extend some of their results to the nonsmooth case (i.e., ε and μ piecewise constant and nonsmooth boundaries) using HUM.

The stabilization of Maxwell's equations with Ohm's law or with Silver–Müller absorbing boundary conditions is treated in [18, 28, 29, 30].

The relationship between exact controllability results and some inverse problems was underlined by Yamamoto [33] for the wave equation. For Maxwell's equations with constant permittivity and permeability, the determination of antennas from boundary measurements was obtained in [34]. Our second goal is to extend his result to the inhomogeneous case and to show reconstruction of antennas from boundary measurements.

Let us now define our framework and shortly describe our results. Let Ω be a

†Université de Valenciennes et du Hainaut Cambrésis, LIMAV, Institut des Sciences et Techniques de Valenciennes, F-59313 - Valenciennes Cedex 9, France (snicaise@univ-valenciennes.fr).

bounded, simply connected domain with a Lipschitz boundary Γ. We suppose that Ω is occupied by an electromagnetic medium of electric permittivity ε and magnetic permeability μ, which are real-valued bounded functions and uniformly positive definite (i.e., there exist $\varepsilon_0, \mu_0 > 0$ such that $\varepsilon(x) \geq \varepsilon_0, \mu(x) \geq \mu_0$ for all $x \in \Omega$). Two particular cases will retain our attention: First is the case when ε and μ are smooth and constant near Γ and a smooth boundary Γ. Second is the case when ε and μ are piecewise constant with Lipschitz polyhedral subdomains, in the sense that we assume that there exists a partition $\mathcal{P}$ of Ω in a finite set of Lipschitz polyhedra $\Omega_1, \ldots, \Omega_J$ such that on each Ω_j, $\varepsilon = \varepsilon_j$ and $\mu = \mu_j$, where ε_j and μ_j are positive constants (throughout this paper a Lipschitz polyhedron is a bounded, simply connected Lipschitz domain with piecewise plane boundary).

For any $T > 0$, we denote by Q_T the cylinder $\Omega\times]0,T[$ and by $\Sigma_T = \Gamma\times]0,T[$ its lateral boundary. If Γ_0 is a fixed open part of Γ, we will write $\Sigma_{0T} = \Gamma_0\times]0,T[$. When no confusion is possible we drop the index T.

We now consider (nonstationary) Maxwell's equations:

$$
\left\{
\begin{array}{l}
\varepsilon \frac{\partial E}{\partial t} - \mathbf{curl}\, H = 0 \text{ in } Q_T, \\
\mu \frac{\partial H}{\partial t} + \mathbf{curl}\, E = 0 \text{ in } Q_T, \\
\operatorname{div}(\varepsilon E) = \operatorname{div}(\mu H) = 0 \text{ in } Q_T, \\
H \times \nu = J \text{ on } \Sigma_{0T}, \\
H \times \nu = 0 \text{ on } \Sigma_T \setminus \Sigma_{0T},\ E \cdot \nu = 0 \text{ on } \Sigma_T, \\
E(0) = E_0,\ H(0) = H_0 \text{ in } \Omega,
\end{array}
\right. \tag{1.1}
$$

where ν denotes the unit outer normal vector on Γ. This means that we suppose that the time evolution of the electric field E and magnetic field H is driven by an externally applied density of current J flowing tangentially on Γ_0.

In that paper we want to find sufficient conditions that guarantee that the next exact controllability problem is solvable: Given a time $T > 0$ and initial data $\{E_0, H_0\}$, find a surface density of current J in appropriate function spaces such that the solution of (1.1) satisfies

$$E(T) = H(T) = 0 \text{ in } \Omega.$$

As already mentioned, this exact controllability problem was already investigated in [1, 19, 20, 22, 24, 29, 30, 31] but in the smooth case. Our goal is then to extend some of their results to the inhomegeneous case and for nonsmooth boundaries, which requires some nontrivial adaptations. The first step is to introduce and analyze adapted function spaces. Existence results for equations like (1.1) with homogeneous boundary conditions follow from semigroup theory. Afterwards we shall attack the exact controllability problem by means of the HUM of Lions [23] as in [22]. In that case, the exact controllability problem is equivalent to the unique solvability of the adjoint problem of (1.1), which is obtained with the help of observation estimates. In the general situation, we introduce the notion of weak and strong observation estimates satisfied by Σ_0. In both cases, we conclude the exact controllability with different controls on Σ_0. When ε and μ are smooth and constant near Γ and Γ is smooth, the strong observation estimate can be deduced from [24, 30], when Σ_0 satisfies the geometrical control property. These authors actually use microlocal analysis extending the method which has been developed by Bardos, Lebeau, and Rauch in [3] for the wave equation. When ε and μ are piecewise constant with Lipschitz polyhedra Ω_j, using multiplier techniques, we prove that Σ satisfies the weak and strong observation

estimates under some assumptions ensuring regularity properties of some function spaces [9, 10] as well as a geometrical condition (namely the condition (6.17)) in order to avoid internal control (in the homogeneous case, the first assumptions reduce to the convexity of Ω, while the geometrical condition (6.17) disappears). In this setting, a nonglobal strong observation estimate (i.e., for $\Sigma_0 \neq \Sigma$) is probably available using microlocal analysis, but this requires more investigations (see [6, 7] in the case of the wave equation with Dirichlet boundary conditions in nonsmooth domains). Note that the multiplier technique has the advantage of allowing us to get an estimate of the minimal time T_0 for which the observation estimates hold. Consequently, we obtain an estimate of the minimal time of control. Remark that when ε and μ are in $C^1(\bar{\Omega})$ and Γ is smooth, the multiplier method allows us to show that Σ satisfies the weak and strong observation estimates under some monotonicity assumptions on ε and μ. Carleman's estimate for Maxwell's equations with ε and μ in $C^2(\bar{\Omega})$ has been recently proved in [35, 14]. Such an estimate yields controllability results but with another kind of boundary controls.

As an application of the above results, we finally solve an inverse source problem in the spirit of [33, 34], namely the determination and reconstruction of antennas from boundary measurements.

Note that we have not considered Maxwell's equations with Ohm's law (which consists in adding to the left-hand side of the first equation of (1.1) the term σE, when $\sigma \geq 0$ is the conductivity of the medium) because our method only yields a controllability result for σ small enough. Probably another choice of the boundary observation would be more judicious.

The schedule of the paper is the following one: In section 2, we introduce some function spaces and prove some useful properties. Section 3 is devoted to the well-posedness of the adjoint problem of (1.1), established using the theory of maximal dissipative operators. In section 4, we introduce the notion of observation estimates and deduce from them the exact controllability results using the HUM. Section 5 is devoted to the inverse source problem. Finally, in section 6, for ε and μ piecewise constant with Lipschitz polyhedral subdomains, we establish different observation estimates for Σ adapting to our setting the results of [22, section 3], and we give an estimate of the minimal time of control.

2. Functions spaces. For any $s \geq 0$, $H^s(\Omega)$ denotes the usual Sobolev space on Ω [17]. In what follows, $\mathcal{D}(\Omega)$ is the space of all C^∞ functions with compact support in Ω while $C^\infty(\bar{\Omega})$ is the space of restrictions to Ω of functions from $\mathcal{D}(\mathbf{R}^3)$.

Let us now introduce the following spaces (compare with [21, 22]):

$$J(\Omega, \varepsilon) = \{\chi \in L^2(\Omega)^3 | \operatorname{div}(\varepsilon\chi) = 0\}, \tag{2.1}$$

$$\hat{J}(\Omega, \varepsilon) = \{\chi \in J(\Omega, \varepsilon) | \chi \cdot \nu = 0 \text{ on } \Gamma\}. \tag{2.2}$$

According to the definition of the spaces $J(\Omega)$ and $\hat{J}(\Omega)$ in [21, 22] corresponding to ε constant, we first prove the following lemma.

LEMMA 2.1. *The space $J(\Omega, \varepsilon)$ is equal to the closure in $L^2(\Omega)^3$ of*

$$X = \{\varphi \in L^2(\Omega)^3 | \varepsilon\varphi \in C^\infty(\bar{\Omega}) \text{ and } \operatorname{div}(\varepsilon\varphi) = 0\}.$$

Similarly, the space $\hat{J}(\Omega, \varepsilon)$ is equal to the closure in $L^2(\Omega)^3$ of

$$\hat{X} = \{\varphi \in L^2(\Omega)^3 | \varepsilon\varphi \in \mathcal{D}(\Omega) \text{ and } \operatorname{div}(\varepsilon\varphi) = 0\}.$$

Proof. Let us first assume that $\varepsilon = 1$. In that case, the second density result is proved in Theorem I.2.8 of [16]. For the first one, let us fix $u \in J(\Omega, 1)$. Then by Theorem I.3.4 of [16], there exists $\psi_0 \in H^1(\Omega)^3$ such that

$$u = \mathbf{curl}\, \psi_0.$$

Since $C^\infty(\bar{\Omega})$ is dense in $H^1(\Omega)$ (see, for instance, Theorem 1.4.2.1 of [17]), there exists a sequence of $\psi_n \in C^\infty(\bar{\Omega})^3$ such that

$$\mathbf{curl}\, \psi_n \to \mathbf{curl}\, \psi_0 \text{ in } L^2(\Omega)^3, \text{ as } n \to \infty.$$

Consequently, $\mathbf{curl}\, \psi_n$ belongs to $C^\infty(\bar{\Omega})$, is divergence-free, and converges to u in $L^2(\Omega)^3$.

For an arbitrary ε, we simply use the equivalence $\varphi \in J(\Omega, \varepsilon)$ (resp., $\hat{J}(\Omega, \varepsilon)$) if and only if $\varepsilon\varphi \in J(\Omega, 1)$ (resp., $\hat{J}(\Omega, 1)$). ∎

For the different formulations of our Maxwell equation (1.1), we further need the following spaces:

$$J^1_\nu(\Omega, \mu) = \{\chi \in \hat{J}(\Omega, \mu) |\, \mathbf{curl}\, \chi \in L^2(\Omega)^3\}, \tag{2.3}$$

$$J^1_\tau(\Omega, \varepsilon) = \{\chi \in J(\Omega, \varepsilon) |\, \mathbf{curl}\, \chi \in L^2(\Omega)^3 \text{ and } \chi \times \nu = 0 \text{ on } \Gamma\}, \tag{2.4}$$

$$J^\star_\nu(\Omega, \varepsilon, \mu) = \{\chi \in J^1_\nu(\Omega, \mu) |\, \mathbf{curl}(\varepsilon^{-1}\, \mathbf{curl}\, \chi) \in L^2(\Omega)^3 \text{ and } \mathbf{curl}\, \chi \times \nu = 0 \text{ on } \Gamma\}, \tag{2.5}$$

$$J^\star_\tau(\Omega, \varepsilon, \mu) = \{\chi \in J^1_\tau(\Omega, \varepsilon) |\, \mathbf{curl}(\mu^{-1}\, \mathbf{curl}\, \chi) \in L^2(\Omega)^3 \text{ and } \mathbf{curl}\, \chi \cdot \nu = 0 \text{ on } \Gamma\}. \tag{2.6}$$

When ε and μ are constant in Ω and Ω has a $C^{1,1}$ boundary, the above spaces coincide with those introduced in [21, 22], owing to Theorems 2.9 and 2.12 of [2] and the results from [8, 9]. When $\varepsilon = \mu = 1$ and Ω is a polyhedral domain, these spaces no longer coincide, in general, with those of [21, 22] according to the results of [8, 9] (see also [5, 15]; note that if Ω is convex, then the spaces $J^1_\nu(\Omega, 1)$ and $J^1_\tau(\Omega, 1)$ are embedded into $H^1(\Omega)$). Indeed in these papers, it is shown that any function in the above spaces admits a decomposition into a regular part with the optimal regularity (H^1 for the first two spaces and H^2 for the last two ones) and a singular part induces by some singularities of the Laplace operator with Dirichlet and Neumann conditions in Ω. The same kind of results were recently extended to the case when ε and μ are piecewise constant with polyhedral subdomains in [10].

For further purposes, we need the following results.

THEOREM 2.2. *There exist two positive constants c_1, c_2 such that*

$$\|\chi\|_{J^1_\nu(\Omega,\mu)} \le c_1 \|\, \mathbf{curl}\, \chi\|_{L^2(\Omega)^3} \quad \forall \chi \in J^1_\nu(\Omega, \mu), \tag{2.7}$$

$$\|\chi\|_{J^1_\tau(\Omega,\varepsilon)} \le c_2 \|\, \mathbf{curl}\, \chi\|_{L^2(\Omega)^3} \quad \forall \chi \in J^1_\tau(\Omega, \varepsilon). \tag{2.8}$$

Proof. The proof is based on the compact embeddings of $J^1_\nu(\Omega, \mu)$ and $J^1_\tau(\Omega, \varepsilon)$ into $L^2(\Omega)^3$ [32]. ∎

LEMMA 2.3. *The space $J^1_\tau(\Omega, \varepsilon)$ is dense in $J(\Omega, \varepsilon)$, while $J^1_\nu(\Omega, \mu)$ is dense in $\hat{J}(\Omega, \mu)$.*

Proof. Endow $L^2(\Omega)^3$ with the inner product

$$(\chi, \varphi) = \int_\Omega \varepsilon\chi \cdot \varphi \, dx,$$

and let P be the orthogonal projection on $J(\Omega,\varepsilon)$ in $L^2(\Omega)^3$. As $\mathcal{D}(\Omega)$ is dense in $L^2(\Omega)$, the subspace $P\mathcal{D}(\Omega)^3$ is clearly dense in $J(\Omega,\varepsilon)$. Consequently the first density result will be proved if the inclusion

$$P\mathcal{D}(\Omega)^3 \subset J^1_\tau(\Omega,\varepsilon) \tag{2.9}$$

holds. Fix $\chi \in \mathcal{D}(\Omega)^3$; then for any $\varphi \in \mathcal{D}(\Omega)^3$, we have

$$\int_\Omega \mathbf{curl}(P\chi)\cdot\varphi\,dx = \int_\Omega \varepsilon P\chi\cdot(\varepsilon^{-1}\,\mathbf{curl}\,\varphi)\,dx.$$

As the function $\varepsilon^{-1}\,\mathbf{curl}\,\varphi$ belongs to $J(\Omega,\varepsilon)$, the usual property of the projection yields

$$\int_\Omega \mathbf{curl}(P\chi)\cdot\varphi\,dx = \int_\Omega \varepsilon\chi\cdot(\varepsilon^{-1}\,\mathbf{curl}\,\varphi)\,dx.$$

This last identity shows that

$$\mathbf{curl}(P\chi) = \mathbf{curl}\,\chi. \tag{2.10}$$

This implies that $\mathbf{curl}(P\chi)$ belongs to $L^2(\Omega)^3$, and by Green's formula [16, section I.2], we have

$$\begin{aligned}\int_\Omega \mathbf{curl}(P\chi)\cdot\varphi\,dx = &\int_\Omega \varepsilon(P\chi)\cdot(\varepsilon^{-1}\,\mathbf{curl}\,\varphi)\,dx\\ &+\langle(P\chi)\times\nu,\varphi\rangle,\forall\varphi\in H^1(\Omega)^3.\end{aligned}$$

As the function $\varepsilon^{-1}\,\mathbf{curl}\,\varphi$ still belongs to $J(\Omega,\varepsilon)$, we get

$$\begin{aligned}\int_\Omega \mathbf{curl}(P\chi)\cdot\varphi\,dx = &\int_\Omega \varepsilon\chi\cdot(\varepsilon^{-1}\,\mathbf{curl}\,\varphi)\,dx\\ &+\langle(P\chi)\times\nu,\varphi\rangle,\forall\varphi\in H^1(\Omega)^3.\end{aligned}$$

Owing to (2.10), we arrive at

$$\langle(P\chi)\times\nu,\varphi\rangle = 0 \quad \forall\varphi\in H^1(\Omega)^3,$$

which shows that

$$(P\chi)\times\nu = 0 \text{ on } \Gamma.$$

This property and (2.10) prove that the inclusion (2.9) holds.

The second density result is similarly proved by endowing $L^2(\Omega)^3$ with the inner product $\int_\Omega \mu\chi\cdot\varphi\,dx$ and considering the orthogonal projection on $\hat{J}(\Omega,\mu)$ in $L^2(\Omega)^3$. □

3. Weak and strong solutions of the adjoint Maxwell equation. The homogeneous adjoint problem to (1.1) is (see section 5 for a justification)

$$\left\{\begin{array}{l}\mu\frac{\partial\varphi}{\partial t} - \mathbf{curl}\,\psi = 0 \text{ in } Q,\\ \varepsilon\frac{\partial\psi}{\partial t} + \mathbf{curl}\,\varphi = 0 \text{ in } Q,\\ \mathrm{div}(\mu\varphi) = \mathrm{div}(\varepsilon\psi) = 0 \text{ in } Q,\\ \varphi\times\nu = 0, \psi\cdot\nu = 0 \text{ on } \Sigma,\\ \varphi(0) = \varphi_0,\ \psi(0) = \psi_0 \text{ in } \Omega.\end{array}\right. \tag{3.1}$$

Contrary to [22], where a vector potential is used leading to a second order evolution equation, we shall prove existence of (3.1) by keeping the first order system (compare with [13, 18]). For that reason, let us introduce the Hilbert space

$$H = J(\Omega,\mu) \times \hat{J}(\Omega,\varepsilon),$$

equipped with the inner product

$$\left(\begin{pmatrix} \varphi \\ \psi \end{pmatrix}, \begin{pmatrix} \varphi_1 \\ \psi_1 \end{pmatrix} \right)_H = \int_\Omega \{\mu\varphi\bar{\varphi}_1 + \varepsilon\psi\bar{\psi}_1\}\, dx.$$

Now define the operator A as

$$\begin{aligned} D(A) &= J^1_\tau(\Omega,\mu) \times J^1_\nu(\Omega,\varepsilon), \\ A \begin{pmatrix} \varphi \\ \psi \end{pmatrix} &= \begin{pmatrix} \mu^{-1}\,\mathbf{curl}\,\psi \\ -\varepsilon^{-1}\,\mathbf{curl}\,\varphi \end{pmatrix}. \end{aligned}$$

We then see that formally problem (3.1) is equivalent to

$$\left\{ \begin{array}{l} \frac{\partial \Phi}{\partial t} = A\Phi, \\ \Phi(0) = \Phi_0, \end{array} \right. \tag{3.2}$$

when $\Phi = \begin{pmatrix} \varphi \\ \psi \end{pmatrix}$ and $\Phi_0 = \begin{pmatrix} \varphi_0 \\ \psi_0 \end{pmatrix}$.

We shall prove that this problem (3.2) has a unique solution using Lumer–Phillips's theorem [27] by showing the following lemma.

LEMMA 3.1. *A and $-A$ are maximal dissipative operators.*

Proof. We start with the dissipativeness of $\pm A$; in other words we need to show that

$$\Re(A\Phi,\Phi)_H = 0 \quad \forall \Phi \in D(A). \tag{3.3}$$

With the above notation we have

$$(A\Phi,\Phi)_H = \int_\Omega \{\mathbf{curl}\,\psi\bar{\varphi} - \mathbf{curl}\,\varphi\bar{\psi}\}\, dx.$$

But the definition of $D(A)$ implies that φ belongs to $H_0(\mathbf{curl},\Omega)$, where (see [16, 2])

$$H_0(\mathbf{curl},\Omega) = \{\chi \in L^2(\Omega)^3 |\, \mathbf{curl}\,\chi \in L^2(\Omega)^3 \text{ and } \chi \times \nu = 0 \text{ on } \Gamma\}.$$

Moreover, by section I.2.3 of [16], the space $\mathcal{D}(\Omega)^3$ is dense in $H_0(\mathbf{curl},\Omega)$. Consequently, there exists a sequence φ_n of functions in $\mathcal{D}(\Omega)^3$ such that

$$\varphi_n \to \varphi \text{ in } H_0(\mathbf{curl},\Omega), \text{ as } n \to \infty.$$

Now applying Green's formula (I.2.22) of [16] to the couple (φ_n,ψ), we get

$$\int_\Omega \{\mathbf{curl}\,\psi\bar{\varphi}_n - \mathbf{curl}\,\bar{\varphi}_n\psi\}\, dx = 0.$$

Taking the limit on n, we arrive at the identity

$$\int_\Omega \mathbf{curl}\,\psi\bar{\varphi}\, dx = \overline{\int_\Omega \mathbf{curl}\,\varphi\bar{\psi}\, dx}.$$

The real part of this identity yields (3.3).

Let us now pass to the maximality. This means that for all $\begin{pmatrix} f \\ g \end{pmatrix}$ in H, we are looking for $\begin{pmatrix} \varphi \\ \psi \end{pmatrix}$ in $D(A)$ such that

$$(I \pm A) \begin{pmatrix} \varphi \\ \psi \end{pmatrix} = \begin{pmatrix} f \\ g \end{pmatrix}.$$

Equivalently, we have

$$\psi = g \pm \varepsilon^{-1} \mathbf{curl}\, \varphi \tag{3.4}$$

and

$$\varphi + \mu^{-1} \mathbf{curl}(\varepsilon^{-1} \mathbf{curl}\, \varphi) = f \mp \mu^{-1} \mathbf{curl}\, g.$$

This last problem has a unique solution φ in $J^1_\tau(\Omega, \mu)$ because its variational formulation is

$$\int_\Omega \{\varepsilon^{-1} \mathbf{curl}\, \varphi\, \mathbf{curl}\, \bar{\theta} + \mu \varphi \bar{\theta}\}\, dx = \int_\Omega \{\mu f \bar{\theta} \mp g\, \mathbf{curl}\, \bar{\theta}\}\, dx \quad \forall \theta \in J^1_\tau(\Omega, \mu). \tag{3.5}$$

This problem has a unique solution by the Lax–Milgram lemma because the bilinear form defined as the left-hand side is directly coercive on $J^1_\tau(\Omega, \mu)$.

It then remains to show that ψ given by (3.4) belongs to $J^1_\nu(\Omega, \varepsilon)$. By (3.5), we see that

$$\mathbf{curl}\, \psi = \pm \mu (f - \varphi),$$

which shows that $\mathbf{curl}\, \psi \in L^2(\Omega)^3$. The other properties of ψ follow from (3.4) and from the fact that $g \in \hat{J}(\Omega, \varepsilon)$ and $\varphi \in J^1_\tau(\Omega, \mu)$ (recall that the boundary condition $\varphi \times \nu = 0$ implies that $\mathbf{curl}\, \varphi \cdot \nu = 0$). □

Since Lemma 2.3 guarantees the density of $D(A)$ into H, by Lumer–Phillips's theorem (see, for instance, Theorem I.4.3 of [27]), we conclude that A generates a C_0-group of contraction $T(t)$. Therefore, we have the following existence result.

THEOREM 3.2. *For all $\Phi_0 \in H$, the problem* (3.2) *has a weak solution $\Phi \in C([0, \infty), H)$ given by $\Phi = T(t)\Phi_0$. If, moreover, $\Phi_0 \in D(A^k)$, with $k \in \mathbf{N}^*$, the problem* (3.2) *has a strong solution $\Phi \in C([0, \infty), D(A^k)) \cap C^1([0, \infty), D(A^{k-1}))$.*

In the particular case $k = 1$ and 2, our result is in accordance with those from [22] because we easily see that

$$D(A^2) = J^\star_\tau(\Omega, \mu, \varepsilon) \times J^\star_\nu(\Omega, \mu, \varepsilon).$$

To finish this section, we establish the conservation of energy for weak and strong solutions.

LEMMA 3.3. *If $\Phi = \begin{pmatrix} \varphi \\ \psi \end{pmatrix}$ is a weak solution of problem* (3.2) *(or equivalently* (3.1)*), define the energy at time t by*

$$E(t) = \frac{1}{2} \int_\Omega \{\mu |\varphi(x,t)|^2 + \varepsilon |\psi(x,t)|^2\}\, dx.$$

Then we have

$$E(t) = E(0) \quad \forall t \geq 0. \tag{3.6}$$

Proof. Since $D(A)$ is dense in H, it suffices to prove (3.6) for $\begin{pmatrix} \varphi_0 \\ \psi_0 \end{pmatrix}$ in $D(A)$. For such an initial datum, φ and ψ are differentiable and therefore

$$\begin{aligned} \frac{d}{dt}E(t) &= \Re \int_\Omega \left\{ \mu \frac{\partial \varphi}{\partial t}\bar{\varphi} + \varepsilon \frac{\partial \psi}{\partial t}\bar{\psi} \right\} dx \\ &= \Re \int_\Omega \{ \mathbf{curl}\, \psi \bar{\varphi} - \mathbf{curl}\, \varphi \bar{\psi} \}\, dx \\ &= \Re \left(A \begin{pmatrix} \varphi \\ \psi \end{pmatrix}, \begin{pmatrix} \varphi \\ \psi \end{pmatrix} \right)_H = 0, \end{aligned}$$

owing to (3.3). ∎

LEMMA 3.4. *If* $\Phi = \begin{pmatrix} \varphi \\ \psi \end{pmatrix}$ *is a strong solution of problem* (3.2) *(or equivalently* (3.1)*) with initial datum in* $D(A)$*, define the modified energy at time* t *by*

$$\tilde{E}(t) = \frac{1}{2}\int_\Omega \{\mu^{-1} |\, \mathbf{curl}\, \psi(x,t)|^2 + \varepsilon^{-1} |\, \mathbf{curl}\, \varphi(x,t)|^2\}\, dx.$$

Then we have

$$\tilde{E}(t) = \tilde{E}(0) \quad \forall t \geq 0. \tag{3.7}$$

Proof. The proof is a direct consequence of the fact that

$$\frac{d}{dt}\tilde{E}(t) = \Re \left(A \begin{pmatrix} \frac{\partial \varphi}{\partial t} \\ \frac{\partial \psi}{\partial t} \end{pmatrix}, \begin{pmatrix} \frac{\partial \varphi}{\partial t} \\ \frac{\partial \psi}{\partial t} \end{pmatrix} \right)_H. \qquad \blacksquare$$

Let us finally notice that the compact embeddings of $J^1_\tau(\Omega,\mu)$ and $J^1_\nu(\Omega,\varepsilon)$ into $L^2(\Omega)^3$ imply that $D(A)$ is also compactly embedded into H. This fact and the monotonicity of A guarantee that A has a discrete spectrum included in the imaginary axis and that the set of associated eigenvectors forms an orthonormal basis of H.

4. Exact controllability. We start with the following definition.

DEFINITION 4.1. *Let* Γ_0 *be an open part of* Γ *and* $T > 0$*. We say that* $\Sigma_0 = \Gamma_0 \times (0,T)$ *satisfies the* (ε,μ)*-strong observation estimate (in short* (ε,μ)*-SOE) if there exists* $C > 0$ *such that*

$$\tilde{E}(0) \leq C \int_{\Sigma_0} \varepsilon^{-1} |\, \mathbf{curl}\, \varphi|^2 d\sigma dt \tag{4.1}$$

for all solutions (φ,ψ) *of* (3.1)*.*

We say that Σ_0 *satisfies the* (ε,μ)*-weak observation estimate (in short* (ε,μ)*-WOE) if there exists* $C > 0$ *such that*

$$\tilde{E}(0) \leq C \int_{\Sigma_0} (\varepsilon^{-1} |\, \mathbf{curl}\, \varphi|^2 + \mu^{-1} |\, \mathbf{curl}\, \psi|^2) d\sigma dt \tag{4.2}$$

for all solutions (φ,ψ) *of* (3.1)*.*

We will see that the weak and strong observation estimates yield control results at time T. Here are two examples where they hold. If ε and μ are smooth and constant near Γ and if Γ is smooth, then combining the results from [3] and the techniques from [24, 30], we can define the rays of the principal symbol, the diffractive

points of Σ and finally we can say that Σ_0 satisfies the geometrical control property if any ray encounters a nondiffractive point of Σ_0 (see [3, 24, 30] for the details). The method developed in [24, 30] then allows us to show that if Σ_0 satisfies the geometrical control property, then Σ_0 satisfies the (ε, μ)-SOE. If ε and μ are piecewise constant with Lipschitz polyhedral subdomains, we shall give in section 6 sufficient conditions ensuring that Σ satisfies the weak and strong observation estimates; we further obtain an explicit upper bound on the constants C appearing in (4.1) and (4.2).

If Σ_0 satisfies the (ε, μ)-SOE, the expression

$$\|\{\varphi_0, \psi_0\}\|_{F_1} = \left(\int_{\Sigma_0} |\operatorname{\mathbf{curl}} \varphi|^2 d\sigma dt \right)^{1/2}, \tag{4.3}$$

defines a norm on $J^\star_\tau(\Omega, \mu, \varepsilon) \times J^\star_\nu(\Omega, \mu, \varepsilon)$. We then define F_1 as the closure of this space for the norm (4.3). From (4.1), the following algebraic and topological inclusion holds:

$$F_1 \subset J^1_\tau(\Omega, \mu) \times J^1_\nu(\Omega, \varepsilon).$$

Unfortunately, this space does not furnish boundary controls in $L^2(\Sigma_0)^3$. We then use the next argument inspired from [22].

LEMMA 4.2. *If Σ_0 satisfies the (ε, μ)-SOE, then*

$$E(0) \leq C \sup_{x \in \Gamma_0} \varepsilon(x) \int_{\Sigma_0} |\psi|^2 d\sigma dt \tag{4.4}$$

for all solutions (φ, ψ) of (3.1) with initial data satisfying

$$\varphi_0 \in J^1_\tau(\Omega, \mu), \psi_0 \in J^1_\nu(\Omega, \varepsilon),$$

where C is the constant appearing in (4.1).

Proof. Introduce the auxiliary functions

$$\theta = \int_0^t \psi(s) ds + \theta_0, \chi = \int_0^t \varphi(s) ds + \chi_0,$$

where θ_0, χ_0 are chosen such that

$$\theta_0 \in J^\star_\nu(\Omega, \mu, \varepsilon), \operatorname{\mathbf{curl}} \theta_0 = \mu \varphi_0, \tag{4.5}$$

$$\chi_0 \in J^\star_\tau(\Omega, \mu, \varepsilon), \operatorname{\mathbf{curl}} \chi_0 = -\varepsilon \psi_0, \tag{4.6}$$

whose existence follows from the next lemma. Since θ, χ are solutions of (3.1) with initial data θ_0, χ_0, applying the estimate (4.1), we obtain

$$\begin{aligned} E(0) &\leq C \int_{\Sigma_0} \varepsilon^{-1} |\operatorname{\mathbf{curl}} \chi|^2 d\sigma dt \\ &\leq C \sup_{x \in \Gamma_0} \varepsilon(x) \int_{\Sigma_0} |\psi|^2 d\sigma dt, \end{aligned}$$

because $\operatorname{\mathbf{curl}} \chi = -\varepsilon \psi$. ∎

LEMMA 4.3. *The mappings*

$$\begin{aligned} J^\star_\nu(\Omega, \mu, \varepsilon) &\to J^1_\tau(\Omega, \mu) : \theta_0 \to \mu^{-1} \operatorname{\mathbf{curl}} \theta_0, \\ J^\star_\tau(\Omega, \mu, \varepsilon) &\to J^1_\nu(\Omega, \varepsilon) : \chi_0 \to \varepsilon^{-1} \operatorname{\mathbf{curl}} \chi_0 \end{aligned}$$

are onto.

Proof. We first prove that the first mapping is onto. Let us fix $\varphi \in J^1_\tau(\Omega,\mu)$. By Lemma 3.1 of [10], there exists $\psi \in H^1(\Omega)$ such that

$$\begin{aligned} &\mathbf{curl}\,\psi = \mu\varphi \text{ in } \Omega,\\ &\psi\cdot\nu = 0 \text{ on } \Gamma. \end{aligned}$$

We now look for θ_0 in the form

$$\theta_0 = \psi + \nabla u,$$

where u has to be determined so that θ_0 belongs to $J^\star_\nu(\Omega,\mu,\varepsilon)$. We see that it holds if

$$\begin{aligned} &\operatorname{div}(\varepsilon\theta_0) = 0 \text{ in } \Omega,\\ &\theta_0\cdot\nu = 0 \text{ on } \Gamma. \end{aligned}$$

From the expression of θ_0, this is equivalent to

$$\begin{aligned} &\operatorname{div}(\varepsilon\nabla u) = -\operatorname{div}(\varepsilon\psi) \text{ in } \Omega,\\ &\frac{\partial u}{\partial\nu} = 0 \text{ on } \Gamma. \end{aligned}$$

Therefore, it remains to look for the solution $u \in H^1(\Omega)$ of the above problem, whose variational formulation is

$$\int_\Omega \varepsilon\nabla u\nabla v\,dx = -\int_\Omega \varepsilon\psi\cdot\nabla v\,dx \quad \forall v \in H^1(\Omega).$$

This last problem has a unique (up to an additive constant) solution since the right-hand side is a continuous linear form on $H^1(\Omega)/\mathbf{R}$.

The proof of the surjectivity of the second mapping is similar, replacing Lemma 3.1 of [10] by Lemma 3.2 of [10]. □

Thanks to Lemma 4.2, if Σ_0 satisfies the (ε,μ)-SOE, the expression

$$\|\{\varphi_0,\psi_0\}\|_{F_2} = \left(\int_{\Sigma_0} |\psi|^2 d\sigma dt\right)^{1/2}, \tag{4.7}$$

defines a norm on $J^1_\tau(\Omega,\mu)\times J^1_\nu(\Omega,\varepsilon)$. If we define F_2 as the closure of this space for the norm (4.7), from (4.4), the following algebraic and topological inclusion holds:

$$F_2 \subset J(\Omega,\mu)\times\hat{J}(\Omega,\varepsilon).$$

If Σ_0 satisfies the (ε,μ)-WOE, we deduce from (4.2) (see [22] for the details) that

$$\|\{\varphi_0,\psi_0\}\|_{F_3} = \left(\int_{\Sigma_0} (|\,\mathbf{curl}\,\varphi|^2 + |\,\mathbf{curl}\,\psi|^2) d\sigma dt\right)^{1/2} \tag{4.8}$$

is a norm on $J^\star_\tau(\Omega,\mu,\varepsilon)\times J^\star_\nu(\Omega,\mu,\varepsilon)$. We then define F_3 as the closure of this space for the norm (4.8), and we have the following algebraic and topological inclusion:

$$F_3 \subset J^1_\tau(\Omega,\mu)\times J^1_\nu(\Omega,\varepsilon). \tag{4.9}$$

Following section 4 of [22], we deduce that the above observation estimates and the use of HUM allow us to prove exact controllability results for our Maxwell's equations. Here the main difficulty is to make precise the transposition method (the remainder is made exactly as in [22] and is therefore omitted).

Let us now assume that a solution $\{E, H\}$ of (1.1) exists such that

$$E \in C([0,T], J^1_\nu(\Omega,\varepsilon)) \cap C^1([0,T], \hat{J}(\Omega,\varepsilon)),$$
$$H \in C([0,T], J^1_\tau(\Omega,\mu)) \cap C^1([0,T], J(\Omega,\mu)),$$

which is the case if $E_0 \in J^1_\nu(\Omega,\varepsilon)$, $H_0 \in J^1_\tau(\Omega,\mu)$, and J is sufficiently regular.

Fix also a solution $\{\varphi, \psi\}$ of (3.1) with initial data $\{\varphi_0, \psi_0\}$ in $J^1_\tau(\Omega,\mu) \times J^1_\nu(\Omega,\varepsilon)$ with the regularity (thanks to Theorem 3.2)

$$\varphi \in C([0,T], J^1_\tau(\Omega,\mu)) \cap C^1([0,T], J(\Omega,\mu)),$$
$$\psi \in C([0,T], J^1_\nu(\Omega,\varepsilon)) \cap C^1([0,T], \hat{J}(\Omega,\varepsilon)).$$

Then we may write

$$0 = \int_0^t \int_\Omega [\varepsilon(E' - \varepsilon^{-1}\,\mathbf{curl}\, H)\cdot\psi - \mu(H' - \mu^{-1}\,\mathbf{curl}\, E)\cdot\varphi]\, dxds.$$

Applying integration by parts in s and Green's formula in x (allowed thanks to the assumptions (6.1)–(6.2)), we get

$$\int_\Omega (\mu H(t)\varphi(t) - \varepsilon E(t)\psi(t))dx = \int_\Omega (\mu H_0\varphi_0 - \varepsilon E_0\psi_0)dx$$
$$- \int_0^t \int_{\Gamma_0} J\cdot\psi d\sigma ds.$$

We rewrite this identity as

$$\langle\{H(t), -E(t)\}, \{\varphi(t), \psi(t)\}\rangle = \langle\{H_0, -E_0\}, \{\varphi_0, \psi_0\}\rangle - \int_0^t \int_{\Gamma_0} J\cdot\psi d\sigma ds. \tag{4.10}$$

In our two applications J is fixed such that the mapping

$$j : \{\varphi_0, \psi_0\} \to \int_0^t \int_{\Gamma_0} J\cdot\psi d\sigma ds$$

is a continuous linear form on F_k, $k = 2$ or 3. Consequently, the arguments of section 4 of [22] guarantee the existence of a solution $\{H, -E\} \in C([0,T], F_k')$ of (4.10) for all $\{\varphi, \psi\}$ solutions of (3.1) with initial data $\{\varphi_0, \psi_0\}$ in F_k (this solution $\{H, -E\}$ is then called the weak solution of (1.1)) with the property

$$E(T) = H(T) = 0,$$

once $\{H_0, -E_0\} \in F_k'$ is fixed such that (which is always possible)

$$\langle\{H_0, -E_0\}, \{\varphi_0, \psi_0\}\rangle = \|\{\varphi_0, \psi_0\}\|^2_{F_k}.$$

In the case $k = 2$, $J = -\psi \in L^2(\Sigma)^3$, and we directly arrive at the following theorem.

THEOREM 4.4. *Assume that Σ_0 satisfies the (ε,μ)-SOE. Then for all $\{H_0,-E_0\}\in H$, the control $J=-\psi\in L^2(\Sigma_0)^3$ drives our system* (1.1) *to rest at time T.*

In the case $k=3$, as in [22], we impose that

$$-\int_0^t\int_{\Gamma_0} J\cdot\psi d\sigma ds=\int_0^t\int_{\Gamma_0}(|\psi'|^2+|\,\mathbf{curl}\,\psi|^2)d\sigma ds,$$

since the continuity of j is then guaranteed. This yields

$$\begin{aligned} J=\psi''-\mu\sigma\times\varphi'\in(H^1(0,T;L^2(\Gamma_0)^3)'\\ \oplus L^2(\Sigma_0)\times L^2(0,T;H^{-1/2}(\mathrm{curl},\Gamma_0)'). \end{aligned}\tag{4.11}$$

Indeed, from the inclusion (4.9), we deduce that

$$\varphi,\psi\in H^1(0,T;H^{-1/2}(\Gamma_0)^3).\tag{4.12}$$

Moreover, writing

$$\mathbf{curl}\,\psi=\nu\times\frac{\partial\psi}{\partial\nu}+\sigma\times\psi,$$

where σ is a tangential differential operator of order 1, we see that

$$|\,\mathbf{curl}\,\psi|^2=\mu\varphi'\sigma\times\psi=\mu(\varphi'\cdot\nu)(\sigma\times\psi)\cdot\nu,$$

because $\varphi\times\nu=0$ on Σ. Moreover, as $\mathbf{curl}\,\psi\in L^2(\Sigma)^3$, we get

$$(\sigma\times\psi)\cdot\nu=\mathbf{curl}\,\psi\cdot\nu\in L^2(\Sigma).\tag{4.13}$$

The easily checked identity

$$(\sigma\times\psi)\cdot\nu=\mathrm{curl}\,\psi_T\text{ on }\Gamma$$

and (4.12)–(4.13) imply that

$$\psi_T\in L^2(0,T;H^{-1/2}(\mathrm{curl},\Gamma_0)),$$

where

$$H^{-1/2}(\mathrm{curl},\Gamma_0))=\{\chi\in H^{-1/2}(\Gamma_0)^2|\,\mathrm{curl}\,\chi\in L^2(\Gamma_0)\}.$$

Here $\mathrm{curl}\,\chi=\frac{\partial\chi_2}{\partial\tau_1}-\frac{\partial\chi_1}{\partial\tau_2}$ is the scalar curl of $\chi=(\chi_1,\chi_2)$ when $\{\tau_1,\tau_2\}$ is a direct orthonormal basis on Γ.

Therefore $\mu\sigma\times\varphi'$ is defined as

$$\langle\mu\sigma\times\varphi',\psi\rangle=\int_0^t\int_{\Gamma_0}\mu(\varphi'\cdot\nu)(\sigma\times\psi)\cdot\nu\,d\sigma dt.$$

Accordingly, we have proved the following theorem.

THEOREM 4.5. *Assume that Σ_0 satisfies the (ε,μ)-WOE. Then for all $\{H_0,-E_0\}\in D(A)'$, the control J given by* (4.11) *drives our system* (1.1) *to rest at time T.*

5. Determination of antennas. As in [33, 34], we shall give an application of the above results to an inverse problem, namely the determination and reconstruction of antennas from boundary measurements. From [33], we remark that the determination of antennas is simply based on the observation estimate (4.4) and on the isomorphic property of the integral operator K, defined by (5.5) hereafter, proved in [33] (see Theorem 5.1 below). On the contrary, from [33], we see that the reconstruction formula requires the observation estimate (4.4) (which yields the exact controllability result with control in $L^2(\Sigma_0)^3$) and appropriate properties of the operators K and Φ (defined by (5.8)) obtained in [33] (see Theorem 5.2 below). For that last problem, we do not use a relationship between the observation and the eigenvectors orthogonal basis but duality arguments.

To be more precise we consider Maxwell's equations where the volume current is injected from the exterior:

$$\left\{\begin{array}{l} \varepsilon\frac{\partial E}{\partial t} - \mathbf{curl}\, H = j \text{ in } Q, \\ \mu\frac{\partial H}{\partial t} + \mathbf{curl}\, E = 0 \text{ in } Q, \\ \operatorname{div}(\varepsilon E) = \operatorname{div}(\mu H) = 0 \text{ in } Q, \\ E \times \nu = 0, H \cdot \nu = 0 \text{ on } \Sigma, \\ E(0) = 0,\ H(0) = 0 \text{ in } \Omega. \end{array}\right. \tag{5.1}$$

Here $j(x,t)$ corresponds to an antenna and causes the electric and magnetic fields by (5.1). As in [33, 34], we assume that

$$j(x,t) = \lambda(t) f(x) \text{ for } x \in \Omega, t > 0.$$

The case $\lambda(t) = \cos(\omega t)$ for some fixed $\omega \in \mathbf{R}$ corresponds to an exterior current varying harmonically in time.

The problem that we will solve is the following one: Assume that λ is given. Determine f from the observation of H on a part Σ_0 of the boundary Σ. Here we will be concerned with the uniqueness, stability and reconstruction problems. These results are based on the results from Theorem 4.4 exchanging the role of ε and μ; therefore from now on we assume that Σ_0 satisfies the (μ,ε)-SOE.

The uniqueness and stability are mainly direct and were treated in [34] in the homogeneous case (ε and μ constant in Ω). To our knowledge, the reconstruction of f from the observation of H on Σ_0 is new even in the homogeneous case.

Hereafter we assume that

$$\lambda \in C^1([0,\infty)) \text{ and } \lambda(0) \neq 0. \tag{5.2}$$

The regularity assumption on λ guarantees that for any $f \in J(\Omega,\varepsilon)$, there exists a unique solution to (5.1) in $C^1([0,T]; J(\Omega,\varepsilon) \times \hat{J}(\Omega,\mu))$, denoted by $\{E(f), H(f)\}$.

We start with the uniqueness and stability results (compare with Theorems 4.1 and 4.2 of [34]).

THEOREM 5.1. *Under the above assumptions, there exists a positive constant C such that*

$$\int_\Omega \varepsilon |f(x)|^2\, dx \le C \int_{\Sigma_0} \left(|H(f)(x,t)|^2 + \left| \frac{\partial H(f)}{\partial t}(x,t) \right|^2 \right) d\sigma dt. \tag{5.3}$$

Therefore, if the solution $\{E(f), H(f)\}$ of (5.1) satisfies $H(f) = 0$ on Σ_0, then $f = 0$.

Proof. By Duhamel's principle, we have

$$E(f) = K(\varphi(f)), H(f) = K(\psi(f)), \tag{5.4}$$

where K is the integral operator defined by

$$(K\psi)(x,s) = \int_0^t \lambda(t-s)\psi(x,s)\, ds \quad \forall x \in \Gamma_0, t \in [0,T], \tag{5.5}$$

and $\{\varphi(f), \psi(f)\}$ is the unique solution (in $C([0,T]; J(\Omega,\varepsilon) \times \hat{J}(\Omega,\mu))$) of

$$\left\{\begin{array}{l} \varepsilon \frac{\partial \varphi(f)}{\partial t} - \mathbf{curl}\, \psi(f) = 0 \text{ in } Q, \\ \mu \frac{\partial \psi(f)}{\partial t} + \mathbf{curl}\, \varphi(f) = 0 \text{ in } Q, \\ \mathrm{div}(\varepsilon\varphi(f)) = \mathrm{div}(\mu\psi(f)) = 0 \text{ in } Q, \\ \varphi(f) \times \nu = 0, \psi(f) \cdot \nu = 0 \text{ on } \Sigma, \\ \varphi(f)(0) = f,\ \psi(f)(0) = 0 \text{ in } \Omega. \end{array}\right. \tag{5.6}$$

As Lemma 3 of [33] shows that the assumption (5.2) guarantees that K is an isomorphism from $L^2(\Gamma_0 \times (0,T))^3$ into $H^1(0,T; L^2(\Gamma_0)^3)$, there exists a positive constant $C(\lambda, T)$ (which means that the constant depends only on λ and T) such that

$$\int_{\Sigma_0} |\psi(f)(x,t)|^2\, d\sigma dt \le C(\lambda,T) \int_{\Sigma_0} \left(|H(f)(x,t)|^2 + \left| \frac{\partial H(f)}{\partial t}(x,t) \right|^2 \right) d\sigma dt. \tag{5.7}$$

The conclusion now follows from the estimate (4.4). ∎

We now pass to the reconstruction of f from the knowledge of $H(f)$ on Σ_0. First we need to introduce the following mappings. Thanks to Theorem 4.4, the mapping Π hereafter is well defined.

$$\Pi : J(\Omega,\varepsilon) \times \hat{J}(\Omega,\mu) \to L^2(\Sigma_0)^3 : (\varphi_0, \psi_0) \to J(\varphi_0, \psi_0),$$

where $J(\varphi_0, \psi_0)$ is the control (given by Theorem 4.4) which drives the problem

$$\left\{\begin{array}{l} \varepsilon \frac{\partial \varphi}{\partial t} - \mathbf{curl}\, \psi = 0 \text{ in } Q, \\ \mu \frac{\partial \psi}{\partial t} + \mathbf{curl}\, \varphi = 0 \text{ in } Q, \\ \mathrm{div}(\varepsilon\varphi) = \mathrm{div}(\mu\psi) = 0 \text{ in } Q, \\ \varphi \times \nu = -J(\varphi_0, \psi_0), \psi \cdot \nu = 0 \text{ on } \Sigma_0, \\ \varphi \times \nu = 0 \text{ on } \Sigma \setminus \Sigma_0, \psi \cdot \nu = 0 \text{ on } \Sigma, \\ \varphi(0) = \varphi_0,\ \psi(0) = \psi_0 \text{ in } \Omega \end{array}\right.$$

to rest at time T. Moreover, let us consider the bounded operator (see [33])

$$\Phi : L^2(\Sigma_0)^3 \to H^1(0,T; L^2(\Gamma_0)^3) : \eta \to \theta, \tag{5.8}$$

where θ is the unique solution of the Volterra integral equation (of the second kind):

$$\lambda(0)\theta'(x,t) + \int_t^T (\lambda'(\xi - t)\theta'(x,\xi) + \lambda(\xi - t)\theta(x,\xi))\, d\xi = \eta(x,t) \quad \forall (x,t) \in \Sigma_0,$$
$$\theta(x,0) = 0 \quad \forall x \in \Gamma_0.$$

According to section 3, we can finally fix the orthonormal basis $\{\Phi_k\}_{k\in\mathbf{Z}}$ of $J(\Omega,\varepsilon)\times\hat{J}(\Omega,\mu)$ of eigenvectors of the operator A (exchanging the role of ε and μ). For all $k\in\mathbf{Z}$, we shall write $\Phi_k=\{\varphi_k,\psi_k\}$.

We are now ready to state the reconstruction result.

THEOREM 5.2. *For all $k\in\mathbf{Z}$, set*

$$\theta_k=\Phi\Pi\Phi_k. \tag{5.9}$$

Then we have

$$\int_\Omega \varepsilon f\varphi_k\,dx=(H(f),\theta_k)_{H^1(0,T;L^2(\Gamma_0)^3)}\quad\forall k\in\mathbf{Z}. \tag{5.10}$$

Consequently, we have

$$f=\sum_{k\in\mathbf{Z}}(H(f),\theta_k)_{H^1(0,T;L^2(\Gamma_0)^3)}\varphi_k.$$

Proof. Since the set $\{\Phi_k\}_{k\in\mathbf{Z}}$ is a basis of $J(\Omega,\varepsilon)\times\hat{J}(\Omega,\mu)$, we may write

$$(f,0)=\sum_{k\in\mathbf{Z}}c_k\Phi_k,$$

where

$$c_k=\int_\Omega \varepsilon f\varphi_k\,dx.$$

Therefore it remains to prove the identity (5.10).

By (5.4) and the definition of θ_k, we have

$$\begin{aligned}(H(f),\theta_k)_{H^1(0,T;L^2(\Gamma_0)^3)}&=(K(\psi(f)),\Phi\Pi\Phi_k)_{H^1(0,T;L^2(\Gamma_0)^3)}\\&=(\psi(f),K^*\Phi\Pi\Phi_k)_{H^1(0,T;L^2(\Gamma_0)^3)}.\end{aligned}$$

Since it was shown in [33] (identity (5.9)) that $K^*\Phi=I$, the above identity becomes

$$(H(f),\theta_k)_{H^1(0,T;L^2(\Gamma_0)^3)}=\int_{\Sigma_0}\psi(f)\cdot\Pi\Phi_k\,d\sigma dt. \tag{5.11}$$

If we denote by $\{\tilde{\varphi}_k,\tilde{\psi}_k\}$ the (weak) solution of

$$\left\{\begin{array}{l}\varepsilon\frac{\partial\tilde{\varphi}_k}{\partial t}-\mathbf{curl}\,\tilde{\psi}_k=0\text{ in }Q,\\ \mu\frac{\partial\tilde{\psi}_k}{\partial t}+\mathbf{curl}\,\tilde{\varphi}_k=0\text{ in }Q,\\ \operatorname{div}(\varepsilon\tilde{\varphi}_k)=\operatorname{div}(\mu\tilde{\psi}_k)=0\text{ in }Q,\\ \tilde{\varphi}_k\times\nu=-\Pi\Phi_k\text{ on }\Sigma_0,\\ \tilde{\varphi}_k\times\nu=0\text{ on }\Sigma\setminus\Sigma_0,\tilde{\psi}_k\cdot\nu=0\text{ on }\Sigma,\\ \tilde{\varphi}_k(0)=\varphi_k,\ \tilde{\psi}_k(0)=\psi_k\text{ in }\Omega,\\ \tilde{\varphi}_k(T)=\tilde{\psi}_k(T)=0\text{ in }\Omega,\end{array}\right. \tag{5.12}$$

we have (see section 4)

$$\langle\{\tilde{\varphi}_k(0),\tilde{\psi}_k(0)\},\{\tilde{\varphi}_0,\tilde{\psi}_0\}\rangle=\int_{\Sigma_0}\Pi\Phi_k\cdot\tilde{\psi}\,d\sigma dt$$

for all $\{\tilde{\varphi}, \tilde{\psi}\}$ solutions of the adjoint problem to (5.12), i.e.,

$$\begin{cases} \varepsilon \frac{\partial \tilde{\varphi}}{\partial t} - \mathbf{curl}\, \tilde{\psi} = 0 \text{ in } Q, \\ \mu \frac{\partial \tilde{\psi}}{\partial t} + \mathbf{curl}\, \tilde{\varphi} = 0 \text{ in } Q, \\ \operatorname{div}(\varepsilon\tilde{\varphi}) = \operatorname{div}(\mu\psi) = 0 \text{ in } Q, \\ \tilde{\varphi} \times \nu = 0, \tilde{\psi} \cdot \nu = 0 \text{ on } \Sigma, \\ \tilde{\varphi}(0) = \tilde{\varphi}_0,\ \tilde{\psi}(0) = \tilde{\psi}_0 \text{ in } \Omega. \end{cases}$$

Since the pair $\{\varphi(f), \psi(f)\}$ solution of (5.6) is also solution of the above problem, we get

$$\langle \{\tilde{\varphi}_k(0), \tilde{\psi}_k(0)\}, \{f, 0\}\rangle = \int_{\Sigma_0} \Pi\Phi_k \cdot \psi(f)\, d\sigma dt. \tag{5.13}$$

The conclusion follows from the two identities (5.11) and (5.13). □

Remark 5.3. When ε and μ are piecewise constant with Lipschitz polyhedral subdomains, the above observation and reconstruction results hold for $\Sigma_0 = \Sigma$ under the assumptions of Corollary 6.11 (exchanging the rule of ε and μ). In that case the constant C appearing in (5.3) may be estimated as follows (see Lemma 4.2 and Corollary 6.11)

$$C \leq C(\lambda, T) \frac{\sup_{x\in\Gamma} \mu(x) \sup_{x\in\Gamma} m(x)\cdot\nu(x)}{2(T - T_0)},$$

where $C(\lambda, T)$ is the constant appearing in (5.7) and T_0 may be estimated by (6.26).

Similar results from partial observation (i.e., $\Sigma_0 \neq \Sigma$) hold when Σ_0 satisfies the geometrical control property under the assumptions that ε and μ are smooth and constant near Γ and that Γ is smooth (without estimation of the constant in (5.3)); for nonsmooth ε, μ and Γ, some investigations are still necessary (see sections 1 and 4).

6. Checking the observation estimates. In this section, we assume that Ω is a Lipschitz polyhedron. We further suppose that ε and μ are piecewise constant with Lipschitz polyhedra Ω_j. As already mentioned, we will give sufficient conditions on the partition $\mathcal{P}$ and the parameters ε and μ such that the strong and weak observation estimates hold. First of all, we need to introduce the space $PH^1(\Omega, \mathcal{P})$ of piecewise H^1 functions relatively to the partition $\mathcal{P}$; more precisely

$$PH^1(\Omega, \mathcal{P}) = \{\varphi \in L^2(\Omega) | \varphi_j \in H^1(\Omega_j) \quad \forall j = 1, \ldots, J\},$$

where, of course, φ_j means the restriction of φ to Ω_j.

For all $j = 1, \ldots, J$, we denote by $F_{jk}, k = 1, \ldots, k_j$, the open faces of the boundary of Ω_j. Let $\mathcal{F}_{\text{int}} = \{F_{jk} | F_{jk} \subset \Omega\}$ be the set of interior faces (contained in Ω) and let $\mathcal{F}_{\text{ext}}$ be the set of exterior faces (contained in Γ).

6.1. Some identities. As in [22], the observation estimates will be obtained with the help of an identity with multiplier, which, in our case, will be permitted under the following regularity assumptions:

$$J^1_\tau(\Omega, \mu) \hookrightarrow PH^1(\Omega, \mathcal{P})^3, \tag{6.1}$$

$$J^1_\nu(\Omega, \varepsilon) \hookrightarrow PH^1(\Omega, \mathcal{P})^3. \tag{6.2}$$

Owing to Theorem 3.5 of [10], the first inclusion (resp., second) holds if the operator $-\Delta_\mu^{\mathrm{Dir}}$ (resp. $-\Delta_\varepsilon^{\mathrm{Neu}}$) has no edge singular exponents in $(0,1]$ and no corner singular exponents in $(0,1/2]$ (see [10] for the right definitions). Before going on, let us remark that the above assumptions do not guarantee (see Theorem 7.1 of [10]) that the spaces $J_\tau^\star(\Omega,\mu,\varepsilon)$ and $J_\nu^\star(\Omega,\mu,\varepsilon)$ are embedded into the space of piecewise H^2 functions (as it is the case when ε and μ are constant and Γ is smooth [22]). Consequently, the integrations by parts used hereafter in order to establish the identity with multiplier require careful attention.

As already mentioned, when ε and μ are constant, the above inclusions hold if Ω is convex or if Ω has a $C^{1,1}$ boundary. Here are three examples when the inclusions (6.1) and (6.2) hold. In the first one, we leave the general setting of this section, but all the results below still hold for that example.

Example 6.1. Assume that ε and μ are constant. If Ω has a smooth boundary except at some points $x_k, k = 1,\dots,K$, where it coincides with a revolution cone centered at x_k with opening $\theta_k \in]0,\pi[$, then thanks to [8, section 2] and [11, section 18.D], (6.1) holds for all $\theta_k \le \theta_0 \cong 134^\circ$ (which is nonconvex if one θ_k is larger than 90°). On the other hand, by [8, section 2] and Proposition 10 of [12], (6.2) holds $\forall \theta_k \in]0,\pi[$.

Example 6.2. If Ω is a parallelepiped divided into two subdomains separated by a plane parallel to two faces, then by the results from section 7.a of [10], the assumptions (6.1) and (6.2) hold.

Example 6.3. Assume that Ω is convex and that any edge of any Ω_j is an edge of Ω (see Figures 1 and 2). Denote by $\varepsilon_{\min} = \min_{j=1,\dots,J} \varepsilon_j$ and $\varepsilon_{\max} = \max_{j=1,\dots,J} \varepsilon_j$. If the ratio $\frac{\mu_{\min}}{\mu_{\max}}$ (resp., $\frac{\varepsilon_{\min}}{\varepsilon_{\max}}$) is sufficiently close to 1, then (6.1) (resp., (6.2)) holds. Let us sketch the proof of (6.1). With the notation from [10], if we denote by $\nu_{\mu,c}$ (resp., $\nu_{\mu,e}$) the smallest eigenvalue of the Laplace–Beltrami operator $L_{\mu,c}^{\mathrm{Dir}}$ (resp., $L_{\mu,e}^{\mathrm{Dir}}$) associated with the corner c (resp., edge e) (a corner (resp., edge) is any corner (resp., edge) of any Ω_j), by the min-max principle we have

$$\nu_{\mu,c} \ge \frac{\mu_{\min}}{\mu_{\max}} \nu_{1,c},$$
$$\nu_{\mu,e} \ge \frac{\mu_{\min}}{\mu_{\max}} \nu_{1,e}.$$

We further recall that (see [10]) the smallest singular exponent $\lambda_{\mu,c}$ (resp., $\lambda_{\mu,e}$) of $-\Delta_\mu^{\mathrm{Dir}}$ associated with the corner e (resp., edge e) is given by

$$\lambda_{\mu,c} = -\frac{1}{2} + \sqrt{\nu_{\mu,c} + \frac{1}{4}},$$
$$\lambda_{\mu,e} = \sqrt{\nu_{\mu,e}}.$$

Consequently, $\lambda_{\mu,c} > \frac{1}{2}$ (resp., $\lambda_{\mu,e} > 1$) if and only if $\nu_{\mu,c} > \frac{3}{4}$ (resp., $\nu_{\mu,e} > 1$).

As the convexity of Ω and the assumption on $\mathcal{P}$ guarantee that $\lambda_{1,c} > \frac{1}{2}$ and $\lambda_{1,e} > 1$, we conclude that $\lambda_{\mu,c} > \frac{1}{2}$ and $\lambda_{\mu,e} > 1$ if

$$\frac{\mu_{\min}}{\mu_{\max}} > \max\left\{\frac{3}{4\nu_{1,c}}, \frac{1}{\nu_{1,2}}\right\}$$

for all corners c and all edges e.

Note that the assumption on the edges is made for the sake of simplicity; indeed if one edge e of some Ω_j is included into one face of Ω or included into Ω, then $\lambda_{1,e} = 1$

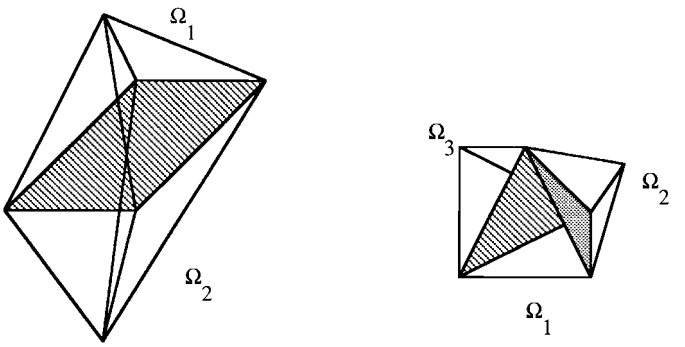

FIG. 1.

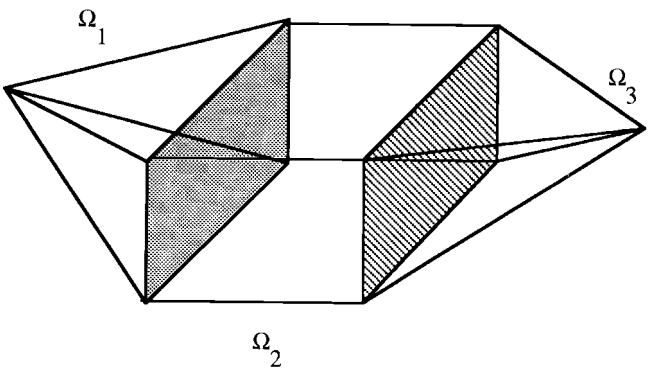

FIG. 2.

and the above argument does not allow us to conclude that $\lambda_{\mu,e} > 1$ (see [26] for some numerical examples). Nevertheless in some particular cases (as in Figure 3), a direct calculation shows that $\lambda_{\mu,e} > 1$ if the ratio $\frac{\mu_{\min}}{\mu_{\max}}$ is sufficiently close to 1.

We further introduce a vector field m defined by

$$m(x) = x - x_0,$$

where x_0 is a fixed point.

Let us now fix $\varphi_0 \in J_\tau^\star(\Omega, \mu, \varepsilon)$ and $\psi_0 \in J_\nu^\star(\Omega, \mu, \varepsilon)$, and let φ, ψ be the solution of (3.1) which has the regularity (due to Theorem 3.2)

$$\varphi \in C^2([0,\infty), J(\Omega,\mu)) \cap C^1([0,\infty), J_\tau^1(\Omega,\mu)) \cap C([0,\infty), J_\tau^\star(\Omega,\mu,\varepsilon)), \tag{6.3}$$

$$\psi \in C^2([0,\infty), \hat{J}(\Omega,\varepsilon)) \cap C^1([0,\infty), J_\nu^1(\Omega,\varepsilon)) \cap C([0,\infty), J_\nu^\star(\Omega,\mu,\varepsilon)). \tag{6.4}$$

We start with a technical property.

LEMMA 6.4. *Under the above assumptions, ψ satisfies*

$$m \cdot \nabla\psi_j \in H(\mathbf{curl}, \Omega_j) \quad \forall j = 1, \dots, J,$$

where we recall that (see [16, 2]*)* $H(\mathbf{curl}, \Omega) = \{\psi \in L^2(\Omega)^3 | \, \mathbf{curl}\, \psi \in L^2(\Omega)^3\}$.

Proof. The fact that $m \cdot \nabla\psi_j$ belongs to $L^2(\Omega_j)^3$ follows from the inclusion

$$J_\nu^\star(\Omega,\mu,\varepsilon) \subset J_\nu^1(\Omega,\varepsilon)$$

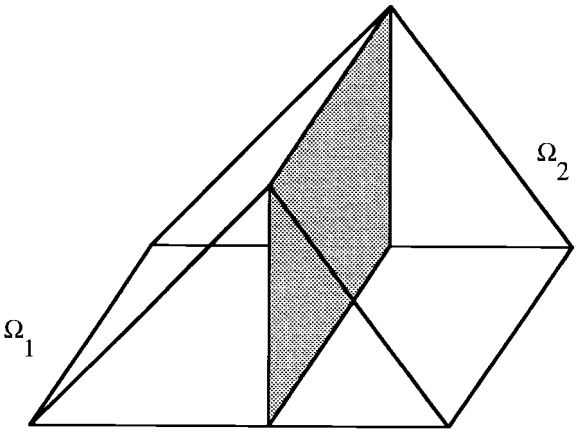

FIG. 3.

and the assumption (6.2).

For the curl, we make use of the identity

$$\mathbf{curl}(m \cdot \nabla\psi) = \mathbf{curl}\,\psi + m \cdot \nabla(\mathbf{curl}\,\psi). \tag{6.5}$$

But the regularity (6.4) implies that

$$\mu^{-1}\,\mathbf{curl}\,\psi \in J^1_\tau(\Omega,\mu),$$

and by the assumption (6.1) we conclude that $\mathbf{curl}\,\psi \in PH^1(\Omega,\mathcal{P})$. □

We now prove the following identity.

LEMMA 6.5. *Under the above assumptions, we have (hereafter ψ' means the time derivative of ψ)*

$$\begin{aligned}\frac{1}{2}\int_\Sigma m\cdot\nu(\varepsilon|\psi'|^2 - \mu^{-1}|\,\mathbf{curl}\,\psi|^2)d\sigma dt\\ +\frac{1}{2}\int_Q(\mu^{-1}|\,\mathbf{curl}\,\psi|^2 - 3\varepsilon|\psi'|^2)dxdt + X_1 + I_1 + I_2 + I_3 = 0,\end{aligned} \tag{6.6}$$

where we have set

$$\begin{aligned}X_1 &= -\int_\Omega \varepsilon\psi' m\cdot\nabla\psi dx|_0^T,\\ I_1 &= \sum_{F\in\mathcal{F}_{\rm int}}\int_{F\times(0,T)}\varphi'\times\nu_F[m\cdot\nabla\psi]_F d\sigma dt,\\ I_2 &= \frac{1}{2}\sum_{F\in\mathcal{F}_{\rm int}}\int_{F\times(0,T)} m\cdot\nu_F[\varepsilon|\psi'|^2]_F d\sigma dt,\\ I_3 &= -\frac{1}{2}\sum_{F\in\mathcal{F}_{\rm int}}\int_{F\times(0,T)}\mu^{-1}m\cdot\nu_F[|\,\mathbf{curl}\,\psi|^2]_F d\sigma dt,\end{aligned}$$

where the jump $[q]_F = q_j - q_{j'}$ if F belongs to $\partial\Omega_j$ and to $\partial\Omega_{j'}$, while ν_F is the normal vector directed from Ω_j to $\Omega_{j'}$.

Proof. Since φ' belongs to $PH^1(\Omega,\mathcal{P})$, by Lemma 6.4, Green's formula yields

$$\int_Q \varphi' \,\mathbf{curl}(m\cdot\nabla\psi)dxdt = \int_Q \mathbf{curl}\,\varphi' m\cdot\nabla\psi dxdt + I_1.$$

As $\mathbf{curl}\,\varphi' = -\varepsilon\psi''$, an integration by parts in t leads to

$$\int_Q \varphi' \,\mathbf{curl}(m\cdot\nabla\psi)dxdt = \int_Q \varepsilon\psi' m\cdot\nabla\psi' dxdt + X_1 + I_1. \tag{6.7}$$

To transform the first term of this right-hand side, we use the identity

$$\psi' m\cdot\nabla\psi' = \frac{1}{2}\mathrm{div}(m|\psi'|^2) - \frac{\mathrm{div}m}{2}|\psi'|^2. \tag{6.8}$$

Moreover, in order to integrate by parts in the term $\int_Q \varepsilon\mathrm{div}(m|\psi'|^2)$, we shall check that

$$m|\psi_j'|^2 \in W_p(\mathrm{div},\Omega_j) \quad \forall j=1,\dots,J \tag{6.9}$$

for some $p>1$. Here we use the space

$$W_p(\mathrm{div},\Omega) = \{u\in L^p(\Omega)^3 | \mathrm{div}u \in L^p(\Omega)\}.$$

In the event that $p=2$, $W_p(\mathrm{div},\Omega)$ is nothing else than $H(\mathrm{div},\Omega)$ [16]. Note that if $u\in W_p(\mathrm{div},\Omega)$, then its trace $u\cdot\nu$ belongs to $W^{-1/p,p}(\Gamma)$ and the next Green's formula holds (the proof follows the same line as the one given in [16] for $p=2$):

$$\int_\Omega (u\cdot\nabla v + \mathrm{div}uv)\,dx = \langle u\cdot\nu, v\rangle \quad \forall v\in W^{1,q}(\Omega), \tag{6.10}$$

when $1/p+1/q=1$.

Let us now verify (6.9). First, as ψ_j' belongs to $H^1(\Omega_j)^3$, the Sobolev imbedding theorem leads to

$$|\psi_j'|^2 \in L^p(\Omega_j) \quad \forall p\le 3.$$

Secondly, using the identity (6.8), it remains to check that

$$\psi_j' m\cdot\nabla\psi_j' \in L^p(\Omega_j) \tag{6.11}$$

for some $p>1$. Using again the above regularity of ψ_j', the Sobolev imbedding theorem, and Hölder's inequality, we arrive at (6.11) for all $p\le 3/2$. Therefore, (6.9) also holds for all $p\le 3/2$.

Using (6.9) and (6.10), we obtain

$$\int_Q \varepsilon\mathrm{div}(m|\psi'|^2) = I_2 + \frac{1}{2}\int_\Sigma \varepsilon m\cdot\nu|\psi'|^2 d\sigma dt.$$

Inserting this identity into (6.7), we arrive at

$$\begin{aligned}\int_Q \varphi' \,\mathbf{curl}(m\cdot\nabla\psi)dxdt &= \frac{1}{2}\int_\Sigma \varepsilon m\cdot\nu|\psi'|^2 \\ &\quad -\frac{3}{2}\int_Q \varepsilon|\psi'|^2 dxdt + X_1 + I_1 + I_2.\end{aligned} \tag{6.12}$$

In a second step using the identity (6.5), we have

$$\int_Q \mu^{-1}\,\mathbf{curl}\,\psi\,\mathbf{curl}(m\cdot\nabla\psi)dxdt = -\frac{1}{2}\int_Q \mu^{-1}|\,\mathbf{curl}\,\psi|^2 dxdt + \frac{1}{2}\int_Q \mu^{-1}\mathrm{div}(m|\,\mathbf{curl}\,\psi|^2)dxdt. \tag{6.13}$$

As before, in order to integrate by parts in the second term of this right-hand side, we readily check that

$$m|\,\mathbf{curl}\,\psi_j|^2 \in W_p(\mathrm{div},\Omega_j) \quad \forall j=1,\dots,J$$

for all $p \le 3/2$. This regularity and (6.10) allow us to transform (6.13) into

$$\int_Q \mu^{-1}\,\mathbf{curl}\,\psi\,\mathbf{curl}(m\cdot\nabla\psi)dxdt = -\frac{1}{2}\int_Q \mu^{-1}|\,\mathbf{curl}\,\psi|^2 dxdt - I_3 + \frac{1}{2}\int_\Sigma \mu^{-1} m\cdot\nu|\,\mathbf{curl}\,\psi|^2 d\sigma dt. \tag{6.14}$$

The difference between (6.12) and (6.14) directly gives (6.6). ∎

The second interesting identity is the goal of the next lemma.

LEMMA 6.6. *Under the above assumptions, we have*

$$\int_Q \varepsilon|\psi'|^2 dxdt = \int_Q \mu^{-1}|\,\mathbf{curl}\,\psi|^2 dxdt - X_2, \tag{6.15}$$

where we have set

$$X_2 = \int_\Omega \mu\varphi\cdot\varphi' dx|_0^T.$$

Proof. We multiply the identity $\psi' + \varepsilon^{-1}\,\mathbf{curl}\,\varphi = 0$ by $\varepsilon\psi'$ and integrate on Q. This gives

$$0 = \int_Q \varepsilon|\psi'|^2 dxdt + \int_Q \mathbf{curl}\,\varphi\psi' dxdt.$$

In this second term we can integrate by parts in each Ω_j, since ψ_j' is in $H^1(\Omega_j)$ and φ_j in $H(\mathbf{curl},\Omega_j)$. This leads to

$$0 = \int_Q \varepsilon|\psi'|^2 dxdt + \int_Q \varphi\,\mathbf{curl}\,\psi' dxdt,$$

because the jump of $\varphi\times\nu_F\cdot\psi'$ is zero through any interior face F. Using now the fact that $\mathbf{curl}\,\psi' = \mu\varphi''$ and an integration by part in t, we arrive at (6.15). ∎

At this stage, we are able to give the main identity with multiplier (compare with the identity (3.12) of [22]).

LEMMA 6.7. *With the above assumptions and notation, it holds that*

$$\frac{1}{2}\int_Q (\varepsilon^{-1}|\,\mathbf{curl}\,\varphi|^2 + \mu^{-1}|\,\mathbf{curl}\,\psi|^2)dxdt = \frac{1}{2}\int_\Sigma m\cdot\nu(\varepsilon^{-1}|\,\mathbf{curl}\,\varphi|^2 - \mu^{-1}|\,\mathbf{curl}\,\psi|^2)d\sigma dt + X_1 + X_2 + I_1 + I_2 + I_3. \tag{6.16}$$

Proof. The identity (6.6) may be equivalently written

$$\int_Q \varepsilon|\psi'|^2 dxdt + \frac{1}{2}\int_Q (\varepsilon|\psi'|^2 - \mu^{-1}|\operatorname{\mathbf{curl}}\psi|^2)dxdt$$
$$= \frac{1}{2}\int_\Sigma m\cdot\nu(\varepsilon|\psi'|^2 - \mu^{-1}|\operatorname{\mathbf{curl}}\psi|^2)d\sigma dt + X_1 + I_1 + I_2 + I_3.$$

Substituting (6.15) into this identity, we get (6.16) because $\psi' = -\varepsilon^{-1}\operatorname{\mathbf{curl}}\varphi$. ∎

At this stage, to obtain the observation estimates, we need a geometrical assumption in order to cancel the interface terms $I_i, i = 1, 2, 3$ (to avoid internal control!). Namely we assume that x_0 may be chosen such that

$$m\cdot\nu_F = 0 \text{ on } F \quad \forall F \in \mathcal{F}_{\text{int}}. \tag{6.17}$$

Note that this condition holds in the setting of Example 6.2. Actually it holds if and only if the planes containing the interior faces have (at least) one point in common (see Figures 1 and 3 for some examples and Figure 2 for a counterexample).

LEMMA 6.8. *Under the assumption* (6.17)*, we have*

$$I_i = 0 \quad \forall i = 1, 2, 3.$$

Proof. The nullity of I_2 and I_3 is direct. For I_1, we use the fact that $\psi\times\nu_F$ is continuous through any interior face F. Consequently, we can prove that

$$(\varphi'\times\nu_F)[m\cdot\nabla\psi]_F = (\varphi'\times\nu_F)m\cdot\nu_F\left[\frac{\partial\psi_T}{\partial\nu_F}\right]_F \text{ on } F,$$

where $\psi_T = \psi - (\psi\cdot\nu_F)\nu_F$ is the tangent part of ψ. ∎

6.2. Some estimates. We are now ready to formulate the desired estimates.

THEOREM 6.9. *Let φ, ψ be the solution of* (3.1) *with the regularity* (6.3)–(6.4)*. Assume that* (6.1), (6.2)*, and* (6.17) *hold. Then there exists a minimal time $T_0 > 0$ such that*

$$(T - T_0)\tilde{E}(0) \le \frac{1}{2}\int_\Sigma m\cdot\nu(\varepsilon^{-1}|\operatorname{\mathbf{curl}}\varphi|^2 - \mu^{-1}|\operatorname{\mathbf{curl}}\psi|^2)d\sigma dt. \tag{6.18}$$

Proof. The assumption (6.2) and Theorem 2.2 guarantee the existence of two positive constants C_1, C_2 such that

$$\left(\int_\Omega \varepsilon|\nabla\chi|^2\,dx\right)^{1/2} \le C_1\left(\int_\Omega \mu^{-1}|\operatorname{\mathbf{curl}}\chi|^2\,dx\right)^{1/2} \quad \forall\chi\in J^1_\nu(\Omega,\varepsilon), \tag{6.19}$$

$$\left(\int_\Omega \mu|\chi|^2\,dx\right)^{1/2} \le C_2\left(\int_\Omega \varepsilon^{-1}|\operatorname{\mathbf{curl}}\chi|^2\,dx\right)^{1/2} \quad \forall\chi\in J^1_\tau(\Omega,\mu). \tag{6.20}$$

These two estimates allow us to estimate X_1 and X_2; namely, by the Cauchy–Schwarz inequality, we have

$$|X_1| \le 2R(x_0)C_1\tilde{E}(0),$$
$$|X_2| \le 2C_2\tilde{E}(0),$$

where we have set

$$R(x_0) = \max_{x\in\bar{\Omega}}|x - x_0|.$$

Starting from the identity (6.16), recalling that the I_i are zero, and using the above estimates, we obtain (6.18) with

$$T_0 = 2\max(C_1 R(x_0), C_2). \qquad \square \tag{6.21}$$

COROLLARY 6.10. *Under the assumptions of Theorem* 6.9, Σ_T *satisfies the* (ε,μ)*-WOE for all* $T > T_0$ *with*

$$C \le \frac{\sup_{x\in\Gamma} m(x)\cdot\nu(x)}{2(T-T_0)}. \tag{6.22}$$

COROLLARY 6.11. *In addition to the above hypotheses* (6.1), (6.2), *and* (6.17), *if we assume that* Γ *is star-shaped with respect to some point* x_0 *(for which* (6.17) *holds), i.e.,*

$$m\cdot\nu \ge 0 \text{ on } \Gamma, \tag{6.23}$$

then Σ_T *satisfies the* (ε,μ)*-SOE for all* $T > T_0$, *with* C *estimated by* (6.22).

Proof. Under the assumption (6.23), the estimate (6.18) simplifies to

$$(T-T_0)\tilde{E}(0) \le \frac{1}{2}\int_\Sigma m\cdot\nu\varepsilon^{-1}|\,\mathbf{curl}\,\varphi|^2 d\sigma dt, \tag{6.24}$$

which proves the corollary. $\square$

Example 6.12. If ε and μ are constant, then Theorems 4.4 and 4.5 hold if Ω is convex, if it has a $C^{1,1}$ boundary or if it satisfies the hypothesis of Example 6.1. The same results hold in the setting of Example 6.2. Finally, in the case of Example 6.3, they hold if, in addition to the hypotheses prescribed in Example 6.3, the assumption (6.17) holds (see Figures 1 and 3).

6.3. Estimate of the minimal time of control. We finish the paper by giving an upper bound on the constants C_1 and C_2 appearing in (6.19) and (6.20), which yields an estimate of the minimal time T_0 for which the observation estimates hold and consequently for which control results hold.

LEMMA 6.13. *If* (6.2) *holds, then* (6.19) *holds with* $C_1 \le C_J^{1/2}$, *where we have set* $C_J = \max_{j=1,\dots,J}\{\varepsilon_j\mu_j\}$.

Proof. By Lemma 2.2 and Theorem 2.1 of [10], it holds that

$$\int_\Omega \varepsilon|\nabla\chi|^2\,dx = \int_\Omega \varepsilon(|\,\mathbf{curl}\,\chi|^2 + |\mathrm{div}\chi|^2)\,dx \quad \forall\chi\in\mathbf{H}_T(\Omega,\varepsilon),$$

where the space $\mathbf{H}_T(\Omega,\varepsilon)$ is defined by

$$\mathbf{H}_T(\Omega,\varepsilon) = \{\chi\in PH^1(\Omega,\mathcal{P})^3 | \mathrm{div}(\varepsilon\chi)\in L^2(\Omega) \text{ and } \chi\cdot\nu = 0 \text{ on } \Gamma\}.$$

Since the assumption (6.2) guarantees that $J^1_\nu(\Omega,\varepsilon)\subset\mathbf{H}_T(\Omega,\varepsilon)$, the above identity implies that

$$\int_\Omega \varepsilon|\nabla\chi|^2\,dx = \int_\Omega \varepsilon|\,\mathbf{curl}\,\chi|^2\,dx \quad \forall\chi\in J^1_\nu(\Omega,\varepsilon).$$

This identity allows us to conclude because $\varepsilon \le C_J\mu^{-1}$. $\square$

LEMMA 6.14. *If* (6.1) *and* (6.17) *hold, then* (6.20) *holds with* $C_2 \le R(x_0)C_J^{1/2}$.

Proof. Fix $\chi \in J^1_\tau(\Omega,\mu)$. By Green's formula, we have

$$\int_\Omega \mu\, \mathbf{curl}\, \chi \cdot (m \times \chi)\, dx = \int_\Omega \mu\chi \cdot \mathbf{curl}(m \times \chi)\, dx + \sum_{F \in \mathcal{F}_{\rm int}} \int_F \chi \times \nu_F \cdot [\mu m \times \chi]_F d\sigma.$$

By the assumption (6.17) and the fact that $[\mu\chi \cdot \nu_F]_F = 0$ on F, we conclude that $[\mu m \times \chi]_F$ is orthogonal to $F\ \forall\ F \in \mathcal{F}_{\rm int}$. As $\chi \times \nu_F$ is tangent to F, for all $F \in \mathcal{F}_{\rm int}$, the boundary terms of the above identity are equal to zero. Since

$$\mathbf{curl}(m \times \chi) = -2\chi + (m \cdot \nabla)\chi,$$

the above identity becomes

$$2\int_\Omega \mu|\chi|^2\, dx = \int_\Omega \mu(\chi \cdot (m \cdot \nabla)\chi - \mathbf{curl}\, \chi \cdot (m \times \chi))\, dx.$$

By the Cauchy–Schwarz inequality, we get

(6.25)
$$2\left(\int_\Omega \mu|\chi|^2\, dx\right)^{1/2} \le R(x_0)\left\{\left(\int_\Omega \mu|\nabla\chi|^2\, dx\right)^{1/2} + \left(\int_\Omega \mu|\,\mathbf{curl}\,\chi|^2\, dx\right)^{1/2}\right\}.$$

As before, the assumption (6.1) and Lemma 2.2 and Theorem 2.1 of [10] imply that

$$\int_\Omega \mu|\nabla\chi|^2\, dx \le C_J \int_\Omega \varepsilon^{-1}|\,\mathbf{curl}\,\chi|^2\, dx.$$

Inserting this estimate in (6.25) and using the fact that $\mu \le C_J\varepsilon^{-1}$, we arrive at the conclusion. ∎

Corollary 6.15. *Under the assumptions of Theorem* 6.9*, we have*

$$T_0 \le 2R(x_0)\left(\max_{j=1,\dots,J}\{\varepsilon_j\mu_j\}\right)^{1/2}. \tag{6.26}$$

Remark 6.16. In the case where ε and μ are constant in the whole of Ω, the above estimate reduces to $T_0 \le 2R(x_0)\sqrt{\varepsilon\mu}$, which is in accordance with the estimate obtained for the wave equation [23] and with Theorem 1.3 of [20]. In particular, if Ω is convex, then for $x_0 \in \Omega$ such that $2R(x_0) = \operatorname{diam}\Omega$, we hit the optimal time of control since the speed of propagation of the electromagnetic wave is $\frac{1}{\sqrt{\varepsilon\mu}}$. In the case where ε and μ are piecewise constant, the estimate (6.26) is rather good since its right-hand side only retains the slower wave.

Acknowledgments. We thank Dr. F. Jochmann and Dr. K. D. Phung for some fruitful discussions. We are also grateful to the referees for useful remarks and comments on the first version of this paper, allowing its improvement.

A NEW SUBOPTIMAL APPROACH TO THE FILTERING PROBLEM FOR BILINEAR STOCHASTIC DIFFERENTIAL SYSTEMS*

FRANCESCO CARRAVETTA†, ALFREDO GERMANI†‡, AND MARAT K. SHUAKAYEV§

Abstract. The aim of this paper is to present a new approach to the filtering problem for the class of bilinear stochastic multivariable systems, consisting in searching for suboptimal state-estimates instead of the conditional statistics. As a first result, a finite-dimensional optimal linear filter for the considered class of systems is defined. Then, the more general problem of designing polynomial finite-dimensional filters is considered. The equations of a finite-dimensional filter are given, producing a state-estimate which is optimal in a class of polynomial transformations of the measurements with arbitrarily fixed degree. Numerical simulations show the effectiveness of the proposed filter.

Key words. square integrable martingales, wide-sense Wiener processes, stochastic bilinear systems, Kronecker algebra, Kalman–Bucy filtering, polynomial filtering, vector Ito formula

1. Introduction.

Let us consider the class of nonlinear stochastic systems defined on some probability space, namely $(\Omega, \mathcal{F}, P)$, described by the Ito equations

$$dX(t) = A(t)X(t)dt + B^1(X(t), dW(t)), \tag{1.1}$$

$$dY(t) = C(t)\big(X(t)\big)dt + B^2(X(t), dW(t)), \tag{1.2}$$

where $X(t) \in \mathbf{R}^n$; $Y(t) \in \mathbf{R}^q$; $W(t) \in \mathbf{R}^p$ is a standard Wiener process with respect to some increasing family of σ-algebras, namely $\{\mathcal{F}_t\}$; $A(t), C(t)$ are matrices of proper dimensions; B^1 and B^2 are bilinear forms. System (1.1), (1.2) is commonly referred to in the literature as a *bilinear stochastic system* (BLSS) [4], [5], [6], [7], [8], [10].

The problem we are faced with consists in searching for finite-dimensional filters for the BLSS (1.1), (1.2). Indeed, for such a system even the *linear* optimal finite-dimensional filtering problem is still an interesting one.

With the name of finite-dimensional filter, we understand a stochastic differential equation in the form

$$dz(t) = f(z(t))dt + g(z(t))dY(t), \tag{1.3}$$

endowed with an output transformation

$$\hat{X}(t) = h(z(t)), \tag{1.4}$$

where $\{z(t),\ t > 0\}$ is some process taking values on a finite-dimensional linear space. We say that (1.3), (1.4) is a finite-dimensional optimal filter for system (1.1), (1.2) if

$$\hat{X}(t) = E(X(t)/\mathcal{F}_t^Y), \tag{1.5}$$

where we have denoted $\mathcal{F}_t^Y$ the σ-algebra generated by the observations $\{Y(s),\ 0 \leq s \leq t\}$.

As is well known, the optimal filter for system (1.1), (1.2) is an infinite-dimensional one. Nevertheless, from an application point of view, it becomes crucial to look for finite-dimensional approximations of the optimal filter.

In this paper we will derive, as an auxiliary result, the *optimal linear filtering* equations for a BLSS in the form of (1.1), (1.2) which will result in the finite-dimensional form (1.3), (1.4). We point out that in [3] the optimal linear filter is derived in the more general setting of linear stochastic equations driven by wide-sense Wiener (WSW) processes, resulting in a Kalman–Bucy scheme [1], [2]. Then, the optimal linear filter is defined for a scalar BLSS by representing the bilinear form as a WSW process. We will follow the same basic methodology in deriving the optimal linear filter for a *vector* BLSS.

Because of the infinite-dimensionality of the optimal filter for system (1.1), (1.2), it is of a great interest from an application point of view to search for finite-dimensional *suboptimal* filters showing a *better performance* with respect to the linear one.

This suboptimal approach has been recently developed for discrete-time systems in [9], [10], where a general *polynomial filter* of any arbitrarily fixed degree is defined for linear non-Gaussian systems [9] and bilinear systems [10]. The polynomial filter is able to produce, recursively, the optimal state-estimate in a class of polynomials of all the currently available measurements including the linear transformations. For this reason, in a non-Gaussian setting, it represents an improvement of the classical Kalman filtering. Indeed, many numerical simulations have shown that the improvement in performance may be very large especially when noise distributions are very far from Gaussianity.

In this paper we will propose this suboptimal approach for the filtering problem of continuous-time BLSSs. This will allow us to define a finite-dimensional filter in the form (1.3), (1.4), giving the optimal state-estimate in a suitably defined class of polynomial transformations of the measurements.

The program of the polynomial filtering methodology consists essentially in the following three steps.

(i) A class of polynomial estimators is defined.

(ii) The problem of finding the optimal filter for the BLSS in the above class of polynomial estimators is reduced to an optimal linear filtering problem for a suitable *augmented system*. The augmented system will result in a linear SDE with WSW diffusions. In particular, the state of the augmented system (augmented state) contains the original state, its Kronecker powers, and also Kronecker products with the observation process. The output of the augmented state (augmented observation) contains the original output process together with its Kronecker powers up to a fixed degree.

(iii) A Kalman–Bucy scheme is applied to the augmented system. This will give us the required polynomial filter.

The paper is organized as follows. Section 2 deals with point (i). In section 3, the overall setup of the problem is presented. Sections 4, 5, and 6 are concerned with some preliminary results. In particular, in section 4, a method for transforming a vector BLSS in a linear system with WSW diffusions is presented. In section 5 a vector Ito formula is defined by using the Kronecker formalism. In section 6, a general formula defining the stochastic differential of the Kronecker power of some process, solution of a bilinear SDE, is found. In section 7, point (ii) is treated. Finally, in

section 8, the complete solution of the problem is presented, resulting in a system of equations which defines a polynomial filter (of an arbitrarily fixed degree) for a BLSS. In section 9, numerical simulations are presented for a linear and third degree polynomial filter applied to a second order BLSS. A comparision is made with respect to the extended Kalman filter, which shows an unstable behavior for the presented case. Two appendices are included in order to make the paper more readable.

2. Suboptimal filtering. This section is devoted to the definition of the class of estimators considered in this paper. First of all, let us recall some results of linear filtering [3].

Let I be an interval (bounded or not) in the real line and consider a family $\{\xi_t,\ t \in I\}$ of L^2 random variables valued on some finite-dimensional euclidean space. For $t \in I$, let us define *the subspace* $\mathcal{L}_t(\xi) \subset L^2$ *linearly spanned by* $\{\xi_s,\ s \le t\}$ as the L^2-closure of the set $\mathcal{L}'_t(\xi)$:

$$\mathcal{L}'_t(\xi) \triangleq \Big\{ \lambda \in L^2 \ :\ \exists j \in \mathbf{N}, \exists t_1, \dots, t_j \in I,\ t_1 \le \cdots \le t_j \le t,$$
$$\exists \text{ matrices } M_{t_1}, \dots, M_{t_j}, \exists \text{ a vector } b, \text{ such that } \lambda = \sum_{i=1}^{j} M_{t_i} \xi_{t_i} + b \Big\}.$$

Let $\Pi(\cdot/\mathcal{L}_t(\xi))$ denote the orthogonal projection operator onto $\mathcal{L}_t(\xi)$. Then, for any given L^2 random variable η we can define the *optimal linear estimate of* η *given* $\{\xi_s,\ s \le t\}$ as $\Pi(\eta/\mathcal{L}_t(\xi))$. Now, suppose there exists an integer ν such that

$$E(\|\xi_t\|^{2\nu}) \le +\infty \quad \forall\ t \in I.$$

Let us denote by $X^{[i]}$ the ith Kronecker power of a vector X. We can give the following definition.

DEFINITION 2.1. *We call* ν*th degree polynomial estimate of* η *given* $\{\xi_s,\ s \le t\}$ *the random variable* $\Pi(\eta/\mathcal{P}_t^{(\nu)}(\xi))$*, where*

$$\mathcal{P}_t^{(\nu)}(\xi) \triangleq \mathcal{L}_t(\xi^{(\nu)})$$

and $\xi^{(\nu)}$ *is the process*

$$\xi^{(\nu)} \triangleq \begin{bmatrix} \xi^{[\nu]} \\ \xi^{[\nu-1]} \\ \vdots \\ \xi \\ 1 \end{bmatrix}.$$

From Definition 2.1 we see that $\Pi(\eta/\mathcal{P}_t^{(\nu)})$ is the mean square optimal estimate of η among all estimates, namely λ, that are either in the form

$$\lambda = \sum_{i,j=1}^{k} M_{i,j} \xi_{t_i}^{[j]} + b$$

for such a $k \in \mathbf{N}$, $t_1, \dots, t_k \in I$, $t_1 \le \cdots \le t_k$ for such a vector b and matrices $M_{i,j}$, $i, j = 1, \dots, k$, or are mean square limits of these. $\Pi(\eta/\mathcal{P}_t^{(\nu)})$ includes the linear estimates and, moreover,

$$\mathcal{P}_t^{(\nu)}(\xi) \subset \mathcal{P}_t^{(\nu+1)}(\xi) \quad \forall\ \nu \ge 1,$$

so that, for the polynomial estimates $\hat{\eta}^{(\nu)} = \Pi(\eta/\mathcal{P}_t^{(\nu)}(\xi))$, $\hat{\eta}^{(\nu+1)} = \Pi(\eta/\mathcal{P}_t^{(\nu+1)}(\xi))$ one has

$$E(\|\eta - \hat{\eta}^{(\nu+1)}\|^2) \leq E(\|\eta - \hat{\eta}^{(\nu)}\|^2) \quad \forall\ \nu \geq 1.$$

That is, the estimation quality is not decreasing for increasing ν.

Now, the aim of this paper can be expressed in a more precise manner as follows: for any given ν find a finite-dimensional filter in the form (1.3), (1.4) such that $\hat{X}(t)$ is the optimal νth degree polynomial estimate of the state of system (1.1), (1.2). Such a filter will be referred to in the following as a *νth degree polynomial filter*.

A crucial topic involved in the derivation of the polynomial filter is the linear estimation of stochastic processes generated by linear models driven by WSW processes, which we briefly describe below (see [3, Chap. 15], for a detailed discussion with proofs).

Let $\tilde{W}^{(i)}(t) \in \mathbf{R}^l$, $i = 1, \ldots, m$, be mutually uncorrelated WSW processes. Let us consider the linear stochastic system

$$\begin{aligned} dX(t) &= A(t)X(t)dt + \sum_{i=1}^{m} B_i(t)d\tilde{W}^{(i)}(t), \quad X(0) = \bar{X}, \\ dY(t) &= C(t)X(t)dt + \sum_{i=1}^{m} D_i(t)d\tilde{W}^{(i)}(t), \quad Y(0) = 0, \end{aligned} \tag{2.1}$$

where $t \in [0\ t_M]$, $X(t) \in \mathbf{R}^n$, $Y(t) \in \mathbf{R}^q$, $A(t), C(t), B_i(t), D_i(t)$, $i = 1, \ldots, m$, are suitably dimensioned matrices and $\bar{X}$ is a square integrable random vector. Model (2.1) can be interpreted as a continuous-time linear non-Gaussian system. We can consider the processes X, Y evolving in suitable L^2 spaces of square integrable random vectors. Let us denote with $\hat{X}(t)$ the optimal linear estimate of $X(t)$, that is $\hat{X}(t) = \Pi(X(t)/\mathcal{L}_t(Y))$. Then the following system of equations can be easily derived from [3, Thm. 15.3]:

(2.2)

$$\begin{aligned} d\hat{X}(t) &= A(t)\hat{X}(t)dts \\ &\quad + \left(\sum_{i=1}^{m} B_i(t)D_i(t)^T + P(t)C(t)^T\right) R(t)^{-1}(dY(t) - C(t)\hat{X}(t)dt), \\ \frac{dP(t)}{dt} &= A(t)P(t) + P(t)A(t)^T + Q(t) \\ &\quad - \left(\sum_{i=1}^{m} B_i(t)D_i(t)^T + P(t)C(t)^T\right) R(t)^{-1} \left(\sum_{i=1}^{m} B_i(t)D_i(t)^T + P_t(t)C(t)^T\right)^T, \\ \hat{X}(0) &= E(\bar{X}), \quad P(0) = E\Big((\bar{X} - E(\bar{X}))(\bar{X} - E(\bar{X}))^T\Big), \end{aligned}$$

where

$$R(t) \triangleq \sum_{i=1}^{m} D_i(t)D_i(t)^T; \quad Q(t) \triangleq \sum_{i=1}^{m} B_i(t)B_i(t)^T,$$

and $P(t)$ represents the filtering error covariance matrix. Note that in (2.2) the nonsingularity of the matrix function $R(t)$ over the time interval $[0\ t_M]$ is required.

As we will see in the next section, the BLSSs can be represented in the form (2.1). Then, (2.2) will allow us to obtain the optimal linear filter for a BLSS. This is a crucial point in the methodology here described. The way to derive the polynomial filter equations will consist indeed in reducing the original filtering problem to a linear one for a suitably defined BLSS.

3. The system to be filtered. Let $T = [0\ t_{_M}]$, let $(\Omega, \mathcal{F}, P)$ be a probability triple, and let $\{\mathcal{F}_t\}$, $t \in T$, be a family of nondecreasing sub-σ-algebras of $\mathcal{F}$. Moreover let $(W(t), \mathcal{F}_t)$ be an $\mathbf{R}^p$-valued standard Wiener process and $\bar{X} \in \mathbf{R}^n$ an $\mathcal{F}_0$-measurable random variable, independent of W, such that

$$E(\|\bar{X}\|^{2\nu}) < +\infty$$

for some integer $\nu \geq 1$. For the random variable $\bar{X}$ we suppose the moments, namely $m_{\bar{X}}^{(i)}$,

$$m_{\bar{X}}^{(i)} \triangleq E(\bar{X}^{[i]}), \quad i = 1, \ldots, 2\nu, \tag{3.1}$$

are known. Let us consider the stochastic system

$$\begin{aligned} dX(t) &= A(t)X(t)dt + H(t)u(t)dt \\ &\quad + \sum_{k=1}^{p} \big(B_k X(t) + F_k\big) dW_k(t), \quad X(0) = \bar{X}, \end{aligned} \tag{3.2}$$

$$\begin{aligned} dY(t) &= C(t)X(t)dt \\ &\quad + \sum_{k=1}^{p} \big(D_k X(t) + G_k\big) dW_k(t), \quad Y(0) = 0, \end{aligned} \tag{3.3}$$

where $A(t) \in \mathbf{R}^{n\times n}$, $C(t) \in \mathbf{R}^{q\times n}$, $H(t) \in \mathbf{R}^{n\times m}$, $B_k \in \mathbf{R}^{n\times n}$, $F_k \in \mathbf{R}^n$, $D_k \in \mathbf{R}^{q\times n}$, $G_k \in \mathbf{R}^q$, for $k = 1, \ldots, p$, $W_k(t)$ denotes the kth component of the standard Wiener process $W(t) \in \mathbf{R}^p$, and $u(t) \in \mathbf{R}^m$ is a deterministic input. Equation (3.2) is endowed with the initial condition $X(0) = \bar{X}$. In the following, we shall denote with I_α, $\alpha = 0, 1, \ldots$, the $\alpha \times \alpha$ identity matrix; we assume $I_0 = 1$. We make the following assumption on system (3.2), (3.3).

Assumption 3.1. There exists a $\bar{k}$, $1 \leq \bar{k} \leq p$, such that the matrix $D_{\bar{k}} D_{\bar{k}}^T$ is nonsingular.

Remark 3.2. Assumption 3.1 implies that we can assume, without loss of generality, that there exists a $\bar{k}$, $1 \leq \bar{k} \leq p$, such that

$$D_{\bar{k}} = [I_q\ 0]. \tag{3.4}$$

Indeed, let $\bar{k}$ be such that $D_{\bar{k}} D_{\bar{k}}^T$ is nonsingular, and define the matrix $T \in \mathbf{R}^{n\times n}$ as

$$T = \begin{bmatrix} D_{\bar{k}} \\ R \end{bmatrix},$$

where $R \in \mathbf{R}^{(n-q)\times n}$ is chosen such that the whole T results in a nonsingular matrix. It is easy to verify that $D_{\bar{k}} T^{-1} = [I_q\ 0]$. Hence we can always modify system (3.2), (3.3) by using T as a matrix performing a change of coordinates in the state space, and we can ensure that the representation (3.4) holds for at least one $\bar{k} \in \{1, \ldots, p\}$.

The problem we are faced with consists in finding a finite-dimensional filter in the form of (1.3), (1.4), such that

$$\widehat{X}(t) = \Pi\Big(X(t)/\mathcal{P}_t^{(\nu)}(Y)\Big), \tag{3.5}$$

where the space $\mathcal{P}_t^{(\nu)}(Y)$ is given by Definition 2.1.

As above mentioned (see point (ii) in the introduction), we will prove that there exists an augmented linear system for which the optimal linear filtering problem is equivalent to the original polynomial filtering problem for system (3.2), (3.3). To this purpose, in the next two sections we state some preliminary results.

4. Optimal linear filtering for BLSSs. Before treating the more general polynomial case, in this section we limit ourselves in considering the optimal linear filtering problem for the BLSS (3.2), (3.3). The reason for considering this particular case in advance is twofold. First of all, as we will see later, the polynomial case reduces to the linear one once a suitable augmented system has been constructed. Moreover, the optimal (finite-dimensional) *linear* filtering problem for a BLSS is interesting by itself, in that it was up to now unsolved in the general case [3]. In this section, we give a solution of this problem, in that we will prove the existence of a *linear* stochastic system with WSW diffusions, which is equivalent to the original BLSS (3.2), (3.3). Indeed, a version of the classical Kalman–Bucy theory [3] solves the optimal linear filtering problem in this case.

Let $M \in \mathbf{R}^{\alpha\times\alpha}$ be a symmetric positive semidefinite matrix, such that $\operatorname{rank}(M) = \rho \leq \alpha$. As is well known, there exists a full rank matrix $N \in \mathbf{R}^{\alpha\times\rho}$ such that $NN^T = M$. We will use the notation

$$M^{(\frac{1}{2})} \triangleq N,$$

that is, a "rectangular square root" of the matrix M. Note that, by definition, the matrix ${M^{(1/2)}}^T M^{(1/2)}$ is nonsingular.

Let ξ be a random vector; in the following we will use the notation $\operatorname{cov}(\xi,\xi) = E\big((\xi - E(\xi))(\xi - E(\xi))^T\big)$. Let us denote $m_X(t) = E(X(t))$, $\Psi_X(t) = \operatorname{cov}(X(t), X(t))$, where X is the state process of system (3.2), (3.3). Moreover, let us denote $\bar{m}_X = E(\bar{X})$ and $\bar{\Psi}_X = \operatorname{cov}(\bar{X}, \bar{X})$, where $\bar{X}$ is the initial state vector of (3.2).

THEOREM 4.1. *Let us consider the system* (3.2), (3.3). *Suppose that the matrix* $\Psi_X(t)$ *is nonsingular for any* $t \in T$. *Let us consider, for* $k = 1, \ldots, p$, *the integers* $\rho_k \leq n$, $\sigma_k \leq q$ *such that*

$$\begin{aligned} \rho_k &=^{\Delta} \operatorname{rank}\Big\{B_k \cdot \Psi_X(t) \cdot {B_k}^T\Big\} \\ \sigma_k &=^{\Delta} \operatorname{rank}\Big\{D_k \cdot \Psi_X(t) \cdot {D_k}^T\Big\} \end{aligned} \qquad \forall\ t \in T. \tag{4.1}$$

Then there exists the representation

$$dX(t) = A(t)X(t)dt + H(t)u(t) + \sum_{k=1}^{2p} \tilde{B}_k(t)d\tilde{W}_{k,1}(t), \quad X(0) = \bar{X}, \tag{4.2}$$

$$dY(t) = C(t)X(t)dt + \sum_{k=1}^{2p} \tilde{D}_k(t)d\tilde{W}_{k,2}(t), \qquad Y(0) = 0, \tag{4.3}$$

where, for $k = 1, \dots, p$: $\tilde{B}_k(t) \in \mathbf{R}^{n \times \rho_k}$ *and* $\tilde{D}_k(t) \in \mathbf{R}^{n \times \sigma_k}$ *are given by*

$$\tilde{B}_k(t) \triangleq \Big(B_k \cdot \Psi_X(t) \cdot B_k^T \Big)^{(\frac{1}{2})}, \tag{4.4}$$

$$\tilde{D}_k(t) \triangleq \Big(D_k \cdot \Psi_X(t) \cdot {D_k}^T \Big)^{(\frac{1}{2})} \tag{4.5}$$

for $k = p+1, \dots, 2p$:

$$\tilde{B}_k(t) \triangleq B_{k-p} E\big(X(t)\big) + F_{k-p}, \tag{4.6}$$

$$\tilde{D}_k(t) \triangleq D_{k-p} E\big(X(t)\big) + G_{k-p}. \tag{4.7}$$

For $i = 1, 2$, *the set* $\{\tilde{W}_{k,i},\ k = 1, \dots, 2p\}$ *is a set of* $2p$ *mutually uncorrelated standard WSW processes. In particular, for* $k = 1, \dots, p$, $\tilde{W}_{k,1}(t) \in \mathbf{R}^{\rho_k}$, $\tilde{W}_{k,2}(t) \in \mathbf{R}^{\sigma_k}$; *for* $k = p+1, \dots, 2p$:

$$\tilde{W}_{k,1}(t) = \tilde{W}_{k,2}(t) = W_{k-p}(t). \tag{4.8}$$

Proof. For $k = 1, \dots, p$, let us define the processes $\tilde{W}_{k,1}, \tilde{W}_{k,2}$ as

$$\tilde{W}_{k,1}(t) = \int_0^t \big(\tilde{B}_k(\tau)^T \tilde{B}_k(\tau) \big)^{-1} \tilde{B}_k(\tau)^T B_k\big(X(\tau) - m_X(\tau)\big) dW_k(\tau), \tag{4.9}$$

$$\tilde{W}_{k,2}(t) = \int_0^t \big(\tilde{D}_k(\tau)^T \tilde{D}_k(\tau) \big)^{-1} \tilde{D}_k(\tau)^T D_k\big(X(\tau) - m_X(\tau)\big) dW_k(\tau), \tag{4.10}$$

where $\tilde{B}_k, \tilde{D}_k$ are given by (4.4), (4.5). Let us show that $\tilde{W}_{k,i}$, $i = 1, 2$, are standard WSW processes. As a matter of fact, using well-known properties of the Ito integral and (4.4), it results, for $s < t$:

$$\begin{aligned} &E\big(\tilde{W}_{k,1}(t) \tilde{W}_{k,1}(s)^T\big) \\ &\quad = \int_0^s \big(\tilde{B}_k(\tau)^T \tilde{B}_k(\tau) \big)^{-1} \tilde{B}_k(\tau)^T \Big(B_k \Psi_X(\tau) B_k^T \Big) \tilde{B}_k(\tau) \big(\tilde{B}_k(\tau)^T \tilde{B}_k(\tau) \big)^{-1} \, d\tau \\ &\quad = \int_0^s \big(\tilde{B}_k(\tau)^T \tilde{B}_k(\tau) \big)^{-1} \tilde{B}_k(\tau)^T \big(\tilde{B}_k(\tau) \tilde{B}_k(\tau)^T \big) \cdot \tilde{B}_k(\tau) \big(\tilde{B}_k(\tau)^T \tilde{B}_k(\tau) \big)^{-1} \, d\tau \\ &\quad = I_{\rho_k} \cdot s. \end{aligned}$$

Similarly, taking again an $s < t$, it can be proved that

$$E\big(\tilde{W}_{k,2}(t) \tilde{W}_{k,2}(s)^T\big) = I_{\sigma_k} \cdot s,$$

and hence, since the Wiener's process components $W_1, \dots, W_p$, are mutually independent, we have that, for $i = 1, 2$, $\{\tilde{W}_{k,i},\ k = 1, \dots, p\}$ is a family of mutually independent (vector) WSW processes with identity covariance.

Now let us show that, for $k = 1, \dots, p$ (almost surely),

$$\tilde{B}_k(t) d\tilde{W}_{k,1}(t) = B_k\big(X(t) - m_X(t)\big) dW_k(t), \tag{4.11}$$

$$\tilde{D}_k(t) d\tilde{W}_{k,2}(t) = D_k\big(X(t) - m_X(t)\big) dW_k(t). \tag{4.12}$$

From the hypotheses the symmetric positive-definite matrix $\Psi(t)^{1/2}$ is well defined. Hence, for any $y(t) \in \mathbf{R}^n$ we can define $\bar{y}(t) \in \mathbf{R}^n$ such that $y(t) = \Psi_x(t) \bar{y}(t)$. Next, let us consider the decomposition $\bar{y}(t) = \bar{y}_1(t) + \bar{y}_2(t)$, where

$$\bar{y}_1(t) \in \mathcal{R}\big(\Psi_X(t)^{1/2} B_k^T\big), \quad \bar{y}_2(t) \in \Big\{ \mathcal{R}\big(\Psi_X(t)^{1/2} B_k^T\big) \Big\}^{\perp} = \mathcal{N}\big(B_k \Psi_X(t)^{1/2}\big), \tag{4.13}$$

where $\mathcal{N}(M)$, $\mathcal{R}(M)$ denote the null-space and the range, respectively, of a matrix M. Using (4.13) and choosing a $\bar{z}(t)$ such that $\bar{y}_1(t) = \Psi_X(t)^{1/2} B_k \bar{z}(t)$, we have

$$B_k y(t) = B_k \Psi_X(t)^{\frac{1}{2}} \bar{y}(t) = B_k \Psi_X(t)^{\frac{1}{2}} \bar{y}_1(t) = B_k \Psi_X(t) B_k^T \bar{z}(t) = \tilde{B}_k(t) \tilde{B}_k(t)^T \bar{z}(t),$$

where the definition of $\tilde{B}_k(t)$, given by (4.4) has been used. It follows that for any $y(t) \in \mathbf{R}^n$ there exists a $z(t) \in \mathbf{R}^{\rho_k}$ (indeed $z(t) = \tilde{B}_k(t)^T \bar{z}(t)$) such that

$$B_k y(t) = \tilde{B}_k(t) z(t) \quad \forall\, t \in T. \tag{4.14}$$

Then, for any $y(t)$ we have

$$\begin{aligned} \tilde{B}_k(t) \Big(\tilde{B}_k(t)^T \tilde{B}_k(t) \Big)^{-1} \tilde{B}_k(t)^T B_k y(t) &= \tilde{B}_k(t) \Big(\tilde{B}_k(t)^T \tilde{B}_k(t) \Big)^{-1} \tilde{B}_k(t)^T \tilde{B}_k(t) z(t) \\ &= \tilde{B}_k(t) z(t) = B_k y(t), \end{aligned}$$

from which, using the definition of $\tilde{W}_{k,1}$ given by (4.9), equality (4.11) follows. A similar argument can be used to prove (4.12).

Finally, by adding and subtracting the state-expectation $m_{_X}(t)$, in the bilinear forms of (3.2), (3.3) and taking into account (4.11), (4.12), we obtain the representation (4.2), (4.3). The thesis follows as soon as it is proven that, for $i = 1, 2$, $\tilde{W}_{k',i}(t)$ $(p+1 \le k' \le 2p)$ is uncorrelated with $\tilde{W}_{k'',i}(t)$ $(1 \le k'' \le p)$. As a matter of fact, from (4.8), for $p+1 \le k' \le 2p$, $k'' \ne k' - p$,

$$E\big(\tilde{W}_{k'',1}(t) \tilde{W}_{k',1}(t)^T\big) = E\big(\tilde{W}_{k'',1}(t) W_{k'-p}(t)^T\big) = 0,$$

and, for $k'' = k' - p$,

$$\begin{aligned} &E\big(\tilde{W}_{k'',1}(t) \tilde{W}_{k',1}(t)^T\big) = E\big(\tilde{W}_{k'',1}(t) W_{k''}(t)^T\big) \\ &= E\left(\int_0^t \big(\tilde{B}_{k''}(\tau)^T \tilde{B}_{k''}(\tau)\big)^{-1} \tilde{B}_{k''}(\tau)^T B_{k''} \big(X(\tau) - m_{_X}(\tau)\big) dW_{k''}(\tau) \cdot \int_0^t dW_{k''}(\tau) \right) \\ &= \int_0^t E\Big(\big(\tilde{B}_{k''}(\tau)^T \tilde{B}_{k''}(\tau)\big)^{-1} \tilde{B}_{k''}(\tau)^T B_{k''} \big(X(\tau) - m_{_X}(\tau)\big) \Big) d\tau = 0. \end{aligned}$$

In the same way, it is possible to show that $E\big(\tilde{W}_{k'',2}(t) \tilde{W}_{k',2}(t)^T\big) = 0$ for $p+1 \le k' \le 2p$. □

In the following theorem a sufficient condition will be given which guarantees the nonsingularity of $\Psi_X(t)$. Let us consider a time-invariant version of the BLSS given by (3.2), (3.3):

$$dX(t) = AX(t)dt + Hu(t)dt + \sum_{k=1}^{p} (B_k X(t) + F_k) dW_k(t), \quad X(t_0) = \bar{X}, \tag{4.15}$$

$$dY(t) = CX(t)dt + \sum_{k=1}^{p} (D_k X(t) + G_k) dW_k(t), \qquad Y(t_0) = 0, \tag{4.16}$$

where $t_0 \in \mathbf{R}$ is any "initial time." We suppose that system (4.15), (4.16) is well defined over the time interval $[t_0\ \infty)$.

THEOREM 4.2. *Let the matrix $\Psi_X(t_0)$ be nonsingular (or the pair (A, F_k) of the state equation* (4.15) *be controllable for at least one $k = 1, \dots, p$); then the state covariance matrix $\Psi_X(t)$ is nonsingular for any $t \ge t_0$, $(t > 0)$.*

Proof. Let us denote $\tilde{X}(t) = X(t) - m_X(t)$. Taking the expectations of (4.15), we have

$$dm_X(t) = Am_X(t)dt + Hu(t)dt, \qquad m_X(0) = \bar{m}_X.$$

Subtracting this from (4.15) results in

$$d\tilde{X}(t) = A\tilde{X}(t)dt + \sum_{k=1}^{p} B_k\tilde{X}(t)dW_k(t) + \sum_{k=1}^{p}(B_k m_X(t) + F_k)dW_k(t), \quad \tilde{X}(t_0) = \bar{X} - \bar{m}_X$$

or

$$\begin{aligned}\tilde{X}(t) = e^{A(t-t_0)}\tilde{X}(t_0) &+ \sum_{k=1}^{p}\int_{t_0}^{t} e^{A(t-\tau)}B_k\tilde{X}(\tau)dW_k(\tau) \\ &+ \int_{t_0}^{t} e^{A(t-\tau)}(B_k m_X(\tau) + F_k)dW_k(\tau).\end{aligned} \tag{4.17}$$

From (4.17) the following equation is easily recognized to hold for $\Psi_X(t)$:

$$\begin{aligned}\Psi_X(t) = e^{A(t-t_0)}\Psi_X(t_0)e^{A^T(t-t_0)} &+ \sum_{k=1}^{p}\int_{t_0}^{t} e^{A(t-\tau)}B_k\Psi_X(\tau)B_k^T e^{A^T(t-\tau)}d\tau \\ &+ \sum_{k=1}^{p}\int_{t_0}^{t} e^{A(t-\tau)}(B_k m_X(\tau) + F_k)(B_k m_X(\tau) + F_k)^T e^{A^T(t-\tau)}d\tau.\end{aligned} \tag{4.18}$$

The thesis follows by noting that the three terms in the right-hand side of (4.18) are at least symmetric nonnegative definite and, in particular, the nonsingularity of $\phi_X(t_0)$ implies the positive definiteness of the first term, whereas the hypothesis of controllability of (A, F_k) for some k implies the positive definiteness of the term $\int e^{A(t-\tau)}F_k F_k^T e^{A^T(t-\tau)}d\tau$. □

Remark 4.3. Note that, when theorem 4.2 holds with $t_0 < 0$, it results that, for any finite time-interval $T \subset [t_0 \ +\infty)$, the state-covariance has the property $\Psi_X(t) > \alpha \cdot I \ \forall \ t \in T$ (I denotes the identity) for some real number $\alpha > 0$, (it is *unifomly nonsingular in* T).

Now, we can state the following theorem, which defines the optimal linear filter for a BLSS.

THEOREM 4.4. *Let the time-invariant BLSS as defined in* (4.15), (4.16) *be given. Let the hypotheses of Theorem* 4.2 *be satisfied. Moreover, let us suppose that*

(H1) $\operatorname{rank}(D_k) = q$ *or* $\operatorname{rank}(G_k) = q$ *for some* k.

Then, with reference to the notations of section 2, *the optimal linear estimate of the state process* X, *namely* $\hat{X}$, *and the error covariance*

$$P(t) = E\big((X(t) - \hat{X}(t))(X(t) - \hat{X}(t))^T\big)$$

satisfy the following system of equations:

$$\begin{aligned}\frac{dm_X(t)}{dt} &= Am_X(t) + Hu(t), \qquad m(0) = \bar{m}, \\ \frac{d\Psi_X(t)}{dt} &= A\Psi_X(t) + \Psi_X(t)A^T + \sum_{k=1}^{p} B_k\Psi_X(t)B_k^T\end{aligned} \tag{4.19}$$

$$+\sum_{k=1}^{p}(B_k m_X(t)+F_k)(B_k m_X(t)+F_k)^T, \qquad \Psi_X(0)=\bar{\Psi}_X, \tag{4.20}$$

$$\tilde{B}_k(t)=\begin{cases}\left(B_k\cdot\Psi_X(t)\cdot B_k^T\right)^{(\frac{1}{2})}, & 1\le k\le p,\\ B_{k-p}m_X(t)+F_{k-p}, & p+1\le k\le 2p,\end{cases} \tag{4.21}$$

$$\tilde{D}_k(t)=\begin{cases}\left(D_k\cdot\Psi_X(t)\cdot D_k^T\right)^{(\frac{1}{2})}, & 1\le k\le p,\\ D_{k-p}m_X(t)+G_{k-p}, & p+1\le k\le 2p,\end{cases} \tag{4.22}$$

$$R(t)=\sum_{i=1}^{2p}\tilde{D}_i(t)\tilde{D}_i(t)^T, \tag{4.23}$$

$$\begin{aligned}\frac{dP(t)}{dt}&=AP(t)+P(t)A^T+R(t),\\ &-\left(\sum_{i=1}^{2p}\tilde{B}_i(t)\tilde{D}_i(t)^T+P(t)C^T\right)R(t)^{-1}\left(\sum_{i=1}^{2p}\tilde{B}_i(t)\tilde{D}_i(t)^T+P(t)C^T\right)^T,\end{aligned} \tag{4.24}$$

$$P(0)=\bar{\Psi}_X, \tag{4.25}$$

$$d\hat{X}(t)=A\hat{X}(t)dt+\left(\sum_{i=1}^{2p+1}\tilde{B}_i(t)\tilde{D}_i(t)^T+P(t)C^T\right)R(t)^{-1}(dY(t)-C\hat{X}(t)dt), \tag{4.26}$$

$$\hat{X}(0)=\bar{m}. \tag{4.27}$$

Proof. (4.19) readily derives by taking the expectations of both sides of (4.15). Moreover, (4.20) is easily obtained by differentiating (4.18). From Theorem 4.2 and Remark 4.3, $\Psi_X(t)$ is uniformly nonsingular in T. Then, we can apply Theorem 4.1 in order to put system (4.15), (4.16) in the form of a linear stochastic system with suitable WSW state and output diffusions, deriving from (4.2), (4.3). Note that such an equivalent system is a time-varying one even if it is derived from the time-invariant BLSS (4.15), (4.16). Now from (4.22), (4.23) it results that

$$R(t)\triangleq\sum_{k=1}^{p}D_k\Psi_X(t)D_k^T+\sum_{k=1}^{p}(D_k m_X(t)+G_k)(D_k m_X(t)+G_k)^T,$$

which is uniformly nonsingular in T, by the hypothesis (H1) (and possibly by the uniform nonsingularity of $\Psi_X(t)$). The thesis easily derives from an application of [3, Thm. 15.3] to the representation (4.2), (4.3). □

Remark 4.5. In the general case, when the BLSS is time-varying the uniform nonsingularity of $\Psi_X(t)$ cannot be guaranteed. Nevertheless, in all the cases of a nonsingular $\Psi_X(t)$, the equations of the optimal linear filter can be still derived using the representation given by Theorem 4.1. The resulting system of equations is formally similar to (4.19)–(4.27), but the constant parameters are replaced with the corresponding time-varying ones.

5. The vector Ito formula in the Kronecker formalism. In this section, by using a formalism derived from the Kronecker algebra, we present a new version of the Ito formula which has, with respect to the classical formulation, the advantage of

being much more compact and will allow us to calculate, for a given stochastic process ϕ, the stochastic differential of the process $\phi^{[h]}$, where $[h]$ is any integer Kronecker power.

Let $x \in \mathbf{R}^n$ and F be any C^2 function in $\mathbf{R}^{m\times p}$; we introduce the matrix $(d/dx)\otimes F(x)$, having dimensions $m \times (n \cdot p)$, defined as

$$\frac{d}{dx} \otimes F(x) \triangleq \Big[\frac{\partial F(x)}{\partial x_1} \ \cdots \ \frac{\partial F(x)}{\partial x_n}\Big], \tag{5.1}$$

where the operator d/dx is given by

$$\frac{d}{dx} \triangleq \Big[\frac{\partial}{\partial x_1} \ \cdots \ \frac{\partial}{\partial x_n}\Big]. \tag{5.2}$$

Note that in (5.1) the rules defining the Kroneker product between matrices (see Definition A.1) are formally satisfied, provided that the "multiplication" between the differential operator $\partial/\partial x_i$ and a matrix function $F(x)$ is conventionally defined as

$$\frac{\partial}{\partial x_i} \cdot F(x) = \frac{\partial F(x)}{\partial x_i},$$

where the right-hand side has the usual meaning. Similarly, we can define the operator:

$$\frac{d}{dx} \otimes \frac{d}{dx} \triangleq \Big[\frac{\partial^2}{\partial x_1^2} \ \frac{\partial^2}{\partial x_1 \partial x_2} \ \cdots \ \frac{\partial^2}{\partial x_n^2}\Big].$$

Also in this case the composition rule of the Kronecker product is satisfied, but the "multiplication" between the differential operators $\partial/\partial x_i$ and $\partial/\partial x_i$ had to be interpreted as resulting in the differential operator $\partial^2/\partial x_i \partial x_j$. In general, we will adopt the convention: the multiplication between a differential operator and a function F results in a function (the derivative of F), whereas the multiplication between two differential operators results in a differential operator (the second order differential operator). Obviously, this convention could be generalized in order to give a precise meaning to the quantity

$$\frac{d^{[h]}}{dx^{[h]}} \otimes F(x)$$

for any integer $h \geq 0$. However, in this paper we are concerned at most with second-order derivatives.

It is easy to recognize that for any matrix, namely M, and for any pair of differentiable matrix functions having suitable dimensions, namely $V(x)$ and $W(x)$, it results that

$$\frac{d}{dx} \otimes (V(x) \otimes W(x)) = \Big(\frac{d}{dx} \otimes V(x)\Big) \otimes W(x) + V(x) \otimes \Big(\frac{d}{dx} \otimes W(x)\Big), \tag{5.3}$$

$$\frac{d}{dx} \otimes (MW(x)) = M\Big(\frac{d}{dx} \otimes W(x)\Big). \tag{5.4}$$

Moreover, the following "associative" property holds:

$$\frac{d}{dx} \otimes \frac{d}{dx} \otimes F(x) = \Big(\frac{d}{dx} \otimes \frac{d}{dx}\Big) \otimes F(x) = \frac{d}{dx} \otimes \Big(\frac{d}{dx} \otimes F(x)\Big).$$

Using the above notation, we can prove the following lemma, which will be very useful in the following sections.

LEMMA 5.1. *For any integer $h \geq 1$ and $x \in \mathbf{R}^n$, it results that*

$$\frac{d}{dx} \otimes x^{[h]} = U_n^h (I_n \otimes x^{[h-1]}), \tag{5.5}$$

and for any $h > 1$,

$$\frac{d}{dx} \otimes \frac{d}{dx} \otimes x^{[h]} = O_n^h (I_{n^2} \otimes x^{[h-2]}), \tag{5.6}$$

where the matrices $C_{u,v}^T$, $u, v \in \mathbf{N}$, are the commutation matrices defined by Theorem A.3 *and*

$$U_n^h \triangleq \left(\sum_{\tau=0}^{h-1} C_{n,n^{h-1-\tau}}^T \otimes I_{n^\tau} \right), \quad O_n^h \triangleq \sum_{\tau=0}^{h-1} \sum_{s=0}^{h-2} (C_{n,n^{h-1-\tau}}^T \otimes I_{n^\tau})(I_n \otimes C_{n,n^{h-2-s}}^T \otimes I_n).$$

Proof. According to the definition of the differential operator (5.1) and using (5.3), we have

$$\begin{aligned} Q^h \triangleq \frac{d}{dx} \otimes x^{[h]} &= \frac{d}{dx} \otimes \left(x \otimes x^{[h-1]} \right) = I_n \otimes x^{[h-1]} + x \otimes \left(\frac{d}{dx} \otimes x^{[h-1]} \right) \\ &= I_n \otimes x^{[h-1]} + x \otimes Q^{(h-1)}, \end{aligned} \tag{5.7}$$

from which, using Theorem A.3, we obtain

$$\frac{d}{dx} \otimes x^{[h]} = \sum_{\tau=0}^{h-1} x^{[h-1-\tau]} \otimes I_n \otimes x^{[\tau]} = \sum_{\tau=0}^{h-1} C_{n,n^{h-1-\tau}}^T \left(I_n \otimes x^{[h-1-\tau]} \right) \otimes x^{[\tau]},$$

from which (5.5) follows, taking into account the property (A.3c).

Similarly, by exploiting (5.3), (5.5), and (A.3c), it results that

$$\begin{aligned} &\frac{d}{dx} \otimes \frac{d}{dx} \otimes x^{[h]} \\ &= \frac{d}{dx} \otimes \left(\left(\sum_{\tau=0}^{h-1} C_{n,n^{h-1-\tau}}^T \otimes I_{n^\tau} \right) \left(I_n \otimes x^{[h-1]} \right) \right) \\ &= \sum_{\tau=0}^{h-1} \left(C_{n,n^{h-1-\tau}}^T \otimes I_{n^\tau} \right) \left(\frac{d}{dx} \otimes \left(I_n \otimes x^{[h-1]} \right) \right) \\ &= \sum_{\tau=0}^{h-1} \left(C_{n,n^{h-1-\tau}}^T \otimes I_{n^\tau} \right) \left(I_n \otimes \left(\frac{d}{dx} \otimes x^{[h-1]} \right) \right) \\ &= \sum_{\tau=0}^{h-1} \left(C_{n,n^{h-1-\tau}}^T \otimes I_{n^\tau} \right) \left(I_n \otimes \left(\left(\sum_{s=0}^{h-2} C_{n,n^{h-2-s}}^T \otimes I_{n^s} \right) \left(I_n \otimes x^{[h-2]} \right) \right) \right) \\ &= \sum_{\tau=0}^{h-1} \sum_{s=0}^{h-2} \left(C_{n,n^{h-1-\tau}}^T \otimes I_{n^\tau} \right) \left(I_n \otimes \left(\left(C_{n,n^{h-2-s}}^T \otimes I_{n^s} \right) \left(I_n \otimes x^{[h-2]} \right) \right) \right) \\ &= \sum_{\tau=0}^{h-1} \sum_{s=0}^{h-2} \left(C_{n,n^{h-1-\tau}}^T \otimes I_{n^\tau} \right) \left(\left(I_n \otimes \left(C_{n,n^{h-2-s}}^T \otimes I_{n^s} \right) \right) \left(I_n \otimes \left(I_n \otimes x^{[h-2]} \right) \right) \right), \end{aligned}$$

so that the proof is completed. □

Now, we are able to rewrite the vector valued version of the Ito formula in the Kronecker formalism.

THEOREM 5.2. *Let $(X_t, \mathcal{F}_t)$ be a vector-continuous semimartingale in $\mathbf{R}^n$ described by the Ito stochastic differential*

$$dX_t = d\beta_t + dM_t, \tag{5.8}$$

where $(\beta_t, \mathcal{F}_t)$ is an almost surely continuous bounded variation process and $(M_t, \mathcal{F}_t)$ is a square integrable martingale. Let

$$F : \mathbf{R}^n \to \mathbf{R}^p$$

be a continuous function endowed with the first and second derivatives. Then the process $Z_t = F(X_t)$ is a square integrable semimartingale, whose differential is given by

$$dZ_t = \left(\frac{d}{dx} \otimes F(x)\right)_{x=X_t} dX_t + \frac{1}{2}\left(\frac{d}{dx} \otimes \frac{d}{dx} \otimes F(x)\right)_{x=X_t} (dM_t)^{[2]}, \tag{5.9}$$

with $(dM_t)^{[2]}$ denoting the associate quadratic variation process whose arguments are

$$(dM_t)^{[2]} = \begin{bmatrix} d < M_1, M_1 >_t \\ d < M_1, M_2 >_t \\ \vdots \\ d < M_n, M_n >_t \end{bmatrix}, \tag{5.10}$$

with obvious meaning of symbols [11, 12].

Proof. Formula (5.10) can be directly verified by using the Ito formula in the scalar case (see for instance [11, Thm. 4.2.1]) and by taking into account the definition of the differential operator d/dx. □

6. Stochastic differential for the Kronecker power of a BLSS solution. Using the Ito formula, in the version given by Theorem 5.2, we can now prove the following theorem, which defines the stochastic differential for the power process of the solution of a bilinear SDE. This will be the fundamental tool in the derivation of the augmented system.

THEOREM 6.1. *Let $\phi(t) \in \mathbf{R}^d$ be the process defined by the following SDE:*

$$d\phi(t) = (\Gamma(t)\phi(t) + \gamma(t))dt + \sum_{k=1}^{p} (\Theta_k \phi(t) + \chi_k) dW_k(t), \tag{6.1}$$

where $\Gamma(t), \Theta_k \in \mathbf{R}^{d\times d}$, $\gamma(t), \chi_k \in \mathbf{R}^d$. Then, defining

$$\Phi_2 \stackrel{\Delta}{=} \sum_{k=1}^{p} \Theta_k^{[2]}, \quad \Phi_1 \stackrel{\Delta}{=} \sum_{k=1}^{p} (\Theta_k \otimes \chi_k + \chi_k \otimes \Theta_k), \quad \Phi_0 \stackrel{\Delta}{=} \sum_{k=1}^{p} \chi_k^{[2]}, \tag{6.2}$$

it results for $i \geq 2$ that

$$\begin{aligned} d\phi^{[i]}(t) = &\left(\mathcal{M}_i^0(t)\phi^{[i]}(t) + \mathcal{M}_i^1(t)\phi^{[i-1]}(t) + \mathcal{M}_i^2\phi^{[i-2]}(t)\right) dt \\ &+ \sum_{k=1}^{p} \left(\mathcal{G}_{k,i}^0 \phi^{[i]}(t) + \mathcal{G}_{k,i}^1 \phi^{[i-1]}(t)\right) dW_k(t), \end{aligned}$$

where

$$\mathcal{M}_i^0(t) = U_d^i(\Gamma(t) \otimes I_{d^{i-1}}) + \frac{1}{2} O_d^i(\Phi_2 \otimes I_{d^{i-2}}),$$
$$\mathcal{M}_i^1(t) = U_d^i(\gamma(t) \otimes I_{d^{i-1}}) + \frac{1}{2} O_d^i(\Phi_1 \otimes I_{d^{i-2}}),$$
$$\mathcal{M}_i^2 = \frac{1}{2} O_d^i\big(\Phi_0 \otimes I_{d^{i-2}}\big),$$
$$\mathcal{G}_{k,i}^0 = U_d^i(\Theta_k \otimes I_{d^{i-1}}),$$
$$\mathcal{G}_{k,i}^1 = U_d^i(\chi_k \otimes I_{d^{i-1}}).$$

Proof. By using property (A.3c) the following formula is easily recognized to hold for any $k = 0, 1, \ldots$, $j = 1, 2, \ldots$, $\psi \in \mathbf{R}^\sigma$, $M \in \mathbf{R}^{r \times \sigma^k}$:

$$\left(I_r \otimes \psi^{[j]}\right) M \psi^{[k]} = (M \otimes I_{\sigma^j}) \psi^{[k+j]}. \tag{6.3}$$

Let us apply Theorem 5.2 for $X = \phi$, $F(\phi) = \phi^{[i]}$, $d\beta = (\Gamma\phi + \gamma)dt$, and $dM = d\Lambda$, where Λ is the martingale:

$$\Lambda(t) \triangleq \int_0^t \sum_{k=1}^p \big(\Theta_k(\tau)\phi(\tau) + \chi_k(\tau)\big) dW_k(\tau).$$

Using formulas (5.5), (5.6), it results that (understanding time dependencies)

$$d\phi^{[i]} = U_d^i \left(I_d \otimes \phi^{[i-1]}\right) (\Gamma\phi dt + \gamma dt + d\Lambda) + \frac{1}{2} O_d^i \left(I_{d^2} \otimes \phi^{[i-2]}\right) (d\Lambda)^{[2]}. \tag{6.4}$$

By exploiting the definition (5.10) it results that

$$(d\Lambda)^{[2]} = \big(\Phi^2 \phi_{[2]} + \Phi_1 \phi + \Phi_0\big)\, dt, \tag{6.5}$$

where Φ_2, Φ_1, and Φ_0 are given by (6.2). By substituting (6.5) in (6.4) and using formula (6.3), the thesis follows. ∎

7. The augmented system. Let us return to consider the BLSS (3.2), (3.3). In this section, by means of a repeated application of Theorem 6.1, we will show that the process (X, Y) and its powers up to a certain degree represent a solution of a suitably defined bilinear SDE. The latter will be next transformed into a linear system with WSW diffusions, generating the powers of the observation Y up to the required degree (the augmented system).

Let $x \in \mathbf{R}^d$ and h be a positive integer. We recall that the following relations hold, linking together the *reduced hth Kroneker power of* x [3], [15], namely $x_{[h]}$ and the (ordinary) hth Kronecker power $x^{[h]}$:

$$x^{[h]} = T_d^h x_{[h]}, \quad x_{[h]} = \tilde{T}_d^h x^{[h]}, \tag{7.1}$$

where T_d^h and $\tilde{T}_d^h$ are suitably dimensioned transformation matrices [3].

Let us define the process Z as

$$Z(t) \triangleq \begin{bmatrix} Y(t) \\ X(t) \end{bmatrix} \tag{7.2}$$

and let $\delta = \dim(Z)$. Moreover, let us define the augmented process:

$$\mathcal{Z}(t) \triangleq \begin{bmatrix} Z(t) \\ Z_{[2]}(t) \\ \vdots \\ Z_{[\nu]}(t) \end{bmatrix}. \tag{7.3}$$

We can derive an SDE for the process $\mathcal{Z}$ in the following way. First, note that, from (3.2), (3.3), Z satisfies the following SDE:

$$dZ(t) = \left(\tilde{A}(t)Z(t) + \alpha(t)\right)dt + \sum_{k=1}^{p}\left(B_k Z(t) + \tilde{\beta}_k\right)dW_k(t), \tag{7.4}$$

where

$$\tilde{A}(t) \triangleq \begin{bmatrix} 0 & C(t) \\ 0 & A(t) \end{bmatrix}; \quad \alpha(t) \triangleq \begin{bmatrix} 0 \\ Hu \end{bmatrix}; \quad B_k \triangleq \begin{bmatrix} 0 & D_k \\ 0 & B_k(t) \end{bmatrix}; \quad \beta_k = \begin{bmatrix} G_k \\ F_k \end{bmatrix}. \tag{7.5}$$

Next, by applying Theorem 6.1 to the process Z, it results for $i = 2, \dots, \nu$ that

$$\begin{aligned} dZ^{[i]}(t) = &\left(L_i^0(t)Z^{[i]}(t) + L_i^1(t)Z^{[i-1]}(t) + L_i^2 Z^{[i-2]}(t)\right)dt \\ &+ \sum_{k=1}^{p}\left(V_{k,i}^0 Z^{[i]}(t) + V_{k,i}^1 Z^{[i-1]}(t)\right)dW_k(t), \end{aligned} \tag{7.6}$$

where

$$L_i^0(t) = U_\delta^i\left(\tilde{A}(t) \otimes I_{\delta^{i-1}}\right) + \frac{1}{2}O_\delta^i\left(\Psi_2 \otimes I_{\delta^{i-2}}\right), \tag{7.7}$$

$$L_i^1(t) = U_\delta^{(i)}(\alpha(t) \otimes I_{\delta^{i-1}}) + \frac{1}{2}O_\delta^i\left(\Psi_1 \otimes I_{\delta^{i-2}}\right), \tag{7.8}$$

$$L_i^2 = \frac{1}{2}O_\delta^i\left(\Psi_0 \otimes I_{\delta^{i-2}}\right), \tag{7.9}$$

$$V_{k,i}^0 = U_\delta^i\left(\tilde{B}_k \otimes I_{\delta^{i-1}}\right), \tag{7.10}$$

$$V_{k,i}^1 = U_\delta^i(\beta_k \otimes I_{\delta^{i-1}}), \tag{7.11}$$

and Ψ_2, Ψ_1, and Ψ_0 are given by

$$\Psi_2 \triangleq \sum_{k=1}^{p}\tilde{B}_k^{[2]}, \quad \Psi_1 \triangleq \sum_{k=1}^{p}\left(\tilde{B}_k \otimes \beta_k + \beta_k \otimes \tilde{B}_k\right), \quad \Psi_0 \triangleq \sum_{k=1}^{p}\beta_k^{[2]}.$$

Observing that, from (7.1) we have

$$Z^{[i]} = T_\delta^i Z_{[i]}, \quad Z_{[i]} = \tilde{T}_\delta^i Z^{[i]},$$

and using (7.6), we can state the following proposition.

PROPOSITION 7.1. *The process $\mathcal{Z}$ defined in* (7.3) *satisfies the bilinear SDE*

$$d\mathcal{Z}(t) = \left(\mathcal{A}(t)\mathcal{Z}(t) + \mathcal{U}(t)\right)dt + \sum_{k=1}^{p}\left(\mathcal{B}_k\mathcal{Z}(t) + \mathcal{V}_k\right)dW_k(t), \tag{7.12}$$

where

$$\mathcal{A}(t) = \begin{bmatrix} \tilde{A}(t) & 0 & \dots & & 0 \\ L_2^1(t) & \tilde{T}_\delta^2 L_2^0(t) T_\delta^2 & 0 & & \\ L_3^2 & \tilde{T}_\delta^3 L_3^1(t) T_\delta^2 & \tilde{T}_\delta^3 L_3^0(t) T_\delta^3 & & \vdots \\ & \ddots & \ddots & \ddots & \\ 0 & \dots & \tilde{T}_\delta^\nu L_\nu^2 T_\delta^{\nu-2} & \tilde{T}_\delta^\nu L_\nu^1(t) T_\delta^{\nu-1} & \tilde{T}_\delta^\nu L_\nu^0(t) T_\delta^\nu \end{bmatrix}, \tag{7.13}$$

$$\mathcal{B}_k = \begin{bmatrix} \tilde{B}_k & 0 & \dots & & 0 \\ V_{k,2}^1 & \tilde{T}_\delta^2 V_{k,2}^0 T_\delta^2 & & & \vdots \\ 0 & \tilde{T}_\delta^3 V_{k,3}^1 T_\delta^2 & \tilde{T}_\delta^3 V_{k,3}^0 T_\delta^3 & & \\ \vdots & & \ddots & \ddots & \\ 0 & \dots & & \tilde{T}_\delta^\nu V_{k,\nu}^1 T_\delta^{\nu-1} & \tilde{T}_\delta^\nu V_{k,\nu}^0 T_\delta^\nu \end{bmatrix}, \tag{7.14}$$

$$\mathcal{U}(t) = \begin{bmatrix} \alpha(t) \\ L_2^2 \\ 0 \\ \vdots \\ 0 \end{bmatrix}, \quad \mathcal{V}_k = \begin{bmatrix} \beta_k \\ 0 \\ \vdots \\ 0 \end{bmatrix}. \tag{7.15}$$

The block matrices in (7.13), (7.14) *are given by* (7.7)–(7.11) *and* (7.5), *and the matrices* $\tilde{T}_\cdot, T_\cdot$, *are the reduction matrices defined in* (7.1).

Now, we can use Theorem 4.1 in order to rewrite the bilinear SDE (7.12) in the form of a *linear* SDE with WSW diffusion term. The underlying hypothesis is that the covariance matrix of the process $\mathcal{Z}$ defined in (7.3), namely $\Phi_Z(t)$, is uniformly nonsingular over T. There are many ways to assure this, starting from some suitable, nonrestrictive hypothesis on the original system. As a matter of fact, since we are here concerned with a finite interval T, it is easy to recognize that the uniform nonsingularity of $\Phi_Z(t)$ is assured as soon as it is assumed that the covariance of the initial original state $X(0)$ is positive definite. Henceforth, we will understand the uniform nonsingularity in T of $\Phi_Z(t)$.

PROPOSITION 7.2. *Let* ρ_k, $k = 1, \dots, p$, *be the ranks of the matrices* $\mathcal{B}_k$, *given in* (7.12). *Then the process* $\mathcal{Z}$ *satisfies the SDE*

$$d\mathcal{Z}(t) = \big(\mathcal{A}(t)\mathcal{Z}(t) + \mathcal{U}(t)\big)dt + \sum_{k=1}^{2p} \tilde{\mathcal{B}}_k(t) d\tilde{W}_k(t), \tag{7.16}$$

where $\tilde{W}_k$, $k = 1, \dots, 2p$ *are independent standard WSW processes,* $\tilde{W}_k \in \mathbf{R}^{\rho_k}$ *for* $k = 1, \dots, p$, $\tilde{W}_k = W_k \in \mathbf{R}$, *for* $k = p+1, \dots, 2p$, *and*

$$\tilde{\mathcal{B}}_k(t) \triangleq \begin{cases} \big(\mathcal{B}_k \Psi_Z(t) \mathcal{B}_k^T\big)^{(\frac{1}{2})}, & 1 \le k \le p, \\ \mathcal{B}_{k-p} m_Z(t) + \mathcal{V}_{k-p}, & p+1 \le k \le 2p, \end{cases} \tag{7.17}$$

with $m_Z = E(\mathcal{Z})$.

In order to write down the equations of the *augmented system* we need to split out the vector SDE (7.12) into two SDEs: one for the *observed* components of $\mathcal{Z}$ and the other one for the remaining entries.

From the definition (7.2) we see that the components of the vector $\mathcal{Z}$ are of the form

$$X_1^{i_1} \cdots X_n^{i_n} \cdots Y_1^{j_1} \cdots Y_q^{j_q}, \tag{7.18}$$

where X_l, Y_l denote the lth component of vectors X, Y, respectively, and $0 \leq i_l, j_r \leq \nu$ for $l = 1, \ldots, n$, $r = 1, \ldots, q$, $\sum_{l=1}^{n} i_l \leq \nu$, $\sum_{r=1}^{q} j_r \leq \nu$. The observed components are those of the form (7.18) with $i_1 = \cdots = i_n = 0$. Denote by $\mathcal{Y}$ the vector of all such components:

$$\mathcal{Y} \triangleq \begin{bmatrix} Y \\ Y_{[2]} \\ \vdots \\ Y_{[\nu]} \end{bmatrix}.$$

Moreover, let us denote by $\mathcal{E}_{\mathcal{Y}}$ the $(0,1)$-matrix such that

$$\mathcal{Y} = \mathcal{E}_{\mathcal{Y}} \mathcal{Z}. \tag{7.19}$$

It is easy to recognize that

$$\mathcal{E}_{\mathcal{Y}} = \begin{bmatrix} \mathcal{E}_{\mathcal{Y}}^1 & 0 & \ldots & 0 \\ 0 & \mathcal{E}_{\mathcal{Y}}^2 & \ddots & \\ \vdots & \ddots & \ddots & \\ 0 & \ldots & 0 & \mathcal{E}_{\mathcal{Y}}^{\nu} \end{bmatrix}, \tag{7.20}$$

where the diagonal blocks $\mathcal{E}_{\mathcal{Y}}^j$, $j = 1, \ldots, \nu$ are defined as

$$\mathcal{E}_{\mathcal{Y}}^j Z_{[j]} = Y_{[j]} \tag{7.21}$$

and have the expressions

$$\mathcal{E}_{\mathcal{Y}}^j = [I_q \;\; 0]^{[j]} T_{\delta}^j, \tag{7.22}$$

where T_{δ}^j is the expansion matrix defined in (7.1). Let us denote with $\mathcal{X}$ the aggregate vector of all the components in $\mathcal{Z}$ which are not components of $\mathcal{Y}$. Moreover, let us denote by $\mathcal{E}_{\mathcal{X}}$ the $(0,1)$-matrix such that

$$\mathcal{X} = \mathcal{E}_{\mathcal{X}} \mathcal{Z}. \tag{7.23}$$

A simple way to compute $\mathcal{E}_{\mathcal{X}}$ is just to remove from the identity matrix $I_{d_{\mathcal{Z}}}$ with $d_{\mathcal{Z}} = \dim(\mathcal{Z})$ (note that $I_{d_{\mathcal{Z}}}$ includes all the rows of $\mathcal{E}_{\mathcal{Y}}$) all those rows which are rows of $\mathcal{E}_{\mathcal{Y}}$.

From the above the aggregate matrix $\mathcal{I}$,

$$\mathcal{I} \triangleq \begin{bmatrix} \mathcal{E}_{\mathcal{Y}} \\ \mathcal{E}_{\mathcal{X}} \end{bmatrix} \tag{7.24}$$

results to be invertible. Let us consider the matrices $\mathcal{I}_1$, $\mathcal{I}_2$ such that

$$\mathcal{Z} = \mathcal{I}_1 \mathcal{Y} + \mathcal{I}_2 \mathcal{X}. \tag{7.25}$$

Note that, from (7.19), (7.23), and because of the invertibility of the matrix $\mathcal{I}$, it results that the matrices $\mathcal{I}_1, \mathcal{I}_2$ defined in (7.25) are obtained by means of a suitable partition of the matrix $\mathcal{I}^{-1} = [\mathcal{I}_1\ \mathcal{I}_2]$.

Using (7.19), (7.23), (7.25), and (7.12), we can now state the following proposition.

PROPOSITION 7.3. *The processes $\mathcal{X}$, $\mathcal{Y}$ defined in* (7.23) *and* (7.19) *satisfy the pair of SDEs (augmented system)*

$$d\mathcal{X}(t) = \big(\mathcal{A}_1(t)\mathcal{Y}(t) + \mathcal{A}_2(t)\mathcal{X}(t) + \mathcal{U}_1(t)\big)dt + \sum_{k=1}^{2p} \mathcal{B}_k^1(t)d\tilde{W}_k(t), \tag{7.26}$$

$$d\mathcal{Y}(t) = \big(\mathcal{C}_1(t)\mathcal{Y}(t) + \mathcal{C}_2(t)\mathcal{X}(t) + \mathcal{U}_2(t)\big)dt + \sum_{k=1}^{2p} \mathcal{D}_k^1(t)d\tilde{W}_k(t), \tag{7.27}$$

where

(7.28)

$$\mathcal{A}_1(t) = \mathcal{E}_{\mathcal{X}}\mathcal{A}(t)\mathcal{I}_1, \quad \mathcal{A}_2(t) = \mathcal{E}_{\mathcal{X}}\mathcal{A}(t)\mathcal{I}_2, \quad \mathcal{U}_1(t) = \mathcal{E}_{\mathcal{X}}\mathcal{U}(t), \quad \mathcal{B}_k^1(t) = \mathcal{E}_{\mathcal{X}}\tilde{\mathcal{B}}_k(t),$$
$$\mathcal{C}_1(t) = \mathcal{E}_{\mathcal{Y}}\mathcal{A}(t)\mathcal{I}_1, \quad \mathcal{C}_2(t) = \mathcal{E}_{\mathcal{Y}}\mathcal{A}(t)\mathcal{I}_2, \quad \mathcal{U}_2(t) = \mathcal{E}_{\mathcal{Y}}\mathcal{U}(t), \quad \mathcal{D}_k^1(t) = \mathcal{E}_{\mathcal{Y}}\tilde{\mathcal{B}}_k(t),$$

$\mathcal{A}$, $\tilde{\mathcal{B}}_k$, $\mathcal{U}$, are the matrix coefficients of (7.16)*, the matrices $\mathcal{E}_{\mathcal{X}}$, $\mathcal{E}_{\mathcal{Y}}$, $\mathcal{I}_1$, $\mathcal{I}_2$, are defined by means of* (7.19), (7.23), (7.25)*, and $\{\tilde{W}_k,\ k = 1, \dots, 2p\}$ is a set of mutually uncorrelated standard WSW processes.*

8. Polynomial filter equations. Proposition 7.3 states that the augmented observation process $\mathcal{Y}$ defined in (7.19) can be generated as the output process of the augmented representation (7.26), (7.27). This implies that the problem of finding the νth degree polynomial filter for the original system (7.26), (3.3) is now reduced to an *optimal linear filtering* problem for the linear system (7.26), (7.27). Indeed, by denoting with $\hat{\mathcal{X}}(t)$ the optimal linear estimate given $\{\mathcal{Y}_s,\ s \le t\}$ of the augmented state $\mathcal{X}(t)$, we have (see section 2)

$$\hat{\mathcal{X}}(t) = \Pi\Big(\mathcal{X}(t)/\mathcal{L}_t(\mathcal{Y})\Big).$$

On the other hand, from Definition 2.1 and taking into account the structure of the augmented observation $\mathcal{Y}$, it results that $\mathcal{L}_t(\mathcal{Y}) = \mathcal{P}_t^{(\nu)}(Y)$, where Y is the original observation process given by (3.3). Hence we have

$$\hat{\mathcal{X}}(t) = \Pi\Big(\mathcal{X}(t)/\mathcal{P}_t^{(\nu)}(Y)\Big),$$

and, as we will see later, we can get $\hat{X}(t)$ (which is given by (3.5)) by extracting a suitable subvector in $\hat{\mathcal{X}}(t)$.

In [3] the optimal linear filter is defined for the class of linear stochastic systems whose noise terms are represented by WSW processes. System (7.26), (7.27) comes within this class of systems, and we can use here the same approach as in [3] in order to obtain the optimal linear filter with respect to the augmented observation process $\mathcal{Y}$ (and, hence the optimal νth degree polynomial filter with respect to the original observed process Y). In order to do this, first of all we state the following theorem, whose proof is given in Appendix B, showing the uniform nonsingularity in T of the output-noise covariance of system (7.26), (7.27), namely

$$\mathcal{R}(t) \triangleq \sum_{k=1}^{2p} \mathcal{D}_k^1(t)\mathcal{D}_k^1(t)^T. \tag{8.1}$$

Indeed, the uniform nonsingularity of (8.1) is required, in order to apply the Kalman–Bucy scheme to system (7.26), (7.27).

THEOREM 8.1. *The noise covariance matrix function of the augmented measurement equation* (7.27)*, given by* (8.1)*, is uniformly nonsingular over* T.

Proof. See Appendix B. □

Now, we can prove the main theorem, defining the νth degree polynomial filter for system (3.2), (3.3). We remind readers that ρ_k is the dimension of the WSW process $\tilde{W}_k$ when $k = 1, \dots, p$, and for $k = p+1, \dots, 2p$, $\tilde{W}_k = W_k \in \mathbf{R}$. Let us denote with γ the dimension of the augmented process $\mathcal{Z}$. Moreover, we shall denote with $\operatorname{cov}(\chi, \eta)$ the cross-covariance between two random variables χ, η. Finally, we shall denote with $M^\dagger$ the Moore–Penrose pseudoinverse of the square matrix M.

THEOREM 8.2. *The νth order polynomial filter for system* (3.2), (3.3) *is described by the following system of equations:*

$$\frac{dm_{_Z}(t)}{dt} = \mathcal{A}(t)m_{_Z}(t) + \mathcal{U}(t), \tag{8.2}$$

$$\bar{\mathcal{B}}_k(t) = \mathcal{B}_k m_{_Z}(t) + \mathcal{V}_k, \quad 1 \le k \le p, \tag{8.3}$$

$$\frac{d\Psi_Z(t)}{dt} = \mathcal{A}(t)\Psi_Z(t) + \Psi_Z(t)\mathcal{A}(t)^T + \sum_{k=1}^{p} \mathcal{B}_k \Psi_Z(t) \mathcal{B}_k^T + \sum_{k=1}^{p} \bar{\mathcal{B}}_k(t)\bar{\mathcal{B}}_k(t)^T, \tag{8.4}$$

$$\tilde{\mathcal{B}}_k(t) = \left(\mathcal{B}_k \Psi_Z(t) \mathcal{B}_k^T\right)^{(\frac{1}{2})}, \quad 1 \le k \le p, \tag{8.5}$$

$$\mathcal{J}(t) = \sum_{k=1}^{p} \mathcal{E}_{\mathcal{X}}\big(\tilde{\mathcal{B}}_k(t)\tilde{\mathcal{B}}_k(t)^T + \bar{\mathcal{B}}_k(t)\bar{\mathcal{B}}_k(t)^T\big)\mathcal{E}_{\mathcal{Y}}^T, \tag{8.6}$$

$$\mathcal{R}(t) = \sum_{k=1}^{p} \mathcal{E}_{\mathcal{Y}}\Big(\tilde{\mathcal{B}}_k(t)\tilde{\mathcal{B}}_k(t)^T + \bar{\mathcal{B}}_k(t)\bar{\mathcal{B}}_k(t)^T\Big)\mathcal{E}_{\mathcal{Y}}^T, \tag{8.7}$$

$$\mathcal{Q}(t) = \sum_{k=1}^{p} \mathcal{E}_{\mathcal{X}}\Big(\tilde{\mathcal{B}}_k(t)\tilde{\mathcal{B}}_k(t)^T + \bar{\mathcal{B}}_k(t)\bar{\mathcal{B}}_k(t)^T\Big)\mathcal{E}_{\mathcal{X}}^T, \tag{8.8}$$

$$\begin{aligned}\frac{d\mathcal{P}(t)}{dt} &= \mathcal{A}_2(t)\mathcal{P}(t) + \mathcal{P}(t)\mathcal{A}_2(t)^T + \mathcal{Q}(t) \\ &\quad - \Big(\mathcal{J}(t) + \mathcal{P}(t)\mathcal{C}_2(t)^T\Big)\mathcal{R}(t)^{-1}\Big(\mathcal{J}(t) + \mathcal{P}(t)\mathcal{C}_2(t)^T\Big)^T,\end{aligned} \tag{8.9}$$

$$\begin{aligned}d\hat{\mathcal{X}}(t) &= \Big(\mathcal{A}_1(t)\mathcal{Y}(t) + \mathcal{A}_2(t)\hat{\mathcal{X}}(t) + \mathcal{U}_1(t)\Big)dt + \Big(\mathcal{J}(t) + \mathcal{P}(t)\mathcal{C}_2(t)^T\Big)\mathcal{R}(t)^{-1} \\ &\quad \cdot\big(d\mathcal{Y}(t) - \big(\mathcal{C}_1(t)\mathcal{Y}(t) + \mathcal{C}_2(t)\hat{\mathcal{X}}(t) + \mathcal{U}_2(t)\big)dt\big),\end{aligned} \tag{8.10}$$

$$\hat{X}(t) = \mathcal{T}_\nu \hat{\mathcal{X}}(t), \tag{8.11}$$

where $\mathcal{T}_\nu$ is the operator extracting the first n entries of a vector, the matrices $\mathcal{A}(t)$, $\mathcal{U}(t)$, $\mathcal{A}_1(t), \mathcal{A}_2(t)$, $\mathcal{B}_1(t), \mathcal{B}_2(t), \mathcal{U}_1(t), \mathcal{U}_2(t)$ are defined in (7.16) *and* (7.28)*, the matrices $\mathcal{B}_k$ are defined in* (7.14)*, $\rho_k = \operatorname{rank}(\mathcal{B}_k)$, and* (8.2), (8.4), (8.9), (8.10) *are endowed with the initial conditions*

$$\begin{aligned}m_{_Z}(0) &= E(\mathcal{X}(0)), \\ \Psi_Z(0) &= \operatorname{cov}(\mathcal{X}(0), \mathcal{X}(0)), \\ \hat{\mathcal{X}}(0) &= E(\mathcal{X}(0)) + \operatorname{cov}(\mathcal{X}(0), \mathcal{Y}(0))\operatorname{cov}(\mathcal{Y}(0), \mathcal{Y}(0))^\dagger\big(\mathcal{Y}(0) - E(\mathcal{Y}(0))\big), \\ \mathcal{P}(0) &= \operatorname{cov}(\mathcal{X}(0), \mathcal{X}(0)) - \operatorname{cov}(\mathcal{X}(0), \mathcal{Y}(0))\operatorname{cov}(\mathcal{Y}(0), \mathcal{Y}(0))^\dagger \operatorname{cov}(\mathcal{X}(0), \mathcal{Y}(0))^T.\end{aligned}$$

Proof. Equations (8.6)–(8.10) easily derive from an application of [3, Thm. 15.3] to the representation (7.26), (7.27). The augmented-state covariance $\Psi_Z(t)$, appearing in the definition of $\tilde{\mathcal{B}}_k$ given by (8.5) (see also (7.17)), satisfies the ODE (8.4). This can be readily proved in the same way of (4.20), but the time-varying BLSS (7.12) is considered now, and the semigroup generated by $\{\mathcal{A}(t),\ t \in T\}$ should be used.

The so-obtained estimate $\hat{\mathcal{X}}_t$ is the optimal one among all the linear transformation of the augmented observation process $\{\mathcal{Y}_s,\ s \le t\}$, and hence it is the νth degree polynomial estimate of the augmented state $\mathcal{X}_t$. In order to obtain the νth degree polynomial estimate of the state X_t of the original system (3.2), (3.3), first of all note that, because $\hat{\mathcal{X}}_t$ is the L^2-projection of $\mathcal{X}_t$ onto the closed subspace linearly spanned by $\{\mathcal{Y}_s,\ s \le t\}$, we have that each entry of $\hat{\mathcal{X}}_t$ agrees with the L^2-projection (onto the same subspace) of the corresponding entry in $\mathcal{X}_t$. Now, by definition, $\mathcal{X}(t)$ includes the components of the original state X_t. From (7.2), (7.3), and by the definition of the extracting operator $\mathcal{E}_{\mathcal{X}}$, it results that these components are placed in the first n entries of the vector $\mathcal{X}$. Hence, $\hat{X}(t)$ can be obtained simply by extracting the first n components of $\hat{\mathcal{X}}_t$, that is (8.11). □

9. Simulation example. In order to test the algorithm described in the previous sections, the filtering problem for the following second-order system has been considered:

$$dX(t) = AX(t)dt + BX(t)dW(t) + UdN(t), \quad X(0) = 0, \tag{9.1}$$

$$dY(t) = CX(t)dt + DX(t)dV(t), \qquad Y(0) = 0, \tag{9.2}$$

where

$$A = \begin{bmatrix} a_1 & 1 \\ 0 & a_2 \end{bmatrix}, \quad B = \begin{bmatrix} b_1 & 0 \\ 0 & b_2 \end{bmatrix}, \quad U = \begin{bmatrix} u_1 \\ u_2 \end{bmatrix},$$
$$C = [\,1 \quad 1\,], \qquad D = [\,g \quad 0\,],$$

and W, N, and V are mutually independent scalar Wiener processes.

The well-known extended Kalman filter (EKF) was up to now the classical tool for the filtering of a nonlinear system in the form of (9.1), (9.2). However, nothing is known about the working conditions or the performances of the EFK. In the present case, for instance, the EKF does not work at all. Indeed the state-expectation is zero and hence the state process is expected to cross the zero. Since the term $D\hat{X}(t)\hat{X}(t)^T D^T$ ($\hat{X}$ denoting the EKF estimation) needs to be inverted in the EKF equations, we should expect a failure of the algorithm. This really happens in the simulations we carried out for several values of the parameters $a_1, a_2, b_1, b_2, u_1, u_2, g$. We have always observed a sudden and strong deviation to infinity. In order to improve the working conditions we have substituted the term $D\hat{X}(t)\hat{X}(t)^T D^T$ with $\epsilon + D\hat{X}(t)\hat{X}(t)^T D^T$, where the number ϵ has been chosen small enough. In these cases we have observed an improvement of the algorithm, in that for a small initial time-interval the EKF shows a good performance, even better than the third-degree polynomial filter below described (no theoretical argument is known about this). However, unavoidably, the EKF diverges in spite of the trick used, whereas the polynomial filters continue to work.

The linear, the second degree (quadratic), and the third degree (cubic) filters have been built up by using (8.2)–(8.11). We remind the reader that the matrices $\mathcal{A}$, $\mathcal{U}$, $\mathcal{B}_k$, and $\mathcal{V}_k$ that appear in the filter equations are the system-matrices of the augmented (7.12). These matrices can be obtained from the original system-matrices

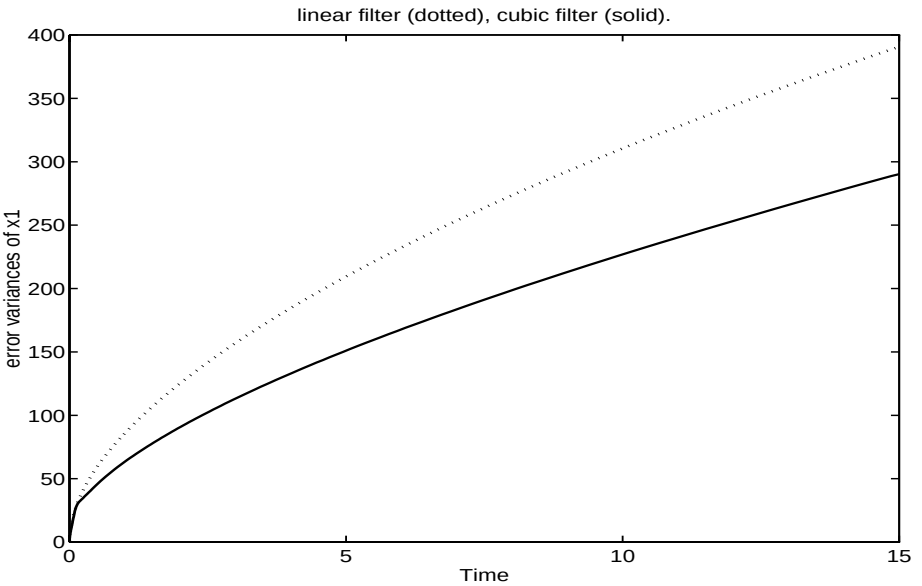

FIG. 9.1

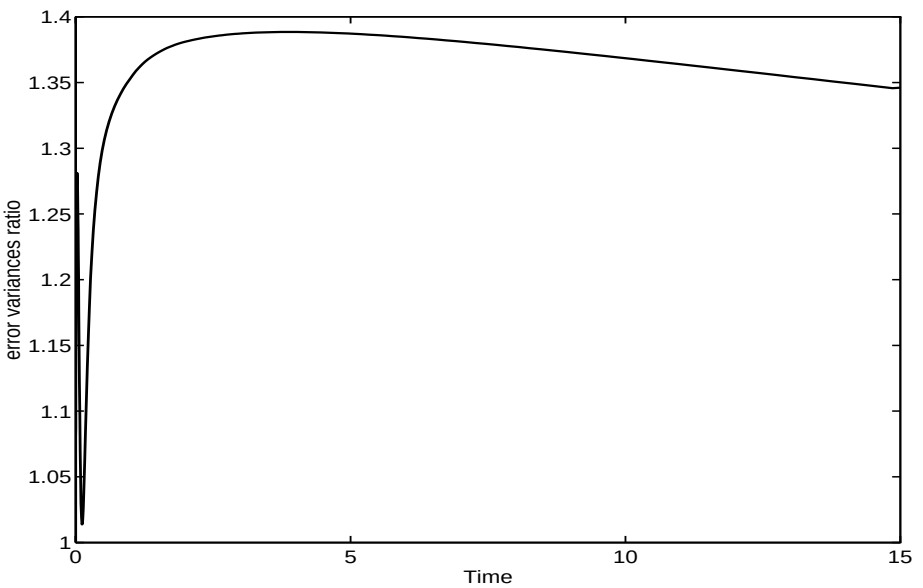

FIG. 9.2

by using the formulas given in section 7 for any polynomial degree. We show below our simulation results for the linear and cubic filters, with the following values of the parameters:

$$a_1 = -0.01, \quad a_2 = -0.5, \quad u_1 = 30, \quad u_2 = 2, \\ b_1 = 0.1, \quad b_2 = 0.1, \quad g = 0.1. \tag{9.3}$$

We do not show graphs related to the quadratic filter simulation because, in our case,

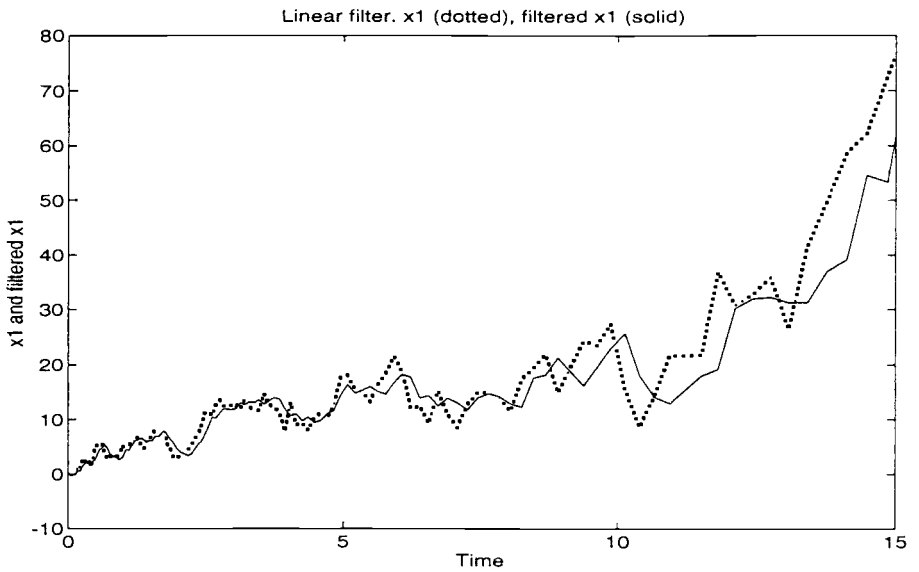

FIG. 9.3

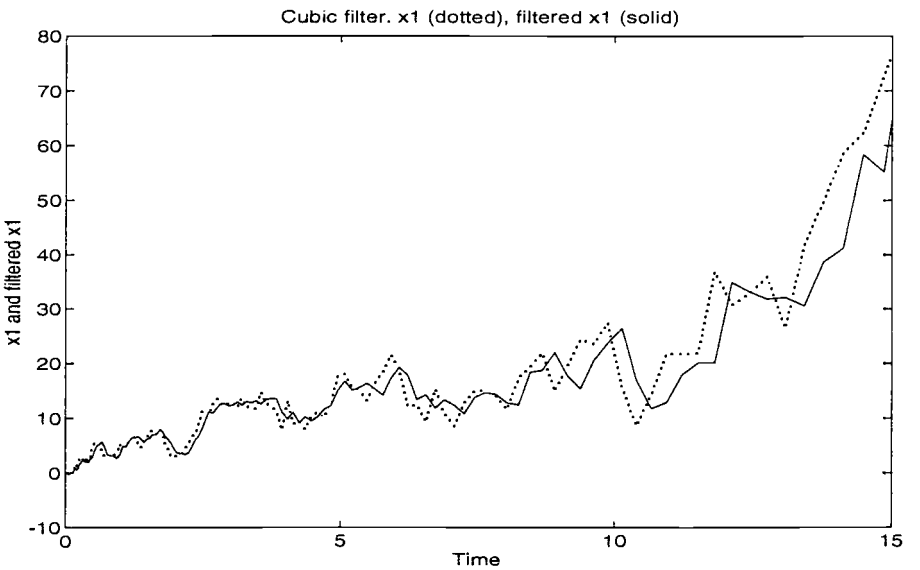

FIG. 9.4

the quadratic filter does not show any valuable improvement with respect to the linear case. Differently from the EKF, for the polynomial filters we are able to compute the a priori state-estimate error variances that are entries of the matrix $\mathcal{P}(t)$ given by (8.9), that is $\mathcal{P}_{1,1}(t)$, $\mathcal{P}_{2,2}(t)$ for the first and second state components, respectively. In our example these values are growing with time. The reason for this is that system (9.1), (9.2), with the values given by (9.3), is unstable. Nevertheless, as shown in Figure 9.1, the time-evolution of $\mathcal{P}_{1,1}(t)$ for the cubic filter (namely $P_C(t)$) is ever less than the $\mathcal{P}_{1,1}(t)$ for the linear filter (namely $P_L(t)$). In Figure 9.2 the evolution of

the ratio $\rho(t) = P_L(t)/P_C(t)$ is shown. We can see that $\rho(t)$ stabilizes over the value $\bar{\rho} = 1.30$. Hence the improvement in the a priori performance of the cubic filter with respect to the linear one can be considered almost 30%.

The time-evolutions of filtered paths for the linear and cubic filters, compared with the corresponding true 1st component state path, are reported in Figures 9.3, 9.4. As we can see, even a visual comparison between the signal time-evolutions shows a valuable improvement in the estimation quality of the cubic filter with respect to the linear one. Several Monte Carlo runs have been carried out. For each one of these runs, the ratio, namely ρ_S, between the sampled error variances of the linear and cubic filters has been computed. We have chosen the paths with $\rho_S = 1.35$.

The simulation of the EKF confirms also in this case its unsatisfactory behavior. Indeed, after almost 0.01 time units the EKF estimate starts up and quickly goes to infinity.

All the simulations have been carried out using the standard functions of the Matlab software package for Windows. The computer was a PC, endowed with a 200 MHz Pentium processor.

10. Conclusions. Equations (8.2)–(8.11) define a finite-dimensional filter for the BLSS (3.2), (3.3) which is optimal in a class of polynomial estimates. Although the considered class does not include all the polynomials of the currently available measurements, it includes the linear estimates, and, moreover, it defines a nondecreasing sequence of spaces for increasing polynomial degree. This implies that the polynomial filter had to improve the estimation performance for increasing polynomial degree.

We underline that the proposed filter is finite-dimensional. Of course, it is always possible to approximate the optimal filter (for instance, by applying a finite-elements method to the Zakai equation, as shown in [13]) with an arbitrary approximation degree. However, the more accurately the approximation level is chosen, the heavier the computational burden of the algorithm is. The computational effort is prohibitive even for small approximation degrees. Moreover, it makes no sense, within this approach, to use a large approximation degree in order to make the filtering algorithm really implementable. Counterwise, our suboptimal approach allows us to get meaningful estimates also for small polynomial degrees, which do not present difficult implementation problems.

In section 4 we have presented the equations of the optimal linear filter for a BLSS. We highlight that this result is interesting by itself in that it was up to now known only for the scalar case. The main tool is given by Theorem 4.1, stating the existence of a linear representation for a general vector BLSS. The optimal linear filter is then obtained by an application of a classical Kalman–Bucy scheme. Nevertheless, in the framework of this paper, the main purpose of Theorem 4.1 remains its application to the bilinear SDE (7.12), which allows us to obtain the linear representation (7.16).

Theorem 8.1 states that the output noise covariance of the augmented system is uniformly nonsingular, as required by the Kalman–Bucy scheme, provided that the output noise covariance of the original system (3.2), (3.3) is nonsingular. The proof is presented in Appendix B.

In section 9 a numerical simulation is shown, where a second-order BLSS has been filtered using the polynomial filters up to the third degree. The EFK has been also simulated, however its performance is resulted to be unsatisfactory. The simulation results show that the estimation quality really improves as polynomial degree grows, and for the cubic filter we obtained an improvement valuable over 30% with respect

to the linear filter.

We stress that, due to the well-known approximation capabilities of the polynomial functions, with the aim to define better and better implementable approximation schemes of the optimal filter, the use of polynomial estimators appears to be very promising.

Appendix A. Kronecker algebra.

Throughout this paper, we have widely used Kronecker algebra [14], [15]. Here, for the sake of completeness, we recall some definitions and properties on this subject.

DEFINITION A.1. *Let M and N be matrices of dimension $r \times s$ and $p \times q$, respectively. Then the Kronecker product $M \otimes N$ is defined as the $(r \cdot p) \times (s \cdot q)$ matrix*

$$M \otimes N = \begin{bmatrix} m_{11}N & \dots & m_{1s}N \\ \dots\dots\dots\dots\dots & & \\ m_{r1}N & \dots & m_{rs}N \end{bmatrix},$$

where the m_{ij} are the entries of M.

Of course this kind of product is not commutative.

DEFINITION A.2. *Let M be the $r \times s$ matrix*

$$M = [\, m_1 \quad m_2 \quad \dots \quad m_s \,], \tag{A.1}$$

where m_i denotes the ith column of M, and then the stack of M is the $r \cdot s$ vector

$$st(M) = [\, m_1^T \quad m_2 \quad \dots \quad m_s \,]^T. \tag{A.2}$$

Observe that a vector as in (A.2) can be reduced to a matrix M as in (A.1) by considering the inverse operation of the stack denoted by st^{-1}. With reference to the Kronecker product and the stack operation, the following properties hold [15]:

$$(A+B) \otimes (C+D) = A \otimes C + A \otimes D + B \otimes C + B \otimes D, \tag{A.3a}$$

$$A \otimes (B \otimes C) = (A \otimes B) \otimes C, \tag{A.3b}$$

$$(A \cdot C) \otimes (B \cdot D) = (A \otimes B) \cdot (C \otimes D), \tag{A.3c}$$

$$(A \otimes B)^T = A^T \otimes B^T, \tag{A.3d}$$

$$st(A \cdot B \cdot C) = (C^T \otimes A) \cdot st(B), \tag{A.3e}$$

$$u \otimes v = st(v \cdot u^T), \tag{A.3f}$$

$$tr(A \otimes B) = tr(A) \cdot tr(B), \tag{A.3g}$$

where A, B, C, and D are suitably dimensioned matrices, u and v are vectors, and $tr(M)$ denotes the trace of a square matrix M. The Kronecker power of the matrix M is defined as

$$M^{[0]} = 1,$$
$$M^{[n]} = M \otimes M^{[n-1]} = M^{[n-1]} \otimes M, \quad n > 0.$$

As an easy consequence of (A.3b) and (A.3g), it follows that

$$tr(A^{[h]}) = \big(tr(A)\big)^h. \tag{A.3h}$$

It is easy to verify that for $u \in \mathbf{R}^r$, $v \in \mathbf{R}^s$, the ith entry of $u \otimes v$ is given by

$$(u \otimes v)_i = u_l \cdot v_m; \quad l = \left[\frac{i-1}{s}\right] + 1, \quad m = |i-1|_s + 1, \tag{A.4}$$

where $[\cdot]$ and $|\cdot|_s$ denote integer part and s-modulo, respectively. Although the Kronecker product is not commutative, the following property holds [9, 15].

THEOREM A.3. *For any given pair of matrices $A \in \mathbf{R}^{r\times s}$, $B \in \mathbf{R}^{n\times m}$, we have*

$$B \otimes A = C_{r,n}^T (A \otimes B) C_{s,m}, \tag{A.5}$$

where the commutation matrix $C_{u,v}$ is the $(u \cdot v) \times (u \cdot v)$ matrix such that its (h,l) entry is given by

$$\{C_{u,v}\}_{h,l} = \begin{cases} 1 & \text{if } l = (|h-1|_v)u + \left(\left[\frac{h-1}{v}\right] + 1\right), \\ 0 & \text{otherwise.} \end{cases} \tag{A.6}$$

Observe that $C_{1,1} = 1$; hence in the vector case when $a \in \mathbf{R}^r$ and $b \in \mathbf{R}^n$, (A.5) becomes

$$b \otimes a = C_{r,n}^T (a \otimes b). \tag{A.7}$$

COROLLARY A.4. *For any given matrices A, B, C, D, having dimensions $n_A \times m_A$, $n_B \times m_B$, $n_C \times m_C$, $n_D \times m_D$, respectively, denoted with $I(l)$, the identity matrix in $\mathbf{R}^l$, we have*

$$A \otimes B \otimes C \otimes D = \left(I(n_A) \otimes C^T_{n_C n_D, n_B}\right)(A \otimes C \otimes D \otimes B)\left(I(m_A) \otimes C_{m_C m_D, m_B}\right).$$

Proof. See [3]. □

Appendix B. Proof of Theorem 8.1. We need to state in advance some preliminary definitions and lemmas.

Let δ and j be two positive integers.

DEFINITION B.1. *Let $r, s \in \{1, 2, \ldots, \delta^j\}$. The pair (r,s) is said to be (δ, j)-redundant ((δ, j)-R for short) if $\forall\ x \in \mathbf{R}^\delta$, it results that $\left(x^{[j]}\right)_r = \left(x^{[j]}\right)_s$, where $\left(x^{[j]}\right)_l$ denotes the lth entry of the vector $x^{[j]}$. Otherwise, the pair (r,s) is said to be (δ, j)-nonredundant ((δ, j)-NR for short).*

Example B.2. The pair $(2,3)$ is $(2,2)$-R; however, it is $(3,2)$-NR. The pairs $(1,1)$, $(2,2), \ldots$ are (δ, j)-NR for any δ and j.

Remark B.3. Let $x \in \mathbf{R}^\delta$. For some $s, r \in \{1, 2, \ldots, \delta^j\}$ let us consider the multi-indexes $s_1, \ldots, s_j$ and $r_1, \ldots, r_j$ in $\{1, \ldots, \delta\}$ defined by the identities

$$\left(x^{[j]}\right)_s = x_{s_1} x_{s_2} \cdots x_{s_j}, \quad \left(x^{[j]}\right)_r = x_{r_1} x_{r_2} \cdots x_{r_j}.$$

Then, we immediately realize that (r,s) is (δ, j)-R if and only if there exists a permutation of indexes transforming $s_1, \ldots, s_j$ in $r_1, \ldots, r_j$ (and vice versa).

Remark B.4. It is easy to verify that the (δ, j)-R condition defines an equivalence relation in the set $\{1, 2, \ldots, \delta^j\}$. We shall denote with $\rho(s; \delta, j)$ the equivalence class generated by $s \in \{1, \ldots, \delta^j\}$ via the (δ, j)-R relation

$$\rho(s; \delta, j) \triangleq \left\{ r \in \mathbf{N} \ :\ 1 \le r \le \delta^j,\ (s,r)\ \textit{is}\ (\delta, j)\text{–R} \right\}. \tag{B.1}$$

We shall denote with δ_j the number of equivalence classes of the (δ, j)-R relation, partitioning the set $\{1, 2, \ldots, \delta^j\}$. Moreover, we introduce the sets $\rho'(s; \delta, j)$, $\rho''(s; \delta, j) \subset \rho(s; \delta, j)$ defined as

$$\rho'(s;\delta,j) \triangleq \left\{ i \in \rho(s;\delta,j) \;\Big/\; \left[\frac{i}{\delta^{j-1}}\right] = \left[\frac{s}{\delta^{j-1}}\right] \right\}, \tag{B.2}$$

$$\rho''(s;\delta,j) \triangleq \rho(s;\delta,j) \setminus \rho'(s;\delta,j), \tag{B.3}$$

where we have used in (B.2) the notation $[\,\cdot\,]$ to indicate the integer part. The above defined sets have the following meaning. Let $x \in \mathbf{R}^\delta$ and note that

$$x^{[j]} = \begin{bmatrix} x_1 \cdot x^{[j-1]} \\ x_2 \cdot x^{[j-1]} \\ \vdots \\ x_\delta \cdot x^{[j-1]} \end{bmatrix}, \tag{B.4}$$

where every subvector $x_i x^{[j-1]}$ has dimension δ^{j-1}. By setting $l = [s/\delta^{j-1}]$ and observing in (B.4) the structure of $x^{[j]}$, we realize that the set defined in (B.2) is composed with the integers i such that (i, s) is (δ, j)-R and $\big(x^{[j]}\big)_i \in x_l x^{[j-1]}$. Counterwise, the set defined in (B.3) is composed with the integers i such that (i, s) is (δ, j)-R and $\big(x^{[j]}\big)_i$ does not belong to $x_l x^{[j-1]}$. Let us denote by $|n_1|_{n_2}$ the remainder of the integer division n_1/n_2. Then, again from (B.4), it is easily recognized that

$$\big(x^{[j]}\big)_s = x_l\big(x^{[j-1]}\big)_r, \quad r \triangleq |s|_{\delta^{j-1}}. \tag{B.5}$$

Remark B.5. Note that the number δ_j agrees with the number of entries of $x_{[j]}$ for $x \in \mathbf{R}^\delta$.

LEMMA B.6. *Let $r, s \in \{1, \ldots, \delta^{j-1}\}$ such that (r, s) is $(\delta, j-1)$-R. Then, for any $l = 0, 1, \ldots, \delta - 1$, the pair $(r + l\delta^{j-1}, s + l\delta^{j-1})$ is (δ, j)-R. Counterwise, if $r, s \in \{1, \ldots, \delta^j\}$ are (δ, j)-R and $r' = s'$ with*

$$r' \triangleq \left[\frac{r}{\delta^{j-1}}\right], \quad s' \triangleq \left[\frac{s}{\delta^{j-1}}\right],$$

then, denoting $r'' = |r|_{\delta^{j-1}}$, $s'' = |s|_{\delta^{j-1}}$, it results that (r'', s'') is $(\delta, j-1)$-R.

Proof. From Definition B.1 it results that

$$\big(x^{[j-1]}\big)_r = \big(x^{[j-1]}\big)_s \quad \forall\, x \in \mathbf{R}^\delta. \tag{B.6}$$

From (B.4) we see that

$$\big(x^{[j]}\big)_{r+l\delta^{j-1}} = x_l\big(x^{[j-1]}\big)_r, \quad \big(x^{[j]}\big)_{s+l\delta^{j-1}} = x_l\big(x^{[j-1]}\big)_s,$$

and hence, from (B.6),

$$\big(x^{[j]}\big)_{r+l\delta^{j-1}} = \big(x^{[j]}\big)_{s+l\delta^{j-1}}.$$

Counterwise, if $r, s \in \{1, \ldots, \delta^j\}$ are (δ, j)-R, then, taking into account (B.5), we have

$$\big(x^{[j]}\big)_r = x_{r'}\big(x^{[j-1]}\big)_{r''} = x_{s'}\big(x^{[j-1]}\big)_{s''} = \big(x^{[j]}\big)_s \quad \forall\, x \in \mathbf{R}^\delta. \tag{B.7}$$

Since, by hypothesis, $r' = s'$, (B.7) implies that $\left(x^{[j-1]}\right)_{r''} = \left(x^{[j-1]}\right)_{s''}$. □

Let $\mathcal{I} \subset \mathbf{N}$ and $n \in \mathbf{N}$. In the following, we will use the notation $\mathcal{I} - n$ to indicate the *translated* set:

$$\mathcal{I} - n = \{i \ / \ i \in \mathbf{N},\ \exists i' \in \mathcal{I},\ \text{such that } i = i' - n\}. \tag{B.8}$$

LEMMA B.7. *Suppose that*

$$\left[\frac{s}{\delta^{j-1}}\right] = l < \delta. \tag{B.9}$$

Then, for any $q < \delta - l$ it results that

$$\rho'(s; \delta, j) = \rho'(s + q\delta^{j-1}; \delta, j) - q\delta^{j-1},$$

where ρ' is the set defined in (B.2).

Proof. It suffices to show that for any $r \in \{1, \ldots, \delta^j\}$ such that $[r/\delta^{j-1}] = l$ and such that (r, s) is (δ, j)-NR ((δ, j)-R), the pair $(r + q\delta^{j-1}, s + q\delta^{j-1})$ is (δ, j)-NR ((δ, j)-R).

Suppose first that (r, s) is (δ, j)-NR. Let $x \in \mathbf{R}^\delta$ and $z = x^{[j]}$. From the structure (B.4) of the vector z and taking into account (B.9), we see that $z_s, z_r \in x_l \cdot x^{[j-1]}$. Hence since (s, r) is (δ, j)-NR, we have that, there exist integers $h_1, \ldots, h_\delta$ and $h'_1, \ldots, h'_\delta$, $h_1 + \cdots + h_\delta = h'_1 + \cdots + h'_\delta = j - 1$ such that it results that

$$\begin{aligned} z_s &= x_l \cdot x_1^{h_1} \cdots x_\delta^{h_\delta}, \\ z_r &= x_l \cdot x_1^{h'_1} \cdots x_\delta^{h'_\delta}. \end{aligned} \tag{B.10}$$

Since $z_r \neq z_s$ it follows that

$$x_1^{h_1} \cdots x_\delta^{h_\delta} \neq x_1^{h'_1} \cdots x_\delta^{h'_\delta}. \tag{B.11}$$

Again, looking at (B.4), we readily realize that

$$z_{s+q\delta^{j-1}} = x_{l+q} \cdot x_1^{h_1} \cdots x_\delta^{h_\delta}, \tag{B.12}$$

and

$$z_{r+q\delta^{j-1}} = x_{l+q} \cdot x_1^{h'_1} \cdots x_\delta^{h'_\delta}, \tag{B.13}$$

and hence, taking into account (B.11), it follows that $z_{s+q\delta^{j-1}} \neq z_{r+q\delta^{j-1}}$; that is $(s + q\delta^{j-1}, r + q\delta^{j-1})$ is (δ, j)-NR.

Next, suppose that (r, s) is (δ, j)-R. Then $z_s, z_r \in x_l \cdot x^{[j-1]}$, $z_s = z_r$, and by (B.10) it follows that $h_i = h'_i$, $i = 1, \ldots, \delta$. This in turn implies, taking into account (B.12), (B.13), that $z_{s+q\delta^{j-1}} = z_{r+q\delta^{j-1}}$; that is $(s + q\delta^{j-1}, r + q\delta^{j-1})$ is (δ, j)-R. □

LEMMA B.8. *Let (r, s) be a (δ, j)-R pair such that*

$$\left[\frac{r}{\delta^{j-1}}\right] = l, \qquad \left[\frac{s}{\delta^{j-1}}\right] = m, \quad l < m < \delta. \tag{B.14}$$

Then for any $q < \delta - l$ the pair $(r + q\delta^{j-1}, s + q\delta^{j-1})$ is (δ, j)-NR.

Proof. As in the proof of Lemma B.7 it is readily verified that, for some integers $h_1, \ldots, h_\delta$ such that $h_1 + \cdots + h_\delta = j - 1$, it results that

$$z_r = x_l \cdot x_1^{h_1} \cdots x_l^{h_l} \cdots x_m^{h_m} \cdots x_\delta^{h_\delta}. \tag{B.15}$$

Since $z_s = z_r$, (B.15) implies that

$$z_s = x_m \cdot x_1^{h_1} \cdots x_l^{h_l+1} \cdots x_m^{h_m-1} \cdots x_\delta^{h_\delta}.$$

Hence we have

$$z_{r+q\delta^{j-1}} = x_{l+q} \cdot x_1^{h_1} \cdots x_l^{h_l} \cdots x_m^{h_m} \cdots x_\delta^{h_\delta} = x_{l+q}\frac{z_r}{x_l},$$
$$z_{s+q\delta^{j-1}} = x_{m+q} \cdot x_1^{h_1} \cdots x_l^{h_l+1} \cdots x_m^{h_m-1} \cdots x_\delta^{h_\delta} = x_{m+q}\frac{z_s}{x_m}.$$

From this, since $z_r = z_s$ and $l \neq m$, it follows that $z_{r+q\delta^{j-1}} \neq z_{s+q\delta^{j-1}}$. ∎

Let us consider the state and output processes X, Y, of system (3.2), (3.3). We remind the reader that q and δ are the dimensions of the vectors Y and $Z = [Y^T\ X^T]^T$, respectively. Note that the components of $Z^{[j]}$ can be divided into two groups: the one including monomials composed only with components of the vector Y, and the other one including the remaining monomials. We shall call the components belonging to the former group *the Y-monomials*.

Let us consider the extraction matrix $\mathcal{E}_{\mathcal{Y}}$ defined in (7.19), and recall that the diagonal blocks $\mathcal{E}_{\mathcal{Y}}^j$, $j = 1, \ldots, \nu$, appearing there are such that (7.21) holds. According to the above defined notation (see Remark B.5), we shall denote by q_j the dimension of the vector $Y_{[j]}$. Finally, let us consider the reduction matrix $\tilde{T}_\delta^j$ defined in (7.1) and the matrix U_δ^j defined in (5.5). We can prove the following lemma.

LEMMA B.9. *There exists a full (row) rank matrix, namely L_δ^j, having dimensions $q_j \times q\delta^{j-1}$, such that*

$$\mathcal{E}_{\mathcal{Y}}^j \tilde{T}_\delta^j U_\delta^j = [\, L_\delta^j \quad 0\,].$$

Proof. Using (7.21) and property (5.4) we have

$$\begin{aligned}\mathcal{E}_{\mathcal{Y}}^j\Big(\frac{d}{dZ} \otimes Z_{[j]}\Big) &= \frac{d}{dZ} \otimes \mathcal{E}_{\mathcal{Y}}^j Z_{[j]} = \frac{d}{dZ} \otimes Y_{[j]} \\ &= \Big[\frac{\partial}{\partial Y} \quad \frac{\partial}{\partial X}\Big] \otimes Y_{[j]} = \Big[\frac{\partial}{\partial Y} \otimes Y_{[j]} \quad 0\Big].\end{aligned} \tag{B.16}$$

On the other hand, by (7.1), (5.3), and using formula (5.5),

$$\begin{aligned}\mathcal{E}_{\mathcal{Y}}^j\Big(\frac{d}{dZ} \otimes Z_{[j]}\Big) &= \mathcal{E}_{\mathcal{Y}}^j\Big(\frac{d}{dZ} \otimes \tilde{T}_\delta^j Z^{[j]}\Big) = \mathcal{E}_{\mathcal{Y}}^j \tilde{T}_\delta^j U_\delta^j \big(I_\delta \otimes Z^{[j-1]}\big) \\ &= \mathcal{E}_{\mathcal{Y}}^j \tilde{T}_\delta^j U_\delta^j \begin{bmatrix} I_q \otimes Z^{[j-1]} & 0 \\ 0 & I_{\delta-q} \otimes Z^{[j-1]} \end{bmatrix}.\end{aligned} \tag{B.17}$$

Using (B.16), (B.17), and defining L_δ^j as the matrix composed by the first $q\delta^{j-1}$ columns of $\mathcal{E}_{\mathcal{Y}}^j \tilde{T}_\delta^j U_\delta^j$, it results that

$$[\, \tfrac{\partial}{\partial Y} \otimes Y_{[j]} \quad 0\,] = [\, L_\delta^j \quad S\,] \begin{bmatrix} I_q \otimes Z^{[j-1]} & 0 \\ 0 & I_{\delta-q} \otimes Z^{[j-1]} \end{bmatrix},$$

from which it follows that $S = 0$ and

$$\frac{d}{dY} \otimes Y_{[j]} = L_\delta^j\Big(I_q \otimes Z^{[j-1]}\Big). \tag{B.18}$$

Let $V = (d/dY) \otimes Y_{[j]}$. Note that the components of the matrix V are either zero or they are monomials of $j-1$st degree. It results that V has linearly independent rows (in the sense of linear independence of monomial functions). As a matter of fact, any row is different from zero, and there cannot exist two (nonzero) similar monomials on the same column, because $Y_{[j]}$ has not repeated entries. Hence L^j_δ necessarily has linearly independent rows. Indeed, suppose there exists $u \neq 0$ such that $u^T L^j_\delta = 0$; then we would have $u^T V = 0 \ \ \forall\, Y \in \mathbf{R}^q$, which is a contradiction. □

LEMMA B.10. *Let $s \in \{1, \dots, q\delta^{j-1}\}$ and denote with λ_i, $i = 1, \dots, q\delta^{j-1}$, the ith column of the matrix L^j_δ. The following properties hold:*

(A) *$\forall\ i \in \{1, \dots, q\delta^{j-1}\}$, λ_i has zero entries, but possibly one, nonnegative;*

(B) *the set $\{\lambda_i /\ i \in \rho'(s; \delta, j)\}$, with $\rho'(s; \delta, j)$ given by* (B.2)*, is a set of linearly dependent vectors;*

(C) *if the sth component of $Z^{[j]}$ is not a Y-monomial, then $\lambda_s = 0$.*

Proof. Let us define l and r as

$$l \triangleq \left[\frac{s}{\delta^{j-1}}\right], \quad r \triangleq |s|_{\delta^{j-1}}. \tag{B.19}$$

Consider again the relation (B.18):

$$\frac{d}{dY} \otimes Y_{[j]} = \left[\ \tfrac{\partial}{\partial Y_1} Y_{[j]} \quad \dots \quad \tfrac{\partial}{\partial Y_q} Y_{[j]}\ \right] = L^j_\delta \big(I_q \otimes Z^{[j-1]}\big). \tag{B.20}$$

From (B.20) it results that

$$\frac{\partial}{\partial Y_l} Y_{[j]} = \tilde{L}^{(l)} Z^{[j-1]}, \tag{B.21}$$

where

$$\tilde{L}^{(l)} \triangleq \left[\, \lambda_{(l-1)\delta^{j-1}+1} \quad \lambda_{(l-1)\delta^{j-1}+2} \quad \dots \quad \lambda_{l\delta^{j-1}} \,\right].$$

Now, from (B.21) we see that each component of $(\partial/\partial Y_l) Y_{[j]}$ either is equal to zero or is equal (unless an *integer positive* coefficient) to some component of $Z^{[j-1]}$. Let h be the position of a nonzero entry of $(\partial/\partial Y_l) Y_{[j]}$, and let $r \in \{1, \dots, \delta^{j-1}\}$ be a position for which it appears (unless a coefficient, and possibly repeated) in $Z^{[j-1]}$. Then it results that the hth row of $\tilde{L}$ has, possibly, nonzero (hence positive) elements in the set $\rho(r; \delta, j-1)$. Indeed, this set of positions is determined by the position (r) of the component to be extracted in $Z^{[j-1]}$, endowed with all its $(\delta, j-1)$-R positions.

Let $i \in \{1, \dots, l\delta^{j-1}\}$ such that $\lambda_{(l-1)\delta^{j-1}+i}$ has a nonzero component, namely the hth. Then $\big(\lambda_{(l-1)\delta^{j-1}+i}\big)_k = 0$ for $k = 1, \dots, q_j$ and $k \neq h$. As a matter of fact, if $\big(\lambda_{(l-1)\delta^{j-1}+i}\big)_k \neq 0$, and $k \neq h$, then some monomial, equal to the ith, would be taken in $Z^{[j-1]}$, and hence we would have two equal components in $(\partial/\partial Y_l) Y_{[j]}$, which is impossible because $Y_{[j]}$ has no redundancies. This proves part (A) of the lemma.

From the above it follows that all the columns $\{\lambda_{(l-1)\delta^{j-1}+i},\ i \in \rho(r; \delta, j-1)\}$ have zero entries, but possibly one, placed in the same position h for any $i \in \rho(r; \delta, j-1)$. Hence, they constitute a set of linearly dependent vectors. Part (B) of the lemma follows as soon as it is noticed that, using Lemma B.6 and taking into account (B.19), it results that $\{\lambda_{(l-1)\delta^{j-1}+i},\ i \in \rho(r; \delta, j-1)\} = \{\lambda_i,\ i \in \rho'(s; \delta, j)\}$.

Finally, in order to prove part (C), note that, since $l \leq q$ (and hence, by recalling the structure of Z, given by (7.2), it results that $Z_l = Y_l$), we have that the sth component of $Z^{[j]}$ is of the form $Y_l Z_1^{h_1} \cdots Z_\delta^{h_\delta}$, where the powers $h_1, \dots, h_\delta$ are such

that $h_1 + \cdots + h_\delta = j - 1$, and it is not a Y-monomial by the hypothesis. Hence the monomial $Z_1^{h_1} \cdots Z_\delta^{h_\delta}$ is not a Y-monomial of $Z^{[j-1]}$, and then it cannot belong to the left-hand side of (B.21). This in turn implies, again by (B.21), that the rth column of $\tilde{L}^{(l)}$ (that is the sth column of L_δ^j, because l, r are defined by (B.19)) must be zero. □

Before proving Theorem 8.1, we need to give the following definition.

DEFINITION B.11. *We define the (δ, j)-Kronecker space, namely $\mathbf{K}(\delta, j)$, as the following subspace of $\mathbf{R}^{\delta^j}$:*

$$\mathbf{K}(\delta, j) = \operatorname{span}\left(\left\{ z \in \mathbf{R}^{\delta^j} \;\middle/\; \exists x \in \mathbf{R}^\delta \text{ such that } z = x^{[j]} \right\}\right).$$

Remark B.12. From Definition B.11 it follows that

$$\mathbf{K}(\delta, j) = \left\{ z \in \mathbf{R}^{\delta^j} \;\middle/\; z_r = z_s \text{ if } (r, s) \text{ is } (\delta, j) - R \right\}.$$

Proof of Theorem 8.1. By exploiting the definition of $\mathcal{D}_k^1$ given in (7.28), and the definition of $\tilde{\mathcal{B}}_k$ given by (7.17), we can rewrite the matrix $\mathcal{R}(t)$, defined in (8.1), as

$$\mathcal{R}(t) = \sum_{k=1}^{p} \mathcal{E}_{\mathcal{Y}} \mathcal{B}_k \Phi_Z(t) \mathcal{B}_k^T \mathcal{E}_{\mathcal{Y}}^T + \sum_{k=1}^{p} \mathcal{E}_{\mathcal{Y}} \big(\mathcal{B}_k m_Z(t) + \mathcal{V}_k\big) \big(\mathcal{B}_k m_Z(t) + \mathcal{V}_k\big)^T \mathcal{E}_{\mathcal{Y}}^T. \tag{B.22}$$

We will prove the theorem by showing that the matrix $\mathcal{E}_{\mathcal{Y}} \mathcal{B}_k \Phi_Z \mathcal{B}_k^T \mathcal{E}_{\mathcal{Y}}^T$ is uniformly nonsingular for some $k = 1, \ldots, p$, or (which is the same because $\Phi_Z(t)$ is uniformly nonsingular over T) that $\mathcal{E}_{\mathcal{Y}} \mathcal{B}_k$ is a full (row) rank matrix for some k.

In order to verify this, first of all note that, from Assumption 3.1 and Remark 3.2, it results that there exists a $\bar{k}$ such that $\operatorname{rank}(D_{\bar{k}}) = q$ (we remind the reader that q is the dimension of the original observation Y). Indeed, we have

$$D_{\bar{k}} = [I_q \; 0]. \tag{B.23}$$

For such a $\bar{k}$, let us show that

$$\operatorname{rank}\big(\mathcal{E}_{\mathcal{Y}} \mathcal{B}_{\bar{k}}\big) = q + q_2 + \cdots + q_\nu; \tag{B.24}$$

that is, it is a full (row) rank matrix (remember that q_i is the dimension of $Y_{[i]}$). From the definition of $\mathcal{B}_k$ and $\mathcal{E}_{\mathcal{Y}}$, given in (7.14) and (7.20), respectively, using (7.10) and taking into account the block triangular structure of $\mathcal{B}_k$, it results that condition (B.24) is equivalent to:

$$\operatorname{rank}\big(\mathcal{E}_{\mathcal{Y}}^1 \tilde{B}_{\bar{k}}\big) = q, \tag{B.25}$$

$$\operatorname{rank}\big(\mathcal{E}_{\mathcal{Y}}^j \tilde{T}_\delta^j U_\delta^j (\tilde{B}_{\bar{k}} \otimes I_{\delta^{j-1}}) T_\delta^j\big) = q_j \quad \forall\, j = 2, \ldots, \nu. \tag{B.26}$$

Now, from (7.22) we see that $\mathcal{E}_{\mathcal{Y}}^1 \in \mathbf{R}^{q \times \delta}$, $\mathcal{E}_{\mathcal{Y}}^1 = [I_q \; 0]$. Hence, by the definition of $\tilde{B}_k$ given in (7.5) and taking into account (B.23), it results that $\mathcal{E}_{\mathcal{Y}}^1 \tilde{B}_{\bar{k}} = [0 \; I_q \; 0]$, and hence condition (B.25) is verified.

It remains to prove (B.26). In order to do this, first note that, from the definition of $\tilde{B}_k$ given in (7.5) and taking into account (B.23), we can consider the following partition of the matrix $\tilde{B}_{\bar{k}} \otimes I_{\delta^{j-1}}$:

$$\tilde{B}_{\bar{k}} \otimes I_{\delta^{j-1}} = \begin{bmatrix} M_1 \\ M_2 \end{bmatrix}, \tag{B.27}$$

where M_1 has dimensions $q\delta^{j-1} \times \delta^j$ and has the following structure:

$$M_1 = [\,0 \quad I_{q\delta^{j-1}} \quad 0\,], \tag{B.28}$$

where the first null-block has dimensions $q\delta^{j-1} \times q\delta^{j-1}$. Using Lemma B.9 and (B.27), we have

$$\mathcal{E}_{\mathcal{Y}}^j \tilde{T}_\delta^j U_\delta^j (\tilde{B}_{\bar{k}} \otimes I_{\delta^{j-1}}) T_\delta^j = [\,L_\delta^j \quad 0\,] \begin{bmatrix} M_1 \\ M_2 \end{bmatrix} T_\delta^j = L_\delta^j M_1 T_\delta^j. \tag{B.29}$$

Now note that the range of the *expansion* matrix T_δ^j is equal to the Kronecker space $\mathbf{K}(\delta, j)$ (we remind the reader that T_δ^j performs the operation $Z^{[j]} = T_\delta^j Z_{[j]}$). Then by (B.29), we have that (B.26) is implied by the following condition: the operator $L_\delta^j M_1 : \mathbf{R}^{\delta^j} \to \mathbf{R}^{q_j}$, restricted to $\mathbf{K}(\delta, j)$ is surjective.

Let $y \in \mathbf{R}^{q_j}$, and we will prove that there exists a $z \in \mathbf{K}(\delta, j)$ such that $y = L_\delta^j M_1 z$. By Lemma B.9, $\operatorname{rank}(L_\delta^j) = q_j$; then there exist q_j indexes. $1 \le i_1, i_2, \ldots, i_{q_j} \le q\delta^{j-1}$, such that the columns $\lambda_{i_1}, \lambda_{i_2}, \ldots, \lambda_{i_{q_j}}$ (λ_i denotes as usual the ith column of L_δ^j) are linearly independent. For every i_s, $s = 1, \ldots, q_j$, let us consider the sets $\rho'(i_s; \delta, j) \subset \rho(i_s; \delta, j)$ defined in (B.2). Let us define $\bar{\lambda}_{i_s}$ as

$$\bar{\lambda}_{i_s} \triangleq \sum_{i \in \rho'(i_s;\delta,j)} \lambda_i. \tag{B.30}$$

From Lemma B.10, parts (A) and (B), we have that the set $\{\bar{\lambda}_{i_s},\ s = 1, \ldots, q_j\}$ is a set of linearly independent vectors, and hence there exist real numbers $\alpha_{i_1}, \alpha_{i_2}, \ldots, \alpha_{i_{q_j}}$, such that

$$y = \alpha_{i_1} \bar{\lambda}_{i_1} + \cdots + \alpha_{i_{q_j}} \bar{\lambda}_{i_{q_j}}. \tag{B.31}$$

Now let us show that the elements of the set $\{i_s + q\delta^{j-1}\ s = 1, \ldots, q_j\}$ are pairwise (δ, j)-NR. To this purpose, for any pair (i_r, i_s), $r \neq s$, $r, s = 1, \ldots, q_j$, we can distinguish the following two cases.

(i)

$$\left[\frac{i_r}{\delta^{j-1}}\right] = \left[\frac{i_s}{\delta^{j-1}}\right].$$

In this case, since λ_{i_r} and λ_{i_s} are linearly independent, it follows that (i_r, i_s) is (δ, j)-NR. Indeed, if (i_r, i_s) were (δ, j)-R, then Lemma B.10, part (B) would imply that λ_{i_r} and λ_{i_s} are linearly dependent vectors. Hence, since (i_r, i_s) is (δ, j)-NR, Lemma B.7 implies that $(i_r + q\delta^{j-1}, i_s + q\delta^{j-1})$ is (δ, j)-NR.

(ii)

$$i'_r \triangleq \left[\frac{i_r}{\delta^{j-1}}\right] \neq \left[\frac{i_s}{\delta^{j-1}}\right] \triangleq i'_s. \tag{B.32}$$

In this case, if (i_r, i_s) is (δ, j)-R then Lemma B.8 directly implies the same conclusion of (i). Else, if (i_r, i_s) is (δ, j)-NR, then we can show that $(i_r + q\delta^{j-1}, i_s + q\delta^{j-1})$ is again (δ, j)-NR. For, let $h_1, \ldots, h_\delta$, $h'_1, \ldots, h'_\delta$ such that $h_1 + \cdots + h_\delta = h'_1 + \cdots + h'_\delta = j - 1$ and

$$\begin{aligned} \left(Z^{[j]}\right)_{i_r} &= Z_{i'_r} Z_1^{h_1} \cdots Z_\delta^{h_\delta}, \\ \left(Z^{[j]}\right)_{i_s} &= Z_{i'_s} Z_1^{h'_1} \cdots Z_\delta^{h'_\delta}, \end{aligned} \tag{B.33}$$

where i'_r, i'_s are given by (B.32). Since λ_{i_r} and λ_{i_s} are linearly independent (hence nonzero), Lemma B.10, part (C) implies that both the monomials in (B.33) are Y-monomials. If $(i_r + q\delta^{j-1}, i_s + q\delta^{j-1})$ were (δ, j)-R, we should have

$$Z_{i'_r+q} Z_1^{h_1} \cdots Z_\delta^{h_\delta} = Z_{i'_s+q} Z_1^{h'_1} \cdots Z_\delta^{h'_\delta},$$

which is possible if and only if

$$\begin{aligned} &h_{i'_r+q} = h'_{i'_r+q} - 1, \quad h_{i'_s+q} = h'_{i'_s+q} + 1, \\ &h_i = h'_i \quad \forall\ i \neq i'_r + q, i'_s + q. \end{aligned} \tag{B.34}$$

Now $i'_r, i'_s \leq q$, and then we have that $Z_{i'_r+q}$ and $Z_{i'_s+q}$ are not components of the vector Y, hence condition (B.34) can be verified if and only if both the monomials in (B.33) are not Y-monomials, which is a contradiction.

Since the elements of the set $\{i_s + q\delta^{j-1},\ s = 1, \dots q_j\}$ are pairwise (δ, j)-NR, we have that

$$\rho(i_s + q\delta^{j-1}; \delta, j) \cap \rho(i_r + q\delta^{j-1}; \delta, j) = \emptyset \quad \forall\ r, s = 1, \dots, q_j,\ r \neq s. \tag{B.35}$$

From (B.35) it results that the following vector $z \in \mathbf{R}^{\delta^{j-1}}$ is well defined:

$$z_l = \begin{cases} \alpha_{i_s} & \text{if } l \in \rho(i_s + q\delta^{j-1}; \delta, j), \\ 0 & \text{otherwise.} \end{cases} \tag{B.36}$$

Noting that, by construction, $z \in \mathbf{K}(\delta, j)$, the theorem is proven as soon as it is shown that $y = L_\delta^j M_1 z$ with y given by (B.31).

Let $z' = M_1 z$. By the structure of the matrix M_1 (B.28), it follows that

$$z'_l = \begin{cases} \alpha_{i_s} & \text{if } l \in \rho(i_s + q\delta^{j-1}; \delta, j) - q\delta^{j-1}, \\ 0 & \text{otherwise,} \end{cases} \tag{B.37}$$

where the definition of translated set, given by (B.8), has been used. Observing (B.37), (B.31), and the definition of the $\bar{\lambda}_{i_s}$s (B.30), we see that the equality $y = L_\delta^j z'$, and hence the theorem is implied by the condition

$$\sum_{i \in \rho'(i_s; \delta, j)} \lambda_i = \sum_{i \in \rho(i_s + q\delta^{j-1}; \delta, j) - q\delta^{j-1}} \lambda_i \quad \forall\ s = 1, \dots, q_j. \tag{B.38}$$

Now, from Lemma B.7 we have $\rho'(i_s; \delta, j) = \rho'(i_s + q\delta^{j-1}; \delta, j) - q\delta^{j-1}$; moreover, by (B.3)

$$\rho(i_s + q\delta^{j-1}; \delta, j) = \rho'(i_s + q\delta^{j-1}; \delta, j) \cup \rho''(i_s + q\delta^{j-1}; \delta, j),$$

and hence (B.38) becomes

$$\sum_{i \in \rho''(i_s + q\delta^{j-1}; \delta, j) - q\delta^{j-1}} \lambda_i = 0 \quad \forall\ s = 1, \dots, q_j,$$

which is implied by

$$\lambda_i = 0 \quad \forall\ i \in \rho''(i_s + q\delta^{j-1}; \delta, j) - q\delta^{j-1}. \tag{B.39}$$

In order to prove (B.39), first note that by Lemma B.8, for any $i \in \rho''(i_s+q\delta^{j-1};\delta,j)-q\delta^{j-1}$, we must have that (i,i_s) is (δ,j)-NR and such that $(i+q\delta^{j-1}, i_s+q\delta^{j-1})$ is (δ,j)-R. Now, let $h_1,\dots,h_\delta$, $h'_1,\dots,h'_\delta$ such that $h_1+\cdots+h_\delta = h'_1+\cdots+h'_\delta = j-1$ and

$$\begin{aligned} \left(Z^{[j]}\right)_i &= Z_{i'} Z_1^{h_1}\cdots Z_\delta^{h_\delta}, \\ \left(Z^{[j]}\right)_{i_s} &= Z_{i'_s} Z_1^{h'_1}\cdots Z_\delta^{h'_\delta}, \end{aligned} \tag{B.40}$$

with $i' = [i/\delta^{j-1}]$, $i'_s = [i_s/\delta^{j-1}]$. Since $(i+q\delta^{j-1}, i_s+q\delta^{j-1})$ is (δ,j)-R, it results that

$$Z_{i'+q} Z_1^{h_1}\cdots Z_\delta^{h_\delta} = Z_{i'_s+q} Z_1^{h'_1}\cdots Z_\delta^{h'_\delta},$$

which in turn implies the following condition:

$$\begin{aligned} &h_{i'+q} = h'_{i'+q} - 1, \quad h_{i'_s+q} = h'_{i'_s+q} + 1, \\ &h_i = h'_i \quad \forall\, i \neq i'+q, i'_s+q. \end{aligned} \tag{B.41}$$

Since $i', i'_s \leq q$, $Z_{i'+q}$ and $Z_{i'_s+q}$ are not components of the vector Y. Hence, condition (B.41) implies that both the monomials in (B.40) are not Y-monomials. In particular, since $\left(Z^{[j]}\right)_i$ is not a Y-monomial, Lemma B.10, part (C) gives $\lambda_i = 0$, that is (B.39). □

CONTINUITY OF OPTIMAL VALUES AND SOLUTIONS FOR CONTROL OF MARKOV CHAINS WITH CONSTRAINTS*

MABEL M. TIDBALL†, ARIEL LOMBARDI‡, ODILE POURTALLIER§, AND EITAN ALTMAN§

Abstract. We consider in this paper constrained Markov decision processes. This type of control model has many applications in telecommunications and other fields [E. Altman and A. Shwartz, *IEEE Trans. Automat. Control*, 34 (1989), pp. 1089–1102, E. A. Feinberg and M. I. Reiman, *Probab. Engrg. Inform. Sci.*, 8 (1994), pp. 463–489, A. Hordijk and F. Spieksma, *Adv. in Appl. Probab.*, 21 (1989), pp. 409–431, A. Lazar, *IEEE Trans. Automat. Control*, 28 (1983), pp. 1001–1007, P. Nain and K. W. Ross, *IEEE Trans. Automat. Control*, 31 (1986), pp. 883–888, K. W. Ross and B. Chen, *IEEE Trans. Automat. Control*, 33 (1988), pp. 261–267]. We address the issue of the convergence of the value and optimal policies of the problem with discounted costs, to the ones for the problem with expected average cost. We consider the general multichain ergodic structure. We present two stability results in this paper. We establish the continuity of optimal values and solutions of as well as some type of robustness of some suboptimal solutions in the discount factor. Our proof relies on same general theory on continuity of values and solutions in convex optimization that relies on well-known notions of Γ-convergence.

1. Introduction.

We consider a sequence $\mathbf{MP}_n$, $n = 1, 2, \ldots$ of constrained Markov decision processes (CMDPs), and a "limit" one, denoted by $\mathbf{MP}_\infty$, or simply by $\mathbf{MP}$. These are defined on some vector spaces, possibly infinite dimensional ones. $\mathbf{MP}$ is assumed to be feasible (it has at least one solution). However, for any given n, $\mathbf{MP}_n$ need not be feasible, and even if it is, it need not possess an optimal solution (i.e., it may only have ϵ-optimal solutions). We are interested in the following questions.

(i) Do the values of $\mathbf{MP}_n$ converge to the value of $\mathbf{MP}$?
(ii) Do optimal (or almost optimal) policies converge in some sense?
(iii) Given an (almost) optimal policy for $\mathbf{MP}_n$, will it be an almost optimal policy for $\mathbf{MP}$ if n is sufficiently large?
(iv) Conversely, given an optimal policy for $\mathbf{MP}$, will it be an almost optimal policy for $\mathbf{MP}_n$ for all n sufficiently large?

By reducing our control problem to equivalent mathematical programs, we show that the epigraph theory and the Γ-convergence theory provide sufficient conditions for having convergence in the sense of (i) and (ii) above. It turns out that the answers for (iii) and for (iv) are in general negative, unlike the unconstrained case. The reason is that an optimal policy for $\mathbf{MP}_n$ may be unfeasible for $\mathbf{MP}$, and vice versa. We shall, however, establish sufficient conditions for the following slightly weaker versions of (iii) and (iv).

(iii′) Given an optimal policy for $\mathbf{MP}_n$, can we perturb it "slightly" so that it becomes almost optimal for $\mathbf{MP}$ if n is sufficiently large?

(iv′) Given an optimal policy for $\mathbf{MP}$, can we perturb it "slightly" so that it becomes almost optimal for $\mathbf{MP}_n$ for all n sufficiently large?

The answers for (iii′) and (iv′) follow from continuity properties of the solutions and values of mathematical programming. We use in particular notions of Γ-convergence (see [16] and [37]). We extend and adapt existing theorems and tools for the sensitivity of solutions of convex optimization to obtain the appropriate framework for analyzing CMDPs.

We focus here on the convergence in the discount factor α_n as it converges to some limit within the unit interval. We present sufficient conditions for the convergence of the values and of optimal policies, as well as some robustness properties of suboptimal policies. Related results were already obtained in [1] but had a strong restriction on the ergodic structure of the controlled model. It was required to have a single ergodic class under any stationary policy. This condition enabled us to restrict our problem to stationary policies, for which some general theorem on approximation [2] could be used. In the present paper we make no assumption on the ergodic structure, thus allowing a multichain situation. For such ergodic structure, it is known that stationary policies need not be optimal (nor even ϵ-optimal) for the expected average cost criterion, and one has to use either Markov policies (see [25, 27]) or mixed-stationary policies (this term was raised by Feinberg [21] in a similar context; it refers to policies that are highly nonstationary). We use the latter approach to establish, with the help of the results from the first part of the paper, the convergence of the values and policies.

We briefly mention some related work on the continuity and sensitivity analysis of mathematical programs and of control problems. Many papers and books studied similar problems in the case of finite dimensional state, e.g., [17, 24, 36]. Several special issues of scientific journals were devoted to these questions, as well as other related sensitivity, stability, and parametric analysis: *Mathematical Programming* 21, 1984, *Annals of Operations Research* 27, 1990. Convergence results for constrained dynamic control problems were obtained in [1, 2, 4, 6, 8]. Conditions were obtained there for the convergence in the transition probabilities, in the horizon, and in the immediate cost. These results were applied to adaptive control problems [6] and to problems of finite state approximations of CMDPs. Similar questions to those addressed in this paper were studied in [23] and in [43], and some of the results there are close to those in the first part of our paper. The main difference lies in the types of assumptions made. In [23] the central assumption is stated in terms of constraints set convergence making the use of a metric. In [43] less regularity on the constraints sets are required (convergence of the constraint sets in the Hausdorff topology). Nevertheless only points (i) and (ii) are studied there. Some related questions but in the context of min-max problems and Stakelberg equilibrium are studied in [31, 32, 34]. Some other references related to the current paper are [13, 16, 28, 33, 42, 44].

2. CMDPs: The convergence in the discount factor. We consider CMDPs, known also as controlled Markov chains, with a general ergodic structure (multichain). We consider the discounted cost and the average cost. We shall obtain new results on the convergence of the values and optimal policies of the discounted cost, as the discount factor tends to one, to the value and to optimal policies corresponding to the expected average cost. A similar result for the special unichain case was obtained

in [1].

Consider a Markov decision process (MDP) with a finite state space $\mathbf{X} = \{0, 1, \ldots, N\}$ and a finite *action space* $\mathbf{A}$. Without loss of generality, we assume that in any state x all actions in $\mathbf{A}$ are available. The probability to go from state x to state y given that action a is used is given by the transition probability P_{xay}. A policy u in the *policy space* $\mathbf{U}_h$ is described as $u = (u_1, u_2, \ldots)$, where u_t, applied at time epoch t, is a probability measure over $\mathbf{A}$ conditioned on the whole history of actions and state prior to t, as well as the state at time t. Given an initial distribution β on $\mathbf{X}$, each policy u induces a probability measure denoted by P^u_β on the space of sample paths of states and actions (which serves as the canonical sample space Ω). The corresponding expectation operator is denoted by E^u_β. On this probability space are defined the state and action processes, X_t, A_t, $t = 1, 2, \ldots$.

A *Markov policy* $u \in \mathbf{U}_M$ is characterized by the dependence of u_{t+1} on the current state and the time only. A *stationary policy* $g \in \mathbf{U}_S$ is characterized by a single conditional probability measure $p^g_{\cdot|x}$ over $\mathbf{A}$, so that $p^g_{\mathbf{A}|x} = 1$; under g, X_t becomes a Markov chain with stationary transition probabilities, given by $P^g_{xy} = \sum_{a\in\mathbf{A}} p^g_{a|x} P_{xay}$. The class of *stationary deterministic policies* $\mathbf{U}_D$ is a subclass of $\mathbf{U}_S$, and every $g \in \mathbf{U}_D$ is characterized by a mapping g:$\mathbf{X} \to \mathbf{A}$, so that $p^g_{\cdot|x} = \delta_{g(x)}(\cdot)$ is concentrated at the point $g(x)$ for each x. Let L be the number of stationary deterministic policies among $\mathbf{U}_D$, and enumerate the policies in $\mathbf{U}_D$ such that $\mathbf{U}_D = \{u^1, \ldots, u^L\}$.

It will often be useful to extend the definition of a policy $u = (u_1, u_2, \ldots)$ so as to allow u_t to depend not only on the history, but also on some additional randomizing mechanism. In particular, for any finite class of policies $G \subset \mathbf{U}_h$, we define $\overline{M}(G)$ to be the class of mixed policies generated by G. We call these mixed-G policies. A mixed-G policy $\hat{q}$ is identified with a distribution q over G; the controller first uses q to choose some policy $u \in G$ and then proceeds with that policy from time 1 onwards. Define $\mathcal{U} := \overline{M}(U_D)$. Finally, we denote $\mathbf{U} = \mathbf{U}_h \cup \mathcal{U}$.

DEFINITION 2.1. *For any initial distribution q over the set $\mathbf{U}_D$, we shall identify the policy $m(q) \in \mathcal{U}$ to be the one that chooses initially the policy u^j with probability q_j.*

Remark 2.2. Although we consider here a more general definition of policies than $\mathbf{U}_h$, these policies are in fact equivalent to those in $\mathbf{U}_h$ (details are given in Remark 3.1). A randomization over actual classes of policies has already been considered in [20, 29]. An alternative for the randomization over policies is the randomization over the strategic measures they generate. If we identify a policy with the strategic measure it generates, then it follows that the large class $\overline{M}(\mathbf{U}_h)$ is equivalent to the class of Markov policies $\mathbf{U}_M$, as was shown in [19].

For any given distribution β for the initial state (at time 1) and a policy u, define a probability measure P^u_β on which the stochastic processes X_t and A_t of the states and actions are defined. When β is concentrated on some state x (i.e., $\beta = \delta_x$), we shall use the notation P^u_x instead of P^u_β.

Let $c : \mathbf{X} \times \mathbf{A} \to \mathbb{R}$ and $d : \mathbf{X} \times \mathbf{A} \to \mathbb{R}^K$ be immediate cost functions, $d = (d^1, d^2, \ldots, d^k)$.

Fix some discount factor $\alpha \in [0, 1)$, and define the normalized discounted costs corresponding to an initial distribution β and a policy u by

$$C_\alpha(\beta, u) = \sum_{t=1}^{\infty} (1-\alpha) E^u_\beta \alpha^{t-1} c(X_t, A_t),$$

$$D_\alpha^k(\beta,u)=\sum_{t=1}^{\infty}(1-\alpha)E_\beta^u\alpha^{t-1}d^k(X_t,A_t),\qquad k=1,\dots,K.$$

Define the average costs associated with a policy u and with an initial distribution β on $\mathbf{X}$:

$$C_{ea}(\beta,u)=\overline{\lim_{t\to\infty}}\,\frac{1}{t}E_\beta^u\left[\sum_{s=1}^{t}c(X_s,A_s)\right],$$

$$D_{ea}^k(\beta,u)=\overline{\lim_{t\to\infty}}\,\frac{1}{t}E_\beta^u\left[\sum_{s=1}^{t}d^k(X_s,A_s)\right],\qquad k=1,\dots,K.$$

Given a vector $V\in\mathbb{R}^K$, we consider the subset $\Pi_V\subset\mathbf{U}$ of policies satisfying the constraints

$$D(\beta,u)\le V. \tag{2.1}$$

A policy $u\in\Pi_V$ is called feasible. We introduce the following constrained problem (COP): find a policy u^* that achieves

$$C(\beta):=\inf_{u\in\Pi_V}C(\beta,u). \tag{2.2}$$

In (2.1) and (2.2), the costs stand for either the discounted or the average cost. The COP is said to be feasible if Π_V is nonempty.

We are now ready to state the first main result.

THEOREM 2.3 (convergence of the value). *Assume that the following Slater condition holds: there exists some policy $v\in\mathbf{U}$ such that*

$$D^k(\beta,v)\le V^k-\eta\qquad\forall k=1,\dots,K \tag{2.3}$$

for some $\eta>0$. Then, the value converges in the discount factor:

$$\lim_{\alpha\to1}C_\alpha(\beta)=C_{ea}(\beta).$$

The proof of this theorem, as well as the convergence of optimal policies, are delayed to the next section.

3. Convergence of the values and the policies. In order to be able to define the convergence of optimal policies, we shall show that one may restrict the search of optimal policies to the simple subclasses of policies $\mathcal{U}$, without loss of optimality. Moreover, we should relate the solutions of the COP to solutions of mathematical programming, in order to be able to apply the tools that we developed. Note that the control problem is already of the form of a mathematical program, but the cost is not convex in the policies. We shall show that when restricting to $\mathcal{U}$, the costs are convex functions.

There are several ways to solve (2.2). For the discounted cost, the solution was given by Kallenberg in [27] using a linear program (LP) approach. For the expected average cost, there are several possible LP approaches: the one by Hordijk and Kallenberg [25, 27], the one by Feinberg [21], and a related one by Altman and Shwartz [9]; for a definition slightly different than in (2.2), an efficient LP method for computing ϵ-optimal solutions was obtained by Ross and Varadarajan; see [40, 41]. Lagrangian

techniques have also been used to solve CMDPs with a single constraint; see Beutler and Ross [11, 12] and Sennott [45, 46]. The relation between the Lagrange and the LP approaches was pointed out in [10].

Remark 3.1. All the references above considered the solution of the constrained MDP among the policies $\mathbf{U}_h$. However, a standard argument due to Derman and Strauch [18] shows (in a constructive way) that for any policy $u \in \mathbf{U}$, there exists an equivalent policy $\chi \in \mathbf{U}_M$ under which the marginal probabilities of the states and actions are the same as those under u, and in particular, both the discounted and the expected average costs are the same. Thus below, whenever we obtain an optimal policy among $\mathcal{U}$, one may consider the policy χ instead without loss of optimality. Note, however, that one cannot in general restrict further to the stationary policies $\mathbf{U}_S$. Indeed, it is shown in [25, 27] that they are not sufficient for the expected average cost with a general multichain structure.

We would like to prove the convergence results by showing that there is a correspondence between values and optimal solutions of the control problem, and values and optimal solutions of related LPs, and then use the general results from the previous section. While this is possible for the unichain case, it turns out that for the multichain case, the LP introduced by Kallenberg [27] for the discounted cost is completely different than any of the LPs for the expected average cost (e.g., the number of decision variables is different). Therefore, as a first step, we shall introduce a new LP method for computing the value and optimal policies for the discounted cost problem, which is an adaptation of the one for the expected average cost in Feinberg [21] and Altman and Shwartz [9]. This will allow us to have the same type of LP for both the discounted and the average cost.

Denote the simplex $S(L) := \{\gamma \in R^L : \gamma_i \geq 0, i = 1, \ldots, L, \ \sum_{i=1}^L \gamma_i = 1\}$. Introduce the following $\mathbf{LP}_\alpha$: Find $\gamma^* \in S(L)$ that achieves

$$\mathcal{C}_\alpha^* := \min_{\gamma \in S(L)} \sum_{i=1}^L \gamma_i C_\alpha(\beta, u^i), \qquad \textit{such that (s.t.)} \tag{3.1}$$

$$\mathcal{D}_\alpha^k(\gamma) := \sum_{i=1}^L \gamma_i D_\alpha^k(\beta, u^i) \leq V^k, \ k = 1, \ldots, K. \tag{3.2}$$

Define $\mathcal{C}_\alpha(\gamma) := \sum_{i=1}^L \gamma_i C_\alpha(\beta, u^i)$. We say that the LP is feasible if the subset of $S(L)$ satisfying the constraints (3.2) is nonempty.

THEOREM 3.2 (relation between LP and the CMDP, the discounted cost).

(i) *For any $\gamma \in S(L)$, the policy $m(\gamma) \in \mathcal{U}$ (see Definition 2.1) satisfies*

$$C_\alpha(\beta, m(\gamma)) = \mathcal{C}_\alpha(\gamma), \qquad D_\alpha^k(\beta, m(\gamma)) = \mathcal{D}_\alpha^k(\gamma), \qquad k = 1, \ldots, K.$$

(ii) *For any vector of costs*

$$\{C_\alpha(\beta, u), D_\alpha^k(\beta, u), k = 1, \ldots, K\},$$

achievable by some policy $u \in \mathbf{U}$, there exists some $v \in \mathcal{U}$ achieving the same vector of costs.

(iii) *COP_α is feasible if and only if LP_α is and the optimal values are the same: $\mathcal{C}_\alpha^* = C_\alpha(\beta)$. Moreover, if γ^* is optimal for LP_α, then $m(\gamma^*)$ is optimal for COP_α.*

Proof. Denote

$$f_\alpha(\beta,u;y,a) := (1-\alpha)\sum_{t=1}^{\infty}\alpha^{t-1}P_\beta^u(X_t=y,A_t=a), \qquad x\in\mathbf{X}, a\in\mathbf{A},$$

and let $f_\alpha(\beta,u)$ be the vector whose (y,a)th elements are given by $f_\alpha(\beta,x;y,a)$. Then (see, e.g., [14])

$$C_\alpha(\beta,u) = c\cdot f_\alpha(\beta,u) = \sum_{y\in\mathbf{X}}\sum_{a\in\mathbf{A}} c(y,a)f_\alpha(\beta,u;y,a), \tag{3.3}$$

with a similar representation for the costs $D_\alpha^k(\beta,u)$. For any class of policies $\overline{U}$, denote $\mathbf{L}_\alpha(\beta,\overline{U}) = \cup_{u\in\overline{U}} f_\alpha(\beta,u)$. It is known that the set $\mathbf{L}_\alpha(\beta,\mathbf{U}_h)$ is convex, compact, and its extreme points are contained in $\{f_\alpha(\beta,u), u\in\mathbf{U}_D\}$; see [14, 27]. For any probability γ over $\mathbf{U}_D$, we clearly have

$$f_\alpha(\beta,m(\gamma)) = \sum_{i=1}^{L}\gamma_i f_\alpha(\beta,u^i). \tag{3.4}$$

Consequently, $\mathbf{L}_\alpha(\beta,\mathbf{U})$ is convex, compact, and its extreme points are $\{f_\alpha(\beta,u), u\in\mathbf{U}_D\}$.

Combining this with (3.3), we conclude that the set of achievable costs

$$\cup_{u\in\mathbf{U}}\{C_\alpha(\beta,u), D_\alpha^k(\beta,u), k=1,\dots,K\} \tag{3.5}$$

is also convex, compact, and its extreme points are

$$\{C_\alpha(\beta,u), D_\alpha^k(\beta,u), k=1,\dots,K, u\in\mathbf{U}_D\}. \tag{3.6}$$

By combining (3.3) with (3.4), we get, for any probability γ over $\mathbf{U}_D$,

$$C_\alpha(\beta,m(\gamma)) = \sum_{i=1}^{L}\gamma_i C_\alpha(\beta,u^i), \qquad D_\alpha^k(\beta,m(\gamma)) = \sum_{i=1}^{L}\gamma_i D_\alpha(\beta,u^i),\ k=1,\dots,K.$$

Hence, the set of performance measures achievable by $u\in\mathcal{U}$ is also convex, compact, with the extreme points in the set (3.6), and thus, equal to the set (3.5) achievable by all policies. This establishes (i) and (ii) and implies (iii). □

The LP method corresponding to (3.1) for the expected average cost, due to Feinberg [21], is the same: $\mathbf{LP_{ea}}$: Find $\gamma^*\in S(K)$ that achieves

$$\mathcal{C}_{ea}^* := \min_{\gamma\in S(L)}\sum_{i=1}^{L}\gamma_i C_{ea}(\beta,u^i), \qquad s.t. \tag{3.7}$$

$$\mathcal{D}_{ea}^k(\gamma) := \sum_{i=1}^{L}\gamma_i D_{ea}^k(\beta,u^i) \le V^k,\ k=1,\dots,K. \tag{3.8}$$

Define $\mathcal{C}_{ea}(\gamma) := \sum_{i=1}^{L}\gamma_i C_{ea}(\beta,u^i)$.

THEOREM 3.3 (relation between LP and the CMDP, the expected average cost).

(i) *For any $\gamma\in S(L)$, the policy $m(\gamma)\in\mathcal{U}$ (see Definition 2.1) satisfies*

$$C_{ea}(\beta,m(\gamma)) = \mathcal{C}_{ea}(\gamma), \qquad D_{ea}^k(\beta,m(\gamma)) = \mathcal{D}_{ea}^k(\gamma), \qquad k=1,\dots,K.$$

(ii) *For any vector of costs*

$$\{C_{ea}(\beta,u), D^k_{ea}(\beta,u), k=1,\dots,K\}$$

achievable by some policy $u \in \mathbf{U}$*, there exists a dominating* $v \in \mathcal{U}$*, i.e., such that*

$$C_{ea}(\beta,v) \le C_{ea}(\beta,u), \quad D^k_{ea}(\beta,v) \le D^k_{ea}(\beta,u), k=1,\dots,K.$$

(iii) COP_{ea} *is feasible if and only if* LP_{ea} *is and the optimal values are the same:* $\mathcal{C}^*_{ea} = C_{ea}(\beta)$*. Moreover, if* γ^* *is optimal for* LP_{ea}*, then* $m(\gamma^*)$ *is optimal for* COP_{ea}*.*

Proof. Denote

$$f^t_{ea}(\beta,u;y,a) := t^{-1}\sum_{s=1}^{t} P^u_\beta(X_s=y, A_s=a), \qquad x\in\mathbf{X}, a\in\mathbf{A},$$

and let $f^t_{ea}(\beta,u)$ be the vector whose (y,a)th elements are given by $f^t_{ea}(\beta,x;y,a)$. For any $u \in U_D$, since the state process is a Markov chain, it is known that

$$f_{ea}(\beta,u) = \lim_{t\to\infty} f^t_{ea}(\beta,u) \text{ exists}, \tag{3.9}$$

and it is straightforward to show that

$$C_{ea}(\beta,u) = c\cdot f_{ea}(\beta,u) = \sum_{y\in\mathbf{X}}\sum_{a\in\mathbf{A}} c(y,a) f_{ea}(\beta,u;y,a), \tag{3.10}$$

with a similar representation for the costs $D^k_{ea}(\beta,u)$. It is then clear that (3.9) and (3.10) hold in fact for any $u \in \mathcal{U}$, which establishes (i).

For a fixed initial distribution β, for any policy $v \in \mathbf{U}_h$, and for any accumulation point f of the sequence $f^t_{ea}(\beta,u)$, there exists some $u \in \mathcal{U}$ such that $f_{ea}(\beta,u) = f$. This is a direct consequence of Theorem 2 in [25] and is a special case of the result in [21] (who studies the semi-Markov case). Combining this with the fact that (3.9) and (3.10) hold for any $u \in \mathcal{U}$ establishes (ii), by using Corollary 2.5 in [7]. Finally, (iii) is a consequence of (i) and (ii). □

For a given $u \in \mathcal{U}$ we shall understand below $\pi_\delta(u) = m(\pi_\delta(\gamma))$, where γ is such that $u = m(\gamma)$ and π_δ is defined in (B.17). We are now ready to state the second main result for MDPs.

THEOREM 3.4. *Assume that the Slater condition* (2.3) *holds. Consider a sequence* α_n *converging to* 1*, and let* COP_n *be the constrained optimal control problem corresponding to the discount factor* α_n*. Let* δ *be such that* $\eta > \delta > 0$*. Then we have the following.*

(i) *Let* $u_n \in \mathcal{U}$ *be* ϵ_n*-optimal for* COP_n*,* $\limsup_n \epsilon_n \le \epsilon$*. Then there exists* $N(\epsilon,\delta)$ *such that* $\forall n \ge N(\epsilon,\delta)$*,* $\pi_\delta(u_n)$ *is* $O(\epsilon+\delta)$*-optimal for* COP_{ea}*.*

(ii) *Let* $u \in \mathcal{U}$ *be optimal for* COP_{ea}*. Then there exists* $N(\epsilon,\delta)$ *such that* $\forall n \ge N(\epsilon,\delta)$*,* $\pi_\delta(u)$ *is* $O(\epsilon+\delta)$*-optimal for* COP_n*.*

(iii) *Let* $u_n \in \mathcal{U}$ *be optimal for* COP_n *and let* $\gamma_n \in S(L)$ *be such that* $u_n = m(\gamma_n)$*. Assume that* γ_n *converges to some* γ*. Then* $m(\gamma)$ *is optimal for* COP_{ea}*.*

Proof of Theorems 2.3 *and* 3.4. We apply below Theorems B.1, B.4, and B.15, which present sensitivity results for general convex optimization problems, to obtain the convergence of the optimal values and the convergence and robustness of policies

LP_α to the optimal value of LP_{ea}, and consequently, by Theorems 3.2(ii), (iii), and 3.3(ii), (iii), the convergence for the original constrained optimal control problems. It remains to show that the required conditions in Theorems B.1, B.4, and B.15 hold.

It is well known that for any $u \in U_D$,

$$\lim_{\alpha\to 1} C_\alpha(\beta,u) = C_{ea}(\beta,u), \qquad \lim_{\alpha\to 1} D^k_\alpha(\beta,u) = D^k_{ea}(\beta,u),\ k=1,\dots,K. \tag{3.11}$$

Choose an arbitrary $u \in \mathcal{U}$, and let γ be such that $u = m(\gamma)$. Then, due to Theorems 3.2(i) and 3.3(i),

$$\begin{aligned} &|C_\alpha(\beta,u) - C_{ea}(\beta,u)| \\ &\le \left| \sum_{j=1}^{L} \gamma_j \left[C_\alpha(\beta,u^j) - C_{ea}(\beta,u^j) \right] \right| \\ &\le \max_{1\le j\le L} |C_\alpha(\beta,u^j) - C_{ea}(\beta,u^j)|, \end{aligned}$$

which does not depend on u.

With the same applied to the costs D^k, this implies that (3.11) holds for any $u \in \mathcal{U}$, and that the convergence is uniform over $\mathcal{U}$. Equivalently, for any $\gamma \in S(L)$,

$$\lim_{\alpha\to 1} \mathcal{C}_\alpha(\gamma) = \mathcal{C}_{ea}(\gamma), \qquad \lim_{\alpha\to 1} \mathcal{D}^k_\alpha(\gamma) = \mathcal{D}^k_{ea}(\gamma),\ k=1,\dots,K \tag{3.12}$$

uniformly in γ. This establishes conditions (A.2) and (A.3).

The set $S(L)$ is clearly convex. As the costs are linear in γ, conditions (A.4) and (A.5) hold. Since γ is bounded in a simplex, this implies condition (A.6).

It follows from condition (2.3) and from Theorem 3.3 that there exists some $\eta > 0$ and some $\gamma \in S(L)$ such that the policy $m(\gamma)$ satisfies

$$\mathcal{D}^k_{ea}(\gamma) = D^k_{ea}(\beta, m(\gamma)) \le V^k - \eta, \qquad k = 1,\dots,K.$$

This establishes condition (A.7). Finally, condition (A.8) trivially holds, as $V = V_n$ do not depend on n. □

4. Concluding remarks. We have presented sufficient conditions for the continuity of the optimal values of constrained optimization problems and established several results on convergence of optimal solutions. Using these general tools, we obtained a new result for the convergence of discounted MDPs to the expected average cost one, under a general multichain ergodic structure. This was done by showing that one could restrict without loss of optimality to some subclass of policies, and then that an equivalent LP can be used to compute the values and the optimal policies. Since our results in the first part of the paper hold for convex programs and not just for LPs, this suggests that they could be used for establishing convergence properties in control problems with more complex cost functions.

One can further use the continuity of the optimal values and solutions of constrained opimtization to obtain other important features in constrained control of Markov chains. One can obtain convergence of the values and optimal policies of finite horizon problems to infinite ones, and one can establish the convergence of problems with finite state spaces to those with infinite state spaces (see [1, 3]). Another interesting question is on the structure of optimal policies in CMDPs. Ross [38] has shown that CMDPs with finite state and action spaces have optimal stationary policies that require at most $K+1$ randomizations, where K is the number of

constraints. Borkar [15] has extended this to a countable state space. Our approach allows us to obtain the same result as Borkar using the fact that limits of policies that are optimal for truncated (finite state) problems (which can be chosen with no more than $K+1$ randomization, according to [38]) are optimal for the original countable state problem (see details in [1, 3]).

Appendix A. Solutions of convex optimization. Let X be a convex subset of a topological vector space $V_n = (V_n^1, \dots, V_n^K) \in \mathbb{R}^K$, $n = 1, 2, \dots, \infty$, $(V_\infty = V)$ and

$$C_n : X \to \mathbb{R}, \quad n = 1, \dots, \infty \quad (C_\infty = C),$$

$$D_n : X \to \mathbb{R}^K, \quad n = 1, \dots, \infty \quad (D_\infty = D),$$

$$\Delta_n = \{x \in X : D_n(x) \le V_n\}, \quad n = 1, 2, \dots, \infty \quad (\Delta_\infty = \Delta).$$

We define the values of the constrained problems:

$$R_n = \inf_{u \in \Delta_n} C_n(u); \qquad R = \inf_{u \in \Delta} C(u).$$

We want to answer the following questions.

(i) Does $R_n \to R$ when $n \to \infty$?

(ii) Convergence of policies: Let $\pi : X \to \Delta$, and fix some $\epsilon \ge 0$. Let ϵ_n be a sequence of positive real numbers such that $\overline{\lim}_{n\to\infty} \epsilon_n \le \epsilon$. Assume that u_n^* is an ϵ_n-optimal policy for the nth optimal cost function R_n. Is $\pi(u_n^*)$ "almost" optimal for the limit optimal cost function R, for n large enough?

(iii′) Robustness of the optimal policy: If u^* is ϵ-optimal for the limit optimal cost function, can we derive of it an "almost" optimal policy for the nth approximating optimal cost function for all n large enough?

(iv′) Let $\overline{u} \in X$ be some limit point of u_n^*, defined above. Is $\overline{u}$ ϵ-optimal for the limit optimal cost function?

We can give an answer to questions (i) and (iv′) using the notion of Γ-convergence [16]. In fact, let X be a topological space, $\mathcal{N}(u)$ the set of all open neighborhoods of $u \in X$, and F_n a sequence of functions from X to $\mathbb{R} \cup \infty$.

We define

$$\Gamma - \underline{\lim}_{n\to\infty} F_n(u) = \sup_{V \in \mathcal{N}(u)} \underline{\lim}_{n\to\infty} \inf_{y \in V} F_n(y),$$

$$\Gamma - \overline{\lim}_{n\to\infty} F_n(u) = \sup_{V \in \mathcal{N}(u)} \overline{\lim}_{n\to\infty} \inf_{y \in V} F_n(y).$$

We say that F_n Γ-converge to F if and only if

$$\Gamma - \overline{\lim}_{n\to\infty} F_n(u) \le F(u) \le \Gamma - \underline{\lim}_{n\to\infty} F_n(u). \tag{A.1}$$

It is known that if there exists F that verifies (A.1) we obtain properties about minima and minimizers of function F (see [16]). As these properties are related with questions (i) and (iv′) of our problem, we are going to rewrite them in the context of Γ-convergence and ask for some assumptions on the data problem in order to obtain (A.1) for an appropriate definition of F_n and F.

We assume there exists $M_1 > 0$ such that

$$\lim_{n\to\infty} D_n = D, \quad \text{uniformly in} \quad \bigcup_{k\geq M_1} \Delta_k \cup \Delta, \tag{A.2}$$

$$\lim_{n\to\infty} C_n = C, \quad \text{uniformly in} \quad \bigcup_{k\geq M_1} \Delta_k \cup \Delta, \tag{A.3}$$

$$D : X \to \mathbb{R}^K \quad \text{is a lower semicontinuous and convex function,} \tag{A.4}$$

$$C : X \to \mathbb{R} \quad \text{is a lower semicontinuous and convex function,} \tag{A.5}$$

$$\exists M > 0 \quad \text{such that} \quad -M \leq C(x) \quad \forall x \in X, \tag{A.6}$$

$$\exists v \in U, \exists \eta > 0 \quad \text{such that} \quad D^k(v) \leq V^k - \eta \ \forall k = 1, \ldots, K, \tag{A.7}$$

$$V_n \to V, \quad n \to \infty. \tag{A.8}$$

We shall denote by (**H**) the set of hypotheses (A.2)–(A.8).

For any vector $\mathcal{V} \in \mathbb{R}^K$ and any constant $v \in \mathbb{R}$, we shall understand below $\mathcal{V} + v$ to mean the vector in $\mathbb{R}^K$ obtained by adding the constant v to each of the components of $\mathcal{V}$. We shall say that $x \in X$ is ϵ-optimal for R_n if $x \in \Delta_n$ and $C_n(x) \leq R_n + \epsilon$.

Appendix B. Key theorems for approximations. In this section we shall prove the approximation theorems.

Let us define

$$F_n(u) = \begin{cases} C_n(u) & \text{if} \quad u \in \Delta_n, \\ \infty & \text{if} \quad u \notin \Delta_n \end{cases} \tag{B.1}$$

and

$$F(u) = \begin{cases} C(u) & \text{if} \quad u \in \Delta, \\ \infty & \text{if} \quad u \notin \Delta. \end{cases} \tag{B.2}$$

We first establish the Γ-converge of F_n.

THEOREM B.1. *If* (**H**) *holds, then* F_n Γ*-converge to* F *as* $n \to \infty$.

Proof. Let x be such that $D(x) < V$ (then $F(x) = C(x)$). Let ϵ be a positive real number. Because of the lower semicontinuity (l.s.c.) of C there exists $U \in \mathcal{N}(x)$ such that

$$C(x) - \epsilon < C(y) \qquad \forall y \in U. \tag{B.3}$$

Now, given $\delta > 0$, we can take $N_1 \geq M_1$ such that if $n \geq N_1$, then, from (A.3),

$$|C_n(y) - C(y)| < \delta \qquad \text{when} \quad y \in \bigcup_{k\geq M_1} \Delta_k \cup \Delta, \tag{B.4}$$

and finally, by (A.2) and (A.8), it is possible to choose $N \geq N_1$ such that $x \in \Delta_n$ for all $n \geq N$. Then we have

$$\inf_{y \in U} F_n(y) = \inf_{y \in U \cap \Delta_n} C_n(y) \qquad \text{when} \quad n \geq N. \tag{B.5}$$

Taking into account the relations

$$U \cap \Delta_n \subset \bigcup_{k \geq M_1} \Delta_k \cup \Delta,$$

$$U \cap \Delta_n \subset U,$$

we obtain, from (B.3) and (B.4) for all $n \geq N$,

$$C(x) - \epsilon - \delta \leq \inf_{y \in U \cap \Delta_n} C(y) - \delta \leq \inf_{y \in U \cap \Delta_n} C_n(y),$$

and from the arbitrariness of δ it follows that

$$C(x) - \epsilon \leq \liminf_{n \to \infty} \inf_{y \in U} F_n. \tag{B.6}$$

On the other hand, if $V \in \mathcal{N}(x)$ and $n \geq N$, then

$$\inf_{y \in V} F_n(y) \leq C_n(x),$$

and taking into account that $C_n(x)$ converge to $C(x)$, we obtain

$$\limsup_{n \to \infty} \inf_{y \in V} F_n(x) \leq C(x) \qquad \forall V \in \mathcal{N}(x). \tag{B.7}$$

Finally, from (B.6) and (B.7) and because ϵ is also arbitrarily chosen, we deduce

$$\sup_{V \in \mathcal{N}(x)} \liminf_{n \to \infty} \inf_{y \in V} F_n(y) = C(x),$$

$$\sup_{V \in \mathcal{N}(x)} \limsup_{n \to \infty} \inf_{y \in V} F_n(y) = C(x);$$

that is,

$$(\Gamma - \lim F_n)(x) = F(x).$$

Now, we consider the second case: let x be such that $D(x) > V$ (then $F(x) = \infty$). Because of the l.s.c. of D, given $\lambda > 0$, there exists $U \in \mathcal{N}(x)$ such that if ϵ is sufficiently small, then

$$V + \epsilon < D(x) - \lambda < D(y) \qquad \forall y \in U.$$

Let $N \geq M_1$ be such that (by hypotheses (A.8) and (A.2))

$$|V - V_n| < \frac{\epsilon}{2} \qquad \text{and} \qquad |D(y) - D_n(y)| < \frac{\epsilon}{2} \qquad \forall y \in \bigcup_{k \geq M_1} \Delta_k \cup \Delta$$

whenever $n \geq N$. Therefore, if $n \geq N$ and $y \in U \cap (\bigcup_{k \geq M_1} \Delta_k \cup \Delta)$, then $D_n(y) > V_n$ and then $F_n(y) = \infty$. On the other hand, if $y \in U \setminus (\bigcup_{k \geq M_1} \Delta_k \cup \Delta)$, we also have $F_n(y) = \infty$. Thus, for all $n \geq N$

$$F_n(y) = \infty \qquad \forall y \in U,$$

and from that it follows that

$$\liminf_{n \to \infty} \inf_{y \in U} F_n(y) = \limsup_{n \to \infty} \inf_{y \in U} F_n(y) = \infty;$$

that is,

$$(\Gamma - \lim F_n)(x) = F(x).$$

Now, we consider the last case. Let x be such that $D(x) = V$. We will use the following property: If $U \in \mathcal{N}(x)$ and $\delta > 0$, there exists $y \in U$ such that

$$D(y) < V \qquad \text{and} \qquad C(y) < C(x) + \delta. \tag{B.8}$$

In fact, because of (A.7) there exists $v \in \Delta$ such that $D(v) < V$. From the convexity of C and D it follows that the segment $[v, x]$ is contained in Δ, and we have

$$D((1-t)v + tx) \leq (1-t)D(v) + tD(x) < V,$$

$$C((1-t)v + tx) \leq (1-t)C(v) + tC(x)$$

for all $t \in [0, 1]$. Then we can choose t sufficiently close to 1 and $y = (1-t)v + tx$ such that $y \in U$ and $C(y) < C(x) + \delta$.

Now, let $V \in \mathcal{N}(x)$, and let $\delta > 0$. We can choose $y \in V$ such that (B.8) holds. Then, because of (A.2) and (A.8), there exists $k \in \mathbb{N}$ such that $y \in \Delta_n$ for all $n \geq k$. Then

$$\liminf_n \inf_{x \in V} F_n(x) \leq \liminf_n C_n(y) = C(y) \leq C(x) + \delta,$$

and from the arbitrariness of δ it follows that

$$\liminf_n \inf_{x \in V} F_n(x) \leq C(x). \tag{B.9}$$

Let ϵ be a positive real number. Let $U \in \mathcal{N}(x)$ be such that (because of the l.s.c. of C)

$$C(x) - \frac{\epsilon}{2} < C(y) \qquad \forall y \in U, \tag{B.10}$$

and let $x_0 \in U$ be such that (by the property proved above)

$$D(x_0) < V.$$

Then x_0 satisfies $C(x) - \epsilon < C(x_0)$. There exists (by assumptions (A.2) and (A.8)) $N_1 \geq M_1$ such that $D_n(x_0) < V_n$ for all $n \geq N_1$. Finally, taking into account (B.10) and (A.3), we can take $N \geq N_1$ such that if $n \geq N$, then

$$C(x) - \epsilon < C_n(y) \qquad \forall y \in U \cap \Big(\bigcup_{k \geq M_1} \Delta_k \cup \Delta \Big). \tag{B.11}$$

Then we have

$$C(x) - \epsilon \leq \liminf_{n\to\infty} \inf_{y\in U} F_n(y),$$

where the last inequality follows from (B.11) and the relation

$$x_0 \in U \cap \Delta_n \subset U \cap \Big(\bigcup_{k\geq M_1} \Delta_k \cup \Delta \Big) \qquad \forall n \geq N.$$

Now, because of the arbitrariness of ϵ, we have

$$\sup_{V\in\mathcal{N}(x)} \liminf_{n} \inf_{x\in V} F_n(x) \geq C(x). \tag{B.12}$$

From (B.9) it holds that for all $V \in \mathcal{N}(x)$ and (B.12) we have

$$(\Gamma\text{-}\liminf_n F_n)(x) = F(x). \qquad \square$$

The Γ-convergence of F_n to F is proved. With some additional hypotheses we can answer (i) (Theorem B.3) and (iv) (Theorem B.5). Theorem B.4 gives an answer to (iv) for $\epsilon = 0$.

DEFINITION B.2. *We say that the sequence (G_n) is equicoercive if for all $t \in \mathbb{R}$ there exists a closed countably compact subset K_t of X such that $\{G_n \leq t\} \subseteq K_t$ for every $n \in \mathbb{N}$.*

THEOREM B.3 (see Dal Maso [16]). *Suppose that (G_n) is equicoercive in X and that Γ-converge to a function G in X. Then*

$$\min_{x\in X} G(x) = \lim_{n\to\infty} \inf_{x\in X} G_n(x).$$

THEOREM B.4 (see Dal Maso [16]). *Assume that (F_h) Γ-converge to a function F in X. For every $h \in \mathbb{N}$, let x_h be a minimizer of F_h in X (or, more generally, an ϵ_h-minimizer, where (ϵ_h) is a sequence of real numbers converging to 0). If x is a cluster point of (x_h), then x is a minimizer of F in X, and*

$$F(x) = \limsup_{h\to\infty} F_h(x_h).$$

If (x_h) converges to x in X, then x is a minimizer of F in X, and

$$F(x) = \lim_{h\to\infty} F_h(x_h).$$

THEOREM B.5 (see Rockafellar–Wets [37]). *Let $X = \mathbb{R}^N$. Suppose that (f_n) Γ-converge to f with $-\infty < \inf f < \infty$. Then we have the following.*

1. *$\inf f_n \to \inf f$ if and only if there exist for every $\epsilon > 0$ a compact set $B \subset \mathbb{R}^N$ and $k \in \mathbb{N}$ such that*

$$\inf_B f_n \leq \inf f_n + \epsilon \qquad \forall n \geq k.$$

2. *For all $\epsilon \geq 0$,*

$$\limsup_n (\epsilon\text{-}\operatorname{argmin} f_n) \subset \epsilon\text{-}\operatorname{argmin} f,$$

and consequently,

$$\limsup_n (\epsilon_n\text{-}\operatorname{argmin} f_n) \subset \operatorname{argmin} f \quad \textit{whenever} \quad \epsilon_n \searrow 0.$$

3. *Under the assumption that* $\inf f_n \to \inf f$, *there exists a sequence* $\epsilon_n \searrow 0$ *such that* $\epsilon_n-\operatorname{argmin} f_n \to \operatorname{argmin} f$. *Conversely, if such a sequence exists, and if* $\operatorname{argmin} f \neq \emptyset$, *then* $\inf f_n \to \inf f$.

COROLLARY B.6. *Suppose* (f_n) *is an equicoercive sequence of real functions in* $\mathbb{R}^n$ *that* Γ*-converges to* f. *Let* $\epsilon > 0$ *and* $\delta > 0$, *and let* $x_n \in \epsilon-\operatorname{argmin} f_n$. *Then there exists* $N \in \mathbb{N}$ *such that*

$$B(x_n, \delta) \cap \epsilon-\operatorname{argmin} f \neq \emptyset$$

whenever $n \geq N$.

Proof. If it is not true, then there exists a subsequence (x_{n_k}) such that

$$B(x_{n_k}, \delta) \cap \epsilon-\operatorname{argmin} f = \emptyset. \tag{B.13}$$

Now, if $t = \epsilon + \sup(\inf_{x\in\mathbb{R}_n} f_n, n \in \mathbb{N})$ (it is finite), then there exists a compact set K_t such that $\{f_n \leq t\} \subseteq K_t$ for every $n \in \mathbb{N}$, and then the sequence (x_{n_k}) has a limit point x. By statement 2 of Theorem B.5, $x \in \epsilon-\operatorname{argmin} f$. But, if k is sufficiently large, then $x \in B(x_{n_k}, \delta)$, and this contradicts (B.13). □

We cannot answer (iii), as we cannot directly construct the function of the type of π from the Γ-convergence. But we can answer the following question:

(iii″) If x_0 is ϵ-optimal for R, is it possible to find an arbitrarily small neighborhood of x_0 and an ϵ-optimal policy $x(n)$ for R_n for n sufficiently large?

THEOREM B.7. *Suppose that the sequence* (F_n) Γ*-converges to a function* F *and*

$$\min_{x\in X} F(x) = \lim_n \inf_{x\in X} F_n(x). \tag{B.14}$$

If $x_0 \in \epsilon-\operatorname{argmin} F$, $U \in \mathcal{N}(x_0)$, *and* $\bar{\epsilon} > \epsilon$, *then there exists* $N \in \mathbb{N}$ *such that*

$$U \cap \bar{\epsilon}-\operatorname{argmin} F_n \neq \emptyset \qquad \textit{when} \quad n \geq N.$$

Proof. By definition,

$$F(x_0) = \sup_{V\in\mathcal{N}(x_0)} \liminf_n \inf_{y\in V} F_n(y) = \sup_{V\in\mathcal{N}(x_0)} \limsup_n \inf_{y\in V} F_n(y).$$

Then, if $U \in \mathcal{N}(x_0)$, we have

$$\limsup_n \inf_{y\in U} F_n(y) \leq F(x_0).$$

Thus, given $\lambda > 0$, there exists N_1 such that

$$\inf_{y\in U} F_n(y) \leq F(x_0) + \lambda \qquad \text{when} \quad n \geq N_1.$$

For each $n \geq N_1$ we can choose $y_n \in U$ such that

$$F_n(y_n) \leq F(x_0) + 2\lambda \qquad \text{when} \quad n \geq N_1. \tag{B.15}$$

On the other hand, it follows from (B.14) that there exists $N \geq N_1$ such that

$$F(x_0) - \epsilon - \lambda \leq \inf_{x\in X} F_n(x) \qquad \text{when} \quad n \geq N. \tag{B.16}$$

Finally, from (B.15) and (B.16), we obtain

$$0 \leq F_n(y_n) - \inf_{x\in X} F_n(x) \leq \epsilon + 3\lambda$$

for all $n \geq N$, and then, by choosing λ sufficiently small, we have

$$y_n \in U \cap \bar{\epsilon}\text{−argmin}F_n \qquad \forall n \geq N. \qquad \square$$

To answer questions (ii) and (iii), we present the following definitions and results.

DEFINITION B.8. *For each δ such that $0 < \delta < \eta$ (where η is defined in* (A.7)*) and for each $u \in X$ we set*

$$\epsilon_\delta(u) = \min\{\lambda \ : \ \lambda \in [0,1], \text{and } \lambda D(v) + (1-\lambda)D(u) \leq V - \delta\},$$

and

$$\pi_\delta(u) = \epsilon_\delta(u)v + (1 - \epsilon_\delta(u))u. \tag{B.17}$$

Remark B.9. $\pi_\delta(u) \in \Delta$, because of the convexity of X we have $\pi_\delta(u) \in X$, and by the definition of $\epsilon_\delta(u)$ and the fact that D is a convex function (A.4), we have

$$D(\pi_\delta(u)) \leq V - \delta. \tag{B.18}$$

Remark B.10. Let δ be such that $0 < \delta < \eta$. If (A.2), (A.4), (A.7), and (A.8) hold, there exists $\overline{N}(\delta)$ such that $\pi_\delta(u) \in \Delta_n$ if $n \geq \overline{N}(\delta)$ $\forall u \in X$. In fact, by (A.2) there exists $N(\delta)$ such that if $n \geq N(\delta)$, $D_n(\pi_\delta(u)) \leq D(\pi_\delta(u)) + \delta/2 \ \ \forall u \in X$, and by (B.18)

$$D_n(\pi_\delta(u)) \leq D(\pi_\delta(u)) + \frac{\delta}{2} \leq V - \delta + \frac{\delta}{2} \leq V - \frac{\delta}{2}.$$

Then, by (A.8) we have that there exists $\hat{N}$ such that $V - \delta/2 \leq V_n$ if $n \geq \hat{N}$, so, we have $D_n(\pi_\delta(u)) \leq V_n$ for all $n \geq \overline{N}(\delta) = \max(N(\delta), \hat{N})$.

LEMMA B.11. *Let δ be such that $0 < \delta < \eta$. If* (A.2)*,* (A.7)*, and* (A.8) *hold, then*

$$\limsup_{n\to\infty} \left\{ \sup_{u\in\Delta_n} \epsilon_\delta(u) \right\} \leq \frac{\delta}{\eta}.$$

Proof. By definition of Δ_n we have that $\forall u \in \Delta_n$, $D_n(u) \leq V_n$. By (A.2) and (A.8) we have

$$\forall \hat{\epsilon} > 0 \quad \exists N(\hat{\epsilon}) \text{ such that } \quad \forall n \geq N(\hat{\epsilon}), \forall u \in \Delta_n, \quad D(u) \leq V + 2\hat{\epsilon}. \tag{B.19}$$

By (A.7) and (B.19) we have $\forall \hat{\epsilon} > 0$, $u \in \Delta_n$, $\lambda \in [0,1]$,

$$\lambda D(v) + (1-\lambda)D(u) \leq \lambda(V - \eta) + (1-\lambda)(V + 2\hat{\epsilon}). \tag{B.20}$$

But

$$\lambda(V-\eta) + (1-\lambda)(V+2\hat{\epsilon}) \leq V - \delta \iff \lambda \geq \frac{2\hat{\epsilon} + \delta}{2\hat{\epsilon} + \eta} \quad \forall \hat{\epsilon} > 0. \tag{B.21}$$

By (B.20) and (B.21) we obtain

$$\left[\frac{2\hat{\epsilon} + \delta}{2\hat{\epsilon} + \eta}, 1\right] \subseteq \{\lambda \in [0,1] : \lambda D(v) + (1-\lambda)D(u) \leq V - \delta\} \quad \forall \hat{\epsilon} > 0 \ \ \forall u \in \Delta_n,$$

and then, by definition of $\epsilon_\delta(u)$, we have

$$\epsilon_\delta(u) \le \frac{2\hat{\epsilon}+\delta}{2\hat{\epsilon}+\eta} \qquad \forall u \in \Delta_n, \quad n \ge N(\hat{\epsilon}) \quad \forall \hat{\epsilon} > 0.$$

From this last inequality we deduce

$$\sup_{u\in\Delta_n} \epsilon_\delta(u) \le \frac{2\hat{\epsilon}+\delta}{2\hat{\epsilon}+\eta} \qquad n \ge N(\hat{\epsilon}) \qquad \forall \hat{\epsilon} > 0,$$

and this last inequality implies

$$\limsup_{n\to\infty} \left[\sup_{u\in\Delta_n} \epsilon_\delta(u) \right] \le \frac{\delta}{\eta}. \qquad \square$$

Remark B.12. Let δ be such that $\eta > \delta > 0$. In the same way of Lemma B.11, and if (A.7) holds, we can prove that

$$\sup_{u\in\Delta} \epsilon_\delta(u) \le \frac{\delta}{\eta}.$$

For the proof it is only necessary to remark that (B.20) and (B.21) become

$$\lambda D(v) + (1-\lambda)D(u) \le \lambda(V-\eta) + (1-\lambda)V,$$

$$\lambda(V-\eta) + (1-\lambda)V \le V - \delta \Longleftrightarrow \lambda \ge \frac{\delta}{\eta}.$$

LEMMA B.13. *Let δ be such that $\eta > \delta > 0$. If* (A.2), (A.5), (A.6), (A.7), *and* (A.8) *hold, then*

$$\limsup_{n\to\infty} \left[\sup_{u\in\Delta_n} \{C(\pi_\delta(u)) - C(u)\} \right] \le (C(v)+M)\frac{\delta}{\eta}.$$

Proof. $\forall u \in \Delta_n$ by (A.5) and (B.17) we obtain

$$C(\pi_\delta(u)) - C(u) \le \epsilon_\delta(u)C(v) + (1-\epsilon_\delta(u))C(u) - C(u) = \epsilon_\delta(u)[C(v) - C(u)].$$

Then by this last equation, (A.6), and Lemma B.11 we have

$$\limsup_{n\to\infty} \sup_{u\in\Delta_n} \epsilon_\delta(u)[C(v)-C(u)] \le (C(v)+M) \limsup_{n\to\infty} \sup_{u\in\Delta_n} \epsilon_\delta(u) \le (C(v)+M)\frac{\delta}{\eta}. \qquad \square$$

Remark B.14. Let δ be such that $0 < \delta < \eta$. By Remark B.12 and if (A.5) and (A.7) hold, we can obtain

$$\sup_{u\in\Delta} \{C(\pi_\delta(u)) - C(u)\} \le (C(v)+M)\frac{\delta}{\eta}.$$

THEOREM B.15. *Suppose that* (**H**) *holds and let F_n and F defined by* (B.1) *and* (B.2), *respectively. We also suppose*

$$\lim_n \inf_{x\in X} F_n(x) = \inf_{x\in X} F(x).$$

Then,

1. *If* $u \in \epsilon-\text{argmin}F$ *and* $\lambda > 0$*, there exist* $N \in \mathbb{N}$ *and* $\delta > 0$ *such that if* $n \geq N$*, then*

$$\pi_\delta(u) \in (\epsilon+\lambda)-\text{argmin}F_n. \tag{B.22}$$

2. *Let* $u_n \in \epsilon-\text{argmin}F_n$ *and* $\lambda > 0$*. There exist* $N \in \mathbb{N}$ *and* $\delta_0 > 0$ *such that if* $n \geq N$ *and* $\delta < \delta_0$*, then*

$$\pi_\delta(u_n) \in (\epsilon+\lambda)-\text{argmin}F. \tag{B.23}$$

Proof.

1. We have

$$C_n(\pi_\delta(u)) - C(u) = [C_n(\pi_\delta(u)) - C(\pi\delta(u))] + [C(\pi_\delta(u)) - C(u)].$$

From the convergence of (C_n) to C, Remark B.14, and taking into account that for each $\delta > 0$ if n is sufficiently large then $\pi_\delta(u) \in \Delta$, it follows that if $\lambda > 0$ is given, we can choose $N_1 \in \mathbb{N}$ and $\delta > 0$ sufficiently small, such that if $n > N$, then each term in the right side of the last equation is less than $\frac{\lambda}{3}$, and the equation becomes

$$C_n(\pi_\delta(u)) - C(u) < \frac{2}{3}\lambda.$$

Then, keeping in mind the ϵ-optimality of u, we have

$$C_n(\pi_\delta(u)) < C(u) + \frac{2}{3}\lambda < \inf_{x\in X} F(x) + \epsilon + \frac{2}{3}\lambda < \inf_{x\in X} F_n(x) + \epsilon + \lambda$$

if $n \geq N$ for some $N \geq N_1$, and that is (B.22).

2. We have

$$C(\pi_\delta(u_n)) - C_n(u_n) = [C(\pi_\delta(u_n)) - C(u_n)] + [C(u_n) - C_n(u_n)].$$

From Lemma B.13 and the convergence of (C_n) to C, if $\lambda > 0$ is given, we can choose $N_1 \in \mathbb{N}$ and $\delta > 0$ sufficiently small, such that if $n > N_1$, then each term in the right side of the last equation is less than $\frac{\lambda}{3}$, and the equation becomes

$$C(\pi_\delta(u_n)) - C_n(u_n) < \frac{2}{3}\lambda.$$

Then, keeping in mind the ϵ-optimality of u_n, we have

$$C(\pi_\delta(u_n)) < C_n(u_n) + \frac{2}{3}\lambda < \inf_{x\in X} F_n(x) + \epsilon + \frac{2}{3}\lambda < \inf_{x\in X} F(x) + \epsilon + \lambda$$

if $n \geq N$ for some $N \geq N_1$, and that is (B.23). ∎

PROPOSITION B.16. *Suppose* **(H)** *holds. We set* $K_{\epsilon,n} = \epsilon-\text{argmin}F_n$*,* $K_\epsilon = \epsilon-\text{argmin}F$*,* $R_n = \inf_{x\in X} C_n(x)$*, and* $R = \inf_{x\in X} C(x)$*. Then*

$$K_{\epsilon,n} \cap K_\epsilon \neq \emptyset.$$

Proof. Let $x \in K_{\frac{\epsilon}{4}} \subset K_\epsilon$; then $D(x) \le V$. We will consider the case $D(x) = V$. The case $D(x) < V$ is similar and simpler. Let $w \in \Delta$ be such that $D(w) < V$. Then the segment $[w, x]$ is contained in Δ. Besides,

$$C((1-t)w + tx) \le (1-t)C(w) + tC(x) < C(x) + \frac{\epsilon}{4}$$

if $t \in [T, 1]$, for some T with $0 < T < 1$. We take a such t, and we put $x_0 = (1-t)w + tx$. Then $x_0 \in K_{\frac{\epsilon}{2}} \subset K_\epsilon$, and $D(x_0) < V$, from which it easily follows that $x_0 \in \Delta_n$ if $n \ge N_1$ for some $N_1 \in \mathbb{N}$. We can take $N \ge N_1$ such that for every $n \ge N$

$$|C_n(x_0) - C(x_0)| < \frac{\epsilon}{4} \qquad \text{and} \qquad |R_n - R| < \frac{\epsilon}{4}.$$

Therefore, if $n \ge N$, we have

$$C_n(x_0) < C(x_0) + \frac{\epsilon}{4} < R + \frac{3}{4}\epsilon < R_n + \epsilon,$$

that is $x_0 \in K_{\epsilon,n}$, and then

$$K_\epsilon \cap K_{\epsilon,n} \neq \emptyset \qquad \forall n \ge N. \qquad \square$$

ADAPTIVE IMAGE RECONSTRUCTION USING INFORMATION MEASURES*

ULRIKE HERMANN† AND DOMINIKUS NOLL‡

Abstract. We present a class of nonlinear adaptive image restoration filters which may be steered to preserve sharp edges and contrasts in the restorations. From a theoretical point of view we discuss the associated variational problems and prove existence of solutions in certain Sobolev spaces $W^{1,p}$ or in a BV-space. The degree of regularity of the solution may be understood as a mathematical explanation of the heuristic properties of the designed filters.

Key words. adaptive image restoration filter, image restoration, variational methods

1. Motivation and purpose. Various inverse problems require reconstructing an unknown density function $u(x)$, $x \in \Omega \subset \mathbf{R}^n$, from a finite number of measurements of the form

$$\int_\Omega \big(a_k(x)u(x) + b_k(x) \cdot \nabla u(x)\big)\, dx \;=\; c_k, \qquad k = 1, \dots, N. \tag{1.1}$$

Examples of particular interest are in medical imaging, where the data c_k represent attenuation coefficients of transmission x-rays, or in image restoration, where the c_k are gray levels at pixels k of a blurred version of the true image $u(x)$. Restoring the original $u(x)$ is usually an ill-posed problem, and the inevitable measurement noise may make this a difficult task. One way to restore $u(x)$ in the presence of noise is to stabilize inversion of (1.1) by introducing a regularizing functional of the form

$$I[u] \;=\; \int_\Omega h\big(u(x), \nabla u(x)\big)\, dx, \tag{1.2}$$

closely related to the specific restoration problem. Introducing linear operators A, B by

$$(Au)_k = \int_\Omega a_k(x)u(x)\, dx, \qquad (Bv)_k = \int_\Omega b_k(x) \cdot v(x)\, dx, \tag{1.3}$$

we consider the following inverse methods which we call the *tolerance* and the *penalization approaches,* respectively:

$$(P)_{\mathrm{tol}} \qquad \begin{array}{ll} \text{minimize} & I[u] \\ \text{subject to} & \big|Au + B\nabla u - c\big| \le \varepsilon, \\ & \displaystyle\int_\Omega u(x)\, dx = 1 \end{array}$$

and

$$(P)_{\text{pen}} \qquad \begin{array}{ll} \text{minimize} & I[u] + \frac{\alpha}{2}|Au + B\nabla u - c|^2 \\ \text{subject to} & \displaystyle\int_\Omega u(x)\,dx = 1 \end{array}$$

($|\cdot|$ = Euclidean norm). A well-known method based on the scheme $(P)_{\text{pen}}$ is *Tychonov-regularization*, where the functional (1.2) is a square norm of $u(x)$ or $\nabla u(x)$ (cf. [16, 12, 13]). However, in image restoration this choice is known to produce poor results, and more sophisticated functionals $I[u]$ are required. In our present work, we shall consider a class of functionals $I[u]$ of information type that are particularly suited for image restoration problems and that we motivate by a heuristic argument. The remaining parts of the paper address the mathematical problems arising from this choice.

The values $u(x)$ are relative gray levels of the unknown image, hence the normalization $\int u\,dx = 1$. Since gray levels are nonnegative, we require reconstructions $u(x) \geq 0$, and this may be guaranteed by our choice of $I[u]$. For the moment consider the model $(P)_{\text{tol}}$. The data being noisy, we should not force equality $Au + B\nabla u = c$, but allow for a tolerance $\varepsilon > 0$, typically estimated using a χ^2-statistics (cf. [18]). The role of the functional $I[u]$ is now to avoid picking highly irregular objects u which would fit the tolerance condition. In other terms, minimizing $I[u]$ subject to the constraint $|Au + B\nabla u - c| \leq \varepsilon$ to some degree means filtering the unknown object $u(x)$. However, as mentioned before, default choices like $I[u] = \int_\Omega |\nabla u|^2\,dx$ tend to smooth away sharp edges in the image. Smoothing while retaining edges is needed, and this requires adapting the filter to the image.

Consider the class of functionals (1.2) defined through the integrands

$$h(u,\xi) = \begin{cases} u\phi\big(\xi/u\big) & \text{if } u > 0, \\ \phi^{0+}(\xi) & \text{if } u = 0, \\ +\infty & \text{otherwise,} \end{cases} \tag{1.4}$$

where $\phi : \mathbf{R}^n \to \mathbf{R}$ is a convex functional and ϕ^{0+} denotes its recession function, needed to render the functional h lower semicontinuous (lsc),

$$\phi^{0+}(\xi) = \sup_{t>0} \frac{\phi(\eta + t\xi) - \phi(\eta)}{t},$$

for an arbitrary fixed η in $\text{dom}\phi$ (cf. [21, p. 66ff]). Then h is jointly convex in (u,ξ), and (1.4) will be called *Csiszár information measures*. An important special case is $\phi(t) = |t|^2$, which is Fisher's information (cf. [19]). Notice that since $h(u,\xi) = +\infty$ for $u < 0$, the objectives (1.4) force nonnegative solutions, as required.

In order to motivate the inverse approach based on (1.4), let us specialize even further by considering functionals of the form $\phi(\xi) = \psi(|\xi|)$ for convex $\psi : \mathbb{R} \to \mathbb{R}$. Since $|\nabla u|$ is invariant under rigid motions, so is $h(u, \nabla u)$ defined through (1.4); hence, this choice will lead to methods invariant under rigid motions of the image. Proceeding in a purely formal way, we first do a change of variables $u(x) = e^{v(x)}$ to account for the condition $u(x) > 0$. The Euler–Lagrange equation for the transformed problem $(P)_{\text{pen}}$ is then

$$\begin{aligned} -\operatorname{div}\left(\frac{\psi'\big(|\nabla v|\big)}{|\nabla v|}\nabla v\right) - \psi'\big(|\nabla v|\big)|\nabla v| + \psi(|\nabla v|) \\ + \alpha(A^T - \operatorname{div}B^T)(Ae^v + B(\nabla e^v) - c) \;=\; 0 \end{aligned} \tag{1.5}$$

with adjoints A^T, B^T, and div B^T defined as

$$A^T(\lambda) = \sum_{k=1}^{N} \lambda_k a_k, \qquad B^T(\lambda) = \sum_{k=1}^{N} \lambda_k b_k, \qquad \mathrm{div}B^T(\lambda) = \sum_{k=1}^{N} \lambda_k \mathrm{div} b_k.$$

Consider the case $\Omega \subset \mathbb{R}^2$. Following an idea originating from [8] and extended in [2, 26], sharp edges (contrasts) in the image $v(x, y)$ occur along level curves $v(x, y) = c$, the indication being that the gradient $\nabla v(x, y)$ becomes large. In this case, smoothing across the edge $v(x, y) = c$ should be dispensed with, while smoothing along the edge is still needed to suppress irregular behavior.

For a point (x, y) on the level curve $v = c$, consider the adapted cartesian coordinates $T(x, y), N(x, y)$ meaning tangential and normal directions to the level curve $v = c$ at (x, y):

$$N(x, y) = \frac{\nabla v(x, y)}{|\nabla v(x, y)|}, \qquad T(x, y) \perp N(x, y).$$

Expanding the divergence term in (1.5) gives

$$-\mathrm{div}\left(\frac{\psi'\big(|\nabla v|\big)}{|\nabla v|}\,\nabla v\right) = -\frac{\psi'(|\nabla v|)}{|\nabla v|}\,\Delta v - \left(\frac{\psi''(|\nabla v|)}{|\nabla v|^2} - \frac{\psi'(|\nabla v|)}{|\nabla v|^3}\right)\nabla v \cdot \nabla^2 v \cdot \nabla v.$$

Observe that the Laplacian is invariant under orthogonal transformations, $\Delta v = v_{xx} + v_{yy} = v_{TT} + v_{NN}$, and secondly that $\frac{\nabla v}{|\nabla v|} \cdot \nabla^2 v \cdot \frac{\nabla v}{|\nabla v|} = v_{NN}$. Then the Euler equation in (T, N)-coordinates reads

$$-\left(\frac{\psi'(|\nabla v|)}{|\nabla v|}\right) v_{TT} - \psi''(|\nabla v|)\, v_{NN} - \psi'(|\nabla v|)|\nabla v| + \psi(|\nabla v|) + \alpha(A^T - \mathrm{div}B^T)(Ae^v + B(\nabla e^v) - c) = 0.$$

Suppose $|\nabla v|$ is small, indicating that $v = c$ is not an edge, and hence smoothing should be encouraged. Assuming (i) $\psi'(0) = 0$ and (ii) $\psi''(0) > 0$, in a neighborhood of (x, y), the Euler equation is qualitatively of the form

$$-\psi''(0)\big(v_{TT} + v_{NN}\big) + \psi(0) + \alpha(A^T - \mathrm{div}B^T)(Ae^v + B(\nabla e^v) - c) = 0.$$

Due to $v_{TT} + v_{NN} = v_{xx} + v_{yy} = \Delta v$, this may be considered as having a strong smoothing effect around (x, y).

Assume, on the other hand, that $|\nabla v|$ is large at (x, y), indicating an edge. Then we wish to smooth in T-direction but not in N-direction. This is achieved, for instance, by having

$$\text{(iii)} \qquad \frac{\psi'(t)}{t} \gg \psi''(t)$$

for large t. The coefficient of v_{NN} then being negligible in a neighborhood of (x, y), the differential equation is qualitatively of the form

$$-C\, v_{TT} - \psi'(|\nabla v|)|\nabla v| + \psi(|\nabla v|) + \alpha(A^T - \mathrm{div}B^T)(Ae^v + B(\nabla e^v) - c) = 0,$$

indicating a preference for smoothing in T-direction, since as before the tendency to smoothing is governed by the second order terms. As an example for (iii), consider a

ψ which for large t behaves like $\psi(t) = t^p$ for some $p > 1$. This gives $\frac{\psi'(t)}{t}/\psi''(t) = 1/(p-1)$, which could be made as large as desired by choosing p close to 1.

The conditions (i)–(iii) do not entirely fix the function ψ, so further evidence (theoretical and numerical) is needed to propose a best choice. The present paper, rather, addresses the theoretical aspects of the models $(P)_{\text{tol}}$ and $(P)_{\text{pen}}$, particularly the question of existence of solutions. Our method of proving existence may be considered a fairly general scheme including a large variety of possible applications. It does not rely on compactness arguments but exploits the convexity of the problems.

A second problem associated with the variational methods $(P)_{\text{pen}}$ and $(P)_{\text{tol}}$ is to justify the Euler–Lagrange equation (1.5), formally derived above. This problem, which is difficult, is treated in [10].

It is intuitively clear that the choices $\psi(t) = |t|^p$ discussed above should lead to image restorations exhibiting more and more sharp edges when $p > 1$ approaches 1. One way to corroborate this in the variational context is by showing that the solutions of the corresponding programs $(P)_{\text{pen}}$ and $(P)_{\text{tol}}$ are in a Sobolev space $W^{1,1+\varepsilon(p)}$, with $\varepsilon(p) \to 0$ as $p \to 1$ (cf. Example 3 at the end of section 6). In the limiting case $p = 1$, we would get solutions which degrade to BV-functions, allowing even for discontinuities. We mention that the latter is sometimes considered as a natural setting for image processing, particularly if the purpose is segmentation or edge detection (cf. [17, 5, 24, 27]).

Numerical experiments for special choices $\psi(t)$ have been presented in [19, 20]. The authors of [2, 26] report experiments with objectives of the form $h(u, \xi) = \phi(|\xi|)$ built on a related philosophy. A comparative study of adaptive filters will be presented elsewhere. We mention that the class of functionals (1.4) has various other applications. See in particular [18] for variational problems involving Fisher's information $(p = 2)$.

2. Outline of the method. We start by giving an outline of our method of proving existence of solutions and then point to the steps which cause particular difficulties. Our approach may be called a *bidual relaxation* scheme: Writing (P) for any of the formulations $(P)_{\text{pen}}$ or $(P)_{\text{tol}}$ and proceeding in a formal way, we first obtain a concave dual program (P^*). Formal means that we do not try to find a dual pair of Banach spaces in which the duality may be justified rigorously. In a second step we repeat the same for (P^*), but this time we use the full convexity machinery. This means we prove a Lagrange multiplier theorem for (P^*). The multiplier $\bar{u}$ is an element of the dual Banach space $M(\bar{\Omega})$ of signed Radon measures and an optimal solution to a properly defined convex bidual (P^{**}). We may therefore interpret $\bar{u}$ as a generalized solution to the original program (P). In a third step we show that under mild additional conditions, we get a solution $\bar{u}$ in a Sobolev space or even in a classical space $C^1(\bar{\Omega})$.

Notice that this scheme has been used various times. However, the difficulties are in the details; in particular, technical problems arise if we are not satisfied with solutions in a BV-space, but wish to prove regularity results (cf. section 4). For complementary literature we refer to [7, 3, 4, 2].

Let us now consider some of the details. First, dualizing (P^*) requires a Lagrange multiplier theorem. This type of result typically needs a constraint qualification hypothesis, which should not be artificial in the light of the original problem (P). The existence result Proposition 4.1 in fact avoids any such hypothesis by providing a solution $u \in M(\bar{\Omega})$, the space of Radon measures.

The second step in our scheme is to show that the generalized solution $u \in M(\bar{\Omega})$

is a BV-function. This is done in Proposition 4.3 and requires a richness hypothesis $(A1)$. Condition $(A1)$ excludes objectives (1.2) where $h(x,\xi)$ is linear in ξ. With $h(x,\xi) = g(x) + \eta \cdot \xi$ linear in ξ, it is possible to construct examples where the generalized solution $\bar{u}$ is not a BV-function, although this may be guaranteed under coercivity assumptions on $g(x)$. We consider objectives (1.2) linear in ξ as of minor importance for possible applications and therefore do not pursue their analysis here.

In a third step of Proposition 4.6, we show that the solution $\bar{u}$, so far a BV-function, is an element of the Sobolev space $W^{1,1}(\Omega)$ if a slightly stronger regularity hypothesis $(A2)$ is satisfied. Hypothesis $(A2)$ may be understood as a weak coercivity condition on h, implying in particular that for fixed x, $h(x,\xi)$ grows stronger than linearly in ξ as $|\xi| \to \infty$.

In practice, it is often enough to have solutions in $W^{1,1}(\Omega)$, in particular, if the natural domain of the functional I_h is a better Sobolev space $W^{1,p}(\Omega)$ for some $p > 1$. Here the solution will automatically be an element of $W^{1,p}(\Omega)$. In section 6 we present an extended version of this observation, showing that under a stronger hypothesis $(A3)$, the solution $\bar{u}$ is improved to be of class $W^{1,p}(\Omega)$ for some $p > 1$, with the possibility to having classical solutions if p is large enough. Hypothesis $(A3)$ is seen to be a coercivity condition on h, satisfied, e.g., if h^* grows at most polynomially (see section 6).

We mention that bidual relaxation as presented here is not aimed at image restoration exclusively. In fact, the hypotheses $(A1)$–$(A3)$ are fairly general and ensure a broad applicability. Nonetheless, in image enhancement, $(A2)$ and $(A3)$ might be considered too strong, in particular under the agreement that images be best represented as BV-functions. This point of view, initiated by Osher and Rudin [23, 24, 25], is widely accepted if the aim is edge detection or segmentation (cf. [13, 15, 6]), although it is clear that many images continue to be modeled as continuous or even smooth functions. This is particularly so in cases where the physical image generating process is taken into account (astronomy, medical imaging). We hold that our approach of modeling images in Sobolev spaces may offer a compromise.

3. Lagrangian formulation for $(P)_{\mathrm{pen}}$. In this section we present the first part of the scheme for program $(P)_{\mathrm{pen}}$. We provide a suitable Lagrangian formulation and a corresponding concave dual program (P^*). The second step of the relaxation scheme, dualizing the dual to obtain the bidual, will be presented in section 4.

For the following, let us fix some notations and definitions. Let Ω be a bounded open subset of $\mathbb{R}^N$, and suppose $a_k \in C(\overline{\Omega})$, $b_k \in C^1(\overline{\Omega})^n$ for $k = 1, \dots, N$. (It would be sufficient to require piecewise continuity of a_k and piecewise continuous differentiability of b_k.) Then the linear operators A and B defined by (1.3) are bounded on $L_1(\Omega)$ and $L_1(\Omega)^n$, respectively.

Let $h : \mathbb{R} \times \mathbb{R}^n \to \mathbb{R} \cup \{\infty\}$ be a proper convex lsc function with nonempty domain $\operatorname{dom} h$ (cf. [21]). Then

$$I_h[u] = \int_\Omega h(u(x), \nabla u(x))\, dx$$

is a proper convex lsc functional defined for all $u \in W^{1,1}(\Omega)$. Notice that we do not exclude the possibility $I_h[u] = +\infty$, as would, for instance, occur for a classical functional like $\int_\Omega |\nabla u|^2\, dx$, whose natural domain is $W^{1,2}(\Omega)$. A value $I_h[u] = +\infty$ simply means that u does not contribute to the minimization process. On the other hand, $I_h[u] = -\infty$ is impossible as a consequence of the lower semicontinuity of I_h (cf. [22] for this and other facts about convex integral functionals).

In cases when we wish to force positivity of the solution, we require $h(u,\xi) = +\infty$ whenever $u < 0$. Then $I_h[u] = +\infty$ unless $u \geq 0$ almost everywhere (a.e.) on Ω.

To avoid trivial situations, we will generally assume that $(P)_{\text{pen}}$ and $(P)_{\text{tol}}$ are feasible. More precisely, we assume existence of a function $u \in C^1(\overline{\Omega})$ with $I_h[u] < \infty$, $\int_\Omega u(x)\,dx = 1$, respectively, $|Au + B\nabla u - c| \leq \varepsilon$ in the case of the tolerance model. The value of program (P) will be denoted by $V(P)$, and we will require $V(P) > -\infty$ because otherwise no optimal solution exists. So altogether we adopt $-\infty < V(P) < \infty$ as our standing hypothesis. In the present section we consider $(P)_{\text{pen}}$. Analogous results for $(P)_{\text{tol}}$ will be presented in section 5.

We proceed to give a Lagrangian formulation of $(P)_{\text{pen}}$. By introducing dummy variables $v = \nabla u$ and $e = Au + Bv - c$ and by defining

$$J_h(u,v) := \int_\Omega h(u(x), v(x))\,dx$$

we rewrite $(P)_{\text{pen}}$ in the form

$$(P)_{\text{pen}} \qquad \begin{aligned} &\text{minimize} && J_h(u,v) + \frac{\alpha}{2}|e|^2 \\ &\text{subject to} && \nabla u = v,\ Au + Bv - c = e, \\ & && \int_\Omega u(x)\,dx = 1 \end{aligned}$$

with $e \in \mathbb{R}^N$ and $u \in C^1(\overline{\Omega}), v \in C(\overline{\Omega})^n$. This suggests using the Lagrangian

$$\begin{aligned} L(u,v,e;w,\lambda,\mu) = J_h(u,v) + \frac{\alpha}{2}|e|^2 + \langle w, \nabla u - v\rangle \\ + \lambda\cdot(Au + Bv - c - e) + \mu\bigg(\int_\Omega u(x)\,dx - 1\bigg), \end{aligned}$$

where $\langle .,. \rangle$ denotes the dual form either between $C(\bar{\Omega})^n$ and $M(\bar{\Omega})^n$ or between $L_1(\Omega)^n$ and $L_\infty(\Omega)^n$. We can now write $(P)_{\text{pen}}$ in the equivalent form

$$\inf_{u,v,e} \sup_{w,\lambda,\mu} L(u,v,e;w,\lambda,\mu). \tag{3.1}$$

As usual, the corresponding concave dual program is then defined by switching the inf and sup:

$$\sup_{w,\lambda,\mu} \inf_{u,v,e} L(u,v,e;w,\lambda,\mu). \tag{3.2}$$

We do not attempt to prove directly that (P) and (P^*) are equivalent or at least have equal values, since this will follow later as a consequence of the bidual relaxation scheme. Instead, we investigate (3.2) a little further by explicitly calculating the inner infimum.

To do this, we start by calculating the partial Legendre–Fenchel transform of L in its first three variables, defined as

$$L^*(y,z,d;w,\lambda,\mu) = \sup_{u,v,e} \big(\langle u,y\rangle + \langle v,z\rangle + e\cdot d - L(u,v,e;w,\lambda,\mu)\big),$$

and then recognize $-L^*(0,0,0;w,\lambda,\mu)$ as the objective of the dual (3.2), to be maximized over (w,λ,μ). While [21] is the basic reference for notions from finite dimensional convexity, a rigorous justification of (P^*) as obtained below would call for

methods as used in section 4 or in [7]. In particular, it would require calculating the conjugate L^* with respect to the space $C(\bar{\Omega})$ and its dual $M(\bar{\Omega})$, the space of signed Radon measures on $\bar{\Omega}$. Instead of calculating $(J_h)^*$, defined on a space of measures, we restrict the dual to the classical spaces $C(\bar{\Omega})$ and $C^1(\bar{\Omega})^n$, where it suffices to calculate J_{h^*} with the approach described as formal in section 2.

Written as a convex program, the dual is of the following form:

$$(P^*) \qquad \begin{aligned} \text{minimize} \quad & J_{h^*}(y,z) + \frac{1}{2\alpha}|\lambda|^2 + \lambda \cdot c + \mu \\ \text{subject to} \quad & y = \operatorname{div} z + \operatorname{div} B^T\lambda - A^T\lambda - \mu, \\ & y \in C(\overline{\Omega}), z \in C^1(\overline{\Omega})^n, \lambda \in \mathbb{R}^N, \mu \in \mathbb{R}. \end{aligned}$$

Here h^* is the Legendre–Fenchel conjugate of h and $J_{h^*}(y,z) := \int_\Omega h^*(y(x), z(x))\,dx$.

Example 1. For the class of Csiszár information measures (1.4) we have

$$h^*(y,z) = \begin{cases} 0, & y + \phi^*(z) \le 0, \\ \infty, & y + \phi^*(z) > 0. \end{cases}$$

As is easy to see, (P^*) has feasible points, so the value $V(P^*) < +\infty$. Also, the fact that the dual was obtained by flipping sup and inf gives $V(P^*) \ge -V(P) > -\infty$, so $V(P^*)$ is finite. The relation $V(P^*) \ge -V(P)$ is often referred to as weak duality (cf. [7]).

4. Existence of solutions for $(P)_{\text{pen}}$. The second part of our scheme now requires dualizing (P^*) again to obtain what we call a bidual relaxation (P^{**}) of the original program $(P)_{\text{pen}}$. As opposed to the formal way we employed to derive (P^*), we shall now have to rigorously dualize (P^*). As a consequence, the bidual (P^{**}) will be formulated in a dual Banach space, a space of measures. In a third step, also presented in the section, we will show that under reasonable conditions, the generalized solutions are functions in the Sobolev space $W^{1,1}(\Omega)$. A fourth step, to be presented in section 6, will examine under what circumstances a classical solution in $C^1(\overline{\Omega})$ may be obtained.

As before, duality requires an appropriate Lagrangian formulation, which we obtain by attaching a multiplier $u \in M(\bar{\Omega})$ to the equality constraint in (P^*). The dual Lagrangian is then

$$L_D(y,z,\lambda,\mu;u) = J_{h^*}(y,z) + \frac{1}{2\alpha}|\lambda|^2 + \lambda \cdot c + \mu + \langle u, \operatorname{div} z + \operatorname{div} B^T\lambda - A^T\lambda - \mu - y\rangle,$$

and an equivalent way of writing (P^*) is the minimax form:

$$(P^*) \qquad \inf_{\substack{y \in C(\overline{\Omega}) \\ z \in C^1(\overline{\Omega})^n \\ \lambda \in \mathbb{R}^N, \mu \in \mathbb{R}}} \sup_{u \in M(\overline{\Omega})} L_D(y,z,\lambda,\mu;u).$$

Switching inf and sup leads to the corresponding bidual program,

$$(P^{**}) \qquad \sup_u \inf_{y,z,\lambda,\mu} L_D(y,z,\lambda,\mu;u),$$

and immediately gives $V(P^{**}) \le V(P^*)$ (weak duality). Proving equality requires more work.

PROPOSITION 4.1. *We have $V(P^{**}) = V(P^*)$, and (P^{**}) admits an optimal solution $\overline{u} \in M(\overline{\Omega})$.*

Proof. (a) Let us first consider the case where h is not affine. The function $f : C(\overline{\Omega}) \to \mathbb{R} \cup \{+\infty\}$, defined by

$$f(\eta) = \inf \Big\{ J_{h^*}(y,z) + \frac{1}{2\alpha}|\lambda|^2 + \lambda \cdot c + \mu : y \in C(\overline{\Omega}), z \in C^1(\overline{\Omega})^n, \lambda \in \mathbb{R}^N, \mu \in \mathbb{R}, \\ \operatorname{div} z + \operatorname{div} B^T\lambda - A^T\lambda - \mu - y = \eta \Big\},$$

is proper convex lsc and we have $f(0) = V(P^*)$, which is finite. According to the general theory (cf. [7]) it remains to show that $\partial f(0)$, the subdifferential of f at 0, is nonempty, since every $\overline{u}$ with $-\overline{u} \in \partial f(0)$ is a solution to (P^{**}), showing in addition $V(P^*) = V(P^{**})$. Notice here that f, being defined on $C(\overline{\Omega})$, has subgradients in the dual space $M(\overline{\Omega})$. Proving $\partial f(0) \neq \emptyset$ requires two arguments. First we establish the existence of a supporting functional. Then we argue that the latter must be continuous since f is lsc.

(b) By the Hahn–Banach theorem, existence of a supporting functional will follow if we show that 0 is an algebraic interior point of $\operatorname{dom} f$. That means for every $\eta \in C(\overline{\Omega})$ we have to find $\rho > 0$ such that $\rho\eta \in \operatorname{dom} f$. Equivalently, we have to show that for every $\eta \in C(\overline{\Omega})$ we can find $\varrho > 0$ such that the equation

$$\operatorname{div} z + \operatorname{div} B^T\lambda - A^T\lambda - \mu - y = \varrho\eta$$

admits a solution (y, z, λ, μ) with $(y, z) \in \operatorname{dom} J_{h^*}$.

As h is not affine, $\operatorname{dom} h^*$ consists of at least two points. By convexity this means that either the projection $\Pi_y(\operatorname{dom}\ h^*)$ of $\operatorname{dom} h^*$ on the first coordinate contains a ball $|y - y_0| \leq \varepsilon$, or that $\Pi_z(\operatorname{dom} h^*)$ contains a segment.

(c) First consider the case where $\Pi_y(\operatorname{dom} h^*)$ has nonempty interior. By convexity there exists an affine function $y \mapsto z(y)$ such that $(y, z(y)) \in \operatorname{dom} h^*$ for all $|y - y_0| \leq \varepsilon$ and some fixed y_0. Let $z(y) = ay + b$, with $a, b \in \mathbb{R}^n$. Setting $y(x) = y_0 + \tilde{y}(x), \mu = -y_0$, and $\lambda = 0$, we have to solve the linear equation

$$a \cdot \nabla\tilde{y} - \tilde{y} = \varrho\eta$$

for $\|\tilde{y}\|_\infty \leq \epsilon$. Assuming without loss that $a_1 \neq 0$, a possible solution is the smooth function

$$\tilde{y}(x) = \varrho\, c(x)\, e^{x_1/a_1}, \quad \text{where} \quad c(x) = \frac{1}{a_1} \int_{\xi_1}^{x_1} \eta(\xi, x_2, \ldots, x_n)\, e^{\xi/a_1}\, d\xi$$

with a suitable $\xi_1 \in \mathbb{R}$. For ϱ sufficiently small we get in fact $\|\tilde{y}\|_\infty \leq \varepsilon$; hence $(\tilde{y}(x), z(\tilde{y}(x))) \in \operatorname{dom} h^*$ for every $x \in \Omega$ and hence $(\tilde{y}, z(\tilde{y})) \in \operatorname{dom} J_{h^*}$ by continuity of $\tilde{y}$. So in the first case the problem is solved.

(d) Now consider the case where $\Pi_y(\operatorname{dom}\ h^*) = \{y_0\}$. Since h is not affine, $\Pi_z(\operatorname{dom} h^*)$ contains at least two points. This means that (eventually with a change of coordinates) $\operatorname{dom} h^*$ contains a convex set of the form

$$\{y_0\} \times \{z_{01}\} \times \cdots \times \{z_{0r}\} \times B_{n-r},$$

with B_{n-r} an open ball with center $(z_{0,r+1}, \ldots, z_{0n})$ in a subspace of dimension $n - r \geq 1$. In the worst case $n - r = 1$, the first $n - 1$ coordinates are fixed, but z_n is free to

vary on an interval. Choosing $y \equiv y_0$, $\mu = -y_0$, and $z = z_0 + \tilde{z}$ with $\tilde{z} = (0, \dots, 0, \tilde{z}_n)$, defined by

$$\tilde{z}_n = \varrho \int_{\xi_n}^{x_n} \eta(x_1, \dots, x_{n-1}, \xi)\, d\xi,$$

we get a z having div $z = \varrho\eta$. Also $|z(x) - z_0| \le \varepsilon$ for all $x \in \Omega$ if ϱ is sufficiently small. Then $(y, z) \in \text{dom } J_{h^*}$ as required. So in both subcases, 0 is an algebraic interior point of dom f, and a supporting functional at 0 exists. Continuity of the latter follows from the lower semicontinuity of J_{h^*}. This completes the argument started in (a).

(e) Finally, consider the case where h is affine, and hence dom h^* consists of a single point (y_0, z_0). Define the function $f : C(\overline{\Omega}) \to \mathbb{R} \cup \{\infty\}$ as before. Since the value $V(P^*)$ is finite, $0 \in \text{dom } f$, and since the operators A, B have a finite dimensional range, dom f itself is contained in a finite dimensional linear subspace L of $C(\overline{\Omega})$. Linearity of A, B even gives dom$f = L$. Choose a supporting functional at $0 \in L$, and extend it to a continuous linear functional on all of $C(\overline{\Omega})$. □

Proposition 4.1 gives existence of a solution of (P^{**}) in $M(\overline{\Omega})$. We argue that under mild additional assumptions, $\bar{u}$ is in fact a function. We will even show a little more, namely, every u feasible for (P^{**}) satisfies $u \in L_\sigma(\Omega)$ for some $\sigma > 1$. Consider $u \in M(\overline{\Omega})$ with

$$\inf_{y,z,\lambda,\mu} L_D(y, z, \lambda, \mu; u) > -\infty,$$

where the infimum is over $y \in C(\bar{\Omega})$, $z \in C^1(\bar{\Omega})^n$, and $\lambda \in \mathbb{R}^N$, $\mu \in \mathbb{R}$ as before. Exploiting the form of L_D leads to three conditions:

$$\inf_{y,z} \left(J_{h^*}(y, z) + \langle u, \text{div } z - y\rangle\right) > -\infty, \tag{4.1}$$

$$\inf_{\lambda} \left(\frac{1}{2\alpha}|\lambda|^2 + \lambda \cdot c + \langle u, \text{div } B^T\lambda - A^T\lambda\rangle\right) > -\infty, \tag{4.2}$$

$$\inf_{\mu} \left(\mu - \langle u, \mu\rangle\right) > -\infty, \quad \text{i.e., } \int_\Omega du = 1. \tag{4.3}$$

As we shall see, the first condition allows for regularity considerations, while (4.2) and (4.3) will lead back to the original formulation of the constraints in (P).

First consider condition (4.1). We want to show that under suitable assumptions on h every feasible u possesses a Radon–Nikodym derivative lying in every space $L_\sigma(\Omega)$ with $1 < \sigma < \frac{n}{n-1}$. To do this we will need the following estimation for the Newton potential of a function $\varphi \in C_0^\infty(\Omega)$: Let φ be an element of $C_0^\infty(\Omega)$ and consider the corresponding Newton potential

$$v(x) = \int_\Omega \Gamma(x - s)\, \varphi(s)\, ds$$

with

$$\Gamma(x - s) = \begin{cases} \frac{1}{2\pi} \log|x - s|, & n = 2, \\ \frac{1}{n(2-n)\omega_n}|x - s|^{-(n-2)}, & n > 2, \end{cases}$$

where ω_n is the volume of the unit ball in $\mathbb{R}^n$. Then we have $v \in C^2(\overline{\Omega})$, $\Delta v = \varphi$, and

$$D_k v(x) = \int_\Omega D_k\Gamma(x - s)\, \varphi(s)\, ds \tag{4.4}$$

(cf. [9, Chapter 4]).

LEMMA 4.2. *Let* $1 < \sigma < \frac{n}{n-1}$. *Then*

$$|D_k v(x)| \le K \, \|\varphi\|_{\sigma'} \quad \textit{for all} \quad x \in \Omega \quad \textit{and for every} \quad \sigma' > n, \tag{4.5}$$

where the constant K *depends only on* σ' *and* Ω, *and* $1/\sigma + 1/\sigma' = 1$.

Proof. Using (4.4) and Hölder's inequality

$$|D_k v(x)| \le \|D_k \Gamma(x - .)\|_\sigma \, \|\varphi\|_{\sigma'}$$

provided $\|D_k \Gamma(x - .)\|_\sigma$ is finite. But for $n \ge 2$ we have

$$\int_\Omega |D_k \Gamma(x - s)|^\sigma \, ds = C_1 \int_\Omega \left(\frac{|x_k - s_k|}{|x - s|^n} \right)^\sigma \, ds \le C_2 \int_0^R r^{(n-1)(1-\sigma)} \, dr$$

with $\Omega \subset \{z \in \mathbb{R}^n : |z| \le R\}$ using n-dimensional spherical coordinates. As the last integral is finite for $(n-1)(1-\sigma) > -1$, or what is the same, $\sigma < \frac{n}{n-1}$, the lemma is proved. □

Now we want to use (4.5) and (4.1) to show that the map $\varphi \mapsto \langle u, \varphi \rangle$ is bounded on $C_0^\infty(\Omega)$ with respect to the $\|.\|_{\sigma'}$-norm, hence the Radon–Nikodym derivative of u is an element of $L_\sigma(\Omega)$, $(1/\sigma + 1/\sigma' = 1)$. To do this, we need to impose a richness condition on the domain of h^*:

$$\Pi_z(\text{dom } h^*) \text{ contains a segment.} \tag{A1}$$

As before, $\Pi_z : (y, z) \to z$ denotes the projection onto the last n coordinates.

Remark 1. Let us discuss the meaning of (A1). If $\Pi_z(\text{dom } h^*)$ does not contain a segment, dom $h^* \subset \mathbb{R} \times \{z\}$ for some $z \in \mathbb{R}^n$. This implies $h(x, y) = g(x) + y \cdot z$ for a convex function g, that is, h is linear in its second variable. We observe in a first place that z must be in the linear hull of the b_k. Therefore, in cases where we have no constraints on derivatives, $b = 0$ implies $z = 0$, leaving us with a problem without reference to derivatives. In case $b \ne 0$, the problem may be analyzed rather along classical lines as found in [7], although in general the result of Proposition 4.3 below is no longer valid. We consider objectives $h(x, \xi)$ linear in ξ as of minor importance for possible applications and do not pursue this class of objectives any further.

PROPOSITION 4.3. *Under the assumption* (A1) *every* $u \in M(\overline{\Omega})$ *feasible for* (P^{**}) *is absolutely continuous with respect to Lebesgue measure. Its Radon–Nikodym derivative lies in* $L_\sigma(\Omega)$ *whenever* $1 < \sigma < \frac{n}{n-1}$. *Furthermore, for every such* u *there exists a signed Borel vector measure* $m = m(u) \in M(\overline{\Omega})^n$ *satisfying*

$$\langle u, \operatorname{div} z \rangle = -\langle m(u), z \rangle \quad \textit{for all} \quad z \in C^1(\overline{\Omega})^n.$$

Remark 2. $m(u)$ is an extension of the distribution vector ∇u on $C(\overline{\Omega})^n$ and shall as well be denoted as ∇u. Notice however that this measure contains singular parts supported on $\partial\Omega$.

Proof. Step 1. Using a reduction argument similar to the one employed in the proof of Proposition 4.1, we may without loss assume that $\Pi_z(\text{dom} h^*)$ has nonempty interior in $\mathbb{R}^n$. The general case consists in repeating the same argument in the affine subspace generated by $\Pi_z(\text{dom} h^*)$, which by (A1) has dimension ≥ 1.

With these arrangements, assumption (A1) guarantees the existence of a ball $|z - z_0| \le \varepsilon$ and an affine function $y = y(z)$ such that $(y(z), z) \in$ dom h^* for all

$|z - z_0| \le \varepsilon$. Consider $\varphi \in C_0^\infty(\Omega)$ with $\|\varphi\|_{\sigma'} \le \frac{\varepsilon}{K}$ ($\frac{1}{\sigma} + \frac{1}{\sigma'} = 1$) for the constant K from (4.5) and let v be the corresponding Newton potential. Then using (4.5) we have $|D_k v(x)| \le \varepsilon$. Setting $z = z_0 + \nabla v$ and $y = y(z)$ we get from (4.1)

$$J_{h^*}(y(z), z) + \langle u, \varphi - y(z)\rangle > -\infty.$$

Now by construction we have $|J_{h^*}(y(z), z) + \langle u, -y(z)\rangle| \le K_1$ for some $K_1 > 0$, so we get

$$\inf_{\|\varphi\|_{\sigma'} \le \frac{\varepsilon}{K}} \langle u, \varphi\rangle > -\infty.$$

By linearity we conclude that the functional $\varphi \mapsto \langle u, \varphi\rangle$ is bounded on $(C_0^\infty(\Omega), \|.\|_{\sigma'})$ which is a dense subspace of $L_{\sigma'}(\Omega)$. For short $u \in L_\sigma(\Omega)$.

Step 2. For the second statement we have to show that for feasible u the functional $z \mapsto \langle u, \operatorname{div} z\rangle$ is bounded on $(C^1(\overline{\Omega}), \|.\|_\infty)$. This follows from (4.1) and the boundedness of $J_{h^*}(y(z), z)$ and $\langle u, -y(z)\rangle$ on the ball $\|z\|_\infty \le r$. □

For the following suppose condition (*A*1) is satisfied. In order to simplify our arguments, we continue to consider the case where $\Pi_z(\mathrm{dom} h^*)$ has nonempty interior in $\mathbb{R}^n$. Performing the same steps in the affine subspace L generated by $\mathrm{dom}(h^*)$ will settle the general case.

As a consequence of Propositions 4.1 and 4.3, and on exploiting the structure of L_D, (P^{**}) now reads

$$(P^{**}) \quad \inf_u \Big\{ \sup\big\{\langle u, y\rangle + \langle \nabla u, z\rangle - J_{h^*}(y, z) : y \in C(\overline{\Omega}), z \in C^1(\overline{\Omega})^n\big\} + \sup\Big\{-\frac{1}{2\alpha}|\lambda|^2 - \lambda \cdot c + \langle u, A^T\lambda - \operatorname{div} B^T\lambda\rangle : \lambda \in \mathbb{R}^N\Big\} : \int_\Omega u(x)\,dx = 1\Big\}.$$

To calculate the inner supremum over y and z we would like to use the following result of Rockafellar's [21] describing the conjugate of a convex integral functional J_{h^*} with respect to the dual pairing $(C(\overline{\Omega}) \times C(\overline{\Omega})^n, M(\overline{\Omega}) \times M(\overline{\Omega})^n)$.

LEMMA 4.4 (see Rockafellar [21]). *Let $\overline{\Omega}$ be a compact subset of $\mathbb{R}^n$ and suppose* $\mathrm{int}(\mathrm{dom}\ h^*) \ne \emptyset$. *Then for $\mu \in M(\overline{\Omega}) \times M(\overline{\Omega})^n$ with Lebesgue decomposition $\mu = \mu_a + \mu_s$ the conjugate of J_{h^*} equals*

$$J^*_{h^*}(\mu) = \int_\Omega h^{**}\left(\frac{d\mu_a}{dx}\right) dx + \int_\Omega \sup_{w \in \mathrm{dom}\, h^*} \left(w \cdot \frac{d\mu_s}{d\vartheta}\right) d\vartheta,$$

where μ_s is absolutely continuous with respect to the nonnegative Borel measure ϑ.

In order to apply Lemma 4.4 to (P^{**}), we first need to replace the supremum over $z \in C^1(\overline{\Omega})$ by a supremum $z \in C(\overline{\Omega})$. That this may be done without changing its value is guaranteed by the following lemma, whose proof will be given in the appendix.

LEMMA 4.5. *Let m be a measure in $M(\overline{\Omega})$, $f \in L_1(\Omega, m)$, $g \in L_1(\Omega, m)^k$ ($k \in \mathbb{N}$), and $\Phi : \mathbb{R}^k \to \mathbb{R} \cup \{\infty\}$ be a proper convex lsc function. Then for the proper convex lsc functional*

$$F(z) = \int_\Omega [\Phi(z(x))f(x) + z(x) \cdot g(x)]\, dm(x)$$

on $L_1(\Omega, m)^k$ we have

$$\inf_{z \in C^1(\overline{\Omega})^k} F(z) = \inf_{z \in L_1(\Omega, m)^k} F(z).$$

Furthermore, the values of the infima over all function spaces $\mathcal{F}$ with $C^1(\overline{\Omega})^k \subset \mathcal{F} \subset L_1(\Omega, m)^k$ agree.

Applying Lemma 4.5 to (P^{**}) with $k = n+1$, letting $z(x)$ stand for the pair $(y(x), z(x))$, $g(x) = \nabla u(x)$, and letting $\Phi(z(x))f(x)$ represent the term $h^*(y(x), z(x)) + u(x)y(x)$, we are now allowed to calculate

$$\sup_{\substack{y \in C(\overline{\Omega}) \\ z \in C(\overline{\Omega})^n}} \left(\langle u, y \rangle + \langle \nabla u, z \rangle - J_{h^*}(y, z) \right) \tag{4.6}$$

in (P^{**}), and Lemma 4.4 then shows that (4.6) equals

$$J_{h^{**}}(u, (\nabla u)_a) + \int_\Omega \sup_{z \in \Pi_z(\operatorname{dom} h^*)} \left(z \cdot \frac{d(\nabla u)_s}{d\vartheta}(x) \right) d\vartheta(x), \tag{4.7}$$

where $\nabla u = (\nabla u)_a + (\nabla u)_s$ denotes Lebesgue decomposition and $d(\nabla u)_s \ll d\vartheta$. A possible choice for ϑ is, for instance, the total variation of $d(\nabla u)_s$. For every feasible u we get in particular

$$\int_\Omega \sup_{z \in \Pi_z(\operatorname{dom} h^*)} \left(z \cdot \frac{d(\nabla u)_s}{d\vartheta}(x) \right) d\vartheta(x) = \int_\Omega \sigma_{\Pi_z(\operatorname{dom} h^*)} \left(\frac{d(\nabla u)_s}{d\vartheta}(x) \right) d\vartheta(x) < \infty. \tag{4.8}$$

Here $\sigma_{\Pi_z(\operatorname{dom} h^*)}(y)$ denotes the support function of the convex set $\Pi_z(\operatorname{dom} h^*)$ (cf. [21]).

Example 2. For the Csiszár information measures (1.4) we have $\Pi_z(\operatorname{dom} h^*) = \operatorname{dom} \phi^*$. From [21, Theorem 13.3] we deduce $\sigma_{\operatorname{dom} \phi^*} = \phi^{0+}$, the recession function of ϕ:

$$\phi^{0+}(y) = \lim_{\lambda \to \infty} \frac{1}{\lambda} (\phi(x + \lambda y) - \phi(x)) \quad \text{for an arbitrary} \quad x \in \operatorname{dom} \phi.$$

For the particular case $\phi(t) = |t|^p$, $p > 1$, we have

$$\phi^{0+}(y) = \begin{cases} \infty & \text{if } y \neq 0, \\ 0 & \text{if } y = 0, \end{cases}$$

while the case $p = 1$, $\phi(t) = |t|$ gives $\phi^{0+}(y) = |y|$. So for $p > 1$ the singular part of ∇u in (4.7) must vanish, since $\phi^{0+}((d(\nabla u)_s / d\vartheta)(x)) < \infty$ only for $(d(\nabla u)_s / d\vartheta)(x) = 0$ a.e. On the other hand, in case $p = 1$ we cannot argue that $(\nabla u)_s = 0$, so we only get $u \in BV(\Omega)$.

In general we need the assumption

$$\Pi_z(\operatorname{dom} h^*) \text{ is an affine subspace of dimension } \geq 1 \tag{A2}$$

to get $u \in W^{1,1}(\Omega)$. Notice that $(A2)$ readily implies $(A1)$. To understand the meaning of $(A2)$, consider the case where $\Pi_z(\operatorname{dom} h^*) = \mathbb{R}^n$. Then $h(x, \xi)$ is coercive in its ξ-variable. More precisely, $\Pi_z(\operatorname{dom} h^*) = \mathbb{R}^n$ implies that for every fixed x, $h(x, \xi)$ grows stronger than linearly as $|\xi| \to \infty$.

Proposition 4.6. *If assumption $(A2)$ is satisfied, every u which is feasible for (P^{**}) lies in $W^{1,1}(\Omega)$, and (P^{**}) has the form*

$$\inf_{u \in W^{1,1}(\Omega)} \left\{ I_h[u] + \frac{\alpha}{2} |Au + B\nabla u - c|^2 \, : \, \int_\Omega u(x)\, dx = 1 \right\}. \tag{P^{**}}$$

Remark 3. This means that (P^{**}) coincides with $(P)_{\rm pen}$, formulated in the Sobolev space $W^{1,1}(\Omega)$. Notice again here that this does not exclude situations where the natural space for the objective $I_h[u]$ is smaller, e.g., $\mathrm{dom} I_h \subset W^{1,2}(\Omega)$. In this case, $u \notin W^{1,2}(\Omega)$ will have $I_h[u] = \infty$ and the solution will automatically be an element of $W^{1,2}(\Omega)$.

Proof. As before, we present the argument in the case $\Pi_z(\mathrm{dom} h^*) = \mathbb{R}^n$, i.e., where the affine subspace L generated by dom h^* has dimension n. The general case is settled by repeating the argument in L.

Under these circumstances, condition $(A2)$ in tandem with $h = h^{**}$ allows reducing (4.7) to $J_h(u, \nabla u) = I_h[u]$. Indeed, with $z \in \Pi_z(\mathrm{dom}\, h^*)$ arbitrary, the supremum under the integral sign in (4.7) is $+\infty$, unless $(\nabla u)_s = 0$. Hence $(\nabla u)_a = \nabla u$, and the claim follows. Further, we can write (4.2) in the form

$$\sup_{\lambda\in\mathbb{R}^N}\left(-\frac{1}{2\alpha}|\lambda|^2 - \lambda\cdot c + \langle u, A^T\lambda - \mathrm{div}\, B^T\lambda\rangle\right)$$
$$= \sup_{\lambda\in\mathbb{R}^N}\left(\lambda\cdot(Au + B\nabla u - c) - \frac{\alpha}{2}|\lambda|^2\right) = \frac{1}{2\alpha}|Au + B\nabla u - c|^2,$$

so (P^{**}) is $(P)_{\rm pen}$ formulated in the space $W^{1,1}(\Omega)$. ∎

Propositions 4.3 and 4.6 now yield the main result for $(P)_{\rm pen}$.

THEOREM 4.7. *Under the hypothesis* $(A2)$*, the penalization model* $(P)_{\rm pen}$ *admits a solution* $\overline{u} \in W^{1,1}(\Omega)$.

5. Existence of solutions for $(P)_{\rm tol}$. Similar to $(P)_{\rm pen}$, the tolerance model $(P)_{\rm tol}$ can be written in the form

$$\inf_{u,v,e}\sup_{w,\lambda,\mu,\nu\geq 0}\tilde{L}(u, v, e; w, \lambda, \mu, \nu)$$

with

$$\tilde{L}(u, v, e; w, \lambda, \mu, \nu) = J_h(u, v) + \langle w, \nabla u - v\rangle + \lambda\cdot(Au + Bv - c - e)$$
$$+\mu\left(\int_\Omega u(x)\,dx - 1\right) + \nu(|e|^2 - \varepsilon^2).$$

Here we get the analogous results by similar reasoning so we will only cite the main theorem.

THEOREM 5.1. *If* $(A2)$ *is satisfied, the tolerance model* $(P)_{\rm tol}$ *admits a solution* $\overline{u} \in W^{1,1}(\Omega)$.

6. Regularity. In this section we show that the regularity of the solutions $\bar{u}$ of $(P)_{\rm pen}$ and $(P)_{\rm tol}$ may be improved to give $\bar{u} \in W^{1,p}(\Omega)$ for some $p > 1$ if condition $(A2)$ is strengthened. For $1 \leq \varrho \leq r$ consider the condition

$(A3)$ there exists a measurable function $y \mapsto y(z)$, $\mathbb{R}^n \to \mathbb{R}$, such that
(i) $|y(z)| \leq K(1 + |z|^\varrho)$ for every $z \in \mathbb{R}^n$, and
(ii) $J_{h^*}(y(z), z)$ is bounded on a ball $\{z \in C^1(\overline{\Omega}) : \|z\|_r \leq C\}$.

Clearly $(A3)$ implies $(A2)$ and may be understood as a coercivity condition on the integrand h. Notice that $(A3)$ is, for instance, satisfied if h^* satisfies the growth condition

(ii′) $h^*(y, z) \leq K(1 + |y|^{r/\varrho} + |z|^r)$,

which translates into a coercivity condition for h. In this case, $y(z) = |z|^\rho$ satisfies (i).

COROLLARY 6.1. *Suppose (A3) (with $1 \le \varrho \le r$) is satisfied. Then every u feasible for $(P)_{\rm pen}$ (resp., $(P)_{\rm tol}$) lies in $W^{1,p(r,\varrho)}(\Omega)$ with*

$$p(r,\varrho)\begin{cases} = \infty, & \varrho = r = 1,\\ = \frac{r}{r-1}, & \varrho = 1 < r,\\ = \frac{r}{r-1}, & \varrho > 1 \text{ and } r > n(\varrho-1),\\ < \frac{n(\varrho-1)}{n(\varrho-1)-1}, & \varrho > 1 \quad \text{and } r \le n(\varrho-1).\end{cases}$$

In particular, this is true for the solution $\overline{u}$ of $(P)_{\rm pen}$ or $(P)_{\rm tol}$.

For the proof we need the following.

LEMMA 6.2. *Given $u \in W^{1,1}(\Omega)$ with $\nabla u \in L_p(\Omega)^n$ for some $p > 1$ we have $u \in W^{1,p}(\Omega)$.*

Proof. We have to show $u \in L_p(\Omega)$. Consider the sequence

$$u_n(x) = \begin{cases} u(x), & |u(x)| \le n,\\ n, & u(x) > n,\\ -n, & u(x) < -n.\end{cases}$$

Then [28, Corollary 2.1.8] gives

$$\nabla u_n(x) = \begin{cases} \nabla u(x), & |u(x)| < n,\\ 0, & |u(x)| \ge n,\end{cases}$$

hence $u_n \in W^{1,p}(\Omega)$ for all n. We want to show that $\|u_n\|_p$ is bounded so the Fatou lemma will give the result. Following [1, Theorem 4.20] for each $\varepsilon > 0$ there exists a set $\Omega_\varepsilon \subset\subset \Omega$ such that for every $v \in W^{1,p}(\Omega)$,

$$\|v\|_p \le K\varepsilon\|\nabla v\|_p + K\|v\|_{p,\Omega_\varepsilon}$$

with $K = K(p,\Omega)$. (Here $\|v\|^p_{p,\Omega_\varepsilon} = \int_{\Omega_\varepsilon} |v(x)|^p\,dx$.) Now since $u \in L_p^{\rm loc}(\Omega)$ (cf. [11, Theorem 4.5.13]) we have $\|u\|_{p,\Omega_\varepsilon} < \infty$, and from the definition of u_n we get

$$\|u_n\|_p \le K\varepsilon\|\nabla u_n\|_p + K\|u_n\|_{p,\Omega_\varepsilon} \le K\varepsilon\|\nabla u\|_p + K\|u\|_{p,\Omega_\varepsilon} = C < \infty$$

for every n. Now, using $u_n(x) \to u(x)$ a.e., Fatou's lemma provides

$$\|u\|_p \le \liminf_{n\to\infty} \|u_n\|_p \le C,$$

hence $u \in L_p(\Omega)$. ∎

We proceed to complete the proof of the corollary.

Proof. We give the argument for $(P)_{\rm pen}$, the tolerance case being similar. Suppose $u \in W^{1,1}(\Omega)$ is feasible for $(P)_{\rm pen}$. By Proposition 4.6, it is then feasible for (P^{**}) as well, so we have

$$\inf_{z\in C^1(\overline{\Omega})^n} (J_{h^*}(y(z),z) + \langle u, y(z)\rangle + \langle \nabla u, z\rangle) > -\infty. \tag{6.1}$$

We want to construct a decreasing (possibly breaking off) sequence of exponents $r_k \ge r$ such that the term $J_{h^*}(y(z),z) + \langle u, y(z)\rangle$ is bounded on a ball $\|z\|_{r_k} \le C$, giving $\nabla u \in L_{p_k}(\Omega)$ with $p_k = \frac{r_k}{r_k-1}$ by (6.1). Lemma 6.2 will imply $u \in W^{1,p_k}(\Omega)$.

The procedure is the following. Suppose we have already constructed $r_k > r, p_k = r_k/(r_k - 1) > 1$, with $u \in W^{1,p_k}(\Omega)$ by the argument above. Then by the Sobolev embedding theorem (cf. [1, p. 97]) we have $u \in L_{s_k}(\Omega)$ with

$$s_k \begin{cases} \text{arbitrary if } \ p_k \geq n, \\ = \frac{np_k}{n-p_k} \ \text{ if } \ p_k < n. \end{cases}$$

Using Hölder's inequality and condition (i) of $(A3)$ we have

$$|\langle u, y(z)\rangle| \leq \|u\|_{s_k} \|y(z)\|_{s'_k} \leq \tilde{K} \|u\|_{s_k} \|z\|_{\varrho s'_k}$$

with $\frac{1}{s_k} + \frac{1}{s'_k} = 1$. On the other hand, condition (ii) of $(A3)$ implies that $J_{h^*}(y(z), z)$ is bounded on $\|z\|_r \leq C$. Hence we choose $r_{k+1} = \max(r, \varrho s'_k)$. By construction the sequence (r_k) is strictly decreasing unless $r_k = r$, the lowest exponent we can possibly achieve. As soon as $r_k = r$ for some index k, the process stops giving $u \in W^{1,\frac{r}{r-1}}(\Omega)$. (Notice that if $p_k \geq n$ for some k, we can always choose s_k large enough to guarantee $\varrho s'_k \leq r$, viz. $r_{k+1} = r$.)

Now we want to compute the r_k explicitly: From Theorem 4.7 we know $u \in W^{1,1}(\Omega)$, i.e., $p_0 = 1$, giving $s_1 = \frac{n}{n-1}$ and $r_1 = \max(r, \varrho n)$. So we can actually stop after the first step if $r \geq \varrho n$. Otherwise we get $p_1 = \frac{\varrho n}{\varrho n - 1}$,

$$\begin{cases} s_1 = \frac{n\varrho}{n\varrho - \varrho - 1} \ \text{ and } \ r_2 = \max(r, \frac{n\varrho^2}{1+\varrho}) & \text{for } \ \frac{n\varrho}{n\varrho - 1} < n, \\ r_2 = r & \text{if } \ \frac{n\varrho}{n\varrho - 1} \geq n. \end{cases}$$

Proceeding like this we get

$$r_k = \begin{cases} \frac{n}{k} \to 0 & \text{if } \ \varrho = 1, \\ n\frac{\varrho - 1}{1 - \varrho^{-(k+1)}} \searrow n(\varrho - 1) & \text{if } \ \varrho > 1, \end{cases}$$

so the process will break off, giving $u \in W^{1,\frac{r}{r-1}}(\Omega)$, unless $\varrho > 1$ and $r \leq n(\varrho - 1)$. In the latter case we still get $u \in W^{1,p}(\Omega)$ for every $p < \frac{n(\varrho-1)}{n(\varrho-1)-1}$. □

Example 3. For the Csiszár information measures with $\phi(t) = |t|^p$ discussed in the preparatory section 1, we may choose $y(z) = K|z|^{p'}$ $(\frac{1}{p} + \frac{1}{p'} = 1)$, so $r := \varrho := p'$ will do, and the corollary gives $u \in W^{1,\tilde{p}}(\Omega)$ with

$$\tilde{p} \begin{cases} = p, & p > n, \\ < \frac{n}{n-p+1} = 1 + \frac{p-1}{n-p+1}, & p \leq n. \end{cases}$$

In particular, for p close to 1 we have $\tilde{p} = 1 + \epsilon(p)$ and $u \in W^{1,1+\varepsilon(p)}(\Omega)$ with $\varepsilon(p) := \frac{p-1}{n-p+1} \downarrow 0$ for $p \downarrow 1$.

Appendix. We still have to prove Lemma 4.5.

LEMMA 4.5. *Let m be a measure in $M(\overline{\Omega})$, $f \in L_1(\Omega, m)$, $g \in L_1(\Omega, m)^k$ $(k \in \mathbb{N})$, and $\Phi : \mathbb{R}^k \to \mathbb{R} \cup \{\infty\}$ be a proper convex lsc function. Then for the proper convex lsc functional*

$$F(z) = \int_\Omega [\Phi(z(x))f(x) + z(x) \cdot g(x)]\, dm(x)$$

on $L_1(\Omega, m)^k$ we have

$$\inf_{z \in C^1(\overline{\Omega})^k} F(z) = \inf_{z \in L_1(\Omega,m)^k} F(z).$$

Furthermore, the values of the infima over all function spaces $\mathcal{F}$ with $C^1(\overline{\Omega})^k \subset \mathcal{F} \subset L_1(\Omega, m)^k$ agree.

Proof. We give the argument in the case where dom Φ has nonempty interior in $\mathbb{R}^k$, the general case being reducible to the former.

It is sufficient to show that for any $z \in L_1(\Omega, \mu)^m$ with $F(z) < \infty$ and any $\varepsilon_0 > 0$ we can find a $y \in C^1(\overline{\Omega})^m$ such that $F(y) \leq F(z) + \varepsilon_0$. The construction of such a y will be divided into three steps. First we will prove the existence of a function $\tilde{z} \in L_1(\Omega, \mu)^m$ with values only in int(dom Φ) having $F(\tilde{z}) \leq F(z) + \frac{\varepsilon_0}{3}$. Then we will modify $\tilde{z}$ to get a function $\tilde{z}_{n_0}$ which maps Ω into a compact subset of int(dom Φ), again having $F(\tilde{z}_{n_0}) \leq F(\tilde{z}) + \frac{\varepsilon_0}{3}$. For the last step we will use the Lipschitz continuity of Φ on compact subsets of int(dom Φ) to find a suitable measure ν such that the approximation of $\tilde{z}_{n_0}$ with respect to ν by $C^1(\overline{\Omega})^m$-functions will also approach $F(\tilde{z}_{n_0})$. This will finally prove the existence of a $y \in C^1(\overline{\Omega})^m$ with $F(y) \leq F(\tilde{z}_{n_0}) + \frac{\varepsilon_0}{3}$, giving $F(y) \leq F(z) + \varepsilon_0$ altogether.

Step 1. Consider $z \in L_1(\Omega, \mu)^m$ with $F(z) < \infty$. Then we have $z(x) \in \operatorname{dom} \Phi$ a.e. for every representative of z. In particular, we can choose a measurable representative also denoted by z having $z(x) \in \operatorname{dom} \Phi$ for all $x \in \Omega$.

For fixed $\varepsilon > 0, \delta > 0$ we define the set-valued mapping

$$\Gamma(x) = \{\zeta \in \text{int}(\text{dom } \Phi) : |\zeta - z(x)| \leq \varepsilon,\ \Phi(\zeta) \leq \Phi(z(x)) + \delta\} \text{ for all } x \in \Omega.$$

We want to show that Γ admits a measurable selector using the Kuratovski and Ryll-Nardczevski measurable selection theorem [14]: Suppose Γ is a measurable set-valued mapping with nonempty closed images. Then there exists a measurable $\tilde{z} : \Omega \to \mathbb{R}^m$ having $\tilde{z}(x) \in \Gamma(x)$ for every $x \in \Omega$.

As will be seen, for sufficiently small ε, δ, this selector satisfies $F(\tilde{z}) \leq F(z) + \frac{\varepsilon_0}{3}$.

We have to verify three properties of Γ:

$\Gamma(x)$ *is closed for every* $x \in \Omega$: Fix $x \in \Omega$ and suppose (ζ_n) is a sequence in $\Gamma(x)$ converging to some $\zeta \in \text{int}(\text{dom } \Phi)$. Then we have $|\zeta - z(x)| = \lim_{n\to\infty} |\zeta_n - z(x)| \leq \varepsilon$ and $\Phi(\zeta) \leq \liminf_{n\to\infty} \Phi(\zeta_n) \leq \Phi(z(x)) + \delta$, so $\zeta \in \Gamma(x)$ and $\Gamma(x)$ is closed in int(dom Φ).

$\Gamma(x)$ *is nonempty for all* $x \in \Omega$: Since Φ is proper convex and lsc, epi Φ is a closed convex subset of $\mathbb{R}^m \times \mathbb{R}$ with

$$\operatorname{epi} \Phi = \overline{\operatorname{int}(\operatorname{epi} \Phi)}$$

(cf. [21, p. 46]). Hence any point $(z(x), \Phi(z(x))) \in \operatorname{epi} \Phi$ can be approximated by a sequence $(\zeta_n, \Phi(\zeta_n) + \delta_n) \in \text{int}(\text{epi } \Phi)$; that means $\zeta_n \in \text{int}(\text{dom } \Phi)$ and $\delta_n > 0$. But then we must have $\zeta_n \in \Gamma(x)$ for n sufficiently large, so $\Gamma(x)$ is nonempty.

Γ *is measurable:* We have to show that for each measurable $M \subset \mathbb{R}^m$ the preimage $\Gamma^{-1}(M)$ is a measurable subset of Ω. Here, without loss of generality, we can assume $M \subset \text{int}(\text{dom } \Phi)$. We get

$$\begin{aligned}
\Gamma^{-1}(M) &= \big\{x \in \Omega : \exists\, \zeta \in M :\ z(x) \in B(\zeta, \varepsilon), \Phi(z(x)) \geq \Phi(\zeta) - \delta\big\} \\
&= \big\{x \in \Omega : \exists\, y \in B(0, \varepsilon),\ \exists\, \zeta \in M :\ z(x) = y + \zeta,\ \Phi(z(x)) \geq \Phi(\zeta) - \delta\big\} \\
&= \big\{x \in \Omega : \exists\, y \in B(0, \varepsilon) \colon (z(x), \Phi(z(x))) \in \operatorname{epi}(\Phi - \delta) \cap (M \times \mathbb{R}) + \{(y, 0)\}\big\} \\
&= \big\{x \in \Omega :\ (z(x), \Phi(z(x))) \in \operatorname{epi}(\Phi - \delta) \cap (M \times \mathbb{R}) + B(0, \varepsilon) \times \{0\}\big\} \\
&= (z, \Phi(z))^{-1} \left(\operatorname{epi}(\Phi - \delta) \cap (M \times \mathbb{R}) + B(0, \varepsilon) \times \{0\}\right).
\end{aligned}$$

Since epi $(\Phi - \delta)$ is closed and therefore measurable, $\Gamma^{-1}(M)$ is now the preimage of a measurable set under the measurable map $x \mapsto (z(x), \Phi(z(x)))$; hence $\Gamma^{-1}(M)$ is measurable.

Now we can apply the selection theorem of Kuratovski and Ryll-Nardczevski to get a measurable function $\tilde{z}$ with $\tilde{z}(x) \in \Gamma(x)$ for all $x \in \Omega$. By the definition of Γ we have $\tilde{z} \in L_1(\Omega, \mu)^m$ and

$$F(\tilde{z}) \leq F(z) + \delta \int_\Omega |f(x)|\, d\mu(x) + \varepsilon \int_\Omega |g(x)|\, d\mu(x),$$

so for sufficiently small δ and ε, $F(\tilde{z}) \leq F(z) + \frac{\varepsilon_0}{3}$, and the first step is proven.

Step 2. Without loss of generality, assume $0 \in \text{int}(\text{dom } \Phi)$ and $\Phi(0) = 0$. Now choose an increasing sequence (D_n) of compact subsets of $\mathbb{R}^m$ having $0 \in D_1$ and

$$D_n \uparrow \text{int}(\text{dom } \Phi),\ D_n \subseteq \{\zeta \in \mathbb{R}^m : |\Phi(\zeta)| \leq n\},\ D_n \subset \text{int}\,(D_{n+1}).$$

Defining $\Omega_n = \tilde{z}^{-1}(D_n) = \{x \in \Omega : \tilde{z}(x) \in D_n\}$ and letting $\tilde{z}_n = \chi_{\Omega_n} \cdot \tilde{z}$, we have $\tilde{z}_n(x) \to \tilde{z}(x)$ and $\Phi(\tilde{z}_n(x)) \to \Phi(\tilde{z}(x))$ pointwise, since $\Omega_n \uparrow \Omega$. Now

$$|F(\tilde{z}_n)| \leq \int_\Omega |\Phi(\tilde{z}(x))f(x) + \tilde{z}(x) \cdot g(x)|\, d\mu(x) \quad \text{for all} \quad n \in \mathbb{N}$$

and dominated convergence implies $F(\tilde{z}_n) \to F(\tilde{z})$, so we can choose some $n_0 \in \mathbb{N}$ with $F(\tilde{z}_{n_0}) \leq F(\tilde{z}) + \frac{\varepsilon_0}{3}$.

Step 3. Now we have $\tilde{z}_{n_0}(x) \in D_{n_0}$ for all $x \in \Omega$, so if we want to approach $\tilde{z}_{n_0}$ by smooth functions we can restrict ourselves to functions with values in D_{n_0+1} since D_{n_0} is a compact subset of $\text{int}\,(D_{n_0+1})$ having a positive distance from its boundary. But for each $y \in C^1(\overline{\Omega})^m$ with values in D_{n_0+1} we get

$$|F(\tilde{z}_{n_0}) - F(y)| \leq \int_\Omega |\tilde{z}_{n_0}(x) - y(x)|\ (L_{n_0+1}|f(x)| + |g(x)|)\ d\mu(x),$$

where L_{n_0+1} denotes the Lipschitz constant of Φ on D_{n_0+1}. So we have to approximate $\tilde{z}_{n_0}$ with respect to the measure $d\nu = (L_{n_0+1}|f| + |g|)\, d\mu$. Choosing $y \in C^1(\overline{\Omega})^m$ with $\|\tilde{z}_{n_0} - y\|_{L_1(\Omega,\nu)^m} \leq \frac{\varepsilon_0}{3}$ (notice $\tilde{z}_{n_0} \in L_1(\Omega, \nu)^m$, hence such a y exists), we finally get

$$F(y) \leq F(\tilde{z}_{n_0}) + \frac{\varepsilon_0}{3} \leq F(\tilde{z}) + 2\frac{\varepsilon_0}{3} \leq F(z) + \varepsilon_0,$$

and the proof is complete. ∎

PARAMETERIZED LMIs IN CONTROL THEORY*

PIERRE APKARIAN† AND HOANG DUONG TUAN‡

Abstract. A wide variety of problems in control system theory fall within the class of parameterized linear matrix inequalities (LMIs), that is, LMIs whose coefficients are functions of a parameter confined to a compact set. Such problems, though convex, involve an infinite set of LMI constraints and hence are inherently difficult to solve numerically.

This paper investigates relaxations of parameterized LMI problems into standard LMI problems using techniques relying on directional convexity concepts. An in-depth discussion of the impact of the proposed techniques in quadratic programming, Lyapunov-based stability and performance analysis, μ analysis, and linear parameter-varying control is provided. Illustrative examples are given to demonstrate the usefulness and practicality of the approach.

Key words. linear matrix inequalities, robust semidefinite programming, directional convexity, robustness analysis, parametric uncertainty, linear parameter-varying control

1. Introduction.

LMI techniques are now well-rooted as a unifying framework for formulating and solving problems in control theory with a remarkable degree of simplicity. The main thrust of these techniques is that certain complicated control problems can be solved very efficiently. Specifically, the interior-point methods for semidefinite programming have worst-case polynomial complexity with respect to the problem size. From a practical viewpoint, extensive experience shows that interior-point methods solve problems in roughly less than a hundred iterations, independent of the problem size. Each elementary iteration reduces to solving a least-square problem which incurs the main computational overhead. Recent and thorough studies of interior-point techniques for semidefinite programming are, among others, Jarre [23], Vandenberghe and Boyd [43], Rendl, Vanderbei, and Wolkowicz [34], and the master book by Nesterov and Nemirovski [28].

Basically, the simple feasibility problem of semidefinite programming consists in seeking a solution to the LMI

$$F_0 + z_1 F_1 + \cdots + z_r F_r < 0\,, \tag{1.1}$$

where the F_i's are given real symmetric matrices and the z_i's are the sought decision variables. A significantly more complicated generalization of problem (1.1) is the feasibility problem

$$F_0(\theta) + z_1(\theta) F_1(\theta) + \cdots + z_r(\theta) F_r(\theta) < 0, \tag{1.2}$$

where $\theta := [\theta_1, \ldots, \theta_N]^T$ is an additional parameter allowed to take any value in a compact set H of $\mathbf{R}^N$, typically a polytope. In contrast to problem (1.1) the problem

data, $F_i(\theta)$, are now symmetric matrix-valued functions of θ, and we are seeking (arbitrary) functions of θ, $z_i(\theta)$ such that the LMI constraints (1.2) hold for any admissible value of θ. The complexity of problem (1.2) is twofold:

1. It is infinite-dimensional since the $z_i(.)$'s are sought in the infinite-dimensional space of functions of θ.

2. This is an infinitely constrained LMI problem for which each constraint corresponds to a given point in the range of θ.

A common and practical approach to overcome the difficulties arising from dimensionality is to select a finite basis of functions for the z_i's and reconsider the problem over the resulting spanned finite-dimensional space. In such a case, problem (1.2) simplifies to an LMI problem of the form

$$F_0(\theta) + z_1 F_1(\theta) + \cdots + z_r F_r(\theta) < 0, \qquad \forall \theta \in H, \tag{1.3}$$

where $z_1, \ldots, z_r$ are conventional scalar decision variables as in (1.1) and H is a compact set. Such problems are referred to as *robust semidefinite programming* problems in [4] and are designated here as *parameterized LMI* (PLMI) problems to stress the connections with the LMI control theory literature.

For reasons raised above, PLMI feasibility problems still have high complexity and are even known to be NP-hard [4]. The aim of this paper is to develop systematic relaxation techniques to turn, potentially conservatively, this problem into a standard LMI problem. A fruitful technique for turning PLMI problems into conventional LMI problems is the well-known **S**-procedure [45, 14]. With this approach, scaling or multipliers are utilized to eliminate the LMI parameter-dependence. The price to pay is the insuperable conservatism of the resulting conditions and also the extra computational effort, often prohibiting, introduced by the multiplier variables. This paper exploits competitive techniques invoking directional convexity concepts to derive a finite set of LMI conditions. Generally speaking, the approach requires significantly less variables than **S**-procedure techniques whilst producing more LMI constraints. Since the flop cost of interior-point techniques is roughly linear with respect to the size of the LMI constraint but polynomial with respect to the number of decision variables, the proposed techniques offer a valuable alternative to **S**-procedure techniques. It is, however, difficult to draw definitive conclusions at this stage since the respective performance of each technique is probably problem-dependent. As demonstrated in the body of the paper, the techniques therein also offer possibilities for handling polytopic representations, that is when the parameter θ designates polytopic coordinates, $\sum_{i=1}^{N} \theta_i = 1$, $\theta_i \geq 0$. We also briefly discuss relaxations of linear objective minimization problems subject to PLMI constraints and PLMI problems subject to algebraic constraints on the parameter θ.

The scope of applications of PLMIs is quite large and goes far beyond the area of robust control theory. In [4, 5], Ben-Tal and Nemirovski lay the foundations of *robust convex programming* and investigate its theoretical *tractability* in conjunction with the analysis of some generic uncertain convex programs. The same stream of ideas are applied to a truss topology design problem in [6]. In [29], the authors provide a thorough study of the regularity properties of solutions to PLMIs using the **S**-procedure and discuss its implications for a variety of topics: linear programming, polynomial interpolation, integer programming, and so forth. Our contribution is in line with that of [29] or what is called "approximate robust counterpart" of an uncertain semidefinite programming problem in [4]. The general instance of the problems is essentially intractable and we are constructing relaxed forms, generally conservative,

that are directly amenable to the use of interior-point methods. Note also that alternative techniques to those considered here are developed in [40] using either convex approximations or difference convex (d.c.) representations.

This work is mostly control theory oriented, and special attention is paid to the following topics:

(i) *Quadratic programming.* It is shown that some neither convex nor concave quadratic programming problems can be converted into boolean programming problems. The results so introduced constitute the core of the subsequent derivations and have a direct impact for relaxing PLMI problems.

(ii) *Lyapunov-based stability and performance analysis.* A rich catalog of Lyapunov-based stability and performance criteria for uncertain systems can be handled via PLMIs, thus providing generalizations of the single quadratic Lyapunov function approach.

(iii) *μ-analysis.* PLMIs have direct applications in the μ-analysis context or robust non-singularity analysis and can be utilized to refine the computation of upper-bounds.

(iv) *Linear parameter-varying (LPV) control synthesis.* PLMIs and the concepts developed here are also central in LPV control synthesis to overcome the difficulties arising from gridding phases and reduce the computational efforts.

The paper is structured as follows. Section 3 discusses a variety of directional convexity concepts and their implications in functional optimization. These results are then extended to PLMI problems in section 4. Important robust and LPV control issues mentioned above are investigated in section 5. Numerical examples illustrating the techniques and tools are given in section 6.

2. Preliminaries. The following definitions and notations are used throughout the paper.

$\mathbf{R}$ and $\mathbf{C}$ denote the sets of real and complex numbers, respectively. M^T is the transpose of the matrix M, and M^* denotes its complex-conjugate transpose. The notation $\operatorname{Tr} M$ stands for the trace of M. For Hermitian or symmetric matrices, $M > N$ means that $M - N$ is positive definite and $M \geq N$ means that $M - N$ is positive semidefinite.

Let S be a convex subset of $\mathbf{R}^n$. A function $f : S \to \mathbf{R}$ is quasi-convex if and only if for all u, v in S and α in [0, 1],

$$f(\alpha u + (1-\alpha)v) \leq \max\{f(u), f(v)\} .$$

Strict quasi-convexity is obtained when the inequality is strict for all $0 < \alpha < 1$. This notion is weaker than convexity, which requires

$$f(\alpha u + (1-\alpha)v) \leq \alpha f(u) + (1-\alpha) f(v) .$$

The relative interior, the closure, and the relative boundary of S are denoted as $\operatorname{ri} S$, $\operatorname{cl} S$, and $\operatorname{rbd} S$, respectively. We then have $\operatorname{rbd} S = \operatorname{cl} S \setminus \operatorname{ri} S$.

A polytope Π in $\mathbf{R}^n$ is defined as the compact set

$$\Pi := \left\{ \sum_{i=1}^{L} \alpha_i v_i : \sum_{i=1}^{L} \alpha_i = 1,\ \alpha_i \geq 0,\ v_i \in \mathbf{R}^n \right\} .$$

Equivalently, it is also the convex hull of the set $V = \{v_1, \ldots, v_L\}$, denoted $\operatorname{co} V$. The notation $\operatorname{vert} \Pi$ designates the set of vertices of Π, $\operatorname{vert} \Pi := V$. The affine hull, $\operatorname{aff} S$,

of a set S is defined as the set of all affine combinations of elements of S, i.e.,

$$\operatorname{aff} S := \left\{ \sum_{i=1}^{k} \alpha_i s_i : \ s_i \in S, \quad \sum_{i=1}^{k} \alpha_i = 1 \right\} .$$

The direction space associated to aff S is defined as aff $S - s_0$, where s_0 is any point of aff S. The notation $\#S$ stands for the number of elements in a set S.

3. Extreme point results. This section introduces some useful tools that permit us to convert the maximization of a function over a polytope Π into the combinatorial problem of maximizing f over $\operatorname{vert} \Pi$. We begin with a general result which is the core of the subsequent derivations.

THEOREM 3.1 (Central result). *Consider a polytope* Π *and assume that for any* x *in* Π*, there exists a direction* d *in the direction space of* aff Π *such that* f *is quasi-convex on the line segment*

$$L_d(x) := \{ z \in \Pi : \ z = x + \lambda d, \ \lambda \in \mathbf{R} \} .$$

Then, f *has a maximum over* Π *in* $\operatorname{rbd} \Pi$.

Proof. Assume f has a maximum $\hat{x}$ in $\operatorname{ri} \Pi$. Consider a line segment $L_d(\hat{x})$ where f is quasi-convex. From this property, we infer that f has a maximum point in $\operatorname{rbd} \Pi \cap L_d(\hat{x})$, and therefore

$$f(\hat{x}) \leq f(\bar{x}),$$

for some $\bar{x}$ in $\operatorname{rbd} \Pi \cap L_d(\hat{x})$. ∎

By virtue of Theorem 3.1, the search of a maximum point is reduced to exploring the relative boundary of Π. This result is analogous to the well-known *maximum principle* for analytic functions of complex variables. Although this constitutes an appealing result which might find applications, it is still hardly tractable for our particular purpose. A stronger result is obtained by forcing the directions d to be parallel to the edges of the polytope. The corollary below clarifies this fact.

COROLLARY 3.2 (Multi-quasi-convexity). *Consider a polytope* Π *and the directions* $d_1, \ldots, d_q$ *determined by the edges of* Π*. Assume that for any* x *in* Π*, the function* f *is quasi-convex on the line segments* $L_{d_i}(x)$ *for* $i = 1, \ldots, q$*. Then,* f *has a maximum over* Π *at a vertex of* Π.

Proof. Immediate by application of Theorem 3.1 to Π and to the (polytopic) faces and edges of Π. ∎

An obvious consequence of Theorem 3.1 is the following.

COROLLARY 3.3. *Under the hypotheses of Corollary* 3.2*, the following conditions are equivalent:*

(i) $f(x) < 0 \quad \forall x \in \Pi$.
(ii) $f(x) < 0 \quad \forall x \in \operatorname{vert} \Pi$.

As claimed previously, the maximization problem in Corollary 3.2 and the sign verification problem in Corollary 3.3 are turned into simpler combinatorial problems of lower complexity. This is a consequence of the multi-quasi-convexity property defined in Corollary 3.2. Note that the term *multi-quasi-convex* emphasizes the fact that f is separately quasi-convex along parallels to the edges of the polytope. This property is attached to the function f but is also intimately related to the particular geometry of the polytope.

Quasi-convexity is a less stringent requirement than usual convexity, the counterpart being the difficulty of its verification even for differentiable functions. Alternative

conditions that are more easily amenable to numerical computation are derived by replacing quasi-convexity with convexity in Theorem 3.1 and Corollaries 3.2 and 3.3. For twice continuously differentiable functions, Corollary 3.2 then becomes as follows.

COROLLARY 3.4 (Multiconvexity). *With the definitions in Corollary* 3.2, *f has a maximum over Π in* $\operatorname{vert}\Pi$ *whenever it holds that*

$$\frac{\partial^2 f(x+\lambda d_i)}{\partial \lambda^2} \geq 0 \quad \forall x \in \Pi, \quad i = 1, \ldots, q\,. \tag{3.1}$$

Affine functions are trivially multi-quasi-convex functions, so any of the above results is applicable. It is instructive to consider the case in which f is a quadratic function and Π is a hyperrectangle.

COROLLARY 3.5 (Quadratic functions). *Consider a quadratic function, $f(x) = x^T Q x + c^T x + a$, and assume Π is a hyperrectangle with edges paralleling the axes of coordinates, that is, $x = [x_1, \ldots, x_n]^T$ with*

$$\alpha_i \leq x_i \leq \beta_i, \quad i = 1, \ldots, n\,.$$

Assume further that

$$Q_{ii} \geq 0, \quad i = 1, \ldots, n. \tag{3.2}$$

Then, f has a maximum over Π in $\operatorname{vert}\Pi$.

Proof. From Corollary 3.4, the conditions (3.2) express multiconvexity of the quadratic function. □

Clearly, the conditions (3.2) are less demanding than (global) convexity which requires $Q \geq 0$. When such conditions hold, the maximization of f over the polytope Π reduces to a boolean programming problem [35], which is much simpler (though possibly costly) than the maximization of a general f. One possible advantage is that some costly but practically useful concave minimization techniques, such as simplicial and conical partitioning (branch and bound) techniques like those of Tuy and Thach, might be used to find a global optimal solution. The reader is referred to the book of Tuy [41] for a thorough treatment.

4. Relaxation of PLMIs. This section presents some applications of these results to PLMIs whose coefficients are dependent on a parameter evolving in a polytopic set. To emphasize the fact that these parameters might be interpreted as uncertainties or scheduled variables of robust control or LPV control problems, the free variable x is denoted θ or α, hereafter.

Before proceeding further, it is instructive to have in mind the following important facts from [4]. Consider the "robust counterpart" (parameterized convex program in our terminology) of a general uncertain convex program:

$$\begin{array}{c} \text{minimize } c^T z\,, \\ \text{subject to } F(z,\theta) \in K, \forall \theta \in H, \end{array} \tag{4.1}$$

where K is a closed convex cone, H is a generalized ellipsoidal set including as instances standard ellipsoids but also ellipsoidal cylinders and polyhedras, $F(z,\theta)$ is K-concave with respect to z. A key additional assumption is that $F(z,\theta)$ must be K-concave with respect to θ. With these assumptions in place, Ben-Tal and Nemirovski established the following:

(i) The robust counterpart of an uncertain linear program is a conic quadratic program; thus it is perfectly tractable.

(ii) The robust counterpart of an uncertain quadratically constrained convex quadratic program is a semidefinite program, hence tractable, but is NP-hard for intersections of ellipsoidal uncertainty sets.

(iii) The robust counterpart of an uncertain semidefinite program is generally NP-hard even for a single ellipsoidal uncertainty set.

The problems examined in what follows fall within the latter class, so they are generally NP-hard. They also generally fail to satisfy the K-concavity in θ, mentioned above. By virtue of its inherent complexity, one must, as a last resort, use relaxation techniques to end up with tractable "approximate" programs. Again with reference to [4], we take advantage of some directional K-concavity instead of complete K-concavity in the uncertain parameter to derive such relaxations.

4.1. PLMIs with quadratic parameter dependence. We consider PLMIs in the class

$$\mathcal{L}(z,\alpha) := M_0(z) + \sum_{i=1}^{L} \alpha_i M_i(z) + \sum_{i,j=1}^{L} \alpha_i \alpha_j M_{ij}(z) < 0, \tag{4.2}$$

where z stands for the decision variable and $M_0(.)$, $M_i(.)$, and $M_{ij}(.)$ are real symmetric matrix-valued and linear functions of z. In addition, it is supposed that the parameter $\alpha = [\alpha_1, \ldots, \alpha_L]^T$ evolves in the simplex

$$\Gamma := \left\{ \alpha : \sum_{i=1}^{L} \alpha_i = 1,\ \alpha_i \geq 0 \right\}. \tag{4.3}$$

Note that the problem presented in (4.2) involves infinitely many LMIs associated with each value of the parameter α and is known to be intractable [4]. By enforcing some constraints of geometric nature on the functional dependence in α, it is however possible to reduce, potentially conservatively, the problem to solving a finite number of LMIs. This is established in the next proposition.

PROPOSITION 4.1. *The infinite set of LMIs* (4.2) *is feasible for some z whenever the finite set of LMIs*

$$M_0(z) + M_k(z) + M_{kk}(z) < 0, \tag{4.4}$$

$$M_{ii}(z) + M_{jj}(z) - (M_{ij}(z) + M_{ji}(z)) \geq 0, \tag{4.5}$$

where $1 \leq k \leq L$ and $1 \leq i < j \leq L$, is feasible for some z.

Proof. Note first that the conditions (4.2) are equivalent to $x^T \mathcal{L}(z,\alpha) x < 0\ \forall\ x \neq 0$. For fixed $x \neq 0$, consider $x^T \mathcal{L}(z,\alpha) x$ as function of α. By virtue of Corollary 3.4, it is negative whenever it is multiconvex along lines paralleling the edges of Γ and furthermore is negative over $\operatorname{vert} \Gamma$. The remainder of the proof follows from the fact that $\operatorname{vert} \Gamma$ is composed of the canonical basis of $\mathbf{R}^L$, and the directions of the edges of Γ are determined by vectors with all but two zero coordinates, the nonzero coordinates having opposite signs:

$$d_1 := [1, -1, 0, \ldots, 0],$$
$$d_2 := [1, 0, -1, 0, \ldots, 0],\ \ldots.$$

Repeating the reasoning for all $x \neq 0$ yields the condition (4.4) and (4.5), as desired. ∎

Remarks. By strengthening the conditions in (4.4), one can slightly relax the multiconvexity requirement in (4.5). As an example, the solutions (z, Z_i) to the LMI feasibility problem

$$M_0(z) + \sum_{i=1}^{L} \alpha_i M_i(z) + \sum_{i,j=1}^{L} \alpha_i \alpha_j M_{ij}(z) < -\sum_{i=1}^{L} \alpha_i^2 Z_i \qquad \forall \alpha \in \Gamma,$$
$$Z_i \geq 0, \quad i = 1, \ldots, L,$$

give solutions z to the feasibility problem (4.2). Arguing as in proposition 4.1, associated sufficient solvability conditions are easily obtained as

$$M_0(z) + M_k(z) + M_{kk}(z) < -Z_k, \tag{4.6}$$
$$M_{ii}(z) + M_{jj}(z) - (M_{ij}(z) + M_{ji}(z)) \geq -(Z_i + Z_j), \tag{4.7}$$
$$Z_k \geq 0\,, \tag{4.8}$$

where $1 \leq k \leq L$ and $1 \leq i < j \leq L$. Due to the strict nature of (4.6), the nonstrict inequalities in (4.7) and (4.8) can be changed into strict inequalities without any loss of generality. In the strict form, such problems are readily solved using interior-point semidefinite programming techniques such as those in [8, 42, 27]. Note also that the Z_i's can be chosen as general symmetric matrices whose size is that of the LMI condition (4.2). Less costly characterizations are obtained by using diagonal or scalar matrices instead, such as

$$Z_i = \operatorname{diag} \lambda_i \quad \text{or} \quad Z_i = \lambda_i I\,.$$

When Γ is a hyperrectangle and the LMIs (4.2) are expressed in terms of the Cartesian coordinates of α (as opposed to polytopic ones), the main result in [18] is recovered as a special case. Assume $\theta := [\theta_1, \ldots, \theta_N]^T$ ranges over a hyperrectangle, denoted H, that is,

$$\underline{\theta}_i \leq \theta_i \leq \bar{\theta}_i\,. \tag{4.9}$$

Then

$$\mathcal{L}(z, \theta) := M_0(z) + \sum_{i=1}^{N} \theta_i M_i(z) + \sum_{i,j=1}^{N} \theta_i \theta_j M_{ij}(z) < 0 \quad \forall \theta \in H$$

whenever

$$\begin{array}{lcl} \mathcal{L}(z, \theta) < 0, & \theta & \in \quad \text{vert } H, \\ M_{ii}(z) \geq 0, & i & = \quad 1, \ldots, N. \end{array}$$

As before, one can relax the multiconvexity requirement above by replacing these conditions with

$$\mathcal{L}(z, \theta) < -\sum_{i=1}^{N} \theta_i^2 \lambda_i I, \quad \theta \in \text{vert } H \tag{4.10}$$
$$M_{ii}(z) \geq -\lambda_i I, \quad i = 1, \ldots, N. \tag{4.11}$$

More generally, any nonpositive matrix-valued function of θ is a good candidate for the right-hand side of (4.10). More complicated polynomial functions lead naturally to more costly characterizations. From our practical experience, a reasonable compromise between computational efficiency and tightness of the test is obtained with nonhomogeneous functions of the form $-(\lambda_0 + \sum_{i=1}^{N} \theta_i^2 \lambda_i)\, I$.

4.2. Gridding techniques. The techniques developed in sections 3 and 4 provide sufficient and computationally simple conditions for checking the sign of a function or the feasibility of a PLMI problem. These conditions may introduce conservatism though it turns out to be small from our practical experience. A different technique which is guaranteed to provide a nonconservative answer but is potentially optimistic and generally computationally intensive, is to use a fine gridding of the parameter range and solve a finite set of LMIs corresponding to each point on the grid. Denoting the grid as G, the PLMI problem (4.2) is then replaced with the finite set of LMIs

$$M_0(z) + \sum_{i=1}^{L} \alpha_i M_i(z) + \sum_{i,j=1}^{L} \alpha_i \alpha_j M_{ij}(z) < 0, \quad \alpha \in G\,.$$

Such a technique is currently used in stability analysis and LPV control. It is, however, limited to problems of reasonable size, say less than three parameters. There is also the risk of missing a critical value of the parameter, hence leading to overly optimistic answers. With the approaches presented earlier, these difficulties are inherently ruled out. These techniques can be mixed with gridding approaches, hence offering alternative possibilities. Indeed, instead of gridding the entire parameter range, there is only a need to grid a surface of lower dimension whenever the function is quasiconvex or convex along some direction. This is an immediate consequence of Theorem 3.1. A simple illustration of this fact is given below. For the sake of simplicity, we restrict the discussion to 2 parameters θ_1 and θ_2 evolving in the normalized square

$$|\theta_1| \le 1, \qquad |\theta_2| \le 1\,, \tag{4.12}$$

and we consider the PLMI problem

$$M_0(z) + \sum_{i=1}^{2} \theta_i M_i(z) + \sum_{i,j=1}^{2} \theta_i \theta_j M_{ij}(z) < 0\,. \tag{4.13}$$

A potential technique for checking the feasibility of this problem consists first of enforcing convexity in the direction of θ_1. This is equivalent to the LMI constraint

$$M_{11}(z) \ge 0\,. \tag{4.14}$$

Thanks to this condition, it is then enough to grid the line segments

$$\theta_1 = \pm 1 \quad \text{and} \quad |\theta_2| \le 1$$

to check the feasibility of (4.13).

Finally, let us note that the approaches presented in the previous subsections are also very useful for developing a global optimization algorithm solving PLMIs. Indeed, the main difficulty in global optimization is "the curse of dimensionality," i.e., the size of the space where the global search is performed. Thus exploiting convexity properties such as directional convexity is very important for developing an efficient global optimization algorithm (see, e.g., [24, 41]) since it allows us to drastically simplify the problem by limiting the global search to a restricted region of the feasible domain. For instance, with condition (4.14), it is sufficient to perform a global search for (4.13) just on the line segment $|\theta_2| \le 1$ instead of on the square (4.12) in R^2.

4.3. PLMIs with polynomial parameter dependence. In this section, we are considering polynomially θ-dependent PLMIs of the form

$$\mathcal{L}(\theta, z) := \sum_{\nu \in J} \theta^{[\nu]} M_\nu(z) < 0\,, \tag{4.15}$$

where the terms $M_\nu(z)$ denote symmetric matrix-valued functions of the decision variable z that are linear in z. The notation $[\nu]$ is the vector of partial degrees $[\nu] = [\nu_1, \ldots, \nu_N]$ associated with the lexicographically ordered term

$$\theta^{[\nu]} = \theta_1^{\nu_1} \theta_2^{\nu_2} \ldots \theta_N^{\nu_N}\,,$$

with the convention $\theta^{[0]} = 1$. It is assumed that θ ranges over a hyperrectangle H as in (4.9). J is a set of N-tuples of partial degrees describing the polynomial expansion (4.15). Again exploiting Corollary 3.4, it is possible to reduce (conservatively) this problem to a finitely constrained LMI problem. The symbols d_k and d designate the partial and total degrees in the matrix polynomial expansion.

LEMMA 4.2. *Consider the PLMI* (4.15)*, where θ ranges over a hyperrectangle. Then the LMI conditions*

$$\mathcal{L}(\theta, z) < 0 \quad \forall \theta \in H \tag{4.16}$$

hold for some z, whenever the finite family of LMI conditions

$$\mathcal{L}(\theta, z) < 0 \quad \forall \theta \in \operatorname{vert} H, \tag{4.17}$$

$$(-1)^m \frac{\partial^{2m}}{\partial \theta_{l_1}^2 \ldots \partial \theta_{l_m}^2} \mathcal{L}(\theta, z) \le 0, \quad \forall \theta \in \operatorname{vert} H\,, \tag{4.18}$$

where

$$1 \le l_1 \le l_2 \le \cdots \le l_m \le N, \quad 1 \le m \le \frac{d}{2},$$

$$2\#\{l_j = k :\ j \in \{1, \ldots, m\}\} \le d_k, \quad k = 1, 2, \ldots, N,$$

are feasible for some z.

Proof. The proof is obtained by a repeated use of Corollary 3.4. ∎

As an example, consider the PLMI feasibility problem

$$\mathcal{L}(z, \theta) := M_0(z) + \theta_1^2 \theta_2 M_{112}(z) + \theta_2^3 M_{222}(z) \ < \ 0, \qquad |\theta_i| \le 1\,.$$

Replacing this problem with, for instance,

$$\widetilde{\mathcal{L}}(z, \theta) := M_0(z) + \theta_1^2 \theta_2 M_{112}(z) + \theta_2^3 M_{222}(z) + \lambda_0 I + \lambda_1 \theta_1^2 I + \lambda_2 \theta_2^2 I \ < \ 0, \qquad |\theta_i| \le 1,$$

and using Lemma 4.2 yields the LMI conditions:

$$\widetilde{\mathcal{L}}(z, \theta) < 0 \quad \forall \theta \in \operatorname{vert} H$$

$$-\frac{\lambda_1}{2} I \le M_{112}(z) \le \frac{\lambda_1}{2} I, \qquad -\frac{\lambda_2}{3} I \le M_{222}(z) \le \frac{\lambda_2}{3} I, \quad \lambda_1 \ge 0, \quad \lambda_2 \ge 0\,.$$

It is of interest to note that when PLMIs also involve full-matrix parameters Δ_j, it is more appropriate for computational reasons to take advantage of a combined use of directional convexity concepts and of the **S**-procedure to formulate a feasibility test.

4.4. Algebraically constrained PLMI problems. PLMI problems with algebraic constraints are described as

$$\mathcal{L}(z,\theta) < 0 \quad \forall \theta \in H \tag{4.19}$$

subject to

$$g_1(\theta) = 0, \ldots, g_q(\theta) = 0\,, \tag{4.20}$$

where $g_1, \ldots, g_q$ are polynomials in θ. Note that for consistency, the algebraic surface (4.20) should have a nonvoid intersection with the hypercube H.

It is readily verified that solutions to the unconstrained PLMI problem

$$\mathcal{L}(z,\theta) < \sum_{i=1}^{q} g_i(\theta)^2 \lambda_i I \quad \forall \theta \in H, \tag{4.21}$$

$$\lambda_i \geq 0, \quad i = 1, \ldots, q, \tag{4.22}$$

also solve (4.19)–(4.20). Recast as the sufficient conditions (4.21)–(4.22), the hard problem (4.19)–(4.20) can be handled with the technical machinery developed in section 4 and is therefore amenable to a conventional LMI problem. Once again, there is some practically useful flexibility for selecting the right-hand side of the first inequality in (4.21).

4.5. Linear objective minimization under PLMI constraints. The directional convexity concepts introduced previously are applicable with minor changes to linear objective minimization problems subject to PLMI constraints. This means problems of the form

$$\begin{array}{c} \text{minimize } c^T z \\ \text{subject to } \mathcal{L}(z,\theta) < 0, \quad \theta \in H\,, \end{array} \tag{4.23}$$

where c is a given vector and the inequalities constitute a PLMI constraint. It is also possible to handle min-max problems of the form

$$\begin{array}{c} \text{minimize } \max\limits_{\theta \in H} c(\theta)^T z \\ \text{subject to } \mathcal{L}(z,\theta) < 0, \quad \theta \in H\,, \end{array} \tag{4.24}$$

using standard manipulations [4, 29]. Defining

$$\widetilde{z} = \begin{bmatrix} z \\ \lambda \end{bmatrix}, \ \widetilde{c} = \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \ \widetilde{\mathcal{L}}(\widetilde{z},\theta) = \begin{bmatrix} \mathcal{L}(z,\theta) & 0 \\ 0 & c(\theta)^T z - \lambda \end{bmatrix},$$

problem (4.24) is equivalently formulated as

$$\begin{array}{c} \text{minimize } \widetilde{c}^T \widetilde{z} \\ \text{subject to } \widetilde{\mathcal{L}}(\widetilde{z},\theta) < 0, \quad \theta \in H\,, \end{array} \tag{4.25}$$

which has a form similar to problem (4.23).

In this form, provided that the parameter dependence is polynomial, such problems are easily converted into standard LMI problems using directional convexity concepts. This is left to the reader. Finally, we note that since these concepts amount to shrinking the z-feasible set, the optimal value of the relaxed LMI optimization problem is an upper bound for problems (4.23) and (4.24).

5. Applications in control theory. The techniques and tools presented in sections 3 and 4 enjoy a wide scope of applications. They are useful for the analysis of both the stability and the performance of uncertain systems. Potentially, all Lyapunov-based stability and performance measures can be handled with the proposed techniques which are more general and less conservative than single quadratic function approaches [7, 3]. They also have implications in the context of μ analysis where some upper bounds can be refined into less conservative upper bounds. Another important domain of application concerns LPV control techniques. For brevity, we only report a few of these applications.

5.1. Robust stability. We consider the linear uncertain system

$$\dot{x} = A(\alpha)x, \qquad A(\alpha) := \alpha_1 A_1 + \cdots + \alpha_L A_L\,, \tag{5.1}$$

where α is a fixed uncertain parameter evolving in the simplex (4.3). It follows that the uncertain matrix $A(\alpha)$ ranges over a matrix polytope

$$A(\alpha) \in \text{co}\,\{A_1, \ldots, A_L\}\,.$$

We are seeking a quadratic parameter-dependent Lyapunov function with similar structure,

$$V(x,\alpha) := x^T\,(\,\alpha_1 X_1 + \cdots + \alpha_L X_L\,)\,x,$$

establishing stability of the uncertain system for all admissible dynamics. If we make explicit the Lyapunov conditions for stability

$$V(x,\alpha) > 0, \quad \frac{d}{dt}V(x,\alpha) < 0 \qquad \forall x \neq 0\,,$$

we obtain

$$\begin{aligned} \alpha_1 X_1 + \cdots + \alpha_L X_L &> 0, \\ A(\alpha)^T(\alpha_1 X_1 + \cdots + \alpha_L X_L) + (\alpha_1 X_1 + \cdots + \alpha_L X_L)A(\alpha) &< 0\,, \end{aligned}$$

which constitutes a PLMI problem. Thus, Proposition 4.1 can be used to convert the problem into a finite number of LMI feasibility conditions. The following sufficient test for robust stability is derived.

PROPOSITION 5.1. *Assume one of the A_i's is stable. Then, the uncertain system* (5.1) *is stable whenever there exist symmetric matrices $X_1, \ldots, X_L$ and scalars $\lambda_1, \ldots, \lambda_L$ such that the following LMI conditions hold for $k = 1, \ldots, L$ and $1 \le i < j \le L$:*

$$\begin{aligned} A_k^T X_k + X_k A_k &< -\lambda_k I, \\ A_i^T X_i + X_i A_i + A_j^T X_j + X_j A_j - (A_i^T X_j + X_j A_i + A_j^T X_i + X_i A_j) &\ge -(\lambda_i + \lambda_j) I, \\ \lambda_k &\ge 0\,. \end{aligned}$$

In such case, the Lyapunov function $V(x,\alpha)$ establishes stability of the uncertain system (5.1).

Proof. The above conditions ensure that $\frac{d}{dt}V(x,\alpha) < 0$ for all admissible values of the parameter. Moreover, $V(x,\alpha)$ is a candidate Lyapunov function since at least one of the A_i's is stable, and since $\alpha_1 X_1 + \cdots + \alpha_L X_L$ cannot be singular, we infer that $\alpha_1 X_1 + \cdots + \alpha_L X_L > 0$ for all α in the simplex (4.3). ∎

5.2. Robust performance. As claimed earlier, the proposed techniques are potentially applicable to any Lyapunov-based performance measure. We illustrate this claim with the H_2 performance criterion. See [9] for a Lyapunov characterization of the H_2 norm.

Consider the uncertain system

$$\begin{array}{rcl} \dot{x} & = & A(\alpha)x + B(\alpha)w, \\ z & = & C(\alpha)x, \end{array} \tag{5.2}$$

where

$$\begin{bmatrix} A(\alpha) & B(\alpha) \\ C(\alpha) & 0 \end{bmatrix} \in \text{co} \left\{ \begin{bmatrix} A_1 & B_1 \\ C_1 & 0 \end{bmatrix}, \ldots, \begin{bmatrix} A_L & B_L \\ C_L & 0 \end{bmatrix} \right\}.$$

By virtue of Proposition 4.1, and paralleling the argument in Proposition 5.1, we deduce that the H_2 norm from w to z of the uncertain system (5.2) is bounded by ν for all values of α in the simplex (4.3) whenever there exist symmetric matrices $X_1, \ldots, X_L$, Q and scalars $\lambda_1, \ldots, \lambda_L$ such that the following LMI conditions hold:

$$\begin{array}{rcl} U_k(X_k) & < & -\lambda_k I, \\ V_i(X_i) + V_j(X_j) - (V_i(X_j) + V_j(X_i)) & \geq & -(\lambda_i + \lambda_j) I, \\ \lambda_k \geq 0, \quad \begin{bmatrix} P_k & C_k^T \\ C_k & Q \end{bmatrix} > 0, \quad \text{Tr}\, Q & < & \nu \end{array}$$

for $k = 1, \ldots, L$ and $1 \leq i < j \leq L$, with the definitions

$$U_i(X_j) := \begin{bmatrix} A_i^T X_j + X_j A_i & X_j B_i \\ B_i^T X_j & -I \end{bmatrix}, \quad V_i(X_j) := \begin{bmatrix} A_i^T X_j + X_j A_i & X_j B_i \\ B_i^T X_j & 0 \end{bmatrix}.$$

Extensions and reformulations for time-varying uncertain parameters, pole clustering in LMI regions, H_∞ and passivity constraints, and many others are straightforward. When the dependence on the parameter is polynomial, the same line of attack is still valid with the assistance of Lemma 4.2.

5.3. μ analysis. The structured singular value (SSV) or μ is an important linear algebra tool to study a class of matrix perturbation problems [11, 12, 36]. Since many robust stability/performance problems can be recast as one of computing μ with respect to an appropriate block-diagonal structure, it is also particularly useful in control theory and practice. The computation of μ involves an optimization problem which is not convex and is known to be NP-complete [32], so that it is difficult to compute μ exactly. Fortunately, it is possible to compute lower and upper bounds for μ with reasonable computational effort [13, 46]. This is the approach considered in this section.

The computation of μ can be formulated as computing the smallest norm perturbation for which the matrix $I - \Delta M$ becomes singular, where M denotes the plant's transfer function at some given frequency and Δ stands for uncertainties which are generally assumed to have a specific block-diagonal structure. In this section, we assume without loss of generality that uncertainties are real, $\Delta_{ij} \in \mathbf{R}$, and range over a polytope

$$\Delta \in \text{co}\, \{\Delta_1, \ldots, \Delta_L\}.$$

Extensions to mixed real/complex uncertainties are readily derived.

Our goal is to determine sufficient conditions for which $I - \Delta M$ remains nonsingular for all admissible uncertainties. Our approach is inspired by the work in [15, 26] and goes as follows. A necessary and sufficient condition for the nonsingularity of $(I - \Delta M)$ is the existence of a parameter-dependent matrix $F(\Delta)$, such that

$$F(\Delta)(I - \Delta M) + (I - \Delta M)^* F(\Delta)^* < 0\,. \tag{5.3}$$

The awkward condition (5.3) is simplified by restricting the search of $F(\Delta)$ matrices to those having the form

$$F(\Delta) := \sum_{i=1}^{L} \alpha_i F_i\,,$$

where the α_i's are the coordinates of Δ in the convex decomposition

$$\Delta := \sum_{i=1}^{L} \alpha_i \Delta_i\,.$$

With these restrictions, it is not difficult to see that inequality (5.3) takes a form similar to (4.2), that is, a PLMI feasibility problem. Therefore, by a direct application of Proposition 4.1 or its refined version (4.6)–(4.8), sufficient conditions for the nonsingularity of $I - \Delta M$ express as the existence of suitably dimensioned complex matrices F_1, $F_2, \ldots$, F_L such that

$$\begin{array}{rcl} F_k + F_k^* - (F_k \Delta_k M + (F_k \Delta_k M)^*) & < & -\lambda_k I, \\ (F_i \Delta_i M + F_j \Delta_j M) - (F_i \Delta_j M + F_j \Delta_i M) + (\star)^* & \leq & (\lambda_i + \lambda_j) I, \\ \lambda_k & \geq & 0\,. \end{array}$$

This new upper bound for μ reduces to the upper bound proposed by Fu and Barabanov in [15] when $F = F_1 = \cdots = F_L$; thus it is less conservative but also more costly. It is also less conservative than the more classical upper bound in [13], as is easily proved by choosing $F = F_1 = \cdots = F_L = -D - jM^*G$. A similar approach, though somewhat more conservative, has been proposed by Chen and Sugie in [10].

5.4. Linear parameter-varying control. In this section, we more thoroughly investigate how the concepts and tools introduced can be utilized in the context of LPV control. For clarity, we recall the general statement of the problem.

We are considering an LPV plant with state-space realization

$$\begin{array}{rcl} \dot{x} & = & A(\theta)x + B_1(\theta)w + B_2(\theta)u, \\ z & = & C_1(\theta)x + D_{11}(\theta)w + D_{12}(\theta)u, \\ y & = & C_2(\theta)x + D_{21}(\theta)w\,, \end{array} \tag{5.4}$$

where

$$A \in \mathbf{R}^{n \times n}, \quad D_{12} \in \mathbf{R}^{p_1 \times m_2}, \qquad \text{and} \quad D_{21} \in \mathbf{R}^{p_2 \times m_1}$$

define the problem dimension. It is assumed that

(A1) the state-space data $A(\theta)$, $B_1(\theta), \ldots$ are bounded continuous functions of θ,

(A2) the time-varying parameter $\theta(t) := [\theta_1(t), \ldots, \theta_N(t)]^T$ and its rate of variation $\dot{\theta}(t)$, defined at all times and continuous, evolve in hyperrectangles H and H_d, that is,

$$\theta_i(t) \in [\underline{\theta}_i, \bar{\theta}_i] \quad \forall t \geq 0\,, \tag{5.5}$$

$$\dot{\theta}_i(t) \in [\underline{\nu}_i, \bar{\nu}_i] \quad \forall t \geq 0\,. \tag{5.6}$$

The assumptions (A1) and (A2) are general. They secure existence and uniqueness of the solutions to (5.4) for given initial conditions and also specify the parameter trajectories under consideration.

With these assumptions in place, the general LPV control problem with guaranteed L_2-gain performance consists of finding a dynamic LPV controller with state-space equations

$$\begin{array}{rcl} \dot{x}_K & = & A_K(\theta,\dot{\theta})x_K + B_K(\theta,\dot{\theta})y, \\ u & = & C_K(\theta,\dot{\theta})x_K + D_K(\theta,\dot{\theta})y, \end{array} \tag{5.7}$$

which ensures internal stability and a guaranteed L_2-gain bound γ for the closed-loop operator (5.4)–(5.7) from the disturbance signal w to the error signal z, that is,

$$\int_0^T z^T z\, d\tau \le \gamma^2 \int_0^T w^T w\, d\tau \quad \forall T \ge 0$$

for all admissible parameter trajectories $\theta(t)$.

Sufficient solvability conditions for this problem can be derived using a suitable extension of the bounded real lemma [44] and by confining the search of (Lyapunov) variables to some finite-dimensional subspace of functions of θ. The next theorem provides such a set of conditions for the general LPV control problem. An alternative approach, based on polytopic covering techniques, is proposed by Yu and Sideris in [47]. For technical reasons that are clarified in the proof, we also assume that

(A3) the matrices $[\, B_2^T(\theta) \quad D_{12}^T(\theta)\,]$, $[\, C_2(\theta) \quad D_{21}(\theta)\,]$ have full row-rank over H.

Note that the dependence of data and variables on θ, or $\dot{\theta}$, is generally dropped for simplicity.

THEOREM 5.2. *With the assumptions* (A1)–(A3) *in force, the following conditions are equivalent:*

(i) *The bounded real lemma conditions with L_2-gain performance level γ hold for some quadratic Lyapunov function*

$$V(x,x_K,\theta) := \begin{bmatrix} x \\ x_K \end{bmatrix}^T P(\theta) \begin{bmatrix} x \\ x_K \end{bmatrix},$$

where $P(\theta)$ is continuously differentiable, and for some LPV controller (5.7).

(ii) *There exist continuously differentiable parameter-dependent symmetric matrices $X(\theta)$ and $Y(\theta)$ such that the following PLMI problem is feasible:*

$$\left[\begin{array}{c|c} \mathcal{N}_X & 0 \\ \hline 0 & I \end{array}\right]^T \left[\begin{array}{cc|c} \dot{X}+XA+A^TX & XB_1 & C_1^T \\ B_1^TX & -\gamma I & D_{11}^T \\ \hline C_1 & D_{11} & -\gamma I \end{array}\right] \left[\begin{array}{c|c} \mathcal{N}_X & 0 \\ \hline 0 & I \end{array}\right] < 0, \tag{5.8}$$

$$\left[\begin{array}{c|c} \mathcal{N}_Y & 0 \\ \hline 0 & I \end{array}\right]^T \left[\begin{array}{cc|c} -\dot{Y}+YA^T+AY & YC_1^T & B_1 \\ C_1Y & -\gamma I & D_{11} \\ \hline B_1^T & D_{11}^T & -\gamma I \end{array}\right] \left[\begin{array}{c|c} \mathcal{N}_Y & 0 \\ \hline 0 & I \end{array}\right] < 0, \tag{5.9}$$

$$\begin{bmatrix} X & I \\ I & Y \end{bmatrix} > 0 \tag{5.10}$$

for all $(\theta,\dot{\theta})$ on $H \times H_d$ and where $\mathcal{N}_X$ and $\mathcal{N}_Y$ designate any bases of the nullspaces of $[\, C_2 \quad D_{21}\,]$ and $[\, B_2^T \quad D_{12}^T\,]$, respectively.

(iii) *There exist continuously differentiable parameter-dependent symmetric matrices* $X(\theta)$ *and* $Y(\theta)$ *and a scalar* σ *solving the PLMI problem:*

$$\begin{bmatrix} \dot{X}+XA+A^TX & XB_1 & C_1^T \\ B_1^TX & -\gamma I & D_{11}^T \\ C_1 & D_{11} & -\gamma I \end{bmatrix} - \sigma \begin{bmatrix} C_2^T \\ D_{21}^T \\ 0 \end{bmatrix} \begin{bmatrix} C_2 & D_{21} & 0 \end{bmatrix} < 0, \tag{5.11}$$

$$\begin{bmatrix} -\dot{Y}+YA^T+AY & YC_1^T & B_1 \\ C_1Y & -\gamma I & D_{11} \\ B_1^T & D_{11}^T & -\gamma I \end{bmatrix} - \sigma \begin{bmatrix} B_2 \\ D_{12} \\ 0 \end{bmatrix} \begin{bmatrix} B_2^T & D_{12}^T & 0 \end{bmatrix} < 0\,, \tag{5.12}$$

$$\begin{bmatrix} X & I \\ I & Y \end{bmatrix} > 0 \tag{5.13}$$

for all $(\theta, \dot{\theta})$ *on* $H \times H_d$.

Proof. See Appendix A. □

Equipped with Theorem 5.2, it is relatively straightforward to show how multiconvexity concepts can be used to reduce complexity in LPV control problems with polynomial parameter-dependence.

For simplicity of the presentation, it is first assumed the the state-space data in (5.4) and the Lyapunov variables are affine functions of the parameter θ, that is,

$$A(\theta) := A_0 + \sum_{i=1}^{N} \theta_i A_i, \quad B_1(\theta) := B_{10} + \sum_{i=1}^{N} \theta_i B_{1i} \ \ \ldots. \tag{A4}$$

THEOREM 5.3. *With the assumptions* (A1)–(A4) *above, there exists an LPV controller* (5.7) *solution to the LPV control problem with guaranteed* L_2*-gain performance with level* γ *whenever there exist symmetric matrices* X_0, $X_1, \ldots, X_N$ *and* Y_0, $Y_1, \ldots,$ Y_N *and scalars* λ_0, $\lambda_1, \ldots \lambda_N$, μ_0, $\mu_1, \ldots \mu_N$, *and* σ *such that*

$$\begin{bmatrix} \dot{X}+XA+A^TX & XB_1 & C_1^T \\ B_1^TX & -\gamma I & D_{11}^T \\ C_1 & D_{11} & -\gamma I \end{bmatrix} - \sigma \begin{bmatrix} C_2^T \\ D_{21}^T \\ 0 \end{bmatrix} \begin{bmatrix} C_2 & D_{21} & 0 \end{bmatrix} < -\left(\lambda_0 + \sum_{i=1}^{N} \theta_i^2 \lambda_i\right) I, \tag{5.14}$$

$$\begin{bmatrix} -\dot{Y}+YA^T+AY & YC_1^T & B_1 \\ C_1Y & -\gamma I & D_{11} \\ B_1^T & D_{11}^T & -\gamma I \end{bmatrix} - \sigma \begin{bmatrix} B_2 \\ D_{12} \\ 0 \end{bmatrix} \begin{bmatrix} B_2^T & D_{12}^T & 0 \end{bmatrix} < -\left(\mu_0 + \sum_{i=1}^{N} \theta_i^2 \mu_i\right) I, \tag{5.15}$$

$$\begin{bmatrix} X & I \\ I & Y \end{bmatrix} > 0 \tag{5.16}$$

for $(\theta, \dot{\theta}) \in \operatorname{vert} H \times \operatorname{vert} H_d$ *and*

$$\begin{bmatrix} X_iA_i + A_i^TX_i & X_iB_{1i} \\ B_{1i}^TX_i & 0 \end{bmatrix} - \sigma \begin{bmatrix} C_{2i}^TC_{2i} & C_{2i}^TD_{21i} \\ D_{21i}^TC_{2i} & D_{21i}^TD_{21i} \end{bmatrix} \geq -\lambda_i I, \tag{5.17}$$

$$\begin{bmatrix} Y_iA_i^T + A_iY_i & Y_iC_{1i}^T \\ C_{1i}Y_i & 0 \end{bmatrix} - \sigma \begin{bmatrix} B_{2i}B_{2i}^T & B_{2i}D_{12i}^T \\ D_{12i}B_{2i}^T & D_{12i}D_{12i}^T \end{bmatrix} \geq -\mu_i I\,, \tag{5.18}$$

and

$$\lambda_0 \geq 0, \quad \lambda_i \geq 0, \quad \mu_0 \geq 0, \quad \mu_i \geq 0 \tag{5.19}$$

for $i = 1, \ldots, N$ with the notations

$$X := X_0 + \sum_{i=1}^{N} \theta_i X_i, \qquad Y := Y_0 + \sum_{i=1}^{N} \theta_i Y_i \,.$$

Proof. The proof is a direct consequence of Theorem 5.2 combined with an application of Proposition 4.1 or Lemma 4.2 to the particular case where data and variables are affine with respect to θ. ∎

Remarks. The conditions in Theorem 5.3 constitute a standard semidefinite programming problem. The linear objective γ should be minimized subject to a finite number of LMI constraints, and a number of softwares are available for this purpose. The characterization is easily modified to encompass any polynomial parameter dependence for both the state-space data and the variables $X(\theta)$ and $Y(\theta)$ by direct application of Lemma 4.2. The multiconvexity requirements in (5.17) and (5.18) can be relaxed using the simple techniques in section 4. When either the multiconvexity approach is too conservative or brute force gridding of the parameter range is too costly (more than two parameters), it might be appropriate to enforce multiconvexity along some direction and to grid a surface of lower dimension. See the examples in section 6 for illustrations.

5.4.1. LPV controller construction. The PLMI conditions (ii) and (iii) in Theorem 5.2 are equivalent and provide lossless solvability conditions for problem (i). The characterization in Theorem 5.3 may be conservative but give tractable conditions for solving the same problem. Clearly, when any of the latter problems is feasible, the state-space data (5.7) of an LPV controller solving the problem can be constructed for any pair $(\theta, \dot\theta)$ in $H \times H_d$ from any solutions $X(\theta)$, $Y(\theta)$, and σ by the very same algebraic formulae. For completeness, we provide the following sequential scheme:

(i) Compute D_K solution to

$$\overline{\sigma}(D_{11} + D_{12} D_K D_{21}) < \gamma, \tag{5.20}$$

and set $D_{c\ell} := D_{11} + D_{12} D_K D_{21}$.

(ii) Compute $\widehat{\boldsymbol{B}}_K$ and $\widehat{\boldsymbol{C}}_K$ solutions to the linear matrix equations

$$\begin{bmatrix} 0 & D_{21} & 0 \\ D_{21}^T & -\gamma I & D_{c\ell}^T \\ 0 & D_{c\ell} & -\gamma I \end{bmatrix} \begin{bmatrix} \widehat{\boldsymbol{B}}_K^T \\ \star \end{bmatrix} = - \begin{bmatrix} C_2 \\ B_1^T X \\ C_1 + D_{12} D_K C_2 \end{bmatrix}, \tag{5.21}$$

$$\begin{bmatrix} 0 & D_{12}^T & 0 \\ D_{12} & -\gamma I & D_{c\ell} \\ 0 & D_{c\ell}^T & -\gamma I \end{bmatrix} \begin{bmatrix} \widehat{\boldsymbol{C}}_K \\ \star \end{bmatrix} = - \begin{bmatrix} B_2^T \\ C_1 Y \\ (B_1 + B_2 D_K D_{21})^T \end{bmatrix}. \tag{5.22}$$

(iii) Compute

$$\begin{aligned} \widehat{\boldsymbol{A}}_K \; &= - (A + B_2 D_K C_2)^T \\ &+ \begin{bmatrix} X B_1 + \widehat{\boldsymbol{B}}_K D_{21} & (C_1 + D_{12} D_K C_2)^T \end{bmatrix} \begin{bmatrix} -\gamma I & D_{c\ell}^T \\ D_{c\ell} & -\gamma I \end{bmatrix}^{-1} \begin{bmatrix} (B_1 + B_2 D_K D_{21})^T \\ C_1 Y + D_{12} \widehat{\boldsymbol{C}}_K \end{bmatrix}. \end{aligned} \tag{5.23}$$

(iv) Solve for N, M, the factorization problem

$$I - XY = N M^T \,.$$

(v) Finally, compute A_K, B_K, and C_K with the help of

$$A_K = N^{-1}(X\dot{Y} + N\dot{M}^T + \widehat{\boldsymbol{A}}_K - X(A - B_2 D_K C_2)Y - \widehat{\boldsymbol{B}}_K C_2 Y - X B_2 \widehat{\boldsymbol{C}}_K) M^{-T}, \tag{5.24}$$

$$B_K = N^{-1}(\widehat{\boldsymbol{B}}_K - X B_2 D_K), \tag{5.25}$$

$$C_K = (\widehat{\boldsymbol{C}}_K - D_K C_2 Y) M^{-T}. \tag{5.26}$$

The reader might consult [17, 16, 22, 37, 1] for details on this construction.

6. Numerical examples. In this section, the concepts and tools developed above are illustrated by some numerical examples. All LMI-related computations were performed on an ULTRA 1 SUN station using the LMI control toolbox [19].

6.1. Stability analysis. We consider the following example from [39]. The A matrix of the uncertain system is given in the form

$$A(\theta_1, \theta_2) = \begin{bmatrix} -2+\theta_1 & 0 & -1+\theta_1 \\ 0 & -3+\theta_2 & 0 \\ -1+\theta_1 & -1+\theta_2 & -4+\theta_1 \end{bmatrix}.$$

We are seeking the maximum rectangle in the (θ_1, θ_2) space for which stability is guaranteed. In this context, Proposition 5.1 is directly applicable to the polytope of extreme values of the parameters θ_1 and θ_2. The uncertain system is found stable for all values of θ_1 and θ_2 in the rectangle

$$-1e6 \le \theta_1 \le 1.7499, \qquad -1e6 \le \theta_2 \le 2.99\,.$$

This result is consistent with the true domain of stability ($\theta_1 < 1.75$, $\theta_2 < 3$) and is markedly superior to existing results [39].

6.2. LPV synthesis example. The following example provides an illustration of the proposed LPV control synthesis techniques. The discussion emphasizes the complexity and cost associated with various LPV synthesis strategies. The problem setup comes from [33]. It has been slightly complicated to incorporate two time-varying parameters for illustration purposes while retaining the same design specifications.

The LPV model of the longitudinal dynamics of the missile is given as

$$\begin{bmatrix} \dot{\alpha} \\ \dot{q} \end{bmatrix} = \begin{bmatrix} -0.89 & 1 \\ -142.6 & \end{bmatrix} \begin{bmatrix} \alpha \\ q \end{bmatrix} + \begin{bmatrix} 0 & -0.89 \\ 178.25 & 0 \end{bmatrix} \begin{bmatrix} w_{\theta_1} \\ w_{\theta_2} \end{bmatrix} + \begin{bmatrix} -0.119 \\ -130.8 \end{bmatrix} \delta_{\text{fin}},$$

$$\begin{bmatrix} w_{\theta_1} \\ w_{\theta_2} \end{bmatrix} = \begin{bmatrix} \theta_1 & 0 \\ 0 & \theta_2 \end{bmatrix} \begin{bmatrix} -1 & 0 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} \alpha \\ q \end{bmatrix},$$

$$\begin{bmatrix} \eta_z \\ q \end{bmatrix} = \begin{bmatrix} -1.52 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} \alpha \\ q \end{bmatrix},$$

where α, q, η_z, and δ_{fin} denote the angle of attack, the pitch rate, the vertical accelerometer measurement, and the fin deflection, respectively; and θ_1, θ_2 are two time-varying parameters, measured in real time, resulting from changes in missile aerodynamic conditions (angle of attack from 0 up to 20 degrees). The synthesis structure used in this problem is depicted in Figure 6.1.

The problem specifications are as follows:

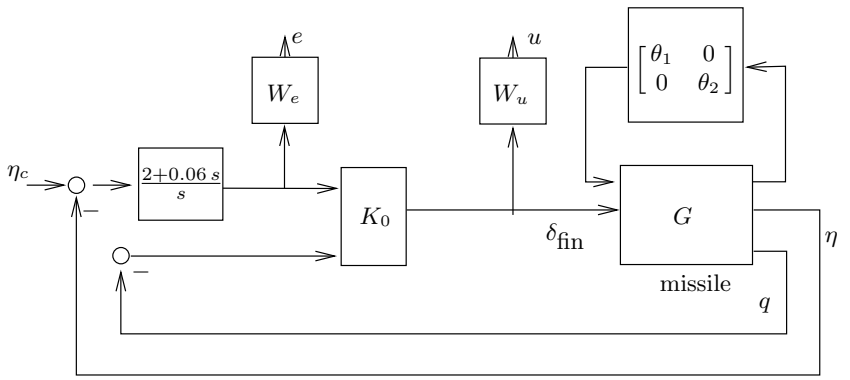

FIG. 6.1. *Synthesis structure.*

(i) A settling time of 0.2 second with minimal overshoot and zero steady-state error for the vertical acceleration η_z in response to a step command η_c.

(ii) The controller must achieve an adequate high-frequency roll-off for noise attenuation and to withstand neglected dynamics and flexible modes. Magnitude constraints of 2 are also imposed to the control signal δ_{fin}.

Moreover, those specifications must be met for all parameter values:

$$|\theta_1| \le 1, \qquad |\theta_2| \le 1\,.$$

An integrator has been introduced on the acceleration channel to ensure zero steady-state error. It turns out that the resulting LPV controller K is obtained as the composition of the operators K_0 and

$$\begin{bmatrix} \frac{2+0.06\,s}{s} & 0 \\ 0 & 1 \end{bmatrix}.$$

The weighting functions W_e and W_u were chosen to be

$$W_e = 0.8, \qquad W_u = \frac{0.001s^3 + 0.03s^2 + 0.3s + 1}{\text{1e-5}s^3 + \text{3e-2}s^2 + 30s + 10000}\,.$$

The design synthesis consists of the computation of a parameter-dependent controller $K_0(\theta_1, \theta_2)$ such that all specifications above are met. For simplicity of the discussion, we assume that the LPV model can be considered as a parameterized family of linear time-varying models. Similar conclusions can be drawn with time-varying parameters with bounded rates of variation. The synthesis problem is attacked via three different strategies with increasing conservatism and decreasing computational effort:

(i) The full gridding approach makes use of a 6×6 point gridding of the parameter range of (θ_1, θ_2).

(ii) The mixed strategy uses a grid in the θ_2 direction and enforces multiconvexity along the θ_1 direction.

(iii) The multiconvexity approach enforces multiconvexity in both directions θ_1 and θ_2.

Results and numerical features of each technique are collected in Table 6.1.

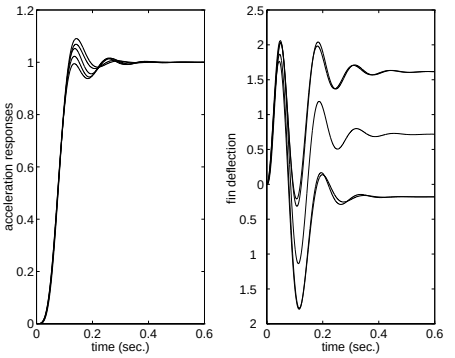

FIG. 6.2. *Time domain responses—LPV controller* 1 *full-gridding technique.*

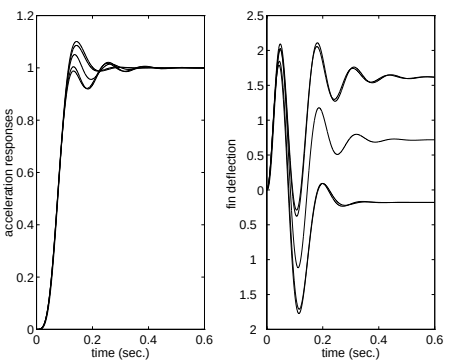

FIG. 6.3. *Time domain responses—LPV controller* 2 *mixed technique.*

TABLE 6.1
Numerical comparisons of LPV synthesis techniques.

	# of gridding points	# of LMIs	cputime	Achieved perf. level
Full gridding	36	108	17 min. 24 sec.	0.1265
Mixed strategy	12	30	6 min. 20 sec.	0.1282
Multiconvexity	0	16	3 min. 12 sec.	0.1293

It is instructive to see that all techniques provide about the same performance level. This indicates that there is no significant growth of conservatism when using multiconvexity concepts to reduce or eradicate the gridding points. This is confirmed by the time-domain simulations in Figures 6.2–6.4, which correspond, for each derived LPV controller, to parameter values at the vertices and the center of the (θ_1, θ_2) range. Performance specs, as well as the roll-off property of the controllers, have been found to be satisfactory for each technique. In spite of the consistency in the results, it must be born in mind that the multiconvex synthesis is the only one to provide theoretical stability and performance guarantees at any operating condition of the parameter range. The full-gridding technique gives similar guarantees solely at the grid points, and the achieved performance γ is necessarily a lower bound of the actual performance. The situation is slightly more embarrassing for the mixed strategy since the performance level is overestimated in the direction of θ_2 and underestimated in the

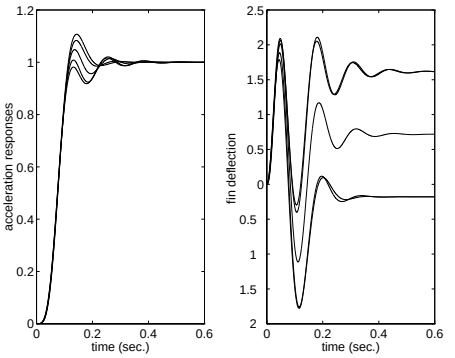

FIG. 6.4. *Time domain responses—LPV controller* 3 *multiconvexity technique.*

direction of θ_1. So we cannot decide whether the result is conservative or optimistic on the whole parameter range. Nevertheless, the approach is of practical interest for computational reasons. It appears clearly in Table 6.1 that LPV syntheses exploiting either partial or complete multiconvexity are significantly cheaper than full-gridding techniques. This difference is likely to be even more dramatic for problems involving more than two parameters for which full gridding is practically prohibited. This is a direct consequence of the exponential growth of the number of LMIs in the full-gridding approach. Note that we do not account for scalar dimensional constraints of the type λ_i, $\mu_i \geq 0$ in Table 6.1, as they negligibly affect the overall computational time.

Any of the LPV synthesis techniques considered in this section turn out to be less conservative than linear fractional transformation (LFT) gain-scheduling techniques [30, 2, 20, 38] which disregard the parameter variation rates. About 10 percent degradation of the performance level has been observed in this simple application. Finally, the techniques behave as theoretically expected and provide valuable LPV synthesis alternatives.

7. Conclusion. A general framework for relaxing PLMI problems into conventional LMI problems has been introduced. The techniques are simple and exploit or enforce directional convexity properties of PLMI problems. A nonexhaustive list of implications of the proposed techniques in control theory have been examined with a particular focus on LPV synthesis, a most important emerging technique in recent years.

This work raises some open questions, some of which might be beyond reach, but also suggests some directions for future research:

(i) For affine PLMI problems, directional convexity concepts are less conservative than the **S**-procedure but a theoretical comparison is still lacking in the general case. From the viewpoint of computational efforts, one can hardly draw definitive conclusions but the proposed approach is better exploited by using primal SDP interior-point techniques since it involves less decision variables than the **S**-procedure. We note experimentally that the multiconvexity approach is more efficient for problems with significantly more states than parameters, which is a common situation in control applications.

(ii) An unsolved issue is the following: Is it possible to exploit directional quasi-convexity instead of directional convexity for some classes of PLMI problems?

(iii) Other topics not examined in this paper and for which the proposed techniques might prove useful are robust least-squares and robust interpolation and approximation. The relaxation of some intractable generic robust convex programs is also of interest.

Appendix A. Proof of Theorem 5.2. Following [44], the LPV control problem with guaranteed L_2-gain performance γ is solvable whenever one can find an LPV controller such that a suitable extension of the bounded real lemma is satisfied with a quadratic parameter-dependent Lyapunov function, continuously differentiable with respect to θ. This is nothing else than statement (i) of the theorem.

In turn, the latter conditions are equivalent to the existence of continuously parameter-dependent symmetric matrices $X(\theta)$ and $Y(\theta)$ such that LMI conditions (5.8)–(5.10) hold for all $(\theta, \dot{\theta})$ on $H \times H_d$. This assertion is a slight extension of the main result in [44, 17, 22]. Assume a (closed-loop) Lyapunov function establishing L_2-gain performance is

$$V(x, x_K, \theta) := \begin{bmatrix} x \\ x_K \end{bmatrix}^T P(\theta) \begin{bmatrix} x \\ x_K \end{bmatrix},$$

where

$$P := \begin{bmatrix} X & N \\ N^T & \star \end{bmatrix} \quad \text{and} \quad P^{-1} := \begin{bmatrix} Y & M \\ M^T & \star \end{bmatrix}.$$

It trivially holds that

$$I - XY = NM^T.$$

Then, defining

$$\Pi_Y := \begin{bmatrix} Y & I \\ M^T & 0 \end{bmatrix}, \qquad \Pi_X := \begin{bmatrix} I & X \\ 0 & N^T \end{bmatrix}$$

yields the identities $P\Pi_Y = \Pi_X$, and

$$\Pi_Y^T \frac{d}{dt} P \Pi_Y = \begin{bmatrix} -\dot{Y} & -(X\dot{Y} + N\dot{M}^T)^T \\ -(X\dot{Y} + N\dot{M}^T) & \dot{X} \end{bmatrix},$$

which is the only additional term with respect to the customary H_∞ control problem in [17]. This establishes statement (ii).

To prove assertion (iii), we first note that the rates of variation $\dot{\theta}_i$ are involved linearly in (5.8) and (5.9), and thus it suffices to assess feasibility of these LMIs over $H \times \operatorname{vert} H_d$. By virtue of Finsler's lemma [31, 22], the LMIs (5.8)–(5.9) with $(\theta, \dot{\theta})$ ranging over $H \times \operatorname{vert} H_d$ are feasible if and only if there exists a function $\sigma(.)$ of θ such that

$$\begin{bmatrix} \dot{X} + XA + A^T X & XB_1 & C_1^T \\ B_1^T X & -\gamma I & D_{11}^T \\ C_1 & D_{11} & -\gamma I \end{bmatrix} - \sigma(\theta) \begin{bmatrix} C_2^T \\ D_{21}^T \\ 0 \end{bmatrix} \begin{bmatrix} C_2 & D_{21} & 0 \end{bmatrix} < 0, \tag{A.1}$$

$$\begin{bmatrix} -\dot{Y} + YA^T + AY & YC_1^T & B_1 \\ C_1 Y & -\gamma I & D_{11} \\ B_1^T & D_{11}^T & -\gamma I \end{bmatrix} - \sigma(\theta) \begin{bmatrix} B_2 \\ D_{12} \\ 0 \end{bmatrix} \begin{bmatrix} B_2^T & D_{12}^T & 0 \end{bmatrix} < 0. \tag{A.2}$$

Therefore, we end up with an infinite set of LMIs whose members are all of the form

$$\Psi(\theta) - \sigma(\theta) R(\theta) R(\theta)^T < 0, \qquad \theta \in H\,. \tag{A.3}$$

Denote $R_\perp$ a continuous basis of the nullspace of R^T. This is always possible [21, 25] by virtue of assumption (A3). It follows that $[\, R(\theta) \quad R_\perp(\theta)\,]$ is a continuous invertible matrix over H. With the *proviso* that the LMIs (A.3) are feasible, it is not difficult to see using Schur complements that admissible σ are described as

$$\sigma(\theta) > l(\theta) := \overline{\lambda}\left\{(R^T\Psi R - (R^T\Psi R_\perp)(R_\perp^T\Psi R_\perp)^{-1}(R^T\Psi R_\perp)^T)(R^T R R^T R)^{-1}\right\}, \quad \theta \in H, \tag{A.4}$$

where $\overline{\lambda}(.)$ stands for the maximum eigenvalue of a matrix. From the continuity of both the plant's state-space data (assumption (A1)) and the variables $X(\theta)$ and $Y(\theta)$, we deduce that $l(\theta)$ in (A.4) is also continuous with respect to θ. Now since H is a compact set, the choice

$$\sigma(\theta) := \sigma > \sup_{\theta \in H} l(\theta)$$

is again a valid choice for σ. It follows that the LMIs (A.1) and (A.2) are feasible if and only if this is so for a *constant* sufficiently large σ. This completes the proof of the theorem. □

PIERI HOMOTOPIES FOR PROBLEMS IN ENUMERATIVE GEOMETRY APPLIED TO POLE PLACEMENT IN LINEAR SYSTEMS CONTROL*

BIRKETT HUBER† AND JAN VERSCHELDE‡

Abstract. Huber, Sottile, and Sturmfels [*J. Symbolic Comput.*, 26 (1998), pp. 767–788] proposed Pieri homotopies to enumerate all p-planes in $\mathbb{C}^{m+p}$ that meet n given $(m+1-k_i)$-planes in general position, with $k_1+k_2+\cdots+k_n=mp$ as a condition to have a finite number of solution p-planes. Pieri homotopies turn the deformation arguments of classical Schubert calculus into effective numerical methods by expressing the deformations algebraically and applying numerical path-following techniques. We describe the Pieri homotopy algorithm in terms of a poset of simpler problems. This approach is more intuitive and more suitable for computer implementation than the original chain-oriented description and provides also a self-contained proof of correctness. We extend the Pieri homotopies to the quantum Schubert calculus problem of enumerating all polynomial maps of degree q into the Grassmannian of p-planes in $\mathbb{C}^{m+p}$ that meet $mp+q(m+p)$ given m-planes in general position sampled at $mp+q(m+p)$ interpolation points. Our approach mirrors existing counting methods for this problem and yields a numerical implementation for the dynamic pole placement problem in the control of linear systems.

Key words. cheater's homotopy, combinatorial root count, continuation methods, control theory, dynamic pole placement problem, enumerative geometry, Grassmannian, linear system, localization pattern, numerical Schubert calculus, Pieri homotopy, polynomial system, poset, quantum Schubert calculus

1. Introduction.

A general method to solve geometric problems proceeds by moving the input data to a special position, solving the special configuration, and then deforming the solutions of the special problem into those of the original configuration. As long as the number of solutions remains finite, this number is constant during deformation. This principle of "conservation of number" was developed by Pieri [27], Schubert [34], and Zeuthen [50].

A classical example in enumerative geometry as explained in [18] consists of finding the two lines in projective 3-space that meet four given lines. More generally, we want to enumerate all p-planes in $\mathbb{C}^{m+p}$ that meet mp given m-planes. In the late nineteenth century, Schubert [35] established recursive and explicit formulas for the *number* of p-planes meeting a set of mp m-planes in general position. This problem was also treated by Pieri in [27]. In the early 1980s, Brockett and Byrnes [5] showed that these p-planes correspond to feedback laws which control a machine whose evolution is governed by a linear system of first-order differential equations. This problem of control theory [6], [10], [17], [48] is known as the (static) pole placement problem.

Based on his geometric proof of Pieri's formula [27], Sottile introduced intrinsic deformations in [38] to solve general intersection conditions given by n planes in general position of dimension $m+1-k_i$ for $i=1,2,\ldots,n$. The condition that $k_1+k_2+\cdots+k_n=mp$ guarantees a finite number of p-planes meeting those n given planes. In [16], Huber, Sottile, and Sturmfels reinterpreted these deformations as computational procedures. The resulting algorithm was called the Pieri homotopy algorithm.

Our understanding arose from a first implementation of the Pieri homotopy algorithm and yielded the notion of what we call a "localization pattern." We feel that this is the key concept in our derivation of the algorithm. It is the vehicle through which the combinatorial techniques for enumerating solutions are translated back into synthetic geometry and realized. Since our aim is to understand practical complexity issues, we excuse ourselves from the explicit use of Schubert varieties (as in [15]) in our description. Nevertheless we obtain a self-contained proof of correctness, independent of [16]. The backbone of our approach is the poset of localization patterns used to count the roots combinatorially [43]. We use this poset to set up the homotopies and to control the flow of data between them. Our current description of the algorithm in [16] is both simpler than the original and also more suitable for computer implementation.

A novel feature of this paper is the development of Pieri homotopies for the dynamic pole placement problem. The connection between this problem and the Schubert calculus was established by Rosenthal in [31] and further developed in [28], [29], [46], and [47]. We arrived at this generalization thanks to a hint by Sottile (explicitly pronounced in [40]) by reverse engineering the root counting procedure described in [30]. Given $mp+q(m+p)$ general m-planes in $\mathbb{C}^{m+p}$ sampled at $mp+q(m+p)$ interpolation points, we can compute all polynomial maps of degree q producing p-planes that meet those given m-planes at the prescribed interpolation points.

Other root counts for these enumerative problems are given in [4]. In [42], quantum Gröbner and SAGBI homotopies are derived. The adjective "quantum" refers to the important connections between this problem of enumerative geometry and physics [7], although as mentioned in [4], one could also speak of "modular" Schubert calculus because of the "modulo $(m+p)$" calculations. Another related problem is the eigenvalue completion problem [13]. We mention [3] as a recent alternative approach to the dynamic pole placement problem.

Homotopies for enumerative geometry are available in a separate module of the publicly available software PHCpack [44]. The Pieri homotopy algorithm consists of a combinatorial root count, the symbolic setup of the homotopies, and the tracing of the solution curves. This last stage accounts for most of the computational work and is achieved using numerical continuation methods. See [1], [22] for introductions to and [2], [19] for recent surveys of numerical continuation. Computational experience suggests that the Pieri homotopies perform better than the Gröbner and SAGBI homotopies described in [16]. An explanation for this might be that the Pieri homotopies are more finely tuned to the geometry of the intersection problem than these other, extrinsic methods. In addition we point out that those Gröbner and SAGBI homotopies are restricted to the hypersurface $(k_i=1)$ intersection conditions.

In our study of the Pieri homotopy algorithm, we first specialized the general description of [16] into the simpler case of hypersurface intersection conditions. Our presentation below reflects this progression from the special to the general. In the next section we show how to find the two lines in projective 3-space that meet four

given lines. This example is then generalized to hypersurface and general intersection conditions in the third and fourth sections. In the fifth section we describe our quantum Pieri homotopies and their use in solving the dynamic pole placement problem. The key step is the extension of our notion of localization patterns to degree q-maps of p-planes. The development of numerical algorithms for the pole placement problem is formulated as an open problem in [33]. At the end of this paper we list computational experiences to illustrate the efficiency of our solution method.

2. The geometry of the Pieri deformations. We can illustrate the geometry of the Pieri deformations on the simplest example of determining the two lines meeting four given lines in projective 3-space.

Recall that projective 3-space is the set of 1-dimensional subspaces of $\mathbb{C}^4$. We write $\mathbb{C}^4$ as the span $\langle \mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3, \mathbf{e}_4 \rangle$ of the standard basis vectors $\mathbf{e}_1 = (1,0,0,0)$, $\mathbf{e}_2 = (0,1,0,0)$, $\mathbf{e}_3 = (0,0,1,0)$, and $\mathbf{e}_4 = (0,0,0,1)$. Denote the four given lines by L_1, L_2, L_3, and L_4. Without loss of generality we assume that L_3 is spanned by the first two basis vectors, $L_3 = \langle \mathbf{e}_1, \mathbf{e}_2 \rangle$, and L_4 by the last two basis vectors, $L_4 = \langle \mathbf{e}_3, \mathbf{e}_4 \rangle$. In general, the other two lines L_1 and L_2 do not meet each other. This general situation is at the right of Figure 2.1. Here we are visualizing the real positive orthant of projective 3-space as the interior of the tetrahedron spanned by $\mathbf{e}_1$, $\mathbf{e}_2$, $\mathbf{e}_3$, and $\mathbf{e}_4$.

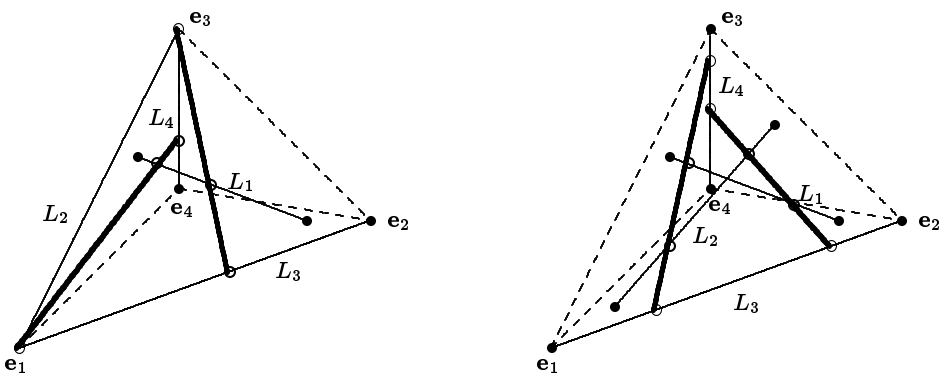

FIG. 2.1. *In $\mathbb{P}^3$ two thick lines meet four given lines L_1, L_2, L_3, and L_4 in a point. At the left we see a special configuration and the general configuration is at the right.*

The special position of L_3 and L_4 allows the following special choice of coordinates for lines X which meet them:

$$X = \langle \mathbf{x}_1, \mathbf{x}_2 \rangle = \begin{bmatrix} x_{11} & 0 \\ x_{21} & 0 \\ 0 & x_{32} \\ 0 & x_{42} \end{bmatrix}. \tag{2.1}$$

Here the two columns of X, its first and second generators, are chosen to be its points of intersection with L_3 and L_4, respectively. Lines expressed in these coordinates already satisfy the intersection conditions imposed by L_3 and L_4. Since the columns of X may be scaled independently we have exactly the two degrees of freedom needed to meet the two remaining intersection conditions imposed by L_1 and L_2.

If we take $L_2 = \langle \mathbf{e}_1, \mathbf{e}_3 \rangle$, as at the left of Figure 2.1, we solve the problem as follows. The lines passing through both L_2 and L_3 form the plane $\langle \mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3 \rangle$ which

intersects L_4 at $\mathbf{e}_3$. Similarly we see that lines through L_2 and L_4 form the plane $\langle \mathbf{e}_1, \mathbf{e}_3, \mathbf{e}_4 \rangle$ which must intersect L_3 at $\mathbf{e}_1$. Thus we see that any line other than L_2 which meets L_2, L_3, and L_4 must contain either $\mathbf{e}_1$ or $\mathbf{e}_3$. In the first case, consider the set of lines passing through $\mathbf{e}_1$ and intersecting L_4. These lines form a plane $\langle \mathbf{e}_1, \mathbf{e}_3, \mathbf{e}_4 \rangle$ which must intersect L_1 in a unique point $\mathbf{a}$ and thus the line $\langle \mathbf{e}_1, \mathbf{a} \rangle$ is the unique line through $\mathbf{e}_1$ intersecting L_1, L_2, L_3, and L_4. In the second case, the set of lines through $\mathbf{e}_3$ which intersect L_3 form a plane which intersects L_1 in a unique point $\mathbf{a}'$. So we find that the line $\langle \mathbf{e}_3, \mathbf{a}' \rangle$ is the unique line passing through $\mathbf{e}_3$ and intersecting L_1, L_2, L_3, and L_4.

An algebraic way to look at this argument goes as follows. Any line which meets both L_3 and L_4 must be expressible in the form (2.1). In order for X to meet $L_2 = \langle \mathbf{e}_1, \mathbf{e}_3 \rangle$ we must be able to find nontrivial linear combinations such that $\lambda_1 \mathbf{x}_1 + \lambda_2 \mathbf{x}_2 = \gamma_1 \mathbf{e}_1 + \gamma_2 \mathbf{e}_3$. That is, the system

$$\begin{bmatrix} 1 & x_{11} & 0 & 0 \\ 0 & x_{21} & 0 & 0 \\ 0 & 0 & 1 & x_{32} \\ 0 & 0 & 0 & x_{42} \end{bmatrix} \begin{bmatrix} -\gamma_1 \\ \lambda_1 \\ -\gamma_2 \\ \lambda_2 \end{bmatrix} = 0 \tag{2.2}$$

must have a nontrivial solution. This can clearly happen only when $x_{21} = 0$ or $x_{42} = 0$. The first case then describes the plane of lines containing $\mathbf{e}_1$ and meeting L_4 and gives rise to the solution $\langle \mathbf{e}_1, \mathbf{a} \rangle$ as above, while $x_{42} = 0$ yields the solution $\langle \mathbf{e}_3, \mathbf{a}' \rangle$.

Schubert's principle [34], [50] of "conservation of number" suggests that the number of solutions to the general problem will be the same as the number of the solutions in the special case we just looked at, i.e., 2. In order to adjust this argument to allow us to *find* the solutions as well as count them we must consider the process of deforming L_2 to special position.

The special position we use for L_2 is given by $S = \langle \mathbf{e}_1, \mathbf{e}_3 \rangle$, so our deformed problem is the following: find all X such that $\det(X|L_1) = 0$, $\det(X|S) = 0$, $\det(X|L_3) = 0$, and $\det(X|L_4) = 0$. Note that the last two equations are already satisfied when X is chosen as in (2.1). Specializing the second condition can be achieved by moving the line S into L_2 taking a convex combination $(1-t)S + tL_2$ of the generating matrices S and L_2 with t varying from 0 to 1. Fixing the first condition and enforcing nontrivial intersection with the moving line yields the homotopy

$$H(X,t) = \begin{cases} \det(X|(1-t)S + tL_2) = 0, & \text{where} \quad X = \langle \mathbf{x}_1, \mathbf{x}_2 \rangle, \\ \det(X|L_1) = 0, & \mathbf{x}_1 \in L_3, \mathbf{x}_2 \in L_4. \end{cases} \tag{2.3}$$

Numerical continuation methods trace the solution paths starting at the two solutions $X = \langle \mathbf{e}_1, \mathbf{a} \rangle$ and $X = \langle \mathbf{e}_3, \mathbf{b} \rangle$ calculated above for $t = 0$ to the solutions of the original problem at $t = 1$.

The straightforward application of this geometric principle of conservation of number may fail if our special position is too special in the sense that it is a singular point in the parameter space of configurations. This is a very subtle condition that is a property of the special position as a member of the set of problem instances and can not be determined by considering the geometry of the special position itself. Therefore we need to examine the algebraic formulation of the deformation near $t = 0$. As local coordinates we choose $x_{11} = 1$ and $x_{32} = 1$. Then $\det(X|S) = 0 \Leftrightarrow x_{21} x_{42} = 0$. So, at $t = 0$, as either $x_{21} = 0$ or $x_{42} = 0$, the structure of the matrix of partial derivatives

of the system $H(X, t = 0)$ is

$$\begin{bmatrix} x_{42} & x_{21} \\ C_{13}x_{42} - C_{14} & C_{13}x_{21} - C_{23} \end{bmatrix}, \tag{2.4}$$

with C_{ij} the 2-by-2 minor by selecting rows i and j from the matrix representation of L_4. For L_1 in general position, the two start solutions are regular and admit well-defined deformations. For general L_2, this regularity is maintained up to $t = 1$.

3. Pieri-type deformations for hypersurface conditions. In this section we extend the approach of the last section to produce an algorithm for computing all p-planes in $\mathbb{C}^{m+p}$ that intersect mp given m-planes L_i in general position. In order to have a uniform description of the algorithm, we will skip the step of specializing the last two m-planes, and the last step of using linear algebra to intersect with the first m-plane. Instead we will describe the algorithm solely in terms of the continuation step which involved deforming L_2 to S. Later we shall see that adding these linear algebra steps back in amounts to truncating the algorithm as we describe it and does yield a significant computational savings.

We represent p-planes in $\mathbb{C}^{m+p}$ by $(m + p) \times p$-matrices whose columns form a set of generators. Solutions to our problem are represented by variable $(m + p) \times p$-matrices. We move the input data into special positions such that the solution planes have matrix representations with zero coordinates at specific positions. To specify those positions, we need the following definition.

DEFINITION 3.1. *A* localization pattern *is an element of* $\{0, \star\}^{(m+p)\times p}$ *such that all stars in a column are contiguous and the row indices in which the bottommost and topmost stars occur strictly increase as functions of the column number. These row indices are called the* top *and* bottom pivots*, respectively. A p-plane* fits a localization pattern *if it can be represented by a matrix of generators with zero entries everywhere the localization pattern prescribes them.*

Consider, for example, the case where $p = 2, m = 4$ and we are looking for all 2-planes which meet eight 4-planes. We can take the last two planes as $L_7 = \langle \mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3, \mathbf{e}_4 \rangle$ and $L_8 = \langle \mathbf{e}_3, \mathbf{e}_4, \mathbf{e}_5, \mathbf{e}_6 \rangle$. For any 2-plane that meets both these planes nontrivially we may choose its generators such that one generator lies in L_7 and the other in L_8. Such a 2-plane is represented by a variable matrix

$$\begin{bmatrix} x_{11} & 0 \\ x_{21} & 0 \\ x_{31} & x_{32} \\ x_{41} & x_{42} \\ 0 & x_{52} \\ 0 & x_{62} \end{bmatrix} \text{ which fits the pattern } \begin{bmatrix} \star & 0 \\ \star & 0 \\ \star & \star \\ \star & \star \\ 0 & \star \\ 0 & \star \end{bmatrix}. \tag{3.1}$$

Planes which satisfy this localization pattern already meet L_7 and L_8. Equivalently, any specialization of the variables x_{ij} in the pattern will result in a p-plane which has nontrivial intersection with L_7 and L_8. Thus our problem is to find values of these variables such that the plane represented by (3.1) meets the remaining 4-planes. We achieve this by specializing the input planes as follows.

DEFINITION 3.2. *Given a localization pattern* X*,* the special m-plane for the top (bottom) pivots of X *is the* m*-plane* S_X *spanned by the standard basis vectors not indexed by top (bottom) pivots.*

It turns out that p-planes, which fit a localization pattern X and meet its special m-plane S_X, must fit a set of localization patterns easily derived from X in the following way.

DEFINITION 3.3. *A* top (bottom) child *of a localization pattern X is a localization pattern obtained by turning a topmost (bottommost) star of X to a zero.*

For the bottom localization pattern in Figure 3.1 having bottom pivots [3 5], the special 4-plane is $\langle \mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_4, \mathbf{e}_6 \rangle$. Lemma 3.4 states that all 2-planes meeting this special 4-plane and fitting the bottom pattern must fit one of its two children.

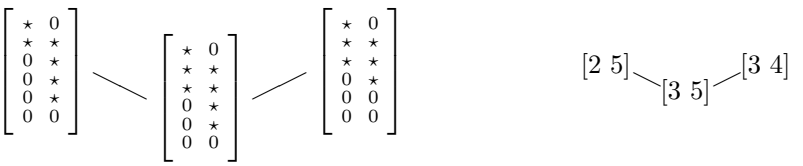

FIG. 3.1. *A localization pattern with bottom pivots* [3 5] *and its two children* [2 5] *and* [3 4]. *At the right we see the bottom pivots used as a shorthand notation.*

LEMMA 3.4 (hypersurface Pieri rule). *Let S_X be the special m-plane for top (bottom) pivots of the localization pattern X. Every p-plane that fits X and meets S_X also fits one of the (at most p) children of X. Conversely every p-plane that fits a child of X fits X and meets S_X.*

Proof. A p-plane that fits X meets S_X if and only if, for all specific values for the variables corresponding to the stars in the pattern X, we can find a linear combination of the columns of the p-plane which lies in S_X. This means that the intersection of the p-plane with S_X can be represented as a linear combination of the columns of S_X. Finding this linear combination is equivalent to finding a nontrivial element of the kernel of $[X|S_X]$. Since the m columns of S_X have pivots distinct from those of the p columns of X, the matrix $[X|S_X]$ is an $(m+p) \times (m+p)$-matrix with $m+p$ distinct pivot rows. So we can rearrange $[X|S_X]$ into a triangular matrix, which is singular precisely when one of the diagonal elements coming from X is specialized to zero. ∎

The repeated application of Lemma 3.4 builds up a poset diagram which allows us to count the solution planes as shown in Figure 3.2. The poset starts at the trivial localization pattern X_0 whose ith column has its top pivot in row i and its bottom pivot in row $m+i$. While there are p-planes that do not fit X_0, the set of p-planes that do fit X_0 includes those for which all Plücker coordinates are nonzero. This is a dense open subset of the Grassmannian, and with the general position assumption on our input planes, it will suffice to count the number of solution planes which fit X_0. This start pattern, X_0 has exactly $mp+p$ stars, and our original list of conditions contains exactly mp given m-planes. Initially we apply Theorem 3.5 starting at $X = X_0$ and $n = mp$ in the following.

THEOREM 3.5. *Consider a localization pattern X with $p+n$ stars. For $n = 0$, X counts for one solution. For $n > 0$, the number of p-planes fitting X and meeting n general m-planes equals the sum of the number of solution planes fitting the children of X and meeting $n-1$ general m-planes.*

Theorem 3.5 is proven by induction and follows from Lemma 3.7 establishing the correctness of the Pieri homotopy. Applying the Pieri homotopy algorithm following the root counting procedure through the poset yields an effective algorithm for actually finding the solutions.

DEFINITION 3.6. *Let X be a localization pattern and S_X the special m-plane*

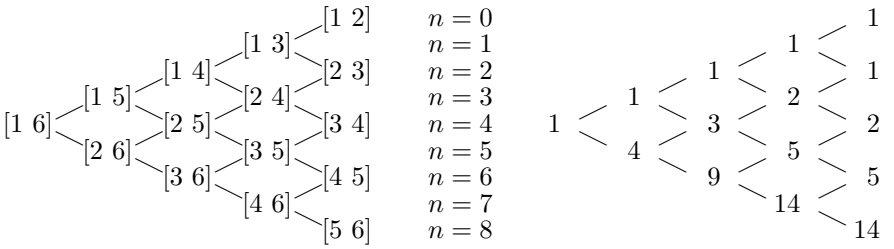

FIG. 3.2. *Combinatorial root count for $p = 2$, $m = 4$. The brackets at the left are the bottom pivots. The top pivots remain* [1 2]. *The trivial localization pattern X_0 corresponds to* [5 6]. *The roots are counted at the right, starting at the top and adding up the numbers at the leaves while moving down to the root of the poset yielding* 14 *solutions.*

for top (bottom) pivots of X. Suppose that $n-1$ general intersection conditions are satisfied for children Y of X, i.e., $\det(Y|L_i) = 0$ *for $i = 1, 2, \ldots, n-1$. To satisfy the nth intersection condition, the* Pieri homotopy $H(X,t) = \mathbf{0}$ *is*

$$H(X,t) = \begin{cases} \det(X|(1-t)S_X + tL_n) = 0, & \\ \det(X|L_i) = 0, \quad i = 1, 2, \ldots, n-1, & t \in [0,1]. \end{cases} \tag{3.2}$$

To illustrate the Pieri homotopy, we consider the situation as in going down to [3 5], with the three 2-planes that fit the left child [2 5] and two 2-planes that fit the right child [3 4]. Locally the situation is pictured in Figure 3.1, with the global root counting procedure in Figure 3.2. At $t = 0$, $n = 4$, and we have already folded in the first four intersection conditions and are moving the special 4-plane $\langle \mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_4, \mathbf{e}_6 \rangle$ to the fifth input plane. In general we have the situation as in the following Lemma.

LEMMA 3.7. *Consider a localization pattern X with $p+n$ stars and n complex m-planes L_i in general position. Suppose we are given all p-planes that meet L_i, $i = 1, 2, \ldots, n-1$, and fit one of the children of X. Then the Pieri homotopy defines regular paths of p-planes that start at the given p-planes and end at those p-planes which meet all n general m-planes L_i while fitting X.*

Proof. Our working space is a product of projective spaces, with as many spaces as there are columns in X. To describe this multiprojective space more precisely, we count the stars in X. For X defined by p-tuples of top and bottom pivots, respectively, $\alpha, \beta \in \mathbb{N}^p$, we embed the p-planes into $\mathbb{P}^{d_1} \times \mathbb{P}^{d_2} \times \cdots \times \mathbb{P}^{d_p}$ with $d_i = \beta_i - \alpha_i$, $i = 1, 2, \ldots, p$. To fix an affine coordinate chart we set one coordinate to 1 in every column by scaling the corresponding generator of the p-plane.

Essentially we are applying a multihomogeneous homotopy [23, 24] in a general situation. By the assumption of Lemma 3.7, all p-planes at $t = 0$ are regular solutions, as the m-planes L_i are in general position. This general position is maintained for all $t \in [0,1]$, ensuring the smoothness of the solution paths.

We still have to show that we will find all p-planes. Suppose that at $t = 1$ there are more solutions than the number of paths we started with. Going backward with those additional solutions from $t = 1$ to $t = 0$ we move either to a singular solution or to a solution at infinity. But at $t = 0$, all solutions are regular. By Lemma 3.4, all solutions have been found and since the localization patterns admit any affine chart, there are no solutions at infinity for $t = 0$. ∎

We remark that the root count in Figure 3.2 obtained by changing only bottom pivots is just one possibility. One could alternatingly change bottom and top pivots

in building up the levels of the poset. As was done in section 2, linear algebra can be applied to intersect with the first input plane. Another, more significant optimization includes the special position of the last two input planes. Choosing a basis so that the last two m-planes are already in special position $L_{mp-1} = \langle \mathbf{e}_1, \ldots, \mathbf{e}_m \rangle$ and $L_{mp} = \langle \mathbf{e}_{p+1}, \ldots, \mathbf{e}_{m+p} \rangle$ amounts to enforcing a different starting pattern for the poset. This has two advantages. The first is that it really forces any pattern meeting all original planes to meet the starting localization pattern regardless of the genericity of the remaining input planes. The second is that it saves the work of doing the two final and most costly (because of highest dimension) continuation steps.

In contrast to the approach of [16], our description treats the hypersurface Pieri homotopy algorithm separately from the case of general intersection conditions. This allows us to simplify the definition of special m-planes. However, when all input m-planes are spanned by real matrices, we need the more general choice of special m-planes as defined in [16] to enforce complex arithmetic and avoid quadratic turning points along the solution paths. Also for the general intersection conditions we need the definition of [16] for special m-planes. So in Definition 3.2 we replace each of the standard basis vectors $\mathbf{e}_i$ by vectors $\mathbf{b}_i$ that have random complex entries in rows i and higher (lower) for bottom (top) pivots i. We assume this adaptation of Definition 3.2 for the rest of the paper.

4. General intersection conditions. In the general case we are looking for p-planes in $\mathbb{C}^{m+p}$ which nontrivially meet a list of generic subspaces $L_1, L_2, \ldots, L_n$, where each L_i has dimension $m+1-k_i$. It turns out each of these conditions removes k_i degrees of freedom, and thus we will expect a finite number of solutions when $k_1 + k_2 + \cdots + k_n = mp$.

In specializing the ith $(m+1-k_i)$-plane L_i we move it to the intersection of k_i special m-planes. This deformation of the solution p-planes while moving L_i from general to special position proceeds in k_i steps, each time specializing some of the coordinates of our current representation for the solution planes to zero. In modeling this deformation we need to be aware of the left and right sides of our localization patterns when working, respectively, with bottom and top pivots.

DEFINITION 4.1. *For the localization patterns X^1 and X^2 we write $X^1 \supset_{c_1} X^2$ to indicate that X^2 is the child of X^1 obtained by turning the pivot in column c_1 of X^1 to zero. We say that the* chain of length j

$$C = X^1 \supset_{c_1} X^2 \supset_{c_2} \cdots \supset_{c_{j-1}} X^j \tag{4.1}$$

is bottom-left *if $c_i \leq c_{i-1}$, $i = 2, \ldots, j$, for bottom pivots c_i, or* top-right *if $c_i \geq c_{i-1}$, $i = 2, \ldots, j$, for top pivots c_i. If C is bottom-left (resp., top-right), we will call any child X^{j+1} of X^j a* bottom-left child *(resp.,* top-right child*) of C if the chain $X^1 \supset_{c_1} \cdots \supset_{c_{j-1}} X^j \supset_{c_j} X^{j+1}$ is also bottom-left (resp., top-right).*

In other words, in a bottom-left (top-right) chain, we never take away a bottom (top) pivot in a column to the right (left) of one we have already taken. Note that when $C = X^1$ is a chain of length 1, we have not taken any pivots away yet and all children of X^1 are bottom-left (top-right) children of C.

Notice that the pivots of $X^1 \supset_{c_1} X^2$ are the same except in column c_1 and that the new pivot of X^2 cannot have been a pivot of X^1 (otherwise X^2 would not be a localization pattern). Thus $S_{X^1} \cap S_{X^2}$ has dimension $m-1$. Similarly we can see that the intersection $S_{X^1} \cap S_{X^2}$ with S_{X^3} drops the dimension by 1 whenever X^3 is a child of X^2 obtained by deleting a pivot in a column with index less than or equal to c_1. This justifies the dimension of the following definition.

DEFINITION 4.2. *For a bottom-left (top-right) chain* $C = X^1 \supset_{c_1} X^2 \supset_{c_2} \cdots \supset_{c_{j-1}} X^j$ *and an index* $1 \le k \le j$ *we define a* special $(m+1-k)$-plane S_C^k *to be* $S_C^k = \cap_{i=1}^k S_{X^i}$, *where the* S_{X^i} *are the special* m*-planes associated to the* X^i *in* C.

From now on we assume that we work with bottom pivots.

LEMMA 4.3 (general Pieri rule). *Let* C *be a bottom-left chain of length* j *ending at* X^j.

(1) *All* p*-planes fitting* X^j *and meeting* S_C^j *must fit at least one of* X^j*'s children.*
(2) *A child* X^{j+1} *meets* S_C^j *if and only if* X^{j+1} *is a bottom-left child of* C, *i.e., if and only if* $X^j \supset_{c_j} X^{j+1}$, *where* $c_{j+1} \le c_j$.

Proof. Any p-plane which fits X^j and meets S_C^j must also meet S_{X^j} and thus must be a child of X^j by Lemma 3.4. This proves the first claim.

Recall from the proof of Lemma 3.4 that X^{j+1} meets S_C^j if and only if, given any specification of the variables of X^j for which the pivot elements are nonzero, it is possible to find a linear combination of the columns which lies in S_C^j. Clearly any such linear combination must involve the decremented column c_{j+1} and no columns after it, since all pivots of vectors in S_C^j must be nonpivots of X^j.

If $c_{j+1} \le c_j$, then the first $c_j - 1$ columns of X^{j+1} have remained unchanged all the way through the chain, and the last has only had successive pivots removed. Thus S_C^j must contain a basis vector with a pivot row in each nonpivot of the first c_{j+1} columns of X^j. So if we take these basis vectors along with the first c_{j+1} columns of X^j we get a set of r_j column vectors with r_j distinct pivots all in rows r_j. Since X^{j+1} is obtained from X^j by deleting the pivot of column c_{j+1} we find that the (c_{j+1})th column must be in the span of the remaining columns, and this linear relation can be rewritten to express a vector of S_C^j as a linear combination of columns of X^{j+1}.

On the other hand, if $c_{j+1} > c_j$, then at least one nonpivot of these first c_{j+1} columns of X^j must have been a pivot previously and S_C^j must have no vector with a pivot in this row. In other words we are looking for a solution to a subsystem of the previous system where we have removed some number of columns (aside from that corresponding to column c_{j+1} of X^{j+1}). Looking at just the pivot rows appearing we get either a square triangular system with nonzeros on the diagonal (if the pivot of column c_{j+1} did not appear) or a nonsquare system with nonzero pivots in each column. In either case no nontrivial solution is possible. □

THEOREM 4.4. *Let* X^1 *be a localization pattern with* $p + \sum_{i=1}^{n-1} k_i$ *stars where the* k_i *are the codimension conditions specified in the problem (i.e.,* $\dim(L_i) = m+1-k_i$). *Further suppose that* $C = X^1 \supset_{c_1} X^2 \supset_{c_2} \cdots \supset_{c_{j-1}} X^j$ $(1 \le j \le k_n)$ *is a bottom-left chain starting at* X_1. *For* $1 \le k \le j$ *let* U_C^k *be a generic* $(m+1-k_n)$*-dimensional subspace of* $S_C^k = \cap_{i=1}^k S_{X^i}$. *Then the number of* p*-planes meeting* U_C^{j-1} *as well as* $L_1, \ldots, L_{n-1}$ *and fitting* X^j *is equal to the sum of the numbers of* p*-planes meeting* $U_C^j, L_1, \ldots, L_{n-1}$ *and meeting* Y *as* Y *runs over all bottom-left children of* C.

As with the hypersurface case, Theorem 4.4 is proved by induction and follows from the correctness of a homotopy. Before describing this homotopy we will show that the theorem provides a root count procedure generalizing that of the last section. Combining the homotopy with this counting procedure will yield an effective technique for producing all solutions. It is a little easier to understand the implications of the theorem for root counting if we restate it without reference to the intermediate steps where our input planes are partially specialized.

COROLLARY 4.5. *Suppose* X *is a localization pattern with* $p + \sum_{i=1}^{n} k_i$ *stars where the* k_i *are codimension conditions specified in the problem (i.e.,* $\dim(L_i) = m+1-k_i$). *Then the number of* p*-planes fitting* X *and meeting* $L_1, \ldots, L_n$ *is equal to the total*

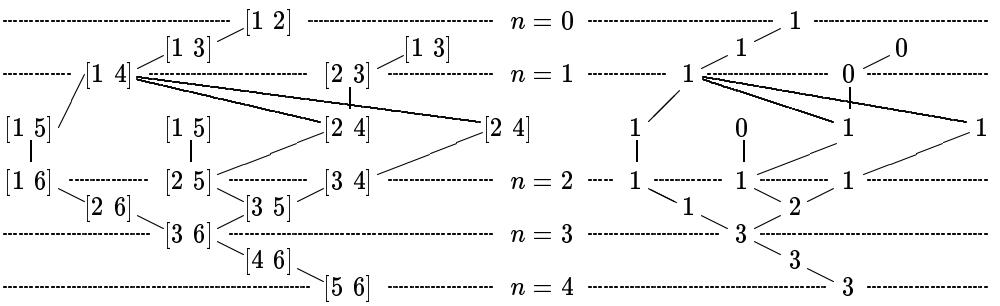

FIG. 4.1. *Bottom pivots for $p = 2$, $m = 4$, $k_i = 2$, $i = 1, 2, 3, 4$. Only those arcs and nodes are drawn that connect localization patterns reachable by bottom-left chains. The corresponding root count is at the right.*

number of p-planes meeting $L_1, \ldots, L_{n-1}$ and fitting at least one descendant Y of X accessible as a bottom-left child of a bottom-left chain of length k_n starting at X.

Proof. To see that the corollary follows from Theorem 4.4, consider applying the theorem k_n times starting from the hypothesis of Corollary 4.5. Note that the first application of the theorem leaves us with the problem of counting the number of p-planes meeting $L_1, \ldots, L_{n-1}$, and also meeting an $m + 1 - k_n$ plane lying in S_X and fitting a child of X. Each of these numbers can now be counted by applying the theorem to the new case with $n = n - 1$, $j = 2$, and $C = C^1 \supset C^2$. This process continues until all our chains have length k_n and the subspace $U_C^{j+1} = S_C^{k_n}$ in the conclusion of Theorem 4.4 is a special $m + 1 - k_n$ space and that Lemma 4.3 implies that any p-plane fitting a bottom-left child of C will meet S_C^j. ∎

Figure 4.1 illustrates the combinatorial counting method arising from Theorem 4.4 just as Figure 3.2 did for the hypersurface case. Starting at the root of the poset we apply the theorem to the case $n = 4$, $j = 1$, $C = [5\ 6]$ to see that the number of 2-planes which fit the pattern [5 6] and meet 4 general 3-planes L_1, L_2, L_3, L_4 is equal to the number of p-planes which fit [4 6], meet the 3 general 3-planes L_1, L_2, L_3, and meet a general 3-plane lying inside the special 4-plane $S_{[5\ 6]}$. A second application of the theorem in the case $n = 3$, $j = 2$, $C = [5\ 6] \supset_1 [4\ 6]$ now tells us that this number is equal to the number of p-planes fitting the pattern [3 6] and meeting the 3 general 3-planes L_1, L_2, L_3. Note that by Lemma 4.3 we do not get any solutions fitting the pattern [4 5] (so we omitted [4 5] in Figure 4.1). Continuing, with $n = 3$, $j = 1$, $C = [3\ 6]$, we find that the number of 2-planes fitting the pattern [3 6] and meeting L_1, L_2, L_3 is equal to the sum of the numbers fitting the two children of [3 6] and meeting L_1, L_2, and a general 3-plane lying inside of $S_{[3\ 6]}$. Applying the theorem with $n = 3$, $j = 2$, to the chains $[3\ 6] \supset_1 [2\ 6]$ and $[3\ 6] \supset_2 [3\ 5]$ we find that the total number of 2-planes fitting the pattern defined by [3 6] and meeting L_1, L_2, and L_3 is equal to the sum of the numbers of 2-planes meeting L_1 and L_2 and fitting any of the localization patterns defined by [1 6], [2 5], and [3 4].

It is important to note that during the intermediate steps when the chains C have length $j > 1$, the number of solutions at a node depends on both the localization pattern and the chain. Thus we can only share nodes corresponding to the $j = 1$ case, i.e., those nodes with no partially specified input planes. In Figure 4.1 these cases (with $j = 1$) are indicated by dotted horizontal lines. Also note that some chains may not make it k_n steps and may simply stop and fail to yield any solutions. Both these points are illustrated by considering the localization pattern [1 5] in Figure 4.1.

Applying Theorem 4.4 with $n = 2$, $j = 2$, on the chains [1 6] $\supset_2$ [1 5] yields an equivalence with the numbers of solutions fitting [1 4] and meeting L_1, while applying the theorem to with $n = 2$, $j = 2$, and the chain [2 5] $\supset_1$ [1 5] yields no solutions at all since this chain has no bottom-left children. We are now ready to define the homotopy which provides our effective proof of Theorem 4.4.

DEFINITION 4.6. *Let X, n, j, and C be as in Theorem* 4.4*, and suppose that the subspaces U_C^j and U_C^{j-1} are represented by $(m+p)\times(m+1-k_n)$-dimensional matrices made up of random linear combinations of the S_C^j and S_C^{j-1} (except that $U_C^0 = L_n$). We define the* Pieri homotopy *$H_C^j(X,t) = \mathbf{0}$ to be*

$$H_C^j(X,t) = \begin{cases} \text{all maximal minors of } [X|(1-t)U_C^j + tU_C^{j-1}], & \\ \text{all maximal minors of } [X|L_i] = 0, & t \in [0,1]. \\ \qquad\qquad\qquad\qquad i = 1,2,\ldots,n-1, & \end{cases} \tag{4.2}$$

Note that while this homotopy may well have more equations than unknowns it will turn out to define a nonsingular path of solutions through each starting point. Here we will prove that these equations define a homotopy which can be used to find all solutions. We will defer a discussion of techniques for actually following these paths numerically to section six.

LEMMA 4.7. *Supposing that the solutions of $H_C^j(X,0) = \mathbf{0}$ are all nonsingular as X varies over all bottom-left extensions of C then the Pieri homotopy $H_C^j(X,t) = \mathbf{0}$ defines regular paths through these solutions which lead to all solutions of $H_C^j(X,1)$.*

Proof. As in the proof of Theorem 3.5, our working space is the product $\mathbb{P}^{d_1}\times\mathbb{P}^{d_2}\times\cdots\times\mathbb{P}^{d_p}$ of projective spaces where d_j is the number of stars in each column of X, and we are essentially applying a multihomogeneous homotopy [23, 24]. By assumption all p-plane solutions at $t = 0$ are regular, and since U^j defines an $(m+1-k_n)$-dimensional subspace of S_C^{j-1} we see that U^{j-1}, which defines a generic $(m+1-k_n)$-dimensional subspace of S_C^{j-1}, must also define an intersection problem with a solution set consisting of a finite number of regular p-planes. This general position is maintained for all $t \in [0,1]$, ensuring the smoothness of the solution paths.

It remains to show that we will find all p-planes. This argument is exactly analogous to the proof of Theorem 3.5 except that we rely on Lemma 4.3 to show that all solutions found must fit some bottom-left child of C when we go backwards. □

Theorem 4.4 follows from the lemma by induction. We start at the tops of the counting poset where the localization patterns all have exactly p stars and no subspace conditions to meet and hence define unique solutions. The hypotheses of the homotopy lemma are then met and this forces the conditions to be met all the way down.

5. Control of linear systems and quantum Schubert calculus. This section is organized into three parts. We first rephrase the dynamic pole placement problem into a problem of enumerative geometry [31]. Thereafter we derive the critical dimension [47] for this problem to have a finite number of solutions. Lastly we state the root-counting theorem [29] and prove it inductively from the correctness of the Pieri homotopies.

Suppose we want to control a plant with n internal states $\mathbf{x} \in \mathbb{R}^n$ that takes m-inputs $\mathbf{u} \in \mathbb{R}^m$ and produces p-outputs $\mathbf{y} \in \mathbb{R}^p$ with a dynamic compensator that has q internal states $\mathbf{z} \in \mathbb{R}^q$. We picture this situation schematically in Figure 5.1.

The evolution in time of the plant is described by a system of first-order differential

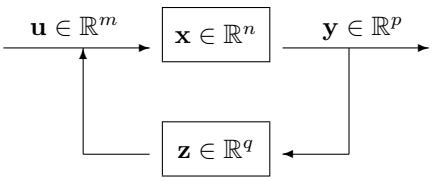

FIG. 5.1. *Control of an m-input and p-output plant by a qth-order dynamic compensator.*

equations:

$$\begin{cases} \dot{\mathbf{x}} = A\mathbf{x} + B\mathbf{u} \\ \mathbf{y} = C\mathbf{x} \end{cases} \quad \begin{array}{l} \text{with } \mathbf{x} \in \mathbb{R}^n, \mathbf{u} \in \mathbb{R}^m, \mathbf{y} \in \mathbb{R}^p, \\ \text{and } A \in \mathbb{R}^{n \times n}, B \in \mathbb{R}^{n \times m}, C \in \mathbb{R}^{p \times n}. \end{array} \tag{5.1}$$

The dynamic compensator obeys a qth-order differential equation, described by the system

$$\begin{cases} \dot{\mathbf{z}} = F\mathbf{z} + G\mathbf{y} \\ \mathbf{u} = H\mathbf{z} + K\mathbf{y} \end{cases} \quad \text{with} \quad \mathbf{z} \in \mathbb{R}^q \quad \text{and} \quad \begin{array}{l} F \in \mathbb{R}^{q \times q}, G \in \mathbb{R}^{q \times p}, \\ H \in \mathbb{R}^{m \times q}, K \in \mathbb{R}^{m \times p}. \end{array} \tag{5.2}$$

After elimination of $\mathbf{u}$ and $\mathbf{y}$, concatenation of (5.1) and (5.2) yields the following closed-loop system:

$$\begin{bmatrix} \dot{\mathbf{x}} \\ \dot{\mathbf{z}} \end{bmatrix} = \begin{bmatrix} A + BKC & BH \\ GC & F \end{bmatrix} \begin{bmatrix} \mathbf{x} \\ \mathbf{z} \end{bmatrix}. \tag{5.3}$$

The behavior of this closed-loop system is determined by the $n+q$ eigenvalues of the matrix in (5.3). For a plant given by the matrix triplet (A, B, C) and $n+q$ eigenvalues, the dynamic pole placement problem asks for the matrix quadruples (F, G, H, K) which determine the dynamic compensators that yield closed-loop systems with a specific set of eigenvalues.

We can formulate the dynamic pole placement problem as a geometric problem. In rewriting the characteristic equation of (5.3) the subscripts in I denote the dimension of the identity matrix. There is only some hindsight involved in deriving (5.6). The rest of the equivalences are deduced by elementary row and column operations.

$$\det\left(s \begin{bmatrix} I_n & 0 \\ 0 & I_q \end{bmatrix} - \begin{bmatrix} A + BKC & BH \\ GC & F \end{bmatrix} \right) = 0, \tag{5.4}$$

$$\Leftrightarrow \det \begin{bmatrix} sI_n - A - BKC & -BH \\ -GC & sI_q - F \end{bmatrix} = 0, \tag{5.5}$$

$$\Leftrightarrow \det \begin{bmatrix} sI_n - A - BKC & -BH & BK & -B \\ -GC & sI_q - F & G & 0 \\ 0 & 0 & I_p & 0 \\ 0 & 0 & 0 & I_m \end{bmatrix} = 0, \tag{5.6}$$

$$\Leftrightarrow \det \begin{bmatrix} sI_n - A & 0 & 0 & -B \\ 0 & sI_q - F & G & 0 \\ C & 0 & I_p & 0 \\ 0 & -H & K & I_m \end{bmatrix} = 0, \tag{5.7}$$

$$\Leftrightarrow \det \begin{bmatrix} I_n & 0 & 0 & -(sI_n - A)^{-1}B \\ 0 & I_q & (sI_q - F)^{-1}G & 0 \\ C & 0 & I_p & 0 \\ 0 & -H & K & I_m \end{bmatrix} = 0, \tag{5.8}$$

$$\Leftrightarrow \det \begin{bmatrix} I_n & 0 & 0 & -(sI_n - A)^{-1}B \\ 0 & I_q & (sI_q - F)^{-1}G & 0 \\ 0 & 0 & I_p & C(sI_n - A)^{-1}B \\ 0 & 0 & H(sI_q - F)^{-1}G + K & I_m \end{bmatrix} = 0. \tag{5.9}$$

The last $m+p$ rows and columns of (5.9) represent the intersection of m-planes defined by the given triplet (A, B, C) with p-planes determined by the unknown quadruple (F, G, H, K). As these p-planes depend on the variable s introduced by the term $(sI_q - F)^{-1}$, they have maximal minors of degree q and we call them degree q-maps. Thus the dynamic pole placement problem is equivalent to the computation of all degree q-maps into the Grassmannian of p-planes that meet n given m-planes at prescribed s-values. It is easy to see that for each specification of an eigenvalue λ_i the condition that the characteristic polynomial (5.9) vanish at $s = \lambda_i$ enforces one polynomial condition on the set of degree q-maps.

Note that when $q = 0$ we are solving the static pole placement problem ($\mathbf{u} = K\mathbf{y}$ and $F, G, H = 0$) and are looking for maps of degree 0 (i.e., constant maps) which meet a specific set of given m-planes. In this case the characteristic equation (5.9) has degree n and we can find solution planes whenever n is less than the dimension mp of the space of p-planes in $(m + p)$-dimensional space. At the critical dimension $n = mp$, we expect the number of such solutions to be finite. In other words when $q = 0$ and $n = mp$ this analysis transforms the static pole placement problem into the problem of finding all p-planes meeting a set of mp given m-planes as dealt with in section 3. For general q we will be able to use similar methods to solve it, but will need the following lemma which specifies the critical dimension and allows us to produce localization patterns for our maps.

LEMMA 5.1. *Let $q = dp + r$ with $d, r \in \mathbb{N}$ and $r < p$. The set of $(m + p) \times p$ degree q-maps is of dimension $mp+q(m+p)$ and has a dense open subset which can be represented by matrices with entries of maximum degree d in all but the last r columns and degree $d + 1$ in the remaining r columns.*

Proof. Given a polynomial matrix we will define the degree of a column to be the maximum degree of any of its entries. Also note that two $(m + p) \times p$ polynomial matrices define the same map if there is an invertible $p \times p$-matrix $U(s)$ which takes one into the other by right multiplication. Lemma 3.1 from [47] tells us that for any $(m + p) \times p$ degree q-map $X'(s)$, there is a unique choice of column degrees $d_1 \leq \cdots \leq d_p$ (with $q = d_1 + \cdots + d_p$) such that the $X'(s)$ is equivalent to a matrix $X(s)$ with these column degrees. In other words the sets $U_{d_1,\ldots,d_p}$ of degree q-maps which can be represented by $(m + p) \times p$-matrices with column degrees $d_1, \ldots, d_p$ disjointly cover the set of degree q-maps.

In order to find the dimension of $U_{d_1,\ldots,d_p}$ we will want to find a canonical form for a general member. By a general member of $U_{d_1,\ldots,d_p}$ we mean a matrix $X(s)$ whose entries are polynomials of appropriate degrees with no algebraic relations among the coefficients. If we write $a^k_{i,j}$ for the coefficient of s^k in the (i, j)th entry of $X(s)$, we can express our normal form by requiring $a^0_{i,i} = 1$ for $i = 1, \ldots, p$, and if for all $i < j$ we have $a^k_{i,j} = 0$ if $k \leq d_j - d_i$ and $a^0_{j,i} = 0$ if $d_j = d_i$. This normal form is illustrated in Figure 5.2 and can be achieved by the following algorithm:

$$\begin{bmatrix} 1 & 0 & 0 & 0+0s & 0+0s+0s^2 \\ 0 & 1 & 0 & 0+0s & 0+0s+0s^2 \\ 0 & 0 & 1 & 0+0s & 0+0s+0s^2 \\ \star & \star & \star & 1+\star s & 0+0s+\star s^2 \\ \star & \star & \star & \star+\star s & 1+\star s+\star s^2 \\ \star & \star & \star & \star+\star s & \star+\star s+\star s^2 \\ \star & \star & \star & \star+\star s & \star+\star s+\star s^2 \end{bmatrix} \qquad \begin{bmatrix} 1 & 0 & 0+0s & 0+0s & 0+0s \\ 0 & 1 & 0+0s & 0+0s & 0+0s \\ \star & \star & 1+\star s & 0+\star s & 0+\star s \\ \star & \star & 0+\star s & 1+\star s & 0+\star s \\ \star & \star & 0+\star s & 0+\star s & 1+\star s \\ \star & \star & \star+\star s & \star+\star s & \star+\star s \\ \star & \star & \star+\star s & \star+\star s & \star+\star s \end{bmatrix}$$

$U_{0,0,0,1,2}$ $U_{0,0,1,1,1}$

FIG. 5.2. *Standard forms for $m = 2$, $p = 5$, and $q = 3$ with 28 and 31 stars, respectively.*

for $i = 1, 2, \ldots, p$ do
  $X_i := \frac{1}{a^0_{i,i}} X_i$;
  for $j = i+1, i+2, \ldots, p$ do
    if $d_i = d_j$, then $X_i := X_i - \frac{a^0_{j,i}}{a^0_{j,j}} X_j$; *zero out* $a^0_{j,i}$;
    for $k = 0, 1, \ldots, d_j - d_i$ do $X_j := X_j - \frac{a^k_{i,j}}{a^0_{i,i}} s^k X_i$; *zero out* $a^k_{i,j}$.

The genericity of $X(s)$ ensures that the replacements in this algorithm each introduce no zeros besides the desired one in the coefficient $a^k_{i,j}$ so that the algorithm is well defined and will terminate having introduced exactly the zeros required for the canonical form. It is easy to check that each of the replacements appearing in the algorithm is equivalent to the application of an invertible transformation. Thus the result defines the same map as the input. Also note that replacing any column of a matrix in this form by a nontrivial linear combination of the other columns yields a matrix which is no longer in this form. Thus any two maps in this form are equivalent if and only if they have the same specifications for the remaining variables, i.e., the result provides an affine chart defined on a Zariski dense open subset of $U_{d_1,\ldots,d_p}$.

Since each column of degree d_i polynomials has $(d_i+1)(m+p)$ coefficients, the total number of parameters we started with was $(p+q)(m+p) = mp+q(m+p)+p^2$. Finally, the algorithm specifies the p diagonal constant coefficients to 1 and introduces at least two zeros for each ordered pair $i < j$. In fact the number of zeros introduced is 2 if $d_i = d_j$ or $1 + d_j - d_i$ otherwise. Rewriting this last number as $2 + (d_j - d_i - 1)$ and adding up over all $\frac{p(p-1)}{2}$ ordered pairs $1 \le i < j \le p$ we find that the number of parameters specified is $p^2 + \sum_{i<j} \max(d_j - d_i - 1, 0)$. The conclusion of the lemma now follows since the choice of column degrees specified is the only way to choose the d_i's so that they add up to q and no two differ from each other by more than 1. ∎

The normal form used above was easy to define for general $U_{d_1,\ldots,d_p}$ and was used in [47] where they use the $U_{d_1,\ldots,d_p}$ as cells in a cellation of the space of degree q-maps. For our purposes we need only work in the largest of these cells $U_{d,\ldots,d,d+1,\ldots,d+1}$. Since this cell has dimension $mp+q(m+p)$ and each root of the degree $n+q$ characteristic equation (5.9) enforces one polynomial condition on the space of degree q-maps, we will expect no solutions whenever n is greater than the critical degree $mp+q(m+p)-q$ and a finite number of solutions when $n = mp+q(m+p)-q$. In both cases we expect no solutions of a generic dynamic pole placement problem to lie on these lower-dimensional pieces. In order to work on $U_{d,\ldots,d,d+1\ldots,d+1}$, however, we will want to use a different normal form analogous to the form used in section 3. To describe it we start by identifying $(m+p)$-vectors of degree d polynomials with their $(m+p)(d+1)$-element

coefficient vectors as follows:

$$\begin{bmatrix} a_1^0 + a_1^1 s + \cdots + a_1^d s^d \\ a_2^0 + a_2^1 s + \cdots + a_2^d s^d \\ \vdots \\ a_{m+p}^0 + a_{m+p}^1 s + \cdots + a_{m+p}^d s^d \end{bmatrix} \Leftrightarrow \begin{bmatrix} a_1^0 \\ a_2^0 \\ \vdots \\ a_{m+p}^0 \\ a_1^1 \\ \vdots \\ a_{m+p}^1 \\ \vdots \\ a_1^d \\ \vdots \\ a_{m+p}^d \end{bmatrix}; \tag{5.10}$$

i.e., the coefficient a_j^k of s^k in polynomial entry in row j in the representation on the left is stored in the $((k+1)(m+p)+j)$th position in the representation on the right.

DEFINITION 5.2. *Let $q = dp + r$ with $d, r \in \mathbb{N}$ and $r < p$. A* localization pattern *for $(m+p) \times p$-maps of degree q is given by a table of p columns of zeros and stars, where the first $p-r$ columns have dimension $(d+1)(m+p)$ and the remaining columns have dimensions $(d+2)$. As in the degree 0 case, all stars within a column should be contiguous and the row indices in which the bottommost and topmost stars occur strictly increase as a function of the column index. These row indices are called the* top *and* bottom *pivots, respectively. It is further required that no two top (bottom) pivots differ by $m+p$ or more. We say that a map* fits *a localization pattern if it is equivalent to a map given by a matrix of polynomials with the column degrees specified by the pattern and zero coefficients everywhere the pattern requires them.*

The dimension of the space of degree q-maps which meet a localization pattern X with n stars is $n-p$. To see this note the requirement that no pivots differ by $m+p$ places ensures that no multiple of any column by a power of s has a bottommost star in a pivot row of any other column. This implies that any linear combination involving more than one column has the lowest bottommost pivots and highest topmost pivots of the columns used. Thus only by scaling each column can we change the entries of a generic map fitting a localization pattern without producing a map which no longer fits that pattern. On the other hand we may freely scale each column to set one nonzero entry to 1. This also tells us that patterns with two equal pivots or pivots that differ by $m+p$ or more will be fit by a space of dimension lower than $n-p$.

Given appropriate generality we can use invertible column operations to transform the normal form for $U_{d,\ldots,d,d+1,\ldots,d+1}$ into a localization pattern as follows. First we allow each column to be arbitrarily scaled and thus turn all ones into stars. Next, we use column operations with constant scalars on the first block of $p-r$ dimension $(d+1)(m+p)$ columns to move all the zeros below the diagonal to the bottom of the columns. We then use multiples of these columns by s to introduce $p-r$ rows of zeros to the tops of the block or r $(d+2)(m+p)$-dimensional columns. Finally, we can use scalar column operations on this block to move the below diagonal elements of the normal form to the bottoms of the columns. This process is illustrated in Figure 5.3, and by counting diagonally in each block we see that the resulting localization pattern has top pivots $[1, 2, \ldots, p]$ and bottom pivots $[d(m+p)+m+r+1, \ldots, d(m+p)+m+p, (d+1)(m+p)+m+1, \ldots, (d+1)(m+p)+m+1+r]$. We thus see that

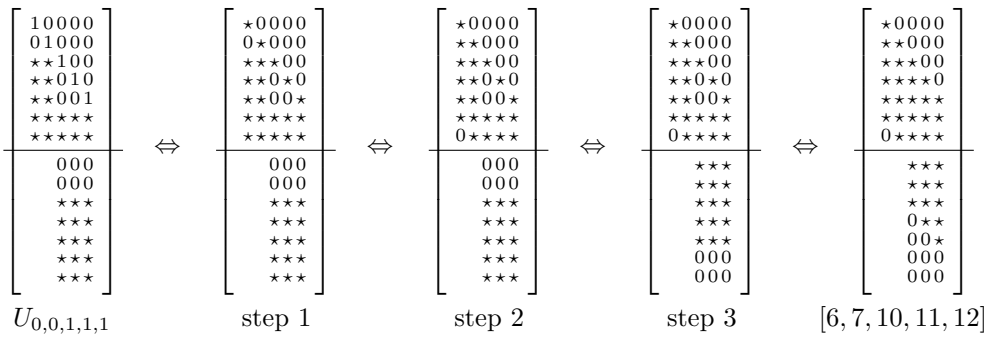

FIG. 5.3. *Transforming standard form for $m = 2$, $p = 5$, and $q = 3$ to top level localization pattern.*

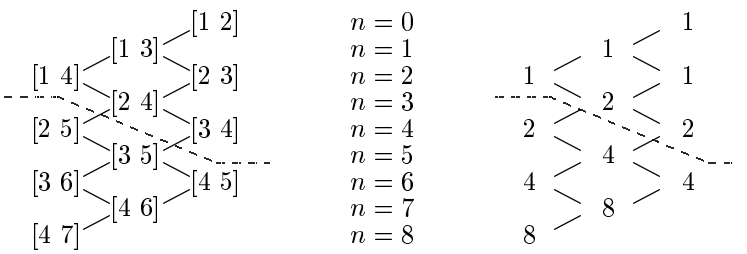

FIG. 5.4. *Combinatorial root count for $p = 2 = m$, $q = 1$. The brackets at the left are the bottom pivots. The top pivots remain* [1 2]. *The trivial localization pattern $X_0(s,t)$ corresponds to* [4 7]. *The dashed line marks the transition between $q = 0$ and $q = 1$. The root count is at the right.*

set of maps which fit this localization pattern has dimension $mp + q(m + p)$ and will account for all solutions of the problem of finding degree q-maps meeting $mp+q(m+p)$ generic m-planes at $mp + q(m + p)$ specified s values. In analogy to the approach used in section 3, we will proceed by successively specializing the input planes to yield problems over smaller localization patterns involving fewer conditions.

When specializing the input planes we also must specialize the values for s by fixing the interpolating points. For bottom pivots we focus on the highest-degree coefficients and move s to ∞ to select those coefficients. For top pivots the lowest-degree coefficients are specialized and we move s to 0. To deal with both situations we add an additional variable t to homogenize the polynomials. So we consider localization patterns of homogeneous polynomials and denote those by $X(s,t)$. The special m-planes of the hypersurface Pieri case are recycled when we evaluate $X(s,t)$ at $(s,t) = (1,0)$ for bottom pivots, or at $(s,t) = (0,1)$ for top pivots. The solutions to the problem in special position can be found in the child patterns that differ from $X(s,t)$ in exactly one position. The analogue to Definition 3.3 is immediate. The main root-counting theorem follows from the correctness of the Pieri homotopies. See Figure 5.4 for an example.

THEOREM 5.3. *Consider a localization pattern $X(s,t)$ with $p + n$ stars. For $n = 0$, $X(s,t)$ counts for one solution. For $n > 0$, the number of maps fitting $X(s,t)$ and meeting n general m-planes at n values for (s,t) equals the sum of the number of solution maps fitting the children of $X(s,t)$ and meeting $n-1$ general m-planes at $n-1$ values for (s,t).*

Note that in the definition of the Pieri homotopies we abuse notation in the sense that t denotes both the continuation parameter and the variable added to homogenize

the maps. This abuse is justified for bottom pivots because we move t from 0 to 1 to move the interpolation point from its specific value $(s,t) = (1,0)$ at ∞ to a general value $(s,t) = (s_n, 1)$. For top pivots we swap the roles of s and t.

DEFINITION 5.4. *Let $X(s,t)$ be a localization pattern and S_X be the special m-plane for bottom pivots at $(s,t) = (1,0)$. Suppose that the children $Y(s,t)$ of $X(s,t)$ meet $n-1$ general m-planes L_i at (s_i,t_i), i.e., $\det(Y(s_i,t_i)|L_i) = 0$ for $i = 1,2,\ldots,n-1$. To satisfy the nth intersection condition with L_n at (s_n,t_n), the* Pieri homotopy *is defined as*

$$H(X(s,t),s,t) = \begin{cases} \det(X(s,t)|(1-t)S_X + tL_n) = 0, \\ (s-1)(1-t) + (s-s_n)t = 0, \\ \det(X(s_i,t_i)|L_i) = 0, \\ i = 1,2,\ldots,n-1, \end{cases} \qquad t \in [0,1]. \tag{5.11}$$

For top pivots s and t swap roles and we consider s_n^{-1} as the target value for s. When we remove entries from both top and bottom, two independent s-variables are used. Theorem 5.3 follows from the correctness of the Pieri homotopy, proven in Lemma 5.5.

LEMMA 5.5. *Consider a localization pattern $X(s,t)$ with $p+n$ stars and n complex m-planes L_i in general position at the values (s_i,t_i). Suppose we are given all maps that meet L_i at (s_i,t_i), $i = 1,2,\ldots,n-1$, and fit one of the children of $X(s,t)$. Then the Pieri homotopy defines regular solution paths as t varies from 0 to 1, that start at the given maps and end at those maps that meet all n general m-planes L_i at (s_i,t_i) while fitting $X(s,t)$.*

Proof. Observe that in the Pieri homotopy (5.11) at $(s,t) = (1,0)$ we select in the first equation with the special m-plane S_X in the expansion of $\det(X(1,0)|S_X) = 0$ those stars that are indexed by the bottom pivots. So the first equation in (5.11) looks like

$$H_1(X(s,t),s,t) = p(X(1,0)) + t(f(X(s,t),s,t) + O(t)), \tag{5.12}$$

where $p(X(1,0))$ denotes the product of all pivot stars and where $f(X(s,t),s,t)$ is a polynomial not divisible by t. Ordering the variables as (s,t,x_{ij}), the matrix of all partial derivatives of the homotopy has the following structure:

$$\begin{bmatrix} \frac{\partial H_1}{\partial s} & \frac{\partial H_1}{\partial t} & A \\ 1 & 1-s_n & B \\ 0 & 0 & C \end{bmatrix}. \tag{5.13}$$

Since the $n-1$ planes L_i are in general position the rank of C is $n-1$. Thus the Jacobian matrix (5.13) is of full rank if and only if $\frac{\partial H_1}{\partial s}\frac{\partial H_1}{\partial t} \neq 0$ at $(s,t) = (1,0)$. We can show that $f(X(1,0),1,0) \neq 0$, which implies $\frac{\partial H_1}{\partial t} \neq 0$. If $f(X(1,0),1,0)$ were equal to 0, then $f(X(s,t),s,t)$ would be identically zero and H_1 could not contain any term that is linear in t. This could happen only for very special choices of L_n. Hence at $(s,t) = (1,0)$, all solutions are regular.

To compactify our space we choose again a multihomogenization according to the columns of the matrices. The regularity of the homotopy is maintained as t moves to 1 since L_n is in general position. Suppose we would have more solutions at $(s,t) = (s_n,1)$ than the number of paths we have started with. Going backward, when in the Pieri homotopy we let t go from 1 to 0, we would arrive at solutions at

$(s,t) = (1,0)$ that do not fit any of the child patterns of $X(s,t)$. But any other child pattern that is not provided in the root count does not allow enough freedom to meet the general intersection conditions L_i at (s_i,t_i) for $i = 1,2,\ldots,n-1$. □

We can reformulate the Pieri rule for the general case to deal with general intersection conditions for any q when the codimensions conditions k_i, $i = 1,2,\ldots,n$, satisfy $k_1 + k_2 + \cdots + k_n = mp + q(m+p)$. In the case where $q > 0$ we work with brackets modulo $(m+p)$ to represent the top and bottom pivots.

Consider a chain C ending at the pattern $X(s,t)$. Let α denote the bracket with the indices of the basis vectors in the intersection of the special m-planes for the patterns in the chain C. Let β denote the pivots modulo $(m+p)$ for a child $Y(s,t)$ of $X(s,t)$. Define γ as the bracket obtained from concatenating α and β, sorted in increasing order. Note that γ may contain repeated entries. We say that $Y(s,t)$ is *a valid child of the chain* C if there exists an index i such that

$$|\gamma_i - \gamma_1| < i - 1 \quad \text{for bottom pivots } \beta \tag{5.14}$$

or

$$|\gamma_l - \gamma_i| < l - i \quad \text{for top pivots } \beta, \tag{5.15}$$

where l is the index of the last element in γ. This rule is consistent with the general Pieri rule for $q = 0$ and allows us to compute intersection numbers for any q and for general codimension conditions.

6. Computational experiments and experiences. The Pieri homotopy algorithm is part of the module of PHCpack [44] that also provides the SAGBI homotopies. We compare with those homotopies and give comments on the organization of the code, numerical aspects, and applications. All timings reported concern a 166 MHz Pentium II processor with 64 Mb internal memory running Linux, unless indicated otherwise.

6.1. Implementation issues. In setting up the Pieri homotopy algorithm, we restricted to the case where the input planes are all in general position. In this case, all the deformations are free from multiplicities. To solve a nongeneric, specific instance of the problem instance we first solve a generic case and then apply a cheater's homotopy to obtain solutions to the original problem. The paradigm of cheater's homotopy [20], [21] or coefficient-parameter polynomial continuation [25], [26] makes it straightforward to set up this homotopy. This paradigm ensures that singularities can occur only at the end of the solution paths and only when the original problem has singular solutions.

The general intersection conditions are represented by overdetermined polynomial systems. A direct method to solve an overconstrained polynomial system of N equations in n unknowns is to multiply it by an $n \times N$-matrix of random complex numbers to construct a square system, as proposed in [36]. This reduction to a square system destroys the geometric structure and creates many excess solution paths to follow. In our situation, the overdetermined polynomial systems we have to deal with are the Pieri homotopies for general intersection conditions, which are overdetermined homotopies. From the geometry we know which solution paths we have to follow so that we maintain the optimal number of solution paths; see [16, section 4]. To control the correctness and to detect numerical failures, we evaluate the original overconstrained system at the computed end points of the paths. The complexity of Newton's method and path-following algorithms for overdetermined systems is analyzed in [9].

The geometric intersection conditions treated in section 4 are expressed by determinantal equations, which are a special kind of polynomial system. Just as sparse polynomial systems allow fewer perturbations on the coefficient structure than general polynomial systems (whence they have a better numerical condition [8] and can be more easily solved), we expect that the polynomial systems arising from these geometric intersection conditions are numerically easier to solve. We have done some tests on working directly with the matrix structures, but we abandoned this approach because the general linear algebra operations turn out to be slower than the nested Horner schemes that are used to evaluate the expanded determinantal forms. Nevertheless, we expect computational progress from Newton's method adapted to this specific geometric situation [11], in combination with secant methods [49].

6.2. Computational and numerical experiments. The description in [16] leads to path following in a chain-by-chain fashion as defined by Pieri trees. Contemplating the posets in Figures 3.2 and 4.1 one sees that one can avoid the tracing of many solution paths when the continuation matches the poset structure. To solve a generic complex instance encoded by $(m, p) = (4, 3)$, the chain-by-chain Pieri algorithm takes 4 h 15 m 58 s 220 ms and has to trace 2310 solution paths. The new poset-oriented Pieri homotopies take only 1 h 7 m 20 s 160 ms (see Table 6.1) to trace 1663 paths. This saving is only partially explained by the reduction in the number of paths. The poset structure allows us to organize the symbolic homotopy constructors in a much more economical way.

TABLE 6.1

Number of paths and timings for $(m, p) = (4, 3)$ at every even level n, up to the total resolution time for a generic complex intersection problem. The first total is added to the time needed for solving a real target instance and results in the last line.

n	#paths	User cpu time
2	18	800 ms
4	72	6 s 918 ms
6	187	1 m 8 s 40 ms
8	462	8 m 27 s 460 ms
10	462	18 m 46 s 390 ms
12	462	38 m 42 s 360 ms
Total	1663	1 h 7 m 20 s 160 ms
Target	462	5 h 4 m 46 s 610 ms
Total	2125	6 h 13 m 15 s 840 ms

In Table 6.1 we summarize the computational results with pivoting done in a mixed fashion. Here we are removing pivots from both the top and the bottom, as in the original chain-by-chain original description in [16]. In this case, the Pieri homotopy has two moving equations:

$$H(X,t) = \begin{cases} \det(X|(1-t)S_X^t + tL_n) = 0, \\ \det(X|(1-t)S_X^b + tL_{n-1}) = 0, \\ \det(X|L_i) = 0, \\ i = 1, 2, \ldots, n-2, \end{cases} \qquad t \in [0,1], \tag{6.1}$$

where S_X^t and S_X^b are the special m-planes, respectively, for top and bottom pivots of X. The input 4-planes for the real target problem are osculating a rational normal curve, as prescribed in one of the Shapiro–Shapiro conjectures [32], [39], [45]. For these inputs, all solution 3-planes turn out to be real on the examples we ran, in

accordance with the Shapiro–Shapiro conjectures. Dividing the total time on the last line in Table 6.1 by 462, we arrive at 48 s 476 ms cpu time as the cost for one solution, which is the cost for one feedback law.

Note that one can change basis to bring two input 4-planes into special position and thus save the time spent at stage $n = 12$ in Table 6.1. Another optimization involves using linear algebra instead of continuation to satisfy the intersection conditions at the top level of the poset; see [16, Proposition 3.1]. But this optimization cuts off only milliseconds.

The input planes are represented by matrices of generators which are equivalent up to a transformation of basis. We have noticed that an orthonormal representation of the input planes—filtered through the QR-algorithm [14]—is responsible for considerable computational savings and an increased numerical accuracy of the solution planes. The difference between random and orthonormal inputs becomes especially significant for higher-dimensional problems. For instance, the case $(m, p) = (5, 3)$ leads to a 15-dimensional polynomial system of cubics with 6006 solutions. A 450 MHz Intel Pentium machine needs 16 h 17 m 16 s cpu time on random inputs, whereas it takes only 10 h 12 m 38 s on orthonormal input planes.

6.3. Comparison with SAGBI homotopies. The SAGBI homotopies were proposed in [16] to compute all p-planes that meet mp given m-planes in general position. The second author implemented those homotopies to verify large instances of the Shapiro–Shapiro conjectures. See [45] for a description and [32] and [39], [41] for other tests and related work on these conjectures.

To solve a generic complex instance, encoded by $(m, p) = (4, 3)$, the Pieri homotopy algorithm takes 1 h 7 m 20 s 160 ms (see Table 6.1). As reported in [45], SAGBI homotopies need 2 h 23 m 27 s 630 ms for the same problem using the localization patterns that lead to polynomials of lowest degree, and 5 h 23 m 36 s 840 ms with localization patterns used by Pieri homotopies. The common optimization of bringing two input planes into special position to diminish the dimension with two forces those localization patterns that lead to higher-degree polynomials, increasing the complexity of SAGBI homotopies.

SAGBI homotopies suffer from two drawbacks, not shared by the Pieri homotopies. First, they cannot solve the more general intersection problem treated in section 4. Second, a polyhedral continuation is needed to start up the SAGBI homotopies. These continuations happen in the top dimension, which makes them computationally intensive. In addition, these homotopies are both highly nonlinear in the continuation parameter, which leads to numerical instabilities as the problems get larger. Although the techniques in [12] help, they always involve a lower bound that may be too high for the machine precision.

To conclude the comparison, we contrast the analytic geometry as used in the SAGBI homotopies with the intrinsic geometry of the Pieri homotopies. With the SAGBI homotopies we lose all geometric information after the transformation of the problem into a polynomial system. The Pieri homotopies use the polynomial equations merely as a means to compute and are better able to exploit the evolving geometry.

6.4. Reality issues. The Pieri homotopies arose from the question [37], [38] whether a problem of enumerative geometry can have all its solutions be real. The developed software may be useful for verifying instances of conjectures such as the Shapiro–Shapiro conjectures; see [32], [39], [41], and [45]. Note that for the quantum Schubert calculus a counterexample to one of the analogues of the Shapiro–Shapiro conjectures is given in [40] for the case $q = 1$, $m = 2 = p$. For engineering applications,

where the machines are specified with real matrices, only real feedback laws are of interest. Several explicit root counting formulas are given in [29] which allow one to quickly determine the parity of the intersection numbers.

We end this paper describing some computational experiences with random real inputs. Table 6.2 gives the number of paths and timings reported for solving the case of $m = 3$, $p = 2$, and $q = 1$. For this random real instance, 25 real and 30 complex maps were found. The timings are for a 350 Mhz Intel II Pentium processor, with 64 Mb internal memory, running SunOs 5.7.

TABLE 6.2

Number of paths and timings for $(m, p) = (3, 2)$ for $q = 1$, at every odd level n. The first total concerns the time needed for the quantum Pieri homotopy algorithm on a random complex instance. Note that this is less than the time needed to solve a random real target system.

n	#paths	User cpu time
1	3	$<$ 1ms
3	8	240ms
5	21	1s 690ms
7	55	18s 390ms
9	55	35s 560ms
11	55	1m 16s 560ms
Total	197	2m 12s 880ms
Target	55	2m 25s 280ms
Total	252	4m 39s 760ms

TABLE 6.3

Number of paths and timings for $(m, p) = (4, 3)$, $q = 0$, and $k_i = 3$, for $i = 1, 2, 3, 4$, listed at every even level. The timings for the general Pieri homotopy algorithm, on a random complex instance are added up into the first total. The last total includes the resolution of a random real target system.

n	#paths	User cpu time
2	1	20ms
4	1	190ms
6	1	570ms
8	1	6s 800ms
10	1	4s 910ms
12	1	22s 780ms
Total	6	38s 190ms
Target	1	19s 500ms
Total	7	1m 25s 340ms

In the last example we indicate what could be done when the number of the solution is even, following the spirit of Sottile's original ideas [37]. In the hypersurface case for $(m, p) = (4, 3)$, there are 462 solution 3-planes. Since 462 is even, there might be a chance that all of them are complex. But suppose you specialize the input somewhat, so that we have 4 sets of three 4-planes that each meet at 1 line (= 2-plane) common to their set. Then we may replace the original hypersurface intersection conditions by the requirement that the solution 3-planes meet those 4 common 2-planes. Each of these 4 2-planes gives a codimension 3 condition and as $12 = 3+3+3+3$ we can apply the general Pieri algorithm which gives exactly 1 solution, which is real for real inputs. Note that this involves the resolution of a polynomial system of 84 cubic equations in 12 variables. Table 6.3 summarizes the computations.

Acknowledgments. We are indebted to Frank Sottile for the many explanations that helped us through the first implementation and for the hint that Pieri homotopies exist for the quantum Schubert calculus. The explanations of Joachim Rosenthal were most helpful. We thank MSRI for the opportunity of sharing an office for one full year. Frank Sottile and Mengnien Wu gave valuable comments on the preprint version of this paper. We are grateful for the remarks of the anonymous referees.

HOMOGENEOUS STATE FEEDBACK STABILIZATION OF HOMOGENOUS SYSTEMS*

LARS GRÜNE†

Abstract. We show that for any asymptotically controllable homogeneous system in euclidean space (not necessarily Lipschitz at the origin) there exists a homogeneous control Lyapunov function and a homogeneous, possibly discontinuous state feedback law stabilizing the corresponding sampled closed loop system. If the system satisfies the usual local Lipschitz condition on the whole space we obtain semiglobal stability of the sampled closed loop system for each sufficiently small fixed sampling rate. If the system satisfies a global Lipschitz condition we obtain global exponential stability for each sufficiently small fixed sampling rate. The control Lyapunov function and the feedback are based on the Lyapunov exponents of a suitable auxiliary system and admit a numerical approximation.

Key words. homogeneous system, state feedback stabilization, control Lyapunov functions, Lyapunov exponents

1. Introduction.

In this paper we consider the problem of state feedback stabilization of homogeneous control systems in $\mathbb{R}^n$. This problem has been considered by a number of authors during the last few years; see, e.g., [16, 17, 18, 19, 22, 23, 24, 27] to mention just a few examples. Stability in this context will always mean asymptotic stability.

Homogeneous systems appear naturally as local approximations to nonlinear systems; cf., e.g., [15]. In order to make use of this approximation property in the design of locally stabilizing feedbacks for nonlinear systems the main idea lies in the construction of homogeneous feedbacks, i.e., feedback laws that preserve homogeneity for the resulting closed loop system. Utilizing a corresponding homogeneous Lyapunov function, those laws can then be shown to be locally stabilizing also for the approximated nonlinear system; cf. [15, 19, 21]. Regarding the existence of homogeneous stabilizing feedback laws, it was shown in [16] that if the system admits a continuous, but not necessarily homogeneous, stabilizing state feedback law, then there exists a homogeneous dynamic feedback stabilizing the system. Unfortunately, if we are looking for static state feedback laws, it is generally not true that any continuously stabilizable homogeneous system is stabilizable by a continuous *and* homogeneous state feedback law, as the examples in [24] show. Even worse, there exist homogeneous systems, e.g., Brockett's classical example [2], which—although asymptotically controllable—do not admit a stabilizing continuous state feedback law at all.

Brockett's results especially inspired the search for alternative feedback concepts. In the present paper we are going to use discontinuous state feedback laws for which the corresponding closed loop systems are defined as sampled systems. Although this is not a new concept (see, e.g., [13, 14, 25]), it has recently received new attention;

see, e.g., the survey in [26]. In particular, it was shown in [5] that (global) asymptotic controllability is equivalent to the existence of a (globally) stabilizing discontinuous state feedback law for the sampled closed loop system. Stability in this context means asymptotic stability for the sampled trajectories (i.e., the feedback is evaluated only at discrete *sampling times* with the values being used until the next sampling time) where—in general—the intervals between two sampling times have to tend to zero close to the equilibrium and far away from it. A related but slightly different concept of a discontinuous feedback is the notion of discrete feedback introduced in [8]; here sampled trajectories are also considered, but with fixed intersampling times. With this approach it was possible to show in [11] that for semilinear systems asymptotic controllability is equivalent to (exponential) discrete feedback stabilizability.

The goal of the present paper is to provide a link between these two concepts in the framework of homogeneous systems. As in [11] we use a spectral characterization of asymptotic controllability by means of Lyapunov exponents, and obtain stability results for fixed sampling rates; as in [5] we construct the feedback based on a suitable (and here also homogeneous) control Lyapunov function and obtain stability not only for fixed intersampling times but for all sufficiently small ones. Furthermore, and this is a key feature of our construction, the resulting stabilizing state feedback law is homogeneous, thus rendering the corresponding closed loop system homogeneous. All this will be done under just the assumption that the corresponding homogeneous system is asymptotically controllable.

The organization of this paper is as follows. In section 2 we define homogeneous systems and introduce a class of auxiliary systems we call homogeneous-in-the-state. In some sense these systems have a built in homogeneity for each control value and can be simplified by suitable coordinate and time transformations. Section 3 provides the concepts of asymptotic controllability and stabilization by means of sampled feedback laws. After stating our main theorem at the end of this section, in section 4 we turn to the proof of this result for systems homogeneous-in-the-state by characterizing asymptotic controllability by means of Lyapunov exponents and constructing a suitable control Lyapunov function and a stabilizing feedback. After giving some hints about a numerical approximation of this feedback law in section 5, we will return to the homogeneous systems in section 6 and prove the stabilization result by showing that these systems can easily be transformed into systems homogeneous-in-the-state without losing the asymptotic controllability property. Finally, in section 7 we discuss two examples.

2. Homogeneous systems. We consider a class of systems

$$\dot{x}(t) = g(x(t), w(t)) \tag{2.1}$$

on $\mathbb{R}^n$, where $w(\cdot) \in \mathcal{W}$ and $\mathcal{W}$ denotes the space of measurable and locally essentially bounded functions from $\mathbb{R}$ to $W \subset \mathbb{R}^m$. We assume that the vector field g is continuous, $g(\cdot, w)$ is locally Lipschitz on $\mathbb{R}^n \setminus \{0\}$ for each $w \in W$, and g satisfies the following property.

DEFINITION 2.1. *We call* g homogeneous *if there exist* $r_i > 0$, $i = 1, \dots, n$, $s_j > 0$, $j = 1, \dots, m$, *and* $\tau \in (-\min_i r_i, \infty)$ *such that*

$$g(\Lambda_\alpha x, \Delta_\alpha w) = \alpha^\tau \Lambda_\alpha g(x, w) \text{ for all } w \in W, \alpha \geq 0, \tag{2.2}$$

where

$$\Lambda_\alpha = \begin{pmatrix} \alpha^{r_1} & 0 & \cdots & 0 \\ 0 & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ 0 & \dots & 0 & \alpha^{r_n} \end{pmatrix} \quad \textit{and} \quad \Delta_\alpha = \begin{pmatrix} \alpha^{s_1} & 0 & \cdots & 0 \\ 0 & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ 0 & \dots & 0 & \alpha^{s_m} \end{pmatrix}$$

are called dilation matrices. *With* $k = \min_i r_i$ *we denote the* minimal power *(of the state dilation) and the value* $\tau \in (-k, \infty)$ *is called the* degree *of the system.*

This definition generalizes the one given in [24] to the case of a multidimensional control input; see, e.g., [15] for an alternative definition (equivalent on $\mathbb{R}^n$) for vector fields on arbitrary manifolds. The use of dilation matrices instead of the usual dilation functions allows a more compact notation in what follows. Observe that if g is Lipschitz in the origin, then $\tau \geq 0$, and if g is globally Lipschitz, then $\tau = 0$. Furthermore, the definition implies $g(0,0) = 0$.

Corresponding to the dilation matrix Λ_α we define a function $N : \mathbb{R}^n \to [0,\infty)$ which can be interpreted as a "dilated norm" with respect to Λ_α. Denoting $d = 2\prod_{i=1}^n r_i$ we define $N(x)$ by

$$N(x) := \left(\sum_{i=1}^n x_i^{\frac{d}{r_i}} \right)^{\frac{1}{d}} \tag{2.3}$$

implying $N(0) = 0$, $N(x) > 0$ if $x \neq 0$, and $N(\Lambda_\alpha x) = \alpha N(x)$.

Note that the trajectories of (2.1) may tend to infinity in finite time if $\tau > 0$ and that uniqueness of the trajectory may not hold if $\tau < 0$; however, it holds away from the origin. As long as uniqueness holds (i.e., if $\tau \geq 0$ or the trajectory does not cross the origin) we denote the (open loop) trajectories of (2.1) by $x(t, x_0, w(\cdot))$ for each $x_0 \in \mathbb{R}^n$ and each $w(\cdot) \in \mathcal{W}$, where $x(0, x_0, w(\cdot)) = x_0$. Then from Definition 2.1 we obtain

$$x(t, \Lambda_\alpha x_0, \Delta_\alpha w(\alpha^\tau \cdot)) = \Lambda_\alpha x(\alpha^\tau t, x_0, w(\cdot)) \tag{2.4}$$

for $x_0 \in \mathbb{R}^n$. If uniqueness fails to hold, $x(\cdot, x_0, w(\cdot))$ shall denote one possible trajectory; in this case we implicitly assume the definitions of section 3 below to be valid for *all* possible trajectories.

In the remainder of this section we introduce and discuss a class of auxiliary systems which are homogeneous-in-the-state and will turn out to be useful for our analysis: Consider the class of systems

$$\dot{x}(t) = f(x(t), u(t)) \tag{2.5}$$

on $\mathbb{R}^n$, where $u(\cdot) \in \mathcal{U}$ and $\mathcal{U}$ denotes the space of measurable functions from $\mathbb{R}$ to some compact set $U \subset \mathbb{R}^m$. We assume that the vector field f is continuous, $f(\cdot, u)$ is locally Lipschitz on $\mathbb{R}^n \setminus \{0\}$ for each $u \in U$, and f satisfies the following property.

Definition 2.2. *We call* f homogeneous-in-the-state *if there exist* $r_i > 0$, $i = 1, \dots, n$ *and* $\tau \in (-\min_i r_i, \infty)$ *such that*

$$f(\Lambda_\alpha x, u) = \alpha^\tau \Lambda_\alpha f(x, u) \text{ for all } u \in U, \tag{2.6}$$

where Λ_α *is the* dilation matrix *as in Definition* 2.1, $k = \min_i r_i$ *is called the* minimal power, *and the value* $\tau \in (-k, \infty)$ *is called the* degree *of the system.*

Note that this definition implies $f(0,u) = 0$ for all $u \in U$. We denote the trajectories of (2.5) with initial value x_0 at the time $t = 0$ and control function $u(\cdot) \in \mathcal{U}$ again by $x(t, x_0, u(\cdot))$. Observe also that the trajectories of (2.5) may escape in finite time if $\tau > 0$ and that uniqueness of the trajectory may not hold in the origin if $\tau < 0$ (here again we use the convention as for the trajectories of (2.1)). As long as the trajectories exist and uniqueness holds we obtain from Definition 2.2 that

$$x(t, \Lambda_\alpha x_0, u(\alpha^\tau \cdot)) = \Lambda_\alpha x(\alpha^\tau t, x_0, u(\cdot)) \tag{2.7}$$

for all $x_0 \in \mathbb{R}^n$.

Besides being useful auxiliary systems for our stabilization problem for homogeneous systems, homogeneous-in-the-state systems themselves form an interesting class of systems. They generalize homogeneous bilinear and semilinear systems (see, e.g., [6, 7, 8, 11]). One interpretation of this structure is that the control affects parameters in the system rather than representing some force acting on the system; cf. the examples in [9, 10]. For this class of systems there also exist examples which are stabilizable but not with a continuous feedback law; see [26, example after Theorem A]. Note that this class can be generalized analogously to the generalization of semilinear systems made in [11]; all results in this paper can easily be adapted to that case.

The connection between homogeneous and homogeneous-in-the-state systems is easily seen: Given some homogeneous system (2.1) satisfying

$$g(\Lambda_\alpha x, \Delta_\alpha u) = \alpha^\tau \Lambda_\alpha (x, u)$$

we define

$$f(x,u) := g(x, \Delta_{N(x)} u). \tag{2.8}$$

Then it is immediate from the property $N(\Lambda_\alpha x) = \alpha N(x)$ of the dilated norm N that

$$\begin{aligned} f(\Lambda_\alpha x, u) &= g(\Lambda_\alpha x, \Delta_{N(\Lambda_\alpha x)} u) = g(\Lambda_\alpha x, \Delta_{\alpha N(x)} u) \\ &= g(\Lambda_\alpha x, \Delta_\alpha \Delta_{N(x)} u) = \alpha^\tau \Lambda_\alpha g(x, \Delta_{N(x)} u) \\ &= \alpha^\tau \Lambda_\alpha f(x,u); \end{aligned}$$

i.e., f is homogeneous-in-the-state.

Homogeneous and homogeneous-in-the-state systems can be considerably simplified applying suitable coordinate and time transformations. We will make use of this procedure for homogeneous-in-the-state systems: Using the dilated norm N from (2.3) the function

$$P(x) := \Lambda^{-1}_{N(x)} x$$

defines a projection from $\mathbb{R}^n \backslash \{0\}$ onto $N^{-1}(1)$ satisfying $P(\Lambda_\alpha x) = P(x)$ for all $\alpha > 0$. We denote the $n-1$ dimensional embedded unit sphere $\{x \in \mathbb{R}^n \mid \|x\| = 1\}$ by $\mathbb{S}^{n-1}$. Then, since $N(tx)$ is strictly increasing in $t \geq 0$ the function $S : N^{-1}(1) \to \mathbb{S}^{n-1}$, $S(x) = x/\|x\|$ is a diffeomorphism between these two manifolds. Thus, we can define a coordinate transformation $y = \Psi(x)$ by

$$\Psi(x) = N(x)^k S(P(x)), \quad \Psi^{-1}(y) = \Lambda_{\sqrt[k]{\|y\|}} S^{-1}\left(\frac{y}{\|y\|}\right),$$

and $\Psi(0) = 0$, $\Psi^{-1}(0) = 0$, which is continuous on $\mathbb{R}^n$ and C^1 on $\mathbb{R}^n \setminus \{0\}$. This definition implies

$$\Psi(\Lambda_\alpha x) = \alpha^k \Psi(x), \quad \Psi^{-1}(\alpha^k y) = \Lambda_\alpha \Psi^{-1}(y)$$

and by differentiation of $\Psi(\Lambda_\alpha x)$ and $\alpha^k \Psi(x)$ one sees

$$D\Psi(\Lambda_\alpha x) = \alpha^k \Lambda_\alpha^{-1} D\Psi(x).$$

Thus defining

$$\tilde{f}(y,u) = D\Psi(\Psi^{-1}(y)) f(\Psi^{-1}(y), u)$$

we obtain (with $x = \Psi^{-1}(y)$)

$$\tilde{f}(\alpha^k y, u) = D\Psi(\Lambda_\alpha x) f(\Lambda_\alpha x, u) = \alpha^k \Lambda_\alpha^{-1} D\Psi(x) \alpha^\tau \Lambda_\alpha f(x,u) = \alpha^\tau \alpha^k \tilde{f}(y,u)$$

implying

$$\tilde{f}(\alpha y, u) = \alpha^{\gamma+1} \tilde{f}(y,u),$$

with $\gamma = \tau/k$; i.e., $\tilde{f}$ is homogeneous-in-the-state with respect to the standard dilation $\Lambda_\alpha = \alpha \mathrm{Id}$, with mimimal power $k = 1$, and with degree $\tau = \gamma$.

Furthermore setting $\bar{f}(y,u) = \tilde{f}(y,u)\|y\|^{-\gamma}$ (which defines a time transformation for $\tilde{f}$) we obtain a system with degree $\tau = 0$.

In section 4 we will therefore first consider systems satisfying

$$f(\alpha x, u) = \alpha f(x,u) \text{ for all } x \in \mathbb{R}^n,\ \alpha \geq 0 \tag{2.9}$$

and will then retranslate the results to the general case. Observe that the transformed f is now globally Lipschitz with a uniform constant which we will denote by L.

3. Asymptotic controllability and feedback stabilization. In this section we give the precise definitions of asymptotic controllability and feedback stabilization. For this purpose we briefly describe the idea of sampling and the concept of control Lyapunov functions. We formulate the concepts for system (2.1) with the obvious modifications; however, all definitions also apply to system (2.5).

DEFINITION 3.1. *We call system* (2.1) asymptotically controllable (to the origin) *if for each* $x_0 \in \mathbb{R}^n$ *there exists* $w_{x_0}(\cdot) \in \mathcal{W}$ *such that* $\|x(t, x_0, w_{x_0}(\cdot))\| \to 0$ *as* $t \to \infty$.

We now discuss the concept of homogeneous state feedbacks. A *state feedback law* is a map $F : \mathbb{R}^n \to W$. A *homogeneous* state feedback law satisfies $F(\Lambda_\alpha x) = \Delta_\alpha F(x)$ for all $x \in \mathbb{R}^n$ and all $\alpha \geq 0$, thus implying $g(\Lambda_\alpha x, F(\Lambda_\alpha x)) = \alpha^\tau \Lambda_\alpha g(x, F(x))$; i.e., the *closed loop system* using F becomes homogeneous. Observe that W needs to satisfy some structural condition in order to allow nontrivial homogeneous feedbacks. In what follows we will assume

$$\Delta_\alpha W \subseteq W \text{ for all } \alpha \geq 0, \quad \text{where } \Delta_\alpha W := \{\Delta_\alpha w \,|\, w \in W\}$$

which gives a necessary and sufficient condition for the fact that given some $c > 0$ any homogeneous map $F : \mathbb{R}^n \to \mathbb{R}^m$ satisfying $F(x) \in W$ on $\{x \in \mathbb{R}^d \,|\, N(x) = c\}$ satisfies $F(x) \in W$ for all $x \in \mathbb{R}^n$.

Note that we do not require any continuity property of F. This is due to the fact that in many examples stabilizing continuous feedbacks cannot exist; cf., e.g.,

[26, section 2.2], where Brockett's classical example [2] is discussed also which—in suitable coordinates—is in fact a homogeneous system. Furthermore, even if stabilizing continuous feedback laws exist, it is possible that no such law is homogeneous, as the examples in [24] show (Brockett's example and the first example from [24] will be discussed in section 7). However, using discontinuous feedbacks for the solutions of the classical closed loop system $\dot{x} = g(x, F(x))$ the usual existence and uniqueness results might not hold. In order to obtain a meaningful solution for the closed loop system we use the following concept of a sampled closed loop system.

DEFINITION 3.2 (sampled closed loop system). *Consider a feedback law $F : \mathbb{R}^n \to W$. An infinite sequence $\pi = (t_i)_{i\in\mathbb{N}_0}$ of times satisfying*

$$0 = t_0 < t_1 < t_2 < \cdots \quad \text{and} \quad t_i \to \infty \text{ as } i \to \infty$$

is called a sampling schedule. *The values*

$$\Delta t_i := t_{i+1} - t_i \quad \text{and} \quad d(\pi) := \sup_{i\in\mathbb{N}_0} \Delta t_i$$

are called the intersampling times *and the* sampling rate, *respectively. For any sampling schedule π the corresponding* sampled *or* π-trajectory $x_\pi(t, x_0, F)$ *with initial value $x_0 \in \mathbb{R}^n$ at initial time $t_0 = 0$ is defined inductively by*

$$x_\pi(t, x_0, F) = x(t - t_i, x_i, F(x_i)) \text{ for all } t \in [t_i, t_{i+1}], i \in \mathbb{N}_0,$$

where $x_i = x_\pi(t_i, x_0, F)$ and $x(t, x_i, F(x_i))$ denotes the (open loop) trajectory of (2.1) *with constant control value $F(x_i)$ and initial value x_i.*

Observe that this definition guarantees the existence and uniqueness of trajectories in positive time on their maximal intervals of existence (except possibly at the origin if $\tau < 0$, in which case we use the same convention as for open loop trajectories). Moreover, the sampled π-trajectories have a meaningful physical interpretation, as they correspond to an implementation of the feedback law F using a digital controller.

The next definition introduces control Lyapunov functions which will be vital for the construction of the feedback. Here we make use of the lower directional derivatives; see, e.g., [4] for an equivalent definition.

DEFINITION 3.3. *A continuous function $V : \mathbb{R}^n \to [0, \infty)$ is called a* control Lyapunov function (CLF) *if it is positive definite (i.e., $V(x) = 0$ if and only if $x = 0$), proper (i.e., $V(x) \to \infty$ as $\|x\| \to \infty$), and there exists a continuous and positive definite function $P : \mathbb{R}^n \to [0, \infty)$ such that for each bounded subset $G \subset \mathbb{R}^n$ there exists a compact subset $W_G \subset W$ with*

$$\min_{v\in \operatorname{cog}(x,W_G)} DV(x; v) \le -P(x) \text{ for all } x \in G.$$

Here $DV(x; v)$ denotes the lower directional derivative

$$DV(x; v) := \liminf_{t\searrow 0, v'\to v} \frac{1}{t} \left(V(x + tv') - V(x)\right),$$

$g(x, W_G) := \{g(x, w) \,|\, w \in W_G\}$, and $\operatorname{cog}(x, W_G)$ denotes the convex hull of $g(x, W_G)$.

The following definition now describes the stability concepts we will use in this paper. For this definition recall that a function $\gamma : [0, \infty) \to [0, \infty)$ is of class $\mathcal{K}$ if it satisfies $\gamma(0) = 0$ and is continuous and strictly increasing, and a function $\beta :$

$[0,\infty)^2 \to [0,\infty)$ is of class $\mathcal{KL}$ if it is decreasing to zero in the second and of class $\mathcal{K}$ in the first argument.

DEFINITION 3.4. *We call the sampled closed loop system from Definition* 3.2

(i) semiglobally practically stable with fixed sampling rate *if there exists a class* $\mathcal{KL}$ *function* β *such that for each open set* $B \subset \mathbb{R}^n$ *and each compact set* $K \subset \mathbb{R}^n$ *satisfying* $0 \in B \subset K$ *there exists* $h > 0$ *such that*

$$x_\pi(t, x_0, F) \notin B \;\;\Rightarrow\;\; \|x_\pi(t, x_0, F)\| \le \beta(\|x_0\|, t)$$

for all $x_0 \in K$ *and all* π *with* $d(\pi) \le h$,

(ii) semiglobally stable with fixed sampling rate *if* (i) *holds and the sampling rate* $h > 0$ *can be chosen independently of* B,

(iii) globally practically stable with fixed sampling rate *if* (i) *holds and the sampling rate* $h > 0$ *can be chosen independently of* K,

(iv) globally stable with fixed sampling rate *if* (i) *holds and the sampling rate* $h > 0$ *can be chosen independently of* K *and* B.

We call the stability in (i)–(iv) exponential *if* β *can be chosen such that the inequality* $\beta(\|x_0\|, t) \le Ce^{-\sigma t}\|x_0\|$ *holds for constants* $C, \sigma > 0$ *which may depend on* K, *and* uniformly exponential *if* $C, \sigma > 0$ *can be chosen independently of* K.

Note that each of the concepts (ii)–(iv) implies (i) which is equivalent to the s-stability property as defined in [5]; also cf. [26, sections 3.1 and 5.1]. Hence any of these concepts imply *global stability* for the (possibly nonunique) limiting trajectories as $h \to 0$. The difference lies "only" in the performance with a *fixed* sampling rate. From the applications point of view, however, this is an important issue, since, e.g., for an implementation of a feedback using some digital controller, arbitrary small sampling rates in general will not be realizable. Furthermore, if the sampling rate tends to zero the resulting stability may be sensitive to measurement errors if the feedback is based on a nonsmooth CLF; see [20, 26]. In contrast to this it is quite straightforward to see that for a fixed sampling rate the stability is in fact robust to small errors in the state measurement (small, of course, relative to the norm of the current state of the system) if the corresponding CLF is Lipschitz; cf. [26, Theorem E].

The main result we will prove in this paper is the following theorem on the existence of a homogeneous CLF V and a homogeneous stabilizing feedback F.

THEOREM 3.5. (a) *Consider system* (2.1) *satisfying Definition* 2.1 *with dilation matrices* Λ_α *and* Δ_α, *minimal power* $k > 0$, *and degree* $\tau \in (-k, \infty)$, *and assume asymptotic controllability. Then there exist* $\mu > 0$ *and a CLF* V *being Lipschitz on* $\mathbb{R}^n \setminus \{0\}$, *satisfying*

$$V(\Lambda_\alpha(x)) = \alpha^{2k} V(x)$$

and

$$\min_{v \in \operatorname{cog}(x, W_x)} DV(x; v) \le -2\mu N^\tau(x) V(x)$$

for the function N *from* (2.3) *and* $W_x = \Delta_{N(x)} U$ *for some suitable compact subset* $U \subset W$.
